# PLEASE READ—IMPORTANT INFORMATION

The *Gale Encyclopedia of Diets: A Guide to Health and Nutrition* is a health reference product designed to inform and educate readers about a wide variety of diets, nutrition and dietary practices, and diseases and conditions associated with nutrition choices. The Gale Group believes the product to be comprehensive, but not necessarily definitive. It is intended to supplement, not replace, consultation with a physician or other healthcare practitioners. While The Gale Group has made substantial efforts to provide information that is accurate, comprehensive, and up-to-date, The Gale Group makes no representations or warranties of any kind, including without limitation, warranties of merchantability or fitness for a particular purpose, nor does it guarantee the accuracy, comprehensiveness, or timeliness of the information contained in this product. Readers should be aware that the universe of medical knowledge is constantly growing and changing, and that differences of opinion exist among authorities. Readers are also advised to seek professional diagnosis and treatment for any medical condition, and to discuss information obtained from this book with their healthcare provider.

# INTRODUCTION

The *Gale Encyclopedia of Diets: A Guide to Health and Nutrition* is a one-stop source for diet and nutrition information that covers popular and special diets, nutrition basics, and nutrition-related health conditions. It also particularly addresses health and nutrition concerns across all age groups from infancy through old age. This encyclopedia avoids medical jargon and uses language that laypersons can understand, while still providing thorough coverage of each topic. The *Gale Encyclopedia of Diets: A Guide to Health and Nutrition* is not meant to be an endorsement for any one diet or lifestyle but rather it presents authoritative, balanced information.

## SCOPE

Approximately 275 full-length articles are included in *The Gale Encyclopedia of Diets: A Guide to Health and Nutrition*. Articles follow a standardized format that provides information at a glance. Rubrics include:

**Special/Popular Diets**

- Definition
- Origins
- Description
- Function
- Benefits
- Precautions
- Risks
- Research and general acceptance
- Questions to ask your doctor
- Resources
- Key terms

**Nutrition Basics**

- Definition
- Purpose
- Description
- Precautions
- Interactions
- Aftercare
- Complications
- Parental concerns
- Resources
- Key terms

**Health**

- Definition
- Description
- Demographics
- Causes and symptoms
- Diagnosis
- Treatment
- Nutrition/Dietetic concerns
- Therapy
- Prognosis
- Prevention
- Resources
- Key terms

## INCLUSION CRITERIA

A preliminary list of diets and nutrition topics was compiled from a wide variety of sources, including professional medical guides and textbooks, as well as consumer guides and encyclopedias. The advisory board evaluated the topics and made suggestions for inclusion. Final selection of topics to include was made by the advisors in conjunction with Gale Group editors.

## ABOUT THE CONTRIBUTORS

The essays were compiled by experienced medical writers, including registered dieticians, nutritionists, healthcare practitioners and educators, pharmacists, and other healthcare professionals. The advisors reviewed all of the completed essays to insure that they are appropriate, up-to-date, and medically accurate.

## HOW TO USE THIS BOOK

*The Gale Encyclopedia of Diets: A Guide to Health and Nutrition* has been designed with ready reference in mind:

- Straight **alphabetical arrangement** allows users to locate information quickly.
- Bold faced terms function as *print hyperlinks* that point the reader to related entries in the encyclopedia.
- A list of **key terms** is provided where appropriate to define unfamiliar words or concepts used within the context of the essay. Additional terms may be found in the **glossary**.
- **Cross-references** placed throughout the encyclopedia direct readers to where information on subjects without their own entries can be found. Synonyms are also cross-referenced.
- A **Resources section** directs users to sources of further information.
- A comprehensive **general index** allows users to easily target detailed aspects of any topic.

## GRAPHICS

*The Gale Encyclopedia of Diets: A Guide to Health and Nutrition* is enhanced with approximately 200 full-color images, including photos, tables, and customized line drawings.

# A

## Abs diet

### Definition

The Abs diet is a six-week plan that combines nutrition and exercise. It emphasizes twelve power foods that are the staples of the diet. It focuses on building muscle through strength training, aerobic exercises, and a dietary balance of proteins, **carbohydrates**, and fat.

### Origins

David Zinczenko, editor of *Men's Health*, developed the diet in 2004. He introduced it in the magazine and in his book, *The Abs Diet: The Six-Week Plan to Flatten Your Stomach and Keep You Lean for Life*. Zinczenko says he grew up as an overweight child and at age 14, he was five feet 10 inches tall and weighed 212 pounds. He learned about fitness while in the U.S. Naval Reserve and nutrition from his tenure at *Men's Health*.

Despite its name, the diet does not specifically target abdominal fat. Exercise helps the body burn excess fat but it is not possible to target specific areas of fat, such as the abdomen. Diet and exercise will help eliminate excess fat from all over. If the bulk of a person's fat is around the belly, then that is where the greatest amount of fat-burning will occur. The Abs diet is designed to provide the necessary **vitamins**, **minerals**, and **fiber** for good health, while it promotes building muscle that helps increase the body's fat burning process.

### Description

The Abs diet developer David Zinczenko says it will allow people to lose weight —primarily fat—while developing a leaner abdomen and increasing muscle tone, strength, general health, and sexual health. The diet has two components: exercise and nutrition. There are six general guidelines that are the basic principles of the diet. These are: eat six meals a day, drink smoothies regularly, know what to drink and what not to; do not count calories; eat anything you want for one meal a week; and focus on the Abs diet twelve power foods.

The diet strongly recommends its followers eat six meals a day since it helps to maintain what researchers call an energy balance. This is the number of calories burned in an hour versus the number of calories taken in. Georgia State University researchers found that if the hourly surplus or deficit of calories is 300–500 at any given time, the body is most susceptible to burning fat and building lean muscle mass. To stay within this range, Zinczenko recommends the following daily meal schedule: breakfast, mid-morning snack, lunch, mid-afternoon snack, dinner, and evening snack.

Another guideline is to drink smoothies regularly in place of a meal or snack. Smoothies are mixtures of low-fat milk and yogurt with ingredients such as ice, **protein** powder, fruits, and peanut butter, that are prepared in a blender. Although there are no definitive studies, some researchers suggest that the **calcium** in the milk and yogurt helps to burn body fat and restricts the amount of fat produced by the body.

A third guideline details what to drink and not drink. Drinking eight glasses of **water** daily is recommended. The benefits of 64-oz of water are that it helps to alleviate hunger pangs, it flushes waste products from the body, and it delivers nutrients to muscles. Other acceptable drinks are low-fat milk, **green tea**, and no more than two glasses of diet soda a day. Alcohol is not recommended at all since it does not help to make a person feel full. It also decreases by one-third the body's ability to burn fat and makes the body store more of the fat from food. In addition, it decreases production of testosterone and human growth hormone that help burn fat and increase muscle mass.

## KEY TERMS

**Aerobic exercise**—An exorcise that increases breathing and heart rates.

**Carbohydrates**—An organic compound that is an important source of energy in humans, found in foods such as pasta, cereal, and bread.

**Cardiovascular**—Relating to the heart and blood vessels.

**Endocrinologist**—A physician who specializes in disorders of the endocrine system

**Energy balance**— The number of calories burned in an hour versus the number of calories taken in.

**Erectile dysfunction**—The inability to get or maintain an erection.

**Human growth hormone**—An amino acid that stimulates growth and cell reproduction in humans.

**LDL**—Low-density lipoprotein (LDL), also known bad cholesterol, is a fat protein that is high in cholesterol and low in protein.

**Obliques**—Types of abdominal muscle.

**Testosterone**—A male sex hormone that is responsible for secondary sex characteristics.

**Transverse abdominis**—A muscle layer of the wall of the abdomen.

**Urologist**—A physician that specializes in disorders of the urinary tract and male genitals.

**Vegan**—A vegetarian who excludes all animal products from the diet.

Although burning calories is required to lose fat, Zinczenko says calorie counting makes people lose focus and motivation. The foods allowed on the diet are energy-efficient and will help dampen feelings of hunger, according to Zinczenko.

Another guideline is that dieters are allowed to cheat for one meal a week. The meal should include foods that the dieter misses most, including items high in carbohydrates and **fats**. This helps prevent diet fatigue that many people go though when dieting.

The last guideline is to focus on the twelve power foods of the diet to help meet core nutritional requirements. The twelve power foods are:

- almonds and other nuts (unsalted and unsmoked)
- beans (except refried and baked)
- green vegetables, including spinach, broccoli, brussels sprouts, and asparagus
- non-fat or low-fat dairy products
- instant oatmeal (unsweetened and unflavored)
- eggs and egg substitute products
- lean meats, including turkey, chicken, fish, and beef
- peanut butter
- olive oil
- whole-grain breads and cereals
- whey protein powder
- berries

Other foods that can be eaten often include almond butter, apples, avocados, bananas, bean dips, brown rice, Canadian bacon, canola oil, cashew butter, citrus fruit and juices, edamame, fruit juices (sugar-free), garlic, hummus, lentils, mushrooms, melons, pasta (whole-wheat), peaches, peanut oil, peas, peppers (green, yellow, and orange), popcorn (fat-free), pretzels (whole-wheat), pumpkin seeds, sesame oil, shellfish, soup (broth-based), sunflower seeds, sweet potatoes, tomatoes, and yellow wax beans.

### *Exercise*

Adequate exercise is as important as good nutrition in losing fat and flattening the stomach in the Abs diet. It includes strength training three times a week, abdominal exercises two or three days a week, and optional aerobic exercises two or three times a week. There are three basic principles to the exercise program: leave at least 48 hours between weights workouts of the same body part; do no exercises one day a week; and warm up for five minutes before exercising by jogging lightly, riding a stationary bike, jumping rope, or doing jumping jacks. There are three components of the plan that target different types of exercise:

- Strength training—Total-body workouts three days a week, with one workout placing extra emphasis on the leg muscles.
- Cardiovascular exercises—Do these twice a week in-between strength training days. Activities include cycling, running, swimming, brisk walking, and stair climbing.
- Abdominal (ab) exercises—Do ab exercises two or three times a week, before strength training workouts.

**GETTING STARTED.** People who are not already exercising should do light strengthening exercises three days a week for the first two weeks. One sample routine is to alternate between three sets of eight to 10 pushups and three sets of 15–20 squats with no weights. Rest for one minute between sets. When it

becomes easy to do 10 or more pushups and 20 or more squats, increase the number of pushups and add weights to the squats, using either a barbell or dumbbells. The weights routine should be followed by 30 minutes of brisk walking.

People who already exercise regularly should consider switching from their current workout routine to the Abs diet workout for at least the first few weeks, according to Zinczenko. For maximum results, it is best to change the workout routine every month to keep the body from adapting to a repetitious routine that can slow muscle development. The Abs diet suggests the basic workout be done on Mondays and Wednesdays, starting with one set of an ab exercise from each of the five categories of abdominal regions. Follow this with two circuits of one set of the core exercises in the order listed. On Tuesdays and Thursdays, do 20–30 minutes of cardiovascular exercise. On Friday, do the Monday through Wednesday workout but instead of the ab exercises, traveling lunges, 10–12 reps, and step-ups, 10–12 reps each leg. Do two complete circuits.

**ABDOMINAL EXERCISES.** These exercises strengthen the abdominal muscles in five regions: upper abs, 12–15 reps; lower abs, 6–12 reps; obliques, 10 each side; transverse abdominis, 5–10 reps; and lower back, 12–15 reps. The following are exercises for each of the five abdominal regions. Upper abs: traditional crunch and modified raised-feet crunch; lower abs: figure-eight crunch and bent-leg knee raise; transverse abdominis: two-point bridge and Swiss ball pull-in; obliques: medicine ball torso rotation and two-handed wood chop; lower back: twisting back extension and Swiss ball Superman.

**CORE EXERCISES.** These are the basic exercises that promote muscle strength: squat, 10–12 repetitions (reps); bench press, 10 reps; pulldown,10 reps; military press,10 reps; upright row,10 reps; triceps pushdown, 10–12 reps; leg extension, 10–12 reps; biceps curl, 10 reps; and leg curl,10–12 reps.

## Function

The primary purpose of the Abs diet is to help people, especially men, develop a lean, flat, and hard stomach—referred to in fitness circles as a 'six-pack'—and to maintain a healthy weight and lifestyle. The diet is designed to promote a longer and healthier life by helping prevent **cancer**, heart disease, high blood pressure, diabetes, and other diseases. These diseases are more prevalent in overweight and obese people compared to people who maintain a normal or below normal weight. The diet is also designed to promote a healthier sex life in men since some of the causes of erectile dysfunction are **obesity**, heart disease, and diabetes.

## Benefits

Excessive fat, especially around the belly, is a major risk factor for heart disease, high blood pressure, high LDL (bad cholesterol), diabetes, erectile dysfunction, and other diseases. By reducing or elimination excess body fat, people can live healthier and longer lives. The health benefits increase when regular exercise is added. People on the Abs diet can expect to lose up to 12 pounds in the first two weeks followed by 5–8 pounds in the next two weeks, according to Juliette Kellow, a registered dietician who reviews diets for the Website Weight Loss Resources (<http://www.weightlossresources.co.uk>).

Most diets include cardiovascular (aerobic) exercise as part of a weight loss routine. Studies have shown that people who engage in aerobic exercise burn more calories than people who did strength training, or weightlifting. However, additional research indicates that the fat-burning metabolic effects of aerobic exercise lasts 30–60 minutes while the metabolic effect of strength training lasts up to 48 hours. Also, the Abs diet promotes increased muscle mass, which increases **metabolism** so that the body burns up to 50 calories per day for every pound of muscle. So adding 10 pounds of muscle can burn up to 500 extra calories each day.

## Precautions

Overall, the diet is healthy and poses no known dangers. Some of the items listed in the 12 power foods can contain high amounts of **sodium**, such as canned and frozen vegetables, instant oatmeal, and peanut butter. People who want to limit salt intake or who have high blood pressure may want to avoid these food. Since exercise is a main component of the diet, people with arthritis or back, knee, or other joint problems should discuss the diet with their physicians before starting exercise. People who are allergic to peanuts or nuts should avoid food containing these products.

The diet does not address if it is suitable for vegetarians or vegans. Menus in the book do not have meatless options. However, eight of the 12 power foods do not contain meat or animal products. All of the protein required in the diet can be obtained by adding more beans and legumes to the diet and replacing meat with **soy** protein sources, such as tofu and meat substitutes that are high in protein. Brands

## QUESTIONS TO ASK YOUR DOCTOR

- Am I healthy enough to do the exercise routine required on the Abs Diet?
- Will I need any dietary supplements if I adopt the Abs Diet?
- Do you see any health risks for me in the diet?
- Are there any other diets you would recommend that would help me accomplish my goals?
- Have you treated other patients who are on the Abs Diet? If so, what has their response to the diet been?

Morningstar Farms, Boca, and Gardenburger make meatless burgers, hot dogs, chicken breasts and strips, and other items.

### Risks

Since the diet includes a rigorous and regular exercise program, people with heart disease or certain other health problems should consult their physicians before going on the diet. Men with erectile dysfunction should discuss their condition with their physicians, urologists, or endocrinologists. Also, one of the 12 power foods is nuts, so people with peanut or other nut allergies should eliminate or modify the nut component of the diet.

### Research and general acceptance

There is no specific research that proves the Abs diet delivers on what it promises: fat loss, muscle increase, increased sex drive, and six-pack abs. It is also unclear whether the diet will maintain a healthy weight once the initial weight is lost. The book contains many anecdotal stories of success but there are no scientific studies that document the claims.

In an article in the October 2004 issue of *Health*, registered dietician Maureen Callahan comments on the merits of the Abs diet, calling it an overall good diet and exercise plan. She adds that the diet is mostly healthy but she questions its promotion of protein powder, one of the diet's 12 power foods. She says people can get extra protein by eating low-fat cottage cheese or a few additional ounces of lean meat or fish.

# Acne diet

## Definition

The acne diet or more accurately, the acne-free diet, is simply a way of eating claims to improves or eliminates acne. There is some debate in the medical community about the impact of diet on acne; however, there is a body of evidence to support the idea that what is eaten may affect the skin.

By reviewing research from over 40 years, doctors such as dermatologist, Dean Goodless have developed a set of recommendations regarding foods that may prevent acne. In his book *The Acne-Free Diet Plan*, Dr. Goodless presents his recommendations. He suggests eating a diet low in fat and high in **fiber** along with avoiding peanut product, fried foods, excessive salt, dairy products, foods that are high in refined sugars, and high carbohydrate foods.

## Origins

As long as people have had pimples, there have been attempts to clear them up quickly or prevent them all together. Most cultures have folk remedies to help clear the skin. It wasn't until the last 50 years that serious scientific research has been conducted to confirm or disprove these folk tales and myths. One of the earliest studies about food and acne focused on chocolate. This study found that chocolate did not increase acne breakouts. Other studies since have confirmed this finding.

For the most part, acne treatment has been the emphasis of research; however, there have been isolated studies that explored the effect of specific vitamin and mineral supplements on acne. Other studies have investigated ethnic groups and communities from the Pacific Islands to Africa where there is little or no incidence of acne, even during puberty. When the diets of these people are compared to the typical Western diet, there are nutritionally significant differences. The ethnic groups with very low incidence of acne ate predominately plant-based diets that were low in fat and virtually sugar-free. The typical Western diet is heavy in meats, saturated fat, refined sugar, and highly processed foods. By studying these differences, doctors and researchers have developed suggestions for dietary changes to improve or eliminate acne.

## Description

Integrating the results of many studies, dermatologists and nutritionists have developed a list of foods to avoid and beneficial **vitamins** and **minerals** to consume. The following acne diet has been proposed to help prevent acne breakouts:

- Eat 20 to 30 grams of fiber every day–Fiber helps keep the colon clean and may remove toxins from the body before they reach the skin.
- Eat a low fat diet–The cultures whose natural diet was low in fat, had less acne, and high fat consumption may elevate hormone levels in the body that cause blemishes on the skin.
- Avoid peanut products–Peanut products were found to cause acne flare ups in a study of 500 adolescents.
- Avoid fried foods—Fried foods were found to caused break outs.
- Limit salt intake especially table salt or iodized salt–Many people with acne have elevated levels of iodine, found in table salt, in their blood stream during acne flare ups.
- Avoid highly salty sacks such as chips, lunch meats, canned foods, and salted popcorn–These foods are high in salt and, in some cases, fat.

## KEY TERMS

**Acne Vulgaris**—An inflammatory disease of the skin characterized by pimples and cysts that may cause scarring in severe cases.

**Carbohydrate**—An organic compound that supplies energy to the body.

**Dermatologist**—A doctor who specializes in the treatment of the skin.

**Glycemic index**—A scale for rating how quickly foods are converted to glucose or sugar by the body. It describes the impact on insulin levels of foods as they are digested.

**Hormone**—Substances in the body that regulate a process such as metabolism or growth.

**Insulin**—A hormone that regulates the conversion of food into glucose or sugar so it can be used by the body for energy.

**Metabolism**—The process by which food is converted into energy.

**Nutritionist**—A specialist in the field of diet and nutrition.

**PreMenstrual**—The days prior to menstruation in a woman.

**Sebaceous glands**—Small glands in the skin, usually part of hair follicles, that produce a fatty substance called sebum.

**Sebum**—The fatty substance secreted by sebaceous glands. It helps moisturize and protect skin and hair.

- Avoid dairy products such as milk, cheese and ice cream
- Avoid highly processed carbohydrates such as sodas, candy, and baked goods–High carbohydrate foods raise the level of insulin in the blood and elevated insulevel may raise the levels of acne–causing hormones in the body.

In addition to following the acne diet suggestions, taking the following supplements are proposed to also help prevent acne:

- Vitamin A (may be toxic consult your doctor first)
- Vitamin E
- Vitamin $B_6$
- Selenium
- Zinc
- Omega-3 Fatty Acid
- Chromium

### Function

Opinions vary in the medical community as to whether or not diet plays a significant role in acne. Some common misconceptions about the connection between food and acne breakouts have been disproved. For example, according to several studies, chocolate does not cause acne.. Acne is caused when glands in the skin called sebaceous glands begin to form sticky oil called sebum. These glands are stimulated by hormones that become active at puberty which is why acne occurs most often in adolescence when these hormones are produced in abundance. The oils formed by the sebaceous glands hold dead skin cells preventing them form being sloughed off. As these cells die, they create the perfect environment for bacteria to grow. When these bacteria called Acne Vulgaris become too plentiful, they will attempt to erupt from the skin causing a pimple. Sometimes, when the bacteria grow, the body sends white blood cells to fight the infection. This natural reaction can cause painful, large cysts to form in the deeper layers of skin. Chocolate may not cause acne, but the fat and sugar that usually accompanies chocolate may.

Eliminating certain foods from the diet and increasing the amount of specific vitamins and minerals may help reduce the amount of sebum produced and prevent acne breakouts. However, the interaction between diet and acne is not a simple cause and effect relationship. If an oily food is eaten, the oil does not travel to the skin or cause it to be oily, but high levels of fat in the blood may effect the production of hormones such as testosterone. Higher levels of hormones may cause acne to worsen.

Many high carbohydrate foods are believed to worsen acne. Researchers have discovered that high carbohydrate foods increase the levels of insulin in the blood. High levels of insulin can raise hormone levels in the blood.

Researchers recognize that not all **carbohydrates** are bad. Some carbohydrates digest more slowly than others, causing a gradual rise in blood sugar after eating. Researchers have developed a glycemic index to rank carbohydrates and other foods according to the effect they have on blood sugar.

The glycemic index is a scale of 0–100. Foods with higher glycemic index ratings break down quickly and cause a sharp spike in blood sugar. When blood sugar rises quickly, the body produces a surge of insulin to lower the amount of glucose in the blood. Insulin is a hormone that helps the body take sugar (glucose) out of the bloodstream and put it into cells, where it can be

used for energy or stored in fat. Foods with lower glycemic index ratings break down more slowly. They cause a more gradual rise in blood sugar, which means less insulin will be needed.

Foods that have a high glycemic index rating include: white bread, white rice, white potatoes depending on how they are cooked, beer, corn products and some products containing refined sugars. Foods with moderate glycemic index ratings include: whole grain breads and pastas, brown rice, sweet potatoes, green peas, many fruits (especially when eaten alone) and yogurt. Many of these foods are on the list of foods to avoid in the acne diet.

Low glycemic index or no GI foods include: rye grain, nuts, legumes such as black beans and lentils, green vegetables, apricots, and cherries. These foods may be enjoyed an may not worsen acne.

Foods that are high in fiber tend to have lower glycemic index numbers, because fiber takes longer to digest. Studies have shown that the presence of other foods such as **fats** like olive oil, can also slow digestion and keep blood sugar from rising too quickly. The glycemic index can be used along with the acne diet, to help choose which carbohydrates can be eaten with the least effect on blood sugar.

## Benefits

Even if many dermatologists do not believe dietary changes will improve acne, they see little harm in adopting a diet that encourages eating fruits and vegetables and limits processed and high sugar foods.

Eating foods low on the glycemic index may help prevent other medical conditions such as diabetes, heart disease, and **obesity**.

## Precautions

Limiting the amount of dairy products in the diet may limit the amount of **calcium** consumed, for that reason, a calcium supplement may be needed to insure daily dietary calcium requirements are met. Poor intakes of calcium can be very damaging to one's health.

**Zinc** supplements can cause stomach upset. Authors of acne diet plans recommend no more than 30mg of zinc per day to avoid this.

**Vitamin A** is a fat soluble vitamin. That means that excess vitamin A is stored in your body rather than eliminated in your urine. Too much vitamin A can be harmful. Consult a doctor before taking vitamin A supplements.

## QUESTIONS TO ASK THE DOCTOR

- What type of acne do I have?
- Will this diet improve my acne?
- Can this diet hurt me?
- Will this diet make my acne worse?
- How long do I need to follow this diet?

Pregnant women or those who may become pregnant should not take vitamin A supplements. Excessive amounts of vitamin A may cause birth defects in the unborn children of women who consume too much vitamin A.

## Risks

There are few risks associated with an acne diet. Most relate to taking zinc, vitamin A, and calcium. Zinc may prevent the body from absorbing enough copper. To avoid this, take a supplement that specifically states that it does not prevent copper absorption.

High doses of vitamin A can be toxic. Many acne prescriptions contain concentrated forms of vitamin A. Consult a doctor before taking vitamin A supplements.

Limiting intake of calcium can cause deficiency and significant health problems. Supplementation may be necessary.

High doses of vitamin A can cause birth defects if taken during pregnancy. Pregnant women should, under no circumstances take vitamin A supplements or medications containing vitamin A.

## Research and general acceptance

### *General acceptance*

While most dermatologists will not confirm that altering diet may prevent acne, it is standard practice for many doctors to advice patients to avoid foods that seem to cause more severe breakouts.

It is widely accepted that supplements such as zinc and vitamin A help reduce the number and severity of acne breakouts. In fact, Acutane and Retin A, popular prescription medications used to treat acne are both made from forms of vitamin A.

### *Research*

Early studies about diet and acne focused on specific foods believed to trigger acne breakouts. Most of

these studies found no evidence that individual foods cause acne.

Studies of the diets of ethnic groups that have a low incidence of acne form the basis of most of the acne diets. Studies of the diets of tribes in New Guinea, Paraguay, and the Bantu of South Africa, all of whom have little or no acne, show that they eat a primarily plant-based diet. Similarly, in other countries where the diet is plant-based such as Japan, there is a relatively low occurrence of acne.

Studies have shown that half of acne patients tested had abnormal glucose levels, and in another study, 80%of premenstrual women with acne had abnormal glucose **metabolism**. These data and others that show a high carbohydrate diet increases the levels of testosterone in the blood of both men and women, have lead to the recommendation of reducing the amount high carbohydrate foods or foods containing high levels of refined sugar to treat acne.

Researchers have developed a method for measuring how quickly carbohydrates are converted into glucose. The more rapidly a food is converted to glucose, the higher the level of insulin is secreted into the blood. The scale is called the glycemic index. Eating lower glycemic index foods may help reduce the number and severity of acne breakouts.

A large study of over 45,000 nurses found a link between the amount of dairy products these women consumed and the severity of acne they experienced. Women who reported consuming higher amounts of dairy products reported more severe acne. Similarly, the two ethnic groups with little or no acne also consumed no dairy products.

Several studies have compared the results of zinc supplementation with oral antibiotic therapy to resolved acne and found zinc to be almost as effective as the antibiotic tetracycline.

# ADHD diet

## Definition

Attention deficit **hyperactivity** disorder (ADHD) is defined as the combination of inattentive, hyperactive and impulsive behavior which are severe, developmentally inappropriate, and impair function at home and in school. Common features include mood swings, anxiety, impulsivity, hostility, poor concentration and sleeping disorders, along with physical complaints such as headaches, migraines, and stomach upsets. ADHD individuals are also more likely to have been of low birth weight and to have allergies or auto-immune problems. Proportionally more males than females are affected, with inattention tending to be a more female trait and hyperactivity more common in males.

ADHD does persist into adulthood, although symptoms tend to diminish with time, but the main focus relates to the problems of children with ADHD. Growing children are especially vulnerable to nutritional and environmental factors that influence brain development and function, which can have either a negative or positive impact. The symptoms of this difficult condition can also significantly compromise their education, making them challenging to teach and consequently having a deleterious effect on their

**Possible causes of ADHD-like behavior**

- A sudden change in the child's life—the death of a parent or grandparent; parents' divorce; a parent's job loss
- Undetected seizures, such as in petit mal or temporal lobe seizures
- A middle ear infection that causes intermittent hearing problems
- Vision problems
- Medical disorders that may affect brain functioning
- Underachievement caused by learning disability
- Anxiety or depression

SOURCE: National Institute of Mental Health, National Institutes of Health, U.S. Department of Health and Human Services

**Behaviors associated with ADHD can be caused by other factors. It is best to consult a medical professional to rule out these possibilities.** *(Illustration by GGS Information Services/ Thomson Gale.)*

life-potential. The daily challenges of living with ADHD place a huge strain on families and reduces overall quality of life for all involved.

## Origins

Back in 1981, Colquhoun and Bunday undertook a comprehensive survey of children with ADHD and discovered that many showed physical signs of essential fatty acid (EFA) deficiency, including excessive thirst, polyuria, dry hair and skin. These authors were the first to propose that fatty acid deficiency may be a factor in ADHD, and their ground-breaking work prompted more research studies and clinical trials designed to increase understanding of those nutritional factors involved in ADHD.

It has now been proposed that many developmental and psychiatric conditions, including ADHD along with dyslexia, dyspraxia, autism, depression, and schizophrenia, may involve deficiencies of certain long-chained **fats**, especially eicosapentaenoic acid ( EPA) and docosahexaenoic acid (DHA). Both **iron** deficiency and **zinc** deficiency have also been associated with the development of ADHD.

## Description

### *Dietary Fats*

Fats have a fundamental structural and functional role in the brain and central nervous system (CNS) and are a key factor in the development ADHD. The two fats that are thought to be especially important are EPA and DHA, not only because of their role in the brain and body but because of the relative lack of them in many people's diets. EPA is the precursor of a complex group of substances, called eicosanoids, which perform numerous regulatory functions in the brain and body. DHA is a major 'building block' of brain and neuronal membranes and as such has a profound influence on cell signalling. Both EPA and DHA are omega-3 fats and can be made from the omega-3 essential fatty acid, alpha linolenic acid (ALA). However, this conversion process can be problematic as genetic and environmental factors, including diet, can cause great variation in an individual's constitutional ability to convert ALA into EPA and DHA. Dietary factors known to adversely affect this conversion include low intakes of ALA, high intakes of omega-6 fats, saturated fat, hydrogenated fat and alcohol, in addition to vitamin and mineral deficiencies, testosterone and stress hormones. Unfortunately, many dietary surveys have revealed that a typical modern-day diet is rich in omega-6 fats, saturated fats and hydrogenated fats and often low in omega-3 fats and micronutrients. ADHD children are often found to be deficient in iron and zinc and the fact that more boys than girls tend to be affected may be partly explained by the negative effect of testosterone on this conversion process.

In order to avoid a functional deficiency of these important fats, the diet should have a smaller ratio of the omega-6 essential fat, linoleic acid (LA) to omega-3 essential fat (ALA), at an ideal ratio of no more than 5:1, as well as adequate amounts of pre-formed EPA and DHA. The richest dietary sources of LA are certain vegetable and seed oils, including sunflower, safflower, soya, palm, peanut and sesame, all of which should be eaten in good amounts along with oils that are rich in ALA such as rapeseed (canola), **flaxseed** (linseed) and walnut oil. Olive oil is also recommended, despite having quite a low ALA content, as it is rich in beneficial monounsaturated fats. Looking at types of spreading fat available, many margarines have been specifically formulated to be rich in ALA, although some brands still contain harmful hydrogenated fats, but it is worth remembering that butter actually has a low LA content and when mixed with equal quantities of rapeseed or olive oil, the saturated fat content is much reduced. Other sources of ALA include green, leafy vegetables such as rocket, watercress and spinach as well as fresh green herbs, such as basil, coriander, mint and parsley. Consequently, the food products of animals allowed to graze on open pasture will also be rich in ALA and so organic, free-range and outdoor-reared meat, milk and eggs are the best choice.

When it comes to sources of EPA and DHA, fish and seafood are the best sources with oily fish , such as salmon, trout, mackerel, sardines, herring and anchovies, being especially rich. Fresh tuna is classed as an

## KEY TERMS

**Autism**—Autism, or autistic spectrum disorder (ASD), is a serious developmental disorder, characterized by profound deficits in language, communication, socialisation and resistance to learning.

**Auto-immunity**—A response, involving the immune system, that results in a person's own tissues being attacked.

**Benzoic Acid**—A type of preservative used in processed foods known to cause food sensitivity in some individuals when consumed in the diet.

**Carnitine**—This is a naturally occurring substance, needed for the oxidation of fatty acids, a deficiency of which is known to have major adverse effects on the CNS.

**Dietitian**—A Healthcare Professional, qualified to degree or post-graduate level, who advises individuals on diet and nutrition as part of a treatment strategy for particular medical conditions or for disease prevention.

**Dyslexia**—An inherent dysfunction affecting the language centres of the brain which results in difficulties with reading and writing.

**Dyspraxia**—A developmental disorder that affects co-ordination and movement.

**Elimination Diet**—A diet consisting of a limited range of foods, classed as low risk in terms of causing food sensitivity or allergy.

**Essential Fatty Acid**—A type of fat that is necessary for the normal function of the brain and body and that the body is unable to produce itself, making them 'essential' to be taken through the diet and / or supplements.

**Ferritin**—Iron is stored in the body, mainly in the liver, spleen and bone marrow, as ferritin.

**Functional Deficiency**—The depleted state of a particular nutrient that precipitates compromised function within the brain or body.

**Hydrogenated Fats**—A type of fat made by the process of hydrogenation, which turns liquid oils into solid fat. Bio-hydrogenation occurs in ruminant animals (eg. cows) and so small amounts of hydrogenated fats are found in butter, dairy foods and meat but these are accepted as being harmless. The commercial hydrogenation of oils produces large quantities of hydrogenated fats and have been implicated in the development of coronary heart disease and impaired cell signalling in the brain.

**Lipid Peroxidation**—This refers to the chemical breakdown of fats.

**Neurotoxic**—A substance that has a specific toxic effect on the nervous system.

**Oxidative Injury**—Damage that occurs to the cells and tissues of the brain and body by highly reactive substances known as free radicals.

**Polyuria**—An excessive production of urine.

**Sodium Benzoate**—A type of preservative used in processed foods known to cause food sensitivity in some individuals when consumed in the diet.

**Sodium Metabisulphite**—A type of sulphite preservative used in processed foods known to cause food sensitivity in some individuals when consumed in the diet.

**Sulphites**—A type of preservative used in processed foods known to cause food sensitivity in some individuals when consumed in the diet.

**Sulphur Dioxide**—A type of preservative used in processed foods known to cause food sensitivity in some individuals when consumed in the diet.

**Vanillin**—A synthetic version of vanilla flavoring.

oily fish but the canning process causes a significant loss of fatty acids so tinned tuna has an EPA and DHA content comparable to white fish, such as cod, haddock and plaice. Certain varieties of fish are more likely to contain large amounts of pollutants such as mercury and lead which are known to be neurotoxic and so it is prudent for people with ADHD, and all children under 16 years of age, to avoid eating shark, marlin and swordfish. DHA can also be found in liver and egg yolks and so these foods should be incorporated into the diet regularly, unless you are taking a nutritional supplement that contains **vitamin A** in which case you should not eat liver or foods containing liver such as pâté.

A general recommendation of a combined daily dose of 500 mg EPA and DHA is needed to avoid functional deficiency of these important fats, although individuals with ADHD may have an even higher requirement. This weekly total of 3,500 mg is the equivalent of ~3 portions of salmon every week. In

the UK, the recommended amount per week for girls and women of childbearing age is two and for boys, men, and women past childbearing age is four. The relative amounts of EPA and DHA does vary greatly between varieties of fish , with mackerel providing 2700 mg per average portion and haddock providing a much lower 170 mg for a medium sized fillet. For many people this variability in EPA and DHA intake is unlikely to have significant consequences as long as fish is regularly consumed , but for individuals with ADHD it may compromise brain function. For this reason pure fish oil supplements that provide a daily standard dose of EPA and DHA are useful in addition to a diet containing fish and seafood. Increasing evidence from well designed clinical trials have indeed shown that supplementation with EPA and DHA alleviate ADHD-related symptoms in some children. These supplements also have the advantage of being relatively safe and offering general health benefits, specifically in terms of cardiovascular protection. Although pure fish oil supplements may be beneficial in some individuals with ADHD it is important to note that more research needs to be done to fully establish the durability of any treatment effects as well as optimal dosages and formulations.

### *Dietary Antioxidants*

If intakes of long-chained polyunsaturated fats (PUFAs), such as EPA and DHA, increase then so does the risk of lipid peroxidation by the action of harmful free radicals, smoking, and pollutants, etc.; substances produced in the body by normal processes such as breathing and **metabolism**. PUFAs are highly susceptible to attack from these reactive substances and need the protection of **antioxidants** to avoid getting damaged and thus affecting the structure of the lipid membranes of the brain and CNS. When free radical production is insufficiently countered by antioxidants the resultant damage to the brain and body is termed 'oxidative injury'.

Dietary antioxidants include nutrients such as **vitamin E** and **selenium** as well as biologically active substances such as flavonols, anthocyanins and **carotenoids**, found in highly colored fruits and vegetables, nuts, tea and red wine. Vitamin E is naturally found in PUFA-rich foods like oils and nuts whilst selenium is found in fish, seafood, liver, egg, brazil nuts, mushrooms and lentils. Eating the recommended daily minimum of 5 portions of fruit and / or vegetables should provide adequate amounts of complementary dietary antioxidants, especially if a wide range of colors and varieties are chosen.

### *Dietary Iron*

Iron deficiency has been associated with ADHD in children and tends to be worse even when compared with iron-deficient non-ADHD controls. Lower serum ferritin levels correlate with more severe ADHD symptoms and greater cognitive deficits.

Dietary sources of iron include red meat, fortified breakfast cereals, pulses and dried apricots and these foods should feature regularly in the ADHD diet. Additional supplementary iron may be required in cases of proven iron deficiency.

### *Dietary Zinc*

Zinc has a range of important functions in the body, including the metabolism of neurotransmitters and fatty acids, with zinc deficiency possibly having an effect on the development of ADHD. Children with ADHD who have been treated with supplementary zinc have exhibited reduced hyperactive, impulsive and impaired-socialisation symptoms.

Foods known to be rich in zinc include seafood, liver, pine nuts, cashew nuts and wholegrain cereals and so should be eaten regularly to help avoid deficiency.

### *Synthetic Food Additives*

Certain synthetic food colorings, flavorings and preservatives, have been linked to increase hyperactivity in some ADHD and non-ADHD children. Many of these additives are unnecessary and are frequently used to sell poor-quality foods, that are often marketed specifically at children.

The following additives have been implicated in adverse reactions:

- E102
- E104
- 107
- E110
- E122
- E123
- E124
- 128
- 133
- E142
- E150
- E151
- E154
- E155
- E180

- E220
- E221
- E222
- E223
- E224
- E226
- E227
- E228
- benzoic acid
- sodium benzoate
- sodium metabisulphite
- sulphur dioxide
- vanillin

### Function

The ADHD diet works by providing the right type and amount of fats needed for the brain and CNS as well as providing sufficient amounts of iron and zinc to avoid nutritional deficiencies that are known to be associated with worsening ADHD symptoms. Nutritional supplements should be taken upon the advice of a Doctor or Dietitian and taken in addition to a healthy, balanced diet. Dietary provision of antioxidants are needed to protect the long-chained fats from breakdown which would affect brain structure and compromise signalling within the brain and CNS. Finally, the ADHD diet excludes those synthetic food additives that have been identified as having the potential to adversely affect the behavior of ADHD, and non-ADHD children alike.

### Benefits

The key benefit of the ADHD diet is that it provides the correct types of foods needed to support the nutritional requirements of both the brain and body. It provides the nutrients needed to sustain good growth and development in children, as well as general health promotion for all, whilst excluding potential antagonistic additives. The diet supports other treatment strategies, including stimulant medication, and so helps to improve the quality of life and educational possibilities of those individuals affected.

### Precautions

Detailed, personalized advice should always be sought from a suitably qualified dietitian, especially when dealing with children. Any nutritional supplements should always be taken according to the manufacturers instructions and at the prescribed dosage. If other medication is being taken then advice should be sought from a doctor.

#### QUESTIONS TO ASK YOUR DOCTOR

- Which nutritional supplements are recommended for ADHD?
- What are the best food choices for ADHD?
- Which food additives should be avoided?
- What are the vegetarian sources of omega 3 fats?

### Risks

It has been reported that fish oil supplements when taken along side stimulant medication can exacerbate hyperactive behavior in some ADHD individuals. In these circumstances, the supplement should continue to be taken and the dosage of the medication be altered accordingly, under the supervision of a Doctor.

Fish oil supplements can also reduce blood clotting times and so should not be used if anti-coagulant medication is already being taken.

There is no risk attached to the ADHD diet in terms of foods chosen and the diet can be safely followed by ADHD and non-ADHD individuals alike.

### Research and general acceptance

Among the specialists working in this particular field, there is a general consensus that ADHD is a disorder that involves a functional deficiency of the long-chained fats, EPA and DHA that frequently coexists with zinc and iron deficiencies. Among the wider community there remains a great deal of scepticism about ADHD and the role that diet has in its development or management.

In terms of supplementation, insufficient data is available to formulate a standardized treatment strategy and it is unclear whether the micronutrient deficiencies are a cause of, or secondary to, ADHD. Other intervention studies have looked in to carnitine supplementation and **elimination diets** but their findings remain inconclusive.

It is certainly well accepted that there is still very much more to be learned about ADHD and how nutrients interact to either exacerbate or improve ADHD-related symptoms. More research is planned

and hopefully more useful findings will help improve the life of all those affected by this debilitating condition.

# Adolescent nutrition

## Definition

Nutrition describes the processes by which all of the food a person eats are taken in and the nutrients that the body needs are absorbed. Good nutrition for adolescents can help prevent disease and promote proper health, growth, and development.

Adequate intakes of **vitamins** and **minerals** are an important part of nutrition. Vitamins are organic substances present in food. They are required by the body in small amounts to regulate **metabolism** and to maintain normal growth and functioning. Minerals are vital because they are the building blocks that make up the muscles, tissues, and bones. They also are

**Healthy eating at fast food restaurants**

- Skip "value-sized" or "super-sized" meals
- Choose a grilled chicken sandwich or a plain, small burger
- Use mustard instead of mayonnaise
- Limit fried foods or remove breading from fried chicken, which can cut half the fat
- Order garden or grilled chicken salads with light or reduced-calorie dressings
- Choose water or fat-free or low-fat milk instead of sweetened soda

SOURCE: National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, U.S. Department of Health and Human Services

*(Illustration by GGS Information Services/Thomson Gale.)*

## KEY TERMS

**Anorexia nervosa**—A serious eating disorder characterized by a pathological fear of weight gain.

**Bulimia nervosa**—A serious eating disorder characterized by compulsive overeating followed by purging by self-induced vomiting or abuse of laxatives to induce diarrhea.

**Osteoporosis**—A condition that affects bone mass, usually later in life, making bones brittle and easily breakable.

important to many life-supporting systems, such as hormones, transport of oxygen, and enzyme systems.

There are many nutrients the body absorbs from food and each of the food groups supplies at least one nutrient. For example, oat bran, which is a whole grain, can supply **fiber** and a mineral called **magnesium**. A good nutrition plan will ensure that a balance of food groups, and adequate amounts of the nutrients supplied by each group, is eaten.

## Purpose

Proper nutrition is essential to keeping teens healthy and able to grow and develop properly. Eating right also helps teens participate better in school and athletic activities. The nutritional status and health of children and adolescents has declined in recent years. Government surveys have shown that at least 16% of children and adolescents age 6 to 19 years old are considered overweight and at least 11% of adolescents now are classified as obese. In 2000, more than 16% of the population under age 18 years lived in poverty, often receiving poor nutrition as a result.

Many adolescents consume more calories than they need, yet they don't meet recommended daily intakes for a number of nutrients. Of particular concern for children and adolescents are adequate levels of **calcium**, potassium, fiber, magnesium, and **vitamin E** from the diet.

**Eating disorders** lead to poor nutritional status and can affect growth and development for teenagers of both sexes. They rank as the third most common form of chronic illness in adolescent girls, affecting as many as 5% of teenage girls.

Studies have shown that eating habits and nutrition in adolescence can affect not only adult weight, but other health issues later in life. For instance, not eating enough calcium as a teenager can increase risk of **osteoporosis** as an older adult.

Finally, adolescent nutrition is important because some teens have health problems that require special diets. Type 1 diabetes, also called juvenile diabetes, is diagnosed in as many as 13,000 children a year, often during their teens. It requires, controlling both diet and lifestyle factors which can be particularly difficult for busy teenagers. Surprisingly, increases in **obesity** mean that Type 2 diabetes, which in the past has only been diagnosed in adults, now is diagnosed with increasing frequency in adolescents as well.

## Description

The United States Department of Agriculture (USDA) and the United States Department of Health and Human Services revised the *Dietary Guidelines for Americans* in 2005. The guidelines are science-based and outline advice for choosing a nutritious diet and maintaining a healthy weight. Although the guidelines are written for adults, the nutritional elements are the same for anyone over age two years old, with key recommendations for children and adolescents. The 2005 guidelines also address physical activity and **food safety**. The USDA revised the traditional food pyramid to make it customized for individuals.

### *Basic food groups*

The following are the basic food groups included in the pyramid provided by the USDA:

- Grains. The guidelines recommend eating at least three ounces of whole grain bread, cereal, crackers, rice, or pasta every day and adolescents should be encouraged to eat whole grains often. At least one-half of all grains should be whole grains, which can

be determined by looking for the word "whole" before the grain name on the list of ingredients.

- Vegetables. The pyramid recommends eating more dark green and orange vegetables, as well as more dry beans and peas.
- Fruits. A variety of fresh, frozen, or canned fruit is good, but the USDA recommends limiting consumption of fruit juices.
- Milk, yogurt, and cheeses. The USDA recommends getting plenty of calcium-rich food from low-fat or fat-free milk. Adolescents should consume three c. per day of fat-free or low-fat milk or equivalent milk products. Teens who can't drink milk should be given lactose-free products or other sources of calcium, such as hard cheeses and yogurt.
- Meat and beans. Lean protein should come from low-fat or lean meats and poultry that is prepared by grilling, baking, or broiling. Varying choices is recommended, so that more fish, beans, peas, nuts, and seeds that provide protein are part of the diet.
- Oils and fats. Most fat sources should come from fish, nuts, and vegetable oils. Solid fats such as butter, stick margarine, shortening, and lard should be limited. Adolescents should receive no more than 25% to 35% of calories from fats.

### *Adopting a balanced eating pattern*

The **Dietary Guidelines** recommend adopting a balanced eating pattern. Using the USDA's new pyramid can help customize a plan for teens that provides adequate nutrients for needed energy, growth, and development. Teenagers often report eating high levels of junk food, sweet sodas, especially when away from home. More than one-half of adolescents do not meet the Dietary Guidelines for fruit and vegetable consumption and nearly two-thirds consume more than the recommended amount of fat. Reports also show that at least two-thirds of adolescent boys and girls have tried to lose weight using unsuccessful methods. While many efforts have been made on national and local scales to improve the nutritional selections of school lunches and vending machines, the Dietary Guidelines offer a healthy way to provide a balanced diet at home and in lunch choices brought from home.

### *Fluid*

Many adolescents ignore the role that fluids play in nutrition. It is important to moderate drinking of high-sugar beverages and fruit juices especially between meals. **Caffeine** from sodas and coffee drinks can interfere with sleep if consumed late at night, which already is a health and school performance issue for many teens. The Dietary Guidelines also say that adolescents should not drink alcoholic beverages. Adolescents need to drink an adequate amount of **water**, though they do not need to overhydrate.

### *Nutrition for strength*

Adolescents who are physically active and play sports will have different nutrition needs than typical teenagers of the same age. For example, they will require more fluids while exercising. In general, those who are very active also require more **carbohydrates** in their diets than typical teens. Carbohydrates provide energy, but they should come from whole grains and fruits, not from refined sugars.

### *Vegetarian diets*

A minority of adolescents are vegetarians, though popularity of various vegetarian diets has increased among adolescents in recent years. For the most part, teenagers can meet most nutritional requirements and achieve adequate growth with a well-planned vegetarian diet. But the trend toward **vegetarianism** has contributed to nutrient deficiencies in American adolescents because of restrictive eating in the formative years. Teens have been reported to suffer stunted growth, fragile bones, and stress fractures from lack of nutrients on vegetarian diets.

The Dietary Guidelines are designed so that vegetarians can achieve recommended nutrient intakes through careful selection of certain foods. However, research has shown that teenage girls often have low levels of nutrients such as **zinc**, **iron**, and calcium, which can be more difficult to obtain from a vegetarian diet. Only one in four teenage girls eat the recommended quantity of meat on a daily basis. Vegan and macrobiotic diets may require supplementation of for teens.

### *Processed and prepared foods*

Americans are eating out more than ever and are buying foods in the grocery store that are prepackaged. Reading labels is encouraged. In general, fresh foods are healthier than those that are packaged. Highly processed foods do not contain significant amounts of essential minerals. They often contain high amounts of **fats** and sugar, as well as **artificial preservatives** and other additives. In recent years, a major emphasis has been placed on improving the nutritional value of lunch choices in schools. At one point, about 75% of junior high and high school

students had access to vending machines, school stores, canteens, or snack bars. Nutrition experts have worked with educators to present adolescents with healthier choices at school, to decrease or change the messages of food advertising, and to better educate students in the classroom about good nutritional choices.

### *Calories and weight management*

The new guidelines and pyramid focus on the basics of calorie management. It's all about balancing energy, or the amount of calories eaten vs. the amount of calories used by the body. By managing portions, eating a balanced diet from the food groups, and not taking in too many calories on high-sugar or high-fat foods, adolescents can maintain a reasonable intake of calories. Regular physical activity can help to balance energy. Research has shown that subtracting just 100 calories a day from the diet can help manage weight. The typical soda contains 150 calories. Adults need to help teens understand that balanced eating and calorie management help manage weight, not unhealthy stretches of fasting or reliance on **fad diets**. Physical activity also helps manage weight. Encouraging more participation in sports or just spending time outside with family and friends vs. "screen time" in front of the television, computer, and video games, also can help manage weight safely.

Dieting is an important predictor of eating disorders among adolescents. Girls who practiced rigid dieting are about 18 times more likely to have eating disorders such as **anorexia nervosa**, **bulimia nervosa**, or eating disorder not otherwise specified. Teen girls who have dieted moderately are five times more likely to be diagnosed with an eating disorder. If an eating disorder is diagnosed, the adolescent will receive therapy with behavioral and nutritional approaches.

Nutritional therapy for teens with eating disorders will first correct possible malnutrition caused by the eating disorder. Refeeding must be carefully planned to avoid complications brought on by sudden increased calories and weight gain. The meal plan will be based on the Dietary Guidelines with gradual increases in calories as the teen's lean body mass increases.

Some adolescents with diabetes have been known to use doses of insulin below those recommended by their physicians to promote weight loss. Teens with Type 1 diabetes will have nutritional counseling upon diagnosis and regular checks with a registered dietician. They will have to count carbohydrates and carefully plan diet around exercise to avoid weight gain. Teens with Type 2 diabetes also will be taught how to control blood glucose levels.

## Precautions

Like adults, adolescents need to understand that it is best to achieve recommended levels of nutrients through consumption of foods instead of through vitamins and supplements. Use of supplements should be done only under the supervision of a professional medical provider who understands adolescent nutrition needs. Adolescents should understand that the best way to manage weight is through a balanced approach to eating fresh foods and through remaining physically active, not through fasting, use of drugs or supplements, or through participation in fad diets.

## Complications

Failing to eat a nutritious diet can cause growth and developmental problems in adolescents and cause long-term complications such as obesity or osteoporosis. Eating disorders can lead to serious complications in teens, including malnutrition, changes to heart function caused by starvation, stomach bleeding, and may cause depression leading to suicide. Improper management of diabetes can lead to loss of consciousness and seizures, and in the longer term, eye disease, kidney and heart disease, or nerve damage.

## Parental concerns

Parents are up against the peer pressures and constant conflicting images that adolescents get from the media. On the one hand, teens see unrealistic images of body types on television and in magazines. On the other hand, they are bombarded with advertisements for processed, convenient, and unhealthy foods. Girls also frequently read magazine articles about dieting and weight loss, a practice that leads to unhealthy weight control behaviors. Internet Web sites even provide advice to teens on how to accomplish and hide their eating disorders and what sorts of products help people with bulimia nervosa in their purging of foods.

Parents can help by promoting healthy habits at home. Teens can be encouraged to snack on healthy foods. Parents can educate their teens about nutrition and the nutrients that are essential to them as they grow. Houses with teens should have fresh fruits and vegetables on hand to hold hunger off after school. Teens also should be encouraged to participate in

sport and recreational activities or at least to replace daily screen time with walking the family dog or joining the family or friends in physical activity.

# Adult nutrition

## Definition

Nutrition describes the processes by which all of the food a person eats are taken in and the nutrients that the body needs are absorbed. Good nutrition can help prevent disease and promote health.

**Vitamins** and **minerals** are an important part of nutrition. Vitamins are organic substances present in food. They are required by the body in small amounts to regulate **metabolism** and to maintain normal growth and functioning. Minerals are vital because they are the building blocks that make up the muscles, tissues, and bones. They also are important to many life-supporting systems, such as hormones, transport of oxygen, and enzyme systems.

There are many nutrients the body absorbs from food and each of the food groups supplies at least one nutrient. For example, oat bran, which is a whole grain, can supply **fiber** and a mineral called **magnesium**. A good nutrition plan will ensure that a balance of food groups, and the nutrients supplied by each group, is eaten.

**Percentage of healthy, overweight, and obese adults in the United States**

| Age 20 ≥ yrs. | Healthy weight BMI 18.5 to 24.9 | Overweight BMI 25.0–29.9 | Obese BMI 30 and above |
|---|---|---|---|
| All Adults | 32.9% | 34.1% | 32.2% |
| Women | 35.4% | 28.6% | 34.6% |
| Men | 30.4% | 39.7% | 31.1% |

## Purpose

As children, nutrition is important for normal growth and development. As adults, nutrition still promotes health and reduces risk of disease. Studies have shown that Americans have gained weight largely because they eat too much and because they choose to eat the wrong foods. Good nutrition can help prevent weight gain by focusing on consuming calories that are high in nutrients, not in sugars and fat. Nutrition also plays a role in preventing and controlling diseases. For example, poor nutrition can lead to high cholesterol, which causes **coronary heart disease**. Lowering salt in the diet can control high blood pressure. People with diabetes must follow special diets to control their blood glucose levels.

Examples of people with medical conditions and diseases show the effect that certain nutrients, or a lack of certain nutrients, can have on the human body. Some specific diseases linked to poor diet and physical inactivity are cardiovascular disease, type 2 diabetes, high blood pressure, **osteoporosis**, and certain types of **cancer**. Being overweight, and especially obese, also is linked to many health problems. Eating a poorly balanced diet that is low in nutrients but high in total calories can lead to weight gain.

Special diets or nutritional therapy may be used to complement other treatments subscribed by a physician to treat particular diseases and conditions. Examples include:

- High cholesterol. Eating a diet high in fiber and low in saturated fats and cholesterol can help keep cholesterol in check.
- High blood pressure. Reducing salt and certain fats, as well as reducing overall weight, helps lower blood pressure. Special diets have been developed to lower risk of high blood pressure and heart disease.

## KEY TERMS

**Monounsaturated fat**—Fats that contain one double or triple bond per molecule. Though these fats still have lots of calories, they can help lower blood cholesterol if used in place of saturated fats. Examples of monounsaturated fats are canola oil and olive oil.

**Polyunsaturated fat**—Fats that contain two or more double or triple bonds per molecule. Examples include fish, safflower, sunflower, corn, and soybean oils.

- Diabetes. Nutrition is critical to adults with type 2 diabetes. They will have to control portions, eat regularly and eat nutrient-rich foods, along with other dietary guidelines.
- Anemia. People with anemia need to get more iron from their diets and will be encouraged to eat more foods such as soybeans, spinach, and others.

Sometimes, people who are ill need artificial nutrition to help them receive the proper nutrients. The nutrition may come in the form of special drinks that supplement their diets or even be provided through intravenous (IV) injections in a hospital or other facility.

Nutrition is important throughout adults' lives. As younger adults, good nutrition helps keep people strong as they need energy for active lives that may involve athletic pursuits and busy days filled with work and raising children. Pregnant women will need to pay particular attention to nutrition. In the middle years, proper nutrition helps prevent disease and weight gain that normally is associated with aging and lives that may become more sedentary. And as people reach their mature years, nutrition becomes critical, as many people in their later years fail to eat properly due to medical conditions and medications or social factors.

## Description

The United States Department of Agriculture (USDA) and the United States Department of Health and Human Services revised the *Dietary Guidelines for Americans* in 2005. The guidelines are science-based and outline advice for choosing a nutritious diet and maintaining a healthy weight. The 2005 guidelines also address physical activity and **food safety** and make recommendations for special population groups. Finally, calorie requirements and servings are based more on gender, age, and level of physical activity, while in 2000, the servings were more uniform for all adults. The USDA also revised the traditional food pyramid to make it customized for individuals.

### *Basic food groups*

The following are the basic food groups included in the pyramid provided by the USDA:

- Grains. The guidelines recommend eating at least three ounces of whole grain bread, cereal, crackers, rice, or pasta every day. At least one-half of all grains should be whole grains, which can be determined by looking for the word "whole" before the grain name on the list of ingredients.
- Vegetables. The pyramid recommends eating more dark green and orange vegetables, as well as more dry beans and peas.
- Fruits. A variety of fresh, frozen, or canned fruit is good, but the USDA recommends taking it easy on fruit juices.
- Milk, yogurt, and cheeses. The USDA recommends getting plenty of calcium-rich food from low-fat or fat-free milk. People who can't drink milk should turn to lactose-free products or other sources of calcium, such as hard cheeses and yogurt.
- Meat and beans. Lean protein should come from low-fat or lean meats and poultry that is prepared by grilling, baking, or broiling. Varying choices is recommended, so that more fish, beans, peas, nuts, and seeds that provide protein are part of the diet.
- Oils and fats. Most fat sources should come from fish, nuts, and vegetable oils. Solid fats such as butter, stick margarine, shortening, and lard should be limited.

**FOOD GROUPS TO ENCOURAGE.** The new guidelines encourage eating enough fruits and vegetables to stay within energy needs. Two cups of fruit and about 2 and one-half cups of vegetables per day are adequate for a person consuming 2,000 calories per day. Those eating more or less than 2,000 calories can adjust their fruits and vegetables up or down.

**FOOD GROUPS TO MANAGE CAREFULLY.** Total fat should be between 20% and 35% of calories and most fat should come from polyunsaturated and monounsaturated **fats**. Most people should consume less than about 1 tsp. of salt per day. They also should choose food and beverages with little added sugars or high-calorie sweeteners. Alcohol should be consumed in moderation, about one drink per day for women and

two drinks per day for men. Drinking alcohol with meals helps.

### *Adopting a balanced eating pattern*

The **Dietary Guidelines** recommend adopting a balanced eating pattern. Using the USDA's pyramid can help customize a plan or adults can choose the DASH eating plan. DASH is a plan that was created to help prevent high blood pressure by minimizing salt in the diet, by providing a balance of nutrients, and by keeping weight down.

### *Recommendations for specific adult populations*

Not every adult has the same nutritional needs. In addition to specific nutritional needs related to diseases or activity, the following recommendations apply to certain groups:

- People over age 50. Guidelines recommend consuming vitamin $B_{12}$ in fortified foods or supplements.
- Women of childbearing age. If a woman many become pregnant, she should eat iron-rich plant foods or those that help absorb iron, such as vitamin-C rich foods. Women in their first trimester of pregnancy should consume adequate synthetic folic acid daily from fortified foods or supplements in addition to food forms from a varied diet.
- Older adults, people with dark skin, and people not exposed to sufficient sunlight. These individuals should consume extra vitamin D from vitamin-D fortified foods and/or from supplements.

### *Getting adequate nutrients*

The actual amount of any nutrient a person needs, as well as the amount each individual gets from his or her diet will vary. Many adults do not receive enough **calcium** from their diets, which can lead to osteoporosis later in life. Other nutrients of concern are potassium, fiber, magnesium, and **vitamin E**. Some population groups also need to get more **vitamin $B_{12}$**, **iron**, folic acid, and **vitamin D**. These nutrients should come from food when possible, then from supplements if necessary.

### *Fluid*

Many adults ignore the role that fluids play in nutrition. It is important to moderate drinking of high-sugar beverages and fruit juices, as well as alcoholic beverages. Most people will get adequate hydration from normal thirst and drinking behavior, especially by consuming fluids with meals.

### *Nutrition for strength*

Adults who are physically active and who strength train or pursue athletic activities will have different nutrition needs than typical adults of the same age. For example, they will require more fluids while exercising. In general, athletes and those who are very active also require more **carbohydrates** in their diets than typical Americans. Carbohydrates provide energy, but they should come from whole grains and fruits, not from refined sugars.

### *Vegetarian diets*

Vegetarians can achieve recommended nutrient intakes by carefully choosing foods from the basic food groups. They will need to pay special attention to intake of **protein**, iron, and other vitamins, depending on the type of vegetarian program they follow. Choosing nuts, seeds, and legumes from the meat and beans group, as well as eggs if they desire, can provide enough nutrients at the proper serving level.

### *Processed and prepared foods*

Americans are eating out more than ever and are buying foods in the grocery store that are prepackaged. It is more difficult to judge the nutrients and calories in many of these foods and in general, fresh foods are healthier than those that are packaged. Highly processed foods do not contain significant amounts of essential minerals. They often contain high amounts of fats and sugar, as well as **artificial preservatives** and other additives. Many restaurants, including fast food restaurants, are trying to offer healthier selections. The USDA offers tips for eating out to help people stay within their healthy pyramid servings and portions.

### *Calories and weight management*

The new guidelines and pyramid focus back on the basics of calorie management. It's all about balancing energy, or the amount of calories eaten vs. the amount of calories used by the body. By managing portions, eating a balanced diet from the food groups and not using discretionary calories on high-sugar or high-fat foods, people can maintain a reasonable intake of calories. Regular physical activity can help use calories to provide better balance. Research has shown that subtracting just 100 calories a day from the diet can help manage weight, and eating 500 fewer calories a day can result in losing one pound per week in weight. But every individual is different and it is recommended to involve a physician or dietician in a weight loss plan.

## Precautions

Though supplementation of nutrients sometimes is necessary, physicians and dieticians recommend that nutrients come from food, not from vitamins and supplements. Excessive use of vitamins and mineral supplements can lead to serious health problems and it is best to involve a physician to ensure that supplements are being used at appropriate and safe levels. It also is best not to change a diet without the advice of a nutritional expert or health care professional. People who are chronically ill, and women who are pregnant or **breastfeeding** only should change their diets under professional supervision.

## Parental concerns

The recommendations in the Dietary Guidelines are for Americans over two years of age.

# African diet

## Definition

Africa, the second largest continent in the world, is rich in geographic and cultural diversity. It is a land populated by peoples with histories dating to ancient times and cultures shaped by innumerable tribes, languages, and traditions. Because it is the birthplace of *Homo sapiens* and the land of origin for much of the world's population, the culture of food and eating in the different regions of Africa is important to people throughout the world.

**Male and female life expectancy at birth in Africa, 2004**

| Country | Male | Female |
|---|---|---|
| Algeria | 69 | 72 |
| Angola | 38 | 42 |
| Botswana | 40 | 40 |
| Burkina Faso | 47 | 48 |
| Burundi | 42 | 47 |
| Chad | 45 | 48 |
| Congo | 53 | 55 |
| Ivory Coast | 41 | 47 |
| Ethiopia | 49 | 51 |
| Gambia | 55 | 59 |
| Ghana | 56 | 58 |
| Kenya | 51 | 50 |
| Liberia | 39 | 44 |
| Mozambique | 44 | 46 |
| Namibia | 52 | 55 |
| Nigeria | 45 | 46 |
| Rwanda | 44 | 47 |
| Senegal | 54 | 57 |
| Sierra Leone | 37 | 40 |
| South Africa | 47 | 49 |
| Uganda | 48 | 51 |
| Zimbabwe | 37 | 34 |

*(Illustration by GGS Information Services/Thomson Gale.)*

## Origins

### *Early History of Africa*

The early history of man is the story of food in Africa. *Homo sapiens* evolved apart from other apes in Africa, and the adaptation of humans has been shaped by adaptations to diet. For example, some anthropologists believe that the selection pressure that led to bipedalism (walking on two legs) was an adaptation to changing environments that involved travel in search of tubers (rounded underground plant stems, such as potatoes). Africa's history includes some of humankind's earliest food production, with one of the most fertile centers located in Northern Africa, the Nile Valley. The Nile Valley historically was and continues to be a rich source of fish, animal, and plant food. In the drier African savannas, especially after the Sahara region became arid after 6000 B.C.E., nomad tribes raised cattle, goats, or sheep, which served as part of the tribes' food source. Crops that were less affected by extreme weather like cereals (such as wheat, barley, millet, and sorghum) and tubers (such as yams) slowly became popular throughout the continent and have remained important staples in the African diet today.

The African Climate and Terrain. The historic influences on the African diet began in ancient times and continue to the present day. Great geographic differences across the African continent caused much of the variety in the African diet. In addition, many

tribes and peoples migrated or traded, bringing spices and foods from each other's culture into their own. However, though each region of Africa has its distinct cuisines, African food has its basic staples.

## Description

Throughout Africa, the main meal of the day is lunch, which usually consists of a mixture of vegetables, legumes, and sometimes meat. However, though different meats are considered staples in many areas, many Africans are not able to eat meat often, due to economic constraints. Beef, goat, and sheep (mutton) are quite expensive in Africa, so these foods are reserved for special days. However, fish is abundant in coastal regions and in many lakes.

The combination of various foods is called stew, soup, or sauce, depending on the region. This mixture is then served over a porridge or mash made from a root vegetable such as cassava or a grain such as rice, corn, millet, or teff. Regional differences are reflected in variations on this basic meal, primarily in the contents of the stew. The greatest variety of ingredients occurs in coastal areas and in the fertile highlands. Flavorings and spiciness have varied principally due to local histories of trade. In the traditional African diet, meat and fish are not the focus of a meal, but are instead used to enhance the stew that accompanies the mash or porridge. Meat is rarely eaten, though it is well-liked among carnivorous (meat-eating) Africans.

Traditional Cooking Methods. Traditional ways of cooking involve steaming food in leaf wrappers (banana or corn husks), boiling, frying in oil, grilling beside a fire, roasting in a fire, or baking in ashes. Africans normally cook outdoors or in a building separate from the living quarters. African kitchens commonly have a stew pot sitting on three stones arranged around a fire. In Africa, meals are normally eaten with the hands.

### *North Africa*

The countries of North Africa that border the Mediterranean Sea are largely Muslim countries. As a result, their diet reflects Islamic traditions. The **religion** of Islam does not permit eating pork or any animal product that has not been butchered in accordance with the traditions of the faith. Like other regions of Africa, much of the diet is based on grains. However, cooking with olive oil, onions, and garlic is more common in the countries of North Africa. Notable spices include cumin, caraway, clove, and cinnamon. Flat breads are a common staple and can accompany any meal, including breakfast, which is usually porridge prepared from millet or chickpea flour. *Couscous* (made from hard wheat and millet) is often the main dish at lunch, which is the primary meal. This may be accompanied by vegetable salads. Other main dishes include *tajine*, named for the conical clay pot in which a whole meal is prepared. Lamb is cooked in tajines as well as on kabobs (roasted on a skewer). Vegetables include okra, meloukhia (spinach-like greens), and radishes. Common fruits are oranges, lemons, pears, and mandrakes. Legumes such as broad beans (fava beans), lentils, yellow peas, and black-eyed peas are also important staples. Alcoholic drinks are forbidden by Islamic tradition. Mint tea and coffee are very popular beverages in this region.

## KEY TERMS

**Anemia**—Low level of red blood cells in the blood.

**Calorie**—Unit of food energy.

**Famine**—Extended period of food shortage.

### *West Africa*

Within West Africa, there is considerable variation in the staple food. Rice is predominant from Mauritania to Liberia and across to the Sahel, a region that stretches across the continent between the Sahara and the southern savannas. Couscous is the prevalent dish in the Sahara. Along the coast from Côte d'Ivoire (Ivory Coast) to Nigeria and Cameroon, root crops, primarily varieties of yam and cassava, are common. Cassava, imported from Brazil by the Portuguese, is boiled and then pounded into a nearly pure starch. Yam is the chief crop in West Africa and is served in a variety of dishes, including *amala* (pounded yam) and *egwansi* (melon) sauce. Millet is also used for making porridge or beer.

Palm oil is the base of stew in the Gambia, southern, and eastern regions. In the Sahalian area, groundnut paste (peanut butter) is the main ingredient for stew. Other stews are based on okra (a vegetable native to the rainforests of Africa), beans, sweet potato leaves, or cassava. Other vegetables are eggplant, cabbage, carrots, chilies, french beans, lettuce, okra, onions, and cherry tomatoes. All the stews in this territory tend to be heavily spiced, often with chilies.

West African Fruit. Plantain, a variety of banana, is abundant in the more tropical West Africa. Sweet plantains are normally fried, while hard plantains are boiled or pounded into *fufu*. Dates, bananas, guava,

melons, passionfruit, figs, jackfruit, mangos, pineapples, cashews, and wild lemons and oranges are also found here.

Protein Sources. Meat sources of protein include cattle, sheep, chicken, and goat, though beef is normally reserved for holidays and special occasions. Fish is eaten in the coastal areas. Because of the Islamic influence, pork is localized to non-Muslim areas. In these regions, "bush meat" is widely eaten, including bush rat, a large herbivorous rodent, antelope, and monkey. Giant snails are also eaten in various parts of West Africa.

### *East Africa*

Extensive trade and migrations with Arabic countries and South Asia has made East African culture unique, particularly on the coast. The main staples include potatoes, rice, *matake* (mashed plantains), and a maize meal that is cooked up into a thick porridge. Beans or a stew with meat, potatoes, or vegetables often accompany the porridge. Beef, goat, chicken, or sheep are the most common meats. Outside of Kenya and the horn of Africa, the stew is not as spicy, but the coastal area has spicy, coconut-based stews. This is quite unique in comparison to the central and southern parts of Africa.

Two herding tribes, the Maasai and Fulbe, have a notably different eating pattern. They do not eat very much meat, except for special occasions. Instead, they subsist on fresh and soured milk and butter as their staples. This is unusual because very few Africans consume milk or dairy products, primarily due to lactose intolerance.

The horn of Africa, which includes modern-day Somalia and Ethiopia, is characterized by its remarkably spicy food prepared with chilies and garlic. The staple grain, teff, has a considerably higher **iron** and nutrient content than other grain staples found in Africa. A common traditional food here is *injera*, a spongy flat bread that is eaten by tearing it, then using it to scoop up the meat or stew.

### *Southern Africa*

Outside of the temperate zones, in the southern part of the continent, a greater variety of fruits and vegetables are available. Fruits and vegetables in southern Africa include bananas, pineapples, pau-pau (papaya), mangoes, avocadoes, tomatoes, carrots, onions, potatoes, and cabbage. Nonetheless, the traditional meal in southern Africa is centered on a staple crop, usually rice or maize, served with a stew. The most common dish made from cornmeal is called *mealie meal*, or *pap* in South Africa. Also known as *nshima* or *nsima* further north, it is usually eaten with stew poured over it. The stew may include a few boiled vegetables, such as cabbage, spinach, or turnips, or on more special occasions, fish, beans, or chicken.

## Risks

### *Nutrition and Disease*

White South Africans (Dutch descendants called Afrikaaners), Europeans, and Asian Indians in Africa have diets similar to their countries of origin. In urban areas, however, the diet of (black) Africans is increasingly dependent on meat, much like the diet of some West African pastoral tribes, as well as on empty calories from prepackaged foods similar to those found in the West. The result is an unbalanced diet. In many parts of Africa, the traditional diets of indigenous peoples are often inadequate in essential **vitamins**, **minerals**, and protein, which can lead to a variety of diseases. Micronutrient deficiencies, particularly **vitamin A**, **iodine**, and iron deficiencies, which can result in vision impairment, goiter, and anemia, respectively, are prevalent throughout much of Africa, particularly in the arid areas where the soil is deficient either naturally or due to overuse.

### *Food Security*

A far greater threat comes from increasingly insecure food sources (a lack of consistent and affordable food staples) arising from adverse weather (drought and floods) and war. During the late 1900s, famine became increasingly frequent in Africa. In addition, a new threat to the food supply emerged due to the worsening HIV/AIDS epidemic. As adults fall ill and die, agricultural production declines. Rural communities are the hardest hit, and women are particularly at risk given their unique physiologic needs tied to their roles as mothers, as well as their vulnerability due to lower economic and social status.

With its immense population, resources, and growing population, Africa is a continent that struggles to keep its people and cultures healthy. African history, the proliferation of foods and spices across the land, and the preservation of land that can still be farmed, will continue to be important. Weather, geography, politics, culture, and religion are forces that have caused strife within Africa for centuries, and will continue to do so. A land that was once pure and fertile can only be restored through land preservation and food availability.

# African-American diet

## Definition

The 2000 U.S. Census revealed that there were almost 35 million African Americans, or about 13%of the total U.S. population. This small percentage of the populace has had a significant influence on American cuisine, not only because African-American food is diverse and flavorful, but also because of its historical beginnings. Despite their cultural, political, economic, and racial struggles, African Americans have retained a strong sense of their culture, which is, in part, reflected in their food.

## Origins

### *The After effects of Slavery*

The roots of the diversity of African-American cuisine may be traced back to 1619, when the first African slaves were sold in the New World. In a quest to build new cities in America, Europeans actively transported Africans and West Indians (people from the West Indies) to the new land. The West Indies (in the Caribbean Sea) was part of the slave route to America. Because the West Indians' skin color was similar to that of Africans, they were not treated any differently. As a result, some West Indian food traditions are similar to those of African Americans.

It is not surprising that African-American food has a distinctive culinary heritage with diverse flavors, as it includes traditions drawn from the African continent, the West Indies, and from North America. While the European nations were busy establishing new societies, they did not realize that the African and West Indian slaves who worked for them brought their own vibrant and and rich culture—a culture that would withstand and adapt to the harsh centuries of slavery.

Food historian Karen Hess writes about the struggle of African Americans to maintain some of their original culture through food. "The only thing that Africans brought with them "from Africa" was their memories." Slave traders attempted to craft culturally sensitive rations for the Africans by including yams, rice, corn, plantains, coconuts, and scraps of meat in the slaves' provisions.

Southern slaves established their own cooking culture using foods that were similar to foods that were part of their African and West Indian heritages, and many popular foods in the African-American diet are directly associated with foods in Africa. For instance, the African yam is similar to the American sweet potato. White rice is also popular because it was a major part of the diet in West Africa. African Americans infuse plain rice dishes with their own savory ingredients (popular rice dishes include gumbo and "hoppin' John," a dish made with rice, black-eyed peas, and salt pork or bacon).

## KEY TERMS

**Nutrient**—Dietary substance necessary for health.

**Type II diabetes**—inability to regulate level of sugar in the blood due to a reduction in the number of insulin receptors on the body's cells

### *The Legacy of African-American Cuisine*

Popular southern foods, such as the vegetable okra (brought to New Orleans by African slaves), are often attributed to the importation of goods from Africa, or by way of Africa, the West Indies, and the slave trade. Okra, which is the principal ingredient in the popular Creole stew referred to as gumbo, is believed to have spiritual and healthful properties. Rice and seafood (along with sausage or chicken), and filé (a sassafras powder inspired by the Choctaw Indians) are also key ingredients in gumbo. Other common foods that are rooted in African-American culture include black-eyed peas, benne seeds (sesame), eggplant, sorghum (a grain that produces sweet syrup and different types of flour), watermelon, and peanuts.

Though southern food is typically known as "soul food," many African Americans contend that soul food consists of African-American recipes that have been passed down from generation to generation, just like other African-American rituals. The legacy of African and West Indian culture is imbued in many of the recipes and food traditions that remain popular today. The staple foods of African Americans, such as rice, have remained largely unchanged since the first Africans and West Indians set foot in the New World, and the southern United States, where the slave population was most dense, has developed a cooking culture that remains true to the African-American tradition. This cooking is aptly named *southern cooking, the food*, or *soul food*. Over the years, many have interpreted the term *soul food* based on current social issues facing the African-American population, such as the civil rights movement. Many civil rights advocates believe that using this word perpetuates a negative connection between African Americans and slavery. However, as Doris Witt notes in her book *Black Hunger* (1999), the "soul" of the food refers loosely to the food's origins in Africa.

In his 1962 essay "Soul Food," Amiri Baraka makes a clear distinction between southern cooking and soul food. To Baraka, soul food includes chitterlings (pronounced chitlins), pork chops, fried porgies, potlikker, turnips, watermelon, black-eyed peas, grits, hoppin' John, hushpuppies, okra, and pancakes. Today, many of these foods are limited among African Americans to holidays and special occasions. Southern food, on the other hand, includes only fried chicken, sweet potato pie, collard greens, and barbecue, according to Baraka. The idea of what soul food is seems to differ greatly among African Americans.

## General Dietary Influences

In 1992 it was reported that there is little difference between the type of foods eaten by whites and African Americans. There have, however, been large changes in the overall quality of the diet of African Americans since the 1960s. In 1965, African Americans were more than twice as likely as whites to eat a diet that met the recommended guidelines for fat, **fiber**, and fruit and vegetable intakes. By 1996, however, 28%of African Americans were reported to have a poor-quality diet, compared to 16% of whites, and 14% of other racial groups. The diet of African Americans is particularly poor for children two to ten years old, for older adults, and for those from a low socioeconomic background. Of all racial groups, African Americans have the most difficulty in eating diets that are low in fat and high in fruits, vegetables, and whole grains. This represents an immense change in diet quality. Some explanations for this include: (1) the greater market availability of packaged and processed foods; (2) the high cost of fresh fruit, vegetables, and lean cuts of meat; (3) the common practice of frying food; and (4) using **fats** in cooking.

Regional differences. Although there is little overall variability in diets between whites and African Americans, there are many notable regional influences. Many regionally influenced cuisines emerged from the interactions of Native American, European, Caribbean, and African cultures. After emancipation, many slaves left the south and spread the influence of soul food to other parts of the United States. Barbecue is one example of Africaninfluenced cuisine that is still widely popular throughout the United States. The Africans who came to colonial South Carolina from the West Indies brought with them what is today considered signature southern cookery, known as *barbacoa*, or barbecue. The original barbecue recipe's main ingredient was roasted pig, which was heavily seasoned in red pepper and vinegar. But because of regional differences in livestock availability, pork barbecue became popular in the eastern United States, while beef barbecue became popular in the west of the country.

Other Ethnic Influences. Cajun and Creole cooking originated from the French and Spanish but were transformed by the influence of African cooks. African chefs brought with them specific skills in using various spices, and introduced okra and native American foodstuffs, such as crawfish, shrimp, oysters, crabs, and pecans, into both Cajun and Creole cuisine. Originally, Cajun meals were bland, and nearly all foods were boiled. Rice was used in Cajun dishes to stretch out meals to feed large families. Today, Cajun cooking tends to be spicier and more robust than Creole. Some popular Cajun dishes include pork-based sausages, jambalayas, gumbos, and coush-coush (a creamed corn dish). The symbol of Cajun cooking is, perhaps, the crawfish, but until the 1960s crawfish were used mainly as bait.

More recently, the immigration of people from the Caribbean and South America has influenced African-American cuisine in the south. New spices, ingredients, combinations, and cooking methods have produced popular dishes such as Jamaican jerk chicken, fried plantains, and bean dishes such as Puerto Rican *habichuelas* and Brazilian *feijoada*.

Holidays and Traditions. African-American meals are deeply rooted in traditions, holidays, and celebrations. For American slaves, after long hours working in the fields the evening meal was a time for families to gather, reflect, tell stories, and visit with loved ones and friends. Today, the Sunday meal after church continues to serve as a prime gathering time for friends and family.

Kwanzaa, which means "first fruits of the harvest," is a holiday observed by more than 18 million people worldwide. Kwanzaa is an African-American celebration that focuses on the traditional African values of family, community responsibility, commerce, and self-improvement. The Kwanzaa Feast, or Karamu, is traditionally held on December 31. This symbolizes the celebration that brings the community together to exchange and to give thanks for their accomplishments during the year. A typical menu includes a black-eyed pea dish, greens, sweet potato pudding, cornbread, fruit cobbler or compote dessert, and many other special family dishes.

Folk beliefs and remedies. Folk beliefs and remedies have also been passed down through generations, and they can still be observed today. The majority of African-American beliefs surrounding food concern the medicinal uses of various foods. For example, yellow root tea is believed to cure illness and lower blood sugar. The bitter yellow root contains the antihistamine berberine and may cause mild low blood pressure. One of the most popular folk beliefs is that excess blood will travel to the head when one eats large amounts of pork, thereby causing **hypertension**. However, it is not the fresh pork that should be blamed for this rise in blood pressure, but the salt-cured pork products that are commonly eaten. Today, folk beliefs and remedies are most often held in high regard and practiced by the elder and more traditional members of the population.

## Risks

### *Effects of Socioeconomic Status: Poverty and Health*

Many of the foods commonly eaten by African Americans, such as greens, yellow vegetables, legumes, beans, and rice, are rich in nutrients. Because of cooking methods and the consumption of meats and baked goods, however, the diet is also typically high in fat and low in fiber, **calcium**, and potassium. In 1989, 9.3 million of the black population (30.1%) had incomes below the poverty level. Individuals who are economically disadvantaged may have no choice but to eat what is available at the lowest cost. In comparison to other races, African Americans experience high rates of **obesity**, hypertension, type II diabetes, and heart disease, which are all associated with an unhealthful diet.

Obesity and hypertension are major causes of heart disease, diabetes, kidney disease, and certain cancers. African Americans experience disproportionately high rates of obesity and hypertension, compared to whites.

High blood pressureand obesity have known links to poor diet and a lack of physical activity. In the United States, the prevalence of high blood pressure in African Americans is among the highest in the world. The alarming rates of increase of obesity and high blood pressure, along with the deaths from diabetes-related complications, heart disease, and kidney failure, have spurred government agencies to take a harder look at these problems. As a result, many U.S. agencies have created national initiatives to improve the diet quality and the overall health of African Americans.

## Looking Forward to a Healthier Tomorrow

African-American food and its dietary evolvement since the beginning of American slavery provide a complicated, yet extremely descriptive, picture of the effects of politics, society, and the economy on culture. The deep-rooted dietary habits and economic issues that continue to affect African Americans present

great challenges regarding changing behaviors and lowering disease risk. In January 2000, the U.S. Department of Health and Human Services launched Healthy People 2010, a comprehensive, nationwide health promotion and disease prevention agenda. The overarching goal of this program is to increase quality and years of healthy life and eliminate health disparities between whites and minority populations, specifically African Americans. As national health initiatives and programs continue to improve and target African Americans and other populations in need, preventable diseases will be lowered, creating a healthier U.S. society.

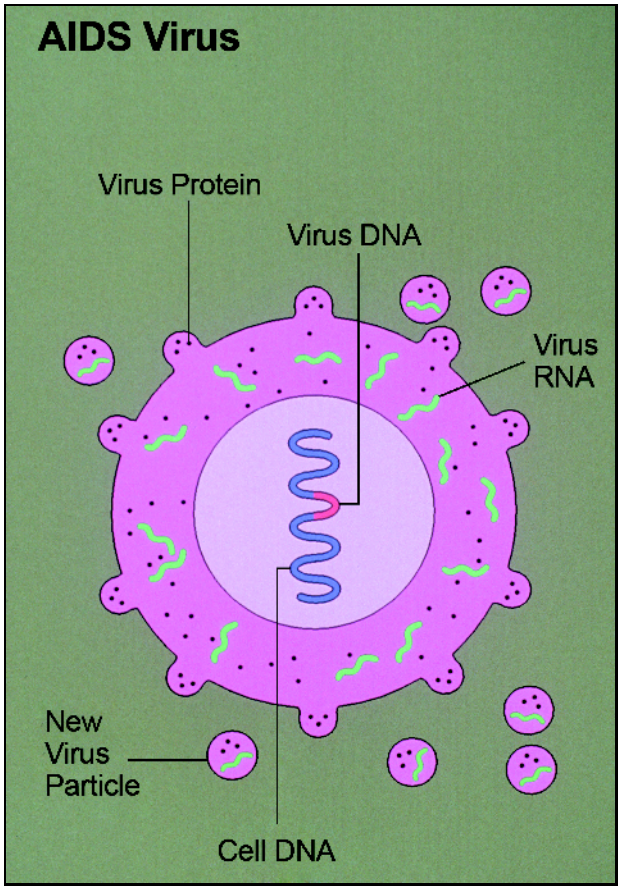
# AIDS/HIV infection

## Definition

Human immunodeficiency virus (HIV) infection is a complex illness caused by a retrovirus, which is a single-strand virus that replicates by using reverse transcription to produce copies of DNA that become incorporated within the genome of the host cell. The HIV virus destroys a type of white blood cell known as CD4+ T lymphocytes, or T helper cells. These cells are important in maintaining the various functions of the human immune system. When the level of CD4+ T cells in the bloodstream falls, the patient loses the ability to fight off bacteria, viruses, and fungi that would not cause disease in a person with a strong immune system. Infections that occur in people with weakened immune systems are called opportunistic infections.

Acquired immunodeficiency syndrome (AIDS) is an advanced form of HIV infection in which the patient has developed opportunistic infections or certain types of **cancer** and/or the CD4+ T cell count has dropped below 200/μL. According to the Centers for Disease Control and Prevention (CDC), an estimated 1,039,000 to 1,185,000 persons in the United States were living with HIV/AIDS at the end of 2003, with 24–27% undiagnosed and unaware that they are infected. More than 40 million persons around the world are infected with HIV as of 2007, with approximately 14,000 new infections every day. The disease



**The AIDS virus.** *(National Institutes of Health.)*

causes 3 million deaths worldwide each year, 95% of them in developing countries.

Nutritional issues are common in patients with HIV infection. Some problems with diet and nutrition are caused by HIV infection directly while others are related to opportunistic infections or medication side effects. Maintaining adequate food intake and balanced nutrition in patients with HIV infection is complicated not only by the many ways in which the disease can affect the body—including the fact that the virus mutates rapidly—but also by frequent updating of treatment strategies for AIDS, including nutritional therapy. As a result, nutritional care of patients with AIDS must be tailored to each person and reviewed carefully every few months. In 2004, the American Dietetic Association (ADA) and the Dietitians of Canada (DC) issued a position statement on the care of persons with HIV infection that said, "Individualized nutrition care plans will be an essential feature of the medical management of persons with HIV infection and AIDS." The ADA has a specialized dietetic practice group (DPG) for AIDS and HIV patients that can be contacted from the website listed below.

## Origins

AIDS is a relative newcomer to the list of major infectious diseases. According to the National Institutes of Health (NIH), researchers think that HIV originated in a species of chimpanzees native to west equatorial Africa and jumped the species barrier into humans through hunters' contact with the blood of infected chimpanzees—most likely somewhere in western Africa in the second half of the twentieth century. The earliest known case of HIV infection was found in a blood sample collected from a man in Kinshasa in the Congo in 1959.

The first cases of AIDS were not diagnosed in the United States until June 1981, when the CDC reported a cluster of five cases of an opportunistic lung infection among homosexual men in Los Angeles. In the first 15 years of the epidemic, there were no effective treatments for HIV infection (there is still no cure as of 2007). As a result, many patients turned to alternative dietary treatments to help them manage the nausea, weight loss, and other symptoms associated with the infection. Alternative food-related therapies that were used in this period included:

- Herbal compounds used in traditional Chinese medicine (TCM) for the treatment of fevers or energy deficiency, particularly medicines containing astragalus (*Astragalus membranaceus*).
- Western herbal preparations recommended by naturopaths, including goldenseal (*Hydrastis canadensis*), licorice (*Glycyrrhiza glabra*), osha root (*Ligusticum porteri*), and echinacea.
- Detoxification diets, including the Master Cleanser lemon juice diet.
- Juice fasts, often taken together with laxatives or colonics.
- Nutritional supplements, particularly blue-green algae, zinc, vitamin C, beta-carotene, and catechin (an antioxidant).
- Vegetarian and raw food diets.

Prior to 1996, nutritional management of AIDS patients focused largely on weight loss and wasting, sometimes called the "slim disease." After the introduction of highly active antiretroviral therapy (HAART) in 1996, however, nutritionists were confronted with a range of other dietary problems related either to the new drugs or to prolonged survival itself.

## KEY TERMS

**Acquired immune deficiency syndrome (AIDS)**—HIV infection that has led to certain opportunistic infections, cancers, or a CD4+ T-lymphocyte (helper cell) blood cell count lower than 200/mL.

**Acute retroviral syndrome (ARS)**—A syndrome that develops in about 30% of HIV patients within a few weeks of infection. ARS is characterized by nausea, vomiting, fever, headache, general tiredness, and muscle cramps.

**Carrier**—A person who bears or carries a disease agent in or on their body and can transmit the disease to others, but is immune to the disease or has no symptoms of it.

**Colonic**—Sometimes called colonic hydrotherapy, a colonic is a procedure similar to an enema in which the patient's colon is irrigated (washed out) with large amounts of water. Some people undergoing a detoxification diet have one or more colonics to remove fecal matter remaining in the intestines during the diet; however, this procedure is discouraged by mainstream physicians because of its potential risks to health.

**Dietitian**—A health care professional who specializes in individual or group nutritional planning, public education in nutrition, or research in food science. To be licensed as a registered dietitian (RD) in the United States, a person must complete a bachelor's degree in a nutrition-related field and pass a state licensing examination. Dietitians are also called nutritionists.

**Highly active antiretroviral therapy (HAART)**—The major form of pharmacological treatment for HIV since 1996. HAART is a combination of several different antiretroviral drugs selected for patients on an individual basis. It is not a cure for HIV infection but acts to slow the replication of the virus and discourage new mutations. HAART has a number of side effects that complicate maintaining good nutrition in HIV patients.

**Lipodystrophy**—The medical term for redistribution of body fat in response to HAART, insulin injections in diabetics, or rare hereditary disorders.

**Malabsorption syndrome**—A condition characterized by indigestion, bloating, diarrhea, loss of appetite, and weakness, caused by poor absorption of nutrients from food as a result of HIV infection itself, giardiasis or other opportunistic infections of the digestive tract, or certain surgical procedures involving the stomach or intestines.

**Opportunistic infection**—An infection caused by a normally harmless organism that causes disease when the host's immune system in weakened. Opportunistic infections are a major problem in the medical and nutritional care of HIV patients.

**Retrovirus**—A single-stranded virus that replicates by reverse transcription to produce DNA copies that are incorporated into the genome of infected cells. AIDS is caused by a retrovirus.

**Wasting syndrome**—A combination of weight loss and change in composition of body tissues that occurs in patients with HIV infection. Typically, the patient's body loses lean muscle tissue and replaces it with fat as well as losing weight overall.

HAART is not one drug but a combination of various antiretroviral agents given to patients to prevent the virus from replicating and to discourage mutations of the virus. The drugs must be taken in combination because no medication by itself is able to suppress HIV for very long. One early problem with HAART was the complicated dosing schedules of the different drugs prescribed for an individual patient. To encourage adherence to treatment schedules (which must be at least 98% complete to protect the patient from developing a strain of the virus resistant to HAART), some pharmaceutical companies developed fixed-dose combinations. A fixed-dose combination is a medication in which several antiretroviral drugs that are known to work well together are combined in a single pill.

Guidelines for offering HAART treatment to patients were published in the late 1990s because the drugs have so many adverse effects (including hair loss, muscle cramps and pains, kidney or liver failure, insomnia, inflammation of the pancreas, dizziness and mental confusion, headache, nausea and vomiting, and numbness in hands or feet) that many patients were not compliant with dosage schedules and developed drug-resistant mutations of the HIV virus. Recommendations for HAART have been revised several

times by the U.S. Department of Health and Human Services. The following is the most recent set of standards, issued in October 2005:

- All patients with history of an AIDS-defining illness or severe symptoms of HIV infection should receive antiretroviral therapy regardless of CD4+ T cell count.
- Antiretroviral treatment is recommended for asymptomatic patients with less than 200 CD4+ T cells/mL.
- Asymptomatic patients with CD4+ T cell counts of 201—350 cells/mL should be offered antiretroviral treatment.
- For asymptomatic patients with CD4+ T cell of greater than 350 cells/mL and plasma HIV RNA greater than 100,000 copies/ml, most experienced clinicians defer therapy but some clinicians may consider initiating antiretroviral treatment.
- Antiretroviral therapy should be deferred for patients with CD4+ T cell counts of greater than 350 cells/mL and plasma HIV RNA less than 100,000 copies/ml.

It is this set of guidelines for HAART that nutritionists currently work with when planning healthful diets for patients with HIV infection and AIDS.

## Description

While there is no standard "HIV diet" or "AIDS diet" because patients' symptoms, medication regimens, and corresponding nutritional needs vary so widely, there are general practices followed by registered dietitians who work with doctors and other health care professionals to care for these patients.

### *Dietetics consultation and follow-up*

Patients with HIV infection should consult a registered dietitian (RD) as soon as possible after diagnosis, because good nutrition is essential to maintaining a normal level of activity and self-care as well as supporting the patient's immune system. RDs use several screening questionnaires to evaluate patients for potential nutritional problems. On the patient's first visit, he or she is given a quick nutrition screen or QNS to fill out. A sample QNS from a California medical center may be found online at http://www.rwca2006.com/presentation/workshop/Tuesday_08.29.06/Workshop_C/432_Quick%20Screen.pdf. The QNS identifies such problems as unintentional weight loss, nausea, difficulty swallowing, and diarrhea. The dietitian then measures the patient's height, weight, skinfold thickness, and the circumference of the muscles on the patient's midarm. These last two measurements are needed in order to monitor changes in body fat distribution and muscle wasting that often accompany HIV infection.

The next step in the initial assessment the patient's completion of a food intake record (FIR). The patient is asked to record everything he or she eats or drinks in a 24-hour period, including snacks and alcoholic beverages. If possible, the patient will fill out two FIRs, one for a working day and one for a weekend day or holiday. The FIR allows the dietitian to evaluate the patient's usual eating habits, portion sizes, food preferences, and average calorie intake. It also establishes a baseline for the individual patient, so that loss of appetite later on or other nutritional problems can be detected as quickly as possible.

Follow-up visits to the dietitian are scheduled according to the degree of the patient's nutritional risk. The American Dietetic Association and the Los Angeles County Commission on HIV Health Services use the following timelines for HIV patients at nutritional risk:

- Low risk: The patient's weight is stable, with a balanced and adequate food intake; normal blood levels of cholesterol, triglycerides, and glucose; no evidence of kidney or liver disorders; regular physical exercise; and low levels of psychosocial stress. Low-risk patients are evaluated by the RD as needed, but at least once a year.
- Moderate risk: The patient is obese or suffers from changing patterns of body fat distribution; has high blood cholesterol levels or high blood pressure; has developed an eating disorder, nausea, vomiting, or diarrhea; has been recently diagnosed with type 2 diabetes or food allergies; is in recovery from substance abuse; or is under psychosocial stress. Moderate-risk patients should be seen by the RD within a month.
- High risk: The patient is pregnant; suffers from poorly controlled diabetes; has lost 10% of body weight over the previous 4–6 months; has lost 5% of body weight in the previous 4 weeks; has dental problems, involvement of the central nervous system, severe nausea or vomiting, severe pain on swallowing, or chronic diarrhea; has one or more opportunistic infections; or is under severe psychosocial stress. These patients should be seen by an RD within one week.

In addition to assessment of the patient's nutritional needs, RDs also evaluate his or her living situation and other issues that may affect receiving adequate nutrition.

### *Specific issues in nutritional care of HIV patients*

**NAUSEA, VOMITING, AND DIARRHEA.** Nausea and vomiting are common symptoms of HIV infection as well as side effects of HAART. They can lead to long-term damage to the esophagus and dental problems as well as weight loss and inability to take needed medications. About 30% of patients develop nausea and vomiting within 1 to 4 weeks following infection as part of a condition called acute retroviral syndrome or ARS, which resembles influenza or mononucleosis. Most patients, however, develop nausea, vomiting, and diarrhea later on in the course of the disease as side effects of HAART or from opportunistic infections of the gastrointestinal system. Patients with HIV infection are highly susceptible to such diseases as **giardiasis**, cryptosporidiosis, listeriosis, *Campylobacter* infections, and *Salmonella* infections.

Treatment of nausea, vomiting, and diarrhea in patients with HIV infections may require a number of diagnostic tests and imaging studies as well as evaluation of the patient's medications in order to determine the cause(s) of the symptoms.

**LIPODYSTROPHY.** Lipodystrophy is the medical term for the redistribution of body fat that sometimes occurs in patients with HIV infection as a result of HAART, genetic factors, the length of time a person has been HIV-positive, and the severity of the disease. It is not completely understood as of the early 2000s why antiretroviral drugs and other factors have this effect. The patient may notice new deposits of fat at the back of the neck (sometimes called "buffalo humps") and around the abdomen. Conversely, fat may be lost under the skin of the face, resulting in sunken cheeks, or lost under the skin of the buttocks, arms, or legs. Lipodystrophy is not necessarily associated with weight loss.

Lipodystrophy may be accompanied by other changes in the patient's **metabolism**, particularly insulin resistance and higher levels of blood cholesterol and **triglycerides**. One recommendation nutritionists often give to patients with lipodystrophy and metabolic changes is to follow the **Mediterranean diet**, which is high in fiber-rich whole grains and vegetables and low in saturated **fats**. Another recommendation is to maintain a schedule of regular physical exercise (particularly weight training), which has been shown to lower insulin resistance and decrease abdominal fat deposits.

**WASTING.** Wasting refers to rapid unintentional weight loss (usually defined as 5% of body weight over a period of 6 months) combined with changes in the composition of body tissue. Specifically, the patient is losing lean muscle tissue and replacing it with fat. The patient's outward appearance may not be a reliable guide to wasting, particularly if he or she also has lipodystrophy. Weight loss associated with wasting may result from nausea and vomiting related to opportunistic infections of the digestive tract as well as from reactions to medication.

Nutrition is the first line of defense against wasting. To help the patient maintain weight, nutritionists recommend raising the daily calorie intake from 17–20 calories per pound of body weight (a guideline used for patients whose weight has been stable) to 25 calories per pound. Patients with wasting syndrome may require as much as 3500 calories per day to maintain their weight. Nutrient ratios should be 15–20% **protein**, 50–60% **carbohydrates**, and 25% fats to protect the body's muscle tissue. Patients who need more calories or protein may benefit from adding such supplements as Ensure or Instant Breakfast to their daily diet. In addition, weight training or other forms of regular exercise help to maintain muscle tissue.

Other treatments for wasting include the use of appetite stimulants to increase food intake and hormonal treatments to build lean muscle tissue, particularly in male patients.

**MEDICATION INTERACTIONS.** Most medications used in HAART have the potential to cause nausea and vomiting. Some antiretroviral medications should be taken with food to minimize these side effects. Digestive disturbances are the single most common reason given by patients for discontinuing antiretroviral therapy. In some cases, switching to a different combination of drugs helps to relieve nausea, vomiting, or diarrhea.

## Function

The function of nutritional education and dietary management in patients with HIV infection and AIDS is to maintain the patient's energy level and ability to carry out normal activities of daily life; lower the risk of opportunistic infections of the digestive system; and minimize the side effects of HAART on the patient's ability to eat and enjoy food.

## Benefits

The benefits of good nutritional care of patients with HIV infection are prolonged survival, improved quality of life, and fewer or less severe side effects from medical treatment.

## Precautions

### *Food safety issues*

**Food safety** is an important concern for patients with HIV infection because their immune systems have difficulty fighting off food- or water-borne disease organisms. While most people can get **food poisoning** or parasitic infections of the digestive tract if they drink contaminated **water** or do not prepare food properly, patients with HIV infection can get severely ill as a result of these diseases. Food-borne illnesses are also much more difficult to treat in persons with AIDS or HIV infection, and may lead to malabsorption syndrome, a condition in which the body cannot absorb and make use of needed nutrients in food. The CDC and NIH have brochures with detailed instructions for patients about safety issues in purchasing and preparing foods, particularly when traveling abroad. Basic safeguards include the following:

- Wash hands repeatedly in warm soapy water before and after preparing or eating food. Instant hand sanitizers should be used when away from home.
- Cook all meats, fish, and poultry to the well-done stage; do not eat sushi, raw oysters, or raw meat in any form.
- Do not use unpasteurized milk or dairy products.
- Do not eat raw, soft-boiled, or "wet" scrambled eggs, or Caesar salad made with raw egg in the dressing. Hard-boiled or hard-scrambled eggs are safe.
- Rinse all fruits and vegetables carefully in clean, safe water, and clean all cutting boards and knives that touch chicken and meat with soap and hot water before using these utensils with other food items.
- Keep all refrigerated foods below 40°F; check expiration dates on food packaging.
- Completely reheat leftovers before eating, and do not eat leftovers that have been stored in the refrigerator for longer than 3 days.
- Do not drink water that comes directly from lakes, streams, rivers, or springs, and ask for drinks without ice in restaurants.

### *HIV patients with special needs*

Patients with special needs include those with limited food budgets or without access to a kitchen for preparing their own food. Advice regarding community resources and other forms of assistance can be found on the website of the Tufts University School of Medicine Nutrition/Infection Unit at the URLs listed under "Other" below.

### *CAM dietary treatments*

In general, multivitamins, other **dietary supplements**, or herbal teas prepared by reliable manufacturers and approved by the patient's physician are useful complementary treatments for HIV patients. Traditional Chinese medicines made outside the United States, however, should be used with great caution as their purity cannot be guaranteed.

Patients interested in a vegetarian diet should consult their physician and nutritionist before starting one; raw-food vegetarian diets should be avoided because of the increased risk of contracting food-borne diseases. **Detoxification diets** and colonics are risky practices for HIV patients and should not be used.

## Risks

There are no known risks to nutritional management of patients with HIV infection by qualified professionals working with the patient's physicians and nurses. There are few risks to the use of naturopathic dietary supplements or herbal formulas provided that the patient reports the use of alternative therapies to the medical care team and does not use them as substitutes for HAART or other mainstream medications.

## Research and general acceptance

Research in the field of nutrition for HIV patients is ongoing and can be expected to produce revised guidelines for dietary management every few years for the foreseeable future. These changes will result as much from mutations in the disease organism as from discoveries of new drugs and other forms of treatment for HIV infection.

Rebecca J. Frey, PhD

# Alcohol consumption

## Definition

Alcohol consumption is drinking beer, wine, or distilled spirits such as gin, whiskey, or vodka, that contains ethyl alcohol.

**Calories in alcohol**

| Beverage | Serving amount (ounce) | Average (calories) |
|---|---|---|
| **Beer** | | |
| Regular | 12 | 149 |
| Light | 12 | 110 |
| **Distilled (80 proof)** | | |
| Gin, rum, vodka, whisky, tequila | 1.0 | 65 |
| Brandy, cognac | 1.0 | 65 |
| Liqueurs (Drambuie, Cointreau, Kahlua) | 1.5 | 188 |
| **Wine** | | |
| Red | 4 | 80 |
| Dry white | 4 | 75 |
| Sweet | 4 | 105 |
| Sherry | 2 | 75 |
| Port | 2 | 90 |
| Champagne | 4 | 84 |
| Vermouth, sweet | 3 | 140 |
| Vermouth, dry | 3 | 105 |
| **Cocktails** | | |
| Martini | 3.5 | 140 |
| Manhattan | 3.5 | 164 |
| Daiquiri | 4 | 122 |
| Whiskey sour | 3 | 122 |
| Margarita cocktail | 4 | 168 |
| Coolers | 6 | 150 |

SOURCE: National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, U.S. Department of Health and Human Services

*(Illustration by GGS Information Services/Thomson Gale.)*

## Purpose

In earlier times, when subsistence agriculture was the norm, alcoholic beverages, usually beer or mead (fermented honey and **water**), provided a substantial percentage of calories in the diet. Today people drink alcohol to relax and socialize, to get high, or because they are physically addicted to it.

## Description

Ethyl alcohol, or ethanol, is produced by yeast fermentation of the natural sugars in plants, such as grapes (wine), hops (beer), sugar cane (rum), agave (tequila), or rice (saki). The process of fermenting plants to produce alcohol is at least 10,000 years old and appears to have developed independently in many cultures.

Alcohol affects almost every system of the body. Research suggests that when alcohol is consumed in moderation, there are some health benefits and some health risks. Heavy use of alcohol has no health benefits and many health risks. The federal *Dietary Guidelines for Americans 2005*. define moderate alcohol consumption as one drink per day for women and two drinks per day for men. This difference by gender is because women tend to be smaller than men, and their bodies contain a lower percentage of water, so an equivalent amount of alcohol in a woman's bloodstream will be more concentrated than in a man's. A "drink" according to these guidelines contains about 14 grams of alcohol and is defined as:

- 12 fluid ounces of regular beer
- 5 fluid ounces of wine
- 1.5 fluid ounces of 80 proof distilled spirits

Using this definition, one regular beer contains about 145 calories. One glass of red wine has 105 calories, and white wine has about 100 calories. One shot of distilled spirits has about 95 calories plus any calories in the mixer used mixed drinks.

### *Benefits of moderate alcohol consumption*

Good evidence based on more than 100 studies shows that moderate alcohol consumption can help prevent heart attack, sudden cardiac death, peripheral vascular disease, and stroke caused by blood clots (ischemic stroke). The risk of these diseases is reduced between 25% and 40% in both men and women. The reduction is seen in both people who have no apparent heart disease and those who are at high risk of heart disease because they have type 2 diabetes, high blood pressure (**hypertension**), angina (chest pain), or have already had one heart attack. Researchers suggest that this protective effect occurs because alcohol increases the amount of HDL or "good" cholesterol and also affects various proteins in ways that make blood clotting less likely.

In two other large studies, people who were moderate drinkers also were less likely to develop type 2 diabetes and **gallstones**. Gallstones are hard masses of cholesterol and **calcium** that form in the gallbladder. Finally, moderate drinking serves a social purpose that can provide psychological benefits.

### *Risks of moderate alcohol consumption*

Moderate alcohol consumption also carries with it some risks. In women, even moderate drinking is associated with a modest increase in the risk of developing breast **cancer**. However, researchers suggest that taking at least 600 mg of folic acid daily will counteract this increased risk.

Even moderate alcohol consumption by a pregnant woman can damage the developing fetus. Alcohol consumption can also alter sleep patterns and interact with many medications (see Interactions below). However, by far the greatest risk of moderate

## KEY TERMS

**B-complex vitamins**—a group of water-soluble vitamins that often work together in the body. These include thiamine ($B_1$), riboflavin ($B_2$), niacin ($B_3$), pantothenic acid ($B_5$), pyridoxine ($B_6$), biotin ($B_7$ or vitamin H), folate/folic acid ($B_9$), and cobalamin ($B_{12}$).

**Essential amino acid**—an amino acid that is necessary for health but that cannot be made by the body and must be acquired through diet.

**Folic acid**—also called vitamin $B_9$, a stable synthetic form of folate that is found in dietary supplements and is added to fortified foods such as flour and cereal.

**Mineral**—an inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

**Peripheral vascular disease**—diseases of any blood vessels except those that supply blood to the heart.

**Tolerance**—adjustment of the body to a drug so that it takes more and more to produce the same physiological or psychological effect

**Type 2 diabetes**—sometime called adult-onset diabetes, this disease prevents the body from properly using glucose (sugar).

**Vitamin**—a nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet

drinking is that for some people it will lead to heavy alcohol consumption, alcohol abuse, and alcohol dependency. Twin and family studies indicated that there is an inherited tendency for some individuals to develop alcohol abuse disorders.

### *Risks of heavy alcohol consumption*

Heavy alcohol consumption is defined for men as consuming 15 or more alcoholic drinks per week and for women as consuming 8 or more drinks per week. Between moderate and heavy alcohol consumption is a gray area of potentially problem drinking that includes binge drinking.

Binge drinking is heavy alcohol consumption that occurs intermittently. Bingeing for men means consuming 5 or more drinks in a period of about two hours. For women, it is consuming 4 or more drinks in the same time period. About 60% of men ages 18–25 binge drink.

Heavy alcohol consumption leads to two alcohol abuse disorders that are recognized in the *Diagnostic and Statistical Manual for Mental Disorders Fourth Edition (DSM-IV-TR)* published by the American Psychiatric Association. More men abuse alcohol than women, and these men begin drinking at an earlier age than women.

Alcohol dependence is diagnosed when one or more of the following occur within a 12-month period.

- Repeated alcohol use causes failure to fulfill obligations at work, home, or school.
- The individual repeatedly performs hazardous activities such as driving or operating machinery while under the influence of alcohol.
- Alcohol use causes legal problems.
- Alcohol use continues despite problems it causes in relationships.
- These symptoms do not rise to the level of alcohol dependence.

Alcohol abuse, or alcoholism, is diagnosed when three or more of the following occur within a 12-month period.

- Tolerance to the effects of alcohol develops.
- Stopping drinking causes, or would cause, physical symptoms of withdrawal.
- More alcohol is regularly drunk than is intended.
- Efforts to reduce alcohol consumption are unsuccessful
- Getting alcohol, drinking, and recovering from drinking alcohol consumes a great deal of time.
- Work, social, and recreational activities are replaced by drinking or recovering from drinking.
- Alcohol use continues despite its causing obvious physical and/or psychological problems.

On any given day, about 7% of Americans, or more than 17 million people, are alcohol dependent or have alcoholism. Costs related to alcohol disorders are estimated to be more than $185 billion annually. Alcohol disorders are related to increased rates of motor vehicle deaths, homicides, suicides, and domestic violence. About 34% of Americans never drink alcohol.

People with alcoholism do not eat healthy, balanced diets. When 30% or more of an individual's calories come from alcohol, serious nutritional deficiencies develop. Not only do people with alcoholism fail to get the **protein**, **vitamins**, and **minerals** they need, alcohol interferes with the absorption of the nutrients they do eat. People who abuse alcohol develop malnutrition

and deficiencies in essential amino acids, B-complex vitamins (especially vitamins $B_1$, $B_2$, and $B_6$), and **vitamin C**. They may develop either deficiencies or excesses of **vitamin A**. Along with nutritional deficiencies, the person with alcoholism often has liver damage. Cirrhosis, a disease in which the liver develops scar tissue and stops functioning, is the cause of death in about 32% of people with alcoholism worldwide. Alcoholism also substantially increases the chance of dying by violence or developing esophageal cancer, mouth cancer, and liver cancer or breast cancer in women. Heavy drinking increases the risk of stroke and cardiovascular disease and can cause brain damage, loss of judgment, loss of motor skills, and memory loss.

## Precautions

Some people who should never drink alcohol. These include:

- children and adolescents under age 21
- women who are pregnant, breastfeeding, or who could become pregnant
- people who cannot control their drinking and keep it at the level of moderate consumption
- people who plan to drive, fly a plane, operate dangerous equipment, act as a lifeguard, or perform any activity that requires quick reactions, good judgment, and coordination
- people who are unable to control their aggression when they drink
- people taking certain medications (see below)
- people with liver or kidney damage
- people who are recovering from alcoholism

## Interactions

Alcohol is a central nervous system depressant. More than 150 drugs interact with alcohol. Some of these interactions can be fatal, especially those that involve narcotic drugs that also depress the central nervous system. Categories of drugs that interact with alcohol include:

- narcotic drugs
- sleeping pills
- antidepressants
- anti-anxiety medications
- antihistamines

## Aftercare

The best-known treatment for alcohol abuse disorders is the 12-step program of Alcoholics Anonymous. This program uses social support, rewards, and mentoring to change behavior. For it to succeed, the person with alcoholism must want to recover and must be willing to work at achieving sobriety. Relapses are common. Families of alcoholics may be helped by Al-Non and teens by Alateen, whether or not their family member with alcoholism participates in Alcoholics Anonymous.

The United States Food and Drug Administration (FDA) approved three medications for the treatment of alcoholism. Disulfiram (Antabuse) makes the individual feel ill after drinking alcohol. Naltrexone (Depade, ReVia) act on the brain to reduce the craving for alcohol, and acamprosate (Canpral) reduces withdrawal symptoms. These medications are more effective with some people than others.

## Complications

Complications of moderate and heavy alcohol abuse are listed above. In addition to physical complications, alcohol consumption can take an emotional and psychological toll on relationships and families, especially on children who have a parent with alcoholism.

## Parental concerns

Alcohol consumption by adolescents substantially increases their risk of being in both fatal and nonfatal motor vehicle accidents. It also increases the chance of participating in risky sexual behavior, failing or dropping out of school, committing suicide, and being a homicide victim. Children who begin to drink before age 15 are four times more likely to develop alcoholism than people who begin drinking at age 21.

# American Diabetes Association

## Location

American Diabetes Association (ADA) PO Box 363 Mount Morris, IL 61054-0363 USA Toll-Free: (800) 342-2383 or 1-800-DIABETES E-mail: askada@diabetes.org Website: http://www.diabetes.org

## Description

Founded in 1940 The American Diabetes Association (ADA) is the nation's leading 501(C)3 nonprofit health organization. It boasts more than 280,000 Members and has a network of more than one million volunteers. The ADA serves 800 Local Groups within 53 State Groups.

## Mission

The mission of the ADA is to prevent and cure diabetes and to improve the lives of all people affected by diabetes.

To fulfill their mission, the ADA promotes research, information and advocates for finding a prevention and cure for diabetes. The ADA uses different techniques to educate people at risk of diabetes and with diabetes so they can improve their quality of life. They also disseminate information to the health care professionals, family and care givers of those with or at risk of diabetes. The ADA advocates for scientific research for finding a cure and prevention of the different types of diabetes. They are also one of the largest advocates for the rights of diabetics.

## ADA Members

Their members include but are not limited to Physicians, nurses, dietitians, physical/occupational therapists, other health professionals, and laypersons affected by **diabetes mellitus**. The ADA offers memberships to both consumers and health professionals who pay annual Membership dues.

## Consumer Membership

The consumer membership is for people with diabetes, their families and caregivers. Consumer members receive monthly issues of Diabetes Forecast(r) magazine, discounts on ADA books and cookbooks, and access to a network of diabetes support and informational resources. Consumer membership dues are $28 annually.

## Professional Membership

Professional membership provides health professionals, research scientists, and diabetes educators with recent information in diabetes research and treatment options. As members they receive, but not limited to, access to the ADA journal that is most relevant to their practice, registration discounts for ADA Scientific Sessions and for medical journals and books. Professional memberships can range from $50-350.00 annually.

## Resources

The ADA supports a variety of tools to educate its members and the public.

Their National Call Center provides diabetes information and referral for callers nationwide through their toll-free 800 number. The Call Center responds to approximately 350,000 inquiries each year.

The ADA also supports a website that is available for anyone with Internet access and links them to pertinent diabetes and diabetes prevention information, advocacy, membership information and community and local events.

## ADA Research

Founded in October 1994, the American Diabetes Association Research Foundation (ADARF) was created to raise money to directly fund diabetes research. This unique program is intended to complement the governments National Institutes of Health (NIH) diabetes research program through supporting new investigators and innovative research ideas. Through donations, the ADA has been able to provide nearly $40 million towards diabetes research in 2005.

Funds provided by ADARF support peer-reviewed basic and clinical diabetes research proposed to prevent, treat, and/or cure diabetes. Past research projects supported by the ADARF varied from the microcellular research to exploring education and psychological issues related to diabetes.

All ADARF grants become part of the Diabetes Research database that is accessible to anyone with access to the ADA website. This database provides brief descriptions of each funded project, and gives brief summaries on the value the study findings may have for the field of diabetes research. Database contents are updated at least every six months.

Other methods ADA uses to distribute research findings are through Access: Diabetes Research, and the Forefront Research Magazine. Both present summaries of diabetes research.

## Education Program Recognition

To ensure quality education for people with diabetes, the ADA endorses the National Standards for Diabetes Self-Management Education Programs. The Standards are designed to endorse any health care setting offering diabetes education, from physicians' offices and HMOs to clinics and hospitals. All applicants must meet the National Standards before they are awarded the endorsement from the ADA.

The National Diabetes Advisory Board (NDAB) developed the National Standards for Diabetes Patient Education Programs. The ADA then endorsed the Standards in 1983 while participating in the nationwide pilot testing of the Standards and review criteria in 1984. The first edition of the Standards was published in Diabetes Care in 1984. In 1986 an application and review process was established through the ADA to determine whether an education program met the Standards. Then in 1987, the first programs to meet the Standards were recognized by the ADA.

The Standards are reviewed and revised every five-year cycle. In 1995 and in 2000, a task force of representatives from the diabetes community completed a review of the Standards. The representatives are compiled from the American Association of Diabetes Educators, American Diabetes Association, American Dietetic Association, Centers for Disease Control and Prevention, Department of Veterans Affairs, Diabetes Research and Training Centers, Indian Health Service, Juvenile Diabetes Foundation and National Certification Board for Diabetes Educators.

The revised Standards are now called the National Standards for Diabetes Self-Management Education and are endorsed by all organizations involved in its development. When changes occur, the Education Program Recognition Committee of the ADA revises the application for Recognition, currently the 6th edition, to reflect the revised Standards.

## Professional Services

The Association provides educational and informative materials and programs for health professionals thru various media. Annually they sponsor a scientific sessions diabetes conference, in addition to other medical and scientific programs. The ADA publishes and updates their medical care guidelines and recommendations for health professionals. They also support special interest groups for professionals.

## Publications

The ADA is the world's foremost publisher in the field of diabetes literature, including Diabetes Forecast, a monthly consumer magazine, and a range of publications and journals for research and health care professionals, such as Diabetes, Diabetes Care, Diabetes Spectrum, Clinical Diabetes, and access to a comprehensive library of medical management guides.

## Fund Raising Activities

Each year, the ADA state chapters organize local events to increase awareness of diabetes within their

community, while at the same time help raise money for the ADA. The state chapters assist in organizing the ADA signature fund raising events. The signature events that occur annually are;

- America's Walk for Diabetes(r),
- Tour De Cure(r) a cycling event that takes place in over 70 cities nationwide,
- and School Walk for Diabetes(r) that is an educational, school based program that promotes community service, school spirit and healthy living to students.
- Another unique fund-raising campaign, Kiss-A-Pig(r), is a tribute to the pig for aiding in discovering the role of insulin for people with diabetes. It ends with the participant who raises the most money kissing the Kiss-A-Pig pig.

### *Public Awareness*

One of the goals of the ADA is to make the public aware of diabetes and the serious health effects it may have on a person. Throughout the year the ADA sponsors events to educate the public about diabetes and diabetes prevention. The National public awareness campaigns are:

American Diabetes Month is the Association's annual, month-long public awareness activity held each November. The goal is to raise awareness about serious and often preventable diabetes complications. A variety of events and educational activities are included in this awareness effort.

The American Diabetes Alert is conducted annually on the fourth Tuesday in March to raise awareness about the seriousness of pre-diabetes and diabetes and its risk factors. The centerpiece of the Alert is the diabetes risk test, which is widely distributed and promoted through community activities and national and local media.

## Program Services

The ethnic groups in the United States with the highest risk of developing type 2 diabetes are African Americans, Mexican Americans, and Pima Indians as well as Asian Americans and Pacific Islanders. The ADA reaches out to these communities through community campaigns.

### *The Diabetes Assistance and Resources Program (DAR)*

DAR, which means, "to give" in Spanish, provides valuable information in English and Spanish to the Latino/Hispanic community. The goal of the DAR program is to increase awareness about the seriousness of diabetes and the importance of prevention and control.

### *Diabetes Sunday and Get Up and Move.*

The African American Program's goal is to increase awareness about the seriousness of diabetes in the community and importance of early diagnosis and treatment. The program includes fun and informative church and community-based activities.

### *Awakening the Spirit: Pathways to Diabetes Prevention and Control*

Aimed at the Native American community, including American Indians, Alaska Natives, and Native Hawaiians. The program stresses the importance of choosing a healthy lifestyle for oneself and the generations that will follow.

### *Youth Programs*

The ADA is the largest provider of camps for children with diabetes in the world. Each year, more than 10,000 children benefit from camping programs provided through ADA funding.

They have developed a youth zone program that provides a web site especially for kids. It offers games, tips, links, and information to help kids manage their diabetes.

For the teen, the ADA provides information and resources directed to teens. It gives information on how diabetes may impact their lifestyle. It gives resources and tools to help the teen understand diabetes and how it impacts the choices they make and their health.

## Advocacy

Realizing a need for equality for those with diabetes, the ?ADA formed the Government Affairs & Advocacy program to help fulfill their mission of improving the lives of all those affected with diabetes. The main goals of this program are to:

- Improve access to quality medical care for people with diabetes
- Eliminate discrimination against people because of their diabetes
- Ensure the federal government is adequately funding diabetes research and programs.

## Description

The American Dietetic Association (ADA) was founded in Cleveland, Ohio, in 1917 during WWI by a visionary group of women, led by Lenna F. Cooper and ADA's first president, Lulu C. Graves. It was intended to aid the government in food conservation and enhance the public's health and nutrition. With approximately 67,000 members, in 52 states including the District of Columbia and Puerto Rico, it has an annual budget of 26 million. The ADA has grown to become the nation's largest organization of food and nutrition professionals.

The ADA and its members are committed to helping the public benefit from a healthy lifestyle. To do this, the ADA focuses on five critical health areas facing all Americans: Obesity and overweight, with special emphasis on children, healthy aging, having a safe, sustainable and nutritious food supply, nutrigenetics and **nutrigenomics**, integrative medicine, including supplements and alternative medicine.

## Mission

The ADA's Mission is 'Leading the future of dietetics.' They envision the members of the ADA as the most valued source of food and nutrition services.

## ADA Members

Most of ADA's members are registered dietitians with a small percentage coming from dietetic technicians, registered. Other members include clinical and community dietetics professionals, consultants, food service managers, educators, researchers, dietetic technicians and students. ADA members are able to join focused Dietetic Practice groups within the American Dietetic Association. These groups represent a wide range of practice areas and interests including public health; **sports nutrition**; medical nutrition therapy; diet counseling, cholesterol reduction, diabetes, heart and kidney disease; **vegetarianism**; food service management in business, hospitals, restaurants, long-term care facilities and education systems; education of other health-care professionals, entrepreneurism and scientific research.

Professionals choose to belong to ADA to receive the membership benefits. ADA provides, but not limited to, continuing education opportunities, access to the ADA Evidence Analysis Library, subscription to the Journal of the American Dietetic Association and access to information and resources. Membership dues are paid annually and range from $45-206.

## Nutrition Resource for the Public

The ADA promotes nutrition information for consumers and the media through various media. They support a website filled with content from news releases and consumer tips to Nutrition Fact Sheets, consumer FAQs and the Good Nutrition Reading List. Consumers seeking the services of a registered dietitian can locate one through their website.

Another way they promote healthy eating to the public was developed in 1973. Each March the National Nutrition Month (r) campaign begins. During this month, the ADA offers food and nutrition information through numerous programs and services.

Relatively new to ADA are their position statements which are regularly produced by the association and it's members. These position statements encompass the multifaceted issues related to nutrition. And are the official opinions of the ADA on issues that affect the nutritional and health status of the public. These statements are based on the latest scientific research available and have a process where they are reviewed and updated.

## Journal of the American Dietetic Association

The ADA publishes the Journal of the American Dietetic Association. The Journal is peer-reviewed and written by and for dietetics professionals. The journal brings professional knowledge across the range of research and practice issues such as: nutritional science, medical nutrition therapy, public health nutrition, food science and biotechnology, foodservice systems, leadership and management, and dietetics education to nutrition and dietetics professionals throughout the world. It is the most popular peer-reviewed periodical in the dietetics field.

## Government and Public Policy

To help fulfill their mission, the ADA began an advocacy network based in Washington, D.C. This government affairs office negotiates with state and federal legislators and agencies on public policy issues that affect the public and the scope of dietetics. Through their efforts the ADA has influenced Medicare coverage of medical nutrition therapy; child nutrition; **obesity**; the Dietary Guidelines for Americans and other health and nutrition concerns.

## The American Dietetic Association Foundation (ADAF)

The ADAF was established in 1966 as a 501(C)(3) public charity and is the philanthropic arm of the American Dietetic Association. They provide money for research, education and public awareness programs. The Foundation's primary focus is for funding of scholarships for nutrition and dietetic students, supporting food and nutrition research and to be a leader in promoting and achieving healthy weight for children, and helping to reduce the growing prevalence of **childhood obesity**. To do this, their mission is to fund the future of the dietetics profession through research and education. They are the largest grantor of scholarships in the nutrition and dietetic fields by awarding graduate, undergraduate and continuing education scholarships.

A 13-member board of directors that includes the President-Elect, Financial Officer and CEO of the American Dietetic Association as well as up to five public members governs the ADA Foundation. They have an operating budget over $7 million in endowed support for their causes and operations. Both individuals and industry have donated these funds. Approximately $1.4 million of the operating budget goes to support fundraising and grant making activities.

## Credentialing

The ADA is involved in the process for accredited education programs for RD's and DTR's. They also are affiliated with the Commission on Dietetic Registration who oversees the registration of dietitians and diet technicians.

The development of a accreditation process was incorporated into the ADA to serve the publics best interest by creating and enforcing eligibility requirements and accreditation standards that ensure the quality and continued improvement of nutrition and dietetics education programs. The Commission on Accreditation for Dietetics Education (CADE) was formed and is ADA's accrediting agency for education programs that prepare dietetic students for careers as nutrition professionals. Recognized by the United States Department of Education and the Council for Higher Education Accreditation, CADE is a reliable authority on the quality of nutrition and dietetics education programs. All dietetic programs meeting their standards are accredited through CADE.

## What is a Registered Dietitian?

***A registered dietitian (RD) is a professional who has met academic training in the areas of food and nutrition. The requirements needed are:***

- Bachelor's degree with course work approved by ADA's Commission on Accreditation for Dietetics Education. Coursework typically includes food and nutrition sciences, foodservice systems management, business, economics, computer science, sociology, biochemistry, physiology, microbiology and chemistry.
- Completion of an accredited, supervised, experiential practice program at a health-care facility, community agency or foodservice corporation.
- Pass a national examination administered by the Commission on Dietetic Registration.
- Complete continuing professional educational requirements to maintain registration.

Some RDs hold additional certifications in specialized areas of practice, such as pediatric or **renal nutrition** and diabetes education.

## What is a Dietetic Technician, Registered?

Dietetic technicians, registered, (DTRs) must complete a two-year associate's degree in an approved dietetic technician program, have supervised practice experience and pass a nationwide examination administered by the ADA to earn the DTR credential and must complete continuing education courses throughout their careers.

## The Commission on Dietetic Registration

The Commission on Dietetic Registration (CDR) is the overseer of the Registered Dietitian (RD); Dietetic Technician, Registered (DTR); Board Certified Specialist in Renal Nutrition (CSR); and Board Certified Specialist in Pediatric Nutrition (CSP); Board Certified Specialist in Sports Dietetics (CSSD) and Board Certified Specialist in Gerontological Nutrition (CSG). Since the credentialing process began, over 78,000 dietitians and dietetic technicians worldwide have taken the CDR exams.

The Commission's RD/DTR certification programs are fully accredited by the National Commission for Certifying Agencies (NCAA), the accrediting arm of the National Organization for Competency Assurance (NOCA) based in Washington, D.C. This accreditation reflects achievement of the highest standards of professional credentialing for nutrition professionals.

The CDR consists of eleven members consisting of seven RDs, one RD Specialist, and one DTR who serve a five-year term. In addition, the CDR appoints a newly credentialed RD for a one-year term. A public representative, appointed by CDR members, has full rights and privileges for a five-year term. The Chair and Vice-Chair are elected by the Commission for a one-year term June 1 - May 31.

# Anne Collins weight loss program

## Definition

The Anne Collins weight loss program is a weight loss system accessed on-line after payment of a yearly subscription fee. The system consists of nine separate diet plans plus advice regarding nutrition, exercise, and specific physical disorders; an on-line support community; and personal advice available through e-mail. There are no diet foods, nutritional supplements, appetite suppressants, exercise equipment, or any other products sold as part of the system.

## Origins

Anne Collins is an Irish nutritionist who says about herself, "For 24 years I have been involved in the weight loss and fitness industry as a diet consultant, nutritionist, and personal adviser. I have written for many newspapers and magazines including a weekly weight loss and health column." She states that she first formulated her weight loss system in 1982 but does not mention the date that her Internet Web site opened.

The Anne Collins Web site claims that it has had nearly 7.5 million visitors and is ranked the eighth most popular online diet Web site by Hitwise (an online competitive intelligence service that researches market trends). However, a much lower number of people have actually tried the Anne Collins system. The Web site states that it helps "over 250,000 people all over the world to lose really stubborn fat deposits and to achieve a lean body." Therefore, it appears that most visitors to the Web site choose not to subscribe to the system.

## Description

### *Overview*

The Anne Collins system is available only through the author's Internet Web site (URL: <http://www.anne-collins.com>). Some parts of the Web site are available to the public, but most pages require a $19.97 US annual subscription. The subscription fee must be paid online by credit card, as there is no telephone number on the public portion of the Web site. A comment on the Web site encourages visitors to subscribe immediately and states that rates will be increasing due to the site's popularity. It is unknown on what date the promotion actually ends.

What the dieter obtains for the subscription fee is access to the following: any and all of the e-books for the nine specific diet plans; a community forum; updates to the existing diets and any new diet plans; advice about nutrition and exercise; shopping lists; advice and tips to stay motivated; and personal support either online or by telephone available any day of the year. The e-books average 55–60 pages in length; they contain daily meal plans for a 28-day period, including options for snacks and fast foods. The motivational articles, nutrition information, and other sections of the Web site come to about 600 pages of material.

The Anne Collins weight loss system is not available in a print edition, either paperback or hardcover, even though there is an illustration of what looks like a paperback book on the Web site. In addition, neither the Library of Congress nor the British Library has a record of any book on nutrition or weight loss written by Anne Collins.

### *Specific diets*

**LOW-CARBOHYDRATE DIET.** The Anne Collins low-carbohydrate diet is designed to be followed for 28 days, after which the dieter may repeat the 28-day cycle or switch to another Anne Collins plan. The four weeks are divided into two phases of 14 days each.

Phase one supplies meal plans for three meals a day, averaging 30 g of **carbohydrates** per day. In phase two, the day's carbohydrate allotment is raised to 55 g per day. This plan claims that the dieter loses as much as 10 lb during phase one.

This diet plan includes a number of food substitutes, advice on eating in fast-food restaurants, a shopping list, and a list of acceptable snack foods.

**LOW GLYCEMIC INDEX DIET.** The glycemic index (GI) is a measurement system devised at the University of Toronto in 1981 for ranking dietary carbohydrates. The GI measures carbohydrates in individual foods on a gram-for-gram basis in regard to their effect on blood glucose levels in the first two hours after a meal. The higher the index number, the more rapidly the carbohydrate breaks down in the digestive tract and the more rapidly it raises blood sugar levels. A lower GI number is thought to relate to a longer feeling of fullness in the stomach, better control over insulin and blood sugar levels, and lower levels of blood lipids.

The Anne Collins low glycemic index diet plan is designed for people with type 2 diabetes, insulin resistance, or women with polycystic ovarian syndrome (PCOS, an endocrine disorder associated with **obesity** and insulin resistance) who need or want to lose weight rapidly. Like the Anne Collins low-carbohydrate diet, the low GI diet has a 28-day cycle of meal plans and shopping lists, but is not divided into two phases. It is fundamentally a lean-protein with low-GI carbohydrate diet, intended to stabilize the dieter's blood glucose level during weight loss. The meal plans allow about 1,100 calories per day but may be adjusted upward to 2,000 calories for men (and for dieters who wish to lose weight more slowly) by adding calorie-controlled snacks.

**10-MINUTE MEALS DIET.** The Anne Collins 10-minute meals diet is geared for dieters who wish to lose weight rapidly but have little time to cook. This plan is also for 28 days and is not divided into phases. The lunch menus have fast-food, brown-bag, and quick-cook options. Dinners provide fast-food, quick-cook, and two-day meal options; which are dinners intended to last for two days, thus freeing the dieter from having to cook twice.

Like the meal plans for the low GI diet, the meal plans for the 10-minute meals diet allow about 1,100 calories per day, adjustable upward to 2,000 or 2,100 calories through a choice of snacks, including fast-food options. After four weeks, the dieter can either repeat the 28-day cycle or choose another Anne Collins diet plan.

**CHOLESTEROL-LOWERING DIET.** This diet is intended for people who must lower blood cholesterol levels while losing weight and/or who wish to lose weight rapidly. The 28-day cycle of meal plans shows the total fat, saturated fat, and cholesterol content of every food item on the diet as well as the calorie values. The diet allows about 1,200 calories per day, with an average content of 22 g total fat, 4 g saturated fat, and 120 mg cholesterol. The meal plans are rich in dietary **fiber**, particularly soluble fiber, which has a number of important health benefits that include lowering blood cholesterol levels. The cholesterol and fat values of this diet plan fall within the guidelines recommended by the U.S. Food and Drug Administration (FDA). As with other Anne Collins diet plans, the calorie level can be adjusted upward for men and people who desire to lose weight more slowly.

The e-book that comes with this plan contains suggestions about and guidelines for exercise as a way to further lower blood cholesterol levels. The diet plan suggests that cholesterol levels should begin to fall within two to three weeks of beginning the diet. After four weeks, the dieter may repeat the cycle if blood cholesterol has not fallen to the desired level, or choose another diet in the program to continue losing weight.

**14-DAY LOW-CALORIE BOOSTER DIET.** This diet plan has only a 14-day rather than a 28-day cycle. It is intended for dieters who have only a short-term weight-loss goal (such as fitting into a specific outfit for an important event) or feel unable to reach a long-term goal and want a quick breakthrough. The plan allows for six meals or snacks per day to promote rapid food **metabolism**. The meal plans include a number of quick-cook recipes and convenience food or fast-food options.

The basic diet plan allows about 1,000 calories a day to maximize weight loss but can be adjusted upward for men.

**VEGETARIAN QUICK-START DIET.** The Anne Collins vegetarian quick-start diet is a rapid weight-loss plan for committed vegetarians, those who would like to try a vegetarian lifestyle, and those who would simply like to lower their meat and poultry consumption. Technically, the diet is ovolactovegetarian, which means that it includes eggs and dairy products.

This diet plan is based on a 28-day cycle, and allows about 1,250 calories per day, adjustable upward to about 2,000 calories for men. It also contains about 90

recipes, advice about cooking whole grains, vegetarian fast-food options, and calorie counts for all menu items.

**NO-NONSENSE BALANCED DIET.** The no-nonsense diet plan is intended for dieters who want to lose weight rapidly but also want some flexibility in a diet plan. This diet also has a 28-day cycle, with meal plans averaging 1,100 calories per day. Flexibility includes home-cooked and convenience meal options for every lunch as well as every dinner.

As with the other Anne Collins plans, the calorie level can be adjusted upward for men. Sample menus from this diet are as follows:

- Breakfast: 2 low-fat pancakes; 1 tbsp maple syrup; 2 slices Canadian bacon; one-half cup berries. Alternate menu: 1 cup fat-free yogurt; 2 tbsp wheat germ; 1 medium banana; 1 tbsp sesame seeds.
- Lunch: Convenience option: Subway six-inch roasted chicken breast submarine sandwich and 1 serving fruit. Home-cooked option: 1 cup low-fat ready-to-serve soup; 2 slices whole wheat bread spread with 2 tbsp fat-free mayonnaise and filled with chopped vegetables; 1 oz fat-free cheese.
- Dinner: Convenience meal option: Lean Cuisine angel-hair pasta meal; 2 cup salad; 1 tbsp fat-free dressing; 2 graham crackers with 1 tbsp fat-free cream cheese; 1 serving fruit. Home recipe option: 1 oz (dry weight) pasta or thin spaghetti; 3 oz very lean ground beef; one-half cup sliced bell peppers; 1 large tomato, chopped; 1 clove garlic, minced; one-half tsp oregano, one-half tsp Italian seasoning.
- Snacks: Select from list included with diet plan.

**DIET FOR LIFE.** The diet for life is essentially a slow weight-loss or maintenance-level diet plan that contains a 14-day starter set of meal plans. The meal plans are low in fat, moderate in **protein**, and high in carbohydrates. In addition to the usual calorie counts, this plan contains guidelines for lifelong sensible eating habits. It can be continued indefinitely, or the dieter may switch to another Anne Collins plan.

The basic calorie allowance in the diet for life is 1,300 calories per day, adjustable upward to 2,000 or 2,100 calories.

**VEGETARIAN DIET FOR LIFE.** The vegetarian diet for life is similar to the general diet for life plan, with a 14-day set of starter menus, a large number of easy-to-prepare recipes, and advice about lifelong sensible eating habits. Like the diet for life, the vegetarian diet for life plan is low in fat and moderate in protein. The menu plans provide about 1,250 calories per day and can be adjusted upward.

## QUESTIONS TO ASK YOUR DOCTOR

- What is your professional opinion of the Anne Collins weight loss system?
- Do you know of any published clinical studies of the Anne Collins program?
- Have any of your other patients tried it?
- Which of the nine diets did they use?
- Were they able to lose weight and keep it off?

### Function

The Anne Collins weight loss system is intended for the dieter who is "looking for safe permanent weight loss without using pills, special foods, or gimmicks of any sort." Most of the nine specific plans are intended for more rapid weight loss, but several are maintenance diets including a maintenance diet for vegetarians. All the specific plans can be tailored to allow higher calorie intakes for men or for dieters less concerned to about losing weight rapidly.

### Benefits

The system's Web site claims the following benefits for the nine diets:

- The dieter can lose weight "without going hungry. . . . Have you ever felt that horrible gnawing feeling on other diets when you feel that your stomach is eating itself? Well you'll never feel this with my system. If you're feeling hungry my advice is always to go eat."
- The dieter will "stay motivated. . . . With the Anne Collins Weight Loss Program you will be supported every step of the way and if you happen to slip up at any stage I'll be there to pick you up, dust you down and get you back on track. You can say goodbye to yo-yo dieting forever."
- The system does not depend on appetite suppressants, dietary supplements, or other special products.
- There are no forbidden foods. The dieter can fit fast foods, chocolate, and other foods that are avoided on most diets into most of the specific diets.
- The dieter will lose the excess weight permanently. "With my system you will learn how to make realistic and sustainable changes to your eating habits for ever."

One benefit mentioned by several reviewers of the Anne Collins system as a whole is its accommodation of vegetarians—at least ovolactovegetarians. Of the

nine diets, two—a quick weight-loss diet and a maintenance diet—are designed for vegetarians who use eggs and dairy products. Another benefit noted by reviewers is the relatively low cost of the Anne Collins plans. The $19.97 subscription fee is roughly the same as the cost of most novels in e-book form, and subscribers may download all nine PDFs if they wish. The fact that the system is not associated with a line of potentially expensive diet products is also appealing to reviewers.

Many dieters seem to like the flexibility of the Anne Collins plans, in particular the option of using convenience foods and switching among the various plans to avoid monotony. Opinion is mixed, however, regarding the use of fast foods in the Collins plans. Some reviewers maintain that the fast-food options are a necessary adaptation to contemporary eating patterns, while others regard the fast-food choices as exposing dieters to a high degree of temptation to cheat on the diet together with a high level of unhealthy saturated **fats** and sugars.

## Precautions

Although none of the Anne Collins diet plans are very low calorie diets (VLCDs) or otherwise extreme, it is always a good idea for people who need to lose 30 pounds or more; are pregnant or nursing; are below the age of 18; or have such chronic disorders as diabetes, kidney disease, or liver disease to check with a physician before starting a weight-reduction diet.

## Risks

There do not appear to be any significant health risks associated with any of the nine plans for dieters who have been evaluated by a physician for any previously undiagnosed disorders.

## Research and general acceptance

Although three physicians are listed on the Web site as approving the Collins system, two are identified only by initials. The Anne Collins system does not appear to have been used in any clinical trials reported in the medical literature, possibly because of the sheer number of different diet plans included in the program. In addition, Collins's credentials as a nutritionist are not listed on her Web site, which makes it difficult to verify her qualifications as a weight loss expert. Existing feedback about this diet is informal as of early 2007, consisting solely of testimonials on the Web site itself and comments or reviews on various Internet diet Web sites and online chat groups.

## KEY TERMS

**Glycemic index (GI)**—A system that ranks carbohydrates in individual foods on a gram-for-gram basis in regard to their effect on blood glucose levels in the first two hours after a meal. There are two commonly used GIs, one based on pure glucose as the reference standard and the other based on white bread.

**Insulin resistance**—A condition in which normal amounts of insulin in a person's blood are not adequate to produce an insulin response from fat, muscle, and liver cells. Insulin resistance is often a precursor of type 2 (adult-onset) diabetes.

**Lipids**—Organic substances containing hydrocarbons that are relatively insoluble in water. Lipids in the blood include such substances as cholesterol and fatty acids.

**Ovolactovegetarian**—A vegetarian who consumes eggs and dairy products as well as plant-based foods.

**Polycystic ovarian syndrome (PCOS)**—An endocrine disorder characterized by irregular ovulation in women of childbearing age and excessive amounts of androgens (masculinizing hormones). It is a leading cause of infertility and thought to affect between 5 and 10% of women. PCOS is often associated with obesity and insulin resistance. PCOS is also known as Stein-Leventhal syndrome.

**Soluble fiber**—The part of a food plant that resists digestion and absorption in the human small intestine but is fermented partially or completely in the large intestine. This fermentation yields short-chain fatty acids, which are beneficial to health by stabilizing blood glucose levels, lowering blood cholesterol levels, and supporting the immune system.

**Very low -calorie diet (VLCD)**—A term used by nutritionists to classify weight-reduction diets that allow around 800 calories or fewer a day.

# Anorexia nervosa

## Definition

Anorexia nervosa is an eating disorder that involves self-imposed starvation. The individual is obsessed with becoming increasingly thinner and limits food intake to the point where health is compromised. Anorexia nervosa can be fatal.

## Description

Anorexia is often thought of as a modern problem, but the English physician Richard Morton first described it in 1689. In the twenty-first century anorexia nervosa is recognized as a psychiatric disorder in the *Diagnostic and Statistical Manual for Mental Disorders Fourth Edition (DSM-IV-TR)* published by the American Psychiatric Association.

Individuals with anorexia are on an irrational, unrelenting quest to lose weight, and no matter how much they lose and how much their health is compromised, they want to lose more weight. Recognizing the development of anorexia can be difficult, especially in a society that values and glamorizes thinness. Dieting is often the trigger that starts a person down the road to anorexia. The future anorectic may begin by skipping meals or taking only tiny portions. She (most anorectics are female) always has an excuse for why she does not want to eat, whether it is not feeling hungry, feeling ill, having just eaten with someone else, or not liking the food served. She also begins to read food labels and knows exactly how many calories and how much fat are in everything she eats. Many anorectics practically eliminate fat and sugar from their diets and seem to live on diet soda and lettuce. Some future anorectics begin to exercise compulsively to burn extra calories. Eventually these practices have serious health consequences. At some point, the line between problem eating and an eating disorder is crossed.

Anorexia nervosa is diagnosed when most of the following conditions are present:

- an overriding obsession with food and thinness that controls activities and eating patterns every hour of every day
- the individual weighs less than 85% of the average weight for his or her age and height group and willfully and intentionally refuses to maintain an appropriate body weight
- extreme fear of gaining weight or becoming fat, even when the individual is significantly underweight.
- a distorted self-image that fuels a refusal to admit to being underweight, even when this is demonstrably true
- refusal to admit that being severely underweight is dangerous to health
- for women, three missed menstrual periods in a row after menstruation has been established

Anorectics spend a lot of time looking in the mirror, obsessing about clothing size, and practicing negative self-talk about their bodies. Some are secretive about eating and will avoid eating in front of other people. They may develop strange eating habits such as chewing their food and then spitting it out, or they may have rigid ideas about "good" and "bad" food. Anorectics will lie about their eating habits and their weight to friends, family, and healthcare providers. Many anorectics experience depression and anxiety disorders.

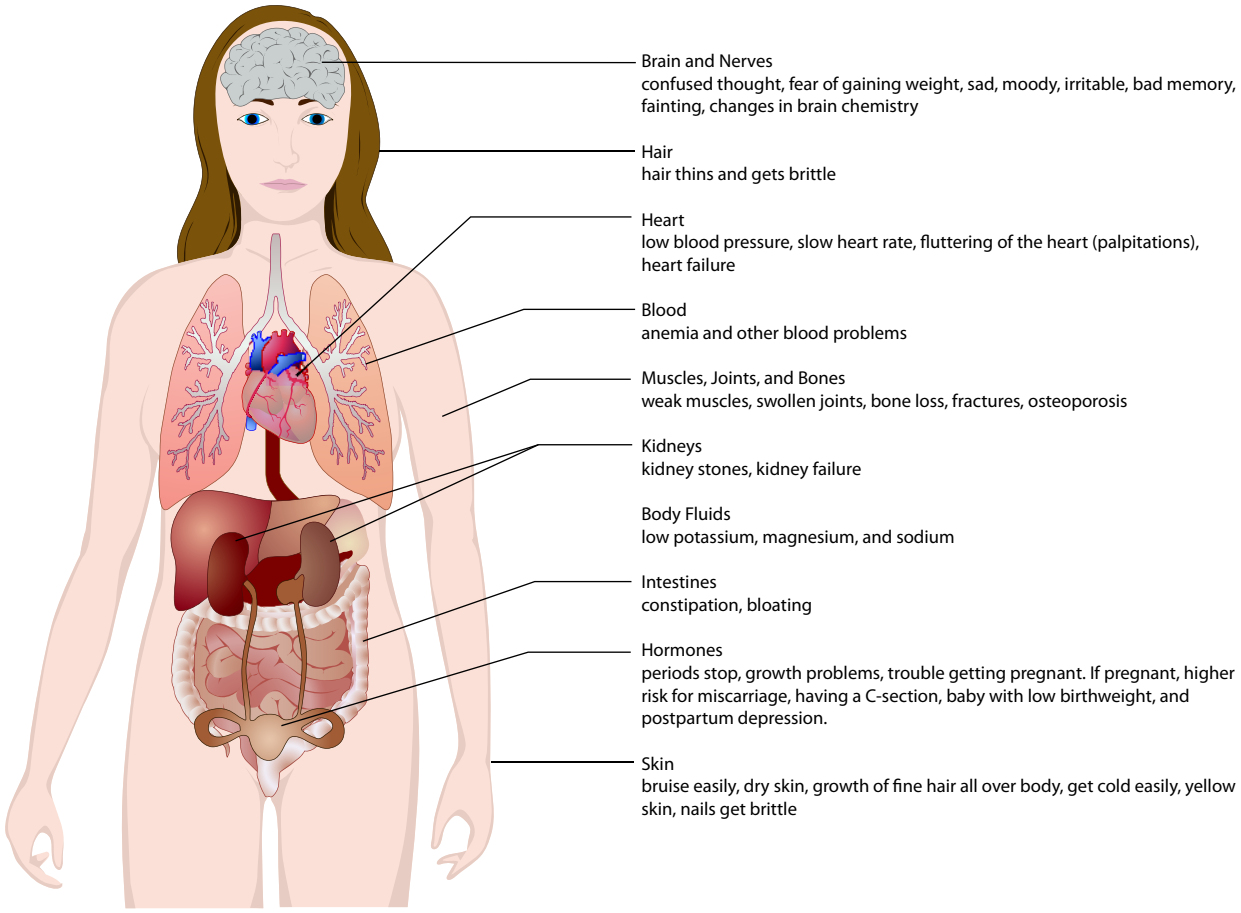
There are two major subtypes of anorectics. Restrictive anorectics control their weight by rigorously limiting the amount of calories they eat or by fasting. They may exercise excessively or abuse drugs or herbal remedies claim to increase the rate at which the body burns calories. Purge-type anorectics eat and then get rid of the calories and weight by self-induced vomiting, excessive laxative use, and abuse of **diuretics** or enemas.

## Demographics

Anorexia is a disorder of industrialized countries where food is abundant and the culture values a thin appearance. About 1% of Americans are anorectic and female anorectics outnumber males 10:1. In men, the disorder is more often diagnosed in homosexuals than in heterosexuals. Some experts believe that number of diagnosed anorectics represents only the most severe cases, and that many more people have anorexic tendencies, but their symptoms do not rise to the level needed for a medical diagnosis.

Anorexia has been characterized as a "rich white girl" disorder. Most anorectics are white, and about three-quarters of them come from households at the middle income level or above. However, in the 2000s, the number of blacks and Hispanics diagnosed with anorexia has increased. Competitive athletes of all races have an increased risk of developing anorexia nervosa, especially in sports where weight it tied to performance. Jockeys, wrestlers, figure skaters, cross-country runners, and gymnasts (especially female gymnasts) have higher than average rates of anorexia. People such as actors, models, cheerleaders, and dancers (especially ballet dancers) who are judged mainly on their appearance are also at high risk of developing the disorder.

Effects of anorexia on the body



SOURCE: Office on Women's Health, U.S. Department of Health and Human Services

*(Illustration by GGS Information Services/Thomson Gale.)*

Anorexia can occur to people as young as age 7. However, the disorder most usually begins during adolescence. It is most likely to start at one of two times, either age 14 or 18. Interestingly, this corresponds with the age of transitioning into and out of high school. The younger the age at which anorexic behavior starts, the more difficult it is to cure. Preteens who develop anorexia often show signs of compulsive behavior and depression in addition to anorexia.

## Causes and symptoms

### *Causes*

Anorexia is a complex disorder that does not have a single cause. Research suggests that some people have a predisposition toward anorexic and that something then triggers the behavior, which then becomes self-reinforcing. Hereditary, biological, psychological and social factors all appear to play a role.

- Heredity. Twin studies show that if one twin has anorexia nervosa, the other has a greater likelihood of developing the disorder. Having a close relative, usually a mother or a sister, with anorexia nervosa also increases the likelihood of other (usually female) family members developing the disorder. However, when compared to many other diseases, the inherited component of anorexia nervosa appears to be fairly small.
- Biological factors. There is some evidence that anorexia nervosa is linked to abnormal neurotransmitter activity in the part of the brain that controls pleasure and appetite. Neurotransmitters are also involved in

## KEY TERMS

**Diuretic**—A substance that removes water from the body by increasing urine production.

**Electrolyte**—Ions in the body that participate in metabolic reactions. The major human electrolytes are sodium (Na+), potassium (K+), calcium (Ca 2+), magnesium (Mg2+), chloride (Cl−), phosphate ($HPO_4$ 2−), bicarbonate ($HCO_3$−), and sulfate ($SO_4$ 2−).

**Neurotransmitter**—One of a group of chemicals secreted by a nerve cell (neuron) to carry a chemical message to another nerve cell, often as a way of transmitting a nerve impulse. Examples of neurotransmitters include acetylcholine, dopamine, serotonin, and norepinephrine.

other mental disorders such as depression. Research in this area is relatively new and the findings are unclear. People with anorexia tend to feel full sooner than other people. Some researchers believe that this is related to the fact that stomach of people with anorexia tends to empty more slowly than normal; others think it may be related to the appetite control mechanism of the brain.

- Psychological factors. Certain personality types appear to be more vulnerable to developing anorexia nervosa. Anorectics tend to be perfectionists who have unrealistic expectations about how they "should" look and perform. They tend to have a black-or-white, right-or-wrong, all-or-nothing way of seeing situations. Many anorectics lack a strong sense of identity and instead take their identity from pleasing others. Virtually all anorectics have low-self worth. Many experience depression and anxiety disorders, although researchers do not know if this is a cause or a result of the eating disorder.
- Social factors. Anorectics are more likely to come either from overprotective families or disordered families where there is a lot of conflict and inconsistency. Either way, the anorectic feels a need to be in control of something, and that something becomes body weight. The family often has high, sometimes unrealistic and rigid, expectations. Often something stressful or upsetting triggers the start of anorexic behaviors. This may be as simple as a family member as teasing about the person's weight, nagging about eating junk food, commenting on how clothes fit, or comparing the person unfavorably to someone who is thin. Life events such as moving, starting a new school, breaking up with a boyfriend, or even entering puberty and feeling awkward about one's changing body can trigger anorexic behavior. Overlaying the family situation is the unrelenting media message that thin is good and fat is bad; thin people are successful, glamorous, and happy, fat people are stupid, lazy, and failures.

### *Signs and Symptoms*

Anorexic behavior has physical and psychological consequences. These include:

- excessive weight loss; loss of muscle
- stunted growth and delayed sexual maturation in preteens
- gastrointestinal complications: liver damage, diarrhea, constipation, bloating, stomach pain
- cardiovascular complications: irregular heartbeat, low pulse rate, cardiac arrest
- urinary system complications: kidney damage, kidney failure, incontinence, urinary tract infections
- skeletal system complications: loss of bone mass, increased risk of fractures, teeth eroded by stomach acid from repeat vomiting
- reproductive system complications (women): missed menstrual periods, infertility
- reproductive system complications (men): loss of sex drive, infertility
- fatigue, irritation, headaches, depression, anxiety, impaired judgment and thinking
- fainting, seizures, low blood sugar
- chronically cold hands and feet
- weakened immune system, swollen glands, increased susceptibility to infections
- development of fine hair called lanugo on the shoulders, back, arms, and face, head hair loss, blotchy, dry skin
- potentially life-threatening electrolyte imbalances
- coma
- increased risk of self-mutilation (cutting)
- increased risk of suicide
- death

## Diagnosis

Diagnosis is based on several factors including a patient history, physical examination, laboratory tests, and a mental status evaluation. A patient history is less helpful in diagnosing anorexia than in diagnosing many diseases because many people with anorexia lie repeatedly about how much they eat and their use of laxatives, enemas, and medications. The patient

may, however, complain about related symptoms such as fatigue, headaches, dizziness, **constipation**, or frequent infections.

A physical examination begins with weight and blood pressure and moves through all the signs listed above. Based on the physical exam, the physician will order laboratory tests. In general these tests will include a complete blood count (CBC), urinalysis, blood chemistries (to determine electrolyte levels), and liver function tests. The physician may also order an electrocardiogram to look for heart abnormalities.

Several different mental status evaluations can be used. In general, the physician will evaluate things such as whether the person is oriented in time and space, appearance, observable state of emotion (affect), attitude toward food and weight, delusional thinking, and thoughts of self-harm or suicide.

## Treatment

Treatment choices depend on the degree to which anorexic behavior has resulted in physical damage and whether the person is a danger to him or herself. Medical treatment should be supplemented with psychiatric treatment (see Therapies below). Patients are frequently uncooperative and resist treatment, denying that their life may be endangered and insisting that the doctor only wants to "make them get fat."

Hospital impatient care is first geared toward correcting problems that present as immediate medical crises, such as severe malnutrition, severe electrolyte imbalance, irregular heart beat, pulse below 45 beats per minute, or low body temperature. Patients are hospitalized if they are a high suicide risk, have severe clinical depression, or exhibit signs of an altered mental state. They may also need to be hospitalized to interrupt weight loss, stop the cycle of vomiting, exercising and/or laxative abuse, treat substance disorders, or for additional medical evaluation.

Day treatment or partial hospitalization where the patient goes every day to an extensive treatment program provides structured mealtimes, nutrition education, intensive therapy, medical monitoring, and supervision. If day treatment fails, the patient may need to be hospitalized or enter a full-time residential treatment facility.

Anorexia nervosa is a chronic disease and relapses are common and to be expected. Outpatient treatment provides medical supervision, nutrition counseling, self-help strategies, and therapy after the patient has reached some weight goals and shows stability.

## Nutrition/dietetic concerns

A nutrition consultant or dietitian is an essential part of the team needed to successfully treat anorexia. The first treatment concern is to get the individual medically stable by increasing calorie intake and balancing **electrolytes**. After that, nutritional therapy is needed support the long process of recovery and stable weight gain. This is an intensive process involving of nutrition education, meal planning, nutrition monitoring, and helping the anorectic develop a healthy relationship with food.

## Therapy

Medical intervention helps alleviate the immediate physical problems associated with anorexia, but by itself, it rarely changes behavior. Psychotherapy plays a major role in the helping the anorectic understand and recover from anorexia. Several different types of psychotherapy are used depending on the individual's situation. Generally, the goal of psychotherapy is help the individual develop a healthy attitude toward their body and food. This may involve addressing at the root causes of anorexic behavior as well as addressing the behavior itself.

Some types of psychotherapy that have been successful in treating anorectics are listed below.

- Cognitive behavior therapy (CBT) is designed to change the individual's thoughts and feelings about his or her body and behaviors toward food, but it does not address why those thoughts or feelings exist. This therapy is relatively short-term.
- Psychodynamic therapy, also called psychoanalytic therapy, attempts to help the individual gain insight into the cause of the emotions that trigger their anorexic behavior. This therapy tends to be longer term that CBT.
- Interpersonal therapy is short-term therapy that helps the individual identify issues and problems in relationships. The individual may be asked to look back at his or her family history to try to recognize problem areas and work toward resolving them.
- Family and couples therapy is helpful in dealing with conflict or disorder that may be a factor in perpetuating anorexic behavior. Family therapy is especially useful in helping parents who are anorectics avoid passing on their attitudes and behaviors on to their children.

## Prognosis

Anorexia nervosa is difficult to treat successfully. Medical stabilization, nutrition therapy, continued

medical monitoring, and substantial psychiatric treatment give a person with anorexia the best chance of recovery. Estimates suggest that between 20% and 30% of people in treatment drop out too soon and have major relapses. Even those who stay in treatment relapse occasionally. Treating anorexia is often a long, slow, frustrating process that can cost many thousands of dollars. The earlier in life that the disorder starts and the longer the disorder continues untreated, the more difficult it is bring about recovery. Many individuals with anorexia are willfully uncooperative and do not want to recover.

About half the people treated for anorexia nervosa recover completely and are able (sometimes with difficulty) to maintain a normal weight. Of the remaining 50% between 6% and 20% die, usually of health complications related to starvation. About 20% remain dangerously underweight, and the rest remain thin.

## Prevention

Some ways to prevent anorexia nervosa from developing are as follows:

- If you are a parent, do not obsess about your own weight and appearance in front of your children.
- Do not tease your children about their body shapes or compare them to others.
- Make it clear that you love and accept your children as they are.
- Try to eat meals together as a family whenever possible.
- Remind children that the models they see on television and in fashion magazines have extreme, not normal or healthy bodies.
- Do not put your child on a diet unless advised to by your pediatrician.
- Block your child from visiting pro-anorexia Websites. These are sites where people with anorexia give advice on extreme weight loss techniques and support each other's distorted body image.
- If your child is a competitive athlete, get to know the coach and the coach's attitude toward weight.
- If you think your child has an eating disorder, do not wait to intervene and the professional help. The sooner the disorder is treated, the easier it is to cure.

Relapses happen to many people with anorexia. People who are recovering from anorexia can help prevent themselves from relapsing by:

- never dieting; instead plan healthy meals
- staying in treatment
- monitoring negative self-talk; practicing positive self-talk
- spending time doing something enjoyable every day
- staying busy, but not overly busy; getting at least seven hours of sleep each night
- spending time each day with people you care about and who care about you

**Anti-Aging Diet**

| Benefits | Risks and disadvantages |
|---|---|
| Can improved health | Hunger, food cravings, and obsession with food |
| Research shows it adds years to the lifespan and extends youthful years | Loss of strength or stamina and loss of muscle mass, which can affect physical activities |
| Can prevent or forestall many diseases, including heart disease, cancer, stroke, diabetes, osteoporosis, Alzheimer's, and Parkinson's | Decreased levels of testosterone |
| Most physiologic functions and mental abilities of animals on reduced calorie diets correspond to those of much younger animals | Rapid weight loss (more than two pounds a week) which can have an overall negative impact on health |
| Shown to extend the maximum lifespan of most life forms it has been tested on | Slower wound healing |
| | Reduced bone mass |
| | Increased sensitivity to cold |
| | Reduced energy reserves |
| | Menstrual irregularity |
| | Drastic appearance changes from loss of fat and muscle, causing people to look thin or anorexic |
| | Problems can arise over family meals, eating in restaurants, workplace food, parties, and holidays |
| | Can cause psychological problems, including anorexia, binging, and obsessive thoughts about food |

# Anti-aging diet

## Definition

The anti-aging diet is one that restricts calorie intake by 30–50% of normal or recommended intake with the goal of increasing human lifespan by at least 30%. People on the diet also have improved health providing they consume adequate **vitamins**, **minerals**, and other essential nutrients.

## Origins

The idea that a calorie-restrictive diet can significantly increase lifespan has been around since the 1930s. In 1935, Cornell University food researchers Clive McCay and Leonard Maynard published their first in a series of studies of experiments in which laboratory rats were fed a diet that contained one-third less calories (compared to a control group of rats) but still contained adequate amounts of vitamins, minerals, **protein**, and other essential nutrients. This calorie-restrictive diet provided much less energy than researchers had previously thought rats needed to maintain growth and normal activities. The rats on the lower calorie diet lived 30–40% longer than the rats on a normal calorie diet. Since then, more than 2,000 studies have been done, mostly on animals, about the connection between **calorie restriction** and increased longevity.

A reduced calorie diet was taken a step further by the University of California, Los Angeles, pathologist Roy Walford who studied the biology of aging. In 1986 he published *The 120-Year Diet* and a follow-up in 2000, *Beyond the 120-Year Diet* in which he argued that human longevity can be significantly increased by adhering to a strict diet that contains all the nutrients needed by humans but with about one-third the calories. In 1994 he co-authored *The Anti-Aging Plan: Strategies and Recipes for Extending Your Healthy Years*. His anti-aging plan is based on his own research and that of other scientists. Included is his study of diet and aging conducted as chief physician of the Biosphere 2 project in Arizona in the early 1990s. Walford was one of eight people sealed in Biosphere 2 from 1991 to 1993 in an attempt to prove that an artificial closed ecological system could sustain human life. He also co-founded the Calorie Restriction Society in 1994.

## Description

Anti-aging diets are regimes that reduce the number of calories consumed by 30–50% while allowing

## KEY TERMS

**Alzheimer's disease**—A degenerative disorder that effects the brain, causing dementia and loss of memory usually late in life.

**Antioxidant**—Substance that inhibits the destructive effects of oxidation in the body.

**Body mass index (BMI)**—A scale that expresses a person's weight in relation to height.

**Calorie reduction**—A decrease in the number of calories that a person consumes.

**Deoxyribonucleic acid (DNA)**—A nucleic acid molecule in a twisted double strand, called a double helix, that is the major component of chromosomes. DNA carries genetic information and is the basis of life.

**Free radicals**—Highly reactive atoms or molecules that can damage DNA.

**Osteoporosis**—A disease that causes bones to become porous, break easily, and heal slowly.

**Parkinson's disease**—An incurable nervous disorder marked by symptoms of trembling hands and a slow, shuffling walk.

**Testosterone**—A male sex hormone responsible for secondary sex characteristics.

the necessary amounts of vitamins, minerals, and other nutrients the body needs to sustain itself and grow. This calorie restriction has been shown to increase the lifespan of various animals, including rats, fish, fruit flies, dogs, and monkeys, by 30–50%. Some human studies have also been done—and long-term studies are underway— but evidence of its impact on humans is very limited compared to results available from the animal studies. The completed studies indicate that calorie restriction can increase the maximum human lifespan by about 30%. The problem preventing scientists from offering substantive proof that humans can greatly increase their lifespan by restricting calories is that the current maximum human lifespan is 110–120 years and full compliance with the diet is difficult. A 30% increase would extend the human lifespan to 143–156. This is an exceptionally long time for a scientific study and requires involvement of several generations of scientists. Only several hundred people have ever been documented to lived past age 110 and there are only two people with confirmed documentation who have lived to at least age 120: Jeanne Louise Calmet (1875–1997) of France who lived 122 years and 164 days; and Shigechiyo Izumi (1865–1986) of Japan who lived 120 years and 237 days, according to *Guinness World Records*.

Since 1980, dozens of books have been published offering specific calorie reduction diets aimed at increasing lifespan. The most popular diets include the Okinawa Diet, Anti-Inflammation Diet, Longevity Diet, **Blood Type Diet**, Anti-Aging Plan, and the 120-Year Diet.

Calorie restriction is a lifelong approach to eating by significantly lowering daily calorie intake while still getting all the body's required nutrients. People who experience starvation or famine receive no longevity benefits since their low calorie intake contains little nutrition. The diet is believed to most benefit people who start in their mid-20s, with the beneficial effects decreasing proportionately with the age one begins the diet.

Although there are variations between anti-aging diets, most reduced calorie diets recommend a core set of foods. These include vegetables, fruits, fish, **soy**, low-fat or non-fat dairy products, nuts, avocados, and olive oil. The primary beverages recommended are **water** and green or black tea.

Guidelines on calorie reduction vary from diet to diet, ranging from a 10% reduction to a 50% reduction of normal intake. Roy L. Walford (1924–2004), author of several books on anti-aging diets, says a reasonable goal is to achieve a 10–25% reduction in a person's normal weight based on age, height, and body frame. The Anti-Aging Plan diet recommends men of normal weight lose up to 18% of their weight in the first six months of the diet. For a six-foot male weighing 175 lb, that means a loss of about 31 pounds. For a small-framed woman who is five-foot, six-inches tall and weighs 120 pounds, the plan recommends losing 10% of her weight in the first six months, a loss of 12 lb.

Walford's Anti-Aging Plan is a diet based on decades of animal experimentation. It consists of computer generated food combinations and meal menus containing all of the U.S. Department of Agriculture's Recommended Daily Allowances of vitamins and other essential nutrients using foods low in calories. On the diet, the maximum number of calories allowed is 1,800 per day. There are two methods for starting the diet: rapid orientation and gradual orientation.

The rapid orientation method allows people to eat low calorie meals rich in nutrients. This is a radical change for most people and requires a good deal of willpower. All foods low in nutrients are eliminated from the diet. The nutritional value and calories in

foods and meals is determined by a software program available for purchase from Walford's Calorie Restriction Society.

The gradual orientation method allows people to adopt the diet over time. The first week, people eat a high-nutrient meal on one day. This increases by one meal a week until participants are eating one meal high in nutrients every day at the end of seven weeks. Other meals during the day are low-calorie, healthy foods but there is no limit on the amount a person can eat. After two months, participants switch to eating low-calorie, high-nutrition foods for all meals.

On his Web site (http://www.walford.com), Walford states: "Going for longevity on the Anti-Aging Plan requires caloric limitation. We advise, however, that you view this as a lifestyle change and not a quick-fix program or a diet. Any person can physiologically adapt to this level of limitation and experience no physical hunger provided that nearly every calorie eaten is a nutrient-rich calorie."

A sample one-day low-calorie, high-nutrition menu developed by Walford is:

- Breakfast: One cup of orange juice, one poached egg, one slice of mixed whole-grain bread, and one cup of brewed coffee or tea.
- Lunch: One-half a cup of low-fat cottage cheese mixed with one-half a cup of non-fat yogurt and one tablespoon of toasted wheat germ, an apple, and one whole wheat English muffin.
- Dinner: Three ounces of roasted chicken breast without the skin, a baked potato, and one cup of steamed spinach.
- Snack: Five dates, an oat bran muffin, and one cup of low-fat milk.

The three meals and snack contain 1,472 calories, 92 g protein, 24 g fat, 234 g **carbohydrates**, 27 g **fiber**, and 310 g cholesterol.

## Function

The goal of the anti-aging diet is to slow the aging process, thereby extending the human lifespan. Even though it is not a weight loss diet, people taking in significantly fewer calories than what is considered normal by nutritionists are likely to lose weight. Exercise is not part of calorie reduction diets. Researchers suggest people gradually transition to a reduced calorie diet over one or two years since a sudden calorie reduction can be unhealthy and even shorten the lifespan.

There is no clear answer as to why severely reducing calorie intake results in a longer and healthier life. Researchers have various explanations and many suggest it may be due to a combination of factors. One theory is that calorie restriction protects DNA from damage, increases the enzyme repair of damaged DNA, and reduces the potential of genes being altered to become cancerous. Other calorie reduction (CR) theories suggest:

- CR helps reduce the production of free radicals; unstable molecules that attack healthy, stable molecules. Damage caused by free radicals increases as people age.
- CR delays the age-related decline of the human immune system and improved immune function may slow aging.
- CR slows metabolism, the body's use of energy. Some scientists propose that the higher a person's metabolism, the faster they age.

## Benefits

The primary benefits of the anti-aging diet are improved health and prevention or forestalling diseases such as heart disease, **cancer**, stroke, diabetes, **osteoporosis**, Alzheimer's, and Parkinson's. Studies show that most physiologic functions and mental abilities of animals on reduced calorie diets correspond to those of much younger animals. The diet has also demonstrated extension of the maximum lifespan for most life forms on which it has been tested.

## Precautions

A reduced calorie diet is not recommended for people under the age of 21 since it may impair physical growth. This impairment has been seen in research on young laboratory animals. In humans, mental development and physical changes to the brain occur in teenagers and people in their early 20s that may be negatively affected by a low-calorie diet.

Other individuals advised against starting a calorie-restricted diet include women who plan on getting pregnant, women who are pregnant, and those who are nursing babies. A low **body mass index** (BMI), which occurs with a low-calorie diet, is a risk factor in pregnancy and can result in dysfunctional ovaries and infertility. A low BMI also can cause premature birth and low birth weights in newborns. People with existing medical conditions or diseases are discouraged from reduced calorie diets. They should be especially cautious and consult with their physician before starting.

It is imperative that participants ensure that they continue to consume adequate levels of essential

nutrients. Nutritional supplements and other forms of nutritional help may be necessary.

### Risks

There are a wide range of risks associated with an anti-aging, reduced calorie diet. These risks include physical, mental, social, and lifestyle issues.

- Hunger, food cravings, and obsession with food.
- Loss of strength or stamina and loss of muscle mass, which can affect physical activities, such as sports.
- Decreased levels of testosterone, which can be compensated with testosterone supplementation.
- Rapid weight loss (more than two pounds a week), which can negatively impact health
- Slower wound healing
- Reduced bone mass, which increases the risk of fracture
- Increased sensitivity to cold
- Reduced energy reserves and fatigue
- Menstrual irregularity
- Headaches
- Drastic appearance changes from loss of fat and muscle, causing people to look thin or anorexic

Social issues can arise over family meals, since not all family members may be on a reduced calorie diet. Conflict related to the types of food served, the amount of food served and the number of meals in a day, and fasting may develop. Other social issues involve eating in restaurants, workplace food, parties, and holidays. The long-term psychological effects of a reduced calorie diet are unknown. However, since a low calorie diet represents a major change in a person's life, psychological problems can be expected, including anorexia, binging, and obsessive thoughts about food and eating.

### Research and general acceptance

An anti-aging diet that restricts calories may slow the aging of the heart and lengthen lifespan, according to a study by Washington University School of Medicine in St. Louis, Missouri. The small study, released in 2006, followed 25 people aged 41–65 who consumed only 1,400–2,000 calories a day for six years. Results of the study showed participants had heart functions that resembled people 15 years younger and their blood pressure was significantly lower than a control group who had a calorie intake of 2,000–3,000 per day, the amount of a normal Western diet.

A calorie-restrictive diet may reverse early stages of Parkinson's disease, according to a study released in 2005 by the Oregon Health and Science University and the Portland Veterans Affairs Medical Center in Portland, Oregon. Researchers said mice in the early stages of Parkinson's disease who had their calorie intake reduced by 50% had elevated levels of glutamate, an essential brain chemical that is lost due to Parkinson's disease. Results of this study are optimistic, but further research is necessary to prove any level of effectiveness in humans.

### QUESTIONS TO ASK YOUR DOCTOR

- Do I need to take any vitamin, mineral, or other nutritional supplements if I go on the diet?
- Will an anti-aging diet have any negative impacts on my health?
- Are there other diets you would recommend that would allow me to reach the same goals as the anti-aging diet?
- How will restricting my calorie intake effect my metabolism and energy level?

Ken R. Wells

**Anti-inflammatory diet**

| Anti-inflammatory foods | |
|---|---|
| Fruits | Fresh fruits, berries, blueberries, blackberries, and strawberries |
| Legumes and beans | Pinto, kidney, borlotti, mung, cannelloni, adzuki, fava, and black beans; soybeans; garbanzo or chickpeas |
| Nuts and seeds | Walnuts, flax seeds, pumpkin seeds (raw, unsalted) |
| Oils | Expeller pressed canola oil, extra-virgin olive oil, or rice bran, grape seed, evening primrose and walnut oil |
| Poultry, lean | Grass fed, free of preservatives, sodium, nitrates or coloring |
| Soy products | Soybeans, edemame, tofu, tempeh, soymilk, other products from soybeans |
| Spices and herbs | Replaces salt, sugar, added saturated fat |
| Seafood and wild fish | Herring, mackerel, salmon, trout |
| Vegetables, fresh | Green leafy vegetables, brightly colored vegetables |
| Water | Free of toxic chemicals |
| Whole grains | Amaranth, barley, bulgur, wild rice, millet, oats, quinoa, rye, spelt, wheat berries, buckwheat, whole wheat |
| **Pro-inflammatory foods** | |
| Dairy products, high fat | Butter, cream, sour cream, whole milk |
| Processed meats | Lunch meats, hot dogs, sausages |
| Red meats | Beef, lamb, pork |
| Refined grains | White bread, white rice, pasta (unless whole grain), chips, products made with white flour, such as cake, cookies, crackers, pretzels, doughnuts, bagels, muffins |
| Saturated fats | Meats, dairy products, eggs |
| Sugars, refined, and high sugar foods | Sodas, pastries, presweetened cereals, candy, white and brown sugar, confectioners sugar, corn syrup, processed corn fructose |
| *Trans* fats | In meats, dairy products, cakes, cookies, crackers, pies, bread, margarine, fried potatoes, potato chips, corn chips, popcorn, household shortening, salad dressing |

# Anti-inflammatory diets

## Definition

There is no one anti-inflammatory diet, rather, there are diets designed around foods that are believed to decrease inflammation and which shun foods that aggravate the inflammatory processes. Many anti-inflammatory diets are based around whole grains, legumes, nuts, seeds, fresh vegetables and fruits, wild fish and seafood, grass-fed lean turkey and chicken which are thought to aid in the bodies healing of inflammation. They exclude foods that are thought to trigger inflammation such as refined grains, wheat, corn, full-fat dairy, red meat, **caffeine**, alcohol, peanuts, sugar, saturated and trans-saturated **fats**.

The common foundation of anti-inflammatory diets is the belief that low grades of inflammation are the precursor and/or antagonizer to many chronic diseases. Once removed, the body can begin healing itself.

## Origins

The philosophical genesis of anti-inflammatory diets dates back to the original healers throughout

history who have worked with foods, herbs, teas and other natural remedies to assist the body's own healing energy.

Beginning in the 1970s investigators began exploring physiological mechanisms of fever, weight loss, and acute phase responses to acute and chronic infection. Research results from these studies began to change the mainstream attitudes about disease pathogenesis. Accumulating evidence linked proteins, produced by macrophages and other immune cells, not pathogens, as formerly believed, to the cause of tissue damage and disease syndromes in experimental animals. Thus the medical profession began looking into original treatments for chronic diseases. Then in the 1980s, research showed that proteins, newly named cytokines, and hormone-like substances, named prostaglandins and leukotrienes, revealed that they possessed pleiotropic biological activities that were either beneficial or injurious to the bodies' tissues.

From this research emerged the cytokine theory of disease. The concept that cytokines produced by the immune system, can cause the signs, symptoms, and damaging after effects of chronic diseases. Change did not occur until the measurement of C-reactive **protein** (CRP), a marker of inflammation circulating in the blood, was proposed as a method to identify persons at risk of chronic diseases. As pioneering research began to show that higher levels of C-reactive protein was linked to heart disease, conventional thought among the medical profession began. Originally discovered by W. S. Tillett and T. Francis Jr. in 1930, C-reactive protein was discovered as a substance in the serum of patients diagnosed with acute inflammation that reacted with the C-polysaccharide of pneumoccocus.

Today, a growing consensus among medical professionals is that inflammation is believed to play a role in the pathogenesis of chronic diseases such as heart disease, stroke, diabetes, and colon **cancer** to name a few. Mainstream thinking is beginning to accept that treating the underlying cause may ameliorate cardiovascular disease, metabolic syndrome, **hypertension**, diabetes, and **hyperlipidemia**, inflammation caused by visceral adipose tissue.

## KEY TERMS

**Inflammation:**—Swelling, redness, heat, and pain produced in an area of the body as a reaction to injury or infection.

**Chronic disease:**— an illness or medical condition that lasts over a long period of time and sometimes causes a long-term change in the body.

**C-reactive protein (CRP):**— a marker of inflammation circulating in the blood has been proposed as a method to identify persons at risk of these diseases.

**Flavonoid:**—refers to compounds found in fruits, vegetables, and certain beverages that have diverse beneficial biochemical and antioxidant effects.

**Anti-oxidant:**—A chemical compound or substance that inhibits oxidation. A substance, such as vitamin E, vitamin C, or beta-carotene.

## Description

### *Inflammation*

Inflammation is a localized reaction of tissue to injury, whether caused by bacteria or viral infection, trauma, chemicals, heat or other phenomenon that causes irritation. The 'irritation' causes the tissues within the body to release multiple substances that cause changes within the tissues. This complex response is called inflammation. Inflammation is characterized by such symptoms that include (1) vasodilatation of the local blood vessels resulting in excess local blood flow, (2) increases in the permeability of the capillaries with leakage of large quantities of fluid into the interstitial spaces, (3) May include clotting of the fluid in the interstitial spaces due to excess amounts of fibrinogen and other proteins leaking from the capillaries, (4) relocation of granulocytes and monocytes into the tissue in large quantities, thus (5) swelling of the tissue cells.

The common substances released from the tissues that result in inflammation are histamine, bradykinin, serotonin, prostaglandins, multiple hormonal substances called lymphokines that are released by sensitized T-cells and various other reaction products of other systems within the body. Many of these substances activate the macrophage system, which are sent out to dispose of the damaged tissue but also which further injure the still-living tissue and cells.

### *Conditions with chronic inflammation*

Inflammation has been associated as a component of, but not limited to, arthritis, heart disease, diabetes, strokes, asthma, allergies, irritable bowel disease, **Celiac disease** or other digestive system diseases, **obesity**, chronic stress, sleep disorders such as sleep apnea,

Alzheimer's disease, high blood pressure, elevated lipids such as **triglycerides** and cholesterol.

### *Medical Anti-Inflammatory Treatments*

General anti-inflammatory medical treatments include relaxation, moderate exercise such as walking, weight maintenance or loss, and medications designed to reduce the inflammation and control the pain if present.

These medications may include: ibuprofen or aspirin, Non Steroidal Anti-Inflammatory Drugs (NSAIDs), or steroid medications. The NSAIDs are widely used as the initial form of therapy. Unfortunately, long-term use of these medications can irritate the stomach and lead to **ulcers**. And in some cases can lead to kidney, as well as other medical problems.

## Function

### *Diet and chronic inflammation*

Registered dietitians, and Naturopathic physicians often prescribe diets to lessen the inflammatory symptoms of diseases. Although these diets have not been compared to other treatments in many formal research settings to date, it is thought that anti-inflammatory diets result in a reduced amount of inflammation and a healthier response by the immune system.

Adding foods that reduce inflammation is thought to improve symptoms of chronic diseases and help decrease risk for chronic diseases. These foods help in supplying the nutrients that are needed to decrease inflammation. One example is **omega-3 fatty acids**. The human body uses these fats to manufacture prostaglandins, chemicals that play an important role in inflammation and a healthy immune response. Another beneficial component of fish oil that plays an important role is eicosapentaenoic acid (EPA), an essential fatty acid derived from omega-3 fatty acids. EPA promotes the production of certain forms of prostaglandins having anti-inflammatory properties by reducing inflammation and decreasing the production of inflammatory substances.

## Foods that reduce chronic inflammation

### *Whole grains*

Whole grains or foods made from them, whether cracked, crushed, rolled, extruded, and/or cooked, contain the essential parts and nutrients of the entire grain seed. Research has shown that diets high in whole grain products are associated with decreased concentrations of inflammatory markers and increased adiponectin levels. The protective effects of a diet high in whole grains on systemic inflammation may be explained, in part, by reduction in overproduction of oxidative stress that results in inflammation.

A whole grain will include the following parts of the grain kernel–the bran, germ and endosperm. Such whole grains are amaranth, barley, bulgur, wild rice, millet, oats, quinoa, rye, spelt, wheat berries, buckwheat, and whole wheat.

### *Legumes*

Diets high in legumes are inversely related to plasma concentrations of C-reactive protein (CRP). Among the many varieties of legumes are; pinto beans, lentils, kidney beans, borlotti beans, mung beans, soybeans, cannelloni beans, garbanzo or chickpeas, adzuki beans, fava beans, and black beans.

### *Nuts, seeds*

Nuts and seeds are rich in unsaturated fat and other nutrients that may reduce inflammation. Frequent nut consumption is associated with lower levels of inflammatory markers. This may explain why there is a lower risk of cardiovascular disease and type 2 diabetes with frequent nut and seed consumption. With the exception of peanuts, be sure to add in walnuts, flax seeds and pumpkin seeds. Nuts and seeds are best eaten when unsalted and raw.

### *Fresh vegetabless*

Green leafy vegetables, and brightly colored vegetables provide beta-carotene; **vitamin C** and other **antioxidants** have been shown to reduce cell damage and to have anti-inflammatory effects. Aim for 3 or more servings per day.

### *Fresh fruits*

Flavonoids found in fresh fruits among other substances are thought to increase the antioxidant effects of vitamin C. research has shown that fruits have an anti-inflammatory effect. Aim for two or more servings daily. Be sure to include berries in your weekly choices of fruits such as blueberries, blackberries, and strawberries.

### *Wild fish and seafood*

Oily fish such as Herring, Mackerel, Salmon and Trout are an excellent source of omega-3 fatty acids, as are shellfish such as mussels and clams. Including fish or seafood high in omega-3 fatty acids at least three times a week is recommended.

### *Lean poultry*

Protein is used in the body to repair and manufacture cells, make antibodies, enzymes and hormones. Lean protein has been associated with lower levels of inflammatory biomarkers.

When choosing poultry, choose grass-fed animals, which tend to have a higher amount of essential fatty acids. Select poultry with limited amounts of, or free of, preservatives, **sodium**, nitrates or coloring. Also, in an ideal diet, only 10-12% of daily calories should come from protein. On average, an adult needs 0.36 grams of protein per pound of body weight.

### *Soy products*

Anti-inflammatory properties of the isoflavones, a micronutrient component of **soy**, have been reported in several experimental models and disease conditions. Data suggests the possibility of beneficial effects of isoflavone-rich soy foods when added to the diet. Soy products include; soybeans, edema me, tofu, tempeh, soymilk, as well as many other products made from soybeans.

### *Oils*

Expeller pressed Canola oil and Extra Virgin Olive oil are types of oils that have been linked to reduced inflammation. Other oils thought to aid in reducing inflammation include rice bran, grape seed, evening primrose and walnut oil. It is suggested to use these oils in moderation when cooking, baking and flavoring of foods. Also, when purchasing oils, make sure they are pure oils rather than blended oils. Blended oil usually contains less healthful oils.

### *Water in the form of fresh drinking water free of toxic chemicals*

**Water** is an essential substance for every function of the body. It is a medium for chemical processes; a solvent for body wastes and dilutes their toxicity and aids in their excretion. Water aids in ingestion, absorption and transport of vital nutrients that have anti-inflammatory effects. Water is also needed for basic cell functioning, repairing of body tissues and is the base of all blood and fluid secretions.

### *Herbs and Spices*

A greater amount of research is emerging on the antioxidant properties of herbs and spices and their use in the management of chronic inflammation. Herbs and spices can be used in recipes to partially or wholly replace less desirable ingredients such as salt, sugar and added saturated fat, know for their inflammatory effects, thus reducing the damaging properties of these foods.

## Precautions

### *Foods that irritate inflammation*

Best referred to in research articles as 'the western dietary pattern', it credits a diet that is high in refined grains, red meat, butter, processed meats, high-fat dairy, sweets and desserts, pizza, potato, eggs, hydrogenated fats, and soft drinks. This pattern of eating is positively related to an increase in circulating blood CRP levels and higher risks for chronic diseases, obesity and cancers. These foods, termed 'pro-inflammatory' may increase inflammation, thus increasing a persons risk for chronic diseases as well as exacerbate symptoms from these chronic conditions.

There is some support for the belief that **food sensitivities** or allergens to foods may be a trigger for inflammation. Often hard to detect with common blood tests, some people have seen alleviation of symptoms of chronic diseases, such as arthritis, when the aggravating foods are removed from their diet. Common allergic foods are milk and dairy, wheat, corn, eggs, beef, yeast and soy.

Other pro-inflammatory foods have been shown to have substances that activate or support the inflammatory process. Unhealthy trans fats and saturated fats used in preparing and processing certain foods are linked to increased inflammation. Processed meats such as lunchmeats, hot dogs and sausages contain chemicals such as nitrites that are associated with increased inflammation and chronic disease.

Saturated fats naturally found in meats, dairy products and eggs contain fatty acids called arachidonic acid. While some arachidonic acid is essential for health, excess arachidonic acid in the diet has been shown to worsen inflammation.

Research supports that diets high in sugar produce acute oxidative stress within the cells, associating it with inflammation. Elimination of high sugar foods such as sodas, soft drinks, pastries, presweetened cereals and candy has been shown to be beneficial. As well as switching from refined grains to whole grains.

## Benefits

The effects of the anti-inflammatory diet are unobtrusive. There is a series of research articles that demonstrate a benefit in reduction of chronic diseases such as cardiovascular disease, neurodegenerative diseases, and cancers when following a dietary pattern associated with the anti-inflammatory diet. But the

## QUESTIONS TO ASK YOUR DOCTOR

- May any of my medical conditions be aided by adopting an anti-inflammatory diet?
- What foods can I eat to decrease my dosage of anti-inflammatory medications?
- How might the anti-inflammatory diet help me in reducing my risks of chronic diseases?
- Would you recommend that I adopt more anti-inflammatory foods into my diet?

benefits go beyond disease prevention. Studies have shown an alleviation of symptoms associated with chronic diseases. As well, a person may decrease or discontinue their dosage of medications prescribed to control symptoms related to inflammatory conditions, and reduce the side affects associated with anti-inflammatory agents.

It has also been documented that people who followed the anti-inflammatory diet stated they experienced loss of weight, had an elevation of energy, and reported better mental and emotional health.

### Risks

The risks associated with following the anti-inflammatory diet are limited and not supported by research. The general concern associated with following any diet without the consent of a primary physician would apply. Anyone attempting to follow the anti-inflammatory diet should discuss it with their primary care physician and get a referral to see a Registered Dietitian, educated in the diet for maximal benefit and decreased risk of following a diet that eliminates certain foods from the dietary pattern to ensure proper intake of all macro and micro-nutrients.

### Research and general acceptance

As stated previously, there is no one anti-inflammatory diet but rather there are foods that are thought to increase the inflammatory process and ones that are beneficial to the inflammatory processed within the body. Because of this, many medical professionals and other health providers may not support the concept of a diet that decreases the anti-inflammatory response within the body.

There is substantial evidence supported through research that shows the beneficial effects on the body in reducing markers of inflammation such as CPH and reduction in chronic disease and its symptoms. Most medical professionals have an easier time accepting the **Mediterranean diet** which includes many of the foods found in the anti-inflammatory diet, and is the closest termed dietary eating pattern to the anti-inflammatory diet.

Megan C.M. Porter, RD, LD

# Antioxidants

### Definition

Antioxidants are molecules that prevent oxygen molecules from interacting with other molecules in a process called oxidation. In the body, antioxidants combine with potentially damaging molecules called free radicals to prevent the free radicals from causing damage to cell membranes, DNA, and proteins in the cell. Common antioxidants important to human health are **vitamins** A, C, E, beta-carotene, and **selenium**. In the mid-2000s, about 20% of North Americans and Europeans were taking at least one antioxidant dietary supplement.

### Purpose

The role of antioxidants in the body is complex and not completely understood. Antioxidants combine with free radicals so that the free radicals cannot react with, or oxidize, other molecules. In this way, antioxidants help slow or prevent damage to cells. Damage caused by free radicals is thought to cause or contribute to cardiovascular disease, **cancer**, Alzheimer's disease, age-related changes in vision, and other signs of aging. However, no direct cause and effect relationship between antioxidant intake and disease prevention has been proven. Antioxidants unrelated to those of importance in the body have commercial uses in the preservation of processed food and in many industrial processes.

### Description

Oxygen is essential to many reactions that occur within cells. Free radicals form mainly as a result of normal cellular **metabolism** involving oxygen. They can also form in abnormally large amounts when the body is exposed to radiation, ultraviolet light, and toxins such as cigarette smoke or certain chemicals.

**Health benefits of antioxidants and their food sources**

| Antioxidant | Health benefits | Food sources |
|---|---|---|
| Selenium | Helps maintain healthy hair and nails, enhances immunity, works with vitamin E to protect cells from damage. Reduces the risk of cancer, particularly lung, prostate, and colorectal. | Garlic, seeds, Brazil nuts, meat, eggs, poultry, seafood, whole grains. The amount in plant sources varies according to the content of the soil. |
| Beta-carotene | Keeps skin healthy, helps prevent night blindness and infections, promotes growth and bone development. | Red, yellow-orange, and leafy green vegetables and fruits, including carrots, apricots, cantaloupe, peppers, tomatoes, spinach, broccoli, sweet potatoes, and pumpkin. |
| Vitamin E | Acts as the protector of essential fats in cell membranes and red blood cells. Reduces risk of cancer, heart disease, and other age-associated diseases. | Peanut butter, nuts, seeds, vegetable oils and margarine, wheat germ, avocado, whole grains, salad dressings. |
| Vitamin C | Destroys free radicals inside and outside cells. Helps in the formation of connective tissue, the healing of wounds, and iron absorption, and also helps to prevent bruising and keep gums healthy. May reduce risk of cataracts, heart disease, and cancer. | Peppers, tomatoes, citrus fruits and juices, berries, broccoli, spinach, cabbage, potatoes, mango, papaya. |

*(Illustration by GGS Information Services/Thomson Gale.)*

The common feature of free radicals is that their molecular structure contains and unpaired electron. Free radical molecules with an unpaired electron are unstable and have a strong tendency to react with other molecules by "stealing" an electron from them to form a more stable electron pair. This reaction is called oxidation (even when it happens with molecules other than oxygen). In the body, free radicals cause damage when they react with deoxyribonucleic acid (DNA—genetic material), proteins, and lipids (**fats**). Antioxidants are molecules that react with free radicals in ways that neutralize them so they no longer are able to "steal" electrons and cause damage.

Some important human antioxidants must be acquired through diet, while others can be made by the body. **Vitamin C** (ascorbic acid), **vitamin E** (alpha-tocopherol), **vitamin A** (retinol), and beta-carotene are the most important antioxidants the body must obtain from food sources. Flavonoids found in tea, chocolate, grapes, berries, onions, and wine also appear to have antioxidant activity, although their role in health is unclear. Selenium is sometimes classified as an antioxidant, although strictly, it is not. Selenium is a mineral that must be acquired through diet. Plants grown in geographic locations with selenium rich soil provide a rich source of this mineral. Brazil nuts and tuna also have high levels of selenium. It is a necessary part of enzymes involved in antioxidant reactions. Glutathione and coenzyme Q (ubiquinone) are the most important antioxidants the body can make for itself.

### *Antioxidants and health*

When free radicals build up faster than antioxidants can neutralize them, the body develops a condition called oxidative stress. Oxidative stress reduces the body's ability to deal with damage to cells and is thought to play a role in the development of chronic diseases such as cardiovascular disease, cancer, and Alzheimer's disease. Researchers know that a diet high in fruits and vegetables containing antioxidants promotes health and decreases the risk of developing some chronic diseases such as atherosclerosis (hardening of the arteries). In the early 2000s, **dietary supplements** containing antioxidants were popularized as a way to reduce oxidative stress, prevent health problems such as cancer, stroke, heart attack, and dementia, and live longer. Research has since shown that although there are relationships between antioxidant levels and health, antioxidant dietary supplements are not magic bullets to prevent age-related diseases.

One problem in determining whether there is a cause and effect relationship between oxidative stress and disease is that often it is not possible to tell if oxidative stress causes a disease or if the disease brings about oxidative stress as a result of biochemical changes in diseased cells. Also, everyone develops oxidative stress as they age, but not everyone develops the same diseases. The interactions between an individual's diet, environment, genetic make-up, and health are complex and still not well understood. Antioxidants remain of great interest to researchers seeking ways to prevent and cure chronic disease. Many clinical trials are underway to determine safety and effectiveness of different antioxidants, both alone and in combination with other drugs and supplements.

**CARDIOVASCULAR DISEASE.** The strongest link between antioxidant levels and health is related to the development of cardiovascular disease. Low-density

lipoprotein cholesterol (LDL or "bad cholesterol") appears to react with free radicals. This changes the LDL cholesterol in a way that allows it to accumulate in cells lining the blood vessels. These cholesterol-loaded cells are precursors to the development of plaque, hard deposits that line blood vessels and cause cardiovascular disease, heart attack, and stroke.

Researchers thought increasing the amount of antioxidants in the blood by taking supplements would decrease the number of free radicals available to interact with LDL cholesterol and thus lower the risk of developing cardiovascular disease. This theory has not been proved. In fact, a paper published in the *Journal of the American Medical Association* on February 28, 2007, analyzed 68 trials of antioxidant supplements involving about 232,600 patients. The authors concluded that antioxidant supplements did not prolong life. In fact, when only rigorous, well-controlled studies were analyzed, the risk of dying increased 5%. This analysis is quite controversial, with some experts questioning the analytical methods used. However, the American Heart Association and similar organizations in other countries advocate cardiovascular disease prevention through consumption of fruits, vegetables, whole grains and nuts high in antioxidants and other heart-protecting nutrients instead of antioxidant supplements.

**CANCER.** Free radicals damage DNA, and sometimes this damage leads to development of cancer. In laboratory cell cultures and animal studies, antioxidants appear to slow the development of cancer. The results have been mixed in studies where humans took antioxidant dietary supplements. A large study of 29,000 men showed that when a beta-carotene dietary supplement was taken by men who smoked, they developed lung cancer at a rate 18% higher and died at a rate 8% higher than men who did not receive the supplement. Another study that gave men dietary supplements of beta-carotene and vitamin A was stopped when researchers found the men receiving the beta-carotene had a 46% greater chance of dying from lung cancer than those who did not receive the supplement. Other large studies have shown either no or only slight protective effects against cancer. The position of the American Cancer Society, the National Cancer Institute, and several international health organizations is that antioxidants should come from a healthy diet high in fruits and vegetables and low in fat and not from dietary supplements.

**AGE-RELATED VISION IMPAIRMENT.** Cataracts and age-related macular degeneration are two types of vision impairment common in older individuals. Cataracts develop because of changes in the **protein** in the lens of the eye. These changes cause the lens to become cloudy and limit vision. The changes may be due to damage by free radicals. Age-related macular degeneration is an irreversible disease of the retina that causes blindness. Two carotenoid antioxidants, zeaxanthin and lutein, are found in the retina and are essential to vision. However, study participants who took antioxidant supplements over several years did not have a reduced risk of developing these diseases.

## KEY TERMS

**Coenzyme**—Also called a cofactor; a small non-protein molecule that binds to an enzyme and catalyzes (stimulates) enzyme-mediated reactions.

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Enzyme**—A protein that changes the rate of a chemical reaction within the body without themselves being used up in the reaction.

**Free radical**—A molecule with an unpaired electron that has a strong tendency to react with other molecules in deoxyribonucleic acid (DNA), proteins, and lipids (fats), resulting in damage to cells. Free radicals are neutralized by antioxidants.

**Mineral**—An inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

**Oxidation**—Interaction in which one molecule removes an electron from another molecule to stabilize itself.

**Retina**—The layer of light-sensitive cells on the back of the eyeball that function in converting light into nerve impulses.

**Vitamin**—An essential nutrient the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

### Precautions

The mixed results obtained in human studies of antioxidant supplements suggests that all antioxidants should come from foods and not from dietary

supplements. There is also little information on the safety of antioxidant supplements in children and women who are pregnant or **breastfeeding**.

## Interactions

The interaction among various antioxidants, enzymes, coenzymes, drugs, herbal and dietary supplements is complex and incompletely understood. Specific antioxidants may have known interactions and should be discussed with a physician.

## Complications

Antioxidants acquired by eating fruits and vegetables promote health. No complications are expected from antioxidants in food. Antioxidant dietary supplements may interact with other supplements, prescription drugs, over-the-counter drugs, and herbal supplements in ways that cause undesirable side effects. Consult a physician prior to taking an antioxidant supplement.

## Parental concerns

Parents should encourage their children to eat a healthy and varied diet high in fruits, vegetables, and whole grains. There is no need to give children antioxidant dietary supplements. The safety of these supplements in children has not been studied.

Antiscorbutic vitamin *see* **Vitamin C**

# Arthritis diet

## Definition

Arthritis is the general medical term for the inflammation of a joint or a disorder characterized by such inflammation. There are a number of different arthritides (the plural form of arthritis), and therefore there is no "arthritis diet" as such that has been proposed as a treatment for all these different joint disorders. Dietary therapies for osteoarthritis (OA) and rheumatoid arthritis (RA), the two most common forms of arthritis, fall into three major categories: mainstream management strategies that focus on weight reduction and well-balanced diets as a way to relieve stress on damaged joints and slow the progression of arthritis; **dietary supplements** of various types that have been evaluated in clinical trials and have been found to benefit at least some patients; and alternative medical approaches that rely on dietary adjustments (including **elimination diets**) and/or traditional herbal remedies to treat arthritis.

### *Osteoarthritis*

The reader should be aware of the differences between OA and RA in order to understand both mainstream and alternative approaches to these disorders. Osteoarthritis (OA) is the more common of the two in the general North American population, particularly among middle-aged and older adults. It is estimated to affect about 21 million adults in the United States, and to account for $86 billion in health care costs each year. It is also the single most common condition for which people seek help from complementary and alternative medical (CAM) treatments. The rate of OA increases in older age groups; about 70% of people over 70 are found to have some evidence of OA when they are X-rayed. Only half of these elderly adults, however, are affected severely enough to develop noticeable symptoms. OA is not usually a disease that completely disables people; most patients can manage its symptoms by watching their weight, staying active, avoiding overuse of affected joints, and taking over-the-counter or prescription pain relievers. OA most commonly affects the weight-bearing joints in the hips, knees, and spine, although some people first notice its symptoms in their fingers or neck. It is often unilateral, which means that it affects the joints on only one side of the body. The symptoms of OA vary considerably in severity from one patient to another; some people are only mildly affected by the disorder.

*(Illustration by GGS Information Services/Thomson Gale.)*

OA results from progressive damage to the cartilage that cushions the joints of the long bones. As the cartilage deteriorates, fluid accumulates in the joints, bony overgrowths develop, and the muscles and tendons may weaken, leading to stiffness on arising, pain, swelling, and limitation of movement. OA is gradual in onset, often taking years to develop before the person notices pain or a limited range of motion in the joint. OA is most likely to be diagnosed in people over 45 or 50, although younger adults are occasionally affected. OA affects more men than women under age 45 while more women than men are affected in the age group over 55. As of the early 2000s, OA is thought to result from a combination of factors, including heredity (possibly related to a mutation on chromosome 12); traumatic damage to joints from accidents, type of employment, or sports injuries; and **obesity**. It is not, however, caused by the aging process itself. Race does not appear to be a factor in

## KEY TERMS

**Arthritis (plural, arthritides)**—A general term for the inflammation of a joint or a condition characterized by joint inflammation.

**Avocado soybean unsaponifiables (ASU)**—A compound of the fractions of avocado oil and soybean oil that cannot be used in the production of soap. ASU shows promise in the treatment of OA. It is available only by prescription in France, where it was first studied, but can be purchased over the counter in the United States.

**Ayurveda**—The traditional system of natural medicine that originated in India around 3500 BC. Its name is Sanskrit for "science of long life." Some people have tried Ayurvedic medicines and dietary recommendations in the treatment of arthritis.

**Chondroitin sulfate**—A compound found naturally in the body that is part of a large protein molecule (proteoglycan) helping cartilage to retain its elasticity. Chondroitin sulfate derived from animal or shark cartilage can be taken as a dietary supplement by people with OA.

**Disease-modifying antirheumatic drugs (DMARDs)**—A class of prescription medications given to patients with rheumatoid arthritis that suppress the immune system and slow the progression of RA.

**Elimination diet**—A diet in which the patient excludes a specific food (or group of foods) for a period of time in order to determine whether the food is responsible for symptoms of an allergy or other disorder. Elimination diets are also known as food challenge diets.

**Glucosamine**—A type of amino sugar that is thought to help in the formation and repair of cartilage. It can be extracted from crab or shrimp shells and used as a dietary supplement by people with OA.

**Naturopathy**—A system of disease treatment that emphasizes natural means of health care, as water, natural foods, dietary adjustments, massage and manipulation, and electrotherapy, rather than conventional drugs and surgery. Naturopaths (practitioners of naturopathy) often recommend dietary therapy in the treatment of arthritis.

**Nonsteroidal anti-inflammatory drugs (NSAIDs)**—A class of drugs commonly given to treat the inflammation and pain associated with both RA and OA. NSAIDs work by blocking prostaglandins, which are hormone-like compounds that cause pain, fever, muscle cramps, and inflammation. Some NSAIDs are prescription drugs while others are available in over-the-counter (OTC) formulations.

**Osteoarthritis (OA)**—The most common form of arthritis, characterized by erosion of the cartilage layer that lies between the bones in weight-bearing joints. OA is also known as degenerative joint disease or DJD.

**Rheumatoid arthritis (RA)**—An autoimmune disorder that can affect organ systems as well as the joints. It is much less common that OA but is potentially much more serious.

**Rheumatologist**—A physician, usually a pediatrician or internist, who has additional specialized training in the diagnosis and treatment of diseases that affect the bones, muscles, and joints.

**Turmeric**—A perennial herb of the ginger family used as a coloring agent as well as a spice in food preparation. It is used in some traditional Ayurvedic medicines for the relief of joint pain and inflammation.

**Vegan**—A vegetarian who excludes all animal products from the diet, including those that can be obtained without killing the animal. Vegans are also known as strict vegetarians. Some people believe that a vegan diet is helpful in managing arthritis.

OA, although some studies indicate that African American women have a higher risk of developing OA in the knee joints. Other risk factors for OA include **osteoporosis** and **vitamin D** deficiency.

RA, by contrast, is most likely to be diagnosed in adults between the ages of 30 and 50, two-thirds of whom are women. RA affects about 0.8% of adults worldwide, or 25 in every 100,000 men and 54 in every 100,000 women. Unlike OA, which is caused by degeneration of a body tissue, RA is an autoimmune disorder—one in which the body's immune system attacks some of its own tissues. It is often sudden in onset and may affect other organ systems, not just the joints. RA is a more serious disease than OA; 30% of patients with RA will become permanently disabled within two to three years of diagnosis if they are not treated. In addition, patients with RA have a higher

risk of heart attacks and stroke. RA differs from OA, too, in the joints that it most commonly affects—often the fingers, wrists, knuckles, elbows, and shoulders. RA is typically a bilateral disorder, which means that both sides of the patient's body are affected. In addition, patients with RA often feel sick, feverish, or generally unwell, while patients with OA usually feel normal except for the stiffness or discomfort in the affected joints.

## Origins

The role of diet and nutrition in both OA and RA has been studied since the 1930s, but there is little agreement as of 2007 regarding the details of dietary therapy for these disorders. One clear finding that has emerged from seven decades of research is the importance of weight reduction or maintenance in the treatment of patients with OA, and the need for nutritional balance and healthy eating patterns in the treatment of either form of arthritis. Findings regarding the use of dietary supplements or CAM therapies will be discussed in more detail below.

Various elimination diets (diets that exclude specific foods from the diet) have been proposed since the 1960s as treatments for OA. The best-known of these is the Dong diet, introduced by Dr. Collin Dong in a book published in 1975. This diet is based on traditional Chinese beliefs about the effects of certain foods in increasing the pain of arthritis. The Dong diet requires the patient to cut out all fruits, red meat, alcohol, dairy products, herbs, and all foods containing additives or preservatives. There is, however, no clinical evidence as of 2007 that this diet is effective.

Another type of elimination diet, still recommended by naturopaths and some vegetarians in the early 2000s, is the so-called nightshade elimination diet, which takes its name from a group of plants belonging to the family Solanaceae. There are over 1700 plants in this category, including various herbs, potatoes, tomatoes, bell peppers, and eggplant as well as nightshade itself, a poisonous plant also known as belladonna. The nightshade elimination diet began in the 1960s when a researcher in horticulture at Rutgers University noticed that his joint pains increased after eating vegetables belonging to the nightshade family. He eventually published a book recommending the elimination of vegetables and herbs in the nightshade family from the diet. There is again, however, no clinical evidence that people with OA will benefit from avoiding these foods.

## Description

### *Osteoarthritis*

**WEIGHT REDUCTION.** The major dietary recommendation approved by mainstream physicians for patients with OA is keeping one's weight at a healthy level. The reason is that OA primarily affects the weight-bearing joints of the body, and even a few pounds of extra weight can increase the pressure on damaged joints when the person moves or uses the joint. It is estimated that that a force of three to six times the weight of the body is exerted across the knee joint when a person walks or runs; thus being only 10 pounds overweight increases the forces on the knee by 30 to 60 pounds with each step. Conversely, even a modest amount of weight reduction lowers the pain level in persons with OA affecting the knee or foot joints. Obesity is a definite risk factor for developing OA; data from the National Institutes of Health (NIH) indicate that obese women are 4 times as likely to develop OA as non-obese women, while for obese men the risk is 5 times as great.

Although some doctors recommend trying a vegetarian or vegan diet as a safe approach to weight loss for patients with OA, most will approve any nutritionally sound calorie-reduction diet that works well for the individual patient.

**DIETARY SUPPLEMENTS.** Dietary supplements are commonly recommended for managing the discomfort of OA and/or slowing the rate of cartilage deterioration:

- Chondroitin sulfate. Chondroitin sulfate is a compound found naturally in the body that is part of a large protein molecule called a proteoglycan, which imparts elasticity to cartilage. The supplemental form is derived from animal or shark cartilage. Recommended daily dose is 1200 mg.
- Glucosamine. Glucosamine is a form of amino sugar that is thought to support the formation and repair of cartilage. It can be extracted from crab, shrimp, or lobster shells. The recommended daily dose is 1500 mg. Dietary supplements that combine chondroitin sulfate and glucosamine can be obtained over the counter in most pharmacies or health food stores.
- Botanical preparations: Some naturopaths recommend extracts of yucca, devil's claw, hawthorn berries, blueberries, and cherries. These extracts are thought to reduce inflammation in the joints and enhance the formation of cartilage. Powdered ginger has also been used to treat joint pain associated with OA.
- Vitamin therapy. Some doctors recommend increasing one's daily intake of vitamins C, E, A, and $B_6$, which are required to maintain cartilage structure.

- Avocado soybean unsaponifiables (ASU). ASU is a compound of the fractions of avocado oil and soybean oil that are left over from the process of making soap. It contains one part avocado oil to two parts soybean oil. ASU was first developed in France, where it is available by prescription only under the name Piasclédine, and used as a treatment for OA in the 1990s. It appears to work by reducing inflammation and helping cartilage to repair itself. ASU can be purchased in the United States as an over-the-counter dietary supplement. The recommended daily dose is 300 mg.

**CAM DIETARY THERAPIES.** Two traditional alternative medical systems have been recommended in the treatment of OA. The first is Ayurveda, the traditional medical system of India. Practitioners of Ayurveda regard OA as caused by an imbalance among the three *doshas*, or subtle energies, in the human body. This imbalance produces toxic byproducts during digestion, known as *ama*, which lodges in the joints of the body instead of being eliminated through the colon. To remove these toxins from the joints, the digestive fire, or *agni*, must be increased. The Ayurvedic practitioner typically recommends adding such spices as turmeric, cayenne pepper, and ginger to food, and undergoing a three-to five-day detoxification diet followed by a cleansing enema to purify the body.

Traditional Chinese medicine (TCM) treats OA with various compounds containing **ephedra**, cinnamon, aconite, and coix. A combination herbal medicine that has been used for at least 1200 years in TCM is known as *Du Huo Ji Sheng Wan*, or Joint Strength. Most Westerners who try TCM for relief of OA, however, seem to find acupuncture more helpful as an alternative therapy than Chinese herbal medicines.

### *Rheumatoid arthritis*

**DIETARY ALTERATIONS.** There is some indication that patients with RA benefit from cutting back on meat consumption or switching entirely to a vegetarian or vegan diet. One follow-up study of RA patients on a vegetarian diet showed that improvement continued after one and two years on the diet.

Another dietary adjustment that appears to benefit some people with RA is switching from cooking oils that are high in omega-6 fatty acids (which increase inflammation) to oils that are high in **omega-3 fatty acids** (which reduce inflammation. This second group includes olive oil, canola oil, and **flaxseed** oil.

**DIETARY SUPPLEMENTS.** The most common dietary supplements recommended for patients with RA are as follows:

- Fish oil. The oils from cold-water fish have been reported to reduce inflammation and relieve joint pain in some patients with RA. The recommended daily dose is 1 to 2 teaspoons.
- Plant oils that are high in gamma-linoleic acid (GLA), which reduces inflammation in the joints. These plant oils include evening primrose oil, borage oil, and black current oil. The recommended daily dose is 200 to 300 mg.
- Green tea. Drinking 3 to 4 cups of green tea per day is thought to benefit RA patients by reducing inflammation in the joints.

**CAM DIETARY THERAPIES.** Ayurvedic medicine recommends a compound of ginger, turmeric, boswellia, and ashwaganda to relieve the pain and fever associated with RA.

Traditional Chinese medicine (TCM) uses such plants as hare's ear (*Bupleurum falcatum*) and thunder god vine (*Tripterygium wilfordii*) to reduce fever and joint pain in patients with RA.

## Function

### *Osteoarthritis*

The function of dietary treatment for OA is to lower (or maintain) the patient's weight to a healthy level in order to minimize stress on damaged weight-bearing joints; to maintain the structure and composition of the cartilage in the joints; to protect the general health of tissues by including bioflavonoids and **antioxidants** in the diet; and by conducting food challenges when appropriate to determine whether specific foods are affecting the patient's symptoms.

### *Rheumatoid arthritis*

Dietary treatment of RA is primarily adjunctive, as the disease cannot be managed by nutritional changes alone. Patients with RA must take a combination of medications, usually a combination of disease-modifying anti-rheumatic drugs (DMARDs) and nonsteroidal anti-inflammatory drugs (NSAIDs), to control pain, inflammation, and slow the progression of the disease. A well-balanced and healthful diet, however, can help to offset the emotional depression that often accompanies RA and to enable patients to maintain a normal schedule of activities. It also helps to prevent nutritional deficiencies in these patients that may be caused by the use of prescription drugs to control the disease.

## Benefits

### *Osteoarthritis*

The benefits of weight reduction in overweight patients with OA are a noticeable reduction in discomfort and improved range of motion in the affected joints. The benefits of dietary supplements vary from patient to patient depending on the specific joints affected and the degree of erosion of the joint cartilage.

### *Rheumatoid arthritis*

The benefits of dietary adjustments or dietary supplements for RA vary considerably from patient to patient. Maintenance of a balanced diet, however, is valuable in preventing the nutritional deficiencies that sometimes occur in patients with RA as side effects of high dosages of DMARDs and NSAIDs.

## Precautions

Some general precautions for all persons with arthritis:

- Before beginning any form of dietary treatment for joint pain, consult a physician to obtain an accurate diagnosis of the type of arthritis that is causing the pain. When RA is suspected, it is vital to get systemic treatment as soon as possible to minimize long-term damage to health.
- Consult a physician before taking any dietary supplements, as certain OTCs and prescription medications can interact with these compounds. Chondroitin sulfate, for example, may increase bleeding time in some people, particularly if it is taken together with aspirin.
- Purchase dietary supplements only from well-established companies that can be held accountable for the quality of their products.
- Do not stop taking any medications currently prescribed by a doctor without consulting him or her.
- If maintaining a primarily vegetarian diet, be aware of the potential for iron deficiency.

People with either form of arthritis who are more than 30 pounds overweight; are pregnant, nursing, or under the age of 18; or diagnosed with type 2 diabetes, kidney disorders, or liver disorders should consult a physician before attempting a weight-reduction program.

### *Osteoarthritis*

People with diabetes should monitor blood sugar levels more frequently if they are taking **glucosamine**, because it is an amino sugar. Similarly, persons who are taking blood thinners should have their blood clotting time checked periodically if they are taking chondroitin sulfate. ASU has not been reported to cause drug interactions as of 2007.

### *Rheumatoid arthritis*

Plant oils containing GLA have been reported to cause intestinal gas, bloating, diarrhea, and nausea in some persons. In addition, these oils may interact with other prescription medications, particularly blood thinners. Some borage seed oil preparations contain ingredients known pyrrolizidine alkaloids, or PAs, that can harm the liver or worsen liver disease. Only forms of borage oil that are certified to be PA-free should be used. Last, evening primrose oil may interact with a group of tranquilizers used in the treatment of schizophrenia known as phenothiazines. This group of drugs includes chlorpromazine and prochlorperazine.

Fish oil may affect the rate of blood clotting and cause nausea or a fishy odor to the breath in some persons. Some fish oil supplements may also contain overly high levels of **vitamin A** or mercury. In addition, patients who take fish oil supplements must usually take them for several months before they experience any benefits.

## Risks

### *Osteoarthritis*

Most dietary supplements for OA appear to be safe when purchased from reputable manufacturers and used as directed. Glucosamine and chondroitin sulfate have been reported to cause intestinal gas or mild diarrhea in some people. ASU causes nausea and skin rashes in some people.

Cost may be a consideration for some people, as these supplements cost between $1.50 and $3 per day, and are not usually covered by health insurance.

### *Rheumatoid arthritis*

Chinese thunder god vine is reported to weaken bone structure and increase the risk of osteoporosis in patients with RA. Fish oils with high levels of vitamin A have been reported to cause vitamin A toxicity in some people.

## Research and general acceptance

### *Osteoarthritis*

No mainstream clinical studies have found that patients with OA benefit from elimination diets. With regard to dietary supplements, findings are mixed. A major 4-year study of glucosamine and chondroitin sulfate supplements, the Glucosamine/chrondoitin

## QUESTIONS TO ASK YOUR DOCTOR

- Would you recommend glucosamine and chondroitin supplements for mild OA?
- Have any of your other patients benefited from taking ASU or other dietary supplements for arthritis?
- What is your opinion of elimination diets as treatment for arthritis?
- Would you recommend a vegetarian diet for patients with OA as well as patients with RA?

Arthritis Intervention Trial (GAIT), reported in 2006 that these supplements appear to be more beneficial to a small subgroup of patients with severe pain from OA than to a larger group with only mild to moderate levels of discomfort. There is better evidence that ASU is beneficial, but only limited evidence for the usefulness of Du Huo Ji Sheng Wan. Some clinical studies carried out in India report that an Ayurvedic compound that combines ginger, turmeric, and **zinc** reduced pain in patients with OA of the knees even when other aspects of Ayurvedic practice were not followed.

### *Rheumatoid arthritis*

The National Center for Complementary and Alternative Medicine (NCCAM) has noted in a recent review of alternative treatments of RA that few high-quality studies of these treatments have been published as of 2006. Several studies indicate that vegetarian or vegan diets and the **Mediterranean diet** do in fact benefit patients with RA. Fish oil has been reported to reduce the risk of heart attacks in patients with RA as well as reduce joint pain and inflammation. **Green tea** has been tested on mice with RA but has not yet been tested on human subjects. A study conducted at the University of Arizona reported in 2006 that turmeric by itself inhibits the destruction of joint tissue in rats with RA as well as reducing joint inflammation; but as with green tea, turmeric supplements have not yet been used in clinical trials with human subjects with RA.

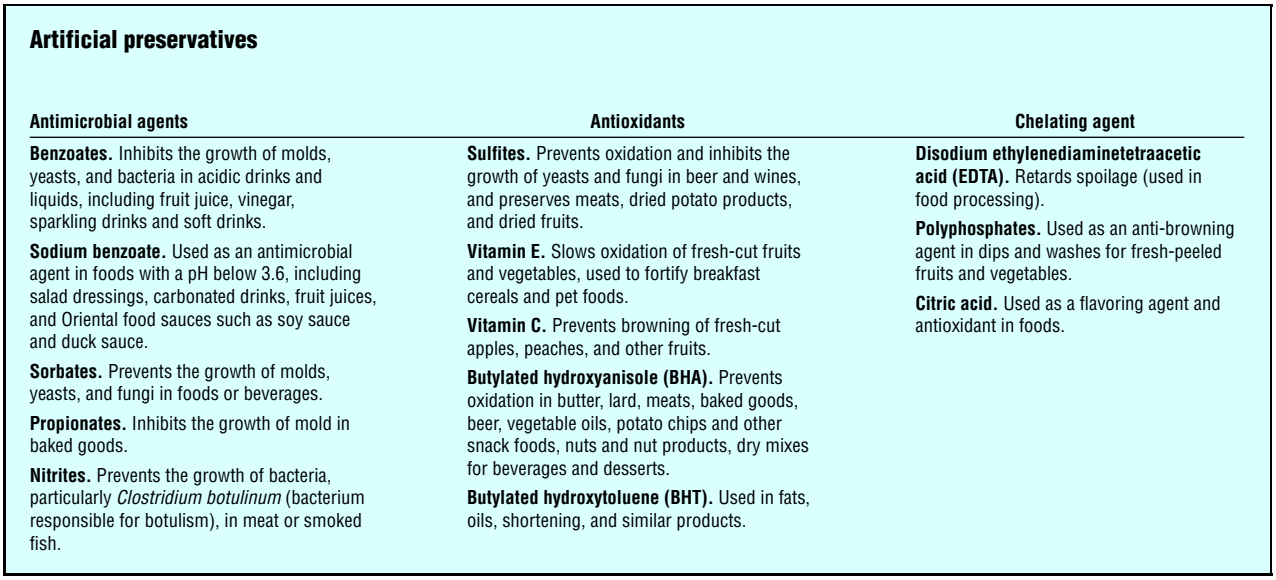
# Artificial preservatives

## Definition

Artificial preservatives are a group of chemical substances added to food, sprayed on the outside of food, or added to certain medications to retard spoilage, discoloration, or contamination by bacteria and other disease organisms. Most preservatives are categorized by the federal government as *food additives*, which are defined by the Federal Food, Drug, and Cosmetic Act (FD&C) of 1938 as "any substance, the intended use of which results directly or indirectly, in its becoming a component or otherwise affecting the characteristics of food." A subcategory of food preservatives are classified as *generally recognized as safe* (GRAS), which means that the government accepts the current scientific consensus on their safety, based on either their use prior to 1958 or to well-known scientific information.

The categorization of any artificial preservative is never permanent; it may change as new information about the preservative's safety is reported and analyzed. Certain preservatives that were once considered safe—most notably sulfites and nitrites—have been banned in recent years or greatly restricted in their permissible uses. Information about the current status of more than three thousand substances (including coloring and flavoring agents as well as preservatives) that the FDA has either approved as food additives or listed or affirmed as GRAS may be obtained from EAFUS, an online database maintained by the FDA's Center for **Food Safety** and Applied Nutrition



**The types of artificial preservatives, their role in food preservation, and foods containing preservatives.** *(Illustration by GGS Information Services/Thomson Gale.)*

(CFSAN). EAFUS is an acronym for "Everything Added to Food in the United States."

Artificial preservatives as used in the early 2000s are an extension of centuries-old methods of food preservation, some of which involved adding naturally occurring chemicals to food. To keep food from spoiling before it could be eaten, early humans found ways to dry it or (in colder climates) freeze it. Drying or dehydrating foods, a process known as desiccation, worked well with fruits, herbs, some meats, and some vegetables. Another method for preserving fruit was sugar preservation, which involved cooking the fruit in a high concentration of sugar that discouraged the growth of bacteria. In terms of natural chemicals, vinegar, ethanol (beverage alcohol), olive oil, and salt have been used for centuries to preserve foods by pickling, while meats and some types of fish have been preserved by smoking and curing, which draws moisture from the meat without cooking it. Smoking introduces **antioxidants** into meat or fish, while some spices used to flavor foods, such as curries and hot chilies, contain antimicrobial compounds.

## Purpose

The purpose of the major groups of artificial preservatives is to prevent food from spoiling or discoloring during the time it takes to transport the food from the producer to the consumer—including storage time in a restaurant or the individual consumer's home. Spoilage usually involves one of two processes: contamination by microorganisms (bacteria, molds, fungi, and yeasts are the primary offenders) or oxidation. Oxidation is the scientific name for the process that takes place in some foods when they combine with the oxygen in the atmosphere in the presence of heat, light, or certain metals. Oxidized foods typically turn brown, develop black spots, or acquire a bad or "off" smell. Cooking oils, oily foods like potato chips, sausage, or nuts, or buttery spreads that develop an unpleasant taste or smell are said to have gone rancid. Some **minerals** in food—particularly **iron** and copper—can also speed up the process of food spoilage through oxidation. Preservatives added to food to prevent oxidation related to these minerals are called chelating agents.

Some antimicrobial preservatives are added to medications to prevent the growth of bacteria in them. Most of these preparations are topical, which means that they are intended for use on the outside of the body—the skin, the eyes, or the ears. Eye drops formulated to relieve dry eyes are the most common topical medications that may contain artificial preservatives, but some asthma drugs also contain benzoates or other antimicrobials. Sulfites (sometimes spelled sulphites) are added to asthma inhalers, injectable epinephrine, and some other medications to prevent browning of the solution.

## Description

Artificial food preservatives can be divided into three major groups, antimicrobial agents, antioxidants, and chelating agents.

## KEY TERMS

**Anaphylaxis**—A severe and potentially fatal systemic allergic reaction characterized by itching, hives, fainting, and respiratory symptoms. Sulfites may trigger anaphylaxis in a small number of people who are unusually sensitive to them.

**Antimicrobial**—A type of food preservative that works by preventing the growth of bacteria, fungi, molds, or yeast in foods.

**Antioxidant**—A type of food preservative that prevents rancidity in oils and fatty foods.

**Botulism**—A potentially deadly disease characterized by respiratory and musculoskeletal paralysis caused by a bacterium called *Clostridium botulinum*. Botulism is a medical emergency. Nitrites are sometimes used to prevent the growth of *C. botulinum* spores in meat and smoked fish.

**Carcinogen**—A substance or other agent that causes cancer. Some artificial preservatives have been banned in the United States on the grounds that they may be carcinogens or produce carcinogenic substances when added to food.

**Chelating agent**—A type of food preservative that works by binding (or sequestering) metal ions (usually iron or copper) in certain foods in order to prevent the metals from oxidizing and speeding up spoilage. The name comes from the Greek word for a crab's claw, because chelating agents have two groups of atoms that encircle the metal ion like the claws of a crab. Chelating agents are also known as sequestrants.

**Desiccation**—Drying or dehydrating food as a method of preservation,

**Food additive**—Defined by the Federal Food, Drug, and Cosmetic Act (FD&C) of 1938 as "any substance, the intended use of which results directly or indirectly, in its becoming a component or otherwise affecting the characteristics of food." Food additives include flavoring and coloring agents as well as artificial preservatives.

**Generally recognized as safe (GRAS)**—A phrase used by the federal government to refer to exceptions to the FD&C Act of 1938 as modified by the Food Additives Amendment of 1958. Artificial food preservatives that have a scientific consensus on their safety based on either their use prior to 1958 or to well-known scientific information may be given GRAS status.

**Nitrosamine**—Any of various organic compounds produced by the interaction of nitrites in food with the breakdown products of amino acids. Nitrosamines are also found in tobacco smoke. Some nitrosamines are powerful carcinogens.

**Oxidation**—In food chemistry, the process that takes place in some foods when they combine with the oxygen in the atmosphere in the presence of heat, light, or such metals as iron or copper.

**pH**—A measure of the acidity or alkalinity of a solution. Solutions with a pH below 7 are considered acidic while those above 7 are alkaline. A pH of exactly 7 (pure water) is neutral.

**Rancid**—Having a bad or "off" smell or taste as a result of oxidation.

**Salt**—In chemistry, an ionic crystalline compound of positively charged ions and negatively charged ions such that the product is neutral (without a net charge).

**Topical**—Referring to a type of medication that is applied to the surface of the body or instilled into the eye or ear. Some topical medications contain artificial preservatives.

### *Antimicrobials*

Antimicrobial preservatives are added to food to destroy bacteria or to inhibit the growth of mold on foods.

**BENZOATES.** Benzoates are salts of benzoic acid, a weak acid that was at one time derived from benzoin resin, a gum obtained from the bark of trees native to Thailand and Indonesia. The benzoates used as food preservatives are potassium benzoate and **sodium** benzoate. Potassium benzoate works best in products with a low pH (below 4.5); it is used to inhibit the growth of molds, yeasts, and bacteria in acidic drinks and liquids, including fruit juice, vinegar, sparkling drinks, and soft drinks.

Sodium benzoate can be produced commercially by reacting sodium hydroxide with benzoic acid. It is used as an antimicrobial agent in foods with a pH below 3.6, including salad dressings, carbonated drinks, fruit juices, and such Oriental food sauces as **soy** sauce and duck sauce. It is also used as a preservative in some mouthwashes. Sodium benzoate occurs naturally in cranberries, prunes, greengage plums,

cloves, cinnamon, and apples. Although the FDA limits the concentration of sodium benzoate as a preservative to 0.1% of the food by weight, organically grown cranberries and prunes may contain levels of this benzoate above this limit.

**SORBATES.** The sorbates are a group of antimicrobial food preservatives comprising sorbic acid and its three mineral salts, potassium sorbate, **calcium** sorbate, and sodium sorbate. The name of the group comes from the botanical name of the rowan tree, *Sorbus aucuparia*, because sorbic acid was first isolated from unripe rowan berries. In general, food manufacturers prefer the three salts of sorbic acid to the acid itself because they are easier to dissolve in **water**.

The sorbates are used to prevent the growth of molds, yeasts, and fungi in foods or beverages with a pH below 6.5. They are generally used at concentrations of 0.025 percent–0.10 percent. Potassium sorbate, which is made by reacting sorbic acid with potassium hydroxide, is a mild preservative that is often used to stabilize wine as well as to prevent the growth of molds in cheese, yogurt, and baked goods. Allergic reactions to the sorbates are uncommon and limited to minor skin rashes or itching.

**PROPIONATES.** Propionates are salts of propionic acid. The three propionates most commonly used as food preservatives are calcium propionate, sodium propionate, and potassium propionate, used to inhibit the growth of mold in baked goods. Calcium propionate is also added to animal feed to prevent milk fever in cows. The propionates are often used instead of benzoates in bakery products because they do not require an acidic environment to be effective.

**NITRITES.** Nitrites are salts of nitrous acid that were used more often in the past for curing meat than they are now. The most commonly used nitrite in food preservation is sodium nitrite. When added to meat or smoked fish, it prevents the growth of bacteria, particularly *Clostridium botulinum*, the bacterium responsible for botulism, a potentially deadly disease. Sodium nitrite also turns meat an appealing dark red color when it interacts with myoglobin, the primary oxygen-carrying pigment in muscle tissue.

Nitrites are being gradually phased out of food processing for two reasons. First, they are themselves toxic in large amounts; a lethal dose of nitrites for a human being is 22 mg per kg of body weight. Second, nitrites in meat can react with the breakdown products of amino acids in the acidic environment of the human stomach to form nitrosamines, substances that are known to be carcinogenic. To be permitted to use sodium nitrite to prevent the growth of *C. botulinum* in smoked fish or meat, the manufacturer must show that the maximum amount of nitrite in the food will be no more than 200 parts per million (ppm). Sodium ascorbate, a salt of ascorbic acid (**vitamin C**), is often added to foods containing nitrites to inhibit or prevent the formation of nitrosamines.

### *Antioxidants*

**SULFITES.** The sulfites are a group of compounds containing charged molecules of sulfur compounded with oxygen. There are five used as antioxidant preservatives: sodium sulfite, sodium bisulfite, sodium metabisulfite, potassium bisulfite, and potassium metabisulfite. They are applied to foods as dips or sprays. Sodium metabisulfite and potassium metabisulfite are commonly used to stabilize wine or beer. When added to these fluids, the sulfite compounds release sulfur dioxide gas, which prevents oxidation and also inhibits the growth of yeasts and fungi. Sodium sulfite is used to preserve meats, dried potato products, and dried fruits.

Sulfites have been used for centuries as food preservatives, since they occur naturally in almost all wines. Of all the groups of food preservatives, however, sulfites are the most likely to produce hypersensitivity reactions. Asthmatics and people with allergies to aspirin are at an elevated risk for this type of reaction to sulfites. A severe systemic reaction known as anaphylaxis or anaphylactic shock may be fatal and requires immediate treatment at an emergency room. Anaphylaxis is characterized by hives, difficulty breathing, and cardiovascular collapse.

**VITAMIN E.** **Vitamin E** (tocopherol) is a fat-soluble vitamin that occurs as a natural antioxidant in many foods, particularly vegetable oils, whole grains, nuts, wheat germ, and green leafy vegetables. It may be added to fresh-cut fruits and vegetables to slow oxidation. It is also used to fortify some breakfast cereals and pet foods.

**VITAMIN C.** Vitamin C (ascorbic acid) also occurs naturally in many fruits and vegetables, particularly citrus fruits. It is a water-soluble vitamin. The salts of ascorbic acid—sodium ascorbate, calcium ascorbate, and potassium ascorbate—are also water-soluble and are often added to fresh-cut apples, peaches, and other fruits to prevent browning. These three compounds are not fat-soluble and cannot be used to prevent **fats** from going rancid. To protect fats or oils from oxidation, a fat-soluble ester of ascorbic acid known as ascorbyl palmitate must be used.

**BUTYLATED HYDROXYANISOLE (BHA).** BHA, which is a white or slightly yellow waxy solid in its pure form, is widely used in the food industry to prevent oxidation in butter, lard, meats, baked goods, beer, vegetable oils, potato chips and other snack foods, nuts and nut products, dry mixes for beverages and desserts, and many other foods. BHA is also used in cosmetics, particularly lipsticks and eye shadows. It is effective as an antioxidant because oxygen reacts preferentially with it rather than with the fats or oils containing it, thereby protecting them from spoilage. Although the FDA considers BHA a GRAS substance when its content is no greater than 0.02% of the total fat content of the product by weight (200 ppm), the National Toxicology Program (NTP) listed it in 2005 as "reasonably anticipated to be a human carcinogen" on the basis of experimental findings in animals. The NTP stated that the maximum content of BHA in various foods that it sampled ranged from 2 to 1000 ppm.

**BUTYLATED HYDROXYTOLUENE (BHT).** BHT is similar to BHA in its structure and uses as an antioxidant, although it is ordinarily a white powder rather than a waxy substance at room temperature. BHT is often added to packaging materials as well as directly to fats, oils, shortening, and similar products. It was first approved by the FDA as a food preservative in 1954. BHT has been banned in Japan, Romania, Sweden, and Australia though not in the United States. Although the use of BHT is controversial, it has not been shown conclusively to be carcinogenic as of 2007.

### *Chelating agents*

Chelating agents work by binding (or sequestering) metal ions (usually iron or copper) in certain foods in order to prevent the metals from oxidizing and speeding up spoilage of the food.

**DISODIUM ETHYLENEDIAMINETETRAACETIC ACID (EDTA).** EDTA is used in food processing to bind **manganese**, cobalt, iron, or copper ions in order to retard spoilage. It is sometimes added to eye drops to reinforce the action of other preservatives. It is also used in dentistry to wash out teeth during root canal procedures and in medicine to treat mercury or lead poisoning. Last, EDTA is added to soft drinks containing both ascorbic acid (vitamin C) and sodium benzoate to prevent the formation of benzene, which is a carcinogen.

**POLYPHOSPHATES.** Polyphosphates are chelating agents with limited solubility in cold water that are used as antibrowning agents in dips and washes for fresh-peeled fruits and vegetables, in low concentrations of 0.5 to 2 percent. They are also used to soften water and to remove mineral deposits from beverage production equipment. Polyphosphates are considered nontoxic.

**CITRIC ACID.** Citric acid, which is found naturally in citrus fruits, can be used not only as a flavoring agent and antioxidant in foods but also as a chelating agent in soaps and detergents. By chelating the minerals that are present in hard water, citric acid allows the cleaning agents to produce foam without the need for added water softeners. Allergic reactions to citric acid are rare; it is regarded as a safe food additive by all major international food regulatory organizations as well as by the FDA, because excess citric acid is easily metabolized by the body and excreted.

## Precautions

### *Government regulations of artificial preservatives*

Artificial preservatives, like other food additives, are strictly regulated by the U.S. Food and Drug Administration (FDA). In 1958 an amendment regarding all categories of food additives was attached to the Food, Drug, and Cosmetic Act of 1938. The 1958 amendment stipulates that a food manufacturer must apply for FDA approval before adding a new preservative to food, before using a different amount of a previously approved preservative, or before using an approved preservative in a different way. The application must show:

- That the amount of the preservative that will be eaten with the food, or the amount of any substance formed in or on the food as a result of using the preservative, is a safe amount.
- That the preservative will not have a harmful cumulative effect in the diet.
- Whether the preservative is carcinogenic or has other toxic effects in humans or animals.

In addition, the application for approval must show that the preservative does not deceive consumers by changing the appearance of food. For example, sulfites may not be added to meat because they restore its red color, thus making it look fresh when it may not be in fact.

### *Consumer precautions*

**PURCHASING FOOD.** Allergic reactions to artificial preservatives (or coloring or flavoring additives) in food may involve the skin (flushing, itching, or rashes), the digestive system (nausea, vomiting, or diarrhea), the respiratory system (wheezing, cough, or runny nose), or the muscles (cramping or aching sensations). Some doctors think that reactions to food

additives are underdiagnosed because they are not often suspected; most maintain, however, that hypersensitivity to food additives involves at most 1% of the adult population and perhaps 2% of children.

Consumers who are concerned about a specific artificial preservative in their food can check for its presence by reading the labels of processed foods, which are required by law to state the ingredients in order by weight from the greatest amount to the least. Those who wish to cut down on their intake of preservatives in general can try growing some of their own produce, or purchase fresh fruits and vegetables only from local farmers during the growing season.

**EATING OUT.** Some hypersensitivity reactions to food preservatives occur in relation to food eaten at restaurants. Restaurant foods are most likely to be the culprit when the person has a reaction to a specific dish served in a restaurant but not to that same food when made at home. People who already know that they are sensitive to sulfites may need to ask about specific dishes at a restaurant ahead of time to inquire whether they are made from foods containing high levels of sulfites.

People allergic to high levels of sulfites should avoid anything containing or garnished with bottled (non-frozen) lemon or lime juice, wine, molasses, grape juices, pickled cocktail onions, dried potatoes, wine vinegar, gravies or sauces, Maraschino cherries, fruit toppings, and sauerkraut. People who are sensitive to moderate or low levels of sulfites should also avoid fresh mushrooms, canned clams, avocado dip or guacamole, pickles and relishes, maple syrup, corn syrup, fresh shrimp, apple cider, and cider vinegar.

**MEDICATIONS.** People who suspect that they are sensitive to artificial preservatives in eye drops can ask their doctor or pharmacist for a formula made without preservatives. Asthma inhalers that do not contain sulfites are available for asthmatics with sulfite allergies.

## Interactions

No negative interactions between food preservatives and prescription medications have been reported. Some researchers in dentistry, however, are testing the hypothesis that benzoates interact positively with **fluoride** by reinforcing the effects of fluoride in preventing dental cavities.

## Aftercare

Hypersensitivity to food preservatives is usually tested by a food challenge. The patient is given a diet free of the suspected additive for a week or two and then given foods containing the additive to see whether the symptoms previously reported by the patient recur. If they do, the advice of physicians and researchers in the field is to simply avoid foods or other products containing that preservative.

Testing for sulfite allergy should be done only by a physician who has been trained in this procedure and has some experience in using it. The test involves administering increasing amounts of sulfites by mouth to the patient while the doctor monitors the patient's lung function and other vital signs (blood pressure, pulse rate, etc.) A sudden and significant drop in lung function indicates that the patient is sensitive to sulfites.

## Complications

There are no known complications to testing people for hypersensitivity to artificial preservatives in foods or to treating such hypersensitivity by avoiding the additive in question.

## Parental concerns

### *Allergies*

In general, food preservatives are no more likely to cause allergic reactions in children than either coloring agents or flavoring agents, which are the other major categories of food additives. Some people develop hives, itching, or nasal congestion when exposed to one particular type of yellow food coloring, FD&C 5, known as tartrazine. Monosodium glutamate (MSG), a food additive sold under the trade name of Accent, is also added to soups, broths, and some restaurant dishes to intensify the flavors already present in the food. Although MSG was reported to cause headaches, dry mouth, and asthma attacks in some people—a group of symptoms referred to as "Chinese restaurant syndrome" since the late 1960s, recent double-blind studies indicate that there is no causal connection between MSG and the reported symptoms.

The food preservatives most likely to cause allergic reactions are the sulfites and the benzoates. Prior to 1986, sulfites were commonly added to fresh produce in supermarkets and on restaurant salad bars to prevent browning. Reports of sensitivity reactions, however, led the FDA to ban the use of sulfites on fresh produce, especially lettuce put out on salad bars. As of 2007, the FDA requires all foods containing more than 10 ppm of sulfites to declare sulfites on the label. Foods containing less than 10 ppm of sulfites have not been shown to cause allergic symptoms even in people who are hypersensitive to sulfites.

Sodium benzoate has been reported to cause skin rashes or facial swelling in some people when used as a preservative in acidic foods and beverages, and to worsen asthma attacks in some patients taking asthma medications. Reactions to benzoates, however, are a very low percentage of food allergies; one team of physicians in Italy rated reactions to benzoates as no more than 2% of all allergic responses to foods or drugs.

### *Reporting food-related problems*

To report allergic reactions to preservatives or other food additives, consumers should contact the FDA's consumer complaint coordinator in their geographic area. Links to those persons can be found on the FDA's website at http://www.fda.gov/opacom/backgrounders/problem.htmlndashfood. If the problem concerns food eaten in or purchased from a restaurant, however, it should be reported to the local or state health department.

### *Toxicity*

With the exception of large quantities of nitrites, no food preservatives approved for use by the FDA or its international counterparts are directly toxic to human beings.

# Artificial sweeteners

## Definition

Artificial sweeteners, which are also called sugar substitutes, alternative sweeteners, or non-sugar sweeteners, are substances used to replace sugar in foods and beverages. They can be divided into two large groups: nutritive sweeteners, which add some energy value (calories) to food; and nonnutritive sweeteners, which are also called high-intensity sweeteners because they are used in very small quantities as well as adding no energy value to food. Nutritive sweeteners include the natural sugars—sucrose (table sugar; a compound of glucose and fructose), fructose (found in fruit as well as table sugar), and galactose (milk sugar)—as well as the polyols, which are a group of carbohydrate compounds that are not sugars but provide about half the calories of the natural sugars. The polyols are sometimes called sugar replacers, sugar-free sweeteners, sugar alcohols, or novel sugars. Polyols occur naturally in plants but can also be produced commercially. They include such compounds as sorbitol, mannitol, xylitol, and hydrogenated starch hydrolysates.

**Artificial sweeteners**

| Sweetener | Times sweeter than sugar | Calories | Brand name(s) |
|---|---|---|---|
| aspartame | 200 | 4 kcal/g | Nutrasweet and Equal |
| saccharin | 200–700 | 0 | Sweet'N Low, Twin, and Necta Sweet |
| acesulfame-K (potassium) | 200 | 0 | Sunett and Sweet One |
| neotame | 7,000–13,000 | 0 | Neotame |
| sucralose | 600 | 0 | Splenda |

SOURCE: Food and Drug Administration, U.S. Department of Health and Human Services

*(Illustration by GGS Information Services/Thomson Gale.)*

Nonnutritive sweeteners are synthetic compounds that range between 160 and 13,000 times as sweet as sucrose, which is the standard for the measurement of sweetness. There are five nonnutritive sweeteners approved by the Food and Drug Administration (FDA) for use in the United States as of 2007. They are saccharin, aspartame, acesulfame potassium (or acesulfame-K), sucralose, and neotame. There are other nonnutritive sweeteners that have been approved for use elsewhere in the world by the Scientific Committee on Food (SCF) of the European Commission, the Joint Expert Committee of Food Additions (JECFA) of the United Nations Food and Agricultural Organization, and the World Health Organization (WHO) but have not been approved by the FDA. These substances are alitame, cyclamate, neohesperidine dihydrochalcone, stevia, and thaumatin. All of these will be described in further detail below.

The FDA uses two categories to classify both nutritive and nonnutritive sweeteners for regulatory purposes. Some are classified as *food additives*, which is a term that was introduced by the Federal Food, Drug, and Cosmetic (FD&C) Act of 1938. This legislation was passed by Congress in response to a mass poisoning tragedy that took the lives of over a hundred people in 1937. A company in Tennessee that manufactured an antibacterial drug known as sulfanilamide, which had been used safely in powdered or pill form to treat childhood infections, dissolved the sulfanilamide in diethylene glycol—related to the active ingredient in automobile antifreeze—in order to market it as a liquid medicine. Diethylene glycol is highly

## KEY TERMS

**Acceptable daily intake level (ADI)**—The level of a substance that a person can consume every day over a lifetime without risk. The ADIs for artificial sweeteners are very conservative measurements.

**Carcinogen**—A substance or other agent that causes cancer. Some artificial sweeteners have been banned in the United States on the grounds that they may be carcinogens.

**Food additive**—Defined by the Federal Food, Drug, and Cosmetic Act (FD&C) of 1938 as "any substance, the intended use of which results directly or indirectly, in its becoming a component or otherwise affecting the characteristics of food."

**Excipient**—An inert substance, such as certain gums or starches, used to make drugs easier to take by allowing them to be formulated into tablets or liquids. Some artificial sweeteners are used as excipients.

**Fructose**—A simple sugar that occurs naturally in sucrose and fruit. It can be added in combination with sucrose in the form of high-fructose corn syrup (HFCS) to sweeten foods because it is sweeter than sucrose. Large amounts of fructose can cause diarrhea in infants and young children.

**Generally recognized as safe (GRAS)**—A phrase used by the federal government to refer to exceptions to the FD&C Act of 1938 as modified by the Food Additives Amendment of 1958. Sweeteners that have a scientific consensus on their safety, based on either their use prior to 1958 or to well-known scientific information, may be given GRAS status.

**Gulf war syndrome (GWS)**—A disorder characterized by a wide range of symptoms, including skin rashes, migraine headaches, chronic fatigue, arthritis, and muscle cramps, possibly related to military service in the Persian Gulf war of 1991. GWS was briefly attributed to the troops' high consumption of beverages containing aspartame, but this explanation has been discredited.

**High-intensity sweetener**—Another term for nonnutritive sweetener, used because these substances add sweetness to food with very little volume.

**Nonnutritive sweetener**—Any sweetener that offers little or no energy value when added to food.

**Nutritive sweetener**—Any sweetener that adds some energy value to food.

**Phenylketonuria (PKU)**—A rare inherited metabolic disorder resulting in accumulation of phenylalanine, an amino acid, in the body. It can lead to mental retardation and seizures. People with PKU should not use products containing the artificial sweetener aspartame because it is broken down into phenylalanine (and other products) during digestion.

**Sucrose**—The natural sweetener commonly used as table sugar; sucrose is a compound of two simple sugars, glucose and fructose. It is used as the standard for measuring the sweetening power of high-intensity artificial sweeteners.

toxic to human beings and household pets, causing painful death from kidney failure. In 1937 there was no requirement for medications to be tested for toxicity before being placed on the market. The FD&C Act of 1938 thus included a legal definition of a food additive "any substance, the intended use of which results directly or indirectly, in its becoming a component or otherwise affecting the characteristics of food"

The FDA asks the following questions in evaluating a proposed new sweetener as a food additive:

- How is the sweetener made?
- What are its properties when it is added to foods or beverages?
- How much of the sweetener will be digested or otherwise absorbed by the body?
- Are certain groups of people likely to be more susceptible than others to the additive?
- Does the sweetener have any known toxic effects, including hereditary disorders or cancer?

Other sweeteners are classified as *generally regarded as safe* or GRAS, and are not defined for legal purposes as food additives. The GRAS category was created in 1958 when the FD&C Act was modified by the passage of the Food Additives Amendment. A sweetener, whether nutritive or nonnutritive, can be given GRAS status on the basis of "experience based on common use in food" or a scientific consensus represented by published studies. Sorbitol and a few other polyols have GRAS status along with the natural sugars. Most artificial sweeteners, however, are considered food additives by the FDA.

## Purpose

Artificial sweeteners are used in food products for several reasons: to lower the calorie content of soda pop and other sweet treats as part of weight reduction and weight maintenance diets; to assist patients with diabetes in controlling blood sugar levels more effectively; and to lower the risk of tooth decay. They are also added as excipients (inert substances used to make drugs easier to take in tablet or liquid form) to some prescription medications to disguise unpleasant tastes because they do not react with the active drug ingredients as natural sugars sometimes do. Sorbitol and mannitol are commonly added to toothpaste, mouthwash, breath mints, cough drops, cough syrups, sugarless gum, over-the-counter liquid antacids, and similar personal oral care products to add bulk to the product's texture as well as minimize the risk of tooth decay.

In addition to adding a sweet flavor, artificial sweeteners are also used in the manufacture of baked goods, beverages, syrups, and other food products to improve texture, add bulk, retard spoilage, or as part of a fermentation process. The polyols in particular are used to retard spoilage because they do not support the growth of mold or bacteria to the same extent as natural sugars.

## Description

### *Nutritive sweeteners*

- Natural sugars. Natural sugars, which are also called primary sweeteners, include sucrose, a compound of glucose and fructose commonly used in crystalline form as table sugar; and fructose, which is a simple sugar found in sucrose and fruit, and is added to foods and beverages in combination with sucrose as high-fructose corn syrup or HFCS. These sweeteners provide about 4 calories per gram. Fructose is sweeter than sucrose; thus smaller amounts of it can be used to sweeten foods and drinks, which allows for some reduction in calories.
- Polyols. Polyols provide between 1.6 calories per gram (mannitol) and 3 calories per gram (hydrogenated starch hydrolysates). They are absorbed very slowly and incompletely during digestion, which is why they can be beneficial to patients with diabetes who want to avoid sudden or sharp increases in blood sugar levels.

### *Nonnutritive sweeteners approved by the FDA*

There are five nonnutritive sweeteners approved by the FDA for use in the United States as of 2007:

- Acesulfame potassium (acesulfame-K). Acesulfame potassium is a high-intensity nonnutritive sweetener that is about 200 times sweeter than sucrose; 95% of it is excreted from the body unchanged. It was discovered by a German company, Hoechst AG, in 1967. It was first approved by the FDA for use in nonalcoholic beverages in 1998 and for general use in 2003. In addition to its usefulness in reducing the calorie content of foods, in diabetic diets, and in not promoting tooth decay, acesulfame potassium remains stable at the high temperatures used for cooking and baking, has a long shelf life, does not leave any bitter aftertaste, and combines well with other sweeteners. It is sold under the brand names ACK, Sunett, Sweet & Safe, and Sweet One.
- Aspartame. Aspartame, which is also about 200 times sweeter than sugar, was discovered in 1965 by a researcher at Searle Laboratories working on antiulcer medications. It is unusual among nonnutritive sweeteners in that it is completely broken down during digestion into its basic components—the amino acids aspartic acid and phenylalanine plus a small amount of methanol. Aspartame was approved by the FDA for tabletop use in 1981 and for use in carbonated beverages in 1983. As of the early 2000s, the United States uses 75% of the aspartame produced in the world, 70% of this amount consumed in diet beverages. Aspartame is the nonnutritive sweetener that has received the greatest amount of negative attention in the mass media because of a rumor that it caused Gulf War syndrome (GWS) in veterans of the Persian Gulf conflict of 1991, and because of a study done in Europe in 2005 that linked aspartame to two types of cancer (leukemia and lymphomas) in female laboratory rats. In response to the 2005 European study, the National Cancer Institute (NCI) conducted a study of half a million people in the United States in 2006 and found no connection between cancer rates and aspartame consumption. The details of this study can be found in a fact sheet available on the NCI website. Another study conducted by the National Toxicology Program (NTP) of the National Institute of Environmental Health Sciences (NIEHS) of aspartame as a possible carcinogen found no evidence that the sweetener causes cancer in humans. Aspartame is sold under the brand names NutraSweet, Equal, and Sugar Twin (blue box).
- Neotame. Neotame is similar chemically to aspartame but is between 7000 and 13,000 times sweeter than sugar. In July 2002, neotame was approved as a general-purpose sweetener by the FDA. Neotame is partially absorbed in the small intestine, the remainder

excreted in urine and feces. It is not concentrated in any body organs and has not been identified as a cancer risk. Like acesulfame potassium, neotame has a clean taste with no bitter aftertaste, combines well with other sweeteners, and is stable when used in cooking and baking. It is also used to enhance the flavors of fruit and other ingredients in food. Neotame is manufactured in the United States by the NutraSweet Company of Mount Prospect, Illinois, but does not have a commercial or brand name as of early 2007.

- Saccharin. Saccharin is the oldest nonnutritive sweetener, having been discovered in 1879 by a chemist working at Johns Hopkins University. It is about 200 to 700 times as sweet as sugar. It was used extensively during World Wars I and II, when sugar was rationed in the United States as well as in Europe. It is still the least expensive high-intensity sweetener used around the world—about 65 million pounds per year in the late 1990s. Saccharin passes through the body essentially unchanged. It was so widely used in the United States that it was considered a GRAS substance when the Food Additives Amendment was passed in 1958, but it lost that status when studies performed on laboratory rats in the 1970s indicated that it might cause bladder cancer. At that point Congress mandated that all foods containing saccharin must carry a warning label that they might be hazardous to health. Later studies indicated that the bladder tumors in rats are caused by a mechanism that does not operate in humans, and that there is no evidence that saccharin is unsafe for humans. In 2000 the NTP took saccharin off its list of carcinogens and the saccharin-warning label was removed from food. Details of the controversy over saccharin and cancer can be found on the NCI website. Saccharin is presently sold under the trade names of Sweet 'N Low, Sweet Twin, and Necta Sweet.
- Sucralose. Sucralose is unusual in that it is the only nonnutritive sweetener made from sugar, but it is about 600 times as sweet as table sugar. Sucralose is manufactured from sugar by substituting three chlorine atoms for three hydroxyl groups in the sugar molecule. Only about 11% of sucralose is absorbed during digestion; the remainder is excreted unchanged. The FDA approved sucralose in 1998 as a tabletop sweetener and in 1999 as a general-purpose sweetener. The acceptable daily intake (ADI) for sucralose is 5 mg per kilogram of body weight per day. Like acesulfame potassium, sucralose is highly heat-stable and works well in foods that must be baked or cooked. Sucralose is sold under the trade name Splenda for table use.

***Nonnutritive sweeteners not approved for use in the United States***

- Alitame. Alitame is a compound of aspartic acid, D-alanine, and an amide; it is 2000 times sweeter than sugar. In 1986 it was reviewed by the FDA, which found the application to be deficient. As of 2007, alitame is approved for use only in Australia, New Zealand, Mexico, Colombia, and China.
- Cyclamate. Cyclamate, which is about 30 times sweeter than sugar, was used as a nonnutritive sweetener in the United States until 1969, when it was shown to cause cancer in laboratory rats when combined with saccharin. Although cyclamate by itself was found by the National Academy of Sciences not to be a carcinogen in 1985 and is approved for use in over 50 countries, it has not been reinstated by the FDA for use in the United States as of 2007.
- Neohesperidine dihydrochalcone. Neohesperidine dihydrochalcone is a compound that is about 1500 times sweeter than sugar and adds a slight licorice flavor to foods and beverages. The FDA considers neohesperidone GRAS as a flavoring but not as a sweetener.
- Stevia. Stevia is a sweetener derived from a shrub native to South America. The FDA has not received sufficient scientific evidence to indicate that stevia is safe for use as a food additive.
- Thaumatin. Thaumatin is an intensely sweet mixture of proteins that also acts as a flavor enhancer. The FDA has given thaumatin GRAS status as a flavor adjunct but has not approved it as a sweetener as of 2007.

## Precautions

Artificial sweeteners are generally regarded as safe when used appropriately. The official position of the American Dietetic Association is that nutritive and nonnutritive sweeteners are safe as long as one's diet follows the current federation recommendations for nutrition.

The Institute of Medicine (IOM) maintains measurements of acceptable daily intake (ADI) levels for artificial sweeteners approved for use in the United States. The ADI is a regulatory definition that is often misunderstood. It is a very conservative estimate of the amount of a sweetener that can be safely consumed on a daily basis over the course of a person's lifetime. The ADI is *not* intended to be used as a specific point at which safe use ends and health risks begin, as occasional use of an artificial sweetener over the ADI is not of concern. To use aspartame as an

example, its ADI is 50 mg per kilogram of body weight per day. An adult weighing 150 pounds would have to drink 20 12-ounce containers of diet soft drink containing aspartame, eat 42 servings of gelatin, or use 97 packets of tabletop sweetener to reach the ADI.

Some specific artificial sweeteners must be used cautiously by certain groups of people:

- Polyols: Some polyols—most commonly mannitol and sorbitol—have a laxative effect in some people if they are consumed in large amounts (more than 50 g/day of sorbitol or 20 g/day of mannitol). Persons with diabetes may wish to limit their consumption of products containing polyols or increase their use gradually until they see how their bodies react to these sweeteners.
- Aspartame: Because aspartame is broken down in the body to the amino acid phenylalanine, foods or beverages containing aspartame should not be used by persons with phenylketonuria (PKU), a rare inherited disease that causes phenylalanine to accumulate in the body. The FDA requires all products containing aspartame sold in the United States to be labeled with the following warning: "Phenylketonurics: Contains Phenylalanine." Although the breakdown products of neotame also include phenylalanine, the amount is so small that it does not affect people with PKU.

## Interactions

There are no known interactions with prescription drugs caused by the use of nutritive or nonnutritive sweeteners. As was noted above, some nonnutritive sweeteners are considered useful excipients for medications precisely because they are chemically inert.

## Parental concerns

There have been concerns expressed about the use of artificial sweeteners by children because children consume more sweeteners, both nutritive and nonnutritive, per pound of body weight on a daily basis than adults. The use of fruit juice and other sweet beverages by children has greatly increased since the 1980s; however, studies indicate that even children who drink large amounts of diet soda and other beverages usually remain well below the ADI levels for aspartame and other nonnutritive sweeteners. The chief risk to children's digestive health is fructose, which is found in such popular children's drinks as apple juice. Fructose is incompletely digested by children below the age of 18 months and may cause diarrhea in older children. Children diagnosed with nonspecific diarrhea may benefit from being given smaller amounts of fruit juice to drink.

During the early 1990s, some researchers identified a possible connection between high levels of aspartame consumption and attention-deficit **hyperactivity** disorder (ADHD) in children. Two studies published in 1994 in *Pediatrics* and the *New England Journal of Medicine* respectively, however, found no connection between aspartame and ADHD, even when the children were given 10 times the normal daily amount of aspartame. Aspartame and other nonnutritive sweeteners, however, may have an additive effect on nerve cell development when they are combined with food colorings. This possibility was suggested by a 2006 study of laboratory mice in the United Kingdom, but the implications for humans are far from clear.

High intake of sweeteners added to food is of greatest concern during adolescence. As people age, they generally lower their intake of calories from added sugars. Fewer than 10% of adults over age 50 derive more than 25% of their daily calories from sugars, which is the maximal intake value established by the IOM. Nearly a third of adolescent females exceed this level, however, with almost a third of the extra sugar intake coming from carbonated beverages sweetened with high-fructose corn syrup. Although the rise in **obesity** in children and adolescents is a complex problem that cannot be attributed to a single factor, preliminary studies suggest that nonnutritive sweeteners may be useful in reducing adolescents' consumption of drinks sweetened with HFCS.

# Asian diet

## Definition

The Asian diet is an ancient and time honored way of eating. For thousands of years people of the Asian world have eaten a diet based on plant foods such as rice, vegetables, and fresh fruits. Unlike Western diets, meat is rarely the main dish of any meal but rather an accent and flavor compliment. Fish is often eaten in main courses.

In many Asian cultures diet is closely related to religious practices and tradition. It is an extremely healthful diet. Asian populations who have access to a sufficient variety of traditional foods are some of the healthiest and longest lived people on Earth. Many chronic illnesses that plague Western cultures such as heart disease, **cancer**, and **obesity** occur rarely in these cultures.

## Origins

Over 43 countries follow a form of Asian diet. Nearly half the world's population may be considered Asian. Food is an important part of daily life. Religious practices often dictate the type of foods eaten and the meal is an essential part of family relationships. The diet is based on fresh food prepared primarily raw, steamed, stir-fried, or deep fried.

There are four major types of Asian diets:

***East Asian Food: China, Japan, and Korea.***

China is the largest country in the world and has many different cuisines. Although China stretches across mid-Asia as well as to the east, Chinese food as a whole is considered East Asian food. Throughout most of China, rice is an important food staple. However, in some regions, noodles rather than rice are the foundation of the diet. Most food is prepared by mincing and cooking it, along with a small amount of oil, in a wok.

**Merits of traditional Asian diets**

| | Staple foods | Merits of diet |
|---|---|---|
| Cambodian | Rice<br>Fish<br>Tea | Low in fat<br>Low in sugar |
| Chinese | Rice<br>Vegetables<br>Green Tea | Reduces risk for heart disease and certain cancers |
| Filipino | Rice<br>Vegetables<br>Seafood<br>Fruit | Reduces risk for heart disease and cancers |
| Hmong | Rice<br>Vegetables<br>Meat<br>Fish | Low in fat<br>Low in sugar |
| Asian Indian | Cereals<br>Rice<br>Vegetables | Low in fat<br>Low in sugar |
| Laotian | Rice<br>Vegetables<br>Fish | Low in fat<br>Low in sugar |
| Vietnamese | Rice<br>Fish<br>Fruit | Low in fat<br>Low in sugar |

## KEY TERMS

**Antioxidants**—Substances believed to protect the body from the damage of oxidation.

**Diabetes**— A disease that causes an abnormally high level of glucose (sugar), to build up in the blood.

**Hinduism**—A broad group of religious and philosophical beliefs from India. It is characterized by belief in reincarnation, one God with many forms, and the pursuit of transcending the evils of earth.

**Hypertension**—High blood pressure.

**Menopause**—The time in a woman's life when menstruation stops.

**Obesity**—Over weight.

**Osteoporosis**—A weakening of the bones that is caused by calcium deficiency.

Within China there are three distinct regional cuisines: Shanghainese, whose regional food is known for its hot and spicy chili pepper flavoring and distinctive red-colored meats. Cantonese and Chaozhao regions associated with flavorful meat and vegetable combinations. Beijing, Mandarin, and Shandong regions serve noodles and steamed bread dumplings used instead of rice as the foundation of most meals.

Japan is an island nation and much of its food uses fish and fish-based ingredients. Rice is a staple in Japanese cooking as are sliced, salted vegetables. **Soy** products such as tofu, soy sauce and soy paste called miso are used in many dishes. Foods of Japan also include sushi, meats flavored with teriyaki sauce, and lightly battered and fried meats, fish, and shellfish called tempura.

Korean food is a blend of Chinese and Japanese influence, yet it has its own distinct flavors including soy sauces, garlic, ginger, chilies, pine nuts, and sesame seeds among other spices and foods. Traditional Korean meals include meats and seafood. Most meals include a vegetable dish called gimchi made of grated vegetables pickled with garlic, chili, and ginger.

### *Southeast Asian Food: Vietnam, the Philippines, Malaysia, and Singapore.*

Vietnamese cuisine relies on rice and vegetables as its foundation with meat and fish used sparingly. Fish sauces called *nuocmam* is the main flavoring. Fruits such as bananas, mangoes, papayas, coconut, and pineapple are also an important part of each meal.

Philippines cuisine is a unique blend of Spanish, Japanese, Chinese, Islamic, and American influences. The typical day includes four meals, three main meals and a light afternoon snack. Unlike other Asian diets, meat is very important. Favorite meats include pork, beef chicken, and **water** buffalo in the rural provinces. Rice and noodles are served with most meals and vegetables such as broccoli, bitter melon, mung bean, bean sprouts, and okra.

Malaysia and Singapore share a spicy cuisine incorporating Chinese, Muslim, and Indian influences. Traditional foods include meat kebabs called Satays which are served with a spicy peanut sauce. Curry is a favorite spice and is mixed with meat and marinades. Rice and Chinese noodles are eaten daily. Deserts made from coconut milk, green noodles, sugar syrup, and sweet beans are local favorites.

### *Southern Asian Food: India.*

Indian cuisine has influenced food from the Indian peninsula, across the regions to the West including Afghanistan, Pakistan, Sri Lanka, and as far south as Indonesia. Indian cuisine is the only Asian diet that includes dairy products usually in the form of yogurt and cheese. Known for its spicy seasoning, Indian cuisine uses a variety of spices such as curry, saffron, cumin, cardamom, ginger turmeric, coriander, tamarind,

mustard, and aniseed. Fruit and vegetables comprise the majority of the diet. Much of India practices Hinduism. For the Hindu, the cow is a sacred symbol and is never eaten. For this reason beef is rarely found in Indian cuisine. Most of the **protein** content in the diet comes from dairy products, legumes, and nuts. Rice is also a staple of the Indian diet.

## Origins

In general, the Asian diet is not measured and does not include exact portion sizes, but rather guidelines for what should be eaten daily, weekly, and monthly. Rather than prohibitions and prescriptions, the Asian diet suggests balance. The typical daily calorie content is approximately 1200 to 1400.

Suggested daily foods include :

- Grains and Breads: Grains form the basis of the Asian diet. Rice is the predominant grain and is eaten daily. Other grains include noodles, corn, millet, and bread. Also included in this category are potatoes and cereals.
- Vegetables: Many fresh vegetables are eaten daily and in large quantities. There are many vegetables to be enjoyed following the Asian diet such as carrots, cabbage, green leafy vegetables, onions, sprouts, and many others. Vegetables provide necessary daily vitamins and fiber.
- Fruit: Many fruits are used as flavoring, ingredients, deserts, and enjoyed raw. Eating a variety of fruits insures proper vitamin and minerals in the diet.
- Nuts and Legumes: In the Asian diet, nuts and legumes or beans provide the primary source of protein. Soy beans in many forms such as tofu, soy milk, and soy flour are used almost daily. Nuts and seeds also play a vital role in the diet providing necessary protein and minerals. Tofu, nuts, seeds and beans are used in soups, salads, main dishes and even deserts.
- Vegetable Oils: Essential fats come from the vegetable oils used in cooking. Some of the oils used are high is saturated fat and are a very small part of the Asian diet used primarily for cooking.
- Optional Daily Foods: Daily products that could be consumed daily are dairy products and fish. Dairy products are not a part of most Asian diets. If dairy is included on a daily diet it should be low fat and eaten in moderation.

Fish is a staple in many Asian diets and eaten very little in others. Geography has historically determined whether or not fish is in the diet. Fish is a very healthy food linked with the prevention of chronic diseases such as heart disease and cancer.

Suggested weekly foods include:

- Sweets: Sweets are eaten rarely in the Asian diet as a treat. They are high in sugar and usually high in fat. Fruit is an excellent substitute for high fat and high sugar deserts.
- Poultry and Eggs: Eggs, chicken , and turkey are used weekly as ingredients to main dishes.

Suggested monthly foods include:

- Red Meat: Meat is eaten very sparingly in the Asian diet. It may be eaten a few times a monthly or more frequently if in small servings.

Diana My Tran in her book, *The Asian Diet*, provides 18 days of menus. Her interpretation of the Asian diet is influenced by her Vietnamese heritage, but it incorporates recipes and flavors from many other Asian cuisines. Her diet plan encourages a diet rich in fruits and vegetables. Grains such as rice and cereal are eaten daily and at most meals. Meat is offered in the daily recipes, but a vegetarian option is also included. Her plan recommends an ounce of cereal or rice along with fruit and coffee or tea for breakfast. Lunch options are lighter meals including grain, protein (either meat or tofu dishes), vegetables, and tea. The plan presents one snack a day, usually fruit. Dinner is the largest meal of the day and it includes grain, meat, vegetables and fruit-based desert. Her meal plan provide 1300–1400 calories per day.

Eating the Asian way, according to Tran, involves the benefits of fresh fruits and vegetables and uses vivid flavors and spices to enhance the eating experience. Asian eating uses vegetables, broths, and spices to make the calories filling so that eating few calories is still very satisfying.

## Function

Asian diets are influenced by culture, **religion**, and agriculture. Research has shown that this way of eating is extremely healthful. Low in fat, high in **fiber** and full of fresh fruits and vegetables, many believe it is the secret to a long and healthy life.

By eating a diet that is predominantly plant-based, the calories are low. The spices and manner of cooking provide the palate with a stimulating eating experience and help the dieter feel satisfied.

## Benefits

Countries that eat a traditional Asian diet have lower rates of many illnesses that plague the Western

world such as diabetes, heart disease, **hypertension**, cancer, and obesity. The Asian diet is plant-based. Most calories come from grains, vegetables, and fruit. The benefits of a diet rich in fruits and vegetables are well documented. Full of **vitamins**, **minerals**, and **antioxidants**, the Asian diet is very healthful.

Antioxidants are a category of vitamins and minerals that help to prevent damage to the body caused by substances called free radicals. Free radicals are the by-products of molecular functions in the body and environmental toxins ingested such as tobacco smoke and radiation. Antioxidants are believed to reduce the negative impact of these free radicals and reduce the risk of certain forms of cancer and heart disease.

Fruits and vegetables also provide fiber. Many studies have shown that adequate amounts of fiber in the diet may reduce the risk of several forms of cancer including colon cancer, the third most prevalent cancer among both men and women in the United States.

The Asian diet limits fat in general and almost completely eliminates saturated fat. A diet high in saturated fat has been shown to cause chronic illnesses such as coronary artery disease, obesity, and cancer. Many researchers believe this is the primary reason such diets are so healthy.

## Precautions

Traditional Asian diets include little or no dairy products. This limits the amount of **calcium** consumed since milk and other dairy products contain high amounts of calcium and are the usual food group to provide this essential nutrient. Modern version of this diet presented to the Western world generally include low-fat or reduced-fat dairy products in moderation. Pregnant or nursing women will need to take calcium supplements to insure that they have enough calcium. Dieters who do not wish to consume dairy products may also decide to take calcium supplements. In Asia, most people are far more active than typical Westerners. Their activities often involve lifting heavy objects and manual labor. Weight bearing exercise has been shown to strengthen bones and my offset the lower amounts of calcium consumed.

The Asian diet is a wholesome option for most healthy adults. However, children and pregnant women may not receive the proper balance of nutrition needed. Children may need the calcium dairy products provide and increased fat consumption during stages of rapid growth and development. Pregnant women need to insure sufficient intake of calories and other nutrients that meats, **fats** and dairy products provide.

### QUESTIONS TO ASK YOUR DOCTOR

- Is this diet appropriate for me?
- What are the potential benefits for a person of my age, sex, and lifestyle in adopting an Asian diet?
- What are the potential health risks, if any, of this diet for me as an individual?
- Will I need any dietary supplements if I follow the Asian diet?
- How much exercise should I do each week in conjunction with this diet?

## Risks

A traditional Asian diet is low in dairy products and may, therefore, be low in calcium. Diets low in calcium can lead to **osteoporosis**, a weakening or the bones. Women are especially vulnerable to this disease after menopause when lower levels of hormones weaken bones as well. Similarly, pregnant women and children have higher calcium requirements. To insure that adequate amounts of calcium are in the diet, a calcium supplement may be needed or the addition of low-fat dairy products.

Attempting to follow an Asian diet by eating at Asian style restaurants in the West may not be successful or healthy since many of these restaurants have adapted to Western tastes by adding high levels of fats and **sodium**. To enjoy the benefits of Asian style eating, it may be necessary to prepare the foods at home. Though many communities enjoy authentic Asian restaurants and it may be possible to find healthy Asian cuisine.

## Research and general acceptance

### *General acceptance*

Asian style diets are considered by many nutritionists and doctors to be the model of healthy eating. Low in fat and high in vitamins, minerals, and antioxidants, the Asian diet is believed to prevent many illnesses of the Western world such as diabetes, coronary artery disease, hypertension, cancer, and obesity.

### *Research*

In 2000, The American Heart Association issued revised **dietary guidelines** for reducing the risk of heart disease and stroke. These recommendations include eating a diet low in fat and full vegetables and fruits. They also recommend increasing the consumption of fish. All of these recommendations are found in the Asian diet.

Many studies show the benefit of eating a diet such as the Asian diet. These studies show that lipid (fat) levels in the blood, a major risk factor for heart disease and stroke, may be dramatically reduced by following a low fat, plant-centered diet. The effects of years of unhealthy eating habits may be reversed by altering the diet to limit intake of high fat foods and increasing the amount of low fat foods, fruits, and vegetables.

In 2000, one study confirmed the results of previous research that a diet low in saturated fat and high in fruits and vegetables lowers blood pressure in patients with untreated hypertension. Doctors believe following such as the Asian diet could prevent hypertension.

# Atkins diet

## Definition

The Atkins diet is named for Robert C. Atkins, M.D., the diet's founder. It is based on restrictions of **carbohydrates** and focuses on eating mostly **protein** and fat, along with use of vitamin and mineral supplements.

The Atkins diet has been one of the most popular **fad diets** in the United States. It started a "low-carb revolution," leading to development of low carbohydrate choices in grocery stores and restaurants around the world. The diet's founder, Robert C. Atkins, died in February 2003.

## Origins

Dr. Atkins introduced his *Diet Revolution* in 1972. From the beginning, Dr. Atkins, a cardiologist, said that limiting intake of carbohydrates (sugars and starches) would improve health and aid in weight control. The original premise for developing the diet came about because of Atkins' frustration with the increasing rates of **obesity** and chronic diseases such as diabetes.

## Description

Throughout the diet, Dr. Atkins recommended drinking at least eight 8-oz. glasses of **water** each day to avoid **dehydration** and **constipation**. He also recommended daily intake of nutrients through a good multi-vitamin supplement. Finally, Dr. Atkins mentioned getting plenty of exercise to speed weight loss. The Atkins diet consists of four distinct phases that participants should go through to achieve and maintain weight loss.

### *Induction*

The induction phase is not required, but that doing so jump starts weight loss as dieters cut back significantly on carbohydrate consumption. According to Atkins Advantage notes, the induction phase can make people feel revitalized, since carbohydrates cause blood sugar spikes that lead to fatigue and other symptoms. The diet also claims that the induction phase will help dieters see the benefits of fat-burning and strengthen their immune systems.

This is by far the most restrictive of the four phases, allowing no more than 20 net carbohydrates per day. This equals roughly three cups of salad greens or other non-starchy vegetables. Participants can eat

**Phases of the Atkins Diet**

**Induction—At least two weeks**
No more than 20 net carbohydrates per day
Liberal amounts of protein, including meats, fish, poultry, and eggs, as well as healthy fats
Fatty condiments (mayonnaise, sour cream, guacamole, and butter) are allowed in unlimited quantities
Weight loss during the induction phase may be significant

**Ongoing weight loss—Begin after two weeks**
Slow introduction of foods with carbohydrates that are considered nutrient dense (green beans, Brazil nuts, avocados, berries, and whole grains)
In week one, add 25 grams of carbohydrates per day
In week two, 30 grams of carbohydrates are allowed
The addition of five grams per week continues until weight loss stalls, then drop back to the previous gram level

**Pre-maintenance goal—Begin when within 5 to 10 pounds of weight-loss goal**
Gradually increase carbohydrate intake by 10 grams per week until weight is gained, then drop back to the previous carbohydrate gram level
Level weight loss to less than one pound per week

**Lifetime maintenance—Begin one month after weight-loss goal is achieved**
May be able to consume from 90 to 120 grams of carbohydrates a day, depending on age, gender, and activity level
Maintaining weight goal is more likely if carbohydrate intake remains at the level discovered in pre-maintenance

*(Illustration by GGS Information Services/Thomson Gale.)*

liberal amounts of protein, including meats, fish, poultry, and eggs, as well as healthy **fats**. Healthy fats include vegetable and seed oils. High fat condiments such as mayonnaise, sour cream, guacamole, and butter are allowed in virtually unlimited quantities. The Atkins theory is that these high fat foods enhance the flavor of meals, making the Atkins diet easier to maintain. Atkins has reminded dieters that while unlimited quantities of fats and proteins are allowed, the advice is not a license to gorge. Dieters are said to feel hungry for the first 48 hours as their bodies adjust to the abrupt reduction in carbohydrates. Weight loss during the induction phase is said to be significant. The phase is recommended to last at least two weeks.

### *Ongoing weight loss*

The second phase of the Atkins diet moves into ongoing weight loss. It involves slow introduction of foods with carbohydrates that also are considered nutrient dense. Most of the carbohydrate calories come from vegetables. Atkins dieters still eat a higher proportion of proteins and fat, but they gradually add more carbohydrates into the diet. According to Atkins, the purpose of the phase is to continue to burn and dissolve fat while maintaining appetite and craving control. This phase also introduces the dieter to a broader range of foods and helps to determine the dieter's threshold level of carbohydrate consumption. It is the intention of this phase to deliberately slow weight loss.

If weight loss continues, carbohydrate intake is gradually increased each week. In week one, the dieter can add 25 grams of carbohydrates per day. In week two, 30 grams of carbohydrates are allowed. This addition of five grams per week continues until weight loss stalls, then the dieter drops back to the previous gram level. Typical tolerance levels may range anywhere from 30 grams to 90 grams per day. Atkins literature says that the more a dieter exercises, the more carbohydrates he or she can tolerate. The Atkins diet recommends choosing carbohydrates first from vegetables that are low in carbohydrates, then from other sources that are fresh foods high in nutrients and **fiber**. Examples of low-carbohydrate vegetables are lettuce, raw celery, and cucumbers. Nutrient-rich carbohydrates are green beans, Brazil nuts, avocados, berries, and whole grains.

### *Pre-maintenance*

The Atkins diet considers the third phase a practice for lifetime maintenance of goal weight and "healthy eating habits". When the goal weight is within five to 10 pounds, the dieter gradually begins to increase carbohydrate intake by 10 grams per week until weight is gained, then drops back to the previous carbohydrate gram level. The purpose is to level weight loss to less than one pound per week. The dieter should continue at this rate until the goal weight is reached, then for one month past that time. The goal is to achieve a level at which weight is neither gained nor lost and to internalize the habits that become part of a permanent lifestyle.

Examples of vegetables that contain about 10 grams of carbohydrates are 3/4 c. of carrots, 1/2 c. of acorn squash, 1 c. of beets, and 1/4 c. of white potatoes. Legumes and fruit are the next preferred food groups for adding 10 grams daily. One-half apple contains 10 grams of carbohydrates, as does 1/3 c. of kidney beans.

## KEY TERMS

**Ketoacidosis**—An imbalance in the makeup of body fluids caused by the increased production of ketone bodies. Ketones are caused by fat breakdown.

*Lifetime maintenance*

This final phase of the Atkins diet occurs when a dieter reaches goal weight. Although an adult may be able to consume from 90 to 120 grams of carbohydrates a day, depending on age, gender, and activity level, maintaining goal weight is more likely if carbohydrate intake remains at the level discovered in pre-maintenance. The key, according to Atkins, is never letting weight vary by more than three to five pounds before making corrections.

## Function

From the beginning, Dr. Atkins said that the traditional approach to weight loss of counting calories and cutting fat must not be working. He blamed carbohydrates for adding to the expanding waistlines and declining health of Americans. Through several updates of the Atkins diet, the same basic premise held with minor revisions. The function of the diet is to enjoy eating while severely limiting carbohydrates. Atkins Advantage mostly makes a distinction between trans fats and other fats. A more clear distinction also is made in the later version between carbohydrates in general and sugar in particular. All along, Atkins has emphasized that a focus on protein builds energy, repairs muscles and bones, and boosts the **metabolism**.

## Benefits

Some dieters have had at least initial success with the diet and have found the liberal rules regarding protein and fats more tasteful and filling than other diets, Advice from the Atkins plan concerning behavioral changes can be helpful, such as shopping the perimeter of the grocery store, where the unprocessed foods are located. In recent years, the program has attempted to modify some of its advice to more closely fit traditional advice from registered dieticians. For example, more clearly defining the types of fats to emphasize in the diet may help avoid mistakes by some who follow the diet to overeat unhealthy fats and increase risk for heart disease. However, experts have said that the diet still contradicts mainstream views concerning health promotion and disease prevention.

## Precautions

The average carbohydrate intake recommended by the Atkins diet is well below averages generally recommended by other experts. Studies have shown that even though people may lose weight on the Atkins plan, they do not necessarily keep the weight off long-term because the diet does not teach sustainable lifestyle changes.

Like many fad diets, the Atkins plan produces and promotes many food products associated with its diet plan. As of 2007, these products included bars, shakes, and candy. So although the plan argues against processed foods and snacking, the company also heavily promotes use of its nutritional products to support weight loss or maintenance.

Most importantly, followers of the Atkins diet have reported suffering from muscle cramps, diarrhea, general weakness, and rashes more frequently than people on low-fat diets. Others have reported constipation, bad breath, headache, and fatigue. The American Dietetic Association has warned that any diet that severely limits one food group should raise a red flag to dieters.

## Risks

Beyond the reported side effects and concerns about the diet's long-term effectiveness, some serious problems may arise for Atkins diet followers. One problem that has been documented is called ketoacidosis. This occurs when there is a buildup of the by-products of fat breakdown because the body does not have enough glucose available. The condition can be dangerous, resulting in cell damage, severe illness, and even death. The low carbohydrates eaten by those on the diet are below those needed to supply the brain and muscles with sugar. Critics of the diet have also long focused on the risks of unlimited fat intake that the Atkins diet allows. Eating large amounts of saturated fat, even if weight is dropping, can lead to high levels of cholesterol and heart disease. However, this is not necessarily always the case. Cholesterol levels tend to decrease in many individuals when they lose weight, even if eating an unbalanced diet. Long-term research remains to be done in this area.

## Research and general acceptance

Research results have varied over the years concerning the Atkins diet. The research has tended to support that Atkins followers have experienced comparable or higher weight loss than people on traditional low-fat diets with higher amounts of carbohydrates, but for only a six-month period. After 12 months, weight loss was about equal. Some research also has shown that the diet has not produced damaging cholesterol or heart effects, but these studies have not been large, long-term trials. For example, effects of increased fat consumption on diet followers' hearts may take years to

## QUESTIONS TO ASK YOUR DOCTOR

- What aspects of the Atkins diet do you feel are appropriate for weight loss?
- How often would I need to be seen by a physician or registered dietitian while following the atkins diet?

surface and in any medical research, large numbers of participants are needed to account for many variables.

In 2004, Jody Gorran, a 53-year-old businessman from Florida, sued the promoters of the Atkins diet, saying that the plan clogged his arteries and nearly killed him. Mr. Gorran claimed that he was seduced by the plan and that by eating the high levels of protein and fats touted by the plan, his cholesterol soared. His lawsuit was backed by the Washington-based advocacy group called Physicians Committee for Responsible Medicine. Mr. Gorran sought damages and to seek an injunction preventing the sale of Atkins' books and products without fair and adequate warnings about the dangers of the diet. The lawsuit was dismissed late in 2006 by a judge, but an appeals continue.

Atkins' company filed for Chapter 11 bankruptcy protection in July 2005. The company completed its Chapter 11 reorganization by January 2006, having streamlined some operations, and continued to operate early in 2007, making Dr. Atkins' diet run more than 35 years long.

Controversy even surrounded Atkins' death in 2003. Though he died when he slipped on the ice outside his office in February 2003. He spent eight days in a coma before dying, and a copy of the medical examiner's report showed that his weight upon death was 258 pounds. Critics of Atkins's diet said that this was considered obese for a man who was six feet tall. His allies said that most of the pounds were gained in Atkins' time in a coma because of fluid retention. But even while Atkins was alive, he had reported problems with his heart, though his physician's council said the trouble was from an enlarged heart, which had stemmed from a viral infection, not from his diet.

Though Dr. Atkins added that numerous studies pointed to the fact that carbohydrates were to blame for weight gain, an explanation for how his diet program worked was never really offered by researchers. Numerous studies continued throughout the 1990s and even after Dr. Atkins' death. Though some studies showed that people on the Atkins diet often lost weight faster in six months than those on other weight loss programs, the long-term effectiveness and possible harmful effects of the Atkins diet required more study.

In 1992, Dr. Atkins updated his *Diet Revolution* and by 2004 *Dr. Atkins' New Diet Revolution* had sold more than 45 million copies and been translated into 25 languages. The new plan was the same, but the maintenance portion of the diet was made a little more liberal. The diet was extremely popular, as were Atkins Nutritionals products, such as vitamin supplements and numerous food items. A later Web-based version called the Atkins Advantage emphasized the products of Atkins Nutritionals and offered additional books, software, and information on a company Website to support the program's goals and products.

# B

## Bariatric surgery

### Definition

Bariatric surgery is a surgical weight-loss procedure that reduces or bypasses the stomach or small intestine so that severely overweight people can achieve significant and permanent weight loss.

### Purpose

Bariatric surgery, is performed only on severely overweight people who are more than twice their ideal weight. This level of **obesity** often is referred to as morbid obesity since it can result in many serious, and potentially deadly, health problems, including **hypertension**, Type II **diabetes mellitus** (non-insulin dependent diabetes), increased risk for coronary disease, increased unexplained heart attack, **hyperlipidemia**, and a higher prevalence of colon, **prostate**, endometrial, and, possibly, breast **cancer**. In 2003, researchers concluded that obesity surgery could cure Type II diabetes in many people who were not yet morbidly obese. Therefore, this surgery is performed on people whose risk of complications of surgery is outweighed by the need to lose weight to prevent health complications, and for whom supervised weight-loss and exercise programs have repeatedly failed. Obesity surgery, however, does not make people thin. Most people lose about 60% of their excess weight through this treatment. Changes in diet and exercise still are required to maintain a normal weight.

The theory behind obesity surgery is that if the volume the stomach holds is reduced and the entrance into the intestine is made smaller to slow stomach emptying, or part of the small intestine is bypassed or shortened, people will not be able to consume and/or absorb as many calories. With obesity surgery the volume of food the stomach can hold is reduced from about four cups to about 1/2 cup.

Insurers may consider obesity surgery elective surgery and not cover it under their policies. Documentation of the necessity for surgery and approval from the insurer should be sought before this operation is performed.

### Precautions

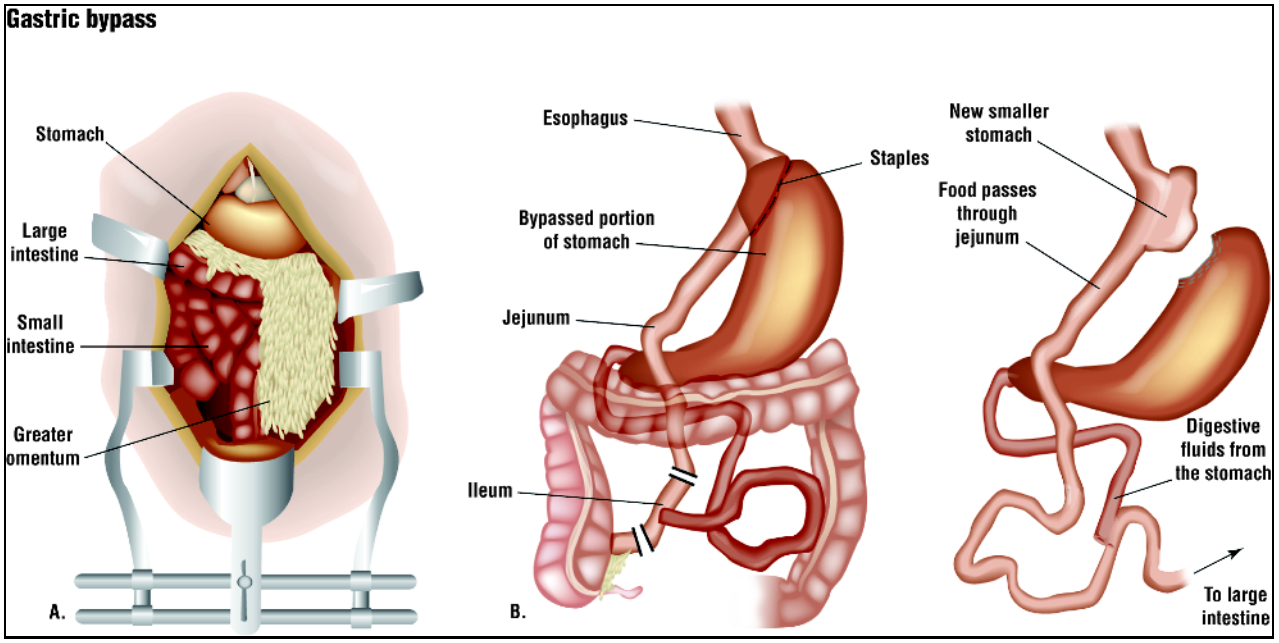
Obesity surgery should not be performed on people who are less than twice their ideal weight. It also is not appropriate for people who have substance addictions or who have psychological disorders. Other considerations in choosing candidates for obesity surgery include the general health of the person and his or her willingness to comply with follow-up treatment.

### Description

Obesity surgery is usually performed in a hospital by a surgeon who has experience with obesity surgery or at a center that specializes in the procedure. General anesthesia is used, and the operation takes 2–3 hours. The hospital stay lasts about a week.

Three procedures are currently used for obesity surgery:

- Gastric bypass surgery. Probably the most common type of obesity surgery, gastric bypass surgery has been performed in the United States for about 25 years. In this procedure, the volume of the stomach is reduced by four rows of stainless steel staples that separate the main body of the stomach from a small, newly created pouch. The pouch is attached at one end to the esophagus. At the other end is a very small opening into the small intestine. Food flows through this pouch, bypassing the main portion of the stomach and emptying slowly into the small intestine where it is absorbed.
- Vertical banding gastroplasty. In this procedure, an artificial pouch is created using staples in a different section of the stomach. Plastic mesh is sutured into



**In this Roux-en-Y gastric bypass, the stomach is separated into two sections. Food is bypassed from the larger stomach to the smaller stomach.** *(Illustration by GGS Information Services/Thomson Gale.)*

part of the pouch to prevent it from dilating. In both surgeries the food enters the small intestine farther along that it would enter if exiting the stomach normally. This reduces the time available for absorption of nutrients. The procedure is normally done laparoscopically, meaning that the surgeon makes one or more small incisions in the abdomen and inserts the necessary tools and instruments through the tiny holes. He or she can view the patient's organs via an inserted camera that displays pictures on a monitor. This method makes for a faster and easier recovery than a large incision.

- Jejunoileal bypass. Now a rarely performed procedure, jejunoileal bypass involves shortening the small intestine. Because of the high occurance of serious complications involving chronic diarrhea and liver disease, it has largely been abandoned for the other, safer procedures

## Preparation

After patients are carefully selected as appropriate for obesity surgery, they receive standard preoperative blood and urine tests and meet with an anesthesiologist to discuss how their health may affect the administration of anesthesia. Pre-surgery counseling is done to help patients anticipate what to expect after the operation.

## Aftercare

Immediately after the operation, most patients are restricted to a liquid diet for 2–3 weeks; however, some may remain on it for up to 12 weeks. Patients then move on to a diet of pureed food for about a month, and, after about two months, most can tolerate solid food. High fat food is restricted because it is hard to digest and causes diarrhea. Patients are expected to work on changing their eating and exercise habits to assist in weight loss. Most people eat 3–4 small meals a day once they return to solid food. Eating too quickly or too much after obesity surgery can cause nausea and vomiting as well as intestinal "dumping," a condition in which undigested food is shunted too quickly into the small intestine, causing pain, diarrhea, weakness, and dizziness.

## Risks

As in any abdominal surgery, there is always a risk of excessive bleeding, infection, and allergic reaction to anesthesia. Specific risks associated with obesity surgery include leaking or stretching of the pouch and loosening of the gastric staples. Although the average death rate associated with this procedure is less than one percent, the rate varies from center to center, ranging from 0–4%. Long-term failure rates can reach 50%, sometimes making additional surgery necessary. Other complications of obesity surgery

include an intolerance to foods high in **fats**, lactose intolerance, bouts of vomiting, diarrhea, and intestinal discomfort

Studies on the risks of these surgeries continue. A 2003 report showed that gastric bypass surgery risk increases with age, weight and male gender. Patients age 55 and older experienced more complications than did younger patients and male patients had more life-threatening complications than female patients, particularly those who were more severely obese.

### Normal results

Many people lose about 60% of the weight they need to reach their ideal weight through obesity surgery. However, surgery is not a magic weight-loss operation, and success also depends on the patient's willingness to exercise and eat low-calorie foods. A 2003 report showed that super obese patients had a lower success rate with laparoscopic vertical banding gastroplasty than those considered morbidly obese. However, the overall success rate was nearly 77% of patients carrying less than 50% excess weight four years after the procedure.

## Bernstein diet

### Definition

The Bernstein diet is a low-carbohydrate, **high-fat diet** for people with diabetes (diabetics). It goes against the conventional high-carbohydrate, low-fat diabetic diet recommended by much of the medical community.

### Origins

The diet was developed by endocrinologist and Type I diabetic Richard K. Bernstein and first published in his 1997 book *Dr. Bernstein's Diabetes Solution: A Complete Guide to Achieving Normal Blood Sugars*. It is intended for diabetics and people with insulin resistance syndrome. Diabetes is a disease in which the body does not produce or properly use insulin. Insulin is a hormone that is needed to convert sugar, starches and other food into energy. Insulin resistance often goes along with other health problems, like diabetes, high cholesterol, high blood pressure and heart attack. When a person has many of these problems together, it is called insulin resistance syndrome.

Bernstein was diagnosed with diabetes in 1946 at the age of twelve. He was put on the standard low-fat, high-carbohydrate diet for diabetics. He remained on this diet, even though his condition worsened and he developed many complications of the disease, until 1969. During this time, he experienced frequent bouts of hypoglycemia (excessively low blood sugar) along with headaches and fatigue, which he said was caused by the large doses of insulin he was taking to help regulate his blood sugar levels. He blames this cycle of hypoglycemia followed by insulin injections on his high-carbohydrate diet. Doctors recommend a high-carbohydrate diet for diabetics because it raises blood sugar. When blood sugar levels get too high in Type I diabetics, they must be brought down with insulin injections. In 1969, Bernstein, an engineer, began adjusting his insulin regimen from one injection a day to two and cut down on **carbohydrates** in his diet. The changes had only minimal effect. In 1972, he began checking his blood sugar levels five to eight times a day, making small changes to his insulin regimen and diet to see what the effects would be. Within a year, Bernstein said he had refined his diet and insulin injection schedule to the point of having nearly constant normal blood sugar levels. His health improved considerably. He spent the next few years trying to convince the major medical journals and physicians who treated diabetes that his method of closely monitoring his blood sugar levels and maintaining a relatively constant, normal blood sugar level could help other diabetics. The attempts failed. So in 1979, Bernstein quit his engineering job and entered medical school. In 1983, he opened his own medical practice in New York. After that, he began formulating his diet plan that became the focus of his 1997 book.

### Description

The Bernstein diet is designed as a medical diet rather than for weight loss, although people can lose weight on it as it is similar in many respects to the **Atkins diet**. Both diets stress foods that are high in **fats** and **protein** and low in carbohydrates. That formula is

controversial in weight loss and health circles but the Bernstein diet is also controversial in the diabetic community. That is because the Bernstein diet, designed for people with diabetes, goes against the conventional low-fat, high-carbohydrate diet advocated by health professionals for more than 50 years.

The Bernstein diet doesn't recommend a specific ratio of the three main food groups: proteins, fats, and carbohydrates. Instead, he advocates an individualized approach to a diabetic's diet. At the center of the diet is the need for diabetics to test their blood sugar levels at least five to eight times a day. On his Website, (http://www.diabetes-normalsugars.com) Bernstein states, "There is simply no way to determine objectively how any given food at any given time is going to behave in any given individual, unless blood sugar is tested before and for a number of hours after its consumption." In his books and on his Website, Bernstein details how each of the three primary food groups, protein, fats, and carbohydrates, fit into his diet.

Bernstein has three basic rules for diabetics when developing meal plans that normalize blood sugar levels. They are:

- Eliminate all foods from the diet that contain simple sugars, which are fast-acting carbohydrates. These foods include table sugar, most starchy foods such as breads and pasta, grains, and potatoes.
- Limit total carbohydrate intake to an amount that will work with insulin, either injected or produced naturally by the body. This will avoid a post-meal blood sugar increase, and will avoid any remaining insulin-producing beta cells of the pancreas.
- Stop eating when there is no longer a feeling of hunger. He says people should not leave the table while they are still hungry but should also not wait until they feel stuffed to stop eating.

Bernstein tells diabetics to avoid hidden dangers in foods, especially sugar-free foods, that can cause blood sugar levels to rise too much and too rapidly. Food labels should be carefully checked for these substances and foods containing any of them should be avoided. These include carob, honey, saccharose, corn syrup, lactose, sorbitol, dextrin, levulose, sorghum, dextrose, maltodextrin, treacle, dulcitol, maltose, turbinado, fructose, mannitol, xylitol, glucose, mannose, xylose, and molasses.

The Bernstein diet recommends diabetics avoid eating the following foods: breakfast cereals, snack foods (candy, cookies, cakes, potato and tortilla chips, popcorn, and pretzels), protein bars, milk and cottage cheese (except for **soy** milk), fruits and fruit juices, certain vegetables (beans, beets, carrots, corn, potatoes, tomatoes (including tomato sauce and paste), canned and packaged soups, and most 'health' foods.

## KEY TERMS

**Carbohydrates**—An organic compound that is an important source of food and energy.

**Diabetes**—A disease in which the blood glucose (sugar) levels are too high and the body does not make insulin (which helps regulate blood sugar) or does not make or use insulin well.

**Endocrinologist**—A medical specialist who treats diseases of the endocrine (glands) system, including diabetes.

**Hypoglycemia**—Abnormally low blood sugar levels.

**Insulin**—A hormone that regulates the level of glucose (sugar) in the blood.

**Insulin resistance syndrome**—A medical condition in which insulin fails to function normally in regulating blood glucose (sugar) levels.

**Ketoacidosis**—Dangerously high blood sugar levels.

**Monounsaturated fat**—A type of fat found in vegetable oils such as olive, peanut, and canola.

**Polyunsaturated fat**—A type of fat found in some vegetable oils, such as sunflower, safflower, and corn.

Foods that are allowed under the Bernstein diet include meat, fish and seafood, poultry, eggs, tofu, soy meat substitutes, cheese, butter, margarine, cream, yogurt, soy milk, soy flour, and bran crackers. Other food items allowed include toasted nori (seaweed), **artificial sweeteners** (Equal, Sweet'n Low, NutraSweet, and Splenda), No-Cal brand syrups, Da Vinci Gourmet brand syrups, flavor extracts, herbs and spices, low-carbohydrate salad dressings, nuts, and sugar-free gelatin and puddings.

Bernstein admits his diet is somewhat restrictive and that people will still have **cravings** for sweets and bakery items. "Most of my patients initially feel somewhat deprived, but also grateful because they feel more alert and healthier," he says in his book and on his Website. "I fall into this category myself. My mouth waters whenever I pass a bakery shop and

sniff the aroma of fresh bread, but I am also grateful simply to be alive and sniffing."

## Function

The main function of the Bernstein diet is to help people with diabetes to maintain constant, normal blood sugar levels throughout the day. Maintaining control of their blood sugar levels can help diabetics avoid long-term complications of the disease, including neuropathy of the feet, amputation, cataracts and blindness, heart disease, erectile dysfunction, glaucoma, **ulcers** of the feet, high blood pressure, and high cholesterol. Since the diet is similar to the Atkins diet in that it emphasizes low-carbohydrate foods, people who are overweight or obese can lose weight on the Bernstein diet.

## Benefits

The primary benefits of the Bernstein diet come from diabetics being able to maintain constant, normal blood sugar levels. Doing this over the long-term can help reduce the number of diabetics who develop complications from the disease. These complications include heart disease, high blood pressure, eye problems, serious conditions affecting the feet that sometimes lead to amputation, gastroparesis (a condition in which the stomach requires significantly longer than its normal time to empty), kidney disease, and fatigue. The importance of maintaining constant, normal blood sugar levels (by checking the levels at least five to eight times a day with home glucose monitors and then adjusting insulin levels accordingly) was proven by the Diabetes Control and Complications Trial, a study of diabetics from 1983–1993, the most comprehensive large-scale diabetes study ever conducted. The study found that in diabetics who intensely controlled their blood sugar levels, the risk for eye disease was reduced by 76 percent, nerve disease by 60 percent, and kidney disease by 50 percent. The diet can also help diabetics who are overweight or obese to lose weight.

## Precautions

There are no major precautions associated with the diet, although it is not recommended for diabetics by major medical organizations including the American Medical Association, American Dietary Association, and American Diabetes Association. Diabetics should discuss the diet with their doctor or a specialist in diabetes called an endocrinologist, who may refer the person to a diabetic dietician or nutritionist. The diet is high in fat so people on it should use fats from monounsaturated and polyunsaturated sources such as olive and canola oils.

### QUESTIONS TO ASK YOUR DOCTOR

- Will I need any dietary supplements if I adopt the Bernstein diet?
- Do you see any health risks for me in the diet?
- Are there any other diets you would recommend that would help me accomplish my weight loss goals?
- Have you treated other patients who are on a low-carbohydrate, high-fat diet? If so, what has their response to the diet been?
- How will the Bernstein diet affect my diabetes or insulin resistance syndrome?
- How important is it for me to maintain constant normal blood sugar levels throughout the day?

## Risks

There are no general health risks associated with the Bernstein diet. Critics of the diet say it contains too much fat, is not nutritionally balanced, and is not a long-term solution for losing weight and keeping it off. They also say it is difficult for many people to maintain a **low-carb diet** over the long-term. Also, people with type 1 diabetes who take insulin are at a high risk of hypoglycemia (abnormally low blood sugar levels) and ketoacidosis (dangerously high blood sugar levels) if they remove too much carbohydrate from their meals.

## Research and general acceptance

Critics of the Bernstein diet for diabetics are quick to point out that there are no major long-term scientific studies on the effectiveness of the low-carbohydrate, high-fat diet. However, the same can be said for the traditional low-fat, high-carbohydrate diet that has been the standard diabetic diet for more than 50 years. In one review of Bernstein's 1997 book, *Dr. Bernstein's Diabetes Solution: A Complete Guide to Achieving Normal Blood Sugars*, the diet was criticized because it required diabetics to be meticulous in self-managing the disease. But there are major long-term scientific studies that show that there is significant benefit in such meticulous self-management, including the landmark Diabetes Control and Complications Trial and the United Kingdom Prospective Diabetes Study.

Among the critics of the Bernstein diabetic diet are the American Diabetes Association, American Dietary Association, American Medical Association, American Heart Association, United States Department of Agriculture, and the Physicians Committee for Responsible Medicine. They say that high-fat, low-carbohydrate diets are generally unhealthy because they are low in **fiber**, **calcium**, fruits, and vegetables, and high in cholesterol, fat, and saturated fat. On the surface, it would seem that a diet that is the opposite of what the world's leading diabetes organization recommends would not be acceptable for diabetics. However, since 2002, a number of scientific studies that compared high- and low-carbohydrate diets concluded that a low-carbohydrate diet reduces blood sugars and risk factors for heart disease. That is why many practicing endocrinologists endorse the Bernstein diet and other low-carbohydrate diets for their patients. They point out that the American Diabetes Association (ADA) has always been very slow in reacting and adjusting to new development in diabetes monitoring and treatment. For example, the ADA did not endorse patient blood glucose monitors until 1983, about 10 years after they were developed. What is lacking in the low-carb versus high-carb diet controversy is major long-term studies that track patients for longer than a year.

People with Type II diabetes may be able to improve control of their blood sugar levels, lose weight, and lower cholesterol levels significantly with a low-carbohydrate diet, such as the Bernstein diet, that with diets that restrict calorie intake, according to two studies presented in 2006 at the American Diabetes Association annual scientific sessions. One of the studies, conducted by Duke University researchers, was funded by the Robert C. Atkins Foundation. Atkins authored a number of popular books on the Atkins low-carbohydrate diet.

Ken R. Wells

# Beverly Hills diet

## Definition

The Beverly Hills diet is a diet created by Judy Mazel. She believes that weight loss can be achieved by eating foods in the proper combinations and in the correct order.

## Origins

Judy Mazel says that she was always an overweight child, and beginning when she was nine years old, she went to see doctor after doctor trying to find out why she could not be thin. For 20 years she continued to struggle with her weight and was finally told by a doctor that she was destined to always be fat. Six months after this pronouncement, she went skiing and broke her leg. While she was recuperating, she read a book on nutrition that a friend had given her. From this she developed her ideas about how the body works and what is needed to lose weight and stay thin.

Mazel reports that she used her new theories to lose 72 lb (29 kg), and has kept off the weight ever since. In 1981, she published her diet in a book *The Beverley Hills Diet*. The original book reportedly sold more than a million copies, and in 1996 Mazel published a revised and updated version of the diet called *The New Beverly Hills Diet*. Mazel has also written a cookbook designed to go with the diet and *The New Beverly Hills Diet Skinny Little Companion*, a slim volume designed to provide inspiration and tips to help dieters through their first 35 days on the diet.

## Description

The Beverly Hills diet is a food combination diet. It is based on the idea that it is not what a person eats, or even how much food is eaten that causes a person to gain weight. Mazel believes the combinations in which foods are eaten and the order in which they are eaten causes weight gain. She says that eating foods in the wrong order can stop some foods from being digested, and it is the undigested foods that cause fat build-up.

The groups into which Mazel divides foods are **carbohydrates**, proteins, fruits, and **fats**. She believes that fruit must be eaten alone and must be eaten before anything else is consumed during the day. She also says that for correct digestion, each type of fruit must be eaten alone. This means that if a dieter eats an orange, the dieter must wait at least one full hour before eating another type of fruit, such as a pear. If the dieter eats a different type of food, such as a **protein**, the dieter must wait until the next day to eat fruit again.

On the Beverly Hills diet, protein and carbohydrates cannot be eaten together. Most dairy products go into the protein group for purposes of categorization. This means that dieters can drink milk with protein meals, but not with carbohydrate meals. Fat is allowed to be eaten with either group, but may not be eaten with fruit.

### KEY TERMS

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Mineral**—An inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

**Type 2 diabetes**—sometime called adult-onset diabetes, this disease prevents the body from properly using glucose (sugar), but can often be controlled with diet and exercise.

**Vitamin**—A nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

The order throughout the day in which food is eaten is very important on the Beverly Hills diet. Mazel says that each day fruit should be eaten first. After fruit, the carbohydrate group can be eaten. After carbohydrates comes food from the protein group. Once a dieter has changed food groups, he or she cannot eat from the previous groups again until the next day. Dieters must wait two hours between eating foods from different food groups.

During the diet, Mazel says that dieters must not consume diet sodas or anything with **artificial sweeteners**. Because milk is considered a protein, the dieter is very limited in when it can be consumed. Unlike many other diets, alcohol is not as restricted on the Beverly Hills diet. Mazel categorizes most alcoholic drinks, such as beer, vodka, and rum, as carbohydrates, and says they must only be consumed with carbohydrates. Wine is categorized as a fruit, and unlike the rules for eating other fruits, wine does not have to be consumed alone but can be drunk with another fruit. Mazel says that champagne is a neutral food and can be drunk with anything.

Mazel provides dieters with a 35-day plan for losing weight. Every day dieters are told what foods are allowed, and in what order they must be eaten. Most foods do not have a quantity limit. Instead, dieters may consume as much of a given food as desired until they move on to the next food. Dieters must eat the foods in the order listed and cannot go back or make substitutions. The diet is very restrictive,

with most days allowing no more than two or three types of foods.

For example, on the first day of the diet, dieters are instructed to eat pineapple, corn on the cob, and a salad made of lettuce, tomatoes, and onions with Mazel dressing. (Mazel dressing is a recipe included in the book, and shows up frequently throughout the 35-day diet.) This means that dieters may eat as much pineapple as desired in the morning, but once they beginning eating corn on the cob they cannot go back and eat more pineapple. Once the salad is eaten, both corn on the cob and pineapple are no longer allowed. Dieters are instructed to wait between changing foods to ensure proper digestion.

Some days on the diet only one type of food is permitted during the entire day. Day three of the diet allows the dieter only to consume grapes. On other days the dieter is only allowed to eat watermelon. Although these rules are extremely restrictive, they are not as restrictive as the rules set out in the original Beverly Hills diet. On that diet, dieters were only allowed to eat fruit for the first 10 days of the diet. No animal protein was allowed at all until the 19th day. The New Beverly Hills diet includes vegetables and carbohydrates occasionally during the first week, and includes lamb chops and shrimp on the sixth day.

## Function

The Beverly Hills diet promises dieters that they will lose up to 25 lb (11.5 kg) in 35 days. The diet's Website claims that the average dieter will lose 15–20 lb (7–9 kg). Mazel promises that by following the guidelines set out by her diet, dieters will be able to eat anything they want, including foods forbidden on most diets, such as cheesecake and hamburgers. They only have to ensure that they eat them at the right times, in the right combinations, and in the right order. Doing this, Mazel claims, will let dieters become thin and stay thin, all while eating fatty foods forbidden by other diets. The Beverly Hills diet is intended to be a life changing diet, and dieters are expected to continue to follow the rules of the diet after the 35 days of meal plans are finished. Mazel does not provide exercise recommendations, nor does she provide information to help dieters improve other aspects of their lives, such as advice on stress reduction.

## Benefits

The Beverly Hills diet claims that dieters can lose 20 lb (9 kg) in 35 days. Many health benefits are associated with significant weight loss if it is achieved through healthy eating and exercise and occurs at a moderate pace. These benefits can include a decreased risk of Type II diabetes, cardiovascular disease, **hypertension**, and other **obesity** related diseases and conditions.

There may be some benefits to following the Beverly Hills diet. The diet emphasizes eating a wide variety of fruit. Fruits contain many **vitamins** and **minerals** that are necessary for good health. Eating a diet with more fruits and vegetables can help dieters stick to an otherwise well-balanced, reduced-calorie diet because fruits and vegetables generally contain fewer calories per volume than other foods. This means that a dieter can feel full while eating fewer calories. The diet also restricts prepared foods and foods with **artificial preservatives**, sweeteners, and flavors. Eating a diet that contains mainly fresh foods can be very healthy because prepared foods are often very high in **sodium** and have fewer vitamins and minerals than fresh foods.

## Precautions

The New Beverly Hills diet's website cautions dieters that there are some people for whom the diet is not appropriate. These include women who are pregnant or **breastfeeding** and anyone with diabetes, **ulcers**, spastic colon, and various forms of irritable bowel disease. The website also cautions that anyone with serious illness or chronic disease should only begin this diet under medical supervision.

Even dieters who do not have serious illness should consult a doctor or other medical professional when considering this diet. Daily requirements of calories, vitamins, minerals, and other nutrients can differ from person to person depending on age, weight, sex, activity level, and the presence of certain diseases or conditions. A physician can help the dieter determine if this diet will be safe given a dieter's specific nutritional requirements, so that the dieter can reach his or her weight loss goals without risking good health.

## Risks

This diet requires that dieters eat only a small variety of foods each day, and on some days only one type of food is allowed. No protein is allowed until the sixth day of the diet, and it is not included regularly after that. This means that it will be extremely hard for dieters to get the vitamins, minerals, and nutrients that are needed each day for good health. If dieters are considering this diet, they should consult a physician about taking a multivitamin or other dietary supplement to reduce the risk of serious nutritional deficiencies. However, no vitamin or supplement can replace eating a healthy, balanced diet.

## QUESTIONS TO ASK THE DOCTOR

- Is this diet safe for me?
- Is this the best diet to meet my long term weight loss goals?
- Do I have any dietary requirements this diet might not meet?
- Would a multivitamin or other dietary supplement be appropriate for me if I were to begin this diet?
- Are there any sign or symptoms that might indicate a problem while on this diet?

Although the New Beverly Hills diet does include more foods than the original diet, which only allowed fruit for the first 10 days, the diet still contains a significant amount of fruit. Fruit is required as the first food each day, and on many days only fruit is allowed. In the first week of the diet there are two days that only allow fruit: day three only allows grapes, and day five allows pineapple, then papaya, then more pineapple. Because of this excessive consumption of fruit and the limited consumption of other foods, there is a significant risk of diarrhea, which can lead to severe **dehydration** and malnutrition. Dieters thinking of beginning this diet should be extremely cautious.

### Research and general acceptance

There have been no significant scholarly studies done showing the effectiveness of the food combining theory of eating in general, or the effectiveness of this diet in particular.

In 1981 the *Journal of the American Medical Association* published an article stressing the dangers of the original Beverly Hills diet. It called the diet "the latest, and perhaps worst, entry in the diet-fad derby," and said that the diet could cause severe enough diarrhea to cause fever, muscle weakness, and in the most severe cases might be able to cause extreme drops in blood pressure that could lead to death. The article told physicians to discourage their patients from trying this diet.

Although the New Beverly Hills diet has been updated, and more foods have been included, experts are not much more enthusiastic. David W. Grotto, a spokesman for the American Dietetic Association, is quoted on WebMD.com as saying that "sustaining the diet...would be a concern because of a lack of nutritional adequacy," and even went on to say "I would almost lump [the] dietary program in with the obscure and useless programs—like Alexander the Great's nothing-but-alcohol diet. It's nutritionally incomplete and there's better programs out there."

# Binge eating

## Definition

Binge eating an abnormal eating pattern in which an individual eats significantly more food in a limited time than most people typically would eat. The timeframe for a binge is usually 1–2 hours.

## Description

The **eating disorders anorexia nervosa** and **bulimia nervosa** are considered psychiatric disorders and have formal diagnostic criteria that are define in the

**Possible health consequences of binge-eating**

- Anxiety
- Depression
- Obesity
- Obesity-related diseases
- Poor self-esteem
- Sleep problems
- Stress
- Substance abuse
- Suicidal thoughts
- Weight gain
- Weight obsession

*(Illustration by GGS Information Services/Thomson Gale.)*

*Diagnostic and Statistical Manual for Mental Disorders Fourth Edition-Text Revision (DSM-IV-TR)* published by the American Psychiatric Association (APA). Binge eating is an acknowledged problem, but it has not risen to the level a separate psychiatric disorder as defined by the APA. Some experts believe binge eating is a subtype of bulimia, an eating disorder characterized by episodes of binge eating followed by purging the body of calories. Other experts believe that binge eating should be classified as an obesity-related behavior. Some healthcare providers place binge-eating disorder in the APA category of eating disorders not otherwise specified. Although the way a healthcare professional views binge eating does not change the behavior, it may influence the type of therapy recommended and affect the degree to which treatment is covered by heath insurance providers.

Everyone eats too much occasionally, but people with binge-eaters disorder have an abnormal eating pattern that occurs frequently. Many eating disorder specialists define binge-eating disorder as binge eating behavior that occurs at least twice a week for three months and has a negative effect on the individual's relationships and daily activities.

Binge eaters exhibit many of the following behaviors.

- They eat abnormally large amounts of food at one sitting, often consuming 3,000–10,000 calories in a short period.
- They gobble their food, eating much faster than usual.
- During a binge, they feel out of control and unable to stop eating, even though they may want to.
- Despite feeling full or even painfully uncomfortable, they continue to eat.
- Binge eaters tend to diet constantly but never lose weight.
- Then often eat alone and hide empty food containers to disguise from others how much they eat.
- They are ashamed and embarrassed about their bingeing.
- Food hoarding is common.
- After a binge, they feel guilty, upset, disgusted and/or depressed about how much they have eaten.
- They vow to themselves never to binge again, but cannot keep this promise.

Binge-eating disorder is different from bulimia. The two disorders are similar in their bingeing behavior, but people with bulimia follow a binge by purging the body of calories. They do this by some combination of self-induced vomiting, laxative, diuretic, or enema abuse, fasting, and compulsive exercising beyond reasonable levels. People with binge-eating disorder do nothing to purge the body of the extra calories they have eaten, although they often try to diet between binges. Many people who are bulimic also

## KEY TERMS

**Electrolyte**—ions in the body that participate in metabolic reactions. The major human electrolytes are sodium (Na+), potassium (K+), calcium (Ca 2+), magnesium (Mg2+), chloride (Cl-), phosphate ($HPO_4$ 2-), bicarbonate ($HCO_3$-), and sulfate ($SO_4$ 2-).

**Neurotransmitter**—One of a group of chemicals secreted by a nerve cell (neuron) to carry a chemical message to another nerve cell, often as a way of transmitting a nerve impulse. Examples of neurotransmitters include acetylcholine, dopamine, serotonin, and norepinephrine.

**Obese**—more than 20% over the individual's ideal weight for their height and age or having a body mass index (BMI) of 30 or greater.

**Placebo**—a pill or liquid given during the study of a drug or dietary supplement that contains no medication or active ingredient. Usually study participants do not know if they are receiving a pill containing the drug or an identical-appearing placebo.

**Triglycerides**—a type of fat found in the blood. High levels of triglycerides can increase the risk of coronary artery disease

**Type 2 diabetes**—sometime called adult-onset diabetes, this disease prevents the body from properly using glucose (sugar).

have anorexic behaviors. There is no overlap between binge-eating disorder and anorexia. Most people who have binge-eating disorder are obese, but not all obese people have binge eating behaviors.

## Demographics

Estimates of the number of Americans who have binge-eating disorder range from less than 1% to 4%, with 2% being the most commonly cited figure. Although women with binge-eating disorder outnumber men 3:2, binge eating is the most common male eating disorder. The disorder affects blacks and whites equally; little research as been done on other racial or ethnic groups. Unlike the eating disorders anorexia nervosa or bulimia nervosa that start in the teenage or young adult years, binge eating disorder is more likely to occur in middle-aged adults between the ages of 46 and 55. Although binge eaters may be of normal weight, binge eating is a common disorder among people who are obese. Some estimates suggest that up to half the obese people in formal weight loss programs have problems with binge-eating.

People at higher risk of developing binge-eating disorder share certain characteristics. These include:

- frequent dieting. People who go on rigorous diets or who frequently gain and lose large amounts of weight (weight cycling) are more likely to become binge eaters.
- impulsiveness. Binge eaters, like bulimics, have problems with impulse control.
- low self-worth and negative self-talk. This occurs almost universally among people with all types of eating disorders.
- difficulty managing anger and appropriately expressing feelings.
- preoccupation with body image and weight.
- sexual abuse. Some, but by no means all, people with binge eating disorder report being sexually abused as children. This is an area of ongoing research.
- depression. It is not clear whether depression causes binge eating or if binge eating causes depression, but the two are often found together.

## Causes and symptoms

Binge eating is a relatively new area of research. Like all eating disorders, binge eating appears to have multiple causes. Some people seem to be genetically predisposed to become binge eaters. Researchers think this may be related to abnormalities in neurotransmitters in the brain that help to regulate appetite. Research continues actively in this area.

For many binge eaters, stress is the factor that triggers a binge. Stress can be caused by very restrictive dieting, but it is often caused by social and cultural factors, such as family conflict, job-related stress, dysfunctional relationships, and the repeated message from the media that a thin body is a sign of success, while being obese results in failure to find a mate or succeed in life.

Symptoms of binge eating may be difficult to detect. Binge eating is different from continuously snacking, and it is often done in private. **Obesity** and obesity-related diseases such as **hypertension** (high blood pressure) Type II diabetes, and joint pain are signs that binge-eating disorder could be present, but not all obese people are binge-eaters. Behaviors such as secretive eating, constant dieting without losing weight, obsessive concern about weight, depression, anxiety, and substance abuse are all clues, but none of these signs are definitive. The individual may complain about symptoms related to obesity, such as fatigue and shortness of breath, or mention unsuccessful dieting, but again, these signs are not definitive.

## Diagnosis

Binge eating can be hard for healthcare providers to diagnose. Binge eaters often go out of their way to hide how much they eat. They may, for example, buy snack food at the grocery store and eat it in the car before they go home, or they may buy food in secret and hoard it, so that people close to them will not know they are bingeing. Normally healthcare professionals begin diagnosis with a family and personal history. However, people with binge-eating disorder often lie about their eating habits.

A physician will begin with a physical examination and usually order standard laboratory tests such as a complete blood count (CBC), urinalysis, and blood tests to check the level of cholesterol, **triglycerides**, and **electrolytes**. Additional tests, such as a thyroid function test, may be ordered to rule out other disorders. If the individual is obese, tests may be done check for obesity-related diseases such as diabetes, cardiovascular disease, and sleep apnea.

Several different evaluations can be used to examine a person's mental state. A doctor or **mental health** professional will assess the individual's thoughts and feelings about themselves, their body, their relationships with others, and their risk for self-harm.

## Treatment

The medical community does not completely agree on the best treatment for binge eating. Medical

specialists are more likely first to treat weight control issues with drugs, diet, and nutrition counseling in order to reduce the health risks of obesity-related diseases. Although there are no drugs specifically approved by the United States Food and Drug Administration for treating binge-eating disorder, the FDA has approved selective serotonin reuptake inhibitors (SSRIs) such as fluoxetine (Prozac) and sertraline (Zoloft) for the treatment of bulimia. Bulimia also involves binge-eating behavior. These medications increase serotonin levels in the brain and are thought to affect the body's sense of fullness. They are used whether or not the patient shows signs of depression. SSRIs are often prescribed for people with binge-eating disorder. Appetitive suppressants are also sometimes prescribed to help control binge eating. Treatment is most successful when group therapy occurs in conjunction with psychotherapy (see Therapies below).

## Nutrition/Dietetic concerns

People with binge-eating disorder understand that their eating pattern is abnormal and unhealthy. Nutrition counseling and meal planning can help bring weight under control, but they do not address the inability to control the impulse to binge. Nutrition counseling needs to be part of a broader treatment program that includes psychotherapy and possibly drug therapy.

## Therapy

Psychologists are more likely to approach the problem of binge eating by using therapy that helps the individual change his or her behavior and by treating emotional and psychological problems that cause it. For them, treating obesity is secondary to treating the behavior and the thought patterns that cause it. Psychologists tend to think that once the individual understands and can control bingeing behavior, obesity will be easier to treat.

Some types of psychotherapy that have been successful in treating people with binge-eating disorder are listed below.

- Cognitive behavior therapy (CBT) is designed to confront and then change the individual's thoughts and feelings about his or her body and behaviors toward food, but it does not address why those thoughts or feelings exist. Strategies to maintain self-control may be explored. This therapy is relatively short-term.
- Interpersonal therapy is short-term therapy that helps the individual identify specific issues and problems in relationships. The individual may be asked to look at his or her family and personal history to try to recognize problem areas and to work toward resolving them.
- Dialectical behavior therapy consists of structured private and group sessions in which the therapist and patient(s) work at reducing behaviors that interfere with quality of live, finding alternate solutions to current problem situations, and learning to regulate emotions.
- Family therapy is helpful in treating children who are binge eaters. It teaches strategies to reduce conflict, disorder, and stress that may be factors in triggering binge eating.
- Some people with binge-eating disorder find self-help groups and structured weight-loss programs useful, while others do not.

## Prognosis

There is no clear prognosis for binge eating disorder. Since stress often triggers bingeing, relapses are apt to occur in response to stressful life events. Some individuals find that simply seeking help improves their control over binge eating. For example, some studies have found that receiving a placebo is as effective as receiving medication. This is one reason why some parts of the medical community refuse to accept binge eating as a genuine disorder. Many studies are underway to test different approaches to treating binge eating. Individuals interested in participating in a clinical trial at no cost can find a list of studies currently enrolling volunteers at <http://www.clinicaltrials.gov>

## Prevention

Since binge eating is difficult to detect, it is also difficult to prevent. Some prevention strategies are listed below.

- Parent should not obsess about their weight, appearance, and diet in front of their children.
- Do not tease people about their body shapes or compare them to others.
- Make it clear that family members are loved and accepted as they are.
- Try to eat meals together as a family whenever possible; avoid eating alone.
- Avoid using food for comfort in times of stress.
- Monitoring negative self-talk; practice positive self-talk
- Spend time doing something enjoyable every day
- Stay busy, but not overly busy

- Become aware of the situations that make you want to binge and look for ways to avoid or defuse them. Do not go on extreme diets.
- Be alert to signs of low self-worth, anxiety, depression, and drug or alcohol abuse and seek help as soon as these signs appear.

# Bioengineered foods

## Definition

Bioengineered foods are foods that have had a gene from a different species of plant or other organism introduced to produce desired characteristics or traits.

## Purpose

The general purpose of bioengineering is to create plants that are in some way superior to the current plant breed being used. Some genetically engineered plants are engineered to resist specific insects or diseases. This means that these plants are more likely to grow big and stay healthy. Because most farming uses pesticides or insecticides to protect plants, plants that are bioengineered to be pest resistant allow farmers to use less of these chemicals. This is positive for the environment, as well as possibly less costly for the farmer, and can often provide cheaper products for the consumer.

In addition to producing heartier crops, some bioengineering is done to improve the taste of crops. Other bioengineering is done to introduce traits that will help the crops get to the consumer in better

condition or have a longer period of freshness. In 1994, the first bioengineered food to be introduced to the consumer market in the United States was the Flavr Savr tomato. This tomato was bioengineered to ripen more slowly and to remain on the vine longer so that it would be available to consumers later in the year than other tomatoes.

Bioengineering can also be used to increase the nutrient content of foods, or to add **vitamins** that are not usually found in a certain food. A variety of rice, sometimes referred to as "golden rice," that includes beta-carotene has been developed. Beta-carotene is a provitamin to **vitamin A**, which means that the body can use it to produce vitamin A. Rice is a staple of the diet of many Asians, and because rice does not normally contain vitamin A, many people in Asia are vitamin A deficient. This deficiency is believed to have resulted in blindness in a quarter of a million children in southeast Asia alone. If the new strain of rice that contains beta-carotene is introduced to the area, it could help to eliminate vitamin A deficiency and significantly reduce childhood blindness.

## Description

All people have deoxyribonucleic acid (DNA) in their cells. DNA is where all of the information needed to produce and sustain life is stored. DNA is made up of strands of nucleic acids that are grouped to form individual genes. Each gene contains the information about how to synthesize a particular **protein**. The proteins synthesized lead to individual characteristics, such as hair and eye color in humans.

Plants also contain DNA, as do almost all other living things. When scientists genetically engineer a plant, they take a gene from another plant or organism such as a bacterium and insert it into the original plant or trade it for a gene in the original plant. This trading of genes is called transposing.

Scientists did not learn how to insert and transpose genes successful until the 1980s. However, long before this people had been trying to create better, heartier plants and animals through selective breeding. For hundreds of years farmers had selected and bred animals based on characterizes that they wanted the offspring to have. Farmers might decide to breed a cow that gave a higher quantity of milk than other cows in the hopes of producing more cows that gave an above average quantity of milk. Farmers also planted the seeds of plants that had desirable characteristics hoping to produce more plants with those same traits.

Although many people were engaged in trying to make new, better, plants and animals for many years it was not until the work of Gregor Mendel in the nineteenth century that people began to be understood how traits were passed from one generation to the next. He did research on pea plants and discovered that traits were passed from one generation to the next in a way that could be predicated. Peas had a much simpler inheritance pattern than most organisms, so even with this knowledge it was very difficult for scientists to produce plants with the exact traits they wanted. Plants with the desired trait had to be cross bred, and then plants from the resulting generation that had the desired traits had to be selected and cross bred again and again. It takes many generations of plants to produce offspring that regularly have the desired trait.

Today, scientists do not have to cross breed plants repeatedly to get a new variety of plant that has the traits or characteristics they desire. Instead, they search for a gene in another plant that will produce the desired characteristics and insert it into the DNA of the original plant. Often two or three different genes are inserted, sometimes each from different plants or animals. Plants that have had this done are considered bioengineered. It is estimated that more than 50% of the soybeans grown in the United States, and more than 25% of the corn have been bioengineered in some way. About two-thirds of processed foods contain some form of bioengineered crop.

Bioengineered foods are regulated and monitored by three different government agencies: the United States Food and Drug Administration (FDA) the United States Department of Agriculture (USDA) and the Environmental Protection Agency (EPA). The FDA is responsible for the regulation and labeling of the bioengineered foods, the USDA oversees the safety and completeness of test fields used by bioengineering companies to test their new plants, and the EPA regulates any bioengineered plants that contain pesticide-related genes.

Before companies can put a genetically engineered food on the market they need to prove that it is safe for consumers. The FDA requires that companies prove that the bioengineered food is just as safe and nutritious as the non-bioengineered equivalent. This includes providing information for the FDA to review about the kinds of proteins synthesized by the new gene or genes, nutritional content, toxicology reports, and other information. Labeling of bioengineered foods is voluntary, and is left to the discretion of the company.

## Precautions

There is a small chance that some people might have an unexpected allergic reaction to proteins

## KEY TERMS

**Gene**—A section of DNA that includes information about how to create certain proteins

**Provitamin**—a substance that the body can convert into a vitamin

synthesized by plants that have been genetically modified. This is unlikely, however, as the FDA regulates bioengineered foods and requires tests for safety and the presence of known allergens before the food is allowed on the market.

### Interactions

There are no expected interactions between bioengineered foods and any other foods, medicines, or products.

### Complications

There are no complications expected from consuming bioengineered foods.

### Parental concerns

Some parents might be concerned that allergens that could affect their child might be introduced into unexpected plant species. Ninety percent of food allergies in the United States are to milk, eggs, fish, shellfish, nuts, wheat, and legumes (including peanuts and soybeans). The FDA ensures that each bioengineered food is tested to ensure that none of the common proteins that cause reactions before these foods can be sold to consumers. They also test for additional, less common, proteins that have been known to cause allergic reactions. It is extremely unlikely that a child who is allergic to one food would have a spontaneous reaction to another food product.

# Biotin

## Definition

Biotin, also known as vitamin H or vitamin $B_7$, belongs to the group of B-complex water-soluble **vitamins**. Humans make only a small amount of biotin, so most biotin must come from the foods they eat. Biotin is involved in conversion of **carbohydrates**, **fats**, and **protein** into usable energy in the body.

## Purpose

Biotin joins with enzymes that regulate the breakdown of foods and their use in the body. Some researchers believe that biotin also plays a role in the duplication and "reading" (replication and transcription) of deoxyribonucleic acid (DNA—genetic material). Biotin is often promoted as a dietary supplement to help improve the strength of fingernails and prevent hair loss. These claims are unproven.

## Description

Biotin is one of the less familiar B vitamins. It was discovered in the 1930s by researchers experimenting with different diets for chickens and rats, and later it was discovered to be essential to human health. Bacteria, yeasts, mold, algae, and some plants make biotin. The human large intestine (colon) contains some bacteria that synthesize biotin. Researchers believe that a portion of this biotin is absorbed into the bloodstream, but they are uncertain how much or how available it is to the body.

Biotin is essential to life because it combines with four different enzymes that control different metabolic reactions related to energy production and building new molecules from simple nutrients. These are:

- Forming glucose from fats and amino acids (but not from carbohydrates)
- Building fatty acids
- Synthesizing leucine, an amino acid necessary for health
- Metabolizing amino acids, cholesterol, and some fatty acids

**Biotin**

| Age | Recommended dietary allowance (mcg/day) |
|---|---|
| Children 0–6 mos. | 5 |
| Children 7–12 mos. | 6 |
| Children 1–3 yrs. | 8 |
| Children 4–8 yrs. | 12 |
| Children 9–13 yrs. | 20 |
| Children 14–-18 yrs. | 25 |
| Adults 19≥ yrs. | 30 |
| Pregnant women | 30 |
| Breastfeeding women | 35 |

| Food | Biotin (mcg) |
|---|---|
| Liver, cooked, 3 oz. | 27 |
| Egg, 1 cooked | 25 |
| Bread, whole wheat, 1 slice | 6 |
| Swiss chard, cooked, ½ cup | 5.2 |
| Salmon, cooked, 3 oz. | 4 |
| Chicken, cooked, 3 oz. | 3 |
| Cauliflower, raw, ½ cup | 2 |
| Pork, cooked, 3 oz. | 2 |

mcg = microgram

*(Illustration by GGS Information Services/Thomson Gale.)*

## KEY TERMS

**B-complex vitamins**—A group of water-soluble vitamins that often work together in the body. These include thiamine ($B_1$), riboflavin ($B_2$), niacin ($B_3$), pantothenic acid ($B_5$), pyridoxine ($B_6$), biotin ($B_7$ or vitamin H), folate/folic acid ($B_9$), and cobalamin ($B_{12}$).

**Coenzyme**—Also called a cofactor; a small non-protein molecule that binds to an enzyme and catalyzes (stimulates) enzyme-mediated reactions.

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Enzyme**—A protein that changes the rate of a chemical reaction within the body without themselves being used up in the reaction.

**Fatty acids**—Complex molecules found in fats and oils. Essential fatty acids are fatty acids the body needs but cannot synthesize. They are made by plants and must be present in the diet to maintain health.

**Glucose**—A simple sugar resulting from the breakdown of carbohydrates. Glucose circulates in the blood and is the main source of energy for the body.

**Vitamin**—A nutrient the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

**Water-soluble vitamin**—A vitamin that dissolves in water and can be removed from the body in urine.

Some researchers have found that biotin binds to proteins called histones that open up chromosomes so that their DNA becomes accessible and can be copied. If this is true, then biotin could play a role in gene expression.

Dietary supplement makers promote biotin to treat brittle fingernails, dry skin, and to prevent hair loss. It is sold as a dietary supplement in capsules or tablets, either alone, in a multivitamin, or combined with brewer's yeast. Biotin is also added to cosmetics and skin creams. In animal studies, biotin improves the condition of horse hooves, but no controlled studies have shown the same effect on human fingernails. Biotin deficiency does cause hair loss, but there is no proof that supplemental biotin prevents hair loss.

### *Normal biotin requirements*

The United States Institute of Medicine (IOM) of the National Academy of Sciences has developed values called **Dietary Reference Intakes** (DRIs) for vitamins and **minerals**. The DRIs consist of three sets of numbers. The Recommended Dietary Allowance (RDA) defines the average daily amount of the nutrient needed to meet the health needs of 97–98% of the population. The Adequate Intake (AI) is an estimate set when there is not enough information to determine an RDA. The Tolerable Upper Intake Level (UL) is the average maximum amount that can be taken daily without risking negative side effects. The DRIs are calculated for children, adult men, adult women, pregnant women, and **breastfeeding** women.

The IOM has not set RDA values for biotin because of incomplete scientific information. Instead, it has set AI levels for all age groups. AI levels for biotin are measured by weight (micrograms or mcg). No UL levels have been set for biotin because large doses of biotin do not appear to cause any side effects.

The following are the AIs for biotin for healthy individuals:

- Children birth–6 months: 5 mcg
- Children 7–12 months: 6 mcg
- Children 1–3 years: 8 mcg
- Children 4–8 years: 12 mcg

- Children 9–13 years: 20 mcg
- Children 14–18 years: 25 mcg
- Adults age 19 and older: 30 mcg
- Pregnant women: 30 mcg
- Breastfeeding women: 35 mcg

### *Sources of biotin*

Biotin is found in small quantities in many foods. Bacteria in the large intestine also make biotin. Unlike some vitamins, biotin is recycled and reused by the body. Daily intake does not need to be high because only small amounts are lost in urine. Biotin is stable and little is lost when foods are exposed to heat, light, or air.

The approximate biotin content in common foods is:

- Bread, whole wheat, 1 slice: 6 mcg
- Egg, 1 cooked: 25 mcg
- Liver, cooked, 3 ounces: 27 mcg
- Chicken, cooked, 3 ounces: 3 mcg
- Pork, cooked, 3 ounces: 2 mcg
- Salmon, cooked, 3 ounces: 4 mcg
- Swiss chard, cooked, 1/2 cup: 5.2 mcg
- Cauliflower, raw, 1/2 cup: 2 mcg

### *Biotin deficiency*

Biotin deficiency is very rare worldwide. Only a few conditions are known to cause biotin deficiency. Two rare inherited genetic disorders cause the body to need excessive amounts of biotin. These disorders are treated with high-dose biotin supplements. Prolonged (months or years) consumption of raw egg whitescan also cause a deficiency. A protein in raw egg whites binds biotin and makes it unavailable to the body. Cooking the egg releases the biotin. Receiving all nutrition through intravenous feeding (total parenteral nutrition or TPN) for an extended period may also lead to a shortage of biotin in the body.

Symptoms of biotin deficiency include skin and hair problems, such as a red scaly rash on the face, increased susceptibility to fungal infections, brittle hair, and hair loss. Individuals may also develop seizures, problems with coordination, and muscle cramps. Biotin deficiency has not been known to cause death. These symptoms have many other causes that should be considered first because biotin deficiency is so rare.

## Precautions

In many species, pregnant animals who are biotin deficient give birth to offspring with birth defects at a higher rate than animals who have adequate levels of biotin. The same effect has not been seen in humans. However, blood levels of biotin tend to drop in pregnant women, causing concern among researchers that pregnant women may develop marginal biotin deficiency with no visible symptoms. **Dietary supplements** of biotin are not routinely recommended for women who are pregnant, but these women should make a special effort to get an adequate intake of 30 mcg biotin daily through diet. Pregnant and breastfeeding women should not take a biotin dietary supplement unless directed by their healthcare provider.

## Interactions

Biotin is known to interact with a few drugs and dietary supplements.

- Antibiotics taken over a long period may reduce the amount of bacteria in the large intestine that synthesize biotin.
- Long-term use of drugs used to prevent seizures such as phenytoin (Dilantin), primidone (Mysoline), carbamazepine (Tegretol), phenobarbitol (Solfoton) and possibly valproic acid cause a reduction in the blood level of biotin.
- High doses of pantothenic acid may decrease the amount of biotin absorbed from the large intestine.

## Complications

No complications are expected from biotin. Even when large doses are taken for long periods, there are no reported side effects.

## Parental concerns

Biotin deficiency is rare and biotin excess is so benign that parents should have almost no concern about their children's biotin needs being met by diet.

**Purported benefits of the Blood Type diet**

**Blood type O**
Weight loss
Prevents blood clotting disorder and inflammatory diseases, including arthritis, hypothyroidism, ulcers, and asthma

**Blood type A**
Weight loss
Reduced risk of heart disease, cancer, anemia, liver and gallbladder disorders, and type I diabetes

**Blood type B**
Weight loss
Reduction of the risk of type I diabetes, chronic fatigue syndrome, and autoimmune disorders such as Lou Gehrig's disease, lupus, and multiple sclerosis

**Blood type AB**
Weight loss
Reduction in the risk of developing heart disease, cancer, or anemia

# Blood type diet

## Definition

The Blood Type diet is a way of eating that relies on an individual's blood type (A, B, AB, or O) to dictate one's diet. In his book, *Eat Right for Your Blood Type*, naturopathic doctor Peter D'Adamo, presents the idea that an individual's blood type determines which foods are healthy for him and which foods are not. The book presents the anthropological origins of each of the four blood types and explains why each blood type developed specific antibodies against certain foods.

Antibodies are proteins within the blood that identify and attack substances that are foreign to the body. Specific proteins called lectins are found in all foods. During digestion, lectins are released from the foods eaten. When they enter the blood stream, some of these lectins can bind to red blood cells causing them to stick together. This process is called agglutination. Dr. D'Adamo suggests this process causes many health problems such as stomach pains, poor digestion, headaches, diarrhea, liver disease, and kidney problems, and more.

The Blood Type diet includes extensive lists of foods that are beneficial for each blood type. The food lists also include foods that each blood type should avoid and foods that are neutral or benign. Dr. D'Adamo reports that following this diet will not only improve health but will help achieve an ideal weight.

## Origins

In 1901, Dr. Karl Landsteiner discovered that there were four types of human blood. He named them A, B, AB, and O. He discovered that blood types are not compatible with each other because of antibodies. These antibodies cause blood to clump together if a different blood type is mixed with it. According to Dr. D'Adamo, it was also discovered that foods can cause blood cells to become sticky and clump together in a process called agglutination.

Dr. D'Adamo's father, James, is also a naturopathic physician noticed that different diets worked better with some patients than others. In his book, *One Man's Food—Is Someone Else's Poison*, he attributed this to the differences in blood type.

Dr. Peter D'Adamo continued his father's research by studying the agglutination process that occurs between specific blood types and certain foods. He believes it is the result of the evolution of the unique blood types.

Anthropologists have traced the origins of each blood type. The earliest human blood type was type O. Since these people were ancient hunter-gatherers and ate a diet dominated by meat, blood type O individuals developed antibodies against the lectins found in agricultural foods such as wheat and other grains. Dr. D'Adamo suggests that individuals with type O blood should eat a diet more similar to their ancient ancestors—that is a diet with more meats and fewer grains.

## KEY TERMS

**Agglutination**—The clumping or clotting of cells.

**Anthropological**—Pertaining to anthropology or the study or the natural and cultural history of humans.

**Antibodies**—Proteins within blood that seek and destroy foreign bodies or substances in the body.

**Lectins**—Protein substances found in foods that bind with carbohydrates in blood causing it to clot.

**Naturopathy (naturopathic)**—An approach to medicine that does not use pharmaceuticals and surgery to treat disease but rather uses alternative therapies, supplements, special diets, and other natural remedies to help the body heal itself.

**Rh Factor**—Rh factor is a subset of blood type it may be either positive or negative.

The next blood type to evolve was type A. As the environmental conditions changed, humans began to grow food rather than hunt it. The diet shifted from predominantly meat to plant-based. As the diet changed and the blood type A evolved, antibodies for lectins to meat were formed. According to Dr. D'Adamo, individuals with blood type A have antibodies against many lectins found in meat and will benefit from a largely vegetarian or plant-based diet.

The next blood type to emerge was type B. As ancient peoples migrated and adapted to further climate change blood type B evolved. The diet included both meats and plants as well as dairy products. Dr. D'Adamo believes this is the reason individuals with blood type B developed fewer antibodies against lectins found in meat and grain. He also believes this is why people with blood type B are more tolerant of milk products than other blood types.

The final blood type to evolve was type AB. It is a rare blood type even today with fewer than 5% of the world's population having type AB blood. Type AB evolved when the A and B blood types intermingled. Dr D'Adamo describes this blood type as a complex blood type with many strengths and many contradictions.

### Description

D'Adamo divides all foods into sixteen food groups.

The food groups are:

- Meats and poultry, pork, and chicken Seafood-fish and shellfish
- Dairy and eggs—milk, yogurt, ice cream, cheese, and eggs
- Oils and fats—all oils such as peanut oil, linseed oil, sesame oil, etc.
- Nuts and seeds—all nuts or seeds
- Beans and legumes—all beans and peas
- Cereals—oats, barley, cream of wheat, corn flakes, puffed rice, etc.
- Breads and muffins—all baked goods such as loaf breads, crackers, etc.
- Grains and pasta—all flour, buckwheat, all noodles, spaghetti, etc.
- Vegetables—all vegetables, olives, peppers, and avocado
- Fruit—fresh fruits, dried fruits, and canned fruits
- Juices and fluids—all fruit juices fresh and concentrate
- Spices—all spices fresh and dried, syrups, miso, soy sauce, and other sauces that are not dairy based
- Condiments—mayonnaise, mustard, ketchup, jellies and jams, pickles, pickle relish,and salad dressing
- Herbal teas—all herbal teas
- Miscellaneous beverages—coffee, black tea, green tea, seltzer waters, colas, wine, beer, and liquor

Within each of the sixteen food groups, he describes individual foods as foods that encourage weight gain, foods that encourage weight loss, beneficial foods, neutral foods, and foods to avoid. In this way the diet is unique and individual for each blood type. For example, chicken is considered neutral for individuals with blood type O and blood type A and is found on the foods to avoid list for individuals with blood type B and blood type AB. Another example is grains such as wheat. Dr. D'Adamo reports there are no wheat products that are beneficial for people with type O blood. They are to be avoided. Similarly, he advises individuals with type B blood to avoid wheat as well. On the other hand wheat is highly beneficial for people with blood type A and neutral for those with blood type AB. There are recipes and sample menus for each blood type as well.

In addition to specific and detailed **dietary guidelines**, *Eat Right for Your Blood Type* also includes advice for each blood type concerning the impact of stress on the body and strategies for coping with stress.

Dr. D'Adamo outlines the best supplements for each blood type and addresses the best form of exercise for individuals of each blood type.

## Function

The Blood Type diet is based on the fact that all foods have lectins, or proteins that can interact with antibodies in blood. Dr. D'Adamo has tested most foods and determined which blood types react adversely to lectins in most foods.

When a specific food's lectin reacts with a specific blood type (A, B, AB, or O), it causes a process called agglutination to occur. In agglutination, the lectins cause the blood to become sticky. Dr. D'Adamo believes these sticky blood cells can lead to medical conditions such as impaired digestion, kidney and liver problems, headache, diabetes, **obesity**, and many others.

In order to reverse the problems caused by agglutination, an individual must avoid or limit the consumption of foods that cause it. Dr. D'Adamo has tested foods to determine which foods react adversely with which blood types. By following the Blood Type diet, these foods and the offending lectins may be avoided, and health may be improved.

In addition to the main blood types of A, B, AB, and O, there are many subtypes. These are other factors that are contained within your blood. These additional subtypes include secretor status and Rh. Rh is the part of blood that determines if a blood type is positive or negative. The Rh factor of blood type is not affected by diet; however, when blood type is reported, it is usually given as well.

Secretor status does influence the role diet plays in the functions of the body. Secretor status refers to whether or not blood type antigens, the part of the blood that determines type, are in other fluids of your body such as saliva and urine. Approximately 80% of all people are secretors. For these people, blood type can be determined by testing other bodily fluids. In the remaining 20% of the population, blood type antigens are found only in the blood. According to Dr. D'Adamo, secretors are more sensitive to interactions with food lectins. Secretors would have a more severe reaction over more systems in the body than non-sectretors. There is a test to determine if an individual is a secretor; however, since 80% of the population are secretors, chances are that most people who attempt the Blood Type diet are secretors.

## Benefits

Dr. D'Adamo reports health benefits in his patients that follow the Blood Type diet. His official website is full of testimonials from satisfied Blood Type diet followers. Not only do they report weight loss, but, according to Dr. D'Adamo, each blood type is more susceptible to certain illnesses than the others.

According to Dr. D'Adamo, the benefits of following the Blood Type diet for people with blood type A include weight loss and a reduced risk of heart disease, **cancer**, anemia, liver and gallbladder disorders, and type I diabetes.

For individuals with blood type B, the benefits if following the Blood Type diet include weight loss and a reduction of the risk of type I diabetes, chronic fatigue syndrome, and auto immune disorders such as Lou Gehrig's disease, lupus, and multiple sclerosis.

People with blood type AB who follow the Blood Type diet may lose weight and have a reduction in the risk of developing heart disease, cancer, or anemia.

For individuals with blood type O, following the Blood Type diet may help them lose weight and may prevent blood clotting disorder, inflammatory diseases such as arthritis, hypothyroidism, **ulcers**, and asthma.

Even critics of the diet suggest that features of the diet such as limiting the amount of saturated fat and highly processed "junk foods" will benefit most people.

## Precautions

Since blood type is a fixed characteristic of an individual, it never changes. Following a diet based on blood type would theoretically never need to change. However, there are many medical conditions that change as a person ages. Diseases may develop such as diabetes, **hypertension** (high blood pressure), and heart disease that may require an individual with type O blood to reduce consumption of meat and increase intake of fruits and vegetables. Following this diet may be harmful if variations in the diet necessary for health maintenance are not allowed.

Encouraging a specific blood type to gradually increase dairy consumption may cause discomfort to individuals with a natural lactose intolerance, regardless of blood type. Conversely limiting diary can lead to poor **calcium** intakes and bone related diseases

Certain individuals with **protein** deficiency or anemia may need to consume more meat to insure sufficient protein consumption, regardless of blood type.

## Risks

Unbalanced diets put one at risk of nutritional deficiencies or long term poor intakes that will affect

## QUESTIONS TO ASK YOUR DOCTOR

- Is this diet appropriate for me?
- How long should I follow this diet?
- Are there any special precautions I should follow?
- What are the potential health risks, if any, for me as an individual?
- Are there any drug precautions I should be aware of while following this diet?
- Will I need any dietary supplements if I adopt a this diet?
- In light of my other medical conditions, is this diet safe for me to follow?

one's health. This risk and the fact that there is no scientific evidence to back up the claims needs to be emphasized more strongly Since there is no data that confirms the efficacy of this diet for individuals with medical conditions that require careful monitoring of diet. Individuals with diseases such as diabetes, coronary artery disease, compromised liver function, or any kidney disease may not be able to follow a diet tailored for blood type alone.

## Research and general acceptance

### *General acceptance*

While many followers of the Blood Type diet report improved health and weight loss, the Blood Type diet is not widely accepted. Dr. D'Adamo cites many anthropological and microbiological studies to support his theories. However, critics argue there is virtually no data to support his diet plan. They charge that he has no well designed, well control studies to validate his claims that blood type is critical to the impact of diet. Noting that he has not conducted simple before and after blood studies to demonstrate his claim that lectin protein in foods cause blood cells to agglutinate or stick together.

Furthermore, they argue, if agglutination were as wide spread and common as Dr. D'Adamo claims, thousands of people would die each year from organ failure caused by this process and that pathologists would easily see evidence of this. Yet, no such evidence is presented or found in a review of the literature.

Additionally, critics argue that reducing people to a set of criteria based solely on blood type is tantamount to biological astrology. Characterizing all blood type O individuals as hunter-gatherers who need meat and blood type A individuals as more passive agrarians who will benefit most from a nearly vegetarian diet, they argue is far too simplistic for beings as genetically diverse and complex as humans.

### *Research*

There have been no controlled studies comparing those who follow the Blood Type diet with those who do not, or those who follow other diets. Dr. D'Adamo cites studies that demonstrate the effect of specific food lectin on animals such as rabbits which develop symptoms similar to arthritis when lentil lectins are injected into the knees of those sensitive to lentil lectins.

Dr. D'Adamo reports he has tested lectins from most common foods against individual blood types to determine which blood types are sensitive to the lectins of which foods.

Similarly, he reports measuring the impact of lectins on his patients by using the Indian Scale, a measure of the effectiveness of the bowels. Higher values on the Indian Scale indicate reduced function of the liver and intestines and increased levels of toxins. Dr. D'Adamo reports that the Indian Scale scores of his patients have decreased significantly after following the correct Blood Type diet.

Dr. D'Adamo cites multiple individual case studies of patients he has treated using the Blood Type diet with great success.

# Bob Greene's diet

## Definition

Bob Greene's diet is two separate but similar programs with two different websites *Get with the Program! (GWTP!)* and *The Best Life Diet*. *GWTP!* is divided into four phases: Truth, commitment, and self-control; Revving up your **metabolism**; Getting real about emotional eating; and Securing a life of health and emotional well-being. The Best Life Diet is comprised of three phases: establishing a regular pattern of exercise and eating; exploring the physical and emotional reasons for hunger; and learning weight management for life. Both programs are moderate and nutritionally balanced weight loss regimens combined with an exercise program and psychological introspection.

## Origins

Greene is a personal trainer with educational and professional credentials in physical education and exercise physiology. He maintains that his interest in health and fitness began as early as seven, when he was told that the reason his great-grandmother was bedridden was her excess weight. He noticed that many of his other relatives were overweight and began to read articles about food and nutrition in the daily newspaper.

After high school, Greene majored in physical education at the University of Delaware and completed a master's degree in exercise physiology at the University of Arizona. He worked as the director of exercise physiology for a medical management company and as the manager and trainer of the fitness staff at a health spa in Telluride, Colorado.

Both GWTP! and the Best Life program were preceded by Greene's first book, *Make the Connection: 10 Steps to a Better Body—And a Better Life*, which he co-authored with talk show host Oprah Winfrey and published in 1996. He met Winfrey while working at the spa in Telluride, later moving to Chicago to set up a training practice and make regular appearances on her television show.

## Description

### *Get with the Program!*

*GWTP!* is a four-phase program that focuses on the user's slow and gradual development of new eating and exercise habits. Dieters proceed through the phases of the program at their own pace. *GWTP!* emphasizes the importance of organization in personal weight loss.

**PHASE 1: TRUTH, COMMITMENT, AND SELF-CONTROL.** The theory behind this phase is that an individual will make healthier lifestyle choices if they care about their well-being. The program offers participants a contract they can use to make a commitment to themselves for a healthier lifestyle. The participant is encouraged to post it where it can be seen every day as a reminder of commitment. Physical exercise in this phase consists of flexibility, stretching, and range-of-motion exercises. Phase one should be completed in one to three weeks. Completion of the Phase 1 checklist signifies preparation for the next phase.

**PHASE 2: REVVING UP YOUR METABOLISM.** Many participants make the mistake of trying to cut back on calories too quickly rather than increasing their level of physical activity. Phase 2 introduces the participant to a physical fitness program that increases their body's rate of food metabolism. Exercise has an effect known as after-burn— the body burns calories at a higher rate for several hours after an exercise session, not only during the workout. It also reinforces the participant's commitment to more healthful eating because physical changes usually present fairly rapidly. Cardiovascular workouts average 50 to 75

## KEY TERMS

**After-burn**—The increased rate of body metabolism that lasts for several hours after a session of vigorous exercise.

**Emotional eating**—Term for eating to alter mood or relieve stress, boredom, or loneliness.

**Ovolactovegetarian**—A vegetarian who consumes eggs and dairy products as well as plant-based foods.

**Personal trainer**—An individual specializing in diet and exercise who works with clients on an individual basis.

**Pesce/pollo vegetarian**—A vegetarian who avoids the use of red meat but will include fish (*pesce* in Italian) or chicken (*pollo* in Italian) in the diet.

minutes per week in this phase. After one to three months, participants should be ready for Phase 3.

**PHASE 3: GETTING REAL ABOUT EMOTIONAL EATING.** The primary component of Phase 3 is recognizing emotional eating habits. The focus on this behavior is a distinctive feature of Greene's overall approach to health and fitness. A participant needs to understand the distinction between physical hunger and eating for such emotional reasons as boredom, loneliness, job-related stress, or general anxiety. In order to learn how to tell the difference, the participant is asked to choose a specific day and delay their normal meal times for several hours so that they can experience real physical hunger. (Diabetics are advised to consult their physician before undertaking this step). After reestablishing an awareness of physical hunger, the participant is advised to keep a journal in which events or other stimuli (television advertising, eating out, the smell of food from a nearby restaurant, assignment deadlines at work or school, etc.) that trigger episodes of emotional eating are recorded. In time, the person is encouraged to identify counterproductive patterns and behaviors of which they were previously unaware and take steps to modify the behavior. One such behavior modification involves substituting other activities for eating. Suggested activities include reading, taking a class, working on a hobby or craft, or going for a walk. Exercise during phase three is increased to 100 to 125 minutes per week. Phase 3 typically lasts one to three months.

**PHASE 4: SECURING A LIFE OF HEALTH AND EMOTIONAL WELL-BEING.** Phase four is focuses on enhancing the changes in activity level and conscious food choices made in the first three phases. By phase four the participant's exercise program has been scaled up to include weight training and advice is provided for continuing healthy eating habits. A checklist verifies that the participant met the major program goals. No specific timeline is provided for this phase since it leads to a lifetime of weight management using the tools acquired throughout the program.

*GWTP!* stresses many of the same themes in all four phases. Participants are continuously encouraged to increase their activity level, drink more **water**, become aware of what triggers their hunger, and eat sensibly. Guidelines for exercise are provided at each phase. Information about nutrition and making healthy food selections is also provided. Greene believes that many people overeat because they eat haphazardly, without any meal planning, and that this lack of structure is conducive to poor nutrition and exercise habits. He recommends a schedule of three meals and two snacks a day, with a cutoff point for stopping food consumption, namely two hours before bedtime.

### *The Best Life diet*

**PHASE 1: THE REV-UP.** The chief objective in the Best Life diet is to establish a regular pattern of exercise and eating. Phase 1 begins with an initial weigh-in followed by an increase in physical activity. The participant is allowed three meals plus one or two snacks daily, but no alcohol, and no eating for a minimum of two hours before bedtime. If the overall weight loss has been a pound or more per week and the daily objectives outlined in the plan are met consistently, the participant may move on to Phase 2 at the end of four weeks or continue in this phase until the objectives are met.

**PHASE 2: THE SWITCH.** Phase 2 emphasizes significant and consistent weight loss through controlling hunger and implementing changes in eating patterns. The participant is expected to explore the physical and emotional reasons for hunger, and to use a 10-point scale to rate feelings of hunger (1 = Your stomach acid is churning, 6 = You feel satisfied, and 10 = You are so full you feel nauseous). Participants are also expected to eat smaller food portions and remove six foods from their diet that lack nutritional value or are problem foods. Physical activity may be increased. Weight is checked every week for four weeks. When the participant is within 20 lb of their goal weight and the weight loss has stopped it is time to begin phase 3.

**PHASE 3: HAPPILY EVER AFTER.** This is the lifetime maintenance phase. The objective is to continue

improving the quality of the participant's diet for good health and long-term weight maintenance. The participant is asked to weigh themselves a minimum of once a month but no more than once a week. Additional nutritious foods should replace less wholesome foods on shopping lists and menus. Physical activity remains a focus and levels should be increased as the participant improves their fitness.

**SAMPLE MENUS.** Week 1, Day 1

- Breakfast: Skim milk, pear muffin, 1 fresh apple
- Snack: Low-fat yogurt
- Lunch: Walnut cannelini wrap + chopped green salad
- High-calcium snack: Whole-grain crackers with reduced-fat cheddar cheese
- Dinner: Pasta with chicken or shrimp + mixed green salad
- "Anytime treat": 1 oz piece of dark chocolate

Week 1, Day 2

- Breakfast: Best Life Kashi Go Lean Mix with pecans and skim milk, plus one half grapefruit
- Snack: Iced vanilla soy latte with graham cracker
- Lunch: Nut butter and pear whole-wheat sandwich + carrot sticks
- High-calcium snack: Maple-nut yogurt
- Dinner: Lemon and herb grilled trout + corn + sautéed sugar peas with ginger
- "Anytime treat":Low-fat ice cream

Both the *GWTP!* and *The Best Life Diet* programs are available either in book format or by joining the specific online program through Greene's Web sites. Both online programs are affiliated with eDiets.com and charge a weekly fee for membership, approximately US$5 per week. *GWTP!* is available in audio CD or audiotape formats as well.

The print editions of both books contain the core of Greene's diet plan. They are roughly 300 pages long and contain recipes, meal plans, and suggestions for reexamining and making changes in one's food choices. Many participants find the information in the books adequate for their needs. A daily journal is available for purchase with either program. Two additional books can be used with *GWTP!*: *Get with the Program! Guide to Good Eating* containing supplementary recipes and menu plans, and *Get with the Program! Guide to Fast Food and Family Restaurants* covering over 75 restaurants and how eat healthy off their menus.

Dieters who choose to pay a weekly fee for online membership in either *GWTP!* or the Best Life diet receive customized advice tailored to their age, weight, height, sex, and level of physical activity. The home page of each website invites the user to fill out an online form with this personal information as well as their goal weight. The online fee for *GWTP!* "Basic Training" includes the following:

- A workout plan based on the customer's general fitness needs and current activity level.
- 3-D animated exercises.
- 24/7 advice and support from experts
- Access to a support group moderated by eDiets.com nutrition and fitness experts.
- Menus, recipes, and shopping lists.
- Online tracking of the customer's progress.
- Current news articles on topics related to health, fitness, diet, nutrition, and emotional well-being

A personalized diet plan in addition to the fitness plan is available for an additional fee.

## Function

The function of Greene's diet plan is a restructuring of the participant's present eating and exercise habits, phased in gradually at the participant's own pace. This restructuring requires a committed intention to lose weight based on a willingness to look honestly at one's patterns of food consumption, including emotional as well as physical reasons for eating.

## Benefits

The benefits of Bob Greene's diet program are its commonsense approach to the necessity of personal commitment to change as well as lifestyle modifications if people wish to lose weight and keep it off. Many users find the plan's emphasis on introspection and emotional honesty helpful in breaking the psychological patterns that cause them to regain the pounds after a period of successful weight loss.

The flexibility of food choices built into the program makes it easier for participants with food allergies or those who must cook for or share meals with a family to use this plan. The foods Greene recommends are moderate in cost; there are no pricey recipes or ingredients in his plan. Vegetarians also find it easy to adjust for an ovolactovegetarian or pesce/pollo vegetarian diet.

## Precautions

Dieters who select the individualized programs offered on Greene's websites should check with their primary care physician to verify the physical exercises suggested for them are appropriate. Diabetics and

## QUESTIONS TO ASK YOUR DOCTOR

- What do you like and dislike about Bob Greene's programs?
- What is your opinion regarding the amount of exercise recommended?
- What aspects of these programs worked for other patients?

individuals with other medical conditions should also note Greene's warning regarding the importance of consulting their physician before undertaking the physical hunger experiment.

### Risks

Greene's diet plan does not pose any risks to health for users who have had a recent medical checkup and have consulted their health care provider about specific forms of exercise.

### Research and general acceptance

His educational background in exercise physiology adds credibility to his insistence on physical activity as an integral part of a long-term weight loss or weight maintenance regimen.

Most references to Bob Greene's diet are in popular print media—daily newspapers and monthly women's magazines with wide circulations—rather than medical or nutritional journals. Although Greene does not publicize his associations with celebrities, his websites as well as newspaper and magazine articles always emphasize that he is Oprah Winfrey's personal trainer. Crediting Winfrey as the co-author of his first book is generally regarded as the key to Greene's rapid success in the late 1990s.

There are no published reports on clinical trials of Bob Greene's diet plan as of 2007. Reviews of the diet plan by professional nutritionists are generally favorable; they typically describe it as a simple program that establishes the groundwork for a lifetime of healthy living. The programs are easy to follow and include **dietary guidelines** aligned with those recommended by the USDA. Greene is realistic about the difficulty of long-term weight loss and up-front about the commitment required to make long-term changes.

On the other hand, some nutritionists point out that Greene's diets require a greater time commitment for journaling and exercise than most people can manage on a regular basis.

# Body for Life diet

### Definition

Body for Life is a 12-week diet and rigorous exercise program designed by former competitive bodybuilder Bill Phillips. The program promises those who follow it faithfully that after 12 weeks they will not only have lost about 25 lb (10 kg) if they are

**Body for Life diet**

| 5–6 meals a day | Foods approved |
|---|---|
| Lean protein-rich food<br>Portion equal to dieter's hand | Lean poultry, most fish and seafood, egg whites, low-fat cottage cheese, and lean beef and ham<br>For vegetarians, approved proteins include tempeh, soy, textured vegetable protein, and seitan |
| Unrefined or whole-grain carbohydrates<br>Portion equal to dieter's fist | Baked potato, sweet potato, brown and white rice, pasta, whole-wheat bread, whole-wheat tortillas, dried beans, oatmeal, and whole grains such as quinoa. Approved carbohydrates include apples, melon, strawberries, oranges, and corn |
| Vegetable portion (eaten a least two meals)<br>Portion equal to dieter's fist | Lettuce, tomato, carrots, broccoli, cauliflower, asparagus, spinach, mushrooms, zucchini, peas, bell peppers, celery, and onions. Served plain, without sauce |
| Water | 10 or more glasses daily |

Supplement diet with 1 tbsp. daily of oil high in monounsaturated fats (can include unsaturated oils such as canola, olive, safflower, or flaxseed); salmon three times a week; or avocados, natural peanut butter, or a handful of nuts or seeds daily

*(Illustration by GGS Information Services/Thomson Gale.)*

overweight, but they have a new shape and more muscular body.

## Origins

Bill Phillips, the originator of the Body for Life program, is a former bodybuilder and was the founder of EAS, a dietary supplement manufacturer. In Body for Life, he has taken some of the principles of bodybuilding and incorporated them into a motivational program that is easily understandable to the general public. In 1996, when Phillips still owned EAS (he has since sold the company), he began the "EAS Grand Spokesperson Challenge." The following year he changed its name to the Body for Life Challenge. This is a self-improvement competition based on the Body for Life program.

The Body for Life program became widely known with the publication of *Body for Life: 12 Weeks to Mental and Physical Strength*. in 1999. Other books, videos, and a Web site have followed. Phillips claims that in a decade more than 2 million people have successfully changed their bodies and their lives through the Body for Life program.

## Description

Body for Life is both a diet and a rigorous exercise program served up with a big helping of motivational psychology. The diet part of the plan is relatively simple and offers some benefits over other plans in that it does not require calorie counting or careful measuring of food.

### *Diet*

The Body for Life diet works this way. For 12 weeks, people eat five or six small meals a day. The meals consist of a portion of lean, protein-rich food, and a portion of unrefined or whole-grain **carbohydrates**. In addition, at least two meals daily must include a vegetable portion, and the diet should be supplemented by one tablespoon daily of oil high in monounsaturated **fats**. A portion is defined as the being equal to the size and thickness of the dieter's hand (**protein**) or fist (carbohydrates and vegetables). Dieters estimate portion size rather than measuring.

Approved proteins include lean poultry, most fish and seafood, egg whites, low-fat cottage cheese, and, unlike many diets, lean beef and ham. For vegetarians, approved proteins include tempeh, **soy**, textured vegetable protein, and seitan. Vegetarians will have a hard time meeting the protein requirements of this diet. Vegans will most likely not be able to.

Approved carbohydrates include baked potato, sweet potato, both brown and white rice, pasta, whole wheat bread, whole wheat tortillas, dried beans, oatmeal, and whole grains such as quinoa. Also included in the approved carbohydrates list are apples, melon, strawberries, oranges, and corn. This is a much less restrictive list of carbohydrates than appears in many diets.

Approved vegetables include lettuce, tomato, carrots, broccoli, cauliflower, asparagus, spinach, mushrooms, zucchini, peas, bell peppers, celery, and onions. All are to be served as plain vegetables without sauce. The daily oil allotment can come from salad dressing.

The fats requirement of this diet can be met with unsaturated oils such as canola, olive, safflower, or **flaxseed**, but also through eating salmon three times a week or with avocados, natural peanut butter, or a handful of nuts or seeds daily.

In addition to allowed foods, the dieter is required to drink 10 or more glasses of **water** daily. The diet is to be followed rigorously for six days. On the seventh day, the dieter can eat anything he or she wants. Overall, this diet allows more different foods than many diets, but it is a high protein, **low fat diet** with about half the calories consumed coming from protein and very few from fats. Generally dietitians recommend a diet that is about 55% carbohydrates, with emphasis on whole-grain carbohydrates, 15–20% protein, and

## KEY TERMS

**Dietary supplement**—a product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health

**Glycogen**—A compound made when the level of glucose (sugar) in the blood is too high. Glycogen is stored in the liver and muscles for release when blood glucose levels are too low.

**Hormone**—a chemical messenger that is produced by one type of cell and travels through the bloodstream to change the metabolism of a different type of cell

**Insulin**—a hormone made by the pancreas that controls blood glucose (sugar) levels by moving excess glucose into muscle, liver, and other cells for storage.

**Pancreas**—a gland near the liver and stomach that secretes digestive fluid into the intestine and the hormones insulin and glucagon into the bloodstream.

**Quinoa**—a high-protein grain native to South America (pronounced keen-wah)

no more than 30% fat. On the positive side, the diet recommends unsaturated fats and restricts sweets, junk food, and empty calories that add few nutrients. One troubling thing about the diet is that Phillips repeatedly recommends **dietary supplements** made by his former company.

### *Exercise*

The exercise portion of Body for Life is more complicated than the food portion. It consists of a two-week block of exercises. Forty-five minute weight-training exercises for either the upper or lower body alternate with a minimum of 20-minute aerobic exercises with every seventh day as a day of rest.

Exercises are to be done at specific levels of exertion using a 10-point rating scale developed by the American College of Sports Medicine. This scale allows the level of difficulty to be personalized to the individual. Most exercises consist of multiple repetitions beginning around level 5, (hard, but with plenty of reserves to continue). They move on to a completely flat effort at level 10 where the individual is putting out the maximal effort possible. These exercises are difficult, and they are intended to be that way. Phillips believes that short bursts of maximal exercise burn more calories than longer exercise periods at lower intensities. Another drawback is that these exercises are best done in a gym with equipment and a supervised environment because of their intensity.

### *Motivation*

Bill Phillips uses strong motivational techniques to help people succeed in the Body for Life Program. The program asks the dieter to determine his or her reasons for wanting to change and then set a goal for that change. Phillips then applies the psychology of competition by encouraging people to become involved in the Body for Life Challenge. This is a contest to see which dieter can improve his or her body the most using the program. Prizes in 2007 were substantial. The grand prize was $50,000, a home gym, and a $5,000 gift certificate for EAS supplement products. Eight category champions receive $20,000, a home gym, and a $2,500 gift certificate for EAS products. The official Body for Life Web site offers inspiring stories and pictures of former champions and plenty of tips and information on how to succeed.

## Function

The theory behind the Body for Life diet is that eating may small meals high in protein during the day helps keep insulin levels steady and boosts **metabolism** so that the body burns calories at a higher rate. Insulin is a hormone that regulates blood glucose (sugar) levels in the body. When blood glucose is too high, cells store the extra glucose as glycogen or fat. In addition, Phillips says that protein suppresses energy and is essential for building muscle mass. The goal of the Body for Life plan is not just to lose weight, but to develop a sculpted body.

## Benefits

With increased exercise, a low fat, **high protein diet**, and reduced portion sizes, Body for Life does help people lose weight rapidly. People do gain muscle and strength through exercise. The main drawback to achieving these benefits is the rigorousness of the program and the difficulty people have staying on it. Eating five or six times a day and finding time to exercise daily requires a major lifestyle change. The committed will see benefits, but this program is definitely not for everyone.

## QUESTIONS TO ASK THE DOCTOR

- Are there health risks to me caused by the level of exercise Body for Life requires?
- Is there another diet and exercise program that would meet my needs better?
- Will following this rigorous diet for 12 weeks help me achieve long-term weight loss?
- How much will I have to exercise to maintain my muscle mass and strength after the diet ends?
- Do I really need dietary supplements? Are EAS supplements the best for my needs?
- Would you recommend someone in your family going on this diet?

### Precautions

Because of the high level of exercise involved in this program, dieters should talk to their doctor about whether their physical condition will allow them to participate. This is probably not a good program for people with heart or respiratory problems. Children and teens who are still growing, and pregnant women also are unlikely candidates for this program. People with kidney disease should discuss the diet aspect of the program with their doctor since their kidneys may not be able to handle a high protein diet. Anecdotally, the program appears to be most successful with out-of-shape athletes who want to lose weight and get back in shape.

### Risks

People who are not used to the level of exercise required by Body for Life are at high risk for develop injuries as a result of the exercise component of the program. In addition, many **obesity** experts feel that rapid weight loss, that is loss of more than 1–1.5 lb (0.5–7 kg) per week, increases the chance of **weight cycling** or putting the weight back on once the dieter begins eating a regular diet. Weight cycling is thought to have some harmful cardiovascular effects.

### Research and general acceptance

No scholarly research has been done on Body for Life. However, bodybuilders have used the diet and exercise principles behind the program for many years. Nutritionists like the idea of eating many small meals during the day and of using only unsaturated fats. They tend to dislike the high protein content of the diet. The thing nutritionists tend to criticize most strongly, however, is the need for dietary supplements in this program. Body for Life unabashedly pushes dieters to use EAS supplements. Many nutritionists feel that a good, healthy diet should not require protein shakes and other supplements beyond perhaps a multivitamin for certain dieters.

# Body image

### Definition

Body image is a person's mental opinion or description of his or her own physical appearance. It also involves the reactions of others toward that person's physical body based on what is perceived by that person. The concept of body image slowly develops

**Steps to help your child develop a positive body image**

- Make sure your child understands that weight gain is a normal part of development, especially during puberty
- Avoid negative statements about food, weight, and body size and shape
- Allow your child to make decisions about food, while making sure that plenty of healthy and nutritious meals and snacks are available
- Compliment your child on her or his efforts, talents, accomplishments, and personal values
- Restrict television viewing, and watch television with your child and discuss the media images you see
- Encourage your school to enact policies against size and sexual discrimination, harassment, teasing, and name-calling; and support the elimination of public weigh-ins and fat measurements
- Keep the communication lines with your child open

SOURCE: National Women's Health Information Center, U.S. Department of Health and Human Services

*(Illustration by GGS Information Services/Thomson Gale.)*

over time, generally beginning in infancy. Perception of body image among people can widely range from very negative to very positive. Depending on age and other factors, the degree of concern with body image can also widely vary among an individual.

A person who has a poor body image perceives their body as unattractive to others, while someone with a good body image views their body as being attractive to others. Body image is studied within the area of psychoanalysis, which is a psychological theory that involves mental functions of humans both consciously and unconsciously.

Generally, within psychoanalytic study, body image is not related to any objective measure (based on facts) but is subjective (based on opinions and feelings) in nature. Consequently, one's opinion of their own body image may or may not parallel how others judge that person's body image. For instance, people judging a person may view that person as attractive, however, that person may judge themselves as having an unattractive body image. On the other hand, a person may perceive their body image as attractive but be judged unattractive by most people who come in contact with the person.

Body image, especially with young people going through puberty (a stage of physical and mental development that begins sexual reproduction), can become a problem especially when parents are overly concerned with their children's weights and appearances; parents, especially mothers, are very self aware with their own weights and appearance; other children use excess pressure on their peers (fellow children) to look or act a particular way; and mass media advertisements and other such means that try to actively imply a certain body look (such as, thin is an ideal body image). Body image is also closely associated with self-esteem, which is defined as the amount of value and worthiness a person inwardly feels.

## KEY TERMS

**Anorexia nervosa**—A mental eating disorder that features an extreme fear and obsession of becoming overweight, which leads to extreme forms of dieting even with incidences that result in sickness and sometimes even death.

**Binge eating disorder**—A mental eating disorder that features the consumption of large amounts of food in short periods of time.

**Body dysmorphic disorder**—A mental disorder that features a distorted or disturbed body image by the subject who is very critical of their physical body and body image even though no defect is easily visible.

**Bulimia**—A mental eating disorder that is characterized by periods of overeating followed with periods of undereating.

**Narcissism**—Excessive admiration of one's self.

**Objective**—Based on facts.

**Obsessive compulsive disorder**—A mental disorder that is characterized by obsessive thoughts and related compulsive activities that in the subject's mind are attempts to counter and remove the unusual thoughts.

**Psychoanalysis**—A psychological theory that concerns the mental functions of humans both on the conscious and unconscious levels.

**Puberty**—A stage of physiological maturity that marks the start of being capable of sexual reproduction.

**Subjective**—Based on feelings and opinions.

Older children and young adults are more concerned about how other people view them than other age groups, so are much more sensitive with body image and vulnerable to external pressures. This can affect their self-esteem as their body goes through dramatic changes from adolescence to adulthood (puberty). Boys may be overly concerned with height when seeing girls of their same age growing upward faster. Girls may feel sensitive about their height, weight, or other noticeable changes happening within their body.

Statistically, according to the National Eating Disorders Association, 91% of young college women

report having been on at least one diet. Seventy percent of young college men report being unhappy with their body image—with 32% of all college men stating that they have been on one or more diets. Other studies show similar percentages in older children and young adults, which help to support the contention that young people are very concerned with body image—a body image where the ideal is to be very slim.

## Purpose

Scientists have found that body image is first formed as an infant during contact, or lack of contact, with people such as parents and family members. Personal contacts in the form of hugs, kisses, and other forms of affection can help develop an early positive body image. Lack of such contact, can have the opposite effect, forming an early negative body image.

The purpose of body image is generally used as a way for individuals to compare themselves against a model (ideal) image and for people to compare others through physical traits and characteristics. It is usually measured against an ideal body shape with respect to various physical characterizations such as facial features and overall body weight of the human body including fatness and muscle mass.

Within the field of psychoanalysis, a person's body image is often measured by asking a person to rate parts of his/her current body (such as face, stomach, and buttocks) with respect to a series of pictures representing an ideal body image. The difference in rating between a person's current body image and a perceived idea body image is generally considered the amount a person is dissatisfied with their body.

## Description

Concern with body image is generally more important with women than it is with men. Women usually are more critical of their overall body and individual parts of their body than are men. However, the gap between the two genders has been narrowing over recent years as men become more concerned with their body image.

A perception of a poor body image often relates with a feeling of being overweight, especially with women. Men, on the other hand, desire more muscle mass when considering their body image. Their feeling to be more masculine parallels this desire to add additional muscle mass and to produce more definition in their current muscles.

Generally, a poor body image can lead to constant and fad dieting, **obesity**, and eating disorders, along with low self-esteem, depression, anxiety, and overall emotional distress. However, for the most part, people with good exercise habits, positive personal and sexual experiences, and excellent emotional and mental states have better and more accurate perceptions of their body image than people without those characteristics and experiences. These people also have fewer problems associated with a poor body image.

## Precautions

Exaggerated and distorted concerns with body image have been linked in medical studies with decreases in self esteem and increases in dieting and eating disorders, including **anorexia nervosa**, **binge eating** disorder, and bulimia. People with body image problems can also have a condition called body dysmorphic disorder, which involves a distorted body image without any eating disorders. Excessive preoccupation with body image and an exaggerated obsession on positive body image has, in the past, been associated with the personality disorder called narcissism (self-admiration, or an overestimation about one's appearance).

## Interactions

Body image can be affected by outside influences. Media sources, such as television, the Internet, and magazines, often portray people closer to the commonly accepted ideal body type than the average body image in order to sell their products and services. Consequently, people, especially older children and young adults, are overly influenced and swayed by such depictions of body image. For instance, according to Association Body Image for Disordered Eating (ABIDE), the average U.S. citizen was exposed to about 5,000 advertising messages each and every day in 2003. Studies of network television commercials have shown that attractiveness is a desirable trait that advertisers regularly use to convince viewers to purchase their products.

Family life can also affect a person's perception of their body image. Parents that criticize their children, such as in the way they look, talk, or act, often may have a negative effect on the development of self-esteem in their offspring.

Young people may also be affected by the comments of classmates and peers when it comes to their body image. Teasing is often a method used by young people to convey negative comments and hurtful words. Teasing can come in a form of being too small or too large; too smart or too dumb; too popular or not very popular; and any of a number of other

characterizations. Racial, sexual, and other types of teasing are mores serious and can have a negative impact on body image and self-esteem. Children often try to pressure their peers to conform to what is currently popular in clothing styles, language, and other characteristics—all that can potentially hurt one's perception of their body image.

### Complications

Without a healthy regard for one's self, people can often become very self-conscious of their body image. Sometimes feelings of depression, anxiety, and isolation occur. With low self-esteem and body image problems, some people use alcohol or drugs to offset those negative feelings. Others turn away from their regular activities and their usual friends—becoming withdrawn and showing lack of interest in themselves and the world around them.

Sometimes, a person can recover from such feelings by re-focusing their life on good qualities, accepting things that cannot be changed, and realistically working on things can could be improved. In some cases, outside help is needed in the form of a guidance counselor, parent, coach, religious leader, or someone else that is trusted and accepting of personal feelings. Crisis hotlines are also available to help with such problems.

### Parental concerns

Parents should be concerned if their children have excessive concerns about their appearance and looks. All children will be concerned with some aspect of their body. This concern is normal and is not a medical problem. However, an obsession with one's physical body and appearance is not normal. In fact, an obsession with one's body image is called body dysmorphic disorder (BDD).

The mental disorder called BDD usually appears in adolescence, already a period in one's life that causes sensitivities in one's appearance and body image. In BDD, the person is very critical of their body image even though nothing out of the ordinary is seen by anyone looking at the person. The major criteria for BDD involve a preoccupation with an imagined defect in one's appearance or an excessive concern with a minor physical blemish or flaw; a reaction that produces excessive distress in one's social and personal life and/or impairs one's professional life; and a medical diagnosis that eliminates the cause from being other mental disorders.

Symptoms of BDD include compulsive use of mirrors and other reflective objects, social withdrawal, abnormal grooming behaviors, compulsive touching of one's skin and body, obsession with plastic surgery, lowered self-esteem, and compulsive attraction toward one or more celebrity figures (often with features that the subject feels they are lacking). The body parts most often the topic of a BDD person's attention are skin and hair, general face (especially nose, chin, teeth, and lips), stomach, breasts/chest/nipples, eyes and eyebrows, general legs (especially thighs), and buttocks. The person is often concerned with their weight, body build, and bone structure.

BDD can often leads to depression, anxiety (especially when in social situations), obsessive compulsive disorder, and suicide. Parents should be aware of any BDD symptoms in their children and consult with their family doctor about their concerns for the health and well-being of their children.

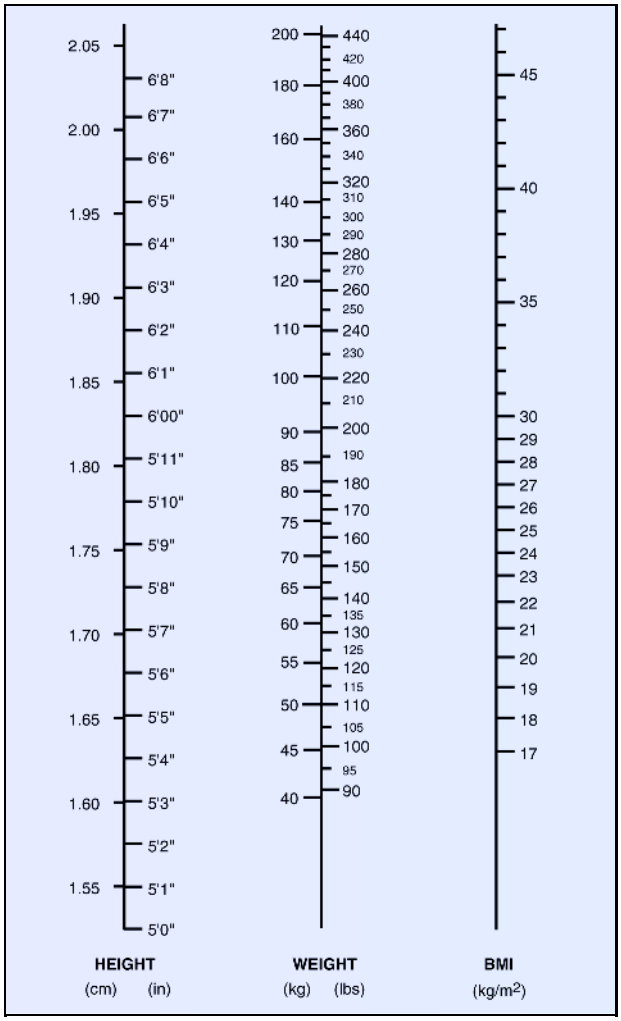
## Body mass index

### Definition

Body mass index (BMI), also called the Quetelet Index, is a calculation used to determine an individual's amount of body fat.



**Body/mass index can be calculated by locating your height and weight on the chart and drawing a diagonal line between the two. Where the line crosses over the third bar is the approximate BMI.** *(Illustration by Argosi, Inc./Thomson Gale.)*

## Purpose

The BMI gives healthcare professionals a consistent way of assessing their patients' weight and an objective way of discussing it with them. It is also useful in suggesting the degree to which the patient may be at risk for obesity-related diseases.

## Description

BMI is a statistical calculation intended as an assessment tool. It can be applied to groups of people to determine trends or it can be applied to individuals. When applied to individuals, it is only one of several assessments used to determine health risks related to being underweight, overweight, or obese.

### *The history of BMI*

The formula used to calculate BMI was developed more than one hundred years ago by Belgian mathematician and scientist Lambert Adolphe Quetelet (1796-1874). Quetelet, who called his calculation the Quetelet Index of **Obesity**, was one of the first statisticians to apply the concept of a regular bell-shaped statistical distribution to physical and behavioral features of humans. He believed that by careful measurement and statistical analysis, the general characteristics of populations could be mathematically determined. Mathematically describing the traits of a population led him to the concept of the hypothetical "average man" against which other individuals could be measured. In his quest to describe the weight to height relationship in the average man, he developed the formula for calculating the body mass index.

Calculating BMI requires two measurements: weight and height. To calculate BMI using metric units, weight in kilograms (kg) is divided by the height squared measured in meters (m). To calculate BMI in imperial units, weight in pounds (lb) is divided by height squared in inches (in) and then multiplied by 703. This calculation produces a number that is the individual's BMI. This number, when compared to the statistical distribution of BMIs for adults ages 20–29, indicates whether the individual is underweight, average weight, overweight, or obese. The 20–29 age group was chosen as the standard because it represents fully developed adults at the point in their lives when they statistically have the least amount of body fat. The formula for calculating the BMI of children is the same as for adults, but the resulting number is interpreted differently.

Although the formula for calculating BMI was developed in the mid-1800s, it was not commonly used in the United States before the mid-1980s. Until then, fatness or thinness was determined by tables that set an ideal weight or weight range for each height. Heights were measured in one-inch intervals, and the ideal weight range was calculated separately for men and women. The information used to develop these ideal weight-for-height tables came from several decades of data compiled by life insurance companies. These tables determined the probability of death as it related to height and weight and were used by the companies to set life insurance rates. The data excluded anyone with a chronic disease or anyone who, for whatever health reason, could not obtain life insurance.

Interest in using the BMI in the United States increased in the early 1980s when researchers became concerned that Americans were rapidly becoming

## KEY TERMS

**Anorexia nervosa**—A psychiatric disorder signified by obsession with weight loss and voluntary self-starvation accompanied by serious, potentially fatal health problems.

**Morbid obesity**—A term used to describe individuals 100 lb (45 kg) or more than 50% overweight and/or who have a body mass index above 40.

**Triglycerides**—A type of fat found in the blood. High levels of triglycerides can increase the risk of coronary artery disease.

obese. In 1984 the national percentage of overweight individuals was reported in a major assessment of the nation's health. Men having a BMI of 28 or greater were considered overweight. This BMI number was chosen to define overweight because 85% of American men ages 20–29 fell below it. A different calculation, not BMI, was used for women in the report.

In 1985, the term overweight was redefined as a BMI equal to or greater than 27.8 for men and equal to or greater than 27.3 for women. No BMI was selected to define underweight individuals. This definition of overweight was used in reports on obesity until 1998. In 1998, the United States National Institutes of Health revised its weight definitions to bring them in line with the definitions used by the World Health Organization. Overnight 30 million Americans went from being classified as normal weight to being classified as overweight. Overweight is now defined for both men and women as a BMI of 25 or less. At the same time, an underweight classification was added, as was the classification of obese for individuals with a BMI greater than or equal to 30.

### *Interpreting BMI calculations for adults*

All adults age 20 and older are evaluated on the same BMI scale as follows:

- BMI below 18.5: Underweight
- BMI 18.5–24.9: Normal weight
- BMI 25.0–29.9: Overweight
- BMI 30 and above: Obese

Some researchers consider a BMI of 17 or below an indication of serious, health-threatening malnourishment. In developed countries, a BMI this low in the absence of disease is often an indication **anorexia nervosa**. At the other end of the scale, a BMI of 40 or greater indicates morbid obesity that carries a very high risk of developing obesity-related diseases such as stroke, heart attack, and type 2 diabetes.

### *Interpreting BMI calculations for children and teens*

The formula for calculating the BMI of children ages 2–20 is the same as the formula used in calculating adult BMIs, but the results are interpreted differently. Interpretation of BMI for children takes into consideration that the amount of body fat changes as children grow and that the amount of body fat is different in boys and girls of the same age and weight.

Instead of assigning a child to a specific weight category based on their BMI, a child's BMI is compared to other children of the same age and sex. Children are then assigned a percentile based on their BMI. The percentile provides a comparison between their weight and that of other children the same age and gender. For example, if a girl is in the 75th percentile for her age group, 75 of every 100 children who are her age weigh less than she does and 25 of every 100 weigh more than she does. The weight categories for children are:

- Below the 5th percentile: Underweight
- 5th percentile to less than the 85th percentile: Healthy weight
- 85th percentile to less than the 95th percentile: At risk of overweight
- 95th percentile and above: Overweight

### *Application of BMI information*

The BMI was originally designed to observe groups of people. It is still used to spot trends, such as increasing weight in a particular age group over time. It is also a valuable tool for comparing body mass among different ethnic or cultural groups, and can indicate to what degree populations are undernourished or overnourished.

When applied to individuals, the BMI is not a diagnostic tool. Although there is an established link between BMI and the prevalence of certain diseases such as type 2 diabetes, some cancers, and cardiovascular disease, BMI alone is not intended to predict the likelihood of an individual developing these diseases. The National Heart, Lung, and Blood Institute recommends that the following measures be used to assess the impact of weight on health:

- BMI
- Waist circumference (an alternate measure of body fat)

- Risk factors for disease associated with obesity. These include high blood pressure, high LDL or "bad" cholesterol
- Low HDL or "good" cholesterol
- High blood glucose (sugar)
- High triglycerides
- Family history of cardiovascular disease
- Low physical activity level
- Cigarette smoking

### Precautions

BMI is very accurate when defining characteristics of populations, but less accurate when applied to individuals. However, because it is inexpensive and easy to determine BMI is widely used. Calculating BMI requires a scale, a measuring rod, and the ability to do simple arithmetic or use a calculator. Potential limitations of BMI when applied to individuals are:

- BMI does not distinguish between fat and muscle. BMI tends to overestimate the degree of "fatness" among elite athletes in sports such as football, weightlifting, and bodybuilding. Since muscle weighs more than fat, many athletes who develop heavily muscled bodies are classified as overweight, even though they have a low percentage of body fat and are in top physical condition.
- BMI tends to underestimate the degree of fatness in the elderly as muscle and bone mass is lost and replaced by fat for the same reason it overestimates fatness in athletes.
- BMI makes no distinction between body types. People with large frames (big boned) are held to the same standards as people with small frames.
- BMI weight classes have absolute cut-offs, while in many cases health risks change gradually along with changing BMIs. A person with a BMI of 24.9 is classified as normal weight, while one with a BMI of 25.1 is overweight. In reality, their health risks may be quite similar.
- BMI does not take into consideration diseases or drugs that may cause significant water retention.
- BMI makes no distinction between genders, races, or ethnicities. Two people with the same BMI may have different health risks because of their gender or genetic heritage.

BMI is a comparative index and does not measure the amount of body fat directly. Other methods do give a direct measure of body fat, but these methods generally are expensive and require specialized equipment and training to be performed accurately. Among them are measurement of skin fold thickness, underwater (hydrostatic) weighing, bioelectrical impedance, and dual-energy x-ray absorptiometry (DXA). Combining BMI, waist circumference, family health history, and lifestyle analysis gives healthcare providers enough information to analyze health risks related to weight at minimal cost to the patient.

### Parental concerns

**Childhood obesity** is an increasing concern. Research shows that overweight children are more likely to become obese adults than normal weight children. Excess weight in childhood is also linked to early development of type 2 diabetes, cardiovascular disease, and early onset of certain cancers. In addition, overweight or severely underweight children often pay a heavy social and emotional price as objects of scorn or teasing.

Both the American Academy of Pediatrics (AAP) and the United States Centers for Disease Control and Prevention (CDC) recommend that the BMI of children over age two be reviewed at regular intervals during pediatric visits. Parents of children whose BMI falls above the 85th percentile (at risk of being overweight and overweight categories) should seek information from their healthcare provider about health risks related to a high BMI and guidance on how to moderate their child's weight. Strenuous dieting is rarely advised for growing children, but healthcare providers can give guidance on improving the chid's diet, eliminating empty calories (such as those found in soda and candy) and increasing the child's activity level in order to burn more calories and improve fitness.

Tish Davidson, A.M.

## Bodybuilding diet

### Definition

The bodybuilding diet is designed to build muscle and reduce body fat. It emphasizes foods high in **protein** and complex **carbohydrates**, such as whole grain bread, pasta, and cereal. There are many variations of the bodybuilding diet but an essential component remains the same throughout, a regular strength-building exercise building program.

### Origins

Many scholars believe bodybuilding diets began with the ancient Greeks, whose gods, like Hercules

and Apollo, were often portrayed as quite muscular. This influenced ancient Greek society to emulate the concept of a perfect physique. The same desire for physical perfection is found in ancient Rome and Egypt. The modern era of bodybuilding began in the late 1800s in England; German strongman Eugen Sandow is credited with being the first professional bodybuilder of the modern era. He was a featured attraction at the 1893 World Columbian Exposition in Chicago for his feats of strength. He opened a chain of 20 weight training studios in England and published a magazine that included tips on diet. Sandow's own diet was high in calories, protein, carbohydrates, and **fats**.

## Description

A bodybuilding diet generally contains 2,500–5,500 calories per day for men and 1,500–3,000 calories daily for women, depending on the types and levels of exercise. The diet's ratio of protein, carbohydrates, and fat can differ. Some programs recommend 40% carbohydrates, 40% protein, and 20% fats. Others suggest a ratio of 40% protein, 30% carbohydrates, and 30% fat. There are many variations of this diet where the calorie intake and ratios are different. Most bodybuilding diets include nutritional supplements as well as protein powders. The focus of bodybuilding has shifted away from an emphasis on health toward an emphasis on appearance at all costs. To achieve a bigger, better body, many bodybuilders have placed a huge emphasis on nutritional and other types of supplements, including the illegal use of steroids.

All diets require an exercise routine of three to seven days a week, usually with weightlifting and cardiovascular exercises. The body burns up to 50 calories per day for every pound of muscle. So adding 10 pounds of muscle can burn up to 500 extra calories each day. The exact diet and exercise routine can vary greatly and can be confusing, especially to people new to bodybuilding. When it comes to either diet or exercise, no two people follow the same routine.

### *Basic nutrition of bodybuilding*

The three main components of a bodybuilding diet are the three **macronutrients**: carbohydrates, protein, and fat.

**CARBOHYDRATES.** Carbohydrates are the main source of energy for the body. They are especially important in aerobic exercise and high-volume weight training, including aiding in muscle recovery. Eating carbohydrates causes the pancreas to release the hormone insulin, which helps regulate blood glucose (sugar) levels. Insulin takes carbohydrates and stores them as fat, in muscle, or in the liver as glycogen. Insulin also takes amino acids from protein and stores them in muscle cells that aid in recovery and repair following strength-building exercise. All carbohydrates are broken down into glucose by the body and released into the blood; the speed at which this process occurs varies depending on the type of carbohydrate

## KEY TERMS

**Amino acids**—A group of organic acids that are constituents of protein.

**Carbohydrates**—An organic compound that is an important source of food and energy.

**Cardiovascular**—Pertaining to the heart and blood vessels.

**Cholesterol**—A solid compound found in blood and a number of foods, including eggs and fats.

**Epidemiologist**—A scientist or medical specialist who studies the origins and spread of diseases in populations.

**Glycemic index (GI)**—A method of ranking of carbohydrates by the way they affect blood glucose levels.

**Glycemic load (GL)**—A more practical ranking of how an amount of a particular food will affect blood glucose levels. The glycemic index (GI) is part of the equation for determining ranking.

**Glycogen**—A compound stored in the liver and muscles that is easily converted to glucose as an energy source.

**Insulin**—A hormone that regulates the level of glucose (sugar) in the blood.

**Monounsaturated fat**—A type of fat found in vegetable oils such as olive, peanut, and canola.

**Pancreas**—A digestive gland of the endocrine system that regulates several hormones, including insulin.

**Polyunsaturated fat**—A type of fat found in some vegetable oils, such as sunflower, safflower, and corn.

**Saturated fat**—A type of fat generally found in meat products with visible fat and dairy products.

**Trans fat**—A type of fat generally found in butter, whole milk products, fried foods, shortening, and coconut, palm, and other tropical oils.

and the presence of fat and protein in the stomach. This rate of absorption is a critical factor in maintaining energy levels, reducing body fat, and maintaining overall health.

Carbohydrates are often referred to as either simple or complex. A bodybuilding diet contains both simple and complex carbohydrates. Complex carbohydrates have a chemical structure composed of three or more sugars. They provide energy that is sustained over time. Simple carbohydrates have a chemical structure composed of one or two sugars and provide quick but short-lasting energy. A bodybuilding diet contains mostly complex carbohydrates eaten throughout the day. Simple carbohydrates are eaten immediately after working out to aid in faster recuperation and repair of muscles. Complex carbohydrates are found in whole-grain bread, pasta, cereal, beans, and most vegetables. Simple carbohydrates are found in fruit and sugary foods such as candy, juice, and sport drinks.

There are two other ways bodybuilding diets classify carbohydrates besides the simple and complex designations: glycemic index (GI) and glycemic load. The GI measures the quality rather than the quantity of carbohydrates found in food. Quality refers to how quickly blood sugar levels are raised following eating. The standard for GI is white bread, which is assigned an index value of 100. Other foods are compared to the standard to arrive at their ratings. The higher the GI number, the faster blood sugar increases when that particular food is consumed. A high GI is 70 and greater, a medium GI is 56–69, and a low GI value is 55 or less. The GI is not a straightforward formula when it comes to reducing blood sugar levels. Various factors affect the GI value of a specific food, such as how the food is prepared (boiled, baked, sautéed, or fried, for example) and what other foods are consumed with it. Foods that are readily broken down and absorbed by the body are typically high on the GI. Foods that are digested slower, such as hose high in **fiber**, have a lower GI value.

In 1997, epidemiologist and nutritionist Walter Willett of the Harvard School of Public Health developed the glycemic load as a more useful way of rating carbohydrates compared to the glycemic index. The glycemic load factors in the amount of a food eaten whereas the glycemic index does not. The glycemic load of a particular food or meal is determined by multiplying the amount of net carbohydrates in a serving by the glycemic index and dividing that number by 100. Net carbohydrates are determined by taking the amount of total carbohydrates and subtracting the amount of dietary fiber. For example, popcorn has a glycemic index of 72, which is considered high, but a serving of two cups has 10 net carbs for a glycemic load of seven, which is considered low.

**PROTEIN.** Muscle is composed primarily of protein and **water**. Protein builds muscle mass but not all protein consumed in the diet goes directly to muscle. Adequate consumption of protein helps preserve muscle tissue and enhance recovery from strenuous weight-bearing workouts. Since weight-bearing exercises cause significant damage to muscle tissue, the subsequent repair and growth of muscle requires a recovery period of at least 24 hours. If an inadequate amount of protein is consumed, muscle mass will suffer along with a decrease in **metabolism**. Most bodybuilding diets recommend 1–1.5 grams of protein per day for each pound of lean body mass (body weight minus body fat). Daily consumption of more than 3g per kilogram body mass can lead to serious health problems, especially kidney damage. Protein is found in lean meat, poultry, and fish, eggs, tofu, and **soy** products.

**FATS.** Fat in a diet is needed to maintain a healthy metabolism. There are four types of fat: saturated, trans, polyunsaturated, and monounsaturated. Saturated and trans fats are limited because high consumption is a risk factor for heart disease, **obesity**, high cholesterol, diabetes, and some cancers. Sources of saturated and trans fats are butter, whole milk products, fried foods, shortening, and coconut, palm, and other tropical oils. Meat with visible fat is also a source of saturated fat. Monounsaturated and polyunsaturated fats are good fats because they lower the risks of heart disease, diabetes, high cholesterol, and obesity. These fats are derived from avocados, most nuts, fish, flax, and olive, canola, peanut, safflower, corn, sunflower, soybean, and cottonseed oils.

Two other important factors in the bodybuilding diet are water and the number and timing of meals. Bodybuilding diets suggest drinking at least eight eight-ounce glasses of water a day. In addition, bodybuilders drink about a quarter cup of water every fifteen minutes during their workout. Water helps control appetite and drinking cold water increases metabolism.

The number and content of meals is important as is the timing and quality of foods, especially just before and just after workouts. An efficient way to burn fat is to elevate the body's metabolism. The process of digesting meals burns calories in itself, so a concept of this diet is to eat more frequently to make the process more efficient. Most bodybuilding diets recommend consuming six to eight smaller meals a day, starting with breakfast. Carbohydrates are important right after a workout because the body's

supply of glycogen (a compound easily converted to glucose for energy) is depleted. Many bodybuilding nutritionists recommend that the post-workout meal contain twice the calories, protein, and carbohydrates as the other meals of the day. The pre-workout meal contains foods high in carbohydrates since they improve exercise performance and enhance muscle recovery.

### Function

The purpose of the bodybuilding diet is to gain muscle mass and lose fat. It is not a weight loss diet and most people will likely gain weight. Nutrition provides the body, especially muscles, with the raw materials needed for energy, recuperation, growth, and strength.

### Benefits

The benefits of the bodybuilding diet are health and appearance. The bodybuilding diet promotes increased muscle mass, which increases metabolism.

### Precautions

When monitored by a health professional, the bodybuilding diet can be healthy method for increasing strength and body mass. Caution should be used in regard to nutritional supplements, especially protein powders. Excess protein intake is known to cause serious health problems such as kidney damage and **dehydration**. Bodybuilders should discuss any supplements with their doctor, and steroids, such as human growth hormone and testosterone, should only be used for medical reasons and with a doctor's prescription. Since exercise is a main component of the diet, people with arthritis or back, knee, or other joint problems should discuss the fitness regimen with their physicians before starting exercise. Making major changes to a person's diet should be done in small incremental steps so the body can adapt to the changes. A sudden reduction or increase in calories can cause the body to store or hoard fat.

### Risks

The rigorous and regular exercise component of this diet is a risk to people with heart disease or certain other health problems. Individuals with these conditions should consult their physician before starting the diet. A bodybuilding diet is not recommended for women who are pregnant or nursing.

## QUESTIONS TO ASK YOUR DOCTOR

- What health factors should I be concerned about if I were to increase my exercise regimen and begin a bodybuilding diet?
- Which dietary supplements should I consider if I adopt the bodybuilding diet?
- What are the health risks involved with this diet?
- What other diets should I consider following to accomplish my bodybuilding goals?
- Have you treated other patients who are on a bodybuilding diet? If so, what has their response to the diet been?

### Research and general acceptance

The bodybuilding diet is generally accepted by the medical and bodybuilding communities as being safe and effective in helping increase muscle mass and decrease fat. There is no general acceptance on the exact ratio of protein, carbohydrates, and fats.

Protein is considered the basic nutrient in repairing muscle that is broken down during weightlifting and for muscle maintenance and growth. The recommended dietary allowance (RDA) per day for protein is 0.8 g/kg. However, research shows that a greater amount of protein is needed for weightlifters. Depending on a person's level of activity, the amount of protein needed for a bodybuilder is greater than the RDA, but not more than 1.5-2 g/kg. Research indicates that muscles double the rate of protein synthesis following exercise and remains elevated for at least 24 hours.

The amount of carbohydrates in a bodybuilder's diet can range from 40–60 percent, but such levels are not necessarily effective. An inadequate consumption of carbohydrates can have a negative effect of exercise performance and duration. Other studies have shown that the dominant factor in weight loss is a reduction of calorie intake. There has been a great deal of research on bodybuilding nutrition from the 1980s forward.

# Breastfeeding

## Definition

Breastfeeding is the practice of feeding an infant milk through the mother's breast. According to La Leche League International (LLLI), human milk is 'a living fluid that protects babies from disease and actively contributes to the development of every system in baby's body'". Breastfeeding stimulates babies' immune systems and protects against diarrhea and infection.

## Description

The mother's body prepares for breastfeeding while she is pregnant. The fatty tissue of the breast is replaced by glandular tissue that is necessary to produce milk. When baby suckles the breast the hormone oxytocin is released. This causes the muscle cells of the breast to squeeze milk from the milk ducts to the nipple.

## History

Throughout time millions of mothers have breastfed their babies. During ancient times mothers breastfed their babies for 12-18 months or until the mother's menstrual cycle returned.

For thousands of years breastfeeding was the only source of nutrition for the first part of a baby's life. Before the invention of formula few alternatives were available. If a mother could not breastfeed a wet nurse was found or the baby was fed animal milk or "pap", a mixture of flour, rice, and **water**. In the early 1900's most babies in America were still breastfed, and over half of them were breastfed for one year or longer. However, as more women entered the workforce and supplemental methods of feeding were introduced, breastfeeding rates in America decreased. According to a survey from Ross Labs, by 1971 only 24.7% of

**Benefits of breastfeeding**

| Benefits for Infant | Benefits for Mother |
|---|---|
| • Perfect food for infant | • Promotes faster shrinking of the uterus |
| • Guarantees safe, fresh milk | • Promotes less postpartum bleeding |
| • Enhances immune system | • Promotes faster return to pre-pregnancy weight |
| • Protects against infectious and noninfectious diseases | • Eliminates the need for preparing and mixing formula |
| • Protects against food allergies and intolerances | • Saves money not spent on formula |
| • Decreases risk of diarrhea and respiratory infections | • Decreases risk of breast and ovarian cancer |
| • Promotes correct development of jaw, teeth, and speech patterns | • Increases bonding with infant |
| • Decreases risk of childhood obesity | • Enhances self-esteem in the maternal role |
| • Increases cognitive function | • Delays the menstrual cycle |
| • Increases bonding with mother | |

**Statistics developed by La Leche League International (LLLI) in 2003 revealed the percentage of women breastfeeding their infants at birth and at 2-4 months.** *(Illustration by GGS Information Services/Thomson Gale.)*

American babies were breastfed at birth, and of these babies, only 5.4% of them were still breastfed at 6 months.

## Demographics

In 1982, the United States experienced resurgence in breastfeeding and rates have continued to increase. The National Immunization Survey conducted by the Center for Disease Control and Prevention (CDC) in 2005 revealed that 72% of American babies were breastfed at birth and 39% were still breastfed at 6 months.

The developing world has experienced a decline in breastfeeding rates as well due to urbanization, social change, and the promotion of formula. Mothers who choose to feed their babies formula often encounter unsafe hygienic conditions in which to prepare the bottles, or they cannot afford to purchase the fuel needed to heat the water. Two of the major causes of infant mortality in developing countries are diarrhea and acute respiratory infections. Both are conditions that breastfeeding can protect against.

The World Health Organization (WHO) and the United Nations Children Fund (UNICEF) are working together to bring about a change in the global breastfeeding culture. In 2002, they developed "The Global Strategy for Infant and Young Child Feeding", which recommends that all babies are exclusively breastfed for the first 6 months of life with continued breastfeeding up to 2 years or beyond. Exclusive breastfeeding means that breast milk is the child's only food source of nutrition for the first 6 months of life and that no other solids or liquids such as formula or water are introduced at this time, with the exception of liquid **vitamins** or medicines. Despite this recommendation, only one-third of all babies in the developing world were exclusively breastfed for 6 months in 2004. The highest rates of exclusive breastfeeding were in the East Asia/Pacific region (43%) and the lowest rates were in the Western/Central Africa region (20%).

## Composition of Breast Milk

Breast milk is the perfect food for an infant. It contains all the nutrients a baby needs to grow and stay healthy:

- Fats: Breast milk contains omega-3 fatty acids essential for the growth and development of the brain and nerve tissue. The amount of fat a baby receives depends on the length of the feeding. The milk at the beginning of the feeding is called the foremilk. It is the low fat milk. The hind milk that comes at the end of the feeding contains higher concentrations of

## KEY TERMS

**Exclusive breastfeeding**—Breast milk is the child's only food source of nutrition for the first 6 months of life. No other solids or liquids such as formula or water are introduced at this time, with the exception of liquid vitamins or medicines.

**Oxytocin**—A hormone that produces a calm, relaxed feeling.

**Postpartum**—This refers to the period of time after childbirth.

fat. Therefore, the longer the baby nurses the higher the fat content.

- Proteins: The whey proteins found in breast milk are easier to digest than formula. Taurine, an amino acid that is important in the development of brain tissue, is found in breast milk but not in cow's milk.
- Sugars: Breast milk contains lactose, a milk sugar that provides energy. Breast milk contains 20-30% more lactose than cows milk.
- Vitamins and minerals: Breast milk provides the most balanced source of vitamins and minerals for an infant.
- Immune system boosters: White blood cells and immunoglobulins are responsible for fighting and destroying infection.

The content of breast milk varies from feeding to feeding, at different times of day, and as the baby grows.

### Breastfeeding Benefits

#### *Benefits for Baby*

There are a plethora of benefits for the breastfeeding baby, including:

- Increased immunity: Breast milk contains antibodies that are relayed by the mother and help to protect the baby from bacteria and viruses. These immunoboosters are not found in formula.
- Low incidence of ear infections and respiratory infections
- Higher intelligence: Several studies have found higher levels of brain-boosting DHA in the blood levels of breastfed babies than in formula-fed babies.
- Improved digestion and less constipation.
- Decreased risk of diarrhea, pneumonia, urinary tract infections, and certain types of spinal meningitis.
- Decrease in food allergies and eczema.
- Promotes normal weight gain: Breastfed babies are less likely to be overweight than formula-fed babies.
- Reduced risk of juvenile (Type 1) and adult onset (Type 2) diabetes, celiac disease, cancer, rheumatoid arthritis, multiple sclerosis, liver disease, and acute appendicitis.
- Lower risk of Sudden Infant Death Syndrome (SIDS).
- Reduced risk of breast cancer (in daughters who have been nursed).
- Promotes development of jaw and facial structure.
- Promotes bonding between mother and child.

#### *Benefits for Mother*

Breastfeeding women also enjoy many benefits:

- Reduced risk of breast, ovarian, and uterine cancers.
- Natural contraceptive: Many women who breastfeed exclusively for six months experience a delay of fertility.
- Faster postpartum recovery: Breastfeeding uses up extra calories so it's easier for moms to lose their pregnancy weight. Nursing also helps the uterus shrink back to its normal size faster.
- Relaxation: When a mother is breastfeeding her body produces oxytocin, a hormone that induces a calm, content feeling.
- Protection from osteoporosis.
- Saves time and money: Breast milk is cheaper than formula and the mother doesn't have to spend time preparing bottles.
- Better for the environment as there are no bottles to wash or cans to dispose of.

### Mother nutrition

The ideal diet of a breastfeeding woman is comprised of healthy and nutritious foods from the five basic food groups. The main concentration (50–55%) should be made up of carbohydrate foods such as pastas, grains, and fruits. Healthy **fats** such as fatty fish and avocados should be 30%, and proteins should equal 15–20% . Breastfeeding women should make sure to eat foods that contain lots of **calcium**, such as dairy products, broccoli, and beans, and make sure they eat plenty of iron-rich foods like lean red meat, fish and poultry.

In order to compensate for the energy they expend breastfeeding their babies, breastfeeding women should add 300–500 extra nutritious calories to their diet each day and drink extra fluids. Breastfeeding mothers should also continue to take a prenatal vitamin.

## Complications

### *Breastfeeding concerns*

Every substance that a breastfeeding mother puts into her body has the potential to pass to her baby through her breast milk. This includes food, medicine, alcohol, and cigarettes.

- Foods: Foods such as dairy products, caffeine, grains and nuts, gassy foods, and spicy foods may cause the baby to fuss if the food upsets the baby's stomach. If this occurs, the mother should eliminate the suspect food from her diet for 10-14 days to see if the trouble stops.
- Medications: Any medication taken while breastfeeding should be approved by a doctor.
- Birth control pills: The high estrogen type of birth control pills may decrease a breastfeeding mother's milk supply and are not recommended. A progestin-only pill such as the "mini-pill" is the least likely to cause milk supply issues.
- Alcohol: Infants have a hard time detoxifying from the alcohol that passes through their mother's breast milk to them. It is recommended to limit alcohol consumption while breastfeeding.
- Cigarettes: Cigarettes contain toxins that can pass through to the baby and are not recommended for breastfeeding women.

### *When breastfeeding is not an option*

Although breastfeeding is the optimal way to feed an infant, sometimes it is not possible or feasible. A small percentage of women have conditions that prevent breast milk production, such as insufficient development of milk production glands, and cannot breastfeed. Women with HIV are advised against breastfeeding as the virus may be passed to their babies. Women who are newly diagnosed with infectious tuberculosis should not breastfeed unless they are on medication. Babies with galactosemia, a rare genetic disorder where the infant cannot metabolize the sugar in breast milk, cannot breastfeed.

British diet *see* **Northern European diet**

# British Heart Foundation diet

## Definition

The British Heart Foundation diet is a three day diet that claims to allow dieters to lose 10 pounds in three days if they follow the diet's specific meal plan. It was not created by nor is it endorsed by the British Heart Foundation.

## Origins

The origins of the British Heart Foundation diet are unclear. It was not created by the British Heart Foundation as its name implies, and the British Heart Foundation does not endorse or recommend this diet in any way. The diet seems to circulate mainly from person to person and on the internet.

It is not clear in which country the diet originated, as some versions call for Ritz Crackers (an American product), some call for Snax crackers (an Australian product), and some call for biscuits (a British term). It is probable that the diet developed in Britain because of the reference to the British Heart Foundation and because most versions call for "beetroot," which is a British term for what Americans call beets.

## Description

The British Heart Foundation diet is a diet that is intended to be done over the course of three days.

## KEY TERMS

**Calorie**—A measurement of the energy content of food, also known as a large calorie, equal to 1000 scientific calories.

**Diabetes mellitus**—A condition in which the body either does not make or cannot respond to the hormone insulin. As a result, the body cannot use glucose (sugar). There are two types, type 1 or juvenile onset and type 2 or adult onset.

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Mineral**—An inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

**Vitamin**—A nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

During these three days the diet claims that a dieter can lose ten pounds if the diet is followed exactly. There are many variations of this diet, with the main differences being in which crackers or sausages are called for. These differences may reflect cultural food differences between the different places in the world that this diet has been circulated.

During this diet, the dieter is provided with a meal plan for three meals a day for each of three days. Amounts of food are specified in ounces, so to follow this diet effectively a dieter needs a kitchen scale or other means of accurately weighing food. The diet requires that dieters drink five eight-ounce glasses of **water** each day, and nothing else except the black tea or coffee specified in the meal plan. The diet says that it must be followed exactly to result in the promised weight loss.

### *Day One*

Breakfast: For breakfast the dieter must drink black coffee or tea, and eat 1/2 of a grapefruit, one slice of dry toast, and 2 teaspoons of peanut butter.

Lunch: For lunch the dieter must again drink black coffee or tea. The dieter must eat 4 ounces of tuna and one slice of dry toast.

Dinner: For dinner the dieter must eat 2 slices of any cold meat, 1 cup of string beans, 4 ounces of beets, 1 small apple, and 4 ounces of vanilla ice cream. No specific requirement is made for a drink with this meal, so only water is allowed.

### *Day Two*

Breakfast: For breakfast on day two the dieter may again drink black tea or coffee. Today the dieter must eat 1 egg (boiled or poached), 1 slice of dry toast, and 1/2 of a banana.

Lunch: For lunch the dieter must eat 4 ounces of cottage cheese and 5 crackers. The brand of cracker varies, some versions require Ritz, Tuc, Snax, or Saltine brand crackers.

Dinner: For dinner the dieter must eat 3 ounces of broccoli, 2 ounces of carrots, 1/2 of a banana, and 2 hot dogs. Some versions call for frankfurters instead of hot dogs. Dinner is again finished with 4 ounces of vanilla ice cream.

### *Day Three*

Breakfast: For breakfast the dieter may drink black tea or coffee and eat 5 crackers, 1 slice of cheddar cheese, and 1 small apple.

Lunch: Lunch on the third day is 1 hard boiled egg and 1 slice of dry toast. There is no specified drink so the dieter must drink water.

Dinner: Dinner on the last day of the diet is 4 ounces of tuna, 4 ounces of beets, 4 ounces of cauliflower, 1/2 of a melon, and 4 ounces of vanilla ice cream.

Some versions of the diet specify that the tuna must be the type packed in water, not oil, although some do not. This makes sense as tuna packed in oil can contain many more calories and many more grams of fat than the type that is packed in water. No specifications are made for whole grain toast, but whole grain bread is usually considered to be more healthy and to contain more **vitamins** and **minerals** than white bread.

## Function

This diet claims to help dieters lose 10 pounds in 3 days. It is not intended to be a long term diet, although many versions of the diet tell dieters that they can repeat the diet as often as desired, and even claim that dieters can lose up to 40 pounds in one month. The diet is not intended to be a lifestyle change, but is intended instead to be a brief, quick, weight loss tool. It does not provide any recommendations for exercise

or advice about any other lifestyle changes, such as techniques for stress reduction.

## Benefits

The British Heart Foundation diet claims that it will allow dieters to lose 10 pounds in only 3 days. Many experts suggest that if weight loss does occur this quickly, the weight lost will mainly be water weight that will be gained back when the dieter begins to eat normally again. A possible benefit however, is that losing weight quickly may help give dieters the positive outlook required to help them continue to lose weight using a more balanced approach. This psychological benefit may be undone if the weight is regained quickly after the diet is completed.

There are many benefits to losing weight if it is done at a safe, moderate pace through a combination of healthy eating and exercise. There are many conditions for which **obesity** is considered a significant risk factor, including type II diabetes and cardiovascular disease. The risk of these and other diseases may be reduced through weight loss. This is especially true for very obese people who are generally thought to be at the greatest risk. The **Sacred Heart diet** is not considered appropriate for long term weight loss, and losing 10 pounds in 3 days is not considered a moderate pace.

## Precautions

Dieters should consult a physician or other medical professional before beginning this or any other diet. Daily requirements of vitamins and minerals can differ significantly between people, depending on age, weight, gender, and the presence of certain diseases and conditions. Getting all required nutrients can be difficult when on a diet that severely limits the types or amounts of food allowed. This diet may contain as few as 700 calories a day if followed exactly. This is not considered to be a safe number of calories for weight loss unless the diet is done under a physicians's close supervision. Pregnant or **breastfeeding** women should be especially cautious because what is eaten by the mother can affect unborn or nursing babies.

## Risks

There are some risks with any diet, but following a diet that severely limits the foods the dieter is allowed to eat generally has higher risks. When a dieter consumes very few different foods it is difficult for the dieter to get all of the different vitamins and nutrients required for good health. The British Heart Foundation diet is only intended to be done over three days. Because it is a very low calorie diet, repeating this diet frequently or over an extended period may greatly increase the risk of problems relating from deficiencies of vitamins, minerals, or calories. Pregnant or breastfeeding women should be especially cautious, because even minor deficiencies can carry risks for babies who are still receiving their nutrients from their mother. Anyone beginning this, or any other very limiting diet, should consult a medical practitioner about whether a multivitamin or supplement might be appropriate for to help reduce the risk of deficiency. Multivitamins and s! upplements have their own associated risks.

### QUESTIONS TO ASK THE DOCTOR

- Is this diet safe for me?
- Is this diet the best diet to meet my goals?
- Do I have any dietary requirements this diet might not meet?
- Would a multivitamin or other dietary supplement be appropriate for me if I were to begin this diet?
- Is this diet safe for my entire family?
- Is it safe for me to follow this diet over an extended period of time?
- Are there any sign or symptoms that might indicate a problem while on this diet?

## Research and general acceptance

There have been no significant scientific studies of the safety or effectiveness of this diet. Although it is named the British Heart Foundation diet, it was not created by the British Heart Foundation, and the Foundation does not endorse or recommend it. Instead the British Heart Foundation makes recommendations for slow, healthy weight loss and weight control that involve light to moderate exercise and a well balanced, healthy diet. The recommendations endorsed by the British Heart Foundation for a healthy diet are generally similar to those provided by the United States Department of Agriculture's MyPyramid guide.

MyPyramid recommends that adults eat the equivalent of 2 to 3 cups of vegetables each day for good health. The British Heart Foundation diet may meet this requirement. Each day requires that the dieter eat two different types of vegetables at dinner.

For many people these amounts might be enough to meet the minimum requirements. Vegetables are an especially important part of any weight loss plan, as well as part of any healthy diet, because they are often low in calories but have high volume, which can help a dieter feel full and satisfied while eating fewer calories.

The British Heart Foundation diet may also meet the recommendations for fruit. MyPyramid recommends that healthy adults eat the equivalent of 1 1/2 to 2 cups of fruit per day. 1 cup of fruit is equivalent to 1 small apple, or 1 large orange. This diet includes two different types of fruit each day, one at breakfast and one at dinner. This may meet the recommendations for most people.

Dairy products are generally considered to be part of a healthy diet. MyPyramid recommends the equivalent of 3 cups of low-fat or non-fat dairy each day for healthy adults. The British Heart Foundation Diet would not meet this recommendation. The diet provides dairy, about half of which is in the form of four ounces of ice cream eaten each night. Ice cream is not considered an optimal way to get required dairy, as it is often high in fat. The diet also does not provide enough dairy, and because the dieter is not allowed to drink skim milk while on the diet there is no way for the dieter to increase dairy intake while still strictly following to the diet.

MyPyramid recommends that healthy adults eat the equivalent of 3 to 4 ounces of grains each day, of which at least half should be whole grains. This is equivalent to about one piece of whole grain bread. The British Heart Foundation diet would provide about two servings of grains per day. These are in the form of toast and crackers, which are not specified as whole grain. This would not meet the MyPyramid recommendation.

The MyPyramid recommendation for the meat and beans group is that healthy adults eat between 5 and 6 1/2 ounces of food from this group each day. One egg or one tablespoon of peanut butter are equivalent to about one ounce from this group. The British Heart Foundation diet may provide dieters with enough servings from this food group.

The diet requires dieters to drink five eight-ounce glasses of water each day, and nothing else except for the drinks required by the meal plan. Generally it is recommended that adults drink eight eight-ounce glasses of water each day, so this diet would not meet this recommendation.

The British Heart Foundation diet does not include any recommendations for exercise. In 2007, the Center for Disease Control recommended that healthy adults get at least 30 minutes per day of light to moderate exercise. Regular exercise has been shown to have many health benefits including decreasing the risk of cardiovascular disease. Additionally, studies have shown that regular exercise can help dieters manage their weight. Plans that include diet and exercise together have been shown to help dieters lose more weight than just diet or exercise done alone.

# Bulimia nervosa

## Definition

Bulimia nervosa is an eating disorder that involves repeated **binge eating** followed by purging the body of calories to avoid gaining weight. The person who has bulimia has an irrational fear of gaining weight and a distorted **body image**. Bulimia nervosa can have potentially fatal health consequences.

## Description

Bulimia is an eating disorder whose main feature is eating an unreasonably large amount of food in a short time, then following this binge by purging the body of calories. Purging is most often done by self-induced vomiting, but it can also be done by laxative, enema, or diuretic abuse. Alternately, some people with bulimia do not purge but use extreme exercising and post-binge fasting to burn calories. This can lead to serious injury. Nonpurging bulimia is sometimes called exercise bulimia. Bulimia nervosa is officially recognized as a psychiatric disorder in the *Diagnostic*

SOURCE: National Women's Health Information Center, Office on Women's Health, U.S. Department of Health and Human Services

*(Illustration by GGS Information Services/Thomson Gale.)*

*and Statistical Manual for Mental Disorders Fourth Edition-Text Revision (DSM-IV-TR)* published by the American Psychiatric Association.

Bulimia nervosa is diagnosed when most of the following conditions are present:

- Repeated episodes of binge eating followed by behavior to compensate for the binge (i.e. purging, fasting, over-exercising). Binge eating is defined as eating a significantly larger amount of food in a limited time than most people typically would eat.
- Binge/purge episodes occur at least twice a week for a period of three or more months.
- The individual feels unable to control or stop an eating binge once it starts and will continue to eat even if uncomfortably full.
- The individual is overly concerned about body weight and shape and puts unreasonable emphasis on physical appearance when evaluating his or her self-worth.
- Bingebingeinging and purging does not occur exclusively during periods of anorexia nervosa.

Many people with bulimia will consume 3,000–10,000 calories in an hour. For example, they will start out intending to eat one slice of cake and end up eating the entire cake. One distinguishing aspect of bulimia is how out of control people with bulimia feel when they are eating. They will eat and eat, continuing even when they feel full and become uncomfortable.

Most people with bulimia recognize that their behavior is not normal; they simply cannot control it. They usually feel ashamed and guilty over their binge/purge habits. As a result, they frequently become secretive about their eating and purging. They may, for example, eat at night after the family has gone to bed or buy food at the grocery store and eat it in the car before going home. Many bulimics choose high-fat, high-sugar foods that are easy to eat and easy to regurgitate. They become adept at inducing vomiting, usually by sticking a finger down their throat and triggering the gag reflex. After a while, they can vomit at will. Repeated purging has serious physical and emotional consequences.

Many individuals with bulimia are of normal weigh, and a fair number of men who become bulimic were overweight as children. This makes it difficult for family and friends to recognize that someone suffering from this disorder. People with bulimia often lie about induced vomiting and laxative abuse, although they may complain of symptoms related to their binge/purge cycles and seek medical help for those problems. People with bulimia tend to be more impulsive than people with other **eating disorders**. Lack of impulse control often leads to risky sexual behavior, anger management problems, and alcohol and drug abuse.

A subset of people with bulimia also have **anorexia nervosa**. Anorexia nervosa is an eating disorder that involves self-imposed starvation. These people often purge after eating only a small or a normal-sized portion of food. Some studies have shown that up to 60% of people with bulimia have a history of anorexia nervosa.

Dieting is usually the trigger that starts a person down the road to bulimia. The future bulimic is very concerned about weight gain and appearance, and may constantly be on a diet. She (most people with bulimia are female) may begin by going on a rigorous low-calorie diet. Unable to stick with the diet, she then

## KEY TERMS

**Diuretic**—A substance that removes water from the body by increasing urine production.

**Electrolyte**—Ions in the body that participate in metabolic reactions. The major human electrolytes are sodium (Na+), potassium (K+), calcium (Ca 2+), magnesium (Mg2+), chloride (Cl−), phosphate ($HPO_4$ 2−), bicarbonate ($HCO_3$−), and sulfate ($SO_4$ 2−).

**Neurotransmitter**—One of a group of chemicals secreted by a nerve cell (neuron) to carry a chemical message to another nerve cell, often as a way of transmitting a nerve impulse. Examples of neurotransmitters include acetylcholine, dopamine, serotonin, and norepinephrine.

**Obsessive-compulsive disorder**—A psychiatric disorder in which a person is unable to control the desire to repeat the same action over and over.

eats voraciously far more than she needs to satisfy her hunger, feels guilty about eating, and then exercise or purges to get rid of the unwanted calories. At first this may happen only occasionally, but gradually these sessions of bingeing and purging become routine and start to intrude on the person's friendships, daily activities, and health. Eventually these practices have serious physical and emotional consequences that need to be addressed by healthcare professionals.

## Demographics

Bulimia nervosa is primarily a disorder of industrialized countries where food is abundant and the culture values a thin appearance. Internationally, the rate of bulimia has been increasing since the 1950s. Bulimia is the most common eating disorder in the United States. Overall, about 3% of Americans are bulimic. Of these 85–90% are female. The rate is highest among adolescents and college women, averaging 5–6%. In men, the disorder is more often diagnosed in homosexuals than in heterosexuals. Some experts believe that number of diagnosed bulimics represents only the most severe cases and that many more people have bulimic tendencies, but are successful in hiding their symptoms. In one study, 40% of college women reported isolated incidents of bingeing and purging.

Bulimia affects people from all racial, ethnic, and socioeconomic groups. The disorder usually begins later in life than anorexia nervosa. Most people begin bingeing and purging in their late teens through their twenties. Men tend to start at an older age than women. About 5% of people with bulimia begin the behavior after age 25. Bulimia is uncommon in children under age 14.

Competitive athletes have an increased risk of developing bulimia nervosa, especially in sports where weight it tied to performance and where a low percentage of body fat is highly desirable. Jockeys, wrestlers, bodybuilders, figure skaters, cross-country runners, and gymnasts have higher than average rates of bulimia. People such as actors, models, cheerleaders, and dancers who are judged mainly on their appearance are also at high risk of developing the disorder. This same group of people is also at higher risk for developing anorexia nervosa. Some people are primarily anorexic and severely restrict their calorie intake while also purging the small amounts they do eat. Others move back and forth between anorectic and bulimic behaviors.

## Causes and symptoms

Bulimia nervosa is a complex disorder that does not have a single cause. Research suggests that some people have a predisposition toward bulimia and that something then triggers the behavior, which then becomes self-reinforcing. Hereditary, biological, psychological and social factors all appear to play a role.

### *Causes*

- Heredity. Twin studies suggest that there is an inherited component to bulimia nervosa, but that it is small. Having a close relative, usually a mother or a sister, with bulimia slightly increases the likelihood of other (usually female) family members developing the disorder. However, when compared other inherited diseases or even to anorexia nervosa, the genetic contribution to developing this disorder appears less important than many other factors. Family history of depression, alcoholism, and obesity also increase the risk of developing bulimia.
- Biological factors. There is some evidence that bulimia is linked low levels of serotonin in the brain. Serotonin is a neurotransmitter. One of its functions is to help regulate the feeling of fullness or satiety that tells a person to stop eating. Neurotransmitters are also involved in other mental disorders such as depression that often occur with bulimia. Other research suggests that people with bulimia may have abnormal levels of leptin, a protein that helps regulate weight by telling the body to take in less food. Research in this area is relatively new, and the findings are still unclear.

- Psychological factors. Certain personality types appear to be more vulnerable to developing bulimia. People with bulimia tend to have poor impulse control. They are of often involved in risky behavior such as shoplifting, drug and alcohol abuse and risky sexual activities. People with bulimia have low-self worth and depend on the approval of others to feel good about themselves. They are aware that their behavior is abnormal. After a binge/purge session, they are ashamed and vow never to repeat the cycle, but the next time they are unable to control the impulse to eat and purge. They also tend to have a black-or-white, all-or-nothing way of seeing situations. Major depression, obsessive-compulsive disorder, and anxiety disorders are more common among individuals who are bulimic.
- Social factors. The families of people who develop bulimia are more likely to have members who have problems with alcoholism, depression, and obesity. These families also tend to have a high level of open conflict and disordered, unpredictable lives. Often something stressful or upsetting triggers the urge to diet stringently and then begin binge/purge behaviors. This may be as simple as a family member as teasing about the person's weight, nagging about eating junk food, commenting on how clothes fit, or comparing the person unfavorably to someone who is thin. Life events such as moving, starting a new school, and breaking up with a boyfriend can also trigger binge/purge behavior. Overlaying the family situation is the false, but unrelenting, media message that thin is good and fat is bad; thin people are successful, glamorous, and happy, fat people are stupid, lazy, and failures.

### *Signs and symptoms*

Binge/purge cycles have physical consequences. These include:

- teeth damaged from repeated exposure to stomach acid from vomiting; eroded tooth enamel;
- swollen salivary glands; sores in mouth and throat
- dehydration
- sores or calluses on knuckles or hands from using them to induce vomiting
- electrolyte imbalances revealed by laboratory tests
- dry skin
- fatigue
- irregular or absent menstrual cycles in women
- weight, heart rate and blood pressure may be normal

## Diagnosis

Diagnosis is based on several factors including a patient history, physical examination, the results of laboratory tests, and a mental status evaluation. A patient history is less helpful in diagnosing bulimia than in diagnosing many diseases because many people with bulimia lie about their bingeing and purging and their use of laxatives, enemas, and medications. The patient may, however, complain about related symptoms such as fatigue or feeling bloated. Many people with bulimia express extreme concern about their weight during the examination.

A physical examination begins with weight and blood pressure and moves through the body looking for the signs listed above. Based on the physical exam and patient history, the physician will order laboratory tests. In general these tests will include a complete blood count (CBC), urinalysis, and blood chemistries (to determine electrolyte levels). People suspected of being exercise bulimic may need to have x rays to look for damage to bones from over-exercising.

Several different evaluations can be used to examine a person's mental state. A doctor or **mental health** professional will assess the individual's thoughts and feelings about themselves, their body, their relationships with others, and their risk for self-harm.

## Treatment

Treatment choices depend on the degree to which the bulimic behavior has resulted in physical damage and whether the person is a danger to him or herself. Hospital impatient care may be needed to correct severe electrolyte imbalances that result from repeated vomiting and laxative abuse. Electrolyte imbalances can result in heart irregularities and other potentially fatal complications. Most people with bulimia do not require hospitalization. The rate of hospitalization is much lower than that for people with anorexia nervosa because many bulimics maintain a normal weight.

Day treatment or partial hospitalization where the patient goes every day to an extensive treatment program provides structured mealtimes, nutrition education, intensive therapy, medical monitoring, and supervision. If day treatment fails, the patient may need to be hospitalized or enter a full-time residential treatment facility.

Outpatient treatment provides medical supervision, nutrition counseling, self-help strategies, and psychotherapy. Self-help groups receive mixed reviews from healthcare professionals who work with bulimics. Some groups offer constructive support in stopping the

binge/purge cycle, while others tend to reinforce the behavior.

Drug therapy helps many people with bulimia. Selective serotonin reuptake inhibitors (SSRIs) such as fluoxetine (Prozac) and sertraline (Zoloft) have been approved by the United States Food and Drug Administration (FDA) for treatment of bulimia. These medications increase serotonin levels in the brain and are thought to affect the body's sense of fullness. They are used whether or not the patient shows signs of depression. Drug treatment should always be supplemented with psychotherapy. (see Therapies below).

Other drugs are being explored for use in the treatment of bulimia. Individuals with bulimia interested in entering a clinical trial at no cost can find a list and description of clinical trials currently enrolling volunteers at <http://www.clinicaltrials.gov>.

## Nutrition/Dietetic concerns

A nutrition consultant or dietitian is part of the team needed to successfully treat bulimia. These professionals usually do a dietary review along with nutritional counseling so that the recovering bulimic can plan healthy meals and develop a healthy relationship with food.

## Therapy

Medical intervention helps alleviate the immediate physical problems associated with bulimia. Medication can help the person with bulimia break the binge/purge cycle. However drug therapy alone rarely produces recovery. Psychotherapy plays a major role helping the individual with bulimia recover from the disorder. Several different types of psychotherapy are used depending on the individual's situation. Generally, the goal of psychotherapy is help the individual change his or her behavior and develop a healthy attitude toward their body and food.

Some types of psychotherapy that have been successful in treating people with bulimia are listed below.

- Cognitive behavior therapy (CBT) is designed to confront and then change the individual's thoughts and feelings about his or her body and behaviors toward food, but it does not address why those thoughts or feelings exist. Strategies to maintain self-control may be explored. This therapy is relatively short-term. CBT is often the therapy of choice for people with bulimia, and it is often successful at least in the short term.
- Interpersonal therapy is short-term therapy that helps the individual identify specific issues and problems in relationships. The individual may be asked to look back at his or her family history to try to recognize problem areas and work toward resolving them. Interpersonal therapy has about the same rate of success in people with bulimia as CBT.
- Family and/or couples therapy is helpful in dealing with conflict or disorder that may be a factor in triggering binge/purge behavior at home.
- Supportive-expressive therapy or group therapy may be helpful in addition to other types of therapy.

## Prognosis

The long-term outlook for recovery from bulimia is mixed. About half of all bulimics show improvement in controlling their behavior after short-term interpersonal or cognitive behavioral therapy with nutritional counseling and drug therapy. However, after three years, only about one-third are still doing well. Relapses are common, and binge/purge episodes and bulimic behavior often comes and goes for many years. Stress seems to be a major trigger for relapse.

The sooner treatment is sought, the better the chances of recovery. Without professional intervention, recovery is unlikely. Untreated bulimia can lead to death directly from causes such as rupture of the stomach or esophagus. Associated problems such as substance abuse, depression, anxiety disorders, and poor impulse control also contribute to the death rate.

## Prevention

Some ways to prevent bulimia nervosa from developing are as follows:

- If you are a parent, do not obsess about your own weight, appearance, and diet in front of your children.
- Do not tease your children about their body shapes or compare them to others.
- Make it clear that you love and accept your children as they are.
- Try to eat meals together as a family whenever possible.
- Remind children that the models they see on television and in fashion magazines have extreme, not normal or healthy bodies.
- Do not put your child on a diet unless advised to by your pediatrician.
- Block your child from visiting pro-bulimia Websites. These are sites where people with bulimia give advice

on how to purge and support each other's binge/purge behavior.

- If your child is a competitive athlete, get to know the coach and the coach's attitude toward weight.
- be alert to signs of low self-worth, anxiety, depression, and drug or alcohol abuse and seek help as soon as these signs appear.
- If you think your child has an eating disorder, do not wait to intervene and the professional help. The sooner the disorder is treated, the easier it is to cure.

Relapses happen to many people with bulimia. People who are recovering from bulimia can help prevent themselves from relapsing by:

- never dieting; instead plan healthy meals
- eating with other people, not alone.
- staying in treatment; keep therapy appointments
- monitoring negative self-talk; practicing positive self-talk
- spending time doing something enjoyable every day
- staying busy, but not overly busy; getting at least seven hours of sleep each night
- spending time each day with people you care about and who care about you

## Cabbage soup diet

### Definition

The cabbage soup diet is a quick weight loss program intended to be followed for seven days. The centerpiece of the diet is a recipe for cabbage soup, which the dieter may consume in unlimited quantities. In addition to the cabbage soup, there are certain other foods the dieter must eat on specific days during the week. There are several versions of the diet, most of which promise a 10-17 lb weight loss during the week.

The cabbage soup diet has a number of other names:

- TWA Stewardess Diet
- Model's Diet
- Dolly Parton Diet
- Military Cabbage Soup Diet
- Mayo Clinic Diet
- Sacred Heart Hospital Diet
- Miami Heart Institute Diet
- Spokane Diet
- Fat Burning Diet
- T. J.'s Miracle Soup Diet
- The Skinny

### Origins

The cabbage soup diet may be the oldest fad diet still in use; it seems to resurface with a new name every 10 to 15 years. It has been described by some historians of popular culture as a good example of an urban legend—a type of modern folklore passed from person to person via word of mouth, photocopies, or e-mail. Urban legends are often stories or anecdotes, but some can be called "widely accepted misinformation."

No one seems to know when the cabbage soup diet was first formulated or the identity of its originator. According to the American Dietetic Association's timeline of **fad diets**, the cabbage soup diet originated around 1950, but it may date back even earlier. There is a recipe for "Doughboy Cabbage Soup" dating back to World War I (1914–1918), when American soldiers fighting in France had few other vegetables available and eating cabbage offered protection against scurvy, a deficiency disease caused by inadequate **vitamin C** in the diet. The name "Military Cabbage Soup Diet" is likely derived from the World War I soup recipe, although that early recipe lacked the tomatoes, bouillon cubes, and other seasonings included in recent versions of the diet.

After the 1950s, the cabbage soup diet was revived in the early 1980s not only as the Dolly Parton Diet but also as the Trans World Airlines (TWA) Stewardess Diet and the Model's Diet. It acquired these names because of the belief that celebrities, models, and flight attendants had to meet rigorous periodic weight check-ins in order to keep their jobs. The cabbage soup diet was passed around from person to person in the form of photocopies during this period. It often claimed that the dieter would lose 10-17 lb during the first week either because cabbage supposedly has no calories at all or because it contains a "miracle fat-burning" compound.

The cabbage soup diet reappeared in the mid-1990s, when fax machines and the Internet made it easy for people to transmit copies of the diet to friends and workplace colleagues. The diet was also published in magazines such as *Cosmopolitan* and *Gentlemen's Quarterly* (now *GQ*) in 1995. The diet was attributed to health associations as well as the cardiology departments of several hospitals and medical centers in this period. These institutions supposedly gave the diet to overweight patients preparing for heart surgery to help them to lose weight quickly before their operations. Thus, the diet acquired such names as the **Sacred Heart diet** or the Spokane diet (from the names of hospitals in Brussels, Belgium, Montreal, Quebec, and

## KEY TERMS

**Flatulence**—The medical term for intestinal gas expelled through the anus.

**Scurvy**—A deficiency disease caused by a lack of dietary vitamin C, characterized by spongy gums, eventual loss of teeth, and bleeding into the skin and mucous membranes.

**Urban legend**—A story, anecdote, or piece of advice based on hearsay and circulated by person-to-person transmission.

Spokane, Washington), the American Heart Association Diet, the **Mayo Clinic Diet**, and the Miami Heart Institute Diet.

## Description

### *Cabbage soup recipes*

Most versions of the cabbage soup diet begin with a recipe for the soup. One change that has evolved since the diet first appeared in the 1950s is the cooking instructions; the earliest versions of the diet recommended cooking the soup for an hour, which would destroy most of the nutrients in the cabbage and other ingredients. Recent soup recipes recommend simmering the soup no more than 10 to 15 minutes after being brought to a boil.

**STANDARD RECIPE.** Ingredients:

- 6 large green onions
- 2 green peppers
- 1 or 2 cans diced tomatoes
- 1 bunch of celery
- 1 envelope of dry onion soup mix
- 1 or 2 bouillon cubes (some versions specify low-sodium vegetable flavor) if desired
- 1 large head of cabbage
- 1 8-oz can of V-8 juice (optional)

Preparation of the soup is simple. Vegetables are cut into small pieces and covered with **water** (and V-8, if desired) in a large pot. The mixture is brought to a boil and simmered for 10 to 15 minutes or until vegetables are tender. Parsley, Worcestershire sauce, and/or black pepper may be added to taste.

**MILITARY DIET RECIPE.** Ingredients:

- 2 13-ounce cans of chicken broth
- 1 large bunch of celery
- 2 bunches of spring onions
- 1 large head of cabbage
- 1 large can of whole tomatoes
- 3 large bell peppers
- Salt and pepper to taste

Considered the original cabbage soup recipe on some websites, this version is prepared by cutting vegetables into small pieces and covering them with chicken broth and canned tomatoes in a large pot. The mixture is cooked over low heat for 15 minutes.

**GREEN CABBAGE SOUP RECIPE.** Ingredients:

- One-half of a green cabbage, chopped
- 3 large onions, diced
- 1 large green pepper, sliced
- 1 cup fresh mushrooms, washed and sliced
- 1 or 2 cups washed fresh spinach leaves
- 1 can of diced tomatoes
- 1 envelope of dry onion soup mix
- 3 vegetable-flavored bouillon cubes
- 8 to 12 cups of water
- Oregano, cilantro, garlic powder, basil, pepper, and/or parsley to taste

Preparation involves combining vegetables in a large pot with water, soup mix, bouillon cubes, and canned tomatoes. Additional water may be added if needed to fully cover the vegetables. The mixture is cooked over low heat about 15 minutes or until the vegetables are soft.

### *Cabbage soup diet plan*

Dieters are supposed to follow specific menus for each day of the diet, with the understanding that an unlimited amount of cabbage soup can be eaten each day.

- Day One: Eat only the cabbage soup and all the fruit you want (except bananas). Cantaloupe and watermelon are recommended. Permissible drinks are water, black coffee, cranberry juice, or unsweetened tea.
- Day Two: No fruit. Raw or cooked vegetables can be eaten in unlimited quantity along with the soup, except for corn, peas, and beans. A baked potato with butter can be eaten at dinnertime.
- Day Three: Unlimited fruit or vegetables, but no baked potato.
- Day Four: Eat at least three and as many as eight bananas, and drink an unlimited amount of skim milk. Day Four is supposed to curb a desire for sweets.
- Day Five: Eat 10-20 oz of beef and up to six fresh tomatoes (or one can of stewed tomatoes. Cabbage soup must be eaten for at least one meal. Drink 6-8

glasses of water to flush acids from the body. Baked or broiled chicken (without the skin) or fish may be substituted for beef at one meal.

- Day Six: Eat cabbage soup at least once during the day; otherwise, an unlimited amount of beef and vegetables can be consumed, but no baked potato.
- Day Seven: Eat an unlimited amount of brown rice and vegetables and drink an unlimited amount of unsweetened fruit juice. Cabbage soup must be eaten at least once during the day. No bread, alcohol, or carbonated beverages (including diet soda) are allowed.

#### *Additional instructions*

Some Internet versions of the cabbage soup diet include additional instructions for the dieter:

- Follow the diet religiously
- Drink at least four glasses of water each day
- Only follow the diet for seven days
- Eat unlimited amounts of cabbage soup to prevent hunger
- Take a good multivitamin supplement every day
- Try different spices to liven up the soup and add variety

#### *Cabbage soup diet pills*

Diet pills available on the Internet supposedly represent the cabbage soup used in the diet in dehydrated form. Discovery of the pills is credited to a woman who works in a food processing plant that makes meals ready to eat (MREs) for the military. She is said to have tried dehydrating cabbage soup in the ovens for preparing MREs and ended up with a powder that tasted like the original soup when warm water was added. A local manufacturer of homeopathic remedies supposedly began packaging the powder in pill form. The cabbage soup diet pills claim to speed up weight loss, melt fat, curb appetite, cure depression, detoxify the digestive tract, boost the immune system, and protect against **cancer**.

## Function

The cabbage soup diet is intended only for short-term weight loss. It is usually recommended as a quick way to lose weight after holiday-related overeating or to fit into an outfit for a special occasion. A few Internet versions claim the cabbage soup diet can be used for weight maintenance or for long-term nutrition. A book published on the diet in 1997 and revised in 2004 does contain an appropriate maintenance diet intended for use after the seven-day soup diet.

## Benefits

The cabbage soup diet does work for some people as a short-term way to lose weight rapidly. Some people like the fact that the diet offers a break from junk food or fast food, and does not require any unusual or expensive ingredients, complex recipes, or appetite suppressants. Also, the soup can be stored in the refrigerator for convenience or frozen for later use.

## Precautions

The cabbage soup diet is safe for most adults in good health who follow it no longer than seven days. The diet should not be used by individuals with type 2 diabetes, **eating disorders**, or other disorders requiring special diets without consulting a doctor or registered dietitian. Dieters who do use this diet should be aware that most of the weight they lose during the week is water weight, and is easily regained when return to their previous eating habits.

Due to the restrictive and repetitive nature of this diet, it is difficult to sustain for any length of time. Such diets are not useful for long-term weight loss and weight maintenance. Frequent use could lead to yo-yo dieting, which has been shown to be detrimental to health.

The cabbage soup diet does not include an adequate balance of nutrients and may be too low in calories to make it suitable for long-term use. Claims that the diet can be used indefinitely or repeated within three days of completing the first cycle should be ignored as they are not safe.

The diet does not require spending large amounts of time cooking or assembling ingredients, but it may be difficult to follow when cooking for a family.

## Risks

Side effects from the diet may include dizziness, light-headedness, and flatulences (intestinal gas). The latter may be a social risk due to embarrassment related to passing gas in public. Common versions of the soup recipe are high in salt. Dieters who must restrict their **sodium** intake should discuss variations with their physician.

## Research and general acceptance

#### *Basic nutritional information about cabbage*

The cabbage soup diet has not been the subject of any mainstream clinical trials as of 2007, most likely because it is a classic fad diet. Cabbage by itself, however, has been studied by nutritionists and food chemists for some years, and is considered a good food to include in

## QUESTIONS TO ASK YOUR DOCTOR

- Do you have any patients who have tried the cabbage soup diet?
- In your opinion, is this diet safe to use for a week as long as it is not repeated?
- Can someone with high blood pressure use this diet as long as they are taking prescription medications for that condition?

any healthful and well-balanced diet. The cabbage used as food by modern humans, *Brassica oleracea*, was developed from a variety of wild mustard native to southern Italy and France several centuries before the Christian era. It was eaten both raw and cooked by the ancient Greeks and Romans. Ancient physicians used a paste made from raw cabbage to reduce inflammation surrounding a wound. Cabbage is a cool-weather crop that can be harvested in 50 to 80 days, which helps explain why it is a dietary staple in northern and central Europe as well as in Korea and other parts of Asia.

According to the U.S. Department of Agriculture (USDA) database, raw cabbage contains 20 calories per 100g (about 3-1/2 oz), 5.6g of **carbohydrates**, and 32mg of vitamin C—about 53% of an adult's daily requirement. The carbohydrate content includes 3.2g of sugars per 100g, which are released during cooking, and 2.3g of dietary **fiber**. Thus, the cabbage soup diet does make use of some scientific findings about the nutritional value and low calorie content of cabbage: the short period of cooking recommended by the soup recipe helps remove the bitter taste of raw cabbage without destroying its dietary fiber or **vitamins**.

### *Evaluations of the cabbage soup diet*

The American Heart Association (AHA) and the hospitals whose names have been associated with the cabbage soup diet have issued formal disclaimers warning the public that they do not endorse this diet. The Hôpital du Sacré-Coeur de Montréal states in its 2004 press release that the diet is contrary to healthy feeding patterns and even presents potential dangers to good health. The Sacred Heart Medical Center (SHMC) in Spokane requests that people do not affiliate the diet with their hospital as they do not consider it a safe or healthy method of weight loss. A SHMC disclaimer states, "This diet did not originate at SHMC and it is not endorsed by the dietitians or the staff of our cardiac rehabilitation program. One of our major concerns about this diet plan is it emphasizes the consumption of fruits and vegetables while excluding the consumption of meat or fish, cereal grains and milk products on most days. Any diet that focuses on only certain food groups will be low or deficient in essential nutrients and, therefore, lead to poor nutritional status long-term. Our experience with any low calorie diets like this one is that they do not lead to permanent weight loss. Once individuals start eating in a more normal pattern, the weight is regained. A very important factor in obtaining a healthy weight is to evaluate your physical activity and other lifestyle concerns. This is most appropriately done by consulting with a registered dietitian."

Scientific evidence is not yet available to support claims that cabbage has unique detoxifying, fat-burning, immunoprotective, antidepressant, or anticancer properties. Claims regarding the possibility of losing 17 pounds by the end of one week on this diet are exaggerated. In addition, there is no indication that the government of Australia (or any other government) has ever sponsored clinical trials of cabbage soup, whether in pill form or fully constituted.

# Caffeine

## Definition

Caffeine is a mild alkaloid stimulant made by some plants. It is found in coffee beans, tea leaves, and cocao beans, added to soft drinks, energy drinks, energy bars, and sold in capsules and tablets as a dietary supplement. Caffeine has no nutritional value.

## Purpose

Caffeine is a mild stimulant. It is used to temporarily relieve fatigue and increase mental alertness. Caffeine is added to some antihistamine drugs to help counteract the sleepiness they may cause. It is also added to over-the-counter headache remedies (e.g., Excedrin) and migraine headache drugs to enhance their painkilling effects. Under medical supervision, citrated caffeine (a prescription drug) is used to treat breathing problems in premature infants.

## Description

Caffeine, from the Italian word cafée, meaning coffee, is naturally made by about 60 plants. The most familiar of these are coffee leaves and beans, tea leaves, kola nuts, yerba mate, guarana berries, and cacao (the source of chocolate). In plants, caffeine is a pesticide. Insects eating plants that contain caffeine become disabled or die.

Humans have eaten plants containing caffeine for thousands of years; first chewing the seeds and leaves, and later boiling them and drinking the resulting liquid. Coffee, a major source of caffeine, was introduced to Europe from the Middle East in the seventeenth century and rapidly became a popular drink. Coffee houses began appearing in London in the mid-1600s. A German chemist purified caffeine in 1819. Today, besides being found naturally in coffee, tea, and chocolate, it is added to soft drinks, energy drinks and bars, headache remedies, and is sold as a dietary supplement to improve mental and physical functioning. The United States is a highly caffeinated nation. In 2007, it was estimated that 90% of North Americans consumed caffeine daily.

Caffeine is the most widely used psychoactive compound in the world. It has no nutritional value, but has these effects on the body:

- increases heart rate
- temporarily increases blood pressure
- increases urine output (a diuretic)
- relaxes smooth muscle cells in the airways
- releases fatty acids and glycerol in the body for energy use
- easily crosses the blood-brain barrier and changes the level of neurotransmitters in the brain
- passes into breast milk

Caffeine is absorbed in the stomach. Its effects are noticeable in about 15 minutes and usually last several hours. However, there is huge variation among people

both in their sensitivity to caffeine and in how long it stays in their bodies. Although the average time it takes half a dose of caffeine to be eliminated from the body is three to four hours, this time may extend to six hours in women taking oral contraceptives, and be much longer in pregnant women and in people with liver damage.

Many well-designed, well-documented studies show that caffeine makes people more alert, improves short-term memory, enhances the ability to concentrate, increases the individual's capacity for physical work and speeds up reaction time. However, caffeine achieves this by preventing detrimental effects of withdrawal in habitual caffeine drinkers. It does not boost functioning to above normal levels. All these effects are temporary. Caffeine does not replace the need for rest or sleep.

Caffeine is on the United States Food and Drug Administration (FDA) list of foods generally recognized as safe (GRAS list). In moderate amounts, caffeine does not appear to be harmful to humans, although it is poisonous to dogs, horses, and some birds. "Moderate" generally means consumption in the rage of 300–400 mg or 3–4 cups of coffee daily. Caffeine has not been shown to cause birth defects and is considered safe in reasonable amounts during pregnancy. The March of Dimes Birth Defects Foundation recommends that pregnant women limit their caffeine intake to the equivalent of two cups of coffee per day, and that women who are having difficulty becoming pregnant eliminate caffeine from their diet.

By law, caffeine must be listed as an ingredient on food labels, but the amount of caffeine per serving is not required to be disclosed. Since caffeine is added to so many products, it is difficult to the amount of caffeine in an individual's diet. Caffeine content of coffees and teas varies depending on where the plants were grown and how the beverages are prepared. The approximate amounts of caffeine is some common products are:

- coffee, brewed 8 oz: 135 mg
- coffee, decaffeinated, 8 oz: 5 mg
- coffee, espresso, 1 oz: 40 mg
- green tea, brewed, 8 oz: 15 mg
- black tea, brewed, 8 oz: 50 mg
- tea, decaffeinated, 8 oz: 4 mg
- Mountain Dew, 1 can (12 oz): 55 mg
- Coca-Cola Classic, 1 can (12 oz): 34 mg
- Diet Coke: 1 can (12 oz) 45 mg
- Pepsi Cola, 1 can (12 oz): 37 mg
- Sunkist Orange, regular or diet, 1 can (12 oz): 41 mg
- Barq's Root Beer: 1 can (12 oz): 22 mg
- diet Barq's Root Beer: 1 can (12 oz): 0 mg
- Sprite, diet or regular: 1 can (12 oz) 0 mg
- 7-Up, 1 can (12 ounces): 0 mg
- Red Bull energy drink, 8.5 oz: 80 mg
- Cocaine energy drink, 8.5 oz: 280 mg
- SoBe No Fear energy drink, 8 oz: 80 mg
- Hershey's Special Dark chocolate, 1 bar (1.5 oz): 31 mg
- Hershey's Milk Chocolate, 1 bar (1.5 oz): 10 mg
- Excedrin headache tablet, 1: 65 mg
- caffeine tablet, 1: 200 mg

## Precautions

People vary in their sensitivity to caffeine based on their weight, age, medications they may be taking, and personal biology. Individuals should be alert to how much caffeine they consume during a day and how it makes them feel, then moderate their intake accordingly. Caffeine does not replace the need for sleep. All mental and physical benefits are temporary and a "crash" is likely to occur after a dose of caffeine wears off. People who use caffeine to stay awake to drive or operate heavy machinery are at risk of being involved in an accident because of excessive tiredness once the effect of caffeine wears off.

Caffeine stays in the system of pregnant women and people with liver damage longer than normal. These people should closely monitor their caffeine intake.

Caffeine passes into breast milk and although it may have no effect on the **breastfeeding** woman, it may make the infant restless, irritable, and less likely to sleep.

Athletes should be aware that the International Olympic Committee tests for caffeine levels over 12 mg/ml of urine. This level could be reached by drinking four large cups of coffee.

## Interactions

Caffeine appears to enhance the effectiveness of over-the-counter headache remedies. Some of these medications contain a mixture of caffeine and painkiller. People with a high sensitivity to caffeine should read the labels carefully.

People taking diuretic medication (**water** pills) may see increased urine output because caffeine is a weak diuretic.

## Complications

Although caffeine in moderate amounts poses no major health risks, the body quickly develops tolerance

to the effects of caffeine, along with a mild physical and psychological dependency. For example, tolerance to caffeine-related sleep disruption disappears in about a week among people who drink 3–4 cups of coffee daily. The amount of caffeine it takes to reach this state is highly variable.

Discontinuing caffeine among regular users causes withdrawal symptoms. These can include headaches (very common), irritability, nausea, fatigue, sleepiness, inability to concentrate, and mild depression. Caffeine withdrawal symptoms begin 12–24 hours after caffeine is stopped. Withdrawal symptoms peak at around 48 hours, and can last up to five days. Tapering caffeine use, for example cutting down on caffeine by the equivalent of half a cup of coffee (about 50 mg) a day, minimizes or eliminates withdrawal symptoms.

People who use more than about 500 mg (the amount varies greatly among individuals) of caffeine a day may develop a condition called caffeinism. Caffeinism produces unpleasant sensations, some of which are similar to withdrawal symptoms. Symptoms caffeine overuse include restlessness, irritability, nervousness, anxiety, muscle twitching, headaches, inability to fall asleep, and a racing heart. Severe overuse of caffeine can cause four psychiatric disorders recognized by the American Psychiatric Association and described in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition*. Caffeine is considered the cause of these disorders after other causes have been ruled out.

- Caffeine intoxication: Usually the result of taking caffeine pills (e.g., NoDoz), this condition causes mental changes, rambling thoughts and speech, irregular heart beat, and all symptoms associated with overuse. In severe cases death can result from ventricular fibrillation (unsynchronized contractions of the ventricle of the heart).
- Caffeine-induced anxiety disorder: Severe anxiety that interferes with daily social interactions and occurs after caffeine intoxication or heavy long-term use of caffeine.
- Caffeine-induced sleep disorder: An inability to sleep that is so great it requires medical/psychiatric attention and occurs after prolonged caffeine consumption.
- Non-specific caffeine-induced disorder: Disorders not listed that are attributable to either acute or long-term caffeine consumption.

## Parental concerns

Children get most of their caffeine from soft drinks. Parents should choose soft drinks that contain little or no caffeine or replace soft drinks with water, fruit juice, or low-fat milk. Adolescents are increasingly using energy drinks and energy bars containing caffeine. At the same time, many adolescents start drinking coffee. Parents educate their children about the effects of caffeine and encourage them to monitor their caffeine consumption from all sources.

Accidental overdose from caffeine pills can be fatal. Caffeine tablets, like all drugs, should be kept out of reach of children. Children who accidentally eat caffeine pills need immediate medical attention from a physician or emergency room.

### KEY TERMS

**Alkaloid**—An organic, compound found in plants; chemically it is a base and usually contains at least one nitrogen atom.

**Blood-brain barrier**—A specialized, semi-permeable layer of cells around the blood vessels in the brain that controls which substances can leave the circulatory system and enter the brain.

**Neurotransmitter**—One of a group of chemicals secreted by a nerve cell (neuron) to carry a chemical message to another nerve cell, often as a way of transmitting a nerve impulse. Examples of neurotransmitters include acetylcholine, dopamine, serotonin, and norepinephrine.

**Tolerance**—Adjustment of the body to a drug so that it takes more and more to produce the same physiological or psychological effect, or adjustment to a drug so that side effects are diminished.

# Calcium

## Definition

Calcium (Ca) is the most abundant mineral in the body. About 99% of calcium in the body is in bones and teeth. The remaining 1% is in blood and soft tissue. Calcium in body fluids is an electrolyte with a charge of +2. Humans must meet their need for calcium through diet.

## Purpose

Calcium is essential for:

- building and maintaining strong bones and teeth
- muscle contraction
- blood vessel contraction and relaxation
- nerve impulse transmission
- regulating fluid balance in the body

## Description

Most calcium in the body is stored in bones and teeth. Here it combines with phosphate to form strong, stable crystals. The remaining 1% is dissolved in body fluids and much of it forms Ca 2+ ions. In the body, these electrically charged particles are called **electrolytes**. Calcium and other electrolytes are not distributed evenly throughout the body. Dissolved calcium is found mainly in the fluid outside cells (extracellular fluid). Metabolic events cause the movement of calcium across cell membranes result in muscle contraction, nerve impulse transmission, and various chemical reactions. The cell then uses energy to restore the balance of calcium between the inside and outside of the cell membrane, so that the event can be repeated.

To remain healthy, the amount of calcium dissolved in body fluids must be stay within a very narrow range. Bone acts like a calcium bank. Bone is constantly being broken down by cells called osteoclasts and built up

again by cells called osteoblasts. This process is called bone remodeling, and it continues throughout an individual's life. When excess calcium is present in the blood, osteoblasts deposit calcium into bones. When too little calcium is in the blood, osteoblasts dissolve calcium from bones and move it into the blood. This process is controlled by parathyroid hormone (PTH) secreted by the parathyroid glands. The parathyroid glands are extremely sensitive to the level of calcium in the blood, and in a healthy individual they are able to maintain the concentration of calcium ions fluctuates very little.

### *Normal calcium requirements*

The United States Institute of Medicine (IOM) of the National Academy of Sciences has developed values called **Dietary Reference Intakes** (DRIs) for many **vitamins** and **minerals**. The DRIs consist of three sets of numbers. The Recommended Dietary Allowance (RDA) defines the average daily amount of the nutrient needed to meet the health needs of 97–98% of the population. The Adequate Intake (AI) is an estimate set when there is not enough information to determine an RDA. The Tolerable Upper Intake Level (UL) is the average maximum amount that can be taken daily without risking negative side effects. The DRIs are calculated for children, adult men, adult women, pregnant women, and **breastfeeding** women.

The IOM has not set RDAs for calcium, but instead it has set AI levels for all age groups based on observed and experimental information. However, many studies show that Americans across almost all age groups are not meeting these AI levels. One large study, the Continuing Survey of Food Intakes of Individuals, found that in children ages 6–11 44% of boys and 58% of girls were getting lower than recommended amounts of calcium. In adolescents ages 12–19, the rate of deficiency was higher—64% for boys and a huge 87% for girls. Adults over age 20 did not do much better with 55% of men and 78% of women taking in less calcium than recommended. IAs and ULs for calcium are measured in milligrams (mg). The following list gives the recommended AL and UL levels of calcium for each age group.

- children birth–6 months: AI 210 mg; UL not established;.
- children 7–12 months: AI 270 mg; UL not established.
- children 1–3 years: AI 500 mg; UL 2,500 mg
- children 4–8 years: AI 800 mg; UL 2,500 mg
- children 9–13 years: RDA 9 mg; UL 2,500 mg
- adolescents 14–18 years: IA 1,300 mg; UL 2,500 mg
- adults age 19–50: RDA 1,000 mg; UL 2,500 mg
- adults over age 50: RDA 1,200 mg; UL 2,500 mg
- pregnant women 18 years and younger: RDA 1,300 mg; UL 2,500 mg
- pregnant women over age 18: RDA 1,000 mg; UL 2,500 mg
- breastfeeding women 18 years and younger: RDA 1,300 mg; UL 2,500 mg
- breastfeeding women over age 18: RDA 1,000 mg; 2,500 mg

## KEY TERMS

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Diuretic**—A substance that removes water from the body by increasing urine production.

**Electrolyte**—Electrically charged particles (ions) that form when salts dissolve in water or fluids. Electrolytes regulate water balance in the body and play a critical role in almost every metabolic reaction.

**Enzyme**—Proteins that change the rate of a chemical reaction within the body without themselves being used up in the reaction.

**Mineral**—An inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

### *Sources of calcium*

In the United States, dairy products—milk, yogurt, and cheese—are the main sources of dietary calcium. Low-fat dairy products, such as skim milk or reduced-fat cheese, contain about the same amount of calcium as whole milk products. Other sources of calcium include canned fish with bones, dark green leafy vegetables, and tofu made with calcium sulfate. Other types of tofu do not contain significant amounts of calcium. Processed foods such as orange juice, breakfast cereal, instant breakfast drinks, and bread are often fortified with calcium. This will be indicated on the label.

The following list gives the approximate **manganese** content for some common foods:

- milk, any type, 1 cup (8 ounces): 300 mg
- yogurt, plain, 8 ounces: 415 mg
- yogurt with fruit, 8 ounces: 245–384 mg

- cheddar cheese, 1.5 ounces: 305 mg
- mozzarella cheese, 1.5 ounces: 372 mg
- sardines with bones, canned in oil, 3 ounces: 324
- salmon with bones, canned, 3 ounces: 181 mg
- tofu, firm, made with calcium sulfate, 1/2 cup: 204 mg
- pinto or red beans, cooked, 1/2 cup: 43 mg
- white beans, cooked, 1/2 cup: 113 mg
- bok choy, 1/2 cup cooked: 61 mg
- spinach, cooked, 1/2 cup: 120 mg
- bread, whole wheat, 1 slice 20 mg
- orange juice, fortified, 6 ounces: 200–260 mg
- instant breakfast drink, powder prepared with water, 105–250 mg
- breakfast cereal, fortified, 1 cup: 100–1,000 mg

Although experts recommend that people meet as many of their vitamins and minerals needs through diet as possible, it is difficult for many people to get enough calcium from food alone. This is especially true for vegans, who eat no dairy products, adolescent girls who are very calorie conscious and tend to avoid milk and replace it with diet sodas, and people with lactose intolerance who cannot easily digest dairy products. Pregnant women and older individuals may also have a hard time eating enough to meet their calcium needs. People who do not get enough calcium through diet can benefit from taking a dietary supplement containing calcium.

Calcium supplements are available over-the-counter. The most common supplements supply calcium in the form of calcium carbonate or calcium citrate. Calcium carbonate is usually the most economical calcium supplement. People who are taking medications to reduce stomach acid may more easily absorb calcium citrate. Some supplements combine calcium and **vitamin D** because vitamin D helps the body absorb calcium. No calcium supplement contains enough calcium meet the entire daily adequate intake, because the pill would be too large to swallow. In addition, the body absorbs calcium best in doses of 500 mg or less. People who need more than 500 mg of supplemental calcium should divide the dose in half to be taken morning and evening.

### *Calcium deficiency*

Calcium deficiency, called hypocalcemia, can occur because of inadequate calcium intake, excess calcium excretion by the kidney (usually caused by kidney damage), the inability to adequately absorb calcium, or because of interactions between calcium and some prescription drugs. People at highest risk of calcium deficiency are teenagers, women past the age of menopause, individuals who are lactose intolerant, vegans, and people with kidney (renal) damage.

Calcium deficiency rarely shows up in blood tests because calcium is withdrawn from the bones to maintain blood levels of calcium. The bones then become less dense, weaker, and more likely to break. This condition is called **osteoporosis** and it is most noticeable in the elderly who have a high rate of broken bones resulting from falls. Osteoporosis is a part of aging, but eating a healthy diet high in calcium, getting adequate vitamin D, and doing weight-bearing exercises regularly can delay its onset. Severe calcium deficiency, is usually caused by a medical condition rather than inadequate calcium intake. It causes symptoms such as muscle cramps, tingling in the fingers, lethargy, convulsions, heart rhythm abnormalities, and death. These symptoms can also be caused by many other diseases.

### *Calcium excess*

Calcium excess is called hypercalcemia. It usually results from poor kidney function (renal failure) or from a malignant **cancer** tumor. It can also be caused by very large supplemental doses of vitamin D. Very rarely is hypercalcemia caused by too much calcium from food or **dietary supplements**. High levels of calcium interfere with the absorption of other minerals such as **iron**, **zinc**, **magnesium**, and phosphorous. People with hypercalcemia usually have multiple medical problems and are under the supervision of a physician.

## Precautions

People of all ages, races, and gender need to be alert to getting enough calcium in their diet. Building strong, dense bones begins in childhood and adolescence, even though the results cannot be seen until old age. People mentioned above as being at especially high risk of low dietary calcium intake should investigate taking a calcium supplement.

## Interactions

Absorption of calcium is affected by several conditions.

- Age. Infants absorb as much as 60% of the calcium in their digestive system. This decreases to 15–20% in adulthood, and even less in old age.
- Pregnancy. Pregnancy increases the efficiency of calcium absorption in the intestine to meet the demands of fetal development.
- Amount of calcium consumed. The more calcium consumed at one time, the less efficient absorption

becomes. Calcium from supplements should be spaced out during the day for maximum absorption.

- Vitamin D. The presence of vitamin D improves calcium absorption. Vitamin D deficiency can worsen calcium deficiency.
- Plant products. Phytic found in beans and oxalic acid found in spinach and leafy greens decrease the amount of calcium absorbed from those foods, but does not affect the absorption of calcium from other foods present at the same time in the intestine. Fiber such as wheat bran also reduced calcium absorption.

Prescription medications can also affect or be affected by the absorption of calcium. These include:

- digoxin
- fluroquinolones
- levothyroxine
- tetracycline antibiotics
- anticonvulsants
- thiazide-type diuretics
- glucacorticoids
- mineral oil
- stimulant laxatives
- antacids

People taking these drugs should check with their healthcare provider or pharmacist about potential adjustments in their medications or calcium intake.

## Complications

No complications are expected when healthy people take calcium in amounts equal to the AI level and less than the UL level. Some people experience gas, nausea, and abdominal discomfort from calcium supplements. Taking the supplement with meals, taking smaller doses spread out over the day, or changing the type of supplement usually solves this problem. Complications of excess calcium and calcium deficiency are discussed above.

## Parental concerns

Building strong bones starts in childhood, and parents should be aware of how much calcium their child needs compared to how much he or she is getting. As children get older they tend to replace milk in their diet with juice, bottled **water**, and especially carbonated soft drinks. This leads to large calcium deficiencies during adolescence. Parents should monitor their child's diet and encourage calcium supplements if they cannot induce their adolescents to eat more dairy products and other calcium-rich food.

# Calorie restriction

## Definition

The definition of calorie restriction is when the body does not receive an adequate intake of energy. This can result as a consequence of lack of availability of adequate volumes of food. However, sometimes the failure to consume an adequate calorie intake may be a conscious and deliberate decision, for example, in individuals seeking to lose weight or people who suffer with the eating disorder, **anorexia nervosa**. Calorie restriction can result in malnutrition or a deficiency of one or more nutrients.

## Purpose

The human body requires an adequate amount of energy or calories to enable us to grow, perform daily activities, produce hormones and to minimize the risk of nutrition-related complications. Calorie requirements for individuals vary from one individual to the next and are dependent on variables including gender, age, activity levels, climate and environment and the presence or absence of medical or nutritional complications. Consequently, it is possible that individuals of similar weight and age may have different energy requirements owing to unique individual needs. In addition to the body requiring energy to perform the aforementioned tasks, energy is also required to support activity of the internal organs and to maintain body temperature. This energy is called the basal or resting **metabolism**. The basal metabolic rate (BMR) is determined experimentally when an individual is lying down at complete physical and mental rest under standardized environmental conditions. Research over many years has provided researchers with guidelines on how to assess and determine an individuals BMR using specific calculations.

**Estimated daily calorie needs**

| | Calorie range | |
|---|---|---|
| | Sedentary | Active |
| **Children** | | |
| 2–3 years | 1,000 | 1,400 |
| **Females** | | |
| 4–8 years | 1,200 | 1,800 |
| 9–13 | 1,600 | 2,200 |

## Description

Individuals require a certain number of calories on a daily basis, which incidentally may vary subject to activity levels and physical status but overall is within a relatively stable range. When dietary intake remains stable weight too remains unchanged. Conversely, increases or decreases in intake can result in weight changes. To clarify,

- When energy intake equals energy expenditure, weight remains unchanged.
- When energy intake exceeds expenditure, weight increases.
- When energy intake is less than expenditure, weight will decrease.

It is when expenditure exceeds calorie intake that the body experiences a negative energy balance and weight loss ensues.

There is little research available to help us understand the impact of starvation on humans. Understandably, ethically it would not be appropriate to impose such situations on individuals, however, two major studies did impose such situations in 1919 and

1950. This first of these studies involved the recruitment of 34 volunteers who were underfed for three months to facilitate a weight loss of 10%. This study highlighted that resting metabolic rate (RMR) decreased rapidly at first and then more slowly with continuing weight loss. The second study, carried out by Keys and colleagues, again exposed a group of male volunteers to a reduced calorie intake over a period of 24 weeks to achieve a weight loss of 25%. They confirmed a decrease in metabolic rate and estimated that 65% of the decrease in metabolic rate could be attributed to the loss of the metabolic activity of the tissue. This study also provided useful information in respect of the symptoms associated with starvation when individuals adopt restrictive eating patterns. The study highlighted that many of the signs and symptoms that people typically associate with people who suffer with an eating disorder are very likely to develop in non-eating disordered individuals if they were to be exposed to a similar extreme reduction in their dietary intake. These symptoms include an increased preoccupation with food, adoption of unusual eating patterns including concoctions of food, spending a long time consuming food, social withdrawal and a lowering of mood and an associated decrease in libido.

## KEY TERMS

**BMI**—This relates weight to height and is used as part of the nutritional assessment of individuals. BMI is the weight (in kg) divided by the height (in meters) squared. The acceptable healthy range is 20–25.

**Calorie**—The amount of heat needed to raise 1g of water by 10C. For nutritional purposes the Calorie (or kilocalorie) is the amount of heat needed to raise 1,000g of water by 10. The modern unit is the joule. One calorie is a little over 4 joules.

**Malnutrition**—A disorder resulting from an inadequate diet or failure to absorb or assimilate nutrients.

**Minerals**—Elements that are essential for the body to function correctly including calcium, iron, phosphorous, magnesium, sodium, chloride, iodine, manganese, copper, and zinc.

**Starvation**—A long-term consequence of food deprivation.

**Vitamins**—Compounds required by the body in small amounts to assist in energy production and in cell growth and maintenance. They are essential for life and with the exception of vitamin D, cannot be made in the body. They should ideally be consumed from food. However, individuals who struggle to eat can obtain their vitamin requirements from dietary supplements.

## Complications

### *Physical effects of starvation*

Malnutrition occurs when is there is a deficiency of one or more nutrients. It may be mild or severe. Severe Malnutrition is rare in developed countries but sadly remains prevalent in many developing countries. Weight loss is an obvious sign of a diet too low in calories or energy. Protein-energy malnutrition occurs when the diet provides too little energy and **protein**. Malnutrition is assessed in terms of degrees of weight loss in adults, whilst in children height and weight are used and compared with growth charts. Weight loss in adults and failure to thrive in children are the most obvious signs of insufficient energy intake. In adults, this is usually noticed by a drop in the **body mass index** (BMI), which is a method used to relate weight to height and is used as part of the process in determining an individuals' nutritional status. In children, insufficient energy intakes are noticed when children fail to meet expected growth milestones. In the long-term, stunted growth may result as a consequence of insufficient energy requirements and children may not reached an expected height for weight ratio.

It is important to remember that individuals of a healthy body weight could still be classified as malnourished if they are lacking in essential nutrients. Therefore, overall nutritional status of individuals cannot be assessed solely on body weight. Consequently, nutritional assessment screening tools are useful to help identify individuals who may be at risk of malnutrition in hospitals, care homes and primary care settings. In summary, malnutrition may develop owing to a number of factors including a decreased dietary intake, increased nutritional requirements or increased losses or an inability to absorb or utilize nutrients.

Severe cases of low energy intake result in starvation and life threatening conditions called Kwashiorkor (characterized by protein deficiency) and Marasmus (primarily a deficiency of energy-providing foods). Marasmus is a chronic condition of semi-starvation, characterized in later stages by muscle wasting and an absence of subcutaneous fat and to which children adjust, to some extent, by reduced growth. In Kwashiorkor, subcutaneous fat is usually preserved; muscle wasting occurs but is often masked by edema (swelling). Overall the physical effects of malnutrition are dependent on what nutrients are missing from the diet, for example,

calories, protein, fat, **vitamins** or **minerals**. Usually, when individuals dietary intake is inadequate there is likely to be an overall deficiency of many nutrients.

Below is a list of some of the general effects of starvation.

- tiredness
- lethargy
- poor concentration
- weakness
- hair loss and sometimes the growth of additional hair on the arms and back. (The growth of additional hair called lanugo hair and is frequently evident on people who suffer with anorexia nervosa.)
- decreased muscle mass and tone
- weight loss
- menstruation may stop if weight loss is serious
- delayed puberty in adolescents
- iron-deficiency anemia
- poor immunity
- decrease in bone mineral density and an increased risk of osteoporosis if weight loss is not reversed
- constipation
- deficiencies of various vitamins and minerals
- delayed gastric emptying

#### *Cognitive changes associated with starvation*

As the body starts to lose weight as a as a result of insufficient energy intake, the ability of the brain to function correctly is impaired. The symptoms associated with changes in the way the brain functions are referred to as cognitive changes.

The cognitive changes associated with starvation include

- increased risk of depression-related symptoms
- poor decision making skills
- irritable
- anxiety
- very reactive
- poor concentration

#### *Social and sexual changes associated with starvation*

- withdrawal from social activities
- decreased libido
- decreased enjoyment in previously enjoyed activities

### Parental concerns

As mentioned above, children who have an insufficient energy intakes over prolonged periods of time may not reach expected growth rates. Furthermore, they may lose weight and ultimately experience stunted growth and develop nutrition-related complications. Parents should ensure that a registered doctor monitors growth rates regularly or a suitably qualified professional.

## Cambridge diet

### Definition

The Cambridge diet is a commercial very-low-calorie diet (VLCD). The diet was first used only in weight-loss clinics in the United Kingdom. In the early 1980s, the products associated with the diet (powder mix, meal bars, and liquid meals) started selling commercially in the United States and the United Kingdom. Formulations of the Cambridge diet in the United Kingdom differ from that sold in the United States. In both the United Kingdom and North America, the Cambridge products are available only from distributors; they cannot be purchased over the counter at pharmacies or supermarkets.

**Cambridge diet**

**British version—4 stages**

**Preparation**
Reduce food intake gradually over a week or 10 days before beginning the diet

**Losing weight (Sole Source program)**
Women shorter than 5' 8": three servings of Cambridge diet products daily and no other food
Women taller than 5' 8" and men: four servings of Cambridge diet products daily and no other food
Coffee, tea, and tap and bottled water allowed
Drink at least 2 quarts of fluid per day
415 to 554 calories per day

**Stabilization**
After 4 weeks on the Sole Source program, add a meal of 3 oz. of lean white fish or poultry, cottage cheese, and a portion of green or white vegetables to the basic Cambridge meals
Total of 790 calories per day
Return, if necessary, to the Sole Source regimen for further rapid weight loss
Other options allow 1,000 or 1,200 calories per day for more gradual weight loss or to accommodate lifestyles

**Weight maintenance**
Begins at an intake of 1,500 calories per day

**American version—5 programs**

**Regular**
Designed for a weight loss of 2–5 pounds per week
820 calories per day: 3 servings of Cambridge Food for Life formula plus one 400-calorie conventional meal
A minimum of 8–10 glasses (8oz.) of water daily
Tea and coffee allowed, but not as substitutes for the water
Continue on the program until weight loss goal achieved

**Fast start**
For rapid and safe weight loss
Regimen is similar to the British Sole Source program
Do not remain on the program longer than 2 weeks at a time
Return to the Regular Program and contact a physician if experiencing headaches, nausea, or vomiting

**Physician-monitored**
Recommended for weight loss of 30 pounds or more, or for persons under doctor's care for other medical conditions
Essentially the British Sole Source program, with the added provision that the dieter switch to the Regular Program when 10 to 15 pounds from weight goal

**Maintenance**
Essentially the use of the Cambridge's Food for Life nutrition formula as a foundation, adding conventional foods while determining caloric level to maintain body weight

**Lifetime nutrition**
Use Cambridge diet products as meal substitutes for one or two meals a day, or as healthy snacks

*(Illustration by GGS Information Services/Thomson Gale.)*

## Origins

### *United Kingdom and Western Europe*

A scientist at Cambridge University in England, Alan Howard, initiated the research that eventually lead to the development of the Cambridge diet in the 1960s. Howard became interested in **obesity** as an increasingly common nutritional problem. He worked together with Ian McLean-Baird, a physician at the West Middlesex Hospital, to create a formula diet food that would allow people to lose weight rapidly without losing lean muscle tissue, create a mild ketosis (a condition in which the body begins to use fat rather than **carbohydrates** as a source of energy), and contain enough **vitamins**, **minerals**, and micronutrients to maintain health. Howard and Mc-Lean Baird also organized the first national symposium on obesity in the United Kingdom, which was held in 1968.

The formula that satisfied the researchers' goals was successful in helping people in hospital obesity clinics lose weight, but was not particularly appetizing. The researchers collaborated with food technologists to improve the flavor of the formula. After further testing with clinic patients, the Cambridge diet was marketed commercially in the United Kingdom in 1984, four years after it was available in the United States. In 1985 the Cambridge diet became available in Germany, France, and the Scandinavian countries, and in 1990 in Poland and Eastern Europe. The British company, Cambridge Manufacturing Company Limited (CMC), which manufactures the diet products as well as the Cambridge Health and Weight Plan, were owned by the Howard Foundation between 1982 and 2005, a charitable trust established by Alan Howard to offer scholarships to international students and to fund research in obesity and nutrition. In 2005 the Cambridge Manufacturing Company was sold to its three senior managers and became Cambridge Nutritional Foods Limited.

The present Cambridge diet products available in the United Kingdom are sachets (packets) of powder, Mix-a-Mousse granules, liquid meals, and meal bars. The sachets are intended to be mixed with a half-pint of **water** (hot or cold) to produce a shake or soup. The sachets, which provide about 138 calories, are sold in boxes of 21 servings, a week's supply. There are 12 different flavors including banana, mixed fruit, and chicken mushroom. The dieter may also purchase Mix-a-Mousse granules that add 20 calories to the powdered formula but give it a thicker texture. The liquid formula is available in a ready-to-drink version packaged as Tetra Briks—sealed cartons with straws. Tetra Briks come in banana or chocolate flavor. There are four flavors of chocolate-covered meal bars (caramel, chocolate, orange, and toffee), one of which can be consumed each day.

Each sachet or liquid formula contains enough nutrients to be used as a complete meal. The meal bars can replace a meal as well but have extra carbohydrates and should only be eaten once a day. The Cambridge diet products can be consumed exclusively

## KEY TERMS

**Body mass index (BMI)**—The ratio between a person's weight and the square of their height. A BMI over 25 is considered overweight; below 20 is considered underweight.

**Cholelithiasis**—The medical term for gallstones. People on a VLCD have an increased risk of developing gallstones from an increase of cholesterol content in the bile produced by the liver.

**Cognitive behavioral therapy (CBT)**—An approach to psychotherapy based on modifying the patient's day-to-day thoughts and behaviors, with the aim of changing long-standing emotional patterns. Some people consider CBT a useful or even necessary tool in maintaining long-term weight reduction.

**Ketosis**—An abnormal increase in the number of ketone bodies in the body, produced when the liver breaks down fat into fatty acids and ketone bodies. Ketosis is a common side effect of low-carbohydrate diets or VLCDs. If continued for a long period of time, ketosis can cause serious damage to the kidneys and liver.

**Very low-calorie diet (VLCD)**—A term used by nutritionists to classify weight-reduction diets that allow around 800 calories or fewer a day.

as meal replacements or used in conjunction with regular food (e.g., sachet for breakfast, Tetra Brik for lunch, and normal dinner).

### *United States*

Rights to the original Cambridge diet formula—a powder to be mixed in a blender with water or diet soft drinks—in the United States were obtained by Cambridge Direct Sales in 1979. After working to improve the formula's flavor, the diet was placed on the market in 1980. It was initially quite popular. The original version of the Cambridge diet is sometimes known as the "Original 330 Formula" in the company's promotional literature because Dr. Howard's first rapid weight-loss program called for a total daily consumption of only 330 calories, provided by three servings of the original powder formula (110 calories per serving). The nutrient ratio of the original formula is 10–11 g of **protein** per serving, 15 g of carbohydrates (derived primarily from fructose or fruit sugar), and 1 g of fat.

In 1984 Cambridge Direct Sales hired Dr. Robert Nesheim to develop Cambridge Food for Life products. Like the Original 330 Formula, Food for Life is a powder that comes in a can to be reconstituted with conventional foods. Food for Life is available in a super oats cereal version as well as flavor choices including tomato, potato, mushroom, chicken soup, vanilla, chocolate, strawberry, and eggnog. Nesheim was specifically asked to meet guidelines for nutrition supplements established by the U.S. Food and Drug Administration (FDA). The company states that Nesheim "increased the protein and carbohydrate content for an extra margin of safety when used as the sole source of nutrition." Food for Life contains 140 calories per serving, 13–15 g of protein, 18 g of carbohydrates, and 1 g of fat.

The American company introduced a Cambridge nutrition bar in 1983, but was unsuccessful as the product had a short shelf life, and lacked flavor appeal. Dr. Nesheim tripled the shelf life of the nutrition bars and improved their taste. Each bar contains 170 calories, with 10 g of protein, 19–22 g of carbohydrates, and a low fat content.

## Description

### *British version*

The British version of the Cambridge diet cannot be used without the supervision of an official counselor, who "provide[s] a personal screening, advisory, monitoring and support service." The counselors are trained and accredited by the company, and must follow a code of conduct in their dealings with customers. According to the company, most counselors are people who have successfully used the Cambridge diet themselves.

The British version of the Cambridge diet is for adults over the age of 16 and has four stages:

- Preparation: The dieter is asked to reduce food intake gradually over a week to 10 days before beginning the diet.
- Losing weight: This initial step is called the "Sole Source" program and gives the dieter between 415 and 554 calories per day. Dieters are advised not to remain on the Sole Source program for longer than four weeks at a time. They are required to obtain a signed certificate from their doctor before they can begin the Sole Source program. Female dieters shorter than 5 ft 8 in take three servings of Cambridge diet

products per day and eliminate other food; women taller than 5 ft 8 in and men are allowed four servings. Allowable beverages include coffee, tea, and tap or bottled water; forbidden beverages include alcoholic drinks, coffee or tea with milk added, fruit juices, and any drink containing sugar. The dieter is advised to drink at least 2 qt of fluid per day.

- Stabilization: After four weeks on the Sole Source program, the dieter can add a meal of 3 oz lean white fish or poultry, cottage cheese, and a portion of green or white vegetables to the basic Cambridge meals for a total of 790 calories per day. The dieter can then return to the Sole Source regimen for further rapid weight loss. There are other options allowing the dieter 1,000-1,200 calories per day that are better suited for gradual weight loss.
- Weight maintenance: Begins at an intake of 1,500 calories per day.

### *American version*

The American version of the Cambridge diet is divided into five separate programs:

- Regular: Designed for a weight loss of 2–5 lb per week, the Regular Program provides 820 calories per day: three servings of Cambridge Food for Life formula plus one 400 calorie conventional meal. The dieter is advised to drink a minimum of 8–10 8-oz glasses of water each day. Tea and coffee are allowed, but not as substitutes for the water. There is no stipulation that the Regular program is limited to four weeks.
- Fast Start: Similar to the British Sole Source program, the Fast Start program is to be followed no longer than two weeks at a time. The dieter is advised to return to the Regular Program and contact a physician if they experience headaches, nausea, or vomiting.
- Physician-Monitored: Recommended for persons who need to lose 30 lb or more, or who are under a doctor's care for other medical conditions. It is essentially the British Sole Source program with the added provision that the dieter should switch to the Regular Program when he or she is 10–15 lb from their goal weight.
- Maintenance: Uses the Food for Life nutrition formula as a foundation, while adding conventional foods until a caloric intake is determined to maintain an ideal weight.
- Lifetime Nutrition: The Food for Life company recommends using the Cambridge diet products as meal substitutes for one or two meals a day, or as snacks indefinitely. This maintenance program is not endorsed by any government agency.

## Function

The Cambridge diet claims to be a flexible plan that can be used as a VLCD for rapid initial weight loss and then modified to serve as a maintenance diet.

## Benefits

The Cambridge diet offers a rapid initial weight loss that compensates (for some dieters) the low calorie intake and other food restrictions. The American version also offers a peer support network and a self-instruction program based on cognitive behavioral therapy (CBT) called Control for Life.

## Precautions

People under a physician's care for high blood pressure, kidney or liver disease, diabetes, or who need to lose more than 30 lb should consult their physician before starting the Cambridge diet or any VLCD. The Cambridge diet should not be used by adolescents under the age of 16, and should be used by elderly persons, pregnant women, or nursing women only with caution.

## Risks

VLCDs in general should not be attempted without consulting a physician, and the Cambridge diet is no exception. The diet is not suitable for people whose work or athletic training requires high levels of physical activity. One physical risk from this diet, as from other VLCDs, is an increased likelihood of developing cholelithiasis, or **gallstones**.

There is also some financial risk to using the Cambridge diet. Although the American website states that the Physician-Monitored version is less expensive than VLCD hospital programs, all forms of the Cambridge diet cost $95–100 for a 15-day supply of the Original 330 Formula or $85–89 for a 15-day supply of the Food for Life formula. A case of six cans of the Original 330 Formula, supplying a total of 126 servings, is about $160. Although the cost per meal is between $1.25 and $1.45, the fact that the dieter must purchase at least a two-week quantity at a time is a risk for people who may not like the products well enough to remain on the diet.

A common criticism of the Cambridge diet, as of all VLCDs, is that it does not teach the dieter how to make wise food choices or the other lifestyle changes necessary to maintain weight loss. The British website states rather defensively, "To these armchair critics [the Cambridge diet] is just another fad diet. Nothing could be further from the truth as anyone can vouch

## QUESTIONS TO ASK YOUR DOCTOR

- Have any of your patients ever tried the Cambridge diet? If so, how much weight did they lose? How long did they maintain the weight loss?
- Have you ever supervised anyone on the "Physician-Monitored" form of this diet?
- Do you know of anyone who has ever had health problems or adverse effects from following the "Regular" or "Fast Start" versions of the Cambridge diet?
- Have you read any of the research studies published about this diet? If so, what is your opinion of their findings?
- In your opinion, is cognitive behavioral therapy a helpful addition to a VLCD?

who has used the diet as a sole source of nutrition for several weeks. For the first time one realises that vast quantities of food are not indispensable to life. It trains you to live without having food continually on your mind and the experience has a beneficial effect on most people."

### Research and general acceptance

Proponents of the Cambridge diet claim that it is scientific and has been subjected to clinical research, however, there are no recent studies in mainstream medical journals specific to this diet. The British Cambridge diet website cites research papers from the late 1990s on VLCDs as a group, most of them concerning studies conducted in England, Sweden, and Finland. In addition, neither the two British researchers who originally developed the diet nor the American scientist who reformulated the British products for the American market in 1984 began their careers as weight reduction experts. John Marks was trained as a psychiatrist and published a number of books in psychological medicine, dependence as a clinical phenomenon, and the misuse of benzodiazepine tranquilizers as well as editing an encyclopedia of psychiatry. He wrote a book on the use of vitamins in medical practice in 1985, one year before the book he co-authored with Alan Howard on the Cambridge diet.

Robert Nesheim, the American physician credited with reformulating the original Cambridge diet products for the American market, began as a researcher in agricultural medicine. Dr. Nesheim acted as chief of research and development at the Quaker Oats Company until he retired in 1983. He believed in promoting products on the basis of taste, convenience, and cost.

Opinion is somewhat divided among medical and health care professionals on the subject of VLCDs as a group of weight reduction regimens, with European researchers tending to be more favorable to these plans than physicians in North America. The first report of the National Task Force on the Prevention and Treatment of Obesity on these diets noted that ":Current VLCDs are generally safe when used under proper medical supervision in moderately and severely obese patients (**body mass index** 30) and are usually effective in promoting significant short-term weight loss. . . . [but] long-term maintenance of weight loss with VLCDs is not very satisfactory and is no better than with other forms of obesity treatment."

In general, researchers in the United States and Canada maintain that VLCDs are not superior in any way to conventional low-calorie diets (LCDs). One Canadian study reported in 2005 that a history of **weight cycling** tended to lower the health benefits that obese patients could receive from VLCDs, while a 2006 study carried out at the University of Pennsylvania in Philadelphia found that the use of liquid meal replacement diets (LMRs) with a daily calorie level of 1000–1500 calories "provide[d] an effective and less expensive alternative to VLCDs." The American Academy of Family Practice (AAFP), a professional association of primary care physicians, discourages the use of VLCDs in general, and categorizes the Cambridge diet in particular as a liquid "fad diet." The only study that reported that VLCDs are "one of the better treatment modalities related to long-term weight-maintenance success" was completed in the Netherlands in 2001. The Dutch researchers added, however, that an active follow-up program, including behavior modification therapy or cognitive behavioral therapy and exercise, is essential to the long-term success that they reported.

Rebecca J. Frey, PhD

# Cancer

## Definition

Cancer is a group of diseases characterized by uncontrolled growth of cells in the human body and the ability of these cells to travel from the original site and spread to distant sites. Another name for cancer cells is malignant cells. Diet and nutrition play an important role in cancer prevention and cancer treatment.

## Description

By definition, cancer is a disease of the genes. A gene is a small part of DNA, which is the master molecule of the cell. Genes make proteins, which serve as the workhorses of the body's cells. These proteins allow the body to carry out all of the many processes that permit breathing, thinking, moving, and others often taken for granted.

Throughout people's lives, the cells in their bodies are growing, dividing, and replacing themselves. Many genes produce proteins that are involved in controlling the processes of cell growth and division. Any alteration, or mutation, to the DNA molecule can disrupt the genes and produce faulty proteins. This causes the cell to become abnormal and lose the restraints on its growth. The abnormal cell will begin to divide uncontrollably. The new growth it forms will be called a tumor or neoplasm. Not all tumors are cancerous. Those that are cancerous spread to other parts of the body near the original cancer site or to distant sites. Cancerous tumors are called malignancies. A tumor that is not cancerous is called benign.

Cancer can occur in anyone and is the second leading cause of death in the United States. Although cancer may be inherited, it also may occur due to certain environmental risk factors or behaviors. For example, it is well known that smoking can lead to lung cancer or that unprotected sun exposure is a risk factor for skin cancer. Diet and physical activity also play a role in cancer risk.

## Demographics

The American Cancer Society (ACS) estimated that almost one and one-half million new cases of cancer would be diagnosed in 2007 in the United States. And more than 1,500 people a day were projected to die of cancer in 2007. Lung cancer remains the leading cause of cancer deaths among U.S. men and women. **Prostate** cancer is the second-leading cause of cancer deaths among men and breast cancer is the second-leading cause of death among U.S. women. Colon and rectal cancer is the third-leading

**Most prevalent cancer-related deaths, 2002**

| Male cancers | Deaths (000) | Female cancers | Deaths (000) |
|---|---|---|---|
| Trachea/ bronchus/lung | 886 | Breast | 474 |
| Stomach | 523 | Trachea/ bronchus/lung | 353 |
| Liver | 428 | Stomach | 326 |
| Colon/rectum | 321 | Colon/rectum | 299 |
| Oesophagus | 284 | Cervix Uteri | 239 |
| Prostate | 268 | Liver | 191 |

## KEY TERMS

**Benign**—Mild, does not threaten health or life. When referring to a tumor, it generally means noncancerous.

**Malignant**—Unfavorable, tending to produce deterioration or death. For a tumor, it generally means cancerous.

**Radiopharmaceutical**—A drug that is radioactive. It is used for diagnosing or treating diseases.

cause of cancer death among U.S. men and women. There are various racial and ethnic differences in incidence of cancer and deaths from cancer in the United States. Some of these differences may be due to cultural factors such as behaviors or access to care. Others may be related to genetics. Survival rates for all races and types of cancer combined continue to increase substantially. From 1996-2002, 66% of cancer survivors lived five years or longer, combined with only 50% between 1975 and 1977.

### Causes and symptoms

There are numerous risk factors and causes of cancer. Among them are age, sex, and family medical history. Some risk factors depend on the type of cancer. In some cases, a person may have more than one risk factor for the disease. Another person may be diagnosed with cancer and have no apparent risk factor. Genetic causes can't be controlled by an individual, but people who know they are at risk because a close relative had a particular cancer should follow all recommendations for screening and prevention.

Often, physicians cannot explain what causes cancer. In addition to a family history of cancer, overall risk factors for cancer include aging, tobacco or alcohol use, exposure to sunlight or ionizing radiation, exposure to certain chemicals or substances, and exposure to some viruses and bacteria. Poor diet, lack of physical activity, or being overweight also are risk factors for cancers. Not all of these risk factors pertain to all cancers. For example, exposure to sunlight is a risk factor for skin cancer, while certain hormones increase the risk of breast cancer.

Cancer may not produce pain. And many symptoms may be due to a condition that is not cancer. But any signs similar to those for a particular cancer or that show a change in health should be checked by a physician. Symptoms vary depending on the type of cancer, but some common symptoms of cancer include:

- feeling weak or very tired
- a lump in the breast or any other part of the body
- a new mole or changes in an existing mole
- changes to bowel or bladder habits
- hoarseness or a cough that won't go away
- a sore that doesn't heal
- difficulty swallowing
- unexplained weight loss or weight gain
- unusual discharge or bleeding

### Diagnosis

Generally, the earlier cancer is found, the better. Many cancer types have screening methods to help find them early. For example, screening mammography helps detect breast cancer before symptoms occur. A Pap test screens for cervical cancer. Several tests, such as colonoscopy, are recommended for people of certain ages or with certain risk factors, to screen for colon and rectal cancer. It is important to follow the guidelines of organizations such as the American Cancer Society concerning recommended screening for cancers.

Physicians use a combination of family and medical history, screening examination results, laboratory examinations, imaging examinations, and other procedures to diagnose cancer. Family and medical history are important to look for hereditary links to many cancers. Medical history helps to determine if a person may have behaviors, such as smoking, that increase risk for many cancers.

Laboratory examinations may test a person's blood, urine, or other fluids. These tests often are conducted to search for levels of substances called tumor markers. Laboratory tests alone cannot diagnose cancer, but can help lead a physician toward or away from a suspected diagnosis.

X rays are traditional imaging and may be the first type of imaging performed. Mammography is a form of x ray; it is the screening and diagnostic examination used to detect breast cancer. Chest x rays may be used to detect lung cancer. Other types of x rays may be used in cancer diagnosis.

Computed tomography (CT) scanning. Because the use of the computer can generate finer, cross-sectional detail in combination with x rays, CT scans often are used to image a particular area. And CT scans have been used to screen for lung cancer, though the practice still is in debate. CT colonography can screen for polyps and other lesions in the large intestine, much like a colonoscopy. But CT is noninvasive, meaning it does not penetrate the skin or enter the body. CT may involve use of contrast that is injected to help make certain fluids or tissues more visible on the image for the radiologist.

Nuclear medicine or radionuclide scans involve injection of a small amount of a radiopharmaceutical into a vein. The agent flows through the bloodstream and collects in certain areas or organs. When a special camera is used to take images, the agent will show in "hot spots," which the radiologist will use to interpret the results. Often, nuclear medicine scans will be used to check for spread of cancer to bone, but they also have other uses. Most of the radiopharmaceutical passes out of the body in urine or stool and the rest disappears through natural loss of radioactivity over time. Reaction to the agent is rare.

Ultrasound is an imaging examination that does not use radiation. Instead, high-frequency sound waves are used to produce images. Ultraound often is used to follow up in suspicious mammogram findings. Ultrasound images show fluids and soft tissues very well and often help radiologists determine if a mass is most likely a benign cyst or a malignant (cancerous) solid mass. Other common areas that ultrasound is used to image when diagnosing cancer are the thyroid, the abdomen, the pelvic area (ovaries, uterus), and the prostate.

Magnetic resonance imaging (MRI) also does not require use of radiation. Instead, a strong magnetic field and radio waves provide clear and detailed pictures through a computer display. MRI has proven to be the most sensitive examination for brain tumors. MRI also has become increasingly useful in breast cancer imaging in recent years, as well as for many other suspected cancers.

Positron emission tomography, or PET, scanning is a nuclear medicine procedure that acquires images based on detection of radiation, as in a radionuclide scan, but through emission of positrons. Positrons are tiny particles emitted from a radioactive substance administered to the patient. Cancer cells sometimes show up as areas of high activity. In recent years, physicians have been able to combine these images with CT images, fusing them with one another to show superb detail of the anatomy from CT scans along with the functional details gained from PET. These images improve diagnosis, staging, and tracking of treatment progress for cancer patients.

In most cases, at least for cancers that are solid tumors, a biopsy is the only definite method for confirming cancer diagnosis. Before many of the imaging methods discussed above were developed, a biopsy only could be performed through surgery, where a small sample of the tissue was cut out and sent to a laboratory for evaluation by a pathologist. Today, these samples can be extracted using small needles. The physician can be guided to the site of the suspected cancer by use of ultrasound, CT, MRI, or other imaging methods. The biopsy method often is called fine needle aspiration biopsy or core needle biopsy. Biopsies also may be performed during surgery, particularly to verify and stage cancer when a mass is removed as part of treatment. Removal and biopsy of the entire tumor is called excisional biopsy, while removal of only a portion of the tumor is called incisional biopsy.

## Treatment

Planning treatment for cancer first involves staging of the cancer. Once the physician has gathered the information needed to determine the cancer's stage, the physician will communicate with the patient about treatment options. The most common treatments for cancer are chemotherapy, radiation, and surgery. A cancer patient may receive one or all of these treatments or a combination of them in any order. The particular use and details of each treatment depend on the type of cancer, the stage, and many other factors individual to each patient.

### *Staging*

Cancer staging determines the extent of the cancer in the body. It usually is based on the size of the original tumor, whether the cancer has spread to the lymph nodes, and whether the cancer has spread to organs of the body that are distant from the original site. Each cancer has its own staging system using letters and numbers. The T in cancer staging describes the original tumor and the N stands for whether the cancer has spread to nearby lymph nodes. The M stands for metastases, or distant spread of the cancer. Numbers area assigned along with the letters. Stage I cancers are the least advanced and have the best outlook for survival. Stage IV is the most advanced level. A cancer's stage

does not change, even if cancer recurs or distant spread develops.

### *Chemotherapy*

Cancer can spread, even early in the cancer cells' development. Chemotherapy uses cancer-killing drugs that are given to the patient by mouth or by intravenous injection. The drugs travel through the bloodstream to try to kill cancer cells throughout the body, not just at the original tumor site. Usually, the drugs are given in cycles and treatment can last up to six months. Chemotherapy may cause side effects, including fatigue, nausea, and increased susceptibility to colds and infections.

### *Radiation therapy*

Also called radiotherapy or radiation treatment, radiation therapy usually is used to shrink or control growth of a tumor. The radiation destroys the cancer cells' ability to reproduce and the body naturally gets rid of the cells. In the past, radiation only came from external beam radiation therapy, where x-ray beams were directed toward the tumor from a machine outside the patient's body. But patients also may receive brachytherapy, a procedure in which radioactive sources, sometimes called seeds, are placed inside the body at the tumor site. Radiation therapy techniques have improved dramatically in recent years. Using computers and 3-D imaging, radiation oncologists and radiation therapists can precisely target the tumor area, sparing healthy tissues. Newer techniques even take into account natural movements such as breathing to better target the cancer cells. Radiation can produce some side effects, such as skin changes. Most of the effects are short term.

### *Surgery*

When a surgeon removes cancerous tissue, he or she often removes a little bit of the tissue around it. This is to ensure that all of the cancer cells were removed, to help minimize chance of recurrence. Surgery may require a hospital stay and recovery time, depending on the type and extent of the surgery. The belief that surgery for cancer leads to spreading of the disease is untrue.

## Nutrition/Dietetic concerns

Diet also is an important part of cancer treatment. It is important to eat the right kinds of foods before treatment, during treatment, and after treatment.

The American Cancer Society says that according to scientific evidence, about one-third of the cancer deaths that occur in the United States each year are due to nutrition and physical activity factors. These factors include excess weight. In 2006, the ACS recommended that Americans maintain a healthy weight throughout life, adopt a physically active lifestyle as adults and children, and consume a healthy diet with an emphasis on plant sources. The physical activity suggestions include at least 30 minutes of moderate to vigorous physical activity for adults five or more days a week, with 45 to 60 minutes of activity preferred. Children and adolescents should engage in at least 60 minutes of activity at least five days a week.

The ACS recommends choosing food and beverages that help to achieve and maintain a healthy weight. The society also recommends eating nine or more servings of a variety of fruits and vegetables per day. Whole grains should replace processed grains and the recommendations say to limit consumption of processed and red meats. Scientific evidence shows that populations with diets rich in vegetables and fruits but low in animal fat, meat, and calories have reduced risk of some common cancers.

Diet also is important during cancer treatment. Cancer and its treatment can cause nutritional deficiencies. Many cancer treatments can cause loss of appetite, and chemotherapy can additionally cause nausea. Radiation also can affect appetite, depending on the location of the tumor and treatment. Other nutritional needs for cancer patients arise because of a tendency to lose weight and muscle mass. When cancer is diagnosed, many patients will be placed on high-protein and high-calorie diets for a period of time to help maintain muscle and weight.

During treatment, the physician may recommend diet strategies to help soothe side effects. If patients are having trouble chewing or difficulty swallowing, thick liquids such as milkshakes may be suggested. Other semi-solid foods such as mashed potatoes may be helpful until swallowing or chewing ability improves. Other patients may have pain, nausea, vomiting, or diarrhea. Eating a meal before treatment may ease nausea. Eating small meals several times a day and choosing bland foods are some suggestions caregivers will offer patients to deal with nausea caused by cancer treatment. Diarrhea can be treated by eating broth, soups, sports drinks, or bananas and avoiding greasy foods. Loss of appetite can be overcome by eating small snacks that contain plenty of calories and **protein** and eating foods with odors that are appealing, as well as by trying new foods. Sometimes, cancer treatment alters the taste of foods. Rinsing the mouth before eating, using plastic utensils if foods taste metallic and adding spices to foods may help ease the symptoms.

After cancer treatment, it is important to resume healthy eating habits, following the recommendations of the American Cancer Society to maintain a healthy weight, be as physically active as possible, and to eat a balanced diet that leans toward whole grains and plant-based foods instead of red meats and processed foods.

### Therapy

Some cancer patients will need nutrition therapy to restore nutrients and remain nourished, particularly if they experience malnutrition because of their cancer or cancer treatment. Nutrition therapy may consist of enteral nutrition, also known as tube feeding. Enteral nutrition is food given in liquid form directly through a tube that is inserted into the stomach or small intestine. Parenteral nutrition is delivered into the blood stream through a thin tube, or catheter, inserted into a vein. Eating by mouth always is preferred to these methods, and patients are encouraged to eat as soon as they can following these nutrition therapies.

Some patients may receive palliative care for cancer. Palliative care is not treatment of the cancer, but steps taken to improve the patient's quality of life and symptom side effects. Hospice is a program of special care for patients who are at the end of their life. It may be provided in a hospital, special hospice facility, or in cooperation with the patient's family and other caregivers in the patient's home.

### Prognosis

Cancer prognosis depends on the type and stage of cancer at diagnosis, the person's overall health at diagnosis, and treatment success. Studies show that physicians sometimes are reluctant to provide information about prognosis, so it is important for cancer patients to ask specific questions about their likelihood of survival if they want detailed information.

### Prevention

In addition to following the American Cancer Society guidelines concerning diet, nutrition, and activity, it is important to follow recommendations from the ACS, family physicians, and other credible health sources regarding behaviors that might lead to cancer. Examples of these behaviors include tobacco use and exposure to ultraviolet rays (sunshine) without protection. Anyone who has a first-degree relative with cancer should speak with their physician about their risk for the same type of cancer and participate in recommended screening as recommended. In cancer, early detection is essential to treatment and good prognosis.

## Cancer-fighting foods

### Definition

It appears more than ever, that there is a great deal of truth to the philosophy of eating fruits and vegetables to maintain optimum health. It is not only because of the nutrients they contain in the form of **vitamins** and **minerals**, also because of the chemicals found in these foods. Scientists continue to extensively study the nutrient quality and quantity of foods we consume. Although scientists are still not certain about the specifics, they're beginning to close in on the healthful constituents of plant-based foods. In particular, they're looking closely at two components: phytochemicals and **antioxidants**. The goal is to determine precisely how and why these substances in fruits and vegetables can prevent or stop the development of tumors and **cancer**. When animals are given vegetables and fruits before being exposed to carcinogen (cancer-causing agents), they are less likely to develop cancer. Although additional experimental data needs to be collected in humans, there is evidence to suggest that consuming generous amounts of fruits and vegetables plays an important role in preventing cancer.

### Purpose

Phytochemicals, are plant chemicals that are naturally occurring substances in plants. Several hundred types of phytochemicals have been identified, but many more likely remain to be identified. Some examples include indoles in cabbage or cauliflower, saponins in

**Cancer-fighting foods**

| Foods | Effects on cancer |
|---|---|
| Avocados | May attack free radicals in the body by blocking intestinal absorption of certain fats; may be useful in treating viral hepatitis (a cause of liver cancer) |
| Beans | May prevent or slow genetic damage to cells, prevent prostate cancer, and lower the risk of digestive cancers |
| Berries | May help prevent skin, bladder, lung, and breast cancers and slow the reproduction of cancer cells |
| Cabbage and cauliflower | May slow cancer growth and development and help to reduce the risk of lung, prostate, and bladder cancers |
| Broccoli | May prevent some types of cancer, including stomach, colon and rectal |
| Carrots | May reduce a wide range of cancers including lung, mouth, throat, stomach, intestine, bladder, prostate and breast |
| Chili peppers and jalapeños | May prevent cancers such as stomach cancer |
| Cruciferous vegetables (broccoli, cauliflower, kale, Brussels sprouts, and cabbage) | May help decrease prostate and other cancers |
| Dark green leafy vegetables | May reduce the risk of lung and breast cancer |
| Figs | May shrink tumors |
| Flax | May reduce the risk of breast, skin, and lung cancer |
| Garlic | May increase the activity of immune cells that fight cancer and indirectly help break down cancer causing substances. May help block carcinogens from entering cells and slow tumor development. May render carcinogens in the liver inactive May lower risk of a variety of cancers including stomach, colon, lung and skin |
| Grapefruits | May prevent cancer by sweeping carcinogens out of the body and inhibit the proliferation of breast-cancer cells in vitro |
| Grapes | May inhibit the enzymes that can stimulate cancer-cell growth and suppress immune response |
| Kale | May help stop the conversion of certain lesions to cancerous cells in estrogen-sensitive tissues, suppress tumor growth, and block cancer-causing substances from reaching their targets |
| Licorice root | May prevent the growth of prostate cancer |
| Mushrooms | May help the body fight cancer and build the immune system |
| Nuts | May suppress the growth of cancers |
| Oranges and lemons | May stimulate cancer-killing immune cells like lymphocytes that may function in breaking down cancer-causing substances |
| Papayas | May reduce absorption of cancer-causing nitrosamines from the soil or processed foods. May minimize cervical dysplasia and certain cancers |
| Red wine | May inhibit cell proliferation and help prevent cancer |
| Rosemary | May inhibit the development of breast and skin tumors |
| Seaweed and other sea vegetables | May help in the fight against breast cancer |
| Soy products like tofu | May help to prevent breast and prostate cancer by blocking and suppressing cancerous changes |
| Sweet potatoes | May prevent cancer cells from dividing, reduce the risk of cancer of the stomach, lung, colon, rectum, liver and pancreas, and protect against various types of cancer |
| Tomatoes | May combat prostate cancer and protect against breast, lung, mouth, stomach, and pancreatic cancer. May reduce risk of breast, prostate, pancreas and colorectal cancer. May prevent cellular damage that leads to cancer. |
| Tumeric | May inhibit the production of the inflammation-related enzyme cyclo-oxygenase 2 (COX-2), which reaches abnormally high levels in certain inflammatory diseases and cancers, especially bowel and colon cancer |
| Whole grains | May help decrease the risk of developing most types of cancer |

*(Illustration by GGS Information Services/Thomson Gale.)*

peas and beans, genstain in soybeans and isoflavones in **soy** milk and tofu. Over the past 20 years, nutrition scientists have consistently found that individuals that eat greater amounts of vegetables and fruits have lower rates of cancer. It has been only recently that the mechanism(s) by which phytochemicals assist the body in resisting cancer have begun to be understood. The phytochemicals present in fruits and vegetables protect the body by stunting the growth of malignant cells. Investigators have only an inkling of how many phytochemicals exist and how they work. They are confident, however, that an individual can get a basketful of anticancer nutrients by mixing and matching at least five servings a day of fruits and vegetables with seven or more starchy or protein-rich plant foods such as grains, peas and beans, and potatoes.

Supplements containing vitamins and minerals can help an individual gain some of the benefits of these substances. However, vitamin and mineral supplements are not a total replacement for real food.

This is because vitamin and mineral supplements, though very beneficial, do not supply the thousands of phytochemicals that might be present in fruits and vegetables, according to the Cleveland Clinic Foundation in Ohio. For example, eating a sweet potato with its skin, which is a great source of both beta carotene and **fiber**, provide at least 5,000 phytochemicals that are not present in a beta carotene supplement. That's an extremely important difference. Isolating a few compounds in a pill will not provide you with the hundred of protective benefits that plant food provide. The best advice is to obtain phytochemicals by eating a good variety of plant foods every day. Whether fruits and vegetables are consumed in raw or cooked form does not really matter with regard to phytochemical content. Even canned, frozen and juiced fruits and vegetables pack a phytochemical punch. However, raw or steamed vegetables would provide the best nutrient value.

The antioxidants found in fruits, vegetables, and other plant-based foods fight free radicals, which are compounds in the body that attack and destroy cell membranes. The uncontrolled activity of free radicals is believed to cause many cancers. Examples of antioxidants include **carotenoids**, such as beta carotene, lycopene, and vitamins C and E.

The carotenoids, in particular, which give fruits and vegetables their bright yellow, orange, and red colors, are now gaining recognition for their nutritional worth. Numerous studies have extolled the virtues of lycopene (the carotenoid that makes tomatoes red) in preventing **prostate** cancer. One such study at Harvard University found that men who include tomato products in their meals twice a week could reduce their risk of developing prostate cancer by one-third compared with men who do not consume tomatoes.

Other lycopene-rich foods, such as watermelon, red grapefruit, and guava, are now piquing the interest of researchers. Watermelon not only yields more lycopene per serving (15 mg in 11/2 cups) than raw tomatoes (11 mg per 11/2 cups), but it's also a rich source of vitamins A and C.

Whether antioxidants can reduce the incidence of cancer is still uncertain at this point because of the lack of sufficient studies. However, research data obtained thus far indicates that antioxidants do appear to provide health benefits.

The National Cancer Institute estimates that roughly one-third of all cancer deaths may be diet related. Scientists have recently estimated that approximately 30 to 40% of all cancers could be averted if people ate more fruits, vegetables, and plant-based foods and minimized high-fat, high-calorie edibles that have scant nutritional value. What you eat can hurt you, but it can also help you. In the past, researchers had linked fat consumption with the development of cancers, but they currently believe that eating fruits, vegetables, and grains may be more important in preventing the disease than not eating fat. Many of the common foods found in grocery stores or organic markets contain cancer-fighting properties, from the antioxidants that neutralize the damage caused by free radicals to the powerful phytochemicals that scientists are just beginning to explore. There isn't a single element in a particular food that does all the work. The best thing to do is eat a variety of foods.

## KEY TERMS

**antioxidants**—A substance, such as vitamin E, vitamin C, or beta carotene, thought to protect body cells from the damaging effects of oxidation.

**phytochemicals**—A nonnutritive bioactive plant substance, such as a flavonoid or carotenoid, considered to have a beneficial effect on human health.

## Description

There are a number of foods that have been demonstrated to have the ability to help stave off cancer and some can even help inhibit cancer cell growth or reduce tumor size. The following is a list of foods that because of the nutrients they contain, have been determined to be the best cancer fighters:

Avocados: They are rich in glutathione, a powerful antioxidant that attacks free radicals in the body by blocking intestinal absorption of certain **fats**. They also supply even more potassium than bananas and are a strong source of **vitamin E**. Scientists also believe that avocados may also be useful in treating viral hepatitis (a cause of liver cancer), as well as other sources of liver damage.

Beans: Beans contain a number of phytochemicals, which have been shown to prevent or slow genetic damage to cells. While this makes beans beneficial for helping to reduce your risk of many types of cancer, specific research has suggested they are especially potent in preventing prostate cancer. As an added bonus, the high fiber content of beans has been connected with a lower risk of digestive cancers.

Berries: The two most widely studied cancer-fighting compounds in berries are ellagic acid (richest in strawberries and raspberries) and anthocyanosides (richest in

blueberries). Ellagic acid is believed to help prevent skin, bladder, lung, and breast cancers, both by acting as an antioxidant and by slowing the reproduction of cancer cells. The anthocyanosides in blueberries are currently the most powerful antioxidants known to scientists and are beneficial in the prevention of all types of cancer. Raspberries contain many vitamins, minerals, plant compounds and antioxidants known as anthocyanins that may protect against cancer. According to a recent research study reported by Cancer Research, rats fed diets of 5% to 10% black raspberries saw the number of esophageal tumors decrease by 43% to 62%. A diet containing 5% black raspberries was more effective than a diet containing 10% black raspberries. Research reported in the journal Nutrition and Cancer in May 2002 shows black raspberries may also thwart colon cancer. Black raspberries are rich in antioxidants, thought to have even more cancer-preventing properties than blueberries and strawberries.

Cabbage, and cauliflower: All cruciferous vegetables including cabbage and cauliflower, are rich in a variety of compounds that have been shown to slow cancer growth and development in a number of laboratory studies. These vegetables contain a chemical component called indole-3-carbinol that can combat breast cancer by converting a cancer-promoting estrogen into a more protective variety. Other larger human studies have shown that cruciferous vegetables can help to reduce the risk of lung, prostate, and bladder cancers.

Broccoli: Broccoli, which is also a cruciferous vegetable, contains the phytochemical sulforaphane, a product of glucoraphanin, that is believed to aid in preventing some types of cancer, like stomach, colon and rectal cancer. Sulforaphane induces the production of certain enzymes that can deactivate free radicals and carcinogens. The enzymes have been shown to inhibit the growth of tumors in laboratory animals. However, be aware that the Agriculture Department studied 71 types of broccoli plants and found a 30-fold difference in the amounts of glucoraphanin. It appears that the more bitter the broccoli is, the more glucoraphanin it has. Broccoli sprouts have been developed under the trade name BroccoSprouts that have a consistent level of sulforaphane that is as much as 20 times higher than the levels found in mature heads of broccoli.

Carrots: They contain a plentiful amount of beta carotene, which may help reduce a wide range of cancers including lung, mouth, throat, stomach, intestine, bladder, prostate and breast. Some research indicated beta carotene may actually cause cancer, but this has not proven that eating carrots, unless in very large quantities i.e. 2 to 3 kilos a day, can cause cancer. In fact, a substance called falcarinol that is found in carrots has been found to reduce the risk of cancer, according to researchers at Danish Institute of Agricultural Sciences (DIAS). It has been demonstrated that isolated cancer cells grow more slowly when exposed to falcarinol. This substance is a polyacethylen.

Chili peppers and jalapenos: They contain a chemical, capsaicin, which may neutralize certain cancer-causing substances called nitrosamines and may help prevent cancers such as stomach cancer.

Cruciferous vegetables - broccoli, cauliflower, kale, Brussels sprouts, and cabbage contain two antioxidants, lutein and zeaxanthin that may help decrease prostate and other cancers.

Dark Green Leafy Vegetables: Leafy-green vegetables-like romaine lettuce, mustard greens, chicory, and Swiss chard-are rich sources of antioxidants called carotenoids. These compounds scavenge dangerous free radicals from the body before they can promote cancer growth. The vegetables are also rich in **folate**, a vitamin shown to reduce the risk of lung and breast cancer.

Figs: Apparently figs contain a derivative of benzaldehyde. It has been reported by investigators at the Institute of Physical and Chemical Research in Tokyo that benzaldehyde is highly effective at shrinking tumors, though further experiments need to be conducted. In addition, the U.S. Department of Agriculture says figs, which contain vitamins A and C, and **calcium**, **magnesium** and potassium, may curtail appetite and improve weight-loss efforts. Fig juice is also a potent bacteria killer in test-tube studies.

Flax: Flax contains lignans, which may have an antioxidant effect and block or suppress cancerous changes. Flax is also high in **omega-3 fatty acids**, which are thought to protect against colon cancer and heart disease. **Flaxseed** in the form of oil and meal contains phytoestrogens believed to reduce the risk of breast, skin, and lung cancer. Research on the potency of flaxseed as an anti-cancer food is still ongoing. A specialized diet called the Budwig diet, which has been used by some cancer patients, uses the combination of flax seed oil and cottage cheese. When these two foods are consumed simultaneously, it is said that they increase the levels of substances called phosphatides and lipoproteins in the blood. Dr. Johanna Budwig, the creator of the diet claims that the diet is both preventative and curative in regard to cancer.

Garlic: This herb has immune-enhancing allium compounds (dialyl sultides) that appear to increase the activity of immune cells that fight cancer and indirectly help break down cancer causing substances.

These substances also help block carcinogens from entering cells and slow tumor development. Diallyl sulfide, a component of garlic oil, has also been shown to render carcinogens in the liver inactive. Studies have linked garlic as well as onions, leeks, and chives to lower risk of a variety of cancers including stomach, colon, lung and skin cancer. Dr. Lenore Arab, professor of epidemiology and nutrition at the UNC-CH (University of North Carolina at Chapel Hill) schools of public health and medicine and colleagues analyzed a number of studies and reported their findings in the October 2000 issue of the American Journal of Clinical Nutrition. According to the report, individuals who consume raw or cooked garlic regularly face about half the risk of stomach cancer and two-thirds the risk of colorectal cancer as individuals who eat little or none. Their studies did not show garlic supplements had the same effect. It is believed garlic may help prevent stomach cancer because it has anti-bacterial effects against a bacterium, Helicobacter pylori, found in the stomach and known to promote cancer there.

Grapefruits: Like oranges and other citrus fruits, grapefruits contain monoterpenes, that are believed to help prevent cancer by sweeping carcinogens out of the body. Some studies show that grapefruit may inhibit the proliferation of breast-cancer cells in vitro. Grapefruits also contain **vitamin C**, beta-carotene, and folic acid.

Grapes: Particularly red and purple grapes, are a rich source of resveratrol, a potent antioxidant and anti-inflammatory agent, which inhibits the enzymes that can stimulate cancer-cell growth and suppress immune response. Resveratrol is thought to work by preventing cell damage before it begins. Grapes also contain ellagic acid, a compound that blocks enzymes that are necessary for cancer cells. Ellagic acid also appears to help slow the growth of tumors. Red grapes also contain bioflavonoids, which are powerful antioxidants that work as cancer preventives.

Kale: This cruciferous vegetable contains indoles, which are a nitrogen compound that may help stop the conversion of certain lesions to cancerous cells in estrogen-sensitive tissues. In addition, isothiocyanates, phytochemicals found in kale, are thought to suppress tumor growth and block cancer-causing substances from reaching their targets.

Licorice root: It has a chemical, glycyrrhizin, that blocks a component of testosterone and therefore may help prevent the growth of prostate cancer. However, excessive amounts can lead to elevated blood pressure.

Mushrooms: There are a number of mushrooms that appear to help the body fight cancer and build the immune system. They include Shiitake, maitake, reishi, Agaricus blazei Murill, and Coriolus Versicolor. The active ingredient in medicinal mushrooms are polysaccharides called beta-glucans. These beta-glucans are powerful compounds that help in building immunity. Examples of beta-glucans include Lentinan and a unique beta-glucan called D-fraction, that is found in the Maitake mushroom. This D-fraction is believed to be responsible for the many health benefits of Maitake. These mushrooms also have a **protein** called lectin, which attacks cancerous cells and prevents them from multiplying. They also contain Thioproline. These mushrooms can stimulate the production of interferon in the body. Extracts from mushrooms have been successfully tested in recent years in Japan as an adjunct to chemotherapy.

Nuts: Many nuts contain the antioxidants quercetin and campferol that may suppress the growth of cancers. Brazil nuts contain 80 micrograms of **selenium**, which is important for those with prostate cancer.

Oranges and lemons: They both contain Iimonene which stimulates cancer-killing immune cells like lymphocytes that may also function in breaking down cancer-causing substances.

Papayas: They have vitamin C that works as an antioxidant and may also reduce absorption of cancer-causing nitrosamines from the soil or processed foods. Papaya contains folacin (also known as folic acid), which has been shown to minimize cervical dysplasia and certain cancers.

Red wine: Even without alcohol, red wine has polyphenols that may protect against various types of cancer. Polyphenols are potent antioxidants, compounds that help neutralize disease-causing free radicals. Also, researchers at the University of North Carolina's medical school in Chapel Hill found the compound resveratrol, which is found in grape skins. It appears that resveratrol inhibits cell proliferation and can help prevent cancer. However, the findings didn't extend to heavy imbibers, so it should be used in moderation. In addition, alcohol can be toxic to the liver and to the nervous system, and many wines have sulfites, which may be harmful to your health. Since some research indicates that alcohol is considered a class "A" carcinogen that can actually cause cancer, it is probably best to consume non-alcoholic wines.

Rosemary: This herb may help increase the activity of detoxification enzymes. An extract of rosemary, termed carnosol, has inhibited the development of both breast and skin tumors in animals. We haven't found any studies done on humans. Rosemary can be used as a seasoning and it can also be consumed as a tea.

Seaweed and other sea vegetables: They contain beta-carotene, protein, vitamin $B_{12}$, fiber, and chlorophyll, as well as chlorophylones, which are important fatty acids that may help in the fight against breast cancer. Many sea vegetables also have high concentrations of the minerals potassium, calcium, magnesium, **iron**, and **iodine**.

Soy products like tofu: These contain several types of phytoestrogens which are weak, nonsteroidal estrogens that resemble some of the body's natural hormones. These compounds could help prevent both breast and prostate cancer by blocking and suppressing cancerous changes. There are a number of isoflavones in soy products, but research has shown that genistein is the most potent inhibitor of the growth and spread of cancerous cells. It appears to lower breast-cancer risk by inhibiting the growth of epithelial cells and new blood vessels that tumors require to flourish and is being scrutinized as a potential anti-cancer drug. However, there are some precautions to consider when adding soy to the diet. Eating up to 4 or 5 ounces of tofu or other soy a day is probably fine, but research is being done to see if loading up on soy could cause hormone imbalances that stimulate cancer growth. As a precaution, women who have breast cancer or are at high risk should talk to their doctors before taking pure isoflavone powder and pills, extracted from soy.

Sweet potatoes: They contain many anticancer properties, including beta-carotene, which may protect DNA in the cell nucleus from cancer-causing chemicals outside the nuclear membrane.

Teas: **Green tea** and Black tea contain certain antioxidants known as polyphenols (catechins) which appear to prevent cancer cells from dividing. Green tea is best, followed by our more common black tea (herbal teas do not show this benefit). According to a report in the July 2001 issue of the *Journal of Cellular Biochemistry*, these polyphenols that are abundant in green tea, red wine and olive oil, may protect against various types of cancer. Dry green tea leaves, which are about 40% polyphenols by weight, may also reduce the risk of cancer of the stomach, lung, colon, rectum, liver and pancreas, study findings have suggested.

Tomatoes: Tomatoes contain lycopene, an antioxidant that attacks roaming oxygen molecules, known as free radicals, which are suspected of triggering cancer. Lycopene appears to be more easily absorbed if the tomatoes are eaten in processed form—either as tomato sauce, paste, or juice. It appears that the hotter the weather, the more lycopene tomatoes produce. Lycopene, has been shown to be especially potent in combating prostate cancer and may also protect against breast, lung, stomach, and pancreatic cancer. Scientists in Israel have shown that lycopene can kill mouth cancer cells. An increased intake of lycopene has already been linked to a reduced risk of breast, prostate, pancreas and colorectal cancer. Recent studies indicate that for proper absorption, the body also needs some oil along with lycopene. Tomatoes also have vitamin C, an antioxidant that can prevent cellular damage that leads to cancer. Watermelons, carrots, and red peppers also contain these substances, but in lesser quantities. It is concentrated by cooking tomatoes.

Tumeric: A member of the ginger family, that is claimed to have medicinal properties. Tumeric appears to inhibit the production of the inflammation-related enzyme cyclo-oxygenase 2 (COX-2), which reaches abnormally high levels in certain inflammatory diseases and cancers, especially bowel and colon cancer. A pharmaceutical company Phytopharm in the UK hopes to introduce a natural product, P54, that contains certain volatile oils, which greatly increase the potency of the turmeric spice.

Whole Grains: Whole grains contain a variety of anti-cancer compounds, including fiber, antioxidants, and phytoestrogens. When eaten as part of a balanced diet, whole grains can help decrease the risk of developing most types of cancer.

A considerable amount of information and knowledge has been accumulated regarding the cancer fighting foods. No single food or food substance alone can protect an individual against cancer, but the right combination of plant-based foods in the diet can greatly increase the chances of avoiding cancer. Evidence is mounting that the minerals, vitamins, antioxidants and phytochemicals in many plant foods interact to provide extra cancer protection by working synergistically in the body. For this reason, many nutrition scientists recommend that at least 2/3 of the diet should consist of vegetables, fruit, whole grains and beans.

## Precautions

In some cases, high intakes of individual vitamins can be harmful. An example of this is the risk of high levels of beta-carotene increasing the risk of lung cancer in smokers.

## Parental concerns

Children can greatly benefit from a diet rich in cancer-fighting foods. The healthy diet will promote a lifetime of good health as well as encourage proper growth. However, vitamin supplementation is not recommended outside of a physician's or registered dietetian's care as children have different vitamin

requirements and the level of doses appropriate for an adult may not be the same for a child.

# Carbohydrate addict's diet

## Definition

The carbohydrate addict's diet is an eating plan that emphasizes foods low in **carbohydrates** (carbs). It is based on the theory that some people develop unmanageable **cravings** for high-carb foods due to the pancreas producing too much insulin, leading to weight gain.

## Origins

American research scientists Rachel Heller and Richard Heller developed the carbohydrate addict's diet in the early 1990s after the husband and wife lost a combined 200 lb (75 kg) on the diet. Both Hellers are professors and researchers specializing in biomedical sciences. They outlined their method in their first book, *The Carbohydrate Addict's Diet*, published in 1991. They have since expanded upon the diet in subsequent books and several updates of the original book. The term "carbohydrate addiction" was coined in 1963 by Robert Kemp, a biochemist at Yale University.

## Description

The carbohydrate addict's diet is a program based on the theory that balancing insulin levels in the body will lead to reduced insulin resistance and less cravings for foods high in carbohydrates. The diet has two steps: reduce the high-carbohydrate foods that are consumed, and regulate insulin levels by using **dietary supplements**. Although the Hellers recommend an exercise program with the diet, there is not a major emphasis on exercise. The Hellers define carbohydrate addiction as a compelling hunger, craving, or desire for foods high in carbohydrates, or an escalating and recurring need for starchy foods, snack foods, junk foods, and sweets. These foods include breads, bagels, cakes, cereals, chocolate, cookies, crackers, pastry, fruit and fruit juices, ice cream, potato chips, pasta, potatoes, pretzels, rice, pies, popcorn, and sugar-sweetened beverages. The Hellers also advocate avoiding sugar substitutes (Equal, NutraSweet, Splenda), which they theorize causes the body to release insulin and the body to store fat.

Up to 75% of people who are overweight are addicted to carbohydrates, according to the Hellers. Carbohydrate addiction is caused by an over-production of the hormone insulin when foods high in carbohydrates are eaten. The insulin tells the body to take in more food and once the food is eaten, the insulin signals the body to store the extra food energy as fat, the Hellers hypothesize. When too much insulin is released after eating, it is called *post-prandial reactive hyperinsulinemia*. Over time, some people with this condition develop insulin resistance, where cells in tissue stop responding to insulin. The body continues to produce insulin but because the tissues do not respond to it, the body is unable to use the glucose (sugar) properly. Insulin resistance is often found with other health problems, including diabetes, high cholesterol, high **triglycerides**, high blood pressure and cardiovascular disease. When more than one of these diseases are found together, it may be termed "insulin resistance syndrome".

There is no medical test to indicate carbohydrate addiction so the Hellers developed a self-administered quiz to determine if a person is a carbohydrate addict. The quiz, which is available in their books and on their Website, asks ten "yes" or "no" questions. They are:

- Are you hungry before lunch even if you've had a full breakfast?
- Is it hard to stop eating starches, snack foods, junk food, or sweets?
- Do you feel unsatisfied despite having just finished a meal?

- Does seeing, smelling, or thinking of food make you want to eat?
- Do you eat when you are not hungry?
- Do you snack at night?
- Are you lethargic after a big meal?
- Are you tired and/or hungry in the afternoon without a reason to be?
- Do you continue to eat even when you are full?
- Do you yo-yo diet?

Scoring of the quiz is based on the number of "yes" answers. A score of 0–2 indicates no carbohydrate addiction. A score of 3–4 suggests a mild carbohydrate addiction. A score of 5–7 suggests a moderate addiction. A score of 8–10 indicates a severe addiction to carbohydrates.

The carbohydrate addict's diet begins with the entry plan, which allows two complementary meals and one reward meal each day for the first week. In subsequent weeks, the diet is adjusted depending on a person's weight loss goal and amount of weight lost in the previous week. The diet also allows for a snack and salads. The complementary meal is composed of one serving of meat and two cups of low-carb vegetables or two cups of salad. There is an extensive list of meats and vegetables to choose from. The reward meal can be as large as the person wants but it must be composed of equal portions of **protein**, low-carb vegetables, and high-carb foods (including dessert). The reward meal must be eaten in an hour. A snack is the same as a complementary meal but half the size. The diet allows for an unlimited amount of **water**, diet drinks, and unsweetened coffee and tea.

Very few people need a morning breakfast to provide energy through the day, according to the Hellers. Since food takes several hours to clear the stomach and a few more hours to be processed in the small intestine, it is the food that is eaten the night before that gives a person energy for the first part of the next day, the Hellers say. For people who are not hungry in the morning, the Hellers recommend skipping breakfast and having just coffee or tea. Skipping breakfast is not a practice widely recommended among dieticians and nutritionists.

### *Children and teens*

There are two different carbohydrate addict's diets for children and teenagers. Both are outlined in the Hellers' book, *Carbohydrate-Addicted Kids*. Carbohydrate addiction affects up to 74% of children and teens, according to the Hellers. It is also a problem in adolescents with behavior, motivation, concentration, and learning problems, and mood swings. On the step-by-step carbohydrate addict's diet, children go at a slower pace, and are offered additional food incentives besides the rewards meal. The jump-start carbohydrate addict's diet is designed for older children and teens. It offers foods high in **fiber** and protein for meals and snacks. Like the adult diet, it provides a reward meal in which dieters can eat anything they want, provided it is equal portions of protein, low-carb vegetables, and high-carb foods. The book also provides information on meals for special occasions, such as birthdays, holidays, vacations, and other celebrations. The diets for adolescents also have a vegetarian component.

## KEY TERMS

**Carbohydrate addiction**—A compelling hunger, craving, or desire for foods high in carbohydrates, or an escalating and recurring need for starchy foods, snack foods, junk foods, and sweets.

**Carbohydrates**—An organic compound that is an important source of food and energy.

**Cardiovascular**—Pertaining to the heart and blood vessels.

**Cholesterol**—A compound found in blood and a number of foods, including eggs and animal fats.

**Endocrinologist**—A medical specialist who treats diseases of the endocrine (glands) system, including diabetes.

**Insulin**—A hormone that regulates the level of glucose (sugar) in the blood.

**Pancreas**—A digestive gland of the endocrine system that regulates and produces several hormones, including insulin.

**Post-prandial reactive hyperinsulinemia**—A condition resulting from excess insulin production after eating.

## Function

The premise of the carbohydrate addict's diet is to correct the body's excess release of insulin, which occurs following consumption of foods high in carbohydrates. The excess release of insulin triggers an intense and recurring craving for more carbohydrate-rich foods. The diet, combined with exercise, is designed to correct the underlying cause of the cravings, the excess release of insulin.

## Benefits

The primary benefit of the carbohydrate addict's diet is that carb-addicts can control their cravings and

lose weight by eating high-carb foods only once a day. The diet is less strict than the Atkins **low-carb diet** since it allows for one meal a day with three equal portions of foods high in carbohydrates, high in protein, and low in carbohydrates. The carbohydrate addict's diet is suitable for vegetarians (though not vegans) since it allows for low-fat cheeses, egg whites, egg substitutes, and tofu.

### Precautions

Like any strict diet, the carbohydrate addict's diet should be undertaken with the supervision of a doctor. People with diabetes should consult an endocrinologist, who may recommend discussing the diet with a dietitian. Persons considering the carbohydrate addict's diet should ask their doctors if they need to take any vitamin, mineral, or nutritional supplements, based on their overall health and any specific medical conditions they may have.

### Risks

There are no general health risks associated with the carbohydrate addict's diet. Critics of the diet claim it contains too much fat, is not nutritionally balanced, and is not a long-term solution for losing weight and keeping it off. It may be difficult for people to maintain a low-carb diet over the long-term. The diet is not recommended for women who are pregnant or nursing. Individuals who have a history of stroke, diabetes, heart disease, high cholesterol, or kidney stones should talk to their doctor before starting any low-carb diet.

### Research and general acceptance

There is mixed acceptance of the carbohydrate addict's diet and low-carb diets in general by the medical community and dietitians. Some studies have shown low-carb diets can be effective in controlling blood sugar levels in diabetics and in helping people lose weight. Other studies have contradicted these findings. No major studies or research has shown that low-carb diets are harmful to a person's health; however most professional organizations do not support low-carb diets.

A 2003 study by researchers at the University of Pennsylvania School of Medicine found that a low-carb diet produced a greater weight loss than a conventional low-calorie, **low-fat diet** after six months. However, after one year, the two diets produced similar weight loss results. A 2004 study by the same medical center found that both a low-carb and conventional diet produced similar weight loss results after one year but that a low-carb diet improved the health of people with atherogenic dyslipidemia, a cholesterol disorder characterized by the elevation of triglycerides and a decrease in "good cholesterol" high-density lipoprotein (HDL) levels in the blood. This lipid disorder is associated with an increased risk of developing cardiovascular disease. Also, individuals participating in the study had better control of blood sugar levels.

## QUESTIONS TO ASK YOUR DOCTOR

- Which dietary supplements do you recommend for the carbohydrate addict's diet?
- What are the health risks involved with this diet?
- What other diets you would recommend to help me accomplish my weight loss goals?
- Have you treated other patients on the carbohydrate addict's diet? If so, what has been their response to the diet?

Ken R. Wells

# Carbohydrates

## Definition

Carbohydrates are compounds that consist of carbon, hydrogen, and oxygen, linked together by energy-containing bonds. There are two types of carbohydrates: complex and simple. The complex carbohydrates, such as starch and **fiber**, are classified as polysaccharides. Simple carbohydrates are known as sugars and they are classified as either monosaccharides (one sugar molecule) or disaccharides (two sugar molecules).

**Carbohydrates**

| Refined and processed carbohydrates | Whole grain and high-fiber carbohydrates |
|---|---|
| White bread | 100% whole wheat bread |
| White rice | Oatmeal |
| White potatoes | Brown rice |
| Pasta | Whole wheat pasta |
| Sugary cereals | Whole grain crackers |
| Cinnamon toast | Popcorn |
| Sweets | Cornmeal |
| Jellies | Hulled barley |
| Candy | Whole wheat bulgur |
| Soft drinks | Bran cereals |
| Sugars | Rye wafer crackers |
| Fruit drinks (fruitades and fruit punch) | English muffins |
| | Dry beans and peas |
| Cakes, cookies and pies | Navy beans |
| Dairy desserts | Kidney beans |
| Ice cream | Split peas |
| Sweetened yogurt | Lentils |
| Sweetened milk | White beans |
| | Pinto beans |
| | Green peas |
| | Soybeans |
| | Whole fruits, fresh, frozen or canned |
| | Vegetables |
| | Low-fat milk |

*(Illustration by GGS Information Services/Thomson Gale.)*

## Purpose

In the digestive tract, carbohydrates are broken down into glucose, which provides energy for the body's cells and tissues. Glucose is the body's primary source of fuel.

## Description

Carbohydrates are one of the three major food groups, along with proteins and **fats**. They are essential to human life and health. Carbohydrates are either simple or complex. Both have four calories per gram, and both are further reduced by the body to glucose, but complex carbohydrates, which undergo most of their digestion in the large intestine, take longer to digest. Carbohydrates come almost exclusively from plants, vegetables, and grains. Milk is the only animal-based product that contains a significant amount of carbohydrate. Simple carbohydrates include the single sugars, or monosaccharides, and the double sugars, or disaccharides. The monosaccharides include glucose, fructose, and galactose. Disaccharides include lactose,

which is made of glucose and galactose; maltose, made of two glucose units; and sucrose, made of glucose and fructose. Monosaccharides can be absorbed directly into the bloodstream, but disaccharides need to be broken down into their monosaccharide components before they can be absorbed.

When food is eaten, the digestion of carbohydrates begins in the mouth, where an enzyme in saliva breaks down starch molecules into the disaccharide maltose. The food then moves into the stomach where it mixes with the stomach's acid and other juices. In the small intestine, starch is further broken down into disaccharides and small polysaccharides by an enzyme released from the pancreas. Cells lining the small intestine then secrete an enzyme that further splits these disaccharides and polysaccharides into monosaccharides. The cells lining the small intestine can absorb these monosaccharides, which are then taken to the liver. The liver converts fructose and galactose to glucose. If there is an excess of fructose or galactose, it may also be converted to fat. Lastly, the glucose is transported to the body's cells by the circulatory system, where it can be used for energy.

When there is an excess of glucose, the muscle and liver cells often convert it to glycogen, which is the storage form of glucose. The muscles store two thirds of the body's glycogen solely for themselves, and the liver stores the other one third, which can be used by the brain or other organs. When blood glucose levels decline, the body breaks down some of its glycogen stores, and uses the glucose for energy. If blood glucose (sugar) levels are too high, the excess glucose is taken to the liver where it is converted to glycogen and stored for future use.

### *Fiber*

One of the complex carbohydrates, fiber, is a polysaccharide in which the bonds holding it together cannot be digested by humans. Fiber can be either water-soluble or water-insoluble. Even though these compounds cannot be digested by humans, they serve several important functions. The main function of insoluble fiber is to bind bile acids, which reduces fat and cholesterol absorption. Sources of insoluble fiber include wheat bran, whole grains, and brown rice. Soluble fiber, which helps decrease low-density lipoprotein (LDL) cholesterol, also called the "bad" cholesterol, can be found in barley, fruit, legumes, and oats.

Fiber is an extremely important part of the diet. It aids in weight control by displacing calorie-dense fats in the diet. Fiber also absorbs **water** and slows the movement of food through the digestive tract, promoting a feeling of fullness. Recommended intakes of fiber should be about 27 to 40 grams per day. The United States Department of Agriculture (USDA) Dietary Guidelines were designed by health professionals to help consumers make nutritious food choices. The guidelines, released in 2005, replace the food pyramid that the USDA used for many years. Instead of recommending a certain number of servings per food group, as the food pyramid did, the new guidelines advise consumers to eat a diet that emphasizes fruits, vegetables, whole grains, and fat-free or low-fat milk and milk products; includes lean meats, poultry, fish, beans, eggs, and nuts; and is low in saturated fats, trans fats, cholesterol, salt, and added sugars. The guidelines recommend that 45–65% of total calories come from carbohydrates and that foods containing complex carbohydrates (such as whole-grains) are preferred over simple carbohydrates (such as table sugar and white flour.) As an example, one cup of whole-grain brown rice has more nutritional value and fiber that processed white rice.

## KEY TERMS

**Diabetes**—A condition characterized by inadequate use of insulin preventing a person from controlling blood sugar levels.

**Fructose**—A monosaccharide known as fruit sugar.

**Galactose**—A monosaccharide known as milk sugar.

**Glucose**—A monosaccharide used for energy; also known as blood sugar.

**Lactose**—A disaccharide known as milk sugar.

**Low-density lipoprotein (LDL)**—The so-called bad cholesterol that contains a large amount of cholesterol and transports lipids (fats) to other tissues in the body.

**Maltose**—A disaccharide known as malt sugar.

**Sucrose**—A disaccharide known as table sugar.

**Polysaccharides**—Long chains of glucose units linked together.

## Precautions

A common concern among consumers is that a high intake of carbohydrate-rich foods will cause weight gain. Consuming too much of any particular food can cause an increase in weight, but eating a balanced diet with plenty of fruits, vegetables, and grains will help promote weight management. General

guidelines recommend that about 45–65% of daily calories come from carbohydrates. This percentage varies depending on age, general health, health problems (including being overweight or obese), and activity level.

## Interactions

There are no known adverse dietary interactions associated with carbohydrates.

## Aftercare

Registered dietitians and nutritionists are the professionals most qualified to educate individuals on the role of carbohydrates in a healthy diet, as well as the complications associated with low-carbohydrate intakes. Medical doctors, including endocrinologists (specialists that tread diseases of the endocrine (glands) system, including diabetes) and nursing professionals also play an important role in treating carbohydrate-related conditions such as diabetes, while dietitians serve to make recommendations concerning the nutritional needs of these individuals.

## Complications

When carbohydrate intake is low, there is insufficient glucose production, which then causes the body to use its **protein** for energy. This ultimately prevents the body's protein from performing its more important functions, such as maintaining the body's immune system. Without carbohydrate, the body also goes into a state of ketosis, in which by-products of fat breakdown, called ketones, accumulate in the blood. This causes a shift in the acid-base balance of the blood, which can be fatal.

### *Diabetes*

Diabetes is a disease in which the body cannot metabolize carbohydrates, and either doesn't make or doesn't respond to insulin, a hormone secreted by the pancreas that is used to transport glucose to the body's cells. In individuals with type 1 diabetes, the pancreas fails to produce insulin, thus causing blood glucose levels to remain the same after meals. This condition is known as hyperglycemia. These individuals must receive daily injections of insulin to control their blood glucose levels. In type 2 diabetes, there may be sufficient insulin, but the body's cells may be resistant to it. Once again, this causes blood glucose levels to rise. Type 2 diabetes can be treated through oral medication and proper diet, although the need for insulin injections may develop later on. There is some disagreement in the medical community about the type of diet diabetics, especially type 1 diabetics, should be on. The conventional diet is one of low-fat, high-carbohydrate food, which is recommended by the American Diabetes Association. Some doctors, particularly endocrinologists, recommend the **Bernstein diet**, which is low in carbohydrates and high in fat, to maintain constant, normal blood sugar levels throughout the day.

### *Carbohydrate intolerance*

Carbohydrate intolerance is the inability of the small intestine to completely process the nutrient carbohydrate (a classification that includes sugars and starches) into a source of energy for the body. This is usually due to deficiency of an enzyme needed for digestion. Lactose intolerance is the inability to digest the sugar found in milk.

## Parental concerns

Parents should consult their child's pediatrician, physician, or endocrinologist if they are unsure the child's diet has a nutritional balance of carbohydrates. A doctor also should be consulted before a child or adolescent goes on a low-carbohydrate diet (such as the Atkins, Zone, and Sugar Busters diets) for weight loss.

Ken R. Wells

# Caribbean Islander diet

## Origins

Travel advertisements for the Caribbean Islands portray long stretches of sun-drenched beaches and swaying palm trees, with people dancing to jazz, calypso, reggae, or meringue music. Indeed, the beauty, warmth, and lush landscapes had Christopher Columbus in awe in 1492 when he came upon these tropical islands, stretching approximately 2,600 miles between Florida and Venezuela.

### *European Settlement*

The Arawaks and Caribs, the first natives of the islands, were not treated kindly, however, as the Spanish, French, Dutch, and British conquered the islands at different periods, all but wiping out the native populations. Today, only a few aboriginals remain in the Caribbean.

The European settlers soon realized that sugarcane was a profitable crop that could be exported to the European market. However, there was a shortage of European farmers, and slaves were brought from Africa to work on the sugar plantations. The slave trade started in 1698. European settlers fought to keep their territories and hoped for great wealth, while actively pursuing the sugar and slave trades.

Two things changed the situation on the islands. In 1756, missionaries from Germany (Moravian Protestants), came to the islands, though the landowners were opposed to their presence, fearing that any education of the slaves could lead to a revolution. At about the same time a German scientist by the name of Margraf discovered that sugar could be produced from beets, and many European countries began to produce their own sugar.

In 1772, after many revolts and uprisings, the Europeans began to free their slaves. The sugar plantations

**Popular dishes of selected Caribbean islands**

| Island | Special dishes |
|---|---|
| Antigua, Montserrat, Nevis | Fish soup, pepper pot soup (any available fish, meat, chicken, and vegetables cooked in fermented cassava juice); saltfish with avocado and eggplant |
| Barbados | Flying fish; jug-jug (mashed stew of pigeon peas, usually served at Christmas)<br>Black pudding (a type of sausage made by combining cooked rice mixed with fresh pig's blood, seasoned with salt, pepper, and other condiments, and placed in thoroughly cleaned pieces of pig's intestine, and then tied on both ends and boiled in seasoned water) |
| Belize | Rice and chicken, tamales, conch fritters, refried beans and iswa (fresh corn tortillas) |
| Dominica | Tannia (coco, a starch tuber soup); mountain chicken (frog's legs) |
| Grenada | Callaloo (soup with green vegetables)<br>Lambi souse (conch marinated in lime juice, hot pepper, onion); oil-down (a highly seasoned dish of coconut milk and salted fish) |
| Guyana | Mellagee (one-pot stew of pickled meat/fish and coconut milk with tubers and vegetables); rice treat (rice with shrimp, vegetables, and pineapple) |
| Jamaica | Saltfish and ackee (a fruit commonly used as a vegetable, boiled and then sautéed in oil); escoveitched fish (fried fish marinated in vinegar spices, seasoning); roasted breadfruit; asham or brown George (parched dried corn that is finely beaten in a mortar, sifted, and mixed with sugar) |
| St. Vincent and the Grenadines | Stewed shark |
| British Virgin Islands | Fish chowder, conch salad, saltfish and rice |
| Trinidad and Tobago | Pelau (rice with meat, fish, peas, vegetables); pakoras; kachouri; palouri (fried vegetable fritters) |
| Guadeloupe and Martinique | Mechoui (spit-roasted sheep); pate en pot (finely chopped sheep and lamb parts cooked into a thick, highly seasoned stew) |

*(Illustration by GGS Information Services/Thomson Gale.)*

## KEY TERMS

**Absorption**—Uptake by the digestive tract.

**Asthma**—A respiratory disorder marked by wheezing, shortness of breath, and mucus production.

**Malnutrition**—Chronic lack of sufficient nutrients to maintain health.

**Tuber**—swollen plant stem below the ground.

still needed laborers, however, and indentured workers were brought from China and India to work in the fields. Sugar cane, and its by-products, molasses and rum, brought great prosperity to the settlers. However, not wanting to depend solely on sugar, they began to grow yams, maize, cloves, nutmeg, cinnamon, coconuts, and pineapples on a very large scale. Coffee also began to flourish. Many of the islands had wild pigs and cattle on them, and spiced, smoked meat became part of the diet. Today, jerk meat is a specialty.

## Description

### *Foods of the Islands*

The foods of the Caribbean are marked by a wide variety of fruits, vegetables, meats, grains, and spices, all of which contribute to the area's unique cuisine. Foods of Creole, Chinese, African, Indian, Hispanic, and European origin blend harmoniously to produce mouth-watering dishes.

Fruits and Vegetables. There are many fruits and vegetables found in the various Caribbean Islands, and because many of them have been exported to North America and Europe, people have become familiar with them. This exotic array of fruits and vegetables in vibrant colors forms the heart of island cooking.

Chayote, also called Christophene or Cho-cho, is a firm pear-shaped squash used in soups and stews. The Chinese vegetable bokchoy (or pakchoy) has become widely used on the islands. Plantains, which resemble bananas, are roasted, sautéed, fried, and added to stews and soups. The breadfruit grows profusely, and is either boiled or baked, sliced, and eaten hot, or ground into flour. The breadfruit blossoms make a very good preserve.

Yucca, also known as cassava or manioc, is a slender tuber with bark-like skin and a very starchy flesh that must be cooked and served like a potato, or it can be made into cassava bread. Mangoes can be picked from the tree and eaten by peeling the skin and slicing the flesh off the large pit. They are used in salads, desserts, frozen drinks, and salsa. Papaya, which has a cantaloupe-like flavor, contains the enzyme papain, which aids in digestion. To be eaten, the black seeds must be removed and the flesh scooped out.

The soursop is a large, oval, dark-green fruit with a thick skin that is soft to the touch when it ripens. The fruit has a creamy flesh with a sweet, tart flavor. Its rich custard-like flavor can be made into a sherbet, ice cream, or refreshing drink.

Spices and Condiments. The food of the Caribbean can be highly spiced. The Scotch bonnet, a colorful pepper with a hot aroma, is widely used in soups, salads, sauces, and marinades. Some other important spices are annatto, curry, pimento, cinnamon, and ginger. Annatto seeds are often steeped in oil and used to flavor soups, stews, and fish dishes. Curry powder is made from a variety of freshly grounded spices. Curry dishes and hot sauces, which are used regularly in cooking, were brought to the islands by Indian settlers.

Pimento, also known as allspice, is used in pickles, marinades, soups, and stews and is an important ingredient in jerking, a method of cooking meat and poultry over an open fire. To bring out the flavor of meat and chicken, they are marinated in a mixture of scallions, garlic, thyme, onion, lemon juice, and salt. The spices and the method of slow cooking over a fire give jerk meat its distinctive flavor.

**Protein** sources. Although fish, conch (a pink shellfish), goat meat, pork, and beef are used throughout the Caribbean, legumes make up a fair percentage of the region's protein intake. Kidney and lima beans, chickpeas, lentils, black-eyed peas, and other legumes are used in soups, stews, and rice dishes. Accra fritters, made from soaked black-eyed peas that are mashed, seasoned with pepper, and then fried, is a dish of West African origin similar to the Middle Eastern falafel. Sancocho is a hearty Caribbean stew made with vegetables, tubers, and meats.

Cooking Methods. A "cook-up" dish is one made with whatever ingredients an individual has on hand, and is an opportunity to be creative. Such a dish will often include rice, vegetables, and possibly meat. By adding coconut milk, this could turn into an enticing coconut-scented pilaf. Burning sugar to color stews is another technique used in island cooking. This process begins by heating oil, then adding sugar, and stirring until the sugar becomes an amber color.

The roti is a griddle-baked flour wrapping that is filled with curried meat, chicken, or potatoes. Coucou, or fungi, is a cornmeal mush that is served with meat, poultry, fish, or vegetable dishes.

Beverages and desserts. A variety of fruit beverages are often served in the Caribbean. Beverages include **green tea** and "bush tea," served sweetened with sugar or honey, with or without milk. Bush tea is an infusion of tropical shrubs, grasses, and leaves that has a number of medicinal uses. People drink it as a remedy for gas, the common cold, asthma, high blood pressure, fever, and other ailments. Sweetened commercial drinks made from carrot, beet, guava, tamarind, and other fruits and vegetables are also popular.

A number of fermented drinks are also popular. *Garapina* is made from pineapple peelings, while *mauby* is made from the bark of the mauby tree. Grated ginger is used to produce ginger beer. *Horlicks* is a malted milk made with barley.

Fruit is eaten anytime of the day, but is not considered a dessert unless prepared in a fruit salad or some other form. Coconut and banana form the basis for many desserts. A sweet pudding that goes by many names (e.g., duckunoo, blue drawers, pain me, paimee, and konkee) is made from grated banana, plantain, or sweet potato, which is then sugared, spiced, and mixed with coconut milk or grated coconut, and then wrapped in banana leaves and boiled in spiced **water**. A prepared sweet pone (pudding) cake or pie is a popular dessert. Black fruitcake, made from dried fruits soaked in wine, is popular at Christmas time, and is also used for weddings and other celebrations.

## Benefits

### *Innovative Programs*

Due to insufficient resources and less than adequate planning, the school feeding programs on most of the islands exhibit many shortcomings. However, on the island of Dominica, where a self-help initiative involving the parents was introduced, the eating habits of school-aged children improved and the parents and communities adopted many of the program's menus and preparation methods. As a result, school attendance increased and the attention span of the children in class improved.

School nutrition programs need constant monitoring to improve the nutritional status of the children involved. Furthermore, a good nutrition promotion campaign must be designed to educate and promote a healthy lifestyle for the population at large.

The Caribbean region has the tremendous task of putting in place appropriate policies, plans, and programs to address the changing health and disease patterns of the region's people. This effort is made more difficult because of the socioeconomic, political, and cultural differences among the Caribbean countries. The various countries must not only examine the food availability and how it is consumed, but they must also assess and evaluate the quality of the food and the nutrition intake of those most at risk.

The Caribbean Food and Nutrition Institute (CFNI), established in 1967, aims to improve the food and nutrition status in member countries, which include Anguilla, Antigua, Bahamas, Barbados, Belize, the British Virgin Islands, Cayman Islands, Dominica, Grenada, Guyana, Jamaica, Montserrat, St. Christopher-Nevis, St. Lucia, St. Vincent, Suriname, Trinidad and Tobago, and Turks and Caicos Islands.

The governments of the Caribbean have come together under an initiative called Caribbean Cooperation in Health. They hope to work closely together through five types of activities: service, education training, providing information, coordination, and research. The food goals of each country must be analyzed, with care and attention paid to the agricultural policies and economic opportunities in each specific country.

### *Forming Healthy Communities*

Desiring a longer and richer quality of life, many governments of the Caribbean Islands have introduced programs to combat chronic diseases and promote a more physically active lifestyle. For example, in Grenada, a campaign to "grow what you eat and eat what you grow" demonstrates a move to increase consumption of local foods.

Adequate nutrition cannot be achieved without the consumption of sufficient foods containing a wide array of nutrients. Poor health status, whether as a result of insufficient food intake, overconsumption, or nutrition imbalance, threatens longevity and increases health care costs. The challenge is to improve the availability of nutritious foods and the eating habits of the varied population.

## Risks

### *Health Issues*

In the Caribbean region, nutrition-related chronic diseases are common, threatening the well-being of the people of the islands. In the 1950s, the governments of the Caribbean were concerned about the malnutrition that permeated the region. They were able to increase the protein and calorie needs by making meat, **fats**, oils, and refined sugar more available. The health and nutrition initiatives introduced helped curbed the malnutrition, but new and related health and nutrition problems began to emerge.

The health administrators of the Caribbean region are concerned with the rise of iron-deficiency anemia in pregnant women and school-aged children due to inadequate **iron** intake and poor absorption. The increased incidence of diabetes, **hypertension**, **coronary heart disease**, **cancer**, and **obesity**, especially in the thirty-five-and-over age group, is thought to be directly linked to the existing lifestyle and dietary practices of the islanders.

The Caribbean Islands have seen a proliferation of fast-food restaurants, and the increased consumption of meals high in fat, sugar, and salt has contributed to the increase in chronic diseases. In addition, there has been a reduction in the amount of cereals, grains, fruits, vegetables, tubers, and legumes that are eaten. The popularity of fast foods among the young has led the government to focus on improving nutrition in the schools. Also contributing to the health problems is the dependency on costly imported processed foods that do the body harm. Overconsumption of imported foods high in fat and **sodium** has led to a deterioration of the health status of people throughout the region, with an increase in health problems such as obesity, diabetes, hypertension, cardiovascular disease, and cancer.

# Carotenoids

## Definition

Carotenoids are fat-soluble plant pigments, some of which are important to human health. The most common carotenoids in the diet of North Americans are alpha-carotene, beta-carotene, beta-cryptoxanthin, lutein, zeaxanthin, and lycopene.

## Purpose

The role carotenoids play in human health is not well understood. Carotenoids are **antioxidants** that react with free radicals. Molecules called free radicals form during normal cell **metabolism** and with exposure to ultraviolet light or toxins such as cigarette smoke. Free radicals cause damage by reacting with **fats** and proteins in cell membranes and genetic material. This process is called oxidation. Antioxidants are compounds that attach themselves to free radicals so that it is impossible for the free radical to react with, or oxidize, other molecules. In this way, antioxidants may protect cells from damage. Although carotenoids have antioxidant activity in the laboratory, it is not clear how much they function as antioxidants in the body. Claims that carotenoids can protect against **cancer** and cardiovascular disease are primarily based on their antioxidant properties.

One subgroup of carotenoids that includes alpha-carotene, beta-carotene, and beta-cryptoxanthine is converted into **vitamin A** (retinol) by the body. Vitamin A affects is important for maintaining good vision, a healthy immune system, and strong bones. Vitamin A also helps turn on and off certain genes (gene expression) during cell division and differentiation. The degree to which this group of provitamin A carotenoids is converted into vitamin A appears to depend on whether or not the body is getting enough vitamin A in other forms. Only 10% of all carotenoids can be converted into vitamin A.

## Description

Carotenoids are highly colored red, orange, and yellow pigments found in many vegetables. A German scientist isolated the first carotenoid in 1826 from carrots and named it beta-carotene. Since then, more than 600 carotenoids have been identified in plants, algae, fungi, and bacteria. Carotenoids must be dissolved in a small amount of fat to be absorbed from the intestine. **Dietary supplements** of carotenoids contain oil, which makes them more readily available to the body than carotenoids in food. Carotenoids in

**Carotenoids**

| Carotenoid | Food sources |
|---|---|
| Alpha-carotene | Carrots<br>Collard greens<br>Peas<br>Plantains<br>Pumpkin<br>Tangerines<br>Tomatoes, raw<br>Winter squash |
| Beta-carotene | Broccoli<br>Cantaloupe<br>Carrot juice<br>Carrots<br>Dandelion greens<br>Kale<br>Pumpkin<br>Spinach<br>Turnip greens<br>Sweet potatoes<br>Winter squash |
| Beta-cryptoxanthin | Carrots<br>Corn, yellow<br>Nectarines<br>Orange juice<br>Oranges<br>Papaya<br>Pumpkin<br>Red bell peppers<br>Tangerines<br>Watermelon |

*(Illustration by GGS Information Services/Thomson Gale.)*

vegetables are best absorbed if they are cooked in oil or eaten in a meal that contains at least some fat. (A very tiny amount of fat is adequate).

The United States Institute of Medicine (IOM) of the National Academy of Sciences develops values called **Dietary Reference Intakes** (DRIs) for **vitamins** and **minerals**. The DRIs define the amount of a nutrient a person needs to consume daily and the largest daily amount from food or dietary supplements that can be taken without harm. The IOM has not developed any DRIs for carotenoids because not enough scientific information is available and because no diseases have been identified as being caused by inadequate intake of carotenoids. The IOM, the American Cancer Society, and the American Heart Association all recommend that people get all their antioxidants, including carotenoids, from a diet high in fruits, vegetables, and whole grains rather than from dietary supplements.

### *Health claims for carotenoids*

Many health claims for carotenoids are based on laboratory and animal studies. Results from human studies are often inconsistent and confusing. One difficulty in evaluating these studies comes from the variety of ways in which they are conducted. When increased carotenoid intake comes from eating foods high in carotenoids, it is hard to separate the effects of the carotenoids from the effects of other vitamins and minerals in the food. When a dietary supplement is given to increase the level of a specific carotenoid, the outcomes often differ from those that occur in a diet of carotenoid-rich vegetables. In addition, the fact that some carotenoids are converted into vitamin A blurs the line between their effects and that of vitamin A from other sources. More controlled research needs to be done on these compounds. Many clinical trials are underway to determine safety and effectiveness of different carotenoids, both alone and in combination with other drugs and supplements.

**BETA-CAROTENE.** Beta-carotene is a yellow-orange provitamin A carotenoid. Good sources of beta-carotene include carrots, sweet potatoes, winter squash, pumpkin, spinach, kale, and broccoli. When vitamin A stores are low, the body can convert beta-carotene into vitamin A to prevent symptoms of vitamin A deficiency. It takes 12 mcg of beta-carotene to make 1 mcg of retinol, the active form of vitamin A. Therefore, vitamin A deficiency is usually more effectively treated by eating more foods high in vitamin A and/or taking a vitamin A supplement than by increasing beta-carotene intake.

The only use for beta-carotene dietary supplements proven in well-controlled clinical trials is to treat a rare genetic disorder called erythropoietic protoporphyria. This disorder causes the skin to be painfully sensitive to sunlight and causes the development of **gallstones** and problems with liver function. Symptoms are relieved by giving beta-carotene supplements under the supervision of a physician.

A diet high in vegetables rich in beta-carotene appears to reduce the risk of developing certain cancers. However, in a large study of 29,000 men, when a beta-carotene dietary supplement was taken by men who smoked, they developed lung cancer at a rate 18% higher and died at a rate 8% higher than men who did not take the supplement. Another study that gave men dietary supplements of beta-carotene and vitamin A was stopped when researchers found the men receiving the beta-carotene had a 46% greater chance of dying from lung cancer than those who did not take it. The official position of the IOM is that "beta-carotene supplements are not advisable for the general population."

**ALPHA-CAROTENE.** Alpha-carotene is the lesser-known cousin of beta-carotene. It also is a provitamin A carotenoid, but it takes 24 mcg of alpha-carotene to make 1 mcg of retinol. Good sources of alpha-carotene include pumpkin, carrots, winter squash, collard greens, raw tomatoes, tangerines, and peas. Less research has been done on alpha-carotene than beta-carotene, but it is not recommended as a dietary supplement.

**BETA-CRYPTOXANTHIN.** Beta-cryptoxanthin is also a provitamin A carotenoid. It takes 24 mcg of beta-cryptoxanthin to make 1 mcg of retinol. Good sources of beta-cryptoxanthin include pumpkin, red bell peppers, papaya, tangerines, nectarines, oranges and orange juice, carrots, yellow corn, and watermelon.

**LUTEIN AND ZEAXANTHIN.** Lutein and zeaxanthin do not have vitamin A activity. They are the only carotenoids found in the human eye. It has been proposed, but not proven, that they may help slow the development of cataracts. Cataracts are changes in the lens of the eye that result in clouding and vision loss. These carotenoids are also found in the retina. They absorb light in the blue wavelength range. It is theorized that they can help slow or prevent age-related breakdown of the retina (age-related macular degeneration), a common cause of vision loss in the elderly. Good sources of lutein and zeaxanthin include spinach, kale, turnip, collard, and mustard greens, summer squash, peas, broccoli, Brussels sprouts, and yellow corn.

**LYCOPENE.** Lycopene is the carotenoid that gives tomatoes, watermelons, and guavas their reddish color. In the American diet, almost all dietary lycopene comes from tomato products.

The relationship between dietary intake of lycopene and the risk of men developing **prostate** cancer is of great interest to researchers. One large study of 58,000 Dutch men found no relationship between the two. However, an analysis of 21 studies examining the relationship between lycopene intake and prostate cancer found that men with the highest dietary intake of lycopene were less likely to develop prostate cancer. The reduction appeared real, but modest—11–19%.

## KEY TERMS

**Antioxidant**—A molecule that prevents oxidation. In the body antioxidants attach to other molecules called free radicals and prevent the free radicals from causing damage to cell walls, DNA, and other parts of the cell.

**Cell differentiation**—The process by which stem cells develop into different types of specialized cells such as skin, heart, muscle, and blood cells.

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Provitamin**—A substance the body can convert into a vitamin.

**Retina**—The layer of light-sensitive cells on the back of the eyeball that function in converting light into nerve impulses.

### Precautions

The relationship between lung cancer and beta-carotene strongly suggests that all carotenoids should be obtained through diet and not through dietary supplements. There is also no information on the safety of carotenoid dietary supplements in children or women who are either pregnant or **breastfeeding**.

### Interactions

Interactions of specific carotenoids with drugs, herbs, and dietary supplements have not been well studied. In general, cholesterol-lowering drugs, **orlistat** (Xenical or Alli), and mineral oil reduce the absorption of carotenoids from the intestine, but it is not known whether this has an effect on health.

### Complications

There are no identified complications from carotenoid deficiency.

Beta-carotene supplements of 30 mg per day or more or excessive consumption of carrots and other beta-carotene rich food can cause the skin to become yellow, a condition called carotenodermia. Carotenodermia is not associated with any health problems and disappears when beta-carotene intake is reduced.

Lycopene supplements or excessive intake of tomatoes and tomato products can cause the skin to turn orange, a condition called lycopenodermia. This condition disappears when lycopene intake is reduced.

No recommendations have been set about the maximum daily intake of carotenoids from diet, but dietary supplements of carotenoids are not recommended by the IOM, the American Heart Association or the American Cancer Society.

### Parental concerns

Parents should encourage their children to eat a healthy and varied diet high in fruits, vegetables, and whole grains. There is no need to give children dietary supplements of carotenoids. The safety of these supplements in children has not been studied.

## Caveman diet

### Definition

The caveman diet is a diet that is intended to mimic, as closely as possible, the way that the ancestors of humans ate more than 10,000 years ago.

### Origins

The caveman diet is also sometimes referred to as the Paleolithic diet. The Paleolithic period is the period occurring before 10,000 years ago. During the Paleolithic period the ancestors of humans were hunters and gatherers. They ate the foods that they could find in the wild, including game that could be killed and fruits and vegetables that grew locally. Everything during this time was consumed raw. Milk and other dairy products were not available because animals had not yet been domesticated.

10,000 years ago the Neolithic period began. During the Neolithic period fire was mastered, allowing

the cooking of foods, and agriculture was adopted. Agriculture led to an increased consumption of grains as they were farmed for the first time and so became available abundantly. Anything that became available during the Neolithic period is not allowed on the Caveman diet.

It is not clear when the interest in going back to the diet of Paleolithic humans began. There are many different people who recommend different versions of the diet. There are many commonalities between the various versions of the caveman diet, but in general there is one main difference. Some proponents of the diet suggest eating a variety of very lean meats raised as most like animals in the wild as possible, and some proponents who encourage eating a large quantity of red meats with high fat contents.

The two most popular versions of the diet come from Ray Audette and Loren Cordain. Audette wrote the book "Neaderthin" and Cordain is the author of the book "The Paleo Diet". These diets have many similarities and differ mainly on what types of meats and how much fat should be eaten. They also differ in the way that they suggest beginning the diet and on the strictness with which they require the diet to be followed.

## KEY TERMS

**Diabetes mellitus**—A condition in which the body either does not make or cannot respond to the hormone insulin. As a result, the body cannot use glucose (sugar). There are two types, type 1 or juvenile onset and type 2 or adult onset.

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Mineral**—An inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

**Vitamin**—A nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

## Description

The caveman diet is intended to include only foods that were available to humans that existed more than 10,000 years ago. The most basic meaning of this is that only foods that can be eaten raw can be included, as fire was not discovered until after this time period. On the diet however, the food does not actually have to be eaten plain and raw, it can be moderately prepared. Food can be cooked but should be eaten very close to its raw state, without complex preparation methods being used. Because the food has to be able to be eaten raw this excludes some foods like many members of the legume family (such as beans, peas, and peanuts) because they have to be cooked.

The other basic premise is that nothing that requires technology can be eaten. Technology in this case encompasses things as diverse as agricultural methods to complex processing and canning. This means that any kind of food that has been processed in any way is forbidden. This excludes all forms of refined sugars, and large amounts of the foods normally eaten by average consumers today.

No dairy products are allowed while on this diet. This means no milk, cheese, butter, or anything else that comes from milking animals. This is because milking did not occur until animals were domesticated, sometime after the Paleolithic age. Eggs are allowed however, because Paleolithic man would probably have found eggs in bird's nests during foraging and hunting.

Because agriculture did not exist during the Paleolithic era this means that no grains of any kind can be eaten while on the caveman diet. Although wild grains did exist during the Paleolithic period, many of them were very different than the grains that exist today. They were unlikely to have been as robust and would have provided little nutrition. Additionally grains could not be collected in any significant way until pottery (another invention of the Neolithic age) was invented so that there was an available method to collect and store it. So on the caveman diet grains in all forms are forbidden. This includes rice, wheat, and even corn.

Root vegetables that are starchy are also forbidden on the diet. These include potatoes and sweet potatoes. Yams and Cassava are also not allowed, and some people believe beets are acceptable on the diet and some do not. These foods are not allowed because they generally have to be cooked and are not believed to have been eaten during Paleolithic times.

Meat and fat recommendations for while on this diet are where the two main proponents of the diet show their biggest dietary difference. Audette believes that eating fat can help a dieter feel fuller on less, and even reports that he eats a pound of bacon for breakfast each morning. Cordain believes the dieter should take an approach that limits the intake of such fatty meats and includes a variety of lean meats. He believes

that Paleolithic humans ate meat that was leaner because animals raised in the wild, instead of captivity, tend to have less fat and leaner muscle. To mimic this he suggests eating a variety of animals such as elk and buffalo that are raised on grass and are more free to roam than regular farm animals.

Different versions of the caveman diet differ in their recommendations about exercise. Some versions do not make recommendations, while others suggest significant amounts of exercise, especially outdoor exercise. The premise is that Paleolithic humans spent most of their time hunting and gathering food, which would have required a significant amount more physical activity than average humans engage in today.

Cordain believes that when beginning the caveman diet it is often advisable to begin slowly, and slowly include more meals that follow the diet's guidelines as time goes on. He also believes that having what he calls "open meals," during which the guidelines are relaxed, can be a good way to help the dieter stick to the diet in the long run. Cordain also believes that even just following some of the recommendations of the caveman diet can be beneficial, and encourages people to do as much as they are comfortable with. Audette generally takes a more hard line approach and does not allow for any bending of the rules with certain meals. He reports that not only do he and his wife follow this diet strictly, but that their son has been on the diet since birth, as well.

## Function

The caveman diet is intended to promote weight loss and overall better health by mimicking a diet similar to the diet of the humans who lived during the Paleolithic age. It is believed that the human body is not designed to be able to process foods that were not consumed during the Paleolithic age. It is also thought that eliminating these foods will allow the body to function more in the manner for which it was designed, leading to better health and a decreased risk of many of the diseases that are prevalent in the industrialized world such as **obesity**, diabetes, and heart disease.

## Benefits

There are many benefits to losing weight if it is done at a moderate pace through healthy eating and increased exercise. Obesity causes an increased risk of diabetes, cardiovascular disease, and many other diseases and conditions. The greater the obesity the greater the risk of these diseases, and the greater the severity of the symptoms associated with them. Losing weight can reduce the risks of these and other obesity-related diseases as well as reduce the severity of the symptoms if the diseases have already occurred.

In addition to the general benefits of weight loss, the caveman diet may provide a variety of other health benefits. Fresh fruits and vegetables are high in many **vitamins** and **minerals**, which are important for overall good health. Some versions of the caveman diets that recommend free range, grass-fed lean meats may have additional benefits as these meats may be higher than regular meats in **omega-3 fatty acids**, which are believed have positive health benefits for the heart and cardiovascular system.

Varieties of the caveman diet that recommend large amounts of exercise may have additional health benefits. Regular exercise can help weight loss to occur more quickly by helping the body use more calories and creating muscle mass. Regular exercise also may reduce the risk of cardiovascular disease.

## Precautions

Anyone thinking of beginning a new diet should consult a medical practitioner. Requirements of calories, fat, and nutrients can differ significantly from person to person, depending on gender, age, weight, and many other factors such as the presence of any diseases or conditions. Pregnant or **breastfeeding** women should be especially cautious because deficiencies of vitamins or minerals can have a significant negative impact on a baby.

## Risks

There are some risks with any diet. It is often difficult to get enough of some vitamins and minerals when eating a limited variety of foods. All varieties of the caveman diet exclude all milk and dairy products. Because these foods are excellent sources of **calcium** it is possible that people on the caveman diet may not get enough calcium in their diet. Lack of calcium can lead to many different disease and conditions such as **osteoporosis** and rickets. Anyone beginning this diet may want to consult their physician about whether taking a vitamin or supplement might help them reduce this risk. Also such a low starchy carbohydrate intake could cause health problems such as lethargy and fatigue due to low energy.

Versions of the caveman diet that allow and encourage large quantities of high fat red meat being eaten have their own risks. High-fat diets, especially diets high in animal **fats**, have been shown to increase the risk of cardiovascular disease. Versions of the diet

## QUESTIONS TO ASK THE DOCTOR

- Would a multivitamin or other dietary supplement be appropriate for me if I were to begin this diet?
- Is this diet appropriate for my entire family?
- Is it safe for me to follow this diet over a long period of time?
- Is this diet the best diet to meet my goals?
- Are there any sign or symptoms that might indicate a problem while on this diet?

that encourage the consumption mainly of lean meats probably do not have this increased risk.

### Research and general acceptance

There have been various scholarly studies aimed at determining what the likely diet of Paleolithic humans ate. However, there is not a significant body of research examining how this kind of diet would affect modern humans. There is however research indicating that a healthy, varied diet including many different fruits and vegetables is important for good overall health.

Some experts find concern in the fact that the diet completely eliminates dairy products, which are generally considered to be part of a healthy diet. The United States Department of Agriculture's MyPyramid, the updated version of the Food Guide Pyramid, recommends the equivalent of 3 cups of low-fat or non-fat dairy products per day for healthy adults. The caveman diet also does not allow grains, although whole grains are also generally considered an important part of a healthy diet. MyPyramid recommends the equivalent of 3 to 4 ounces of grains each day, of which at least half should be whole grains, for healthy adults.

The Center for Disease Control recommended in 2007 that healthy adults get at least 30 minutes of light to moderate exercise everyday. The versions of the caveman diet that recommend large amounts of regular exercise would exceed this minimum recommendation. Regular exercise is generally accepted as an excellent way of improving health, reducing the risk of disease, and managing weight.

The caveman diets that recommend large amounts of red meat and eggs, and encourage the consumption of fattier meats, are extremely controversial. Although many diets that are low in **carbohydrates** and high in meat, such as the very popular **Atkins diet**, have gained many followers, especially in the mid 2000s, physicians, nutritionists, and other health and science professionals continue to debate their various health benefits and risks. It is generally accepted, however, that regularly eating a diet high in saturated fats, which are often found in high quantities in red meat, has a detrimental effect on the health in the long run and studies have shown that it can lead to increased incidence of cardiovascular disease.

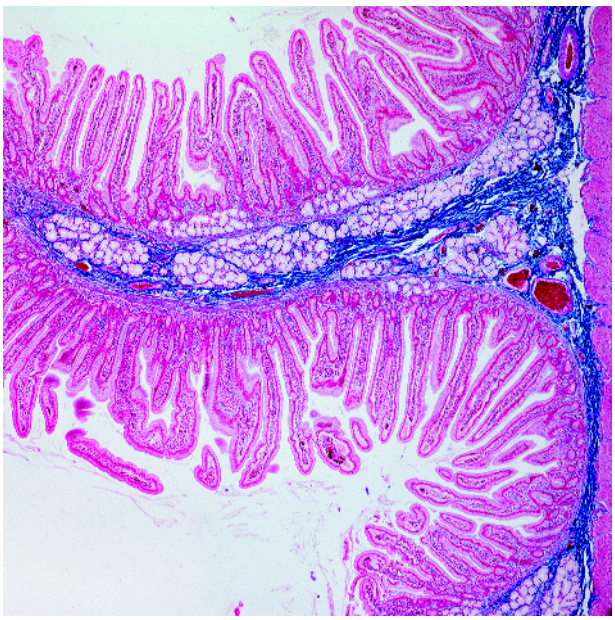
# Celiac disease

### Definition

Celiac disease, also known as sprue, celiac sprue, nontropical sprue, and gluten-sensitive enteropathy, is a life-long autoimmune disease in which the body's reaction to gluten causes damage to the intestines that results in poor absorption of nutrients.

### Description

Absorption of most nutrients occurs in the small intestine. The intestine is lined with microscopic, hair-like projections called villi, and it is through these villi that nutrients are absorbed. Villi project into the



**Light micrograph of healthy villi (tiny finger-like projections) on the lining of the small intestine. When people with celiac disease eat foods or use products containing gluten, their immune system responds by damaging or destroying the villi. Villi allows nutrients from food to be absorbed into the bloodstream; without healthy villi, a person becomes malnourished, regardless of the quantity of food eaten.** *(Eye of Science/Photo Researchers, Inc. Reproduced by permission.)*

intestine and provide an increased the surface area for absorption. Damage to the villi results in inadequate absorption, especially of **vitamins**, **minerals**, and **fats**.

Celiac disease is an autoimmune disease. Whenever immune system cells in the body sense the presence of foreign material, they produce proteins called antibodies that act to disable the foreign material. In an autoimmune disease, the body treats some of its own cells as foreign and attacks them. Celiac disease is also classified as a malabsorption disease because the cells that are damaged by the body's immune system are cells of the villi lining the small intestine. When these cells are damaged, the villi flatten out, decreasing the surface area available for absorption. Nutrients are not properly absorbed, and vitamin and mineral deficiencies often develop.

The symptoms of celiac disease were describe as early as 1888, but it was not until the 1950s that physicians began to understand what caused the disease. A Dutch pediatrician, W. K. Dicke, was the first person to make the connection between the consumption of foods containing wheat and symptoms of celiac disease. Today researchers know that the problem substance is gluten found in wheat, rye, and barley, and products such as four, bread, and pasta made from these grains. The role of oats and oat products in celiac disease remains controversial.

## Demographics

Celiac disease is most common among people of Northern European ancestry and is uncommon to rare among people of African or Asian ancestry. Initially celiac disease was thought to be uncommon in the United States, but recent improvements in genetic testing and disease awareness have changed that picture. Experts now believe that in the United States and other areas of the world settled primarily by Europeans (e.g. Australia), about 1 of every 133 people has celiac disease. The disease has an inherited component, and the rate increases to 1 of every 22 people who are blood relatives of a parent, sibling, or child with the disease. In about 70% of identical twins, if one has celiac disease, the other also has it. Celiac disease is also more common among people with other genetically-related autoimmune diseases such as systemic lupus erythematosus, type 1 diabetes (juvenile diabetes), rheumatoid arthritis, and autoimmune thyroid disease.

People of any age can be diagnosed with celiac disease. However, there are two common peaks for diagnosis, one between 8–15 months, which is shortly after infants usually begin eating wheat products, and another between 30–40 years in adults.

## Causes and symptoms

Researchers have traced the genetic component of celiac disease to a cluster of genes on chromosome six. Multiple genes are involved, which may account for the variation in symptoms and inheritability of the disease. Often, symptoms of the disease develop after a serious infection, physical trauma, pregnancy, or surgery. Researchers do not know why stress on the body appears to trigger symptoms.

Symptoms of celiac disease are varied. Some people have the disease (as diagnosed by samples that show damage to the small intestine), but they show no symptoms. Others go along for years with annoying or intermittent symptoms, and some, especially children, show severe symptoms of malnutrition that stunt growth despite eating a healthy diet. Symptoms are similar to those of other, more common, **digestive diseases**. Often celiac disease is initially misdiagnosed.

Common symptoms of celiac fall into two categories, those primarily related to the immediate problems of digesting food and those that result mainly from long-term deficiencies in vitamins and minerals.

## KEY TERMS

**Antibody**—a protein produced by the immune system to fight infection or rid the body of foreign material. The foreign material that stimulates the production of antibodies is called an antigen. Specific antibodies are produced in response to each different antigen and can only inactivate that particular antigen.

**Mineral**—an inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

**Osteoporosis**—a condition found in older individuals in which bones decrease in density and become fragile and more likely to break. It can be caused by lack of vitamin D and/or calcium in the diet.

**Quinoa**—a high-protein grain native to South America (pronounced keen-wah)

**Systemic lupus erythematosus (SLE)**—a serious autoimmune disease of connective tissue that affects mainly women. It can cause joint pain, rash, and inflammation of organs such as the kidney.

**Triticale**—man-made hybrid plant that combines wheat and rye and that produces a higher protein flour

**Type 1 diabetes**—also known as insulin-dependent diabetes mellitus (IDDM), or juvenile diabetes, an autoimmune disease in which the body appears to disable cells in the pancreas that produce insulin. Without insulin, the body cannot use glucose (sugar).

**Vitamin**—a nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet

Symptoms primarily related to immediate difficulties in digestion include:

- chronic diarrhea
- foul-smelling grayish stools. These result from inability to properly digest fats.
- gas, abdominal bloating
- abdominal cramps
- weight loss

Other symptoms that develop because of vitamin and mineral deficiencies can include:

- iron deficiency anemia, low red blood cell count
- joint pain, muscle pain, muscle cramps
- osteoporosis (inadequate calcium absorption)
- tingling in the legs from nerve damage
- seizures
- bleeding disorders (inadequate vitamin K)
- missed menstrual periods
- infertility (women), frequent miscarriages
- failure to thrive in infants
- delayed mental and physical growth in children

Other symptoms include:

- fatigue
- irritability and behavioral changes especially in children
- pale sores inside the mouth
- dermatitis herpetiformis, an itchy skin rash that usually appears on the trunk, buttocks, neck, and scalp.

### Diagnosis

Celiac disease can be difficult to diagnose because its symptoms are similar to those of so many other diseases. Often it is initially misdiagnosed as **irritable bowel syndrome** or **Crohn's disease**. Stool examination, blood tests, and lactose (milk sugar) tolerance tests are often done when the patient first complains of symptoms, but there are two definitive tests for celiac disease.

The immune system of people with celiac disease produces higher than normal levels of certain antibodies. Blood tests can detect abnormal levels of these antibodies. If blood tests are positive, a small bowel endoscopy with biopsies is done. Endoscopies are usually performed in a doctor's office or an outpatient clinic while the patient is under light sedation. In this procedure, the physician inserts a tube called an endoscope down the patient's throat, through the patient's stomach and into the upper part of the small intestine. A tiny camera at the end of the endoscope allows the doctor to see if there is damage to villi. During this procedure, the doctor also removes small tissue samples (biopsies) from the intestinal lining in order to look for cell damage under the microscope. Presence of a specific type of damage is a positive diagnosis for celiac disease.

### Treatment

There is no cure for celiac disease. The only treatment is life-long avoidance of any foods that contain gluten. This means not eating foods that contain wheat, rye, and barley, such as bread or baked goods, pizza,

spaghetti, and many processed foods that use flour as a thickening agent.

When individuals fail to improve on a **gluten-free diet**, it is sometimes because they are unintentionally consuming sources of hidden gluten. A few people on truly gluten-free diets do not improve. They can be treated with corticosteroid drugs to reduce inflammation, but this does not heal the intestine. Clinical trials concerning treatment of celiac disease are underway. Patients interested in participating in a clinical trial at no cost can find a list of trials currently enrolling volunteers at <http://www.clinicaltrials.gov>

## Nutrition/Dietetic concerns

Individuals newly diagnosed with celiac disease need counseling from a nutritionist and help in meal planning from a dietitian. Two issues need to be addressed. First, what is safe to eat, and second, how to get the right balance of nutrients in a gluten-free diet. Complicating matters, damage to the intestines may make some people lactose intolerant, so that they either cannot eat or must limit dairy products in their diet.

Many cookbooks are available to help people on a gluten-free diet. Home cooks must learn to substitute ingredients such as cornstarch and rice flour for wheat flour in their foods. An increasing number of gluten-free foods are available commercially. However, these often cost more than their gluten-containing counterparts. Below are listed just a few foods people with celiac disease can safely eat.

- plain fruits and vegetables
- plain meat that has not been breaded, coated, or mixed with fillers
- potatoes
- rice (all types)
- cornmeal, cornstarch, and products made of corn, such as corn tortillas
- tapioca
- buckwheat
- dried beans and peas
- nuts
- quinoa
- amaranth
- arrowroot

Other foods must be avoided. Individuals with celiac disease must also avoid cross-contamination with these foods. For example, they should not cut gluten-free bread using a knife that has cut regular wheat bread unless the knife has been thoroughly washed. Even small amounts of gluten can cause damage to the intestine. Some of the foods people with celiac disease must avoid are listed below.

- wheat flours including durum flour, enriched flour, graham flour, semolina flour, and white flour
- wheat germ, wheat starch, wheat bran, cracked wheat
- products made with the above mentioned wheat products such as pasta, bread, cakes, cookies
- barley, barley flour, and products made with barley
- rye, rye flour, and products made with rye
- triticale and other wheat hybrids

Learning how to read food labels is very important to people who must avoid gluten. However, this may become easier in the future. In January 2007, the United States Food and Drug Administration (FDA) published preliminary regulations s for foods that could be labeled "gluten free." Labeling will be voluntary. The FDA hopes to have these rules take effect by August 2008. This will make it easier for shoppers who must avoid gluten to find products they can safely eat. Meanwhile, people with celiac disease must be alert to "hidden" sources of gluten that often serve as binders or thickeners in commercially prepared foods. Some of these non-obvious sources of gluten that may appear on food labels are listed below.

- starch (type unspecified)
- modified food starch
- hydrolyzed vegetable protein (HVP)
- hydrolyzed plant protein (HPP)
- texturized vegetable protein (TVP)
- binders
- fillers
- extenders
- excipients (ingredients used in medications that do not have medicinal value, such as coatings of tablets. Consult a pharmacist or physician about whether before taking drugs, vitamins, etc.)
- malt

Some brands of commercially prepared french fries, potato chips, hot dogs, meatballs, gravy mixes, soups, **soy** sauce, and candy contain these hidden sources of gluten. Others are gluten-free. A nutritionist and dietitian can help people with celiac disease learn to read labels accurately to distinguish that foods are safe for them.

## Therapy

Switching to a gluten-free diet requires major lifestyle changes. It can be especially hard on children and teens who want to be able to go out with their friends

and eat pizza and fast food. Many people find Internet support groups are helpful in making the transition to a gluten-free diet.

### Prognosis

The intestines of people with celiac disease who go on a gluten-free diet heal. In children the healing usually takes 3–6 months. In adults healing can take 2 years. The intestinal villi remain intact and function properly so long as the diet remains free of gluten, but the disease is never cured.

People who are not diagnosed or who do not stay on a gluten-free diet face increased chances of developing **cancer** of the intestine. They may also develop **osteoporosis** because of poor **calcium** absorption. Other vitamin and mineral deficiencies may contribute to a multitude of health problems. Untreated pregnant women have higher than normal rates of miscarriage and babies born with birth defects, especially neural tube defects, which arise from inadequate amounts of folic acid. Untreated children may have stunted mental and physical growth.

### Prevention

Celiac disease is a genetic autoimmune disorder that cannot be prevented. Once diagnosed, the only way to prevent symptoms and complications is to follow a strictly gluten-free diet.

## Central American and Mexican diet

### Definition

The diets of peoples in Mexico and Central America (Guatemala, Nicaragua, Honduras, El Salvador, Belize, and Costa Rica) have several commonalities, though within the region great differences in methods of preparation and in local recipes exist. The basis of the traditional diet in this part of the world is corn (maize) and beans, with the addition of meat, animal products, local fruits, and vegetables. As in other parts of the world, the diet of people in this area has expanded to include more processed foods. In many parts of Mexico and Central America, access to a variety of foods remains limited, and undernutrition, particularly among children, is a major problem. Although access to an increased variety of foods can improve the adequacy of both macronutrient and micronutrient status, there is evidence that the use of processed foods is contributing to the rapidly increasing prevalence of **obesity** and diet-related chronic diseases such as diabetes.

**Common foods of Central America and Mexico**

Avocado
Bananas
Beans
Beef
Cacti
Calabaza (pumpkin)
Carrots
Chicken
Chile peppers
Con leche (coffee, milk, cinnamon, and sugar)
Corn
Eggs
Fish
Greens, locally grown
Guavas
Limes
Mangoes
Melons
Nances (fruit)
Onions
Oranges
Papayas
Pineapple
Plantains
Pork
Queso del pais, a mild, soft white cheese
Tomatillos
Tomatoes
Tortillas, corn and flour
Tunas (prickly pears from cacti)

*(Illustration by GGS Information Services/Thomson Gale.)*

## Origins

### *Traditional Dietary Habits*

The traditional diet of Mexico and Central America is based on corn and beans, but offers a wide diversity of preparations. Coupled with locally available fruits, vegetables, meat and dairy products, the diet can be highly nutritious. However, poverty frequently limits access to an adequate variety of quality foods, resulting in malnutrition. At the same time, the increasing use of processed foods is contributing to obesity, diabetes, and other chronic conditions in this region. The balance between improving access to variety and maintaining dietary quality poses a challenge for public health.

The central staple in the region is maize, which is generally ground and treated with lime and then pressed into flat cakes called *tortillas*. In Mexico and Guatemala, these are flat and thin, while in other Central American countries tortillas are thicker. In El Salvador, for example, small, thick cakes of maize, filled with meat, cheese, or beans, are called *pupusas*. Maize is also used in a variety of other preparations, including tacos, tamales, and a thin gruel called atole. The complementary staple in the region is beans (*frijoles*), most commonly black or pinto beans. Rice is also widely used, particularly in the southernmost countries, such as El Salvador, Honduras, Nicaragua, and Costa Rica. Historically, major changes in the traditional diet occurred during colonial times, when the Spaniards and others introduced the region to wheat bread, dairy products, and sugar. Wheat is commonly consumed in the form of white rolls or sweet rolls, or, in the northern part of Mexico, as a flour-based tortilla. Noodles (*fideos*), served in soups or mixed with vegetables, have also become popular.

The consumption of meat and animal products, although popular, is often limited due to their cost. Beef, pork, chicken, fish, and eggs are all used. Traditional cheeses are prepared locally throughout the region as *queso del pais*, a mild, soft, white cheese, and milk is regularly used in *café con leche* and with cereal gruels.

The region is a rich source of a variety of fruits and vegetables. Best known among these are the chile peppers, tomatoes, and tomatillos that are used in the salsas of Mexico. Avocado is also very popular in Mexican and Central American cuisines. Other commonly used vegetables include *calabaza* (pumpkin), carrots, plantains, onions, locally grown greens, and cacti. Fruits are seasonal but abundant in the rural areas and include guavas, papayas, mangoes, melons, pineapples, bananas, oranges, and limes, as well as less-known local fruits such as *nances, mamey*, and *tunas* (prickly pears from cacti). Traditional drinks (*frescos, chichas*, or *liquados*) are made with fruit, **water**, and sugar.

## Description

### *Methods of Cooking*

The traditional preparation of maize involves boiling and soaking dried maize in a lime-water solution and then grinding it to form a soft dough called *masa*. Soaking in lime softens the maize and is an important source of **calcium** in the diet. The masa is shaped and cooked on a flat metal or clay surface over an open fire. In some areas, lard or margarine, milk, cheese, and/or baking powder may be added to the tortilla during preparation. Beans are generally boiled with seasonings such as onion, garlic, and sometimes tomato or chile peppers. They are served either in a soupy liquid or are "refried" with lard or oil into a drier, and higher fat, preparation.

Meat, poultry, and fish are commonly prepared in local variations of thin soup (*caldo* or *sopa*), or thicker soups or stews (*cocido*) with vegetables. In Mexico and

## KEY TERMS

**Macronutrient**—Nutrient needed in large quantities.

**Malnutrition**—Chronic lack of sufficient nutrients to maintain health.

**Micronutrient**—Nutrient needed in very small quantities.

**Undernutrition**—Food intake too low to maintain adequate energy expenditure without weight loss.

Guatemala, grilled meats are cut into pieces and eaten directly on corn tortillas as tacos.

These are often served with a variety of salsas based on tomato or tomatillo with onion, chile, coriander leaves (cilantro), and other local seasonings. Tamales are made with corn (or corn and rice) dough that is stuffed with chicken and vegetables. The tamales are steamed after being wrapped in banana leaves. Salvadorian *pupusas* are toasted tortillas filled with cheese, beans, or pork rind eaten with coleslaw and a special hot sauce.

### *Central American and Mexican Dishes*

Beyond the basic staples, the cuisine of Mexico and Central America is rich with many regional variations. The tortilla-based Mexican preparations familiar in the United States are generally simpler in form in Mexico. *Tacos* are generally made with meat, chicken, or fish grilled or fried with seasoning and served on tortillas; *enchiladas* are filled tortillas dipped in a chile-based sauce and fried; and *tostadas* are fried tortillas topped with refried beans or meat, and sometimes with vegetables and cream. *Chiles rellenos* are made with the large and sweet chile *poblano* and filled with ground meat. Examples of specialty dishes include *mole*, a sauce made with chocolate, chile, and spices and served over chicken, beef, or enchiladas; and *ceviche*, raw marinated fish or seafood made along the coast throughout Central America and Mexico.

### *Influence of Central American and Mexican Culture*

As two cultures intermingle, foods and preparations from each tend to infiltrate the other. This is clearly the case near the U.S.-Mexican border, where Mexican immigrants and return immigrants have incorporated foods from U.S. diets into their traditional diets. The result has been a modified form of Mexican cuisine popularly known as "Tex-Mex." Beyond the border, this Americanized version of popular Mexican foods has spread throughout the United States through the popularity of Mexican restaurants. In the United States, tacos and tostadas tend to have less Mexican seasoning, but include lettuce and shredded processed cheese. Flour, rather than corn, tortillas are more widely used along the border. Many foods, such as soups and chiles, prepared along the border have become known for their spicy hotness, due to the Mexican-influenced use of chiles and chile powder.

## Benefits

The staple diet of the region—corn and beans, supplemented with meat, dairy products, and local fruit and vegetables—is nutritionally complete and well suited to a healthful lifestyle. The proper combination of tortilla and beans provides an excellent complement of amino acids, thus supplying the necessary amount of complex **protein**. The process of liming the maize makes the calcium and the **niacin** in the tortilla more bioavailable, and this food is a major source of these nutrients. In addition, the traditional preparation of tortillas with a hand mill and grinding stones appears to add **iron** and **zinc** to the tortilla. Beans are excellent sources of B **vitamins**, **magnesium**, **folate**, and **fiber**. The tomato and chile-based salsas, along with several of the tropical fruits such as limes and oranges are important sources of **vitamin C**, and the variety of vegetables and yellow fruits such as papaya, melon, and mango provide excellent sources of **carotenoids**, which are precursors of **vitamin A**.

## Risks

Unfortunately, limited financial access to this variety of foods for many people in Central America and Mexico means that the diet often does not include sufficient levels of vitamins and **minerals**. For low-income groups, lack of access to animal products contributes to deficiencies in iron, zinc, vitamin A, and other nutrients. When animal products are included, there has been a tendency to choose high-fat products such as sausage and fried pork rinds (*chicharron*). The use of lard and a preference for fried foods also contributes to high intakes of saturated fatand cholesterol among subsets of the population.

### *Changes in Dietary Practices*

Throughout the world, the diets of traditional cultures have experienced what has been called the "nutrition transition," particularly during the last few decades of the twentieth century. In Mexico and

Central America, as elsewhere, this transition has been fueled by globalization and urbanization. Major dietary changes include an increased use of animal products and processed foods that include large amounts of sugar, refined flour, and hydrogenated **fats**. At the same time, a decline in the intake of whole grains, fruit, and vegetables has been documented. While the increased variety has improved micronutrient status for many low-income groups, the inclusion of more animal fat and refined foods has contributed to a rapid increase in obesity and chronic disease throughout the region.

These changes are more evident among immigrants to the United States, where adoption of U.S. products has been shown to have both positive and negative impacts on nutritional status. Studies that compared diets of Mexican residents to newly arrived Mexican-American immigrants and to second-generation Mexican Americans have documented both nutritionally positive and negative changes with acculturation. On the positive side, acculturated Mexican Americans consume less lard and somewhat more fruit, vegetables, and milk than either newly arrived immigrants or Mexican residents. On the negative side, they also consume less tortilla, beans, soups, stews, gruels, and fruit-based drinks, with greater use of meat, sweetened ready-to-eat breakfast cereals, soft drinks, candy, cakes, ice cream, snack chips, and salad dressings.

## Central European and Russian diet

### Description

A health gap separates Central and Eastern Europe from the United States, Canada, Japan, and the Western part of Europe. This East-West gap in health started during the 1960s. Almost half of this gap was due to cardiovascular disease (CVD) mortality differentials. There has been a marked increase of CVD in Central and Eastern Europe, which is only partially explainable by the high prevalence of the three traditional CVD risk factors (hypercholesterolemia, **hypertension**, and smoking) in these countries. There is an extreme nonhomogeneity of the former Soviet bloc, and the data from each country must be analyzed individually. The aim here is to present the latest available data, which show the health status of various regions of postcommunist Europe. All data used are taken from the World Health Organization (WHO) Health for All Database (as updated in June 2003). The last available data from most countries are from the year 2002.

As premature mortality was considered the most important information, the standardized death rate (SDR) for the age interval 0–64 years was used (SDR is the age-standardized death rate calculated using the direct method; it represents what the crude death rate would have been been if the population had the same age distribution as the standard European population).

#### *Central Europe (Poland, Hungary, Czech Republic, Slovakia)*

Total, CVD and **cancer** mortality in Central Europe was relatively low at the beginning of the 1960s, but then an increase occurred. While the differences in 1970 between the nations of the European Union (EU) and the Central European communist countries were not great, from the mid-1970s on, the relative trends in CVD mortality in EU countries and Central Europe showed a marked change: mortality in Central Europe increased, whereas in EU countries it decreased steadily. Between 1985 and 1990, the male CVD mortality in Central Europe was more than two times higher than in EU countries. A substantial proportion of this divergence was attributable to ischemic heart disease. After the collapse of Communism, however, a decrease in CVD mortality in Central Europe was observed.

#### *The Former Soviet Union (Russian Federation)*

The most significant changes in CVD mortality have been observed in the region of the former Soviet

**Male and female life expectancy at birth in Europe, 2004**

| Country | Males | Females |

*(Illustration by GGS Information Services/Thomson Gale.)*

Union (USSR). Between the years 1980 and 1990, male premature mortality was relatively stable in all regions of the USSR, and two to three times higher than in EU nations, or average. After the collapse of the USSR, CVD mortality began to rise dramatically in all the new independent states within the territory of the former USSR. In 1994 the male CVD mortality in Russia and Latvia was more than five times higher than the EU average. Women in these countries have been affected to almost the same degree as men, and the CVD mortality trends were strongest among young adults and middle-aged individuals. Cancer mortality was stable during this period, however. In 1994 the life expectancy of Russian men was almost twenty years less than that of men in Japan and some European countries. After 1994, however, there was a sudden drop in mortality both in males and females, followed by a further increase.

## Origins

### *Lifestyle and Nutrition*

Communist period (1970–1989). The socioeconomic situation in the democratic part of Europe and in the United States after World War II was substantially different than that in the Soviet bloc. The United States and the European democratic states were prosperous countries with effective economies and a rich variety of all kinds of foods. The communist states, however, had ineffective centralized economies and lower standards of living. The amount of various foods, especially foods of animal origin, was almost always insufficient in the USSR and the majority of its satellite countries. Data on food consumption compiled by the Food and Agricultural Organization (FAO) confirm that meat consumption was, between 1961 and 1990, substantially lower in the USSR, Poland, Romania, and Bulgaria than in Western Europe or the United States. Similarly, the consumption of milk and butter in Bulgaria, Hungary, and Romania was significantly lower in comparison with Western and Northern Europe.

The increase of CVD mortality within the Soviet bloc seems to be only partially associated with a high prevalence of traditional risk factors. Efforts to apply the experience gained from successful preventive projects in Finland or the United States without analyzing the specificity of risk factors in this region, could lead to an incorrect formulation of priorities when determining preventive measures. The contribution of physical activity remains an open issue, but due to technical backwardness (lower number of cars, lower mechanization, etc.), the physical activity of people working in industry, agriculture, and services was generally higher in Eastern Europe than in the West.

Some authors believe that economic conditions were the principal determinant of the gap in health status between the East and West. The close relationship between the gross national product per capita and life expectancy is well known, but the inhabitants of Central Europe were less healthy than their wealth predicted. The dramatic changes that occurred after the onset of communism created a toxic psychosocial environment. A loss of personal perspectives, chronic stress, tension, anger, hostility, social isolation, frustration, hopelessness, and apathy led to a lowered interest in health and to a very high incidence of alcoholism and suicide. People living for many decades in the informationally polluted environment rejected even useful health education.

## KEY TERMS

**Antioxidant**—Substance that prevents oxidation, a damaging reaction with oxygen.

**Free radical**—Highly reactive molecular fragment, which can damage cells.

**Hypercholesterolemia**—High levels of cholesterol in the blood.

**Hypertension**—High blood pressure.

**Plasma**—The fluid portion of the blood, distinct from the cellular portion.

It is widely believed that chronic stress can aggravate the development of chronic diseases. However, the reasons for the high cancer and CVD mortality in Eastern Europe are (with the significant exception of male smoking) not yet known. It is possible that in communist countries the effect of traditional risk factors has been intensified unidentified factors. Hypothetically, such factors can comprise psychosocial disorders, alcoholism, environmental pollution and specific nutritional deficiencies (e.g., very low intake of antioxidant **vitamins**, folic acid, and bioflavonoids). Very low blood levels of **antioxidants**, especially of **vitamin C** and **selenium**, were found in various regions of Central and Eastern Europe between 1970 and 1990.

Postcommunist period (after 1989). Thanks to its geographical location, Central Europe was best prepared for the democratic changes that occurred after 1989. After the collapse of communism, the decrease in CVD mortality in politically and economically more consolidated countries occured. The positive changes in Central European countries can be explained by higher consumption of healthful food, including a substantial increase in the consumption of fruit and vegetables, a decrease in butter and fatty milk consumption, and an increase in the consumption of vegetable oils and high-quality margarines. There was also a rapid improvement in the availability and quality of modern CVD health care.

Finnish and Russian epidemiologists compared the plasma ascorbic-acid concentrations among men in North Karelia (Finland) and in the neighboring Russian district. Almost all Russian men had levels suggesting a severe vitamin C deficiency, while more than 95% Finns had normal vitamin C levels. Comparison of fifty-year-old men in Sweden and Lithuania found significantly lower plasma concentrations of some antioxidant vitamins (beta-carotene, lycopene, gamma-tocopherol) in Lithuanian men. They also had substantially lowered resistance of low-density lipoprotein to oxidation than Swedish men. It is probable that in Russia an imbalance arose in which factors enhancing the production of free radicals (alcoholism, smoking, and pollution) dominated protective antioxidant factors.

High prevalence of smoking and alcoholism has also been an important factor in high CVD mortality rates in Russia. A substantial proportion of CVD deaths in Russia, particularly in the younger age groups, have been sudden deaths due to cardiomyopathies related to alcoholism. Alcoholism has evidently played a key role in the extremely high incidence of CVD mortality, as well as in the numbers of accidents, injuries, suicides, and murders. There is no way to determine a reliable estimation of the actual consumption of alcohol in Russia, since alcohol is being smuggled into the country on a large scale.

### Risks

Normalization in the Russian Federation will likely be more difficult than in Central Europe. Trends in lifestyle, smoking, food selection, **alcohol consumption**, and other areas will be determined by both economic and political factors. The successfulness of the economic transformation, which provides hope for a sensible life, will be a key factor in improving health status in postcommunist countries. A significant decrease in cardiovascular and cancer mortality in Central Europe provides hope for the Russian Federation. Unfortunately, differences in life expectancy between these countries and Western Europe are still very great.

## ChangeOne diet

### Definition

The aim of "ChangeOne: Lose Weight Simply, Safely, and Forever" is to provide a simple, straightforward plan for gradual, permanent weight loss. The book features a twelve-week eating plan that outlines portion sizes, recipes and meal suggestions designed to achieve weight loss. A major distinguishing feature of the ChangeOne plan is its emphasis on making lifestyle changes gradually over a three month interval, rather than advocating a complete, abrupt transformation of existing eating patterns. The diet is based on everyday foods, both home-prepared and available in restaurants and does not require purchase of special foods or supplements.

### Origins

ChangeOne is published by the Reader's Digest Association, a New York-based company which also owns and operates *Reader's Digest*, the best-selling consumer magazine in the United States. ChangeOne has been dubbed "The Official Reader's Digest Diet".

The lead author is John Hastings, a senior staff editor for health at *Reader's Digest*. Co-authors are Peter Jaret, a health journalist, and Mindy Hermann, a Registered Dietitian.

The principles underlying this diet reflect the influence of the Dietary Guidelines for Americans and the Food Guide Pyramid set by the United States Department of Agriculture. These guidelines emphasize moderation, portion control and the use of plant foods—grains, fruits and vegetables—as the basis for meals.

## Description

The cornerstone of this diet is the progressive, gradual nature in which it promotes behavior change. Readers are advised to approach weight loss one meal at a time, one day at a time, beginning with a week-long focus on breakfast. The reader starts out by completing a quiz assessing readiness for permanent lifestyle changes.

Meal plans are designed to meet the following daily intakes:

- Calories: 1,300-1,600
- Calories from fat: 30 to 35% of total calories
- Saturated and hydrogenated ("trans") fats: no more than 10% of calories
- Fiber: at least 25 grams
- Calcium: approximately 1,000 milligrams
- Fruits and vegetables: at least five servings

The ChangeOne diet is flexible in letting readers set their own calorie target within the recommended range and adjust it throughout the program to suit their needs. Those who are physically inactive and weigh less then 190 pounds are advised to aim for the lower end of the calorie range. Readers who weigh more than 190 pounds or get more than thirty minutes of daily vigorous exercise are advised to aim for the higher calorie intake.

A key idea underlying the ChangeOne plan is that all foods can fit within a balanced plan for long term weight management. The authors recognize that food restrictions tend to intensify **cravings**; for this reason, no foods are forbidden on this plan. The crux of the diet lies in portion control. Household items such as tennis balls, golf balls and checkbooks are suggested for gauging portions. The reader is not required to count calories, but must adhere to the recommended food types and portion sizes. Presumably, if the portion sizes are followed correctly, the day's total calories will fall within the targeted range.

The ChangeOne program advocates eating at a slow pace, both to enhance enjoyment of meals and to help the body properly assess hunger and satisfaction levels while eating. The authors recommend a high consumption of **water** and other non-calorie beverages for their satisfying effect. For the same reason, an unlimited intake of non-starchy vegetables such as those used in salads and stir-fries is allowed. Alcohol intake is allowed, but limited to one standard serving of beer or wine per day. Each chapter features recipes to complement the meal plan, as well as "Fast Track" suggestions for accelerating progress, such as increasing minutes spent on physical activity, or using a journal to keep track of foods eaten. Readers learn to use rewards to reinforce positive behavior changes until the weight loss provides the necessary reinforcement.

### KEY TERMS

**Acceptable Macronutrient Distribution Range (AMDR)**—A range of intakes for a particular energy source that is associated with reduced risk of chronic disease while providing adequate intakes of essential nutrients. An AMDR is expressed as a percentage of total energy intake.

**Dietitian/Registered Dietitian**—A health professional who has a Bachelor's degree specializing in foods and nutrition, as well as a period of practical training in a hospital or community setting. The title "Registered Dietitian" and "Dietitian" are protected by law so that only qualified practitioners who have met education qualifications can use that title.

**Emotional Eating**—Eating as a way to suppress or soothe negative emotions, such as stress, anger, anxiety, boredom, sadness and loneliness. Emotional eating is a cause of weight gain and can sabotage weight loss efforts.

**Hydrogenated (Trans) Fats**—Hydrogenation is a process of turning liquid oil into solid fat. During this process, a type of trans fat may be formed that raises cholesterol levels in the blood. This increases the risk of coronary heart disease.

**National Academy of Sciences**—A private, nonprofit society of scholars with a mandate to advise the United States government on scientific and technical matters.

**National Weight Control Registry (NWCR)**—The largest prospective study of long-term successful weight loss. The NWCR is tracking over 5,000 individuals who have lost at least 30 pounds and kept it off for at least one year.

### *The Program at a Glance*

**WEEK ONE: BREAKFAST.** Eating a morning meal is cited as being crucial to weight management. The authors refer to data from the National Weight Control Registry that suggest that eating breakfast every day is associated with losing weight and keeping it off. The ChangeOne breakfast plan encourages a balance of starchy foods, fruit and a calcium-rich food. High-fiber foods are promoted for their satisfying quality and nutrient-density. Sample recipes include vegetable frittata and dried cranberry scones with orange glaze.

**WEEK TWO: LUNCH.** The second week of the program has dieters planning ahead for both home-prepared and purchased lunches that are satisfying and portion-controlled. The mid-day meal is comprised of a small portion of lean meat, fish or a vegetarian alternative, along with a starchy food, one fruit and unlimited vegetables. Restaurant meals can fit the plan as long as recommended portion sizes are honored. Readers are encouraged to anticipate the difficulty of making healthy restaurant choices by creating a list of ChangeOne meals that can be ordered in restaurants. This chapter provides an overview of best options in fast food restaurants. Sample recipes include grilled turkey Caesar salad and roasted vegetable wraps with chive sauce.

**WEEK THREE: SNACKS.** On the ChangeOne regime, dieters plan for two snacks each day. The authors point to scientific evidence that eating frequently throughout the day can assist with weight management by regulating blood sugar levels and warding off cravings and intense hunger. This chapter teaches readers to properly interpret hunger cues and encourages an awareness of emotional eating. It offers strategies to manage hunger and appetite. Sample recipes include chocolate snacking cake and multigrain soft pretzels.

**WEEK FOUR: DINNER.** The fourth week of the program places as much emphasis on how to eat as it does on what and how much to eat. The author provides an overview of the principles of effective goal setting, advising that goals be time-bound, realistic, inspiring and measurable). This chapter provides plenty of practical suggestions for meal preparation, including tips for low-fat cooking, such as the use of marinades to tenderize lean cuts of meat and the use of seasonings and herbs to add flavor without calories. The dinner meal plan features a small serving of lean meat or another protein-rich food, paired with a starchy side dish and unlimited vegetables. Sample recipes include Thai noodle salad and red snapper with Spanish rice. By the end of the fourth week, dieters should have all three meals and two snacks under good control.

**WEEK FIVE: DINING OUT.** The authors recommend eating in restaurants at least twice in the fifth week of the program in order to gain practice navigating menus and making healthy choices. This chapter opens with an eye-opening discussion of how restaurant meals distort our understanding of sensible portions. The keys to sticking with the ChangeOne plan when eating out, the authors contend, is being both prepared and discerning. When possible, reviewing the menu prior to arriving at the restaurant is recommended. Readers are advised to keep a list of restaurants on hand that are known to offer good tasting options that are lower in calories. Dieters are encouraged to be assertive when ordering by requesting ingredient substitutions and smaller portions. Discipline is required to stick to the portion sizes recommended in the meal plans, leaving excess food uneaten. The chapter outlines best menu options for such favorites as Italian, Mexican and Chinese restaurants, surf and turf, diners and coffee shops.

**WEEK SIX: WEEKENDS AND HOLIDAYS.** ChangeOne is realistic in acknowledging that routines tend to change over the weekend. The authors advise against viewing weekends as vacations from the healthy eating patterns implemented during the workweek; to do so implies that the diet is merely a temporary effort to improve eating habits. This chapter encourages enlisting friends and family for support but warns against saboteurs and others who will apply pressure to abandon new healthy eating habits. Strategies are offered for staying on track during the holidays (for example, having low-calorie snacks on hand and directing activities that don't involve food). The recipe section features calorie-wise alternatives to traditional holiday fare, including a revamped turkey dinner and Sunday brunch.

**WEEK SEVEN: FIXING YOUR KITCHEN.** The challenge this chapter proposes is that of taking stock of the food supplies in the kitchen so that they support the reader's new healthy eating habits. The first step advised to get the kitchen diet-ready is purging the shelves of anything that might sabotage healthy eating efforts. The authors offer strategies for smart grocery shopping such as not shopping on an empty stomach, sticking to planned purchases, and spending the most time shopping around the store's perimeter, avoiding aisles laden with processed foods. The reader is advised to inspect foodstuffs and "read the small print", but specifics on how to read and interpret nutrition labels are not offered. The chapter closes with a few recipes that feature basic ingredients found in most pantries.

**WEEK EIGHT: HOW AM I DOING?.** This week serves as a checkpoint for assessing progress and provides an opportunity to reshape goals and renew commitment.

The authors guide in trouble-shooting common stumbling blocks like portion distortion and lack of meal planning. Practical suggestions are offered for dealing with emotional stress and the temptation to quit. The authors advise their readers to revisit their expectations for what constitutes weight loss success. Dieters are taught to pace their long term goals by setting more tangible milestones and rewarding small successes along the way.

**WEEK NINE: STRESS RELIEF.** In week nine, dieters are encouraged to consider the relationship between weight management and stress management. The authors explain how high levels of stress affect the body's hormonal balance, triggering food cravings and promoting fat deposition. Readers are advised to analyze the stressors in their lives and begin brainstorming solutions. The authors emphasize participation in physical activity and the support of friends as effective stress management tools. Readers are encouraged to try a step-by-step 20-minute daily relaxation routine to relieve tension and enhance coping. This week's featured recipes are calorie-reduced versions of traditional comfort foods such as meatloaf, chicken pot pie and beef stew.

**WEEK TEN: STAYING ACTIVE FOR SUCCESS.** In the program's tenth week, healthy eating and active living are shown to be synergistic. The author presents research showing that dieters who exercise regularly enjoy greater success in their weight loss programs than those who are physically inactive. Rather than advocating intense gym workouts, the authors highlight the calories expended in activities of daily living and encourage being active in ways that are enjoyable. For optimal fat burning, however, readers are advised to check their pulse and aim for an intensity equivalent to 60% to 80% of maximum heart rate. The chapter is consistent with the book's message of making changes gradually; it encourages starting out with 10 to 15 minute walks each day and slowly working up to 30 minutes of daily physical activity.

**WEEK ELEVEN: KEEPING ON TRACK.** This week's goal is developing strategies for monitoring progress and trouble-shooting areas of difficulty in order to avoid set-backs. Readers are advised to anticipate small weight fluctuations but to take action before a few pounds of weight gain become a full relapse. The authors provide a diagnostic checklist for identifying areas of difficulty. They advise weekly weigh-ins to gauge long term progress. Dieters are encouraged to monitor and make a written record of mood states in order to uncover their relationship to emotional eating.

**WEEK TWELVE: AVOIDING BOREDOM AND MAINTAINING CHANGES IN THE LONG TERM.** ChangeOne acknowledges that boredom with a set routine is a big obstacle in maintaining changes over the long term. The authors encourage their readers to break their routine slightly every week to foster continued enjoyment of eating. Suggestions include trying a new food every week, creating a salad bar at home for dinner and concocting signature flavor combinations for standbys like homemade pasta and pizza. Again, dieters are reminded to keep the process from becoming tedious by setting rewards for small steps taken towards the achievement of the ultimate goal.

Part Two of the ChangeOne book is a collection of resources, including meal plans, recipes and an eight-week fitness program complete with color photographs of aerobic, strengthening and stretching exercises.

Readers are encouraged to visit http://www.changeone.com for online support. For a fee, dieters have access to online journaling tools, recipe archives, meal plans and activity plans.

## Function

The ChangeOne diet promotes a gradual calorie deficit by remodeling eating habits one meal at a time. Ultimately, three low-calorie meals plus two small snacks provide a total of 1300 to 1600 calories per day, which represents a significant reduction in calorie consumption for the average North American adult.

Meal plans are presented in a style that allows the reader to mix and match set amounts of preferred foods. This flexibility allows the reader to create enjoyable meals that are calorie-controlled, thus promoting weight loss.

Part Two of the ChangeOne book includes recipes and daily menus to support readers who desire the structure of a set meal plan.

## Benefits

The ChangeOne diet promises "no fads, no risks, no craziness". It is based on nutrition principles that are scientifically sound, and it echoes the nutrient balance endorsed by the USDA Food Pyramid. Meals consist of lean **protein**, high-fiber starchy foods, fruits, vegetables and low-fat dairy. No foods are disallowed, and no special foods or supplements are necessary. Meals can be prepared at home or purchased in restaurants. Varied meal plans and tasty menus, combined with numerous recipes and cooking tips make the book practical and informative.

ChangeOne is written in a straightforward, engaging manner. Changes are promoted in a step-wise fashion, in contrast to the all-or-nothing approach

espoused by most diets. Rather than simply providing guidance on what to eat, ChangeOne encourages exploration of the reasons for eating.

### Precautions

The ChangeOne program is a suitable weight loss plan for most adults. A health care provider, however, should be consulted before beginning any weight loss program. The upper limit of 1,600 calories per day may be insufficient for those with high physical activity demands. The use of **artificial sweeteners** is not appropriate for everyone. Readers should get clearance with their doctors regarding ideal exercise type, intensity and duration before beginning any exercise program.

### Risks

Because this diet emphasizes sound patterns of healthy eating, there are no significant risks in following its principles. Dieters should note that the program is not designed for rapid weight loss.

### Research and General Acceptance

The ChangeOne program echoes the principles of healthy eating promoted in the USDA Food Guidelines for Americans. In particular, the diet mirrors the National Academy of Sciences' Acceptable Macronutrient Distribution Ranges (AMDR) for fat, **carbohydrates**, and protein, which are 20 to 35% of total calories, 45 to 65% of total calories, and 10 to 35% of total calories, respectively. The recommended intake of fat, as well as calories from unhealthy (saturated and hydrogenated) **fats**, **fiber** and **calcium** also complies with the recommendations set by the National Academy of Sciences.

Much of the advice and strategies recommended in ChangeOne have a strong scientific basis. The authors substantiate their recommendations by quoting research from reputable sources such as Harvard University, Penn State University, the Journal of the American Medical Association and the Center for Science in the Public Interest. The authors also draw data from the National Weight Control Registry, the largest study of its kind investigating factors associated with successful weight loss and maintenance.

Lead author John Hastings notes that physicians served as advisors in the development of the eating plan. The diet was pilot-tested by volunteers, mostly from the Reader's Digest workforce. Participants lost an average of 17 pounds over the 12 week program. There is no mention of the number of participants involved in testing the diet, and whether these results bear any statistical significance.

### QUESTIONS TO ASK YOUR DOCTOR

- What would be a healthy weight for me?
- What is a realistic time frame for losing this weight?
- Is it safe for me to start doing physical activity?
- What are the best types of physical activity for me?
- The ChangeOne diet advises the use of artificial sweeteners instead of sugar in coffee and tea. Is this safe for me? Are there any artificial sweeteners that I should avoid?
- How can I find a Registered Dietitian who can support me in my weight loss efforts?
- What groups and prgrams are available in the community to help me with my nutrition goals?

# Chicken soup diet

## Definition

The chicken soup diet is a seven day diet that allows the dieter to eat one of five approved breakfasts each day and as much chicken soup as desired.

## Origins

The origins of the chicken soup diet are not clear. It seems to circulate mostly from person to person and on the Internet. For many years, people have believed that chicken soup has various health properties. Many different cultures give versions of chicken soup to people who are sick. This belief in the health benefits of chicken soup may have something to do with its popularity as a diet food.

## Description

The chicken soup diet is a diet that is designed to be followed for seven days, although many versions of the diet say that it can be followed for as long as desired, or repeated at any time. It consists of a soup recipe and five breakfast choices. After breakfast, the only thing that the dieter is allowed to eat until the next morning is the soup. This diet also tells dieters what they may or may not drink while on the diet.

### *The Soup*

- 2 tablespoons of oil (olive oil is recommended)
- 4 parsnips (about 1 pound) cut into 1/2 inch pieces
- 4 ribs of celery
- 1 turnip (about 3/4 of a pound) cut into 1/2 inch pieces
- 1 jalapeno pepper, seeded and chopped
- 1 tablespoon of chopped garlic
- 2 teaspoons of salt
- 1/2 teaspoon of cayenne pepper
- 16 cups of reduced fat, low sodium chicken broth
- 7 (5 oz.) cans of chicken or 1 1/2 pound (5 cups) cooked fresh chicken
- 1 bag (16 oz.) frozen carrots
- 1 box (10 oz.) frozen broccoli florets
- 1 box (10 oz.) frozen chopped collard greens
- 1 1/2 cups frozen chopped onions
- 1/4 cup of lemon juice
- 1/4 cup chopped fresh dill or 1 tablespoon dried dill

Directions: Heat the oil over medium heat in a large soup pot. Add the garlic, salt, cayenne pepper, jalapeno, parsnips, celery, and turnip to the pot. Cook these until the vegetables are tender but still crisp, which will take approximately 15 minutes. Next, add the carrots, collard greens, broccoli, onions, chicken broth, and lemon juice to the pot. Bring to a boil, then reduce the heat and allow the soup to simmer for 5 minutes. This recipe is said to make approximately 26 one cup servings. There may be slightly different versions of this recipe, but this one is the most common.

### *Breakfasts*

The chicken soup diet allows the dieter to chose one breakfast each day from five possible breakfasts. Most versions of the diet encourage dieters to eat each breakfast once for the first 5 days, and then choose the breakfasts they liked best and repeat them for days 6 and 7. The breakfasts are:

Breakfast 1: The dieter may eat 1 cup of nonfat vanilla yogurt and 1/2 cup of fruit salad sprinkled with wheat germ.

Breakfast 2: Breakfast 2 allows the dieter to eat 1 cup of ricotta cheese combined with 1/2 teaspoon of sugar and a dash of cinnamon. The dieter may also eat 2 pieces of toasted whole-grain bread and 3 dried figs.

## KEY TERMS

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Mineral**—An inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

**Obese**—More than 20% over the individual's ideal weight for their height and age or having a body mass index (BMI) of 30 or greater.

**Vitamin**—A nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

Breakfast 3: The dieter may eat 1 1/2 cups of Total brand cereal, along with 1/2 cup of nonfat milk and 1/2 cup of **calcium** enriched orange juice.

Breakfast 4: This breakfast allows the dieter to eat 1 small whole-wheat bagel that is topped with 1 ounce of melted fat-free cheddar cheese, along with 1/2 cup of prune juice.

Breakfast 5: Breakfast 5 allows the dieter to eat 1 1/2 cups of cooked Wheatena brand cereal along with 1/2 cup of nonfat milk.

After the dieter eats one of these breakfasts, only the chicken soup may be consumed for the rest of the day.

### Function

The chicken soup diet does not make any claims about how much weight a dieter can lose during the seven days of the diet, although it is usually implied that the dieter will be able to lose a substantial amount of weight. It does not have any exercise or healthy living recommendations. Some versions of the diet suggest that it would be a good diet to use if a dieter wanted to "jump start" a more comprehensive dieting plan, or if a dieter needed to lose a large amount of weight quickly for an upcoming special event.

### Benefits

There are many benefits to losing weight if it is done at a safe, moderate pace through a combination of healthy eating and exercise. There are many conditions for which **obesity** is considered a risk factor, including type II diabetes and heart disease. The risk of these diseases may be reduced through weight loss. This is especially true for very obese people who are generally thought to be at the greatest risk. This diet, however, is not considered appropriate for long term moderate weight loss.

The chicken soup diet may have some other benefits in addition to the claim that it can allow a dieter to lose a large amount of weight in a short amount of time. The soup is usually low in calories and contains many different vegetables, which are an important part of a healthy diet. Eating a soup like the one in this diet may be able to help dieters feel more full without eating very many calories, which may make it easier for some dieters stick to a healthy reduced calorie diet.

### Precautions

Anyone thinking of beginning a new diet should consult a doctor or other medical practitioner. Requirements of calories, fat, and nutrients can differ from person to person, depending on gender, age, weight, and other factors such as the presence of diseases or conditions. The chicken soup diet does not allow very many different foods, and although the soup may be healthy, it is unlikely to be able to provide all the **vitamins** and **minerals** needed for healthy adults each day. Pregnant or **breastfeeding** women should be especially cautious if beginning a very restricted diet like this one because deficiencies of vitamins and other nutrients can negatively impact a baby that is receiving its nutrients from its mother.

### Risks

There are some risks associated with any diet. The chicken soup diet does not allow the dieter to eat very many different foods each day. This means that it is unlikely that the dieter will get enough of all vitamins and minerals required each day for good health. Any dieter thinking of beginning this diet may want to consult a healthcare provider about a multi-vitamin or supplement that would be appropriate to take while on this diet to help reduce the risk of deficiencies. This is especially true for any dieter considering following a very limited diet for an extended period of time. Supplements have their own associated risks.

### Research and general acceptance

The chicken soup diet has not been the subject of any significant scientific studies. In 2000 researchers at the University of Nebraska Medical Center did laboratory research that showed that chicken soup may

## QUESTIONS TO ASK THE DOCTOR

- Is this diet safe for me?
- Is this diet the best diet to meet my goals?
- Do I have any dietary requirements this diet might not meet?
- Would a multivitamin or other dietary supplement be appropriate for me if I were to begin this diet?
- Is this diet safe for my entire family?
- Is it safe for me to follow this diet over an extended period of time?
- Are there any sign or symptoms that might indicate a problem while on this diet?

have anti-inflammatory properties that could help reduce the symptoms of the flu and colds. This research lends credibility to what many people already believed, that chicken soup was good for people who were ill. The research done was very preliminary and was done in a laboratory, not using human subjects, so it is not clear what the effect on the immune system of a human would actually be. The soup used in the research was not made using the recipe given in this diet, although it did contain some of the same ingredients.

The United States Department of Agriculture makes recommendations for how many servings of each type of food most adults need to eat each day for good health. These recommendations are given in MyPyramid, the updated version of the food guide pyramid. The chicken soup diet is extremely limited in what foods it allows dieters to eat. This makes it unlikely that dieters following this diet would get enough of all the necessary food groups. It also makes the diet likely to be especially unhealthy if followed for a long time or repeated frequently.

The chicken soup diet would probably allow most dieters to get the recommended daily allowance of vegetables. MyPyramid, recommends that healthy adults eat the equivalent of 2 to 3 cups of vegetables each day. The soup contains many different vegetables, and because it is the only food allowed after the prescribed breakfasts, it is likely that most dieters would eat enough of the soup during the day to get the recommended amount of vegetables. These vegetables would be the same ones each day, however, and because different vegetables contain different vitamins and nutrients it is generally recommended that a variety be consumed for optimum health.

MyPyramid also recommends that healthy adults eat the equivalent of 1 1/2 to 2 cups of fruit per day. Dieters following the diet strictly would not be able to get this recommended amount of fruit each day. The soup itself does not contain any fruit, and although 4 of the 5 breakfasts do contain some fruit, 1/2 cup of fruit salad or 1/2 cup of orange juice is not enough to meet the recommendations. Because the diet does not make recommendations for what can be drank while on the diet, a dieter may decide to drink fruit juice while on the diet. This would help the dieter get enough servings of fruit each day.

Dairy products are generally considered to be part of a healthy diet. The soup in the chicken soup diet does not contain any dairy, although each breakfast option does contain dairy of some kind. MyPyramid recommends the equivalent of 3 cups of low-fat or non-fat dairy per day for healthy adults. The breakfasts prescribed by the diet do not include enough dairy to meet this requirement. The diet does not tell a dieter what to drink while on the diet. If a dieter were to choose to drink skim milk while on the diet, this requirement might be met.

The chicken soup diet does not provide many sources of starches or grains. MyPyramid recommends the equivalent of 3 to 4 ounces of grains each day for healthy adults, of which at least half should be whole grains. Although 4 of the 5 breakfasts provide a serving or more of grains, it would not be enough to meet the requirements for a full day. There are no significant sources of grains or starches in the soup.

MyPyramid recommends that healthy adults eat between 5 and 6 1/2 ounces of meat or beans each day, and specifies that lean meat is preferable. The breakfasts allowed do not provide any servings of meat or beans, but the soup does contain chicken that is a healthy lean meat. Because the amount of soup allowed to be eaten is unlimited, it is likely that a person following this diet would consume enough chicken to meet this requirement. The dieter would however only be consuming one type of meat. Variety is generally considered important for a healthy diet because different meats and beans contain different vitamins and minerals.

In 2007, the Centers for Disease Control recommended that healthy adults get 30 minutes or more of light to moderate exercise each day. The chicken soup diet does not include any recommendation for exercise. Exercise is generally accepted to be an important part of any weight loss program. Studies have shown that weight loss programs are more effective when they combine diet and exercise instead of focusing on just one aspect alone.

# Childhood nutrition

## Definition

Childhood nutrition refers to the dietary needs of healthy children aged 2 years through 11 years of age. Since children younger than 2 years of age and children over the age of 11 years of age have unique nutritional requirements and concerns, the focus of this summary is primarily on healthy children aged 2 to 11 years. (Children with special health care needs and who have special dietary needs require additional guidance beyond what will be discussed and should seek the skills of a Pediatrician or a Registered Dietitian).

Proper nutrition for a healthy child aged 2-11 years of age should provide adequate essential nutrients, **fiber** and energy, sufficient enough to maintain proper growth, maximize cognitive development and promote health. It should introduce balance among the foods consumed such that foods rich in some nutrients do not displace foods that are rich in other nutrients. Balance within the diet helps to ensure adequate nutrient intake within the diet. A child's diet should provide sufficient energy intake for proper growth and development while preventing excess weight gain. To do so, foods selected should be high in nutrient density, meaning the food should have a high nutrient to calorie ratio. The diet should be moderate enough so not to deliver too much of a dietary constituent. It should also ensure variety using different foods on different occasions to ensure adequacy, balance and moderation among all nutrients needed to support the child's growth and developmental needs.

## Origins

Prior to World War II, the main nutritional problems in the United States stemmed from both a limited supply of food and lack of nutrient variety. During this time, scientists began to discover essential nutrients for basic growth and development and began the process of defining the minimum nutrients essential for growth and survival. In the United States the health status of children improved over the decades. An improvement in child nutrition was seen in lower rates of infant mortality and declines in infant, and child nutrient deficiencies.

As the food supply in the United States became more accessible and varied, nutritional concerns began to focus on an overabundance of food and specific nutrients. Around this time, research began to demonstrate links between dietary excesses and chronic diseases such as heart disease and cancers. While the number of children who were overweight increased.

These findings led to the development of dietary recommendations intended to reduce Americans' risk of chronic disease. By the late 1970s, the U.S. Senate Select Committee on Nutrition and Human Needs issued the Dietary Goals for the United States. Since then, dietary guidance for children has broadened from an earlier focus on issues of under consumption

## KEY TERMS

**Dietary deficiency**—Lack or shortage of certain vitamins or minerals within the diet that can result in illnesses.

**Healthy Eating Index (HEI)**—A measure of diet quality that assesses conformance to federal dietary guidance.

and nutrient deficiencies to over consumption and decreased energy expended in physical activity. As more research in childhood nutrition began to emerge, it placed more of a focus on optimal growth and cognitive development of children.

## Description

Public health **dietary guidelines** for childhood nutrition resonate a diet that relies on fruits, vegetables, whole grains, low-fat and nonfat dairy products, legumes, fish, and lean meats. They also emphasize low intakes of saturated **fats** cholesterol, added sugar and salt while recommending little to no trans fat intake.

## Function

Healthful eating habits in childhood have been shown to prevent chronic under-nutrition and growth retardation as well as acute child nutrition problems such as iron-deficiency anemia and dental caries. A healthful childhood diet should also help prevent **obesity** and weight-related diseases, such as diabetes.

Adequate intake of **calcium** are the first preventative measure against **osteoporosis** later in life. Calcium intake is crucial during childhood, adolescence and early adulthood to help reach peak bone mass. Failure of children to meet calcium requirements in combination with a sedentary lifestyle makes achievement of maximal skeletal growth and bone mineralization challenging. Thus, most recommendations include two to three servings a day of milk or dairy products within a children's diet.

**Iron** deficiency has negative effects on a child's motor and mental development and thus on their capacity to do school work. Foods high in iron, such as meats and fortified breakfast cereals are important to a child's diet to ensure that iron requirements are met.

Research supports that children who are overweight experience psychological stress, decreased **body image** scores, and lower self-esteem when compared to normal weight children of the same age. They are also more likely than normal-weight children to become obese adults, which can increase their risk of **coronary heart disease**, **hypertension**, type 2 diabetes, gallbladder disease, osteoarthritis, and some cancers. For this reason, many guidelines will support enough calories for growth and activity while limiting foods of low nutritional value and high in refined sugar.

High intakes of saturated fat have been associated with increased plasma total and low-density lipoprotein (LDL) cholesterol in childhood and can ultimately increase the risk of cardiovascular disease. Most recommendations will suggest fat reduced foods such as lean meats, low- or non-fat dairy products and limited high fat snacks, pastries and candies.

## Guidelines

Many children's health organizations support the guidelines of the United States Department of Agriculture, Food Guide Pyramid for children.

### *Grains*

At least half of the grains a child consumes each day should be from whole grains, such as oatmeal, or 100% whole-wheat products. The amount should increase gradually from age 2 to 5 years, at age 2 this would be too much, about one quarter to a third should be whole grains. Consuming whole grains adds dietary fiber to the diet that can help protect against diseases like heart disease and diabetes, and also help control a child's weight. Refined grains, such as those in white bread and white rice, which have been processed, and many of the nutrients have been taken out are to be used in reduced amounts.

### *Dairy*

Low-fat or non-fat dairy products are recommended In the United Kingdom, low-fat milk is not recommended for children until they reach age 2 and skim milk is not recommended until age 5. Children 2 to 8 years old are suggested to have the equivalent to 2, 8-ounces of milk per day. For children 9 to 11 years old should have the equivalent to 3, 8-ounces of milk per day.

### *Fruits*

Aim for 1–2 cups of fruits per day. Limit fruit juice consumption to meal times. Consumption of whole fruits, fresh, frozen, canned, dried, rather than fruit juice for the majority of the total daily amount is suggested to ensure adequate fiber intake.

## QUESTIONS TO ASK YOUR DOCTOR

- How can I teach my child healthy eating behaviors?
- How much should I feed my child?
- How should I handle food struggles?
- How can I get my child to try new foods?
- Is my child growing at a proper height-for-weight ratio?
- What can I do if my child does not drink milk?
- Should I give my child vitamin/mineral supplements?

#### *Vegetables*

Children should have 2–3 cups of vegetables per day. Select from dark green, orange, starchy vegetables, and other vegetables several times per week. Offer them for snacks and with meals daily.

#### *Lean protein, legumes, nuts/seeds, meat alternatives*

Recommend 2 grams of **protein** for each pound the child weighs. This can be in the form of cooked lean protein or fish, nuts, seeds, eggs or legumes and **soy** products. Children should also eat from lean protein sources and include non-fried fish into their diets on a regular basis.

### Precautions

The Healthy Eating Index (HEI) is used to assess a populations diet quality. The HEI score for children ages 2 to 9 years determined that most **children's diets** "needed improvement" or were "poor". The percentage of children's diets that were reported to "need improvement" among children 2 to 3, 4 to 6, and 7 to 9 years was 60%, 76%, and 80%, respectively; diets reported as "poor" were 4%, 7%, and 8%, respectively.

Average intakes of most **vitamins** and **minerals** for children 2 to 11 years of age exceed 100% of the 1989 RDA. Average dietary fiber intake among children ages 3 to 5 years and 6 to 11 years is 11.4 g/day and 13.1 g/day, respectively; and has remained virtually unchanged since 1976. The food choices of most US children do not meet the recommended food group servings from the Food Guide Pyramid. Children do not eat the recommended amount of fruits and vegetables. For children 2 to 9 years of age, 63% are not consuming the recommended number of servings of fruits, and 78% are not consuming the recommended number of servings for vegetables. Average daily servings are 2.0 for fruits and 2.2 for vegetables. For children 6 to 11 years of age, average daily total grain intake was 6.5 servings, whereas daily whole grain intake was 0.9 servings per day. The proportion consuming an average of two or more servings of whole grains daily was 12.7%. There is also an increase in restau! rant food consumption and other eating outside the home, larger portion sizes, shifts in beverage consumption, meal patterns and meal frequency, and school meal participation among children 2 to 11 years of age. This data shows that many children can improve their diets using the above recommendations from the USDA.

### Research and general acceptance

Numerous research articles support that healthy eating is associated with reduced risk for many diseases, including the three leading causes of death: heart disease, **cancer**, and stroke. It is common knowledge among child nutrition experts that healthy eating in childhood and adolescence is important for proper growth and development and can prevent health problems such as obesity, dental caries, and iron deficiency anemia.

# Childhood obesity

### Definition

Childhood **obesity** is the condition of being overweight or severely overweight which causes risks to health between the ages of 2 and 19.

**Risks associated with childhood obesity**

- ✓ Cardiovascular disease
- ✓ Degenerative joint disease
- ✓ Depression
- ✓ Early puberty and early start of menstruation in girls
- ✓ Eating disorders
- ✓ Exposure to social prejudice and discrimination
- ✓ Fat accumulation in the liver (fatty liver/liver disease)
- ✓ Gallbladder disease
- ✓ High cholesterol
- ✓ Hypertension
- ✓ Increased anxiety and stress
- ✓ Joint pain
- ✓ Low self-esteem
- ✓ Sleep apnea
- ✓ Type 2 diabetes mellitus

*(Illustration by GGS Information Services/Thomson Gale.)*

## KEY TERMS

**Hypothyroidism**—disorder in which the thyroid gland in the neck produces too little thyroid hormone. One of the functions of thyroid hormone is to regulate metabolic rate.

**Type 2 diabetes**—sometime called adult-onset diabetes, this disease prevents the body from properly using glucose (sugar).

## Description

Childhood obesity is of increasing concern as a public health problem in the United States. Overweight and obesity are defined by most healthcare professionals using the **Body Mass Index** (BMI). BMI is a calculation that compares a person's weight and height to arrive at a specific number. For details of how to calculate BMI see the body mass index entry.

Children between the ages of 2 and 19 are assigned a percentile based on their BMI number. The percentile tells them how their weight compares to that of other children who are their same age and gender. For example, if a boy is in the 65th percentile for his age group, 65 of every 100 children who are his age weigh less than he does and 35 of every 100 weigh more than he does. Adult BMI is interpreted differently.

The BMI weight categories for children are:

- Below the 5th percentile: Underweight
- 5th percentile to less than the 85th percentile: Healthy weight
- 85th percentile to less than the 95th percentile: At risk of overweight
- 95th percentile and above: Overweight

There is some debate about what to call children who are in the at risk for overweight and overweight categories. Some healthcare organizations such as the American Obesity Association use the term overweight for those at or above the 85th percentile and obese for those at or above the 95th percentile. The National Institutes of Health prefers to avoid applying the term obese to children, in part because of the social stigma the word carries. Whatever term is used to describe children in the top 15th percentile, these children are at risk of developing health problems because of their weight.

## Demographics

There is no doubt that American children are getting heavier, and although the problem of overweight is growing fastest in the United States, the trend toward heavier children is occurring in most in most developed countries. In the United States, the National Center for Health Statistics has tracked children's weight for several decades and recorded the following changes in the percent of children who are overweight (above the 85th percentile):

- Children ages 2–5: 1971–74 5% 1988–94 7.2% 2003–04 13.9%
- Children ages 6–11: 1971–74 4% 1988–94 11.3% 2003–04 18.8%
- Children ages 12–19: 1971–74 6.1% 1988–94 10.5% 2003–04 17.4%

In terms of numbers, this means that 12.5 million children were overweight in 2003–04. During the same time, 32.2% of adults, or 66 million people, were obese. Other surveys have found the total obesity rate among children and adolescents to be between 21% and 24%.

Significant differences exist in the number of children who are overweight in different races and ethnic groups, and these mirror the differences in the adult population. Significantly more Mexican American boys are overweight than non-Hispanic black or white boys. Significantly more Mexican American girls and non-Hispanic black girls are overweight than white girls. Native Americans and Hawaiians also have higher rates of overweight than whites.

## Causes and symptoms

At its simplest, overweight is caused by taking in more calories than the body uses. This difference is

called the "energy gap." A 2006 study done by the Harvard School of Public Health and published in the journal *Pediatrics* found that, on average, American children consumed between 110 and 165 extra calories than they use up every day. Over a 10-year period, these extra calories would add 10 lbs to their weight. However, already overweight teens took in an average of 700–1,000 extra calories every day, resulting in an average of 58 extra pounds.

### *Causes*

There are many reasons why the energy gap exists, these reasons are related to both increased food intake and decreased energy use. Food intake reasons include:

- increased consumption of sugary beverages, and along with this, a decreased consumption of milk
- tendency to super-size portions. In some fast food restaurants portions have almost tripled since the 1970s.
- more meals eaten away from home
- more use of prepared foods in the home
- increased snacking between meals along with fewer meals eaten together as a family
- heavy advertising of high-sugar, high-fat foods to children
- decrease in children carrying their lunch to school from home
- poor eating habits such as skipping breakfast and later snacking on high fat, sugary foods

Inadequate energy use reasons include:

- more time spent watching television or using the computer.
- fewer physical education requirements at school. According to the Centers for Disease Control, in 2000, only 8% of elementary schools, 6.4% of middle schools, and 5.8% of high school required daily physical education classes.
- fewer children walking to school. In 1969 half of all school children walked or biked to school. The rate was 87% for children living within 1 mile of their school. In 2003, only 15% of children walked or biked to school.
- decreased recess in grades 1–5. More than 28% of schools do not provide a regularly scheduled recess in these grades.
- fear of crime, which limits outdoor activities of children
- more affluence. Teen access to cars has increased over the past 30 years.

Other factors that affect childhood obesity include an inherited tendency toward weight gain, mental illness, **binge eating** disorder, and eating in response to stress, boredom, and loneliness, poor sleeping habits, and having at least one obese parent.

In rare cases, medical or genetic disorders can cause obesity. For example, Prader-Willi syndrome is a genetic disorder that causes an uncontrollable urge to eat. The only way to prevent a person with Prader-Willi disorder from constant eating is to keep them in an environment where they have no free access to food. Other genetic and hormonal disorders (e.g. hypothyroidism) can cause obesity. Certain medications also can cause weight gain (e.g. cortisone, tri-cyclic antidepressants), but these situations are the exception. Most children are too heavy because they eat to much and/or exercise too little.

### *Symptoms*

The most obvious symptom of obesity is an accumulation of body fat. Other symptoms involve changes in body chemistry. Some of these changes cause disease in children, while others put the child at risk for developing health problems later in life. Children who are overweight are at increased risk of:

- type 2 diabetes. This disease is appearing in children and young adults at an alarmingly high rate. In the past, it was usually seen in older adults.
- high blood pressure (hypertension)
- fat accumulation in the liver (fatty liver/liver disease)
- sleep apnea
- early puberty; early start of menstruation in girls
- eating disorders
- joint pain
- depression
- increased anxiety and stress
- low self-worth
- exposure to social prejudice and discrimination

## Diagnosis

Diagnosis is usually made on the basis of the child's BMI. To better assess the problem, the physician will take a family history and a medical history and do a complete physical examination, including standard blood and urine tests. A thyroid hormone test may be done to rule out hypothyroidism as the cause of obesity. Based on the physician's findings, other tests may be performed to rule medical causes of obesity.

## Treatment

Overweight children and their parents may be referred to a registered dietician or nutritionist who can help them develop a plan for eliminating empty calories and increasing the amount of nutrient-rich, low-calorie foods in their diets. Nutrition education usually involves the entire family. Children may be asked to keep a food diary to record everything that they eat in order to determine what changes in behavior and diet need to be made. Typically, children are encouraged to increase their level of exercise rather than to drastically reduce calories.

Drug therapy and weight-loss surgery are very rarely used in children, except in the most extreme cases of health-threatening obesity when other methods of weight control have failed. Some teenagers benefit from joining a structured weight-loss program such as **Weight Watchers** or Jenny Craig. They should check with their physician before joining.

## Nutrition/Dietetic concerns

Teaching children how to eat a healthy diet sets a framework for their lifetime eating habits. A nutritionist or dietitian can help families to understand how much and what kinds of food are appropriate for their child's age, weight, and activity level.

The American Heart Association has adapted the following dietary suggestions from the federal Dietary Guidelines for Americans 2005. These guidelines apply to people over age 2. Separate guidelines exist for **infant nutrition**.

- For children ages 2–3, no more than 35% of their calories should come from fats.
- Children over age 3 should limit their fat intake to about 30% of their total calories. These fats should be monounsaturated or polyunsaturated. Saturated fats and *trans* fats should be avoided.
- Fruit and vegetable intake should be increased, but fruit juice should be limited.
- At least half of all grains eaten should be whole grains.
- Sugary drinks, such as carbonated soft drinks, should be extremely restricted.
- Dairy products should be fat-free or low fat after age 2. Before age 2 children need milk fats for proper growth and development of the nervous system.
- A variety of foods should be offered children, including fish and shellfish.
- Overfeeding children or making them "clean their plates." should be avoided.

It is often difficult for parents to understand how much food their child should eat at a particular age. Parents tend to overestimate the amount of food small children need. The daily amounts of some common foods that meet the American Heart Association guidelines for different ages are listed below. These amounts are based on children who are sedentary or physically inactive. Active children will need more calories and slightly larger amounts of food.

- children age 2– 3 years: Total daily calories 1,000; milk 2 cups; lean meat or beans 2 ounces, fruits 1 cup; vegetables 1 cup; grains 3 ounces.
- girls ages 4–8 years: Total daily calories 1,200; milk 2 cups; lean meat or beans 3 ounces; fruits 1.5 cups; vegetables 1 cups; grains 4 ounces.
- boys ages 4–8 years: Total daily calories 1,400; milk 2 cups; lean meat or beans 4 ounces, fruits 1.5 cup; vegetables 1.5 cups; grains 5 ounces.
- girls ages 9–13 years: Total daily calories 1,600; milk 3 cups; lean meat or beans 5 ounces, fruits 1.5 cups; vegetables 2 cups; grains 5 ounces.
- boys ages 9–13 years: Total daily calories 1,800; milk 3 cups; lean meat or beans 5 ounces, fruits 1.5 cups; vegetables 2.5 cups; grains 6 ounces.
- girls ages 14–18 years: Total daily calories 1,800; milk 3 cups; lean meat or beans 5 ounces, fruits 1.5 cups; vegetables 2.5 cups; grains 6 ounces.
- boys ages 14–18 years Total daily calories 2,200; milk 3 cups; lean meat or beans 6 ounces, fruits 2 cups; vegetables 3 cups; grains 7 ounces.

## Therapy

Children who are overweight often have psychological and social problems that can be helped with psychotherapy in addition to nutritional counseling.

- Cognitive behavior therapy (CBT) is designed to confront and then change the individual's thoughts and feelings about his or her body and behaviors toward food, but it does not address why those thoughts or feelings exist. Strategies to maintain self-control may be explored. This therapy is relatively short-term.
- Family therapy may help children who eat for emotional reasons related to conflict within the family. Family therapy teaches strategies to reduce conflict, disorder, and stress that may be factors in triggering emotional eating.
- Although drugs are rarely prescribed for weight control in children, many overweigh children have depression and anxiety. Drug therapy to treat these conditions may help the child to better deal with his

or her weight and become more involved in physical activities and weight loss strategies.

## Prognosis

The younger the child is when weight control strategies begin, the better the chance that the child will be able to maintain a normal weight. When it comes to weight control, one advantage children over adults is that they grow. If a child can maintain his weight without gaining, he may grow into a normal weight as he becomes taller. Parents need to be careful about how they approach weight loss in children. Critical comments about weight from parents or excess zeal in putting their child on a rigorous diet can trigger **eating disorders** such as **anorexia nervosa** or **bulimia nervosa** in some children, especially adolescent girls.

Children who remain overweight have a much greater likelihood of being overweight adults with all the health problems that obesity brings. Studies have found that 26–41% of preschoolers who are obese become obese adults. In school-aged children, 42–63% of children with obesity become obese adults. The greater the degree of overweight, the higher the likelihood that overweight will continue into adulthood.

## Prevention

Parents must take the lead in preventing obesity in children. Some of the ways they can do this are:

- Serve a healthy variety of foods; keep healthy snacks on hand.
- Choose low-fat cooking methods such as broiling or baking
- Eliminate junk snack food and sugary beverages from the house. This removes temptation and eliminates the need to nag.
- Eat meals together as a family rather than grabbing something quick on the run.
- Limit visits to fast-food restaurants.
- Limit television and computer time.
- Plan family activities that involve physical activity, such as hiking, biking, or swimming.
- Encourage children to become more active in small ways such as walking to school, biking to friends' houses, or doing chores such as waking the dog or mowing the lawn.
- Avoid using food as a reward.
- Pack healthy homemade lunches on school days.
- Encourage school officials to eliminate soda machines on campus, bake sales, and fundraising with candy and cookies.
- Set realistic goals for weight control and reward children's efforts.
- Model the eating behaviors and active lifestyle you would like your child adopt.

# Children's diets

## Definition

Because children grow at different rates and at different times, it becomes harder to distinguish if a child is overweight compared to establishing overweight in adults. To determine if a child is within an un-healthy weight range, a doctor will use certain criteria to measure a child's height and weight. The **body mass index** (BMI), expressed as body weight in kilograms divided by the square of height in meters (kg/m2), is a weight-for-height index. The BMI is the standard **obesity** assessment in adults, and its use within the pediatric population has limited research to support its effectiveness is still considered the standard measure of overweight in children. The International Task Force on Obesity approved that BMI provides a reasonable index of adiposity and provides a reliable measure across pediatric age groups.

**Healthy snack foods for children**

- Applesauce cups (unsweetened)
- Apples or pears and low-fat cheese
- Baby carrots and celery
- Bagels pizzas with tomato sauce and melted low-fat cheese
- Baked potato chips or tortilla chips with salsa
- Cereal, dry or with low-fat milk
- Cucumber or zucchini slices
- Dried fruits such as raisins, apple rings, or apricots
- Fresh fruit
- Fruit canned in juice or light syrup
- Fruit juice
- Fruit salad
- Frozen fruit bars
- Frozen grapes
- Low-fat chocolate milk
- Low-fat frozen yogurt with fresh berries
- Low-fat yogurt with fruit
- Nonfat cottage cheese with fruit
- Popcorn, air popped or low-fat microwave
- Pretzels (lightly salted or unsalted) and a glass of low-fat milk
- Raw vegetable sticks with low-fat yogurt dip, cottage cheese or hummus
- Rice cakes with peanut butter
- Smoothies with low-fat milk or yogurt and sliced bananas or strawberries
- String cheese and fruit (canned or fresh)
- Vanilla wafers, gingersnaps, graham crackers, animal crackers or fig bars and a glass of milk
- Whole-grain crackers or English muffin with peanut butter
- Whole-wheat crackers with cheese or peanut butter

*(Illustrated by GGS Information Services/Thomson Gale.)*

A children's BMI score is the criteria used by medical professionals to determine an un-healthy weight. Any child who's BMI falls between the 85th and 95th percentile for age and sex should be evaluated for secondary complications of obesity, including **hypertension** and dyslipidemias. An extensive change in BMI would also call for evaluation and possible treatment of the child. Although the degree of change that indicates risk has not been defined, an annual increase of three to four BMI units is thought to reflect concern due to possible increases in a child's body fat.

## Origins for childhood diets

In the United States and elsewhere in developed countries, the prevalence of **childhood obesity** has drastically risen in the past several decades.

Since the 1960s, the prevalence of obesity in children has been assessed by several nationally representative surveys. These include the National Health Examination Survey Cycles I to III and the National Health and Nutrition Examination Surveys I to III. Based on these surveys, the obesity among children is

## KEY TERMS

**Obesity**—Having a body mass index (BMI) at or above the sex- and age-specific 95th percentile of the 2000 Centers for Disease Control and Prevention BMI cutoff points. Obesity having too much body fat.

**Overweight**—When a person's weight is greater than what is considered healthy for his or her height.

**Body mass index (BMI)**—Expressed as body weight in kilograms divided by the square of height in meters (kg/m2), is a weight-for-height index.

**Idiopathic**—Used to describe a disease or disorder that has no known cause.

**Endogenous**—With no apparent external cause, originating within the organism or tissue.

**Behavior therapy**—A non-biological form of therapy that developed largely out of learning theory research and is normally applied to the treatment of specific maladaptive behavior patterns.

estimated to be 25–30%. Furthermore, they estimated the proliferation of obesity has increased by 54% in children six to 11 years of age and by 39% in adolescents 12 to 17 years of age. Morbid obesity jumped 98% and 64% within these groups, respectively. Hispanic, Native American and black children tend to have higher rates in relation to other populations.

Because of these statistics, weight loss diets for children have surfaced. Although weight loss in children is a hot debate in the medical field, there are times when a child's weight should be evaluated and possibly treated by medical professionals who specialize in weight loss for children.

### Complications

Childhood obesity can cause complications in many organ systems. These obesity-related medical conditions include cardiovascular disease; type 2 **diabetes mellitus**, and degenerative joint disease.

Orthopedic complications include slipped capital femoral epiphysis that occurs during the adolescent growth spurt and is most frequent in obese children. The slippage causes a limp and/or hip, thigh and knee pain in children and can result in considerable disability.

Blount's disease (tibia vara) is a growth disorder of the tibia (shin bone) that causes the lower leg to angle inward, resembling a bowleg. The cause is unknown but is associated with obesity. It is thought to be related to weight-related effects on the growth plate. The inner part of the tibia, just below the knee, fails to develop normally, causing angulation of the bone.

Overweight children with hypertension may experience blurred margins of the optic disks that may indicate pseudotumor cerebri, this creates severe headaches and may lead to loss of visual fields or visual acuity.

Research shows that 25 out of 100 overweight, inactive children tested positive for sleep-disordered breathing. The long-term consequences of sleep-disordered breathing on children are unknown. As in adults, obstructive sleep apnea can cause a lot of complications, including poor growth, headaches, high blood pressure and other heart and lung problems and they are also potentially fatal disorders.

Abdominal pain or tenderness may reflect gall bladder disease, for which obesity is a risk factor in adults, although the risk in obese children may be much lower. Children who are overweight have a higher risk for developing gallbladder disease and **gallstones** because they may produce more cholesterol, a risk factor for gallstones. Or due to being overweight, they may have an enlarged gallbladder, which may not work properly.

Endocrinologic disorders related to obesity include noninsulin-dependent diabetes mellitus (NIDDM), an increasingly common condition in children that once used to be extremely rare. The link between obesity and insulin resistance is well documented and which is a major contributor to cardiovascular disease.

Hypertension (high blood pressure), and dyslipidemias (high blood lipids), conditions that add to the long-term cardiovascular risks conferred by obesity are common in obese children.

Childhood obesity also threatens the psychosocial development of children. In a society that places such a high premium on thinness, obese children often become targets of early and systematic discrimination that can seriously hinder healthy development of **body image** and self-esteem, thus leading to depression and possibly suicide.

In all of these examples, it is recommended that the primary clinician should consult a pediatric obesity specialist about an appropriate weight-loss or weight maintenance program.

## Causes of Obesity

Only a small percentage of childhood obesity is associated with a hormonal or genetic defect, with the remainder being environmental in nature due to lifestyle and dietary factors. Although rarely encountered, hypothyroidism is the most common endogenous abnormality in obese children and seldom causes massive weight gain.

Of the diagnosed cases of childhood obesity, roughly 90% of the cases are considered environmental in nature and about 10% are endogenous in nature.

## Goals of therapy

The Division of Pediatric Gastroenterology and Nutrition, New England Medical Center, Boston, Massachusetts as well as many child organizations agree that the primary goal of a weight loss program for children to manage uncomplicated obesity is healthy eating and activity, not achievement of ideal body weight. Any program designed for the overweight or obese child should emphasize behavior modification skills necessary to change behavior and to maintain those changes.

For children with a secondary complication of obesity, improvement or resolution of the complication is an important medical goal. Abnormal blood pressure or lipid profile may improve with weight control, and will reinforce to the child and their parents/caregivers that weight control leads to improvement in health even if the child does not approach ideal body weight.

## Weight goals

In review of much research, expert advice is that most children who are overweight should not be placed on a weight loss diet solely intended to lose weight. Instead they should be encouraged to maintain current weight, and gradually "grow into" their weight, as they get taller. Furthermore, children should never be put on a weight-loss diet without medical advice as this can affect their growth as well as mental and physical health. In view of current research, prolonged weight maintenance, done through a gradual growth in height results in a decline in BMI and is a satisfactory goal for many overweight and obese children. The experience of clinical trials suggests that a child can achieve this goal through modest changes in diet and activity level.

For most children, prolonged weight maintenance is an appropriate goal in the absence of any secondary complication of obesity, such as mild hypertension or dyslipidemia. However, children with secondary complications of obesity may benefit from weight loss if their BMI is at the 95th percentile or higher. For children older than 7 years, prolonged weight maintenance is an appropriate goal if their BMI is between the 85th and 95th percentile and if they have no secondary complications of obesity. However, weight loss for children in this age group with a BMI between the 85th and 95th percentile who have a nonacute secondary complication of obesity and for children in this age group with a BMI at the 95th percentile or above is recommended by some organizations.

When weight loss goals are set by a medical professional, they should be obtainable and should allow for normal growth. Goals should initially be small; one-quarter of a pound to two pounds per week. An appropriate weight goal for all obese children is a BMI below the 85th percentile, although such a goal should be secondary to the primary goal of weight maintenance via healthy eating and increases in activity.

Components of a Successful Weight Loss Plan Many studies have demonstrated a familial correlation of risk factors for obesity. For this reason, it is important to involve the entire family when treating obesity in children. It has been demonstrated that the long-term effectiveness of a weight control program is significantly improved when the intervention is directed at the parents as well as the child. Below describes beneficial components that should be incorporated into a weight maintenance or weight loss effort for overweight or obese children.

- Attainable and safe weight-loss; a rate of 1 to 4 lb per month.
- Dietary management goals should be provided; specify total number of calories allotted per day, broken down into percentage of calories from fat, protein and carbohydrates.
- Physical activity recommended should match the child's fitness and mobility level, with an ultimate goal of 20 to 30 minutes per day of structured movement.
- Behavior modification techniques should be incorporated; self-monitoring tools, nutritional education, identification and modification of stimulus controls, family role modeling, positive reinforcements and non-food rewards.
- Encourages and supports family involvement; family involved in individual or class session, encouraged to attain healthier eating patterns and lead an active lifestyle.

## QUESTIONS TO ASK YOUR DOCTOR

- Will my child just grow out of his/her weight?
- How do you know if my child's weight may be negatively affecting his or her health?

### Complications of Weight-Management Programs

Adverse effects of childhood weight loss may include gall bladder disease, which can occur in adolescents who lose weight rapidly. Another concern is inadequate nutrient intake of essential or non-essential nutrients. Linear growth may slow during weight loss. However, impact on adult stature appears to be minimal. Loss of lean body mass may occur during weight loss. The effects of rapid weight loss (more than 1 pound per month) in children younger than 7 years are unknown and are thus not recommended.

There is a clear association between obesity and low self-esteem in adolescents. This relation brings other concerns that include the psychological or emotional harm a weight loss program may infer on a child. **Eating disorders** may arise, although a supportive, nonjudgmental approach to therapy and attention to the child's emotional state minimize this risk. A child or parent's preoccupation with the child's weight may damage the child's self-esteem. If weight, diet, and activity become areas of conflict, the relationship between the parent and child may deteriorate.

### Preventing Obesity: Tips for Parents/caregivers

- Respect a child's appetite: children know when they are full and do not need to finish every bottle or meal.
- Prepare and supply fresh, non-processed foods often. Avoid sugared foods when possible.
- Limit the amount of high-calorie foods kept in the home. Do not supply sodas; sugar flavored drinks, candy, cakes, cookies in the home.
- Provide low fat foods such as, lean proteins, and low- or non-fat dairy products and choose lower fat options for foods when available. Skim milk may safely replace whole milk at 2 years of age.
- Choose high fiber foods by selecting whole grains, legumes and fresh fruit and vegetables.
- Do not provide food for comfort or as a reward, instead use positive reinforcement.
- Do not "force" a child to eat their meal in order to get dessert.
- Limit amount of sedentary activities such as television viewing, computer time, and video games to two hours or less per day.
- Encourage active play by offering the support needed for the child to be active.
- Establish regular family activities such as daily walks, and other outdoor or indoor activities.

### Treatments

Once the need for obesity treatment has been identified, a medical professional may suggest one or more options. Consultation with a dietitian / nutritionist that specializes in children's needs is often a valuable part of obesity treatment.

#### *Behavior Therapy*

Behavior therapy involves changes in diet and physical activity habits that promote weight maintenance or loss. Some behavioral therapy strategies for children and adolescents should include parent and family involvement. And should be supervised by a medical professional.

**DRUG TREATMENT.** The U.S. Food and Drug Administration has not yet approved the use of any drugs to treat obesity in children. However, clinical trials are under way.

**SURGERY.** Surgical procedures such as gastric bypass have been performed successfully on adolescents. However surgery for adolescents is usually considered only when severe medical conditions are present that can improve with the surgery and other treatment options have failed.

# Chocolate diet

## Definition

The Chocolate diet is a weight-loss plan that includes the daily consumption of limited amounts of chocolate. The phrase "chocolate diet" also signifies the consumption of chocolate because of claims of health benefits such as lowering cholesterol.

## Origins

Chocolate originated during the Classic Period Maya (250–900) in Mesoamerica, an area that encompassed the Tropic Cancer in Mexico, Guatemala, Belize, El Salvador, and parts of Honduras, Nicaragua, and Costa Rica. The Maya and their ancestors developed a method of converting the beans from the *Theobroma cacao* tree into a chocolate beverage. This process started with the harvesting, fermenting, and roasting of the beans. The beans were then ground a paste and mixed with ingredients including **water**, chile peppers, and corn meal.

The Maya and the Aztecs in the15th century used the bitter-tasting beverage in religious and royal ceremonies. Those were just some uses for the products of the cacao tree. Christopher Columbus saw that the Aztecs used cacao beans as currency. He took some cacao beans back to Queen Isabella and King Ferdinand. Later explorers brought back the knowledge about how to convert the beans into a beverage. The Spanish added spices like cinnamon and sugar to the beverage to make it sweeter. The new beverage remained Spain's secret for a century.

Then other Europeans found out about the chocolate drink. It was an expensive indulgence, only affordable to the upper classes. That changed with the Industrial Revolution of the 1800s. Mass production brought down the cost of manufacturing treats including solid chocolate. Another milestone occurred in 1875 when Daniel Peter and Henri Nestle; created milk chocolate by adding condensed milk to chocolate.

### *Composition of chocolate*

Cocoa beans contain approximately 50% fat, and one ounce (28.3 grams) of chocolate contains approximately 150 calories and 8.5 grams of fat. While the calorie and fat gram count could produce a weight gain, the **fats** in chocolate won't raise cholesterol levels. The cocoa butter in chocolate contains oleic acid, which is a monounsaturated fat. That means that it is low in saturated fat, which is connected to cholesterol levels. Chocolate also contains forms of saturated fat known as stearic and palmitic acids. Saturated fats are connected to increases in LDL (Low-Density Lipoprotein). Also known as bad cholesterol, increased LDL cholesterol can clog arteries, raising the risk for heart disease. Palmitic acid, which affects cholesterol levels, forms one-third of the fat calories in chocolate. The stearic acid appeared to have no effect on cholesterol levels.

Chocolate also contains **caffeine** and theobromine, a chemical similar to caffeine. There's also some phenylethylamine, a chemical that creates the sensation people feel when they're in love.

Cacao beans also contain flavanoids, a broad category of plant products that act as **antioxidants**. Flavanoids relax blood vessels, allowing blood to circulate. Antioxidants are thought to be effective in helping to prevent cancer, heart disease, and strokes. Sources of flavonoids include citrus fruits, onions, **green tea**, red wine, and dark chocolate with a cocoa content of 70% or higher. Chocolate belongs to a subgroup of flavonoids called flavonols.

The presence of plant chemicals like flavonoids is related the color of the chocolate. There are more flavonoids in darker chocolate than there are in milk chocolate. Dark chocolate is also known as semisweet or bittersweet chocolate because it contains little or no sugar. It is frequently identified by the percentage of cocoa. The cocoa content in dark chocolate ranges from 30% for sweet dark chocolate to 70% or sometimes above 80%. A higher percentage indicates there is more of a bitter after-taste.

Milk chocolate contains fewer flavonoids than dark chocolate and tastes sweeter. American chocolate contains milk; European varieties often contain condensed milk.

White chocolate lacks flavanoids because there are no cocoa solids in it. It is considered a chocolate because cocoa butter is usually an ingredient. Some white chocolate is made with vegetable fats.

## KEY TERMS

**Body Mass Index**—2Also known as BMI, the index determines whether a person is at a healthy weight, underweight, overweight, or obese. The BMI can be calculated by converting the person's height into inches. That amount is multiplied by itself and then divided by the person's weight. That number is then multiplied by 703. The metric formula for the BMI is the weight in kilograms divided by the square of height in meters.

**Calorie**—The nutritional term for a kilocalorie, the unit of energy needed to raise the temperature of one liter of water by one degree centigrade at sea level. A nutritional calorie equals 1,000 calories.

**Carbohydrate**—A nutrient that the body uses as an energy source. A carbohydrate provide 4 calories of energy per gram.

**Cholesterol**—A fatty substance found each cell of the human body and in animal foods.

**Fat**—A nutrient that the body uses as an energy source. Fats produce 9 calories per gram.

**Fiber**—A complex carbohydrate not digested by the human body. Plants are the source of fiber.

**Low-Density Lipoprotein**—Also known as LDL, the type of cholesterol that may cause clog arteries. A high LDL level increases the risk for heart disease.

**Obese**—A person with a high amount of body fat; someone with a Body Mass Index of 30 or higher.

**Overweight**—A person is too heavy for his or her height; someone with a Body Mass Index of from 25 to 30.

**Protein**—A nutrient that the body uses as an energy source. Proteins produce 4 calories per gram.

### *Food of the gods*

The cacao tree's name, *Theobroma cacao*, translates to " Food of the gods." Humans found numerous medical uses for that food throughout the years. The Maya and Aztecs used it to treat conditions including seizures, fevers, and skin infections. During the 17th century, people used chocolate as a sleep aid, blood purifier, and a pain reliever during childbirth. Some people believed that chocolate helped them live longer.

People realized that chocolate gave them energy. They knew it could be fattening, but excess weight was a sign of prosperity in the 19th century. A thin figure meant that a person wasn't well-off financially, and chocolate was sold as a weight-gain powder. Standards changed during the early decades of the 20th century, when the ideal image was a thin figure. Chocolate became known as a forbidden food for dieters. The role of chocolate in diets started to change during the 1990s.

### *Chocolate health plans*

During the 1990s and in subsequent years, researchers began investigating the health benefits of chocolate. In unrelated actions, several books promoted weight-loss plans that involved chocolate.

**THE PASTA-POPCORN-CHOCOLATE DIET.** A diet detailed on some websites in the spring of 2007 was attributed to Lenny Neimark, a film maker and screenwriter. Neimark wrote *The Pasta-Popcorn-Chocolate Diet*, a 32-page book published in 1999 by Soul Proprietor. It was out-of-print in April of 2007 when Amazon.com carried a link to a bookseller offering one copy of it for $.192.01. According to online information, Neimark based his book on "his unique and humorous perspective of human nature, drama, and people's desire to look, feel, and be thin, scientific facts," and the case histories of overweight patients. The histories were provided by his brother, a doctor with a family medicine practice in California.

The book's title described three foods allowed on a diet, according to descriptions on websites including idiet4u.com. Also on the weight-loss plan were fruits, vegetables, and 1 ounce (28.3 grams)of chocolate each day. Chapter titles included "Thinking Thin" "The Science and Mathematics of Losing Weight," and & "How to Maintain Results."

**THE CHOCOLATE DIET.** Sally Ann Voak's *The Chocolate Diet* is a 235-page book published in 2001. Voak, a British journalist, was then the *The Sun* newspaper's slimming editor. Her writing credits include *The Fatfield Diet,* a book about a weight-loss plan that she created for the British village of Fatfield. Residents were challenged to follow the healthy weight-loss plan. Their progress was tracked on "Bazaar " a popular BBC daytime program.

Voak targeted *The Chocolate Diet* at chocoholics, people who have trouble resisting chocolate. Her book included six diets and the promise that people could eat chocolate and lose weight. Although the paperback book is out of print, copies were available through Amazon.com in the spring of 2007.

## Description

The once forbidden food for dieters was incorporated into some weight-loss plans by the end of the 20th Century. Furthermore, people concerned about health issues like high cholesterol could turn to chocolate as a potential preventive measure.

### *The Pasta-Popcorn-Chocolate Diet*

Details about Neimark's diet on the Internet were limited to what foods were allowed and what were excluded. There was no information about how long the diet lasted or how much weight a dieter could expect to lose. There were limited recommendations for serving sizes. The specified portions included 1 ounce (28.3 grams) of chocolate. This is the equivalent of one baking chocolate square.

The online versions of the diet showed a menu plan for one day, with several meal selections for the dieter to choose from. Other variety in the diet came from choosing different fruits, vegetables, and low-fat pasta sauces. Popcorn could be topped with nonfat butter substitutes or a bit of parmesan cheese. Salt was not permitted.

The diet of three meals and three snacks consists of:

- Breakfast of fresh fruit, fruit salad, or shredded wheat with non-fat milk and strawberries.
- A morning snack of air-popped popcorn or fruit.
- Lunch of salad, pasta salad, or spaghetti. Pasta sauces should be meatless, low fat, and low sodium. Low-calorie salad dressing is allowed
- An afternoon snack of popcorn or a fruit smoothie made with 1 cup (236.6 milliliters) non-fat skim milk.
- Dinner of fettuccini with garlic tomato sauce, whole-wheat pasta primavera salad, or steamed vegetables.
- Evening snack of popcorn or 1 ounce (28.3 grams) of chocolate.

The dieter should drink 2 quarts (2 liters) of water but could not consume

- Coffee or other caffeinated beverages or carbonated soft drinks.
- Sugars, raisins and dates because of the high sugar content, and snack foods like cakes and pie.
- Oils, fried foods, and oily foods like avocados, olives, and coconut.
- Oils, fried foods, and oily foods like avocados, olives, and coconut.
- Red meats and dairy products.
- Nuts, seeds, and snack foods like chips.

### *Sally Ann Voak's chocolate diets*

The front cover of *The Chocolate Diet* promised that the reader could eat chocolate and lose seven pounds in two weeks. Voak's book contains quizzes to determine whether a person is a chocoholic and which of the six diets a person should follow. Each weight loss plan includes selections that fit within the calorie count for meals, strategies for a person to follow, and recommendations for exercises and other activities. The book also includes recipes and a calorie guide for chocolate candies that fit within the diet plan. British and American brands of chocolate are listed.

Each of the diets starts with a week of withdrawal from chocolate. During this time, Voak wrote, people start to control their **cravings** for chocolate. All weight-loss plans include unlimited amounts of vegetables from a list of 28 low-calorie selections. The free vegetables include asparagus, broccoli, mushrooms, red and green peppers, spinach, tomatoes, and watercress. The six diets include items from all of the food groups. The diets were designed for women; men consume 300 more calories each day.

Voak's diet plans are for:

- Secret Bingers, people who hide chocolate and don't want others to know they eat it. The plan consists of a 250-calorie breakfast, two light meals of 350 calories each, a 400-calore main meal, and a 100-calorie treat. In the second week and in following weeks, there is a daily chocolate allowance of 150 calories. Dieters may also have a 200-calorie dessert or beverage, with choices selected from recipes in the book.
- Romantics are often single and use chocolate as a substitute for love. Their menu plan is a 250-calorie breakfast, 350-calorie light meal, 400-calore main meal, and a 100-calorie treat. After the second week, they may spend 300 calories on a chocolate treat three times a week.
- Comfort eaters consume chocolate when tired or faced with a problem. Their plan consists of a 250-calorie breakfast, 350-calorie light meal, 400-calore main meal, and two 50-calorie treats. In the second week, there is a daily chocolate allowance of 200 calories. In following weeks, the allowance is 50 calories.
- Weekend Indulgers associate chocolate with celebrations. Their daily calorie allowance is 1,350 during the week and 1,600 on the weekend. The menu plan is a 250-calorie breakfast, 350-calorie light meal, 400-calore main meal, and two 100-calorie treats. After the second week, 300 calories in chocolate is allowed on each weekend day.

- Sugar addicts often get most of their calories from carbohydrates and may use chocolate as a fix when tired. Their plan consists of a 250-calorie breakfast, two light meals of 250 calories each, a 400-calore main meal, and a 100-calorie treat. In the second week and in following weeks, there is a daily chocolate allowance of 200 calories.
- Premenstrual cravers overindulge in chocolate during some days of the month. Their plan is followed as needed one to two weeks before or during a menstrual period. The diet consists of a five 250-calorie meals and a 100-calorie treat. In the second week, and in following weeks, the daily chocolate allowance is 100 calories.

### *CocoaVia plan*

Consumers are advised to eat two CocoaVia Heart Healthy Chocolate Snacks bars each day to achieve health benefits. The chocolate should be consumed as part of a lifestyle that includes a healthy diet and exercise. Mars' line of CocoaVia products included dark chocolate bars, milk chocolate candy, and the Rich Chocolate Indulgence beverage, as of the spring of 2007. Calorie amounts and fat content varied by product.

According to the nutritional label, the 22-gram (0.78-ounce) Original Chocolate bar contained 100 milligram of cocoa flavanols and 1.1 gram of natural plant extract (sterol). Each bar had 100 calories with 60 calories from fat. There were 6 grams of total fat, 3.5 grams of saturated fat, 2 grams of **fiber**, 9 grams of sugars, 12 grams of **carbohydrates**, and 1 gram of **protein**.

A 5.65-ounce (.167-liter) bottle of the chocolate beverage contained 100 milligram of flavanols, 150 calories, 25 fat calories, 3 fat grams, 1 gram of saturated fat, 3 grams of fibers, and 6 grams of protein.

## Function

Neiman and Voak's diets are used to satisfy dieters' cravings by allowing limited amounts of chocolate. The dark chocolate plan also permits limited amounts of chocolate because consuming it may provide health benefits.

For people trying to lose weight, the Pasta-Popcorn-Chocolate Diet's chocolate restriction and the emphasis on complex carbohydrates should produce a weight loss. Complex carbohydrates come from plants. They are low in calories and provide fiber in the diet. The carbohydrates take longer to digest, so a person experiences a sense of fullness for a longer time. As a result, the person eats less.

Voaks' Chocolate Diet plans are designed for dieters to break their addictions to chocolate and then learn to eat it in moderation. People undergo this behavior change while following one of six nutritionally balanced low-calorie diets. The unlimited allowance of vegetables permits dieters to fill up on complex carbohydrates. The plans call for physical exercise and feature strategies to help dieters cope with issues that could lead to eating too much chocolate.

People eat CocoaVia snacks because of research indicating that regular consumption of the products could benefit cardiovascular health and cholesterol levels. Flavanols in the snacks may improve the flexibility of blood vessels, resulting in healthy blood circulation. According to Mars, clinical research shows that the regular consumption of plant sterols can reduce LDL and total cholesterol levels in the normal range for most people.

## Benefits

People who enjoy pasta, popcorn, and chocolate will be able to eat those foods on Neimark's diet. They should lose weight on the pasta-popcorn-chocolate diet because it is a low-calorie, **high-fiber diet**. Popcorn is a whole-grain food, a food type recommended by organizations including the American Heart Association and the United States Department of Agriculture. Three cups (680.3 grams) of popcorn is equal to 1 ounce (28.3 grams) of whole grains. One cup (226.8 grams) of air-popped popcorn is 30 calories and contains 1.2 grams of fiber. Whole-grain pastas would also be beneficial in a healthy diet, according to organizations including the USDA.

Voak's book could be used for a self-directed weight loss program. It features recommendations for meals and recipes to help dieter lose weight while learning healthy eating habits. Dieters also incorporate exercise into their schedules as well as moderate amounts of chocolate. There are instructions for a yoga-type exercise program and tips for using massage and mediation to handle emotions that dieters formerly may have soothed with chocolate.

Furthermore, regular consumption of flavonol-rich dark chocolate may lower blood pressure and lessen the risk of heart disease.

## Precautions

People who are allergic to chocolate should not prescribe to regimens that involve eating it. People with other conditions such as elevated LDL or total cholesterol levels should consult their physicians before beginning a diet or health regimen involving

## QUESTIONS TO ASK YOUR DOCTOR

- How much weight should I lose?
- Should I have my cholesterol tested?
- Would any health condition prevent me from starting a diet or exercise program?
- Would any health condition prevent me from starting a diet or exercise program?
- Would you recommend the pasta-popcorn-chocolate diet?
- Are any of Sally Ann Voak's diets consistent with a healthy weight-loss plan??
- Will I still lose weight if I eat chocolate?
- Is there a health benefit to eating dark chocolate every day?
- Will eating chocolate affect medication including drugs for managing cholesterol?
- What is the best type of exercise for me?
- How long should I do this exercise?
- How many times a week should I exercise?
- Are there any instructions I need to prevent injuries?

the daily consumption of chocolate. It may be necessary to have their cholesterol tested. Overweight or obese people should ask their health professionals whether it is wise to include chocolate in their diets.

In addition, the Pasta-Popcorn-Chocolate Diet is not nutritionally balanced because it limits dairy products and proteins. All food groups are included in Voak's plans. However, some diets are less than 1,200 calories per day. That's the medically recognized minimum calorie allowance for people not following a medically supervised diet.

# Choline

## Definition

Choline is a nutrient required by the body. It does not meet the classic definition of a vitamin because the body makes some choline, but not enough to support health. The remainder must be acquired through diet. For practical purposes, choline is grouped with the B-complex **vitamins** because it is a water-soluble compound that performs some functions similar to these vitamins.

## Purpose

Choline has several functions in the body. It is incorporated into the fat (lipid)-containing structures in cell membranes, and is necessary for the formation of certain signaling chemicals made by cells to activate other molecules. Choline is also necessary for the formation of acetylcholine. Acetylcholine is a neurotransmitter that transfers information from nerves to muscles. Acetylcholine is also thought to be important to memory and learning in the brain. Finally, choline, like several other B vitamins, is active in the metabolic pathway that breaks down homocysteine and removes it from the body. Homocysteine is an amino acid that circulates in the blood. When too much homocysteine

**Choline**

| Age | Adequate Intake (mg) | Tolerable upper intake level (mg) |
|---|---|---|
| Children 0–6 mos. | 125 | Not established |
| Children 7–12 mos. | 150 | Not established |
| Children 1–3 yrs. | 200 | 1,000 |
| Children 4–8 yrs. | 250 | 1,000 |
| Children 9–13 yrs. | 375 | 2,000 |
| Boys 14–18 yrs. | 550 | 3,000 |
| Girls 14–18 yrs. | 400 | 3,000 |
| Men 19≥ yrs. | 550 | 3,500 |
| Women 19≥ yrs. | 425 | 3,500 |
| Pregnant women | 450 | 3,500 |
| Breastfeeding women | 550 | 3,500 |

| Food | Choline (mg) |
|---|---|
| Beef liver, fried, 3 oz. | 355 |
| Wheat germ, toasted, 1 cup | 172 |
| Egg, 1 large | 126 |
| Cod, cooked, 3 oz. | 71 |
| Brussels sprouts, cooked, 2 cups | 63 |
| Broccoli, cooked, 1 cup | 62 |
| Peanut butter, 2 tbsp. | 20 |
| Milk chocolate, 1.5 oz. | 20 |

mg = milligram

*(Illustration by GGS Information Services/Thomson Gale.)*

builds up, it appears to damage blood vessel walls and promote clot formation in blood vessels.

Well-designed, reproducible research has shown that people who have high levels of homocysteine in the blood are more likely to develop cardiovascular diseases such as coronary artery disease and stroke. Clinical trials are underway to investigate the effects of choline oh Alzeheimer's disease, heart disease, and fetal exposure to alcohol.

## KEY TERMS

**Amino acid**—Molecules that are the basic building blocks of proteins.

**B-complex vitamins**—A group of water-soluble vitamins that often work together in the body. These include thiamine ($B_1$), riboflavin ($B_2$), niacin ($B_3$), pantothenic acid ($B_5$), pyridoxine ($B_6$), biotin ($B_7$ or vitamin H), folate/folic acid ($B_9$), and cobalamin ($B_{12}$).

**Dietary fiber**—Also known as roughage or bulk. Insoluble fiber moves through the digestive system almost undigested and gives bulk to stools. Soluble fiber dissolves in water and helps keep stools soft.

**Fatty liver**—A condition in which liver cells accumulate fat. The condition is associated with alcohol abuse, obesity, and pregnancy and can result in serious damage to the liver.

**Neurotransmitter**—One of a group of chemicals secreted by a nerve cell (neuron) to carry a chemical message to another nerve cell, often as a way of transmitting a nerve impulse. Examples of neurotransmitters include acetylcholine, dopamine, serotonin, and norepinephrine.

**Triglycerides**—A type of fat found in the blood. High levels of triglycerides can increase the risk of coronary artery disease.

**Water-soluble vitamin**—A vitamin that dissolves in water and can be removed from the body in urine.

## Description

Choline has not been the subject of as much research as many of the other micronutrients. Not until 1998 did the Food and Nutrition Board of the United States Institute of Medicine (IOM), a part of the National Academy of Sciences, declare choline to be an essential nutrient and establish **dietary guidelines** for it.

### *Normal choline requirements*

The IOM has developed values called **Dietary Reference Intakes** (DRIs) for many vitamins, **minerals**, and essential micronutrients. The DRIs consist of three sets of numbers. The Recommended Dietary Allowance (RDA) defines the average daily amount of the nutrient needed to meet the health needs of 97–98% of the population. The Adequate Intake (AI) is an estimate set when there is not enough information to determine an RDA. The Tolerable Upper Intake Level (UL) is the average maximum amount that can be taken daily without risking negative side effects. The DRIs are calculated for children, adult men, adult women, pregnant women, and **breastfeeding** women.

The IOM has not set RDAs for choline because of the scarcity of large, long-term dietary studies on this micronutrient. Instead it has set AI levels for all age groups based on the best observed and experimental information available. For choline, the AI level was established as the average daily amount needed to prevent the development of a condition called fatty liver. It may not be the amount needed for optimal health. IAs and ULs for choline are measured in

milligrams (mg). The following list gives the recommended AL and UL levels of choline for each age group.

- children birth–6 months: AI 125 mg; UL not established. All choline should come from breast milk and infant formula or infant food.
- children 7–12 months: AI 150 mg; UL not established. All choline should come from food, not dietary supplements.
- children 1–3 years: AI 200 mg; UL 1,000 mg
- children 4–8 years: AI 250 mg; UL 1,000 mg
- children 9–13 years: RDA 375 mg; UL 2,000 mg
- boys 14–18 years: IA 550 mg; UL 3,000 mg
- girls 14–18 years: IA 400 mg; UL 3,000 mg
- adult men age 19 and older: RDA 550 mg; UL 3,500 mg
- adult women age 19 and older: RDA 425 mg; UL 3,500 mg
- pregnant women all ages: RDA 450 mg; UL 3,500 mg
- breastfeeding women all ages: RDA 550 mg; UL 3,500 mg

### *Sources of choline*

Research suggests that the body makes only between 10% and 20% of the choline it needs to maintain health. The rest comes from diet. Foods rich in choline include beef liver, egg yolks, peanuts, and soybeans. Most choline in foods is in the form of phosphatidylcholine, which is also known as lecithin. Much less information is available about the choline content of specific foods than is available for other nutrients. Most people can meet the AI levels of choline through their normal diet. Some foods that have been analyzed for choline are listed below.

- beef liver, 3 ounces fried: 355 mg
- wheat germ, 1 cup toasted: 172 mg
- egg, 1 large: 126 mg (choline is concentrated in the yolk)
- cod, 3 ounces cooked: 71 mg
- Brussels sprouts, 2 cup cooked: 63 mg
- broccoli, 1 cup cooked: 62 mg
- peanut butter, 2 Tablespoons: 20 mg
- milk chocolate, 1.5 ounces: 20 mg

Choline chloride and choline bitartrate are also sold as a **dietary supplements**. Choline is also found in dietary supplements marketed as lecithin. Soybeans are the most common source for lethicin in dietary supplements. These supplements contain a much smaller and more variable amount of choline than choline chloride or choline bitartrate supplements. Consumers should read the lethicin labels carefully. Some children's multivitamins also contain choline.

## Precautions

Moderate choline deficiency is associated with an increase in the blood levels of homocysteine. High levels of this molecule are known to increase the risk of cardiovascular disease. Extreme choline deficiency can result in a condition called fatty liver. Fat accumulates in liver cells where, in the absence of choline, it cannot be packaged and transported through the body. As a result, **fats** in the blood called **triglycerides** increase, creating an increased risk of heart disease and other health problems. Choline deficiency in pregnant women appears to have a negative effect on the development of the fetal brain and may cause learning, memory, and attention problems for affected children later in life.

Large excesses (10 g or more) of choline can cause nausea and extreme sweating. However, the most noticeable symptom of excess is the development of a highly unpleasant fishy body odor that results from the excretion of a choline breakdown product from the skin, urine, and breath. Large doses of choline dietary supplements do not appear to improve either physical or mental performance, nor do they appear to confer any specific health benefits.

## Interactions

Methotrexate, a drug used to treat **cancer**, psoriasis, and rheumatoid arthritis causes choline deficiency in laboratory animals. Individuals taking this drug should discuss possible side effects with their physician. Choline also is involved in many of the same metabolic pathways as other B-complex vitamins. Deficiencies or excesses of any of these B vitamins may potentially alter choline **metabolism**.

## Complications

No complications are expected when choline is taken in amounts equal to or exceeding the AI level. Doses much higher than the UL level have been tolerated without any obvious serious negative side effects (but also without any observed benefits).

## Parental concerns

Animal studies suggest that choline has a positive effect in stimulating the developing brain of the fetus and that choline supplements given after birth may offset some of the effects of fetal alcohol exposure. Some

Dietary supplement sellers have hyped these results, calling choline a miracle brain supplement or a genius supplement. Pregnant and breastfeeding women do need to eat a diet that provides adequate intake of choline, but should not be taken in by claims that choline supplements will increase the intelligence of their baby. As of 2007, these choline studies had only been done on rats where "learning" and "genius" were related to negotiating a laboratory maze. It remains to be seen if or how these findings relate to brain development in children.

# Chromium

## Definition

Chromium is a mineral that is essential to humans. It is found naturally in a variety of foods, and supplements are available in capsules or tablets. Supplements are prepared using a number of formulas, including chromium (III), chromium aspartate, chromium chloride, chromium citrate, chromium nicotinate, chromium picolinate, GTF chromium, and trivalent chromium.

**Chromium**

| Age | Adequate Intake (mcg/day) |
|---|---|
| Children 0–6 mos. | 0.2 |
| Children 7–12 mos. | 5.5 |
| Children 1–3 yrs. | 11 |
| Children 4–8 yrs. | 15 |
| Boys 9–13 yrs. | 25 |
| Girls 9–13 yrs. | 21 |
| Boys 14–18 yrs. | 35 |
| Girls 14–18 yrs. | 24 |
| Men 19–50 yrs. | 35 |
| Women 19–50 yrs. | 25 |
| Men 50> yrs. | 30 |
| Women 50> yrs. | 20 |
| Pregnant women 18≤ yrs. | 29 |
| Pregnant women 19≥ yrs. | 30 |
| Breastfeeding women 18≤ yrs. | 44 |
| Breastfeeding women 19≥ yrs. | 45 |

| Food | Chromium (mcg) |
|---|---|
| Broccoli, ½ cup | 11 |
| Grape juice, 1 cup | 8 |
| English muffin, whole wheat, 1 | 4 |
| Garlic, dried, 1 tsp. | 3 |
| Potatoes, mashed, 1 cup | 3 |
| Basil, dried, 1 tbsp. | 2 |
| Beef cubes, 3 oz. | 2 |
| Orange juice, 1 cup | 2 |
| Turkey breast, 3 oz. | 2 |
| Whole wheat bread, 2 slices | 2 |
| Red wine, 5 oz. | 1–13 |
| Apple, unpeeled, 1 med. | 1 |
| Banana, 1 med. | 1 |
| Green beans, ½ cup | 1 |

mcg = microgram

*(Illustration by GGS Information Services/Thomson Gale.)*

## Purpose

Chromium supports the normal function of insulin, which is a hormone secreted by the pancreas. Insulin helps transport glucose from the bloodstream into liver, muscle, and fat cells. Once it is inside these cells, the sugar is metabolized into a source of energy. Insulin is also involved in regulating protein, fat, and catalytic enzyme processes. People with diabetes do not produce insulin (or produce very little) or their bodies cannot properly use the insulin that is produced. As a result, sugar builds up in the bloodstream, causing serious health effects. Numerous scientific studies have shown that chromium is useful in treating insulin resistance (metabolic syndrome) and diabetes. Diabetic peripheral neuropathy, a form of nerve damage that is a direct result of diabetes, is indirectly related to a lack of sufficient chromium.

## Description

Several studies have shown that chromium supplements may improve insulin sensitivity, and lower blood glucose and elevated body fat. In February 2004, the University of Pennsylvania School of Medicine began a comprehensive study of chromium as a therapy for insulin resistance. This condition occurs when the body fails to respond properly to the insulin it already produces. People who are insulin resistant may have the ability to overcome this problem by producing more insulin. However, if the body cannot produce sufficient amounts of insulin, glucose levels in the bloodstream rise, and type 2 diabetes ultimately occurs. It is estimated that up to 80 million Americans have insulin resistance.

A study conducted by Isala Clinics and University Hospital Groningen in the Netherlands, and released in 2003, showed that a daily dose of 1,000 micrograms of chromium significantly reduced blood sugar levels in people with poorly controlled type 2 diabetes who use insulin.

Chromium has also been used as an effective treatment for polycystic ovarian syndrome (PCOS), a hormonal condition affecting about two million American women. The condition can lead to infertility if untreated, and is associated with insulin resistance and type 2 diabetes. A study released in 2003 by the State University of New York at Stony Brook showed that insulin sensitivity increased an average of 35% after two months of daily treatment with 1,000 micrograms (mcg) of chromium.

Through its involvement with insulin function, chromium plays an indirect role in lowering blood lipids. Studies suggest, but have not proven, that chromium supplementation can reduce the risk of cardiovascular (heart) disease in men, and may decrease total cholesterol and triglyceride levels. However, several studies contradict these claims. Studies in animals suggest chromium supplementation may reduce hypertension (high blood pressure). Lipid reduction is secondary to insulin regulation and control; therefore, persons whose insulin is well regulated and controlled may not achieve reduced heart disease risk by taking chromium supplements.

Chromium supplements in high doses—1,000 mcg or more a day—are sometimes used in weight loss and muscle development. However, a number of scientific studies have found that chromium supplements are not effective in these areas. In fact, precautions warn against chromium doses exceeding 1,000 mcg per day. Weight loss and muscle development are secondary to insulin regulation and control. Therefore, when insulin is well regulated and controlled, chromium may not impact weight loss or muscle development.

### KEY TERMS

**Calcium carbonate**—A salt that is used in many antacids.

**Diabetes**—Several metabolic disorders in which the body produces insufficient insulin.

**Glucose**—Sugar.

**Hypertension**—High blood pressure, which, if untreated, can lead to heart disease and stroke.

**Insomnia**—The inability to sleep.

**Insulin**—A hormone that helps liver, muscle and fat cells take up sugars, starches, and other foods for conversion into energy the body needs.

**Insulin resistance**—Also called metabolic syndrome, a condition in which the body fails to properly respond to the insulin it produces.

**Polycystic ovarian syndrome**—PCOS, a hormonal condition in women that if untreated can lead to the inability to have children.

A complete lack of chromium is rare, and the United States Food and Drug Administration (FDA) has not established recommended dietary allowances (RDA) for the mineral. However, national statistics on the prevalence of diabetes, heart disease, and obesity suggest that chromium deficiencies may be common. Chromium occurs naturally in meat, seafood, dairy products, eggs, whole grains, black pepper, and almonds. According to *The PDR Family Guide to Natural Medicines and Healing Therapies*, the usual chromium supplement dose for children ages seven and older and adults is 50–200 mcg a day in tablets or capsules. For persons with type 2 diabetes who are not taking insulin, doses from 200–1,000 mcg daily may be taken. However, persons should only take doses at these levels after consulting with a physician. Chromium should not be taken in doses exceeding 1,000 mcg a day. The cost of a bottle of 100 tablets or capsules (200 mcg) of chromium picolinate ranges from $5 to $10.

## Precautions

Doses of 200–1,000 mcg of chromium should be taken only after consultation with a physician. Pregnant or breastfeeding women are advised to consult a physician before taking chromium supplements. Chromium should not be taken in doses exceeding

1,000 mcg a day. Increased dietary sugar may be associated with higher urinary excretion of chromium.

### Interactions

Persons who are taking antacids are advised to talk with a physician before taking chromium supplements. Studies in animals suggest that antacids, especially those containing calcium carbonate, may reduce the body's ability to absorb chromium. Studies have shown that chromium may enhance the effectiveness of drugs taken by people who have type 2 diabetes or insulin resistance. These drugs include glimepiride, glipizide, glyburide, insulin, and metformin. Individuals taking these drugs should discuss chromium supplementation with a physician because improved insulin function may necessitate medication dosage changes.

### Complications

Several studies have noted occasional reports of irregular heartbeats with chromium use. Infrequently, chromium has been reported to cause such sleep pattern changes as insomnia and increased dream activity. Irritability has also been reported. In rare instances, persons may be allergic to a chromium formula. The symptoms of an allergic reaction include difficulty breathing, chest pain, hives, rash, and itchy or swollen skin. If this happens, the patient is advised to seek medical care immediately. High doses may also cause liver and kidney damage, or gastric irritation, although these side effects are rare.

## Cleveland Clinic 3-day diet

### Definition

The Cleveland Clinic three-day diet is a very low-calorie diet (VLCD) or quick weight loss program intended to be followed, as the name indicates, for three days. There are certain foods (e.g., specific vegetables, hot dogs, vanilla ice cream, and saltine crackers) that the dieter must eat on specific days during the three-day period, although some versions of the diet allow substitutions. Most Internet versions of this diet promise a 10 lb (4.5 kg) weight loss over the first three days, or 40 lb (18 kg) if the diet is followed for a month. The Cleveland Clinic diet plan is primarily available on the Internet.

A number of other three-day diets share similar concepts as the Cleveland Clinic version, some of which are derived from other healthcare institutions or the military:

- Cardiac diet
- Birmingham Hospital cardiac unit diet
- American Heart Association (AHA) diet
- Three-day Army diet
- Three-day Navy diet
- Hot dog diet (or hot dog and ice cream diet)
- Kaiser three-day diet

## KEY TERMS

**Urban legend**—A story, anecdote, or piece of advice based on hearsay and circulated by person-to-person transmission, often by e-mail.

**Very low-calorie diet (VLCD)**—A term used by nutritionists to classify weight-reduction diets that allow around 800 or fewer calories a day.

- Dr. Perricone's three-day diet
- Dr. Christopher's three-day cleansing program
- Bubba's three-day diet
- Oregon Health and Science University (OHSU) diet

## Origins

The Cleveland Clinic diet development is attributed to the Cleveland Clinic located in Cleveland, Ohio. However, there is no official record of the diet's use in the facility. In fact, the origins of the diet have become somewhat of an urban legend. Many variations of the diet and stories of its development can be found posted by anonymous sources on Web sites and blogs. It is possible that the diet became associated with the Cleveland Clinic because the clinic does publish specialized cookbooks and nutrition guides for persons with kidney disorders or diabetes.

There are no books or privately published versions of the Cleveland Clinic diet in print, which makes it difficult to date this diet let alone trace it back to its original source. Although some accounts maintain that the Cleveland Clinic diet first began to circulate around 1985, the Oregon Health and Science University's disclaimer about this diet states that an early form of it called the University of Oregon Medical School diet has been passed around the Pacific Northwest since 1975. The Cleveland Clinic diet has been attributed to the cardiology departments of various hospitals and medical centers. Supposedly these facilities have overweight patients scheduled for heart surgery use the diet to help them lose weight before the operation.

## Description

Most versions of the Cleveland Clinic diet begin with the claim that the dieter will lose weight by means of a chemical breakdown. In fact, weight loss on this diet results from simple **calorie restriction**; the diet allows between 600 and 1,100 calories per day.

### *Basic three-day diet plan*

Day One:

- Breakfast: Black coffee, water, or tea; half of a grapefruit or pink grapefruit juice; and one slice of toast with 1 or 2 tbl of peanut butter
- Lunch: Black coffee, water, or tea; 1/2 cup of water-packed tuna; and one slice of dry toast
- Dinner: Black coffee, water, or tea; 3 oz lean meat; 1 cup green beans; 1 cup beets; 1 cup vanilla ice cream; and one small apple

Day Two:

- Breakfast: Black coffee, water, or tea; one egg, any style; one banana (some versions say 1/2 banana); and one slice of dry toast
- Lunch: Black coffee, water, or tea; 1 cup of cottage cheese; and five saltine crackers
- Dinner: Black coffee, water, or tea; two hot dogs; 1/2 cup carrots; 1 cup broccoli (or cabbage); one banana (some versions say 1/2 banana); and 1/2 cup vanilla ice cream

Day Three:

- Breakfast: Black coffee, water, or tea; five saltine crackers; one egg (or one slice cheddar cheese); and one 4-oz glass of apple juice
- Lunch: Black coffee, water, or tea; one hard-boiled egg; one small apple; and one slice of dry toast
- Dinner: Black coffee, water, or tea; 1 cup tuna, chicken, or turkey; 1 cup cauliflower or green beans; 1 cup beets; 1 cup cantaloupe or one small apple; and 1/2 cup vanilla ice cream

### *Instructions*

Some Internet versions of the Cleveland Clinic diet include tips and instructions for the dieter:

- Do not alter amounts or make substitutions on the diet menu.
- Drink at least four glasses of water or diet soda each day.
- Salt and pepper may be used but no other seasonings.
- No snacks allowed.
- Use this diet for three consecutive days each week.
- After three days of dieting, resume eating as usual but avoid binging.
- After four days of normal eating, repeat the three-day diet.
- Cheating on the diet will make it ineffective.
- Strictly follow the rules of the diet.

### *Variations of the three-day diet*

Some versions of the Cleveland Clinic diet allow herbs, lemon juice, vinegar, **soy** sauce, mustard, catsup, and Worcestershire sauce to add spice or flavor foods.

Versions of this diet that allow food substitutions do so on the basis that it is a calorie based diet. As long as food substitutions have equivalent calorie amounts, the diet will remain effective. Other versions provide specific lists of permitted substitutions:

- An orange instead of grapefruit
- Tuna instead of cottage cheese and vice versa
- Frozen yogurt instead of ice cream
- Cauliflower instead of broccoli and vice versa
- Green beans instead of broccoli or cauliflower
- Beets instead of carrots
- A slice of toast instead of five crackers or vice versa

## Function

The primary function of the Cleveland Clinic three-day diet is rapid short-term weight loss. Most variations of the diet imply that the diet can be used indefinitely, following a three-days on and four-days off pattern. Some online versions of this diet claim that it is a detoxification and weight regulation diet. The Cleveland Clinic three-day diet is also claimed to reduce the dieter's risk of heart disease by lowering blood pressure and cholesterol levels.

## Benefits

There are no benefits to health from the Cleveland Clinic diet other than a few pounds of temporary weight loss. Some dieters like the simple menu and no requirements for over-the-counter appetite suppressants.

## Precautions

The so-called Cleveland Clinic three-day diet or any of its three-day variations cannot be recommended for anyone who needs to lose weight; in particular, it poses risks to health for anyone with a history of heart disease or an eating disorder. In addition to avoiding **fad diets** such as this one, a general precaution for anyone seeking to lose weight is to consult a physician before trying any specific diet. This precaution is particularly important for adolescents, women who are pregnant or nursing, people with kidney or liver disorders, people with **eating disorders**, anyone who has had recent surgery, and anyone who needs to lose more than 30 lb (13.5 kg).

## QUESTIONS TO ASK YOUR DOCTOR

- Have any of your other patients actually tried the Cleveland Clinic Diet or any other three-day diet? If so, did they experience any side effects?
- Why or why wouldn't you recommend this diet to anyone even for a three-day trial period?
- What types of food substitutions would be acceptable?
- What is your opinion on cycling the program each week (three days on, four days off)?

## Risks

The Cleveland Clinic three-day diet is touted on some websites as a regimen that will lower blood cholesterol levels and the risk of heart disease. On the contrary, the diet requires foods that are high in fat, saturated fat, and cholesterol; all of which have been linked to heart disease.

The rigid rules associated with this diet as well as its calorie restriction place individuals diagnosed with eating disorders at risk of a relapse. A study at the University of Minnesota reported in 2007 that adolescent girls are at particularly high risk of developing or retaining disordered eating patterns with frequent exposure to magazine or online articles recommending diets, including such fad diets as the Cleveland Clinic diet.

Very restrictive diets such as the Cleveland Clinic diet may have an effect on dieter's morale. Some nutritionists have expressed concern that when dieters fail to lose weight on these diets, the dieters see themselves as weak or lacking willpower rather than recognizing that the diet is unsustainable.

## Research and general acceptance

The Cleveland Clinic diet is rejected by mainstream physicians and dietitians. The American Heart Association (AHA) and the hospitals whose names have been associated with the **cabbage soup diet** have issued formal disclaimers warning the public that they do not endorse this diet. The Oregon Health and Science University stated in 2003 that the "hot dog and ice cream diet . . . has been a thorn in our side for years. . . . We will not publish the entire meal plan for fear that someone might take it seriously."

The UAB Health System not only disowns the three-day diet, but notes its specific nutritional inadequacies,

including not providing adequate **iron** and **calcium** needed for a healthy diet.

Other critics of the Cleveland Clinic diet note its association with yo-yo dieting or **weight cycling**. Yo-yo dieting is a phrase coined in the early 1980s by Kelly Brownell, an **obesity** specialist at Yale University, to describe a repetitive pattern of weight loss and regaining in which the dieter's weight goes up and down like a yo-yo. The weight cycle may be as small as 5–10 lb (2–5 kg) or as large as 50 lb (22 kg). Weight cycling is no longer thought to affect **metabolism** but it does appear to increase a dieter's risk of **gallstones**, high cholesterol levels, and high blood pressure. Therefore, it is healthier to lose weight slowly through lifestyle changes (including more exercise) and keep it off than to use fad diets like the Cleveland Clinic diet as part of a weight cycling pattern.

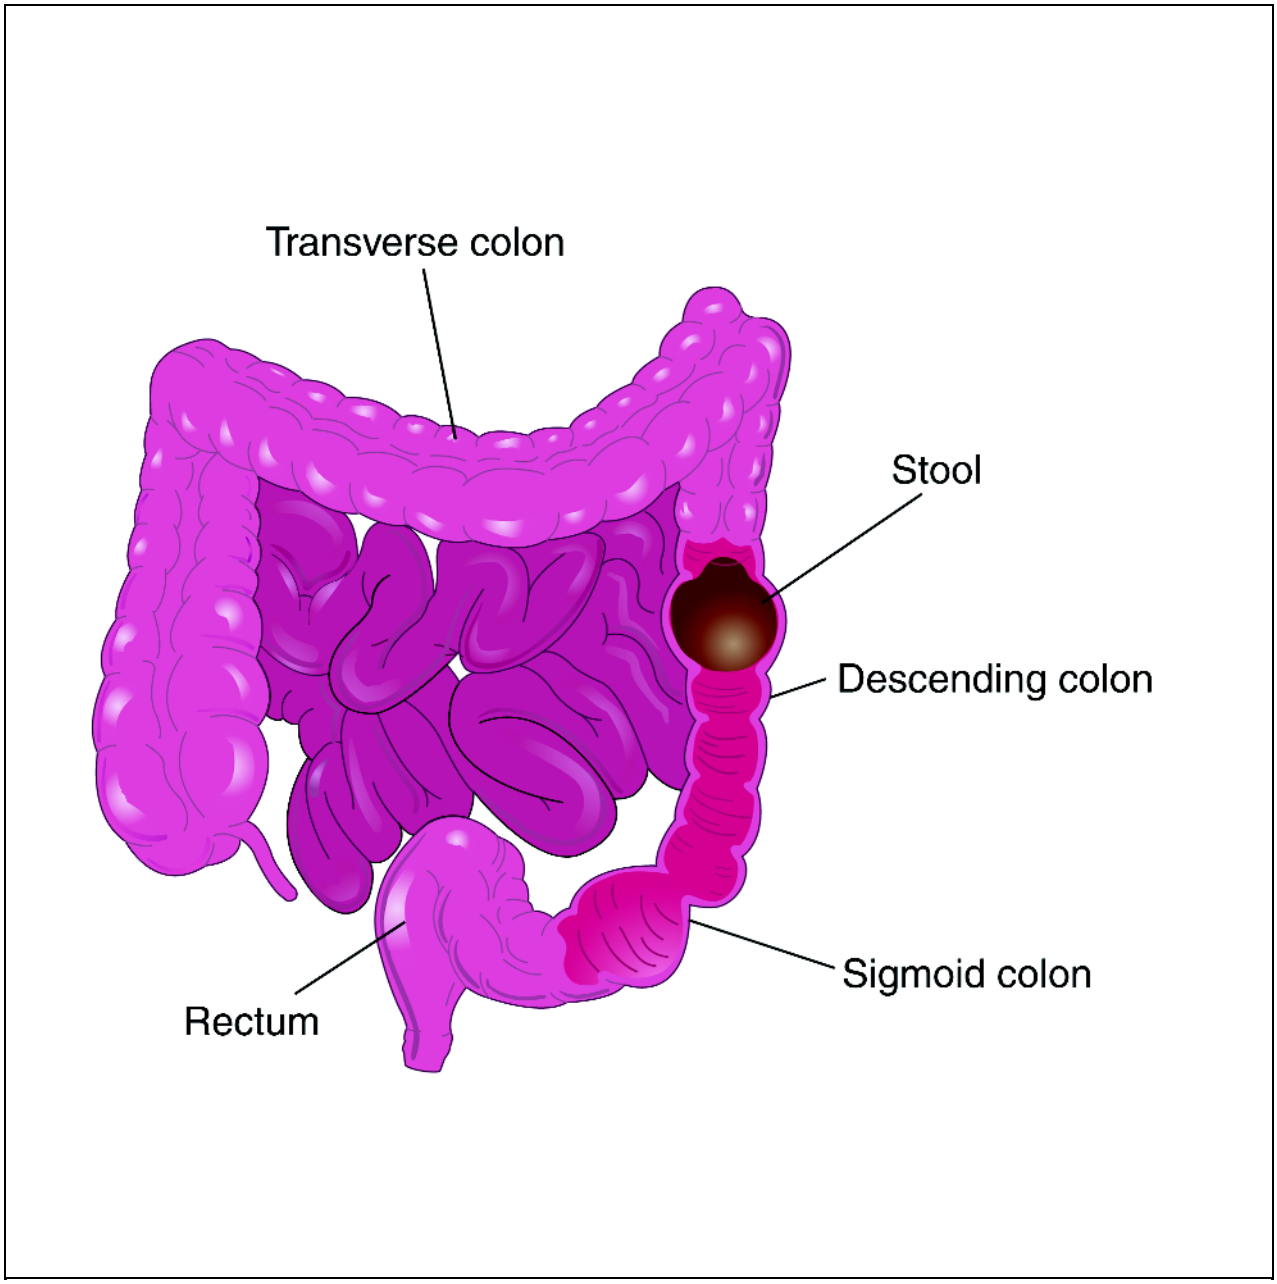
# Constipation

## Definition

Constipation is a symptom characterized by either having fewer than three bowel movements a week or having difficulty passing stools that are often hard, small, and dry.

## Description

Food in the process of being digested moves through the intestines in as a slurry or watery mush. In the small intestine, nutrients are absorbed from this material. After most of the nutrients have been absorbed, the material passes into the colon, or large intestine. Here much of the **water** in the slurry is absorbed back into the



**Constipation is an acute or chronic condition in which bowel movements occur less often than usual or consist of hard, dry stools that are painful or difficult to pass.** *(Illustration by Electronic Illustrators Group/Thomson Gale.)*

bloodstream, and the remaining solid material is eliminated as waste or stool. Constipation occurs when too much water is removed from the slurry, and it becomes difficult or painful to eliminate the stool. The most common reason why too much water is removed is that the material stays too long in the colon.

The frequency of bowel movements varies greatly from person to person and is influenced by age, health, diet, and lifestyle. It is a common misperception that a daily bowel movement is necessary for health. This is not true. For some healthy people, it is normal to have three bowel movements a day, while other healthy people have only three a week. Determining whether an individual is constipated must start with knowing what frequency of bowel movements is normal for that person.

## Demographics

Constipation is a very common complaint. About 2% of Americans complain of frequent or constant constipation. In 2005, constipation accounted for about 2.5 million visits to the doctor. In the United States more black Americans report being constipated than white Americans. In Africa, the reverse is true, suggesting that diet plays a more important role than race in determining who develops constipation. This is also supported by the fact that very few Asians who eat an **Asian diet** report being constipated, while those who adopt a Western diet report constipation much more frequently. Complaints about constipation are more likely to come from women than from men and from people over age 65. Pregnant women are at higher risk to become constipated, as are people who have had surgery and who are taking narcotic painkillers.

## Causes and symptoms

Constipation is not a disorder but a symptom of a health problem, like a fever or a cough. There are two general categories of constipation, idiopathic constipation, and functional constipation. Idiopathic means "of unknown origin." Idiopathic constipation is constipation that arises from an unknown cause. It may be related to hormonal abnormalities, nerve, or muscle damage, or something physicians do not yet understand. Functional constipation occurs when the bowel is healthy, but constipation develops because of diet, lifestyle habits, psychological disorders, or abnormalities in the rectum or anus.

Symptoms of constipation may include:

- bowel movements that occur less frequently than normal
- straining to eliminate stools
- small, hard, dry, painful, stools
- a feeling of pressure in the rectum
- a feeling of abdominal fullness or bloating
- leakage of small amounts of liquid stool. This occurs when there is a blockage or impaction and the colon is abnormally stretched.

Constipation has many causes. The most common cause in the United States is poor diet. A diet that increases the chances of developing constipation is one that is high in meat, dairy products, and refined sugar and low in dietary **fiber**. Other causes include:

- little physical exercise. This is a particular problem in the elderly.
- medications, especially narcotic drugs used to treat pain, but also antidepressants, antacids containing aluminum, iron supplements, tranquilizers, antispasmodics and anticonvulsants
- pregnancy
- change in routine, for example traveling
- irritable bowel syndrome
- not drinking enough fluids; dehydration
- laxative abuse (People become dependant on laxatives and need higher and higher doses to avoid constipation.)
- poor bowel habits, such as ignoring the urge to have a bowel movement or refusal to use public toilets
- tumor or other mechanical blockage
- eating disorders such as anorexia nervosa or bulimia nervosa where there is low calorie intake and (for bulimia) vomiting
- stroke or other conditions causing nerve damage such as multiple sclerosis, Parkinson's disease, and spinal cord injuries
- disorders that affect the muscles that cause material to move through the colon
- hormonal disorders such as diabetes, hypercalcemia (too much calcium), and hypothyroidism (too little thyroid hormone)
- abnormalities of the rectum or anus
- iron supplements

### KEY TERMS

**Anus**—The opening from the rectum to the outside of the body through which stools pass. The opening and closing of the anus is controlled by a strong ring of muscles under somewhat voluntary control.

**Dietary fiber**—Also known as roughage or bulk. Insoluble fiber moves through the digestive system almost undigested and gives bulk to stools. Soluble fiber dissolves in water and helps keep stools soft.

**Idiopathic**—Occurring from unknown causes.

**Laxative**—A substance that stimulates movement of food through the bowels. Laxatives are used to treat constipation.

**Rectum**—The last few inches of the large intestine.

## Diagnosis

Diagnosis begins with a medical history so that the physician can determine the normal frequency of

bowel movements and the length of time the individual has been constipated. The clinical definition of constipation requires that it be present for at least 12 weeks out of the past 12 months. The 12 weeks do not have to be consecutive.

A physical examination including a rectal exam and blood tests. Other tests, such as a thyroid hormone test, may be necessary to rule out other disorders. When symptoms are severe or do not improve with treatment, the physician may order specialized tests to determine how long material stays in the colon, evaluate the condition of the muscles of the rectum and anus, and look for evidence of **cancer** or other disease. These tests may include a sigmoidoscopy, barium enema x ray, colorectal transit study, and anorectal function tests.

## Treatment

The first choice in treating constipation is a change of diet. People with constipation are advised to eat more foods high in dietary fiber, decrease dairy, egg, and meat products to a healthy balance, and increase the amount of water and non-caffeinated beverages they drink. They are also encouraged to increase their level of physical activity and respond promptly to the urge to have a bowel movement.

When changes in diet and exercise do not work, laxatives can be used to stimulate movement of the bowels. Many types of laxatives can be purchased without a prescription. Americans spend about $725 million annually on laxatives. However, laxative dependency can become a problem with all laxatives. People who have been using laxatives regularly and wish to stop should reduce their use gradually. Each type of laxative has benefits and drawbacks. Individuals should discuss which one is best for them with their healthcare provider or pharmacist. Laxatives usually take 6–12 hours to stimulate a bowel movement.

Bulk-forming or fiber supplement laxatives are generally the safest type of laxative. Some common brand names of fiber-supplement laxatives are Metamucil, Citrocel, Fiberall, Konsyl, and Serutan. These must be taken with water. They provide extra fiber that absorbs water and helps keep the stool soft. The extra bulk also helps move materials through the colon.

Stool softeners help prevent the stool from drying out. They are recommended for people who should not strain to have a bowel movement, for example, people recovering from abdominal surgeries or childbirth. Brand names include Colace and Surfak.

Stimulant laxatives such as Ducolax, Senokot, Correctol, and Purge increase the rhythmic contractions of the colon and move the material along faster.

Lubricants add grease to the stool so that it moves more easily through the colon. Mineral oil is the most common lubricant.

Saline laxatives such as Milk of Magnesia draw water from the body into the colon to help soften and move the stool.

In the case of serious constipation, prescription drugs such as tegaserod (Zelnorm) may be used under the supervision of a doctor. Other medical treatment involves treating the underlying cause of the constipation such as changing a medication, removing tumors, or correcting a hormonal imbalance.

## Nutrition/dietetic concerns

The major cause of constipation is poor diet. Studies find that the average American eats only 5–14 grams of fiber daily. The United States Institute of Medicine (IOM) of the National Academy of Sciences has issued the following guidelines for daily consumption of fiber.

- men age 50 and younger: 38 grams
- women age 50 and younger: 25 grams
- men age 51 and older: 30 grams
- women age 51 and older: 21 grams

There are two types of dietary fiber, and both play a role in controlling constipation. Insoluble fiber passes through the intestines undigested, adds bulk to stool, and increases the speed with which it moves through the colon. Good sources of insoluble fiber include many whole grains such as wholemeal bread, brown rice, and high bran cereals. Soluble fiber dissolves in water and forms a gel that keeps the stool soft. It also has health benefits such as lowering cholesterol (see entry for **high fiber diet**). Good sources of soluble fiber include oats, apples, beans, peas, citrus fruits, barley, and carrots.

The American Dietetic Association and several other health organizations encourage people to increase the amount of fiber in their diet for many health reasons, not just to control or prevent constipation. The following list gives the fiber content of some common foods.

- split peas, cooked, 1 cup: 16.3 g
- lentils, cooked, 1 cup: 14.6 g
- kidney beans, cooked, 1 cup: 13.1 g
- brown rice, cooked, 1 cup: 3.5 g
- 100% bran cereal, 1/2 cup: 8.4 g

- oatmeal, 1 cup: 4.0 g
- peas, cooked, 1/2 cup: 3.6 g
- carrots, cooked, 1/2 cup: 2.3 g
- potato, baked with skin: 2.5 g
- potato, baked without skin: 1.4 g
- apple with skin: 3.5 g
- apple without skin: 2.7 g
- pear with skin, 1/2: 3.1 g
- pear without skin, 1/2: 2.5 g
- prunes, 3: 3.0 g
- whole-wheat bread, 1 slice: 1.9 g
- popcorn, air popped, 2 cups: 2.4 g
- peanuts, 10: 1.4 g

## Therapy

Biofeedback training may help individuals whose constipation is caused by dysfunctional control of the muscles that control the anus.

## Prognosis

Many people have short bouts of constipation, especially when traveling, after childbirth or surgery, or with a change in lifestyle. These usually can be resolved through attention to diet and exercise. People who have chronic idiopathic constipation, **irritable bowel syndrome**, and the elderly (especially those who are bed or wheelchair bound), often continue to have long-term problems with constipation despite attention to diet and become dependent on laxatives. Since many people self-treat constipation with over-the-counter laxatives, rates of improvement are difficult to determine.

Some people develop **hemorrhoids** and cracks in their skin at the anus (anal fissures) as the result of constipation. These are painful, but not usually medically serious. Some people also develop rectal prolapse from straining to produce a bowel movement. In this case, the lining of the rectum bulges out through the anus. The most serious complication from constipation is an impaction, which is a hard mass of stool that blocks the colon. Removing an impaction often requires professional medical intervention.

## Prevention

A diet high in fiber, whole grains, fruits, and vegetables and low in sugar, **fats**, and refined grains helps promote good bowel health in most people. Adequate amounts of fluid and regular exercise also help prevent constipation from becoming a problem.

# Copper

## Definition

Copper is an essential mineral that plays an important role in iron absorption and transport. It is considered a trace mineral because it is needed in very small amounts. Only 70–80 mg of copper are found in the body of a normal healthy person. Even though the body needs very little, copper is an important nutrient that holds many vital functions in the body.

## Purpose

Copper is essential for normal development of the body because it:

- Participates in a wide variety of important enzymatic reactions in the body.
- Is a component of or a cofactor for approximately 50 different enzymes. These enzymes need copper to function properly.
- Is essential for iron absorption and transport. Iron is needed to make hemoglobin, a main component of red blood cells. Therefore, copper deficiency is often linked to iron-deficiency anemia.
- Is required to build elastin and collagen, which are an important components of bones and connective tissues. Therefore, copper is believed to protect the bones and joints against degeneration and osteoporosis.
- Is required for melanin production. People with copper deficiency may have pale skin and hair.
- Is a key mineral for the immune system. Copper promotes wound healing. Studies show that premature infants or children with genetic copper defects are at high risk of getting infections and would significantly improve with copper supplementation.
- Attacks free radicals. Copper is a strong antioxidant. It works by attaching itself to the enzyme Superoxide dismutase (SOD). Copper also binds to a protein to form ceruloplasmin, which is an antioxidant.
- Helps the body produce energy. Copper participates in many oxidative reactions that break down fats in fat tissue to produce much needed energy. Copper deficiency has been associated with high cholesterol levels.
- Is necessary for normal functioning of insulin. Copper deficiency is also associated with poor blood glucose control.
- Is needed for normal functioning of the cardiovascular system.
- Protects the structure and function of the nervous system, including the brain. Copper protects nerve fiber by maintaining myelin, the insulating sheath that surrounds nerve cells. It also aids the transmission of nerve signals in the brains.

**Copper**

| Age | Recommended Dietary Allowance (mcg/day) |
|---|---|
| Children 0–6 mos. | 200 (AI) |
| Children 7–12 mos. | 220 (AI) |
| Children 1–3 yrs. | 340 |
| Children 4–8 yrs. | 440 |
| Children 9–13 yrs. | 700 |

Copper supplements may be beneficial in treating or preventing copper deficiency. Copper deficiency used to be relatively rare because the body requires so little of it, only about 2 mg per day. In addition, it is available naturally in a variety of foods such as whole grains, shellfish, nuts, beans, and leafy vegetables. Additional sources of copper are the copper water pipes that run through homes or the copper cookware in the kitchen. These sources leach copper into the water we drink and the food we eat. The level of copper in drinking water is sometimes so high that it becomes a public concern. However, scientists now realize that copper deficiency, especially borderline cases, is more common than once thought. Copper deficiency is currently on the rise due to a decrease of whole foods in the diet and high consumption of fatty and processed foods.

## Description

It was discovered in 2001 that vegetarian diets generally contain more copper, but that the absorption

## KEY TERMS

**Antioxidants**—Antioxidants are nutrients that deactivate reactive molecules (free radicals) and prevent harmful chain reactions.

**Lacto-ovo vegetarian**—People who do not eat meat, but do include dairy products and eggs in their diets.

**Minerals**—Inorganic chemical elements that are found in plants and animals and are essential for life. There are two types of minerals: major minerals, which the body requires in large amounts, and trace elements, which the body needs only in minute amounts.

efficiency was lower for lacto-ovo vegetarians than for nonvegetarians. The study also showed that the increased amounts of copper in the vegetarian diets allow for greater copper content.

Besides dietary causes, certain diseases or conditions may reduce copper absorption, transport or increase its requirements, resulting in abnormally low copper blood levels. Increased copper intake through diet or supplementation may be necessary in the following conditions:

- premature infants fed only cow's milk
- pregnant women
- malnutrition
- celiac disease, sprue, cystic fibrosis, or short-bowel syndrome (these diseases cause poor absorption of dietary copper)
- kidney disease
- high consumption of zinc or iron (these minerals interfere with copper absorption)
- highly processed foods (copper is stripped away during food processing)
- Menkes syndrome (copper deficiency is caused by genetic defects of copper transport; Menkes syndrome patients cannot use copper supplied by the diet efficiently)

Symptoms of copper deficiency include:

- anemia
- malnourished infants
- prominently dilated veins
- pale hair or skin
- poorly formed bones
- nervous system disorders
- high cholesterol levels
- heart disease
- loss of taste
- increased susceptibility to infections
- infertility
- birth defects

Exceeding the daily requirement is dangerous, however, because copper toxicity commonly occurs. Copper toxicity is a very serious medical problem. Acute toxicity due to ingestion of too much supplement, for example, may cause nausea, vomiting, abdominal pain, diarrhea, dizziness, headache, and a metallic taste in the mouth. Chronic toxicity is often caused by genetic defects of copper metabolism, such as Wilson's disease. In this disease, copper is not eliminated properly and is allowed to accumulate to toxic levels. Copper is therefore present at high concentration where it should not be, such as in the liver, the lens of the eye, kidneys, or brain.

### *Disease prevention*

Copper is a good antioxidant. It works together with an antioxidant enzyme, superoxide dismutase (SOD), to protect cell membranes from being destroyed by free radicals. Free radicals are any molecules that are missing one electron. Because this is an unbalanced and unstable state, a radical is desperately finding ways to complete its pair. Therefore, it reacts to any nearby molecules to either steal an electron or give away the unpaired one. In the process, free radicals initiate chain reactions that destroy cell structures. Like other antioxidants, copper scavenges or cleans up these highly reactive radicals and changes them into inactive, less harmful compounds. Therefore, it can help prevent cancer. In 2001, a study reported that concentrations of copper sulfate and ascorbate may inhibit breast cancer growth. With further study, the combination may even prove useful as a chemotherapy agent for certain breast cancer patients.

Copper may also help prevent degenerative diseases or conditions such as premature aging, heart disease, autoimmune diseases, arthritis, cataracts, Alzheimer's disease, or diabetes.

### *Osteoporosis*

Copper may play a role in preventing osteoporosis. Calcium and vitamin D have long been considered the mainstay of osteoporosis treatment and prevention. However, a recent study has shown that they can be even more effective in increasing bone density and preventing osteoporosis if they are used in combination with copper and two other trace minerals, zinc and manganese.

### *Rheumatoid arthritis*

Copper has been a folklore remedy for rheumatoid arthritis since 1500 B.C. in ancient Egypt. Some people believe that wearing jewelry made of copper may relieve arthritic symptoms. To evaluate the effect of copper for the treatment of rheumatoid arthritis, Dr. Walker and his colleagues conducted a study of 77 arthritic patients. Patients were divided into two groups: treatment group wearing copper jewelry and placebo group wearing nothing or aluminum jewelry. In this study, patients who wore copper bracelets felt significantly better than those in the placebo group. In addition, patients in the treatment group reported recurrences of symptoms after the bracelets were removed. To explain the effects of the copper bracelets, these researchers suggested that copper contained in the bracelets was dissolved in sweat and then absorbed through the skin. They suspected that copper's effectiveness may be related to its role as an antioxidant. They also believe that copper may function as both an anti-inflammatory agent and as an antioxidant. Thus, it is possibly effective in reducing inflammatory response to such conditions as rheumatoid arthritis.

Copper is contained in many multivitamin/mineral preparations. It is also available as a single ingredient in the form of tablets. These tablets should be swallowed whole with a cup of water, preferably with meals, to avoid stomach upset. A person may choose any of the following preparations: copper gluconate, copper sulfate, or copper citrate. However, copper gluconate may be the least irritating to the stomach.

Zinc and copper compete with each other for absorption in the gastrointestinal tract. As a result, excessive copper intake may cause zinc deficiency, and vice versa. Therefore, a person should take zinc and copper supplements together in ratios of 10:1 or 15:1.

## Precautions

Those adding copper supplements to their diets should consider:

- Informing their doctors for proper instruction and monitoring of side effects. Copper toxicity due to excessive doses of copper supplements has been reported.
- Although there currently is no recommended daily allowance (RDA) established for copper, 2 mg of copper per day is considered sufficient and safe. Nausea and vomiting may occur in persons taking more than 20 mg of copper daily.
- It is not known if copper supplementation may harm a growing fetus. However, as with any drugs, pregnant or nursing women should not take copper or any other supplements or drugs without first consulting their doctors.
- In certain areas, drinking water may contain high levels of copper. Periodic checks of copper levels in drinking water may be necessary.
- Because individual antioxidants often work together as a team to defend the body against free radicals, the balance between copper, zinc, and iron must be maintained. Excessive intake of one nutrient might result in a deficiency of other minerals and decreased resistance to infections and increased risk of heart disease, diabetes, arthritis, and other diseases.

## Interactions

### *Factors that increase copper concentrations*

Certain disorders have been known to increase copper levels. Persons with these conditions should not take copper supplements as they may cause copper toxicity.

- recent heart attacks
- lupus erythematosus
- cirrhosis of the liver
- schizophrenia
- leukemia and some other forms of cancer
- viral infections
- ulcerative colitis (This inflammatory bowel disease may cause accumulation of copper in the body. Excessive amount of copper may worsen many symptoms of this disease by increasing susceptibility to infections and inhibiting wound healing.)
- Wilson's disease (This disease causes accumulation of copper in the tissues. As a result, patients have liver disease, mental retardation , tremor and poor muscle coordination. They also have copper deposits in the cornea of the eye. To manage this disease, patients are put on a low-copper diet and given penicillamine, a drug that attaches itself to copper and increases its excretion.)

## Complications

A person should stop taking copper supplements and seek medical help immediately if having the following signs or symptoms:

- anemia
- nausea
- vomiting
- abdominal pain

# Coronary heart disease

## Definition

Coronary heart disease is the narrowing or blockage of the arteries and vessels that provide oxygen and nutrients to the heart. It is caused by a condition called atherosclerosis, which is the gradual buildup of fatty materials on the arteries' inner linings. The blockage that results from the buildup restricts blood flow to the heart. When the blood flow is completely cut off, a heart attack can occur.

## Description

Coronary heart disease also may be called coronary artery disease or simply heart disease. It is the leading cause of death in the United States among men and women.

When the heart works harder and needs more oxygen, the coronary arteries expand. But buildup of fatty materials, or plaque, from atherosclerosis causes the arteries to harden and narrow. If the arteries are unable to expand because of coronary artery disease, the heart is deprived of oxygen. The heart muscle can't work properly without oxygen. The reduced blood flow and oxygen supply may cause angina, which is pain in the chest. It also may cause shortness of breath or other symptoms. Complete blockage or clotting at the site where the blood enters the heart can cause a heart attack.

Coronary heart disease can worsen over time. The heart muscles may weaken, even though no symptoms may be evident. Eventually, this leads to heart failure. In heart failure, the heart doesn't suddenly stop, but fails to pump blood to the body the way that it should. Coronary heart disease also can lead to heart arrhythmias, or changes in the normal rhythm of heartbeat. These can be serious.

## Demographics

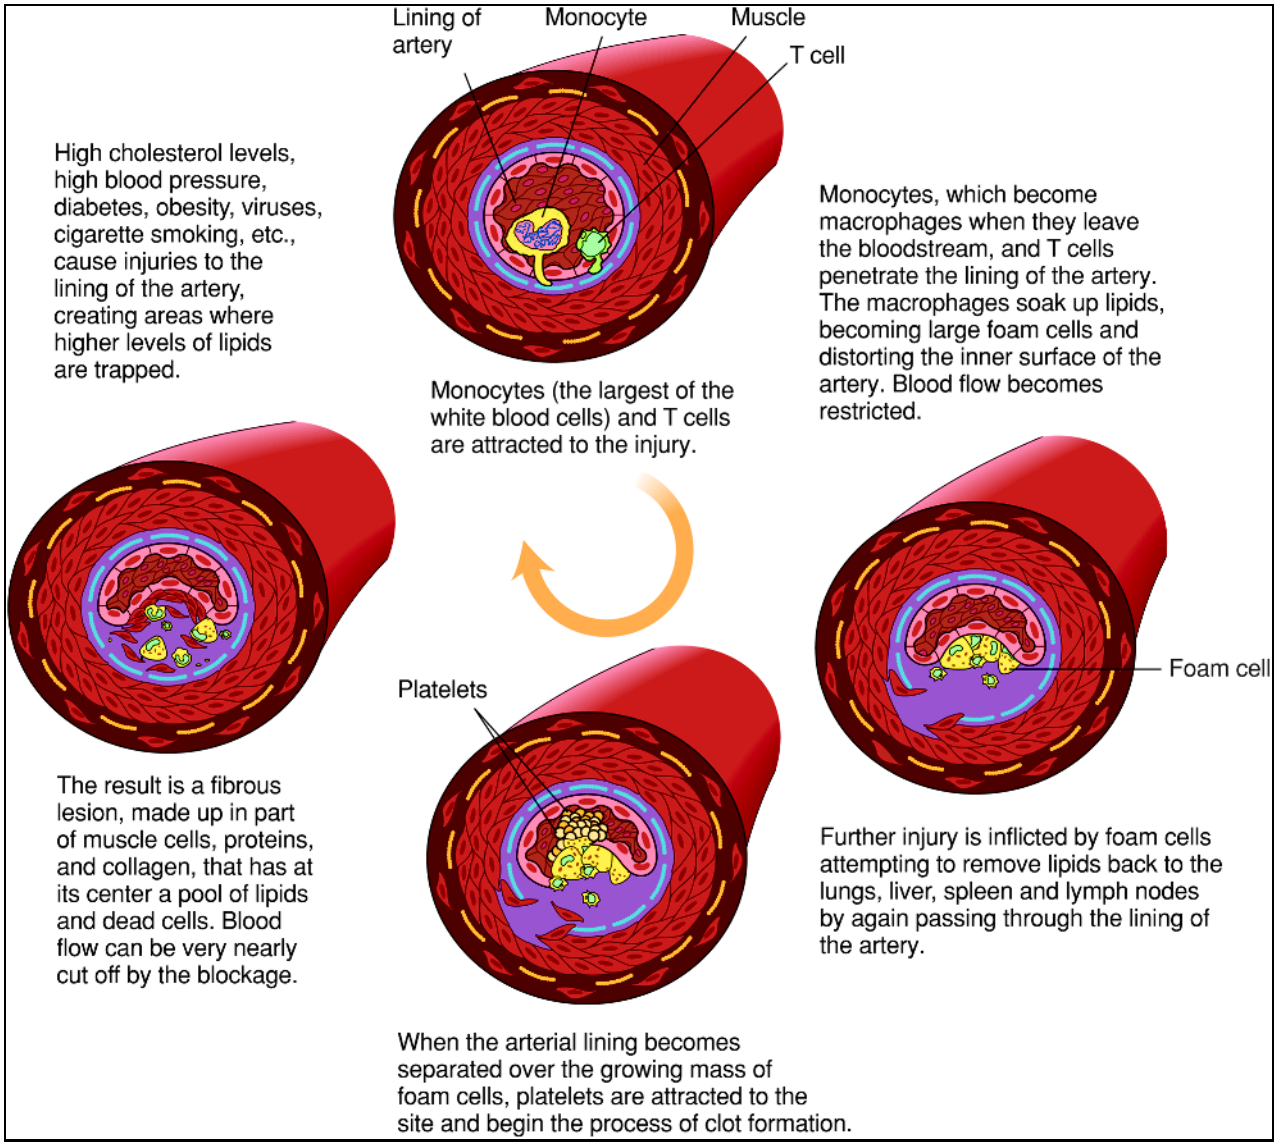
According to the American Heart Association, coronary heart disease caused more than 250,000 deaths in 2004. But the number of deaths from the disease declined 33% from 1994 to 2004. Although about 325,000 people a year die of coronary attacks in hospital emergency departments without even being hospitalized, more than 15 million people in America live with a history of heart attack, angina pectoris, or both. More of these are males, but not by a wide margin. Black males have a higher death rate per 100,000 than white males, and men generally have a higher chance of dying from coronary heart disease than women.

## Causes and symptoms

Coronary heart disease is caused by atherosclerosis. Some risk factors for coronary heart disease can't be changed, such as inheriting a genetic risk for the disease.

### *Causes and risk factors*

Age is a major risk factor for death from coronary heart disease. Over 83% of people who die from coronary heart disease are over age 65. Gender plays a role too, since men have a higher risk of heart attacks. Men tend to get heart disease earlier than women. While mean are at higher risk for coronary heart disease by about age 45, women are at risk for heart disease later in life, beginning at about age 55. People whose parents had heart disease also are at higher risk for coronary heart disease. Certain racial groups have higher risk as well, often because of a greater tendency toward **obesity**, high blood pressure, or diabetes.



**The progression of artherosclerosis.** *(Illustration by Electronic Illustrators Group/Thomson Gale.)*

Other risk factors can be affected by diet and lifestyle changes. Smoking is a big contributor to coronary heart disease. Not only do smokers have a risk two to four times that of nonsmokers of developing coronary heart disease, but they also have a higher risk of heart attack from the disease. In fact, a smoker with coronary heart disease is twice as likely as a nonsmoker with coronary heart disease to die suddenly from the disease.

Cholesterol and saturated fat play a role in developing coronary heart disease. The body produces cholesterol and a person's age, sex, and heredity can affect cholesterol levels. But diet also affects cholesterol. Both cholesterol and saturated fat tend to be found in the same foods. Dietary sources of both are meat, eggs, and other animal products. Risk of developing coronary heart disease rises steadily as levels of low-density lipoprotein (LDL) cholesterol rise or if a person has high cholesterol levels combined with high blood pressure and smoking.

Other diseases and conditions contribute to risk of coronary heart disease. High blood pressure makes the heart work harder and weakens it over time. **Diabetes mellitus** can be a serious risk for coronary heart disease and cardiovascular disease, which includes other disease to other arteries throughout the body. About three-fourths of people with diabetes die from heart disease or blood vessel disease.

## KEY TERMS

**Angina pectoris**—Chest pain or discomfort. Angina pectoris is the more common and stable form of angina. Stable angina has a pattern and is more predictable in nature, usually occurring when the heart is working harder than normal.

**Atherosclerosis**— The hardening and narrowing of the arteries caused by the slow build-up of fatty deposits, or plaque, on the artery walls.

**Triglyceride**—A fat that comes from food or is made up of other energy sources in the body. Elevated triglyceride levels contribute to the development of atherosclerosis.

Weight and physical activity play a role in risk of coronary heart disease. Being overweight makes the heart work harder to do its everyday job of pumping blood to the body. Even when people have no other risk factors, obesity greatly increases risk of heart disease, particularly if weight is concentrated at the waist. Excess weight also raises blood pressure and affects cholesterol and triglyceride levels. Losing as little as 10 pounds can decrease risk for coronary heart disease, though maintaining a healthy weight is best. Being inactive contributes to weight gain and all of the associated conditions that then lead to coronary heart disease.

Stress also may play a role in coronary heart disease risk. However, the real problem is how people react to stress. For instance, overeating in response to stress leads to risk factors listed above. Drinking too much alcohol can cause some of the conditions listed above and lead to heart failure. However, studies have shown that moderate amounts of alcohol, described as about 1.5 fluid oz. of 80-proof spirits, 1 fluid oz. of 100-proof spirits, 4 fluid oz. of wine, or 12 fluid oz. of beer per day, may be good for the heart. The American Heart Association does not recommend that people who do not drink begin drinking or that anyone increase alcohol intake to meet these amounts, however.

### *Symptoms*

The restricted blood flow to the heart caused by narrowing arteries may not produce any symptoms at first and many people are completely unaware that they have coronary heart disease. As the plaque builds up, symptoms begin to develop. One of the first signs may be chest pain that is triggered by physical or emotional stress. This pain often is referred to as angina. The pain feels much like pressure or tightening in the chest or it may be felt in the arm, neck, jaw, shoulder, or back. Sometimes the pain is confused with indigestion. Women may notice pain more often in the back or arm than in the chest and the pain may be brief and pass quickly.

Shortness of breath also is a symptom of coronary heart disease. This results from the heart's decreasing ability to pump enough blood to the body to meet its needs. The person with shortness of breath also may feel very tired.

The most serious symptom of coronary heart disease is heart attack. Although some heart attacks start suddenly and are clearly occurring, most start slowly with uncertain symptoms. Discomfort in the center of the chest that lasts for several minutes that feels like squeezing, fullness, or pain is a sign that a heart attack is occurring or about to occur. The pain also may go away and come back. The pain may occur in one or both upper arms, the back, neck, jaw, or stomach. A person may experience shortness of breath with or without chest pain. Some people break out in a sweat or experience nausea or lightheadedness.

## Diagnosis

A physician will ask questions about edical history, symptoms, and relatives with heart disease, as well as diet and lifestyle. A physical examination and routine blood tests also may be ordered as part of the evaluation. In addition, several examinations can be done to diagnose and evaluate coronary heart disease. These include:

- Resting electrocardiogram (ECG or EKG). This records electrical signals as they travel through the heart and usually is performed in a physician's office. It is noninvasive and involves placing electrodes on the body.
- Holter monitoring. Also called ambulatory electrocardiography, this involves wearing a portable EKG unit for 24 hours to monitor inadequate blood flow to the heart as a person goes about everyday activities.
- Exercise stress test. This test takes an EKG reading while a person is walking on a treadmill or riding a stationary bicycle. It often is used to evaluate people who experience symptoms when exercising. A nuclear stress test may be used as well. In this examination, the patient exercises and the flow of blood to the heart while at rest and during exercise is measured by injecting minor amounts of a radioactive material into the bloodstream. A special camera

can show which parts of the heart may receive less blood flow than normal.

- Angiogram. This is an x ray of the heart taken when a small tube, or catheter, is inserted into the arteries through a blood vessel in the groin or arm. The tip of the catheter can be guided to the coronary arteries and contrast is released. The contrast will be visible on x rays and will help show blood flow in the heart's chambers. Today, angiograms can be performed through the use of contrast and imaging with computed tomography or magnetic resonance imaging.
- Computed tomography (CT) scan. A CT scan, which is a cross-sectional x ray of the body or an organ of the body, can show images of the arteries to determine atherosclerosis. Ultra-fast CT imaging also can detect calcium within plaque.
- Magnetic resonance imaging (MRI). This noninvasive method may be used to examine the tissues of the heart. MRI uses no radiation. Magnetic resonance angiography provides an alternative to the more invasive method that involves introducing a catheter into the body.
- Other imaging methods may be used to detect coronary heart disease, such as single photon emission computed tomography (SPECT).

## Treatment

There are many ways to treat coronary heart disease, and the choice of treatment depends on the cause of the disease and its severity. Treatment ranges from lifestyle changes and use of medication to surgical procedures. People with less severe disease and fewer risk factors may be able to manage their disease through lifestyle changes and drug therapy. Changes in diet and an increase in exercise, as well as quitting smoking, can gain control of coronary heart disease. Often all treament procedures are used. Lifestyle factors such as diet and exercise are first line prevention and treatment methods. They are to be continued even after beginning medications and following surgery.

Medications used to treat coronary heart disease include:

- cholesterol-lowering medicines such as statins and fibrates
- blood thinners, or anticoagulants, to prevent blood clots from forming
- aspirin, also to help prevent clotting
- blood pressure medicines to lower blood pressure, such as angiotensin-converting enzyme (ACE) inhibitors
- calcium channel blockers, to relax blood vessels and lower blood pressure
- beta blockers to slow heart rate and lower blood pressure

Surgery or other procedures also may be recommended to treat coronary heart disease. A physician may be able to use a catheter to guide a tiny balloon into the artery. Once in place, the balloon is inflated and used to widen the artery by pushing the plaque up against the artery wall, Next, a stent, or mesh tube, is placed in the widened area to help keep the artery opened and clear for adequate blood flow.

Coronary artery bypass surgery reroutes, or bypasses, blood flow around the arteries that have clogged to improve blood flow to the heart. To perform the procedure, the surgeon takes a healthy blood vessel from another part of the body and uses it to create a detour around the clogged artery. This procedure requires open heart surgery and is reserved for people with multiple areas of artery blockage.

Heart attacks from coronary heart disease require emergency medical treatment.

## Nutrition/Dietetic concerns

Nutrition is key to preventing and controlling coronary heart disease. The American Heart Association recommends that adults get no more than 300 mg of cholesterol a day in their diet and that those with heart disease get no more than 200 mg a day. It also is important to limit cholesterol that comes from animal-based foods and from saturated **fats**. All animal foods contain some cholesterol, so eating lean meats, fish, and poultry in smaller servings helps to control the amount eaten. Eating fat-free or low-fat dairy products also helps keep cholesterol and fats in check.

Controlling blood pressure helps prevent or manage coronary heart disease. A diet low in salts and high in fruits, vegetables, and whole grains helps to control blood pressure. The **DASH diet** is a balanced approach to controlling **hypertension**.

Eating lots of sugars and simple **carbohydrates** can lead to or complicate diabetes and affect triglyceride levels, increasing risk of coronary heart disease. It is important for people with diabetes to control their intake of white bread, bagels, cakes, soft drinks, and other carbohydrates. Studies show that whole-wheat breads, brown rice, and legumes are healthier choices to provide carbohydrates and **protein** in the diet. Even people with coronary heart disease who do not have diabetes should try to eat the recommended daily amounts of grains and fats and to get them from whole grains when possible.

In the past, there have been recommendations to follow high-protein, high-fat diets to control coronary heart disease. Studies have not shown these types of diets, such as the **Atkins diet**, to be successful at controlling weight long term or to reducing coronary heart disease. Research has shown that diets lower in carbohydrates and higher in vegetable sources of fat and protein moderately reduce the risk of coronary heart disease in women. Certain foods, such as fish and foods high in **fiber** (whole grains, fruits, and fresh vegetables) are healthy foods for the diets of people with coronary heart disease.

The most important aspect of nutrition and diet for people with coronary heart disease is to eat a balanced diet that helps them to lose and manage weight. The United States Department of Agriculture (USDA) and the United States Department of Health and Human Services revised the *Dietary Guidelines for Americans* in 2005. The guidelines are science-based and outline advice for choosing a nutritious diet and maintaining a healthy weight. The 2005 guidelines also address physical activity and **food safety** and make recommendations for special population groups. Finally, calorie requirements and servings are based more on gender, age, and level of physical activity, while in 2000, the servings were more uniform for all adults. The USDA also revised the traditional food pyramid to make it customized for individuals. These guidelines form the basis for healthy eating. The American Heart Association and the American Dietetic Association also offer heart healthy diet recommendations, as do family physicians and cardiologists.

### Therapy

Some patients with coronary heart disease will be referred for cardiac rehabilitation, particularly following bypass surgery or if they have experienced angina or a heart attack. The rehabilitation may consist of an exercise plan to help regain stamina safely based on individual ability and needs, and education, counseling, and training. Training may include ways to better manage stress, as well as how to manage other lifestyle factors that contribute to coronary heart disease.

### Prognosis

Coronary heart disease can be successfully managed and treated in many cases. Advances in diagnosis and techniques such as stenting have helped to improve the lives of people with the disease, bringing about a significant decline in death rates from coronary heart disease since the mid-1980s. However, as the leading cause of death in the United States, coronary heart disease is a serious condition that is best prevented and that requires careful management and attention once diagnosed. The more risk factors a person has, the worse the prognosis.

### Prevention

Preventing coronary heart disease begins with knowing the risk factors and taking action to act on those factors. Managing all those contributing factors that can be avoided goes a long way in preventing the advancement of atherosclerosis and eventual coronary heart disease. By quitting smoking, moderating alcohol use, controlling blood pressure, preventing diabetes, and maintaining healthy cholesterol levels, people can prevent many of the causes of coronary heart disease. Maintaining a healthy body weight by eating a balanced diet with healthy-sized portions and participating in regular physical activity helps to prevent the disease. Those with known hereditary or other risk factors for coronary heart disease should have regular physical examinations with their physicians and should pay careful attention to the signs and symptoms of coronary heart disease and heart attack.

## Cravings

### Definition

Most people, at some time, have a strong desire for some particular food, such as ice cream or pizza. Such a desire for a particular food, even when one is not hungry, is called a craving.

## Description

There are a number of theories as to why people crave certain foods, including:

- self-imposed food restriction
- a psychological desire for a "comfort" food
- hormonal changes
- gender differences
- response to stress

Food restriction. The theory of food restriction holds that people desire those foods that they feel should be avoided. According to the dietitian Debra Waterhouse, food cravings do not cause weight gain, but denying the cravings does. This creates a vicious cycle. For example, a person may feel guilty for wanting a giant cinnamon roll that he or she smells upon entering a shopping mall. The urge is avoided, but a couple of hours later, the person may want the cinnamon roll more than ever, give in to the craving, and quickly eat the entire cinnamon roll. This leads to even stronger feelings of guilt, along with the resolve not to eat anything remotely similar for some period of time. Soon, however, the craving strikes again. The cycle becomes one of denial leading to deprivation, then to overindulgence, and then back to denial. This denial-deprivation-overindulgence pattern confirms the negative view of all food as either good or bad. It would be better, however, to imagine a world where foods are not designated as bad and not allowed, but where reasonable portions of any food can be part of a healthful diet. Portion control is the key.

Comfort foods. Certain foods are usually served during holidays or special occasions. These foods become associated with comfort and happy times, eliciting feelings of relaxation and reduced stress, and are thus called "comfort foods." Some common comfort foods are ice cream, macaroni and cheese, meatloaf, pudding, cookies, and chicken. One's cultural background plays a large part in comfort-food choices. Mood also plays a roll in cravings for comfort food. Women are more likely to eat when they are sad, mad, or anxious, while men look to food when bored or lonely.

Those who find themselves reaching for comfort foods frequently should ask themselves if they are truly hungry, or whether they are using food to soothe their mood. For those who are feeding emotions with food, it is helpful to begin to replace the food with healthier activities, such as taking a walk, participating in a favorite form of exercise, or reading a good book.

### KEY TERMS

**Calorie**—Unit of food energy.

**Estrogen**—Hormone that helps control female development and menstruation.

**Neurotransmitter**—Molecule released by one nerve cell to stimulate or inhibit another.

**Serotonin**—Chemical used by nerve cells to communicate with one another.

**Testosterone**—Male sex hormone.

Hormones and cravings. How do hormone changes affect food cravings? For women, these cravings can be more intense than for men. Hormonal changes tied to the menstrual cycle are often a cause of cravings. Immediately prior to the menstrual period, the body's estrogen level drops, as does the serotonin level in the brain.

Serotonin is a neurotransmitter, or brain chemical, that plays a role in maintaining a relaxed feeling. When the level decreases, irritability and mood swings increase as does the craving for carbohydrate- and fat-rich foods such as chocolate, cookies, cake, potato chips, and roasted nuts. There is nothing wrong with eating a piece of chocolate, of course, but when chocolate and other craved foods become the mainstay of the diet and healthier choices get overlooked, then the cravings have gotten out of control and health may be compromised.

Gender differences. Is there a difference between the sexes when it comes to food cravings? According to Waterhouse, the foods most frequently craved or preferred by men include hot dogs, eggs, and meat, which are all **protein** foods, while women reach for chocolate, ice cream, and bread. She attributes these differences to sex hormones and body composition. Men have larger amounts of the hormone testosterone and about forty pounds more muscle mass than women. They eat increased amounts of protein to build, repair, and synthesize muscle.

Stress response. Many people today lead stressful lives, which can lead to stress eating. Increased stress results in a need for **carbohydrates** to provide energy for the stress response, also known as the *fight-or-flight* response (a defense reaction of the body that prepares it to fight or flee by triggering certain cardiovascular, hormonal, and other changes). When coping with stress, a person needs increased energy to deal with the demands placed on the body. Carbohydrates

provide a fairly rapid source of fuel to the body by raising blood-glucose levels. However, when life becomes hectic and feels out of control, it is common to reach for any available food regardless of calories or nutritional content.

### Conquering Cravings

Life will always have its stresses, but dealing with stress in a healthful, nutritional way can have a positive impact on self-esteem, energy level, emotional outlook, and weight. There are a number of positive ways to deal with cravings, including:

Start the day off with breakfast, which helps prevent overwhelming hunger later in the day.

Eliminate feelings of guilt related to labeling food as either good or bad. Some choices are healthier than others, but snacks and treats can be consumed in reasonable amounts.

Plan ahead for each new week. Think about one's school, work, and activity schedule and how healthful snacks can be incorporated into it.

Keep healthful snacks close at hand, both at home and at work.

Try not to go for long periods of time without eating.

Combine lean protein foods with high-fiber carbohydrate sources to provide energy that lasts for several hours, such as a slice of vegetable pizza or a bean burrito.

Cravings can be the exception instead of the rule when it comes to one's diet. Developing a lifestyle that includes healthful food selections and regular meals and snacks can help control cravings. The extra time it takes in planning meals or snacks, whether eating at home or eating on the run, is easily made up for in increased energy and improved mood.

## Crohn's disease

### Definition

Crohn's disease is a chronic inflammatory disorder that affects the digestive tract.

### Description

Crohn's disease is named for Dr. Burril Crohn who, with his colleagues, first described the disease in 1932. Crohn's disease can affect any part of the digestive system, however, it develops most often in the section of the small intestine just before the large intestine begins. This region is called the ileum, and Crohn's disease that develops there is sometimes called ileitus. The other common site for Crohn's disease is in the colon or large intestine.

Crohn's disease is one of several inflammatory bowel diseases. In can be mistaken for ulcerative colitis. Both these diseases cause watery diarrhea or bloody diarrhea and abdominal cramps or pain. However, ulcerative colitis affects only the layer of cells that line the intestine forming sores or **ulcers** on this surface. Crohn's disease begins in these same surface cells, but eats its way inward, damaging all four layers of the intestine and sometimes creating a hole (fistula) through the intestine and into other tissue. Another major difference between Crohn's disease and ulcerative colitis is that Crohn's disease can develop simultaneously in several spots in the digestive tract, resulting in areas of damaged with patches with healthy tissue in between. Ulcerative colitis, on the other hand, spreads uniformly across an area. Crohn's disease is somewhat treatable, but not curable, and can cause many complications beyond the digestive system. Eventually in Crohn's disease the walls of the intestine thicken and blockages may occur that can only be corrected by surgery.

### Demographics

About half a million Americans, or 7 people out of every 100,000 have Crohn's disease. Of these, about 4% are children under age 5, and 10% are under age 18. Most people are diagnosed with the disease between ages 15 and 35, although they may have had the disease before that. In the United States the rate of Crohn's disease has been increasing since the 1950s.

Although most common among non-Hispanic whites, the rate of Crohn's disease among American blacks, especially urban blacks, has been steadily increasing. Jews who trace their ancestry middle Europe are 2-4 times more likely to develop the disease than the

**Small intestine (lower right) infected by Crohn's disease.** *(John Bavosi/Photo Researchers, Inc. Reproduced by permission.)*

general white population or Jews who trace their origins to other regions. Internationally, Crohn's disease is rare in Africa, Asia, and South America. It is more common in urban areas than in rural areas, suggesting that environment plays a role in the disease.

## Causes and symptoms

At one time, researchers thought that stress and diet caused Crohn's disease. Now researchers know that these are not factors, although both stress and diet can worsen symptoms in people who already have the disease. What researchers do know is that Crohn's disease is caused by an inappropriate immune system reaction that affects cells in the digestive tract. Beyond that, the reasons why some people develop the disease are not clear.

There is almost certainly an inherited component that predisposes some people to the disease. Individuals who are blood relatives of a parent, sibling, or child with Crohn's disease are 30 times more likely to develop the disease than the general population. Scientists believe multiple genes are involved in development of the disease. However, more than genetics determines who gets Crohn's disease, because only about 44% of identical twins both develop the disease. Researchers have found several mutated (altered) genes in many, but not all, people who have Crohn's disease but do not yet have a clear understanding of what these genes do.

### KEY TERMS

**Abscess**—A pocket of pus formed by an infection.

**Antibody**—A protein produced by the immune system to fight infection or rid the body of foreign material. The foreign material that stimulates the production of antibodies is called an antigen. Specific antibodies are produced in response to each different antigen and can only inactivate that particular antigen.

**Anus**—The opening from the rectum to the outside of the body through which stools pass. The opening and closing of the anus is controlled by a strong ring of muscles under somewhat voluntary control.

**Mineral**—An inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

**Vitamin**—A nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

Current thinking is that interplay between genes, the environment, the individual's health, and body chemistry affect who develops Crohn's disease. When foreign materials (antigens) enter the body, the immune system produces antibodies, which are proteins that neutralize the foreign invader. One theory about Crohn's disease is that some foreign organism or material stimulates an immune system response in the digestive system, and then through an error in genetic control, the response cannot be "turned off." A second theory suggests that the cells of the immune system mistake good bacteria, food, or some other substance that is normally present in the digestive tract and make antibodies against this material as if it were a foreign substance. Either way, an inappropriate immune system response occurs that appears to be the root cause for the symptoms people with Crohn's disease experience.

Symptoms of Crohn's disease vary, depending on the location of the damaged cells and the length of time the individual has had the disease. Symptoms can be mild or severe. They can develop suddenly or gradually, and they may improve or even disappear, and then worsen many times throughout an individual's life. In general, symptoms can be divided into those

that affect the digestive tract and those that affect the rest of the body.

The most common symptoms that affect the digestive tract are:

- chronic diarrhea, the most common symptom
- abdominal pain or cramps, often in the lower right portion of the abdomen
- rectal bleeding
- blood in the stool, black tarry stool
- ulcers in the digestive tract, usually the in the intestine
- fistulas, or holes in the intestine that connect the intestine to other parts of the body such as the bladder, stomach, vagina, or another section of bowel
- nausea and vomiting , usually from Crohn's disease in the stomach
- abscesses, fistulas, and ulcers around the anus, usually from Crohn's disease in the colon. This occurs in about 45% of patients
- constipation, usually after many years when the bowel has thickened and the diameter of the intestine has narrowed

Symptoms of Crohn's disease also appear in other systems in the body. Some are the result of infection when fistulas develop. Others come from poor absorption of nutrients in the intestine over a long period. Some symptoms that occur outside the digestive tract include:

- persistent low-grade fever
- loss of appetite and weight loss
- fatigue
- anemia from blood loss and/or poor iron absorption
- skin infections
- eye infections
- arthritis and sore joints, usually in the large joints such as the knees or hip
- osteoporosis from poor calcium and vitamin D absorption
- poor blood clotting from inadequate vitamin K absorption
- stunted growth in children
- delayed puberty

## Diagnosis

Several gastrointestinal diseases can resemble the more common symptoms of Crohn's disease. These include ulcerative colitis, **irritable bowel syndrome**, intestinal parasites, and intestinal obstruction. Normally the physician will begin with a medical and family history and standard blood and stool tests. The next step toward diagnosis is usually imaging studies, most often an upper GI series. An upper GI series, sometimes called a barium swallow, includes x rays of the esophagus, stomach, and upper part of the intestine. The patient drinks a solution of barium to improve contrast on the x rays, thus the name barium swallow.

An upper endoscopy or a colonoscopy is another routine part of the diagnostic procedure. An upper endoscopy is done if abnormalities appear to be in the esophagus, stomach, or upper part of the small intestine (the duodenum). A colonoscopy uses the same technique examine the colon. These procedures are usually performed in a doctor's office or an outpatient clinic under light sedation. A tube called an endoscope is inserted down the throat and into the stomach and duodenum or up the rectum and into the colon. At the end of the endoscope is a tiny camera that allows the doctor to see if there is damage to the cells lining digestive tract. During this procedure, the doctor also removes small tissue samples (biopsies) in order to look for abnormal cells under the microscope.

Special blood tests are available that can help differentiate between Crohn's disease and ulcerative colitis. These tests may be done if the results of other tests are questionable. According to the Crohn's & Colitis Foundation of America, in about 10% of patients, it is quite difficult to tell these two diseases apart.

## Treatment

There is no cure for Crohn's disease. Treatment is aimed at controlling inflammation, preventing **vitamins** and **minerals** deficiencies, and relieving symptoms. Treatment options include a combination of drugs, biologic therapies, nutritional supplements, and surgery.

Individuals with mild to moderate Crohn's disease are usually treated first with anti-inflammatory drugs such as sulfasalazine (Azulfidine) or mesalamine (Asacol, Rowasa, Canasa). Individuals with moderate to severe Crohn's disease often are prescribed corticosteroid drugs. Prendisone (Deltasone, Orasone, Meticorten) is often the corticosteroid of choice. These drugs have significant side effects and cannot be used for long-term suppression of symptoms. Antibiotics are used to treat infection that may develop, for example, from fistula formation.

Biologic therapies use manmade antibodies. Infliximab (Remicade) is a laboratory-made antibody that blocks the production of an immune system factor that causes inflammation. This treatment is relatively new, but appears to have a good success rate for relieving symptoms. Additional biologic therapies for

Crohn's disease are under development. Individuals interested in participating in a clinical trial of a new drug or therapy for Crohn's disease at no cost can find a list of trials currently enrolling volunteers at <http://www.clinicaltrials.gov.>

Medical treatment becomes less effective over time. When medical treatment fails or if the intestine becomes thickened and so that blockages occur, surgery may be necessary. About 80% of all people with Crohn's disease eventually need surgery. Surgery to remove part of the intestine usually relieves symptoms for a few years, but surgery is not a cure for Crohn's disease, and symptoms almost always return within a few years.

## Nutrition/Dietetic concerns

People with Crohn's disease tend to have vitamin and mineral deficiencies because damage to the lining of the intestine interferes with the absorption of nutrients, and chronic diarrhea hastens the loss of other nutrients. These deficiencies can cause specific disorders in other parts of the body. In addition, children with Crohn's disease also may need special high-calorie, high-nutrient liquid supplements to maintain normal growth. A nutritionist consulting with the patient's gastroenterologist can help determine the best diet and supplements to prevent nutritional deficiencies.

Although eating certain foods does not cause Crohn's disease, specific foods can worsen symptoms. Many people with Crohn's disease become lactose intolerant and must limit or eliminate dairy products from their diet. Alcohol, high **fiber** foods such as popcorn, and spicy foods can worsen diarrhea and abdominal cramping. Individuals must be alert to the effect of food on their symptoms until they figure out which foods to avoid.

## Therapy

Crohn's disease can be very disruptive. Individuals may be reluctant to go places or do certain things because frequent diarrhea requires them to be near a toilet. Support groups, either on the Web or in person, help many people adjust to the difficulties of living with this chronic disease. Other people find that psychotherapy (talk therapy) guided by a psychologist or psychiatrist experienced in the stresses of chronic illness can help them make a better adjustment to life with Crohn's disease.

## Prognosis

Crohn's disease is a life-long disease. Symptoms may improve or disappear for periods, but overall, symptoms and complications tend to worsen, although the disease itself is rarely fatal. Most people with Crohn's disease eventually need surgery as the disease becomes less and less responsive to medication. Living with Crohn's disease can be a difficult challenge that requires major lifestyle adjustments.

## Prevention

Crohn's disease cannot be prevented.

# CSIRO total wellbeing diet

## Definition

The CSIRO total wellbeing diet (TWD) is a high-protein, low-fat, moderate-carbohydrate weight-loss and maintenance diet developed by Australia's national science agency, the Commonwealth Scientific and Industrial Research Organization (CSIRO). It is a very structured, calorie-controlled, and nutritionally balanced diet that includes exercise and large amounts of **protein** from meat, fish, and poultry.

## Origins

The TWD was developed by CSIRO researchers at its Clinical Research Unit in Adelaide, South Australia. The CSIRO research was initiated in response to a large number of inquiries from dieticians concerning popular high-protein diets, whose use did not appear to be supported by scientific evidence. Previous CSIRO research had suggested that high-protein low-fat diets were at least as effective for weight loss as high-carbohydrate low-fat diets.

In research partially funded by Meat and Livestock Australia and Dairy Australia, the CSIRO team, led by Dr. Manny Noakes, developed the TWD for overweight and obese women. Dr. Grant Brinkworth was the exercise/nutrition physiologist on the team. The TWD was the culmination of eight years of research on diet composition, weight loss, and risks for developing diabetes and heart disease, conducted at CSIRO's Human Nutrition Clinic. In initial clinical studies the researchers claimed to have found clear health benefits and significant weight loss associated with their high-protein **low-fat diet**. They further claimed that clinical studies showed the diet to be superior to a high-carbohydrate low-fat diet with identical caloric intake, at least in a subset of women.

Meat and Livestock Australia distributed a booklet about the CSIRO diet in a women's magazine. The publisher Penguin then commissioned Noakes and Dr. Peter Clifton, director of the CSIRO Nutrition Clinic, to write the book, *The CSIRO Total Wellbeing Diet*. It was a runaway bestseller in Australia upon its publication in 2005. A sequel appeared in 2006.

## Description

### *Key components of the TWD*

The key components of the TWD are:

- high amounts of protein from lean meat, fish, and low-fat dairy products
- moderate amounts of carbohydrates
- low fat
- adequate fiber from whole grains, fruits, and vegetables
- caloric restriction
- exercise.

With the exception of its emphasis on meat, the TWD recommendations follow standard nutritional guidelines. The diet offers a variety of healthy food choices, including large amounts of fruits and vegetables, along with moderate exercise.

The basic daily TWD consists of:

- lean dinner protein, 7 oz (200 g) raw weight of lean red meat (beef, lamb, veal) four times per week, fish twice per week, chicken once per week
- lean lunch protein, up to 4 oz (110 g)
- wholegrain bread, two 1-oz (28-g) slices
- fruit, two medium pieces
- high-fiber cereal, 1.5 oz (42 g) or about one cup
- low-fat dairy, threde servings
- salad, one-half cup
- vegetables, four one-half-cup servings
- oil or margarine, three teaspoons
- indulgence foods, two servings per week
- exercise, 30 minutes daily.

### *Levels*

The TWD has four different diet levels, which are designed to cover the varying energy requirements of the majority of people. Level 1 is approximately 1,337 calories (5,600 kilojoules) per day. Levels 3 and 4 have higher allowances of lean protein, low-fat dairy, and high-fiber cereal. Before choosing a level, CSIRO recommends that people calculate their basal metabolic rate (BMR), which is based on height, weight, age, and gender. The Harris-Benedict Equation then uses the BMR and a factor based on a person's activity level to

## KEY TERMS

**Basal metabolic rate**—BMR; the rate of energy consumption when at complete rest.

**Calorie**—The heat- or energy-producing value of food when it is oxidized in the body; the amount of food having an energy-producing value of one calorie. Also called a large calorie or kilocalorie; equivalent to 4.2 kilojoules.

**Carbohydrates**—Sugars, starches, and celluloses produced by plants and ingested by animals.

**Cholesterol**—A steroid alcohol in animal cells and body fluids that controls the fluidity of membranes and functions as a metabolic precursor.

**Fiber**—Roughage; a complex mixture found in plant foods that includes the carbohydrates cellulose, hemicellulose, gum, mucilages, and pectins, as well as lignin.

**Glycemic index**—GI; a measure of the rate at which an ingested carbohydrate raises the glucose level in the blood.

**Glycemic load**—GL; a measure of the GI of a given food.

**HDL cholesterol**—High-density lipoprotein containing cholesterol in a healthy form.

**Kilojoule**—1,000 joules; a unit equivalent to 0.239 calories.

**LDL cholesterol**—Low-density lipoprotein containing a high proportion of cholesterol that is associated with the development of arteriosclerosis.

**Metabolic rate**—The BMR adjusted by an activity factor with the Harris-Benedict Formula to determine total daily energy expenditure in calories or kilojoules.

**Omega-3 fatty acids**—A type of polyunsaturated fat that may be beneficial for the heart.

**Syndrome X**—Metabolic syndrome; a metabolic condition characterized by excess abdominal fat, high blood pressure, low HDL cholesterol, high fasting blood-glucose levels, and high blood triglycerides, that may affect at least one in four women and increase their risk of developing type 2 diabetes and heart disease.

**Triglycerides**—Neutral fats; lipids formed from glycerol and fatty acids that circulate in the blood as lipoproteins.

determine daily energy expenditure in calories or kilojoules.

In general the level 1 and 2 plans are suitable for women and the level 3 and 4 plans are suitable for men, who tend to be taller and heavier than women. A basic daily TWD for men consists of:

- 7–9 oz (200–250 g) raw weight of lean meat, chicken, or fish for dinner
- 4 oz (110 g) cooked weight of meat, ham, chicken, or tuna for lunch
- wholegrain bread, two slices
- fruit, two pieces
- high-fiber cereal, 1.5 oz (40–50 g)
- low-fat dairy, three servings
- vegetables, two cups
- margarine/oil, four teaspoons
- one optional glass of wine.

### *Protein*

The TWD calls for a high amount of lean protein to prevent hunger. For dinner the TWD recommends 28 oz (800 g) raw weight of red meat per week or an average of 4 oz (110 g) per day, as well as at least 14 oz (400 g) of fish per week, or 2 oz (56 g) per day, and 7 oz (200 g) per week of skinless chicken with the fat removed. The diet calls for another 3.5 oz (100 g) of protein for lunch, based on the cooked weight of processed meat, chicken, or tuna.

An extra serving of dairy can be substituted for 1.7 oz (50 g) of protein at lunch. One dairy serving is:

- a low-fat or diet yoghurt
- a dairy dessert, 7 oz (200 g)
- low-fat milk, 8.5 oz (250 ml)
- cheddar or other full-fat cheese, 1 oz (28 g)
- reduced-fat cheese (10% fat), 1.7 oz (50 g).

### *Carbohydrates*

The TWD contains moderate amounts of slow-releasing **carbohydrates** that are necessary for energy and maintaining blood-glucose levels. These carbohydrates, primarily fruit and dairy, tend to have a low glycemic index (GI). They are digested slowly and help to keep blood-glucose levels steady. Since total carbohydrate is limited to 40% of the total calories or

kilojoules in the diet, the TWD has a low glycemic load (GL).

Fruits are limited to 11 oz (300 g) per day, as two servings of unsweetened fresh or canned fruit (5.3 oz, 150 g) or unsweetened juice (5 oz, 150 ml). Equal amounts of dried or frozen fruit, vegetables, or unsweetened vegetable juice (5 oz, 150 ml) may be substituted for one serving of a fruit or vegetable.

Simple sugars and refined carbohydrates are not recommended. Sugar or honey as sweeteners can be used only in small amounts. Small amounts of sweeteners or thickeners can be used occasionally in cooking. One level teaspoon of sugar is equivalent to 10–14 calories (40–60 kilojoules).

### *Fats*

The TWD contains very small amounts of fatty foods and oils. It calls for less than 30% of calories from fat or about 50 g of fat per day. The TWD assumes that low-fat foods contain no more than 3 g of fat per 3.5 oz (100 g) of solid food or 1.5 g of fat per 3.5 oz (100 g) of liquid. Fat-free foods contain no more than 0.15 g of fat per 3.5 oz (100 g). Reduced/low-fat milk contains 1–2% fat and skim/nonfat milk contains less than 0.16% fat.

The TWD recommends that the daily fat allowance be consumed as:

- canola oil
- olive oil
- sunflower oil
- soft/light margarine
- avocados
- nuts and seeds. Two teaspoons of lite margarine is equal to one teaspoon of oil. Three teaspoons of oil is equivalent to 2 oz (56 g) of avocado or 0.7 oz (20 g) of nuts.

### *Snacks*

Allowable snacks include:

- leftover portions from main meals
- low-calorie soup
- a cappuccino or café latte with skim milk from the milk allowance
- low-fat yogurt or custard
- fresh fruit from the fruit allowance.

### *Alcohol*

The level 1 TWD allows for two glasses (10 oz, 300 ml) of wine or about 205 calories (860 kilojoules) per week. Equivalent amounts of other alcohol or treats, such as 1.5 oz (40 g) of chocolate, may be substituted. It is suggested that **alcohol consumption** be kept to a minimum during the first few weeks of the diet because alcohol can increase the appetite. Presuming that other medical conditions do not limit the acceptable alcohol intake, other TWD levels and the maintenance diet allow for increased amounts. However alcohol intake should not exceed the recommended two standard drinks per day for women and four for men.

### *'Free' food*

The TWD includes a 'free' food list with minimal calories. Diet or low-calorie soups are an optional daily extra. Packet soups containing about 38 calories (160 kilojoules) per serving or vegetable soups made from the 'free' list are appropriate daily. The TWD includes an average of two–two and one-half cups of vegetables or about 14 oz (400 g) per day. Since vegetables tend to be very low in calories, eating more vegetables is acceptable and many vegetables are included in the 'free' list.

Foods that can be consumed as desired include:

- all green, orange, yellow, red, and most white vegetables, except potatoes and sweet potatoes
- diet soft drinks, unflavored bottled water, teas, coffee, cocoa
- stock cubes and clear soups
- diet jellies
- oil-free salad dressing
- sauces such as tomato, chili, and soy
- condiments
- garlic
- lemons
- herbs and spices.

### *Substitutions and adjustments*

Allowable diet adjustments include swapping the mid-day and evening meals or distributing the diet components differently over the course of the day. However the quantities and total intake should be the same each day. Other lean protein food can be substituted for meat. For example, a dinner might include 3.5 oz (100 g) of meat, chicken, or fish and a vegetable protein such as 4.5 oz (130 g) of cooked beans or 3.5 oz (100 g) of tofu. Eggs are protein foods and one egg can be substituted for 1.7 oz (50 g) of lean meat, chicken, turkey, ham, pork, fish, or low-lat cheese. Soy-milk products or low-lactose milk products may be used for the dairy requirement.

Allowable substitutions within food groups include:

- eggs for other protein
- non-dairy products for dairy
- rice or beans for bread
- toast for cereal
- frozen, canned, or dried fruit or vegetables for fresh fruit
- milk or yogurt for other dairy
- fruit juice for fruit
- vegetable juice for vegetables
- avocados or nuts for fats and oils
- other drinks or snacks for wine.

Wholegrain bread should be high in **fiber**, containing at least 3 g per serving. Wholegrain means that all of the components of the grain—the bran, germ, and endosperm—are present. One of the two daily slices of bread may be replaced with:

- one-third–one-half cup of chickpeas, lentils, or beans
- two pieces of crispbread
- one medium potato (about 5.3 oz or 150 g)
- one-third cup of cooked rice or noodles
- one-half cup of cooked pasta.

A low-fat coffee drink may be substituted for a similar drink such as tea with low-fat milk. Cocoa and herbal tea are on the 'free' list.

### *Vegetarians*

Vegetarians can substitute cooked beans or lentils (9 oz, 260 g) or tofu (7 oz, 200 g) for meat, chicken, or fish (7 oz, 200 g). One egg can be substituted for 1.7 oz (50 g) of meat, ham, pork, chicken, turkey, fish, or low-fat cheese. Legumes, including beans, split peas, lentils, and chickpeas, or tofu or other **soy** products can also be substituted for red meat. Vegetarians can substitute two eggs or 3.5 oz (100 g) of low-fat cheese for the 3.5 oz (100 g) of the lunch protein requirement.

### *Eating out*

When choosing from a restaurant menu the TWD recommends foods that are:

- grilled
- steamed
- poached
- stir-fried.

Foods to be avoided include:

- deep-fried
- pan-fried
- battered
- crumbed
- sauces with cheese, oil, butter, or cream
- fried potatoes.

### *Maintenance diet*

The weekly menu plans are repeated until the desired weight loss is achieved and then a maintenance plan is implemented. The maintenance plan is the same as the weekly diet plan with the addition of about 120 calories (500 kilojoules) to the diet, as long as weight is not regained. Each week the following foods can be added back in any order:

- week 1: two slices of wholegrain bread daily
- week 2: one-half cup cooked rice or pasta
- week 3: extra milk such as low-fat milk, yogurt, ice cream
- week 4: an extra potato
- week 5: an extra snack food
- week 6: one extra restaurant meal.

Snack choices for the maintenance diet include:

- 0.7 oz (20 g) of nuts
- two plain sweet biscuits
- one–two wholegrain biscuits or crackers and low-fat cheese
- 2 oz (56 g) of chips in canola or olive oil
- part of an avocado
- one fruit bar.

On the maintenance diet the following foods may be exchanged:

- 8 oz (250 ml) of wine or 2 fl oz (60 ml) of other alcohol for one snack
- one medium potato with skin, 2 oz (56 g) of fries, or 0.7 oz (20 g) of pretzels for one slice of bread or one piece of fruit
- three-quarter cup of boiled pasta or rice for two slices of bread
- 2 oz (56 g) or ten small squares of chocolate for one snack
- one fruit bar for one piece of fruit.

### *The books*

*The CSIRO Total Wellbeing Diet* explains and details the diet and contains over 100 recipes. *Book 2* includes some revisions and additions:

- The caloric intake is slightly higher.
- Calcium intake is increased by an extra daily serving of dairy.

- The daily folic-acid intake is increased to 400 mcg for adults and 600 mcg for pregnant and breastfeeding women.
- Eighty new recipes and substitutions have been added.
- Twelve weeks of sample menu plans give examples of how to organize the diet.
- New tips on eating out and packing a lunch are included.
- A simple, structured, do-anywhere exercise plan has been added.
- There is a section on maintaining focus on the diet.

## Function

The TWD is designed to result in a weight loss of 1–2 lbs (0.5–1 kg) per week. The subsequent maintenance diet is designed to maintain the desired weight. The higher protein in the TWD helps control appetite and prevent muscle loss. The TWD can be used to feed an entire family, although family members who do not need to lose weight may eat more carbohydrates with their meals, such as extra bread, pasta, rice, or potatoes.

## Benefits

Because the TWD diet is high in protein, it tends to satisfy hunger and prevent overeating. Men, in particular, seem to appreciate the amount of meat in this diet. It provides nutrients such as **iron**, **zinc**, and **calcium** that may be minimal on a lower-protein diet. There are additional benefits from a high-protein meat diet:

- Lean red meat is the best source of well-absorbed iron and meat is rich in zinc.
- Iron and zinc, which help boost the immune system, are more easily absorbed from meat than from plant foods.
- Meat, poultry, fish, and eggs are excellent sources of vitamin $B_{12}$, which is not found in plants.
- Fish and seafood are the best sources of omega-3 fats, which help protect the heart. Beef and lamb are the next best sources.

The TWD can significantly reduce **triglycerides** and LDL ('bad') cholesterol. Sustained weight loss, exercise, and moderate alcohol intake can increase HDL ('good') cholesterol. Therefore CSIRO researchers believe that the high protein in the TWD may help prevent heart disease and type 2 diabetes. Some experts also consider the TWD superior to other diets because it calls for a fiber intake in excess of 28 g per day.

The TWD has other advantages:

- It includes a large variety of foods.
- It is a very flexible diet and allows many substitutions.
- Daily meals can be consumed in any order.
- Tested recipes and menus are available online.
- Shopping lists can be downloaded from the CSIRO Website.
- The TWD is designed for long-term maintenance.

## Precautions

Dr. Rosemary Stanton, a leading Australian nutritionist, has pointed out that the high amount of red meat in the TWD contradicts the Australian government's own recommendations. Whereas the *Australian Guide to Healthy Eating* recommends 2–4 oz (56–112 g) of lean red meat three–four times per week, the TWD prescribes more than twice that amount. Consumers may be confused by these descrepancies. In addition, the trade organization Meat and Livestock Australia provided CSIRO with research funds and heavily promoted the book, suggesting possible conflicts of interest. Vegetarians in particular may have a difficult time following the TWD.

The TWD was based on clinical studies of overweight women, some of whom had metabolic dysfunction. Therefore the advantages of the TWD for men and healthy women are unclear.

CSIRO claims that the TWD is suitable for pregnant and **breastfeeding** women. However breastfeeding women may need up to 700 extra calories (3,000 extra kilojoules) per day. CSIRO recommends that breastfeeding women should start with level 1 or 2 and include three servings of dairy for calcium. Additional bread and fruit can be added to satiate hunger and increase energy. Furthermore, because of the large amount of fish and seafood in the diet, pregnant women should check for the types of fish that are safe to eat during pregnancy.

The TWD is suitable for overweight children, as long as it includes three units of dairy. However a dietician should adjust the number of calories for the age, size, and activity level of the child.

CSIRO claims that the TWD can be used effectively by people with diabetes, **celiac disease** (gluten intolerance), **fructose intolerance**, and **irritable bowel syndrome**. However diabetics should consult their doctor or dietician before using the TWD. People with gluten intolerance should choose gluten- or wheat-free substitutes or substitute rice, beans, chickpeas, or lentils for bread. Those with irritable bowel syndrome may substitute a lower-fiber cereal and take

## QUESTIONS TO ASK YOUR DOCTOR

- Am I a person who would be expected to lose weight and maintain my health and weight loss on the TWD?
- Do I have symptoms of 'syndrome X'?
- Should I be eating such a large amount of protein?
- Should I be eating such a large amount of meat?
- Have you had other patients try the TWD?
- Are there other types of diets that I should consider?

psyllium supplements of 30 g per day to obtain adequate fiber. CSIRO recommends that a dietician be consulted if significant adjustments to the diet are required.

The TWD was designed for foods readily available to Australians and assumes the intake of significant amounts of processed foods. It is not suitable for societies and cultures with eating habits that are very different from those of Australians. A high-carbohydrate diet may be better suited to those who prefer to not eat large amounts of protein.

### Risks

Although many people find it relatively easy to lose weight on high-protein low-carbohydrate diets during the first few weeks, some people find it difficult to maintain a diet that is high in meat. In addition some dieters find it difficult to maintain low-carbohydrate diets.

Nutritionist Patrick Holford has argued in the prestigious scientific journal *Nature* that the abnormally high amount of meat in the TWD could lead to long-term health problems, such as breast or **prostatecancer**, kidney stress, or reduced bone mass. Although some research has suggested that diets high in meat can increase the risk of colon cancer, other research has contradicted this or suggested that the risk is associated only with high-fat processed meat, which is not a part of the TWD.

### Research and general acceptance

#### *Research*

The TWD is based on research conducted by physicians at CSIRO, a highly-respected organization. Earlier research had indicated that high-protein diets were at least as good, if not better, for women than high-carbohydrate diets, in terms of weight loss and muscle preservation. As of 2007 CSIRO had completed five studies on the TWD, one funded by Meat and Livestock Australia and one by the dairy industry. The other studies were funded by CSIRO. According to CSIRO, their research proves that the TWD:

- is safe
- leads to improved nutritional status
- results in weight loss
- lessens the risk factors for diabetes and heart disease.

In the initial CSIRO study, 100 overweight and obese women were divided into two groups. One group was placed on a high-protein low-fat diet and the other group on a high-carbohydrate low-fat diet for 12 weeks. The **high-protein diet** consisted of 34% protein, 20% fat, and 46% carbohydrate. The high-carbohydrate diet consisted of 17% protein, 20% fat, and 63% carbohydrate. The caloric content of each diet was the same. The researchers monitored weight loss, changes in body composition, vitamin-$B_{12}$ status, bone-turnover markers, and disease-risk factors including LDL cholesterol and triglycerides.

Although on average the women in each group lost the same amount of weight—18–20 lb (8–9 kg)—women with high triglyceride levels lost significantly more weight on the high-protein diet. Only women with high triglycerides lost more abdominal fat than the women on the high-carbohydrate diet. The two groups of women did not differ in the other benchmarks that were examined. The researchers did find that more women dropped off the high-carbohydrate diet and that the women appeared to prefer the high-protein diet.

In subsequent studies CSIRO found that women with symptoms of 'syndrome X,' also called metabolic syndrome, a condition that increases the risk of developing heart disease and type 2 diabetes, lost more weight and twice the amount of body fat on a high-protein low-fat diet, as compared with similar women on a high-carbohydrate low-fat diet. It was pointed out in *Nature* that the TWD proved superior to the high-carbohydrate diet only for the subpopulation of overweight women with this type of metabolic dysfunction.

As of 2007, CSIRO was expanding its studies on the TWD to include male volunteers. However the TWD has not been compared with other alternative diets. In particular CSIRO has been criticized for not comparing the TWD to a high-protein vegetarian diet or comparing a high-protein vegetarian diet with a high-carbohydrate vegetarian diet. Furthermore the

long-term maintenance of weight loss with the TWD has not been determined.

### *General acceptance*

*The CSIRO Total Wellbeing Diet* became the number-one bestselling book in Australia when it appeared in 2005. Over 600,000 copies were sold in the first year, making it the fastest-selling book ever in that country. Since the diet is based on research from Australia's leading scientific agency and the books were written by internationally known scientists, many consumers have taken its advice very seriously. The scientific team that performed the research was awarded the 2005 CSIRO Research Achievement Medal. However the popularity of the diet has been primarily limited to Australia, in part because Australians tend to eat higher amounts of protein, particularly meat.

Many people object to the amount of meat in the TWD, from a health standpoint, from a cost standpoint, and because of the environmental consequences of producing large quantities of meat.

## DASH diet

### Definition

DASH stands for the Dietary Approaches to Stop **Hypertension**. The DASH diet is based on DASH Study results published in 1997. The study showed that a diet rich in fruits, vegetables and low fat dairy foods, with reduced saturated and total fat could substantially lower blood pressure. It is the diet recommended by the National Heart, Lung and Blood Institute (part of the National Institute of Health) for lowering blood pressure

### Origins

High blood pressure affects about one in four in the United States and United Kingdom and is defined as blood pressure consistently above 140/90 mmHg. The top number, 140, is the systolic pressure exerted by the blood against the arteries while the heart is contracting. The bottom number, 90, is the diastolic pressure in the arteries while the heart is relaxing or between beats. The concern is the higher the blood pressure, the greater the risk for developing heart and kidney disease and stroke. High blood pressure is known as the silent killer as it has no symptoms or warning signs.

The DASH study by the National Lung, Blood and Heart Institute (NHLBI), published in the *New England Journal of Medicine* in 1977, was the first study to look at the effect a whole diet rich in potassium, **magnesium** and **calcium** foods, not supplements, had on blood pressure.

The study involved 459 adults with and without high blood pressure. Systolic blood pressures had to be less than 160 mm Hg and diastolic pressures 80 to 95 mm Hg. Approximately half the participants were women and 60% were African Americans. Three eating plans were compared. The first was similar to a typical American diet—high in fat (37% of calories) and low in fruit and vegetables. The second was the American Diet, but with more fruits and vegetables. The third was a plan rich in fruits, vegetables, and low fat dairy foods and low fat (less than 30% of calories). It also provided 4,700 mg potassium, 500 mg magnesium and 1,240 mg calcium per 2,000 calories. This has become known as the DASH diet. All three plans contained equal amounts of **sodium**, about 3,000 mg of sodium daily, equivalent to 7 g of salt. This was approximately 20% below the average intake for adults in the United States and close to the current salt recommendations of 5–6 g. Calorie intake was adjusted to maintain each person's weight. These two factors were included to eliminate salt reduction and weight loss as potential reasons for any changes in blood pressure. All meals were prepared for the participants in a central kitchen to increase compliance on the diets.

Results showed that the increased fruit and vegetable and DASH plans lowered blood pressure, but the DASH plan was the most effective. It reduced blood pressure by 6 mmHg for systolic and 3 mmHg for diastolic, those without high blood pressure. The results were better for those with high blood pressure–the drop in systolic and diastolic was almost double at 11 mmHg and 6 mmHg respectively. These results showed that the DASH diet appeared to lower blood pressure as well as a 3 g salt restricted diet, but more importantly, had a similar reduction as seen with the use of a single blood pressure medication. The effect was seen within two weeks of starting the DASH plan, which is also comparable to treatment by medication, and continued throughout the trial. This trial provided the first experimental evidence that potassium, calcium, and magnesium are important

**DASH Eating Plan**

| Food group | Daily servings | Serving sizes |
|---|---|---|
| Grains* | 6–8 | 1 slice bread<br>1 oz. dry cereal†<br>½ cup cooked rice, pasta, or cereal |
| Vegetables | 4–5 | 1 cup raw leafy vegetable<br>½ cup cut-up raw or cooked vegetable<br>½ cup vegetable juice |
| Fruits | 4–5 | 1 medium fruit<br>¼ cup dried fruit<br>½ cup fresh, frozen, or canned fruit<br>½ cup fruit juice |
| Fat-free or low-fat milk and milk products | 2–3 | 1 cup milk or yogurt<br>1½ oz cheese |
| Lean meats, poultry, and fish | 6 or less | 1 oz cooked meats, poultry, or fish<br>1 egg |
| Nuts, seeds, and legumes | 4–5 per week | ⅓ cup or 1½ oz nuts<br>2 Tbsp peanut butter<br>2 Tbsp or ½ oz seeds<br>½ cup cooked legumes (dry beans and peas) |
| Fats and Oils | 2–3 | 1 tsp soft margarine<br>1 tsp vegetable oil<br>1 Tbsp mayonnaise<br>2 Tbsp salad dressing |
| Sweets and added sugars | 5 or less per week | 1 Tbsp sugar<br>1 Tbsp jelly or jam<br>½ cup sorbet, gelatin<br>1 cup lemonade |

*Whole grains are recommended for most grain servings as a good source of fiber and nutrients.
†Servings sizes vary between ½ cups, depending on cereal type. Check the product's Nutrition Facts label.

dietary factors in determinants of blood pressure than sodium alone.

The original DASH plan did not restrict sodium. As a result, a second DASH-Sodium trial from 1997-1999 (published 2001) looked at the effect the DASH diet with different sodium levels (3,300, 2,300 or 1,500mg) had on blood pressure. This is known as the DASH-sodium diet. The highest amount recommended by the 2005 U.S. **dietary guidelines** is 2,300 mg. The amount recommended by the Institute of Medicine, as a minimum to replace the amount lost through urine and to achieve a diet that provides sufficient amounts of essential nutrients, is 1,500 mg. The results showed that the combined effect of a lower sodium intake with the DASH diet was greater than just the DASH diet or a low salt diet. Like earlier studies, the greatest effect was with the lower sodium intake of 1,500mg (4 g or 2–3 tsp of salt), particularly for those without hypertension. For this group, the systolic dropped about 7.1 mmHg and the diastolic about 3.7 mmHg. However, the reduction in blood pressure for hypertensives was 11.5 mmHg for systolic and 5.7 mmHg for diastolic, quite similar to the reductions seen with the DASH diet.

## Description

The diet is based on 2,000 calories with the following nutritional profile:

- Total fat: 27% of calories
- Saturated fat: 6% of calories
- Protein: 18% of calories
- Carbohydrate: 55% of calories
- Cholesterol: 150 mg
- Sodium: 2,300 mg
- Potassium: 4,700 mg
- Calcium: 1,250 mg
- Magnesium: 500 mg
- Fiber: 30 g

These percentages translate into more practical guidelines using food group servings.

- Grains and grain products: 7-8 servings per day. One serving is equivalent to one slice bread, half a cup of dry cereal or cooked rice or pasta. These foods provide energy, carbohydrate and fiber.
- Vegetables: 4-5 servings per day. One serving size is one cup leafy vegetables, half cup cooked vegetables, half cup vegetable juice. Fruits and vegetables provide potassium, magnesium and fiber. Consuming the full number of vegetable servings is a key component of the diet.
- Fruits: 4-5 servings per day. One serving is one medium fruit, half cup fruit juice, one-quarter cup dried fruit.
- Low fat dairy foods: 2-3 servings per day. One serving is equivalent to one cup milk or yogurt or 1 oz (30 g) cheese. Dairy provides rich sources of protein and calcium.
- Meat, fish, poultry: 2 or fewer servings per day. One serving is 2.5 oz (75 g). The emphasis is on lean meats and skinless poultry. These provide protein and magnesium.
- Nuts, seeds, and beans: 4-5 servings a week. Portion sizes are half cup cooked beans, 2 tbl seeds, 1.5 oz (40 g). These are good vegetable sources of protein, as well as magnesium and potassium.
- Fats and oils: 2-3 servings per day. One serving is 1 tsp oil or soft margarine. Fat choices should be heart healthy unsaturated sources (canola, corn, olive or

## KEY TERMS

**Cardiac arrhythmia**—A group of conditions in which the muscle contraction of the heart is irregular or is faster or slower than normal.

**Cochrane reviews**—Evaluations based on the best available information about healthcare interventions. They explore the evidence for and against the effectiveness and appropriateness of treatments in specific circumstances.

**Dietary guidelines for Americans**—Dietary guidelines published every five years since 1980 by the Department of Health and Human Services (HHS) and the U.S. Department of Agriculture (USDA). They provide authoritative advice for people two years and older about how good dietary habits can promote health and reduce risk for major chronic diseases. They serve as the basis for federal food and nutrition education programs.

**High density lipoprotein (HDL)**—Often referred to as good cholesterol. HDL carries cholesterol away from cells and back to the liver where it is broken down or excreted.

**Hypertensives**—Individuals with high blood pressure.

**Low density lipoprotein (LDL)**—Often referred to as bad cholesterol. It carries cholesterol from the liver to the cells and can cause harmful build-up of cholesterol.

**MyPyramid**—A guide of what to eat each day created by the U.S. Department of Agriculture based on the 2005 dietary guidelines for Americans.

**Normotensives**—Individuals with normal blood pressure.

**PREMIER Study**—A research study that tested the effects of comprehensive and simultaneous lifestyle changes on blood pressure—weight loss, exercise, and a healthy diet.

sunflower). Saturated and trans fat consumption should be decreased.

- Sweets: 5 servings a week. A serving is 1 tbl pure fruit jam, syrup, honey, and sugar. The plan still allows for treats, but the healthier the better.

An example breakfast menu is: cornflakes (1 cup) with 1 tsp sugar, skimmed milk (1 cup), orange juice (1/2 cup), a banana and a slice of whole wheat bread with 1-tablespoon jam. Suggested snacks during the day include dried apricots (1/4 cup), low fat yogurt (1 cup) and mixed nuts (1.5 oz, 40g).

These guidelines are available in the National Institutes of Health (NIH) updated booklet "Your Guide to Lowering Your Blood Pressure with DASH", which also provides background information, weekly menus, and recipes.

Although the DASH diet provides two to three times the amount of some nutrients currently consumed in the average American diet, the recommendations are not dissimilar to the 2005 U.S. dietary guidelines (United States Department of Agriculture (USDA) and U.S. Department of Health and Human Services). It also resembles the **USDA Food Guide Pyramid**, which advocates low-fat dairy products and lean meats. The main difference is the emphasis on more fruit and vegetables servings, 8 to 10 as opposed to the 5 to 13 as in the U.S. dietary recommendations. In addition, it separates nuts, seeds, and beans from the meat, fish, and poultry food groups and recommends four to five weekly servings of nuts, seeds, and dry beans.

The Dash diet was not designed for weight loss but it can be adapted for lower calorie intakes. The NIH booklet provides guidelines for a 1,600-calorie diet. Vegetarians can also use the diet, as it is high in fruits, vegetables, beans, seeds, and low-fat dairy, which are the main sources of **protein** in a vegetarian diet.

### Function

The DASH meal plan is a healthy diet recommended for those with and without high blood pressure.

### Benefits

The DASH diet may lower blood pressure as much as taking medication, but without the risk of unwanted side effects. The dietary changes can also have immediate effects comparable with drug therapy. A blood pressure reduction of the degree seen in the DASH study is estimated to reduce the incidence of coronary artery disease by 15% and stroke by 27%.

The DASH plan may also lower blood pressure as well as restrictive low salt diets with 3-4 g of salt per day. Low salt foods tend to be bland and with 75-80% of salt intake coming from salt added to processed foods, including baked foods such as breads, adherence may pose a problem with low salt diets. The DASH diet is an adaptation on healthy eating, so it

has no restrictions but follows standard dietary guidelines for the general public.

## Precautions

Adding high **fiber** foods to the diet should be done gradually to avoid side effects such as gas, bloating, and diarrhea. It is important to increase fluid at the same time, as fiber draws **water** into the bowel. High fiber with inadequate fluid can cause hard stools and **constipation**.

Increasing fruits and vegetables increases the potassium content of the diet. For healthy people with normal kidney function, a higher potassium intake from foods does not pose a risk as excess potassium is excreted in the urine. However, individuals whose urinary potassium excretion is impaired, such as those with end-stage renal disease, severe heart failure, and adrenal insufficiency may be at risk of hyperkalaemia (high levels of potassium in the blood). Hyperkalaemia may cause cardiac arrthymias (irregular heart beat), which could be serious. Some common drugs can also decrease potassium excretion. Individuals at risk should consult a doctor before staring the DASH diet, as higher potassium intakes in the form of fruit and vegetables may not be suitable. Care should also be taken with potassium containing salt substitutes.

## Risks

Currently, there are no known risks associated with the DASH diet. However, the long-term effects of the diet on morbidity and mortality are still unknown.

## Research and general acceptance

Studies over the years have suggested high intakes of salt play a role in the development of high blood pressure so dietary advice for the prevention and lowering of blood pressure has focused primarily on reducing sodium or salt intake. A 1989 study looked at the response an intake of 3-12 g of salt per day had on blood pressure. The study found that modest reductions in salt, 5-6 g salt per day caused blood pressures to fall in hypertensives. The best effect was seen with only 3 g of salt per day with blood pressure falls of 11 mmHg systolic and 6 mmHg diastolic. More recently, the use of low salt diets for the prevention or treatment of high blood pressure has come into question. The Trials of Hypertension Prevention Phase II in 1997 indicated that energy intake and weight loss were more important than the restriction of dietary salt in the prevention of hypertension. A 2006 Cochrane review, which looked at the effect of longer-term modest salt reduction on blood pressure, found that modest reductions in salt intake could have a significant effect on blood pressure in those with high blood pressure, but a lesser effect on those without. It agreed that the 2007 public health recommendations of reducing salt intake from levels of 9-12 g/day to a moderate 5-6 g/day would have a beneficial effect on blood pressure and cardiovascular disease.

The effectiveness of the DASH diet for lowering blood pressure is well recognized. The 2005 Dietary Guidelines for Americans recommends the DASH Eating Plan as an example of a balanced eating plan consistent with the existing guidelines and it forms the basis for the USDA MyPyramid. DASH is also recommended in other guidelines such as those advocated by the British Nutrition Foundation, American Heart Association, and American Society for Hypertension.

Although results of the study indicated that reducing sodium and increasing potassium, calcium, and magnesium intakes play a key role on lowering blood pressure, the reasons why the DASH eating plan or the DASH-Sodium had a beneficial affect remains uncertain. The researchers suggest it may be because whole foods improve the absorption of the potassium, calcium and magnesium or it may be related to the cumulative effect of eating these nutrients together than the individual nutrients themselves. It is also speculated that it may be something else in the fruit, vegetables, and low-fat dairy products that accounts for the association between the diet and blood pressure.

The Salt Institute supports the DASH diet, but without the salt restriction. They claim that the DASH diet alone, without reduced sodium intake from manufactured foods, would achieve the desired blood pressure reduction. Their recommendation is based on the fact that there are no evidence-based studies supporting the need for dietary salt restriction for the entire population. The Cochrane review in 2006 showed that modest reductions in salt intake lowers blood pressure significantly in hypertensives, but a lesser effect on individuals with normal blood pressure. Restriction of salt for those with out hypertension is not recommended.

There is continued call for the food industry to lower their use of salt in processed foods from governments and health associations. These groups claim if the reduction of intake to 6 g salt/day is achieved by gradual reduction of salt content in manufactured foods, those with high blood pressure would gain significant health benefit, but nobody's health would be adversely affected. In 2003, the UK Department of Health and Foods Standards Agency, several leading supermarkets and food manufacturers set a target for

an average salt reduction of 32% on 48 food categories. In June 2006, the American Medical Association (AMA) appealed for a minimum 50% reduction in the amount of sodium in processed foods, fast food products, and restaurant meals to be achieved over the next ten years.

Researchers have evaluated other dietary modifications, such as the role of potassium, magnesium, and calcium on blood pressure. Substantial evidence shows individuals with diets high in fruits and vegetables and, hence, potassium, magnesium, and calcium, such as vegetarians, tend to have lower blood pressures. However, in studies where individuals have been supplemented with these nutrients, the results on their effects on blood pressure have been inconclusive.

There is some debate on whether patients can follow the diet long-term. The 2003 premier study (a multi-center trial), which included the DASH diet when looking at the effect of diet on blood pressure, found that the DASH diet results were less than the original study. This difference is thought to be because in the DASH study participants were supplied with prepared meals, while participants on the premier study prepared their own foods. As a result, only half the fruit and vegetable intake was achieved in the premier study, which affected the overall intakes of potassium and magnesium. The researches concluded that compliance to the DASH diet in the long term is questionable, but agreed that patients should still be encouraged to adopt healthy interventions such as the DASH diet, as it does offer health benefits.

In terms of heart health, the Dash diet lowered total cholesterol and LDL cholesterol, but it was associated with a decrease in high-density lipoprotein (HDL), the "good" cholesterol. Low HDL levels are considered a risk factor for **coronary heart disease** (CHD) while high levels are thought to be protective of heart disease. The decrease was greatest in individuals who started with a higher level of the protective HDL. Researchers agree that the reasons for the decrease in HDL levels needs further review, but concluded that the overall effects of the DASH diet are beneficial to heart disease.

While long term health effects of the DASH diet are yet to be established, the diet closely resembles the **Mediterranean diet**, which has been shown to have other health benefits including a reduced risk for heart disease and **cancer** rates. It is thought that the DASH diet is likely to offer similar health benefits.

## QUESTIONS TO ASK YOUR DOCTOR

- How will the Dash diet impact my need for blood pressure medication?
- What foods are recommended for the DASH diet?
- What is your opinion on using the DASH diet for weight loss?
- What modifications are necessary to accommodate vegetarians?
- How long will I need to stay on the DASH diet?

# Dean Ornish's Eat More, Weigh Less

## Definition

Dean Ornish's Eat More, Weigh Less diet focuses on eating a diet of plant products low in fat, oils, and simple **carbohydrates** to achieve weight loss and better health without feelings of deprivation and hunger. It also emphasizes stress reduction techniques and light exercise. Dean Ornish, M.D. not only recommends this style of diet for weight loss, but also believes it can prevent and even reverse some forms of heart disease.

## Origins

Dean Ornish is a professor of clinical medicine at the University of California, San Francisco, and a practicing physician. He received his Bachelor of Arts degree from the University of Texas, Austin, then attended Baylor College of Medicine and Harvard Medical School. He received further medical training at Massachusetts General Hospital. He is the founder and president of the Preventive Medicine Research Institute located in Sausalito, California.

While Dr. Ornish was a medical student he became interested in heart disease. In 1978 he began doing research on patients with coronary artery disease (a common form of heart disease). He created a diet that was very low in fat and completely vegetarian and studied its effects on the symptoms experienced by these patients. The patients also learned a variety of stress reduction techniques. He discovered that for many patients this diet caused a significant lessening of their symptoms. This was the beginning of Dr. Ornish's research on the effects of low fat, low or no-meat diets on weight loss, health, and heart disease. This original diet is the basis for his Eat More, Weigh Less diet, as well as his other related diets.

Over the years, Dr. Ornish has published many different books and articles, and has recommended diets with many different names. All his diets revolve around the same basic principles, with additions or changes in emphasis, based on the goal that the diet is intended to achieve. For example, Dr. Ornish's heart disease prevention diet allows small amounts of lean meat or fish, while his heart disease reversal diet is completely vegetarian.

## Description

Dr. Ornish presents his Eat More, Weigh Less diet as more of a spectrum of choices than a set of hard and fast rules. He believes that because people have many different goals, from moderate weight loss to actual heart disease reversal, no one set of dietary rules will fit everyone. He also emphasizes overall lifestyle change, not just through what a person eats but also through stress reduction, moderate exercise, and if applicable, quitting smoking.

The main component of the Dr. Ornish diet is eating more vegetable products and many fewer meat products. For people trying to lose moderate amounts of weight this may mean eating small amounts of lean chicken or fish as well as some skim milk or egg whites. For those with more ambitious goals, the diet may be almost completely vegan (containing no meat or animal products at all).

The diet is also extremely low in fat, with fewer than 10% of calories coming from fat. The strictest forms of the diet do not allow any nuts, seeds, or avocados. The only oil Dr. Ornish allows is a small amount of fish oil

## KEY TERMS

**Antioxidant**—A molecule that prevents oxidation. In the body antioxidants attach to other molecules called free radicals and prevent the free radicals from causing damage to cell walls, DNA, and other parts of the cell.

**Coronary Artery**—The arteries that supply blood to the tissues of the heart from the aorta.

**Mineral**—An inorganic substance found in the earth that are essential to the body in small quantities. Examples: zinc, copper, iron.

**Vegan**—A diet containing no meat or animal products.

**Vitamin**—A nutrient the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

each day because some research has shown it to be beneficial and may help prevent heart attack.

Foods that are encouraged include nearly all fruit and vegetable products. Especially recommended are leafy greens, **soy** products, and whole grains. Whole grains contain many **vitamins** and **minerals** that are removed when these grains are processed. Whole grains include things such as brown rice, oat bran, and wheat bran. They are broken down by the body more slowly than processed grains, meaning that energy is released more slowly and is available for a longer period of time.

A portion of food made up of processed foods and animal products usually contains many more calories and fat than a similarly sized portion consisting mainly of vegetables, whole grains, fruits, and soy. This means that a person can eat a larger quantity of food while still consuming fewer calories and fat if the foods are chosen correctly. This is the key to the idea that on Dr. Ornish's diet a person may be able to actually eat more and still lose weight. Eating more foods low in caloric density (calories per quantity) means the stomach is fuller and helps prevent feelings of hunger.

Dr. Ornish's diet does not just focus on food. It also makes recommendations for other lifestyle changes. He recommends moderate exercise of 20 to 30 minutes daily of at least a moderate walking pace. Dr. Ornish also suggests making small changes throughout the day to get more exercise, such as parking a few spaces further from the door, or even just walking up or down the stairs instead of taking the elevator. This kind of daily exercise adds up and is recommended over working out strenuously only occasionally.

Stress-reduction techniques are an important part of the total lifestyle plan. Dr. Ornish contends that doing even a few minutes of yoga, deep breathing, or meditation each day can have many positive effects on both the body and mind. Dr. Ornish also highly recommends that individuals quit smoking.

### Function

Dr. Ornish's diet can be used for weight loss, or for a variety of other healthy living goals including prevention or possible reversal of heart disease.

### Benefits

Because this diet includes almost only plant products, it is high in substances thought to promote health such as **antioxidants** and **fiber**, as well as low in substances that are harmful to the health such as fat and cholesterol. Following the diet's recommendation of light exercise can also be very beneficial. Walking 20 or 30 minutes a day instead of being completely sedentary has significant health benefits and may even reduce the chance of early death by half.

Although Dr. Ornish's diets are effective at causing weight loss and improved overall health, the most researched and discussed benefit of his diet program is the prevention and even reversal of heart disease. Dr. Ornish and colleagues have done extensive research showing that following a very strict, completely vegetarian form of his diet can not only prevent heart disease from occurring or getting more severe, but can actually cause a reversing of artery constriction allowing blood to flow to the heart better. Dr. Ornish also believes his diet may be effective at preventing or reversing other forms of disease such as **prostate cancer**.

### Precautions

Anyone thinking of beginning a new diet should consult their physician. Requirements of calories, fat, and nutrients can differ significantly from person to person, depending on gender, age, weight, and many other factors such as the presence of any diseases or conditions. Pregnant or **breastfeeding** women should be especially cautious because deficiencies of vitamins or minerals can have a significant negative impact on a baby.

Patients with heart disease should be especially careful when beginning a diet. Although Dr. Ornish has published data about how his diet may be able to

prevent or reverse heart disease, everyone reacts differently and no major dietary changes should be made without consulting a physician. Dr. Ornish's diet is not a replacement for cholesterol-lowering drugs or any other medications prescribed by a doctor, and is not a replacement for medically recommended procedures. It is important to discuss all possible options with a physician and make all decisions based on professional recommendations.

### Risks

Dr. Ornish's diet is very low in fat and limits meat and animal product intake to little or none. Many important vitamins and minerals such as **zinc** and vitamin $B_{12}$ are acquired from these sources in a normal diet. Without these sources there is a significant possibility of deficiency. Also, because of the very low fat allowance of the diet there is some concern that people on this diet may not get enough **vitamin E**, which is found mainly in nuts and oil. These are too high in fat to be eaten regularly while on this diet. Dr. Ornish often recommends taking supplements while following his diet, and taking a complete multivitamin may help reduce the risk of a deficiency. Multivitamins and supplements however have their own risks, especially for pregnant or breastfeeding women and individuals with medical issues such as renal disease.

### Research and general acceptance

The benefits of any diet low in fat that includes many different fruits, vegetables, and whole grains are generally accepted. However, some concern has been expressed about Dr. Ornish's Eat More, Weigh Less diet because of dietary deficiencies that may occur due to the restriction of so many food types. For some people this cause for concern may outweigh the possible benefits.

One benefit of the Dr. Ornish diet that he and other researchers have studied extensively is the possible prevention or reversal of heart disease in some people. Dr. Ornish has led many controlled research studies to test his diet, and published the results in peer-reviewed journals such as the *Journal of the Society of Behavioral Medicine*, the *Lancet*, and the *Journal of the American Medical Association*.

In 1990, Dr. Ornish and several coauthors published an article titled "Can Lifestyle Changes Reverse Coronary Heart Disease? The Lifestyle Heart Trial" in the *Lancet*. This was the first study to investigate whether changes in lifestyle alone, without the use of prescription drugs, could stop the progress of, or even reverse, coronary heart disease. The patients selected to participate had severe coronary heart disease and were divided randomly into two groups, those who would follow Dr. Ornish's program, and those who would follow the usual recommendations for such patients, including moderate lifestyle changes and cholesterol-lowering medications, if necessary.

Dr. Ornish's regimen included a diet very low in fat and completely vegetarian. It also emphasized moderate exercise, stress-reduction techniques, and, for those patients who smoked, quitting. The diameter of the coronary artery was measured at the beginning of the study, and again at the end of the study one year later. For patients following the usual recommendations for coronary patients, the average percentage of narrowing was 42.7% at the beginning of the study and increased 3.4% to 46.1% at the end of the study. For patients who followed Dr. Ornish's plan the average percentage of constriction was reduced 2.2% during the period of the study from 40.0% to 37.8%. For the patients with the most constriction the difference was even greater.

Since the original Lifestyle Heart Study, Dr. Ornish and various co-authors have continued to research how lifestyle changes alone can positively affect heart disease. He has also done research over longer periods of time to see if people are able to stay on his diet and continue to see positive effects. He has also studied very short time spans to see if improvement can occur very quickly. In 2007 he published a study in the *Journal of the Society of Behavioral Medicine* showing that, in as little as three months, his

### QUESTIONS TO ASK THE DOCTOR

- Is this diet the best diet to meet my goals? Why or why not?
- What special dietary needs do I have that this diet might not meet?
- What types of risk could this diet pose for me?
- What type of multivitamin or other dietary supplement would be appropriate for me if I begin this diet?
- How could I integrate this diet into our family meals?
- How long is it safe for me to follow this diet?
- What are the signs or symptoms that might indicate a problem while on this diet?

lifestyle change program could significantly reduce the risk factors of coronary heart disease.

# Dehydration

## Definition

Dehydration is a condition in which the body looses too much **water** usually as a result of excess sweating, vomiting, and/or diarrhea.

**Signs of dehydration**

**General dehydration**

- Thirst
- Less frequent urination
- Dry skin
- Fatigue
- Light-headedness
- Dark colored urine

**Dehydration in children**

- Dry mouth and tongue
- No tears when crying
- No wet diapers for 3 hours or more
- Sunken abdomen, eyes, or cheeks
- High fever
- Listlessness or irritability
- Skin that does not flatten when pinched and released

## Description

Dehydration occurs because more fluid is lost from the body than is taken in. Water is essential for life. Transporting nutrients throughout the body, removing wastes, regulating body temperature, lubrication of joints and membranes, and chemical reactions that occur during cellular **metabolism** all require water.

The amount of water a person needs to prevent dehydration varies widely depending on the individual's age, weight, level of physical activity, and the environmental temperature. The individual's health and the medications they take may also affect the amount of water a person needs. Most dehydration results from an acute, or sudden, loss of fluids. However, slow-developing chronic dehydration can occur, most often in the frail elderly and infants and young children who must rely on others to supply them with liquids.

Healthy people lose water from urination, elimination of solid wastes, sweating, and breathing out water vapor. This water must be replaced through diet. Water makes up about 75% of the body weight of infants, 65% of the weight of children and 60% of the weight of an adult. In 2004, the United States Institute of Medicine (IOM) recommended that relatively inactive adult men take in about 3.7 L (about 15 cups) of fluids daily and that women take in about of 2.7 liters (about 10 cups) to replace lost water. These recommendations are for total fluid intake from both beverages and food. Highly active adults and those living in very warm climates need more fluids.

## KEY TERMS

**Diabetes**—a condition in which the body either does not make or cannot respond to the hormone insulin. As a result, the body cannot use glucose (sugar). There are two types, type 1 and type 2.

**Diuretic**—a substance that removes water from the body by increasing urine production

**Electrolyte**—ions in the body that participate in metabolic reactions. The major human electrolytes are sodium (Na+), potassium (K+), calcium (Ca 2+), magnesium (Mg2+), chloride (Cl-), phosphate ($HPO_4$ 2-), bicarbonate ($HCO_3$-), and sulfate ($SO_4$ 2-).

**Laxative**—A substance that stimulates movement of food through the bowels. Laxatives are used to treat constipation.

About 80% of the water the average person needs is replaced by drinking liquids. The other 20% is found in food. Below are listed some foods and the percentage of water that they contain.

- iceberg lettuce 96%
- squash, cooked. 90%
- cantaloupe, raw, 90%
- 2% milk 89%
- apple, raw 86%
- cottage cheese 76%
- potato, baked 75%
- macaroni, cooked 66%
- turkey, roasted 62%
- steak, cooked 50%
- cheese, cheddar 37%
- bread, white 36%
- peanuts, dry roasted 2%

Dehydration involves more than just water deficiency. **Electrolytes** are ions that form when salts dissolve in water or body fluids. In order for cells to function correctly, the various electrolytes, such as **sodium** (Na+) and potassium (K+), must remain within a very narrow range of concentrations. Often electrolytes are lost along with water. For example sodium is lost in sweat. To prevent the effects of dehydration, both water and electrolytes must be replaced in the correct proportions.

## Demographics

The very young and the very old are most likely to become dehydrated. Young children are at greater risk because they are more likely to get diseases that cause vomiting, diarrhea, and fever. Worldwide, dehydration is the leading cause of death in children. In the United States, 400–500 children under the age of 5 die every year of dehydration. The elderly are at risk because they are less likely to drink when they become dehydrated. The thirst mechanism often becomes less sensitive as people age. Also, their kidneys lose the ability to make highly concentrated urine. Older individuals who are confined to wheelchairs or bed and cannot get water for themselves (e.g. nursing home and hospital patients) are at risk of developing chronic dehydration.

## Causes and symptoms

Diarrhea, often accompanied by vomiting, is the leading cause of dehydration. Both water and electrolytes are lost in large quantities. Diarrhea is often caused by bacteria, viruses, or parasite. Fever that often accompanies disease accelerates the amount of water that is lost through the skin. The smaller the child, the greater the risk of dehydration. Worldwide, acute diarrhea accounts for the death of about 4 million children each year. In the United States, about 220,000 children are hospitalized for dehydration caused by diarrhea annually.

Heavy sweating also causes dehydration and loss of electrolytes. Athletes, especially endurance athletes and individuals with active outdoor professions such such as roofers and road crew workers are at high risk of becoming dehydrated. Children who play sports can also be vulnerable to dehydration.

Certain chronic illnesses that disrupt fluid balance can cause dehydration. Kidney disease and hormonal disorders, such as diabetes, adrenal gland, or pituitary gland disorders, can cause fluid and electrolyte loss through excessive urination. Disorders such as cystic fibrosis or other genetic disorders resultING in inadequate absorption of nutrients from the intestines can cause chronic diarrhea that leads to dehydration. Individuals with **eating disorders** who abuse laxatives, **diuretics**, and enemas, or regularly cause themselves to vomit are vulnerable to severe electrolyte imbalances and dehydration. The same is true of people with alcoholism. People who have severe burns over a large part of their body also are likely to become dehydrated

because they no longer have skin to act as a barrier to evaporation.

Dehydration can be mild, moderate or severe. Mild dehydration occurs when fluid losses equal 3–5%. At this point, the thirst sensation is felt, and is often accompanied by dry mouth and thick saliva.

Moderate dehydration occurs when fluid losses equal 6–9% of their body weight. This can occur rapidly in young children who are vomiting and/or have diarrhea. In an infant, a loss of as little as 2–3 cups of liquids can result in moderate dehydration. Signs of moderate dehydration include intense thirst, severely reduced urine production, sunken eyes, headache, dizziness, irritability, and decreased activity.

Severe dehydration occurs when fluid losses are 10% or more of their body weight. Severe dehydration is a medical emergency for individuals of any age. A loss of fluids equaling 20% of a person's body weight is fatal. Signs of severe dehydration include all those of moderate dehydration as well as lack of sweating, little or no urine production, dry skin that has little elasticity, low blood pressure, rapid heartbeat, fever, delirium, or coma.

## Diagnosis

Dehydration is diagnosed by physical symptoms. A healthcare professional or observant adult can usually tell by looking at someone that they are moderately or severely dehydrated. Blood tests and a urinalysis may be done to check for electrolyte imbalances and to determine if the kidneys are damaged. However, visual signs are enough to begin treatment.

## Treatment

The goal of treatment is to restore fluid and electrolyte balance. For individuals with mild dehydration, this can be done in infants and children by giving them oral rehydration solutions such as Pedialyte, Infalyte, Naturalyte, Oralyte, or Rehydralyte. These are available in supermarkets and pharmacies without a prescription. These solutions have the proper balance of salts and sugars to restore the electrolyte balance. Water, apple juice, chicken broth, sodas, and similar fluids are effective in treating mild dehydration. Oral rehydration fluids can be given young children in small sips as soon as vomiting and diarrhea start. They may continue to vomit and have diarrhea, but some of the fluid will be absorbed. Breastfed infants should continue to nurse on demand. Babies who are formula fed should continue to get their regular formula unless directed otherwise by a pediatrician.

Older children who are dehydrated can be given oral rehydration solutions or sports drinks such as Gatorade for moderate and severe dehydration, otherwise general fluids are fine. Athletes who are dehydrated should be given sports drinks. According to the American College of Sports Medicine, sports drinks are effective in supplying energy for muscles, maintaining blood sugar levels, preventing dehydration, and replacing electrolytes lost in sweat. Adults who are mildly or moderately dehydrated usually improve by drinking water and avoiding coffee, tea, and soft drinks that do not contain **caffeine**.

Individuals of all ages who are seriously dehydrated need to be treated by a medical professional. In the case of severe dehydration, the individual may be hospitalized and fluids given intravenously (IV; directly into the vein).

## Nutrition/Dietetic concerns

Dehydration is usually an acute condition, and once fluid balance is restored, there are no additional nutritional concerns. In the mobility-impaired elderly, the main concern is making sure that they have adequate access to fluids.

## Prognosis

Most people recover from dehydration with few complications so long as rehydration fluids are available and treatment begins before the condition becomes severe. However, severe dehydration can be fatal.

## Prevention

The best way to prevent dehydration is to be alert to situations in which it could occur, such as exercising in hot weather or vomiting and diarrhea in infants and young children. Athletes and people who work in hot conditions should drink regularly, whether or not they feel thirsty. Rehydration of young children should begin at the first sign of fluid loss. A healthcare provider should be consulted before the situation becomes serious. Caregivers of the mobility impaired elderly and infants and young children who cannot get water for themselves should be offered fluids on a regular basis.

# Denise Austin Fit Forever

## Definition

Denise Austin's Fit Forever is an Internet based diet and exercise program that focuses on developing a personalized plan for healthy eating and an active lifestyle. Individuals who join the Fit Forever program receive customized exercise regimens based on their body type; daily meal plans and recipes; as well as motivational assistance in the form or support groups, testimonials, and information on creating a healthier lifestyle.

## Origins

Denise Austin was born on February 13, 1957, and grew up in San Pedro, California. She attended the University of Arizona on an athletic scholarship and then earned a Bachelor of Arts degree in Physical Education from California State University, Long Beach in 1979.

After college, Austin's interest in exercise and fitness continued and she became an aerobics instructor in Los Angeles. She soon began hosting her own exercise program on local television. Her popularity grew and she quickly became a national fitness personality. In 2002 she was appointed to the President's Council on Physical Fitness and Sports, and she helped the United States Department of Agriculture to develop MyPyramid and primarily serves as a spokesperson for the food guidance system that replaced the Food Guide Pyramid in 2005. Austin has sold more than 20 million exercise videos and DVDs, and written nine books. She also writes a regular column in *Prevention* magazine, and appears in two daily fitness shows on the *Lifetime* television channel.

With Fit Forever, Austin continues to try to help people become more fit, more active, and enjoy better overall health. Through the Web site she delivers many different tips, inspirational messages, and guidelines to help people personalize their program.

## Description

Denise Austin's Fit Forever program operates primarily online. It is intended to help guide individuals through the weight loss process educating them on proper nutrition, exercise, and general healthy lifestyles. It is also intended to help people maintain their new healthy lifestyle once it has been achieved. The Fit Forever program has two main components, diet and exercise. Each provides many options so that it can be tailored to meet an individual's specific needs.

The diet plan offers choices of diets that provide 1,400, 1,600, or 1,800 calories a day based on an individual's weight loss goals and activity level. Meal plans for each day are provided, as are shopping lists associated with the meal plans. Substitutions are allowed whenever they are desired, as long as each day's total caloric intake is on target. Austin provides her own diet philosophy that involves six aspects of healthy eating:

- Control portions
- Maximize fiber
- Savor good fat
- Boost fruits and vegetables
- Hone in on hunger
- Change behaviors

## KEY TERMS

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Mineral**—An inorganic substance found in the earth that is essential in small quantities for the body. Examples: zinc, copper, iron.

**Vitamin**—A nutrient the body requires in small amounts to remain healthy but the body cannot manufacture for itself and must acquire through diet.

To help control portions Austin suggests practicing until it is possible to accurately judge how much food is in one portion, and always checking nutrition labels to see how many servings are in a package. To maximize **fiber** she suggests eating a variety of high-fiber vegetables, such as fresh spinach, and whole grain foods, such as brown rice.

Denise Austin does not suggest completely cutting fat out of the diet. Instead, she suggests trying to limit foods that contain bad **fats** (i.e., saturated and trans fats) and more food that contain good fats (i.e., mono- and poly-unsaturated oils). Foods she suggests as sources of good fats include avocados, nuts, fish, and olive oil.

One of the most important aspects of Fit Forever is the emphasis on increasing fruits and vegetables in the diet. Austin provides many recipes and suggestions for eating fruits and vegetables as meals, snacks, and on-the-go treats.

Austin believes that **binge eating** and eating for reasons other than hunger are common sources of weight gain and are often the source of problems when trying to loose weight. She suggests paying more attention to the signals of hunger that the body sends, and only eating in response to those signals. Eating should not be a response to other signals such as stress or habit. She also suggests trying to remember the goal of being healthy, slim, and fit, and using that to overcome the desire to eat too much or when not actually hungry.

The behavioral changes Austin addresses in her program refer to eating for reasons other than hunger, such as stress, unhappiness, or even happiness. She recommends modifying this behavior by identifying the underlying problem for the unwanted eating behavior. Once the problem has been identified, an activity other than eating can alleviate the feeling or fix the problem. For example, if the problem is feeling overwhelmed, the activity may be talking to a close friend, taking a break, or spending some time alone. According to Austin, finding solutions that are more appropriate than food are also more likely to relieve the unwanted feelings.

Although diet is a very important part of the Fit Forever program, it only comprises about half of the overall regimen. Exercise is equally emphasized by Austin, if not more so. The Fit Forever program provides suggested exercises for beginner, intermediate, or advanced fitness levels. The program also provides exercise plans that target the midsection, upper body, or lower body. The basic workout suggested by Austin takes about 20 minutes, including stretching and cool down times. She also provides a "Body Blast" workout routine that only takes about 10 minutes, for when there is not enough time in the day for the usual workout. Daily routines and customized workouts are available online to members of the Fit Forever program. Nonmembers can access workouts using her books, videos, or television shows.

In addition to her main workout routines, Austin emphasizes the importance of getting exercise in other ways. She believes in the importance of walking regularly, and suggests ways to make it more fun such as listening to music or walking with friends. Austin encourages walking at least four times each week.

Austin believes workouts should vary throughout the week to make sure each muscle group is used. Her workouts involve cardio training to help the heart and cardiovascular system, weight training for muscle tone, and targeted workouts to focus on areas where excess fat may be a problem. She offers a variety of workouts including yoga, Pilates, a fat-burning dance mix, and boot camp interval training, and suggests ways in which shorter routines can be added or even substituted for certain parts to keep exercise interesting.

The Fit Forever diet and exercise plan includes not only suggestions about which foods to eat, and which exercises to do, but also provides motivational tips. On the Website, dieters can read messages or listen to audio clips from Austin providing encouragement and cheering them on. Individuals following the Fit Forever diet can support each other through online discussion boards. People from varying geographical areas and backgrounds can exchange helpful hints, ask questions, share frustrations and obstacles, and provide support for each another. A dietician is also available to answer questions and give advice.

## Function

The Fit Forever diet and exercise plan is intended to be a lifestyle changing regimen helping dieters lose weight and increase overall health and fitness. The diet and exercise aspects of Fit Forever are designed to be used together, with each providing increased benefits in the presence of the other. Although Fit Forever is largely about losing weight, the overall lessons of eating healthier foods and getting plenty of regular exercise are intended as long term lessons to keep weight off and provide better overall health.

## Benefits

There are many research supported benefits to eating less fat, more fiber, and more fruits and vegetables. The benefits of weight loss can be enormous. People who are obese are at higher risk of diabetes, heart disease, and many other diseases and disorders. Weight loss, if achieved at a moderate pace through a healthy diet and regular exercise can reduce the risk of these and many other obesity-related diseases.

## Precautions

Anyone thinking of beginning a new diet or exercise regimen should consult their physician. Requirements of calories, fat, and nutrients can differ significantly from person to person, depending on gender, age, weight, and many other factors such as the presence of any disease or conditions. Pregnant or **breastfeeding** women should be especially cautious because deficiencies of **vitamins** or **minerals** can have a significant negative impact on a baby. Exercise should be started gradually to see how the body responds.

## Risks

With any diet or exercise plan there are some risks. It is often difficult to get enough of some vitamins and minerals when eating a limited diet. Anyone beginning a diet may want to consult their physician or a registered dietitian about whether taking a vitamin or supplement might help them reduce this risk. Injuries can occur during exercise, such as strained or sprained muscles, and proper warm up and cool down procedures should be followed to minimize these risks. It is often best to begin with light or moderate exercise and increase the intensity slowly over weeks or months to minimize the risk of serious injury, such as heart attack, that could occur if strenuous exercise is begun suddenly and the body is not able to keep up.

## QUESTIONS TO ASK THE DOCTOR

- Why or why wouldn't this diet best meet my weight loss goals?
- At what level of intensity is it appropriate for me to begin exercising?
- What types of risks would this diet or exercise program pose for me?
- What type of multivitamin or dietary supplement would be appropriate for me if I were to begin this diet?
- How long is it safe for me to follow this diet?
- What are the signs and symptoms I should watch for after beginning this diet?

## Research and general acceptance

Denise Austin's Fit Forever has not been the subject of any significant scholarly research. However, moderately limiting caloric intake, eating a diet low in fats and **carbohydrates** and high in vegetable and plant products is generally accepted as a healthy diet for most people. The U.S. Center for Disease Control recommends a minimum of 30 minutes per day of light to moderate exercise for healthy adults. Following Austin's fitness and exercise program would meet, and in most cases exceed, this minimum recommendation.

# Detoxification diets

## Definition

Detoxification diets, or detox diets for short, are a group of short-term diets intended to release accumulated toxins and waste products from the body. They are based on a theory of digestion and elimination usually associated with naturopathy, an alternative medical system that emphasizes the role of nutrition in restoring or improving the body's own self-healing properties. In general, detox diets emphasize the following:

- Minimal intake of chemicals on or in food by choosing organic or non-processed foods
- Increased intake of fruits, vegetables, and other foods thought to aid the process of detoxification
- Increased intake of foods and fluids that speed up the processes of urination and defecation

Detoxification diets can be categorized into several subgroups: raw food diets, which are based on the premise that uncooked foods prevent the accumulation of toxins in the digestive system; mono diets, in which the dieter consumes only one or two foods (sometimes in liquid form only) for a period of 10–14 days; juice fasting, in which the dieter consumes large quantities of fruit and vegetable juices along with **water** and herbal teas for one to three days; and vegetarian or semi-vegetarian detox diets, which allow the dieter some variety of cooked whole grains, steamed vegetables, fresh fruit, and small amounts of **protein** foods as well as several glasses of water and herbal teas each day.

## Origins

Detoxification diets as a general practice can be traced back for over 5,500 years to an annual ritual of bodily and spiritual preparation known as *pancha karma*, which is part of the practice of Ayurvedic medicine in India. Ayurveda is a traditional system of health care that dates back to about 3500 BC; its name is Sanskrit for "science of long life." Pancha karma is undergone for disease prevention, which in Ayurvedic practice requires spiritual renewal and the breaking of negative emotional patterns as well as physical purification. It has three phases: a preparation phase, in which the person eliminates sweets, caffeinated drinks, and processed foods from the diet, as well as spending more time in meditation and taking walks in natural surroundings; the cleansing phase, which includes bloodletting, emesis (forced vomiting), nasal cleansing, and the use of enemas and laxatives as well as a very restricted diet of grains and vegetables; and a rejuvenation phase, in which solid foods are gradually reintroduced to the diet. Practitioners of Ayurveda in Canada and the United States generally omit vomiting and bloodletting in the second phase of pancha karma.

*(Illustration by Stanley Publishing/Thomson Gale.)*

In Europe and North America the most important factor in the popularity of detoxification diets is naturopathy, an alternative approach to health care developed out of the natural healing movement in Germany and North America in the late nineteenth century. Naturopathy is closely connected with **vegetarianism**, particularly its raw-food offshoot. Naturopaths of the twenty-first century use a variety of techniques in treating patients, including hydrotherapy, spinal manipulation, and physical therapy as well as nutrition and dietary advice. There has been a revival of interest in naturopathy in the United States since the 1980s.

Naturopaths frequently recommend detoxification diets as a way of ridding the body of various toxins that they identify as coming from several sources:

- Heavy metals. These include such substances as cadmium, arsenic, nickel, aluminum, chromium, mercury, vanadium, strontium, antimony, cobalt, and lead, which are used in various manufacturing processes and some medical procedures as well as being present in batteries, electronic equipment,

## KEY TERMS

**Amaranth**—An herb cultivated as a food crop in Mexico and South America. Its grains can be toasted and mixed with honey or molasses as a vegetarian treat.

**Ayurveda**—The traditional system of natural medicine that originated in India around 3500 BC. Its name is Sanskrit for "science of long life." Some historians of medicine think that detoxification diets can be traced back to Ayurvedic practice.

**Choline**—A compound found in egg yolks and legumes that is essential to liver function.

**Colonic**—Sometimes called colonic hydrotherapy, a colonic is a procedure similar to an enema in which the patient's colon is irrigated (washed out) with large amounts of water. This procedure is discouraged by mainstream physicians because of its potential risks to health.

**Fruitarian**—A vegetarian who eats only plant-based products (fruits, seeds, and nuts) that can be obtained without killing the plant.

**Methionine**—A crystalline amino acid found in many protein foods. It is sometimes taken as a supplement during a detox diet.

**Mono diet**—A type of detoxification diet based on the use of only one food or beverage, such as apples, grapes, lemonade, or other raw fruits or vegetables.

**Naturopathy**—A system of disease treatment that emphasizes natural means of health care, as water, natural foods, dietary adjustments, massage and manipulation, and electrotherapy, rather than conventional drugs and surgery. Naturopaths (practitioners of naturopathy) often recommend detox diets as a way of cleansing the body.

**Pancha karma**—An intensive one- to two-week ritual of detoxification practiced in Ayurvedic medicine that includes enemas, bloodletting, and nasal irrigation as well as fasting.

**Pasteurization**—A process for partial sterilization of milk or beverage juices by raising the liquid to a temperature that destroys disease organisms without changing its basic taste or appearance. Raw foodists avoid pasteurized food products.

**Pau d'arco**—A medicinal bark derived from a tree native to the Amazon rainforest. Pau d'arco is often brewed as a tea and taken as a diuretic or anti-inflammatory preparation.

**Quinoa**—An herb native to the Andes that produces starchy seeds that can be ground into flour and used as food.

**Raw foodism**—A term that refers to a group of dietary regimens composed entirely of foods that have not been raised above a certain temperature. Many raw foodists are vegans, although some eat raw meat or fish and use unpasteurized dairy products.

**Vegan**—A vegetarian who excludes all animal products from the diet, including those that can be obtained without killing the animal. Vegans are also known as strict vegetarians.

coins, cookware, food containers, and other common household items.

- Toxic chemicals taken directly into the digestive tract through alcoholic beverages, pesticide residues on supermarket produce, additives in processed foods, or drugs of abuse; or taken into the respiratory tract through breathing household solvents (nail polish remover, spot or stain removers containing benzene, etc.).
- Toxins in the digestive tract produced by yeast and other microorganisms. Ridding the body of this group of toxins is frequently cited as a reason for combining laxatives or enemas with detoxification diets. Mainstream physicians dispute the notion that normal digestion produces toxic substances in the colon that must be removed by a laxative or enema.
- Ammonia, urea, and other breakdown products of protein metabolism. Naturopaths often recommend a vegetarian lifestyle as well as periodic intensive detoxification practices in order to minimize the production of these byproducts of meat and dairy products consumption.

A third factor that has contributed to interest in detox diets in the 1990s and early 2000s is the environmental movement. Some people who are concerned about the impact on the environment of raising animals for food use detox diets as a transition into a long-term vegetarian or vegan lifestyle. In addition, growing awareness of the effects of exposure to industrial chemicals, pesticides, secondhand tobacco smoke, and other contaminants in the home environment as well as the workplace has led many people to consider detoxification diets as a preventive health practice to lower their risk of arthritis and other degenerative diseases.

## Description

Practitioners of alternative medicine generally recommend the warmer months as the best time of year for a detox diet, although some dieters prefer January in order to counteract the effects of overindulgence in food and drink during the holidays. Many people suggest beginning a detox diet on the weekend or scheduling time off from work in order to allow time for extra rest if needed. Detox diets are usually used only once or twice a year.

Many detoxification diet books include a questionnaire or symptom checklist to help readers evaluate whether they need detoxification. The following list is typical; more than four "yes" answers indicates the individual could benefit from a detox diet:

- Do you have only one bowel movement per day, or only one every other day?
- Do you take prescription, recreational, or over-the-counter drugs?
- Do you eat meat more than twice a week?
- Do you eat fast foods or processed foods?
- Do you smoke, or are you exposed to secondhand smoke?
- Do you have any skin problems or digestive gas and bloating?
- Do you drink alcohol?
- Do you live in a major city?
- Do you drink tap water, coffee, or soda?
- Do you feel tired, sleep poorly, or have low energy?

Individuals considering a detox diet should prepare by cutting down gradually on caffeinated beverages a week to 10 days before the diet, as sudden elimination of these drinks often causes headaches. Dieters should also reduce their intake of sugary foods, chocolate, alcohol, dairy products, foods high in fat, foods containing wheat or yeast, and grains containing gluten (an elastic protein found in barley and rye). Recommended foods for detox diets (except the mono diets) include fresh organic fruits and vegetables; rice (both brown and basmati rice), rice cakes, and rice pasta; other grains such as millet, quinoa, and buckwheat; beans, lentils, and dried green or yellow peas; unsalted nuts; seeds; olive oil; and herbal teas. The dieter should plan to drink at least eight glasses of filtered or other non-tap water per day on a detox diet.

At the end of a detox diet, the dieter should return gradually to a full diet, perhaps vegetable soup or steamed vegetables the first day. They should not add fruits or vegetables until the second or third day.

### *Raw food diets*

Raw food detox diets consist of foods that have not been heated above 92° to 118°F (33° to 48°C). These diets are based on the belief that raw foods have higher nutrient value and contain enzymes that assist digestion, allowing the other enzymes in the body to regulate other biological processes. Raw foodists also believe raw foods prevent **obesity** by lowering excessive food consumption, and their high **fiber** content helps detoxify the body by speeding up digestion and elimination.

### *Juice fasting*

In a juice fast, the dieter is instructed to drink between 32 and 64 oz of fruit or vegetable juice per day, in addition to six glasses of warm filtered water. Although some modified **juice fasts** allow a small quantity of steamed vegetables, most are short-term **liquid diets**. Some therapists recommend one or more cups of herbal tea each day in addition to the juice and water. The juice must be fresh, obtained from organic fruits and vegetables processed through a juicer or juice extractor. Prepackaged juices cannot be used for a juice fast because they have been pasteurized. In addition, fresh juice must be consumed within a half hour of extraction; it cannot be refrigerated.

### *Mono diets*

Mono diets are detox diets in which the dieter consumes only one food, usually apples, grapes, or some other fruit or vegetable, or one liquid, for a period of 10 to 14 days. The oldest mono diet is the so-called Miracle Grape Cure, attributed to Johanna Brandt, a woman from South Africa who claimed that eating grapes cured her of stomach **cancer**. In a book she published in 1928, Brandt stated that she alternated 12 hours of drinking only natural (unchlorinated) water with 12 hours of eating only purple grapes or drinking grape juice made from purple grapes. Recent modifications of this diet recommend following Brandt's plan to the letter for five weeks, followed by one week of a raw-food vegetarian diet.

The best-known mono diet is variously known as the Master Cleanser, lemonade diet, or maple syrup diet. Stanley Burroughs is generally credited with inventing this diet in 1941, although he did not publish it in book form until 1976. His book, which is only about fifty pages long, is still in print even though Burroughs died in 1991. The Master Cleanser involves drinking a mixture of lemon juice, cayenne pepper, and grade B maple syrup for a period of 10 to 14 days. The lemon/maple syrup drink is then followed

by drinking a "saltwater flush," which is supposed to purge toxins from the stomach and bowels. This diet was popularized in the early 2000s by a book by Peter Glickman titled *Lose Weight, Have More Energy and Be Happier in 10 Days*, which is a modernization of Burrough's regimen.

### *Vegetarian or semivegetarian diets*

Less stringent detox diets that allow some protein foods have been published; a typical example is the following diet plan for a week-long detox regimen by Elson Haas. Haas begins with general guidelines for the dieter:

- Eat slowly and chew the food well.
- Relax for a few minutes before and after each meal.
- Eat in a comfortable sitting position.
- Drink only herbal teas (peppermint, chamomile, or pau d'arco) after dinner.

The daily diet plan:

- Morning: two glasses of filtered or spring water, one glass with half a lemon squeezed into it.
- Breakfast: One piece of fresh fruit at room temperature, followed 15 to 30 minutes later by a bowl of cooked whole grains (millet, buckwheat, quinoa, brown rice, or amaranth), flavored with 2 tbl of fruit juice.
- Lunch: One or two medium bowls of steamed vegetables, using a variety of root vegetables, leafy vegetables, asparagus, cabbage, kale, or others. A maximum of 3 tsp daily of a mixture of butter and canola or olive oil can be used for seasoning.
- Dinner: Same as lunch.
- Midmorning and midafternoon: One or two cups of vegetable water saved from the steamed vegetables, with a little sea salt or kelp added.
- A small portion (3 or 4 oz) of a protein food (fish, organic chicken, lentils, black beans, or garbanzo beans) may be eaten midafternoon if the dieter feels weak or extremely hungry.

### *Supplemental recommendations*

An important part of many detoxification diets is the use of laxatives or enemas to cleanse the lower digestive tract. The removal of wastes is considered essential to prevent toxins in the intestines from being reabsorbed into the bloodstream. Some alternative therapists recommend mixtures of slippery elm or other herbs to cleanse the colon; others prefer saltwater laxatives, enemas, or colonics for cleansing the bowel. A colonic is a procedure in which a large amount of water, sometimes as much as 20 gal (76 L), is infused into the colon through the rectum a few pints at a time. It differs from an enema in that much more fluid is used; and a colonic is infused into the colon, whereas an enema infuses water or a cleansing solution into the rectum only. Mainstream physicians do not recommend colonics on the grounds that they are unnecessary, based on a nineteenth-century misunderstanding of the process of digestion, and very often uncomfortable for the patient. In some cases they pose serious risks to health.

Some therapists recommend the use of such **dietary supplements** as multivitamins, **vitamin C**, **choline** and methionine, milk thistle, or a laxative tea known as Smooth Move during a detox diet. These supplements are supposed to aid liver function and decrease such side effects of detox diets as headaches and nausea.

Many advocates of detox diets suggest the use of meditation, affirmations, yoga, and other spiritual practices in order to improve the mental and emotional well-being. Others recommend undertaking the detox diet at a health spa, where such services as massage therapy, sauna baths, and whirlpool therapy or other forms of hydrotherapy are available.

## Function

The primary function of detoxification diets is physical purification—removal of toxic substances from the body including the skin and respiratory system as well as the digestive tract—in order to raise energy levels; relieve such minor health complaints as poor skin, bad breath, or headaches; and improve the body's ability to heal from various diseases. These diets are not primarily intended as weight reduction regimens.

### *Spiritual or religious practice*

Some people undertake detoxification diets as part of a general religious or spiritual retreat. The first stage of Ayurvedic pancha karma includes extra time given to meditation and nature walks as well as gradual exclusion of stimulants and solid foods from the diet. Many people also report relief from insomnia or other symptoms of emotional stress as a side benefit of detoxification diets.

### *Treatment of specific illnesses*

Detoxification diets are sometimes recommended for the treatment of specific diseases and disorders, most commonly arthritis, autoimmune disorders, and depression, but they have also been claimed to be an effective treatment for severe infections (including

AIDS) and cancer. However, there is insufficient evidence to support such claims.

### Benefits

Claimed benefits of detox diets include higher energy levels, increased mental clarity and ability to concentrate, clearer skin, improved digestion, and more restful sleep. Many of these improvements may simply be due to better hydration as such diets encourage high fluid intake. Some people also lose weight on detox diets, but emphasize that weight reduction should never be the primary purpose of following one of these regimens.

### Precautions

In general, anyone considering a detoxification diet should consult a health professional beforehand. Some serious diseases, including cancer, may have minor symptoms at onset, including headaches, low back pain, and fatigue. These symptoms can easily be misattributed to stress or poor eating habits. Some therapists recommend requesting blood, urine, stool, and liver function tests from a physician before undergoing a detoxification diet.

Individuals who should not undertake a detoxification diet are:

- Pregnant or lactating women.
- Children.
- People with diabetes, hypothyroidism, heart disease, anorexia or bulimia nervosa, kidney or liver disease, stomach ulcers, impaired immune function, epilepsy, cancer, terminal illness, active infections, or ulcerative colitis.
- People who are underweight.
- People with alcohol or drug addictions.
- People who have recently undergone surgery or treatment for severe burns.

Prescription medications should be taken as usual during a detoxification diet. The dieter should not discontinue medications or reduce dosages without consulting a physician.

Anyone on a detoxification diet who feels faint or dizzy, develops an abnormal heart rhythm, feels nauseated or vomits, or has signs of low blood pressure, should discontinue the fast and consult their doctor at once.

Detox diets may encourage yo-yo dieting, which is detrimental to health. They should not be undertaken more than three times a year without medical supervision.

## QUESTIONS TO ASK YOUR DOCTOR

- What type of detoxification diet would you recommend for me?
- What is your opinion of alternative practitioners' explanations of the need for detoxification?
- Have any of your other patients ever tried a mono diet? If so, did they develop any health problems?

### Risks

The major risks to health from detoxification diets include metabolic crises in patients with undiagnosed diabetes; flare-ups or worsening of stomach **ulcers**; dizziness or fainting due to sudden lowering of blood pressure; diarrhea that may result in **dehydration** and an imbalance of **electrolytes** in the body; and protein or **calcium** deficiencies from unsupervised long-term juice fasts. Some people develop dental erosion from raw-food detoxification diets.

Other side effects reported include headaches (often caused by sudden withdrawal from **caffeine**), fatigue, **constipation** (from extra fiber combined with inadequate water intake), acne, irritability, dysmenorrhea (painful periods) in women, and intense hunger.

Raw-food detoxification diets increase the risk of contracting parasites or other foodborne illnesses caused by organisms normally destroyed in cooking or pasteurization. In addition, some raw vegetables, such as rhubarb leaves and stalks, buckwheat greens, kidney beans, kidney bean sprouts, and raw potatoes that have turned green are toxic, particularly if consumed in large quantities.

People on detoxification diets who undergo colonics are at risk of contracting an infection from improperly sterilized colonic equipment; of serious illness or death from electrolyte imbalances in the blood; or of serious illness or death resulting from perforation of the intestinal wall by improperly inserted equipment. Colonics can also worsen the symptoms of ulcerative colitis.

### Research and general acceptance

Detoxification diets are generally dismissed as fads by such professional nutritionists' organizations as the American Dietetic Association (ADA) and other mainstream medical groups. Most physicians point out that the human body is a remarkably efficient organism that

can rid itself of toxins through normal digestion, respiration, and excretion without elaborate diets or the assistance of enemas and laxatives. In addition, some fruits and vegetables may contain more toxins than meat, fish, and other protein-rich foods usually condemned by proponents of detoxification diets. Lastly, many physicians object to the naturopathic view of the digestive tract as a source of illness or toxicity.

Rebecca J. Frey, PhD

# DHEA

## Definition

Dehydroepiandrosterone (DHEA) is a precursor (prohormone) of the sex hormones estrogen and testosterone. It is a steroid produced naturally by the adrenal glands and is also sold as a dietary supplement.

## Purpose

Many claims have been made for DHEA including that it fights aging, burns fat, increases muscle mass, boosts the immune system, eliminated symptoms of menopause, prevents Alzheimer's disease, and can treat everything from inflammatory bowel syndrome to cocaine withdrawal. There is little or highly questionable evidence to support most of these claims. DHEA does have medical uses in treating adrenal insufficiency (Addison's disease) and systemic lupus erythematosus (SLE).

**Tablet form of DHEA.** *(James Keyser//Time Life Pictures/Getty Images. Reproduced by permission.)*

## Description

DHEA is a supplement with a long history of controversy. In the 1980s it was promoted by supplement makers as a "miracle" product that would improve athletic performance, build muscle, burn fat, restore sexual potency, and prevent aging. Many of these claims are still made by supplement makers today. In 1985, the Food and Drug Administration (FDA) banned DHEA for sale in the United States because of its potential for abuse and the high risk of serious side effects. DHEA was also banned by several sports organizations including the International Olympic Committee and the National Football League. However, in 1994, the United States Congress passed the Dietary Supplement Health and Education Act (DSHEA). Under this law, DHEA met the definition of a dietary supplement and could once again be sold without a prescription in the United States.

DSHEA regulates supplements such as DHEA in the same way that food is regulated. Like food manufacturers, manufacturers of **dietary supplements** do not have to prove that their product is either safe or effective before it can be sold to the public. Manufacturers of conventional pharmaceutical drugs, however, must prove both safety and effectiveness in humans before a new drug is approved for use. With dietary supplements, the burden of proof falls on the FDA to show that the supplement is either unsafe or ineffective before it can be restricted or banned. Information about a supplement's safety and effectiveness is normally gathered only after people using the product develop health problems or complain that the product does not work. In the mid-2000s, there was pressure to reclassify DHEA as a hormone and ban its over-the-counter sale, but dietary supplement manufacturers have successfully fought this move. Federal law requires that all manufacturers of dietary supplements and over-the-counter drugs report consumer complaints of adverse events (negative side effects) to the FDA. This makes accumulating information on the safety of DHEA faster and easier.

DHEA is produced mainly in the adrenal glands. These are small, compact hormone-producing tissues located just above each kidney. The adrenal glands convert cholesterol into DHEA and release it into the bloodstream. DHEA is also produced in smaller amounts by the testes, liver, and possibly the brain.

## KEY TERMS

**Conventional medicine**—Mainstream or Western pharmaceutical-based medicine practiced by medical doctors, doctors of osteopathy, and other licensed health care professionals.

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Hormone**—A chemical messenger produced by one type of cell and travels through the bloodstream to change the metabolism of a different type of cell.

**Prohormone**—A substance the body can convert into a hormone.

**Steroid**—A family of compounds that share a similar chemical structure. This family includes estrogen and testosterone, vitamin D, cholesterol, and the drugs cortisone and prendisone.

**Systemic lupus erythematosus (SLE)**—A serious autoimmune disease of connective tissue that affects mainly women. It can cause joint pain, rash, and inflammation of organs such as the kidney.

DHEA is a prohormone, meaning that the body can convert it into several different hormones including the female hormone estrogen and the male hormone testosterone. During development, the fetal adrenal glands produce large amounts of DHEA. After birth, production drops and remains low during childhood. As adulthood approaches, the rate of DHEA production increases, reaching a peak between ages 25–30. From age 30 on, the level of DHEA declines steadily until by age 80, men have only about 10% as much DHEA in their blood as they did at age 25.

Some researchers, observing the relationship between aging and decreased levels of DHEA, hypothesized the decrease in DHEA caused age-related problems such as cardiovascular disease, decreased sexual function, and dementia. They theorized that aging could be delayed using dietary supplements to restore DHEA levels to those of a younger person. This was only a hypothesis and had not been tested, yet supplement manufacturers grabbed on to the cause and effect idea and began promoting DHEA as a miracle supplement that could increase longevity and ward off a number of age-related changes.

The researchers tended to be much more cautious. For one thing, humans and other primates (apes, monkeys) produce substantial amounts of DHEA, but common laboratory animals such as rats and mice produce almost none. Therefore, it is unclear whether results of testing DHEA in lab animals can be applied to humans. Some researchers have spoken out against supplement makers, complaining that their research has been taken out of context, misrepresented, or just plain altered to support the claims of manufacturers selling DHEA, especially those selling over the Internet.

### *DHEA's role in health care*

DHEA has two uses accepted by practitioners of conventional medicine. Under supervision of a physician, DHEA has been used to successfully treat Addison's disease. Addison's disease is the result of adrenal insufficiency. The adrenal glands do not produce enough hormones. DHEA supplements simply replace what the body should be making.

DHEA has also been used by physicians to treat symptoms of systemic lupus erythematosus (SLE). SLE is a complicated autoimmune disease where the body attacks and damages its own tissues. It is not clear why DHEA improves SLE symptoms such as joint pain and inflammation of the tissue surrounding the heart, but the majority of clinical trials in humans support this use.

There is mixed evidence to support two other claims for DHEA—that it helps with weight loss and that it relieves depression symptoms. A rigorous study led by researchers at the Mayo Clinic and published in 2006, found no anti-aging effects in elderly participants who took DHEA for two years. There were no measurable improvements in muscle strength, body fat, physical performance, insulin sensitivity, or quality of life.

DHEA is sold as a dietary supplement in the form of tablets, capsules, and a liquid injection. Dosages range from 25–250 mg per day. An independent study of DHEA supplements found that many supplements contained amounts DHEA ranging from 0–150% that were inconsistent with the amount described on the label.

Dietary supplement manufacturers continue to use unsubstantiated claims about DHEA that appeal to individuals searching for the fountain of youth. These include claims that DHEA improves memory, eliminates or improves symptoms of Alzheimer's disease, prevents cardiovascular disease, increases bone density, treats chronic fatigue syndrome, treats cocaine

withdrawal, improves symptoms of Crohn's disease and inflammatory bowel syndrome, slows the development of AIDS, restores fertility, cures erectile dysfunction, treats symptoms of menopause such as hot flashes, helps manage schizophrenia, increases muscle strength and athletic performance, stimulates the immune system, prevents skin aging, and treats the symptoms of fibromyalgia. There are no independent, controlled, rigorous studies to support any of these uses. The National Center for Complementary and Alternative Medicine (NCCAM) does not recommend the use of DHEA supplements as a means to improve any health problems. The National Institute for Aging (NIA) advises against the use of DHEA supplements due to the lack of evidence proving any form of anti-aging benefit.

DHEA remains of great interest to researchers. Clinical trials are underway to determine safety and effectiveness of DHEA in a variety of situations.

## Precautions

People under age 40 should not take DHEA supplements.

Pregnant women should not take DHEA. There is some evidence that it can induce early labor. The effect on the developing fetus is unknown.

**Breastfeeding** women should avoid DHEA supplementation because DHEA passes into breast milk and may affect development of the infant.

People who have a high risk of developing estrogen- or testosterone-sensitive cancers, such as breast **cancer** or **prostate** cancer, should not take DHEA supplements. DHEA is converted into estrogen or testosterone. These hormones appear to stimulate the growth of certain cancers.

Athletes should be aware that some athletic governing bodies ban DHEA supplement use and test for abnormally high levels of DHEA as part of routine drug testing.

## Interactions

High levels of DHEA may interfere with the way the liver processes certain drugs. As a result, these drugs may accumulate in the body in high levels and cause adverse effects or be more rapidly deactivated and not produce a therapeutic response. Drugs that may be affected by high levels of DHEA are anticonvulsants, antipsychotics, corticosteroids, oral contraceptives, hormone replacement therapy drugs, insulin, and drugs to treat insomnia.

## Complications

DHEA supplementation in healthy people can cause major side effects. Many of these come about because of the conversion of DHEA into high levels of testosterone and estrogen. These include:

- masculization of women, including deepening voice and increased body hair
- menstrual irregularities in women
- feminization of men including, enlarged breasts and shrunken testicles
- decreased HDL ("good") cholesterol
- high blood pressure (hypertension)
- liver damage

Less serious side effects include acne, increased sweating, breast tenderness, insomnia, nausea, and abdominal pain.

## Parental concerns

DHEA should never be given to children. Parents should keep this and all drugs and supplements stored safely out of reach of children to prevent accidental poisoning.

# Diabetes mellitus

## Definition

Diabetes mellitus is a condition in which the pancreas no longer produces enough insulin or cells stop responding to the insulin that is produced, so that glucose in the blood cannot be absorbed into the cells of the body. Symptoms include frequent urination, lethargy, excessive thirst, and hunger. The treatment includes changes in diet, oral medications, and in some cases, daily injections of insulin.

## Description

Diabetes mellitus is a chronic disease that causes serious health complications including renal (kidney) failure, heart disease, stroke, and blindness. Approximately 17 million Americans have diabetes. Unfortunately, as many as one-half are unaware they have it.

**Target blood glucose levels for people with diabetes**

| | |
|---|---|
| Before meals | 90 to 130 |
| 1 to 2 hours after the start of a meal | less than 180 |

SOURCE: National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, U.S. Department of Health and Human Services

*(Illustration by GGS Information Services/Thomson Gale.)*

### *Background*

Every cell in the human body needs energy in order to function. The body's primary energy source is glucose, a simple sugar resulting from the digestion of foods containing **carbohydrates** (sugars and starches). Glucose from the digested food circulates in the blood as a ready energy source for any cells that need it. Insulin is a hormone or chemical produced by cells in the pancreas, an organ located behind the stomach. Insulin bonds to a receptor site on the outside of cell and acts like a key to open a doorway into the cell through which glucose can enter. Some of the glucose can be converted to concentrated energy sources like glycogen or fatty acids and saved for later use. When there is not enough insulin produced or when the doorway no longer recognizes the insulin key, glucose stays in the blood rather entering the cells.

The body will attempt to dilute the high level of glucose in the blood, a condition called hyperglycemia, by drawing **water** out of the cells and into the bloodstream in an effort to dilute the sugar and excrete it in the urine. It is not unusual for people with undiagnosed diabetes to be constantly thirsty, drink large quantities of water, and urinate frequently as their bodies try to get rid of the extra glucose. This creates high levels of glucose in the urine.

At the same time that the body is trying to get rid of glucose from the blood, the cells are starving for glucose and sending signals to the body to eat more food, thus making patients extremely hungry. To provide energy for the starving cells, the body also tries to convert **fats** and proteins to glucose. The breakdown of fats and proteins for energy causes acid compounds called ketones to form in the blood. Ketones also will be excreted in the urine. As ketones build up in the blood, a condition called ketoacidosis can occur. This condition can be life threatening if left untreated, leading to coma and death.

### *Types of diabetes mellitus*

Type I diabetes, sometimes called juvenile diabetes, begins most commonly in childhood or adolescence. In this form of diabetes, the body produces

## KEY TERMS

**Cataract**—A condition where the lens of the eye becomes cloudy.

**Diabetic peripheral neuropathy**—A condition where the sensitivity of nerves to pain, temperature, and pressure is dulled, particularly in the legs and feet.

**Diabetic retinopathy**—A condition where the tiny blood vessels to the retina, the tissues that sense light at the back of the eye, are damaged, leading to blurred vision, sudden blindness, or black spots, lines, or flashing lights in the field of vision.

**Glaucoma**—A condition where pressure within the eye causes damage to the optic nerve, which sends visual images to the brain.

**Hyperglycemia**—A condition where there is too much glucose or sugar in the blood.

**Hypoglycemia**—A condition where there is too little glucose or sugar in the blood.

**Insulin**—A hormone or chemical produced by the pancreas, insulin is needed by cells of the body in order to use glucose (sugar), the body's main source of energy.

**Ketoacidosis**—A condition due to starvation or uncontrolled Type I diabetes. Ketones are acid compounds that form in the blood when the body breaks down fats and proteins. Symptoms include abdominal pain, vomiting, rapid breathing, extreme tiredness, and drowsiness.

**Kidney dialysis**—A process where blood is filtered through a dialysis machine to remove waste products that would normally be removed by the kidneys. The filtered blood is then circulated back into the patient. This process also is called renal dialysis.

**Pancreas**—A gland located behind the stomach that produces insulin.

little or no insulin. It is characterized by a sudden onset and occurs more frequently in populations descended from Northern European countries (Finland, Scotland, Scandinavia) than in those from Southern European countries, the Middle East, or Asia. In the United States, approximately three people in 1,000 develop Type I diabetes. This form also is called insulin-dependent diabetes because people who develop this type need to have daily injections of insulin.

Brittle diabetics are a subgroup of Type I where patients have frequent and rapid swings of blood sugar levels between hyperglycemia (a condition where there is too much glucose or sugar in the blood) and hypoglycemia (a condition where there are abnormally low levels of glucose or sugar in the blood). These patients may require several injections of different types of insulin during the day to keep the blood sugar level within a fairly normal range.

The more common form of diabetes, Type II, occurs in approximately 3–5% of Americans under 50 years of age, and increases to 10–15% in those over 50. More than 90% of the diabetics in the United States are Type II diabetics. Sometimes called age-onset or adult-onset diabetes, this form of diabetes occurs most often in people who are overweight and who do not exercise. It is also more common in people of Native American, Hispanic, and African-American descent. People who have migrated to Western cultures from East India, Japan, and Australian Aboriginal cultures also are more likely to develop Type II diabetes than those who remain in their original countries.

Type II is considered a milder form of diabetes because of its slow onset (sometimes developing over the course of several years) and because it usually can be controlled with diet and oral medication. The consequences of uncontrolled and untreated Type II diabetes, however, are the just as serious as those for Type I. This form is also called noninsulin-dependent diabetes, a term that is somewhat misleading. Many people with Type II diabetes can control the condition with diet and oral medications, however, insulin injections are sometimes necessary if treatment with diet and oral medication is not working.

Another form of diabetes called gestational diabetes can develop during pregnancy and generally resolves after the baby is delivered. This diabetic condition develops during the second or third trimester of pregnancy in about 2% of pregnancies. In 2004, incidence of gestational diabetes were reported to have increased 35% in 10 years. Children of women with gestational diabetes are more likely to be born prematurely, have hypoglycemia, or have severe jaundice at birth. The condition usually is treated by diet, however, insulin injections may be required. These women who have diabetes during pregnancy are at higher risk for developing Type II diabetes within 5–10 years.

Diabetes also can develop as a result of pancreatic disease, alcoholism, malnutrition, or other severe illnesses that stress the body.

## Causes and symptoms

### *Causes*

The causes of diabetes mellitus are unclear, however, there seem to be both hereditary (genetic factors passed on in families) and environmental factors involved. Research has shown that some people who develop diabetes have common genetic markers. In Type I diabetes, the immune system, the body's defense system against infection, is believed to be triggered by a virus or another microorganism that destroys cells in the pancreas that produce insulin. In Type II diabetes, age, **obesity**, and family history of diabetes play a role.

In Type II diabetes, the pancreas may produce enough insulin, however, cells have become resistant to the insulin produced and it may not work as effectively. Symptoms of Type II diabetes can begin so gradually that a person may not know that he or she has it. Early signs are lethargy, extreme thirst, and frequent urination. Other symptoms may include sudden weight loss, slow wound healing, urinary tract infections, gum disease, or blurred vision. It is not unusual for Type II diabetes to be detected while a patient is seeing a doctor about another health concern that is actually being caused by the yet undiagnosed diabetes.

Individuals who are at high risk of developing Type II diabetes mellitus include people who:

- are obese (more than 20% above their ideal body weight)
- have a relative with diabetes mellitus
- belong to a high-risk ethnic population (African-American, Native American, Hispanic, or Native Hawaiian)
- have been diagnosed with gestational diabetes or have delivered a baby weighing more than 9 lbs (4 kg)
- have high blood pressure (140/90 mmHg or above)
- have a high density lipoprotein cholesterol level less than or equal to 35 mg/dL and/or a triglyceride level greater than or equal to 250 mg/dL
- have had impaired glucose tolerance or impaired fasting glucose on previous testing

Several common medications can impair the body's use of insulin, causing a condition known as secondary diabetes. These medications include treatments for high blood pressure (furosemide, clonidine, and thiazide **diuretics**), drugs with hormonal activity (oral contraceptives, thyroid hormone, progestins, and glucocorticorids), and the anti-inflammation drug indomethacin. Several drugs that are used to treat mood disorders (such as anxiety and depression) also can impair glucose absorption. These drugs include haloperidol, lithium carbonate, phenothiazines, tricyclic antidepressants, and adrenergic agonists. Other medications that can cause diabetes symptoms include isoniazid, nicotinic acid, cimetidine, and heparin. A 2004 study found that low levels of the essential mineral chromium in the body may be linked to increased risk for diseases associated with insulin resistance.

### *Symptoms*

Symptoms of diabetes can develop suddenly (over days or weeks) in previously healthy children or adolescents, or can develop gradually (over several years) in overweight adults over the age of 40. The classic symptoms include feeling tired and sick, frequent urination, excessive thirst, excessive hunger, and weight loss.

Ketoacidosis, a condition due to starvation or uncontrolled diabetes, is common in Type I diabetes. Ketones are acid compounds that form in the blood when the body breaks down fats and proteins. Symptoms include abdominal pain, vomiting, rapid breathing, extreme lethargy, and drowsiness. Patients with ketoacidosis will also have a sweet breath odor. Left untreated, this condition can lead to coma and death.

With Type II diabetes, the condition may not become evident until the patient presents for medical treatment for some other condition. A patient may have heart disease, chronic infections of the gums and urinary tract, blurred vision, numbness in the feet and legs, or slow-healing wounds. Women may experience genital itching.

## Diagnosis

Diabetes is suspected based on symptoms. Urine tests and blood tests can be used to confirm a diagnose of diabetes based on the amount of glucose found. Urine can also detect ketones and **protein** in the urine that may help diagnose diabetes and assess how well the kidneys are functioning. These tests also can be used to monitor the disease once the patient is on a standardized diet, oral medications, or insulin.

### *Urine tests*

Clinistix and Diastix are paper strips or dipsticks that change color when dipped in urine. The test strip is compared to a chart that shows the amount of glucose in the urine based on the change in color. The level of glucose in the urine lags behind the level of glucose in the blood. Testing the urine with a test stick, paper strip, or tablet that changes color when

sugar is present is not as accurate as blood testing, however it can give a fast and simple reading.

Ketones in the urine can be detected using similar types of dipstick tests (Acetest or Ketostix). Ketoacidosis can be a life-threatening situation in Type I diabetics, so having a quick and simple test to detect ketones can assist in establishing a diagnosis sooner.

Another dipstick test can determine the presence of protein or albumin in the urine. Protein in the urine can indicate problems with kidney function and can be used to track the development of renal failure. A more sensitive test for urine protein uses radioactively tagged chemicals to detect microalbuminuria, small amounts of protein in the urine, that may not show up on dipstick tests.

### *Blood tests*

**FASTING GLUCOSE TEST.** Blood is drawn from a vein in the patient's arm after a period at least eight hours when the patient has not eaten, usually in the morning before breakfast. The red blood cells are separated from the sample and the amount of glucose is measured in the remaining plasma. A plasma level of 7.8 mmol/L (200 mg/L) or greater can indicate diabetes. The fasting glucose test is usually repeated on another day to confirm the results.

**POSTPRANDIAL GLUCOSE TEST.** Blood is taken right after the patient has eaten a meal.

**ORAL GLUCOSE TOLERANCE TEST.** Blood samples are taken from a vein before and after a patient drinks a thick, sweet syrup of glucose and other sugars. In a non-diabetic, the level of glucose in the blood goes up immediately after the drink and then decreases gradually as insulin is used by the body to metabolize, or absorb, the sugar. In a diabetic, the glucose in the blood goes up and stays high after drinking the sweetened liquid. A plasma glucose level of 11.1 mmol/L (200 mg/dL) or higher at two hours after drinking the syrup and at one other point during the two-hour test period confirms the diagnosis of diabetes.

A diagnosis of diabetes is confirmed if there are symptoms of diabetes and a plasma glucose level of at least 11.1 mmol/L, a fasting plasma glucose level of at least 7 mmol/L; or a two-hour plasma glucose level of at least 11.1 mmol/L during an oral glucose tolerance test.

Home blood glucose monitoring kits are available so patients with diabetes can monitor their own levels. A small needle or lancet is used to prick the finger and a drop of blood is collected and analyzed by a monitoring device. Some patients may test their blood glucose levels several times during a day and use this information to adjust their doses of insulin.

## Treatment

There is currently no cure for diabetes. The condition, however, can be managed so that patients can live a relatively normal life. Treatment of diabetes focuses on two goals: keeping blood glucose within normal range and preventing the development of long-term complications. Careful monitoring of diet, exercise, and blood glucose levels are as important as the use of insulin or oral medications in preventing complications of diabetes. In 2003, the American Diabetes Association updated its Standards of Care for the management of diabetes. These standards help manage health care providers in the most recent recommendations for diagnosis and treatment of the disease.

### *Dietary changes*

Diet and moderate exercise are the first treatments implemented in diabetes. For many Type II diabetics, weight loss may be an important goal in helping them to control their diabetes. A well-balanced, nutritious diet provides approximately 50–60% of calories from carbohydrates, approximately 10–20% of calories from protein, and less than 30% of calories from fat. The number of calories required by an individual depends on age, weight, and activity level. The calorie intake also needs to be distributed over the course of the entire day so surges of glucose entering the blood system are kept to a minimum.

Keeping track of the number of calories provided by different foods can become complicated, so patients usually are advised to consult a nutritionist or dietitian. An individualized, easy to manage diet plan can be set up for each patient. Both the American Diabetes Association and the American Dietetic Association recommend diets based on the use of food exchange lists. Each food exchange contains a known amount of calories in the form of protein, fat, or carbohydrate. A patient's diet plan will consist of a certain number of exchanges from each food category (meat or protein, fruits, breads and starches, vegetables, and fats) to be eaten at meal times and as snacks. Patients have flexibility in choosing which foods they eat as long as they stick with the number of exchanges prescribed.

For many Type II diabetics, weight loss is an important factor in controlling their condition. The food exchange system, along with a plan of moderate exercise, can help them lose excess weight and improve their overall health.

### *Oral medications*

Oral medications are available to lower blood glucose in Type II diabetics. In 1990, 23.4 outpatient prescriptions for oral antidiabetic agents were dispensed. By 2001, the number had increased to 91.8 million prescriptions. Oral antidiabetic agents accounted for more than $5 billion dollars in worldwide retail sales per year in the early twenty-first century and were the fastest-growing segment of diabetes drugs. The drugs first prescribed for Type II diabetes are in a class of compounds called sulfonylureas and include tolbutamide, tolazamide, acetohexamide, and chlorpropamide. Newer drugs in the same class are now available and include glyburide, glimeperide, and glipizide. How these drugs work is not well understood, however, they seem to stimulate cells of the pancreas to produce more insulin. New medications that are available to treat diabetes include metformin, acarbose, and troglitizone. The choice of medication depends in part on the individual patient profile. All drugs have side effects that may make them inappropriate for particular patients. Some for example, may stimulate weight gain or cause stomach irritation, so they may not be the best treatment for someone who is already overweight or who has stomach **ulcers**. Others, like metformin, have been shown to have positive effects such as reduced cardiovascular mortality, but but increased risk in other situations. While these medications are an important aspect of treatment for Type II diabetes, they are not a substitute for a well planned diet and moderate exercise. Oral medications have not been shown effective for Type I diabetes, in which the patient produces little or no insulin.

Constant advances are being made in development of new oral medications for persons with diabetes. In 2003, a drug called Metaglip combining glipizide and metformin was approved in a dingle tablet. Along with diet and exercise, the drug was used as initial therapy for Type 2 diabetes. Another drug approved by the U.S. Food and Drug Administration (FDA) combines metformin and rosiglitazone (Avandia), a medication that increases muscle cells' sensitivity to insulin. It is marketed under the name Avandamet. So many new drugs are under development that it is best to stay in touch with a physician for the latest information; physicians can find the best drug, diet and exercise program to fit an individual patient's need.

### *Insulin*

Patients with Type I diabetes need daily injections of insulin to help their bodies use glucose. The amount and type of insulin required depends on the height, weight, age, food intake, and activity level of the individual diabetic patient. Some patients with Type II diabetes may need to use insulin injections if their diabetes cannot be controlled with diet, exercise, and oral medication. Injections are given subcutaneously, that is, just under the skin, using a small needle and syringe. Injection sites can be anywhere on the body where there is looser skin, including the upper arm, abdomen, or upper thigh.

Purified human insulin is most commonly used, however, insulin from beef and pork sources also are available. Insulin may be given as an injection of a single dose of one type of insulin once a day. Different types of insulin can be mixed and given in one dose or split into two or more doses during a day. Patients who require multiple injections over the course of a day may be able to use an insulin pump that administers small doses of insulin on demand. The small battery-operated pump is worn outside the body and is connected to a needle that is inserted into the abdomen. Pumps can be programmed to inject small doses of insulin at various times during the day, or the patient may be able to adjust the insulin doses to coincide with meals and exercise.

Regular insulin is fast-acting and starts to work within 15–30 minutes, with its peak glucose-lowering effect about two hours after it is injected. Its effects last for about four to six hours. NPH (neutral protamine Hagedorn) and Lente insulin are intermediate-acting, starting to work within one to three hours and lasting up to 18–26 hours. Ultra-lente is a long-acting form of insulin that starts to work within four to eight hours and lasts 28–36 hours.

Hypoglycemia, or low blood sugar, can be caused by too much insulin, too little food (or eating too late to coincide with the action of the insulin), **alcohol consumption**, or increased exercise. A patient with symptoms of hypoglycemia may be hungry, cranky, confused, and tired. The patient may become sweaty and shaky. Left untreated, the patient can lose consciousness or have a seizure. This condition is sometimes called an insulin reaction and should be treated by giving the patient something sweet to eat or drink like a candy, sugar cubes, juice, or another high sugar snack.

### *Surgery*

Transplantation of a healthy pancreas into a diabetic patient is a successful treatment, however, this transplant is usually done only if a kidney transplant is performed at the same time. Although a pancreas transplant is possible, it is not clear if the potential

benefits outweigh the risks of the surgery and drug therapy needed.

### *Alternative treatment*

Since diabetes can be life-threatening if not properly managed, patients should not attempt to treat this condition without medical supervision. A variety of alternative therapies can be helpful in managing the symptoms of diabetes and supporting patients with the disease. Acupuncture can help relieve the pain associated with diabetic neuropathy by stimulation of certain points. A qualified practitioner should be consulted. Herbal remedies also may be helpful in managing diabetes. Although there is no herbal substitute for insulin, some herbs may help adjust blood sugar levels or manage other diabetic symptoms. Some options include:

- fenugreek (*Trigonella foenum-graecum*) has been shown in some studies to reduce blood insulin and glucose levels while also lowering cholesterol
- bilberry (*Vaccinium myrtillus*) may lower blood glucose levels, as well as helping to maintain healthy blood vessels
- garlic (*Allium sativum*) may lower blood sugar and cholesterol levels
- onions (*Allium cepa*) may help lower blood glucose levels by freeing insulin to metabolize them
- cayenne pepper (*Capsicum frutescens*) can help relieve pain in the peripheral nerves (a type of diabetic neuropathy)
- gingko (*Gingko biloba*) may maintain blood flow to the retina, helping to prevent diabetic retinopathy

Any therapy that lowers stress levels also can be useful in treating diabetes by helping to reduce insulin requirements. Among the alternative treatments that aim to lower stress are hypnotherapy, biofeedback, and meditation.

## Prognosis

Uncontrolled diabetes is a leading cause of blindness, end-stage renal disease, and limb amputations. It also doubles the risks of heart disease and increases the risk of stroke. Eye problems including cataracts, glaucoma, and diabetic retinopathy also are more common in diabetics.

Diabetic peripheral neuropathy is a condition where nerve endings, particularly in the legs and feet, become less sensitive. Diabetic foot ulcers are a particular problem since the patient does not feel the pain of a blister, callous, or other minor injury. Poor blood circulation in the legs and feet contribute to delayed wound healing. The inability to sense pain along with the complications of delayed wound healing can result in minor injuries, blisters, or callouses becoming infected and difficult to treat. In cases of severe infection, the infected tissue begins to break down and rot away. The most serious consequence of this condition is the need for amputation of toes, feet, or legs due to severe infection.

Heart disease and kidney disease are common complications of diabetes. Long-term complications may include the need for kidney dialysis or a kidney transplant due to kidney failure.

Babies born to diabetic mothers have an increased risk of birth defects and distress at birth.

## Prevention

Research continues on diabetes prevention and improved detection of those at risk for developing diabetes. While the onset of Type I diabetes is unpredictable, the risk of developing Type II diabetes can be reduced by maintaining ideal weight and exercising regularly. The physical and emotional stress of surgery, illness, pregnancy, and alcoholism can increase the risks of diabetes, so maintaining a healthy lifestyle is critical to preventing the onset of Type II diabetes and preventing further complications of the disease.

# Diarrhea diet

## Definition

A diarrhea diet is used to help alleviate diarrhea, a condition characterized by unusually frequent bowel movements and excessive evacuations of watery stools.

## Origins

Diarrhea is a symptom that is not only uncomfortable, but also dangerous to health, as it is usually indicative of an underlying infection. Some causes of diarrhea include:

- Taking antibiotics. Some antibiotics have diarrhea as a side effect.
- Celiac disease. Disease that damages the small intestine in people who cannot tolerate gluten, a protein found in wheat, rye, and barley.
- Crohn's disease. Inflammatory disease that usually occurs in the last section of the small intestine (ileum), causing swelling in the intestines. It can also occur in the large intestine.
- Diverticulitis. Inflammation of the small pouches (diverticula) that can form in the weakened muscular wall of the large intestine.
- Dysentery. Inflammation of the intestine with severe diarrhea and intestinal bleeding, resulting from drinking water containing a parasite called *Entamoeba histolytica*.
- Food poisoning. Eating foods that are spoiled or tainted because they either contain harmful microorganisms, or toxic substances that make them unfit for consumption.
- Gardiasis. Infection of the intestine by the parasite *Giardia intestinalis*. The parasite is one of the most common causes of waterborne disease in the United States and can be found in both drinking and recreational water.
- Infectious diarrhea. Diarrhea resulting from bacterial or viral infections. Bacterial diarrhea is most commonly caused by *Campylobacter jejuni*, *Salmonella*, *Shigella*, *Escherichia coli* O157:H7. Rotavirus is the commonest cause of viral diarrhea in the United States. Other viruses causing diarrhea include Norwalk virus, and cytomegalovirus.
- Irritable bowel syndrome (IBS). IBS, also called spastic colon, or irritable colon, is a condition in which the colon muscle contracts more readily than it should.
- Lactose intolerance. The inability to digest significant amounts of lactose, the major sugar found in milk, due to a shortage of lactase, the enzyme produced by the cells lining the small intestine. Lactase breaks down milk sugar into two simpler forms of sugar that are then absorbed into the bloodstream. If not present, lactose is not broken down.
- Malabsorption. Poor absorption of nutrients by the small intestine.
- Traveler's diarrhea. Diarrhea resulting from eating or drinking food or water contaminated by infected human bowel waste. Travelers to developing

countries of the world are especially at risk, hence the name.

- Ulcerative colitis. Inflammation of the inner lining of the colon, characterized by open sores that appear in its mucous membrane.
- Viral gastroenteritis. Inflammation of the digestive tract, primarily of the stomach, small and large intestines. It is a mild viral infection that usually goes away on its own within a few days. It is often called "stomach flu".
- Excessive exercise.

## Description

In most diarrhea cases, treatment first seeks to prevent the body from losing too much fluid (**dehydration**) and the salts and **minerals** required by the body (**electrolytes**). A diarrhea diet accordingly includes drinking plenty of **water**. However, broths and soups that contain **sodium**, and fruit juices, mineral water, soft fruits, or vegetables that contain potassium, are also extremely important to restore the electrolyte levels and correct nutritional deficiencies. Until the diarrhea stops, it is also recommended to avoid **caffeine**, milk products, and foods that are high in **fiber**, or very high in simple sugars, as they tend to aggravate diarrhea. For example, soft drinks, undiluted fruit juices, and presweetened cereals should be avoided. Also, fried or fatty foods should be avoided because of their tendency to delay stomach emptying. Carbonated drinks can also affect intestinal contractions and make diarrhea worse. A heath care practitioner may also recommend the BRAT diet that includes bananas, plain rice, applesauce, and toast.

Some specific diarrheas have their own dietary requirements. For instance, avoiding dairy products in cases of lactose intolerance, or gluten in cases of malabsorption. Diarrhea caused by antibiotics can also be reduced by taking probiotic yogurt with live active cultures.

As the diarrhea improves, soft, bland foods can usually be added to the diet, supplementing bananas, plain rice, and toast with boiled potatoes, crackers, cooked carrots, and baked chicken without the skin or fat. Other recommended foods include cereals (rice, wheat, and oat cereals), and yogurt. Once the diarrhea has stopped, a person can usually return to a normal and balanced diet. The Schiffert Health Center offers the following dietary tips for the first several days after experiencing diarrhea:

- Begin eating bland, easy-to-digest foods after the first 24 hours of diarrhea.
- Slowly progress to other foods as you can tolerate them.
- Avoid food and drink that cause discomfort, cramping or gas for the first few days. Examples of food to avoid may include: spicy foods (black pepper, chili powder), caffeine, chocolate, carbonated drinks and cola drinks, alcohol, fried foods and greasy foods, acidic fruit juices (orange, grapefruit), gaseous vegetables (broccoli, cabbage, corn, cauliflower, onions).
- Initially, eat smaller meals evenly spaced throughout the day to reduce stomach acidity.
- Eat slowly and chew food well.

A progressive bland diet may propose the following eating plan:

- Day 1: Drinking clear liquids at room temperature such as sports drinks (Powerade/Gatorade), weak tea (decaffeinated), non-caffeinated sodas;
- Day 2: Slowly adding bland foods in small amounts as can be tolerated during the day. Examples are: oatmeal or cream of wheat made with water, dry cereal (without milk), plain rice or pasta (no butter, oil, or sauces), crackers or pretzels, gingersnaps, plain toast (no butter or jelly), mashed potatoes (no skins), ripe bananas (ripe), applesauce, chicken noodle soup.
- Day 3: Gradually adding more variety of foods in small, more frequent meals evenly spaced throughout the day. Examples are: soft boiled eggs or scrambled eggs, plain baked potato, fish or chicken (no skin) well-cooked, baked or grilled (not fried), plain yogurt, cottage cheese, cooked carrots or green beans, milk (skim or low-fat after diarrhea has stopped).

## Function

The primary function of a diarrhea diet is to assist the treatment seeking to correct the cause. This almost always includes preventing dehydration and replenishing lost electrolytes, especially serious in babies and young children. In serious cases, a physician may also recommend electrolyte solutions, available at drugstores. Medicines that stop diarrhea may be helpful, but they are not recommended for people whose diarrhea is caused by a bacterial infection or a parasite, because the diarrhea helps to purge the pathogen. Viral infections are either treated with medication or left to run their course, depending on the severity and type of virus.

## Benefits

Certain foods are considered beneficial such as bananas because they contain potassium, required to control the body's fluid balance, while boiled rice and toast provide low-fiber **carbohydrates** that do not irritate the bowel. Applesauce has a low GI and low fiber

## KEY TERMS

**Acidophilus**—Bacteria found in yogurt that, when ingested, helps restore the normal bacterial populations in the human digestive system.

**Acute**—Acute means sudden or severe. Acute symptoms appear, change, or worsen rapidly. It is the opposite of chronic.

**Bacteria**—Microorganisms found in the environment. Bacteria can multiply quickly in food, and can cause foodborne illnesses. Not all bacteria are harmful: some are used to make yogurt and cheese.

**Bland diet**—A diet that is free of irritating or stimulating foods.

**Chronic**—Chronic refers to a symptom or disease that continues or persists over an extended period of time.

**Colon**—Part of the large intestine, located in the abdominal cavity. It consists of the ascending colon, the transverse colon, the descending colon, and the sigmoid colon.

**Contamination**—The undesired occurrence of harmful microorganisms or substances in food.

**Digestive tract**—The tube connecting and including the organs and paths responsible for processing food in the body. These are the mouth, the esophagus, the stomach, the liver, the gallbladder, the pancreas, the small intestine, the large intestine, and the rectum.

**Duodenum**—The first section of the small intestine, extending from the stomach to the jejunum, the next section of the small intestine.

**Electrolytes**—Chemicals such as salts and minerals required for various functions in the body.

**Fecal**—Relating to feces.

**Feces**—Waste product of digestion formed in the large intestine. About 75% of its mass is water, the remainder is protein, fat, undigested roughage, dried digestive juices, dead cells, and bacteria.

**Foodborne illness**—Illness caused by pathogenic bacteria transmitted to humans by food.

**Ileum**—The last section of the small intestine located between the jejunum and the large intestine.

**Immune system**—The integrated body system of organs, tissues, cells, and cell products such as antibodies that protects the body from foreign organisms or substances.

**Inflammation**—A response of body tissues to injury or irritation characterized by pain and swelling and redness and heat.

**Intestinal flora**—The sum of all bacteria and fungi that live in the intestines. It is required to break down nutrients, fight off pathogens and helps the body build the vitamin E and K. An unbalanced intestinal flora can lead to many health problems.

**Jejunum**—The section of the small intestine located between the duodenum and the ileum.

**Large intestine**—The terminal part of the digestive system, site of water recycling, nutrient absorption, and waste processing located in the abdominal cavity. It consists of the caecum, the colon, and the rectum.

**Microorganism**—A general term for bacteria, molds, fungus, or viruses, that can be seen only with a microscope.

**Pathogen**—A disease-causing microorganism.

**Small intestine**—The part of the digestive tract located between the stomach and the large intestine. It consists of the duodenum, the jejunum, and the ileum.

content. To get the digestive system working properly after diarrhea, it is necessary to rebuild the intestinal flora, especially if antibiotics were taken. Eating probiotic yogurt (with acidophilus) helps restore the intestinal flora.

### Precautions

For most people, any liquid that they normally drink should be adequate to bring fluid levels back to normal (rehydration). However, too much water alone, at any age, can be harmful, because water does not have any sugars or important electrolytes, such as sodium. This is why the diet must include foods and drinks that restore electrolyte levels. In this respect, mineral water is recommended. Signs of dehydration include:

- Thirst
- Dry mouth and tongue, parched throat
- Reduced need to urinate
- Dry skin and hair

- Lack of energy, tiredness
- Light-headedness
- Dark urine

Very young infants also pose special problems because their risk of dehydration is much higher. They should be given a bottle frequently. A pediatrician may recommend solutions such as Pedialyte as these fluids also contain the necessary salts lost with diarrhea. Salt tablets should never be used as they may worsen diarrhea.

Diarrhea is often caused by foodborne or waterborne pathogens. The Mayo Clinic offers the following advice to prevent food contamination at home:

- Washing hands, utensils and food surfaces often to prevent cross-contamination, i.e. the transfer of harmful bacteria from one surface to another.
- Keeping raw foods separate from ready-to-eat foods, also to prevent cross-contamination.
- Cooking foods to kill harmful organisms (to temperatures between 140°F (60°C) and 180°F (82°C).
- Refrigerating or freezing perishable foods to avoid rapid growth of harmful bacteria.
- Throwing food out when in doubt.
- Drinking water only from a trusted source.

## Risks

There are no risks associated with a bland diet or with drinking liquids that replenish fluid levels as long as electrolytes are also provided.

## Research and general acceptance

There is broad consensus among health practitioners that a bland diet combined with replenishing lost fluids and electrolytes is beneficial to treat most cases of diarrhea.

The Division of Digestive Diseases and Nutrition at the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) supports basic and clinical research into gastrointestinal conditions, including diarrhea. Among other areas, NIDDK researchers are studying how the processes of absorption and secretion in the digestive tract affect the content and consistency of stool, the relationship between diarrhea and pathogenic bacteria, motility in chronic diarrhea, and chemical compounds that may be useful in treating diarrhea.

## QUESTIONS TO ASK YOUR DOCTOR

- What is causing my diarrhea ?
- How long will it last ?
- How is diarrhea treated ?
- Are there tests that should be done ?
- Can Traveller's diarrhea be prevented ?
- Is drinking water enough to prevent dehydration ?
- What is causing my baby's diarrhea ?
- How do I know if my baby is dehydrated ?
- Are there foods that should be avoided ?
- Are there foods that are recommended ?
- Would seeing a dietician for an eating plan help ?
- If my antibiotics cause diarrhea, should I stop taking them ?

# Diet drugs

## Definition

Diet drugs are medications that may help obese people lose weight when the drugs are used together with a program of diet and exercise. Historically, many drugs have been used as weight loss aids, and some ineffective products have been marketed with claims of helping in a program of weight loss.

## Purpose

All diet drugs are intended to reduce caloric intake or increase calorie usage, however the methods vary.

## Description

### *Appetite suppressants (anorexiants)*

Most FDA-approved weight loss drugs suppress appetite by affecting one or more neurotransmitters in the brain. These are hormones control appetite and mood. The model for these drugs is amphetamine, although there are many closely related drugs including the botanical product epehdrine. The mechanism of action of amphetamines on appetite suppression is not fully understood. It is known that amphetamines and amphetiamine-like drugs cause the release of norepinephrine and dopamine. Although they are stimulants, amphetamines do not increase the basal metabolic rate, the rate at which the body uses energy while in a resting state. Phenylpropanolamine had been approvel by the United States Food & Drug Administration as an over-the-counter aid to diet in 1983, but this approval was withdrawn after several reports of hemorrhagic stroke associated with use of the drug.

Most weight loss drugs are approved for only a few weeks, and weight rapidly returns once the drug is discontinued. Long-term studies do indicate that continued use of weight loss drugs may be effective in maintaining weight loss, but in most cases long-term studies have not been conducted to adequately demonstrate safety. This was a particular problem with amphetamine and its derivatives, which are classified as controlled substances. Sibutramine, sold under the brand name Meridia, was approved by the FDA in 1997 for use up to two years. Safety and efficacy beyond two years has not been established. Sibutramine reduces appetite by inhibiting the reuptake of norepinephrine, dopamine, and serotonin. One study found that patients taking sibutramine lost an average of 7–10 lb (3–5 kg) more over one year than those on a low-calorie diet alone.

High **fiber** foods have also been advocated as appetite syppressants. A typical example is glucomannan, a dietary fiber derived from the root of the elephant yam or konjac plant, which is native to Asia. The theory behind use of foods that contain nondigestable fiber had been that these foods caused abdominal distention, swelling of the stomach, which was believed to cause a feeling of fullness, without increasing calorie intake. Studies and reviews of the effects of glucomannan and other non-nutritive fiber products such as bran have had varying results, but several of these studies have been encouraging. One Norwegian study compared three different kinds of fiber along with a highly calorie restricted diet and reported "Glucomannan induced body weight reduction in healthy overweight subjects, whereas the addition of guar gum and alginate did not seem to cause additional loss of weight." A British study reviewed the effects of guar gum, a fiber which is often used as a thickening agent in food products, for its value in weight reduction. The researchers concluded that guar gum was not effective in aiding weight loss and the risks associated with taking guar gum outweight its benefits. It appears that fiber, or the stomach expansion which fiber causes, is not adequate to reduce calorie intake. If there is a special benefit to glucomannan as indicated by the positive studies, its mechanism of action has not been explained.

Past evidence indicated that elevated blood glucose reduced appetite. This belief was the basis for the claim that sweets before meals would ruin an appetite.

**Diet pills approved by the U.S. Food and Drug Administration**

| Generic name | Trade name(s) | Drug type | FDA approval date |
|---|---|---|---|
| **Approved for short-term use** | | | |
| diethylpropion | Tenuate, Tenuate dospan | appetite suppressant | 1959 |
| phendimetrazine | Bontril, Plegine, Prelu-2, X-Trozine, Adipost | appetite suppressant | 1982 |
| phentermine | Adipex-P, Fastin, Ionamin, Oby-trim, Pro-Fast, Zantryl | appetite suppressant | 1959 |
| **Approved for long-term use** | | | |
| orlistat | Xenical | lipase inhibitor | 1999 |
| sibutramine | Meridia | appetite suppressant | 1997 |

SOURCE: National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, U.S. Department of Health and Human Services

**Most currently available weight-loss medications are FDA-approved for short-term use, meaning a few weeks, but doctors may prescribe them for longer periods of time. Sibutramine and orlistat are the only weight-loss medications approved for longer-term use in patients who are significantly obese. Their safety and effectiveness have not been established for use beyond two years.** *(Illustration by GGS Information Services/Thomson Gale.)*

High glucose diet aids were marketed based on this concept. One example was the Ayds diet candy, which contained more sugar than regular candy, and was widely marketed in the 1970s. These products were found to be ineffective as an adjunct to diet and exercise in a weight loss regimen. While Ayds was reformulated to contain phenylpropanolamine, the similarity of the name to the disease AIDS eventually drove this product off the market.

### *Topical anesthetics*

In 1983, the Food & Drug Administration approved the use of benzocaine, a topical anesthetic widely used in first aid sprays, as an aid to weight-loss programs. The claim was that benzocaine, in the form of lozenges or gums, would anesthetize the tongue, making food less attractive. More recent studies have failed to show any significant benefit to benzocaine as a weight loss.

### *Lipase inhibitors*

In 1999 the FDA approved orlistat—the first of a new class of anti-obesity drugs called lipase inhibitors—for long-term use. **Orlistat**, marketed under the brand name Xenical inhibits the pancreatic enzyme lipase that breaks down dietary fat. This decreases the body's absorption of dietary fat by as much as 30%. The undigested fat is excreted in the stool.

Orlistat is prescribed for overweight or obese patients who also have:

- high cholesterol
- diabetes
- high blood pressure
- heart disease.

On February 7, 2007, the FDA approved orlistat for non-prescription sale.

### *Other agents*

A large number of other agents have been offered for over-the-counter sale as weight loss agents, however they have not been either adequately studied or properly standardized, and so can not be recommended. One typical example is chitosan a fiberous material made of shellfish shells. This material may adsorb **fats**, preventing their digestion, and thereby reducing caloric intake. Several studies have reported favorably on the effects of chitosan, but a careful analysis of these studies indicates that in the best conducted studies, the overall weight reduction benefits are trivial, and preparations containing chitosan cannot be recommended.

Many of the products marketed as herbal have been found to be adulterated with active drugs, including sibutramine and amphetamine. People taking these agents under the impression that they are safe because they are labeled as natural products may be taking inappropriate doses of active drugs. One Chinese remedy was found to contain Aristolochic acid which was found to be responsible for six deaths due to kidney failure among patients at a Belgian health spa.

Another reviewer examined studies relating to complimentary and alternative treatments for **obesity**. None of the drugs reviewed appeared to show convincing evidence of value based on published studies, although hyponotherapy did appear to be of potential value in weight reduction. While the overwhelming majority of complimentary and alternative medicines marketed for weight reduction are harmless, the lack

## KEY TERMS

**Anorexiant**—A drug that causes loss of appetite

**Caloric**—Relating to heat or calories, also, full of calories, and so likely to be fattening.

**Dopamine**—A neurotransmitter and precursor of norepinephrine; found in high concentrations in the brain.

**Fiber**—Nutrients in the diet which are not digested by enzymes. Insoluable fiber travels through the digestive tract and has a laxative effect.

**Glucomannan**—A plant substance composed of long chains of the sugars glucose and mannose. It is not digested, and may be ised as a laxative. The material has been claimed to provide a feeling of abdominal and intestinal fullness.

**Hemorrhagic**—Relating to escape of blood from the vessels. Bleeding.

**Homeopathic**—Relating to homeopathy, a system of treating diseases by giving people very small doses of natural substances which, in healthy people, cause the same symptoms as the disease being treated.

**Norepinephrine**—A hormone that constricts blood vessels.

**Stroke**—The sudden death of brain cells when the blood supply is disrupted either through blockage or bleeding.

**Thermogenic**—Producing heat. Relating to diet drugs the term is used to indicate a drug which causes increased use of calories without exercise.

of evidence of efficacy makes their use inadvisable since there is no reason to accept any risk.

Some products claim to increase the body's thermogenesis. According to these claims, the body will burn more calories in the resting state, leading to increased weight loss. At one time, thyroid hormone was prescribed for this purpose, but because of the very high risks associated with thyroid, this use has been discontinued. Comparable claims have been made for **green tea** extract, but the weight loss benefits of these products are not clear. In one study, patients taking green tea had greater weight loss than the subjects in the control group, but on careful review, it was found that patients in the active group were exercising more than patients taking placebo.

Homeopathic remedies have been offered as weight loss products. Homeopathy itself is controversial at best, and there have been no reputable studies indicating that homeopathic remedies have any value in weight reduction.

Starch blockers are products which inhibit the digestion of starch, and so reduce its caloric value. This, in theory, should lead to reduced effective calorie intake, however the value of these products has not been demonstrated. Because these products are made from bean husks, there has been an ongoing dispute in the courts. The manufacturers argue that their products are animal feed, and not subject to regulation as drugs, while the FDA has argued that the intended use of the starch blockers is as a drug, and should be subject to regulation. The courts have been divided on how these products should be defined.

### Precautions

Because of the lack of standardization and high frequency of adulteration in some products marketed as herbal or natural weight loss remedies, people choosing to buy products of this type should deal only with a known and reputable supplier.

No weight loss product has demonstrated the ability to induce weight loss without diet, exercise, and behavioral modification. Although orlistat has been approved for long-term use, this is defined as up to two years, and in controlled studies, patients taking the drug showed increases in weight during the second year.

### Aftercare

Weight-loss drugs are used as short-term adjuncts to programs of diet, exercise, and behavioral changes, such as portion control, that are intended to maintain lifetime weight goals. These behaviors must be continued after the drugs are discontinued.

### Parental concerns

Weight-loss drugs are not normally indicated for children under the age of 16. Children should not use these drugs without proper medical supervision.

# Dietary cholesterol

## Definition

Cholesterol is a soft, white, waxy substance found in the lipids of the bloodstream and in the cells of the body. There are two sources of cholesterol. The first is the body, mainly the liver, which produces typically about 1g per day. The second are cholesterol-containing foods from animal sources, especially egg yolks, meat, poultry, fish, seafood and whole-milk dairy products. This is the cholesterol called dietary cholesterol, because it is obtained from the diet.

**Dietary cholesterol**

| Food | Cholesterol (mg) |
|---|---|
| Beef liver, cooked, 3 oz | 331 |
| Beef sweetbreads, cooked, 3 oz. | 250 |
| Squid, cooked, 3 oz. | 227 |
| Egg, whole, large | 212 |
| Shrimp, cooked, 3 oz. | 166 |
| Ice cream, gourmet, 1 cup | 90 |
| Salmon, baked, 3.5 oz. | 87 |
| Lamb chop, cooked, 3 oz. | 75 |
| Chicken breast, cooked, 3 oz. | 72 |
| Beef, round, cooked, 3 oz. | 71 |

## Purpose

Cholesterol is found in every cell of the body and it has several important functions in maintaining health such as:

- keeping cell membranes intact
- boosting mental performance
- helping digestion
- building strong bones
- building muscle
- maintaining energy, vitality, and fertility
- regulating blood sugar levels
- repairing damaged tissue
- protecting against infectious diseases

However, excess cholesterol has been shown to accumulate in the bloodstream and on the walls of arteries, forming "plaques" that can clog the blood vessels (atherosclerosis) and lead to heart attacks and strokes. Because high blood cholesterol is one of the major risk factors for heart disease, dietary cholesterol has been the focus of much debate over what represents

## KEY TERMS

**Artery**—A blood vessel that carries blood from the heart to the body.

**Atherosclerosis**—Clogging, narrowing, and hardening of the large arteries and medium- sized blood vessels. Atherosclerosis can lead to stroke, heart attack, eye problems and kidney problems.

**Blood plasma**—The pale yellowish, protein-containing fluid portion of the blood in which cells are suspended. 92% water, 7% protein and 1% minerals.

**Cholesterol**—Soft, waxy substance found among the lipids present in the bloodstream and in all cells of the body.

**Extrahepatic**—Originating or occurring outside the liver.

**Fatty acid**—Any of a large group of monobasic acids, especially those found in animal and vegetable fats and oils, having the general formula CnH.

**Heart attack**—A heart attack occurs when blood flow to the heart muscle is interrupted. This deprives the heart muscle of oxygen, causing tissue damage or tissue death.

**Hyperlipidemia**—Elevation of lipid levels (fats) in the bloodstream. These lipids include cholesterol, cholesterol compounds, phospholipids and triglycerides, all carried in the blood as part of large molecules called lipoproteins.

**Lipids**—Group of chemicals, usually fats, that do not dissolve in water, but dissolve in ether.

**Saturated fat**—A type of fat that comes from animals and that is solid at room temperature.

**Stroke**—he sudden death of some brain cells due to a lack of oxygen when the blood flow to the brain is impaired by blockage or rupture of an artery to the brain.

**Triglycerides**—Triglycerides are the chemical form in which most fat exists in food as well as in the body.

**Unsaturated fat**—A type of fat derived from plant and some animal sources, especially fish, that is liquid at room temperature.

healthy or unhealthy levels of cholesterol in the blood and how to lower cholesterol in the diet.

### Description

Dietary cholesterol is found in animal food sources such as meat, poultry, seafood and dairy products. Foods from plants, such as fruits, vegetables, vegetable oils, grains, cereals, nuts and seeds, do not contain cholesterol. Major sources of dietary cholesterol include:

- beef liver, 3 ounces cooked (331mg)
- beef sweetbreads, 3 ounces cooked (250mg)
- squid, 3 ounces cooked (227mg)
- egg, whole, large (212mg)
- shrimp, 3 ounces cooked (166mg)
- scallops, 3 ounces cooked (27mg)
- milk, whole, 1 cup (33mg)
- cheese, regular cheddar, 1 ounce (30mg)
- cheese, reduced fat, 1 ounce (6mg)
- ice cream, gourmet, 1 cup (90mg)
- ice cream, light, 1 cup (31mg)
- beef, sirloin, 3 ounces cooked (71mg)
- beef, round, 3 ounces cooked (71mg)
- beef, rib eye, 3 ounces cooked (65mg)
- pork chop, 3 ounces cooked (71mg)
- ham, regular, 3 ounces cooked (50mg)
- lamb chop, 3 ounces cooked (75mg)
- chicken breast, 3 ounces cooked (72mg)
- chicken, dark, 3 ounces cooked (70mg)

Cholesterol does not dissolve in blood. It has to be transported to and from the cells by special carriers called lipoproteins. These are present in blood plasma and the most important are:

- Very high-density lipoprotein (VHDL). VHDL consists of proteins and a high concentration of free fatty acids.
- High-density lipoprotein (HDL). HDL helps remove fat from the body by binding with it in the bloodstream and carrying it back to the liver for excretion in the bile and disposal. A high level of HDL may lower chances of developing heart disease or stroke.
- Intermediate-density lipoprotein (IDL). IDLs are formed during the degradation of very-low-density lipoproteins; some are cleared rapidly into the liver and some are broken down to low-density lipoproteins.
- Low-density lipoproteins (LDL). LDL transports cholesterol from the liver and small intestine to

tissues outside the liver (extrahepatic) and other parts of the body. A high LDL level may increase chances of developing heart disease.

- Very low-density lipoprotein (VLDL). VLDLs carry triglycerides from the intestine and liver to fatty (adipose) and muscle tissues; they contain primarily triglycerides. A high VLDL level can cause the buildup of cholesterol in arteries and increase the risk of heart disease and stroke.
- Chylomicrons. Proteins that transport cholesterol and triglycerides from the small intestine to tissues after meals.

Generally speaking, LDL levels should be low, because LDL deposits cholesterol in the arteries and causes them to become clogged, and HDL levels should be high, because HDL helps clean fat and cholesterol from arteries, carrying it to the liver for removal from the body. This is why HDL is often called the "good cholesterol" and LDL the "bad cholesterol".

## Precautions

The National Heart, Lung and Blood Institute (NHLBI), through its National Cholesterol Education Program (NCEP), recommends that adults begin cholesterol screening at age 20 and repeat the screening every five years. Persons who have one or more risk factors for developing heart disease (for example diabetes, kidney disease, high blood pressure, vascular disease, a history of elevated cholesterol levels) should have their cholesterol levels checked more often.

Simple blood tests are done to check blood cholesterol levels. A lipoprotein test, also called a fasting lipid test, is commonly performed as part of a routine medical examination. A cholesterol test measures lipid levels and usually reports on four groups:

- Total cholesterol (normal: 100–199 mg/dL)
- LDL (normal: less than 100 mg/dL)
- HDL (normal: 40–59 mg/dL)
- Triglycerides (normal: less than 150 mg/dL)

## Interactions

Dietary **fats** are known to interact with cholesterol as follows:

- monounsaturated fats (olives, olive oil, canola oil, nuts, avocados) lower LDL, raise HDL
- polyunsaturated fats (corn, soybean, safflower, cottonseed oils, fish) lower LDL, raise HDL;
- saturated fats (whole milk, butter, cheese, ice cream, red meat; chocolate, coconuts) raise both LDL and HDL;
- trans fats (most margarines, vegetable shortening, partially hydrogenated vegetable oil, deep- fried chips, many fast foods, most commercial baked goods) raise LDL

## Aftercare

The American Heart Association (AHA) endorses the following dietary recommendations for people with high blood cholesterol:

- total fat: 25% of total calories
- saturated fat: less than 7% total calories
- polyunsaturated fat: up to 10% total calories
- monounsaturated fat: up to 20% total calories
- carbohydrates: 50–60% total calories
- protein: about 15% total calories
- cholesterol: less than 200 mg/dL
- plant sterols: 2g
- soluble fiber such as psyllium: 10– 25g

Categories of appropriate foods include:

- lean meat/fish: less than 5oz/day
- eggs: less than 2 yolks per week (whites unlimited)
- low-fat dairy products (<1% fat): 2–3 servings/day
- grains, especially whole grains: 6–8 tsp/day
- vegetables: less than 6 servings per day
- fruits: 2–5 servings per day

## Complications

If dietary cholesterol intake is excessive, it can lead to an elevation of lipid levels in the bloodstream (**hyperlipidemia**). These lipids include cholesterol, phospholipids and **triglycerides** (fats). Hypercholesterolemia is the term for high cholesterol levels, and **hypertriglyceridemia** is the term for high triglyceride levels. Because cholesterol-rich foods are also usually high in saturated fat, hypercholesterolemia is often combined to hypertriglyceridemia. Hyperlipidemias have been shown to represent a major risk factor for heart disease, the leading cause of death in the United States.

## Parental concerns

Parents can make dietary choices that can prevent cholesterol levels from being too high. For instance, they can follow these guidelines:

- Select only the leanest meats, poultry, fish and shellfish. Choose chicken and turkey without skin or remove skin before eating. Some fish, like cod, have less saturated fat than either chicken or meat.

- Limit goose and duck. They are high in saturated fat, even with the skin removed.
- Some chicken and turkey hot dogs are lower in saturated fat and total fat than pork and beef hot dogs. There are also lean beef hot dogs and vegetarian sausages that are low in fat and saturated fat.
- Dry peas, beans and tofu can be used instead of meat because they are low in saturated fat and cholesterol. Dry peas and beans also have a lot of fiber, which can help to lower blood cholesterol.
- Egg yolks are high in dietary cholesterol. A yolk contains about 213 mg. They should be limited to no more than 2 per week, including the egg yolks in baked goods and processed foods. Egg whites have no cholesterol, and can be substituted for whole eggs when baking.
- Regular dairy foods that contain fat, such as whole milk, cheese, and ice cream, are also high in saturated fat and cholesterol. But dairy products are an important source of important nutrients such as calcium and the diet should include 2 to 3 servings per day of low- fat or nonfat dairy products.
- When shopping for hard cheeses, select them fat-free, reduced fat, or part skim.
- Select frozen desserts that are lower in saturated fat, such as ice milk, low- fat frozen yogurt, low-fat frozen dairy desserts, sorbets, and popsicles.
- Saturated fats should be replaced with unsaturated fats. Select liquid vegetable oils that are high in unsaturated fats, such as canola, corn, olive, peanut, safflower, sesame, soybean, and sunflower oils.
- Limit butter, lard, and solid shortenings. They are high in saturated fat and cholesterol.
- Select light or nonfat mayonnaise and salad dressings.
- Fruits and vegetables are very low in saturated fat and total fat, and have no cholesterol. Fruits and vegetables should be eaten as snacks, desserts, salads, side dishes, and main dishes.
- Breads, cereals, rice, pasta, grains, dry beans, and peas are high in starch and fiber and low in saturated fat and calories. They also have no dietary cholesterol, except for some bakery breads and sweet bread products made with high fat, high cholesterol milk, butter and eggs.
- Select whole grain breads and rolls whenever possible. They have more fiber than white breads.
- Most dry cereals are low in fat. Limit high-fat granola, and cereal products made with coconut oil and nuts, which increases the saturated fat content.
- Restrict sweet baked goods that are made with saturated fat from butter, eggs, and whole milk such as croissants, pastries, muffins, biscuits, butter rolls, and doughnuts.
- Snacks such as cheese crackers, and some chips are often high in saturated fat and cholesterol. They can be replaced by low-fat snacks such as bagels, bread sticks, cereals without sugar, frozen grapes or banana slices, dried fruit, non-oil baked tortilla chips, popcorn or pretzels.

# Dietary guidelines

## Definition

The Dietary Guidelines for Americans are the foundation of national nutrition policy for the United States. They are designed to help Americans make food choices that promote health and reduce the risk of disease. The guidelines are published jointly by the U.S. Department of Agriculture (USDA) and U.S.

Department of Health and Human Services (HHS). The first set of guidelines was published as *Nutrition and Your Health: Dietary Guidelines for Americans* in 1980. Since then, an advisory committee has been appointed every five years to review and revise the guidelines based on the latest research in nutrition and health.

## Description

### *Early Dietary Advice in the United States*

The first half of the twentieth century was a period of enormous growth in nutrition knowledge. The primary goal of nutrition advice at this time was to help people select foods to meet their energy (calorie) needs and prevent nutritional deficiencies. During the Great Depression of the 1930s, food was rationed and people had little money to buy food. They needed to know how to select an adequate diet with few resources, and the USDA produced a set of meal plans that were affordable for families of various incomes. To this day, a food guide for low-income families—the Thrifty Food Plan—is issued regularly by the USDA and used to determine food stamp allotments. In addition to meal plans, the USDA developed food guides—tools to help people select healthful diets. Over the years the food guides changed, based on the current information available.

### *Food Guides versus Dietary Guidelines*

Food guides are practical tools that people can use to select a healthful diet. Food guide recommendations, such as how many servings of grains to eat, are based on dietary guidelines that are overall recommendations for healthful diets. For example, the Dietary Guidelines for Americans include the recommendation that Americans "choose a variety of grains daily, especially whole grains." To help people reach this goal, the USDA's Food Guide Pyramid is built on a base of grain foods and recommends six to eleven servings daily with several servings from whole grains. Thus, the Food Guide Pyramid supports the recommendations of the Dietary Guidelines.

### *Evolution of the Dietary Guidelines*

During the 1970s, scientists began identifying links between people's usual eating habits and their risk for chronic diseases such as heart disease and cancer. They realized that a healthful diet was important not only to prevent nutrient deficiencies, but because it might play a role in decreasing the risk for chronic diseases. Since heart disease and **cancer** were, and still are, major causes of death and disability in the United States, there was a need to help Americans select health-promoting diets.

The first major step in federal dietary guidance was the 1977 publication of *Dietary Goals for the United States* by the Senate Select Committee on Nutrition and Human Needs, which recommended an increased intake of carbohydrates and a reduced intake of fat, saturated fat, cholesterol, salt, and sugar. There was heated debate among nutrition scientists when the Dietary Goals were published. Some nutritionists believed that not enough was known about effects of diet and health to make suggestions as specific as those given.

In 1980, the first edition of Dietary Guidelines for Americans was released by the USDA and HHS. The seven guidelines were: (1) Eat a variety of foods; (2) Maintain ideal weight; (3) Avoid too much fat, saturated fat, and cholesterol; (4) Eat foods with adequate starch and fiber; (5) Avoid too much sugar; (6) Avoid too much **sodium**; and (7) If you drink alcohol, do so in moderation. The second edition, released in 1985, made a few changes, but kept most of the guidelines intact. Two exceptions were the weight guideline, which was changed to "Maintain desirable weight" and the last guideline, in which "alcohol" was changed to "alcoholic beverages."

Following publication of the second edition of the Dietary Guidelines, two influential reports concerning diet and health were issued. The *Surgeon General's Report on Nutrition and Health* was published in 1988, and the National Research Council's report *Diet and Health—Implications for Reducing Chronic Disease Risk* was published in 1989. These two reports supported the goal of the Dietary Guidelines to promote eating habits that can help people stay healthy. In 1990, the third edition of the guidelines took a more positive tone than previous editions, using phrases such as "Choose a diet. . ." or "Use . . . only in moderation," rather than "Avoid too much. . ." This was seen as a positive step by many nutrition educators.

The fourth edition was the first to include the Food Guide Pyramid, which had been introduced in 1992. It also was the first edition to address vegetarian diets and the recently introduced "Nutrition Facts" panel for food labels. The fifth edition, issued in 2000, expanded the number of guidelines to ten and organized them into three messages: "Aim for Fitness, Build a Healthy Base, and Choose Sensibly" (ABC).

The Dietary Guidelines for Americans have evolved since they were first published in 1980. Their recommendations represent the latest research in diet and health promotion, and, as new research emerges,

the guidelines will continue to change to reflect new insights into diet and health. People can take steps toward healthier lifestyles by following the recommendations of the Dietary Guidelines and using tools like the Food Guide Pyramid to guide their food choices.

### The 2000 Dietary Guidelines for Americans

Aim for Fitness

- Aim for a healthy weight
- Be physically active each day

Build a Healthy Base

- Let the Pyramid guide your food choices
- Choose a variety of grains daily, especially whole grains
- Choose a variety of fruits and vegetables daily
- Keep food safe to eat

Choose Sensibly

- Choose a diet that is low in fat and cholesterol and moderate in fat
- Choose beverages and foods to moderate your intake of sugar
- Choose and prepare foods with less salt
- If you drink alcoholic beverages, do so in moderation

# Dietary reference intakes

## Definition

Dietary reference intakes (DRI) are a set of reference values for **vitamins**, **minerals**, and other nutrients important to human health. DRIs provide guidance about the appropriate amount of each nutrient that should be consumed based on American and Canadian diets. DRIs are specific to age group, gender, and for women, reproductive status.

## Purpose

DRIs are tools intended to be used in planning and assessing diets of individuals and groups. They are based on data that applies to American and Canadian populations and replace previously issued Recommended Dietary Allowances (RDAs) in the United States and Recommended Nutrient Intakes (RNIs) in Canada.

## Description

Health is strongly affected by the food that people eat, and proper diet can delay, prevent, or treat certain diseases and disorders. Research on dietary vitamins and minerals in the 1920s and 1930s led to the publication of the first RDAs in 1941 by the Food and Nutrition Board of the National Academy of Sciences. These early RDAs were based on the amount of each vitamin or mineral that was needed to prevent symptoms of the corresponding nutrient-deficiency disease. For example, the RDA for **vitamin A** was set at a level that would prevent symptoms of night blindness. The availability of RDAs gave a boost to food fortification programs that helped eliminate many vitamin deficiency disorders such as pellagra, which is caused by **niacin** deficiency.

The RDAs were reviewed about every five years and the values were adjusted as additional research became available, but for many years the underlying assumption remained one of setting dietary intake level of each nutrient to prevent disease. Multi-vitamin **dietary supplements** have been in use for many years. By the early 1980s single-ingredient dietary supplements, many claiming to boost athletic or sexual performance, increase energy, prevent disease, or control weight, had become much more common. Research on these dietary supplements showed that some vitamins and minerals taken in quantities larger than the RDA appeared to provide benefits to healthy individuals, but the same supplement taken in too large a quantity could be harmful. The Institute of Medicine

## KEY TERMS

**Amino acid**—Molecules that are the basic building blocks of proteins.

**Bioavailability**—The degree to which a compound can be absorbed and used by the body.

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Fatty acids**—Complex molecules found in fats and oils. Essential fatty acids are fatty acids that the body needs but cannot synthesize. Essential fatty acids are made by plants and must be present in the diet to maintain health.

**Macronutrient**—A substance needed in large quantities to maintain growth and health such as the energy-producing molecules that come from proteins, carbohydrates, and fats.

**Micronutrient**—Substances that are needed in very small, even trace, amounts to maintain normal growth and health.

**Mineral**—An inorganic substance found in the earth that is necessary in small quantities for the body to maintain health. Examples include zinc, copper, iron.

**Toxic**—Harmful or poisonous to the body.

**Vitamin**—A nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

of the National Academy of Sciences decided that an expanded set of reference values was needed to incorporate this new research and provide better nutrition guidance to both health professionals and consumers. In 1997, in cooperation with nutrition authorities in Canada, they began replacing RDAs (and RNIs in Canada) with the first Dietary Reference Intakes or DRIs.

### *Components of the DRIs*

DRIs cover micronutrients (e.g., vitamins and minerals) essential to human health. Dietary guidance in a different form is also given for **macronutrients** (e.g., **protein**, **carbohydrates**, and **fats**). The DRIs for vitamins and minerals consist of four values that reflect both the lower and upper daily intake limits beyond which adverse health effects may occur. They also include and an average or recommended daily value meets the health needs of most of the population.

DRIs are intended to apply only to people who appear healthy. They are calculated based on the nutritional needs of each age group and gender: infants 0–6 months and 6–12 months; children ages 1–3 years, 4-8 years, and 9–13 years; adolescents 14–18 years, and adults. The adult group is subdivided into women who are pregnant, women who are **breastfeeding**, and sometimes into younger and older adults, depending on the nutrient. The values for each nutrient are measured against a specific reference goal. Examples of these goals include preventing symptoms of a nutrient deficiency disease, maintaining normal growth, maintaining a specific level of the nutrient circulating in the blood, or preventing symptoms associated with nutrient excess.

Four reference values make up the DRI for micronutrients:

- Estimated Average Requirement (EAR). The EAR is the average daily intake of a nutrient that will meet the nutritional needs of half the individuals in the group. In other words, if half the healthy children between ages four and eight received the EAR for iron for their age group, about 50% would show signs of iron deficiency and 50% would not.
- Recommended Dietary Allowance (RDA). The RDA is the amount of a nutrient that meets the needs of 97–98% of all healthy individuals within the group. For example, if all children ages 4–8 years old were receiving the RDA for iron for their age group, only one or two of every hundred children would be iron deficient. The RDA is calculated using the EAR and the amount of variability (standard deviation [SD]) of the need for the nutrient within each group. Mathematically RDA = EAR + (2 x SD of the nutrient).
- Average Intake (AI). Calculating the RDA requires that enough information is available to calculate the EAR. This information is not always available because of practical and ethical limitation on experimenting with humans. When insufficient information is available to calculate the RDA, an estimate of the average daily intake is made. Just like the RDA, the AI expected to meet or exceed the nutritional need of almost everyone in the group. Although both the RDA and the AI are intended to give guidance about how much of a particular nutrient a healthy individual in a specific group should, on average, get daily, the AI is an estimate based on experimental evidence and observation, not a defined calculation like the RDA.

- Tolerable Upper Intake Level (UL). The UL is the highest daily amount that is unlikely to cause adverse (negative) risks to health in almost all of the members of the group. In other words, if all the children ages 4–8 were taking the UL for iron, most of them would remain healthy, but over time one or two per hundred might show signs of iron excess. The higher the amount of nutrient consumed above the UL, the higher the risk of adverse health effects. Some micronutrients such as folic acid, niacin, and magnesium, have ULs that apply only to dietary supplements and not the quantity of the nutrient obtained from food. The inclusion of a UL value for the first time acknowledges that too much of a nutrient can be toxic and harmful to health.

Macronutrients are what most people call food—nutrients that provide calories (energy). These include carbohydrates, fat, fatty acids, cholesterol, protein, and amino acids. **Fiber** is an included nutrient but it does not provide energy. In the body, carbohydrates, proteins, and fats can in some cases be used interchangeably. In addition, it is not possible to link specific quantities of these macronutrients to the prevention or development of chronic diseases such as diabetes and cardiovascular disease. In place of DRIs, the Institute of Medicine has developed Acceptable Macronutrient Distribution Ranges (AMDRs) for energy-yielding nutrients. AMDRs are expressed, not as absolute numbers, but as a percentage of total energy (calorie) intake.

## Controversies about DRIs

The four components of the DRI are intended to provide more guidance than a single number alone would provide. However, they are not without their critics. Some criticism stems from statistical assumptions made in the calculations. Other criticism is based on the fact that different forms of certain nutrients have a different bioavailability. For example, **iron** in meat is more easily absorbed than iron in plant foods, and the **vitamin E** in dietary supplements is more biologically active than vitamin E in food. Although this should not be a source of confusion to healthcare professionals, it can be confusing to the average consumer.

The greatest controversies among experts are over the UL. These center around four areas:

- Very little experimental data is available about the upper limit of certain nutrients in special populations such as children, pregnant women, and elderly individuals.
- Some experts are not comfortable with the way the Institute of Medicine derived UL values. Experts point out that in some cases the UL for one subgroup overlaps the RDA for another subgroup and that in other cases the typical intake of certain groups already exceeds the UL with no apparent harmful effects (e.g., iron in young children). The vitamin C UL appear to be especially controversial.
- No distinction is made between short-term (acute) and long-term (chronic) overdose of nutrients.
- The ULs do not take into consideration genetic diversity of the population and are much less sensitive to the life stage of the individual than RDAs. This is in part because of limited data available for certain age groups.
- Much of the data used to determine the UL is based on short-term (a few days) intake information and therefore has a high degree of unreliability. Human experiments with potentially toxic mega doses of nutrients is generally unethical, making an adequate amount of reliable data in the UL range difficult to obtain.

DRIs and AMRDs continue to be researched and revised as more data becomes available. Despite the controversy, they offer both healthcare professionals and individuals some guidelines about the benefits and dangers of nutrient consumption.

## Precautions

DRIs are intended as guidelines for population groups, not individuals. Although they give values for daily intake of nutrients, these values are intended to apply over time. Except in cases of acute mega doses, the effects of too much or too little of a nutrient develop gradually over time. In any given day, an individual may eat more or less than the DRI of a particular nutrient and still remain healthy.

DRIs are intended to be applied to a healthy population. Individuals under the supervision of a healthcare professional may be advised to take more or less of particular nutrients than the DRIs indicate. In this situation, the advice of the healthcare professional should be followed.

Nutrients interact with each other and with pharmaceuticals and herbal remedies. These interactions are not entirely understood and may affect the absorption, utilization, and excretion of various vitamins and minerals in ways that change the RDA.

Certain population groups, such as vegans, have dietary needs that may be satisfied only with dietary supplements or very carefully controlled diets.

## Parental concerns

Parents should discuss DRIs with a healthcare professional who can translate them into healthy

eating guidelines to provide a healthy diet for their children over time. A diet high in fruits and vegetables and low in fats will meet most DRIs for both children and adults.

# Dietary supplements

## Definition

In the United States, dietary supplements are defined by the 1994 Dietary Supplement Health and Education Act as products that are not used exclusively as food, but are intended to be consumed in addition to an individual's diet. The law states that dietary supplements are taken by mouth and contain

**Drug interactions**

| Dietary supplement | Drug |
|---|---|
| Calcium | Heart medicine (e.g., Digoxin) thiazide diuretics (Thiazide, and aluminum- and magnesium-containing antiacids) |
| Magnesium | Thiazide and loop diauretics (e.g., Lasiz®), some cancer drugs (Cisplatin), and magnesium-containing antiacids. |
| Vitamin K | Blood thinners (e.g., Coumadin) |
| St. John's Wort | Selective serotonin reuptake inhibitor (SSRI) drugs (antidepressant drugs and birth control pills) |

SOURCE: Office of Dietary Supplements, National Institutes of Health, U.S. Department of Health and Human Services

*(Illustration by GGS Information Services/Thomson Gale.)*

one or more dietary ingredients. Examples of dietary ingredients include **vitamins**, **minerals**, herbs or other biological material, amino acids, and enzymes. Dietary supplements are sold in the form of tablets, capsules, powders, liquids, extracts, or teas. Products sold as dietary supplements are required to be clearly labeled as such.

## Purpose

Dietary supplements serve a wide range of purposes. Some of these are medically appropriate, while others may do nothing or harm the individual. Reasons for taking dietary supplements include:

- Replacing a necessary substance not found in large enough quantities in the diet
- Preventing or decreasing the risk of developing a disease or condition
- Boosting the immune system and improving general health
- Boosting energy levels
- Improving mental or physical performance
- Stimulating weight loss
- Reducing symptoms of a disease or health condition

## Description

Dietary supplements comprise a variety of products ranging from familiar multivitamins found in every supermarket to exotic botanicals such as the South African herb **hoodia**. Millions of Americans take dietary supplements daily; their use has become increasingly common since the 1990s. The United States Food and Drug Administration (FDA) estimates that in 1999 more than 12 million Americans were taking **ephedra**, a weight-loss supplement that was later banned because it can cause serious side effects. Due to the large number of different supplements and their range of uses, testing and regulation of these products is difficult and often ineffective.

### *Dietary supplements and the law*

The FDA regulates dietary supplements under the 1994 Dietary Supplement Health and Education Act (DSHEA). At the time the act was passed, legislators believed that because many dietary supplements come from natural sources such as plants and have been used for hundreds of years by practitioners of complementary and alternative medicine (CAM), these products did not need to be as rigorously regulated as prescription and over-the-counter drugs used in conventional medicine.

DSHEA regulates supplements in the same way food is regulated. Like food manufacturers, manufacturers of dietary supplements do not have to prove that a supplement is either safe or effective before it can be sold to the public. Manufacturers of conventional pharmaceutical drugs, however, must prove both safety and effectiveness in humans before a new drug is approved for use. With dietary supplements, the burden of proof falls on the FDA to show that the supplement is either unsafe or ineffective before the supplement can be restricted or banned. Information about a supplement's safety and effectiveness is normally gathered only after people using the product develop health problems or complain that the product does not work. Initially, supplement manufacturers were not required to report consumer complaints of complications or side effects to the FDA. However, beginning in 2007, a federal law requires all manufacturers of dietary supplements and over-the-counter drugs to report consumer complaints of adverse events (negative side effects) to the FDA. This makes accumulating information on the safety of these products faster and easier.

Dietary supplements are required to be clearly labeled with the word "supplement." The label must also show the volume or weight of the contents, the serving size, a list of dietary ingredients and non-dietary ingredients (e.g., artificial color, binders, fillers, flavorings), the name of the manufacturer, packer, or distributor, and directions for use. If the supplement is an herb, the label must contain its scientific name.

Unlike conventional drugs, the label for a dietary supplement does not have to provide statements about possible side effects. However, dietary supplements are not legally allowed to claim they can "cure,"

"treat," "mitigate," "prevent," or "diagnose" a specific disease. They may make the following claims:

- Health claims—Statements indicating a relationship between an ingredient in the supplement and the reduction in the risk of developing a disease or condition. (e.g., Increased intake of folic acid by pregnant women helps reduce the risk of neural tube defects in their offspring.)
- Nutrient content claims—Statements describing the amount of supplement in the product and may contain words such as "high in," "good source of," "fortified," "enriched," or "high potency."
- Structure or function claims—Description of how the supplement may affect organs or systems in the body without mentioning a specific disease or condition. (e.g., Calcium builds strong bones.) Labels with structure or function claims must also contain the words "This statement has not been evaluated by the FDA. This product is not intended to diagnose, treat, cure, or prevent any disease."

Manufacturers of supplements are required to follow federal Good Manufacturing Practices (GMPs) that regulate sanitary and other conditions under which these products are prepared, packaged, and stored. These GMPs are much less stringent than those that regulate the manufacture of conventional drugs. They do not, for example, assure that the amount of active ingredient in each pill or capsule of a dietary supplement is the same. Some supplement manufacturers try to assure consistency of their product by making sure each batch contains the same amounts of active ingredients. This type of standardization is not required by law, and the word "standardized" on the label is not an indication that the product meets any legal requirements as to quality or consistency of contents.

### *Dietary supplements in conventional medicine*

Conventional medicine, also called Western or mainstream medicine, is practiced by licensed medical doctors (MD) and doctors of osteopathy (DO), dentists (DDS or DMD), registered nurses (RN), licensed practical nurses (LPN), pharmacists, and similar health care professionals. Some dietary supplements are routinely used as an accepted part of conventional medicine. The most common of these are vitamin and mineral supplements taken in accordance with established **dietary reference intakes** (DRIs). DRIs are a set of values for different nutrients that indicate the daily amount of that nutrient necessary to meet the needs of most individuals, as well as the largest amount of the nutrient that can be consumed daily without harmful effects. Other supplements, such as folic acid, are prescribed for pregnant women in order to decrease the risk of neural tube defects in their offspring. Still other supplements, such as enzymes, may be given when the body fails to produce adequate amounts of the enzyme as the result of a genetic disorder such as cystic fibrosis. When taken under supervision of a conventional health care professional, dietary supplements tend to be extremely safe.

### *Dietary supplements in complementary and alternative medicine*

Most dietary supplements are used within a system of complementary and alternative medicine (CAM). Complementary medicine uses treatments that are not part of conventional medicine to supplement conventional medicine. Alternative medicine uses treatments that are not part of conventional medicine as a complete replacement for conventional medicine. Alternative medicine includes well-established treatment systems such as homeopathy, traditional Chinese medicine, and Ayurvedic, or traditional Indian medicine, as well as newer fad-driven treatments. Many CAM treatments have their roots in tradition and folklore.

Herbs are some of the most common dietary supplements used in CAM. Many have been used for hundreds of years and show evidence of effectiveness. Others are ineffective or may harm the individual either directly or when used as a replacement for conventional drugs and treatments whose effectiveness has been proven. Vitamin and mineral supplements used as part of conventional medicine become part of the CAM system when they are used in mega-doses that far exceed DRI values or when they are used to prevent or treat a specific condition (e.g., **vitamin C** to prevent colds). Likewise, enzymes and amino acids that have specific uses within conventional medicine become part of the CAM system of dietary supplements when they are used in non-conventional ways or in non-standard doses. Some dietary supplements, such as bee pollen, are used exclusively in CAM.

## Precautions

It is difficult to determine whether dietary supplements are safe or effective because of the way they are regulated. Many of the studies done on supplements are poorly designed, have a small sample size, or are sponsored by the manufacturer of the supplement, making the results questionable. Natural Standard is an independent organization that evaluates studies, scientific evidence, and expert opinion on CAM treatments and therapies and makes impartial judgments concerning their safety and effectiveness. The National Center for

Complementary and Alternative Medicine is a government organization within the National Institutes of Health that investigates CAM treatments and runs rigorous clinical trials to determine safety and effectiveness.

Individuals interested in using dietary supplements should consult their health care provider and other reputable sources of information before taking any new supplements. Pregnant or **breastfeeding** women should be especially careful to discuss the supplements they may want to take with their health care provider. Many herbs and other dietary supplements cross the placenta or are secreted into breast milk and may affect the fetus or nursing baby. In addition, care should be taken in giving children dietary supplements. Few studies have been done specifically on children and the recommended dosage for adults may be harmful to children. As with any medication, more is not necessarily better. Overdose is a common cause of adverse side effects in dietary supplements. In the event of side effects, the supplement should be stopped immediately and the side effects reported to a health care professional.

## Interactions

Dietary supplements may interact with both conventional drugs and other herbs or dietary supplements. Individuals should seek information about specific interactions from their health care provider. Many dietary supplements should be stopped several days before surgery to reduce the risk of excess bleeding.

## Complications

There is strong evidence that some dietary supplements can cause serious harm or death. For example, the weight-loss supplement ephedra was found to have contributed to the death of the Baltimore Oriole's pitching prospect Steve Belcher in 2003. The FDA later banned ephedra-containing supplements. According to the American Association of Poison Control Centers, there have been over 62,000 reports of vitamin poisonings, over 23,000 cases linked to minerals, and over 23,000 reports linked to herbs. Twenty-seven deaths were attributed to dietary supplements in 2005, of which 13 were attributed to herbs. It should be remembered that "natural" does not mean safe; for example, many wild mushrooms are completely natural and cause death when eaten.

Complications may arise from dietary supplements themselves or their misuse or poor regulation of the manufacturing process. This is especially true of those supplements imported into the United States from developing countries. Independent laboratory analyses of dietary supplements have found:

- Contamination with pesticides
- Contamination with heavy metals
- Presence of ingredients not listed on the label
- Amount of dietary ingredient not the same as the amount listed on the label

Some health professionals believe the number of complications related to dietary supplements is severely under-reported. This should improve with

### KEY TERMS

**Alternative medicine**—A system of healing that rejects conventional, pharmaceutical-based medicine and replaces it with the use of dietary supplements and therapies such as herbs, vitamins, minerals, massage, and cleansing diets. Alternative medicine includes well-established treatment systems such as homeopathy, Traditional Chinese medicine, and Ayurvedic medicine.

**Amino acid**—Molecules that are the basic building blocks of proteins.

**Botanical**—An herb; a dietary supplement derived from a plant.

**Complementary medicine**—Includes many of the same treatments used in alternative medicine, but uses them to supplement conventional drug and therapy treatments, rather than to replace conventional medicine.

**Conventional medicine**—Mainstream or Western pharmaceutical-based medicine practiced by medical doctors, doctors of osteopathy, and other licensed health care professionals.

**Enzyme**—Proteins that change the rate of a chemical reaction within the body without themselves being used up in the reaction

**Herb**—A plant used in cooking or for medical purposes. Examples include Echinacea and ginseng.

**Mineral**—An inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples include zinc, copper, and iron.

**Vitamin**—A nutrient that the body needs in small amounts to remain healthy but that the body cannot adequately manufacture for itself and must acquire through diet.

the 2007 requirement that dietary supplement manufacturers report adverse side effects to the FDA.

### Parental concerns

Parents should be aware that the RDA and UL for vitamins and minerals are much lower for children than for adults. Accidental overdose may occur if children are give adult vitamins or dietary supplements.

Tish Davidson, A.M.

# Dietwatch

### Definition

Dietwatch is an online weight loss program that focuses on helping dieters lose weight at a moderate, healthy pace through healthy eating, regular exercise, and motivational support.

### Origins

Dietwatch was launched in 1999. It is an online only program, and can be found at <http://www.dietwatch.com>. In December 2000, Dietwatch acquired cyberdiet.com, which greatly expanded its operations. Since its launch, more than a million people have visited the Web site. Dietwatch has won a number of awards for excellence in Internet content, including a Best of the Web Award from Forbes Magazine. It is operated by DietWatch.com, Inc., which is headquartered in East Rockaway, New York.

The nutritional aspects of Dietwatch are headed by Jennifer May, the Manager of Nutritional Services. She is a registered dietician who holds both a Masters degree in Nutrition Science and a Masters degree in Exercise Physiology, both from Indiana University. The Mastering Eating program was developed by Dr. Roger Gould. Dr. Gould has published a variety of scholarly articles and was the head of the University of California, Los Angeles outpatient and community psychiatry department.

## KEY TERMS

**Dietary supplement**—a product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health

**Mineral**—An inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

**Vitamin**—A nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

## Description

Dietwatch is an online program designed to support and guide dieters to healthy, maintainable weight loss. It provides advice from fitness and nutrition experts, meal plans, and tips and motivation, as well as an online community where dieters can help each other through dieting's rough patches.

There are four options for meal plans provided by Dietwatch. It offers a "no restrictions" plan that is simply a reduced calorie, well balanced diet. Dietwatch says that this is the plan for dieters who do not have any specific concerns or preferences, as it includes a variety of types and styles of food. Another available plan is the "reduced carbs plan," which limits **carbohydrates** to 40% of a dieters total caloric intake each day. This is not a low carbohydrate plan but a limited carbohydrate plan. Unlike popular low carb diets such as Atkins, it does not restrict carbohydrates to just a few grams each day.

Another diet option is the "heart healthy-Mediterranean plan," which limits saturated and *trans* **fats** while including a high level of unsaturated fats. The style of the food and diet is Mediterranean and combines many flavors and food groups. The last meal plan alternative is the "vegetarian plan," which is a plan specially designed to meet the **protein** and other needs of vegetarians who are on a diet. The plan does include eggs and milk products, but no chicken, fish, or meat.

Customers can personalize the meal plans offered by Dietwatch by switching meals or ingredients to meet individual preferences. The program also offers shopping lists that are customized to the dieter's meal plan. This makes the meal plan easier to fit into a busy schedule.

In addition to meal plans, Dietwatch offers exercise and fitness plans and advice that the dieter can use to help customize a fitness plan to meet individual needs. There are a variety or strength training, aerobic, relaxation, and other suggested workouts available.

Motivation and emotional health are important aspects of Dietwatch. There are motivational tips from nutritionists and other experts, as well as discussion boards where dieters share frustrations, achievements, and tips. Dieters can search based on age, sex, weight, or other characteristics to find dieters to partner with for more one-on-one motivation and help.

Behavior understanding and modification is an important aspect of the Dietwatch program. Dr. Roger Gould developed a program called Mastering Food that is available to Dietwatch members. It is a 12-week program designed to help dieters overcome negative eating habits. Its goal is to help dieters discover why they eat when they are not hungry and help them find ways to deal with the problems underlying their eating behaviors. Overcoming emotional eating problems can help dieters be more successful in sticking to their diets and allow for more productive, successful weight loss.

Dietwatch also offers a variety of tools that can be used at the dieter's discretion. A food journal lets dieters track everything that they eat each day. The tracker can tally calories, fat grams, and other information to help dieters ensure that they are getting all the nutrients they need. Also available is a tool for tracking a dieter's daily calorie balance. This tool combines information about activity level and exercise with information about food eaten during the day to come up with the total calorie balance. This way dieters can check to see that they are burning more calories than they are taking in and if they are on track for their desired weight loss.

There is a wealth of information available on Dietwatch for dieters who are interested in learning more about health and nutrition. There is information about different nutrients and how they work in the body and explanations about why certain nutrients are required for good health. Also available is nutritional information for many foods, including information about a number of different restaurants. There is also general information about good eating and maintain a healthy approach to food.

## Function

Dietwatch is intended to help dieters make long-term comprehensive lifestyle changes that will help them lose weight and keep it off. To do this, it helps dieters with healthy eating and moderate exercise, as

well as stress reduction and other techniques aimed at better emotional health. The newest program, the Mastering Eating program, is intended to help dieters identify and change negative eating habits for better control over food in their lives. Dietwatch is also intended to help dieters become more fit and to attain overall better health.

### Benefits

There are many benefits to losing weight if it is done at a moderate pace through healthy eating and increased exercise. **Obesity** is a risk factor for many diseases and conditions including type 2 diabetes, cardiovascular disease, and **hypertension**. People who are the most obese are generally at the greatest risk and are likely to have more severe symptoms if these diseases develop. Losing weight can reduce the risk of these and other obesity-related diseases, and in some cases it can help reduce the severity of symptoms if the diseases have already occurred.

The Dietwatch program is designed to provide dieters with support for all the phases and processes of weight loss. Many dieters may find having all this support and information available in one place to be very helpful. The nutritional information may help dieters make more informed eating decisions, especially when eating out. The inclusion of a vegetarian meal planning option makes this diet available for vegetarian dieters who may be underserved by other diets offering meal plans.

One of the main aspects of the Dietwatch program is motivation. This comes in many forms including helpful and motivational tips from nutritionists and other dieters. Many dieters may find that the opportunity to find a dieting buddy that shares their same goals and challenges provides support that is more personal and effective than is usually available in commercial diet programs. Many dieters may also appreciate the opportunity to ask dieticians and other health professionals specific questions instead of relying on general information.

### Precautions

Anyone thinking of beginning a new diet should consult a doctor or other medical professional. Individuals have different requirements for calories, **vitamins**, **minerals**, and other nutrients. Talking to a doctor can help dieters insure that a new diet is the right diet to meet all their personal needs and that weight loss can be achieved without sacrificing good health. Pregnant and **breastfeeding** women should be especially cautious when beginning a new diet because what a mother eats can have a significant impact on a baby.

#### QUESTIONS TO ASK THE DOCTOR

- Is this diet the best diet to meet my goals?
- Would a multivitamin or other dietary supplement be appropriate for me if I were to begin this diet?
- Do I have any special nutritional needs that this diet might not meet?
- At what level of intensity is it appropriate for me to begin exercising?
- Does diet or exercise pose any special risk for me that I should be aware of?
- Is this diet appropriate for my entire family?
- Is it safe for me to follow this diet over a long period of time?
- Are there any sign or symptoms that might indicate a problem while on this diet?

### Risks

There are some risks to any diet. Eating a limited diet can make it difficult for a dieter to get all of the vitamins and minerals required for good health. Generally, when following a good diet that contains many different fruits and vegetables this risk is not too significant, but dieters may want to consult a doctor about taking a multivitamin or dietary supplement to help reduce the risk of deficiency.

When beginning a new exercise routine, it is important that dieters begin with light or moderate exercise and slowly increase the intensity of the activity over weeks or months. Suddenly beginning a strenuous exercise routine can have many risks, especially if the dieter has been inactive for many years. Less serious risks include the risk of straining or spraining a muscle, but more serious risks can even include heart attack if the exercise is very strenuous and is begun suddenly. Risk of injury during exercise can be reduced if proper warm up and cool down procedures are followed, including stretching all appropriate muscle groups. Dieters should consult a doctor before beginning any new exercise routine, especially if it is possible that they have heart disease or other cardiovascular problems that might put them at high risk for serious injury.

## Research and general acceptance

The diets and activities recommended by Dietwatch generally meet the standards for moderate weight loss of 1–2 pounds a week. This weight loss can be achieved through moderately reduced calorie meal plans and regular exercise. This is the approach that most experts recommend to successfully achieve permanent weight loss and better health.

The United States Department of Agriculture makes recommendations about the number of servings from each food group required daily for good health. These recommendations are in its MyPyramid food guide, available online at <http://www.MyPyramid.gov> Any diet that follows these basic guidelines for good health is generally considered a safe and healthy diet for most people. Diewatch's personalized daily food log can help dieters determine how many calories, grams of fat, carbohydrates, and amounts of other nutrients are eaten each day. This can help dieters ensure that they are following guidelines for a healthy diet.

In 2007, the Centers for Disease Control recommended that healthy adults get 30 minutes or more of light to moderate exercise each day for good health. Although Dietwatch does not make specific exercise plans for each individual, most of their recommendations meet or exceed this minimum recommendation. Studies have shown that exercise and diet are more effective at producing weight loss when done together than either diet or exercise done alone. Dietwatch encourages dieters not only to combine diet and exercise, but also to alter problem eating behaviors, which many experts believe is important for long-term weight loss.

# Digestive diseases

## Definition

Digestive diseases, also called gastrointestinal diseases, are the diseases that affect the digestive system, which consists of the organs and pathways and processes responsible for processing food in the body.

## Description

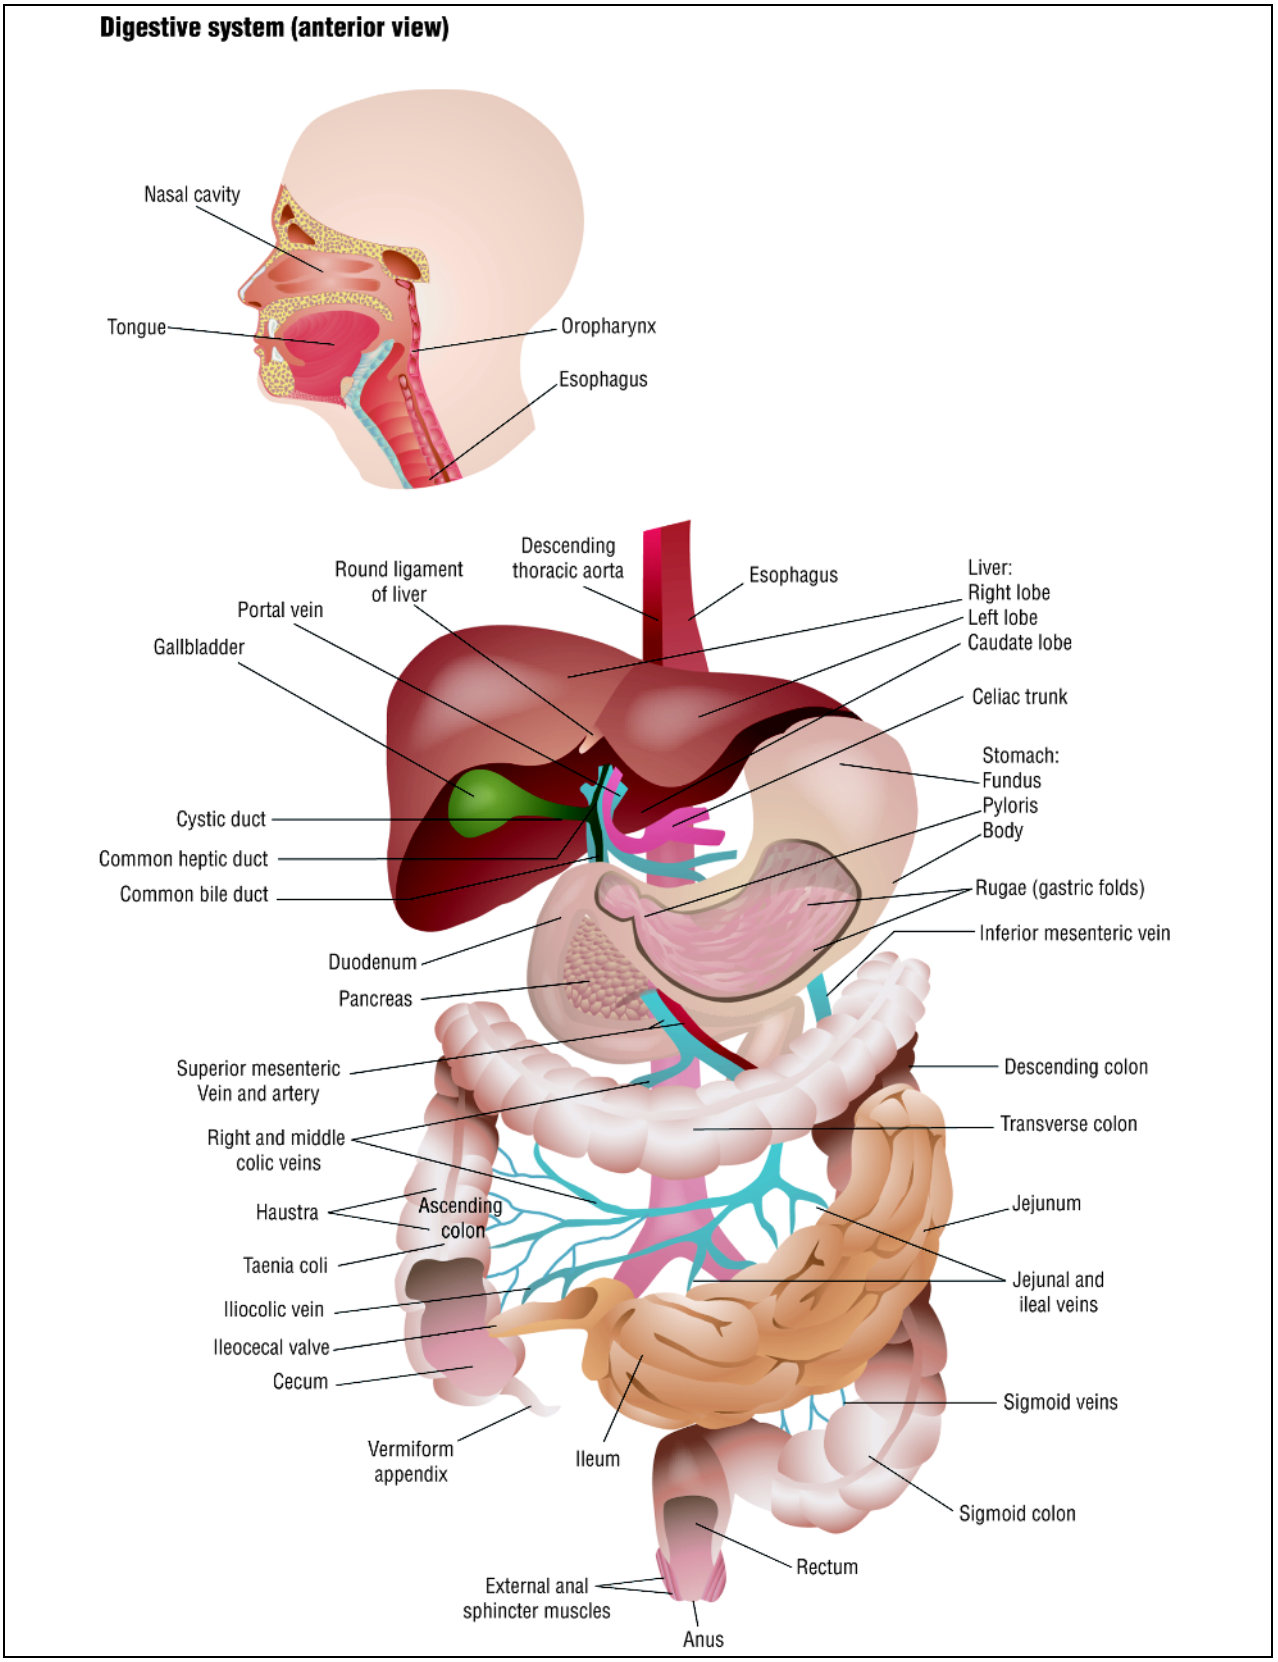
The digestive system, or digestive tract, includes the mouth, the esophagus, the stomach, the gallbladder, the small intestine, the large intestine, and the anus, all linked as a long twisting tube that starts at the mouth and ends at the anus. It also includes the liver and the pancreas, two organs that produce substances needed for digestion such as enzymes, reaching the intestine through small tubes. The function of the digestive system is to transform ingested food for use by the cells that make up the body. Food enters through the mouth and proceeds to the gut (digestive tract) where it is chemically modified (digestion) for absorption by the body or waste disposal. Digestive diseases are numerous and can affect any part of the digestive system. They can be grouped into the following five broad categories.

### *Diseases of the esophagus and stomach*

- Gastroesophageal reflux disease (GORD). GORD is the result of a malfunctioning lower esophageal sphincter (LES), the ring of muscle at the end of the esophagus that acts like a valve opening into the stomach. GORD prevents its proper closure and stomach contents return (reflux) to the esophagus, causing a burning sensation in the chest or throat (heartburn).
- Gastroparesis. Also called delayed gastric emptying, gastroparesis causes slow digestion and emptying, vomiting, nausea, and bloating.
- Peptic ulcer. A sore in the mucosal lining of the esophagus (esophageal ulcer) or stomach (gastric ulcer).

### *Diseases of the liver, pancreas, and gallbladder*

- Budd-Chiari syndrome. A rare liver disease in which the veins that drain blood from the liver are blocked or narrowed.
- Cholecystitis. Infection of the gallbladder.
- Cirrhosis. A life-threatening disease that scars liver tissue and damages its cells. It severely affects liver



**The parts of the human gastrointestinal tract.** *(Illustration by GGS Information Services/Thomson Gale.)*

function, preventing it from removing toxins like alcohol and drugs from the blood.

- Hepatitis. Inflammation of the liver that can result in permanent liver damage.
- Non-alcoholic fatty liver disease (NAFLD). Fatty inflammation of the liver related to insulin resistance, obesity, type II diabetes and high blood pressure.
- Pancreatitis. Irritation of the pancreas that can alter its structure and its function.
- Primary biliary cirrhosis (PBC). A liver disease that slowly destroys the bile ducts in the liver, thus preventing the release of bile.
- Primary sclerosing cholangitis (PSC). Irritation, scarring, and narrowing of the liver bile ducts. The accumulation of bile in the liver damages liver cells.

#### *Diseases of the small and large intestines*

- Appendicitis. Inflammation of the appendix, the small, finger-like structure attached to the first part of the large intestine.
- Celiac disease. Disease that damages the small intestine in people who cannot tolerate gluten, a protein found in wheat, rye, and barley.
- Crohn's disease. Inflammatory disease that usually occurs in the last section of the small intestine (ileum), causing swelling in the intestines. It can also occur in the large intestine.
- Diverticulosis. Small pouches (diverticula) that push outward through weak spots in the large intestine.
- Diverticulitis. Infection or rupture of the diverticula.
- Duodenal ulcers. Ulcers associated with alcoholism, chronic lung and kidney disease, and thyroid disorders.
- Dysentery. Inflammation of the intestine with severe diarrhea and intestinal bleeding, resulting from eating food or water containing a parasite called *Entamoeba histolytica* or *Shigella* bacteria.
- Giardiasis. Infection of the intestine by the parasite *Giardia intestinalis*. The parasite is one of the most common causes of waterborne disease in the United States and can be found in both drinking and recreational water.
- Infectious diarrhea. Illness resulting from bacterial or viral infections. Bacterial diarrhea is most commonly caused by *Campylobacter jejuni*, *Salmonella*, *Shigella*, *Escherichia coli* O157:H7. Rotavirus is the commonest cause of viral diarrhea in the United States. Other viruses causing diarrhea include Norwalk virus, and cytomegalovirus.
- Irritable bowel syndrome (IBS). IBS (also called spastic colon, or irritable colon) is a condition in which the colon muscle contracts more readily than it should.
- Lactose intolerance. The inability to digest significant amounts of lactose, the major sugar found in milk, due to a shortage of lactase, the enzyme produced by the cells lining the small intestine. Lactase breaks down milk sugar into two simpler forms of sugar which are then absorbed into the bloodstream. If not present, lactose is not broken down.
- Ulcerative colitis. Inflammation of the inner lining of the colon, characterized by open sores that appear in its mucous membrane.

#### *Diseases of the anus*

- Hemorrhoids. Commonly known as piles, hemorrhoids are characterized by swollen blood vessels that line the anal opening.
- Anal fissures. Splits or cracks in the lining of the anus resulting from the passage of very hard or watery stools.
- Perianal abscesses. These can occur when the tiny anal glands that open on the inside of the anus become blocked and infected by bacteria. When pus develops, an abscess forms.

## Demographics

According to the National Center for Health Statistics, 41.3 million Americans consulted physicians for digestive system disorders in 2005 and 6.9 million were diagnosed with **ulcers**. In the 1990-1992 period, 1.9 million people were disabled by digestive diseases with 234,000 deaths and over 6 million diagnostic and therapeutic procedures recorded in 2002.

In the United States, 100 million people are affected by acute diarrhea every year. Most diarrhea is believed to be viral and not bacterial in origin, but bacteria remain an important cause, as evidenced by the increasing public health warnings concerning contaminated foods. Nearly half of patients with acute diarrhea must restrict activities, 10% consult physicians, 250,000 require hospitalization, and approximately 3000 die.

## Causes and symptoms

#### *Causes*

The causes of some digestive diseases are well-known, especially for those resulting from viral (hepatitis, CMV), bacterial (diarrhea) or parasitic (gardiasis) infections, because the microorganisms can be clearly identified. Most peptic ulcers are also caused by a type of bacteria called *Helicobacter pylori* that weakens the protective mucous lining of the gut. As for the non-infectious

## KEY TERMS

**Abdominal cavity**—The hollow part of the body that extends from the chest to the groin.

**Anus**—The terminal opening of the digestive tract.

**Ascites**—Abnormal accumulation of fluid in the abdominal cavity.

**Bacteria**—Microscopic, single-celled organisms found in air, water, soil, and food. Only a few actually cause disease in humans.

**Bile**—Fluid made by the liver and stored in the gallbladder. Bile helps break down fats and gets rid of wastes in the body.

**Bile ducts**—Tubes that carry bile from the liver to the gallbladder for storage and to the small intestine for use in digestion.

**Cecum**—The pouch-like start of the large intestine that links it to the small intestine.

**Colon**—Part of the large intestine, located in the abdominal cavity.

**Colon polyps**—Extra tissue that grows in the colon.

**Diverticula**—Small pouches in the muscular wall of the large intestine.

**Duodenum**—The first section of the small intestine, extending from the stomach to the jejunum, the next section of the small intestine.

**Esophagus**—Muscular tube through which food passes from the pharynx to the stomach.

**Feces**—Waste product of digestion formed in the large intestine. About 75% of its mass is water, the remainder is protein, fat, undigested roughage, dried digestive juices, dead cells, and bacteria.

**Ileum**—The last section of the small intestine located between the jejunum and the large intestine.

**Insulin**—Hormone secreted by the pancreas that regulates carbohydrate metabolism in the body. It regulates the liver's ability to store or release glucose.

**Insulin resistance**—Condition in which normal amounts of insulin are inadequate.

**Jejunum**—The section of the small intestine located between the duodenum and the ileum.

**Large intestine**—The terminal part of the digestive system, site of water recycling, nutrient absorption, and waste processing located in the abdominal cavity. It consists of the caecum, the colon, and the rectum.

**Lower esophageal sphincter (LES)**—Ring of muscle at the bottom of the esophagus that acts like a valve between the esophagus and stomach.

**Mucosa**—Lining of the digestive tract. In the mouth, stomach, and small intestine, the mucosa contains glands that produce juices to digest food.

**Pancreas**—The pancreas is a flat, glandular organ lying below the stomach. It secretes the hormones insulin and glucagon that control blood sugar levels and also secretes pancreatic enzymes in the small intestine for the breakdown of fats and proteins.

**Pharynx**—Part of the neck and throat that connects the mouth to the esophagus.

**Rectum**—Short, muscular tube that forms the lowest portion of the large intestine and connects it to the anus.

**Small intestine**—The part of the digestive tract located between the stomach and the large intestine. It consists of the duodenum, the jejunum, and the ileum.

**Villi intestinales**—Microscopic hair-like structures covered with epithelial cells measuring 1–1.5 mm that line the mucous inner membrane of the small intestine.

diseases, medical researchers have only recently started to understand their numerous causes. For example, stomach ulcers can also result from the use of anti-inflammatory medications such as aspirin, ibuprofen, or naproxen. Similarly, it is also known that 80% of **gallstones** consist of hardened cholesterol and form when bile contains too much cholesterol, too much bilirubin, or not enough bile salts. It is also known that chronic alcoholism and hepatitis C are the most common causes of cirrhosis of the liver. As for diverticulitis, strong evidence suggests that it result mainly from a low-fiber diet. Gastroparesis is most often caused by diabetes, smooth muscle disorders and nervous system diseases while pancreatitis most often results from gallstones or alcohol abuse. Lactose intolerance is directly linked to a shortage of the enzyme lactase.

The causes of several digestive diseases however, are still unknown. In the case of colitis and **Crohn's disease**, the prevailing theories suggest that they are due to an immune system response to a virus or a

bacterium and causing ongoing inflammation in the intestinal wall. As for IBS, researchers suggest that affected people seem to have a colon that is more sensitive than normal to a variety of foods and stress while other evidence points to a malfunctioning immune system.

Increasingly however, researchers and physicians are realizing that one of the most common causes of digestive diseases is that people do not have healthy eating habits, and are also not aware of the many sources of food contamination. Besides bacterial or parasite infections, it is now understood that the digestive system can also be damaged by poor diets, prescription drugs, and food additives, especially antibiotics.

### *Symptoms*

Since there are many types of digestive diseases, symptoms can accordingly vary widely, depending on the organ that is affected. Telltale signs are blood in the stool, changes in bowel habits, and weight loss. Additionally, physicians look for symptoms that may include one or more of the following:

- Acute abdominal pain. A sharp pain in the lower right abdomen is one of the symptoms of colitis or Crohn's disease. A stomach that is very tender to the touch is indicative of diverticulitis or pancreatitis or an ulcer. Acute pain is also a symptom of gallstones.
- Ongoing abdominal pain. Depending on where the pain occurs, it will point to a specific digestive disease. For instance, if the pain goes away after taking antiacid medication, it points to a peptic ulcer. If it starts in the upper middle or upper right abdomen, and occurs after eating greasy or fatty foods, it is indicative of gallstones or infection of the gallbladder. If it occurs after eating milk products, it suggests lactose intolerance. Celiac disease is also accompanied by recurring abdominal pain.
- Bloating. Abdominal bloating is a symptom of lactose intolerance, Celia disease, IBS, and diverticulosis.
- Changes in bowel movements. Yellow and greasy stools that float are indicative of impaired pancreas function or celiac disease. Excess gas and loose, foul-smelling stools are a symptom of gardiasis or various bowel infections. Alternating loose and hard bowel movements are indicative of IBS.
- Bloody stools. Blood in the stools is one of the symptoms of Crohn's disease, colitis, dysentery and hemorrhoids.
- Dark urine. Dark urine, accompanied by a yellowing of the skin or the eyes is indicative of hepatitis.
- Diarrhea. Watery bowel movements that occur many times throughout the day. If not bacterial or viral, diarrhea can be indicative of celiac disease, Crohn's disease, gardiasis, or colitis.
- Fever. Fever accompanies several digestive diseases, in particular infectious diarrhea, dysentery, appendicitis, and colitis.

## Diagnosis

Diagnosis can be very difficult to establish because many digestive diseases share similar symptoms. For instance, **celiac disease** is commonly misdiagnosed as IBS, Crohn's disease, or diverticulitis. This is why physicians believe that the key to an accurate diagnosis is careful and detailed history-taking during patient medical interviews. Physicians accordingly combine the patient's gastrointestinal history to tests that can involve any of the following procedures:

- Barium enema. This test, also called a "lower gastrointestinal (GI) series", uses x rays to detect abnormal growths, ulcers, polyps, and small pouches (diverticula) in the large intestine and rectum. An enema tube is inserted into the patient's rectum and a barium solution is allowed to flow in to improve the contrast of the x rays.
- CAT Scan. Technique that uses a computerized x-ray scanner to take multiple views of a patient's abdominal organs. The information is analyzed by a computer that produces cross-sectional images of the organ of interest. CT is used for viewing the more solid digestive organs such as the liver and pancreas.
- Colonoscopy. Test that allows the physician to look inside the colon using a colonoscope, a long, flexible tube that has a miniaturized color-TV camera at one end. It is inserted through the rectum into the colon, and provides a view of the lining of the lower digestive tract on a television monitor. The test is used to evaluate intestinal inflammation, ulceration, bleeding, diverticulitis, and colitis.
- Endoscopic retrograde cholangiopancreatography (ERCP). ERCP is a technique used to diagnose problems in the liver, gallbladder, bile ducts, and pancreas. It uses both x rays and an endoscope, which is a long, flexible, lighted tube, inserted through the patient's esophagus, stomach, and duodenum. Using the endoscope, the examining physician can see the inside of the digestive tract, and inject contrast dyes into the bile ducts and pancreas so that they can be seen with x rays.
- Endoscopic ultrasound (EUS). Technique that uses sound waves to create a picture of the inside of the body. It uses a special endoscope that has an ultrasound device at the tip. It is placed in the gastrointestinal tract, close to the area of interest.

- Esophagogastroduodenoscopy (EGD). EGD is a technique used to look inside the esophagus, stomach, and duodenum. It uses an endoscope to investigate swallowing difficulties, nausea, vomiting, reflux, bleeding, indigestion, abdominal pain, or chest pain.
- Flexible sigmoidoscopy. Technique that allows to look at the inside of the large intestine from the rectum through the last part of the colon, called the sigmoid colon. It is used to investigate diarrhea, abdominal pain, or constipation.
- Stool tests. Collection of stool to identify microorganisms that may be infecting the intestine. Stools are examined under a microscope or analyzed for the substances they contain. For example, normal stool contains almost no fat. But, in certain types of digestive diseases, fat is not completely absorbed and remains in the stool.
- Swallowing test. In this procedure, the patient is asked to drink a solution of barium before the X-ray examination of the upper digestive tract (esophagus, stomach, and small intestine).

## Treatment

The treatment of digestive diseases varies depending on the condition being treated. Almost all treatment seeks the relief of symptoms and combine changes in eating habits with medications specific to the disease. In serious cases, surgical procedures are used, which can involve the complete removal of the affected organ.

- Gastroesophageal reflux disease GORD. Treatment may involve lifestyle changes, such as avoiding alcohol, loosing weight and eating smaller meals. Antacid medication, such as Alka-Seltzer, Maalox, Mylanta, Pepto-Bismol, Rolaids, and Riopan, can also relieve heartburn. Other drugs, such as foaming agents (Gaviscon), work by covering the stomach contents with foam to prevent reflux. H2 blockers, such as cimetidine (Tagamet HB), famotidine (Pepcid AC), nizatidine (Axid AR), and ranitidine (Zantac 75), can also reduce acid production. Proton pump inhibitors such as omeprazole (Prilosec), lansoprazole (Prevacid), pantoprazole (Protonix), rabeprazole (Aciphex), and esomeprazole (Nexium) are now considered more efficient. Surgery is an option when medications do not work. A standard surgical treatment is fundoplication which wraps the upper part of the stomach around the LES to strengthen it and prevent acid reflux.
- Gastroparesis. When related to diabetes, treatment seeks to control the blood sugar levels with insulin and oral medications, such as metoclopramide (Reglan) to stimulate stomach muscle contractions which helps empty food. In severe cases, intravenous feeding may be required to bypass the stomach entirely. This is achieved by inserting a jejunostomy tube through the skin of the abdomen into the small intestine. The procedure allows nutrients and medication to be delivered directly into the small intestine.
- Peptic ulcer. Ulcers caused by *Helicobacter pylori* are treated with drugs to kill the bacteria, reduce stomach acid, and protect the stomach lining. Antibiotics are usually prescribed. The acid-suppressing drugs commonly used are H2 blockers and proton pump inhibitors. Medications such as bismuth subsalicylate are also used as protectors in the case of stomach ulcers. Surgery may also be required, such as a vagotomy, a procedure that cuts parts of the vagus nerve that transmits messages from the brain to the stomach. This interrupts messages to produce acid, hence reducing acid secretion.
- Budd-Chiari syndrome. Treatment usually involves sodium restriction, diuretics to control the accumulation of fluid in the abdominal cavity (ascites), and prescription of anticoagulants such as heparin and warfarin. Surgical shunts that divert blood flow around the obstruction or the liver may be required. In very serious cases, liver transplantation is the only effective treatment.
- Cholecystitis. If acute, treatment may require hospitalization to reduce stimulation to the gallbladder. Antibiotics are usually prescribed to fight the infection as well as acid-suppressing medications. In some cases, the gallbladder may be surgically removed (cholecystectomy).
- Cirrhosis. Treatment depends on the cause of the cirrhosis and on the complications that may be present. Alcoholic cirrhosis is first treated by completely abstaining from alcohol. Hepatitis-related cirrhosis is treated with medications specific to the different types of hepatitis, such as interferon for viral hepatitis and corticosteroids for autoimmune hepatitis. Treatment also includes medications to help remove fluid from the body. When complications cannot be controlled or when the liver becomes so damaged that it can no longer function, a liver transplant is required.
- Hepatitis. Hepatitis A is treated by bed rest and medications to relieve symptoms such as fever, nausea and diarrhea if any. Hepatitis B is treated with a course of interferon injections, usually for some months. Additionally, drugs such as lamivudine and dipivoxil are prescribed for a period of one year. Over time, hepatitis B may cause the liver to stop functioning and require a liver transplant. As for hepatitis C, it is treated with peginterferon,

usually in combination with ribavirin. Hepatitis C may also require a liver transplant.

- Non-alcoholic fatty liver disease NAFLD. No single truly effective treatment has yet been found. If obese or overweight, patients are encouraged to loose weight and to follow a balanced diet. Increasing physical activity and avoiding alcohol is also recommended.
- Pancreatitis. If no complications occur, pancreatitis usually improves on its own. Treatment seeks to support body functions and prevent complications with hospitalization usually required to replace body fluids intravenously.
- Primary biliary cirrhosis. No treatment has been shown to be beneficial in slowing the progression of PBC. Patients are usually prescribed vitamins and calcium to help prevent loss of bone (osteoporosis), a common complication.
- Primary sclerosing cholangitis. There is no cure for PSC, but effective treatment is available for symptoms, such as the itching resulting from too much bile in the bloodstream, which can be controlled with drugs such as Questran or Actigall. Swelling of the abdomen and feet, due to fluid retention, can be treated with diuretics. In some cases, surgical procedures may be used to open major blockages in bile ducts. In the most severe cases, a liver transplant is performed.
- Infectious diarrhea. In healthy people, usual practice is to let the illness take its course, which can last from a few days to a week. Drinking plenty of liquids is required and medications such as Pedialyte, Ceralyte, and Infalyte can be provided to replace electrolyte losses. Treatment with antibiotics is increasingly complicated by the bacteria having developed drug resistance.
- Celiac disease. The only treatment for celiac disease is a gluten-free diet.
- Crohn's disease. There is no cure available, and the goal of treatment is to control inflammation in the intestine and reduce the symptoms of pain, diarrhea, and bleeding. Medications prescribed to reduce inflammation include Azulfidine (sulfasalazine), mesalamine or 5-ASA agents such as Rowasa, Pentasa or Asacol. Serious cases usually require more powerful drugs such as prednisone, antibiotics, or drugs that weaken the body's immune system such as Imuran (azothioprine), Purinethol (6-mercaptopurine, 6-MP), Methotrexate or Remicade (Infliximab).
- Lactose intolerance. Removing milk products from the diet is the standard treatment. Lactase enzymes can also be added to milk or taken in capsule or chewable tablet form.
- Appendicitis. Surgery is performed to remove the appendix with prescription of pain medication.
- Ulcerative colitis. Treatment seeks to control acute attacks, prevent new attacks, and promote healing of the colon. Corticosteroids are usually prescribed to reduce inflammation. Medications prescribed to decrease the frequency of attacks include mesalamine, azathioprine and 6-mercaptopurine. In severe cases, the colon may be removed surgically.
- Diverticulosis. Besides a fiber-rich diet, treatment depends on symptoms. When diverticulitis occurs, simple bowel rest and antibiotics are prescribed. In severe cases, patients may require intravenous antibiotics or surgery to remove the affected portion of the colon.
- Dysentery. Rest and drinking plenty of fluids is the usual treatment. Hospitalization may be required for intravenous therapy.
- Giardiasis. Anti-infective medications such as metronidazole (Flagyl, Protostat) or quinacrine may be used. In pregnant women, treatment is not started until after delivery, because the drugs can be harmful to the fetus.
- Irritable bowel syndrome. IBS has no cure and treatment is based on diet changes, medication and stress relief therapy.
- Hemorrhoids. Corticosteroid creams and lidocaine ointments are used to reduce itching, pain and swelling. For severe cases, surgical removal of the hemorrhoids may be performed (hemorrhoidectomy).
- Anal fissures. Treatment may include the application of a hydrocortisone cream to the anal area to help relieve irritation, oral pain-killers such as acetaminophen, a stool softener such as Colace or Surfak to prevent constipation until the fissure heals, soaking the anal area in a warm chamomile infusion for 20 minutes to prevent infection and provide soothing relief, and avoidance of strenuous effort to pass stool. If a fissure does not respond to conservative treatment, surgery may be required, involving an operation that removes the area of the fissure and any underlying scar tissue.
- Perianal abscesses. Treatment involves surgical drainage of the abscess as antibiotics are ineffective. A small incision is made over the area and pus is expelled with manual pressure. The wound is packed with iodophor gauze, removed after 24 hours, and the patient is instructed to take Sitz baths 3–4 times a day for some two weeks.

## Nutrition/Dietetic concerns

Some digestive diseases require special diets while others only require patients to follow the rules of basic

good nutrition, avoiding only those foods that cause problems. The vitamin **dietary supplements** recommended for all adults can also benefit patients. However the medical profession advises against taking megadoses of **vitamins**, special herbal extracts, and other unproven therapies. Digestive diseases with special dietary requirements include:

- Gastroesophageal reflux disease. Diets recommended for GORD are usually low-fat and include the basic food groups of cereals, vegetables, fruits, dairy products, and meats. A vitamin C supplement may be needed if the patient does not tolerate lemons, oranges, tomatoes, and grapefruits.
- Gastroparesis. Patients are asked to avoid foods that are high in fat and normally delay the emptying of the stomach. High fiber foods such as broccoli and cabbage also tend to stay in the stomach and are also restricted when symptoms are severe. Liquids always leave the stomach faster than solid food, so liquid foods are recommended.
- Peptic ulcer. In the past, physicians advised people with ulcers to avoid spicy, fatty, or acidic foods. Research has shown however that such diets are ineffective for treating ulcers. In most patients, no particular diet has emerged as being particularly helpful.
- Budd-Chiari syndrome. A low-sodium diet is required for the control of ascites.
- Cholecystitis. A low-fat diet is usually recommended with research showing that the pectin in apples may be beneficial, as well as the cellulose contained in celery and other crisp fruits and vegetables.
- Cirrhosis. Regardless of the type of cirrhosis, a healthy low-sodium diet is usually prescribed with total avoidance of alcohol.
- Hepatitis. Stimulating the liver can stress the liver and stimulants such as colas, chocolate, coffee, and tea are restricted. Fruit juices also, because they contain high levels of concentrated sugar which stress the digestive process and the pancreas, while feeding the virus.
- Non-alcoholic fatty liver disease NAFLD. A healthy diet controlling elevated cholesterol, triglycerides, and blood sugar is considered beneficial.
- Pancreatitis. Dietary guidelines recommend foods low in fat and high in carbohydrates and protein to decrease the work load of the pancreas. Pancreas stimulants such as coffee, alcohol, spicy and gas-forming foods are also restricted.
- Primary sclerosing cholangitis. A low-sodium diet is usually recommended to reduce fluid retention.
- Celiac disease. Patients work with a dietician to design a diet plan that is totally gluten-free. This means not eating foods that contain wheat, rye, and barley. Restrictions include most pasta, cereal, and processed foods.
- Infectious diarrhea. Diarrhea causes the body to loose too much fluid (dehydration) and electrolytes. Drinking plenty of water is accordingly extremely important. Broth and soups that contain sodium, and fruit juices, soft fruits, or vegetables that contain potassium, are required to restore the electrolyte levels.
- Lactose intolerance. If milk is removed from the diet, other sources of calcium are added, such as fermented milk products like yogurt that can usually be tolerated. Non-dairy foods that are high in calcium include fruits and vegetables such as kale, collard greens, broccoli, and oranges. Foods fortified with added calcium, such as soy milk, juices, cereals, and pasta, are also good sources of calcium.
- Colitis. Patients are advised to eliminate any foods or beverages from their diet that seem to make symptoms worse. This usually includes limiting dairy products, a low-fat diet high in fibers, eating small meals and drinking plenty of water.
- Diverticulosis. Since the lack of fiber and bulk in the diet is the major cause of diverticular disease, adding fiber and bulk to the diet is accordingly considered very important. Foods rich in fiber, such as bran cereals, whole wheat breads, a variety of beans, and fresh fruits and vegetables help keep the stools soft and bulky.
- Dysentery. Patients are asked to fast as long as acute symptoms are present, taking only orange juice and water or buttermilk. After the acute phase, rice, curd, fresh ripe fruits, especially banana and pomegranate and skimmed milk are allowed. Solid foods are reintroduced very carefully in the diet depending on the pace of recovery.
- Giardiasis. Drinking water to prevent dehydration is recommended, as well as replenishing the electrolytes lost as a result of diarrhea.
- Irritable bowel syndrome. People with IBS are usually asked to avoid food that is high in fat, insoluble fiber, caffeine, coffee, carbonated sodas, and alcohol.
- Hemorrhoids, anal fissures and perianal abscesses. A high-fiber diet consisting of fruits, vegetables, bran, whole-wheat grains with fiber supplements such as Metamucil, Citrucel, Fibercon is usually recommended along with a daily intake of plenty of water to prevent stool hardening.

## Therapy

The management and treatment of digestive diseases is disease-specific and pharmacologic and other

therapies are accordingly tailored to individual cases, depending on severity and patient history.

### Prognosis

Prognosis for some digestive diseases is excellent, for example the infectious diseases that clear up once the infectious agent is destroyed. Outcomes for most of the other diseases depends on the severity of complications and the underlying causes.

### Prevention

A healthy diet can help to prevent some digestive diseases altogether, such as diverticulitis, and lessen chances of developing others, such as colitis or alcoholic cirrhosis. Healthy nutrition is based on eating foods that meet the Recommended Dietary Allowances (RDA) of the National Research Council. These foods should be from the four major food groups: dairy products, meat and nuts, cereals and grains, and fruits and vegetables. It is also recommended to drink eight glasses of **water** per day to help eliminate ingested toxins and maintain the pH balance of the stomach.

Another important prevention area is being careful about food contamination, directly responsible for all the digestive infectious diseases. These diseases can be avoided by simple precautions such as washing fruits and vegetables, cooking meat thoroughly, drinking only water from trusted sources, and basic hygiene.

## Diuretics and diets

### Definition

Diuretics are a group of drugs given to help the body eliminate excess fluid through the kidneys in order to treat **hypertension** (high blood pressure), kidney and liver disorders, glaucoma, congestive heart failure (CHF), and idiopathic intracranial hypertension (pseudotumor cerebri), a condition characterized by increased fluid pressure within the blood vessels supplying the brain.

In addition to prescription diuretics, there are several types of diuretics available in over-the-counter formulations or commonplace beverages.

### Purpose

Diuretics have several purposes in mainstream clinical medicine:

- To lower blood pressure in people with hypertension.
- To lower fluid pressure inside the eyeball in patients with glaucoma.
- To reduce increased cerebrospinal fluid pressure in idiopathic intracranial hypertension.
- To reduce blood pressure and swelling during surgical procedures.
- To reduce bloating and discomfort associated with fluid retention in the premenstrual phase of a woman's monthly cycle.

## KEY TERMS

**Caffeine**—A plant alkaloid found in coffee, tea, hot chocolate, and some soft drinks that functions as a diuretic as well as a central nervous system stimulant.

**Edema**—Abnormal and excessive accumulation of fluid in body tissues or certain cavities of the body. Edema is a symptom of a number of different kidney, liver, and circulatory disorders and is commonly treated with diuretics.

**Electrolyte**—Any of several chemicals dissolved in blood and other body fluids that are capable of conducting an electric current. The most important electrolytes in humans and other animals are sodium, potassium, calcium, magnesium, chloride, phosphate, and hydrogen carbonate.

**Ethanol**—The chemical name of beverage alcohol.

**Glaucoma**—An eye disorder marked by increased fluid pressure within the eyeball that can lead to gradual loss of vision. Glaucoma is sometimes treated with diuretics.

**Hypercalcemia**—Abnormally high levels of calcium in the blood.

**Hypertension**—The medical name for high blood pressure.

**Idiopathic intracranial hypertension**—Increased fluid pressure within the blood vessels supplying the brain. Obese women are at increased risk of developing this disorder.

**Nephrotic syndrome**—A disorder marked by a deficiency of albumin (a protein) in the blood and its excretion in the urine.

**Ototoxicity**—Damage caused to the nerves in the ear that are involved in hearing or balance. Ototoxicity is a rare but serious adverse affect of loop diuretics.

**Pamabrom**—A mild diuretic found in several over-the-counter compounds for the relief of premenstrual discomfort and water retention.

**Purging**—A behavior associated with eating disorders that includes self-induced vomiting and abuse of laxatives as well as diuretics.

**Theobromine**—A breakdown product of caffeine that is responsible for the diuretic effect of coffee and tea.

The connection between diuretics and dieting is twofold. First, many of the conditions that are treated by administration of prescription diuretics—particularly hypertension, CHF, and idiopathic intracranial hypertension—are more common in obese patients, more difficult to treat in the obese population, or both. Thus weight loss and lifestyle change are commonly recommended to these patients along with prescription diuretics.

The second connection is that many dieters use or abuse diuretics as a means to quick weight loss. Abuse of diuretics frequently coexists with self-induced vomiting and abuse of laxatives in patients with **eating disorders**. This combination of behaviors is called purging. Purging may occur in some patients with eating disorders as a means to a slender appearance, but it is also common in high school and college athletes participating in such weight-related sports as rowing, wrestling, gymnastics, and long-distance running. Athletes may also abuse diuretics like furosemide (Lasix) in order to mask the fact that they are taking other drugs to enhance performance in competition. People who abuse diuretics may take herbal preparations reported to have diuretic effects or over-the-counter preparations containing **caffeine** or pamabrom as well as prescription diuretics.

## Description

### *Prescription diuretics*

There are five major types of prescription diuretics.

**LOOP DIURETICS.** Loop diuretics are the strongest of the prescription diuretics. They take their name from the fact that they work in the ascending limb of the loop of Henle, a structure in the kidney in which **magnesium** and **calcium** are ordinarily reabsorbed. By disrupting the reabsorption of these two ions, loop diuretics bring about increased urine production, which in turn lowers blood volume, leading to lowered blood pressure. Loop diuretics also cause the veins to dilate, which lowers blood pressure mechanically. This vasodilation is independent of the drug's diuretic effect.

Loop diuretics are usually given to treat edema (accumulation of fluid in body tissues) associated with heart failure; cirrhosis of the liver; impaired kidney function or nephrotic syndrome (a condition in which the kidneys leak **protein** from blood into the urine); hypertension; or severe hypercalcemia (abnormally

high levels of calcium in the blood). They are also given together with other drugs to treat edema of the brain or lungs, conditions that require rapid diuresis. Drugs classified as loop diuretics include furosemide (Lasix), bumetanide (Bumex), ethacrynic acid (Edecrin), and torsemide (Demadex).

**THIAZIDE DIURETICS.** Thiazide diuretics are derived from a chemical called benzothiadi(A)zene. Unlike the loop diuretics, which work in the loop of Henle, thiazide diuretics work in a different structure called the distal convoluted tubule, although they function in a similar way to increase urine production by decreasing the kidney's reabsorption of **sodium** and calcium. They are not as strong as loop diuretics and have fewer adverse effects.

Thiazide diuretics are commonly prescribed to manage high blood pressure because they help to dilate blood vessels as well as lower blood volume by increasing urine output. They are also sometimes given to patients with high levels of calcium in the urine to prevent the formation of kidney stones and lower the risk of **osteoporosis**. They include such drugs as hydrochlorothiazide (HydroDiuril, Esidrix), chlorothiazide (Diachlor, Diuril), and chlorthalidone (Hygroton, Hylidone).

**POTASSIUM-SPARING DIURETICS.** Potassium-sparing diuretics include such drugs as amiloride (Midamor) and triamterene (Dyrenium). They are usually given together with loop diuretics in treating CHF or high blood pressure to prevent the patient's potassium level from falling too low. They work by decreasing sodium reabsorption in the collecting tubules of the kidneys.

There are two formulations that combine the potassium-sparing diuretic triamterene with the thiazide diuretic hydrochlorothiazide in one pill—Maxzide and Dyazide—thus simplifying the patient's dosage schedule.

**OSMOTIC DIURETICS.** Osmotic diuretics are substances that cannot be reabsorbed in the kidney and so increase urine volume by osmosis. The most commonly used osmotic diuretic is mannitol, a sugar alcohol or polyol that is also added to sugar-free candies, mouthwashes, and similar products as an artificial sweetener. Mannitol (Osmitrol) is given intravenously to patients with glaucoma to lower fluid pressure inside they eyeball, and to patients with acute kidney failure following cardiovascular surgery.

Until early 2007, high-dose mannitol was recommended as treatment to reduce fluid accumulation inside the skull in cases of head trauma, on the basis of randomized trials conducted by a neurosurgeon in Brazil who committed suicide in 2005. His papers on the use of mannitol in head surgery were called into question in late 2006; neither his former coauthors nor the journal editors who published his studies have been able to verify his data; and the university he claimed as his affiliation has never employed him.

**CARBONIC ANHYDRASE INHIBITORS.** Carbonic anhydrase inhibitors are a class of diuretics that increase **water** loss through the kidneys by changing the acidity of urine. Their most common use, however, is to treat glaucoma by lowering the fluid pressure inside the eyeball. The most common diuretic in this group, acetazolamide (Diamox), is also used as an anticonvulsant (drug given to prevent seizures). Other carbonic anhydrase inhibitors include dichlorphenamide (Daranide) and methazolamide (Neptazane).

### *Nonprescription diuretics*

Nonprescription diuretics are often used by dieters to flush water from the body in the belief that this practice will promote rapid weight loss. According to the Centers for Disease Control and Prevention (CDC), 1% of adult male dieters in the United States and 2% of adult women have used over-the-counter diuretics as part of weight loss attempts.

**CAFFEINE.** Caffeine is a xanthine alkaloid found naturally in coffee beans, tea leaves, kola nuts, cocoa beans, and a few other plants. It is well known as a central nervous system (CNS) stimulant, enjoyed in brewed coffee, tea, hot chocolate, cola beverages, and energy drinks. It is also available in tablet form as an over-the-counter stimulant in such compounds as NoDoz. Caffeine is broken down in the liver to three substances, one of which is theobromine, which acts as a diuretic and increases urine volume. Some dieters drink coffee as much for its diuretic effects as for its effectiveness is counteracting the fatigue that often accompanies low-calorie diets.

**HERBAL PREPARATIONS.** Naturopaths and other practitioners of alternative medicine often recommend certain herbal preparations, including herbal teas, as diuretics available without a prescription. Herbs commonly recommended for their diuretic qualities include uva ursi, dandelion, hydrangea, parsley, butcher's broom, buchu, juniper, horsetail, buckthorn, and asparagus.

**ALCOHOL.** Beverage alcohol (ethanol) is known to have a diuretic effect; in fact, many of the symptoms of an alcohol hangover, such as headache, nausea, and diarrhea, are related to the **dehydration** resulting from alcohol intoxication. Many weight-reduction diets (the **Mediterranean diet** being a notable exception) forbid alcohol because it contains more calories than

most people realize—7 calories per gram, in comparison to 9 calories per gram for fat and 4 calories per gram for protein. Some women, however, drink an occasional glass of wine or beer for its diuretic effect, to relieve the discomfort of fluid retention before the onset of their menstrual period.

**PAMABROM.** Pamabrom is a mild diuretic related chemically to theophylline, one of the breakdown products of caffeine. It is compounded with acetaminophen in a number of over-the-counter (OTC) remedies for premenstrual bloating and backache associated with fluid retention, including New Tylenol for Women, Backaid, and Diurex.

## Precautions

Both prescription and nonprescription diuretics should be used with care.

### *Prescription diuretics*

Prescription diuretics should be used only under a doctor's supervision and monitored in long-term users, as dosage requirements may change or the doctor may recommend **dietary supplements** to compensate for **electrolytes** and nutrients lost through the use of some diuretics. In addition, patients should not stop taking prescription diuretics or change the dosage without consulting their doctor.

- Loop diuretics. Patients taking loop diuretics may require supplemental potassium, folic acid, and vitamin $B_1$. In addition, they should learn to recognize the symptoms of potassium depletion, as loss of potassium is a common adverse effect of this type of diuretic.
- Thiazide diuretics. Nursing mothers should not use thiazide diuretics during the first month of breastfeeding, as they can pass into the milk and in some cases decrease the flow of milk. Thiazide diuretics should also be taken with food or milk to lower the risk of upset stomach. They should be used very cautiously in patients with diabetes, as they tend to raise blood sugar levels.
- Potassium-sparing diuretics. Patients should avoid the use of salt substitutes containing potassium while taking this type of diuretic, as it may lead to overly high levels of potassium in the blood. In addition, patients should be advised to avoid driving or operating dangerous machinery until they know how these drugs affect them, because potassium-sparing diuretics may cause dizziness and blurred vision.
- Osmotic diuretics. Sodium levels in the patient's blood should be closely monitored, particularly if the patient develops muscle cramps.
- Carbonic anhydrase inhibitors. Acetazolamide should not be given to patients with a history of liver or kidney disorders, Addison's disease, known sensitivity to sulfonamide drugs, or angle-closure glaucoma; and used cautiously in patients with diabetes or gout. The patient should be advised to take this type of diuretic in the morning to prevent sleep interruption.

### *Nonprescription diuretics*

Nonprescription diuretics can still cause adverse effects even though they are weaker than prescription diuretics:

- Caffeine. A dose of caffeine higher than 400 milligrams (more than 3 or 4 cups of brewed coffee) will produce a state of caffeine intoxication in most adults. Over-the-counter caffeine tablets, however, typically contain more caffeine than brewed coffee, usually 100–200 mg per tablet. In very high doses (around 5 g), caffeine will produce nausea, coma, convulsions, and eventually death.
- Herbal preparations. Herbal preparations should be purchased only from reliable sources, as their potency may vary from batch to batch. In addition, herbal products made outside the United States may be adulterated with filler products or contaminated by industrial byproducts.
- Alcohol. Alcohol should always be consumed in moderation and never combined with driving or operating heavy machinery.
- Pamabrom. Pamabrom is a mild diuretic that causes skin rashes in a few people who take it for backache or menstrual cramps.

## Interactions

Prescription diuretics interact with some other prescription drugs as well as with herbal products:

- Loop diuretics. Loop diuretics are known to interact with licorice, digitalis, and buckthorn or alder buckthorn.
- Thiazide diuretics. Thiazide diuretics interact with insulin to inhibit its effects in lowering blood sugar; they intensify the toxic side effects of lithium therapy; and they increase the effects of corticosteroids in causing loss of potassium.
- Potassium-sparing diuretics. May increase the toxicity of lithium.
- Osmotic diuretics. None reported as of 2007.
- Carbonic anhydrase inhibitors. Enhance the effects of amphetamines and tricyclic antidepressants; increase the excretion of lithium and phenobarbital;

increase the risk of aspirin toxicity for patients taking aspirin or other salicylates.

### *Nonprescription diuretics*

Nonprescription diuretics, particularly alcohol, may interact with a variety of substances:

- Caffeine. Caffeine is known to intensify the effects of cimetidine (a drug that lowers the secretion of stomach acid) and theophylline.
- Herbal preparations. Herbal preparations with diuretic effects should be strictly avoided by people taking prescription diuretics, as the herbs may intensify the effects of the prescription drugs and lead to various cardiovascular side effects.
- Alcohol. Alcohol is known to interact with a wide number of prescription medications. It should never be taken together with other drugs that depress the central nervous system. These types of medications include antidepressants, benzodiazepines (tranquilizers), barbiturates, other sleeping medications, narcotic pain relievers (codeine and other derivatives of opium), and antihistamines. Alcohol may interact with antipsychotic medications to cause liver damage, with aspirin to cause stomach bleeding, and with some cardiovascular medications to cause dizziness and fainting.
- Pamabrom. No interactions between pamabrom and other medications have been reported as of 2007.

## Aftercare

Aftercare following abuse of diuretics varies according to the substance and the consumption pattern. Caffeine intoxication can usually be treated by tapering intake of caffeinated beverages and/or discontinuing use of caffeine tablets. Alcohol hangovers may require rehydration as well as administration of **vitamin $B_6$**. Abuse of diuretics in patients with eating disorders requires long-term medical nutrition therapy supervised by a professional nutritionist. The position statement of the American Dietetic Association (ADA) is as follows: "It is the position of the American Dietetic Association (ADA) that nutrition education and nutrition intervention by a registered dietitian is an essential component of the team treatment of patients with **anorexia nervosa**, **bulimia nervosa**, and eating disorders not otherwise specified (EDNOS) during assessment and treatment across the continuum of care." Similarly, adolescents who abuse diuretics as part of athletic training regimens require supervision by a registered dietitian as well as by a specialist in sports medicine.

## Complications

Prescription diuretics have a number of side effects:

- Loop diuretics. Loop diuretics may produce several different types of adverse reactions. The first type are related to diuresis and electrolyte balance. Loop diuretics may cause loss of potassium and magnesium from the body; the loss of magnesium may lead to the loss of additional potassium. Patients taking loop diuretics should be taught to recognize the signs of potassium deficiency (hypokalemia), which include weakness, loss of appetite, irregular heartbeat, constipation, muscle cramps, a weak or heavy feeling in the legs, mental confusion, or unusual tiredness. The second type of adverse reaction to loop diuretics is ototoxicity, or damage to the nerves in the ears that control hearing and the sense of balance. Symptoms of ototoxicity include ringing in the ears (tinnitus) and dizziness. The third type of adverse effect of loop diuretics is uncommon but may occur in patients who are also taking ACE inhibitors (medications to control blood pressure) and nonsteroidal anti-inflammatory drugs (NSAIDs). This so-called "triple whammy" may lead to kidney failure.
- Thiazide diuretics. Thiazide diuretics may cause low blood potassium levels, impotence in men, and increased levels of blood cholesterol. They also cause photosensitivity in some people, which means that the person will be more sensitive to sunlight and sunburn more readily. Last, thiazide diuretics can raise the levels of glucose and uric acid in the blood, which increases the patient's risk of developing gout.
- Potassium-sparing diuretics. Adverse effects may include loss of interest in sex (in both men and women), visual disturbances and dizziness, shortness of breath, nausea and vomiting.
- Osmotic diuretics. Use of mannitol causes high blood pressure, blurred vision, chills, fever, nausea, and vomiting in some patients.
- Carbonic anhydrase inhibitors. May depress the activity of bone marrow, leading to anemia; may contribute to liver dysfunction; increases the patient's risk of developing gut; may lead to overly low blood levels of sodium, potassium, magnesium, and calcium.

### *Nonprescription diuretics*

Adverse effects from nonprescription diuretics may include:

- Caffeine. Adverse effects from high doses of caffeine include nervousness, insomnia, restlessness, twitching,

tingling or flushing of the face, nausea or vomiting, diarrhea, and dehydration.

- Herbal preparations. Herbal preparations used as diuretics have a wide range of potential adverse effects, ranging from intensifying the effects of prescription diuretics to indigestion, skin rashes, headache, and diarrhea.
- Alcohol. Complications associated with ethanol consumption include the risks of dehydration and electrolyte imbalance caused by intoxication; alcohol abuse; trauma from alcohol-related accidents; and interactions with other medications.
- Pamabrom. Pamabrom has been reported to cause skin rashes and dependence in a very small minority of patients.

## Parental concerns

Parents do not ordinarily need to be concerned about children or adolescents abusing prescription diuretics, as these drugs do not produce mood alteration or relieve pain. Adolescents, however, are likely to abuse nonprescription diuretics in relation to eating disorders or athletic competition; one study found that 64% of adolescents diagnosed with eating disorders were using herbal diuretics. A few adolescents may develop caffeine-related disorders apart from eating disorders or sports.

### *Eating disorders*

Abuse of over-the-counter diuretics is common among adolescents with eating disorders accompanied by purging, although it is slightly less common than self-induced vomiting or abuse of laxatives. Although eating disorders are classified as **mental health** problems, they can have serious lifelong digestive and nutritional consequences, including erosion of tooth enamel, loss of bone density leading to eventual osteoporosis, and ongoing problems with water retention.

### *Athletic competition*

Numerous reports of diuretic abuse among athletes in high school and college sports programs have accumulated since the late 1980s. Abuse of OTC diuretics is higher among both males and females in such weight-related sports as wrestling and rowing than among participants in sports that do not classify athletes by weight (distance running, swimming, basketball, etc.). More males than females abuse diuretics at both the high school and college levels; the average age of initial misuse of diuretics in one sample was 15.6 years for males and 16.2 years for females. Abuse of diuretics puts young athletes, particularly males, at risk of dehydration, chest pains, fainting, and irregular heart rhythms, particularly when combined with ephedrine or other stimulants.

### *Caffeine dependence and intoxication*

According to *DSM-IV*, caffeine use typically begins in the mid-teens in the United States and Canada, with levels of consumption increasing into the early adult years (20s and 30s). Among teenagers, caffeine use is usually higher among boys than girls, and higher among smokers than nonsmokers. Most fatal cases of caffeine overdose occur among adults in their early 20s, usually as a result of taking OTC caffeine tablets by mouth or inhaling crushed tablets.

Rebecca J. Frey, PhD

# Diverticular disease diet

## Definition

A diverticular disease diet is a diet that increases dietary **fiber** to recommended levels.

## Origins

Diverticulosis is a condition characterized by small pouches (diverticula) that form and push outward through weak spots in the large intestine. Once diverticula have formed, there is no way to reverse the process. When diverticula become infected, the condition is called diverticulitis. Most people with diverticulosis do not experience symptoms. As for diverticulitis, the most common symptom is abdominal pain with tenderness around the left side of the lower abdomen. Fever, nausea, vomiting, chills, cramping, and **constipation** may occur as well. Diverticular disease is common in industrialized countries, especially in the United States, Canada, the United Kingdom, and Australia, and fairly rare in Asia and Africa. It affects about 50% of Americans by age 60 and nearly all by age 80. A low-fiber diet is believed to be the main cause of the disease. It was first described in the United States in the early 1900s, at the time when processed foods were introduced into the American diet and many of these foods contain refined flour. Unlike whole-wheat flour, refined flour has no wheat bran and is accordingly a low-fiber food. The prevalence of the disease in industrialized countries seems to confirm the connection of diverticular disease with a low-fiber diet, since it occurs rarely in Asia or Africa, where people eat high-fiber, vegetable-based diets.

## Description

It has been shown that increasing the amount of fiber in the diet may reduce symptoms of diverticular disease. The American Dietetic Association recommends a daily intake of 20–35 grams of fiber. A diverticular disease diet will accordingly seek to increase dietary fiber to these levels to prevent constipation and the undue colon pressure that causes diverticula.

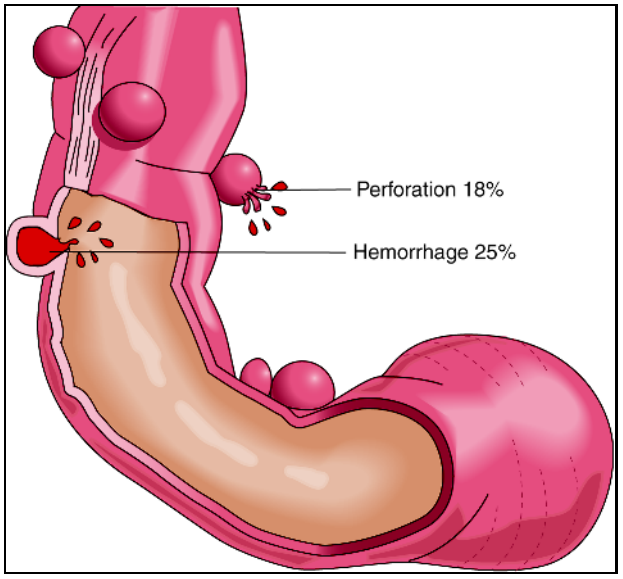

**Illustration of diverticula in the sigmoid colon. Diverticulosis is almost always located in the descending or sigmoid colon.** *(Delmar Publishers, Inc. Reproduced by permission.)*

Examples of foods that contain fiber and can be part of a diverticular disease diet include (amounts of fiber shown for a medium fruit or 1 cup of vegetable, fruit or grain):

- Apple, raw, with skin (3.3g)
- Peach, raw (1.5g)
- Pear, raw (5.1g)
- Pineapple (1.9g)
- Tangerine, raw (1.9g)
- Blueberries (4.0g)
- Cranberries (4.0g)
- Raspberries (8.3g)
- Asparagus, 4 spears, fresh, cooked (1.2g)
- Broccoli, fresh, cooked (5.2g)
- Brussels sprouts, fresh, cooked (4g)
- Cabbage, fresh, cooked (3g)
- Carrot, fresh, cooked (4.6g)
- Cauliflower, fresh, cooked (3.4g)
- Celery, raw (2.1g)
- Romaine lettuce (1.2g)
- Spinach, fresh, cooked (4.4g)
- Summer squash, cooked (2.5g)
- Tomato, raw (1g)
- Winter squash, cooked (5.7g)
- Baked beans, canned, plain (12.6g)
- Kidney beans, fresh, cooked (11.4g)
- Lima beans, fresh, cooked (13.2g)
- Potato, fresh, cooked (2.3g)
- Bread, whole-wheat, 1 slice (1.9g)
- Brown rice, cooked (3.5g)
- Cereal, bran flake (7.1g)
- Oatmeal, plain, cooked (4g)
- White rice, cooked (0.6g)

There are several types of dietary fiber, which makes it easy to include it in the diet:

- Cellulose. Found in bran, legumes, peas, root vegetables, the cabbage family, the outer covering of seeds, and most fruits.
- Hemicellulose. A major constituent of cereal fiber, found in bran and whole grains.
- Polyfructoses. Examples are inulins and oligofructans, found in onions, garlic, artichokes, soybean.
- Gums. These are substances secreted by a plant at injury sites. They are composed of various sugars and sugar derivatives. Found oatmeal, barley, and legumes.
- Mucilages. Gelatinous substances found in most plants.
- Pectins. Water-soluble and gel-forming substances found in apples, strawberries, and citrus fruits.
- Lignin. This is the primary noncarbohydrate component of fiber. It is highest in mature root vegetables like carrots or fruits with edible seeds like strawberries.
- Resistant starches. These are starches that are classified as fibers because they are not digested by the body. They are found in whole legumes, potatoes and bananas and plantains.

To help increase dietary fiber in the diet, breakfast should include a bowl of porridge made with millet, oats or brown rice, toast made with whole-grain bread instead of white bread, whole-grain ready-to-eat cereals with milk, and a bowl of fruit instead of fruit juice. During the day, snacks can include fresh fruit, or dried fruits like raisins, prunes, dates, apricots, or a few wholegrain crackers. In meals, brown rice should replace white rice. Pasta dishes should include more vegetables and fruit? to increase the fiber content of the meal. Serve fruit after meals instead of a dessert. Vegetables should also be eaten at each meal. Sandwiches should be made with whole-grain bread and include vegetables.

Besides adding fiber foods to a diverticular disease diet, the health practitioner may also prescribe a fiber supplement such as Citrucel or Metamucil once a day. These products supply 2–3.5g of fiber per tablespoon, mixed with 8 ounces of **water**. Some physicians also recommend to avoid nuts, popcorn, and sunflower, pumpkin, caraway, and sesame seeds as they believe that particles of these foods could enter, block, or

## KEY TERMS

**Abdomen**—Part of the body that extends from the chest to the groin.

**Abdominal cavity**—The hollow part of the body that extends from the chest to the groin. It is located between the diaphragm, which is the thin muscle below the lungs and heart, and the pelvis, the basin-shaped cavity that contains the reproductive organs, bladder, and rectum. The abdominal cavity contains the abdominal organs.

**Bile**—Digestive juice secreted by the liver and stored in the gallbladder; helps in the digestion of fats.

**Colon**—Part of the large intestine, located in the abdominal cavity. It consists of the ascending colon, the transverse colon, the descending colon, and the sigmoid colon.

**Diverticulitis**—Inflammation of the small pouches (diverticula) that can form in the weakened muscular wall of the large intestine.

**Feces**—Waste product of digestion formed in the large intestine. About 75% of its mass is water, the remainder is protein, fat, undigested roughage, dried digestive juices, dead cells, and bacteria.

**Gastrointestinal tract (GI tract)**—The tube connecting and including the organs and paths responsible for processing food in the body. These are the mouth, the esophagus, the stomach, the liver, the gallbladder, the pancreas, the small intestine, the large intestine, and the rectum.

**Immune system**—The integrated body system of organs, tissues, cells, and cell products such as antibodies that protects the body from foreign organisms or substances.

**Inflammation**—A response of body tissues to injury or irritation characterized by pain and swelling and redness and heat.

**Insoluble**—That cannot be dissolved.

**Insulin**—A hormone secreted by the pancreas and required for the regulation of the metabolism of carbohydrates and fats.

**Intestinal flora**—The sum of all bacteria and fungi that live in the intestines. It is required to break down nutrients, fight off pathogens and helps the body build the vitamin E and K. An unbalanced intestinal flora can lead to many health problems.

**Inulin**—Naturally occurring oligosaccharides (several simple sugars linked together) produced by many types of plants. They belong to a class of carbohydrates known as fructans.

**Large intestine**—The terminal part of the digestive system, site of water recycling, nutrient absorption, and waste processing located in the abdominal cavity. It consists of the caecum, the colon, and the rectum.

**Mucilage**—A sticky substance used as an adhesive. A gummy substance obtained from certain plants.

**Nutrient**—A chemical compound (such as protein, fat, carbohydrate, vitamins, or minerals) that make up foods. These compounds are used by the body to function and grow.

**Soluble**—Capable of being dissolved.

**Syndrome X**—A group of risk factors that together, put someone at higher risk of coronary artery disease. These risk factors include: central obesity (excessive fat tissue in the abdominal region), glucose intolerance, high triglycerides and low HDL cholesterol, and high blood pressure.

irritate the diverticula. However, no scientific evidence support this opinion. The seeds in tomatoes, zucchini, cucumbers, strawberries, and raspberries, as well as poppy seeds, are generally considered harmless. An eating plan for diverticular disease is usually based on what works best for each person. To help the colon rest, the treating physician may also recommend bed rest and a liquid diet.

### Function

Fiber is the edible part of fruits, vegetables, and grains that the body cannot digest. Since they are not absorbed into the body, dietary fibers are not considered a nutrient. Some fiber dissolves easily in water and becomes soft in the intestines, while insoluble fiber passes almost unchanged through the intestines. Both kinds of fiber are required to make stools soft and easy to pass. Fiber also prevents constipation, which makes the bowel muscles strain to move stool that is too hard. It is believed to be the main cause of increased pressure in the colon that may cause the weak colon spots to bulge out and become diverticula.

Many plant foods contain both soluble and insoluble fibers. For example, psyllium husks, contain a mixture of 70% soluble and 30% insoluble fibers. Despite the general use of the terms “soluble” and

"insoluble" to describe the health benefits of dietary fiber, many nutrition experts are now using the terms "viscous" and "fermentable" to describe the functions and health benefits of dietary fiber. These include:

- Reducing blood cholesterol levels: Viscous fibers lower cholesterol levels by reducing the absorption of dietary cholesterol. In addition, they combine with bile acids. These are compounds produced by the liver from cholesterol that are required for the breakdown of fats. After combining with bile acids, the compounds are removed from circulation and do not make it back to the liver. As a result, the liver must use additional cholesterol to manufacture new bile acids. Soluble fiber may also reduce the amount of cholesterol manufactured by the liver.
- Normalizing blood sugar levels: Viscous fibers are also involved in controlling blood glucose levels because they slow down the rate at which food leaves the stomach and delay the absorption of glucose after a meal. Viscous fibers also increase insulin sensitivity. As a result, viscous fibers are believed to play a role in the prevention and treatment of type 2 diabetes.
- Supporting bowel regularity: Fermentable fibers are fermented by the intestinal flora, the bacteria and fungi that live in the intestines. The fermentation of dietary fiber in the large intestine produces a short-chain fatty acid called butyric acid, which is used as fuel by the cells of the large intestine and helps maintain the health of the colon. Fermentable fibers also help maintain healthy populations of bacteria in the intestinal flora. Fibers that are not fermentable help maintain bowel regularity by increasing the bulk of the feces and decreasing the time required by fecal matter to move through the intestines.

## Benefits

Fiber keeps stool soft and lowers pressure inside the colon so that bowel contents can move through easily. This is why it is considered beneficial for diverticular disease. Eating a **high-fiber diet** will not only treat diverticular disease, it is also believed to play a role in the prevention and treatment of the following health conditions:

- breast cancer
- cardiovascular disease
- colon cancer
- diabetes
- gallstones
- high cholesterol
- irritable bowel syndrome
- obesity
- syndrome X

## Precautions

When increasing the fiber content of the diet, it is recommended to add fiber progressively, adding just a few grams at a time to allow the intestinal tract to adjust. Otherwise, abdominal cramps, gas, bloating, and diarrhea or constipation may result. Intake of dietary fiber exceeding of 50g per day may also lead to intestinal obstruction. Excessive intake of fiber can also cause a fluid imbalance, leading to **dehydration**. This is why people who start increasing their fiber intake are often advised to also increase their water intake. Excessive intake of dietary fiber has been linked with reduced absorption of **vitamins**, **minerals**, proteins, and calories. However, it is unlikely that healthy people who consume fiber in amounts within the recommended ranges will have problems with nutrient absorption.

Parents are urged to use caution when adding extra fiber to their child's diet. Excessive amounts of high-fiber foods may cause a child to fill up quickly, reducing appetite and possibly depriving the child of needed nutrients from a well-balanced diet. Elderly people and those who have had gastrointestinal surgery should also exercise caution when increasing their dietary fiber intake.

## Risks

Most people recover fully after treatment for diverticular disease. If not treated however, diverticulitis can lead to the following serious conditions:

- Intestinal perforation: The diverticula burst because of increased pressure within the intestine.
- Peritonitis: This is a serious infection of the abdominal cavity outside the intestine. It often occurs after perforation, when the contents of the intestine are leaked into the abdominal cavity.
- Abscess formation: Sacs of infected intestinal material and pus can form that are very difficult to cure.
- Fistula formation: An abnormal connection between the colon and another organ can form. This occurs when the colon, damaged by infection, comes in contact with other tissue, such as the bladder, the small intestine, or the inside of the abdominal wall, and sticks to it. Fecal material from the colon can then get into the other tissue.
- Blockage of the intestine: This can result from hard fecal matter reaching out of diverticula.
- Bleeding in the intestine: Stool that is trapped in a diverticulum may cause bleeding.

## QUESTIONS TO ASK YOUR DOCTOR

- What are diverticulosis and diverticulitis?
- How serious is this condition?
- What are the possible complications?
- What causes diverticular disease?
- What is the treatment for diverticular disease?
- Will tests be required?
- Will surgery be necessary?
- Are there foods that should be avoided?
- Are there foods that are recommended?
- How can I tell if I am getting enough fiber in my diet?
- How will I know if I am getting too much fiber in my diet?
- Would seeing a dietician for an eating plan help?
- How effective is diet in controlling this disease?
- Is there a cure for diverticular disease?
- What is the function of dietary fiber?
- Do you recommend intestinal cleansing?
- What are some simple steps for increasing the fiber intake of my meals?
- Should I eat one type of fiber more than another?

### Research and general acceptance

Most health practitioners agree that the lack of fiber and bulk in the diet is the major cause of diverticular disease. As foods are becoming more highly refined, more people are suffering from diverticular disease symptoms. Eating a high-fiber diet is accordingly the only requirement highly emphasized by the medical profession. Eliminating specific foods is not considered necessary as no research supports that it may improve the condition. A gradual switch to a diet with increased intake of soluble fiber (green vegetables, oat bran) usually leads to an improvement in bowel function. There is general agreement on food sources being more efficient fiber sources than supplements since they also supply additional nutrients. Excessive use of fiber supplements can also lead to acute digestive problems and blockages.

In its most recent 2005 public health recommendations for dietary fiber, the National Academy of Sciences established an Adequate Intake (AI) level of 38g of total daily fiber for males 19–50 years of age and 25g for women in this same age range. The report also states that individuals in this age range in the United States only get about half this much fiber each day. The recommendation for children older than 2 years is to increase dietary fiber intake to an amount equal to or greater than their age plus 5 g/day. There are currently no published studies that indicate optimal dietary fiber intakes for infants and children under 2 years of age. Until more information becomes available, a sensible guideline is to introduce a variety of fruits, vegetables, and easily digested cereals after weaning.

It is understood that, as the body ages, the outer layer of the intestinal wall thickens, which narrows the intestine. As a result, stool moves more slowly through the colon, increasing the pressure. Hard stools, such as those produced by a diet low in fiber, can further increase pressure. Repeated straining during bowel movements also increases pressure and contributes to formation of diverticula. As for the cause of diverticulitis, there is broad agreement that it occurs when diverticula become infected or inflamed, but medical experts are not know precisely what causes the infection. It is believed to start when stool or bacteria are caught in the diverticula.

The United States Food and Drug Administration (FDA) has approved the following claims about dietary fiber that can be listed on food labels:

- Good Source of Fiber, Contains Fiber or Provides Fiber: Any food product that contains 2.5 to less than 5g of fiber per serving (less than 20% of the daily value of dietary fiber) and is low in total fat per serving (3g or less fat per serving).
- High Fiber, Rich in Fiber, Excellent Source of Fiber: Any food product that contains at least 5g or more of dietary fiber per serving (20% or more of the fiber daily value) and is low in total fat per serving (3g or less fat per serving).

# Dr. Feingold diet

## Definition

The Dr. Feingold diet is a diet that eliminates many different forms of additives and other compounds from the diet. It is intended to reduce the symptoms of Attention Deficit Disorder and Attention Deficit **Hyperactivity** Disorder. Many proponents of the diet suggest that it can be used to improve other common problems as well.

## Origins

The Dr. Feingold diet was developed by Dr. Ben F. Feingold during the 1970s. Dr. Feingold was born on June 15th, 1899 in Pittsburg, Pennsylvania. He received his Bachelor of Science degree from the University of Pittsburgh in 1921, and his Medical Degree from the same institution in 1924. Following this, he did an internship from 1924 to 1925 at Passavant Hospital, also in Pittsburgh, and then a fellowship in pathology at the University of Goettingen in Germany. He then spent 1928 and 1929 working with children in Austria before returning to the United States to be an instructor of pediatrics at the Northwestern University School of Medicine.

Dr. Feingold continued to work with children, specifically in the developing area of allergy studies. During World War II he was a commander in the US Navy, and then returned from the war to be chief of pediatrics at Cedars of Lebanon Hospital in Los Angeles, California. He worked at various other hospitals and established all of the Departments of Allergy for Northern California for Kaiser Foundation Hospitals and Permanente Medical Group in 1951. He died on March 23, 1982.

During his career Dr. Feingold mainly studied allergies in children. He noticed, however, that during his career the increase of children exhibiting symptoms of hyperactivity seemed to correspond with the increased consumption by children of various food additives. He hypothesized that these food additives were what was causing the symptoms he observed. During the 1970s he set out to study this relationship, and believed he had found a link. In 1975 be published the book "Why Your Child is Hyperactive," laying out his beliefs. The Dr. Feingold diet is derived from this book. Since then, the children he called "hyperactive" have been identified as having Attention Deficit Disorder (ADD) or Attention Deficit Hyperactivity Disorder (ADHD).

Although Dr. Feingold died in 1982, his followers and adherents continue to update his diet and ideas. Although he intended his diet only for the treatment of hyperactivity, the Feingold Association of the United States has identified many other problems that my be alleviated by the diet. They have also continued to update the foods and additives believed to cause behavior and other problems in children.

## Description

The Dr. Feingold diet involves eliminating from the diet all forms of additives and chemicals believed by its proponents to be the cause of a variety of diseases and disorders, most generally ADD and ADHD. The diet occurs in two stages, the first stage involves eliminating all of the offending foods, and the second stage involves reintroducing one substance at a time to see which can be tolerated.

There are four main groups of chemicals and additives that are eliminated during the Dr. Feingold diet. The first of these are all forms of synthetic coloring. These are often made from by-products of petroleum and are believed to be one of the causes of hyperactivity. This means that any food products that have artificial colors (which include many popular children's foods and treats) are strictly forbidden.

## KEY TERMS

**Calorie**—A measurement of the energy content of food, also known as a large calorie, equal to 1000 scientific calories.

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Mineral**—An inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

**Vitamin**—A nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet.

The diet also requires that all forms of artificial flavoring be removed from the diet. The Feingold Association believes that many of these additives have not been studied carefully and can cause unwanted behaviors in children. Of special concern is the artificial vanilla flavoring vanillin, which is often made from by-products of paper production.

The Dr. Feingold diet also requires the elimination of aspartame, an artificial sweetener sold mainly under the brand name NutraSweet. This restriction is not as limiting as it may have been in the past because of the introduction of low calorie sweeteners derived from sugar during the mid 2000s.

**Artificial preservatives** are also eliminated completely when on this diet. These include the preservatives BHA (Butylated Hydroxyanisole) and BHT (Butylated Hydroxytoluene), which are derived from petroleum. The purpose of these preservatives is mainly to delay the oxidization of **fats** in foods. It is this oxidization that makes fats go rancid, so these preservatives give foods a longer shelf-life.

During stage one of the diet many salicylates are removed from the diet, but may be reintroduced later during state two. Salicylates are a group of chemicals, some of which are naturally occurring, which are related to aspirin. This eliminates certain natural foods such as apples, berries, grapes, oranges, peaches, plums, tangerines, and tomatoes, along with many others.

The Dr. Feingold diet can be very time consuming to follow, especially at first, because many of the forbidden substances occur under a variety of names on labels, all of which must be learned. The Feingold Association of the United States produces a set of materials intended to help people beginning the diet, including an 150 page food guide. These can be ordered for a fee from their website, www.feingold.com

### Function

The Dr. Feingold diet is generally used for children, although it may be effective for adults as well. It is intended to remove substances that some people believe cause ADD and ADHD. According to the Feingold Association of the United States it can also be effective in reducing or eliminating impulsiveness, compulsiveness, disruptive behaviors, poor self-control, abusive or unpredictable behavior, and destructive behaviors. They also believe it can change workaholic habits, chewing on clothing or other inappropriate objects, depression, frequent crying, irritability, panic, low self-esteem, mood swings, impatience, distraction, inability to follow directions, poor muscle coordination, speech difficulties, tics, seizures, and difficulty with comprehension. The association also states that it can help physical problems such as ear infections, asthma, bedwetting, and **constipation**, and sleep problems such as resistance going to bed, difficulty falling asleep, and nightmar! es.

### Benefits

There are many benefits for children who eat a balanced diet including many fresh fruits and vegetables. Because the Dr. Feingold diet excludes many forms of artificial additives, it may limit the amount of processed food available to consume, leading to a more balanced diet with more healthful food. This is not necessarily the case however, as many fresh fruits must be eliminated during stage one because of naturally occurring salicylates. The diet may result in reduced symptoms of ADD and ADHD and is reported by the American Feingold Association to be able to resolve other psychical, emotional, and sleep complaints.

### Precautions

When starting any diet there are some risks, especially when beginning a diet that is very restrictive. Although the Dr. Feingold diet does not restrict very many types of foods, it is inflexible on the point that all foods containing offending additives or compounds be completely eliminated from the diet. This can limit the availability of convenience and processed foods especially, although many other foods are forbidden as

well. It is important for all adults to get a balanced diet that follows the United States Department of Agriculture's MyPyramid guidelines, but this is especially important for children. Not getting the right amounts of **vitamins** and **minerals** each day can have negative effects on a child's growth and development. This may be a concern for children on the Dr. Feingold diet because stage one limits many child-friendly fruits such as apples, oranges, and grapes.

One problem some families may find when on the Dr. Feingold diet is that it is very time intensive. For adults who go on the diet there are significant amounts of time required to learn all the rules of the diet, and to learn to identify the various forbidden additives in all of the forms in which they may appear on labels. For parents putting a child on the diet, the time required is even greater. Not only must the parent learn to identify which foods are allowable for the child, but the time must be taken to educate the child on this complicated issue as well. This is especially true for older children who may make more of their own eating decisions outside of the watchful eyes of their parents. Children have to learn which foods can be eaten and how to read labels. They also need to learn coping skills to be able to explain to other children and any adults who might be offering them food (such as their friend's parents) which foods are not allowed. It may be a! dvisable also to go over some skills to help children explain to friends and classmates why they are on a special diet in a way which is not upsetting or embarrassing to them. Many people also choose to make chidlren's teachers, babysitters, and others aware of the new diet which can take time as well.

Although there are no specific studies investigating the social effects of the Dr. Feingold diet on children, there are many pieces of anecdotal evidence illustrating some of it possible negative effects. One concern for some parents may be that being an such a strict diet, that has to be followed all of the time including at school and at friends' houses, children may feel different than their peers. It can be very hard for children who feel or seem different than those around them, and other children might not understand why they cannot have the same candy, or have to eat special meals brought from home. Another issue brought up by some people who were on the diet as children is that it puts children who do give into temptation (and there are many temptations for children on this diet) into a very difficult position. Because the Feingold Association maintains the diet must be followed exactly at all times to be effective, children who have eaten something forbi! dden must decide whether to admit it or lie to their parents. It can also put children and parents into an antagonistic relationship because often if the diet does not cure the disease or disorder, it is assumed that it is because forbidden foods have been consumed. This can lead to a negative spiral of accusations, guilt, and anger. These problems certainly will not occur with every child in every family, but it may be something that parents considering this diet for their child or children would want to consider.

## QUESTIONS TO ASK THE DOCTOR

- Does my child have symptoms of ADD, ADHD or another problem that may be helped by this diet?
- Is this diet appropriate for the whole family?
- Will I or my child get all required vitamins and minerals if on this diet?
- Are other interventions, in addition to diet, appropriate to help my child at this time?
- Are there any signs or symptoms that may indicate a problem while on this diet?

### Risks

There are some risks associated with starting any diet. Although there are no significant scientifically documented risks for starting this diet there is some chance that it may cause feelings of isolation in the child because he or she feels different than those around him or her. There is also some risk that this diet may put significant stress on the family because it is very time intensive and must be followed strictly. The diet may also cause some tension in parent-child relationships because the child may react negatively to being put on the diet or may be tempted to eat forbidden foods.

### Research and general acceptance

The Dr. Feingold diet is extremely controversial. Since the 1970s many different experiments have been done in an attempt to determine if it capable of the results it claims. Dr. Feingold himself did some preliminary studies in the 1970s, the results of which are still hotly debated by many people. There are many methods used in attempts to determine the effectiveness of the diet. These include putting children on the diet and monitoring any improvement in behaviors. To study its effects in an opposite way, scientists have tried reintroducing additives thought to be harmful into the diets of children who have been on the diet and watching to see if behavior deteriorates. The

evidence has been mixed, and many studies are interpreted differently by each side of the debate. The Feingold Association of the United States cites many different studies on its websites, and gives short excerpts or summaries of some of the evidence. The Association cites these studies as proof t! hat the diet is effective for most children. There has not been any significant research done on whether the diet is effective in achieving positive results for problems not related to ADD or ADHD.

Some health professionals however, are not convinced that the diet can help children with ADD or ADHD. One common argument against the effectiveness of the diet is that there may be other causes for the improvement shown in children on the diet. Because the diet is extremely complicated and involves reading labels carefully, and closely monitoring everything that is eaten (as well as exposure to some things such as soaps and perfumes), parents are forced to become extremely involved in their child's life while their child is on this diet. Some experts have argued that any improved behavior is probably a result of this increased parental participation, and not a direct result of the diet. Another critcism of the studies on the effectiveness of the diet is that often the behavioral changes are reported by parents and are not confirmed by outside, unbiased observers.

# Dr. Phil's diet

## Definition

Dr. Phil's diet is named for Dr. Phillip C. McGraw, Ph.D., the psychologist and life strategist seen on syndicated television. Popularly known as "Dr. Phil" he developed a line of "Shape Up!" weight loss products and simultaneously developed and published a book titled "The Ultimate Weight Loss Solution: The 7 Keys to Weight Loss Freedom."

The Ultimate Weight Loss Solution was promoted as a combination of healthy diet, exercise, behavior modification, and thinking differently about food.

## Origins

Dr. Phil was a private practice psychologist in Wichita Falls, Texas, before starting a trial consulting firm. It was in this business that he worked with television star Oprah Winfrey, consulting with her during a 1995 trial brought against Ms. Winfrey by members of the beef industry. Shortly after, Dr. Phil began appearing on Ms. Winfrey's syndicated television show. By 2002, he was hosting his own syndicated daily television show and had become a well-known author and popular figure.

Dr. Phil has said that for 30 years, he counseled people battling weight problems and **obesity**. He has said that he wanted to more widely address the problem of obesity with a behavioral and nutritional approach. In 2003, he introduced the book and a line of nutritional products. The diet products were marketed by CSA Nutraceuticals, along with involvement of companies that have produced similar health and nutrition products. At the same time that the products and book were being marketed, Dr. Phil focused on weight loss themes on his television show. However, he did not refer to the weight loss products on the show. He introduced his diet on a nationally broadcast television special featuring Katie Couric and 13 weight loss challengers.

Dr. Phil's son Jay McGraw followed in his father's footsteps and authored a book with a similar plan written specifically for teenagers. This book also was published in 2003.

## Description

Dr. Phil's diet involved a book outlining a diet plan and a line of diet food products and supplement pills. The food products included flavored shakes and snack bars. The shakes and snack bars were fortified

## KEY TERMS

**Metabolize**—To produce the chemical changes in the body's living cells that provide energy for vital processes and activities.

with 24 **vitamins** and **minerals**. The products' supplements were geared toward helping people with apple or pear body shapes. The products were only on the market for about one year.

The introduction to Dr. Phil's book follows his "down-to-earth" delivery style. He tells readers that he is not going to tell them what they want to hear. He says that seven critical pieces, or keys, help achieve long-term weight loss. The book is filled with personal anecdotes, self-assessment quizzes, and chapters on each key. Dr. Phil writes that those who have kept their weight off use all seven keys. The seven keys are described below.

### *Right thinking*

Dr. Phil refers to a person's personal truth, or whatever it is about one's self and the weight problem that a person has come to believe. He says that part of learning to lose weight is learning to get rid of thoughts that don't work for weight loss and instead gain access to inner power and self-control. Dr. Phil says this helps people break the negative cycle of failed weight loss efforts and negative momentum. In the chapter, Dr. Phil lists 10 self-defeating messages that people often think about weight and weight control. For example, those who have problems with weight may label themselves or be labeled by others.

### *Healing feelings*

This key refers to the way that some people eat to medicate themselves. Dr. Phil says that often people eat in response to negative emotions such as loneliness, stress, or boredom. Dr. Phil says that admitting to emotional triggers for overeating and learning to overcome the connection between emotions and food helps gain control over eating. The key helps to identify a process that is broken down into five manageable steps. Dr. Phil talks about forgiving one's self and about learning to cope without food.

### *A no-fail environment*

This key helps people manage the environment so that they can be more successful when trying to lose weight. The book provides advice on how to prevent needless snacking, overeating, and bingeing by removing tempting foods from the home, then from other environments such as work. He talks about shopping strategies, bringing healthy food choices into the environment, and even removing large-size clothes from the closet.

### *Mastery over food*

Dr. Phil's fourth key advises people to control habits by gaining mastery over food and through impulse control. The fourth key focuses on wiping bad, weight-gaining habits from their lives and replacing them with healthier behaviors. He lists weight-gaining behaviors and various pay-offs they offer to people. The chapter concludes with suggested behaviors to replace the weight-gaining behaviors, as well as the payoffs from the healthier behaviors.

### *High-response, high-yield foods*

In this key, Dr. Phil discusses the nutritional value of various foods by describing a "high-response cost, high-yield food" plan. Instead of offering meal plans or calorie-cutting, Dr. Phil's diet talks about and lists foods that take longer to prepare and eat, and therefore are healthier. He contrasts these foods with those that take little time to prepare and eat, which normally offer higher calories and less nutritional value. He also mentions vitamin and mineral supplements in addition to high-yield foods.

### *Exercise*

Dr. Phil calls his sixth key to weight loss intentional exercise. He says that instead of becoming obsessed about exercise, people need to take a balanced approach of regular strength-building and heart-conditioning activities to burn calories. Dr. Phil says that intentional exercise can open the door to body control, a state where the body can better metabolize energy for losing weight and keeping weight off. He breaks exercise into categories of moderate activities and vigorous activities. In addition, the book lists the physical and psychological benefits of exercise.

### *Support*

The final key to weight loss provided by Dr. Phil involves social control. He says people can gain this by having a circle of support. People in a circle of support encourage a person trying to lose or maintain weight and also provide accountability to help achieve weight loss goals. He points out that the key to social support is not just having supportive friends and family in the

circle, but also managing or staying away from people who sabotage weight loss efforts.

The book concludes with several appendices, such as food lists, a workout diary, and a sample exercise for stress relief and relaxation. Dr. Phil reminds readers that weight is managed, not cured. He explains danger zones that allow people to drift off course in managing their weight, then discusses avoiding these danger zones.

## Function

Dr. Phil's weight loss solution is for people who want to lose or manage weight. He presents the diet as an alternative to crash and **fad diets**. As a psychologist, Dr. Phil approaches the diet from behavioral aspects as well as from the nutritional aspects.

## Benefits

Dr. Phil says that in typical diets, the emotion fades soon after starting the diet. In interviews about his weight loss solution, Dr. Phil said that people have better chances of succeeding on weight loss efforts if they reprogram their lives and follow the seven keys to success. He said that fear keeps people from addressing the emotions involved in overeating. The diet also focuses on being healthy and having realistic expectations for a person's age.

## Precautions

Some nutritionists and scientists have questioned the evidence quoted by Dr. Phil for the success rate of his plan and nutritional products. Following any particular diet plan should be done only after consultation with a physician and/or licensed dietician. The advice of involving a nutritionist comes late in Dr. Phil's book.

## Risks

Among concerns was the nutritional balance of some of the Shape Up food products. Although Dr. Phil's diet does not lean toward one food group and advises generally traditional diet advice of balanced diet mixed with exercise, it is best to involve a health care professional or registered dietary professional to ensure that the strategies are healthful and successful.

## Research and general acceptance

In the book, Dr. Phil cites a bibliography, a consulting nutritionist, and an 80% success rate. But there are no specific scientific studies published or referred to that prove the success of the program or its individual strategies. After developing the Shape Up products, which consisted of herbal supplements, shakes, and snack bars, a lawsuit was filed stating that Dr. Phil had made false claims about their benefits. Reports showed that although the nutrition shakes were in good ranges for **carbohydrates** and fat, the nutrition bars were in relatively high carbohydrate and fat ranges. The lawsuit was filed in 2004 on behalf of three disappointed consumers. They said that that Dr. Phil had defrauded fans, making false statements about the supplement pills. CSA Nutraceuticals agreed to stop making the supplements in early 2004 when it faced an investigation from the Federal Trade Commission concerning false-advertising claims. The plaintiffs sought class action status for the lawsuit and reached a $10.5 million settlement in September 2006.

In an article in *Food Processing* magazine, a diet expert at the University of California at Berkeley was quoted as saying that Dr. Phil's diet advice was not innovative. Yet she added that the advice was common sense. A review in the *Tufts University Health & Nutrition Letter* said there were several flaws with the book's advice and that some of the advice contradicted other points in the book or did not make sense. The review listed some good points, including the fact that a dieter does not have to be strong 24 hours a day, seven days a week.

An American Dietetic Association fact sheet said that some of the book's advice is good, such as behavior modification strategies that have been used in weight control programs for many years. But the review said that the book also contained nutrition and dietary recommendations that were mistaken or outdated. The review also stated that the advice for dealing with complicated emotional and other eating-related issues is made seemingly simple, but that managing these issues alone is not easy.

## QUESTIONS TO ASK YOUR DOCTOR

- What do you know about Dr. Phil's diet and its success?
- How can I use the strategies in the diet but incorporate more current nutritional information?

DRIs *see* **Dietary Reference Intakes**

# Dyspepsia

## Definition

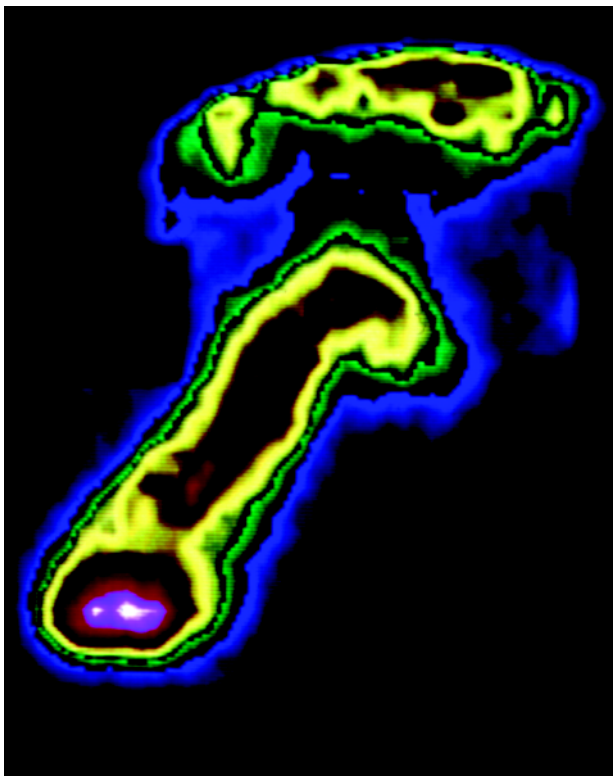
Dyspepsia is gastric upset due to the inability to digest one's food.

## Origins

Dyspepsia is a word that has been used in English since the early eighteenth century not only for a variety of stomach ailments but also for bad moods or temper outbursts that were thought to be caused by indigestion. The English word comes from two Greek words meaning "hard or difficult" and "digestion." For many years dyspepsia was a catchall term for any kind of stomach upset characterized by burning, nauseous, or gassy sensations in the upper abdomen. Several phrases that are still used almost interchangeably for the condition are gastric indigestion, nervous dyspepsia, and impaired gastric function.

Dyspepsia was not defined more closely until the mid-1980s, when an international group of gastroenterologists (doctors who specialize in treating disorders of the digestive system) met in Rome to create a set of criteria for distinguishing dyspepsia from other disorders of the upper digestive tract (known as the Rome criteria); and to distinguish between organic dyspepsia—stomach upset that can be shown to have a physical cause (for example, stomach irritation caused by **alcohol consumption**), and functional dyspepsia (FD)—dyspepsia that cannot be traced to any specific physical cause. FD accounts for a majority of cases of dyspepsia, as many as 60% in some studies, and for 30–50% of all referrals from primary care doctors to gastroenterologists.

Dyspepsia is considered a difficult condition to treat, even though it is widespread in the general population. An estimated 25–40% of adolescents and adults in North America experience dyspepsia each year. Most people with the disorder do not seek medical treatment because it may be intermittent as well as persistent. FD is responsible for high health care costs in terms of prescription as well as over-the-counter medications, diagnostic tests, and time lost from work.



**A false-color gamma scan of a human stomach with dyspepsia, or indigestion, during tests to study its rate of emptying.** *(Photograph by Jean-Perrin, Custom Medical Stock Photo, Inc. Reproduced by permission.)*

In the nineteenth and early twentieth centuries, FD was commonly treated with various forms of dietary therapies. Treatments commonly recommended by doctors in the 1920s included vegetarian diets as well as the use of laxatives and enemas to cure the patient of autointoxication—an imaginary disorder that originated in ancient Egypt and is based on the belief that the contents of the colon are toxic and capable of poisoning other body organs. Folk dietary remedies for dyspepsia included drinking peppermint tea or milk, eating spearmint leaves, or chewing mint-flavored chewing gum, which first became popular in the 1860s.

Although FD is not fully understood, there are several theories regarding its underlying mechanisms or possible causes:

- FD reflects greater than average sensitivity to uncomfortable sensations in the digestive tract. This theory

## KEY TERMS

**Autointoxication**—A belief, now discredited, that the contents of the intestine are toxic and produce poisons that can damage other body organs.

**Endoscope**—A special tube-shaped instrument that allows a doctor to examine the interior of or perform surgery inside the stomach or intestines. An examination of the digestive system with this instrument is called an endoscopy.

**Gastroenterologist**—A doctor who specializes in diagnosing and treating disorders of the digestive system.

**Gastroesophageal reflux disease (GERD)**—A disorder caused by the backward flow of stomach acid into the esophagus. It is usually caused by a temporary or permanent change in the sphincter that separates the lower end of the esophagus from the stomach.

***Helicobacter pylori***—A spiral-shaped Gram-negative bacterium that lives in the lining of the stomach and is known to cause gastric ulcers.

**Placebo effect**—A term that describes the improvement in symptoms that some patients experience when they are given a placebo (sugar pill or other inert substance that does not contain any medication) as part of a clinical trial. Patients with functional dyspepsia show a high rate of placebo effect in trials of new medications for the disorder.

**Prokinetic drugs**—A class of medications given to strengthen the motility of the digestive tract.

**Rome criteria**—A set of guidelines for defining and diagnosing functional dyspepsia and other stomach disorders, first drawn up in the mid-1980s by a group of specialists in digestive disorders meeting in Rome, Italy. The Rome criteria continue to be revised and updated every few years.

holds that patients with FD perceive sensations in the stomach or intestines as painful that most people experience as ordinary or do not feel at all.

- FD is a motility disorder. FD may result from a decreased ability of the digestive system to contract and push food through the system. This, in turn, causes lower than normal stomach emptying.
- FD is caused by *Helicobacter pylori* infection. *H. pylori* is a spiral-shaped bacterium that is the only known microorganism that can live in the acidic environment of the stomach. It is now known to be a cause of peptic ulcers, but doctors do not yet agree on its role in functional dyspepsia.

## Description

The Rome criteria for FD specify that the patient must have had 12 weeks (not necessarily consecutively) of the following symptoms in the previous 12 months:

- Persistent or recurrent pain or discomfort centered in the upper abdomen.
- No evidence of an organic disease (including the findings from an endoscopy of the upper digestive tract) that is likely to explain the symptoms; and
- No evidence that the dyspepsia is relieved exclusively by defecation or associated with the onset of a change in bowel habits.

The Rome criteria specify three subtypes of FD based on the most bothersome symptom: ulcer-like dyspepsia (pain in the upper abdomen); dysmotility-like dyspepsia (an unpleasant but nonpainful feeling of bloating, fullness, or nausea); and unspecified dyspepsia (patient's digestive discomfort does not fit either of the first two categories).

FD is widespread in the general population, however, the subtypes identified by the Rome working group appear to show slight gender differences. Ulcer-like dyspepsia appears to be more common in men and dysmotility-like dyspepsia more common in women. FD is equally widespread in all racial and ethnic groups.

Some medications other than aspirin and other over-the-counter pain relievers may cause dyspepsia: alendronate (Fosamax); codeine and aspirin fortified with codeine; **iron** supplements; metformin (Glucophage); oral antibiotics, particularly erythromycin; **orlistat** (Xenical); corticosteroids, especially prednisone; and theophylline. Patients should consult their doctors before discontinuing these drugs or changing the dosage.

## Treatment

### *Dietary*

Dietary treatment for dyspepsia generally consists of cutting down on alcohol intake; avoiding fatty or highly spiced foods; and avoiding any other food that appears to trigger episodes of dyspepsia. Therapeutic fasting, which is thought to give the digestive system a

period of rest before making other changes in the patient's diet or beginning medication therapy, may be recommended.

Patients with FD may also benefit from discontinuing certain herbal remedies that produce symptoms of dyspepsia. These include garlic, gingko, saw palmetto, feverfew, chaste tree berry, and willow bark.

### *Other treatments*

Other treatments for functional dyspepsia include complementary and alternative (CAM) therapies and psychotherapy. CAM treatments include such herbal remedies as peppermint, turmeric, and aloe vera gel taken by mouth, and such non-dietary treatments as yoga, meditation, relaxation techniques, acupuncture, and music therapy. Psychotherapy is most likely to be helpful for patients with a history of abuse or post-traumatic stress as well as functional dyspepsia.

Prokinetic drugs may be prescribed for patients with dysmotility-like FD. These medications speed up or strengthen the contractions of the small intestine. Available medications include metoclopramide (Reglan), cisapride (Propulsid), and domperidone (Motilium). Domperidone is not approved for use in the United States because its adverse effects include abnormalities of heart rhythm. In addition to prokinetic drugs, some doctors prescribe antidepressant medications in order to lower the patient's stress level and awareness of sensations coming from the stomach and intestines, but only a minority of patients with FD benefit from either prokinetics or antidepressants.

### *Medical*

Medical management of FD in patients typically begins with either testing and treating the patient for infection with *H. pylori* or by prescribing medications to lower the level of stomach acid secretions for a trial period of 4–8 weeks. The two classes of medications most commonly prescribed to reduce acid secretion are $H_2$-receptor blockers and proton pump inhibitors (PPIs). The first group, which is the older of the two, was developed in the late 1970s and early 1980s and includes such drugs as cimetidine (Tagamet) and ranitidine (Zantac). The proton pump inhibitors are more powerful than the $H_2$-receptor blockers and have fewer adverse effects. The PPIs include omeprazole (Prilosec), lansoprazole (Prevacid), esomeprazole (Nexium), pantoprazole (Protonix), and rabeprazole (Rabecid). In general, trial therapy with acid-reducing medications is considered more effective for FD than testing for and treating *H. pylori* infection, because only a small minority of patients with FD report improvement in their symptoms after treatment for the infection.

## QUESTIONS TO ASK YOUR DOCTOR

- What are the chances that dyspepsia in a person of my age and sex represents a serious disorder?
- What is your opinion of dietary changes in treating dyspepsia?
- Would you recommend therapeutic fasting before beginning medication treatment for dyspepsia?

## Function

The function of medical and dietary treatment of FD is to manage or relieve the patient's symptoms in order to improve his or her quality of life. Therapeutic fasting is intended to give the digestive system a brief period of rest prior to medication therapy or antibiotics to eradicate *H. pylori*. Since the cause(s) of FD are not yet known for certain, these treatments cannot be considered cures.

## Benefits

The benefits of medical and dietary treatment of FD are improved symptom management and better quality of life, with less time lost from school or work.

## Precautions

Patients who experience dyspepsia for several weeks or longer should consult their physician for an evaluation to rule out more serious disorders; even if the indigestion is intermittent rather than continuous. Patients over age 45 who develop dyspepsia suddenly should see their doctor immediately, particularly if the indigestion is accompanied by black tarry stools, loss of appetite, painful swallowing, bloody vomit, or unintentional weight loss.

Patients who experience indigestion unrelated to eating, or indigestion accompanied by sweating, shortness of breath, or pain radiating to the neck, jaw, or arm should also see a doctor at once, as these symptoms may indicate a heart attack.

## Risks

There are no known risks associated with modifying one's diet to relieve functional dyspepsia, although patients considering a therapeutic fast should consult

their doctor first. Medications given to treat FD may have any of the following adverse effects: skin rashes; **constipation** or diarrhea; confusion; higher risk of **osteoporosis** and bone fractures; headache; fatigue; dizziness; and low blood pressure. Cimetidine has been reported to cause impotence and loss of interest in sex in males; these symptoms disappear when the drug is discontinued.

## Research and general acceptance

A population-based case-control study of adults in Minnesota found that there was no detectable difference in the consumption of frequently suspected culprit foods by patients with FD and the control subjects. There is also no evidence that a strictly vegetarian diet is useful in treating FD. Recent studies carried out in Germany indicate that a brief period of fasting under a doctor's supervision is beneficial to patients with FD.

Research is ongoing to improve the number and effectiveness of treatment options for dyspepsia. In 2006, a new drug called itopride was tested for eight weeks on a group of 523 patients with functional dyspepsia. The drug requires further study, but the results of the initial trial are encouraging. Clinical trials sponsored by the National Institutes of Health are recruiting subjects to study medications or other forms of therapy for dyspepsia. They include studies of the effectiveness of acid-reducing therapy or eradication of *H. pylori*, and evaluation of food hypersensitivity in patients with dyspepsia.

In the field of CAM therapies, studies are being conducted of peppermint oil and turmeric as plant- or food-based treatments for dyspepsia. With regard to aloe vera, research indicates that it should not be taken by mouth as a remedy for dyspepsia because it has laxative qualities and can lower the body's absorption of prescription medications. Other CAM approaches for dyspepsia being studied are mind/body approaches like relaxation training, yoga, and hypnosis, and energy therapies like acupuncture and therapeutic touch. European studies indicate that hydrotherapy and massage therapy are beneficial to patients with functional FD.

## Eating disorders

### Definition

Eating disorders are psychiatric illnesses that result in abnormal eating patterns that have a negative effect on health.

### Description

Eating disorders are mental disorders. They develop when a person has an unrealistic attitude toward or abnormal perception of his or her body. This causes behaviors that lead to destructive eating patterns that have negative physical and emotional consequences. Individuals with eating disorders often hide their symptoms and resist seeking treatment. Depression, anxiety disorders, and other mental illnesses often are present in people who have eating disorders, although it is not clear whether these cause the eating disorder or are a result of it.

The two best-known eating disorders, **anorexia nervosa** and **bulimia nervosa**, have formal diagnostic criteria and are recognized as psychiatric disorders in the *Diagnostic and Statistical Manual for Mental Disorders Fourth Edition (DSM-IV-TR)* published by the American Psychiatric Association (APA). Other eating disorders have recognized sets of symptoms, but have not been researched thoroughly enough to be considered separate psychiatric disorders as defined by the APA.

#### *Well-known eating disorders*

In the North America and Europe, anorexia nervosa is the most publicized of all eating disorders. It gained widespread public attention with the rise of the ultra-thin fashion model. People who have anorexia nervosa are obsessed with body weight. They constantly monitor their food intake and starve themselves to become thin. No matter how much weight they lose, they continue to restrict their calorie intake in an effort to become ever thinner. Some anorectics exercise to extreme or abuse drugs or herbal remedies that they believe will help them burn calories faster. A few purge their body of the few calories they do eat by abusing laxatives, enemas, and **diuretics**. In time, they reach a point where their health is seriously, and potentially fatally, impaired.

People with anorexia nervosa have an abnormal perception of their body. They genuinely believe that they are fat, even when the clearly are life-threateningly thin. They will deny that they are too thin, or, if they admit they are thin, deny that their behavior will affect their health. People with anorexia will lie to family, friends, and healthcare provides about how much they eat. Many vigorously resist treatment and accuse the people trying to cure them of wanting to make them fat. Anorexia nervosa is the most difficult eating disorder to recover from.

Bulimia nervosa is the only other eating disorder with specific diagnostic criteria defined by the *(DSM-IV-TR)*. People with bulimia often consume unreasonably large amounts of food in a short time. Afterwards, they purge their body of calories. This is done most often by self-induced vomiting, often accompanied by laxative abuse. A subset of people with bulimia does not vomit after eating, but fast and exercise obsessively to burn calories. Both behaviors result in impaired health.

People with bulimia feel out of control when they are **binge eating**. Unlike people with anorexia, they

**Symptoms of eating disorders**

| Anorexia nervosa | Bulimia nervosa | Binge-eating disorder |
|---|---|---|
| Resistance to maintaining body weight at or above a minimally normal weight for age and height | Recurrent episodes of binge eating, characterized by eating an excessive amount of food within a discrete period of time and by a sense of lack of control over eating during the episode | Recurrent episodes of binge eating, characterized by eating an excessive amount of food within a discrete period of time and by a sense of lack of control over eating during the episode |
| Intense fear of gaining weight or becoming fat, even though underweight | Recurrent inappropriate compensatory behavior in order to prevent weight gain, such as self-induced vomiting or misuse of laxatives, diuretics, enemas, or other medications (purging); fasting; or excessive exercise | The binge-eating episodes are associated with at least 3 of the following: eating much more rapidly than normal; eating until feeling uncomfortably full; eating large amounts of food when not feeling physically hungry; eating alone because of being embarrassed by how much one is eating; feeling disgusted with oneself, depressed, or very guilty after overeating |
| Disturbance in the way in which one's body weight or shape is experienced, undue influence of body weight or shape on self-evaluation, or denial of the seriousness of the current low body weight | The binge eating and inappropriate compensatory behaviors both occur, on average, at least twice week for 3 months | Marked distress about the binge-eating behavior |
| Infrequent or absent menstrual periods (in females who have reached puberty) | Self-evaluation is unduly influenced by body shape and weight | The binge eating occurs, on average, at least 2 days a week for 6 months |
| | | The binge eating is not associated with the regular use of inappropriate compensatory behaviors (e.g., purging, fasting, excessive exercise) |

SOURCE: National Institute of Mental Health, National Institutes of Health, U.S. Department of Health and Human Services

*(Illustration by GGS Information Services/Thomson Gale.)*

recognize that their behavior is abnormal. Often they are ashamed and feel guilty about their behavior and will go to great lengths to hide their binge/purge cycles from their family and friends. People with bulimia are often of normal weight. Although their behavior results in negative health consequences, because they are less likely to be ultra-thin, these consequences are less likely to be life-threatening.

The APA does not formally recognize binge eating as an eating disorder. Binge eating is quite common, but it only rises to the level of a disorder only when bingeing occurs at least twice a week for three months or more. People with binge-eating disorder may eat thousands of calories in an hour or two. While they are eating, they feel out of control and may continue to eat long after they feel full. Binge eaters do not purge or exercise to get rid of the calories they have eaten. As a result, many, but not all, people with binge-eating disorder, are obese, although not all obese people are binge eaters.

Binge eaters are usually ashamed of their behavior and try to hide it by eating in secret and hording food for future binges. After a binge, they usually feel disgusted with themselves and guilty about their eating behavior. They often promise themselves that they will never binge again, but are unable to keep this promise. Binge-eating disorder often takes the form of an endless cycle—rigorous dieting followed by an eating binge followed by guilt and rigorous dieting, followed by another eating binge. The main health consequences of binge eating are the development of obesity-related diseases such as type 2 diabetes, sleep apnea, stroke, and heart attack.

### *Lesser-known eating disorders*

Quite a few eating problems are called disorders even though they do not have formal diagnostic criteria. They fall under the APA definition of eating disorders not otherwise specified. Many have only recently come to the attention of researchers and have been the subject of only a few small studies. Some have been known to the medical community for years but are rare.

Purge disorder is thought by some experts to be a separate disorder from bulimia. It is distinguished from bulimia by the fact that the individual maintains a normal or near normal weight despite purging by vomiting or laxative, enema, or diuretic abuse.

Anorexia athletica is a disorder of compulsive exercising. The individual places exercise above work, school, or relationships and defines his or her self-worth in terms of athletic performance. People with anorexia athletica also tend to be obsessed less with body weight than with maintaining an abnormally low percentage of body fat. This disorder is common among elite athletes.

Muscle dysmorphic disorder is the opposite of anorexia nervosa. Where the anorectic thinks she is always too fat, the person with muscle dysmorphic

## KEY TERMS

**Fast**—a period of at least 24 hours in which a person eats nothing and drinks only water.

**Type 2 diabetes**—sometime called adult-onset diabetes, this disease prevents the body from properly using glucose (sugar).

disorder believes he is always too small. This believe is maintained even when the person is clearly well muscled. Abnormal eating patterns are less of a problem in people with muscle dysmorphic disorder than damage from compulsive exercising (even when injured) and the abuse of muscle-building drugs such as anabolic steroids.

Orthorexia nervosa is a term coined by Steven Bratman, a Colorado physician, to describe "a pathological fixation on eating 'proper,' 'pure,' or 'superior' foods." People with orthorexia allow their fixation with eating the correct amount of properly prepared healthy foods at the correct time of day to take over their lives. This obsession interferes with relationships and daily activities. For example, they may be unwilling to eat at restaurants or friends' homes because the food is impure or improperly prepared. The limitations they put on what they will eat can cause serious vitamin and mineral imbalances. Orthorectics are judgmental about what other people eat to the point where it interferes with personal relationships. They justify their fixation by claiming that their way of eating is healthy. Some experts believe orthorexia may be a variation of obsessive-compulsive disorder.

Rumination syndrome occurs when an individual, either voluntarily or involuntarily, regurgitates food almost immediately after swallowing it, chews it, and then either swallows it or spits it out. Regurgitation syndrome is the human equivalent of a cow chewing its cud. The behavior often lasts up to two hours after eating. It must continue for at least one month to be considered a disorder. Occasionally the behavior simply stops on its own, but it can last for years.

Pica is eating of non-food substances by people developmentally past the stage where this is normal (usually around age 2). Earth and clay are the most common non-foods eaten, although people have been known to eat hair, feces, lead, laundry starch chalk, burnt matches, cigarette butts, light bulbs, and other equally bizarre non-foods. This disorder has been known to the medical community for years, and in some cultures (mainly tribes living in equatorial Africa) is considered normal. Pica is most common among people with mental retardation and developmental delays. It only rises to the level of a disorder when health complications require medical treatment.

Prader-Willi syndrome is a genetic defect that spontaneously arises in chromosome 15. It causes low muscle tone, short stature, incomplete sexual development, mental retardation, and an uncontrollable urge to eat. People with Prader-Willi syndrome never feel full. The only way to stop them from eating themselves to death is to keep them in environments where food is locked up and not available. Prader-Willi syndrome is a rare disease, and although it is caused by a genetic defect, tends not to run in families, but rather is an accident of development. Only 12,000–15,000 people in the United States have Prader-Willi syndrome.

### Demographics

In general, more women have eating disorders than men. About 90% of people with anorexia and bulimia nervosa are female. Almost as many men as women develop binge-eating disorder. Anorexia athletica, muscle dysmorphic disorder, and orthorexia nervosa tend to be more common in men. Rumination, pica, and Prader-Willi syndrome affect men and women equally.

Anorexia nervosa begins primarily between the ages of 14 and 18 and affects mainly white girls. Bulimia usually develops slightly later in the late teens and early twenties. Binge-eating disorder is a problem of middle age and affects blacks and whites equally. Prader-Willi syndrome begins in the toddler years. Not enough is known about the other disorders to determine when they are most likely to develop or which races or ethnic groups are most likely to be at risk.

Depression, low self-worth, and anxiety disorders are all common among people with eating disorders. Some disorders have obsessive-compulsive elements. The association between these psychiatric disorders and eating disorders is strong, but the cause and effect relationship is still unclear.

### Causes and symptoms

Eating disorders have multiple causes. There appears to be a genetic predisposition in some people toward developing an eating disorder. Biochemistry also seems to play a role. Neurotransmitters in the brain, such as serotonin, play a role in regulating appetite. Abnormalities in the amount of some neurotransmitters are thought to play a role in anorexia, bulimia, and binge-eating

disorder. Other disorders have not been studied enough to draw any conclusions. Interestingly, serotonin also helps regulate mood, and low serotonin levels are thought to play a role in causing depression.

Personality type can also put people at risk for developing an eating disorder. Low self-worth is common among all people with eating disorders. Binge eaters and people with bulimia tend to have problems with impulse control and anger management. A tendency toward obsessive-compulsive behavior and black-or-white, all-or-nothing thinking also put people at higher risk.

Social and environmental factors also affect the development and maintenance of eating disorders and may trigger relapses during recovery. Relationship conflict, a disordered, unstructured home life, job or school stress, transition events such as moving or starting a new job all seems to act as triggers for some people to begin disordered eating behaviors. Dieting (nutritional and social stress) is the most common trigger of all. The United States in the early twenty-first century is a culture obsessed with thinness. The media constantly send the message through words and images that being not just thin, but ultra-thin, is fashionable and desirable. Magazines aimed mostly at women devote thousands of words every month to diet and exercise advice that creates a sense of dissatisfaction, unrealistic goals, and a distorted **body image**.

## Diagnosis

Diagnosis involves four components: a health history, a physical examination, laboratory tests, and a mental status evaluation. Health histories tend to be unreliable, because many people with eating disorders lie about their eating behavior, purging habits, and medication abuse. Based on the health history and physical examination, the physician will order appropriate laboratory tests. Mental status can be evaluated using several different scales. The goal is to get an accurate assessment of the individuals's physical condition and her thinking in relationship to self-worth, body image, and food.

## Treatment

Treatment depends on the degree to which the individual's health is impaired. People with anorexia or bulimia may need to be hospitalized or attend structured day programs for an extended period. Some people are helped with antidepressant medication, but the mainstay of treatment is psychotherapy. An appropriate therapy is selected based on the type of eating disorder and the individual's psychological profile. Some of the common therapies used in treating eating disorders include:

- Cognitive behavior therapy (CBT) is designed to confront and then change the individual's thoughts and feelings about his or her body and behaviors toward food, but it does not address why those thoughts or feelings exist. Strategies to maintain self-control may be explored. This therapy is relatively short-term. CBT is often the therapy of choice for people with eating disorders.
- Psychodynamic therapy, also called psychoanalytic therapy, attempts to help the individual gain insight into the cause of the emotions that trigger their dysfunctional behavior. This therapy tends to be more long term than CBT.
- Interpersonal therapy is short-term therapy that helps the individual identify specific issues and problems in relationships. The individual may be asked to look back at his or her family history to try to recognize problem areas or stresses and work toward resolving them.
- Dialectical behavior therapy consists of structured private and group sessions in which the therapist and patient(s) work at reducing behaviors that interfere with quality of life, finding alternate solutions to current problem situations, and learning to regulate emotions.
- Family and couples therapy is helpful in dealing with conflict or disorder that may be a factor in perpetuating the eating disorder. Family therapy is especially useful in helping parents who are anorectics avoid passing on their attitudes and behaviors on to their children.

## Nutrition/Dietetic concerns

Eating disorders result in abnormal nutrition that can have life-threatening consequences. A nutritionist or dietitian who can provide nutritional counseling and healthy meal planning is an essential part of the treatment team for any eating disorder. However, nutritional counseling alone will not resolve an eating disorder.

## Prognosis

Recovery from eating disorders can be along, difficult process interrupted by relapses. About half of all anorectics recover. Up to 20% die of complications of the disorder. The recovery rate for people with bulimia is slightly higher. Binge eaters experience many relapses and may have trouble controlling their weight even if they stop bingeing. Not enough is known about the

other eating disorders to determine recovery rates. All eating disorders have serious social and emotional consequences. All except rumination disorder have serious health consequences. The sooner a person with an eating disorder gets professional help, the better the chance of recovery.

## Prevention

Prevention involves both preventing and relieving stresses and enlisting professional help as soon as abnormal eating patterns develop. Some things that may help prevent an eating disorder from developing are listed below:

- Parent should not obsess about their weight, appearance, and diet in front of their children.
- Parents should not put their child on a diet unless instructed to by a pediatrician.
- Do not tease people about their body shapes or compare them to others.
- Make it clear that family members are loved and accepted as they are.
- Try to eat meals together as a family whenever possible; avoid eating alone.
- Avoid using food for comfort in times of stress.
- Monitoring negative self-talk; practice positive self-talk
- Spend time doing something enjoyable every day
- Stay busy, but not overly busy; get enough sleep every night
- Become aware of the situations that are personal triggers for abnormal eating behaviors and look for ways to avoid or defuse them.
- Do not go on extreme diets.
- Be alert to signs of low self-worth, anxiety, depression, and drug or alcohol abuse and seek help as soon as these signs appear.

# Eating for Life

## Definition

Eating for Life refers to a diet and nutrition plan that recommends eating six small, low-fat meals daily, popularized in the 2003 book *Eating for Life*, written by Bill Phillips.

A person who follows the Eating for Life program consumes about 40–50% **protein**, 40–50% **carbohydrates**, and small amounts of fat. Meals should be consumed about two to three hours apart. The program can be used as a way to lose or maintain weight or to supplement a fitness or resistance training regimen.

## Origins

The Eating for Life plan was developed by Bill Phillips, a bodybuilder, former editor-in-chief of *Muscle Media* magazine, and former chief executive officer of EAS, a performance supplement company owned by Abbott Laboratories.

Prior to publishing Eating for Life in 2003, Phillips authored his first book, *Body for Life: 12 Weeks to Mental and Physical Strength*, a *New York Times* bestseller.

The Body-for-Life program began in the mid-1990s when Phillips first challenged dieters to make the best body transformation during a 12-week period, using the exercise and nutrition principles outlined in his now-defunct fitness magazine, *Muscle Media*. The first year of the challenge, Phillips offered his Lamborghini Diablo to the contestant who made the most radical transformation within 3 months. As of 2007, individuals and couples still compete for cash prizes and free exercise equipment in the annual Body-for-Life Challenge.

## Description

Phillips, the author of *Eating for Life*, calls his program the "anti-diet," claiming that enjoying food and eating often are the keys to healthy weight loss and maintenance. Instead of focusing on the deprivation that typical accompanies weight-loss plan, Eating for Life claims to help its followers make wise eating choices that are sustainable over a long period of time. Phillips maintains that food is not the enemy, but rather, it's an essential part of an overall lifestyle choice.

The first 10 chapters of *Eating for Life* that comprise Part I describe the extent of the overweight and **obesity** epidemic in the United States, identify common obstacles to health and fitness, such as easy access to fast food and restriction associated with traditional dieting, deconstruct popular dieting myths, and prepare the reader to begin using the Eating for Life nutrition plan and recipes.

The second part of the 405-page book includes photos and instructions for cooking the 150 recipes included in *Eating for Life*. The book includes recipes for dinner entrees, desserts, breakfasts, lunches, snacks, and nutrition shakes, as well as sample meal plans and a grocery guide. Sample recipes are also available on Phillips' Eating for Life website.

The final portion of the book includes motivational success stories of people who have lost weight with the Body for Life/Eating for Life diet and exercise plan, nutrition definitions, and tips for cooking healthy.

### KEY TERMS

**Aerobic exercise**—Moderate intensity exercise, done over a long duration, that uses oxygen. Aerobic exercise strengthens the cardiovascular system and lungs.

**Bodybuilding**—Developing muscle size and tone, usually for competitive exhibition.

**Carbohydrate**—A source of energy in the diet containing 4 calories per gram, often founds in foods such as breads, cereals, fruits, vegetables, and milk and dairy products. There are two kinds of carbohydrates: simple and complex.

**Cardiovascular**—Involving the heart and blood vessels.

**Fat**— A major source of energy in the diet. All food fats have 9 calories per gram. Fat is found in oils, nuts, seeds, avocadoes, meats, and high-fat dairy products, as well as in packaged, processed foods.

**Protein**—A nutrient that helps build many parts of the body, including muscle and bone. Protein provides 4 calories per gram. It is found in foods like meat, fish, poultry, eggs, dairy products, beans, nuts, and tofu.

**Resistance training**—Also called strength or weight training, this type of exercise increases muscle strength by working the muscles against a weight or force. Free weights, weight machines, resistance bands, or a person's body weight can be used in resistance training.

Six days a week, dieters are encouraged to eat six small meals consisting of one serving of protein and one serving of carbohydrate. Meals should be consumed about two to three hours apart. The benefit of this practice, according to Phillips, is that it keeps the **metabolism** elevated and energy levels stable.

Two of the daily meals should include vegetable servings, and 1 tablespoon of healthy fat is encouraged daily. Alternatively, three servings of fatty fish such as salmon could be consumed weekly to meet the healthy fat requirement.

On the seventh day, Eating for Life encourages a day of less restrained eating, in which dieters eat reasonable portions of unauthorized foods they've been craving throughout the week. Eating for Life does not prohibit particular foods, but encourages readers to save them for the "free day" and savor the pleasure they provide. This practice will help readers sustain healthy eating choices the rest of the time, Phillips maintains.

To aid in weight loss, Phillips says readers should choose from 82 "authorized foods," divided into five food categories, including proteins, vegetarian proteins, carbohydrates, vegetables, and **fats**. Recommended protein foods include lean red meat (including beef, buffalo, and venison), poultry (chicken and turkey), fish and shellfish, egg whites and egg substitutes, or low-fat cottage cheese; recommended carbohydrate sources include fruit, sweet potatoes, brown rice, oatmeal, barley, and whole-grain breads.

A sample daily menu might include:

- breakfast: zesty breakfast burrito
- midmorning: chocolate-mint nutrition shake
- lunch: grilled chicken soup
- midafternoon: strawberry-frost nutrition shake
- dinner: grilled salmon and potato
- late evening: cinnamon roll supreme nutrition shake

As part of the Eating for Life method, it is suggested that dieters plan their meals and grocery lists in advance and record their protein and carbohydrate servings daily. Phillips also suggests that dieters drink 10 cups of **water** each day.

Eating for Life does not prohibit alcohol or **caffeine** consumption, but suggests limiting both.

Eating for Life also advocates portion control as an essential practice for weight loss. For example, a protein serving is about the size of a person's palm, whereas a carbohydrate serving should be about the size of the person's clenched fist. Counting calories or points or measuring food portions with a scale do not play a role in the Eating for Life plan.

Eating for Life also recommends readers participate in weight or resistance training three days a week and cardiovascular exercise three times a week. Doing so will help dieters build and maintain muscle mass, which is crucial for the body's ability to burn fat, Phillips says.

## Function

Eating for Life is a program adopted by people who wish to lose weight or who are seeking a nutrition program to support their bodybuilding or resistance training efforts.

## Benefits

Because of the six-day-a-week recommended exercise plan described in Body for Life, Eating for Life may work well for people who are serious about weight training for health and fitness. This plan may also benefit people who desire regimented eating and exercise programs as they attempt to lose weight.

The six small meals a day and regular exercise recommended in the Eating for Life plan are sound strategies for weight loss. However, the strict nature of the diet (readers are admonished to adhere to a list of authorized foods) may make it difficult for a person to maintain any weight loss long-term.

## Precautions

Although *Eating for Life* does not formally require their use, supplements including meal replacement shakes and protein bars are frequently recommended by Phillips. Dieters are encouraged to consume up to three meal replacement products or shakes daily, such as the Myoplex brand marketed by EAS, the performance supplement company started by Phillips. These supplements can be difficult to find in conventional grocery outlets as well as expensive. For example, 20 servings of the Myoplex protein powder often recommended in Eating for Life and Body for Life starts at $59.95 on the EAS website (www.eas.com). Myoplex and other supplements recommended by Phillips are also available at health food and supplement chain stores, such as GNC, or online.

Eating for Life does not exclude vegetarian eaters, however, Phillips admits it may be difficult for vegans (people who do not eat any animal products, including eggs or dairy products) to find enough varied protein sources to eat according to the Eating for Life plan.

Most of the recipes in the *Eating for Life* book include some type of meat, such as chicken, beef, turkey, or fish.

In addition, the weightlifting program advocated in *Body for Life* and *Eating for Life* may be daunting for the inexperienced beginner. With little regard for a person's cardiovascular fitness level, weightlifting experience, or propensity for injuries, Phillips advocates readers to begin exercising six days a week, even if they have been couch potatoes in the past. This "all-or-nothing" approach may be difficult for people to achieve or maintain over the suggested 12 weeks required for a Body for Life challenge, and someone who experiences an injury that prevents exercise may find it difficult to maintain their dieting motivation.

## Risks

The protein intake suggested by Eating for Life, although not technically dangerous for most individuals, may be too much for the body to use on a daily basis. According to sports nutritionists, extra protein is broken down, the excess nitrogen is simply excreted in the urine, the carbon skeleton is used/stored as energy. For some people, however, the amount of daily protein recommended by a plan such as Eating for Life may be a problem. People with preexisting kidney or liver disease, such as cirrhosis or fatty liver, should not attempt a popular diet plan such as Eating for Life without checking with their health care providers first.

In addition, dieters may need to be conscious of consuming enough fruits and vegetables while Eating for Life. Phillips encourages dieters to eat only two servings of vegetables daily, however, as of 2007 the U.S. Department of Agriculture (USDA) urges people eating about 2,000 calories a day to consume at least 4.5 cups of fruits and vegetables with their daily meals. Dieters may find it difficult to eat enough fruit and vegetable servings to satisfy the USDA recommendations while on the Eating for Life nutrition plan, especially since counts fruit servings as carbohydrates on the plan, thereby limiting them to one per meal.

## Research and general acceptance

Although there is no scientific data to point to Eating for Life's effectiveness, Phillips provides anecdotal stories and dramatic before-and-after photos of people who have successfully lost weight using Body for Life and the accompanying Eating for Life plan.

Some nutritionists have also suggested that although the small meals and suggestions to exercise are important components of weight loss, in general the diet may be overly restrictive, making it difficult for dieters to maintain any losses long-term.

### QUESTIONS TO ASK YOUR DOCTOR

- What are the potential benefits for a person of my age, sex, and lifestyle in adopting the Eating for Life plan?
- What are the potential health risks, if any, for me as an individual?
- Are there any health concerns associated with the protein intake recommended in Eating for Life?
- Is it advisable for me to take the meal replacements or supplements recommended in Eating for Life?
- Do I need to worry about vitamin, mineral, or nutrient deficiencies if I eat according to the Eating for Life plan?
- Do I need to take precautions before starting the strength and cardiovascular conditioning recommended by Eating for Life?
- Have you had any patients who have used the Body for Life or Eating for Life plan? What were their results and did they maintain weight loss over the long term?

# Echinacea

## Definition

Echinacea is a perennial plant native to North America that is farmed in both the United States and Europe for use in **dietary supplements**. Echinacea is a genus in the aster family containing nine plant species. Three species, *Echinacea angustifolia*, *E. purpurea*, and *E. pallida* are used in complementary and alternative medicine in the United States and Europe.

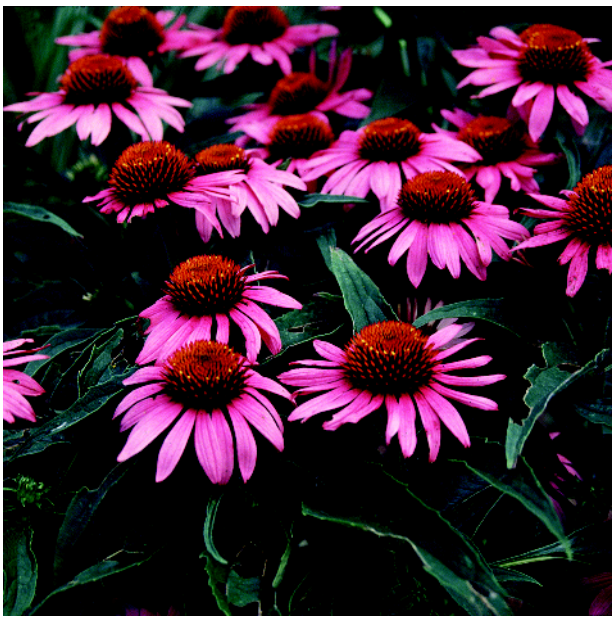
Echinacea species are commonly called coneflowers. The common name for *E. purpurea* is purple coneflower. *E. pallida* is known as pale purple coneflower and *E. angustifolia* as narrow-leaf coneflower. Echinacea is sold as an herbal dietary supplement under a variety of trade names. It is also a common ingredient in many supplements containing multiple ingredients.

## Purpose

Echinacea has been used as a medicinal herb in North America for more than 400 years. Native Americans used echinacea to treat wounds, snakebites, infections, and as a general booster of health. In the 1930s the herb was very popular in both the United States and Europe, as it was thought to fight infection by boosting the immune system. It was used to treat conditions as diverse as colds, influenza, eczema, many different types of infections, malaria, syphilis, **cancer**, and diphtheria. As antibiotics became more widely available after World War II, echinacea's popularity declined, only to rise again in the 1980s. It is one of the most frequently used herbal remedies in the North America and Europe. Echinacea is especially popular in Germany, where many practitioners of conventional medicine accept it as a safe and effective treatment for cold symptoms. In 2003, echinacea was one of the top three selling herbs in the United States, and in 2006 it was estimated to account for 10% of all dietary supplement sales in the United States.

## Description

Echinacea is a perennial herb with slender, rough leaves arranged opposite each other on a stem that grows to a height of about 18 in (45 cm) and produces a single large purplish flower. Both the above ground parts of the plant and the roots are used in dietary supplements. Fresh leaves are pressed and the resulting juice is used in extracts or tinctures, or it is combined with other ingredients to make a paste that can be applied to the skin. Dried leaves and roots are powered and made into tea or capsules. An injectable form of echinacea is available in Europe, but not in the United States. The active ingredients of echinacea have not been adequately identified. As a result, it is difficult to compare the strength and potency of different forms of the herb or the same formulation made by different manufacturers.



**Echinacea flowers, also called purple coneflowers.** *(Photo Researchers, Inc. Reproduced by permission.)*

### *Safety and effectiveness of Echinacea*

Although echinacea has been used for hundreds of years, only recently have researchers started to examine its effectiveness in large, independent, rigorously controlled studies. Many early studies done in Germany suggested that the herb was effective in treating certain conditions. In the United States, the National Center for Complementary and Alternative Medicine (NCCAM), a government organization within the National Institutes of Health, is currently conducting studies on the safety and effectiveness of echinacea in treating a variety of conditions.

In the United States, the Food and Drug Administration (FDA) regulates dietary supplements such as echinacea using the same laws that regulate food, rather than the laws that regulate prescription and over-the-counter medications. Unlike conventional drugs, dietary supplements are not required to undergo rigorous testing to show that they are safe and effective before they are marketed to the public. One consequence of this is that there are many fewer

## KEY TERMS

**Alternative medicine**—A system of healing that rejects conventional, pharmaceutical-based medicine and replaces it with the use of dietary supplements and therapies such as herbs, vitamins, minerals, massage, and cleansing diets. Alternative medicine includes well-established treatment systems such as homeopathy, traditional Chinese medicine, and Ayurvedic medicine, as well as more-recent, fad-driven treatments.

**Complementary medicine**—Includes many of the same treatments used in alternative medicine, but uses them to supplement conventional drug and therapy treatments, rather than to replace conventional medicine.

**Conventional medicine**—Mainstream or Western pharmaceutical-based medicine practiced by medical doctors, doctors of osteopathy, and other licensed health care professionals.

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Perennial herb**—A plant that lives for several years with new growth appearing each year.

**Placebo**—A pill or liquid given during the study of a drug or dietary supplement that contains no medication or active ingredient. Usually study participants do not know if they are receiving a pill containing the drug or an identical-appearing placebo.

studies of dietary supplements, and some of those studies are sponsored by the manufacturers who have an economic investment in positive outcomes. Too often, studies of dietary supplements are small, poorly designed, poorly controlled, or incompletely reported, making it is difficult to draw hard conclusions about the effectiveness and safety of the product.

The most common use of echinacea in the United States and Europe is to prevent or shorten and reduce the severity of symptoms of the common cold, including sneezing, runny, nose, cough, and fever. Natural Standard, an independent organization that evaluates studies, scientific evidence, and expert opinion on complementary and alternative treatments and makes impartial judgments concerning their safety and effectiveness has found that the evidence of effectiveness of echinacea in treating cold symptoms is mixed. Some studies have shown that individuals who take echinacea during cold season are less likely to catch a cold, but more have found that echinacea has no effect on whether an individual catches a cold. On the other hand, more than half of a substantial number of well-designed European studies found that people who take echinacea at the first sign of a cold feel better sooner than those who take a placebo or who take nothing. These results have been contradicted by several large, well-designed American studies, including one in 2005 of children ages 2–11 that found on average echinacea did not reduce the length of time the children showed cold symptoms. Two studies sponsored by NCCAM also found echinacea did not shorten the symptoms of colds or influenza or prevent colds.

For years, echinacea has been taken to improve general health and to treat a variety of infections because it is thought to boost the immune system. Laboratory analyses of the ingredients in echinacea and some animal studies have suggested that echinacea does stimulate immune system cells. However, this result has not been confirmed in humans. Research continues on this use of echinacea.

Claims have also been made that individuals with AIDS, cancer, and genital herpes can benefit from taking echinacea. Although there is some theoretical basis for these claims, there is no clear evidence that echinacea has an effect on these conditions in humans.

Despite mixed evidence about the effectiveness of echinacea, the herb generally appears to be safe when taken by adults in moderate amounts. There is no standardization of the amount of active ingredient in products containing echinacea. Guidelines of normal doses for a 150 lb (70 kg) adult taken three times a day are:

- 1–2 g dried leaves or root brewed into tea
- 2–3 mL tincture
- 200 mg powdered extract

Lower doses of echinacea for children, based on the weight of the child, are generally thought to be safe, although in the cold study mentioned above, children showed an increased risk of developing a rash. One study of pregnant women using echinacea found that moderate use of the herb during the first three months of pregnancy did not increase the likelihood of the baby being born with major birth defects. The safety of echinacea use in **breastfeeding** women has not been adequately studied.

## Precautions

Individuals interested in taking echinacea should consult their health care provider and other reputable sources of information before starting the herb. Pregnant or breastfeeding women should be especially careful to discuss the use of echinacea and all other drugs and supplements with their health care provider. One animal study indicated that the increase in white blood cells normally seen during pregnancy was reduced or eliminated in women who took echinacea during pregnancy. This suggests that women who should avoid the drug during pregnancy. A separate study designed to evaluate the safety of echinacea during pregnancy failed to show any harm to either the mother or the fetus. In addition, care should be taken in giving children echinacea. Few studies have been done specifically on children.

As with any medication, more is not necessarily better, and the words "natural" or "organic" on the label do not mean the product is safe. Overdose can cause serious side effects. In the event of side effects, echinacea should be stopped immediately and the side effects reported to a health care professional. People with autoimmune diseases (e.g., AIDS, multiple sclerosis) are often counseled to avoid echinacea, because of theoretical, but unproven, negative effects on the immune system.

## Interactions

Echinacea may interact with both conventional drugs and other herbs or dietary supplements, but few rigorous studies have been done on potential interactions. Individuals should tell their health care provider about all the conventional drugs and dietary supplements they are taking before beginning any new drug or supplement.

Since echinacea may stimulate the immune system, it is recommended that individuals who are taking immune system suppressant drugs following cancer treatment or organ transplant avoid echinacea. This interaction has not been verified experimentally, and some trials suggest that echinacea can actually benefit cancer patients.

Echinacea may also interact with econazole, an antifungal drug. Individuals who take echinacea while taking econazole to treat fungal infections appear more likely to have reoccurrence of the fungal infection.

## Complications

People who are allergic to ragweed, chrysanthemums, marigolds, daisies, and related plants have a greater chance of being allergic to echinacea. Allergic reactions have on rare occasions been reported to be severe and cause breathing difficulties, especially in people with asthma. Much more common are allergic reactions consisting of a rash, sneezing, or runny nose.

## Parental concerns

Parents should be aware that the safe dose of many herbal supplements has not been established for children. Accidental overdose may occur if children are give adult herbal supplements.

# eDiets

## Definition

The eDiets.com website provides information on several diet programs, fitness regimens, as well as support from health professionals. The term e-diets may be used to describe any diet program found on the internet.

## Origins

American internet entrepreneur David R. Humble started eDiets.com in 1996. Unable to find investors for the site, Humble invested $500,000 of his own money to begin the company. Humble discovered a niche in the fee-based online dieting community. The eDiets website uses a unique software program to provide customized diet and fitness plans for individuals. From a small office in Deerfield Beach, FL, eDiets.com has grown into an international business with websites in Germany, Spain, and Portugal. Over two million members have joined eDiets.com since its inception. The company also operates eFitness.com and publishes *glee* Magazine*, a leading internet magazine focusing on lifestyle issues. In spring 2004 and 2005, eDiets.com was named "Best of the Web" for diet and nutrition by *Forbes* and was selected as "Editors' Choice" by *PC Magazine*.

## Description

The eDiets.com website asks prospective members to enter information about their physical description (height, weight, gender, body shape, etc.), activity level, and eating habits. This data is used to generate a customized weight loss program based on the 24 specialized options available. Program options include the **Mayo Clinic Plan**, Atkins, the Glycemic Impact Diet, the New **Mediterranean Diet**, as well as eDiets own program. **Trim Kids** is available for children and teens. Members can indicate special dietary restrictions, such as lactose or wheat intolerance, low-sodium, or vegetarian, which will be accounted for in the meal plans. The type of diet plan selected can be changed or modified at any time.

Pricing for the basic eDiets program is approximately four dollars a day. This typically provides the member with customized weekly meal plans complete with grocery shopping lists, fitness program based on the member's profile, access to community forums, newsletters, and articles on a variety of mind and body issues. Features that require an additional monthly fee include the recipe club, online chat groups and meetings, and access to experts for advice or consultation.

New members are paired with an existing member as part of the eDiets mentor program. The mentor offers support and assistance with the program. In addition, members can choose to participate in online meetings, chat rooms, take advantage of 24-hour support, or find emotional support through interactive tools. These resources aim to provide community and accountability that can help individuals maintain their weight loss program.

An online shopping section features fitness equipment, books, videos, nutritional supplements, and other health related products. To make the program even more convenient, a meal delivery plan is available allowing members to have their meals prepared and delivered to their door for approximately $15-25 per day.

## Function

The premise of eDiets.com is to provide an informative and supportive environment available to members at their convenience. This type of weight loss program appeals to individuals who are uncomfortable with face-to-face group programs or who cannot attend local support sessions. The flexibility and customization of meal and fitness plans is another highlight.

The eDiets.com proprietary software provides individuals with information on their **body mass index** (BMI) and offers diet plans based on the data entered. From the data provided in the member's profile, the program generates a meal guide that targets the member's optimal calorie intake to lose weight. A shopping list and recipe recommendations simplify food preparation. Additionally, members can switch from one weight-loss program to another at any time (such as from the New Mediterranean Diet to Atkins) while maintaining the other features and programs associated with their eDiets membership.

## Benefits

An eDiets membership offers a wide array of support methods, meal preferences, fitness programs, and other features that help individuals stay motivated to reach their weight loss goals. The low monthly membership fee is attractive, typically half the cost of joining a local program such as **Weight Watchers**.

The option of adjusting the meal plan to accommodate eating habits is a great benefit. Menus can include convenience foods (including fast-food), self-prepared meals, or both. They can also be modified to account for special diets or dietary restrictions. A prepared shopping list that corresponds to the menu selections adds to the ease.

An important advantage is the fitness program component. A customized workout is created based on an individual's lifestyle, age, and other personal information provided. The option to work one-on-one with a trainer or have more personalized fitness plans developed are available for an additional monthly fee.

Member support is an significant part of eDiets. The website offers six different support areas:

- Support Groups—Over 120 specialized groups cover age groups, language spoken, women's issues, relationships, type of diet, etc.
- Mentor Program—New members are paired with existing members for 30 days of one-on-one support and guidance.
- Chat Rooms—24-hour communication with other members as well as online meetings are available, an additional monthly fee is usually required.
- Experts—A panel of experts moderate online support groups and meetings, provide feedback to individual members, and write articles for the eDiets newsletter.
- Circle of Winners—Small support groups created by members to find other members with similar needs or interests.
- Success Stories—Members share their success with eDiets.com to offer inspiration to other members.

## Precautions

As with any weight loss program, it is important to talk with a physician about the intended changes. A disclaimer on eDiets.com states that the advice and recommendations on the website are not intended to be medical advice or take the place of a physician's advice. Recommendations for diet plans, optimal weight loss, and exercise programs on the website are calculated using a proprietary software program. They are based on data provided by the individual and, therefore, are only as accurate as the information entered. It is imperative to be honest when entering the requested data.

If an individual already has an ideal weight, the program indicates additional weight loss is not necessary. However, the individual may choose to join in order to improve their eating habits and/or fitness level.

In general, members should use the eDiets website with the same caution as other websites. Articles and information presented should be reviewed for timeliness and reliability. Members must be careful when providing personal identification information, especially in e-mail or chat rooms with other members. Members who falsify their identity are a possibility.

## Risks

Risks related to using eDiets.com are minimal. When registering for membership, individuals should carefully review the terms and conditions. Dissatisfied members complain about poor customer service and difficulty canceling membership. They also cite frustration with identifying plan pricing and fees for several features on the website.

Before beginning any of the diet plans or exercise programs individuals should talk with a physician to identify risks specific to the type of diet or exercise selected.

## Research and general acceptance

The University of Vermont Department of Nutrition and Food Sciences has performed several studies on the effectiveness of commercial online weight loss programs versus more traditional weight loss programs. Between February 2003 and March 2005 they

## QUESTIONS TO ASK YOUR DOCTOR

- What is an ideal target weight or body mass index?
- Which meal plan best accommodates special diets or dietary restrictions?
- What type of exercise should be avoided?
- How often should follow-up care be scheduled?

studied the effectiveness of a structured internet behavioral weight loss program (VTrim) compared to a commercial internet weight loss program (eDiets.com). The results found the structured behavioral weight loss program, led by a therapist, to be significantly more effective than the self-led commercial weight loss program. VTrim participants lost twice as much weight throughout the study and were nearly twice as likely to have kept it off after twelve months. While the internet is a practical medium for commercial weight loss programs, their impact would be more noticeable if they integrated more structure such as that used in VTrim.

Another study at the University of Vermont involved participants using an internet based behavioral weight loss program for one year. All participants used the same program, but half supplemented with face-to-face meetings once a month. The study concluded that participants lost approximately the same amount of weight whether or not they attended meetings in person.

The University of Pennsylvania School of Medicine began a year long controlled study in 2001 comparing eDiets.com to a weight loss manual to gage overall effectiveness for modifying an individuals lifestyle. Forty-seven female participants followed either eDiets.com or the LEARN Program for Weight Control. This small study concluded the manual had a greater impact on weight loss than eDiets since women following the manual lost approximately four percent of their body weight as compared to only one percent loss in women who used eDiets.com.

Research on the effectiveness of online diet programs remains limited. Studies at major universities demonstrate that websites such as eDiets.com can be effective tools for weight loss, but are usually most successful when coupled with personalized feedback.

# Electrolytes

## Definition

Electrolytes are ions that form when salts dissolve in **water** or fluids. These ions have an electric charge. Positively charged ions are called cations. Negatively charged ions are called anions. Electrolytes are not evenly distributed within the body, and their uneven distribution allows many important metabolic reactions to occur. **Sodium** ($Na^+$), Potassium ($K^+$), **Calcium** (Ca2+), **Magnesium** (Mg2+), chloride ($Cl^-$), phosphate ($HPO_4$2-), bicarbonate ($HCO_3$-), and Sulfate ($SO_4$-) are important electrolytes in humans.

## Purpose

Electrolytes play a critical role in almost every metabolic reaction in the body. For example, they:

- Help control water balance and fluid distribution in the body
- Create an electrical gradient across cell membranes that is necessary for muscle contraction and nerve transmission

## KEY TERMS

**Diuretic**—A substance that removes water from the body by increasing urine production.

**Glucose**—A simple sugar that results from the breakdown of carbohydrates. Glucose circulates in the blood and is the main source of energy for the body.

**Homeostasis**—The complex set of regulatory mechanisms that works to keep the body at optimal physiological and chemical stability in order for cellular reactions to occur.

**Hormone**—A chemical messenger produced by one type of cell and travels through the bloodstream to change the metabolism of a different type of cell.

**Serum**—The clear fluid part of the blood that remains after clotting. Serum contains no blood cells or clotting proteins, but does contain electrolytes.

- Regulate the acidity (pH) of the blood
- Help regulate the level of oxygen in the blood
- Are involved in moving nutrients into cells and waste products out of cells

## Description

Water is essential to life. **Dehydration** occurs when more water is lost from the body than is replaced. A loss of 20% of the body's water can be fatal. Water balance and electrolyte concentrations are closely intertwined. Dehydration is a major cause of electrolyte imbalances.

Electrolytes, proteins, nutrients, waste products, and gasses are dissolved in fluid in the body. This fluid is not distributed evenly. About two-thirds of it is found inside cells (intracellular fluid). The rest is found in the spaces between cells (interstitial fluid), in the circulatory system, and in small amounts in other places such as the stomach. Changes in the concentration of electrolytes results in changes to the distribution of water throughout the body as water moves into or out of cells.

The components of body fluid—electrolytes, proteins, and so forth—are not evenly distributed either. Different types of cells have membranes that allow some electrolytes (and other components of the fluid) to pass across them while blocking others. This difference in the distribution of electrolytes (and thus electric charges) on either side of cell membranes makes it possible for many metabolic reactions to take place.

Water passes easily across cell membranes. When fluid with two different concentrations of electrolytes is separated by a cell membrane, there is pressure (called osmotic pressure) for water to flow across the membrane from fluid that contains fewer electrolytes (less concentrated) into fluid that contains more electrolytes (more concentrated). The cell uses energy to resist osmotic pressure and maintain different concentrations of electrolytes on either side of the membrane because even small changes in the concentrations and distribution of electrolytes can result in large movements of water in and out of cells. Maintaining this difference, or gradient, across cell membranes is a major part of the complex regulatory events called homeostasis that keep conditions within the body stable within very narrow limits. When there is an imbalance in electrolytes many systems in the body are affected and serious, even fatal, health problems can result.

### *Causes of electrolyte imbalances*

An electrolyte imbalance occurs when the concentration of a specific electrolyte is either too high or too low. The concentration of electrolytes is strongly affected by the amount of fluid in the body. Fluid balance is largely controlled by hormones that act on the kidneys and regulate how much urine the kidneys produce. The average male adult loses about 1.5-2.5 L of water daily through urine production, sweating, breathing out water vapor, and bowel movements depending on exercise levels and environmental temperature. The United States Institute of Medicine recommends that adult men drink a minimum of 3 L of liquids a day, and that women drink a minimum of 2.2 L to replace lost water.

Dehydration is a major cause of electrolyte imbalance. It occurs whenever water is lost from the body and not replaced fairly quickly. When fluids are lost, electrolytes in those fluids are lost too, increasing the risk of electrolyte imbalance. Dehydration can be caused in many ways. These include:

- Heavy exercise, especially in hot weather. Sodium and water are both lost through the skin with heavy sweating.
- Limited fluid intake. This is a particular problem with the elderly, especially those who are unable to walk or are bedridden.
- Severe vomiting and diarrhea. Large amounts of water and many electrolytes that would normally be absorbed in the intestines are lost with diarrhea

and vomiting. Small children with diarrhea can become seriously dehydrated in less than one day. Infants can become dehydrated within hours.

- High fever. Increased water loss through the skin due to fever is especially serious in infants and young children.
- Severe burns. More water is lost from the surface of the body when the skin is not there to prevent evaporation, and damaged cells release their electrolytes into interstitial fluid, upsetting the electrolyte balance.

Electrolyte imbalances can have other causes unrelated to dehydration. These include:

- Kidney damage or kidney failure. This is a common cause of electrolyte imbalances in the elderly and can be fatal.
- Anorexia nervosa (self starvation) or bulimia nervosa (binge and purge eating).
- Excessive intake of water. Called water intoxication, this can result in swelling in the brain. In 2007, a Sacramento, California, woman died when she participated in a radio station contest that involved drinking large amounts of water in a short period of time.
- Some drugs, herbal supplements, and chemotherapy. Some medications/treatments selectively increase the excretion of certain electrolytes, cause the body to retain excess water, or stimulate the kidneys to produce excess urine.
- Hormonal imbalances in the production of hormones that regulate the kidneys. This causes too little or too much urine to be produced.
- Cancer. Some tumors produce chemicals that upset electrolyte balance.
- Abuse of electrolyte supplements.

### *Specific electrolyte imbalances*

Each electrolyte has a special function in the body, although if one electrolyte is out of balance, the concentrations and actions of other electrolytes are often affected. The serum concentration of sodium, potassium, and chloride can be measured in a simple blood test. Sodium, chloride, potassium, and calcium concentrations can also be determined from a urine sample. A urine test helps show how well the kidneys are functioning. Electrolyte imbalances are most common among the seriously ill and the elderly. Kidney (renal) failure is the most common cause of electrolyte imbalances.

**SODIUM.** Sodium affects how much urine the kidney produces and is involved in the transmission of nerve impulses and muscle contraction. Too high a concentration of sodium in the blood causes a condition called hypernatremia. Causes of hypernatremia include excessive water loss (e.g., severe diarrhea), restricted water intake, untreated diabetes (causes water loss), kidney disease, hormonal imbalances, and excessive salt (NaCL) intake. Symptoms include signs of dehydration such as extreme thirst, dark urine, sunken eyes, fatigue, irregular heart beat, muscle twitching, seizures, and coma.

Too low a concentration of sodium in the blood causes hyponatremia. This is one of the most common electrolyte imbalances, and occurs in about 1% of hospitalized individuals. It can result from vomiting, diarrhea, severe burns, taking certain drugs that cause the kidneys to selectively excrete sodium, inadequate salt intake, water intoxication (a problem among the elderly with dementia), hormonal imbalances, kidney failure, and liver damage. Symptoms include nausea, vomiting, headache, tissue swelling (edema), confusion, mental disorientation, hallucinations, muscle trembling, seizures, and coma.

**POTASSIUM.** Potassium ions play a major role in regulating fluid balance in cells, the transmission of nerve impulses, and in muscle contractions. Too high a concentration of potassium causes a condition called hyperkalemia that is potentially life threatening. The most common cause is kidney failure. It can also result from severe burns or injury (excess potassium released from injured cells), inadequate adrenal hormones (Addison's disease), the use of certain medications, and excessive use of potassium supplements. Sometimes hyperkalemia occurs in conjunctions with hypernatremia. Symptoms include nausea, diarrhea, weakness, muscle pain, and irregular heart beat, coma and death.

Abnormally low concentrations of potassium cause hypokalemia. Hypokalemia can result from excess adrenal hormones (Cushing's disease), kidney disease, long-term use of certain diuretic drugs, laxative abuse, bulimia, and kidney failure. Symptoms include increased production of urine, muscle pain, paralysis, irregular heart beat, and low blood pressure.

**CALCIUM.** Calcium is needed to build and maintain bones. It also plays a role in nerve impulse transmission and muscle contraction. Excess calcium results in a condition called hypercalcemia. Hypercalcemia can be caused by too much parathyroid hormone (PTH), certain cancers, some genetic disorders, and excessive use of antacids containing calcium in rare cases. Symptoms include bone and muscle pain, mental changes such as depression and confusion, increased urine production, fatigue, nausea, and vomiting.

Abnormally low concentrations of calcium cause hypocalcemia. Hypocalcemia can be caused by too little parathyroid hormone, kidney failure, and **vitamin D** deficiency. Vitamin D is necessary for the body to absorb calcium. Symptoms include muscle twitches and spasms, convulsions, mental changes such as depression and irritability, dry skin, and brittle nails.

**MAGNESIUM.** Magnesium is involved in **protein** synthesis and cellular **metabolism**. Abnormally high concentrations of magnesium, or hypermagnesemia, may occur with severe (end-stage) renal failure or by overdose of magnesium-containing intravenous fluids. Hypermagnesemia is rare. Symptoms include exhaustion, low blood pressure, depressed heart and breathing rate, and slow reflexes.

Abnormally low concentrations of magnesium, or hypomagnesemia, are most common among people with alcoholism and those who are severely malnourished. Other causes include digestive disorders that interfere with the absorption of magnesium from the intestines. Symptoms of hypomagnesemia include vomiting, weight lose, leg cramps, muscle spasms, seizures, and irregular heartbeat.

**CHLORIDE.** Chloride is involved in regulating blood pressure. High concentrations of chloride, called hyperchloremia, can be caused by kidney failure, kidney dialysis, and an overproduction of parathyroid hormone. Symptoms include weakness, headache, nausea, and vomiting. In people with diabetes, hyperchloremia makes it difficult to control blood glucose levels.

Hypochloremia often occurs along with hyponatremia or hypokalemia and is caused by excessive fluid loss (e.g., diarrhea). Serious deficiencies of chloride cause the blood to become less acidic, resulting in a condition called metabolic alkalosis. Symptoms of severe hypochloremia include confusion, paralysis, and difficulty breathing.

**PHOSPHATE.** Phosphate helps control the acidity level (pH) of the blood. Phosphate also causes calcium to be deposited in bones. High blood levels of phosphate, or hyperphosphatemia, often result in too low levels of calcium, or hypocalcemia. Hyperphosphatemia is usually caused by kidney failure. It can also result from kidney dialysis, parathyroid gland dysfunction, and several inherited diseases. Mild hyperphosphatemia usually produces no symptoms. Severe imbalance can cause tingling in the fingers, muscle cramps, and convulsions.

Hypophosphatemia, or abnormally low concentrations of phosphate in the blood, often occurs along with hypomagnesemia and hypokalemia. It can also be caused by kidney disease, kidney dialysis, vitamin D deficiency, and hormonal imbalances. Up to 30% of individuals admitted to hospital intensive care units have hypophosphatemia.

### *Electrolyte supplements*

Most people get all the electrolytes and water they need from a normal diet. However, some individuals, such as athletes, people with severe diarrhea and vomiting, **cancer** patients, people with hormonal imbalances, and other very ill people, need fluid and electrolyte replacement therapy. Short-term therapy often quickly restores electrolyte balances.

Electrolyte replacement supplements can be sold either over-the-counter or by prescription. Prescription supplements are used for seriously ill or hospitalized patients and can be given by mouth or intravenously under supervision of a physician.

In North America, commonly used over-the-counter electrolyte replacements include:

- Sports drinks formulated to replace electrolytes lost through sweating. These drinks, such as Gatorade and Powerade, also contain sugars and sometimes caffeine. According to the American College of Sports Medicine, sports drinks are effective in supplying energy for muscles, maintaining blood sugar levels, preventing dehydration, and replacing electrolytes lost in sweat.
- Dietary supplements in the form of tablets and powders containing electrolytes. These are popular among athletes who participate in endurance sports. Some also contain herbs and flavorings. They are regulated by the United States Food and Drug Administration (FDA) as dietary supplements.
- Electrolyte replacements for children such as Pedialyte, Naturalyte, or Rehydralyte. These are sold in supermarkets and pharmacies and are used primarily in children who have lost fluids through vomiting and diarrhea. Children should not be given sports drinks for this purpose.

## Precautions

As with any dietary supplement, electrolyte replacements can be abused. When used properly, they are of great benefit and have no undesirable side effects.

Sports drinks should not be given to children who need rehydration because of vomiting and diarrhea. Instead, oral rehydration liquids specially formulated for children should be used.

### Interactions

The goal of electrolyte replacement therapy is to restore the body to its natural condition. When used this way, electrolyte replacement does not interfere with other drugs. Many drugs, however, have the potential to cause electrolyte imbalances. When starting a new drug, individuals should discuss possible side effects with their healthcare provider.

### Complications

No complications are expected when electrolyte replacement therapy is used as directed. Seriously ill individuals and those using long-term electrolyte replacement therapy should have their electrolyte levels checked regularly.

### Parental concerns

Dehydration is a real threat to children, especially infants and toddlers. Parents should be alert to dehydration caused by illness or athletic activity and begin oral fluid and electrolyte replacement therapy immediately. Parents of young children with vomiting, diarrhea, or high fever should consult their healthcare provider promptly about steps to take to prevent dehydration.

## Elimination diets

### Definition

Elimination diets are diets in which people stop eating specific foods for a period and then challenge their body by adding the food back into their diet and evaluating how the body responds. Elimination diets are used to detect food allergies and food intolerances. They are not nutritionally balanced and are intended to be used only for diagnostic purposes.

### Origins

For centuries it has been known that some people develop unpleasant symptoms (adverse reactions) to certain foods that other people can eat without any problems. However, it was not until the 1900s that food allergies began to be investigated in rigorous and scientific ways, and studies on food allergies started appearing in reputable medical journals. Elimination diets developed out of this scientific interest in the effects of food on the body.

### Description

Adverse reactions to food fall into two main categories, food allergies, and food intolerances. Food allergies cause a response by the immune system. When a person has a food allergy, his or her body responds to something in food by treating it like a threatening foreign material. Immune system cells produce proteins called antibodies that act to disable this material. This process often causes inflammation and results undesirable symptoms that range from mild and annoying to life threatening. The reason why some people respond to certain foods and others do not is probably genetically based.

Food intolerances, on the other hand, also cause adverse reactions, but these reactions do not involve the immune system and are not life threatening. Lactose (milk sugar) intolerance is an example of a food intolerance. It is caused by the body producing too little of the enzyme needed to digest lactose. Interestingly, although surveys show that in the United States up to 30% of families believe they have at least one

## KEY TERMS

**Antibody**—A protein produced by the immune system to fight infection or rid the body of foreign material. The foreign material that stimulates the production of antibodies is called an antigen. Specific antibodies are produced in response to each different antigen and can only inactivate that particular antigen.

member with a food allergy, the actual documented rate of food allergies is about 6% in infants and children and 3.7% in adults. On the other hand, in Hispanic, Jewish, and Southern European populations, the rate of lactose intolerance is about 70%, and it reaches 90% or more in Asian and African populations. Food intolerances are much more common, but true food allergies tend to be much more severe. In this article, **food sensitivities** are used to include both food allergies and food intolerance.

The most common symptoms of food sensitivities are nausea, diarrhea, bloating, excessive gas, hives, rashes, eczema, headaches, migraine, asthma, wheezing, and hay fever-like symptoms. These symptoms may occur immediately after eating the trigger food or may not develop for hours. Most immediate reactions are severe allergic responses that can result in anaphylactic shock, a condition in which the airways swell shut and the person cannot breathe. One study found that in about one-third of individuals in anaphylactic shock who were brought for treatment to the emergency room at the at the Mayo Clinic in Minnesota, the shock trigger had been a food. Foods most likely to cause immediate reactions are peanuts, tree nuts, and shellfish.

Delayed symptoms are difficult to detect and are sometimes called “maskedrdquo; food sensitivities. The most common causes of delayed sensitivities are dairy products, egg, wheat, and **soy**, however, sensitivities vary widely and can be caused by many foods. The amount of a trigger food that it takes to cause a response varies considerably from person to person.

A true elimination diet is very rigorous and needs to be implemented under the direction of a physician often in consultation with a dietitian or nutritionist. For the elimination diet to be useful, the patient must follow the diet strictly. Cheating invalidates the results.

For 2–3 weeks, a person on the elimination diet eats only the following foods (This list may be modified by the physician):

- grains: rice and rice products, sago, tapioca, buckwheat products, millet products
- proteins: veal, lamb, chicken, turkey, rabbit, tuna, bream, whiting, dried peas, lentils
- fruit: peeled pears, peeled apples, pawpaw.
- vegetables: potatoes, sweet potatoes, lettuce, parsley, bamboo shoots, celery, cabbage
- sweeteners and seasonings: sugar, maple syrup, sunflower oil, safflower oil, salt, garlic
- beverages: water, fresh pear juice

The individual must avoid all medicines containing aspirin (salicylates) and food colorings. After several weeks on these restricted foods, one new food is introduced in larger than normal amounts. This is the challenge food, and it is eaten for three days in a row. If no symptoms appear, the dieter continues to eat that food in normal amounts and adds another challenge food. If symptoms appear, the challenge food is stopped immediately and no new challenge food is introduced until symptoms disappear. During this time the dieter keeps a food journal, writing down everything that is eaten and any symptoms, either physical or emotional, that appear. It can take 2 to 3 months to work through all challenge foods.

### Function

Elimination diets are the first part of a diagnostic technique for determining what foods are causing undesirable symptoms. Their purpose is to prepare the patient for the second part of the diagnostic process, the food challenge by cleansing the body of all possible foods that could be causing the symptoms. During the challenge phase, the patient eats the suspect food and waits to see if symptoms reappear. Elimination and challenge give healthcare professionals a way to reproducibly pinpoint exactly which foods are causing an adverse reactions so that the patient can exclude these foods from their diet.

### Benefits

People with symptoms that interfere with their daily life benefit greatly from pinpointing which foods are causing the symptoms so that these foods can be eliminated from the diet. People with less severe symptoms may find the process of elimination and challenge too costly and disruptive to make it worthwhile.

### Precautions

Many people who suspect that certain foods are causing their symptoms try modified elimination diets

## QUESTIONS TO ASK THE DOCTOR

- Could my symptoms be caused by another disease? If so, should diagnostic tests be done before I begin the elimination diet?
- What do I need to do to get balanced nutrition while on this diet?
- Can you provide me with information about hidden sources of forbidden foods such as those in processed food and medications?
- Is there a better way to eliminate my food sensitivity symptoms?

found on the Internet or elimination diets they devise themselves. These diets have varying degrees of success. For example, many people try eliminating all dairy products to see if their symptoms of lactose intolerance—bloating, cramping, diarrhea, and gas—improve. This do-it-yourself approach may be adequate for people with mild sensitivities to only one food or food group, but it is risky for people with severe intolerances. People with moderate to severe sensitivities need professional guidance to eliminate non-obvious sources of the potential problem food.

### Risks

One risk of all elimination diets is that they are not nutritionally balanced. They increase the risk that vitamin and mineral deficiencies will develop. Anyone going on a full elimination regimen needs to consult a dietitian or nutritionist about how to use **dietary supplements** to assure adequate, balanced nutrition

A second risk is that people who self-diagnose symptoms as food intolerances using a non-medically-supervised elimination diet may be ignoring symptoms of more serious and progressive diseases such as **celiac disease**, Crohn's disease, **gastroesophageal reflux disease**, irritable syndrome, and other health problems that need medical treatment.

Finally, anyone suspected of having a moderate to severe food allergy should be under the care of a physician. Any food challenging must be done in a healthcare setting, as severe reactions can cause anaphylactic shock and death.

### Research and general acceptance

The medical community accepts elimination diets as a standard way to diagnose food sensitivities. A true elimination diet is quite restrictive, takes a long time to implement, and should be supervised by a healthcare professional. Many short cut do-it-yourself elimination-style diets are available on the Internet. Although people who believe they have a food intolerance often try these diets, they are not accepted by healthcare professionals as diagnostically accurate, and they may cause short-term vitamin and mineral deficiencies.

# Encopresis

## Definition

Encopresis is defined as the repeated passage or leaking of feces in inappropriate places in a child over 4 years of age that is not caused by a physical illness or disability.

## Description

Over 80% of cases of encopresis begin with the child's experience of a painful bowel movement or passing a very large bowel movement. Over time, the child comes to associate using the toilet with pain and begins to hold in, or retain, his or her bowel movements to avoid the pain. The child may occasionally try to pass some of the hardened stool and develop a crack in the skin surrounding the anus known as an anal fissure. Anal fissures cause additional pain and usually reinforce the child's habit of retaining feces. As the mass of stool grows, the colon stretches to many times its normal diameter—a condition known as megacolon. The child also loses the natural urge to have a bowel movement because the muscles in the wall of the colon cannot contract and push the stool out.

Encopresis is thought to affect between 1–2% of children in the United States below the age of 10. Boys are six times as likely to develop encopresis. It is not known to be related to race or social class, the size of the family, the child's birth order, or the age of the parents.

## KEY TERMS

**Anal fissure**—A crack or slit that develops in the mucous membrane of the anus, often as a result of a constipated person pushing to expel hardened stool. Anal fissures are quite painful and difficult to heal.

**Biofeedback**—A technique for improving awareness of internal bodily sensations in order to gain conscious control over digestion and other processes generally considered to be automatic.

**Constipation**—Abnormally delayed or infrequent passage of feces. It may be either functional (related to failure to move the bowels) or organic (caused by another disease or disorder).

**Enema**—The injection of liquid through the anus into the rectum in order to soften hardened stools.

**Impaction**—The medical term for a mass of fecal matter that has become lodged in the lower digestive tract. Removal of this material is called disimpaction.

**Laxative**—A drug usually administered by mouth to produce a bowel movement. Laxatives are also known as cathartics.

**Megacolon**—A condition in which the colon becomes stretched far beyond its usual size. Children with long-term constipation may develop megacolon.

**Suppository**—A tablet or capsule, usually made of glycerin, inserted into the rectum to stimulate the muscles to contract and expel feces.

## Treatment

There is no universal agreement among doctors as to the best method of treatment for encopresis, including dietary recommendations. It is a disorder resulting from the interaction of bodily, psychological, and social factors in the child's life. As a result, there have been no large-scale controlled studies of different treatment methods.

### *Dietary treatment*

Dietary treatment of encopresis is intended to help the child develop regular bowel habits after disimpaction and to minimize the risk of recurrent **constipation**. Dietary modifications usually include:

- Reducing the child's intake of milk and other dairy products that tend to cause constipation. Some pediatricians recommend soy milk as a substitute for cow's milk during maintenance treatment.
- Adding dietary fiber to the child's diet in the form of high-fiber breads and cereals, vegetables and fruits that are high in fiber, or over-the-counter fiber supplements.
- Increasing the child's water intake, particularly during warm weather.
- Encouraging the child to participate in vigorous physical activity. Exercise helps to move food through the digestive system.
- Increasing the child's intake of fruit and fruit juices. Fruit juices, particularly prune juice, have a laxative effect. Fruit and fruit juices cannot be used by themselves as maintenance treatment for encopresis because few children are able to drink or eat the amounts required for laxative treatment. Fruit is recommended over fruit juice since it has more nutrients.

### *Medical approaches*

Medical treatment of encopresis begins with disimpaction, or softening and removal of the mass of fecal material in the lower colon. Disimpaction may be accomplished by administering enemas or a series of enemas; one or a series of suppositories; laxatives taken by mouth; or a combination of these treatments. Commonly used enemas include homemade soap-and-water solutions and commercial saline preparations. Dulcolax (bisacodyl) and BabyLax are popular brands of suppositories. Laxatives, which work by increasing the amount of **water** in the large intestine to soften the impacted stool, include citrate of magnesia, Fleet Phospho-soda, Colyte, or GoLYTELY. Other laxatives sometimes used are mineral oil and senna, a plant native to the tropics that has been used to treat constipation for over three thousand years.

Following disimpaction, the child is given maintenance medications intended to produce soft stools once or twice daily to prevent constipation from recurring. They also help the child break the mental and emotional connection between defecation and pain. The child may be given glycerine or bisacodyl suppositories once or twice a day, or mineral oil, senna syrup (Senokot), milk of magnesia, lactulose, or sorbitol twice a day by mouth. Maintenance treatment typically takes several months.

Glucomannan, a complex sugar derived from the roots of the Japanese konjac plant, is an effective **fiber** supplement for children that appears to be well tolerated and has fewer side effects than many laxatives. Glucomannan is a water-soluble fiber that forms a gel-like mass in the digestive tract and helps to push fecal matter through the lower bowel more rapidly.

### *Psychological treatment*

Psychological treatment is part of maintenance therapy for encopresis because of the emotional stress the condition causes the child and other family members. In many cases the child has become depressed or developed other behavioral problems as a result of punishment, teasing, or social rejection related to episodes of soiling. Psychological treatment begins with education; the doctor explains to the parents as well as the child how encopresis develops, what causes it, and why medications are used to treat it.

If the child's encopresis is involuntary, behavioral therapy is often used. This approach employs such techniques as star charts and daily diaries to teach the child to recognize the body's internal cues. Some doctors also recommend biofeedback for maintenance therapy in encopresis.

If the child's episodes of soiling are intentional rather than involuntary, he or she will usually be referred to a child psychiatrist for specialized evaluation and treatment.

## Function

The function of dietary treatment for encopresis is as a form of maintenance therapy. The goal is to prevent stool from building up in the child's colon, allow the colon to return to its normal shape and muscular function, and to help the child have bowel movements in the toilet at appropriate times.

## Benefits

The benefit of dietary treatment for encopresis is prevention of future episodes of constipation while providing adequate nutrition for the child. Medications are used to clear impacted fecal material from the colon and relieve discomfort associated with defecation.

## Precautions

Parents should follow the doctor's advice about laxatives and enemas during maintenance treatment for encopresis, as some of these products have side effects or interact with other medications that the child may be taking.

## Risks

There are no reported adverse effects of dietary treatment for encopresis.

Enemas and laxatives often produce side effects including abdominal cramping, intestinal gas, nausea, and vomiting. The child's doctor may be able to change the dosage or type of product for a child on maintenance treatment. Lactulose should not be given to patients with diabetes because it contains a form of sugar, while sorbitol may reduce the effectiveness of other medications. Mineral oil sometimes causes seepage into underwear and itching in the anal area. Senna and citrate of magnesia may lead to electrolyte imbalance if used in high doses over a long period of time.

## Research and general acceptance

Disagreements regarding treatment for encopresis focus on three subjects: whether enemas are preferable to laxatives taken by mouth or whether enemas are emotionally traumatic to the child; whether or not adding fiber to the child's diet is useful; and whether

placing the child on the toilet at set times helps in establishing bowel control or whether it creates emotional conflict between parents and child. Opinion is divided about the effectiveness of placing the child on the toilet at fixed times during the day; some doctors think that taking the child to the toilet after a meal helps to teach good bowel habits, while others think it is not a good idea if the child does not feel an urge to defecate.

There is no evidence that long-term use of laxatives creates dependency on them or causes colon **cancer**.

# Ephedra

## Definition

Ephedra is a genus of plants found worldwide. One species, *Ephedra sinica* or Chinese ephedra, has a long history of use in complementary and alternative medicine (CAM). In the late twentieth century, ephedra gained popularity as a weight-loss supplement. The herb can cause life-threatening side effects, and since April 2004, sale of products containing ephedra have been banned in the United States. In Traditional Chinese Medicine (TCM) ephedra is called ma huang.

## Purpose

Ephedra (ma huang) has been used in TCM for about 5,000 years primarily to treat sneezing, runny nose, coughing and other symptoms of a cold,

**Ephedra (*Ephedra sinica*).** *(PlantaPhile Germany. Reproduced by permission.)*

influenza, bronchitis, and allergy. In the 1990s ephedra was marketed in the United States as a dietary supplement that stimulated weight loss. It was also marketed to adolescents as a mood-altering "herbal Ecstacy" and to athletes to improve performance. In 2005 use of ephedra-containing supplements in the United States was banned.

## Description

Ephedra is an evergreen plant with tiny leaves that grows to a height of about 12 in (30 cm). Many species of ephedra are found worldwide, but *E. sinica* used in herbal medicine grows mainly in dry, rocky areas of Mongolia and northern China. The stems and roots of the plant are used medicinally. Many other species of ephedra, for example, *E. nevadensis* or Mormon tea that grows in the western United States, do not have the same active ingredients as *E. sinica*.

The active ingredients in ephedra are the alkaloids ephedrine and pseudoephedrine. These chemicals have effects similar to amphetamines. They stimulate the central nervous system and affect the heart and circulatory system. Ephedra causes blood vessels to narrow, increases heart rate, and raises blood pressure. These effects are enhanced when ephedra is taken with **caffeine**. Ephedra also expands the airways, making breathing easier. Researchers generally agree that ephedra is effective in treating cold and allergy symptoms.

Standardized amounts of manufactured ephedrine and pseudoephedrine, the active ingredients found in ephedra, are used in many cold and allergy products made by traditional pharmaceutical companies and approved for sale by the FDA. For years, these drugs were sold in the United States over the counter without restrictions. Beginning in the early 2000s, a movement developed to limit access to these drugs by placing them behind the counter at the pharmacy, limiting the amount an individual could buy, and requiring identification to purchase the drugs. This came about more because ephedrine and pseudoephedrine are used in the manufacture of illicit methamphetamines (e.g., crystal meth) than because of safety concerns about the drugs.

Ephedrine and pseudoephedrine are also effective appetite suppressants, especially when combined with caffeine. Many people who took diet pills containing ephedra or a combination of ephedra and caffeine did lose weight. However, they also experienced an increased risk of dangerous, sometimes fatal, side effects. Ephedra was brought to the attention of the FDA in the mid-1990s by a large increase in the number of reports from poison control centers and health care providers about serious adverse effects related to ephedra-containing weight-loss supplements. These side effects included dangerously high blood pressure, fast heart rate, stoke, and heart attack. By 2003, at least 155 deaths were linked to ephedra use, including that of Baltimore Oriole's pitching prospect Steve Belcher. That same year, an analysis of side effects related to herbal therapy published in the *Annals of Internal Medicine* found that ephedra accounted for less than 1% of all herbal supplement sales, but was responsible for 64% of all reported negative events caused by herbs.

## Ephedra and the Law

The FDA regulates ephedra and other **dietary supplements** under the 1994 Dietary Supplement Health and Education Act (DSHEA). At the time the act was passed, legislators felt that because many dietary supplements come from natural sources such as plants and because they have been used for hundreds of years by practitioners of CAM, these products did not need to be regulated as rigorously as prescription and over-the-counter drugs used in conventional medicine. The legislators decided that dietary supplements should be regulated the same way food is regulated. As a result, manufacturers of ephedra supplements, just like the manufacturers of cheese or cereal, did not have to prove that ephedra was either safe or effective before it could be sold to the public. They also were not required to tell the public about possible side

## KEY TERMS

**Alternative medicine**—A system of healing that rejects conventional, pharmaceutical-based medicine and replaces it with the use of dietary supplements and therapies such as herbs, vitamins, minerals, massage, and cleansing diets. Alternative medicine includes well-established treatment systems such as homeopathy, traditional Chinese medicine, and Ayurvedic medicine, as well as more-recent, fad-driven treatments.

**Amphetamine**—A drug that stimulates the central nervous system and can be physically and psychologically addictive.

**Complementary medicine**—Includes many of the same treatments used in alternative medicine, but uses them to supplement conventional drug and therapy treatments, rather than to replace conventional medicine.

**Conventional medicine**—Mainstream or Western pharmaceutical-based medicine practiced by medical doctors, doctors of osteopathy, and other licensed health care professionals.

**Dietary supplement**—A product such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Traditional Chinese Medicine (TCM)**—An ancient system of medicine based on maintaining a balance in vital energy or qi that controls emotions, spiritual, and physical well being. Diseases and disorders result from imbalances in qi, and treatments such as massage, exercise, acupuncture, nutritional and herbal therapy are designed to restore balance and harmony to the body.

effects of the herb. (Conventional pharmaceuticals must include potential side effects in their packaging.)

With ephedra and all other dietary supplements, the burden of proof falls on the FDA to show that the supplement is either unsafe or ineffective before the supplement can be restricted or banned. Information about a supplement's safety and effectiveness is normally gathered only after people using the product develop health problems or complain that the product does not work.

The FDA involvement with ephedra in weight-loss supplements began in 1996 after receiving more than 800 reports of adverse events in people taking products containing ephedra. In 1997 the FDA proposed regulating ephedra by requiring that the product carry a warning on the label stating that adults should take no more than 8 mg of ephedra at one time and no more than 24 mg in one day. The proposed regulation was fought by the diet supplement industry. During the course of public comment about the regulation, it became clear that there was little or no standardization of ephedra content among products or even within different batches of product from the same manufacturer. This lack of standardization made it difficult for consumers to know and control how much ephedra they were taking from day to day.

In 2002, the FDA commissioned and independent organization to study ephedra-related complications and deaths. As a result of this study, the FDA banned the uncontrolled sale of dietary supplements containing ephedra based on the what the FDA called an "unreasonable risk of illness or injury." The ban took effect on April 14, 2005.

Several supplement makers have challenged the ban on ephedra-containing supplements in federal and state courts. They argue that the FDA did not test supplements containing low doses of ephedra for safety and effectiveness and that a total ban on ephedra supplements based only on high-dose products was illegal. The FDA took the position that it was unethical to do more human testing of ephedra given the findings that ephedra-containing supplements increase the risk of stroke, heart attack, irregular heart beat, and similar serious cardiovascular events. On October 18, 2006, after several legal challenges, the United States Court of Appeals Tenth Circuit upheld the FDA ban on all ephedra-containing supplements regardless of dose. Nutraceutical Corporation, the plaintiff in the case, vowed to file another a petition for review with the United States Supreme Court.

The ban on ephedra-containing supplements continues to be controversial. There is general agreement that ephedra does treat cold symptoms and does help people with short-term weight loss. However, these benefits do not, in the opinion of FDA scientists, outweigh the health risks associated with the ephedra-containing products. Ephedra continues to be legal in countries such as Germany, Japan, India, and China where it is widely used. Ephedra-containing supplements are easily available over the Internet, and it is estimated that several million Americans continue to use them.

### Precautions

The FDA warns that no one should take dietary supplements that contain ephedra because they can

cause serious, sometimes fatal, side effects. Some individuals choose to ignore this warning. In that case, people with high blood pressure, heart problems, thyroid problems, enlarged **prostate**, and glaucoma, should avoid ephedra because there is a high risk the supplement will worsen their condition and could cause serious complications. Ephedra-containing supplements should not be given to children, pregnant women, or **breastfeeding** women.

### Interactions

Studies have shown that ephedra interacts with many drugs used in conventional medicine, especially those used to treat heart problems and monoamine oxidase inhibitors (MAOI) used to treat mental depression, anxiety, and phobias.

### Complications

At low doses, adverse side effects include headache, restlessness, anxiety, sleeplessness, nausea, difficulty urinating, and racing heart. At high doses, adverse reactions include sweating, enlarged pupils, fever, spasms, and death, usually through heart failure or stroke.

### Parental concerns

Ephedra is a dangerous herbal supplement and should not be given to children. Accidental use of ephedra by children can result in serious side effects. In the case of accidental poisoning in the United States, call the national poisoning hotline at 1-800-222-1222, the local hospital emergency room, or emergency services.

## Ergogenic aids

### Definition

Ergogenic aids are substances, foods, or training methods that enhance energy production, use or recovery and provide athletes with a competitive advantage.

### Purpose

New ergogenic products claiming to enhance performance appear on the market almost every week. Most are offered as supplements. Unfortunately, this means that both the contents of the product and the

claims on the label have not been evaluated by the United States Food and Drug Administration (FDA) and may not have any scientific basis. Surveys have shown that 76% of college athletes, and 100% of body builders take supplements. Athletes strive for the leading edge and they use ergogenic aids to improve their energy and performance. It is now known that the only healthy ergogenic aids are those that are legal, and have been proven safe. To gain a more competitive edge, the best aids are proper training, proper rest, good nutrition, correct technique, and good coaching.

## Description

Safe ergogenic aids include the following:

- Carbohydrate loading: It is now recognized that adequate dietary carbohydrate in the days and hours before strenuous training and competition is critical to maintaining adequate glycogen levels in the muscles. Increasing consumption of carbohydrates in liquid or food form normally three days prior to an endurance-type event is therefore a way to enhance performance. Endurance athletes, such as marathon runners, rely on their stores of glycogen as a source of energy during competition and carbohydrate loading is a method for boosting the amount of glycogen in the body before a competition.
- Proper nutrition: Proper nutrition means selecting good food choices and diets that lead to maintaining health while also reducing major risk factors for diseases. The estimated average daily calorie requirement is 1940 calories per day for women and 2550 for men. If the level of activity is increased, high performance can be achieved by increasing the calorie intake according on a sound nutrition basis.
- Electrolyte solutions: The body requires a certain amount of fluid intake on a daily basis to function and the minimum is about equal to four 8-ounce glasses (one liter or one quart). Strenuous activity and excessive sweating call for two to three times this basic amount. It has been shown that a fluid loss equivalent to 2% of body weight can impair performance and lead to heat exhaustion at 5%. Electrolyte solutions not only provide fluid, but also contain electrolytes, the salts and minerals required for various functions by the body and that are also lost by sweating.
- Stress management: The increased stress of competitive sports can affect athletes both physically and mentally such that their performance abilities are lowered. Stress may lead to excessive tension, increased heart rates, cold sweats, and anxiety about the outcome of the competition. Stress management techniques are recognized ergogenic aids that help maintain concentration, confidence, control and commitment.
- Relaxation techniques: Relaxation is especially important for high performance athletic activities. It promotes rest, recovery and recuperation while removing stress related reactions, such as increased muscular tension. In addition, relaxation contributes to the maintenance of positive physical and mental states.

## Precautions

Some ergogenic aids are known to have harmful side effects and this is the reason why they are banned by sports governing authorities because they are unsafe and unethical. The most abused aids include the following:

- Anabolic steroids: These are synthetic hormones used to increase muscle mass and strength. They also produce a "steroid rush", a state of euphoria and decreased fatigue that allows the athlete to train harder and longer. Many adverse effects have been documented from using these steroids.
- Blood doping: This is another dangerous ergogenic aid. It involves taking blood or blood products such as erythropoietin (EPO), a hormone that stimulates the bones to make red blood cells, to an athlete to improve endurance and speed. It can also have harmful side effects.
- Human growth hormone (HGH): HGH is a widely abused ergogenic aid by body builders. Some body builders take large doses to decrease fat and increase muscle mass. Many adverse effects have been documented.
- Caffeine: Caffeine affects the central nervous system by increasing mental alertness and lowering fatigue. Excessive use however, can cause irritability, restlessness, diarrhea, insomnia, and anxiety. It is found in coffee, tea, chocolate, and soft drinks.
- Ephedrine: Some athletes use ephedrine-containing supplements to improve their performance, have more energy or decrease their body fat. Unfortunately, athletes who use ephedrine may find that it helps them run farther and faster, but research findings have shown that it also puts them at risk of potentially life-threatening side effects. This is why the National Football League, the National Collegiate Athletic Association and the International Olympic Committee have all taken steps to keep it off the playing fields.
- Gene doping: Gene doping is the non-therapeutic use of cells, genes, genetic elements, to improve athletic

performance. Besides being a complex ethical as well as a philosophical issue, the long term effects on health have not been investigated to date.

## Interactions

Athletes who train hard frequently complain about energy drain and fatigue. Because they are regularly reminded to consume adequate fluids and fuel to minimize early fatigue and to maximize performance and recovery, many have turned to "energy" drinks". These are liquid food products that contain both fluid and energy together in one bottle. Recent research sponsored by the Food and Nutrition Information Center of the United States Department of Agriculture (USDA) has shown however, that some energy drinks were found to contain herbs, amino acids, **protein**, and other substances in such small amounts that they were unlikely to have any noticeable effect on performance. Other energy drinks were found to have contents that may result in inefficient absorption of fluid and nutrients from the intestine, with the possibility of gastrointestinal distress. The absorption of nutrients involves a delicate balance of interactions among various nutrients and the body and boosting intake of one may upset that balance.

Athletes are always looking for sound, effective aids to boost performance and many believe that herbs can improve athletic performance. Herbs are non-woody plants or parts of plants that have a long history of medicinal or therapeutic use. In fact, many common medications, such as aspirin and quinine, were first developed from herb extracts. However, if herbs can act as drugs, they are also associated with potential adverse effects or interactions with foods, other herbs, or medications.

## Aftercare

Treatment for excessive use of ergogenic supplements starts with complete avoidance. Depending on the supplement used and the medical complications, aftercare is tailored to individual cases and depend on the nature of the resulting medical condition.

## Complications

Harmful effects have been reported for several ergogenic products. Anabolic steroids have many adverse effects, most related to the unwanted androgenic effects, such as shrinking testicles, enlarged **prostate** gland, and lower sperm levels. Some of the adverse effects are potentially serious and irreversible and they include heart, liver, and immune system problems. Behavior changes may include aggression, paranoia, mood swings, low sex drive, and depression. Blood doping has been linked to strokes, allergic reactions, and infections. HGH adverse effects include heart and nerve diseases, glucose intolerance, and higher levels of blood **fats**. Other effects also come from the extra HGH levels in the body along with what is already produced by the pituitary glands. Ergogenic doses of **caffeine** may cause restlessness, nervousness, insomnia, and tremors. At least 17 deaths have been linked to products that combine caffeine and ephedrine. Additional risky supplements in the ephedrine class include androstenedione and other "prohormone" precursors to testosterone, yohimbine, and products that contain kava. Adverse effects have also been reported with carbohydrate supplementation. Increased insulin levels after carbohydrate consumption were shown to significantly decrease blood glucose levels in some athletes, and fructose-containing solutions have been associated with adverse gastrointestinal effects in some studies.

## Parental concerns

Parents should educate their teenagers concerning the use of ergogenic aids, and strive to increase their awareness of illegal ones. Most teens however, seem very smart in that they stay away from steroids. As part of a 2002 study funded by the National Institute for Drug Abuse, teens were asked if they had ever tried steroids, even if only once. Results were that only 2.5% of 8th graders had ever tried steroids, only 3.5% of 10th graders, and 4% of 12th graders. For teenagers, hormone balance is especially important since they are at the age of puberty. Hormones are involved in the development of feminine traits in girls and masculine traits in boys. When teenagers use steroids, there is a risk of gender mix-ups. Boys can experience shrunken testicles and can also end up with breasts (gynecomastia). Using steroids, girls can develop deeper voices and grow excessive body hair with a decrease of breast size.

Steroid users may be very pleased when they flex muscle in a mirror, but they may develop health problems that may hurt them for the rest of their lives, and even shorten their lives. Ergogenic supplements, unlike medicines and other drugs, do not undergo rigorous testing and screening for efficacy and safety, but information is still available, for instance from health care providers and sport medicine practitioners or at Supplement Watch (www.supplementwatch.com) and Consumer Lab (www.consumerlab.com), which provide independent test results and information to help people evaluate and select supplements.

## KEY TERMS

**Amphetamines**—Stimulant drugs whose effects are very similar to cocaine.

**Anabolic**—Pertaining to the putting together of complex substances from simples ones, especially to the building of muscle protein from amino acids.

**Anabolic steroid**—A group of synthetic hormones that promote the storage of protein and the growth of tissue, sometimes used by athletes to increase muscle size and strength.

**ATP**—Adenosine triphosphate, a high-energy phosphate molecule required to provide energy for cellular function. The energy source of muscles for short bursts of power.

**Blood doping**—Practice of illicitly boosting the number of red blood cells in the circulation in order to enhance athletic performance.

**Calorie**—A unit of food energy. In nutrition terms, the word calorie is used instead of the scientific term kilocalorie which represents the amount of energy required to raise the temperature of one liter of water by one degree centigrade at sea level. In nutrition, a calorie of food energy refers to a kilocalorie and is therefore equal to 1000 true calories of energy.

**Carbohydrate loading**—Increase consumption of carbohydrates in liquid or food form normally three days prior to an endurance type event.

**Central nervous system (CNS)**—The central nervous system (CNS) is composed of the brain and spinal cord. The brain receives sensory information from the nerves that pass through the spinal cord, as well as other nerves such as those from sensory organs involved in sight and smell. Once received, the brain processes the sensory signals and initiates responses.

**Ephedrine**—Central nervous system stimulant that that increases serum levels of norepinephrine. The herbs ma huang, ephedra sinica and sida cordifolia contain ephedrine, which structurally is similar to amphetamines.

**Erythropoietin (EPO)**—Hormone secreted by the kidneys which stimulates the bones to make red blood cells (erythrocytes).

**Gene doping**—Use of gene transfer technology by athletes to improve performance.

**Glucose**—A monosaccharide sugar occurring widely in most plant and animal tissue. In humans, it is the main source of energy for the body.

**Glycogen**—The storage form of glucose found in the liver and muscles.

**Heat exhaustion**—A mild form of heat stroke, characterized by faintness, dizziness, and heavy sweating.

**Hormone**—A chemical substance produced in the body that controls and regulates the activity of certain cells or organs.

**Human growth hormone (HGH)**—A hormone produced in the pituitary gland that stimulates growth of bone and muscle.

**Norepinephrine**—Hormone released by the sympathetic nervous system onto the heart, blood vessels, and other organs, and by the adrenal gland into the bloodstream as part of the fight-or-flight response.

**Steroid**—Naturally occurring or synthetic fat-soluble organic compounds having as a basis 17 carbon atoms arranged in four rings and including the sterols and bile acids, adrenal and sex hormones, certain natural drugs such as digitalis compounds, and the precursors of certain vitamins.

**Stimulant**—An agent, especially a chemical agent such as caffeine, that temporarily arouses or accelerates physiological or organic activity.

**Testosterone**—A hormone that promotes the development and maintenance of male sex characteristics.

## Fad diets

### Definition

Many fad diets defy logic, basic biochemistry, and even appetite appeal. They are popular because they promise quick results, are relatively easy to implement, and claim remarkable improvements in how their followers will look or feel. Unfortunately, the one thing most fad diets have in common is that they seldom promote sound weight loss. More important, they only work short-term. As many as 95% of people who lose weight gain it back within five years. It is not surprising that nearly 25% of Americans are confused when it comes to information about dieting.

### Purpose

Despite the popularity of dieting, the prevalence of overweight and **obesity** has increased steadily since the 1970s. In 1980, 25% of adults in the United States were overweight. By 1991, this figure had risen to 33 percent, and by 2001, over 66% of the adult population were classified as overweight or obese. Each year, Americans spend more than $30 billion fighting fat—often for gimmicks that do not work. Most people who are trying to lose weight are not using the recommended combination of reducing caloric intake and increasing physical activity. Fad diets provide advice counter to that provided by science-based governmental and nongovernmental organizations.

### Description

Fad diets take many forms. Over the years, they have promoted consumption of specific foods (e.g., the **Cabbage Soup diet**, the Drinking Man's diet, the **Grapefruit diet**), specific combinations of foods (e.g., the Zone) and specific times that foods must be eaten (e.g., the Rotation diet). Some popular diets recommend elimination of certain foods (e.g., carbohydrates in the **Atkins diet**, **Protein** Power, the Carbohydrate Addict's diet, Life without Bread, and Sugar Busters!). Others recommend eating based on a person's blood type (e.g., Eat Right for Your Type), or eating like a caveman (e.g., Neanderthin). Celebrities promote diets (e.g., Suzanne Somers' Get Skinny on Fabulous Food), and fad diets have taken the name of well-known places associated with wealth, fame, and thinness (e.g., the **Beverly Hills diet**, the **South Beach diet**). If any one of these fad diets worked, the problem of obesity would likely have been solved long ago.

Some fad diets have been popular for many years (e.g., Atkins Diet Revolution). Books appear as "new, revised" editions and continue to sell millions of copies. Unfortunately, there is nothing new or revised about the diets; they simply appeal to a new generation of overweight, frustrated dieters. The underlying reason why diets (including fad diets) work is that they result in decreased caloric intake. When energy intake is less than energy expenditure, people lose weight. Fad diets that lead to decreased caloric intake, whether by eliminating **carbohydrates**, eating cabbage soup all day, or adding grapefruit to every meal, will result in weight loss. If a person followed such a diet long-term, he or she would keep the weight off. Of course, no one wants to live on cabbage soup forever, or eliminate carbohydrates forever, so people break the "diet" and gain back the weight they lost—and often even more. The accompanying table provides information about some common fad diets.

The American Heart Association provides some tips that can be used to recognize a fad diet. First, does the diet contain magic or miracle foods or proprietary ingredients? There are no "super foods" or "magic ingredients" that can undo the long-term effects of overeating and lack of activity. Next, beware of fad diets that claim rapid weight loss (e.g., "lose 10 pounds this weekend!"). Though quite appealing, weight loss occurring this quickly is due to loss of fluid, not fat. Studies show that gradual weight loss increases a person's success at keeping it off permanently. Sound weight loss plans aim for losing no more than one to two pounds per week.

**Common fad diets: summary of information**

| Diet | Philosophy | Foods to eat | Foods to avoid | Practicality | Lose and maintain weight? |
|---|---|---|---|---|---|
| Dr. Atkins' New Diet Revolution | Eating too many carbohydrates (CHO) causes obesity and other health problems; elimination of CHO solves problems. | Meat, fish, poultry, eggs, cheese, low-CHO vegetables, butter, oil; no alcohol. | Carbohydrates, specifically bread, pasta, milk, most fruits and vegetables | Limited food choices. | Yes, but initial weight loss is mostly water. Difficult to maintain long-term due to food restrictions. |
| The Zone | Eating the right combination of foods leads to metabolic state at which body functions at peak level, and results in weight loss and increased energy. | Most foods, so long as they are consumed in the exact proportion (40/30/30) at each meal. | Carbohydrates, specifically bread, pasta, some fruits, and saturated fats | Difficult to calculate portions and follow. | Yes, because of lower caloric intake. Could result in weight maintenance if followed long-term. However, diet rigid and difficult to maintain long-term. |
| Protein Power | Eating CHO releases insulin that contributes to obesity and other health problems. | Meat, fish, poultry, eggs, cheese, low-CHO vegetables, butter, oil, salad dressings, alcohol in moderation. | Carbohydrates | Rigid rules. Not practical long-term. | Yes, via caloric restriction. Could result in weight maintenance if followed long-term. However, diet rigid and difficult to maintain long-term. |
| Sugar Busters! | Sugar is toxic, leads to insulin resistance, which then makes you overweight. | Protein and fat. Low-glycemic-index foods. Alcohol in moderation. | Potatoes, white rice, corn, carrots, beets, white bread, all refined white flour products | Eliminates many carbohydrates; discourages eating fruit with meals. | Yes, via caloric restriction. Difficult to maintain long-term due to food restrictions. |

*(Illustration by GGS Information Services/Thomson Gale.)*

Another sign of a fad diet is losing weight without exercise. Studies consistently show that the single most important variable that predicts long-term success at weight loss and maintenance (not gaining back the weight that was lost) is physical activity. Simple activities like walking or riding a bike (to and from school, for example) should be incorporated into one's life. Also, beware of the promotion of bizarre quantities of foods or the elimination of other types of foods (e.g., cabbage soup for breakfast, lunch, and dinner; avoiding dairy foods; and eliminating carbohydrates). Forbidding certain foods or entire food groups, in addition to being unhealthy, may increase the likelihood that one will cheat, binge, or just give up on the diet. Finally a rigid menu or rigid schedule of eating is a good sign that one should avoid the diet. Limiting food choices and adhering to specific eating times is a daunting task. Rather, one should look for a plan that can be followed not for a week or a month, but for an entire lifetime.

Knowledgeable practitioners do not recommend fad diets because such diets do not work long-term. Even though they might work in the short run, there is little value in losing weight if one is only going to regain it after the diet ends. With repeated dieting, weight loss becomes more difficult and results in frustration, feelings of failure, and loss of self-esteem.

From a nutritional standpoint, many fad diets lack important nutrients. For example, high-fat, low-carbohydrate diets (such as the Atkins Diet) are low in **vitamins** E, A, thiamin, $B_6$, **folate**, **calcium**, **magnesium**, **iron**, **zinc**, potassium, and dietary fiber, and they also require supplementation. In addition, they are high in saturated fat and cholesterol. On the other hand, when individuals are allowed to choose foods from all food groups, their diet is likely to be nutritionally adequate and healthful long-term.

Most fad diets do not result in long-term weight loss and are often nutritionally inadequate for long-term use.

## KEY TERMS

**Folate**—One of the B vitamins, also called folic acid.

**Saturated fat**—A fat with the maximum possible number of hydrogens; more difficult to break down than unsaturated fats.

# Fat flush diet

## Definition

The fat flush diet is a combination weight-loss and detoxification ('detox') or cleansing diet, formulated by the well-known nutritionist Ann Louise Gittleman. It is a low-carbohydrate, restricted-calorie diet, which is designed to boost **metabolism**, decrease **water** retention, and promote loss of fat.

## Origins

Ann Louise Gittleman, a certified nutrition specialist with a Ph.D. in holistic nutrition, first introduced the idea of 'fat flush' in her 1988 book *Beyond Pritikin*. Gittleman created her diet after working as a nutritionist at the Pritikin Longevity Center in Florida, where she observed that many of her clients did very poorly on Nathan Pritikin's extremely **low-fat diet**. The author of some 25 books on nutrition, dieting, and health, Gittleman is America's self-described 'First Lady of Nutrition.' *The Fat Flush Plan* became a bestselling diet book in 2002. It received additional publicity in the 2006 film *Last Holiday* starring Queen Latifah.

## Description

### *Theory*

The theory behind the fat flush diet is that eating the correct combinations of foods and eating more often will increase the body's metabolism and lead to the efficient burning of fat. Therefore, rather than totally restricting fat, the fat flush diet calls for eating the correct **fats**, as well as the correct **carbohydrates** and proteins. However, in order to maximize the body's burning of stored body fat 24 hours per day, the liver and lymphatic system must first be detoxified.

According to Gittleman there are five 'hidden factors' that sabotage weight loss, lower energy levels, and interfere with good health:

- A liver that is overloaded with toxins and functioning poorly cannot burn fat properly.
- Food sensitivities and intolerances lead to water retention and 'waterlogged tissues.' The fat flush diet eliminates foods that cause water retention and prescribes protein-rich foods, filtered water, and diuretics to remove excess water.
- People are afraid of eating fat. The fats in Gittleman's diet accelerate fat burning, satisfy hunger, and maintain lean muscle mass.
- Insulin is a fat-storing hormone and excess insulin is caused by food that are high in rapidly released carbohydrates.
- The stress hormone cortisol causes the body to store fat, particularly around the abdomen. Cortisol levels can be controlled by timing meals.

### *Diet components*

The fat flush diet includes:

- 8 oz (225 g) daily of lean protein as lean meat, eggs, and fish
- fruits and vegetables
- omega-3-rich fats such as flaxseed oil and evening primrose oil
- spices such as ginger, cayenne, mustard, and cinnamon, to speed up metabolism
- 'long life cocktail' consisting of one teaspoon of powdered psyllium husks or one tablespoon of ground or milled flaxseed in 8 oz (237 ml) cran-water (one part unsweetened cranberry juice, four parts filtered water), a diuretic to speed the detoxification process and balance hormones
- a supplement called GLA. Gamma linolenic acid or GLA is an essential fat from black current seed oil that Gittleman sells as 90-mg capsules. Gittleman claims that GLA-90 boosts weight loss by activating brown adipose tissue (BAT) and 'balancing the body's sodium/potassium pump.'

Specific fat flushing diet rules include:

- only one protein item per meal, with the exception of eggs
- no fruits and vegetables together
- no milk and meat together
- no water with meals, fluids only between meals
- eating about every three hours.

There are three phases to the fat flush diet:

- Phase 1 is a two-week very restrictive cleansing diet.
- Phase 2 is a less restrictive diet that is continued until the desired weight or body size is achieved.

## KEY TERMS

**Brown adipose tissue**—BAT; brown fat; a heat-producing tissue found primarily in human fetuses and infants and hibernating animals.

**Cellulite**—Fat deposited in pockets just below the surface of the skin around the hips, thighs, and buttocks.

**Chromium**—An essential mineral that must be obtained from the diet and is important for the metabolism of fats and carbohydrates and for insulin metabolism, as well as for many enzymatic reactions in the body.

**Cortisol**—Hydrocortisone; a glucocorticoid that is produced by the adrenal cortex and regulates various metabolic processes and has anti-inflammatory and immunosuppressive properties. Blood levels may become elevated in response to stress.

**Cran-water**—A diuretic drink consisting of one part unsweetened cranberry juice in four parts filtered water.

**Detoxification**—Detox; cleansing; to remove toxins or poisons from the body.

**Diuretic**—An agent that increases urine excretion.

**Evening primrose oil**—Oil extracted from the seeds of the evening primrose, *Oenothera biennis*; contains GLA.

**Flaxseed**—Linseed; the seed of flax, *Linum usitatissimum*, used as a source of oil for treating inflammation of the respiratory, intestinal, and urinary tracts, and as a dietary supplement.

**GLA**—Gamma-linolenic acid; an essential fatty acid found in evening primrose oil.

**Insulin**—A hormone made in the pancreas that is essential for the metabolism of carbohydrates, lipids, and proteins, and that regulates blood sugar levels.

**L-carnitine**—A molecule in muscle that is responsible for transporting fatty acids across mitochondrial membranes; obtained from meat and milk.

**Lignan**—Compounds in plants that have antioxidant and estrogenic activities.

**Lipotropic**—Factors that promote the utilization of fat by the body.

**Long life cocktail**—A drink consisting of one teaspoon of powdered psyllium husks or one tablespoon of ground or milled flaxseed in 8 oz (237 ml) cran-water.

**Omega-3 fatty acids**—A type of polyunsaturated fatty acids that appear to be beneficial for the heart.

**Psyllium**—Fleawort; plants of the genus *Plantago* whose seed husks have laxative activity.

- Phase 3 is a typical low-carbohydrate diet that can be maintained for life.

**PHASE 1.** The two-week phase 1 of the fat flush diet is designed to detoxify the liver so that it can efficiently burn fat. It calls for eight glasses per day of cran-water to reduce water retention or 'bloating', lose fat, cleanse the lymphatic system, and reduce cellulite. Caloric intake is restricted to 1100–1200 calories per day. So-called 'metabolism blockers,' such as wheat and dairy, are prohibited.

The phase 1 diet consists of:

- cran-water
- long life cocktail
- one tablespoon twice daily of organic high-lignan flaxseed oil in non-heated food
- GLA supplements twice daily for a total of 360–400 mg
- hot water with the juice of one-half lemon before breakfast as a detox drink for the liver and kidneys
- 8 oz (225 g) of lean protein daily
- one–eggs per day
- at least two portions of fruit daily
- unlimited raw or steamed vegetables
- one chicken, beef, or vegetable stock without salt for cooking
- herbs and spices.

The lean **protein** may be:

- any fish or seafood
- lean beef, veal, or lamb
- skinless chicken or turkey
- tofu
- high-protein whey powder for thickening.

Allowable vegetables include:

- asparagus
- aubergine
- bamboo shoots
- black olives without oil
- broccoli
- Brussels sprouts

- cabbage
- cauliflower
- celery
- cucumbers
- green beans
- mushrooms
- onions
- peppers
- radicchio
- spinach
- tomatoes
- water chestnuts.

Acceptable fruits are:

- blackberries
- blueberries
- cherries
- cranberries
- grapefruit
- oranges
- nectarines
- peaches
- plums
- raspberries
- strawberries.

Allowable herbs and spices are:

- anise
- apple cider vinegar
- bay leaf
- cayenne
- cinnamon
- cloves
- coriander, cilantro
- cumin
- dill
- dried mustard
- fennel
- garlic
- ginger
- parsley
- tumeric.

Forbidden foods during phase 1 include:

- oils and fats, except flaxseed oil
- margarine
- grains
- bread
- cereal
- sugar
- starchy vegetables such as beans, potatoes, carrots, corn, and peas
- dairy products
- most herbs and spices
- alcohol.

A sample phase 1 daily meal plan calls for:

- upon waking: a long life cocktail
- before breakfast: 8 oz (237 ml) of hot water with lemon juice
- breakfast: 'vegetable scramble'—two scrambled eggs with spinach, green onions, scallions, and parsley; 8 oz (237 ml) of cran-water
- snack: one-half of a large grapefruit
- 20 minutes before lunch: 8 oz (237 ml) of cran-water
- lunch: 4 oz (110 g) of salmon with lemon and garlic, warm asparagus, mixed-green salad with broccoli florets and cucumber, one tablespoon of flaxseed oil, 8 oz (237 ml) of cran-water
- mid-afternoon snack: 16 oz (474 ml) of cran-water
- 4 P.M. snack: one apple
- 20 minutes before dinner: 8 oz (237 ml) of cran-water
- dinner: 4 oz (110 g) of grilled lamb chop with a pinch of cinnamon and dried mustard, sautéed kale in broth, baked summer squash with a bit of clove, one tablespoon of flaxseed oil
- mid-evening: long life cocktail.

**PHASE 2.** This ongoing phase of the fat flush diet is designed for continued weight loss with a more moderate cleansing program and a slightly increased variety of foods. The caloric allowance is raised to 1200–1500 calories. Phase 2 is continued until the desired weight loss or size is achieved.

Carbohydrates that may be added back into the diet, at the rate of one per week, include:

- sweet potato
- brown rice
- fresh or frozen peas
- carrots
- butternut squash.

**PHASE 3.** Phase 3 is a lifelong weight-maintenance plan with a daily caloric allowance of 1500 calories or more. The diet is made up of 40% carbohydrates, 30% protein, and 30% fat, and may include two dairy products and four carbohydrates per day. Some starchy vegetables, fruits, gluten-free grains, dairy products, and more oils are introduced into the diet one at a time, to check for any adverse reactions.

### *Other fat flush components*

There are very few options for eating out on the fat flush diet, although choices such as fish tacos or grilled chicken sandwiches are possible. Since **caffeine** stresses the liver and, according to Gittleman, impedes fat burning, coffee should be tapered off and eventually replaced with one cup of herbal coffee per day. Alcohol is strictly forbidden during phases 1 and 2 because of its damaging effects on the liver.

Exercise is an important component of the fat flush plan. The first two phases call for brisk walking for 20–30 minutes five times per week and five minutes daily of 100 jumping jacks on a mini-trampoline. Exercise is increased in phase 3 and includes lifting weights for strength training twice per week.

The fat flush plan calls for exactly eight hours of sleep per night and for the dieter to keep a journal.

### *Kits*

Gittleman runs residential fat flush and 'Fast Track' cleansing programs and an online forum. She sells a line of organic processed foods and a 30-day fat flush detoxification kit that includes **vitamins** and **minerals**, GLA-90, and a weight-loss formula. The latter contains high amounts of chromium and L-carnitine. Chromium is a nutrient that can assist the body in utilizing protein, sugar, and fat. According to Gittleman, L-carnitine maximizes fat burning by helping the body transform food into energy. Her formula is also advertised to contain blood-sugar-stabilizing agents, appetite controllers, fat burners, and lipotropic nutrients and herbs.

## Function

The fat flush diet first uses a detoxification regimen to improve fat burning and then implements a plan for losing weight rapidly, followed by a maintenance plan. It is considered to be a healthy weight-loss program. It is a balanced diet with a significant exercise component and is designed to be followed for life.

## Benefits

Benefits of the fat flush diet may include:

- detoxification or cleansing of the liver and lymphatic system
- rapid weight loss of up to 10 lb (4.5 kg) in the first two weeks
- elimination of bloating
- weight loss accompanied by body toning
- maintenance of weight loss
- decreased hips, waist, and thigh measurements

According to Gittleman, this plan will also:

- increase metabolism
- permanently eliminate cellulite
- increase energy
- improve sleep
- improve health and appearance
- manage hormones and stabilize mood swings
- improve attitude
- create a healthy lifestyle.

## Precautions

The fat flush diet is only appropriate for people who can maintain a very strict diet for the first few weeks in order to lose weight rapidly. It may not be appropriate for vegetarians because it specifies animal protein. Vegans should add an amino-acid supplement and possibly protein powder. It is not known how often the fat flush diet leads to permanent weight loss. As with most diets, if healthy eating habits are not maintained long term, any weight lost will be regained and the other benefits will be lost.

Some experts advise against following diets that eliminate entire food groups and/or require the taking of supplements whose effects are unknown. The fat flush diet prohibits wheat and dairy during phases 1 and 2 and requires supplements. Whole-wheat grains are considered to be one of the best foods for reducing the risk of heart disease. Low-fat dairy products provide **calcium** and nutrients such as **magnesium** and **riboflavin** that may be hard to obtain from other foods. The fat flush diet requires expensive supplements including **flaxseed** oil, evening primrose oil, GLA, and protein powders.

Those following the fat flush diet should be aware of additional precautions:

- The caloric allowance in phase 1 may be too low for some people, particularly men.
- The calorie levels in phases 1 and 2 are too low to support a strenuous exercise regimen.
- The low calories may slow down, rather than speed up, metabolism.
- Although eight hours of sleep is sufficient for many people, other people require more sleep, particularly with 40 minutes of brisk walking per day and two strength-training sessions per week.

- Medications should be taken an hour before or after the life long cocktail because the fiber in the cocktail may interfere with absorption of medicine.

## Risks

The fat flush plan can disrupt menstrual cycles. Gittleman suggests using black current seed oil rather than evening primrose oil as a GLA source to avoid this. According to Gittleman black current seed oil has a better omega-6 to omega-3 ratio for balancing hormones.

Gittleman's fast flush kit contains chromium, which has been linked to **ulcers** and liver and kidney damage. Large doses of chromium can be lethal.

## Research and general acceptance

### *Research*

There is little scientific evidence to support claims made for the benefits of detox diets. Gittleman claims that her plan speeds up metabolism, detoxifies the liver by flushing out waste and fat, and helps digest fatty globules in the lymphatic system. Registered dietician Jane Kirby, in her book *Dieting for Dummies*, says that there is no scientific evidence that the liver is a 'fat-burning furnace.' She says: 'It's just a low-calorie diet. Most people lose weight when calories are cut this low.' Dr. Donald Hensrud of the Mayo Clinic was quoted in *O: the Oprah Magazine* in August of 2006: 'There's no such thing as a metabolism-blocking food; the liver and lymphatic system have no link to weight loss that we know of; there's no medical purpose for cleansing the body with a diuretic; and while the fat-burning supplement recommended [GLA] has been tested in animals, there's very little data on its effect in humans.'

### *General acceptance*

The fat flush diet is very popular. Gittleman is a highly respected nutritionist who has written many articles and books on women's health, nutrition, and **detoxification diets**, and the fat flush diet has received much publicity in the popular press. Testimonials as to the success of the diet are abundant on the Internet. According to Gittleman's Website, some individuals have lost up to 12 inches (30 cm) from their buttocks, hips, and thighs in the two-week phase 1 of the diet. One individual claims that it eliminated 95% of her intractable chronic pain. The fat flush diet has proved so popular that other entrepreneurs are selling their own fat flush kits.

## QUESTIONS TO ASK YOUR DOCTOR

- Have you had other patients who have tried the fat flush diet?
- Is the calorie allowance in this diet adequate for my activity level?
- Is it healthy for me to completely eliminate grains and dairy from my diet?
- Is eight hours of sleep adequate for my needs?
- Should I be taking a diuretic?
- Should I take GLA and other supplements?
- Could the medications that I take interact with the herbs, supplements, and nutrients in the fat flush kit?
- Are there vitamin and mineral supplements that I should take while following this diet?

# Fat replacers

## Definition

Fat replacers, also called fat substitutes, are substances that take the place of all or some of the fat in a food and yet give the food a taste, texture, and mouth feel similar to the original full-fat food.

## Purpose

Fat replacers serve two purposes. They reduce the amount of fat in food, and they usually reduce the calorie content of the food.

## Description

Fat is not a single substance, but a collection of different compounds that are all made of a glycerol molecule and three varying fatty acids. Fat is a necessary part of a healthy diet. It provides essential fatty acids, helps regulate cholesterol **metabolism**, carries fat-soluble **vitamins** and **carotenoids** throughout the body, contains the building blocks for prostaglandins, and provides nine calories of energy per gram.

Although there is no official recommended daily allowance (RDA) for fat, the American Heart Association strongly recommends that **fats** provide no more than 30% of one's total daily calories. The average American gets about 34% of his or her calories from fat (down from about 41% in the 1950s).

As of 2000, there were more than 5,000 reduced-fat foods on the market. New reduced- and low-fat foods were being introduced at the rate of about 1,000 per year. Concern about heart disease, **obesity**, diabetes, and their relationship to diet has turned processed foods containing fat replacers into a multi-billion dollar industry.

To be labeled "low fat" a product must contain 3 g of fat or less per serving. To be labeled "reduced fat" or "reduced calorie," a product must contain 25% less fat or 25% fewer calories than the regular version of the product. "Light" foods contain half the fat or one-third the calories of the regular product. "Fat-free" means the food has less than 0.5 g of fat per serving. Fat enhances food flavor, adds volume, and gives food a particular texture and mouth feel. Removing fat from food usually results in unappealing, unmarketable products. To achieve fat and calorie reduction, processors have turned to fat replacers.

### *Types of fat replacers*

Fat replacers are either carbohydrate-based, protein-based, or fat-based. Most foods use several different fat replacers that come from different sources. Many are substances that have been found in foods for years, but are now being used in different ways.

Carbohydrate-based fat substitutes include guar gum, polydextrose (Litess), gum Arabic, xanthum gum, carrageenan (an extract from seaweed), dried plum paste, modified food starches, oat **fiber**, and wheat fiber. Carbohydrate-based fat replacers have the creaminess of fat. They absorb **water**, add volume, thicken, and stabilize foods. They are used in baked goods, frozen desserts, yogurts, cheeses, sour cream, low-fat puddings, processed meats, salad dressings, sauces, and spreads. Because fat contains nine calories

**Carbohydrate-based fat replacers**

| | Brand names | Foods |
|---|---|---|
| Cellulose | Avicel® cellulose gel, Methocel™, Solka-Floc® | Dairy-type products, sauces, frozen desserts, salad dressings |
| Dextrins | Amylum, N-Oil® | Salad dressings, puddings, spreads, dairy-type products, frozen desserts |
| Fiber | Opta™, Oat Fiber, Snowite, Ultracel™, Z-Trim | Baked goods, meats, spreads, extruded products |
| Gums | KELCOGEL®, KELTROL®, Slendid™ | Reduced-calorie and fat-free salad dressings, other formulated foods, including desserts, processed meats |
| Inulin | Raftiline®, Fruitafit®, Fibruline® | Yogurt, cheese, frozen desserts, baked goods, icings, fillings, whipped cream, dairy products, fiber supplements, processed meats |
| Maltodextrins | CrystaLean®, Lorelite, Lycadex®, MALTRIN®, Paselli®D-LITE, Paselli®EXCEL, Paselli®SA2, STAR-DRI® | Baked goods, dairy products, salad dressings, spreads, sauces, frostings, fillings, processed meat, frozen desserts, extruded products, beverages |
| Nu-Trim | | Baked goods, milk, cheese, ice cream |
| Oatrim (hydrolyzed oat flour) | Beta-Trim™, TrimChoice | Baked goods, fillings and frostings, frozen desserts, dairy beverages, cheese, salad dressings, processed meats, confections |
| Polydextrose | Litesse®, Sta-Lite™ | Baked goods, chewing gums, confections, salad dressings, frozen dairy desserts, gelatins, puddings |
| Polyols | many brands available | Reduced-fat and fat-free products |
| Starch and Modified Food Starch | Amalean®I & II, Fairnex™VA15, & VA20, Instant Stellar™, N-Lite, OptaGrade®, Perfectamyl™AC, AX-1, & AX-2, PURE-GEL®, STA-SLIM™ | Processed meats, salad dressings, baked goods, fillings and frostings, sauces, condiments, frozen desserts, dairy products |
| Z-Trim | | Baked goods, burgers, hot dogs, cheese, ice cream, yogurt |

**Fat replacers are ingredients that substitute fat in many foods and beverages. Most fat replacers are reformulations of existing food ingredients (e.g., starches, gums, cellulose). Additionally, the food industry has formulated a variety of new fat replacer ingredients. Fat replacers generally fall into one of three categories: carbohydrate-based, protein-based, or fat-based.** *(Illustration by GGS Information Services/Thomson Gale.)*

per gram and **carbohydrates** contain only four calories per gram, every gram of fat replaced with a gram of a carbohydrate-based fat substitute reduces the calorie content of the food by five calories as well as reducing the fat content. Carbohydrate-based fat replacers cannot be used in frying.

Protein-based fat replacers (e.g., Simplesse) are made from milk **protein** and/or egg white protein. These proteins are heated and then whirled violently in blenders to produce very tiny particles in a process called microparticulation. These microparticles give protein-based fat replacers the same mouth feel as fats. Like carbohydrate-based substitutes, protein provides four calories per gram so they reduce the calorie content of food by five calories per gram of fat replaced. Protein-based fat replacers are used in butter, cheese, frozen dairy desserts, mayonnaise, soups, salad dressings, and sour cream. They do not work well in baked goods and cannot be used for frying.

Fat-based fat replacers (e.g., Caprenin, Benefat, Olean) are made of fat molecules that are modified so that they cannot be absorbed (Olean) or can be only partially absorbed (Caprenin, Benefat) in the intestine. Olestra, now marketed under the name Olean, is the best known of these products. Olestra is made of six to eight fatty acids bound to a sucrose (sugar) molecule. Normal fats have only three fatty acids. Adding the extra fatty acids makes the olestra molecule too large to be absorbed, so it simply passes through the intestine and is eliminated as waste. In this way, it adds no calories to food. Proctor & Gamble spent 25 years and more than $200 million developing this fat replacement.

Olestra has all the properties of regular fat and can be used in frying. It is used mainly in crunchy snack foods such as potato chips. Other fat-based fat replacers such as Caprenin and Benefat are partially absorbed by the body and contain about five calories per gram. Emulsifiers can also be used as fat replacers. They contain the same number of calories per gram as fat, but fewer grams of emulsifier are needed to achieve the same taste, texture, and mouth feel as fat.

### *Health considerations*

All fat replacers on the market are on the generally recognized as safe (GRAS) list approved by the United States Food and Drug Administration (FDA). When olestra was first introduced for use in snack foods in 1996, it was required by the FDA to

**Protein and fat-based fat replacers**

| Protein-based fat replacers | Brand names | Foods |
|---|---|---|
| Microparticulated Protein | Simplesse® | Dairy products (ice cream, butter, sour cream, cheese, yogurt), salad dressing, margarine- and mayonnaise-type products, baked goods, coffee creamer, soups, sauces |
| Modified Whey Protein concentrate | Dairy-Lo® | Milk/dairy products (cheese, yogurt, sour cream, ice cream), baked goods, frostings, salad dressing, mayonnaise-type products |
| Other | K-Blazer®, ULTRA- BAKE™, ULTRA-FREEZE™, Lita® | Frozen desserts and baked goods |
| **Fat-based fat replacers** | | |
| Emulsifiers | Dur-Lo®, EC™-25 | Cake mixes, cookies, icing, dairy products |
| Salatrim | Benefat™ | Confections, baked goods, dairy, other applications |
| **Lipid (Fat/Oil) analogs** | | |
| Esterified Propoxylated Glycerol (EPG) | | Consumer and commercial applications, including formulated products, baking, frying. |
| Olestra | Olean® | Salty snacks and crackers |
| Sorbestrin | | Fried foods, salad dressing, mayonnaise, baked goods |

**Fat replacers are ingredients that substitute fat in many foods and beverages. Most fat replacers are reformulations of existing food ingredients (e.g., starches, gums, cellulose). Additionally, the food industry has formulated a variety of new fat replacer ingredients. Fat replacers generally fall into one of three categories: carbohydrate-based, protein-based, or fat-based.** *(Illustration by GGS Information Services/Thomson Gale.)*

carry the following warning: "This Product Contains Olestra. Olestra may cause abdominal cramping and loose stools. Olestra inhibits the absorption of some vitamins and other nutrients. Vitamins A, D, E, and K have been added." In 2003, after additional controlled studies and consumer education, the FDA allowed the warning to be removed from olestra-containing foods. The FDA requires small amounts (far less than the RDA) of vitamins A, D, E, and K be added to foods containing Olestra. This helps compensate for the small amount of these fat-soluble vitamins that dissolve in Olestra and is carried out of the body rather than being absorbed. Other vitamins are not affected.

A diet too high in fat can increase levels of blood lipids and increase risk of plaque build up on the walls of arteries and result in the development of cardiovascular disease. Reducing the amount of fat intake along with other lifestyle changes can help reduce this risk. In addition, obesity increases the risk of developing diabetes and other health problems. Studies have shown reduced-fat foods can be part of an effective weight-loss program that combines a healthy diet, reduced calorie intake, and exercise. The American Heart Association states, "Within the context of a healthy dietary pattern, fat substitutes, when used judiciously, may provide some flexibility in dietary planning, although additional research is needed to fully determine the longer-term health effects."

## Precautions

People who have disorders that interfere with the absorption of nutrients from the intestine, such as **celiac disease**, Crohn's disease, or **inflammatory bowel disease**, should consider avoiding foods containing Olestra.

Fat replacers are often found in high-calorie foods. These foods may contain extra sugar to compensate for the absence of fat. Many reduced-fat products contain as many or almost as many calories as the full-fat equivalent. Consumers concerned about calorie intake should read the label and not assume that reduced-fat implies a reduced-calorie product.

## Interactions

Olestra reduces the absorption of the fat-soluble vitamins A, D, E, and K, and carotenoids. Olestra-containing products have extra fat-soluble vitamins, but not carotenoids, added to compensate for this.

## Complications

Large amounts of Olestra and the carbohydrate-based fat replacer polydextrose can cause loose stools and diarrhea in some people. Individuals should start with a small amount of foods containing these substances and see how they are affected.

## KEY TERMS

**Carotenoids**—Fat-soluble plant pigments, some of which are important to human health.

**Fat-soluble vitamin**—A vitamin that dissolves in and can be stored in body fat or the liver.

**Fatty acids** —Complex molecules found in fats and oils. Essential fatty acids are fatty acids that the body needs but cannot synthesize. Essential fatty acids are made by plants and must be present in the diet to maintain health.

**Prostaglandins**—A group of biologically important molecules that have hormone-like actions. They help regulate expansion of the blood vessels and the airways, control inflammation, are found in semen, and cause the uterus to contract. They are made from fatty acids.

### Parental concerns

Reduced-fat foods may appear healthy, but they may contain as many calories and more sugar than the equivalent full-fat product. Parents should encourage their children to eat a healthy diet high in fruits and vegetables and low in fats and not rely on fat substitutes to control fat and calorie intake.

# Fat smash diet

## Definition

The fat smash diet is a 90-day, four-phase weight-loss program that is designed to 'smash' bad habits and make permanent lifestyle changes in eating and physical activity.

## Origins

Dr. Ian Smith, M.D., developed the fat smash diet plan after he became weight-loss consultant and judge for the VH1 hit television program *Celebrity Fit Club*. The plan was originally designed for celebrities trying to lose weight on the show. Smith's bestselling book, *The Fat Smash Diet: The Last Diet You'll Ever Need*, was published in 2006. In April of 2007 Smith published the *Extreme Fat Smash Diet*, an alternative program for people wanting to lose weight in a short period of time.

## Description

### *Principles*

According to Smith, the fat smash diet plan is designed to 'rewire' the body and its relationship to food and physical activity. It is based on lifestyle changes that will enable people to maintain their weight once they have achieved their weight-loss goals. The aim of the plan is to eliminate bad habits, while enjoying food without overindulging. The fat smash diet is very flexible and utilizes a wide variety of healthy everyday foods, with the emphasis on whole grains, fresh produce, lean meat, fish, poultry, and healthy **fats**. Smith's book includes more than 50 quick and simple recipes. Although the diet does not involve calorie counting, quantities are suggested as a guide for keeping portions small.

The major principles behind the fat smash diet plan are:

- eating four–five small meals or large snacks daily, no more than three–four hours apart, with the last meal at least one and one-half hours before bedtime
- establishing a regular eating schedule to avoid hunger pangs
- eating small portions—just enough to feel full
- including fresh fruits and vegetables with meals
- eating 'good' carbohydrates and avoiding 'bad' carbohydrates
- eating foods raw, baked, steamed, or grilled
- a large exercise component, preferably with a partner
- avoidance of stress.

The rules for success on the fat smash diet are:

- not overeating
- always eating fruits and vegetables, regardless of the diet stage
- not eating fried foods
- not skipping meals
- continuing the exercise regimen
- maintaining emotional and mental focus.

Before beginning the fat smash plan dieters are instructed to:

- record their pre-diet weight
- determine their body mass index (BMI)
- take photographs of themselves.

### *The pyramid*

The fat smash diet is constructed as a pyramid, with each of the four phases building on the previous phases:

- Phase 1 is the nine-day detoxification, 'detox,' stage to rid the body of impurities.
- Phase 2 is the three-week foundation stage.
- Phase 3 is the four-week construction stage.
- Phase 4 is the lifelong temple stage.

The fat smash diet is designed to allow for mistakes. Dieters who overindulge or eat a prohibited food can return to phase 1 for about a week and then pick up the diet at the phase where they left off.

**PHASE 1—DETOXIFICATION.** The 9-day natural detoxification stage is not a fasting diet. Rather it is a vegetarian diet consisting primarily of fruits and vegetables, with some dairy and egg whites allowed. There are no absolute restrictions on how much to eat. The diet is designed to rid the body of toxins from processed foods and the environment, including the elimination of **caffeine** and alcohol, to make it easier to lose weight. Phase 1 includes 30 minutes of aerobic exercise five times per week, with a suggested 20–25-minute walk after dinner to increase the **metabolism**.

Foods allowed during phase 1 include:

- all fresh fruits in any quantity
- all vegetables in any quantity, except white or red potatoes and avocados; vegetables should be raw or lightly cooked (steamed or grilled)
- one cup daily of fresh-squeezed—not canned—fruit or vegetable juice
- one cup daily of cooked unsweetened oatmeal, grits, farina, or cream of wheat
- up to four egg whites daily
- any dried beans such as lentils or chickpeas
- 2 cups daily of cooked brown rice
- tofu
- a maxiumum of two tablespoons per day of tahini (sesame paste)
- 2 cups daily of low-fat or nonfat milk or soy milk
- 6 oz (170 g) of low-fat yogurt, maximum of 12 oz (340 g) daily
- a maximum of two pickles per day
- one–two teaspoons of low-fat virgin olive oil for grilling vegetables
- low-fat dressing, no more than three tablespoons per salad

## KEY TERMS

**Anaerobic exercise**—Brief, strength-based activity, such as sprinting or weight training, in which anaerobic (without oxygen) metabolism occurs in the muscles.

**Body mass index**—BMI, a measure of body fat determined from the ratio of one's weight in kg to the square of one's height in meters; the BMI from weight in lb and height in inches is determined from tables; an adult BMI of 25—29.9 is considered overweight and 30 or above indicates obesity.

**Detoxification**—Detox; cleansing; to remove toxins or poisons from the body.

**Fiber**—Roughage; a complex mixture found in plant foods that includes the carbohydrates cellulose, hemicellulose, gum, mucilages, and pectins, as well as lignin.

**Glycemic index**—GI; a measure of the rate at which an ingested carbohydrate raises the glucose level in the blood.

- herbs and spices
- hot-air popcorn without butter or margarine
- a maximum of two tablespoons per day of artificial sweetener
- 2 cups daily of unsweetened decaffeinated herbal or green tea
- unlimited water.

Foods prohibited during phase 1 include:

- meat
- bread
- cheese, including soy cheese
- fried food
- nuts
- fast food
- desserts
- soda
- coffee
- alcohol.

Canned foods should be rinsed thoroughly to remove excess salt.

Although phase 1 lasts only nine days, dieters can choose to stay with phase 1 for one to two extra weeks or longer.

**PHASE 2—THE FOUNDATION.** In phase 2 the quantity of food is increased slightly and exercise is increased by 10–15% over phase 1, to 35 minutes five times per week. Weight lifting and other types of anaerobic exercise are not recommended during phase 2.

Foods added during phase 2 include:

- 3–4 oz (85–110 g) daily of lean meat, turkey, chicken, or fish (no pork)
- an additional one-half cup of unsweetened hot cereal
- one and one-half cups of unsweetened cold cereal such as shredded wheat
- one whole egg daily
- 1 oz (28 g) of cheese
- 2 teaspoons of peanut butter
- one-half avocado
- up to four teaspoons of sugar or artificial sweetener or one tablespoon of honey per day
- up to two teaspoons of salt per day and unlimited herbs and spices.

**PHASE 3—THE CONSTRUCTION.** The four-week construction phase requires at least four meals per day. It adds **protein** and whole grains to the diet, allows for larger portions, and continues ample amounts of fruits and vegetables. Exercise levels are increased by another 25% to 45 minutes daily. Smith recommends exercising twice per day several days per week to boost metabolism.

Phase 3 allows:

- up to 5 oz (140 g) of meat daily, although seafood remains at 3 oz (85 g)
- two whole eggs daily
- four thin slices of wholegrain bread daily
- additional brown rice
- 1 cup of whole-wheat pasta
- up to 16 oz (475 ml) of fresh-squeezed fruit juice
- up to 3 cups of skim or soy milk daily
- 1.3 oz (37 g) of low-fat or fat-free cheese daily
- fat-free mayonnaise
- one daily dessert—one scoop of low-fat ice cream or two–three oreo-sized chocolate-chip or oatmeal-raisin cookies or graham crackers
- 2 cans of diet soda daily
- 10 oz (300 ml) of coffee.

Smith recommends that the phase 1 regimen be followed at least one day a week during phase 3 to expedite weight loss. If weight-loss goals have not been reached by the end of phase 3, phases 1–3 can be repeated as many times as necessary.

**PHASE 4—THE TEMPLE.** Any and all foods are allowed during the maintenance phase 4 including:

- white starches such as potatoes and white rice in limited amounts
- three glasses of wine or beer per week.

Phase 4 includes one hour of moderate to intense exercise, including weight training, five times per week. If weight is regained, the dieter can return to phase 1 for about a week.

### *Extreme fat smash*

Smith's extreme fat smash diet is an alternative to the fat smash diet for people who want to lose weight rapidly by raising their metabolism, with a goal of losing up to 12 lb (5.4 kg) in the first three weeks. He writes: 'Extreme fat smash is for people who are determined to reach what they might've considered unthinkable success in a weight-loss journey. The idea is simple: if you want big results, then you'll have to push yourself beyond the normal limits to attain them.'

Like the original fat smash, extreme fat smash utilizes healthy foods and relies on portion control—eating only to satisfy hunger, with the knowledge that another meal or snack will be coming soon. It differs

from the fat smash in that it requires organizing the day around meals and exercise:

- The diet is very specific and must be followed exactly.
- Meals and snacks are on a schedule that must be followed exactly.
- Meals are simple but repetitive.
- The diet includes increased fiber and foods with a lower glycemic index (GI) to stabilize blood sugar levels.
- It includes a 40-minute workout with a specific exercise program for conditioning the heart, muscles, and lungs.

The book *Extreme Fat Smash Diet* includes:

- 75 simple recipes for easily-prepared meals
- tips and strategies for sticking to the diet
- a newly designed maintenance plan
- meal plans and corresponding journal pages.

The extreme fat smash diet consists of three one-week cycles:

- The first cycle is a very strict diet with a set menu. Some fruits, such as bananas and pineapples, are prohibited.
- The second cycle adds back some fruit, bread, and peanut butter that were not allowed in the first week.
- The third cycle, although still a strict diet, is more flexible.

At the end of the three weeks, the dieter has the option of repeating the three cycles to lose more weight or of entering the maintenance phase. The same cycle cannot be followed for two weeks in a row.

There is an extensive snack food list that includes:

- fruit
- popcorn
- chocolate.

Unlike the original fat smash, the cycles are adjusted for individual body types, dieting profiles, and weight-loss goals of 5 lb (2.3 kg), 10 lb (4.5 kg), or 15 lb (7 kg) and up. For example an active person who has healthy eating habits but still can't lose weight should:

- increase the cardiovascular exercise by 10 minutes on some days
- reduce the carbohydrate option by one-half cup on some days
- consume fewer calories.

## Function

The fat smash diet is designed to make small but significant adjustments in food consumption and in attitudes toward food and physical activity. It can be followed easily by vegetarians and vegans as well as meat lovers. It is a diet for people who eat too much junk food and are not used to exercising very much; for people who need to lose anywhere from 50–100 lb (23–46 kg) or more. It is probably too strict a diet for active people with only a few pounds to lose.

The extreme fat smash diet is for people who want to lose 10–25 lb (4.5–11 kg) in a healthy manner in a short period of time and to maintain the weight loss.

## Benefits

The fat smash diet is a healthy, well-balanced, and flexible plan. It is a sustainable diet that allows unlimited fruits and vegetables and relies on regular inexpensive foods. Its calorie control, via portion control, and emphasis on exercise should lead to weight loss. Smith claims that people can lose from 6—10 lb (3—5 kg) during phase 1. He further claims that the fat smash diet:

- detoxifies the body
- promotes rapid weight loss
- teaches sustainable weight-maintenance skills
- reduces the risk of diet-related disease
- leads to a healthier lifestyle.

Portion control is a key to the fat smash diet and Smith claims that even people who eat unhealthy foods can lose 10–15 lb (5–7 kg) in a year by practicing portion control—eating smaller meals that still satisfy hunger—without making any other changes.

## Precautions

The fat smash diet may be difficult for some people to adhere to, particularly during the nine-day detoxification phase. The weight loss in phase 1 is due to its severe **calorie restriction**. There is little allowance for occasional indulgences. Eating out is almost impossible during phases 1 and 2. The recipes in the book are sometimes inconsistent, with some phase 1 recipes containing prohibited ingredients.

The extreme fat smash may be too extreme and inflexible for many people.

## Risks

The fat smash plan is a healthy well-balanced diet that should have few health risks. The extreme fat

## QUESTIONS TO ASK YOUR DOCTOR

- Is the fat smash diet plan a reasonable approach for me to lose weight?
- How much weight do I need to lose?
- Should I make any adjustments in following the plan?
- Should I take any vitamins or other supplements while on this plan?
- Is the exercise required by the plan suitable for me?
- Is the extreme fat smash diet a healthy option for me?

smash diet may be too rapid a weight loss for some people.

## Research and general acceptance

### *Research*

With its emphasis on fruits and vegetables, whole-grain foods, lean meats, portion control, and physical activity, the fat smash diet is considered to be scientifically sound. Tara Gidus of the American Dietetic Association told *AOL Diet & Fitness*: 'It helps people eat more low-calorie, nutrient dense foods, exercise more and get rid of unhealthy habits. I love that it encourages so much aerobic exercise.' Although the fat smash detox is relatively moderate, there is no scientific evidecne to show a person can detoxify their body through diet.

Most research suggests that slow, gradual, and consistent weight loss is the healthiest way to lose weight and increases the likelihood of maintaining the weight loss.

### *General acceptance*

Although *The Fat Smash Diet* earned mixed reviews among diet critics, Ian Smith enjoys a high degree of credibility among his audience. He is a Harvard-trained medical doctor and on the board of directors of the American Council on Exercise. Before joining the *Celebrity Fit Club* Smith was medical correspondent for the *Today* show and NBC News. Millions of viewers have watched celebrities lose as much as 41 lb (19 kg) in a season of *Celebrity Fit Club*. Thus Smith's legions of fans have been accepting of his diet plan.

On April 7, 2007, Dr. Ian, as he is commonly called, launched the '50 Million Pound Challenge.' Aimed primarily at the black community, he called on five million people to lose 10 lb (4.5 kg) each.

# Fats

## Definition

Fats are also known as lipids. A lipid is a substance that is poorly soluble or insoluble in **water**. The term 'dietary fat' encompasses many different types of fat. Over 90% of dietary fats are called triacylglycerols or **triglycerides**. Other dietary fats include cholesterol.

Triacylglycerols contain three fatty acids attached to a glycerol molecule. Fatty acids vary according to their length, which is composed of carbon and hydrogen atoms joined together to form a hydrocarbon chain. The number of double bonds that occur between the carbon molecules also varies. The chemical structure of each type of fatty acid determines its physical characteristics and its nutritional and physiological function. Regardless of the type of fatty acid present, all triacylglycerols provide 9 kcal (37 KJ) per gram; this makes fat the most concentrated source of energy in the diet. Fatty acids should provide no more than 30–35% of dietary energy or approximately no more than 70 g a day for women and no more than 90 g a day for men.

Typical high sources of fat in the diet include cooking fats and oils, fried food, fatty and processed meats. These should form a very small part of the diet. Care should be taken to reduce fried foods; avoid adding fats and oils during cooking; to grill food, which allows fat to drip out; and to choose lean meats and low fat dairy products. A product is thought to be low in fat if it contains less than 3 g fat per 100 g and high in fat if it contains more than 20 g fat per 100 g or 21 g fat per serving.

## Purpose

Some types of fatty acids are essential nutrients. They must be consumed in the diet for the body to function properly. Fats form the structure of cell membranes, they are involved in the transport, breakdown and excretion of cholesterol and they are the building blocks for many important compounds such as hormones, blood clotting agents, and compounds involved in immune and inflammatory responses. Fats also transport fat soluble **vitamins** and **antioxidants**; provide the body with insulation and form a protective layer around organs; are a structural component of the brain and nervous system; and provide a reserve supply of energy in the form of adipose tissue (body fat). Excess amounts of adipose tissue defines **obesity** and may lead to health problems such as diabetes, **cancer** and heart disease.

## Description

### *Saturated fatty acids*

Saturated fatty acids have a hydrocarbon chain where each carbon atom carries its maximum number of hydrogen atoms except for the end carboxyl group and they do not have any double bonds. The molecules are straight, allowing them to pack closely together. For this reason, they are solid at room temperature with a high melting point. Saturated fatty acids are chemically stable both within the body and in food.

Saturated fatty acids are named according to the number of carbon atoms they contain. Each one has a common name (e.g., stearic acid), a systematic name (e.g., octadecanoic acid because stearic acid has 18 carbon atoms), and a notational name (e.g., 18:0 as stearic acid has 18 carbon atoms but no double bonds).

Animal products such as meat fat, dripping, lard, milk, butter, cheese and cream are the primary sources of saturated fatty acids. Most plant products have a lower amount of saturated fat with the exception of coconut and palm oil.

**SATURATED FATTY ACIDS AND HEALTH.** Saturated fatty acids increase the body's levels of cholesterol, including low density lipoprotein (LDL) cholesterol. LDL cholesterol is commonly known as 'bad' cholesterol. High levels of LDL cholesterol in the blood increase the risk of cardiovascular disease. LDL cholesterol transports excess cholesterol through the bloodstream where it can become deposited in the walls of the arteries and form a hardened plaque. This is called atherosclerosis. This thickening of the artery walls reduces the flow of blood supplying the heart, brain, and other organs. A heart attack or stroke is caused by a blood clot blocking these narrowed arteries. Saturated fatty acids also contribute to production of these blood clots as they are converted into substances that can increase the stickiness of the blood and increase its tendency to clot. For this reason **dietary guidelines** recommend that no more than 10% of dietary energy should come from saturated fatty acids. This means that on a daily basis approximately no more than 22 g saturated fat should be consumed

**Fats**

| Type of fat | Dietary source | Effect on cholesterol | How often to choose |
|---|---|---|---|
| Trans fat | • "Hydrogenated" or "partially hydrogenated" oils<br>• Vegetable shortenings, stick margarine, deep fried foods, some fast foods and snack foods (i.e., cookies and crackers) | Raises LDL | Less often |
| Saturated fat | • Tropical oils such as palm and coconut oils, cocoa butter, coconuts and coconut milk<br>• Red meat, the skin from chicken and other birds, butter, whole milk and milk products (i.e., cheese and ice cream) | Raises LDL | Less often |
| Monounsaturated fat | • Avocados, olives, certain nuts<br>• Olive, canola, and peanut oils | Lowers LDL when substituted for saturated fat | More often |
| Polyunsaturated fat (includes omega-3 and omega-6 fatty acids) | • Plant oils like corn, sunflower, and safflower<br>• Fish (especially salmon, trout, and herring)<br>• Flaxseed oil | Lowers LDL when substituted for saturated fat | More often |

by a woman consuming 2,000 calories a day and no more than 28 g saturated fat should be consumed by a man consuming 2,500 calories a day. A product is considered low in saturated fat if it contains less than 1.5 g per 100 g and high in saturated fat if it contains more than 5 g of fat per 100 g.

### *Monounsaturated fatty acids*

Monounsaturated fatty acids have a hydrocarbon chain that contains one unsaturated carbon bond that is not fully saturated with hydrogen atoms. Instead, it has a double bond to the adjoining carbon atom. Double bonds are either in a *cis* or *trans* formation. In the *cis* formation the hydrogen atoms bonded to the carbon atoms in the double bond are positioned on the same side of the double bond. This creates a kink in the hydrocarbon chain. There is also a free electron or slightly negative charge surrounding the double bond causing them to repel each other. The molecules are not packed closely together and become liquid (oil) at room temperature. In the *trans* formation the hydrogen atoms are on opposite sides of the carbon-carbon double bond resembling the characteristics of a saturated fatty acid. There is less kinking of the hydrocarbon chain and the fat is more solid at room temperature. *trans* bonds are rarely seen in nature.

Monounsaturated fatty acids are named according to the number of carbons they contain and the position of their double bond. Like saturated fatty acids, they each have a common name, a systematic name, and a notational name. Fatty acids with double bonds in the ninth position are sometimes called n-9s or omega-9s.

The most concentrated sources of monounsaturated fatty acids in the diet are olive oil and rapeseed oil. They are present in many other foods including nuts and seeds, avocados, eggs, fish and meat fat.

**MONOUNSATURATED FATTY ACIDS AND HEALTH.** Monounsaturated fatty acids reduce the level of total and LDL cholesterol. It also has a significant effect on increasing and maintaining the body's level of high density lipoprotein (HDL) cholesterol. HDL cholesterol is commonly known as 'good' cholesterol because it removes cholesterol from the blood transferring it to body tissues where it is used to make hormones and other substances the body needs. Therefore, higher levels of HDL cholesterol are associated with a reduction in the risk of cardiovascular disease. Between 10–20% of dietary energy should come from monounsaturated fat.

### *Polyunsaturated fatty acids*

Polyunsaturated fatty acids have a hydrocarbon chain containing two or more double bonds not fully saturated with hydrogen atoms. The double bonds may either be in the *cis* or *trans* formation. The majority of naturally occurring polyunsaturated fats are in the *cis* form. In this form the hydrogen atoms bonded to the carbon atoms in the double bond are positioned on the same side of the double bond. This creates a kink in the hydrocarbon chain. There is also a free electron or slightly negative charge surrounding the double bond causing them to repel each other. The molecules are not packed closely together and become liquid (oil) at room temperature. The presence of one or more double bonds with free electrons and a negative charge makes them unstable molecules ready to

## KEY TERMS

**Antioxidant**—A chemical that has the ability to neutralize free radicals and prevent damage that would otherwise occur through oxidation.

**Atherosclerosis**—A thickening of the artery walls that impedes the flow of blood supplying the heart, brain, and other organs.

**Bile acids**—Produced by the liver, from cholesterol, for the digestion and absorption of fat.

**Carboxyl group**—The carbon atom at the end of a fatty acid hydrocarbon chain is attached by a double bond to oxygen and by a single bond to hydrogen forming the chemical structure carboxyl.

***cis* formation**—The arrangement of atoms where hydrogen atoms sit on the same side of the carbon to carbon double bond.

**Electron**—A component of an atom or molecule. It has a negative charge when a free or unpaired electron exists making it chemically unstable and likely to initiate chemical reactions.

**Essential fatty acid**—A molecule that cannot be made by the body and must be supplied by food in order to prevent deficiency.

**Fatty acid**—A molecule consisting of mainly carbon atoms joined together to form a carbon chain to which hydrogen atoms are attached. Fatty acids vary according to their degree of saturation (i.e., the number of hydrogen atoms attached and the length of the hydrocarbon chain).

**High density lipoprotein (HDL)**—One of several proteins in the blood that transports cholesterol to the liver and away from the arteries.

**Hydrogenated**—Usually refers to partial hydrogenation of oil, a process where hydrogen is added to oils to reduce the degree of unsaturation. This converts fatty acids from a *cis* to *trans* fatty acids.

**Omega-3**—Polyunsaturated fatty acid where the first double bond occurs on the third carbon-to-carbon double bond from the methyl end of the hydrocarbon chain.

**Omega-6**—Polyunsaturated fatty acid where the first double bond occurs on the sixth carbon-to-carbon double bond from the methyl end of the hydrocarbon chain.

**Omega-9**—Polyunsaturated fatty acids where the first double bond occurs on the ninth carbon-to-carbon double bond from the methyl end of the hydrocarbon chain.

**Oxidation**—A chemical reaction in which electrons are lost from a molecule or atom. In the body these reactions can damage cells, tissues, and deoxyribonucleic acid (DNA) leading to cardiovascular disease or cancer.

***trans* fatty acids**—Monounsaturated or polyunsaturated fats where the double bonds create a linear formation. They are formed largely by the manufacture of partial hydrogenation of oils, which converts much of the oil into *trans* fat. Hydrogenated fats and *trans* fats are often used interchangably.

react with other chemicals. Polyunsaturated fatty acids are susceptible to chemical changes or oxidation within food leading to cell damage in the body.

Polyunsaturated fatty acids are named similar to other fatty acids. They have a common name, a systematic name, and a notational name. Fatty acids with double bonds starting in the sixth position are commonly known as n-6s or omega-6s.

**POLYUNSATURATED FATTY ACIDS AND HEALTH.** Polyunsaturated fatty acids are divided into two groups, omega-6s and omega-3s. There is one essential fatty acid in each of these groups from which all other fatty acids can be made in the human body. These essential fatty acids cannot be made by the body and must be obtained from the diet. They are a necessary component of the diet; without them deficiency symptoms and poor health would result. Linoleic acid (omega-6) and alpha-linolenic acid (omega-3) are the essential fatty acids. Linoleic acid should provide at least 1% of dietary energy and alpha-linoleic acid should provide 0.2% dietary energy. These essential fatty acids are converted into longer chain fatty acids that form important substances in the body such as hormones, blood clotting agents, and compounds involved in immune and inflammatory responses.

These long chain fatty acids are not technically essential, but they have an important role in the body. Examples of long chain fatty acids include arachadonic acid (AA), eicosapentaenoic acid (EPA), and docosahexanoic acid (DHA). Long chain **omega-3**

**fatty acids** become essential if there is insufficient linoleic and aplha-linolenic acid available in the diet. These fats play a significant role in development of the brain, nervous system, and retina in fetal development and early life.

**OMEGA-6.** The most concentrated sources of omega-6 in the diet is vegetable oils, such as sunflower, safflower, corn, cottonseed, canola, and soya oils. They are also present in plant seeds, nuts, vegetables, fruit and cereals. In addition to being a source of linoleic acid, omega-6s have been shown to have a lowering effect on both LDL and HDL cholesterol. However, there are health concerns with excessive omega-6 intakes. Omega-6 fats are susceptible to oxidation within the body and may contribute to tissue damage that leads to atherosclerosis and cancer. Omega-6 fats should contribute no more than 10% of dietary energy. Antioxidant nutrients such as **vitamin E** are required to reduce this oxidation with higher intakes of omega-6 fats. Omega-6s compete with the more beneficial omega-3 fatty acids, so it is recommended that the omega-6:omega-3 ratio is reduced to 4:1.

**OMEGA-3.** Short chain omega-3 fats are found in **flaxseed** or linseed oil, walnut oil, canola oil, and rapeseed oil. The best sources of long chain omega-3s are fish and fish oil.

Evidence suggests that consuming long chain omega-3 fats has cadiovascular health benefits. This believed to be the result of their anti-clotting effect. Growing evidence also suggests that consuming long chain omega-3s has benefits beyond those achieved when consuming shorter chain fatty acids. The United Kingdom's government Food Standards Agency recommends that oily fish be consumed at least once a week.

There has been much interest in the effect of EPA and DHA deficiency and supplementation on behavior in children, particularly those with learning difficulties. Although there is some evidence of benefit with EPA, in 2006 the U.K. Food Standards Agency concluded that there was insufficient evidence to reach a firm conclusion and additional clinical trials were needed.

There is also interest in the anti-inflammatory properties of long chain omega-3s in inflammatory conditions such as Crohn's disease and rheumatoid arthritis. The role of omega-3s has been evaluated in treatment of depression and prevention of cognitive decline but more research is needed to confirm these benefits.

Omega-3 fats have been shown to reduce blood pressure and triglyceride levels (another fat in the blood that contributes to raising the risk of cardiovascular disease). To achieve these benefits, omega-3s must be taken in pharmacological doses and there are small risks associated with these high doses such as raised LDL cholesterol, poor control of diabetes, and increased risk of bleeding. Large doses of omega-3s should only be taken under the supervision of a qualified medical doctor.

### *Trans fatty acids*

***Trans* fatty acids** are monounsaturated or polyunsaturated fatty acids where the double bond is in the *trans* rather than *cis* formation. They occur naturally in small amounts in lamb, beef, milk, and cheese as they are created in the rumen of cows and sheep. The majority of *trans* fat in the diet comes from the partial hydrogenation of vegetable oils. This is a process in food manufacture that adds hydrogen atoms to unsaturated fatty acids so that oils become more hardened at room temperature. The process results in some of the double bonds of the fatty acid molecules becoming saturated and some of the remaining double bonds changing from a *cis* to a *trans* formation. For example, when partially hydrogenated oleic acid becomes elaidic acid or 9 *trans*-octadecenoic acid. *Trans* fats are semi-solid at room temperature and more stable within food. Partial hydrogenation of oils has traditionally been used to develop spreading fats and margarines, for fast food, and in cakes and biscuits. Manufacturers are using it less because of the health problems associated with it. In 2006, New York City adopted the United States' first major ban on all but trace amounts of artificial *trans* fats in restaurant cooking. As of July 2008, a serving of food must not contain more than half a gram of *trans* fat. Food legislation in the United States and the European Union states that hydrogenated or partially hydrogenated fats must be labeled in the ingredients of food and in some cases the amounts of *trans* fat must also be labeled.

***TRANS* FATTY ACIDS AND HEALTH.** *Trans* fat raises LDL cholesterol in a similar way to saturated fat and it reduces HDL cholesterol. It may also raise blood triglyceride levels. The combination of both these effects means that it is most likely to increase cardiovascular risk. The World Health Organization recommends phasing out *trans* fat in food manufacture and reducing *trans* fat consumption to no more than 1% of dietary energy or 2.5 g per day.

### *Cholesterol*

Cholesterol is essential to the structure of cell membranes and production of bile acids for digestion, steroid hormones, and **vitamin D**. **Dietary cholesterol**

## QUESTIONS TO ASK YOUR DOCTOR

- Why or why wouldn't you recommend a full lipid profile for me?
- What is my cholesterol level? Is it within a normal range?
- What is my risk of heart disease or stroke?

has little effect on blood cholesterol levels because an increased dietary intake reduces the amount the body produces. Only extreme dietary levels of cholesterol need to be restricted. For most individuals, dietary measures that reduce saturated fat also avoid excessive cholesterol consumption. However, individuals with familial hypercholesterolemia may need to consume less than 300 mg/day, which requires avoidance of most animal products.

The most concentrated dietary sources of cholesterol include liver, offal, and products made from egg yolk, mayonnaise, fish roes, and shellfish.

### Precautions

The guidelines for the recommended levels of dietary fat is not appropriate for those under two years of age, for those who are ill or malnourished, or for those diagnosed with **anorexia nervosa**.

### Parental concerns

A study conducted by the International Study of Asthma and Allergies in Childhood (ISAAC) found a strong correlation between *trans* fatty acids and increased occurrence of allergies in adolescents. Parents should provide healthy alternatives to foods containing fatty acids and monitor the amount and type of fats consumed in their diet. These preventative measures help avoid serious health problems including heart disease and stroke that can result from high levels of fatty acids in the diet.

# Fen-Phen

## Definition

Fen-Phen was an anti-obesity regimen composed of fenfluramine or the closely related drug dexfenfluramine (marketed under the brand name Redux) and phentermine (sold under several brand names including Adipex-P, Anoxine-AM, Fastin, Ionamin. Obephen, Obermine, Obestin-30 and Phentrol). The combination was found to cause damage to heart valves, and fenfluramine and dexfenfluramine were removed from the United States market in 1997.

## Purpose

The combination of these two drugs had been reported to be significantly more effective than placebo in promoting weight loss when used in combination with diet, exercise and behavior modification.

## Description

Phentermine was first approved for use by the United States Food & Drug Administration (FDA) in 1959. It's claimed advantage over other appetite suppressants available at the time was a reduced risk of abuse. While the drug was chemically related to the amphetamines, with the same side effects, the incidence of these side effects was reportedly lower than with the amphetamines.

Fenfluramine was approved by the FDA in 1973 and dexfenfluramine (Redux) was approved for use in 1996. Fenfluramine is the racemic form of dexfenfluramine. The drugs were approved for short term use as part of a program of diet and exercise. Although fenfluramine is chemically related to the amphetamines, its action appears to be based on increasing levels of *serotonin* in the brain and blood stream. Ddexfenfluramine had been marketed in Europe for over a decade without detection of an association between dexfenfluramine and heart valve problems, however the FDA noted that the number of patients having heart valve problems was very low compared to the total number of patients using the drug, and heart valve screening is not a routine part of drug monitoring.

Neither fenfluramine nor phentermine had been approved for use in long term treatment or combination therapy. The drugs were indicated only as short term adjuncts in patients with **obesity**.

In 1992, a research group from the University of Rochester published reports indicating that the combination of fenfluramine and phentermine might be a valuable adjunct to diet and exercise in a controlled program of weight loss. A total of 121 patients were initially enrolled in the study, and 9 dropped out during the active study period. After the first 34 weeks of the study, patients on the fen-phen regimen had lost an average of 14.2 Kg, compared with a 4.9 Kg. weight loss in the placebo control group. The researchers noted that upon discontinuation of the drugs, patients regained most of the weight lost during the study, and after 210 weeks, the agerage weight loss was only 1.4 Kg below the baseline. Patients who had received active drug tended to regain weight more rapidly than those who received placebo. The authors concluded that despite long periods of time at weights much lower than baseline, permanent resetting of weight control mechanisms could not be shown for most participants.

In spite of the disappointing long term results, these reports lead to the wide use of the fen-phen regimen for people attempting to lose weight. In

## KEY TERMS

**Anorectic**—A drug which suppresses the appetite.

**Dexfenfluramine**—An anorectic drug formerly marketed under the brand name Redux.

**Etiology**—The cause of a disease or medical condition.

**Fenluramine**—An anorectic drug formerly marketed under the brand name Pondimin.

**Fluoxetine**—An antidepressant drug, sold under the brand name Prozac

**Fluvoxamine**—An antidepressant drug sold under the brand name Luvox

**Indicated**—In medical terminology, reviewed and approved by the United States Food & Drug Administration, or the comparable agency in other nations, for a specific use.

**Mono-amine oxidase inhibitor**—A class of antidepressant drugs that act by blocking an ezyme that destroys some of the hormones in the bRain. These drugs have a large number of food and drug interactions.

**Mitral valve**—a heart valve, also called the *bicuspid valve* which allow blood to flow from the left auricle to the ventricle, but does not allow the blood to flow backwards.

**Paroxetine**—An antidepressant drug sold under the brand name Paxil

**Phentermine**—An anorectic drug sold under a large number of brand names

**Primary pulmonary hypertension**—Abnormally high blood pressure in the arteries of the lungs, with no other heart disease causing this problem.

**Racemic**—A chemical term, relating to the way a compound turns a bean of light. Racemic compounds are composed of equal amounts of left turning and right turning molecules. Molecules which turn a beam of light to the right are *dextrorotatory* while those which turn a beam to the left are *levorotatory*.

**Regurgitational valvular heart disease**—A type of damage to the heart valves which allows blood to leak back through the valve.

**Serotonine**—A hormone that stimulates brain cells and also causes blood vessels to constrict.

**Sertraline**—An antidepressant drug sold under the brand name Zoloft

1996, fenfluramine was the 46th most frequently prescribed drug in the United States. with sales of $176 million per year (roughly $209 million in 2006 dollars). No long term studies were performed for these dtrugs, and they were never approved for use in combination therapy.

On July 8, 1997, *The New England Journal of Medicine* published a report from the Mayo Clinic describing 24 cases of *regurgitational valvular heart disease* in women who had been treated with fenfluramine and phentermine. By September 30th, the FDA had received a total of 144 reports of heart value problems associated with fenfluramine, with or without phentermine.

On November 19, 1997, the Centers for Communicable Disease Cintrol published a review of the cases of heart valve damage associated with fenfluramine:

*. . . Of these 113 cases, 111 (98%) occurred among women; the median age of case-patients was 44 years (range: 22 68 years). Of these 113 cases, two (2%) used fenfluramine alone; 16 (14%), dexfenfluramine alone; 89 (79%), a combination of fenfluramine and phentermine; and six (5%), a combination of all three drugs. None of the cases used phentermine alone. The median duration of drug use was 9 months (range: 1 39 months). Overall, 87 (77%) of the 113 cases were symptomatic. A total of 27 (24%) case-patients required cardiac valve-replacement surgery; of these, three patients died after surgery….*

The Food & Drug Admibnistration removed fenfluramine from the market. Approximately 18,000 people sued American Home Products, which had marketed the drug, to recover damages, either from the costs of actual injuries, or the cost of tests to determine whether any damage had been done. In a class action lawsuit, American Home Products agreed to establish a trust fund with a reported value of $3.75 billion, with the money to be distributed among victims of the drug, depending on extent of injury. People exposed to fenflursamine will be monitored for heart valve problems for a period of 20 years.

Although fen-phen has been associeted with another very important adverse effect, *primary pulmonary hypertension*, the focus of all regulatory and legal problems has been on the heart valve problems associated with the drug.

## Precautions

Phentermine hydrochloride tablets and capsules are indicated only as short-term monotherapy for the management of exogenous obesity. The safety and efficacy of combination therapy with phentermine and any other drug products for weight loss, including selective serotonin reuptake inhibitors (eg, fluoxetine, sertraline, fluvoxamine, paroxetine), have not been established. Therefore, coadministration of these drug products for weight loss is not recommended.

Serious regurgitant cardiac valvular disease, primarily affecting the mitral, aortic and tricuspid valves, has been reported in otherwise healthy persons who had taken a combination of phentermine with fenfluramine or dexfenfluramine for weight loss. The etiology of these valvulopathies has not been established and their course in individuals after the drugs are stopped is not known. The possibility of an association between valvular heart disease and the use of phentermine alone cannot be ruled out; there have been rare cases of valvular heart disease in patients who reportedly have taken phentermine alone.

Tolerance to the anorectic effect usually develops within a few weeks. When this occurs, the recommended dose should not be exceeded in an attempt to increase the effect; rather, the drug should be discontinued.

## Interactions

Phentermine hydrochloride may decrease the hypotensive effect of guanethidine.

Mono-amine oxidase inhibitors (MAOIs) may increase the pressor response to the anorexiants. Possible hypertensive crisis and intracranial hemorrhage may occur. This interaction may also occur with furazolidone, an antimicrobial with MAOI activity. Avoid combining with phentermine hydrochloride. There should be a 14 day interval between use of any MAOI and phentermine.

## Aftercare

For those patients who had been exposed to fenfluramine, aftercare depends on the extent of damage. For those patients with significant heart valve damage, surgical valve replacement may be in order. Those who received the drug but show no damage should be monitored by a cardiologist for the possibility of late onset damage.

Although phentermine alone has been associated with rare instances of valvular heart disease, there are no recommendations for routine aftercare or monitoring.

## Parental concerns

Phentermine is not indicated for patients under the age of 16 years.

# Fiber

## Definition

Fiber is found only in foods of plant origin. It occurs in the skins, seeds, leaves and roots of fruits and vegetables, and in the germ and bran layers of grains. Pectins, lignans, cellulose, gums and mucilages are all different forms of fiber found in these foods. Because humans lack the digestive enzymes to break down fiber, it passes through the digestive tract largely unchanged.

## Purpose

Depending on the type, fiber may either slow down or speed up the passage of food through the digestive tract. It contributes to stool bulk and stimulates the colon walls to contract. Foods rich in soluble fiber are often recommended to help improve blood glucose and cholesterol levels, while diets containing high amounts of insoluble fiber are known to contribute to bowel regularity and the prevention of diverticular disease. Since high-fiber diets tend to be satisfying but relatively low in calories, they are often promoted for weight management.

## Description

Dietary fiber belongs to one of two types, depending on whether or not it is able to dissolve in **water**. Fiber that dissolves in water is called *soluble*, while fiber that cannot be dissolved in water is known as *insoluble*. Upon ingestion, soluble fiber dissolves in the fluids secreted by the digestive tract, forming a gel. This gel moves slowly through the digestive tract, thus slowing the rate of digestion and absorption. Diets containing large amounts of soluble fiber have been shown to stabilize blood sugar levels in people with diabetes, and have been shown to reduce blood levels of unhealthy (LDL) cholesterol. Foods high in soluble fiber include beans, lentils, oats, psyllium, citrus fruits, barley and apples. In contrast, insoluble fiber acts as roughage. It contributes to stool bulk and promotes regularity. Foods rich in insoluble fiber include wheat bran, whole grains, dried beans, nuts, seeds, and those fruits and vegetables with an edible outer skin or seeds.

In 2001, the Food and Nutrition Board of the Institute of Medicine established its first recommendations for fiber intake. The recommendations are based on the findings of numerous studies showing a reduced risk of heart disease and type 2 diabetes with a daily fiber intake of approximately 14 grams for every 1,000 calories consumed. For adults who are 50 years of age and younger, the recommended fiber intake is 38 g/day for men and 25 g/day for women. For adults over 50 years of age, the recommendation is 30 g/day for men and 21 g/day for women.

On average, North Americans consume less than 50% of the dietary fiber recommended for good health.

**Fiber**

| Age | Recommended Intakes (g/day) |
|---|---|
| Children 1< yr. | Not established |
| Children 1–3 yrs. | 19 |
| Children 4–8 yrs. | 25 |
| Boys 9–13 yrs. | 31 |
| Girls 9–13 yrs. | 26 |
| Boys 14–18 yrs. | 38 |
| Girls 14–18 yrs. | 26 |
| Men 19–50 yrs. | 38 |
| Women 19–50 yrs. | 25 |
| Men 50> yrs. | 30 |
| Women 50> yrs. | 21 |
| Pregnant women | 28 |
| Breastfeeding women | 29 |

| Food | Fiber (g) |
|---|---|
| Beans, lima, fresh, cooked, ½ cup | 6.6 |
| Beans, baked, canned, plain, ½ cup | 6.3 |
| Beans, black, cooked, ½ cup | 6.1 |
| Beans, kidney, fresh, cooked, ½ cup | 5.7 |
| Winter squash, cooked, 1 cup | 5.7 |
| Spaghetti, whole wheat, plain, 1 cup | 5.6 |
| Cereal, bran flake, ¾ cup | 5.3 |
| Cereal, shredded wheat, 1 cup | 5.2 |
| Pear, raw, 1 med. | 5.1 |
| Turnips, cooked, ½ cup | 4.8 |
| Rice, brown, cooked, 1 cup | 3.5 |
| Apple, raw, with skin, 1 med. | 3.3 |
| Oatmeal, plain, cooked, ¾ cup | 3.0 |
| Broccoli, fresh, cooked, ½ cup | 2.6 |
| Summer squash, cooked, 1 cup | 2.5 |
| Carrot, fresh, cooked, ½ cup | 2.3 |
| Potato, fresh, cooked, 1 | 2.3 |
| Spinach, fresh, cooked, ½ cup | 2.2 |
| Brussels sprouts, fresh, cooked, ½ cup | 2.0 |
| Bread, whole-wheat, 1 slice | 1.9 |
| Tangerine, raw, 1 med. | 1.9 |
| Cauliflower, fresh, cooked, ½ cup | 1.7 |
| Cabbage, fresh, cooked, ½ cup | 1.5 |
| Peach, raw, 1 med. | 1.5 |
| Asparagus, fresh, cooked, 4 spears | 1.2 |
| Romaine lettuce, 1 cup | 1.2 |
| Peanuts, dry roasted, 1 tbsp. | 1.1 |
| Tomato, raw, 1 | 1.0 |
| Rice, white, cooked, 1 cup | 0.6 |
| Almonds, slivered, 1 tbsp. | 0.6 |

g = gram

## Potential Benefits

- A high fiber intake promotes bowel health by preventing constipation and diverticular disease.

- High-fiber diets may assist with weight management because they tend to be satisfying without being calorie-dense.
- Soluble fiber has been shown to help lower blood cholesterol by binding to cholesterol molecules in the digestive tract, thus encouraging their elimination from the body.
- High consumption of fiber-rich whole grains is associated with a lower risk of developing type 2 diabetes.
- Soluble fiber slows the emptying of food from the stomach to the small intestine, thus causing a gradual release of glucose into the bloodstream after a meal. For this reason, a diet high in soluble fiber may promote better blood sugar management in those with diabetes.
- A low-fat, high-fiber diet combined with daily exercise appears to be associated with a reduced risk of developing breast cancer.
- Studies investigating whether a high-fiber diet is protective against colon cancer are inconclusive. Those that support the protective effect of fiber suggest that fiber encourages the movement of food waste through the bowel, possibly reducing the body's exposure to carcinogens in the waste products.
- High-fiber foods tend to be rich in phytochemicals that have been linked to cancer protection.
- High-fiber diets that are comprised of large amounts of fruits, vegetables and whole grains are associated with better blood pressure control.

### Interactions

Fiber supplements such as psyllium may reduce the absorption of certain medications when taken at the same time. In general, medications should be taken at least one hour before or two hours after fiber supplements.

# Fit for Life diet

## Definition

Fit for Life is a combination diet diet that emphasizes eating foods in the correct combination and avoiding the wrong combinations of foods rather than counting calories or controlling portion size. Several aspects of this diet have been disputed by dietitians and nutritionists.

## Origins

Fit for Life is the creation of Harvey and Marilyn Diamond. The diet first came to the attention of the public in the mid-1980s with the publication of the book *Fit for Life*, which has sold millions of copies. On the official Fit for Life website, Diamond claims that the diet "spawned juice and salad bars, fruit sellers on the streets of New York, and the juice industry." He also claims the book "launched a nutritional awakening in the United States and other Western countries." These are impressive claims for a book written by a man whose "doctoral degree" came from the American College of Life Science, a non-accredited correspondence school founded in 1982 by a high school dropout.

Diamond has appeared on dozens of television talk shows explaining his theories on how eating foods in the correct combination and avoiding the "wrong" combinations of food can bring about weight loss without calorie counting or exercise. In the 2000s, the Fit for Life system added the Personalized FFL Weight Management Program. This program uses what they call Biochemical Analyzation, Metabolic Typing and Genetic Predispositions to individualize and personalize the dietary protocols. The resulting diet is said to be effective only for one specific

## KEY TERMS

**Alternative medicine**—a system of healing that rejects conventional, pharmaceutical-based medicine and replaces it with the use of dietary supplements and therapies such as herbs, vitamins, minerals, massage, and cleansing diets. Alternative medicine includes well-established treatment systems such as homeopathy, Traditional Chinese Medicine, and Ayurvedic medicine, as well as more-recent, fad-driven treatments.

**Cholesterol**—a waxy substance made by the liver and also acquired through diet. High levels in the blood may increase the risk of cardiovascular disease.

**Conventional medicine**—mainstream or Western pharmaceutical-based medicine practiced by medical doctors, doctors of osteopathy, and other licensed health care professionals

**Dietary fiber**—also known as roughage or bulk. Insoluble fiber moves through the digestive system almost undigested and gives bulk to stools. Soluble fiber dissolves in water and helps keep stools soft.

**Dietary supplement**—a product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health

**Enzyme**—a protein that change the rate of a chemical reaction within the body without themselves being used up in the reaction

**Mineral**—an inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

**Naturopathic medicine**—An alternative system of healing that uses primarily homeopathy, herbal medicine, and hydrotherapy and rejects most conventional drugs as toxic.

**Vitamin**—a nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet

individual and can be used for that person's entire life. Diamond has also begun selling nutritional supplements, many of which are strongly recommended in his newest version of the Fit for Life system.

### Description

Fit for Life is a food combining diet based on the theory that to lose weight, one must not eat certain foods together. The philosophy behind the diet comes from Diamond's interest in natural hygiene, an offshoot of naturopathic medicine. In his original book, Diamond claimed that if a person ate foods in the wrong combination, they would "rot" in the stomach. He also categorized foods as "dead foods" that "clog" the body and "living foods" that cleanse the body. The newest version of Fit for Life talks less about rotting, dead, and living foods and more about "enzyme deficient foods." However, the general message about food combining is the same.

According to Diamond, dead foods are meats and starches. Living foods are raw fruits and vegetables. His diet plan requires that these foods not be eaten together. Some of the Fitness for Life rules include:

- Only fruit and fruit juice should be eaten from the time one awakes until noon. Fruits cleanse the body.
- Fruits are good for health only if they are eaten alone. They should never be eaten with any other food.
- Lunch and dinner can consist of either carbohydrates and vegetables or proteins and vegetables.
- Carbohydrates and proteins should never be put in the stomach at the same time.
- No dairy foods should ever be eaten.
- Water should never be drunk at meals.
- One day each week (the same day every week) is a free day, when the individual can eat whatever he or she wants."

### Function

The goal of the Fit for Life diet is to help people lose weight and keep their body healthy through diet. Diamond states that people do not gain weight because they eat too many calories and exercise too little. Instead, he considers the cause of weight gain to be eating protein-rich foods at the same time as carbohydrate-rich foods. He argues that enzymes that digest proteins interfere with enzymes that digest **carbohydrates**, and therefore, these two foods should not be eaten together. His program makes little mention of the role of different types of fats—saturated, unsaturated, and *trans* fat—in diet, dietary **fiber**, the role of **water** in health, or of the need to exercise.

The Fit for Life program says it is a lifestyle program that will teach people to be healthier. Along with the personalized diet program, dieters get a "Clinical Manual" that claims to teach them how their body works, what is healthy for them, and what is not. The program is heavily infused with an alternative medicine approach to health and diet, and many of the explanations it gives for the way the body works are scientifically questionable and not accepted by practitioners of conventional medicine.

## Benefits

The benefits claimed by Fit for Life are not supported by any scholarly research and are, in fact, refuted by some research (see below). The main claim, supported by testimonials and before and after pictures, is that people who follow Fit for Life will lose weight and keep it off. Along with weight loss will come a gnereral improvement in health. The official Fit for Life Website claims an "86% success rate" and mentions "clinical trials" without providing any details.

Some benefits of the plan are that it encourages people to increase their consumption of fresh fruits and vegetables. Unlike some diets, Fit for Life that it does not require dieters to buy special foods, keeping food costs moderate. It does, however, encourage dieters to purchase enzyme supplements from Fit for Life Industries.

## Precautions

The Fit for Life Web site is heavy on the theory behind the Fit for Life diet, but give few specifics on how the diet cam be put into effect in daily life. Sample meal plans and approved food lists are not available until the dieter signs up for the program at a substantial fee. This is very different from programs such as Body for Life or **Weight Watchers** which give potential program participants very specific information about diet, menus, and exercise before they pay for the plan.

Fit for life claims that their rules for eating benefit everyone from young children to pregnant women to older adults. Their personalized diet is intended to be a diet for a lifetime, but it does not take into account changes in lifecycle nutrition.

## Risks

Nutritionists feel that the Fit for Life diet can lead to serious vitamin and mineral deficiencies. Banning dairy products makes it extremely difficult for dieters to get the recommended daily allowance of **calcium**. Calcium is needed to keep bones strong and in many metabolic reactions in the body. Other potential vitamin deficiencies spotted by dietitians who have analyzed this diet include deficiencies in vitamin B and $B_{12}$.

### QUESTIONS TO ASK THE DOCTOR

- Do I have health conditions that might be affected by this diet?
- Is there another diet that would meet my weight and health goals better?
- If I go on this diet, will I need to take dietary supplements? If so, which ones?
- Will this diet meet my long-term dietary needs?
- Does this diet pose any special risks for me that I should be aware of?
- Is this diet safe and effective for all members of my family?
- Would you recommend someone in your family going on this diet?

## Research and general acceptance

Many professionals in the nutrition community consider Fit for Life an unhealthy fad diet. The concept behind food combining was tested in a study published in the April 2007 issue of the *International Journal of Obesity*. In this study, participants were fed a 1,100 calorie a day diet to promote weight loss. One group ate balanced meals containing all the major food groups. The other group ate a similar diet, but tested the food-combining theory by avoiding eating certain food groups at the same time. At the end of six weeks, the blood sugar, cholesterol, insulin, and blood **fats** were the same for each group. The balanced-meal group had lost an average of 16.5 lb and the food-combining group had lost 13.6 lb. This strongly suggests that eating a low calorie diet is much more important than eating foods in certain combinations.

# Flaxseed

## Definition

Flaxseed is the seed of the plant *Linum usitatissimum*. It is a rich source of alpha-linolenic acid (ALA), an essential nutrient in the human diet. Flaxseed has health and possibly medical benefits. Flaxseed oil is a vegetable oil derived from pressed flaxseed. Flaxseed and flaxseed oil have different properties and nutritional values.

**Golden flax seeds.** *(Phanie/Photo Researchers, Inc. Reproduced by permission.)*

## Purpose

Flaxseed is a good source of ALA and is thought to improve health by lowering blood cholesterol. Flaxseeds may also protect against certain cancers. It can also be used as a laxative.

## Description

*L. usitatissimum* is a slender plant with narrow leaves and blue flowers that grows anywhere from 8–45 in (20–130 cm) tall. The plant originated in India but has been farmed across the world for thousands of years. Archeologists discovered evidence that flax was cultivated in ancient Babylon as early as 3,000 B.C. Today, in Europe and Asia, a tall variety of flax is grown primarily for its fibers, which are used to make linen. A shorter, bushier variety is grown for its seeds in North America. The Canadian provinces of Alberta, Manitoba, and Saskatchewan are the leading producers of flax in North America. North Dakota produces most of the flax grown in the United States.

Seed flax is grown for both consumption and industrial use. The seed is about 42% oil. Solvent-extracted oil from flax seeds is used for industrial purposes and is often called linseed oil. It is used in manufacturing oil paints, varnishes, and linoleum. The material that remains after oil has been extracted from the seeds is called linseed cake or linseed meal. It is often added to animal feed as a **protein** and omega-3 fatty acid supplement. Omega-3 enriched eggs, for example, come from chickens fed flax. Omega-3 enriched pork is available in

## KEY TERMS

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Fatty acids**—Complex molecules found in fats and oils. Essential fatty acids are fatty acids that the body needs but cannot synthesize. Essential fatty acids are made by plants and must be present in the diet to maintain health.

**Lignans**—A group of compounds found in plants that have characteristics similar to the female hormone estrogen. They appear to have some anti-cancer and anti-oxidant effects.

**Triglycerides**—A type of fat found in the blood. High levels of triglycerides can increase the risk of coronary artery disease.

Canada and Japan. The **fiber** in the stems of seed flax is used in the production of cigarette papers.

Human consumption of flaxseed and flaxseed oil has increased substantially since the mid-1990s. Flaxseed oil for human consumption is produced through solvent-free cold pressing at low temperatures. The oil is sold in bottles to be used as food or in capsules to be taken as a dietary supplement.

Flax seeds come in brown, golden, and yellow varieties and have a slightly nutty flavor. All colors of seed have the same nutritional value. Seeds are sold whole or ground (milled flax). Whole seeds can be stored at room temperature for up to one year. Ground seeds are easier to digest than whole seeds, but they spoil and develop an unpleasant taste more rapidly. Ground seeds can be kept in an airtight container in the refrigerator for up to three months. However, when ground flax is needed, it is preferable to grind whole seeds in a coffee grinder, blender, or food processor immediately before use. Flaxseed and flaxseed oil are sold primarily in health food stores or by mail order.

### *Nutritional information*

Flaxseed is an excellent source of alpha-linolenic acid. ALA is an essential fatty acid for humans. Essential fatty acids are molecules the body needs but cannot synthesize for itself from other nutrients. Thus, essential fatty acids, just like essential **vitamins**, must be obtained through diet. Eating 1 tbsp (8 g) of ground flax or 1 tsp (5 g) of flax oil provides enough ALA to meet daily diet requirements.

According to the Flax Council of Canada, 1 tbsp ground flaxseed provides about 36 calories, 1.8 g of ALA, 1.6 g of protein, and 2.2 grams of dietary fiber. Ground flax is preferred over whole seeds because it is easier to digest. One teaspoon of flax oil provides 44 calories and 2.8 g of ALA, but contains no protein or fiber. The oil in flaxseed is very high in polyunsaturated fat (a healthy type of fat) and contains no trans fat or cholesterol. Flaxseed also provides vitamins C, E, K, $B_1$ (**thiamin**), $B_2$ (**riboflavin**), and $B_6$, along with the **mineralscalcium**, **iron**, **magnesium**, phosphorous, **zinc**, copper, **manganese**, and **selenium**. Flaxseed is low in **sodium** and **carbohydrates**. The seed, but not the oil, is also an excellent source of lignin, a nutrient thought to have anti-cancer properties.

Flaxseed can be added to the diet in several ways. Ground, a daily serving can be sprinkled on hot or cold cereal or mixed into yogurt or smoothies. Larger amounts can be added to pancake or waffle mix or baked goods such as muffins or cookies. Flax oil can be added to salad dressings or smoothies. Frying in flax oil is not recommended. Three tablespoons of ground flax can replace one tablespoon of butter, margarine, or vegetable oil in recipes. One tablespoon of ground flax mixed with three tablespoons of **water**, when left to stand for two minutes before use, can replace one egg in many recipes.

### *Health claims*

Major health claims for flaxseed and flax oil arise from the fact that these products contain high levels of ALA. ALA can be converted by the body into two different long chain **omega-3 fatty acids**. Long chain omega-3 fatty acids have been shown to lower the risk of heart attack in people with heart disease. They appear to lower the level of cholesterol in the blood, especially low-density lipoprotein (LDL) or "bad" cholesterol. Other health claims for omega-3 fatty acids include lowering blood pressure, lowering **triglycerides** (**fats**) in the blood, and reducing the tendency of blood to clot in veins.

Cold-water oily fish such as salmon and fresh tuna (canned is not a source) are good sources of omega-3 fatty acids. Vegans and vegetarians use flaxseed, along with walnuts and canola oil, get enough ALA in their diet, which is then converted into beneficial omega-3 fatty acids. However, many of the health benefits claimed for omega-3 fatty acids require higher doses than necessary to meet daily dietary requirements. Flaxseed and flaxseed oil have been found to lower

blood cholesterol levels in animal studies, but few high-quality human studies have been done using flax products. Results that do exist have been mixed.

Another health claim for flaxseed (but not flax oil) is that it has anti-cancer properties. Flaxseed and sesame seed both contain large amounts of lignans. Lignans are naturally occurring molecules found in plants that mimic the effect of the female hormone estrogen. Lignans compete with estrogen for binding sites on cells. They can either act as antagonists and lessen the estrogen response where there is continual estrogen exposure (increasing risk of breast **cancer**) or they can mimic estrogen and boost the response where exposure is limited (post menopause) helping to prevent post menopausal symptoms. Few well-designed, well-controlled human studies of the effect of lignans on cancer have been completed. Although the results of animal studies are encouraging, there is not enough evidence to say that lignans, or flaxseed, can slow or prevent cancer.

Researchers generally agree that ground flaxseed is an effective laxative. Flaxseed provides dietary fiber and, along with the oil it naturally contains, helps move material through the bowel. Whole seed may have the reverse effect, swelling and blocking the bowel.

Some studies have shown that flaxseed oil supplements can reduce symptoms of attention deficit-hyperactivity disorder (ADHD) in some children. Other studies claim that flaxseed can lower blood sugar levels in people with diabetes. Initial results also suggest that flaxseed may reduce symptoms of menopause. None of these health claims have been substantiated with large, well-controlled human studies.

## Precautions

ALA, which is found in large quantities in flaxseed, appears to increase the risk of developing **prostate** cancer. This finding is preliminary and not yet substantiated. Individuals with prostate cancer or a history of prostate cancer should consult their oncologist before using flax products.

Although no health risks are known when flaxseed and flax oil are used in reasonable and moderate quantities, no studies have been done on the safety of flax in pregnant or **breastfeeding** women or in children.

## Interactions

No specific drug interactions are known.

## Complications

Complications are unlikely to occur when flax products are used to meet daily dietary needs. Whole flaxseed can cause blockage of the intestines when taken with inadequate amounts of liquids.

## Parental concerns

Parents should be aware that the safe dose of many herbal supplements has not been established for children. Accidental overdose may occur if children are given adult **dietary supplements**.

# Fluoride

## Definition

Fluoride is a naturally occurring element found in **water** and food. It is important for the development of strong bones and teeth.

## Purpose

In addition to occurring naturally in some water, fluoride is added to toothpastes, mouthwashes, and some public water supplies to prevent tooth decay (dental caries).

## Description

Fluoride is found naturally in seawater and in some drinking water and is present in small amounts in almost all soil, plants, and animals. In water, fluoride dissolves to form a negatively charged ion ($F^-$). In the body, this ion is absorbed into the bloodstream from the small intestine. It then binds with **calcium** in bones and teeth. The adult body contains less than one-tenth of one ounce (about 2.5 g) of fluoride. Ninety-five percent of this is found in bones and teeth.

The importance of fluoride for dental health has been recognized since the 1930s when an association between the fluoride content of drinking water and the prevalence of dental caries was first noted. Acids found in food or released by bacteria that feed on sugar in the mouth cause tooth erosion. These acids eat away at the enamel on the surface of the tooth. Fluoride prevents tooth decay two ways. First, the fluoride in saliva reacts with calcium and phosphate in teeth to repair damage to the tooth's surface. The new surface formed when the tooth is repaired is stronger than the original enamel and is better able to resist decay. This process is called tooth remineralization. Second, fluoride interferes with the metabolic processes of bacteria in the mouth so that they produce less decay-causing acid.

**Suggested amounts of dietary fluoride supplements**

| | Fluoride ion level in drinking water (ppm)* | | |
|---|---|---|---|
| **Age** | **< 0.3 ppm** | **0.3–0.6 ppm** | **> 0.6 ppm** |
| Birth–6 months | None | None | None |
| 6 months–3 years | 0.25 mg/day** | None | None |
| 3 years–6 years | 0.50 mg/day | 0.25 mg/day | None |
| 6 years–16 years | 1.0 mg/day | 0.50 mg/day | None |

* 1.0 part per million (ppm) = 1 milligram/liter (mg/L)
** 2.2 mg sodium fluoride contains 1 mg fluoride ion

SOURCE: American Dental Association

**It is suggested that children between the ages of 6 months to 16 years living in non-fluoridated areas use dietary fluoride supplements. Your dentist can prescribe the correct dosage for your child based on the level of fluoride in your drinking water.** *(Illustration by GGS Information Services/Thomson Gale.)*

Since teeth containing fluoride become stronger, some researchers have suggested that fluoride might also make bones stronger and prevent or delay **osteoporosis** (age related thinning of the bones). These researchers have generally found that the amount of fluoride that prevents tooth decay does not affect the strength or density of bones. High doses of fluoride are potentially toxic, and very large doses (5–15 times the daily adequate intake) taken over time cause bones to become chalky and brittle. Consequently, researchers have concluded that fluoride supplements are not an appropriate way to prevent or treat osteoporosis.

### *Normal fluoride requirements*

Fluoride, in the proper amount, can cut the level of tooth decay in half and substantially reduce the amount of money spent on dental care. Too much fluoride, especially in children, results in a condition called dental fluorosis. The surface of the teeth becomes discolored by chalky white splotches. This is a cosmetic problem only and does not affect the health of the teeth.

High doses of fluoride can be toxic. Doses between 20–80 mg per day can result in changes in bone that can be crippling, as well as changes in kidney function, and possibly nerve and muscle function. Doses as high as 5–10 g per day can be fatal.

The United States Institute of Medicine (IOM) of the National Academy of Sciences developed values called **Dietary Reference Intakes** (DRIs) for many **vitamins** and **minerals**. The DRIs consist of three sets of numbers. The Recommended Dietary

## KEY TERMS

**Osteoporosis**—A condition found in older individuals in which bones decrease in density and become fragile and more likely to break. It can be exacerbated by lack of vitamin D and/or calcium in the diet.

Allowance (RDA) defines the average daily amount of the nutrient needed to meet the health needs of 97–98% of the population. The Adequate Intake (AI) is an estimate set when there is not enough information to determine an RDA. The Tolerable Upper Intake Level (UL) is the average maximum amount that can be taken daily without risking negative side effects. The DRIs are calculated for children, adult men, adult women, pregnant women, and **breastfeeding** women. Similar recommendations have been defined elsewhere, e.g., Canada, the United Kingdom, and other European countries.

Fluoride is not considered an essential nutrient so the IOM has not set RDAs for it. Instead, it has set AI and UL levels for all age groups. The daily AIs and ULs for fluoride for healthy individuals as established by the IOM are:

- Children birth–6 months: AI 0.01 mg; UL 0.7 mg
- Children 7–12 months: AI 0.5 mg; UL 0.9 mg
- Children 1–3 years: RDA 0.7 mg; UL 1.2 mg
- Children 4–8 years: RDA 1.0 mg; UL 2.2 mg
- Children 9–13 years: RDA 2.0 mg; UL 10 mg
- Adolescents 14–18 years: RDA 3.0 mg; UL 10 mg
- Men age 19 and older: RDA 4.0 mg; UL 10 mg
- Women age 19 and older: RDA 3.0 mg; UL 10 mg
- Pregnant women of all ages: 3.0 RDA mg; 10 UL mg
- Breastfeeding women of all ages: 3.0 RDA mg; 10 mg

### *Sources of fluoride in diet*

The overwhelming source of fluoride for most people is water. In 1945, Grand Rapids, Michigan, was the first city to add fluoride to its public water supply. About two-thirds of Americans now drink fluoridated water. From the 1950s to the 1970s, the issue of fluoridating public water supplies caused heated debate. Some scientists claimed that fluoridation caused birth defects, **cancer**, and liver disease. Multiple independent, well-designed studies have conclusively demonstrated that this is false. Fluoridation of water at a level that prevents tooth decay does not increase health risks.

Critics of fluoridation still persist. Some reject existing scientific research and claim that fluoridation is ineffective and/or harmful. For others, fluoridation of public water raises moral issues about personal rights versus the government's rights. The decision to fluoridate drinking water has generally rested with local governments and communities. The recommended rate of fluoride in water is between 0.7 and 1.2 parts per million (ppm). The fluoridation rate is usually at the low end of the range in warm places and at the high end of the range in cold places because people drink more water and thus get more fluoride where it is warm.

A few foods contain significant amounts of fluoride. Since it is found in seawater, ocean fish contain fluoride. It is also concentrated in tea leaves. The approximate fluoride content for some common foods:

- Tea, 3.5 ounces (100 mL): 0.1–0.6 mg
- Canned sardines with bones, 3.5 oz (100 g): 0.2–0.4 mg
- Fish without bones, 3.5 oz (100 g): 0.01–0.17 mg
- Chicken, 3.5 oz (100 g): 0.06–0.10 mg

Toothpaste and mouthwashes containing fluoride provide significant protection against tooth decay. For children who do not drink fluoridated water, the American Dental Association (ADA) and the American Academy of Pediatrics recommend prescription fluoride supplements from age six months onward. Supplements come as liquids and chewable tablets of varying strengths and are prescribed by a pediatrician, family physician, or dentist. In addition, dentists may apply fluoride pastes or varnishes directly to children's teeth for additional protection. This is usually done at six-month intervals at regular dental check-ups.

## Precautions

The amount of fluoride occurring naturally in drinking water varies widely depending on location. People who use wells should have them tested for fluoride. People on public water supplies should call their local public health office to determine if their water is fluoridated. People who primarily use bottled water should consult their supplier about whether or not it contains fluoride. Some built-in home water softening systems may remove fluoride from water. Consult the manufacturer or installer for specific information.

## Interactions

Antacids containing aluminum hydroxide and calcium supplements can decrease the absorption of fluoride from the small intestine.

## Complications

No complications are expected for people who get daily doses of fluoride falling between the AI and UL limits.

Too little fluoride results in increased tooth decay. Too much fluoride can cause illness or death. A 40 lb (18 kg) child would likely begin to show symptoms of fluoride poisoning after consuming about 55 mg of fluoride (3 mg/kg of body weight), and a dose of 290 mg (16 mg/kg of body weight) would likely be fatal. In 2004, the American Association of Poison Control Centers reported 24,180 incidents involving toothpaste with fluoride, 440 of which required emergency room treatment. About 22,000 of these incidents were with children under age six who ate toothpaste. Symptoms of fluoride poisoning include nausea, vomiting, diarrhea, headaches, muscle spasms, irregular heart beat, coma, and death. Besides toothpaste and mouthwash, fluoride is also found in pesticides, rodent poisons, and chrome polish for automobiles.

## Parental concerns

Children should be taught not to eat toothpaste, and an adult should supervise tooth brushing for children under age six. Mouthwash containing fluoride and prescription fluoride supplements should be kept out of reach of children. A child who eats fluoridated toothpaste or mouthwash should receive an immediate medical evaluation.

# Folate

## Definition

Folate is a naturally occurring water-soluble vitamin that the body needs to remain healthy. Folic acid is a stable synthetic form of folate that is found in **dietary supplements** and is added to fortified foods such as flour and cereal. Humans cannot make folate or folic acid, so they must get it from foods in their diet or as a dietary supplement. Folic acid and folate are both converted into an active form in that the body can use, although folic acid is more easily used (more bioavailable) in the body. Folic acid is also called vitamin $B_9$

## Purpose

Folate is necessary to create new DNA (genetic material) and RNA when cells divide. It plays a critical role in developing healthy red blood cells. Folate also helps protect DNA from damage that may lead to diseases such as **cancer**. Along with **vitamins** $B_6$ and

**Folate (Folic Acid)**

| Age | Recommended Dietary Allowance (mcg) | Tolerable Upper Intake Level (mcg) |
|---|---|---|
| Children 0–6 mos. | 65 (AI) | Not established |
| Children 7–12 mos. | 89 | Not established |
| Children 1–3 yrs. | 150 | 300 |
| Children 4–8 yrs. | 200 | 400 |
| Children 9–13 yrs. | 300 | 600 |
| Children 14–18 yrs. | 400 | 800 |
| Adults 19≥ yrs. | 400 | 1,000 |
| Pregnant women | 600 | 1,000 |
| Breastfeeding women | 500 | 1,000 |

| Food | Folate (Folic Acid) (mcg) |
|---|---|
| Cereal, 100% fortified, ¾ cup | 400 |
| Beans, pinto, cooked, ½ cup | 147 |
| Turnip greens, cooked, ½ cup | 135 |
| Asparagus, cooked, ½ cup | 132 |
| Spinach, cooked, ½ cup | 131 |
| Beans, navy, cooked, ½ cup | 127 |
| Beans, great northern, cooked, ½ cup | 90 |
| Broccoli, steamed, ½ cup | 85 |
| Beets, boiled, ½ cup | 68 |
| Rice, long-grain white, enriched, cooked, ½ cup | 65 |
| Corn, yellow, cooked, ½ cup | 37 |
| Tomato juice, canned, 6 oz. | 35 |
| Bread, white, enriched, 1 slice | 25 |
| Bread, whole wheat, enriched, 1 slice | 25 |
| Raspberries, ½ cup | 16 |

AI = Adequate Intake
mcg = microgram

*(Illustration by GGS Information Services/Thomson Gale.)*

$B_{12}$, folate helps regulate the level of the amino acid homocysteine in the blood. Homocysteine regulation is related to cardiovascular health. In the fetus, folate is necessary for the proper development of the brain and spinal cord.

## Description

Folate is one of eight B-complex vitamins. Its function is closely intertwined with that of vitamins $B_6$ and $B_{12}$. Folate, from the Latin word *folium* meaning leaf, was discovered in the late 1930s in yeast and later found in spinach and other green leafy vegetables and in liver. Starting in 1998, the United States Food and Drug Administration (FDA) required certain foods, such as flour, corn meal, bread, cereal, rice, and pasta, to be fortified with a folic acid. In Canada and Chile fortification of flour is mandatory.

### *Folate's role in health*

Folate is essential for the normal development of the neural tube in the fetus. The neural tube develops into the brain and spinal cord. It closes between the third and fourth week after conception. Too little folate at this time can lead to serious malformations of the spine (spina bifida) and the brain (anencephaly). Because many women do not realize that they are pregnant so soon after conception, the United States has included folic acid in its fortified foods program. Adding folic acid to common foods made with grains has substantially reduced the number of babies born with neural tube defects in the United States.

The body also needs folate to produce healthy red blood cells. When not enough folate is present, the red blood cells do not divide; instead they grow abnormally large. These malformed cells have a reduced ability to carry oxygen to other cells in the body. This condition is called megaloblastic anemia. It is identical to the condition of the same name caused by too little vitamin $B_{12}$. Folate also aids in the production of other new cells. Adequate supplies of folate are especially important in fetuses and infants because they are growing rapidly. However, since the lifespan of a red blood is only about four months, the body needs a continuous supply of folate throughout life to create healthy new replacement blood cells.

Folate acts together with vitamin $B_6$ and vitamin $B_{12}$ to lower the level of homocysteine in the blood. Homocysteine is an amino acid that is naturally produced when the body breaks down **protein**. Moderate to high levels of homocysteine in the blood are linked to an increased risk of cardiovascular disease (e.g. atherosclerosis, heart attack, stroke). The trio of folate, vitamin $B_6$, and vitamin $B_{12}$ lower homocysteine levels. However, it is not clear whether taking large doses of these vitamins, either alone or in combination, will prevent heart disease from developing in healthy individuals. The official position of the American Heart Association stated in its Diet and Lifestyle Recommendations Revision 2006 is that "Available evidence is inadequate to recommend folic acid and other B vitamin supplements as a means to reduce CVD [cardiovascular disease] risk at this time."

Damage to DNA appears to contribute to the development of many different cancers. Because folate helps protect against DNA damage, researchers have looked at whether it can reduce the risk of developing cancer. Results are mixed, with benefits seen for some cancers, but not for others. The American Cancer Society in its 2006 Guidelines on Nutrition and Physical Activity for Cancer Prevention states: "Folate deficiency may increase the risk of cancers of the colorectal and breast, especially in people who consume alcoholic beverages. Current evidence suggests that to reduce cancer risk, folate is best obtained through consumption of vegetables, fruits, and enriched grain

## KEY TERMS

**Alzheimer's disease**—an incurable disease of older individuals that results in the destruction of nerve cells in the brain and causes gradual loss of mental and physical functions

**Amino acid**—molecules that are the basic building blocks of proteins

**B-complex vitamins**—a group of water-soluble vitamins that often work together in the body. These include thiamine ($B_1$), riboflavin ($B_2$), niacin ($B_3$), pantothenic acid ($B_5$), pyridoxine ($B_6$), biotin ($B_7$ or vitamin H), folate/folic acid ($B_9$), and cobalamin ($B_{12}$).

**Dietary supplement**—a product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health

**Diuretic**—a substance that removes water from the body by increasing urine production

**Enzyme**—a protein that change the rate of a chemical reaction within the body without themselves being used up in the reaction

**Ribonucleic acid (RNA)**—A molecule that helps decode genetic information (DNA) and is necessary for protein synthesis

**Vitamin**—a nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet

**Water-soluble vitamin**—a vitamin that dissolves in water and can be removed from the body in urine

products." The American Cancer Society does not endorse taking megadoses of folic acid to prevent cancer.

Clinical trials are underway to determine safety and effectiveness of folate/folic acid both alone and in combination with other vitamins in preventing cancer, cardiovascular disease, and dementias such as Alzheimer's disease. Cognitive decline and some forms of dementia, including Alzheimer's disease, are associated with lower folate levels, which is common amongst older people in some countries. Individuals interested in participating in a clinical trial at no charge can find a list of open trials at <http://www.clinicaltrials.gov>.

### *Normal folate requirements*

The United States Institute of Medicine (IOM) of the National Academy of Sciences has developed values called **Dietary Reference Intakes** (DRIs) for vitamins and **minerals**. The DRIs consist of three sets of numbers. The Recommended Dietary Allowance (RDA) defines the average daily amount of the nutrient needed to meet the health needs of 97–98% of the population. The Adequate Intake (AI) is an estimate set when there is not enough information to determine an RDA. The Tolerable Upper Intake Level (UL) is the average maximum amount that can be taken daily without risking negative side effects. The DRIs are calculated for children, adult men, adult women, pregnant women, and **breastfeeding** women.

The IOM has not set RDAs for folate in children under one year old because of incomplete scientific information. Instead, it has set AI levels for this age group. RDAs and ULs for folate are measured in micrograms (mcg). Unlike the UL for many vitamins, the UL for folate/folic acid refers only to folic acid that comes from fortified food or that is in folic acid dietary supplements, multivitamins, or B-complex vitamins. There is no UL for folate found in natural plant and animal foods. Dietary supplements containing more than 1,000 mcg (1 mg) of folic acid require a prescription. 1 mcg of folate from natural food sources is equal in biological activity in humans to 0.6 mcg of folic acid from supplements or fortified food.

The following are the daily RDAs and IAs and ULs for folic aside for healthy individuals:

- children birth–6 months: AI 65 mcg; UL not established
- children 7–12 months: AI 89 mcg; UL not established
- children 1–3 years: RDA 150 mcg; UL 300 mcg
- children 4–8 years: RDA 200 mcg; UL 400 mcg
- children 9–13 years: RDA 300 mcg; UL 600 mcg
- children 14–18 years: 400 RDA mcg; UL 800 mcg
- adults age 19 and older: RDA 400 mcg; UL 1,000 mcg
- pregnant women: RDA 600 mcg; UL 1,000 mcg
- breastfeeding women: RDA 500 mcg; 1,000 mcg

### *Sources of folate*

People need a continuous supply of folate from their diet because of the role it plays in creating new blood cells. Because folate is water-soluble, little is stored in the body; any excess is excreted in urine. Since the folic acid fortification program began in 1998, most healthy Americans get enough folate from their diet. The exception is pregnant women who should, under medical supervision, take a folic

acid supplement (400 mcg for most women and higher does for those who have already had a baby with a neural tube defect). Good natural sources of folate include beef liver, green leafy vegetables, and dried beans. Cooking animal products does not reduce the folate content much, but cooking vegetables can reduce the amount of folate by up to 40% depending on the vegetable and the cooking method.

The following list gives the approximate folate/folic acid content for some common foods:

- asparagus, cooked, 1/2 cup: 132 mcg
- spinach, cooked, 1/2 cup: 131 mcg
- turnip greens, cooked, 1/2 cup: 135 mcg
- broccoli, steamed 1/2 cup: 85 mcg
- beets, boiled; 1/2 cup: 68 mcg
- great northern beans, cooked 1/2 cup: 90 mcg
- pinto beans, cooked, 1/2 cup: 147 mcg
- navy beans, cooked, 1/2 cup: 127 mcg
- tomato juice, canned, 6 ounces: 35 mcg
- raspberries 1/2 cup: 16 mcg
- corn, yellow, cooked, 1/2 cup: 37 mcg
- breakfast cereal, fortified 100%, 3/4 cup: 400 mcg
- bread, white or whole wheat 1 slice: 25 mcg
- rice, white, enriched long-grain, cooked, 1/2 cup: 65 mcg
- bread, whole wheat, 1 slice: .07 mg
- bread, white, enriched, 1 slice: .09 mg

### *Folate deficiency*

Most healthy people in the United States get enough folate in their diet because folate is added to many common foods such as bread; however, this is not the case elsewhere.In Europe, low intakes are commonly reported particularly in teenage girls and older people. Causes of folate deficiency include inadequate intake, impaired absorption, (**celiac disease**, Crohn's disease, certain medications), inability of the body to use folate (enzyme deficiencies), increased folate needs (pregnancy, cancer), or increased loss or excretion (kidney dialysis, alcoholism). As a group, the elderly are the largest group at risk to develop folate deficiency.

The major symptom of folate deficiency in pregnant women is having a baby born with a brain or spinal cord abnormality. Other symptoms of folate deficiency include slow growth in infants and children, megaloblastic anemia, digestive problems such as diarrhea, sore tongue, irritability, forgetfulness and changes in mental state. These changes can also have other causes and should be evaluated by a healthcare professional.

## Precautions

Since many pregnancies are unplanned and unrecognized until after the critical period for brain and spinal cord formation, any woman who may become pregnant should be careful to include enough folate in her diet and folic acid supplements should be taken before and in the first trimester of pregnancy.

Folic acid may mask vitamin $B_{12}$ deficiency. Folic acid supplements will reverse anemia symptoms, but they do not stop nerve damage caused by $B_{12}$ deficiency. Permanent nerve damage may result. People with suspected folate deficiency who begin taking folic acid supplements should also be evaluated for vitamin $B_{12}$ deficiency.

## Interactions

The following medications may interfere with the ability of the body to absorb and use folate. Individuals taking these medications should check with their physician about the effects they may have on folate/folic acid levels in the body:

- seizure medications such as dilantin, phenytoin, and primidone
- metaformin (Fortamet, Glucophage, Glucophage XR, Riomet) used to treat type 2 diabetes
- sulfasalazine used to treat Chron's disease and inflammatory bowel disease
- triameterene, a diuretic or "water pill"
- barbiturate sedatives
- methotrexate, used to treat cancer, rheumatoid arthritis, and psoriasis
- drugs used to treat gastroesophageal reflux disease (GERD), such as omeprazole (Prilosec), lansoprazole (Prevacid), cimetidine (Tagamet), famotidine (Pepsid), nizatidine (Axid), or ranitidine (Zantac)

## Complications

No complications are expected when folate/folic acid is taken within recommended levels. Complications related to deficiencies are discussed above. Complications of excess folic acid intake at levels above 1,000 mcg daily over an extended period can include seizures in individuals taking anticonvulsant medications and general irritability, and restlessness in otherwise healthy individuals.

## Parental concerns

Parents need to be aware that infants and rapidly growing children are at higher risk for folate deficiency. Parents of children with digestive disorders or allergies to wheat products should discuss the need for a folic acid supplement with their pediatrician.

# Food additives

## Definition

The United States Food and Drug Administration (FDA) defines food additives as "any substance, the intended use of which results or may reasonably be expected to result, directly or indirectly, in its becoming a component or otherwise affecting the characteristics of any food." In other words, an additive is any substance that is added to food.

**Food additives**

| Types of ingredients | What they do | Examples of uses | Names found on product labels |
|---|---|---|---|
| Preservatives | Prevent food spoilage from bacteria, molds, fungi, or yeast (antimicrobials); slow or prevent changes in color, flavor, or texture and delay rancidity (antioxidants); maintain freshness | Fruit sauces and jellies, beverages, baked goods, cured meats, oils and margarines, cereals, dressings, snack foods, fruits and vegetables | Ascorbic acid, citric acid, sodium benzoate, calcium propionate, sodium erythorbate, sodium nitrite, calcium sorbate, potassium sorbate, BHA, BHT, EDTA, tocopherols (Vitamin E) |
| Sweeteners | Add sweetness with or without the extra calories | Beverages, baked goods, confections, table-top sugar, substitutes, many processed foods | Sucrose (sugar), glucose, fructose, sorbitol, mannitol, corn syrup, high fructose corn syrup, saccharin, aspartame, sucralose, acesulfame potassium (acesulfame-K), neotame |
| Color Additives | Offset color loss due to exposure to light, air, temperature extremes, moisture and storage conditions; correct natural variations in color; enhance colors that occur naturally; provide color to colorless and "fun" foods | Many processed foods (candies, snack foods margarine, cheese, soft drinks, jams/jellies, gelatins, pudding and pie fillings) | FD&C Blue Nos. 1 and 2, FD&C Green No. 3, FD&C Red Nos. 3 and 40, FD&C Yellow Nos. 5 and 6, Orange B, Citrus Red No. 2, annatto extract, beta-carotene, grape skin extract, cochineal extract or carmine, paprika oleoresin, caramel color, fruit and vegetable juices, saffron (Note: Exempt color additives are not required to be declared by name on labels but may be declared simply as colorings or color added) |
| Flavors and Spices | Add specific flavors (natural and synthetic) | Pudding and pie fillings, gelatin dessert mixes, cake mixes, salad dressings, candies, soft drinks, ice cream, BBQ sauce | Natural flavoring, artificial flavor, and spices |
| Flavor Enhancers | Enhance flavors already present in foods (without providing their own separate flavor) | Many processed foods | Monosodium glutamate (MSG), hydrolyzed soy protein, autolyzed yeast extract, disodium guanylate or inosinate |
| Fat Replacers (and components of formulations used to replace fats) | Provide expected texture and a creamy "mouth-feel" in reduced-fat foods | Baked goods, dressings, frozen desserts, confections, cake and dessert mixes, dairy products | Olestra, cellulose gel, carrageenan, polydextrose, modified food starch, microparticulated egg white protein, guar gum, xanthan gum, whey protein concentrate |

## Purpose

Direct additives are those that are intentionally added to foods for a specific purpose. Indirect additives are those to which the food is exposed during processing, packaging, or storing. Preservatives are additives that inhibit the growth of bacteria, yeasts, and molds in foods.

## Description

Additives and preservatives have been used in foods for centuries. When meats are smoked to preserve them, compounds such as butylated hydroxyanisole (BHA) and butyl gallate are formed and provide both antioxidant and bacteriostatic effects. Salt has also been used as a preservative for centuries. Salt lowers the water activity of meats and other foods and inhibits bacterial growth. Excess water in foods can enhance the growth of bacteria, yeast, and fungi. Pickling, which involves the addition of acids such as vinegar, lowers the pH of foods to levels that retard bacterial growth. Some herbs and spices, such as curry, cinnamon, and chili pepper, also contain antioxidants and may provide bactericidal effects.

### *Uses of Additives and Preservatives in Foods*

Additives and preservatives are used to maintain product consistency and quality, improve or maintain nutritional value, maintain palatability and wholesomeness, provide leavening, control pH, enhance flavor, or provide color. Food additives may be classified as:

- Antimicrobial agents, which prevent spoilage of food by mold or microorganisms. These include not only vinegar and salt, but also compounds such as calcium

**Food additives**

| Types of ingredients | What they do | Examples of uses | Names found on product labels |
|---|---|---|---|
| Nutrients | Replace vitamins and minerals lost in processing (enrichment), add nutrients that may be lacking in the diet (fortification) | Flour, breads, cereals, rice, macaroni, margarine, salt, milk, fruit beverages, energy bars, instant breakfast drinks | Thiamine hydrochloride, riboflavin (Vitamin B2), niacin, niacinamide, folate or folic acid, beta carotene, potassium iodide, iron or ferrous sulfate, alpha tocopherols, ascorbic acid, Vitamin D, amino acids (L-tryptophan, L-lysine, L-leucine, L-methionine) |
| Emulsifiers | Allow smooth mixing of ingredients, prevent separation. Keep emulsified products stable, reduce stickiness, control crystallization, keep ingredients dispersed, and help products dissolve more easily | Salad dressings, peanut butter, chocolate, margarine, frozen desserts | Soy lecithin, mono- and diglycerides, egg yolks, polysorbates, sorbitan monostearate |
| Stabilizers and thickeners, binders, texturizers | Produce uniform texture, improve "mouth-feel" | Frozen desserts, dairy products, cakes, pudding and gelatin mixes, dressings, jams and jellies, sauces | Gelatin, pectin, guar gum, carrageenan, xanthan gum, whey |
| pH Control agents and acidulants | Control acidity and alkalinity, prevent spoilage | Beverages, frozen desserts, chocolate, low-acid canned foods, baking powder | Lactic acid, citric acid, ammonium hydroxide, sodium carbonate |
| Leavening agents | Promote rising of baked goods | Breads and other baked goods | Baking soda, monocalcium phosphate, calcium carbonate |
| Anti-caking agents | Keep powdered foods free-flowing, prevent moisture absorption | Salt, baking powder, confectioner's sugar | Calcium silicate, iron ammonium citrate, silicon dioxide |
| Humectants | Retain moisture | Shredded coconut, marshmallows, soft candies, confections | Glycerin, sorbitol |
| Yeast nutrients | Promote growth of yeast | Breads and other baked goods | Calcium sulfate, ammonium phosphate |
| Dough strengtheners and conditioners | Produce more stable dough | Breads and other baked goods | Ammonium sulfate, azodicarbonamide, L-cysteine |
| Firming agents | Maintain crispness and firmness | Processed fruits and vegetables | Calcium chloride, calcium lactate |
| Enzyme preparations | Modify proteins, polysaccharides and fats | Cheese, dairy products, meat | Enzymes, lactase, papain, rennet, chymosin |
| Gases | Serve as propellant, aerate, or create carbonation | Oil cooking spray, whipped cream, carbonated beverages | Carbon dioxide, nitrous oxide |

*(Illustration by GGS Information Services/Thomson Gale.)*

propionate and sorbic acid, which are used in products such as baked goods, salad dressings, cheeses, margarines, and pickled foods.

- Antioxidants, which prevent rancidity in foods containing fats and damage to foods caused by oxygen. Examples of antioxidants include vitamin C, vitamin E, BHA, BHT (butylated hydroxytolene), and propyl gallate.
- Artificial colors, which are intended to make food more appealing and to provide certain foods with a color that humans associate with a particular flavor (e.g., red for cherry, green for lime).
- Aritificial flavors and flavor enhancers, the largest class of additives, function to make food taste better, or to give them a specific taste. Examples are salt, sugar, and vanilla, which are used to complement the flavor of certain foods. Synthetic flavoring agents, such as benzaldehyde for cherry or almond flavor, may be used to simulate natural flavors. Flavor enhancers, such as monosodium glutamate (MSG) intensify the flavor of other compounds in a food.
- Bleaching agents, such as peroxides, are used to whiten foods such as wheat flour and cheese.
- Chelating agents, which are used to prevent discoloration, flavor changes, and rancidity that might occur during the processing of foods. Examples are citric acid, malic acid, and tartaric acid.
- Nutrient additives, including vitamins and minerals, are added to foods during enrichment or fortification. For example, milk is fortified with vitamin D, and rice is enriched with thiamin, riboflavin, and niacin.
- Thickening and stabilizing agents, which function to alter the texture of a food. Examples include the emulsifier lecithin, which, keeps oil and vinegar blended in salad dressings, and carrageen, which is used as a thickener in ice creams and low-calorie jellies.

## Precautions

### *Regulating Safety of Food Additives and Preservatives*

Based on the 1958 Food Additives Amendment to the Federal Food, Drug, and Cosmetic (FD&C) Act of 1938, the FDA must approve the use of all additives. The manufacturer bears the responsibility of proving that the additive is safe for its intended use. The Food Additives Amendment excluded additives and preservatives deemed safe for consumption prior to 1958, such as salt, sugar, spices, vitamins, vinegar, and monosodium glutamate. These substances are considered "generally recognized as safe" (GRAS) and may be used in any food, though the FDA may remove additives from the GRAS list if safety concerns arise. The 1960 Color Additives Amendment to the FD&C Act required the FDA to approve synthetic coloring agents used in foods, drugs, cosmetics, and certain medical devices. The Delaney Clause, which was included in both the Food Additives Amendment and Color Additives Amendment, prohibited approval of any additive that had been found to cause cancer in humans or animals. However, in 1996 the Delaney Clause was modified, and the commissioner of the FDA was charged with assessing the risk from consumption of additives that may cause cancer and making a determination as to the use of that additive.

The FDA continually monitors the safety of all food additives as new scientific evidence becomes available. For example, use of erythrosine (FD&C Red No. 3) in cosmetics and externally applied drugs was banned in 1990 after it was implicated in the development of thyroid tumors in male rats. However, the cancer risk associated with FD&C Red No. 3 is about 1 in 100,000 over a seventy-year lifetime, and its use in some foods, such as candies and maraschino cherries, is still allowed. Tartrazine (FD&C Yellow No. 5) has been found to cause dermatological reactions ranging from itching to hives in a small population subgroup. Given the mild nature of the reaction, however, it still may be used in foods.

Nitrites are also a controversial additive. When used in combination with salt, nitrites serve as antimicrobials and add flavor and color to meats. However, nitrite salts can react with certain amine in food to produce nitrosamines, many of which are known carcinogens. Food manufacturers must show that nitrosamines will not form in harmful amounts, or will be prevented from forming, in their products. The flavoring enhancer MSG is another controversial food additive. MSG is made commercially from a natural fermentation process using starch and sugar.

### KEY TERMS

**Bacteria**—Single-celled organisms without nuclei, some of which are infectious.

**Bactericidal**—A state that prevents growth of bacteria.

**Bateriostatic**—A substance that kills bacteria.

**Carcinogen**—A cancer-causing substance.

**Enrichment**—The addition of vitamins and minerals to improve the nutritional content of a food.

**Fermentation**—A reaction performed by yeast or bacteria to make alcohol.

**Fortification**—The addition of vitamins and minerals to improve the nutritional content of a food.

**Leavening**—Yeast or other agents used for rising bread.

**Microorganism**—Bacteria and protists; single-celled organisms.

Despite anecdotal reports of MSG triggering headaches or exacerbating asthma, the Joint Expert Committee on Food Additives of the United Nations Food and Agriculture Organization, the World Health Organization, the European Community's Scientific Committee for Food, the American Medical Association, and the National Academy of Sciences have all affirmed the safety of MSG at normal consumption levels.

In the United States, food additives and preservatives play an important role in ensuring that the food supply remains the safest and most abundant in the world. A major task of the FDA is to regulate the use and approval of thousands of approved food additives, and to evaluate their safety. Despite consumer concern about use of food additives and preservatives, there is very little scientific evidence that they are harmful at the levels at which they are used.

In Europe, food additives and preservatives are evaluated by the European Commission's Scientific Committee on Food. Regulations in European Union countries are similar to those in the United States. The Food and Agricultural Organization (FAO) of the United Nations and the World Health Organization (WHO) Expert Committee on Food Additives work together to evaluate the safety of food additives, as well as contaminants, naturally occurring toxicants, and residues of veterinary drugs in foods. Acceptable Daily Intakes (ADIs) are established on the basis of toxicology and other information.

# Food allergies

## Definition

Food allergies are the body's response to proteins found in food. For more than 12 million Americans alone, food allergy is a significant medical condition. All food contains proteins that enter the body when the food is eaten, or in some cases if it is touched. Allergic reaction occurs when the body reacts to these proteins as if they were harmful, and for individuals with food allergy, the offending food is harmful.

Symptoms of food allergy vary and can range from mildly annoying to dangerous and life threatening. Symptoms of food allergy include:

- tingling of the mouth
- tingling or numbness in arms or legs
- rash or hives
- itching
- abdominal cramps
- vomiting
- diarrhea
- breathing difficulties
- sudden drop in blood pressure (hypotension)
- swelling of the tongue
- swelling of the throat
- loss of consciousness
- death

The most serious symptom of food allergy is anaphylaxis. Anaphylaxis, also called anaphylactic shock, is a sudden and potentially life threatening allergic reaction in which the whole body reacts to an allergen. During anaphylaxis the airway constricts making breathing difficult. Vomiting and diarrhea may also occur as the digestive tract constricts. The skin may swell and become itchy with rash or hives especially in the face. This swelling may block airways as well. The heart may race and the heart beat may become irregular as blood vessels around the heart expand.

**Hives on the back of a young woman's legs. The accompanying inflammation develops as an allergic reaction which ranges in size from small spots to patches measuring several inches across.** *(© Custom Medical Stock Photo, Inc. Reproduced by permission.)*

Anaphylaxis is caused when the body encounters a substance it believes is toxic. This substance is an allergen and is also called IgE. When this occurs, the body produces a substance called histamine. Histamine is a protein that the body releases in reaction to a substance in the blood that the body believes is toxic. Histamine causes blood vessels to dilate or become larger and this causes the symptoms of anaphylaxis. The treatment for anaphylaxis is medication called antihistamine. The most common antihistamine is diphenhydramine hydrochloride which is found over–the–counter drugs such as Benadryl. If taken immediately, this antihistamine can stop anaphylaxis before it becomes too serious.

In cases of severe allergy, an injection of a strong antihistamine called epinephrine or adrenaline may be needed. If allergy is suspected or if an individual has had a previous allergic reaction, an injectable form of epinephrine may be prescribed. An auto–injectable form of epinephrine that looks similar to a large ball point pen is kept on hand at all times. If a severe

## KEY TERMS

**Adrenaline**—(also called epinephrine) A hormone released by the body during times of stress, it increase heart rate and blood pressure. As a medication, it may be used to constrict blood vessels, relax breathing tubes, and as a treatment for anaphylaxis.

**Allergen**—Any substance that produces an allergic reaction.

**Anaphylaxis (Anaphylactic shock)**—A sudden, severe, and potentially fatal allergic reaction characterized by difficulty breathing, low blood pressure, hives, and swelling.

**Antibody**—Proteins in the blood that help defend the body against infection.

**Antihistamine**—Medication that stops the action of histamines.

**Anti–inflammatory**—Medication such as aspirin or Ibuprophen that reduces swelling.

**Diphenhydramine hydrochloride (Benadryl)**—An antihistamine that relieves allergy symptoms.

**Epi-Pen**—A the brand name of the auto–injectable form of epinephrine. Used to stop or prevent anaphylaxis after expose to an allergen.

**Epinephrine**—(also called adrenaline) A hormone released by the body during times of stress, it increase heart rate and blood pressure. As a medication, it may be used to constrict blood vessels, relax breathing tubes, and as a treatment for anaphylaxis.

**Histamine**—A substance that is released by the body in the presence of allergens. It stimulates dilation of blood vessels, constriction of breathing tubes, and decreased blood pressure.

**IgE**—A substance in the body that triggers the body to release histamine when an allergen enters the body. IgE is measured in allergy tests.

allergic reaction occurs,the auto–injector (brand named Epi-Pen) is held against the skin and the medication is administered with a shot. Epinephrine is a strong antihistamine that stops anaphylaxis very quickly.

There is no cure for food allergies; however, food allergies may be prevented. By avoiding foods that cause allergic reactions, an individual can prevent allergic reaction. Avoiding foods that cause allergic reactions is called an elimination diet.

Before food allergies can be avoided, the offending food must be identified. There are eight foods that cause 90% of all food allergies these foods include:

- milk
- eggs
- peanuts
- tree nuts (walnuts, cashews, pecans, etc.)
- fish
- shellfish
- soy
- wheat

### Origins

The fact that some foods cause physical illness has been recognized throughout history. It was the ancient Greek, Lucretius who first said, "One man's food may be another man's poison." Throughout history, people have avoided foods that seemed to cause ill health. In the 1960s researchers began to document food allergies and to verify that avoiding these foods reduced or eliminated the allergy symptoms all together.

In the following 50 years, screening tests such as blood tests and skin tests were developed to assist in identifying food allergies. Treatment including antihistamines and anti–inflammatory medications have helped relieve symptoms, but an elimination diet remains the single most effective method to treat food allergies.

### Description

Food allergies occur when the body has an abnormal reaction to a food eaten or touched. In some individuals, certain foods cause the body to produce histamine. This histamine travels throughout the body causing symptoms such as hives, swelling, wheezing, vomiting, or diarrhea. Once a food allergy has been identified, an elimination diet is the only effective treatment. By eliminating the food that causes the allergic reaction, allergic reaction to food may be prevented.

To identify food allergies, a doctor first records a detailed medical history. The patient will usually keep a food diary documenting exactly what is eaten and when. The patient will also record any physical symptoms and when they occur. In most cases, patterns of reaction to specific foods can be seen in the food diary. Other means of diagnosis food allergies includes

- Blood tests (RAST, CAP–RAST)—A sample of blood is drawn and sent to the lab. These tests measure antibodies in the blood. These antibodies form in response to specific foods. These antibodies occur after the body has been exposed to a food and has

become allergic. This test measures IgE which is specific for each food. Individual food allergies may be identified by this test.

- Skin Tests—In a skin allergy test, a small amount of extract of a food that is suspected of causing an allergic reaction is placed on the skin, the skin is scratched in that area, and observed for reaction. If an allergy exists, a small bump (similar to a mosquito bite) will appear usually within 15 minutes. This is a rapid way to see if a food allergy exists.
- Food Challenge—This is a food test in which neither the testing doctor nor the patient knows what food is given. Opaque capsules are filled (by an assistant or another doctor) with foods that are suspected of causing allergies and foods that are not. The capsules prevent the patient from tasting or smelling the food. The patient swallows a capsule, and the doctor observes to see if a reaction occurs. This teat is not appropriate a person who has had a severe allergic reaction. It is time consuming and is usually performed when a doctor suspects the allergic reaction is not being caused by food. The test can rule out food as a cause for allergic reactions.

After a food allergy is diagnosed, an elimination diet may be implemented. Avoiding foods that cause allergic reaction may sound simple, but it can be quite difficult. It is easy to avoid eating scrambled eggs or a handful of raw peanuts; however, many common food allergy foods are ingredients in many foods.

### *Reading Food Labels*

It is essential that individuals with food allergies read the labels of every food they eat. Federal law called the Food Allergen Labeling and Consumer Protection Act (FALPCA) took effect January 1, 2006. This law mandates that all food containing milk, eggs, fish, crustacean shell fish, peanuts, tree nuts, wheat, or soy must note this on the label. To follow an elimination diet, it is essential to read these labels.

Ingredients that may cause allergies are listed on the label after the word "Contains". If these ingredients have names which are not readily known as versions of foods that may cause allergic reactions, the manufacturer will list the allergen in parenthesis. For example, albumin (egg) or casein (milk) Foods that may be present as additives for coloring or texture must be listed as well. Manufacturer must also list the individual ingredient used and 160 foods that have been identified as causing food allergies must be listed.

According to the American Academy of Allergy, Asthma, and Immunology, many other foods and ingredients may contain parts of foods that cause allergies. These foods should be avoided when on an elimination diet.

Here is a list of other foods and ingredients that may contain foods which cause allergies:

- These may contain milk: Butter flavor, butter, butter fat, butter oil, buttermilk, casein, casemates, rennet casein, cheese, cream, half and half cottage cheese, custard, yogurt, pudding, ghee, all forms of milk from animals such as goats, sour cream, milk solids, lactalbumin, lactalbumin phosphate, lactoglobulin, and lactulose.
- These may contain eggs: eggnog, albumin or albumen, lysozyme, mayonnaise, meringue, surimi, lecithin, pasta, marzipan, marshmallows, and nougat.
- These may contain peanuts or ingredients that may affect people with peanut allergies: any nut or nut product, any nut butter, peanut oil, arachis oil, goobers, mandelonas, many candies and baked goods, nougat, sunflower seeds, and foods from ethnic restaurants such as—African, Chinese, Indonesian, Mexican, Thai, and Vietnamese.

Be aware of the date of manufacturing of the foods in the pantry or on the store shelf. The new labeling requirements went into effect on January 1, 2006. Any food packaged prior to that date may not list all potentially allergy causing foods.

## Function

The function of an elimination diet is to prevent potentially life threatening allergic reactions caused by food. Food allergies begin the second time an allergy–causing food is eaten or, in some cases, touched. The first time the food is consumed, the body reacts with an abnormal biological alarm. As the food is digested and broken down into proteins that enter the blood stream, protective cells called antibodies are formed. Normally, antibodies are used to attack germs such as bacteria or viruses that invade the body. In this case, antibodies protect from disease by destroying the germs. Antibodies prompt other reactions in the body such as fever to kill disease cells or dilating of blood cells so that blood can reach infected areas of the body more rapidly.

The second time the food is ingested, these antibodies alert the body that an invader is present, and the body mounts an attack. The body responds causing the symptoms of itching, rash, hives, breathing difficulties, swelling, or irregular heart beat. Doctors suspect that the reason some people become allergic to foods and other do not is genetic. Children of parents who have a significant allergic reaction to a food are more likely to have that food allergy as well.

## Benefits

The benefits of following an elimination diet to prevent symptoms of food allergies include avoiding the discomfort of symptoms such as itching, stomach upset, and diarrhea. For individuals with severe food allergies, following an elimination diet may be lifesaving.

## Precautions

If food allergy is suspected, it is best to consult a doctor. Removing foods from the diet can cause an unbalanced diet that may be deficient in necessary nutrients. Since some of the most common foods that cause allergies include milk, eggs, and wheat, significant sources of protein, calcium and fiber may be removed. With the assistance of healthcare professions, diets may be modified and healthy substitutions may be found.

Food allergy is becoming more common in children. Food allergies in children may be more severe. Anaphylaxis generally occurs suddenly. Symptoms of food may initially be more subtle in children. It is important to discuss any suspected food allergies with a doctor.

Most individuals with food allergy are allergic to only one food; however, peanut allergy may indicate reaction to tree nuts as well. Many manufacturers who process peanut products, process other nut products as well. Machines that handle and package these products may spread small pieces of peanut to other products. The FALPCA mandates that labels note this fact as well.

## Risks

Risks of food allergy range from minor discomfort to death. Allergic reactions to food are serious and should be discussed with a doctor. Food allergy can come on suddenly. A food that did not previously cause a reaction may suddenly cause a severe reaction as the levels of antibodies in the body increase and allergy develops.

If food allergy is suspected, or if an allergic reaction has occurred, a doctor should be consulted. It may be necessary to keep an auto–injector of epinephrine on hand in case a sudden allergic reaction occurs again. These antihistamine injectors require a prescription and should only be used if a doctor has advised it.

There are few risks of following an elimination diet. However, a doctor should be consulted before eliminating foods rich in necessary nutrients such as milk, eggs, or bread. Suitable substitutions should be incorporated to insure that all necessary vitamins and minerals are maintained in the diet. Many children have food allergies. It is especially important to maintain a balanced diet in children during the important years of development.

Individuals following a special diet to treat other medical conditions should consult with a doctor before altering that diet. Eliminating foods from a previously prescribed diet may aggravate a medical condition and may be harmful.

## Research and general acceptance

### *General acceptance*

The elimination diet is standard treatment for preventing allergic reactions to food once food allergy has been diagnosed. Virtually all doctors agree and there is much data to support the effectiveness of an elimination diet.

Some individuals report food sentivities. Food sensitivity is more subtle than food allergy and rarely causes anaphylaxis. Many people report being sensitive to a variety of foods and food additives. Food sensitivity is less well understood than food allergy. However, the numbers of individuals reporting food sensitivity is increasing, especially in the Western world. In response, there are more studies investigating food sensitivity.

Some doctors doubt the validity of claims of multiple food sensitivities. Food allergy has been well studied and well documented. Most individuals with a food allergy are allergic to only one food. Many people with food sensitivities report reactions to many foods. These reactions are sometimes vague but can be marked and significant. Reported symptoms of food sensitivity include:

- rash
- itching
- stomach upset
- chronic diarrhea
- insomnia
- forgetfulness
- asthma
- inflammation of the joints
- hyperactivity (especially in children)

Children may be affected by food sensitivity. Many parents report changes in behavior after a child has eaten a food for which they may be sentitive. Currently, researchers are investigating the role of diet, food allergy, and food sensitivity in children

## QUESTIONS TO ASK YOUR DOCTOR

- Could I have more than one food allergy?
- Is an elimination diet safe for me?
- Are there any special precautions I should follow?
- Are there any drug precautions I should be aware of while following this diet?
- Do I need an Epi–Pen?

who have been diagnosed with attention deficit disorder and autism. Both conditions are affecting more children each year.

Doctors disagree about the impact of food on children with these conditions. However, many parents report successfully improving symptoms such as inability to concentrate, hyperactivity, and sleep disturbances by eliminating foods such as wheat from the diets of their children.

### *Research*

In the early 20th century, pediatricians, Clements von Pirquet and Bela Schick coined the term allergy from the Greek words *allos*, meaning changed or altered, and *ergon*, meaning reaction. Dr. von Clements was one of the first doctors to study reactions to what would later be called allergens.

In 1943 the American Academy of Allergy, Asthma, and Immunology was formed. This and other organizations of physicians help coordinate and implement many of the research finding of the many studies conducted on allergies each year.

Allergy reportedly affects 38% of all Americans. The Royal College of Physicians reports that one in three adults have an allergy. In a survey of over 3000 adults, 43% reported food allergies.

Multiple studies report a decrease of symptoms when foods that cause allergic reactions are eliminated from the diet.

# Food contamination

## Definition

Food contamination refers to foods that are spoiled or tainted because they either contain microorganisms, such as bacteria or parasites, or toxic substances that make them unfit for consumption.

## Purpose

Food contamination is a serious issue because it results in foodborne diseases that each year affect an estimated seventy-six million people in the United States, while leading to some 325,000 hospitalizations and 5,000 deaths. Hence, awareness of potential sources of food contamination is an important component of good nutrition.

## Description

Food contamination can be microbial or environmental, with the former being more common. Environmental contaminants that can enter the food supply chain include pesticides, heavy metals, and other chemical agents. Many opportunities exist for food to become contaminated as it is produced and distributed. Toi start with, bacteria are present in the animals raised for food. Meat and poultry can become contaminated during slaughter through cross-contamination from intestinal fecal matter. Similarly, fresh fruits and vegetables can be contaminated if they are washed using water contaminated with animal manure or human sewage. During food processing, contamination is also possible from infected food handlers. Lastly, poor hygiene in the home is also a factor.

### *Bacterial food contamination*

Many bacteria can contaminate food. The most common include the following:

- *Campylobacter jejuni*. Mishandling of raw poultry and consumption of undercooked poultry are the main causes of *C. jejuni* contamination.

**Cutting boards and food safety**

- **Type of boards**

  Choose either wood or a nonporous surface cutting board such as plastic, marble, glass, or pyroceramic. Nonporous surfaces are easier to clean than wood.
- **Avoid cross-contamination**

  Use one cutting board for fresh produce and bread and a separate one for raw meat, poultry, and seafood. This will prevent bacteria on a cutting board that is used for raw meat, poultry, or seafood from contaminating a food that requires no further cooking.
- **Cleaning cutting boards**

  To keep all cutting boards clean, wash them with hot, soapy water after each use; then rinse with clear water and air dry or pat dry with clean paper towels. Nonporous acrylic, plastic, or glass boards and solid wood boards can be washed in a dishwasher (laminated boards may crack and split).

  Both wooden and plastic cutting boards can be sanitized with a solution of 1 tablespoon of unscented, liquid chlorine bleach per gallon of water. Flood the surface with the bleach solution and allow it to stand for several minutes. Rinse with clear water and air dry or pat dry with clean paper towels.
- **Replace worn cutting boards**

  All plastic and wooden cutting boards wear out over time. Once cutting boards become excessively worn or develop hard-to-clean grooves, they should be discarded.

SOURCE: Food Safety and Inspections Service, U.S. Department of Agriculture

*(Illustration by GGS Information Services/Thomson Gale.)*

- *Clostridium botulinum*. Bacteria producing a toxin in food responsible for botulism, the deadly paralytic nerve illness.
- *Escherichia coli*. A leading cause of food contamination. Based on a 1999 estimate, 73,000 cases of infection and 61 deaths occur in the United States each year. The *E. coli* 0157:H7 strain is found in ground beef, raw milk, chicken, vegetables, and fruit.
- *Salmonella typhimurium*. Salmonella contamination can occur in meats, poultry, eggs or milk products.
- *Shigella*. The most common food that these bacteria can contaminate include: salads (potato, chicken, seafood, vegetable), raw vegetables, milk and other dairy products, and meat products especially poultry.
- *Staphylococcus aureus*. Can be found in custard or cream-filled baked goods, ham, poultry, eggs, potato salad, cream sauces, sandwich fillings.
- *Vibrio cholera*. These bacteria cause the well-known disease cholera that has caused many outbreaks all over the world. It can be transmitted by water or food.
- *Vibrio vulnificus*. Free-living ocean bacteria that can cause food borne illnesses from contaminated seafood. Especially dangerous in the warm weather months when eating shellfish that are undercooked or raw.

- *Yersinia enterocolitica*. Often found in raw milk, chocolate milk, water, pork, other raw meats.

Spoiled milk is also mostly caused by bacteria such as *Lactococcus cremoris* or *Enterobacter aerogenes*, that cause the milk to form long white strands.

Water contamination is usually due to the presence of three bacteria, *E. coli*, *Clostridium perfringens*, and enterococci, the bacteria normally found in the feces of people and many animals.

### *Parasitic food contamination*

Parasites are organisms that lives in or on a host, and obtain nourishment without benefiting or killing the host. They enter the body through the mouth when contaminated food or drink is swallowed. There are many different types and range in size from single-celled, microscopic organisms (protozoa) to larger, multi-cellular worms (helminths) that can be seen without a microscope. Parasites that contaminate food include:

- *Entamoeba histolytica*. Parasite that causes amoebic dysentery, characterized by severe diarrhea. It is transmitted by contaminated water, and is often called "traveler's dysentery" because of its prevalence in developing nations.
- *Giardia duodenalis*. Microscopic parasite that can live in the intestines of animals and people. It is found in every region of the world and is one of the most common causes of waterborne and foodborne) illness.
- *Cryptosporidium parvum*. Microscopic parasite, a significant cause of water contamination worldwide. It is found in the intestines of many herd animals including cows, sheep, goats, deer, and elk.
- *Cyclospora cayetanensis*. Single-celled, microscopic parasite. Little is known about this organism, although cases of infection are being reported from various countries with increasing frequency.
- *Toxoplasma gondii*. Single-celled, microscopic parasite found throughout the world. Found in foods such as raw or undercooked meats, especially pork, lamb, or wild game, and in drinking untreated water.
- *Trichinella spiralis*. Intestinal roundworm whose larvae may migrate from the digestive tract and form cysts in various muscles of the body. In the United States, infections are most prevalent where pork or wild game is consumed raw or undercooked.
- *Taenia saginata/solium*. *Taenia saginata* (beef tapeworm) and *Taenia solium* (pork tapeworm) are parasitic worms (helminths). They are now uncommon in the United States, although travelers and immigrants are occasionally infected.

## KEY TERMS

**Amoeba**—A single-celled organism, many species of which live in free in water.

**Amoebic dysentery**—Disease characterized by severe diarrhea, caused by infection of the gut by *Entamoeba histolytica*.

**Bacteria**—Microorganisms found in the environment. Bacteria can multiply quickly in food, and can cause foodborne illnesses. Not all bacteria are harmful: some are used to make yogurt and cheese.

**Contamination**—The undesired occurrence of harmful microorganisms or substances in food.

**Cross-contamination**—The transfer of harmful bacteria from one food to another, or also from hands to food.

**Feces**—Waste product of digestion formed in the large intestine. About 75% of its mass is water, the remainder is protein, fat, undigested roughage, dried digestive juices, dead cells, and bacteria.

**Foodborne illness**—Illness caused by pathogenic bacteria transmitted to humans by food.

**Microorganism**—A general term for bacteria, molds, fungus, or viruses, that can be seen only with a microscope.

**Parasite**—An organism that lives in or on a host; it obtains nourishment from the host without benefiting or killing the host. The parasites responsible for foodborne illnesses are mostly single-cell organisms such as amoeba, giardia, and trichomonas, while others have a worm-like appearance.

**Pathogen**—A disease-causing microorganism.

## Precautions

Simple precautions can reduce the risk of contamination. For instance, meat left at room temperature promotes bacterial growth and refrigeration helps to suppress it. One can also be careful about eating certain foods. Eating raw meats and fish should be avoided as well as salads prepared in restaurants where meats and vegetables share a common surface during preparation.

Most food-related illnesses can be avoided by washing fresh fruits and vegetables, cooking meat thoroughly, drinking only pasteurized milk, and common-sense hygiene. Heating food to an internal temperature above 160 °F, or 78 °C, is usually sufficient to kill

parasites, viruses or bacteria, except for the Clostridium bacteria, which produce heat-resistant spores. These can only be killed at temperatures above boiling.

The Mayo Clinic offers the following advice to prevent food contamination at home:

- Wash hands, utensils and food surfaces often. Keeping hands, utensils and food preparation surfaces clean can prevent cross-contamination, i.e. the transfer of harmful bacteria from one surface to another.
- Keep raw foods separate from ready-to-eat foods. When shopping, preparing food or storing food, keep raw meat, poultry, fish and shellfish away from other foods. This also prevents cross-contamination.
- Cook foods to a safe temperature. You can kill harmful organisms in most foods by cooking them to temperatures between 140°F and 180°F.
- Refrigerate or freeze perishable foods. Harmful bacteria can reproduce rapidly if foods are not properly cooled. Refrigerate or freeze perishable foods within two hours of purchasing or preparing them.
- Defrost food safely. Bacteria can reproduce rapidly on meat, poultry and fish at room temperature. To defrost food safely, tightly wrap meat, poultry and fish so that the juices do not drip on other food as they thaw in the refrigerator. Another method is to put the frozen food in a plastic bag and immerse it in cold water, changing the water every 30 minutes. The sealed food package can also be placed under cold, running water. Cook food immediately after defrosting.
- Use caution when serving food. Throw out any leftovers that have been at room temperature for more than two hours or in hot weather for more than an hour. If cold food needs to sit out for longer than two hours, use a tray of ice under the food to keep it cold. If hot food must sit out for longer than two hours, use warming trays to keep the food hot.
- Throw it out when in doubt. If you are not sure if a food has been prepared, served or stored safely, throw it away.
- Know when to avoid certain foods altogether.

## Interactions

Food contamination usually causes abdominal discomfort and pain, and diarrhea, but symptoms vary depending on the type of infection. Transmission usually occurs via the fecal/oral route with the ingestion of the pathogen present in the contaminated food. After they are ingested, there is a delay, (incubation period) before symptoms appear, that may range from hours to days, depending on the organism. During this period, the microbes pass through the stomach into the intestine, where they start to multiply. Some types stay in the intestine, others produce a toxin that is absorbed into the bloodstream, and others can directly invade the deeper body tissues. The symptoms depend on the type of infection. Numerous pathogens cause similar symptoms, for instance diarrhea, abdominal cramps, and nausea.

## Aftercare

There are many different kinds of foodborne diseases and they may require different treatments, depending on the symptoms they cause. Illnesses that cause diarrhea or vomiting lead to dehydration if the person loses more body fluids and salts (electrolytes) than they take in. Replacing the lost fluids and electrolytes is therefore important. If diarrhea is severe, oral medication such as Ceralyte, Pedialyte or Oralyte, can be taken to replace the fluid losses. Preparations of bismuth subsalicylate, such as Pepto-Bismol, can help reduce the duration and severity of the diarrhea.

## Complications

Food poisoning is especially serious and potentially life-threatening for young children, pregnant women and their fetuses, older adults, and people with weakened immune systems.

Data from the Centers for Disease Control and Prevention's (CDC) FoodNet surveillance system suggests that although younger individuals usually face far higher rates of infection from foodborne pathogens, older adults, along with the very young are more likely to have severe complications from these infections. In particular, research has shown that the elderly are more vulnerable to gastroenteritis-induced deaths. It is also estimated that 2–3% of all acute foodborne illnesses develop secondary long-term illnesses and complications called chronic sequellae. These can occur in any part of the body, such as the joints, nervous system, kidneys, or heart.

## Parental concerns

A bottle-fed infant is at higher risk for severe infections with bacteria that can grow in a bottle of warm formula if it is left at room temperature for many hours. Particular care is needed to keep baby bottles clean and disinfected. Leftover milk formula or juice should also not be kept in the bottle for many hours.

# Food labeling

## Definition

Food labeling tells consumers about the, ingredients, and nutritional composition of packaged food for sale. Labels may also contain information about the conditions under which the food was produced. In the United States, food labeling is regulated by several federal agencies. Some labeling information is mandatory, while others is voluntary.

## Purpose

Food labeling is designed to protect the health and well being of consumers. It allows them to:

- know what ingredients are in the food
- determine the relative amounts of each ingredient
- determine how much of selected vitamins, minerals, and other nutrients a food contains. This information may be given either by weight OR as a percentage of a daily requirement value.
- examine foods for potential allergens, additives, or ingredients that they wish to avoid
- learn about the conditions under which certain ingredients were produced (e.g. organic, free-range)
- compare the price per unit volume or weight of similar products
- determine if nutrients have been added or removed from the base food (e.g. enriched, reduced fat)

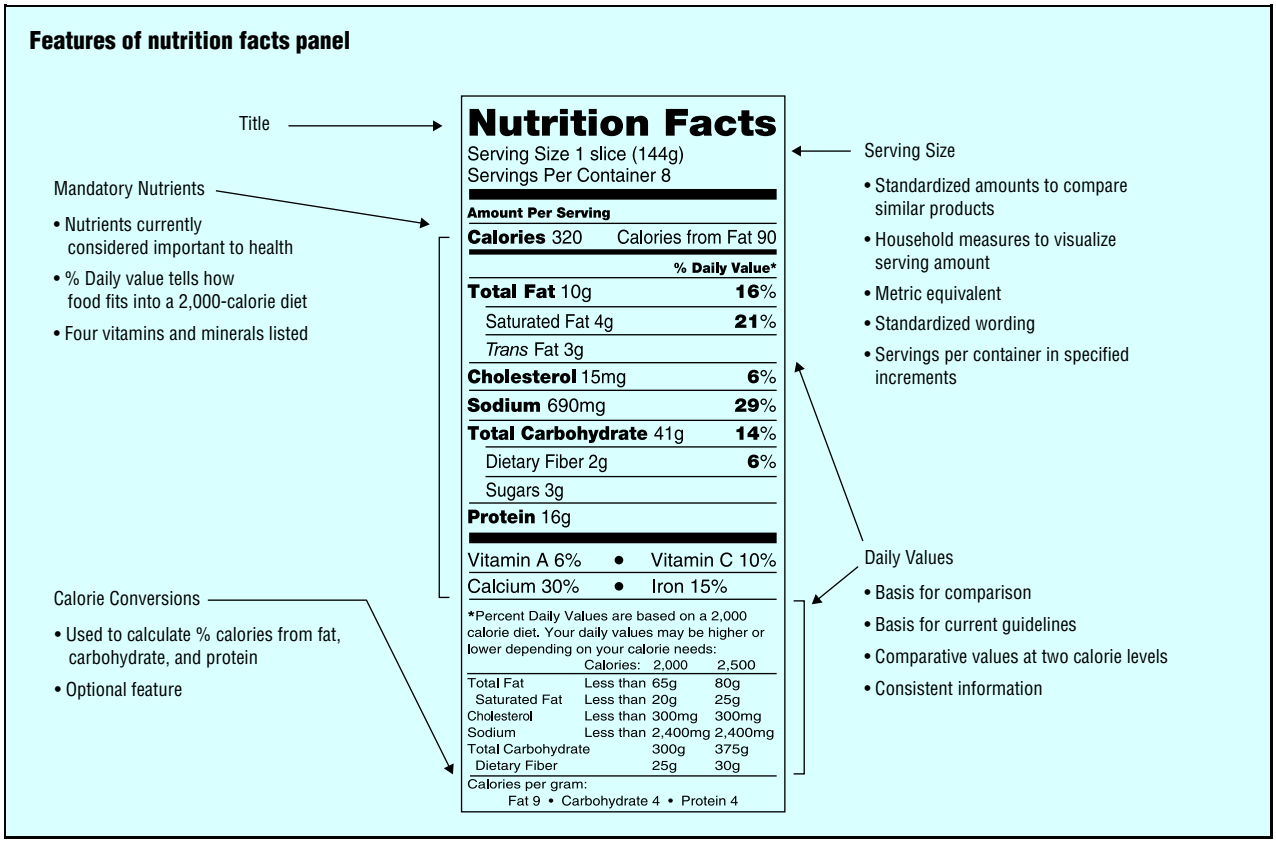
## Description

In the United States, food labeling is regulated by a great deal of very specific, complex, ever-evolving legislation. The United States Department of Agriculture (USDA) and the United States Food and Drug Administration (FDA) are the federal agencies most involved with food labeling issues and enforcement of food labeling laws. The USDA is responsible for the labeling of meat, poultry, and egg products. The FDA regulates the labeling most other foods, including seafood and **bioengineered foods**. The FDA also regulates **dietary supplements** and nutraceuticals. States also may regulate food labeling. For example, some states require sell-by or use-by information of food labels. When state and federal laws conflict, federal laws must be followed.

Different types of food have different labeling requirements. For example, canned or frozen foods are required to have different information on their labels than fresh meat, poultry, and fish. Fresh vegetables are usually subject to voluntary labeling unless they are being sold as "organic" produce. Legislation covers things as specific as the definitions of certain words used on the label (e.g. low fat), to the size of the print used on the label, to where certain information must be placed on the package. Milk and milk products are often subject to additional regulation by state dairy boards. The federal Bureau of Alcohol, Tobacco, Firearms, and Explosives regulates alcoholic beverages. The United States Customs Service requires certain information on processed foods that are imported into the U.S. This entry discusses general aspects of food labeling, with the understanding that there are complications and exceptions to almost every aspect of food labeling requirements.

### *Basic mandatory information*

Both the FDA and the USDA require certain information to be listed in English on the label of



*(Illustration by GGS Information Services/Thomson Gale.)*

packaged food available for sale. This information includes:

- Name of the product. Laws regulating what some products may be called based on their content and processing. This explains why some substances that look like cheese are called "cheese food" or "processed cheese product," and some juice-like products are called "fruit drinks" or "fruit beverages" and not juice.
- Net quantity. This is the amount of food by weight in the package. It does not include the weight of the packaging. Meat and poultry labels are required to give the weight in Imperial(avoirdupois) measures such as pounds or ounces. Other foods are required to give the weight in both English and metric (grams, kilograms) units.
- serving size and number of servings the package contains, except for single-serving packages.
- Nutrition facts. Calories, calories from fat, total fat, saturated fat, *trans* fat, cholesterol, sodium, total carbohydrates, dietary fiber, sugars, protein, vitamin A, vitamin C, calcium, and iron must be listed for a single serving of the food. This information is not required on fresh meat, fresh poultry, fresh seafood, or fresh fruit and vegetables.
- ingredient list. Every ingredient must be listed in order from the greatest to least by weight. There are exceptions for certain artificial colors and flavorings which may be listed generically by terms like "artificial coloring."
- Name of manufacturer or distributor. In some cases a full street address also is required.

### *Supplemental required information*

Certain foods are required to have additional information on the label. Some of these requirements are listed below.

- Foods containing the fat replacer olestra must state this on the label. See the entry on fat replacers for additional information.
- Foods containing sorbital or mannitol, both artificial sweeteners must list the amount.
- Foods packaged under pressure must indicate the contents are under pressure.
- Juices that have not been completely pasteurized must state they have not been completely processed.

## KEY TERMS

**Allergen**—something that causes an allergic reaction

**Dietary supplement**—a product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health

**Mineral**—an inorganic substance found in the earth that is necessary in small quantities for the body to maintain a health. Examples: zinc, copper, iron.

**Nutraceuticals**—also called functional foods, these products are marketed as having health benefits or disease-preventing qualities beyond their basic supply of energy and nutrients. Often these health benefits come in the form of added herbs, minerals, vitamins, etc.

**Vitamin**—a nutrient that the body needs in small amounts to remain healthy but that the body cannot manufacture for itself and must acquire through diet

- Foods containing raw or not ready-to-eat meat or poultry products must be labeled as such.
- Juices must show the percent real juice the product contains (e. g. 100% grapefruit juice."
- Imported foods must list their country of origin
- Foods to which vitamins and minerals have been added must be labeled as enriched with the appropriate nutrient(s).

### *Optional label information*

Certain information on food labels is optional. However, any optional information on the label must follow set guidelines and not be misleading. Foods that are labeled as "low fat," ":reduced calorie," "sugar free," or that make similar claims must meet the official FDA definition of these words (see below). Foods may list a specific amount of a particular nutrient, such as ":3 grams of carbohydrates," so long as it is not done in a misleading way. The FDA must approve any health claims the label makes that relate a specific ingredient to a specific disease (such as **calcium** helping to prevent **osteoporosis**).

Plant foods labeled "organic" are made from crops raised without synthetic fertilizers or sewage sludge fertilizer, and they have not been treated with most conventional pesticides or are not genetically engineered (see bioengineered food). Animal products that are labeled "organic" come from livestock that has been fed 100% organic feed and raised without growth hormones or antibiotics in an environment where they have access to the outdoors. There continues to be debate about the exact requirements to label animal products "cage-free," "free-range," or "grass-fed."

### *Reading a food label*

The many descriptive words on a food label cannot be used unless they meet very specific legal requirements. Some of the common descriptions found on FDA-regulated foods are listed below.

- Fat-free: less than 0.5 grams of fat per serving.
- Low fat: no more than 3 grams or less of fat per serving.
- Less fat: A minimum of 25% less fat than the comparison food.
- Light (fat) A minimum of 50% less fat than the comparison food.
- Cholesterol-free: Less than 2 mg of cholesterol and 2 g of saturated fat per serving.
- Low cholesterol: no more than 20 mg of cholesterol and 2 grams of saturated fat per serving.
- Reduced calorie: A minimum of 25% fewer calories than the comparison food.
- Low calorie: No more than 40 calories per serving.
- Light (calories): A minimum of one-third fewer calories than the comparison food.
- Sugar-free: Less than 0.5 grams of sugar per serving.
- Low sodium: No more than 140 mg of sodium per serving.
- Very low sodium: No more than 35 mg of sodium per serving.
- High fiber: 5 or more grams of fiber per serving.
- High, rich in, excellent source of: 20% or more of the Daily Value of the nutrient.
- Good source of: 10% or more of the Daily Value of the nutrient than the comparison food.
- Less, fewer, reduced: 25% or less of the named nutrient than the comparison food.

The USDA also has specific requirements for words used in labeling meat and poultry. Some of these include:

- Certified: inspected, evaluated, graded, and approved the USDA Food Safety and Inspection Service.
- Free-range or free-roaming: indicates that the animals have access to the outdoors.

- Fresh (poultry): A complicated regulation that in general says that the raw meat has never been held at a temperature below 26 °F, although there are some adjustments to this that allow a temperature fluctuation of up to 2 degrees while poultry is in stores.
- Frozen (poultry): The temperature of the raw meat is 0 °F or lower.
- Halal: prepared at a federally inspected meat-packing plant that also is overseen by an Islamic authority and meets the requirements of Islamic dietary law.
- Kosher: prepared at a federally inspected meat-packing plant that also is overseen by an Rabbi and meets the requirements of Jewish dietary law.
- Natural: containing no artificial ingredients or added color and processed in a way that does not alter the raw product.
- oven prepared: the item is cooked and ready to eat without additional cooking.
- oven ready: the item is uncooked, but is ready to cook without additional preparation.

Consumers may also see a USDA grade on the label of cuts of beef and lamb. Pork, veal, and mutton are also graded, but the grades are not usually shown on store packaging. All USDA graded meat is inspected and wholesome, but some grades are more tender and better suit to certain cooking methods than others.

- Prime: the highest quality and most tender and juicy cuts, but also the most expensive. Prime cuts contain the most fat. They make excellent steaks and roasts.
- Choice: very tender, juicy, and flavorful. This is the most popular grade of meat sold in the United States.
- Select: very lean with less fat. These cuts are best suited to long, moist cooking methods such as soups and stews.

Two other lower grades of beef, standard and commercial, are sometimes sold as ungraded "store brand" meats. These cuts are wholesome and nutritious, but tend to be tougher and dryer than the higher grades. Utility, cutter, and canner beef, the lowest of the eight grades, are almost never seen in stores. These cuts of meat are used to make ground beef, hot dogs, and other processed meat products.

### *Understanding the nutrition facts panel*

The Nutrition Labeling and Education Act of 1990 and subsequent revisions require certain nutritional information be clearly displayed on many foods. It does not apply to meat and poultry, raw fruits and vegetables, ready-to-eat food such as cookies or cakes sold at a bakery, food sold by sidewalk vendors, and a few other exceptions. Counter cards instead of packaging labels provide voluntary nutrition information for many common fruits, vegetables, raw seafood, and wild game or exotic meats (e.g. ostrich). The nutrition facts panel is designed to encourage health eating. It gives consumers a way to compare the nutritional value of products and to see how specific products can meet their dietary needs.

The nutrition facts panel consists of several sections. The serving size is given in both a familiar units such as cups or ounces and in metric units. Serving sizes are standardized for similar foods, so that consumers can make easy comparisons. If the package contains a single serving, the serving size is not required. Under the serving size the servings per container lists the total number of servings contained in the package.

All information listed below the servings per container is given per single serving. People who eat more than one serving will take in more calories and nutrients than the amount listed on the label. Calories and calories from fat, the first nutrient listed, give the consumer a quick idea of how much energy the food provides and how healthful it is (or isn't).

The next section of the nutrient facts panel deals with specific nutrients. The information is given by weight in metric units (grams or mg) and as a percent daily value. The percent daily value shows how much of each nutrient the food contributes toward meeting the daily recommended amount of each specific nutrient. Percent daily values are based on the recommended dietary allowances (RDAs) of the nutrient for a person who is eating a 2,000-calorie diet. Percent daily values of 5% or less are considered low and values of 20% or greater are considered high.

The nutrients listed next on the panel are ones that Americans generally eat enough or too much of and that they should try to limit. The first of these are total fat, saturated fat and *trans* fat. High consumption of saturated fat and *trans* fat are linked to the development of cardiovascular disease. People should try to consume as little of these **fats** as possible. *Trans* was not part of the original nutrient facts panel, but was added beginning January 1, 2006. Not enough information is available to calculate a percent daily value for *trans* fat. Cholesterol and **sodium** complete the list of nutrients that Americans consume in large amounts and should try to consume less of.

The nutrient panel also lists total **carbohydrates**, dietary **fiber**, sugars, and proteins. Americans should try to increase the amount of dietary fiber they consume. A percent daily value for **protein** is not required unless the food makes the claim "high in protein." In

that case, the daily value must be 20% or greater. No recommendations have been made about how much sugar should be consumed in a day, so no percent daily value can be calculated.

At the bottom of the label, percent daily values, but no weights, are listed for four nutrients: **vitamin A**, **Vitamin C**, calcium, and **iron**. These percentages give consumes an idea how low or high the food is in these particular nutrients.

Larger labels have a footnote at the very bottom. The information in this footnote is the always same regardless of the type of food in the package. The footnote explains that the percent daily values are calculated based on a 2,000 calorie diet, and that an individual's needs may be greater or less than the listed percent daily value depending on the individual's energy (calorie) needs. The footnote then gives dietary guidance by showing the maximum recommended grams of fat, saturated fat, cholesterol, and sodium, and the minimum grams of carbohydrates and dietary fibers a person on a 2,000 or 2,500-calorie diet should consume. This guidance is based on the Dietary Guidelines for Americans 2005. Whether this footnote is included in the label depends on the space is available. By using all the information available on food labels, consumers can make informed decision about the nutritional content of what they eat and maintain a healthy diet.

## Precautions

Labeling requirements change occasionally as more research becomes available, There is a two-year phase-in period whenever labeling requirements are changed. This eases the financial impact on companies whose products require new labels. Occasionally labels will not reflect all the most recent regulations. In 2007, regulations that would require soluble dietary fiber to be listed on food labels were under consideration.

## Parental concerns

Special labeling requirements are in effect for foods designed to consumed mainly by children age four and younger. See the entry on **infant nutrition** for additional details.

# Food poisoning

## Definition

Food poisoning comes from eating food or drinking **water** that is the contaminated with a virus, bacterium, parasite, or chemical that causes illness. It is also called gastroenteritis.

## Description

Foodborne illness is a serious public health concern in the United States and around the world. More than 250 foodborne diseases have been identified. Most food poisoning is unpleasant but not severe enough to require professional medical treatment. However, the economic impact of food poisoning is substantial. The United States Centers for Disease Control (CDC) estimates that food poisoning costs the United States between 5 and 6 billion dollars annually in direct medical care and lost productivity.

The organisms and chemicals that cause food poisoning can contaminate food at any point during the production process. Animal products cause the majority of food poisonings. They can become contaminated during slaughter, processing, transport, storage, or preparation. A vegetarian diet, however, does not protect a person from food poisoning. Fruits and vegetables can be contaminated in the fields from animal feces or pesticides, as well as during harvesting, processing, distribution, and storage. The CDC estimates that about 97% of all food poisoning comes from improper food handling. Of that, 80% occurs from food prepared in businesses (e.g. restaurants or work cafeterias) or institutions (e.g. schools or jails). The remaining 20% occurs from food prepared at home. In the twenty-first century, American bioterrorism experts have become increasingly concerned that a disease-causing organism could intentionally be introduced into the food or water supply to cause a mass outbreak of food poisoning illness.

## Demographics

The CDC estimates that about 76 million cases of food poisoning occur in the United States each year. The specific organism causing the disease is identified in only about 14 million cases. Most cases of food poisoning are mild, but about 325,000 individuals are hospitalized for food poisoning each year in the United States, and about 5,000 die. Internationally, food poisoning is about five times more common in developing countries than in the United States and Europe. In underdeveloped countries where contaminated water supplies are common and refrigeration is rare, foodborne illnesses may cause a billion illnesses and 4–6 million deaths each year.

Food poisoning is an equal opportunity illness. It affects people independent of race, age, or gender. However, the very young, the elderly, pregnant women, and people with weakened immune systems (e.g. people with HIV/AIDS, leukemia, transplant patients) are more likely to have severe cases that result hospitalization and life-threatening complications.

## Causes and symptoms

Food poisoning can be divided into two basic types: illness caused by infectious organisms and illness caused by chemicals. The infectious organisms (pathogens) that cause food poisoning are bacteria, viruses, and parasites. Chemicals can be either natural toxins (poisons) found in plants (e.g. poisonous mushrooms) and animals (Japanese puffer fish) or they can be man-made chemicals such as pesticides or herbicides.

Symptoms of food poisoning usually develop anywhere within 1–48 hours after eating contaminated food. Symptoms of chemical food poisoning often appear very quickly. The type of symptoms and their severity depend on the cause of the food poisoning, the amount of contaminated food eaten, and the health of the individual. Symptoms usually develop suddenly. Some common symptoms of food poisoning include:

- nausea followed by forceful vomiting
- frequent diarrhea. Stools can be extremely watery and may or may not contain blood.
- painful stomach cramps
- fever
- headache
- dizziness
- blurred vision, difficulty breathing, tingling in hands and feet (chemical food poisoning)

**Microorganisms responsible for common food-borne illness**

| Microorganism | Food-borne illness | Symptoms | Common food sources | Incubation |
|---|---|---|---|---|
| Bacillus cereus | Intoxication | Watery diarrhea and cramps, or nausea and vomiting | Cooked product that is left uncovered —milk, meats, vegetables, fish, rice, and starchy foods | 0.5–15 hours |
| Campylobacter jejuni | Infection | Diarrhea, perhaps accompanied by fever, abdominal pain, nausea, headache, and muscle pain | Raw chicken, other foods contaminated by raw chicken, unpasteurized milk, untreated water | 2–5 days |
| Clostridium botulinum | Intoxication | Lethargy, weakness, dizziness, double vision, difficulty speaking, swallowing, and/or breathing; paralysis; possible death | Inadequately processed, home-canned foods; sausages; seafood products; chopped bottled garlic; honey | 18–36 hours |
| Clostridium perfringens | Infection | Intense abdominal cramps, diarrhea | Meats, meat products, gravy, Tex-Mex type foods, other protein-rich foods | 8–24 hours |
| Escherichia coli group | Infection | Watery diarrhea, abdominal cramps, low-grade fever, nausea, malaise | Contaminated water, undercooked ground beef, unpasteurized apple juice and cider, raw milk, alfalfa sprouts, cut melons | 12–72 hours |
| Listeria Monocytogenes | Infection | Nausea, vomiting, diarrhea; may progress to headache, confusion, loss of balance and convulsions; may cause spontaneous abortion | Ready-to-eat foods contaminated with bacteria, including raw milk, cheeses, ice cream, raw vegetables, fermented raw sausages, raw and cooked poultry, raw meats, and raw and smoked fish | Unknown; may range from a few days to 3 weeks |
| Salmonella species | Infection | Abdominal cramps, diarrhea, fever, headache | Foods of animal origin; other foods contaminated through contact with feces, raw animal products, or infected food handlers. Poultry, eggs, raw milk, meats are frequently contaminated. | 12–72 hours |
| Shigella | Infection | Fever, abdominal pain and cramps, diarrhea | Fecally contaminated foods | 12–48 hours |
| Staphylococcus aureus | Intoxication | Nausea, vomiting, abdominal cramping | Foods contaminated by improper handling and holding temperatures—meats and meat products, poultry and egg products, protein-based salads, sandwich fillings, cream-based bakery products | 1–12 hours |
| Hepatitis A | Infection | Jaundice, fatigue, abdominal pain, anorexia, intermittent nausea, diarrhea | Raw or undercooked molluscan shellfish or foods prepared by infected handlers | 15–50 days |
| Norwalk-type viruses | Infection | Nausea, vomiting, diarrhea, abdominal cramps | Shellfish grown in fecally contaminated water; water and foods that have come into contact with contaminated water | 12–48 hours |
| Giardia lamblia | Infection | Diarrhea, abdominal cramps, nausea | Water and foods that have come into contact with contaminated water | 1–2 weeks |
| Trichinella spiralis | Infection | Nausea, diarrhea, vomiting, fatigue, fever, abdominal cramps | Raw and undercooked pork and wild game products | 1–2 days |

*(Illustration by GGS Information Services/Thomson Gale.)*

Contamination that causes food poisoning can occur at every level of the food production process Some examples follow.

- Growers: application of illegal pesticides and herbicides or their application higher than approved concentrations. In the United States, pesticides use is regulated by the United States Department of Agriculture (USDA) and the Environmental Protection Agency (EPA).
- Processors: use of contaminated water in processing, inadequate disinfecting of processing equipment, inadequate time and temperature in processing canned or cooked foods, contamination with poisons used to control factory pests, and improper handling of raw materials. In the United States, meatpacking plants are inspected by the USDA, and other food processing plants are inspected by the United States Food and Drug Administration (FDA).
- Storage and transportation: holding fresh or frozen foods at improper temperatures, inappropriate use of fumigants in warehouses or trucks, inadequate sanitizing of food-carrying tanker trucks (e.g. milk, corn syrup), and contamination by insects or rodent droppings in storage areas
- Retail outlets and restaurants: food kept at improper temperatures, cross-contamination between raw and cooked food, improper disinfecting of food preparation surfaces, transmission by infected food handlers,

## KEY TERMS

**Pathogen**—An organism that causes a disease.

**Toxin**—A general term for something that harms or poisons the body.

and failure of food handlers to wash their hands. Restaurants are inspected by local health authorities.

- Home preparation: letting food sit out too long at room temperature, inadequate cooking, cross-contamination between cooked and raw food, failure to properly reheat leftovers

### *Bacteria*

Bacterial contamination is the leading cause of food poisoning. At room temperature, bacteria reproduce at astounding rates. A single bacterium that divides every half hour can produce 17 million offspring in 12 hours. Bacteria fall into two general categories. One group causes symptoms of food poisoning by directly infecting the intestines causing irritation and diarrhea. The other group release toxins (poisons) as they grow and reproduce. These toxins affect the digestive system and often cause vomiting first followed by diarrhea. Many bacteria cause food poisoning. A few of the more common ones are described below.

Bacteria of the genus *Salmonella* are common in reptiles, birds, and mammals. They are found most often in eggs, poultry, dairy products, and beef. Infection with *Salmonella* causes nausea, vomiting, stomach cramps, headache, and low-grade fever. Symptoms begin anywhere from 6 to 48 hours after exposure and may last for 7 days. In people with weakened immune systems, *Salmonella*

Bacteria of the genus *Campylobacter* cause more diarrhea illnesses worldwide than any other group of bacteria. They produce fairly mild diarrhea, fever, and stomach cramps. *Campylobacter* bacteria are found in almost all raw chicken and turkey. Cross-contamination, that is putting cooked food down where raw food had been, is a leading cause of food poisoning from *Campylobacter*. These bacteria are also transmitted by water contaminated with animal feces.

*Escherichia coli* are a large group of bacteria, only some of which cause food poisoning. *E. coli* food poisoning usually begins with watery diarrhea that later turns bloody. One strain of *E. coli* known as 0157:H7 is most often found in undercooked hamburger, but has also been found in ready-to-eat raw spinach. This particular strain can cause kidney failure and death, especially in children and the elderly.

*Clostridium botulinium* is a bacteria that causes the disease botulism. *C. botulinium* produces a toxin that affects the nervous system and can cause difficulty breathing and paralysis. Symptoms do not appear until 1 to 4 days after exposure. Botulism is associated with improperly canned food, smoked fish, and honey. Infection with *C. botulinium* is serious and often fatal.

### *Viruses*

A large group of viruses called Norwalk or Norwalk-like viruses are an extremely common cause of foodborne illness. In the mid-2000s, Norwalk viruses were often in the news for causing outbreaks of gastrointestinal disease on cruise ships and in nursing homes. They cause more vomiting than diarrhea than any other viruses. Unlike many of the other causes of food poisoning, these viruses are not usually naturally present in food. They are usually transferred from the hands of infected food handlers to the food that they are preparing, especially to foods such as salads and sandwiches.

### *Parasites*

Parasites that cause food poisoning usually come from contaminated water. They often cause mild symptoms that are slow to develop but last for several weeks. *Giardia* causes watery diarrhea and is often acquired by drinking untreated water from lakes or streams. *Cyrptosporidium* is a parasite that causes large amounts of watery diarrhea for 3–4 days. Healthy people usually recover quickly, but in people with weakened immune systems, symptoms can persist for a long time.

### *Natural toxins*

Natural poisons found in some wild mushrooms can cause anything from nausea and vomiting to hallucinations, coma, and death, depending on the amount and species of mushroom eaten. Mushroom poisoning is a medical emergency. People who believe they have eaten a poisonous mushroom should, if possible, take a sample of the mushroom or their vomit to the emergency room with them. Identifying the type of mushroom causing the illness can help determine the most effective treatment.

Oysters, clams, mollusks, and scallops can contain toxins that affect the nervous system. Symptoms usually begin with a tingling in the mouth, then the arms and legs. Individuals may become dizzy and may have difficulty breathing. Shellfish poisoning is a medical emergency because the muscles needed for breathing

may become paralyzed. Similar symptoms result from eating the Japanese puffer fish which contains a natural poison that in its skin and digestive system that affects the nervous system.

### *Manmade toxins*

Manmade toxins include all pesticides, fertilizers, disinfectants, and any other chemicals remaining in food when it is eaten that can cause illness. Contamination is accidental, and often the result of ignorance or a misunderstanding of how to apply the chemical. Symptoms may develop rapidly or slowly depending on the type of chemical and the amount of exposure. Chemical poisoning requires prompt medical evaluation.

## Diagnosis

Food poisoning is caused by many different organisms, but identifying the exact organism is not usually necessary. Most mild food poisoning is diagnosed by the symptoms of vomiting, diarrhea, and stomach cramps coupled with information about that the individual has recently eaten. The length of time between eating the suspect food and the start of symptoms gives physicians a clue about what particular organism may be causing the food poisoning. Blood and urine tests may be ordered to determine the individual's degree of **dehydration** and electrolyte (chemical) imbalances. In most cases, determining the exact pathogen that is causing the food poisoning is relatively unimportant, as treatment tends to be the similar for most causes. However, if diarrhea is persistent, a stool culture may be done to provide more specific information.

When chemical or natural toxin poisoning is suspected, determining the exact cause is more important, and treatment is specific to the cause. The stomach may be pumped and the contents tested. Extensive blood tests are usually needed. Sometimes activated charcoal is used to help absorb the poison in the stomach.

## Treatment

The main goal of treatment for food poisoning is to keep the individual from becoming dehydrated. A loss of 20% of a person's body fluid is fatal, and 10-15% is serious. In food poisoning, huge amounts of both water and **electrolytes** can be lost quite rapidly. Vomiting and diarrhea in infants and young children require especially prompt professional treatment because small children can become dehydrated within hours.

Mild cases of food poisoning can usually be treated at home, especially if they are not accompanied by a fever. Dehydration in infants and children can be prevented or treated by giving them oral rehydration solutions such as Pedialyte, Infalyte, Naturalyte, Oralyte, or Rehydralyte. These are available in supermarkets and pharmacies without a prescription. Oral rehydration solutions have the proper balance of salts and sugars to restore fluid and electrolyte balance. They can be given to young children in small sips as soon as vomiting and diarrhea start. Children may continue to vomit and have diarrhea, but some of the fluid will be absorbed. In the past, parents were told to withhold solid food from children who had diarrhea. New research indicates that it is better for children should to be allowed to eat solid food should they want it, even though diarrhea continues.

Older children and adults who are dehydrated can be given oral rehydration solutions or sports drinks such as Gatorade. Adults and older children with food poisoning should avoid drinking coffee, tea, and soft drinks, especially soft drinks that contain **caffeine**, as these liquids promote dehydration. Over-the counter medications to stop or slow diarrhea such as Kaopectate, Pepto-Bismol, or Imodium will not shorten the duration of the disease, but may give the individual some control over his or her bowels. Consult a physician before giving these over-the-counter medicines to children.

Individuals of all ages who are seriously dehydrated need to be treated promptly by a medical professional. In the case of severe dehydration, the individual may be hospitalized and fluids given intravenously (IV; directly into the vein). Drugs may also be prescribed to stop persistent vomiting. Although bacteria cause many cases of food poisoning, antibiotics are not routinely used in treatment. Some studies have shown that antibiotics are necessary only in about 10% of cases.

Individuals who think their food poisoning symptoms are caused by chemicals or natural toxins should seek emergency medical care immediately. These types of food poisoning are too serious to try to treat at home.

## Nutrition/Dietetic concerns

Certain foods are more commonly associated with food poisoning than others. These include:

- raw and undercooked meat, especially ground meat
- raw or undercooked poultry
- raw or undercooked eggs and egg products such as mayonnaise or raw cookie dough. Estimates are that 1 of every 20,000 eggs is contaminated with *Salmonella*.
- unpasteurized milk products or unpasteurized fruit juice
- raw shellfish, especially oysters, clams, scallops, and mussels
- ready-to-eat raw fruits and vegetables

- alfalfa and bean sprouts
- wild mushrooms. Note: many mushrooms that are poisonous in North America look almost identical to safe-to-eat mushrooms found in Europe.
- improperly prepared fish such as barracuda or Japanese puffer fish.
- improperly canned foods (homemade or commercial). Note: any can that is leaking or bulging should be discarded.
- soft cheeses such as brie or feta
- lunch meats or deli meats

Although the food in the United States is very safe, occasionally major outbreaks of food poisoning occur that can be traced to a breakdown in the food handling system. Larger outbreaks can be identified and traced to their source because each state has a list of diseases that health professionals are required to report to the county public health service once positive diagnosis is made. Most states require that doctors and hospitals report confirmed cases of disease caused by *Salmonella* and *E. coli* 0157:H7 and several other food poisoning pathogens. This information is then passed on to the CDC.

Most food poisoning occurs to single individual or to a small group of people, such as a family at a picnic. A major food poisoning outbreak is suspected when many people develop the same symptoms of food poisoning within a short time or within the same geographic area. A major outbreak sets off a full investigation by a team of microbiologists, food scientists, process engineers, specialists in food sanitation, and others. In a larger outbreak, the CDC usually coordinates the investigation. The CDC has established a special system called FoodNet to monitor food poisoning reports and look for patterns that suggest an outbreak. Information on chemical and natural toxin poisonings is also collected by the American Association of Poison Control Centers.

## Prognosis

Most people have unpleasant gastrointestinal symptoms—vomiting and diarrhea—for a few days and then recover fully from food poisoning. In young children, dehydration is always a cause for concern. Worldwide, dehydration from diarrhea is the biggest killer of children under age 5. If dehydration can be controlled in young children with food poisoning, most recover with few complications. However, E. coli 0157:H7 can cause fatal renal failure in 3–5% of children. This bacteria is most often acquired by eating unpasteurized apple cider or apple juice, alfalfa or bean sprouts.

More serious long-term health problems often result from chemical poisonings. Toxins found in some wild mushrooms and some fish can cause permanent liver damage requiring a liver transplant or death. Pesticides and other chemical contamination can cause liver damage, kidney failure, and nervous system complications. In 2007, apparent chemical contamination of pet food caused the death of hundreds of dogs and cats in the United States.

## Prevention

Appropriate food handling procedures at every level of the production process can go a long way in preventing food poisoning. Growers should apply only approved pesticides and herbicides at levels recommended by the Environmental Protection Agency and the Department of Agriculture. Processors must use clean sources of water to wash produce. Processing machinery must be disinfected regularly, and pesticides used in processing plants must be safe for use around food. In restaurants, food must not be held under warming lights of on buffet tables for long periods.

At home, individuals can help prevent food poison by following these guidelines.

- Wash hands, food preparation surfaces, and utensils often when handling food.
- Prevent cross-contamination of raw and cooked food. Do not put cooked food back on the same plate or surface that held it when it was raw.
- Cook foods to internal temperatures between 140°F and 180°F (60–83° C).
- Refrigerate or freeze fresh foods and leftovers promptly
- Defrost food in the refrigerator or microwave and not on the counter at room temperature. Cook promptly when defrosted.
- Keep food at temperatures above 140°F (60°C) or below 40°F (4° C).
- Throw out food that has sat at room temperature for 2 hours or more.

# Food safety

## Definition

Food safety involves the safe handling of food from the time it is grown, packaged, distributed, and prepared to prevent foodborne illnesses. Food safety is the responsibility of those who handle and prepare food commercially for delivery to consumers and of consumers who prepare and eat food in their homes.

Foodborne illness, or **food poisoning**, may be caused by bacteria that grow on food or by viruses that are spread because food is not cleaned, stored, or handled properly. These illnesses may cause minor symptoms or serious symptoms and even death in some people. Contaminated foods also can carry harmful parasites, toxins, chemicals, and physical contaminants. It is estimated that about 76 million people in the United States become ill from foodborne pathogens each year and that about 5,000 of these people die.

**Safe cooking temperatures**

| Food | Internal temperature Fahrenheit | Celsius |
|---|---|---|
| **Ground meats** | | |
| Beef, veal, pork, lamb | 160° | 71° |
| Turkey, chicken | 165° | 74° |
| **Fresh beef, veal, lamb** | | |
| Medium rare | 145° | 63° |
| Medium | 160° | 71° |
| Well done | 170° | 77° |
| **Poultry** | | |
| Chicken, turkey, whole | 165° | 74° |
| Poultry breasts | 165° | 74° |
| Poultry thighs, wings | 165° | 74° |
| Duck, goose | 165° | 74° |
| Stuffing (cooked alone or in bird) | 165° | 74° |
| **Fresh pork** | | |
| Medium | 160° | 71° |
| Well done | 170° | 77° |
| **Ham** | | |
| Fresh (raw) | 160° | 71° |
| Pre-cooked (reheated) | 140° | 60° |
| **Seafood** | | |
| Fish | 145° | 63° |
| Shellfish | Shells red and flesh opaque | |
| Clams, oysters, mussels | Shells open | |
| Scallops | Milky white or opaque and firm | |
| **Eggs and egg dishes** | | |
| Eggs | Yolk and white firm | |
| Egg dishes | 160° | 71° |
| **Leftovers and casseroles** | 165° | 74° |

*(Illustration by GGS Information Services/Thomson Gale.)*

## Purpose

Avoiding foods that that are contaminated can help prevent illness, especially in certain people. Consumers can take simple steps to reduce the risk of foodborne illness in their homes. Government and the food and restaurant industries can work together to prevent foodborne illness from occurring in the American population.

### *Foodborne illnesses*

The following are some of the foodborne illnesses that can occur as a result of food contamination:

- Campylobacter, which is the most common bacterial cause of diarrhea, and can be caused by undercooked

chicken or other foods contaminated with juices that drip from raw chicken.

- Salmonella, a bacterium that can spread from food of animal origin. Symptoms include fever, diarrhea, and abdominal cramps and can become serious in some individuals.
- *E. coli* 0157:H7 is a bacteria that resides in cattle and similar animals. Humans usually get the illness from consuming food or water that has been contaminated with small amounts of cow feces.
- Calcivirus, or Norwalk-like virus, is common but rarely diagnosed because no laboratory test can diagnose it. It causes more vomiting than diarrhea.

The farmer who grows produce, the packager, the produce department employee, the fast food worker, and the parent in the kitchen preparing a family's meal, each have to work to keep food as safe as possible. Although there are several measures to take, they are not complicated or time-consuming. Yet food safety came into increasing public light in 2006 and 2007.

In September, 2006, Natural Selection Foods of San Juan Bautista, California, issued a nationwide recall of all of its fresh spinach and ready-made salads with spinach. Sold under 31 brand names, the company's product was found to be source of E. coli contamination. E. coli is a rare but dangerous organism usually found in undercooked meat products. But in this case, the organism had gotten into packages of the fresh spinach and sickened more than 200 people in 26 states and Canada, resulting in three deaths. Within months, news spread of E.coli from lettuce at Taco Bell restaurants in the Northeastern United States. In early 2007, several peanut butter brands were recalled after salmonella was found in a manufacturer's batch of peanut butter. These cases brought renewed attention to food safety.

In light of these outbreaks, the food and restaurant industries were working with United States government agencies to improve oversight and inspection of food sources in the country. Increased federal regulation may produce safety standards that are consistent and that apply to all produce grown in the United States or imported into the United States from other countries. New standards may be specific to particular foods. Many public education programs aim to keep the general public informed about home food safety, which is the part of food safety that individuals can monitor and control.

Families should take particular note of food safety for certain family members. Babies and young children are particularly vulnerable to food poisoning.

## KEY TERMS

**Immunocompromised**—Having an impaired or weakened immune system. The immune system protects the body from foreign substances, cells, and tissues.

Summer picnics and cookouts, including barbecues and outdoor buffets, can create opportunities for food poisoning in young children and is a key source of food poisoning for others. And parents need to be particularly careful in handling breast milk and infant formulas, which can harbor bacteria. Pregnant women, older family members, and anyone who is immunocompromised also may be more susceptible to food poisoning.

## Description

Most home food safety focuses on four key areas: proper cleaning of food, of hands, and of food preparation areas, keeping raw foods such as meats and poultry separated from ready-to-eat foods, keeping food properly chilled, and cooking food to the proper temperature.

### *Cleaning food and surfaces*

When it comes to handling food, consumers can't be too clean. Many food safety experts recommend that when preparing and eating food, people should wash their hands often. This is even more important after handling raw meat, poultry, eggs, or seafood. Thoroughly washing hands means applying soap and rubbing the hands together under warm, running **water** for at least 20 seconds. The American Dietetic Association says that singing two choruses of "Happy Birthday" while lathering up helps keep hand-washing time at 20 seconds. It's also important to rub soap between fingers, down to the wrists and into fingernails to ensure a thorough cleansing. Hands should be dried on paper towels rather than teatowels, which can easily spread bateria.

Cleaning some foods is recommended too. Fresh fruits and vegetables should be washed after discarding outside leaves and just before cooking or eating. They should be washed under clean running water and scrubbed with a clean brush or with both hands. Drying the fruits and vegetables after washing with a clean cloth or disposable towel also is important if they won't be eaten right away, since free moisture on the surface can

promote growth of microbial populations. Even fresh fruits and vegetables with skins and rinds that won't be eaten should be cleaned. Raw meat and poultry should not be washed, because it only adds to the possibility of cross-contamination between surfaces.

Food preparation tools and surfaces should be carefully and regularly cleaned. This includes cutting boards, kitchen utensils, dishes, appliances, kitchen bins and counter tops. Hot, soapy water can be used for cleaning surfaces. Dish cloths and dish towels should only be washed in the hot water cycle. Sponges should be disinfected in a chlorine bleach solution and replaced frequently. In 2007, research showed that placing a wet kitchen sponge in the microwave for two minutes would clean it, removing dangerous bacteria. The sponge should not be touched immediately after the two minutes are up, as it will be hot. And the sponge must be wet before being placed in the microwave. Any sponge, dish cloth, dish towel, or other food preparation item or surface that is smelly is a sign of bacteria build-up. It should be properly cleaned as described above or discarded. Bacteria thrive in damp conditions.

### *Separating foods*

The juices from raw meat, poultry, seafood, and eggs should never touch uncooked, ready-to-eat foods, such as fruits and vegetables. This is one reason why it is so important to thoroughly wash hands after each time raw meats and other raw foods are touched. Even when storing foods from shopping and in the refrigerator, care should be taken to contain juices. Fresh meats, poultry, and seafood can be sealed in plastic bags to prevent juices leaking onto refrigerator surfaces.

The cutting board is an opportune location for cross-contamination. It is best not to use a wooden board with cracks, crevices and knife scars. In fact, old cutting boards such as these should be discarded. Food safety experts say the safest way to avoid cross-contamination is to assign one cutting board strictly for cutting raw meat, poultry, and seafood, and another board for cutting vegetables, breads, and other ready-to-eat foods. Labeling the boards or using colors (green for vegetables) can help keep family members from confusing them. After using a board to cut raw meats, it should be thoroughly cleaned with hot, soapy water or in the dishwasher.

Care also must be taken when cooking foods not to re-use a plate that has contained raw meat, poultry, or seafood. For instance, when grilling, the cooked meats should be placed on a clean plate, not on the one that the meats were brought to the grill on, that contains remnants of juices from the raw food.

### *Properly chilling foods*

Bacteria growth is slowed by colder temperatures. Refrigerators should be kept at a temperature no higher than 40°F and the freezer at 0°F. It is recommended to keep a refrigerator thermometer in the refrigerator at all times to monitor the temperature. It's important to refrigerate foods promptly after bringing them home from the store, particularly during warmer summer months.

The length of time foods can be safely stored in the refrigerator varies. Foods usually are marked by manufacturers and grocery stores. Raw meat, poultry, eggs, seafood, and cut fruit and vegetables should never sit out of the refrigerator or freezer for more than two hours (one hour if the temperature is above 90°F. Leftovers should be refrigerated promptly. Most will last three to four days in the refrigerator but exceptions are stuffing and some cooked patties and gravies or broths, which only should be kept one to two days. Bacterial growth may not cause any sort of smell or discoloration, so there may be no way to tell by looking or smelling. It is better to be safe than sorry, or as food safety experts recommend, "If in doubt, throw it out." Plus, overstuffing the refrigerator keeps cold air from circulating properly, so cleaning it out often serves two purposes.

Foods such as raw meats should be marinated in the refrigerator, not on a kitchen counter. Food never should be defrosted at room temperature, but in a refrigerator. If food is defrosted more rapidly by submerging in warm water or by using a microwave, it should be cooked immediately.

### *Cooking to proper temperature*

Too often, consumers rely on the look of foods to determine if they are cooked. But trying to judge doneness by color of meat or juices does not accurately determine safe temperature. It is important to invest in a good meat thermometer and to use it appropriately because uncooked or undercooked meat, poultry, and eggs, as well as egg products, are potentially unsafe.

Accurate temperature readings on a thermometer require placing it in the thickest portion of meats and poultry pieces, away from bone, fat, and gristle. The thermometer should be placed in the center of casseroles and egg dishes. The following minimum temperatures are advised for some common foods:

- hamburger (patties, meatballs) 160°F (71°C)
- roasts and steaks 165°F (74°C)
- whole chicken, turkey 180°F (82°C)
- chicken drumstick (thighs, wings, dark meat) 180°F (82°C)

- fish 140°F (60° C)
- egg dishes, casseroles 160°F (71°C)

When cooking food in the microwave, it is important to avoid cold spots. This is why microwave heating directions often include instructions to stir food halfway through cooking; stirring helps to eliminate cold spots and evenly distribute heat. Reheated leftovers should reach a minimum temperature of 165°F (74°C). It is best to cook leftover sauces, soups, and gravy to a boil.

### Precautions

New information on food safety constantly is developed and released, so consumers should watch for updated information. This is particularly true of product recalls, such as those that occurred in late 2006.

### Complications

By not following food safety guidelines, consumers run the risk of developing food poisoning or causing it in a family member or other person served food. There have been reports of food poisoning at family and community events because a preparer or those gathered did not follow food safety precautions. Eating or drinking contaminated food almost always causes diarrhea, which can be a serious health risk for infants and other people at risk of complications. Depending on the cause and type of foodborne illness, a person also might experience fever, nausea, vomiting, and abdominal cramps. Many people mistakenly believe that symptoms of food poisoning must appear within hours of eating the contaminated food. But symptoms can appear in 30 minutes, 12 hours or up to one week later. The safety of the American food supply may improve as greater scrutiny, coordination, and possibly regulations are applied to the production, packaging, and preparation of food in the country. This concern for better scrutiny also applies in other countries.

### Parental concerns

Pregnant women need to pay particular attention to food hygiene and avoidance of some high risk foods is recommended.

Although potentially fatal cases of diarrhea from e. coli in young children have declined in recent years, it is important to remember that infants and young children are very vulnerable to food poisoning. It is important to carefully store breast milk and infant formula, keeping mixed formula no longer than 24 hours in the refrigerator. Any formula that is past the expiration date listed on the container should be discarded and when feeding an infant, parents and caregivers should throw away the formula or breast milk that is left in a bottle after feeding. Bottles should not sit around, but should be refrigerated. After two hours of sitting out, a bottle can be contaminated with salmonella. Babies under age one should never receive any food containing honey, even if it is cooked, as honey can contains botulism spores. Botulism can be deadly for babies.

When babies and toddlers start eating solid foods, it is important to check the expiration date and seal on the baby food jar. Dipping the spoon into the jar after using it to feed the baby and then refrigerating the jar with leftovers inside is not recommended. Germs from the baby's mouth can contaminate the food. Instead, the food should be poured from the jar into a dish and the baby should be fed from the dish.

## Food sensitivities

### Definition

Food sensitivity, also known as food intolerance, can be defined as a reproducible, adverse reaction to a food, or food ingredient, at a dose tolerated by most people. It is technically described as non-allergenic food hypersensitivity as it does not involve the immune system, unlike in cases of food allergy where an immune response is involved. Typically the features of food sensitivity are less severe and take a longer time to manifest, compared with food allergy where symptoms can be potentially life-threatening and occur soon after ingestion.

**Common food sensitivities**

- Eggs
- Milk and dairy
- Peanuts and other nuts
- Shellfish
- Soy
- Strawberries
- Wheat

**Possible symptoms**

- Abdominal pain and bloating
- Constipation
- Diarrhea
- Excess coughing
- Hyperactivity
- Infantile colic
- Irritable bowel syndrome
- Itchy skin
- Migraine
- Skin rash
- Sneezing
- Unexplained joint and muscle pain
- Vomiting
- Wheezing

*(Illustration by GGS Information Services/Thomson Gale.)*

## Origins

Food sensitivity is often misdiagnosed due to the lack of well-controlled clinical trials proving its existence. However, it is very difficult to investigate food sensitivity in the same way as you would a particular medical intervention because of the number of variable factors involved, such as the type, amount and frequency of foods consumed in a typical diet as well as other environmental factors that could provoke similar symptoms.

Food sensitivities that involve particular food additives are more easy to study and have indeed shown that certain individuals can be sensitive to synthetic colourings, such as azo dyes, as well as the preservatives, **sodium** benzoate, benzoic acid, sulphur dioxide and sulphites.

Other studies have excluded gluten (a **protein** found in wheat, barley and rye) and casein (a protein found in milk and dairy products ) in children with autistic spectrum disorder (ASD) and attention deficit **hyperactivity** disorder (ADHD) and have noted improvements in behaviour and communication. It is important to note that these trials did not take any baseline dietary measurements and so the 'exclusion' diet, whilst excluding certain food groups are highly likely to increase intakes of fruits, vegetables, fish, seafood, nuts, brown rice and soya-based foods ( eg. tofu and soya milk ), all of which are rich sources of key nutrients known to be vital for good physical and **mental health**. The positive outcomes highlighted from these studies may have more to do with which foods were included, rather than excluded, or even a combination of both.

## Description

Food sensitivity can occur for a variety of reasons, outlined in detail below:

- Enzyme -Deficiency: The classic example would be the loss of the lactase enzyme needed to breakdown lactose found in milk and dairy foods. The undigested lactose is fermented by gut bacteria that produce large amounts of organic acids and gases, resulting in abdominal pain, distension and diarrhoea.
- Pharmacological: Some foods contain pharmacologically active substances that can cause adverse effects in some people. Good examples include caffeine, found in in coffee and cola drinks, and monosodium glutamate, often used in manufactured foods and some Chinese meals.
- Histamine-Release: Foods, such as shellfish and strawberries, contain histamine-releasing agents which can cause adverse reactions in sensitive individuals.
- Irritant: Excessive consumption of foods such as onions, nuts and prunes can act as an irritant to the gastrointestinal tract (gut) and result in unpleasant symptoms.
- Toxic: A small number of foods contain naturally occurring toxic compounds, such as lectins found in under-cooked kidney beans, which can be lethal.

Depending on the actual cause, food sensitivity can cause adverse effects throughout the body. If the gut is involved, symptoms can include vomiting, diarrhoea, **constipation**, **irritable bowel syndrome**, infantile colic, abdominal pain and bloating. However, these symptoms may also be a consequence of poor nutrition and dysbiosis, which is when the beneficial bacteria that live in the gut are out of balance with more harmful varieties. This can often occur following a period of gastroenteritis or after taking broad-spectrum antibiotics. Including probiotic-enriched food and drinks in your diet and eating foods that contain prebiotics, which help feed the probiotic bacteria, can help redress the balance in favour of beneficial bacteria and consequently improve gut function. Prebiotic-rich foods include oats, bananas, onion, garlic, leeks, artichokes and asparagus.

If the gut is not working properly then potentially any food could exacerbate the situation and cause symptoms to worsen. In these situations it is difficult to differentiate between food sensitivity and compromised gut function.

## KEY TERMS

**Aetiology**—This refers to the cause of a disease.

**ADHD**—The combination of inattentive, hyperactive and impulsive behaviour which are severe, developmentally inappropriate and impair function at home and in school. Common features include mood swings, anxiety, impulsivity, hostility, poor concentration and sleep problems as well as physical complaints such as stomach aches, headaches and migraines.

**Antibodies**—A protein produced by certain cells in the body in the presence of a specific antigen, which bind with it to neutralize, inhibit or destroy it.

**Antigens**—Any substance that when introduced into the tissues or blood induces the formation of antigen-specific antibodies.

**ASD**—Autistic Spectrum Disorder (ASD) refers to the features of individuals who have a degree of the condition known as autism. Autism is a serious developmental disorder characterised by profound deficits in language, communication, socialisation and resistance to learning.

**Benzoic Acid**—A type of preservative used in processed foods known to cause food sensitivity in some individuals when consumed in the diet.

**Cardiovascular Disease**—This describes medical conditions that relate to disease of the heart and circulatory system ( blood vessels) such as angina, heart attacks and strokes.

**Dietitian**—A Healthcare Professional, qualified to degree or post-graduate level, who advises individuals on diet and nutrition as part of a treatment strategy for particular medical conditions or for disease prevention.

**Dysbiosis**—The general term to describe the overgrowth of undesirable microflora in the intestines.

**Food Allergy**—A hypersensitivity reaction to particular food proteins involving the immune system.

**Immune System**—The defence system of the body that responds when challenged by antigens.

**Microflora**—This term describes the collection of small micro-organisms, such as bacteria, that colonise the gastrointestinal tract (gut).

**Sodium Benzoate**—A type of preservative used in processed foods known to cause food sensitivity in some individuals when consumed in the diet.

**Sulphites**—A type of preservative used in processed foods known to cause food sensitivity in some individuals when consumed in the diet.

**Sulphur Dioxide**—A type of preservative used in processed foods known to cause food sensitivity in some individuals when consumed in the diet.

Other features of food sensitivity can include skin rash, itchy skin, excessive coughing , sneezing, wheezing as well as migraine, hyperactivity and unexplained joint and muscle pain.

### Function

The diet suitable for people with food sensitivity will depend on which food, or food ingredient, is causing the problem. If a particular food, or food ingredient, is suspected then the tried and tested method for diagnosis is a period of dietary exclusion followed by re-introduction of the food without the sufferer knowing to see if it has any effect and then a second exclusion. If the presence and absence of the food correlates with the presence and absence of symptoms then a positive diagnosis can be made.This should only be the case if the testing is blinded. If a reaction is severe re-introduction should be carried out with medical supervision.

In cases where multiple foods are suspected, a *few foods* diet, which consists of foods highly unlikely to cause a reaction ( eg. rice, lamb, pears ), is followed until symptoms disappear. This is then followed by a systematic blinded re-introduction of single foods, one at a time, allowing the identification of any *problem* foods to be easily identified whilst avoiding unnecessary restrictions.

Individuals with suspected or proven food sensitivity, who are excluding major food groups, should seek the advice of a qualified Dietitian to avoid compromising nutrient intakes and consequently their physical and mental health.

### Benefits

The diet suitable for food sensitivity benefits the individual by removal of the offending food, or food ingredient, leading to an improvement in symptoms. It is also worth noting that some types of food sensitivity can be transitory and so re-introduction of the

*offending* food, or food ingredient, is recommended every 3-6 months to test whether the sensitivity still persists.

Many people who have been motivated to change their diet in an attempt to relieve the effects of food sensitivity will remain interested in maintaining good nutritional health and continue to eat well. A well-balanced food sensitivity diet can still be rich in fibre, **vitamins** and **minerals**, all of which are vital for good brain and body functioning as well as reducing the risk of developing certain cancers and cardiovascular disease.

## Precautions

Very young children and babies should not have any dietary restrictions imposed upon them unless they are clinically indicated and are supervised by a Doctor and Dietitian. The restricted nutrient intake that might result can significantly compromise children's growth and development.

The same risk applies to older children and adolescents because of their high requirements needed to sustain good physical growth and mental development

Women planning a pregnancy, are already pregnant or are breast feeding should also avoid any dietary restrictions, unless recommended by a Doctor or Dietitian, as they can compromise nutrient intakes and ultimately the health of both mother and baby.

Individuals suffering from any chronic medical condition or recovering from surgery should not follow a restricted diet without medical supervision as this can exacerbate symptoms and slow down recovery and wound healing.

## Risks

The most nutritionally balanced diet is one that includes a wide range of different foods and so the main risk attached to the food sensitivity diet depends on the particular restrictions involved. In some cases, avoidance of the offending foods is nutritionally insignificant and can be easily excluded eg. **caffeine** drinks and strawberries.

The greatest nutritional risk is associated with the exclusion of entire food groups, such as dairy foods and gluten-containing cereals. Gluten-free diets can be low in fibre, which is needed for good bowel function and helps to protect against cardiovascular disease, and cows milk-free diets can be low in **calcium** and **iodine**, which are important for bone strength and brain function.

Advice from a Dietitian should ideally be sought to ensure nutritional adequacy and allow discussion of suitable substitute foods and **dietary supplements**, where appropriate.

A final point worth mentioning is that substitute foods are not always available, are usually more expensive and following these diets can make eating out and social occasions more difficult.

### QUESTIONS TO ASK YOUR DOCTOR

- How do I know if I have a food sensitivity ?
- How do you test for food sensitivity ?
- Could probiotics help ?
- Do I need to take calcium supplements if I follow a dairy-free diet ?
- What are the best sources of fibre in a gluten-free diet ?

## Research and general acceptance

The subject of food sensitivity remains contentious, with many healthcare professionals debating its prevalence. The lack of well designed clinical trials and the huge increase in self-diagnosis has certainly made it difficult to establish the true incidence and aetiology of food sensitivity. Another problem is that conditions can go undiagnosed if individuals self-diagnose food intolerances or rely on dubious tests.

Research findings support the view that some sensitive individuals can react badly to certain food additives but intolerance to major food groups has been difficult to evaluate. Those trials that have demonstrated improvements on a gluten-free and casein-free diets have not taken into account the other changes that have occurred in the diet and are often assessed by parents and carers, making their findings subjective.

Fundamentally in cases of food sensitivity the diet needs to be fully assessed to see what is missing, in terms of foods that provide key nutrients, as well as what is being included that could be triggering an intolerance.

# French paradox

## Definition

The French Paradox refers to the low rate of **coronary heart disease** (CHD) in France despite the diet being rich in saturated fat.

## Origins

2002 data from the Food and Agriculture Organization of the United Nations (FAO), showed that although the intake of saturated fat in France was higher than in the United States (US), 108 grams (g) compared to 72g per day, France had a 30–40% lower risk of CHD. Over the years, studies suggest that one of the reasons the French have a lower rate of CHD, despite higher saturated fat intakes, may be related to their regular consumption of red wine.

Links to alcohol and heart disease were first observed in 1976. English Physician William Heberden's classic descrition of angina pectoris, included "wines and liquors . . . afford considerable relief". This led to the assumption that alcohol was a coronary vasodilator.

The French Paradox was first noted by Irish cardiologist Samuel Black in 1819. He found that the French had lower heart rate deaths compared to the Irish and attributed this to "the French habits and modes of living, coinciding with benignity of their climate and the peculiar character of their moral affections". This was the beginning of more current thinking that other dietary and lifestyle factors may play a part in the risk for heart disease.

In the 1970s, epidemiological studies began to show that moderate intakes of alcohol were associated with a low rate of CHD. In 1997, a large American study by Thun et al., demonstrated that at least one drink a day reduced death risk from CHD, but more than three drinks daily was associated with an increased death rate. McElduff et al. followed this up in the same year and found that frequency was as important as quantity in risk for heart disease. Lowest risk was among those who drank moderate of alcohol amounts 4–6 days a week. At the time there were issues with defining heavy and moderate drinking and as of 2007 there is still some debate. However, there is a general agreement that 3 unit of alcohol a day for men and 2 or more a day for women is considered unhealthy.

It was not until the 1990s that the French Paradox was looked at again. Dr. Serge Renaud, a scientist from Bordeaux University in France, coined the term "French Paradox" after his 1992 study. This was a large study of middle age French men. He found they have a long life expectancy despite a diet high in saturated fat. Although the diet included butter, cheese, eggs and cream, contributing to 15% of calories from saturated **fats**, the incidence of CHD was only 40% of the American incidence of CHD. He concluded that two to three glasses of wine a day wine reduced death rates from all disease by up to 30%, but four glasses a day were found to have an adverse effect on health. He suggested that the combined effect of the alcohol and **antioxidants** in wine played a role in reducing CHD. The French Paradox became internationally recognized when in 1991 he, together with another French Paradox supporter Dr. R. Curtis Ellison of Boston University School of Medicine, outlined the research on the "60 minutes" documentary in the USA. Interestingly,soon after this, red wine sales in the United States increased by 40%.

Further studies have supported this hypothesis, including the 1995 Copenhagen Heart Study that ran from 1976 to 1988 and confirmed the health benefits of

## KEY TERMS

**Angina**—Pain that comes from the heart, caused by the narrowing of the coronary arteries.

**Binge drinking**—British Medical Association states there is no consensus on the definition of binge drinking, but is usually used to refer to heavy drinking over an evening or similar time span. Sometimes also referred to as heavy episodic drinking.

**Epidemiological studies**—These studies look at factors affecting the health and illness of populations.

**Foie Gras**—Liver of a duck or goose that has been specially fattened. It can be sold whole or prepared as pate or mousse.

**High-density lipoprotein (HDL)**—Often referred to as good cholesterol. This takes cholesterol away from the cells and back to the liver, where it's broken down or excreted.

**Homocysteine**—This is an amino acid. High blood levels are now considered a risk factor for several diseases, including CHD.

**Low-density lipoprotein (LDL)**—Often referred to as bad cholesterol. It carries cholesterol from the liver to the cells and can cause harmful build-up of cholesterol.

**Procyanidin**—These are associated with flavanoid antioxidants derived from grape seed extract, grape skin and red wine. Like Quercetin and Resveratrol they have many health-promoting benefits.

**Quercetin**—A natural compound which belongs to a group of plant pigments called flavonoids that are largely responsible for the colours of many fruits, flowers, and vegetables. They have many health-promoting benefits that may protect against cancer and cardiovascular disease.

**Resveratrol**—A natural compound found in grapes, mulberries, peanuts and red wine that may protect against cancer and cardiovascular disease.

**Vasodilator**—A substance that causes blood vessels the body to become wider allowing the blood to flow more easily.

regular, moderate wine consumption. Those who drank wine daily had half the risk of dying compared with non-drinkers or consumers of other alcoholic beverages. The researchers suggested the antioxidants in red wine, such as tannins and flavonoids, were key factors in its protective effects. The 1980 Seven Countries Study (Yugoslavia, Italy, Greece, Finland, Netherlands, United States and Japan) compared the relationship between diet and other risk factors to the occurrence of CHD. High intakes of animal foods, with the exception of fish, were associated with higher CHD death rates. With its reliance on meat and butter fat and less on fruits, vegetables, legumes and grains, the 40-year Zutphen study, the Dutch arm of the Seven Countries Study, looked independently at the effect of wine consumption. Their conclusion, reported at the 2007 American Heart Association's 47th Annual Conference on Cardiovascular Disease Epidemiology and Prevention, was "Drinking a little alcohol every day, especially wine, may be associated with an increase in life expectancy".

More recent studies have also found that any alcohol is responsible for most of the cardio protective effects previously seen with wine. A 1994 study of British doctors and 2002 study of U. S. male doctors indicated that the lowest risk of death was associated with one to two alcoholic drinks of any type per day, but there was no benefit from additional drinks.

However, 20 years on, there is still no conclusive evidence as to why with a diet high in saturate fat the French live longer. The World Health Organization (WHO) states "There is convincing evidence that low to moderate alcohol intake reduces the risk of coronary heart disease", but as of 2007, the French Paradox has not been tested by the gold standard of research, a controlled clinical study. Until then moderate alcohol intakes with food may be the key to the French Paradox.

## Description

While the French diet includes high fat foods such as cheese, croissants, pastries, butter, sausages and cold cuts, it also contains other heart healthy foods, which have a beneficial effect.

### *Alcohol*

Although the French drink more alcohol a year than the British, it is generally with a meal. Unlike the UK, binge drinking is a rarity. The French have a moderate consumption of 1–2 glasses of wine a day, which has shown to help reduce the risk of heart disease.

### *Fiber*

The French eat two to three times more soluble **fiber** from pulses, such as beans and chickpeas, fruit and vegetables, whole grains and grain products than the English and Americans. Soluble fiber helps to lower cholesterol levels. In addition these foods are a good source of antioxidants, such as Quercetin also found in red wine, which may reduce oxidation of harmful low-density lipoproteins (LDL) that can cause atherosclerosis (hardening of the arteries).

### *Vegetable sources of protein*

A diet rich in animal meat may result in high levels of homocysteine in the blood, which can lead to atherosclerosis. Low levels of **folate** are associated with high homocysteine levels—an independent risk factor for CHD especially in men. The French diet is high in legumes, fresh fruits and vegetables, especially dark-green leafy vegetables that are a rich source of folate or folic acid, a B vitamin. Their animal **protein** dishes are generally accompanied by generous salads and pulses are a large part of typical winter foods, such as soups and stews, which may help to control levels of homocysteine.

### *Unsaturate fat*

Although the French diet is high in fat, it includes plenty of unsaturated fat like olive oil, olives and nuts, which help lower the level of harmful LDL cholesterol. Like red wine, peanuts also contain significant amounts of the heart healthy antioxidant Resveratrol. One ounce of peanuts contains approximately 73 micrograms of Resveratrol, while a glass of red wine contains 160 micrograms per 30 millilitres (ml).

### *Goose and duck fat*

These fats are commonly used for cooking and to make pate or mousse,such as foie gras (goose or duck liver). Although high in fat, these fats have a nutritional composition closer to that of olive oil than butter or lard. Olive oil has about 76% monounsaturated fat and 15% saturated fat. Goose fat is 56% monounsaturated fat and 27% saturated fat while butter is only 33% monounsaturated fat and a huge 63% saturated fat. The benefit of monounsaturated fats is they lower total and LDL cholesterol without affecting beneficial high-density lipoprotein (HDL) cholesterol.

### *Portion sizes*

The French may have a diet high in fat, but they eat fewer calories consequently are slimmer than Americans. 11% of the French are obese compared with 30% in the United States. Fat stimulates the release of cholecystokinin, a hormone that acts as a hunger suppressant and prevents over eating and snacking. In addition, portion sizes in France tend to be a third to a half of American portions. For example, in Paris a croissant weighs in at 30g, while in Philadelphia it is 60g

### *Lifestyle*

A 2004 survey completed by the French government's Committee for Health Education (CFES) on French food and health showed that French eating habits have not really changed in the last 10 years. Most people in France still eat home-prepared meals, take their time eating and generally do not snack. Whereas in America snacking is a $30 billion industry.

However, the only justification for the lower CHD rates that has been most scientifically proven is the moderate consumption of wine with meals.

## Function

There are several potential benefits of red wine in lowering CHD risk.

Red wine contains flavanoid antioxidants, Resveratrol and Quercetin, which help prevent the build-up of fatty deposits within the wall of the arteries. Both are found in the skin of red grapes. A 2006 study indicates that antioxidant, procyanidin, found in red wines from the South West of France, which has the lowest incidence of CHD in France, helps lower blood pressure and may account for the lower rates of heart disease.

Alcohol itself has been shown to raise good HDL cholesterol levels, but as of 2007, the exact mechanism is still unknown. HDL cholesterol helps to carry LDL cholesterol away from the walls of the arteries and back to the liver for reprocessing or excretion. This prevents build-up of cholesterol in the artery walls and protects against heart disease.

Alcohol also has the effect of decreasing thrombosis or blood-clotting .It decreases fibrinogen production, a blood-clotting enzyme, which reduces the stickiness of platelets. This reduces the incidence of clots, which may lead to a heart attack or stroke.

## Benefits

Moderate consumption of alcohol can have health benefits other than reducing the risk for CHD.

In 1997, a study by the American Cancer Society found the risk of death of any cause was lower for those who had moderate intakes of alcohol compare

to non-drinkers. It is thought that the amount of Resveratrol in 2-3 glasses of red wine helps to starve cancer cells by blocking a key protein that feeds them. France has relatively low rates of stomach and colon cancer and the second-lowest world incidence of heart disease after Japan. However, drinking more can lead to a greater risk of cancer.

Data from the third National Health and Nutrition Examination Survey Study (NHANES III) in 1999 showed that regular alcohol intakes lowered the risk for **gallstones** by 25% in both men and women.

## Precautions

Individuals involved with activities that require attention, skill, or coordination, such as driving or operating machinery, should avoid alcoholic beverages. Alcohol has a depressant effect on the central nervous system and slows down brain function, which can affect judgment and emotions as well as behaviour.

The 2005 Centers for Disease Control and Prevention (CDC) guidelines advise women who may become pregnant or are pregnant not to drink. Moderate drinking during pregnancy may result in behavioural or neuro-cognitive problems in children.

There is conflicting advise on moderate alcohol or no alcohol with breast feeding. The American Academy of Paediatricians still recommends avoiding alcohol while breast-feeding. Alcohol can be passed on to the baby through the milk, which can affect the baby's feeding, sleeping or digestion. Heavy alcohol intakes have also been shown to reduce lactation. The National Childbirth Trust and the Association of Breastfeeding Mothers in UK advocate similar advice. The recommendation is to allow sufficient time between drinking and breast-feeding so the mother can fully metabolise the alcohol.

Individuals taking prescription and over the counter medications also need to be aware of the potential interactions any of their medications may have with alcohol and should consult a doctor.

## Risks

Higher intakes of alcohol drinking levels seem to offset the benefits of moderate drinking on CHD, by increasing risk of death from many other diseases.

Excessive intake of any kind of alcohol increases the risk of cancer of the mouth, oesophagus, stomach, liver, breast and colon. The Cancer Prevention Study in 2002 found that one drink or less in postmenopausal women increased the risk of death from breast cancer by 30%. They did not find an increased risk in premenopausal women.

Excessive alcohol can increase blood pressure, which increases the risk for CHD. Cutting back to moderate drinking can lower systolic blood pressure by up to 10mmHg.

According to a US study published in 2005, older men who drink more than the daily recommendations of alcohol may be more likely to suffer from a stroke.

**Triglycerides** are a type of fat found in food. High levels in the blood are associated with an increased risk if CHD and the liver make more triglycerides with excess alcohol, sugar and calories.

The risk of cirrhosis seems connected more with alcohol abuse than moderate use. Excessive drinkers will develop fatty liver, the first stage of alcoholic liver disease, but this can disappear when alcohol is reduced to moderate levels. Continued excessive alcohol can lead to alcoholic hepatitis or cirrhosis and liver failure.

Heavy alcohol use for 10 years or more is the usual cause of Chronic Pancreatitis. Acute pancreatitis with severe abdominal pain can occur before this and will settle if drinking is discontinued.

## Research and general acceptance

There has never been a controlled clinical trial testing the effect of alcohol, but there is agreement that while drinking too much of any kind of alcohol is not healthy, moderate alcohol intakes may have some health benefits. As such, a number of medical associations including the European Society of Cardiology, The National Institute on Alcohol Abuse and Alcoholism, American Dietetic Association, American Heart Association, Royal College of Physicians, and British Heart Foundation have the recommendation for alcohol as "If you use alcohol, do so in moderation". Recommendation on how many drinks per day equate moderation differs from country to country. In the United States, moderation is defined as up to one drink per day for women and up to two drinks per day for men. In the United Kingdom, moderation is defined as not exceeding 2–3 units for women and 3–4 units for men. There is also agreement that the evidence is not convincing enough to make a recommendation to start drinking alcohol if teetotal.

However, Dr Malcolm law and Nicholas Wald, British specialists in preventive medicine at St. Bartholomew's and the Royal London School of Medicine and Dentistry and Dr. Marion Nestle, chairwoman of the department of nutrition at New York University, have put forward another explanation for the French

## QUESTIONS TO ASK YOUR DOCTOR

- What does moderate drinking mean?
- How much red wine should I be drinking?
- What health problems are associated with drinking?
- Can I drink when I am pregnant?
- What does one unit of alcohol include?
- Can I save all my daily alcohol units for the weekend?

diet and health. They argue that it is related to France's history of lower animal fat intakes rather then their consumption of red wine. Up to 1970, the French ate less animal fat and had significantly lower blood cholesterol levels than the British. Now French habits are changing, they are eating more meat and fast foods and their consumption of animal fat is similar to those in Britain. The 1999 National Survey on Individual Food in France by the Research Center for the Study and Monitoring of Living Standards shows that between 1950 and 1980 the consumption of meat fat and oils doubled and alcohol intake halved. The rate of **obesity** in France has also increased from 8% in 1997 to 12% (The 2003 National Health and Wellness Survey by Consumer Health Sciences) and over 40% of the French are now considered overweight, not far off the 50% figure for the British and Americans. They say it takes 25-35 years for increased fat intakes to translate into heart disease and it is only a matter of time before France faces the obesity epidemics and CHD rates that began in America and Britain nearly 20 years ago.

Tracy J Parker, RD

# Frozen-food diet

## Definition

Frozen-food diets rely on packaged frozen foods for weight loss and weight control that are based on standardized portions, as well as for convenience and saving time.

## Origins

A frozen-food diet was first introduced in *Good Housekeeping* magazine in September of 1998. In October of 2005 *Good Housekeeping* debuted a new frozen-food diet that consisted entirely of microwaveable meals. The new plan, based on research performed at the Department of Food Science and Human Nutrition at the University of Illinois at Champaign-Urbana, promised slightly increased weight loss and even less preparation time than the original diet.

Other frozen-food diets have also been developed. Nutrition expert Joy Bauer prepared a nine-day meal plan for the American Frozen Food Institute (AFFI) that consists entirely of frozen foods. Commercial frozen-food diets that are home-delivered weekly are also available. One such diet was devised by Dr. Caroline J. Cederquist, a board-certified physician in bariatrics, the medical specialty of weight management.

## Description

### *The original Good Housekeeping* diet

The original *Good Housekeeping* frozen-food diet consists of seven days of menus. However any meal can be switched for the same meal on a different day. It is a 1,400-calorie per day diet and the plan calls for 45 minutes of exercise four–five days per week. Brand-name products may be substituted with similar foods having the same number of calories. Spices, garlic, lemon, **soy** sauce, and vinegar are permitted.

**BREAKFASTS.** The day 1 breakfast consists of:

- one-half cup of Post 100% Bran or Kellogg's Bran Buds or three-quarters cup Kellogg's All Bran Original or Complete Bran Flakes
- one cup of fat-free milk
- 100 calories of fruit.

The day 2 breakfast is:

- three frozen low-fat Aunt Jemima pancakes (150 calories) or two frozen low-fat Eggo Homestyle waffles (180 calories), with one-third cup of frozen unsweetened berries
- one cup of fat-free milk.

The day 3 breakfast is:

- one frozen single-serving Weight Watchers Smart Ones English muffin sandwich with ham and cheese (210 calories) or one frozen Swift Premium Morning Maker ham, egg, and cheese sandwich (250 calories)
- one 50-calorie fruit or 4 oz (118 ml) of calcium-fortified orange juice.

The day 4 breakfast consists of:

- one-half of a 3-oz (85-g) frozen Lender's Big'n Crusty bagel (230 calories) with 1 oz (28 g) of light Jarlsberg or reduced-fat cheddar cheese, broiled, or one Thomas's English muffin (110 calories)
- one cup of calcium-fortified orange juice.

The day 5 breakfast is the same as day 2 except that 6 oz (177 ml) of calcium-fortified orange juice may be substituted for the milk. The day 6 breakfast is the same as day 1. The day 7 breakfast is:

- one-half of a frozen Lender's Big'n Crusty toasted bagel with one teaspoon of light butter or margarine or one Thomas's English muffin (110 calories)
- one cup of fat-free Dannon yogurt
- one 50-calorie fruit.

**LUNCHES.** The day 1 lunch is:

- one frozen Celentano Great Choice Low Fat Stuffed Shells, Manicotti, or Lasagna (250 calories) or one Healthy Choice Manicotti with Three Cheeses frozen entree (260 calories)
- two cups of loosely-packed ready-to-eat salad greens with two tablespoons of fat-free Italian dressing or balsamic, rice, or raspberry vinegar
- two breadsticks
- one cup of fat-free milk.

The day 2 lunch consists of:

- one frozen Old El Paso Bean & Cheese Burrito with two tablespoons of salsa or one Weight Watchers Smart Ones Santa Fe Style Rice & Beans frozen entree (290 calories)

## KEY TERMS

**Bariatrics**—A medical specialty that deals with weight management and the treatment of obesity.

**Complex carbohydrates**—Starches; polysaccharides that are made up of hundreds or thousands of monosaccharides or single sugar units; found in foods such as rice and pasta.

**Couscous**—A North African food consisting of steamed semolina—milled durum wheat—that is also used to make pasta.

**Diuretic**—A substance that increases the excretion of urine.

**Lactose**—Milk sugar; a disaccharide in milk that consists of one glucose molecule and one galactose molecule.

**Monosodium glutamate**—MSG; sodium glutamate; a salt derived from glutamic acid that is used to enhance the flavor of foods.

**Pita**—Pitta; pita bread; a round, double-layered or pocket flatbread made from wheat and yeast.

**Simple carbohydrates**—Simple sugars; monosaccharides, such as fructose found in fruit, and disaccharides made up of two sugar units, such as lactose and sucrose or table sugar.

- one 50-calorie fruit
- one cup of fat-free milk.

The day 3 lunch is:

- a chicken sandwich made with three one-quarter-inch-thick slices of leftover chicken breast from the day 1 dinner or 10 deli-thin slices of chicken breast, lettuce, sliced tomato, and one tablespoon of light mayonnaise or honey mustard, on two slices of whole-wheat bread
- one 50-calorie fruit
- one cup of fat-free milk.

The day 4 lunch consists of:

- one frozen Lean Pockets Chicken Parmesan, Turkey, or Ham with Cheddar stuffed sandwich (280 calories) or one Ken & Robert's Truly Amazing Veggie Pocket, Oriental or Broccoli & Cheddar (250 calories)
- two cups of salad as for day 1
- one 50-calorie fruit
- one cup of fat-free milk.

The day 5 lunch is:

- a tuna and bean salad made from three cups of ready-to-eat, loosely packed salad greens, 1 oz (28 g) of crumbled reduced-fat feta cheese, one-third cup of canned drained red kidney beans, 2 oz (56 g) of water-packed canned tuna, drained and flaked, and 2 tablespoons of fat-free Italian dressing or flavored vinegar
- three breadsticks
- a 100-calorie fruit.

The day 6 lunch is:

- one frozen Stouffer's Lean Cuisine Swedish Meatballs with Pasta or Three Bean Chili with Rice (250–280 calories) or one frozen Lean Pockets stuffed sandwich (250 calories) or one Healthy Choice Chicken Enchilada Suiza frozen entree (270 calories)
- one small sliced tomato with two teaspoons of flavored vinegar
- one cup of fat-free milk.

The day 7 lunch consists of:

- one whole-wheat mini pita stuffed with one frozen Tyson or Banquet fat-free chicken-breast pattie (80–100 calories), diced tomatoes, 1 oz (28 g) of crumbled reduced-fat feta cheese, and a splash of red-wine vinegar
- a 100-calorie fruit
- one cup of fat-free milk.

**DINNERS.** Several of the dinner selections make three–four servings and the serving sizes can be increased for other family members. The day 1 dinner is:

- one-half of a fully cooked rotisserie chicken breast without the skin, about 4.5 oz (130 g)
- two-thirds of a cup of Ore-Ida mashed potatoes cooked with one-third cup of low-fat milk
- one-third cup of heated fat-free chicken gravy from a jar
- one cup of steamed chopped frozen broccoli
- one 50-calorie fruit.

The day 2 dinner consists of:

- frozen Master Choice Four Cheeses Gourmet pizza or Tombstone Oven Rising Crust Three Cheese pizza, topped with a single layer of two cups of frozen chopped broccoli or spinach; makes four–six servings of 320 calories each; for one person, one-half cup of Stouffer's Lean Cuisine Cheese French Bread Pizza and one-half cup of vegetables
- two cups of the day 1 lunch salad
- one 50-calorie fruit.

The day 3 dinner is:

- shrimp and couscous: one-half cup of frozen peas and carrots and 3 oz. (85 g) of peeled, raw, frozen shrimp (about eight medium shrimp) and one-half cup of chicken broth, heated to boiling, and one-third cup of couscous and some hot pepper sauce;

or for one person, frozen Healthy Choice Herb Baked Fish (340 calories) or Chicken Francesca frozen meal (330 calories)
- a 100-calorie fruit.

The day 4 dinner is:

- one 9-oz (250-g) package of frozen Tyson Chicken Breast Strips with Rib Meat (90 calories per serving) and the frozen sauce from one Green Giant Create a Meal! Sweet & Sour Stir Fry (130 calories per serving), stir-fried with rice, and the frozen vegetables and pineapple, for three one-quarter-cup servings, with three-quarters cup of cooked rice per serving; for 1 person, frozen Healthy Choice Sweet and Sour Chicken (360 calories)
- two breadsticks
- one 50-calorie fruit.

The day 5 dinner consists of:

- five Mrs. T's Pierogies Potato and Cheddar Pasta Pockets (300 calories), with one-third cup of salsa and two tablespoons of fat-free sour cream, or three Golden Potato Blintzes (270 calories)
- one cup of cooked frozen green beans
- one 50-calorie fruit.

The day 6 dinner is:

- one whole-wheat mini pita pocket stuffed with one frozen Boca Burger—Chef Max's Favorite (110 calories), lettuce, tomato, onion, and one tablespoon of ketchup, or 1 frozen low-fat Gardenburger, hamburger style (110 calories), or one frozen Morningstar Farms Garden Veggie Pattie (150 calories)
- 4 oz (110 g) of baked frozen French fries (20–23 fries)
- one 100-calorie fruit.

The day 7 dinner is:

- one 6-oz (170-g) individually frozen fish fillet, not breaded or flavored, sprinkled with one tablespoon of grated Parmesan cheese, two teaspoons of dried bread crumbs, paprika, salt, pepper, and two teaspoons of olive oil, and baked at 500°F (260°C) for about seven minutes
- two cups of frozen Ore-Ida country-style hash browns, cooked by the fat-free method (128 calories)
- one cup of cooked sliced zucchini.

**SNACKS.** Snacks can be eaten at any time of day. The day 1 snacks are:

- one Dole Fruit Juice Bar (45 calories) or one 50-calorie fruit
- four reduced-fat Triscuits (65 calories) with 1 oz (28 g) of light Jarlsberg or reduced-fat cheddar cheese
- one dill pickle.

The day 2 snacks are:

- one Starbucks Ice Cream Mocca Frappuccino blended coffee bar (120 calories) or a Quaker Chewy granola bar (about 110 calories)
- one 50-calorie fruit.
- eight raw baby carrots.

The day 3 snacks include:

- one cup of fat-free Dannon yogurt (110 calories)
- one Dole fruit juice bar or one 50-calorie fruit
- 15 raw baby carrots.

The day 4 snacks are:

- one Dole Fruit Juice Bar or one 50-calorie fruit
- one-half of a 3-oz (85-g) frozen Lender's Big'n Crusty toasted bagel with one teaspoon of jam or preserves
- one dill pickle.

The day 5 snacks include:

- four reduced-fat Triscuits (65 calories) with 1 oz (28 g) of light Jarlsberg or reduced-fat cheddar cheese
- one frozen Haagen-Dazs sorbet bar (80 calories) or Betty Crocker Healthy Temptations ice-cream sandwich (80 calories)
- one dill pickle.

The day 6 snacks are the same as for day 2. The day 7 snacks are:

- one-half of a 3-oz (85-g) frozen Lender's Big'n Crusty toasted bagel with one teaspoon of jam or preserves
- one frozen Haagen-Dazs sorbet bar or Betty Crocker Healthy Temptations ice-cream sandwich
- one dill pickle.

**FRUITS.** The 50-calorie fruit choices are:

- one-half cup of unsweetened applesauce
- three apricots
- one cup of blackberries
- one-quarter of a medium cantaloupe or one-half cup of cubes
- one-half of a medium grapefruit
- one cup of honeydew melon cubes
- one medium nectarine
- one large peach or two-thirds cup of frozen, unsweetened peaches
- one-half cup of juice-packed canned peaches, pears, or fruit cocktail
- two one-half-inch-thick slices of fresh pineapple or three-quarters cup of cubes
- one large plum
- two tablespoons of raisins

- one cup of fresh raspberries or two-thirds cup of frozen, unsweetened raspberries
- eight medium strawberries or two-thirds cup of frozen, unsweetened strawberries
- one medium tangerine.

The 100-calorie fruits are:

- one large apple
- three dried apricot halves
- one cup blueberries
- one medium banana
- 1 cup (21) cherries
- three-quarters cup (28) grapes
- two medium kiwifruit
- one large orange
- three dried peach halves
- one medium pear
- two-thirds cup of juice-packed canned pineapple
- two and one-half cups of watermelon cubes.

### *The new Good Housekeeping* diet

The more recent *Good Housekeeping* frozen-food diet relies on strict portion control for weight loss. The diet consists of 28 microwaveable frozen meals and supplemental foods that follow strict nutritional criteria. It includes calorie-free beverages and a daily multivitamin/multimineral supplement.

**BREAKFAST.** The frozen-food diet breakfast consists of:

- one cup of fat-free milk or 6 oz (170 g) of light yogurt
- three-quarters cup of Kashi GoLean or three-quarters cup of Cheerios or Wheaties mixed with one-quarter cup All-Bran Extra Fiber
- one serving of fruit.

One serving of fruit is about 60 calories and is equivalent to:

- one small apple
- one-half of a banana
- three-quarters cup of blueberries
- one cup of cubed cantaloupe or honeydew melon
- one-half of a large grapefruit
- 17 grapes
- one kiwi
- one-half of a small mango
- one nectarine
- one small orange
- one large peach
- one-half of a large pear
- three-quarters cup of fresh pineapple
- one-half cup of canned pineapple packed in juice
- one cup of raspberries
- one and one-quarter cup of whole strawberries
- two small tangerines.

**LUNCH.** Lunch consists of:

- a frozen meal
- two cups of salad greens of alternating varieties with one-half cup of bite-sized steamed or raw vegetables
- two tablespoons of reduced-calorie salad dressing, maximum 50 calories, or one teaspoon of olive oil mixed with flavored vinegar.

The frozen lunches are:

- Ethnic Gourmet Chicken Korma
- Ethnic Gourmet Tandoori with Spinach
- Ethnic Gourmet Kung Pao Chicken
- Healthy Choice Apple Glazed Pork Medallions
- Healthy Choice Princess Chicken
- Lean Cuisine Dinnertime Select Steak Tips Dijon
- Lean Cuisine Spa Cuisine Salmon with Basil and one extra serving of fruit
- Smart Ones Chicken Parmesan
- Smart Ones Chicken Tenderloins with Barbecue Sauce
- Smart Ones Lasagna Florentine
- South Beach Mediterranean Style Chicken with Couscous
- Stouffer's Chicken Teriyaki
- Uncle Ben's Roasted Chicken & Vegetable
- Uncle Ben's Savory Beef Portabello.

Allowable salad vegetables are:

- bell pepper
- broccoli
- cauliflower
- celery
- cucumber
- mushrooms
- onions
- radishes
- tomatoes.

**DINNER.** The dinner menu consists of:

- one frozen meal
- salad as with lunch
- salad dressing as with lunch.

The frozen dinners are:

- Amy's brand Cheese Ravioli with Sauce

- Amy's brand Santa Fe Enchilada
- Ethnic Gourmet brand Chicken Biryani over Rice
- Healthy Choice brand Salisbury Steak
- Lean Cuisine brand Dinnertime Selects Chicken Fettucini
- Lean Cuisine brand Dinnertime Selects Chicken Portabello
- Organic Classics Cajun Style Chicken Tettrazini with Penne Pasta
- Organic Classics Chicken Cacciatore with Penne Pasta
- Organic Classics Penne Pasta with Sauce & Meatballs
- South Beach Cashew Chicken with Sugar Snap Peas
- Stouffer's Rigatoni Pasta with Roasted White Meat Chicken
- Stouffer's Tuna Noodle Casserole
- Uncle Ben's Sweet and Sour Chicken
- Uncle Ben's Thai-Style Chicken.

**ADDITIONAL FOODS.** The following foods may be eaten once a day with meals or as a snack:

- one cup of fat-free milk or 6 oz (170 g) of light yogurt
- one serving of fruit
- one serving of whole grain, about 80 calories.

The 80-calorie whole grains may be:

- 1 oz (28 g) of mini wholegrain pita bread
- a 1-oz (28-g) slice of 100% whole-wheat bread
- four pieces of thin whole-wheat crispbread
- four Triscuits
- one mini bag of low-fat popcorn.

One treat of about 100 calories is permitted twice per week:

- one-half cup of light ice cream
- one Nabisco 100-calorie pack, any variety
- 13 roasted almonds
- four Hershey's Kisses
- 4 oz (118 ml) of red or white wine
- one light beer.

### *The AFFI diet*

All of the meals in the AFFI diet include at least one serving of frozen fruits or vegetables. Daily meal plans are for 1,600-, 2,200-, and 2,800-calorie diets. A sample daily menu for a 1,580-calorie diet consists of 58 g of **protein**, 38 g of **fiber**, and 28 g of fat.

A typical breakfast consists of:

- two calcium-fortified, wholegrain frozen waffles
- one cup of thawed frozen blueberries
- 8 oz (237 ml) of calcium-fortified orange juice from frozen concentrate
- one multivitamin and mineral supplement.

A sample lunch consists of:

- 2.5 oz (70 g) of frozen vegetable burger
- one cup of frozen mixed vegetables
- one cup of cooked frozen long-grain brown rice.

A typical dinner is:

- 4 oz (110 g) of frozen breaded baked fish filet (170 calories or less)
- one cup of boiled frozen artichokes, drained
- one cup of boiled frozen Brussels sprouts, drained
- one cup of boiled frozen asparagus tips, drained
- two-thirds cup of frozen whipped sweet potato.

The afternoon and evening snacks consist of:

- one small frozen oat-bran muffin (200 calories or less)
- one slice of low-fat frozen cheesecake (150 calories or less).

### *Commercial diets*

Like the other frozen-food diets, commercial frozen-food diets are designed for nutritional balance and portion control. Cederquist's diet delivers an average 1,200 calories, with a range of 1,100–1,400 calories, in three daily meals and two snacks. The calories come from lean protein and complex **carbohydrates** rather than from simple carbohydrates and **fats**. The diet avoids foods such as white bread, potatoes, and pasta that contain simple sugars. The program accommodates one dinner outside of the diet per week.

Cederquist's diet recommends:

- drinking a minimum of 64 oz (2 l) or eight glasses of water daily, as regular water, flavored water, decaffeinated diet soda, or diet fruit juices, to keep the body hydrated and 'flushed'
- limiting caffeinated drinks, such as coffee, tea, or diet soda, to two per day, since caffeine is a diuretic and will cause body cells to retain water, thereby slowing weight loss.
- drinking coffee black or with a low-fat creamer and/or a sugar substitute
- avoiding fruit juices because they are high in sugar
- drinking low-fat (1%) or skim milk for protein, limited to 8 oz (237 ml) per day because of the lactose.

## Function

Frozen-food diets are used for weight-loss and weight-control, for convenience, and to save time.

These diets are especially useful for people who are unable to cook or prefer not to cook. Since the ingredients and portions of the meals are predetermined, the diets are much easier to follow than those that require counting calories or weighing ingredients. The *Good Housekeeping* frozen-food diet is aimed especially at people who feel that they don't have time to diet, particularly if they have to prepare a different meal for the rest of the family. Some frozen-food diets are designed for diabetics, without simple sugars that could rapidly increase blood-sugar levels. Frozen-food diets may be difficult for vegetarians to follow.

## Benefits

In addition to being quick and convenient, frozen-food diets are designed by nutritionists to be well-balanced, low in fat and calories, and to provide the necessary **vitamins** and **minerals**. They supply a variety of different foods. The meals in the original *Good Housekeeping* frozen-food diet take less than 10 minutes to prepare and enables the dieter to lose 1 lb (0.45 kg) per week. The meals in the newer *Good Housekeeping* frozen-food diet take 9 minutes or less to prepare and enable the dieter to lose about 1.5 lb (0.7 kg) per week or 20 lb (9 kg) in just over three months. Commercial frozen-food diets make weight-loss claims of an average of 2–3 lb (0.9–1.4 kg) per week.

Frozen foods avoid spoilage problems associated with fresh foods, particularly those that are harvested, transported long distances, and stored before they reach the consumer. Frozen foods also require fewer trips to the grocery store.

## Precautions

Frozen food, particularly frozen meals and entrées, can be very expensive compared to buying fresh or canned food and preparing meals, although frozen fruits and vegetables may be less expensive than fresh produce. Frozen-food diets also require a significant amount of frozen storage capacity. Recommended choices, such as those in the *Good Housekeeping* frozen-food diets, may be biased toward advertisers or corporate sponsors.

Like many processed foods, frozen foods—especially frozen diet foods—contain various chemicals that some believe may be harmful. Frozen diet foods often contain monosodium glutamate (MSG), flavorings, and hydrolyzed vegetable protein. In large quantities glutamate may be damaging to the brain and nervous system.

## Risks

Frozen food is considered to be safe. Freezing inhibits the growth of some pathogens and reduces the risk of food contamination. However the thawing and refreezing of frozen foods may pose a risk. Frozen foods can remain too long in the freezer and can suffer from freezer burn and the formation of ice crystals.

## Research and general acceptance

### *Research*

In the 1990s the U.S. Food and Drug Administration declared frozen fruits and vegetables to be as nutritious as fresh produce and, in some cases, more nutritious.

The 2003 University of Illinois research study found that women who ate frozen main courses for lunch and dinner for an eight-week period lost an average of 12 lb (5.4 kg). In contrast the women who followed a diet that was equivalent in calories to the frozen-food diet, but which required them to plan and cook meals, lost an average of only 8 lb (3.6 kg). According to LeaAnn Carson, a research dietician and one of the study's authors, the results suggest that women who prepare their own food actually consume more calories because they do not accurately measure the ingredients, whereas the portion sizes of the frozen-food entrees are strictly controlled.

According to Cederquist, medical research has shown that a diet that varies the number of daily calories slightly is preferable to one that strictly adheres to a set number of calories. Varying the caloric intake prevents the body's **metabolism** from adjusting to the set point and making it progressively harder to lose more weight and maintain the weight loss.

### *General acceptance*

Frozen foods are a huge industry and frozen dinners and entrees constitute the largest category of frozen foods. Consumer demand for frozen meals grew steadily in the first years of the twenty-first century. The average American eats six frozen meals per month. In a survey reported by the AFFI, frozen-food products were among the top three food items that Americans did not want to live without. A poll conducted by the Tupperware Corporation found that on an average trip to the supermarket 94% of American shoppers sometimes purchase frozen food and 30% always buy some frozen food.

Surveys conducted in 2006 under the auspices of the AFFI found that the majority of American shoppers believe that frozen foods have many of the same

## QUESTIONS TO ASK YOUR DOCTOR

- How much weight do I need to lose?
- Would I be expected to lose weight on a frozen-food diet?
- What factors should I take into consideration in choosing a frozen-food diet?
- Should I be concerned about MSG or other additives in the frozen food?
- Should I take vitamin and/or mineral supplements while following a frozen food diet?

good qualities as fresh foods and retain the same or more nutrients as foods that have not been frozen. Consumers generally believe that in recent years frozen foods have significantly improved in taste, variety, and ease of preparation. In general they also believe that frozen foods are safer than prepared refrigerated foods.

# Fructose intolerance

## Definition

Fructose intolerance is a condition where the body has difficult digesting and using fructose and fructose-containing foods. It is treated by complete elimination of fructose and sucrose from the diet.

## Origins

There are two types of fructose intolerances. The first, hereditary fructose intolerance (HFI), also known as fructosemia or fructose aldolase B-deficiency, is a rare genetic disease of the **metabolism** of fructose due to the absence of the enzyme that breaks it down (aldolase B). As a result, fructose accumulates in the liver, kidney, and small intestine and the body is unable to convert its energy storage material (glycogen) into glucose. If untreated, the blood sugar level falls (hypoglycemia) and there is formation of harmful substances that damage the liver. HFI is difficult to diagnose so its incidence rate is not known, but it is believed to be quite rare (between 1 in 12,000 to 1 in 58,000). Since it is inherited, it lasts for life.

The second type of fructose intolerance is dietary fructose intolerance (DFI), also called fructose malabsorption. DFI is quite common, affecting up to 30% of people in the United States. Its incidence is also difficult to evaluate since many people show no symptoms at all and its cause is not precisely known. It

**Sugars and sweeteners**

| Tolerated | Not tolerated |
|---|---|
| Aspartame | Agave syrup |
| Barley malt syrup | Baker's sugar |
| Birch sugar (if pure) | Beet sugar |
| Corn starch | Brown rice syrup |
| Corn sugar | Brown sugar |
| Dextrin | Cane sugar |
| Erythitol (if pure) | Carob powder |
| Glucose | Corn syrup |
| Glucose polymers | Date sugar |
| Neotame | Dulcitol |
| Saccharin | Fruit juice sweeteners |
| | Grape syrup |
| | Gur |
| | Honey |
| | Maple syrup |
| | Molasses |
| | Polydextrose |
| | Sorbitol |
| | Stevia |
| | Turbinado |
| | Wasanbon |

**This list of sugars and sweeteners for fruitose intolerant individuals was prepared by the HFI Laboratory at Boston University.** *(Illustration by GGS Information Services/Thomson Gale.)*

seems to be caused by the lack of special cells (epithelial cells) on the surface of the intestine that are not available to help digestion. As a result, the body is not able to absorb fructose efficiently.

Although having different causes, both HFI and DFI are treated by dietary adjustments. Complete elimination of fructose and sucrose from the diet is the only effective treatment for HFI. As for DFI, treatment also involves a fructose-free diet, with the treating physician allowing some concessions in mild cases. Some patients may find a threshold level where they can eat some fructose without getting symptoms. Close dietary monitoring is important for good outcome and should include at least semiannual visits to a biochemical geneticist (for HFI) and monthly meetings with a nutritionist.

## Description

A strict fructose-free diet involves exclusion of any beverage or food containing fructose, sucrose, or sorbitol. Fructose is a monosaccharide, or simple sugar, that has the same chemical formula as glucose, the main source of energy for the body, but a different molecular structure. It is found in all fruits, in some vegetables and in honey. Fructose and other sugars are **carbohydrates**, which are important sources of energy for the body. The main types of sugars found in beverages and foods are:

- Lactose: Disaccharide containing glucose and galactose. It occurs naturally in milk.
- Maltose: Disaccharide containing two glucoses. It is obtained from starch.
- Dextrose: Other name for glucose, it is obtained from sugar cane, sugar beets and starches.
- Corn syrup: Sugar that consists chiefly of single glucose molecules. It is produced from corn starch.
- High fructose corn syrup (HFCS): A mixture of glucose and fructose sugars, also produced from corn starch.

The HFI Laboratory at Boston University has prepared a list of sugars and their tolerance for patients. Some of the most common food sweeteners listed include:

- Agave syrup: Commonly used in Texan-Mexican foods, tequila, margaritas, soft drinks. High in fructose and not tolerated.
- Aspartame: FDA-approved sugar substitute sold as Equal, NutraSweet, NutraTase. Tolerated.
- Baker's sugar: Another name for sucrose, the finest of all granulated sugars. Not tolerated.
- Barley malt syrup: Obtained from sprouted grains of barley, kiln dried and cooked with water. Tolerated.
- Beet sugar: Sucrose. Not tolerated.
- Birch sugar: A sugar alcohol, xylitol. Trade name: The Ultimate Sweetener. Tolerated if pure.
- Brown rice syrup: Obtained from brown rice. Possibly contains sucrose. Not tolerated.
- Brown sugar: Sucrose coated with molasses. Not tolerated.
- Cane sugar: Sucrose, table sugar. Not tolerated.
- Carob powder: Obtained from the carob tree, it is 75% sucrose, plus glucose and fructose. Not tolerated.
- Corn starch: Derived from corn, consists of straight or branched chains of glucose. Tolerated.
- Corn sugar: Obtained from corn starch, contains glucose and maltose. Tolerated.
- Corn syrup: Also obtained from corn starch, but in making the syrup, it usually has either maltose or fructose or both added. Not tolerated.
- Date sugar: Made from dried, pulverized dates and likely to contain sucrose. Not tolerated.
- Dextrin: Glucose molecules linked together in chains that do not break down to pure glucose. Tolerated.
- Dulcitol: Naturally occurring sugar alcohol. Not tolerated.
- Erythitol: Sugar alcohol. Tolerated if pure.

## KEY TERMS

**Acidosis**—Excessive acidity of body fluids due to accumulation of acids.

**Carbohydrate**—Any of a group of substances that includes sugars, starches, celluloses, and gums and serves as a major calorie source in food.

**Digestion**—The process by which food is chemically converted into nutrients that can be absorbed and used by the body.

**Disaccharide**—Any of a class of sugars, including lactose and sucrose, that are composed of two monosaccharides.

**Enzyme**—A protein that accelerates the rate of specific chemical reactions.

**FDA**—The Food and Drug Administration is the United States Department of Health and Human Services agency responsible for ensuring the safety and effectiveness of all drugs, biologics, vaccines, and medical devices.

**Fructose**—Sugar found in fruits.

**Galactose**—A sugar contained in milk. Galactose makes up half of the sugar called lactose that is found in milk.

**Glucose**—A monosaccharide sugar occurring widely in most plant and animal tissue. In humans, it is the main source of energy for the body.

**Glycogen**—The storage form of glucose found in the liver and muscles.

**Hypoglycemia**—A deficiency of sugar in the blood caused by too much insulin or too little glucose.

**Malabsorption**—Poor absorption of nutrients by the small intestine, difficulty in the digestion of nutrients.

**Monosaccharide**—Any of several carbohydrates, such as glucose, fructose, galactose, that cannot be broken down to simpler sugars.

**Nutrient**—A source of nourishment, especially a nourishing ingredient in a food.

**Sorbitol**—Sugar alcohol food additive used as a sweetener in commercially prepared low sugar foods and gum.

**Starch**—A naturally abundant nutrient carbohydrate found in seeds, fruits, tubers, and roots.

- Fruit juice sweeteners: Derived from grapes, apples or pears, heated to reduce water, leaving a sweeter more concentrated juice. Not tolerated.
- Grape syrup: Pure fructose. Not tolerated.
- Glucose: Simple sugar. Tolerated.
- Glucose polymers: Chains of glucose. Tolerated.
- Gur: Consists of 35% sucrose, and 15% mixture of glucose plus fructose, made from palm dates or sugar cane juice. Used in Thai cooking. Not tolerated.
- Honey: Natural syrup containing about 35% glucose, 40% fructose, 25 % water. Not tolerated.
- Maple syrup: From maple trees, mostly sucrose. Not tolerated.
- Molasses: By-product of sugar cane with 24% water. Fructose level varies. Not tolerated.
- Neotame: Sugar substitute. Tolerated.
- Polydextrose: Food additive synthesized from dextrose, plus about 10% sorbitol and 1% citric acid. It is commonly used as a replacement for sugar, starch, and fat in commercial cakes, candies, dessert mixes, gelatins, frozen desserts, puddings, and salad dressings. Not tolerated.
- Saccharin: FDA-approved sugar substitute. No longer commonly used. Known as Sweet N' Low, Sugar Twin, Sucryl, Featherweight. More than 6 servings per day may increase bladder cancer risk and it is no longer approved for use in Canada. Tolerated.
- Sorbitol: Sugar alcohol common in fruits, particularly skin of ripe berries, cherries and plums. Not tolerated.
- Stevia: Natural sweetener from a South American plant. Not tolerated.
- Turbinado: Another name for raw sugar. Not tolerated.
- Wasanbon: Grown on an island in the area of Japan from a special variety of sugar cane. Not tolerated.

Foods not allowed in a fructose and sucrose-free diet include:

- Meats: Cold cuts, hot dogs, sausages, any meat products that contain sugar.
- Cereals: Any cereal sweetened with sugar, fructose, or sorbitol.
- Sweeteners: Sugar, sucrose, fructose, sorbitol, brown sugar, molasses, honey.
- Fruits: All fruits, fruit juices, fruit extracts, dehydrated fruits, and products that contain fruit or are sweetened with fruit juice or concentrate.

- Fats: Mayonnaise, mustards and dressings with sugar.
- Milk: Milk and dairy products with added sugar.
- Nuts: Candy-covered nuts or nuts prepared with sugar, fructose or sorbitol.
- Breads: Any type of sweet bread, or any that may contain sugar, fructose or sorbitol.
- Potatoes: Sweet potatoes.
- Fish: Processed fish with sugar.
- Desserts: Any dessert that contains sugar, fructose or sorbitol.
- Vegetables: Carrot, tomato, corn, canned vegetables with sugar.
- Other foods: Catsup, sauces that contain sugar, chile piquin with lemon, all regular soft drinks and sodas, jams, jellies, marmalades, maple syrup, canned or bottled fruits, corn syrup.

All types of fruits must be eliminated from fructose and sucrose-free diet. Examples of foods that are allowed include:

- Meats: Red meat, pork, chicken and turkey.
- Cereals: Any that do not contain sugar, fructose or sorbitol.
- Sweeteners: Aspartame, dextrine, no-calorie sweeteners.
- Fats: Butter, margarine, oil, salad dressings without sugar.
- Eggs: Any type.
- Milk: Any type.
- Nuts: Any type that has no sugar.
- Breads: Any type that does not contain sugar, fructose or sorbitol as ingredient.
- Potatoes: White potatoes.
- Pasta and soups: Macaroni, spaghetti, rice, soup pasta.
- Fish: Any fresh fish.
- Desserts: Natural yogurt, cakes and ice-cream made without sugar.
- Cheese: Any type.
- Vegetables: Asparagus, cauliflower, peppers, lettuce, spinach, celery, root vegetables except carrots.
- Other foods: Coffee, tea, diet soft drinks that contain artificial sweeteners, cocoa, salt, pepper and other spices.

Additional guidelines for a fructose-free diet include:

- Fructose, sucrose and sorbitol are used in many manufactured foods to such an extent that very few processed foods are allowed in the diet. Sugar is used in many other less obvious products such as canned food, bottled sauces
- Flavorings is another possible trace source of these sugars as they are sometimes used to carry flavoring compounds into foods.
- Only vegetables that contain predominantly starch are allowed in the diet. Cooked vegetables have a lower fructose content and should be selected rather than raw vegetables as the cooking process results in a loss of free sugars.
- New potatoes have a higher fructose content than old potatoes.
- Wholemeal flour contains more fructose than white flour because both germ and bran contain sucrose. Other wholegrain foods (brown rice and wholemeal pasta) also contain more sucrose than the refined products.
- Sorbitol is very often used as an artificial sweetener, especially in diabetic foods and drinks which should accordingly be avoided. Isomalt and lycasin, alternative sweeteners that are predominantly used in confectionary, also contain sorbitol. Glucose can be used as an alternative sweetener and as a source of energy.
- Sucrose and sorbitol are also often used in medications as bulking agents or to improve the taste.

## Function

The symptoms of both types of fructose intolerance are gastrointestinal distress, flatulence, bloating, diarrhea, fatigue, vomiting, low **iron** and other nutrient deficiency. For dietary fructose intolerance, there is clinical evidence also associating it with mood disturbances and depression. The function of a fructose-free diet is to eliminate dietary sugar intake so as to alleviate these symptoms.

## Benefits

Absolute elimination of fructose and glucose from the diet produces good outcomes in most people with fructose intolerance. For the rapidly diagnosed and treated infant, the outcome for a normal state of health is excellent. In the absence of substantial liver damage, life expectancy is normal.

## Precautions

Eating out is one of the most challenging parts of maintaining a fructose-free diet. This is because restaurant employees have little time to check food contents from the labels of the ingredients used by the kitchen to prepare menus. Some guidelines in dealing with restaurant staff include:

- Be as clear and explicit as possible when talking with the waiting staff. Explain your fructose intolerance in brief terms and order only foods that you know cannot have sugars and how they should be prepared. For example, order a steak, broiled on a piece of aluminum foil with no seasonings at all, a baked potato with butter, a lettuce-only salad with a small slice of lemon and oil on the side, plain steamed spinach and coffee/tea/milk.
- The person who knows the ingredients in the food is the person who prepares it. Ask to speak to that person. It can be the chef, or the cook, rarely the restaurant manager.
- Be careful of soups. Except for upscale restaurants, most soups are canned. Ask to read the label. If the soup is made at the restaurant it may also contain ingredients not compatible with a fructose-free diet.
- Whether grilled or broiled, seasoning is routinely used in meat preparation, so specify no seasonings in your order. The chef will know if a sauce has fructose-containing ingredients. Canned sauces are also used in many restaurants. Request to check the ingredient list.
- Non-dairy products are often used in restaurants, and may contain untolerated ingredients. Three frequently used non-dairy products in restaurants are non-dairy creamer, non-dairy potato topping, and non-dairy whipped topping. Also ask to read their labels.

With the increasing popularity of processed foods, sugar is often an ingredient about which the consumer is not aware, and not only in restaurants. For example, high fructose corn syrup (HFCS) is present and unsuspected in numerous products including soft drinks, fruit drinks, sports drinks, baked goods, candies, jams, yogurts, condiments, canned and packaged foods, and other prepared and sweetened foods. Also, potatoes, when prepared a certain way, may provide a significant amount of fructose. For this reason, the advice of a highly trained nutritionist is required in the treatment of fructose intolerance.

## Risks

After ingesting fructose, infants and children may become sufficiently ill to require hospitalization. If untreated, fructose intolerance leads to hypoglycemia and acidosis that may act together to cause organ shock and coma. Ongoing liver damage may result in cirrhosis and eventual liver failure. Death may result from any or all of the above. Hereditary fructose intolerance may be relatively mild or a very severe disease. In the severe form, even eliminating fructose and sucrose from the diet may not prevent progressive liver disease.

## QUESTIONS TO ASK YOUR DOCTOR

- What is the difference between dietary fructose intolerance and hereditary fructose intolerance ?
- How common are dietary fructose intolerance and hereditary fructose intolerance ?
- Do I have dietary fructose intolerance and hereditary fructose intolerance ?
- How did I get it ?
- What are the complications ?
- Can I be cured ?
- How is fructose intolerance identified ?
- What are the symptoms of dietary fructose intolerance and hereditary fructose intolerance ?
- How is fructose intolerance treated ?
- Which foods and beverages contain fructose ?
- Which foods and beverages contain high fructose corn syrup ?
- Can I consume any fructose at all ?
- Can I consume artificial sweeteners ?

## Research and general acceptance

Clinical intolerance to fructose was initially described in 1956. Some 4-5 years later, the defect in aldolase B enzyme in the liver was demonstrated, and hereditary fructose intolerance (HFI) became clinically recognized. The rapid early progress in the understanding of this disorder may be due to the fairly clear symptoms associated with ingestion of fructose, which are difficult to miss. In many young infants, the age of onset of symptoms leads to the diagnosis. Genetic counseling may be of value to prospective parents with a family history of fructose intolerance. Medical experts agree that definitive treatment simply consists of eliminating fructose from the diet. By doing so early in the course, the affected child's health is usually fully restored within days.

Recent research performed at the University of Innsbruck in Austria shows that fructose and sorbitol-reduced diet in subjects with fructose malabsorption does not only reduce gastrointestinal symptoms but also improves mood and early signs of depression. Improvement of the signs of depression was also more pronounced in females than in males

Medical researchers unanimously agree that symptoms can improve in dietary fructose intolerance patients willing to adhere to a low fructose diet.

# Fruitarian diet

## Definition

A fruitarian diet is a strict form of a vegetarian diet that is generally limited to eating fresh fruits.

## Origins

The fruitarian diet has been around for hundreds of years and probably longer. In his writings, artist, scientist, and inventor Leonardo da Vinci (1452–1519) indicated he was a fruitarian. Despite the popular view that early man was primarily meat-eaters, there is some scientific evidence to indicate that they ate a diet composed primarily of fruits, nuts, and berries. Some religious scholars argue that the original fruitarians were Adam and Eve in the Garden of Eden. There are a number of historical references to a fruitarian diet in the 1800s and 1900s. In much of the historical documentation, people who became fruitarians switched to a more accepted diet after a few months or years, often renouncing the diet. Indian spiritual and political leader Mahatma Gandhi (1869–1948) was a fruitarian for six months in the early 1900s before going back to a vegetarian diet.

**U.S. Centers for Disease Control and Prevention recommended amount of fruit per day**

| Age | Less active (cup) | Moderately active (cup) | Active (cup) |
|---|---|---|---|
| Children 2–3 yrs. | 1 | 1 | 1 |
| Boys 4–8 yrs. | 1½ | 1½ | 1½ |
| Girls 4–8 yrs. | 1 | 1½ | 1½ |
| Boys 9–13 yrs. | 1½ | 1½ | 2 |
| Girls 9–13 yrs. | 1½ | 1½ | 1½ |
| Boys 14–18 yrs. | 2 | 2 | 2½ |
| Girls 14–18 yrs. | 1½ | 2 | 2 |

## Description

A fruitarian diet, also called a fructarian diet, is a form of vegan diet that is generally limited to eating fruits. The definition of what is a fruit often varies among fruitarians (also called fructarians or frugivores). Some adhere to a strict interpretation, consuming only fruits from plants and trees. Some fruitarians include berries in their diet, others broaden the definition to include nuts and seeds, while yet others include some food that is commonly thought of as vegetables, including peppers, tomatoes, cucumbers, and avocados. A fourth type of fruitarian includes grains in the diet. One definition of a fruitarian is someone who has a diet composed of more than 50% fruit. The Website Beyond **Vegetarianism** (http://www.beyondveg.com) defines a fruitarian diet as one containing at least 75% fruit (which includes grains and nuts) and the remainder

of the diet being raw vegan foods other than fruits. Most fruitarians consume raw, fresh fruit over canned, frozen, or processed fruit. A few fruitarians also consume green leafy vegetables, root vegetables, or both in their diet.

Fruitarians can choose from seven basic fruit groups:

- Acid fruits: Citrus, pineapples, strawberries, pomegranates, kiwi, cranberries, and sour apples.
- Subacid fruits: Sweet apples, sweet cherries, raspberries, blackberries, blueberries, peaches, pears, cherimoyas, papayas, figs, apricots, and mangos.
- Sweet fruits: Bananas, grapes, melons, and persimmons.
- Nuts: Pecans, almonds, Brazil, cashews, walnuts, macadamias, pistachios, pine nuts, hazelnuts, beechnuts, and hickory.
- Seeds: Sunflower, sesame, squash, and pumpkin.
- Dried fruits: Dates, figs, apricots, apples, raisins, cherries, prunes, bananas, and cranberries.

Oily fruits: Avocados, coconuts, and olives.

Many fruitarians believe the quality of fruit available in most commercial supermarkets is poor. This is due to hybridization, chemical fertilization, chemical pesticides, and harvesting before the fruit is at the peak of ripeness. They suggest buying certified organic fruit, preferably heirloom, often found at farmers' markets and health food stores.

Fruitarian and author David Wolfe says it is best to eat one type of fruit at a time and wait 45 minutes before another type of fruit is eaten. The Fruitarian Foundation recommends waiting at least 90 minutes between fruit types. If a person still is hungry after eating one type of fruit, they should eat more of the same type of fruit until their hunger is satisfied. People on the diet should eat only when hungry and then eat as much as they want until their hunger is satisfied. Those on a diet where only one type of fruit is eaten at a time will know when they have eaten enough, according to Wolfe. Their appetite will turn off and they will suddenly feel like they have eaten too much. Once satiated they will not gain the same satisfaction from the fruit. This is a signal from the body to stop eating, Wolfe states. The signal to stop eating is not as strong in people who eat more than one type of fruit at the same time. For a person who eats only fruit, there is no need to drink **water**. All the water the body needs is contained in the fruits. People whose diet is less than 100% fruit should supplement it with water. Some fruitarians fast one day a week. People fasting must drink a normal amount of water, usually eight to 10 glasses a day.

## KEY TERMS

**Anorexia**—The abbreviated term for anorexia nervosa, an eating disorder.

**Carbohydrates**—An organic compound that is an important source of food and energy.

**Cholesterol**—A solid compound found in blood and a number of foods, including eggs and fats.

**Diabetes**—A disease in which the blood glucose (sugar) levels are too high and the body does not make insulin (which helps regulate blood sugar) or does not make or use insulin well.

**HDL**—High-density lipoprotein, the so-called good cholesterol, found in the blood.

**Hybridization**—Relating to a plant produced from a cross between two genetically different plants.

**Insulin resistance syndrome**—A medical condition in which insulin fails to function normally in regulating blood glucose (sugar) levels.

**LDL**—Low-density lipoprotein, the so-called bad cholesterol, found in the blood.

**Triglyceride**—A natural fat found in body tissue.

### *One-day meal plan*

The following is a typical one-day meal plan from the Fruitarian Foundation for a fruitarian diet:

- Early morning (6–9 a.m.): The juice of three to five lemons immediately upon waking, raisins, and an unlimited amount of melon or melon juice.
- Midmorning (9 a.m. to 12 p.m.): An unlimited amount of apples, pineapple, figs, pears, grapes, yellow plums, lima beans, kiwi, and cucumber.
- Noon (12–3 p.m.): Oranges or tangerines, peaches, apricots, and papayas in any amount desired.
- Midafternoon (3–6 p.m.): Mango, cherries, strawberries, red plums, persimmons, pomegranates, watermelon, and tomatoes.
- Evening 6–9 p.m.): Grapes, blackberries, and raspberries.
- Late evening (9 p.m. to 12 a.m.): Mango, cherries, strawberries, red plums, persimmons, pomegranates, watermelon, and tomatoes.

Items that can be eaten at anytime are bananas, coconut, organic olives, ripe avocados, any type of raw nuts, and lemon juice. The only items that should be consumed from midnight to 3 a.m., if desired, are

four to six passion fruit, a small amount of water (if needed), and lemon juice.

Many people on a fruitarian diet give up the diet after a few months or several years because they find it too difficult to maintain. The problems include intense obsessions with food, social isolation, psychological problems, and frequent hunger. Because of these reasons and others, many people adopt a high-fruit diet composed of 50–75% fruit. The rest of the diet contains vegetables, including beans for **protein**. In some cases, the diet is still one of only raw (uncooked and unprocessed) foods while in other cases, it may include some cooked foods, such as potatoes.

### *Social implications*

Most Websites about fruitarianism emphasize that there are social concerns associated with a fruitarian diet. Much of this is because many fruitarians adopt the diet as part of a larger philosophical shift that is outside the mainstream of Western society. This includes animal rights and environmental activism, New Age spiritualism, meditation, and pacifism. In the United States, becoming or being a fruitarian or vegetarian is often seen as both a social and political statement. This can sometimes lead to conflict with family, friends, and even society at large.

"Those who live on their own and don't have any friends will have no problem changing their diet, though they may lead a bit of a lonely life," write fruitarians Lawrence and Michael Sartorius on the Website The New Earth (http://www.thenewearth.org). "For most of us, however, eating with families and friends is a daily experience and we need to consider how best to interact with them so that at the very least we do not cause a lot of inconvenience or appear cranky and antisocial with others. Younger readers especially may find themselves in conflict with their families and friends, putting them under severe pressure to 'give up this nonsense and eat sensibly like everybody else' "

For people facing these problems, the Sartorius' recommend explaining a decision to become a fruitarian with clear facts and strongly expressing personal views. This includes explaining that there is a growing trend towards healthier foods. Also, point out the growing health problems in the United States, including **obesity**, heart disease, **cancer**, diabetes, high blood pressure, and high cholesterol, which are often related to a bad diet and bad eating habits. Explain to friends the specific benefits of being a fruitarian or vegetarian, which includes living a longer, healthier life.

## Function

There are as many reasons for being a fruitarian as there are variations of the fruitarian diet. One reason is the opposition to killing animals for food, another is opposition to consuming any products that come from animals. Other reasons include opposition to killing any plant for food, health benefits, environmental concerns, and spiritual beliefs. The primary function of a fruitarian diet is to promote health and energy. Once someone adopts a fruit diet, they become physically, mentally, emotionally, and spiritually healthier, according to the Fruitarian Foundation (http://www.fruitarian.com). The foundation's philosophy states that fruitarians develop a fine-tuned body and experience few or no headaches, develop a greater resistance to illness, pain, and aging, and need less sleep. "The proper application of fruitarian dietary and lifestyle is calculated to allow the human to produce healthy offspring, live more than 100 years of age, be free of all disease, and only Lsquo;mature' while not aging, as most people think of it, and die a natural death in their sleep," according to a statement on the foundation's Website. "Man cannot eat of everything and maintain his good health. Man was created to eat of the fruits of the trees."

## Benefits

The benefits of a fruitarian diet are mostly promoted by people on the diet, rather than scientific research. These benefits include increased mental power and clarity, creativity, happiness, energy, confidence, self-esteem, and concentration. Physical health benefits, according to the Fruitarian Foundation, include preventing and curing cancer, **constipation**, insomnia, depression, and digestive problems, weight loss, wound healing, strengthening the immune system, reducing or eliminating menstruation, increasing sexual vitality, improvements in the health and appearance of skin, hair, eyes, and nails, improving muscle coordination, and the ability to control addictions to alcohol, drugs, and tobacco. The United States Department of Agriculture recommends fruit be included in daily meal planning, although the amount depends on age, gender, weight, height, level of physical activity, and weight loss goals. It must be noted that there is no scientific evidence that eating a fruit-only diet can cure any disease.

Eating a fruit or mostly fruit diet can improve cholesterol levels: raising the "good" cholesterol (high-density lipoprotein or HDL) and reducing the "bad" cholesterol (low-density lipoprotein or LDL). It can also reduce high triglyceride levels. Most of the cholesterol that contributes to clogged arteries and heart

disease comes from animal products and certain non-animal processed **fats**. Fruits, grains, and nuts contain little or no cholesterol and can help reduce cholesterol in the blood, according to the Website The New Earth.

Tom Billings, a writer and long-time vegetarian, was a self-described fruitarian for about 10 years. His experiences as both a vegetarian and fruitarian are chronicled on the Website Beyond Vegetarianism. He lists the benefits of a fruitarian diet as including:

- Fruit is the best tasting raw food and eating fruit is a pleasant experience.
- It helps cleanse the body of toxins.
- Fruit grown and sold locally is environmentally friendly.
- It promotes weight loss.
- It can improve the function of the respiratory system.
- It sharpens the senses, especially those of taste and smell.
- It reduces the amount of water a person needs to drink since most fruit has a high water content.

## Precautions

To get all of the **vitamins**, **minerals**, and nutrients that a body needs, a fruitarian must eat a wide variety of fruit and in many cases, large quantities. Very little protein can be obtained from fruit. To obtain the necessary amounts, fruitarians must include in their diet fruits and nuts that are highest in protein, including avocados, nuts, and dates. Still, it will be difficult to get the amount of protein the body needs on a daily basis. Vitamin, mineral, and other nutritional supplements can be taken to insure that a person is getting the recommended amounts. However, this does not fit into the nature-only philosophy of many fruitarians. Doctors strongly recommend that women who are pregnant or nursing not be on a fruitarian diet. Doctors also say children should not be on a fruitarian diet because their bodies require extra nutrients to sustain normal growth along with mental and physical development.

## Risks

There are many risks associated with a fruitarian diet and the risks grow as the degree of fruitarianism increases. That is, a person whose diet is 75% fruit is likely to have more health issues that a person on a diet consisting of 50% fruit. There are serious risks associated with the diet for diabetics, since fruit has a high sugar content. People with diabetes and insulin resistance syndrome should not go on an all-fruit diet. There are also the risks of serious nutritional deficiencies, including vitamin $B_{12}$, **calcium**, **iron**, **zinc**, omega-3 and omega-6 amino acids, and protein. There is also the risk of severe weight loss, which can lead to anorexia and other health problems.

### QUESTIONS TO ASK YOUR DOCTOR

- Do you see any health risks for me in a fruitarian diet?
- If there are health concerns, how can they be addressed within my diet guidelines?
- Have you treated other patients who were on a fruitarian diet?
- Can you recommend a dietician or nutritionist that is familiar with a fruitarian (or vegan) diet?

In 2001, a husband and wife from Surrey, England, were convicted of child cruelty in the death of their nine-year-old daughter. A pediatrician had testified in court that the infant, who died from a chest infection caused by malnutrition, was not developing properly because the mother's breast milk was nutritionally deficient. The couple ate a diet of only raw vegetables, fruits, and nuts.

## Research and general acceptance

There is little, if any, scientific research that supports fruitarianism as a healthy lifestyle, especially over the long-term, unless foods such as beans, green vegetables, **soy**, and whole grains are included in the diet. However, there is much scientific documentation on the benefits of a vegetarian diet. There is general and widespread disapproval of an all-fruit diet by the medical, scientific, fitness, and vegetarian communities. Many people experience positive results after initially going on a fruitarian diet but over time develop health problems, including emaciation, constant hunger, weakness, and fatigue.

## Gallstones

### Definition

Gallstones are solid material that forms in the gallbladder or bile ducts. They are made of cholesterol, bilirubin, and **calcium** and range in size from a grain of sand to a golf ball. A single stone may be present, or they may exist in large numbers. Gallstones are also called choleliths.

### Description

The gallbladder is a sac-like organ that lies on the right side of the abdomen underneath the liver. The liver makes bile that is then stored in the gallbladder. Bile is a yellowish-green fluid that helps digest **fats** and dissolve cholesterol. It contains bile salts, fats, proteins, cholesterol, and bilirubin. When a person eats a meal containing fat, the gallbladder contracts, and bile flows along the common bile duct, past the pancreatic duct that leads to the pancreas, and into the upper part of the small intestine (the duodenum) where it helps break down fat.

Gallstones form when some of the material in bile solidifies. At first the solid particles are small and may form a semi-solid sludge in the gallbladder. Gradually particles come together to form larger solid masses. As many as 20% of Americans have gallstones, and most do not know it. These are called asymptomatic gallstones, and they do not need treatment. Sometimes the stones are incidentally discovered during imaging tests (e.g. x rays, CT scan) being done for other purposes. Whether gallstones cause symptoms or not depends on their size and number and whether they move out of the gallbladder and block the common bile duct or the pancreatic duct.

Gallstones are categorized by their composition, not their shape or size. Cholesterol gallstones are the most common type of gallstone found in people in Western industrialized countries. In the United States, about 80% of gallstones are of this type. They are made of hardened cholesterol with small amounts of other substances. Pigment gallstones are black or dark brown stones made primarily of calcium and bilirubin. About 15–20% of gallstones are pigment stones. Primary bile duct stones are a third type of stone. These form directly in the bile duct instead of in the gallbladder and are rare.

### Demographics

Whites, Mexican Americans, and Native American are more likely to develop gallstone disease than blacks or Asians. Women are two to three times more likely than men to develop gallstones. The lifetime risk of a woman developing gallstones is 50% but only 30% for a man. This difference is thought to be related to the effect of estrogen, a female hormone, on increasing the production of cholesterol.

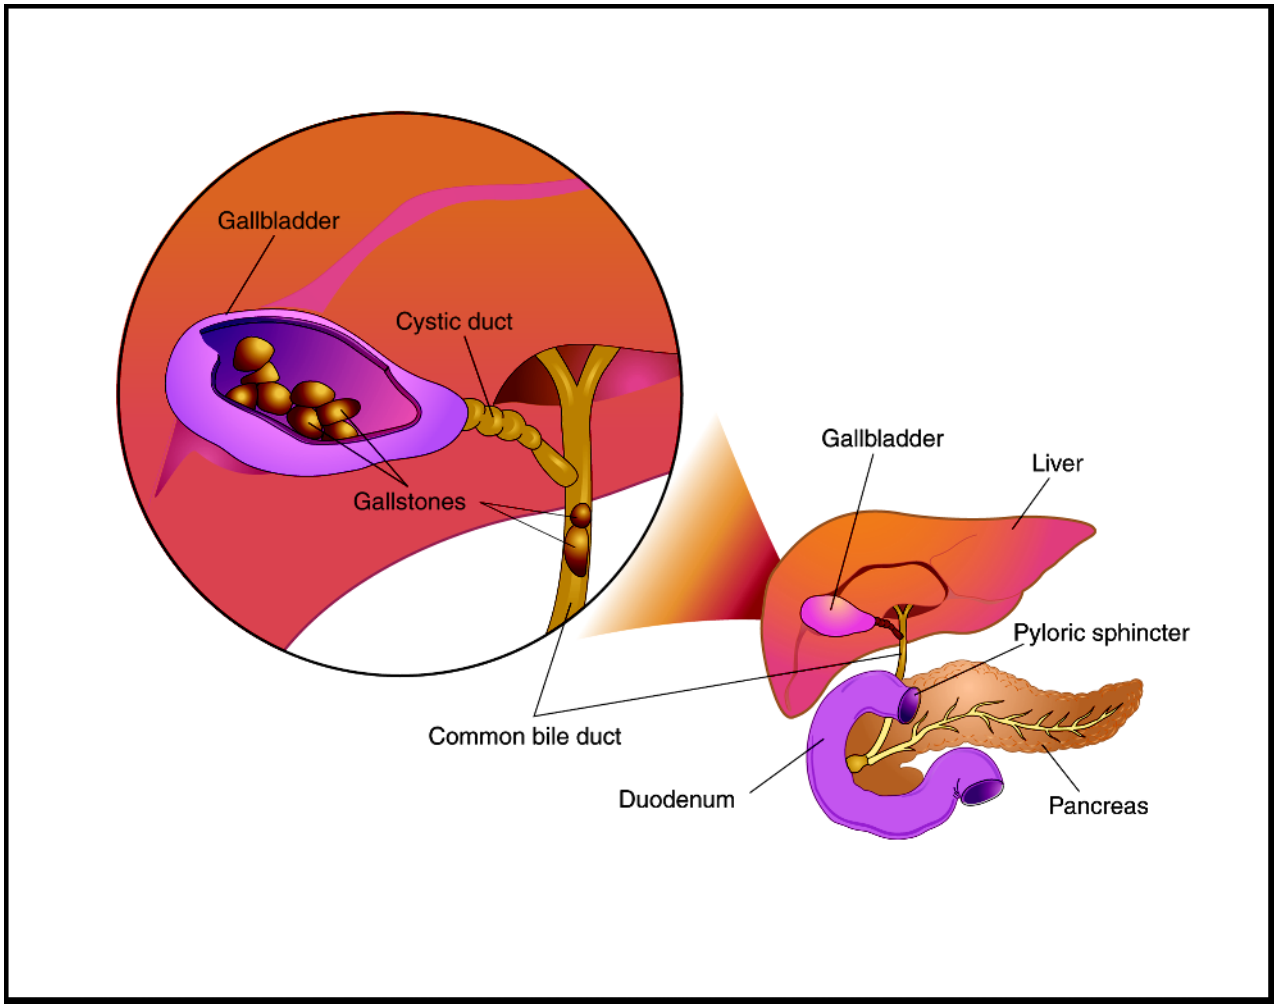
Each year 1–3% of Americans develop symptoms of gallstone disease. Gallbladder surgery is the most commonly performed abdominal surgery in the United States. About half a million gallbladder operations are done each year. Gallstones are uncommon in children, and when present are usually related to disorders orders present at birth (congenital disorders).

### Causes and symptoms

Researchers are not exactly sure why some people develop gallstones and others do not. One thought is that gallstones are more likely to develop when the gallbladder contracts infrequently or sluggishly and does not empty completely. Twin studies also suggest that heredity plays a moderate role in who develops gallstones.

What researches do know is that certain factors increase the risk of developing cholesterol gallstones. These include:

- overweight or obesity. The rate of gallstone formation increases with increasing weight. A body mass index



**Gallstones in the gallbladder and the common bile duct.** *(Illustration by Electronic Illustrators Group/Thomson Gale.)*

(BMI) of 18.5–24.9 is considered normal weight and a BMI of 25.0–29.9 is overweight. A BMI of 30 and above is obese. A woman with a BMI of 32 has about a three times greater risk of developing gallstones than a woman with a BMI of 25.

- too much cholesterol. If the liver makes too much cholesterol, it may not stay dissolved in bile, but may crystallize out and form a solid. The amount of cholesterol in bile is not related to the amount of cholesterol in blood, and lowering-lowering drugs do not affect the amount of cholesterol the liver makes.
- female gender, pregnancy, and estrogen drugs. The female hormone estrogen causes the liver to make more cholesterol. Women of reproductive age have higher levels of estrogen, which may explain why more women develop gallstones than men. In addition oral contraceptives (birth control pills) contain estrogen, and until recently, many women took drugs containing estrogen to combat hot flashes and other symptoms of menopause. Gallstone formation also increases during pregnancy, a time of increased estrogen levels.
- severe dieting. Losing weight rapidly—3 or more pounds a week— increases the likelihood of developing gallstones. About one-quarter of people who go on very low calorie diets (800 calories daily under medical supervision) and stay on them for several months develop gallstones. One-third of these people have symptoms severe enough to need gallbladder surgery. About one-third of people who have weight-loss surgery (bariatric surgery) also develop gallstones, usually in the first few months after surgery. Experts believe that somehow that triggers gallstone formation.

The chance of developing pigment gallstones is increased in individuals who have diseases such as sickle-cell anemia where there is an unusually high

## KEY TERMS

**Bile**—a greenish-yellow digestive fluid produced by the liver and stored in the gallbladder. It is released into the small intestine where it helps digest fat, and then is removed from the body in feces.

**Bilirubin**—a yellowish pigment found in bile that is produced through the normal breakdown of red blood cells

**Cholesterol**—a waxy substance made by the liver and also acquired through diet. High levels in the blood may increase the risk of cardiovascular disease.

**Pancreas**—a gland near the liver and stomach that secretes digestive fluid into the intestine and the hormone insulin into the bloodstream.

**Perforation**—a whole in the wall of an organ in the body

rate of red blood cell turnover. Bilirubin is the main component of pigment gallstones, and these diseases increase amounts of bilirubin formed in the liver.

Many people with gallstones and never have any symptoms. Symptoms tend to occur when a gallstone moves out of the gallbladder and irritates or blocks the common bile duct or the entrance to the pancreatic duct. Sometimes symptoms come and go, as when stones irritating bile duct move into the much larger small intestine.

Symptoms can include the following:

- sudden pain in the upper right part of the abdomen that lasts anywhere from 15 minutes to several hours and does not go away with changes in position.
- pain radiating up into the back or right shoulder blade
- nausea and vomiting
- fever
- jaundice, a yellowing of the skin and whites of the eyes

Pain can occur frequently or at long intervals. Jaundice and fever are signs of advanced gallstone disease and infection. Sudden intense pain, especially if accompanied by high fever, nausea, vomiting, jaundice, and dark urine are signs of a medical emergency. Medical care should be sought immediately. Untreated bile duct blockages can lead to perforation of the bile duct, infection, and death.

### Diagnosis

Diagnosis is made on the basis of a physical examination and imaging studies. Ultrasound is the least invasive and often the most effective way to locate gallstones. Other imaging studies, such as plain x rays and computed tomography (CT) scans, may also be used. These diagnostic tools may fail to located gallstones in the bile duct.

Other diagnostic tests can be used to better locate gallstones in the bile duct. A radionuclide scan, also called cholescintigraphy or HIDA scan, uses a small amount of radioactive tracer material that is injected into a vein. A machine locates the radioactive tracer as it moves through the body and in this way can tell if a stone is blocking the entrance or exit to the gallbladder or the common bile duct. Endoscopic retrograde cholangiopancreatography (ERCP) is an endoscopic procedure use to locate, and sometimes remove, gallstones from the bile and pancreatic ducts. In this procedure, a thin tube called an endoscope is passed down the throat, through the stomach, and into the first part of the small intestine. Air and dye are then injected that allows the physician to see the place where the bile duct empties into the small intestine. If stones are present, a special tool may be inserted through the endoscope to remove them.

### Treatment

By far, the most common and most successful treatment for gallstone disease is surgical removal of the gallbladder, an operation called a cholecystectomy. Removing the gallbladder has little effect on digestion. Bile simply goes directly from the liver to the small intestine instead of being stored. The difference is that the intestine receives a continuous flow of bile rather than receiving it only when it is needed. In about 1% of people, this continuous flow of bile causes mild diarrhea.

Most gallbladder surgery can be done laparoscopically. This means that surgery is done through a small cut in the abdomen instead of opening the entire abdominal cavity. A thin instrument called a laparoscope that contains a miniature video camera and a light is inserted through the cut. The surgeon uses the image from the video camera to insert small instruments through the incision and remove the gallbladder. Recovery from laparoscopic gallbladder surgery often takes only a few days.

If the gallbladder or pancreas is infected, a serious complication, or if there is scarring from previous surgeries, open gallbladder surgery is necessary. This involves making a large incision in the abdomen.

Recovery time usually involves 5–7 days in the hospital and several weeks at home.

Some people are not healthy enough to undergo surgery. In this case, treatment options include a medication called ursodiol (Actigall) that helps dissolve cholesterol stones. However, the dissolving process can take 6ndash;18 months. Sometimes this drug is given to people going on medically supervised very-low-calorie diets for fast weight loss to help prevent them from developing gallstones. The other nonsurgical treatment option is sound wave therapy (extracorporeal shock wave lithotripsy). High-frequency sound waves are aimed at the gallstones to shatter them into smaller pieces. The pieces are then dissolved using the ursodiol. With nonsurgical treatment gallstones often reoccur. When the patient is healthy enough for surgery, gallbladder removal is usually the preferred option.

### Nutrition/Dietetic concerns

Once recovery from surgery is complete, individuals who have had their gallbladder removed can return to a normal healthy diet.

### Prognosis

Gallbladder surgery is quite safe, although all surgery carries risk of infection, reaction to anesthesia, and unintentional damage to other tissue. Once the gallbladder is removed, no more gallstones can form. Most complications from gallstones arise when treatment is delayed and the pancreas or gallbladder becomes infected. This is a serious, potentially fatal, complication because infection can spread rapidly and overwhelm the body. Gallstone disease is responsible for about 10,000 deaths in the United States each year, of which only a few hundred are caused by surgical complications. The vast majority are caused by gallstone disease that has caused infection.

### Prevention

The formation of gallstones cannot be prevented. However maintaining a healthy weight, exercising regularly, and eating a diet high in whole grains and fresh fruit and vegetables and low in fat and cholesterol decrease the chance that gallstones will develop.

## Gastroesophageal reflux disease

### Definition

GERD, or gastroesophageal reflux disease, occurs when gastric juice from the stomach backs up into the bottom of the esophagus and causes irritation, inflammation or erosion of the cells lining the esophagus. GERD is sometimes called acid reflux disease.

### Description

The esophagus carries food from the mouth to the stomach. A ring of strong muscle called the lower esophageal sphincter (LES) is located at the spot where the esophagus enters the stomach. The LES relaxes and opens when a person swallows, allowing food to enter the stomach. The LES stays closed in healthy people the rest of the time, preventing the contents of the stomach from backing up into the esophagus. In people with GERD, the LES is weak and opens at inappropriate times, allowing a backwash of stomach contents into the bottom part of the esophagus.

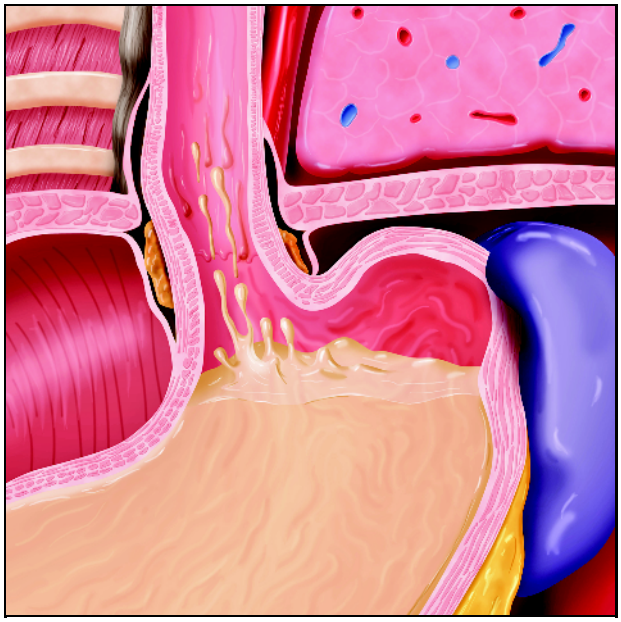

**Illustration of acidic stomach contents moving up into the esophagus.** *(Copyright Hector Aiza/Phototake. Reproduced by permission.)*

The stomach makes hydrochloric acid that is needed to digest food and help kill bacteria and other foreign organisms that are accidentally consumed with food. The cells lining the stomach secrete a thick layer of mucus that protects them from damage by stomach acid. The cells lining the esophagus do not secrete mucus, so when the LES opens and the acid mixture from the stomach come into contact with them, they become first irritated, then later inflamed, and finally eroded. The individual often feels this damage as heartburn. Heartburn is a pain or burning behind the breastbone. GERD is diagnosed when the stomach acid comes in contact with the esophagus twice or more in a week on a regular basis.

## Demographics

Acid reflux or heartburn is extremely common. About 7% of Americans, or more than 15 million people, have heartburn every day. About 60 million Americans have heartburn at least once a month, although not everyone who has heartburn has GERD, and not everyone who has GERD has heartburn. The exact number of people with GERD is difficult to determine, as many people self-treat symptoms with over-the-counter medications.

People of any race or age can develop GERD, including infants and children, but the disease is most common among people over age 50, pregnant women, and people who are overweight or obese. The condition is often overlooked in infants and children and is likely to be underdiagnosed in this group.

## Causes and symptoms

GERD is caused by stomach acid coming in contact with cells of the esophagus. The most common cause for this is weakening of the LES. Hiatal hernia is thought to increase the likelihood of developing GERD. The diaphragm is a sheet of muscle that divides the chest cavity from the abdominal cavity. With a hiatal hernia, a tear develops in the diaphragm and a portion of the stomach protrudes through the hole and up into the chest cavity. Hiatal hernias are very common, especially in people over age 50, and usually do not cause health problems or need treatment. However, the diaphragm gives support to the LES. When it is torn, this support is weakened, and the LES closes less tightly. The relationship between hiatal hernia and GERD is somewhat controversial. Many people with a hiatal hernia do not have heartburn, and some people who do not have a hiatal hernia do have heartburn.

Certain lifestyle choices increase the likelihood of developing GERD. These include:

- smoking
- alcohol consumption
- obesity
- pregnancy
- poor posture
- eating large meals shortly before bedtime

Certain foods also increase the likelihood of developing GERD. These foods include:

- greasy or fried foods
- citrus fruits or juices (e.g. orange, grapefruit)
- caffeinated beverages (e.g. coffee, colas)
- garlic and onions
- tomato-based foods (e.g. spaghetti sauce, chili)
- chocolate
- foods flavored with mint
- garlic and onions
- spicy foods
- wine, beer, and distilled spirits

## Symptoms

The most common symptom of GERD is heartburn. Heartburn is a sharp pain in the center of the chest that can spread to the neck and last for up to 2 hours. The pain can be substantial enough to be confused with angina or a heart attack. Note that if there is any question about whether the pain is caused by a

heart attack, the individual should seek medical attention immediately. Heartburn pain does not get worse with physical activity, but often worsens when bending over or lying down. As noted above, heartburn is extremely common. Almost everyone experiences it at some time, usually after eating an unusually large or spicy meal.

GERD also has less typical symptoms. Some people regurgitate or involuntarily bring up the contents of the stomach into the mouth. This causes a bitter taste, and if it occurs often enough can erode tooth enamel.

Other less typical symptoms are wheezing, shortness of breath, increased incidence of asthma, and a persistent dry cough. GERD can also cause the person's voice to sound hoarse. Hoarseness is usually worse in the morning. These symptoms are caused by contents of the stomach approaching or enter the airways.

Some people have difficulty swallowing or feel as if the food they have eaten is stuck behind their breastbone. This symptom can also be caused by a narrowing of the esophagus where it enters the stomach.

The most common symptoms of GERD in infants and children are repeated non-projectile vomiting (spitting up), persistent coughing, and wheezing.

## Diagnosis

Often GERD is tentatively diagnosed on the basis of the patient reporting heartburn twice or more a week on a regular basis. Normally the physician will suggest lifestyle changes (see treatment below), and if there is no improvement will order more extensive tests.

An upper GI series, sometimes called a barium swallow, includes x rays of the esophagus, stomach, and upper part of the intestine. Often the patient drinks a solution of barium to improve contrast on the x rays. These x rays help rule out abnormalities such as a narrowing of the esophagus (esophageal stricture) and **ulcers**.

An upper endoscopy is a diagnostic procedure that allows the physician to see the lining of the esophagus and stomach. It is performed in a doctor's office or an outpatient clinic under light sedation. A tube called an endoscope is inserted down the throat. At the end of the endoscope is a tiny camera that allows the doctor to see if there is damage to the cells lining the esophagus. During this procedure, the doctor may use also remove small tissue samples (a biopsy) from the esophagus in order to look for abnormal cells under the microscope.

Occasionally 24-hour pH monitoring is necessary. The pH scale measures the strength of acids. In this test, a tube put down the esophagus measures how much stomach acid back up into the esophagus. Monitoring usually for continues for 24 hours.

GERD is categorized according to the degree of damage to the esophagus.

- Grade I: redness and irritation of the esophagus
- Grade II: some non-adjacent spots of erosion of esophageal cells
- Grade III: increased and continuous patches of erosion
- Grade IV: Barrett's esophagus, a precancerous condition in which normal cells are replaced by abnormal ones.

## Treatment

The goals of treating GERD are to eliminate heartburn and other symptoms, heal damage to the esophagus, and prevent return of symptoms. Treatment proceeds in four stages: lifestyle changes, over-the-counter remedies, prescription drug therapy, and surgery.

Lifestyle changes are the easiest and least expensive approach to treating GERD. They bring relief to many people. Recommended lifestyle changes include:

- Quitting smoking
- If overweight, losing weight
- Stopping drinking alcoholic beverages
- Avoiding foods likely to cause heartburn
- Avoiding eating at least 3 hours before going to bed
- Elevating the head of the bed about 4 inches on blocks or using a sloped piece of foam under the mattress to raise the head 6 or more inches.

When lifestyle changes are not enough to relieve symptoms within a few weeks, the next step is to use over-the-counter medications. Antacids, such as Alka-Seltzer, Maalox, Rolaids, or Tums, reduce the acidity of liquid already in the stomach. Many antacids contain aluminum and **magnesium**. They should not be taken regularly for long periods because these **minerals** may disrupt the chemical balance in the body.

Drugs known as H2 blockers help reduce the production of acid in the stomach. H2 blockers that are available without a prescription include cimetidine (Tagamet), ranitidine (Zantac), ranitidine (Zantac), and nizatidine (Axid). Some of these are also available in higher strengths with a doctor's prescription.

H2 blockers are most effective when taken about an hour before meals. They do not affect acid already in the stomach.

Proton pump inhibitors use a different chemical mechanism to block acid production by the stomach. They are more effective than H2 blockers and are used when H2 blockers fail. Some are available in over-the-counter strengths, while others require a prescription. Common proton pump inhibitors include omeprazole (Prilosec), lansoprazole (Prevacid), rabeprazole (Aciphex), esomeprazole (Nexium), and metoclopramide (Reglan).

Surgery is the most drastic treatment for GERD. It is used when all other treatments fail and symptoms remain. The most common surgical operation to correct GERD is called fundoplication. This surgery is done laparoscopically; the entire abdomen does not need to be opened. A small slit is made in the abdomen and a camera guides the surgeon who manipulates small instruments through this slit to wrap the top of the stomach (the fundus) like a cuff around the bottom of the esophagus. This provides additional support for the LES, and is initially successful in stopping GERD about 92% of the time. Long-term success rates are variable. Laparoscopic fundoplication usually requires a hospital stay of 1–3 days and takes about 2–3 weeks for complete recovery.

In 2000, the United States Food and Drug Administration (FDA) approved two other procedures to treat chronic acid reflux. On involves putting stitches in the LES to create small pleats that make the muscle stronger. The other involves making small cuts in the LES. The scar tissue that forms when the muscle heals makes the LES stronger. There is little data on the long-term success of these procedures. More recently, the FDA has approved an implant that does not require surgery. The implant reinforces and strengthens the LES reinforces. This procedure is too new to have any data concerning long-term success.

## Nutrition/Dietetic concerns

Nutritional concerns related to GERD involve lifestyle changes designed to reduce or eliminate heartburn. These dietary changes are likely to have other beneficial health effects as well. Foods to avoid include:

- alcoholic beverages
- coffee, tea, and caffeinated soft drinks
- fatty or fired foods
- acidic foods such as citrus fruit or juice and tomato-based foods
- chocolate or foods with mint flavorings
- highly spiced foods

## Prognosis

About 80% of people get relief from GERD through lifestyle changes and medication, although relapses are common. H2-blockers successfully treat 50 to 60% of people with grade I or grade II GERD. Most people not helped by H2 blockers can be healed by 6–8 weeks of treatment with proton pump inhibitor drugs. Of the 20% of people not helped by medication, 92% improve with fundoplication surgery.

The most serious complication of GERD is Barrett's esophagus. In this disease, normal cells lining the esophagus are replaced with abnormal cells. About 30% of people with Barrett's esophagus go on to develop **cancer** of the esophagus. Those at highest risk are white men.

Other long-term complications of GERD include narrowing or scarring of the base of the esophagus, a condition called peptic stricture. This can cause difficulty swallowing. Also, people with GERD may have more ear infections and laryngitis. GERD may worsen asthma.

## Prevention

Prevention of GERD is very similar to the lifestyle changes suggested in the initial stage of treatment—stop smoking, lose weight, reduce or eliminate **alcohol consumption**, and avoid foods likely to cause heartburn.

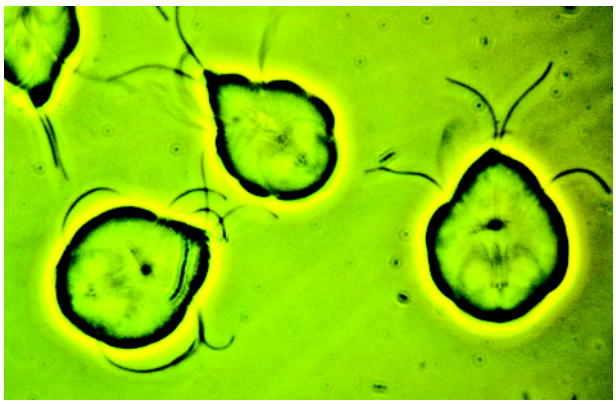
# Giardiasis

## Definition

Giardiasis is a communicable gastrointestinal disease characterized by acute diarrhea. It is caused by a parasite, *Giardia lamblia*, also known as *Giardia intestinalis*. Giardiasis is the most common water-borne infection of the human intestine worldwide, affecting as many as 200 million people each year. According to the Centers for Disease Control and Prevention (CDC), there were 90 major community outbreaks of giardiasis in the United States between 1964 and 1984, and 34 major outbreaks since 1985.

The organism that causes giardiasis, *G. lamblia*, is a protozoan, a single-celled organism formerly classified as a member of the animal kingdom. It is a pear-shaped parasite with four flagella, which are long whip-like extensions of the cell that allow the organism to move. It was first seen under a microscope by the Dutch lens maker Antony van Leeuwenhoek in the 17th century. *G. lamblia* was found in human stool samples in 1859 by a Czech physician named Lambl, but was not identified as the cause of giardiasis until the 1970s. It was given its present name in 1915 to honor Alfred Giard, a French biologist, as well as Dr. Lambl.



**Giardiasis is a diarrheal illness caused by a one-celled, microscopic parasite, Giardia intestinalis (also known as Giardia lamblia).** *(Dr. George Wilder/Visuals Unlimited/Getty Images. Reproduced by permission.)*

## Origins

Dietary treatment of patients with giardiasis has been a gradual process, dependent on better understanding of the causes of the disease as well as the development of nutritionally adequate rehydration solutions and anti-infective medications. A large part of dietary therapy for giardiasis, in fact, consists of measures to prevent the spread of the disease, not just to treat the symptoms after they appear.

## Description

### *Life cycle of G. lamblia*

In order to understand the symptoms, treatment, and prevention of giardiasis, it is helpful to understand the life cycle of *G. lamblia*. The parasite that causes giardiasis has a simple two-stage life cycle that does not require an intermediate host; it can be spread directly among human beings. The cycle begins when a person swallows as few as 10 to 15 cysts of *G. lamblia*. The cyst is a protective shell that the organism forms around itself that enables it to survive outside a human or animal host. The cysts of *G. lamblia* are smooth-

## KEY TERMS

**Barberry**—A shrub native to southern Europe and western Asia that produces oblong red berries that have a sour taste. Barberry has been used as a natural treatment for giardiasis.

**Beaver fever**—An informal name for giardiasis, so called because beavers are a common animal reservoir of the parasite that causes giardiasis.

**Carrier**—A person who bears or carries a disease agent in or on their body and can transmit the disease to others, but is immune to the disease or has no symptoms of it. Some people can be carriers of the organism that causes giardiasis without developing diarrhea.

**Cyst**—The protective shell formed by *G. lamblia* that keeps the organism alive after it has been expelled from the host's body.

**Endoscope**—A special tube-shaped instrument that allows a doctor to examine the interior of or perform surgery inside the stomach or intestines.

**Flatulence**—The passage of intestinal gas. Flatulence is a common symptom of giardiasis.

**Gastroenterologist**—A doctor who specializes in the diagnosis and treatment of diseases of the stomach and intestines.

**Lactose**—A sugar found in milk and milk products that requires an enzyme called lactase to digest it. Some people with giardiasis must avoid foods containing lactose for several weeks or months after they are treated for the disease because their bodies are temporarily unable to produce enough lactase to digest the milk sugar.

**Malabsorption syndrome**—A condition characterized by indigestion, bloating, diarrhea, loss of appetite, and weakness, caused by poor absorption of nutrients from food as a result of giardiasis, other bowel disorders, or certain surgical procedures involving the digestive tract.

**Protozoan**—Any member of a phylum of one-celled eukaryotes (organisms with nuclei) that are able to move but are not animals in the strict sense. The organism that causes giardiasis is a protozoan.

**Reservoir**—A term used for animals that can carry parasites that cause disease in humans without falling ill themselves. Beavers, dogs, cats, cattle, and horses are common reservoirs of *G. lamblia*.

**Steatorrhea**—The passage of large amounts of fat or grease in the stool, caused by failure to absorb it during digestion. Steatorrhea is often associated with chronic giardiasis.

**Traveler's diarrhea (TD)**—A nonspecific term for a form of diarrhea that frequently affects tourists abroad. TD is the most common illness affecting visitors to other countries. Some cases of TD are caused by *G. lamblia*, but others result from infection with various bacteria, rotaviruses, and other intestinal parasites.

**Trophozoite**—The active feeding stage in the life cycle of *G. lamblia*. It is the trophozoites that multiply within the small intestine and cause the diarrhea and other symptoms of giardiasis.

walled and oval in shape, about 8–12 micrometers long and 5–15 micrometers wide. They are hardy and can survive for several months in cold **water**. They usually enter the human body through the mouth. The cysts may be transferred to the mouth directly from unwashed hands that have touched fecal matter containing cysts, or through having oral sex with an infected person. They may also enter the mouth through eating food or swallowing liquids contaminated by fecal matter containing *G. lamblia* cysts. *G. lamblia* is not, however, transmitted through blood.

Once inside the body, the cysts pass through the digestive tract until they reach the small intestine. Each cyst then opens—often within 5 minutes after arrival—and releases two trophozoites, which are the active feeding stage of the parasite. The trophozoites multiply rapidly, reproducing every 9 to 12 hours. They may remain free within the central cavity (lumen) of the small intestine or attach themselves to the mucous tissue lining the intestine by a sucking disk located on their ventral surface. It is the trophozoites that cause the violent diarrhea, nausea, intestinal gas, and cramping associated with giardiasis. As of 2007, however, researchers do not know the exact reason for the symptoms; some think that the parasites compete with the host for nutrients, while others think that they affect the host's immune system, cause damage to the tissues lining the intestine, or block the functioning of the intestinal mucosa by their sheer numbers.

As the trophozoites are carried toward the colon, they begin to secrete proteins to form the walls of a new cyst. Within the next 24 hours, the trophozoite

completes the construction of its cyst and is shed into the outside environment through the person's feces.

### *Symptoms*

About 15% of people who swallow cysts are asymptomatic. These cases are usually detected only if the person's stool is tested during a community outbreak. They are significant, however, because persons carrying the cysts in their digestive tract, known as carriers, can still transmit giardiasis to others even if they do not develop the symptoms of the illness. It is estimated that between 30 and 60% of children in daycare centers and adults on Native American reservations are carriers of *G. lamblia*. Some domestic and wild animals can also be carriers of *G. lamblia*, dogs and beavers being the most common animal reservoirs.

Of the patients who have symptoms, 90% develop acute diarrhea within 7 to 10 days of ingesting the cysts; and 70–75% have abdominal cramps, bloating, vomiting, and flatulence (the passage of intestinal gas). A small percentage of patients develop symptoms within 3 days of swallowing the cysts, including violent diarrhea, extremely foul-smelling intestinal gas, severe vomiting, fever, and headache. Most patients lose their appetite, and 50% lose weight—an average of 10 pounds in adults. Without treatment, these symptoms can last for as long as 7 weeks or even longer.

Between 20 and 40% of adults with giardiasis develop a temporary difficulty with digesting lactose, a sugar found in milk or milk products. This condition is called lactose intolerance and may last for a month or so after treatment with anti-parasite medications for giardiasis. Having lactose intolerance does not mean that the person has become reinfected.

There is no universal pattern to recovery from giardiasis. It is rarely fatal except in severely dehydrated and malnourished children, but may develop into chronic forms—malabsorption syndrome in adults and failure to thrive in children. Chronic giardiasis in adults is characterized by episodes of diarrhea that come and go, alternating with periods of **constipation** and normal bowel movements. Other symptoms of chronic giardiasis in adults include:

- Ongoing weight loss apart from intentional weight reduction.
- Steatorrhea. Steatorrhea is the medical term for the passage of large amounts of fat or greasy-looking material in the stool.
- Discomfort in the stomach or abdomen that is worse after a meal.
- Persistent bad breath or burping that smells like sulfur.
- Ongoing bloating, flatulence, or abdominal cramping.
- Recurrent headaches.
- Malaise (general feeling of sickness), fatigue, or weakness.

The symptoms of chronic giardiasis in children include:

- Failure to grow and gain weight at a normal rate for the child's age and sex.
- Recurrent episodes of pale, frothy, foul-smelling diarrhea.
- Loss of appetite.
- Abdominal pain and vomiting.
- Nutritional deficiencies caused by the inability to absorb nutrients in food.

### *Demographics*

In the United States and other developed countries, giardiasis is most likely to affect children, particularly children in daycare centers. About 20 to 25% of the children in daycare centers are infected with giardiasis even though they may not be symptomatic. Most of the community outbreaks in the United States since the 1980s, in fact, began in daycare centers.

Older adolescents and adults are more likely to be infected with giardiasis while hiking or traveling abroad. *G. lamblia* is a common cause of so-called **traveler's diarrhea**, although it is not the only organism that causes it. Giardiasis acquired its nickname of "beaver fever" because backpackers and hikers who drink water from or swim in streams close to beaver colonies are likely to ingest *G. lamblia* cysts shed into the water by infected animals. The CDC reports that as many as 80% of water samples from lakes, streams, and ponds in the United States contain *G. lamblia* cysts.

Outbreaks of giardiasis are most likely to occur in Canada and the United States during warmer weather, particularly in summer and fall. Race does not appear to be a factor in contracting giardiasis; however, males in all age groups are about 1.2 times more likely than females to develop the disease.

### *Risk factors*

Some people are at increased risk of contracting giardiasis because of their location or lifestyle:

- Parents of infected small children.
- Employees (and their family members) of daycare centers in which some of the children are not yet toilet-trained.
- Employees (and their family members) of nursing homes or other custodial facilities.

- Male homosexuals, particularly those with several or many partners.
- People who swim in or boat on rivers, lakes, streams, or other bodies of water liable to contamination by fecal matter. The greatest risk of infection comes from accidentally swallowing a mouthful of water while swimming, diving, rafting, or water skiing.
- People who depend on well water for their household drinking supply.

Some people are at increased risk of a severe case of giardiasis because they have other health problems:

- An impaired immune system.
- Crohn's disease, cystic fibrosis, or other diseases that weaken the intestines.
- Malnutrition.
- Recent surgery on the stomach or taking medications to lower stomach acid secretion (stomach acid kills *G. lamblia*).

## Treatment

Most people with giardiasis can be diagnosed and treated by their primary care physician. Diagnosis is usually done by examining stool samples under a microscope for the characteristic cysts and trophozoites of *G. lamblia* (both forms of the organism may appear in the stool); by enzyme-linked immunosorbent assay (ELISA) tests; or by an Entero-test. The Entero-test, also called the string test, consists of a gelatin capsule containing a nylon string attached to a weight. The patient tapes one end of the string to the inside of the cheek and swallows the capsule. The string is left in place for 4 to 6 hours or overnight while the patient is fasting; it is then removed and the mucus on the string is examined for trophozoites.

Patients suspected of having chronic giardiasis may be referred to a gastroenterologist, who is a doctor with special training in digestive disorders. In some cases, the doctor may need to examine the patient's small intestine through an endoscope or remove a sample of tissue from the lining of the patient's intestine to make sure that the patient's symptoms are caused by a parasite and not by some other disorder.

### *Medications*

Giardiasis is most commonly treated with one of the following drugs, which cause the death of the disease organisms:

- Metronidazole (Flagyl). The most common drug given to treat giardiasis. Adults are usually given three doses per day over a 5-day period, while children are usually given a 10-day course.
- Furazolidone (Furoxone). Some doctors prefer to treat children with this drug because it is available in a liquid form.
- Nitazoxanide (Alinia). This drug is also preferred for treating children because it causes fewer adverse effects in younger patients.
- Tinidazole (Tindamax). Tinidazole is a relatively new anti-infective drug; it was approved by the Food and Drug Administration (FDA) only in 2004. It has the advantage of requiring only one dose of 2000 mg for treatment of giardiasis rather than several days of repeated doses.
- Paramomycin (Humatin). Paramomycin is the only drug effective against *G. lamblia* that is considered safe to give pregnant women.

Some herbalists and naturopaths recommend barberry (*Berberis vulgaris*) as an anti-infective agent in treating giardiasis.

Children or adults who are carrying cysts are sometimes given anti-infective drugs even if they are not symptomatic, in order to lower the risk of transmission to other children in a daycare center or other family members.

### *Dietary treatment*

People with mild cases of giardiasis may not need any special dietary therapy after they have started taking medications to kill the parasites.

Children and adults who have become dehydrated because of severe diarrhea may be given a rehydration drink (Lytren, Rehydralyte, or Pedialyte) to sip. Adults should drink 1 cup of water or rehydration drink for each large passage of watery stool. Children should be given 1/2 to 1 cup of rehydration fluid (or Pedialyte frozen pops) per hour, as **dehydration** is more dangerous to them than to adults. Children should not be given undiluted sports drinks, soda pop, or fruit juice, as these contain too much sugar and not enough **electrolytes**. If a commercial rehydration drink is not available and the diarrhea does not stop within 24 hours, the World Health Organization (WHO) formula for oral rehydration can be used. To make the WHO formula at home, combine 1 quart of boiled or purified water with 2 teaspoons table sugar, 1/2 teaspoon salt, and 1/2 teaspoon of baking soda (**sodium** bicarbonate).

Dietary therapy for adults recovering from giardiasis includes the following:

- Take clear liquids only (beef broth, soda, vegetable or chicken bouillon, etc.) for the first 24 hours of acute symptoms; do not try to eat solid foods.

- Begin eating mild foods without spices on the second day. These foods include plain boiled rice, dry toast, saltines, applesauce, and bananas.
- Avoid spicy foods, citrus fruits, caffeinated beverages, and alcohol until two days after the last symptoms of giardiasis have disappeared.
- Avoid milk and other dairy products for three days after the last symptoms of giardiasis.

Patients who have developed lactose intolerance as a result of giardiasis can usually treat the problem themselves by avoiding milk and dairy products for a full month (or longer) after the end of symptoms, and then add them to the diet in small amounts on a gradual basis. They may also wish to consider some alternative products such as **soy** milk, almond milk, oat milk, or rice milk, or try some of the lactose-free milk and cheese products that are now available.

## Benefits

### *Medications*

Anti-infective medications benefit the patient by killing the parasites responsible for giardiasis, thereby lowering the risk of developing chronic giardiasis and malabsorption syndrome.

### *Dietary treatment*

Dietary treatment for giardiasis benefits the patient by giving the digestive tract a rest and by replacing nutrients and electrolytes lost by acute diarrhea or vomiting.

## Precautions

### *Medications*

Patients taking anti-infective drugs should tell their doctor about any other medications they may be taking, including over-the-counter drugs, to lower the risk of drug interactions.

Pregnant women should not take any anti-infective medication for giardiasis except paramomycin, and then only if they are severely ill.

Anti-infective medications should be taken with food to lower the risk of nausea or heartburn. They should, however, *never* be taken with alcohol, as they will interact to cause severe nausea and vomiting. Alcoholic beverages should be avoided for at least 48 hours after the last dose of the medication.

### *Preventive dietary and public health measures*

The risk of contracting giardiasis can be lowered by simple dietary and personal cleanliness measures:

## QUESTIONS TO ASK YOUR DOCTOR

- What can I do to prevent giardiasis in my household?
- What precautions would you advise before a family vacation trip?

- Avoid drinking untreated or unpurified water when hiking or camping. Boil the water for at least 1 full minute or add commercial purification tablets before drinking.
- When traveling in other countries known to have high rates of giardiasis, drink only bottled water and do not eat raw fruits or vegetables or drink beverages containing ice made from untreated water. The CDC maintains a frequently updated list of travelers' advisories on its website.
- Wash hands often, particularly after using the toilet, changing diapers, helping someone else use the toilet, or before food preparation.
- Avoid swallowing water when swimming in lakes, rivers, or streams.
- Protect others by avoiding swimming pools, hot tubs, the ocean, or lakes and streams while infected with *G. lamblia*, and for at least 2 weeks after the diarrhea stops. It is possible to pass the organism in stool and contaminate water for several weeks after the symptoms have ended.
- Avoid exposure to fecal material during sexual activity.

## Risks

### *Medications*

The anti-infective drugs listed above cause some adverse effects in some patients, including nausea, constipation, headache, temporary discoloration of the urine, a metallic taste in the mouth, drowsiness, skin rashes or itching, dry mouth, or depression.

Anti-infective medications interact with such other drugs as cimetidine, praziquantel, tricyclic antidepressants, selective serotonin reuptake inhibitors (SSRIs), lithium, phenytoin, and others. They counteract the effects of some of these medications and intensify the effects of others.

### *Dietary treatment*

There are no risks associated with modifying the patient's normal diet as part of recovery from giardiasis.

No adverse effects have been reported from the use of rehydration solutions in treating patients with giardiasis.

### Research and general acceptance

Anti-infective medications for the treatment for giardiasis have been tested and used for several decades as of 2007. The WHO formula for oral rehydration has been used in developing nations since the 1960s in treating people dehydrated by diarrhea resulting from cholera, giardiasis, and other intestinal disorders.

## Ginseng

### Definition

Ginseng refers to two closely related herbs of the genus *Panax*. Asian ginseng (*P. ginseng*) and American ginseng (*P. quinquefolius*) have traditionally been used for healing. Asian ginseng is also known as Korean red ginseng, Chinese ginseng, Japanese ginseng, ginseng radix, ninjin, sang, and ren shen. American ginseng is also known as Canadian ginseng, North American ginseng, Ontario ginseng, Wisconsin ginseng, red berry, sang, and ren shen. Siberian ginseng (*Eleutherococcus senticosus*) is a plant with different properties that belongs to a completely different genus. Ginseng in this entry refers only to Asian and American ginseng of the genus *Panax*.

### Purpose

Ginseng has been used for about 2,000 years in Traditional Chinese Medicine (TCM) to boost energy, hasten recovery from illness or injury, reduce stress, improve mental and physical performance (including sexual performance) and to treat a several dozen different infections, gastrointestinal disorders, circulatory problems, and conditions as diverse as burns, cancers, diabetes, migraine headaches, and weight loss. The genus name *Panax* means "heal all," and ginseng is considered by herbalists to be an almost universal remedy. Most of these traditional uses of ginseng have not yet been substantiated by conventional medicine, however encouraging results from some well-designed, controlled human studies strongly suggest that ginseng may improve mental performance and have other health benefits.

### Description

Ginseng is a perennial herb that grows in cool, damp, shady forests. Asian ginseng is native to

**Cultivated American gingseng.** *(JLM Visuals. Reproduced by permission.)*

Northern China and today is grown as a cash crop in China, Korea, Japan, and Russia. American ginseng once grew wild from the Appalachian Mountains to Minnesota. Today it is cultivated mainly in Wisconsin and in the Canadian provinces of Ontario and British Columbia. Most cultivated ginseng from North America is exported to Asia. In both Asia and North America, wild ginseng is threatened with extinction from over harvesting. In the United States, a government permit is usually required to export wild ginseng. High-quality wild ginseng is very expensive. Illegal harvesting of wild ginseng from public lands is an ongoing law enforcement problem for the United States Fish and Wildlife Service.

Ginseng is a slow-growing plant that reaches a height of 12–30 inches and produces red berries. Only the root used for medicinal purposes. Ginseng is difficult to cultivate. Plants must grow 4–6 years before the roots can be harvested. Ginseng roots are forked and twisted, looking somewhat like a miniature human body. They are occasionally used fresh but more often are dried and ground or powdered. The root can be soaked to make an extract or tincture. Ground ginseng can be added to tea and powered ginseng put into capsules. Ginseng extract can be added to products as diverse as chewing gum and soft drinks. Ginseng is sold under dozens of different brand names. It is often found in multi-herb remedies sold under a huge variety of names. The active ingredients of ginseng are thought to be more than twenty compounds called ginsenosides. Some manufacturers standardize the amount of ginsengosides in their product while others do not. Standardized products usually contain 4–% ginsenosides.

### *Regulation of ginseng sales*

In the United States, ginseng is regulated by the Food and Drug Administration (FDA) as a dietary supplement under the 1994 Dietary Supplement Health and Education Act (DSHEA). At the time the act was passed, legislators felt because many **dietary supplements** such as ginseng come from natural sources and have been used for hundreds of years by practitioners of complementary and alternative medicine (CAM), these supplements did not need to be regulated as rigorously as prescription and over-the-counter drugs used in conventional medicine.

The DSHEA regulates ginseng in the same way that food is regulated. Like food manufacturers, manufacturers of herbal products containing ginseng do not have to prove that they are either safe or effective before they can be sold to the public. This differs from conventional pharmaceutical drugs, which must undergo extensive human testing to prove their safety and effectiveness before they can be marketed. Also unlike conventional drugs, the label for a dietary supplement such as ginseng does not have to contain any statements about possible side effects. All herbal supplements sold in the United States must show the scientific name of the herb on the label. Consumers should look for ginseng of the *Panax* variety. Sometimes less expensive herbs such as Siberian "ginseng" are substituted for true ginseng.

### *Health claims*

Dozens of health claims are made for ginseng, many based on traditional or folk use of the herb. These claims are difficult to substantiate in ways that satisfy conventional medicine for several reasons including:

- The amount and strength of ginseng in dietary supplements is not standardized and a wide range of doses are used in different studies.
- Ginseng is often one of several herbs contained in herbal remedies, making it difficult to tell if the effects are due to ginseng or another herb.
- Many studies done on ginseng are poorly designed so that it is impossible to show a direct link between cause and effect, or they poorly reported, making analysis of the results difficult.
- Many rigorous and well-designed human studies have a small sample size.

## KEY TERMS

**Alternative medicine**—A system of healing that rejects conventional, pharmaceutical-based medicine and replaces it with the use of dietary supplements and therapies such as herbs, vitamins, minerals, massage, and cleansing diets. Alternative medicine includes well-established treatment systems such as homeopathy, Traditional Chinese Medicine, and Ayurvedic medicine, as well as more-recent, fad-driven treatments.

**Alzheimer's disease**—An incurable disease of older individuals that results in the destruction of nerve cells in the brain and causes gradual loss of mental and physical functions.

**Conventional medicine**—Mainstream or Western pharmaceutical-based medicine practiced by medical doctors, doctors of osteopathy, and other licensed health care professionals.

**Dietary supplement**—A product, such as a vitamin, mineral, herb, amino acid, or enzyme, that is intended to be consumed in addition to an individual's diet with the expectation that it will improve health.

**Traditional Chinese Medicine (TCM)**—An ancient system of medicine based on maintaining a balance in vital energy or *qi* that controls emotions, spiritual, and physical well being. Diseases and disorders result from imbalances in qi, and treatments such as massage, exercise, acupuncture, nutritional and herbal therapy is designed to restore balance and harmony to the body.

- Many studies are sponsored by ginseng growers, manufacturers, or importers who have a financial interest in obtaining positive results.

Despite these drawbacks, there is enough evidence that ginseng provides health benefits that the National Center for Complementary and Alternative Medicine (NCCAM), a government organization within the National Institutes of Health, is sponsoring clinical trials to determine safety and effectiveness ginseng as a treatment for several diseases and disorders. Individuals interested in participating in a clinical trial at no charge can find a list of open trials at <http://www.clinicaltrials.gov>.

Some health claims for ginseng appear more promising than others. There is good evidence that ginseng can cause short-term improvement in mental performance in both healthy young adults and elderly ill adults. Not enough information is available to determine if long-term gains also occur, but the results have been promising enough that ginseng is being studied in patients with Alzheimer's disease and other dementias. Along with improved mental performance, some studies have shown that ginseng improves the sense of well being and quality of life. Results of these studies are mixed, with some finding improvements and others finding no change. The situation is complicated by the fact that different studies define and measure "well being" and "quality of life" in different ways. In general, people with the worst quality of life report the most improvement.

Many claims are made that ginseng boosts the immune system, thus helping to prevent disease and promote a more rapid recovery from illness and injury. Some studies also claim that ginseng boosts the effect of antibiotics and improves the body's response to influenza vaccines. Some studies of patients with diseases that cause a low white cell count (white cells are a part of the immune system) show that white cell count increases with high doses of ginsenosides. Better studies are needed before the effect of ginseng on the immune system can be determined.

There is good evidence that ginseng lowers blood sugar in people with type 2 (non-insulin dependent) diabetes. The effect of ginseng on blood sugar in people with type 1 (insulin dependent) diabetes has not been studied enough to produce any definite findings.

Ginseng has been promoted as a preventative and/or cure for **cancer**. According the American Cancer Society in 2007, "There is no reliable scientific evidence that ginseng is effective in preventing or treating cancer in humans." However, controversial evidence from some studies done in Asia suggests the possibility that ginseng powder or extract may prevent some cancers. More and better studies are needed to clarify these results.

Some studies have reported that ginseng improves stamina and athletic performance and decreases fatigue, while other studies find no effect. There are so many other lifestyle variables in most of these studies that it is difficult to separate the effect of ginseng from other factors.

Studies of the effect of ginseng on the circulatory system are mixed. Some studies find that ginseng lowers blood pressure and in combination with other herbs prevents coronary artery disease and possibly congestive heart failure. Other studies find no effect, or that the effect is apparent only at very high, and possibly unsafe, doses. The effect of ginseng on the circulatory system continues to be investigated.

Many other health claims are made for herbal mixtures that contain ginseng. These claims are extremely difficult to evaluate because of the number of variables, including the strength of the mixture, the effects of the different herbs, and potential interactions among other herbs. Until much more is known about the chemical properties and active ingredients of common medicinal herbs, it is almost impossible to evaluate these mixtures in a way that satisfies the demands of conventional medicine.

## Precautions

Ginseng is generally safe and causes few side effects when taken at recommended doses. The generally recommended dose is 100–200 mg of standardized ginseng extract containing 4% ginsenosides once or twice daily. The safety of ginseng in children and pregnant and **breastfeeding** women has not been studied. Pregnant and breastfeeding women should be aware that some tinctures of ginseng contain high levels of alcohol. Some herbalists recommend that individuals take ginseng for 2–3 weeks and then take a break of 1–2 weeks before beginning the herb again.

Independent laboratory analyses have repeatedly found that many products labeled as ginseng contain little or none of the herb. True ginseng is expensive, and unscrupulous manufacturers often substitute low-cost herbs for ginseng. Another problem is that some ginseng products have been found to be contaminated with pesticides and other chemicals that can cause serious side effects.

## Interactions

Ginseng appears to interact with blood-thinning and anti-coagulant medicines such as warfarin (Coumadin), clopidogrel (Plavix), aspirin, and nonsteroidal anti-inflammatory drugs (e.g. Advil, Motrin). Individuals taking these drugs should not begin taking ginseng without consulting their health care provider.

Because ginseng lowers blood sugar levels, individuals who are taking insulin or other medications that also lower blood sugar, and those with type 2 diabetes, should be monitored for low blood sugar if they begin taking ginseng. Adjustments are needed in their other medications.
