Cardiovascular: **Malaise/fatigue**, angina, cardiopulmonary arrest, ECG changes, flushing, hypotension, shock, tachycardia, vascular occlusive events

Central nervous system: **Headache**, drowsiness, fever, dizziness, anxiety, cold sensation, extrapyramidal reactions, grand mal seizures, oculogyric crisis

Dermatologic: Pruritus, rash, urticaria, angioedema

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Constipation, diarrhea

Genitourinary: Gynecological disorder, urinary retention

Hepatic: Increased ALT/AST

Local: Injection site reaction

Neuromuscular & skeletal: Paresthesia, dystonic reactions

Respiratory: Hypoxia bronchospasm, laryngeal edema, laryngospasm, shortness of breath, stridor

Miscellaneous: Anaphylaxis, hypersensitivity reactions, hiccups

Signs and Symptoms of Overdose Sudden transient blindness, severe constipation, hypotension, flushing, and vasovagal episode with transient secondary heart block have been reported in some cases of overdose. I.V. doses of up to 252 mg/day have been inadvertently given without adverse effects.

Admission Criteria/Prognosis Admit any symptomatic patient or ingestion exceeding 1.5 mg/kg

Pharmacodynamics/Kinetics

Onset of action: ~30 minutes

Distribution: V_d: Children: 1.7-3.7 L/kg; Adults: 2.2-2.5 L/kg

Protein binding, plasma: 70% to 76%

Metabolism: Extensively hepatic via hydroxylation, followed by glucuronide or sulfate conjugation; CYP1A2, CYP2D6, and CYP3A4 substrate; some demethylation occurs

Bioavailability: Oral: 56% to 71%; Rectal: 58% to 74%

Half-life elimination: Children <15 years: 2-7 hours; Adults: 3-6 hours

Mild-to-moderate hepatic impairment: Adults: 12 hours

Severe hepatic impairment (Child-Pugh C): Adults: 20 hours

Time to peak: Oral: ~2 hours

Excretion: Urine (44% to 60% as metabolites, 5% to 10% as unchanged drug); feces (~25%)

Dosage Children:

I.V.:

Chemotherapy-induced emesis: 4-18 years: 0.15 mg/kg/dose administered 30 minutes prior to chemotherapy, 4 and 8 hours after the first dose **or** 0.45 mg/kg/day as a single dose

Postoperative nausea and vomiting: 2-12 years:

≤ 40 kg: 0.1 mg/kg

> 40 kg: 4 mg

Oral: Chemotherapy-induced emesis:

4-11 years: 4 mg 30 minutes before chemotherapy; repeat 4 and 8 hours after initial dose, then 4 mg every 8 hours for 1-2 days after chemotherapy completed

≥ 12 years: Refer to adult dosing.

Oral: Gastroenteritis - ODT prep:

Weight 8-15 kg: 2 mg; 16-30 kg: 4 mg; > 31 kg: 8 mg

Adults:

I.V.: Chemotherapy-induced emesis:

0.15 mg/kg 3 times/day beginning 30 minutes prior to chemotherapy

or

0.45 mg/kg once daily **or**

8-10 mg 1-2 times/day **or**

24 mg or 32 mg once daily

I.M., I.V.: Postoperative nausea and vomiting: 4 mg as a single dose approximately 30 minutes before the end of anesthesia, or as treatment if vomiting occurs after surgery

Oral: Chemotherapy-induced emesis:

Highly-emetogenic agents/single-day therapy: 24 mg given 30 minutes prior to the start of therapy

Moderately-emetogenic agents: 8 mg every 12 hours beginning 30 minutes before chemotherapy, continuously for 1-2 days after chemotherapy completed

Total body irradiation: 8 mg 1-2 hours before daily each fraction of radiotherapy

Single high-dose fraction radiotherapy to abdomen: 8 mg 1-2 hours before irradiation, then 8 mg every 8 hours after first dose for 1-2 days after completion of radiotherapy

Daily fractionated radiotherapy to abdomen: 8 mg 1-2 hours before irradiation, then 8 mg 8 hours after first dose for each day of radiotherapy

Postoperative nausea and vomiting: 16 mg given 1 hour prior to induction of anesthesia

Elderly: No dosing adjustment required

Dosage adjustment in renal impairment: No dosing adjustment required

Dosage adjustment in hepatic impairment: Maximum daily dose: 8 mg in patients with severe liver disease (Child-Pugh score ≥ 10)

Monitoring Parameters Frequency of emesis

Administration Oral: Oral dosage forms should be administered 30 minutes prior to chemotherapy; 1-2 hours before radiotherapy; 1 hour prior to the induction of anesthesia

Orally-disintegrating tablets: Do not remove from blister until needed.

Peel backing off the blister, do not push tablet through. Using dry hands, place tablet on tongue and allow to dissolve. Swallow with saliva.

I.M.: Should be administered undiluted

I.V.: Give first dose 30 minutes prior to beginning chemotherapy; the I.V.

preparation has been successful when administered orally

IVPB: Infuse over 15-30 minutes; 24-hour continuous infusions have been reported, but are rarely used

OPIUM ALKALOIDS (HYDROCHLORIDES)

Contraindications Hypersensitivity to ondansetron, other selective 5-HT₃ antagonists, or any component of the formulation

Warnings For chemotherapy, ondansetron should be used on a scheduled basis, not on an "as needed" (PRN) basis, since data support the use of this drug only in the prevention of nausea and vomiting (due to antineoplastic therapy) and not in the rescue of nausea and vomiting. Ondansetron should only be used in the first 24-48 hours of chemotherapy. Data do not support any increased efficacy of ondansetron in delayed nausea and vomiting. Does not stimulate gastric or intestinal peristalsis; may mask progressive ileus and/or gastric distension. Orally-disintegrating tablets contain phenylalanine. Safety and efficacy for children <1 month of age have not been established.

Dosage Forms [DSC] = Discontinued product

Infusion [premixed in D₅W, preservative free]:

Zofran®: 32 mg (50 mL)

Injection, solution:

Zofran®: 2 mg/mL (2 mL, 20 mL)

Solution, oral:

Zofran®: 4 mg/5 mL (50 mL) [contains sodium benzoate; strawberry flavor]

Tablet:

Zofran®: 4 mg; 8 mg; 24 mg [DSC]

Tablet, orally disintegrating:

Zofran® ODT: 4 mg, 8 mg [each strength contains phenylalanine <0.03 mg/tablet; strawberry flavor]

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) oral ingestions >1.5 mg/kg; activated charcoal

Supportive therapy: Diphenhydramine can be used to manage pruritus, rashes, extrapyramidal signs (along with benztropine), and restlessness

Drug Interactions **Substrate** of CYP1A2 (minor), 2C9 (minor), 2D6 (minor), 2E1 (minor), 3A4 (major); **Inhibits** CYP1A2 (weak), 2C9 (weak), 2D6 (weak)

Apomorphine: Due to reports of profound hypotension during concomitant therapy, the manufacturer of apomorphine contraindicates its use with ondansetron.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of ondansetron. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins. The manufacturer does not recommend dosage adjustment in patients receiving CYP3A4 inducers.

Pregnancy Risk Factor B

Pregnancy Implications Clinical effects on the fetus: No data available on crossing the placenta; no effects on the fetus from two case reports.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications First dose should be given 30 minutes prior to beginning chemotherapy

Additional Information I.V. product has been successful when used orally; elderly have a slightly decreased hepatic clearance rate; this does not, however, require a dose adjustment. Not effective in preventing motion sickness; more effective than metoclopramide in preventing emesis in cisplatin treatment; may be useful in treating acetaminophen-induced or theophylline-induced vomiting.

Opium Alkaloids (Hydrochlorides)

Synonyms Opium Alkaloids

Impairment Potential Yes

Use Relief of severe pain

Adverse Reactions

Cardiovascular: **Hypotension**, bradycardia, peripheral vasodilation, sinus bradycardia, palpitations

Central nervous system: **Fatigue, drowsiness, dizziness**, CNS depression, agitation, increased intracranial pressure, cognitive dysfunction, paranoia

Dermatologic: Pruritus

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone

Gastrointestinal: **Nausea, vomiting**, constipation (more constipating than morphine), biliary tract spasm

Genitourinary: Urinary tract spasm

Neuromuscular & skeletal: **Weakness**

Ocular: Miosis

Respiratory: Apnea, respiratory depression

Miscellaneous: Physical and psychological dependence, histamine release

Signs and Symptoms of Overdose Apnea, coma, delirium, dysphoria, hypotension, miosis, myoglobinuria, ptosis, pulmonary edema, respiratory depression, rhabdomyolysis, seizures (in neonates)

Pharmacodynamics/Kinetics

Absorption: Oral: Variable, more slowly absorbed than morphine

Distribution: V_d: 3-4 L/kg

Protein binding: 35%

Metabolism: In the liver via glucuronide conjugation

Half-life:

Neonates: Prolonged 6% to 10%

Adults: 2-4 hours

Elimination: Unchanged in urine

Dosage Adults: I.M., SubQ: 5-20 mg every 4-5 hours

Monitoring Parameters Pain relief, respiratory and mental status, blood pressure

Contraindications Hypersensitivity to opium alkaloids

Dosage Forms Injection: 20 mg/mL (1 mL)

Overdosage/Treatment Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at 2/3 the response dose/hour) may be required

Antidote(s)

● Nalmefene [ANTIDOTE]

● Naloxone [ANTIDOTE]

Drug Interactions CNS depressants, MAO inhibitors may potentiate adverse effects

Pregnancy Risk Factor B/D (prolonged periods or high doses at term)

Nursing Implications Observe patient for excessive sedation, respiratory depression, implement safety measures, assist with ambulation

Specific References

Day J, Charles B, Slawson M, et al, "Determination of Five Opium-Related Compounds in Human Hair by LC-MS," *J Anal Toxicol*, 2004, 28:291.

Opium Tincture

Synonyms DTO (error-prone abbreviation); Opium Tincture, Deodorized

Impairment Potential Yes

Use Treatment of diarrhea or relief of pain

Mechanism of Action Contains many narcotic alkaloids including morphine; its mechanism for gastric motility inhibition is primarily due to this morphine content; it results in a decrease in digestive secretions, an increase in gastrointestinal muscle tone, and therefore a reduction in gastrointestinal propulsion

Adverse Reactions

Cardiovascular: **Palpitations, hypotension, bradycardia**, peripheral vasodilation

Central nervous system: CNS depression, agitation, increased intracranial pressure, dysphoria, paranoia, **drowsiness, dizziness**

Dermatologic: Pruritus

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone

Gastrointestinal: Nausea, vomiting, constipation, biliary tract spasm

Genitourinary: Urinary tract spasm

Neuromuscular & skeletal: **Weakness**

Ocular: Miosis

Respiratory: Apnea, respiratory depression

Miscellaneous: Physical and psychological dependence, histamine release

Signs and Symptoms of Overdose Apnea, coma, hypotension, miosis, myasthenia gravis (exacerbation or precipitation), myoglobinuria, ptosis, pulmonary edema, respiratory depression, rhabdomyolysis, seizures (in neonates)

Pharmacodynamics/Kinetics

Duration: 4-5 hours

Absorption: Variable

Metabolism: Hepatic

Excretion: Urine

Dosage

Oral:

Children:

Diarrhea: 0.005-0.01 mL/kg/dose every 3-4 hours for a maximum of 6 doses/24 hours

Analgesia: 0.01-0.02 mL/kg/dose every 3-4 hours

Adults:

Diarrhea: 0.3-1 mL/dose every 2-6 hours to maximum of 6 mL/24 hours

Analgesia: 0.6-1.5 mL/dose every 3-4 hours

Monitoring Parameters Observe patient for excessive sedation, respiratory depression, implement safety measures, assist with ambulation

Contraindications Hypersensitivity to morphine sulfate or any component of the formulation; increased intracranial pressure; severe respiratory depression; severe hepatic or renal insufficiency; pregnancy (prolonged use or high dosages near term)

Warnings Opium shares the toxic potential of opiate agonists, and usual precautions of opiate agonist therapy should be observed; some preparations contain sulfites which may cause allergic reactions; infants <3 months of age are more susceptible to respiratory depression, use with caution and generally in reduced doses in this age group; this is **not** paregoric, dose accordingly

Dosage Forms Liquid: 10% (120 mL, 480 mL) [0.6 mL equivalent to morphine 6 mg; contains alcohol 19%]

Overdosage/Treatment Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at $\frac{2}{3}$ the response dose/hour) may be required

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Diagnostic Procedures

- Morphine, Urine
- Opiates, Qualitative, Urine

Test Interactions ↑ aminotransferases (ALT, AST) (S)

Drug Interactions Increased toxicity: CNS depressants, MAO inhibitors, tricyclic antidepressants may potentiate the effects of opiate agonists; dextroamphetamine may enhance the analgesic effect of opiate agonists

Pregnancy Risk Factor B/D (prolonged use or high doses at term)

Lactation Enters breast milk/use caution

Nursing Implications Observe patient for excessive sedation, respiratory depression, implement safety measures, assist with ambulation

Orlistat

U.S. Brand Names Xenical®

Use Management of obesity, including weight loss and weight management when used in conjunction with a reduced-calorie diet; reduce the risk of weight regain after prior weight loss; indicated for obese patients with an initial body mass index (BMI) ≥ 30 kg/m² or ≥ 27 kg/m² in the presence of other risk factors.

Mechanism of Action A reversible inhibitor of gastric and pancreatic lipases, thus inhibiting absorption of dietary fats by 30% (at doses of 120 mg 3 times/day).

Adverse Reactions

Central nervous system: **Headache (31%)**, fatigue, anxiety, sleep disorders

Dermatologic: Dry skin, angioedema, pruritus, rash, urticaria

Endocrine & metabolic: Menstrual irregularities

Gastrointestinal: **Oily spotting (27%)**, **abdominal pain/discomfort (26%)**, **flatus with discharge (24%)**, **fatty/oily stool (20%)**, **fecal urgency (22%)**, **oily evacuation**, **increased defecation**, fecal incontinence, nausea, infectious diarrhea, rectal pain/discomfort, vomiting

Neuromuscular & skeletal: **Back pain**, arthritis, myalgia

Otic: Otitis

Respiratory: **Upper respiratory infection (38%)**

Miscellaneous: Allergic reactions, anaphylaxis

Pharmacodynamics/Kinetics

Absorption: Minimal

Metabolism: Metabolized within the gastrointestinal wall; forms inactive metabolites

Excretion: Feces (83% as unchanged drug)

Dosage Oral: Children ≥ 12 years and Adults: 120 mg 3 times/day with each main meal containing fat (during or up to 1 hour after the meal); omit dose if meal is occasionally missed or contains no fat.

Contraindications Hypersensitivity to orlistat or any component of the formulation; chronic malabsorption syndrome or cholestasis

Warnings Patients should be advised to adhere to dietary guidelines; gastrointestinal adverse events may increase if taken with a diet high in fat (>30% total daily calories from fat). The daily intake of fat should be distributed over three main meals. If taken with any one meal very high in fat, the possibility of gastrointestinal effects increases. Patients should be counseled to take a multivitamin supplement that contains fat-soluble vitamins to ensure adequate nutrition because orlistat has been shown to reduce the absorption of some fat-soluble vitamins and beta-carotene. Some patients may develop increased levels of urinary oxalate following treatment; caution should be exercised when prescribing it to patients with a history of hyperoxaluria or calcium oxalate nephrolithiasis. As with any weight-loss agent, the potential exists for misuse in appropriate patient populations (eg, patients with anorexia nervosa or bulimia). Safety and efficacy have not been established in children <12 years of age. Write/fill prescription carefully. Dispensing errors have been made between Xenical® (orlistat) and Xeloda® (capecitabine).

Dosage Forms Capsule: 120 mg

Overdosage/Treatment Essentially entirely supportive therapy, with most symptoms resolving spontaneously. For the patient who ingests >1 g, suggest observing for 24 hours or until GI symptoms abate.

Drug Interactions Amiodarone: Orlistat may decrease amiodarone absorption; monitor.

Cyclosporine: Cyclosporine serum levels may be decreased; administer cyclosporine 2 hours before or after orlistat; monitor.

Warfarin: Orlistat does not alter the pharmacokinetics of warfarin, however, vitamin K absorption may be decreased during orlistat therapy. Therefore, patients stabilized on warfarin should be monitored for changes in warfarin effects.

Pregnancy Risk Factor B

Pregnancy Implications There are no adequate and well-controlled studies of orlistat in pregnant women. Because animal reproductive studies are not always predictive of human response, orlistat is not recommended for use during pregnancy. Teratogenicity studies were conducted in rats and rabbits at doses up to 800 mg/kg/day. Neither study showed embryotoxicity or teratogenicity. This dose is 23 and 47 times the daily human dose calculated on a body surface area basis for rats and rabbits, respectively.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Single doses of 800 mg and multiple doses of up to 400 mg 3 times/day for 15 days have been studied in normal weight and obese patients, without significant adverse findings; in case of significant overdose, it is recommended that the patient be observed for 24 hours.

Orphenadrine

CAS Number 4682-36-4

U.S. Brand Names Norflex™

Synonyms Orphenadrine Citrate

Impairment Potential Yes

Use Treatment of muscle spasm associated with acute painful musculoskeletal conditions; supportive therapy in tetanus

Mechanism of Action Indirect skeletal muscle relaxant thought to work by central atropine-like effects; has some euphoric and analgesic properties

Adverse Reactions

Cardiovascular: Tachycardia, palpitations, sinus tachycardia

Central nervous system: **Dizziness**, fatigue, **drowsiness**

Gastrointestinal: Xerostomia, nausea, constipation

Neuromuscular & skeletal: Weakness

Ocular: **Blurred vision**

Signs and Symptoms of Overdose Anticholinergic symptoms, arrhythmias, blurred vision, confusion, dystonic reactions, hypertension, myoglobinuria, paralysis, psychosis, respiratory arrest, rhabdomyolysis, seizures, tachycardia, vasodilation

Pharmacodynamics/Kinetics

Onset of effect: Peak effect: Oral: 2-4 hours

Duration: 4-6 hours

Protein binding: 20%

Metabolism: Extensively hepatic

Half-life elimination: 14-16 hours

Excretion: Primarily urine (8% as unchanged drug)

Dosage

Adults:

Oral: 100 mg twice daily

I.M., I.V.: 60 mg every 12 hours

Administration

Do not crush sustained release drug product.

Contraindications Hypersensitivity to orphenadrine or any component of the formulation; glaucoma; GI obstruction; cardiospasm; myasthenia gravis

Warnings Use with caution in patients with CHF or cardiac arrhythmias; some products contain sulfites

Dosage Forms

Injection, solution, as citrate: 30 mg/mL (2 mL)

Norflex™: 30 mg/mL (2 mL) [contains sodium bisulfite]

Tablet, extended release, as citrate: 100 mg

Norflex™: 100 mg

Reference Range

Toxic: 2-3 mg/mL

Fatal: 4-8 mg/L

Overdosage/Treatment

Decontamination: Emesis not recommended due to potential for seizures; lavage (within 1 hour) in early ingestions after control of seizures; activated charcoal of benefit

Supportive therapy: Treatment is predominantly symptomatic and supportive; physostigmine has been used for life-threatening anticholinergic symptoms; bethanechol has been used to control peripheral symptoms; alkaline diuresis/mannitol has been used in rhabdomyolysis

Enhancement of elimination: Hemodialysis and peritoneal dialysis is ineffective; multiple-dose activated charcoal of unknown value, may be of benefit in ingestions of long-acting product

OSELTAMIVIR

Drug Interactions

Substrate (minor) of CYP1A2, 2B6, 2D6, 3A4; **Inhibits** CYP1A2 (weak), 2A6 (weak), 2B6 (weak), 2C9 (weak), 2C19 (weak), 2D6 (weak), 2E1 (weak), 3A4 (weak)

Anticholinergic agents: May increase potential for anticholinergic adverse effects; includes drugs with high anticholinergic activity (diphenhydramine, TCAs, phenothiazines)

CNS depressants: Sedative effects may be additive. Monitor.

Levodopa: Effects may be decreased by orphenadrine. Monitor.

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Nursing Implications Do not crush sustained release drug product; raise bed rails, institute safety measures, assist with ambulation

Additional Information Aplastic anemia has occurred, rarely.

Osetamivir

Pronunciation (oh sel TAM i vir)

U.S. Brand Names Tamiflu®

Use Treatment of uncomplicated acute illness due to influenza (A or B) infection in adults and children >1 year of age who have been symptomatic for no more than 2 days; prophylaxis against influenza (A or B) infection in adults and adolescents ≥13 years of age

Mechanism of Action Osetamivir, a prodrug, is hydrolyzed to the active form, osetamivir carboxylate. It is thought to inhibit influenza virus neuraminidase, with the possibility of alteration of virus particle aggregation and release. In clinical studies of the influenza virus, 1.3% of post-treatment isolates had decreased neuraminidase susceptibility to osetamivir carboxylate.

Adverse Reactions

As seen with **treatment** doses: 1% to 10%:

- Central nervous system: Insomnia (adults 1%), vertigo (adults 1%)
- Gastrointestinal: Nausea (adults 10%), vomiting (adults 9%, children 15%), abdominal pain (children 5%)
- Ocular: Conjunctivitis (children 1%)
- Otic: Ear disorder (children 2%)
- Respiratory: Epistaxis (children 3%)

Similar adverse effects were seen in **prophylactic** use, however, the incidence was generally less. The following reactions were seen more commonly with prophylactic use: Headache (20%), fatigue (8%), diarrhea (3%)

<1% and case reports (any indication): Aggravation of diabetes, anemia, arrhythmia, confusion, hepatitis, humerus fracture, peritonsillar abscess, pneumonia, pseudomembranous colitis, pyrexia, rash, seizure, transaminases increased, toxic epidermal necrolysis, unstable angina, swelling of face or tongue

Pharmacodynamics/Kinetics

Absorption: Well absorbed

Distribution: V_d : 23-26 L (oseltamivir carboxylate)

Protein binding, plasma: Osetamivir carboxylate: 3%; Osetamivir: 42%
Metabolism: Hepatic (90%) to osetamivir carboxylate; neither the parent drug nor active metabolite has any effect on CYP

Bioavailability: 75% reaches systemic circulation in active form

Half-life elimination: Osetamivir carboxylate: 6-10 hours; similar in geriatrics (68-78 years)

Time to peak: C_{max} : Osetamivir: 65 ng/mL; Osetamivir carboxylate: 348 ng/mL

Excretion: Urine (as carboxylate metabolite)

Dosage

Oral:

Treatment: Initiate treatment within 2 days of onset of symptoms; duration of treatment: 5 days:

Children: 1-12 years:

- ≤15 kg: 30 mg twice daily
- >15 kg - ≤23 kg: 45 mg twice daily
- >23 kg - ≤40 kg: 60 mg twice daily
- >40 kg: 75 mg twice daily

Adolescents ≥13 years and Adults: 75 mg twice daily

Prophylaxis: Adolescents ≥13 years and Adults: 75 mg once daily for at least 7 days; treatment should begin within 2 days of contact with an infected individual. During community outbreaks, dosing is 75 mg once daily. May be used for up to 6 weeks; duration of protection lasts for length of dosing period

Dosage adjustment in renal impairment:

Cl_{cr} 10-30 mL/minute:

Treatment: Reduce dose to 75 mg once daily for 5 days

Prophylaxis: 75 mg every other day

Cl_{cr} <10 mL/minute: Has not been studied

Dosage adjustment in hepatic impairment: Has not been evaluated

Elderly: No adjustments required

Stability Capsules: Store at 25°C (77°F).

Oral suspension: Store powder for suspension at 25°C (77°F). Reconstitute with 23 mL of water (to make 25 mL total suspension). Once

reconstituted, store suspension under refrigeration at 2°C to 8°C (36°F to 46°F); do not freeze. Use within 10 days of preparation.

Contraindications Hypersensitivity to osetamivir or any component of the formulation

Warnings Osetamivir is not a substitute for the influenza virus vaccine. Use caution with renal impairment; dosage adjustment is required for creatinine clearance between 10-30 mL/minute. Also consider primary or concomitant bacterial infections. Safety and efficacy for use in hepatic impairment or for treatment or prophylaxis in immunocompromised patients have not been established. Efficacy has not been established if treatment begins >40 hours after the onset of symptoms or in the treatment of patients with chronic cardiac and/or respiratory disease. Rare but severe hypersensitivity reactions (anaphylaxis, severe dermatologic reactions) have been associated with use. Safety and efficacy in children (<1 year of age) have not been established.

Dosage Forms Capsule, as phosphate:

Tamiflu®: 75 mg

Powder for oral suspension:

Tamiflu®: 12 mg/mL (25 mL) [contains sodium benzoate; tutti-frutti flavor]

Drug Interactions Influenza virus vaccine nasal spray (fluMist™): Safety and efficacy for use with influenza virus vaccine nasal spray have not been established. Do not administer nasal spray until 48 hours after stopping antiviral; do not administer antiviral for 2 weeks after receiving influenza virus vaccine nasal spray.

Pregnancy Risk Factor C

Pregnancy Implications There are insufficient human data to determine the risk to a pregnant woman or developing fetus. Studies evaluating the effects on embryo-fetal development in rats and rabbits showed a dose-dependent increase in the rates of minor skeleton abnormalities in exposed offspring. The rate of each abnormality remained within the background rate of occurrence in the species studied.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Have patient take with food to decrease the nausea associated with this medicine; administer at breakfast and dinner when used for treatment (dosing is once daily when used for prophylaxis). Shake suspension well before using; may be stored under refrigeration or at room temperature.

Oubain

CAS Number 11018-89-6; 630-60-4

Use Treatment of congestive heart failure; slows the ventricular rate in tachyarrhythmias such as fibrillation (atrial), flutter (atrial), tachycardia (ventricular), paroxysmal atrial tachycardia, cardiogenic shock; may not be as useful for tachyarrhythmias due to antegrade conduction

Mechanism of Action Derived from *Strophanthus gratus*; oubain is a cardiac glycoside with actions similar to digitalis

Adverse Reactions

Cardiovascular: Sinus bradycardia, AV block, SA block, ectopic beats (atrial or nodal), tachycardia (ventricular), arrhythmias (ventricular), bigeminy, trigeminy, tachycardia (atrial) with AV block; congestive heart failure

Central nervous system: Drowsiness, fatigue, disorientation, dizziness, auditory and visual hallucinations, paranoia, headache

Neuromuscular & skeletal: Neuralgia, chorea (extrapyramidal)

Ocular: Vision color changes (blue tinge)

Toxicodynamics/Kinetics

Onset of action: 3-10 minutes

Peak effect: 0.5-2 hours

Half-life: 21 hours

Elimination: Renal (47%)

Dosage Average digitalizing dose: I.V.: 0.03-0.5 g

Stability Protect from light; not compatible with procaine

Overdosage/Treatment

Supportive therapy: Antidote: Life-threatening digoxin toxicity is treated with Digibind®; phenytoin, magnesium, and lidocaine are useful for cardiac arrhythmias; atropine is useful for bradycardia; avoid quinidine, bretylium, or cardioversion; ventricular pacing should be reserved for patients not responding to Digibind®; delirium can respond to Digibind®; torsade de pointes can be treated with magnesium sulfate and overdrive pacing (try to avoid isoproterenol)

Antidote(s)

- Atropine [ANTIDOTE]
- Digoxin Immune Fab [ANTIDOTE]

Oxazepam

CAS Number 604-75-1

U.S. Brand Names Serax®

Impairment Potential Yes. Serum oxazepam levels >0.2 mg/L are consistent with driving impairment. Brief or extended periods of exposure are less likely to cause driving impairment in the elderly compared with the longer half-life benzodiazepines. (Baselt RC and Cravey RH,

Disposition of Toxic Drugs and Chemicals in Man, 4th ed, Foster City, CA: Chemical Toxicology Institute, 1995, 569.)

Use Treatment of anxiety and management of alcohol withdrawal

Unlabeled/Investigational Use Anticonvulsant in management of simple partial seizures; hypnotic

Mechanism of Action Benzodiazepine anxiolytic sedative that produces CNS depression at the subcortical level, except at high doses, whereby it works at the cortical level

Adverse Reactions

Cardiovascular: Syncope

Central nervous system: **Drowsiness**, headache, dizziness, lethargy, slurred speech, ataxia

Dermatologic: Rash, erythema multiforme, urticaria, purpura, pruritus; bullous eruptions, exanthem

Endocrine & metabolic: Decreased libido

Gastrointestinal: Nausea, xerostomia

Hematologic: Leukopenia

Hepatic: Jaundice, hepatic dysfunction

Neuromuscular & skeletal: Tremor, paresthesia

Signs and Symptoms of Overdose Coma, confusion, dyspnea, hyperglycemia (spurious), hypoactive reflexes, hypochloremia, hyponatremia, hyporeflexia, nystagmus, slurred speech, unsteady gait

Pharmacodynamics/Kinetics

Absorption: Almost complete

Protein binding: 86% to 99%

Metabolism: Hepatic to inactive compounds (primarily as glucuronides)

Half-life elimination: 2.8-5.7 hours

Time to peak, serum: 2-4 hours

Excretion: Urine (as unchanged drug (50%) and metabolites)

Dosage Oral:

Children: 1 mg/kg/day has been administered

Adults:

Anxiety: 10-30 mg 3-4 times/day

Alcohol withdrawal: 15-30 mg 3-4 times/day

Hypnotic: 15-30 mg

Monitoring Parameters Respiratory and cardiovascular status

Administration Administer orally in divided doses

Contraindications Hypersensitivity to oxazepam or any component of the formulation (cross-sensitivity with other benzodiazepines may exist); narrow-angle glaucoma (not in product labeling, however, benzodiazepines are contraindicated); not indicated for use in the treatment of psychosis; pregnancy

Warnings

May cause hypotension (rare) - use with caution in patients with cardiovascular or cerebrovascular disease, or in patients who would not tolerate transient decreases in blood pressure. Serax® 15 mg tablet contains tartrazine; use is not recommended in pediatric patients <6 years of age; dose has not been established between 6-12 years of age. Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics), or renal impairment. Use with caution in patients with respiratory disease or impaired gag reflex. Avoid use in patients with sleep apnea.

Causes CNS depression (dose-related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury and should be used with extreme caution in patients who are at risk of these events (especially the elderly).

Use caution in patients with depression, particularly if suicidal risk may be present. Use with caution in patients with a history of drug dependence. Benzodiazepines have been associated with dependence and acute withdrawal symptoms on discontinuation or reduction in dose. Acute withdrawal, including seizures, may be precipitated after administration of flumazenil to patients receiving long-term benzodiazepine therapy.

Benzodiazepines have been associated with anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Dosage Forms Capsule: 10 mg, 15 mg, 30 mg

Tablet: 15 mg [contains tartrazine]

Reference Range Therapeutic: 0.2-1.4 mcg/mL (SI: 0.7-4.9 µmol/L)

Overdosage/Treatment

Decontamination: Lavage pediatric ingestions >90 mg (within 1 hour)/activated charcoal

Supportive therapy: Treatment for benzodiazepine overdose is supportive. Rarely is mechanical ventilation required. Flumazenil has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression.

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; not dialyzable (0% to 5%)

Antidote(s)

● Flumazenil [ANTIDOTE]

Diagnostic Procedures

● Oxazepam, Serum

Test Interactions Visine®, Drano®, bleach may cause false-negative urine tests; oxazepam may interfere resulting in falsely elevated glucose

Drug Interactions Ethanol and other CNS depressants may increase the CNS effects of oxazepam
Levodopa: Therapeutic effects may be diminished in some patients following the addition of a benzodiazepine; limited/inconsistent data
Theophylline and other CNS stimulants may antagonize the sedative effects of oxazepam

Zidovudine: Increased incidence of headache with concurrent use.

Pregnancy Risk Factor D

Lactation Enters breast milk/not recommended

Nursing Implications Provide safety measures (ie, side rails, night light, and call button); remove smoking materials from area; supervise ambulation

Additional Information Excreted without need for liver metabolism

Oxcarbazepine

CAS Number 28721-07-5

U.S. Brand Names Trileptal®

Synonyms GP 47680; OCBZ

Use Monotherapy or adjunctive therapy in the treatment of partial seizures in adults and children (4-16 years of age) with epilepsy

Unlabeled/Investigational Use Bipolar disorder; treatment of neuropathic pain

Mechanism of Action Pharmacological activity results from both oxcarbazepine and its monohydroxy metabolite (MHD). Precise mechanism of anticonvulsant effect has not been defined. Oxcarbazepine and MHD block voltage sensitive sodium channels, stabilizing hyperexcited neuronal membranes, inhibiting repetitive firing, and decreasing the propagation of synaptic impulses. These actions are believed to prevent the spread of seizures. Oxcarbazepine and MHD also increase potassium conductance and modulate the activity of high-voltage activated calcium channels.

Adverse Reactions

As reported in adults with doses of up to 2400 mg/day (includes patients on monotherapy, adjunctive therapy, and those not previously on AEDs); incidence in children was similar.

Cardiovascular: Angioedema, bradycardia, cardiac failure, cerebral hemorrhage, chest pain, flushing, hypotension, hypertension, leg edema, palpitations, postural tachycardia

Central nervous system: Abnormal coordination, **abnormal gait**, abnormal thinking, abnormal feelings, agitation, aggressive reaction, amnesia, anguish, anxiety, apathy, aphasia, **ataxia**, aura, confusion, consciousness decreased, convulsions aggravated, delusion, delirium, **dizziness**, drunk feeling, dysmetria, dysphonia, dystonia, EEG abnormalities, emotional lability, euphoria, extrapyramidal disorder, **fatigue**, fever, **headache**, hypoesthesia, hysteria, insomnia, malaise, manic reaction, nervousness, oculogyric crisis, panic disorder, paralysis, paroniria, personality disorder, psychosis, **somnolence**, speech disorder, stupor, syncope, **vertigo**

Dermatologic: Acne, alopecia, bruising, contact dermatitis, eczema, erythema multiforme, erythematous rash, facial rash, folliculitis, heat rash, maculopapular rash, photosensitivity reaction, psoriasis, purpura, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, ulcerative stomatitis, urticaria, vitiligo

Endocrine & metabolic: Hyponatremia, hot flushes, hyperglycemia, hypocalcemia, hypoglycemia, hypokalemia, intermenstrual bleeding, libido decreased/increased, menorrhagia

Gastrointestinal: **Abdominal pain**, appetite increased, biliary pain, blood in stool, cholelithiasis, colitis, constipation, diarrhea, dry mouth, duodenal ulcer, dysphagia, dyspepsia, enteritis, eructation, esophagitis, flatulence, gastritis, gastric ulcer, gingival bleeding, gum hyperplasia, hemorrhoids, **nausea**, rectal hemorrhage, retching, sialoadenitis, taste perversion, **vomiting**, weight gain, weight loss

Genitourinary: Dysuria, genital pruritus, micturition frequency, priapism
Hematologic: Eosinophilia, hematuria, hematemesis, leukopenia, leukorrhea, thrombocytopenia

Hepatic: GGT increased, liver enzymes elevated, serum transaminases increased

Neuromuscular & skeletal: Arthralgia, back pain, falling down, hemiplegia, hyperkinesia, hyperreflexia, hypertonia, hypokinesia, hyporeflexia, muscle contractions (involuntary), **muscle tremor**, neuralgia, rigors, sprains/strains, tetany, **tremor**, weakness

Ocular: Abnormal accommodation, **abnormal vision**, cataract, conjunctival hemorrhage, **diplopia**, eye edema, hemianopia, mydriasis, **nystagmus**, photophobia, ptosis, scotoma, xerophthalmia

Otic: Otitis externa, tinnitus

OXCARBAZEPINE

Renal: Renal calculus, renal pain, urinary tract pain
Respiratory: Asthma, dyspnea, epistaxis, laryngismus, pleurisy, rhinitis, sinusitis, upper respiratory tract infection
Miscellaneous: Chest infection, hiccups, hypersensitivity reaction, hypochondrium pain, lymphadenopathy, systemic lupus erythematosus
Signs and Symptoms of Overdose May include: Bradycardia, CNS depression (somnia, ataxia), diplopia, hyponatremia, hypotension, nausea, tinnitus, vertigo, vomiting.

Pharmacodynamics/Kinetics

Absorption: Complete; food has no effect on rate or extent
Distribution: MHD: V_d : 49 L
Protein binding, serum: MHD: 40%
Metabolism: Hepatic to 10-monohydroxy metabolite (MHD; active); MHD is further conjugated to DHD (inactive)
Bioavailability: Decreased in children <8 years; increased in elderly >60 years
Half-life elimination: Parent drug: 2 hours; MHD: 9 hours; renal impairment (Cl_{cr} 30 mL/minute): MHD: 19 hours
Clearance of MHD is increased in younger children (~80% in children 2-4 years of age) and approaches that of adults by ~13 years of age
Time to peak, serum: 4.5 hours (3-13 hours)
Excretion: Urine (95%, <1% as unchanged oxcarbazepine, 27% as unchanged MHD, 49% as MHD glucuronides); feces (<4%)

Dosage Oral:

Children 4-16 years:

Adjunctive therapy: 8-10 mg/kg/day, not to exceed 600 mg/day, given in 2 divided daily doses. Maintenance dose should be achieved over 2 weeks, and is dependent upon patient weight, according to the following:

20-29 kg: 900 mg/day in 2 divided doses
29.1-39 kg: 1200 mg/day in 2 divided doses
>39 kg: 1800 mg/day in 2 divided doses

Conversion to monotherapy: Oxcarbazepine 8-10 mg/kg/day in twice daily divided doses, while simultaneously initiating the reduction of the dose of the concomitant antiepileptic drug; the concomitant drug should be withdrawn over 3-6 weeks. Oxcarbazepine dose may be increased by a maximum of 10 mg/kg/day at weekly intervals. See below for recommended total daily dose by weight.

Initiation of monotherapy: Oxcarbazepine should be initiated at 8-10 mg/kg/day in twice daily divided doses; doses may be titrated by 5 mg/kg/day every third day. See below for recommended total daily dose by weight.

Range of maintenance doses by weight during monotherapy:

20 kg: 600-900 mg/day
25-30 kg: 900-1200 mg/day
35-40 kg: 900-1500 mg/day
45 kg: 1200-1500 mg/day
50-55 kg: 1200-1800 mg/day
60-65 kg: 1200-2100 mg/day
70 kg: 1500-2100 mg/day

Adults:

Adjunctive therapy: Initial: 300 mg twice daily; dose may be increased by as much as 600 mg/day at weekly intervals; recommended daily dose: 1200 mg/day in 2 divided doses. Although daily doses >1200 mg/day demonstrated greater efficacy, most patients were unable to tolerate 2400 mg/day (due to CNS effects).

Conversion to monotherapy: Oxcarbazepine 600 mg/day in twice daily divided doses while simultaneously initiating the reduction of the dose of the concomitant antiepileptic drug. The concomitant dosage should be withdrawn over 3-6 weeks, while the maximum dose of oxcarbazepine should be reached in about 2-4 weeks. Recommended daily dose: 2400 mg/day.

Initiation of monotherapy: Oxcarbazepine should be initiated at a dose of 600 mg/day in twice daily divided doses; doses may be titrated upward by 300 mg/day every third day to a final dose of 1200 mg/day given in 2 daily divided doses

Dosing adjustment in renal impairment: Therapy should be initiated at one-half the usual starting dose (300 mg/day) and increased slowly to achieve the desired clinical response

Dosing adjustment in hepatic impairment: Adjustment not needed for mild-to-moderate impairment

Monitoring Parameters Seizure frequency, serum sodium (particularly during first 3 months of therapy), symptoms of CNS depression (dizziness, headache, somnolence). Additional serum sodium monitoring recommended during maintenance treatment in patients receiving other medications known to decrease sodium levels, in patients with signs/symptoms of hyponatremia, and in patients with an increase in seizure frequency or severity.

Administration Suspension: Prior to using for the first time, firmly insert the plastic adapter provided with the bottle. Cover adapter with child-resistant cap when not in use. Shake bottle for at least 10 seconds,

remove child-resistant cap and insert the oral dosing syringe provided to withdraw appropriate dose. Dose may be taken directly from oral syringe or may be mixed in a small glass of water immediately prior to swallowing. Rinse syringe with warm water after use and allow to dry thoroughly. Discard any unused portion after 7 weeks of first opening bottle.

Contraindications Hypersensitivity to oxcarbazepine or any component of the formulation

Warnings Clinically significant hyponatremia (sodium <125 mmol/L) can develop during oxcarbazepine use; monitor serum sodium, particularly during the first 3 months of therapy or in patients at risk for hyponatremia. Potentially serious, sometimes fatal, dermatologic reactions (eg, Stevens-Johnson, toxic epidermal necrolysis) and multiorgan hypersensitivity reactions have been reported in adults and children; monitor for signs and symptoms of skin reactions and possible disparate manifestations associated with lymphatic, hepatic, renal and/or hematologic organ systems; gradual discontinuation and conversion to alternate therapy may be required. As with all antiepileptic drugs, oxcarbazepine should be withdrawn gradually to minimize the potential of increased seizure frequency. Use of oxcarbazepine has been associated with CNS related adverse events, most significant of these were cognitive symptoms including psychomotor slowing, difficulty with concentration, and speech or language problems, somnolence or fatigue, and coordination abnormalities, including ataxia and gait disturbances. Use caution in patients with previous hypersensitivity to carbamazepine (cross-sensitivity occurs in 25% to 30%). May reduce the efficacy of oral contraceptives (nonhormonal contraceptive measures are recommended).

Dosage Forms Suspension, oral: 300 mg/5 mL (250 mL) [contains ethanol; packaged with oral syringe]

Tablet: 150 mg, 300 mg, 600 mg

Reference Range Blood therapeutic range: 8-20 mg/L (20-200 μ mol/L). Adverse effects occur with serum levels >35 mg/L. Serum oxcarbazepine (10-hydroxymetabolite) level of 45.6 mg/L is associated with bradycardia and hypotension.

Overdosage/Treatment

Treatment is symptomatic and supportive. Experience is limited; the largest reported overdose has been 24,000 mg.

Decontamination: Oral: Gastric lavage and/or activated charcoal for adult ingestions >2.5 g.

Supportive therapy: I.V. crystalloid infusion to treat hypotension; bradycardia responds to atropine

Enhanced elimination: Multiple dosing of activated charcoal is of uncertain benefit.

Drug Interactions **Inhibits** CYP2C19 (weak); **Induces** CYP3A4 (strong)

Carbamazepine: Oxcarbazepine serum concentrations may be reduced by a mean 40%

CYP3A4 substrates: Oxcarbazepine may decrease the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, clarithromycin, cyclosporine, erythromycin, estrogens, mirtazapine, nateglinide, nefazodone, nevirapine, protease inhibitors, tacrolimus, and venlafaxine.

Felodipine: Metabolism is increased due to enzyme induction; similar effects may be anticipated with other dihydropyridine calcium channel blockers

Hormonal contraceptives: Metabolism may be increased due to enzyme induction; use alternative contraceptive measures; oxcarbazepine with oral contraceptives has been shown to decrease plasma concentrations of the two hormonal components, ethinyl estradiol (48% and 52%) and levonorgestrel (32% and 52%).

Phenobarbital: Phenobarbital levels are increased (average of 14%); oxcarbazepine levels are decreased (average of 25%)

Phenytoin: Phenytoin levels may be increased (high dosages) by an average of 40%; oxcarbazepine levels may be decreased (by an average of 30%) during concurrent therapy; monitor phenytoin levels

Valproic acid decreases oxcarbazepine levels by an average of 18%

Verapamil's metabolism may be increased due to enzyme induction; verapamil may reduce blood levels of oxcarbazepine's active metabolite (MHD)

Pregnancy Risk Factor C

Pregnancy Implications Oxcarbazepine crosses the human placenta. Teratogenic effects have been observed in animal studies. Oxcarbazepine is structurally related to carbamazepine (teratogenic in humans), use during pregnancy only if the benefit to the mother outweighs the potential risk to the fetus. Nonhormonal forms of contraception should be used during therapy.

Lactation Enters breast milk/not recommended

Nursing Implications Inform those patients who have exhibited hypersensitivity reactions to carbamazepine that there is the possibility of cross-sensitivity reactions with oxcarbazepine. Inform patients of child-bearing age that hormonal contraceptives may be less effective when used with oxcarbazepine. Caution should be exercised if alcohol is taken with oxcarbazepine, due to the possible additive sedative effects. Advise patients that oxcarbazepine may cause dizziness and somnolence and that early in therapy they are advised not to drive or operate machinery.

Oxtripitan**Related Information**

- Tryptophan

CAS Number 4350-09-8; 56-69-9

Use Approved in U.S. as an orphan drug for use in postanoxic intention myoclonus

Unlabeled/Investigational Use Antidepressant, also used for sleep disorders, migraine headaches; epilepsy, Parkinsons, psychostimulant

Mechanism of Action A precursor of serotonin which is a neurotransmitter

Adverse Reactions

- Cardiovascular: Transient hypotension
 Central nervous system: Hypomania, agitation, anxiety, insomnia, akinesia
 Dermatologic: Scleroderma
 Gastrointestinal: Nausea, anorexia, diarrhea, vomiting
 Respiratory: Dyspnea

Toxicodynamics/Kinetics

- Absorption: 1-2 hours
 Protein binding: 19%
 Metabolism: Hepatic and peripheral decarboxylation to serotonin and 5-hydroxyindoleacetic acid
 Bioavailability: 47% to 84%
 Half-life: 4.3 hours
 Elimination: Renal

Dosage Postanoxic myoclonus: Initial: 25 mg 4 times/day; can increase dose by 100 mg every 3-5 days

Depression: Initial: 10 mg/day; maximum daily dose: 600 mg
 I.V.: 1-2 mg/kg

Monitoring Parameters CBC, ECG, electrolytes

Overdosage/Treatment

Decontamination: Lavage within 1 hour of ingestion (especially if coingestants involve drugs listed in "warning" section); activated charcoal

Supportive therapy: Nausea can be treated with prochlorperazine (5-10 mg); diarrhea can be treated with diphenoxylate

Additional Information An orphan drug for postanoxic intention myoclonus, available through Circa pharmaceuticals (516-842-8383), or in combination with carbidopa through Du Pont pharmaceuticals (1-800-474-2762). Has been used to treat LSD-induced psychosis

Oxycodone

CAS Number 124-90-3; 76-42-6

U.S. Brand Names OxyContin[®]; Oxydose[™]; OxyFast[®]; OxyIR[®]; Roxicodone[™] Intenso[™]; Roxicodone[™]

Synonyms Dihydrohydroxycodone; Oxycodone Hydrochloride

Impairment Potential Yes**Use**

Management of moderate to severe pain, normally used in combination with non-narcotic analgesics

OxyContin[®] is indicated for around-the-clock management of moderate to severe pain when an analgesic is needed for an extended period of time. **Note:** OxyContin[®] is not intended for use as an "as needed" analgesic or for immediately-postoperative pain management (should be used postoperatively only if the patient has received it prior to surgery or if severe, persistent pain is anticipated).

Mechanism of Action Binds to opiate receptors in the CNS, causing inhibition of ascending pain pathways, altering the perception of and response to pain; produces generalized CNS depression

Adverse Reactions

- Cardiovascular: Postural hypotension, syncope, vasodilation
 Central nervous system: **Fatigue, drowsiness, dizziness, somnolence,** nervousness, headache, restlessness, malaise, confusion, anxiety, abnormal dreams, euphoria, thought abnormalities, hallucinations,

intracranial pressure increased, mental depression, paradoxical CNS stimulation

Dermatologic: **Pruritus,** rash, exfoliative dermatitis, urticaria

Endocrine & metabolic: Hyponatremia, SIADH

Gastrointestinal: **Nausea, vomiting, constipation,** anorexia, stomach cramps, xerostomia, biliary spasm, abdominal pain, dyspepsia, gastritis, dysphagia, ileus, paralytic ileus

Genitourinary: Ureteral spasms, decreased urination, urinary retention

Local: Pain at injection site

Neuromuscular & skeletal: **Weakness**

Respiratory: Dyspnea, hiccoughs

Miscellaneous: Diaphoresis, anaphylaxis, anaphylactoid reactions, histamine release, physical and psychological dependence, withdrawal syndrome (may include seizures)

Note: Deaths due to overdose have been reported due to misuse/abuse after crushing the sustained release tablets.

Signs and Symptoms of Overdose CNS depression, coma, light-headedness, miosis, noncardiogenic pulmonary edema, respiratory depression

Pharmacodynamics/Kinetics

Onset of action: Pain relief: 10-15 minutes

Peak effect: 0.5-1 hour

Duration: 3-6 hours; Controlled release: ≤ 12 hours

Metabolism: Hepatic

Half-life elimination: 2-3 hours

Excretion: Urine

Dosage

Oral:

Immediate release:

Children:

6-12 years: 1.25 mg every 6 hours as needed

> 12 years: 2.5 mg every 6 hours as needed

Adults: 5 mg every 6 hours as needed

Controlled release: Adults:

Opioid naive (not currently on opioid): 10 mg every 12 hours

Currently on opioid/ASA or acetaminophen or NSAID combination:

1-5 tablets: 10-20 mg every 12 hours

6-9 tablets: 20-30 mg every 12 hours

10-12 tablets: 30-40 mg every 12 hours

May continue the nonopioid as a separate drug.

Currently on opioids: Use standard conversion chart to convert daily dose to oxycodone equivalent. Divide daily dose in 2 (for every 12-hour dosing) and round down to nearest dosage form.

Note: 80 mg or 160 mg tablets are for use **only** in opioid-tolerant patients. Special safety considerations must be addressed when converting to OxyContin[®] doses ≥ 160 mg every 12 hours. Dietary caution must be taken when patients are initially titrated to 160 mg tablets.

Dosing adjustment in hepatic impairment: Reduce dosage in patients with severe liver disease

Monitoring Parameters Pain relief, respiratory and mental status, blood pressure

Administration Do not crush controlled-release tablets; 80 mg and 160 mg tablets are for use **only** in opioid-tolerant patients. Do not administer OxyContin[®] 160 mg tablet with a high-fat meal.

Contraindications Hypersensitivity to oxycodone or any component of the formulation; significant respiratory depression; hypercarbia; acute or severe bronchial asthma; OxyContin[®] is also contraindicated in paralytic ileus (known or suspected); pregnancy (prolonged use or high doses at term)

Warnings

Use with caution in patients with hypersensitivity reactions to other phenanthrene derivative opioid agonists (morphine, hydrocodone, hydromorphone, levorphanol, oxycodone, oxymorphone), respiratory diseases including asthma, emphysema, or COPD. Use with caution in pancreatitis or biliary tract disease, acute alcoholism (including delirium tremens), adrenocortical insufficiency, CNS depression/coma, kyphosis (or other skeletal disorder which may alter respiratory function), hypothyroidism (including myxedema), prostatic hyperplasia, urethral stricture, and toxic psychosis.

Use with caution in the elderly, debilitated, severe hepatic or renal function. Hemodynamic effects (hypotension, orthostasis) may be exaggerated in patients with hypovolemia, concurrent vasodilating drugs, or in patients with head injury. Respiratory depressant effects and capacity to elevate CSF pressure may be exaggerated in presence of head injury, other intracranial lesion, or pre-existing intracranial pressure. Some preparations contain sulfites which may cause allergic reactions.

[U.S. Boxed Warning]: Healthcare provider should be alert to problems of abuse, misuse, and diversion. Tolerance or drug dependence may result from extended use.

Controlled-release formulations:

[U.S. Boxed Warnings]: Do NOT crush controlled-release tablets; 80 mg and 160 mg strengths are for use **only** in opioid-tolerant patients

requiring high daily dosages > 160 mg (80 mg formulation) or > 320 mg (160 mg formulation). OxyContin® is not for use as an "as-needed" analgesic and is suitable only of continuous, around-the-clock management of moderate to severe pain.

- Dosage Forms** Capsule, immediate release, as hydrochloride: 5 mg OxyIR®: 5 mg
 Solution, oral, as hydrochloride: 5 mg/5 mL (500 mL)
 Roxicodone®: 5 mg/5 mL (5 mL, 500 mL) [contains alcohol]
 Solution, oral concentrate, as hydrochloride: 20 mg/mL (30 mL)
 ETH-Oxydose™: 20 mg/mL (30 mL) [contains sodium benzoate; berry flavor]
 OxyFast®: 20 mg/mL (30 mL) [contains sodium benzoate and dry natural rubber]
 Roxicodone®: 20 mg/mL (30 mL) [contains sodium benzoate]
 Tablet, as hydrochloride: 5 mg, 15 mg, 30 mg
 Roxicodone®: 5 mg, 15 mg, 30 mg
 Tablet, controlled release, as hydrochloride:
 OxyContin®: 10 mg, 20 mg, 40 mg, 80 mg, 160 mg
 Tablet, extended release, as hydrochloride: 10 mg, 20 mg, 40 mg, 80 mg

Reference Range Blood level of 5 mg/L associated with fatality

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at 2/3 the response dose/hour) may be required

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Drug Interactions Substrate of CYP2D6 (major)

CNS depressants, MAO inhibitors, general anesthetics, and tricyclic antidepressants: May potentiate the effects of opiate agonists; dextroamphetamine may enhance the analgesic effect of opiate agonists
 CYP2D6 inhibitors: May decrease the effects of oxycodone. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Pregnancy Risk Factor B/D (prolonged use or high doses at term)

Pregnancy Implications Should be used in pregnancy only if clearly needed. Use of narcotics during pregnancy may produce physical dependence in the neonate; respiratory depression may occur in the newborn if narcotics are used prior to delivery (especially high doses).

Lactation Enters breast milk/use caution

Nursing Implications Observe patient for excessive sedation, respiratory depression, implement safety measures, assist with ambulation

Additional Information When taken with a high-fat meal, peak concentration is 25% greater following a single OxyContin® 160 mg tablet as compared to two 80 mg tablets. Prophylactic use of a laxative should be considered.

Oxymetazoline

CAS Number 1491-59-4;2315-02-8

U.S. Brand Names 4-Way® Long Acting [OTC]; Afrin® Extra Moisturizing [OTC]; Afrin® Original [OTC]; Afrin® Severe Congestion [OTC]; Afrin® Sinus [OTC]; Afrin® [OTC]; Duramist® Plus [OTC]; Duration® [OTC]; Genasal [OTC]; Neo-Synephrine® 12 Hour Extra Moisturizing [OTC]; Neo-Synephrine® 12 Hour [OTC]; Néstrilla® [OTC]; OcuClear® [OTC] [DSC]; Twice-A-Day® [OTC]; Vicks Sinex® 12 Hour Ultrafine Mist [OTC]; Visine® L.R. [OTC]

Synonyms Oxymetazoline Hydrochloride

Use Symptomatic relief of nasal mucosal congestion and adjunctive therapy of middle ear infections, associated with acute or chronic rhinitis, the common cold, sinusitis, hay fever, or other allergies
 Ophthalmic: Relief of redness of eye due to minor eye irritations, conjunctivitis

Mechanism of Action Sympathomimetic; stimulates alpha-adrenergic receptors in the arterioles of the nasal mucosa to produce vasoconstriction; imidazoline decongestant

Adverse Reactions

Primarily local **burning**, hypothermia, xerostomia; may be porphyrinogenic; intra-arterial injection can cause localized gangrene due to ischemia; peripheral vasoconstriction due to nasal application is very rare

Cardiovascular: Bradycardia, sinus bradycardia, sinus tachycardia
 Central nervous system: Headache, psychosis, mania, seizures (in children), insomnia

Respiratory: **Dryness of the nasal mucosa, sneezing**

Signs and Symptoms of Overdose Apnea, bradycardia, cardiovascular collapse, CNS depression, coma, hypothermia

Pharmacodynamics/Kinetics

Onset of action: Intranasal: 5-10 minutes
 Duration: 5-6 hours

Dosage Therapy should not exceed 3-5 days

Intranasal:
 Children 2-5 years: 0.025% solution: Instill 2-3 drops in each nostril twice daily

Children ≥6 years and Adults: 0.05% solution: Instill 2-3 drops or 2-3 sprays into each nostril twice daily up to 3 days

Ophthalmic: Adults: 0.025% solution: Instill 1-2 drops into affected eye(s) every 6 hours up to 4 days

Stability Do not use if solution changes colors or becomes cloudy

Contraindications Hypersensitivity to oxymetazoline or any component of the formulation

Warnings

Nasal: Rebound congestion may occur with extended use (>3 days). Prior to self-medication (OTC use), contact healthcare provider in the presence of hypertension, diabetes, hyperthyroidism, heart disease, coronary artery disease, cerebral arteriosclerosis, or long-standing bronchial asthma.

Ophthalmic: Prior to OTC use, contact healthcare provider in the presence of glaucoma or if needed for >72 hours.

Dosage Forms Solution, intranasal, as hydrochloride [spray]: 0.05% (15 mL, 30 mL)

Afrin® Extra Moisturizing: 0.05% (15 mL) [contains benzyl alcohol and glycerin; regular or no drip formula]

Afrin® Original: 0.05% (15 mL, 30 mL) [contains benzalkonium chloride]

Afrin® Original: 0.05% (15 mL) [contains benzyl alcohol and benzalkonium chloride; no drip formula]

Afrin® Severe Congestion: 0.05% (15 mL) [contains benzyl alcohol and menthol; regular or no drip formula]

Afrin® Sinus: 0.05% (15 mL) [contains benzyl alcohol, benzalkonium chloride, camphor, phenol; regular or no drip formula]

Duramist® Plus, Neo-Synephrine® 12 Hour, Néstrilla®, Vicks Sinex® 12 Hour Ultrafine Mist, Vicks Sinex® 12 Hour, 4-Way® 12 Hour: 0.05% (15 mL) [contains benzalkonium chloride]
 Duration®: 0.05% (30 mL) [contains benzalkonium chloride]
 Genasal, NRS®: 0.05% (15 mL, 30 mL) [contains benzalkonium chloride]
 Neo-Synephrine® 12 Hour Extra Moisturizing: 0.05% (15 mL) [contains glycerin]
 Solution, ophthalmic, as hydrochloride (Visine® L.R.): 0.025% (15 mL, 30 mL) [contains benzalkonium chloride]

Overdosage/Treatment

Decontamination: Oral: Activated charcoal

Supportive therapy: Seizures can be treated with benzodiazepines or phenytoin; nitroprusside can be used to treat hypertension

Drug Interactions Increased toxicity with MAO inhibitors

Pregnancy Risk Factor C

Nursing Implications Spray/drops should not be used for >3 days without direct physician supervision

Additional Information Often best when used short-term in conjunction with long-term nasal corticosteroid

Oxymetholone

Pronunciation (oks i METH oh lone)

CAS Number 434-07-1

U.S. Brand Names Anadrol®

Use Anemias caused by the administration of myelotoxic drugs

Mechanism of Action Stimulates receptors in organs and tissues to promote growth and development of male sex organs and maintains secondary sex characteristics in androgen-deficient males

Adverse Reactions

Male:

Postpubertal:

Central nervous system: Insomnia, chills

Dermatologic: **Acne**

Endocrine & metabolic: **Gynecomastia**, decreased libido

Gastrointestinal: Nausea, diarrhea

Genitourinary: **Bladder irritability, priapism**, prostatic hypertrophy (elderly)

Hematologic: Iron deficiency anemia, suppression of clotting factors

Hepatic: Hepatic dysfunction, hepatic necrosis, hepatocellular carcinoma

Prepubertal:

Central nervous system: Chills, insomnia

Dermatologic: **Acne**, hyperpigmentation

Endocrine & metabolic: **Virilism**

Gastrointestinal: Diarrhea, nausea

Hematologic: Iron deficiency anemia, suppression of clotting factors

Hepatic: Hepatic necrosis, hepatocellular carcinoma, peliosis hepatitis

Female:

Central nervous system: Chills, insomnia

Endocrine & metabolic: **Virilism**, hypercalcemia

Gastrointestinal: Nausea, diarrhea

Hematologic: Iron deficiency anemia, suppression of clotting factors

Hepatic: Hepatic dysfunction, hepatic necrosis, hepatocellular carcinoma

Signs and Symptoms of Overdose Abnormal liver function test, confusion

Toxicodynamics/Kinetics

Half-life: 9 hours

Elimination: Primarily in urine

Dosage Adults: Erythropoietic effects: Oral: 1-5 mg/kg/day in 1 daily dose; maximum: 100 mg/day; give for a minimum trial of 3-6 months because response may be delayed

Monitoring Parameters Liver function, blood sugars, lipid profile, iron studies, hemoglobin/hematocrit, x-ray of bones every 6 months (prepubertal patients); signs of virilization (females)

Contraindications Hypersensitivity to oxymetholone or any component of the formulation; breast cancer in men; breast cancer in women with hypercalcemia; prostate cancer; severe liver dysfunction; nephrosis; pregnancy

Warnings [U.S. Boxed Warning]: Anabolic steroids may cause peliosis hepatis, liver cell tumors, and blood lipid changes with increased risk of arteriosclerosis; monitor diabetic patients carefully. Use with caution in elderly men; they may be at greater risk for prostate hyperplasia and cancer. Use caution with cardiac, renal, or hepatic disease; may develop edema. In breast cancer, may cause hypercalcemia by stimulating osteolysis. Use caution in children; may accelerate epiphyseal maturation thereby compromising adult height.

Dosage Forms Tablet: 50 mg

Overdosage/Treatment Decontamination: Oral: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Test Interactions Altered glucose tolerance tests, thyroid function tests, and metyrapone tests

Drug Interactions Cyclosporine: Androgens may enhance the hepatotoxic effect of cyclosporine.

Warfarin: Androgens may enhance the anticoagulant effect of warfarin.

Pregnancy Risk Factor X

Pregnancy Implications Oligospermia or amenorrhea may occur resulting in an impairment of fertility

Lactation Excretion in breast milk unknown/not recommended

Additional Information May increase glucagon levels

Oxymorphone

CAS Number 357-07-3; 76-41-5

U.S. Brand Names Numorphan®

Synonyms Oxymorphone Hydrochloride

Impairment Potential Yes

Use Management of moderate to severe pain and preoperatively as a sedative and a supplement to anesthesia

Mechanism of Action Oxymorphone (Numorphan®) is a potent narcotic analgesic with uses similar to those of morphine. The drug is a semisynthetic derivative of morphine (phenanthrene derivative) and is closely related to hydromorphone chemically (Dilaudid®).

Adverse Reactions

Cardiovascular: **Hypotension**, palpitations, bradycardia, peripheral vasodilation, sinus bradycardia

Central nervous system: **Fatigue, drowsiness, dizziness**, CNS depression, agitation, increased intracranial pressure

Dermatologic: Pruritus

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone

Gastrointestinal: **Nausea, vomiting, constipation**, biliary tract spasm

Genitourinary: Urinary tract spasm

Neuromuscular & skeletal: **Weakness**

Ocular: Miosis

Respiratory: Apnea, respiratory depression

Miscellaneous: **Histamine release**, physical and psychological dependence,

Pharmacodynamics/Kinetics

Onset of action: Analgesic: I.V., I.M., SubQ: 5-10 minutes

Duration: Analgesic: Parenteral: 3-4 hours

Protein binding: 10% to 12%

Metabolism: Hepatic via glucuronidation to active and inactive metabolites

Bioavailability: Oral: 10%

Half-life elimination: Oral: Immediate release: 7-9 hours; Extended release: 9-11 hours

Excretion: Urine

Dosage Adults: **Note:** More frequent dosing may be required.

I.M., SubQ: 0.5 mg initially, 1-1.5 mg every 4-6 hours as needed

I.V.: 0.5 mg initially

Rectal: 5 mg every 4-6 hours

Stability Refrigerate suppository

Monitoring Parameters Respiratory rate, heart rate, blood pressure, CNS activity

Administration Administer immediate release and extended release tablets 1 hour before or 2 hours after eating. Opana® ER tablet should be swallowed; do not break, crush, or chew.

Contraindications

Hypersensitivity to oxymorphone, other morphine analogs (phenanthrene derivatives) or any component of the formulation; paralytic ileus (known or suspected); increased intracranial pressure; severe respiratory depression (unless in monitored setting with resuscitative equipment); acute/severe bronchial asthma; hypercarbia; pregnancy (prolonged use or high doses at term).

Note: Oral formulations are also contraindicated in moderate-to-severe hepatic impairment

Warnings

An opioid-containing analgesic regimen should be tailored to each patient's needs and based upon the type of pain being treated (acute versus chronic), the route of administration, degree of tolerance for opioids (naïve versus chronic user), age, weight, and medical condition. The optimal analgesic dose varies widely among patients. Doses should be titrated to pain relief/prevention.

May cause respiratory depression. Use extreme caution in patients with COPD or other chronic respiratory conditions characterized by hypoxia, hypercapnea, or diminished respiratory reserve (myxedema, cor pulmonale, kyphoscoliosis, obstructive sleep apnea, severe obesity). Use with caution in patients (particularly elderly or debilitated) with impaired respiratory function, adrenal disease, thyroid dysfunction, prostatic hypertrophy, renal impairment, or severe hepatic dysfunction. Use only with extreme caution (if at all) in patients with head injury or increased intracranial pressure (ICP); potential to elevate ICP and/or blunt papillary response may be greatly exaggerated in these patients. Use with caution in biliary tract disease or acute pancreatitis (may cause constriction of sphincter of Oddi).

Oxymorphone shares the toxic potential of opiate agonists and usual precautions of opiate agonist therapy should be observed; may cause hypotension in patients with acute myocardial infarction, volume depletion, or concurrent drug therapy which may exaggerate vasodilation. The elderly may be particularly susceptible to the CNS depressant and constipating effects of narcotics. Safety and efficacy have not been established in children < 18 years of age.

[U.S. Boxed Warning]: Healthcare provider should be alert to problems of abuse, misuse, and diversion. Tolerance or drug dependence may result from extended use. Use caution in patients with a history of drug dependence or abuse. Abrupt discontinuation may precipitate withdrawal syndrome.

Extended release formulation:

[U.S. Boxed Warnings]: Opana® ER is an extended release oral formulation of oxymorphone and is not suitable for use as an “as needed” analgesic; tablets should not be broken, chewed, dissolved, or crushed; tablets should be swallowed whole. Opana® ER is intended for use in long-term, continuous management of moderate to severe chronic pain. It is not indicated for use in the immediate post-operative period (12-24 hours). [U.S. Boxed Warning]: The co-ingestion of ethanol or ethanol-containing medications with OPANA ER may result in accelerated release of drug from the dosage form, abruptly increasing plasma levels, which may have fatal consequences.

Dosage Forms Injection, solution, as hydrochloride:

Numurphan®: 1 mg (1 mL)

Tablet, as hydrochloride:

Oprana: 5 mg, 10 mg

Tablet, extended release, as hydrochloride:

Oprana® ER: 5 mg, 10 mg, 20 mg, 40 mg

Overdosage/Treatment Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at ²/₃ the response dose/hour) may be required

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Drug Interactions CNS depressants (includes antipsychotics, benzodiazepines, barbiturates): May potentiate the CNS depressant effects of opiate agonists; reduce oxymorphone dosage in patients receiving other CNS depressants.

Dextroamphetamine: May enhance the analgesic effect of opiate agonists.

General anesthetics: May potentiate the CNS depressant effects of opiate agonists.

MAO inhibitors: May potentiate the CNS depressant effects of opiate agonists; monitor.

SSRIs: Analgesics (narcotic) may enhance the serotonergic effect of selective serotonin reuptake inhibitors. This may cause serotonin syndrome.

Tricyclic antidepressants: May potentiate the CNS depressant effects of opiate agonists; monitor.

Pregnancy Risk Factor B/D (prolonged use or high doses at term)

Pregnancy Implications Teratogenic effects were not observed in animal studies, however, decreased fetal weight, decreased litter size, increased stillbirths, and increased neonatal death were noted. Chronic opioid use during pregnancy may lead to a withdrawal syndrome in the neonate. Symptoms include irritability, hyperactivity, loss of sleep pattern, abnormal crying, tremor, vomiting, diarrhea, weight loss, or failure to gain weight. Opioid analgesics are considered pregnancy risk factor D if used for prolonged periods or in larger doses near term.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Observe patient for excessive sedation, respiratory depression, implement safety measures, assist with ambulation

Specific Reference

Mcllwain H and Ahdieh H, “Safety, Tolerability, and Effectiveness of Oxymorphone Extended Release for Moderate to Severe Osteoarthritis Pain: A One-Year Study,” *Am J Ther*, 2005, 12(2):106-12.

Oxyphencyclimine

Pronunciation (oks i fen SYE kli meen)

CAS Number 7081-38-1

Synonyms Oxyphencyclimine Hydrochloride

Use Management of inflammatory disorders, as an analgesic in the treatment of mild to moderate pain and as an antipyretic; I.V. form used as an alternate to surgery in management of patent ductus arteriosus in premature neonates; acute gouty arthritis; removed from U.S. market

Mechanism of Action Anti-inflammatory effect is a prominent feature of the drug's pharmacology. Several hypotheses have been presented for the mode of action. One of the main events in an inflammatory reaction is a leukocyte infiltration of the inflammatory site. An inhibition of leukocyte migration would restrict the entry of leukocytes and suppress, but not stop, the ensuing inflammation; has been observed to inhibit *in vitro* migration of total human leukocytes in a dose-dependent manner.

Adverse Reactions

Cardiovascular: Circulatory collapse

Central nervous system: Headache, aseptic meningitis, psychosis, cognitive dysfunction, coma, seizures

Dermatologic: **Rash, dry skin**, pruritus

Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, fluid retention

Gastrointestinal: **Abdominal pain, constipation, dry throat, xerostomia**, feces discoloration (black), nausea, vomiting, GI bleeding, GI ulceration, diarrhea, dyspepsia

Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia, aplastic anemia (rare), platelet inhibition

Hepatic: Elevated transaminases, hepatitis (fulminant)

Otic: Ototoxicity, tinnitus

Renal: Renal failure (acute), nephrotic syndrome, chronic renal failure, albuminuria

Respiratory: **Dry nose**, wheezing, respiratory depression

Miscellaneous: **Diaphoresis (decreased)**, hypersensitivity

Signs and Symptoms of Overdose Arthralgia, cognitive dysfunction, drowsiness, gastritis, GI bleeding, hypothyroidism, nausea, nephrotic syndrome, ototoxicity, tinnitus, vomiting, wheezing. Severe poisoning can manifest with apnea, coma, feces discoloration (greenish gray; pink), hypotension, leukocytosis, metabolic acidosis, nystagmus, renal failure and/or hepatic failure, respiratory depression, seizures

Dosage

Adults: Oral:

Rheumatoid arthritis: 100-200 mg 3-4 times/day until desired effect, then reduce dose to not exceed 400 mg/day

Acute gouty arthritis: Initial: 400 mg then 100 mg every 4 hours until acute attack subsides, not longer than 1 week

Contraindications Hypersensitivity to oxyphencyclimine or any component of the formulation; angle-closure glaucoma; obstructive GI tract or uropathy; severe ulcerative colitis; myasthenia gravis; intestinal atony

Warnings Use with caution in patients with hepatic or renal disease, ulcerative colitis, hyperthyroidism, cardiovascular disease, hypertension, tachycardia, GI obstruction, obstruction of the urinary tract

Dosage Forms Tablet, as hydrochloride: 10 mg

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/charcoal

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage

Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone

Test Interactions ↑ chloride (S), sodium (S), bleeding time

Drug Interactions Increased anticholinergic side effects by amantadine; decreased phenothiazines, antiparkinsonian drugs, Haldol® effects

Pregnancy Risk Factor C

Nursing Implications Do not crush tablet

Oxytocin

CAS Number 50-56-6

U.S. Brand Names Pitocin®

Synonyms Pit

Use Induction of labor at term; control of postpartum bleeding; adjunctive therapy in management of abortion

Mechanism of Action Produces the rhythmic uterine contractions characteristic to delivery and stimulates breast milk flow during nursing

Adverse Reactions

Frequency not defined.

Fetus or neonate:

Cardiovascular: Arrhythmias (including premature ventricular contractions), bradycardia

Central nervous system: Brain or CNS damage (permanent), neonatal seizures

Hepatic: Neonatal jaundice

Ocular: Neonatal retinal hemorrhage

Miscellaneous: Fetal death, low Apgar score (5 minute)

Mother:

Cardiovascular: Arrhythmias, hypertensive episodes, premature ventricular contractions

Gastrointestinal: Nausea, vomiting

Genitourinary: Pelvic hematoma, postpartum hemorrhage, uterine hypertonicity, tetanic contraction of the uterus, uterine rupture, uterine spasm

Hematologic: Afibrinogenemia (fatal)

Miscellaneous: Anaphylactic reaction, subarachnoid hemorrhage

Pharmacodynamics/Kinetics

Onset of action: Uterine contractions: I.M.: 3-5 minutes; I.V.: ~1 minute

Duration: I.M.: 2-3 hour; I.V.: 1 hour

Metabolism: Rapidly hepatic and via plasma (by oxytocinase) and to a smaller degree the mammary gland

Half-life elimination: 1-5 minutes

Excretion: Urine

Dosage

I.V. administration requires the use of an infusion pump. Adults: Induction of labor: I.V.: 0.5-1 milliunits/minute; gradually increase dose in increments of 1-2 milliunits/minute until desired contraction pattern is established; dose may be decreased after desired frequency of contractions is reached and labor has progressed to 5-6 cm dilation. Infusion rates of 6 milliunits/minute provide oxytocin levels similar to those at spontaneous labor; rates of >9-10 milliunits/minute are rarely required.

Postpartum bleeding:

I.M.: Total dose of 10 units after delivery

I.V.: 10-40 units by I.V. infusion in 1000 mL of intravenous fluid at a rate sufficient to control uterine atony

Adjunctive treatment of abortion: I.V.: 10-20 milliunits/minute; maximum total dose: 30 units/12 hours

Monitoring Parameters Fluid intake and output during administration; fetal monitoring

Administration An infusion pump is required for administration

Contraindications Hypersensitivity to oxytocin or any component of the formulation; significant cephalopelvic disproportion; unfavorable fetal positions; fetal distress; hypertonic or hyperactive uterus; contraindicated vaginal delivery (invasive cervical cancer, active genital herpes, prolapse of the cord, cord presentation, total placenta previa, or vasa previa)

Warnings [U.S. Boxed Warning]: To be used for medical rather than elective induction of labor. May produce antidiuretic effect (ie, water intoxication and excess uterine contractions); high doses or hypersensitivity to oxytocin may cause uterine hypertonicity, spasm, tetanic contraction, or rupture of the uterus; severe water intoxication with convulsions, coma, and death is associated with a slow oxytocin infusion over 24 hours

Dosage Forms Injection, solution: 10 units/mL (1 mL, 10 mL)

Pitocin®: 10 units/mL (1 mL)

Reference Range Plasma oxytocin level following an infusion of 132 milliunits/minute ranges from 228-241 pg/mL

Overdosage/Treatment Supportive therapy: Ritodrine (6 mg I.V.) can be used to inhibit oxytocin-induced labor; while diazepam or lorazepam can be used to treat seizures, electrolytes (particularly sodium) need to be monitored and normalized for effective seizure control; arteriospasm has been treated successfully with intra-arterial injection of 1% lidocaine (3 mL), papaverine (2 mL) and heparin (10,000 units) following discontinuation of the drug

Drug Interactions Dinoprostone, misoprostol: May increase the effect of oxytocin; wait 6-12 hours after dinoprostone or misoprostol administration before initiating oxytocin.

Pregnancy Risk Factor X

Pregnancy Implications Reproduction studies have not been conducted. When used as indicated, teratogenic effects would not be expected. Nonteratogenic adverse reactions are reported in the neonate as well as the mother.

Lactation Excretion in breast milk unknown/use caution

Additional Information Sodium chloride 0.9% (NS) and dextrose 5% in water (D₅W) have been recommended as diluents; dilute 10-40 units to 1 L in NS, LR, or D₅W

vomiting, diarrhea, enterocolitis, intestinal obstruction, pancreatitis, paralytic ileus

Hematologic: **Myelosuppression, leukopenia, neutropenia** (6% to 21%), **thrombocytopenia**, anemia

Onset: 8-11 days

Nadir: 15-21 days

Recovery: 21 days

Hepatic: **Mild increases in liver enzymes**, hepatic encephalopathy

Local: Necrotic changes and ulceration following extravasation

Neuromuscular & skeletal: **Arthralgia, myalgia**

Neurotoxicity: Peripheral neuropathy, **sensory and/or autonomic neuropathy (numbness, tingling, burning pain), myopathy or myopathic effects (25% to 55%), and central nervous system toxicity.** May be cumulative and dose-limiting. **Note:** Motor neuropathy is uncommon at doses <250 mg/m²; sensory neuropathy is almost universal at doses >250 mg/m²; myopathic effects are common with doses >250 mg/m², generally occurring within 2-3 days of treatment, resolving over 5-6 days; pre-existing neuropathy may increase the risk of neuropathy.

Ocular: Visual disturbances (scintillating scotomata)

Otic: Ototoxicity (tinnitus and hearing loss)

Respiratory: Interstitial pneumonia, pulmonary fibrosis, radiation pneumonitis

Signs and Symptoms of Overdose Agranulocytosis, chest pain, congestive heart failure, diplopia, dysphagia, dyspnea, erythema, granulocytopenia, leukopenia, myopathy, neuritis, neuropathy (peripheral), neutropenia, stomatitis, ventricular arrhythmias, wheezing

Pharmacodynamics/Kinetics

Distribution:

V_d: Widely distributed into body fluids and tissues; affected by dose and duration of infusion

V_{ass}:

1- to 6-hour infusion: 67.1 L/m²

24-hour infusion: 227-688 L/m²

Protein binding: 89% to 98%

Metabolism: Hepatic via CYP2C8 and 3A4; forms metabolites (primarily 6 α -hydroxypaclitaxel)

Half-life elimination:

1- to 6-hour infusion: Mean (beta): 6.4 hours

3-hour infusion: Mean (terminal): 13.1-20.2 hours

24-hour infusion: Mean (terminal): 15.7-52.7 hours

Excretion: Feces (~70%, 5% as unchanged drug); urine (14%)

Clearance: Mean: Total body: After 1- and 6-hour infusions: 5.8-16.3 L/hour/m²; After 24-hour infusions: 14.2-17.2 L/hour/m²

Dosage

Premedication with dexamethasone (20 mg orally or I.V. at 12 and 6 hours or 14 and 7 hours before the dose), diphenhydramine (50 mg I.V. 30-60 minutes prior to the dose), and cimetidine, famotidine or ranitidine (I.V. 30-60 minutes prior to the dose) is recommended

Adults: I.V.: Refer to individual protocols

Ovarian carcinoma: 135-175 mg/m² over 3 hours every 3 weeks or

50-80 mg/m² over 1-3 hours weekly or

1.4-4 mg/m²/day continuous infusion for 14 days every 4 weeks

Metastatic breast cancer: 175-250 mg/m² over 3 hours every 3 weeks or

50-80 mg/m² weekly or

1.4-4 mg/m²/day continuous infusion for 14 days every 4 weeks

Nonsmall cell lung carcinoma: 135 mg/m² over 24 hours every 3 weeks

AIDS-related Kaposi's sarcoma: 135 mg/m² over 3 hours every 3 weeks or

100 mg/m² over 3 hours every 2 weeks

Dosage modification for toxicity (solid tumors, including ovary, breast, and lung carcinoma): Courses of paclitaxel should not be repeated until the neutrophil count is \geq 1500 cells/mm³ and the platelet count is \geq 100,000 cells/mm³; reduce dosage by 20% for patients experiencing severe peripheral neuropathy or severe neutropenia (neutrophil <500 cells/mm³ for a week or longer)

Dosage modification for immunosuppression in advanced HIV disease: Paclitaxel should not be given to patients with HIV if the baseline or subsequent neutrophil count is <1000 cells/mm³. Additional modifications include: Reduce dosage of dexamethasone in premedication to 10 mg orally; reduce dosage by 20% in patients experiencing severe peripheral neuropathy or severe neutropenia (neutrophil <500 cells/mm³ for a week or longer); initiate concurrent hematopoietic growth factor (G-CSF) as clinically indicated

Dosage adjustment in hepatic impairment: **Note:** These recommendations are based upon the patient's first course of therapy where the usual dose would be 135 mg/m² dose over 24 hours or the 175 mg/m² dose over 3 hours in patients with normal hepatic function. Dosage in subsequent courses should be based upon individual tolerance. Adjustments for other regimens are not available.

24-hour infusion:

If transaminase levels <2 times upper limit of normal (ULN) and bilirubin level \leq 1.5 mg/dL: 135 mg/m²

Paclitaxel

Related Information

- Docetaxel

CAS Number 33069-62-4

U.S. Brand Names Onxol™, Taxol®

Synonyms NSC-125973; NSC-673089

Use Treatment of breast, lung (small cell and nonsmall cell), and ovarian cancers

Unlabeled/Investigational Use Treatment of bladder, cervical, prostate, and head and neck cancers

Mechanism of Action Derived from the rare Pacific yew tree (*Taxus brevifolia*), it induces microtubule formation while disrupting mitosis

Adverse Reactions

Allergic: Appear to be primarily nonimmunologically mediated release of histamine and other vasoactive substances; almost always seen within the first hour of an infusion (~75% occur within 10 minutes of starting the infusion); incidence is significantly reduced by premedication

Cardiovascular: **Bradycardia (transient, 25%)**, myocardial infarction, atrial fibrillation

Central nervous system: Ataxia, neuroencephalopathy, seizures

Dermatologic: **Alopecia (87%), venous erythema, tenderness, discomfort**, phlebitis, pruritus, radiation recall, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Gastrointestinal: **Severe, potentially dose-limiting mucositis, stomatitis (15%)**, most common at doses >390 mg/m²; mild nausea and

If transaminase levels 2- < 10 times ULN and bilirubin level \leq 1.5 mg/dL: 100 mg/m²

If transaminase levels < 10 times ULN and bilirubin level 1.6-7.5 mg/dL: 50 mg/m²

If transaminase levels \geq 10 times ULN and bilirubin level > 7.5 mg/dL: Avoid use

3-hour infusion:

If transaminase levels < 10 times ULN and bilirubin level \leq 1.25 times ULN: 175 mg/m²

If transaminase levels < 10 times ULN and bilirubin level 1.26-2 times ULN: 135 mg/m²

If transaminase levels < 10 times ULN and bilirubin level 2.01-5 times ULN: 90 mg/m²

If transaminase levels \geq 10 times ULN and bilirubin level > 5 times ULN: Avoid use

Stability

Store intact vials at room temperature of 20°C to 25°C (68°F to 77°F). Dilute in NS or D₅W to a concentration of 0.3-1.2 mg/mL; reconstituted solution is stable for up to 27 hours at room temperature (25°C) and ambient light conditions. Solutions in D₅W, NS, D₅NS, and D₅LR are stable for up to 48 hours at room temperature (25°C).

Paclitaxel should be dispensed in either glass or Excel™/PAB™ containers. Should also use **nonpolyvinyl** (non-PVC) tubing (eg, polyethylene) to minimize leaching. Formulated in a vehicle known as Cremophor® EL (polyoxyethylated castor oil). Cremophor® EL has been found to leach the plasticizer DEHP from polyvinyl chloride infusion bags or administration sets. Contact of the undiluted concentrate with plasticized polyvinyl chloride (PVC) equipment or devices is not recommended. Administer through I.V. tubing containing an in-line (NOT > 0.22 μ) filter; administration through IVEX-2® filters (which incorporate short inlet and outlet polyvinyl chloride-coated tubing) has not resulted in significant leaching of DEHP.

Monitoring Parameters Monitor for hypersensitivity reactions

Administration

Anaphylactoid-like reactions have been reported: Corticosteroids (dexamethasone), H₁-antagonists (diphenhydramine), and H₂-antagonists (famotidine), should be administered prior to paclitaxel administration to minimize potential for anaphylaxis

Administer I.V. infusion over 1-24 hours; use of a 0.22 micron in-line filter and nonsorbing administration set is recommended during the infusion

Nonpolyvinyl (non-PVC) tubing (eg, polyethylene) should be used to minimize leaching. Formulated in a vehicle known as Cremophor® EL (polyoxyethylated castor oil). Cremophor® EL has been found to leach the plasticizer DEHP from polyvinyl chloride infusion bags or administration sets. Contact of the undiluted concentrate with plasticized polyvinyl chloride (PVC) equipment or devices is not recommended. Administer through I.V. tubing containing an in-line (NOT > 0.22 μ) filter; administration through IVEX-2® filters (which incorporate short inlet and outlet polyvinyl chloride-coated tubing) has not resulted in significant leaching of DEHP.

Contraindications Hypersensitivity to paclitaxel, Cremophor® EL (polyoxyethylated castor oil), or any component of the formulation; pregnancy

Warnings

Hazardous agent – use appropriate precautions for handling and disposal. **[U.S. Boxed Warning]: Severe hypersensitivity reactions have been reported;** prolongation of the infusion (to \geq 6 hours) plus premedication may minimize this effect. Stop infusion and do not rechallenge for severe hypersensitivity reactions (hypotension requiring treatment, dyspnea requiring bronchodilators, angioedema, urticaria). Minor hypersensitivity reactions (flushing, skin reactions, dyspnea, hypotension, or tachycardia) do not require interruption of treatment. **[U.S. Boxed Warning]: Bone marrow suppression is the dose-limiting toxicity; do not administer if baseline absolute neutrophil count (ANC) is < 1500 cells/mm³ (< 1000 cells/mm³ for patients with AIDS-related KS);** reduce future doses by 20% for severe neutropenia (< 500 cells/mm³ for 7 days or more) and consider the use of supportive therapy, including growth factor treatment.

Use extreme caution with hepatic dysfunction (myelotoxicity may be worsened); dose reductions are recommended. Peripheral neuropathy may occur; patients with pre-existing neuropathies from chemotherapy or coexisting conditions (eg, diabetes mellitus) may be at a higher risk; reduce dose by 20% for severe neuropathy. Paclitaxel formulations contain dehydrated alcohol; may cause adverse CNS effects. Hypotension, bradycardia, and hypertension may occur; frequent monitoring of vital signs is recommended, especially during the first hour of the infusion. Rare but severe conduction abnormalities have been reported; conduct cardiac monitoring during subsequent infusions for these patients. When administered as sequential infusions, taxane derivatives (docetaxel, paclitaxel) should be administered before platinum derivatives (carboplatin, cisplatin) to limit myelosuppression. Elderly patients have an increased risk of toxicity (neutropenia, neuropathy). **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.** Safety and efficacy in children have not been established.

Dosage Forms Injection, solution: 6 mg/mL (5 mL, 16.7 mL, 25 mL, 50 mL) [contains alcohol and purified Cremophor® EL (polyoxyethylated castor oil)]

Onxol™: 6 mg/mL (5 mL, 25 mL, 50 mL) [contains alcohol and purified Cremophor® EL (polyoxyethylated castor oil)]

Taxol®: 6 mg/mL (5 mL, 16.7 mL, 50 mL) [contains alcohol and purified Cremophor® EL (polyoxyethylated castor oil)]

Reference Range

Mean maximum serum concentrations: 435-802 ng/mL following 24-hour infusions of 200-275 mg/m² and were approximately 10% to 30% of those following 6-hour infusions of equivalent doses; not detected in cerebrospinal fluid

Overdosage/Treatment Supportive therapy: Amitriptyline may be helpful for neuropathy; epinephrine, crystalloid fluids, diphenhydramine (25-50 mg in adults) and methylprednisolone (125 mg in adults) should be given for anaphylaxis; high-dose corticosteroids can be given to treat pneumonitis; corticosteroids should be given for myositis; pulmonary infiltrates can be treated with steroids. Oral glutamine suspension as a swish and swallow, starting on day 7 every 4 hours around-the-clock for a total dose of 24 g daily, is effective in preventing oral mucositis; gabapentin can be used to treat myalgia. Atropine can be given for bradycardia.

Test Interactions \uparrow serum triglyceride; minor increase of renal function or liver function tests

Drug Interactions **Substrate** (major) of CYP2C8, 2C9, 3A4; **Induces** CYP3A4 (weak)

Carboplatin, cisplatin (platinum derivatives): When administered as sequential infusions, taxane derivatives should be administered before platinum derivatives to limit myelosuppression and to enhance efficacy. CYP2C8 inducers: May decrease the levels/effects of paclitaxel. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C9 inducers: May decrease the levels/effects of paclitaxel. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C8 inhibitors may increase the levels/effects of paclitaxel. Example inhibitors include atazanavir, gemfibrozil, and ritonavir.

CYP2C9 inhibitors may increase the levels/effects of paclitaxel. Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nifedipine, NSAIDs, sulfonamides and tolbutamide.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of paclitaxel. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of paclitaxel. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nifedipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Doxorubicin: Paclitaxel may increase doxorubicin levels/toxicity. **Pregnancy Risk Factor** D; Enters breast milk/contraindicated, antineoplastic agents are generally contraindicated.

Pregnancy Implications Teratogenic effects have been observed in animal studies; women of childbearing potential should be advised to avoid becoming pregnant

Lactation Excretion in breast milk unknown/contraindicated

Additional Information Skin necrosis can occur with subcutaneous extravasation. Products contain ethanol as a vehicle, which has caused intoxication in high-dose regimens.

Pamidronate

CAS Number 109552-15-0; 40391-99-9

U.S. Brand Names Aredia®

Synonyms Pamidronate Disodium

Use Treatment of hypercalcemia associated with malignancy; treatment of osteolytic bone lesions associated with multiple myeloma or metastatic breast cancer; moderate to severe Paget's disease of bone

Unlabeled/Investigational Use Treatment of pediatric osteoporosis, treatment of osteogenesis imperfecta

Mechanism of Action Inhibits osteoclastic bone resorption of calcium

Adverse Reactions

As reported with hypercalcemia of malignancy; percentage of adverse effect varies upon dose and duration of infusion.

Cardiovascular: Atrial fibrillation, hypertension, syncope, tachycardia, atrial flutter, cardiac failure, hypotension

Central nervous system: **Fever, fatigue**, somnolence, psychosis, insomnia

Dermatologic: Angioedema

Endocrine & metabolic: **Hypophosphatemia** (9% to 18%), **hypokalemia** (4% to 18%), **hypomagnesemia** (4% to 12%), **hypocalcemia** (1% to 12%), hypothyroidism

Gastrointestinal: **Nausea, anorexia** (1% to 12%), constipation, stomatitis

Hematologic: Leukopenia, neutropenia, thrombocytopenia

Local: **Infusion site reaction**

Neuromuscular & skeletal: Myalgia, osteonecrosis (primarily jaws)

Ocular: Iritis, episcleritis, scleritis, uveitis

Renal: Uremia

Respiratory: Rales, rhinitis, upper respiratory tract infection, dyspnea

Miscellaneous: Allergic reactions, anaphylactic shock

Signs and Symptoms of Overdose Fever, hypocalcemia, hypokalemia, hypomagnesemia, hypophosphatemia, hypotension, taste perversion

Pharmacodynamics/Kinetics

Onset of action: 24-48 hours

Peak effect: Maximum: 5-7 days

Absorption: Poor; pharmacokinetic studies lacking

Metabolism: Not metabolized

Half-life elimination: 21-35 hours

Excretion: Biphasic; urine (~50% as unchanged drug) within 120 hours

Dosage

Drug must be diluted properly before administration and infused intravenously slowly. Due to risk of nephrotoxicity, doses should not exceed 90 mg. I.V.: Adults:

Hypercalcemia of malignancy:

Moderate cancer-related hypercalcemia (corrected serum calcium: 12-13.5 mg/dL): 60-90 mg, as a single dose, given as a slow infusion over 2-24 hours; dose should be diluted in 1000 mL 0.45% NaCl, 0.9% NaCl, or D₅W

Severe cancer-related hypercalcemia (corrected serum calcium: > 13.5 mg/dL): 90 mg, as a single dose, as a slow infusion over 2-24 hours; dose should be diluted in 1000 mL 0.45% NaCl, 0.9% NaCl, or D₅W

A period of 7 days should elapse before the use of second course; repeat infusions every 2-3 weeks have been suggested, however, could be administered every 2-3 months according to the degree and of severity of hypercalcemia and/or the type of malignancy.

Note: Some investigators have suggested a lack of a dose-response relationship. Courses of pamidronate for hypercalcemia may be repeated at varying intervals, depending on the duration of normocalcemia (median 2-3 weeks), but the manufacturer recommends a minimum interval between courses of 7 days. Oral etidronate at a dose of 20 mg/kg/day has been used to maintain the calcium lowering effect following I.V. bisphosphonates, although it is of limited effectiveness.

Osteolytic bone lesions with multiple myeloma: 90 mg in 500 mL D₅W, 0.45% NaCl or 0.9% NaCl administered over 4 hours on a monthly basis

Osteolytic bone lesions with metastatic breast cancer: 90 mg in 250 mL D₅W, 0.45% NaCl or 0.9% NaCl administered over 2 hours, repeated every 3-4 weeks

Page's disease: 30 mg in 500 mL 0.45% NaCl, 0.9% NaCl or D₅W administered over 4 hours for 3 consecutive days

Dosing adjustment in renal impairment: Not recommended in severe renal impairment (patients with bone metastases)

Dosing adjustment in renal toxicity: In patients with bone metastases, treatment should be withheld in patients who experience deterioration in renal function (increase of serum creatinine \geq 0.5 mg/dL in patients with normal baseline or \geq 1.0 mg/dL in patients with abnormal baseline). Resumption of therapy may be considered when serum creatinine returns to within 10% of baseline.

Monitoring Parameters Serum electrolytes, monitor for hypocalcemia for at least 2 weeks after therapy; serum calcium, phosphate, magnesium, potassium, CBC with differential; monitor serum creatinine prior to each dose

Administration Administer in 0.5-1 L of normal saline or 5% dextrose; do not use Ringer's lactate. Drug must be properly diluted before administration and slowly infused intravenously (over at least 2 hours).

Contraindications Hypersensitivity to pamidronate, other bisphosphonates, or any component of the formulation; pregnancy

Warnings

Bisphosphonate therapy has been associated with osteonecrosis, primarily of the jaw; this has been observed mostly in cancer patients, but also in patients with postmenopausal osteoporosis and other diagnoses. Risk factors include a diagnosis of cancer, with concomitant chemotherapy, radiotherapy or corticosteroids; anemia, coagulopathy, infection or pre-existing dental disease. Symptoms included nonhealing extraction socket or an exposed jawbone. There are no data addressing whether discontinuation of therapy reduces the risk of developing osteonecrosis. However, as a precautionary measure, dental exams and preventative dentistry should be performed prior to placing patients with risk factors on chronic bisphosphonate therapy. Invasive dental procedures should be avoided during treatment.

Infrequently, severe (and occasionally debilitating) bone, joint, and/or muscle pain have been reported during bisphosphonate treatment. The onset of pain ranged from a single day to several months. Symptoms usually resolve upon discontinuation. Some patients experienced recurrence when rechallenged with same drug or another bisphosphonate; avoid use in patients with a history of these symptoms in association with bisphosphonate therapy.

May cause deterioration in renal function. Use caution in patients with renal impairment and avoid in severe renal impairment. Assess serum creatinine prior to each dose; withhold dose in patients with bone metastases who experience deterioration in renal function. Leukopenia has been observed with oral pamidronate and monitoring of white blood cell counts is suggested. Patients with pre-existing anemia, leukopenia, or thrombocytopenia should be closely monitored during the first 2 weeks of treatment.

Vein irritation and thrombophlebitis may occur with infusions. Monitor serum electrolytes, especially in the elderly.

Dosage Forms Injection, powder for reconstitution, as disodium: 30 mg, 90 mg

Aredia®: 30 mg, 90 mg

Injection, solution: 3 mg/mL (10 mL); 6 mg/mL (10 mL); 9 mg/mL (10 mL)

Reference Range Calcium (total): Adults: 9.0-11.0 mg/dL (SI: 2.05-2.54 mM/L), may slightly decrease with aging; phosphorus: 2.5-4.5 mg/dL (SI: 0.81-1.45 mM/L)

Overdosage/Treatment Supportive therapy: Monitor for hypocalcemia; in one report (supplied by the drug company), fever and hypotension were corrected with use of steroids, but no formal studies could be found

Test Interactions ↓ calcium (S), phosphate

Drug Interactions Aminoglycosides: May lower serum calcium levels with prolonged administration. Concomitant use may have an additive hypocalcemic effect.

Antacids: May decrease the absorption of bisphosphonate derivatives; should be administered at a different time of the day. Antacids containing aluminum, calcium, or magnesium are of specific concern.

Calcium salts: May decrease the absorption of bisphosphonate derivatives. Separate oral dosing in order to minimize risk of interaction.

Iron salts: May decrease the absorption of bisphosphonate derivatives. Only oral iron salts and oral bisphosphonates are of concern.

Magnesium salts: May decrease the absorption of bisphosphonate derivatives. Only oral magnesium salts and oral bisphosphonates are of concern.

Nonsteroidal anti-inflammatory drugs (NSAIDs): May enhance the gastrointestinal adverse/toxic effects (increased incidence of GI ulcers) of bisphosphonate derivatives.

Phosphate supplements: Bisphosphonate derivatives may enhance the hypocalcemic effect of phosphate supplements.

Pregnancy Risk Factor C

Pregnancy Implications Pamidronate has been shown to cross the placenta and cause nonteratogenic embryo/fetal effects in animals. There are no adequate and well-controlled studies in pregnant women; manufacturer states pamidronate should not be used in pregnancy. Based on limited case reports, serum calcium levels in the newborn may be altered if pamidronate is administered during pregnancy. Bisphosphonates are incorporated into the bone matrix and gradually released over time. Theoretically, there may be a risk of fetal harm when pregnancy follows the completion of therapy.

Lactation Excretion in breast milk unknown/use caution

Additional Information Pamidronic acid causes severe bone pain in cystic fibrosis.

Papaverine

CAS Number 32808-09-6; 39024-96-9; 58-74-2; 61-25-6

U.S. Brand Names Para-Time S.R.®

Synonyms Papaverine Hydrochloride; Pavabid [DSC]

Use Relief of peripheral and cerebral ischemia associated with arterial spasm

Unlabeled/Investigational Use Investigational: Parenteral: Various vascular spasms associated with muscle spasms as in myocardial infarction, angina, peripheral and pulmonary embolism, peripheral vascular disease, angiospastic states, and visceral spasm (ureteral, biliary, and GI colic); testing for impotence

Mechanism of Action Smooth muscle spasmolytic producing a generalized smooth muscle relaxation including vasodilatation, gastrointestinal sphincter relaxation, bronchiolar muscle relaxation and potentially a depressed myocardium; it is an inhibition of cellular respiration and

PARA-AMINOSALICYLATE SODIUM

phosphodiesterase along with being a calcium antagonist (inhibits uptake of adenosine)

Adverse Reactions

Cardiovascular: Flushing of the face, tachycardia, hypotension, cardiac arrhythmias with rapid I.V. use consisting of AV block, premature ventricular contraction, sinus tachycardia, arrhythmias (ventricular), vasodilation

Central nervous system: Depression, dizziness, drowsiness, sedation, headache

Dermatologic: Pruritus

Gastrointestinal: Xerostomia, nausea, constipation, vomiting, abdominal pain

Genitourinary: Priapism with intracavernous injection

Hematologic: Eosinophilia

Hepatic: Hepatic hypersensitivity, cirrhosis

Local: Thrombosis at the I.V. administration site

Respiratory: Apnea with rapid I.V. use

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Asthenia, AV block, constipation, coma, diplopia, drowsiness, hyperglycemia, hypokalemia, lactic acidosis, liver damage, mydriasis, penile fibrosis, respiratory alkalosis

Pharmacodynamics/Kinetics

Onset of action: Oral: Rapid

Protein binding: 90%

Metabolism: Rapidly hepatic

Half-life elimination: 0.5-1.5 hours

Excretion: Primarily urine (as metabolites)

Dosage Children: I.M., I.V.: 1.5 mg/kg 4 times/day

Adults:

Oral: 100-300 mg 3-5 times/day

Oral, sustained release: 150-300 mg every 12 hours

I.M., I.V.: 30-120 mg every 3 hours as needed

Stability Protect from heat or freezing; not do refrigerate injection; solutions should be clear to pale yellow; precipitates with lactated Ringer's; **incompatible** with bromides and iodides

Administration Rapid I.V. administration may result in arrhythmias and fatal apnea; administer no faster than over 1-2 minutes.

Contraindications Hypersensitivity to papaverine or any component of the formulation

Warnings Use with caution in patients with glaucoma; administer I.V. cautiously since apnea and arrhythmias may result; may, in large doses, depress AV and intraventricular cardiac conduction leading to serious arrhythmias (eg, premature beats, paroxysmal tachycardia); chronic hepatitis noted with jaundice, eosinophilia, and abnormal LFTs

Dosage Forms Capsule, sustained release, as hydrochloride: 150 mg

Para-Time SR®: 150 mg

Injection, solution, as hydrochloride: 30 mg/mL (2 mL, 10 mL)

Reference Range Peak plasma papaverine level of 1 mg/L noted after 1 mg/kg intravenous dose

Overdosage/Treatment

Decontamination: Ipecac (within 30 minutes)/activated charcoal is useful

Supportive therapy: Lorazepam or diazepam 10-20 mg (0.25-0.4 mg/kg for children) is helpful for seizures; I.V. fluids and alpha-adrenergic pressors should be used for hypotension; sodium bicarbonate (1 mEq/kg) is useful to treat acidosis; calcium gluconate (10% I.V. solution; 0.2-0.5 mL/kg/dose up to 10 mL/dose over 5-10 minutes) can be used to treat hypotension or heart block; dopamine can also be used to treat hypotension while atropine, isoproterenol and/or glucagon can be used for heart block

Enhanced elimination: Multiple dosing of activated charcoal may be useful

Drug Interactions Decreased effect: Papaverine decreases the effects of levodopa

Increased toxicity: Additive effects with CNS depressants

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Rapid I.V. administration may result in arrhythmias and fatal apnea

Additional Information Therapeutic value is lacking

Specific References

Perk G, Hanna S, and Stalniewicz R, "Lethal Oral Papaverine Overdose," *Am J Emerg Med*, 2003, 21(3):245.

Gastrointestinal: Nausea, vomiting, diarrhea

Hepatic: Hepatitis, jaundice

Miscellaneous: Allergy, mononucleosis-like syndrome

Pharmacodynamics/Kinetics

Absorption: Readily

Distribution: Widely distributed but appears in CSF only within inflamed meninges

Protein binding: 60% to 70%

Metabolism: Intestinal and liver

Half-life, elimination: ≈ 1 hour

Peak concentrations: Within 1-4 hours

Elimination: Primarily in urine within 12 hours

Dosage

Oral:

Children: 240-360 mg/kg/day in 3-4 divided doses

Adults: 12-15 g/day in 3-4 divided doses

Contraindications Known hypersensitivity to para-aminosalicylate

Warnings Avoid use in patients with hepatic or renal dysfunction, gastric bleeding disorders

Dosage Forms Tablet: 500 mg

Reference Range Inhibition of *Mycobacterium tuberculosis* at a level of 1 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Test Interactions Urine glucose

Drug Interactions Interferes with rifampin absorption; displaces phenytoin from albumin thus raising free phenytoin levels; probenecid can increase serum concentration

Pregnancy Risk Factor C

Additional Information Capsules contain bentonite which may decrease absorption of concomitantly ingested drugs.

Paraldehyde

Related Information

- Seizures, Neonatal Guidelines

CAS Number 123-63-7

UN Number 1264

U.S. Brand Names Paral®

Synonyms Paracetaldehyde

Impairment Potential Yes

Use Cyclic acetaldehyde trimer which is utilized as a treatment of status epilepticus and tetanus-induced seizures; has been used as a sedative/hypnotic, no longer used in the treatment of alcohol withdrawal symptoms

Mechanism of Action Unknown mechanism of action; causes depression of CNS, including the ascending reticular activating system to provide sedation/hypnosis and anticonvulsant activity

Adverse Reactions

Cardiovascular: Cardiovascular collapse, tachycardia, sinus bradycardia, sinus tachycardia

Central nervous system: **Drowsiness**, clumsiness, dizziness, "hangover effect"

Dermatologic: **Skin rash**

Endocrine & metabolic: Metabolic acidosis

Gastrointestinal: **Strong and unpleasant breath**, abdominal pain, **nausea, vomiting, stomach pain, irritation of mucous membrane**

Hematologic: Leukocytosis, porphyrinogenic

Hepatic: Hepatitis

Local: Thrombophlebitis

Renal: Acidosis (renal tubular), albuminuria, acute tubular necrosis

Respiratory: **Coughing**, respiratory depression, pulmonary edema, laryngeal spasm

Miscellaneous: Psychological and physical dependence with prolonged use

Signs and Symptoms of Overdose Acetone breath, coma (may last > 30 hours), confusion, cough (seen early in the course of toxicity), dyspnea, feces discoloration (black), hemorrhagic gastritis, hyperventilation, mental confusion, metabolic acidosis, mild hypotension, myasthenia gravis (exacerbation or precipitation), pulmonary edema, pulmonary hemorrhage, renal failure, respiratory depression, stomatitis, tachypnea. Death has occurred with as little as 12-25 mL, usually due to pulmonary edema.

Pharmacodynamics/Kinetics

Onset of hypnosis:

Oral: Within 10-15 minutes

I.M.: Within 2-3 minutes

Duration: 6-8 hours

Distribution: Crosses the placenta

Metabolism: ≈ 70% to 80% of a dose metabolized in the liver

Half-life: Adults: 3.5-10 hours

Elimination: Up to 30% excreted as unchanged drug in expired air via the lungs; trace amounts excreted in urine unchanged

Para-Aminosalicylate Sodium

CAS Number 133-10-8; 6018-19-5

Synonyms Aminosalicylate Sodium; PAS

Use Adjunctive treatment of tuberculosis

Adverse Reactions

Cardiovascular: Myocardial depression, congestive heart failure, sinus tachycardia

Central nervous system: Mania

Dermatologic: Alopecia, lichen planus

Endocrine & metabolic: Hypokalemia

Dosage Oral: Sedation:
 Children: 0.15-0.3 mL/kg
 Adults: 4-8 mL
 I.M., I.V.: I.V. use is rare and should be diluted (4% to 5% solution): 0.1-0.3 mL/kg
 Rectal:
 Children: 0.3 mL/kg to a maximum dose of 5 mL
 Adults: 4-8 mL diluted with sodium chloride

Stability Decomposes with exposure to air and light to acetaldehyde which then oxidizes to acetic acid; store in tightly closed containers; protect from light

Administration Oral: Dilute in milk or iced fruit juice
 Rectal: Mix paraldehyde 2:1 with oil (cottonseed or olive)
 Do **not** use any plastic equipment for administration, use glass syringes and rubber tubing

Contraindications Hypersensitivity to paraldehyde or any component of the formulation; severe hepatic insufficiency; respiratory disease; GI inflammation or ulceration; concurrent disulfiram

Warnings Use with caution in patients with asthma or other bronchopulmonary disease; do not abruptly discontinue in patients receiving chronic therapy

Dosage Forms Liquid, oral or rectal: 1 g/mL (30 mL)

Reference Range Antiseizure therapeutic blood level: 100-200 mg/L; toxic level: >270 mg/L; blood level approaching 500 mg/L associated with fatality

Overdosage/Treatment

Decontamination: Lavage (within 30 minutes)/activated charcoal; **do not** induce emesis

Supportive therapy: Treat acidosis with sodium bicarbonate; for hypotension, fluid challenge with isotonic saline or placement of patient in Trendelenburg position; vasopressors (dopamine or norepinephrine) can be used for refractory cases

Test Interactions Ketonuria may be present

Drug Interactions CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect

Disulfiram: Concurrent use of paraldehyde and disulfiram produces a "disulfiram reaction," this combination is contraindicated

Pregnancy Risk Factor C

Nursing Implications Discard unused contents of any container which has been opened for more than 24 hours; do **not** use discolored solution; do **not** use any plastic equipment for administration; parenteral solution may be given orally; should be given in milk or iced fruit juice or dilute to 200 mL with saline

Additional Information Minimal lethal dose: Oral: 25 mL; I.V.: 35 mL; Rectal: 12 mL

Do not abruptly discontinue in patients receiving chronic therapy; decomposes to acetic acid in air; 4-8 mL of paraldehyde is equivalent to 30 mg of phenobarbital; was used for the treatment of delirium, tremors, but its use has been supplanted by benzodiazepines; odor of acetic acid indicates that decomposition has occurred; may be irritating to mucosa

Paramethadione

CAS Number 115-67-3

Use Control absence (petit mal) seizures refractory to other drugs

Mechanism of Action Elevates the cortical and basal seizure thresholds, and reduces the synaptic response to low frequency impulses; similar properties to troxidone

Adverse Reactions

Central nervous system: **Drowsiness, dizziness, sedation, headache**
 Dermatologic: Exfoliative dermatitis, rash, photosensitivity
 Gastrointestinal: Feces discoloration (black)
 Hematologic: Agranulocytosis, aplastic anemia, thrombocytopenia, exacerbation of porphyria
 Hepatic: Hepatitis
 Neuromuscular & skeletal: Myasthenia gravis (exacerbation)
 Ocular: **Photophobia, diplopia**, blurred vision, nystagmus
 Renal: Nephrosis, proteinuria
 Miscellaneous: Systemic lupus erythematosus

Signs and Symptoms of Overdose Agranulocytosis, ataxia, granulocytopenia, leukopenia, nausea, neutropenia, visual disturbances, vision color changes (white tinge)

Toxicodynamics/Kinetics

Absorption: Rapid from gastrointestinal tract
 Distribution: Widely throughout the body
 Protein binding: Insignificant
 Metabolism: Hepatic metabolism via microsomal enzymes
 Half-life: 12-24 hours
 Elimination: Slow renal excretion (primarily as active metabolites)

Dosage

Oral:
 Children: 300-900 mg/day in 3-4 equally divided doses
 Adults: Initial: 900 mg/day in 3-4 equally divided doses, increase by 300 mg at weekly intervals to maximum of 2.4 g/day

Dosing adjustment in renal/hepatic impairment: Avoid use in patients with $Cl_{cr} < 10$ mL/minute or with severe liver disease

Reference Range Therapeutic: 5-50 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal is useful. Consider gastric decontamination for ingestions > 1 g.
 Enhanced elimination: Alkalinization of the urine increases elimination of the active metabolite; multiple dosing of activated charcoal may be useful

Test Interactions ↑ alkaline phosphatase (S); ↓ calcium (S), thyroxine (S)

Pregnancy Implications Associated with high incidence of congenital malformations, 4 times more hazardous than ethosuximide

Nursing Implications Raise side rails, institute safety measures, assist with ambulation

Additional Information Lethal dose: 5 g. Only supplied graduated dropper should be used to measure oral solution; clean, colorless liquid with aromatic odor

Paregoric

CAS Number 8029-99-0

Synonyms Camphorated Tincture of Opium (error-prone synonym)

Impairment Potential Yes

Use Treatment of diarrhea or relief of pain; neonatal opiate withdrawal (heroin or methadone-induced withdrawal seizures)

Mechanism of Action Increases smooth muscle tone in gastrointestinal tract, decreases motility and peristalsis, diminishes digestive secretions

Adverse Reactions

Cardiovascular: **Hypotension**, bradycardia, vasodilation, sinus bradycardia

Central nervous system: **Drowsiness, dizziness**, CNS depression, increased intracranial pressure, agitation, sedation

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone

Gastrointestinal: **Constipation**, nausea, vomiting, biliary tract spasm

Genitourinary: Urinary retention, ADH release, urinary tract spasm

Neuromuscular & skeletal: **Weakness**

Ocular: Miosis

Respiratory: Apnea, respiratory depression

Miscellaneous: Physical and psychological dependence, histamine release

Pharmacodynamics/Kinetics

In terms of opium:

Metabolism: Hepatic

Excretion: Urine (primarily as morphine glucuronide conjugates and unchanged drug - morphine, codeine, papaverine, etc)

Dosage

Oral:

Neonatal opiate withdrawal: 3-6 drops every 3-6 hours as needed, or initially 0.2 mL every 3 hours; increase dosage by approximately 0.05 mL every 3 hours until withdrawal symptoms are controlled; it is rare to exceed 0.7 mL/dose. Stabilize withdrawal symptoms for 3-5 days, then gradually decrease dosage over a 2- to 4-week period.

Children: 0.25-0.5 mL/kg 1-4 times/day

Adults: 5-10 mL 1-4 times/day

Stability Store in light-resistant, tightly closed container

Contraindications Hypersensitivity to opium or any component of the formulation; diarrhea caused by poisoning until the toxic material has been removed; pregnancy (prolonged use or high doses)

Warnings Use with caution in patients with respiratory, hepatic or renal dysfunction, severe prostatic hyperplasia, or history of narcotic abuse; opium shares the toxic potential of opiate agonists, and usual precautions of opiate agonist therapy should be observed; some preparations contain sulfites which may cause allergic reactions; infants <3 months of age are more susceptible to respiratory depression, use with caution and generally in reduced doses in this age group; tolerance or drug dependence may result from extended use

Dosage Forms Liquid, oral: Morphine equivalent 2 mg/5 mL (473 mL) [equivalent to opium 20 mg powder; contains alcohol 45% and benzoic acid]

Overdosage/Treatment Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at $\frac{2}{3}$ the response dose/hour) may be required

Antidote(s)

● Naloxone [ANTIDOTE]

Test Interactions ↑ aminotransferases (ALT, AST) (S)

Drug Interactions Increased effect/toxicity with CNS depressants (eg, alcohol, narcotics, benzodiazepines, TCAs, MAO inhibitors, phenothiazine)

Pregnancy Risk Factor B/D (prolonged use or high doses)

PAROXETINE

Lactation Enters breast milk/use caution

Nursing Implications Observe patient for excessive sedation, respiratory depression, implement safety measures, assist with ambulation

Additional Information Contains morphine 0.4 mg/mL and alcohol 45%

Paroxetine

Related Information

● Antidepressant Agents

CAS Number 61869-08-7; 78246-49-8

U.S. Brand Names Paxil CR™; Paxil®; Pexeva™

Synonyms Paroxetine Hydrochloride; Paroxetine Mesylate

Impairment Potential Yes

Use

Treatment of depression in adults; treatment of panic disorder with or without agoraphobia; obsessive-compulsive disorder (OCD) in adults; social anxiety disorder (social phobia); generalized anxiety disorder (GAD); post-traumatic stress disorder (PTSD)

Paxil CR™: Treatment of depression; panic disorder; premenstrual dysphoric disorder (PMDD), social anxiety disorder (social phobia)

Unlabeled/Investigational Use May be useful in eating disorders, impulse control disorders, self-injurious behavior; premenstrual disorders, vasomotor symptoms of menopause; treatment of depression and obsessive-compulsive disorder (OCD) in children

Mechanism of Action Paroxetine is a selective serotonin reuptake inhibitor (similar to fluvoxamine maleate), chemically unrelated to tricyclic, tetracyclic, or other antidepressants; presumably, the inhibition of serotonin reuptake from brain synapse stimulated serotonin activity in the brain; a phenylpiperidine derivative

Adverse Reactions

Cardiovascular: Bradycardia, hypotension, palpitations, vasodilation, hypotension (orthostatic), sinus bradycardia, sinus tachycardia, atrial fibrillation, bradycardia, bundle branch block, torsade de pointes, ventricular fibrillation, ventricular tachycardia

Central nervous system: **Headache, somnolence, dizziness, insomnia,** nervousness, anxiety, exacerbation of parkinsonism, extrapyramidal reaction, akathisia, electroencephalogram abnormalities, exacerbation of migraine headaches, fever, hyperthermia, somnambulism, mania, eclampsia, Guillain-Barré syndrome, neuroleptic malignant syndrome, seizures (including status epilepticus), dysphasia, agitation

Dermatologic: Alopecia, toxic epidermal necrolysis, acne, angioedema, xerosis, urticaria, purpura, photosensitivity, ecchymoses, erythema nodosum, exanthem, cutaneous vasculitis, erythema multiforme, exfoliative dermatitis

Endocrine & metabolic: Amenorrhea, syndrome of inappropriate anti-diuretic hormone secretion leading to hyponatremia, serotonin syndrome, decreased libido, hyperglycemia, galactorrhea

Gastrointestinal: **Constipation, diarrhea, nausea, xerostomia,** anorexia, flatulence, vomiting, gastritis, aphthous stomatitis, stomatitis, colitis, dysphagia, pancreatitis

Genitourinary: **Ejaculatory disturbances,** priapism, scrotal pruritus

Hematologic: Granulocytopenia, anemia, leukopenia, neutropenia, agranulocytosis, aplastic anemia, bone marrow aplasia, hemolytic anemia, pancytopenia, porphyria, thrombocytopenia

Hepatic: Reversible elevation of liver enzymes, acute renal failure, hepatic necrosis

Neuromuscular & skeletal: **Weakness,** arthritis, tremors, paresthesia, clonus, myoclonus, chorea, akinesia, myasthenia

Ocular: Eye pain, acute angle-closure glaucoma, aggravation of glaucoma, optic neuritis, blurred vision

Otic: Ear pain

Respiratory: Asthma, rhinitis, allergic alveolitis, laryngospasm, pulmonary hypertension

Miscellaneous: **Diaphoresis,** bruxism, thirst, restless legs syndrome, withdrawal reactions (dizziness, sensory disturbances [eg, paresthesias such as electric shock sensations; agitation; anxiety; nausea; diaphoresis] particularly following abrupt withdrawal), anaphylactoid reaction

Signs and Symptoms of Overdose Anxiety, confusion, diarrhea, dyspepsia, ejaculatory disturbances, extrapyramidal reaction, fatigue, hyponatremia, hypotension, insomnia, priapism, tachycardia, urinary frequency

Admission Criteria/Prognosis Admit pediatric ingestions >120 mg

Pharmacodynamics/Kinetics

Absorption: Completely absorbed following oral administration

Distribution: V_d : 8.7 L/kg (3-28 L/kg)

Protein binding: 93% to 95%

Metabolism: Extensively hepatic via CYP enzymes via oxidation and methylation; nonlinear pharmacokinetics may be seen with higher doses and longer duration of therapy. Saturation of CYP2D6 appears to account for the nonlinearity. C_{min} concentrations 70% to 80% greater in the elderly compared to nonelderly patients; clearance is also decreased.

Half-life elimination: 21 hours (3-65 hours)

Time to peak, serum: Immediate release: 5.2 hours; controlled release: 6-10 hours

Excretion: Urine (64%, 2% as unchanged drug); feces (36% primarily via bile)

Dosage Oral:

Children:

Depression (unlabeled use; not recommended by FDA): Initial: 10 mg/day and adjusted upward on an individual basis to 20 mg/day
OCD (unlabeled use): Initial: 10 mg/day and titrate up as necessary to 60 mg/day

Self-injurious behavior (unlabeled use): 20 mg/day

Social phobia (unlabeled use): 2.5-15 mg/day

Adults:

Depression:

Paxil®, Pexeva™: Initial: 20 mg once daily, preferably in the morning; increase if needed by 10 mg/day increments at intervals of at least 1 week; maximum dose: 50 mg/day

Paxil CR™: Initial: 25 mg once daily; increase if needed by 12.5 mg/day increments at intervals of at least 1 week; maximum dose: 62.5 mg/day

GAD (Paxil®): Initial: 20 mg once daily, preferably in the morning; doses of 20-50 mg/day were used in clinical trials, however, no greater benefit was seen with doses >20 mg. If dose is increased, adjust in increments of 10 mg/day at 1-week intervals.

OCD (Paxil®, Pexeva™): Initial: 20 mg once daily, preferably in the morning; increase if needed by 10 mg/day increments at intervals of at least 1 week; recommended dose: 40 mg/day; range: 20-60 mg/day; maximum dose: 60 mg/day

Panic disorder:

Paxil®, Pexeva™: Initial: 10 mg once daily, preferably in the morning; increase if needed by 10 mg/day increments at intervals of at least 1 week; recommended dose: 40 mg/day; range: 10-60 mg/day; maximum dose: 60 mg/day

Paxil CR™: Initial: 12.5 mg once daily; increase if needed by 12.5 mg/day at intervals of at least 1 week; maximum dose: 75 mg/day

PMDD (Paxil CR™): Initial: 12.5 mg once daily in the morning; may be increased to 25 mg/day; dosing changes should occur at intervals of at least 1 week. May be given daily throughout the menstrual cycle or limited to the luteal phase.

PTSD (Paxil®): Initial: 20 mg once daily, preferably in the morning; increase if needed by 10 mg/day increments at intervals of at least 1 week; range: 20-50 mg

Social anxiety disorder:

Paxil®: Initial: 20 mg once daily, preferably in the morning; recommended dose: 20 mg/day; range: 20-60 mg/day; doses >20 mg may not have additional benefit

Paxil CR™: Initial: 12.5 mg once daily, preferably in the morning; may be increased by 12.5 mg/day at intervals of at least 1 week; maximum dose: 37.5 mg/day

Vasomotor symptoms of menopause (unlabeled use, Paxil CR™): 12.5-25 mg/day

Elderly: C_{min} concentrations 70% to 80% greater in the elderly compared to nonelderly patients; clearance is also decreased.

Paxil®, Pexeva™: Initial: 10 mg/day; increase if needed by 10 mg/day increments at intervals of at least 1 week; maximum dose: 40 mg/day

Paxil CR™: Initial: 12.5 mg/day; increase if needed by 12.5 mg/day increments at intervals of at least 1 week; maximum dose: 50 mg/day

Note: Upon discontinuation of paroxetine therapy, gradually taper dose:

Paxil®: Taper-phase regimen used in PTSD/GAD clinical trials involved an incremental decrease in the daily dose by 10 mg/day at weekly intervals; when 20 mg/day dose was reached, this dose was continued for 1 week before treatment was discontinued.

Paxil CR™: Patients receiving 37.5 mg/day in clinical trials had their dose decreased by 12.5 mg/day to a dose of 25 mg/day and remained at a dose of 25 mg/day for 1 week before treatment was discontinued.

Dosage adjustment in severe renal/hepatic impairment: Adults:

Cl_{cr} <30 mL/minute: Mean plasma concentration is ~4 times that seen in normal function.

Cl_{cr} 30-60 mL/minute and hepatic dysfunction: Plasma concentration is 2 times that seen in normal function.

Paxil®, Pexeva™: Initial: 10 mg/day; increase if needed by 10 mg/day increments at intervals of at least 1 week; maximum dose: 40 mg/day

Paxil CR™: Initial: 12.5 mg/day; increase if needed by 12.5 mg/day increments at intervals of at least 1 week; maximum dose: 50 mg/day

Monitoring Parameters Mental status for depression, suicidal ideation (especially at the beginning of therapy or when doses are increased or decreased), anxiety, social functioning, mania, panic attacks; akathisia

Administration May be administered with or without food. Do not crush, break, or chew controlled release tablets.

Contraindications Hypersensitivity to paroxetine or any component of the formulation; use of MAO inhibitors or within 14 days; concurrent use with thioridazine or pimozide

Warnings *Major psychiatric warnings:*

- **[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders;** consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. A medication guide concerning the use of antidepressants in children and teenagers should be dispensed with each prescription. **Paroxetine is not FDA approved for use in children.**
- A higher incidence of suicidal behaviors has been observed in young adults receiving paroxetine for both depressive and nondepressive indications.
- The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Patients treated with antidepressants (for any indication) should be observed for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy.
- Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression or psychosis occur.
- May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Paroxetine is not FDA approved for the treatment of bipolar depression.**

Key adverse effects:

- Serotonin syndrome: Symptoms of agitation, confusion, hallucinations, hyperreflexia, myoclonus, shivering, and tachycardia may occur with concomitant proserotonergic drugs or agents which reduce paroxetine's metabolism. Concurrent use of serotonin precursors (eg, tryptophan) is not recommended.
- Akathisia: Inability to remain still due to feelings of agitation or restlessness has been observed with paroxetine and other SSRIs. Usually occurs within the first few weeks of therapy.
- Anticholinergic effects: Has low potential for sedation and anticholinergic effects relative to cyclic antidepressants; however among the SSRI class these effects are relatively higher.
- CNS depression: Has a low potential to impair cognitive or motor performance; caution operating hazardous machinery or driving.
- SIADH and hyponatremia: Has been associated with the development of SIADH; hyponatremia has been reported rarely, predominantly in the elderly

Concurrent disease:

- Cardiovascular disease: Use caution in patients with cardiovascular disease; paroxetine has not been systemically evaluated in patients with a recent history of MI or unstable heart disease.
- Hepatic impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.
- Narrow-angle glaucoma: Associated with an increased risk of mydriasis in patients with controlled narrow angle glaucoma.
- Platelet aggregation: May impair platelet aggregation, resulting in bleeding.
- Renal impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.
- Seizure disorders: Use caution with a previous seizure disorder or condition predisposing to seizures such as brain damage or alcoholism.
- Sexual dysfunction: May cause or exacerbate sexual dysfunction.

Concurrent drug therapy:

- Agents which lower seizure threshold: Concurrent therapy with other drugs which lower the seizure threshold.
- Anticoagulants/Antiplatelets: Use caution with concomitant use of NSAIDs, ASA, or other drugs that affect coagulation; the risk of bleeding is potentiated.
- CNS depressants: Use caution with concomitant therapy.
- MAO inhibitors: Potential for severe reaction when used with MAO inhibitors; autonomic instability, coma, death, delirium, diaphoresis, hyperthermia, mental status changes/agitation, muscular rigidity, myoclonus, neuroleptic malignant syndrome features, and seizures may occur. Concurrent use with paroxetine is contraindicated.

- Thioridazine and pimozide: Potential for QT_c prolongation and arrhythmia; concurrent use of paroxetine with either of these agents is contraindicated.

Special populations:

- Elderly: Use caution in elderly patients.
- Pregnancy: Avoid use in the first trimester.

Special notes:

- Electroconvulsive therapy: May increase the risks associated with electroconvulsive therapy; consider discontinuing, when possible, prior to ECT treatment.
- Withdrawal syndrome: May cause dysphoric mood, irritability, agitation, dizziness, sensory disturbances, anxiety, confusion, headache, lethargy, emotional lability, insomnia, hypomania, tinnitus, and seizures. Upon discontinuation of paroxetine therapy, gradually taper dose. If intolerable symptoms occur following a decrease in dosage or upon discontinuation of therapy, then resuming the previous dose with a more gradual taper should be considered.

Dosage Forms

Note: Available as paroxetine hydrochloride or mesylate; mg strength refers to paroxetine

Suspension, oral, as hydrochloride (Paxil®): 10 mg/5 mL (250 mL) [orange flavor]

Tablet, as hydrochloride (Paxil®): 10 mg, 20 mg, 30 mg, 40 mg

Tablet, as mesylate (Pexeva®): 10 mg, 20 mg, 30 mg, 40 mg

Tablet, controlled release, as hydrochloride (Paxil CR®): 12.5 mg, 25 mg, 37.5 mg

Reference Range Oral doses of 40 mg produced a peak serum level of 26.6 ng/mL; postmortem blood levels following overdose range from 0.993-4.0 mg/L. Postmortem blood paroxetine level >0.4 mg/L may indicate that this drug was the cause of death.

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Crystalloid infusion for hypotension; amantadine (100-200 mg 2 times/day) has been used successfully in treating sexual dysfunction; bruxism can be treated with buspirone (5 mg at night)

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Test Interactions ↑ LFTs; ↓ sodium (especially in elderly)

Drug Interactions

Substrate of CYP2D6 (major); **Inhibits** CYP1A2 (weak), 2B6 (moderate), 2C9 (weak), 2C19 (weak), 2D6 (strong), 3A4 (weak)

Amphetamines: SSRIs may increase the sensitivity to amphetamines, and amphetamines may increase the risk of serotonin syndrome.

Aspirin (and other antiplatelet drugs): Concomitant use of paroxetine and NSAIDs, aspirin, or other drugs affecting coagulation has been associated with an increased risk of bleeding; monitor.

Atomoxetine: Paroxetine may increase the levels/effects; dose reduction of atomoxetine may be required.

Buspirone: Combined use with SSRIs may cause serotonin syndrome.

Carbamazepine: May increase levels/effects of paroxetine; monitor.

Carvedilol: Serum concentrations may be increased; monitor carefully for increased carvedilol effect (hypotension and bradycardia).

Cimetidine: Cimetidine may reduce the first-pass metabolism of paroxetine resulting in elevated paroxetine serum concentrations; consider an alternative H₂ antagonist.

Clozapine: May increase serum levels of clozapine; monitor for increased effect/toxicity.

CYP2B6 substrates: Paroxetine may increase the levels/effects of CYP2B6 substrates. Example substrates include bupropion, promethazine, propofol, selegiline, and sertraline.

CYP2D6 inhibitors: May increase the levels/effects of paroxetine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP2D6 substrates: Paroxetine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Paroxetine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

Cyproheptadine: May inhibit the effects of serotonin reuptake inhibitors; monitor for altered antidepressant response; cyproheptadine acts as a serotonin agonist.

Dextromethorphan: Metabolism of dextromethorphan may be inhibited; visual hallucinations occurred; monitor.

Galantamine: Paroxetine may increase levels/effects; monitor.

Haloperidol: Metabolism may be inhibited and cause extrapyramidal symptoms (EPS); monitor patients for EPS if combination is utilized.

HMG-CoA reductase inhibitors: Metabolism may be inhibited by SSRIs; particularly lovastatin and simvastatin resulting in myositis and rhabdomyolysis; paroxetine appears to have weak interaction with CYP3A4, and therefore, appears to have a low risk of this interaction.

- Lithium:** Patients receiving SSRIs and lithium have developed neurotoxicity; if combination is used; monitor for neurotoxicity.
- Loop diuretics:** SSRIs may cause hyponatremia; additive hyponatremic effects may be seen with combined use of a loop diuretic (bumetanide, furosemide, torsemide); monitor for hyponatremia.
- MAO inhibitors:** SSRIs should not be used with nonselective MAO inhibitors (isocarboxazid, phenelzine); fatal reactions have been reported; this combination should be avoided.
- Meperidine:** Combined use may cause serotonin syndrome; monitor.
- Nefazodone and trazodone:** May increase the risk of serotonin syndrome with SSRIs; monitor.
- NSAIDs:** Concomitant use of paroxetine and NSAIDs, aspirin, or other drugs affecting coagulation has been associated with an increased risk of bleeding; monitor.
- Phenytoin:** Metabolism of phenytoin may be inhibited, resulting in phenytoin toxicity; monitor for toxicity (ataxia, confusion, dizziness, nystagmus, involuntary muscle movement).
- Pimozide:** Paroxetine may increase the levels/effects; concomitant use contraindicated.
- Procyclidine:** Paroxetine increases AUC of procyclidine by 35%; this may result in increased anticholinergic effects; procyclidine dose reduction may be necessary.
- Risperidone:** Paroxetine, a potent CYP2D6 inhibitor, inhibits the metabolism of risperidone (CYP2D6 substrate) resulting in elevated plasma risperidone levels. The clinical implications are unclear, but clinicians should monitor for potential extrapyramidal symptoms (EPS).
- Ritonavir:** Combined use of paroxetine with ritonavir may cause serotonin syndrome; monitor.
- Selegiline:** SSRIs have been reported to cause mania or hypertension when combined with selegiline; this combination is best avoided; concurrent use with SSRIs has also been reported to cause serotonin syndrome; as an MAO type B inhibitor, the risk of serotonin syndrome may be less than with nonselective MAO inhibitors.
- Serotonergic uptake inhibitors:** Combined use with other drugs which inhibit the reuptake may cause serotonin syndrome.
- Sibutramine:** May increase the risk of serotonin syndrome with SSRIs; avoid coadministration.
- Sumatriptan (and other serotonin agonists):** Concurrent use may result in toxicity; weakness, hyper-reflexia, and incoordination have been observed with sumatriptan and SSRIs. In addition, concurrent use may theoretically increase the risk of serotonin syndrome; includes sumatriptan, naratriptan, rizatriptan, and zolmitriptan.
- Sympathomimetics:** May increase the risk of serotonin syndrome with SSRIs.
- Theophylline:** Paroxetine may elevate serum levels of theophylline; monitor.
- Thioridazine:** Paroxetine may inhibit the metabolism of thioridazine, resulting in increased plasma levels and increasing the risk of QTc interval prolongation. Concurrent use is contraindicated.
- Tramadol:** Combined use may cause serotonin syndrome; monitor.
- Tricyclic antidepressants:** The metabolism of tricyclic antidepressants (amitriptyline, desipramine, imipramine, nortriptyline) may be inhibited by SSRIs resulting in elevated serum levels; if combination is warranted, a low dose of TCA (10-25 mg/day) should be utilized.
- Tryptophan:** May increase serotonergic effects; concomitant use not recommended.
- Venlafaxine:** Combined use with paroxetine may increase the risk of serotonin syndrome.
- Warfarin:** May alter the hypoprothrombinemic response to warfarin; monitor INR.
- Zolpidem:** At least one case of acute delirium in association with combined therapy has been reported.
- Pregnancy Risk Factor C**
- Pregnancy Implications** Teratogenic effects were not observed in animal studies. Nonteratogenic effects including respiratory distress, cyanosis, apnea, seizures, temperature instability, feeding difficulty, and tremor have been reported in the neonate immediately following delivery. Adverse effects may be due to toxic effects of SSRI or drug discontinuation. There are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if the potential benefit to the mother outweighs the possible risk to the fetus. If treatment during pregnancy is required, consider tapering therapy during the third trimester.
- Lactation** Enters breast milk/use caution (AAP rates "of concern")
- Additional Information** Paxil CR™ incorporates a degradable polymeric matrix (Geomatrix™) to control dissolution rate over a period of 4-5 hours. An enteric coating delays the start of drug release until tablets have left the stomach. Paroxetine has properties similar to fluvoxamine maleate. Buspirone (15-60 mg/day) may be useful in treatment of sexual dysfunction during treatment with a selective serotonin reuptake inhibitor.

Pemoline

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 18968-99-5; 2152-34-3; 68942-31-4

U.S. Brand Names Cylert®; PemADD® CT; PemADD®

Synonyms Phenylisohydantoin; PIO

Impairment Potential Yes

Use Controlling undirected hyperkinetic behavior; treat narcolepsy and antihistamine-induced drowsiness

Unlabeled/Investigational Use Narcolepsy

Mechanism of Action Sympathetic amine similar in action to amphetamines; central nervous system stimulant

Adverse Reactions

Central nervous system: **Insomnia**, stuttering

Endocrine & metabolic: Growth suppression

Gastrointestinal: **Anorexia, weight loss**

Hepatic: Fulminant liver failure (4-17 times general population rate)

Signs and Symptoms of Overdose Anorexia, choreoathetosis, dyskinesias, elevated liver function tests (1% to 2%), exacerbation of Tourette's syndrome, hallucinations (visual, tactile, and auditory), hyperthermia, insomnia, leukocytosis, mania, mydriasis, neutropenia, nystagmus, rhabdomyolysis, stuttering, vomiting

Pharmacodynamics/Kinetics

Onset of action: Peak effect: 4 hours

Duration: 8 hours

Protein binding: 50%

Metabolism: Partially hepatic

Half-life elimination: Children: 7-8.6 hours; Adults: 12 hours

Time to peak, serum: 2-4 hours

Excretion: Urine; feces (negligible amounts)

Dosage Oral: Initial: 37.5 mg increasing by 18.75 mg weekly; usual dose: 56.25-75 mg/day; maximum: 112.5 mg

Monitoring Parameters Liver enzymes (baseline and every 2 weeks)

Administration Administer medication in the morning.

Contraindications Hypersensitivity to pemoline or any component of the formulation; hepatic impairment (including abnormalities on baseline liver function tests); children < 6 years of age; Tourette's syndrome; psychosis

Warnings

[U.S. Boxed Warning]: Not considered first-line therapy for ADHD due to association with hepatic failure. The manufacturer has recommended that signed informed consent following a discussion of risks and benefits must or should be obtained prior to the initiation of therapy. Therapy should be discontinued if a response is not evident after 3 weeks of therapy. Pemoline should not be started in patients with abnormalities in baseline liver function tests, and should be discontinued if clinically significant liver function test abnormalities are revealed at any time during therapy. Use with caution in patients with renal dysfunction or psychosis. In general, stimulant medications should be used with caution in patients with bipolar disorder, diabetes mellitus, cardiovascular disease, seizure disorders, insomnia, porphyria, or hypertension (although pemoline has been demonstrated to have a low potential to elevate blood pressure relative to other stimulants). May exacerbate symptoms of behavior and thought disorder in psychotic patients. Potential for drug dependency exists - avoid abrupt discontinuation in patients who have received for prolonged periods. Stimulant use has been associated with growth suppression, and careful monitoring is recommended. Stimulants may unmask tics in individuals with coexisting Tourette's syndrome.

Dosage Forms [DSC] = Discontinued product

Tablet (Cylert® [DSC], PemADD® [DSC]): 18.75 mg, 37.5 mg, 75 mg
Tablet, chewable (Cylert® [DSC], PemADD® CT [DSC]): 37.5 mg

Reference Range Therapeutic plasma range: 1-7 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: Diazepam can be used to treat choreoathetosis and may be more effective than benzotropine; alkaline diuresis with a diuretic (mannitol or furosemide) should be used to prevent renal failure due to rhabdomyolysis

Test Interactions May produce false acid phosphatase elevations

Drug Interactions Anticonvulsants: Pemoline may decrease seizure threshold; efficacy of anticonvulsants may be decreased

CNS depressants: Effects may be additive; use caution when pemoline is used with other CNS acting medications

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown/not recommended

Additional Information Choreiform movements can occur in children at doses as low as 2 mg/kg; similar to dexamphetamine sulfate

Warnings Avoid abrupt discontinuation in patients with a history of CAD; slowly wean while monitoring for signs and symptoms of ischemia. Use caution with concurrent use of beta-blockers and either verapamil or diltiazem; bradycardia or heart block can occur. Use caution in patients with PVD (can aggravate arterial insufficiency). Use cautiously in diabetics because it can mask prominent hypoglycemic symptoms. Can mask signs of thyrotoxicosis. Can cause fetal harm when administered in pregnancy. Beta-blockers with intrinsic sympathomimetic activity (including penbutolol) do not appear to be of benefit in CHF.

Dosage Forms Tablet, as sulfate: 20 mg

Reference Range 50 mg dose results in peak serum concentration of 770 ng/mL after 1 hour

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Sympathomimetics (eg, epinephrine or dopamine), atropine, glucagon, or a pacemaker can be used to treat the toxic bradycardia, asystole, and/or hypotension; initially fluids may be the best treatment for toxic hypotension

Enhancement of elimination: Charcoal hemoperfusion can be used to lower serum levels

Drug Interactions Alpha-blockers (prazosin, terazosin): Concurrent use of beta-blockers may increase risk of orthostasis.

Albuterol (and other beta₂ agonists): Effects may be blunted by nonspecific beta-blockers.

Clonidine: Hypertensive crisis after or during withdrawal of either agent.

Drugs which slow AV conduction (digoxin): Effects may be additive with beta-blockers.

Epinephrine (including local anesthetics with epinephrine): Penbutolol may cause hypertension.

Glucagon: Penbutolol may blunt the hyperglycemic action.

Insulin and oral hypoglycemics: May mask symptoms of hypoglycemia.

NSAIDs (ibuprofen, indomethacin, naproxen, piroxicam) may reduce the antihypertensive effects of beta-blockers.

Penbutolol masks the tachycardia that usually accompanies insulin-induced hypoglycemia.

Salicylates may reduce the antihypertensive effects of beta-blockers.

Sulfonyleureas: beta-blockers may alter response to hypoglycemic agents.

Verapamil or diltiazem may have synergistic or additive pharmacological effects when taken concurrently with beta-blockers.

Pregnancy Risk Factor C (manufacturer); D (2nd and 3rd trimester - expert analysis)

Lactation Enters breast milk/use caution

Usage Implications Advise against abrupt withdrawal

Monitor orthostatic blood pressures, apical and peripheral pulse and mental status changes (ie, confusion, depression)

Specific References

Chobanian AV, Bakris GL, Black HR, et al, "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, 289(19):2560-71.

Penbutolol

Related Information

- Selected Properties of Beta-Adrenergic Blocking Drugs

CAS Number 38363-32-5; 38363-40-5

U.S. Brand Names Levatol®

Synonyms Penbutolol Sulfate

Use Treatment of mild to moderate arterial hypertension

Mechanism of Action Blocks both beta₁- and beta₂-receptors and has mild intrinsic sympathomimetic activity; has negative inotropic and chronotropic effects and can significantly slow AV nodal conduction

Adverse Reactions

Cardiovascular: Exacerbation of Raynaud's phenomenon, hypotension, congestive heart failure, AV block, chest pain, edema, heart failure, sinus bradycardia, angina, myocardial depression, QRS prolongation

Central nervous system: Nightmares, fatigue, insomnia, ataxia, drowsiness, CNS depression, confusion, dizziness, headache

Dermatologic: Alopecia, purpura, pruritus, psoriasis, exanthem

Gastrointestinal: Constipation, abdominal pain, diarrhea, nausea, vomiting

Genitourinary: Impotence, nocturia, enuresis

Ocular: Diplopia

Miscellaneous: Cold extremities

Pharmacodynamics/Kinetics

Absorption: ~ 100%

Protein binding: 80% to 98%

Metabolism: Extensively hepatic (oxidation and conjugation)

Bioavailability: ~ 100%

Half-life elimination: 5 hours

Excretion: Urine

Dosage Adults: Oral: Initial: 20 mg once daily, full effect of a 20 or 40 mg dose is seen by the end of a 2-week period, doses of 40-80 mg have been tolerated but have shown little additional antihypertensive effects; usual dose range (JNC 7): 10-40 mg once daily

Contraindications Hypersensitivity to penbutolol or any component of the formulation; uncompensated congestive heart failure; cardiogenic shock; bradycardia or heart block (except in patients with a functioning artificial pacemaker); sinus node dysfunction; asthma; bronchospastic disease; COPD; pulmonary edema; pregnancy (2nd and 3rd trimester)

Penicillin G (Parenteral/Aqueous)

CAS Number 113-98-4; 61-33-6; 69-57-8

U.S. Brand Names Pfizerpen®

Synonyms Benzylpenicillin Potassium; Benzylpenicillin Sodium; Crystalline Penicillin; Penicillin G Potassium; Penicillin G Sodium

Use Active against most gram-positive organisms except *Staphylococcus aureus*; some gram-negative such as *Neisseria gonorrhoeae* and some anaerobes and spirochetes; although ceftriaxone is now the drug of choice for Lyme disease and gonorrhea

Mechanism of Action Interferes with bacterial cell wall synthesis during active multiplication, causing cell wall death and resultant bactericidal activity against susceptible bacteria

Adverse Reactions

Cardiovascular: Myocarditis (hypersensitivity), myocarditis, vasculitis

Central nervous system: Convulsions, anxiety, confusion, drowsiness, fever, Jarisch-Herxheimer reaction, hyperthermia, aseptic meningitis

Dermatologic: Rash, angioedema, urticaria, dermatographism, cutis laxa, systemic contact dermatitis, immunologic contact urticaria, acute generalized exanthematous pustulosis, alopecia, toxic epidermal necrolysis, purpura, Stevens-Johnson syndrome, pruritus, exanthem

Endocrine & metabolic: Electrolyte imbalance, hypernatremia with sodium salt, hyperkalemia with potassium salt

Gastrointestinal: Nausea, diarrhea, pseudomembranous colitis, metallic taste, esophagitis

Hematologic: Hemolytic anemia, positive Coombs' reaction, neutropenia, thrombocytopenia

Hepatic: Granulomatous hepatitis, cholestasis, aminotransferase level elevation (asymptomatic)

Local: Thrombophlebitis

Neuromuscular & skeletal: Myoclonus

Renal: Acute interstitial nephritis (after large I.V. doses)

Respiratory: Asthma, bronchospasm

PENTAMIDINE

Miscellaneous: Hypersensitivity reactions, anaphylaxis (0.05% frequency with injection), total allergic reactions (1% to 10%), lymphadenopathy, mucocutaneous syndrome (febrile)

Signs and Symptoms of Overdose Colitis, dyspnea, eosinophilia, coagulopathy, leukopenia or neutropenia (agranulocytosis, granulocytopenia); pemphigus, periarteritis nodosa, pseudotumor cerebri, tongue discoloration

Pharmacodynamics/Kinetics

Distribution: Poor penetration across blood-brain barrier, despite inflamed meninges; crosses placenta; enters breast milk
Relative diffusion from blood into CSF: Good only with inflammation (exceeds usual MICs)

CSF:blood level ratio: Normal meninges: <1%; Inflamed meninges: 3% to 5%

Protein binding: 65%

Metabolism: Hepatic (30%) to penicilloic acid

Half-life elimination:

Neonates: <6 days old: 3.2-3.4 hours; 7-13 days old: 1.2-2.2 hours; >14 days old: 0.9-1.9 hours

Children and Adults: Normal renal function: 20-50 minutes

End-stage renal disease: 3.3-5.1 hours

Time to peak, serum: I.M.: ~30 minutes; I.V. ~1 hour

Excretion: Urine

Dosage

I.M., I.V. (do not give intrathecal):

Neonates:

Postnatal age <7 days:

<2000 g: 25,000 units/kg/dose every 12 hours; meningitis: 50,000 units/kg/dose every 12 hours

>2000 g: 20,000 units/kg/dose every 8 hours; meningitis: 50,000 units/kg/dose every 8 hours

Postnatal age >7 days:

<1200 g: 25,000 units/kg/dose every 12 hours; meningitis: 50,000 units/kg/dose every 12 hours

1200-2000 g: 25,000 units/kg/dose every 8 hours; meningitis: 75,000 units/kg/dose every 8 hours

>2000 g: 25,000 units/kg/dose every 6 hours; meningitis: 50,000 units/kg/dose every 6 hours

Infants and Children (sodium salt is preferred in children): 100,000-250,000 units/kg/day in divided doses every 4 hours; maximum: 4.8 million units/24 hours

Severe infections: Up to 400,000 units/kg/day in divided doses every 4 hours; maximum dose: 24 million units/day

Adults: 2-24 million units/day in divided doses every 4 hours

Dosing interval in renal impairment:

Cl_{cr} 30-50 mL/minute: Administer every 6 hours

Cl_{cr} 10-30 mL/minute: Administer every 8 hours

Cl_{cr} <10 mL/minute: Administer every 12 hours

Stability Reconstituted parenteral solution is stable for 7 days when refrigerated; for I.V. infusion in NS or D₅W, solution is stable for 24 hours at room temperature; thawed solutions stable for 24 hours at room temperature or 14 days at refrigeration

Monitoring Parameters Observe for signs and symptoms of anaphylaxis during first dose

Administration Administer I.M. by deep injection in the upper outer quadrant of the buttock

Contraindications Hypersensitivity to penicillin or any component of the formulation

Warnings Avoid intra-arterial administration or injection into or near major peripheral nerves or blood vessels since such injections may cause severe and/or permanent neurovascular damage; use with caution in patients with renal impairment (dosage reduction required), pre-existing seizure disorders, or with a history of hypersensitivity to cephalosporins

Dosage Forms Infusion, as potassium [premixed iso-osmotic dextrose solution, frozen]: 1 million units (50 mL), 2 million units (50 mL), 3 million units (50 mL) [contains sodium 1.02 mEq and potassium 1.7 mEq per 1 million units]

Injection, powder for reconstitution, as potassium (Pfizerpen®): 5 million units, 20 million units [contains sodium 6.8 mg (0.3 mEq) and potassium 65.6 mg (1.68 mEq) per 1 million units]

Injection, powder for reconstitution, as sodium: 5 million units [contains sodium 1.68 mEq per 1 million units]

Reference Range After 500 mg oral dose, peak plasma level is 1.5-2.7 mg/L

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage within 1 hour (rarely necessary)/activated charcoal can be used

Supportive therapy: Allergic reactions can be treated with epinephrine, diphenhydramine, and corticosteroids

Enhancement of elimination: Hemodialysis or charcoal hemoperfusion can be useful in removing penicillin; moderately dialyzable (20% to 50%)

Antidote(s)

- Epinephrine [ANTIDOTE]

Diagnostic Procedures

- Electrolytes, Urine

Test Interactions False-positive or negative urinary glucose determination using Clinistest®; positive Coombs' [direct]; false-positive urinary and/or serum proteins; interferes with the Guthrie test for phenylketonuria

Drug Interactions Aminoglycosides: May be synergistic against selected organisms

Methotrexate: Penicillins may increase the exposure to methotrexate during concurrent therapy; monitor.

Oral contraceptives: Anecdotal reports suggesting decreased contraceptive efficacy with penicillins have been refuted by more rigorous scientific and clinical data.

Probenecid, disulfiram: May increase penicillin levels

Tetracyclines: May decrease penicillin effectiveness

Warfarin: Effects of warfarin may be increased

Pregnancy Risk Factor B

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk/compatible

Nursing Implications Administer I.M. by deep injection in the upper outer quadrant of the buttock; dosage modification required in patients with renal insufficiency; give around-the-clock to promote less variation in peak and trough levels

Additional Information Toxic dose: 10,000,000 units (or 6 g)

1 million units is approximately equal to 625 mg.

Penicillin G potassium injection:

Potassium content per million units: 65.6 mg (1.7 mEq)

Sodium content per million units: 23.5 mg (1.02 mEq)

Pentamidine

CAS Number 140-64-7

U.S. Brand Names NebuPent®; Pentam-300®

Synonyms Pentamidine Isethionate

Use Treatment and prevention of pneumonia caused by *Pneumocystis carinii* (PCP)

Treatment of trypanosomiasis and visceral leishmaniasis

Mechanism of Action Interferes with RNA/DNA, phospholipids and protein synthesis, through inhibition of oxidative phosphorylation and/or interference with incorporation of nucleotides and nucleic acids into RNA and DNA, in protozoa

Adverse Reactions

Cardiovascular: **Chest pain**, hypotension, tachycardia, hypotension (orthostatic), torsade de pointes, sinus bradycardia, palpitations, sinus tachycardia, arrhythmias (ventricular), vasculitis

Central nervous system: Dizziness, fever, Jarisch-Herxheimer-like reaction, insomnia, gustatory hallucinations

Dermatologic: **Rash**, mucormycosis, Stevens-Johnson syndrome, bullous skin disease, xerosis, urticaria, purpura, pruritus, exanthem

Endocrine & metabolic: **Hyperkalemia**, hypoglycemia, hyperglycemia, hypocalcemia, hyperinsulinemia

Gastrointestinal: Vomiting, metallic taste in mouth, pancreatitis, gagging, hemorrhagic pancreatitis, xerostomia

Hematologic: Megaloblastic anemia, granulocytopenia, leukopenia, thrombocytopenia, eosinophilia

Local: **Pain at injection site**

Renal: Mild renal or hepatic injury, acidosis (renal tubular) type IV

Respiratory: **Cough, dyspnea, pharyngitis, wheezing**, irritation of the airway bronchospasm, rhinitis, eosinophilic pneumonia

Signs and Symptoms of Overdose No published cases of acute oral overdose. Agranulocytosis, anorexia, azotemia, cardiac arrhythmias, conjunctivitis, cough, granulocytopenia, hyperglycemia, hypocalcemia, hypoglycemia, hypomagnesemia, hypotension, leukopenia, myoglobinuria, neutropenia, QT prolongation, rhabdomyolysis, toxic epidermal necrolysis, wheezing

Pharmacodynamics/Kinetics

Absorption: I.M.: Well absorbed; Inhalation: Limited systemic absorption

Distribution: V_d: Steady state: 3-32 L/kg; systemic accumulation of pentamidine does not appear to occur following inhalation therapy

Protein binding: 69%

Half-life elimination: Terminal: 6.4-9.4 hours; may be prolonged with severe renal impairment

Excretion: Urine (33% to 66% as unchanged drug)

Dosage

Children:

Treatment of PCP pneumonia: I.M., I.V. (I.V. preferred): 4 mg/kg/day once daily for 10-14 days

Prevention of PCP pneumonia:

I.M., I.V.: 4 mg/kg monthly or every 2 weeks

Inhalation (aerosolized pentamidine in children ≥ 5 years): 300 mg/dose given every 3-4 weeks via Respigard® II inhaler (8 mg/kg dose has also been used in children < 5 years)

Treatment of trypanosomiasis (unlabeled use): I.V.: 4 mg/kg/day once daily for 10 days

Adults:

Treatment: I.M., I.V. (I.V. preferred): 4 mg/kg/day once daily for 14-21 days

Prevention: Inhalation: 300 mg every 4 weeks via Respigard® II nebulizer

Dialysis: Not removed by hemo or peritoneal dialysis or continuous arteriovenous or venovenous hemofiltration; supplemental dosage is not necessary

Dosing adjustment in renal impairment: Adults: I.V.:

Cl_{cr} 10-50 mL/minute: Administer 4 mg/kg every 24-36 hours

$Cl_{cr} < 10$ mL/minute: Administer 4 mg/kg every 48 hours

Monitoring Parameters Liver function tests, renal function tests, blood glucose, serum potassium and calcium, ECG, blood pressure

Administration

Inhalation: Deliver until nebulizer is gone (30-45 minutes)

I.V.: Infuse slowly over a period of at least 60 minutes or administer deep I.M.

Contraindications Hypersensitivity to pentamidine isethionate or any component of the formulation (inhalation and injection)

Warnings Use with caution in patients with diabetes mellitus, renal or hepatic dysfunction, hyper-/hypotension, leukopenia, thrombocytopenia, asthma, or hypo-/hyperglycemia.

Dosage Forms Injection, powder for reconstitution, as isethionate (Pentam-300®): 300 mg

Powder for nebulization, as isethionate (NebuPent®): 300 mg

Reference Range Peak plasma concentration after 2-hour I.V. infusion of 4 mg/kg pentamidine was 612 ng/mL; plasma concentration of 794 ng/mL obtained after an overdose of 160 mg/kg

Overdosage/Treatment

Supportive therapy: Bronchospasm can be treated with beta-adrenergic agonist agents; diphenhydramine (25 mg) or hydroxyzine hydrochloride (25 mg) can be used to treat pruritus or skin rash

Enhanced elimination: Charcoal hemoperfusion may be useful in enhancing elimination

Diagnostic Procedures

- Creatinine, Serum

Test Interactions \uparrow insulin; \downarrow glucose

Drug Interactions

Substrate of CYP2C19 (major); **Inhibits** CYP2C8/9 (weak), 2C19 (weak), 2D6 (weak), 3A4 (weak)

CYP2C19 inducers: May decrease the levels/effects of pentamidine. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of pentamidine. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

QT_c-prolonging agents: Pentamidine may potentiate the effect of other drugs which prolong QT interval (cisapride, sparfloxacin, gatifloxacin, moxifloxacin, pimozide, and type Ia and type III antiarrhythmics).

Pregnancy Risk Factor C

Pregnancy Implications Based on animal data, the reference doses for embryolethality and for teratogenicity are estimated to be 0.08 mcg/kg/day and 4 mcg/kg/day, respectively. Aerosolized pentamidine can pass embryolethal doses to healthcare workers.

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Infuse I.V. slowly over a period of at least 60 minutes or administer deep I.M.

Additional Information Do not use NS as a diluent; NS is incompatible with pentamidine; infuse over at least 1 hour; hypotension associated with I.V. administration

Cardiovascular: Hypotension, circulatory depression, shock, tachycardia, syncope, flushing

Central nervous system: Malaise, headache, nightmares, insomnia, CNS depression, sedation, hallucinations, confusion, disorientation, dizziness, euphoria, drowsiness, lightheadedness, irritability, chills, excitement

Dermatologic: Rash, pruritus, dermatitis, urticaria, Stevens-Johnson syndrome, toxic epidermal necrolysis, erythema multiforme

Gastrointestinal: Nausea, vomiting, xerostomia, constipation, anorexia, diarrhea, abdominal distress

Genitourinary: Urinary retention

Hematologic: WBCs decreased, eosinophilia

Local: Tissue damage and irritation with I.M./SubQ use

Neuromuscular & skeletal: Weakness, tremor, paresthesia

Ocular: Blurred vision, miosis

Otic: Tinnitus

Respiratory: Dyspnea, respiratory depression (rare)

Miscellaneous: Physical and psychological dependence, facial edema, diaphoresis, anaphylaxis

Signs and Symptoms of Overdose Asterixis, diarrhea, diplopia, dry mouth, erythema multiforme, hypertension, hyperthermia, miosis, myalgia, nephrotic syndrome, nystagmus, respiratory depression, seizures, tachycardia, toxic epidermal necrolysis

Pharmacodynamics/Kinetics

Onset of action: Oral, I.M., SubQ: 15-30 minutes; I.V.: 2-3 minutes

Duration: Oral: 4-5 hours; Parenteral: 2-3 hours

Protein binding: 60%

Metabolism: Hepatic via oxidative and glucuronide conjugation pathways; extensive first-pass effect

Bioavailability: Oral: $\sim 20\%$; increased to 60% to 70% with cirrhosis

Half-life elimination: 2-3 hours; prolonged with hepatic impairment

Excretion: Urine (small amounts as unchanged drug)

Dosage Preoperative/pre-anesthetic: Children 1-16 years: I.M.: 0.5 mg/kg

Analgesia:

Children: I.M.:

5-8 years: 15 mg

8-14 years: 30 mg

Children > 12 years and Adults: Oral: 50 mg every 3-4 hours; may increase to 100 mg/dose if needed, but should not exceed 600 mg/day

Adults:

I.M., SubQ: 30-60 mg every 3-4 hours, not to exceed total daily dose of 360 mg

I.V.: 30 mg every 3-4 hours (maximum: 360 mg/day)

Elderly: Elderly patients may be more sensitive to the analgesic and sedating effects. The elderly may also have impaired renal function. If needed, dosing should be started at the lower end of dosing range and adjust dose for renal function.

Dosing adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer 75% of normal dose

$Cl_{cr} < 10$ mL/minute: Administer 50% of normal dose

Dosing adjustment in hepatic impairment: Reduce dose or avoid use in patients with liver disease

Stability Store at room temperature, protect from heat and from freezing; I.V. form is **incompatible** with aminophylline, amobarbital (and all other I.V. barbiturates), glycopyrrolate (same syringe), heparin (same syringe), nafcillin (Y-site)

Monitoring Parameters Relief of pain, respiratory and mental status, blood pressure

Administration Rotate injection site for I.M., SubQ use; avoid intra-arterial injection; avoid SubQ use unless absolutely necessary (may cause tissue damage)

Contraindications Hypersensitivity to pentazocine, naloxone, or any component of the formulation; increased intracranial pressure (unless the patient is mechanically ventilated); pregnancy (prolonged use or high doses at term)

Warnings Use with caution in seizure-prone patients, acute myocardial infarction, patients undergoing biliary tract surgery, patients with renal and hepatic dysfunction, head trauma, increased intracranial pressure, and patients with a history of prior opioid dependence or abuse; pentazocine may precipitate opiate withdrawal symptoms in patients who have been receiving opiates regularly; injection contains sulfites which may cause allergic reaction; tolerance or drug dependence may result from extended use. **[U.S. Boxed Warning]: Talwin® NX is intended for oral administration only - severe vascular reactions have resulted from misuse by injection.**

Dosage Forms Injection, solution (Talwin®): 30 mg/mL (1 mL, 10 mL) [10 mL size contains sodium bisulfite]

Tablet (Talwin® NX): Pentazocine 50 mg and naloxone 0.5 mg

Reference Range

Therapeutic: 0.05-0.2 mg/L

Fatal: > 1.0 mg/L

Pentazocine

Related Information

- Meptazinol

CAS Number 17146-95-1; 2276-52-0; 359-83-1; 64024-15-3

U.S. Brand Names Talwin® NX; Talwin®

Synonyms Naloxone Hydrochloride and Pentazocine Hydrochloride; Pentazocine Hydrochloride and Naloxone Hydrochloride; Pentazocine Hydrochloride; Pentazocine Lactate

Impairment Potential Yes

Use Relief of moderate to severe pain; has also been used as a sedative prior to surgery and as a supplement to surgical anesthesia

Mechanism of Action Binds to opiate receptors in the CNS, causing inhibition of ascending pain pathways, altering the perception of and response to pain; produces generalized CNS depression; partial agonist-antagonist

Adverse Reactions

Frequency not defined.

PENTOBARBITAL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** induce emesis

Supportive therapy: Naloxone hydrochloride (large doses may be required); seizures can be treated with diazepam, lorazepam, phenytoin, or phenobarbital

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Drug Interactions

May potentiate or reduce analgesic effect of opiate agonist (eg, morphine) depending on patients tolerance to opiates can precipitate withdrawal in narcotic addicts

Increased effect/toxicity with tripeleminamine (can be lethal), CNS depressants (phenothiazines, tranquilizers, anxiolytics, sedatives, hypnotics, or alcohol)

Pregnancy Risk Factor

B/D (prolonged use or high doses at term)
Pregnancy Implications Pentazocine was not found to be teratogenic in animal studies. Pentazocine and naloxone have been shown to cross the human placenta. Use should be avoided during labor and delivery of premature infants. Abstinence syndromes in the newborn have been reported after long-term use of pentazocine during pregnancy. Other adverse effects in the newborn have been reported following abuse of pentazocine during pregnancy; these effects may be due to pentazocine, other drugs abused, the mother's lifestyle, or a combination of all factors.

Lactation

Excretion in breast milk unknown/use caution
Nursing Implications Rotate injection site for I.M., SubQ use; avoid intra-arterial injection; observe patient for excessive sedation, respiratory depression, implement safety measures, assist with ambulation; observe for narcotic withdrawal

Additional Information Lethal oral dose: 0.3 g. Pentazocine hydrochloride: Talwin[®] NX tablet (with naloxone); naloxone is used to prevent abuse by dissolving tablets in water and using as injection; may be combined with tripeleminamine (Ts and blues)

Pentobarbital

CAS Number 57-33-0; 76-74-4

U.S. Brand Names Nembutal[®]

Synonyms Pentobarbital Sodium

Impairment Potential Yes

Use Sedative/hypnotic; preanesthetic; high-dose barbiturate coma for treatment of increased intracranial pressure or status epilepticus unresponsive to other therapy

Mechanism of Action Short-acting barbiturate with sedative, hypnotic, and anticonvulsant properties

Adverse Reactions

Cardiovascular: **Cardiac arrhythmias, hypotension**, sinus bradycardia, congestive heart failure, myocardial depression, **arterial spasm**, vasculitis

Central nervous system: **Drowsiness, CNS stimulation or CNS depression, impaired judgment**, decreased deep tendon reflexes, hypothermia, **lethargy, "hangover" effect**

Dermatologic: Rash, exfoliative dermatitis, erythema multiforme, angioedema, toxic epidermal necrolysis, urticaria, purpura, Stevens-Johnson syndrome, pruritus, erythema nodosum, exanthem, photoallergic reaction

Gastrointestinal: Nausea, vomiting

Local: **Pain at injection site, thrombophlebitis with I.V. use**

Renal: Oliguria

Respiratory: Laryngospasm, respiratory depression, apnea (especially with rapid I.V. use)

Miscellaneous: Physical and psychological dependency with chronic use; **gangrene with inadvertent intra-arterial injection**, systemic lupus erythematosus, fixed drug eruption

Signs and Symptoms of Overdose Bullous skin lesions, confusion, fever, hypoglycemia, hypotension, hypothermia, jaundice, myoglobinuria, ptosis, renal failure, rhabdomyolysis, slurred speech, unsteady gait, vision color changes (green tinge; yellow tinge)

Pharmacodynamics/Kinetics

Onset of action: I.M.: 10-15 minutes; I.V.: ~ 1 minute

Duration: I.V.: 15 minutes

Distribution: V_d: Children: 0.8 L/kg; Adults: 1 L/kg

Protein binding: 35% to 55%

Metabolism: Extensively hepatic via hydroxylation and oxidation pathways

Half-life elimination: Terminal: Children: 25 hours; Adults: Healthy: 22 hours (range: 15-50 hours)

Excretion: Urine (<1% as unchanged drug)

Dosage

Children:

Hypnotic: I.M.: 2-6 mg/kg; maximum: 100 mg/dose

Preoperative/preprocedure sedation: ≥ 6 months:

Note: Limited information is available for infants < 6 months of age.

I.M.: 2-6 mg/kg; maximum: 100 mg/dose

I.V.: 1-3 mg/kg to a maximum of 100 mg until asleep
Conscious sedation prior to a procedure: Children 5-12 years: I.V.: 2 mg/kg 5-10 minutes before procedures, may repeat one time
Adolescents: Conscious sedation: I.V.: 100 mg prior to a procedure
Children and Adults: Barbiturate coma in head injury patients: I.V.: Loading dose: 5-10 mg/kg given slowly over 1-2 hours; monitor blood pressure and respiratory rate; Maintenance infusion: Initial: 1 mg/kg/hour; may increase to 2-3 mg/kg/hour; maintain burst suppression on EEG

Status epilepticus: I.V.: **Note:** Intubation required; monitor hemodynamics

Children: Loading dose: 5-15 mg/kg given slowly over 1-2 hours; maintenance infusion: 0.5-5 mg/kg/hour

Adults: Loading dose: 2-15 mg/kg given slowly over 1-2 hours; maintenance infusion: 0.5-3 mg/kg/hour

Adults:

Hypnotic:

I.M.: 150-200 mg

I.V.: Initial: 100 mg, may repeat every 1-3 minutes up to 200-500 mg total dose

Preoperative sedation: I.M.: 150-200 mg

Dosing adjustment in hepatic impairment: Reduce dosage in patients with severe liver dysfunction

Monitoring Parameters Respiratory status (for conscious sedation, includes pulse oximetry), cardiovascular status, CNS status; cardiac monitor and blood pressure monitor required

Administration Pentobarbital may be administered by deep I.M. or slow I.V. injection.

I.M.: No more than 5 mL (250 mg) should be injected at any one site because of possible tissue irritation.

I.V.: I.V. push doses can be given undiluted, but should be administered no faster than 50 mg/minute; parenteral solutions are highly alkaline; avoid extravasation; avoid rapid I.V. administration >50 mg/minute; avoid intra-arterial injection

Contraindications Hypersensitivity to barbiturates or any component of the formulation; marked hepatic impairment; dyspnea or airway obstruction; porphyria; pregnancy

Warnings

Tolerance to hypnotic effect can occur; do not use for >2 weeks to treat insomnia. Potential for drug dependency exists, abrupt cessation may precipitate withdrawal, including status epilepticus in epileptic patients. Do not administer to patients in acute pain. Use caution in elderly, debilitated, renally impaired, hepatic dysfunction, or pediatric patients. May cause paradoxical responses, including agitation and hyperactivity, particularly in acute pain and pediatric patients. Use with caution in patients with depression or suicidal tendencies, or in patients with a history of drug abuse. Tolerance, psychological and physical dependence may occur with prolonged use.

May cause CNS depression, which may impair physical or mental abilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Effects with other sedative drugs or ethanol may be potentiated. Use of this agent as a hypnotic in the elderly is not recommended due to its long half-life and potential for physical and psychological dependence.

May cause respiratory depression or hypotension, particularly when administered intravenously. Use with caution in hemodynamically unstable patients or patients with respiratory disease. High doses (loading doses of 15-35 mg/kg given over 1-2 hours) have been utilized to induce pentobarbital coma, but these higher doses often cause hypotension requiring vasopressor therapy.

Dosage Forms Injection, solution, as sodium: 50 mg/mL (20 mL, 50 mL) [contains alcohol 10% and propylene glycol 40%]

Reference Range

Hypnotic: 1-5 mcg/mL (SI: 4-22 µmol/L)

Drowsy: 6-10 mcg/mL (SI: 44 µmol/L)

Stuporous: 11-17 mcg/mL (SI: 46-76 µmol/L)

Coma: 20-50 mcg/mL (SI: 88-221 µmol/L)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: If hypotension occurs, administer I.V. fluids and place the patient in the Trendelenburg position. If unresponsive, an I.V. vasopressor (eg, dopamine, epinephrine) may be required.

Enhancement of elimination: Forced alkaline diuresis is of no value in the treatment of intoxications with short-acting barbiturates. Charcoal hemoperfusion or hemodialysis may be useful in the harder to treat intoxications, especially in the presence of very high serum barbiturate levels with coma; multiple dosing of activated charcoal may be effective. Hemodialysis clearance is ~22 mL/minute (18% fractional removal of drug during 4 hours); hemoperfusion clearance ranges from 50-300 mL/minute (27% fractional removal of drug in 4 hours)

Test Interactions ↑ ammonia (B); ↓ bilirubin (S)

Drug Interactions

Induces CYP2A6 (strong), 3A4 (strong)

Acetaminophen: Barbiturates may enhance the hepatotoxic potential of acetaminophen overdoses

Antiarrhythmics: Barbiturates may increase the metabolism of antiarrhythmics, decreasing their clinical effect; includes disopyramide, propafenone, and quinidine

Anticonvulsants: Barbiturates may increase the metabolism of anticonvulsants; includes ethosuximide, felbamate (possibly), lamotrigine, phenytoin, tiagabine, topiramate, and zonisamide; does not appear to affect gabapentin or levetiracetam

Antineoplastics: Limited evidence suggests that enzyme-inducing anticonvulsant therapy may reduce the effectiveness of some chemotherapy regimens (specifically in ALL); teniposide and methotrexate may be cleared more rapidly in these patients

Antipsychotics: Barbiturates may enhance the metabolism (decrease the efficacy) of antipsychotics; monitor for altered response; dose adjustment may be needed

Beta-blockers: Metabolism of beta-blockers may be increased and clinical effect decreased; atenolol and nadolol are unlikely to interact given their renal elimination

Calcium channel blockers: Barbiturates may enhance the metabolism of calcium channel blockers, decreasing their clinical effect

Chloramphenicol: Barbiturates may increase the metabolism of chloramphenicol and chloramphenicol may inhibit barbiturate metabolism; monitor for altered response

Cimetidine: Barbiturates may enhance the metabolism of cimetidine, decreasing its clinical effect

CNS depressants: Sedative effects and/or respiratory depression with barbiturates may be additive with other CNS depressants; monitor for increased effect; includes ethanol, sedatives, antidepressants, narcotic analgesics, and benzodiazepines

Corticosteroids: Barbiturates may enhance the metabolism of corticosteroids, decreasing their clinical effect

Cyclosporine: Levels may be decreased by barbiturates; monitor

CYP2A6 substrates: Pentobarbital may decrease the levels/effects of CYP2A6 substrates. Example substrates include ifosfamide and rifampin.

CYP3A4 substrates: Pentobarbital may decrease the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, clarithromycin, cyclosporine, erythromycin, estrogens, mirtazapine, nateglinide, nefazodone, nevirapine, protease inhibitors, tacrolimus, and venlafaxine.

Doxycycline: Barbiturates may enhance the metabolism of doxycycline, decreasing its clinical effect; higher dosages may be required

Estrogens: Barbiturates may increase the metabolism of estrogens and reduce their efficacy

Felbamate may inhibit the metabolism of barbiturates and barbiturates may increase the metabolism of felbamate

Griseofulvin: Barbiturates may impair the absorption of griseofulvin, and griseofulvin metabolism may be increased by barbiturates, decreasing clinical effect

Guanfacine: Effect may be decreased by barbiturates

Immunosuppressants: Barbiturates may enhance the metabolism of immunosuppressants, decreasing its clinical effect; includes both cyclosporine and tacrolimus

Loop diuretics: Metabolism may be increased and clinical effects decreased; established for furosemide, effect with other loop diuretics not established

MAO inhibitors: Metabolism of barbiturates may be inhibited, increasing clinical effect or toxicity of the barbiturates

Methadone: Barbiturates may enhance the metabolism of methadone resulting in methadone withdrawal

Methoxyflurane: Barbiturates may enhance the nephrotoxic effects of methoxyflurane

Oral contraceptives: Barbiturates may enhance the metabolism of oral contraceptives, decreasing their clinical effect; an alternative method of contraception should be considered

Theophylline: Barbiturates may increase metabolism of theophylline derivatives and decrease their clinical effect

Tricyclic antidepressants: Barbiturates may increase metabolism of tricyclic antidepressants and decrease their clinical effect; sedative effects may be additive

Valproic acid: Metabolism of barbiturates may be inhibited by valproic acid; monitor for excessive sedation; a dose reduction may be needed

Warfarin: Barbiturates inhibit the hypoprothrombinemic effects of oral anticoagulants via increased metabolism; this combination should generally be avoided

Pregnancy Risk Factor D**Lactation** Enters breast milk/contraindicated**Pentostatin****CAS Number** 53910-25-7**U.S. Brand Names** Nipent®**Synonyms** 2'-Deoxycoformycin; CL-825; Co-Vidarabine; dCF; Deoxycoformycin; NSC-218321**Use** Treatment of hairy cell leukemia; non-Hodgkin's lymphoma, cutaneous T-cell lymphoma**Mechanism of Action** An irreversible inhibitor of adenosine deaminase (ADA) in the erythrocyte and lymphatic tissue which causes a build-up of deoxyadenosine thus inhibiting purine metabolism; also inhibits ribonucleotide reductase which blocks DNA synthesis**Adverse Reactions**

Cardiovascular: Chest pain, arrhythmia, peripheral edema

Central nervous system: **Fever, chills, headache**, opportunistic infections, anxiety, confusion, depression, dizziness, insomnia, nervousness, somnolence, myalgias, malaise, lethargy, seizures, coma (uncommon at doses <4 mg/m²)Dermatologic: **Skin rashes (25% to 30%), alopecia**, dry skin, eczema, pruritusGastrointestinal: **Mild to moderate nausea, vomiting (60%), stomatitis, diarrhea, anorexia**, constipation, flatulence, weight lossGenitourinary: **Acute renal failure (35%)**, dysuriaHematologic: **Thrombocytopenia (50%)**, dose-limiting in 25% of patients; **anemia (40% to 45%); neutropenia**, mild to moderate, not dose-limiting

Nadir: 7 days

Recovery: 10-14 days

Hepatic: **Mild to moderate increases in transaminase levels (30%)**, usually transient; **hepatitis (19%)**, usually reversible

Local: Thrombophlebitis

Neuromuscular & skeletal: Paresthesia, weakness

Ocular: Moderate to severe keratoconjunctivitis, abnormal vision, eye pain

Otic: Ear pain

Renal: Hematuria, BUN increased

Respiratory: **Pulmonary edema (15%)**, may be exacerbated by fludarabine; dyspnea, pneumonia, bronchitis, pharyngitis, rhinitis, epistaxis, sinusitisMiscellaneous: **Infection (57%; 35% severe, life-threatening)**, hypersensitivity reactions**Pharmacodynamics/Kinetics**Distribution: I.V.: V_d: 36.1 L (20.1 L/m²); rapidly to body tissues

Half-life elimination: Distribution half-life: 30-85 minutes; Terminal: 5-15 hours

Excretion: Urine (~50% to 96%) within 24 hours (30% to 90% as unchanged drug)

Dosage Refractory hairy cell leukemia: Adults (refer to individual protocols): 4 mg/m² every other week; I.V. bolus over ≥3-5 minutes in D₅W or normal saline at concentrations ≥2 mg/mL; patients should receive previous I.V. hydration with 500-1000 mL of 0.45% saline; patient should also receive 500 mL of 0.45% saline with 5% dextrose after infusion; reassess after usually 6 months of treatment**Monitoring Parameters** CBC, renal function tests**Administration** Administer I.V. as a 15- to 30-minute infusion; continuous infusion regimens have been reported, but are not commonly used I.V. bolus over ≥3-5 minutes in D₅W or NS at concentrations ≥2 mg/mL**Contraindications** Hypersensitivity to pentostatin or any component; pregnancy**Warnings** Hazardous agent - use appropriate precautions for handling and disposal. **[U.S. Boxed Warnings]: Severe renal, liver, pulmonary and CNS toxicities have occurred with doses higher than recommended; do not exceed the recommended dose. Do not administer concurrently with fludarabine; concomitant use has resulted in serious and fatal pulmonary toxicity.** Bone marrow suppression may occur, primarily early in treatment; if neutropenia persists beyond early cycles, evaluate for disease status. In patients who present with infections prior to treatment, infections should be resolved, if possible, prior to initiation of treatment. Use cautiously in patients with renal dysfunction; appropriate dosing guidelines in renal insufficiency have not been determined. May cause elevations (reversible) in liver function tests. Withhold treatment for CNS toxicity or severe rash. Pulmonary edema and hypotension have been reported in patients treated with pentostatin in combination with carmustine, etoposide or high dose cyclophosphamide as part of a myeloablative regimen for bone marrow transplant. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.** Safety and efficacy in children have not been established.**Dosage Forms** Injection, powder for reconstitution: 10 mg**Reference Range** Pentostatin plasma levels between 1-5 μM achieved after therapeutic dose**Overdosage/Treatment** Supportive therapy: Keep patient hydrated; erythrocyte transfusions may be indicated when the erythrocyte deoxyadenosine triphosphate to ATP ratio exceeds 1.0**Drug Interactions** Increased toxicity: Vidarabine, allopurinol; combined use with fludarabine may lead to severe, even fatal, pulmonary toxicity**Pregnancy Risk Factor D****Pregnancy Implications** Pentostatin has been found to be teratogenic in animals. There are no adequate or well-controlled studies in humans.

PENTOXIFYLLINE

Women of childbearing potential should be advised to avoid becoming pregnant. If used during pregnancy, the patient should be apprised of the potential risk to the fetus.

Lactation Excretion in breast milk unknown/contraindicated

Additional Information Treatment with pentostatin should either be avoided or administered with great caution in patients with a history of fludarabine-associated hemolytic anemia; may contain sodium hydroxide or hydrochloric acid for pH adjustment (pH of solution 7-8.5); infections (particularly disseminated herpes zoster) may occur; withhold dose if serum creatinine increases; polyethylene gloves should be utilized when administering this agent; extravasation injuries not reported

Pentoxifylline

CAS Number 6493-05-6

U.S. Brand Names Pentoxil®; Trental®

Synonyms Oxpentifylline

Use Treatment of intermittent claudication on the basis of chronic occlusive arterial disease of the limbs; may improve function and symptoms, but not intended to replace more definitive therapy

Unlabeled/Investigational Use AIDS patients with increased TNF, CVA, cerebrovascular diseases, diabetic atherosclerosis, diabetic neuropathy, gangrene, hemodialysis shunt thrombosis, vascular impotence, cerebral malaria, septic shock, sickle cell syndromes, and vasculitis

Mechanism of Action Mechanism of action remains unclear; is thought to reduce blood viscosity and improve blood flow by altering the rheology of red blood cells

Adverse Reactions

Cardiovascular: Chest pain, edema, hypotension
Central nervous system: Dizziness, headache, anxiety, arrhythmias, aseptic meningitis, confusion, depression, hallucinations, seizures
Dermatologic: Angioedema, rash
Gastrointestinal: Dyspepsia, nausea, vomiting
Hepatic: Cholecystitis, hepatitis, jaundice
Neuromuscular & skeletal: Tremor
Ocular: Blurred vision
Respiratory: Congestion, dyspnea
Miscellaneous: Anaphylactoid reactions

Signs and Symptoms of Overdose Agitation, atrioventricular block, dyspepsia, fever, flushing, hyperglycemia, hypokalemia (lasts for 12 hours), hypotension, laryngitis, mydriasis, myoclonus, seizures, syncope, tachycardia, thrombocytopenia

Admission Criteria/Prognosis Admit ingestions > 50 mg/kg; monitor for seizures in ingestions > 75 mg/kg; patients asymptomatic 12 hours post-ingestion can be discharged

Pharmacodynamics/Kinetics

Absorption: Well absorbed
Metabolism: Hepatic and via erythrocytes; extensive first-pass effect
Half-life elimination: Parent drug: 24-48 minutes; Metabolites: 60-96 minutes
Time to peak, serum: 2-4 hours
Excretion: Primarily urine (active metabolites); feces (4%)

Dosage

Adults: Oral: 400 mg 3 times/day with meals; may reduce to 400 mg twice daily if gastrointestinal or CNS side effects occur
Behçet disease: 600 mg 2 times/day for 2 weeks

Administration Tablets should be swallowed whole; do not chew, break, or crush.

Contraindications Hypersensitivity to pentoxifylline, xanthines (eg, caffeine, theophylline), or any component of the formulation; recent cerebral and/or retinal hemorrhage

Warnings Use with caution in patients with renal and hepatic impairment; start with lower doses in elderly patients and monitor renal function. Use caution in patients receiving anticoagulant therapy or at risk for bleeding complications; monitor PT/INR, hematocrit, and/or hemoglobin as necessary. May lower blood pressure; monitor with concomitant antihypertensive agent use. Safety and efficacy in pediatric patients have not been established.

Dosage Forms Tablet, extended release (Pentoxil®, Trental®): 400 mg

Reference Range

Therapeutic: 100-400 ng/mL; peak levels of 100 ng/mL obtained 2-3 hours after a 400 mg dose; serum level of 51,000 ng/mL associated with emesis, hypokalemia, and survival
Postmortem blood and urine levels of 0.63 mg/dL and 0.08 mg/dL found in a mixed pentoxifylline/diltiazem overdose.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) ingestions > 50 mg/kg; activated charcoal; **do not** induce emesis
Supportive therapy: Seizures can be treated with diazepam, lorazepam, phenobarbital, or phenytoin. Hypotension can be treated with crystalloid infusion and Trendelenburg. Dopamine and norepinephrine can also be given for refractory hypotension. Atropine can be used to treat bradycardia.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; extracorporeal removal may also be effective although there is no experience with this modality

Test Interactions ↓ calcium (S), magnesium (S); false-positive theophylline levels are not likely

Drug Interactions Theophylline: Increased toxicity

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic effects were not observed in animal studies. There are no adequate and well-controlled studies in pregnant women.

Lactation Enters breast milk/not recommended

Pergolide

CAS Number 66104-23-2; 66104-32-2

U.S. Brand Names Permax®

Synonyms Pergolide Mesylate

Use Adjunctive treatment to levodopa/carbidopa in the management of Parkinson's disease

Unlabeled/Investigational Use Tourette's disorder, chronic motor or vocal tic disorder

Mechanism of Action Pergolide is a semisynthetic ergot alkaloid similar to bromocriptine but stated to be more potent and longer-acting; it is a centrally-active dopamine agonist stimulating both D₁ and D₂ receptors

Adverse Reactions

Cardiovascular: Hypotension or postural hypotension, peripheral edema, chest pain, vasodilation, palpitation, syncope, arrhythmias, hypertension, MI, AV block, intracranial hypertension, pericarditis, pericardial effusion, vasculitis
Central nervous system: **Dizziness (19%), hallucinations, dystonia, somnolence, confusion**, insomnia, pain, anxiety, psychosis, EPS, incoordination, chills, facial paralysis, neuritis, neuroleptic malignant syndrome (NMS; associated with rapid discontinuation)
Dermatologic: Rash
Gastrointestinal: **Nausea (24%), constipation**, diarrhea, dyspepsia, abdominal pain, pancreatitis, anorexia, xerostomia, vomiting, dysphagia, nausea, intestinal obstruction
Genitourinary: Retroperitoneal fibrosis
Hematologic: Anemia
Neuromuscular & skeletal: **Dyskinesia (62%)**, myalgia, neuralgia
Ocular: Abnormal vision, diplopia
Respiratory: **Rhinitis**, dyspnea, epistaxis, laryngeal edema, pleural effusion, pleural fibrosis, pleuritis, pneumothorax
Miscellaneous: Flu syndrome, hiccups, valvular fibrosis

Pharmacodynamics/Kinetics

Absorption: Well absorbed
Protein binding, plasma: 90%
Metabolism: Extensively hepatic
Half-life elimination: 27 hours
Excretion: Urine (~50%); feces (50%)

Dosage When adding pergolide to levodopa/carbidopa, the dose of the latter can usually and should be decreased. Patients no longer responsive to bromocriptine may benefit by being switched to pergolide. Oral: Children and Adolescents: Tourette's disorder, chronic motor or vocal disorder (unlabeled uses): Up to 300 mcg/day

Adults: Parkinson's disease: Start with 0.05 mg/day for 2 days, then increase dosage by 0.1 or 0.15 mg/day every 3 days over next 12 days, increase dose by 0.25 mg/day every 3 days until optimal therapeutic dose is achieved, up to 5 mg/day maximum; usual dosage range: 2-3 mg/day in 3 divided doses

Monitoring Parameters Blood pressure (both sitting/supine and standing), symptoms of parkinsonism, dyskinesias, mental status

Contraindications Hypersensitivity to pergolide mesylate, other ergot derivatives, or any component of the formulation; ergot alkaloids are contraindicated with potent inhibitors of CYP3A4 (includes protease inhibitors, azole antifungals, and some macrolide antibiotics)

Warnings

Symptomatic hypotension occurs in 10% of patients; use with caution in patients with a history of cardiac arrhythmias, hallucinations, or mental illness. Cardiac valvular, pleural, and peritoneal fibrosis have been reported with prolonged daily use. Avoid rapid dose reduction or abrupt discontinuation.

Pergolide has been associated with somnolence. Some patients have been reported to fall asleep during activities of daily living, including driving, while taking this medication. Not all patients exhibited somnolence prior to these events. Patients should be advised of this issue and factors which may increase risk (sleep disorders or other sedating medications) and instructed to report daytime somnolence or any episode of falling asleep during activities to the prescriber. Patients should use caution in performing activities which require alertness

(driving or operating machinery), and to avoid other medications which may cause CNS depression, including ethanol.

Dosage Forms Tablet: 0.05 mg, 0.25 mg, 1 mg

Overdosage/Treatment Decontamination: Lavage within 1 hour adult ingestions >5 mg/activated charcoal

Drug Interactions **Substrate** of CYP3A4 (major); **Inhibits** CYP2D6 (strong), 3A4 (weak)

Antifungals, azole derivatives (itraconazole, ketoconazole) increase levels of ergot alkaloids by inhibiting CYP3A4 metabolism, resulting in toxicity; concomitant use is contraindicated.

Antipsychotics: May diminish the effects of pergolide (due to dopamine antagonism); these combinations should generally be avoided.

CYP2D6 substrates: Pergolide may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Pergolide may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 inhibitors: May increase the levels/effects of pergolide. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Levodopa: Concurrent use may result in a higher frequency of hallucinations.

Macrolide antibiotics: Erythromycin, clarithromycin, and troleandomycin may increase levels of ergot alkaloids by inhibiting CYP3A4 metabolism, resulting in toxicity (ischemia, vasospasm); concomitant use is contraindicated.

MAO inhibitors: The serotonergic effects of ergot derivatives may be increased by MAO inhibitors. Monitor for signs and symptoms of serotonin syndrome.

Metoclopramide: May diminish the effects of pergolide (due to dopamine antagonism); concurrent therapy should generally be avoided.

Protease inhibitors (ritonavir, amprenavir, indinavir, nelfinavir, and saquinavir) increase blood levels of ergot alkaloids by inhibiting CYP3A4 metabolism, acute ergot toxicity has been reported; concomitant use is contraindicated.

Sibutramine: May cause serotonin syndrome; concurrent use with ergot alkaloids is contraindicated.

Serotonin agonists: Concurrent use with pergolide may increase the risk of serotonin syndrome (includes buspirone, SSRIs, TCAs, nefazodone, sumatriptan, and trazodone).

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Monitor closely for orthostasis and other adverse effects; raise bed rails and institute safety measures; aid patient with ambulation, may cause postural hypotension and drowsiness

Additional Information Lowers serum prolactin and growth hormone levels

Permethrin

CAS Number 52645-53-1

U.S. Brand Names A200[®] Lice [OTC]; Acticin[®]; Elimate[®]; Nix[®] [OTC]; Rid[®] Spray [OTC]

Use Single application treatment of infestation with *Pediculus humanus capitis* (head louse) and its nits, or *Sarcoptes scabiei* (scabies); also active against mosquitoes, blackflies, and tsetse flies

Mechanism of Action Inhibits sodium ion influx through nerve cell membrane channels in parasites resulting in delayed repolarization and thus paralysis of the pest (a pyrethroid)

Adverse Reactions

Cardiovascular: Edema, tachycardia, sinus tachycardia

Central nervous system: Convulsions, headache, dizziness, stuttering

Dermatologic: Pruritus, numbness or scalp discomfort, erythema, rash of the scalp

Gastrointestinal: Vomiting, sore throat

Local: Burning, stinging, tingling, cheek/perioral numbness

Neuromuscular & skeletal: Paresthesia

Ocular: Visual evoked potential abnormalities

Respiratory: Wheezing, dyspnea, sneezing

Signs and Symptoms of Overdose Oral ingestion: Anorexia, asthenia, coma, dizziness, fasciculations, headache, numbness, nausea, vomiting, and seizures can occur at doses >200 mL.

Pharmacodynamics/Kinetics

Absorption: <2%

Metabolism: Hepatic via ester hydrolysis to inactive metabolites

Excretion: Urine

Dosage

Topical:

Head lice: Children >2 months and Adults: After hair has been washed with shampoo, rinsed with water, and towel dried, apply a sufficient

volume of topical liquid to saturate the hair and scalp. Leave on hair for 10 minutes lice or nits still present.

Scabies: Apply cream from head to toe; leave on for 8-14 hours before washing off with water, a single application is usually adequate; may repeat in 1 week if lice or nits still present. For infants, also apply on the hairline, neck, scalp, temple, and forehead.

Administration Because scabies and lice are so contagious, use caution to avoid spreading or infecting oneself; wear gloves when applying Cream: Apply from neck to toes. Bathe to remove drug after 8-14 hours. Repeat in 7 days if lice or nits are still present. Report if condition persists or infection occurs.

Cream rinse/lotion: Apply immediately after hair is shampooed, rinsed, and towel-dried. Apply enough to saturate hair and scalp (especially behind ears and on nape of neck). Leave on hair for 10 minutes before rinsing with water. Remove nits with fine-tooth comb. May repeat in 1 week if lice or nits are still present.

Contraindications Hypersensitivity to pyrethroid, pyrethrin, chrysanthemums, or any component of the formulation; lotion is contraindicated for use in infants <2 months of age

Warnings Treatment may temporarily exacerbate the symptoms of itching, redness, swelling; for external use only; use during pregnancy only if clearly needed

Dosage Forms Cream, topical (Acticin[®], Elimate[®]): 5% (60 g) [contains coconut oil]

Lotion, topical: 1% (59 mL)

Liquid, topical [creme rinse formulation] (Nix[®]): 1% (60 mL) [contains isopropyl alcohol 20%]

Solution, spray [for bedding and furniture]:

A200[®] Lice: 0.5% (180 mL)

Nix[®]: 0.25% (148 mL)

Rid[®]: 0.5% (150 mL)

Overdosage/Treatment

Decontamination: Activated charcoal; wash exposed skin thoroughly with soap and water

Supportive therapy: Epinephrine or diphenhydramine for allergic reactions; nebulized bronchodilators for wheezing; treat seizures with diazepam, lorazepam, phenytoin, or phenobarbital

Drug Interactions No data reported

Pregnancy Risk Factor B

Lactation Effect on infant unknown

Nursing Implications Avoid contact with eyes during administration; shake well before using

Additional Information Available in 1% formulation; suitable for aircraft disinfection

Specific References

Centers for Disease Control and Prevention (CDC), "Human Exposure to Mosquito-Control Pesticides—Mississippi, North Carolina, and Virginia, 2002 and 2003," *MMWR Morb Mortal Wkly Rep*, 2005, 3;54(21): 529-32.

Perphenazine

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antipsychotic Agents

CAS Number 58-39-9

U.S. Brand Names Trilafon[®] [DSC]

Impairment Potential Yes

Use Treatment of severe schizophrenia; nausea and vomiting

Unlabeled/Investigational Use Ethanol withdrawal; dementia in elderly; Tourette's syndrome; Huntington's chorea; spasmodic torticollis; Reye's syndrome; psychosis

Mechanism of Action Blocks postsynaptic mesolimbic dopaminergic receptors in the brain; exhibits a strong alpha-adrenergic blocking effect and depresses the release of hypothalamic and hypophyseal hormones

Adverse Reactions

Cardiovascular: **Hypotension**, tachycardia, cardiac arrhythmias, bradycardia, AV block, sinus bradycardia, sinus tachycardia, **orthostatic hypotension**

Central nervous system: Sedation, drowsiness, restlessness, anxiety, extrapyramidal reactions, **pseudoparkinsonian signs and symptoms**, seizures, altered central temperature regulation, **akathisia**, **dystonias**, **tardive dyskinesia**, **dizziness**, somnambulism

Dermatologic: Hyperpigmentation, pruritus, rash, photosensitivity reactions, Stevens-Johnson syndrome, exfoliative dermatitis, angioedema, urticaria, purpura, exanthem

Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, syndrome of inappropriate antidiuretic hormone, black galactorrhea

Gastrointestinal: Xerostomia, **constipation**, GI upset, weight gain

Genitourinary: Urinary retention

Hematologic: Agranulocytosis (more often in women between fourth and tenth weeks of therapy), leukopenia (usually in patients with large doses for prolonged periods)

Neuromuscular & skeletal: Torticollis, rhabdomyolysis

PHENAZOPYRIDINE

Ocular: Blurred vision, nystagmus, photophobia, **retinal pigmentation**

Respiratory: **Nasal congestion**

Miscellaneous: Systemic lupus erythematosus, **diaphoresis**, hiccups

Signs and Symptoms of Overdose Abnormal involuntary muscle movements, agitation, agranulocytosis, arrhythmias (QT_c prolongation), AV block, coma, deep sleep, dystonic reactions, extrapyramidal reaction, galactorrhea, granulocytopenia, gynecomastia, hypotension, impotence, jaundice, leukopenia, neuroleptic malignant syndrome, neutropenia, Parkinson's-like symptoms, seizures, thrombocytopenia, torsade de pointes, urine discoloration (pink; red; red-brown), ventricular tachycardia/fibrillation, vision color changes (brown tinge; yellow tinge). Children may have convulsive seizures.

Pharmacodynamics/Kinetics

Absorption: Oral: Well absorbed

Distribution: Crosses placenta

Metabolism: Extensively hepatic to metabolites via sulfoxidation, hydroxylation, dealkylation, and glucuronidation

Half-life elimination: Perphenazine: 9-12 hours; 7-hydroxyperphenazine: 11.3 hours

Time to peak, serum: Perphenazine: 1-3 hours; 7-hydroxyperphenazine: 2-4 hours

Excretion: Urine and feces

Dosage

Oral:

Children:

Schizophrenia/psychoses:

1-6 years: 4-6 mg/day in divided doses

6-12 years: 6 mg/day in divided doses

> 12 years: 4-16 mg 2-4 times/day

Adults:

Schizophrenia/psychoses: 4-16 mg 2-4 times/day not to exceed 64 mg/day

Nausea/vomiting: 8-16 mg/day in divided doses up to 24 mg/day

Elderly: Behavioral symptoms associated with dementia: Initial: 2-4 mg 1-2 times/day; increase at 4- to 7-day intervals by 2-4 mg/day. Increase dose intervals (bid, tid, etc) as necessary to control behavior response or side effects. Maximum daily dose: 32 mg; gradual increase (titration) and bedtime administration may prevent some side effects or decrease their severity.

Hemodialysis: Not dialyzable (0% to 5%)

Dosing adjustment in hepatic impairment: Dosage reductions should be considered in patients with liver disease although no specific guidelines are available

Monitoring Parameters Vital signs; lipid profile, fasting blood glucose/Hgb A_{1c}; BMI; mental status, abnormal involuntary movement scale (AIMS), extrapyramidal symptoms (EPS)

Contraindications Hypersensitivity to perphenazine or any component of the formulation (cross-reactivity between phenothiazines may occur); severe CNS depression; subcortical brain damage; bone marrow suppression; blood dyscrasias; coma

Warnings

May cause hypotension. May be sedating, use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Caution in patients with hemodynamic instability; predisposition to seizures; severe cardiac, hepatic, renal, or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use - use with caution in patients at risk of pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May alter cardiac conduction - life-threatening arrhythmias have occurred with therapeutic doses of phenothiazines. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications which may predispose).

Phenothiazines may cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention); therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other neuroleptics, perphenazine has a low potency of cholinergic blockade.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is moderate-high relative to other neuroleptics). Older patients are at increased risk for developing tardive dyskinesia. May be associated with neuroleptic malignant syndrome (NMS) or pigmentary retinopathy.

Dosage Forms Tablet: 2 mg, 4 mg, 8 mg, 16 mg

Reference Range 0.004-0.064 mg/L (therapeutic serum level)

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam, diazepam, or phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 gram), while other antiarrhythmics can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50 mg I.M. or I.V. slow push followed by a maintenance dose for 48-72 hours. When these reactions are unresponsive to diphenhydramine, benzotropine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes.

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; forced diuresis or hemodialysis is of no benefit; not dialyzable (0% to 5%)

Test Interactions ↑ cholesterol (S), glucose; ↓ uric acid (S)

Drug Interactions **Substrate** of CYP1A2 (minor), 2C9 (minor), 2C19 (minor), 2D6 (major), 3A4 (minor); **Inhibits** CYP1A2 (weak), 2D6 (weak) Acetylcholinesterase inhibitors (central): May increase the risk of anti-psychotic-related extrapyramidal symptoms; monitor.

Aluminum salts: May decrease the absorption of phenothiazines; monitor Amphetamines: Efficacy may be diminished by antipsychotics; in addition, amphetamines may increase psychotic symptoms; avoid concurrent use

Anticholinergics: May inhibit the therapeutic response to phenothiazines and excess anticholinergic effects may occur; includes benzotropine, trihexyphenidyl, biperiden, and drugs with significant anticholinergic activity (TCAs, antihistamines, disopyramide)

Antihypertensives: Concurrent use of phenothiazines with an antihypertensive may produce additive hypotensive effects (particularly orthostasis)

Bromocriptine: Phenothiazines inhibit the ability of bromocriptine to lower serum prolactin concentrations

CNS depressants: Sedative effects may be additive with phenothiazines; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents

CYP2D6 inhibitors: May increase the levels/effects of perphenazine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Epinephrine: Chlorpromazine (and possibly other low potency antipsychotics) may diminish the pressor effects of epinephrine

Guanethidine and guanadrel: Antihypertensive effects may be inhibited by phenothiazines

Levodopa: Phenothiazines may inhibit the antiparkinsonian effect of levodopa; avoid this combination

Lithium: Phenothiazines may produce neurotoxicity with lithium; this is a rare effect

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk. Phenytoin: May reduce serum levels of phenothiazines; phenothiazines may increase phenytoin serum levels

Propranolol: Serum concentrations of phenothiazines may be increased; propranolol also increases phenothiazine concentrations

Polypeptide antibiotics: Rare cases of respiratory paralysis have been reported with concurrent use of phenothiazines

QT_c-prolonging agents: Effects on QT_c interval may be additive with phenothiazines, increasing the risk of malignant arrhythmias; includes type Ia antiarrhythmics, TCAs, and some quinolone antibiotics (sparfloxacin, moxifloxacin, and gatifloxacin)

Sulfadoxine-pyrimethamine: May increase phenothiazine concentrations Tricyclic antidepressants: Concurrent use may produce increased toxicity or altered therapeutic response

Trazodone: Phenothiazines and trazodone may produce additive hypotensive effects

Valproic acid: Serum levels may be increased by phenothiazines

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Phenazopyridine

CAS Number 136-40-3; 94-78-0

U.S. Brand Names Azo-Gesic® [OTC]; Azo-Standard® [OTC]; Proidium® [OTC]; Pyridium®; ReAzo [OTC]; Uristat® [OTC]; UTI Relief® [OTC]

Synonyms Phenazopyridine Hydrochloride; Phenylazo Diamino Pyridine Hydrochloride

Use Symptomatic relief of urinary burning, itching, frequency and urgency in association with urinary tract infection or following urologic procedures

Mechanism of Action An azo dye which exerts local anesthetic or analgesic action on urinary tract mucosa through an unknown mechanism

Adverse Reactions

Central nervous system: **Headache, dizziness**, aseptic meningitis
 Gastrointestinal: **Stomach cramps, feces discoloration (orange-red)**
 Genitourinary: Red-staining urine, urolithiasis
 Dermatologic: Skin pigmentation (yellow-orange), rash, pruritus
 Hematologic: Methemoglobinemia, hemolytic anemia, thrombocytopenia, neutropenia, methemoglobinemia followed by hemolysis
 Hepatic: Hepatitis, hepatomegaly
 Renal: Acute renal failure
 Miscellaneous: Anaphylactoid reaction

Signs and Symptoms of Overdose Acute tubular necrosis, dyspnea, hepatic impairment, methemoglobinemia followed by hemolytic anemia, rhabdomyolysis (after a 6 g ingestion), yellow skin pigmentation

Admission Criteria/Prognosis Admit any ingestion > 1 g; hematologic effects usually manifest itself within 4 hours; admit patients with symptomatic methemoglobinemia

Pharmacodynamics/Kinetics

Metabolism: Hepatic and via other tissues
 Excretion: Urine (65% as unchanged drug)

Dosage

Oral:
 Children: 12 mg/kg/day in 3 divided doses administered after meals for 2 days

Adults: 100-200 mg 3 times/day after meals for 2 days when used concomitantly with an antibacterial agent

Dosing interval in renal impairment:

Cl_{cr} 50-80 mL/minute: Administer every 8-16 hours
 Cl_{cr} <50 mL/minute: Avoid use

Monitoring Parameters Methemoglobin levels, CBC, renal/liver function, urine analysis

Contraindications Hypersensitivity to phenazopyridine or any component of the formulation; kidney or liver disease; patients with a Cl_{cr} <50 mL/minute

Warnings Does not treat infection, acts only as an analgesic; drug should be discontinued if skin or sclera develop a yellow color; use with caution in patients with renal impairment. Use of this agent in the elderly is limited since accumulation of phenazopyridine can occur in patients with renal insufficiency. Use is contraindicated in patients with a Cl_{cr} <50 mL/minute.

Dosage Forms Tablet, as hydrochloride: 100 mg, 200 mg

AZO-Gesic[®], AZO-Standard[®], Uristat[®]: 95 mg
 Baridium[®]: 97.2 mg
 ReAzo: 95 mg
 Pyridium[®]: 100 mg, 200 mg
 UTI Relief[®]: 97.2 mg

Overdosage/Treatment

Decontamination: Activated charcoal
 Supportive therapy: Methylene blue (1-2 mg/kg) for symptomatic methemoglobin cases or methemoglobin levels >30%
 Enhanced elimination: Exchange transfusion may be useful in infants

Antidote(s)

- Methylene Blue [ANTIDOTE]

Test Interactions Phenazopyridine may cause delayed reactions with glucose oxidase reagents (Clinistix[®], Tes-Tape[®]); occasional false-positive tests occur with Tes-Tape[®]; cupric sulfate tests (Clinitest[®]) are not affected; interference may also occur with urine ketone tests (Acetest[®], Ketostix[®]) and urinary protein tests; tests for urinary steroids and porphyrins may also occur. Can cause false elevation of serum total protein, and a false-negative leukocyte esterase on urine dipstick; may cause elevation of urinary vanillylmandelic acid assay

Drug Interactions No data reported

Pregnancy Risk Factor

Lactation Excretion in breast milk unknown

Additional Information Stains on clothing due to phenazopyridine can be removed by soaking fabric in a 0.25% solution of sodium dithionite

Phenelzine

Related Information

- Selegiline
- Therapeutic Drugs Associated with Hallucinations

CAS Number 156-51-4; 51-71-8

U.S. Brand Names Nardil[®]

Synonyms Phenelzine Sulfate

Use Symptomatic treatment of atypical, nonendogenous or neurotic depression

Unlabeled/Investigational Use Selective mutism

Mechanism of Action Thought to act by increasing endogenous concentrations of epinephrine, norepinephrine, dopamine, and serotonin

through inhibition of monoamine oxidase, which is responsible for the breakdown of these neurotransmitters

Adverse Reactions

Cardiovascular: **Orthostatic hypotension**, edema, vasoconstriction
 Central nervous system: **Drowsiness**, psychosis, headache, auditory and visual hallucinations, vascular encephalopathy
 Dermatologic: Skin rash

Endocrine & metabolic: **Decreased sexual ability**, syndrome of inappropriate antidiuretic hormone

Gastrointestinal: Xerostomia, constipation, nausea

Genitourinary: Urinary retention

Hematologic: Aplastic anemia

Hepatic: Jaundice, hepatic failure

Neuromuscular & skeletal: **Trembling, weakness**, clonus, myoclonus

Ocular: **Blurred vision**, photophobia, mydriasis, nystagmus, amblyopia, periodic gaze disturbance ("ping-pong gaze")

Miscellaneous: Lupus-like reaction, serotonin syndrome (flushing, diarrhea)

Signs and Symptoms of Overdose Coma, delirium, drowsiness, dry mouth, ejaculatory disturbances, exfoliative dermatitis, extrapyramidal reaction, fever, flushing, hallucinations, hyperthermia, hypotension, impotence, insomnia, mania, metabolic acidosis, methemoglobinemia, muscle myoclonus, muscle rigidity, mydriasis, myoglobinuria, neuroleptic malignant syndrome, nystagmus, palpitations, photosensitivity, ptosis, restlessness, rhabdomyolysis, seizures, sinus tachycardia, sweating, tachypnea, transient hypertension

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints or hypotension should be admitted.

Pharmacodynamics/Kinetics

Onset of action: Therapeutic: 2-4 weeks; geriatric patients receiving an average of 55 mg/day developed a mean platelet MAO activity inhibition of about 85%.

Duration: May continue to have a therapeutic effect and interactions 2 weeks after discontinuing therapy

Absorption: Well absorbed

Metabolism: Oxidized via monoamine oxidase (primary pathway) and acetylation (minor pathway)

Half-life elimination: 11 hours

Excretion: Urine (primarily as metabolites and unchanged drug)

Dosage

Oral:
 Children: Selective mutism (unlabeled use): 30-60 mg/day

Adults: Depression: 15 mg 3 times/day; may increase to 60-90 mg/day during early phase of treatment, then reduce to dose for maintenance therapy slowly after maximum benefit is obtained; takes 2-4 weeks for a significant response to occur

Elderly: Depression: Initial: 7.5 mg/day; increase by 7.5-15 mg/day every 3-4 days as tolerated; usual therapeutic dose: 15-60 mg/day in 3-4 divided doses

Stability Protect from light

Monitoring Parameters Blood pressure, heart rate, diet, weight, mood (if depressive symptoms)

Contraindications Hypersensitivity to phenelzine or any component of the formulation; uncontrolled hypertension; pheochromocytoma; hepatic disease; congestive heart failure; CNS depressants, ethanol, meperidine, bupropion, buspirone, guanethidine, serotonergic drugs (including SSRIs) - do not use within 5 weeks of fluoxetine discontinuation or 2 weeks of other antidepressant discontinuation; general anesthesia, local vasoconstrictors; spinal anesthesia (hypotension may be exaggerated); sympathomimetics (and related compounds); foods high in tyramine content; supplements containing tyrosine, phenylalanine, tryptophan, or caffeine

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. Phenelzine is FDA approved for the treatment of depression in children ≥ 16 years of age.

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require

discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. Phenelzine is not FDA approved for the treatment of bipolar depression.

Use with caution in patients who are hyperactive, hyperexcitable, or who have glaucoma, hyperthyroidism, suicidal tendencies, or diabetes. Hypertensive crisis may occur with tyramine, tryptophan, or dopamine-containing foods. Should not be used in combination with other antidepressants. Hypotensive effects of antihypertensives (beta-blockers, thiazides) may be exaggerated. May cause orthostatic hypotension - use with caution in patients with hypotension or patients who would not tolerate transient hypotensive episodes (cardiovascular or cerebrovascular disease) - effects may be additive with other agents which cause orthostasis. Use with caution in patients at risk of seizures, or in patients receiving other drugs which may lower seizure threshold. Toxic reactions have occurred with dextromethorphan. Discontinue at least 48 hours prior to myelography. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery.

The MAO inhibitors are effective and generally well tolerated by older patients. It is the potential interactions with tyramine or tryptophan-containing foods and other drugs, and their effects on blood pressure that have limited their use.

Dosage Forms Tablet: 15 mg

Reference Range Suggested plasma therapeutic range for phenelzine is 8-55 ng/mL. Chronic daily dosing of 60 mg will usually produce plasma phenelzine levels <10 ng/mL.

Overdosage/Treatment

Decontamination: **Do not** induce emesis; activated charcoal is useful. Supportive therapy: Competent supportive care is the most important treatment for an overdose with a monoamine oxidase (MAO) inhibitor. Both hypertension or hypotension can occur with intoxication. Hypotension may respond to I.V. fluids or vasopressors; hypertension usually responds to an alpha-adrenergic blocker. While treating hypertension, care is warranted to avoid sudden drops in blood pressure, since this may worsen MAO inhibitor toxicity. Muscle irritability and seizures often respond to diazepam or lorazepam, while hyperthermia is best treated with antipyretics and cooling blankets. Dantrolene sodium (2.5 mg/kg I.V. every 6 hours) has been used successfully in treatment of hyperthermia/hypermetabolic state due to phenelzine overdose. Cardiac arrhythmias are best treated with phenytoin or procainamide. Hypertensive crisis can be treated with nitroprusside, phentolamine (2-10 mg slow I.V. injection in adults). Aortic counter-pulsation has been used to treat phenelzine-induced cardiogenic shock.

Enhancement of elimination: Charcoal hemoperfusion may be useful in decreasing phenelzine serum levels but there is no documentation of clinical improvement.

Test Interactions ↓ glucose; peaked T waves noted on ECG

Drug Interactions Amphetamines: MAO inhibitors in combination with amphetamines may result in severe hypertensive reaction; concurrent use is contraindicated.

Anorexiant: Concurrent use of anorexiant may result in serotonin syndrome; these combinations are best avoided; includes dexfenfluramine, fenfluramine, or sibutramine

Barbiturates: MAO inhibitors may inhibit the metabolism of barbiturates and prolong their effect

Bupropion: Concurrent use is contraindicated; allow at least 14 days between discontinuing MAO inhibitor and starting bupropion.

Buspirone: May cause hypertension; wait at least 10 days between discontinuing one agent and starting the other.

CNS stimulants: MAO inhibitors in combination with stimulants (methylphenidate) may result in severe hypertensive reaction; concurrent use is contraindicated.

Dextromethorphan: Concurrent use of MAO inhibitors may result in serotonin syndrome; concurrent use is contraindicated.

Disulfiram: MAO inhibitors may produce delirium in patients receiving disulfiram; monitor.

Guanadrel and guanethidine: MAO inhibitors inhibit the antihypertensive response to guanadrel or guanethidine; concurrent use is contraindicated; use an alternative antihypertensive agent.

Hypoglycemic agents: MAO inhibitors may produce hypoglycemia in patients with diabetes; monitor.

Levodopa: MAO inhibitors in combination with levodopa may result in hypertensive reactions; monitor.

Lithium: MAO inhibitors in combination with lithium have resulted in malignant hyperpyrexia; this combination is best avoided.

Meperidine: May cause serotonin syndrome when combined with an MAO inhibitor; concurrent use is contraindicated; avoid use of meperidine within 2 weeks of phenelzine use.

Nefazodone: Concurrent use of MAO inhibitors may result in serotonin syndrome; these combinations are best avoided

Norepinephrine: MAO inhibitors may increase the pressor response of norepinephrine (effect is generally small); monitor

Reserpine: MAO inhibitors in combination with reserpine may result in hypertensive reactions; monitor

Serotonin agonists: Theoretically may increase the risk of serotonin syndrome; includes sumatriptan, naratriptan, rizatriptan, and zolmitriptan

SSRIs: May cause serotonin syndrome when combined with an MAO inhibitor; avoid this combination. Allow 5 weeks between discontinuing fluoxetine and starting an MAO inhibitor; allow at least 10 days after discontinuing MAO inhibitor and starting fluoxetine.

Succinylcholine: MAO inhibitors may prolong the muscle relaxation produced by succinylcholine via decreased plasma pseudocholinesterase

Sympathomimetics (indirect-acting): MAO inhibitors in combination with sympathomimetics such as dopamine, metaraminol, phenylephrine, and decongestants (pseudoephedrine) may result in severe hypertensive reaction; concurrent use is contraindicated.

Tramadol: May increase the risk of seizures and serotonin syndrome in patients receiving an MAO inhibitor

Trazodone: Concurrent use of MAO inhibitors may result in serotonin syndrome; these combinations are best avoided

Tricyclic antidepressants: May cause serotonin syndrome when combined with an MAO inhibitor; avoid this combination

Venlafaxine: Concurrent use of MAO inhibitors may result in serotonin syndrome; these combinations are best avoided

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Watch for hypotension (orthostatic); monitor blood pressure carefully, especially at therapy onset or if other CNS drugs or cardiovascular drugs are added; check for dietary and drug restriction

Additional Information Tyramine-containing foods: red wine, cheese (except cottage, ricotta, and cream), smoked or pickled fish, beef or chicken liver, dried sausage, fava or broad bean pods, yeast vitamin supplements

Phenmetrazine

Related Information

- Dextroamphetamine

CAS Number 134-49-6; 13931-75-4; 1707-14-8

Synonyms Phenmetrazine Hydrochloride

Impairment Potential Yes. Blood and urine phenmetrazine levels >0.5 mg/L and 56 mg/L, respectively, may be associated with driving impairment.

Use Anorectic agent

Mechanism of Action A central nervous system stimulant similar to dexamphetamine; a methylchloroformate derivative

Adverse Reactions

Cardiovascular: Hypertension, tachycardia (ventricular), tachycardia, palpitations, cardiac arrhythmias, vasculitis, pulmonary hypertension

Central nervous system: **Insomnia**, headache, **nervousness**, dizziness, seizures, mania, may precipitate Tourette's syndrome, CNS depression, dysphonia, irritability, agitation, euphoria, hallucination, extrapyramidal reaction, movement disorders, paranoia

Endocrine & metabolic: Growth suppression, respiratory alkalosis, increased serum thyroxine (hyperthyroidism)

Gastrointestinal: Anorexia, nausea, vomiting, diarrhea, abdominal cramps, metallic taste, xerostomia

Genitourinary: Impotence

Hematologic: Porphyria

Neuromuscular & skeletal: Tremors, choreoathetoid movements, fasciculations

Ocular: Cataracts

Renal: Myoglobinuria

Respiratory: Tachypnea

Signs and Symptoms of Overdose Anxiety, coma, confusion, dizziness, dysrhythmias, hallucinations, headache, hypertension, noncardiogenic pulmonary edema, retinal vein occlusion, seizures, shock, tachycardia, tachypnea, tremor

Pharmacodynamics/Kinetics

Metabolism: Hepatic

Half-life: 8 hours

Elimination: Renal

Normal pH: 19%

Acidic pH: 46% within 16 hours

Dosage Oral: 12.5-75 mg/day

Dosage Forms Tablet: 25 mg, 75 mg

Reference Range

Therapeutic serum level: 60-130 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Seizures can be treated with diazepam or lorazepam; phenytoin or phenobarbital can be used for refractory seizures; sodium nitroprusside (initial dose: 3 mcg/kg/minute) can be used to treat hypertension; droperidol (up to 0.1 mg/kg) or haloperidol (up to 0.1 mg/kg) can be used to treat agitation

Enhanced elimination: **Do not** acidify urine

Additional Information Primarily found in Europe

Phenobarbital

Related Information

- Seizures, Neonatal Guidelines
- Therapeutic Drugs Associated with Hallucinations

CAS Number 50-06-6; 57-30-7

U.S. Brand Names Luminal® Sodium

Synonyms Phenobarbital Sodium; Phenobarbitone; Phenylethylmalonylurea

Impairment Potential Yes

Use Management of generalized tonic-clonic (grand mal) and partial seizures; sedative

Unlabeled/Investigational Use Febrile seizures in children; may also be used for prevention and treatment of neonatal hyperbilirubinemia and lowering of bilirubin in chronic cholestasis; neonatal seizures; management of sedative/hypnotic withdrawal

Mechanism of Action Interferes with transmission of impulses from the thalamus to the cortex of the brain resulting in an imbalance in central inhibitory and facilitatory mechanisms

Adverse Reactions

Cardiovascular: **Hypotension, cardiac arrhythmias, bradycardia, arterial spasm**, sinus bradycardia, vasodilation

Central nervous system: **Drowsiness, CNS stimulation or CNS depression, impaired judgment**, visual hallucinations, hypothermia, electroencephalogram abnormalities, depression, anticonvulsant hypersensitivity syndrome, **dizziness, lightheadedness, "hangover" effect, lethargy**

Dermatologic: Rash, bullous eruptions, systemic contact dermatitis, exfoliative dermatitis, erythema nodosum

Gastrointestinal: Nausea, vomiting, ileus

Hematologic: Thrombocytopenia

Hepatic dysfunction (idiosyncratic reaction), cholestasis

Local: **Thrombophlebitis** with I.V. use, **pain at injection site**

Ocular: Nystagmus

Renal: Oliguria, renal failure (secondary to hypotension), renal vasculitis

Respiratory: Laryngospasm, respiratory depression, apnea (especially with rapid I.V. use)

Miscellaneous: **Gangrene with inadvertent intra-arterial injection**, mucocutaneous syndrome (febrile), fixed drug eruption

Signs and Symptoms of Overdose Asterixis, ataxia, bullous lesions, cognitive dysfunction, confusion, dysarthria, extrapyramidal reaction, fever, focal neurological signs, gingival hyperplasia, hyperactivity, hyporeflexia, hypotension, hypothermia, hypothyroidism, jaundice, methemoglobinemia, miosis, myocardial depression, myoglobinuria, pemphigus, porphyria, ptosis, pulmonary edema, rhabdomyolysis, slurred speech, toxic epidermal necrolysis, unsteady gait, vision color changes (green tinge)

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or phenobarbital levels >60 mcg/mL should be admitted

Pharmacodynamics/Kinetics

Onset of action: Oral: Hypnosis: 20-60 minutes; I.V.: ~5 minutes

Peak effect: I.V.: ~30 minutes

Duration: Oral: 6-10 hours; I.V.: 4-10 hours

Absorption: Oral: 70% to 90%

Protein binding: 20% to 45%; decreased in neonates

Metabolism: Hepatic via hydroxylation and glucuronide conjugation

Half-life elimination: Neonates: 45-500 hours; Infants: 20-133 hours;

Children: 37-73 hours; Adults: 53-140 hours

Time to peak, serum: Oral: 1-6 hours

Excretion: Urine (20% to 50% as unchanged drug)

Dosage

Children:

Sedation: Oral: 2 mg/kg 3 times/day

Hypnotic: I.M., I.V., SubQ: 3-5 mg/kg at bedtime

Preoperative sedation: Oral, I.M., I.V.: 1-3 mg/kg 1-1.5 hours before procedure

Adults:

Sedation: Oral, I.M.: 30-120 mg/day in 2-3 divided doses

Hypnotic: Oral, I.M., I.V., SubQ: 100-320 mg at bedtime

Preoperative sedation: I.M.: 100-200 mg 1-1.5 hours before procedure

Anticonvulsant: Status epilepticus: **Loading dose:** I.V.:

Infants and Children: 10-20 mg/kg in a single or divided dose; in select patients may administer additional 5 mg/kg/dose every 15-30 minutes until seizure is controlled or a total dose of 40 mg/kg is reached

Adults: 300-800 mg initially followed by 120-240 mg/dose at 20-minute intervals until seizures are controlled or a total dose of 1-2 g

Anticonvulsant maintenance dose: Oral, I.V.:

Infants: 5-8 mg/kg/day in 1-2 divided doses

Children:

1-5 years: 6-8 mg/kg/day in 1-2 divided doses

5-12 years: 4-6 mg/kg/day in 1-2 divided doses

Children >12 years and Adults: 1-3 mg/kg/day in divided doses or 50-100 mg 2-3 times/day

Sedative/hypnotic withdrawal (unlabeled use): Initial daily requirement is determined by substituting phenobarbital 30 mg for every 100 mg pentobarbital used during tolerance testing; then daily requirement is decreased by 10% of initial dose

Dosing interval in renal impairment: $Cl_{cr} < 10$ mL/minute: Administer every 12-16 hours

Hemodialysis: Moderately dialyzable (20% to 50%)

Dosing adjustment/comments in hepatic disease: Increased side effects may occur in severe liver disease; monitor plasma levels and adjust dose accordingly

Stability Protect elixir from light; not stable in aqueous solutions; use only clear solutions; do not add to acidic solutions, precipitation may occur

Monitoring Parameters Phenobarbital serum concentrations, mental status, CBC, LFTs, seizure activity

Administration Avoid rapid I.V. administration >50 mg/minute; avoid intra-arterial injection; parenteral solutions are highly alkaline; avoid extravasation

Contraindications Hypersensitivity to barbiturates or any component of the formulation; marked hepatic impairment; dyspnea or airway obstruction; porphyria; pregnancy

Warnings Potential for drug dependency exists, abrupt cessation may precipitate withdrawal, including status epilepticus in epileptic patients. Do not administer to patients in acute pain. Use caution in elderly, debilitated, renally or hepatic dysfunction, and pediatric patients. May cause paradoxical responses, including agitation and hyperactivity, particularly in acute pain and pediatric patients. Use with caution in patients with depression or suicidal tendencies, or in patients with a history of drug abuse. Tolerance, psychological and physical dependence may occur with prolonged use. May cause CNS depression, which may impair physical or mental abilities. Patients must cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Effects with other sedative drugs or ethanol may be potentiated. May cause respiratory depression or hypotension, particularly when administered intravenously. Use with caution in hemodynamically unstable patients (hypovolemic shock, CHF) or patients with respiratory disease. Due to its long half-life and risk of dependence, phenobarbital is not recommended as a sedative in the elderly. Use has been associated with cognitive deficits in children. Use with caution in patients with hypoadrenalism.

Dosage Forms Elixir: 20 mg/5 mL (473 mL) [contains alcohol]

Injection, solution, as sodium: 65 mg/mL (1 mL); 130 mg/mL (1 mL) [contains alcohol and propylene glycol]

Luminal® Sodium: 60 mg/mL (1 mL); 130 mg/mL (1 mL) [contains alcohol 10% and propylene glycol]

Tablet: 15 mg, 30 mg, 32 mg, 60 mg, 65 mg, 100 mg

Reference Range

Therapeutic:

Infants and children: 15-30 mcg/mL (SI: 65-129 μ mol/L)

Adults: 20-40 mcg/mL (SI: 86-172 μ mol/L)

Toxic: >40 mcg/mL (SI: >172 μ mol/L); levels >80 mcg/mL (SI: 344 μ mol/L) are associated with coma

Fatal: 50-130 mcg/mL (SI: 215-559 μ mol/L)

Overdosage/Treatment

Decontamination: Gastric lavage for life-threatening overdoses within 1 hour; activated charcoal is effective

Supportive therapy: Hypotension: Isotonic I.V. fluid (10-20 mL/kg) is effective along with placement in Trendelenburg position; dopamine (2-5 mcg/kg progressing to 5-10 mcg/kg) or norepinephrine (0.1-0.2 mcg/kg/minute for children or 8-12 mcg/kg in adults to a maintenance dose of 2-4 mcg/minute) is effective. Exchange transfusion may be of benefit in treating a neonatal intoxication.

Enhancement of elimination: Repeated oral doses of activated charcoal significantly reduce the half-life of phenobarbital resulting from an enhancement of nonrenal elimination. The usual dose is 12.5-25 g every 1-2 hours until concentrations are <20 mg/L or unless the patient has no bowel movement, causing the charcoal to remain in the gastrointestinal tract. Assure adequate hydration and renal function.

Urinary alkalinization with I.V. sodium bicarbonate also helps to enhance elimination. Hemodialysis is of uncertain value. Patients in stage IV coma due to high serum barbiturate levels may require charcoal hemoperfusion; moderately dialyzable (20% to 50%). Hemodialysis clearance is ~80 mL/minute with 33% of drug removed in 4 hours. Hemoperfusion clearance ranges from 80-290 mL/minute with 39% of drug removed in 4 hours; continuous arteriovenous hemoperfusion clearance rates are 290 ± 25 mL/minute. Multiple dosing of activated charcoal is superior to urinary alkalinization in enhancing phenobarbital elimination.

Diagnostic Procedures

- Phenobarbital, Blood

Test Interactions ↑ alkaline phosphatase (S), ammonia (B); ↓ bilirubin (S), calcium (S)

Drug Interactions

Substrate of CYP2C9 (minor), 2C19 (major), 2E1 (minor); **Induces** CYP1A2 (strong), 2A6 (strong), 2B6 (strong), 2C8 (strong), 2C9 (strong), 3A4 (strong)

Acetaminophen: Barbiturates may enhance the hepatotoxic potential of acetaminophen overdoses

Antiarrhythmics: Barbiturates may increase the metabolism of antiarrhythmics, decreasing their clinical effect; includes disopyramide, propafenone, and quinidine

Anticonvulsants: Barbiturates may increase the metabolism of anticonvulsants; includes ethosuximide, felbamate (possibly), lamotrigine, phenytoin, tiagabine, topiramate, and zonisamide; does not appear to affect gabapentin or levetiracetam

Antineoplastics: Limited evidence suggests that enzyme-inducing anticonvulsant therapy may reduce the effectiveness of some chemotherapy regimens (specifically in ALL); teniposide and methotrexate may be cleared more rapidly in these patients

Antipsychotics: Barbiturates may enhance the metabolism (decrease the efficacy) of antipsychotics; monitor for altered response; dose adjustment may be needed

Beta-blockers: Metabolism of beta-blockers may be increased and clinical effect decreased; atenolol and nadolol are unlikely to interact given their renal elimination

Calcium channel blockers: Barbiturates may enhance the metabolism of calcium channel blockers, decreasing their clinical effect

Chloramphenicol: Barbiturates may increase the metabolism of chloramphenicol and chloramphenicol may inhibit barbiturate metabolism; monitor for altered response

Cimetidine: Barbiturates may enhance the metabolism of cimetidine, decreasing its clinical effect

CNS depressants: Sedative effects and/or respiratory depression with barbiturates may be additive with other CNS depressants; monitor for increased effect; includes ethanol, sedatives, antidepressants, narcotic analgesics, and benzodiazepines

Corticosteroids: Barbiturates may enhance the metabolism of corticosteroids, decreasing their clinical effect

Cyclosporine: Levels may be decreased by barbiturates; monitor

CYP1A2 substrates: Phenobarbital may decrease the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, estrogens, fluvoxamine, mirtazapine, ropinirole, and theophylline.

CYP2A6 substrates: Phenobarbital may decrease the levels/effects of CYP2A6 substrates. Example substrates include ifosfamide and rifampin.

CYP2B6 substrates: Phenobarbital may decrease the levels/effects of CYP2B6 substrates. Example substrates include bupropion, efavirenz, promethazine, selegiline, and sertraline.

CYP2C8 Substrates: Phenobarbital may decrease the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP2C9 Substrates: Phenobarbital may decrease the levels/effects of CYP2C9 substrates. Example substrates include bosentan, celecoxib, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, sulfonamides, trimethoprim, warfarin, and zafirlukast.

CYP2C19 inducers: May decrease the levels/effects of phenobarbital. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of phenobarbital. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

CYP3A4 substrates: Phenobarbital may decrease the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, clarithromycin, cyclosporine, erythromycin, estrogens, mirtazapine, nateglinide, nefazodone, nevirapine, protease inhibitors, tacrolimus, and venlafaxine.

Doxycycline: Barbiturates may enhance the metabolism of doxycycline, decreasing its clinical effect; higher dosages may be required

Estrogens: Barbiturates may increase the metabolism of estrogens and reduce their efficacy

Felbamate may inhibit the metabolism of barbiturates and barbiturates may increase the metabolism of felbamate

Griseofulvin: Barbiturates may impair the absorption of griseofulvin, and griseofulvin metabolism may be increased by barbiturates, decreasing clinical effect

Guanfacine: Effect may be decreased by barbiturates

Immunosuppressants: Barbiturates may enhance the metabolism of immunosuppressants, decreasing its clinical effect; includes both cyclosporine and tacrolimus

Loop diuretics: Metabolism may be increased and clinical effects decreased; established for furosemide, effect with other loop diuretics not established

MAO inhibitors: Metabolism of barbiturates may be inhibited, increasing clinical effect or toxicity of the barbiturates

Methadone: Barbiturates may enhance the metabolism of methadone resulting in methadone withdrawal

Methoxyflurane: Barbiturates may enhance the nephrotoxic effects of methoxyflurane

Oral contraceptives: Barbiturates may enhance the metabolism of oral contraceptives, decreasing their clinical effect; an alternative method of contraception should be considered

Theophylline: Barbiturates may increase metabolism of theophylline derivatives and decrease their clinical effect

Tricyclic antidepressants: Barbiturates may increase metabolism of tricyclic antidepressants and decrease their clinical effect; sedative effects may be additive

Valproic acid: Metabolism of barbiturates may be inhibited by valproic acid; monitor for excessive sedation; a dose reduction may be needed

Warfarin: Barbiturates inhibit the hypoprothrombinemic effects of oral anticoagulants via increased metabolism; this combination should generally be avoided

Pregnancy Risk Factor D

Pregnancy Implications Crosses placenta; no direct causal relationship established with congenital malformations; folate deficiency and hypoprothrombinemia has been noted in infants of mothers receiving phenobarbital; exposure to phenobarbital *in utero* may result in significantly lower verbal intelligence scores in males (0.5 SD); exposure in the last trimester appears to cause the greatest detriment

Lactation Enters breast milk/not recommended (AAP recommends use "with caution")

Nursing Implications Parenteral solutions are highly alkaline; avoid extravasation; avoid rapid I.V. administration >50 mg/minute; avoid intra-arterial injection; institute safety measures to avoid injuries

Additional Information Sodium content of injection (65 mg, 1 mL): 6 mg (0.3 mEq); the elderly may be more sensitive to the sedative effects of phenobarbital

Phenol

Pronunciation (FEE nol)

CAS Number 108-95-2

UN Number 1671 (solid); 2312 (molten); 2821 (solution)

U.S. Brand Names Chloraseptic® Gargle [OTC]; Chloraseptic® Mouth Pain Spray [OTC]; Chloraseptic® Rinse [OTC]; Chloraseptic® Spray for Kids [OTC]; Chloraseptic® Spray [OTC]; Ca⁺pastat® Extra Strength [OTC]; Ca⁺pastat® [OTC]; Pain-A-Lay® [OTC]; Ulcerease® [OTC]

Synonyms Carbolic Acid

Commonly Includes Production of resin; industrial coatings, adhesives, dyes, perfumes, textiles, lubricating oils, antiseptic agents

Use Relief of sore throat pain, mouth, gum, and throat irritations, neurologic pain, rectal prolapse, hemorrhoids, hydrocele

Mechanism of Action Cardiac effects may be due to sodium channel blockage; at concentrations >5%, it can denature protein

Adverse Reactions

Cardiovascular: Hypotension, cardiovascular collapse, tachycardia, arrhythmias (atrial and ventricular), sinus tachycardia

Central nervous system: CNS depression, slurred speech, coma, agitation, confusion, seizures, panic attacks (with inhalation)
 Dermatologic: Skin irritation, burns; white, red, or brown skin discoloration
 Gastrointestinal: Nausea, vomiting, hemorrhage, GI ulceration, GI bleeding
 Genitourinary: Urine discoloration (green)
 Neuromuscular & skeletal: Rabbit syndrome
 Renal: Nephritis
 Respiratory: Pulmonary edema, wheezing, coughing, dyspnea, pneumonia
 Miscellaneous: Oral burns

Signs and Symptoms of Overdose Cyanosis, dermal burns, hematuria, hypothermia, nephritis, seizures, urine discoloration (dark; brown; green), wheezing, Encephalopathy

Admission Criteria/Prognosis

Mild exposure: Asymptomatic patients may be discharged after 6 hours of observation

Serious exposure: Observe for 18-24 hours; death usually occurs within 24 hours of exposure

Can discharge patients who are asymptomatic 4 hours postexposure

Toxicodynamics/Kinetics

Absorption: Readily absorbed through the lungs (60% to 88%), orally (90%), through mucous membranes, and dermally (~0.35 m³/hour)

Distribution: Not known

Metabolism: Hepatic hydroxylation and sulfate conjugation

Half-life: 13.86 hours (dermal exposure) Conjugated phenol: 1 hour;

Elimination: 1-4.5 hours

Elimination: Renally with 52% unchanged

Dosage Allow to dissolve slowly in mouth; may be repeated every 2 hours as needed

Administration

Oral: Allow to lozenge dissolve slowly in mouth. Spray should be allowed to remain in mouth for ~15 seconds, then expectorate.

Topical: Castellani Paint Modified: May stain skin and clothing; apply to clean area

Warnings

When used for self-medication (OTC) for sore throat: Not for use > 7 days or if pain, redness, or irritation continues. If sore throat is severe, not for use > 2 days or if followed by fever, headache, rash, nausea, or vomiting. Oral gargles and sprays should not be swallowed.

When used for self-medication (OTC) as a topical antiseptic: Do not use in eyes, or apply to large areas of the body, deep or puncture wounds, animal bites or burns. Do not use for > 7 days; do not bandage affected area.

Dosage Forms

Lozenge, oral:

Cá[®]pastat[®]: 14.5 mg (18s) [sugar free; contains menthol; cherry flavor]

Cá[®]pastat[®] Extra Strength: 29 mg (18s) [sugar free; contains menthol; eucalyptus flavor]

Solution, oral: 1.4% (180 mL) [spray]

Cheracol[®] [spray]: Phenol 1.4% (180 mL) [alcohol and sugar free; contains tartrazine]

Chloraseptic[®] [gargle]: 1.4% (296 mL) [alcohol and sugar free; cool mint flavor]

Chloraseptic[®] Mouth Pain [rinse]: 1.4% (240 mL) [cinnamon flavor]

Chloraseptic[®] [spray]: 1.4% (20 mL, 30 mL) [alcohol and sugar free; cherry flavor]; (180 mL) [alcohol and sugar free; cherry, cool mint, and menthol flavors]

Chloraseptic[®] for Kids [spray]: 0.5% (177 mL) [grape flavor]

Pain-A-Lay[®] [gargle]: 1.4% (240 mL, 540 mL) [contains tartrazine]

Pain-A-Lay[®] [spray]: 1.4% (180 mL) [contains tartrazine]

Phenaseptic [spray]: 1.4% (180 mL) [cherry flavor]

Ulcerase[®] [gargle]: 0.6% (180 mL) [alcohol, dye, and sugar free; contains glycerin]

Solution, topical:

Castellani Paint Modified: Phenol 1.5% (30 mL) [contains alcohol 13%, acetone, basic fuchsin, resorcinol]

Castellani Paint Modified [colorless]: Phenol 1.5% (30 mL) [contains alcohol 13%, acetone, and resorcinol]

Swabs, topical (Phenol EZ[®]): 89% (30s) [~0.2 mL]

Reference Range

Lowest reported toxic serum phenol level: 27 mcg/mL

Toxic: >75 mg/L (urine)

Fatal: 3 g ingestion may be fatal

Dinitrophenol or hydroquinone may produce methemoglobin BEI (urine) is 250 mg/g creatinine; serum levels <20 mg/L not associated with acute toxicity

Urinary excretion of phenol (free plus conjugates) in humans with no known exposure: ~8.7±2.0 mg/day

Mean phenol urine concentration of 214 mg/L (range 208-220 mg/L) associated with fatal phenol poisoning

Overdosage/Treatment

Decontamination:

Oral: Ipecac is contraindicated; lavage within 1 hour with water or polyethylene glycol/activated charcoal is useful for gastric decontamination

Dermal: Remove clothing, wash exposed skin with isopropyl alcohol, polyethylene glycol, or industrial methylated spirits

Inhalation: Remove from source and provide oxygen

Ocular: Flush eyes with copious amounts of water (if exposed); low or high (3500) molecular weight polyethylene glycol can be useful for dermal irrigation of affected areas

Supportive therapy: I.V. sodium bicarbonate (1-2 mEq/kg) can be used to treat acidosis

Enhanced elimination: Charcoal hemoperfusion has been used successfully and can be considered for blood phenol levels >175 mcg/mL (associated with a 0.44 mg/kg exposure)

Antidote(s)

● Methylene Blue [ANTIDOTE]

Diagnostic Procedures

● Electrolytes, Blood

● Methemoglobin, Blood

Pregnancy Risk Factor C

Additional Information Colorless or white crystals, acrid odor. Odor threshold of 0.05 ppm in air and 8 ppm in water; TLV-TWA: 5 ppm; IDLH: 100 ppm; PEL-TWA: 5 ppm. Atmospheric half-life: 0.6-1 day; soil half-life is <5 days. River water in the U.S. contains from 10-100 ppb of phenol; ~64 square inches of body surface area exposure to phenol can be fatal.

Phenolphthalein

CAS Number 77-09-8

Synonyms Phenolphthalein, White; Phenolphthalein, Yellow

Use Stimulant laxative

Mechanism of Action A diphenylmethane compound which stimulates peristalsis by directly irritating the smooth muscle of the intestine, possibly the colonic intramural plexus

Adverse Reactions

Dermatologic: Rash, irritation and burning sensation of rectal mucosa, proctitis, toxic epidermal necrolysis, erythema multiforme, Stevens-Johnson syndrome, exfoliative dermatitis, angioedema, bullous skin disease, urticaria, pruritus, exanthem

Endocrine & metabolic: Electrolyte imbalance, hypoglycemia

Gastrointestinal: Abdominal cramps, nausea, vomiting

Miscellaneous: Systemic lupus erythematosus, fixed drug eruption

Signs and Symptoms of Overdose Abdominal pain, diarrhea, disseminated intravascular coagulation, feces discoloration (black; red), hypoglycemia, hypokalemia, hypotension, nephrotic syndrome, pancreatitis, pulmonary edema, seizures, tongue discoloration, toxic epidermal necrolysis

Pharmacodynamics/Kinetics

Onset of action: Within 6-8 hours

Elimination: In feces and skin, with up to 15% excreted in the urine as the conjugate; enterohepatically recycled

Dosage

Oral:

Children: 15-60 mg

Adults: 60-200 mg preferably at bedtime

Monitoring Parameters Monitor stools daily or weekly; fluid/electrolyte status

Contraindications Do not use in patients with abdominal pain, obstruction, nausea or vomiting; not to be used during pregnancy or lactation

Warnings Habit-forming and may result in laxative dependence and loss of normal bowel function with prolonged use, can cause skin hypersensitivity and fixed drug eruption

Dosage Forms Gum: 97.2 mg

Tablet: 60 mg, 90 mg, 97.2 mg, 130 mg

Tablet, chewable: 65 mg, 90 mg, 97.2 mg, 120 mg

Wafer: 64.8 mg

Wafer, chewable: 80 mg

Reference Range Serum phenolphthalein level of 0.4 mcg/L associated with fatality

Overdosage/Treatment

Decontamination: Activated charcoal is useful (**do not** use a cathartic)

Supportive therapy: I.V. fluid and electrolyte replacement

Enhancement of elimination: Multiple dosing of activated charcoal may be useful

Test Interactions ↓ calcium (S), potassium (S)

Pregnancy Risk Factor C

Additional Information Toxic dose: Children: 600 mg; Adults: 2 g

The chronic use of stimulant cathartics is inappropriate and should be avoided although constipation is a common complaint from elderly, such complaints require evaluation; short-term use of stimulants is best; if prophylaxis is desired, this can be accomplished with bulk agents (psyllium), stool softeners, and hyperosmotic agents (sorbitol 70%); stool softeners are unnecessary if stools are well hydrated, soft, or "mushy"

Phenolphthalein, white: Alophen Pills[®] [OTC], Medilax[®] [OTC], Modane[®] [OTC], Modane[®] Mild [OTC], Phenolax[®] [OTC], Prulel[®] [OTC]

PHENOXYBENZAMINE

Phenolphthalein, yellow: Evac-U-Gen® [OTC], Evac-U-Lax® [OTC], Ex-Lax® [OTC], Feen-A-Mint® [OTC], Lax-Pills® [OTC] Yellow is 2-3 times more potent than white. Urine or stool may be red or pink; produces an alkaline stool; does not decrease food absorption.

Phenoxybenzamine

CAS Number 59-96-1; 63-92-3

U.S. Brand Names Dibenzylin®

Synonyms Phenoxybenzamine Hydrochloride

Use Symptomatic management of pheochromocytoma; treatment of hypertensive crisis caused by sympathomimetic amines

Unlabeled/Investigational Use Micturition problems associated with neurogenic bladder, functional outlet obstruction, and partial prostate obstruction

Mechanism of Action Produces long-lasting noncompetitive alpha-adrenergic blockade of postganglionic synapses in exocrine glands and smooth muscle; relaxes urethra and increases opening of the bladder

Adverse Reactions

Cardiovascular: Postural hypotension, tachycardia (reflex), syncope, shock

Central nervous system: Lethargy, headache, confusion, fatigue, seizures (due to rapid administration of drug)

Gastrointestinal: Vomiting, nausea, diarrhea, xerostomia

Genitourinary: Inhibition of ejaculation

Neuromuscular & skeletal: Weakness

Ocular: Miosis

Respiratory: Nasal congestion

Signs and Symptoms of Overdose Dizziness, hypotension, lethargy, shock, tachycardia

Admission Criteria/Prognosis Admit any symptomatic patient or with ingestion > 1.5 mg/kg

Pharmacodynamics/Kinetics

Onset of action: ~2 hours

Peak effect: 4-6 hours

Duration: ≥ 4 days

Half-life elimination: 24 hours

Excretion: Primarily urine and feces

Dosage

Oral:

Children: Initial: 0.2 mg/kg (maximum: 10 mg) once daily, increase by 0.2 mg/kg increments; usual maintenance dose: 0.4-1.2 mg/kg/day every 6-8 hours, higher doses may be necessary

Adults: Initial: 10 mg twice daily, increase by 10 mg every other day until optimum dose is achieved; usual range: 20-40 mg 2-3 times/day

Urinary retention: 10 mg twice daily

Monitoring Parameters Blood pressure, pulse, urine output, orthostasis

Administration GI irritation may be reduced by giving in divided doses

Contraindications Hypersensitivity to phenoxybenzamine or any component of the formulation; conditions in which a fall in blood pressure would be undesirable (eg, shock); concurrent use with phosphodiesterase-5 (PDE-5) inhibitors including sildenafil (>25 mg), tadalafil, or vardenafil

Warnings Use with caution in patients with renal impairment, cerebral, or coronary arteriosclerosis, can exacerbate symptoms of respiratory tract infections. Because of the risk of adverse effects, avoid the use of this medication in the elderly if possible.

Dosage Forms Capsule, as hydrochloride: 10 mg [contains benzyl alcohol]

Overdosage/Treatment

Decontamination: Oral: Activated charcoal should be administered. Lavage can be considered if ingestion occurred within 2 hours. Consider gastric decontamination at ingestions > 1.5 mg/kg.

Supportive therapy: Hypotension and shock should be treated with fluids and by placing the patient in the Trendelenburg position; only alpha-adrenergic pressors such as norepinephrine (0.1-0.2 mcg/kg/minute; titrate to desired effect) should be used; mixed agents such as epinephrine, may cause more hypotension

Drug Interactions Alpha adrenergic agonists decrease the effect of phenoxybenzamine.

Beta-blockers may result in increased toxicity (hypotension, tachycardia). Sildenafil, tadalafil, vardenafil: Blood pressure-lowering effects are additive. Use of vardenafil or tadalafil is contraindicated by the manufacturer. Use sildenafil with extreme caution (dose ≤ 25 mg).

Pregnancy Risk Factor C

Pregnancy Implications Placental transfer can occur resulting in fetal respiratory depression and transient hypotension

Nursing Implications Monitor for orthostasis; assist with ambulation

Phensuximide

CAS Number 86-34-0

Use Control of absence (petit mal) seizures; ethosuximide must be used in combination with other anticonvulsants in patients with both absence and tonic-clonic seizures

Mechanism of Action Increases the seizure threshold and suppresses paroxysmal spike-and-wave pattern in absence seizures; depresses nerve transmission in the motor cortex

Adverse Reactions

Central nervous system: Dizziness, drowsiness, headache, aggressiveness, CNS depression, night terrors, tiredness, paranoid psychosis, ataxia, psychosis

Dermatologic: Stevens-Johnson syndrome, rash, exfoliative dermatitis, hypertrichosis, alopecia, purpura, pruritus

Gastrointestinal: Anorexia, nausea, vomiting, weight loss, gingival hyperplasia

Genitourinary: Urine discoloration (pink/red to red/brown)

Hematologic: Agranulocytosis, leukopenia, aplastic anemia, thrombocytopenia, pancytopenia

Neuromuscular & skeletal: Weakness

Ocular: Photophobia

Miscellaneous: Hiccups, systemic lupus erythematosus

Signs and Symptoms of Overdose Acute: Ataxia, blood dyscrasias, CNS depression, coma, hypotension, night terrors, photophobia, stupor, urinary frequency

Chronic: Albuminuria, ataxia, confusion, hematuria, hepatic dysfunction, skin rash

Toxicodynamics/Kinetics

Absorption: Oral: Well absorbed

Protein binding: 0%

Metabolism: In the liver to norphensuximide (30%)

Half-life: 5-12 hours (8 hours for metabolite)

Time to peak serum concentration: Within 1-4 hours

Elimination: In urine as active and inactive metabolites

Dosage Children and Adults: Oral: 0.5-1 g 2-3 times/day

Reference Range Therapeutic: 10-20 mcg/mL (SI: 57-114 μmol/L)

Overdosage/Treatment

Decontamination: Do not induce emesis; lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Forced diuresis is of no benefit; multiple dosing of activated charcoal may be useful; although data is lacking, hemodialysis or hemoperfusion may be effective

Test Interactions ↑ alkaline phosphatase (S); positive Coombs' [direct]; ↓ calcium (S)

Phentermine

CAS Number 1197-21-3; 122-09-8

U.S. Brand Names Adipex-P®; Ionamin®

Synonyms Phentermine Hydrochloride

Impairment Potential Yes

Use Short-term adjunct in a regimen of weight reduction based on exercise, behavioral modification, and caloric reduction in the management of exogenous obesity for patients with an initial body mass index ≥ 30 kg/m² or ≥ 27 kg/m² in the presence of other risk factors (diabetes, hypertension)

Mechanism of Action Phentermine is structurally similar to dextroamphetamine and is comparable to dextroamphetamine as an appetite suppressant, but is generally associated with a lower incidence and severity of CNS side effects. Phentermine, like other anorexiant, stimulates the hypothalamus to result in decreased appetite; anorexiatic effects are most likely mediated via norepinephrine and dopamine metabolism. However, other CNS effects or metabolic effects may be involved.

Adverse Reactions

Cardiovascular: Hypertension, tachycardia, arrhythmias, palpitations, pulmonary hypertension, sinus tachycardia

Central nervous system: Euphoria, nervousness, insomnia, confusion, CNS depression, restlessness, headache, paranoid psychosis, psychosis, paranoia

Dermatologic: Alopecia

Endocrine & metabolic: Changes in libido

Gastrointestinal: Nausea, vomiting, diarrhea, abdominal cramps, constipation

Genitourinary: Dysuria

Hematologic: Blood dyscrasias

Neuromuscular & skeletal: Tremors, myalgia, rhabdomyolysis

Ocular: Blurred vision, mydriasis

Renal: Polyuria

Respiratory: Dyspnea

Miscellaneous: Diaphoresis (increased)

Signs and Symptoms of Overdose Agitation, hyperactivity, hypertension, hyperthermia, insomnia, seizures

Pharmacodynamics/Kinetics

Duration: Resin produces more prolonged clinical effects

Absorption: Well absorbed; resin absorbed slower

Half-life elimination: 20 hours

Excretion: Primarily urine (as unchanged drug)

Dosage

Oral:

Children 3-15 years: Obesity: 5-15 mg/day for 4 weeks

Adults: Obesity: 8 mg 3 times/day 30 minutes before meals or food or 15-37.5 mg/day before breakfast or 10-14 hours before retiring

Monitoring Parameters CNS

Contraindications Hypersensitivity or idiosyncrasy to sympathomimetic amines or any component of the formulation; patients with advanced arteriosclerosis, symptomatic cardiovascular disease, moderate to severe hypertension (stage II or III), hyperthyroidism, glaucoma, agitated states; patients with a history of drug abuse; use during or within 14 days following MAO inhibitor therapy; children <16 years of age (per manufacturer)

Warnings

Use with caution in patients with bipolar disorder, diabetes mellitus, cardiovascular disease, seizure disorders, insomnia, porphyria, or mild hypertension (stage I). May exacerbate symptoms of behavior and thought disorder in psychotic patients. Stimulants may unmask tics in individuals with coexisting Tourette's syndrome. Potential for drug dependency exists; avoid abrupt discontinuation in patients who have received for prolonged periods. Stimulant use has been associated with growth suppression, and careful monitoring is recommended.

Primary pulmonary hypertension (PPH), a rare and frequently fatal pulmonary disease, has been reported to occur in patients receiving a combination of phentermine and fenfluramine or dexfenfluramine. The possibility of an association between PPH and the use of phentermine alone cannot be ruled out.

Use in weight reduction programs only when alternative therapy has been ineffective. Serious, potentially life-threatening toxicities may occur when thyroid hormones (at dosages above usual daily hormonal requirements) are used in combination with sympathomimetic amines to induce weight loss. Treatment of obesity is not an approved use for thyroid hormone.

Dosage Forms Capsule, as hydrochloride: 15 mg, 30 mg

Adipex-P®: 37.5 mg

Capsule, resin complex:

Ionamin®: 15 mg; 30 mg [DSC]

Tablet, as hydrochloride: 37.5 mg

Adipex-P®: 37.5 mg

Reference Range Therapeutic plasma level: 30-90 ng/mL (does not correlate with weight loss)

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage (within 1 hour)/activated charcoal

Supportive therapy: There is no specific antidote for phentermine intoxication and the bulk of the treatment is supportive. Hyperactivity and agitation usually respond to reduced sensory input, however with extreme agitation diazepam (10-20 mg orally in adults or 0.1 mg/kg in children) or I.V. droperidol (0.1 mg/kg) or haloperidol (0.1 mg/kg) may be required. Hyperthermia is best treated with external cooling measures, or when severe or unresponsive, muscle paralysis with pancuronium may be needed. Hypertension is usually transient and generally does not require treatment unless severe. For diastolic blood pressures >120 mm Hg, a nitroprusside infusion should be initiated. Seizures usually respond to diazepam IVP and/or phenytoin maintenance regimens. Alkaline diuresis with mannitol or furosemide may be required to treat rhabdomyolysis; do not acidify urine.

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; extracorporeal removal has not been shown to be beneficial

Drug Interactions Antihypertensives: Phentermine may decrease the effect of antihypertensive medications

Antipsychotics: Efficacy of anorexiant may be decreased by antipsychotics; in addition, amphetamines or related compounds may induce an increase in psychotic symptoms in some patients

Furazolidone: Amphetamines (and related compounds) may induce hypertensive episodes in patients receiving furazolidone

Guanethidine: Amphetamines (and related compounds) inhibit the antihypertensive response to guanethidine; probably also may occur with guanadrel

Hypoglycemic agents: Dosage may need to be adjusted when phentermine is used in a diabetic receiving a special diet

Linezolid: Due to MAO inhibition (see note on MAO inhibitors), this combination should generally be avoided

MAO inhibitors: Concurrent use may be associated with hypertensive episodes

SSRIs: Concurrent use may be associated with a risk of serotonin syndrome

Pregnancy Risk Factor C

Nursing Implications Dose should not be given in evening or at bedtime

Phenylbutazone

CAS Number 50-33-9

Use As an analgesic in the treatment of mild to moderate pain and as an antipyretic; I.V. form used as an alternate to surgery in management of patent ductus arteriosus in premature neonates; acute gouty arthritis. Off the market since 1992.

Mechanism of Action Phenylbutazone is an anti-inflammatory, antipyretic, uricosuric, and analgesic; mechanism of action is thought to be due primarily to prostaglandin inhibition, leukocyte migration inhibition, and lysosomal enzyme stabilization

Adverse Reactions

Cardiovascular: Tachycardia, hypotension, myocarditis (hypersensitivity), fibrillation (atrial), flutter (atrial), angina, congestive heart failure, myocardial depression, pericardial effusion/pericarditis, sinus tachycardia

Central nervous system: Dizziness, drowsiness, headache, fatigue, seizures, gustatory hallucinations

Dermatologic: Rash, edema, erythema multiforme, toxic epidermal necrolysis, cutaneous vasculitis

Endocrine & metabolic: Parotitis

Gastrointestinal: Dyspepsia, heartburn, nausea, vomiting, abdominal pain, peptic ulcer, GI bleeding, GI perforation, loss of taste perception, esophagitis

Hematologic: Anemia, platelet inhibition, thrombocytopenia, coagulopathy, leukopenia, neutropenia, agranulocytosis, granulocytopenia, red blood cell aplasia

Hepatic: Hepatitis, granulomatous hepatitis, primary biliary cirrhosis

Ocular: Vision changes

Otic: Ototoxicity, tinnitus

Renal: Renal failure (acute), myoglobinuria, glomerulonephritis, renal vasculitis

Respiratory: Pulmonary edema, pulmonary vasculitis

Miscellaneous: Systemic lupus erythematosus, lymphadenopathy

Signs and Symptoms of Overdose Abdominal pain, agitation, ataxia, chest pain, cholestatic jaundice, coagulopathy, colitis, coma, dermatitis, diarrhea, drowsiness, dysosmia, erythema multiforme, exfoliative dermatitis, feces discoloration (black; greenish-gray; pink; red; red-brown), gastritis, hematuria, GI bleeding, hyperventilation, hypotension, hypothyroidism, jaundice, lichenoid eruptions, pemphigus, periarteritis nodosa, pericarditis, photosensitivity, respiratory arrest, rhabdomyolysis, seizures, stomatitis, toxic epidermal necrolysis, urine discoloration (red; red-brown)

Pharmacodynamics/Kinetics

Onset of action: 30-60 minutes

Duration: 3-5 days

Absorption: Oral: Well absorbed from gastrointestinal tract

Distribution: Most body tissues and synovial spaces

Protein binding: 98%

Metabolism: To oxyphenbutazone and hydroxyphenbutazone in the liver

Half-life: 50-100 hours (increases with hepatic impairment)

Time to peak serum concentration: Within 30-60 minutes

Elimination: Urinary excretion primarily as metabolites (99%)

Dosage

Adults: Oral: Initial:

Rheumatoid arthritis: 100-200 mg 3-4 times/day until desired effect, then reduce dose to not exceed 400 mg/day

Acute gouty arthritis: 400 mg, 100 mg every 4 hours until acute attack subsides, not to continue longer than 1 week

Dosing adjustment in hepatic impairment: Should not be administered to patients with liver dysfunction

Contraindications Active gastrointestinal bleeding, ulcer disease, hypersensitivity to phenylbutazone or any component

Warnings May cause agranulocytosis and aplastic anemia; is not just a simple analgesic; use only when other NSAIDs have failed; use with caution in patients with congestive heart failure, hypertension, decreased renal or hepatic function, history of gastrointestinal disease (bleeding or ulcers), or those receiving anticoagulants; safety and efficacy in children <6 months of age have not yet been established; because of severe hematologic adverse effects, discontinue use if no favorable response is seen

Dosage Forms Capsule: 100 mg

Tablet: 100 mg

Reference Range

Therapeutic: 50-100 mcg/mL (SI: 162-324 µmol/L)

Toxic: > 100 mcg/mL (SI: >324 µmol/L)

Overdosage/Treatment

Supportive therapy: Management is primarily supportive and symptomatic. Fluid therapy is commonly effective in managing the hypotension except when this is due to an acute blood loss. Recurrent seizures should be treated with I.V. diazepam or lorazepam.

Enhancement of elimination: Multiple doses of charcoal may be needed to reduce the potential for delayed toxicities; charcoal hemoperfusion may remove 5% to 20% of drug

Test Interactions ↓ uric acid (S)

PHENYLEPHRINE

Drug Interactions May inhibit phenytoin or warfarin metabolism and methotrexate excretion

Pregnancy Risk Factor D

Pregnancy Implications Crosses the placenta

Phenylephrine

CAS Number 59-42-7; 61-76-7

U.S. Brand Names AK-Dilate®; AK-Nefrin®; Formulation R™ [OTC]; Medicone® [OTC]; Mydrfrin®; Neo-Synephrine® Extra Strength [OTC]; Neo-Synephrine® Mild [OTC]; Neo-Synephrine® Ophthalmic; Neo-Synephrine® Regular Strength [OTC]; Nostril® [OTC]; Phenoptic®; Prefrin™ [DSC]; Relief® [OTC]; Vicks® Sinex® Nasal Spray [OTC]; Vicks® Sinex® UltraFine Mist [OTC]

Synonyms Phenylephrine Hydrochloride; Phenylephrine Tannate

Use Treatment of hypotension, vascular failure in shock; as a vasoconstrictor in regional analgesia; symptomatic relief of nasal and nasopharyngeal mucosal congestion; as a mydriatic in ophthalmic procedures and treatment of wide-angle glaucoma; supraventricular tachycardia

Mechanism of Action Potent, direct-acting alpha-adrenergic stimulator with weak beta-adrenergic activity; causes vasoconstriction of the arterioles of the nasal mucosa and conjunctiva; activates the dilator muscle of the pupil to cause contraction; produces vasoconstriction of arterioles in the body

Adverse Reactions

Nasal:

Central nervous system: Psychosis, insomnia; visual, tactile, and auditory hallucinations; paranoid delusions, mania

Local: **Burning**

Respiratory: **Rebound congestion, sneezing**

Dermatologic: **Stinging, dryness**

Ophthalmic:

Central nervous system: Headache, browache

Dermatologic: Contact dermatitis, periorbital dermatitis

Ocular: **Transient stinging, mydriasis**, blurred vision, photophobia, lacrimation

Systemic:

Cardiovascular: Peripheral vasoconstriction, hypertension, angina, reflex bradycardia, arrhythmias

Central nervous system: Restlessness, excitability

Local: Extravasation injury

Neuromuscular & skeletal: **Tremor**

Pharmacodynamics/Kinetics

Onset of action: I.M., SubQ: 10-15 minutes; I.V.: Immediate; Ophthalmic: 10-15 minutes

Duration: I.M.: 0.5-2 hours; I.V.: 15-30 minutes; SubQ: 1 hour; Ophthalmic: Maximal mydriasis: 1 hour, recover time: 3-6 hours

Metabolism: Hepatic, via intestinal monoamine oxidase to phenolic conjugates

Excretion: Urine (90%)

Dosage

Ophthalmic procedures:

Infants < 1 year: Instill 1 drop of 2.5% 15-30 minutes before procedures

Children and Adults: Instill 1 drop of 2.5% or 10% solution, may repeat in 10-60 minutes as needed

Nasal decongestant: (therapy should not exceed 5 continuous days)

Children:

2-6 years: Instill 1 drop every 2-4 hours of 0.125% solution as needed

6-12 years: Instill 1-2 sprays or instill 1-2 drops every 4 hours of 0.25% solution as needed

Children > 12 years and Adults: Instill 1-2 sprays or instill 1-2 drops every 4 hours of 0.25% to 0.5% solution as needed; 1% solution may be used in adult in cases of extreme nasal congestion; do not use nasal solutions more than 3 days

Hypotension/shock:

Children:

I.M., SubQ: 0.1 mg/kg/dose every 1-2 hours as needed (maximum: 5 mg)

I.V. bolus: 5-20 mcg/kg/dose every 10-15 minutes as needed

I.V. infusion: 0.1-0.5 mcg/kg/minute

Adults:

I.M., SubQ: 2-5 mg/dose every 1-2 hours as needed (initial dose should not exceed 5 mg)

I.V. bolus: 0.1-0.5 mg/dose every 10-15 minutes as needed (initial dose should not exceed 0.5 mg)

I.V. infusion: 10 mg in 250 mL D₅W or normal saline (1:25,000 dilution) (40 mcg/mL); start at 100-180 mcg/minute (2-5 mL/

minute; 50-90 drops/minute) initially; when blood pressure is stabilized, maintenance rate: 40-60 mcg/minute (20-30 drops/minute)

Maternal hypotension: 0.1 mg/dose

Paroxysmal supraventricular tachycardia: I.V.:

Children: 5-10 mcg/kg/dose over 20-30 seconds

Adults: 0.25-0.5 mg/dose over 20-30 seconds

Stability Is stable for 48 hours in 5% dextrose in water at pH 3.5-7.5; do not use brown colored solutions

Monitoring Parameters Blood pressure, heart rate, arterial blood gases, central venous pressure

Administration Concentration and rate of infusion can be calculated using the following formulas: Dilute 0.6 mg × weight (kg) to 100 mL; then the dose in mcg/kg/minute = 0.1 × the infusion rate in mL/hour

Contraindications Hypersensitivity to phenylephrine or any component of the formulation; hypertension; ventricular tachycardia

Oral: Use with or within 14 days of MAO inhibitor therapy

Ophthalmic: Narrow-angle glaucoma

Warnings Some products contain sulfites which may cause allergic reactions in susceptible individuals.

Intravenous: Use with caution in the elderly, patients with hyperthyroidism, bradycardia, partial heart block, myocardial disease, or severe CAD. Not a substitute for volume replacement. Avoid hypertension; monitor blood pressure closely and adjust infusion rate. Infuse into a large vein if possible. Watch I.V. site closely. Avoid extravasation. **[U.S. Boxed Warning]: Should be administered by adequately trained individuals familiar with its use.**

Nasal, oral, rectal: Use caution with hyperthyroidism, diabetes mellitus, cardiovascular disease, ischemic heart disease, increased intraocular pressure, prostatic hyperplasia or in the elderly. Rebound congestion may occur when nasal products are discontinued after chronic use. When used for self-medication (OTC), notify healthcare provider if symptoms do not improve within 7 days (oral, rectal) or 3 days (nasal), are accompanied by fever (oral), or if bleeding occurs (rectal).

Ophthalmic: Use caution with or within 21 days of MAO inhibitor therapy. When used for self-medication (OTC), notify healthcare provider in case of vision changes, continued redness, or if symptoms worsen or do not improve within 3 days.

Dosage Forms [DSC] = Discontinued product

Cream, rectal, as hydrochloride (Formulation R™): 0.25% (54 g) [contains sodium benzoate]

Injection, solution, as hydrochloride: 1% [10 mg/mL] (1 mL, 5 mL) [may contain sodium metabisulfite]

Neo-Synephrine®: 1% (1 mL) [contains sodium metabisulfite]

Ointment, rectal, as hydrochloride:

Formulation R™: 0.25% (30 g, 60 g) [contains benzoic acid]

Rectacaine: 0.25% (30 g) [contains shark liver oil]

Solution, intranasal drops, as hydrochloride:

Neo-Synephrine® Extra Strength: 1% (15 mL) [contains benzalkonium chloride]

Neo-Synephrine® Regular Strength: 0.5% (15 mL) [contains benzalkonium chloride]

Rhinall: 0.25% (30 mL) [contains benzalkonium chloride and sodium bisulfite]

Solution, intranasal spray, as hydrochloride:

Neo-Synephrine® Extra Strength: 1% (15 mL) [contains benzalkonium chloride]

Neo-Synephrine® Mild: 0.25% (15 mL) [contains benzalkonium chloride]

Neo-Synephrine® Regular Strength: 0.5% (15 mL) [contains benzalkonium chloride]

Rhinall: 0.25% (40 mL) [contains benzalkonium chloride and sodium bisulfite]

Vicks® Sinex®, Vicks® Sinex® UltraFine Mist: 0.5% (15 mL) [contains benzalkonium chloride]

Solution, ophthalmic, as hydrochloride: 2.5% (1 mL, 2 mL, 3 mL, 5 mL, 15 mL) [may contain sodium bisulfite]

AK-Dilate®: 2.5% (2 mL, 15 mL); 10% (5 mL)

Altrafrin: 0.12% (15 mL) [OTC]; 2.5% (5 mL, 15 mL) [RX; contains benzalkonium chloride]; 10% (5 mL) [RX; contains benzalkonium chloride]

Mydrfrin®: 2.5% (3 mL, 5 mL) [contains sodium bisulfite]

Neo-Synephrine®: 2.5% (15 mL); 10% (5 mL) [contains benzalkonium chloride] [DSC]

Neo-Synephrine® Viscous: 10% (5 mL) [contains benzalkonium chloride] [DSC]

Suppository, rectal, as hydrochloride: 0.25% (12s)

Anu-Med, Tronolane®: 0.25% (12s)

Medicone®: 0.25% (18s, 24s)

Rectacaine: 0.25% (12s) [contains shark liver oil]

Suspension, oral, as tannate (Ná Sop™): 7.5 mg/5 mL (120 mL) [orange flavor]

Tablet, as hydrochloride (Sudafed PE™): 10 mg

Tablet, chewable, as hydrochloride:

PHENYLPROPANOLAMINE (WITHDRAWN FROM U.S. MARKET)

AH-chew® D: 10 mg [DSC]

Tablet, orally dissolving, as hydrochloride (Ná Sop™): 10 mg [contains phenylalanine 4 mg/tablet; bubble gum flavor]

Reference Range Peak plasma phenylephrine concentration after an oral dose of 9 mg: ~0.03 mg/L

Overdosage/Treatment Supportive therapy: Agitation can be treated with a benzodiazepine; propranolol (1 mg I.V. as needed to a total adult dose of 5 mg or 0.01-0.1 mg/kg in pediatrics to a total dose of 1 mg I.V.) or esmolol (50-100 mcg/kg/minute) can be given to treat tachycardia; atropine can be given for severe bradycardia with hypotension (not to be given for reflex bradycardia due to hypertension); nitroprusside, nifedipine, labetalol, hydralazine or esmolol can be used to treat hypertension

Drug Interactions Beta-blockers (nonselective) may increase hypertensive effect; avoid concurrent use.

MAO inhibitors: May potentiate hypertension and hypertensive crisis; avoid concurrent use.

Methyldopa can increase the pressor response; be aware of patient's drug regimen.

Tricyclic antidepressants: May enhance the vasopressor effect phenylephrine; avoid concurrent use.

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications May cause necrosis or sloughing tissue if extravasation occurs during I.V. administration or SubQ administration

Extravasation: Use phentolamine as antidote; mix 5 mg with 9 mL of NS; inject a small amount of this dilution into extravasated area; blanching should reverse immediately. Monitor site; if blanching should recur, additional injections of phentolamine may be needed.

Additional Information Do not administer if the patient is exposed to chloroform, cyclopropane, halothane, trichloroethylene or other organic solvents in that ventricular arrhythmia may occur; pKa is ~8.8

Phenylpropanolamine (Withdrawn from U.S. Market)

CAS Number 154-41-6

Impairment Potential Yes

Use Anorexiant and nasal decongestant

Mechanism of Action Releases tissue stores of epinephrine and thereby produces an alpha- and beta-adrenergic stimulation; this causes vasoconstriction and nasal mucosa blanching; also appears to depress central appetite centers

Adverse Reactions

Cardiovascular: **Palpitations**, reflex bradycardia, cardiac arrhythmias, chest pain, **hypertension**, angina, vasculitis, AV block, sinus bradycardia, sinus tachycardia, arrhythmias (ventricular)

Central nervous system: Anxiety, psychosis, nervousness, restlessness, headache, insomnia, mania, paranoia, sympathetic storm, dystonia

Endocrine & metabolic: Hypokalemia

Genitourinary: Dysuria, urinary incontinence

Neuromuscular & skeletal: Rhabdomyolysis

Ocular: Mydriasis

Respiratory: Rhinitis

Miscellaneous: Fixed drug eruption

Signs and Symptoms of Overdose Anorexia, cognitive dysfunction, extrapyramidal reaction, hypertension, hyperthermia, palpitations, paresthesia, reflex bradycardia, renal failure, seizures, tachycardia, vomiting

Toxicodynamics/Kinetics

Onset of action: Nasal decongestion: 15-30 minutes

Duration: Tablet: 3 hours; Extended release: 12-16 hours

Absorption: Oral: Well absorbed

Distribution: V_d : 4.5 L/kg

Metabolism: In the liver to norephedrine

Bioavailability: ~100%

Half-life: 4.6-6.6 hours

Elimination: Primarily in urine as unchanged drug (80% to 90%)

Dosage

Oral:

Children: Decongestant:

2-6 years: 6.25 mg every 4 hours

6-12 years: 12.5 mg every 4 hours not to exceed 75 mg/day

Adults:

Decongestant: 25 mg every 4 hours or 50 mg every 8 hours, not to exceed 150 mg/day

Anorexic: 25 mg 3 times/day 30 minutes before meals or 75 mg (timed release) once daily in the morning

Precision release: 75 mg after breakfast

Reference Range Peak serum phenylpropanolamine: ~0.28 mg/L 6 hours after oral ingestion of 150 mg sustained release dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Lorazepam or diazepam 5-10 mg I.V. (0.25-0.4 mg/kg for children) or phenobarbital may be used for excitation and seizures; nitroprusside can be used for hypertension while labetalol or

esmolol can be used for tachycardia; ventricular ectopy can be treated with lidocaine

Enhancement of elimination: Multiple dosing of activated charcoal should be performed for sustained release preparation. Alkalinization can reduce the renal rate of elimination.

Nursing Implications Give dose early in day to prevent insomnia; observe for signs of nervousness, excitability

Phenytoin

Related Information

- Fosphenytoin
- Mephenytoin
- Seizures, Neonatal Guidelines
- Therapeutic Drugs Associated with Hallucinations

CAS Number 57-41-0

U.S. Brand Names Dilantin®; Phenytek™

Synonyms Diphenylhydantoin; DPH; Phenytoin Sodium, Extended; Phenytoin Sodium, Prompt; Phenytoin Sodium

Impairment Potential Yes; can be ergolytic (impair athletic performance)

Use Management of generalized tonic-clonic (grand mal), simple partial and complex partial seizures; prevention of seizures following head trauma/neurosurgery; ventricular arrhythmias, including those associated with digitalis intoxication; beneficial effects in the treatment of migraine or trigeminal neuralgia in some patients

Unlabeled/Investigational Use Ventricular arrhythmias, including those associated with digitalis intoxication, prolonged QT interval and surgical repair of congenital heart diseases in children; epidermolysis bullosa

Mechanism of Action Stabilizes neuronal membranes and decreases seizure activity by increasing efflux or decreasing influx of sodium ions across cell membranes in the motor cortex during generation of nerve impulses; prolongs effective refractory period and suppresses ventricular pacemaker automaticity, shortens action potential in the heart

Adverse Reactions

Effects not related to plasma phenytoin concentrations: Hypertrichosis, gingival hypertrophy, thickening of facial features, carbohydrate intolerance, folic acid deficiency, peripheral neuropathy, vitamin D deficiency, osteomalacia, systemic lupus erythematosus

Concentration-related effects: Nystagmus, blurred vision, diplopia, ataxia, slurred speech, dizziness, drowsiness, lethargy, coma, rash, fever, nausea, vomiting, gum tenderness, confusion, mood changes, folic acid depletion, osteomalacia, hyperglycemia

Rarely seen effects: SLE-like syndrome, lymphadenopathy, hepatitis, Stevens-Johnson syndrome, blood dyscrasias, dyskinesias, pseudolymphoma, venous irritation and pain, coarsening of the facial features, hypertrichosis

Dose related:

Cardiovascular: Myocarditis (hypersensitivity), AV block, facial edema

Central nervous system: **Slurred speech, psychiatric changes, dizziness, drowsiness**, psychosis, fever, visual hallucinations, ataxia, anticonvulsant hypersensitivity syndrome, insomnia

Dermatologic: Rash, exfoliative dermatitis, erythema multiforme, acne, acute generalized exanthematous pustulosis, linear IgA bullous dermatosis, hirsutism, hypertrichosis

Endocrine & metabolic: Folic acid depletion, osteomalacia, hyperglycemia, reduced plasma testosterone, gynecomastia, hypoglycemia

Gastrointestinal: **Nausea, constipation, vomiting, gingival hyperplasia**, burning tongue syndrome

Genitourinary: Priapism, possible urinary retention in children

Hematologic: Neutropenia, thrombocytopenia, anemia (megaloblastic), thrombocytopenia, megaloblastic anemia

Neuromuscular & skeletal: Sensory paresthesia (long-term treatment), choreoathetosis, chorea, osteoporosis

Ocular: Nystagmus, blurred vision, diplopia

Renal: Nephrotic syndrome

Miscellaneous: Mutism, pseudolymphoma, lymphadenopathy, mucocutaneous syndrome (febrile)

I.V.:

Cardiovascular: Hypotension, bradycardia, cardiac arrhythmias, cardiovascular collapse (especially with rapid I.V. use),

Local: Extravasation injury due to solvents and excipients

Signs and Symptoms of Overdose Acrodynia, agranulocytosis, chorea (extrapyramidal), cognitive dysfunction, coma, confusion, delirium, dementia, drowsiness, dysarthria, dysosmia, encephalopathy, enuresis, eosinophilia, extrapyramidal reaction, fever, granulocytopenia, gynecomastia, headache, hyperglycemia, hyperprolactinemia, hyperreflexia, hyperthermia, hypocalcemia, hypoglycemia, hypotension, hypothermia, hypothyroidism, leukemoid reaction, leukopenia, myasthenia gravis (exacerbation or precipitation), mydriasis, myocarditis, myoclonus, myoglobinuria, nausea, nephrotic syndrome, neutropenia, ophthalmoplegia, Parkinson's-like symptoms, periarteritis nodosa, pseudotumor

PHENYTOIN

cerebri, psychosis, respiratory depression, rhabdomyolysis, slurred speech, toxic epidermal necrolysis, tremors, unsteady gait, vision color changes (white tinge).

While toxicity from oral ingestion is relatively low, cardiac toxicity due to I.V. administration is primarily due to propylene glycol moiety. See table.

Manifestations of Phenytoin Toxicity	
Levels	Manifestation
20 mcg/mL (79 μ mol/L)	Nystagmus
30 mcg/mL (118.9 μ mol/L)	Ataxia
40 mcg/mL (159 μ mol/L)	Decreased mental status
50 mcg/mL (200 μ mol/L)	Coma
95 mcg/mL (377 μ mol/L)	Fatal

Admission Criteria/Prognosis Admit any patient with mental status changes or total phenytoin level > 50 mcg/mL, or free phenytoin level > 5 mcg/mL

Pharmacodynamics/Kinetics

Onset of action: I.V.: ~0.5-1 hour

Absorption: Oral: Slow

Distribution: V_d :

Neonates: Premature: 1-1.2 L/kg; Full-term: 0.8-0.9 L/kg

Infants: 0.7-0.8 L/kg

Children: 0.7 L/kg

Adults: 0.6-0.7 L/kg

Protein binding:

Neonates: $\geq 80\%$ ($\leq 20\%$ free)

Infants: $\geq 85\%$ ($\leq 15\%$ free)

Adults: 90% to 95%

Others: Decreased protein binding

Disease states resulting in a decrease in serum albumin concentration: Burns, hepatic cirrhosis, nephrotic syndrome, pregnancy, cystic fibrosis

Disease states resulting in an apparent decrease in affinity of phenytoin for serum albumin: Renal failure, jaundice (severe), other drugs (displacers), hyperbilirubinemia (total bilirubin > 15 mg/dL), Cl_{cr} < 25 mL/minute (unbound fraction is increased two- to threefold in uremia)

Metabolism: Follows dose-dependent capacity-limited (Michaelis-Menten) pharmacokinetics with increased V_{max} in infants > 6 months of age and children versus adults; major metabolite (via oxidation), HPPA, undergoes enterohepatic recirculation

Bioavailability: Form dependent

Half-life elimination: Oral: 22 hours (range: 7-42 hours)

Time to peak, serum (form dependent): Oral: Extended-release capsule: 4-12 hours; Immediate release preparation: 2-3 hours

Excretion: Urine (< 5% as unchanged drug); as glucuronides

Clearance: Highly variable, dependent upon intrinsic hepatic function and dose administered; increased clearance and decreased serum concentrations with febrile illness

Dosage

Status epilepticus: I.V.:

Neonates: Loading dose: 15-20 mg/kg in a single or divided dose; maintenance dose: Initial: 5 mg/kg/day in 2 divided doses; usual: 5-8 mg/kg/day in 2 divided doses; some patients may require dosing every 8 hours

Infants and Children: Loading dose: 15-20 mg/kg in a single or divided dose; maintenance dose: Initial: 5 mg/kg/day in 2 divided doses, usual doses:

6 months to 3 years: 8-10 mg/kg/day

4-6 years: 7.5-9 mg/kg/day

7-9 years: 7-8 mg/kg/day

10-16 years: 6-7 mg/kg/day, some patients may require every 8 hours dosing

Children with acute neurotrauma:

0.5-9 years: 8-10 mg/kg/day

10-16 years: 6-8 mg/kg/day

Adults: Loading dose: 15-20 mg/kg in a single or divided dose, followed by 100-150 mg/dose at 30-minute intervals up to a maximum of 1500 mg/24 hours; maintenance dose: 300 mg/day or 5-6 mg/kg/day in 3 divided doses

Cocaine abuse treatment: 300 mg/day

Anticonvulsant: Children and Adults: Oral:

Loading dose: 15-20 mg/kg; based on phenytoin serum concentrations and recent dosing history; administer oral loading dose in 3 divided doses given every 2-4 hours to decrease gastrointestinal adverse effects and to ensure complete oral absorption; maintenance dose: 300 mg/day or 5-6 mg/kg/day in 3 divided doses

Dosing adjustment/comments in renal impairment or hepatic disease: Safe in usual doses in mild liver disease; clearance may be substantially reduced in cirrhosis and plasma level monitoring with dose

adjustment advisable. Free phenytoin levels should be monitored closely.

Stability Capsule, tablet: Store below 30°C (86°F); protect from light and moisture

Oral suspension: Store at room temperature of 20°C to 25°C (68°F to 77°F); protect from freezing and light.

Solution for injection: Store at room temperature of 15°C to 30°C (59°F to 86°F); use only clear solutions free of precipitate and haziness, slightly yellow solutions may be used. Precipitation may occur if solution is refrigerated and may dissolve at room temperature.

Further dilution of the solution for I.V. infusion is controversial and no consensus exists as to the optimal concentration and length of stability. Stability is concentration and pH dependent. Based on limited clinical consensus, NS or LR are recommended diluents; dilutions of 1-10 mg/mL have been used and should be administered as soon as possible after preparation (some recommend to discard if not used within 4 hours). Do not refrigerate.

I.V. form is highly **incompatible** with many drugs and solutions. Mixing with other medications is not recommended.

Monitoring Parameters Blood pressure, vital signs (with I.V. use), plasma phenytoin level, CBC, liver function tests

Administration

Oral: Suspension: Shake well prior to use. Absorption is impaired when phenytoin suspension is given concurrently to patients who are receiving continuous nasogastric feedings. A method to resolve this interaction is to divide the daily dose of phenytoin and withhold the administration of nutritional supplements for 1-2 hours before and after each phenytoin dose.

I.M.: Although approved for I.M. use, I.M. administration is not recommended due to erratic absorption and pain on injection. Fosphenytoin may be considered.

I.V.: Vesicant. Fosphenytoin may be considered for loading in patients who are in status epilepticus, hemodynamically unstable, or develop hypotension/bradycardia with I.V. administration of phenytoin. Phenytoin may be administered by IVP or IVPB administration. The maximum rate of I.V. administration is 50 mg/minute. Highly sensitive patients (eg, elderly, patients with pre-existing cardiovascular conditions) should receive phenytoin more slowly (eg, 20 mg/minute). An in-line 0.22-5 micron filter is recommended for IVPB solutions due to the high potential for precipitation of the solution. Avoid extravasation. Following I.V. administration, NS should be injected through the same needle or I.V. catheter to prevent irritation.

pH: 10.0-12.3

SubQ: SubQ administration is not recommended because of the possibility of local tissue damage.

Contraindications Hypersensitivity to phenytoin, other hydantoin, or any component of the formulation; pregnancy

Warnings May increase frequency of petit mal seizures; I.V. form may cause hypotension, skin necrosis at I.V. site; avoid I.V. administration in small veins; use with caution in patients with porphyria; discontinue if rash or lymphadenopathy occurs; use with caution in patients with hepatic dysfunction, sinus bradycardia, SA block, or AV block; use with caution in elderly or debilitated patients, or in any condition associated with low serum albumin levels, which will increase the free fraction of phenytoin in the serum and, therefore, the pharmacologic response. Sedation, confusional states, or cerebellar dysfunction (loss of motor coordination) may occur at higher total serum concentrations, or at lower total serum concentrations when the free fraction of phenytoin is increased. Abrupt withdrawal may precipitate status epilepticus.

Dosage Forms Capsule, extended release, as sodium: 100 mg

Dilantin®: 30 mg [contains sodium benzoate], 100 mg

Phenytek™: 200 mg, 300 mg

Capsule, prompt release, as sodium: 100 mg

Injection, solution, as sodium: 50 mg/mL (2 mL, 5 mL) [contains alcohol and propylene glycol]

Suspension, oral: 125 mg/5 mL (240 mL)

Dilantin®: 125 mg/5 mL (240 mL) [contains alcohol < 0.6%, sodium benzoate; orange vanilla flavor]

Tablet, chewable:

Dilantin®: 50 mg

Reference Range

Timing of serum samples: Because it is slowly absorbed, peak blood levels may occur 4-8 hours after ingestion of an oral dose. The serum half-life varies with the dosage and the drug follows Michaelis-Menten kinetics. The average adult half-life is about 24 hours. Steady-state concentrations are reached in 5-10 days.

Children and Adults: Toxicity is measured clinically, and some patients require levels outside the suggested therapeutic range

Therapeutic range:

Total phenytoin: 10-20 mcg/mL (children and adults), 8-15 mcg/mL (neonates)

Concentrations of 5-10 mcg/mL may be therapeutic for some patients but concentrations < 5 mcg/mL are not likely to be effective

50% of patients show decreased frequency of seizures at concentrations > 10 mcg/mL

86% of patients show decreased frequency of seizures at concentrations > 15 mcg/mL

Add another anticonvulsant if satisfactory therapeutic response is not achieved with a phenytoin concentration of 20 mcg/mL

Free phenytoin: 1-2.5 mcg/mL

Toxic: <30-50 mcg/mL (SI: <120-200 μmol/L)

Lethal: >100 mcg/mL (SI: >400 μmol/L)

When to draw levels: This is dependent on the disease state being treated and the clinical condition of the patient

Key points:

Slow absorption of extended capsules and prolonged half-life minimize fluctuations between peak and trough concentrations, timing of sampling not crucial

Trough concentrations are generally recommended for routine monitoring. Daily levels are not necessary and may result in incorrect dosage adjustments. If it is determined essential to monitor free phenytoin concentrations, concomitant monitoring of total phenytoin concentrations is not necessary and expensive.

After a loading dose: Draw level within 48-96 hours

Rapid achievement: Draw within 2-3 days of therapy initiation to ensure that the patient's metabolism is not remarkably different from that which would be predicted by average literature-derived pharmacokinetic parameters; early levels should be used cautiously in design of new dosing regimens

Second concentration: Draw within 6-7 days with subsequent doses of phenytoin adjusted accordingly

If plasma concentrations have not changed over a 3- to 5-day period, monitoring interval may be increased to once weekly in the acute clinical setting

In stable patients requiring long-term therapy, generally monitor levels at 3- to 12-month intervals

Adjustment of serum concentration: See tables.

Adjustment of Serum Concentration in Patients with Low Serum Albumin				
Measured Total Phenytoin Concentration (mcg/mL)	Patient's Serum Albumin (g/dL)			
	3.5	3	2.5	2
	Adjusted Total Phenytoin Concentration (mcg/mL)*			
5	6	7	8	10
10	13	14	17	20
15	19	21	25	30

*Adjusted concentration = measured total concentration divided by [(0.2 × albumin) + 0.1].

Adjustment of Serum Concentration in Patients with Renal Failure (Cl _{cr} ≤ 10 mL/min)					
Measured Total Phenytoin Concentration (mcg/mL)	Patient's Serum Albumin (g/dL)				
	4	3.5	3	2.5	2
	Adjusted Total Phenytoin Concentration (mcg/mL)*				
5	10	11	13	14	17
10	20	22	25	29	33
15	30	33	38	43	50

*Adjusted concentration = measured total concentration divided by [(0.1 × albumin) + 0.1].

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Treatment is supportive for hypotension; treat with I.V. fluids and place patient in Trendelenburg position; seizures may be controlled with lorazepam or diazepam 5-10 mg (0.25-0.4 mg/kg in children); extravasation can be treated with compressive dressing, elevation and splinting of extremity; systemic corticosteroids should be used for phenytoin hypersensitivity syndrome

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; peritoneal dialysis, diuresis, hemodialysis, hemoperfusion, and plasmapheresis is of little value

Diagnostic Procedures

- Phenytoin, Blood

Test Interactions ↑ glucose, alkaline phosphatase (S); ↓ thyroxine (S), calcium (S); serum sodium increases in overdose setting; produces

sustained reductions of both free thyroxine and free triiodothyronine levels at therapeutic levels; oxaprozin falsely elevates plasma phenytoin concentrations

Drug Interactions

Substrate of CYP2C9 (major), 2C19 (major), 3A4 (minor); **Induces** CYP2B6 (strong), 2C8 (strong), 2C9 (strong), 2C19 (strong), 3A4 (strong) Acetaminophen: Phenytoin may enhance the hepatotoxic potential of acetaminophen overdoses

Acetazolamide: Concurrent use with phenytoin may result in an increased risk of osteomalacia

Acyclovir: May decrease phenytoin serum levels; limited documentation; monitor

Allopurinol: May increase phenytoin serum concentrations; monitor

Antacids: May decrease absorption of phenytoin; separate oral doses by several hours

Antiarrhythmics: Phenytoin may increase the metabolism of antiarrhythmics, decreasing their clinical effect; includes disopyramide, propafenone, and quinidine; amiodarone also may increase phenytoin concentrations (see CYP inhibitors)

Anticonvulsants: Phenytoin may increase the metabolism of anticonvulsants; includes barbiturates, carbamazepine, ethosuximide, felbamate, lamotrigine, tiagabine, topiramate, and zonisamide; does not appear to affect gabapentin or levetiracetam; felbamate and gabapentin may increase phenytoin levels; monitor

Antineoplastics: Several chemotherapeutic agents have been associated with a decrease in serum phenytoin levels; includes cisplatin, bleomycin, carmustine, methotrexate, and vinblastine; monitor phenytoin serum levels. Limited evidence also suggest that enzyme-inducing anticonvulsant therapy may reduce the effectiveness of some chemotherapy regimens (specifically in ALL). Teniposide and methotrexate may be cleared more rapidly in these patients.

Antipsychotics: Phenytoin may enhance the metabolism (decrease the efficacy) of antipsychotics; monitor for altered response; dose adjustment may be needed; also see note on clozapine

Benzodiazepines: Phenytoin may decrease the serum concentrations of some benzodiazepines; monitor for decreased benzodiazepine effect
Beta-blockers: Metabolism of beta-blockers may be increased and clinical effect decreased; atenolol and nadolol are unlikely to interact given their renal elimination

Calcium channel blockers: Phenytoin may enhance the metabolism of calcium channel blockers, decreasing their clinical effect; calcium channel blockers (diltiazem, nifedipine) have been reported to increase phenytoin levels (case report); monitor.

Capecitabine: May increase the serum concentrations of phenytoin; monitor

Chloramphenicol: Phenytoin may increase the metabolism of chloramphenicol and chloramphenicol may inhibit phenytoin metabolism; monitor for altered response

Cimetidine: May increase the serum concentrations of phenytoin; monitor.

Ciprofloxacin: May decrease serum phenytoin concentrations; monitor.

Clozapine: Phenytoin may decrease levels/effects of clozapine; monitor.

CNS depressants: Sedative effects may be additive with other CNS depressants; monitor for increased effect; includes ethanol, barbiturates, sedatives, antidepressants, narcotic analgesics, and benzodiazepines

Corticosteroids: Phenytoin may increase the metabolism of corticosteroids, decreasing their clinical effect; also see dexamethasone

Cyclosporine and tacrolimus: Levels may be decreased by phenytoin; monitor

CYP2B6 substrates: Phenytoin may decrease the levels/effects of CYP2B6 substrates. Example substrates include bupropion, efavirenz, promethazine, selegiline, and sertraline.

CYP2C9 inducers: May decrease the levels/effects of phenytoin. Example inducers include carbamazepine, phenobarbital, rifampin, rifapentine, and secobarbital.

CYP2C9 Inhibitors may increase the levels/effects of phenytoin. Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nifedipine, NSAIDs, sulfonamides and tolbutamide.

CYP2C8 Substrates: Phenytoin may decrease the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP2C9 Substrates: Phenytoin may decrease the levels/effects of CYP2C9 substrates. Example substrates include bosentan, celecoxib, dapson, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, sulfonamides, trimethoprim, warfarin, and zafirlukast.

CYP2C19 inducers: May decrease the levels/effects of phenytoin. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of phenytoin. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

CYP2C19 substrates: Phenytoin may decrease the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diaze-

pam, methsuximide, propranolol, proton pump inhibitors, sertraline, and voriconazole.

CYP3A4 substrates: Phenytoin may decrease the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, clarithromycin, cyclosporine, erythromycin, estrogens, mirtazapine, nateglinide, nefazodone, nevirapine, protease inhibitors, tacrolimus, and venlafaxine.

Digoxin: Effects and/or levels of digitalis glycosides may be decreased by phenytoin

Disulfiram: May increase serum phenytoin concentrations; monitor

Dopamine: Phenytoin (I.V.) may increase the effect of dopamine (enhanced hypotension)

Doxycycline: Phenytoin may enhance the metabolism of doxycycline, decreasing its clinical effect; higher dosages may be required

Estrogens: Phenytoin may increase the metabolism of estrogens, decreasing their clinical effect; monitor

Folic acid: Replacement of folic acid has been reported to increase the metabolism of phenytoin, decreasing its serum concentrations and/or increasing seizures

HMG-CoA reductase inhibitors: Phenytoin may increase the metabolism of these agents, reducing their clinical effect; monitor

Itraconazole: Phenytoin may decrease the effect of itraconazole

Levodopa: Phenytoin may inhibit the anti-Parkinson effect of levodopa

Lithium: Concurrent use of phenytoin and lithium has resulted in lithium intoxication

Methadone: Phenytoin may enhance the metabolism of methadone resulting in methadone withdrawal

Methylphenidate: May increase serum phenytoin concentrations; monitor

Metronidazole: May increase the serum concentrations of phenytoin; monitor

Neuromuscular-blocking agents: Duration of effect may be decreased by phenytoin

Omeprazole: May increase serum phenytoin concentrations; monitor

Oral contraceptives: Phenytoin may enhance the metabolism of oral contraceptives, decreasing their clinical effect; an alternative method of contraception should be considered

Primidone: Phenytoin enhances the conversion of primidone to phenobarbital resulting in elevated phenobarbital serum concentrations

Quetiapine: Serum concentrations may be substantially reduced by phenytoin, potentially resulting in a loss of efficacy; limited documentation; monitor

SSRIs: May increase phenytoin serum concentrations; fluoxetine and fluvoxamine are known to inhibit metabolism via CYP enzymes; sertraline and paroxetine have also been shown to increase concentrations in some patients; monitor

Sucralfate: May reduce the GI absorption of phenytoin; monitor

Theophylline: Phenytoin may increase metabolism of theophylline derivatives and decrease their clinical effect; theophylline may also increase phenytoin concentrations

Thyroid hormones (including levothyroxine): Phenytoin may alter the metabolism of thyroid hormones, reducing its effect; there is limited documentation of this interaction, but monitoring should be considered

Ticlopidine: May increase serum phenytoin concentrations and/or toxicity; monitor

Tricyclic antidepressants: Phenytoin may increase metabolism of tricyclic antidepressants and decrease their clinical effect; sedative effects may be additive; tricyclics may also increase phenytoin concentrations

Topiramate: Phenytoin may decrease serum levels of topiramate; topiramate may increase the effect of phenytoin

Trazodone: Serum levels of phenytoin may be increased; limited documentation; monitor

Trimethoprim: May increase serum phenytoin concentrations; monitor

Valproic acid (and sulfisoxazole): May displace phenytoin from binding sites; valproic acid may increase, decrease, or have no effect on phenytoin serum concentrations

Vigabatrin: May reduce phenytoin serum concentrations; monitor

Warfarin: Phenytoin transiently increased the hypoprothrombinemia response to warfarin initially; this is followed by an inhibition of the hypoprothrombinemic response

Pregnancy Risk Factor D

Pregnancy Implications Crosses placenta with fetal serum concentrations equal to those of mother; eye, cardiac, cleft palate, and skeletal malformations have been noted; fetal hydantoin syndrome associated with maternal ingestion of 100-800 mg/kg during 1st trimester; lower IQ scores also documented in children born to mothers taking phenytoin during pregnancy

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Nursing Implications I.V. injections should be followed by normal saline flushes through the same needle or I.V. catheter to avoid local irritation of the vein; must be diluted to concentrations <6 mg/mL, in normal saline, for I.V. infusion

Additional Information Less than 5% of total body phenytoin is removed by plasmapheresis and rapid re-equilibration after plasmapheresis can occur resulting in increased free phenytoin levels; intravenous

phenytoin salt has poor water solubility (0.02 mg/mL at a pH of 7) with a high PTT (12) and requires 40% propylene glycol and 10% ethanol

Pilocarpine

CAS Number 16509-56-1; 54-71-7; 92-13-7

U.S. Brand Names Isopto® Carpine; Pilocar®; Pilopine HS®; Salagen®

Synonyms Pilocarpine Hydrochloride

Use

Ophthalmic: Management of chronic simple glaucoma, chronic and acute angle-closure glaucoma

Oral: Symptomatic treatment of xerostomia caused by salivary gland hypofunction resulting from radiotherapy for cancer of the head and neck or Sjögren's syndrome

Unlabeled/Investigational Use Counter effects of cycloplegics

Mechanism of Action Stimulates parasympathetic receptors causing pupillary constriction and ciliary muscle contraction

Adverse Reactions

Ophthalmic:

- Cardiovascular: Hypertension, tachycardia
- Gastrointestinal: Diarrhea, nausea, salivation, vomiting
- Ocular: Burning, ciliary spasm, conjunctival vascular congestion, **corneal granularity** (gel 10%), lacrimation, lens opacity, myopia, retinal detachment, visual acuity decreased, blepharospasm
- Respiratory: Bronchial spasm, pulmonary edema
- Miscellaneous: Diaphoresis

Oral (frequency varies by indication and dose):

- Cardiovascular: Abnormal ECG, angina pectoris, arrhythmia, bradycardia, edema, **flushing**, facial edema, hypertension, hypotension, myocardial infarction, palpitations, peripheral edema, syncope, tachycardia, thrombosis
- Central nervous system: **Chills, dizziness, headache**, pain, fever, somnolence, abnormal dreams, abnormal thinking, anxiety, aphasia, confusion, depression, emotional lability, hypothermia, insomnia, intracranial hemorrhage, migraine, nervousness, speech disorder, twitching, yawning, supraorbital or temporal headache
- Dermatologic: Alopecia, contact dermatitis, dry skin, eczema, erythema nodosum, exfoliative dermatitis, photosensitivity reaction, pruritus, rash, seborrhea, skin ulcer, vesiculobullous rash
- Endocrine & metabolic: Breast pain, hypoglycemia, lymphadenopathy, mastitis, menorrhagia, metrorrhagia, ovarian disorder
- Gastrointestinal: Anorexia, appetite increased, colitis, constipation, diarrhea, dry mouth, dyspepsia, dysphagia, eructation, esophagitis, flatulence, gastritis, gastroenteritis, gastrointestinal disorder, gingivitis, glossitis, hiccup, melena, **nausea**, pancreatitis, parotid

gland enlargement, salivary gland enlargement, salivation increased, stomatitis, taste loss, taste perversion, tongue disorder, vomiting

Genitourinary: Dysuria, hematuria, pyuria, urethral pain, urinary impairment, **urinary frequency**, urinary urgency, urinary incontinence, vaginal hemorrhage, vaginal moniliasis, vaginitis

Hematologic: Leukopenia, platelet abnormality, thrombocytopenia, thrombocytopenia, WBC abnormality

Hepatic: Bilirubinemia, cholelithiasis, hepatitis, liver function test abnormal

Neuromuscular & skeletal: Arthralgia, arthritis, bone disorder, hyperkinesia, hypesthesia, leg cramps, myasthenia, neck pain, paresthesia, tremor, tendon disorder, tenosynovitis, **weakness**

Ocular: Amblyopia, abnormal vision, blurred vision, conjunctivitis, cataract, dry eyes, eye hemorrhage, eye pain, glaucoma, lacrimation

Otic: Deafness, ear pain, tinnitus

Respiratory: Bronchitis, cough increased, epistaxis, laryngismus, pneumonia, **rhinitis**, sputum increased, stridor, sinusitis

Miscellaneous: **Diaphoresis**, allergic reaction, body odor, herpes simplex, moniliasis, salpingitis, voice alteration

Signs and Symptoms of Overdose Abdominal cramps, bronchorrhea, dizziness, nausea, photophobia, third degree AV block (15%), vomiting

Admission Criteria/Prognosis Consider admission for ingestions of >20 mg or intraocular doses >30 drops

Pharmacodynamics/Kinetics

Onset of action:

Ophthalmic: Miosis: 10-30 minutes; Intraocular pressure reduction: 1 hour

Oral: 20 minutes

Duration:

Ophthalmic: Miosis: 4-8 hours; Intraocular pressure reduction: 4-12 hours

Oral: 3-5 hours

Half-life elimination: Oral: 0.76-1.35 hours; increased with hepatic impairment

Excretion: Urine

Dosage Adults:

Ophthalmic:

Glaucoma:

Solution: Instill 1-2 drops up to 6 times/day; adjust the concentration and frequency as required to control elevated intraocular pressure
Gel: Instill 0.5" ribbon into lower conjunctival sac once daily at bedtime

To counteract the mydriatic effects of sympathomimetic agents (unlabeled use): Solution: Instill 1 drop of a 1% solution in the affected eye

Oral: Xerostomia:

Following head and neck cancer: 5 mg 3 times/day, titration up to 10 mg 3 times/day may be considered for patients who have not responded adequately; do not exceed 2 tablets/dose

Sjögren's syndrome: 5 mg 4 times/day

Dosage adjustment in hepatic impairment: Oral: Patients with moderate impairment: 5 mg 2 times/day regardless of indication; adjust dose based on response and tolerability. Do not use with severe impairment (Child-Pugh score 10-15).

Monitoring Parameters Intraocular pressure, funduscopic exam, visual field testing

Administration Oral: Avoid administering with high-fat meal. Fat decreases the rate of absorption, maximum concentration, and increases the time it takes to reach maximum concentration.

Ophthalmic: If both solution and gel are used, the solution should be applied first, then the gel at least 5 minutes later. Following administration of the solution, finger pressure should be applied on the lacrimal sac for 1-2 minutes.

Contraindications Hypersensitivity to pilocarpine or any component of the formulation; acute inflammatory disease of the anterior chamber of the eye; in addition, tablets are also contraindicated in patients with uncontrolled asthma, angle-closure glaucoma, severe hepatic impairment

Warnings Use caution with cardiovascular disease; patients may have difficulty compensating for transient changes in hemodynamics or rhythm induced by pilocarpine.

Ophthalmic products: May cause decreased visual acuity, especially at night or with reduced lighting.

Oral tablets: Use caution with controlled asthma, chronic bronchitis or COPD; may increase airway resistance, bronchial smooth muscle tone, and bronchial secretions. Use caution with cholelithiasis, biliary tract disease, nephrolithiasis; adjust dose with moderate hepatic impairment.

Dosage Forms Gel, ophthalmic, as hydrochloride (Pilopine HS®): 4% (4 g) [contains benzalkonium chloride]

Solution, ophthalmic, as hydrochloride: 0.5% (15 mL); 1% (2 mL, 15 mL); 2% (2 mL, 15 mL); 3% (15 mL); 4% (2 mL, 15 mL); 6% (15 mL) [may contain benzalkonium chloride]

Isopto® Carpine: 1% (15 mL); 2% (15 mL); 4% (15 mL) [contains benzalkonium chloride]

Tablet, as hydrochloride: 5 mg

Salagen®: 5 mg, 7.5 mg

Reference Range After 2 days of oral dosage of 10 mg 3 times/day, maximum serum concentrations are ~41 ng/mL

Overdosage/Treatment

Decontamination: **Oral:** Due to spontaneous emesis, ipecac or lavage is usually not required; activated charcoal can be used. **Ocular:** Irrigate copiously with saline

Supportive therapy: Atropine will reverse most cardiac and muscarinic effects; chlorpromazine can be given for agitation, epinephrine (0.1-1 mg SubQ) or beta-adrenergic agonist agents can be used for bronchodilation

Antidote(s)

- Atropine [ANTIDOTE]
- Epinephrine [ANTIDOTE]

Drug Interactions

Inhibits CYP2A6 (weak), 2E1 (weak), 3A4 (weak)
Concurrent use with beta-blockers may cause conduction disturbances; pilocarpine may antagonize the effects of anticholinergic drugs

Pregnancy Risk Factor

C
Lactation Excretion in breast milk unknown/not recommended

Additional Information Minimal lethal oral dose: 60 mg. Toxic ophthalmic dose: Systemic anticholinergic symptoms will occur after intraocular dose >30 drops (2% solution) or 60 drops (3% solution)

May exacerbate dementia of Alzheimer's disease; can reverse the mydriasis caused by sympathomimetic agents (phenylephrine, hydroxyamphetamine) but is not effective in reversing mydriasis due to antimuscarinic agents (ie, homatropine); no corneal effects due to pilocarpine use

Pimozide

CAS Number 2062-78-4

U.S. Brand Names Orap®

Use Suppression of severe motor and phonic tics in patients with Tourette's disorder who have failed to respond satisfactorily to standard treatment

Unlabeled/Investigational Use Psychosis; reported use in individuals with delusions focused on physical symptoms (ie, preoccupation with parasitic infestation); Huntington's chorea

Mechanism of Action A potent centrally-acting dopamine receptor antagonist resulting in its characteristic neuroleptic effects

Adverse Reactions

Reported with Tourette's disorder:

Cardiovascular: Abnormal ECG

Central nervous system: **Somnolence, sedation**, akathisia, drowsiness, hyperkinesias, insomnia, depression, headache, nervousness

Dermatologic: Rash

Gastrointestinal: **Xerostomia, constipation, increased salivation**, diarrhea, thirst, appetite increased, taste disturbance, dysphagia

Genitourinary: **Impotence**

Neuromuscular & skeletal: **Weakness, muscle tightness, rigidity**, myalgia, torticollis, tremor

Ocular: **Visual disturbance, accommodation decreased**

Miscellaneous: **Speech disorder**

Reported in disorders other than Tourette's disorder: Anorexia, blood dyscrasias, breast edema, chest pain, diaphoresis, dizziness, excitement; extrapyramidal symptoms (akathisia, akinesia, dystonia, pseudo-parkinsonism, tardive dyskinesia); facial edema, gingival hyperplasia (case report), hypertension, hyponatremia, hypotension, jaundice, libido decreased, nausea, neuroleptic malignant syndrome, orthostatic hypotension, palpitations, periorbital edema, postural hypotension, QT_c prolongation, seizure, tachycardia, ventricular arrhythmias, vomiting, weight gain/loss

Signs and Symptoms of Overdose Drowsiness, ECG changes, enuresis, extrapyramidal reaction, galactorrhoea, hypotension, impotence, numbness, Parkinson's-like symptoms, QT interval prolongation, respiratory depression, seizures, torsade de pointes

Admission Criteria/Prognosis Admit any ingestion >50 mg or exhibiting neurological sequelae

Pharmacodynamics/Kinetics

Absorption: 50%

Protein binding: 99%

Metabolism: Hepatic; significant first-pass effect

Half-life elimination: 50 hours

Time to peak, serum: 6-8 hours

Excretion: Urine

Dosage Oral: **Note:** An ECG should be performed baseline and periodically thereafter, especially during dosage adjustment:

Children ≤12 years: Tourette's disorder: Initial: 0.05 mg/kg preferably once at bedtime; may be increased every third day; usual range: 2-4 mg/day; do not exceed 10 mg/day (0.2 mg/kg/day)

PIMOZIDE

Children > 12 years and Adults: Tourette's disorder: Initial: 1-2 mg/day in divided doses, then increase dosage as needed every other day; range is usually 7-16 mg/day, maximum dose: 10 mg/day or 0.2 mg/kg/day are not generally recommended

Note: Sudden unexpected deaths have occurred in patients taking doses > 10 mg. Therefore, dosages exceeding 10 mg/day are generally not recommended.

Dosing adjustment in hepatic impairment: Reduction of dose is necessary in patients with liver disease

Monitoring Parameters ECG should be performed baseline and periodically thereafter, especially during dosage adjustment; vital signs; lipid profile, fasting blood glucose/Hgb A_{1c}; BMI; mental status, abnormal involuntary movement scale (AIMS), extrapyramidal symptoms (EPS)

Contraindications Hypersensitivity to pimozone or any component of the formulation; severe CNS depression; coma; history of dysrhythmia; prolonged QT syndrome; concurrent use with QT_c-prolonging agents; hypokalemia or hypomagnesemia; concurrent use of drugs that are inhibitors of CYP3A4, including concurrent use of azole antifungals, fluvoxamine, macrolide antibiotics (such as clarithromycin or erythromycin) [**Note:** The manufacturer lists azithromycin and dirithromycin in its list of contraindicated macrolides; however, these drugs do not inhibit CYP3A4 and are not expected to interact with pimozone], mesoridazine, nefazodone, protease inhibitors (ie, atazanavir, indinavir, nelfinavir, ritonavir, saquinavir), sertraline, thioridazine, zileuton, and ziprasidone; simple tics other than Tourette's

Warnings May cause hypotension, use with caution in patients with autonomic instability. Moderately sedating, use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Caution in patients with hemodynamic instability; bone marrow suppression; predisposition to seizures; subcortical brain damage; severe cardiac, hepatic, renal, or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use - use with caution in patients at risk of pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May alter cardiac conduction - sudden unexplained deaths have occurred in patients taking high doses (> 10 mg). This may be due to prolongation of the QT interval predisposing patients to ventricular arrhythmias. Monitor ECG at baseline and periodically during dosage titration. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications which may predispose).

May cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention); therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to neuroleptics, pimozone has a moderate potency of cholinergic blockade.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is high relative to other neuroleptics). May be associated with neuroleptic malignant syndrome (NMS) or pigmentary retinopathy.

Avoid grapefruit juice due to potential inhibition of pimozone metabolism

Dosage Forms Tablet: 1 mg, 2 mg

Reference Range 3 mg dose produces a plasma level of 3.3 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Epinephrine should not be used. Seizures commonly respond to lorazepam, diazepam, or phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 gram), while other antiarrhythmics can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50 mg I.M. or I.V. slow push followed by a maintenance dose for 48-72 hours. When these reactions are unresponsive to diphenhydramine, bupropion mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes.

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; forced diuresis or hemodialysis is of no benefit

Drug Interactions **Substrate** (major) of CYP1A2, 3A4; **Inhibits** CYP2C19 (weak), 2D6 (weak), 2E1 (weak), 3A4 (weak)

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Aluminum salts: May decrease the absorption of antipsychotics; monitor
Amphetamines: Efficacy may be diminished by antipsychotics; in addition, amphetamines may increase psychotic symptoms; avoid concurrent use

Anticholinergics: May inhibit the therapeutic response to antipsychotics and excess anticholinergic effects may occur; includes benzotropine, trihexyphenidyl, biperiden, and drugs with significant anticholinergic activity (TCAs, antihistamines, disopyramide)

Antihypertensives: Concurrent use of antipsychotics with an antihypertensive may produce additive hypotensive effects (particularly orthostasis)

Bromocriptine: Antipsychotics inhibit the ability of bromocriptine to lower serum prolactin concentrations

CNS depressants: Sedative effects may be additive with antipsychotics; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents

CYP1A2 inducers: May decrease the levels/effects of pimozone. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of pimozone. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of pimozone. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifampin.

CYP3A4 inhibitors: May increase the levels/effects of pimozone. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil. Concurrent use of strong CYP3A4 inhibitors with pimozone is contraindicated.

Epinephrine: Chlorpromazine (and possibly other low potency antipsychotics) may diminish the pressor effects of epinephrine

Guanethidine and guanadrel: Antihypertensive effects may be inhibited by antipsychotics

Levodopa: Antipsychotics may inhibit the antiparkinsonian effect of levodopa; avoid this combination

Lithium: Antipsychotics may produce neurotoxicity with lithium; this is a rare effect

Macrolide antibiotics: Concurrent use is contraindicated due to CYP inhibition and QT_c-prolonging effects. **Note:** The manufacturer lists azithromycin and dirithromycin in its list of contraindicated macrolides; however, these drugs do not inhibit CYP3A4 and are not expected to interact with pimozone.

Mesoridazine: Concurrent use with pimozone is contraindicated due to potential arrhythmias.

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk.

Phenytoin: May reduce serum levels of antipsychotics; antipsychotics may increase phenytoin serum levels

Propranolol: Serum concentrations of antipsychotics may be increased; propranolol also increases antipsychotics concentrations

QT_c-prolonging agents: Effects on QT_c interval may be additive with antipsychotics, increasing the risk of malignant arrhythmias; includes Class Ia and Class III antiarrhythmics, arsenic trioxide, chlorpromazine, dolasetron, droperidol, halofantrine, levomefentanyl, mefloquine, pentamidine, probucol, tacrolimus, ziprasidone, tricyclic antidepressants, and some quinolone antibiotics (sparfloxacin, moxifloxacin, and gatifloxacin)

Sertraline: Concurrent use is contraindicated; may produce increased toxicity or attenuate therapeutic response.

Sulfadoxine-pyrimethamine: May increase antipsychotics concentrations
Thioridazine: Concurrent use with pimozone is contraindicated due to potential arrhythmias.

Tricyclic antidepressants: Concurrent use may produce increased toxicity or altered therapeutic response (also see note under QT_c prolonging agents)

Trazodone: Antipsychotics and trazodone may produce additive hypotensive effects

Valproic acid: Serum levels may be increased by antipsychotics

Ziprasidone: Concurrent use with pimozone is contraindicated due to potential arrhythmias.

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Nursing Implications Perform ECG at baseline and periodically thereafter, and with dose increases; refer to Contraindications for medicines which may predispose patients to potentially fatal cardiac arrhythmias

Additional Information Less sedation but more likely to cause extrapyramidal signs than chlorpromazine

Pindolol

Related Information

- Selected Properties of Beta-Adrenergic Blocking Drugs
- Therapeutic Drugs Associated with Hallucinations

CAS Number 13523-86-9

U.S. Brand Names Visken®

Impairment Potential Yes

Use Management of hypertension

Unlabeled/Investigational Use Potential augmenting agent for antidepressants; ventricular arrhythmias/tachycardia, antipsychotic-induced akathisia, situational anxiety; aggressive behavior associated with dementia

Mechanism of Action Blocks both beta₁- and beta₂-receptors and has mild intrinsic sympathomimetic activity; pindolol has negative inotropic and chronotropic effects and can significantly slow AV nodal conduction

Adverse Reactions

Cardiovascular: Mesenteric arterial thrombosis, AV block, chest tightness, sinus bradycardia, palpitations, QRS prolongation, sinus tachycardia, Raynaud's phenomenon

Central nervous system: **Dizziness, anxiety, insomnia, fatigue**, auditory hallucinations

Dermatologic: Purpura, erythema multiforme, alopecia, toxic epidermal necrolysis, xerosis, urticaria, onycholysis, pruritus, psoriasis, licheniform eruptions, exanthem

Endocrine & metabolic: **Decreased sexual ability**

Gastrointestinal: Ischemic colitis, abdominal pain

Hematologic: Thrombocytopenia, leukopenia, neutropenia, agranulocytosis, granulocytopenia

Neuromuscular & skeletal: **Arthralgia, weakness, back pain**, fine tremors, paresthesia

Ocular: Diplopia

Respiratory: Wheezing

Miscellaneous: Systemic lupus erythematosus

Signs and Symptoms of Overdose Ataxia, AV block, bradycardia, cold extremities, colitis, coma, confusion, depression, dry mouth, edema (6%), heart block, heart failure and wheezing; hypertension and tachycardia also associated (due to beta agonist properties) followed by severe hypotension, hypoglycemia, impotence, insomnia, myasthenia gravis (exacerbation or precipitation)

Pharmacodynamics/Kinetics

Absorption: Rapid, 50% to 95%

Protein binding: 50%

Metabolism: Hepatic (60% to 65%) to conjugates

Half-life elimination: 2.5-4 hours; prolonged with renal impairment, age, and cirrhosis

Time to peak, serum: 1-2 hours

Excretion: Urine (35% to 50% as unchanged drug)

Dosage

Oral:

Adults:

Hypertension: Initial: 5 mg twice daily, increase as necessary by 10 mg/day every 3-4 weeks (maximum daily dose: 60 mg); usual dose range (JNC 7): 10-40 mg twice daily

Antidepressant augmentation: 2.5 mg 3 times/day

Elderly: Initial: 5 mg once daily, increase as necessary by 5 mg/day every 3-4 weeks

Dosing adjustment in renal and hepatic impairment: Reduction is necessary in severely impaired

Stability Protect from light

Monitoring Parameters Blood pressure, standing and sitting/supine, pulse, respiratory function

Contraindications Hypersensitivity to pindolol, beta-blockers, or any component of the formulation; uncompensated congestive heart failure; cardiogenic shock; bradycardia, sinus node dysfunction, or heart block (2nd or 3rd degree) except in patients with a functioning artificial pacemaker; pulmonary edema; severe hyperactive airway disease (asthma or COPD); Raynaud's disease

Warnings Administer very cautiously to patients with CHF, asthma, diabetes mellitus, hyperthyroidism. May mask signs and symptoms of thyrotoxicosis. Abrupt withdrawal of the drug should be avoided, drug should be discontinued over 1-2 weeks. Do not use in pregnant or nursing women. May potentiate hypoglycemia in a diabetic patient and mask signs and symptoms. Use with caution in patients with myasthenia gravis or peripheral vascular disease. May cause CNS depression; use caution in patients with a history of psychiatric illness. May potentiate anaphylactic reactions and/or blunt response to epinephrine treatment. Beta-blockers with intrinsic sympathomimetic activity (including pindolol) do not appear to be of benefit in CHF.

Dosage Forms Tablet: 5 mg, 10 mg

Reference Range Therapeutic: 0.02-0.04 mcg/mL; 250 mg ingestion was associated with a serum level of 0.66 mcg/mL; 500 mg ingestion produced a serum level of 1.5 mcg/mL

Overdosage/Treatment

Decontamination: **Do not** use ipecac; gastric lavage within 1 hour, activated charcoal should be utilized

Supportive therapy: Sympathomimetics (eg, epinephrine or dopamine), glucagon, atropine, or a pacemaker can be used to treat the toxic bradycardia, asystole, and/or hypotension; initially fluids may be the best treatment for toxic hypotension.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Antidote(s)

- Glucagon [ANTIDOTE]

Test Interactions ↑ cholesterol (S), glucose; ↓ bilirubin (S)

Drug Interactions **Substrate** of CYP2D6 (major); **Inhibits** CYP2D6 (weak)

Albuterol (and other beta₂ agonists): Effects may be blunted by nonspecific beta-blockers

Alpha-blockers (prazosin, terazosin): Concurrent use of beta-blockers may increase risk of orthostasis

AV conduction-slowing agents (digoxin): Effects may be additive with beta-blockers.

Calcium channel blockers (diltiazem, verapamil): May have synergistic or additive pharmacological effects when taken concurrently with beta-blockers

Clonidine: Hypertensive crisis after or during withdrawal of either agent
CYP2D6 inhibitors: May increase the levels/effects of pindolol. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Epinephrine (including local anesthetics with epinephrine): Pindolol may cause hypertension

Glucagon: Pindolol may blunt the hyperglycemic action

Insulin and oral hypoglycemics: May mask symptoms of hypoglycemia

NSAIDs (ibuprofen, indomethacin, naproxen, piroxicam): May reduce the antihypertensive effects of beta-blockers

Salicylates: May reduce the antihypertensive effects of beta-blockers

Sulfonylureas: Beta-blockers may alter response to hypoglycemic agents

Pregnancy Risk Factor B

Pregnancy Implications Pindolol crosses the placenta. Beta-blockers have been associated with bradycardia, hypotension, and IUGR; IUGR is probably related to maternal hypertension. Available evidence suggests beta-blockers are generally safe during pregnancy (JNC-7). Cases of neonatal hypoglycemia have been reported following maternal use of beta-blockers at parturition or during breast-feeding.

Lactation Enters breast milk/use caution

Additional Information May cause hypoglycemia during hemodialysis

Specific References

Chobanian AV, Bakris GL, Black HR, et al, "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, 289(19):2560-71.

Piperacillin and Tazobactam Sodium

U.S. Brand Names Zosyn®

Synonyms Piperacillin Sodium and Tazobactam Sodium; Tazobactam and Piperacillin

Use Treatment of infections caused by susceptible organisms, including infections of the lower respiratory tract (community-acquired pneumonia, nosocomial pneumonia); urinary tract; skin and skin structures; gynecologic (endometritis, pelvic inflammatory disease); bone and joint infections; intra-abdominal infections (appendicitis with rupture/abscess, peritonitis); and septicemia. Tazobactam expands activity of piperacillin to include beta-lactamase producing strains of *S. aureus*, *H. influenzae*, *Bacteroides*, and other gram-negative bacteria.

Mechanism of Action Piperacillin interferes with bacterial cell wall synthesis during active multiplication, causing cell wall death and resultant bactericidal activity against susceptible bacteria; tazobactam prevents degradation of piperacillin by binding to the active site on beta-lactamase

Adverse Reactions

Cardiovascular: Hypertension, hypotension

Central nervous system: Insomnia, headache, agitation, fever, dizziness, confusion, seizures, paresthesia (painful)

Dermatologic: Erythema multiforme

Gastrointestinal: **Diarrhea**, *Clostridium difficile* colitis, pseudomembranous colitis

Dermatologic: Rash, pruritus, Stevens-Johnson syndrome

Gastrointestinal: Constipation, nausea, vomiting, dyspepsia

Hematologic: Hemolytic anemia, leukopenia, thrombocytopenia

Hepatic: Cholestatic jaundice, hepatitis, hepatotoxicity

Renal: Interstitial nephritis

Respiratory: Rhinitis, dyspnea, bronchospasm

Miscellaneous: Serum sickness-like reaction, fever

Several laboratory abnormalities have rarely been associated with piperacillin/tazobactam including reversible eosinophilia, and neutrope-

PIPERAZINE

nia (associated most often with prolonged therapy), positive direct Coombs' test, prolonged PT and aPTT, transient elevations of LFTs, increased creatinine

Signs and Symptoms of Overdose Colitis, eosinophilia, hypokalemia, insomnia, leukopenia or neutropenia (agranulocytosis, granulocytopenia)

Pharmacodynamics/Kinetics

Both AUC and peak concentrations are dose proportional; hepatic impairment does not affect kinetics

Distribution: Well into lungs, intestinal mucosa, skin, muscle, uterus, ovary, prostate, gallbladder, and bile; penetration into CSF is low in subject with noninflamed meninges

Protein binding: Piperacillin and tazobactam: ~30%

Metabolism:

Piperacillin: 6% to 9% to desethyl metabolite (weak activity)

Tazobactam: ~26% to inactive metabolite

Half-life elimination: Piperacillin and tazobactam: 0.7-1.2 hours

Time to peak, plasma: Immediately following infusion of 30 minutes

Excretion: Clearance of both piperacillin and tazobactam are directly proportional to renal function

Piperacillin: Urine (68% as unchanged drug); feces (10% to 20%)

Tazobactam: Urine (80% as inactive metabolite)

Dosage Infants and Children ≥ 6 months: **Note:** Not FDA-approved for use in children < 12 years of age:

I.V.: 240 mg of piperacillin component/kg/day in divided doses every 8 hours; higher doses have been used for serious pseudomonal infections: 300-400 mg of piperacillin component/kg/day in divided doses every 6 hours.

Children > 12 years and Adults:

Nosocomial pneumonia: I.V.: Piperacillin/tazobactam 4/0.5 g every 6 hours for 7-14 days (when used empirically, combination with an aminoglycoside is recommended; consider discontinuation of aminoglycoside if *P. aeruginosa* is not isolated)

Severe infections: I.V.: Piperacillin/tazobactam 4/0.5 g every 8 hours or 3/0.375 g every 6 hours for 7-10 days

Moderate infections: I.M.: Piperacillin/tazobactam 2/0.25 g every 6-8 hours; treatment should be continued for ≥ 7 -10 days depending on severity of disease (**Note:** I.M. route not FDA-approved)

Dosing interval in renal impairment:

Cl_{cr} 20-40 mL/minute: Administer 2/0.25 g every 6 hours (3/0.375 g every 6 hours for nosocomial pneumonia)

Cl_{cr} < 20 mL/minute: Administer 2/0.25 g every 8 hours (2/0.25 g every 6 hours for nosocomial pneumonia)

Hemodialysis: Administer 2/0.25 g every 12 hours (every 8 hours for nosocomial pneumonia) with an additional dose of 0.75 g after each dialysis

Continuous arteriovenous or venovenous hemodiafiltration effects: Dose as for Cl_{cr} 10-50 mL/minute

Stability Store at controlled room temperature; after reconstitution, stable for 24 hours at room temperature and 1 week when refrigerated; unused portions should be discarded after 24 hours at room temperature and 48 hours when refrigerated

Monitoring Parameters LFTs, creatinine, BUN, CBC with differential, serum electrolytes, urinalysis, PT, PTT; monitor for signs of anaphylaxis during first dose

Administration Administer by I.V. infusion over 30 minutes

Some penicillins (eg, carbenicillin, ticarcillin and piperacillin) have been shown to inactivate aminoglycosides *in vitro*. This has been observed to a greater extent with tobramycin and gentamicin, while amikacin has shown greater stability against inactivation. Concurrent use of these agents may pose a risk of reduced antibacterial efficacy *in vivo*, particularly in the setting of profound renal impairment. However, definitive clinical evidence is lacking. If combination penicillin/aminoglycoside therapy is desired in a patient with renal dysfunction, separation of doses (if feasible), and routine monitoring of aminoglycoside levels, CBC, and clinical response should be considered. **Note:** Reformulated Zosyn[®] containing EDTA has been shown to be compatible *in vitro* for Y-site infusion with amikacin and gentamicin, but not compatible with tobramycin.

Contraindications Hypersensitivity to penicillins, beta-lactamase inhibitors, or any component of the formulation

Warnings Bleeding disorders have been observed, particularly in patients with renal impairment; discontinue if thrombocytopenia or bleeding occurs. Due to sodium load and to the adverse effects of high serum concentrations of penicillins, dosage modification is required in patients with impaired or underdeveloped renal function; use with caution in patients with seizures or in patients with history of beta-lactam allergy; associated with an increased incidence of rash and fever in cystic fibrosis patients. Prolonged use may result in superinfection, including pseudomembranous colitis. Safety and efficacy have not been established in children < 2 months of age.

Dosage Forms

Note: 8:1 ratio of piperacillin sodium/tazobactam sodium
Infusion [premixed iso-osmotic solution, frozen]:

2.25 g: Piperacillin 2 g and tazobactam 0.25 g (50 mL) [contains sodium 5.58 mEq (128 mg) and EDTA]

3.375 g: Piperacillin 3 g and tazobactam 0.375 g (50 mL) [contains sodium 8.38 mEq (192 mg) and EDTA]

4.5 g: Piperacillin 4 g and tazobactam 0.5 g (50 mL) [contains sodium 11.17 mEq (256 mg) and EDTA]

Injection, powder for reconstitution:

2.25 g: Piperacillin 2 g and tazobactam 0.25 g [contains sodium 5.58 mEq (128 mg) and EDTA]

3.375 g: Piperacillin 3 g and tazobactam 0.375 g [contains sodium 8.38 mEq (192 mg) and EDTA]

4.5 g: Piperacillin 4 g and tazobactam 0.5 g [contains sodium 11.17 mEq (256 mg) and EDTA]

40.5 g: Piperacillin 36 g and tazobactam 4.5 g [contains sodium 100.4 mEq (2304 mg) and EDTA; bulk pharmacy vial]

Reference Range After a dose of 4 g piperacillin/500 mg tazobactam, mean serum piperacillin and tazobactam levels were 223.7 mcg/mL and 27.2 mcg/mL, respectively

Overdosage/Treatment Enhancement of elimination: Combined charcoal hemoperfusion with hemodialysis may be useful, see Toxicodynamics

Test Interactions Increases ALT, AST; positive Coombs' [direct]

Drug Interactions Aminoglycosides: May be synergistic against selected organisms; physical inactivation of aminoglycosides in the presence of high concentrations of piperacillin and potential toxicity in patients with mild to moderate renal dysfunction

Heparin: Concomitant use with high-dose parenteral penicillins may result in increased risk of bleeding

Methotrexate: Penicillins may increase the exposure to methotrexate during concurrent therapy; monitor.

Neuromuscular blockers: May increase duration of blockade

Oral contraceptives: Anecdotal reports suggesting decreased contraceptive efficacy with penicillins have been refuted by more rigorous scientific and clinical data.

Probenecid: May increase levels of penicillins (piperacillin)

Tetracyclines: May decrease effectiveness of penicillins (piperacillin)

Warfarin: Effects of warfarin may be increased

Pregnancy Risk Factor B

Pregnancy Implications Piperacillin and tazobactam were not teratogenic in animal studies. Both piperacillin and tazobactam cross the human placenta.

Lactation Enters breast milk/use caution

Nursing Implications Administer 1 hour apart from aminoglycosides; give around-the-clock (ie, 6-12-6-12)

Additional Information Total sodium content: 108 mg/vial

Specific References

Lambourne J, Kitchen J, Hughes C, et al, "Piperacillin/Tazobactam-Induced Paresthesia," *Ann Pharmacother*, 2006, 40(5):977-9.

LeClaire AC, Martin CA, and Hoven AD, "Rash Associated with Piperacillin/Tazobactam Administration in Infectious Mononucleosis," *Ann Pharmacother*, 2004, 38(6):996-8.

Piperazine

CAS Number 110-85-0; 142-63-2; 142-88-1; 144-29-6; 14538-56-8; 18534-18-4; 41372-10-5

UN Number 2579

Synonyms Piperazine Citrate

Use Treatment of *Ascaris lumbricoides* (roundworm) and *Enterobius vermicularis*, (pinworm, threadworm); may be effective in treating tropical eosinophilia

Mechanism of Action Blocks acetylcholine response in smooth muscle causing flaccid paralysis; while the drug has its primary effect on the parasite in the gastrointestinal tract, there is no effect on larvae in tissues

Adverse Reactions

Central nervous system: Hypotonia, fever, dementia, CNS depression, depression, paranoia

Dermatologic: Urticaria, erythema multiforme, cutaneous vasculitis

Gastrointestinal: Vomiting, diarrhea

Hematologic: Hemolytic anemia, thrombocytopenia

Hepatic: Hepatitis

Neuromuscular & skeletal: Arthralgia

Ocular: Nystagmus, eye irritant on direct contact, cataract, lacrimation

Respiratory: Bronchospasm, cough, rhinorrhea, asthma

Signs and Symptoms of Overdose Ataxia, chorea, coma, confusion, headache, hyporeflexia, lethargy, myoclonus, nausea, seizures, tremors, vertigo

Pharmacodynamics/Kinetics

Absorption: Well absorbed

Time to peak, serum: 1 hour

Excretion: Urine (as unchanged drug and metabolites)

Dosage Oral (hexahydrate equivalent):

Ascaris lumbricoides:

Children: 75 mg/kg/day for 2 days (maximum daily dose: 3.5 g)

Adults: 3.5 g/day for 2 days
 Enterobiasis:
 Children: 65 mg/kg in one daily dose for 7 days (maximum daily dose: 2.5 g)
 Adults: 65 mg/kg in one daily dose for 7 days (maximum daily dose: 2.5 g)
 Tropical eosinophilia: Adults: 600 mg 3 times/day for 2 weeks
Monitoring Parameters Stool exam for worms and ova
Contraindications Hypersensitivity to piperazine or any component of the formulation; seizure disorders; liver or kidney impairment
Warnings Use with caution in patients with anemia or malnutrition; avoid prolonged use especially in children
Dosage Forms Piperazine citrate is available from Panorama Pharmacy (1-800-247-9767).

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Seizures can be treated with a benzodiazepine, phenytoin, or phenobarbital

Drug Interactions Pyrantel pamoate (antagonistic mode of action)**Pregnancy Risk Factor** B**Piretanide****CAS Number** 55837-27-9**Unlabeled/Investigational Use** Congestive heart failure, hypertension**Mechanism of Action** Inhibits reabsorption of sodium and chloride in the ascending loop of Henle and distal renal tubule, interfering with the chloride-binding cotransport system, thus causing increased excretion of water, sodium, chloride, magnesium, and calcium**Adverse Reactions**

Cardiovascular: Hypotension (orthostatic)
 Central nervous system: Dizziness, headache
 Dermatologic: Eczema, psoriasis, pruritus, exanthema
 Endocrine & metabolic: Hyperglycemia, hypokalemia (less than that with furosemide or hydrochlorothiazide), hypomagnesemia, hypercholesterolemia, hyperuricemia
 Hepatic: Liver toxicity
 Neuromuscular & skeletal: Arthralgia

Signs and Symptoms of Overdose Hyperglycemia, hyperuricemia, hypokalemia, hypomagnesemia, hypotension, muscle cramps**Toxicodynamics/Kinetics**

Onset of diuresis: 30 minutes
 Duration: Oral: 3-4 hours; I.V.: 90 minutes
 Distribution: V_d : 0.17-0.53 L/kg (uremic patients)
 Protein binding: 94%
 Bioavailability: Oral: 80%
 Half-life: 1 hour
 Elimination: Renal (45%)

Dosage

Congestive heart failure:
 Oral: 3-6 mg/day, up to 24 mg/day
 I.V.: 6-12 mg every 12 hours
 Hypertension: 6-12 mg/day
 Renal failure: 6-96 mg/day

Reference Range Peak serum level after 12 mg oral dose: 775 ng/mL; peak serum level after 6 mg I.V. dose: 983 ng/mL**Overdosage/Treatment**

Decontamination: Activated charcoal
 Supportive therapy: I.V. hydration with 0.9% saline

Additional Information 6-12 mg of piretanide is equivalent to the antihypertensive effect of 100 mg of hydrochlorothiazide**Piroxicam****Related Information**

- Nonsteroidal Anti-inflammatory Drugs
- Therapeutic Drugs Associated with Hallucinations

CAS Number 36322-90-4**U.S. Brand Names** Feldene®**Use** Symptomatic treatment of acute and chronic rheumatoid arthritis and osteoarthritis
Ankylosing spondylitis**Mechanism of Action** Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors**Adverse Reactions**

Cardiovascular: Circulatory collapse
 Central nervous system: **Dizziness**, headache, aseptic meningitis, psychosis, cognitive dysfunction, coma, seizures
 Dermatologic: **Rash**, pruritus, photosensitivity/phototoxicity, exfoliative dermatitis, alopecia, angioedema, urticaria, purpura, onycholysis, licheniform eruptions, exanthem
 Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, fluid retention

Gastrointestinal: **Abdominal cramps, heartburn, indigestion, nausea, vomiting**, GI bleeding, GI ulceration, constipation, diarrhea, dyspepsia, esophagitis, aphthous stomatitis, xerostomia
 Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia, aplastic anemia (rare), platelet inhibition
 Hepatic: Elevated transaminases, hepatitis (fulminant), hepatic necrosis
 Neuromuscular & skeletal: Paresthesia
 Otic: Ototoxicity, tinnitus
 Renal: Renal failure (acute), nephrotic syndrome, chronic renal failure, albuminuria

Respiratory: Wheezing, respiratory depression

Miscellaneous: Hypersensitivity, systemic lupus erythematosus (SLE)

Signs and Symptoms of Overdose Coagulopathy, cognitive dysfunction, drowsiness, gastritis, GI bleeding, hyponatremia, nausea, nephrotic syndrome, ototoxicity, pemphigus, photosensitivity, stomatitis, syndrome of inappropriate antidiuretic hormone (SIADH), tinnitus, toxic epidermal necrolysis, vomiting, wheezing. Severe poisoning can manifest with blurred vision, coma, hypotension, renal and/or hepatic failure, respiratory depression, seizures, tremors.**Pharmacodynamics/Kinetics**

Onset of action: Analgesic: ~1 hour

Peak effect: 3-5 hours

Protein binding: 99%

Metabolism: Hepatic

Half-life elimination: 45-50 hours

Excretion: Primarily urine and feces (small amounts) as unchanged drug (5%) and metabolites

Dosage

Oral:

Children: 0.2-0.3 mg/kg/day once daily; maximum dose: 15 mg/day
 Adults: 10-20 mg/day once daily; although associated with increase in GI adverse effects, doses > 20 mg/day have been used (ie, 30-40 mg/day)

Dosing adjustment in hepatic impairment: Reduction of dosage is necessary**Monitoring Parameters** Occult blood loss, hemoglobin, hematocrit, and periodic renal and hepatic function tests; periodic ophthalmologic exams with chronic use**Contraindications** Hypersensitivity to piroxicam, aspirin, other NSAIDs or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy (3rd trimester or near term)**Warnings****[U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension.** Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Not recommended for use in patients with advanced renal disease.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy. A serum sickness-like reaction can rarely occur; watch for arthralgias, pruritus, fever, fatigue, and rash.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

The elderly are at increased risk for adverse effects (especially peptic ulceration, CNS effects, renal toxicity) from NSAIDs even at low doses. Withhold for at least 4-6 half-lives prior to surgical or dental procedures.

Dosage Forms Capsule: 10 mg, 20 mg**Reference Range** Therapeutic plasma piroxicam level: 5-10 mcg/mL; after a 1.8 g overdose, plasma piroxicam level was 241.6 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal
 Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage
 Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be effective; cholestyramine (4 g 3 times/day) may reduce the half-life of piroxicam

Test Interactions ↑ chloride (S), sodium (S), bleeding time

Drug Interactions Substrate of CYP2C9 (minor); **Inhibits** CYP2C9 (strong)

ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet drugs (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatide, tirofiban) can cause an increased risk of bleeding.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids may increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

CYP2C9 Substrates: Piroxicam may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use.

Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose.

Loop diuretics efficacy (diuretic and antihypertensive effect) is reduced. Indomethacin reduces this efficacy, however, it may be anticipated with any NSAID.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Thiazides antihypertensive effects are decreased; avoid concurrent use. Warfarin's INRs may be increased by piroxicam. Other NSAIDs may have the same effect depending on dose and duration. Monitor INR closely.

Use the lowest dose of NSAIDs possible and for the briefest duration.

Pregnancy Risk Factor B/D (3rd trimester or near term)

Lactation Enters breast milk (small amounts)/not recommended (AAP rates "compatible")

Nursing Implications Administer with food to decrease GI adverse effect

Specific References

Wammack R, Remzi M, Seitz C, et al, "Efficacy of Oral Doxepin and Piroxicam Treatment for Interstitial Cystitis," *Eur Urol*, 41(6): 596-600.

Pizotifen

CAS Number 15574-96-6; 5189-11-7

Synonyms Pizotifen Malate

Impairment Potential Yes

Use Migraine prophylaxis

Unlabeled/Investigational Use Cyclical vomiting

Mechanism of Action A serotonin, histamine (H₁ receptor) and tryptamine antagonist; also has weak antimuscarinic actions

Adverse Reactions

Cardiovascular: Tachycardia, edema
 Central nervous system: **Drowsiness** (up to 30%), dizziness, headache
 Gastrointestinal: Weight gain (1-3 kg), nausea, xerostomia, appetite (increased)

Hepatic: Cholestatic jaundice

Ocular: Blurred vision

Neuromuscular & skeletal: Muscle cramps

Signs and Symptoms of Overdose Blurred vision, fever, mydriasis, tachycardia

Pharmacodynamics/Kinetics

Onset: May require several weeks of therapy

Half-life elimination: 26 hours

Time to peak: 5-7 hours

Dosage Migraine prophylaxis:

Children: Up to 1.5 mg/day in divided doses

Adult: Initial: 0.5 mg; usual adult daily dose: ~1.5 mg; maximum daily dose: 4.5 mg

Cyclical vomiting: Children: 1.5 mg nightly

Monitoring Parameters Hepatic function tests (prolonged use)

Contraindications Hypersensitivity to pizotifen or any component of the formulation; concurrent use of MAO inhibitors; gastric outlet obstruction (pyloroduodenal obstruction, stenosing pyloric ulcer)

Warnings Not for use in acute treatment of migraine attacks. May cause sedation; effects may be additive with other CNS depressants or ethanol. Patients must be cautioned to avoid operating machinery or driving until effects are known. Although anticholinergic effects are limited, use with caution in patients intolerant to anticholinergic agents, including tricyclic antidepressants, phenothiazines, or cyproheptadine. Use with caution in patients with narrow angle glaucoma, myasthenia gravis, bladder outlet obstruction (BPH), or other disorders in which anticholinergic effects may be poorly tolerated. Use caution in renal or hepatic disease/insufficiency, diabetes, cardiovascular disease, or in obese patients. Therapeutic response may require several weeks of therapy. Avoid abrupt discontinuation; taper dosage over 2 weeks prior to discontinuation. Tolerance may develop in some patients. Consider drug-free period after several months of treatment. Safety and efficacy have not been established in children <12 years of age.

Dosage Forms [CAN] = Canadian brand name

Tablet:

Sandomigran® [CAN]: 0.5 mg [pizotifen malate 0.73 mg]

Tablet, double strength:

Sandomigran® DS [CAN]: 1 mg [pizotifen malate 1.46 mg]

Overdosage/Treatment

Decontamination: Lavage within 1 hour ingestions >5 mg; activated charcoal

Supportive therapy: Fever can be controlled with cooling fan and tepid sponging

Drug Interactions CNS depressants: Sedative effects may be additive or synergistic with pizotifen. Includes sedative-hypnotics and drugs with significant sedative effects such as tricyclic antidepressants, antipsychotics, and ethanol.

MAO inhibitors: Concurrent use is contraindicated.

Pregnancy Risk Factor Not available

Pregnancy Implications Use only if potential benefit to the mother outweighs possible risk to the fetus.

Additional Information May prevent gastrointestinal adverse effects of calcitonin injections (at a dose of 0.5 mg 3 times/day)

Podophyllum Resin

Pronunciation (po DOF fil um REZ in)

CAS Number 518-28-5; 518-29-6; 568-53-6; 8050-60-0

U.S. Brand Names Podocon-25®

Synonyms Mandrake; May Apple; Podophyllin

Use Topical treatment of condyloma acuminata (venereal warts); therapeutically dispersed as 25% podophyllum resin in tincture of benzoin or alcohol

Mechanism of Action Arrests cells in the metaphase of mitosis

Adverse Reactions

Cardiovascular: Sinus tachycardia
 Central nervous system: Memory disturbances
 Neuromuscular & skeletal: Peripheral neuropathy

Signs and Symptoms of Overdose Develop 12-24 hours post-topical exposure but may develop 4-8 hours after ingestion. Anuria, ataxia, diarrhea, fever, hallucinations, hypotension, hypotonia, nausea, psychosis, tachycardia, and vomiting may occur. Within the first week, pancytopenia and hepatic dysfunction may occur and resolve in 2-3 weeks. Cardiotoxicity, coma, ileus, and memory loss may last 7-10 days. In the second week polyneuropathy may appear and last for 2-3 months. Hypotension (orthostatic) may last 6-9 months. Dermal burns (>0.5% concentration), contact dermatitis, blepharospasm, iritis, keratitis, hallucinations (visual or auditory) may occur.

Admission Criteria/Prognosis Admit any patient who develops symptoms within 8 hours of oral exposure; admit any pediatric oral ingestion >300 mg

Toxicodynamics/Kinetics Absorption: Absorbed well orally and cutaneously

Dosage Apply topically to lesion twice daily for no more than 3 days

Maximum topical exposure: 0.5 mL/day or 10 cm²

Maximum tolerated dose: 2.8 g

Administration Shake well before using. Solution should be washed off within 1-4 hours for genital and perianal warts and within 1-2 hours for accessible meatal warts. Use protective occlusive dressing around warts to prevent contact with unaffected skin

Contraindications Not to be used on birthmarks, moles, or warts with hair growth; cervical, urethral, oral warts; not to be used by diabetic patient or patient with poor circulation; pregnancy

Warnings Use of large amounts of drug should be avoided; avoid contact with the eyes as it can cause severe corneal damage; do not apply to moles, birthmarks, or unusual warts; to be applied by a physician only; for external use only; 25% solution should not be applied to or near mucous membranes

Dosage Forms Liquid, topical: 25% (15 mL) [in benzoin tincture]

Overdosage/Treatment

Decontamination: **Oral:** Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal **Dermal:** Wash with soap and water. **Ocular:** Copious irrigation with saline; mydriatic cycloplegic eye drops with topical corticosteroid application in severe cases

Supportive therapy: Thrombocytopenia and leukopenia should be treated as needed; hypotension should be treated with isotonic I.V. fluids, Trendelenburg positioning, and dopamine or norepinephrine drips

Enhancement of elimination: Resin/charcoal hemoperfusion may facilitate neurologic recovery but should be reserved for those patients who deteriorate despite supportive care; hemodialysis may be helpful for those who develop anuria

Drug Interactions No data reported

Pregnancy Risk Factor X

Pregnancy Implications May be teratogenic when used orally during first trimester of pregnancy; use is discouraged in pregnancy

Lactation Enters breast milk/contraindicated

Additional Information Minimum lethal exposure: Death has occurred with 350 mg (topical) or 10 g (oral)

Podophyllum is a mixture of 16 physiologic compounds: lignins (wood extracts) and flavonols; exists in rhizomes and roots of *Podophyllum peltatum* plant or "May apple" and contains at least 40% podophyllo-toxin

Potassium Chloride

CAS Number 7447-40-7

U.S. Brand Names K+ Care[®]; K+10; K+8; K-Dur[®] 10; K-Dur[®] 20; K-Lor[™]; K-Tab[®]; Kaon-Cl-10[®]; Kaon-Cl[®] 20; Kay Ciel[®]; Klor-Con[®] 10; Klor-Con[®] 8; Klor-Con[®] M; Klor-Con[®]/25; Klor-Con[®]; Klotrix[®]; microK[®] 10; microK[®]; Rum-K[®]

Synonyms KCl

Use Replacement for potassium loss due to diuretics; treatment of hypokalemia and in metabolic acidosis; may be indicated in digitalis induced arrhythmias

Mechanism of Action As a principle intracellular ion, potassium serves as primary source for cellular electrical conduction

Adverse Reactions

Cardiovascular: Arrhythmias (ventricular)

Gastrointestinal: **Diarrhea, nausea, stomach pain, flatulence, vomiting,** esophagitis, bezoar

Signs and Symptoms of Overdose Apnea, bigeminy, confusion, diarrhea, esophageal ulceration, GI bleeding, hyporeflexia, hypotension, muscle cramps, nausea, paresthesia, peaked T waves, P-R prolongation, QRS prolongation, QT interval prolongation, ventricular arrhythmias, vomiting, weakness, widened QRS

Pharmacodynamics/Kinetics

Absorption: Well absorbed from upper GI tract

Distribution: Enters cells via active transport from extracellular fluid

Excretion: Primarily urine; skin and feces (small amounts); most intestinal potassium reabsorbed

Dosage Neonates: Oral, I.V.: 1-2 mEq/kg/day

Infants and older Children: 0.3 mEq/kg/hour; maximum hourly dose, I.V.: ~1 mEq/kg up to 40 mEq/hour; patient should be on a cardiac monitor for infusions over 0.5 mEq/kg/hour

Adults:

I.V.: 10-15 mEq/hour, not to exceed 300 mEq/day if serum potassium is >2.5 mEq/L; at serum potassium levels <2.0 mEq/L, I.V. dose may be at a rate of 40 mEq/hour not to exceed 400 mEq/day

Oral: Replacement therapy due to diuretics: Usual: 60 mEq/day is sufficient, although doses up to 100 mEq/day may be required

Dosing adjustment in renal impairment: Reduce dose and use with caution

Monitoring Parameters Serum potassium, glucose, chloride, pH, urine output (if indicated), cardiac monitor (if intermittent infusion or potassium infusion rates >0.25 mEq/kg/hour)

Administration Maximum concentration (peripheral line): 80 mEq/L

Contraindications Severe renal impairment, untreated Addison's disease, heat cramps, hyperkalemia, severe tissue trauma; solid oral dosage forms are contraindicated in patients in whom there is a structural, pathological, and/or pharmacologic cause for delay or arrest in passage through the GI tract; an oral liquid potassium preparation should be used in patients with esophageal compression or delayed gastric emptying time

Warnings Use with caution in patients with cardiac disease, severe renal impairment, hyperkalemia

Dosage Forms [DSC] = Discontinued product

Capsule, extended release: 10 mEq [750 mg]

microK[®] [microencapsulated]: 8 mEq [600 mg]

microK[®] 10 [microencapsulated]: 10 mEq [750 mg]

Infusion [premixed in D₅W]: 20 mEq (1000 mL); 30 mEq (1000 mL); 40 mEq (1000 mL)

Infusion [premixed in D₅W and LR]: 20 mEq (1000 mL); 30 mEq (1000 mL); 40 mEq (1000 mL)

Infusion [premixed in D₅W and 1/4NS]: 10 mEq (500 mL, 1000 mL); 20 mEq (250 mL, 500 mL, 1000 mL); 30 mEq (1000 mL); 40 mEq (1000 mL)

Infusion [premixed in D₅W and 1/2NS]: 10 mEq (500 mL, 1000 mL); 20 mEq (500 mL, 1000 mL); 30 mEq (1000 mL); 40 mEq (1000 mL)

Infusion [premixed in D₅ and NS]: 20 mEq (1000 mL); 40 mEq (1000 mL)

Infusion [premixed in D₅W and sodium chloride 0.3%]: 10 mEq (500 mL); 20 mEq (1000 mL); 30 mEq (1000 mL); 40 mEq (1000 mL)

Infusion [premixed in D₁₀W and sodium chloride 0.2%]: 20 mEq (250 mL)

Infusion [premixed in NS]: 20 mEq (1000 mL); 40 mEq (1000 mL)

Infusion [premixed in SWFI; concentrate]: 10 mEq (50 mL, 100 mL); 20 mEq (50 mL, 100 mL); 30 mEq (100 mL); 40 mEq (100 mL)

Injection, solution [concentrate]: 2 mEq/mL (5 mL, 10 mL, 15 mL, 20 mL, 30 mL, 250 mL)

Powder, for oral solution: 20 mEq/packet (30s, 100s, 1000s)

K-Lor[™]: 20 mEq/packet (30s, 100s) [fruit flavor]

K+ Potassium: 20 mEq/packet (30s) [orange flavor]

Kay Ciel[®] 10%: 20 mEq/packet (30s, 100s) [sugar free]

Klor-Con[®]: 20 mEq/packet (30s, 100s) [sugar free; fruit flavor]

Klor-Con[®]/25: 25 mEq/packet (30s, 100s) [sugar free; fruit flavor]

Solution, oral: 20 mEq/15 mL (480 mL, 3840 mL); 40 mEq/15 mL (480 mL)

Kaon-Cl[®] 20: 40 mEq/15 mL (480 mL) [sugar free; contains alcohol; cherry flavor]

Kay Ciel[®]: 10%: 20 mEq/15 mL (480 mL) [sugar free; contains alcohol] [DSC]

Rum-K[®]: 20 mEq/10 mL (480 mL) [alcohol free, sugar free; butter/rum flavor]

Tablet, extended release: 8 mEq [600 mg]; 10 mEq [750 mg]; 20 mEq [1500 mg]

K-Dur[®] 10 [microencapsulated]: 10 mEq [750 mg]

K-Dur[®] 20 [microencapsulated]: 20 mEq [1500 mg; scored]

K-Tab[®]: 10 mEq [750 mg]

Kaon-Cl[®] 10: 10 mEq [750 mg]

Klor-Con[®] 8: 8 mEq [600 mg; wax matrix]

Klor-Con[®] 10: 10 mEq [750 mg; wax matrix]

Klor-Con[®] M10 [microencapsulated]: 10 mEq [750 mg]

Klor-Con[®] M15 [microencapsulated]: 15 mEq [1125 mg; scored]

Klor-Con[®] M20 [microencapsulated]: 20 mEq [1500 mg; scored]

Reference Range Normal serum potassium: 3.5-5 mEq/L; symptoms can occur with serum levels >6.5 mEq/L; levels >8 mEq/L can be fatal

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage within 1 hour; activated charcoal does not appear to be useful

Supportive therapy: I.V. calcium (ie, 10 mL of 10% calcium chloride or gluconate given over 1-5 minutes, repeating as necessary) will antagonize adverse cardiac effects, but will not reduce serum potassium levels; while sodium bicarbonate (1-2 mEq/kg), insulin, and glucose will enhance intracellular shift of potassium; sodium polystyrene sulfonate (adult dose: 15 g orally or 30-50 g as an enema, pediatric dose: 1 g/kg) will exchange potassium for sodium; hyaluronidase can be used for extravasation; inhalation beta-adrenergic agonist agents (albuterol, salbutamol) can also result in rapid intravascular movement of potassium; calcium chloride is preferable since more ionized calcium is delivered as compared with the other calcium salts. Avoid the use of lidocaine in treating wide complex tachycardia due to hyperkalemia.

Enhancement of elimination: Dialysis (hemodialysis or peritoneal dialysis) is useful in enhancing elimination

Antidote(s)

- Sodium Bicarbonate [ANTIDOTE]
- Sodium Polystyrene Sulfonate [ANTIDOTE]

Test Interactions Hyperkalemia may cause depression of serum sodium; elevated serum ammonia levels may be falsely normalized during potassium repletion

Drug Interactions Increased effect/levels with potassium-sparing diuretics, salt substitutes, ACE inhibitors

Pregnancy Risk Factor A

Pregnancy Implications High levels are detrimental to fetal cardiac function

Additional Information Toxic oral dose with normal renal function: ~2 mEq/kg; lethal I.V. bolus dose: 0.75-0.9 mEq/kg

Alkalosis decreases serum potassium levels, acidosis elevates serum potassium levels; do not chew or crush tablets; salt substitutes contain from 50-70 mEq potassium per teaspoon; usually not irritating to the eye. Found in foods like cantaloupe, bananas, citrus fruits; foods with the highest potassium content (>1 g of potassium/100 g of food) include dried figs, molasses, and seaweed; other food products with potassium content >0.5 g of potassium/100 g of food include nuts, avocados, bran cereals, wheat germ, lima beans, dried dates or dried prunes. Potassium

POVIDONE-IODINE

chloride is 13.3 mEq/g of salts (524 mg or 13.4 mM); average daily intake of potassium by adults is 2.8-3.9 g (70-100 mEq); radiopaque; liquid preparations should be used as opposed to solid forms in patients with esophageal compression due to left atrial enlargement or bowel hypomotility; total body potassium content is ~3500 mEq in an adult male with 50 mEq being in extracellular fluid compartment. Each 1 mEq/L decrease in serum potassium level can represent a total body potassium deficit of ~100-200 mEq. Whole blood specimen hemolysis can elevate serum potassium by ~0.5 mEq/L.

Povidone-Iodine

CAS Number 25655-41-8

U.S. Brand Names ACU-dyne® [OTC]; Betadine® Ophthalmic; Betadine® [OTC]; Minidyne® [OTC]; Operand® [OTC]; Summer's Eve® Medicated Douche [OTC]; Vagi-Gard® [OTC]

Synonyms Polyvinylpyrrolidone with Iodine; PVP-I

Use External antiseptic with broad microbicidal spectrum against bacteria, fungi, viruses, protozoa, and yeasts

Mechanism of Action Povidone-iodine is known to be a powerful broad spectrum germicidal agent effective against a wide range of bacteria, viruses, fungi, protozoa, and spores. It is an iodophor of which the polyvinylpyrrolidone is a solubilizing agent which liberates free iodine

Adverse Reactions

- Central nervous system: Fever, headache
- Dermatologic: Skin rash, angioedema, acne, contact dermatitis, erythema, chemical burn
- Endocrine & metabolic: Hypothyroidism
- Gastrointestinal: Diarrhea, metallic taste
- Hematologic: Eosinophilia, hemorrhage (mucosal)
- Hepatic: Elevation of serum transaminases and bilirubin
- Neuromuscular & skeletal: Arthralgia
- Ocular: Edema of eyelids
- Otic: Ototoxicity
- Respiratory: Pulmonary edema
- Miscellaneous: Lymph node enlargement, anaphylactic shock

Signs and Symptoms of Overdose Agranulocytosis, circulation collapse, elevated serum osmolarity, gastroenteritis, granulocytopenia, hypernatremia, hypothyroidism, leukopenia, metabolic acidosis with increased lactic acid, neutropenia, renal failure (acute), swelling of glottis or larynx

Pharmacodynamics/Kinetics Absorption: Topical: Absorbed systemically as iodine; amount depends upon concentration, route of administration, characteristics of skin

Dosage

Shampoo: Apply 2 tsp to hair and scalp, lather and rinse; repeat application 2 times/week until improvement is noted, then shampoo weekly

Topical: Apply as needed for treatment and prevention of susceptible microbicidal infections

Monitoring Parameters Renal function, acid base status, electrolytes, CBC

Contraindications Hypersensitivity to iodine or any component of the formulation

Warnings Use caution in patients with thyroid disorders. Toxicity may occur following application of large or prolonged quantities; use caution with renal dysfunction, burns, pediatric patients. When used for self-medication (OTC use) do not apply to deep puncture wounds or serious burns; discontinue in case of redness, swelling, irritation or pain; do not use for longer than 1 week.

Dosage Forms [DSC] = Discontinued product

Gel, topical (Operand®): 10% (120 g)

Liquid, topical: 10% (30 mL)

Ointment, topical: 10% (1 g, 30 g)

Betadine®: 10% (0.9 g, 3.7 g, 30 g) [DSC]

Povidone™: 10% (30 g)

Pad [prep pads]: 10% (200s)

Betadine® SwabAids: 10% (100s)

Scrub brush [solution impregnated]: 7.5% (30s)

Solution, ophthalmic (Betadine®): 5% (50 mL)

Solution, perineal (Operand®): 10% (240 mL) [concentrate]

Solution, topical: 10% (240 mL, 480 mL, 3840 mL)

Betadine®: 10% (15 mL, 120 mL, 240 mL, 480 mL, 960 mL, 3840 mL)

Minidyne®: 10% (15 mL)

Operand®: 10% (60 mL, 120 mL, 240 mL, 480 mL, 960 mL, 3840 mL)

Solution, topical scrub:

Betadine® Surgical Scrub: 7.5% (120 mL, 480 mL, 960 mL, 3840 mL)

Betadine® Skin Cleanser: 7.5% (120 mL)

Operand®: 7.5% (60 mL, 120 mL, 240 mL, 480 mL, 960 mL, 3840 mL)

Solution, topical spray:

Betadine®: 5% (90 mL) [CFC free; contains dry natural rubber]

Operand®: 10% (59 mL)

Solution, vaginal douche:

Operand®: 10% (240 mL) [concentrate]

Summer's Eve® Medicated Douche: 0.3% (135 mL)

Vagi-Gard®: 10% (180 mL, 240 mL) [concentrate]

Solution, whirlpool (Operand®): 10% (3840 mL) [concentrate]

Swab [prep-swab ampul]: 10% (0.65 mL)

Swabsticks: 10% (25s, 50s)

Betadine®: 10% (50s, 150s, 200s)

Swabsticks [gel saturated]: 10% (50s)

Swabsticks, topical scrub: 7.5% (25s, 50s)

Reference Range FDA in adults is 150 mg

Overdosage/Treatment

Decontamination: **Do not** use ipecac; activated charcoal is useful; gastric lavage (within 1 hour) with starch will aid in removal (purple color of effluent)

Enhancement of elimination: Can be enhanced with osmotic diuresis or salt loading

Test Interactions Interferes with thyroid function tests; falsely elevates chloride concentrations

Drug Interactions No data reported

Pregnancy Risk Factor D

Pregnancy Implications Can cause fetal goiter and hypothyroidism

Lactation Enters breast milk/use caution (AAP rates "compatible")

Additional Information Antiseptic action is reduced by alkali solutions

Pramipexole

U.S. Brand Names Mirapex®

Use Treatment of the signs and symptoms of idiopathic Parkinson's disease

Unlabeled/Investigational Use Treatment of depression

Mechanism of Action Pramipexole is a nonergot dopamine agonist with specificity for the D₂ subfamily dopamine receptor, and has also been shown to bind to D₃ and D₄ receptors. By binding to these receptors, it is thought that pramipexole can stimulate dopamine activity on the nerves of the striatum and substantia nigra.

Adverse Reactions

Cardiovascular: **Postural hypotension**, edema, syncope, tachycardia, chest pain

Central nervous system: **Asthenia, dizziness, somnolence, insomnia, hallucinations, abnormal dreams**, malaise, confusion, amnesia, dystonias, akathisia, thinking abnormalities, myoclonus, hyperesthesia, paranoia; dose related: falling asleep during activities of daily living

Endocrine & metabolic: Decreased libido

Gastrointestinal: **Nausea, constipation**, anorexia, weight loss, xerostomia, dysphagia

Genitourinary: Urinary frequency (up to 6%), impotence, urinary incontinence

Hepatic: Elevated liver transaminase levels (<1%)

Neuromuscular & skeletal: **Weakness, dyskinesia, extrapyramidal symptoms (EPS)**, muscle twitching, leg cramps, arthritis, bursitis, myasthenia, hypertonia, gait abnormalities, rhabdomyolysis

Ocular: Vision abnormalities

Respiratory: Dyspnea, rhinitis

Signs and Symptoms of Overdose Lethargy, tachycardia, vomiting

Admission Criteria/Prognosis Admit any ingestion > 10 mg in adults or > 1 mg in infants, or any patient exhibiting postural hypotension in the setting of an overdose.

Pharmacodynamics/Kinetics

Protein binding: 15%

Bioavailability: 90%

Half-life elimination: ~8 hours; Elderly: 12-14 hours

Time to peak, serum: ~2 hours

Excretion: Urine (90% as unchanged drug)

Dosage Adults: Oral: Initial: 0.375 mg/day given in 3 divided doses, increase gradually by 0.125 mg/dose every 5-7 days; range: 1.5-4.5 mg/day

Dosage adjustment in renal impairment:

CL_{cr} 35-59 mL/minute: Initial: 0.125 mg twice daily (maximum dose: 1.5 mg twice daily)

Cl_{cr} 15-34 mL/minute: Initial: 0.125 mg once daily (maximum dose: 1.5 mg once daily)

Cl_{cr} <15 mL/minute (or hemodialysis patients): Not adequately studied

Monitoring Parameters Monitor for improvement in symptoms of Parkinson's disease (eg, mentation, behavior, daily living activities, motor examinations), blood pressure, body weight changes, and heart rate

Administration Doses should be titrated gradually in all patients to avoid the onset of intolerable side effects. The dosage should be increased to achieve a maximum therapeutic effect, balanced against the side effects of dyskinesia, hallucinations, somnolence, and dry mouth.

Contraindications Hypersensitivity to pramipexole or any component of the formulation

Warnings Caution should be taken in patients with renal insufficiency and in patients with pre-existing dyskinesias. May cause orthostatic hypotension; Parkinson's disease patients appear to have an impaired capacity to respond to a postural challenge. Use with caution in patients at risk of hypotension (such as those receiving antihypertensive drugs) or where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). Parkinson's patients being treated with dopaminergic agonists ordinarily require careful monitoring for signs and symptoms of postural hypotension, especially during dose escalation, and should be informed of this risk. May cause hallucinations, particularly in older patients. Pathologic degenerative changes were observed in the retinas of albino rats during studies with this agent, but were not observed in the retinas of pigmented rats or in other species. The significance of these data for humans remains uncertain.

Although not reported for pramipexole, other dopaminergic agents have been associated with a syndrome resembling neuroleptic malignant syndrome on withdrawal or significant dosage reduction after long-term use. Dopaminergic agents from the ergot class have also been associated with fibrotic complications, such as retroperitoneum, lungs, and pleura.

Pramipexole has been associated with somnolence, particularly at higher dosages (> 1.5 mg/day). In addition, patients have been reported to fall asleep during activities of daily living, including driving, while taking this medication. Whether these patients exhibited somnolence prior to these events is not clear. Patients should be advised of this issue and factors which may increase risk (sleep disorders, other sedating medications, or concomitant medications which increase pramipexole concentrations) and instructed to report daytime somnolence or sleepiness to the prescriber. Patients should use caution in performing activities which require alertness (driving or operating machinery), and to avoid other medications which may cause CNS depression, including ethanol.

Dosage Forms Tablet, as dihydrochloride monohydrate: 0.125 mg, 0.25 mg, 0.5 mg, 1 mg, 1.5 mg

Overdosage/Treatment

Decontamination: Consider gastric decontamination for ingestions >6 mg; lavage within 1 hour for ingestions >10 mg

Supportive therapy: Dystonia can be treated with benzotropine (1-4 mg I.V. or I.M. to a maximum daily dose of 6 mg) and/or diphenhydramine (children: 1.25 mg/kg; adults: 25-50 mg, up to 300 mg/day)

Enhancement of elimination: Hemodialysis is not likely to be useful

Drug Interactions Antipsychotics: May decrease the efficiency of pramipexole due to dopamine antagonism

Cationic drugs: Drugs secreted by the cationic transport system (diltiazem, triamterene, verapamil, quinidine, quinine, ranitidine) decrease the clearance of pramipexole by ~20%

Cimetidine: May increase serum concentrations; cimetidine in combination with pramipexole produced a 50% increase in AUC and a 40% increase in half-life

Metoclopramide: May decrease the efficiency of pramipexole due to dopamine antagonism

Pregnancy Risk Factor C

Pregnancy Implications Early embryonic loss and postnatal growth inhibition were observed in animal studies. There are no adequate and well-controlled studies in pregnant women.

Lactation Excretion in breast milk unknown/not recommended

Pramoxine

CAS Number 140-65-8; 637-58-1

U.S. Brand Names Anusol[®] Ointment [OTC]; Itch-X[®] [OTC]; Prax[®] [OTC]; ProctoFoam[®] NS [OTC]; Tronolane[®] [OTC]

Synonyms Pramoxine Hydrochloride

Use Temporary relief of pain and itching associated with anogenital pruritus or irritation; dermatosis, minor burns, or hemorrhoids

Mechanism of Action Pramoxine, like other anesthetics, decreases the neuronal membrane's permeability to sodium ions. Both initiation and conduction of nerve impulses are blocked, thus depolarization of the neuron is inhibited.

Adverse Reactions

Cardiovascular: Edema, sinus bradycardia
Dermatologic: Urticaria, rash, contact eczema

Local: Burning, stinging

Signs and Symptoms of Overdose Agitation, bradycardia, cardiovascular collapse, coma, convulsions, euphoria, hypotension, methemoglobinemia (may occur), myoclonus, ototoxicity, respiratory failure, slurred speech, tinnitus, tremors

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Pharmacodynamics/Kinetics

Onset of action: Therapeutic: 2-5 minutes

Peak effect: 3-5 minutes

Duration: Several days

Dosage Adults: Topical: Apply as directed, usually every 3-4 hours to affected area (maximum adult dose: 200 mg)

Administration Apply sparingly, use the minimal effective dose.

Dosage Forms Cream, topical, as hydrochloride:

Tronolane[®]: 1% (30 g, 60 g) [contains zinc oxide 5%]

Foam, aerosol, topical, as hydrochloride: 1% (15 g)

ProctoFoam[®] NS: 1% (15 g)

Gel, topical, as hydrochloride:

Itch-X[®]: 1% (35.4 g) [contains benzyl alcohol]

Liquid, topical, as hydrochloride:

Curasore[®]: 1% (15 mL) [contains ethyl alcohol; packaged with cotton applicators]

Lotion, topical, as hydrochloride:

Caladryl[®] Clear: 1% (177 mL) [contains zinc acetate 0.1%]

Callergy Clear: 1% (180 mL) [contains zinc acetate 0.1%]

Prax[®]: 1% (15 mL, 120 mL, 240 mL)

Sarna[®] Sensitive: 1% (222 mL)

Ointment, rectal, as hydrochloride:

Anusol[®], Tucks[®] Hemorrhoidal: 1% (30 g) [contains zinc oxide 12.5% and mineral oil; Anusol[®] Ointment renamed Tucks[®] Hemorrhoidal]

Solution, topical spray, as hydrochloride:

CalaMycin[®] Cool and Clear: 1% (60 mL) [contains zinc acetate 0.1%]

Itch-X[®]: 1% (60 mL) [contains zinc oxide 1% and benzyl alcohol]

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Seizures can be treated with diazepam, lorazepam, phenobarbital, or phenytoin; allergic reactions can be treated with epinephrine, diphenhydramine, and corticosteroids

Drug Interactions No data reported

Pregnancy Risk Factor C

Nursing Implications Apply sparingly, use the minimal effective dose

Additional Information Less sensitization than benzocaine

Pravastatin

CAS Number 81093-37-0; 81131-70-6

U.S. Brand Names Pravachol[®]

Synonyms Pravastatin Sodium

Use

Use with dietary therapy for the following:

Primary prevention of coronary events: In hypercholesterolemic patients without established coronary heart disease to reduce cardiovascular morbidity (myocardial infarction, coronary revascularization procedures) and mortality.

Secondary prevention of cardiovascular events in patients with established coronary heart disease: To slow the progression of coronary atherosclerosis; to reduce cardiovascular morbidity (myocardial infarction, coronary vascular procedures) and to reduce mortality; to reduce the risk of stroke and transient ischemic attacks

Hyperlipidemias: Reduce elevations in total cholesterol, LDL-C, apolipoprotein B, and triglycerides (elevations of 1 or more components are present in Fredrickson type IIa, IIb, III, and IV hyperlipidemias)

Heterozygous familial hypercholesterolemia (HeFH): In pediatric patients, 8-18 years of age, with HeFH having LDL-C \geq 190 mg/dL or LDL \geq 160 mg/dL with positive family history of premature cardiovascular disease (CVD) or 2 or more CVD risk factors in the pediatric patient

Mechanism of Action Pravastatin is a competitive inhibitor of 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase, which is the rate-limiting enzyme involved in *de novo* cholesterol synthesis.

Adverse Reactions

As reported in short-term trials; safety and tolerability with long-term use were similar to placebo

Cardiovascular: Chest pain

Central nervous system: Cranial nerve dysfunction, headache, fatigue, fever, flushing, dizziness, insomnia, memory impairment, vertigo

Dermatologic: Alopecia, dermatitis, dermatomyositis, dry skin, edema, erythema multiforme, pruritus, purpura, Stevens-Johnson syndrome, urticaria

Endocrine & metabolic: Libido change, sexual dysfunction

PRAZEPAM

Gastrointestinal: Appetite decreased, diarrhea, gynecomastia, heartburn, nausea, pancreatitis, taste disturbance, vomiting

Hematologic: Hemolytic anemia

Hepatic: Cholestatic jaundice, cirrhosis, elevated transaminases (>3x normal on two occasions - 1%), fulminant hepatic necrosis, hepatitis, hepatoma

Neuromuscular & skeletal: Muscle weakness, myalgia, myopathy, neuropathy, paresthesia, peripheral nerve palsy, polymyalgia rheumatica, rhabdomyolysis, tremor

Ocular: Lens opacity

Respiratory: Cough

Miscellaneous: Allergy, anaphylaxis, ESR increase, influenza, lupus erythematosus-like syndrome, positive ANA

Pharmacodynamics/Kinetics

Onset of action: Several days

Peak effect: 4 weeks

Absorption: Rapidly absorbed; average absorption 34%

Protein binding: 50%

Metabolism: Hepatic to at least two metabolites

Bioavailability: 17%

Half-life elimination: ~2-3 hours

Time to peak, serum: 1-1.5 hours

Excretion: Feces (70%); urine (<20%, 8% as unchanged drug)

Dosage

Oral: **Note:** Doses should be individualized according to the baseline LDL-cholesterol levels, the recommended goal of therapy, and patient response; adjustments should be made at intervals of 4 weeks or more; doses may need adjusted based on concomitant medications

Children: HeFH:

8-13 years: 20 mg/day

14-18 years: 40 mg/day

Dosage adjustment for pravastatin based on concomitant immunosuppressants (ie, cyclosporine): Refer to Adults dosing section

Adults: Hyperlipidemias, primary prevention of coronary events, secondary prevention of cardiovascular events: Initial: 40 mg once daily; titrate dosage to response; usual range: 10-80 mg; (maximum dose: 80 mg once daily)

Dosage adjustment for pravastatin based on concomitant immunosuppressants (ie, cyclosporine): Initial: 10 mg/day, titrate with caution (maximum dose: 20 mg/day)

Elderly: No specific dosage recommendations. Clearance is reduced in the elderly, resulting in an increase in AUC between 25% to 50%. However, substantial accumulation is not expected.

Dosing adjustment in renal impairment: Initial: 10 mg/day

Dosing adjustment in hepatic impairment: Initial: 10 mg/day

Stability Store at 25°C (77°F); excursions permitted to 15°C to 30°C (59°F to 86°F). Protect from moisture and light.

Monitoring Parameters Obtain baseline LFTs and total cholesterol profile; creatine phosphokinase due to possibility of myopathy. Repeat LFTs prior to elevation of dose. May be measured when clinically indicated and/or periodically thereafter.

Administration May be taken without regard to meals.

Contraindications Hypersensitivity to pravastatin or any component of the formulation; active liver disease; unexplained persistent elevations of serum transaminases; pregnancy; breast-feeding

Warnings Secondary causes of hyperlipidemia should be ruled out prior to therapy. Liver function must be monitored by periodic laboratory assessment. Rhabdomyolysis with acute renal failure has occurred. Risk may be increased with concurrent use of other drugs which may cause rhabdomyolysis (including gemfibrozil, fibric acid derivatives, or niacin at doses ≥ 1 g/day). Temporarily discontinue in any patient experiencing an acute or serious condition predisposing to renal failure secondary to rhabdomyolysis. Use caution in patients with previous liver disease or heavy ethanol use. Treatment in patients <8 years of age is not recommended.

Dosage Forms Tablet, as sodium: 10 mg, 20 mg, 40 mg,

Pravachol®: 10 mg, 20 mg, 40 mg, 80 mg

Reference Range Peak plasma levels following a 19.2 mg oral dose: ~27 ng/mL

Overdosage/Treatment

Decontamination: Activated charcoal can be used

Supportive therapy: Treatment is symptomatic

Drug Interactions **Substrate** of CYP3A4 (minor); **Inhibits** CYP2C9 (weak), 2D6 (weak), 3A4 (weak)

Cholestyramine: Reduces pravastatin absorption; separate administration times by at least 4 hours.

Clofibrate and fenofibrate: May increase the risk of myopathy and rhabdomyolysis.

Colestipol: Reduces pravastatin absorption; separate administration by 1 hour.

Cyclosporine: Concurrent use may increase the risk of myopathy and rhabdomyolysis.

Gemfibrozil: Increased risk of myopathy and rhabdomyolysis.

Imidazole antifungals (itraconazole, ketoconazole): May modestly increase pravastatin concentrations (AUC).

Niacin: May increase the risk of myopathy and rhabdomyolysis.

P-glycoprotein inhibitors (eg, amiodarone, cyclosporine, ketoconazole):

May increase pravastatin concentrations.

Pregnancy Risk Factor X

Pregnancy Implications Safety and efficacy have not been established for use during pregnancy (treatment should be discontinued if pregnancy is recognized). Administer to women of childbearing potential only if conception is unlikely; females should be counseled on appropriate contraceptive methods.

Lactation Enters breast milk/contraindicated

Nursing Implications Liver enzyme elevations may be observed during therapy with pravastatin; diet, weight reduction, and exercise should be attempted prior to therapy with pravastatin

Additional Information Before initiation of therapy, patients should be placed on a standard cholesterol-lowering diet for 6 weeks and the diet should be continued during drug therapy.

Prazepam

CAS Number 2955-38-6

Impairment Potential Yes

Use Treatment of anxiety

Unlabeled/Investigational Use Ethanol withdrawal; duodenal ulcer; narcotic addiction; spasticity; partial seizures

Mechanism of Action Benzodiazepine anxiolytic sedative that produces CNS depression at the subcortical level, except at high doses, whereby it works at the cortical level

Adverse Reactions

Cardiovascular: **Tachycardia, chest pain**, cardiac arrest, hypotension, bradycardia, cardiovascular collapse, sinus bradycardia

Central nervous system: **Drowsiness, fatigue, impaired coordination, lightheadedness, memory impairment, insomnia, depression, headache, anxiety, ataxia**, confusion, dizziness, amnesia, slurred speech, paradoxical excitation or rage, delirium, persecutory delusions

Dermatologic: **Rash**

Endocrine & metabolic: **Decreased libido**

Gastrointestinal: **Xerostomia, constipation, diarrhea, decreased salivation, nausea, vomiting, increased or decreased appetite**

Local: Phlebitis, pain with injection

Neuromuscular & skeletal: **Dysarthria**, orofacial dyskinesia

Ocular: **Blurred vision**, nystagmus, diplopia

Respiratory: Decreased respiratory rate, apnea, laryngospasm

Miscellaneous: **Diaphoresis**, physical and psychological dependence with prolonged use

Signs and Symptoms of Overdose Acute myoglobinuria, "alpha" coma (alpha frequency rhythm on EEG), ataxia, confusion, dry mouth, dyspnea, hypoactive reflexes, hyporeflexia, labored breathing, lightheadedness, rhabdomyolysis, visual and auditory hallucinations

Pharmacodynamics/Kinetics

Studies have shown that the elderly are more sensitive to the effects of benzodiazepines as compared to younger adults

Onset of action: Peak actions occur within 6 hours

Duration: 48 hours

Absorption: Readily from gastrointestinal tract

Distribution: V_d : 9.3-19.5 L/kg; distributed widely distributed throughout body

Protein binding: 85% to 97%

Metabolism: First-pass hepatic metabolism, primarily desmethyldiazepam (active)

Half-life: Parent: 78 minutes; Desmethyldiazepam: 30-100 hours; Half-life of desmethyldiazepam is significantly prolonged in elderly men (127.8 hours) as compared to young men (61.8 hours) and older women (75.4 hours); V_d is increased in the elderly

Time to peak serum concentration: Oral single dose: 2.5-6 hours

Elimination: Renal and feces (71%)

Dosage Adults: Oral: 30 mg/day in divided doses, may increase gradually to a maximum of 60 mg/day

Monitoring Parameters Respiratory and cardiovascular status

Contraindications Hypersensitivity to prazepam or any component of the formulation (cross-sensitivity with other benzodiazepines may exist); narrow-angle glaucoma; pregnancy

Warnings

Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics), or renal impairment. Use with caution in patients with respiratory disease, or impaired gag reflex. Avoid use in patients with sleep apnea.

Causes CNS depression (dose-related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury

and should be used with extreme caution in patients who are at risk of these events (especially the elderly).

Use caution in patients with depression, particularly if suicidal risk may be present. Use with caution in patients with a history of drug dependence. Benzodiazepines have been associated with dependence and acute withdrawal symptoms on discontinuation or reduction in dose. Acute withdrawal, including seizures, may be precipitated after administration of flumazenil to patients receiving long-term benzodiazepine therapy. Benzodiazepines have been associated with anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Dosage Forms Capsule: 5 mg, 10 mg, 20 mg
Tablet: 5 mg, 10 mg

Reference Range Therapeutic: 50-240 ng/mL (SI: 156-746 nmol/L)

Overdosage/Treatment

Decontamination: Activated charcoal
Supportive therapy: Treatment for benzodiazepine overdose is supportive; rarely is mechanical ventilation required. Flumazenil (Romazicon™) has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression. Do not use in concomitant tricyclic ingestion; treat hypotension with isotonic crystalloids, place in Trendelenburg position or give dopamine or norepinephrine.
Enhancement of elimination: Multiple dose of activated charcoal may enhance elimination

Antidote(s)

- Flumazenil [ANTIDOTE]

Test Interactions May ↑ LFTs. Visine®, Drano®, and bleach can cause false-negative urine tests.

Drug Interactions Substrate of CYP3A4 (minor)

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect
Oral contraceptives: May decrease the clearance of some benzodiazepines (those which undergo oxidative metabolism); monitor for increased benzodiazepine effect
Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation

Pregnancy Risk Factor D

Pregnancy Implications Suggested to be teratogenic in animal and human data; can precipitate neonatal respiratory depression when given during delivery; crosses placenta

Nursing Implications Monitor for alertness

Additional Information Not available in U.S.

Prazepam offers no significant advantage over other benzodiazepines.

Prazosin

Related Information

- Bunazosin

CAS Number 19216-56-9; 19237-84-4

U.S. Brand Names Minipress®

Synonyms Furazosin; Prazosin Hydrochloride

Use Hypertension, severe congestive heart failure (in conjunction with diuretics and cardiac glycosides)

Unlabeled/Investigational Use Benign prostatic hyperplasia; Raynaud's syndrome

Mechanism of Action Competitively inhibits postsynaptic alpha-adrenergic receptors which results in vasodilation of veins and arterioles and a decrease in total peripheral resistance and blood pressure; effective for ergotism-induced hypertension

Adverse Reactions

Cardiovascular: **Hypotension (orthostatic)**, syncope, palpitations, tachycardia, edema, sinus bradycardia, chest pain, angina, sinus tachycardia, vasodilation
Central nervous system: **Dizziness, drowsiness, headache, malaise, lightheadedness**, night terrors, psychosis, hypothermia
Dermatologic: Rash, angioneurotic edema, alopecia, urticaria, pruritus, licheniform eruptions, exanthem
Endocrine & metabolic: Fluid retention, sexual dysfunction
Gastrointestinal: Nausea, xerostomia, fecal incontinence
Genitourinary: Urinary frequency, priapism, urinary incontinence
Neuromuscular & skeletal: Weakness, paresthesia
Respiratory: Nasal congestion
Miscellaneous: Positive ANA, systemic lupus erythematosus

Signs and Symptoms of Overdose Bone marrow depression, conjunctivitis, drowsiness, hypotension, hypothermia, impotence, enuresis, night terrors, ptosis, respiratory depression, syncope

Pharmacodynamics/Kinetics

Onset of action: BP reduction: ~2 hours
Maximum decrease: 2-4 hours

Duration: 10-24 hours

Distribution: Hypertensive adults: V_d: 0.5 L/kg

Protein binding: 92% to 97%

Metabolism: Extensively hepatic

Bioavailability: 43% to 82%

Half-life elimination: 2-4 hours; prolonged with congestive heart failure

Excretion: Urine (6% to 10% as unchanged drug)

Dosage Oral:

Children: Initial: 5 mcg/kg/dose (to assess hypotensive effects); usual dosing interval: every 6 hours; increase dosage gradually up to maximum of 25 mcg/kg/dose every 6 hours

Adults: Initial: 1 mg/dose 2-3 times/day; usual maintenance dose: 3-15 mg/day in divided doses 2-4 times/day; maximum daily dose: 20 mg

Stability Store in airtight container; protect from light

Monitoring Parameters Blood pressure, standing and sitting/supine

Contraindications Hypersensitivity to quinazolines (doxazosin, prazosin, terazosin) or any component of the formulation; concurrent use with phosphodiesterase-5 (PDE-5) inhibitors including sildenafil (>25 mg), tadalafil, or vardenafil

Warnings May cause significant orthostatic hypotension and syncope, especially with first dose. Risk is increased at doses > 1 mg, hypovolemia, or in patients receiving concurrent beta-blocker therapy. Anticipate a similar effect if therapy is interrupted for a few days, if dosage is rapidly increased, or if another antihypertensive drug is introduced.

Dosage Forms Capsule, as hydrochloride: 1 mg, 2 mg, 5 mg

Reference Range Plasma level of 47.6 ng/mL was noted in an overdose setting 11 hours after a 120 mg ingestion

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral vasoconstrictor may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Treatment is primarily supportive and symptomatic.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Antidote(s)

- Norepinephrine [ANTIDOTE]

Drug Interactions ACE inhibitors: Hypotensive effect may be increased. Beta-blockers: Hypotensive effect may be increased.

Calcium channel blockers: Hypotensive effect may be increased.

NSAIDs may reduce antihypertensive efficacy.

Sildenafil, tadalafil, vardenafil: Blood pressure-lowering effects are additive. Use of tadalafil or vardenafil is contraindicated by the manufacturer. Use sildenafil with extreme caution (dose ≤25 mg).

Tricyclic antidepressants (TCAs) and low-potency antipsychotics: May increase risk of orthostasis.

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Syncope may occur usually within 90 minutes of the initial dose

PrednisolONE

CAS Number 1107-99-9; 125-02-0; 1715-33-9; 2920-86-7; 50-24-8; 5060-55-9; 52-21-1; 52438-85-4; 630-67-1; 7681-14-3

U.S. Brand Names AK-Pred®; Bubbli-Pred™ [DSC]; Econopred® Plus; Orapred ODT™; Orapred®; Pediapred®; Pred Forte®; Pred Mild®; Prelone®

Synonyms Deltahydrocortisone; Metacortandralone; Prednisolone Acetate, Ophthalmic; Prednisolone Acetate; Prednisolone Sodium Phosphate, Ophthalmic; Prednisolone Sodium Phosphate

Use Treatment of palpebral and bulbar conjunctivitis; corneal injury from chemical, radiation, thermal burns, or foreign body penetration; endocrine disorders, rheumatic disorders, collagen diseases, dermatologic diseases, allergic states, ophthalmic diseases, respiratory diseases, hematologic disorders, neoplastic diseases, edematous states, and gastrointestinal diseases; useful in patients with inability to activate prednisone (liver disease)

Mechanism of Action Decreases inflammation by suppression of migration of polymorphonuclear leukocytes and reversal of increased capillary permeability; suppresses the immune system by reducing activity and volume of the lymphatic system

Adverse Reactions

Cardiovascular: Edema, hypertension, QT prolongation, cardiomyopathy, cardiomegaly
Central nervous system: **Insomnia, nervousness**, vertigo, seizures, psychosis, pseudotumor cerebri, headache, mood swings, delirium, hallucinations, euphoria, cognitive dysfunction, depression, mania
Dermatologic: Hirsutism, acne, skin atrophy, bruising, hyperpigmentation, telangiectasia
Endocrine & metabolic: Diabetes mellitus, Cushing's syndrome, pituitary-adrenal axis suppression, growth suppression, glucose intolerance,

PREDNISOLONE

hypokalemia, alkalosis, amenorrhea, sodium and water retention, hyperglycemia

Gastrointestinal: **Increased appetite, indigestion**, abdominal distention, ulcerative esophagitis, pancreatitis, peptic ulcer, nausea, vomiting

Neuromuscular & skeletal: Arthralgia, muscle weakness, osteoporosis, fractures, muscle wasting

Ocular: Cataracts, glaucoma

Respiratory: Epistaxis

Miscellaneous: Hypersensitivity reactions, Kaposi's sarcoma

Signs and Symptoms of Overdose When consumed in excessive quantities for prolonged periods, systemic hypercorticism and adrenal suppression may occur. In those cases discontinuation and withdrawal of the corticosteroid should be done judiciously.

Pharmacodynamics/Kinetics

Duration: 18-36 hours

Protein binding (concentration dependent): 65% to 91%; decreased in elderly

Metabolism: Primarily hepatic, but also metabolized in most tissues, to inactive compounds

Half-life elimination: 3.6 hours; End-stage renal disease: 3-5 hours

Excretion: Primarily urine (as glucuronides, sulfates, and unconjugated metabolites)

Dosage Dose depends upon condition being treated and response of patient; dosage for infants and children should be based on severity of the disease and response of the patient rather than on strict adherence to dosage indicated by age, weight, or body surface area. Consider alternate day therapy for long-term therapy. Discontinuation of long-term therapy requires gradual withdrawal by tapering the dose. Patients undergoing unusual stress while receiving corticosteroids, should receive increased doses prior to, during, and after the stressful situation.

Children:

Acute asthma:

Oral: 1-2 mg/kg/day in divided doses 1-2 times/day for 3-5 days

I.V. (sodium phosphate salt): 2-4 mg/kg/day divided 3-4 times/day

Anti-inflammatory or immunosuppressive dose: Oral, I.V., I.M. (sodium phosphate salt): 0.1-2 mg/kg/day in divided doses 1-4 times/day

Nephrotic syndrome: Oral:

Initial (first 3 episodes): 2 mg/kg/day or 60 mg/m²/day (maximum:

80 mg/day) in divided doses 3-4 times/day until urine is protein free for 3 consecutive days (maximum: 28 days); followed by 1-1.5 mg/kg/dose or 40 mg/m²/dose given every other day for 4 weeks

Maintenance (long-term maintenance dose for frequent relapses):

0.5-1 mg/kg/dose given every other day for 3-6 months

Adults:

Oral, I.V., I.M. (sodium phosphate salt): 5-60 mg/day

Multiple sclerosis (sodium phosphate): Oral: 200 mg/day for 1 week followed by 80 mg every other day for 1 month

Rheumatoid arthritis: Oral: Initial: 5-7.5 mg/day; adjust dose as necessary

Elderly: Use lowest effective dose

Dosing adjustment in hyperthyroidism: Prednisolone dose may need to be increased to achieve adequate therapeutic effects

Hemodialysis: Slightly dialyzable (5% to 20%); administer dose post-hemodialysis

Peritoneal dialysis: Supplemental dose is not necessary

Intra-articular, intralesional, soft-tissue administration:

Tebutate salt: 4-40 mg/dose

Sodium phosphate salt: 2-30 mg/dose

Ophthalmic suspension/solution: Children and Adults: Instill 1-2 drops into conjunctival sac every hour during day, every 2 hours at night until favorable response is obtained, then use 1 drop every 4 hours

Monitoring Parameters Blood pressure, blood glucose, electrolytes

Administration Sodium phosphate injection: For I.V., I.M., intra-articular, intralesional, or soft tissue administration

Tebutate injection: For intra-articular, intralesional, or soft tissue administration only

Contraindications Hypersensitivity to prednisolone or any component of the formulation; acute superficial herpes simplex keratitis; live or attenuated virus vaccines (with immunosuppressive doses of corticosteroids); systemic fungal infections; varicella

Warnings

Use with caution in patients with cirrhosis, nonspecific ulcerative colitis, hypertension, osteoporosis, thromboembolic tendencies, CHF, convulsive disorders, myasthenia gravis, thrombophlebitis, peptic ulcer, diabetes, or tuberculosis; acute adrenal insufficiency may occur with abrupt withdrawal after long-term therapy or with stress; young pediatric patients may be more susceptible to adrenal axis suppression from topical therapy. Changes in thyroid status may necessitate dosage adjustments; metabolic clearance of corticosteroids increases in hyperthyroid patients and decreases in hypothyroid ones.

Prolonged use of corticosteroids may result in glaucoma; damage to the optic nerve (not indicated for treatment of optic neuritis), defects in visual acuity and fields of vision, and posterior subcapsular cataract

formation may occur. Prolonged use of corticosteroids may also increase the incidence of secondary infection, mask acute infection (including fungal infections) or prolong or exacerbate viral infections. Exposure to chickenpox should be avoided; corticosteroids should not be used to treat ocular herpes simplex. Use following cataract surgery may delay healing or increase the incidence of bleb formation.

Corticosteroids should not be used for cerebral malaria. Because of the risk of adverse effects, systemic corticosteroids should be used cautiously in the elderly, in the smallest possible dose, and for the shortest possible time.

Dosage Forms [DSC] = Discontinued product

Solution, ophthalmic, as sodium phosphate: 1% (5 mL, 10 mL, 15 mL) [contains benzalkonium chloride]

AK-Pred®: 1% (5 mL, 15 mL) [contains benzalkonium chloride]

Solution, oral, as sodium phosphate: Prednisolone base 5 mg/5 mL (120 mL)

Bubbli-Pred™: Prednisolone base 5 mg/5 mL (120 mL) [bubble gum flavor] [DSC]

Orapred®: 20 mg/5 mL (240 mL) [equivalent to prednisolone base 15 mg/5 mL; dye free; contains alcohol 2%, sodium benzoate; grape flavor]

Pediapred®: 6.7 mg/5 mL (120 mL) [equivalent to prednisolone base 5 mg/5 mL; dye free; raspberry flavor]

Suspension, ophthalmic, as acetate: 1% (5 mL, 10 mL, 15 mL) [contains benzalkonium chloride]

Econopred® Plus: 1% (5 mL, 10 mL) [contains benzalkonium chloride]

Pred Forte®: 1% (1 mL, 5 mL, 10 mL, 15 mL) [contains benzalkonium chloride and sodium bisulfite]

Pred Mild®: 0.12% (5 mL, 10 mL) [contains benzalkonium chloride and sodium bisulfite]

Syrup, as base: 5 mg/5 mL (120 mL); 15 mg/5 mL (240 mL, 480 mL)

Prelone®: 15 mg/5 mL (240 mL, 480 mL) [contains alcohol 5%, benzoic acid; cherry flavor]

Tablet, as base: 5 mg

Tablet, orally disintegrating, as base:

Orapred ODT™: 10 mg, 15 mg, 30 mg [grape flavor]

Overdosage/Treatment

Decontamination: Activated charcoal; acute overdose does not require tapering of dose

Supportive therapy: Psychosis can be treated with sertraline

Enhanced elimination: Its metabolite (prednisolone) is slightly dialyzable (5% to 20%)

Test Interactions Response to skin tests

Drug Interactions **Substrate** of CYP3A4 (minor); **Inhibits** CYP3A4 (weak)

Aminoglutethimide: May reduce the serum levels/effects of prednisolone; likely via induction of microsomal isoenzymes.

Antacids: May increase the absorption of corticosteroids; separate administration by ≥ 2 hours.

Aprepitant: May increase effects of systemic corticosteroids.

Azole antifungals: May increase the serum levels of corticosteroids; monitor.

Barbiturates: May decrease prednisolone levels; monitor.

Bile acid sequestrants: May decrease the absorption of corticosteroids (oral).

Calcium channel blockers (nondihydropyridine): May increase the serum levels of corticosteroids; monitor.

Cyclosporine: Corticosteroids may increase the serum levels of cyclosporine. In addition, cyclosporine may increase levels of corticosteroids; monitor.

Estrogens: May increase the serum levels of corticosteroids; monitor.

Fluoroquinolones: Concurrent use may increase the risk of tendon rupture, particularly in elderly patients (overall incidence rare).

Isoniazid: Serum concentrations may be decreased by corticosteroids.

Ketoconazole: May decrease metabolism of certain corticosteroids leading to increased levels (up to 60%) and increased risk of adverse effects; monitor.

Macrolide antibiotics: May decrease the metabolism of corticosteroids.

Neuromuscular-blocking agents: Concurrent use with corticosteroids may increase the risk of myopathy.

Nonsteroidal anti-inflammatory drugs (NSAIDs), ophthalmic: Concurrent use with ophthalmic corticosteroids may lead to delayed healing.

Potassium-depleting agents (eg, diuretics, amphotericin B): Concurrent use increases risk of hypokalemia (especially if digitalized); monitor.

Primidone: May increase the metabolism of corticosteroids.

Rifampin: May decrease serum levels/effects of prednisolone; monitor.

Salicylates: Salicylates may increase the gastrointestinal adverse effects of corticosteroids.

Skin tests: Corticosteroids may suppress reactions to skin tests.

Vaccines (dead organisms): Immunosuppressants may diminish the effect of these vaccines.

Vaccines (live organisms): Immunosuppressants may enhance the adverse/toxic effects of these vaccines.

Pregnancy Risk Factor C

Pregnancy Implications Animal studies have demonstrated teratogenic effects. There are no adequate and well-controlled studies in pregnant women.

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications Give oral formulation with food or milk to decrease GI effects; do not give acetate or tebutate salt I.V.

Additional Information Fluid and electrolyte effects are unlikely at daily prednisolone doses < 30 mg.

PredniSONE

Related Information

- Corticosteroids

CAS Number 53-03-1

U.S. Brand Names Deltasone®; Prednisone Intenso!™; Sterapred® DS; Sterapred®

Synonyms Deltacortisone; Deltadehydrocortisone

Use Treatment of a variety of diseases including adrenocortical insufficiency, hypercalcemia, rheumatic and collagen disorders; dermatologic, ocular, respiratory, gastrointestinal, and neoplastic diseases; organ transplantation and a variety of diseases including those of hematologic, allergic, inflammatory, and autoimmune in origin; not available in injectable form, prednisolone must be used; acute urticaria

Unlabeled/Investigational Use Investigational: Prevention of postherpetic neuralgia and relief of acute pain in the early stages

Mechanism of Action Decreases inflammation by suppression of migration of polymorphonuclear leukocytes and reversal of increased capillary permeability; suppresses the immune system by reducing activity and volume of the lymphatic system; suppresses adrenal function at high doses

Adverse Reactions

Cardiovascular: Edema, hypertension, QT prolongation, cardiomegaly, cardiomyopathy

Central nervous system: Dizziness, seizures, psychosis, pseudotumor cerebri, headache, memory disturbance, mania, **insomnia, nervousness**

Dermatologic: Acne, purpura, skin atrophy, angioedema, acanthosis nigricans

Endocrine & metabolic: Cushing's syndrome, pituitary-adrenal axis suppression, amenorrhea, growth suppression, glucose intolerance, hypokalemia, alkalosis

Gastrointestinal: Peptic ulcer, nausea, vomiting, fecal discoloration (black), **increased appetite, indigestion**

Hematologic: Aplastic anemia (rate is 1 in every 3600 to 5000 patients), leukemoid reaction

Hepatic: Fatal hepatotoxicity (rate is 1 in every 24000 to 32000 patients)

Neuromuscular & skeletal: Osteoporosis, fractures, weakness

Ocular: Cataracts, glaucoma

Miscellaneous: Anaphylaxis

Signs and Symptoms of Overdose Primarily neuropsychiatric. Cognitive dysfunction, dementia, depression, eosinopenia, GI bleeding, hirsutism, hyperglycemia, hypertrichosis, hyperuricemia, hypokalemia, increased intraocular pressure, leukocytosis, lymphopenia, mania, memory loss, sexual dysfunction, thrombocytopenia

Pharmacodynamics/Kinetics

Protein binding (concentration dependent): 65% to 91%

Metabolism: Hepatically converted from prednisone (inactive) to prednisolone (active); may be impaired with hepatic dysfunction

Half-life elimination: Normal renal function: 2.5-3.5 hours

See Prednisolone monograph for complete information.

Dosage Dose depends upon condition being treated and response of patient; dosage for infants and children should be based on severity of the disease and response of the patient rather than on strict adherence to dosage indicated by age, weight, or body surface area. Consider alternate day therapy for long-term therapy. Discontinuation of long-term therapy requires gradual withdrawal by tapering the dose.

Children: Oral:

Anti-inflammatory or immunosuppressive dose: 0.05-2 mg/kg/day divided 1-4 times/day

Acute asthma: 1-2 mg/kg/day in divided doses 1-2 times/day for 3-5 days

Alternatively (for 3- to 5-day "burst"):

< 1 year: 10 mg every 12 hours

1-4 years: 20 mg every 12 hours

5-13 years: 30 mg every 12 hours

> 13 years: 40 mg every 12 hours

Asthma long-term therapy (alternative dosing by age):

< 1 year: 10 mg every other day

1-4 years: 20 mg every other day

5-13 years: 30 mg every other day

> 13 years: 40 mg every other day

Severe refractory asthma: 5-10 mg/dose every day or 10-30 mg every other day

Nephrotic syndrome: Initial: 2 mg/kg/day (maximum: 80 mg/day) in divided doses 3-4 times/day until urine is protein free for 5 days (maximum: 28 days); if albuminuria persists, use 4 mg/kg/dose every other day (maximum: 120 mg/day) for an additional 28 days; maintenance: 2 mg/kg/dose (maximum: 80 mg/dose) every other day for 28 days; then taper over 4-6 weeks

Children and Adults: Physiologic replacement: 4-5 mg/m²/day

Adults: 5-60 mg/day in divided doses 1-4 times/day

Urticaria: 20 mg every 12 hours for 4 days

Elderly: Use the lowest effective dose

Erythema multiforme major: I.V.: Cyclophosphamide 150 mg over 1 hour every 24 hours for 2-3 days with prednisone (15 mg every 6 hours)

Monitoring Parameters Blood pressure, blood glucose, electrolytes

Administration Administer with meals to decrease gastrointestinal upset

Contraindications Hypersensitivity to prednisone or any component of the formulation; serious infections, except tuberculous meningitis; systemic fungal infections; varicella

Warnings Withdraw therapy with gradual tapering of dose, may retard bone growth. Use with caution in patients with hypothyroidism, cirrhosis, CHF, ulcerative colitis, thromboembolic disorders, and patients at increased risk for peptic ulcer disease. Corticosteroids should be used with caution in patients with diabetes, hypertension, osteoporosis, glaucoma, cataracts, or tuberculosis. Use caution in hepatic impairment. Because of the risk of adverse effects, systemic corticosteroids should be used cautiously in the elderly, in the smallest possible dose, and for the shortest possible time.

Dosage Forms Solution, oral: 1 mg/mL (5 mL, 120 mL, 500 mL) [contains alcohol 5%, sodium benzoate; vanilla flavor]

Solution, oral concentrate (Prednisone Intenso!™): 5 mg/mL (30 mL) [contains alcohol 30%]

Tablet: 1 mg, 2.5 mg, 5 mg, 10 mg, 20 mg, 50 mg

Sterapred®: 5 mg [supplied as 21 tablet 6-day unit-dose package or 48 tablet 12-day unit-dose package]

Sterapred® DS: 10 mg [supplied as 21 tablet 6-day unit-dose package or 48 tablet 12-day unit-dose package]

Overdosage/Treatment

Decontamination: Activated charcoal; acute overdose does not require tapering of dose

Enhanced elimination: Its metabolite (prednisolone) is slightly dialyzable (5% to 20%)

Test Interactions Skin tests

Drug Interactions **Substrate** of CYP3A4 (minor); **Induces** CYP2C19 (weak), 3A4 (weak)

Decreased effect:

Barbiturates, phenytoin, rifampin decrease corticosteroid effectiveness

Decreases salicylates

Decreases vaccines

Decreases toxoids effectiveness

Increased effect/toxicity: NSAIDs: Concurrent use of prednisone may increase the risk of GI ulceration

Pregnancy Risk Factor B

Pregnancy Implications Crosses the placenta. Immunosuppression reported in 1 infant exposed to high-dose prednisone plus azathioprine throughout gestation. One report of congenital cataracts. Available evidence suggests safe use during pregnancy.

Lactation Enters breast milk/compatible

Nursing Implications Give with meals to decrease gastritis; withdraw therapy with gradual tapering of dose

Primidone

Related Information

- Seizures, Neonatal Guidelines
- Therapeutic Drugs Associated with Hallucinations

CAS Number 125-33-7

U.S. Brand Names Mysoline®

Synonyms Desoxyphenobarbital; Primaclone

Impairment Potential Yes

Use Management of grand mal, psychomotor, and focal seizures

PRIMIDONE

Unlabeled/Investigational Use Benign familial tremor (essential tremor)

Mechanism of Action Decreases neuron excitability, raises seizure threshold similar to phenobarbital

Adverse Reactions

Cardiovascular: **Hypertension**, edema, syncope, palpitations
Central nervous system: **Headache, ataxia, drowsiness, dizziness, lethargy, behavior changes, sedation**, psychosis, irritability, visual hallucinations
Dermatologic: Rash
Gastrointestinal: Nausea, vomiting
Genitourinary: Crystalluria
Hematologic: Leukopenia, malignant lymphoma-like syndrome, anemia (megaloblastic), thrombocytopenia
Neuromuscular & skeletal: Weakness
Ocular: Diplopia, nystagmus, strabismus
Miscellaneous: Systemic lupus-like syndrome

Signs and Symptoms of Overdose Agranulocytosis, ankle clonus, confusion, crystalluria (white, hexagonal crystals), dementia, fever, granulocytopenia, hypotension, hypothermia, hypothyroidism, jaundice, leukopenia, loss of deep tendon reflexes, neutropenia, nystagmus, ptosis, severe flapping tremors, slurred speech, unsteady gait, vision color changes (green tinge)

Admission Criteria/Prognosis Admit any patient with markedly depressed mental status changes, crystalluria or primidone level > 40 mcg/mL

Pharmacodynamics/Kinetics

Distribution: Adults: V_d : 2-3 L/kg
Protein binding: 99%
Metabolism: Hepatic to phenobarbital (active) and phenylethylmalonamide (PEMA)
Bioavailability: 60% to 80%
Half-life elimination (age dependent): Primidone: 10-12 hours; PEMA: 16 hours; Phenobarbital: 52-118 hours
Time to peak, serum: ~4 hours
Excretion: Urine (15% to 25% as unchanged drug and active metabolites)

Dosage

Oral:
Neonates: Loading dose: 15-25 mg/kg/dose as a single dose; 12-20 mg/kg/day in divided doses 2-4 times/day; start with lower dosage and titrate upward
Children <8 years: Initial: 50-125 mg/day given at bedtime; increase by 50-125 mg/day increments every 3-7 days; usual dose: 10-25 mg/kg/day in divided doses 3-4 times/day
Children ≥8 years and Adults: Initial: 125-250 mg/day at bedtime; increase by 125-250 mg/day every 3-7 days; usual dose: 750-1500 mg/day in divided doses 3-4 times/day with maximum dosage of 2 g/day

Dosing interval in renal impairment:

Cl_{cr} 50-80 mL/minute: Administer every 8 hours
 Cl_{cr} 10-50 mL/minute: Administer every 8-12 hours
 Cl_{cr} <10 mL/minute: Administer every 12-24 hours
Hemodialysis: Moderately dialyzable (20% to 50%); administer dose postdialysis or administer supplemental 30% dose

Stability Protect from light

Monitoring Parameters Serum primidone and phenobarbital concentration, CBC, neurological status. Due to CNS effects, monitor closely when initiating drug in elderly. Monitor CBC at 6-month intervals to compare with baseline obtained at start of therapy. Since elderly metabolize phenobarbital at a slower rate than younger adults, it is suggested to measure both primidone and phenobarbital levels together.

Contraindications Hypersensitivity to primidone, phenobarbital, or any component of the formulation; porphyria; pregnancy

Warnings Use with caution in patients with renal or hepatic impairment, pulmonary insufficiency; abrupt withdrawal may precipitate status epilepticus. Potential for drug dependency exists. Do not administer to patients in acute pain. Use caution in elderly, debilitated, or pediatric patients - may cause paradoxical responses. May cause CNS depression, which may impair physical or mental abilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Effects with other sedative drugs or ethanol may be potentiated. Use with caution in patients with depression or suicidal tendencies, or in patients with a history of drug abuse. Tolerance or psychological and physical dependence may occur with prolonged use. Primidone's metabolite, phenobarbital, has been associated with cognitive deficits in children. Use with caution in patients with hypoadrenalism.

Dosage Forms Tablet: 50 mg, 250 mg [generic tablet may contain sodium benzoate]

Dosage forms available in Canada: Tablet: 125 mg, 250 mg. **Note:** 50 mg tablet is **not** available in Canada.

Reference Range

Therapeutic:

Children <5 years: 7-10 mcg/mL (SI: 32-46 μ mol/L)
Adults: 5-12 mcg/mL (SI: 23-55 μ mol/L); toxic effects rarely present with levels <10 mcg/mL (SI: <46 μ mol/L) if phenobarbital concentrations are low

Dosage of primidone is adjusted with reference mostly to the phenobarbital level

Toxic: >15 mcg/mL (SI: >69 μ mol/L) associated with ataxia and/or drowsiness

Serum primidone level required for urinary crystal formation: ~80 mg/L

Overdosage/Treatment

Decontamination: Gastric lavage; activated charcoal is effective
Supportive therapy: Hypotension: Isotonic I.V. fluid (10-20 mL/kg) is effective along with placement in Trendelenburg position; dopamine (2-5 mg/kg progressing to 5-10 mcg/kg) or norepinephrine (0.1-0.2 mcg/kg/minute for children or 8-12 mcg/kg in adults to a maintenance dose of 2-4 mcg/minute) is effective

Enhancement of elimination: Repeated oral doses of activated charcoal significantly reduce the half-life of primidone resulting from an enhancement of nonrenal elimination. The usual dose is 12.5-25 g every 1-2 hours until concentrations are <20 mg/L or the patient has no bowel movement, causing the charcoal to remain in the gastrointestinal tract. Assure adequate hydration and renal function. Urinary alkalization with I.V. sodium bicarbonate also helps to enhance elimination. Hemodialysis is of uncertain value. Patients in stage IV coma due to high serum drug levels may require charcoal hemoperfusion; moderately dialyzable (20% to 50%); clearance by hemodialysis and hemoperfusion is ~98 mL/minute (~55% of drug removed in 4 hours).

Diagnostic Procedures

● Primidone, Blood

Test Interactions ↑ alkaline phosphatase (S); ↓ calcium (S)

Drug Interactions Metabolized to phenobarbital; **Induces** CYP1A2 (strong), 2B6 (strong), 2C8 (strong), 2C9 (strong), 3A4 (strong)

Acetaminophen: Barbiturates may enhance the hepatotoxic potential of acetaminophen overdoses

Antiarrhythmics: Barbiturates may increase the metabolism of antiarrhythmics, decreasing their clinical effect; includes disopyramide, propafenone, and quinidine

Anticonvulsants: Barbiturates may increase the metabolism of anticonvulsants; includes ethosuximide, felbamate (possibly), lamotrigine, phenytoin, tiagabine, topiramate, and zonisamide; does not appear to affect gabapentin or levetiracetam

Antineoplastics: Limited evidence suggests that enzyme-inducing anticonvulsant therapy may reduce the effectiveness of some chemotherapy regimens (specifically in ALL); teniposide and methotrexate may be cleared more rapidly in these patients

Antipsychotics: Barbiturates may enhance the metabolism (decrease the efficacy) of antipsychotics; monitor for altered response; dose adjustment may be needed

Beta-blockers: Metabolism of beta-blockers may be increased and clinical effect decreased; atenolol and nadolol are unlikely to interact given their renal elimination

Calcium channel blockers: Barbiturates may enhance the metabolism of calcium channel blockers, decreasing their clinical effect

Chloramphenicol: Barbiturates may increase the metabolism of chloramphenicol and chloramphenicol may inhibit barbiturate metabolism; monitor for altered response

Cimetidine: Barbiturates may enhance the metabolism of cimetidine, decreasing its clinical effect

CNS depressants: Sedative effects and/or respiratory depression with barbiturates may be additive with other CNS depressants; monitor for increased effect. Includes ethanol, sedatives, antidepressants, narcotic analgesics, and benzodiazepines

Corticosteroids: Barbiturates may enhance the metabolism of corticosteroids, decreasing their clinical effect

Cyclosporine: Levels may be decreased by barbiturates; monitor
CYP1A2 substrates: Primidone may decrease the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, estrogens, fluvoxamine, mirtazapine, ropinirole, and theophylline.

CYP2B6 substrates: Primidone may decrease the levels/effects of CYP2B6 substrates. Example substrates include bupropion, efavirenz, promethazine, selegiline, and sertraline.

CYP2C8 Substrates: Primidone may decrease the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP2C9 Substrates: Primidone may decrease the levels/effects of CYP2C9 substrates. Example substrates include bosentan, celecoxib, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, sulfonamides, trimethoprim, warfarin, and zafirlukast.

CYP3A4 substrates: Primidone may decrease the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, clarithromycin, cyclosporine, erythromycin, estrogens, mirtazapine, nateglinide, nefazodone, nevirapine, protease inhibitors, tacrolimus, and venlafaxine.

Doxycycline: Barbiturates may enhance the metabolism of doxycycline, decreasing its clinical effect; higher dosages may be required

Estrogens: Barbiturates may increase the metabolism of estrogens and reduce their efficacy

Felbamate may inhibit the metabolism of barbiturates and barbiturates may increase the metabolism of felbamate

Griseofulvin: Barbiturates may impair the absorption of griseofulvin, and griseofulvin metabolism may be increased by barbiturates, decreasing clinical effect

Guanfacine: Effect may be decreased by barbiturates

Immunosuppressants: Barbiturates may enhance the metabolism of immunosuppressants, decreasing its clinical effect; includes both cyclosporine and tacrolimus

Loop diuretics: Metabolism may be increased and clinical effects decreased; established for furosemide, effect with other loop diuretics not established

MAO inhibitors: Metabolism of barbiturates may be inhibited, increasing clinical effect or toxicity of the barbiturates

Methadone: Barbiturates may enhance the metabolism of methadone resulting in methadone withdrawal

Methoxyflurane: Barbiturates may enhance the nephrotoxic effects of methoxyflurane

Oral contraceptives: Barbiturates may enhance the metabolism of oral contraceptives, decreasing their clinical effect; an alternative method of contraception should be considered

Theophylline: Barbiturates may increase metabolism of theophylline derivatives and decrease their clinical effect

Tricyclic antidepressants: Barbiturates may increase metabolism of tricyclic antidepressants and decrease their clinical effect; sedative effects may be additive

Valproic acid: Metabolism of barbiturates may be inhibited by valproic acid; monitor for excessive sedation; a dose reduction may be needed

Warfarin: Barbiturates inhibit the hypoprothrombinemic effects of oral anticoagulants via increased metabolism; this combination should generally be avoided

Pregnancy Risk Factor D

Pregnancy Implications Crosses the placenta. Dysmorphic facial features; hemorrhagic disease of newborn due to fetal vitamin K depletion, maternal folic acid deficiency may occur. Epilepsy itself, number of medications, genetic factors, or a combination of these probably influence the teratogenicity of anticonvulsant therapy. Benefit: risk ratio usually favors continued use during pregnancy.

Lactation Enters breast milk/not recommended (AAP recommends use "with caution")

Nursing Implications Observe patient for excessive sedation

Additional Information Hepatic metabolism to active products (phenylethylmalonamide and phenobarbital)

Probenecid

CAS Number 57-66-9

Synonyms Benemid [DSC]

Use Prevention of gouty arthritis; hyperuricemia; prolongation of beta-lactam effect (ie, serum levels)

Mechanism of Action Competitively inhibits the reabsorption of uric acid at the proximal convoluted tubule, thereby promoting its excretion and reducing serum uric acid levels; increases plasma levels of weak organic acids (penicillins, cephalosporins, or other beta-lactam antibiotics) by competitively inhibiting their renal tubular secretion

Adverse Reactions

Cardiovascular: Flushing of face

Central nervous system: **Headache**, dizziness, tonic-clonic epilepsy

Dermatologic: Rash, itching, lichen planus

Gastrointestinal: **Anorexia, nausea, vomiting**, sore gums

Genitourinary: Painful urination

Hematologic: Leukopenia, hemolytic anemia, aplastic anemia

Hepatic: Hepatic necrosis

Neuromuscular & skeletal: **Gouty arthritis (acute)**

Ocular: Retinal edema

Renal: Renal calculi, urate nephropathy, nephrotic syndrome

Miscellaneous: Anaphylaxis

Signs and Symptoms of Overdose Coma, nausea, tonic-clonic seizures, tremors, visual hallucinations, vomiting.

Pharmacodynamics/Kinetics

Onset of action: Effect on penicillin levels: 2 hours

Absorption: Rapid and complete

Metabolism: Hepatic

Half-life elimination (dose dependent): Normal renal function: 6-12 hours

Time to peak, serum: 2-4 hours

Excretion: Urine

Dosage

Oral:

Children:

<2 years: Not recommended

2-14 years: Prolong penicillin serum levels: 25 mg/kg starting dose, then 40 mg/kg/day given 4 times/day

Gonorrhea: <45 kg: 25 mg/kg × 1 (maximum: 1 g/dose) 30 minutes before penicillin, ampicillin or amoxicillin

Adults:

Hyperuricemia with gout: 250 mg twice daily for 1 week; increase to 250-500 mg/day; may increase by 500 mg/month, if needed, to maximum of 2-3 g/day (dosages may be increased by 500 mg every 6 months if serum urate concentrations are controlled)

Prolong penicillin serum levels: 500 mg 4 times/day

Gonorrhea: 1 g 30 minutes before penicillin, ampicillin or amoxicillin

Dosing adjustment in renal impairment: $Cl_{cr} < 50$ mL/minute: Avoid use

Monitoring Parameters Uric acid, renal function, CBC

Administration Administer with food or antacids to minimize GI effects

Contraindications Hypersensitivity to probenecid or any component of the formulation; high-dose aspirin therapy; blood dyscrasias; uric acid kidney stones; children <2 years of age

Warnings Use with caution in patients with peptic ulcer. Salicylates may diminish the therapeutic effect of probenecid. This effect may be more pronounced with high, chronic doses, however, the manufacturer recommends the use of an alternative analgesic even in place of small doses of aspirin. Use of probenecid with penicillin in patients with renal insufficiency is not recommended. Probenecid monotherapy may not be effective in patients with a creatinine clearance <30 mL/minute. May cause exacerbation of acute gouty attack

Dosage Forms Tablet: 500 mg

Reference Range Peak plasma probenecid level following a 2 g dose: ~149 mcg/mL between 3 and 4 hours

Overdosage/Treatment

Decontamination: Do not induce emesis; activated charcoal is especially effective at binding probenecid for GI contamination

Supportive therapy: Seizures should be treated with benzodiazepines and barbiturates

Test Interactions False-positive glucose (U) with Clinitest®

Drug Interactions

Inhibits CYP2C19 (weak)

Carbapenems (ertapenem, imipenem, meropenem): Probenecid may decrease the excretion of carbapenem antibiotics.

Cephalosporins: Probenecid may decrease the excretion of cephalosporin antibiotics. This effect is used advantageously in selected cases to increase serum antibiotic concentrations.

Dapsone: Probenecid may decrease the excretion of dapsone.

Methotrexate: Probenecid may decrease the excretion of methotrexate; concomitant use should be avoided. If used concomitantly, the methotrexate dosage will likely need reduced. Monitor for evidence of methotrexate toxicity.

Nonsteroidal anti-inflammatory agents: Probenecid may increase the serum concentration of NSAIDs. The manufacturer of ketorolac contraindicates concomitant use.

Penicillins: Probenecid may decrease the excretion of penicillin antibiotics. This effect is used advantageously in selected cases to increase serum antibiotic concentrations.

Salicylates: Salicylates may diminish the therapeutic effect of probenecid.

Thiopental: Probenecid may enhance the therapeutic effect of thiopental.

Zidovudine: Probenecid may decrease the metabolism of zidovudine.

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown

Procainamide

Related Information

• Therapeutic Drugs Associated with Hallucinations

CAS Number 51-06-9; 614-39-1

U.S. Brand Names Procanbid®; Pronestyl-SR® [DSC]; Pronestyl® [DSC]

Synonyms PCA (error-prone abbreviation); Procainamide Hydrochloride; Procaine Amide Hydrochloride

Use Treatment of ventricular tachycardia (VT), premature ventricular contractions, paroxysmal atrial tachycardia (PSVT), and atrial fibrillation (AF); prevent recurrence of ventricular tachycardia, paroxysmal supra-ventricular tachycardia, atrial fibrillation or flutter

Unlabeled/Investigational Use ACLS guidelines:

Stable monomorphic VT (EF >40%, no CHF)

Stable wide complex tachycardia, likely VT (EF >40%, no CHF, patient stable)

Atrial fibrillation or flutter, including pre-excitation syndrome (EF >40%, no CHF)

AV reentrant, narrow complex tachycardia (eg, reentrant SVT) [preserved ventricular function]

PALS guidelines: Tachycardia with pulses and poor perfusion (possible VT)

Mechanism of Action Decreases myocardial excitability and conduction velocity and depresses myocardial contractility, by increasing the

PROCAINAMIDE

electrical stimulation threshold of ventricle, His-Purkinje system and through direct cardiac effects; classified as a Class IA antiarrhythmic agent

Adverse Reactions

Cardiovascular: Pericardial effusion/pericarditis, hypotension, tachycardia, cardiac arrhythmias, AV block, QT prolongation, QRS prolongation, myocarditis, sinus tachycardia, exacerbation of Brugada syndrome

Central nervous system: Confusion, psychosis, disorientation, fever, visual hallucinations, ataxia, gustatory hallucinations

Dermatologic: Rash, angioedema, purpura, pruritus, licheniform eruptions, exanthem, cutaneous vasculitis

Endocrine & metabolic: Nephrogenic diabetes insipidus

Gastrointestinal: Nausea, vomiting, gastrointestinal complaints, diarrhea, xerostomia

Genitourinary: Urinary retention

Hematologic: Agranulocytosis, neutropenia, thrombocytopenia, hemolysis, positive Coombs' test, red blood cell aplasia

Hepatic: Granulomatous hepatitis

Neuromuscular & skeletal: Arthralgia, myalgia, myopathy, rhabdomyolysis

Ocular: Blurred vision

Respiratory: Pleural effusion

Miscellaneous: Drug-induced **systemic lupus erythematosus**

Signs and Symptoms of Overdose Agranulocytosis, anticholinergic toxidrome, AV block, coagulopathy, confusion, drowsiness, granulocytopenia, hemoptysis, hyperthermia, hypotension, intraventricular conduction delay, junctional tachycardia, leukopenia, mania, myasthenia gravis (exacerbation or precipitation), neutropenia, oliguria, QRS prolongation, renal failure, respiratory failure, torsade de pointes

Pharmacodynamics/Kinetics

Onset of action: I.M. 10-30 minutes

Distribution: V_d : Children: 2.2 L/kg; Adults: 2 L/kg; Congestive heart failure or shock: Decreased V_d

Protein binding: 15% to 20%

Metabolism: Hepatic via acetylation to produce N-acetyl procainamide (NAPA) (active metabolite)

Bioavailability: Oral: 75% to 95%

Half-life elimination:

Procainamide (hepatic acetylator, phenotype, cardiac and renal function dependent):

Children: 1.7 hours; Adults: 2.5-4.7 hours; Anephric: 11 hours

NAPA (dependent upon renal function):

Children: 6 hours; Adults: 6-8 hours; Anephric: 42 hours

Time to peak, serum: Capsule: 45 minutes to 2.5 hours; I.M.: 15-60 minutes

Excretion: Urine (25% as NAPA)

Dosage Must be titrated to patient's response

Children:

Oral: 15-50 mg/kg/24 hours divided every 3-6 hours

I.M.: 50 mg/kg/24 hours divided into doses of $1/8$ to $1/4$ every 3-6 hours in divided doses until oral therapy is possible

I.V. (infusion requires use of an infusion pump):

Load: 3-6 mg/kg/dose over 5 minutes not to exceed 100 mg/dose; may repeat every 5-10 minutes to maximum of 15 mg/kg/load

Maintenance as continuous I.V. infusion: 20-80 mcg/kg/minute; maximum: 2 g/24 hours

Possible VT (pulses and poor perfusion) [PALS 2005 Guidelines]: I.V.; I.O.: 15 mg/kg over 30-60 minutes

Adults:

Oral: Usual dose: 50 mg/kg/24 hours: maximum: 5 g/24 hours (**Note:** Twice-daily dosing approved for Procanbid®.)

Immediate release formulation: 250-500 mg/dose every 3-6 hours

Extended release formulation: 500 mg to 1 g every 6 hours; Procanbid®: 1000-2500 mg every 12 hours

I.M.: 0.5-1 g every 4-8 hours until oral therapy is possible

I.V. (infusion requires use of an infusion pump):

Loading dose: 15-18 mg/kg administered as slow infusion over 25-30 minutes or 100-200 mg/dose repeated every 5 minutes as needed to a total dose of 1 g. Reduce loading dose to 12 mg/kg in severe renal or cardiac impairment.

Maintenance dose: 1-4 mg/minute by continuous infusion. Maintenance infusions should be reduced by one-third in patients with moderate renal or cardiac impairment and by two-thirds in patients with severe renal or cardiac impairment.

ACLS guidelines: Infuse 20 mg/minute until arrhythmia is controlled, hypotension occurs, QRS complex widens by 50% of its original width, or total of 17 mg/kg is given.

Dosing interval in renal impairment:

Oral:

Cl_{cr} 10-50 mL/minute: Administer every 6-12 hours.

Cl_{cr} < 10 mL/minute: Administer every 8-24 hours.

I.V.:

Loading dose: Reduce dose to 12 mg/kg in severe renal impairment.

Maintenance infusion: Reduce dose by one-third in patients with mild renal impairment. Reduce dose by two-thirds in patients with severe renal impairment.

Dialysis:

Procainamide: Moderately hemodialyzable (20% to 50%): 200 mg supplemental dose posthemodialysis is recommended.

N-acetylprocainamide: Not dialyzable (0% to 5%)

Procainamide/N-acetylprocainamide: Not peritoneal dialyzable (0% to 5%)

Procainamide/N-acetylprocainamide: Replace by blood level during continuous arteriovenous or venovenous hemofiltration

Dosing adjustment in hepatic impairment: Reduce dose by 50%.

Stability Use only clear or slightly yellow solutions; store in airtight containers

Stability of parenteral admixture at room temperature (25°C): 24 hours

Stability of parenteral admixture at refrigeration temperature (4°C): 24 hours

Monitoring Parameters ECG, blood pressure, CBC with differential, platelet count; cardiac monitor and blood pressure monitor required during I.V. administration; blood levels in patients with renal failure or receiving constant infusion > 3 mg/minute for longer than 24 hours

Administration Dilute I.V. With D₅W; maximum rate: 50 mg/minute; administer around-the-clock rather than 4 times/day to promote less variation in peak and trough serum levels. Do **not** crush or chew extended release drug product.

Contraindications Hypersensitivity to procaine, other ester-type local anesthetics, or any component of the formulation; complete heart block (except in patients with a functioning artificial pacemaker); second-degree AV block (without a functional pacemaker); various types of hemiblock (without a functional pacemaker); SLE; torsade de pointes; concurrent cisapride use; QT prolongation

Warnings Monitor and adjust dose to prevent QT_c prolongation. Watch for proarrhythmic effects. May precipitate or exacerbate CHF. Reduce dosage in renal impairment. May increase ventricular response rate in patients with atrial fibrillation or flutter; control AV conduction before initiating. Correct hypokalemia before initiating therapy. Hypokalemia may worsen toxicity. Use caution in digoxin-induced toxicity (can further depress AV conduction). Reduce dose if first-degree heart block occurs. Use caution with concurrent use of other antiarrhythmics. Avoid use in myasthenia gravis (may worsen condition). Hypersensitivity reactions can occur. Some tablets contain tartrazine; injection may contain bisulfite (allergens).

Potentially fatal blood dyscrasias have occurred with therapeutic doses; close monitoring is recommended during the first 3 months of therapy.

[U.S. Boxed Warning]: Long-term administration leads to the development of a positive antinuclear antibody (ANA) test in 50% of patients which may result in a drug-induced lupus erythematosus-like syndrome (in 20% to 30% of patients); discontinue procainamide with SLE symptoms and choose an alternative agent

Dosage Forms Capsule, as hydrochloride: 250 mg, 500 mg

Injection, solution, as hydrochloride: 100 mg/mL (10 mL); 500 mg/mL (2 mL) [contains sodium metabisulfite]

Tablet, extended release, as hydrochloride: 500 mg, 750 mg, 1000 mg

Procanbid®: 500 mg, 1000 mg

Reference Range

Therapeutic: 4-10 mcg/mL for procainamide, <30 mcg/mL for sum of procainamide and N-acetyl procainamide; NAPA levels: 10-30 mcg/mL. Optimal ranges must be ascertained for individual patients, with ECG monitoring.

Toxic (procainamide): > 14 mcg/mL (SI: > 59.5 μmol/L)

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Concurrent sodium bicarbonate and sodium lactate infusions have been effective in reversing the drug-induced cardiac toxicity. Avoid quinidine, disopyramide, and beta-adrenergic blockers.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; hemodialysis or charcoal hemoperfusion are effective in decreasing half-life; NAPA is more effectively removed by hemoperfusion; forced diuresis or peritoneal dialysis is not effective; moderately dialyzable (20% to 50%); hemodialysis clearance of procainamide and NAPA: 65 mL/minute and 45 mL/minute respectively. ~78% of procainamide (and 49% of NAPA) concentration is fractionally removed during 4 hours of hemodialysis. Continuous arteriovenous hemodiafiltration using a high dialysate flow rate can enhance elimination of N-acetylprocainamide.

Drug Interactions

Substrate of CYP2D6 (major)

Amiodarone increases procainamide and NAPA blood levels; consider reducing procainamide dosage by 25% with concurrent use.

Cimetidine increases procainamide and NAPA blood concentrations; monitor blood levels closely or use an alternative H₂ antagonist.

Cisapride and procainamide may increase the risk of malignant arrhythmia; concurrent use is contraindicated.

CYP2D6 inhibitors: May increase the levels/effects of procainamide. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Neuromuscular blocking agents: Procainamide may potentiate neuromuscular blockade.

Ofloxacin may increase procainamide levels due to an inhibition of renal secretion; monitor levels for procainamide closely.

QT_c-prolonging agents (eg, amiodarone, amitriptyline, bepridil, disopyramide, erythromycin, haloperidol, imipramine, pimozone, quinidine, sotalol, and thioridazine): Effects/toxicity may be increased; use with caution.

Sparfloxacin, gatifloxacin, and moxifloxacin may result in additional prolongation of the QT interval; concurrent use is contraindicated.

Trimethoprim increases procainamide and NAPA blood levels; closely monitor levels.

Pregnancy Risk Factor C

Lactation Enters breast milk/use caution (AAP rates "compatible")

Procaine

CAS Number 51-05-8; 59-46-1

U.S. Brand Names Novocain®

Synonyms Procaine Hydrochloride

Use Produce spinal anesthesia and epidural and peripheral nerve block by injection and infiltration methods

Mechanism of Action Blocks both the initiation and conduction of nerve impulses by decreasing the neuronal membrane's permeability to sodium ions, which results in inhibition of depolarization with resultant blockade of conduction

Adverse Reactions

Cardiovascular: Sinus bradycardia, sinus tachycardia

Central nervous system: Aseptic meningitis resulting in paralysis can occur, CNS stimulation followed by CNS depression, psychosis, paranoia, hallucinations, chills

Dermatologic: Skin discoloration; photoallergy

Gastrointestinal: Nausea, vomiting

Local: Burning sensation and pain at site of injection, tissue irritation

Ocular: Miosis, nystagmus, diplopia

Otic: Ototoxicity, tinnitus

Signs and Symptoms of Overdose Cardiac arrhythmias, coma, hypertension, mydriasis, seizures, tachycardia, tachypnea progressing to apnea

Pharmacodynamics/Kinetics

Onset of action: 2-5 minutes

Duration (patient, type of block, concentration, and method of anesthesia dependent): 0.5-1.5 hours

Metabolism: Rapidly hydrolyzed by plasma enzymes to para-aminobenzoic acid and diethylaminoethanol (80% conjugated before elimination)

Half-life elimination: 7.7 minutes

Excretion: Urine (as metabolites and some unchanged drug)

Dosage Dose varies with procedure, desired depth, and duration of anesthesia, desired muscle relaxation, vascularity of tissues, physical condition, and age of patient; maximum dose: 7 mg/kg; maximum dose with epinephrine: 9 mg/kg

Administration Prior to instillation of anesthetic agent, withdraw plunger to ensure needle is not in artery or vein; resuscitative equipment should be available when local anesthetics are administered

Contraindications Hypersensitivity to procaine, PABA, parabens, other ester local anesthetics, or any component of the formulation

Warnings Patients with cardiac diseases, hyperthyroidism, or other endocrine diseases may be more susceptible to toxic effects of local anesthetics; some preparations contain metabisulfite

Dosage Forms Injection, solution, as hydrochloride: 1% [10 mg/mL] (2 mL [contains sodium bisulfite]); 10% (2 mL [contains sodium bisulfite])

Reference Range

Therapeutic: 3-11 mcg/mL

Toxic: >20 mcg/mL are associated with toxicity

Overdosage/Treatment Supportive therapy: Termination of anesthesia by pneumatic tourniquet inflation should be attempted when the agent is administered by infiltration or regional injection. Seizures commonly respond to diazepam or lorazepam, while hypotension responds to I.V. fluids and Trendelenburg positioning. Bradyarrhythmias (when the heart rate is less than 60) can be treated with I.V., I.M., or SubQ atropine 15 mcg/kg. With the development of metabolic acidosis, I.V. sodium bicarbonate 0.5-2 mEq/kg and ventilatory assistance should be instituted. Chlorpromazine may be used to treat acute psychosis.

Drug Interactions Decreased effect of sulfonamides with the PABA metabolite of procaine, chlorprocaine, and tetracaine

Decreased/increased effect of vasopressors, ergot alkaloids, and MAO inhibitors on blood pressure when using anesthetic solutions with a vasoconstrictor

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Procarbazine

CAS Number 366-70-1; 671-16-9

U.S. Brand Names Matulane®

Synonyms Benzmethylzine; N-Methylhydrazine; NSC-77213; Procarbazine Hydrochloride

Use Treatment of Hodgkin's disease

Unlabeled/Investigational Use Treatment of non-Hodgkin's lymphoma, brain tumors, melanoma, lung cancer, multiple myeloma

Mechanism of Action Mechanism of action is not clear, methylating of nucleic acids; inhibits DNA, RNA, and protein synthesis; may damage DNA directly and suppress mitosis in the S phase of cell division; metabolic activation required by host

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), hypertensive crisis

Central nervous system: **Manic reactions**, coma, **hallucinations**, psychosis, mania, **dizziness**, **headache**, **nervousness**, **insomnia**, **night terrors**, **disorientation**, foot drop, decreased reflexes, somnolence, **confusion**, **seizures**, hyperpyrexia, irritability, **ataxia**, CNS depression, **mental depression**, **CNS stimulation**, hyperthermia

Dermatologic: Alopecia, pruritus, dermatitis, alopecia, hypersensitivity rash, hyperpigmentation

Endocrine & metabolic: **Amenorrhea**

Gastrointestinal: Severe **nausea and vomiting** occur frequently and may be dose-limiting; **anorexia**, **abdominal pain**, **stomatitis**, **dysphagia**, **diarrhea**, and **constipation**; use a nonphenothiazine antiemetic, when possible

Genitourinary: Azoospermia, urinary frequency, nocturia

Hematologic: May be dose-limiting toxicity; procarbazine should be discontinued if leukocyte count is <4000 mL or platelet count <100,000 mL; leukopenia, **thrombocytopenia**, **hemolytic anemia**

Hepatic: Hepatotoxicity, jaundice

Neuromuscular & skeletal: Neuropathy (peripheral), arthralgia, myalgia, tremors, **paresthesia**, **weakness**, **tremors**, **decreased reflexes**, **foot drop**

Ocular: **Nystagmus**, diplopia, photophobia

Renal: Hematuria

Respiratory: **Pleural effusion**, **cough**, interstitial pneumonitis, hoarseness

Miscellaneous: Secondary malignancy, flu-like syndrome

Signs and Symptoms of Overdose Alopecia, arthralgia, bone marrow depression, coma, diarrhea, hallucinations, nausea, paresthesia, seizures, vomiting

Pharmacodynamics/Kinetics

Absorption: Rapid and complete

Distribution: Crosses blood-brain barrier; distributes into CSF

Metabolism: Hepatic and renal

Half-life elimination: 1 hour

Excretion: Urine and respiratory tract (<5% as unchanged drug, 70% as metabolites)

Dosage Refer to individual protocols. Dose based on patient's ideal weight if the patient is obese or has abnormal fluid retention. Oral (may be given as a single daily dose or in 2-3 divided doses):

Children:

BMT aplastic anemia conditioning regimen: 12.5 mg/kg/dose every other day for 4 doses

Hodgkin's disease: MOPP/IC-MOPP regimens: 100 mg/m²/day for 14 days and repeated every 4 weeks

Neuroblastoma and medulloblastoma: Doses as high as 100-200 mg/m²/day once daily have been used

Adults: Initial: 2-4 mg/kg/day in single or divided doses for 7 days then increase dose to 4-6 mg/kg/day until response is obtained or leukocyte count decreased <4000/mm³ or the platelet count decreased <100,000/mm³; maintenance: 1-2 mg/kg/day

Dosing in renal/hepatic impairment: Use with caution, may result in increased toxicity; decrease dose if serum creatinine >2 mg/dL or total bilirubin >3 mg/dL

Stability Protect from light

Monitoring Parameters CBC with differential, platelet and reticulocyte count, urinalysis, liver function test, renal function test.

Contraindications Hypersensitivity to procarbazine or any component of the formulation; pre-existing bone marrow aplasia; ethanol ingestion; pregnancy

Warnings Hazardous agent – use appropriate precautions for handling and disposal. Use with caution in patients with pre-existing renal or hepatic impairment; procarbazine possesses MAO inhibitor activity.

PROCHLORPERAZINE

Procarbazine is a carcinogen which may cause acute leukemia; procarbazine may cause infertility. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.**

Dosage Forms Capsule, as hydrochloride: 50 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: Adverse effects, such as marrow toxicity may begin as late as 2-8 weeks after exposure. Hypotension can be treated with isotonic saline (10-20 mL/kg) and Trendelenburg positioning. Refractory hypotension can be treated with treated with dopamine or norepinephrine. Bone marrow depression can be treated with filgrastim (5 mcg/kg/day I.V. or SubQ) for 2 weeks or until absolute neutrophil count exceeds 10,000 cells/mm³.

Test Interactions ↑ potassium (S)

Drug Interactions Increased toxicity:

Procarbazine exhibits weak monoamine oxidase (MAO) inhibitor activity; foods containing high amounts of tyramine should, therefore, be avoided (ie, beer, yogurt, yeast, wine, cheese, pickled herring, chicken liver, and bananas). When a MAO inhibitor is given with food high in tyramine, a hypertensive crisis, intracranial bleeding, and headache have been reported.

Sympathomimetic amines (epinephrine and amphetamines) and antidepressants (tricyclics) should be used cautiously with procarbazine.

Barbiturates, narcotics, phenothiazines, and other CNS depressants can cause somnolence, ataxia, and other symptoms of CNS depression

Ethanol has caused a disulfiram-like reaction with procarbazine; may result in headache, respiratory difficulties, nausea, vomiting, sweating, thirst, hypotension, and flushing

Pregnancy Risk Factor D

Pregnancy Implications Teratogenic with genitourinary malformations, oligodactyly, ventricular septal defects, cerebral hemorrhage, growth retardation, and hemangiomas present

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Protect from light

Additional Information Toxic dose: 1 g/m². Myelosuppressive effects: **WBC:** Moderate. **Platelets:** Moderate: Onset (days): 14. Nadir (days): 21. Recovery (days): 28

Duration: Rectal: 12 hours; Oral: 3-4 hours; I.M., I.V.: Adults: 4-6 hours; I.M.: Children: 12 hours

Distribution: V_d: 1400-1548 L; crosses placenta; enters breast milk

Metabolism: Primarily hepatic; N-desmethyl prochlorperazine (major active metabolite)

Bioavailability: Oral: 12.5%

Half-life elimination: Oral: 3-5 hours; I.V.: ~7 hours

Dosage

Children >10 kg:

Oral, rectal: 0.4 mg/kg/24 hours in 3-4 divided doses; or

9-14 kg: 2.5 mg every 12-24 hours as needed; maximum: 7.5 mg/day

14-18 kg: 2.5 mg every 8-12 hours as needed; maximum: 10 mg/day

18-39 kg: 2.5 mg every 8 hours or 5 mg every 12 hours as needed; maximum: 15 mg/day

I.M.: 0.1-0.15 mg/kg/dose; usual: 0.13 mg/kg/dose; change to oral as soon as possible

I.V.: Not recommended in children <10 kg or <2 years

Adults:

Oral: 5-10 mg 3-4 times/day or sustained release twice daily; usual maximum: 40 mg/day; doses up to 150 mg/day may be required in some patients for treatment of severe psychotic disturbances

I.M.: 5-10 mg every 3-4 hours; usual maximum: 40 mg/day; doses up to 10-20 mg every 4-6 hours may be required in some patients for treatment of severe psychotic disturbances

I.V.: 2.5-10 mg; maximum 10 mg/dose or 40 mg/day; may repeat dose every 3-4 hours as needed

Rectal: 25 mg twice daily

Stability

Injection: Intact vials/ampuls for injection are stable at room temperature; protect from light; clear or slightly yellow solutions may be used.

I.V. infusion: Injection may be diluted in 50-100 mL NS or D₅W.

Suppository: May require refrigeration

Tablet: Stable at room temperature

Monitoring Parameters Vital signs; lipid profile, fasting blood glucose/Hgb A_{1c}; BMI; mental status, abnormal involuntary movement scale (AIMS); periodic ophthalmic exams (if chronically used); extrapyramidal symptoms (EPS)

Administration

May be administered orally, I.M., or I.V.: I.V. doses should be given as a short (~30 minute) infusion or by slow (5-10 minutes) IVP to avoid orthostatic hypotension.

Contraindications Hypersensitivity to prochlorperazine or any component of the formulation (cross-reactivity between phenothiazines may occur); severe CNS depression; coma; pediatric surgery; Reye's syndrome; should not be used in children <2 years of age or <9 kg

Warnings

May be sedating; use with caution in disorders where CNS depression is a feature. May obscure intestinal obstruction or brain tumor. May impair physical or mental abilities; patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Effects with other sedative drugs or ethanol may be potentiated. Use with caution in Parkinson's disease; hemodynamic instability; bone marrow suppression; predisposition to seizures; subcortical brain damage; and in severe cardiac, hepatic, renal or respiratory disease. Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs. Use caution with exposure to heat. May alter cardiac conduction; life-threatening arrhythmias have occurred with therapeutic doses of phenothiazines. May cause orthostatic hypotension; use with caution in patients at risk of hypotension or where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). Hypotension may occur following administration, particularly when parenteral form is used or in high dosages.

Phenothiazines may cause anticholinergic effects (eg, constipation, xerostomia, blurred vision, urinary retention); therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (TD). Use caution in the elderly; incidence of TD may be increased. Children with acute illness or dehydration are more susceptible to neuromuscular reactions (eg, dystonias); use cautiously. May be associated with neuroleptic malignant syndrome (NMS).

Dosage Forms

Injection, solution, as edisylate: 5 mg/mL (2 mL, 10 mL) [contains benzyl alcohol]

Suppository, rectal: 2.5 mg (12s), 5 mg (12s), 25 mg (12s) [may contain coconut and palm oil]

Compro™: 25 mg (12s) [contains coconut and palm oils]

Tablet, as maleate: 5 mg, 10 mg

Reference Range Blood level >1 mcg/mL associated with toxicity

Prochlorperazine

CAS Number 58-38-8

U.S. Brand Names Compazine® [DSC]; Compro™

Synonyms Chlormepazine; Compazine; Prochlorperazine Edisylate; Prochlorperazine Maleate

Impairment Potential Yes

Use Management of nausea and vomiting; psychosis; anxiety
Behavioral syndromes in dementia

Mechanism of Action Blocks postsynaptic mesolimbic dopaminergic receptors in the brain, including the medullary chemoreceptor trigger zone; exhibits a strong alpha-adrenergic blocking effect and depresses the release of hypothalamic and hypophyseal hormones

Adverse Reactions

Cardiovascular: **Hypotension** (especially with I.V. use), **hypotension (orthostatic)**, **tachycardia**, **cardiac arrhythmias**, sinus tachycardia

Central nervous system: Sedation, drowsiness, restlessness, anxiety, extrapyramidal reactions, **pseudoparkinsonian signs and symptoms**, **tardive dyskinesia**, neuroleptic malignant syndrome, seizures, altered central temperature regulation, **dizziness**, **dystonias**

Dermatologic: **Hyperpigmentation**, pruritus, rash, photosensitivity, exfoliative dermatitis, toxic epidermal necrolysis, urticaria, purpura, exanthem

Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, syndrome of inappropriate antidiuretic hormone

Gastrointestinal: GI upset, **xerostomia**, **constipation**, weight gain

Genitourinary: **Urinary retention**, impotence

Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia, (usually in patients with large doses for prolonged periods), thrombocytopenia, hemolysis, eosinophilia

Hepatic: Cholestatic jaundice

Ocular: **Retinal pigmentation**, photophobia, **blurred vision**, phototoxic

Miscellaneous: Anaphylactoid reactions, systemic lupus erythematosus, **diaphoresis (decreased)**, fixed drug eruption

Signs and Symptoms of Overdose Akathisia, coma, deep sleep, extrapyramidal reaction, photosensitivity, impotence, muscle spasm, neuroleptic malignant syndrome, nystagmus, Parkinson's-like symptoms, urine discoloration (pink; red; red-brown), vision color changes (brown tinge)

Pharmacodynamics/Kinetics

Onset of action: Oral: 30-40 minutes; I.M.: 10-20 minutes; Rectal: ~60 minutes

Peak antiemetic effect: I.V.: 30-60 minutes

Overdosage/Treatment

Decontamination: Activated charcoal; charcoal may need to be given in multiple doses for adequate decontamination
 Supportive therapy: Initiate support with fluids, norepinephrine may be useful for hypotension; hypoperfusion states may respond to inotropic support with dobutamine. Bradyarrhythmia or ventricular dysrhythmia may respond to sodium bicarbonate or phenytoin; must avoid class IA and IC antiarrhythmics. Torsade de pointes may respond to magnesium; seizures should be managed with benzodiazepines or barbiturates; extrapyramidal reactions should be managed with diphenhydramine or benztropine.
 Enhancement of elimination: Multiple dosing of charcoal may not be effective; not dialyzable

Test Interactions False-positives for phenylketonuria, urinary amylase, uroporphyrins, urobilinogen

Drug Interactions Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Alpha-/Beta- agonists: May enhance the arrhythmogenic effect of phenothiazines.

Analgesics (narcotic): Phenothiazines may enhance the hypotensive effect of narcotic analgesics.

Antacids: May decrease the absorption of phenothiazines; monitor.

Antidepressants (serotonin reuptake inhibitors/antagonist): Concurrent use may produce increased hypotension.

Anticholinergics: May inhibit the therapeutic response to phenothiazines and excess anticholinergic effects may occur; includes benztropine, trihexyphenidyl, biperiden, and drugs with significant anticholinergic activity (TCAs, antihistamines, disopyramide)

Antihistamines: May enhance the arrhythmogenic effect of phenothiazines.

Antimalarial agents: May increase phenothiazine concentrations.

Antiparkinson's Agents (dopamine agonists such as levodopa): Phenothiazines may inhibit the antiparkinsonian effect of levodopa; avoid this combination.

Attagulgite: May decrease absorption of phenothiazines.

Beta blockers: Serum concentrations of phenothiazines may be increased; phenothiazines may increase hypotensive effects of beta blockers.

CNS depressants: Sedative effects may be additive with phenothiazines; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol and other sedative agents.

Epinephrine: Chlorpromazine (and possibly other low potency antipsychotics) may diminish the pressor effects of epinephrine.

False Neurotransmitters (guanadrel, methyldopa): Antihypertensive effects may be inhibited by phenothiazines.

Lithium: Phenothiazines may produce neurotoxicity with lithium; this is a rare effect Phenytoin: Concurrent use may increase CNS depression.

Polypeptide antibiotics: Rare cases of respiratory paralysis have been reported with concurrent use of phenothiazines.

Pramlintide: May enhance the anticholinergic effects of phenothiazines.

QT_c-prolonging agents: Effects on QT_c interval may be additive with phenothiazines, increasing the risk of malignant arrhythmias; includes type Ia antiarrhythmics, TCAs, and some quinolone antibiotics (sparfloxacin, moxifloxacin, and gatifloxacin).

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Lactation Excretion in breast milk unknown/use caution

Specific References

Walker M and Samii A, "Chronic Severe Dystonia After Single Exposure to Antiemetics," *Am J Emerg Med*, 2006, 24(1):125-7.

Proguanil

CAS Number 500-92-5; 637-32-1

Use Malarial prophylaxis (*Plasmodium falciparum* and *vivax*)

Mechanism of Action Proguanil's active metabolite (cycloguanil) inhibits nucleic acid synthesis by antagonizing *Plasmodium* dihydrofolate reductase; active against pre-erythrocytic forms with some sporontocidal activity

Adverse Reactions

Central nervous system: Dizziness
 Dermatologic: Urticaria, alopecia (reversible), exanthema, photosensitivity
 Gastrointestinal: Anorexia, vomiting, diarrhea, aphthous ulceration
 Hematologic: Pancytopenia, megaloblastic anemia, thrombocytopenia, aplastic anemia (1:10,000 patient years), neutropenia
 Miscellaneous: Thirst

Signs and Symptoms of Overdose Abdominal pain, hematuria (due to renal irritation), vomiting

Toxicodynamics/Kinetics

Absorption: 2-4 hours
 Distribution: V_d: 30.7 L/kg
 Protein binding: 75%

Metabolism: Hepatic metabolism to an active metabolite cycloguanil
 Half-life: Proguanil: 18-40 hours; Cycloguanil: 11.7 hours
 Elimination: Primary: Renal tubular secretion (renal clearance ~0.3 L/hour/kg); feces (10%)

Dosage Malaria prophylaxis may be used with chloroquine:

Adults: 200 mg/day beginning at least 1 day before entering a malarious region and for 6 weeks after leaving the area; lower dosage in renal failure

Children:

< 1 year: 25 mg once daily
 1-4 years: 50 mg once daily
 5-8 years: 100 mg once daily
 9-14 years: 150 mg once daily
 > 14 years: 200 mg once daily

Monitoring Parameters CBC

Reference Range Maximum proguanil and cycloguanil plasma levels after a 200 mg dose: ~170 ng/mL and 41 ng/mL, respectively

Overdosage/Treatment

Decontamination (for acute ingestions >5 mg/kg): Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal
 Supportive therapy: Folate can be given to treat megaloblastic anemia
 Enhanced elimination: Hemodialysis is not effective

Pregnancy Implications No adverse effects on fetus; documented folate supplements may need to be given

Promethazine

Related Information

• Therapeutic Drugs Associated with Hallucinations

CAS Number 58-33-3; 60-87-7

U.S. Brand Names Phenadoz™; Phenergan®

Synonyms Promethazine Hydrochloride

Impairment Potential Yes

Use Symptomatic treatment of various allergic conditions; antiemetic; motion sickness; sedative; postoperative pain (adjunctive therapy); anesthetic (adjunctive therapy); anaphylactic reactions (adjunctive therapy)

Mechanism of Action Blocks postsynaptic mesolimbic dopaminergic receptors in the brain; exhibits a strong alpha-adrenergic blocking effect and depresses the release of hypothalamic and hypophyseal hormones; competes with histamine for the H₁-receptor; reduces stimuli to the brainstem reticular system

Adverse Reactions

Cardiovascular: Bradycardia, hypertension, postural hypotension, tachycardia, nonspecific QT changes
 Central nervous system: Catatonic states, confusion, disorientation, dizziness, drowsiness, dystonias, euphoria, excitation, extrapyramidal symptoms, fatigue, hallucinations, hysteria, insomnia, akathisia, pseudoparkinsonism, tardive dyskinesia, nervousness, neuroleptic malignant syndrome, sedation, seizures, somnolence
 Dermatologic: Angioneurotic edema, photosensitivity, dermatitis, skin pigmentation (slate gray), urticaria
 Endocrine & metabolic: Lactation, breast engorgement, amenorrhea, gynecomastia, hyper- or hypoglycemia
 Gastrointestinal: Xerostomia, constipation, nausea, vomiting
 Genitourinary: Urinary retention, ejaculatory disorder, impotence
 Hematologic: Agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, aplastic anemia, thrombocytopenia, thrombocytopenic purpura
 Hepatic: Jaundice
 Neuromuscular & skeletal: Incoordination, tremors
 Ocular: Blurred vision, corneal and lenticular changes, diplopia, epithelial keratopathy, pigmentary retinopathy
 Otic: Tinnitus
 Respiratory: Apnea, respiratory depression

Signs and Symptoms of Overdose Agranulocytosis, anticholinergic hallucinations, anticholinergic toxidrome, CNS depression, coma, dry mouth, eclampsia, fever, flushing, granulocytopenia, hyperreflexia, hyperthermia, impotence, leukemoid reaction, leukopenia, mydriasis, myoclonus, neutropenia, seizures, tachycardia, urine discoloration (pink; red; red-brown), vision color changes (brown tinge)

Pharmacodynamics/Kinetics

Onset of action: I.M.: ~20 minutes; I.V.: 3-5 minutes
 Peak effect: C_{max}: 9.04 ng/mL (suppository); 19.3 ng/mL (syrup)
 Duration: 2-6 hours
 Absorption:
 I.M.: Bioavailability may be greater than with oral or rectal administration
 Oral: Rapid and complete; large first pass effect limits systemic bioavailability
 Distribution: V_d: 171 L
 Protein binding: 93%
 Metabolism: Hepatic; primarily oxidation; forms metabolites
 Half-life elimination: 9-16 hours

PROMETHAZINE

Time to maximum serum concentration: 4.4 hours (syrup); 6.7-8.6 hours (suppositories)

Excretion: Primarily urine and feces (as inactive metabolites)

Dosage

Children ≥ 2 years:

Allergic conditions: Oral, rectal: 0.1 mg/kg/dose (maximum: 12.5 mg) every 6 hours during the day and 0.5 mg/kg/dose (maximum: 25 mg) at bedtime as needed

Antiemetic: Oral, I.M., I.V., rectal: 0.25-1 mg/kg 4-6 times/day as needed (maximum: 25 mg/dose)

Motion sickness: Oral, rectal: 0.5 mg/kg/dose 30 minutes to 1 hour before departure, then every 12 hours as needed (maximum dose: 25 mg twice daily)

Sedation: Oral, I.M., I.V., rectal: 0.5-1 mg/kg/dose every 6 hours as needed (maximum: 50 mg/dose)

Adults:

Allergic conditions (including allergic reactions to blood or plasma):

Oral, rectal: 12.5 mg 3 times/day and 25 mg at bedtime

I.M., I.V.: 25 mg, may repeat in 2 hours when necessary; switch to oral route as soon as feasible

Antiemetic: Oral, I.M., I.V., rectal: 12.5-25 mg every 4-6 hours as needed

Motion sickness: Oral, rectal: 25 mg 30-60 minutes before departure, then every 12 hours as needed

Sedation: Oral, I.M., I.V., rectal: 12.5-50 mg/dose

Monitoring Parameters

Relief of symptoms, mental status

Administration Formulations available for oral, rectal, I.M./I.V. administration; not for SubQ or intra-arterial administration. Administer I.M. into deep muscle (preferred route of administration). Due to the possibility of orthostatic hypotension, I.V. administration is **not** the preferred route. Solution for injection may be diluted in 25-100 mL NS or D₅W (maximum concentration of 25 mg/mL) and infused over 15-30 minutes at a rate ≤ 25 mg/minute.

Contraindications Hypersensitivity to promethazine or any component of the formulation (cross-reactivity between phenothiazines may occur); coma; treatment of lower respiratory tract symptoms, including asthma; children < 2 years of age

Warnings

[U.S. Boxed Warning]: Respiratory fatalities have been reported in children < 2 years of age. In children ≥ 2 years, use the lowest possible dose; other drugs with respiratory depressant effects should be avoided. Not for SubQ or intra-arterial administration. Injection may contain sodium metabisulfite (may cause allergic reaction). I.M. is the preferred route of parenteral administration. I.V. use has been associated with severe tissue damage; discontinue immediately if burning or pain occurs with administration. May be sedating; use with caution in disorders where CNS depression is a feature. May impair physical or mental abilities; patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in Parkinson's disease; hemodynamic instability; bone marrow suppression; subcortical brain damage; and in severe cardiac, hepatic, renal, or respiratory disease. Avoid use in Reye's syndrome. May lower seizure threshold; use caution in persons with seizure disorders or in persons using narcotics or local anesthetics which may also affect seizure threshold. May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May alter cardiac conduction (life-threatening arrhythmias have occurred with therapeutic doses of phenothiazines). May cause orthostatic hypotension; use with caution in patients at risk of hypotension or where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease).

Phenothiazines may cause anticholinergic effects (constipation, xerostomia, blurred vision, urinary retention); therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia. May be associated with neuroleptic malignant syndrome (NMS).

Dosage Forms

[DSC] = Discontinued product

Injection, solution, as hydrochloride: 25 mg/mL (1 mL); 50 mg/mL (1 mL)
Phenergan[®]: 25 mg/mL (1 mL); 50 mg/mL (1 mL) [contains sodium metabisulfite]

Suppository, rectal, as hydrochloride: 12.5 mg, 25 mg, 50 mg

Phenadoz[™]: 12.5 mg, 25 mg

Phenergan[®]: 25 mg, 50 mg [DSC]

Promethegan[™]: 12.5 mg, 25 mg, 50 mg

Syrup, as hydrochloride: 6.25 mg/5 mL (120 mL, 480 mL) [contains alcohol]

Tablet, as hydrochloride: 12.5 mg, 25 mg, 50 mg

Phenergan[®]: 25 mg [DSC]

Reference Range

Therapeutic: 11-23 ng/mL

Toxic: > 48 ng/mL

Fatal: 156 ng/mL (postmortem)

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam, diazepam, phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 gram), while other antiarrhythmics can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50 mg I.M. or I.V. slow push followed by a maintenance dose for 48-72 hours. When these reactions are unresponsive to diphenhydramine, benztropine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes.

Enhancement of elimination: Multiple dosing of activated charcoal may be helpful; not dialyzable (0% to 5%)

Test Interactions Alters the flare response in intradermal allergen tests; HCG-based pregnancy tests may result in false-negatives or false-positives; increased serum glucose may be seen with glucose tolerance tests

Drug Interactions

Substrate (major) of CYP2B6, 2D6; **Inhibits** CYP2D6 (weak)

Aluminum salts: May decrease the absorption of phenothiazines; monitor
Amphetamines: Efficacy may be diminished by antipsychotics; in addition, amphetamines may increase psychotic symptoms; avoid concurrent use

Anticholinergics: May inhibit the therapeutic response to phenothiazines and excess anticholinergic effects may occur; includes benztropine, trihexyphenidyl, biperiden, and drugs with significant anticholinergic activity (TCAs, antihistamines, disopyramide)

Antihypertensives: Concurrent use of phenothiazines with an antihypertensive may produce additive hypotensive effects (particularly orthostasis)

Bromocriptine: Phenothiazines inhibit the ability of bromocriptine to lower serum prolactin concentrations

CNS depressants: Sedative effects may be additive with phenothiazines; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents

CYP2B6 inducers: May decrease the levels/effects of promethazine. Example inducers include carbamazepine, nevirapine, phenobarbital, phenytoin, and rifampin.

CYP2B6 inhibitors: May increase the levels/effects of promethazine. Example inhibitors include desipramine, paroxetine, and sertraline.

CYP2D6 inhibitors: May increase the levels/effects of promethazine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Epinephrine: Promethazine may diminish the pressor effects of epinephrine.

Guanethidine and guanadrel: Antihypertensive effects may be inhibited by phenothiazines

Levodopa: Phenothiazines may inhibit the antiparkinsonian effect of levodopa; avoid this combination

Lithium: Phenothiazines may produce neurotoxicity with lithium; this is a rare effect

Propranolol: Serum concentrations of phenothiazines may be increased; propranolol also increases phenothiazine concentrations

Polypeptide antibiotics: Rare cases of respiratory paralysis have been reported with concurrent use of phenothiazines

QT_c-prolonging agents: Effects on QT_c interval may be additive with phenothiazines, increasing the risk of malignant arrhythmias; includes type Ia antiarrhythmics, TCAs, and some quinolone antibiotics (sparfloxacin, moxifloxacin, and gatifloxacin)

Sulfadoxine-pyrimethamine: May increase phenothiazine concentrations
Tricyclic antidepressants: Concurrent use may produce increased toxicity or altered therapeutic response

Trazodone: Phenothiazines and trazodone may produce additive hypotensive effects

Valproic acid: Serum levels may be increased by phenothiazines

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta; possible respiratory depression if drug is administered near time of delivery; behavioral changes, EEG alterations, impaired platelet aggregation reported with use during labor.

Lactation Excretion in breast milk unknown/not recommended

Propafenone

CAS Number 34183-22-7; 54063-53-5

U.S. Brand Names Rythmol® SR; Rythmol®

Synonyms Propafenone Hydrochloride

Use

Treatment of life-threatening ventricular arrhythmias
Rythmol® SR: Maintenance of normal sinus rhythm in patients with symptomatic atrial fibrillation

Unlabeled/Investigational Use Supraventricular tachycardias, including those patients with Wolff-Parkinson-White syndrome

Mechanism of Action Type 1C antiarrhythmic agent with sodium channel and weak beta-blocking activity

Adverse Reactions

Cardiovascular: Sinus arrest, bradycardia, heart block, hypotension, bundle branch block, fibrillation (atrial), flutter (atrial), sinus bradycardia, palpitations, sinus tachycardia, arrhythmias (ventricular)

Central nervous system: **Dizziness, drowsiness,** convulsions, psychosis, transient global amnesia, ataxia

Gastrointestinal: **Xerostomia,** bitter taste, constipation

Genitourinary: Impotence

Hepatic: Elevated liver function tests, cholestatic jaundice, cholestatic hepatitis

Neuromuscular & skeletal: Neuropathy (peripheral), clonus, myoclonus

Respiratory: Wheezing

Signs and Symptoms of Overdose AV block (third degree), blood dyscrasias, dizziness, granulocytopenia, hypotension, impotence, metallic taste, myoclonus, QRS prolongation, QT prolongation, seizures, tachycardia

Admission Criteria/Prognosis Admit any patient who is symptomatic or has ECG changes 6 hours postingestion

Pharmacodynamics/Kinetics

Absorption: Well absorbed

Metabolism: Hepatic; two genetically determined metabolism groups exist: fast or slow metabolizers; 10% of Caucasians are slow metabolizers; exhibits nonlinear pharmacokinetics; when dose is increased from 300-900 mg/day, serum concentrations increase tenfold; this nonlinearity is thought to be due to saturable first-pass effect

Bioavailability: 150 mg: 3.4%; 300 mg: 10.6%

Half-life elimination: Single dose (100-300 mg): 2-8 hours; Chronic dosing: 10-32 hours

Time to peak: 150 mg dose: 2 hours, 300 mg dose: 3 hours

Dosage Oral: Adults: **Note:** Patients who exhibit significant widening of QRS complex or second- or third-degree AV block may need dose reduction.

Immediate release tablet: Initial: 150 mg every 8 hours, increase at 3- to 4-day intervals up to 300 mg every 8 hours.

Extended release capsule: Initial: 225 mg every 12 hours; dosage increase may be made at a minimum of 5-day intervals; may increase to 325 mg every 12 hours; if further increase is necessary, may increase to 425 mg every 12 hours

Dosing adjustment in hepatic impairment: Reduction is necessary; however, specific guidelines are not available.

Monitoring Parameters ECG, blood pressure, pulse (particularly at initiation of therapy)

Administration Capsules should be swallowed whole; do not crush or chew.

Contraindications Hypersensitivity to propafenone or any component of the formulation; sinoatrial, AV, and intraventricular disorders of impulse generation and/or conduction (except in patients with a functioning artificial pacemaker); sinus bradycardia; cardiogenic shock; uncompensated cardiac failure; hypotension; bronchospastic disorders; uncorrected electrolyte abnormalities; concurrent use of ritonavir (see Drug Interactions)

Warnings

Monitor for proarrhythmic events. May prolong QT_c interval; use caution with other QT_c-prolonging drugs. **[U.S. Boxed Warning]: In the Cardiac Arrhythmia Suppression Trial (CAST), recent (> 6 days but < 2 years ago) myocardial infarction patients with asymptomatic, nonlife-threatening ventricular arrhythmias did not benefit and may have been harmed by attempts to suppress the arrhythmia with flecainide or encainide. An increased mortality or nonfatal cardiac arrest rate (7.7%) was seen in the active treatment group compared with patients in the placebo group (3%). The applicability of the CAST results to other populations is unknown. Antiarrhythmic agents should be reserved for patients with life-threatening ventricular arrhythmias.** Can cause or unmask a variety of conduction disturbances. May alter pacing and sensing thresholds of artificial pacemakers. Patients

with bronchospastic disease should generally not receive this drug. Monitor for worsening CHF if patient has underlying condition. Administer cautiously in significant hepatic dysfunction.

Dosage Forms Capsule, extended release, as hydrochloride (Rythmol® SR): 225 mg, 325 mg, 425 mg [contains soy lecithin]

Tablet, as hydrochloride (Rythmol®): 150 mg, 225 mg, 300 mg

Reference Range

Therapeutic: 500-2000 ng/mL

Serum propafenone level of 4839 ng/mL 5.5 hours postingestion is associated with severe toxicity; levels > 7000 ng/mL are fatal

Overdosage/Treatment

Decontamination: Ipecac (within 30 minutes)/lavage (within 4 hours)/activated charcoal

Supportive therapy: Avoid flecainide, encainide; pacemaker may be useful; sodium bicarbonate may be useful for AV conduction disturbances or QRS prolongation along with reversing hypotension; atropine or isoproterenol for bradycardia; diazepam or lorazepam are useful to treat seizures

Enhanced elimination: Hemodialysis is not useful

Test Interactions May cause elevated antinuclear antibody titer

Drug Interactions

Substrate of CYP1A2 (minor), 2D6 (major), 3A4 (minor); **Inhibits** CYP1A2 (weak), 2D6 (weak)

Cimetidine: May increase propafenone levels.

CYP2D6 inhibitors: May increase the levels/effects of propafenone.

Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Digoxin: Propafenone may increase digoxin levels; monitor for toxicity.

Metoprolol: Propafenone may increase metoprolol levels.

Phenobarbital: May decrease propafenone levels.

Propranolol: Propafenone may increase propranolol levels.

QT_c-prolonging agents: Effects may be additive with propafenone. Use caution with Class Ia and Class III antiarrhythmics, erythromycin, cisapride, antipsychotics, and cyclic antidepressants.

Quinidine: May increase propafenone levels.

Rifampin: May decrease propafenone levels.

Ritonavir: May increase propafenone levels; concurrent use is contraindicated.

Theophylline: Propafenone may increase theophylline levels.

Warfarin: Propafenone may increase warfarin levels/effects. Monitor INR closely.

Pregnancy Risk Factor C

Pregnancy Implications No adequate and well-controlled studies in pregnant women; use only if potential benefit to the mother justifies potential risk to the fetus.

Lactation Enters breast milk/use caution

Additional Information Sudden death noted in young postoperative heart patients either on propafenone or withdrawn from it

Propofol

CAS Number 2078-24-8

U.S. Brand Names Diprivan®

Use Induction of anesthesia for inpatient or outpatient surgery in patients ≥ 3 years of age; maintenance of anesthesia for inpatient or outpatient surgery in patients > 2 months of age; in adults, for the induction and maintenance of monitored anesthesia care sedation during diagnostic procedures; may be used for patients > 18 years of age who are intubated and mechanically ventilated) as an alternative to benzodiazepines for the treatment of agitation in the intensive care unit

Unlabeled/Investigational Use Postoperative antiemetic; refractory delirium tremens (case reports); conscious sedation

Mechanism of Action Propofol is a hindered phenolic (2,6-di-isopropylphenol) compound with intravenous general anesthetic properties. The drug is unrelated to any of the currently used barbiturate, opioid, benzodiazepine, arylcyclohexylamine, or imidazole intravenous anesthetic agents. It is a gamma-aminobutyric acid (GABA_A) neurotransmitter complex agonist, possibly a glycine (neurotransmitter) antagonist.

Adverse Reactions

Cardiovascular: **Hypotension,** hypertension, arrhythmia, bradycardia, decreased cardiac output, tachycardia, bigeminy, ECG abnormal, flushing, premature atrial contractions, premature ventricular contractions, somnolence, asystole, cardiac arrest, thrombosis, syncope

Central nervous system: **Movement,** agitation, anticholinergic syndrome, dizziness, delirium, fever, somnolence

Dermatologic: Pruritus, rash
 Endocrine & metabolic: Hyperlipidemia, hypomagnesemia, increased serum triglycerides
 Gastrointestinal: Hypersalivation, nausea, postoperative pancreatitis
 Genitourinary: Cloudy urine, urine discoloration (green)
 Hematologic: Leukocytosis, hemorrhage
 Local: **Injection site burning, stinging, or pain;** swelling, blisters and/or tissue necrosis following accidental extravasation
 Neuromuscular & skeletal: Dystonia, extremity pain, hypertonia, myalgia, paresthesia, perioperative myoclonia (rarely including convulsions and opisthotonos), rhabdomyolysis
 Ocular: Amblyopia, vision abnormality

Respiratory: **Apnea, lasting 30-60 seconds; apnea, lasting > 60 seconds,** respiratory acidosis during weaning, chills, cough, hypoxia, laryngospasm, lung function decreased, wheezing, pulmonary edema
 Miscellaneous: Anaphylaxis, anaphylactoid reaction, perinatal disorder, phlebitis, postoperative unconsciousness with or without increase in muscle tone

Signs and Symptoms of Overdose Apnea, AV block, bradycardia, cardiovascular collapse, cough, hair discoloration (green), hiccups, hypotension, metabolic acidosis, myalgia, seizures

Pharmacodynamics/Kinetics

Onset of action: Anesthetic: Bolus infusion (dose dependent): 9-51 seconds (average 30 seconds)
 Duration (dose and rate dependent): 3-10 minutes
 Distribution: V_d : 2-10 L/kg; highly lipophilic
 Protein binding: 97% to 99%
 Metabolism: Hepatic to water-soluble sulfate and glucuronide conjugates
 Half-life elimination: Biphasic: Initial: 40 minutes; Terminal: 4-7 hours (up to 1-3 days)
 Excretion: Urine (~88% as metabolites, 40% as glucuronide metabolite); feces (<2%)
 Clearance: 20-30 mL/kg/minute; total body clearance exceeds liver blood flow

Dosage Dosage must be individualized based on total body weight and titrated to the desired clinical effect; wait at least 3-5 minutes between dosage adjustments to clinically assess drug effects; smaller doses are required when used with narcotics; the following are general dosing guidelines:

General anesthesia:

Induction: I.V.:

Children 3-16 years, ASA I or II: 2.5-3.5 mg/kg over 20-30 seconds; use a lower dose for children ASA III or IV

Adults, ASA I or II, <55 years: 2-2.5 mg/kg (~40 mg every 10 seconds until onset of induction)

Elderly, debilitated, hypovolemic, or ASA III or IV: 1-1.5 mg/kg (~20 mg every 10 seconds until onset of induction)

Cardiac anesthesia: 0.5-1.5 mg/kg (~20 mg every 10 seconds until onset of induction)

Neurosurgical patients: 1-2 mg/kg (~20 mg every 10 seconds until onset of induction)

Maintenance: I.V. infusion:

Children 2 months to 16 years, ASA I or II: Initial: 200-300 mcg/kg/minute; decrease dose after 30 minutes if clinical signs of light anesthesia are absent; usual infusion rate: 125-150 mcg/kg/minute (range: 125-300 mcg/kg/minute; 7.5-18 mg/kg/hour); children ≤5 years may require larger infusion rates compared to older children

Adults, ASA I or II, <55 years: Initial: 150-200 mcg/kg/minute for 10-15 minutes; decrease by 30% to 50% during first 30 minutes of maintenance; usual infusion rate: 100-200 mcg/kg/minute (6-12 mg/kg/hour)

Elderly, debilitated, hypovolemic, ASA III or IV: 50-100 mcg/kg/minute (3-6 mg/kg/hour)

Cardiac anesthesia:

Low-dose propofol with primary opioid: 50-100 mcg/kg/minute (see manufacturer's labeling)

Primary propofol with secondary opioid: 100-150 mcg/kg/minute

Neurosurgical patients: 100-200 mcg/kg/minute (6-12 mg/kg/hour)

Maintenance: I.V. intermittent bolus: Adults, ASA I or II, <55 years: 20-50 mg increments as needed

Monitored anesthesia care sedation:

Initiation:

Adults, ASA I or II, <55 years: Slow I.V. infusion: 100-150 mcg/kg/minute for 3-5 minutes or slow injection: 0.5 mg/kg over 3-5 minutes

Elderly, debilitated, neurosurgical, or ASA III or IV patients: Use similar doses to healthy adults; avoid rapid I.V. boluses

Maintenance:

Adults, ASA I or II, <55 years: I.V. infusion using variable rates (preferred over intermittent boluses): 25-75 mcg/kg/minute or incremental bolus doses: 10 mg or 20 mg

Elderly, debilitated, neurosurgical, or ASA III or IV patients: Use 80% of healthy adult dose; **do not** use rapid bolus doses (single or repeated)

ICU sedation in intubated mechanically ventilated patients: Avoid rapid bolus injection; individualize dose and titrate to response

Adults: Continuous infusion: Initial: 0.3 mg/kg/hour; increase by 0.3-0.6 mg/kg/hour every 5-10 minutes until desired sedation level is achieved; usual maintenance: 0.3-3 mg/kg/hour or higher; reduce dose by 80% in elderly, debilitated, and ASA III or IV patients; reduce dose after adequate sedation established and adjust to response (ie, evaluate frequently to use minimum dose for sedation)

Stability Do not use if there is evidence of separation of phases of emulsion; discard any unused portions at end of the surgical procedure

Monitoring Parameters Cardiac monitor, blood pressure monitor, and ventilator required; serum triglyceride levels should be obtained prior to initiation of therapy (ICU setting) and every 3-7 days thereafter; daily sedation levels using standardized scale

Vital signs: Blood pressure, heart rate, cardiac output, pulmonary capillary wedge pressure should be monitored

Monitor zinc levels in patients predisposed to deficiency (burns, diarrhea, major sepsis). In patients at risk for renal impairment, urinalysis and urine sediment should be monitored prior to treatment and every other day of sedation.

Administration To reduce pain associated with injection, use larger veins of forearm or antecubital fossa; lidocaine I.V. (1 mL of a 1% solution) may also be used prior to administration. Do not use filter with <5 micron for administration. Soybean fat emulsion is used as a vehicle for propofol. Strict aseptic technique must be maintained in handling although a preservative has been added. Do not administer through the same I.V. catheter with blood or plasma. The American College of Critical Care Medicine recommends the use of a central vein for administration in an ICU setting.

Contraindications Hypersensitivity to propofol or any component of the formulation; propofol is also contraindicated when general anesthesia or sedation is contraindicated

Warnings

Use requires careful patient monitoring, should only be used by experienced personnel who are not actively engaged in the procedure or surgery. If used in a nonintubated and/or nonmechanically-ventilated patient, qualified personnel and appropriate equipment for rapid institution of respiratory and/or cardiovascular support must be immediately available.

Use a slower rate of induction and avoid rapid bolus administration in the elderly, debilitated, or ASA III/IV patients. Use with caution in patients who are hypotensive, hypovolemic, hemodynamically unstable, or have abnormally low vascular tone (eg, sepsis). Use caution in patients with severe cardiac disease (ejection fraction <50%) or respiratory disease; may have more profound adverse cardiovascular responses to propofol. Use caution in patients with a history of epilepsy or seizures; risk of seizure during recovery phase. Use caution in patients with increased intracranial pressure or impaired cerebral circulation - substantial decreases in mean arterial pressure and subsequent decreases in cerebral perfusion pressure may occur.

Use caution in patients with hyperlipidemia as evidenced by increased serum triglyceride levels or serum turbidity. Transient local pain may occur during I.V. injection; perioperative myoclonia has occurred. Not recommended for use in obstetrics, including cesarean section deliveries. Safety and efficacy in pediatric intensive care unit patients have not been established. Several deaths associated with severe metabolic acidosis have been reported in pediatric ICU patients on long-term propofol infusion. Concurrent use of fentanyl and propofol in pediatric patients may result in bradycardia.

Abrupt discontinuation prior to weaning or daily wake up assessments should be avoided. Abrupt discontinuation can result in rapid awakening, anxiety, agitation, and resistance to mechanical ventilation; titrate the infusion rate so the patient awakens slowly. Propofol does not have analgesic properties; pain should be treated with analgesic agents, propofol must be titrated separately from the analgesic agent. Propofol emulsion contains soybean oil, egg phosphatide, and glycerol; some formulations also contain sulfites. Some products may contain benzyl alcohol; benzyl alcohol has been associated with the "gasping syndrome" in neonates and low-birth-weight infants.

Dosage Forms Injection, emulsion: 10 mg/mL (20 mL, 50 mL, 100 mL) [products may contain egg lecithin, and soybean oil; may contain benzyl alcohol, sodium benzoate, or sodium metabisulfite]

Diprivan®: 10 mg/mL (20 mL, 50 mL, 100 mL) [contains egg lecithin, soybean oil, and disodium edetate]

Reference Range Propofol blood levels from 1.6-6.4 mcg/mL associated with anesthetic action; levels from 1.0-2.2 mcg/mL associated with regaining consciousness

Overdosage/Treatment Supportive therapy: Hypotension usually responds to I.V. fluids and/or Trendelenburg positioning; parenteral inotropes may be needed. Amiodarone can be used to treat propofol-induced ventricular tachycardia.

Test Interactions ↓ cholesterol (S)

Drug Interactions

Substrate of CYP1A2 (minor), 2A6 (minor), 2B6 (major), 2C9 (major), 2C19 (minor), 2D6 (minor), 2E1 (minor), 3A4 (minor); **Inhibits** CYP1A2

(moderate), 2C9 (weak), 2C19 (moderate), 2D6 (weak), 2E1 (weak), 3A4 (strong)

CNS depressants: Additive CNS depression and respiratory depression may necessitate dosage reduction when used with anesthetics, benzodiazepines, opiates, ethanol, phenothiazines.

CYP1A2 substrates: Propofol may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, fluvoxamine, mexiletine, mirtazapine, ropinirole, theophylline, and trifluoperazine.

CYP2B6 inhibitors: May increase the levels/effects of propofol. Example inhibitors include desipramine, paroxetine, and sertraline.

CYP2C9 Inhibitors may increase the levels/effects of propofol. Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nicardipine, NSAIDs, sulfonamides and tolbutamide.

CYP2C19 substrates: Propofol may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

CYP3A4 substrates: Propofol may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozone are generally contraindicated with strong CYP3A4 inhibitors.

Narcotics: Concomitant use may lead to increased sedative or anesthetic effects of propofol, more pronounced decreases in systolic, diastolic, and mean arterial pressures and cardiac output. Lower doses of propofol may be needed. In addition, fentanyl may cause serious bradycardia when used with propofol in pediatric patients.

Vecuronium: Propofol may potentiate the neuromuscular blockade of vecuronium.

Pregnancy Risk Factor B

Pregnancy Implications Propofol is not recommended for obstetrics, including cesarean section deliveries. Propofol crosses the placenta and may be associated with neonatal depression.

Lactation Enters breast milk/not recommended

Nursing Implications Changes urine color to green with prolonged use

Additional Information On March 26, 2001, a specific warning was issued concerning the use of propofol in pediatric ICU patients. In the opinion of the FDA, a clinical trial evaluating the use of propofol as a sedative agent in this population was associated with a higher number of deaths as compared to standard sedative agents. The warning reminded healthcare professionals that propofol is not approved in the U.S. for sedation in pediatric ICU patients. A new clinical trial is planned to evaluate differences in safety within this population.

Central nervous system: **Dizziness, lightheadedness, sedation, paradoxical excitation and insomnia**, headache, **fatigue**, psychosis, **drowsiness**, agitation, nervousness, restlessness, malaise, confusion, CNS depression, auditory hallucinations, increased intracranial pressure

Dermatologic: Skin rash, hives, pruritus, exanthem

Gastrointestinal: GI upset, **nausea, vomiting, constipation**, anorexia, stomach cramps, xerostomia, paralytic ileus, biliary tract spasm

Genitourinary: Ureteral spasm, decreased urination

Hepatic: Elevated liver enzymes

Neuromuscular & skeletal: Hyperreflexia, **weakness**

Respiratory: Dyspnea, apnea

Miscellaneous: Psychologic and physical dependence, **histamine release**

Signs and Symptoms of Overdose Cardiac arrhythmia (ventricular), coma, cyanosis, deafness, dementia, diabetes insipidus, disorientation, dizziness, hypernatremia, hyperreflexia, hyperthermia, hypothermia, impotence, insomnia, jaundice, miosis, myoglobinuria, neutropenia, nodal tachycardia, nystagmus, primary atrioventricular block, ptosis, pulmonary edema, rhabdomyolysis, seizures, thrombocytopenia, tremors, vomiting. Death can occur within 1 hour.

Admission Criteria/Prognosis Admit any adult ingestion > 1 g or > 500 mg if taken in conjunction with another CNS depressive agent

Pharmacodynamics/Kinetics

Onset of effect: Oral: Within 30-60 minutes

Duration: 4-6 hours

Distribution: V_d : 12-26 L/kg

Protein binding: 78%

Metabolism: First-pass effect; metabolized in the liver to an active metabolite (norpropoxyphene) and inactive metabolites

Bioavailability: Oral: 30% to 70%

Half-life:

Adults: Parent drug: 8-24 hours (mean: ~15 hours); Norpropoxyphene: 34 hours;

Elderly: Parent drug: 37 hours; Norpropoxyphene: 42 hours

Elimination: 20% to 25% excreted in urine

Dosage Oral:

Children: Doses for children are not well established; doses of the hydrochloride of 2-3 mg/kg/d divided every 6 hours have been used

Adults:

Hydrochloride: 65 mg every 3-4 hours as needed for pain; maximum: 390 mg/day

Napsylate: 100 mg every 4 hours as needed for pain; maximum: 600 mg/day

Elderly: Refer to Adults dosing; consider increasing dosing interval

Dosing adjustment in renal impairment: Serum concentrations of propoxyphene may be increased or elimination may be delayed. Avoid use in $Cl_{cr} < 10$ mL/minute. Specific dosing recommendations not available for less severe impairment.

Not dialyzable (0% to 5%)

Dosing adjustment in hepatic impairment: Serum concentrations of propoxyphene may be increased or elimination may be delayed; specific dosing recommendations not available.

Monitoring Parameters Pain relief, respiratory and mental status, blood pressure

Administration Should be administered with glass of water on an empty stomach. Food may decrease rate of absorption, but may slightly increase bioavailability.

Contraindications Hypersensitivity to propoxyphene or any component of the formulation

Warnings

[U.S. Boxed Warning]: When given in excessive doses, either alone or in combination with other CNS depressants (including alcohol), propoxyphene is a major cause of drug-related deaths; recommended dosage must not be exceeded and alcohol intake should be limited. Avoid use in severely depressed or suicidal patients. Should not be prescribed in patients who are addiction prone or suicidal. Use caution in patients taking CNS depressant medications or antidepressants, and in patients who use alcohol in excess.

Use caution in patients dependent on opiates, substitution may result in acute opiate withdrawal symptoms. Tolerance or drug dependence may result from extended use. Propoxyphene should be used with caution in patients with renal or hepatic dysfunction or in the elderly; consider dosing adjustment.

Dosage Forms Capsule, as hydrochloride (Darvon®): 65 mg

Tablet, as napsylate (Darvon-N®): 100 mg

Reference Range

Therapeutic: 0.1-0.4 mcg/mL, ranges published vary and may not correlate with clinical effect

Toxic: > 0.5 mcg/mL (SI: > 1.5 µmol/L)

Fatal: > 1 mcg/mL (SI: 2.9 µmol/L)

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur

Propoxyphene

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 1639-60-7; 469-62-5

U.S. Brand Names Darvon-N®; Darvon®

Synonyms Dextropropoxyphene; Propoxyphene Hydrochloride; Propoxyphene Napsylate

Impairment Potential Yes

Use Management of mild to moderate pain

Mechanism of Action Binds to opiate receptors in the CNS, causing inhibition of ascending pain pathways, altering the perception of and response to pain; produces generalized CNS depression

Adverse Reactions

Cardiovascular: **Hypotension**, sinus tachycardia

PROPRANOLOL

Hair Dextropropoxyphene and norpropoxyphene concentrations at concentrations of 26.4 ng/mg and 71 ng/mg of hair respectively are associated with overdose.

Overdosage/Treatment

Decontamination: Lavage/activated charcoal within 2 hours of ingestion
Supportive therapy: Naloxone hydrochloride for CNS depression, may also stop seizures and alleviate hypotension. Lidocaine or sodium bicarbonate can reverse QRS prolongation and ventricular arrhythmias.
Enhancement of elimination: Multiple dosing of activated charcoal is useful; not dialyzable (0% to 5%)

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Test Interactions False-positive methadone test; ↑ LFTs, ↓ glucose (S), 17-OHCS (U); diphenhydramine may cause a false-positive urinary assay for propoxyphene on the EMIT II immunoassay

Drug Interactions Inhibits CYP2C9 (weak), 2D6 (weak), 3A4 (weak)

Decreased effect with charcoal, cigarette smoking
Increased toxicity: CNS depressants may potentiate pharmacologic effects; propoxyphene may inhibit the metabolism and increase the serum concentrations of carbamazepine, phenobarbital, MAO inhibitors, tricyclic antidepressants, and warfarin

Pregnancy Risk Factor C/D (prolonged use)

Pregnancy Implications Withdrawal symptoms have been reported in the neonate following propoxyphene use during pregnancy. Teratogenic effects have also been noted in case reports. Opioid analgesics are considered pregnancy risk factor D if used for prolonged periods or in large doses near term.

Lactation Enters breast milk/use caution (AAP rates "compatible")

Propranolol

Related Information

- Selected Properties of Beta-Adrenergic Blocking Drugs
- Therapeutic Drugs Associated with Hallucinations

CAS Number 13013-17-7; 13071-11-9; 318-98-9; 3506-09-0; 4199-10-4; 5051-22-9; 525-66-6

U.S. Brand Names Inderal® LA; Inderal® InnoPran XL™; Propranolol Intenso™

Synonyms Propranolol Hydrochloride

Impairment Potential Yes

Use Management of hypertension; angina pectoris; pheochromocytoma; essential tremor; tetralogy of Fallot cyanotic spells; arrhythmias (such as atrial fibrillation and flutter, AV nodal re-entrant tachycardias, and catecholamine-induced arrhythmias); prevention of myocardial infarction; migraine headache; symptomatic treatment of hypertrophic subaortic stenosis

Unlabeled/Investigational Use Tremor due to Parkinson's disease; ethanol withdrawal; aggressive behavior; antipsychotic-induced akathisia; prevention of bleeding esophageal varices; anxiety; schizophrenia; acute panic; gastric bleeding in portal hypertension; thyrotoxicosis

Mechanism of Action Nonselective beta-adrenergic blocker (class II antiarrhythmic); competitively blocks response to beta₁- and beta₂-adrenergic stimulation which results in decreases in heart rate, myocardial contractility, blood pressure, and myocardial oxygen demand

Adverse Reactions

Cardiovascular: **Bradycardia**, hypotension, impaired myocardial contractility, congestive heart failure, worsening of AV conduction disturbances, abnormal T-wave inversion, claudication, syncope, myocardial depression, QRS prolongation, Raynaud's phenomenon
Central nervous system: **Mental depression**, lightheadedness, psychosis, insomnia, vivid dreams, drowsiness, auditory and visual hallucinations, agitation, paranoia
Dermatologic: Exfoliative dermatitis, erythema multiforme, acne, angioedema, toxic epidermal necrolysis, Stevens-Johnson syndrome, onycholysis, photosensitivity, pruritus, licheniform eruptions, exanthem, cutaneous vasculitis
Endocrine & metabolic: **Decreased sexual ability**, hypoglycemia, hyperglycemia
Gastrointestinal: Nausea, vomiting, diarrhea, abdominal pain, gastrointestinal distress, loss of taste perception, xerostomia
Genitourinary: Impotence, penile fibrosis, retroperitoneal fibrosis
Hematologic: Agranulocytosis, thrombocytopenic purpura

Neuromuscular & skeletal: Myotonia, myasthenia gravis (exacerbation), arthralgia, weakness, paresthesia

Ocular: Diplopia, phototoxic

Respiratory: Wheezing, rhinitis

Miscellaneous: Cold extremities, systemic lupus erythematosus

Signs and Symptoms of Overdose Agranulocytosis, alopecia, ataxia, AV block, cardiovascular collapse, cognitive dysfunction, dementia, depression, dyspnea, granulocytopenia, Graves' disease, heart/respiratory failure and wheezing, hyperglycemia, hyperreflexia, hyperthyroidism, hypoglycemia, hypothyroidism, impotence, leukopenia, mesenteric ischemia, myasthenia gravis (exacerbation or precipitation), neutropenia, paranoia, pemphigus, pulmonary edema, purpura, retroperitoneal fibrosis, rhinorrhea, seizures (> 1.5 g ingestion in adults), severe hypotension, sexual dysfunction, shock, sinus bradycardia, urticaria

Admission Criteria/Prognosis Admit an adult ingestion > 1 g, or QRS duration on ECG > 100 ms; patients asymptomatic 6 hours postingestion may be discharged

Pharmacodynamics/Kinetics

Onset of action: Beta-blockade: Oral: 1-2 hours

Duration: ~6 hours

Distribution: V_d: 3.9 L/kg in adults; crosses placenta; small amounts enter breast milk

Protein binding: Newborns: 68%; Adults: 93%

Metabolism: Hepatic to active and inactive compounds; extensive first-pass effect

Bioavailability: 30% to 40%; may be increased in Down syndrome

Half-life elimination: Neonates and Infants: Possible increased half-life;

Children: 3.9-6.4 hours; Adults: 4-6 hours

Excretion: Urine (96% to 99%)

Dosage Akathisia: Oral: Adults: 30-120 mg/day in 2-3 divided doses

Angina: Oral: Adults: 80-320 mg/day in doses divided 2-4 times/day

Long-acting formulation: Initial: 80 mg once daily; maximum dose: 320 mg once daily

Essential tremor: Oral: Adults: 20-40 mg twice daily initially; maintenance doses: usually 120-320 mg/day

Hypertension:

Oral:

Children: Initial: 0.5-1 mg/kg/day in divided doses every 6-12 hours; increase gradually every 5-7 days; maximum: 16 mg/kg/24 hours

Adults: Initial: 40 mg twice daily; increase dosage every 3-7 days; usual dose: ≤320 mg divided in 2-3 doses/day; maximum daily dose: 640 mg; usual dosage range (JNC 7): 40-160 mg/day in 2 divided doses

Long-acting formulation: Initial: 80 mg once daily; usual maintenance: 120-160 mg once daily; maximum daily dose: 640 mg; usual dosage range (JNC 7): 60-180 mg/day once daily

I.V.: Children: 0.01-0.05 mg/kg over 1 hour; maximum dose: 10 mg

Hypertrophic subaortic stenosis: Oral: Adults: 20-40 mg 3-4 times/day

Long-acting formulation: 80-160 mg once daily

Migraine headache prophylaxis: Oral:

Children: Initial: 2-4 mg/kg/day or

≤35 kg: 10-20 mg 3 times/day

>35 kg: 20-40 mg 3 times/day

Adults: Initial: 80 mg/day divided every 6-8 hours; increase by 20-40 mg/dose every 3-4 weeks to a maximum of 160-240 mg/day given in divided doses every 6-8 hours; if satisfactory response not achieved within 6 weeks of starting therapy, drug should be withdrawn gradually over several weeks

Long-acting formulation: Initial: 80 mg once daily; effective dose range: 160-240 mg once daily

Myocardial infarction prophylaxis: Oral: Adults: 180-240 mg/day in 3-4 divided doses

Pheochromocytoma: Oral: Adults: 30-60 mg/day in divided doses

Tachyarrhythmias:

Oral:

Children: Initial: 0.5-1 mg/kg/day in divided doses every 6-8 hours; titrate dosage upward every 3-7 days; usual dose: 2-6 mg/kg/day; higher doses may be needed; do not exceed 16 mg/kg/day or 60 mg/day

Adults: 10-30 mg/dose every 6-8 hours

Elderly: Initial: 10 mg twice daily; increase dosage every 3-7 days; usual dosage range: 10-320 mg given in 2 divided doses

I.V.:

Children: 0.01-0.1 mg/kg/dose slow IVP over 10 minutes; maximum dose: 1 mg for infants; 3 mg for children

Adults (in patients having nonfunctional GI tract): 1 mg/dose slow IVP; repeat every 5 minutes up to a total of 5 mg; titrate initial dose to desired response

Tetralogy spells: Children:

Oral: Palliation: Initial: 1 mg/kg/day every 6 hours; if ineffective, may increase dose after 1 week by 1 mg/kg/day to a maximum of 5 mg/kg/day; if patient becomes refractory, may increase slowly to a maximum of 10-15 mg/kg/day. Allow 24 hours between dosing changes.

I.V.: 0.01-0.2 mg/kg/dose infused over 10 minutes; maximum initial dose: 1 mg

Thyrototoxicosis:

Oral:

Children: 2 mg/kg/day, divided every 6-8 hours, titrate to effective dose

Adolescents and Adults: Oral: 10-40 mg/dose every 6 hours

I.V.: Adults: 1-3 mg/dose slow IVP as a single dose

Dosing adjustment/comments in renal impairment:
Not dialyzable (0% to 5%); supplemental dose is not necessary.
Peritoneal dialysis effects: Supplemental dose is not necessary.

Dosing adjustment/comments in hepatic disease: Marked slowing of heart rate may occur in cirrhosis with conventional doses; low initial dose and regular heart rate monitoring

Stability Compatible in saline, **incompatible** with HCO₃⁻; protect injection from light

Monitoring Parameters Acute cardiac treatment: Monitor ECG and blood pressure with I.V. administration; heart rate and blood pressure with oral administration

Administration I.V. dose is much smaller than oral dose. When administered acutely for cardiac treatment, monitor ECG and blood pressure. May administer by rapid infusion (I.V. push) at a rate of 1 mg/minute or by slow infusion over ~30 minutes. Necessary monitoring for surgical patients who are unable to take oral beta-blockers (prolonged ileus) has not been defined. Some institutions require monitoring of baseline and postinfusion heart rate and blood pressure when a patient's response to beta-blockade has not been characterized (ie, the patient's initial dose or following a change in dose). Consult individual institutional policies and procedures. Do not crush long-acting oral forms.

Contraindications Hypersensitivity to propranolol, beta-blockers, or any component of the formulation; uncompensated congestive heart failure (unless the failure is due to tachyarrhythmias being treated with propranolol), cardiogenic shock, bradycardia or heart block (2nd or 3rd degree), pulmonary edema, severe hyperactive airway disease (asthma or COPD), Raynaud's disease; pregnancy (2nd and 3rd trimesters)

Warnings Administer cautiously in compensated heart failure and monitor for a worsening of the condition (efficacy of propranolol in CHF has not been demonstrated). **[U.S. Boxed Warning]: Beta-blocker therapy should not be withdrawn abruptly (particularly in patients with CAD), but gradually tapered (over 2 weeks) to avoid acute tachycardia, hypertension, and/or ischemia.** Use caution in patient with PVD. Use caution with concurrent use of beta-blockers and either verapamil or diltiazem; bradycardia or heart block can occur. Avoid concurrent I.V. use of both agents. Use cautiously in diabetics because it can mask prominent hypoglycemic symptoms. Can mask signs of thyrotoxicosis. Can cause fetal harm when administered in pregnancy. Use cautiously in hepatic dysfunction (dosage adjustment required). Use care with anesthetic agents which decrease myocardial function. Not indicated for hypertensive emergencies.

Dosage Forms Capsule, extended release, as hydrochloride (InnoPran XL™): 80 mg, 120 mg
Capsule, sustained release, as hydrochloride (Inderal® LA): 60 mg, 80 mg, 120 mg, 160 mg
Injection, solution, as hydrochloride (Inderal®): 1 mg/mL (1 mL)
Solution, oral, as hydrochloride: 4 mg/mL (5 mL, 500 mL); 8 mg/mL (500 mL) [strawberry-mint flavor; contains alcohol 0.6%]
Tablet, as hydrochloride (Inderal®): 10 mg, 20 mg, 40 mg, 60 mg, 80 mg

Reference Range
Therapeutic: 50-100 ng/mL (SI: 190-390 nmol/L) at end of dose interval
Fatal: Levels >2000 ng/mL (SI: >7702 nmol/L)
In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur

Overdosage/Treatment
Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** use ipecac
Supportive therapy: Glucagon (50-150 mcg/kg followed by continuous drip of 1-5 mg/hour) for positive chronotropic effect, inamrinone may need to be added; atropine/isoproterenol can be utilized to increase heart rate; calcium chloride may also be effective but this approach has not thoroughly been investigated; **do not** use epinephrine in that unopposed alpha effects may occur; pacemaker or intra-aortic balloon counter pulsation may be required; calcium chloride may improve the hemodynamic depression or electromechanical disassociation caused by propranolol toxicity but will not affect the heart rate
Enhancement of elimination: Multiple dosing of activated charcoal may be effective; not dialyzable (0% to 5%)

Antidote(s)
● Glucagon [ANTIDOTE]

Test Interactions ↑ thyroxine (S), cholesterol (S), glucose

Drug Interactions **Substrate** of CYP1A2 (major), 2C19 (minor), 2D6 (major), 3A4 (minor); **Inhibits** CYP1A2 (weak), 2D6 (weak)
Albuterol (and other beta₂ agonists): Effects may be blunted by nonspecific beta-blockers.

Alpha-blockers (prazosin, terazosin): Concurrent use of beta-blockers may increase risk of orthostasis.

Aluminum hydroxide: Absorption of propranolol may be decreased.

Cholestyramine, colestipol: Plasma levels of propranolol may be decreased.

Cimetidine increases the plasma concentration of propranolol and its pharmacodynamic effects may be increased.

Clonidine: Hypertensive crisis after or during withdrawal of either agent

CYP1A2 inducers: May decrease the levels/effects of propranolol.
Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of propranolol.
Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

CYP2D6 inhibitors: May increase the levels/effects of propranolol. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Diazepam: Metabolism of diazepam may be inhibited; concentrations of diazepam and metabolites may be increased.

Drugs which slow AV conduction (digoxin): Effects may be additive with beta-blockers.

Epinephrine (including local anesthetics with epinephrine): Propranolol may cause hypertension.

Flecainide: Pharmacological activity of both agents may be increased when used concurrently.

Fluoxetine may inhibit the metabolism of propranolol, resulting in cardiac toxicity.

Glucagon: Propranolol may blunt hyperglycemic action.

Haloperidol: Hypotensive effects may be potentiated.

Hydralazine: The bioavailability propranolol (rapid release) and hydralazine may be enhanced with concurrent dosing.

Insulin: Propranolol inhibits recovery and may cause hypertension and bradycardia following insulin-induced hypoglycemia; also masks the tachycardia that usually accompanies insulin-induced hypoglycemia.

Lidocaine: Metabolism of lidocaine may be decreased.

NSAIDs (ibuprofen, indomethacin, naproxen, piroxicam) may reduce the antihypertensive effects of beta-blockers.

Phenothiazines (chlorpromazine, phenothiazine): Plasma levels of propranolol and phenothiazine may both be increased.

Propafenone: May increase the concentrations/effects of propranolol.

Quinidine: May increase plasma levels of propranolol by decreasing metabolism.

Rifampin: May decrease plasma levels of propranolol by increasing metabolism.

Salicylates may reduce the antihypertensive effects of beta-blockers

Serotonin 5-HT_{1D} receptor agonists (such as rizatriptan, zolmitriptan): Propranolol may increase bioavailability of serotonin 5-HT_{1D} receptor agonists.

Sulfonylureas: Beta-blockers may alter response to hypoglycemic agents.

Theophylline: Theophylline clearance may be decreased by propranolol. Verapamil or diltiazem may have synergistic or additive pharmacological effects when taken concurrently with beta-blockers; avoid concurrent I.V. use of both.

Warfarin: Propranolol may increase bioavailability of warfarin and PT may be increased.

Pregnancy Risk Factor C (manufacturer); D (2nd and 3rd trimesters - expert analysis)

Pregnancy Implications Propranolol crosses the placenta. Beta-blockers have been associated with bradycardia, hypotension, and IUGR. IUGR is probably related to maternal hypertension. Available evidence suggests beta-blockers are generally safe during pregnancy (JNC-7). Cases of neonatal hypoglycemia have been reported following maternal use of beta-blockers at parturition or during breast-feeding.

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications I.V. dose much smaller than oral dose; I.V. administration should not exceed 1 mg/minute

Additional Information Healthy African-American individuals are more sensitive to beta-blockade effects of propranolol than healthy white individuals

Propylhexedrine

Pronunciation (proe pil HEKS e dreen)

CAS Number 1007-33-6; 101-40-6; 3595-11-7; 6192-95-6

U.S. Brand Names Benzedrex® [OTC]

Impairment Potential Yes

Use Topical nasal decongestant

Mechanism of Action Related to amphetamine, propylhexedrine causes vasoconstriction of dilated arterioles (potent alpha-adrenergic agonist)

Adverse Reactions

Local: Nasal: Burning, stinging

Respiratory: Sneezing, nasal discharge increased

Signs and Symptoms of Overdose Chronic abuse has caused cardiomyopathy, dyspnea, foreign body granulation, pulmonary hypertension, and sudden death.

Admission Criteria/Prognosis Consider admission for ingestions over 250 mg, or symptomatic patients 4 hours postexposure

Toxicodynamics/Kinetics

Onset of action: Intranasal: 10 minutes

Duration: Intranasal: 1-2 hours

Elimination: Renal

Dosage Nasal: Children 6-12 years and Adults: Two inhalations in each nostril, not more frequently than every 2 hours

Administration For nasal inhalation only.

Contraindications Hypersensitivity to propylhexedrine or any component of the formulation

Warnings Do not exceed recommended dosage; do not use for more than 3 days; for nasal use only

Dosage Forms Inhaler, nasal: 0.4-0.5 mg/inhalation (1s) [total content 250 mg]

Reference Range Blood propylhexedrine levels with normal therapeutic use range around 0.01 mg/L; serum and urine level of 30 mg/L and 60 mg/L, respectively, associated with fatality

Overdosage/Treatment

Decontamination: **Oral:** Activated charcoal. **Ocular:** Irrigate copiously with saline

Supportive therapy: Propranolol or esmolol can be utilized for tachyarrhythmias

Nursing Implications Drug has been extracted from inhaler and injected I.V. as an amphetamine substitute

Additional Information Drug has been extracted from inhaler and injected I.V. as an amphetamine substitute; often utilized as a drug of abuse (similar to amphetamines) in which sudden death can occur due to heart failure or cardiac arrhythmia; PKA of solution: ~10.4; has been ingested by soaking fibrous interior of inhaler in hot water; exhibits ~10% of effect of CNS stimulation as amphetamine

Propylthiouracil

CAS Number 51-52-5

Synonyms PTU (error-prone abbreviation)

Use Palliative treatment of hyperthyroidism as an adjunct to ameliorate hyperthyroidism in preparation for surgical treatment or radioactive iodine therapy and in the management of thyrotoxic crisis

Mechanism of Action Inhibits the synthesis of thyroid hormones by blocking the oxidation of iodine in the thyroid gland; blocks synthesis of thyroxine and triiodothyronine

Adverse Reactions

Cardiovascular: Edema, leukocytoclastic vasculitis, ANCA-positive vasculitis

Central nervous system: Fever, drowsiness, vertigo, headache, drug fever, dizziness, neuritis

Dermatologic: Skin rash, urticaria, pruritus, exfoliative dermatitis, alopecia, erythema nodosum, cutaneous vasculitis

Endocrine & metabolic: Goiter, weight gain, swollen salivary glands

Gastrointestinal: Nausea, vomiting, loss of taste perception, stomach pain, constipation

Hematologic: Leukopenia, agranulocytosis, thrombocytopenia, bleeding, aplastic anemia

Hepatic: Cholestatic jaundice, hepatitis

Renal: Nephritis, glomerulonephritis, acute renal failure, renal vasculitis

Respiratory: Interstitial pneumonitis, alveolar hemorrhage, pulmonary vasculitis

Neuromuscular & skeletal: Arthralgia, paresthesia

Miscellaneous: SLE-like syndrome, elevated antineutrophilic cytoplasmic antibodies (ANCA)

Signs and Symptoms of Overdose Deafness, dysosmia, enuresis, galactorrhea, hyperthermia, leukopenia or neutropenia (agranulocytosis, granulocytopenia), myopathy

Pharmacodynamics/Kinetics

Onset of action: Therapeutic: 24-36 hours

Peak effect: Remission: 4 months of continued therapy

Duration: 2-3 hours

Distribution: Concentrated in the thyroid gland

Protein binding: 75% to 80%

Metabolism: Hepatic

Bioavailability: 80% to 95%

Half-life elimination: 1.5-5 hours; End-stage renal disease: 8.5 hours

Time to peak, serum: ~1 hour

Excretion: Urine (35%)

Dosage Oral: Administer in 3 equally divided doses at approximately 8-hour intervals; adjust dosage to maintain T₃, T₄, and TSH levels in normal range; elevated T₃ may be sole indicator of adequate treatment, elevated TSH indicates excessive antithyroid treatment

Neonates: 5-10 mg/kg/day in divided doses every 8 hours

Children: Initial: 5-7 mg/kg/day in divided doses every 8 hours or

6-10 years: 50-150 mg/day

> 10 years: 150-300 mg/day

Maintenance: $\frac{1}{3}$ to $\frac{2}{3}$ of the initial dose in divided doses every 8-12 hours; this usually begins after 2 months on an effective initial dosage

Adults: Initial: 300-450 mg/day in divided doses every 8 hours (severe hyperthyroidism may require 600-1200 mg/day); maintenance: 100-150 mg/day in divided doses every 8-12 hours

Elderly: Use lower dose recommendations; initial dose: 150-300 mg/day

Dosing adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer at 75% of normal dose

Cl_{cr} <10 mL/minute: Administer at 50% of normal dose

Monitoring Parameters CBC with differential, prothrombin time, liver function tests, thyroid function tests (TSH, T₃, T₄); periodic blood counts are recommended chronic therapy

Contraindications Hypersensitivity to propylthiouracil or any component of the formulation; pregnancy

Warnings Use with caution in patients >40 years of age because PTU may cause hypoprothrombinemia and bleeding; use with extreme caution in patients receiving other drugs known to cause agranulocytosis; may cause agranulocytosis, thyroid hyperplasia, thyroid carcinoma (usage > 1 year). Discontinue in the presence of agranulocytosis, aplastic anemia, ANCA-positive vasculitis, hepatitis, unexplained fever, or exfoliative dermatitis. Safety and efficacy have not been established in children <6 years of age.

Dosage Forms Tablet: 50 mg

Reference Range Peak serum level of 10 mcg/mL following 400 mg ingestion

Overdosage/Treatment Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal; consider gastrointestinal decontamination for ingestions >5 g

Diagnostic Procedures

● Thyroxine, Blood

Test Interactions ↑ alkaline phosphatase; reverse T₃; ↓ T₃

Drug Interactions Anticoagulants: Anticoagulants may be potentiated by antivitamin-K effect of propylthiouracil. Oral anticoagulant activity is increased only until metabolic effect stabilizes.

Correction of hyperthyroidism may alter disposition of beta-blockers, digoxin, and theophylline, necessitating a dose reduction of these agents.

Pregnancy Risk Factor D

Pregnancy Implications Crosses the placenta and may induce goiter and hypothyroidism in the developing fetus (cretinism). May need to monitor infant's thyroid function periodically.

Lactation Enters breast milk/use caution (AAP rates "compatible")

Additional Information The use of antithyroid thioamides is as effective in elderly as in younger adults; however, the expense, potential adverse effects, and inconvenience (compliance, monitoring) make them undesirable. The use of radioiodine, due to ease of administration and less concern for long-term side effects and reproduction problems, makes it a more appropriate therapy.

Protriptyline**Related Information**

- Antidepressant Agents

CAS Number 1225-55-4; 438-60-8

U.S. Brand Names Vivactil®

Synonyms Protriptyline Hydrochloride

Impairment Potential Yes

Use Treatment of various forms of depression, often in conjunction with psychotherapy

Mechanism of Action Increases the synaptic concentration of serotonin and/or norepinephrine in the central nervous system by inhibition of their reuptake by the presynaptic neuronal membrane

Adverse Reactions

Cardiovascular: Arrhythmias, hypotension, hypotension (orthostatic), palpitations, exacerbation of Brugada syndrome

Central nervous system: **Dizziness, drowsiness, headache**, confusion, delirium, hallucinations, nervousness, restlessness, parkinsonian syndrome, anxiety, seizures, insomnia, nightmares, psychosis, fever, hyperthermia, extrapyramidal reactions

Dermatologic: Alopecia, photosensitivity, petechiae, angioedema, urticaria, purpura, pruritus

Endocrine & metabolic: Breast enlargement, galactorrhea, gynecomastia, syndrome of inappropriate antidiuretic hormone secretion, sexual function impairment

Gastrointestinal: **Xerostomia, constipation, unpleasant taste, weight gain, increased appetite, nausea, diarrhea, heartburn**, trouble with gums, decreased lower esophageal sphincter, tone may cause GE reflux, stomatitis, lingua villosa nigra

Genitourinary: Dysuria, testicular edema

Hematologic: Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia

Hepatic: Cholestatic jaundice, elevated liver enzymes

Neuromuscular & skeletal: **Weakness**, fine muscle tremors, rhabdomyolysis, paresthesia

Ocular: Blurred vision, eye pain, increased intraocular pressure, mydriasis, phototoxic

Otic: Tinnitus

Miscellaneous: Diaphoresis (excessive), allergic reactions

Admission Criteria/Prognosis Admit any patient with neurologic or cardiovascular symptoms occurring 6 hours postingestion

Pharmacodynamics/Kinetics

Distribution: Crosses placenta

Protein binding: 92%

Metabolism: Extensively hepatic via N-oxidation, hydroxylation, and glucuronidation; first-pass effect (10% to 25%)

Half-life elimination: 54-92 hours (average: 74 hours)

Time to peak, serum: 24-30 hours

Excretion: Urine

Dosage

Oral:

Adolescents: 15-20 mg/day in 3 divided doses

Adults: 15-60 mg in 3-4 divided doses

Elderly: 15-20 mg/day

Maximum dose: 60 mg/day

Monitoring Parameters Monitor for cardiac abnormalities in elderly patients receiving doses >20 mg

Administration Make any dosage increase in the morning dose

Contraindications Hypersensitivity to protriptyline (cross-reactivity to other cyclic antidepressants may occur) or any component of the formulation; use of MAO inhibitors within 14 days; use of cisapride; use in a patient during the acute recovery phase of MI

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes,

either increases or decreases. A medication guide should be dispensed with each prescription. **Protriptyline is FDA approved for the treatment of depression in adolescents.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Protriptyline is not FDA approved for the treatment of bipolar depression.**

May cause sedation, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Sedative effects may be additive with other CNS depressants and/or ethanol. The degree of sedation is low relative to other antidepressants. May aggravate aggressive behavior. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Therapy should not be abruptly discontinued in patients receiving high doses for prolonged periods. May alter glucose regulation - use with caution in patients with diabetes.

May cause orthostatic hypotension (risk is moderate relative to other antidepressants) - use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). The degree of anticholinergic blockade produced by this agent is moderate relative to other cyclic antidepressants, however, caution should still be used in patients with urinary retention, benign prostatic hyperplasia, narrow-angle glaucoma, xerostomia, visual problems, constipation, or history of bowel obstruction.

Use with caution in patients with a history of cardiovascular disease (including previous MI, stroke, tachycardia, or conduction abnormalities). The risk of conduction abnormalities with this agent is moderate-high relative to other antidepressants. Use caution in patients with a previous seizure disorder or condition predisposing to seizures such as brain damage, alcoholism, or concurrent therapy with other drugs which lower the seizure threshold. Use with caution in hyperthyroid patients or those receiving thyroid supplementation. Use with caution in patients with hepatic or renal dysfunction and in elderly patients.

Dosage Forms Tablet, as hydrochloride: 5 mg, 10 mg

Reference Range Therapeutic: 70-250 ng/mL (SI: 266-950 nmol/L); Toxic: >500 ng/mL (SI: >1900 nmol/L); levels >1000 ng/mL (SI: >3800 nmol/L) associated with cardiotoxic effects

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage is effective if performed within 90 minutes and may be effective if performed within 6 hours/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated. Ventricular arrhythmias and ventricular conduction defects often respond to concurrent systemic alkalization (sodium bicarbonate 0.5-2 mEq/kg I.V.). Titrate to a serum pH of 7.45-7.55. Arrhythmias unresponsive to this therapy may respond to lidocaine 1 mg/kg I.V. followed by a titrated infusion. Phenytoin is also useful in treating ventricular dysrhythmias (15 mg/kg up to 1 g I.V.). Physostigmine (1-2 mg I.V. slowly for adults or 0.5 mg I.V. slowly for children) may be indicated for seizures or movement disorders but only as a **last resort**. Propranolol may also be utilized for supraventricular arrhythmias (rate: >160) at 1 mg/minute to a maximum of 5 mg in adults; pediatric dosage of 0.1 mg/kg/dose to 1 mg I.V.. Seizures usually respond to lorazepam or diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required. Patients must be monitored for at least 24 hours if any signs or symptoms are exhibited. Dobutamine is preferred over dopamine for hypotension, although there is conflicting animal data. Norepinephrine appears effective in treating hypotension; glucagon (10 mg I.V.) can be given to treat hypotension. Flumazenil is contraindicated; magnesium has potentiated adverse cardiac effects (ie, asystole, decreased left ventricular pressure) in an animal model, although it was used successfully in treating refractory ventricular fibrillation at a dose of 20 nmol I.V. (a total of 2 doses). For treatment of lingua villosa nigra, discontinue causative agent. Clean the tongue with a toothbrush and rinse mouth with a half-strength solution of hydrogen

peroxide or 10% carbamide peroxide. Oral symptoms should subside in a few days.

Test Interactions ↑ glucose

Drug Interactions

Substrate of CYP2D6 (major)

Altrexamine: Concurrent use may cause orthostatic hypertension

Amphetamines: TCAs may enhance the effect of amphetamines; monitor for adverse CV effects

Anticholinergics: Combined use with TCAs may produce additive anticholinergic effects

Antihypertensives: Cyclic antidepressants may inhibit the antihypertensive response to bethanidine, clonidine, debrisoquin, guanadrel, guanethidine, guanabenz, guanfacine; monitor BP; consider alternate antihypertensive agent

Beta-agonists: When combined with TCAs may predispose patients to cardiac arrhythmias

Bupropion: May increase the levels of tricyclic antidepressants; based on limited information; monitor response

Carbamazepine: Tricyclic antidepressants may increase carbamazepine levels; monitor

Cholestyramine and colestipol: May bind TCAs and reduce their absorption; monitor for altered response

Clonidine: Abrupt discontinuation of clonidine may cause hypertensive crisis, cyclic antidepressants may enhance the response

CNS depressants: Sedative effects may be additive with TCAs; monitor for increased effect; includes benzodiazepines, barbiturates, antipsychotics, ethanol, and other sedative medications

CYP2D6 inhibitors: May increase the levels/effects of protriptyline. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Epinephrine (and other direct alpha-agonists): Pressor response to I.V. epinephrine, norepinephrine, and phenylephrine may be enhanced in patients receiving TCAs (**Note**: Effect is unlikely with epinephrine or levonordefrin dosages typically administered as infiltration in combination with local anesthetics)

Fenfluramine: May increase tricyclic antidepressant levels/effects

Hypoglycemic agents (including insulin): TCAs may enhance the hypoglycemic effects of tolazamide, chlorpropamide, or insulin; monitor for changes in blood glucose levels; reported with chlorpropamide, tolazamide, and insulin

Levodopa: tricyclic antidepressants may decrease the absorption (bioavailability) of levodopa; rare hypertensive episodes have also been attributed to this combination

Linezolid: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** with agents which inhibit MAO (serotonin syndrome); this combination should be avoided

Lithium: Concurrent use with a TCA may increase the risk for neurotoxicity

MAO inhibitors: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** (serotonin syndrome); this combination should be avoided

Methylphenidate: Metabolism of tricyclic antidepressants may be decreased

Phenothiazines: Serum concentrations of some TCAs may be increased; in addition, TCAs may increase concentration of phenothiazines; monitor for altered clinical response

QT_c-prolonging agents: Concurrent use of tricyclic agents with other drugs which may prolong QT_c interval may increase the risk of potentially fatal arrhythmias; includes type Ia and type III antiarrhythmics agents, selected quinolones (sparfloxacin, gatifloxacin, moxifloxacin, grepafloxacin), cisapride, and other agents

Ritonavir: Combined use of high-dose tricyclic antidepressants with ritonavir may cause serotonin syndrome in HIV-positive patients; monitor

Sucralfate: Absorption of tricyclic antidepressants may be reduced with coadministration

Sympathomimetics, indirect-acting: Tricyclic antidepressants may result in a decreased sensitivity to indirect-acting sympathomimetics; includes dopamine and ephedrine; also see interaction with epinephrine (and direct-acting sympathomimetics)

Tramadol: Tramadol's risk of seizures may be increased with TCAs

Valproic acid: May increase serum concentrations/adverse effects of some tricyclic antidepressants

Warfarin (and other oral anticoagulants): Tricyclic antidepressants may increase the anticoagulant effect in patients stabilized on warfarin; monitor INR

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Offer patient sugarless hard candy or gum for dry mouth. Clean the tongue with a toothbrush and rinse mouth with a half-strength solution of hydrogen peroxide or 10% carbamide peroxide. Symptoms should subside in a few days.

Pseudoephedrine

CAS Number 345-78-8

U.S. Brand Names Biofed [OTC]; Decofed® [OTC]; Dimetapp® 12-Hour Non-Drowsy Extentabs® [OTC]; Dimetapp® Decongestant [OTC]; Genaphed® [OTC]; Kidkare Decongestant [OTC]; Kodet SE [OTC]; Oranyl [OTC]; PediaCare® Decongestant Infants [OTC]; Silfedrine Children's [OTC]; Sudafed® 12 Hour [OTC]; Sudafed® 24 Hour [OTC]; Sudafed® Children's [OTC]; Sudafed® [OTC]; Sudodrin [OTC]; Triaminic® Allergy Congestion [OTC]

Synonyms *d*-Isoephedrine Hydrochloride; Pseudoephedrine Hydrochloride; Pseudoephedrine Sulfate

Impairment Potential Yes

Use Temporary symptomatic relief of nasal congestion due to common cold, upper respiratory allergies, and sinusitis; also promotes nasal or sinus drainage; prevention of barotrauma during air travel

Mechanism of Action Directly stimulates alpha-adrenergic receptors of respiratory mucosa causing vasoconstriction; directly stimulates beta-adrenergic receptors causing bronchial relaxation, increased heart rate and contractility

Adverse Reactions

Cardiovascular: **Tachycardia, palpitations, cardiac arrhythmias**, chest pain, myocardial ischemia, angina, sinus tachycardia

Central nervous system: **Nervousness, excitation, dizziness, insomnia, headache, drowsiness, transient stimulation**, psychosis, mania, paranoia, CNS depression, seizures

Dermatologic: Systemic contact dermatitis, exfoliative dermatitis, angioedema, urticaria, exanthem, toxic epidermal necrolysis

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Nausea, vomiting, ischemic colitis

Genitourinary: Dysuria

Neuromuscular & skeletal: **Tremors**

Miscellaneous: Fixed drug eruption

Signs and Symptoms of Overdose Arrhythmias, convulsions, depression, insomnia, mydriasis, nausea, vomiting

Pharmacodynamics/Kinetics

Onset of action: Decongestant: Oral: 15-30 minutes

Duration: Immediate release tablet: 4-6 hours; Extended release: ≤ 12 hours

Absorption: Rapid

Metabolism: Partially hepatic

Half-life elimination: 9-16 hours

Excretion: Urine (70% to 90% as unchanged drug, 1% to 6% as active norpseudoephedrine); dependent on urine pH and flow rate; alkaline urine decreases renal elimination of pseudoephedrine

Dosage

Oral:

Children (do not give sustained release tablets):

<2 years: 4 mg/kg/day in divided doses every 6 hours

2-5 years: 15 mg every 6 hours; maximum: 60 mg/24 hours

6-12 years: 30 mg every 6 hours; maximum: 120 mg/24 hours

Adults: 30-60 mg every 4-6 hours, sustained release: 120 mg every 12 hours; maximum: 480 mg/24 hours

Prevention of barotrauma during air travel: 120 mg at least 30 minutes before air travel

Dosing adjustment in renal impairment: Reduce dose

Administration

Do not crush extended release drug product, swallow whole.

Contraindications Hypersensitivity to pseudoephedrine or any component of the formulation; with or within 14 days of MAO inhibitor therapy

Warnings Use with caution in patients >60 years of age; administer with caution to patients with hypertension, hyperthyroidism, diabetes mellitus, cardiovascular disease, ischemic heart disease, increased intraocular pressure, or prostatic hyperplasia. Elderly patients are more likely to experience adverse reactions to sympathomimetics. Overdosage may cause hallucinations, seizures, CNS depression, and death. When used for self-medication (OTC), notify healthcare provider if symptoms do not improve within 7 days or are accompanied by fever.

Dosage Forms

Caplet, extended release, as hydrochloride (Contact® Cold, Sudafed® 12 Hour): 120 mg

Liquid, as hydrochloride: 30 mg/5 mL (120 mL, 480 mL)

Silfedrine Children's: 15 mg/5 mL (120 mL, 480 mL) [alcohol and sugar free; grape flavor]

Simply Stuff®: 15 mg/5 mL (120 mL) [alcohol free; contains sodium benzoate; cherry berry flavor]

Sudafed® Children's: 15 mg/5 mL (120 mL) [alcohol and sugar free; contains sodium benzoate; grape flavor]

Liquid, oral drops, as hydrochloride:

Dimetapp® Decongestant Infant Drops: 7.5 mg/0.8 mL (15 mL) [alcohol free; contains sodium benzoate; grape flavor]

Kidkare Decongestant: 7.5 mg/0.8 mL (30 mL) [alcohol free; contains benzoic acid and sodium benzoate; cherry flavor]

PediaCare® Decongestant: 7.5 mg/0.8 mL (15 mL) [alcohol free, dye free; contains benzoic acid, sodium benzoate; fruit flavor]
 Syrup, as hydrochloride:
 Biofed: 30 mg/5 mL (120 mL, 240 mL, 480 mL, 3840 mL) [alcohol free; contains sodium benzoate]
 ElixSure™ Congestion: 15 mg/5 mL (120 mL) [grape bubble gum flavor]
 Tablet, as hydrochloride: 30 mg, 60 mg
 Genaphed®, Kodet SE, Oranyl, Sudafed®, Sudodrin, Sudo-Tab®: 30 mg
 SudoGest: 30 mg, 60 mg
 Tablet, chewable, as hydrochloride (Sudafed® Children's): 15 mg [sugar free; contains phenylalanine 0.78 mg/tablet; orange flavor]
 Tablet, extended release, as hydrochloride:
 Dimetapp® 12-Hour Non-Drowsy Extentabs®: 120 mg
 Sudafed® 24 Hour: 240 mg

Reference Range Following an oral dose of 180 mg, peak plasma pseudoephedrine levels range from 0.5-0.9 mcg/mL

Overdosage/Treatment

Decontamination: Activated Charcoal.

There is no specific antidote. Treatment is supportive. Hyperactivity and agitation usually respond to reduced sensory input; however, with extreme agitation, haloperidol (2-5 mg I.M. for adults) may be required. Hyperthermia is best treated with external cooling measures, or when severe or unresponsive, muscle paralysis with pancuronium may be needed. Hypertension is usually transient and generally does not require treatment unless severe. For diastolic blood pressures >110 mm Hg, a nitroprusside infusion should be initiated. Seizures usually respond to lorazepam or diazepam I.V. and/or phenytoin maintenance regimens.

Drug Interactions

Decreased effect of methyldopa, reserpine
 Increased toxicity: MAO inhibitors may increase blood pressure effects of pseudoephedrine; propranolol, sympathomimetic agents may increase toxicity

Pregnancy Risk Factor C

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications Do not crush extended release drug product

Additional Information Pseudoephedrine hydrochloride: Cenafed® syrup [OTC], Decofed® syrup [OTC], Neofed® [OTC], Novafed®, Sudafed® [OTC], Sudafed® 12 Hour [OTC], Sudafed® tablet [OTC], Sufedrin® [OTC]
 Pseudoephedrine sulfate: Afrinol® [OTC]

Specific References

Boland DM, Rein J, Lew EO, et al, "Fatal Cold Medication Intoxication in an Infant," *J Anal Toxicol*, 2003, 27:523-6.

Pyrazinamide

CAS Number 98-96-4

Synonyms Pyrazinoic Acid Amide

Use Adjunctive treatment of tuberculosis in combination with other antituberculosis agents

Mechanism of Action Converted to pyrazinoic acid in susceptible strains of *Mycobacterium* which lowers the pH of the environment structurally related to nictinamide

Adverse Reactions

Cardiovascular: Hypertension
 Central nervous system: Malaise, seizures, fever, headache
 Dermatologic: Urticaria, rash, photosensitivity, lichenoid photodermatitis
 Endocrine & metabolic: Gout, hyperuricemia
 Gastrointestinal: Nausea, vomiting, anorexia
 Hematologic: Thrombocytopenia
 Hepatic: Hepatotoxicity, jaundice (40 mg/kg)
 Neuromuscular & skeletal: Arthralgia, rhabdomyolysis
 Renal: Interstitial nephritis, urate retention

Signs and Symptoms of Overdose Gout, GI upset, hepatitis (>3 g/day dosage), hyperuricemia, photophobia

Pharmacodynamics/Kinetics

Bacteriostatic or bactericidal depending on drug's concentration at infection site
 Absorption: Well absorbed
 Distribution: Widely into body tissues and fluids including liver, lung, and CSF
 Relative diffusion from blood into CSF: Adequate with or without inflammation (exceeds usual MICs)
 CSF:blood level ratio: Inflamed meninges: 100%

Protein binding: 50%
 Metabolism: Hepatic
 Half-life elimination: 9-10 hours
 Time to peak, serum: Within 2 hours
 Excretion: Urine (4% as unchanged drug)

Dosage

Oral (calculate dose on ideal body weight rather than total body weight):
Note: A four-drug regimen (isoniazid, rifampin, pyrazinamide, and either streptomycin or ethambutol) is preferred for the initial, empiric treatment of TB. When the drug susceptibility results are available, the regimen should be altered as appropriate. For the treatment of latent TB infection (LTBI), combination pyrazinamide/rifampin therapy should not generally be offered (*MMWR* Aug 8, 2003).

Children and Adults:

Daily therapy: 15-30 mg/kg/day (maximum: 2 g/day)

Directly observed therapy (DOT):

Twice weekly: 50-70 mg/kg (maximum: 4 g)

Three times/week: 50-70 mg/kg (maximum: 3 g)

Elderly: Start with a lower daily dose (15 mg/kg) and increase as tolerated

Dosing adjustment in renal impairment: $Cl_{cr} < 50$ mL/minute: Avoid use or reduce dose to 12-20 mg/kg/day

Dosing adjustment in hepatic impairment: Reduce dose

Monitoring Parameters Periodic liver function tests, serum uric acid, sputum culture, chest x-ray 2-3 months into treatment and at completion

Contraindications Hypersensitivity to pyrazinamide or any component of the formulation; acute gout; severe hepatic damage

Warnings Use with caution in patients with renal failure, chronic gout, diabetes mellitus, or porphyria. Use with caution in patients receiving concurrent medications associated with hepatotoxicity (particularly with rifampin), or in patients with a history of alcoholism (even if ethanol consumption is discontinued during therapy).

Dosage Forms Tablet: 500 mg

Overdosage/Treatment

Decontamination: Activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Drug Interactions Combination therapy with rifampin and pyrazinamide has been associated with severe and fatal hepatotoxic reactions.

Pregnancy Risk Factor C

Lactation Enters breast milk/use caution

Pyrimethamine

CAS Number 58-14-0

U.S. Brand Names Daraprim®

Use Prophylaxis of malaria due to susceptible strains of plasmodia; used in conjunction with quinine and sulfadiazine for the treatment of uncomplicated attacks of chloroquine-resistant *P. falciparum* malaria; used in conjunction with fast-acting schizonticide to initiate transmission control and suppression cure; synergistic combination with sulfonamide in treatment of toxoplasmosis

Mechanism of Action Inhibits parasitic dihydrofolate reductase, resulting in inhibition of tetrahydrofolic acid synthesis

Adverse Reactions

Frequency not defined.

Cardiovascular: Arrhythmias (large doses)

Central nervous system: Depression, fever, insomnia, lightheadedness, malaise, seizures

Dermatologic: Abnormal skin pigmentation, dermatitis, erythema multiforme, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Gastrointestinal: Anorexia, abdominal cramps, vomiting, diarrhea, xerostomia, atrophic glossitis

Hematologic: Megaloblastic anemia, leukopenia, pancytopenia, thrombocytopenia, pulmonary eosinophilia

Genitourinary: Hematuria

Miscellaneous: Anaphylaxis

Signs and Symptoms of Overdose Apnea, fever, megaloblastic anemia, seizures, tachycardia, vomiting

Pharmacodynamics/Kinetics

Onset of action: ~1 hour

Absorption: Well absorbed

Distribution: Widely, mainly in blood cells, kidneys, lungs, liver, and spleen; crosses into CSF; crosses placenta; enters breast milk

Protein binding: 80% to 87%

Metabolism: Hepatic

QUAZEPAM

Half-life elimination: 80-95 hours
Time to peak, serum: 1.5-8 hours
Excretion: Urine (20% to 30% as unchanged drug)

Dosage

Malaria chemoprophylaxis (for areas where chloroquine-resistant *P. falciparum* exists): Begin prophylaxis 2 weeks before entering endemic area:

Children: 0.5 mg/kg once weekly; not to exceed 25 mg/dose

or

Children:

<4 years: 6.25 mg once weekly

4-10 years: 12.5 mg once weekly

Children > 10 years and Adults: 25 mg once weekly

Dosage should be continued for all age groups for at least 6-10 weeks after leaving endemic areas

Chloroquine-resistant *P. falciparum* malaria (when used in conjunction with quinine and sulfadiazine):

Children:

< 10 kg: 6.25 mg/day once daily for 3 days

10-20 kg: 12.5 mg/day once daily for 3 days

20-40 kg: 25 mg/day once daily for 3 days

Adults: 25 mg twice daily for 3 days

Toxoplasmosis:

Infants (congenital toxoplasmosis): Oral: 1 mg/kg once daily for 6 months with sulfadiazine then every other month with sulfa, alternating with spiramycin.

Children: Loading dose: 2 mg/kg/day divided into 2 equal daily doses for 1-3 days (maximum: 100 mg/day) followed by 1 mg/kg/day divided into 2 doses for 4 weeks; maximum: 25 mg/day

With sulfadiazine or trisulfapyrimidines: 2 mg/kg/day divided every 12 hours for 3 days, followed by 1 mg/kg/day once daily or divided twice daily for 4 weeks given with trisulfapyrimidines or sulfadiazine

Adults: 50-75 mg/day together with 1-4 g of a sulfonamide for 1-3 weeks depending on patient's tolerance and response, then reduce dose by 50% and continue for 4-5 weeks or 25-50 mg/day for 3-4 weeks

Prophylaxis for first episode of *Toxoplasma gondii*:

Children \geq 1 month of age: 1 mg/kg/day once daily with dapsone, plus oral folic acid 5 mg every 3 days

Adolescents and Adults: 50 mg once weekly with dapsone, plus oral folic acid 25 mg once weekly

Prophylaxis to prevent recurrence of *Toxoplasma gondii*:

Children \geq 1 month of age: 1 mg/kg/day once daily given with sulfadiazine or clindamycin, plus oral folic acid 5 mg every 3 days

Adolescents and Adults: 25-50 mg once daily in combination with sulfadiazine or clindamycin, plus oral folic acid 10-25 mg daily; atovaquone plus oral folic acid has also been used in combination with pyrimethamine.

Monitoring Parameters CBC, including platelet counts

Administration

Administer with meals to minimize GI distress.

Contraindications Hypersensitivity to pyrimethamine or any component of the formulation; chloroguanide; resistant malaria; megaloblastic anemia secondary to folate deficiency

Warnings When used for more than 3-4 days, it may be advisable to administer leucovorin to prevent hematologic complications; monitor CBC and platelet counts every 2 weeks; use with caution in patients with impaired renal or hepatic function or with possible G6PD. Use caution in patients with seizure disorders or possible folate deficiency (eg, malabsorption syndrome, pregnancy, alcoholism).

Dosage Forms Tablet: 25 mg

Overdosage/Treatment

Decontamination: Lavage within 1 hour, activated charcoal

Supportive therapy: Initiate with I.V. fluids; assure respiratory patency; treat seizures aggressively with benzodiazepines, follow with barbiturates, if necessary; other complications of seizures (acid base, etc), treat conventionally as necessary

Antidote: Leucovorin 10 mg/m² every 6 hours daily for 3 days followed by folic acid 10 mg/day if hematologic toxicity is present

Antidote(s)

- Leucovorin [ANTIDOTE]

Drug Interactions Inhibits CYP2C9 (moderate), 2D6 (moderate)

Antipsychotic agents: Serum levels may be increased by pyrimethamine. Bone marrow suppressive agents: Sulfonamides (synergy), methotrexate, TMP/SMZ, zidovudine may increase the risk of bone marrow suppression.

CYP2C9 Substrates: Pyrimethamine may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

CYP2D6 substrates: Pyrimethamine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Pyrimethamine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

Pregnancy Risk Factor C

Pregnancy Implications There are no adequate or well-controlled studies in pregnant women. Teratogenicity has been reported in animal studies. If administered during pregnancy (ie, for toxoplasmosis), supplementation of folate is strongly recommended. Pregnancy should be avoided during therapy.

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Nursing Implications Monitor complete blood counts and platelet counts twice weekly

Additional Information Leucovorin may be given to prevent hematologic problems due to folic acid deficiency.

Quazepam

CAS Number 36735-22-5

U.S. Brand Names Doral®

Impairment Potential Yes

Use Short-term treatment of insomnia

Mechanism of Action Depresses all levels of the CNS, including the limbic and reticular formation, probably through the increased action of gamma-aminobutyric acid (GABA), which is a major inhibitory neurotransmitter in the brain

Adverse Reactions

Central nervous system: **Drowsiness** (12%), headache (4.5%), fatigue (1.9%), dizziness (1.5%), slurred speech, irritability, dystonia

Dermatologic: Hypertrichosis, alopecia, urticaria, purpura, pruritus

Endocrine & metabolic: Changes in libido

Gastrointestinal: Xerostomia (1.5%), dyspepsia (1.1%)

Genitourinary: Urinary retention, incontinence

Hematologic: Leukocytosis, thrombocytosis

Hepatic: Jaundice, elevated total bilirubin, elevated SGPT (ALT), elevated alkaline phosphatase

Neuromuscular & skeletal: Dysarthria, paresthesia

Renal: Elevated creatinine, elevated BUN

Signs and Symptoms of Overdose Ataxia, confusion, coma, dyspnea, hypoactive reflexes, hyporeflexia, hypotension, slurred speech, somnolence

Pharmacodynamics/Kinetics

Studies have shown that the elderly are more sensitive to the effects of benzodiazepines as compared to younger adults

Absorption: Rapid through gastrointestinal tract

Distribution: V_d: 5-8.6 L/kg; distributed widely throughout body

Protein binding: 95%

Metabolism: In the liver to two active compounds (2-oxoquazepam and N-desalkyl-2-oxoquazepam)

Half-life: Parent: 25-41 hours; Active metabolite: 40-114 hours

In the elderly: Parent: 53 hours; Active metabolite: 39-73 hours

Time to peak serum concentration: 2 hours

Elimination: Excreted in urine (31%) and feces (23%)

Dosage Adults: Oral: Initial: 15 mg at bedtime, in some patients the dose may be reduced to 7.5 mg after a few nights

Elderly: Dosing should be cautious; begin at lower end of dosing range (ie, 7.5 mg)

Dosing adjustment in hepatic impairment: Dose reduction may be necessary

Monitoring Parameters Respiratory and cardiovascular status

Contraindications Hypersensitivity to quazepam or any component of the formulation (cross-sensitivity with other benzodiazepines may exist); narrow-angle glaucoma (not in product labeling, however, benzodiazepines are contraindicated); pregnancy

Warnings

Should be used only after evaluation of potential causes of sleep disturbance. Failure of sleep disturbance to resolve after 7-10 days may indicate psychiatric or medical illness. A worsening of insomnia or the emergence of new abnormalities of thought or behavior may represent unrecognized psychiatric or medical illness and requires immediate and careful evaluation. Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics), or renal impairment. Use with caution in patients with respiratory disease or impaired gag reflex. Avoid use in patients with sleep apnea. Causes CNS depression (dose-related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury and should be used with extreme caution in patients who are at risk of these events (especially the elderly).

Use caution in patients with depression, particularly if suicidal risk may be present. Use with caution in patients with a history of drug dependence.

Benzodiazepines have been associated with dependence and acute withdrawal symptoms on discontinuation or reduction in dose. Acute withdrawal, including seizures, may be precipitated after administration of flumazenil to patients receiving long-term benzodiazepine therapy. Benzodiazepines have been associated with anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Dosage Forms Tablet: 7.5 mg, 15 mg

Reference Range Mean plasma level of 148 ng/mL 1.5 hours after ingestion of 25 mg

Overdosage/Treatment

Decontamination: Activated charcoal
 Supportive therapy: Treatment is supportive. Rarely is mechanical ventilation required. Flumazenil has been shown to reverse benzodiazepine induced CNS depression.
 Enhancement of elimination: Multiple dosing of activated charcoal may be useful

Antidote(s)

- Flumazenil [ANTIDOTE]

Drug Interactions Substrate of CYP3A4 (minor)

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect
 Levodopa: Therapeutic effects may be diminished in some patients following the addition of a benzodiazepine; limited/inconsistent data
 Oral contraceptives: May decrease the clearance of some benzodiazepines (those which undergo oxidative metabolism); monitor for increased benzodiazepine effect
 Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation

Pregnancy Risk Factor X

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Nursing Implications Provide safety measures (ie, side rails, night light, call button); remove smoking materials from area; supervise ambulation

Additional Information More likely than triazolam to cause daytime sedation and fatigue; classified as a long-acting benzodiazepine hypnotic, therefore, may prevent withdrawal symptoms with discontinuation of therapy

Specific References

Kato K, Yasui-Furukori N, Fukasawa T, et al, "Effects of Itraconazole on the Plasma Kinetics of Quazepam and Its Two Active Metabolites After a Single Oral Dose of the Drug," *Ther Drug Monit*, 2003, 25(4):473-7.

Quetiapine

Related Information

- Antipsychotic Agents

U.S. Brand Names Seroquel®

Synonyms Quetiapine Fumarate

Use Treatment of schizophrenia; treatment of acute manic episodes associated with bipolar disorder (as monotherapy or in combination with lithium or valproate)

Unlabeled/Investigational Use Autism, psychosis (children)

Mechanism of Action

Mechanism of action of quetiapine, as with other antipsychotic drugs, is unknown. However, it has been proposed that this drug's antipsychotic activity is mediated through a combination of dopamine type 2 (D₂) and serotonin type 2 (5-HT₂) antagonism. It is an antagonist at multiple neurotransmitter receptors in the brain: serotonin 5-HT_{1A} (IC₅₀=717nM) and 5-HT₂ (IC₅₀=148nM), dopamine D₁ (IC₅₀=1268nM) and D₂ (IC₅₀=329nM), histamine H₁ (IC₅₀=30nM), and adrenergic alpha₁- (IC₅₀=94nM) and alpha₂- (IC₅₀=271nM) receptors; but appears to have no appreciable affinity at cholinergic muscarinic and benzodiazepine receptors.

Antagonism at receptors other than dopamine and 5-HT₂ with similar receptor affinities may explain some of the other effects of quetiapine. The drug's antagonism of histamine H₁-receptors may explain the somnolence observed with it. The drug's antagonism of adrenergic alpha₁-receptors may explain the orthostatic hypotension observed with it.

Adverse Reactions

Cardiovascular: Postural hypotension, tachycardia, palpitations, peripheral edema, bradycardia, QT prolongation
 Central nervous system: **Agitation, dizziness, headache, somnolence, anxiety, fever, pain, abnormal dreams, tardive dyskinesia**
 Dermatologic: Rash, photosensitivity, Stevens-Johnson syndrome
 Endocrine & metabolic: **Cholesterol increased, triglycerides increased**, diabetes mellitus, hyperglycemia, hyperlipidemia, hypothyroidism, hyponatremia, SIADH
 Gastrointestinal: **Weight gain (≥7% body weight, dose related), xerostomia**, abdominal pain (dose related), constipation, dyspepsia

(dose related), anorexia, vomiting, gastroenteritis, appetite increased, salivation increased

Hematologic: Leukopenia, anemia, leukocytosis, agranulocytosis
 Hepatic: AST increased, ALT increased, GGT increased, alkaline phosphatase increased
 Neuromuscular & skeletal: Dysarthria, back pain, weakness, tremor, hypertonia, dysarthria, involuntary movements, rhabdomyolysis
 Ocular: Amblyopia
 Respiratory: Rhinitis, pharyngitis, cough, dyspnea, epistaxis
 Miscellaneous: Diaphoresis, flu-like syndrome, anaphylaxis

Signs and Symptoms of Overdose Agitation, coma, hypotension, tachycardia

Admission Criteria/Prognosis Admit any symptomatic patient or asymptomatic ingestion >25 mg/kg.

Pharmacodynamics/Kinetics

Absorption: Rapidly absorbed following oral administration
 Distribution: V_d: 10 ± 4 L/kg; V_{dss}: ~2 days
 Protein binding, plasma: 83%
 Metabolism: Primarily hepatic; via CYP3A4; forms two inactive metabolites
 Bioavailability: 9% ± 4%; tablet is 100% bioavailable relative to solution
 Half-life elimination: Mean: Terminal: ~6 hours
 Time to peak, plasma: 1.5 hours
 Excretion: Urine (73% as metabolites, <1% as unchanged drug); feces (20%)

Dosage

Oral:
 Children and Adolescents:
 Autism (unlabeled use): 100-350 mg/day (1.6-5.2 mg/kg/day)
 Psychosis and mania (unlabeled use): Initial: 25 mg twice daily; titrate as necessary to 450 mg/day
 Adults:
 Schizophrenia/psychoses: Initial: 25 mg twice daily; increase in increments of 25-50 mg 2-3 times/day on the second and third day, if tolerated, to a target dose of 300-400 mg in 2-3 divided doses by day 4. Make further adjustments as needed at intervals of at least 2 days in adjustments of 25-50 mg twice daily. Usual maintenance range: 300-800 mg/day
 Mania: Initial: 50 mg twice daily on day 1, increase dose in increments of 100 mg/day to 200 mg twice daily on day 4; may increase to a target dose of 800 mg/day by day 6 at increments of ≤200 mg/day. Usual dosage range: 400-800 mg/day

Elderly: 40% lower mean oral clearance of quetiapine in adults >65 years of age; higher plasma levels expected and, therefore, dosage adjustment may be needed; elderly patients usually require 50-200 mg/day

Dosing comments in renal insufficiency: 25% lower mean oral clearance of quetiapine than normal subjects; however, plasma concentrations similar to normal subjects receiving the same dose; no dosage adjustment required

Dosing comments in hepatic insufficiency: 30% lower mean oral clearance of quetiapine than normal subjects; higher plasma levels expected in hepatically impaired subjects; dosage adjustment may be needed

Initial: 25 mg/day, increase dose by 25-50 mg/day to effective dose, based on clinical response and tolerability to patient

Monitoring Parameters Vital signs; fasting lipid profile and fasting blood glucose/Hgb A_{1c} (prior to treatment, at 3 months, then annually); BMI, personal/family history of obesity, waist circumference; blood pressure; mental status, abnormal involuntary movement scale (AIMS); Weight should be assessed prior to treatment, at 4 weeks, 8 weeks, 12 weeks, and then at quarterly intervals. Consider titrating to a different antipsychotic agent for a weight gain ≥5% of the initial weight. Patients should have eyes checked for cataracts every 6 months while on this medication.

Contraindications Hypersensitivity to quetiapine or any component of the formulation; severe CNS depression; bone marrow suppression; blood dyscrasias; severe hepatic disease, coma

Warnings

[U.S. Boxed Warning]: Patients with dementia-related behavioral disorders treated with atypical antipsychotics are at an increased risk of death compared to placebo. Quetiapine is not approved for this indication.

Has been noted to cause cataracts in animals, lens examination on initiation of therapy and every 6 months is recommended. May be sedating, use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Caution in patients with hemodynamic instability; prior myocardial infarction or ischemic heart disease; hypercholesterolemia; thyroid disease; predisposition to seizures; subcortical brain damage; hepatic impairment; severe cardiac, renal, or respiratory disease. May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May alter cardiac conduction - life-threatening arrhythmias have occurred with therapeutic doses of antipsychotics. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications)

which may predispose). Esophageal dysmotility and aspiration have been associated with antipsychotic use - use with caution in patients at risk of pneumonia (ie, Alzheimer's disease).

May cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention); therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other antipsychotics, quetiapine has a moderate potency of cholinergic blockade. The risk of extrapyramidal symptoms, tardive dyskinesia, and neuroleptic malignant syndrome (NMS) in association with quetiapine is very low relative to other antipsychotics. May cause hyperglycemia; in some cases may be extreme and associated with ketoacidosis, hyperosmolar coma, or death. Use with caution in patients with diabetes or other disorders of glucose regulation; monitor for worsening of glucose control.

The possibility of a suicide attempt is inherent in psychotic illness or bipolar disorder; use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care.

Dosage Forms Tablet, as fumarate:

Seroquel®: 25 mg, 50 mg, 100 mg, 200 mg, 300 mg, 400 mg

Reference Range Serum range for quetiapine doses from 300-600 mg: ~44-91 ng/mL. Serum quetiapine level following a 20 g overdose (and associated with deep coma) was 12,700 ng/mL. Postmortem cavity blood and liver quetiapine levels of 170,000 ng/mL and 190 mg/kg, respectively, were found in a quetiapine fatality. Quetiapine may undergo postmortem redistribution.

Overdosage/Treatment

Decontamination: Lavage/activated charcoal can be given for ingestions >25 mg/kg. Care is primarily supportive.

Supportive therapy: Hypotension can be treated initially with isotonic saline and Trendelenburg positioning. Refractory hypotension can be treated with alpha adrenergic agonists such as norepinephrine or phenylephrine. Avoid bretylium due to its alpha adrenergic blocking activity.

Supportive therapy for phenelzine: Quetiapine (50 mg) can be given for phenelzine-induced insomnia.

Test Interactions Quetiapine recipients may exhibit false-positive results on tricyclic antidepressants assays. There is interference by quetiapine with antibodies used in some TCA immunoassays (Syva®, Microgenics®, and Triage®).

Drug Interactions

Substrate of CYP2D6 (minor), 3A4 (major)

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Antihypertensives: Concurrent use with an antihypertensive may produce additive hypotensive effects (particularly orthostasis)

Azole antifungals (fluconazole, itraconazole, ketoconazole): Administration with ketoconazole increases serum concentration of quetiapine by 335%; use with caution.

Cimetidine: May decrease quetiapine's clearance by 20%; increasing serum concentrations.

CNS depressants: Quetiapine may enhance the sedative effects of other CNS depressants; includes antidepressants, benzodiazepines, barbiturates, ethanol, narcotic analgesics, and other sedative agents; monitor for increased effect.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of quetiapine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins. Higher maintenance doses of quetiapine may be required.

CYP3A4 inhibitors: May increase the levels/effects of quetiapine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Divalproex: Concomitant use of quetiapine and divalproex increased the mean maximum plasma concentration of quetiapine at by 17% at steady state. The mean oral clearance of valproic acid was increased by 11%.

Levodopa: Quetiapine may inhibit the antiparkinsonian effect of levodopa; monitor.

Lorazepam: Metabolism of lorazepam may be reduced by quetiapine; clearance is reduced 20% in the presence of quetiapine; monitor for increased sedative effect.

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk. Phenytoin: Metabolism/clearance of quetiapine may be increased; five-fold changes have been noted. Higher maintenance doses of quetiapine may be required.

Thioridazine: May increase clearance of quetiapine, decreasing serum concentrations; clearance may be increased by 65%.

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/not recommended

Quinagolide

CAS Number 87056-78-8; 94424-50-7

Use Treat hyperprolactinemia

Mechanism of Action Potent nonergot dopamine-D₂ receptor agonist; octahydrobenzoyl (g) quinolone compound

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), palpitations, pre-eclampsia, sinus bradycardia

Central nervous system: Headache, dizziness, lethargy, psychosis, delusions, CNS depression, depression

Endocrine & metabolic: Hot flashes

Gastrointestinal: Weight loss, **nausea, vomiting**, constipation, anorexia, xerostomia

Neuromuscular & skeletal: Muscle cramps

Respiratory: Nasal congestion

Toxicodynamics/Kinetics

Onset of action: 2 hours

Peak onset: 4 hours

Dosage Hyperprolactinemia: 0.03-0.5 mg/day; usual dosage range: 0.05-0.1 mg/day at bedtime with food; maximum dose: 1.65 mg/day

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with sorbitol
Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Test Interactions May ↑ serum estradiol levels; ↓ prolactin level (S); may reduce thyroxine level (S)

Additional Information Especially useful in patients resistant to bromocriptine; may be useful in the treatment of acromegaly, Parkinson's disease, or for use in lactation inhibition; promotes reduction in pituitary microadenoma size; decreases galactorrhea

Quinapril

Related Information

- Angiotensin Agents

CAS Number 82586-55-8; 85441-61-8

U.S. Brand Names Accupril®

Synonyms Quinapril Hydrochloride

Use Management of hypertension; treatment of congestive heart failure

Unlabeled/Investigational Use Treatment of left ventricular dysfunction after myocardial infarction

Mechanism of Action Competitive inhibition of angiotensin I being converted to angiotensin II, a potent vasoconstrictor, through the angiotensin I-converting enzyme (ACE) activity, with resultant lower levels of angiotensin II which causes an increase in plasma renin activity and a reduction in aldosterone secretion

Adverse Reactions

Cardiovascular: Hypotension, myocardial infarction, angina pectoris, hypotension (orthostatic), rhythm disturbances, tachycardia, vasculitis, palpitations, syncope, flushing, peripheral edema, chest discomfort, sinus tachycardia, vasodilation

Central nervous system: Dizziness, headache, fatigue, malaise, CNS depression, somnolence, insomnia, fever, depression

Dermatologic: Urticaria, pruritus, angioneurotic edema, exfoliative dermatitis, photosensitivity, exanthem, pemphigus vulgaris

Endocrine & metabolic: Hypoglycemia

Gastrointestinal: Diarrhea, abdominal pain, anorexia, constipation, flatulence, xerostomia, pancreatitis

Hematologic: Neutropenia, bone marrow suppression

Hepatic: Hepatitis

Neuromuscular & skeletal: Gout, arthralgia, shoulder pain, paresthesia

Ocular: Blurred vision, visual hallucinations

Renal: Elevated BUN/serum creatinine

Respiratory: Upper respiratory symptoms, cough, bronchospasm, bronchitis, sinusitis, pharyngeal pain

Miscellaneous: Diaphoresis

Pharmacodynamics/Kinetics

Onset of action: 1 hour

Duration: 24 hours

Absorption: Quinapril: $\geq 60\%$

Protein binding: Quinapril: 97%; Quinaprilat: 97%

Metabolism: Rapidly hydrolyzed to quinaprilat, the active metabolite

Half-life elimination: Quinapril: 0.8 hours; Quinaprilat: 3 hours; increases as Cl_{cr} decreases

Time to peak, serum: Quinapril: 1 hour; Quinaprilat: ~2 hours

Excretion: Urine (50% to 60% primarily as quinaprilat)

Dosage

Adults: Oral:

Hypertension: Initial: 10-20 mg once daily, adjust according to blood pressure response at peak and trough blood levels; initial dose may be reduced to 5 mg in patients receiving diuretic therapy if the diuretic is continued; usual dose range (JNC 7): 10-40 mg once daily

Congestive heart failure or post-MI: Initial: 5 mg once daily, titrated at weekly intervals to 20-40 mg daily in 2 divided doses

Elderly: Initial: 2.5-5 mg/day; increase dosage at increments of 2.5-5 mg at 1- to 2-week intervals.

Dosing adjustment in renal impairment: Lower initial doses should be used; after initial dose (if tolerated), administer initial dose twice daily; may be increased at weekly intervals to optimal response:

Hypertension: Initial:

$Cl_{cr} > 60$ mL/minute: Administer 10 mg/day

$Cl_{cr} 30-60$ mL/minute: Administer 5 mg/day

$Cl_{cr} 10-30$ mL/minute: Administer 2.5 mg/day

Congestive heart failure: Initial:

$Cl_{cr} > 30$ mL/minute: Administer 5 mg/day

$Cl_{cr} 10-30$ mL/minute: Administer 2.5 mg/day

Dosing comments in hepatic impairment: In patients with alcoholic cirrhosis, hydrolysis of quinapril to quinaprilat is impaired; however, the subsequent elimination of quinaprilat is unaltered.

Stability Store at room temperature

Monitoring Parameters BUN, serum creatinine, renal function; nausea, headache, diarrhea, change in taste, cough

Contraindications Hypersensitivity to quinapril or any component of the formulation; angioedema related to previous treatment with an ACE inhibitor; bilateral renal artery stenosis; patients with idiopathic or hereditary angioedema; pregnancy (2nd and 3rd trimesters)

Warnings

Anaphylactic reactions can occur. Angioedema can occur at any time during treatment (especially following first dose). It may involve head and neck (potentially affecting the airway) or the intestine (presenting with abdominal pain). Prolonged monitoring may be required especially if tongue, glottis, or larynx are involved as they are associated with airway obstruction. Those with a history of airway surgery in this situation have a higher risk. Careful blood pressure monitoring with first dose (hypotension can occur especially in volume-depleted patients).

[U.S. Boxed Warning]: Based on human data, ACEIs can cause injury and death to the developing fetus when used in the second and third trimesters. ACEIs should be discontinued as soon as possible once pregnancy is detected. Dosage adjustment needed in renal impairment. Use with caution in hypovolemia; collagen vascular diseases; valvular stenosis (particularly aortic stenosis); hyperkalemia; or before, during, or immediately after anesthesia. Avoid rapid dosage escalation, which may lead to renal insufficiency. Rare toxicities associated with ACE inhibitors include cholestatic jaundice (which may progress to hepatic necrosis) and neutropenia/agranulocytosis with myeloid hyperplasia. If patient has renal impairment, a baseline

WBC with differential and serum creatinine should be evaluated and monitored closely during the first 3 months of therapy.

Hypersensitivity reactions may be seen during hemodialysis with high-flux dialysis membranes (eg, AN69). Patients receiving ACE inhibitors have experienced rare life-threatening anaphylactoid reactions during desensitization. Rare hepatic reactions, progressing from cholestatic jaundice to hepatic necrosis, have been reported with ACE inhibitors. Discontinue if marked elevation of hepatic transaminases or jaundice occurs. Use with caution in unilateral renal artery stenosis and pre-existing renal insufficiency. Deterioration in renal function can occur with initiation.

Dosage Forms Tablet: 5 mg, 10 mg, 20 mg, 40 mg

Accupril®: 5 mg, 10 mg, 20 mg, 40 mg

Reference Range Following a 10 mg dose, peak serum levels of quinapril and quinaprilat are 65 mg/mL and 223 ng/mL, respectively

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Naloxone has been shown to antagonize hypotensive effects of captopril, but routine use in an overdose situation due to this agent is uncertain. For refractory hypotension, angiotensin amide infusion may be attempted.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; hemodialysis is not effective

Test Interactions \uparrow potassium (S)

Drug Interactions Alpha₁ blockers: Hypotensive effect increased.

Aspirin: The effects of ACE inhibitors may be blunted by aspirin administration, particularly at higher dosages (see Cardiovascular Considerations) and/or increase adverse renal effects.

Diuretics: Hypovolemia due to diuretics may precipitate acute hypotensive events or acute renal failure.

Insulin: Risk of hypoglycemia may be increased.

Lithium: Risk of lithium toxicity may be increased; monitor lithium levels, especially the first 4 weeks of therapy.

Mercaptopurine: Risk of neutropenia may be increased.

NSAIDs: May attenuate hypertensive efficacy; effect has been seen with captopril and may occur with other ACE inhibitors; monitor blood pressure. May increase risk of adverse renal effects.

Potassium-sparing diuretics (amiloride, spironolactone, triamterene): Increased risk of hyperkalemia.

Potassium supplements may increase the risk of hyperkalemia.

Quinolones: Absorption may be decreased by quinapril; separate administration by at least 2-4 hours.

Tetracyclines: Absorption may be reduced by quinapril; separate administration by at least 2-4 hours.

Trimethoprim (high dose) may increase the risk of hyperkalemia.

Pregnancy Risk Factor C (1st trimester)/D (2nd and 3rd trimesters)

Pregnancy Implications Decreased placental blood flow, low birth weight, fetal hypotension, preterm delivery, and fetal death have been noted with the use of some ACE inhibitors (ACEIs) in animal studies. Neonatal hypotension, skull hypoplasia, anuria, renal failure, oligohydramnios (associated with fetal limb contractures, craniofacial deformities, hypoplastic lung development), prematurity, intrauterine growth retardation, and patent ductus arteriosus have been reported with the use of ACEIs, primarily in the 2nd and 3rd trimesters. The risk of neonatal toxicity has been considered less when ACEIs have been used in the 1st trimester; however, major congenital malformations have been reported. The cardiovascular and/or central nervous systems are most commonly affected. Unless alternative agents are not appropriate, ACEIs should be discontinued as soon as possible once pregnancy is detected.

Lactation Enters breast milk/use caution

Nursing Implications May cause depression in some patients; discontinue if angioedema of the face, extremities, lips, tongue, or glottis occurs; watch for hypotensive effects within 1-3 hours of first dose or new higher dose

Additional Information Patients taking diuretics are at risk for developing hypotension on initial dosing; to prevent this, discontinue diuretics 2-3 days prior to initiating quinapril; may restart diuretics if blood pressure is not controlled by quinapril alone

Due to frequent decreases in glomerular filtration (also creatinine clearance) with aging, elderly patients may have exaggerated responses to ACE inhibitors; differences in clinical response due to hepatic changes are not observed. ACE inhibitors may be preferred agents in elderly patients with CHF and diabetes mellitus. Diabetic proteinuria is reduced and insulin sensitivity is enhanced. In general, the side effect profile is favorable in elderly and causes little or no CNS confusion; use lowest dose recommendations initially.

Quinidine

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 27555-34-6; 50-54-4; 56-52-2; 6151-39-9; 63717-04-4; 65484-56-2; 6591-63-5; 7054-25-3; 72402-50-7; 747-45-4

U.S. Brand Names Quinaglute® Dura-Tabs® [DSC]

Synonyms Quinidine Gluconate; Quinidine Polygalacturonate; Quinidine Sulfate

Use Prophylaxis after cardioversion of atrial fibrillation and/or flutter to maintain normal sinus rhythm; prevent recurrence of paroxysmal supraventricular tachycardia, paroxysmal AV junctional rhythm, paroxysmal ventricular tachycardia, paroxysmal atrial fibrillation, and atrial or ventricular premature contractions; has activity against *Plasmodium falciparum* malaria

Mechanism of Action Depresses phase 0 of the action potential; decreases myocardial excitability and conduction velocity, and myocardial contractility by decreasing sodium influx during depolarization and potassium efflux in repolarization; also reduces calcium transport across cell membrane; class I antiarrhythmic

Adverse Reactions

Cardiovascular: Syncope, hypotension, tachycardia, heart block, fibrillation (ventricular), vascular collapse, severe hypotension with rapid I.V. administration, torsade de pointes, sinus bradycardia, sinus tachycardia, vasculitis

Central nervous system: Dizziness, confusion, delirium, hallucinations, agitation, psychosis, headache, memory disturbance, insomnia, paranoia

Dermatologic: Angioedema, pruritus, rash, may exacerbate psoriasis, eczematous dermatitis, skin discoloration (blue-gray), exfoliative dermatitis, erythema multiforme, acne, acute generalized exanthematous pustulosis, alopecia, bullous skin disease, toxic epidermal necrolysis, photoallergy, exanthem, cutaneous vasculitis

Endocrine & metabolic: Hyperinsulinemia

Gastrointestinal: Nausea, vomiting, stomach cramps, bitter taste, anorexia, diarrhea, esophagitis, abdominal pain

Hematologic: Blood dyscrasias, thrombocytopenic purpura, hemolysis, agranulocytosis, aplastic anemia

Hepatic: Cholestatic jaundice, granulomatous hepatitis

Ocular: Impaired vision, photophobia, diplopia

Otic: Ototoxicity, tinnitus

Renal: Renal vasculitis

Respiratory: Apnea, respiratory depression, eosinophilic pneumonia

Miscellaneous: Fever with leukocytosis; can cause drug-induced systemic lupus erythematosus or SICCA syndrome or drug fever; cinchonism, lymphadenopathy, fixed drug eruption

Signs and Symptoms of Overdose Absence of P waves, agranulocytosis, anuria, apnea, ataxia, AV block, bradycardia, coma, dementia, depression, drowsiness, granulocytopenia, hallucinations, heart block, hyperthermia, hypoglycemia, leukopenia, lichenoid eruptions, memory loss, myasthenia gravis (exacerbation or precipitation), mydriasis, myoglobinuria, neutropenia, photosensitivity, P-R prolongation, respiratory distress with shallow respirations, QRS prolongation, QT prolongation, rhabdomyolysis, seizures, severe hypotension, syncope, thrombocytopenia, ventricular arrhythmias

Pharmacodynamics/Kinetics

Onset of action: I.M.: 15 minutes

Duration: Oral: Regular tablets or capsules: 6-8 hours; Extended-release tablets: ~12 hours

Absorption: Well from gastrointestinal tract; peak oral absorption: 60-90 minutes

Distribution: V_d : Adults: 2-3.5 L/kg, decreased V_d with congestive heart failure, malaria, increased V_d with cirrhosis; cirrhosis, or acute myocardial infarction; all tissues except brain; concentrates in heart, liver, kidneys, and skeletal muscle

Protein binding: Newborns: 60% to 70%; Adults: 80% to 90%

Decreased protein-binding with cyanotic congenital heart disease

Metabolism: Extensive in the liver

Bioavailability: Sulfate: 80%; Gluconate: 70%

Half-life: Children: 2.5-6.7 hours; Adults: 6-8 hours

Increased half-life with elderly, cirrhosis and congestive heart failure

Time to peak plasma concentration: 1-3 hours

Elimination: Urine (15% to 25% as unchanged drug); clearance: 4.7 mL/kg/minute; ~37% of the drug is normally excreted in 4 hours in a healthy person

Dosage Dosage expressed in terms of the salt: 267 mg of quinidine gluconate = 200 mg of quinidine sulfate.

Children: Test dose for idiosyncratic reaction (sulfate, oral or gluconate, I.M.): 2 mg/kg or 60 mg/m²

Oral (quinidine sulfate): 15-60 mg/kg/day in 4-5 divided doses or 6 mg/kg every 4-6 hours; usual 30 mg/kg/day or 900 mg/m²/day given in 5 daily doses

I.V. **not** recommended (quinidine gluconate): 2-10 mg/kg/dose given at a rate \leq 10 mg/minute every 3-6 hours as needed

Adults: Test dose: Oral, I.M.: 200 mg administered several hours before full dosage (to determine possibility of idiosyncratic reaction)

Oral (for malaria):

Sulfate: 100-600 mg/dose every 4-6 hours; begin at 200 mg/dose and titrate to desired effect (maximum daily dose: 3-4 g)

Gluconate: 324-972 mg every 8-12 hours

I.M.: 400 mg/dose every 2-6 hours; initial dose: 600 mg (gluconate)

I.V.: 200-400 mg/dose diluted and given at a rate \leq 10 mg/minute; may require as much as 500-750 mg

Dosing adjustment in renal impairment: $Cl_{cr} < 10$ mL/minute: Administer 75% of normal dose.

Hemodialysis: Slightly hemodialyzable (5% to 20%); 200 mg supplemental dose posthemodialysis is recommended.

Peritoneal dialysis: Not dialyzable (0% to 5%)

Dosing adjustment/comments in hepatic impairment: Larger loading dose may be indicated, reduce maintenance doses by 50% and monitor serum levels closely.

Stability Do not use discolored parenteral solution

Monitoring Parameters Cardiac monitor required during I.V. administration; CBC, liver and renal function tests, should be routinely performed during long-term administration

Administration Administer around-the-clock to promote less variation in peak and trough serum levels

Oral: Do not crush, chew, or break sustained release dosage forms.

Parenteral: When injecting I.M., aspirate carefully to avoid injection into a vessel; maximum I.V. infusion rate: 10 mg/minute

Contraindications Hypersensitivity to quinidine or any component of the formulation; thrombocytopenia; thrombocytopenic purpura; myasthenia gravis; heart block greater than first degree; idioventricular conduction delays (except in patients with a functioning artificial pacemaker); those adversely affected by anticholinergic activity; concurrent use of quinolone antibiotics which prolong QT interval, cisapride, amprenavir, or ritonavir

Warnings Monitor and adjust dose to prevent QT_c prolongation. Watch for proarrhythmic effects. Correct hypokalemia before initiating therapy. Hypokalemia may worsen toxicity. **[U.S. Boxed Warning]: Antiarrhythmic drugs have not been shown to enhance survival in nonlife-threatening ventricular arrhythmias and may increase mortality; the risk is greatest with structural heart disease. Quinidine may increase mortality in treatment of atrial fibrillation/flutter.** may precipitate or exacerbate CHF. Reduce dosage in hepatic impairment. Use may cause digoxin-induced toxicity (adjust digoxin's dose). Use caution with concurrent use of other antiarrhythmics. Hypersensitivity reactions can occur. Can unmask sick sinus syndrome (causes bradycardia). Has been associated with severe hepatotoxic reactions, including granulomatous hepatitis. Hemolysis may occur in patients with G6PD (glucose-6-phosphate dehydrogenase) deficiency. Different salt products are not interchangeable.

Dosage Forms Injection, solution, as gluconate: 80 mg/mL (10 mL) [equivalent to quinidine base 50 mg/mL]

Tablet, as sulfate: 200 mg, 300 mg

Tablet, extended release, as gluconate: 324 mg [equivalent to quinidine base 202 mg]

Tablet, extended release, as sulfate: 300 mg [equivalent to quinidine base 249 mg]

Reference Range Therapeutic: 2-5 mcg/mL (SI: 6.2-15.4 μ mol/L). Patient dependent therapeutic response occurs at levels of 3-6 mcg/mL (SI: 9.2-18.5 μ mol/L). Optimal therapeutic level is method dependent; > 8 mcg/mL (SI: > 24 μ mol/L) are associated with cinchonism while levels > 14 ng/L are associated with cardiac toxicity

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Electrolyte balance should be monitored and treated, especially when refractory arrhythmias develop. Sodium bicarbonate 1-2 mEq/kg I.V. (or 0.5-1 mEq/kg in children) may decrease conduction defects. Phenytoin or lidocaine are often effective at controlling drug-induced arrhythmias, while phenytoin is preferred due to its beneficial effects on AV conduction velocity. Torsade de pointes can be treated with magnesium sulfate or overdrive pacemaker. Cholestyramine (4-8 g/day) is effective for treating quinidine-induced diarrhea. Dopamine and/or norepinephrine can be used to treat refractory hypotension.

Extracorporeal membrane oxygenation has been used successfully to establish and maintain cardiovascular stability.

Enhancement of elimination: Multiple dosing of activated charcoal is effective; hemodialysis or charcoal hemoperfusion have little effect, although hemoperfusion can be considered in patients with hepatic failure; slightly dialyzable (5% to 20%)

Antidote(s)

- Sodium Bicarbonate [ANTIDOTE]

Test Interactions ↑ prothrombin time; ↓ glucose; may interfere with urinary analysis of catecholamines; triamterene can interfere with the fluorescent measurement of quinidine, leading to falsely elevated quinidine assays

Drug Interactions Substrate of CYP2C9 (minor), 2E1 (minor), 3A4 (major); **Inhibits** CYP2C9 (weak), 2D6 (strong), 3A4 (strong)

Amiloride may cause prolonged ventricular conduction leading to arrhythmias.

Amiodarone may increase quinidine blood levels; monitor quinidine levels.

Cimetidine: Increase quinidine blood levels; closely monitor levels or use an alternative H₂ antagonist.

Cisapride and quinidine may increase risk of malignant arrhythmias; concurrent use is contraindicated.

Codeine: Analgesic efficacy may be reduced.

CYP2D6 substrates: Quinidine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Quinidine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of quinidine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of quinidine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, telithromycin, and verapamil.

CYP3A4 substrates: Quinidine may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Digoxin blood levels may be increased. Monitor digoxin blood levels.

Metoprolol: Increased metoprolol blood levels.

Mexiletine blood levels may be increased.

Nifedipine blood levels may be increased by quinidine; nifedipine may decrease quinidine blood levels.

Propafenone blood levels may be increased.

Propranolol blood levels may be increased.

QT_c-prolonging agents (eg, amiodarone, amitriptyline, bepridil, disopyramide, erythromycin, haloperidol, imipramine, pimozide, procainamide, sotalol, thioridazine): Effects may be additive; use with caution.

Ritonavir, nelfinavir and amprenavir may increase quinidine levels and toxicity; concurrent use is contraindicated.

Sparfloxacin, gatifloxacin, and moxifloxacin may result in additional prolongation of the QT interval; concurrent use is contraindicated.

Timolol blood levels may be increased.

Urinary alkalinizers (antacids, sodium bicarbonate, acetazolamide) increase quinidine blood levels.

Verapamil and diltiazem increase quinidine blood levels.

Warfarin effects may be increased by quinidine; monitor INR closely during addition or withdrawal of quinidine.

Pregnancy Risk Factor C

Lactation Enters breast milk/compatible

Nursing Implications When injecting I.M., aspirate carefully to avoid injection into a vessel; do not crush sustained release drug product

Additional Information Doses > 250 mg/day of quinidine result in increased serum digoxin concentrations about 2.5 times the digoxin concentration before quinidine was added. The new steady-state of digoxin concentration occurs in 7-14 days, with signs of toxicity beginning to appear in 3-7 days after initiation of quinidine therapy. Therefore, **serum digoxin concentrations should be measured before initiation of quinidine therapy and again in 4-6 days.** Measure trough because of variability of peak interval. **Renal failure** prolongs apparent half-life, perhaps through accumulation of fluorescent metabolites. Severe heart failure also prolongs half-life, as does liver disease. Concomitant administration of **phenytoin** increases hepatic metabolism, and therefore decreases half-life and serum quinidine concentrations. Clearance may be diminished in the elderly.

Quinine

Related Information

- Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 130-95-0

Synonyms Quinine Sulfate

Use Suppression or treatment of chloroquine-resistant *P. falciparum* malaria; treatment of *Babesia microti* infection

Prevention and treatment of nocturnal recumbency leg muscle cramps

Mechanism of Action Not completely understood; depresses oxygen uptake and carbohydrate metabolism; intercalates into DNA, disrupting the parasite's replication and transcription; affects calcium distribution within muscle fibers and decreases the excitability of the motor end-plate region; interferes with function of plasmodial DNA; also, recent evidence suggests it may also do this through increased pH of plasmodial organelles; local anesthetic action and analgesic properties

Adverse Reactions

Cardiovascular: Flushing of the skin, angina, syncope, cardiac arrhythmias, hypotension, sinus bradycardia, chest pain, QRS prolongation

Central nervous system: **Severe headache**, CNS depression, seizures, fever, fear, restlessness, psychosis, dizziness, ataxia, insomnia, hyperthermia

Dermatologic: Rash, pruritus, acne, exfoliative dermatitis, angioedema, bullous skin disease, urticaria, purpura, photoallergy, licheniform eruptions, exanthem, cutaneous vasculitis

Endocrine & metabolic: Hypoglycemia, hyperinsulinemia, abortifacient

Gastrointestinal: **Nausea, diarrhea, vomiting**, abdominal pain, altered taste, bitter taste

Hematologic: Thrombocytopenia, leukopenia, neutropenia, agranulocytosis, granulocytopenia, blackwater fever, hemolytic/uremic syndrome, disseminated intravascular coagulation

Hepatic: Hepatitis, elevated liver function test results, granulomatous hepatitis

Neuromuscular & skeletal: Myasthenia gravis (exacerbation or precipitation of)

Ocular: **Blurred vision**, night blindness, diplopia, optic atrophy, photophobia

Otic: **Tinnitus**, ototoxicity

Respiratory: Apnea, respiratory depression

Miscellaneous: Symptoms of cinchonism, hypersensitivity reactions, diaphoresis, fixed drug eruption

Signs and Symptoms of Overdose Abdominal pain, AV block, blindness (with a dose > 5 g), blood dyscrasias, bradycardia, cardiac arrhythmias, cinchonism-ototoxicity, coma, confusion, deafness, erythema multiforme, headache, hemolysis, hypoglycemia, hypokalemia, hypoprothrombinemia, hypotension, methemoglobinemia, mydriasis, myoglobinuria, nausea, nephritis, nystagmus, photosensitivity, renal injury, rhabdomyolysis, tinnitus (38%), toxic epidermal necrolysis, urine discoloration (black; brown; dark; red-brown), vision color changes (green tinge; red tinge), visual disturbance

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Pharmacodynamics/Kinetics

Onset of action: 1-3 hours

Duration: Regular: 6-8 hours; Extended: ~ 12 hours

Absorption: Oral: Readily absorbed, mainly from the upper small intestine even in diarrhea

Distribution: V_d: 1.2-1.7 L/kg; higher in convalescent malaria; distributed in all tissues except brain; concentrates in heart, liver, kidneys, and skeletal muscle

Protein binding: 70% to 95%

Metabolism: Primarily in the liver

Half-life: 6-12 hours; lower in active or convalescent malaria; Adults: 8-14 hours; Patients with liver failure: 66-99 hours

Time to peak serum concentration: Oral: 1-1.5 hours; I.M.: 1 hour

Elimination: Not effectively removed by peritoneal dialysis, removed by hemodialysis; excreted in bile and saliva with <5% excreted unchanged in urine; excretion in urine is twice as rapid if urine is acidic

Dosage

Oral:

Children: Chloroquine-resistant malaria and babesiosis: 25 mg/kg/day in divided doses every 8 hours for 7 days; maximum: 650 mg/dose

RADIOLOGICAL/CONTRAST MEDIA (NONIONIC)

Adults:

Chloroquine-resistant malaria: 650 mg every 8 hours for 7 days in conjunction with another agent

Babesiosis: 650 mg every 6-8 hours for 7 days

Leg cramps: 200-300 mg at bedtime

Dosing interval/adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer every 8-12 hours or 75% of normal dose

Cl_{cr} <10 mL/minute: Administer every 24 hours or 30% to 50% of normal dose

Monitoring Parameters Monitor CBC with platelet count, liver function tests, blood glucose, ophthalmologic examination

Administration

Avoid use of aluminum-containing antacids because of drug absorption problems. Swallow dose whole to avoid bitter taste. May be administered with food.

Contraindications Hypersensitivity to quinine or any component of the formulation; tinnitus, optic neuritis, G6PD deficiency; history of black water fever; thrombocytopenia with quinine or quinidine; pregnancy

Warnings Use with caution in patients with cardiac arrhythmias (quinine has quinidine-like activity) and in patients with myasthenia gravis

Dosage Forms Capsule, as sulfate: 200 mg, 325 mg

Tablet, as sulfate: 260 mg

Reference Range Therapeutic: 2.5-9.6 mcg/mL; Toxic: >10.0 mcg/mL; Fatal: >15.0 mcg/mL

Overdosage/Treatment

Decontamination: Emesis not recommended; lavage (within 1 hour) with 1:10,000 potassium permanganate 100 mg in 1 L water, indicated if early in ingestion

Supportive therapy: Stellate ganglion block procedure has not been shown to be of clear benefit as blindness is usually reversible; effect of nitrates uncertain; treat acidosis, hypoglycemia accordingly; treat cardiac conduction defects with sodium bicarbonate (I.V. 1-3 mEq/kg), titrate to serum pH 7.45-7.50; control seizures with benzodiazepine prior to lavage. Quinine-induced hypoglycemia can be treated with octreotide (50 mcg I.V. every 12 hours)

Arrhythmias: Avoid disopyramide/procainamide (class IA and IC)

Ventricular tachycardia: Pacing, conversion, isoproterenol 2-10 mcg/minute (0.1-1 mcg/kg/minute (children))

Torsade de pointes: MgSO₄ 2 g, then drip at 3-20 mg/minute

Bradycardia: Pacing, standard therapy

Hypotension: Norepinephrine, isoproterenol effective

Enhancement of elimination: Studies have demonstrated enhanced elimination with multiple dose charcoal; hemodialysis minimally effective (not recommended)

Antidote(s)

- Norepinephrine [ANTIDOTE]

Test Interactions ↑ prothrombin time; positive Coombs' [direct]

Drug Interactions **Substrate** (minor) of CYP1A2, 2C19, 3A4; **Inhibits** CYP2C8 (moderate), 2C9 (moderate), 2D6 (strong), 3A4 (weak)

CYP2C8 Substrates: Quinine may increase the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP2C9 Substrates: Quinine may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

CYP2D6 substrates: Quinine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Quinine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

Decreased effect: Phenobarbital, phenytoin, aluminum salt antacids, and rifampin may decrease quinine serum concentrations

Increased toxicity:

To avoid risk of seizures and cardiac arrest, delay mefloquine dosing at least 12 hours after last dose of quinine

Beta-blockers + quinine may increase bradycardia

Quinine may enhance coumarin anticoagulants and potentiate non-depolarizing and depolarizing muscle relaxants

Quinine may increase plasma concentration of digoxin by as much as twofold; closely monitor digoxin concentrations and decrease digoxin dose with initiation of quinine by ¹/₂

Verapamil, amiodarone, urinary alkalinizing agents, and cimetidine may increase quinine serum concentrations

Pregnancy Risk Factor X Oxytocic action

Lactation Enters breast milk/compatible

Nursing Implications Administer by slow I.V. infusion

Additional Information

Adults: Minimum lethal dose: 5 g. Toxic dose: 2 g

Parenteral dosage form may be obtained from the Centers for Disease

Control if needed; a common adulterant in street drugs. The FDA does not allow more than 2.45 mg/ounce of quinine in any carbonated beverage (CRF 21 part 172.575).

Radiological/Contrast Media (Nonionic)

Pronunciation (ray deo LOG ik al/KON trast MEE dia non eye ON ik)

Related Information

- Contrast Media Reactions, Premedication for Prophylaxis

U.S. Brand Names Amipaque® [DSC]; Isovue®; Omnipaque®; Optiray®; ProHance®

Synonyms Iohexol; Iopamidol; Ioversol; Metrizamide

Impairment Potential None

Use Enhance visualization of structures during radiologic procedures

Mechanism of Action Iodine content is radiopaque and thus allows for radiographic visualization.

Adverse Reactions

Cardiovascular: Hypotension, bradycardia, flushing

Central nervous system: Headache, seizures, aphasia

Dermatologic: Pruritus, pallor, urticaria

Endocrine & metabolic: Dehydration

Gastrointestinal: Nausea, vomiting, diarrhea, metallic taste

Hematologic: Hemolysis

Ocular: Cortical blindness

Renal: Renal insufficiency, proteinuria

Respiratory: Cough

Neuromuscular & skeletal: Weakness

Miscellaneous: Hypersensitivity reaction, anaphylaxis

Contraindications Known hypersensitivity

Warnings Anaphylactic-like reactions and hypotension; acute severe back, leg or groin pain; decision to use contrast enhancement should include consideration of risk of the drug, risk of the procedure, expected benefit of the image and patient's underlying disorder

Dosage Forms

[DSC] = Discontinued product

Injection, solution:

Gadoteridol (ProHance®): 279.3 mg/mL (15 mL, 30 mL, 50 mL) [single use vial]; 279.3 mg/mL (20 mL) [prefilled syringe]

Iohexol (Omnipaque®): 140 mg/mL, 180 mg/mL, 210 mg/mL, 240 mg/mL, 300 mg/mL, 350 mg/mL

Iopamidol:

Isovue-128®

Isovue-200®

Isovue-300®

Isovue-370®

Isovue-M 200®

Isovue-M 300®

Ioversol:

Optiray® 160

Optiray® 240

Optiray® 320

Metrizamide: Amipaque® [DSC]

Overdosage/Treatment

Supportive therapy: Ensure adequate hydration; monitor for electrolyte disturbances. Hypotension can be treated with 10-20 mL/kg of crystalloid infusion and placement in Trendelenburg position. Dopamine or norepinephrine can be used for blood pressure support. Bradycardia can be treated with atropine. Hypersensitivity reactions and anaphylaxis can be treated with standard therapy. N-acetylcysteine may be renoprotective.

Enhanced elimination: Hemodialysis can remove most contrast media.

Antidote(s)

- Acetylcysteine [ANTIDOTE]

Test Interactions May interfere with thyroid function tests (especially protein-bound iodine assays).

Drug Interactions Interleukins: Risk of hypersensitivity reactions may be increased.

Metformin: Risk of metformin-induced acidosis may be increased by iodinated contrast agents. Discontinue metformin prior to contrast exposure and withhold for 48 hours.

Pregnancy Implications Diatrizoate D can cross the placenta; no specific fetal abnormalities noted

Specific References

Fedutes BA and Ansani NT, "Seizure Potential of Concomitant Medications and Radiographic Contrast Media Agents," *Ann Pharmacother*, 2003, 37(10):1506-10.

Raloxifene

CAS Number 82640-04-8; 84449-90-1

U.S. Brand Names Evista®

Synonyms Keoxifene Hydrochloride; NSC-706725; Raloxifene Hydrochloride

Use Prevention and treatment of osteoporosis in postmenopausal women
Unlabeled/Investigational Use Risk reduction for invasive breast cancer in postmenopausal women at increased risk for breast cancer

Mechanism of Action A selective estrogen receptor modulator, meaning that it affects some of the same receptors that estrogen does, but not all, and in some instances, it antagonizes or blocks estrogen; it acts like estrogen to prevent bone loss and improve lipid profiles (decreases total and LDL cholesterol but does not raise triglycerides), but it has the potential to block some estrogen effects such as those that lead to breast cancer and uterine cancer

Adverse Reactions

Note: Has been associated with increased risk of thromboembolism (DVT, PE) and superficial thrombophlebitis; risk is similar to reported risk of HRT

Cardiovascular: Chest pain

Central nervous system: Migraine, depression, insomnia, fever

Dermatologic: Rash

Endocrine & metabolic: Hot flashes, hypertriglyceridemia (in women with a history of increased triglycerides in response to oral estrogens)

Gastrointestinal: Nausea, dyspepsia, vomiting, flatulence, gastroenteritis, weight gain

Genitourinary: Vaginitis, urinary tract infection, cystitis, leukorrhea

Neuromuscular & skeletal: Leg cramps, arthralgia, myalgia, arthritis

Ocular: Retinal vein occlusion

Respiratory: Sinusitis, pharyngitis, cough, pneumonia, laryngitis

Miscellaneous: Infection, flu syndrome, diaphoresis

Signs and Symptoms of Overdose Incidence of overdose in humans has not been reported. In an 8-week study of postmenopausal women, a dose of raloxifene 600 mg/day was safely tolerated. No mortality was seen after a single oral dose in rats or mice at 810 times the human dose for rats and 405 times the human dose for mice.

Pharmacodynamics/Kinetics

Onset of action: 8 weeks

Absorption: ~60%

Distribution: 2348 L/kg

Protein binding: >95% to albumin and α -glycoprotein

Metabolism: Hepatic, extensive first-pass effect; metabolized to glucuronide conjugates

Bioavailability: ~2%

Half-life elimination: 27.7-32.5 hours

Excretion: Primarily feces; urine (0.2%)

Dosage Adults: Female: Oral: 60 mg/day which may be administered any time of the day without regard to meals

Monitoring Parameters Radiologic evaluation of bone mineral density (BMD) is the best measure of the treatment of osteoporosis; to monitor for the potential toxicities of raloxifene, complete blood counts should be evaluated periodically.

Administration May be administered any time of the day without regard to meals.

Contraindications Hypersensitivity to raloxifene or any component of the formulation; active or history of venous thromboembolic events; pregnancy; breast-feeding

Warnings Use caution in patients at high risk for venous thromboembolism (deep vein thrombosis, pulmonary embolism); patients with cardiovascular disease; history of cervical/uterine carcinoma; renal/hepatic insufficiency (however, pharmacokinetic data are lacking); concurrent use of estrogens; women with a history of elevated triglycerides in response to treatment with oral estrogens (or estrogen/progestin). Discontinue at least 72 hours prior to and during prolonged immobilization (postoperative recovery or prolonged bedrest). Safety and efficacy in premenopausal women or men have not been established.

Dosage Forms Tablet, as hydrochloride:

Evista®: 60 mg

Overdosage/Treatment

Decontamination: Oral: Lavage, activated charcoal are preferred modalities; cholestyramine can also decrease oral absorption; consider gastric decontamination for ingestions >1 g

Drug Interactions Cholestyramine: May decrease the absorption of raloxifene.

Levothyroxine: Raloxifene may decrease levothyroxine absorption; separate doses by several hours.

Pregnancy Risk Factor X

Pregnancy Implications Raloxifene should not be used by pregnant women or by women planning to become pregnant in the immediate future

Lactation Excretion in breast milk unknown/contraindicated

Additional Information The decrease in estrogen-related adverse effects with the selective estrogen-receptor modulators in general and

raloxifene in particular should improve compliance and decrease the incidence of cardiovascular events and fractures while not increasing breast cancer

Ramipril

Related Information

- Angiotensin Agents

CAS Number 87333-19-5

U.S. Brand Names Altace®

Use Treatment of hypertension, alone or in combination with thiazide diuretics; congestive heart failure treatment postmyocardial infarction

Unlabeled/Investigational Use Treatment of heart failure

Mechanism of Action Ramipril is a prodrug that is converted to ramiprilat in the serum (HOE 498); ramiprilat is an angiotensin-converting enzyme (ACE) inhibitor which prevents the formation of angiotensin II from angiotensin I and exhibits pharmacologic effects that are similar to captopril

Adverse Reactions

Higher rates of adverse reactions have generally been noted in patients with CHF. However, the frequency of adverse effects associated with placebo is also increased in this population.

Cardiovascular: Angina, edema, hypotension, postural hypotension, myocardial infarction, palpitations, symptomatic hypotension, syncope

Central nervous system: Agitation, amnesia, anxiety, cerebrovascular events, convulsions, depression, dizziness, fatigue, headache, insomnia, malaise, nervousness, somnolence, vertigo

Dermatologic: Angioedema, erythema multiforme, onycholysis, pemphigoid, pemphigus, photosensitivity, purpura, Stevens-Johnson syndrome, toxic epidermal necrolysis

Endocrine & metabolic: Hyperkalemia, hyponatremia, impotence

Hematologic: Agranulocytosis, bone marrow depression, decreased hematocrit, decreased hemoglobin, eosinophilia, hemolytic anemia, pancytopenia, thrombocytopenia

Hepatic: Elevated transaminase levels

Gastrointestinal: Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, dysphagia, gastroenteritis, increased salivation, nausea, pancreatitis, taste disturbance, vomiting, weight gain, xerostomia

Neuromuscular & skeletal: Arthralgia, arthritis, chest pain (noncardiac), myalgia, neuralgia, neuropathy, paresthesia, tremor

Ocular: Vision disturbances

Otic: Hearing loss, tinnitus

Renal: Elevated serum creatinine, elevated BUN, renal dysfunction, proteinuria; transient elevations of creatinine and/or BUN may occur more frequently

Respiratory: **Cough (increased)**, dyspnea, epistaxis

Miscellaneous: Anaphylactoid reaction, hypersensitivity reactions (fever, rash, urticaria), increased diaphoresis

Worsening of renal function may occur in patients with bilateral renal artery stenosis or in hypovolemia. In addition, a syndrome which may include fever, myalgia, arthralgia, interstitial nephritis, vasculitis, rash, eosinophilia with positive ANA, and elevated ESR has been reported with ACE inhibitors. Risk of pancreatitis and agranulocytosis may be increased in patients with collagen vascular disease or renal impairment.

Signs and Symptoms of Overdose Hyperuricemia, hyponatremia, insomnia, severe hypotension

Pharmacodynamics/Kinetics

Onset of action: 1-2 hours

Duration: 24 hours

Absorption: Well absorbed (50% to 60%)

Distribution: Plasma levels decline in a triphasic fashion; rapid decline is a distribution phase to peripheral compartment, plasma protein and tissue ACE (half-life 2-4 hours); 2nd phase is an apparent elimination phase representing the clearance of free ramiprilat (half-life: 9-18 hours); and final phase is the terminal elimination phase representing the equilibrium phase between tissue binding and dissociation

Metabolism: Hepatic to the active form, ramiprilat

Half-life elimination: Ramiprilat: Effective: 13-17 hours; Terminal: >50 hours

Time to peak, serum: ~1 hour

Excretion: Urine (60%) and feces (40%) as parent drug and metabolites

Dosage

Adults: Oral: 2.5-5 mg once daily, maximum: 20 mg/day

Dosing adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer 50% to 75% of normal dose

Cl_{cr} <40 mL/minute: Patients should be started on 1.25 mg/day and titrated up to 5 mg/day maximum

Cl_{cr} <10 mL/minute: Administer 25% to 50% of normal dose

Monitoring Parameters BUN, serum creatinine, renal function; nausea, headache, diarrhea, change in taste, cough

Administration Capsule is usually swallowed whole, but may be mixed in water, apple juice, or applesauce.

Contraindications Hypersensitivity to ramipril or any component of the formulation; prior hypersensitivity (including angioedema) to ACE inhibitors; bilateral renal artery stenosis; pregnancy (2nd and 3rd trimesters)

Warnings Anaphylactic or anaphylactoid reactions can occur. Angioedema can occur at any time during treatment (especially following first dose). It may involve head and neck (potentially affecting the airway) or the intestine (presenting with abdominal pain). Prolonged monitoring may be required especially if tongue, glottis, or larynx are involved as they are associated with airway obstruction. Those with a history of airway surgery in this situation have a higher risk. Careful blood pressure monitoring with first dose (hypotension can occur especially in volume-depleted patients).

[U.S. Boxed Warning]: Based on human data, ACEIs can cause injury and death to the developing fetus when used in the second and third trimesters. ACEIs should be discontinued as soon as possible once pregnancy is detected. Dosage adjustment needed in renal impairment. Use with caution in hypovolemia; collagen vascular diseases; valvular stenosis (particularly aortic stenosis); hyperkalemia; or before, during, or immediately after anesthesia. Avoid rapid dosage escalation, which may lead to renal insufficiency. Rare toxicities associated with ACE inhibitors include cholestatic jaundice (which may progress to hepatic necrosis) and neutropenia/agranulocytosis with myeloid hyperplasia. If patient has renal impairment then a baseline WBC with differential and serum creatinine should be evaluated and monitored closely during the first 3 months of therapy. Hypersensitivity reactions may be seen during hemodialysis with high-flux dialysis membranes (eg, AN69). Use with caution in unilateral renal artery stenosis and pre-existing renal insufficiency.

Dosage Forms Capsule: 1.25 mg, 2.5 mg, 5 mg, 10 mg

Reference Range Serum ramipril blood level range: 4.7-8.8 ng/mL associated with a hypotensive effect (~20 mm Hg drop) in patients with severe hypertension; levels up to 357 ng/mL have been reported without adverse effects during long-term therapy

Overdosage/Treatment

Decontamination: Activated charcoal
Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). For refractory hypotension, angiotensin amide infusion may be attempted.

Enhancement of elimination: Multiple dosing of activated charcoal may be useful

Test Interactions ↑ BUN, creatinine, potassium, ESR; positive Coombs' [direct]; ↓ cholesterol (S), reduces plasma aldosterone level by 50%; may cause false-positive urine acetone determinations using sodium nitroprusside reagent

Drug Interactions Alpha₁ blockers: Hypotensive effect increased.

Aspirin: The effects of ACE inhibitors may be blunted by aspirin administration, particularly at higher dosages (see Cardiovascular Considerations) and/or increase adverse renal effects.

Diuretics: Hypovolemia due to diuretics may precipitate acute hypotensive events or acute renal failure.

Insulin: Risk of hypoglycemia may be increased.

Lithium: Risk of lithium toxicity may be increased; monitor lithium levels, especially the first 4 weeks of therapy.

Mercaptopurine: Risk of neutropenia may be increased.

NSAIDs: May attenuate hypertensive efficacy; effect has been seen with captopril and may occur with other ACE inhibitors; monitor blood pressure. May increase risk of adverse renal effects or hyperkalemia.

Potassium-sparing diuretics (amiloflode, spironolactone, triamterene): Increased risk of hyperkalemia.

Potassium supplements may increase the risk of hyperkalemia.

Trimethoprim (high dose) may increase the risk of hyperkalemia.

Pregnancy Risk Factor C (1st trimester)/D (2nd and 3rd trimesters)

Pregnancy Implications Decreased placental blood flow, low birth weight, fetal hypotension, preterm delivery, and fetal death have been noted with the use of some ACE inhibitors (ACEIs) in animal studies. Neonatal hypotension, skull hypoplasia, anuria, renal failure, oligohydramnios (associated with fetal limb contractures, craniofacial deformities, hypoplastic lung development), prematurity, intrauterine growth retardation, and patent ductus arteriosus have been reported with the use of ACEIs, primarily in the 2nd and 3rd trimesters. The risk of neonatal toxicity has been considered less when ACEIs have been used in the 1st trimester; however, major congenital malformations have been reported. The cardiovascular and/or central nervous systems are most commonly affected. Unless alternative agents are not appropriate, ACEIs should be discontinued as soon as possible once pregnancy is detected.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications May cause depression in some patients; discontinue if angioedema of the face, extremities, lips, tongue, or glottis occurs; watch for hypotensive effects within 1-3 hours of first dose or new higher dose

Additional Information Some patients may have a decreased hypotensive effect between 12 and 16 hours; consider dividing total daily dose

into 2 doses 12 hours apart; if the patient is receiving a diuretic, a potential for first-dose hypotension is increased; to decrease this potential, stop diuretic for 2-3 days prior to initiating ramipril; continue diuretic if needed to control blood pressure. Due to frequent decreases in glomerular filtration (also creatinine clearance) with aging, elderly patients may have exaggerated responses to ACE inhibitors. In general, the side effect profile is favorable in elderly and causes little or no CNS confusion; use lowest dose recommendations initially. Ramipril is effective and safe in reducing arterial pressure and reducing microalbuminuria in single-kidney patients without renovascular hypertension. Reduces mortality by 27% when given 3-10 days postmyocardial infarction.

Ranitidine

Related Information

● Therapeutic Drugs Associated with Hallucinations

CAS Number 66357-35-5

U.S. Brand Names Zantac® 75 [OTC]; Zantac®

Synonyms Ranitidine Hydrochloride

Use

Zantac®: Short-term and maintenance therapy of duodenal ulcer, gastric ulcer, gastroesophageal reflux, active benign ulcer, erosive esophagitis, and pathological hypersecretory conditions; as part of a multidrug regimen for *H. pylori* eradication to reduce the risk of duodenal ulcer recurrence

Zantac® 75 [OTC]: Relief of heartburn, acid indigestion, and sour stomach

Unlabeled/Investigational Use Recurrent postoperative ulcer, upper GI bleeding, prevention of acid-aspiration pneumonitis during surgery, and prevention of stress-induced ulcers

Mechanism of Action Competitive inhibition of histamine at H₂-receptors of the gastric parietal cells, which inhibits gastric acid secretion

Adverse Reactions

Cardiovascular: Bradycardia, sinus bradycardia, angina, vasoconstriction, vasculitis

Central nervous system: Dizziness, sedation, malaise, mental confusion, auditory and visual hallucinations, psychosis, delirium, dystonic reactions, headache, restlessness, aseptic meningitis, memory disturbance, drug fever, paranoia, AV block

Dermatologic: Contact dermatitis, rash, toxic epidermal necrolysis, photosensitivity, toxic pustuloderma, acute generalized exanthematous pustulosis, erythema multiforme, angioedema, xerosis, urticaria, purpura, pruritus, psoriasis, exanthem, cutaneous vasculitis

Endocrine & metabolic: Gynecomastia (may be unilateral), parotitis

Gastrointestinal: Constipation, nausea, vomiting, hypergastrinemia, pancreatitis

Genitourinary: Impotence

Hematologic: Thrombocytopenia, bone marrow hypoplasia (especially in renal failure)

Hepatic: Hepatitis (may be hypersensitivity reaction)

Neuromuscular & skeletal: Arthralgias, choreiform movements

Renal: Allergic interstitial nephritis

Respiratory: Wheezing, eosinophilic pneumonia

Miscellaneous: Fixed drug eruption

Signs and Symptoms of Overdose Agranulocytosis, bradycardia, chest pain, cholestatic jaundice, chorea (extrapyramidal), cognitive dysfunction, depression, diarrhea, disorientation, extrapyramidal reaction, granulocytopenia, gynecomastia, hyperprolactinemia, impotence, insomnia, increased intraocular pressure, leukemoid reaction, leukopenia, mania, memory loss, migraine headache (exacerbation), muscular tremors, neutropenia, parotid pain, rapid respiration, vomiting

Pharmacodynamics/Kinetics

Absorption: Oral: 50%

Distribution: Normal renal function: V_d: 1.7 L/kg; Cl_{cr} 25-35 mL/minute: 1.76 L/kg minimally penetrates the blood-brain barrier; enters breast milk

Protein binding: 15%

Metabolism: Hepatic to N-oxide, S-oxide, and N-desmethyl metabolites

Bioavailability: Oral: 48%

Half-life elimination:

Oral: Normal renal function: 2.5-3 hours; Cl_{cr} 25-35 mL/minute: 4.8 hours

I.V.: Normal renal function: 2-2.5 hours

Time to peak, serum: Oral: 2-3 hours; I.M.: ≤15 minutes

Excretion: Urine: Oral: 30%, I.V.: 70% (as unchanged drug); feces (as metabolites)

Dosage Children 1 month to 16 years:

Duodenal and gastric ulcer:

Oral:

Treatment: 2-4 mg/kg/day divided twice daily; maximum treatment dose: 300 mg/day

Maintenance: 2-4 mg/kg once daily; maximum maintenance dose: 150 mg/day

I.V.: 2-4 mg/kg/day divided every 6-8 hours; maximum: 150 mg/day

GERD and erosive esophagitis:

Oral: 5-10 mg/kg/day divided twice daily; maximum: GERD: 300 mg/day, erosive esophagitis: 600 mg/day

I.V.: 2-4 mg/kg/day divided every 6-8 hours; maximum: 150 mg/day or as an alternative

Continuous infusion: Initial: 1 mg/kg/dose for one dose followed by infusion of 0.08-0.17 mg/kg/hour or 2-4 mg/kg/day

Children ≥ 12 years: Prevention of heartburn: Oral: Zantac® 75 [OTC]: 75 mg 30-60 minutes before eating food or drinking beverages which cause heartburn; maximum: 150 mg/24 hours; do not use for more than 14 days

Adults:

Duodenal ulcer: Oral: Treatment: 150 mg twice daily, or 300 mg once daily after the evening meal or at bedtime; maintenance: 150 mg once daily at bedtime

Helicobacter pylori eradication: 150 mg twice daily; requires combination therapy

Pathological hypersecretory conditions:

Oral: 150 mg twice daily; adjust dose or frequency as clinically indicated; doses of up to 6 g/day have been used

I.V.: Continuous infusion for Zollinger-Ellison: 1 mg/kg/hour; measure gastric acid output at 4 hours, if >10 mEq or if patient is symptomatic, increase dose in increments of 0.5 mg/kg/hour; doses of up to 2.5 mg/kg/hour have been used

Gastric ulcer, benign: Oral: 150 mg twice daily; maintenance: 150 mg once daily at bedtime

Erosive esophagitis: Oral: Treatment: 150 mg 4 times/day; maintenance: 150 mg twice daily

Prevention of heartburn: Oral: Zantac® 75 [OTC]: 75 mg 30-60 minutes before eating food or drinking beverages which cause heartburn; maximum: 150 mg in 24 hours; do not use for more than 14 days

Patients not able to take oral medication:

I.M.: 50 mg every 6-8 hours

I.V.: Intermittent bolus or infusion: 50 mg every 6-8 hours

Continuous I.V. infusion: 6.25 mg/hour

Elderly: Ulcer healing rates and incidence of adverse effects are similar in the elderly, when compared to younger patients; dosing adjustments not necessary based on age alone

Dosing adjustment in renal impairment: Adults: $Cl_{Cr} < 50$ mL/minute:

Oral: 150 mg every 24 hours; adjust dose cautiously if needed

I.V.: 50 mg every 18-24 hours; adjust dose cautiously if needed

Hemodialysis: Adjust dosing schedule so that dose coincides with the end of hemodialysis

Dosing adjustment/comments in hepatic disease: Patients with hepatic impairment may have minor changes in ranitidine half-life, distribution, clearance, and bioavailability; dosing adjustments not necessary, monitor

Stability Solution for I.V. infusion in NS or D₅W is stable for 48 hours at room temperature or 30 days when frozen; is stable for 24 hours in TPN solutions; is stable only for 12 hours in total nutrient admixtures (TPN) when lipids are added

Monitoring Parameters AST, ALT, serum creatinine; when used to prevent stress-related GI bleeding, measure the intragastric pH and try to maintain pH >4; signs and symptoms of peptic ulcer disease, occult blood with GI bleeding, monitor renal function to correct dose; monitor for side effects

Administration Ranitidine injection may be administered I.M. or I.V.:

I.M.: Injection is administered undiluted

I.V.: Must be diluted; may be administered IVP or IVPB or continuous I.V. infusion

IVP: Ranitidine (usually 50 mg) should be diluted to a total of 20 mL with NS or D₅W and administered over at least 5 minutes

IVPB: Administer over 15-20 minutes

Continuous I.V. infusion: Administer at 6.25 mg/hour and titrate dosage based on gastric pH by continuous infusion over 24 hours

EFFERdose®:

25 mg tablet: Dissolve in at least 5 mL (1 teaspoonful) of water; wait until completely dissolved before administering

150 mg tablet: Dissolve each dose in 6-8 ounces of water before drinking

Contraindications Hypersensitivity to ranitidine or any component of the formulation

Warnings Use with caution in patients with hepatic impairment; use with caution in renal impairment, dosage modification required; avoid use in patients with history of acute porphyria (may precipitate attacks); long-term therapy may be associated with vitamin B₁₂ deficiency; EFFERdose® formulations contain phenylalanine; safety and efficacy have not been established for pediatric patients <1 month of age

Dosage Forms Capsule 150 mg, 300 mg

Infusion [premixed in NaCl 0.45%; preservative free]:

Zantac®: 50 mg (50 mL)

Injection, solution: 25 mg/mL (2 mL, 6 mL)

Zantac®: 25 mg/mL (2 mL, 6 mL, 40 mL) [contains phenol 0.5% as preservative]

Syrup: 15 mg/mL (10 mL) [contains alcohol 7.5%; peppermint flavor]

Zantac®: 15 mg/mL (473 mL) [contains alcohol 7.5%; peppermint flavor]

Tablet: 75 mg [OTC], 150 mg, 300 mg

Zantac®: 150 mg, 300 mg

Zantac 75®: 75 mg

Zantac 150™: 150 mg

Tablet, effervescent:

Zantac® EFFERdose®: 25 mg [contains sodium 1.33 mEq/tablet, phenylalanine 2.81 mg/tablet, and sodium benzoate]; 150 mg [contains sodium 7.96 mEq/tablet, phenylalanine 16.84 mg/tablet, and sodium benzoate]

Reference Range Plasma level of 100 ng/mL will cause 50% inhibition of gastric acid secretion

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Treatment is primarily symptomatic and supportive

Test Interactions False-positive urine protein using Multistix®, gastric acid secretion test, skin test allergen extracts, serum creatinine and serum transaminase concentrations

Drug Interactions **Substrate** (minor) of CYP1A2, 2C19, 2D6; **Inhibits** CYP1A2 (weak), 2D6 (weak)

Propranolol: Slight delay and increase in peak ranitidine levels

Triazolam: Ranitidine increases bioavailability of triazolam (10% to 30%), possibly by reducing gastric acidity

Warfarin: May increase or decrease prothrombin time when used concomitantly; monitor

Pregnancy Risk Factor B

Pregnancy Implications Ranitidine crosses the placenta, teratogenic effects to the fetus have not been reported. Use with caution during pregnancy.

Lactation Enters breast milk/use caution

Nursing Implications I.M. solution does not need to be diluted before use; monitor creatinine clearance for renal impairment; observe caution in patients with renal function impairment and hepatic function impairment

Additional Information Giving dose at 6 PM may be better than 10 PM bedtime, the highest acid production usually starts at approximately 7 PM, thus giving at 6 PM controls acid secretion better; give I.V. administration over a 30-minute period to avoid bradycardia; causes fewer adverse reactions and interactions than cimetidine; most patient's ulcers have healed within 4 weeks; long-term therapy may cause vitamin B₁₂ deficiency. Cimetidine (400 mg orally twice daily) has been used to treat ranitidine-induced hypergastrinemia.

Rauwolfia serpentina

CAS Number 8063-17-0

Impairment Potential Yes

Use Mild essential hypertension; relief of agitated psychotic states

Adverse Reactions

Cardiovascular: Hypotension, tachycardia, flushing, sinus bradycardia, sinus tachycardia

Central nervous system: Drowsiness, fatigue, CNS depression, coma, parkinsonism, hypothermia

Endocrine & metabolic: Sodium and water retention, gynecomastia, galactorrhea

Gastrointestinal: Abdominal cramps, nausea, vomiting, increased gastric acid secretion, xerostomia, diarrhea

Ocular: Miosis, conjunctival flushing

Respiratory: Nasal congestion

Signs and Symptoms of Overdose Bradycardia, CNS depression, coma, extensor plantar response, facial flushing, galactorrhea, gynecomastia, hypotension, hypothermia, miosis, Parkinson's-like symptoms, tremors, and vomiting

Dosage Adults: Oral: 200-400 mg/day in 2 divided doses

Stability Protect from light

Monitoring Parameters Blood pressure, standing and sitting/supine, ECG for 72 hours after ingestion

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Anticholinergic agents may be useful in reducing the parkinsonian effects. Avoid the use of digoxin in these patients.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

REMIFENTANIL

Pregnancy Risk Factor C

Pregnancy Implications Effects on neurobehavioral development in rodents

Remifentanyl

CAS Number 132539-07-2

U.S. Brand Names Ultiva®

Synonyms GI87084B

Use Analgesic for use during the induction and maintenance of general anesthesia; for continued analgesia into the immediate postoperative period; analgesic component of monitored anesthesia

Unlabeled/Investigational Use Management of pain in mechanically ventilated patients

Mechanism of Action Binds with stereospecific mu-opioid receptors at many sites within the CNS, increases pain threshold, alters pain reception, inhibits ascending pain pathways

Adverse Reactions

Cardiovascular: Hypotension and bradycardia (dose dependent), tachycardia, hypertension, arrhythmias, heart block, syncope, CPK-MB increased, asystole

Central nervous system: Dizziness, headache, agitation, fever, anxiety, confusion, hallucinations, prolonged emergence from anesthesia

Dermatologic: Pruritus

Endocrine & metabolic: Electrolyte disorders

Gastrointestinal: **Nausea, vomiting,** constipation, diarrhea, dysphagia, gastrointestinal

Hematologic: Anemia, thrombocytopenia

Neuromuscular & skeletal: Muscle rigidity (dose dependent)

Ocular: Visual disturbances

Respiratory: Respiratory depression, apnea, hypoxia, bronchospasm, pleural effusion, pulmonary edema

Miscellaneous: Shivering, postoperative pain, anaphylactic/anaphylactoid reactions

Pharmacodynamics/Kinetics

Onset of action: I.V.: 1-3 minutes

Distribution: V_d : 100 mL/kg; increased in children

Protein binding: ~70% (primarily α_1 acid glycoprotein)

Metabolism: Rapid via blood and tissue esterases

Half-life elimination (dose dependent): Terminal: 10-20 minutes; effective: 3-10 minutes

Excretion: Urine

Dosage I.V. continuous infusion: Dose should be based on ideal body weight (IBW) in obese patients (>30% over IBW).

Children birth to 2 months: Maintenance of anesthesia with nitrous oxide (70%): 0.4 mcg/kg/minute (range: 0.4-1 mcg/kg/minute); supplemental bolus dose of 1 mcg/kg may be administered, smaller bolus dose may be required with potent inhalation agents, potent neuraxial anesthesia, significant comorbidities, significant fluid shifts, or without atropine pretreatment. Clearance in neonates is highly variable; dose should be carefully titrated.

Children 1-12 years: Maintenance of anesthesia with halothane, sevoflurane or isoflurane: 0.25 mcg/kg/minute (range 0.05-1.3 mcg/kg/minute); supplemental bolus dose of 1 mcg/kg may be administered every 2-5 minutes. Consider increasing concomitant anesthetics with infusion rate > 1 mcg/kg/minute. Infusion rate can be titrated upward in increments up to 50% or titrated downward in decrements of 25% to 50%. May titrate every 2-5 minutes.

Adults:

Induction of anesthesia: 0.5-1 mcg/kg/minute; if endotracheal intubation is to occur in <8 minutes, an initial dose of 1 mcg/kg may be given over 30-60 seconds

Coronary bypass surgery: 1 mcg/kg/minute

Maintenance of anesthesia: **Note:** Supplemental bolus dose of 1 mcg/kg may be administered every 2-5 minutes. Consider increasing concomitant anesthetics with infusion rate > 1 mcg/kg/minute. Infusion rate can be titrated upward in increments of 25% to 100% or downward in decrements of 25% to 50%. May titrate every 2-5 minutes.

With nitrous oxide (66%): 0.4 mcg/kg/minute (range: 0.1-2 mcg/kg/minute)

With isoflurane: 0.25 mcg/kg/minute (range: 0.05-2 mcg/kg/minute)

With propofol: 0.25 mcg/kg/minute (range: 0.05-2 mcg/kg/minute)

Coronary bypass surgery: 1 mcg/kg/minute (range: 0.125-4 mcg/kg/minute); supplemental dose: 0.5-1 mcg/kg

Continuation as an analgesic in immediate postoperative period: 0.1 mcg/kg/minute (range: 0.025-0.2 mcg/kg/minute). Infusion rate may be adjusted every 5 minutes in increments of 0.025 mcg/kg/minute. Bolus doses are not recommended. Infusion rates >0.2 mcg/kg/minute are associated with respiratory depression.

Coronary bypass surgery, continuation as an analgesic into the ICU: 1 mcg/kg/minute (range: 0.05-1 mcg/kg/minute)

Analgesic component of monitored anesthesia care: **Note:** Supplemental oxygen is recommended:

Single I.V. dose given 90 seconds prior to local anesthetic:

Remifentanyl alone: 1 mcg/kg over 30-60 seconds

With midazolam: 0.5 mcg/kg over 30-60 seconds

Continuous infusion beginning 5 minutes prior to local anesthetic:

Remifentanyl alone: 0.1 mcg/kg/minute

With midazolam: 0.05 mcg/kg/minute

Continuous infusion given after local anesthetic:

Remifentanyl alone: 0.05 mcg/kg/minute (range: 0.025-0.2 mcg/kg/minute)

With midazolam: 0.025 mcg/kg/minute (range: 0.025-0.2 mcg/kg/minute)

Note: Following local or anesthetic block, infusion rate should be decreased to 0.05 mcg/kg/minute; rate adjustments of 0.025 mcg/kg/minute may be done at 5-minute intervals

Mechanically-ventilated patients: Acute pain (moderate-to-severe) (unlabeled use): 0.6-15 mcg/kg/hour

Elderly: Elderly patients have an increased sensitivity to effect of remifentanyl, doses should be decreased by $1/2$ and titrated

Monitoring Parameters Respiratory and cardiovascular status, blood pressure, heart rate

Administration An infusion device should be used to administer continuous infusions. During the maintenance of general anesthesia, I.V. boluses may be administered over 30-60 seconds. Injections should be given into I.V. tubing close to the venous cannula; tubing should be cleared after treatment to prevent residual effects when other fluids are administered through the same I.V. line.

Contraindications Not for intrathecal or epidural administration, due to the presence of glycine in the formulation; hypersensitivity to remifentanyl, fentanyl, or fentanyl analogs, or any component of the formulation

Warnings Remifentanyl is not recommended as the sole agent in general anesthesia, because the loss of consciousness cannot be assured and due to the high incidence of apnea, hypotension, tachycardia and muscle rigidity; it should be administered by individuals specifically trained in the use of anesthetic agents and should not be used in diagnostic or therapeutic procedures outside the monitored anesthesia setting; resuscitative and intubation equipment should be readily available.

Interruption of an infusion will result in offset of effects within 5-10 minutes; the discontinuation of remifentanyl infusion should be preceded by the establishment of adequate postoperative analgesia orders, especially for patients in whom postoperative pain is anticipated. Use caution in the morbidly obese.

Dosage Forms Injection, powder for reconstitution: 1 mg, 2 mg, 5 mg [contains glycine 15 mg]

Reference Range Plasma remifentanyl level in 50% of patients unresponsive to surgical stimuli ranges from 1.5-2 ng/mL

Overdosage/Treatment

Decontamination: Activated charcoal for oral ingestion

Supportive therapy: Naloxone in large doses and/or a continuous infusion may be necessary

Antidote(s)

● Nalmefene [ANTIDOTE]

● Naloxone [ANTIDOTE]

Drug Interactions Anesthetics: Synergistic with other anesthetics, may need to decrease thiopental, propofol, isoflurane and midazolam by up to 75%

CNS depressants: Increased effect of CNS depressants

Pregnancy Risk Factor C

Pregnancy Implications Remifentanyl has been shown to cross the placenta. Neonatal respiratory depression and sedation may occur.

Lactation Excretion in breast milk unknown/use caution

Repaglinide

CAS Number 135062-02-1

U.S. Brand Names Prandin®

Use Management of type 2 diabetes mellitus (noninsulin dependent, NIDDM); may be used in combination with metformin or thiazolidinediones

Mechanism of Action Nonsulfonylurea hypoglycemic agent of the meglitinide class (the nonsulfonylurea moiety of glyburide) used in the management of type 2 diabetes mellitus; stimulates insulin release from pancreatic beta cells

Adverse Reactions

Cardiovascular: Chest pain

Central nervous system: **Headache**

Dermatologic: Alopecia, Stevens-Johnson syndrome

Gastrointestinal: Nausea, heartburn, vomiting, constipation, diarrhea, tooth disorder, pancreatitis

Endocrine & metabolic: **Hypoglycemia**

Genitourinary: Urinary tract infection

Hematologic: Leukopenia, thrombocytopenia, hemolytic anemia

Hepatic: Elevated liver function test results, hepatic dysfunction (severe)

Neuromuscular & skeletal: Arthralgia, back pain, paresthesia

Respiratory: **Upper respiratory tract infection**, sinusitis, rhinitis, bronchitis

Miscellaneous: Allergy, anaphylactoid reaction

Signs and Symptoms of Overdose Agitation, cerebral damage, coma, confusion, convulsions, nausea, severe hypoglycemia, seizures, stupor, sweating, tachycardia, tingling of lips and tongue, yawning

Admission Criteria/Prognosis Admit any symptomatic patient or asymptomatic normoglycemic patient after 8 hours of observation. Admit any ingestion >100 mg.

Pharmacodynamics/Kinetics

Onset of action: Single dose: Increased insulin levels: ~15-60 minutes

Duration: 4-6 hours

Absorption: Rapid and complete

Distribution: V_d : 31 L

Protein binding, plasma: >98%

Metabolism: Hepatic via CYP3A4 isoenzyme and glucuronidation to inactive metabolites

Bioavailability: Mean absolute: ~56%

Half-life elimination: 1 hour

Time to peak, plasma: ~1 hour

Excretion: Within 96 hours: Feces (~90%, <2% as parent drug); Urine (~8%)

Dosage Adults: Oral: Should be taken within 15 minutes of the meal, but time may vary from immediately preceding the meal to as long as 30 minutes before the meal

Initial: For patients not previously treated or whose Hb A_{1c} is <8%, the starting dose is 0.5 mg. For patients previously treated with blood glucose-lowering agents whose Hb A_{1c} is ≥8%, the initial dose is 1 or 2 mg before each meal.

Dose adjustment: Determine dosing adjustments by blood glucose response, usually fasting blood glucose. Double the preprandial dose up to 4 mg until satisfactory blood glucose response is achieved. At least 1 week should elapse to assess response after each dose adjustment.

Dose range: 0.5-4 mg taken with meals. Repaglinide may be dosed preprandial 2, 3 or 4 times/day in response to changes in the patient's meal pattern. Maximum recommended daily dose: 16 mg.

Patients receiving other oral hypoglycemic agents: When repaglinide is used to replace therapy with other oral hypoglycemic agents, it may be started the day after the final dose is given. Observe patients carefully for hypoglycemia because of potential overlapping of drug effects. When transferred from longer half-life sulfonylureas (eg, chlorpropamide), close monitoring may be indicated for up to ≥1 week.

Combination therapy: If repaglinide monotherapy does not result in adequate glycemic control, metformin or a thiazolidinedione may be added. Or, if metformin or thiazolidinedione therapy does not provide adequate control, repaglinide may be added. The starting dose and dose adjustments for combination therapy are the same as repaglinide monotherapy. Carefully adjust the dose of each drug to determine the minimal dose required to achieve the desired pharmacologic effect. Failure to do so could result in an increase in the incidence of hypoglycemic episodes. Use appropriate monitoring of FPG and Hb A_{1c} measurements to ensure that the patient is not subjected to excessive drug exposure or increased probability of secondary drug failure. If glucose is not achieved after a suitable trial of combination therapy, consider discontinuing these drugs and using insulin.

Dosing adjustment in renal impairment:

Cl_{cr} 40-80 mL/minute (mild to moderate renal dysfunction): Initial dosage adjustment does not appear to be necessary.

Cl_{cr} 20-40 mL/minute: Initiate 0.5 mg with meals; titrate carefully.

Dosing adjustment in hepatic impairment: Use conservative initial and maintenance doses. Use longer intervals between dosage adjustments.

Monitoring Parameters Periodically monitor fasting blood glucose and glycosylated hemoglobin (Hb A_{1c}) levels with a goal of decreasing these levels towards the normal range. During dose adjustment, fasting glucose can be used to determine response.

Administration Administer repaglinide 15-30 minutes before meals. Patients who are anorexic or NPO, may need to have their dose held to avoid hypoglycemia.

Contraindications Hypersensitivity to repaglinide or any component of the formulation; diabetic ketoacidosis, with or without coma (treat with insulin); type 1 diabetes (insulin dependent, IDDM)

Warnings Use with caution in patients with hepatic or renal impairment. May cause hypoglycemia; appropriate patient selection, dosage, and patient education are important to avoid hypoglycemic episodes. It may be necessary to discontinue repaglinide and administer insulin if the patient is exposed to stress (fever, trauma, infection, surgery). Safety and efficacy have not been established in pediatric patients. Not indicated for use in combination with NPH insulin due to potential cardiovascular events.

Dosage Forms

Tablet:
Prandin®: 0.5 mg, 1 mg, 2 mg

Reference Range Target range: Adults: Fasting blood glucose: <120 mg/dL. Glycosylated hemoglobin: <7%

Overdosage/Treatment

Decontamination: Oral: Lavage within 1 hour/activated charcoal can be used.

Supportive therapy: 25 g dextrose should be given for hypoglycemia; octreotide (30 ng/kg I.V.) can also be given. (Hypoglycemia usually will be of shorter duration as compared with sulfonylureas.)

Drug Interactions

Substrate of CYP2C8 (major), 3A4 (major)
CYP2C8 inducers: May decrease the levels/effects of repaglinide. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C8 inhibitors may increase the levels/effects of repaglinide. Example inhibitors include atazanavir, gemfibrozil, and ritonavir.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of repaglinide. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of repaglinide. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Gemfibrozil: Gemfibrozil may increase the serum concentration of repaglinide (prolonged, severe hypoglycemia has been reported). The addition of itraconazole may augment the effects of gemfibrozil on repaglinide. Consider alternative therapy.

HMG-CoA reductase inhibitors (eg, atorvastatin, fluvastatin, lovastatin, pravastatin, simvastatin): May increase repaglinide concentrations by decreasing metabolism.

Macrolide antibiotics (eg, clarithromycin, erythromycin, troleandomycin): May increase repaglinide concentrations by decreasing metabolism.

Oral contraceptives (estrogens, such as estradiol, ethinyl estradiol, mestranol): May increase repaglinide concentrations. Repaglinide may increase oral contraceptive (estrogens) serum concentration.

Oral contraceptives (progestins): May increase repaglinide concentrations. Repaglinide may increase oral contraceptive (progestins) serum concentration.

Rifampin: May decrease levels/effects of repaglinide; monitor serum glucose.

Trimethoprim: May increase repaglinide concentrations; monitor serum glucose carefully.

Pregnancy Risk Factor C

Pregnancy Implications Clinical effects on the fetus: Safety in pregnant women has not been established. Use during pregnancy only if clearly needed. Abnormal blood glucose levels are associated with a higher incidence of congenital abnormalities. Insulin is the drug of choice for the control of diabetes mellitus during pregnancy.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Patients who are anorexic or NPO, may need to have their dose held to avoid hypoglycemia

Additional Information Avoid ethanol, gymnema, and garlic (may cause hypoglycemia). When given with food, the AUC of repaglinide is decreased. St John's wort may decrease repaglinide levels.

Reserpine

Related Information

- *Rauwolfia serpentina*

CAS Number 50-55-5

Impairment Potential Yes

Use Management of mild-to-moderate hypertension; treatment of agitated psychotic states (schizophrenia)

Unlabeled/Investigational Use Management of tardive dyskinesia

Mechanism of Action Reduces blood pressure via depletion of sympathetic biogenic amines (norepinephrine and dopamine); this also commonly results in sedative effects

Adverse Reactions

Cardiovascular: Hypotension, tachycardia, hypotension (orthostatic), fibrillation (atrial), flutter (atrial), sinus bradycardia, cardiomyopathy, cardiomegaly, pericardial effusion/pericarditis, sinus tachycardia, vasodilation

Central nervous system: **Dizziness**, drowsiness, fatigue, coma, psychosis, hallucinations, parkinsonism, hypothermia, CNS depression, insomnia, fever, hyperthermia, neuroleptic malignant syndrome, extrapyramidal reactions

Dermatologic: Pruritus

Endocrine & metabolic: Sodium and water retention, gynecomastia, galactorrhea, hyperprolactinemia

Gastrointestinal: **Nausea, xerostomia, diarrhea, anorexia, vomiting**, increased gastric acid secretion, fecal discoloration (black), abdominal cramps

Ocular: Miosis, conjunctival flushing

Respiratory: **Nasal congestion**, rhinitis

Miscellaneous: Systemic lupus erythematosus, breast cancer

Signs and Symptoms of Overdose Bradycardia, CNS depression, coma, depression, extensor plantar response, flushing, galactorrhea, gynecomastia, hyperglycemia, hypertension, hypothermia, hypotension,

impotence, miosis, Parkinson's-like symptoms, ptosis, sexual dysfunction, syncope, tremors, vomiting, wheezing

Pharmacodynamics/Kinetics

Onset of action: Antihypertensive: 3-6 days

Duration: 2-6 weeks

Absorption: ~40%

Distribution: Crosses placenta; enters breast milk

Protein binding: 96%

Metabolism: Extensively hepatic (>90%)

Half-life elimination: 50-100 hours

Excretion: Feces (30% to 60%); urine (10%)

Dosage Note: When used for management of hypertension, full antihypertensive effects may take as long as 3 weeks.

Oral:

Children: Hypertension: 0.01-0.02 mg/kg/24 hours divided every 12 hours; maximum dose: 0.25 mg/day (not recommended in children)

Adults:

Hypertension: Initial: 0.5 mg/day for 1-2 weeks; usual dose range (JNC 7): 0.05-0.25 mg once daily; 0.1 mg every other day may be given to achieve 0.05 mg once daily

Tardive dyskinesia/schizophrenia: Initial: 0.5 mg/day; usual range: 0.1-1 mg

Elderly: Initial: 0.05 mg once daily, increasing by 0.05 mg every week as necessary

Dosing adjustment in renal impairment: $Cl_{cr} < 10$ mL/minute: Avoid use

Dialysis: Not removed by hemo or peritoneal dialysis; supplemental dose is not necessary

Stability Protect oral dosage forms from light; **incompatible** with ethacrynic acid

Monitoring Parameters Blood pressure, standing and sitting/supine

Contraindications Hypersensitivity to reserpine or any component of the formulation; active peptic ulcer disease, ulcerative colitis; history of mental depression (especially with suicidal tendencies); patients receiving electroconvulsive therapy (ECT)

Warnings Use with caution in patients with impaired renal function, inflammatory bowel disease, asthma, Parkinson's disease, gallstones, or history of peptic ulcer disease, and the elderly. At high doses, significant mental depression, anxiety, or psychosis may occur (uncommon at dosages <0.25 mg/day). May cause orthostatic hypotension; use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). Avoid concurrent use of MAO inhibitors and/or drugs with MAO-inhibiting properties. Some products may contain tartrazine.

Dosage Forms Tablet: 0.1 mg, 0.25 mg

Overdosage/Treatment

Decontamination: Lavage within 1 hour, activated charcoal

Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Anticholinergic agents may be useful in reducing the parkinsonian effects. Avoid the use of digoxin in these patients. Alprazolam can reverse reserpine-induced depression. Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Test Interactions ↑ catecholamines (U) 1 or 2 days postingestion; ↑ prolactin

Drug Interactions Antihypertensives: Hypotensive effects may be increased.

CNS depressants, ethanol: Additive CNS effects may occur.

Digitalis glycosides: Concomitant administration may predispose some patients to cardiac arrhythmias.

MAO inhibitors: Reserpine may cause hypertensive reactions; concurrent use is not recommended. Theoretically, risk is decreased if reserpine is initiated several days prior to MAO inhibitors.

Quinidine, procainamide: Reserpine may increase the risk of cardiac arrhythmias effects.

Sympathomimetics: The effects of direct-acting sympathomimetics (eg, epinephrine, norepinephrine) may be modestly increased/prolonged. However, the effects of indirect-acting sympathomimetics (amphetamines, dopamine) may be blocked by reserpine.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta; appears in breast milk

Lactation Enters breast milk/use caution

Nursing Implications Observe for mental depression and alert family members to report any symptoms

Additional Information Full antihypertensive effects may take as long as 3 weeks; at high doses, mental depression is possible and might lead to suicide

Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, 289(19):2560-71.

Reteplase

U.S. Brand Names Retavase®

Synonyms r-PA; Recombinant Plasminogen Activator

Use Acute myocardial infarction (thrombolytic agent)

Mechanism of Action Catalyzes cleavage of endogenous plasminogen to generate plasmin; can decrease fibrinogen levels to <100 mg/dL within 2 hours of injection

Adverse Reactions

Cardiovascular: Pericardial hemorrhage, **hypotension**, **arrhythmias**, **trauma arrhythmias**

Central nervous system: Intracranial hemorrhage (0.8%), fever

Gastrointestinal: **GI bleeding** (5% to 49%), nausea, vomiting

Genitourinary: Bleeding (2% to 10%)

Hematologic: Anemia (1% to 3%), **bleeding**

Pharmacodynamics/Kinetics

Onset of action: Thrombolysis: 30-90 minutes

Half-life elimination: 13-16 minutes

Excretion: Feces and urine

Clearance: Plasma: 250-450 mL/minute

Dosage I.V.: 10 units over 2 minutes followed by a second 10 unit bolus dose in 30 minutes

Monitoring Parameters Monitor for signs of bleeding (hematuria, GI bleeding, gingival bleeding)

Administration Reteplase should be reconstituted using the diluent, syringe, needle and dispensing pin provided with each kit and the each reconstituted dose should be administered I.V. over 2 minutes; no other medication should be added to the injection solution

Contraindications Hypersensitivity to reteplase or any component of the formulation; active internal bleeding; history of cerebrovascular accident; recent intracranial or intraspinal surgery or trauma; intracranial neoplasm, arteriovenous malformations, or aneurysm; known bleeding diathesis; severe uncontrolled hypertension

Warnings

Concurrent heparin anticoagulation can contribute to bleeding; careful attention to all potential bleeding sites. I.M. injections and nonessential handling of the patient should be avoided. Venipunctures should be performed carefully and only when necessary. If arterial puncture is necessary, use an upper extremity vessel that can be manually compressed. If serious bleeding occurs then the infusion of anistreplase and heparin should be stopped.

For the following conditions the risk of bleeding is higher with use of reteplase and should be weighed against the benefits of therapy: recent major surgery (eg, CABG, obstetrical delivery, organ biopsy, previous puncture of noncompressible vessels), cerebrovascular disease, recent gastrointestinal or genitourinary bleeding, recent trauma including CPR, hypertension (systolic BP > 180 mm Hg and/or diastolic BP > 110 mm Hg), high likelihood of left heart thrombus (eg, mitral stenosis with atrial fibrillation), acute pericarditis, subacute bacterial endocarditis, hemostatic defects including ones caused by severe renal or hepatic dysfunction, significant hepatic dysfunction, pregnancy, diabetic hemorrhagic retinopathy or other hemorrhagic ophthalmic conditions, septic thrombophlebitis or occluded AV cannula at seriously infected site, advanced age (eg, >75 years), patients receiving oral anticoagulants, any other condition in which bleeding constitutes a significant hazard or would be particularly difficult to manage because of location.

Coronary thrombolysis may result in reperfusion arrhythmias. Follow standard MI management. Rare anaphylactic reactions can occur. Safety and efficacy in pediatric patients have not been established.

Dosage Forms Injection, powder for reconstitution [preservative free]: 10.4 units [equivalent to reteplase 18.1 mg; contains sucrose and polysorbate 80; packaged with sterile water for injection]

Reference Range Maximal serum Retavase™ levels after a 15 unit bolus: 1536 int. unit/mL

Overdosage/Treatment Supportive therapy: Treat bleeding complications with transfusions of red blood cells, fresh frozen plasma, and cryoprecipitate; do not administer dextran; although human overdose data is lacking, administration of aminocaproic acid (Amicar®) at a dose of 3-5 g I.V. followed by an infusion rate of 1-1.25 g/hour may be useful

Drug Interactions Aminocaproic acid (antifibrinolytic agent) may decrease effectiveness.

Drugs which affect platelet function (eg, NSAIDs, dipyridamole, ticlopidine, clopidogrel, IIb/IIIa antagonists) may potentiate the risk of hemorrhage; use with caution.

Heparin and aspirin: Use with aspirin and heparin may increase bleeding.

However, aspirin and heparin were used concomitantly with reteplase in the majority of patients in clinical studies.

Warfarin or oral anticoagulants: Risk of bleeding may be increased during concurrent therapy.

Pregnancy Risk Factor C

Pregnancy Implications Abortifacient in rabbits

Lactation Excretion in breast milk unknown/use caution
Additional Information Not antigenic; a nonglycosylated deletion mutant of wild type t-PA lacking the kringle-1, finger and growth factor domains of t-PA not compatible with heparin in solution

Specific Reference

Simpson D, Siddiqui AA, Scott CJ, and Hilleman DE, "Retepase: A Review of Its use in the Management of Thrombotic Occlusive Disorders," *Am J Cardiovasc Drugs*, 2006, 6(4):265-85.

Ribavirin

CAS Number 36791-04-5

U.S. Brand Names Copegus®; Rebetol®; Ribasphere™; Virazole®

Synonyms RTCA; Tribavirin

Use

Inhalation: Treatment of patients with respiratory syncytial virus (RSV) infections; specially indicated for treatment of severe lower respiratory tract RSV infections in patients with an underlying compromising condition (prematurity, bronchopulmonary dysplasia and other chronic lung conditions, congenital heart disease, immunodeficiency, immunosuppression), and recent transplant recipients

Oral capsule:

In combination with interferon alfa-2b (Intron® A) injection for the treatment of chronic hepatitis C in patients with compensated liver disease who have relapsed after alpha interferon therapy or were previously untreated with alpha interferons

In combination with peginterferon alfa-2b (PEG-Intron®) injection for the treatment of chronic hepatitis C in patients with compensated liver disease who were previously untreated with alpha interferons

Oral solution: In combination with interferon alfa 2b (Intron® A) injection for the treatment of chronic hepatitis C in patients ≥ 3 years of age with compensated liver disease who were previously untreated with alpha interferons or patients ≥ 18 years of age who have relapsed after alpha interferon therapy

Oral tablet: In combination with peginterferon alfa-2a (Pegasys®) injection for the treatment of chronic hepatitis C in patients with compensated liver disease who were previously untreated with alpha interferons (includes patients with histological evidence of cirrhosis [Child-Pugh class A] and patients with clinically-stable HIV disease)

Unlabeled/Investigational Use Used in other viral infections including influenza A and B and adenovirus

Mechanism of Action Inhibits replication of RNA and DNA viruses; inhibits influenza virus RNA polymerase activity and inhibits the initiation and elongation of RNA fragments resulting in inhibition of viral protein synthesis

Adverse Reactions

Inhalation:

- Cardiovascular: Hypotension, cardiac arrest
- Central nervous system: Fatigue, headache, insomnia
- Gastrointestinal: Nausea, anorexia
- Hematologic: Anemia
- Ocular: Conjunctivitis
- Respiratory: Mild bronchospasm, worsening of respiratory function, apnea
- Miscellaneous: Digitalis toxicity

Note: Incidence of adverse effects (approximate) in healthcare workers: Headache 51%; conjunctivitis 32%; rhinitis, nausea, rash, dizziness, pharyngitis, and lacrimation 10% to 20%

Oral (all adverse reactions are documented while receiving combination therapy with interferon alfa-2b):

- Cardiovascular: Chest pain*
- Central nervous system: **Dizziness, headache*, fatigue*, fever*, insomnia, irritability, depression*, emotional lability*, impaired concentration***, nervousness*; suicidal ideation, vertigo
- Dermatologic: **Alopecia, rash, pruritus**
- Endocrine & metabolic: Diabetes mellitus, gout, thyroid function test abnormalities
- Gastrointestinal: **Nausea, anorexia, dyspepsia, vomiting***, taste perversion, pancreatitis
- Hematologic: **Decreased hemoglobin, decreased WBC, absolute neutrophil count <0.5 × 10⁹/L, thrombocytopenia, hemolysis**, hemolytic anemia
- Hepatic: Hyperbilirubinemia
- Neuromuscular & skeletal: **Myalgia*, arthralgia*, musculoskeletal pain, rigors, weakness**
- Otic: Hearing disorder
- Respiratory: **Dyspnea, sinusitis*, nasal congestion**, pulmonary dysfunction
- Miscellaneous: **Flu-like syndrome***, sarcoidosis

*Similar to interferon alone

Incidence of anorexia, headache, fever, suicidal ideation, and vomiting are higher in children.

Pharmacodynamics/Kinetics

Absorption: Inhalation: Systemic; dependent upon respiratory factors and method of drug delivery; maximal absorption occurs with the use of aerosol generator via endotracheal tube; highest concentrations in respiratory tract and erythrocytes

Distribution: Oral capsule: Single dose: V_d 2825 L; distribution significantly prolonged in the erythrocyte (16-40 days), which can be used as a marker for intracellular metabolism

Protein binding: Oral: None

Metabolism: Hepatically and intracellularly (forms active metabolites); may be necessary for drug action

Bioavailability: Oral: 64%

Half-life elimination, plasma:

Children: Inhalation: 6.5-11 hours

Adults: Oral:

Capsule, single dose (Rebetol®, Ribasphere™): 24 hours in healthy adults, 44 hours with chronic hepatitis C infection (increases to ~298 hours at steady state)

Tablet, single dose (Copegus®): 120-170 hours

Time to peak, serum: Inhalation: At end of inhalation period; Oral capsule:

Multiple doses: 3 hours; Tablet: 2 hours

Excretion: Inhalation: Urine (40% as unchanged drug and metabolites);

Oral capsule: Urine (61%), feces (12%)

Dosage Aerosol inhalation: Infants and children: Use with Viratek® small particle aerosol generator (SPAG-2) at a concentration of 20 mg/mL (6 g reconstituted with 300 mL of sterile water without preservatives). Continuous aerosol administration: 12-18 hours/day for 3 days, up to 7 days in length

Oral capsule or solution:

Children ≥ 3 years: Chronic hepatitis C (in combination with interferon alfa-2b):

25-36 kg: 400 mg/day (200 mg twice daily)

37-49 kg: 600 mg/day (200 mg in morning and 400 mg in evening)

50-61 kg: 800 mg/day (400 mg twice daily)

> 61 kg: Refer to adult dosing

Note: Duration of therapy is 48 weeks in pediatric patients with genotype 1 and 24 weeks in patients with genotype 2,3. Discontinue treatment in any patient if HCV-RNA is not below the limit of detection of the assay after 24 weeks of therapy.

Oral capsule:

Adults:

Chronic hepatitis C (in combination with interferon alfa-2b):

≤ 75 kg: 400 mg in the morning, then 600 mg in the evening

> 75 kg: 600 mg in the morning, then 600 mg in the evening

Note: If HCV-RNA is undetectable at 24 weeks, duration of therapy is 48 weeks. In patients who relapse following interferon therapy, duration of dual therapy is 24 weeks.

Chronic hepatitis C (in combination with peginterferon alfa-2b): 400 mg twice daily; duration of therapy is 1 year; after 24 weeks of treatment, if serum HCV-RNA is not below the limit of detection of the assay, consider discontinuation.

Oral tablet: Adults:

Chronic hepatitis C, genotype 1,4 (in combination with peginterferon alfa-2a):

< 75kg: 1000 mg/day in 2 divided doses for 48 weeks

≥ 75kg: 1200 mg/day in 2 divided doses for 48 weeks

Chronic hepatitis C, genotype 2,3 (in combination with peginterferon alfa-2a): 800 mg/day in 2 divided doses for 24 weeks

Dosage adjustment in renal impairment: Cl_{cr} < 50 mL/minute: Oral route is contraindicated

Dosage adjustment for toxicity: Oral: Capsule, solution, tablet:

Patient **without** cardiac history:

Hemoglobin < 10 g/dL:

Children: 7.5 mg/kg/day

Adults: Decrease dose to 600 mg/day

Hemoglobin < 8.5 g/dL: Children and Adults: Permanently discontinue treatment

Patient **with** cardiac history:

Hemoglobin has ≥ 2 g/dL decrease during any 4-week period of treatment:

Children: 7.5 mg/kg/day

Adults: Decrease dose to 600 mg/day

Hemoglobin < 12 g/dL after 4 weeks of reduced dose: Children and

Adults: Permanently discontinue treatment

Monitoring Parameters Inhalation: Respiratory function, hemoglobin, reticulocyte count, CBC, I & O

Oral: CBC with differential (pretreatment, 2- and 4 weeks after initiation); pretreatment and monthly pregnancy test for women of childbearing age; LFTs, TSH, HCV-RNA after 24 weeks of therapy; ECG in patients with pre-existing cardiac disease

Administration Inhalation: Ribavirin should be administered in well-ventilated rooms (at least 6 air changes/hour). In mechanically-ventilated patients, ribavirin can potentially be deposited in the ventilator delivery system depending on temperature, humidity, and electrostatic forces; this deposition can lead to malfunction or obstruction of the

expiratory valve, resulting in inadvertently high positive end-expiratory pressures. The use of one-way valves in the inspiratory lines, a breathing circuit filter in the expiratory line, and frequent monitoring and filter replacement have been effective in preventing these problems. Solutions in SPAG-2 unit should be discarded at least every 24 hours and when the liquid level is low before adding newly reconstituted solution. Should not be mixed with other aerosolized medication.

Oral: Administer concurrently with interferon alfa injection.

Capsule, in combination with interferon alfa-2b: May be administered with or without food, but always in a consistent manner in regard to food intake.

Capsule, in combination with peginterferon alfa 2b: Administer with food.

Solution, in combination with interferon alfa-2b: May be administered with or without food, but always in a consistent manner in regard to food intake.

Tablet: Should be administered with food.

Contraindications Hypersensitivity to ribavirin or any component of the formulation; women of childbearing age who will not use contraception reliably; pregnancy

Additional contraindications for oral formulation: Male partners of pregnant women; $Cl_{cr} < 50$ mL/minute; hemoglobinopathies (eg, thalassemia major, sickle cell anemia); as monotherapy for treatment of chronic hepatitis C; patients with autoimmune hepatitis, anemia, severe heart disease

Refer to individual monographs for Interferon Alfa-2b (Intron® A) and Peginterferon Alfa-2a (Pegasys®) for additional contraindication information.

Warnings

[U.S. Boxed Warning]: Negative pregnancy test is required before initiation and monthly thereafter. Avoid pregnancy in female patients and female partners of male patients, during therapy, and for at least 6 months after treatment; two forms of contraception should be used. Elderly patients are more susceptible to adverse effects; use caution. Safety and efficacy have not been established in patients who have failed other alpha interferon therapy, received organ transplants, or been coinfecting with hepatitis B or HIV (Copegus® may be used in HIV coinfecting patients unless CD4+ cell count is < 100 cells/microL). **[U.S. Boxed Warning]: Monotherapy not effective for chronic hepatitis C infection.** Safety and efficacy have not been established in patients < 3 years of age.

Inhalation: **[U.S. Boxed Warning]: Use with caution in patients requiring assisted ventilation because precipitation of the drug in the respiratory equipment may interfere with safe and effective patient ventilation; sudden deterioration of respiratory function has been observed;** monitor carefully in patients with COPD and asthma for deterioration of respiratory function. Ribavirin is potentially mutagenic, tumor-promoting, and gonadotoxic. Although anemia has not been reported with inhalation therapy, consider monitoring for anemia 1-2 weeks post-treatment. Pregnant healthcare workers may consider unnecessary occupational exposure; ribavirin has been detected in healthcare workers' urine. Healthcare professionals or family members who are pregnant (or may become pregnant) should be counseled about potential risks of exposure and counseled about risk reduction strategies.

Oral: Severe psychiatric events have occurred including depression and suicidal behavior during combination therapy. Avoid use in patients with a psychiatric history; discontinue if severe psychiatric symptoms occur. **[U.S. Boxed Warning]: Hemolytic anemia is a significant toxicity; usually occurring within 1-2 weeks.** Assess cardiac disease before initiation. Anemia may worsen underlying cardiac disease; use caution. If any deterioration in cardiovascular status occurs, discontinue therapy. Use caution in pulmonary disease; pulmonary symptoms have been associated with administration. Discontinue therapy in suspected/confirmed pancreatitis or if hepatic decompensation occurs. Use caution in patients with sarcoidosis (exacerbation reported).

Hemolytic anemia (hemoglobin < 10 g/dL) was observed in up to 10% of treated patients in clinical trials when alpha interferons were combined with ribavirin; anemia occurred within 1-2 weeks of initiation of therapy.

Dosage Forms Capsule: 200 mg

Rebetol®, Ribasphere™: 200 mg

Powder for solution, inhalation [for aerosol administration]:

Virazole®: 6 g [reconstituted product provides 20 mg/mL]

Solution, oral:

Rebetol®: 40 mg/mL (100 mL) [contains sodium benzoate; bubble-gum flavor]

Tablet: 200 mg

Copegus®: 200 mg

Tablet [dose pack]:

RibaPak™: 400 mg (14s), 600 mg (14s)

Reference Range Cytotoxic at plasma levels > 200 mcg/mL; a 3 mg/kg dose produced a peak plasma level of 1-2 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal for oral ingestion

Enhancement of elimination: Hemodialysis is not useful

Test Interactions May cause transient elevation of serum iron level

Drug Interactions Antiretroviral (nucleoside): Concomitant use of ribavirin and nucleoside analogues may increase the risk of developing lactic acidosis (includes adefovir, didanosine, lamivudine, stavudine, zalcitabine, zidovudine). Concurrent use with didanosine has been noted to increase the risk of pancreatitis, peripheral neuropathy in addition to lactic acidosis. Suspend therapy if signs/symptoms of toxicity are present.

Interferons (alfa): Concurrent therapy may increase the risk of hemolytic anemia.

Lamivudine, stavudine: Antagonistic *in vitro*; use with caution (per manufacturer)

Zidovudine: Antagonistic *in vitro*; use with caution (per manufacturer).

Concurrent therapy with ribavirin/interferon alfa-2a may cause increased risk of severe anemia and/or severe neutropenia.

Pregnancy Risk Factor X

Pregnancy Implications Produced significant embryocidal and/or teratogenic effects in all animal studies at ~ 0.01 times the maximum recommended daily human dose. Use is contraindicated in pregnancy. Negative pregnancy test is required before initiation and monthly thereafter. Avoid pregnancy in female patients and female partners of male patients during therapy by using two effective forms of contraception; continue contraceptive measures for at least 6 months after completion of therapy. If patient or female partner becomes pregnant during treatment, she should be counseled about potential risks of exposure. If pregnancy occurs during use or within 6 months after treatment, report to company (Copegus™: 800-526-6367; Rebetol®: 800-727-7064).

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Inhalation: Keep accurate I & O record; discard solutions placed in the SPAG-2 unit at least every 24 hours and before adding additional fluid; healthcare workers who are pregnant or who may become pregnant should be advised of the potential risks of exposure and counseled about risk reduction strategies including alternate job responsibilities; ribavirin may adsorb to contact lenses

Oral: Educate female patients about prevention of pregnancy and need for monthly pregnancy testing. Educate male patients about protection of female sexual partners from pregnancy.

Additional Information RSV season is usually December to April; viral shedding period for RSV is usually 3-8 days; surgical masks do not prevent inhalation

Food: Oral: High-fat meal increases the AUC and C_{max}

Rifabutin

CAS Number 72559-06-9

U.S. Brand Names Mycobutin®

Synonyms Ansamycin

Use Prevention of disseminated *Mycobacterium avium* complex (MAC) in patients with advanced HIV infection

Unlabeled/Investigational Use Utilized in multidrug regimens for treatment of MAC

Mechanism of Action Inhibits DNA-dependent RNA polymerase at the beta subunit which prevents chain initiation

Adverse Reactions

Cardiovascular: Chest pain, angina

Central nervous system: Fever, headache, seizures, confusion, insomnia

Dermatologic: **Rash**, skin erythema

Gastrointestinal: Abdominal pain, diarrhea, dyspepsia, nausea, vomiting, epigastric pain, anorexia, flatulence, eructation, loss of taste perception

Genitourinary: **Urine discoloration**

Hematologic: Thrombocytopenia, anemia, **leukopenia, neutropenia**

Hepatic: Elevated liver enzymes, jaundice

Neuromuscular & skeletal: Arthralgia, myalgia

Ocular: Anterior uveitis

Signs and Symptoms of Overdose Agranulocytosis, granulocytopenia, leukopenia, neutropenia, polyarthralgia (at doses > 1 g/day)

Pharmacodynamics/Kinetics

Absorption: Readily, 53%

Distribution: V_d : 9.32 L/kg; distributes to body tissues including the lungs, liver, spleen, eyes, and kidneys

Protein binding: 85%

Metabolism: To active and inactive metabolites

Bioavailability: Absolute: HIV: 20%

Half-life elimination: Terminal: 45 hours (range: 16-69 hours)

Time to peak, serum: 2-4 hours

Excretion: Urine (10% as unchanged drug, 53% as metabolites); feces (10% as unchanged drug, 30% as metabolites)

Dosage

Oral:

Children > 1 year:

Prophylaxis: 5 mg/kg daily; higher dosages have been used in limited trials

Treatment (unlabeled use): Patients not receiving NNRTIs or protease inhibitors:

Initial phase (2 weeks to 2 months): 10-20 mg/kg daily (maximum: 300 mg).

Second phase: 10-20 mg/kg daily (maximum: 300 mg) or twice weekly

Adults:

Prophylaxis: 300 mg once daily (alone or in combination with azithromycin)

Treatment (unlabeled use):

Patients not receiving NNRTIs or protease inhibitors:

Initial phase: 5 mg/kg daily (maximum: 300 mg)

Second phase: 5 mg/kg daily or twice weekly

Patients receiving nelfinavir, amprenavir, indinavir: Reduce dose to 150 mg/day; no change in dose if administered twice weekly

Dosage adjustment in renal impairment: $Cl_{cr} < 30$ mL/minute: Reduce dose by 50%

Monitoring Parameters Periodic liver function tests, CBC with differential, platelet count

Administration Should be administered on an empty stomach, but may be taken with meals to minimize nausea or vomiting.

Contraindications Hypersensitivity to rifabutin, any other rifamycins, or any component of the formulation; rifabutin is contraindicated in patients with a WBC $< 1000/mm^3$ or a platelet count $< 50,000/mm^3$

Warnings Rifabutin as a single agent must not be administered to patients with active tuberculosis since its use may lead to the development of tuberculosis that is resistant to both rifabutin and rifampin; rifabutin should be discontinued in patients with AST > 500 units/L or if total bilirubin is > 3 mg/dL. Use with caution in patients with liver impairment; modification of dosage should be considered in patients with renal impairment.

Dosage Forms Capsule: 150 mg

Reference Range Peak and trough plasma levels of a 600 mg dose twice daily is 900 ng/mL and 200 ng/mL, respectively

Overdosage/Treatment

Decontamination: Lavage within 1 hour, activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; hemodialysis or charcoal hemoperfusion may be effective

Drug Interactions **Substrate** of CYP3A4 (major); Induces CYP3A4 (strong)

Alfentanil: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of alfentanil.

Amiodarone: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of amiodarone.

Angiotensin II receptor blockers (irbesartan, losartan): Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of angiotensin II receptor blockers.

Antiemetics (5-HT₃ antagonists): Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of antiemetics (5-HT₃ antagonists).

Antifungal agents (imidazole): Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of antifungal agents (imidazole).

Antifungal agents (imidazole) may decrease the metabolism, via CYP isoenzymes, of rifabutin.

Aprepitant: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of aprepitant.

Barbiturates: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of barbiturates.

Benzodiazepines (metabolized by oxidation): Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of benzodiazepines (metabolized by oxidation).

Beta-blockers: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of beta-blockers.

Bupirone: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of bupirone.

Calcium channel blockers: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of calcium channel blockers.

Clopidogrel: Rifamycin derivatives may enhance the therapeutic effect of clopidogrel.

Corticosteroids (systemic): Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of corticosteroids (systemic).

Cyclosporine: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of cyclosporine.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of rifabutin. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, and phenytoin.

CYP3A4 substrates: Rifabutin may decrease the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, clarithromycin, cyclosporine, erythromycin, estrogens, mirtazapine, nateglinide, nefazodone, nevirapine, protease inhibitors, tacrolimus, and venlafaxine.

Dapsone: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of dapsone.

Disopyramide: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of disopyramide.

Estrogens (oral contraceptives): Rifamycin derivatives may decrease the serum concentration of oral contraceptive (estrogens); contraceptive failure is possible.

Fluconazole: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of fluconazole. Fluconazole may decrease the metabolism, via CYP isoenzymes, of rifabutin.

Gefitinib: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of gefitinib.

HMG-CoA reductase inhibitors: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of HMG-CoA reductase inhibitors.

Isoniazid: Rifamycin derivatives may enhance the hepatotoxic effect of isoniazid; however, this is a frequently employed combination regimen.

Macrolide antibiotics: Macrolide antibiotics may decrease the metabolism, via CYP isoenzymes, of rifamycin derivatives.

Morphine: Rifamycin derivatives may decrease the serum concentration of morphine sulfate.

Phenytoin: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of phenytoin.

Progestins (contraceptives): Rifamycin derivatives may decrease the serum concentration of contraceptives (progestins); contraceptive failure is possible.

Propafenone: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of propafenone.

Protease inhibitors: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of protease inhibitors. Protease inhibitors may decrease the metabolism, via CYP isoenzymes, of rifabutin. Dosage adjustments of both rifabutin and the protease inhibitors are necessary if used together.

Quinidine: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of quinidine.

Repaglinide: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of repaglinide.

Reverse transcriptase inhibitors (non-nucleoside): Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of reverse transcriptase inhibitors (non-nucleoside).

Tacrolimus: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of tacrolimus.

Tamoxifen: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of tamoxifen.

Terbinafine: Rifamycin derivatives may increase the metabolism of terbinafine.

Tocainide: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of tocainide.

Tricyclic antidepressants: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of tricyclic antidepressants.

Warfarin: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of warfarin.

Zaleplon: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of zaleplon.

Zolpidem: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of zolpidem.

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown

Nursing Implications Administer with meals

Additional Information May discolor urine, saliva, and tears a brown-orange color; synergistic effects against *Mycobacterium avium* intracellular complex (MAC) reported when combined with clarithromycin or clofazimine; rifabutin-associated (over 1.2 g/day) uveitis usually resolves within 2 months

Rifampin

CAS Number 13292-46-1

U.S. Brand Names Rifadin®; Rimactane®

Synonyms Rifampicin

Use Management of active tuberculosis in combination with other agents; eliminate meningococci from asymptomatic carriers

Prophylaxis of *Haemophilus influenzae* type b infection; *Legionella* pneumonia; used in combination with other anti-infectives in the treatment of staphylococcal infections; treatment of *M. leprae* infections

Mechanism of Action Inhibits bacterial RNA synthesis by binding to the beta subunit of DNA-dependent RNA polymerase, blocking RNA transcription

Adverse Reactions

Cardiovascular: Chest pain, angina

Central nervous system: Drowsiness, fatigue, confusion, fever, headache, ataxia, electroencephalogram abnormalities, psychosis

Dermatologic: Rash, pruritus, Stevens-Johnson syndrome, cutaneous vasculitis, red discoloration

Gastrointestinal: Nausea, abdominal pain, vomiting, diarrhea, stomatitis, pseudomembranous colitis

Hematologic: Eosinophilia, blood dyscrasias (leukopenia, thrombocytopenia), agranulocytosis, granulocytopenia, red blood cell aplasia

Hepatic: Hepatitis, hepatic vasculitis

Local: Irritation at the I.V. site

Renal: Renal failure, glomerulosclerosis, renal vasculitis

Miscellaneous: Flu-like syndrome

Signs and Symptoms of Overdose Abdominal pain, cholelithiasis, colitis, coma, dyspnea, erythema multiforme, facial edema, feces discoloration (orange-red; red-brown), hepatitis, hyperglycemia, hypersensitivity, leukopenia, myopathy, nausea, nephritis, pemphigus, pruritus, pulmonary edema, red man syndrome, renal failure (acute), scleral discoloration (after 6-10 hours), skin discoloration, stomatitis, thrombocytopenia, toxic epidermal necrolysis, urine discoloration (brown; orange; orange-red; orange-yellow; red), vomiting, wheezing

Pharmacodynamics/Kinetics

Duration: ≤24 hours

Absorption: Oral: Well absorbed; food may delay or slightly reduce peak

Distribution: Highly lipophilic; crosses blood-brain barrier well

Relative diffusion from blood into CSF: Adequate with or without inflammation (exceeds usual MICs)

CSF: blood level ratio: Inflamed meninges: 25%

Protein binding: 80%

Metabolism: Hepatic; undergoes enterohepatic recirculation

Half-life elimination: 3-4 hours; prolonged with hepatic impairment; End-stage renal disease: 1.8-11 hours

Time to peak, serum: Oral: 2-4 hours

Excretion: Feces (60% to 65%) and urine (~30%) as unchanged drug

Dosage

Oral (I.V. infusion dose is the same as for the oral route):

Tuberculosis therapy: Note: A four-drug regimen (isoniazid, rifampin, pyrazinamide, and either streptomycin or ethambutol) is preferred for the initial, empiric treatment of TB. When the drug susceptibility results are available, the regimen should be altered as appropriate.

Infants and Children <12 years:

Daily therapy: 10-20 mg/kg/day usually as a single dose (maximum: 600 mg/day)

Directly observed therapy (DOT): Twice weekly: 10-20 mg/kg (maximum: 600 mg); 3 times/week: 10-20 mg/kg (maximum: 600 mg)

Adults:

Daily therapy: 10 mg/kg/day (maximum: 600 mg/day)

Directly observed therapy (DOT): Twice weekly: 10 mg/kg (maximum: 600 mg); 3 times/week: 10 mg/kg (maximum: 600 mg)

Latent tuberculosis infection (LTBI): As an alternative to isoniazid:

Children: 10-20 mg/kg/day (maximum: 600 mg/day)

Adults: 10 mg/kg/day (maximum: 600 mg/day) for 2 months. **Note:** Combination with pyrazinamide should not generally be offered (*MMWR*, Aug 8, 2003).

H. influenzae prophylaxis (unlabeled use):

Infants and Children: 20 mg/kg/day every 24 hours for 4 days, not to exceed 600 mg/dose

Adults: 600 mg every 24 hours for 4 days

Leprosy: Adults:

Multibacillary: 600 mg once monthly for 24 months in combination with ofloxacin and minocycline

Paucibacillary: 600 mg once monthly for 6 months in combination with dapson

Single lesion: 600 mg as a single dose in combination with ofloxacin 400 mg and minocycline 100 mg

Meningococcal meningitis prophylaxis:

Infants <1 month: 10 mg/kg/day in divided doses every 12 hours for 2 days

Infants ≥1 month and Children: 20 mg/kg/day in divided doses every 12 hours for 2 days

Adults: 600 mg every 12 hours for 2 days

Nasal carriers of *Staphylococcus aureus* (unlabeled use):

Children: 15 mg/kg/day divided every 12 hours for 5-10 days in combination with other antibiotics

Adults: 600 mg/day for 5-10 days in combination with other antibiotics

Synergy for *Staphylococcus aureus* infections (unlabeled use): Adults:

300-600 mg twice daily with other antibiotics

Dosing adjustment in hepatic impairment: Dose reductions may be necessary to reduce hepatotoxicity

Hemodialysis or peritoneal dialysis: Plasma rifampin concentrations are not significantly affected by hemodialysis or peritoneal dialysis.

Stability Reconstituted I.V. solution is stable for 24 hours at room temperature; rifampin oral suspension can be compounded with simple syrup or wild cherry syrup at a concentration of 10 mg/mL; the suspension is stable for 4 weeks at room temperature or in a refrigerator when stored in a glass amber prescription bottle

Monitoring Parameters Periodic (baseline and every 2-4 weeks during therapy) monitoring of liver function (AST, ALT, bilirubin), CBC; hepatic status and mental status, sputum culture, chest x-ray 2-3 months into treatment

Administration I.V.: Administer I.V. preparation once daily by slow I.V. infusion over 30 minutes to 3 hours at a final concentration not to exceed 6 mg/mL.

Oral: Administer on an empty stomach (ie, 1 hour prior to, or 2 hours after meals or antacids) to increase total absorption. The compounded oral suspension must be shaken well before using. May mix contents of capsule with applesauce or jelly.

Contraindications Hypersensitivity to rifampin, any rifamycins, or any component of the formulation; concurrent use of amprenavir, saquinavir/ritonavir (possibly other protease inhibitors)

Warnings

Use with caution and modify dosage in patients with liver impairment; observe for hyperbilirubinemia; discontinue therapy if this in conjunction with clinical symptoms or any signs of significant hepatocellular damage develop; since rifampin has enzyme-inducing properties, porphyria exacerbation is possible; use with caution in patients with porphyria; do not use for meningococcal disease, only for short-term treatment of asymptomatic carrier states. Use with caution in patients receiving concurrent medications associated with hepatotoxicity (particularly with pyrazinamide), or in patients with a history of alcoholism (even if ethanol consumption is discontinued during therapy).

Monitor for compliance and effects including hypersensitivity, thrombocytopenia in patients on intermittent therapy; urine, feces, saliva, sweat, tears, and CSF may be discolored to red/orange; do not administer I.V. form via I.M. or SubQ routes; restart infusion at another site if extravasation occurs; remove soft contact lenses during therapy since permanent staining may occur; regimens of 600 mg once or twice weekly have been associated with a high incidence of adverse reactions including a flu-like syndrome.

Dosage Forms

Capsule: 150 mg, 300 mg

Injection, powder for reconstitution: 600 mg

Overdosage/Treatment

Decontamination: Immediate administration of activated charcoal inhibits absorption by 90%; lavage (within 1 hour) useful in early ingestions; activated charcoal may be of value

Supportive therapy: Mainly supportive and symptomatic treatment; overdose is rare and experience is limited; monitor hepatic and renal function

Enhancement of elimination: Multiple dosing of activated charcoal may be effective due to enterohepatic circulation

Test Interactions ↑ bilirubin (S); positive Coombs' [direct]; rifampin can cause false-positive urine assay of opiates by kinetic interaction of microparticles in solution (KIMS) method up to a concentration of 0.9 mcg/mL

Drug Interactions/Induces CYP1A2 (strong), 2A6 (strong), 2B6 (strong), 2C8 (strong), 2C9 (strong), 2C19 (strong), 3A4 (strong)

Acetaminophen: Rifampin may increase the metabolism of acetaminophen.

Alfentanil: Rifampin derivatives may increase the metabolism, via CYP isoenzymes, of alfentanil.

Amiodarone: Rifampin derivatives may increase the metabolism, via CYP isoenzymes, of amiodarone

Angiotensin II receptor blockers (irbesartan, losartan): Rifampin derivatives may increase the metabolism, via CYP isoenzymes, of angiotensin II receptor blockers.

Antiemetics (5-HT₃ antagonists): Rifampin derivatives may increase the metabolism, via CYP isoenzymes, of antiemetics (5-HT₃ antagonists).

Antifungal Agents (imidazole): Rifampin derivatives may increase the metabolism, via CYP isoenzymes, of antifungal agents (imidazole).

Aprepitant: Rifampin derivatives may increase the metabolism, via CYP isoenzymes, of aprepitant.

Barbiturates: Rifampin derivatives may increase the metabolism, via CYP isoenzymes, of barbiturates.

Benzodiazepines (metabolized by oxidation): Rifampin derivatives may increase the metabolism, via CYP isoenzymes, of benzodiazepines (metabolized by oxidation).

Beta-blockers: Rifampin derivatives may increase the metabolism, via CYP isoenzymes, of beta-blockers.

Buspirone: Rifampin derivatives may increase the metabolism, via CYP isoenzymes, of buspirone.

Calcium channel blockers: Rifampin derivatives may increase the metabolism, via CYP isoenzymes, of calcium channel blockers.

Chloramphenicol: Rifampin may increase the metabolism, via CYP isoenzymes, of chloramphenicol.

Clopidogrel: Rifampin derivatives may enhance the therapeutic effect of Clopidogrel.

Corticosteroids (systemic): Rifampin derivatives may increase the metabolism, via CYP isoenzymes, of corticosteroids (systemic).

Cyclosporine: Rifampin derivatives may increase the metabolism, via CYP isoenzymes, of cyclosporine.

CYP1A2 substrates: Rifampin may decrease the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, estrogens, fluvoxamine, mirtazapine, ropinirole, and theophylline.

CYP2A6 substrates: Rifampin may decrease the levels/effects of CYP2A6 substrates (eg, ifosfamide).

CYP2B6 substrates: Rifampin may decrease the levels/effects of CYP2B6 substrates. Example substrates include bupropion, efavirenz, promethazine, selegiline, and sertraline.

CYP2C8 substrates: Rifampin may decrease the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP2C9 substrates: Rifampin may decrease the levels/effects of CYP2C9 substrates. Example substrates include bosentan, celecoxib, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, sulfonamides, trimethoprim, warfarin, and zafirlukast.

CYP2C19 substrates: Rifampin may decrease the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, proton pump inhibitors, sertraline, and voriconazole.

CYP3A4 substrates: Rifampin may decrease the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, clarithromycin, cyclosporine, erythromycin, estrogens, mirtazapine, nateglinide, nefazodone, nevirapine, protease inhibitors, tacrolimus, and venlafaxine.

Dapsone: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of dapsone.

Disopyramide: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of disopyramide.

Estrogens (oral contraceptives): Rifamycin derivatives may decrease the serum concentration of oral contraceptive (estrogens); contraceptive failure is possible.

Fexofenadine: Rifampin may decrease the serum concentration of fexofenadine.

Fluconazole: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of fluconazole.

Fusidic Acid: Rifampin may decrease the excretion of fusidic acid.

Gefitinib: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of gefitinib.

HMG-CoA reductase inhibitors: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of HMG-CoA reductase inhibitors.

Isoniazid: Rifamycin derivatives may enhance the hepatotoxic effect of isoniazid; however, this is a frequently employed combination regimen.

Macrolide antibiotics: Macrolide antibiotics may decrease the metabolism, via CYP isoenzymes, of rifamycin derivatives.

Methadone: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of methadone.

Morphine: Rifamycin derivatives may decrease the serum concentration of morphine sulfate.

Phenytoin: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of phenytoin.

Progestins (contraceptives): Rifamycin derivatives may decrease the serum concentration of contraceptive (progestins); contraceptive failure is possible.

Propafenone: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of propafenone.

Protease inhibitors: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of protease inhibitors. Concurrent use with saquinavir/ritonavir increases risk of hepatotoxicity. Rifampin administration should be avoided.

Pyrazinamide: Pyrazinamide may enhance the hepatotoxic effect of rifampin.

Quinidine: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of quinidine.

Repaglinide: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of repaglinide.

Reverse transcriptase inhibitors (non-nucleoside): Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of reverse transcriptase inhibitors (non-nucleoside).

Sulfonylureas: Rifampin may increase the metabolism, via CYP isoenzymes, of sulfonylureas.

Tacrolimus: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of tacrolimus.

Tamoxifen: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of tamoxifen.

Terbinafine: Rifamycin derivatives may increase the metabolism of terbinafine.

Tocainide: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of tocainide.

Tricyclic antidepressants: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of tricyclic antidepressants.

Warfarin: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of warfarin.

Zaleplon: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of zaleplon.

Zidovudine: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of zidovudine.

Zolpidem: Rifamycin derivatives may increase the metabolism, via CYP isoenzymes, of zolpidem.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic rate is 4.4% (hydro-cephalus, congenital limb changes)

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Nursing Implications Evaluate hepatic status and mental status; give on an empty stomach (ie, 1 hour prior to, or 2 hours after meals) to increase total absorption

Additional Information Lethal dose: 14 g. Normally used with other anti-TB drugs since resistant strains occur rapidly

Rilmenidine

CAS Number 54187-04-1

Unlabeled/Investigational Use Hypertension

Mechanism of Action Oxazoline derivative which has alpha₂-adrenergic receptor antagonist and an imidazoline receptor agonist with less sedation than clonidine

Adverse Reactions

Cardiovascular: Hypotension, shock

Respiratory: Bronchospasm

Toxicodynamics/Kinetics

Distribution: V_d: 5 L/kg

Protein binding: < 10%

Half-life: 8.31 hours

Time to peak plasma concentration: 2 hours

Elimination: Renal

Dosage Oral: 1-2 mg/day in divided doses

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: For hypotension, give I.V. saline; vasopressors may be necessary. Bronchospasm can be treated with beta-adrenergic agonist agents

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Test Interactions May decrease plasma norepinephrine and epinephrine

Riluzole

CAS Number 1744-22-5

U.S. Brand Names Rilutek®

Synonyms 2-Amino-6-Trifluoromethoxy-benzothiazole; RP-54274

Use Treatment of amyotrophic lateral sclerosis (ALS); riluzole can extend survival or time to tracheostomy

Mechanism of Action Glutamate neuroreceptor antagonist which promotes GABA activity

Adverse Reactions

Central nervous system: CNS depression, depression, vertigo

Gastrointestinal: **Nausea, abdominal pain, constipation**, pancreatitis

Hematologic: Neutropenia (within first 2 months of therapy), methemoglobinemia

Hepatic: **ALT (SGPT) elevations**, elevated liver function tests, hepatitis

Neuromuscular & skeletal: Myalgia, worsening of weakness spasticity or stiffness

Pharmacodynamics/Kinetics

Absorption: 90%; high-fat meal decreases AUC by 20% and peak blood levels by 45%

Protein binding, plasma: 96%, primarily to albumin and lipoproteins

Metabolism: Extensively hepatic to six major and a number of minor metabolites via CYP1A2 dependent hydroxylation and glucuronidation

Bioavailability: Oral: Absolute: 60%

Half-life elimination: 12 hours

Excretion: Urine (90%; 85% as metabolites, 2% as unchanged drug) and feces (5%) within 7 days

Dosage

Adults: Oral: 50 mg every 12 hours; no increased benefit can be expected from higher daily doses, but adverse events are increased

Dosage adjustment in smoking: Cigarette smoking is known to induce CYP1A2; patients who smoke cigarettes would be expected to eliminate riluzole faster. There is no information, however, on the effect of, or need for, dosage adjustment in these patients.

Dosage adjustment in special populations: Females and Japanese patients may possess a lower metabolic capacity to eliminate riluzole compared with male and Caucasian subjects, respectively

Dosage adjustment in renal impairment: Use with caution in patients with concomitant renal insufficiency

RIMANTADINE

Dosage adjustment in hepatic impairment: Use with caution in patients with current evidence or history of abnormal liver function indicated by significant abnormalities in serum transaminase, bilirubin or GGT levels. Baseline elevations of several LFTs (especially elevated bilirubin) should preclude use of riluzole.

Monitoring Parameters Monitor serum aminotransferases including ALT levels before and during therapy. Evaluate serum ALT levels every month during the first 3 months of therapy, every 3 months during the remainder of the first year and periodically thereafter. Evaluate ALT levels more frequently in patients who develop elevations. Maximum increases in serum ALT usually occurred within 3 months after the start of therapy and were usually transient when <5 times ULN (upper limits of normal).

In trials, if ALT levels were <5 times ULN, treatment continued and ALT levels usually returned to below 2 times ULN within 2-6 months.

Treatment in studies was discontinued, however, if ALT levels exceed 5 times ULN, so that there is no experience with continued treatment of ALS patients once ALT values exceed 5 times ULN.

If a decision is made to continue treatment in patients when the ALT exceeds 5 times ULN, frequent monitoring (at least weekly) of complete liver function is recommended. Discontinue treatment if ALT exceeds 10 times ULN or if clinical jaundice develops.

Administration Administer at the same time each day, 1 hour before or 2 hours after a meal.

Contraindications Severe hypersensitivity reactions to riluzole or any component of the formulation

Warnings Among 4000 patients given riluzole for ALS, there were 3 cases of marked neutropenia (ANC <500/mm³), all seen within the first 2 months of treatment. Use with caution in patients with concomitant renal insufficiency. Use with caution in patients with current evidence or history of abnormal liver function; do not administer if baseline liver function tests are elevated. The elderly, female, or Japanese patients may have decreased clearance of riluzole; use with caution. May cause dizziness or somnolence; caution should be used performing tasks which require alertness (operating machinery or driving).

Dosage Forms Tablet: 50 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Methemoglobin which is symptomatic or a methemoglobin level >30% should be treated with methylene blue (50 mg I.V. in adults).

Antidote(s)

- Methylene Blue [ANTIDOTE]

Drug Interactions Substrate of CYP1A2 (major)

CYP1A2 inducers: May decrease the levels/effects of riluzole. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of riluzole. Example inhibitors include amiodarone, ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

Pregnancy Risk Factor C

Pregnancy Implications Impaired fertility, decreased implantation, increased intrauterine death, and adverse effects on offspring growth and viability were observed in animal studies. There are no adequate or well-controlled studies in pregnant women.

Lactation Excretion in breast milk unknown/not recommended

Additional Information May be obtained through Rhone-Poulenc Rorer Inc (Collegeville, PA) for compassionate use (through treatment IND process) by calling 800-727-6737 for treatment of amyotrophic lateral sclerosis; may be more effective for amyotrophic lateral sclerosis of bulbar onset; in animal models, riluzole was a potent inhibitor of seizures induced by ouabain

Specific References

Woolf A, Carstairs SD, Tanen DA, "Riluzole-Induced Methemoglobinemia," *Ann Emerg Med*, 2004, 43(2):294-5.

Rimantadine

CAS Number 13392-28-4; 1501-84-4

U.S. Brand Names Flumadine®

Synonyms Rimantadine Hydrochloride

Use Prophylaxis (adults and children) and treatment (adults) of influenza A viral infection (not influenza B)

Mechanism of Action Similar to amantadine; inhibits viral RNA and protein synthesis

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), edema

Central nervous system: Dizziness, confusion, headache, insomnia, difficulty in concentrating, anxiety, restlessness, irritability, hallucinations

Gastrointestinal: Nausea, vomiting, xerostomia

Genitourinary: Urinary retention

Signs and Symptoms of Overdose Convulsions (especially in the elderly), sedation

Pharmacodynamics/Kinetics

Onset of action: Antiviral activity: No data exist establishing a correlation between plasma concentration and antiviral effect

Absorption: Tablet and syrup formulations are equally absorbed

Metabolism: Extensively hepatic

Half-life elimination: 25.4 hours; prolonged in elderly

Time to peak: 6 hours

Excretion: Urine (<25% as unchanged drug)

Clearance: Hemodialysis does not contribute to clearance

Dosage Oral:

Prophylaxis:

Children < 10 years: 5 mg/kg give once daily

Children > 10 years and Adults: 100 mg twice/day

Treatment: Adults: 100 mg twice/day

In patients with severe hepatic dysfunction or renal function, and in elderly nursing home patients, the dosage should be reduced to 100 mg/day

Monitoring Parameters Monitor for CNS or GI effects in elderly or patients with renal or hepatic impairment

Administration Initiation of rimantadine within 48 hours of the onset of influenza A illness halves the duration of illness and significantly reduces the duration of viral shedding and increased peripheral airways resistance; continue therapy for 5-7 days after symptoms begin

Contraindications Hypersensitivity to drugs of the adamantane class, including rimantadine and amantadine, or any component of the formulation

Warnings Use with caution in patients with renal and hepatic dysfunction; avoid use, if possible, in patients with recurrent and eczematoid dermatitis, uncontrolled psychosis, or severe psychoneurosis. An increase in seizure incidence may occur in patients with seizure disorders; discontinue drug if seizures occur; resistance may develop during treatment; viruses exhibit cross-resistance between amantadine and rimantadine. Due to increased resistance, in June 2006, the CDC recommended that rimantadine no longer be used for the treatment or prophylaxis of influenza A in the United States until susceptibility has been re-established.

Dosage Forms Syrup, as hydrochloride:

Flumadine®: 50 mg/5 mL (240 mL) [raspberry flavor]

Tablet, as hydrochloride: 100 mg

Flumadine®: 100 mg

Reference Range Peak serum levels: 240-320 ng/mL after a 200 mg dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may not be useful

Drug Interactions Acetaminophen: Small reduction in AUC and peak concentration of rimantadine.

Aspirin: Peak plasma and AUC concentrations of rimantadine are slightly reduced.

Cimetidine: Rimantadine clearance is decreased (~18%).

Pregnancy Risk Factor C

Pregnancy Implications Embryotoxic in high dose rat studies.

Lactation Excretion in breast milk unknown/ not recommended

Specific References

Singer C, Papapetropoulos S, Gonzalez MA, et al, "Rimantadine in Parkinson's Disease Patients Experiencing Peripheral Adverse Effects from Amantadine: Report of a Case Series," *Mov Disord*, 2005, 20(7):873-7.

Risedronate

CAS Number 105462-24-6; 115436-72-1

U.S. Brand Names Actonel®

Synonyms Risedronate Sodium

Use Paget's disease of the bone; treatment and prevention of glucocorticoid-induced osteoporosis; treatment and prevention of osteoporosis in postmenopausal women

Mechanism of Action A potent bisphosphonate which inhibits bone resorption via actions on osteoclasts or on osteoclast precursors; decreases the rate of bone resorption direction, leading to an indirect decrease in bone formation

Adverse Reactions

Cardiovascular: Chest pain

Central nervous system: Headache, dizziness

Dermatological: Rash

Gastrointestinal: Abdominal pain, diarrhea, belching, colitis, constipation, nausea

Neuromuscular & skeletal: Arthralgia, bone pain, leg cramps, myasthenia

Respiratory: Bronchitis, rales/rhinitis

Pharmacodynamics/Kinetics

Onset of action: May require weeks

Absorption: Rapid

Distribution: V_d: 6.3 L/kg

Protein binding: ~24%

Metabolism: None
 Bioavailability: Poor, ~0.54% to 0.75%
 Half-life elimination: Initial: 1.5 hours; Terminal: 480 hours
 Excretion: Urine (up to 85%); feces (as unabsorbed drug)

Dosage

Oral:

Adults (patients should receive supplemental calcium and vitamin D if dietary intake is inadequate):

Paget's disease of bone: 30 mg once daily for 2 months

Treatment and prevention of postmenopausal osteoporosis or glucocorticoid-induced osteoporosis: 5 mg once daily (efficacy for use longer than 1 year has not been established)

Elderly: No dosage adjustment is necessary

Dosage adjustment in renal impairment: $Cl_{cr} < 30$ mL/minute: Not recommended

Monitoring Parameters Alkaline phosphatase should be periodically measured; serum calcium, phosphorus, and possibly potassium due to its drug class; use of absorptiometry may assist in noting benefit in osteoporosis; monitor pain and fracture rate

Administration It is imperative to administer risperidone 30-60 minutes before the patient takes any food, drink, or other medications orally to avoid interference with absorption. The patient should take alendronate on an empty stomach with a full glass (8 oz) of plain water (not mineral water) and avoid lying down for 30 minutes after swallowing the tablet to help delivery to stomach.

Contraindications Hypersensitivity to risperidone, bisphosphonates, or any component of the formulation; hypocalcemia; abnormalities of the esophagus which delay esophageal emptying such as stricture or achalasia; inability to stand or sit upright for at least 30 minutes; severe renal impairment ($Cl_{cr} < 30$ mL/minute)

Warnings

Bisphosphonates may cause upper gastrointestinal disorders such as dysphagia, esophagitis, esophageal ulcer, and gastric ulcer. Use caution in patients with renal impairment. Hypocalcemia must be corrected before therapy initiation with risperidone. Ensure adequate calcium and vitamin D intake, especially for patients with Paget's disease in whom the pretreatment rate of bone turnover may be greatly elevated.

Bisphosphonate therapy has been associated with osteonecrosis, primarily of the jaw; this has been observed mostly in cancer patients, but also in patients with postmenopausal osteoporosis and other diagnoses. There are no data addressing whether discontinuation of therapy reduces the risk of developing osteonecrosis. However, as a precautionary measure, dental exams and preventative dentistry should be performed prior to placing patients with risk factors (eg, chemotherapy, corticosteroids, poor oral hygiene) on chronic bisphosphonate therapy. Invasive dental procedures should be avoided during treatment.

Infrequently, severe (and occasionally debilitating) bone, joint, and/or muscle pain have been reported during bisphosphonate treatment. The onset of pain ranged from a single day to several months. Symptoms usually resolve upon discontinuation. Some patients experienced recurrence when rechallenged with same drug or another bisphosphonate; avoid use in patients with a history of these symptoms in association with bisphosphonate therapy.

Safety and efficacy in pediatric patients have not been established.

Dosage Forms Tablet, as sodium:

Actonel®: 5 mg, 30 mg, 35 mg

Reference Range Calcium (total): Adults: 9.0-11.0 mg/dL (2.05-2.54 mM/L), may slightly decrease with aging; phosphorus: 2.5-4.5 mg/dL (0.81-1.45 mM/L)

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Monitor serum calcium and phosphorus; give I.V. hydration

Drug Interactions Aminoglycosides: May lower serum calcium levels with prolonged administration. Concomitant use may have an additive hypocalcemic effect.

Antacids: May decrease the absorption of bisphosphonate derivatives; should be administered at a different time of the day. Antacids containing aluminum, calcium, or magnesium are of specific concern.

Calcium salts: May decrease the absorption of bisphosphonate derivatives. Separate oral dosing in order to minimize risk of interaction.

Iron salts: May decrease the absorption of bisphosphonate derivatives. Only oral iron salts and oral bisphosphonates are of concern.

Magnesium salts: May decrease the absorption of bisphosphonate derivatives. Only oral magnesium salts and oral bisphosphonates are of concern.

Nonsteroidal anti-inflammatory drugs (NSAIDs): May enhance the gastrointestinal adverse/toxic effects (increased incidence of GI ulcers) of bisphosphonate derivatives.

Phosphate supplements: Bisphosphonate derivatives may enhance the hypocalcemic effect of phosphate supplements.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic and nonteratogenic embryo/fetal effects have been reported in animal studies. There are no adequate and well-controlled studies in pregnant women. Bisphosphonates are incorporated into the bone matrix and gradually released over time. Theoretically, there may be a risk of fetal harm when pregnancy follows the completion of therapy. Based on limited case reports with pamidronate, serum calcium levels in the newborn may be altered if administered during pregnancy.

Lactation Excretion in breast milk unknown/not recommended

Specific References

French AE, Kaplan N, Lishner M, et al, "Taking Bisphosphonates During Pregnancy," *Can Fam Physician*, 2003, 49:1281-2.

Risperidone

Related Information

- Antipsychotic Agents

CAS Number 106266-06-2

U.S. Brand Names Risperdal® Consta™; Risperdal® M-Tab®; Risperdal®

Synonyms Risperdal M-Tab®

Impairment Potential Yes

Use Treatment of schizophrenia; treatment of acute mania or mixed episodes associated with bipolar I disorder (as monotherapy or in combination with lithium or valproate)

Unlabeled/Investigational Use Behavioral symptoms associated with dementia in elderly; treatment of Tourette's disorder; treatment of pervasive developmental disorder and autism in children and adolescents

Mechanism of Action Risperidone is a benzisoxazole derivative, mixed serotonin-dopamine antagonist; binds to 5-HT₂-receptors in the CNS and in the periphery with a very high affinity; binds to dopamine-D₂ receptors with less affinity. The binding affinity to the dopamine-D₂ receptor is 20 times lower than the 5-HT₂ affinity. The addition of serotonin antagonism to dopamine antagonism (classic neuroleptic mechanism) is thought to improve negative symptoms of psychoses and reduce the incidence of extrapyramidal side effects. Alpha₁, alpha₂ adrenergic, and histaminergic receptors are also antagonized with high affinity. Risperidone has low to moderate affinity for 5-HT_{1C}, 5-HT_{1D}, and 5-HT_{1A} receptors, weak affinity for D₁ and no affinity for muscarinics or beta₁ and beta₂ receptors

Adverse Reactions

Frequency not defined: Gastrointestinal: Dysphagia, esophageal dysmotility

Cardiovascular: Hypotension (especially orthostatic), tachycardia

Central nervous system: **Insomnia, agitation, anxiety, headache, extrapyramidal symptoms (dose dependent), dizziness (I.M. injection)**, sedation, dizziness (oral formulation), restlessness, dystonic reactions, pseudoparkinsonism, tardive dyskinesia, neuroleptic malignant syndrome, altered central temperature regulation, nervousness, fatigue, somnolence, hallucination, tremor, hypoesthesia, akathisia, stroke

Dermatologic: Photosensitivity (rare), rash, dry skin, seborrhea, acne

Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, sexual dysfunction, diabetes mellitus, hyperglycemia

Gastrointestinal: **Weight gain**, constipation, GI upset, xerostomia, dyspepsia, vomiting, abdominal pain, nausea, anorexia, diarrhea, weight changes

Genitourinary: Polyuria

Neuromuscular & skeletal: Myalgia

Ocular: Abnormal vision

Respiratory: **Rhinitis (I.M. injection)**

Neuromuscular & skeletal: Myalgia

Ocular: Abnormal vision

Respiratory: Rhinitis (oral formulation), coughing, sinusitis, pharyngitis, dyspnea

Miscellaneous: Anaphylactic reaction

Signs and Symptoms of Overdose Dystonia, ejaculatory disturbances, enuresis, hallucinations, hypotension, mania, muscle spasms, neuroleptic malignant syndrome, palpitations, prolonged QT interval, tachycardia, hyponatremia

Pharmacodynamics/Kinetics

Absorption:

Oral: Rapid and well absorbed; food does not affect rate or extent

Injection: <1% absorbed initially; main release occurs at ~3 weeks and is maintained from 4-6 weeks

Distribution: V_d: 1-2 L/kg

Protein binding, plasma: Risperidone 90%; 9-hydroxyrisperidone: 77%

Metabolism: Extensively hepatic via CYP2D6 to 9-hydroxyrisperidone (similar pharmacological activity as risperidone); N-dealkylation is a second minor pathway

Bioavailability: Solution: 70%; Tablet: 66%; orally-disintegrating tablets and oral solution are bioequivalent to tablets

Half-life elimination: Active moiety (risperidone and its active metabolite 9-hydroxyrisperidone)

Oral: 20 hours (mean)

Extensive metabolizers: Risperidone: 3 hours; 9-hydroxyrisperidone: 21 hours

Poor metabolizers: Risperidone: 20 hours; 9-hydroxyrisperidone: 30 hours

Injection: 3-6 days; related to microsphere erosion and subsequent absorption of risperidone

Time to peak, plasma: Oral: Risperidone: Within 1 hour; 9-hydroxyrisperidone: Extensive metabolizers: 3 hours; Poor metabolizers: 17 hours

Excretion: Urine (70%); feces (15%)

Dosage

Oral:

Children and Adolescents:

Pervasive developmental disorder (unlabeled use): Initial: 0.25 mg twice daily; titrate up 0.25 mg/day every 5-7 days; optimal dose range: 0.75-3 mg/day

Autism (unlabeled use): Initial: 0.25 mg at bedtime; titrate to 1 mg/day (0.1 mg/kg/day)

Schizophrenia (unlabeled use): Initial: 0.5 mg once or twice daily; titrate as necessary up to 2-6 mg/day

Bipolar disorder (unlabeled use): Initial: 0.5 mg; titrate to 0.5-3 mg/day

Tourette's disorder (unlabeled use): Initial: 0.5 mg; titrate to 2-4 mg/day

Adults:

Schizophrenia:

Initial: 1 mg twice daily; may be increased by 2 mg/day to a target dose of 6 mg/day; usual range: 4-8 mg/day; may be given as a single daily dose once maintenance dose is achieved; daily dosages >6 mg do not appear to confer any additional benefit, and the incidence of extrapyramidal symptoms is higher than with lower doses. Further dose adjustments should be made in increments/decrements of 1-2 mg/day on a weekly basis. Dose range studied in clinical trials: 4-16 mg/day.

Maintenance: Target dose: 4 mg once daily (range 2-8 mg/day)

Bipolar mania:

Initial: 2-3 mg once daily; if needed, adjust dose by 1 mg/day in intervals \geq 24 hours; dosing range: 1-6 mg/day

Maintenance: No dosing recommendation available for treatment >3 weeks duration.

Elderly: A starting dose of 0.5 mg twice daily, and titration should progress slowly in increments of no more than 0.5 mg twice daily; increases to dosages > 1.5 mg twice daily should occur at intervals of \geq 1 week.

Additional monitoring of renal function and orthostatic blood pressure may be warranted. If once-a-day dosing in the elderly or debilitated patient is considered, a twice daily regimen should be used to titrate to the target dose, and this dose should be maintained for 2-3 days prior to attempts to switch to a once-daily regimen.

I.M.: Adults: Schizophrenia (Risperdal[®] Consta[™]): 25 mg every 2 weeks; some patients may benefit from larger doses; maximum dose not to exceed 50 mg every 2 weeks. Dosage adjustments should not be made more frequently than every 4 weeks.

Note: Oral risperidone (or other antipsychotic) should be administered with the initial injection of Risperdal[®] Consta[™] and continued for 3 weeks (then discontinued) to maintain adequate therapeutic plasma concentrations prior to main release phase of risperidone from injection site. When switching from depot administration to a short-acting formulation, administer short-acting agent in place of the next regularly-scheduled depot injection.

Dosing adjustment in renal impairment: Oral: Starting dose of 0.5 mg twice daily; clearance of the active moiety is decreased by 60% in patients with moderate to severe renal disease compared to healthy subjects.

Dosing adjustment in hepatic impairment: Oral: Starting dose of 0.5 mg twice daily; the mean free fraction of risperidone in plasma was increased by 35% compared to healthy subjects.

Monitoring Parameters Vital signs; lipid profile, fasting blood glucose/Hgb A_{1c}; BMI; mental status, abnormal involuntary movement scale (AIMS), extrapyramidal symptoms; orthostatic blood pressure changes for 3-5 days after starting or increasing dose

Administration Oral: Oral solution can be mixed with water, coffee, orange juice, or low-fat milk, but is **not compatible** with cola or tea. May be administered with or without food.

Risperdal[®] M-Tabs[™] should not be removed from blister pack until administered. Using dry hands, place immediately on tongue. Tablet will dissolve within seconds, and may be swallowed with or without liquid. Do not split or chew.

I.M.: Risperdal[®] Consta[™] should be administered into the upper outer quadrant of the gluteal area. Injection should alternate between the two buttocks. Do not combine two different dosage strengths into one single administration. Do not substitute any components of the dose-pack; administer with needle provided.

Contraindications Hypersensitivity to risperidone or any component of the formulation

Warnings

[U.S. Boxed Warning]: Elderly patients with dementia-related behavioral disorders treated with atypical antipsychotics are at an increased risk of cerebrovascular adverse events and death compared to placebo; risk may be increased with dehydration (increased risk of death observed with concurrent furosemide). Risperidone is not approved for the treatment of dementia-related psychosis.

Low to moderately sedating, use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Caution in patients with hemodynamic instability; bone marrow suppression; predisposition to seizures; subcortical brain damage; severe cardiac, hepatic, or respiratory disease. Use with caution in renal or hepatic dysfunction; dose reduction recommended. Esophageal dysmotility and aspiration have been associated with antipsychotic use; use with caution in patients at risk of aspiration pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (elevates prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects.

May cause orthostasis. Use with caution in patients with cardiovascular diseases (eg, heart failure, history of myocardial infarction or ischemia, cerebrovascular disease, conduction abnormalities). Use caution in patients receiving medications for hypertension (orthostatic effects may be exacerbated) or in patients with hypovolemia or dehydration. May alter cardiac conduction (low risk relative to other neuroleptics); life-threatening arrhythmias have occurred with therapeutic doses of neuroleptics.

May cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention); therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other neuroleptics, risperidone has a low potency of cholinergic blockade.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is low relative to other neuroleptics, and is dose dependent). Risk of neuroleptic malignant syndrome (NMS) may be increased in patients with Parkinson's disease or Lewy Body Dementia; monitor for symptoms of confusion, obtundation, postural instability and extrapyramidal symptoms. May cause hyperglycemia; in some cases may be extreme and associated with ketoacidosis, hyperosmolar coma, or death. Use with caution in patients with diabetes or other disorders of glucose regulation; monitor for worsening of glucose control.

The possibility of a suicide attempt is inherent in psychotic illness or bipolar disorder; use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. Safety and efficacy in children have not been established.

Dosage Forms Injection, microspheres for reconstitution, extended release (Risperdal[®] Consta[™]): 25 mg, 37.5 mg, 50 mg [supplied in a dose-pack containing vial with active ingredient in microsphere formulation, prefilled syringe with diluent, needle-free vial access device, and safety needle]

Solution, oral: 1 mg/mL (30 mL) [contains benzoic acid]

Tablet: 0.25 mg, 0.5 mg, 1 mg, 2 mg, 3 mg, 4 mg

Tablet, orally disintegrating (Risperdal[®] M-Tabs[™]): 0.5 mg [contains phenylalanine 0.42 mg]; 3 mg [contains phenylalanine 0.63 mg]; 4 mg [contains phenylalanine 0.84 mg]

Reference Range

Within 2 hours of a 1 mg oral dose, peak plasma level: 3-8 mcg/L; postmortem blood and urinary risperidone levels following a suicidal ingestion: 1.8 mg/L and 14.4 mg/L, respectively

Overdosage/Treatment

Decontamination: Lavage/activated charcoal within 1 hour

Supportive therapy: Lidocaine or phenytoin for ventricular arrhythmia; magnesium sulfate (I.V.: 2 g) may cause resolution of prolonged QT_c dispersion; sertraline can be used to treat risperidone-induced obsessive compulsive symptoms

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Asymptomatic patients with normal EKG may be discharged after a 6-hour period of observation. Symptomatic patients should be admitted to a setting where careful monitoring of their cardiac rhythm and mental status can occur.

Test Interactions ↑ prolactin

Drug Interactions

Substrate of CYP2D6 (major), 3A4 (minor); **Inhibits** CYP2D6 (weak), 3A4 (weak)

Acetylcholinesterase inhibitors (central): May increase the risk of anti-psychotic-related extrapyramidal symptoms; monitor.

Carbamazepine: Plasma concentrations of risperidone and 9-hydroxyrisperidone were decreased by ~50% with concomitant use. The dose of risperidone may need to be titrated accordingly when carbamazepine is added or discontinued.

Clozapine: Decreases clearance of risperidone, increasing its serum concentrations

CNS depressants: May increase adverse effects/toxicity of other CNS depressants.

CYP2D6 inhibitors: May increase the levels/effects of risperidone. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Lithium: May increase the neurotoxic effects (eg, EPS) of risperidone; monitor.

Pramlintide: May enhance the anticholinergic effect of risperidone. These effects are specific to the GI tract.

SSRIs: May increase the levels/effects of risperidone; monitor.

Verapamil: May increase the levels and effects of risperidone.

Pregnancy Risk Factor C; Enters breast milk/contraindicated

Pregnancy Implications Risperidone and its metabolite are excreted in breast milk; it is recommended that women not breast feed during therapy or for 12 weeks after the last injection if using Risperdal® Consta™.

Lactation Enters breast milk/not recommended

Additional Information Temazepam (30 mg) can be used to treat insomnia due to risperidone. Avoid ethanol, kava kava, gotu kola, valerian, and St John's wort (may increase CNS depression). Risperdal® M-Tabs™ contain phenylalanine.

Risperdal Consta™ is an injectable formulation of risperidone using the extended release Medisorb® drug-delivery system; small polymeric microspheres degrade slowly, releasing the medication at a controlled rate.

Ritodrine

CAS Number 23239-51-2; 26652-09-5

Synonyms Ritodrine Hydrochloride

Use Inhibits uterine contraction in preterm labor

Mechanism of Action Tocolysis due to its uterine beta₂-adrenergic receptor stimulating effects; this agent's beta₂ effects can also cause bronchial relaxation and vascular smooth muscle stimulation

Adverse Reactions

Cardiovascular: Tachycardia, **hypertension** (increases in maternal and fetal heart rates and maternal hypertension), **palpitations**, angina, chest pain, sinus tachycardia, tachycardia (supraventricular)

Central nervous system: Headache, migraine headache (exacerbation of), mania

Endocrine & metabolic: **Hyperglycemia** (temporary) and insulin concentrations, galactorrhea, decreases serum potassium concentrations, parotitis, hypokalemia

Gastrointestinal: **Vomiting, nausea**

Hematologic: Leukocytosis, leukemoid reaction, neutropenia

Neuromuscular & skeletal: **Tremors**

Respiratory: Pulmonary edema

Signs and Symptoms of Overdose Parotid pain

Pharmacodynamics/Kinetics

Distribution: Crosses placenta

Protein binding: 32%

Metabolism: Hepatic

Half-life elimination: 15 hours

Time to peak, serum: 0.5-1 hour

Excretion: Urine (as unchanged drug and inactive conjugates)

Dosage

Adults:

I.V.: 50-100 mcg/minute; increase by 50 mcg/minute every 10 minutes; continue for 12 hours after contractions have stopped

Oral: Start 30 minutes before stopping I.V. infusion; 10 mg every 2 hours for 24 hours, then 10-20 mg every 4-6 hours up to 120 mg/day

Stability Stable for 48 hours at room temperature after dilution in 500 mL of NS, D₅W, or LR I.V. solutions

Monitoring Parameters Hematocrit, serum potassium, glucose, colloidal osmotic pressure, heart rate, and uterine contractions

Administration Monitor amount of I.V. fluid administered to prevent fluid overload; place patient in left lateral recumbent position to reduce risk of hypotension; use microdrip chamber or I.V. pump to control infusion rate

Contraindications Cardiac arrhythmias; pheochromocytoma; pregnancy (before 20th week)

Warnings Monitor hydration status and blood glucose concentrations; fatal maternal pulmonary edema has been reported, sometimes after delivery; fluid overload must be avoided, hydration levels should be monitored closely; if pulmonary edema occurs, the drug should be discontinued; use with caution in patients with moderate pre-eclampsia, diabetes, or migraine; some products may contain sulfites; maternal deaths have been reported in patients treated with ritodrine and concurrent corticosteroids (pulmonary edema)

Dosage Forms Ritodrine hydrochloride:

Injection: 10 mg/mL (5 mL); 15 mg/mL (10 mL)

Tablet: 10 mg

Reference Range After an oral 120 mg dose, maximum blood ritodrine level is 32 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Diazepam or lorazepam can be given for agitation; esmolol (50-100 mcg/kg I.V.) can be used for tachyarrhythmia

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; hemodialysis may be effective

Drug Interactions Decreased effect with beta-blockers

Increased effect/toxicity with meperidine, sympathomimetics, diazoxide, magnesium, betamethasone (pulmonary edema), potassium-depleting diuretics, general anesthetics

Pregnancy Risk Factor B (contraindicated before 20th week)

Pregnancy Implications Increased fetal heart rate; transient fetal hypoglycemia, hyperbilirubinemia in neonates have been noted; crosses the placenta

Nursing Implications Monitor amount of I.V. fluid administered to prevent fluid overload; place patient in left lateral recumbent position to reduce risk of hypotension; use microdrip chamber or I.V. pump to control infusion rate

Ritonavir

U.S. Brand Names Norvir®

Use Treatment of HIV infection; should always be used as part of a multidrug regimen (at least 3 antiretroviral agents)

Mechanism of Action Peptidomimetic inhibitor of HIV-1 and HIV-2 proteases

Adverse Reactions

Protease inhibitors cause dyslipidemia which includes elevated cholesterol and triglycerides and a redistribution of body fat centrally to cause increased abdominal girth, buffalo hump, facial atrophy, and breast enlargement. These agents also cause hyperglycemia.

Cardiovascular: Vasodilation

Central nervous system: Fever, headache, malaise, dizziness, insomnia, somnolence, thinking abnormally

Dermatologic: Rash

Endocrine & metabolic: **Increased triglycerides**, hyperlipidemia, increased uric acid, increased glucose

Gastrointestinal: **Diarrhea, nausea, vomiting, taste perversion**, abdominal pain, anorexia, constipation, dyspepsia, flatulence, local throat irritation

Hematologic: **Anemia, decreased WBCs**, neutropenia, eosinophilia, neutrophilia, prolonged PT, leukocytosis

Hepatic: **Increased GGT**, increased liver function test results

Neuromuscular & skeletal: **Weakness**, increased CPK, myalgia, paresthesia

Respiratory: Pharyngitis

Miscellaneous: Diaphoresis, increased potassium, increased calcium

Pharmacodynamics/Kinetics

Absorption: Variable; increased with food

Distribution: High concentrations in serum and lymph nodes

Protein binding: 98% to 99%

Metabolism: Hepatic via CYP3A4 and 2D6; five metabolites, low concentration of an active metabolite achieved in plasma (oxidative)

Half-life elimination: 3-5 hours

Time to peak, plasma: 2 hours (fasted); 4 hours (nonfasted)

Excretion: Urine (~11%); feces (~86%)

Dosage/Treatment of HIV infection: Oral:

Children >1 month: 350-400 mg/m² twice daily (maximum dose: 600 mg twice daily). Initiate dose at 250 mg/m² twice daily; titrate dose upward every 2-3 days by 50 mg/m² twice daily.

Adults: 600 mg twice daily; dose escalation tends to avoid nausea that many patients experience upon initiation of full dosing. Escalate the dose as follows: 300 mg twice daily for 1 day, 400 mg twice daily for 2 days, 500 mg twice daily for 1 day, then 600 mg twice daily. Ritonavir may be better tolerated when used in combination with other antiretrovirals by initiating the drug alone and subsequently adding the second agent within 2 weeks.

Pharmacokinetic “booster” in combination with other protease inhibitors: 100-400 mg/day

Refer to individual monographs; specific dosage recommendations often require adjustment of both agents.

Note: Dosage adjustments for ritonavir when administered in combination therapy:

Amprrenavir: Adjustments necessary for each agent:

Amprrenavir 1200 mg with ritonavir 200 mg once daily **or**

Amprrenavir 600 mg with ritonavir 100 mg twice daily

Amprrenavir plus efavirenz (3-drug regimen): Amprrenavir 1200 mg twice daily plus ritonavir 200 mg twice daily plus efavirenz at standard dose

Indinavir: Adjustments necessary for both agents:

Indinavir 800 mg twice daily plus ritonavir 100-200 mg twice daily **or**

Indinavir 400 mg twice daily plus ritonavir 400 mg twice daily

Nelfinavir: Ritonavir 400 mg twice daily

Rifabutin: Decrease rifabutin dose to 150 mg every other day

Saquinavir: Ritonavir 400 mg twice daily

Dosing adjustment in renal impairment: None necessary

Dosing adjustment in hepatic impairment: No adjustment required in mild or moderate impairment; however, careful monitoring is required in moderate hepatic impairment (levels may be decreased); caution advised with severe impairment (no data available)

Monitoring Parameters Triglycerides, cholesterol, CBC, LFTs, CPK, uric acid, basic HIV monitoring, viral load, and CD4 count, glucose

Administration Administer with food. Liquid formulations usually have an unpleasant taste. Consider mixing it with chocolate milk or a liquid nutritional supplement. Whenever possible, administer oral solution with calibrated dosing syringe.

Contraindications Hypersensitivity to ritonavir or any component of the formulation; concurrent alfuzosin, amiodarone, cisapride, dihydroergotamine, ergonovine, ergotamine, flecainide, methylergonovine, midazolam, pimozone, propafenone, quinidine, triazolam, and voriconazole (when ritonavir \geq 800 mg/day)

Warnings

[U.S. Boxed Warning]: Ritonavir may interact with many medications, resulting in potentially serious and/or life-threatening adverse events; careful review is required. A listing of medications that should not be used is available with each bottle and patients should be provided with this information. Avoid concurrent use with lovastatin, simvastatin, and St John's wort; atorvastatin should be used at the lowest possible dose, while fluvastatin or pravastatin may be safer alternatives. Cushing's syndrome and adrenal suppression have been reported in patients receiving concomitant ritonavir and fluticasone; avoid concurrent use unless benefit outweighs risk. Dosage adjustment is required for combination therapy with amprrenavir and ritonavir; in addition, the risk of hyperlipidemia may be increased during concurrent therapy. Cardiac and neurological events have been reported with concurrent use of disopyramide, mexiletine, nefazodone, fluoxetine or beta blockers. Pancreatitis has been observed; use with caution in patients with increased triglycerides; monitor serum lipase and amylase. Use with caution in patients with hemophilia A or B; increased bleeding during protease inhibitor therapy has been reported. Changes in glucose tolerance, hyperglycemia, exacerbation of diabetes, DKA, and new-onset diabetes mellitus have been reported in patients receiving protease inhibitors. May be associated with fat redistribution (buffalo hump, increased abdominal girth, breast engorgement, facial atrophy, and dyslipidemia). Immune reconstitution syndrome may develop resulting in the occurrence of an inflammatory response to an indolent or residual opportunistic infection; further evaluation and treatment may be required. May cause hepatitis or exacerbate pre-existing hepatic dysfunction; use with caution in patients with hepatitis B or C and in hepatic disease. Safety and efficacy have not been established in children $<$ 1 month of age.

Dosage Forms Capsule: 100 mg [contains ethanol and polyoxyl 35 castor oil]

Solution: 80 mg/mL (240 mL) [contains ethanol and polyoxyl 35 castor oil; peppermint and caramel flavor]

Reference Range After a 400 mg oral dose, peak serum ritonavir level: \sim 5.3 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Treatment is supportive.

Drug Interactions

Substrate of CYP1A2 (minor), 2B6 (minor), 2D6 (major), 3A4 (major);

Inhibits CYP2C8 (strong), 2C9 (weak), 2C19 (weak), 2D6 (strong), 2E1

(weak), 3A4 (strong); **Induces** CYP1A2 (weak), 2C8 (weak), 2C9 (weak), 3A4 (weak)

Alfuzosin: Serum concentrations may be increased by ritonavir; concurrent use is contraindicated.

Amprrenavir: The serum concentrations of ritonavir may be increased by amprrenavir. In addition, the risk of cholesterol/triglyceride elevations may be increased. Specific dosing has been recommended for both agents.

Analgesics (eg, tramadol, meperidine, propoxyphene): Serum levels of parent drug or metabolite may be increased by ritonavir.

Antiarrhythmics (eg, disopyramide, mexiletine, lidocaine): Toxicity may be greatly increased; concurrent use of ritonavir is contraindicated with amiodarone, flecainide, propafenone, and quinidine.

Anticonvulsants: Ritonavir may increase levels (carbamazepine, ethosuximide) or decrease levels (lamotrigine, divalproex, phenytoin); monitor.

Antidepressants (eg, bupropion, trazodone, nefazodone, fluoxetine, and possibly other SSRIs): Ritonavir may increase the levels/effects of these agents.

Antipsychotics (clozapine, perphenazine, risperidone, thioridazine): Serum concentrations may be increased by ritonavir. Avoid use with thioridazine.

Benzodiazepines (clorazepate, diazepam, estazolam, flurazepam, midazolam, triazolam) toxicity may be increased; concurrent use of midazolam and triazolam is specifically contraindicated.

Beta-blockers: Serum concentrations/effects may be increased by ritonavir.

Calcium channel blockers: Serum concentrations/effects may be increased by ritonavir.

Cimetidine: May increase the levels/effects of ritonavir; monitor.

Cisapride toxicity (arrhythmia) may be increased by ritonavir; concurrent use is contraindicated.

Clarithromycin serum concentrations are increased by ritonavir; dosage adjustment required (based on Cl_{cr}).

CYP2C8 substrates: Ritonavir may increase the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP2D6 substrates: Ritonavir may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Ritonavir may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of ritonavir. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 substrates: Ritonavir may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, and pimozone are generally contraindicated with strong CYP3A4 inhibitors.

Delavirdine: Ritonavir may increase the levels/toxicity of delavirdine.

Desipramine (and possibly other TCAs at high doses) serum levels may be increased by ritonavir in HIV-positive patients, requiring dosage adjustment; monitor.

Didanosine: Administration should be separated by 2.5 hours to avoid formulation incompatibility.

Digoxin: Serum concentrations may be increased by ritonavir; monitor.

Disulfiram: May cause disulfiram reaction (oral solution contains 43% ethanol)

Eplerenone: Ritonavir may increase the levels/effects of eplerenone; monitor.

Ergot alkaloids (dihydroergotamine, ergotamine, ergonovine, methylergonovine) toxicity (peripheral ischemia, vasospasm) is increased by ritonavir; concurrent use is contraindicated.

Estrogen (oral or transdermal contraceptives): Effects may be decreased (not well characterized). Use alternative contraceptive measures.

Fentanyl: Ritonavir may increase the levels/effects; monitor.

HMG-CoA reductase inhibitors (atorvastatin, cerivastatin, lovastatin, simvastatin) serum concentrations may be increased by ritonavir, increasing the risk of myopathy/rhabdomyolysis. Lovastatin or simvastatin should not be used with ritonavir. Use lowest possible dose of atorvastatin. Fluvastatin and pravastatin may be safer alternatives.

Immunosuppressants (cyclosporine, sirolimus, tacrolimus): Serum levels/effects may be increased by ritonavir; monitor.

Indinavir serum concentrations are increased by ritonavir.

Inhaled corticosteroids (eg, budesonide, fluticasone): Serum concentrations may be increased by ritonavir, resulting in decreased serum cortisol, HPA axis suppression; concurrent use is not recommended.

Itraconazole, ketoconazole serum concentrations are increased by ritonavir. Limit ketoconazole dose to \leq 200 mg/day.

Meperidine: Serum concentrations of metabolite (normeperidine) are increased by ritonavir, which may increase the risk of CNS toxicity.

Methadone: Serum concentrations may be decreased by ritonavir; dose adjustment of methadone may be necessary.

Metronidazole: May cause disulfiram reaction (oral solution contains 43% ethanol).

Pimozide toxicity is significantly increased by ritonavir; concurrent use is contraindicated.

Rifabutin and rifabutin metabolite serum concentrations may be increased by ritonavir; reduce rifabutin dose to 150 mg every other day.

Rifampin: May decrease levels/effects of ritonavir; alternative antimicrobial agent recommended.

Saquinavir: Serum concentrations are increased by ritonavir; dosage of both agents should be adjusted.

Sildenafil: Serum concentrations may be increased by ritonavir; when used concurrently, do not exceed a maximum sildenafil dose of 25 mg in a 48-hour period.

Tadalafil: Serum concentrations may be increased by ritonavir. A maximum tadalafil dose of 10 mg in 72 hours is recommended with strong CYP3A4 inhibitors.

Theophylline: Serum concentrations may be decreased by ritonavir.

Trazodone: Serum concentrations/effects may be increased by ritonavir; use caution and reduce trazodone dose.

Vardenafil: Serum concentrations may be increased by ritonavir; do not exceed vardenafil dose of 2.5 mg in 72 hours.

Voriconazole: Serum levels are reduced by ritonavir. Concurrent use is contraindicated with ritonavir dose \geq 800 mg/day. Concomitant use not recommended with lower doses of ritonavir unless benefit outweighs risk.

Zolpidem: Serum levels/effects may be increased by ritonavir; monitor.

Pregnancy Risk Factor B

Pregnancy Implications According to preliminary data, placental passage of ritonavir is minimal. Pregnancy and protease inhibitors are both associated with an increased risk of hyperglycemia. Glucose levels should be closely monitored. Healthcare professionals are encouraged to contact the antiretroviral pregnancy registry to monitor outcomes of pregnant women exposed to antiretroviral medications (1-800-258-4263).

Lactation Excretion in breast milk unknown/not recommended

Additional Information Oral solution contains 43% ethanol by volume.

Rivastigmine

CAS Number 123441-03-2

U.S. Brand Names Exelon®

Synonyms ENA 713; Rivastigmine Tartrate; SDZ ENA 713

Use Mild to moderate dementia from Alzheimer's disease

Mechanism of Action A deficiency of cortical acetylcholine is thought to account for some of the symptoms of Alzheimer's disease; rivastigmine increases acetylcholine in the central nervous system through reversible inhibition of its hydrolysis by cholinesterase

Adverse Reactions

Cardiovascular: Syncope, hypertension, chest pain, peripheral edema, edema, periorbital or facial edema, hypotension, postural hypotension, cardiac failure, atrial fibrillation, bradycardia, AV block, bundle branch block, sick sinus syndrome, cardiac arrest, supraventricular tachycardia, tachycardia, angina pectoris, myocardial infarction, peripheral ischemia, thrombosis, intracranial hemorrhage

Central nervous system: **Dizziness, headache,** fatigue, insomnia, confusion, depression, anxiety, malaise, somnolence, hallucinations, aggressiveness, vertigo, pain, agitation, nervousness, delusion, paranoid reaction, ataxia, convulsions, apraxia, aphasia, dysphonia, fever, hypothermia, migraine, neuralgia, delirium, emotional lability, psychosis

Dermatologic: Rash, rashes (maculopapular, eczema, bullous, exfoliative, psoriaform, erythematous), urticaria, Stevens-Johnson syndrome

Endocrine & metabolic: Hypothyroidism, dehydration

Gastrointestinal: **Nausea, vomiting, diarrhea, anorexia, abdominal pain;** dyspepsia, constipation, flatulence, weight loss, eructation, peptic ulcer, gastroesophageal reflux, GI hemorrhage, intestinal obstruction, pancreatitis, colitis, severe vomiting with esophageal rupture (following inappropriate reinitiation of dose)

Genitourinary: Urinary tract infection

Hematologic: Hematoma, thrombocytopenia, purpura, anemia, leukocytosis

Hepatic: Abnormal hepatic function, cholecystitis

Local: Thrombophlebitis

Neuromuscular & skeletal: Weakness, tremor, back pain, arthralgia, bone fracture, hypokinesia, hyperkinesia, hypertonia, arthritis, peripheral neuropathy

Ocular: Conjunctival hemorrhage, diplopia, glaucoma

Renal: Urinary incontinence, acute renal failure

Respiratory: Rhinitis, upper respiratory tract infections, cough, pharyngitis, bronchitis, epistaxis, bronchospasm, apnea, pulmonary embolism

Miscellaneous: Increased diaphoresis, flu-like syndrome, infection, allergy, lymphadenopathy

Pharmacodynamics/Kinetics

Duration: Anticholinesterase activity (CSF): ~10 hours (6 mg dose)

Absorption: Fasting: Rapid and complete within 1 hour

Distribution: V_d : 1.8-2.7 L/kg

Protein binding: 40%

Metabolism: Extensively via cholinesterase-mediated hydrolysis in the brain; metabolite undergoes N-demethylation and/or sulfate conjugation hepatically; CYP minimally involved; linear kinetics at 3 mg twice daily, but nonlinear at higher doses

Bioavailability: 36% to 40%

Half-life elimination: 1.5 hours

Time to peak: 1 hour

Excretion: Urine (97% as metabolites); feces (0.4%)

Dosage Adults: Mild to moderate Alzheimer's dementia: Oral: Initial:

1.5 mg twice daily to start; if dose is tolerated for at least 2 weeks then it may be increased to 3 mg twice daily; increases to 4.5 mg twice daily and 6 mg twice daily should only be attempted after at least 2 weeks at the previous dose; maximum dose: 6 mg twice daily. If adverse events such as nausea, vomiting, abdominal pain, or loss of appetite occur, the patient should be instructed to discontinue treatment for several doses then restart at the same or next lower dosage level; antiemetics have been used to control GI symptoms. If treatment is interrupted for longer than several days, restart the treatment at the lowest dose and titrate as previously described.

Elderly: Clearance is significantly lower in patients older than 60 years of age, but dosage adjustments are not recommended. Titrate dose to individual's tolerance.

Dosage adjustment in renal impairment: Dosage adjustments are not recommended, however, titrate the dose to the individual's tolerance.

Dosage adjustment in hepatic impairment: Clearance is significantly reduced in mild to moderately impaired patients. Although dosage adjustments are not recommended, use lowest possible dose and titrate according to individual's tolerance. May consider waiting >2 weeks between dosage adjustments.

Stability Store below 25°C (77°F); store solution in an upright position and protect from freezing

Monitoring Parameters Cognitive function at periodic intervals

Administration Should be administered with meals (breakfast or dinner). Capsule should be swallowed whole. Liquid form is available for patients who cannot swallow capsules (can be swallowed directly from syringe or mixed with water, soda, or cold fruit juice). Stir well and drink within 4 hours of mixing.

Contraindications Hypersensitivity to rivastigmine, other carbamate derivatives (eg, neostigmine, pyridostigmine, physostigmine), or any component of the formulation

Warnings Significant nausea, vomiting, anorexia, and weight loss are associated with use; occurs more frequently in women and during the titration phase. If treatment is interrupted for more than several days, reinstate at the lowest daily dose. Use caution in patients with a history of peptic ulcer disease or concurrent NSAID use. Use caution in patients undergoing anesthesia who will receive succinylcholine-type muscle relaxation, patients with sick sinus syndrome, bradycardia or supraventricular conduction conditions, urinary obstruction, seizure disorders, or pulmonary conditions such as asthma or COPD. Safety and efficacy in children have not been established.

Dosage Forms Capsule:

Exelon®: 1.5 mg, 3 mg, 4.5 mg, 6 mg

Solution, oral:

Exelon®: 2 mg/mL (120 mL) [contains sodium benzoate]

Overdosage/Treatment

Decontamination: Oral: Activated charcoal

Supportive therapy: In cases of asymptomatic overdoses, rivastigmine should be held for 24 hours. Cholinergic crisis, caused by significant acetylcholinesterase inhibition, is characterized by severe nausea, vomiting, salivation, sweating, bradycardia, hypotension, respiratory depression, collapse, and convulsions. Treatment is supportive and symptomatic. Atropine (initial dose: 0.03 mg/kg I.M.) can be used for symptomatic treatment. Dialysis would not be helpful. Overdoses as high as 46 mg have resulted in full recovery within 24 hours with supportive care.

Drug Interactions Anticholinergics: Effects may be reduced with rivastigmine

Antipsychotic agents: Acetylcholinesterase inhibitors (central) may increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Beta-blockers without ISA activity: May increase risk of bradycardia
Calcium channel blockers (diltiazem or verapamil): May increase risk of bradycardia

Cholinergic agonists: Effects may be increased with rivastigmine

Digoxin: Increased risk of bradycardia with concurrent use

RIZATRIPTAN

Neuromuscular blockers: Depolarizing neuromuscular blocking agents effects may be increased with rivastigmine

NSAIDs: Although not seen in clinical studies, patients may be at increased risk for peptic ulcers or gastrointestinal bleeding with concomitant use; monitor

Pregnancy Risk Factor B

Pregnancy Implications There are no adequate studies in pregnant women. Should be used only if the benefit outweighs the potential risk to the fetus. It is unknown if rivastigmine is excreted in human breast milk. There is no indication for use in nursing mothers.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Educate patient or caregiver about medicine.

Rizatriptan

U.S. Brand Names Maxalt-MLT[®]; Maxalt[®]

Synonyms MK462

Use Acute treatment of migraine with or without aura

Mechanism of Action Selective agonist for serotonin (5-HT_{1D}) receptor in cranial arteries to cause vasoconstriction and reduce sterile inflammation associated with antidromic neuronal transmission correlating with relief of migraine

Adverse Reactions

Cardiovascular: Systolic/diastolic blood pressure increases (5-10 mm Hg), chest pain, palpitations, angina, arrhythmia, facial edema, bradycardia, tachycardia, myocardial ischemia, myocardial infarction, syncope

Central nervous system: Dizziness, drowsiness, fatigue (13% to 30% - dose related), akinesia, decreased mental activity, chills, hangover effect, neurological/psychiatric abnormalities, stroke

Dermatologic: Skin flushing, pruritus, toxic epidermal necrolysis

Endocrine & metabolic: Mild increase in growth hormone, hot flashes

Gastrointestinal: Nausea, abdominal pain, dry mouth, diarrhea, dysgeusia

Neuromuscular & skeletal: Arthralgia, muscle weakness, myalgia, neck pain, neck stiffness, bradykinesia

Ocular: Blurred vision, dry eyes, eye pain

Otic: Tinnitus

Renal: Polyuria

Respiratory: Dyspnea, nasopharyngeal irritation, pharyngitis

Miscellaneous: Diaphoresis, heat sensitivity

Pharmacodynamics/Kinetics

Onset of action: ~30 minutes

Duration: 14-16 hours

Protein binding: 14%

Metabolism: Via monoamine oxidase-A; first-pass effect

Bioavailability: 40% to 50%

Half-life elimination: 2-3 hours

Time to peak: 1-1.5 hours

Excretion: Urine (82%, 8% to 16% as unchanged drug); feces (12%)

Dosage

Note: In patients with risk factors for coronary artery disease, following adequate evaluation to establish the absence of coronary artery disease, the initial dose should be administered in a setting where response may be evaluated (physician's office or similarly staffed setting). ECG monitoring may be considered.

Oral: 5-10 mg, repeat after 2 hours if significant relief is not attained; maximum: 30 mg in a 24-hour period (use 5 mg dose in patients receiving propranolol with a maximum of 15 mg in 24 hours)

Note: For orally-disintegrating tablets (Maxalt-MLT[™]): Patient should be instructed to place tablet on tongue and allow to dissolve. Dissolved tablet will be swallowed with saliva.

Stability Store in blister pack until administration

Monitoring Parameters Headache severity, signs/symptoms suggestive of angina; consider monitoring blood pressure, heart rate, and/or ECG with first dose in patients with likelihood of unrecognized coronary disease, such as patients with significant hypertension, hypercholesterolemia, obese patients, diabetics, smokers with other risk factors or strong family history of coronary artery disease

Contraindications Hypersensitivity to rizatriptan or any component of the formulation; documented ischemic heart disease or Prinzmetal's angina; uncontrolled hypertension; basilar or hemiplegic migraine; during or within 2 weeks of MAO inhibitors; during or within 24 hours of treatment with another 5-HT₁ agonist, or an ergot-containing or ergot-type medication (eg, methysergide, dihydroergotamine)

Warnings

Use only in patients with a clear diagnosis of migraine. May cause vasospastic reactions resulting in colonic, peripheral, or coronary

ischemia. Use with caution in elderly or patients with hepatic or renal impairment (including dialysis patients), history of hypersensitivity to sumatriptan or adverse effects from sumatriptan, and in patients at risk of coronary artery disease (as predicted by presence of risk factors) unless cardiovascular evaluation provides evidence that the patient is free of cardiovascular disease. In patients with risk factors for coronary artery disease, following adequate evaluation to establish the absence of coronary artery disease, the initial dose should be administered in a setting where response may be evaluated (physician's office or similarly staffed setting). ECG monitoring may be considered. Do not use with ergotamines. May increase blood pressure transiently; may cause coronary vasospasm (less than sumatriptan); avoid in patients with signs/symptoms suggestive of reduced arterial flow (ischemic bowel, Raynaud's) which could be exacerbated by vasospasm.

Patients who experience sensations of chest pain/pressure/tightness or symptoms suggestive of angina following dosing should be evaluated for coronary artery disease or Prinzmetal's angina before receiving additional doses.

Reconsider diagnosis of migraine if no response to initial dose. Long-term effects on vision have not been evaluated.

Dosage Forms Tablet, as benzoate (Maxalt[®]): 5 mg, 10 mg

Tablet, orally disintegrating, as benzoate (Maxalt-MLT[®]): 5 mg [contains phenylalanine 1.05 mg/tablet; peppermint flavor]; 10 mg [contains phenylalanine 2.1 mg/tablet; peppermint flavor]

Overdosage/Treatment

Decontamination for oral ingestion: Lavage within 1 hour/activated charcoal

Supportive therapy: Nitroprusside, nifedipine, or hydralazine for hypertensive crisis; lidocaine or procainamide for ventricular ectopy; nitroglycerin can reverse sumatriptan-induced coronary artery vasoconstriction

Drug Interactions Use within 24 hours of another selective 5-HT₁ agonist or ergot-containing drug should be avoided due to possible additive vasoconstriction

MAO inhibitors and nonselective MAO inhibitors increase concentration of rizatriptan

Propranolol: Plasma concentration of rizatriptan increased 70%

SSRIs: Rarely, concurrent use results in weakness and incoordination; monitor closely

Pregnancy Risk Factor C

Pregnancy Implications There are no adequate and well-controlled studies using rizatriptan in pregnant women. Use only if potential benefit to the mother outweighs the potential risk to the fetus. A pregnancy registry has been established to monitor outcomes of women exposed to rizatriptan during pregnancy (800-986-8999). In some animal studies, administration was associated with decreased weight gain, developmental toxicity and increased mortality in the offspring. Teratogenic effects were not observed.

Lactation Excretion in breast milk unknown/use caution

Rosuvastatin

Pronunciation (roe SOO va sta tin)

U.S. Brand Names Crestor[®]

Synonyms Rosuvastatin Calcium

Use Used with dietary therapy for hyperlipidemias to reduce elevations in total cholesterol (TC), LDL-C, apolipoprotein B, and triglycerides (TG) in patients with primary hypercholesterolemia (elevations of 1 or more components are present in Fredrickson type IIa, IIb, and IV hyperlipidemias); treatment of homozygous familial hypercholesterolemia (FH)

Mechanism of Action Inhibitor of 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase, the rate-limiting enzyme in cholesterol synthesis (reduces the production of mevalonic acid from HMG-CoA); this then results in a compensatory increase in the expression of LDL receptors on hepatocyte membranes and a stimulation of LDL catabolism

Adverse Reactions

2% to 10%:

Cardiovascular: Chest pain, hypertension, peripheral edema, angina, palpitation, arrhythmia, syncope

Central nervous system: Headache, depression, dizziness, insomnia, pain, anxiety, vertigo

Dermatologic: Rash, bruising, pruritus, photosensitivity

Gastrointestinal: Pharyngitis (9%), abdominal pain, constipation, gastroenteritis, vomiting, pancreatitis

Hematologic: Anemia

Hepatic: Hepatitis

Neuromuscular & skeletal: Myalgia, arthritis, arthralgia, hypertonias, paresthesia, neuralgia, myasthenia, myositis, myopathy, rhabdomyolysis

Renal: Kidney failure

Respiratory: Bronchitis, cough

Miscellaneous: Hypersensitivity reactions

Pharmacodynamics/Kinetics

Onset: Within 1 week; maximal at 4 weeks

Distribution: V_d: 134 L

Protein binding: 90%
 Metabolism: Hepatic (10%), via CYP2C9 (1 active metabolite identified)
 Bioavailability: 20% (high first-pass extraction by liver)

Asian patients have been noted to have increased bioavailability.
 Half-life elimination: 19 hours
 Time to peak, plasma: 3-5 hours
 Excretion: Feces (90%), primarily as unchanged drug

Dosage

Adults: Oral:

Heterozygous familial and nonfamilial hypercholesterolemia; mixed dyslipidemia: Initial: 10 mg once daily (20 mg in patients with severe hypercholesterolemia); after 2 weeks, may be increased to 20 mg once daily; dosing range: 5-40 mg/day (maximum dose: 40 mg once daily)
 Homozygous FH: Initial: 20 mg once daily (maximum dose: 40 mg/day)

Dosage adjustment with concomitant medications:

Cyclosporine: Rosuvastatin dose should not exceed 5 mg/day
 Gemfibrozil: Rosuvastatin dose should not exceed 10 mg/day

Dosage adjustment in renal impairment:

Mild to moderate impairment: No dosage adjustment required.

$Cl_{cr} < 30$ mL/minute/1.73 m²: Initial: 5 mg/day; do not exceed 10 mg once daily

Monitoring Parameters Total cholesterol, LDL, and HDL cholesterol; liver function tests should be determined at baseline (prior to initiation), 3 months following initiation, and 3 months after any increase in dose; baseline CPK (recheck CPK in any patient with symptoms suggestive of myopathy)

Administration May be administered with or without food.

Contraindications Hypersensitivity to rosuvastatin or any component of the formulation; active liver disease; unexplained persistent elevations of serum transaminases (> 3 times ULN); pregnancy; breast-feeding

Warnings Secondary causes of hyperlipidemia should be ruled out prior to therapy. Liver function must be monitored by periodic laboratory assessment. Use with caution in patients who consume large amounts of ethanol or have a history of liver disease. Rhabdomyolysis with acute renal failure has occurred. Discontinue in any patient in which CPK levels are markedly elevated (> 10 times ULN) or if myopathy is suspected/diagnosed. An increased incidence of rosuvastatin-associated myopathy has been reported during concomitant therapy with fibric acid derivatives, niacin, cyclosporine, and in certain subgroups of the Asian population. Risk is also elevated at higher dosages of rosuvastatin. Patients should be instructed to report unexplained muscle pain, tenderness, or weakness, particularly if associated with fever and/or malaise. Use caution in patients predisposed to myopathy (eg, renal failure, advanced age, inadequately treated hypothyroidism). Temporarily withhold in patients experiencing an acute or serious condition predisposing to renal failure secondary to rhabdomyolysis (sepsis, hypotension, major surgery, trauma, severe metabolic or endocrine or electrolyte disorders, uncontrolled seizures). Safety and efficacy have not been established in children (limited experience with homozygous FH in patients > 8 years of age).

Dosage Forms Tablet, as calcium: 5 mg, 10 mg, 20 mg, 40 mg

Drug Interactions **Substrate** (minor) of CYP2C9, 3A4

Antacids: Plasma concentrations may be decreased when given with magnesium/aluminum hydroxide-containing antacids. Antacids should be administered at least 2 hours after rosuvastatin.

Cholestyramine and colestipol (bile acid sequestrants): Reduce absorption of several HMG-CoA reductase inhibitors; separate administration times by at least 4 hours. Cholesterol-lowering effects are additive.

Clofibrate and fenofibrate may increase the risk of myopathy and rhabdomyolysis with HMG-CoA reductase inhibitors. Effects on lipid levels may be additive.

Cyclosporine: May increase serum concentrations of rosuvastatin (up to 10 times usual concentrations). Limit dose to 5 mg/day.

Gemfibrozil: Serum concentrations of rosuvastatin may be increased (doubled) during concurrent administration; combination should be avoided. Limit dose to 10 mg/day.

Hormonal contraceptives: Rosuvastatin increases serum concentrations of ethinyl estradiol and norgestrel.

Niacin: May increase the risk of myopathy and rhabdomyolysis with HMG-CoA reductase inhibitors.

Warfarin: Effects may be increased by rosuvastatin. Monitor.

Pregnancy Risk Factor X

Pregnancy Implications Use in women of childbearing potential only if they are highly unlikely to conceive; discontinue if pregnancy occurs.

Lactation Excretion in breast milk unknown/contraindicated

Mechanism of Action Inhibits prostaglandin synthesis, acts on the hypothalamus heat-regulating center to reduce fever, blocks prostaglandin synthetase action which prevents formation of the platelet-aggregating substance thromboxane A₂; inhibits both vitamin K-dependent and independent clotting factors

Adverse Reactions

Cardiovascular: Circulatory collapse, pericardial effusion/pericarditis, fibrillation (atrial), flutter (atrial), angina, sinus tachycardia, vasculitis
Central nervous system: Headache, aseptic meningitis, psychosis, cognitive dysfunction, coma, seizures, electroencephalogram abnormalities, mania, aseptic meningitis

Dermatologic: Rash, pruritus, alopecia, systemic contact dermatitis, immunologic contact urticaria, Stevens-Johnson syndrome, exfoliative dermatitis, pityriasis rosea-like reaction, erythema multiforme, acute generalized exanthematous pustulosis, angioedema, bullous skin disease, toxic epidermal necrolysis, urticaria, purpura, psoriasis, erythema nodosum, licheniform eruptions

Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, hypouricemia, fluid retention

Gastrointestinal: Abdominal pain, **nausea**, vomiting, GI bleeding, GI ulceration, constipation, diarrhea, **dyspepsia**, esophagitis, aphthous stomatitis

Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia, aplastic anemia (rare), platelet inhibition, hypoprothrombinemia, thrombocytopenia

Hepatic: Elevated transaminases, hepatitis (fulminant), impaired gluconeogenesis

Neuromuscular & skeletal: Rhabdomyolysis

Ocular: Diplopia, color vision abnormalities

Otic: Ototoxicity, tinnitus (serum levels > 30 mg/dl)

Renal: Renal failure (acute), albuminuria, nephrotic syndrome, acute tubular necrosis

Respiratory: Wheezing, adult respiratory distress syndrome, apnea, tachypnea, respiratory depression, rhinitis, hyposmia, eosinophilic pneumonia

Miscellaneous: Hypersensitivity, bezoars/concretions, Henoch-Schönlein purpura, fixed drug eruption

Bezoars, chest pain, coagulopathy, cognitive dysfunction, colitis, deafness, delirium, dementia, drowsiness, dry mouth, GI bleeding, gout, hematuria, hyperthermia, hypoglycemia, hyponatremia, hypotension, leukopenia, metabolic acidosis, neutropenia, pylorospasm, thirst, renal failure and/or hepatic failure, respiratory depression, rhabdomyolysis, seizures, urine discoloration (pink).

Severe poisoning can manifest with agranulocytosis, coma, confusion, dizziness, feces discoloration (black; pink; red; tarry), fever, granulocytopenia, headache, hyperglycemia, hyponatremia, hypotension, leukopenia, metabolic acidosis, neutropenia, pylorospasm, thirst, renal failure and/or hepatic failure, respiratory depression, rhabdomyolysis, seizures, urine discoloration (pink).

Phases of salicylate poisoning:

Phase I (up to 12 hours after ingestion): Tachypnea and hyperventilation predominate (respiratory alkalosis) with increased renal secretion of sodium, potassium, and bicarbonate resulting in both an alkaline urine and serum pH

Phase II (12-24 hours after ingestion): Urine becomes more acidic as intracellular potassium decreases. While children < 4 years of age may develop a pure metabolic acidosis, older patients will have significant respiratory compensation and thus serum pH can be alkalotic. Coagulation abnormalities may occur.

Phase III (over 24 hours after ingestion): Severe potassium and bicarbonate depletion occurs with hydrogen being excreted renally; serum pH becomes acidotic; infants may reach this phase within 6 hours

Admission Criteria/Prognosis Admit any patient with acidosis, mental status changes, thermoregulatory abnormality, glucose abnormality, serum salicylate > 50 mg/dL following an acute ingestion

Pharmacodynamics/Kinetics

Absorption: From the stomach and small intestine

Distribution: V_d: 0.2 L/kg (increases in overdose); distributes readily into most body fluids and tissues

Protein binding: 75% to 90%; salicylic acid: 80% at low serum concentrations; 50% at 70 mg/dL and 30% at 120 mg/dL

Metabolism: Hydrolyzed to salicylate (active) by esterases in the gastrointestinal mucosa, red blood cells, synovial fluid and blood; occurs primarily by hepatic microsomal enzymes; metabolic pathways are saturable

Half-life: 15-20 minutes; half-life is dose-dependent ranging from 3 hours at lower doses (300-600 mg), 5-6 hours (after 1 g) and 10 hours with higher doses

Time to peak serum concentration: About 1-2 hours

Elimination: Renal; primarily as free salicylic acid and conjugated metabolites; ≈ 52% of the drug is normally excreted in 4 hours in a normal patient

Dosage

Children:

Analgesic and antipyretic: Oral, rectal: 10-15 mg/kg/dose every 4-6 hours, up to a total of 60-80 mg/kg/24 hours

Salicylate

Related Information

- Methyl Salicylate

CAS Number 50-78-2

Use Treatment of mild to moderate pain, inflammation and fever; may be used as a prophylaxis of myocardial infarction and transient ischemic attacks (TIA)

Anti-inflammatory: Oral: Initial: 60-90 mg/kg/day in divided doses; usual maintenance: 80-100 mg/kg/day divided every 6-8 hours, maximum dose: 3.6 g/day; monitor serum concentrations

Antirheumatic: Oral: 60-100 mg/kg/day in divided doses every 4 hours
Kawasaki disease: Oral: 80-100 mg/kg/day divided every 6 hours; after fever resolves: 8-10 mg/kg/day once daily; monitor serum concentrations

Adults:

Analgesic and antipyretic: Oral, rectal: 325-650 mg every 4-6 hours up to 4 g/day

Anti-inflammatory: Oral: Initial: 2.4-3.6 g/day in divided doses; usual maintenance: 3.6-5.4 g/day; monitor serum concentrations

TIA: Oral: 1.3 g/day in 2-4 divided doses

Myocardial infarction and stroke prophylaxis: 160 mg/day

Dosing adjustment in renal impairment: $Cl_{cr} < 10$ mL/minute: Avoid use

Dosing adjustment in hepatic disease: Avoid use in severe liver disease

Stability Keep suppositories in refrigerator, do not freeze; hydrolysis of aspirin occurs upon exposure to water or moist air, resulting in salicylate and acetate, which possess a vinegar-like odor; do not use if a strong odor is present

Monitoring Parameters Serum concentrations, renal function; hearing changes or tinnitus; monitor for response (ie, pain, inflammation, range of motion, grip strength); observe for abnormal bleeding, bruising, weight gain

Contraindications Bleeding disorders, hypersensitivity to salicylates or other nonsteroidal anti-inflammatory drugs (NSAIDs)

Warnings Do not use aspirin in children < 16 years of age for chickenpox or flu symptoms due to the association with Reye's syndrome; use with caution in patients with platelet and bleeding disorders, renal dysfunction

Dosage Forms

Suppository, rectal: 60 mg, 120 mg, 125 mg, 130 mg, 195 mg, 200 mg, 300 mg, 325 mg, 600 mg, 650 mg, 1200 mg

Tablet: 325 mg, 500 mg, 650 mg

Tablet:

Buffered:

325 mg with aluminum hydroxide 75 mg and magnesium hydroxide 75 mg

325 mg with aluminum hydroxide 150 mg and magnesium hydroxide 150 mg

500 mg with aluminum hydroxide 33 mg and magnesium hydroxide 150 mg

Chewable: 81 mg

Chewing gum: 227 mg

Controlled release: 800 mg

Enteric coated (delayed release): 80 mg, 165 mg, 325 mg, 500 mg, 650 mg, 975 mg

Timed release: 650 mg

Tablet, with caffeine: 400 mg and caffeine 32 mg; 500 mg and caffeine 32 mg

Reference Range

Sample size: 1.5-2 mL blood (lavender top (EDTA) tube)

Timing of serum samples: Peak levels usually occur 2 hours after ingestion; half-life increases with dosage (eg, the half-life after 300 mg is 3 hours, and after 1 g is 5-6 hours, and after 8-10 g is 10 hours)

Salicylate serum concentrations correlate with the pharmacological actions and adverse effects observed. See table.

Overdosage/Treatment

Decontamination: Activated charcoal with cathartic is quite effective; each gram of activated charcoal can bind up to 550 mg of salicylic acid; whole bowel irrigation can also be used; gastric decontamination should occur with ingestions over 150 mg/kg

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with I.V. sodium bicarbonate; hypokalemia will need to be corrected, seizures with benzodiazepines; blood products are indicated, as appropriate, for hemorrhage; antacids may promote gastric absorption

Enhancement of elimination: Forced alkaline diuresis with I.V. sodium bicarbonate to keep urine pH at 8 should be performed for salicylate levels >40 mg/dL; dialysis is indicated for secondary complications, seizures acidosis, or renal failure and not toxin removal alone; consider hemodialysis for acute salicylate levels >100 mg/dL or chronic salicylate levels >60 mg/dL; multiple dosing of activated charcoal may not hasten elimination; dialyzable (50% to 100%); exchange transfusion has been used in a 2-year-old child (elimination rate estimated to be 152 mg/hour) to treat a methyl salicylate intoxication

Test Interactions False-negative results for glucose oxidase urinary glucose tests (Clinistix®); false-positives using the cupric sulfate method (Clinitest®); also, interferes with Gerhardt test (VMA determination), 5-HIAA, xylose tolerance test, T₃, and T₄; can cause false elevations of serum carbon dioxide assays (using the Technicon® RA-1000 system); high salicylate levels can falsely cause hyperchloremia by direct potentiometry; >2 g/day causes a falsely increased free thyroxine level

Drug Interactions Aspirin decreases serum concentrations probably by protein-binding displacement; there is an increased bleeding potential with concomitant warfarin therapy; may increase lithium and methotrexate concentrations by decreasing renal clearance; may decrease diuretic and hypotensive effects of thiazides, loop diuretics, ACE inhibitors, and beta-blockers; may increase nephrotoxicity of cyclosporine; salicylate absorption can be delayed with aluminum hydroxide, antihistamines, tricyclic antidepressants, isoniazid, opiates, neuroleptics, or sedative-hypnotics

By inhibiting gastric alcohol dehydrogenase, aspirin can increase the bioavailability and peak concentrations of ethyl alcohol. Aspirin (1 g) has been shown to increase bioavailability of ethanol (0.3 g/kg) in the fed state but not in the fasting state.

Toluene abuse with aspirin can increase the risk for toluene-induced ototoxicity

Concomitant administration of glyburide and aspirin can cause an increase of insulin levels resulting in transient hypoglycemia; concurrent intake of ethanol and aspirin can reduce the peak aspirin concentration by 25%

Pregnancy Risk Factor C (D if full-dose aspirin in 3rd trimester)

Pregnancy Implications Late term fetus is more sensitive to adverse (acidotic) effects of aspirin; but with low-dose aspirin, no evidence for increased frequency of abruptio placentae or perinatal mortality noted

Nursing Implications Administer with food or a full glass of water to minimize GI distress; do not crush sustained release tablet; previous nonreaction does not guarantee future safe taking of medication

Additional Information

Lethal dose: 300 mg/kg; Toxic dose (acute): 200 mg/kg

To help evaluate the toxicity of nonaspirin salicylate agents, conversion to an aspirin equivalent dose (AED) may be necessary; by multiplying the dose ingested by the aspirin conversion factor (ACF) described in the table, the AED can be calculated. This calculation assumes that the nonaspirin salicylate is 100% absorbed, and there is 100% conversion to salicylate and that the potency of the nonaspirin salicylate is equipotent with aspirin on a mole for mole basis. Zileuton (600 mg 4 times/day orally) can protect asthmatics from idiosyncratic reactions (ie, bronchoconstriction) due to aspirin. Aspirin is not very water soluble, pharmacobezoars/concretions have been reported with overdosage. Ketonuria is seen in ~41% of salicylate-poisoned patients.

Salmeterol

CAS Number 89365-50-4; 94749-08-3

U.S. Brand Names Serevent[®] Diskus[®]; Serevent[®] [DSC]

Synonyms Salmeterol Xinafoate

Use Maintenance treatment of asthma and in prevention of bronchospasm (inhalation aerosol in patients > 12 years of age; inhalation powder in patients ≥ 4 years of age) with reversible obstructive airway disease, including patients with symptoms of nocturnal asthma, who require regular treatment with inhaled, short-acting beta₂ agonists; prevention of exercise-induced bronchospasm; maintenance treatment of bronchospasm associated with COPD

Mechanism of Action Relaxes bronchial smooth muscle by action on beta₂-receptors with little effect on heart rate; longer-acting than albuterol

Adverse Reactions

Cardiovascular: Tachycardia (slight), palpitations, hypertension, flushing, shortened P-R segment, lengthened QT segment, cardiac arrhythmias, sinus tachycardia, torsade de pointes

Central nervous system: **Headache**, dizziness, nervousness, CNS stimulation, hyperactivity, insomnia, mania

Dermatologic: Maculopapular rash, urticaria, pruritus

Endocrine & metabolic: Hypokalemia, hyperglycemia

Gastrointestinal: GI upset

Neuromuscular & skeletal: Tremor

Respiratory: **Pharyngitis**, bronchospasm

Pharmacodynamics/Kinetics

Onset of action: Asthma: 30-48 minutes, COPD: 2 hours

Peak effect: 2-4 hours, COPD: 3.27-4.75 hours

Duration: 12 hours

Protein binding: 96%

Metabolism: Hepatically hydroxylated

Half-life elimination: 5.5 hours

Excretion: Feces (60%), urine (25%)

Dosage

Note: Do **not** use spacer with inhalation powder

Asthma, maintenance and prevention:

Inhalation, aerosol: Children ≥ 12 years and Adults: 42 mcg (2 puffs) twice daily (12 hours apart)

Inhalation, powder (Serevent[®] Diskus[®]): Children ≥ 4 years and Adults: One inhalation (50 mcg) twice daily

Exercise-induced asthma, prevention:

Inhalation, aerosol: Children ≥ 12 years and Adults: 42 mcg (2 puffs) 30-60 minutes prior to exercise; additional doses should not be used for 12 hours

Inhalation, powder (Serevent[®] Diskus[®]): Children ≥ 4 years and Adults: One inhalation (50 mcg) at least 30 minutes prior to exercise; additional doses should not be used for 12 hours

COPD (maintenance treatment of associated bronchospasm):

Inhalation, aerosol: Adults: 42 micrograms (2 puffs) twice daily (morning and evening, 12 hours apart)

Inhalation, powder (Serevent[®] Diskus[®]): Adults: One inhalation (50 mcg) twice daily, ~ 12 hours apart

Stability Aerosol: Store at 15°C to 30°C (59°F to 86°F); store canister with nozzle down; shake well before each use. Protect from freezing temperature. The therapeutic effect may decrease when the canister is cold therefore the canister should remain at room temperature. Do not store at temperatures > 120°F.

Inhalation powder: Store at controlled room temperature 20°C to 25°C (68°F to 77°F) in a dry place away from direct heat or sunlight. Stable for 6 weeks after removal from foil pouch.

Monitoring Parameters FEV₁, peak flow, and/or other pulmonary function tests; blood pressure, heart rate; CNS stimulation; serum glucose, serum potassium. Monitor for increased use of short-acting beta₂-agonist inhalers; may be marker of a deteriorating asthma condition.

Administration Inhalation: Shake well before use. **Not** to be used for the relief of acute attacks.

Contraindications Hypersensitivity to salmeterol, adrenergic amines, or any component of the formulation; need for acute bronchodilation

Warnings

Asthma treatment:[U.S. Boxed Warning]: Long-acting beta₂ agonists may increase the risk of asthma-related deaths. In a large, randomized clinical trial (SMART, 2006), salmeterol was associated with a small, but statistically significant increase in asthma-related deaths (when added to usual asthma therapy); risk may be greater in African-American patients versus Caucasians. Should only be used as adjuvant therapy in patients not adequately controlled on inhaled corticosteroids or whose disease requires two maintenance therapies. Salmeterol is not meant to relieve acute asthmatic symptoms, should not be initiated in patients with significantly worsening or acutely deteriorating asthma, and is not a substitute for inhaled or oral corticosteroids. Short-acting beta₂ agonist should be used for acute symptoms and symptoms occurring between treatments. Corticosteroids should not be stopped or reduced when salmeterol is initiated. During the initiation of salmeterol watch for signs of worsening asthma.

Concurrent diseases: Use caution in patients with cardiovascular disease (eg, arrhythmia, hypertension, or CHF), seizure disorders, diabetes, glaucoma, hyperthyroidism, hepatic impairment, or hypokalemia. Beta agonists may cause elevation in blood pressure, heart rate, and result in CNS stimulation/excitation. Beta₂ agonists may increase risk of arrhythmia, increase serum glucose, or decrease serum potassium

Adverse events: Salmeterol should not be used more than twice daily; do not exceed recommended dose; do not use with other long-acting beta₂ agonists; serious adverse events including fatalities, have been associated with excessive use of inhaled sympathomimetics. Rarely, paradoxical bronchospasm may occur with use of inhaled bronchodilating agents; this should be distinguished from inadequate response. Powder for oral inhalation contains lactose; very rare anaphylactic reactions have been reported in patients with severe milk protein allergy.

Safety and efficacy have not been established in children < 4 years of age.

Dosage Forms Powder for oral inhalation: 50 mcg (28s, 60s) [delivers 50 mcg/inhalation; contains lactose]

Overdosage/Treatment

Decontamination: Activated charcoal for oral ingestion

Supportive therapy: Beta-blockers can be used for hyperadrenergic signs (use with caution in patients with wheezing); mexiletine can be used to treat ventricular arrhythmia

Drug Interactions

Substrate of CYP3A4 (major)

Atomoxetine: May enhance the tachycardia effect of beta₂-agonists.

Beta₂-agonists: May diminish the bradycardia effect of beta-blockers (beta₁ selective).

Beta-blockers (nonselective): May diminish the bronchodilator effect of beta₂-agonists.

CYP3A4 inhibitors: May increase the levels/effects of salmeterol.

Example inhibitors include amprenavir, atazanavir, clarithromycin, delavirdine, diclofenac, fosamprenavir, imatinib, indinavir, isoniazid, itraconazole, ketoconazole, miconazole, nefazodone, nelfinavir, nocardipine, propofol, quinidine, ritonavir, and telithromycin.

Sympathomimetics: May enhance the adverse/toxic effect of salmeterol.

Pregnancy Risk Factor C

Pregnancy Implications Benefits of use should outweigh risks

Lactation Enters breast milk/use caution

Additional Information Tachyphylaxis usually does not occur

Salsalate

CAS Number 552-94-3

U.S. Brand Names Amigesic[®]; Disalcid[®] [DSC]; Mono-Gesic[®]; Salflex[®]

Synonyms Disalicylic Acid; Salicylsalicylic Acid

Use Treatment of minor pain or fever; rheumatoid arthritis, osteoarthritis, and related inflammatory conditions

Mechanism of Action Inhibits prostaglandin synthesis, acts on the hypothalamus heat-regulating center to reduce fever, blocks prostaglandin synthetase action which prevents formation of the platelet-aggregating substance thromboxane A₂

Adverse Reactions

Cardiovascular: Circulatory collapse, sinus tachycardia

SAQUINAVIR

Central nervous system: Headache, aseptic meningitis, psychosis, cognitive dysfunction, dizziness, coma, seizures, mania

Dermatologic: Rash, pruritus

Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, fluid retention

Gastrointestinal: **Stomach pain, dyspepsia, heartburn, nausea, vomiting**, GI bleeding, GI ulceration, constipation, diarrhea

Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia, aplastic anemia (rare), platelet inhibition

Hepatic: Elevated transaminases, hepatitis (fulminant), hepatic necrosis

Otic: Ototoxicity, tinnitus

Renal: Renal failure (acute), nephrotic syndrome, chronic renal failure, albuminuria

Respiratory: Wheezing, respiratory depression

Miscellaneous: Hypersensitivity

Signs and Symptoms of Overdose Bezoars, cognitive dysfunction, drowsiness, gastritis, GI bleeding, hyperthermia, hypoglycemia, hyponatremia, nausea, nephrotic syndrome, nystagmus, ototoxicity, respiratory alkalosis, tachypnea, tinnitus, vomiting, wheezing. Severe poisoning can manifest with coma, feces discoloration (black; pink; red; tarry), hyperglycemia, hypotension, renal failure and/or hepatic failure, respiratory depression, seizures, urine discoloration (pink)

Pharmacodynamics/Kinetics

Onset of action: Therapeutic: 3-4 days of continuous dosing

Absorption: Complete from small intestine

Metabolism: Hepatically hydrolyzed to two moles of salicylic acid (active)

Half-life elimination: 7-8 hours

Excretion: Primarily urine

Dosage

Adults: Oral: 3 g/day in 2-3 divided doses

Dosing comments in renal impairment: In patients with end stage renal disease undergoing hemodialysis: 750 mg twice daily with an additional 500 mg after dialysis

Contraindications Hypersensitivity to salsalate or any component of the formulation; GI ulcer or bleeding; pregnancy (3rd trimester)

Warnings Use with caution in patients with platelet and bleeding disorders, renal dysfunction, erosive gastritis, or peptic ulcer disease, dehydration, previous nonreaction does not guarantee future safe taking of medication; do not use aspirin in children <16 years of age for chickenpox or flu symptoms due to the association with Reye's syndrome

Dosage Forms Tablet: 500 mg, 750 mg

Amigesic®: 500 mg, 750 mg

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage

Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be effective; forced alkaline diuresis with I.V. bicarbonate to keep a urine pH > 8 can hasten elimination

Test Interactions False-negative results for glucose oxidase urinary glucose tests (Clinistix®); false-positives using the cupric sulfate method (Clinitest®); also, interferes with Gerhardt test (VMA determination), 5-HIAA, xylose tolerance test, T₃, and T₄; a serum level of salicylate (by immunoassay) may underestimate salsalate levels; degradation of salsalate to salicylate can occur if specimens are allow to sit at room temperature; > 1.5 g/day causes a falsely increased free thyroxine level

Drug Interactions Decreased effect with urinary alkalizers, antacids, corticosteroids; decreased effect of uricosurics, spironolactone; ACE inhibitor effects may be decreased by concurrent therapy with NSAIDs Increased effect/toxicity of oral anticoagulants, hypoglycemics, methotrexate

Pregnancy Risk Factor C/D (3rd trimester)

Lactation Enters breast milk/contraindicated

Additional Information Does not appear to inhibit platelet aggregation; total dose (mg) multiplied by 1.4 gives aspirin equivalent dose

Saquinavir

CAS Number 127779-20-8; 149845-06-7

U.S. Brand Names Fortovase®; Invirase®

Synonyms Saquinavir Mesylate

Use Treatment of HIV infection; used in combination with at least two other antiretroviral agents

Mechanism of Action As an inhibitor of HIV protease, saquinavir prevents the cleavage of viral polyprotein precursors which are needed to generate functional proteins in and maturation of HIV-infected cells

Adverse Reactions

Protease inhibitors cause dyslipidemia which includes elevated cholesterol and triglycerides and a redistribution of body fat centrally to cause

increased abdominal girth, buffalo hump, facial atrophy, and breast enlargement. These agents also cause hyperglycemia.

Cardiovascular: Chest pain, portal hypertension, syncope

Central nervous system: Anxiety, depression, fatigue, headache, insomnia, pain, ataxia, confusion, seizures

Dermatologic: Rash, verruca, bullous skin eruption, Stevens-Johnson syndrome

Endocrine & metabolic: Hyperglycemia, hypoglycemia, hyperkalemia, libido disorder, serum amylase increased, calcium increased, hypokalemia, triglycerides increased, serum phosphate decreased

Gastrointestinal: **Diarrhea, nausea**, abdominal discomfort, abdominal pain, appetite decreased, buccal mucosa ulceration, constipation, dyspepsia, flatulence, taste alteration, vomiting, pancreatitis, upper quadrant abdominal pain

Hematologic: Acute myeloblastic leukemia, hemoglobin decreased, hemolytic anemia, thrombocytopenia

Hepatic: AST increased, ALT increased, bilirubin increased, alkaline phosphatase increased, ascites, chronic liver disease exacerbation, hepatitis, cholangitis, jaundice, LFTs increased

Local: Thrombophlebitis

Neuromuscular & skeletal: Paresthesia, weakness, CPK increased, neuropathy, polyarthritis

Renal: Creatinine kinase increased

Miscellaneous: Allergic reactions

Pharmacodynamics/Kinetics

Absorption: Poor; increased with high fat meal; Fortovase® has improved absorption over Invirase®

Distribution: V_d: 700 L; does not distribute into CSF

Protein binding, plasma: ~98%

Metabolism: Extensively hepatic via CYP3A4; extensive first-pass effect

Bioavailability: Invirase®: ~4%; Fortovase®: 12% to 15%

Excretion: Feces (81% to 88%), urine (1% to 3%) within 5 days

Dosage Oral: Children ≥ 16 years and Adults: **Note:** Fortovase® and Invirase® are not bioequivalent and should not be used interchangeably; only Fortovase® should be used to initiate therapy:

Unboosted regimen: Fortovase®: 1200 mg (six 200 mg capsules) 3 times/day or 1600 mg twice daily within 2 hours after a meal in combination with a nucleoside analog

Note: Saquinavir hard-gel capsules (Invirase®) should not be used in "unboosted regimens."

Ritonavir-boosted regimens:

Fortovase®: 1000 mg (five 200 mg capsules) twice daily in combination with ritonavir 100 mg twice daily

Invirase®: 1000 mg (five 200 mg capsules or two 500 mg tablets) twice daily given in combination with ritonavir 100 mg twice daily. This combination should be given together and within 2 hours after a full meal in combination with a nucleoside analog.

Dosage adjustments of Fortovase® when administered in combination therapy:

Delavirdine: Fortovase® 800 mg 3 times/day

Lopinavir and ritonavir (Kaletra™): Fortovase® or Invirase® 1000 mg twice daily

Nelfinavir: Fortovase® 1200 mg twice daily

Elderly: Clinical studies did not include sufficient numbers of patients ≥ 65 years of age; use caution due to increased frequency of organ dysfunction

Monitoring Parameters Monitor viral load, CD4 count, triglycerides, cholesterol, glucose

Administration Take saquinavir within 2 hours after a full meal. Avoid direct sunlight when taking saquinavir. When used with ritonavir, saquinavir and ritonavir should be administered at the same time.

Contraindications Hypersensitivity to saquinavir or any component of the formulation; exposure to direct sunlight without sunscreen or protective clothing; severe hepatic impairment; coadministration with amiodarone, bepridil, cisapride, flecainide, midazolam, pimozone, propafenone, quinidine, rifampin, triazolam, or ergot derivatives

Warnings Use caution in patients with hepatic insufficiency. May exacerbate pre-existing hepatic dysfunction; use with caution in patients with hepatitis B or C and in cirrhosis. May be associated with fat redistribution (buffalo hump, increased abdominal girth, breast engorgement, facial atrophy). Use caution in hemophilia. May increase cholesterol and/or triglycerides; hypertriglyceridemia may increase risk of pancreatitis.

Saquinavir interacts with multiple medications (including herbal products) when given concurrently; refer to Drug Interactions. **[U.S. Boxed Warning]: Fortovase® and Invirase® are not bioequivalent and should not be used interchangeably; only Fortovase® should be used to initiate therapy.** Fortovase® is recommended when saquinavir will be given as the sole protease inhibitor; Invirase® may be used only if combined with ritonavir. Safety and efficacy have not been established in children < 16 years of age.

Dosage Forms **Note:** Strength expressed as base; [DSC] = Discontinued product

Capsule, as mesylate:

Invirase®: 200 mg [contains lactose 63.3 mg/capsule]
 Capsule, soft gelatin, as base:
 Fortovase®: 200 mg [DSC]
 Tablet, as mesylate:
 Invirase®: 500 mg

Reference Range Peak serum saquinavir levels after a 600 mg oral dose and 12 mg I.V. dose: ~66 ng/mL and 87 ng/mL, respectively

Overdosage/Treatment

Decontamination: Activated charcoal
 Enhanced elimination: Multiple dosing of activated charcoal may be beneficial

Drug Interactions **Substrate** of CYP2D6 (minor), 3A4 (major); **Inhibits** CYP2C9 (weak), 2C19 (weak), 2D6 (weak), 3A4 (moderate)

Antiarrhythmics: Serum levels/toxicity may be increased by saquinavir; serious and/or life-threatening reactions may occur. Concurrent use with amiodarone, bepridil, flecainide, propafenone, or quinidine is contraindicated. Use caution with systemic lidocaine.

Anticonvulsants: Saquinavir serum concentrations may be decreased by carbamazepine, phenobarbital, or phenytoin; use with caution.

Azole antifungals (itraconazole, ketoconazole): Serum concentrations of saquinavir may be increased. Dose adjustment was not needed at the study dose when used for a limited time (ketoconazole 400 mg once daily and Fortovase® 1200 mg 3 times daily).

Benzodiazepines: An increase in midazolam and triazolam serum levels may occur resulting in significant over sedation when administered with saquinavir. Concurrent use is contraindicated. A decreased dose may be considered when used with alprazolam, clorazepate, diazepam, or flurazepam.

Calcium channel blockers: Use with caution; serum concentrations of calcium channel blockers may be increased.

Cisapride: Saquinavir inhibits the metabolism of cisapride and should not be administered concurrently due to risk of life-threatening cardiac arrhythmias.

Clarithromycin: Serum concentrations of saquinavir and clarithromycin may both be increased. Dose adjustment not was not needed at the study dose when used for 7 days (clarithromycin 500 mg twice daily and Fortovase® 1200 mg 3 times/day); dosage adjustment of clarithromycin is recommended in patients with renal impairment.

Corticosteroids: Dexamethasone may decrease serum concentrations of saquinavir; use with caution.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of saquinavir. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 substrates: Saquinavir may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Ergot alkaloids (dihydroergotamine, ergonovine, ergotamine and methylergonovine): Serum levels/toxicity may be increased by saquinavir; serious and/or life-threatening reactions may occur; concurrent use is contraindicated.

HMG-CoA reductase inhibitors: Saquinavir increased serum concentrations of simvastatin, lovastatin, and atorvastatin; risk of myopathy/rhabdomyolysis may be increased. Avoid use with simvastatin and lovastatin. Use caution with atorvastatin and cerivastatin (fluvastatin, pravastatin, and rosuvastatin are not appreciably metabolized by CYP3A4).

Immunosuppressants: Saquinavir may increase the serum levels of cyclosporine, sirolimus, or tacrolimus.

Methadone: Serum concentrations of methadone may be decreased; an increased dose may be needed when administered with saquinavir

Non-nucleoside reverse transcriptase inhibitors: Saquinavir serum concentrations may be increased by delavirdine. Serum levels of saquinavir and efavirenz may be decreased with concurrent use; saquinavir should not be used as the sole protease inhibitor with efavirenz or nevirapine.

Oral contraceptives: Serum levels of the hormones in oral contraceptives may decrease significantly with administration of saquinavir. Patients should use alternative methods of contraceptives during saquinavir therapy.

PDE-5 inhibitors: Serum concentrations may be increased by saquinavir; dosing adjustment is required. Limit sildenafil dose to 25 mg/48 hours. The maximum dose of tadalafil is 10 mg/72 hours. Vardenafil dosing should not exceed 2.5 mg/24 hours.

Pimozide: Serum levels/toxicity may be increased by saquinavir; serious and/or life-threatening reactions may occur; concurrent use is contraindicated.

Protease inhibitors: Atazanavir, indinavir, and ritonavir may increase serum levels of saquinavir. Serum levels of saquinavir and nelfinavir may be increased with concurrent use. Lopinavir/ritonavir (combination product) may increase serum levels of saquinavir. Refer to Dosage

section. Dosage adjustment recommendations with atazanavir have not been established.

Rifabutin: Serum concentrations of saquinavir are decreased and levels of rifabutin are increased. Saquinavir should not be used as the sole protease inhibitor when given with rifabutin.

Rifampin: Serum concentrations of saquinavir are markedly decreased. Risk of hepatotoxicity is increased with concurrent use of ritonavir-boosted saquinavir therapy. Concurrent use is contraindicated.

Tricyclic antidepressants: Serum concentrations of amitriptyline and imipramine may be increased; monitor.

Warfarin: Serum concentrations of warfarin may be affected; monitor.

Pregnancy Risk Factor B

Pregnancy Implications Preliminary data show that saquinavir pharmacokinetics may be affected by pregnancy; studies are not yet complete. Pregnancy and protease inhibitors are both associated with an increased risk of hyperglycemia. Glucose levels should be closely monitored. Health professionals are encouraged to contact the antiretroviral pregnancy registry to monitor outcomes of pregnant women exposed to antiretroviral medications (1-800-258-4263).

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Observe for signs of opportunistic infections and other illnesses associated with HIV; administer on a full stomach, if possible

Additional Information A high-fat meal maximizes bioavailability. Saquinavir levels may increase if taken with grapefruit juice. Saquinavir serum concentrations may be decreased by St John's wort; avoid concurrent use. Garlic capsules may decrease saquinavir serum concentrations; avoid use if saquinavir is the only protease inhibitor.

Scopolamine

Related Information

• Therapeutic Drugs Associated with Hallucinations

CAS Number 114-49-8; 51-34-3; 6533-68-2

U.S. Brand Names Isopto® Hyoscine; Scopace™; Transderm Scōp®

Synonyms Hyoscine Butylbromide; Hyoscine Hydrobromide; Scopolamine Butylbromide; Scopolamine Hydrobromide

Impairment Potential Yes

Use Preoperative medication to produce amnesia and decrease salivation and respiratory secretions to produce cycloplegia and mydriasis; treatment of iridocyclitis, prevention of nausea and vomiting by motion; produces more CNS depression, mydriasis, and cycloplegia but less effective in preventing reflex bradycardia and effecting the intestines than atropine

Mechanism of Action Blocks the action of acetylcholine at parasympathetic sites in smooth muscle, secretory glands and the CNS; increases cardiac output, dries secretions, antagonizes histamine and serotonin; a tropane alkaloid

Adverse Reactions

Cardiovascular: Tachycardia, palpitations, sinus tachycardia, tachycardia (supraventricular), sinus bradycardia

Central nervous system: Disorientation, drowsiness, hallucinations, confusion, anxiety, psychosis, delirium, electroencephalogram abnormalities, amnesia, lilliputian hallucinations, mania, paranoia

Dermatologic: **Dry skin**

Gastrointestinal: **Xerostomia, dry throat, constipation**

Genitourinary: Urinary retention

Local: **Irritation at injection site**

Ocular: **Blurred vision, photophobia,** cycloplegia, mydriasis, increased intraocular pressure, esotropia

Respiratory: **Dry nose**

Miscellaneous: **Diaphoresis (decreased),** anaphylactoid reactions, allergic reactions

Note: Systemic adverse effects have been reported with both the topical and ophthalmic preparations

Signs and Symptoms of Overdose Bradycardia, bronchospasm, coma, confusion, delirium, dementia, dysuria, hypertension, hyperthermia, increased intraocular pressure, memory loss, mydriasis, photophobia, seizures, tachycardia, visual hallucinations

Pharmacodynamics/Kinetics

Onset of action: Oral, I.M.: 0.5-1 hour; I.V.: 10 minutes

Peak effect: 20-60 minutes; may take 3-7 days for full recovery; transdermal: 24 hours

Duration: Oral, I.M.: 4-6 hours; I.V.: 2 hours

Absorption: Tertiary salts (hydrobromide) are well absorbed; quaternary salts (butylbromide) are poorly absorbed (local concentrations in the GI tract following oral dosing may be high)

Metabolism: Hepatic

Half-life elimination: 4.8 hours

Excretion: Urine (as metabolites)

Dosage

Preoperatively:

Children: I.M., SubQ: 6 mcg/kg/dose (maximum: 0.3 mg/dose) or 0.2 mg/m² may be repeated every 6-8 hours or alternatively:

4-7 months: 0.1 mg
 7 months to 3 years: 0.15 mg
 3-8 years: 0.2 mg
 8-12 years: 0.3 mg

Adults:

I.M., I.V., SubQ: 0.3-0.65 mg; may be repeated every 4-6 hours
 Transdermal patch: Apply 2.5 cm² patch to hairless area behind ear the night before surgery or 1 hour prior to cesarean section (the patch should be applied no sooner than 1 hour before surgery for best results and removed 24 hours after surgery)

Motion sickness: Transdermal: Children >12 years and Adults: Apply 1 disc behind the ear at least 4 hours prior to exposure and every 3 days as needed; effective if applied as soon as 2-3 hours before anticipated need, best if 12 hours before

Ophthalmic:**Refraction:**

Children: Instill 1 drop of 0.25% to eye(s) twice daily for 2 days before procedure

Adults: Instill 1-2 drops of 0.25% to eye(s) 1 hour before procedure

Iridocyclitis:

Children: Instill 1 drop of 0.25% to eye(s) up to 3 times/day

Adults: Instill 1-2 drops of 0.25% to eye(s) up to 4 times/day

Parkinsonism, spasticity, motion sickness: Oral: 0.4-0.8 mg as a range; the dosage may be cautiously increased in parkinsonism and spastic states.

Gastrointestinal/genitourinary spasm (Buscopan® [available in Canada; not available in the U.S.]): Adults:

Oral: 10-20 mg daily (1-2 tablets); maximum: 6 tablets/day

I.M., I.V., SubQ: 10-20 mg; maximum: 100 mg/day

Stability Avoid acid solutions, because hydrolysis occurs at pH <3

Administration When giving I.V., must first be diluted with sterile water for injection

Contraindications Hypersensitivity to scopolamine or any component of the formulation; narrow-angle glaucoma; acute hemorrhage; paralytic ileus, GI or GU obstruction; thyrotoxicosis; tachycardia secondary to cardiac insufficiency; myasthenia gravis

Warnings Use with caution with hepatic or renal impairment since adverse CNS effects occur more often in these patients; use with caution in infants and children since they may be more susceptible to adverse effects of scopolamine; use with caution in patients with GI obstruction, prostatic hyperplasia (nonobstructive), or urinary retention. Discontinue if patient reports unusual visual disturbances or pain within the eye. Use caution in hiatal hernia, reflux esophagitis, and ulcerative colitis. Scopolamine (hyoscine) hydrobromide should not be interchanged with scopolamine butylbromide formulations; dosages are not equivalent. Transdermal patch may contain conducting metal (eg, aluminum); remove patch prior to MRI.

Dosage Forms [CAN] = Canadian brand name

Injection, solution, as hydrobromide: 0.4 mg/mL (1 mL)

Injection, solution, as hyoscine-N-butylbromide:

Buscopan® [CAN]: 20 mg/mL [not available in U.S.]

Solution, ophthalmic, as hydrobromide:

Isopto® Hyoscine: 0.25% (5 mL, 15 mL) [contains benzalkonium chloride]

Tablet, as hyoscine-N-butylbromide:

Buscopan® [CAN]: 10 mg [not available in U.S.]

Tablet, soluble, as hydrobromide:

Maldemar™, Scopace™: 0.4 mg

Transdermal system:

Transderm Scop®: 1.5 mg (4s, 10s, 24s) [releases ~1 mg over 72 hours]

Reference Range Serum level of 890 pg/mL (SI: 7.93 nmol/L) correlated with psychosis

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Physostigmine can be utilized in life-threatening anticholinergic symptoms and has been used to treat paranoia and agitated states; seizures can be treated with diazepam, lorazepam, phenobarbital, or phenytoin

Enhancement of elimination: Multiple dosing of activated charcoal may be useful

Antidote(s)

- Physostigmine [ANTIDOTE]

Drug Interactions Anticholinergic agents: Adverse anticholinergic effects may be additive with other anticholinergic agents (includes tricyclic antidepressants, antihistamines, and phenothiazines).

CNS depressants: Sedative effects may be additive with scopolamine; use caution.

Pregnancy Risk Factor C

Pregnancy Implications Can cause neonatal drowsiness and tachycardia

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications Topical disc is programmed to deliver *in vivo* 0.5 mg over 3 days; wash hands before and after applying the disc to avoid drug contact with eyes

Additional Information Used as a chemical submissive agent in South America

Secobarbital

CAS Number 76-73-3

U.S. Brand Names Seconal®

Synonyms Quinalbarbitone Sodium; Secobarbital Sodium

Impairment Potential Yes. A 200 mg dose results in driving impairment. (O'Hanlon JF, "Driving Performance Under the Influence of Drugs: Rationale for, and Application of, a New Test," *Br J Clin Pharmacol*, 1984, 18(Suppl 1): 121S-9S.)

Use Short-term treatment of insomnia and as preanesthetic agent

Mechanism of Action Interferes with transmission of impulses from the thalamus to the cortex of the brain resulting in an imbalance in central inhibitory and facilitatory mechanisms

Adverse Reactions

Cardiovascular: Hypotension, cardiac arrhythmias, bradycardia, sinus bradycardia

Central nervous system: **Drowsiness, dizziness, lightheadedness, hangover effect**, impaired judgment, CNS stimulation or CNS depression, hypothermia, electroencephalogram abnormalities

Dermatologic: Rash, mucosal ulcerations, bullous eruptions, exfoliative dermatitis, erythema nodosum

Gastrointestinal: Nausea, vomiting

Local: **Pain at injection site**, arterial spasm and gangrene with inadvertent intra-arterial injection; thrombophlebitis with I.V. use

Renal: Oliguria

Respiratory: Laryngospasm, respiratory depression, apnea (especially with rapid I.V. use)

Miscellaneous: Acute atraumatic compartment syndrome

Signs and Symptoms of Overdose CNS depression, confusion, fever, jaundice, hypotension, hypothermia, myasthenia gravis (exacerbation or precipitation), nystagmus, possible bezoars, ptosis, unsteady gait, slurred speech, vision color changes (green tinge)

Pharmacodynamics/Kinetics

Onset of hypnosis: 15-30 minutes

Duration: 3-4 hours with 100 mg dose

Distribution: 1.5 L/kg; crosses the placenta; appears in breast milk

Protein binding: 45% to 60%

Metabolism: Hepatic, by microsomal enzyme system

Half-life elimination: 15-40 hours, mean: 28 hours

Time to peak, serum: Within 2-4 hours

Excretion: Urine (as inactive metabolites, small amounts as unchanged drug)

Dosage

Children:

Hypnotic: I.M.: 3-5 mg/kg/dose; maximum: 100 mg/dose

Preoperative sedation:

Oral: 50-100 mg 1-2 hours before procedure

Rectal: 5 mg/kg or <6 months: 30-60 mg; 6 months to 3 years: 60 mg; >3 years: 60-120 mg

Sedation: Oral: 6 mg/kg/day divided every 8 hours

Adults:

Hypnotic:

Oral, I.M.: 100-200 mg/dose

I.V.: 50-250 mg/dose

Preoperative sedation: Oral: 100-300 mg 1-2 hours before procedure

Sedation: Oral: 20-40 mg/dose 2-3 times/day

Fatal dose: 2-3 g

Stability Do not shake vial during reconstitution, rotate ampul; aqueous solutions are not stable reconstitute with aqueous polyethylene glycol; aqueous (sterile water) solutions should be used within 30 minutes; do not use bacteriostatic water for injection or lactated Ringer's; precipitates when used in solution with cimetidine

Monitoring Parameters Blood pressure, heart rate, respiratory rate, CNS status

Contraindications Hypersensitivity to barbiturates or any component of the formulation; marked hepatic impairment; dyspnea or airway obstruction; porphyria; pregnancy

Warnings Should be used only after evaluation of potential causes of sleep disturbance. Failure of sleep disturbance to resolve after 7-10 days may indicate psychiatric or medical illness. Potential for drug dependency exists, abrupt cessation may precipitate withdrawal, including status epilepticus in epileptic patients. Do not administer to patients in acute pain. Use caution in elderly, debilitated, renally impaired, or pediatric patients. May cause paradoxical responses, including agitation and hyperactivity, particularly in acute pain and pediatric patients. Use with caution in patients with depression or suicidal tendencies, or in patients with a history of drug abuse. Tolerance, psychological and physical dependence may occur with prolonged use. Use with caution in patients with hepatic function impairment. May cause CNS depression, which may impair physical or mental abilities. Patients must cautioned about performing tasks which require mental alertness (eg, operating machinery)

or driving). Effects with other sedative drugs or ethanol may be potentiated. May cause respiratory depression or hypotension, Use with caution in hemodynamically unstable patients or patients with respiratory disease.

Dosage Forms Capsule, as sodium: 100 mg

Reference Range

Therapeutic (serum): 3-5 mcg/mL (SI: 12.6-21.0 µmol/L)

Toxic (serum): >5 mcg/mL (SI: >21.0 µmol/L)

Lethal (serum): ≥20 mcg/mL (SI: >84 µmol/L)

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: If hypotension occurs, administer I.V. fluids and place the patient in the Trendelenburg position. If unresponsive, an I.V. vasopressor (eg, dopamine, epinephrine) may be required.

Enhancement of elimination: Forced alkaline diuresis is of no value in the treatment of intoxications with short-acting barbiturates. Charcoal hemoperfusion may be useful in the harder to treat intoxications, especially in the presence of very high serum barbiturate levels. Hemodialysis is less useful; slightly dialyzable (5% to 20%); hemoperfusion clearance ranges from 20-119 mL/minute; fractional removal of secobarbital by hemoperfusion is ~16% in 4 hours (as compared to 1% in 4 hours with hemodialysis)

Drug Interactions

Induces CYP2A6 (strong), 2C8 (strong), 2C9 (strong)

Acetaminophen: Barbiturates may enhance the hepatotoxic potential of acetaminophen overdoses

Antiarrhythmics: Barbiturates may increase the metabolism of antiarrhythmics, decreasing their clinical effect; includes disopyramide, propafenone, and quinidine

Anticonvulsants: Barbiturates may increase the metabolism of anticonvulsants; includes ethosuximide, felbamate (possibly), lamotrigine, phenytoin, tiagabine, topiramate, and zonisamide; does not appear to affect gabapentin or levetiracetam

Antineoplastics: Limited evidence suggests that enzyme-inducing antineoplastic therapy may reduce the effectiveness of some chemotherapy regimens (specifically in ALL); teniposide and methotrexate may be cleared more rapidly in these patients

Antipsychotics: Barbiturates may enhance the metabolism (decrease the efficacy) of antipsychotics; monitor for altered response; dose adjustment may be needed

Beta-blockers: Metabolism of beta-blockers may be increased and clinical effect decreased; atenolol and nadolol are unlikely to interact given their renal elimination

Calcium channel blockers: Barbiturates may enhance the metabolism of calcium channel blockers, decreasing their clinical effect

Chloramphenicol: Barbiturates may increase the metabolism of chloramphenicol and chloramphenicol may inhibit barbiturate metabolism; monitor for altered response

Cimetidine: Barbiturates may enhance the metabolism of cimetidine, decreasing its clinical effect

CNS depressants: Sedative effects and/or respiratory depression with barbiturates may be additive with other CNS depressants; monitor for increased effect; includes ethanol, sedatives, antidepressants, narcotic analgesics, and benzodiazepines

Corticosteroids: Barbiturates may enhance the metabolism of corticosteroids, decreasing their clinical effect

Cyclosporine: Levels may be decreased by barbiturates; monitor

CYP2A6 substrates: Secobarbital may decrease the levels/effects of CYP2A6 substrates. Example substrates include ifosfamide and rifampin.

CYP2C8 Substrates: Secobarbital may decrease the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP2C9 Substrates: Secobarbital may decrease the levels/effects of CYP2C9 substrates. Example substrates include bosentan, celecoxib, dapson, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, sulfonamides, trimethoprim, warfarin, and zafirlukast.

Doxycycline: Barbiturates may enhance the metabolism of doxycycline, decreasing its clinical effect; higher dosages may be required

Estrogens: Barbiturates may increase the metabolism of estrogens and reduce their efficacy

Felbamate may inhibit the metabolism of barbiturates and barbiturates may increase the metabolism of felbamate

Griseofulvin: Barbiturates may impair the absorption of griseofulvin, and griseofulvin metabolism may be increased by barbiturates, decreasing clinical effect

Guanfacine: Effect may be decreased by barbiturates

Immunosuppressants: Barbiturates may enhance the metabolism of immunosuppressants, decreasing its clinical effect; includes both cyclosporine and tacrolimus

Loop diuretics: Metabolism may be increased and clinical effects decreased; established for furosemide, effect with other loop diuretics not established

MAO inhibitors: Metabolism of barbiturates may be inhibited, increasing clinical effect or toxicity of the barbiturates

Methadone: Barbiturates may enhance the metabolism of methadone resulting in methadone withdrawal

Methoxyflurane: Barbiturates may enhance the nephrotoxic effects of methoxyflurane

Oral contraceptives: Barbiturates may enhance the metabolism of oral contraceptives, decreasing their clinical effect; an alternative method of contraception should be considered

Theophylline: Barbiturates may increase metabolism of theophylline derivatives and decrease their clinical effect

Tricyclic antidepressants: Barbiturates may increase metabolism of tricyclic antidepressants and decrease their clinical effect; sedative effects may be additive

Valproic acid: Metabolism of barbiturates may be inhibited by valproic acid; monitor for excessive sedation; a dose reduction may be needed

Warfarin: Barbiturates inhibit the hypoprothrombinemic effects of oral anticoagulants via increased metabolism; this combination should generally be avoided

Pregnancy Risk Factor D

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications I.V.: Give undiluted or diluted with sterile water for injection, normal saline, or Ringer's injection; maximum infusion rate: 50 mg/15 seconds

Selegiline

CAS Number 14611-51-9; 2079-54-1

U.S. Brand Names Eldepryl®

Synonyms Deprenyl; L-Deprenyl; Selegiline Hydrochloride

Use Adjunct in the management of parkinsonian patients in which levodopa/carbidopa therapy is deteriorating

Unlabeled/Investigational Use Early Parkinson's disease; attention-deficit/hyperactivity disorder (ADHD); negative symptoms of schizophrenia; extrapyramidal symptoms; Alzheimer's disease (studies have shown some improvement in behavioral and cognitive performance)

Mechanism of Action Potent monoamine oxidase (MAO) type-B inhibitor; MAO-B plays a major role in the metabolism of dopamine; selegiline may also increase dopaminergic activity by interfering with dopamine reuptake at the synapse

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), arrhythmias, hypertension, tachycardia, angina, syncope, hypotension, chest pain, palpitations, vasoconstriction

Central nervous system: **Mood changes, dizziness, dyskinesias** (13%), confusion, CNS depression, insomnia, agitation, loss of balance, psychosis, visual hallucinations

Dermatologic: Hypertrichosis, photosensitivity

Endocrine & metabolic: Hyperprolactinemia

Gastrointestinal: **Nausea, vomiting, xerostomia, abdominal pain, anorexia**

Genitourinary: Urinary retention, nocturia

Neuromuscular & skeletal: **Dyskinesias**, involuntary movements (increased), bradykinesia, muscle twitches, paresthesia

Ocular: Blurred vision

Miscellaneous: Bruxism

Admission Criteria/Prognosis Admit any symptomatic patient or ingestion >20 mg

Pharmacodynamics/Kinetics

Onset of action: Therapeutic: Oral: Within 1 hour

Duration: Oral: 24-72 hours

Absorption:

Orally disintegrating tablet: Rapid; greater bioavailability than capsule/tablet

Transdermal: 25% to 30% (of total selegiline content) over 24 hours

Protein binding: ~90%

Metabolism: Hepatic, primarily via CYP2B6 to active (N-desmethylselegiline, amphetamine, methamphetamine) and inactive metabolites

Half-life elimination: Oral: 10 hours; Transdermal: 18-25 hours

Excretion: Urine (primarily metabolites); feces

Dosage

Oral:

Children and Adolescents: ADHD (unlabeled use): 5-15 mg/day

Adults: Parkinson's disease: 5 mg twice daily with breakfast and lunch or 10 mg in the morning

Elderly: Parkinson's disease: Initial: 5 mg in the morning, may increase to a total of 10 mg/day

Monitoring Parameters Blood pressure, symptoms of parkinsonism

SELEGILINE

Administration Oral: Orally disintegrating tablet (Zelapar™): Take in morning before breakfast; place on top of tongue and allow to dissolve. Avoid food or liquid 5 minutes before and after administration.

Topical: Transdermal (Emsam®): Apply to clean, dry, intact skin to the upper torso (below the neck and above the waist), upper thigh, or outer surface of the upper arm. Avoid exposure of application site to external heat source, which may increase the amount of drug absorbed. Apply at the same time each day and rotate application sites. Wash hands with soap and water after handling. Avoid touching the sticky side of the patch.

Contraindications Hypersensitivity to selegiline or any component of the formulation; concomitant use of meperidine

Orally disintegrating tablet: Additional contraindications: Concomitant use of dextromethorphan, methadone, propoxyphene, tramadol, oral selegiline, other MAO inhibitors

Transdermal: Additional contraindications: Pheochromocytoma; concomitant use of bupropion, selective or dual serotonin reuptake inhibitors (including SSRIs and SNRIs), tricyclic antidepressants, buspirone, tramadol, propoxyphene, methadone, dextromethorphan, St. John's wort, mirtazapine, cyclobenzaprine, oral selegiline and other MAO inhibitors; carbamazepine, and oxcarbazepine; elective surgery requiring general anesthesia, local anesthesia containing sympathomimetic vasoconstrictors; sympathomimetics (and related compounds); foods high in tyramine content; supplements containing tyrosine, phenylalanine, tryptophan, or caffeine

Warnings

Oral: MAO-B selective inhibition should not pose a problem with tyramine-containing products as long as the typical oral doses are employed, however, rare reactions have been reported. Increased risk of non-selective MAO inhibition occurs with oral capsule/tablet doses > 10 mg/day or orally disintegrating tablet doses > 2.5 mg/day. Use of oral selegiline with tricyclic antidepressants and SSRIs has also been associated with rare reactions and should generally be avoided. Addition to levodopa therapy may result in exacerbation of levodopa adverse effects, requiring a reduction in levodopa dosage.

Transdermal: Nonselective MAO inhibition occurs with transdermal delivery and is necessary for antidepressant efficacy. Hypertensive crisis as a result of ingesting tyramine-rich foods is always a concern with nonselective MAO inhibition. Although transdermal delivery minimizes inhibition of MAO-A in the gut, there is limited data with higher transdermal doses; dietary restrictions are recommended with doses > 6 mg/24 hours. Monitor for worsening of depression, suicidality and/or associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, hypomania, and mania; worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy; prescriptions should be written for the smallest quantity. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

Transdermal selegiline may worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. Selegiline is not FDA approved for the treatment of bipolar depression. **[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders. Selegiline is not FDA approved for use in children.**

Should not be used in combination with other antidepressants. Do not use within 5 weeks of fluoxetine discontinuation or 1 week of other antidepressant discontinuation. Wait 2 weeks after discontinuing transdermal selegiline before initiating therapy with buspirone or any other contraindicated drug. May cause orthostatic hypotension - use with caution in patients with hypotension or patients who would not tolerate transient hypotensive episodes (cardiovascular or cerebrovascular disease) - effects may be additive with other agents which cause orthostasis. Discontinue at least 10 days prior to elective surgery. Use with caution in renal and hepatic impairment.

Medication should not be stopped abruptly; taper off as rapidly as possible. Safety and efficacy in children < 16 years of age have not been established.

Dosage Forms Capsule, as hydrochloride: 5 mg

Eldepryl®: 5 mg

Tablet, as hydrochloride: 5 mg

Tablet, orally-disintegrating:

Zelapar™: 1.25 mg [contains phenylalanine 1.25 mg/tablet]

Transdermal system [once-daily patch]:

Emsam®: 6 mg/24 hours (30s); 9 mg/24 hours (30s); 12 mg/24 hours (30s)

Reference Range Postmortem blood methamphetamine level following a 60 mg ingestion ranged from 0.17-0.28 mcg/mL

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage (within 1 hour)/activated charcoal is useful

Supportive therapy: Competent supportive care is the most important treatment for an overdose with a monoamine oxidase (MAO) inhibitor. Both hypertension or hypotension can occur with intoxication. Hypotension usually responds to I.V. fluids or vasopressors and hypertension usually responds to an alpha-adrenergic blocker. While treating the hypertension, care is warranted to avoid sudden drops in blood pressure, since this may worsen the MAO inhibitor toxicity. Muscle irritability and seizures often respond to diazepam or lorazepam, while hyperthermia is best treated antipyretics and cooling blankets. Cardiac arrhythmias are best treated with phenytoin or procainamide. Hypertensive crisis can be treated with nitroprusside, phentolamine (2-10 mg slow I.V. injection in adults), diazoxide (50-100 mg I.V.) or oral nifedipine (10 mg). Dantrolene (2.5 mg/kg every 6 hours I.V.) can be used to treat hypermetabolic crisis. Hypertensive crisis can be treated with nitroprusside, phentolamine (2-10 mg slow I.V. injection in adults), diazoxide (50-100 mg I.V.) or oral nifedipine (10 mg); dantrolene (2.5 mg/kg every 6 hours I.V.) can be used to treat hypermetabolic crisis. Avoid phenothiazines.

Drug Interactions **Substrate** of CYP1A2 (minor), 2A6 (minor), 2B6 (major), 2C8 (minor), 2C19 (minor), 2D6 (minor), 3A4 (minor); **Inhibits** CYP1A2 (weak), 2A6 (weak), 2C9 (weak), 2C19 (weak), 2D6 (weak), 2E1 (weak), 3A4 (weak)

Note: Many drug interactions involving selegiline are theoretical, primarily based on interactions with nonspecific MAO inhibitors; at oral (capsule/tablet) doses < 10 mg/day and orally disintegrating tablet doses < 2.5 mg, the risk of these interactions with selegiline may be very low. Transdermal selegiline results in higher plasma levels and nonselective MAO inhibition. Amphetamines: MAO inhibitors in combination with amphetamines may result in severe hypertensive reaction or serotonin syndrome; these combinations are best avoided (contraindicated with transdermal selegiline).

Anorexiant: Concurrent use of selegiline (high dose) in combination with CNS stimulants or anorexiant may result in serotonin syndrome; these combinations are best avoided; includes dexfenfluramine, fenfluramine, or sibutramine

Atomoxetine: MAO inhibitors may increase the toxicity of atomoxetine; avoid concomitant use.

Barbiturates: MAO inhibitors may inhibit the metabolism of barbiturates and prolong their effect

Bupropion: MAO inhibitors may increase the toxicity of bupropion; avoid concomitant use.

Buspirone: Concomitant use with selegiline may cause increased blood pressure; avoid combination.

Carbamazepine: May increase levels/effects of selegiline; concomitant use of transdermal selegiline is contraindicated.

CNS stimulants: MAO inhibitors in combination with stimulants (methylphenidate, dexamethylphenidate) may result in serotonin syndrome; these combinations are best avoided (contraindicated with transdermal selegiline).

COMT inhibitors (eg, entacapone, tolcapone): May increase to toxicity of MAO inhibitors; avoid concomitant use.

CYP2B6 inducers: May decrease the levels/effects of selegiline. Example inducers include carbamazepine, nevirapine, phenobarbital, phenytoin, and rifampin.

CYP2B6 inhibitors: May increase the levels/effects of selegiline. Example inhibitors include desipramine, paroxetine, and sertraline.

Dextromethorphan: Concurrent use of selegiline (high dose) may result in serotonin syndrome; these combinations are best avoided (contraindicated with transdermal and orally disintegrating tablet selegiline).

Disulfiram: MAO inhibitors may produce delirium in patients receiving disulfiram; monitor.

False neurotransmitters (eg, guanadrel and guanethidine): MAO inhibitors inhibit the antihypertensive response to guanadrel or guanethidine; use an alternative antihypertensive agent.

Hypoglycemic agents: MAO inhibitors may produce hypoglycemia in patients with diabetes; monitor.

Levodopa: MAO inhibitors in combination with levodopa may result in hypertensive reactions; monitor.

Lithium: MAO inhibitors in combination with lithium have resulted in malignant hyperpyrexia; this combination is best avoided.

Meperidine: Use with selegiline (high dose) may result in serotonin syndrome; concurrent use contraindicated.

Methadone: Concomitant use with an MAO inhibitor may increase the risk of serotonin syndrome (contraindicated with transdermal and orally disintegrating tablet selegiline).

Mirtazapine, nefazodone: Concurrent use of selegiline (high dose) may result in serotonin syndrome; these combinations are best avoided (contraindicated with transdermal selegiline).

Norepinephrine: MAO inhibitors may increase the pressor response of norepinephrine (effect is generally small); monitor (contraindicated with transdermal selegiline).

Oral contraceptives: Increased selegiline levels have been noted with concurrent administration; monitor

Propoxyphene: Concomitant use with an MAO inhibitor may increase the risk of serotonin syndrome (contraindicated with transdermal and orally disintegrating tablet selegiline).

Reserpine: MAO inhibitors in combination with reserpine may result in hypertensive reactions; monitor.

Sibutramine: May cause serotonin syndrome when combined with an MAO inhibitor; avoid this combination.

SSRIs/SNRIs: Concurrent use of selegiline with a selective serotonin or serotonin/norepinephrine reuptake inhibitor may result in mania or hypertension. It is generally best to avoid these combinations (contraindicated with transdermal selegiline).

St John's wort: May cause serotonin syndrome when combined with an MAO inhibitor; avoid this combination.

Sympathomimetics (indirect-acting): MAO inhibitors in combination with sympathomimetics such as dopamine, metaraminol, phenylephrine, and decongestants (pseudoephedrine) may result in severe hypertensive reaction; these combinations are best avoided (contraindicated with transdermal selegiline).

Tramadol: May increase the risk of seizures and serotonin syndrome in patients receiving an MAO inhibitor (contraindicated with transdermal and orally disintegrating tablet selegiline).

Trazodone: Concurrent use of selegiline (high dose) may result in serotonin syndrome; these combinations are best avoided.

Tricyclic antidepressants: May cause serotonin syndrome when combined with an MAO inhibitor; avoid this combination (contraindicated with transdermal selegiline).

Venlafaxine: Concurrent use of selegiline (high dose) may result in serotonin syndrome; these combinations are best avoided (contraindicated with transdermal selegiline).

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic and adverse behavioral events were noted in animal studies. There are no adequate and well-controlled studies in pregnant women.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Monoamine oxidase inhibitor type "B"; there should **not** be a problem with tyramine-containing products as long as the typical doses are employed

Specific References

Goetz CG, Poewe W, Rascol O, et al, "Evidence-Based Medical Review Update: Pharmacological and Surgical Treatments of Parkinson's Disease: 2001 to 2004," *Mov Disord*, 2005, 20(5):523-39.

Sertindole

Related Information

- Antipsychotic Agents

Unlabeled/Investigational Use Antipsychotic agent

Mechanism of Action Antagonist of dopamine (d₂), serotonin, and norepinephrine (alpha₁-receptors); has limbic selectivity, somewhat similar to clozapine

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), syncope
 Central nervous system: Lethargy, drowsiness, dizziness, **headache**, dystonia
 Genitourinary: Dry ejaculation
 Neuromuscular & skeletal: Tremor, cogwheel rigidity
 Respiratory: Nasal congestion

Toxicodynamics/Kinetics

Peak plasma level: 8-10 hours
 Half-life: 60 hours (may exceed 100 hours in > 10% of patients)
 Protein binding: 99%
 Metabolism: Hepatic to norsertindole and Lu28-092
 Elimination: Fecal

Dosage 4-32 mg/day; usual therapeutic dosage range: 16-20 mg/day

Overdosage/Treatment

Decontamination: Activated charcoal
 Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Additional Information Potent anxiolytic activity, low extrapyramidal reaction; no anticholinergic effects

Impairment Potential Yes, at doses > 500 mg. Serum sertraline level of 1285 mcg/L associated with driving impairment. Although no cases of fatal overdose with only sertraline have been reported, symptoms of nonfatal sertraline-only overdoses include somnolence, nausea, vomiting, tachycardia, ECG changes, anxiety, and dilated pupils with the amounts ingested ranging from 500-6000 mg.

Use Treatment of major depression; obsessive-compulsive disorder (OCD); panic disorder; post-traumatic stress disorder (PTSD); premenstrual dysphoric disorder (PMDD); social anxiety disorder

Unlabeled/Investigational Use Eating disorders; generalized anxiety disorder (GAD); impulse control disorders

Mechanism of Action Antidepressant with selective inhibitory effects on presynaptic serotonin (5-HT) reuptake; it is a naphthylamine derivative

Adverse Reactions

Cardiovascular: Palpitations, atrial arrhythmias, AV block, bradycardia, QT_c prolongation, vasculitis, ventricular tachycardia (including torsade de pointes)
 Central nervous system: **Insomnia, somnolence, dizziness, headache, fatigue**, agitation, anxiety, nervousness, dystonia, extrapyramidal symptoms, hallucinations, neuroleptic malignant syndrome, oculogyric crisis, psychosis
 Dermatologic: Rash, angioedema, Stevens-Johnson syndrome (and other severe dermatologic reactions), photosensitivity
 Endocrine & metabolic: Libido decreased, galactorrhea, gynecomastia, hyperglycemia, hyperprolactinemia, hypothyroidism, serotonin syndrome, SIADH
 Gastrointestinal: **Xerostomia, diarrhea, nausea**, constipation, anorexia, dyspepsia, flatulence, vomiting, weight gain, abdominal pain, gum hyperplasia, pancreatitis (rare)
 Genitourinary: **Ejaculatory disturbances**, micturition disorders, priapism
 Hematologic: Agranulocytosis, aplastic anemia, leukopenia, thrombocytopenia, PT/INR increased
 Hepatic: Bilirubin increased, hepatic failure, hepatitis, hepatomegaly, jaundice, transaminases increased
 Neuromuscular & skeletal: Tremors, paresthesia
 Ocular: Visual difficulty, abnormal vision, blindness, cataract, optic neuritis
 Otic: Tinnitus
 Renal: Acute renal failure
 Respiratory: Pulmonary hypertension
 Miscellaneous: Diaphoresis (increased), allergic reaction, anaphylactoid reaction, lupus-like syndrome, serum sickness
 Additional adverse reactions reported in pediatric patients (frequency > 2%): Aggressiveness, epistaxis, hyperkinesia, purpura, sinusitis, urinary incontinence

Signs and Symptoms of Overdose Agitation, amenorrhea, bone marrow depression, chest pain, conjunctivitis, dermatitis, drowsiness, dysphagia, dysuria, ejaculatory disturbances, fatigue, gynecomastia, hallucinations, hirsutism, hypertension, hypertonia, hypertrichosis, hypertriglyceridemia, hypoglycemia, hypotension, insomnia, lacrimation, mania, muscle twitching, myalgia, myoclonus, purpura, sinus tachycardia (which usually resolves in 12 hours), stomatitis, tachycardia

Pharmacodynamics/Kinetics

Absorption: Slow
 Protein binding: 98%
 Metabolism: Hepatic; extensive first-pass metabolism
 Bioavailability: 88%
 Half-life elimination: Parent drug: 26 hours; Metabolite N-desmethylsertraline: 66 hours (range: 62-104 hours)
 Time to peak, plasma: 4.5-8.4 hours
 Excretion: Urine and feces

Dosage

Oral:
 Children and Adolescents: OCD:
 6-12 years: Initial: 25 mg once daily
 13-17 years: Initial: 50 mg once daily
Note: May increase daily dose, at intervals of not less than 1 week, to a maximum of 200 mg/day. If somnolence is noted, give at bedtime.

Adults:

Depression/OCD: Oral: Initial: 50 mg/day (see "Note" above)
 Panic disorder, PTSD, social anxiety disorder: Initial: 25 mg once daily; increase to 50 mg once daily after 1 week (see "Note" above)
 PMDD: 50 mg/day either daily throughout menstrual cycle **or** limited to the luteal phase of menstrual cycle, depending on physician assessment. Patients not responding to 50 mg/day may benefit from dose increases (50 mg increments per menstrual cycle) up to 150 mg/day when dosing throughout menstrual cycle **or** up to 100 mg/day when dosing during luteal phase only. If a 100 mg/day dose has been established with luteal phase dosing, a 50 mg/day titration step for 3 days should be utilized at the beginning of each luteal phase dosing period.

Elderly: Depression/OCD: Start treatment with 25 mg/day in the morning and increase by 25 mg/day increments every 2-3 days if tolerated to 50-100 mg/day; additional increases may be necessary; maximum dose: 200 mg/day

Sertraline

Related Information

- Antidepressant Agents

CAS Number 79559-97-0; 79617-96-2

U.S. Brand Names Zoloft®

Synonyms Sertraline Hydrochloride

Dosage adjustment/comment in renal impairment: Multiple-dose pharmacokinetics are unaffected by renal impairment.

Hemodialysis: Not removed by hemodialysis

Dosage adjustment/comment in hepatic impairment: Sertraline is extensively metabolized by the liver; caution should be used in patients with hepatic impairment; a lower dose or less frequent dosing should be used.

Monitoring Parameters Monitor nutritional intake and weight; mental status for depression, suicidal ideation, anxiety, social functioning, mania, panic attacks; akathisia; growth in pediatric patients

Administration Oral concentrate: Must be diluted before use. Immediately before administration, use the dropper provided to measure the required amount of concentrate; mix with 4 ounces ($\frac{1}{2}$ cup) of water, ginger ale, lemon/lime soda, lemonade, or orange juice **only**. Do not mix with any other liquids than these. The dose should be taken immediately after mixing; do not mix in advance. A slight haze may appear after mixing; this is normal. **Note:** Use with caution in patients with latex sensitivity; dropper dispenser contains dry natural rubber.

Contraindications Hypersensitivity to sertraline or any component of the formulation; use of MAO inhibitors within 14 days; concurrent use of pimozide; concurrent use of sertraline oral concentrate with disulfiram

Warnings Major psychiatric warnings:

- **[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders;** consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. A medication guide concerning the use of antidepressants in children and teenagers should be dispensed with each prescription. **Sertraline is not FDA approved for use in children with major depressive disorder (MDD). However, it is approved for the treatment of obsessive-compulsive disorder (OCD) in children \geq 6 years of age.**

- The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Patients treated with antidepressants should be observed for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy.

- Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression or psychosis occur.

- May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Sertraline is not FDA approved for the treatment of bipolar depression.**

Key adverse effects:

- Anticholinergic effects: Relatively devoid of these side effects
- CNS depression: Has a low potential to impair cognitive or motor performance; caution operating hazardous machinery or driving.
- SIADH and hyponatremia: Has been associated with the development of SIADH; hyponatremia has been reported rarely, predominantly in the elderly

Concurrent disease:

- Hepatic impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.
- Other concurrent illness: Use caution in patients with certain concomitant systemic illness; due to limited experience.
- Platelet aggregation: May impair platelet aggregation, resulting in bleeding.
- Renal impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.
- Seizure disorders: Use caution with a previous seizure disorder or condition predisposing to seizures such as brain damage or alcoholism.
- Sexual dysfunction: May cause or exacerbate sexual dysfunction.
- Uric acid nephropathy: Use caution in patients at risk of uric acid nephropathy; sertraline acts as a mild uricosuric.
- Weight loss: May cause weight loss. Use caution in patients where weight loss is undesirable.

Concurrent drug therapy:

- Agents which lower seizure threshold: Concurrent therapy with other drugs which lower the seizure threshold.
- Anticoagulants/Antiplatelets: Use caution with concomitant use of NSAIDs, ASA, or other drugs that affect coagulation; the risk of bleeding is potentiated.
- CNS depressants: Use caution with concomitant therapy.
- MAO inhibitors: Potential for severe reaction when used with MAO inhibitors; autonomic instability, coma, death, delirium, diaphoresis, hyperthermia, mental status changes/agitation, muscular rigidity, myoclonus, neuroleptic malignant syndrome features, and seizures may occur.

Special populations:

- Elderly: Use caution in elderly patients.
- Latex sensitivity: Use oral concentrate formulation with caution in patients with latex sensitivity; dropper dispenser contains dry, natural rubber.
- Pediatrics: Monitor growth in pediatric patients.

Special notes:

- Electroconvulsive therapy: May increase the risks associated with electroconvulsive therapy; consider discontinuing, when possible, prior to ECT treatment.
- Withdrawal syndrome: May cause dysphoric mood, irritability, agitation, dizziness, sensory disturbances, anxiety, confusion, headache, lethargy, emotional lability, insomnia, hypomania, tinnitus, and seizures. Upon discontinuation of sertraline therapy, gradually taper dose. If intolerable symptoms occur following a decrease in dosage or upon discontinuation of therapy, then resuming the previous dose with a more gradual taper should be considered.

Dosage Forms Note: Available as sertraline hydrochloride; mg strength refers to sertraline

Solution, oral concentrate:

Zoloft®: 20 mg/mL (60 mL) [contains alcohol 12%]

Tablet: 25 mg, 50 mg, 100 mg

Zoloft®: 25 mg, 50 mg, 100 mg

Reference Range Six hours after doses of 400 mg and 200 mg, peak plasma levels were 253.2 ng/mL and 105.4 ng/mL, respectively; plasma levels correlate poorly to clinical presentation; therapeutic clinical trials: 0.03-0.19 mg/L; postmortem peripheral blood sertraline levels range from 0.23-1 mg/L. Serum sertraline level of 2930 mcg/L and desmethylsertraline level of 1678 mcg/L were recorded after a maximum ingestion of 8 g of sertraline; the patient survived with supportive care. Postmortem blood sertraline level $>$ 1.5 mg/L may indicate that this drug was the cause of death.

Overdosage/Treatment

Overdose of $<$ 100 mg in children $<$ 5 years of age are tolerated well with decontamination and minimal supportive care

Decontamination: Lavage ingestions $>$ 1 g in adults (within 1 hour)/activated charcoal

Supportive therapy: Amantadine (100-200 mg 2 times/day) has been used successfully in treating sexual dysfunction; lorazepam (2 mg I.V.) and nitroglycerin (I.V. infusion of 2 mg/kg/minute) have been used successfully to treat serotonin syndrome induced by sertraline; bruxism can be treated with buspirone (5 mg at night); sildenafil (50-100 mg) can be used to treat sexual dysfunction; nefazodone (100 mg at bedtime) has been used successfully in treating sertraline-induced anorgasmia. Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Diagnostic Procedures

- Sertraline, Blood

Test Interactions \uparrow LFTs, cholesterol, triglycerides; \downarrow uric acid, glucose; sertraline may cause a false-positive urinary benzodiazepine assay using the original cloned enzyme donor immunoassay system

Drug Interactions **Substrate** of CYP2B6 (minor), 2C9 (minor), 2C19 (major), 2D6 (major), 3A4 (minor); **Inhibits** CYP1A2 (weak), 2B6 (moderate), 2C8 (weak), 2C9 (weak), 2C19 (moderate), 2D6 (moderate), 3A4 (moderate)

Amphetamines: SSRIs may increase the sensitivity to amphetamines, and amphetamines may increase the risk of serotonin syndrome

Benzodiazepines: Sertraline may inhibit the metabolism of alprazolam and diazepam resulting in elevated serum levels; monitor for increased sedation and psychomotor impairment

Buspirone: Sertraline inhibits the reuptake of serotonin; combined use with a serotonin agonist (buspirone) may cause serotonin syndrome

Carbamazepine: Sertraline may inhibit the metabolism of carbamazepine resulting in increased carbamazepine levels and toxicity; monitor for altered carbamazepine response

Cimetidine: Concurrent use resulted in an increase in sertraline's AUC, C_{max} , and half-life; monitor.

Clozapine: Sertraline may increase serum levels of clozapine; monitor for increased effect/toxicity

Cyclosporine: Sertraline may increase serum levels of cyclosporine (and possibly tacrolimus); monitor

CYP2B6 substrates: Sertraline may increase the levels/effects of CYP2B6 substrates. Example substrates include bupropion, promethazine, propofol, and selegiline.

CYP2C19 inducers: May decrease the levels/effects of sertraline. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of sertraline. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

CYP2C19 substrates: Sertraline may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, and propranolol.

CYP2D6 inhibitors: May increase the levels/effects of sertraline. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP2D6 substrates: Sertraline may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Sertraline may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 substrates: Sertraline may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozone are generally contraindicated with strong CYP3A4 inhibitors.

Cyproheptadine: May inhibit the effects of serotonin reuptake inhibitors (fluoxetine); monitor for altered antidepressant response; cyproheptadine acts as a serotonin agonist

Dextromethorphan: Some SSRIs inhibit the metabolism of dextromethorphan; visual hallucinations occurred; monitor for serotonin syndrome

Erythromycin: Serotonin syndrome has been reported when added to sertraline; limited documentation

Haloperidol: Serum concentrations may be increased by sertraline (small increase); monitor

HMG-CoA reductase inhibitors: Sertraline may inhibit the metabolism of lovastatin and simvastatin (metabolized by CYP3A4) resulting in myositis and rhabdomyolysis; although its inhibition is weak, these combinations are best avoided

Lamotrigine: Toxicity has been reported following the addition of sertraline; monitor

Lithium: Patients receiving SSRIs and lithium have developed neurotoxicity; if combination is used, monitor for neurotoxicity

Loop diuretics: Sertraline may cause hyponatremia; additive hyponatremic effects may be seen with combined use of a loop diuretic (bumetanide, furosemide, torsemide); monitor for hyponatremia

MAO inhibitors: Sertraline should not be used with nonselective MAO inhibitors (isocarboxazid, phenelzine); fatal reactions have been reported; this combination is contraindicated.

Meperidine: Concurrent use may result in serotonin syndrome; these combinations are best avoided

Nefazodone: May increase the risk of serotonin syndrome

NSAIDs: Concomitant use of sertraline and NSAIDs, aspirin, or other drugs affecting coagulation has been associated with an increased risk of bleeding; monitor.

Phenothiazines: Sertraline may inhibit metabolism of thioridazine or mesoridazine, potentially leading to malignant ventricular arrhythmias. Avoid concurrent use. Wait at least 5 weeks after discontinuing sertraline prior to starting thioridazine.

Phenytoin: Sertraline may inhibit the metabolism of phenytoin and may result in phenytoin toxicity. Studies have demonstrated minimal impact with concurrent dosing, however, monitoring of levels/effects is recommended.

Pimozone: Sertraline may increase serum levels of pimozone. Concurrent use is contraindicated.

Ritonavir: Combined use of sertraline with ritonavir may cause serotonin syndrome in HIV-positive patients; monitor

Selegiline: SSRIs have been reported to cause mania or hypertension when combined with selegiline; this combination is best avoided. Concurrent use with SSRIs has been reported to cause serotonin syndrome. As an MAO type B inhibitor, the risk of serotonin syndrome may be less than with nonselective MAO inhibitors.

Sibutramine: May increase the risk of serotonin syndrome with SSRIs; monitor.

SSRIs: Combined use with other drugs which inhibit the reuptake may cause serotonin syndrome

Sumatriptan (and other serotonin agonists): Concurrent use may result in toxicity; weakness, hyper-reflexia, and incoordination have been observed with sumatriptan and SSRIs. In addition, concurrent use

may theoretically increase the risk of serotonin syndrome; includes sumatriptan, naratriptan, rizatriptan, and zolmitriptan.

Sympathomimetics: May increase the risk of serotonin syndrome with SSRIs

Tolbutamide: Sertraline may decrease the metabolism of tolbutamide; monitor for changes in glucose control.

Tramadol: Sertraline combined with tramadol (serotonergic effects) may cause serotonin syndrome; monitor

Trazodone: Sertraline may inhibit the metabolism of trazodone resulting in increased toxicity; monitor

Tricyclic antidepressants: Sertraline may inhibit the metabolism of tricyclic antidepressants (amitriptyline, desipramine, imipramine, nortriptyline) resulting in elevated serum levels; if combination is warranted, a low dose of TCA (10-25 mg/day) should be utilized

Tryptophan: Sertraline may inhibit the reuptake of serotonin; combination with tryptophan, a serotonin precursor, may cause agitation and restlessness; this combination is best avoided

Venlafaxine: Sertraline may increase the risk of serotonin syndrome

Warfarin: Sertraline may alter the hypoprothrombinemic response to warfarin; monitor

Zolpidem: Onset of hypnosis may be shortened in patients receiving sertraline; monitor

Pregnancy Risk Factor C

Pregnancy Implications There are no adequate and well-controlled studies in pregnant women; use only if potential benefit to the mother justifies potential risk to the fetus.

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Additional Information Buspirone (15-60 mg/day) may be useful in treatment of sexual dysfunction during treatment with a selective serotonin reuptake inhibitor; may exacerbate tics in Tourette's syndrome

Sildenafil

CAS Number 0139755-83-2

U.S. Brand Names Viagra®

Synonyms UK92480

Impairment Potential Unknown

Use Treatment of erectile dysfunction; may be useful to reverse psychotropic-induced erectile dysfunction in men or reduced arousal/delayed orgasm in women

Unlabeled/Investigational Use Psychotropic-induced sexual dysfunction; pulmonary arterial hypertension in children

Mechanism of Action Does not directly cause penile erections, but affects the response to sexual stimulation. The physiologic mechanism of erection of the penis involves release of nitric oxide (NO) in the corpus cavernosum during sexual stimulation. NO then activates the enzyme guanylate cyclase, which results in increased levels of cyclic guanosine monophosphate (cGMP), producing smooth muscle relaxation and inflow of blood to the corpus cavernosum. Sildenafil enhances the effect of NO by inhibiting phosphodiesterase type 5 (PDE5), which is responsible for degradation of cGMP in the corpus cavernosum. When sexual stimulation causes local release of NO, inhibition of PDE5 by sildenafil causes increased levels of cGMP in the corpus cavernosum, resulting in smooth muscle relaxation and inflow of blood to the corpus cavernosum. At recommended doses, it has no effect in the absence of sexual stimulation.

Adverse Reactions

- Cardiovascular: Atrial fibrillation, flushing
- Central nervous system: Dizziness, **headache**, aggressive behavior, insomnia, pyrexia
- Dermatologic: Rash, erythema
- Gastrointestinal: Diarrhea, **dyspepsia**, gastritis
- Genitourinary: Urinary tract infection
- Hematologic: Anemia, leukopenia
- Hepatic: LFTs increased
- Neuromuscular & skeletal: Myalgia, paresthesia
- Ocular: Abnormal vision (color changes, blurred or increased sensitivity to light 3%; up to 11% with doses > 100 mg)
- Respiratory: Dyspnea exacerbated, epistaxis, nasal congestion, rhinitis, sinusitis

Admission Criteria/Prognosis

Admit any symptomatic patient or ingestion > 1 g.

Pharmacodynamics/Kinetics

Onset of action: ~60 minutes
 Duration: 2-4 hours
 Absorption: Rapid; slower with a high-fat meal
 Distribution: V_{ds} : 105 L
 Protein binding, plasma: ~96%
 Metabolism: Hepatic via CYP3A4 (major) and CYP2C9 (minor route)
 Bioavailability: 40%
 Half-life elimination: 4 hours
 Time to peak: 30-120 minutes; delayed by 60 minutes with a high-fat meal
 Excretion: Feces (80%); urine (13%)

Dosage

Adults: Oral:

Erectile dysfunction (Viagra®): For most patients, the recommended dose is 50 mg taken as needed, approximately 1 hour before sexual activity. However, sildenafil may be taken anywhere from 30 minutes to 4 hours before sexual activity. Based on effectiveness and tolerance, the dose may be increased to a maximum recommended dose of 100 mg or decreased to 25 mg. The maximum recommended dosing frequency is once daily.

Pulmonary arterial hypertension (Revatio™): 20 mg 3 times/day, taken 4-6 hours apart

Dosage adjustment for patients > 65 years of age: Hepatic impairment (cirrhosis), severe renal impairment (creatinine clearance < 30 mL/minute): Higher plasma levels have been associated which may result in increase in efficacy and adverse effects; Viagra®: Starting dose of 25 mg should be considered

Dosage considerations for patients taking alpha blockers: Viagra®: Doses of 50 or 100 mg, should not be taken within 4 hours of an alpha blocker; doses of 25 mg may be given at any time

Dosage adjustment for concomitant use of potent CYP3A4 inhibitors:

Revatio™:
 Erythromycin, saquinavir: No dosage adjustment
 Itraconazole, ketoconazole, ritonavir: Not recommended
 Viagra®:
 Erythromycin, itraconazole, ketoconazole, saquinavir: Starting dose of 25 mg should be considered
 Ritonavir: Maximum: 25 mg every 48 hours

Stability Store tablets at controlled room temperature 15°C to 30°C (59°F to 86°F)

Administration Administer 30 minutes to 4 hours before sexual activity (optimally 1 hour before).

Contraindications Hypersensitivity to sildenafil or any component of the formulation; concurrent use of organic nitrates (nitroglycerin) in any form (potentiates the hypotensive effects)

Warnings

Decreases in blood pressure may occur due to vasodilator effects; use caution in patients with resting hypotension (BP < 90/50), hypertension (BP > 170/110), fluid depletion, severe left ventricular outflow obstruction, or autonomic dysfunction, and patients receiving alpha-blockers or other antihypertensive medication. Not recommended for use with pulmonary veno-occlusive disease.

Use caution in patients with cardiovascular disease, including cardiac failure, unstable angina, or a recent history (within the last 6 months) of myocardial infarction, stroke, or life-threatening arrhythmia. Use caution in patients receiving concurrent bosentan. Use caution in patients with bleeding disorders or with active peptic ulcer disease; safety and efficacy have not been established.

There is a degree of cardiac risk associated with sexual activity; therefore, physicians may wish to consider the cardiovascular status of their patients prior to initiating any treatment for erectile dysfunction. Sildenafil should be used with caution in patients with anatomical deformation of the penis (angulation, cavernosal fibrosis, or Peyronie's disease), or in patients who have conditions which may predispose them to priapism (sickle cell anemia, multiple myeloma, leukemia).

Rare cases of nonarteritic ischemic optic neuropathy (NAION) have been reported; risk may be increased with history of vision loss. Other risk factors for NAION include low cup-to-disc ratio ("crowded disc"), coronary artery disease, diabetes, hypertension, hyperlipidemia, smoking, and age > 50 years.

The safety and efficacy of sildenafil with other treatments for erectile dysfunction have not been established; use is not recommended. May cause dose-related impairment of color discrimination. Use caution in patients with retinitis pigmentosa; a minority have generic disorders of retinal phosphodiesterases (no safety information available). Safety and efficacy in pediatric patients have not been established.

Dosage Forms Tablet:

Revatio™: 20 mg
 Viagra®: 25 mg, 50 mg, 100 mg

Overdosage/Treatment

Decontamination: Activated charcoal
 Supportive therapy: Avoid organic nitrate products
 Enhancement of elimination: Dialysis is not expected to be useful

Drug Interactions

Substrate of CYP2C9 (minor), 3A4 (major); **Inhibits** CYP1A2 (weak), 2C9 (weak), 2C19 (weak), 2D6 (weak), 2E1 (weak), 3A4 (weak)
Azole antifungals: May increase the serum concentrations of sildenafil; reduce starting dose to 25 mg.

Alpha-blockers (doxazosin): Concomitant use may lead to symptomatic hypotension in some patients. Patient should be stable on an alpha-blocker prior to initiation of PDE-5 inhibitor. Sildenafil should be started at 25 mg. If patient is taking an optimal dose of PDE-5 inhibitor, alpha-blocker should be initiated at lowest dose.

Bosentan: May decrease serum concentration and effect of sildenafil.

CYP3A4 inhibitors: May increase the levels/effects of sildenafil. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Macrolide antibiotics: May increase serum concentrations of sildenafil; reduce starting dose of Viagra® to 25 mg if used with clarithromycin, erythromycin, telithromycin, or troleanomycin. No adjustments with Revatio™ are required.

Nitroglycerin (other nitrates): Concurrent use with sildenafil is contraindicated due to the potential for severe, potentially fatal, hypotensive responses.

Protease inhibitors: May increase the serum concentrations of sildenafil; reduce dose of Viagra® to 25 mg/24 hours; use of Revatio™ is not recommended.

Pregnancy Risk Factor B

Pregnancy Implications There are no adequate and well-controlled studies in pregnant women.

Lactation Excretion in breast milk unknown/use caution

Silver Nitrate

CAS Number 7761-88-8

UN Number 1493

Synonyms AgNO₃

Use Cauterization of wounds and sluggish ulcers, removal of granulation tissue and warts; aseptic prophylaxis of burns. Industrial uses include cosmetics (at a concentration of up to 4%), photography, manufacture of silver salts, hair dyeing, ivory etching, and as a laboratory reagent.

Mechanism of Action Free silver ions precipitate bacterial proteins by combining with chloride in tissue forming silver chloride; coagulates cellular protein to form an eschar; silver ions or salts or colloidal silver preparations can inhibit the growth of both gram-positive and gram-negative bacteria. This germicidal action is attributed to the precipitation of bacterial proteins by liberated silver ions. Silver nitrate coagulates cellular protein to form an eschar, and this mode of action is the postulated mechanism for control of benign hematuria, rhinitis, and recurrent pneumothorax.

Adverse Reactions

Dermatologic: Burning and skin irritation, staining of the skin
 Endocrine & metabolic: Hyponatremia
 Hematologic: Methemoglobinemia

Signs and Symptoms of Overdose Blackening of skin and mucous membranes, coma, convulsions, death, diarrhea, pain and burning of mouth, salivation, shock, vomiting. Absorbed nitrate can cause methemoglobinemia. Prolonged silver nitrate administration (topically) can result in hyperchloremia, hyponatremia, and late hyperchloremia. If taken orally, gastrointestinal burns with esophageal strictures can occur.

Pharmacodynamics/Kinetics

Absorption: Because silver ions readily combine with protein, there is minimal GI and cutaneous absorption of the 0.5% and 1% preparations
 Excretion: Highest amounts of silver noted on autopsy have been in kidneys, excretion in urine is minimal

Dosage Children and Adults:

Sticks: Apply to mucous membranes and other moist skin surfaces only on area to be treated 2-3 times/week for 2-3 weeks

Topical solution: Apply a cotton applicator dipped in solution on the affected area 2-3 times/week for 2-3 weeks

Stability Must be stored in a dry place; exposure to light causes silver to oxidize and turn brown, dipping in water causes oxidized film to readily dissolve

Monitoring Parameters With prolonged use, monitor methemoglobin levels

Administration Applicators are **not** for ophthalmic use.

Contraindications Hypersensitivity to silver nitrate or any component of the formulation; not for use on broken skin, cuts, or wounds

Warnings Do not use applicator sticks on the eyes. Prolonged use may result in skin discoloration.

Dosage Forms Applicator sticks, topical: Silver nitrate 75% and potassium nitrate 25% (6", 12", 18")

Solution, topical: 10% (30 mL); 25% (30 mL); 50% (30 mL)

Overdosage/Treatment

Decontamination:

Ocular: Irrigation of eyes for at least 15 minutes with normal saline. Sodium chloride can precipitate the silver as insoluble silver chloride.

Dermal: Irrigate for at least 15 minutes with saline. Remove all clothes and jewelry. Clothing can be washed but shoes should be discarded. Pay particular attention to scalp and nail decontamination.

Oral: Rinse out mouth with water. Give milk or water to dilute. Avoid ipecac or lavage since silver is corrosive. Note that patient's vomitus may be caustic and stain on contact.

Supportive therapy: Diazepam or lorazepam can be given to treat seizures. Methylene blue should be considered if cyanosis develops or if methemoglobin levels exceed 30%. Silver antidotes are probably of little to no clinical use.

Pregnancy Risk Factor C

Nursing Implications Silver nitrate solutions stain skin and utensils

Additional Information Fatal dose: As low as 2 g. Applicators are **not** for ophthalmic use.

Simvastatin

CAS Number 79902-63-9

U.S. Brand Names Zocor®

Use

Used with dietary therapy for the following:

Secondary prevention of cardiovascular events in hypercholesterolemic patients with established coronary heart disease (CHD) or at high risk for CHD: To reduce cardiovascular morbidity (myocardial infarction, coronary revascularization procedures) and mortality; to reduce the risk of stroke and transient ischemic attacks

Hyperlipidemias: To reduce elevations in total cholesterol, LDL-C, apolipoprotein B, and triglycerides in patients with primary hypercholesterolemia (elevations of 1 or more components are present in Fredrickson type IIa, IIb, III, and IV hyperlipidemias); treatment of homozygous familial hypercholesterolemia

Heterozygous familial hypercholesterolemia (HeFH): In adolescent patients (10-17 years of age, females >1 year postmenarche) with HeFH having LDL-C \geq 190 mg/dL or LDL \geq 160 mg/dL with positive family history of premature cardiovascular disease (CVD), or 2 or more CVD risk factors in the adolescent patient

Mechanism of Action Simvastatin acts by competitively inhibiting 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase, the enzyme that catalyzes the rate-limiting step in cholesterol biosynthesis

Adverse Reactions

Cardiovascular: Symptomatic hypotension, shock, chest pain, angina, vasculitis

Central nervous system: Headache, psychosis, CNS depression, depression

Dermatologic: Photosensitivity, erythema multiforme, alopecia, angioedema, toxic epidermal necrolysis, urticaria, purpura, Stevens-Johnson syndrome, pruritus, licheniform eruptions, exanthem

Endocrine & metabolic: Gynecomastia

Gastrointestinal: Constipation, dyspepsia, flatulence

Genitourinary: Impotence (onset: 2 days to 27 months)

Hepatic: Persistent elevations in liver enzymes, aminotransferase level elevation (asymptomatic)

Neuromuscular & skeletal: Polymyositis (dermatomyositis), CPK elevations (rarely) in the absence of clinical myopathy, rhabdomyolysis at doses > 160 mg, paresthesia

Ocular: Esotropia

Respiratory: Interstitial lung disease with pleural effusion

Miscellaneous: Systemic lupus erythematosus

Pharmacodynamics/Kinetics

Onset of action: >3 days

Peak effect: 2 weeks

Absorption: 85%

Protein binding: ~95%

Metabolism: Hepatic via CYP3A4; extensive first-pass effect

Bioavailability: <5%

Half-life elimination: Unknown

Time to peak: 1.3-2.4 hours

Excretion: Feces (60%); urine (13%)

Dosage Oral: **Note:** Doses should be individualized according to the baseline LDL-cholesterol levels, the recommended goal of therapy, and the patient's response; adjustments should be made at intervals of 4 weeks or more; doses may need adjusted based on concomitant medications

Children 10-17 years (females >1 year postmenarche): HeFH: 10 mg once daily in the evening; range: 10-40 mg/day (maximum: 40 mg/day)

Dosage adjustment for simvastatin with concomitant cyclosporine, fibrates, niacin, amiodarone, or verapamil: Refer to drug-specific dosing in Adults dosing section

Adults:

Homozygous familial hypercholesterolemia: 40 mg once daily in the evening or 80 mg/day (given as 20 mg, 20 mg, and 40 mg evening dose)

Prevention of cardiovascular events, hyperlipidemias: 20-40 mg once daily in the evening; range: 5-80 mg/day

Patients requiring only moderate reduction of LDL-cholesterol may be started at 10 mg once daily

Patients requiring reduction of >45% in low-density lipoprotein (LDL) cholesterol may be started at 40 mg once daily in the evening

Patients with CHD or at high risk for CHD: Dosing should be started at 40 mg once daily in the evening; simvastatin may be started simultaneously with diet

Dosage adjustment with concomitant medications:

Cyclosporine: Initial: 5 mg simvastatin, should **not** exceed 10 mg/day

Fibrates or niacin: Simvastatin dose should **not** exceed 10 mg/day
 Amiodarone or verapamil: Simvastatin dose should **not** exceed 20 mg/day

Dosing adjustment/comments in renal impairment: Because simvastatin does not undergo significant renal excretion, modification of dose should not be necessary in patients with mild to moderate renal insufficiency.

Severe renal impairment: Cl_{cr} < 10 mL/minute: Initial: 5 mg/day with close monitoring.

Stability Tablets should be stored in well-closed containers at temperatures between 5°C to 30°C (41°F to 86°F)

Monitoring Parameters Creatine phosphokinase levels due to possibility of myopathy; serum cholesterol (total and fractionated)

Obtain liver function tests prior to initiation, dose, and thereafter when clinically indicated. Patients titrated to the 80 mg dose should be tested prior to initiation and 3 months after initiating the 80 mg dose. Thereafter, periodic monitoring (ie, semiannually) is recommended for the first year of treatment. Patients with elevated transaminase levels should have a second (confirmatory) test and frequent monitoring until values normalize. Discontinue if increase in ALT/AST is persistently >3 times ULN.

Administration May be taken without regard to meals.

Contraindications Hypersensitivity to simvastatin or any component of the formulation; acute liver disease; unexplained persistent elevations of serum transaminases; pregnancy; breast-feeding

Warnings Secondary causes of hyperlipidemia should be ruled out prior to therapy. Liver function must be monitored by laboratory assessment. Rhabdomyolysis with acute renal failure has occurred. Risk is dose-related and is increased with concurrent use of lipid-lowering agents which may cause rhabdomyolysis (gemfibrozil, fibric acid derivatives, or niacin at doses \geq 1 g/day), during concurrent use with danazol or strong CYP3A4 inhibitors (including amiodarone, clarithromycin, cyclosporine, erythromycin, telithromycin, itraconazole, ketoconazole, nefazodone,

grapefruit juice in large quantities, verapamil, or protease inhibitors such as indinavir, nelfinavir, or ritonavir). Weigh the risk versus benefit when combining any of these drugs with simvastatin. Do not initiate simvastatin-containing treatment in a patient with pre-existing therapy of cyclosporine or danazol, unless the patient has previously demonstrated tolerance to ≥ 5 mg/day simvastatin. Temporarily discontinue in any patient experiencing an acute or serious major medical or surgical condition which may increase the risk of rhabdomyolysis. Discontinue temporarily for elective surgical procedures. Use caution in patients with renal insufficiency. Use with caution in patients who consume large amounts of ethanol or have a history of liver disease. Safety and efficacy have not been established in patients < 10 years or in premenarcheal girls.

Dosage Forms Tablet: 5 mg, 10 mg, 20 mg, 40 mg
Zocor[®]: 5 mg, 10 mg, 20 mg, 40 mg, 80 mg

Overdosage/Treatment

Decontamination: Activated charcoal
Enhanced elimination: Multiple dosing of activated charcoal may be effective

Drug Interactions

Substrate of CYP3A4 (major); **Inhibits** CYP2C8 (weak), 2C9 (weak), 2D6 (weak)

Amiodarone may increase the risk of myopathy and rhabdomyolysis; dose of simvastatin should not exceed 20 mg/day.

Antacids: Plasma concentrations may be decreased when given with magnesium-aluminum hydroxide containing antacids (reported with atorvastatin and pravastatin). Clinical efficacy is not altered, no dosage adjustment is necessary

Cholestyramine reduces absorption of several HMG-CoA reductase inhibitors. Separate administration times by at least 4 hours.

Cholestyramine and colestipol (bile acid sequestrants): Cholesterol-lowering effects are additive.

Clofibrate and fenofibrate may increase the risk of myopathy and rhabdomyolysis; dose of simvastatin should not exceed 10 mg/day

Cyclosporine: Concurrent use may increase the risk of myopathy and rhabdomyolysis; dose of simvastatin should not exceed 10 mg/day

CYP3A4 inhibitors: May increase the levels/effects of simvastatin.

Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Danazol: May increase risk of myopathy and rhabdomyolysis; dose of simvastatin should not exceed 10 mg/day.

Gemfibrozil: Increased risk of myopathy and rhabdomyolysis; dose of simvastatin should not exceed 10 mg/day.

Grapefruit juice may inhibit metabolism of simvastatin via CYP3A4; avoid high dietary intakes of grapefruit juice.

Niacin (≥ 1 g/day): Concurrent use may increase the risk of myopathy and rhabdomyolysis; dose of simvastatin should not exceed 10 mg/day.

Verapamil may increase the risk of myopathy and rhabdomyolysis; dose of simvastatin should not exceed 20 mg/day.

Warfarin effects (hypoprothrombinemic response) may be increased; monitor INR closely when simvastatin is initiated or discontinued.

Pregnancy Risk Factor X

Pregnancy Implications Cholesterol biosynthesis may be important in fetal development. Contraindicated in pregnancy. Administer to women of childbearing potential only when conception is highly unlikely and patients have been informed of potential hazards.

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Liver enzyme elevations may be observed during simvastatin therapy; combination therapy with other hypolipidemic agents may be required to achieve optimal reductions of LDL cholesterol; diet, weight reduction, and exercise should be attempted to control hypercholesterolemia before the institution of simvastatin therapy

Additional Information Average length of time to development of rhabdomyolysis is one year; with an addition of a fibrate, the average time is about 32 days. Muscle pain (88%) or fatigue (74%) are the two most prominent symptoms in statin-induced rhabdomyolysis.

Sodium Benzoate

CAS Number 532-32-1

Use Adjunctive therapy for the prevention and treatment of hyperammonemia due to suspected or proven urea cycle defects; used to treat urea cycle enzyme deficiency in combination with arginine

Mechanism of Action Assists in lowering serum ammonia levels by activation of a nonurea cycle pathway (the benzoate-hippurate pathway); ammonia in the presence of benzoate will conjugate with glycine to form hippurate which is excreted by the kidney

Adverse Reactions

Cardiovascular: Chest pain, angina
Dermatologic: Urticaria, rash
Gastrointestinal: Nausea, vomiting
Miscellaneous: Anaphylaxis

Pharmacodynamics/Kinetics

Half-life: 0.75-7.4 hours
Elimination: Clearance is largely attributable to metabolism with urinary excretion of hippurate, the major metabolite

Dosage Investigational use (not FDA approved): Children: Oral, I.V.: 0.25 g/kg bolus followed by 0.25-0.5 g/kg/day as continuous infusion or divided every 6-8 hours

Monitoring Parameters Serum ammonia level

Warnings Use with caution in patients with Reye's syndrome, propionic or methylmalonic acidemia; use with caution in neonates with hyperbilirubinemia due to potential displacement of bilirubin from albumin binding sites

Dosage Forms Powder: 454 g

Overdosage/Treatment

Supportive therapy: Treat urticarial rash with epinephrine, diphenhydramine and corticosteroids

Additional Information Not available commercially; oral solutions must be compounded using powder form. I.V. solutions must also be compounded and tested for sterility and pyrogenicity prior to use.

Sodium Chloride

CAS Number 7647-14-5

U.S. Brand Names Altamist [OTC]; Ayr[®] Baby Saline [OTC]; Ayr[®] Saline Mist [OTC]; Ayr[®] Saline [OTC]; Breathe Right[®] Saline [OTC]; Broncho Saline[®] [OTC]; Entsol[®] [OTC]; Muro 128[®] [OTC]; Na-Zone[®] [OTC]; Nasal Moist[®] [OTC]; NaSal[™] [OTC]; Ocean[®] [OTC]; Pediamist[®] [OTC]; Pretz[®] Irrigation [OTC]; SalineX[®] [OTC]; SeaMist[®] [OTC]; Simply Saline[™] [OTC]; Wound Wash Saline[™] [OTC]

Synonyms NaCl; Normal Saline; Salt

Use

Parenteral: Restores sodium ion in patients with restricted oral intake (especially hyponatremia states or low salt syndrome). In general, parenteral saline uses:

Bacteriostatic sodium chloride: Dilution or dissolving drugs for I.M., I.V., or SubQ injections

Essential in lithium or bromide toxicity (I.V. sodium chloride)

Concentrated sodium chloride: Additive for parenteral fluid therapy

Hypertonic sodium chloride: For severe hyponatremia and hypochloremia

Hypotonic sodium chloride: Hydrating solution

Normal saline: Restores water/sodium losses

Pharmaceutical aid/diluent for infusion of compatible drug additives

Ophthalmic: Reduces corneal edema

Oral: Restores sodium losses

Inhalation: Restores moisture to pulmonary system; loosens and thins congestion caused by colds or allergies; diluent for bronchodilator solutions that require dilution before inhalation

Intranasal: Restores moisture to nasal membranes

Irrigation: Wound cleansing, irrigation, and flushing

Traumatic brain injury (hypertonic sodium chloride)

Mechanism of Action There is a fluid shift from intracellular to extracellular space centrally with acute salt poisoning resulting in dehydration of brain cells; principal extracellular cation; functions in fluid and electrolyte balance, osmotic pressure control, and water distribution

Adverse Reactions

Cardiovascular: Thrombosis, hypervolemia, sinus tachycardia

Endocrine & metabolic: Hypermnatremia, dilution of serum electrolytes, overhydration, hypokalemia

Gastrointestinal: Salty taste

Local: Phlebitis, extravasation

Renal: Tubular necrosis (acute)

Respiratory: Congestive conditions, pulmonary edema

Signs and Symptoms of Overdose Coma, congestive heart failure, cramps, diarrhea, dizziness, flat anterior fontanelle (infants), fluid retention, hypokalemia, irritability, nausea, obtundation, pulmonary edema, restlessness, seizures, tachycardia, thirst, vomiting

Admission Criteria/Prognosis Ingestions >0.5 g/kg, symptomatic patients or asymptomatic patients with serum sodium levels >160 mEq/L should be considered for admission

Pharmacodynamics/Kinetics

Absorption: Oral, I.V.: Rapid
Distribution: Widely distributed
Excretion: Primarily urine; also sweat, tears, saliva

Dosage

Children: I.V.: Hypertonic solutions (>0.9%) should only be used for the initial treatment of acute serious symptomatic hyponatremia; maintenance: 3-4 mEq/kg/day; maximum: 100-150 mEq/day; dosage varies widely depending on clinical condition

Replacement: Determined by laboratory determinations mEq
Sodium deficiency (mEq/kg) = [% dehydration (L/kg)/100 × 70 (mEq/L)] + [0.6 (L/kg) × (140 - serum sodium) (mEq/L)]

Children ≥2 years and Adults:

Intranasal: 2-3 sprays in each nostril as needed

Irrigation: Spray affected area

Children and Adults: Inhalation: Bronchodilator diluent: 1-3 sprays (1-3 mL) to dilute bronchodilator solution in nebulizer prior to administration
Adults:

GU irrigant: 1-3 L/day by intermittent irrigation

Heat cramps: Oral: 0.5-1 g with full glass of water, up to 4.8 g/day

Replacement I.V.: Determined by laboratory determinations mEq

Sodium deficiency (mEq/kg) = [% dehydration (L/kg)/100 × 70 (mEq/L)] + [0.6 (L/kg) × (140 - serum sodium) (mEq/L)]

To correct acute, serious hyponatremia: mEq sodium = [desired sodium (mEq/L) - actual sodium (mEq/L)] × [0.6 × wt (kg)]; for acute correction use 125 mEq/L as the desired serum sodium; acutely correct serum sodium in 5 mEq/L/dose increments; more gradual correction in increments of 10 mEq/L/day is indicated in the asymptomatic patient

Chloride maintenance electrolyte requirement in parenteral nutrition: 2-4 mEq/kg/24 hours or 25-40 mEq/1000 kcals/24 hours; maximum: 100-150 mEq/24 hours

Sodium maintenance electrolyte requirement in parenteral nutrition: 3-4 mEq/kg/24 hours or 25-40 mEq/1000 kcals/24 hours; maximum: 100-150 mEq/24 hours.

Ophthalmic:

Ointment: Apply once daily or more often

Solution: Instill 1-2 drops into affected eye(s) every 3-4 hours

Stability Store injection at room temperature; protect from heat and from freezing; use only clear solutions

Monitoring Parameters Serum sodium, potassium, chloride, and bicarbonate levels; I & O, weight

Contraindications Hypersensitivity to sodium chloride or any component of the formulation; hypertonic uterus, hypernatremia, fluid retention

Warnings Use with caution in patients with CHF, renal insufficiency, liver cirrhosis, hypertension, edema; sodium toxicity is almost exclusively related to how fast a sodium deficit is corrected; both rate and magnitude are extremely important; do not use bacteriostatic sodium chloride in newborns since benzyl alcohol preservatives have been associated with toxicity. Wound Wash Saline™ is for single-patient use only.

Dosage Forms

Gel, intranasal:

Ayr® Saline No-Drip: 0.5% (22 mL) [spray gel; contains benzalkonium chloride, benzyl alcohol and soybean oil]

Ayr® Saline: 0.5% (14 g) [contains soybean oil]

Entsol®: 3% (20 g) [contains aloe, benzalkonium chloride, and vitamin E]

Simply Saline® Nasal Moist®: 0.65% (30 g)

Injection, solution [preservative free]: 0.9% (2 mL, 5 mL, 10 mL, 20 mL, 100 mL)

Injection, solution [preservative free, prefilled I.V. flush syringe]: 0.9% (2 mL, 2.5 mL, 3 mL, 5 mL, 10 mL)

Injection, solution: 0.45% (25 mL, 50 mL, 100 mL, 250 mL, 500 mL, 1000 mL); 0.9% (3 mL, 5 mL, 10 mL, 20 mL, 25 mL, 30 mL, 50 mL, 100 mL, 150 mL, 250 mL, 500 mL, 1000 mL); 3% (500 mL); 5% (500 mL)

Syrex: 0.9% (2.5 mL, 5 mL, 10 mL) [prefilled syringe]

Injection, solution [bacteriostatic]: 0.9% (10 mL, 20 mL, 30 mL) [contains benzyl alcohol]

Injection, solution [concentrate]: 14.6% (2.5 mEq/mL) (20 mL, 40 mL); 23.4% (4 mEq/mL) (30 mL, 100 mL, 200 mL, 250 mL)

Ointment, ophthalmic: 5% (3.5 g)

Altachlore, Muro 128®: 5% (3.5 g)

Powder for nasal solution (Entsol®): 3% (10.5 g)

Solution for inhalation: 0.45% (3 mL, 5 mL); 0.9% (3 mL, 5 mL, 15 mL); 3% (15 mL); 10% (15 mL)

Broncho® Saline: 0.9% (90 mL, 240 mL) [for dilution of bronchodilator solutions]

Solution, intranasal: 0.65% (45 mL)

Altamist: 0.65% (60 mL) [spray; contains benzalkonium chloride]

Ayr® Baby Saline: 0.65% (30 mL) [spray/drops; contains benzalkonium chloride]

Ayr® Saline: 0.65% (50 mL) [drops; contains benzalkonium chloride]

Ayr® Saline: 0.65% (50 mL) [mist, contains benzalkonium chloride]

Breathe Right® Saline: 0.65% (44 mL) [spray; contains benzalkonium chloride]

Deep Sea: 0.65% (45 mL) [spray; contains benzalkonium chloride]

Entsol® Mist: 3% (30 mL) [spray; contains benzalkonium chloride]

Entsol® [preservative free]: 3% (100 mL) [spray]

Entsol® [preservative free]: 3% (240 mL) [nasal wash]

Mycinaire™: 0.65% (30 mL) [mist; contains benzalkonium chloride]

Na-Zone®: 0.65% (60 mL) [spray; contains benzalkonium chloride]

NaSal™: 0.65% (15 mL) [drops; contains benzalkonium chloride], (30 mL) [spray; contains benzalkonium chloride]

Nasal Moist®: 0.65% (45 mL) [spray]

Ocean®: 0.65% (45 mL) [mist/spray/drops; contains benzalkonium chloride]; (473 mL) [refill bottle; contains benzalkonium chloride]

Ocean® for Kids: 0.65% (37.5 mL) [drops/spray/stream; contains benzalkonium chloride]

Pretz®: 0.75% (50 mL) [spray; contains benzalkonium chloride and yerba santa]; (240 mL) [irrigation; contains benzalkonium chloride and yerba santa]; (960 mL) [refill bottle; contains benzalkonium chloride and yerba santa]

SalineX®: 0.4% (15 mL) [drops]; (50 mL) [spray]

Simply Saline®: 0.9% (44 mL, 90 mL) [mist]

Simply Saline® Baby: 0.9% (45 mL) [mist]

4-Way® Saline Moisturizing Mist: 0.74% (30 mL) [alcohol free; contains benzalkonium chloride, eucalyptol, and menthol]

Solution for irrigation: 0.45% (1500 mL, 2000 mL); 0.9% (250 mL, 500 mL, 1000 mL, 1500 mL, 2000 mL, 3000 mL, 4000 mL, 5000 mL)

Wound Wash Saline™: 0.9% (90 mL, 210 mL)

Solution, ophthalmic: 5% (15 mL)

Altachlore: 5% (15 mL, 30 mL)

Muro 128®: 2% (15 mL); 5% (15 mL, 30 mL)

Reference Range

Serum/plasma levels:

Neonates: Full-term: 133-142 mEq/L; Premature: 132-140 mEq/L

Children 2 months to Adults: 135-145 mEq/L

Neurologic symptoms occur when serum sodium reaches 150-160 mEq/L; serum sodium levels from 160-185 mEq/L will commonly cause seizures, especially if an attempt is made to rapidly lower serum sodium; >185 mEq/L, death will likely result

Overdosage/Treatment

Decontamination: **Oral:** Emesis within 30 minutes or lavage within 1 hour; activated charcoal probably is not useful. **Ocular:** Irrigate copiously with water.

Supportive therapy: For hypernatremia, give 30-50 mEq/L of sodium (half chloride, half bicarbonate) by slow I.V. infusion; prepare solution by adding 15-25 mEq/L sodium chloride (2.5 mEq/mL) and 15-25 mEq sodium bicarbonate (1 mEq/mL) to 1 liter D₅W; administer at a rate of 2/3 maintenance with a goal of achieving normal serum sodium at 24-36 hours after initiating treatment; seizures may occur if serum sodium is lowered too quickly; I.V. mannitol (0.5-1 g/kg) should be used to treat cerebral edema; seizures can be treated with lorazepam or diazepam 0.1-0.25 mg/kg

Enhancement of elimination: Hypernatremia is resolved through the use of diuretics and free water replacement. Peritoneal dialysis should be considered in infants who are salt poisoned; hemodialysis should be considered in patients who are refractory to other therapies or in patients with renal impairment.

Drug Interactions Decreased levels of lithium

Pregnancy Risk Factor C

Pregnancy Implications Most of dose is concentrated in the decidua and fetal part of the placenta; some diffuses into maternal blood. When hypertonic sodium chloride is injected into the amniotic fluid, the following may result: Disseminated intravascular coagulation, renal necrosis, uterine and cervical lesions, pulmonary embolism, pneumonia, hemorrhage, death.

Nursing Implications Bacteriostatic NS should not be used for diluting or reconstituting drugs for administration in neonates; I.V. infusion of 3% or 5% sodium chloride should not exceed 100 mL/hour and should be administered in a central line only; presence or worsening of rales and degree of peripheral edema with infusions

Additional Information

Lethal dose: 3 g/kg

Deaths have been reported in patients who have consumed salt water as an emetic; ingestion of 0.5-1 g/kg sodium chloride is likely to be toxic; tablets can be radiopaque; 1 tablespoon of tablet salt contains ~305 mEq of sodium and can cause an elevation of serum sodium by 30.5 mEq/L in a child 3 years of age; sodium content of human milk: 7 mEq/L; cow's milk: 21 mEq/L

Sodium Dichloroacetate

CAS Number 2156-56-1; 79-43-6

Impairment Potential Yes, at doses > 50 mg/kg

Use Treatment of chronic or congenital forms of lactic acidosis; also has been used to treat homozygous familial hypercholesterolemia

Mechanism of Action An organohalide which activates the enzyme pyruvate dehydrogenase which results in pyruvate and lactate catabolism and inhibits glycolysis

Signs and Symptoms of Overdose Drowsiness, elevation of liver enzymes, elevation of serum urate and ketone levels, sedation (at doses > 50 mg/kg), peripheral neuropathy (with chronic daily dosing of 50-100 mg/kg)

Toxicodynamics/Kinetics

Distribution: V_d : 0.3 L/kg

Metabolism: Hepatic to glycine, oxalate, and CO_2

Bioavailability: High

Half-life: ~1 hour (single dose); 8 hours (chronic doses)

Time to peak plasma levels: Oral: 15-30 minutes

Dosage Oral: Daily doses of 25-100 mg/kg

I.V.: 50 mg/kg over 30 minutes followed by a second dose in 2 hours

Highest reported dose:

Children: 1.5 g

Adults: 34 g

Should not be given chronically

Reference Range Following a 50 mg/kg intravenous dose, peak plasma DCA concentration is ~116 mcg/mL

Overdosage/Treatment

Decontamination: Oral: Activated charcoal/lavage at doses > 100 mg/kg within 1 hour

Supportive therapy: Peripheral neuropathy usually resolves upon discontinuation of drug

Test Interactions Elevates acetoacetate and beta hydroxybutyrate levels

Additional Information DCA is a product of water chlorination; usual daily dose ingested through drinking water is 2-4 mcg/kg

Sodium Salicylate

CAS Number 54-21-7

Use Treatment of minor pain or fever; arthritis

Mechanism of Action Inhibits prostaglandin synthesis, acts on the hypothalamus heat-regulating center to reduce fever; decreases pain receptor sensitivity. Other proposed mechanisms of action for salicylate anti-inflammatory action are lysosomal stabilization, kinin and leukotriene production, alteration of chemotactic factors, and inhibition of neutrophil activation. This latter mechanism may be the most significant pharmacologic action to reduce inflammation.

Adverse Reactions

Dermatologic: Rash

Gastrointestinal: Nausea, vomiting, GI distress, GI bleeding, ulcers

Hematologic: Platelet inhibition

Hepatic: Hepatotoxicity

Respiratory: Wheezing

Signs and Symptoms of Overdose Bezoars, drowsiness, gastritis, GI bleeding, hyperthermia, hypoglycemia, nausea, nystagmus, ototoxicity, tinnitus, vomiting, wheezing. Severe poisoning can manifest with agranulocytosis, coma, confusion, dizziness, feces discoloration (black; pink; red; tarry), fever, granulocytopenia, headache, hyperglycemia, hyponatremia, hypotension, leukopenia, metabolic acidosis, neutropenia, pylorospasm, rhabdomyolysis, renal failure and/or hepatic failure, respiratory depression, seizures, urine discoloration (pink)

Admission Criteria/Prognosis Admit any patient with acidosis, mental status changes, thermoregulatory abnormality, glucose abnormality, serum salicylate > 40 mg/dL following an acute ingestion

Pharmacodynamics/Kinetics

Absorption: From stomach and small intestine

Half-life elimination, serum: Aspirin: 15-20 minutes; metabolic pathways are saturable such that salicylates half-life is dose-dependent ranging from 3 hours at lower doses (300-600 mg), 5-6 hours (after 1 g) and 15-30 hours with higher doses; in therapeutic anti-inflammatory doses, half-lives generally range from 6-12 hours

Dosage Adults: Oral: 325-650 mg every 4 hours

Monitoring Parameters Serum concentrations, renal function; hearing changes or tinnitus; monitor for response (ie, pain, inflammation, range of motion, grip strength); observe for abnormal bleeding, bruising, weight gain

Contraindications Bleeding disorders (factor VII or IX deficiencies), hypersensitivity to salicylates or other nonsteroidal anti-inflammatory drugs (NSAIDs); tartrazine dye and asthma

Warnings Tinnitus or impaired hearing may indicate toxicity; discontinue use 1 week prior to surgical procedures

Dosage Forms Tablet, enteric coated: 325 mg, 650 mg

Reference Range

Sample size: 1.5-2 mL blood (purple top tube)

Timing of serum samples: Peak levels usually occur 2 hours after ingestion; half-life increases with dosage (eg, the half-life after 300 mg is 3 hours, and after 1 g is 5-6 hours, and after 8-10 g is 10 hours)

Salicylate serum concentrations correlate with the pharmacological actions and adverse effects observed. See table.

Serum Salicylate: Clinical Correlations		
Serum Salicylate Concentration (mg/dL)	Desired Effects	Adverse Effects / Intoxication
~ 10	Antiplatelet	GI intolerance and bleeding, hypersensitivity, hemostatic defects
	Antipyresis	
	Analgesia	
15-20	Anti-inflammatory	Mild salicylism
25-40	Treatment of rheumatic fever	Nausea/vomiting, hyperventilation, salicylism, flushing, sweating, thirst, headache, diarrhea and tachycardia
> 40		Respiratory alkalosis, hemorrhage, excitement, confusion, asterixis, pulmonary edema, convulsions, tetany, metabolic acidosis, fever, coma, cardiovascular collapse, renal and respiratory failure

Overdosage/Treatment

Decontamination: Activated charcoal is quite effective; each gram of activated charcoal can bind up to 550 mg of salicylic acid; whole bowel irrigation can also be used

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with I.V. sodium bicarbonate (hypokalemia will need to be corrected), seizures with benzodiazepines; blood products are indicated, as appropriate, for hemorrhage; antacids may promote gastric absorption

Enhancement of elimination: Forced alkaline diuresis with I.V. sodium bicarbonate to keep urine pH at 8 should be performed for salicylate levels > 40 mg/dL; dialysis is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; consider hemodialysis for acute salicylate levels > 100 mg/dL; multiple dosing of activated charcoal may not hasten elimination; dialyzable (50% to 100%)

Drug Interactions Ammonium chloride, vitamin C (high dose), methionine, antacids, urinary alkalinizers, carbonic anhydrase inhibitors, corticosteroids, nizatidine, alcohol, ACE inhibitors, beta-blockers, loop diuretics, methotrexate, probenecid, sulfapyrazone, spironolactone, sulfonyleureas

Pregnancy Risk Factor C

Nursing Implications Sodium content of 1 g: 6.25 mEq; less effective than an equal dose of aspirin in reducing pain or fever; patients hypersensitive to aspirin may be able to tolerate

Additional Information Sodium content of 1 g: 6.25 mEq; less effective than an equal dose of aspirin in reducing pain or fever; patients hypersensitive to aspirin may be able to tolerate; total dose (mg) multiplied by 1.1 provides aspirin equivalent dose

Sorbitinil

CAS Number 68367-52-2

Unlabeled/Investigational Use Decrease the adverse effects of diabetes mellitus, specifically diabetic, nephropathy, retinopathy, neuropathy, and cataract formation

Mechanism of Action Aldose reductase inhibitor structurally related to hydantoin, decreased amounts of sorbitol and fructose are formed from glucose; thus, less water is drawn into the lens (through osmosis) and neurons, thus possibly leading to less diabetic complications

Adverse Reactions

Dermatologic: Toxic epidermal necrolysis

Hematologic: Leukopenia, thrombocytopenia

Hepatic: Elevated liver function tests

Neuromuscular & skeletal: Myalgia

Respiratory: Adult respiratory distress syndrome

Miscellaneous: Hypersensitivity syndrome (maculopapular rash)

Toxicodynamics/Kinetics

Distribution: V_d : 0.7-1 L/kg
 Half-life: 38-52 hours
 Elimination: Renal (33%); renal clearance: 5.99 mL/1.73 m²/minute

Dosage 200-250 mg once daily

Reference Range After a single 250 mg dose, peak plasma levels were 3.3 mcg/mL in healthy young males, 5.4 mcg/mL in elderly males, and 6.3 mcg/mL in elderly females; after 5 days on above dose, plasma sotalol levels can reach 10.6 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal
 Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Sotalol**Related Information**

- Selected Properties of Beta-Adrenergic Blocking Drugs

CAS Number 959-24-0

U.S. Brand Names Betapace AF[®]; Betapace[®]; Sorine[®]

Synonyms Sotalol Hydrochloride

Use Treatment of documented life-threatening ventricular arrhythmias (ie, sustained ventricular tachycardia), maintenance of normal sinus rhythm in patients with symptomatic atrial fibrillation and atrial flutter currently in sinus rhythm. Manufacturer states substitutions should not be made for Betapace AF[™] since Betapace AF[™] is distributed with a patient package insert specific for atrial fibrillation/flutter.

Mechanism of Action Has both B- and B₂-receptor blocking activity; also passes some type III antiarrhythmic activity

Adverse Reactions

Cardiovascular: Bradycardia, chest pain, palpitations, congestive heart failure, peripheral vascular disorders, edema, abnormal ECG, hypotension, proarrhythmia, Raynaud's phenomenon, syncope, leukocytoclastic vasculitis

Central nervous system: Fatigue, dizziness, lightheadedness, mental confusion, anxiety, headache, sleep problems, depression, emotional lability, clouded sensorium, incoordination, vertigo, paralysis, fever

Dermatologic: Itching/rash, cutaneous vasculitis, red crusted skin, photosensitivity reaction, pruritus, alopecia

Endocrine & metabolic: Decreased sexual ability, hyperlipidemia

Gastrointestinal: Diarrhea, nausea/vomiting, stomach discomfort, flatulence, xerostomia

Genitourinary: Impotence, retroperitoneal fibrosis

Hematologic: Bleeding, thrombocytopenia, eosinophilia, leukopenia

Hepatic: Increased serum transaminases

Local: Phlebitis, skin necrosis after extravasation

Neuromuscular & skeletal: Weakness, paresthesia, extremity pain, back pain, myalgia

Ocular: Visual problems

Respiratory: Dyspnea, upper respiratory problems, asthma, pulmonary edema, bronchiolitis obliterans with organized pneumonia

Miscellaneous: Diaphoresis, cold extremities

Signs and Symptoms of Overdose Bleeding, depression, eosinophilia, heart block, hypoglycemia, impotence, insomnia, leukopenia or neutropenia (agranulocytosis, granulocytopenia), lightheadedness, myasthenia gravis (exacerbation or precipitation), QT prolongation, thrombocytopenia

Admission Criteria/Prognosis Admit any patient with QT prolongation, cardiac arrhythmia; admit any pediatric ingestion > 8 mg/kg or adult ingestion > 1 g

Pharmacodynamics/Kinetics

Onset of action: Rapid, 1-2 hours

Peak effect: 2.5-4 hours

Duration: 8-16 hours

Absorption: Decreased 20% to 30% by meals compared to fasting

Distribution: Low lipid solubility; enters milk of laboratory animals and is reported to be present in human milk

Protein binding: None

Metabolism: None

Bioavailability: 90% to 100%

Half-life elimination: 12 hours; Children: 9.5 hours; terminal half-life decreases with age < 2 years (may be ≥ 1 week in neonates)

Excretion: Urine (as unchanged drug)

Dosage Sotalol should be initiated and doses increased in a hospital with facilities for cardiac rhythm monitoring and assessment. Proarrhythmic events can occur after initiation of therapy and with each upward dosage adjustment.

Children: Oral: The safety and efficacy of sotalol in children have not been established

Note: Dosing per manufacturer, based on pediatric pharmacokinetic data; wait at least 36 hours between dosage adjustments to allow monitoring of QT intervals

≤ 2 years: Dosage should be adjusted (decreased) by plotting of the child's age on a logarithmic scale; see graph or refer to

manufacturer's package labeling.

Age Factor Nomogram

Adapted from U.S. Food and Drug Administration.
<http://www.fda.gov/cder/foi/label/2001/2115s3lbl.pdf>

> 2 years: Initial: 90 mg/m²/day in 3 divided doses; may be incrementally increased to a maximum of 180 mg/m²/day

Adults: Oral:

Ventricular arrhythmias (Betapace[®], Sorine[™]):

Initial: 80 mg twice daily

Dose may be increased gradually to 240-320 mg/day; allow 3 days between dosing increments in order to attain steady-state plasma concentrations and to allow monitoring of QT intervals

Most patients respond to a total daily dose of 160-320 mg/day in 2-3 divided doses.

Some patients, with life-threatening refractory ventricular arrhythmias, may require doses as high as 480-640 mg/day; however, these doses should only be prescribed when the potential benefit outweighs the increased of adverse events.

Atrial fibrillation or atrial flutter (Betapace AF[™]): Initial: 80 mg twice daily

If the initial dose does not reduce the frequency of relapses of atrial fibrillation/flutter and is tolerated without excessive QT prolongation (not > 520 msec) after 3 days, the dose may be increased to 120 mg twice daily. This may be further increased to 160 mg twice daily if response is inadequate and QT prolongation is not excessive.

Elderly: Age does not significantly alter the pharmacokinetics of sotalol, but impaired renal function in elderly patients can increase the terminal half-life, resulting in increased drug accumulation

Dosage adjustment in renal impairment:

Children: Safety and efficacy in children with renal impairment have not been established.

Adults: Impaired renal function can increase the terminal half-life, resulting in increased drug accumulation. Sotalol (Betapace AF[™]) is contraindicated per the manufacturer for treatment of atrial fibrillation/flutter in patients with a Cl_{cr} < 40 mL/minute.

Ventricular arrhythmias (Betapace[®], Sorine[™]):

Cl_{cr} > 60 mL/minute: Administer every 12 hours

Cl_{cr} 30-60 mL/minute: Administer every 24 hours

Cl_{cr} 10-30 mL/minute: Administer every 36-48 hours

Cl_{cr} < 10 mL/minute: Individualize dose

Atrial fibrillation/flutter (Betapace AF[™]):

Cl_{cr} > 60 mL/minute: Administer every 12 hours

Cl_{cr} 40-60 mL/minute: Administer every 24 hours

Cl_{cr} < 40 mL/minute: Use is contraindicated

Dialysis: Hemodialysis would be expected to reduce sotalol plasma concentrations because sotalol is not bound to plasma proteins and does not undergo extensive metabolism; administer dose postdialysis or administer supplemental 80 mg dose; peritoneal dialysis does not remove sotalol; supplemental dose is not necessary

Monitoring Parameters Serum magnesium, potassium, ECG

Administration Food may decrease adsorption

Contraindications Hypersensitivity to sotalol or any component of the formulation; bronchial asthma; sinus bradycardia; second- and third-degree AV block (unless a functioning pacemaker is present); congenital or acquired long QT syndromes; cardiogenic shock; uncontrolled congestive heart failure. Betapace AF[®] is contraindicated in patients with significantly reduced renal filtration (Cl_{cr} < 40 mL/minute).

Warnings

Manufacturer recommends initiation (or reinitiation) and doses increased in a hospital setting with continuous monitoring and staff familiar with the recognition and treatment of life-threatening arrhythmias. Dosage of sotalol should be adjusted gradually with 3 days between dosing increments to achieve steady-state concentrations, and to allow time to monitor QT intervals. Some experts will initiate therapy on an outpatient basis in a patient without heart disease or bradycardia, who has a baseline uncorrected QT interval <450 msec, and normal serum potassium and magnesium levels; close EKG monitoring during this time is necessary. ACC/AHA guidelines for management of atrial fibrillation also recommend that for outpatient initiation the patient not have risk factors predisposing to drug-induced ventricular proarrhythmia (Fuster, 2001). Creatinine clearance must be calculated prior to dosing. Use cautiously in the renally-impaired (dosage adjustment required).

Monitor and adjust dose to prevent QT_c prolongation. Concurrent use with other QT_c-prolonging drugs (including Class I and Class III antiarrhythmics) is generally not recommended; withhold for 3 half-lives. Watch for proarrhythmic effects. Correct electrolyte imbalances before initiating (especially hypokalemia and hyperkalemia). Consider pre-existing conditions such as sick sinus syndrome before initiating. Conduction abnormalities can occur particularly sinus bradycardia. Use cautiously within the first 2 weeks post-MI (experience limited). Administer cautiously in compensated heart failure and monitor for a worsening of the condition. Use caution in patients with PVD (can aggravate arterial insufficiency). Beta-blocker therapy should not be withdrawn abruptly (particularly in patients with CAD), but gradually tapered to avoid acute tachycardia, hypertension, and/or ischemia. Use caution with concurrent use of beta-blockers and either verapamil or diltiazem; bradycardia or heart block can occur. Use cautiously in diabetics because it can mask prominent hypoglycemic symptoms. Can mask signs of thyrotoxicosis. Use care with anesthetic agents which decrease myocardial function.

[U.S. Boxed Warning]: Betapace[®] should not be substituted for Betapace[®] AF; Betapace[®] AF is distributed with an educational insert specifically for patients with atrial fibrillation/flutter.

Dosage Forms Tablet, as hydrochloride: 80 mg, 80 mg [AF], 120 mg, 120 mg [AF], 160 mg, 160 mg [AF], 240 mg
Betapace[®] [light blue]: 80 mg, 120 mg, 160 mg, 240 mg
Betapace AF[®] [white]: 80 mg, 120 mg, 160 mg
Sorine[®] [white]: 80 mg, 120 mg, 160 mg, 240 mg

Reference Range Peak serum level: ~1.7 mg/L after 160 mg oral dose; peak serum sotalol level following a 11.2 g overdose: 20.6 mg/L

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** use ipecac

Supportive therapy: Glucagon (50-150 mcg/kg followed by continuous drip of 1-5 mg/hour) for positive chronotropic effect; glucagon can correct bradycardia and sinus arrest; atropine/isoproterenol can be utilized to increase heart rate; calcium chloride may also be effective; doses > 320 mg are at risk for torsade de pointes; lidocaine has also been used successfully in treating torsade de pointes due to a 3-4 g ingestion of sotalol

Enhancement of elimination: Multiple dosing of activated charcoal is likely to be of benefit; hemodialysis or hemoperfusion may be effective

Antidote(s)

- Glucagon [ANTIDOTE]

Drug Interactions Amiodarone: May cause additive effects on QT_c prolongation as well as decreased heart rate, and has been associated with cardiac arrest in patients receiving beta-blockers.

Antacids (aluminum/magnesium) decrease sotalol blood levels; separate administration by 2 hours.

Antiarrhythmics: Concurrent use of Class Ia or Class III antiarrhythmics may result in additive QT_c prolongation; concurrent use is not recommended.

Beta₂ agonists: Effects may be diminished by concurrent sotalol; use caution.

Beta-blockers: Due to shared pharmacological effects, heart rate reductions may be additive; concurrent use is not recommended.

Calcium channel blockers: Concurrent use may lead to additive effects on AV conduction, ventricular contractility, and/or hypotension; use caution.

Cisapride: Concurrent use with sotalol increases malignant arrhythmias; contraindicated.

Clonidine: Sotalol may cause rebound hypertension after discontinuation of clonidine.

QT_c-prolonging drugs: Concurrent use may result in additive QT_c prolongation, potentially increasing the risk of malignant arrhythmias. Use of cisapride, mesoridazine, thioridazine, and pimozide with other QT_c-prolonging agents is contraindicated. Concurrent use of sotalol with Class I and Class III antiarrhythmics is not recommended; withhold for 3 half-lives. Use caution with other QT_c-prolonging agents (including bepridil, erythromycin, clarithromycin), fluoroquinolones (including sparfloxacin, gatifloxacin, and moxifloxacin), haloperidol, and TCAs.

Phenothiazines (mesoridazine and thioridazine): Concurrent use may result in additive QT_c prolongation, potentially increasing the risk of malignant arrhythmias; contraindicated.

Pimozide: Concurrent use may result in additive QT_c prolongation, potentially increasing the risk of malignant arrhythmias; contraindicated.

Pregnancy Risk Factor B

Pregnancy Implications There are no adequate and well-controlled studies in pregnant women. Beta-blockers have been associated with bradycardia, hypotension, and IUGR; IUGR is probably related to maternal hypertension. Sotalol has been shown to cross the placenta, and is found in amniotic fluid, therefore, sotalol should be used during pregnancy only if the potential benefit outweighs the potential risk. Cases of neonatal hypoglycemia have been reported following maternal use of beta-blockers at parturition or during breast-feeding.

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications Initiation of therapy and dose escalation should be done in a hospital with cardiac monitoring; lidocaine and other resuscitative measures should be available

Additional Information Risk factors for development of sotalol-induced torsade de pointes include female gender, sustained ventricular tachycardia or fibrillation on presentation, medical history of congestive heart failure, and a daily dose >320 mg

Sparfloxacin

CAS Number 110871-86-8

U.S. Brand Names Zagam[®]

Use Treatment of adults with community-acquired pneumonia caused by *C. pneumoniae*, *H. influenzae*, *H. parainfluenzae*, *M. catarrhalis*, *M. pneumoniae* or *S. pneumoniae*; treatment of acute bacterial exacerbations of chronic bronchitis caused by *C. pneumoniae*, *E. cloacae*, *H. influenzae*, *H. parainfluenzae*, *K. pneumoniae*, *M. catarrhalis*, *S. aureus* or *S. pneumoniae*

Mechanism of Action Inhibits DNA-gyrase in susceptible organisms; inhibits relaxation of supercoiled DNA and promotes breakage of double-stranded DNA

Adverse Reactions

Cardiovascular: QT_c interval prolongation, vasodilation, angina pectoris, arrhythmias, atrial fibrillation, atrial flutter, complete AV block, postural hypotension, torsade de pointes

Central nervous system: Insomnia, dizziness, headache, anxiety, confusion, hallucinations, migraine, sleep disorder, vertigo

Dermatologic: Photosensitivity reaction, pruritus, angioedema, ecchymosis, exfoliative dermatitis, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Gastrointestinal: Diarrhea, dyspepsia, nausea, abdominal pain, vomiting, flatulence, taste perversion, dry mouth

Hematologic: Anemia, eosinophilia, leukopenia, pancytopenia

Hepatic: Increased LFTs, hepatic failure

Neuromuscular & skeletal: Tendon rupture, tendonitis

Respiratory: Asthma, dyspnea

Miscellaneous: Allergic reaction, anaphylactoid reaction, anaphylactic shock

Signs and Symptoms of Overdose Symptoms of overdose include acute renal failure, seizures

Pharmacodynamics/Kinetics

Absorption: Unaffected by food or milk; reduced ~50% by concurrent administration of aluminum- and magnesium-containing antacids

Distribution: Widely throughout the body; V_d: 3.9 L/kg

Protein binding: 45%

Metabolism: Hepatic, primarily by phase II glucuronidation

Half-life elimination: Mean terminal: 20 hours (range: 16-30 hours)

Time to peak, serum: 3-5 hours

Excretion: Urine (50%; ~10% as unchanged drug); feces (50%)

Dosage

Adults: Oral:

Loading dose: 2 tablets (400 mg) on day 1

Maintenance: 1 tablet (200 mg) daily for 10 additional days (total 11 tablets)

Leprosy: Loading dose: 400 mg followed by 200 mg/day for 12 weeks

Dosing adjustment in renal impairment: Cl_{cr} <50 mL/minute: Administer 400 mg on day 1, then 200 mg every 48 hours for a total of 9 days of therapy (total 6 tablets)

Monitoring Parameters Evaluation of organ system functions (renal, hepatic, ophthalmologic, and hematopoietic) is recommended periodically during therapy; the possibility of crystalluria should be assessed; WBC and signs and symptoms of infection

Administration May be taken without regard to meals, however, should be administered at the same time each day. Antacids containing aluminum or magnesium; products containing iron, zinc, or calcium; and sucralfate and didanosine should all be given >4 hours after sparfloxacin.

Contraindications Hypersensitivity to sparfloxacin, any component of the formulation, or other quinolones; a concurrent administration with drugs which increase the QT interval including amiodarone, bepridil, bretylium, cisapride, disopyramide, furosemide, procainamide, quinidine, sotalol, albuterol, chloroquine, halofantrine, phenothiazines, prednisone, and tricyclic antidepressants

Warnings Not recommended in children <18 years of age, other quinolones have caused transient arthropathy in children; CNS stimulation may occur (tremor, restlessness, confusion, and very rarely hallucinations or seizures); potential for seizures, although very rare, may be increased with concomitant NSAID therapy. Use with caution in individuals at risk of seizures. Use with caution in patients with known or suspected CNS disorder or renal dysfunction; prolonged use may result in superinfection. Moderate to severe photosensitivity reactions may occur in patients exposed to direct or indirect sunlight, or to artificial ultraviolet light. Patients should avoid unnecessary sunlight exposure during treatment and for 5 days following therapy. Pseudomembranous colitis may occur and should be considered in patients who present with diarrhea. Tendon inflammation and/or rupture have been reported with other quinolone antibiotics. Risk may be increased with concurrent corticosteroids, particularly in the elderly. Discontinue at first sign of tendon inflammation or pain.

Severe hypersensitivity reactions, including anaphylaxis, have occurred with quinolone therapy. If an allergic reaction occurs (itching, urticaria, dyspnea, facial edema, loss of consciousness, tingling, cardiovascular collapse), discontinue drug immediately. Although quinolones may exacerbate myasthenia gravis, sparfloxacin appears to be an exception; caution is still warranted.

Dosage Forms [DSC] = Discontinued product
Tablet: 200 mg [DSC]

Reference Range Following a 400 mg oral dose, peak sparfloxacin plasma level: 1.3 mcg/mL

Overdosage/Treatment GI decontamination and supportive care; not removed by peritoneal or hemodialysis

Drug Interactions Corticosteroids: Concurrent use may increase the risk of tendon rupture, particularly in elderly patients (overall incidence rare). Glyburide: Quinolones may increase the effect of glyburide; monitor Metal cations (aluminum, calcium, iron, magnesium and zinc) bind quinolones in the gastrointestinal tract and inhibit absorption. Concurrent administration of most antacids, oral electrolyte supplements, quinapril, sucralfate, some didanosine formulations (chewable/buffered tablets and pediatric powder for oral suspension), and other highly-buffered oral drugs, should be avoided. Sparfloxacin should be administered 2 hours before or 4 hours after these agents.

Probenecid: May decrease renal secretion of sparfloxacin.

QT_c-prolonging agents: Effects may be additive with sparfloxacin. Avoid concurrent use with Class Ia and Class III antiarrhythmics, erythromycin, cisapride, antipsychotics, and cyclic antidepressants.

Warfarin: The hypoprothrombinemic effect of warfarin may be enhanced by some quinolone antibiotics; monitor INR.

Pregnancy Risk Factor C

Pregnancy Implications Quinolones are known to distribute well into breast milk; consequently use during lactation should be avoided if possible; avoid use in pregnant women unless the benefit justifies the potential risk to the fetus

Lactation Enters breast milk/not recommended

Spirapril

CAS Number 83647-97-6; 94841-17-5

Use Treatment of hypertension, congestive heart failure

Mechanism of Action Angiotensin-converting enzyme inhibitor; inhibits renin-angiotensin system

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), QT prolongation, vasodilation
Central nervous system: Headache, dizziness, migraine headache (exacerbation of), hypoesthesia

Dermatologic: Skin rash

Gastrointestinal: Nausea, diarrhea, vomiting

Neuromuscular & skeletal: Back pain

Ocular: Conjunctivitis

Respiratory: Cough

Pharmacodynamics/Kinetics

Absorption: Oral: 53% to 60% (delayed by high fat meals)

Distribution: V_d: Oral: 270 L; I.V.: 28 L

Protein binding: 86% to 91%

Metabolism: Hepatic to active metabolite spiraprilat

Half-life: 1-2 hours

Elimination: Renal

Dosage Congestive heart failure: Oral: 1.5-6.25 mg

Hypertension: Starting dose: Oral: 12 mg/day in 1-2 divided doses; may increase dose in 2- to 4-week intervals

Contraindications Hypersensitivity to spirapril or any component of the formulation; angioedema or other sensitivity to any ACE inhibitor; bilateral renal artery stenosis; pregnancy (2nd and 3rd trimesters)

Warnings Anaphylactic reactions can occur. Angioedema can occur at any time during treatment (especially following first dose). It may involve head and neck (potentially affecting the airway) or the intestine (presenting with abdominal pain). Prolonged monitoring may be required especially if tongue, glottis, or larynx are involved as they are associated with airway obstruction. Those with a history of airway surgery in this situation have a higher risk. Careful blood pressure monitoring with first dose (hypotension can occur especially in volume-depleted patients). Dosage adjustment needed in renal impairment. Use with caution in hypovolemia; collagen vascular diseases; valvular stenosis (particularly aortic stenosis); hyperkalemia; or before, during, or immediately after anesthesia. Avoid rapid dosage escalation which may lead to renal insufficiency. Rare toxicities associated with ACE inhibitors include cholestatic jaundice (which may progress to hepatic necrosis) and neutropenia/agranulocytosis with myeloid hyperplasia. If patient has renal impairment then a baseline WBC with differential and serum creatinine should be evaluated and monitored closely during the first 3 months of therapy. Hypersensitivity reactions may be seen during hemodialysis with high-flux dialysis membranes (eg, AN69). Deterioration in renal function can occur with initiation. Use with caution in unilateral renal artery stenosis and pre-existing renal insufficiency.

Dosage Forms Tablet: 3 mg, 6 mg, 12 mg, 24 mg

Reference Range After a 6 mg oral dose, peak plasma spirapril and spiraprilat level is ~20 ng/mL and 23 ng/mL, respectively; after a 6 mg I.V. dose, peak serum spiraprilat level is ~45 ng/mL

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. normal saline or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Naloxone may antagonize hypotensive effects. Inhaled sodium cromoglycate (total dose: 40 mg/day) can decrease ACE-inhibitor cough by 50%.

Enhanced elimination: Multiple dosing of activated charcoal may be effective

Drug Interactions Alpha₁ blockers: Hypotensive effect increased.

Aspirin: May decrease ACE inhibitor efficacy and/or increase risk of renal effects.

Diuretics: Hypovolemia due to diuretics may precipitate acute hypotensive events or acute renal failure.

Insulin: Risk of hypoglycemia may be increased.

Lithium: Risk of lithium toxicity may be increased; monitor lithium levels, especially the first 4 weeks of therapy.

Mercaptopurine: Risk of neutropenia may be increased.

NSAIDs: May attenuate hypertensive efficacy; effect has been seen with captopril and may occur with other ACE inhibitors; monitor blood pressure. May increase risk of renal effects.

Potassium-sparing diuretics (amiloride, potassium, spironolactone, triamterene): Increased risk of hyperkalemia.

Potassium supplements may increase the risk of hyperkalemia.

Trimethoprim (high dose) may increase the risk of hyperkalemia.

Pregnancy Risk Factor C (1st trimester); D (2nd and 3rd trimesters)

Pregnancy Implications Cranial defects, hypocalvaria/acalvaria, oligohydramnios, persistent anuria following delivery, hypotension, renal defects, renal dysgenesis/dysplasia, renal failure, pulmonary hypoplasia, limb contractures secondary to oligohydramnios, and stillbirth reported. ACE inhibitors should be avoided during pregnancy, particularly in the 2nd and 3rd trimesters.

Additional Information Not available in U.S.

Spironolactone

CAS Number 52-01-7

U.S. Brand Names Aldactone®

Use Management of edema associated with excessive aldosterone excretion; hypertension; congestive heart failure; primary hyperaldosteronism; hypokalemia; treatment of hirsutism; cirrhosis of liver accompanied by edema or ascites

Unlabeled/Investigational Use Female acne (adjunctive therapy); hirsutism; hypertension (pediatric); diuretic (pediatric)

Mechanism of Action Competes with aldosterone for receptor sites in the distal renal tubules, increasing sodium chloride and water excretion

STANOZOLOL

while conserving potassium and hydrogen ions; may block the effect of aldosterone on arteriolar smooth muscle as well

Adverse Reactions

Cardiovascular: Myocarditis (hypersensitivity), myocarditis, vasculitis, Raynaud's phenomenon
Central nervous system: Lethargy, headache, mental confusion, fever, ataxia, CNS depression, depression
Dermatologic: Rash, alopecia, hypertrichosis, erythema multiforme, xerosis, urticaria, purpura, photosensitivity, pruritus, bullous pemphigoid, licheniform eruptions, exanthem
Endocrine & metabolic: Hyperkalemia (especially in patients with azotemia or receiving potassium supplements), dehydration, hyponatremia, hypokalemia, hyperchloremic metabolic acidosis, postmenopausal bleeding, amenorrhea, gynecomastia
Gastrointestinal: Anorexia, nausea, vomiting, diarrhea, gastritis, loss of taste perception, xerostomia
Hematologic: Eosinophilia
Hepatic: Hepatotoxicity
Neuromuscular & skeletal: Paresthesia
Ocular: Myopia
Renal: Elevated BUN
Miscellaneous: Development of systemic lupus erythematosus

Pharmacodynamics/Kinetics

Duration of action: 2-3 days
Protein binding: 91% to 98%
Metabolism: Hepatic to multiple metabolites, including canrenone (active)
Half-life elimination: 78-84 minutes
Time to peak, serum: 1-3 hours (primarily as the active metabolite)
Excretion: Urine and feces

Dosage To reduce delay in onset of effect, a loading dose of 2 or 3 times the daily dose may be administered on the first day of therapy. Oral:

Neonates: Diuretic: 1-3 mg/kg/day divided every 12-24 hours

Children:

Diuretic, hypertension: 1.5-3.5 mg/kg/day or 60 mg/m²/day in divided doses every 6-24 hours
Diagnosis of primary aldosteronism: 125-375 mg/m²/day in divided doses
Vaso-occlusive disease: 7.5 mg/kg/day in divided doses twice daily (not FDA approved)

Adults:

Edema, hypokalemia: 25-200 mg/day in 1-2 divided doses
Hypertension (JNC 7): 25-50 mg/day in 1-2 divided doses
Diagnosis of primary aldosteronism: 100-400 mg/day in 1-2 divided doses
Hirsutism in women: 50-200 mg/day in 1-2 divided doses
CHF, severe (with ACE inhibitor and a loop diuretic ± digoxin): 12.5-25 mg/day; maximum daily dose: 50 mg (higher doses may occasionally be used). In the RALES trial, 25 mg every other day was the lowest maintenance dose possible.

Note: If potassium > 5.4 mEq/L, consider dosage reduction.

Elderly: Initial: 25-50 mg/day in 1-2 divided doses, increasing by 25-50 mg every 5 days as needed.

Dosing interval in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer every 12-24 hours.

Cl_{cr} < 10 mL/minute: Avoid use.

Monitoring Parameters Blood pressure, serum electrolytes (potassium, sodium), renal function, I & O ratios and daily weight throughout therapy

Contraindications Hypersensitivity to spironolactone or any component of the formulation; anuria; acute renal insufficiency; significant impairment of renal excretory function; hyperkalemia; pregnancy (pregnancy-induced hypertension - per expert analysis)

Warnings Avoid potassium supplements, potassium-containing salt substitutes, a diet rich in potassium, or other drugs that can cause hyperkalemia. Monitor for fluid and electrolyte imbalances. Gynecomastia is related to dose and duration of therapy. Diuretic therapy should be carefully used in severe hepatic dysfunction; electrolyte and fluid shifts can cause or exacerbate encephalopathy. Discontinue use prior to adrenal vein catheterization. When evaluating a heart failure patient for spironolactone treatment, creatinine should be ≤ 2.5 mg/dL in men or ≤ 2 mg/dL in women and potassium < 5 mEq/L. **[U.S. Boxed Warning]: Shown to be a tumorigen in chronic toxicity animal studies. Avoid unnecessary use.**

Dosage Forms Tablet: 25 mg, 50 mg, 100 mg

Reference Range Steady-state of canrenone levels (of spironolactone dosing 50 mg twice daily) are 50-70 ng/mL (trough) and 146-250 ng/mL (peak)

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Hyperkalemia can be treated with glucose/insulin and sodium bicarbonate (1 mEq/kg); sodium polystyrene sulfonate can also be given; I.V. fluids administration of 0.45% sodium chloride with furosemide (1 mg/kg, up to 40 mg) can be used to promote urine flow

Test Interactions May cause false elevation in serum digoxin concentrations measured by RIA

Drug Interactions ACE inhibitors can cause hyperkalemia, especially in patients with renal impairment, potassium-rich diets, or on other drugs causing hyperkalemia; avoid concurrent use or monitor closely.

Cholestyramine can cause hyperchloremic acidosis in cirrhotic patients; avoid concurrent use.

Digoxin's positive inotropic effect may be reduced; serum levels of digoxin may increase.

Mitotane loses its effect; avoid concurrent use.

Potassium supplements may increase potassium retention and cause hyperkalemia; avoid concurrent use.

Salicylates and NSAIDs may interfere with the natriuretic action of spironolactone.

Pregnancy Risk Factor D

Pregnancy Implications Teratogenic effects were not observed in animal studies; however, doses used were less than or equal to equivalent doses in humans. The antiandrogen effects of spironolactone have been shown to cause feminization of the male fetus in animal studies. Two case reports did not demonstrate this effect in humans however, the authors caution that adequate data is lacking. Diuretics are generally avoided in pregnancy due to the theoretical risk that decreased plasma volume may cause placental insufficiency. Diuretics should not be used during pregnancy in the presence of reduced placental perfusion (eg, pre-eclampsia, intrauterine growth restriction).

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Additional Information May be used in patients with hyperuricemia or gout

Stanozolol

CAS Number 10418-03-8

U.S. Brand Names Winstrol®

Use Prophylactic use against hereditary angioedema

Mechanism of Action Synthetic testosterone derivative with similar androgenic and anabolic actions

Adverse Reactions

Male:

Postpubertal:

Central nervous system: Insomnia, chills
Dermatologic: **Acne (cystic)**, seborrheic dermatitis, hypertrichosis
Endocrine & metabolic: **Gynecomastia**, decreased libido
Gastrointestinal: Nausea, diarrhea
Genitourinary: **Priapism, bladder irritability**, prostatic hypertrophy (elderly)
Hematologic: Iron deficiency anemia, suppression of clotting factors
Hepatic: Hepatic necrosis, hepatocellular carcinoma, hepatic dysfunction
Miscellaneous: Antiphospholipid syndrome

Prepubertal:

Central nervous system: Chills, insomnia, factors
Dermatologic: **Acne**, hyperpigmentation
Endocrine & metabolic: **Virilism**
Gastrointestinal: Diarrhea, nausea
Hematologic: Iron deficiency anemia, suppression of clotting
Hepatic: Hepatic necrosis, hepatocellular carcinoma

Female:

Cardiovascular: Edema
Central nervous system: Chills, insomnia, paranoid psychosis, mania, CNS depression, depression
Dermatologic: Hypertrichosis
Endocrine & metabolic: **Virilism**, hypercalcemia
Gastrointestinal: Nausea, diarrhea
Hematologic: Iron deficiency anemia, suppression of clotting factors
Hepatic: Hepatic dysfunction, hepatic necrosis, hepatocellular carcinoma, peliosis hepatitis

Pharmacodynamics/Kinetics

Metabolism: Hepatic

Excretion: Urine (90%); feces (6%)

Dosage Children: Acute attacks:

<6 years: 1 mg/day
6-12 years: 2 mg/day

Adults: Oral: Initial: 2 mg 3 times/day, may then reduce to a maintenance dose of 2 mg/day or 2 mg every other day after 1-3 months

Dosing adjustment in hepatic impairment: Avoid use in patients with severe liver dysfunction

Contraindications Hypersensitivity to stavudine or any component of the formulation; nephrosis; carcinoma of breast or prostate; pregnancy

Warnings May stunt bone growth in children; anabolic steroids may cause peliosis hepatis, liver cell tumors, and blood lipid changes with increased risk of arteriosclerosis; monitor diabetic patients carefully; use with caution in elderly patients, they may be at greater risk for prostatic hyperplasia; use with caution in patients with cardiac, renal, or hepatic disease or epilepsy

Dosage Forms Tablet: 2 mg

Overdosage/Treatment Decontamination: Activated charcoal

Drug Interactions Increased toxicity: ACTH, adrenal steroids may increase risk of edema and acne; zalcitabine enhances the hypoprothrombinemic effects of oral anticoagulants; enhances the hypoglycemic effects of insulin and sulfonylureas (oral hypoglycemics)

Pregnancy Risk Factor X

Lactation Enters breast milk/contraindicated

<60 kg: 15 mg every 12 hours

Cl_{cr} 10-25 mL/minute, hemodialysis (administer dose after hemodialysis on day of dialysis):

≥60 kg: 20 mg every 24 hours

<60 kg: 15 mg every 24 hours

Elderly: Older patients should be closely monitored for signs and symptoms of peripheral neuropathy; dosage should be carefully adjusted to renal function

Monitoring Parameters Monitor liver function tests and signs and symptoms of peripheral neuropathy; monitor viral load and CD4 count

Administration May be administered without regard to meals. Oral solution should be shaken vigorously prior to use.

Contraindications Hypersensitivity to stavudine or any component of the formulation

Warnings Use with caution in patients who demonstrate previous hypersensitivity to zidovudine, didanosine, zalcitabine, pre-existing bone marrow suppression, renal insufficiency, or peripheral neuropathy. Peripheral neuropathy may be the dose-limiting side effect. Zidovudine should not be used in combination with stavudine. **[U.S. Boxed Warning]: Lactic acidosis and severe hepatomegaly with steatosis have been reported with stavudine use, including fatal cases.** Risk may be increased in obesity, prolonged nucleoside exposure, or in female patients. Suspend therapy in patients with suspected lactic acidosis; consider discontinuation of stavudine if lactic acidosis is confirmed.

Pregnant women may be at increased risk of lactic acidosis and liver damage. Severe motor weakness (resembling Guillain-Barré syndrome) has also been reported (including fatal cases, usually in association with lactic acidosis); manufacturer recommends discontinuation if motor weakness develops (with or without lactic acidosis). **[U.S. Boxed Warning]: Pancreatitis (including some fatal cases) has occurred during combination therapy (didanosine with or without hydroxyurea).** Risk increased when used in combination regimen with didanosine and hydroxyurea. Suspend therapy with agents toxic to the pancreas (including stavudine, didanosine, or hydroxyurea) in patients with suspected pancreatitis.

Dosage Forms Capsule: 15 mg, 20 mg, 30 mg, 40 mg

Powder, for oral solution: 1 mg/mL (200 mL) [dye free; fruit flavor]

Reference Range Peak serum level after an oral dose of 4 mg/kg is 4.2 mcg/mL

Overdosage/Treatment Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Drug Interactions Didanosine: Risk of pancreatitis may be increased with concurrent use. Cases of fatal lactic acidosis have been reported with this combination when used during pregnancy; use only if clearly needed.

Doxorubicin: May inhibit intracellular phosphorylation of stavudine; use with caution.

Hydroxyurea: Risk of hepatotoxicity or pancreatitis may be increased with concurrent use.

Ribavirin: Concomitant use of ribavirin and nucleoside analogues may increase the risk of developing hepatic decompensation or other signs of mitochondrial toxicity, including pancreatitis or lactic acidosis. May inhibit intracellular phosphorylation of stavudine; use with caution.

Zalcitabine: May increase risk of peripheral neuropathy; concurrent use not recommended.

Zidovudine: Inhibits intracellular phosphorylation of stavudine; concurrent use not recommended.

Pregnancy Risk Factor C

Pregnancy Implications Cases of fatal and nonfatal lactic acidosis, with or without pancreatitis, have been reported in pregnant women. It is not known if pregnancy itself potentiates this known side effect; however, pregnant women may be at increased risk of lactic acidosis and liver damage. Hepatic enzymes and electrolytes should be monitored frequently during the 3rd trimester of pregnancy. Pharmacokinetics of stavudine are not significantly altered during pregnancy; dose adjustments are not needed. The Perinatal HIV Guidelines Working Group considers stavudine to be an alternative NRTI in dual nucleoside combination regimens; use with didanosine only if no alternatives are available, do not use with zidovudine. Health professionals are encouraged to contact the antiretroviral pregnancy registry to monitor outcomes of pregnant women exposed to antiretroviral medications (1-800-258-4263 or www.APRRegistry.com).

Lactation Excretion in breast milk unknown/contraindicated

Stavudine

CAS Number 3056-17-5

U.S. Brand Names Zerit®

Synonyms d4T

Use Treatment of adults with advanced HIV infection who are intolerant to approved therapies with proven clinical benefit or who have experienced significant clinical or immunologic deterioration while receiving these therapies, or for whom such therapies are contraindicated

Mechanism of Action Inhibits reverse transcriptase of the human immunodeficiency virus (HIV)

Adverse Reactions

All adverse reactions reported below were similar to comparative agent, zidovudine, except for peripheral neuropathy, which was greater for stavudine.

Central nervous system: **Headache, chills/fever, malaise, insomnia, anxiety, depression, pain, insomnia**

Dermatologic: **Rash**

Endocrine & metabolic: Lactic acidosis, redistribution/accumulation of body fat

Gastrointestinal: **Nausea, vomiting, diarrhea, pancreatitis, abdominal pain, anorexia, pancreatitis**

Hematologic: Neutropenia, thrombocytopenia, anemia, leukopenia

Hepatic: Increased hepatic transaminases, increased bilirubin, hepatomegaly, hepatic failure, hepatic steatosis

Neuromuscular & skeletal: **Peripheral neuropathy, myalgia, back pain, weakness, motor weakness (severe)**

Miscellaneous: Allergic reaction

Admission Criteria/Prognosis Admit any patient symptomatic after 6 hours postingestion, liver function test abnormalities or ingested dose >2 mg/kg

Pharmacodynamics/Kinetics

Distribution: V_d : 0.5 L/kg

Bioavailability: 86.4%

Metabolism: Undergoes intracellular phosphorylation to an active metabolite

Half-life elimination: 1-1.6 hours

Time to peak, serum: 1 hour

Excretion: Urine (40% as unchanged drug)

Dosage

Oral:

Newborns (Birth to 13 days): 0.5 mg/kg every 12 hours

Children:

>14 days and <30 kg: 1 mg/kg every 12 hours

≥30 kg: Refer to Adults dosing

Adults:

≥60 kg: 40 mg every 12 hours

<60 kg: 30 mg every 12 hours

Dosing adjustment for toxicity: If symptoms of peripheral neuropathy occur, discontinue until symptoms resolve. Treatment may then be resumed at 50% the recommended dose. If symptoms recur at lower dose, permanent discontinuation should be considered.

Dosing adjustment in renal impairment:

Children: Specific recommendations not available. Reduction in dose or increase in dosing interval should be considered.

Adults:

Cl_{cr} >50 mL/minute:

≥60 kg: 40 mg every 12 hours

<60 kg: 30 mg every 12 hours

Cl_{cr} 26-50 mL/minute:

≥60 kg: 20 mg every 12 hours

Streptokinase

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 9002-01-1

U.S. Brand Names Streptase®

Synonyms SK

STREPTOKINASE

Use Thrombolytic agent used in treatment of recent severe or massive deep vein thrombosis (within 7 days), pulmonary emboli, peripheral arterial thrombosis, myocardial infarction, and occluded arteriovenous cannulas; can prevent venous valvular damage and development of venous hypertension; not effective for strokes

Mechanism of Action Activates the conversion of plasminogen to plasmin by forming a complex, exposing plasminogen-activating site, and clearing a peptide bond that converts plasminogen to plasmin; plasmin degrades fibrin, fibrinogen and other procoagulant proteins into soluble fragments; effective both outside and within the formed thrombus/embolus

Adverse Reactions

Cardiovascular: **Hypotension, trauma arrhythmias, arrhythmias**, chest pain, pericardial effusion/pericarditis, angina

Central nervous system: Headache, chills, hallucinations, Guillain-Barré syndrome, fever, hyperthermia

Dermatologic: **Angioneurotic edema**, rash, cutaneous vasculitis

Gastrointestinal: Nausea, vomiting

Hematologic: **Bleeding (surface), internal bleeding, cerebral hemorrhage**, hemolytic anemia, anemia

Hepatic: Liver hemorrhage

Local: Extravasation injury

Ocular: **Periorbital edema**, ocular hemorrhage,

Renal: Renal failure due to acute tubular necrosis, glomerulonephritis

Respiratory: **Bronchospasm**, epistaxis, alveolar hemorrhage, pulmonary hemorrhage

Miscellaneous: **Anaphylaxis, bleeding at sites of percutaneous trauma**, diaphoresis, acute atraumatic compartment syndrome

Signs and Symptoms of Overdose Bleeding gums, coagulopathy, confusion, depression, eczema, epistaxis, hematoma, hematuria, hemoptysis, intracranial hemorrhage, jaundice, leukocytosis, ocular hemorrhage, oozing at catheter site, spontaneous ecchymosis, tubular necrosis, wheezing

Pharmacodynamics/Kinetics

Onset of action: Activation of plasminogen occurs almost immediately

Duration: Fibrinolytic effect: Several hours; Anticoagulant effect: 12-24 hours

Half-life elimination: 83 minutes

Excretion: By circulating antibodies and the reticuloendothelial system

Dosage I.V.:

Children: Safety and efficacy not established; limited studies have used 3500-4000 units/kg over 30 minutes followed by 1000-1500 units/kg/hour

Clotted catheter: 25,000 units, clamp for 2 hours then aspirate contents and flush with normal saline

Adults: Antibodies to streptokinase remain for at least 3-6 months after initial dose: Administration requires the use of an infusion pump

An intradermal skin test of 100 int. units has been suggested to predict allergic response to streptokinase. If a positive reaction is not seen after 15-20 minutes, a therapeutic dose may be administered.

Guidelines for acute myocardial infarction (AMI): 1.5 million units over 60 minutes

Administration:

Dilute two 750,000 unit vials of streptokinase with 5 mL dextrose 5% in water (D₅W) each, gently swirl to dissolve

Add this dose of the 1.5 million units to 150 mL D₅W

This should be infused over 60 minutes; an in-line filter ≥ 0.45 micron should be used

Monitor for the first few hours for signs of anaphylaxis or allergic reaction. **Infusion should be slowed if lowering of 25 mm Hg in blood pressure or terminated if asthmatic symptoms appear.**

Begin heparin 5000-10,000 unit bolus followed by 1000 units/hour approximately 3-4 hours after completion of streptokinase infusion or when PTT is < 100 seconds

Guidelines for acute pulmonary embolism (APE): 3 million unit dose over 24 hours

Administration:

Dilute four 750,000 unit vials of streptokinase with 5 mL dextrose 5% in water (D₅W) each, gently swirl to dissolve

Add this dose of 3 million units to 250 mL D₅W, an in-line filter ≥ 0.45 micron should be used

Administer 250,000 units (23 mL) over 30 minutes followed by 100,000 units/hour (9 mL/hour) for 24 hours

Monitor for the first few hours for signs of anaphylaxis or allergic reaction. **Infusion should be slowed if blood pressure is lowered by 25 mm Hg or if asthmatic symptoms appear.**

Begin heparin 1000 units/hour $\sim 3-4$ hours after completion of streptokinase infusion or when PTT is < 100 seconds

Monitor PT, PTT, and fibrinogen levels during therapy

Thromboses: 250,000 units to start, then 100,000 units/hour for 24-72 hours depending on location

Cannula occlusion: 250,000 units into cannula, clamp for 2 hours, then aspirate contents and flush with normal saline; **Not recommended; see Warnings**

Stability Keep in refrigerator, use reconstituted solutions within 24 hours; store unopened vials at room temperature

Monitoring Parameters Blood pressure, PT, aPTT, platelet count, hematocrit, fibrinogen concentration, signs of bleeding

Administration I.V. infusion requires an infusion pump; streptokinase is administered by I.V., intra-arterial, or intracoronary infusion; may also be used to clear an occluded arteriovenous cannula

Contraindications Hypersensitivity to anistreplase, streptokinase, or any component of the formulation; active internal bleeding; history of CVA; recent (within 2 months) intracranial or intraspinal surgery or trauma; intracranial neoplasm, arteriovenous malformation, or aneurysm; known bleeding diathesis; severe uncontrolled hypertension

Warnings

Concurrent heparin anticoagulation can contribute to bleeding; careful attention to all potential bleeding sites. I.M. injections and nonessential handling of the patient should be avoided. Venipunctures should be performed carefully and only when necessary. If arterial puncture is necessary, use an upper extremity vessel that can be manually compressed. If serious bleeding occurs then the infusion of streptokinase and heparin should be stopped.

For the following conditions the risk of bleeding is higher with use of thrombolytics and should be weighed against the benefits of therapy: recent (within 10 days) major surgery (eg, CABG, obstetrical delivery, organ biopsy, previous puncture of noncompressible vessels), cerebrovascular disease, recent (within 10 days) gastrointestinal or genitourinary bleeding, recent trauma (within 10 days) including CPR, hypertension (systolic BP > 180 mm Hg and/or diastolic BP > 110 mm Hg), high likelihood of left heart thrombus (eg, mitral stenosis with atrial fibrillation), acute pericarditis, subacute bacterial endocarditis, hemostatic defects including ones caused by severe renal or hepatic dysfunction, significant hepatic dysfunction, pregnancy, diabetic hemorrhagic retinopathy or other hemorrhagic ophthalmic conditions, septic thrombophlebitis or occluded AV cannula at seriously infected site, advanced age (eg, > 75 years), patients receiving oral anticoagulants, any other condition in which bleeding constitutes a significant hazard or would be particularly difficult to manage because of location.

Coronary thrombolysis may result in reperfusion arrhythmias. Hypotension, occasionally severe, can occur (not from bleeding or anaphylaxis). Follow standard MI management. Rare anaphylactic reactions can occur. Cautious repeat administration in patients who have received anistreplase or streptokinase within 1 year (streptokinase antibody may decrease effectiveness or risk of allergic reactions). Safety and efficacy in pediatric patients have not been established.

Streptokinase is not indicated for restoration of patency of intravenous catheters. Serious adverse events relating to the use of streptokinase in the restoration of patency of occluded intravenous catheters have involved the use of high doses of streptokinase in small volumes (250,000 international units in 2 mL). Uses of lower doses of streptokinase in infusions over several hours, generally into partially occluded catheters, or local instillation into the catheter lumen and subsequent aspiration, have been described in the medical literature. Healthcare providers should consider the risk for potentially life-threatening reactions (hypersensitivity, apnea, bleeding) associated with the use of streptokinase in the management of occluded intravenous catheters.

Dosage Forms [DSC] = Discontinued product

Injection, powder for reconstitution: 250,000 int. units; 750,000 int. units; 1,500,000 int. units [DSC]

Reference Range

Partial thromboplastin time (PTT) activated: 20.4-33.2 seconds

Prothrombin time (PT): 10.9-13.7 seconds (same as control)

Fibrinogen: 200-400 mg/dL

Overdosage/Treatment Supportive therapy: Treat bleeding complications with transfusions of red blood cells, fresh frozen plasma, and cryoprecipitate; do not administer dextran; although human overdose data is lacking, administration of aminocaproic acid (Amicar[®]) at a dose of 3-5 g I.V. followed by an infusion rate of 1-1.25 g/hour may be useful

Drug Interactions Aminocaproic acid (antifibrinolytic agent) may decrease effectiveness of thrombolytic agents.

Drugs which affect platelet function (eg, NSAIDs, dipyridamole, ticlopidine, clopidogrel, IIb/IIIa antagonists) may potentiate the risk of hemorrhage; use with caution.

Heparin and aspirin: Use with aspirin and heparin may increase bleeding over aspirin and heparin alone. However, aspirin and heparin were used concurrently in the majority of patients in some major clinical studies of streptokinase.

Warfarin or oral anticoagulants: Risk of bleeding may be increased during concurrent therapy.

Pregnancy Risk Factor C

Pregnancy Implications If streptokinase is used near term, delivery by Cesarean section should be considered

Lactation Excretion in breast milk unknown

Nursing Implications For I.V. or intracoronary use only; avoid I.M. injections; do not mix with other drugs

Additional Information Best results are realized if used within 5-6 hours of myocardial infarction; antibodies to streptokinase remain for 3-6 months after initial dose, use another thrombolytic enzyme (ie, urokinase) if repeat thrombolytic therapy is indicated; 6-month mortality rate in use for ischemic strokes is 44% higher in streptokinase group. Investigators applied analysis to data for patients ≥ 75 years of age from two large trials studying the impact of streptokinase on patient outcome after acute myocardial infarction; their conclusion was that age alone is not a contraindication to the use of streptokinase and that thrombolytic therapy is cost-effective and is beneficial toward the survival of elderly patients. Additional studies are needed to determine if a weight-adjusted dose will maintain efficacy but decrease adverse events such as stroke. Incidence of streptokinase-induced Guillain-Barré syndrome is ~ 5 cases/30,000-40,000 doses.

Streptomycin

CAS Number 3810-74-0; 57-92-1

Synonyms Streptomycin Sulfate

Use Combination therapy of active tuberculosis; used in combination with other agents for treatment of streptococcal or enterococcal endocarditis, mycobacterial infections, plague, tularemia, and brucellosis. Streptomycin is indicated for persons from endemic areas of drug-resistant *Mycobacterium tuberculosis* or who are HIV infected.

Mechanism of Action Inhibits bacterial protein synthesis by binding directly to the 30S ribosomal subunits causing faulty peptide sequence to form in the protein chain

Adverse Reactions

Cardiovascular: Hypotension, myocarditis (hypersensitivity), angina, chest pain, myocarditis, sinus tachycardia

Central nervous system: Drug fever, headache, drowsiness, Jarisch-Herxheimer reaction

Dermatologic: Rash, systemic contact dermatitis, immunologic contact urticaria, lichen planus

Gastrointestinal: Nausea, vomiting

Hematologic: Eosinophilia, anemia, hemolytic anemia

Neuromuscular & skeletal: Neuromuscular blockade, paresthesia, tremor, arthralgia, weakness

Ocular: Oscillating vision

Otic: Ototoxicity (auditory), ototoxicity (vestibular), tinnitus

Renal: Nephrotoxicity

Respiratory: Difficulty breathing, hyposmia

Miscellaneous: Anaphylactoid reactions

Pharmacodynamics/Kinetics

Absorption:

Oral: Poorly absorbed

I.M.: Well absorbed

Distribution: To extracellular fluid including serum, abscesses, ascitic, pericardial, pleural, synovial, lymphatic, and peritoneal fluids; poorly distributed into CSF; crosses placenta; small amounts enter breast milk
Protein binding: 34%

Half-life elimination: Newborns: 4-10 hours; Adults: 2-4.7 hours, prolonged with renal impairment

Time to peak: I.M.: Within 1 hour

Excretion: Urine (90% as unchanged drug); feces, saliva, sweat, and tears (<1%)

Dosage Intramuscular (may also be given intravenous piggyback):

Tuberculosis therapy: **Note:** A four-drug regimen (isoniazid, rifampin, pyrazinamide and either streptomycin or ethambutol) is preferred for the initial, empiric treatment of TB. When the drug susceptibility results are available, the regimen should be altered as appropriate.

Patients with TB and without HIV infection:

OPTION 1:

Isoniazid resistance rate <4%: Administer daily isoniazid, rifampin, and pyrazinamide for 8 weeks followed by isoniazid and rifampin daily or directly observed therapy (DOT) 2-3 times/week for 16 weeks

If isoniazid resistance rate is not documented, ethambutol or streptomycin should also be administered until susceptibility to isoniazid or rifampin is demonstrated. Continue treatment for at least 6 months or 3 months beyond culture conversion.

OPTION 2: Administer daily isoniazid, rifampin, pyrazinamide, and either streptomycin or ethambutol for 2 weeks followed by DOT 2 times/week administration of the same drugs for 6 weeks, and subsequently, with isoniazid and rifampin DOT 2 times/week administration for 16 weeks

OPTION 3: Administer isoniazid, rifampin, pyrazinamide, and either ethambutol or streptomycin by DOT 3 times/week for 6 months

Patients with TB and with HIV infection: Administer any of the above OPTIONS 1, 2, or 3; however, treatment should be continued for a total of 9 months and at least 6 months beyond culture conversion

Note: Some experts recommend that the duration of therapy should be extended to 9 months for patients with disseminated disease, miliary

disease, disease involving the bones or joints, or tuberculosis lymphadenitis

Children:

Daily therapy: 20-30 mg/kg/day (maximum: 1 g/day)

Directly observed therapy (DOT): Twice weekly: 25-30 mg/kg (maximum: 1.5 g)

DOT: 3 times/week: 25-30 mg/kg (maximum: 1 g)

Adults:

Daily therapy: 15 mg/kg/day (maximum: 1 g)

Directly observed therapy (DOT): Twice weekly: 25-30 mg/kg (maximum: 1.5 g)

DOT: 3 times/week: 25-30 mg/kg (maximum: 1 g)

Enterococcal endocarditis: 1 g every 12 hours for 2 weeks, 500 mg every 12 hours for 4 weeks in combination with penicillin

Streptococcal endocarditis: 1 g every 12 hours for 1 week, 500 mg every 12 hours for 1 week

Tularemia: 1-2 g/day in divided doses for 7-10 days or until patient is afebrile for 5-7 days

Plague: 2-4 g/day in divided doses until the patient is afebrile for at least 3 days

Elderly: 10 mg/kg/day, not to exceed 750 mg/day; dosing interval should be adjusted for renal function; some authors suggest not to give more than 5 days/week or give as 20-25 mg/kg/dose twice weekly

Dosing interval in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer every 24-72 hours

Cl_{cr} <10 mL/minute: Administer every 72-96 hours

Removed by hemo and peritoneal dialysis: Administer dose postdialysis

Stability Depending upon manufacturer, reconstituted solution remains stable for 2-4 weeks when refrigerated and 24 hours at room temperature; exposure to light causes darkening of solution without apparent loss of potency

Monitoring Parameters Hearing (audiogram), BUN, creatinine; serum concentration of the drug should be monitored in all patients; eighth cranial nerve damage is usually preceded by high-pitched tinnitus, roaring noises, sense of fullness in ears, or impaired hearing and may persist for weeks after drug is discontinued

Administration Inject deep I.M. into large muscle mass; I.V. administration is not recommended

Contraindications Hypersensitivity to streptomycin or any component of the formulation; pregnancy

Warnings [U.S. Boxed Warning]: May cause neurotoxicity, nephrotoxicity, and/or neuromuscular blockade and respiratory paralysis; usual risk factors include pre-existing renal impairment, concomitant neuro/nephrotoxic medications, advanced age and dehydration. The drug's neurotoxicity can result in respiratory paralysis from neuromuscular blockade, especially when the drug is given soon after anesthesia or muscle relaxants. Use with caution in patients with pre-existing vertigo, tinnitus, hearing loss, neuromuscular disorders, or renal impairment; modify dosage in patients with renal impairment; ototoxicity is directly proportional to the amount of drug given and the duration of treatment; tinnitus or vertigo are indications of vestibular injury and impending bilateral irreversible damage; renal damage is usually reversible. **[U.S. Boxed Warning]:** Parenteral form should be used only where appropriate audiometric and laboratory testing facilities are available.

Dosage Forms Injection, powder for reconstitution: 1 g

Reference Range Peak serum streptomycin level after a 15 mg/kg I.M. dose: ~ 40 mcg/mL

Therapeutic: Peak: 15-40 mcg/mL; Trough: <5 mcg/mL

Toxic: Peak: >50 mcg/mL; Trough: >10 mcg/mL

Overdosage/Treatment

Supportive therapy: Neuromuscular blockade can be reversed by calcium
Enhanced elimination: Can be removed by hemodialysis

Test Interactions False-positive urine glucose with Benedict's solution

Drug Interactions Increased/prolonged effect: Depolarizing and non-depolarizing neuromuscular blocking agents

Increased toxicity: Concurrent use of amphotericin may increase nephrotoxicity

Pregnancy Risk Factor D

Pregnancy Implications Neonatal hearing deficits have been noted

Lactation Enters breast milk/compatible

Additional Information Incidence of cochleotoxicity is $\sim 10\%$ to 63% with loop diuretics and noise exposure being ototoxic synergistic. Inhaled tobramycin appears to exhibit minimal ototoxic effects. There may be a genetic basis (in the mitochondrial 12 S ribosomal RNA gene) for ototoxicity in 17% to 33% of cases. Suggested evaluation for ototoxicity with aminoglycoside treatment includes:

- baseline audiometric evaluation (tonal air conduction thresholds from 250-20,000 Hz)
- monitoring during aminoglycoside treatment (to a tonal-air conduction threshold at frequency >8000 Hz)
- follow-up audiometric assessment (tonal air conduction thresholds at frequencies >8000 Hz) until the threshold stabilizes

Strontium-89

Pronunciation (STRON shee um atey nine)

Related Information

- Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 14158-27-1

U.S. Brand Names Metastron®

Synonyms Strontium-89 Chloride

Use Relief of bone pain in patients with skeletal metastases

Mechanism of Action Similar to calcium; deposits in bone and teeth; stimulates bone formation while inhibiting bone resorption

Adverse Reactions

Most severe reactions of marrow toxicity can be managed by conventional means;

Dermatologic: Flushing sensation following rapid administration (usually over <30 seconds)

Hematologic: Thrombocytopenia (nadir: 4-8 weeks) with a mean reduction of platelets (~20% to 50% reduction)

Signs and Symptoms of Overdose Bone marrow suppression, chills, diarrhea, nausea, vomiting

Toxicodynamics/Kinetics

Half-life: 50.6 days

Elimination (once released from bone): Renal: 70% to 80%; Fecal: 20% to 30%

Dosage Adults: I.V.: 148 megabecquerel (4 millicurie) administered by slow I.V. injection over 1-2 minutes or 1.5-2.2 megabecquerel (40-60 microcurie)/kg; repeated doses are generally not recommended at intervals <90 days; measure the patient dose by a suitable radioactivity calibration system immediately prior to administration

Stability Store vial and its contents inside its transportation container at room temperature

Monitoring Parameters Routine blood tests

Contraindications Hypersensitivity to any strontium-containing compounds or any other component of the formulation; pregnancy; breast-feeding

Warnings Use caution in patients with bone marrow compromise; incontinent patients may require urinary catheterization. Body fluids may remain radioactive up to one week after injection. Not indicated for use in patients with cancer not involving bone and should be used with caution in patients whose platelet counts fall <60,000 or whose white blood cell counts fall <2400. A small number of patients have experienced a transient increase in bone pain at 36-72 hours postdose; this reaction is generally mild and self-limiting. It should be handled cautiously, in a similar manner to other radioactive drugs. Appropriate safety measures to minimize radiation to personnel should be instituted.

Dosage Forms Injection, solution, as chloride [preservative free]: 10.9-22.6 mg/mL [148 megabecquerel, 4 millicurie] (10 mL)

Overdosage/Treatment Decontamination: Oral ingestion: Since absorption is rapid and water should not theoretically be used for gastric lavage, removal is probably not efficacious; give 1.5-10 g of sodium alginate (then 2-4 tablets every 2-4 hours for 24 hours) or 50-100 mL of aluminum phosphate gel (followed by 40 mL every 2 hours) or 65 mL of aluminum hydroxide orally (followed by 40 mL every 1-2 hours)

Pregnancy Risk Factor D

Nursing Implications During the first week after injection, strontium-89 will be present in the blood and urine, therefore, the following common sense precautions should be instituted:

- Where a normal toilet is available, use in preference to a urinal, flush the toilet twice
- Wipe away any spilled urine with a tissue and flush it away
- Have patient wash hands after using the toilet
- Immediately wash any linen or clothes that become stained with blood or urine
- Wash away any spilled blood if a cut occurs

Additional Information Reacts with water (thermic reaction); does not emit gamma radiation

Specific References

Kirrane BM, Hoffman RS, and Nelson LS, "Massive Strontium Ferrate Ingestion Does Not Produce Acute Toxicity," *Clin Toxicol (Phila)*, 2005, 43:749.

Sucralfate

CAS Number 54182-58-0

U.S. Brand Names Carafate®

Synonyms Aluminum Sucrose Sulfate, Basic

Use Short-term management of duodenal ulcers; maintenance for duodenal ulcers; suspension may be used topically for treatment of stomatitis due to cancer chemotherapy and other causes of esophageal and gastric erosions

Unlabeled/Investigational Use Gastric ulcers; suspension may be used topically for treatment of stomatitis due to cancer chemotherapy and other causes of esophageal and gastric erosions; GERD, esopha-

gitis; treatment of NSAID mucosal damage; prevention of stress ulcers; postsclerotherapy for esophageal variceal bleeding

Mechanism of Action Forms a complex, a paste-like, cytoprotective substance, when combined with gastric acid that adheres to the damaged mucosal area. This selectively forms a protective coating that protects the lining against peptic acid, pepsin, and bile salts.

Adverse Reactions

Central nervous system: Dizziness, sleepiness

Dermatologic: Rash, pruritus

Gastrointestinal: Constipation, diarrhea, nausea, gastric discomfort, indigestion, xerostomia, intestinal obstruction may occur secondary to bezoars

Neuromuscular & skeletal: Back pain, dysarthria

Signs and Symptoms of Overdose Toxicity is minimal; may cause bezoars, constipation, encephalopathy

Pharmacodynamics/Kinetics

Onset of action: Paste formation and ulcer adhesion: 1-2 hours

Duration: Up to 6 hours

Absorption: Oral: <5%

Distribution: Acts locally at ulcer sites; unbound in GI tract to aluminum and sucrose octasulfate

Metabolism: None

Excretion: Urine (small amounts as unchanged compounds)

Dosage

Children: Dose not established; doses of 40-80 mg/kg/day divided every 6 hours have been used

Stomatitis: 2.5-5 mL (1 g/10 mL suspension), swish and spit or swish and swallow 4 times/day

Adults:

Duodenal ulcer treatment: 1 g 4 times/day, 1 hour before meals or food and at bedtime for 4-8 weeks, or alternatively 2 g twice daily

Duodenal ulcer maintenance therapy: 1 g twice daily

Stomatitis: 1 g/10 mL suspension, swish and spit or swish and swallow 4 times/day

Stability Shake well and refrigerate suspension

Monitoring Parameters Aluminum

Administration Tablet may be broken or dissolved in water before ingestion. Administer with water on an empty stomach.

Contraindications Hypersensitivity to sucralfate or any component of the formulation

Warnings Successful therapy with sucralfate should not be expected to alter the posthealing frequency of recurrence or the severity of duodenal ulceration; use with caution in patients with chronic renal failure who have an impaired excretion of absorbed aluminum. Because of the potential for sucralfate to alter the absorption of some drugs, separate administration (take other medication 2 hours before sucralfate) should be considered when alterations in bioavailability are believed to be critical

Dosage Forms Suspension, oral: 1 g/10 mL (10 mL)

Carafate®: 1 g/10 mL (420 mL)

Tablet: 1 g

Carafate®: 1 g

Reference Range Normal serum aluminum levels are <15 mcg/L (SI: <555 nmol/L); toxicity can occur at levels >100 mcg/L (SI: >3706 nmol/L)

Overdosage/Treatment Enhancement of elimination: Deferoxamine, traditionally used as an iron chelator, has been shown to increase urinary aluminum output. Deferoxamine chelation of aluminum has resulted in improvements of clinical symptoms and bone histology. Hemofiltration or hemodialysis can lower serum aluminum concentrations.

Drug Interactions Decreased effect: Digoxin, phenytoin (hydantoins), warfarin, ketoconazole, quinidine, ciprofloxacin, norfloxacin (quinolones), tetracycline, theophylline; because of the potential for sucralfate to alter the absorption of some drugs, separate administration (take other medications 2 hours before sucralfate) should be considered when alterations in bioavailability are believed to be critical

Note: When given with aluminum-containing antacids, may increase serum/body aluminum concentrations (see Warnings/Precautions)

Pregnancy Risk Factor B

Pregnancy Implications No data available; available evidence suggests safe use during pregnancy.

Lactation Enters breast milk/compatible

Nursing Implications Monitor for constipation; give 2 hours before or after administration of other oral drugs

Additional Information May decrease gastric emptying; little overdose experience; increased serum aluminum levels can occur after inadvertent I.V. administration

Sufentanil

CAS Number 56030-54-7; 60561-17-3

U.S. Brand Names Sufenta®

Synonyms Sufentanil Citrate

Impairment Potential Yes

Use Analgesic supplement in maintenance of balanced general anesthesia

Mechanism of Action Binds with stereospecific receptors at many sites within the CNS; increases pain threshold, alters pain reception, inhibits ascending pain pathways; ultra short-acting narcotic; not a partial opiate antagonist

Adverse Reactions

Cardiovascular: **Hypotension, bradycardia**, hypertension, tachycardia, arrhythmia, shock, sinus tachycardia
 Central nervous system: **Drowsiness**, electroencephalogram abnormalities, agitation, CNS depression
 Dermatologic: Pruritus
 Endocrine & metabolic: Sexual dysfunction
 Gastrointestinal: **Nausea, vomiting**
 Neuromuscular & skeletal: Skeletal muscle rigidity, clonus, myoclonus, hyporeflexia
 Respiratory: **Respiratory depression**, wheezing, apnea
 Miscellaneous: Physical and psychological dependence with prolonged use

Signs and Symptoms of Overdose Biliary tract spasm, coma, convulsions, myoclonus

Pharmacodynamics/Kinetics

Onset of action: 1-3 minutes
 Duration: Dose dependent; usually 30-60 minutes, may be up to 3.5 hours
 Distribution: V_d : 2.9 L/kg
 Protein binding: 92.5%
 Metabolism: Primarily by the liver
 Half-life: 158 minutes Patients with cardiac surgery: 595 minutes; Patients with abdominal aortic surgery: 12 hours; Patients hyperventilating: 232 minutes; Obese patients: Increased half-life

Dosage Children < 12 years: 10-25 mcg/kg with 100% O₂, maintenance: 25-50 mcg as needed

Adults: Dose should be based on body weight; **Note:** In obese patients (ie, >20% above ideal body weight), use lean body weight to determine dosage
 1-2 mcg/kg with N₂O/O₂ for endotracheal intubation; maintenance: 10-25 mcg as needed
 2-8 mcg/kg with N₂O/O₂ more complicated major surgical procedures; maintenance: 10-50 mcg as needed
 8-30 mcg/kg with 100% O₂ and muscle relaxant produces sleep; at doses of ≥8 mcg/kg maintains a deep level of anesthesia; maintenance: 10-50 mcg as needed

Administration Parenteral: I.V.: Slow I.V. injection or by infusion

Contraindications Hypersensitivity to sufentanil or any component of the formulation

Warnings Sufentanil can cause severely compromised respiratory depression; use with caution in patients with head injuries, hepatic or renal impairment or with pulmonary disease; sufentanil shares the toxic potential of opiate agonists, precaution of opiate agonist therapy should be observed; rapid I.V. infusion may result in skeletal muscle and chest wall rigidity, impaired ventilation, respiratory distress/arrest; nondepolarizing skeletal muscle relaxant may be required

Dosage Forms Injection, solution [preservative free]: 50 mcg/mL (1 mL, 2 mL, 5 mL)

Reference Range Peak serum sufentanil levels are ~11 mcg/L 10 minutes after I.V. administration of 1.5 mcg/kg of the drug

Overdosage/Treatment Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at ²/₃ the response dose/hour) may be required

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Drug Interactions Substrate of CYP3A4 (major)

CYP3A4 inhibitors: May increase the levels/effects of sufentanil. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.
 Increased effect/toxicity with CNS depressants, beta-blockers

Pregnancy Risk Factor C

Nursing Implications Patient may develop rebound respiratory depression postoperatively

Specific References

Boitquin LP, Hecq JD, Vanbeckbergen DF, et al. "Stability of Sufentanil Citrate with Levobupivacaine HCl in NaCl 0.9% Infusion After Microwave Freeze-Thaw Treatment," *Ann Pharmacother*, 2004, 38(11): 1836-9.

media in children and acute exacerbations of chronic bronchitis in adults due to susceptible strains of *H. influenzae* or *S. pneumoniae*; prophylaxis of *Pneumocystis carinii* pneumonitis (PCP), traveler's diarrhea due to enterotoxigenic *E. coli* or *Cyclospora*

I.V. treatment or severe or complicated infections when oral therapy is not feasible, for documented PCP, empiric treatment of PCP in immune compromised patients; treatment of documented or suspected shigellosis, typhoid fever, *Nocardia asteroides* infection, or other infections caused by susceptible bacteria

Unlabeled/Investigational Use Cholera and *Salmonella*-type infections and nocardiosis; chronic prostatitis; as prophylaxis in neutropenic patients with *P. carinii* infections, in leukemics, and in patients following renal transplantation, to decrease incidence of PCP; treatment of *Cyclospora* infection, typhoid fever, *Nocardia asteroides* infection

Mechanism of Action Sulfamethoxazole interferes with bacterial folic acid synthesis and growth via inhibition of dihydrofolic acid formation from para-aminobenzoic acid; trimethoprim inhibits dihydrofolic acid reduction to tetrahydrofolate resulting in sequential inhibition of enzymes of the folic acid pathway

Adverse Reactions

Cardiovascular: QT prolongation, torsade de pointes
 Central nervous system: Confusion, dizziness, CNS depression, hallucinations, seizures, fever, ataxia, aseptic meningitis, kernicterus in neonates, psychosis, Jarisch-Herxheimer reaction

Dermatologic: **Allergic skin reactions, rash, urticaria, photosensitivity** (more common in patients taking large dosages or in patients with AIDS), erythema multiforme, epidermal necrolysis, Stevens-Johnson syndrome, neutrophilic dermatosis (Sweet's syndrome), nail discoloration (brown); overall risk for skin disorders is ~2.8/100,000, exfoliative dermatitis, acute generalized exanthematous pustulosis, angioedema, bullous skin disease, purpura, pruritus, psoriasis, erythema nodosum, licheniform eruptions, exanthem, cutaneous vasculitis

Endocrine & metabolic: Hypoglycemia (lasting ~12 hours), hyponatremia, hyperkalemia

Gastrointestinal: **Nausea, anorexia, vomiting**, glossitis, stomatitis, diarrhea, pseudomembranous colitis, pancreatitis, splenomegaly, fecal discoloration (black), esophagitis, vanishing bile duct syndrome, aphthous stomatitis, lingua villosa nigra, gastrointestinal vasculitis

Genitourinary: Urine discoloration (black, brown, rust, yellow-brown), crystalluria

Hematologic: Thrombocytopenia, anemia (megaloblastic), granulocytopenia, aplastic anemia, porphyria, red blood cell aplasia; overall risk for blood disorders is ~5.6/100,000

Hepatic: Hepatitis, cholestasis, granulomatous hepatitis, hepatic vasculitis

Local: Irritation, pain, phlebitis

Neuromuscular & skeletal: Tremor (at doses > 15 mg/kg/day), rhabdomyolysis

Ocular: Iritis

Otic: Ototoxicity, tinnitus

Renal: Interstitial nephritis, renal vasculitis

Respiratory: Cough, pulmonary vasculitis

Miscellaneous: Serum sickness, periarthritis nodosa, systemic lupus erythematosus, fixed drug eruption

Signs and Symptoms of Overdose Blood dyscrasias, cholestatic jaundice, coagulopathy, colitis, depression, erythema multiforme, jaundice, hyperkalemia, hypoglycemia, leukopenia or neutropenia (agranulocytosis, granulocytopenia), meningitis, methemoglobinemia, pseudotumor cerebri, toxic epidermal necrolysis

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%; admit adult ingestions >10 tablets

Pharmacodynamics/Kinetics

Absorption: Oral: Almost completely, 90% to 100%

Protein binding: SMX: 68%, TMP: 45%

Metabolism: SMX: N-acetylated and glucuronidated; TMP: Metabolized to oxide and hydroxylated metabolites

Half-life elimination: SMX: 9 hours, TMP: 6-17 hours; both are prolonged in renal failure

Time to peak, serum: Within 1-4 hours

Excretion: Both are excreted in urine as metabolites and unchanged drug
 Effects of aging on the pharmacokinetics of both agents has been variable; increase in half-life and decreases in clearance have been associated with reduced creatinine clearance

Dosage Dosage recommendations are based on the trimethoprim component

Children >2 months:

Mild to moderate infections: Oral, I.V.: 8 mg TMP/kg/day in divided doses every 12 hours

Serious infection/*Pneumocystis*: I.V.: 20 mg TMP/kg/day in divided doses every 6 hours

Urinary tract infection prophylaxis: Oral: 2 mg TMP/kg/dose daily

Sulfamethoxazole and Trimethoprim

CAS Number 8064-90-2

U.S. Brand Names Bactrim™ DS; Bactrim™; Septra® DS; Septra®

Synonyms Co-Trimoxazole; SMZ-TMP; Sulfatrim; TMP-SMZ; Trimethoprim and Sulfamethoxazole

Use

Oral treatment of urinary tract infections due to *E. coli*, *Klebsiella* and *Enterobacter* sp, *M. morgani*, *P. mirabilis* and *P. vulgaris*; acute otitis

SULFAMETHOXAZOLE AND TRIMETHOPRIM

Prophylaxis of *Pneumocystis*: Oral, I.V.: 10 mg TMP/kg/day or 150 mg TMP/m²/day in divided doses every 12 hours for 3 days/week; dose should not exceed 320 mg trimethoprim and 1600 mg sulfamethoxazole 3 days/week

Cholera: Oral, I.V.: 5 mg TMP/kg twice daily for 3 days

Cyclospora: Oral, I.V.: 5 mg TMP/kg twice daily for 7 days

Adults:

Urinary tract infection/chronic bronchitis: Oral: 1 double strength tablet every 12 hours for 10-14 days

Sepsis: I.V.: 20 TMP/kg/day divided every 6 hours

Pneumocystis carinii:

Prophylaxis: Oral: 1 double strength tablet daily or 3 times/week

Treatment: Oral, I.V.: 15-20 mg TMP/kg/day in 3-4 divided doses

Cholera: Oral, I.V.: 160 mg TMP twice daily for 3 days

Cyclospora: Oral, I.V.: 160 mg TMP twice daily for 7 days

Nocardia: Oral, I.V.: 640 mg TMP/day in divided doses for several months (duration is controversial; an average of 7 months has been reported)

Dosing adjustment in renal impairment:Adults:

I.V.:

Cl_{cr} 15-30 mL/minute: Administer 2.5-5 mg/kg every 12 hours

Cl_{cr} < 15 mL/minute: Administer 2.5-5 mg/kg every 24 hours

Oral:

Cl_{cr} 15-30 mL/minute: Administer 1 double strength tablet every 24 hours or 1 single strength tablet every 12 hours

Cl_{cr} < 15 mL/minute: Not recommended

Stability Do not refrigerate injection; is less soluble in more alkaline pH; protect from light; do not use NS as a diluent; injection vehicle contains benzyl alcohol and sodium metabisulfite

Stability of parenteral admixture at room temperature (25°C):

5 mL/125 mL D₅W = 6 hours

5 mL/100 mL D₅W = 4 hours

5 mL/75 mL D₅W = 2 hours

Administration Infuse I.V. co-trimoxazole over 60-90 minutes; must be further diluted 1:25 (5 mL drug to 125 mL diluent, ie, D₅W); in patients who require fluid restriction, a 1:15 dilution (5 mL drug to 75 mL diluent, ie, D₅W) or a 1:10 dilution (5 mL drug to 50 mL diluent, ie, D₅W) can be administered

Contraindications Hypersensitivity to any sulfa drug, trimethoprim, or any component of the formulation; porphyria; megaloblastic anemia due to folate deficiency; infants < 2 months of age; marked hepatic damage; severe renal disease; pregnancy (at term)

Warnings

Use with caution in patients with G6PD deficiency, impaired renal or hepatic function or potential folate deficiency (malnourished, chronic anticonvulsant therapy, or elderly); maintain adequate hydration to prevent crystalluria; adjust dosage in patients with renal impairment. Injection vehicle contains benzyl alcohol and sodium metabisulfite.

Chemical similarities are present among sulfonamides, sulfonyleureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonamide allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

Fatalities associated with severe reactions including Stevens-Johnson syndrome, toxic epidermal necrolysis, hepatic necrosis, agranulocytosis, aplastic anemia and other blood dyscrasias; discontinue use at first sign of rash. Elderly patients appear at greater risk for more severe adverse reactions. May cause hypoglycemia, particularly in malnourished, or patients with renal or hepatic impairment. Use with caution in patients with porphyria or thyroid dysfunction. Slow acetylators may be more prone to adverse reactions. Caution in patients with allergies or asthma. May cause hyperkalemia (associated with high doses of trimethoprim). Incidence of adverse effects appears to be increased in patients with AIDS.

Dosage Forms

Note: The 5:1 ratio (SMX:TMP) remains constant in all dosage forms.

Injection, solution: Sulfamethoxazole 80 mg and trimethoprim 16 mg per mL (5 mL, 10 mL, 30 mL) [contains propylene glycol ~400 mg/mL, alcohol, benzyl alcohol, and sodium metabisulfite]

Suspension, oral: Sulfamethoxazole 200 mg and trimethoprim 40 mg per 5 mL (480 mL) [contains alcohol]

Septra®: Sulfamethoxazole 200 mg and trimethoprim 40 mg per 5 mL (480 mL) [contains alcohol 0.26% and sodium benzoate; cherry and grape flavors] [DSC]

Tablet: Sulfamethoxazole 400 mg and trimethoprim 80 mg

Bactrim™: Sulfamethoxazole 400 mg and trimethoprim 80 mg [contains sodium benzoate]

Septra®: Sulfamethoxazole 400 mg and trimethoprim 80 mg

Tablet, double strength: Sulfamethoxazole 800 mg and trimethoprim 160 mg

Bactrim™ DS: Sulfamethoxazole 800 mg and trimethoprim 160 mg [contains sodium benzoate]

Septra® DS: Sulfamethoxazole 800 mg and trimethoprim 160 mg

Reference Range Peak plasma concentrations of 20-50 mg/L (79-198 µmol/L) of SMZ and 0.9-1.9 mg/L (3.1-6.5 µmol/L) of TMP occur after oral ingestion of 800 mg of SMZ and 160 mg of TMP; plasma trimethoprim levels > 5 mg/L (17 µmol/L) may be needed to treat *P. carinii* pneumonia

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Leucovorin (10 mg/m² every 6 hours for 72 hours) for trimethoprim bone marrow toxicity. For treatment of lingua villosa nigra, discontinue causative agent. Clean the tongue with a toothbrush and rinse mouth with a half-strength solution of hydrogen peroxide or 10% carbamide peroxide. Symptoms should subside in a few days.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Test Interactions Falsely increases creatinine (Jaffé alkaline picrate reaction); increased serum methotrexate by dihydrofolate reductase method; does not interfere with RIA method; may cause elevation of serum creatinine due to interference with tubular secretion of creatinine

Drug Interactions Sulfamethoxazole: **Substrate** of CYP2C9 (major), 3A4 (minor); **Inhibits** CYP2C9 (moderate)

Trimethoprim: **Substrate** (major) of CYP2C9, 3A4; **Inhibits** CYP2C8 (moderate) 2C9 (moderate)

ACE Inhibitors and angiotensin receptor antagonists: May increase the risk of hyperkalemia with sulfamethoxazole/trimethoprim.

Amantadine: Concurrent use with sulfamethoxazole/trimethoprim has been associated with toxic delirium (rare).

Cyclosporine: May result in an increased risk of nephrotoxicity when used with sulfamethoxazole/trimethoprim. Sulfonamides may decrease the serum concentrations of cyclosporine.

CYP2C9 inducers: May decrease the levels/effects of sulfamethoxazole and trimethoprim. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C8 Substrates: Trimethoprim may increase the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP2C9 Substrates: Sulfamethoxazole and trimethoprim may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

Dapsone: Trimethoprim may increase the serum concentration of dapsone.

Diuretics, potassium-sparing: May increase the risk of hyperkalemia with sulfamethoxazole/trimethoprim.

Leucovorin: Although occasionally recommended to limit or reverse hematologic toxicity of high-dose sulfamethoxazole/trimethoprim, concurrent use has been associated with a decreased effectiveness in treating *Pneumocystis carinii*.

Methotrexate: Sulfamethoxazole/trimethoprim may increase toxicity of methotrexate (due to displacement from binding sites and/or decreased renal secretion).

Phenytoin: Sulfamethoxazole/trimethoprim may increase phenytoin levels/toxicity. Phenytoin may decrease sulfamethoxazole/trimethoprim levels.

Procainamide: Trimethoprim may decrease the excretion of procainamide.

Pyrimethamine: Concurrent therapy with pyrimethamine (in doses > 25 mg/week) may be at increased risk of megaloblastic anemia.

Sulfonyleureas: Sulfamethoxazole/trimethoprim may increase the hypoglycemic effect of sulfonyleureas; monitor.

Warfarin: Sulfamethoxazole/trimethoprim may increase the hypoprothrombinemic effect of warfarin; monitor INR closely.

Pregnancy Risk Factor C/D (at term - expert analysis)

Pregnancy Implications Do not use at term to avoid kernicterus in the newborn; use during pregnancy only if risks outweigh the benefits since folic acid metabolism may be affected

Lactation Enters breast milk/contraindicated (AAP rates "compatible with restrictions")

Additional Information Injection vehicle contains benzyl alcohol and sodium metabisulfite; folic acid should be given if bone marrow depression occurs; one double-strength tablet of trimethoprim-sulfamethoxazole 5 times/week has been demonstrated to aid in preventing spontaneous bacterial peritonitis in cirrhotic patients. Alkalinization of urine pH to > 7.5 with sodium bicarbonate or acetazolamide may help prevent trimethoprim-induced hyperkalemia.

Sulfasalazine

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 599-79-1

U.S. Brand Names Azulfidine® EN-tabs®; Azulfidine®

Synonyms Salicylazosulfapyridine

Use Management of ulcerative colitis, Crohn's disease; also may be effective in ankylosing spondylitis, scleroderma, rheumatoid arthritis, Behçet's disease and psoriasis; also may be useful in radiation, enteritis, and dermatitis herpetiformis

Unlabeled/Investigational Use Ankylosing spondylitis, collagenous colitis, Crohn's disease, psoriasis, psoriatic arthritis, juvenile chronic arthritis

Mechanism of Action Acts locally in the colon to decrease the inflammatory response and systemically interferes with secretion by inhibiting prostaglandin synthesis

Adverse Reactions

Cardiovascular: Sinus tachycardia

Central nervous system: **Fever, dizziness**, encephalopathy, CNS depression, **headache**, malaise, myopathy, visual hallucinations, confusion, Jarisch-Herxheimer reaction, depression, gustatory hallucinations, extrapyramidal reactions

Dermatologic: **Itching**, toxic epidermal necrolysis, **skin rash, photosensitivity**, Lyell's syndrome, Stevens-Johnson syndrome, alopecia, exfoliative dermatitis, acute generalized exanthematous pustulosis, bullous skin disease, xerosis, urticaria, purpura, psoriasis, erythema nodosum, licheniform eruptions, exanthem, cutaneous vasculitis

Endocrine & metabolic: Thyroid function disturbance

Gastrointestinal: **Anorexia, nausea**, abdominal pain, **vomiting, diarrhea**, colitis, xerostomia

Genitourinary: Crystalluria, urine discoloration (orange, orange-yellow), **reversible oligospermia**

Hematologic: Granulocytopenia, leukopenia, thrombocytopenia, aplastic anemia, hemolytic anemia (Coombs' positive), lymphocytosis, porphyrinogenic

Hepatic: Hepatitis, jaundice

Neuromuscular & skeletal: Chorea

Ocular: Vision color changes (red tinge)

Renal: Interstitial nephritis, acute nephrotoxicity, hematuria, proteinuria

Respiratory: Bronchiolitis obliterans organizing pneumonia, pneumonitis, bilateral lung opacities

Miscellaneous: Systemic lupus erythematosus, serum sickness-like reactions, lymphadenopathy, fixed drug eruption

Signs and Symptoms of Overdose Doses of as little as 2-5 g/day may produce toxicity. The aniline radical is responsible for hematologic toxicity. Abdominal pain, acidosis, agranulocytosis, anorexia, confusion, diarrhea, dizziness, drowsiness, fever, headache, hemolytic anemia, jaundice, nausea, vomiting

Pharmacodynamics/Kinetics

Absorption: 10% to 15% as unchanged drug from small intestine

Distribution: Small amounts enter feces and breast milk

Metabolism: Via colonic intestinal flora to sulfapyridine and 5-aminosalicylic acid (5-ASA); following absorption, sulfapyridine undergoes N-acetylation and ring hydroxylation while 5-ASA undergoes N-acetylation

Half-life elimination: 5.7-10 hours

Excretion: Primarily urine (as unchanged drug, components, and acetylated metabolites)

Dosage

Oral:

Children ≥ 2 years: Ulcerative colitis: Initial: 40-60 mg/kg/day in 3-6 divided doses; maintenance dose: 20-30 mg/kg/day in 4 divided doses

Children ≥ 6 years: Juvenile rheumatoid arthritis: Enteric coated tablet: 30-50 mg/kg/day in 2 divided doses; Initial: Begin with $\frac{1}{4}$ to $\frac{1}{3}$ of expected maintenance dose; increase weekly; maximum: 2 g/day typically

Adults:

Ulcerative colitis: Initial: 1 g 3-4 times/day, 2 g/day maintenance in divided doses; may initiate therapy with 0.5-1 g/day

Rheumatoid arthritis: Enteric coated tablet: Initial: 0.5-1 g/day; increase weekly to maintenance dose of 2 g/day in 2 divided doses; maximum: 3 g/day (if response to 2 g/day is inadequate after 12 weeks of treatment)

Dosing interval in renal impairment:

Cl_{cr} 10-30 mL/minute: Administer twice daily

Cl_{cr} <10 mL/minute: Administer once daily

Dosing adjustment in hepatic impairment:

Avoid use

Stability

Protect from light; shake suspension well

Monitoring Parameters

Stool frequency, hematocrit, reticulocyte count, CBC, urinalysis, renal function tests, liver function tests

Administration

GI intolerance is common during the first few days of therapy (administer with meals).

Contraindications Hypersensitivity to sulfasalazine, sulfa drugs, salicylates, or any component of the formulation; porphyria; GI or GU obstruction; pregnancy (at term)

Warnings Use with caution in patients with renal impairment; impaired hepatic function or urinary obstruction, blood dyscrasias, severe allergies or asthma, or G6PD deficiency; may cause folate deficiency (consider providing 1 mg/day folate supplement). Chemical similarities are present among sulfonamides, sulfonyleureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonamide allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe. Safety and efficacy have not been established in children <2 years of age.

Dosage Forms Tablet (Azulfidine®), Sulfazine): 500 mg

Tablet, delayed release, enteric coated (Azulfidine® EN-tabs®, Sulfazine EC): 500 mg

Reference Range Toxic level of sulfapyridine: >50 mg/L (200 μ mol/L)

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal or cholestyramine can reduce sulfasalazine absorption

Supportive therapy: Anaphylaxis can be treated with standard therapy; acetylcysteine (24 g I.V. over 36 hours) has been used to treat sulfasalazine-induced hepatitis; sulfasalazine-induced agranulocytosis can be treated with filgrastim (300 mcg/day)

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Drug Interactions Azathioprine, mercaptopurine, sulfasalazine: May increase the risk of myelosuppression (due to TPMT inhibition).

Cyclosporine concentrations may be decreased; monitor levels and renal function

Digoxin's absorption may be decreased

Folic acid's absorption may be decreased

Hydantoin levels may be increased; monitor levels and adjust as necessary

Hypoglycemics: Increased effect of oral hypoglycemics (rare, but severe); monitor blood sugar

Methenamine: Combination may result in crystalluria; avoid use

Methotrexate-induced bone marrow suppression may be increased

NSAIDs and salicylates: May increase sulfonamide concentrations

PABA (para-aminobenzoic acid - may be found in some vitamin supplements): Interferes with the antibacterial activity of sulfonamides; avoid concurrent use

Sulfapyridine: May increase sulfonamide concentrations

Thiazide diuretics: May increase the incidence of thrombocytopenia purpura

Thiopental's effect may be enhanced; monitor for possible dosage reduction

Uricosuric agents: Actions of these agents are potentiated

Warfarin and other oral anticoagulants: Anticoagulant effect may be increased; decrease dose and monitor INR closely

Pregnancy Risk Factor

B/D (at term)

Lactation

Enters breast milk/use caution (AAP recommends use "with caution")

Nursing Implications

Gastrointestinal intolerance is common during the first few days of therapy; drug commonly imparts an orange-yellow discoloration to urine and skin. This drug should be administered after food to reduce gastrointestinal irritation; may cause orange-yellow discoloration of urine and skin.

Additional Information

Since sulfasalazine impairs folate absorption, consider providing 1 mg/day folate supplement

Specific References

Borras-Blasco J, Navarro-Ruiz A, Matarredona J, et al, "Photo-Induced Stevens-Johnson Syndrome Due to Sulfasalazine Therapy," *Ann Pharmacother*, 2003, 37(9):1241-3.

Sulfisoxazole

CAS Number 80-74-0

U.S. Brand Names Gantrisin®

Synonyms Sulfisoxazole Acetyl; Sulphafurazole

Use Treatment of lower, uncomplicated urinary tract infections, otitis media, *Chlamydia*; nocardiosis; treatment of acute pelvic inflammatory disease in prepubertal children

Mechanism of Action Interferes with bacterial growth by inhibiting bacterial folic acid synthesis through competitive antagonism of PABA

Adverse Reactions

Cardiovascular: Myocarditis (hypersensitivity), myocarditis

Central nervous system: **Fever, dizziness, headache**, psychosis, Jarisch-Herxheimer reaction, gustatory hallucinations

Dermatologic: **Itching, skin rash, photosensitivity**, Lyell's syndrome, Stevens-Johnson syndrome, nail discoloration (brown), toxic epidermal necrolysis

Endocrine & metabolic: Parotitis, thyroid function disturbance
 Gastrointestinal: **Anorexia, nausea**, abdominal pain, **vomiting, diarrhea**
 Genitourinary: Crystalluria
 Hematologic: Granulocytopenia, leukopenia, thrombocytopenia, aplastic anemia, hemolytic anemia, methemoglobinemia
 Hepatic: Hepatitis, jaundice, cholestasis, granulomatous hepatitis
 Renal: Interstitial nephritis, acute nephropathy, hematuria
 Respiratory: Cough

Miscellaneous: Serum sickness-like reactions, periarteritis nodosa

Signs and Symptoms of Overdose Doses of as little as 2-5 g/day may produce toxicity. The aniline radical is responsible for hematologic toxicity. Abdominal pain, acidosis, agranulocytosis, anorexia, dizziness, drowsiness, fever, hematuria, hemolytic anemia, jaundice, nausea, nephrotoxicity, vomiting.

Pharmacodynamics/Kinetics

Absorption: Sulfisoxazole acetyl is hydrolyzed in GI tract to sulfisoxazole which is readily absorbed

Distribution: Crosses placenta; enters breast milk

CSF:blood level ratio: Normal meninges: 50% to 80%; Inflamed meninges: 80+%

Protein binding: 85% to 88%

Metabolism: Hepatic via acetylation and glucuronide conjugation to inactive compounds

Half-life elimination: 4-7 hours; prolonged with renal impairment

Time to peak, serum: 2-3 hours

Excretion: Urine (95%, 40% to 60% as unchanged drug) within 24 hours

Dosage

Not for use in patients <2 months of age

Children >2 months: Oral: 75 mg/kg stat, 120-150 mg/kg/day in divided doses every 4-6 hours; not to exceed 6 g/day

Adults: Oral: 2-4 g stat, 4-8 g/day in divided doses every 4-6 hours

Dosing interval in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer every 8-12 hours

Cl_{cr} <10 mL/minute: Administer every 12-24 hours

>50% removed by hemodialysis

Children and Adults: Ophthalmic:

Ointment: Apply small amount to affected eye 1-3 times/day and at bedtime

Solution: Instill 1-2 drops to affected eye every 2-3 hours

Stability

Protect from light

Monitoring Parameters

CBC, urinalysis, renal function tests, temperature

Administration

Administer around-the-clock to promote less variation in peak and trough serum levels.

Contraindications

Hypersensitivity to sulfisoxazole, any sulfa drug, or any component of the formulation; porphyria; infants <2 months of age (sulfa compete with bilirubin for protein binding sites); patients with urinary obstruction; sunscreens containing PABA; pregnancy (at term)

Warnings

Use with caution in patients with G6PD deficiency (hemolysis may occur), hepatic or renal impairment; dosage modification required in patients with renal impairment; risk of crystalluria should be considered in patients with impaired renal function. Chemical similarities are present among sulfonamides, sulfonyleureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonamide allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

Dosage Forms

Suspension, oral, pediatric, as acetyl (Gantrisin®): 500 mg/5 mL (480 mL) [contains alcohol 0.3%; raspberry flavor]

Tablet: 500 mg

Reference Range

2 g oral dose results in peak plasma level of 10-15 mg/L (37-56 µmol/L)

Overdosage/Treatment

Decontamination: Activated charcoal
 Enhancement of elimination: Multiple dosing of activated charcoal may be effective; alkalinizing the urine decreases serum half-life by almost 30%; hemodialysis can enhance sulfisoxazole elimination

Test Interactions

False-positive protein in urine; false-positive urine glucose with Clinitest®; can interfere in serum calcium assays, thus giving the appearance of hypocalcemia

Drug Interactions

Substrate of CYP2C9 (major); **Inhibits** CYP2C9 (strong)

Cyclosporine concentrations may be decreased; monitor levels and renal function

CYP2C9 Inducers may decrease the levels/effects of Sulfisoxazole.

Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C9 Substrates: Sulfisoxazole may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

Hydantoin levels may be increased; monitor levels and adjust as necessary

Hypoglycemics: Increased effect of oral hypoglycemics (rare, but severe); monitor blood sugar

Methenamine: Combination may result in crystalluria; avoid use

Methotrexate-induced bone marrow suppression may be increased

NSAIDs and salicylates: May increase sulfonamide concentrations

PABA (para-aminobenzoic acid - may be found in some vitamin supplements): Interferes with the antibacterial activity of sulfonamides; avoid concurrent use

Sulfipyrazone: May increase sulfonamide concentrations

Thiazide diuretics: May increase the incidence of thrombocytopenia purpura

Thiopental's effect may be enhanced; monitor for possible dosage reduction

Uricosuric agents: Actions of these agents are potentiated

Warfarin and other oral anticoagulants: Anticoagulant effect may be increased; decrease dose and monitor INR closely

Pregnancy Risk Factor

B/D (near term)

Pregnancy Implications

Can cause kernicterus in neonates

Lactation

Enters breast milk/compatible

Nursing Implications

Give around-the-clock to promote less variation in peak and trough serum levels; maintain adequate fluid intake

Sulindac

Related Information

● Nonsteroidal Anti-inflammatory Drugs

CAS Number

38194-50-2

U.S. Brand Names

Clinoril®

Use

Management of inflammatory disease, rheumatoid disorders; acute gouty arthritis; structurally similar to indomethacin but acts like aspirin; safest NSAID for use in mild renal impairment

Mechanism of Action

Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors

Adverse Reactions

Cardiovascular: Circulatory collapse, hypotension, vasculitis, Raynaud's phenomenon

Central nervous system: **Dizziness**, headache, aseptic meningitis, psychosis, cognitive dysfunction, coma, seizures, paranoia, gustatory hallucinations

Dermatologic: **Rash**, pruritus, Stevens-Johnson syndrome, exfoliative dermatitis, angioedema, urticaria, licheniform eruption, exanthem, phototoxicity

Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, fluid retention, gynecomastia

Gastrointestinal: **Abdominal cramps, heartburn, indigestion, nausea, vomiting**, GI bleeding, GI ulceration, constipation, diarrhea, dyspepsia, metallic taste, loss of taste perception, aphthous stomatitis, xerostomia, stomatitis

Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia, aplastic anemia (rare), platelet inhibition, erythroblastopenia

Hepatic: Elevated transaminases, hepatitis (fulminant), hepatic necrosis, cholestasis, cholelithiasis

Neuromuscular & skeletal: Paresthesia

Otic: Ototoxicity, tinnitus

Renal: Renal failure (acute), nephrotic syndrome, chronic renal failure, albuminuria

Respiratory: Wheezing, respiratory depression

Miscellaneous: Hypersensitivity, anaphylactoid reactions, fixed drug eruption

Signs and Symptoms of Overdose

Azotemia, chills, coagulopathy, cognitive dysfunction, drowsiness, gastritis, GI bleeding, hyperthermia, insomnia, leukemoid reaction, leukocytosis, nausea, nephritis, nephrotic syndrome, ototoxicity, photosensitivity, purpura, thrombocytopenia, tinnitus, toxic epidermal necrolysis, vomiting, wheezing. Severe poisoning can manifest with alopecia coma, hypotension, renal and/or hepatic failure, respiratory depression, and seizures.

Pharmacodynamics/Kinetics

Onset of action: Analgesic: ~1 hour

Duration: 12-24 hours

Absorption: 90%

Metabolism: Hepatic; prodrug metabolized to sulfide metabolite (active)

for therapeutic effects and to sulfone metabolites (inactive)

Half-life elimination: Parent drug: ~8 hours; Active metabolite: ~16 hours

Excretion: Urine (50%, primarily as inactive metabolites); feces (25%, primarily as metabolites)

Dosage

Maximum therapeutic response may not be realized for up to 3 weeks.
 Oral:

Children: Dose not established

Adults: 150-200 mg twice daily or 300-400 mg once daily; not to exceed 400 mg/day

Dosing adjustment in hepatic impairment: Dose reduction is necessary

Monitoring Parameters Liver enzymes, BUN, serum creatinine, CBC, blood pressure; signs and symptoms of GI bleeding

Administration

Should be administered with food or milk.

Contraindications Hypersensitivity to sulindac, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy (3rd trimester)

Warnings

[U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension. Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Sulindac is not recommended for patients with advanced renal disease. Use caution in patients with renal lithiasis; sulindac metabolites have been reported as components of renal stones. Use hydration in patients with a history of renal stones.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur. May require dosage adjustment in hepatic dysfunction; sulfide and sulfone metabolites may accumulate.

Withhold for at least 4-6 half-lives prior to surgical or dental procedures. Safety and efficacy in pediatric patients have not been established.

Dosage Forms Tablet: 150 mg, 200 mg
Clinoril®: 200 mg

Reference Range Peak plasma levels after a 200 mg oral dose: ~4 mg/L (parent compound); 3 mg/L (sulfide metabolite); and 2 mg/L (sulfone metabolite)

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage

Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be effective

Test Interactions ↑ chloride (S), sodium (S), bleeding time

Drug Interactions ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure. Aminoglycosides: NSAIDs may decrease the excretion of aminoglycosides.

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants (warfarin, heparin, LMWHs): When used with NSAIDs can cause increased risk of bleeding.

Antiplatelet drugs (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatide, tirofiban): Concurrent use may cause an increased risk of bleeding.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Bisphosphonates: NSAIDs may increase the risk of gastrointestinal ulceration.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids: May increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

Dimethyl sulfoxide: May reduce plasma levels of sulindac's active metabolite. Combination may cause peripheral neuropathy; avoid concurrent use.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use.

Lithium: NSAIDs may increase lithium levels; avoid concurrent use if possible or monitor lithium levels and adjust dose. Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again.

Loop diuretic: NSAIDs may decrease the efficacy (diuretic and antihypertensive effect) of loop diuretics.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Pemetrexed: NSAIDs may decrease the excretion of pemetrexed. Patients with Cl_{cr} 45-79 mL/minute should avoid long-acting NSAIDs for 5 days before and 2 days after pemetrexed treatment.

Thiazides antihypertensive effects are decreased; avoid concurrent use.

Treprostinil: May enhance the risk of bleeding with concurrent use.

Vancomycin: NSAIDs may decrease the excretion of vancomycin.

Pregnancy Risk Factor B/D (3rd trimester)

Pregnancy Implications Animal studies have not documented teratogenic effects. However, known effects of NSAIDs suggest the potential for premature ductus arteriosus closure, particularly in late pregnancy.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Structurally similar to indomethacin but acts like aspirin; associated with the highest incidence of upper GI bleeds among NSAIDs

Sulpiride

Related Information

- Antipsychotic Agents
- Tiapride

CAS Number 15676-16-1; 23672-07-3

Impairment Potential Blood sulpiride level of 2.1 mg/L consistent with driving impairment

Unlabeled/Investigational Use Antidepressive agent and antipsychotic agent

Mechanism of Action Substituted benzamide with selective dopamine receptor antagonism

Adverse Reactions

Cardiovascular: Palpitations, hypertension

Central nervous system: Dizziness, headache, neuroleptic malignant syndrome, sedation, Parkinson symptoms, **extrapyramidal effects**, tardive dyskinesia, agitation

Endocrine & metabolic: Galactorrhea, sexual dysfunction, hyperprolactinemia

Gastrointestinal: Nausea, vomiting, xerostomia, constipation

Genitourinary: Impotence

Hematologic: Porphyrinogenic

Hepatic: Cholestatic jaundice, primary biliary cirrhosis

Ocular: Blurred vision

Miscellaneous: Anticholinergic effects, diaphoresis

Toxicodynamics/Kinetics

Distribution: V_d : 1-2.7 L/kg

Protein binding: <40%

Bioavailability: Oral: 35% (food lowers absorption)

Half-life: 6-8 hours; 20-26 hours in renal failure

Elimination: Renal (clearance: 310 mL/minute)

Dosage Oral: 200-400 mg twice daily; may increase gradually to a maximum dose of 1.2 g/day

I.M.: 600-800 mg/day

Reference Range

Therapeutic steady-state serum range for sulpiride: 0.071-1.121 mcg/mL
Postmortem blood sulpiride level of 38 mcg/mL associated with suicidal ingestion of ~12 g

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Additional Information Stimulates prolactin secretion; can exacerbate hypertension caused by pheochromocytoma, cross-hypersensitivity may exist with metoclopramide, tiapride, sultopride

Sulthiamine

CAS Number 61-56-3

Synonyms RP10248; Sultiame; Tetrahydro-2-para-sulfamoylphenyl-1,2-thiazine 1,1 dioxide

Impairment Potential Yes

Use Anticonvulsant agent used for generalized seizures temporal lobe seizures, myoclonic or focal seizures; not useful for absence seizures

Mechanism of Action Antiepileptic agent and a weak carbonic anhydrase inhibitor; a synthetic sulfonamide

Adverse Reactions

Central nervous system: Headache, lethargy, ataxia, vertigo
Genitourinary: Crystalluria
Neuromuscular & skeletal: Paresthesia
Ocular: Ptosis
Respiratory: Hyperpnea, dyspnea

Signs and Symptoms of Overdose Catatonia, crystalluria (in acidic urine), drowsiness, hyperreflexia, hypotension, prolonged extensor plantar reflexes, vomiting

Admission Criteria/Prognosis Admit symptomatic patient or any ingestion > 4 g

Pharmacodynamics/Kinetics

Protein binding: 29%
Half-life: 30 hours
Elimination: Renal

Dosage Oral:

Children: Initial: 3-5 mg/kg/day; can increase daily dose: 10-15 mg/kg; maximum daily dose: 1.2 g

Adults: Initial: 100 mg 2 times/day; can be increased to 200 mg 3 times/day

Monitoring Parameters Urine pH, urine output

Warnings Use with caution in patients with renal impairment

Dosage Forms Suspension: 50 mg/5 mL

Tablets: 50 mg, 200 mg

Reference Range

Therapeutic plasma level is up to 12 mcg/mL; severe toxicity is associated with plasma levels > 30 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: Urine pH should be kept alkaline (by use of I.V. sodium bicarbonate: 1-2 mEq/kg) in order to avoid crystalluria and renal impairment

Drug Interactions By inhibiting its metabolism, sulthiamine can raise phenytoin serum levels

Sumatriptan Succinate

CAS Number 103628-46-2; 103628-47-3; 103628-48-4

U.S. Brand Names Imitrex®

Synonyms Sumatriptan Succinate

Impairment Potential Yes

Use

Acute treatment of migraine with or without aura

Sumatriptan injection: Acute treatment of cluster headache episodes

Mechanism of Action Selective agonist for serotonin (5HT₁, ID subtype receptor) in cranial arteries to cause vasoconstriction and reduces sterile inflammation associated with antidromic neuronal transmission correlating with relief of migraine

Adverse Reactions

Cardiovascular: Chest pain, tightness, heaviness, pressure, flushing (injection); abdominal aortic aneurysm, arrhythmia, atrial fibrillation, cerebral ischemia, cerebrovascular accident, ECG changes, flushing, heart block, Prinzmetal's angina, Raynaud syndrome, shock, thrombosis, transient myocardial ischemia, syncope

Central nervous system: **Dizziness, warm/hot sensation**, drowsiness, malaise, fatigue, headache, anxiety (injection); dizziness, drowsiness, malaise, fatigue, nonspecified pain, vertigo, migraine, sleepiness (tablet); dizziness, vertigo (nasal spray); agitation, convulsions, dystonic reaction, hallucinations, increased intracranial pressure, sensation changes, subarachnoid hemorrhage

Dermatologic: Angioneurotic edema, photosensitivity, pruritus, rash
Endocrine & metabolic: Abnormal menstrual cycle, fluid disturbances (including retention), increased TSH

Gastrointestinal: Nausea, vomiting, hyposalivation, abdominal discomfort, dysphagia; mouth, tongue discomfort (injection); **bad taste, nausea, vomiting** (nasal spray); abdominal discomfort, decreased appetite, diarrhea, dyspeptic symptoms, dysphagia, gastrointestinal pain, intestinal obstruction, ischemic colitis, numbness of tongue, swallowing disorders, xerostomia

Hematologic: Anemia, hemolytic anemia, pancytopenia, thrombocytopenia

Hepatic: Abnormal liver function tests

Local: **Pain at the injection site**, thrombophlebitis

Neuromuscular & skeletal: **Tingling**, numbness; neck, throat, and jaw: pain, tightness, pressure; muscle cramps, weakness, myalgia (injection); neck, throat, and jaw: pain, tightness, pressure (tablet); paresthesia (tablet); joint ache, muscle stiffness, paresthesia

Ocular: Vision alterations (injection); accommodation disorders

Renal: Acute renal failure, hematuria

Respiratory: Nasal disorder, nasal discomfort (nasal spray, injection); throat discomfort (injection, nasal spray); bronchospasm, nose/throat hemorrhage, pulmonary embolism

Miscellaneous: Burning, feeling of heaviness, pressure sensation, feeling of tightness, strange feeling, cold sensation, diaphoresis (injection); nonspecified pressure, tightness, heaviness (tablet); warm sensation, cold sensation, death, dental pain, hiccups, hypersensitivity reactions, phlebitis, psychomotor disorders, severe anaphylaxis/anaphylactoid reactions

Signs and Symptoms of Overdose Angina, chest pain, hypertension, numbness. Fatalities due to myocardial infarction usually occur 3 or more hours after treatment.

Pharmacodynamics/Kinetics

Onset of action: ~30 minutes

Distribution: V_d: 2.4 L/kg

Protein binding: 14% to 21%

Metabolism: Hepatic, primarily via MAO-A isoenzyme

Bioavailability: SubQ: 97% ± 16% of that following I.V. injection; Oral: 15%

Half-life elimination: Injection, tablet: 2.5 hours; Nasal spray: 2 hours

Time to peak, serum: 5-20 minutes

Excretion:

Injection: Urine (38% as indole acetic acid metabolite, 22% as unchanged drug)

Nasal spray: Urine (42% as indole acetic acid metabolite, 3% as unchanged drug)

Tablet: Urine (60% as indole acetic acid metabolite, 3% as unchanged drug); feces (40%)

Dosage

Adults:

Oral: A single dose of 25 mg, 50 mg, or 100 mg (taken with fluids). If a satisfactory response has not been obtained at 2 hours, a second dose may be administered. Results from clinical trials show that initial doses of 50 mg and 100 mg are more effective than doses of 25 mg, and that 100 mg doses do not provide a greater effect than 50 mg and may have increased incidence of side effects. Although doses of up to 300 mg/day have been studied, the total daily dose should not exceed 200 mg. The safety of treating an average of > 4 headaches in a 30-day period have not been established.

Intranasal: A single dose of 5 mg, 10 mg, or 20 mg administered in one nostril. A 10 mg dose may be achieved by administering a single 5 mg dose in each nostril. If headache returns, the dose may be repeated once after 2 hours, not to exceed a total daily dose of 40 mg. The safety of treating an average of > 4 headaches in a 30-day period has not been established.

SubQ: 6 mg; a second injection may be administered at least 1 hour after the initial dose, but not more than 2 injections in a 24-hour period. If side effects are dose-limiting, lower doses may be used.

Dosage adjustment in renal impairment: Dosage adjustment not necessary

Dosage adjustment in hepatic impairment: Bioavailability of oral sumatriptan is increased with liver disease. If treatment is needed, do not exceed single doses of 50 mg. The nasal spray has not been studied in patients with hepatic impairment, however, because the spray does not undergo first-pass metabolism, levels would not be expected to alter. Use of all dosage forms is contraindicated with severe hepatic impairment.

Elderly: Due to increased risk of CAD, decreased hepatic function, and more pronounced blood pressure increases, use of the tablet dosage form in elderly patients is not recommended. Use of the nasal spray has not been studied in the elderly. Pharmacokinetics of injectable sumatriptan in the elderly are similar to healthy patients.

Stability Store at 2°C to 20°C (36°F to 86°F); protect from light

Administration Oral: Should be taken with fluids as soon as symptoms to appear

Injection solution: For SubQ administration; do not administer I.V.; may cause coronary vasospasm

Contraindications Hypersensitivity to sumatriptan or any component of the formulation; patients with ischemic heart disease or signs or symptoms of ischemic heart disease (including Prinzmetal's angina, angina pectoris, myocardial infarction, silent myocardial ischemia); cerebrovascular syndromes (including strokes, transient ischemic attacks); peripheral vascular syndromes (including ischemic bowel disease); uncontrolled hypertension; use within 24 hours of ergotamine derivatives; use within 24 hours of another 5-HT₁ agonist; concurrent administration or within 2 weeks of discontinuing an MAO inhibitor, specifically MAO type A inhibitors; management of hemiplegic or basilar

migraine; prophylactic treatment of migraine; severe hepatic impairment; not for I.V. administration

Warnings

Sumatriptan is indicated only in patients ≥ 18 years of age with a clear diagnosis of migraine or cluster headache.

Cardiac events (coronary artery vasospasm, transient ischemia, myocardial infarction, ventricular tachycardia/fibrillation, cardiac arrest and death), cerebral/subarachnoid hemorrhage and stroke have been reported with 5-HT₁ agonist administration.

Do not give to patients with risk factors for CAD until a cardiovascular evaluation has been performed; if evaluation is satisfactory, the healthcare provider should administer the first dose and cardiovascular status should be periodically evaluated.

Significant elevation in blood pressure, including hypertensive crisis, has also been reported on rare occasions in patients with and without a history of hypertension. Vasospasm-related reactions have been reported other than coronary artery vasospasm. Peripheral vascular ischemia and colonic ischemia with abdominal pain and bloody diarrhea have occurred. Use with caution in patients with history of seizure disorder or in patients with a lowered seizure threshold. Safety and efficacy in pediatric patients have not been established.

Dosage Forms

Note: Strength expressed as sumatriptan base

Injection, solution, as succinate: 8 mg/mL (0.5 mL) [disposable cartridge for use with STATdose System®]; 12 mg/mL (0.5 mL) [disposable cartridge for use with STATdose System® or vial]

Solution, intranasal spray: 5 mg (100 μ L unit dose spray device); 20 mg (100 μ L unit dose spray device)

Tablet, as succinate: 25 mg, 50 mg, 100 mg

Reference Range

Therapeutic range: 18-60 ng/mL

Overdosage/Treatment

Decontamination for oral ingestion: Ipecac within 30 minutes or lavage within 30 minutes/activated charcoal

Supportive therapy: Nitroprusside, nifedipine, or hydralazine for hypertensive crisis; lidocaine or procainamide for ventricular ectopy; nitroglycerin can reverse sumatriptan-induced coronary artery vasoconstriction

Drug Interactions

Note: Use cautiously in patients receiving concomitant medications that can lower the seizure threshold.

Ergot-containing drugs: Prolong vasospastic reactions; do not use sumatriptan or ergot-containing drugs within 24 hours of each other.

MAO inhibitors (MAO type A inhibitors, nonspecific MAO inhibitors): Reduce sumatriptan clearance; concurrent use is contraindicated; wait at least 2 weeks after discontinuing MAO type A inhibitor to start sumatriptan.

Selegiline: Selegiline is a selective MAO type B inhibitor; while not specifically contraindicated, combination may best be avoided until further study.

SSRIs: Can lead to symptoms of hyper-reflexia, weakness, and incoordination; monitor.

Pregnancy Risk Factor C

Pregnancy Implications

There are no adequate and well-controlled studies using sumatriptan in pregnant women. Use only if potential benefit to the mother outweighs the potential risk to the fetus.

Lactation

Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications

Do not administer I.V., may cause coronary vasospasm; pain at injection site lasts <1 hour

Additional Information

May increase growth hormone level; oral dose of 100 mg is investigational; oral sumatriptan (100 mg) may prevent headache recurrence; may exacerbate depression. Hypertension is a risk factor for sumatriptan-associated chest pain for men in particular, as is a family history of acute myocardial infarction. Raynaud's phenomenon is a risk factor for sumatriptan-associated chest pain in women, but not in men. Chest pain due to sumatriptan usually lasts for <2 hours duration.

Tacrine

CAS Number 1684-40-8; 321-64-2

U.S. Brand Names Cognex®

Synonyms Tacrine Hydrochloride; Tetrahydroaminoacrine; THA

Use Treatment of mild to moderate dementia of the Alzheimer's type

Mechanism of Action Inhibits cholinesterase activity similar to neostigmine

Adverse Reactions

Cardiovascular: Chest pain, shock, angina, sinus bradycardia

Central nervous system: Agitation, dizziness, seizures, insomnia

Dermatologic: Purpura, acne, alopecia, bullous skin disease, xerosis, urticaria, pruritus, psoriasis, exanthem

Gastrointestinal: Nausea, abdominal pain, vomiting, diarrhea, belching

Hepatic: Dose-related hepatitis

Ocular: Lacrimation

Respiratory: Asthma, bronchospasm

Signs and Symptoms of Overdose Bradycardia, confusion, depression, hallucination, hypotension, purpura, tachypnea

Pharmacodynamics/Kinetics

Absorption: Oral: Rapid

Distribution: V_d: Mean: 349 L; reduced by food

Protein binding, plasma: 55%

Metabolism: Extensively by CYP450 to multiple metabolites; first pass effect

Bioavailability: Absolute: 17%

Half-life elimination, serum: 2-4 hours; Steady-state: 24-36 hours

Time to peak, plasma: 1-2 hours

Dosage

Adults: Initial: 10 mg 4 times/day; may increase by 40 mg/day adjusted every 6 weeks; maximum: 160 mg/day; best administered separate from meal times.

Dose adjustment based upon transaminase elevations:

ALT ≤ 3 times ULN*: Continue titration

ALT > 3 to ≤ 5 times ULN*: Decrease dose by 40 mg/day, resume when ALT returns to normal

ALT > 5 times ULN*: Stop treatment, may rechallenge upon return of ALT to normal

*ULN = upper limit of normal

Patients with clinical jaundice confirmed by elevated total bilirubin (> 3 mg/dL) should not be rechallenged with tacrine

Monitoring Parameters ALT (SGPT) levels and other liver enzymes weekly for at least the first 18 weeks, then monitor once every 3 months

Contraindications Hypersensitivity to tacrine, acridine derivatives, or any component of the formulation; patients previously treated with tacrine who developed jaundice

Warnings The use of tacrine has been associated with elevations in serum transaminases; serum transaminases (specifically ALT) must be monitored throughout therapy; use extreme caution in patients with current evidence of a history of abnormal liver function tests; use caution in patients with urinary tract obstruction (bladder outlet obstruction or prostatic hyperplasia), asthma, and sick-sinus syndrome, bradycardia, or conduction abnormalities (tacrine may cause bradycardia and/or heart block). Also, patients with cardiovascular disease, asthma, or peptic ulcer should use cautiously. Adverse cardiovascular events may also occur in patients without known cardiac disease. Use with caution in patients with a history of seizures. May cause nausea, vomiting, or loose stools. Abrupt discontinuation or dosage decrease may worsen cognitive function. May be associated with neutropenia.

Dosage Forms Capsule, as hydrochloride: 10 mg, 20 mg, 30 mg, 40 mg

Reference Range

In clinical trials, serum concentrations > 20 ng/mL were associated with a much higher risk of development of symptomatic adverse effects

Peak level: 6.5 ng/mL in 90 minutes after 50 mg dose

Overdosage/Treatment Antidote is atropine for muscarinic symptoms; pralidoxime (2-PAM) may also be needed to reverse severe muscle asthenia or paralysis

Antidote(s)

• Atropine [ANTIDOTE]

• Pralidoxime [ANTIDOTE]

Drug Interactions **Substrate** of CYP1A2 (major); **Inhibits** CYP1A2 (weak)

Anticholinergic agents: Tacrine may antagonize the therapeutic effect of anticholinergic agents (benztropine, trihexyphenidyl); a peripherally-acting agent (glycopyrrolate) has been reported to reduce tacrine-associated gastrointestinal complaints

Antipsychotic agents: Acetylcholinesterase inhibitors (central) may increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Beta-blockers: Tacrine in combination with beta-blockers may produce additive bradycardia

Calcium channel blockers: Tacrine in combination with heart rate lowering calcium channel blockers (diltiazem and verapamil) may produce additive bradycardia

Cholinergic agents: Tacrine in combination with other cholinergic agents (eg, ambenonium, edrophonium, neostigmine, pyridostigmine, bethanechol), will likely produce additive cholinergic effects

CYP1A2 inducers: May decrease the levels/effects of tacrine. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of tacrine. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

Digoxin: Tacrine, in combination with digoxin, may produce additive bradycardia

Haloperidol: Tacrine may worsen Parkinson's disease and inhibit the effects of haloperidol.

TACROLIMUS

Levodopa: Tacrine may worsen Parkinson's disease and inhibit the effects of levodopa

Neuromuscular blocking agents (nondepolarizing): Theoretically, tacrine may antagonize the effect of nondepolarizing neuromuscular blocking agents

Succinylcholine: Tacrine may prolong the effect of succinylcholine

Theophylline: Tacrine may inhibit the metabolism of theophylline resulting in elevated plasma levels; dose adjustment will likely be needed

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/not recommended

Additional Information Discontinue tacrine if ALT exceeds 3 times the upper limit of normal

Tacrolimus

CAS Number 104987-11-3

U.S. Brand Names Prograf®; Protopic®

Synonyms FK506

Use

Oral/injection: Potent immunosuppressive drug used in heart, kidney, or liver transplant recipients

Topical: Moderate-to-severe atopic dermatitis in patients not responsive to conventional therapy or when conventional therapy is not appropriate

Unlabeled/Investigational Use Potent immunosuppressive drug used in lung, small bowel transplant recipients; immunosuppressive drug for peripheral stem cell/bone marrow transplantation

Mechanism of Action Suppresses cellular immunity (inhibits T-lymphocyte activation), possibly by binding to an intracellular protein, FKBP-12

Adverse Reactions

Oral, I.V.:

≥ 15%:

Cardiovascular: Chest pain, hypertension

Central nervous system: Dizziness, headache, insomnia, tremor (headache and tremor are associated with high whole blood concentrations and may respond to decreased dosage)

Dermatologic: Pruritus, rash

Endocrine & metabolic: Diabetes mellitus, hyperglycemia, hyper/hypokalemia, hyperlipemia, hypomagnesemia, hypophosphatemia

Gastrointestinal: Abdominal pain, constipation, diarrhea, dyspepsia, nausea, vomiting

Genitourinary: Urinary tract infection

Hematologic: Anemia, leukocytosis, thrombocytopenia

Hepatic: Ascites

Neuromuscular & skeletal: Arthralgia, back pain, weakness, paresthesia

Renal: Abnormal kidney function, increased creatinine, oliguria, urinary tract infection, increased BUN

Respiratory: Atelectasis, dyspnea, increased cough, pleural effusion

< 15%:

Cardiovascular: Abnormal ECG (QRS or ST segment abnormal), angina pectoris, cardiopulmonary failure, deep thrombophlebitis, heart rate decreased, hemorrhage, hemorrhagic stroke, hypervolemia, hypotension, generalized edema, peripheral vascular disorder, phlebitis, postural hypotension, tachycardia, thrombosis, vasodilation

Central nervous system: Abnormal dreams, abnormal thinking, agitation, amnesia, anxiety, chills, confusion, depression, dizziness, elevated mood, emotional lability, encephalopathy, hallucinations, nervousness, paralysis, psychosis, quadriplegia, seizure, somnolence

Dermatologic: Acne, alopecia, cellulitis, exfoliative dermatitis, fungal dermatitis, hirsutism, increased diaphoresis, photosensitivity reaction, skin discoloration, skin disorder, skin ulcer

Endocrine & metabolic: Acidosis, alkalosis, Cushing's syndrome, decreased bicarbonate, decreased serum iron, diabetes mellitus, hypercalcemia, hypercholesterolemia, hyperphosphatemia, hypoproteinemia, increased alkaline phosphatase

Gastrointestinal: Anorexia, appetite increased, cramps, duodenitis, dysphagia, enlarged abdomen, esophagitis (including ulcerative), flatulence, gastritis, gastroesophagitis, GI perforation/hemorrhage, ileus, oral moniliasis, pancreatic pseudocyst, rectal disorder, stomatitis, weight gain

Genitourinary: Bladder spasm, cystitis, dysuria, nocturia, oliguria, urge incontinence, urinary frequency, urinary incontinence, urinary retention, vaginitis

Hematologic: Bruising, coagulation disorder, decreased prothrombin, hypochromic anemia, leukopenia, polycythemia

Hepatic: Abnormal liver function tests, ALT/AST increased, bilirubinemia, cholangitis, cholestatic jaundice, GGT increased, hepatitis (including granulomatous), jaundice, liver damage, increase LDH

Neuromuscular & skeletal: Hypertonia, incoordination, joint disorder, leg cramps, myalgia, myasthenia, myoclonus, nerve compression, neuropathy, osteoporosis

Ocular: Abnormal vision, amblyopia

Otic: Ear pain, otitis media, tinnitus

Renal: Albuminuria, renal tubular necrosis, toxic nephropathy

Respiratory: Asthma, bronchitis, lung disorder, pharyngitis, pneumonia, pneumothorax, pulmonary edema, respiratory disorder, rhinitis, sinusitis, voice alteration

Miscellaneous: Abscess, abnormal healing, allergic reaction, crying, flu-like syndrome, generalized spasm, hernia, herpes simplex, peritonitis, sepsis, writing impaired

Postmarketing and/or case reports (limited to important or life-threatening): Acute renal failure, anaphylaxis, ARDS, arrhythmia, atrial fibrillation, atrial flutter, blindness, cardiac arrest, cerebral infarction, coma, deafness, delirium, DIC, hearing loss, hemiparesis, hemolytic-uremic syndrome, hemorrhagic cystitis, hepatic necrosis, hepatotoxicity, leukoencephalopathy, lymphoproliferative disorder (related to EBV), myocardial hypertrophy (associated with ventricular dysfunction); reversible upon discontinuation), MI, neutropenia, pancreatitis (hemorrhagic and necrotizing), pancytopenia, quadriplegia, QT_c prolongation, respiratory failure, seizure, Stevens-Johnson syndrome, syncope, toxic epidermal necrolysis, thrombocytopenic purpura, torsade de pointes, TTP, veno-occlusive hepatic disease, venous thrombosis, ventricular fibrillation. Calcineurin inhibitor-induced hemolytic uremic syndrome/thrombotic thrombocytopenic purpura/thrombotic microangiopathy (HUS/TTP/TMA) have been reported (with concurrent sirolimus).

Topical (as reported in children and adults, unless otherwise noted):

> 10%:

Central nervous system: Headache (5% to 20%), fever (1% to 21%)

Dermatologic: Skin burning (43% to 58%; tends to improve as lesions resolve), pruritus (41% to 46%), erythema (12% to 28%)

Respiratory: Increased cough (18% children)

Miscellaneous: Flu-like syndrome (23% to 28%), allergic reaction (4% to 12%)

1% to 10%:

Cardiovascular: Peripheral edema (3% to 4% adults)

Central nervous system: Hyperesthesia (3% to 7% adults), pain (1% to 2%)

Dermatologic: Skin tingling (2% to 8%), acne (4% to 7% adults), localized flushing (following ethanol consumption 3% to 7% adults), folliculitis (2% to 6%), urticaria (1% to 6%), rash (2% to 5%), pustular rash (2% to 4%), vesiculobullous rash (4% children), contact dermatitis (3% to 4%), cyst (1% to 3% adults), eczema herpeticum (1% to 2%), fungal dermatitis (1% to 2% adults), sunburn (1% to 2% adults), dry skin (1% children)

Endocrine & metabolic: Dysmenorrhea (4% women)

Gastrointestinal: Diarrhea (3% to 5%), dyspepsia (1% to 4% adults), abdominal pain (3% children), vomiting (1% adults), gastroenteritis (adults 2%), nausea (1% children)

Neuromuscular & skeletal: Myalgia (2% to 3% adults), weakness (2% to 3% adults), back pain (2% adults)

Ocular: Conjunctivitis (2% adults)

Otic: Otitis media (12% children)

Respiratory: Rhinitis (6% children), sinusitis (2% to 4% adults), bronchitis (2% adults), pneumonia (1% adults)

Miscellaneous: Varicella/herpes zoster (1% to 5%), lymphadenopathy (3% children)

≥ 1%: Alopecia, increased ALT, increased AST, anaphylactoid reaction, angina pectoris, angioedema, anorexia, anxiety, arrhythmia, arthralgia, arthritis, bilirubinemia, breast pain, cellulitis, cerebrovascular accident, cheilitis, chills, constipation, increased creatinine, dehydration, depression, dizziness, dyspnea, ear pain, ecchymosis, edema, epistaxis, exacerbation of untreated area, eye pain, furunculosis, gastritis, hernia, hyperglycemia, hypertension, hypoglycemia, hypoxia, laryngitis, leukocytosis, leukopenia, abnormal liver function tests, lymphadenopathy (0.8%), malaise, migraine, neck pain, neuritis, palpitation, paresthesia, peripheral vascular disorder, photosensitivity reaction, skin discoloration, diaphoresis, taste perversion, unintended pregnancy, vaginal moniliasis, vasodilation, vertigo. Calcineurin inhibitor-induced hemolytic uremic syndrome/thrombotic thrombocytopenic purpura/thrombotic microangiopathy (HUS/TTP/TMA) have been reported (with concurrent sirolimus).

Signs and Symptoms of Overdose Circumoral numbness, coma, delirium, diarrhea, dyspnea, encephalopathy, hirsutism, hyperglycemia, hyperuricemia, hypokalemia, hypomagnesemia, insomnia, leukocytosis, night terrors, pleural effusion, thrombocytopenia

Admission Criteria/Prognosis Admit ingestions > 1.5 mg/kg

Pharmacodynamics/Kinetics

Absorption: Better in resected patients with a closed stoma; unlike cyclosporine, clamping of the T-tube in liver transplant patients does not alter trough concentrations or AUC

Oral: Incomplete and variable; food within 15 minutes of administration decreases absorption (27%)

Topical: Serum concentrations range from undetectable to 20 ng/mL (<5 ng/mL in majority of adult patients studied)

Protein binding: 99%

Metabolism: Extensively hepatic via CYP3A4 to eight possible metabolites (major metabolite, 31-demethyl tacrolimus, shows same activity as tacrolimus *in vitro*)

Bioavailability: Oral: Adults: 7% to 28%, Children: 10% to 52%; Topical: <0.5%; Absolute: Unknown

Half-life elimination: Variable, 21-61 hours in healthy volunteers

Time to peak: 0.5-4 hours

Excretion: Feces (~92%); feces/urine (<1% as unchanged drug)

Dosage

Oral:

Children: **Note:** Patients without pre-existing renal or hepatic dysfunction have required (and tolerated) higher doses than adults to achieve similar blood concentrations. It is recommended that therapy be initiated at high end of the recommended adult I.V. and oral dosing ranges; dosage adjustments may be required. If switching from I.V. to oral, the oral dose should be started 8-12 hours after stopping the infusion. Adjunctive therapy with corticosteroids is recommended early post-transplant.

Liver transplant: Initial dose: 0.15-0.20 mg/kg/day in 2 divided doses, given every 12 hours; begin oral dose no sooner than 6 hours post-transplant

Adults: **Note:** If switching from I.V. to oral, the oral dose should be started 8-12 hours after stopping the infusion. Adjunctive therapy with corticosteroids is recommended early post-transplant.

Heart transplant: Initial dose: 0.075 mg/kg/day in 2 divided doses, given every 12 hours; begin oral dose no sooner than 6 hours post-transplant

Kidney transplant: Initial dose: 0.2 mg/kg/day in 2 divided doses, given every 12 hours; initial dose may be given within 24 hours of transplant, but should be delayed until renal function has recovered; African-American patients may require larger doses to maintain trough concentration

Liver transplant: Initial dose: 0.1-0.15 mg/kg/day in 2 divided doses, given every 12 hours; begin oral dose no sooner than 6 hours post-transplant

I.V.: Children and Adults: **Note:** I.V. route should only be used in patients not able to take oral medications and continued only until oral medication can be tolerated; anaphylaxis has been reported. Begin no sooner than 6 hours post-transplant; adjunctive therapy with corticosteroids is recommended.

Heart transplant: Initial dose: 0.01 mg/kg/day as a continuous infusion

Kidney, liver transplant: Initial dose: 0.03-0.05 mg/kg/day as a continuous infusion

Prevention of graft-vs-host disease: 0.03 mg/kg/day as continuous infusion

Topical: Children ≥ 2 years and Adults: Atopic dermatitis (moderate to severe): Apply minimum amount of 0.03% or 0.1% ointment to affected area twice daily; rub in gently and completely. Discontinue use when symptoms have cleared. If no improvement within 6 weeks, patients should be re-examined to confirm diagnosis.

Dosing adjustment in renal impairment: Evidence suggests that lower doses should be used; patients should receive doses at the lowest value of the recommended I.V. and oral dosing ranges; further reductions in dose below these ranges may be required.

Tacrolimus therapy should usually be delayed up to 48 hours or longer in patients with postoperative oliguria.

Hemodialysis: Not removed by hemodialysis; supplemental dose is not necessary.

Peritoneal dialysis: Significant drug removal is unlikely based on physicochemical characteristics.

Dosing adjustment in hepatic impairment: Use of tacrolimus in liver transplant recipients experiencing post-transplant hepatic impairment may be associated with increased risk of developing renal insufficiency related to high whole blood levels of tacrolimus. The presence of moderate-to-severe hepatic dysfunction (serum bilirubin >2 mg/dL; Child-Pugh score ≥ 10) appears to affect the metabolism of tacrolimus. The half-life of the drug was prolonged and the clearance reduced after I.V. administration. The bioavailability of tacrolimus was also increased after oral administration. The higher plasma concentrations as determined by ELISA, in patients with severe hepatic dysfunction are probably due to the accumulation of metabolites of lower activity. These patients should be monitored closely and dosage adjustments should be considered. Some evidence indicates that lower doses could be used in these patients.

Stability Twenty-four hours in dextrose 5% solutions or normal saline; tacrolimus is completely available from plastic syringes, glass or polyolefin containers; polyvinyl-containing sets (eg, Venoset[®], Accuset[®]) adsorb significant amounts of the drug, and their use may lead to a lower dose being delivered to the patient

Monitoring Parameters Renal function, hepatic function, serum electrolytes, glucose and blood pressure, measure 3 times/week for first few weeks, then gradually decrease frequency as patient stabilizes. Whole blood concentrations should be used for monitoring (trough for oral

therapy). Signs/symptoms of anaphylactic reactions during infusion should also be monitored.

Administration

I.V.: Administer by I.V. continuous infusion only. Do not use PVC tubing when administering dilute solutions. Usually intended to be administered as a continuous infusion over 24 hours.

Oral: If dosed once daily (not common), administer in the morning. If dosed twice daily, doses should be 12 hours apart. If the morning and evening doses differ, the larger dose (differences are never >0.5-1 mg) should be given in the morning. If dosed 3 times/day, separate doses by 8 hours.

Topical: Do not use with occlusive dressings. Burning at the application site is most common in first few days; improves as atopic dermatitis improves. Limit application to involved areas. Continue as long as signs and symptoms persist; discontinue if resolution occurs; re-evaluate if symptoms persist >6 weeks.

Contraindications Hypersensitivity to tacrolimus or any component of the formulation

Warnings

Oral/injection: Insulin-dependent post-transplant diabetes mellitus (PTDM) has been reported (1% to 20%); risk increases in African-American and Hispanic kidney transplant patients. **[U.S. Boxed**

Warning]: Increased susceptibility to infection and the possible development of lymphoma may occur after administration of tacrolimus. Nephrotoxicity and neurotoxicity have been reported, especially with higher doses; to avoid excess nephrotoxicity do not administer simultaneously with cyclosporine; monitoring of serum concentrations (trough for oral therapy) is essential to prevent organ rejection and reduce drug-related toxicity; tonic clonic seizures may have been triggered by tacrolimus. A period of 24 hours should elapse between discontinuation of cyclosporine and the initiation of tacrolimus. Use caution in renal or hepatic dysfunction, dosing adjustments may be required. Delay initiation if postoperative oliguria occurs. Use may be associated with the development of hypertension (common). Myocardial hypertrophy has been reported (rare). Each mL of injection contains polyoxyl 60 hydrogenated castor oil (HCO-60) (200 mg) and dehydrated alcohol USP 80% v/v. Anaphylaxis has been reported with the injection, use should be reserved for those patients not able to take oral medications.

Topical: [U.S. Boxed Warning]: Topical calcineurin inhibitors have been associated with rare cases of malignancy. Avoid use on malignant or skin conditions (eg cutaneous T-cell lymphoma). Topical calcineurin agents are considered second-line therapies in the treatment of atopic dermatitis/eczema, and should be limited to use in patients who have failed treatment with other therapies. **[U.S. Boxed Warning]: They should be used for short-term and intermittent treatment using the minimum amount necessary for the control of symptoms should be used.** Application should be limited to involved areas. Safety of intermittent use for >1 year has not been established.

Should not be used in immunocompromised patients. Do not apply to areas of active viral infection; infections at the treatment site should be cleared prior to therapy. Patients with atopic dermatitis are predisposed to skin infections, and tacrolimus therapy has been associated with risk of developing eczema herpeticum, varicella zoster, and herpes simplex. May be associated with development of lymphadenopathy; possible infectious causes should be investigated. Discontinue use in patients with unknown cause of lymphadenopathy or acute infectious mononucleosis. Not recommended for use in patients with skin disease which may increase systemic absorption (eg, Netherton's syndrome). Avoid artificial or natural sunlight exposure, even when Protopic[®] is not on the skin. Safety not established in patients with generalized erythroderma.

[U.S. Boxed Warning]: The use of Protopic[®] in children <2 years of age is not recommended, particularly since the effect on immune system development is unknown.

Dosage Forms Capsule (Prograf[®]): 0.5 mg, 1 mg, 5 mg

Injection, solution (Prograf[®]): 5 mg/mL (1 mL) [contains dehydrated alcohol 80% and polyoxyl 60 hydrogenated castor oil]

Ointment, topical (Protopic[®]): 0.03% (30 g, 60 g, 100 g); 0.1% (30 g, 60 g, 100 g)

Reference Range Whole blood trough therapeutic level: 9.8-19.4 ng/mL. Tacrolimus whole blood trough concentrations should be kept below 20 ng/mL to avoid adverse events in renal transplant recipients. The incidence of adverse events is 76% with tacrolimus whole blood trough concentrations >30 ng/mL, compared with only 5.3% with concentrations <10 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; dialysis/plasmapheresis not effective

Drug Interactions

Substrate of CYP3A4 (major); **Inhibits** CYP3A4 (weak)

Antacids: Separate administration by at least 2 hours

Anticonvulsants: Carbamazepine, phenobarbital, phenytoin: May decrease tacrolimus blood levels.

Calcium channel blockers: May increase tacrolimus serum concentrations; monitor.

Caspofungin: May decrease tacrolimus serum concentrations.

Cisapride (and metoclopramide): May increase serum concentration of tacrolimus

Cyclosporine: Concomitant use is associated with synergistic immunosuppression and increased nephrotoxicity; give first dose of tacrolimus no sooner than 24 hours after last cyclosporine dose. In the presence of elevated tacrolimus or cyclosporine concentration, dosing of the other usually should be delayed longer.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of tacrolimus. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of tacrolimus. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Ganciclovir: Nephrotoxicity may be additive with tacrolimus; use caution.

Macrolides: May increase tacrolimus serum concentrations (limited documentation); monitor.

Potassium-sparing diuretics: Tacrolimus use may lead to hyperkalemia; avoid concomitant use

Rifabutin, rifampin: May decrease serum levels of tacrolimus.

Sirolimus: May decrease tacrolimus serum concentrations. Concurrent therapy may increase the risk of HUS/TTP/TMA.

St John's wort: May decrease tacrolimus serum concentrations; avoid concurrent use.

Sucralfate: Separate administration by at least 2 hours

Vaccines (live): Vaccine may be less effective; avoid vaccination during treatment if possible

Voriconazole: Tacrolimus serum concentrations may be increased; monitor serum concentrations and renal function. Decrease tacrolimus dosage by 66% when initiating voriconazole.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk/contraindicated

Additional Information Overdoses up to 7 mg/kg have produced little acute symptomatology. A whole blood tacrolimus level of 42.6 ng/mL was obtained after an ingestion of 0.8 mg/kg, with minimal side effects.

Tamoxifen

CAS Number 10540-29-1; 54965-24-1

U.S. Brand Names Nolvadex®; Soltamox™

Synonyms ICI-46474; NSC-180973; TAM; Tamoxifen Citrate

Use Palliative or adjunctive treatment of advanced breast cancer; reduce the incidence of breast cancer in women at high risk; reduce risk of invasive breast cancer in women with ductal carcinoma in situ (DCIS); metastatic female and male breast cancer

Unlabeled/Investigational Use Treatment of mastalgia, gynecomastia, pancreatic carcinoma, melanoma and desmoid tumors; induction of ovulation; treatment of precocious puberty in females, secondary to McCune-Albright syndrome

Mechanism of Action Competitively binds to estrogen receptors on tumors and other tissue targets, producing a nuclear complex that decreases DNA synthesis and inhibits estrogen effects; nonsteroidal agent with potent antiestrogenic properties which compete with estrogen for binding sites in breast and other tissues; cells accumulate in the G₀ and G₁ phases; therefore, tamoxifen is cytostatic rather than cytotoxic

Adverse Reactions

Cardiovascular: Flushing, arterial thrombosis, superior mesenteric artery thrombosis, vasculitis

Central nervous system: Dizziness, psychosis, headache

Dermatologic: Rash, pruritus, leiomyoma growth, radiation recall dermatitis, alopecia, hypertrichosis, xerosis, urticaria, purpura, exanthem, cutaneous vasculitis

Endocrine & metabolic: Vaginal bleeding or discharge, menstrual irregularities, hypercalcemia in patients with bony metastasis, galactorrhea, hot flashes, ovarian cysts, hypoprolactinemia, hypertriglyceridemia

Gastrointestinal: Nausea, weight gain, vomiting is rare, cholestasis, steatohepatitis, xerostomia

Genitourinary: Priapism, endometriosis, recurrent vulvovaginal candidiasis, uterine leiomyosarcoma

Hematologic: Occasional leukopenia, thrombocytopenia, porphyria, agranulocytosis, thromboembolism (3.8% to 6.8%), porphyrinogenic, anemia, hepatotoxicity

Hepatic: Steatosis hepatitis, cirrhosis

Neuromuscular & skeletal: Increased bone and tumor pain

Ocular: Corneal opacification, reduced visual acuity, retinopathy at high doses (120 mg/day for 1 year)

Renal: Nephrotic syndrome

Respiratory: Eosinophilic pneumonia

Miscellaneous: Antiphospholipid syndrome

Signs and Symptoms of Overdose Azoospermia, cataract, depression, galactorrhea, hirsutism, hypercalcemia, lactation, leukopenia or neutropenia (agranulocytosis, granulocytopenia), mental confusion, oligospermia, priapism, sexual dysfunction

Pharmacodynamics/Kinetics

Absorption: Well absorbed; tablet and oral solution are bioequivalent

Distribution: High concentrations found in uterus, endometrial and breast tissue

Protein binding: 99%

Metabolism: Hepatic (via CYP3A4) to major metabolites, N-desmethyl tamoxifen (major) and 4-hydroxytamoxifen (minor), and a tamoxifen derivative (minor); undergoes enterohepatic recirculation

Half-life elimination: Distribution: 7-14 hours; Elimination: 5-7 days; Metabolites: 14 days

Time to peak, serum: 5 hours

Excretion: Feces (26% to 51%); urine (9% to 13%)

Dosage

Oral (refer to individual protocols):

Children: Female: Precocious puberty and McCune-Albright syndrome (unlabeled use): A dose of 20 mg/day has been reported in patients 2-10 years of age; safety and efficacy have not been established for treatment of longer than 1 year duration

Adults:

Breast cancer:

Metastatic (males and females) or adjuvant therapy (females): 20-40 mg/day; daily doses >20 mg should be given in 2 divided doses (morning and evening)

Prevention (high-risk females): 20 mg/day for 5 years

DCIS (females): 20 mg once daily for 5 years

Note: Higher dosages (up to 700 mg/day) have been investigated for use in modulation of multidrug resistance (MDR), but are not routinely used in clinical practice

Induction of ovulation (unlabeled use): 5-40 mg twice daily for 4 days

Monitoring Parameters Monitor WBC and platelet counts, serum calcium, LFTs; abnormal vaginal bleeding

Contraindications Hypersensitivity to tamoxifen or any component of the formulation; concurrent warfarin therapy or history of deep vein thrombosis or pulmonary embolism (when tamoxifen is used for cancer risk reduction); pregnancy

Warnings

Hazardous agent - use appropriate precautions for handling and disposal.

[U.S. Boxed Warning]: Serious and life-threatening events (including stroke, pulmonary emboli, and uterine malignancy) have occurred at an incidence greater than placebo during use for cancer risk reduction; these events are rare, but require consideration in risk/benefit evaluation. An increased incidence of thromboembolic events has been associated with use for breast cancer; risk may increase with chemotherapy addition; use caution in individuals with a history of thromboembolic events. Use with caution in patients with leukopenia, thrombocytopenia, or hyperlipidemias. Decreased visual acuity, retinopathy, corneal changes, and increased incidence of cataracts have been reported. Hypercalcemia has occurred in patients with bone metastasis. Significant bone loss of the lumbar spine and hip was associated with use in premenopausal women. Liver abnormalities such as cholestasis, fatty liver, hepatitis, and hepatic necrosis have occurred. Hepatocellular carcinomas have been reported in some studies; relationship to treatment is unclear. Endometrial hyperplasia, polyps, endometriosis, uterine fibroids, and ovarian cysts have occurred. Increased risk of uterine or endometrial cancer; monitor. Safety and efficacy in children <2 years of age, or for treatment durations >1 year in children 2-10 years, have not been established.

Dosage Forms Solution, oral: 10 mg/5 mL (150 mL) [licorice flavor]

Tablet: 10 mg, 20 mg

Reference Range

Oral dose of 0.3 mg/kg yields a peak blood level of 0.06-0.14 mcg/mL

Peak level of tamoxifen after a 20 mg dose: 42 mcg/L

Peak level of N-desmethyltamoxifen after a 20 mg dose: 12 mcg/L

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Oral clonidine, 0.1 mg/d is effective against tamoxifen-induced hot flashes in postmenopausal women with breast cancer.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective.

Test Interactions False T_4 elevation (no clinical evidence of hyperthyroidism)

Drug Interactions

Substrate of CYP2A6 (minor), 2B6 (minor), 2C9 (major), 2D6 (major), 2E1 (minor), 3A4 (major); **Inhibits** CYP2B6 (weak), 2C8 (moderate), 2C9 (weak), 3A4 (weak)

Anastrozole: Tamoxifen may reduce the levels/effects of anastrozole. Concurrent therapy is not recommended (per manufacturer).

CYP2C8 substrates: Tamoxifen may increase the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP2C9 inducers: May decrease the levels/effects of tamoxifen. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C9 inhibitors: May increase the levels/effects of tamoxifen. Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nicardipine, NSAIDs, sulfonamides, and tolbutamide.

CYP2D6 inhibitors: May increase the levels/effects of tamoxifen. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of tamoxifen. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of tamoxifen. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Rifamycins: Rifamycin derivatives may increase the metabolism (via CYP isoenzymes) of tamoxifen.

Warfarin: Concomitant use is contraindicated when used for risk reduction; results in significant enhancement of the anticoagulant effects of warfarin

Pregnancy Risk Factor D

Pregnancy Implications No adequate or well-controlled studies in pregnant women. For sexually-active women of childbearing age, initiate during menstruation (negative β -hCG immediately prior to initiation in women with irregular cycles). Pregnancy should be avoided for 2 months after treatment has been discontinued.

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Increase of bone pain usually indicates a good therapeutic response

Endocrine & metabolic: Libido decreased (1% to 2%)

Gastrointestinal: Diarrhea (4% to 6%), nausea (3% to 4%), stomach discomfort (2% to 3%), bitter taste (2% to 3%)

Neuromuscular & skeletal: Weakness (8% to 9%), back pain (7% to 8%)

Ocular: Amblyopia (0.2% to 2%)

Respiratory: Pharyngitis (5% to 6%), cough (3% to 5%), sinusitis (2% to 4%)

Miscellaneous: Infection (9% to 11%), tooth disorder (1% to 2%)

< 1% (Limited to important or life-threatening): Orthostasis (symptomatic) (0.2% to 0.4%), syncope (0.2% to 0.4%)

Postmarketing and/or case reports: Allergic reactions (rash, angioedema, pruritus, urticaria) priapism; constipation, palpitation, transaminases increased, vomiting

Signs and Symptoms of Overdose Headache, dizziness, syncope, bradycardia, orthostasis, hypotonia

Pharmacodynamics/Kinetics

Absorption: > 90%

Protein binding: 94% to 99%, primarily to α_1 acid glycoprotein (AAG)

Metabolism: Hepatic via CYP; metabolites undergo extensive conjugation to glucuronide or sulfate

Bioavailability: Fasting: 30% increase

Distribution: V_d : 16 L

Steady-state: By the fifth day of once-daily dosing

Half-life elimination: Healthy volunteers: 9-13 hours; Target population: 14-15 hours

Time to peak: Fasting: 4-5 hours; with food: 6-7 hours

Excretion: Urine (76%, < 10% as unchanged drug); feces (21%)

Dosage

Oral: Adults: 0.4 mg once daily ~ 30 minutes after the same meal each day; dose may be increased after 2-4 weeks to 0.8 mg once daily in patients who fail to respond. If therapy is interrupted for several days, restart with 0.4 mg once daily.

Dosage adjustment in renal impairment:

$Cl_{cr} \geq 10$ mL/minute: No adjustment needed

$Cl_{cr} < 10$ mL/minute: Not studied

Administration Capsules should be swallowed whole; do not crush, chew, or open.

Contraindications Hypersensitivity to tamsulosin or any component of the formulation; concurrent use with phosphodiesterase-5 (PDE-5) inhibitors including sildenafil (>25 mg), tadalafil (if tamsulosin dose >0.4 mg/day), or vardenafil

Warnings Not intended for use as an antihypertensive drug. May cause orthostasis, syncope or dizziness. Patients should avoid situations where injury may occur as a result of syncope. Rule out prostatic carcinoma before beginning therapy with tamsulosin. Intraoperative Floppy Iris Syndrome occurred most often in patients taking their alpha-1 blocker at the time of cataract surgery, but some cases occurred when the alpha-1 blocker was stopped 2-14 days prior to surgery and as long as 5 weeks to 9 months prior to surgery. The benefit of stopping an alpha-1 blocker prior to cataract surgery has not been established. Rarely, patients with a sulfa allergy have also developed an allergic reaction to tamsulosin; avoid use when previous reaction has been severe.

Dosage Forms Capsule, as hydrochloride: 0.4 mg

Overdosage/Treatment

Decontamination: Oral: Administer activated charcoal

Supportive therapy: To treat hypotension, first administer 10-20 mL/kg of isotonic crystalloid solution and then place in Trendelenburg position. If vasopressor is needed, norepinephrine (0.5-1 mcg/minute initial dose in adults; 0.1 mcg/kg/minute initial dose in children - titrate to desired effect) is preferred agent. Seizures can be treated with benzodiazepine or phenobarbital.

Drug Interactions

Substrate (major) of CYP2D6, 3A4

Alpha-adrenergic blockers: Risk of hypotension may increase in combination with other alpha-adrenergic blocking agents.

Beta-blockers: Beta-blockers may increase risk of first-dose orthostatic hypotension of tamsulosin

Calcium channel blockers: Risk of hypotension may increase

Cimetidine: Cimetidine may decrease tamsulosin clearance.

CYP2D6 inhibitors: May increase the levels/effects of tamsulosin. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of tamsulosin. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of tamsulosin. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Sildenafil, tadalafil, vardenafil: Blood pressure-lowering effects are additive. Use of vardenafil is contraindicated by the manufacturer.

Tamsulosin

Pronunciation (tam SOO loe sin)

CAS Number 106463-17-6

U.S. Brand Names Flomax®

Synonyms Tamsulosin Hydrochloride

Use Treatment of signs and symptoms of benign prostatic hyperplasia (BPH)

Mechanism of Action Tamsulosin is an antagonist of α_{1A} adrenoceptors in the prostate. Smooth muscle tone in the prostate is mediated by α_{1A} adrenoceptors; blocking them leads to relaxation of smooth muscle in the bladder neck and prostate causing an improvement of urine flow and decreased symptoms of BPH. Approximately 75% of the α_{1A} receptors in the prostate are of the α_{1A} subtype.

Adverse Reactions

> 10%:

Cardiovascular: Studies specific for orthostatic hypotension: Overall, at least one positive test was observed in 16% of patients receiving 0.4 mg and 19% of patients receiving the 0.8 mg dose. "First-dose" orthostatic hypotension following a 0.4 mg dose was reported as 7% at 4 hours postdose and 6% at 8 hours postdose.

Central nervous system: Headache (19% to 21%), dizziness (15% to 17%)

Genitourinary: Abnormal ejaculation (8% to 18%)

Respiratory: Rhinitis (13% to 18%)

1% to 10%:

Cardiovascular: Chest pain (~ 4%)

Central nervous system: Somnolence (3% to 4%), insomnia (1% to 2%), vertigo (0.6% to 1%)

TEMAZEPAM

Use sildenafil with extreme caution (dose \leq 25 mg). Tadalafil may be used when tamsulosin dose is \leq 0.4 mg/day.

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic effects were not observed in animal studies, however, tamsulosin is not indicated for use in women.

Lactation Not indicated for use in women

Specific References

Anand JS, Chodorowski Z, Wisniewski M, et al, "Acute Intoxiation with Tamsulosin Hydrochloride," *J Tox Clin Tox*, 2005, 43:311.

Temazepam

CAS Number 846-50-4

U.S. Brand Names Restoril®

Impairment Potential Yes. A single oral 20 mg dose at bedtime may cause driving impairment for as long as 12-24 hours. Brief or extended periods of exposure are less likely to cause driving impairment in the elderly compared with the longer half-life benzodiazepines. (Betts TA and Birtle J, "Effect of Two Hypnotic Drugs on Actual Driving Performances Next Morning," *Br Med J*, 1982, 285(6345):852.)

Use Treatment of anxiety and as an adjunct in the treatment of depression; also may be used in the management of panic attacks; transient insomnia and sleep latency

Unlabeled/Investigational Use Treatment of anxiety; adjunct in the treatment of depression; management of panic attacks

Mechanism of Action Benzodiazepine anxiolytic sedative that produces CNS depression at the subcortical level, except at high doses, whereby it works at the cortical level

Adverse Reactions

Cardiovascular: Palpitations

Central nervous system: Drowsiness (9.1%), anxiety (2%), ataxia, fatigue (4.8%), depression (1.7%), headache (8.5%), confusion (1.7%), dizziness (4.5%), amnesia, night terrors (1.2%), nervousness (4.6%), lethargy (4.5%), "hangover" effect (2.5%), euphoria (1.5%), vertigo (1.2%), hallucinations, aggressive behavior

Dermatologic: Urticaria, purpura, bullous eruptions, licheniform eruptions, exanthem

Gastrointestinal: Xerostomia (1.7%), diarrhea (1.7%), abdominal discomfort (1.5%), nausea (3.1%), vomiting, anorexia

Neuromuscular & skeletal: Weakness (1.4%), tremor, backache, paresthesia

Ocular: Blurred vision (1.3%), burning eyes

Respiratory: Dyspnea

Miscellaneous: Diaphoresis, fixed drug eruption, acute atraumatic compartment syndrome

Signs and Symptoms of Overdose Ataxia, cognitive dysfunction, coma, dyspnea, confusion, diarrhea, hypoactive reflexes, hyporeflexia, hypotension, hypothermia, night terrors, slurred speech, somnolence

Pharmacodynamics/Kinetics

Distribution: V_d : 1.4 L/kg

Protein binding: 96%

Metabolism: Hepatic

Half-life elimination: 9.5-12.4 hours

Time to peak, serum: 2-3 hours

Excretion: Urine (80% to 90% as inactive metabolites)

Dosage Adults: Oral: 15-30 mg at bedtime; 15 mg in elderly or debilitated patients

Monitoring Parameters Respiratory and cardiovascular status

Contraindications Hypersensitivity to temazepam or any component of the formulation (cross-sensitivity with other benzodiazepines may exist); narrow-angle glaucoma (not in product labeling, however, benzodiazepines are contraindicated); pregnancy

Warnings

Should be used only after evaluation of potential causes of sleep disturbance. Failure of sleep disturbance to resolve after 7-10 days may indicate psychiatric or medical illness. A worsening of insomnia or the emergence of new abnormalities of thought or behavior may represent unrecognized psychiatric or medical illness and requires immediate and careful evaluation.

Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics), or renal impairment. Use with caution in patients with respiratory disease, or impaired gag reflex. Avoid use in patients with sleep apnea.

Causes CNS depression (dose-related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury and should be used with extreme caution in patients who are at risk of these events (especially the elderly).

Use caution in patients with depression, particularly if suicidal risk may be present. Use with caution in patients with a history of drug dependence.

Benzodiazepines have been associated with dependence and acute withdrawal symptoms on discontinuation or reduction in dose (may occur after as little as 10 days). Acute withdrawal, including seizures, may be precipitated after administration of flumazenil to patients receiving long-term benzodiazepine therapy.

Benzodiazepines have been associated with anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior, have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Dosage Forms Capsule: 15 mg, 30 mg

Restoril®: 7.5 mg, 15 mg, 30 mg

Reference Range Therapeutic: 26 ng/mL after 24 hours; can be quantified by high performance liquid chromatography; postmortem levels $>$ 88.5 ng/mL have been correlated with fatalities

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Treatment for benzodiazepine overdose is supportive. Rarely is mechanical ventilation required. Flumazenil has been shown to reverse benzodiazepine-induced CNS depression.

Enhancement of elimination: Multiple dosing of activated charcoal is effective; hemodialysis/forced diuresis is of no utility

Antidote(s)

● Flumazenil [ANTIDOTE]

Test Interactions Visine®, Drano®, bleach may cause false-negative urine tests; oxazepam may interfere giving falsely elevated glucose results

Drug Interactions **Substrate** (minor) of CYP2B6, 2C9, 2C19, 3A4

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect

Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation

Pregnancy Risk Factor X

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Usage Implications Provide safety measures (ie, side rails, night light, and call button); remove smoking materials from area; supervise ambulation

Additional Information Causes minimal change in REM sleep patterns

Tenecteplase

CAS Number 191588-94-0

U.S. Brand Names TNKase™

Use Thrombolytic agent used in the management of acute myocardial infarction for the lysis of thrombi in the coronary vasculature to restore perfusion and reduce mortality

Unlabeled/Investigational Use Acute MI – combination regimen of tenecteplase (unlabeled dose), abciximab, and heparin (unlabeled dose)

Mechanism of Action Initiates fibrinolysis by binding to fibrin and converting plasminogen to plasmin; more fibrin-specific than alteplase or reteplase. Produced by recombinant DNA technology through Chinese hamster ovary cells.

Adverse Reactions

As with all drugs which may affect hemostasis, bleeding is the major adverse effect associated with tenecteplase. Hemorrhage may occur at virtually any site. Risk is dependent on multiple variables, including the dosage administered, concurrent use of multiple agents which alter hemostasis, and patient predisposition. Rapid lysis of coronary artery thrombi by thrombolytic agents may be associated with reperfusion-related arterial and/or ventricular arrhythmias. The incidence of stroke and bleeding increase in patients $>$ 65 years.

Central nervous system: Stroke, intracranial hemorrhage (0.9%)

Dermatologic: Angioedema, rash, urticaria

Gastrointestinal: GI hemorrhage, retroperitoneal bleeding

Genitourinary: GU bleeding

Hematologic: **Bleeding** (22% minor: ASSENT-2 trial; 5% major: ASSENT-2 trial)

Local: Bleeding at catheter puncture site, **hematoma**

Respiratory: Pharyngeal bleeding, respiratory tract bleeding, laryngeal edema, epistaxis

Miscellaneous: Anaphylaxis, cholesterol embolism (clinical features may include livedo reticularis, "purple toe" syndrome, acute renal failure, gangrenous digits, hypertension, pancreatitis, myocardial infarction, cerebral infarction, spinal cord infarction, retinal artery occlusion, bowel infarction, rhabdomyolysis)

Additional effects associated with use in myocardial infarction:

Cardiovascular: Cardiogenic shock, arrhythmias, AV block, heart failure, cardiac arrest, recurrent myocardial ischemia, myocardial reinfarction, myocardial rupture, cardiac tamponade, pericarditis, pericardial effusion, mitral regurgitation, thrombosis, embolism, electromechanical dissociation, hypotension

Central nervous system: Fever

Gastrointestinal: Nausea, vomiting
Respiratory: Pulmonary edema

Pharmacodynamics/Kinetics

Distribution: V_d is weight related and approximates plasma volume
Metabolism: Primarily hepatic
Half-life elimination: 90-130 minutes
Excretion: Clearance: Plasma: 99-119 mL/minute

Dosage

I.V.:

Adult: Recommended total dose should not exceed 50 mg and is based on patient's weight; administer as a bolus over 5 seconds
If patient's weight is:

- < 60 kg, dose: 30 mg (6 mL in volume)
- ≥ 60 to < 70 kg, dose: 35 mg (7 mL in volume)
- ≥ 70 to < 80 kg, dose: 40 mg (8 mL in volume)
- ≥ 80 to < 90 kg, dose: 45 mg (9 mL in volume)
- ≥ 90 kg, dose: 50 mg (10 mL in volume)

All patients should receive 150-325 mg of aspirin as soon as possible and then daily. Intravenous heparin should be initiated as soon as possible and aPTT maintained between 50-70 seconds.

Dosage adjustment in renal impairment: No formal recommendations for renal impairment

Dosage adjustment in hepatic impairment: Severe hepatic failure is a relative contraindication. Recommendations were not made for mild to moderate hepatic impairment.

Elderly: Although dosage adjustments are not recommended, the elderly have a higher incidence of morbidity and mortality with the use of tenecteplase. The 30-day mortality in the ASSENT-2 trial was 2.5% for patients < 65 years, 8.5% for patients 65-74 years, and 16.2% for patients ≥ 75 years. The intracranial hemorrhage rate was 0.4% for patients < 65, 1.6 % for patients 65-74 years, and 1.7 % for patients ≥ 75. The risks and benefits of use should be weighed carefully in the elderly.

Stability Store at room temperature not to exceed 30°C (86°F) or under refrigeration 2°C to 8°C (36°F to 46°F). If reconstituted and not used immediately, store in refrigerator and use within 8 hours.

Monitoring Parameters CBC, aPTT, signs and symptoms of bleeding, ECG monitoring

Administration Tenecteplase should be reconstituted using the supplied 10 cc syringe with TwinPak™ dual cannula device and 10 mL sterile water for injection. Do not shake when reconstituting. Slight foaming is normal and will dissipate if left standing for several minutes. The reconstituted solution is 5 mg/mL. Any unused solution should be discarded. Tenecteplase is **incompatible** with dextrose solutions. Dextrose-containing lines must be flushed with a saline solution before and after administration. Administer as a single I.V. bolus over 5 seconds.

Contraindications Hypersensitivity to tenecteplase or any component of the formulation; active internal bleeding; history of stroke; intracranial/intraspinal surgery or trauma within 2 months; intracranial neoplasm; arteriovenous malformation or aneurysm; bleeding diathesis; severe uncontrolled hypertension

Warnings Stop antiplatelet agents and heparin if serious bleeding occurs. Avoid I.M. injections and nonessential handling of the patient for a few hours after administration. Monitor for bleeding complications. Venipunctures should be performed carefully and only when necessary. If arterial puncture is necessary, then use an upper extremity that can be easily compressed manually. For the following conditions, the risk of bleeding is higher with use of tenecteplase and should be weighed against the benefits: Recent major surgery, cerebrovascular disease, recent GI or GU bleed, recent trauma, uncontrolled hypertension (systolic BP ≥ 180 mm Hg and/or diastolic BP ≥ 110 mm Hg), suspected left heart thrombus, acute pericarditis, subacute bacterial endocarditis, hemostatic defects, severe hepatic dysfunction, pregnancy, hemorrhagic diabetic retinopathy or other hemorrhagic ophthalmic conditions, septic thrombophlebitis or occluded arteriovenous cannula at seriously infected site, advanced age (see Usual Dosing, Elderly), anticoagulants, recent administration of GP IIb/IIIa inhibitors. Coronary thrombolysis may result in reperfusion arrhythmias. Caution with readministration of tenecteplase. Safety and efficacy have not been established in pediatric patients. Cholesterol embolism has rarely been reported.

Dosage Forms Injection, powder for reconstitution, recombinant: 50 mg [packaged with diluent and syringe]

Reference Range Peak plasma tenecteplase usually exceeds 1000 ng/mL

Overdosage/Treatment Supportive therapy: Treat bleeding complications with transfusions of red blood cells, fresh frozen plasma, and cryoprecipitate; do not administer dextran; although human overdose data is lacking, administration of aminocaproic acid (Amicar®) at a dose of 3-5 g I.V. followed by an infusion rate of 1-1.25 g/hour may be useful

Drug Interactions Aminocaproic acid (antifibrinolytic agent) may decrease effectiveness.

Drugs which affect platelet function (eg, NSAIDs, dipyridamole, ticlopidine, clopidogrel, IIb/IIIa antagonists) may potentiate the risk of hemorrhage; use with caution.

Heparin and aspirin: Use with aspirin and heparin may increase bleeding. However, aspirin and heparin were used concomitantly with tenecteplase in the majority of patients in clinical studies.

Warfarin or oral anticoagulants: Risk of bleeding may be increased during concurrent therapy.

Pregnancy Risk Factor C

Pregnancy Implications Administer to pregnant women only if the potential benefits justify the risk to the fetus. Exercise caution when administering to a nursing woman. No embryo toxicity noted in rodent studies.

Lactation Use caution

Nursing Implications Dextrose-containing lines must be flushed with a saline solution before and after administration. Check frequently for signs of bleeding. Avoid I.M. injections and nonessential handling of patient.

Additional Information Intracranial hemorrhage associated with higher doses of heparin (which is coadministered) and with bolus administration of thrombolytics. Information can be obtained as needed through Genentec, Inc: (800) 551-2231 or (650) 225-1100.

Tenidap

Unlabeled/Investigational Use Rheumatoid arthritis, osteoarthritis
Mechanism of Action Inhibits cyclooxygenase and 5-lipoxygenase impairing prostaglandin and leukotriene production

Adverse Reactions

Central nervous system: Dizziness, headache
Gastrointestinal (noted in ~25% of patients): Nausea, constipation
Otic: Tinnitus
Renal: Reversible proteinuria

Toxicodynamics/Kinetics

Onset of action: Within 24 hours
Protein binding: 99%

Dosage 120 mg/day (usually given in the morning)

Overdosage/Treatment

Decontamination: Activated charcoal
Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage
Enhancement of elimination: Multiple doses of activated charcoal; dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone

Additional Information Oxindole-type nonsteroidal agent similar to indomethacin; may slow progressive joint erosion

Terazosin

CAS Number 63074-08-8; 63590-64-7; 70024-40-7

U.S. Brand Names Hytrin®

Impairment Potential Yes

Use Management of mild to moderate hypertension; alone or in combination with other agents such as diuretics or beta-blockers; benign prostate hyperplasia (BPH)

Mechanism of Action An alpha₁-specific blocking agent with minimal alpha₂ effects; this allows peripheral postsynaptic blockade, with the resultant decrease in arterial tone, while preserving the negative feedback loop which is mediated by the peripheral presynaptic alpha₂-receptors (similar in action to prazosin but longer duration of action)

Adverse Reactions

Cardiovascular: **Hypotension (orthostatic)**, syncope, palpitations, tachycardia, edema, sinus tachycardia, atrial fibrillation
Central nervous system: **Dizziness, lightheadedness**, night terrors, **drowsiness, malaise, headache**, hypothermia
Dermatologic: Rash, licheniform eruptions
Endocrine & metabolic: Fluid retention, sexual dysfunction
Gastrointestinal: Nausea, xerostomia
Genitourinary: Urinary frequency, priapism
Hematologic: Thrombocytopenia
Neuromuscular & skeletal: Weakness, paresthesia
Ocular: Blurred vision, phototoxic
Respiratory: Nasal congestion
Miscellaneous: Allergic reactions, anaphylaxis

Signs and Symptoms of Overdose Drowsiness, dyspnea, hypotension, hypothermia, impotence, night terrors, shock, syncope

Pharmacodynamics/Kinetics

Onset of action: 1-2 hours
Absorption: Rapid
Protein binding: 90% to 95%
Metabolism: Extensively hepatic
Half-life elimination: 9.2-12 hours
Time to peak, serum: ~1 hour
Excretion: Feces (60%); urine (40%)

Dosage**Oral: Adults:**

Hypertension: Initial: 1 mg at bedtime; slowly increase dose to achieve desired blood pressure, up to 20 mg/day; usual dose range (JNC 7): 1-20 mg once daily

Dosage reduction may be needed when adding a diuretic or other antihypertensive agent; if drug is discontinued for greater than several days, consider beginning with initial dose and retitrate as needed; dosage may be given on a twice daily regimen if response is diminished at 24 hours and hypotensive is observed at 2-4 hours following a dose

Benign prostatic hyperplasia: Initial: 1 mg at bedtime, increasing as needed; most patients require 10 mg day; if no response after 4-6 weeks of 10 mg/day, may increase to 20 mg/day

Monitoring Parameters Standing and sitting/supine blood pressure, especially following the initial dose at 2-4 hours following the dose and thereafter at the trough point to ensure adequate control throughout the dosing interval; urinary symptoms

Contraindications Hypersensitivity to quinazolines (doxazosin, prazosin, terazosin) or any component of the formulation; concurrent use with phosphodiesterase-5 (PDE-5) inhibitors including sildenafil (>25 mg), tadalafil, or vardenafil

Warnings Can cause significant orthostatic hypotension and syncope, especially with first dose; anticipate a similar effect if therapy is interrupted for a few days, if dosage is rapidly increased, or if another antihypertensive drug (particularly vasodilators) or a PDE5 inhibitor is introduced. Patients should be cautioned about performing hazardous tasks when starting new therapy or adjusting dosage upward. Prostate cancer should be ruled out before starting for BPH. Use with caution in hepatic impairment. Intraoperative floppy iris syndrome has been observed in cataract surgery patients who were on or were previously treated with alpha₁ blockers. Causality has not been established and there appears to be no benefit in discontinuing alpha blocker therapy prior to surgery. Safety and efficacy in children have not been established.

Dosage Forms Capsule: 1 mg, 2 mg, 5 mg, 10 mg

Reference Range Single dose of 5 mg produces a peak concentration of 45 mcg/L at 2 hours

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral vasoconstrictor may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Treatment is primarily supportive and symptomatic.

Enhancement of elimination: Multiple dosing of activated charcoal would not be expected to be effective

Test Interactions No effect on lipid profile

Drug Interactions

ACE inhibitors: Hypotensive effect may be increased.

Beta-blockers: Hypotensive effect may be increased.

Calcium channel blockers: Hypertensive effect may be increased.

NSAIDs may reduce antihypertensive efficacy.

Sildenafil, tadalafil, vardenafil: Blood pressure-lowering effects are additive. Use of tadalafil or vardenafil is contraindicated by the manufacturer. Use sildenafil with extreme caution (dose ≤25 mg).

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Additional Information Considered a step 2 drug in stepped approach to hypertension

Specific References

Chobanian AV, Bakris GL, Black HR, et al, "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, 289(19):2560-71.

Terbinafine

CAS Number 78628-80-5; 91161-71-6

U.S. Brand Names Lamisil® AT™ [OTC]; Lamisil®

Synonyms Terbinafine Hydrochloride

Use

Active against most strains of *Trichophyton mentagrophytes*, *Trichophyton rubrum*; may be effective for infections of *Microsporum gypseum* and *M. nanum*, *Trichophyton verrucosum*, *Epidermophyton floccosum*, *Candida albicans*, and *Scopulariopsis brevicaulis*

Oral: Onychomycosis of the toenail or fingernail due to susceptible dermatophytes

Topical: Antifungal for the treatment of tinea pedis (athlete's foot), tinea cruris (jock itch), and tinea corporis (ringworm) [OTC/prescription formulations]; tinea versicolor [prescription formulations]

Mechanism of Action Synthetic alkylamine derivative which inhibits squalene epoxidases which is a key enzyme in sterol biosynthesis in fungi to result in a deficiency in ergosterol within fungal cell wall and result in fungal cell death

Adverse Reactions**Oral:**

Central nervous system: Headache, dizziness, vertigo, fatigue, malaise

Dermatologic: Rash, pruritus, urticaria, angioedema, alopecia, precipitation/exacerbation of cutaneous lupus erythematosus, Stevens-Johnson syndrome, toxic epidermal necrolysis

Gastrointestinal: Diarrhea, dyspepsia, abdominal pain, appetite decreased, taste disturbance, vomiting

Hematologic: Lymphocytopenia, agranulocytosis, neutropenia, thrombocytopenia

Hepatic: Liver enzymes increased, hepatic failure

Neuromuscular & skeletal: Arthralgia, myalgia

Ocular: Visual disturbances, changes in ocular lens and retina

Miscellaneous: Allergic reactions, anaphylaxis, precipitation/exacerbation of systemic lupus erythematosus

Topical:

Dermatologic: Pruritus, contact dermatitis, irritation, burning, dryness

Local: Irritation, stinging

Pharmacodynamics/Kinetics

Absorption: Topical: Limited (<5%); Oral: >70%

Distribution: V_d: 2000 L; distributed to sebum and skin predominantly

Protein binding, plasma: >99%

Metabolism: Hepatic; no active metabolites; first-pass effect; little effect on CYP

Bioavailability: Oral: 40%

Half-life elimination:

Topical: 22-26 hours

Oral: Terminal half-life: 200-400 hours; very slow release of drug from skin and adipose tissues occurs; effective half-life: ~36 hours

Time to peak, plasma: 1-2 hours

Excretion: Urine (70% to 75%)

Dosage

Children ≥12 years and Adults:

Topical cream, solution:

Athlete's foot (tinea pedis): Apply to affected area twice daily for at least 1 week, not to exceed 4 weeks [OTC/prescription formulations]

Ringworm (tinea corporis) and jock itch (tinea cruris): Apply cream to affected area once or twice daily for at least 1 week, not to exceed 4 weeks; apply solution once daily for 7 days [OTC formulations]

Adults:

Oral:

Superficial mycoses: Fingernail: 250 mg/day for up to 6 weeks; toenail: 250 mg/day for 12 weeks; doses may be given in two divided doses

Systemic mycosis: 250-500 mg/day for up to 16 months

Topical solution: Tinea versicolor: Apply to affected area twice daily for 1 week [prescription formulation]

Dosing adjustment in renal impairment: GFR <50 mL/minute: Oral administration is not recommended.

Dosing adjustment in hepatic impairment: Clearance is decreased by ~50% with hepatic cirrhosis; use is not recommended.

Stability Cream: Store at 5°C to 30°C (41°F to 86°F).

Solution: Store at 5°C to 25°C (41°F to 77°F); do not refrigerate

Tablet: Store below 25°C (77°F); protect from light

Monitoring Parameters CBC and LFTs at baseline and repeated if use is for >6 weeks

Contraindications Hypersensitivity to terbinafine, naftifine, or any component of the formulation

Warnings While rare, the following complications have been reported and may require discontinuation of therapy: Changes in the ocular lens and retina, pancytopenia, neutropenia, Stevens-Johnson syndrome, toxic epidermal necrolysis. Rare cases of hepatic failure (including fatal cases) have been reported following oral treatment of onychomycosis. Not recommended for use in patients with active or chronic liver disease. Discontinue if symptoms or signs of hepatobiliary dysfunction or cholestatic hepatitis develop. If irritation/sensitivity develop with topical use, discontinue therapy. Oral products are not recommended for use with pre-existing liver or renal disease (≤50 mL/minute GFR). **Use caution in writing and/or filling prescription/orders. Confusion between Lamical® (lamotrigine) and Lamisil® (terbinafine) has occurred.**

Dosage Forms Cream, as hydrochloride:

Lamisil® AT™: 1% (12 g) [contains benzyl alcohol]

Solution, as hydrochloride [topical spray]:

Lamisil® [DSC], Lamisil® AT™: 1% (30 mL)

Tablet:

Lamisil®: 250 mg

Reference Range Peak terbinafine level after a 250 mg oral dose is ~1 mcg/mL

Overdosage/Treatment Decontamination: Activated charcoal

Drug Interactions

Substrate (minor) of 1A2, 2C9, 2C19, 3A4; **Inhibits** CYP2D6 (strong); **Induces** CYP3A4 (weak)

Effects of drugs metabolized by CYP2D6 (including beta-blockers, SSRIs, MAO inhibitors, tricyclic antidepressants) may be increased; warfarin effects may be increased

CYP2D6 substrates: Terbinafine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Terbinafine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

Rifampin: Rifampin increases terbinafine clearance (100%).

Pregnancy Risk Factor B

Pregnancy Implications Avoid use in pregnancy since treatment of onychomycosis is postponable

Lactation Enters breast milk/not recommended

Additional Information Fungistatic against *Candida albicans*

Specific References

Terbutaline

CAS Number 23031-32-5

U.S. Brand Names Brethine®

Synonyms Brethaire [DSC]; Bricanyl [DSC]

Use Bronchodilator in reversible airway obstruction and bronchial asthma

Tocolytic agent (management of preterm labor)

Mechanism of Action Relaxes bronchial smooth muscle by action on β_2 -receptors with less effect on heart rate

Adverse Reactions

Cardiovascular: Tachycardia (slight), palpitations, hypertension, flushing, shortened P-R segment, angina, lengthened QT segment, cardiac arrhythmias, fibrillation (atrial), chest pain, flutter (atrial), sinus tachycardia

Central nervous system: **Restlessness, nervousness, dizziness, headache**, CNS stimulation, hyperactivity, insomnia, mania

Dermatologic: Maculopapular rash

Endocrine & metabolic: Hypokalemia, hyperglycemia

Gastrointestinal: GI upset

Neuromuscular & skeletal: **Trembling**, tremors

Signs and Symptoms of Overdose Arrhythmias, chest pain convulsions, hepatitis, hyperglycemia, hypocalcemia, hypokalemia, insomnia, myoglobinuria, nausea, rhabdomyolysis, vomiting

Pharmacodynamics/Kinetics

Onset of action: Oral: 30-45 minutes; SubQ: 6-15 minutes

Protein binding: 25%

Metabolism: Hepatic to inactive sulfate conjugates

Bioavailability: SubQ doses are more bioavailable than oral

Half-life elimination: 11-16 hours

Excretion: Urine

Dosage

Children < 12 years: Bronchoconstriction:

Oral: Initial: 0.05 mg/kg/dose 3 times/day, increased gradually as required; maximum: 0.15 mg/kg/dose 3-4 times/day or a total of 5 mg/24 hours

SubQ: 0.005-0.01 mg/kg/dose to a maximum of 0.3 mg/dose every 15-20 minutes for 3 doses

Children > 12 years and Adults: Bronchoconstriction:

Oral:
12-15 years: 2.5 mg every 6 hours 3 times/day; not to exceed 7.5 mg in 24 hours

> 15 years: 5 mg/dose every 6 hours 3 times/day; if side effects occur, reduce dose to 2.5 mg every 6 hours; not to exceed 15 mg in 24 hours

SubQ: 0.25 mg/dose repeated in 15-30 minutes for one time only; a total dose of 0.5 mg should not be exceeded within a 4-hour period inhalations

Adults: Premature labor (tocolysis; unlabeled use):

Acute: I.V. 2.5-10 mcg/minute; increased gradually every 10-20 minutes; effective maximum dosages from 17.5-30 mcg/minute have been used with caution. Duration of infusion is at least 12 hours.

Maintenance: Oral: 2.5-10 mg every 4-6 hours for as long as necessary to prolong pregnancy depending on patient tolerance

Dosing adjustment/comments in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer at 50% of normal dose

Cl_{cr} < 10 mL/minute: Avoid use

Stability Store injection at room temperature; protect from heat, light, and from freezing; use only clear solutions

Monitoring Parameters Serum potassium, glucose; heart rate, blood pressure, respiratory rate; monitor for signs and symptoms of pulmonary edema (when used as a tocolytic); monitor FEV₁, peak flow, and/or other pulmonary function tests (when used as bronchodilator)

Administration I.V.: Use infusion pump.

Oral: Administer around-the-clock to promote less variation in peak and trough serum levels

Contraindications Hypersensitivity to terbutaline or any component of the formulation; cardiac arrhythmias associated with tachycardia; tachycardia caused by digitalis intoxication

Warnings

When used for tocolysis, there is some risk of maternal pulmonary edema, which has been associated with the following risk factors, excessive hydration, multiple gestation, occult sepsis and underlying cardiac disease. To reduce risk, limit fluid intake to 2.5-3 L/day, limit sodium intake, maintain maternal pulse to < 130 beats/minute.

Use caution in patients with cardiovascular disease (arrhythmia or hypertension or CHF), convulsive disorders, diabetes, glaucoma, hyperthyroidism, or hypokalemia. Beta agonists may cause elevation in blood pressure, heart rate, and result in CNS stimulation/excitation. Beta₂ agonists may increase risk of arrhythmia, increase serum glucose, or decrease serum potassium.

When used as a bronchodilator, optimize anti-inflammatory treatment before initiating maintenance treatment with terbutaline. Do not use as a component of chronic therapy without an anti-inflammatory agent. Only the mildest form of asthma (Step 1 and/or exercise-induced) would not require concurrent use based upon asthma guidelines. Patient must be instructed to seek medical attention in cases where acute symptoms are not relieved or a previous level of response is diminished. The need to increase frequency of use may indicate deterioration of asthma, and treatment must not be delayed.

Do not exceed recommended dose; serious adverse events including fatalities, have been associated with excessive use of inhaled sympathomimetics. Rarely, paradoxical bronchospasm may occur with use of inhaled bronchodilating agents; this should be distinguished from inadequate response.

Dosage Forms Injection, solution, as sulfate: 1 mg/mL (1 mL)

Tablet, as sulfate: 2.5 mg, 5 mg

Additional dosage forms available in Canada: Powder for oral inhalation (Bricanyl® Turbuhaler): 500 mcg/actuation [50 or 200 metered doses]

Reference Range Peak plasma level after a 0.75 mg SubQ dose: ~10 mcg/L 30 minutes after injection

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Prudent use of a cardioselective beta-adrenergic blocker can be considered, keeping in mind the potential for induction of bronchoconstriction in an asthmatic individual; esmolol (150-300 mg/hour) can be safely used to treat tachycardia with hypotension even during pregnancy

Enhancement of elimination: Dialysis has not been shown to be of value

Drug Interactions

Decreased effect with beta-blockers

Increased toxicity with MAO inhibitors, TCAs

Pregnancy Risk Factor B

Lactation Enters breast milk/compatible

Nursing Implications Injection with SubQ use

Additional Information Used unofficially to delay delivery in preterm labor; has short-lived clinical effectiveness with development of tolerance with chronic use

Testosterone

Related Information

- Androstenedione

CAS Number 1045-69-8; 1255-49-8; 14191-92-5; 15262-86-9; 2697-92-9; 315-37-7; 57-85-2; 5721-91-5; 58-20-8; 58-22-0; 5949-44-0

U.S. Brand Names Androderm®; AndroGel®; Delatestryl®; Depo®-Testosterone; Striant™; Testim™; Testoderm® with Adhesive [DSC]; Testoderm® [DSC]; Testopel®

Synonyms Testosterone Cypionate; Testosterone Enanthate

Use

Injection: Androgen replacement therapy in the treatment of delayed male puberty; male hypogonadism (primary or hypogonadotropic); inoperable female breast cancer (enanthate only)

Pellet: Androgen replacement therapy in the treatment of delayed male puberty; male hypogonadism (primary or hypogonadotropic)

Buccal, topical: Male hypogonadism (primary or hypogonadotropic)

Mechanism of Action Principal endogenous androgen responsible for promoting the growth and development of the male sex organs and maintaining secondary sex characteristics in androgen-deficient males

Adverse Reactions

Frequency not defined.

Cardiovascular: Flushing, edema

TESTOSTERONE

Central nervous system: Excitation, aggressive behavior, sleeplessness, anxiety, mental depression, headache

Dermatologic: Hirsutism (increase in pubic hair growth), acne

Endocrine & metabolic: Menstrual problems (amenorrhea), virilism, breast soreness, gynecomastia, hypercalcemia, hypoglycemia

Gastrointestinal: Nausea, vomiting, GI irritation

Following buccal administration: Bitter taste, gum edema, gum or mouth irritation, gum tenderness, taste perversion

Genitourinary: Prostatic hyperplasia, prostatic carcinoma, impotence, testicular atrophy, epididymitis, priapism, bladder irritability

Hepatic: Hepatic dysfunction, cholestatic hepatitis, hepatic necrosis

Hematologic: Leukopenia, polycythemia, suppression of clotting factors

Miscellaneous: Hypersensitivity reactions

Signs and Symptoms of Overdose Cholestatic jaundice, depression, gynecomastia, hirsutism, hypercalcemia, hypertension, hypertrichosis, impotence, jaundice, leukopenia or neutropenia (agranulocytosis, granulocytopenia), oligospermia

Pharmacodynamics/Kinetics

Duration (route and ester dependent): I.M.: Cypionate and enanthate esters have longest duration, \leq 2-4 weeks

Absorption: Transdermal gel: ~10% of applied dose

Distribution: Crosses placenta; enters breast milk

Protein binding: 98%; bound to sex hormone-binding globulin (40%) and albumin

Metabolism: Hepatic; forms metabolites, including dihydrotestosterone (DHT) and estradiol (both active)

Half-life elimination: 10-100 minutes

Excretion: Urine (90%); feces (6%)

Dosage

Adolescents: I.M.:

Male hypogonadism:

Initiation of pubertal growth: 40-50 mg/m²/dose (cypionate or enanthate ester) monthly until the growth rate falls to prepubertal levels

Terminal growth phase: 100 mg/m²/dose (cypionate or enanthate ester) monthly until growth ceases

Maintenance virilizing dose: 100 mg/m²/dose (cypionate or enanthate ester) twice monthly

Delayed male puberty: 40-50 mg/m²/dose monthly (cypionate or enanthate ester) for 6 months

Adolescents and Adults: Pellet (for subcutaneous implantation): Delayed male puberty, male hypogonadism: 150-450 mg every 3-6 months

Adults:

I.M.:

Female: Inoperable breast cancer: Testosterone enanthate: 200-400 mg every 2-4 weeks

Male: Long-acting formulations: Testosterone enanthate (in oil)/testosterone cypionate (in oil):

Hypogonadism: 50-400 mg every 2-4 weeks

Delayed puberty: 50-200 mg every 2-4 weeks for a limited duration

Transdermal: Primary male hypogonadism **or** hypogonadotropic hypogonadism:

Testoderm®: Apply 6 mg patch daily to scrotum (if scrotum is inadequate, use a 4 mg daily system)

Androderm®: Apply two systems nightly to clean, dry area on the back, abdomen, upper arms, or thighs for 24 hours for a total of 5 mg day

AndroGel®, Testim™: 5 g (to deliver 50 mg of testosterone with 5 mg systemically absorbed) applied once daily (preferably in the morning) to clean, dry, intact skin of the shoulder and upper arms. AndroGel® may also be applied to the abdomen. Dosage may be increased to a maximum of 10 g (100 mg). **Do not apply testosterone gel to the genitals.**

Oral (buccal): Hypogonadism or hypogonadotropic hypogonadism: 30 mg twice daily (every 12 hours) applied to the gum region above the incisor tooth

Dosing adjustment/comments in hepatic disease: Reduce dose

Monitoring Parameters Periodic liver function tests, PSA, cholesterol, hemoglobin and hematocrit; radiologic examination of wrist and hand every 6 months (when using in prepubertal children)

Gel: Morning serum testosterone levels 14 days after start of therapy

Administration

I.M.: Warm to room temperature; shaking vial will help redissolve crystals that have formed after storage. Administer by deep I.M. injection into the upper outer quadrant of the gluteus maximus.

Oral: Striant™: One mucoadhesive for buccal application (buccal system) should be applied to a comfortable area above the incisor tooth. Apply flat side of system to gum. Rotate to alternate sides of mouth with each application. Hold buccal system firmly in place for 30 seconds to ensure adhesion. The buccal system should adhere to gum for 12 hours. If the buccal system falls out, replace with a new system. If the system falls out within 4 hours of next dose, the new buccal system should remain in place until the time of the following scheduled dose. System will soften and mold to shape of gum as it absorbs moisture from mouth. Do not

chew or swallow the buccal system. The buccal system will not dissolve; gently remove by sliding downwards from gum; avoid scratching gum.

Transdermal:

Androderm®: Apply to clean, dry area of skin on the arm, back, or upper buttocks.

Testoderm®: Apply to clean, dry scrotal skin. Dry shave scrotal hair for optimal skin contact. Do not use chemical depilatories.

AndroGel®, Testim™: Apply (preferably in the morning) to clean, dry, intact skin of the shoulder and upper arms (AndroGel® may also be applied to the abdomen). Upon opening the packet(s), the entire contents should be squeezed into the palm of the hand and immediately applied to the application site(s). Alternatively, a portion may be squeezed onto palm of hand and applied, repeating the process until entire packet has been applied. Application sites should be allowed to dry for a few minutes prior to dressing. Hands should be washed with soap and water after application. **Do not apply testosterone gel to the genitals.**

Contraindications Hypersensitivity to testosterone, soy, or any component of the formulation; males with carcinoma of the breast or prostate; pregnancy or women who may become pregnant

Systemic use is contraindicated in hepatic, renal, or cardiac disease; benign prostatic hyperplasia with obstruction; undiagnosed genital bleeding; hypercalcemia

Warnings When used to treat delayed male puberty, perform radiographic examination of the hand and wrist every 6 months to determine the rate of bone maturation. May cause hypercalcemia in patients with prolonged immobilization. May accelerate bone maturation without producing compensating gain in linear growth. Has both androgenic and anabolic activity, the anabolic action may enhance hypoglycemia. Use caution in elderly patients or patients with other demographic factors which may increase the risk of prostatic carcinoma; careful monitoring is required. May cause fluid retention; use caution in patients with cardiovascular disease or other edematous conditions. Prolonged use of orally-active androgens has been associated with serious hepatic effects (hepatitis, hepatic neoplasms, cholestatic hepatitis, jaundice). May potentiate sleep apnea in some male patients (obesity or chronic lung disease). Transdermal patch may contain conducting metal (eg, aluminum); remove patch prior to MRI. Gels and buccal system have not been evaluated in males < 18 years of age; safety and efficacy of injection have not been established in males < 12 years of age.

Dosage Forms [CAN] = Canadian brand name

Capsule, gelatin, as deconate (Andriol™ [CAN]): 40 mg (10s) [not available in U.S.]

Gel, topical:

AndroGel®:

1.25 g/actuation (75 g) [1% metered-dose pump; delivers 5 g/4 actuations; provides 60 1.25 g actuations; contains ethanol]

2.5 g (30s) [1% unit dose packets; contains ethanol]

5 g (30s) [1% unit dose packets; contains ethanol]

Testim®: 5 g (30s) [1% unit-dose tube; contains ethanol]

Injection, in oil, as cypionate: 200 mg/mL (10 mL)

Depo®-Testosterone: 100 mg/mL (10 mL); 200 mg/mL (1 mL, 10 mL) [contains benzyl alcohol, benzyl benzoate, and cottonseed oil]

Injection, in oil, as enanthate: 200 mg/mL (5 mL)

Delatestryl®: 200 mg/mL (1 mL) [prefilled syringe; contains sesame oil]; (5 mL) [multidose vial; contains sesame oil]

Kit [for prescription compounding testosterone 2%; kits also contain mixing jar and stirrer]:

First® Testosterone:

Injection, in oil: Testosterone propionate 100 mg/mL (12 mL) [contains sesame oil and benzyl alcohol]

Ointment: White petroleum (48 g)

First® Testosterone MC:

Injection, in oil: Testosterone propionate 100 mg/mL (12 mL) [contains sesame oil and benzyl alcohol]

Cream: Moisturizing cream (48 g)

Mucoadhesive, for buccal application [buccal system] (Striant®): 30 mg (10s)

Pellet, for subcutaneous implantation (Testopel®): 75 mg (1 pellet/vial)

Transdermal system (Androderm®): 2.5 mg/day (60s); 5 mg/day (30s) [contains ethanol]

Reference Range

Testosterone, urine:

Male: 100-1500 ng/24 hours

Female: 100-500 ng/24 hours

Normal serum ranges (male): 12.1-35.7 nmol/L

Normal ratio of testosterone to epitestosterone: <6

Injected agents can be detectable in urine for 2 months while oral agents can be detectable for 2 weeks

Overdosage/Treatment

Decontamination: Oral: Activated charcoal

Supportive therapy: Clomiphene (100 mg/day) may restore pituitary hormone levels (and free testosterone levels) following recreational

steroid-induced pituitary-gonadal failure. Pruritic rash due to transdermal testosterone can be treated with topical corticosteroids.

Test Interactions May cause a decrease in creatinine and creatine excretion and an increase in the excretion of 17-ketosteroids; decreases total T₄ serum level due to a decrease in thyroxine-binding globulin (free T₄ is unchanged)

Drug Interactions

Substrate (minor) of CYP2B6, 2C9, 2C19, 3A4; **Inhibits** CYP3A4 (weak)
Warfarin: Testosterone may increase the effects warfarin.

Pregnancy Risk Factor X

Pregnancy Implications Testosterone may cause adverse effects, including masculinization of the female fetus, if used during pregnancy. Females who are or may become pregnant should also avoid skin-to-skin contact to areas where testosterone has been applied topically on another person.

Lactation Enters breast milk/contraindicated

Nursing Implications Warm injection to room temperature and shaking vial will help redissolve crystals that have formed after storage; administer by deep I.M. injection into the upper outer quadrant of the gluteus maximus. Transdermal system (Testoderm®) should be applied on clean, dry, scrotal skin. Dry-shave scrotal hair for optimal skin contact. Do not use chemical depilatories. Androderm® and Testoderm® TTS should be applied to clean dry area of skin on the arm, back, or upper buttocks.

Additional Information Relative potency values: Methyltestosterone*: 1.15; mesterolone: 1.15; methandrostenolone: 1.7; metanozolol*: 5; oxandrolone*: 11.3; nandrolone decanoate: 11.3

*Associated with severe hepatic toxicity

Specific References

Maitre A, Saudan C, Mangin P, et al, "Urinary Analysis of Four Testosterone Metabolites and Pregnanediol by Gas Chromatography-Combustion-Isotope Ratio Mass Spectrometry After Oral Administrations of Testosterone," *J Anal Toxicol*, 2004, 28(6):426-31.

Tetracaine

CAS Number 136-47-0; 94-24-6

U.S. Brand Names AK-T-Caine™; Cepacol Viractin® [OTC]; Opticaine®; Pontocaine®

Synonyms Amethocaine Hydrochloride; Tetracaine Hydrochloride

Use Spinal anesthesia; local anesthesia in the eye for various diagnostic and examination purposes; topically applied to nose and throat for various diagnostic procedures; topical gel [OTC] for treatment of pain associated with cold sores and fever blisters; **approximately 10 times more potent than procaine**

Mechanism of Action Blocks both the initiation and conduction of nerve impulses by decreasing the neuronal membrane's permeability to sodium ions, which results in inhibition of depolarization with resultant blockade of conduction

Adverse Reactions

Injection:

Cardiovascular: Cardiac arrest, hypotension
Central nervous system: Chills, convulsions, dizziness, drowsiness, nervousness, unconsciousness
Gastrointestinal: Nausea, vomiting
Neuromuscular & skeletal: Tremors
Ocular: Blurred vision, pupil constriction
Otic: Tinnitus
Respiratory: Respiratory arrest
Miscellaneous: Allergic reaction

Ophthalmic: Ocular: Chemosis, lacrimation, photophobia, transient stinging

With chronic use: Corneal erosions, corneal healing retardation, corneal opacification (permanent), corneal scarring, keratitis (severe)

Signs and Symptoms of Overdose Apnea, bradycardia, cataract, hypotension, lacrimation, ototoxicity, respiratory depression, seizures, tinnitus

Pharmacodynamics/Kinetics

Onset of action: Anesthetic: Rhinology: 5-10 minutes

Duration: Rhinology: ~30 minutes

Metabolism: Hepatic; detoxified by plasma esterases to aminobenzoic acid

Excretion: Urine

Dosage Children ≥2 years and Adults: Topical gel [OTC]: Cold sores and fever blisters: Apply to affected area up to 3-4 times/day for up to 7 days

Adults:

Ophthalmic solution (not for prolonged use): Instill 1-2 drops

Spinal anesthesia:

High, medium, low, and saddle blocks: 0.2% to 0.3% solution

Prolonged (2-3 hours): 1% solution

Subarachnoid injection: 5-20 mg

Saddle block: 2-5 mg; a 1% solution should be diluted with equal volume of CSF before administration

Topical mucous membranes (2% solution): Apply as needed; dose should not exceed 20 mg

Stability Store the solutions in the refrigerator; **incompatible** with alkalis
Administration Before injection, withdraw syringe plunger to make sure injection is not into vein or artery

Contraindications Hypersensitivity to tetracaine, ester-type anesthetics, aminobenzoic acid, or any component of the formulation; injection should not be used when spinal anesthesia is contraindicated

Warnings Use with caution in patients with cardiac disease, hyperthyroidism, abnormal or decreased levels of plasma esterases. Use of the lowest effective dose is recommended. Acutely ill, elderly, debilitated, obstetric patients, or patients with increased intra-abdominal pressure may require decreased doses. Products may contain sodium bisulfite which may cause allergic reactions in some individuals.

Ophthalmic: May delay wound healing. Prolonged use is not recommended. The anesthetized eye should be protected from irritation, foreign bodies, and rubbing to prevent inadvertent damage.

Dosage Forms [DSC] = Discontinued product

Injection, solution, as hydrochloride [preservative free] (Pontocaine®): 1% [10 mg/mL] (2 mL) [contains sodium bisulfite]

Injection, solution, as hydrochloride [premixed in dextrose 6%] (Pontocaine®): 0.3% [3 mg/mL] (5 mL) [DSC]

Injection, powder for reconstitution, as hydrochloride [preservative free] (Pontocaine® Niphanoid®): 20 mg

Solution, ophthalmic, as hydrochloride: 0.5% [5 mg/mL] (15 mL)

Solution, topical, as hydrochloride (Pontocaine®): 2% [20 mg/mL] (30 mL, 118 mL) [for rhinolaryngology]

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/irrigate/activated charcoal

Supportive therapy: Treatment is primarily symptomatic and supportive.

Termination of anesthesia by pneumatic tourniquet inflation should be attempted when the agent is administered by infiltration or regional injection. Seizures commonly respond to diazepam or lorazepam, while hypotension responds to I.V. fluids and Trendelenburg positioning. With the development of metabolic acidosis, I.V. sodium bicarbonate 0.5-2 mEq/kg and ventilatory assistance should be instituted.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Pregnancy Risk Factor C

Pregnancy Implications Animal reproduction studies have not been conducted.

Lactation Excretion in breast milk unknown/use caution

Additional Information Approximately 10 times more potent than procaine

Tetracycline

Related Information

- Minocycline
- Therapeutic Drugs Associated with Hallucinations

CAS Number 1336-20-5; 60-54-8; 64-75-5; 6416-04-2

U.S. Brand Names Sumycin®; Wesmycin®

Synonyms Achromycin; TCN; Tetracycline Hydrochloride

Use Treatment of susceptible bacterial infections of both gram-positive and gram-negative organisms; also some unusual organisms including *Mycoplasma*, *Chlamydia*, and *Rickettsia*; may also be used for acne, exacerbations of chronic bronchitis, treatment of "seal finger", *Helicobacter pylori*, and treatment of gonorrhea and syphilis in patients that are allergic to penicillin

Mechanism of Action Inhibits bacterial protein synthesis by binding with the 30S and possibly the 50S ribosomal subunit(s) of susceptible bacteria; may also cause alterations in the cytoplasmic membrane

Adverse Reactions

Cardiovascular: Intracranial hypertension, myocarditis (hypersensitivity), congestive heart failure, myocardial depression, myocarditis, vasculitis
Central nervous system: Pseudotumor cerebri, visual hallucinations, drug fever, Jarisch-Herxheimer reaction, hyperthermia

Dermatologic: Rash, exfoliative dermatitis, photosensitivity, toxic epidermal necrolysis, angioedema, Stevens-Johnson syndrome, bullous skin disease, urticaria, purpura, psoriasis, yellow fingernail, exanthem, solar urticaria, lichen planus, cutaneous vasculitis

Gastrointestinal: Discoloration of teeth and enamel hypoplasia (infants), nausea, vomiting, diarrhea, stomatitis, glossitis, antibiotic-associated pseudomembranous colitis, esophagitis, xerostomia, pancreatitis, esophageal ulceration, fecal discoloration (black, greenish gray, red, white/speckling), peritoneal adhesions, lingua villosa nigra, photo-onycholysis

Hematologic: Neutropenia, hemolysis, hypoprothrombinemia, aplastic anemia

Hepatic: Hepatic steatosis (at doses > 1 g/day I.V.); fatty degeneration of liver

Local: Extravasation injury

Neuromuscular & skeletal: Myasthenia gravis (exacerbation), paresthesia

Ocular: Myopia, phototoxic

TETRAHYDROZOLINE

Renal: Renal damage, Fanconi-like syndrome, renal tubular acidosis type II, uremia

Respiratory: Pulmonary infiltrates with eosinophilia, asthma, bronchospasm

Miscellaneous: Hypersensitivity reactions, incidence of *Candida* superinfection (increased), exacerbation of systemic lupus erythematosus, injury to growing bones and teeth, fixed drug eruption

Signs and Symptoms of Overdose Azotemia, coagulopathy, colitis, diplopia, dysphagia, Fanconi syndrome, hypoglycemia, hypothermia, lichenoid eruptions, metallic taste, myasthenia gravis (exacerbation or precipitation), nausea, thrombocytopenia, tongue discoloration, toxic epidermal necrolysis, vomiting

Pharmacodynamics/Kinetics

Absorption: Oral: 75%

Distribution: Small amount appears in bile

Relative diffusion from blood into CSF: Good only with inflammation (exceeds usual MICs)

CSF:blood level ratio: Inflamed meninges: 25%

Protein binding: ~65%

Half-life elimination: Normal renal function: 8-11 hours; End-stage renal disease: 57-108 hours

Time to peak, serum: Oral: 2-4 hours

Excretion: Urine (60% as unchanged drug); feces (as active form)

Dosage

Oral:

Children >8 years: 25-50 mg/kg/day in divided doses every 6 hours

Adults: 250-500 mg/dose every 6 hours

Helicobacter pylori eradication: 500 mg 2-4 times/day depending on regimen; requires combination therapy with at least one other antibiotic and an acid-suppressing agent (proton pump inhibitor or H₂ blocker)

Dosing interval in renal impairment:

Cl_{cr} 50-80 mL/minute: Administer every 8-12 hours

Cl_{cr} 10-50 mL/minute: Administer every 12-24 hours

Cl_{cr} <10 mL/minute: Administer every 24 hours

Dialysis: Slightly dialyzable (5% to 20%) via hemo- and peritoneal dialysis or via continuous arteriovenous or venovenous hemofiltration; no supplemental dosage necessary

Dosing adjustment in hepatic impairment: Avoid use or maximum dose is 1 g/day

Stability Outdated tetracyclines have caused a Fanconi-like syndrome

Monitoring Parameters Renal, hepatic, and hematologic function test, temperature, WBC, cultures and sensitivity, appetite, mental status

Administration Should be administered on an empty stomach (ie, 1 hour prior to, or 2 hours after meals) to increase total absorption. Administer at least 1-2 hours prior to, or 4 hours after antacid because aluminum and magnesium cations may chelate with tetracycline and reduce its total absorption.

Contraindications Hypersensitivity to tetracycline or any component of the formulation; do not administer to children ≤8 years of age; pregnancy

Warnings Use of tetracyclines during tooth development may cause permanent discoloration of the teeth and enamel, hypoplasia and retardation of skeletal development and bone growth with risk being the greatest for children <4 years and those receiving high doses; use with caution in patients with renal or hepatic impairment (eg, elderly); dosage modification required in patients with renal impairment since it may increase BUN as an antianabolic agent; pseudotumor cerebri has been reported with tetracycline use (usually resolves with discontinuation); outdated drug can cause nephropathy; superinfection possible; use protective measure to avoid photosensitivity

Dosage Forms Capsule, as hydrochloride: 250 mg, 500 mg
Suspension, oral, as hydrochloride (Sumycin®): 125 mg/5 mL (480 mL) [contains sodium benzoate and sodium metabisulfite; fruit flavor]
Tablet, as hydrochloride (Sumycin®): 250 mg, 500 mg

Reference Range

Therapeutic: Not established

Toxic: >16 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Antacids can be given for epigastric pain; acetazolamide (500 mg twice daily) can be used to treat pseudotumor cerebri. For treatment of lingua villosa nigra, discontinue causative agent. Clean the tongue with a toothbrush and rinse mouth with a half-strength solution of hydrogen peroxide or 10% carbamide peroxide. Symptoms should subside in a few days.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; slightly dialyzable (5% to 20%)

Test Interactions False-negative urine glucose with Clinistix®; may cause an elevation of BUN through a catabolic effect and **not** through renal impairment

Drug Interactions **Substrate** of CYP3A4 (major); **Inhibits** CYP3A4 (moderate)

Antacids: May decrease tetracycline absorption; separate doses.

Calcium supplements (oral): May decrease tetracycline absorption; separate doses.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of tetracycline. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 substrates: Tetracycline may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Didanosine: May decrease tetracycline absorption; separate doses.

Digoxin: Tetracyclines may rarely increase digoxin serum levels.

Iron: May decrease tetracycline absorption; separate doses.

Methoxyflurane anesthesia when concurrent with tetracycline may cause fatal nephrotoxicity.

Oral contraceptives: Anecdotal reports suggesting decreased contraceptive efficacy with tetracyclines have been refuted by more rigorous scientific and clinical data.

Quinapril: May decrease tetracycline absorption; separate doses.

Warfarin with tetracyclines may result in increased anticoagulation.

Pregnancy Risk Factor D (systemic)/B (topical)

Pregnancy Implications Crosses the placenta and enters fetal circulation; may cause permanent discoloration of teeth if used during the last half of pregnancy. Fatty liver may occur during pregnancy with daily ingestions over 4 grams.

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Nursing Implications Give around-the-clock (ie, 6-12-6-12)

Additional Information May reduce serum vitamin B concentrations; D-lactic acidosis may develop in patients with short bowel syndrome due to overgrowth of D-lactate producing organisms (*Lactobacillus* species, *Streptococcus bovis*, *Bifidobacterium* species, or *Eubacterium* species).

Tetrahydrozoline

CAS Number 522-48-5; 84-22-0

U.S. Brand Names Eye-Sine™ [OTC]; Geneye® [OTC]; Murine® Tears Plus [OTC]; Optigene® 3 [OTC]; Tyzine® Pediatric; Tyzine®; Visine® Advanced Relief [OTC]; Visine® Original [OTC]

Synonyms Tetrahydrozoline Hydrochloride; Tetryzoline

Use Symptomatic relief of nasal congestion and conjunctival congestion

Mechanism of Action Stimulates alpha-adrenergic receptors in the arterioles of the conjunctiva and the nasal mucosa to produce vasoconstriction

Adverse Reactions

Cardiovascular: Tachycardia, palpitations, increased blood pressure, increased heart rate

Central nervous system: Headache

Local: **Transient stinging**

Neuromuscular & skeletal: Tremor

Ocular: Blurred vision

Respiratory: **Sneezing**

Signs and Symptoms of Overdose Bradycardia, cardiovascular collapse, coma, CNS depression, hypothermia

Admission Criteria/Prognosis Patients may be discharged if asymptomatic 6 hours postingestion

Pharmacodynamics/Kinetics

Onset of action: Decongestant: Intranasal: 4-8 hours

Duration: Ophthalmic vasoconstriction: 2-3 hours

Dosage Nasal congestion: Intranasal:

Children 2-6 years: Instill 2-3 drops of 0.05% solution every 4-6 hours as needed, no more frequent than every 3 hours

Children >6 years and Adults: Instill 2-4 drops or 3-4 sprays of 0.1% solution every 3-4 hours as needed, no more frequent than every 3 hours

Conjunctival congestion: Ophthalmic: Adults: Instill 1-2 drops in each eye 2-4 times/day

Monitoring Parameters Blood pressure, heart rate, symptom response

Dosage Forms Solution, intranasal, as hydrochloride:

Tyzine®: 0.1% (15 mL) [spray bottle; contains benzalkonium chloride]; (30 mL) [dropper bottle; contains benzalkonium chloride]

Tyzine® Pediatric: 0.05% (15 mL) [spray bottle; contains benzalkonium chloride]

Solution, ophthalmic, as hydrochloride: 0.05% (15 mL)

Eye-Sine™, Geneye®, Optigene® 3: 0.05% (15 mL) [may contain benzalkonium chloride]

Murine® Tears Plus: 0.05% (15 mL, 30 mL) [contains benzalkonium chloride]

Visine® Advanced Relief: 0.05% (30 mL) [contains benzalkonium chloride and polyethylene glycol]

Visine® Original: 0.05% (15 mL, 30 mL) [contains benzalkonium chloride; 15 mL size also available with dropper]

Overdosage/Treatment

Decontamination:

Oral: Do not induce emesis; lavage (with airway protection) may be useful if performed within 1 hour of ingestion; activated charcoal can be given

Ocular: Irrigation copiously with normal saline or water

Supportive therapy: Hypotension and/or bradycardia will usually respond to isotonic I.V. fluid administration (10-20 mL/kg); atropine can cause significant hypertension if given; nitroprusside or phentolamine can be given to treat hypertension while phentolamine can be used to treat localized vasoconstriction; seizures can be treated with lorazepam or diazepam; phenytoin or phenobarbital can be used in refractory cases; naloxone and flumazenil do not appear to be useful

Drug Interactions Increased toxicity: MAO inhibitors can cause an exaggerated adrenergic response if taken concurrently or within 21 days of discontinuing MAO inhibitor; beta-blockers can cause hypertensive episodes and increased risk of intracranial hemorrhage; anesthetics

Pregnancy Risk Factor C

Nursing Implications Do not use for > 3-4 days without direct physician supervision

Specific References

Daggy A, Kaplan R, Roberge R, et al, "Pediatric Visine® (Tetrahydrozoline) Ingestion: Case Report and Review of Imidazoline Toxicity," *Vet Hum Toxicol*, 2003, 45(4):210-2.

tropenia, orthostatic hypotension, pancytopenia, paresthesia, peripheral neuritis, photosensitivity, pleural effusion, psychosis, Raynaud's syndrome, seizures, Stevens-Johnson syndrome, suicide attempt, syncope, thrombosis, toxic epidermal necrolysis, tumor lysis syndrome

Pharmacodynamics/Kinetics

Distribution: V_d: 120 L

Protein binding: 55% to 66%

Metabolism: Nonenzymatic hydrolysis in plasma; forms multiple metabolites

Half-life elimination: 5-7 hours

Time to peak, plasma: 3-6 hours

Excretion: Urine (< 1% as unchanged drug)

Dosage

Oral:

Multiple myeloma: 200 mg once daily (with dexamethasone 40 mg daily on days 1-4, 9-12, and 17-20 of a 28-day treatment cycle)

Cutaneous ENL:

Initial: 100-300 mg/day taken once daily at bedtime with water (at least 1 hour after evening meal)

Patients weighing < 50 kg: Initiate at lower end of the dosing range
Severe cutaneous reaction or patients previously requiring high dose may be initiated at 400 mg/day; doses may be divided, but taken 1 hour after meals

Maintenance: Dosing should continue until active reaction subsides (usually at least 2 weeks), then tapered in 50 mg decrements every 2-4 weeks

Patients who flare during tapering or with a history or requiring prolonged maintenance should be maintained on the minimum dosage necessary to control the reaction. Efforts to taper should be repeated every 3-6 months, in increments of 50 mg every 2-4 weeks.

Behçet's syndrome (unlabeled use): 100-400 mg/day

Graft-vs-host reactions (unlabeled use): 100-1600 mg/day; usual initial dose: 200 mg 4 times/day for use up to 700 days

AIDS-related aphthous stomatitis (unlabeled use): 200 mg twice daily for 5 days, then 200 mg/day for up to 8 weeks

Discoid lupus erythematosus (unlabeled use): 100-400 mg/day; maintenance dose: 25-50 mg

Stability Store at 15°C to 30°C (50°F to 86°F). Protect from light. Keep in original package.

Monitoring Parameters CBC with differential, platelets; signs of neuropathy monthly for the first 3 months, then periodically during treatment; consider monitoring of sensory nerve application potential amplitudes (at baseline and every 6 months) to detect asymptomatic neuropathy. In HIV-seropositive patients: viral load after 1 and 3 months, then every 3 months. Pregnancy testing (sensitivity of at least 50 mIU/mL) is required within 24 hours prior to initiation of therapy, weekly during the first 4 weeks, then every 4 weeks in women with regular menstrual cycles or every 2 weeks in women with irregular menstrual cycles.

Administration Avoid extensive handling of capsules; capsules should remain in blister pack until ingestion. If exposed to the powder content from broken capsules or body fluids from patients receiving thalidomide, the exposed area should be washed with soap and water.

Contraindications Hypersensitivity to thalidomide or any component of the formulation; neuropathy (peripheral); patient unable to comply with STEPS® program (including males); women of childbearing potential unless alternative therapies are inappropriate and adequate precautions are taken to avoid pregnancy; pregnancy

Warnings

Hazardous agent – use appropriate precautions for handling and disposal. [U.S. Boxed Warning]: **Thalidomide is a known teratogen; effective contraception must be used for at least 4 weeks before initiating therapy, during therapy, and for 4 weeks following discontinuation of thalidomide for women of childbearing potential.** Use caution with drugs which may decrease the efficacy of hormonal contraceptives.

[U.S. Boxed Warning]: **Thrombotic events have been reported, generally in patients with other risk factors for thrombosis (neoplastic disease, inflammatory disease, or concurrent therapy with combination chemotherapy). Use in combination with dexamethasone is associated with increased risk for deep vein thrombosis (DVT) and pulmonary embolism (PE). Monitor for signs and symptoms of thromboembolism; patients at risk may benefit from prophylactic anticoagulation or aspirin.**

May cause sedation; patients must be warned to use caution when performing tasks which require alertness. Use caution in patients with renal or hepatic impairment, neurological disorders, or constipation. Thalidomide has been associated with the development of peripheral neuropathy, which may be irreversible; use caution with other medications which may cause peripheral neuropathy. Consider immediate discontinuation (if clinically appropriate) in patients who develop neuropathy. May cause seizures; use caution in patients with a history of seizures, concurrent therapy with drugs which alter seizure threshold, or conditions which predispose to seizures. May cause neutropenia;

Thalidomide

CAS Number 50-35-1

U.S. Brand Names Thalomid®

Synonyms NSC-66847

Use Treatment and maintenance of cutaneous manifestations of erythema nodosum leprosum

Unlabeled/Investigational Use Treatment of Crohn's disease; graft-versus-host reactions after bone marrow transplantation; AIDS-related aphthous stomatitis; Behçet's syndrome; Waldenström's macroglobulinemia; Langerhans cell histiocytosis; may be effective in rheumatoid arthritis, discoid lupus erythematosus, and erythema multiforme

Mechanism of Action A derivative of glutethimide; mode of action for immunosuppression is unclear; inhibition of neutrophil chemotaxis and decreased monocyte phagocytosis may occur; may cause 50% to 80% reduction of tumor necrosis factor - alpha

Adverse Reactions

Controlled clinical trials: ENL:

Cardiovascular: Peripheral edema

Central nervous system: **Somnolence, headache, dizziness, vertigo, chills, malaise**

Dermatologic: **Rash, dermatitis (fungal), nail disorder, pruritus, maculopapular rash**

Gastrointestinal: Constipation, diarrhea, nausea, moniliasis, tooth pain, abdominal pain

Genitourinary: Impotence

Neuromuscular & skeletal: Asthenia, pain, back pain, neck pain, neck rigidity, tremor

Respiratory: Pharyngitis, rhinitis, sinusitis

HIV-seropositive:

General: An increased viral load has been noted in patients treated with thalidomide. This is of uncertain clinical significance.

Cardiovascular: Peripheral edema

Central nervous system: **Somnolence, dizziness, fever, headache, nervousness, insomnia, agitation, chills, neuropathy (up to 8% in HIV-seropositive patients)**

Dermatologic: **Rash, maculopapular rash, acne (3.1% to 11.1%), dermatitis (fungal), nail disorder, pruritus**

Gastrointestinal: **AST increase (2.8% to 12.5%), diarrhea, nausea (≤ 12.5%), oral moniliasis (6.3% to 11.1%), anorexia, constipation, dry mouth, flatulence, LFT multiple abnormalities, abdominal pain**

Hematologic: **Leukopenia, anemia (5.6% to 12.5%)**

Neuromuscular & skeletal: **Paresthesia (5.6% to 15.6%), weakness (5.6% to 21.9%), back pain, pain**

Respiratory: Pharyngitis, sinusitis

Miscellaneous: **Diaphoresis (≤ 12.5%), lymphadenopathy (5.6% to 12.5%), accidental injury, infection**

Postmarketing and/or case reports (limited to important or life-threatening): Acute renal failure, arrhythmias, bradycardia, CML, dyspnea, electrolyte imbalances, erythema multiforme, erythema nodosum, Hodgkin's disease, hypersensitivity, hyperthyroidism, intestinal perforation, lethargy, lymphopenia, mental status changes, myxedema, neu-

THEOPHYLLINE

discontinue therapy if absolute neutrophil count decreases to $<750/\text{mm}^3$. Use caution in patients with HIV infection; has been associated with increased viral loads. May cause orthostasis and/or bradycardia; use with caution in patients with cardiovascular disease or in patients who would not tolerate transient hypotensive episodes. Hypersensitivity, Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) have been reported; withhold therapy and evaluate with skin rashes; permanently discontinue if rash is exfoliative, purpuric, bullous or if SJS or TEN is suspected. Safety and efficacy have not been established in children <12 years of age.

Dosage Forms

Capsule:
Thalomid[®]: 50 mg, 100 mg, 200 mg

Reference Range Therapeutic plasma thalidomide levels in graft-vs-host reactions are 5-8 mcg/mL, although it has been suggested that lower plasma levels (0.5-1.5 mcg/mL) may be therapeutic; peak serum thalidomide level after a 200 mg dose: 1.2 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal with sorbitol

Supportive therapy: Bisacodyl suppositories can be used for constipation

Drug Interactions Abatacept: Thalidomide may be associated with increased risk of serious infection when used in combination with abatacept.

Anakinra: Thalidomide may be associated with increased risk of serious infection when used in combination with anakinra.

CNS depressants: Thalidomide may enhance the sedative activity of other drugs such as ethanol, barbiturates, reserpine, and chlorpromazine

Vaccine (killed): Thalidomide may decrease the effect of vaccines (killed).

Vaccine (live attenuated): Thalidomide may increase the risk of vaccinal infection.

Pregnancy Risk Factor X

Pregnancy Implications Embryotoxic with limb defects noted from the 27th to 40th gestational day of exposure; all cases of phocomelia occur from the 27th to 42nd gestational day; fetal cardiac, gastrointestinal, and genitourinary tract abnormalities have also been described. Effective contraception must be used for at least 4 weeks before initiating therapy, during therapy, and for 4 weeks following discontinuation of thalidomide. Males (even those vasectomized) must use a latex condom during any sexual contact with women of childbearing age. Risk to the fetus from semen of male patients is unknown.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Thalidomide is approved for marketing only under a special distribution program. This program, called the "System for Thalidomide Education and Prescribing Safety" (STEPS[™]), has been approved by the FDA. Prescribing and dispensing of thalidomide is restricted to prescribers and pharmacists registered with the program. Prior to dispensing, an authorization number must be obtained (1-888-423-5436) from Celgene (write authorization number on prescription). No more than a 4-week supply should be dispensed. Blister packs should be dispensed intact (do not repackage capsules). Prescriptions must be filled within 7 days.

U.S. Brand Names Elixophyllin[®]; Quibron[®]-T/SF; Quibron[®]-T; T-Phyl[®]; Theo-24[®]; Theochron[®]; Theolair-SR[®] [DSC]; Theolair[™]; Uniphyll[®]

Synonyms Theophylline Anhydrous

Use Bronchodilator in reversible airway obstruction due to asthma or COPD as maintenance therapy only; for neonatal apnea/bradycardia
Use for clinically-significant atrioventricular nodal blockade following acute inferior myocardial infarction

Mechanism of Action Exact mechanism is unknown; probable mechanism involves increasing tissue concentrations of cAMP and/or occupying adenosine receptors as an antagonist and/or inhibition of phosphodiesterases, PDE III, PDE IV

Adverse Reactions

Uncommon at serum theophylline concentrations ≤ 20 mcg/mL

Central nervous system: Stuttering

Cardiovascular: Palpitations, sinus tachycardia, tachycardia (ventricular), tachycardia (supraventricular), flutter (atrial), chest pain, angina, arrhythmias (ventricular), vasodilation, sinus bradycardia

Central nervous system: Insomnia, irritability, agitation, seizures, nervousness, psychosis, restlessness, visual hallucinations, sympathetic storm, hyperthermia

Dermatologic: Skin rash

Endocrine & metabolic: SIADH

Gastrointestinal: Nausea, vomiting, abdominal pain, bezoars/concretions, Ogilvie's syndrome, decreased esophageal sphincter tone

Neuromuscular & skeletal: Tremors, rhabdomyolysis

Miscellaneous: Allergic reactions, acute atraumatic compartment syndrome

Signs and Symptoms of Overdose Anorexia, bezoars, delirium, diuresis, esophageal ulceration, exfoliative dermatitis, feces discoloration (black), fibrillation (atrial), hypercalcemia, hyperglycemia, hypertension, hypokalemia, hypophosphatemia, hypomagnesemia, hyponatremia, hypotension, insomnia, intestinal pseudo-obstruction (Ogilvie's syndrome), irritability, lactic acidosis, leg cramps, nausea, paroxysmal tachycardia (ventricular), tachycardia, seizures, vomiting. Repetitive vomiting is an indication to hold theophylline therapy and rule out toxicity by serum concentrations.

Pharmacodynamics/Kinetics

Absorption: Oral: Dosage form dependent

Distribution: 0.45 L/kg based on ideal body weight

Metabolism: Children >1 year and Adults: Hepatic; involves CYP1A2, 2E1 and 3A4; forms active metabolites (caffeine and 3-methylxanthine)

Half-life elimination: Highly variable and dependent upon age, liver function, cardiac function, lung disease, and smoking history

Time to peak, serum:

Oral: Liquid: 1 hour; Tablet, enteric-coated: 5 hours; Tablet, uncoated: 2 hours

I.V.: Within 30 minutes

Excretion: Urine

Neonates: 50% unchanged

Children >3 months and Adults: 10% unchanged

Dosage

Use ideal body weight for obese patients

Neonates:

Apnea of prematurity: Oral, I.V.: Loading dose: 4 mg/kg (theophylline); 5 mg/kg (aminophylline)

There appears to be a delay in theophylline elimination in infants <1 year of age, especially neonates; both the initial dose and maintenance dosage should be conservative

I.V.: Initial: Maintenance infusion rates:

Neonates:

≤ 24 days: 0.08 mg/kg/hour theophylline

>24 days: 0.12 mg/kg/hour theophylline

Children >1 year and Adults:

Treatment of acute wheezing: I.V.: Loading dose (in patients not currently receiving aminophylline or theophylline): 6 mg/kg (based on aminophylline) given I.V. over 20-30 minutes; administration rate should not exceed 25 mg/minute (aminophylline).

Approximate I.V. maintenance dosages are based upon **continuous infusions**; bolus dosing (often used in children <6 months of age) may be determined by multiplying the hourly infusion rate by 24 hours and dividing by the desired number of doses/day.

Dosage should be adjusted according to serum level measurements during the first 12- to 24-hour period.

Oral theophylline: Treatment of acute wheezing: Initial dosage recommendation: Loading dose (to achieve a serum level of ~ 10 mcg/mL; loading doses should be given using a rapidly absorbed oral product **not** a sustained release product):

If no theophylline has been administered in the previous 24 hours: 4-6 mg/kg theophylline

If theophylline has been administered in the previous 24 hours, administer $1/2$ the loading dose or 2-3 mg/kg theophylline can be given in emergencies when serum levels are not available.

On the average, for every 1 mg/kg theophylline given, blood levels will rise 2 mcg/mL. Ideally, defer the loading dose if a serum theophylline concentration can be obtained rapidly. However, if

Theophylline

Related Information

- Aminophylline
- Therapeutic Drugs Associated with Hallucinations

CAS Number 58-55-9

this is not possible, exercise clinical judgment. If the patient is not experiencing theophylline toxicity, this is unlikely to result in dangerous adverse effects.

These recommendations, based on mean clearance rates for age or risk factors, were calculated to achieve a serum level of 10 mcg/mL (5 mcg/mL for newborns with apnea/bradycardia). In newborns and infants, a fast-release oral product can be used. The total daily dose can be divided every 12 hours in newborns and every 6-8 hours in infants. In children and healthy adults, a slow-release product can be used. The total daily dose can be divided every 8-12 hours.

Bronchial asthma: Oral theophylline: See table.

Oral Theophylline Dosage for Bronchial Asthma*			
Age	Initial 3 Days	Second 3 Days	Steady-State Maintenance
< 1 y	0.2 × (age in weeks) + 5		0.3 × (age in weeks) + 8
1-9 y	16 up to a maximum of 400 mg/24 h	20	22
9-12 y	16 up to a maximum of 400 mg/24 h	16 up to a maximum of 600 mg/24 h	20 up to a maximum of 800 mg/24 h
12-16 y	16 up to a maximum of 400 mg/24 h	16 up to a maximum of 600 mg/24 h	18 up to a maximum of 900 mg/24 h
Adults	400 mg/24 h	600 mg/24 h	900 mg/24 h

*Dose in mg/kg/24 hours of theophylline.

Increasing dose: The dosage may be increased in approximately 25% increments at 2- to 3-day intervals so long as the drug is tolerated or until the maximum dose is reached.

Maintenance dose: See table.

Maintenance Dose for Acute Symptoms		
Population Group	Oral Theophylline (mg/kg/day)	I.V. Aminophylline
Premature infant or newborn - 6 wk (for apnea/bradycardia)	4	5 mg/kg/day
6 wk - 6 mo	10	12 mg/kg/day or continuous I.V. infusion*
Infants 6 mo-1 y	12-18	15 mg/kg/day or continuous I.V. infusion*
Children 1-9 y	20-24	1 mg/kg/hour
Children 9-12 y, and adolescent daily smokers of cigarettes or marijuana, and otherwise healthy adult smokers under 50 y	16	0.9 mg/kg/hour
Adolescents 12-16 y (nonsmokers)	13	0.7 mg/kg/hour
Otherwise healthy nonsmoking adults (including elderly patients)	10 (not to exceed 900 mg/day)	0.5 mg/kg/hour
Cardiac decompensation, cor pulmonale and/or liver dysfunction	5 (not to exceed 400 mg/day)	0.25 mg/kg/hour

*For continuous I.V. infusion divide total daily dose by 24 = mg/kg/hour.

These recommendations, based on mean clearance rates for age or risk factors, were calculated to achieve a serum level of 10 mcg/mL (5 mcg/mL for newborns with apnea/bradycardia). In newborns and infants, a fast-release oral product can be used. The total daily dose can be divided every 12 hours in newborns and every 6-8 hours in infants. In children and healthy adults, a slow-release product can be used. The total daily dose can be divided every 8-12 hours.

Dose should be further adjusted based on serum levels; see table.

Dosage Adjustment After Serum Theophylline Measurement

Serum Theophylline		Guidelines
Within normal limits	10-20 mcg/mL	Maintain dosage if tolerated. Recheck serum theophylline concentration at 6-12 mo intervals.*
Too high	20-25 mcg/mL	Decrease doses by about 10%. Recheck serum theophylline concentration after 3 d and then at 6-12 mo intervals.*
	25-30 mcg/mL	Skip next dose and decrease subsequent doses by about 25%. Recheck serum theophylline.
	> 30 mcg/mL	Skip next 2 doses and decrease subsequent doses by 50%. Recheck serum theophylline.
Too low	7.5-10 mcg/mL	Increase dose by about 25%.† Recheck serum theophylline concentration after 3 d and then at 6-12 mo intervals.*
	5-7.5 mcg/mL	Increase dose by about 25% to the nearest dose increment† and recheck serum theophylline for guidance in further dosage adjustment (another increase will probably be needed, but this provides a safety check).

From Weinberger M and Hendeles L, "Practical Guide to Using Theophylline," *J Resp Dis*, 1981, 2:12-27.

*Finer adjustments in dosage may be needed for some patients.

†Dividing the daily dose into 3 doses administered at 8-hour intervals may be indicated if symptoms occur repeatedly at the end of a dosing interval.

Dosing adjustment/comments in hepatic disease: Higher incidence of toxic effects including seizures in cirrhosis; plasma levels should be monitored closely during long-term administration in cirrhosis and during acute hepatitis, with dose adjustment as necessary.

Rectal: Adults: 500 mg 3 times/day; avoid using suppositories due to erratic, unreliable absorption

Clinically significant atrioventricular nodal blockade following acute inferior myocardial infarction: 100 mg/minute; I.V. to a maximum: 250 mg

Stability Store injection at room temperature, do not refrigerate; protect from heat and from freezing; use only clear solutions; stability of parenteral admixture at room temperature (25°C): 30 days

Administration

Oral: Long-acting preparations should be taken with a full glass of water, swallowed whole, or cut in half if scored. Do **not** crush. Extended release capsule forms may be opened and the contents sprinkled on soft foods; do **not** chew beads.

Contraindications Hypersensitivity to theophylline or any component of the formulation; premixed injection may contain corn-derived dextrose and its use is contraindicated in patients with allergy to corn-related products

Warnings If a patient develops signs and symptoms of theophylline toxicity (eg, persistent, repetitive vomiting), a serum theophylline level should be measured and subsequent doses held. Due to potential saturation of theophylline clearance at serum levels in or (in some patients) less than the therapeutic range, dosage adjustment should be made in small increments (maximum: 25%). Due to wider interpatient variability, theophylline serum level measurements must be used to optimize therapy and prevent serious toxicity. Use with caution in patients with peptic ulcer, hyperthyroidism, seizure disorders, hypertension, and patients with cardiac arrhythmias (excluding bradyarrhythmias).

THIAMINE

Dosage Forms

Capsule, extended release: 100 mg, 125 mg, 200 mg, 300 mg

TheoCap™: 125 mg, 200 mg, 300 mg [12 hour]

Theo-24®: 100 mg, 200 mg, 300 mg, 400 mg [24 hours]

Elixir:

Elixophyllin®: 80 mg/15 mL (480 mL) [contains alcohol 20%; fruit flavor]

Infusion [premixed in D₅W]: 200 mg (50 mL, 100 mL); 400 mg (100 mL, 250 mL, 500 mL); 800 mg (250 mL, 500 mL, 1000 mL)

Tablet, controlled release:

Uniphyll®: 400 mg, 600 mg [24 hours; contains cetostearyl alcohol]

Tablet, extended release: 100 mg, 200 mg, 300 mg, 450 mg

Theochron®: 100 mg, 200 mg, 300 mg, 450 mg [12-24 hours]

Tablet, immediate release:

Quibron®-T: 300 mg [DSC]

Tablet, sustained release:

Quibron®-T/SR: 300 mg [8-12 hours] [DSC]

Reference Range

Timing of serum samples: If toxicity is suspected, draw a level at any time; if lack of therapeutic is effected, draw a trough immediately before the next oral dose

Therapeutic (theophylline): Neonatal apnea: 6-13 mcg/mL; Therapeutic: 10-20 mcg/mL; Toxic: 10-15 mcg/mL

Overdosage/Treatment

Decontamination: **Do not** use ipecac; lavage should be performed if < 1 hour after ingestion and > 50 mg/kg was ingested; activated charcoal; whole bowel irrigation should be considered for significant sustained release preparation ingestion

Supportive therapy: Metoclopramide or ondansetron can be used for vomiting; 50% of severe theophylline toxic patients respond to 10 mg of metoclopramide to control vomiting; hypotension should be treated with I.V. normal saline hydration. Phenylephrine or levaterenol are preferred vasopressors that can be utilized for hypotension although an I.V. beta-adrenergic blocker (propranolol or esmolol) can be utilized in the patient without a history of bronchospastic disease. Seizures may require diazepam/lorazepam along with phenobarbital; phenytoin is contraindicated. Lidocaine can be used for ventricular arrhythmias; must monitor for hypoglycemia. Nitrazepam can be given if infantile spasm occur due to theophylline toxicity.

Enhancement of elimination: Multiple doses of activated charcoal can reduce the half-life of aminophylline/theophylline to 2-3 hours; do not use if an ileus is present. Charcoal hemoperfusion can increase the clearance of aminophylline/theophylline by approximately twofold to threefold over that of hemodialysis and is thus the extracorporeal modality of choice. Guidelines for charcoal hemoperfusion include a theophylline level >100 mcg/mL in an acute overdose setting (or 50 mcg/mL in a chronic setting), or the following signs if the level is >35 mcg/mL: ventricular arrhythmias, metabolic acidosis, hypotension, refractory to vasopressors or fluid therapy, seizures, ileus. If a sustained release preparation is ingested or patient with chronic ingestion is >60 years of age, the threshold for using charcoal hemoperfusion should be lower. If the patient is experiencing fluid overload due to congestive heart failure, hemodialysis can be performed to remove both theophylline/aminophylline and fluid; continuous arteriovenous hemoperfusion rates are 193 ± 2 mL/minute; drug clearance rate of hemodialysis and hemoperfusion is 185 and 295 mL/kg/hour respectively.

Diagnostic Procedures

- Theophylline, Blood

Test Interactions Caffeine in high concentrations on selected procedures cross reacts as theophylline

Drug Interactions

Substrate of CYP1A2 (major), 2C9 (minor), 2D6 (minor), 2E1 (major), 3A4 (major); **Inhibits** CYP1A2 (weak)

CYP1A2 inducers: May decrease the levels/effects of theophylline.

Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of theophylline.

Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

CYP2E1 inhibitors: May increase the levels/effects of theophylline.

Example inhibitors include disulfiram, isoniazid, and miconazole.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of theophylline.

Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifampin.

CYP3A4 inhibitors: May increase the levels/effects of theophylline.

Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Pregnancy Risk Factor C

Pregnancy Implications Theophylline crosses the placenta; adverse effects may be seen in the newborn. Theophylline metabolism may change during pregnancy; monitor serum levels.

Lactation Enters breast milk/compatible (AAP rates "compatible")

Nursing Implications Do not crush sustained release or enteric coated drug products

Additional Information Elderly, acutely ill, and patients with severe respiratory problems, pulmonary edema, or liver dysfunction are at greater risk of toxicity because of reduced drug clearance. Saliva levels are approximately equal to 60% of plasma levels; infantile spasm can occur; charcoal-broiled foods may increase elimination, reducing half-life by 50%; cigarette smoking may require an increase of dosage by 50% to 100%; aminophylline 100 mg is equivalent to theophylline 79 mg

Thiamine

CAS Number 59-43-8; 67-03-8

U.S. Brand Names Thiamilate® [OTC]

Synonyms Aneurine Hydrochloride; Thiamine Hydrochloride; Thiaminium Chloride Hydrochloride; Vitamin B₁

Use Treatment of thiamine deficiency including beriberi, Wernicke's encephalopathy syndrome, and peripheral neuritis associated with pellagra, alcoholic patients with altered sensorium; various genetic

metabolic disorders; dietary sources include legumes, pork, beef, whole grains, yeast, fresh vegetables; a deficiency state can occur in as little as 3 weeks following total dietary absence

Mechanism of Action An essential coenzyme in carbohydrate metabolism by combining with adenosine triphosphate to form thiamine pyrophosphate

Adverse Reactions

Hypersensitivity is rare

Cardiovascular: Cardiovascular collapse and death (primarily following repeated I.V. administration), shock

Dermatologic: Rash, pigmented purpura, angioedema, purpura, dermatitis

Neuromuscular & skeletal: Tingling

Respiratory: Sneezing

Miscellaneous: Warmth, radiopaque

Pharmacodynamics/Kinetics

Absorption: Oral: Adequate; I.M.: Rapid and complete

Excretion: Urine (as unchanged drug and as pyrimidine after body storage sites become saturated)

Dosage Overall caloric requirement of thiamine: 0.5 mg/1000 calories; dietary supplement (depends on caloric or carbohydrate content of the diet):

Infants: 0.3-0.5 mg/day

Children: 0.5-1 mg/day

Adults: 1-2 mg/day

Note: The above doses can be found as a combination in multivitamin preparations

Children:

Noncritically ill thiamine deficiency: Oral: 10-50 mg/day in divided doses every day for 2 weeks followed by 5-10 mg/day for one month
Beriberi: I.M.: 10-25 mg/day for 2 weeks, then 5-10 mg orally every day for one month (oral as therapeutic multivitamin)

Adults:

Wernicke's encephalopathy: I.M., I.V.: 50 mg as a single dose, then 50 mg I.M. every day until normal diet resumed; alternatively: I.V.: 100 mg/day for 5 days can be given

Noncritically ill thiamine deficiency: Oral: 10-50 mg/day in divided doses

Beriberi: I.M., I.V.: 10-30 mg 3 times/day for 2 weeks, then switch to 5-10 mg orally every day for one month (oral as therapeutic multivitamin)

Stability Protect oral dosage forms from light; **incompatible** with alkaline or neutral solutions and with oxidizing or reducing agents; exposure to heat may inactivate vitamin; **incompatible** with neutral or alkaline solutions; **incompatible** with barbiturates

Administration Administer by slow I.V. injection

Contraindications Hypersensitivity to thiamine or any component of the formulation

Warnings Use with caution with parenteral route (especially I.V.) of administration

Dosage Forms Injection, solution, as hydrochloride: 100 mg/mL (2 mL)

Tablet, as hydrochloride: 50 mg, 100 mg, 250 mg, 500 mg

Reference Range Therapeutic: 1.6-4 mg/dL

Test Interactions False-positive for uric acid using the phosphotungstate method and for urobilinogen using the Ehrlich's reagent; large doses may interfere with the spectrophotometric determination of serum theophylline concentration

Drug Interactions Neuromuscular blocking agents; high carbohydrate diets or I.V. dextrose solutions increase thiamine requirement

Pregnancy Risk Factor A/C (dose exceeding RDA recommendation)

Lactation Enters breast milk/compatible

Nursing Implications Parenteral form may be administered by I.M. or slow I.V. injection

Additional Information Found in green vegetables, pork, liver, fish, eggs; requires adequate magnesium for use as a coenzyme; >4.9 mg/day may result in slower progression of HIV illness (RR=0.6)

Specific References

Thiamphenicol

CAS Number 15318-45-3; 2393-92-2; 2611-61-2; 847-25-6

Unlabeled/Investigational Use Gonorrhea, chancroid, *Gardnerella vaginalis*, vaginitis

Mechanism of Action Reversibly binds to 50S ribosomal subunits of susceptible organisms preventing amino acids from being transferred to growing peptide chains thus inhibiting protein synthesis

Adverse Reactions

Dose-dependent reversible myelosuppression is more frequent than with chloramphenicol; not seen after single-dose use

Central nervous system: Headache, drowsiness, dizziness, polyneuropathy

Dermatologic: Pruritus

Gastrointestinal: Epigastric pain, abdominal pain, nausea, vomiting

Neuromuscular & skeletal: Neuropathy (peripheral) with long-term use

Ocular: Optic neuritis

Toxicodynamics/Kinetics

Absorption: Oral: 75% to 91%; I.M.: 100%

Distribution: V_d : ~0.5 L/kg

Protein binding: 10% to 20%

Half-life: 2.6-7 hours

Elimination: Renal

Dosage Oral: Single dose of 2.5 g (for uncomplicated gonorrhea) or 500 mg 3 times/day for 6 days

I.M.:

Children: 25-30 mg/kg/day

Adults: 1-3 g/day

I.V.: 750 mg to 1 g 3 times/day

Reference Range Serum levels after an I.V. dose of 10 mg/kg: ~13-14 mcg/mL; after an oral dose of 2.5 g, peak serum thiamphenicol levels range from 16-18 mcg/mL

Overdosage/Treatment

Decontamination: Oral: Activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; although there is no human overdose experience, hemodialysis or hemoperfusion may be effective

Pregnancy Implications Crosses the placenta

Additional Information Less likely than chloramphenicol to cause "gray syndrome" in neonates

Thiethylperazine

CAS Number 1179-69-7

U.S. Brand Names Torecan® [DSC]

Use Relief of nausea and vomiting

Treatment of vertigo

Mechanism of Action Blocks postsynaptic mesolimbic dopaminergic receptors in the brain; exhibits a strong alpha-adrenergic blocking effect and depresses the release of hypothalamic and hypophyseal hormones; acts directly on chemoreceptor trigger zone and vomiting center; may also inhibit impulses from peripheral autonomic afferents to the vomiting center

Adverse Reactions

Cardiovascular: Tachycardia, orthostatic hypotension, peripheral edema

Central nervous system: **Drowsiness, dizziness**, confusion, convulsions, extrapyramidal symptoms, tardive dyskinesia, fever, headache

Gastrointestinal: **Xerostomia**, anorexia

Hematologic: Agranulocytosis

Hepatic: Cholestatic jaundice

Ocular: Blurred vision

Otic: Tinnitus

Respiratory: **Dry nose**

Signs and Symptoms of Overdose Abnormal involuntary muscle movements, coma, deep sleep, extrapyramidal reaction, hypotension or hypertension, urine discoloration (pink; red; red-brown)

Toxicodynamics/Kinetics

Following administration antiemetic effects occur within 30 minutes and continue for approximately 4 hours

Absorption: Oral: Well absorbed

Metabolism: Hepatic

Elimination: Renal

Dosage

Children > 12 years and Adults:

Oral, I.M., I.V.: 10 mg 1-6 times/day as needed

Hemodialysis: Not dialyzable (0% to 5%)

Dosing comments in hepatic impairment: Use with caution

Administration

Inject I.M. deeply into large muscle mass, patient should be lying down and remain so for at least 1 hour after administration; although not generally recommended, thiethylperazine can be given as an I.V. infusion over 15-30 minutes; should **not** be given I.V. push; SubQ administration not recommended

Overdosage/Treatment

Decontamination: Activated charcoal; charcoal may need to be given in multiple doses for adequate decontamination

Supportive therapy: Initiate support with fluids, norepinephrine may be useful for hypotension; hypoperfusion states may respond to inotropic support with dobutamine. Bradycardia or ventricular dysrhythmia may respond to sodium bicarbonate or phenytoin; must avoid class 1A and 1C antiarrhythmics. Torsade de pointes may respond to magnesium; seizures should be managed with benzodiazepines or barbiturates; extrapyramidal reactions should be managed with diphenhydramine or benztropine.

THIMEROSAL

Enhancement of elimination: Multiple dosing of charcoal may not be effective

Pregnancy Risk Factor X

Nursing Implications Inject I.M. deeply into large muscle mass, patient should be lying down and remain so for at least 1 hour after administration; help with ambulation

Thimerosal

Pronunciation (thye MER oh sal)

CAS Number 54-64-8

U.S. Brand Names Merso[®] [OTC]; Merthiolate[®] [OTC]

Use Organomercurial antiseptic with sustained bacteriostatic and fungistatic activity; 49.6% mercury by weight; currently not used as a preservative in any U.S. based vaccines

Mechanism of Action Weakly bacteriostatic

Adverse Reactions

Central nervous system: Agitation (from chronic use)

Endocrine & metabolic: Hypokalemia (from chronic use)

Gastrointestinal: Nausea, vomiting, hemorrhagic gastritis

Neuromuscular & skeletal: Dysarthria

Ocular: Ocular irritation

Renal: Neuropathy (peripheral), renal failure

Respiratory: Laryngeal obstruction

Elemental mercury is poorly absorbed orally with minimal adverse effects.

Inhalation acutely can cause chemical pneumonitis, gingivostomatitis, and noncardiogenic pulmonary edema. Chronic exposure to mercury vapor causes acrodynia, fatigue, insomnia, memory loss, and tremor.

Inorganic mercury: Abdominal pain, GI irritation, GI bleeding, shock, renal failure, and acute tubular necrosis will develop after oral administration, with possible CNS toxicity.

Organic mercury: Causes CNS toxicity including ataxia, dysarthria, gastrointestinal distress, hearing and visual loss, and paresthesias.

Dosage Apply 1-3 times/day

Contraindications Hypersensitivity to thimerosal

Warnings Prolonged administration can result in mercury toxicity; contains 49% mercury

Dosage Forms Solution, topical (Merthiolate[®]): 0.1% [1 mg/mL = 1:1000] (30 mL)

Solution, topical spray (Merthiolate[®]): 0.1% [1 mg/mL = 1:1000] (60 g)

Tincture, topical (Merso[®]): 0.1% [1 mg/mL = 1:1000] (120 mL, 480 mL, 4000 mL)

Reference Range Urinary and whole blood levels can be obtained; normally urinary values are <10 mcg/dL and whole blood <2 mcg/dL; whole blood levels <50 mcg/dL are usually associated with gastroenteritis and acute tubular necrosis; urinary levels for organic mercury are not useful since 90% is eliminated through bile in the feces; urinary mercury levels >56 mcg/L can result in neurotoxic effects (due to elemental mercury)

Overdosage/Treatment

Decontamination:

Gastrointestinal: Lavage if ingested within 1 hour; **do not** induce emesis; charcoal has been shown to decrease inorganic mercury absorption in rats and should be used; milk or egg white may also be useful to bind mercury; whole bowel irrigation with GoLYTELY[®] may be beneficial if abdominal x-ray shows evidence of mercury

Inhalation: Patients with inhalation exposures should be monitored for pulmonary edema and pneumonitis; give oxygen if necessary

Dermal: Skin decontamination with soap and water

Ocular: Irrigate ocular exposures with saline

Supportive therapy:

Organic mercury: Oral DMSA (succimer) 10 mg/kg every 8 hours for 5 days then 10 mg/kg every 12 hours for 2 or more weeks will enhance urinary mercury excretion

BAL is not recommended for elemental and organic mercury poisoning since BAL may cause redistribution of mercury to the brain which is the primary target organ in these poisonings

Enhancement of elimination: Generally ineffective

Drug Interactions Increased ocular hypersensitivity may occur with tetracycline exposure

Additional Information Some brands of HBIG, IVIG, and some vaccines have thimerosal as a preservative. High-dose therapy with HBIG and IVIG have caused suspected nephrotoxicity.

Thioridazine

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antipsychotic Agents

CAS Number 13-61-0; 50-52-2

U.S. Brand Names Mellaril[®] [DSC]; Thioridazine Intenso[™]

Synonyms Thioridazine Hydrochloride

Use Management of schizophrenic patients who fail to respond adequately to treatment with other antipsychotic drugs, either because of insufficient effectiveness or the inability to achieve an effective dose due to intolerable adverse effects from those medications

Unlabeled/Investigational Use Psychosis

Mechanism of Action Blocks postsynaptic mesolimbic dopaminergic receptors in the brain; exhibits a strong alpha-adrenergic blocking effect and depresses the release of hypothalamic and hypophyseal hormones

Adverse Reactions

Anticholinergic toxidrome

Cardiovascular: **Hypotension** (especially with I.V. use), **hypotension (orthostatic)**, AV block edema, tachycardia, cardiac arrhythmias, QRS prolongation, T-wave abnormality, ectopy, torsade de pointes, prolonged QT interval, sinus tachycardia, arrhythmias (ventricular), sinus bradycardia

Central nervous system: **Pseudoparkinsonian signs and symptoms, tardive dyskinesia, akathisia, dystonias, dizziness**, sedation, drowsiness, restlessness, Parkinson's, anxiety, extrapyramidal reactions, neuroleptic malignant syndrome, seizures, altered central temperature regulation

Dermatologic: Hyperpigmentation, pruritus, rash, photosensitivity, Stevens-Johnson syndrome, hypertrichosis, alopecia, angioedema, urticaria, purpura, acanthosis nigricans, exanthem

Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, syndrome of inappropriate antidiuretic hormone, parotitis, hyperprolactinemia

Gastrointestinal: **Constipation**, GI upset, xerostomia, abdominal distention, weight gain, Ogilvie's syndrome

Genitourinary: Urinary retention, impotence, priapism

Hematologic: Agranulocytosis, leukopenia (usually in patients with large doses for prolonged periods), thrombocytopenia, hemolysis, eosinophilia, neutropenia, granulocytopenia

Hepatic: Cholestatic jaundice

Neuromuscular & skeletal: Myoclonus, rhabdomyolysis, paresthesia, Meige syndrome

Ocular: **Retinal pigmentation**, blurred vision, mydriasis, retinopathy

Respiratory: **Nasal congestion**, epistaxis

Miscellaneous: **Diaphoresis**, anaphylactoid reaction, pseudolymphoma, systemic lupus erythematosus

Signs and Symptoms of Overdose Abnormal involuntary muscle movements, AV block (first degree), coma, deep sleep, dysphagia, ejaculatory disturbances, extrapyramidal reaction, galactorrhea, gynecomastia, hepatic failure, hirsutism, hyperprolactinemia, hyperreflexia, hypertonia, hypotension or hypertension, hypothermia or hyperthermia, hyponatremia, impotence, myoclonus, neuroleptic malignant syndrome, nystagmus, priapism, QRS prolongation, QT prolongation, renal disorders (oliguria) at overdoses >2.5 g, tachycardia (ventricular), urine discoloration (pink; red; red-brown), vision color changes (brown tinge)

Admission Criteria/Prognosis Admit any symptomatic ingestion >5 mg/kg in children or a total of 500 mg in adults

Pharmacodynamics/Kinetics

Onset of action: 30-60 minutes

Duration: 4-6 hours

Absorption: Absorbed well from gastrointestinal tract

Distribution: V_d: 18 L/kg

Protein binding: ≥90%

Metabolism: Hepatic

Half-life: 26-36 hours

Time to peak serum concentration: Within 1 hour

Elimination: Kidneys (up to 17%)

Dosage

Oral:

Children >2-12 years: Range: 0.5-3 mg/kg/day in 2-3 divided doses; usual: 1 mg/kg/day; maximum: 3 mg/kg/day

Behavior problems: Initial: 10 mg 2-3 times/day, increase gradually

Severe psychoses: Initial: 25 mg 2-3 times/day, increase gradually

Children >12 years and Adults:

Schizophrenia/psychoses: Initial: 50-100 mg 3 times/day with gradual increments as needed and tolerated; maximum: 800 mg/day in 2-4 divided doses; if >65 years, initial dose: 10 mg 3 times/day

Depressive disorders/dementia: Initial: 25 mg 3 times/day; maintenance dose: 20-200 mg/day

Elderly: Behavioral symptoms associated with dementia: Oral: Initial: 10-25 mg 1-2 times/day; increase at 4- to 7-day intervals by 10-25 mg/day; increase dose intervals (qd, bid, etc) as necessary to control response or side effects. Maximum daily dose: 400 mg; gradual increases (titration) may prevent some side effects or decrease their severity.

Hemodialysis: Not dialyzable (0% to 5%)

Stability Protect all dosage forms from light

Monitoring Parameters Baseline and periodic ECG; vital signs; serum potassium, lipid profile, fasting blood glucose/Hgb A_{1c}; BMI; mental status, abnormal involuntary movement scale (AIMS); periodic eye exam; do not initiate if QT_c >450 msec

Administration Oral concentrate must be diluted in 2-4 oz of liquid (eg, water, fruit juice, carbonated drinks, milk, or pudding) before administration

tion. Do not take antacid within 2 hours of taking drug. **Note:** Avoid skin contact with oral suspension or solution; may cause contact dermatitis.

Contraindications Hypersensitivity to thioridazine or any component of the formulation (cross-reactivity between phenothiazines may occur); severe CNS depression; circulatory collapse; severe hypotension; bone marrow suppression; blood dyscrasias; coma; in combination with other drugs that are known to prolong the QT_c interval; in patients with congenital long QT syndrome or a history of cardiac arrhythmias; concurrent use with medications that inhibit the metabolism of thioridazine (fluoxetine, paroxetine, fluvoxamine, propranolol, pindolol); patients known to have genetic defect leading to reduced levels of activity of CYP2D6

Warnings

[U.S. Boxed Warning]: Thioridazine has dose-related effects on ventricular repolarization leading to QT_c prolongation, a potentially life-threatening effect. Therefore, it should be reserved for patients with schizophrenia who have failed to respond to adequate levels of other antipsychotic drugs. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications which may predispose).

Highly sedating, use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Caution in patients with hemodynamic instability; bone marrow suppression; predisposition to seizures; subcortical brain damage; severe cardiac, hepatic, renal, or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use - use with caution in patients at risk of pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects.

Phenothiazines may cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention); therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other neuroleptics, thioridazine has a high potency of cholinergic blockade.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is low relative to other neuroleptics). May be associated with neuroleptic malignant syndrome (NMS). Doses exceeding recommended doses may cause pigmentary retinopathy.

Dosage Forms Tablet, as hydrochloride: 10 mg, 15 mg, 25 mg, 50 mg, 100 mg, 150 mg, 200 mg

Reference Range

Therapeutic: 1.0-1.5 mcg/mL (SI: 2.7-4.1 μmol/L)

Toxic: > 10.0 mcg/mL (SI: > 27.0 μmol/L); no relationship between serum levels and cardiac toxicity

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal. Consider gastrointestinal decontamination for pediatric ingestions >4 mg/kg or adult ingestions >400mg.

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required. Seizures commonly respond to lorazepam, diazepam, or phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 g), while other antiarrhythmics can be used. Lidocaine is usually **not** effective. Cardiac pacing may need to be performed to treat ventricular arrhythmias. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50 mg I.M. or I.V. slow push followed by a maintenance dose for 48-72 hours. When these reactions are unresponsive to diphenhydramine, benzotropine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes. Sodium bicarbonate (1-3 mEq/kg I.V.) can be used for cardiac conduction abnormalities. Priapism can be treated with 0.2-0.4 mL of phenylephrine (1 mg/mL) intracorporeal every 15 minutes until resolution.

Enhancement of elimination: Multiple dosing of activated charcoal may not be effective; forced diuresis is not effective; not dialyzable (0% to 5%)

Antidote(s)

- Physostigmine [ANTIDOTE]

Diagnostic Procedures

- Thioridazine, Quantitative

Test Interactions False-positives for phenylketonuria, urinary amylase, uroporphyrins, urobilinogen; lowers testosterone levels and serum luteinizing hormone concentrations; may interfere with serum tricyclic levels; high doses of thioridazine can cause a false-positive EMIT urinary immunoassay

Drug Interactions

Substrate of CYP2C19 (minor), 2D6 (major); **Inhibits** CYP1A2 (weak), 2C9 (weak), 2D6 (moderate), 2E1 (weak)

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Aluminum salts: May decrease the absorption of phenothiazines; monitor
Amphetamines: Efficacy may be diminished by antipsychotics; in addition, amphetamines may increase psychotic symptoms; avoid concurrent use

Anticholinergics: May inhibit the therapeutic response to phenothiazines and excess anticholinergic effects may occur; includes benzotropine, trihexyphenidyl, biperiden, and drugs with significant anticholinergic activity (TCAs, antihistamines, disopyramide)

Antihypertensives: Concurrent use of phenothiazines with an antihypertensive may produce additive hypotensive effects (particularly orthostasis)

Beta-blockers: May increase the risk of arrhythmia; propranolol and pindolol are **contraindicated**

Bromocriptine: Phenothiazines inhibit the ability of bromocriptine to lower serum prolactin concentrations

Carvedilol: Serum concentrations may be increased, leading to hypotension and bradycardia; avoid concurrent use

CNS depressants: Sedative effects may be additive with phenothiazines; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents

CYP2D6 inhibitors: May increase the levels/effects of thioridazine.

Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole. **Thioridazine is contraindicated with inhibitors of this enzyme.**

CYP2D6 substrates: Thioridazine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Thioridazine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

Epinephrine: Chlorpromazine (and possibly other low potency antipsychotics) may diminish the pressor effects of epinephrine

Guanethidine and guanadrel: Antihypertensive effects may be inhibited by phenothiazines

Levodopa: Phenothiazines may inhibit the antiparkinsonian effect of levodopa; avoid this combination

Lithium: Phenothiazines may produce neurotoxicity with lithium; this is a rare effect

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk.

Phenytoin: May reduce serum levels of phenothiazines; phenothiazines may increase phenytoin serum levels

Polypeptide antibiotics: Rare cases of respiratory paralysis have been reported with concurrent use of phenothiazines

Potassium-depleting agents: May increase the risk of serious arrhythmias with thioridazine; includes many diuretics, aminoglycosides, and amphotericin; monitor serum potassium closely

Propranolol: Serum concentrations of phenothiazines may be increased; propranolol also increases phenothiazine concentrations; may also occur with pindolol. **These agents are contraindicated with thioridazine.**

QT_c-prolonging agents: Effects on QT_c interval may be additive with phenothiazines, increasing the risk of malignant arrhythmias; includes type Ia antiarrhythmics, TCAs, and some quinolone antibiotics (sparfloxacin, moxifloxacin and gatifloxacin). **These agents are contraindicated with thioridazine.**

Sulfadoxine-pyrimethamine: May increase phenothiazine concentrations
Trazodone: Phenothiazines and trazodone may produce additive hypotensive effects

Tricyclic antidepressants: Concurrent use may produce increased toxicity or altered therapeutic response

Valproic acid: Serum levels may be increased by phenothiazines

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Dilute the oral concentrate with water or juice before administration; avoid skin contact with oral suspension or solution; may cause contact dermatitis

Additional Information Lethal dose: ~1 g

Thioridazine may exhibit an increased risk for cardiac arrest and ventricular arrhythmia at doses >600 mg.

THIOTHIXENE

Oral formulations may cause stomach upset; may cause thermoregulatory changes; extrapyramidal reactions are lower with thioridazine than with other phenothiazines due to high antimuscarinic potency

- Thioridazine: Mellaril-S® oral suspension
- Thioridazine hydrochloride: Mellaril® oral solution and tablet

Specific References

Thiothixene

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antipsychotic Agents

CAS Number 22189-31-7; 49746-04-5; 49746-09-0; 5591-45-7; 58513-59-0

U.S. Brand Names Navane®

Synonyms Tiotixene

Impairment Potential Yes

Use Management of schizophrenia

Unlabeled/Investigational Use Psychotic disorders

Mechanism of Action Elicits antipsychotic activity by postsynaptic blockade of CNS dopamine receptors resulting in inhibition of dopamine-mediated effects; also has alpha-adrenergic blocking activity

Adverse Reactions

Cardiovascular: Hypotension (especially with I.V. use), **hypotension (orthostatic)**, tachycardia, cardiac arrhythmias, sinus tachycardia

Central nervous system: **Pseudoparkinsonian signs and symptoms, tardive dyskinesia, akathisia, dystonias, dizziness**, sedation, drowsiness, restlessness, anxiety, extrapyramidal reactions, neuroleptic malignant syndrome, seizures, altered central temperature regulation, electroencephalogram abnormalities, hyperthermia

Dermatologic: Hyperpigmentation, pruritus, rash, photosensitivity

Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, syndrome of inappropriate antidiuretic hormone (may cause hyponatremia due to inappropriate secretion of antidiuretic hormone)

Gastrointestinal: **Constipation**, GI upset, xerostomia, weight gain

Genitourinary: Urinary retention, impotence

Hematologic: Agranulocytosis, leukopenia (usually in patients with large doses for prolonged periods), thrombocytopenia, hemolysis, eosinophilia

Hepatic: Cholestatic jaundice

Neuromuscular & skeletal: Rhabdomyolysis

Ocular: Retinal pigmentation, blurred vision

Respiratory: **Nasal congestion**

Miscellaneous: **Diaphoresis**, anaphylactoid reactions, systemic lupus erythematosus

Signs and Symptoms of Overdose Agranulocytosis, blood dyscrasias, dizziness, drowsiness, ejaculatory disturbances, eosinophilia, extrapyramidal reaction, galactorrhea, granulocytopenia, gynecomastia, hyponatremia, hypotension, impotence, leukocytosis, leukopenia, myoclonus, neuroleptic malignant syndrome, neutropenia, Parkinson's-like symptoms, priapism, rigidity, tremors, urine discoloration (pink; red; red-brown)

Pharmacodynamics/Kinetics

Onset of action: I.M.: 10-30 minutes

Duration: Up to 12 hours

Absorption: Rapid

Distribution: Widely distributed into body

Protein binding: 91% to 99%

Metabolism: Extensive liver metabolism

Half-life: 34 hours

Time to peak serum concentration: 1-3 hours

Elimination: Bile and feces

Dosage

Oral:

Children <12 years (unlabeled): Schizophrenia/psychoses: 0.25 mg/kg/24 hours in divided doses (dose not well established; use not recommended)

Children >12 years and Adults:

Mild to moderate psychosis: 2 mg 3 times/day, up to 20-30 mg/day; more severe psychosis: Initial: 5 mg 2 times/day, may increase gradually, if necessary; maximum: 60 mg/day

Rapid tranquilization of the agitated patient (administered every 30-60 minutes): 5-10 mg; average total dose for tranquilization: 15-30 mg

Hemodialysis: Not dialyzable (0% to 5%)

Stability

Refrigerate

Monitoring Parameters Vital signs; lipid profile, fasting blood glucose/Hgb A_{1c}; BMI; mental status, abnormal involuntary movement scale (AIMS), extrapyramidal symptoms (EPS)

Contraindications Hypersensitivity to thiothixene or any component of the formulation; severe CNS depression; circulatory collapse; blood dyscrasias; coma

Warnings

May be sedating, use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Caution in patients with hemodynamic instability; predisposition to seizures; subcortical brain damage; bone marrow suppression; severe cardiac, hepatic, renal, or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use - use with caution in patients at risk of pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May alter cardiac conduction - life-threatening arrhythmias have occurred with therapeutic doses of neuroleptics. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications which may predispose). Safety and efficacy in children <12 years of age have not been established.

May cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention); therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other neuroleptics, thiothixene has a low potency of cholinergic blockade.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is high relative to other neuroleptics). May be associated with neuroleptic malignant syndrome (NMS) or pigmentary retinopathy.

Dosage Forms [DSC] = Discontinued product

Capsule: 1 mg, 2 mg, 5 mg, 10 mg

Navane®: 1 mg [DSC], 2 mg, 5 mg, 10 mg, 20 mg

Reference Range At 2.5 hours after dosing of 15-60 mg/day, serum levels ranged from 10.0-22.5 ng/mL; therapeutic: 10-40 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam, diazepam, or phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 g), while other antiarrhythmics can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50 mg I.M. or I.V. slow push followed by a maintenance dose for 48-72 hours. When these reactions are unresponsive to diphenhydramine, benztrapine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes. Sodium bicarbonate (1-3 mEq/kg) can be used for cardiac conduction for abnormalities.

Enhancement of elimination: Multiple dosing of activated charcoal may not be effective; forced diuresis is not effective; not dialyzable (0% to 5%)

Diagnostic Procedures

- Thiothixene, Blood

Test Interactions ↑ cholesterol (S), glucose; ↓ uric acid (S)

Drug Interactions

Substrate of CYP1A2 (major); **Inhibits** CYP2D6 (weak)

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Aluminum salts: May decrease the absorption of antipsychotics; monitor. Amphetamines: Efficacy may be diminished by antipsychotics; in addition, amphetamines may increase psychotic symptoms; avoid concurrent use.

Anticholinergics: May inhibit the therapeutic response to antipsychotics and excess anticholinergic effects may occur; includes benztrapine, trihexyphenidyl, biperiden, and drugs with significant anticholinergic activity (TCAs, antihistamines, disopyramide).

Antihypertensives: Concurrent use of antipsychotics with an antihypertensive may produce additive hypotensive effects (particularly orthostasis).

Bromocriptine: Antipsychotics inhibit the ability of bromocriptine to lower serum prolactin concentrations.

CNS depressants: Sedative effects may be additive with antipsychotics; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents.

CYP1A2 inducers: May decrease the levels/effects of thiothixene. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of thiothixene. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

Epinephrine: Chlorpromazine (and possibly other low potency antipsychotics) may diminish the pressor effects of epinephrine.
 Guanethidine and guanadrel: Antihypertensive effects may be inhibited by antipsychotics.
 Levodopa: Antipsychotics may inhibit the antiparkinsonian effect of levodopa; avoid this combination.
 Lithium: Antipsychotics may produce neurotoxicity with lithium; this is a rare effect.
 Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk.
 Propranolol: Serum concentrations of antipsychotics may be increased; propranolol also increases antipsychotics concentrations.
 QT_c-prolonging agents: Effects on QT_c interval may be additive with antipsychotics, increasing the risk of malignant arrhythmias; includes type Ia antiarrhythmics, TCAs, and some quinolone antibiotics (sparfloxacin, moxifloxacin, and gatifloxacin).
 Sulfadoxine-pyrimethamine: May increase antipsychotics concentrations.
 Trazodone: Antipsychotics and trazodone may produce additive hypotensive effects.
 Tricyclic antidepressants: Concurrent use may produce increased toxicity or altered therapeutic response.
 Valproic acid: Serum levels may be increased by antipsychotics.

Pregnancy Risk Factor C

Pregnancy Implications Crosses placenta

Lactation Excretion in breast milk unknown/not recommended

Thyroid

U.S. Brand Names Armour[®] Thyroid; Nature-Throid[®] NT; Westhroid[®]
Synonyms Desiccated Thyroid; Thyroid Extract; Thyroid USP

Use Replacement or supplemental therapy in hypothyroidism; pituitary TSH suppressants (thyroid nodules, thyroiditis, multinodular goiter, thyroid cancer), thyrotoxicosis, diagnostic suppression tests

Mechanism of Action The primary active compound is T₃ (triiodothyronine), which may be converted from T₄ (thyroxine) and then circulates throughout the body to influence growth and maturation of various tissues; exact mechanism of action is unknown; however, it is believed the thyroid hormone exerts its many metabolic effects through control of DNA transcription and protein synthesis; involved in normal metabolism, growth, and development; promotes gluconeogenesis, increases utilization and mobilization of glycogen stores and stimulates protein synthesis, increases basal metabolic rate

Adverse Reactions

Cardiovascular: Palpitations, tachycardia, cardiac arrhythmias, chest pain, sinus tachycardia, tachycardia (supraventricular)
 Central nervous system: Nervousness, insomnia, fever, headache, psychosis
 Dermatologic: Hair loss
 Gastrointestinal: Weight loss, increased appetite, diarrhea, abdominal cramps
 Neuromuscular & skeletal: Tremors
 Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Angina, CHF, delayed tachycardia, fever (within 12-24 hours), flushing, heat intolerance, hyperthermia, insomnia, menstrual irregularities, mild hypertension, mydriasis, nausea, nervousness, sweating, vomiting, weight loss

Admission Criteria/Prognosis Admit any symptomatic patient or if total serum T₄ exceeds 75 mcg/dL

Pharmacodynamics/Kinetics

Absorption: T₄ is 48% to 79% absorbed; T₃ is 95% absorbed; desiccated thyroid contains thyroxine, liothyronine, and iodine (primarily bound); following absorption thyroxine is largely converted to liothyronine
 Protein binding: 99% (bound to albumin, thyroxine-binding globulin, and thyroxin-binding prealbumin); desiccated thyroid contains thyroxine, liothyronine, and iodine (primarily bound)
 Metabolism: Largely converted to liothyronine; liothyronine is metabolized in the liver to inactive compounds
 Half-life: Liothyronine: 1-2 days; Thyroxine: 6-7 days
 Elimination: Excreted in urine as conjugated forms

Dosage Oral:

Children: See table.

Adults: Start at 15 mg/day and titrate by 15 mg/day in increments of 2- to 4-week intervals; usual maintenance dose: 60-120 mg/day

Monitoring Parameters T₃, T₄, TSH, heart rate, blood pressure, clinical signs of hypo- and hyperthyroidism; in cases where T₄ remains low and TSH is within normal limits, an evaluation of "free" (unbound) T₄ is needed to evaluate further increase in dosage. Check levels of T₃ and T₄ after ingestion, and then every 3 days. Thyroid replacement requires periodic assessment of thyroid status; TSH is the most reliable guide for evaluating adequacy of thyroid replacement dosage. TSH may be elevated during the first few months of thyroid replacement despite patients being clinically euthyroid.

Contraindications Hypersensitivity to beef or pork or any component of the formulation; recent myocardial infarction; thyrotoxicosis uncomplicated by hypothyroidism; uncorrected adrenal insufficiency

Warnings [U.S. Boxed Warning]: Ineffective for weight reduction. High doses may produce serious or even life-threatening toxic effects particularly when used with some anorectic drugs. Use cautiously in patients with pre-existing cardiovascular disease (angina, CHD), elderly since they may be more likely to have compromised cardiovascular function. Chronic hypothyroidism predisposes patients to coronary artery disease. Desiccated thyroid contains variable amounts of T₃, T₄, and other triiodothyronine compounds which are more likely to cause cardiac signs or symptoms due to fluctuating levels. Should avoid use in the elderly for this reason. Drug of choice is levothyroxine in the minds of many clinicians.

Dosage Forms

Tablet: 30 mg, 32.5 mg, 60 mg, 65 mg, 90 mg, 120 mg, 130 mg, 180 mg, 240 mg, 300 mg
 Armour[®] Thyroid: 15 mg, 30 mg, 60 mg, 90 mg, 120 mg, 180 mg, 240 mg, 300 mg
 Nature-Throid[®] NT, Westhroid[®]: 32.5 mg, 65 mg, 130 mg, 195 mg

Reference Range

See table.

Laboratory Ranges	
	Normal Values
T ₄ , Total	5.8-11.0 mcg/dL
T ₃	85-185 ng/dL
T ₃ resin uptake (RT ₃ U)	25%-35%
Free thyroxine index (FT ₄ I)	1.3-4.2
TSH	0.4-4.8 μIU/mL

Overdose/Treatment

Decontamination: Gastric emptying indicated for ingestions >5 mg; ipecac within 30 minutes or (lavage within 1 hour) activated charcoal; cholestyramine is an effective agent to decrease T₄ absorption; 50 mg cholestyramine can bind at least 3 mg of thyroxine, therefore, 4 g of cholestyramine given 4 times/day should be administered in order to interrupt enterohepatic recirculation

Supportive therapy: Propranolol may be used for hyperadrenergic signs (1 mg I.V. in adults, 0.01-0.1 mg/kg in pediatrics); sodium iodate (3 g/1.7 m²) has been used in acute ingestion to prevent T₄ to T₃ conversion

Enhancement of elimination: Plasmapheresis increases elimination 30-fold while charcoal hemoperfusion enhances T₄ elimination fivefold

Diagnostic Procedures

• Thyroxine, Blood

Test Interactions Many drugs may affect thyroid function tests; para-aminosalicylic acid, aminoglutethimide, amiodarone, barbiturates, carbamazepine, chloral hydrate, clofibrate, colestipol, corticosteroids, danazol, diazepam, estrogens, ethionamide, fluorouracil, I.V. heparin, insulin, lithium, methadone, methimazole, mitotane, nitroprusside, oxyphenbutazone, phenylbutazone, PTU, perphenazine, phenytoin, propranolol, salicylates, sulfonyleureas, and thiazides

Drug Interactions Decreased effect:

Beta-blocker effect is decreased when patients become euthyroid
 Thyroid hormones increase the therapeutic need for oral hypoglycemics or insulin
 Estrogens increase TBG, thereby decreasing effect of thyroid replacement
 Cholestyramine and colestipol decrease the effect of orally administered thyroid replacement
 Serum digitalis concentrations are reduced in hyperthyroidism or when hypothyroid patients are converted to a euthyroid state
 Theophylline levels decrease when hypothyroid patients converted to a euthyroid state

Increased toxicity: Thyroid may potentiate the hypoprothrombinemic effect of oral anticoagulants

Pregnancy Risk Factor A

Lactation Enters breast milk/compatible

Nursing Implications Monitor pulse rate and blood pressure

Recommended Pediatric Dosage for Congenital Hypothyroidism		
Age	Daily Dose (mg)	Daily Dose/kg (mg)
0-6 mo	15-30	4.8-6
6-12 mo	30-45	3.6-4.8
1-5 y	45-60	3-3.6
6-12 y	60-90	2.4-3
> 12 y	> 90	1.2-1.8

Tiagabine

CAS Number 115103-54-3

U.S. Brand Names Gabitril®

Synonyms Tiagabine Hydrochloride

Use Adjunctive therapy in adults and children ≥ 12 years of age in the treatment of partial seizures

Mechanism of Action Prolongs action of GABA by inhibiting its reuptake into presynaptic neurons

Adverse Reactions

All adverse effects are dose related

Central nervous system: Dizziness, headache, somnolence, CNS depression, ataxia, amnesia, coma, dizziness (27% to 31%), seizures (5%)

Gastrointestinal: Gingivitis, stomatitis, nausea (11%), vomiting (7%), diarrhea (2% to 10%), abdominal pain (5% to 7%)

Hematologic: Thrombocytopenia

Neuromuscular & skeletal: Tremor (9% to 21%), weakness, myoclonus, myalgia (2% to 5%)

Ocular: Amblyopia (4% to 9%)

Signs and Symptoms of Overdose Seizures can occur with ingestions over one gram in adults or more than 100 mgm in children.

Clinical Effects Reported After Overdose with Tiagabine

Symptom	No. of Patients with Reported Effect	Percent of Total
Lethargy	32	56%
Seizures		
Multiple discrete	16	28%
Status epilepticus	3	5%
Single	2	4%
Agitation	18	32%
Confusion	17	30%
Coma	16	28%
Tachycardia	15	26%
Respiratory depression	12	21%
Tremors	11	19%
Dizziness	6	11%
Dystonias/abnormal posturing	6	11%
Hallucinations	3	5%
Hypertension	3	5%
Hypotension	2	4%

Admission Criteria/Prognosis Admit any ingestion > 300 mg.

Pharmacodynamics/Kinetics

Absorption: Rapid (45 minutes); prolonged with food

Protein binding: 96%, primarily to albumin and α_1 -acid glycoprotein

Metabolism: Hepatic via CYP (primarily 3A4)

Bioavailability: Oral: Absolute: 90%

Half-life elimination: 2-5 hours when administered with enzyme inducers;

7-9 hours when administered without enzyme inducers

Time to peak, plasma: 45 minutes

Excretion: Feces (63%); urine (25%); 2% as unchanged drug; primarily as metabolites

Dosage

Oral (administer with food):

Patients receiving enzyme-inducing AED regimens:

Children 12-18 years: 4 mg once daily for 1 week; may increase to 8 mg daily in 2 divided doses for 1 week; then may increase by 4-8 mg weekly to response or up to 32 mg daily in 2-4 divided doses

Adults: 4 mg once daily for 1 week; may increase by 4-8 mg weekly to response or up to 56 mg daily in 2-4 divided doses; usual maintenance: 32-56 mg/day

Patients **not** receiving enzyme-inducing AED regimens: The estimated plasma concentrations of tiagabine in patients not taking enzyme-inducing medications is twice that of patients receiving enzyme-inducing AEDs. Lower doses are required; slower titration may be necessary.

Monitoring Parameters A reduction in seizure frequency is indicative of therapeutic response to tiagabine in patients with partial seizures; complete blood counts, renal function tests, liver function tests, and routine blood chemistry should be monitored periodically during therapy

Contraindications Hypersensitivity to tiagabine or any component of the formulation

Warnings

New-onset seizures and status epilepticus have been associated with tiagabine use when taken for unlabeled indications. Often these seizures have occurred shortly after the initiation of treatment or shortly

after a dosage increase. Seizures have also occurred with very low doses or after several months of therapy. In most cases, patients were using concomitant medications (eg, antidepressants, antipsychotics, stimulants, narcotics). In these instances, the discontinuation of tiagabine, followed by an evaluation for an underlying seizure disorder, is suggested. Use for unapproved indications, however, has not been proven to be safe or effective and is not recommended. When tiagabine is used as an adjunct in partial seizures (an FDA-approved indication), it should not be abruptly discontinued because of the possibility of increasing seizure frequency, unless safety concerns require a more rapid withdrawal. Rarely, nonconvulsive status epilepticus has been reported following abrupt discontinuation or dosage reduction.

Use with caution in patients with hepatic impairment. Experience in patients not receiving enzyme-inducing drugs has been limited; caution should be used in treating any patient who is not receiving one of these medications (decreased dose and slower titration may be required). Weakness, sedation, and confusion may occur with tiagabine use. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Effects with other sedative drugs or ethanol may be potentiated. Animal studies suggest that tiagabine may bind to retina and uvea; however, no treatment-related ophthalmoscopic changes were seen long-term; periodic monitoring may be considered. May cause serious rash, including Stevens-Johnson syndrome. Safety and efficacy have not been established in children < 12 years of age.

Dosage Forms Tablet, as hydrochloride: 2 mg, 4 mg, 6 mg, 8 mg, 10 mg, 12 mg, 16 mg

Reference Range

Maximal plasma level after a 24 mg/dose: 552 ng/mL

Serum level of 710 ng/mL has been associated with status epilepticus following an overdose.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Myoclonus and seizures responds to I.V. benzodiazepines.

Enhancement of elimination: Due to this drug undergoing enterohepatic recirculation, multiple dosing of activated charcoal may be effective

Drug Interactions

Substrate of 3A4 (major)

CNS depressants: Sedative effects may be additive with other CNS depressants; monitor for increased effect; includes ethanol, sedatives, antidepressants, narcotic analgesics, other anticonvulsants, and benzodiazepines

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of tiagabine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of tiagabine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Valproate: Increased free tiagabine concentrations (*in vitro*) by 40%

Pregnancy Risk Factor C

Lactation Enters breast milk/not recommended

Tiapride

CAS Number 51012-32-9; 51012-33-0

Impairment Potential Yes

Unlabeled/Investigational Use Management of behavioral disorders and dyskinesias; also used for alcohol withdrawal

Mechanism of Action A dopamine (D_2 receptor) antagonist (a substituted benzamide)

Adverse Reactions

Cardiovascular: Orthostatic hypotension, torsade de pointes

Central nervous system: Drowsiness, tardive dyskinesia (in the elderly), malignant neuroleptic syndrome, dystonia

Dermatologic: Erythema

Endocrine & metabolic: Hyperprolactinemia

Admission Criteria/Prognosis Admit ingestion > 3 g

Toxicodynamics/Kinetics

Absorption: 1.4 hours
 Distribution: V_d : 1.43 L/kg
 Protein binding: Low
 Metabolism: Hepatic to N-monodesethyl tiapride
 Bioavailability: 75%
 Half-life: 3-4 hours
 Elimination: Urine (50% to 75%)

Dosage Alcohol detoxification: 100 mg 3 times/day

Extrapyramidal symptomatology: 100-300 mg/day (reduce dosage in renal insufficiency)

Reference Range Following 100 mg oral dose, peak plasma tiapride level is ~1.47 mcg/mL

Overdosage/Treatment

Decontamination: Oral: Activated charcoal
 Supportive therapy: Dystonia can be treated with tetrabenzamide and clozapine; biperidine and sulphiride has been also used to treat dystonia with less effect

Ticlopidine

CAS Number 53885-35-1; 55142-85-3

U.S. Brand Names Ticlid[®]

Synonyms Ticlopidine Hydrochloride

Use Prophylaxis of thromboembolic complications; intermittent claudication; prevention of platelet loss during extracorporeal circulatory procedures; may improve graft patency in coronary artery bypass grafts, improves exercise performance in patients with coronary artery disease. May prevent vaso-occlusive crisis in sickle cell disease; may improve mortality in postmyocardial infarction patients; may offer postoperative protective against deep vein thrombosis; may have some antirheumatic activity. Reduces risk for stroke or transient ischemic attacks. Can reduce proteinuria and hematuria while elevating creatinine clearance in patients with glomerulonephritis.

Unlabeled/Investigational Use Protection of aortocoronary bypass grafts, diabetic microangiopathy, ischemic heart disease, prevention of postoperative DVT, reduction of graft loss following renal transplant

Mechanism of Action Ticlopidine is an inhibitor of platelet function with a mechanism which is different from other antiplatelet drugs. The drug significantly increases bleeding time. This effect may not be solely related to ticlopidine's effect on platelets. The prolongation of the bleeding time caused by ticlopidine is further increased by the addition of aspirin; no inhibition on prostaglandin metabolism is noted.

Adverse Reactions

Central nervous system: Dizziness
 Dermatologic: **Skin rash**, ecchymosis, dermatitis, urticaria, pruritus, acute generalized exanthematous pustulosis, toxic erythroderma, angioneurotic edema
 Gastrointestinal: Diarrhea, nausea, vomiting, GI pain, GI bleed, anorexia, flatulence
 Hematologic: Neutropenia, thrombocytopenia (usually within 3 months of starting therapy), agranulocytosis, anemia, prolonged bleeding time, aplastic anemia, hemolytic/uremic syndrome; thrombotic thrombocytopenic purpura (develops within 1 month of therapy)
 Hepatic: Elevated liver function tests, cholestatic jaundice, cholestasis, cholestatic hepatitis
 Ocular: Retinal vasculitis
 Otic: Tinnitus
 Renal: Hematuria, interstitial nephritis, renal insufficiency
 Respiratory: Epistaxis, bronchiolitis obliterans

Signs and Symptoms of Overdose Abdominal pain, ataxia, confusion, hematologic abnormalities, hypotension, metabolic acidosis, retinal vasculitis, seizures, tachycardia, vomiting

Pharmacodynamics/Kinetics

Onset of action: Within 6 hours
 Peak: Achieved after 3-5 days of oral therapy; serum levels do not correlate with clinical antiplatelet activity
 Duration of action: 4-10 days
 Protein binding: 98%
 Metabolism: Extensively in the liver and has at least one active metabolite, a 2-keto derivative (PCR 3787)
 Bioavailability: Oral: 80% to 90%
 Half-life, elimination: 24 hours (acute); 30-50 hours (chronic)
 Elimination: Fecal: 60%; Urine: 25%

Dosage Adults: Oral: 1 tablet twice daily with food; maximum daily dose: 750 mg

Monitoring Parameters Signs of bleeding; CBC with differential every 2 weeks starting the second week through the third month of treatment; more frequent monitoring is recommended for patients whose absolute neutrophil counts have been consistently declining or are 30% less than baseline values. The peak incidence of TTP occurs between 3-4 weeks, the peak incidence of neutropenia occurs at approximately 4-6 weeks, and the incidence of aplastic anemia peaks after 4-8 weeks of therapy.

Few cases have been reported after 3 months of treatment. Liver function tests (alkaline phosphatase and transaminases) should be performed in the first 4 months of therapy if liver dysfunction is suspected.

Administration Oral: Administer with food.

Contraindications Hypersensitivity to ticlopidine or any component of the formulation; active pathological bleeding such as PUD or intracranial hemorrhage; severe liver dysfunction; hematopoietic disorders (neutropenia, thrombocytopenia, a past history of TTP)

Warnings Use with caution in patients who may have an increased risk of bleeding (such as, ulcers). Consider discontinuing 10-14 days before elective surgery. Use caution in mixing with other antiplatelet drugs. Use with caution in patients with severe liver disease or severe renal impairment (experience is limited). **[U.S. Boxed Warning]: May cause life-threatening hematologic reactions, including neutropenia, agranulocytosis, thrombotic thrombocytopenia purpura (TTP), and aplastic anemia.** Routine monitoring is required (see Monitoring Parameters). Monitor for signs and symptoms of neutropenia including WBC count. Discontinue if the absolute neutrophil count falls to $< 1200/\text{mm}^3$ or if the platelet count falls to $< 80,000/\text{mm}^3$.

Dosage Forms Tablet, as hydrochloride: 250 mg

Reference Range An oral dose of 1 g produces a peak blood ticlopidine concentration of 1.2 mg/L

Overdosage/Treatment

Decontamination: Activated charcoal
 Supportive therapy: Seizures should initially be treated with diazepam or lorazepam; if recurrent, phenobarbital or phenytoin can be given; monitor fluid and electrolyte status; granulocyte-stimulating factor can be used to treat neutropenia; high-dose corticosteroid therapy can be useful against aplastic anemia or prolongation of bleeding time; plasmapheresis should be considered for patients exhibiting thrombocytopenic purpura

Test Interactions \uparrow cholesterol (S) (8% to 10%), alkaline phosphatase, transaminases (S)

Drug Interactions Substrate of CYP3A4 (major); **Inhibits** CYP1A2 (weak), 2C9 (weak), 2C19 (strong), 2D6 (moderate), 2E1 (weak), 3A4 (weak)

Antacids reduce absorption of ticlopidine (~18%).

Anticoagulants or other antiplatelet agents may increase the risk of bleeding; use with caution.

Carbamazepine blood levels may be increased by ticlopidine.

Cimetidine increases ticlopidine levels.

Cyclosporine blood levels may be reduced by ticlopidine.

CYP2C19 substrates: Ticlopidine may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

CYP2D6 substrates: Ticlopidine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Ticlopidine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of ticlopidine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

Digoxin blood levels may be decreased by ticlopidine.

Phenytoin blood levels may be increased by ticlopidine (case reports).

Theophylline blood levels may be increased by ticlopidine.

Pregnancy Risk Factor B

Pregnancy Implications No evidence for teratogenesis in mice/rabbit studies

Lactation Excretion in breast milk unknown

Additional Information Discontinue use 10-14 days prior to surgery; ingestion of 10 g in an adult can cause metabolic acidosis; ingestion of 6 g in an adult resulted in liver function test abnormalities

Tilidine

CAS Number 20380-58-9; 2107-79-5; 24357-97-9

Impairment Potential Yes

Unlabeled/Investigational Use Treat moderate to severe pain

Mechanism of Action Binds to opiate receptors in the CNS, causing inhibition of ascending pain pathways, altering the perception of and

response to pain; produces generalized CNS depression; a cogenor of atropine

Adverse Reactions

Central nervous system: Hallucinations, dizziness, confusion
 Dermatologic: Pruritus
 Gastrointestinal: Nausea, vomiting, salivation
 Hematologic: Porphyrinogenic
 Neuromuscular & skeletal: Tremors, hyperreflexia, hyperactive deep tendon reflexes, clonus, myoclonus
 Ocular: Miosis
 Respiratory: Apnea, respiratory depression

Toxicodynamics/Kinetics

Onset of action: Oral: 15-30 minutes
 Duration of action: 4-6 hours
 Distribution: V_d : 3.71 L/kg
 Metabolism: Hepatic to nortilidine (active metabolite) and bis-nortilidine
 Half-life: 5 hours

Dosage Oral:

Children >2 years: 5 mg plus 2.5 mg per year of age, not to exceed 1 mg/kg
 Adults: 50-100 mg up to 4 times/day; maximum daily dose: 400 mg
 Parenteral: Up to 400 mg
 Rectal: 75 mg 4 times/day

Dosing adjustment in renal impairment: Reduce dose

Reference Range Maximum tilidine plasma concentration of 907 ng/mL achieved after 50 mg dose (I.V.); nortilidine peak plasma level after a 50 mg dose: 69 ng/mL

Overdosage/Treatment

Decontamination: Activated charcoal
 Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at $\frac{2}{3}$ the response dose/hour) may be required

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Additional Information Often combined orally with naloxone (ie, Valoron N®)

Timolol

Related Information

- Selected Properties of Beta-Adrenergic Blocking Drugs
- Therapeutic Drugs Associated with Hallucinations

CAS Number 26839-75-8; 26921-17-5

U.S. Brand Names Betimol®; Blocadren®; Timoptic-XE®; Timoptic® OcuDose®; Timoptic®

Synonyms Timolol Hemihydrate; Timolol Maleate

Use Ophthalmic dosage form used to treat elevated intraocular pressure such as glaucoma or ocular hypertension; orally for treatment of hypertension and angina and reduce mortality following myocardial infarction and prophylaxis of migraine; may exacerbate myasthenia gravis

Mechanism of Action Blocks both beta₁-adrenergic and beta₂-adrenergic receptors, reduces intraocular pressure by reducing aqueous humor production or possibly outflow; reduces blood pressure by blocking adrenergic receptors and decreasing sympathetic outflow, produces a negative chronotropic and inotropic activity through an unknown mechanism

Adverse Reactions

Ophthalmic:

Ocular: **Conjunctival hyperemia**, anisocoria, corneal punctate keratitis, keratitis, corneal staining, decreased corneal sensitivity, eye pain, vision disturbances

Miscellaneous: Systemic allergic reaction (anaphylaxis, angioedema, rash, urticaria)

Systemic:

Cardiovascular: Arrhythmias, chest pain, bradycardia, palpitations, edema, congestive heart failure, reduced peripheral circulation, orthostatic hypotension, Raynaud's phenomenon
 Central nervous system: **Drowsiness, insomnia**, mental depression, confusion (especially in the elderly), hallucinations, headache, nervousness, memory loss, nightmares
 Dermatologic: Angioedema, psoriasis, rash, urticaria
 Endocrine & metabolic: **Decreased sexual ability**
 Gastrointestinal: Diarrhea or constipation, nausea, vomiting, stomach discomfort
 Genitourinary: Retroperitoneal fibrosis
 Hematologic: Leukopenia, thrombocytopenia
 Respiratory: Bronchospasm, dyspnea
 Miscellaneous: Cold extremities, anaphylaxis

Signs and Symptoms of Overdose Ataxia, bradycardia, confusion, depression, dyspnea, heart failure, hypertension, hypoglycemia, impotence, myasthenia gravis (exacerbation or precipitation), severe hypotension, wheezing

Pharmacodynamics/Kinetics

Onset of action:

Hypotensive: Oral: 15-45 minutes

Peak effect: 0.5-2.5 hours

Intraocular pressure reduction: Ophthalmic: 30 minutes

Peak effect: 1-2 hours

Duration: ~4 hours; Ophthalmic: Intraocular: 24 hours

Protein binding: 60%

Metabolism: Extensively hepatic; extensive first-pass effect

Half-life elimination: 2-2.7 hours; prolonged with renal impairment

Excretion: Urine (15% to 20% as unchanged drug)

Dosage Children and Adults: Ophthalmic:

Solution: Initial: 0.25% solution, instill 1 drop twice daily; increase to 0.5% solution if response not adequate; decrease to 1 drop/day if controlled; do not exceed 1 drop twice daily of 0.5% solution
 Gel-forming solution (Timoptic-XE®): Instill 1 drop (either 0.25% or 0.5%) once daily

Adults: Oral:

Hypertension: Initial: 10 mg twice daily, increase gradually every 7 days, usual dosage: 20-40 mg/day in 2 divided doses; maximum: 60 mg/day

Prevention of myocardial infarction: 10 mg twice daily initiated within 1-4 weeks after infarction

Migraine headache: Initial: 10 mg twice daily, increase to maximum of 30 mg/day

Monitoring Parameters Blood pressure, apical and radial pulses, fluid I & O, daily weight, respirations, mental status, and circulation in extremities before and during therapy

Administration Ophthalmic: Administer other topically-applied ophthalmic medications at least 10 minutes before Timoptic-XE®; wash hands before use; invert closed bottle and shake once before use; remove cap carefully so that tip does not touch anything; hold bottle between thumb and index finger; use index finger of other hand to pull down the lower eyelid to form a pocket for the eye drop and tilt head back; place the dispenser tip close to the eye and gently squeeze the bottle to administer 1 drop; remove pressure after a single drop has been released; **do not allow the dispenser tip to touch the eye**; replace cap and store bottle in an upright position in a clean area; do **not** enlarge hole of dispenser; do **not** wash tip with water, soap, or any other cleaner. Some ophthalmic solutions contain benzalkonium chloride; wait at least 10 minutes after instilling solution before inserting soft contact lenses.

Contraindications Hypersensitivity to timolol or any component of the formulation; sinus bradycardia; sinus node dysfunction; heart block greater than first degree (except in patients with a functioning artificial pacemaker); cardiogenic shock; uncompensated cardiac failure; bronchospastic disease; pregnancy (2nd and 3rd trimesters)

Warnings

Administer cautiously in compensated heart failure and monitor for a worsening of the condition. [**U.S. Boxed Warning**]: **Beta-blocker therapy should not be withdrawn abruptly (particularly in patients with CAD), but gradually tapered to avoid acute tachycardia, hypertension, and/or ischemia.** Use caution with concurrent use of beta-blockers and either verapamil or diltiazem; bradycardia or heart block can occur. Beta-blockers can aggravate symptoms in patients with PVD. Patients with bronchospastic disease should generally not receive beta-blockers; monitor closely if used in patients with potential risk of bronchospasm. Use cautiously in diabetics because it can mask prominent hypoglycemic symptoms. Can mask signs of thyrotoxicosis. Can cause fetal harm when administered in pregnancy. Use cautiously in severe renal impairment: marked hypotension can occur in patients maintained on hemodialysis. Use care with anesthetic agents which decrease myocardial function. Can worsen myasthenia gravis.

Ophthalmic: Systemic absorption and adverse effects may occur, including bradycardia and/or hypotension. Should not be used alone in angle-closure glaucoma (has no effect on pupillary constriction). Multidose vials have been associated with development of bacterial keratitis; avoid contamination.

Dosage Forms

Note: Unless otherwise specified, strength expressed as base.

Gel-forming solution, ophthalmic, as maleate: 0.25% (5 mL); 0.5% (2.5 mL, 5 mL)

Timoptic-XE®: 0.25% (5 mL); 0.5% (5 mL)

Solution, ophthalmic, as hemihydrate:

Betimol®: 0.25% (5 mL, 10 mL, 15 mL); 0.5% (5 mL, 10 mL, 15 mL) [contains benzalkonium chloride]

Solution, ophthalmic, as maleate: 0.25% (5 mL, 10 mL, 15 mL); 0.5% (5 mL, 10 mL, 15 mL) [contains benzalkonium chloride]

Istalol™: 0.5% (10 mL) [contains benzalkonium chloride and potassium sorbate]

Timoptic®: 0.25% (5 mL); 0.5% (5 mL, 10 mL) [contains benzalkonium chloride]

Solution, ophthalmic, as maleate [preservative free]:

Timoptic® in OcuDose®: 0.25% (0.2 mL); 0.5% (0.2 mL) [single use]

Tablet, as maleate: 5 mg, 10 mg, 20 mg [strength expressed as salt]

Blocadren®: 20 mg [strength expressed as salt]

Reference Range Following single 20 mg dose, levels may range from 60-114 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** use ipecac

Supportive therapy: Sympathomimetics (eg, epinephrine or dopamine), glucagon, atropine or a pacemaker can be used to treat the toxic bradycardia, asystole, and/or hypotension; initially, fluids may be the best treatment for toxic hypotension

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Test Interactions ↑ cholesterol (S), glucose

Drug Interactions Substrate of CYP2D6 (major); **Inhibits** CYP2D6 (weak)

Albuterol (and other beta₂ agonists): Effects may be blunted by nonspecific beta-blockers.

Alpha-blockers (prazosin, terazosin): Concurrent use of beta-blockers may increase risk of orthostasis.

AV conduction-slowing agents (digoxin): Effects may be additive with beta-blockers.

Clonidine: Hypertensive crisis after or during withdrawal of either agent (not reported with timolol ophthalmic solution)

CYP2D6 inhibitors: May increase the levels/effects of timolol. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Epinephrine (including local anesthetics with epinephrine): Timolol may cause hypertension.

Glucagon: Timolol may blunt hyperglycemic action.

Insulin and oral hypoglycemics: May mask symptoms of hypoglycemia.

NSAIDs (ibuprofen, indomethacin, naproxen, piroxicam) may reduce the antihypertensive effects of beta-blockers.

Salicylates may reduce the antihypertensive effects of beta-blockers.

Sulfonylureas: Beta-blockers may alter response to hypoglycemic agents.

Verapamil or diltiazem may have synergistic or additive pharmacological effects when taken concurrently with beta-blockers.

Pregnancy Risk Factor C (manufacturer); D (2nd and 3rd trimesters - expert analysis)

Pregnancy Implications No data available on whether timolol crosses the placenta. Beta-blockers have been associated with bradycardia, hypotension, hypoglycemia, and intrauterine growth rate (IUGR); IUGR is probably related to maternal hypertension. Available evidence suggests beta-blockers are generally safe during pregnancy (JNC-7). Cases of neonatal hypoglycemia have been reported following maternal use of beta-blockers at parturition or during breast-feeding.

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications Apply gentle pressure to lacrimal sac during and immediately following instillation (1 minute) to avoid systemic absorption; stop drug if breathing difficulty occurs

Additional Information First beta-blocker approved for treatment of the postmyocardial infarction patient; does not cause night blindness.

Tirilazad

Unlabeled/Investigational Use Subarachnoid hemorrhage, spinal cord injury, stroke, head traumas

Mechanism of Action A 21-aminosteroid with antioxidant effects similar to methylprednisolone; inhibits lipid peroxidation

Adverse Reactions

Cardiovascular: Tachycardia (supraventricular), tachycardia (ventricular), palpitations, tachycardia, sinus tachycardia, arrhythmias (ventricular)

Central nervous system: Lightheadedness, drowsiness, headache

Gastrointestinal: Nausea, abdominal pain

Hepatic: Elevated liver function tests

Neuromuscular & skeletal: Muscle cramps, leg cramps

Toxicodynamics/Kinetics

Distribution: V_d: 3 L/kg (single dose); 16-30 L/kg (multiple doses)

Protein binding: 99%

Metabolism: Hepatic

Half-life: 16 hours

Elimination: Feces

Dosage Subarachnoid hemorrhage: I.V.: 2-6 mg/kg/day up to 10 days

Spinal cord injury: 10 mg/kg/day for 2 days is being investigated

Reference Range Peak serum levels after a 3 mg/kg dose: 11.2 mcg/L in men and 7.4 mcg/mL in women

Overdosage/Treatment

Supportive therapy: Supportive and symptomatic treatment, including I.V. fluids and Trendelenburg positioning, should be initiated as intoxication may cause hypotension. Although calcium (calcium chloride I.V. 1-2 g in adults or 10-30 mg/kg in children over 5-10 minutes with repeats as needed) has been used as an "antidote" for acute intoxications, there is limited experience to support its routine use and should be reserved for those cases where definite signs of myocardial depression are evident. Heart block may respond to isoproterenol, glucagon, atropine and/or

calcium, although a temporary pacemaker may be required; norepinephrine, dopamine, or inamrinone for refractory hypotension.

Additional Information As of December 28, 1994, clinical trials of this agent were suspended in treatment of head trauma due to increase in mortality compared to placebo; no glucocorticoid activity; probably most effective when used within 4 hours postinjury

Tirofiban

CAS Number 142373-60-2; 144494-65-5; 150915-40-5

U.S. Brand Names Aggrastat®

Synonyms MK383; Tirofiban Hydrochloride

Use In combination with heparin, indicated for the treatment of acute coronary syndrome, including patients who are to be managed medically and those undergoing PTCA or atherectomy. In this setting, it has been shown to decrease the rate of a combined endpoint of death, new myocardial infarction or refractory ischemia/repeat cardiac procedure.

Mechanism of Action Blocks platelet glycoprotein IIb/IIIa receptors; an antiplatelet agent. A reversible antagonist of fibrinogen binding to the GP IIb/IIIa receptor, the major platelet surface receptor involved in platelet aggregation. When administered intravenously, it inhibits *ex vivo* platelet aggregation in a dose- and concentration-dependent manner. When given according to the recommended regimen, >90% inhibition is attained by the end of the 30-minute infusion. Platelet aggregation inhibition is reversible following cessation of the infusion.

Adverse Reactions

Bleeding is the major drug-related adverse effect. Major bleeding was reported in 1.4% to 2.2%, minor bleeding in 10.5% to 12%, transfusion was required in 4.0% to 4.3%.

> 1% (nonbleeding adverse events):

Cardiovascular: Bradycardia, coronary artery dissection, edema (2%)

Central nervous system: Dizziness, fever (> 1%), headache (> 1%), vasovagal reaction

Gastrointestinal: Nausea (> 1%)

Genitourinary: Pelvic pain

Hematologic: Thrombocytopenia: <90,000/mm³ (1.5%)

Neuromuscular & skeletal: Leg pain

Miscellaneous: Diaphoresis

< 1%: Intracranial bleeding (0.0% to 0.1%), GI bleeding (0.1% to 0.2%), retroperitoneal bleeding (0.0% to 0.6%), GU bleeding (0.0% to 0.1%), thrombocytopenia: <50,000/mm³ (0.3%)

Signs and Symptoms of Overdose Bleeding is the most frequent manifestation of overdose

Pharmacodynamics/Kinetics

Distribution: 35% unbound

Metabolism: Minimally hepatic

Half-life elimination: 2 hours

Excretion: Urine (65%) and feces (25%) primarily as unchanged drug

Clearance: Elderly: Reduced by 19% to 26%

Dosage

Adults: I.V.: Initial rate of 0.4 mcg/kg/minute for 30 minutes and then continued at 0.1 mcg/kg/minute; dosing should be continued through angiography and for 12-24 hours after angioplasty or atherectomy. See table.

Tirofiban Dosing (Using 50 mcg/mL Concentration)

Patient Weight (kg)	Patients with Normal Renal Function		Patients with Renal Dysfunction	
	30-Min Loading Infusion Rate (mL/h)	Maintenance Infusion Rate (mL/h)	30-Min Loading Infusion Rate (mL/h)	Maintenance Infusion Rate (mL/h)
30-37	16	4	8	2
38-45	20	5	10	3
46-54	24	6	12	3
55-62	28	7	14	4
63-70	32	8	16	4
71-79	36	9	18	5
80-87	40	10	20	5
88-95	44	11	22	6
96-104	48	12	24	6
105-112	52	13	26	7
113-120	56	14	28	7
121-128	60	15	30	8
128-137	64	16	32	8
138-145	68	17	34	9
146-153	72	18	36	9

Dosing adjustment in severe renal impairment: $Cl_{cr} < 30$ mL/minute:

Reduce dose to 50% of normal rate

Stability Store at 25°C (77°F); do not freeze. Protect from light during storage.

Monitoring Parameters Platelet count. Hemoglobin and hematocrit should be monitored prior to treatment, within 6 hours following loading infusion, and at least daily thereafter during therapy. Platelet count may need to be monitored earlier in patients who received prior glycoprotein IIb/IIIa antagonists. Persistent reductions of platelet counts $< 90,000/mm^3$ may require interruption or discontinuation of infusion. Because tirofiban requires concurrent heparin therapy, aPTT levels should also be followed. Monitor vital signs and laboratory results prior to, during, and after therapy. Assess infusion insertion site during and after therapy (every 15 minutes or as institutional policy). Observe and teach patient bleeding precautions (avoid invasive procedures and activities that could result in injury). Monitor closely for signs of unusual or excessive bleeding (eg, CNS changes, blood in urine, stool, or vomitus, unusual bruising or bleeding). Breast-feeding is contraindicated.

Administration Intended for intravenous delivery using sterile equipment and technique. Do not add other drugs or remove solution directly from the bag with a syringe. Do not use plastic containers in series connections; such use can result in air embolism by drawing air from the first container if it is empty of solution. Discard unused solution 24 hours following the start of infusion. May be administered through the same catheter as heparin. Tirofiban injection must be diluted to a concentration of 50 mcg/mL (premixed solution does not require dilution).

Contraindications Hypersensitivity to tirofiban or any component of the formulation; active internal bleeding or a history of bleeding diathesis within the previous 30 days; history of intracranial hemorrhage, intracranial neoplasm, arteriovenous malformation, or aneurysm; history of thrombocytopenia following prior exposure; history of CVA within 30 days or any history of hemorrhagic stroke; major surgical procedure or severe physical trauma within the previous month; history, symptoms, or findings suggestive of aortic dissection; severe hypertension (systolic BP > 180 mm Hg and/or diastolic BP > 110 mm Hg); concomitant use of another parenteral GP IIb/IIIa inhibitor; acute pericarditis

Warnings Bleeding is the most common complication. Watch closely for bleeding, especially the arterial access site for the cardiac catheterization. Prior to pulling the sheath, heparin should be discontinued for 3-4 hours and ACT < 180 seconds or aPTT < 45 seconds. Use standard compression techniques after sheath removal. Watch the site closely afterwards for further bleeding. Use with extreme caution in patients with platelet counts $< 150,000/mm^3$, patients with hemorrhagic retinopathy, and chronic dialysis patients. Use caution with administration of other drugs affecting hemostasis. Adjust the dose with severe renal dysfunction ($Cl_{cr} < 30$ mL/minute). The use of tirofiban, aspirin and heparin together causes more bleeding than aspirin and heparin alone. Do not administer in the same I.V. line as diazepam.

Dosage Forms

Infusion [premixed in sodium chloride]: 50 mcg/mL (100 mL, 250 mL)

Injection, solution: 250 mcg/mL (50 mL)

Overdosage/Treatment

Decontamination: Oral: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Cessation of therapy and assessment for transfusion.

Tirofiban has a relatively short half-life and its platelet effects dissipate rather quickly. However, when immediate reversal is required, platelet transfusions can be useful. Tirofiban is dialyzable. Seizures should initially be treated with diazepam or lorazepam; if recurrent, phenobarbital or phenytoin can be given; monitor fluid and electrolyte status; granulocyte-stimulating factor can be used to treat neutropenia; high-dose corticosteroid therapy can be useful against aplastic anemia or prolongation of bleeding time

Drug Interactions

Cephalosporins which contain the MTT side chain may theoretically increase the risk of hemorrhage.

Drugs which affect platelet function (eg, aspirin, NSAIDs, dipyridamole, ticlopidine, clopidogrel) may potentiate the risk of hemorrhage.

Heparin and aspirin: Use with aspirin and heparin is associated with an increase in bleeding over aspirin and heparin alone. However, the concurrent use of aspirin and heparin has also improved the efficacy of tirofiban.

Levothyroxine and omeprazole increase tirofiban clearance; however, the clinical significance of this interaction remains to be demonstrated.

Thrombolytic agents theoretically may increase the risk of hemorrhage.

Warfarin and oral anticoagulants: Risk of bleeding may be increased during concurrent therapy.

Other IIb/IIIa antagonists: Concomitant use of other injectable glycoprotein IIb/IIIa antagonists is contraindicated (see Contraindications).

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown/contraindicated

Tizanidine

CAS Number 51322-75-9

U.S. Brand Names Zanaflex®

Synonyms Sirdalud®

Impairment Potential Yes

Use Skeletal muscle relaxant used for treatment of muscle spasticity, tension headaches

Unlabeled/Investigational Use Tension headaches, low back pain, and trigeminal neuralgia

Mechanism of Action An α_2 -adrenergic agonist agent which decreases excitatory input to alpha motor neurons; an imidazole derivative which acts as a centrally acting muscle relaxant with α_2 -adrenergic agonist properties; acts on the level of the spinal cord

Adverse Reactions

Cardiovascular: **Hypotension**, bradycardia, palpitations, sinus bradycardia

Central nervous system: Insomnia, fatigue, headache, dizziness, **drowsiness, sedation, somnolence**

Dermatologic: Pruritus

Gastrointestinal: Nausea, vomiting, **xerostomia**

Neuromuscular & skeletal: Tremor, **muscle weakness**

Signs and Symptoms of Overdose Bradycardia, dry mouth, hypotension

Pharmacodynamics/Kinetics

Duration: 3-6 hours

Bioavailability: 40%

Metabolism: Extensively hepatic

Half-life elimination: 2 hours

Time to peak, serum:

Fasting state: Capsule, tablet: 1 hour

Fed state: Capsule: 3-4 hours, Tablet: 1.5 hours

Excretion: Urine (60%); feces (20%)

Dosage Muscle spasm: Initial: Oral: 2-4 mg 3 times/day; maximum daily dose:

36 mg

Tension headache: Initial: 2 mg 3 times/day; can titrate after 2 week intervals to a maximum daily dose: 18 mg

Reduce dosage in renal or hepatic impairment

Monitoring Parameters Monitor liver function (aminotransferases) at baseline, 1, 3, 6 months and then periodically thereafter; monitor ophthalmic function

Administration Capsules may be opened and contents sprinkled on food; however, extent of absorption is increased up to 20% relative to administration of the capsule under fasted conditions.

Contraindications Hypersensitivity to tizanidine or any component of the formulation; concomitant therapy with ciprofloxacin or fluvoxamine or other potent inhibitors of CYP1A2

Warnings Reduce dose in patients with liver or renal disease. May cause significant orthostatic hypotension or bradycardia; use with caution in patients with hypotension or cardiac disease. Tizanidine clearance is reduced by more than 50% in elderly patients with renal insufficiency ($Cl_{cr} < 25$ mL/minute) compared to healthy elderly subjects; this may lead to a longer duration of effects and, therefore, should be used with caution in renally impaired patients. Due to extensive hepatic metabolism, avoid use or use extreme caution in patients with hepatic impairment.

Dosage Forms Capsule:

Zanaflex®: 2 mg, 4 mg, 6 mg

Tablet: 2 mg, 4 mg

Zanaflex®: 2 mg [DSC], 4 mg

Reference Range

Peak serum level after a 12 mg oral dose: ~ 12 ng/mL

Postmortem heart blood tizanidine level was 2.3 mg/L in a fatality.

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Benzodiazepines for seizure control; atropine can be given for treatment of bradycardia; flumazenil has been used to reverse coma successfully; hypotension may respond to I.V. crystalloid infusion

Enhancement of elimination: Forced diuresis is not helpful; multiple dosing of activated charcoal may be helpful. Following attempts to enhance drug elimination, hypotension should be treated with I.V. fluids and/or Trendelenburg positioning.

Antidote(s)

• Flumazenil [ANTIDOTE]

Drug Interactions

Substrate of CYP1A2 (major)

Baclofen, other CNS depressants: Additive CNS depression may occur. CYP1A2 inhibitors (potent): May increase the levels/effects of tizanidine.

Significant effects (hypotension) may occur. Example inhibitors include ketoconazole, norfloxacin, ofloxacin, and rofecoxib. Concurrent use is contraindicated.

Ciprofloxacin: May increase the levels/effects (eg, hypotension) of tizanidine. Concurrent use is contraindicated.

Diuretics, other alpha adrenergic agonists, antihypertensives: Additive hypotensive effects may occur.

Fluvoxamine: May increase levels/effects (eg, hypotension) of tizanidine). Contraindicated.

Mirtazapine: May antagonize the alpha-agonist effects of tizanidine.

Oral contraceptives: May decrease the clearance of tizanidine.

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/not recommended

Additional Information Food increases maximum concentration of tizanidine by 33% and reduces the time to peak by 40 minutes; extent of absorption is unchanged

Tizanidine, 20 mg/day, is similar in efficacy to baclofen, 50 mg/day, in treating spasticity due to cerebrovascular lesions

Tocainide

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 35891-93-1; 41708-72-9

U.S. Brand Names Tonocard® [DSC]

Synonyms Tocainide Hydrochloride

Use Suppresses and prevents symptomatic ventricular arrhythmias; limited effectiveness in tachycardia (ventricular)

Unlabeled/Investigational Use Trigeminal neuralgia

Mechanism of Action Suppresses automaticity of conduction tissue, by increasing electrical stimulation threshold of ventricle, His-Purkinje system, and spontaneous depolarization of the ventricles during diastole by a direct action on the tissues; blocks both the initiation and conduction of nerve impulses by decreasing the neuronal membrane's permeability to sodium ions, which results in inhibition of depolarization with resultant blockade of conduction

Adverse Reactions

Similar to lidocaine and mexiletine

Cardiovascular: Hypotension, bradycardia, tachycardia, tachycardia (ventricular), palpitations, heart block, pericardial effusion, sinus tachycardia, arrhythmias (ventricular), sinus bradycardia

Central nervous system: **Dizziness, nervousness, confusion, ataxia, lightheadedness, visual hallucinations, seizures, paranoid psychosis, memory disturbance, paranoia, psychosis**

Dermatologic: Rash, skin lesions, Stevens-Johnson syndrome, erythema multiforme

Gastrointestinal: **Nausea, anorexia, vomiting, diarrhea**

Hematologic: Agranulocytosis, anemia, leukopenia, neutropenia, aplastic anemia, thrombocytopenia

Hepatic: Granulomatous hepatitis

Neuromuscular & skeletal: **Tremors, paresthesia**

Ocular: Nystagmus, diplopia

Otic: Tinnitus

Renal: Glomerulonephritis

Respiratory: **Pulmonary fibrosis, respiratory arrest,**

Miscellaneous: Exacerbation of lupus erythematosus, diaphoresis, systemic lupus erythematosus

Signs and Symptoms of Overdose Anorexia, AV block, delirium, diuresis, exfoliative dermatitis, heart block, hematuria, leukopenia or neutropenia (agranulocytosis, granulocytopenia), metallic taste, pericarditis, tachycardia (ventricular), tinnitus

Pharmacodynamics/Kinetics

Absorption: Oral: 99% to 100%

Distribution: V_d : 1.62-3.2 L/kg

Protein binding: 10% to 20%

Metabolism: Hepatic to inactive metabolites; negligible first-pass effect

Half-life elimination: 11-14 hours; Renal and hepatic impairment: 23-27 hours

Time to peak, serum: 30-160 minutes

Excretion: Urine (40% to 50% as unchanged drug)

Dosage Adults: Oral: 1200-1800 mg/day in 3 divided doses, up to 2400 mg/day

Dosing adjustment in renal impairment: $Cl_{cr} < 30$ mL/minute: Administer 50% of normal dose or 600 mg once daily

Dosing adjustment in hepatic impairment: Maximum daily dose: 1200 mg

Monitoring Parameters Monitor for tremor; titration of dosing and initiation of therapy require cardiac monitoring

Contraindications Hypersensitivity to tocainide, any component of the formulation, or any local anesthetics of the amide type; second- or third-degree heart block (except in patients with a functioning artificial pacemaker)

Warnings Watch for proarrhythmic effects. Correct electrolyte imbalances before initiating (especially hypokalemia and hyperkalemia). Use cautiously in heart failure. Adjust dose in patients with significant renal or hepatic impairment. Bone marrow depression can rarely occur during the first 3 months of therapy.

Dosage Forms [DSC] = Discontinued product

Tablet, as hydrochloride [DSC]: 400 mg, 600 mg

Reference Range Therapeutic: 4-10 mcg/mL (SI: 18-43 μ mol/L); toxic: >12 mcg/mL (SI: 52 μ mol/L)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Seizures can be treated with lorazepam or diazepam, phenytoin, or phenobarbital; do not use isoproterenol for arrhythmia treatment. Hypotension can be managed with isotonic saline, with placement in Trendelenburg position; dopamine or norepinephrine can also be used for refractory hypotension; pacemaker placement may need to be performed for heart block.

Enhancement of elimination: Hemodialysis (for 4 hours) or hemoperfusion are effective; moderately dialyzable (20% to 50%)

Drug Interactions

Inhibits CYP1A2 (weak)

Rifampin may reduce tocainide blood levels.

Urinary alkalinizers (antacids, sodium bicarbonate, acetazolamide) may increase tocainide blood levels.

Pregnancy Risk Factor C

Pregnancy Implications Does not appear to be teratogenic

Lactation Enters breast milk/contraindicated

Nursing Implications Monitor for tremor; titration of dosing and initiation of therapy require cardiac monitoring

Additional Information Minimum lethal dose: 16 g; response correlates with response to lidocaine

TOLAZamide

CAS Number 1156-19-0

U.S. Brand Names Tolinase®

Use Adjunct to diet for the management of mild to moderately severe, stable, noninsulin-dependent (type II) diabetes mellitus

Mechanism of Action Stimulates insulin release from the pancreatic beta cells; reduces glucose output from the liver; insulin sensitivity is increased at peripheral target sites

Adverse Reactions

Cardiovascular: Sinus tachycardia, tachycardia (supraventricular)

Central nervous system: **Headache, ataxia, dizziness**

Dermatologic: Rash, hives, photosensitivity, purpura, pruritus, exanthem

Endocrine & metabolic: Disulfiram reactions, hypoglycemia, hyperinsulinemia

Gastrointestinal: **Anorexia, vomiting, nausea, abdominal pain, diarrhea, constipation, heartburn, epigastric fullness**

Genitourinary: Porphyrinogenic

Hematologic: Leukopenia, thrombocytopenia, aplastic anemia, hemolysis, bone marrow suppression, agranulocytosis, porphyria

Hepatic: Jaundice, cholestasis

Neuromuscular & skeletal: Weakness, fasciculations, paresthesia

Miscellaneous: Systemic lupus erythematosus

Signs and Symptoms of Overdose Diuresis, hypoglycemia, hyponatremia, leukopenia or neutropenia (agranulocytosis, granulocytopenia), lichenoid eruptions, photophobia

Pharmacodynamics/Kinetics

Onset of action: 4-6 hours

Duration: 10-24 hours

Protein binding: >98%

Metabolism: Extensively hepatic to one active and three inactive metabolites

Half-life elimination: 7 hours

Excretion: Urine

Dosage Oral (doses >1000 mg/day normally do not improve diabetic control):

Adults: Initial: 100 mg/day, increase at 2- to 4-week intervals; maximum dose: 1000 mg; give as a single or twice daily dose

Conversion from insulin \rightarrow tolazamide

10 units/day = 100 mg/day

20-40 units/day = 250 mg/day

>40 units/day = 250 mg/day and 50% of insulin dose

Doses >500 mg/day should be given in 2 divided doses

Dosing comments in hepatic impairment: Initial and maintenance doses should be conservative

Monitoring Parameters Signs and symptoms of hypoglycemia (fatigue, sweating, numbness of extremities); urine for glucose and ketones; fasting blood glucose; hemoglobin A_{1c} or fructosamine

TOLAZOLINE

Contraindications Hypersensitivity to tolazamide, sulfonyleureas, or any component of the formulation; type 1 diabetes mellitus (insulin dependent, IDDM) therapy; diabetes complicated by ketoacidosis; pregnancy

Warnings

False-positive response has been reported in patients with liver disease, idiopathic hypoglycemia of infancy, severe malnutrition, acute pancreatitis, renal dysfunction. Transferring a patient from one sulfonyleurea to another does not require a priming dose; doses >1000 mg/day normally do not improve diabetic control. Has not been studied in older patients; however, except for drug interactions, it appears to have a safe profile and decline in renal function does not affect its pharmacokinetics. How "tightly" an elderly patient's blood glucose should be controlled is controversial; however, a fasting blood sugar <150 mg/dL is now an acceptable end point. Such a decision should be based on the patient's functional and cognitive status, how well they recognize hypoglycemic or hyperglycemic symptoms, and how to respond to them and their other disease states.

Chemical similarities are present among sulfonamides, sulfonyleureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonyleurea allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

Product labeling states oral hypoglycemic drugs may be associated with an increased cardiovascular mortality as compared to treatment with diet alone or diet plus insulin. Data to support this association are limited, and several studies, including a large prospective trial (UKPDS) have not supported an association.

Dosage Forms [DSC] = Discontinued product

Tablet: 100 mg, 250 mg, 500 mg

Tolinase® [DSC]: 100 mg, 250 mg

Reference Range Fasting blood glucose: Adults: 80-140 mg/dL; Elderly: 100-180 mg/dL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: Glucose (25 g I.V.) is mainstay of therapy. Glucagon (1-5 mg I.V., I.M., or SubQ) (0.03-0.1 mg/kg in pediatrics) will have limited benefit; diazoxide is a third-line agent (3-8 mg/kg/24 hours); octreotide (50 mcg SubQ every 12 hours) may be helpful in sulfonyleurea overdose.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; not dialyzable (0% to 5%)

Antidote(s)

- Dextrose [ANTIDOTE]
- Glucagon [ANTIDOTE]
- Octreotide [ANTIDOTE]

Diagnostic Procedures

- Electrolytes, Blood
- Glucose, Random

Drug Interactions Increased toxicity: Monitor patient closely; large number of drugs interact with sulfonyleureas including salicylates, anticoagulants, H₂ antagonists, TCAs, MAO inhibitors, beta-blockers, thiazides

Pregnancy Risk Factor D

Pregnancy Implications Can cause neonatal hypoglycemia

Lactation Excretion in breast milk unknown

Nursing Implications Patients who are anorexic or NPO may need to have their dose held to avoid hypoglycemia

Specific References

Tolazoline

CAS Number 59-97-2; 59-98-3

U.S. Brand Names Priscoline® [DSC]

Synonyms Benzazoline Hydrochloride; Tolazoline Hydrochloride

Use Treatment of persistent pulmonary vasoconstriction and hypertension of the newborn (persistent fetal circulation), peripheral vasospastic disorders

Mechanism of Action Competitively blocks alpha-adrenergic receptors to produce brief antagonism of circulating epinephrine and norepinephrine; reduces hypertension caused by catecholamines and causes vascular smooth muscle relaxation (direct action); results in peripheral vasodilation and decreased peripheral resistance

Adverse Reactions

Cardiovascular: **Hypotension**, peripheral vasodilation, tachycardia, palpitations (5%), hypertension, arrhythmias, edema, flushing, pulmonary hypertension, vasodilation

Central nervous system: Vertigo (5%)

Endocrine & metabolic: **Hypochloremic alkalosis**

Gastrointestinal: **GI bleeding, abdominal pain**, vomiting, nausea, diarrhea

Hematologic: **Thrombocytopenia**, agranulocytosis (increased), pancytopenia, leukopenia

Local: **Burning at injection site**

Neuromuscular & skeletal: Increased pilomotor activity, piloerection

Ocular: Mydriasis (in premature infants), ptosis

Renal: **Acute renal failure, oliguria**

Respiratory: Alveolar hemorrhage, pulmonary hemorrhage, dyspnea

Miscellaneous: Secretions (increased)

Pharmacodynamics/Kinetics

Half-life elimination: Neonates: 3-10 hours; prolonged with renal impairment

Time to peak, serum: Within 30 minutes

Excretion: Urine (primarily as unchanged drug)

Dosage

Neonates: Initial: I.V.: 1-2 mg/kg over 10-15 minutes via scalp vein or upper extremity; maintenance: 1-2 mg/kg/hour; use lower maintenance doses in patients with decreased renal function. Also used in neonates for acute vasospasm "cath toes" at 0.25 mg/kg/hour (no load); maximum dose: 6-8 mg/kg/hour

Dosing interval in renal impairment in newborns: Urine output <0.9 mL/kg/hour: Decrease dose to 0.08 mg/kg/hour for every 1 mg/kg of loading dose

Adults: Peripheral vasospastic disorder:

Oral: 25-50 mg 4 times/day

I.M., I.V., SubQ: 10-50 mg 4 times/day

Stability Compatible in D₅W, D₁₀W, and saline solutions

Monitoring Parameters Vital signs, blood gases, cardiac monitor

Administration I.V.: Usual maximum concentration: 0.1 mg/mL

Contraindications Hypersensitivity to tolazoline or any component of the formulation; known or suspected coronary artery disease

Warnings Stimulates gastric secretion and may activate stress ulcers; therefore, use with caution in patients with gastritis, peptic ulcer; use with caution in patients with mitral stenosis

Dosage Forms [DSC] = Discontinued product

Injection, solution, as hydrochloride [DSC]: 25 mg/mL (4 mL)

Overdosage/Treatment

Supportive therapy: For treatment of hypotension, I.V. crystalloid infusion while lowering the head can be performed; for refractory cases, intravenous ephedrine (10-25 mg slow I.V. push in adults or 0.2-0.3 mg/kg every 4-6 hours in children) can be used.

Drug Interactions

Decreased effect (vasopressor) of epinephrine followed by a rebound increase in blood pressure

Increased toxicity: Disulfiram reaction may possibly be seen with concomitant ethanol use

Pregnancy Risk Factor C

Nursing Implications Dilute in D₅W; monitor blood pressure for hypotension; observe limbs for change in color; do not mix with any other drug in syringe or bag

TOLBUTamide

CAS Number 473-41-6; 64-77-7

U.S. Brand Names Orinase Diagnostic® [DSC]; Tol-Tab®

Synonyms Tolbutamide Sodium

Use Adjunct to diet for the management of mild to moderately severe, stable, noninsulin-dependent (type II) diabetes mellitus

Mechanism of Action A sulfonyleurea hypoglycemic agent; its ability to lower elevated blood glucose levels in patients with functional pancreatic beta cells is similar to the other sulfonyleurea agents; stimulates synthesis and release of endogenous insulin from pancreatic islet tissue. The hypoglycemic effect is attributed to an increased sensitivity of insulin receptors and improved peripheral utilization of insulin. Suppression of glucagon secretion may also contribute to the hypoglycemic effects of tolbutamide.

Adverse Reactions

Cardiovascular: Venospasm, tachycardia, tachycardia (atrial), sinus tachycardia, tachycardia (supraventricular)

Central nervous system: **Headache, dizziness**, ataxia, seizures

Dermatologic: Pruritus, systemic contact dermatitis, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria, purpura, licheniform eruptions, exanthem, photoallergic reaction

Endocrine & metabolic: Hypoglycemia, disulfiram-type reactions, syndrome of inappropriate antidiuretic hormone, hyperinsulinemia, hyponatremia

Gastrointestinal: **Anorexia, constipation, heartburn, epigastric fullness, diarrhea**, nausea, vomiting

Hematologic: Leukopenia, thrombocytopenia, porphyria

Hepatic: Jaundice, cholestasis, granulomatous liver disease (noncaseating), elevated transaminases, primary biliary cirrhosis

Local: Thrombophlebitis, phlebitis

Neuromuscular & skeletal: Weakness, fasciculations, paresthesia

Ocular: Retrobulbar neuritis

Otic: Ototoxicity, tinnitus, otic neuropathy

Respiratory: Eosinophilic pneumonia

Miscellaneous: Hypersensitivity reaction, scotoma, fixed drug eruption

Signs and Symptoms of Overdose Eczema, hypoglycemia, hypothyroidism, leukopenia or neutropenia (agranulocytosis, granulocytopenia), photophobia, photosensitivity

Pharmacodynamics/Kinetics

Onset of action: Peak effect: Hypoglycemic action: Oral: 1-3 hours

Duration: Oral: 6-24 hours

Absorption: Oral: Rapid

Distribution: V_d : 6-10 L; increased with decreased albumin concentrations

Protein binding: 95% to 97%, primarily to albumin

Metabolism: Hepatic to hydroxymethyltolbutamide (mildly active) and carboxytolbutamide (inactive); metabolism does not appear to be affected by age

Half-life elimination: Plasma: 4-25 hours; Elimination: 4-9 hours

Time to peak, serum: 3-5 hours

Excretion: Urine (<2% as unchanged drug, primarily as metabolites)

Dosage Divided doses may improve gastrointestinal tolerance

Adults:

Oral: Initial: 1-2 g/day as a single dose in the morning or in divided doses throughout the day. Total doses may be taken in the morning; however, divided doses may allow increased gastrointestinal tolerance. Maintenance dose: 0.25-3 g/day; however, a maintenance dose >2 g/day is seldom required.

I.V. bolus: 1 g over 2-3 minutes

Elderly: Oral: Initial: 250 mg 1-3 times/day; usual: 500-2000 mg; maximum: 3 g/day

Dosing adjustment in renal impairment: Adjustment is not necessary

Hemodialysis: Not dialyzable (0% to 5%)

Dosing adjustment in hepatic impairment: Reduction of dose may be necessary in patients with impaired liver function

Stability Use parenteral formulation within 1 hour following reconstitution

Monitoring Parameters Fasting blood glucose, hemoglobin A_{1c} or fructosamine

Administration Oral: Entire dose can be administered in AM, divided doses may improve GI tolerance

Contraindications Hypersensitivity to tolbutamide, sulfonylureas, or any component of the formulation; diabetes complicated by ketoacidosis; treatment of type 1 diabetes; pregnancy

Warnings

False-positive response has been reported in patients with liver disease, idiopathic hypoglycemia of infancy, severe malnutrition, acute pancreatitis. Because of its low potency and short duration, it is a useful agent in the elderly if drug interactions can be avoided. How "tightly" an elderly patient's blood glucose should be controlled is controversial; however, a fasting blood sugar <150 mg/dL is now an acceptable end point. Such a decision should be based on the patient's functional and cognitive status, how well they recognize hypoglycemic or hyperglycemic symptoms, and how to respond to them and their other disease states. Chemical similarities are present among sulfonamides, sulfonylureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonylurea allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

Product labeling states oral hypoglycemic drugs may be associated with an increased cardiovascular mortality as compared to treatment with diet alone or diet plus insulin. Data to support this association are limited, and several studies, including a large prospective trial (UKPDS) have not supported an association.

Dosage Forms Tablet: 500 mg

Reference Range Fasting blood glucose: Adults: 80-140 mg/dL; Elderly: 100-180 mg/dL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Glucose (25 g I.V.) is mainstay of therapy. Glucagon (1-5 mg I.V., I.M., or SubQ) (0.03-0.1 mg/kg in pediatrics) will have limited benefit; diazoxide is a third-line agent (3-8 mg/kg/24 hours); octreotide (50 mcg SubQ every 12 hours) may be helpful in sulfonylurea overdose.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; not dialyzable (0% to 5%)

Antidote(s)

- Dextrose [ANTIDOTE]
- Glucagon [ANTIDOTE]
- Octreotide [ANTIDOTE]

Diagnostic Procedures

- Electrolytes, Blood
- Glucose, Random

Drug Interactions Substrate of CYP2C9 (major), 2C19 (minor); Inhibits CYP2C8 (weak), 2C9 (strong)

CYP2C9 inducers: May decrease the levels/effects of tolbutamide. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C9 Inhibitors may increase the levels/effects of tolbutamide.

Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nicardipine, NSAIDs, and sulfonamides.

CYP2C9 Substrates: Tolbutamide may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluxetidine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

Increased effects with salicylates, probenecid, MAO inhibitors, chloramphenicol, insulin, phenylbutazone, antidepressants, metformin, H_2 antagonists, and others

Decreased effects:

Hypoglycemic effects may be decreased by beta-blockers, cholestyramine, hydantoins, thiazides, rifampin, and others

Ethanol may decrease the half-life of tolbutamide

Pregnancy Risk Factor D

Pregnancy Implications Abnormal blood glucose levels are associated with a higher incidence of congenital abnormalities. Insulin is the drug of choice for the control of diabetes mellitus during pregnancy.

Lactation Enters breast milk/compatible

Nursing Implications Patients who are anorexic or NPO may need to have their dose held to avoid hypoglycemia

Additional Information Sodium content of 1 g vial: 3.5 mEq

Tolmetin

Related Information

- Nonsteroidal Anti-inflammatory Drugs

CAS Number 26171-23-3 (Base); 35711-34-3 (Anhydrous Sodium); 64490-92-2 (Dihydrate Sodium)

U.S. Brand Names Tolectin® DS; Tolectin®

Synonyms Tolmetin Sodium

Use Treatment of rheumatoid arthritis and osteoarthritis, juvenile rheumatoid arthritis

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors

Adverse Reactions

Cardiovascular: Circulatory collapse

Central nervous system: **Dizziness**, headache, aseptic meningitis, psychosis, cognitive dysfunction, coma, seizures

Dermatologic: **Rash**, pruritus, angioedema, toxic epidermal necrolysis, purpura, exanthem

Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, fluid retention, gynecomastia

Gastrointestinal: **Abdominal cramps, heartburn, indigestion, nausea**, vomiting, GI bleeding, GI ulceration, constipation, diarrhea, dyspepsia, esophageal ulceration, aphthous stomatitis, xerostomia, stomatitis

Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia, aplastic anemia (rare), platelet inhibition

Hepatic: Elevated transaminases, hepatitis (fulminant), hepatic necrosis

Otic: Ototoxicity, tinnitus

Renal: Renal failure (acute), nephrotic syndrome, proteinuria, chronic renal failure, albuminuria

Respiratory: Wheezing, respiratory depression

Miscellaneous: Hypersensitivity, systemic lupus erythematosus

Signs and Symptoms of Overdose Cognitive dysfunction, drowsiness, gastritis, GI bleeding, nausea, nephrotic syndrome, ototoxicity, thrombocytopenia, tinnitus, vomiting, wheezing. Severe poisoning can manifest with coma, hypotension, renal and/or hepatic failure, respiratory depression, seizures

Pharmacodynamics/Kinetics

Onset of action: Analgesic: 1-2 hours; Anti-inflammatory: Days to weeks

Absorption: Well absorbed

Bioavailability: Reduced 16% with food or milk

Half-life elimination: Biphasic: Rapid: 1-2 hours; Slow: 5 hours

Time to peak, serum: 30-60 minutes

Excretion: Urine (as inactive metabolites or conjugates) within 24 hours

Dosage

Oral:

Children ≥ 2 years:

Anti-inflammatory: Initial: 20 mg/kg/day in 3 divided doses, then 15-30 mg/kg/day in 3 divided doses

Analgesic: 5-7 mg/kg/dose every 6-8 hours

Adults: 400 mg 3 times/day; usual dose: 600-1.8 g/day; maximum: 2 g/day

Monitoring Parameters Occult blood loss, CBC, liver enzymes, BUN, serum creatinine, periodic liver function test

Contraindications Hypersensitivity to tolmetin, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy (3rd trimester or near term)

Warnings

[U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension. Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Use caution in patients with advanced renal disease.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

The elderly are at increased risk for adverse effects (especially peptic ulceration, CNS effects, renal toxicity) from NSAIDs even at low doses. Withhold for at least 4-6 half-lives prior to surgical or dental procedures. Safety and efficacy have not been established in children <2 years of age.

Dosage Forms

Capsule: 400 mg

Tablet: 200 mg, 600 mg

Tolectin®: 600 mg [contains sodium 54 mg (2.35 mEq)]

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage

Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be effective

Test Interactions ↑ protein

Drug Interactions ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet drugs (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatide, tirofiban) can cause an increased risk of bleeding.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids may increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use.

Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose. Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again.

Loop diuretics efficacy (diuretic and antihypertensive effect) may be reduced.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Thiazides antihypertensive effects are decreased; avoid concurrent use.

Warfarin's INRs may be increased by piroxicam. Other NSAIDs may have the same effect depending on dose and duration. Monitor INR closely. Use the lowest dose of NSAIDs possible and for the briefest duration.

Pregnancy Risk Factor C/D (3rd trimester or at term)

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Nursing Implications Assess audiometric and ophthalmic exam before, during, and after treatment

Additional Information Sodium content of 200 mg: 0.8 mEq. The only NSAID affected by food/milk, which decreases total bioavailability by 16%. If GI upset occurs with tolmetin, take with antacids other than sodium bicarbonate.

Tolrestat

CAS Number 82964-04-3

Unlabeled/Investigational Use Decrease the adverse effects of diabetes mellitus, specifically diabetic, nephropathy, retinopathy, neuropathy, and cataract formation

Mechanism of Action Carboxylic acid; decreased amounts of sorbitol and fructose are formed from glucose; thus, less water is drawn into the lens (through osmosis) and neurons, thus possibly leading to less diabetic complications

Adverse Reactions

Overdose experience has not been reported

Central nervous system: **Dizziness**

Dermatologic: Rash

Endocrine & metabolic: Hyperchloremic acidosis may occur

Hepatic: Elevated liver enzymes

Toxicodynamics/Kinetics

Absorption: Within 2 hours

Protein binding: 99%

Half-life: 10-13 hours

Elimination: Renal (63% to 68%) and fecal (25% to 27%)

Dosage 200 mg before breakfast or 100 mg twice daily

Reference Range Peak plasma level after a 100 mg oral dose: 5.3-8.8 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) if >1.2 g ingested; activated charcoal can be given

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Tolterodine

U.S. Brand Names Detrol® LA; Detrol®

Synonyms Tolterodine Tartrate

Use Treatment of patients with an overactive bladder with symptoms of urinary frequency, urgency, or urge incontinence

Mechanism of Action Tolterodine is a competitive antagonist of muscarinic receptors. In animal models, tolterodine demonstrates selectivity for urinary bladder receptors over salivary receptors. Urinary bladder contraction is mediated by muscarinic receptors. Tolterodine increases residual urine volume and decreases detrusor muscle pressure.

Adverse Reactions

As reported with immediate release tablet, unless otherwise specified

Cardiovascular: Chest pain, tachycardia, peripheral edema, palpitations

Central nervous system: Headache (extended release capsules), somnolence (extended release capsules), fatigue (extended release capsules), dizziness (extended release capsules), anxiety (extended release capsules), hallucinations

Dermatologic: Dry skin, angioedema

Gastrointestinal: **Dry mouth** (extended release capsules), abdominal pain (extended release capsules), constipation (extended release capsules), dyspepsia (extended release capsules), diarrhea, weight gain

Genitourinary: Dysuria (extended release capsules)

Neuromuscular & skeletal: Arthralgia

Ocular: Abnormal vision (extended release capsules), dry eyes (extended release capsules)

Respiratory: Bronchitis, sinusitis (extended release capsules)

Miscellaneous: Anaphylactoid reactions

Admission Criteria/Prognosis Admit any symptomatic patient or with ingestion > 5 mg.

Pharmacodynamics/Kinetics

Absorption: Immediate release tablet: Rapid; ≥ 77%

Distribution: I.V.: V_d : 113 ± 27 L

Protein binding: > 96% (primarily to alpha₁-acid glycoprotein)

Metabolism: Extensively hepatic, primarily via CYP2D6 (some metabolites share activity) and 3A4 usually (minor pathway). In patients with a genetic deficiency of CYP2D6, metabolism via 3A4 predominates. Forms three active metabolites.

Bioavailability: Immediate release tablet: Increased 53% with food

Half-life elimination:

Immediate release tablet: Extensive metabolizers: ~2 hours; Poor metabolizers: ~10 hours

Extended release capsule: Extensive metabolizers: ~7 hours; Poor metabolizers: ~18 hours

Time to peak: Immediate release tablet: 1-2 hours; Extended release tablet: 2-6 hours

Excretion: Urine (77%); feces (17%); excreted primarily as metabolites (<1% unchanged drug) of which the active 5-hydroxymethyl metabolite accounts for 5% to 14% (<1% in poor metabolizers)

Dosage

Adults: Oral: Initial: 2 mg twice daily; the dose may be lowered to 1 mg twice daily based on individual response and tolerability

Dosing adjustment in patients concurrently taking cytochrome P450 3A4 inhibitors: 1 mg twice daily

Dosing adjustment in renal impairment: Use with caution

Dosing adjustment in hepatic impairment: Administer 1 mg twice daily

Administration Extended release capsule: Swallow whole; do not crush, chew, or open

Contraindications Hypersensitivity to tolterodine or any component of the formulation; urinary retention; gastric retention; uncontrolled narrow-angle glaucoma; myasthenia gravis

Warnings Use with caution in patients with bladder flow obstruction, may increase the risk of urinary retention. Use with caution in patients with gastrointestinal obstructive disorders (ie, pyloric stenosis), may increase the risk of gastric retention. Use with caution in patients with controlled (treated) narrow-angle glaucoma; metabolized in the liver and excreted in the urine and feces, dosage adjustment is required for patients with renal or hepatic impairment. Tolterodine has been associated with QT_c prolongation at high (supratherapeutic) doses. The manufacturer recommends caution in patients with congenital prolonged QT or in patients receiving concurrent therapy with QT_c-prolonging drugs (class Ia or III antiarrhythmics). However, the extent of QT_c prolongation even at supratherapeutic dosages was less than 15 msec. Individuals who are poor metabolizers via CYP2D6 or in the presence of inhibitors of CYP2D6 and CYP3A4 may be more likely to exhibit prolongation. Dosage adjustment is recommended in patients receiving CYP3A4 inhibitors (a lower dose of tolterodine is recommended). Safety and efficacy in pediatric patients have not been established.

Dosage Forms Capsule, extended release, as tartrate (Detrol® LA): 2 mg, 4 mg

Tablet, as tartrate (Detrol®): 1 mg, 2 mg

Reference Range 50% inhibitory blood tolterodine level for salivary stimulation is 6-8 mcg/L

Overdosage/Treatment Decontamination: Lavage within 1 hour/activated charcoal

Drug Interactions

Substrate of CYP2C9 (minor), 2C19 (minor), 2D6 (major), 3A4 (major) Acetylcholinesterase inhibitors (central): May reduce the therapeutic efficacy of tolterodine.

Anticholinergic agents: Concomitant use with tolterodine may increase the risk of anticholinergic side effects.

Antifungal agents (eg, ketoconazole, fluconazole): May increase the levels/effects of tolterodine; monitor.

CYP2D6 inhibitors: May increase the levels/effects of tolterodine, which may include QT_c prolongation. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of tolterodine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of tolterodine, which may include QT_c prolongation. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nocardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Pramlintide: Concomitant use with tolterodine may increase the risk of anticholinergic gastrointestinal adverse effects (eg, reduced gut motility).

Warfarin: Tolterodine may increase the effects of warfarin.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic effects were observed in some animal studies. There are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if the potential benefit to the mother outweighs the possible risk to the fetus.

Lactation Excretion in breast milk unknown/not recommended

Topiramate

CAS Number 97240-79-4

U.S. Brand Names Topamax®

Use In adults and pediatric patients, adjunctive therapy for partial onset seizures and adjunctive therapy of primary generalized tonic-clonic seizures; treatment of seizures associated with Lennox-Gastaut syndrome

Unlabeled/Investigational Use Infantile spasms, neuropathic pain, cluster headache

Mechanism of Action Blocks voltage-activated sodium neuronal channels thus enhancing the inhibiting neurotransmitter gamma aminobutyric

acid (GABA) activity at GABA_A receptors; also attenuates activation of glutamate neuronal receptors

Adverse Reactions

Cardiovascular: Chest pain, edema, AV block

Central nervous system: **Dizziness, ataxia, somnolence, psychomotor slowing, nervousness, memory difficulties, speech problems, fatigue**, language problems, abnormal coordination, confusion, depression, difficulty concentrating, hypoesthesia, hallucinations, psychosis, suicide attempts, delirium, encephalopathy, manic reaction, paranoid reaction, psychosis, suicidal behavior, hyperthermia (severe)

Dermatologic: Photosensitivity, erythema multiforme, pemphigus, Stevens-Johnson syndrome, toxic epidermal necrolysis, alopecia, rash

Endocrine & metabolic: **Serum bicarbonate decreased** (up to 67%; marked reductions to <17 mEq/L have been reported in up to 11% of patients); hot flashes; metabolic acidosis (hyperchloremia, nonanion gap); dehydration

Gastrointestinal: **Nausea**, dyspepsia, abdominal pain, anorexia, constipation, xerostomia, gingivitis, weight loss, diarrhea, vomiting, pancreatitis

Genitourinary: Impotence, dysuria

Hematologic: Bone marrow depression, eosinophilia, granulocytopenia, pancytopenia

Hepatic: Hepatic failure, hepatitis

Neuromuscular & skeletal: **Paresthesia, tremor**, myalgia, weakness, back pain, leg pain, rigors, hypertonia, arthralgia, apraxia, dyskinesia, neuropathy, vertigo, tremor, migraine (aggravated)

Ocular: **Nystagmus, diplopia, abnormal vision**, conjunctivitis, syndrome of acute myopia/secondary angle-closure glaucoma, eye pain

Otic: Hearing decreased, tinnitus

Renal: Nephrolithiasis, renal calculus, renal tubular acidosis

Respiratory: **Upper respiratory infection**, pharyngitis, sinusitis, epistaxis

Miscellaneous: Flu-like symptoms, oligohydrosis

Admission Criteria/Prognosis Overdosage experience is limited; suggest admission if acute neurological symptoms are present or if ingestions exceed 2 g

Pharmacodynamics/Kinetics

Absorption: Good, rapid; unaffected by food

Protein binding: 15% to 41% (inversely related to plasma concentrations)

Metabolism: Hepatic via P450 enzymes

Bioavailability: 80%

Half-life elimination: Mean: Adults: Normal renal function: 21 hours; shorter in pediatric patients; clearance is 50% higher in pediatric patients

Time to peak, serum: ~2-4 hours

Excretion: Urine (~70% to 80% as unchanged drug)

Dialyzable: ~30%

Dosage Oral:

Children 2-16 years: Partial seizures (adjunctive therapy), primary generalized tonic-clonic seizures (adjunctive therapy), or seizure associated with Lennox-Gastaut syndrome: Initial dose titration should begin at 25 mg (or less, based on a range of 1-3 mg/kg/day) nightly for the first week; dosage may be increased in increments of 1-3 mg/kg/day (administered in 2 divided doses) at 1- or 2-week intervals to a total daily dose of 5-9 mg/kg/day.

Adults:

Partial onset seizures (adjunctive therapy), primary generalized tonic-clonic seizures (adjunctive therapy): Initial: 25-50 mg/day; titrate in increments of 25-50 mg per week until an effective daily dose is reached; the daily dose may be increased by 25 mg at weekly intervals for the first 4 weeks; thereafter, the daily dose may be increased by 25-50 mg weekly to an effective daily dose (usually at least 400 mg); usual maximum dose: 1600 mg/day

Note: A more rapid titration schedule has been previously recommended (ie, 50 mg/week), and may be attempted in some clinical situations; however, this may reduce the patient's ability to tolerate topiramate.

Migraine, cluster headache (unlabeled uses): Initial: 25 mg/day, titrated at weekly intervals in 25 mg increments, up to 200 mg/day

Dosing adjustment in renal impairment: Cl_{cr} <70 mL/minute: Administer 50% dose and titrate more slowly

Hemodialysis: Supplemental dose may be needed during hemodialysis

Dosing adjustment in hepatic impairment: Clearance may be reduced

Monitoring Parameters Seizure frequency, hydration status; electrolytes (recommended monitoring includes serum bicarbonate at baseline and periodically during treatment); monitor for symptoms of acute acidosis and complications of long-term acidosis (nephrolithiasis, osteomalacia, and reduced growth rates in children); ammonia level in patients with unexplained lethargy, vomiting, or mental status changes; symptoms of secondary angle closure glaucoma

Administration Oral: May be administered without regard to meals Capsule sprinkles: May be swallowed whole or opened to sprinkle the contents on soft food (drug/food mixture should not be chewed).

Tablet: Because of bitter taste, tablets should not be broken.

Contraindications Hypersensitivity to topiramate or any component of the formulation

Warnings Key Adverse Reactions:

- **Metabolic acidosis (hyperchloremic, nonanion gap):** Topiramate may decrease serum bicarbonate concentrations, due to inhibition of carbonic anhydrase and increased renal bicarbonate loss. Decreases in serum bicarbonate are relatively common (7% to 67%) but usually mild to moderate (average decrease of 4 mEq/L at dose of 400 mg/day in adults and 6 mg/kg/day in children). Treatment-emergent metabolic acidosis is less common; however, risk may be increased in patients with a predisposing condition (renal, respiratory and/or hepatic impairment), ketogenic diet, or concurrent treatment with other drugs which may cause acidosis. Metabolic acidosis may occur at dosages as low as 50 mg/day. Serum bicarbonate should be monitored, as well as potential complications of chronic acidosis (nephrolithiasis, osteomalacia, and reduced growth rates in children). Dose reduction or discontinuation (by tapering dose) should be considered in patients with persistent or severe metabolic acidosis. If treatment is continued, alkali supplementation should be considered.
- **Kidney stones:** The risk of kidney stones is about 2-4 times that of the untreated population, the risk of this event may be reduced by increasing fluid intake.
- **Hyperthermia:** May be associated (rarely) with severe oligohydrosis and hyperthermia, most frequently in children; use caution and monitor closely during strenuous exercise, during exposure to high environmental temperature, or in patients receiving drugs with anticholinergic activity.
- **CNS Effects:** Cognitive dysfunction, psychiatric disturbances (mood disorders), and sedation (somnolence or fatigue) may occur with topiramate use; incidence may be related to rapid titration and higher doses. Topiramate may also cause paresthesia and ataxia.
- **Withdrawal:** Avoid abrupt withdrawal of topiramate therapy, it should be withdrawn/tapered slowly to minimize the potential of increased seizure frequency.

Concurrent Disease:

- **Organ dysfunction:** Use cautiously in patients with hepatic or renal impairment; dosage adjustment may be required
- **Glaucoma:** Has been associated with secondary angle-closure glaucoma in adults and children, typically within 1 month of initiation. Discontinue in patients with acute onset of decreased visual acuity or ocular pain.

Concurrent Drug Therapy:

- **Valproate:** Hyperammonemia with or without encephalopathy may occur and has been documented in patients who have tolerated each drug alone. Risk may be increased in patients with inborn errors of metabolism or decreased hepatic mitochondrial activity. Monitor for lethargy, vomiting, or unexplained changes in mental status.

Special populations:

- **Safety and efficacy** have not been established in children <2 years of age for adjunctive treatment and <10 years of age for monotherapy.
- **Pregnancy:** No adequate and well-controlled studies have been conducted; use only if benefit clearly outweighs risk

Dosage Forms Capsule, sprinkle: 15 mg, 25 mg

Tablet: 25 mg, 50 mg, 100 mg, 200 mg

Reference Range

Peak plasma topiramate level after a 1.2 g dose: ~29 mcg/mL
Postmortem blood (central) and vitreous fluid levels following a topiramate overdose was 170 mg/L (490 µmole/L) and 65 mg/L (190 µmole/L), respectively

Overdosage/Treatment

Decontamination: Lavage ingestions >1 g/activated charcoal
Enhanced elimination: Multiple dosing of activated charcoal may be beneficial; topiramate is cleared by hemodialysis at a rate that is almost 6 times that of normal individuals

Drug Interactions

Inhibits CYP2C19 (weak); **Induces** CYP3A4 (weak)

Acetazolamide: Coadministration may increase the chance of nephrolithiasis and/or hyperthermia.

Anticholinergic drugs: Concurrent administration may increase the risk of oligohydrosis and/or hyperthermia; includes drugs with high anticholinergic activity such as antihistamines, cyclic antidepressants, and antipsychotics; use caution

Carbamazepine: May reduce topiramate levels 40%

CNS depressants: Sedative effects may be additive with topiramate; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents.

Digoxin: Blood levels of digoxin are decreased when coadministered with topiramate.

Estrogens: Blood levels of estrogens are decreased when coadministered with topiramate, this may lead to a loss of efficacy.

Oral contraceptives: See interaction with Estrogens; use of alternative nonhormonal contraception is recommended.

Phenytoin: May decrease topiramate levels by as much as 48%; topiramate may increase phenytoin concentration by 25%

Valproic acid: Hyperammonemia with or without encephalopathy has been reported in patients who tolerated either drug alone. These drugs may modestly decrease the serum concentrations of the other drug.

Pregnancy Risk Factor C

Pregnancy Implications Topiramate was found to be teratogenic in animal studies; however, there is limited information in pregnant women; use only if benefit to the mother outweighs the risk to the fetus. Based on limited data, topiramate was found to cross the placenta. Postmarketing experience includes reports of hypospadias following *in vitro* exposure to topiramate.

Lactation Enters breast milk/not recommended

Torseamide

CAS Number 56211-40-6; 72810-59-4

U.S. Brand Names Demadex®

Use Management of edema associated with congestive heart failure and hepatic or renal disease; used alone or in combination with antihypertensives in treatment of hypertension; I.V. form is indicated when rapid onset is desired

Mechanism of Action Inhibits reabsorption of sodium and chloride in the ascending loop of Henle and distal renal tubule, interfering with the chloride-binding cotransport system, thus causing increased excretion of water, sodium, chloride, magnesium, and calcium; less potassium loss than furosemide

Adverse Reactions

Cardiovascular: Orthostatic hypotension, vasculitis

Central nervous system: Dizziness, headache

Dermatologic: Urticaria, photosensitivity, angioedema, cutaneous vasculitis

Endocrine & metabolic: Hypokalemia, hyponatremia, hypochloremia, alkalosis, dehydration, hyperuricemia

Gastrointestinal: Pancreatitis, nausea, oral solutions may cause diarrhea due to sorbitol content

Hematologic: Agranulocytosis, anemia, thrombocytopenia

Otic: Potential ototoxicity, tinnitus

Renal: Nephrocalcinosis, interstitial nephritis, hypercalciuria, prerenal azotemia, renal vasculitis

Respiratory: Rhinitis, pulmonary vasculitis

Signs and Symptoms of Overdose Agranulocytosis, disorientation, diuresis, granulocytopenia, hyperuricemia, hypokalemia, hyponatremia, hypotension, leukopenia, neutropenia, nocturia

Pharmacodynamics/Kinetics

Onset of action: Diuresis: 30-60 minutes

Peak effect: 1-4 hours

Duration: ~6 hours

Absorption: Oral: Rapid

Protein binding, plasma: ~97% to 99%

Metabolism: Hepatic (80%) via CYP

Bioavailability: 80% to 90%

Half-life elimination: 2-4; Cirrhosis: 7-8 hours

Excretion: Urine (20% as unchanged drug)

Dosage Adults: Oral, I.V.:

Congestive heart failure: 10-20 mg once daily; may increase gradually for chronic treatment by doubling dose until the diuretic response is apparent (for acute treatment, I.V. dose may be repeated every 2 hours with double the dose as needed)

Chronic renal failure: 20 mg once daily; increase as described above
Hepatic cirrhosis: 5-10 mg once daily with an aldosterone antagonist or a potassium-sparing diuretic; increase as described above

Hypertension: 2.5-5 mg once daily; increase to 10 mg after 4-6 weeks if an adequate hypotensive response is not apparent; if still not effective, an additional antihypertensive agent may be added

Monitoring Parameters Renal function, electrolytes, and fluid status (weight and I & O), blood pressure

Administration I.V. injections should be administered over ≥ 2 minutes; the oral form may be administered regardless of meal times; patients may be switched from the I.V. form to the oral and vice versa with no change in dose; no dosage adjustment is needed in the elderly or patients with hepatic impairment

To administer as a continuous infusion: 50 mg or 200 mg torsemide should be diluted in 250 mL or 500 mL of compatible solution in plastic containers

Contraindications Hypersensitivity to torsemide, any component of the formulation, or any sulfonyleureas; anuria

Warnings

Adjust dose to avoid dehydration. In cirrhosis, avoid electrolyte and acid/base imbalances that might lead to hepatic encephalopathy. Ototoxicity is associated with rapid I.V. administration of other loop diuretics and has been seen with oral torsemide. Do not administer intravenously in less than 2 minutes; single doses should not exceed 200 mg. Hypersensitivity reactions can rarely occur. Monitor fluid status and renal function in an attempt to prevent oliguria, azotemia, and reversible increases in BUN and creatinine. Close medical supervision of aggressive diuresis is required. Monitor closely for electrolyte imbalances particularly hypokalemia and correct when necessary. Coadministration with antihypertensives may increase the risk of hypotension. Chemical similarities are present among sulfonamides, sulfonyleureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonyleurea allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

Dosage Forms Injection, solution: 10 mg/mL (2 mL, 5 mL)

Tablet: 5 mg, 10 mg, 20 mg, 100 mg

Reference Range

Peak serum level:

Healthy person: 4 mcg/mL 1 hour after 20 mg dose

Edematous patient: 3.7 mcg/mL 1 hour after 20 mg dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Crystalloid (normal saline) with Trendelenburg position for hypotension; dopamine or norepinephrine for refractory hypotension

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; not dialyzable

Antidote(s)

● DOPamine [ANTIDOTE]

● Norepinephrine [ANTIDOTE]

Test Interactions \uparrow uric acid, creatinine

Drug Interactions **Substrate** of CYP2C8 (minor), 2C9 (major); **Inhibits** CYP2C19 (weak)

ACE inhibitors: Hypotensive effects and/or renal effects are potentiated by hypovolemia.

Aminoglycosides: Ototoxicity may be increased.

Anticoagulant activity is enhanced.

Antidiabetic agents: Glucose tolerance may be decreased.

Antihypertensive agents: Effects may be enhanced.

Beta-blockers: Plasma concentrations of beta-blockers may be increased with torsemide.

Chloral hydrate: Transient diaphoresis, hot flashes, hypertension may occur.

Cisplatin: Ototoxicity may be increased.

CYP2C9 inducers: May decrease the levels/effects of torsemide. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

Digitalis: Arrhythmias may occur with diuretic-induced electrolyte disturbances.

Lithium: Plasma concentrations of lithium may be increased; monitor lithium levels.

NSAIDs: Torsemide efficacy may be decreased.

Probenecid: Torsemide action may be reduced.

Salicylates: Diuretic action may be impaired in patients with cirrhosis and ascites.

Thiazides: Synergistic effects may result.

Pregnancy Risk Factor B

Pregnancy Implications A decrease in fetal weight, an increase in fetal resorption, and delayed fetal ossification has occurred in animal studies.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Monitor renal function, electrolytes, and fluid states closely including weight and I & O

Additional Information 10-20 mg torsemide is approximately equivalent to: Furosemide: 40 mg; bumetanide: 1 mg; piretanide: 12 mg

Tramadol

CAS Number 22204-88-2; 27203-92-5; 36282-47-0

U.S. Brand Names Ultram[®] ER; Ultram[®]

Synonyms Tramadol Hydrochloride

Impairment Potential Yes

Use Relief of moderate to moderately severe pain

Treatment of restless legs syndrome

Mechanism of Action Centrally acting analgesic with selective (μ) opioid receptor agonist and norepinephrine and serotonin reuptake inhibition; ~1.5-3 times less potent than morphine but more antitussive effect than codeine

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), shock, tachycardia, sinus tachycardia, sinus bradycardia

Central nervous system: Headache, dizziness, lethargy, stimulation, euphoria, seizures, depression and suicidal ideation, hyperthermia, panic attacks, mania

Dermatologic: Pruritus, erythema, urticaria, exanthem

Gastrointestinal: Constipation, nausea, vomiting, xerostomia

Neuromuscular & skeletal: Hyperreflexia, hyporeflexia, tremor, rhabdomyolysis

Otic: Tinnitus

Respiratory: Respiratory depression, laryngospasm

Miscellaneous: Diaphoresis, anaphylactoid reactions, trismus

Signs and Symptoms of Overdose Coma, miosis, respiratory depression, seizures (at oral doses >700 mg or I.V. doses >300 mg), sleepiness

Admission Criteria/Prognosis Admit any patient with CNS depression, seizures, or ingestions >600 mg.

Pharmacodynamics/Kinetics

Onset of action: ~1 hour

Duration of action: 9 hours

Absorption: Rapid and complete

Distribution: V_d : 2.5-3 L/kg

Protein binding, plasma: 20%

Metabolism: Extensively hepatic via demethylation, glucuronidation, and sulfation; has pharmacologically active metabolite formed by CYP2D6 (M1; O-desmethyl tramadol)

Bioavailability: Immediate release: 75%; Extended release: 85% to 90% as compared to immediate release.

Half-life elimination: Tramadol: ~6-8 hours; Active metabolite: 7-9 hours; prolonged in elderly, hepatic or renal impairment

Time to peak: Immediate release: 2 hours; Extended release: 12 hours

Excretion: Urine (30% as unchanged drug; 60% as metabolites)

Dosage

Moderate-to-severe chronic pain: Oral:

Adults:

Immediate release formulation: 50-100 mg every 4-6 hours (not to exceed 400 mg/day)

For patients not requiring rapid onset of effect, tolerability may be improved by starting dose at 25 mg/day and titrating dose by 25 mg every 3 days, until reaching 25 mg 4 times/day. Dose may then be increased by 50 mg every 3 days as tolerated, to reach dose of 50 mg 4 times/day.

Extended release formulation: 100 mg once daily; titrate every 5 days (maximum: 300 mg/day)

Elderly: >75 years:

TRANLYCYPROMINE

Immediate release: 50 mg every 6 hours (not to exceed 300 mg/day); see dosing adjustments for renal and hepatic impairment.

Extended release formulation: See adult dosing.

Restless legs syndrome: Oral: 50 mg 1 hour before bedtime and as needed for daytime symptoms; maximum daily dose 150 mg

Dosing adjustment in renal impairment:

Immediate release: $Cl_{cr} < 30$ mL/minute: Administer 50-100 mg dose every 12 hours (maximum: 200 mg/day)

Extended release: Should not be used in patients with $Cl_{cr} < 30$ mL/minute

Dosing adjustment in hepatic impairment:

Immediate release: Cirrhosis: Recommended dose: 50 mg every 12 hours

Extended release: Should not be used in patients with severe (Child-Pugh Class C) hepatic dysfunction

Monitoring Parameters Pain relief, respiratory rate, blood pressure, and pulse; signs of tolerance or abuse

Administration

Do not crush or chew extended release tablet.

Contraindications

Hypersensitivity to tramadol, opioids, or any component of the formulation; opioid-dependent patients; acute intoxication with alcohol, hypnotics, centrally-acting analgesics, opioids, or psychotropic drugs

Ultram[®] ER (extended release formulation): Additional contraindications: Severe ($Cl_{cr} < 30$ mL/minute) renal dysfunction, severe (Child-Pugh Class C) hepatic dysfunction

Warnings Should be used only with extreme caution in patients receiving MAO inhibitors. May cause CNS depression and/or respiratory depression, particularly when combined with other CNS depressants. Use with caution and reduce dosage when administered to patients receiving other CNS depressants. An increased risk of seizures may occur in patients receiving serotonin reuptake inhibitors (SSRIs or anorectics), tricyclic antidepressants, other cyclic compounds (including cyclobenzaprine, promethazine), neuroleptics, MAO inhibitors, or drugs which may lower seizure threshold. Patients with a history of seizures, or with a risk of seizures (head trauma, metabolic disorders, CNS infection, or malignancy, or during ethanol/drug withdrawal) are also at increased risk.

Elderly patients and patients with chronic respiratory disorders may be at greater risk of adverse events. Use with caution in patients with increased intracranial pressure or head injury. Avoid use in patients who are suicidal or addiction prone. Use caution in heavy alcohol users. Use caution in treatment of acute abdominal conditions; may mask pain. Use tramadol with caution and reduce dosage in patients with liver disease or renal dysfunction. Not recommended during pregnancy or in nursing mothers. Tolerance or drug dependence may result from extended use (withdrawal symptoms have been reported); abrupt discontinuation should be avoided. Tapering of dose at the time of discontinuation limits the risk of withdrawal symptoms. Safety and efficacy in pediatric patients <18 years of age have not been established; use in this population is not recommended.

Dosage Forms

Tablet, as hydrochloride: 50 mg

Ultram[®]: 50 mg

Tablet, extended release, as hydrochloride:

Ultram[®] ER: 100 mg, 200 mg, 300 mg

Reference Range Serum tramadol levels ranging from 100-300 ng/mL can be considered therapeutic; blood (postmortem) tramadol levels >13 mg/L associated with fatality by suicide attempt

Overdosage/Treatment

Decontamination: Activated charcoal/sorbitol

Supportive therapy: Treat seizures with benzodiazepines or barbiturates; naloxone is probably not effective in treating seizures but may be of some use in treating CNS depression (naloxone may increase the risk for seizures); naloxone is effective in ~1/2 the cases

Elimination: Multiple doses of activated charcoal; hemodialysis or hemoperfusion not likely to be beneficial after absorption and distribution are completed (hemodialysis removes only ~7% of the dose)

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Test Interactions Generally does not interfere with urine opiate screens; false-positive tramadol urinary assay can occur with venlafaxine by tandem mass spectrometry

Drug Interactions

Substrate of CYP2B6 (minor), 2D6 (major), 3A4 (minor)

Carbamazepine: Tramadol metabolism is increased by carbamazepine. Avoid concurrent use; increases risk of seizures.

Cyclobenzaprine: May enhance the neuroexcitatory and/or seizure-potentiating effect of tramadol.

CYP2D6 inhibitors: May decrease the effects of tramadol. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Ethanol: Tramadol may enhance the CNS depressant effect of ethanol.

MAO inhibitors: May increase the neuroexcitatory effects or risk of seizures. Examples of inhibitors include isocarboxazid, linezolid, phenelzine, selegiline, and tranlycypromine.

Naloxone: May increase the risk of seizures (if administered in tramadol overdose).

Quinidine: May increase the tramadol serum concentrations and decrease serum concentrations of M1

SSRIs: May increase the neuroexcitatory effects or risk of seizures with tramadol. Examples of SSRIs include citalopram, escitalopram, fluoxetine, fluvoxamine, paroxetine, sertraline.

Serotonin modulators: May enhance the adverse/toxic effects of tramadol. The development of serotonin syndrome may occur.

Sibutramine: May enhance the serotonergic effects of tramadol. Avoid concurrent use.

Tricyclic antidepressants: May increase the risk of seizures.

Pregnancy Risk Factor C

Pregnancy Implications Crosses placenta with umbilical/maternal venous concentration ratio of 80%

Lactation Enters breast milk/contraindicated

Additional Information Fatal dose: ~3 g. Metoclopramide can be used to treat tramadol-induced nausea and vomiting. Ultracet[®], a short-term (≤5 days) combination product for management of acute pain, contains 37.5 mg of tramadol hydrochloride and 325 mg acetaminophen

Tranlycypromine

CAS Number 13492-01-8; 155-09-9

U.S. Brand Names Parnate[®]

Synonyms Transamine Sulphate; Tranlycypromine Sulfate

Impairment Potential Yes

Use Symptomatic treatment of atypical, nonendogenous or neurotic depression

Unlabeled/Investigational Use Post-traumatic stress disorder

Mechanism of Action Thought to act by increasing endogenous concentrations of epinephrine, norepinephrine, dopamine and serotonin through inhibition of the enzyme (monoamine oxidase) responsible for the breakdown of these neurotransmitters

Adverse Reactions

Cardiovascular: Orthostatic hypotension, edema

Central nervous system: Dizziness, headache, drowsiness, sleep disturbances, fatigue, hyperreflexia, twitching, ataxia, mania, akinesia, confusion, disorientation, memory loss

Dermatologic: Rash, pruritus, urticaria, localized scleroderma, cystic acne (flare), alopecia

Endocrine & metabolic: Sexual dysfunction (anorgasmia, ejaculatory disturbances, impotence), hypernatremia, hypermetabolic syndrome, SIADH

Gastrointestinal: Xerostomia, constipation, weight gain

Genitourinary: Urinary retention, incontinence

Hematologic: Leukopenia, agranulocytosis

Hepatic: Hepatitis

Neuromuscular & skeletal: Weakness, tremor, myoclonus

Ocular: Blurred vision, glaucoma

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Agranulocytosis, delirium, extrapyramidal reaction, fever, granulocytopenia, hypertension, impotence, insomnia, leukopenia, neutropenia, numbness, ptosis, thrombocytopenia

Pharmacodynamics/Kinetics

Onset of action: Therapeutic: 2 days to 3 weeks continued dosing

Half-life elimination: 90-190 minutes

Time to peak, serum: ~2 hours

Excretion: Urine

Dosage Adults: Oral: 10 mg twice daily, increase by 10 mg increments at 1- to 3-week intervals; maximum: 60 mg/day

Monitoring Parameters Blood pressure, mental status

Contraindications Hypersensitivity to tranylcypromine, other MAO inhibitors, dibenzazepine derivatives, or any component of the formulation; cardiovascular disease; cerebrovascular defect; headache history; hepatic disease; hypertension; pheochromocytoma; renal disease; concurrent use of antihistamines, antiparkinson drugs, antihypertensives, bupropion, buspirone, CNS depressants, dexfenfluramine, dextromethorphan, diuretics, ethanol, meperidine, and SSRIs; general anesthesia (discontinue 10 days prior to elective surgery); local vasoconstrictors; spinal anesthesia (hypotension may be exaggerated); sympathomimetics (and related compounds); foods high in tyramine content; supplements containing tyrosine, phenylalanine, tryptophan, or caffeine

Warnings

Risk of suicide: [U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania. The child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. A medication guide should be dispensed with each prescription. **Tranylcypromine is not FDA approved for treatment of children and adolescents.**

Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care.

Disease state precautions: Use with caution in patients who are hyperactive, hyperexcitable, or who have glaucoma, hyperthyroidism, diabetes or hypotension. May cause orthostatic hypotension (especially at dosages >30 mg/day); use with caution in patients who would not tolerate transient hypotensive episodes. Use with caution in patients at risk of seizures, or in patients receiving other drugs which may lower seizure threshold. Discontinue at least 48 hours prior to myelography. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Use with caution in patients with renal impairment. May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Tranylcypromine is not FDA approved for the treatment of bipolar depression.**

Elderly patients: The MAO inhibitors are effective and generally well tolerated by older patients. It is the potential interactions with tyramine or tryptophan-containing foods and other drugs, and their effects on blood pressure that have limited their use.

Dosage Forms Tablet: 10 mg

Reference Range Therapeutic blood level: 0.1 mg/L; serum level of 1 mg/L has been associated with coma

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Diazepam or lorazepam can be used for agitation/seizures. Dantrolene (2.5 mg/kg every 6 hours) can be used for muscle rigidity and hyperthermia. Labetalol may be useful for hypertension, while norepinephrine is the preferred agent for treatment of hypotension. Avoid bretylium for ventricular dysrhythmia, lidocaine or procainamide are preferred. Hypertensive crisis can be treated with nitroprusside, phentolamine (2-10 mg slow I.V. injection in adults), diazoxide (50-100 mg I.V.). Dantrolene (2.5 mg/kg every 6 hours I.V.) can be used to treat hypermetabolic crisis.

Enhancement of elimination: Hemodialysis may be useful.

Diagnostic Procedures

- Electrolytes, Blood

Drug Interactions Inhibits CYP1A2 (moderate), 2A6 (strong), 2C8 (weak), 2C9 (weak), 2C19 (moderate), 2D6 (moderate), 2E1 (weak), 3A4 (weak)

Acetylcholinesterase inhibitors: May diminish the anticholinergic side effects of tranylcypromine.

Alpha-/beta-agonists: MAO inhibitors may enhance the vasopressor effect. Alpha-/beta-agonists (indirect-acting): MAO inhibitors may enhance the vasopressor effect.

Alpha₁-agonist: MAO inhibitors may enhance the hypertensive effects.

Altramamine: May enhance the orthostatic effect of MAO inhibitors.

Amphetamines: MAO inhibitors in combination with amphetamines may result in severe hypertensive reaction; these combinations are best avoided.

Anesthetics, general: Discontinue tranylcypromine 10 days prior to elective surgery.

Anorexiant: Concurrent use of anorexiant may result in serotonin syndrome; contraindicated with dexfenfluramine; avoid use with fenfluramine or sibutramine.

Anticholinergics: May enhance the adverse/toxic anticholinergic effects of tranylcypromine.

Atomoxetine: MAO Inhibitors may enhance the neurotoxic (central) effect of atomoxetine. Avoid combination. Atomoxetine should not be used within 14 days of an MAO inhibitor.

Bupropion: May cause hypertensive crisis; at least 14 days should elapse before initiating bupropion; concurrent use with an MAO inhibitor is contraindicated.

Buspirone: May cause increased blood pressure; concurrent use with an MAO inhibitor should be avoided.

COMT Inhibitors: May enhance the adverse/toxic effect of MAO inhibitors. Avoid concurrent use.

Cyclobenzaprine: May enhance the serotonergic effect of MAO Inhibitors. This could result in serotonin syndrome. Avoid combination.

CYP1A2 substrates: Tranylcypromine may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, fluvoxamine, mexiletine, mirtazapine, ropinirole, theophylline, and trifluoperazine.

CYP2A6 substrates: Tranylcypromine may increase the levels/effects of CYP2A6 substrates. Example substrates include dexmedetomidine and ifosfamide.

CYP2C19 substrates: Tranylcypromine may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, and trimipramine.

CYP2D6 substrates: Tranylcypromine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Tranylcypromine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

Dexmethylphenidate: MAO inhibitors may enhance the hypertensive effect of dexmethylphenidate; avoid concurrent use.

Dextromethorphan: Concurrent use of MAO inhibitors may result in serotonin syndrome; concurrent use is contraindicated.

Disulfiram: MAO inhibitors may produce delirium in patients receiving disulfiram; monitor.

Ethanol: Tranylcypromine may enhance CNS depressant effect of ethanol.

False neurotransmitters: MAO inhibitors inhibit the antihypertensive response to guanadrel or methyl dopa; monitor therapy.

Levodopa: MAO inhibitors in combination with levodopa may result in hypertensive reactions; monitor.

Lithium: MAO inhibitors in combination with lithium have resulted in CNS toxicity (malignant hyperpyrexia, tardive dyskinesias); monitor therapy.

Meperidine: May cause serotonin syndrome when combined with an MAO inhibitor; concurrent use is contraindicated; should not be used within 14 days of an MAO inhibitor.

Methylphenidate: MAO inhibitors may enhance the hypertensive effect of methylphenidate. Avoid combination.

Mirtazapine: MAO inhibitors may enhance the neurotoxic (central) effect of mirtazapine. Avoid combination.

Pramlintide: Pramlintide may enhance the anticholinergic effect of tranylcypromine. Additive effects on reduced GI motility may occur.

Rauwolfia alkaloids: MAO inhibitors may enhance the adverse/toxic effect of rauwolfia alkaloids. If a rauwolfia alkaloid is added to existing MAOI therapy, a burst of catecholamine stimulation (eg, excitation, hypertension) may occur.

Serotonin/norepinephrine reuptake inhibitors (SNRIs): MAO inhibitors may enhance the serotonergic effect of SNRI antidepressants. This may cause serotonin syndrome.

Selective serotonin reuptake inhibitors (SSRIs): MAO Inhibitors may enhance the serotonergic effect of SSRIs. This may cause serotonin syndrome. Avoid concurrent use. Do not use within 5 weeks of fluoxetine discontinuation or 2 weeks of other antidepressant discontinuation.

Serotonin 5-HT_{1D} receptor agonists: May increase the risk of serotonin syndrome. The manufacturers of rizatriptan, sumatriptan, and zolmitriptan state that concurrent use (or use within 2 weeks of MAO therapy) is contraindicated.

Serotonin modulators: May enhance the adverse/toxic effect of other serotonin modulators, such as tranylcypromine. The development of serotonin syndrome may occur.

TRAZODONE

Sibutramine: May enhance the serotonergic effect of tranylcypromine. This may cause serotonin syndrome. Avoid concurrent use.
Thioridazine: Tranylcypromine may decrease the metabolism of thioridazine. Avoid concurrent use.
Tramadol: May enhance the neuroexcitatory and/or seizure-potentiating effect of MAO Inhibitors.
Tricyclic antidepressants: MAO inhibitors may enhance the serotonergic effect of tricyclic antidepressants. This may cause serotonin syndrome. Avoid concurrent use.

Pregnancy Risk Factor C

Lactation Enters breast milk/not recommended

Additional Information Minimum lethal dose: 170 mg

Chronic overdosage (a reported 550 mg/day) has resulted in only reversible thrombocytopenia and delirium.

Trazodone

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antidepressant Agents

CAS Number 19794-93-5; 25332-39-2

U.S. Brand Names Desyrel®

Synonyms Trazodone Hydrochloride

Impairment Potential Yes

Use Treatment of depression

Unlabeled/Investigational Use Potential augmenting agent for antidepressants, hypnotic

Mechanism of Action Inhibits reuptake of serotonin and norepinephrine; hypotension may be due to alpha-receptor blockade

Adverse Reactions

Cardiovascular: Postural hypotension, cardiac arrhythmias, edema, prolongation of QT interval, decreases amplitude of T wave, sinus bradycardia, vasculitis

Central nervous system: **Dizziness, confusion, headache,** drowsiness, sedation, insomnia, agitation, seizures, extrapyramidal reactions, mania, psychosis, gustatory hallucinations, fever, hyperthermia

Dermatologic: Leukocytoclastic dermatitis, erythema multiforme, exacerbation of plaque, psoriasis, bullous lesions, exfoliative dermatitis, alopecia, urticaria, purpura, pruritus, exanthem, cutaneous vasculitis

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone, serotonin syndrome, spontaneous orgasm (when yawning) may occur, hypoprolactinemia, gynecomastia

Gastrointestinal: **Xerostomia, bad taste in mouth, nausea,** constipation, vomiting

Genitourinary: Urinary retention, prolonged priapism

Hepatic: Hepatitis

Neuromuscular & skeletal: **Muscle tremors,** clonus, myoclonus, weakness, paresthesia

Ocular: Blurred vision

Respiratory: Eosinophilic pneumonia

Signs and Symptoms of Overdose Ataxia, AV block (first degree), bradycardia, clitoral hypertrophy, coma, delirium, drowsiness, dry mouth, ejaculatory disturbances, erythema multiforme, extrapyramidal reaction, heart block, hepatic failure, hypotension, incontinence, insomnia, muscle asthenia, myoclonus, ototoxicity, photosensitivity, priapism, prolonged QT interval, respiratory depression, seizures (rarely), tinnitus, torsade de pointes, vomiting

Pharmacodynamics/Kinetics

Onset of action: Therapeutic (antidepressant): 1-3 weeks; sleep aid: 1-3 hours

Protein binding: 85% to 95%

Metabolism: Hepatic via CYP3A4 to an active metabolite (mCPP)

Half-life elimination: 7-8 hours, two compartment kinetics

Time to peak, serum: 30-100 minutes; delayed with food (up to 2.5 hours)

Excretion: Primarily urine; secondarily feces

Dosage

Therapeutic effects may take up to 4 weeks to occur; therapy is normally maintained for several months after optimum response is reached to prevent recurrence of depression

Oral:

Adolescents: Initial: 25-50 mg/day; increase to 100-150 mg/day in divided doses

Adults: Initial: 150 mg/day in 3 divided doses (may increase by 50 mg/day every 3-7 days); maximum: 600 mg/day

Maximum tolerated dose:

Children: 200 mg

Adults: 9 g

Monitoring Parameters ECG for at least 4 hours

Administration Dosing after meals may decrease lightheadedness and postural hypotension

Contraindications Hypersensitivity to trazodone or any component of the formulation

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. **Trazodone is not FDA approved for use in children.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Trazodone is not FDA approved for the treatment of bipolar depression.**

Priapism, including cases resulting in permanent dysfunction, has occurred with the use of trazodone. Not recommended for use in a patient during the acute recovery phase of MI. Trazodone should be initiated with caution in patients who are receiving concurrent or recent therapy with a MAO inhibitor. May cause sedation, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Sedative effects may be additive with other CNS depressants and ethanol. The degree of sedation is very high relative to other antidepressants. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Therapy should not be abruptly discontinued in patients receiving high doses for prolonged periods.

Use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). The risk of postural hypotension is high relative to other antidepressants.

Use caution in patients with a previous seizure disorder or condition predisposing to seizures such as brain damage, alcoholism, or concurrent therapy with other drugs which lower the seizure threshold. Use with caution in patients with hepatic or renal dysfunction and in elderly patients. Use with caution in patients with a history of cardiovascular disease (including previous MI, stroke, tachycardia, or conduction abnormalities). However, the risk of conduction abnormalities with this agent is low relative to other antidepressants.

Dosage Forms Tablet, as hydrochloride: 50 mg, 100 mg, 150 mg, 300 mg

Reference Range

Therapeutic: 0.5-2.5 mcg/mL (SI: 1-6 µmol/L)

Overdoses of 4-5 g are associated with levels of 15-19 mcg/mL

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated supportively. Treat bradycardia with atropine; benzotropine may be useful to treat priapism. Seizures usually respond to lorazepam or diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenobarbital may be required. Priapism can be treated with alpha-adrenergic agonists, aspiration and irrigation of corpora cavernosa with epinephrine solutions and a Winters' shunt.

Diagnostic Procedures

- Trazodone, Blood

Test Interactions Spurious positive amphetamine urinary immunoassay screen can result from trazodone therapy.

Drug Interactions

Substrate of CYP2D6 (minor), 3A4 (major); **Inhibits** CYP2D6 (moderate), 3A4 (weak)

Antipsychotics: Trazodone, in combination with other psychotropics (low potency antipsychotics), may result in additional hypotension (isolated case reports); monitor.

Azole antifungals: Serum concentrations of trazodone may be increased by azole antifungals, via inhibition of CYP3A4. Ketoconazole has been specifically studied. Consider a lower dose of trazodone.

Buspirone: Serotonergic effects may be additive (limited documentation); monitor.

Carbamazepine: Serum concentrations of trazodone may be decreased by carbamazepine, due to induction of CYP3A4. Other CYP inducers are likely to share this effect.

CNS depressants: Sedative effects may be additive with CNS depressants. Includes ethanol, barbiturates, benzodiazepines, narcotic analgesics, and other sedative agents; monitor for increased effect

CYP2D6 substrates: Trazodone may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Trazodone may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of trazodone. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of trazodone. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinine, telithromycin, and verapamil.

Linezolid: Due to MAO inhibition (see note on MAO inhibitors), this combination should be avoided

MAO inhibitors: Concurrent use may lead to serotonin syndrome; avoid concurrent use or use within 14 days

Meperidine: Combined use, theoretically, may increase the risk of serotonin syndrome

Protease inhibitors: Serum concentrations of trazodone may be increased by protease inhibitors, via inhibition of CYP3A4. Consider a lower dose of trazodone.

Serotonin agonists: Theoretically, may increase the risk of serotonin syndrome; includes sumatriptan, naratriptan, rizatriptan, and zolmitriptan

SSRIs: Combined use of trazodone with an SSRI may, theoretically, increase the risk of serotonin syndrome; in addition, some SSRIs may inhibit the metabolism of trazodone resulting in elevated plasma levels and increased sedation; includes fluoxetine and fluvoxamine (see CYP inhibition); low doses of trazodone appear to represent little risk

Venlafaxine: Combined use with trazodone may increase the risk of serotonin syndrome

Pregnancy Risk Factor C

Lactation Enters breast milk/use caution (AAP rates "of concern")

Nursing Implications Use side rails on bed if administered to the elderly; observe patient's activity and compare with admission level

Additional Information Therapeutic effects may take up to 4 weeks to occur; therapy is normally maintained for several months after optimum response is reached to prevent recurrence of depression

Adult ingestions over two grams usually are symptomatic

Tretinoin (Topical)

CAS Number 302-79-4

U.S. Brand Names Altinac™; Avita®; Renova®; Retin-A® Micro; Retin-A®

Synonyms *trans*-Retinoic Acid; Retinoic Acid; Vitamin A Acid

Use Treatment of acne vulgaris, photodamaged skin, and some skin cancers

Unlabeled/Investigational Use Some skin cancers

Mechanism of Action Keratinocytes in the sebaceous follicle become less adherent which allows for easy removal; decreases microcomedone formation

Adverse Reactions

Cardiovascular: Edema, leukocytoclastic vasculitis, cardiomyopathy, cardiomegaly, pericardial effusion/pericarditis, pulmonary hypertension
Central nervous system: Pseudotumor cerebri, insomnia, confusion, anxiety, agitation, truncal ataxia, psychosis, cerebellar hemorrhage, hypothermia

Dermatologic: Excessive dryness, erythema, scaling of the skin, hyperpigmentation or hypopigmentation, photosensitivity, initial acne flare-up, alopecia (14%), neutrophilic dermatosis (Sweet's syndrome)

Endocrine & metabolic: Hypercalcemia

Gastrointestinal: Gastric ulcer (3%)

Hematologic: Basophilia, thrombocytosis, intravascular hemolysis

Local: Stinging, blistering

Ocular: Papilledema

Otic: Hearing loss (6%)

Renal: Acute renal failure

Respiratory: Epistaxis

Signs and Symptoms of Overdose Dyspnea, fever, hypotension, leukocytosis, tachycardia

Pharmacodynamics/Kinetics

Absorption: Minimal

Metabolism: Hepatic for the small amount absorbed

Excretion: Urine and feces

Dosage Topical:

Children >12 years and Adults: Acne vulgaris: Begin therapy with a weaker formulation of tretinoin (0.025% cream, 0.04% microsphere gel, or 0.01% gel) and increase the concentration as tolerated; apply once daily to acne lesions before retiring or on alternate days; if stinging or irritation develop, decrease frequency of application

Adults ≥18: Palliation of fine wrinkles, mottled hyperpigmentation, and tactile roughness of facial skin: Pea-sized amount of the 0.02% or 0.05% cream applied to entire face once daily in the evening

Elderly: Use of the 0.02% cream in patients 65-71 years of age showed similar improvement in fine wrinkles as seen in patients <65 years. Safety and efficacy of the 0.02% cream have not been established in patients >71 years of age. Safety and efficacy of the 0.05% cream have not been established in patients >50 years of age.

Monitoring Parameters Calcium (serum)

Administration Palliation of fine wrinkles, mottled hyperpigmentation, and tactile roughness of facial skin: Cream: Prior to application, gently wash face with a mild soap. Pat dry. Wait 20-30 minutes to apply cream. Avoid eyes, ears, nostrils, and mouth.

Contraindications Hypersensitivity to tretinoin or any component of the formulation; sunburn

Warnings Use with caution in patients with eczema; avoid excessive exposure to sunlight and sunlamps; avoid contact with abraded skin, mucous membranes, eyes, mouth, angles of the nose. Palliation of fine wrinkles, mottled hyperpigmentation, and tactile roughness of facial skin: Do not use the 0.05% cream for longer than 48 weeks or the 0.02% cream for longer than 52 weeks. Not for use on moderate- to heavily-pigmented skin. Gel is flammable; do not expose to high temperatures or flame.

Dosage Forms [DSC] = Discontinued product

Cream, topical: 0.025% (20 g, 45 g); 0.05% (20 g, 45 g); 0.1% (20 g, 45 g)

Avita®: 0.025% (20 g, 45 g)

Renova®: 0.02% (40 g); 0.05% (40 g, 60 g)

Retin-A®: 0.025% (20 g, 45 g); 0.05% (20 g, 45 g); 0.1% (20 g, 45 g)

Gel, topical: 0.025% (15 g, 45 g)

Avita®: 0.025% (20 g, 45 g) [contains ethanol 83%]

Retin-A®: 0.01% (15 g, 45 g); 0.025% (15 g, 45 g) [contains alcohol 90%]

Retin-A® Micro [microsphere gel]: 0.04% (20 g, 45 g); 0.1% (20 g, 45 g) [contains benzyl alcohol]

Liquid, topical (Retin-A®): 0.05% (28 mL) [contains alcohol 55%] [DSC]

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Sweet's syndrome can be treated with methylprednisolone (1 g/day for 3 days); retinoic acid syndrome can be treated with dexamethasone (10 mg I.V. every 12 hours for 3 or more days); tachycardia can be treated with beta-adrenergic blockers while hypotension can be treated with crystalloid fluid bolus (10-20 mL/kg) and Trendelenburg placement; dopamine or norepinephrine can be used for refractory hypotension

Drug Interactions **Substrate** of CYP2A6 (minor), 2B6 (minor), 2C8 (major), 2C9 (minor); **Inhibits** CYP2C9 (weak); **Induces** CYP2E1 (weak)

Increased toxicity: Sulfur, benzoyl peroxide, salicylic acid, resorcinol, any product with strong drying effects (potentiates adverse reactions seen with tretinoin)

Photosensitizing medications (thiazides, tetracyclines, fluoroquinolones, phenothiazines, sulfonamides): Augment phototoxicity; should not be used when treating palliation of fine wrinkles, mottled hyperpigmentation, and tactile roughness of facial skin

TRIAMCINOLONE

Pregnancy Risk Factor C

Pregnancy Implications Oral tretinoin is teratogenic and fetotoxic in rats at doses 1000 and 500 times the topical human dose, respectively; however, tretinoin does not appear to be teratogenic when used topically since it is rapidly metabolized by the skin; ear malformations have been noted

Lactation Enters breast milk/compatible

Nursing Implications Observe for signs of hypersensitivity, blistering, excessive dryness; do not apply to mucous membranes

Additional Information "Retinoic acid syndrome" is seen in patients with acute promyelocytic leukemia taking tretinoin (>45 mg/m²/day); it consists of dyspnea (60%), pleural effusion (20%), bone pain, cardiac failure (6%), fever, tachycardia, nausea and vomiting (57%), renal insufficiency (11%), leukocytosis, and disseminated intravascular coagulation

Triamcinolone

Related Information

- Corticosteroids

CAS Number 124-94-7; 1997-15-5; 5611-51-8; 67-78-7; 76-25-5; 989-96-8

U.S. Brand Names Aristocort® A; Aristocort® Forte; Aristocort®; Aristospan®; Azmacort®; Kenalog-10®; Kenalog-40®; Kenalog® in Orabase®; Kenalog®; Nasacort® AQ; Nasacort® [DSC]; Tri-Nasal®; Triderm®

Synonyms Triamcinolone Acetonide, Aerosol; Triamcinolone Acetonide, Parenteral; Triamcinolone Diacetate, Oral; Triamcinolone Diacetate, Parenteral; Triamcinolone Hexacetonide; Triamcinolone, Oral

Use

Nasal inhalation: Management of seasonal and perennial allergic rhinitis in patients ≥6 years of age

Oral inhalation: Control of bronchial asthma and related bronchospastic conditions

Oral topical: Adjunctive treatment and temporary relief of symptoms associated with oral inflammatory lesions and ulcerative lesions resulting from trauma

Systemic: Adrenocortical insufficiency, rheumatic disorders, allergic states, respiratory diseases, systemic lupus erythematosus (SLE), and other diseases requiring anti-inflammatory or immunosuppressive effects

Topical: Inflammatory dermatoses responsive to steroids

Mechanism of Action Decreases inflammation by suppression of migration of polymorphonuclear leukocytes and reversal of increased capillary permeability; suppresses the immune system by reducing activity and volume of the lymphatic system; suppresses adrenal function at high doses

Adverse Reactions

Systemic:

Cardiovascular: CHF, hypertension

Central nervous system: Convulsions, fever, headache, intracranial pressure increased, vertigo

Dermatologic: Bruising, facial erythema, petechiae, photosensitivity, rash, thin/fragile skin, wound healing impaired

Endocrine & metabolic: Adrenocortical/pituitary unresponsiveness (particularly during stress), carbohydrate tolerance decreased, cushingoid state, diabetes mellitus (manifestations of latent disease), fluid retention, growth suppression (children), hypokalemic alkalosis, menstrual irregularities, negative nitrogen balance, potassium loss, sodium retention

Gastrointestinal: Abdominal distention, diarrhea, dyspepsia, nausea, oral *Monilia* (oral inhaler), pancreatitis, peptic ulcer, ulcerative esophagitis, weight gain

Local: Skin atrophy (at the injection site)

Neuromuscular & skeletal: Femoral/humeral head aseptic necrosis, muscle mass decreased, muscle weakness, osteoporosis, pathologic fracture of long bones, steroid myopathy, vertebral compression fractures

Ocular: Cataracts, intraocular pressure increased, exophthalmus, glaucoma

Respiratory: Cough increased (nasal spray), epistaxis (nasal inhaler/spray), pharyngitis (nasal spray/oral inhaler), sinusitis (oral inhaler), voice alteration (oral inhaler)

Miscellaneous: Anaphylaxis, diaphoresis increased, suppression of skin test reactions

Topical:

Dermatologic: Itching, allergic contact dermatitis, dryness, folliculitis, skin infection (secondary), hypertrichosis, acneiform eruptions, hypopigmentation, skin maceration, skin atrophy, striae, miliaria, perioral dermatitis, atrophy of oral mucosa

Local: Burning, irritation

Signs and Symptoms of Overdose When consumed in excessive quantities, systemic hypercorticism and adrenal suppression may occur.

In those cases discontinuation and withdrawal of the corticosteroid should be done judiciously.

Pharmacodynamics/Kinetics

Duration: Oral: 8-12 hours

Absorption: Topical: Systemic

Time to peak: I.M.: 8-10 hours

Half-life elimination: Biologic: 18-36 hours

Dosage

The lowest possible dose should be used to control the condition; when dose reduction is possible, the dose should be reduced gradually.

Parenteral dose is usually 1/3 to 1/2 the oral dose given every 12 hours.

In life-threatening situations, parenteral doses larger than the oral dose may be needed.

Injection:

Acetonide:

Intra-articular, intrabursal, tendon sheaths: Adults: Initial: Smaller joints: 2.5-5 mg, larger joints: 5-15 mg

Intradermal: Adults: Initial: 1 mg

I.M.: Range: 2.5-60 mg/day

Children 6-12 years: Initial: 40 mg

Children > 12 years and Adults: Initial: 60 mg

Diacetate: Adults:

Intra-articular, intrasynovial: Range: 5-40 mg; duration of effect varies from 1 week to 2 months, although more frequent dosing may be needed in acutely-inflamed joints

Average dose: Knee: 25 mg, finger: 2-5 mg

Intralesional, sublesional: Range: 5-48 mg, dependent upon size of lesion

Maximum: 12.5 mg/injection site, 25 mg/lesion, 75 mg/week

Usual treatment course: 2-3 injections at 1- to 2-week intervals

I.M.: Initial range: 3-48 mg/day; average dose: 40 mg/week

Hexacetonide: Adults:

Intralesional, sublesional: Up to 0.5 mg/square inch of affected skin

Intra-articular: Range: 2-20 mg

Triamcinolone Dosing		
	Acetonide	Hexacetonide
Intrasynovial	5-40 mg	
Intralesional	1-30 mg (usually 1 mg per injection site); 10 mg/mL suspension usually used	Up to 0.5 mg/sq inch affected area
Sublesional	1-30 mg	
Systemic I.M.	2.5-60 mg/dose (usual adult dose: 60 mg; may repeat with 20-100 mg dose when symptoms recur)	
Intra-articular	2.5-40 mg	2-20 mg average
large joints	5-15 mg	10-20 mg
small joints	2.5-5 mg	2-6 mg
Tendon sheaths	2.5-10 mg	
Intradermal	1 mg/site	

Intranasal: Perennial allergic rhinitis, seasonal allergic rhinitis:

Nasal spray:

Children 6-11 years: 110 mcg/day as 1 spray in each nostril once daily.

Children ≥ 12 years and Adults: 220 mcg/day as 2 sprays in each nostril once daily

Nasal inhaler:

Children 6-11 years: Initial: 220 mcg/day as 2 sprays in each nostril once daily

Children ≥ 12 years and Adults: Initial: 220 mcg/day as 2 sprays in each nostril once daily; may increase dose to 440 mcg/day (given once daily or divided and given 2 or 4 times/day)

Oral: Adults:

Acute rheumatic carditis: Initial: 20-60 mg/day; reduce dose during maintenance therapy

Acute seasonal or perennial allergic rhinitis: 8-12 mg/day

Adrenocortical insufficiency: Range 4-12 mg/day

Bronchial asthma: 8-16 mg/day

Dermatological disorders, contact/atopic dermatitis: Initial: 8-16 mg/day

Ophthalmic disorders: 12-40 mg/day

Rheumatic disorders: Range: 8-16 mg/day

SLE: Initial: 20-32 mg/day, some patients may need initial doses ≥ 48 mg; reduce dose during maintenance therapy

Oral inhalation: Asthma:

Children 6-12 years: 100-200 mcg 3-4 times/day or 200-400 mcg twice daily; maximum dose: 1200 mg/day

Children > 12 years and Adults: 200 mcg 3-4 times/day or 400 mcg twice daily; maximum dose: 1600 mcg/day

Oral topical: Oral inflammatory lesions/ulcers: Press a small dab (about 1/4 inch) to the lesion until a thin film develops. A larger quantity may be required for coverage of some lesions. For optimal results use only enough to coat the lesion with a thin film; do not rub in.

Topical:

Cream, Ointment: Apply thin film to affected areas 2-4 times/day
 Spray: Apply to affected area 3-4 times/day

Monitoring Parameters Blood pressure, blood glucose, electrolytes

Administration Injection: Avoid injecting into a previously infected joint; do not inject into unstable joints

I.M.: Inject deep in large muscle mass, avoid deltoid.

Nasal spray, inhalation: Shake well prior to use. Gently blow nose to clear nostrils.

Oral inhalation: Shake well prior to use. Rinse mouth and throat after using inhaler to prevent candidiasis. Use spacer device provided with Azmacort®.

Oral topical: Apply small dab to lesion until a thin film develops; do not rub in. Apply at bedtime or after meals if applications are needed throughout the day.

Tablet: Once-daily doses should be given in the morning.

Topical: Apply a thin film sparingly and avoid topical application on the face. Do not use on open skin or wounds. Do not occlude area unless directed.

Contraindications Hypersensitivity to triamcinolone or any component of the formulation; systemic fungal infections; serious infections (except septic shock or tuberculous meningitis); primary treatment of status asthmaticus; fungal, viral, or bacterial infections of the mouth or throat (oral topical formulation)

Warnings

May cause suppression of hypothalamic-pituitary-adrenal (HPA) axis, particularly in younger children or in patients receiving high doses for prolonged periods. Particular care is required when patients are transferred from systemic corticosteroids to inhaled products due to possible adrenal insufficiency or withdrawal from steroids, including an increase in allergic symptoms. Patients receiving 20 mg per day of prednisone (or equivalent) may be most susceptible. Fatalities have occurred due to adrenal insufficiency in asthmatic patients during and after transfer from systemic corticosteroids to aerosol steroids; aerosol steroids do **not** provide the systemic steroid needed to treat patients having trauma, surgery, or infections. Withdrawal and discontinuation of the corticosteroid should be done slowly and carefully

Use with caution in patients with hypothyroidism, cirrhosis, nonspecific ulcerative colitis and patients at increased risk for peptic ulcer disease. Corticosteroids should be used with caution in patients with diabetes, hypertension, osteoporosis, glaucoma, cataracts, or tuberculosis. Use caution in hepatic impairment. Do not use occlusive dressings on weeping or exudative lesions and general caution with occlusive dressings should be observed; discontinue if skin irritation or contact dermatitis should occur; do not use in patients with decreased skin circulation; avoid the use of high potency steroids on the face.

Because of the risk of adverse effects, systemic corticosteroids should be used cautiously in the elderly, in the smallest possible dose, and for the shortest possible time. Azmacort® (metered dose inhaler) comes with its own spacer device attached and may be easier to use in older patients.

Controlled clinical studies have shown that orally-inhaled and intranasal corticosteroids may cause a reduction in growth velocity in pediatric patients. (In studies of orally-inhaled corticosteroids, the mean reduction in growth velocity was approximately 1 centimeter per year [range 0.3-1.8 cm per year] and appears to be related to dose and duration of exposure.) The growth of pediatric patients receiving inhaled corticosteroids, should be monitored routinely (eg, via stadiometry). To minimize the systemic effects of orally-inhaled and intranasal corticosteroids, each patient should be titrated to the lowest effective dose.

May suppress the immune system, patients may be more susceptible to infection. Use with caution in patients with systemic infections or ocular herpes simplex. Avoid exposure to chickenpox and measles. Injection suspension contains benzyl alcohol; benzyl alcohol has been associated with the "gasping syndrome" in neonates and low-birth-weight infants.

Oral topical: Discontinue if local irritation or sensitization should develop. If significant regeneration or repair of oral tissues has not occurred in seven days, re-evaluation of the etiology of the oral lesion is advised.

Dosage Forms

Aerosol for oral inhalation, as acetate (Azmacort®): 100 mcg per actuation (20 g) [240 actuations]

Aerosol, topical, as acetate (Kenalog®): 0.2 mg/2-second spray (63 g)
 Cream, as acetate: 0.025% (15 g, 80 g, 454 g); 0.1% (15 g, 80 g, 454 g, 2270 g); 0.5% (15 g)

Aristocort® A: 0.025% (15 g, 60 g); 0.1% (15 g, 60 g); 0.5% (15 g) [contains benzyl alcohol]

Triderm®: 0.1% (30 g, 85 g)

Injection, suspension, as acetate:

Kenalog-10®: 10 mg/mL (5 mL) [contains benzyl alcohol; not for I.V. or I.M. use]

Kenalog-40®: 40 mg/mL (1 mL, 5 mL, 10 mL) [contains benzyl alcohol; not for I.V. or intradermal use]

Injection, suspension, as hexacetate (Aristospan®): 5 mg/mL (5 mL); 20 mg/mL (1 mL, 5 mL) [contains benzyl alcohol; not for I.V. use]

Lotion, as acetate: 0.025% (60 mL); 0.1% (60 mL)

Ointment, topical, as acetate: 0.025% (15 g, 80 g, 454 g); 0.1% (15 g, 80 g, 454 g); 0.5% (15 g)

Aristocort® A: 0.1% (15 g, 60 g)

Paste, oral, topical, as acetate: 0.1% (5 g)

Solution, intranasal, as acetate [spray] (Tri-Nasal®): 50 mcg/inhalation (15 mL) [120 doses]

Suspension, intranasal, as acetate [spray] (Nasacort® AQ): 55 mcg/inhalation (16.5 g) [120 doses]

Tablet (Aristocort®): 4 mg [contains lactose and sodium benzoate]

Overdosage/Treatment

Decontamination: Activated charcoal; acute overdose does not require tapering of dose

Enhanced elimination: Its metabolite (prednisolone) is slightly dialyzable (5% to 20%)

Drug Interactions

Decreased effect: Barbiturates, phenytoin, rifampin increase metabolism of triamcinolone; vaccine and toxoid effects may be reduced

Increased effect: Salmeterol: The addition of salmeterol has been demonstrated to improve response to inhaled corticosteroids (as compared to increasing steroid dosage).

Increased toxicity: Salicylates may increase risk of GI ulceration

Pregnancy Risk Factor C

Pregnancy Implications There are no adequate studies in pregnant women, however, triamcinolone is teratogenic in animals; use during pregnancy with caution. Increased incidence of cleft palate, neonatal adrenal suppression, low birth weight, and cataracts in the infant has been reported following corticosteroid use during pregnancy. In general, the use of large amounts, or prolonged use, of topical corticosteroids during pregnancy should be avoided. In the mother, corticosteroids may increase calcium and potassium excretion, elevate blood pressure, and cause salt and water retention.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Once daily doses should be given in the morning; evaluate clinical response and mental status; may mask signs and symptoms of infection; inject I.M. dose deep in large muscle mass, avoid deltoid; avoid SubQ dose; a thin film is effective topically and avoid topical application on the face; do not occlude area unless directed

Additional Information 16 mg triamcinolone is equivalent to 100 mg cortisone (no mineralocorticoid activity); adrenal insufficiency can occur with intramuscular injections >400 mg

Triamterene

CAS Number 396-01-0

U.S. Brand Names Dyrenium®

Use Alone or in combination with other diuretics in treatment of edema and hypertension; decreases potassium excretion caused by kaliuretic diuretics

Mechanism of Action Competes with aldosterone for receptor sites in the distal renal tubules, increasing sodium, chloride, and water excretion while conserving potassium and hydrogen ions; may block the effect of aldosterone on arteriolar smooth muscle as well

Adverse Reactions

Cardiovascular: Bradycardia, sinus bradycardia

Central nervous system: Headache, hyperthermia

Dermatologic: Photosensitivity, purpura

Endocrine & metabolic: Hyperkalemia, hyperuricemia

Gastrointestinal: Nausea, vomiting, diarrhea

Hematologic: Pancytopenia, anemia (megaloblastic)

Renal: Reversible renal failure, renal stone formation, interstitial nephritis, acute tubular necrosis

Genitourinary: Urine discoloration (blue), urine discoloration (fluorescent)

Pharmacodynamics/Kinetics

Onset of action: Diuresis occurs within 2-4 hours

Duration: 7-9 hours

Absorption: Oral: Unreliable

Distribution: V_d: 2.5 L/kg

Protein binding: 55% (parent compound); 90% (active metabolite)

TRIAZOLAM

Metabolism: Hepatic to an active metabolite (hydroxytriamterene sulfate)

Bioavailability: 52%

Half-life: 1.5-2.5 hours

Dosage Adults: Oral: 100-300 mg/day in 1-2 divided doses; maximum dose: 300 mg/day; usual dosage range (JNC 7): 50-100 mg/day

Dosing comments in renal impairment: $Cl_{cr} < 10$ mL/minute: Avoid use.

Dosing adjustment in hepatic impairment: Dose reduction is recommended in patients with cirrhosis.

Monitoring Parameters Blood pressure, serum electrolytes (especially potassium), renal function, weight, I & O

Contraindications Hypersensitivity to triamterene or any component of the formulation; patients receiving other potassium-sparing diuretics; anuria; severe hepatic disease; hyperkalemia or history of hyperkalemia; severe or progressive renal disease; pregnancy (expert analysis)

Warnings

[U.S. Boxed Warning]: Hyperkalemia can occur; patients at risk include those with renal impairment, diabetes, the elderly, and the severely ill. Serum potassium levels must be monitored at frequent intervals especially when dosages are changed or with any illness that may cause renal dysfunction. Avoid potassium supplements, potassium-containing salt substitutes, a diet rich in potassium, or other drugs that can cause hyperkalemia. Monitor for fluid and electrolyte imbalances. Diuretic therapy should be carefully used in severe hepatic dysfunction; electrolyte and fluid shifts can cause or exacerbate encephalopathy. Use cautiously in patients with history of kidney stones and diabetes. Can cause photosensitivity.

Dosage Forms Capsule: 50 mg, 100 mg [contains benzyl alcohol]

Reference Range Peak plasma levels after a 50 mg oral dose: 25 ng/mL (of hydroxytriamterene sulfate - 770 ng/mL)

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Hyperkalemia can be treated with glucose/insulin and sodium bicarbonate (1 mEq/kg); sodium polystyrene sulfonate can also be given; I.V. fluids administration of 0.45% sodium chloride with furosemide (1 mg/kg, up to 40 mg) can be used to promote urine flow

Test Interactions Triamterene can interfere with the fluorescent measurement of quinidine, leading to falsely elevated quinidine assays

Drug Interactions

ACE inhibitors can cause hyperkalemia, especially in patients with renal impairment, potassium-rich diets, or on other drugs causing hyperkalemia; avoid concurrent use or monitor closely.

Potassium supplements may further increase potassium retention and cause hyperkalemia; avoid concurrent use.

Pregnancy Risk Factor B (manufacturer); D (expert analysis)

Pregnancy Implications No data available. Generally, use of diuretics during pregnancy is avoided due to risk of decreased placental perfusion.

Lactation Excretion in breast milk unknown

Nursing Implications Observe for hyperkalemia; assess weight and I & O daily to determine weight loss; if ordered once daily, dose should be given in the morning

Additional Information Abrupt discontinuation of therapy may result in rebound kaliuresis; taper off gradually; can discolor urine to bluish color; has antifolate activity

Specific References

Chobanian AV, Bakris GL, Black HR, et al, "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, (19)289:2560-71.

Dermatologic: Dermatitis, hypertrichosis, alopecia, purpura, photosensitivity, pruritus, exanthem

Gastrointestinal: Xerostomia, constipation, diarrhea, nausea/vomiting, taste alteration

Neuromuscular & skeletal: Paresthesia

Ocular: Visual disturbances

Otic: Tinnitus

Signs and Symptoms of Overdose Ataxia, cholestatic jaundice, cognitive dysfunction, coma, confusion, diminished reflexes, hypotension, hypothermia, mania, myoglobinuria, night terrors, respiratory depression, rhabdomyolysis, slurred speech, somnolence, visual or auditory hallucinations

Admission Criteria/Prognosis Admit any patient with mental status changes or ingestion > 3 mg

Pharmacodynamics/Kinetics

Onset of action: Hypnotic: 15-30 minutes

Duration: 6-7 hours

Distribution: V_d : 0.8-1.8 L/kg

Protein binding: 89%

Metabolism: Extensively hepatic

Half-life elimination: 1.7-5 hours

Excretion: Urine as unchanged drug and metabolites

Dosage

Oral (onset of action is rapid, patient should be in bed when taking medication):

Children < 18 years: Dosage not established

Adults:

Hypnotic: 0.125-0.25 mg at bedtime (maximum dose: 0.5 mg/day)

Preprocedure sedation (dental): 0.25 mg taken the evening before oral surgery; or 0.25 mg 1 hour before procedure

Elderly: Insomnia (short-term use): 0.0625-0.125 mg at bedtime; maximum dose: 0.25 mg/day. Due to the higher incidence of CNS adverse reactions and its short half-life, this benzodiazepine is not a drug of first choice. For short-term only.

Dosing adjustment/comments in hepatic impairment: Reduce dose or avoid use in cirrhosis

Monitoring Parameters Respiratory and cardiovascular status

Administration May take with food. Tablet may be crushed or swallowed whole. Onset of action is rapid, patient should be in bed when taking medication.

Contraindications Hypersensitivity to triazolam or any component of the formulation (cross-sensitivity with other benzodiazepines may exist); concurrent therapy with atazanavir, ketoconazole, itraconazole, nefazodone, and ritonavir; pregnancy

Warnings

Should be used only after evaluation of potential causes of sleep disturbance. Failure of sleep disturbance to resolve after 7-10 days may indicate psychiatric or medical illness. A worsening of insomnia or the emergence of new abnormalities of thought or behavior may represent unrecognized psychiatric or medical illness and requires immediate and careful evaluation. Prescription should be written for a maximum of 7-10 days and should not be prescribed in quantities exceeding a 1-month supply. Abrupt discontinuation after sustained use (generally > 10 days) may cause withdrawal symptoms.

An increase in daytime anxiety may occur after as few as 10 days of continuous use, which may be related to withdrawal reaction in some patients. Anterograde amnesia may occur at a higher rate with triazolam than with other benzodiazepines. Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics), or renal impairment. Use with caution in patients with respiratory disease or impaired gag reflex. Avoid use in patients with sleep apnea.

Causes CNS depression (dose-related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury and should be used with extreme caution in patients who are at risk of these events (especially the elderly).

Use caution with potent CYP3A4 inhibitors, as they may significantly decreased the clearance of triazolam. Use caution in patients with depression, particularly if suicidal risk may be present. Use with caution in patients with a history of drug dependence. Benzodiazepines have been associated with dependence and acute withdrawal symptoms on discontinuation or reduction in dose. Acute withdrawal, including seizures, may be precipitated after administration of flumazenil to patients receiving long-term benzodiazepine therapy.

Paradoxical reactions, including hyperactive or aggressive behavior have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Triazolam

Related Information

● Therapeutic Drugs Associated with Hallucinations

CAS Number 28911-01-5

U.S. Brand Names Halcion®

Impairment Potential Yes. Blood triazolam levels > 4 mcg/L are consistent with driving impairment. Brief or extended periods of exposure are less likely to cause driving impairment in the elderly compared with the longer half-life benzodiazepines. (Joynt BP, "Triazolam Blood Concentrations in Forensic Cases in Canada," *J Anal Toxicol*, 1993, 17(3):171-7.)

Use Short-term treatment of insomnia

Mechanism of Action Depresses all levels of the CNS, including the limbic and reticular formation, probably through the increased action of gamma-aminobutyric acid (GABA), which is a major inhibitory neurotransmitter in the brain

Adverse Reactions

Cardiovascular: Tachycardia, chest pain

Central nervous system: **Drowsiness** (14%), ataxia, confusional states/memory impairment, tiredness, lightheadedness, insomnia, depression, headache (9.7%), transient global amnesia (TGA), dizziness, nervousness, euphoria, night terrors, coordination disorders, amnesia

Dosage Forms Tablet: 0.125 mg, 0.25 mg [contains sodium benzoate]
Reference Range Therapeutic serum triazolam level: 5-20 ng/mL (14.5-58.3 nmol/L); fatalities have been associated with postmortem blood level >47 nmol/L

Overdosage/Treatment

Decontamination: Lavage ingestions >2 mg (within 1 hour)/activated charcoal

Supportive therapy: Treatment for benzodiazepine overdose is supportive. Rarely is mechanical ventilation required. Flumazenil (Romazicon™) may be used to reverse benzodiazepine-induced CNS depression.

Enhancement of elimination: Multiple dose of activated charcoal may be effective

Antidote(s)

- Flumazenil [ANTIDOTE]

Test Interactions Visine®, Drano®, bleach may cause false-negative urine tests; oxazepam may interfere giving falsely elevated glucose results

Drug Interactions Substrate of CYP3A4 (major); **Inhibits** CYP2C8 (weak), 2C9 (weak)

Clozapine: Benzodiazepines may enhance the adverse/toxic effect of clozapine.

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect
 CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of triazolam. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of triazolam. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Disulfiram: May decrease the metabolism, via CYP isoenzymes, of triazolam.

Isoniazid: Isoniazid may increase triazolam levels.

Oral contraceptives: May decrease the clearance and increase the half-life of triazolam; monitor for increased triazolam effect

Proton Pump Inhibitors: May increase the serum concentration of triazolam.

Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation

Pregnancy Risk Factor X

Pregnancy Implications Other benzodiazepines are known to cross the placenta and accumulate in the fetus. Teratogenic effects have been reported. Use of triazolam is contraindicated in pregnancy.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Provide safety measures (ie, side rails, night light, call button); remove smoking materials from area; supervise ambulation

Additional Information Triazolam serum concentration may be increased by grapefruit juice; avoid concurrent use.

Specific References

Tsujikawa K, Kuwayama K, Miyaguchi H, et al, "Urinary Excretion Profiles of Two Major Triazolam Metabolites, α -Hydroxytriazolam and 4-Hydroxytriazolam," *J Anal Toxicol*, 2005, 29(4):240-4.

Gastrointestinal: **Constipation**, GI upset, xerostomia, Ogilvie's syndrome, weight gain

Genitourinary: Urinary retention, impotence

Hematologic: Agranulocytosis, leukopenia, aplastic anemia

Hepatic: Cholestatic jaundice

Ocular: **Retinal pigmentation**, nystagmus, blurred vision, lenticular opacities, blepharospasm

Respiratory: **Nasal congestion**

Miscellaneous: **Diaphoresis (decreased)**, anaphylactoid reactions, systemic lupus erythematosus

Signs and Symptoms of Overdose Abnormal involuntary muscle movements, agranulocytosis, coma, deep sleep, dysphagia, extrapyramidal reaction, facial grimacing, galactorrhea, generalized rigidity, granulocytopenia, gynecomastia, hepatic failure, hyperthermia, hypotension or hypertension, impotence, leukopenia, neuroleptic malignant syndrome, neutropenia, nystagmus, Parkinson's-like symptoms, slurred speech, stridor, torticollis, trismus, urine discoloration (pink; red; red-brown), vision color changes (brown tinge)

Pharmacodynamics/Kinetics

Onset of action: Rapid

Duration: \geq 12 hours

Distribution: Widely distributed into body

Protein binding: \geq 90%

Metabolism: Extensive liver metabolism

Half-life: > 24 hours with chronic use; 7-18 hours with one dose

Time to peak plasma concentration: 2-4 hours

Elimination: Primarily excreted renally; biliary

Dosage

Children 6-12 years: Psychoses:

Oral: Hospitalized or well supervised patients: Initial: 1 mg 1-2 times/day, gradually increase until symptoms are controlled or adverse effects become troublesome; maximum: 15 mg/day

I.M.: 1 mg twice daily

Adults:

Psychoses:

Outpatients: Oral: 1-2 mg twice daily

Hospitalized or well supervised patients: Initial: 2-5 mg twice daily with optimum response in the 15-20 mg/day range; do not exceed 40 mg/day

I.M.: 1-2 mg every 4-6 hours as needed up to 10 mg/24 hours maximum

Nonpsychotic anxiety: Oral: 1-2 mg twice daily; maximum: 6 mg/day; therapy for anxiety should not exceed 12 weeks; do not exceed 6 mg/day for longer than 12 weeks when treating anxiety; agitation, jitteriness, or insomnia may be confused with original neurotic or psychotic symptoms

Stability Store injection at room temperature; protect from heat and from freezing; use only clear or slightly yellow solutions

Monitoring Parameters Vital signs; lipid profile, fasting blood glucose/Hgb A_{1c}; BMI; mental status, abnormal involuntary movement scale (AIMS)

Contraindications Hypersensitivity to trifluoperazine or any component of the formulation (cross-reactivity between phenothiazines may occur); severe CNS depression; bone marrow suppression; blood dyscrasias; severe hepatic disease; coma

Warnings

May be sedating, use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Caution in patients with hemodynamic instability; predisposition to seizures; subcortical brain damage; hepatic impairment; severe cardiac, renal, or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use - use with caution in patients at risk of pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May alter cardiac conduction - life-threatening arrhythmias have occurred with therapeutic doses of phenothiazines. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease or other medications which may predispose). Safety in children < 6 months of age has not been established.

Phenothiazines may cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention); therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other antipsychotics, trifluoperazine has a low potency of cholinergic blockade.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is high relative to other neuroleptics). May be associated with neuroleptic malignant syndrome (NMS) or pigmentary retinopathy.

Dosage Forms Tablet: 1 mg, 2 mg, 5 mg, 10 mg

Trifluoperazine

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antipsychotic Agents

CAS Number 117-89-5; 440-17-5

U.S. Brand Names Stelazine® [DSC]

Synonyms Trifluoperazine Hydrochloride

Impairment Potential Yes

Use Treatment of psychoses and management of anxiety

Unlabeled/Investigational Use Management of psychotic disorders

Mechanism of Action Blocks postsynaptic mesolimbic dopaminergic receptors in the brain; exhibits a strong alpha-adrenergic blocking effect and depresses the release of hypothalamic and hypophyseal hormones

Adverse Reactions

Cardiovascular: **Hypotension** (especially with I.V. use), **hypotension (orthostatic)**, tachycardia, cardiac arrhythmias, sinus tachycardia

Central nervous system: **Pseudoparkinsonian signs and symptoms, dizziness, akathisia, dystonia, tardive dyskinesia**, sedation, drowsiness, restlessness, anxiety, extrapyramidal reactions, neuroleptic malignant syndrome, seizures, altered central temperature regulation, gustatory hallucinations, tardive dystonia

Dermatologic: Hyperpigmentation, pruritus, rash, photosensitivity

Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, syndrome of inappropriate antidiuretic hormone, hyperprolactinemia

Reference Range Therapeutic level: 0.002-0.060 mg/L

Overdose/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam, diazepam, or phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 g), while other antiarrhythmics can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50 mg I.M. or I.V. slow push followed by a maintenance dose for 48-72 hours. When these reactions are unresponsive to diphenhydramine, benztrapine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; not dialyzable (0% to 5%)

Test Interactions ↑ cholesterol (S), glucose; ↓ uric acid (S); may cross react with serum tricyclic assay

Drug Interactions **Substrate** of CYP1A2 (major)

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Aluminum salts: May decrease the absorption of phenothiazines; monitor
Amphetamines: Efficacy may be diminished by antipsychotics; in addition, amphetamines may increase psychotic symptoms; avoid concurrent use

Anticholinergics: May inhibit the therapeutic response to phenothiazines and excess anticholinergic effects may occur; includes benztrapine, trihexyphenidyl, biperiden, and drugs with significant anticholinergic activity (TCAs, antihistamines, disopyramide)

Antihypertensives: Concurrent use of phenothiazines with an antihypertensive may produce additive hypotensive effects (particularly ortho-stasis)

Bromocriptine: Phenothiazines inhibit the ability of bromocriptine to lower serum prolactin concentrations

CNS depressants: Sedative effects may be additive with phenothiazines; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents

CYP1A2 inducers: May decrease the levels/effects of trifluoperazine. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of trifluoperazine. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

Epinephrine: Chlorpromazine (and possibly other low potency antipsychotics) may diminish the pressor effects of epinephrine

Guanethidine and guanadrel: Antihypertensive effects may be inhibited by phenothiazines

Levodopa: Phenothiazines may inhibit the antiparkinsonian effect of levodopa; avoid this combination

Lithium: Phenothiazines may produce neurotoxicity with lithium; this is a rare effect.

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk.

Polypeptide antibiotics: Rare cases of respiratory paralysis have been reported with concurrent use of phenothiazines

Propranolol: Serum concentrations of phenothiazines may be increased; propranolol also increases phenothiazine concentrations

QT_c-prolonging agents: Effects on QT_c interval may be additive with phenothiazines, increasing the risk of malignant arrhythmias; includes type Ia antiarrhythmics, TCAs, and some quinolone antibiotics (sparfloxacin, moxifloxacin, and gatifloxacin)

Sulfadoxine-pyrimethamine: May increase phenothiazine concentrations

Trazodone: Phenothiazines and trazodone may produce additive hypotensive effects

Tricyclic antidepressants: Concurrent use may produce increased toxicity or altered therapeutic response

Valproic acid: Serum levels may be increased by phenothiazines

Pregnancy Risk Factor C

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Nursing Implications Give I.M. injection deep in upper outer quadrant of buttock; watch for hypotension when administering I.M. or I.V.

Additional Information Do not exceed 6 mg/day for longer than 12 weeks when treating anxiety; agitation, jitteriness or insomnia may be confused with original neurotic or psychotic symptoms; radiopaque

Trimeprazine

CAS Number 4330-99-8; 84-96-8

Impairment Potential Yes

Use Cough suppressant; relief of pruritus; anesthesia induction; useful for plant-induced dermatitis; allergic rhinitis; sleep disorders

Mechanism of Action A phenothiazine derivation with antimuscarinic and antihistaminic (H₁-receptor) effects

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), bradycardia, sinus tachycardia
Central nervous system: **Drowsiness**, nightmares, headache, CNS depression, sedation, malignant hyperthermia, dystonia, ataxia

Dermatologic: Angioedema, urticaria, purpura, photosensitivity, pruritus, exanthem

Endocrine & metabolic: Gynecomastia

Gastrointestinal: Xerostomia, constipation, stomatitis

Hematologic: Leukopenia, pancytopenia

Neuromuscular & skeletal: Tremors, paresthesia

Ocular: Mydriasis, diplopia

Otic: Tinnitus

Respiratory: **Thickening of bronchial secretions**, respiratory depression

Miscellaneous: Systemic lupus erythematosus

Signs and Symptoms of Overdose Akathisia, CNS depression, coma, hypotension, parkinsonism

Pharmacodynamics/Kinetics

Absorption: Well absorbed

Metabolism: Extensively hepatically metabolized largely to n-desalkyl metabolites

Bioavailability: Tablet: 70%; the sustained release capsules give closely comparable serum and urinary levels

Half-life, elimination: 4.78 hours

Time to peak serum concentration:

Syrup: 3.5 hours

Tablet: 4.5 hours

Dosage Oral, (maximum daily dose): 100 mg

Children:

> 3 years: 2.5 mg up to 3 times/day

> 6 years: Sustained release (Spansule®) capsule: 5 mg/day

Night walking: 6 mg/kg up to 60 mg

Preoperative anesthesia (children > 2 years): 2-5 mg/kg

Adults:

Pruritus: 2.5 mg 4 times/day

Sustained release (Spansule®) capsule: 5 mg every 12 hours; decrease dose in elderly

Monitoring Parameters ECG, CBC, blood pressure, arterial blood gases

Contraindications Hypersensitivity to trimeprazine or any component

Warnings Phenothiazines elevate prolactin levels and may be associated with breast tumorigenesis. Because phenothiazines lower the seizure threshold, trimeprazine should not be administered for 48 hours before and after myelography. Use with caution in patients with history of narrow-angle glaucoma, bladder neck obstruction, symptomatic prostate hypertrophy, asthma, sleep apnea, and stenosing peptic ulcer

Dosage Forms Tablet, as tartrate: 2.5 mg, 5 mg

Reference Range Therapeutic plasma level: 0.05-4.0 mcg/mL; postmortem blood level of 6.52 mcg/mL associated with fatality due to overdose of trimeprazine (postmortem urine was 6.22 mcg/mL)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam, diazepam, or phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 gram), while other antiarrhythmics can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50 mg I.M. or I.V. slow push followed by a maintenance dose for 48-72 hours. When these reactions are unresponsive to diphenhydramine, benztrapine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes.

Enhancement of elimination: Multiple dosing of activated charcoal may be helpful; not dialyzable (0% to 5%)

Drug Interactions Increased effect/toxicity with CNS depressants, alcohol, MAO inhibitors (avoid concomitant use), oral contraceptives, progesterone, reserpine, nylidrin; reduce narcotic or barbiturate concurrent dosage by 25% to 50%

Pregnancy Risk Factor C

Additional Information Chronic use can cause an increase in prolactin levels

Trimethaphan Camsylate

CAS Number 68-91-7; 7187-66-8

Synonyms Trimetaphan Camsylate; Trimethaphan Camphorsulfonate

Use Immediate and temporary reduction of blood pressure in patients with hypertensive emergencies; controlled hypotension during surgery

Mechanism of Action Blocks transmission in both adrenergic and cholinergic ganglia by blocking stimulation from presynaptic receptors to postsynaptic receptors mediated by acetylcholine; possesses direct peripheral vasodilatory activity and is a weak histamine releaser

Adverse Reactions

Cardiovascular: Hypotension (especially orthostatic), tachycardia, left bundle-branch block, first degree AV block, reduced cardiac output, chest pain, angina, sinus tachycardia, tachycardia (supraventricular), vasodilation

Central nervous system: Restlessness, anxiety, mania, paranoia

Dermatologic: Itching, rash

Endocrine & metabolic: Sodium and water retention

Gastrointestinal: Anorexia, nausea, vomiting, xerostomia, adynamic ileus, constipation

Genitourinary: Urinary retention, impotence

Neuromuscular & skeletal: Weakness

Ocular: Mydriasis, cycloplegia

Respiratory: Apnea, respiratory arrest

Miscellaneous: Anhidrosis

Signs and Symptoms of Overdose AV block, hypotension, impotence, respiratory arrest, tachycardia

Pharmacodynamics/Kinetics

Onset of action: Immediate

Peak effect: 5 minutes

Duration: 10-30 minutes

Metabolism: Primarily by postganglionic pseudocholinesterase

Elimination: Urine

Dosage Administration requires the use of an infusion pump

Severe hypertension and hypertensive emergencies: I.V.:

Children: 50-150 mcg/kg/minute; dilute 150 mg × weight (kg) to 250 mL in D₅W then dose in mcg/kg/minute = 10 × infusion rate in mL/hour

Adults: Initial rate: 0.5-1 mg/minute; titrate dose to the desired effect

Hypertension due to acute dissecting aneurysms: Initial rate: 1-2 mg/minute, adjusting as needed to keep systolic blood pressure of 100-120 mm Hg

Controlled hypotension during surgery: Initial rate: 3-4 mg/minute adjusted to maintain blood pressure at a desirable level; usual dosage needed 0.3-6 mg/minute

Stability Refrigerate; however, is stable for up to 14 days at room temperature

Monitoring Parameters Blood pressure and heart rate

Administration Must be diluted; usually mixed as 1 mg/mL concentration in 5% dextrose

Contraindications Hypersensitivity to trimethaphan camsylate or any component; hypovolemia or shock; anemia; respiratory insufficiency

Warnings Use with caution in patients with arteriosclerosis, cardiac, hepatic and renal dysfunction, diabetes mellitus, or Addison's disease. Pupillary dilation does not necessarily indicate anoxia or the depth of anesthesia since the drug appears to have a specific effect on the pupil.

Dosage Forms Injection: 50 mg/mL (10 mL)

Overdosage/Treatment Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated. Seizures usually respond to lorazepam or diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, dopamine 10 mcg/kg/minute starting dose or norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Physostigmine or neostigmine 0.5-1 mg I.V. slow push reverses many of the drug's acute toxic effects, while Bethanechol has proven useful in treating the drug-induced urinary retention.

Test Interactions ↓ potassium (S)

Drug Interactions Increased effect with anesthetics; increased effect of nondepolarizing neuromuscular blocking agents

Pregnancy Risk Factor C

Pregnancy Implications Can cause meconium ileus in neonates; crosses placenta

Nursing Implications Must be diluted; usually mixed as 1 mg/mL concentration in 5% dextrose; solution should be freshly prepared and any unused portion discarded

Additional Information Pupillary dilation does not necessarily indicate depth of anesthesia; discontinue drug before wound closure

Trimethobenzamide

CAS Number 554-92-7

U.S. Brand Names Tigan®

Synonyms Trimethobenzamide Hydrochloride

Impairment Potential Yes

Use Treatment of nausea and vomiting

Mechanism of Action Acts centrally to inhibit the medullary chemoreceptor trigger zone

Adverse Reactions

Cardiovascular: Hypotension

Central nervous system: Coma, depression, disorientation, dizziness, drowsiness, extrapyramidal symptoms, headache, opisthotonos, Parkinson-like syndrome, seizures

Hematologic: Blood dyscrasias

Hepatic: Jaundice

Neuromuscular & skeletal: Muscle cramps

Ocular: Blurred vision

Miscellaneous: Hypersensitivity reactions

Signs and Symptoms of Overdose CNS depression, hypotension, seizures

Pharmacodynamics/Kinetics

Onset of action: Antiemetic: Oral: 10-40 minutes; I.M.: 15-35 minutes

Duration: 3-4 hours

Absorption: Rectal: ~60%

Bioavailability: Oral: 60% to 100%

Half-life elimination: 7-9 hours

Time to peak: Oral: 45 minutes; I.M.: 30 minutes

Excretion: Urine (30% to 50%)

Dosage

Rectal use is contraindicated in neonates and premature infants

Children:

< 14 kg: Oral, rectal: 100 mg 3-4 times/day

14-40 kg: Oral, rectal: 100-200 mg 3-4 times/day

Adults:

Oral: 250-300 mg 3-4 times/day

I.M., rectal: 200 mg 3-4 times/day

Stability Store capsules, injection solution, and suppositories at room temperature.

Administration

Administer I.M. only; not for I.V. administration. Inject deep into upper outer quadrant of gluteal muscle.

Contraindications Hypersensitivity to trimethobenzamide, benzocaine (or similar local anesthetics), or any component of the formulation; injection contraindicated in children; suppositories contraindicated in premature infants or neonates

Warnings May mask emesis due to Reye's syndrome or mimic CNS effects of Reye's syndrome in patients with emesis of other etiologies; use in patients with acute vomiting should be avoided. May cause drowsiness; patient should avoid tasks requiring alertness (eg, driving, operating machinery). May cause extrapyramidal symptoms (EPS) which may be confused with CNS symptoms of primary disease responsible for emesis. Risk of adverse effects (eg, EPS, seizure) may be increased in patients with acute febrile illness, dehydration, or electrolyte imbalance; use caution.

Dosage Forms

Capsule, as hydrochloride (Tigan®): 300 mg

Injection, solution, as hydrochloride: 100 mg/mL (2 mL)

Tigan®: 100 mg/mL (2 mL [preservative free], 20 mL)

Suppository, rectal, as hydrochloride: 100 mg, 200 mg

Tebamide™: 100 mg, 200 mg [contains benzocaine]

Tigan®, Trimazide [DSC]: 200 mg [contains benzocaine]

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; charcoal may need to be given in multiple doses for adequate decontamination

Supportive therapy: Initiate support with fluids, norepinephrine may be useful for hypotension; hypoperfusion states may respond to inotropic support with dobutamine. Seizures should be managed with benzodiazepines or barbiturates.

Enhancement of elimination: Multiple dosing of charcoal may not be effective

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic effects were not observed in animal studies. Safety and efficacy have not been established in pregnant patients. Trimethobenzamide has been used to treat nausea and vomiting of pregnancy.

Lactation Excretion in breast milk unknown

Nursing Implications Use only clear solution

Additional Information Note: Less effective than phenothiazines but may be associated with fewer side effects; rectal is ~60% absorbed. Concomitant ethanol use should be avoided.

Trimetrexate Glucuronate

Related Information

- Methotrexate

CAS Number 52128-38-5; 82952-64-5

U.S. Brand Names Neutrexin®

Synonyms NSC-352122; Trimetrexate Glucuronate

Use Alternative therapy for the treatment of moderate-to-severe *Pneumocystis carinii* pneumonia (PCP) in immunocompromised patients, including patients with acquired immunodeficiency syndrome (AIDS), who are intolerant of, or are refractory to, co-trimoxazole therapy or for whom co-trimoxazole and pentamidine are contraindicated. **Concurrent folic acid (leucovorin) must always be administered.**

Unlabeled/Investigational Use Treatment of nonsmall cell lung cancer, metastatic colorectal cancer, metastatic head and neck cancer, pancreatic adenocarcinoma, cutaneous T-cell lymphoma

Mechanism of Action Trimetrexate is a folate antimetabolite that inhibits DNA synthesis by inhibition of dihydrofolate reductase (DHFR); DHFR inhibition reduces the formation of reduced folates and thymidylate synthetase, resulting in inhibition of purine and thymidylic acid synthesis.

Adverse Reactions

Central nervous system: Convulsions, fever

Dermatologic: Rash, hyperpigmentation, radiation recall dermatitis

Gastrointestinal: Stomatitis, nausea, vomiting

Hematologic: Neutropenia, thrombocytopenia, anemia

Hepatic: Elevated liver function tests

Neuromuscular & skeletal: Paresthesia

Renal: Elevated serum creatinine

Miscellaneous: Flu-like illness, hypersensitivity reactions

Signs and Symptoms of Overdose Leukopenia or neutropenia (agranulocytosis, granulocytopenia)

Pharmacodynamics/Kinetics

Distribution: V_d : 0.62 L/kg

Protein binding: 80% to 90% (concentration dependent)

Metabolism: Extensively hepatic: O-demethylation followed by conjugation to glucuronide or sulfate (major); N-demethylation and oxidation (minor)

Half-life elimination: 9-18 hours (11 hours with leucovorin)

Excretion: Urine (10% to 40% as unchanged drug); feces (<1% to 8%)

Dosage

Note: Concurrent leucovorin 20 mg/m² every 6 hours must be administered daily (oral or I.V.) during treatment and for 72 hours past the last dose of trimetrexate glucuronate.

Adults: I.V.:

Pneumocystis carinii: 45 mg/m² once daily for 21 days; **alternative dosing based on weight:**

< 50 kg: Trimetrexate glucuronate 1.5 mg/kg/day; leucovorin 0.6 mg/kg 4 times/day

50-80 kg: Trimetrexate glucuronate 1.2 mg/kg/day; leucovorin 0.5 mg/kg/4 times/day

> 80 kg: Trimetrexate glucuronate 1 mg/kg/day; leucovorin 0.5 mg/kg/4 times/day

Note: Oral doses of leucovorin should be rounded up to the next higher 25 mg increment.

Antineoplastic: 6-16 mg/m² once daily for 5 days every 21-28 days or 150-200 mg/m² every 2 weeks

Dosage adjustment in hepatic impairment: Although it may be necessary to reduce the dose in patients with liver dysfunction, no specific recommendations exist.

Stability Reconstituted I.V. solution is stable for 24 hours at room temperature or 7 days when refrigerated; intact vials should be refrigerated at 2°C to 8°C

Monitoring Parameters Check and record patient's temperature daily; absolute neutrophil counts (ANC), platelet count, renal function tests (serum creatinine, BUN), hepatic function tests (ALT, AST, alkaline phosphatase)

Administration Reconstituted solution should be filtered (0.22 μM) prior to further dilution; final solution should be clear, hue will range from colorless to pale yellow; trimetrexate forms a precipitate instantly upon contact with chloride ion or leucovorin, therefore it should not be added to solutions containing sodium chloride or other anions; trimetrexate and leucovorin solutions **must** be administered separately; intravenous lines should be flushed with at least 10 mL of D₅W between trimetrexate and leucovorin

Contraindications Hypersensitivity to trimetrexate, methotrexate, leucovorin, or any component of the formulation; severe existing myelosuppression; pregnancy

Warnings Hazardous agent - use appropriate precautions for handling and disposal. **[U.S. Boxed Warning]: Must be administered with concurrent leucovorin to avoid potentially serious or life-threatening toxicities.** Leucovorin therapy must extend for 72 hours past the last dose of trimetrexate. Hypersensitivity/allergic-type reactions have been reported, primarily when given as a bolus infusion, at higher than recommended doses for PCP, or in combination with fluorouracil or

leucovorin. May cause anaphylactoid reactions (rarely) including acute hypotension and loss of consciousness. Epinephrine should be available for treatment of acute allergic symptoms. Use with caution in patients with mild myelosuppression, severe hepatic or renal dysfunction, hypoproteinemia, hypoalbuminemia, or previous extensive myelosuppressive therapies. Withhold zidovudine during trimetrexate treatment.

Dosage Forms Injection, powder for reconstitution [preservative free]: 25 mg, 200 mg

Reference Range Peak plasma level: Oral: 3 mcg/L after 60 mg/m² dose; I.V.: 12 nmol/L after 30 mg/m² dose

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Severe bone marrow toxicity can result from overdose; leucovorin rescue can reduce the toxicity; administer as quickly as possible 10 mg/m² (5-15 mg) every 6 hours for 72 hours

Enhancement of elimination: Multiple dosing of activated charcoal is effective; renal excretion is optimized at a urinary pH of 7.0. Charcoal hemoperfusion, hydration, and urinary alkalization may enhance elimination and prevent precipitation in renal tubules; not dialyzable (0% to 5%)

Antidote(s)

- Folic Acid [ANTIDOTE]

- Leucovorin [ANTIDOTE]

Test Interactions Mild creatinine elevation, mild liver function test elevation

Drug Interactions Live virus vaccines (ie, yellow fever, BCG, MMP): Trimetrexate, due to immunosuppressive effects, may increase vaccine toxicity (eg, infection).

Zidovudine: May increase the myelotoxicity of trimetrexate. Discontinue zidovudine during trimetrexate treatment.

Pregnancy Risk Factor D

Pregnancy Implications Teratogenic effects and fetal loss were observed in animal studies. May cause fetal harm when administered to pregnant women. Women of childbearing potential should avoid becoming pregnant while receiving treatment. If used in pregnancy, or if patient becomes pregnant during treatment, the patient should be apprised of potential hazard to the fetus.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Notify primary physician of fever ≥ 103°F, generalized rash, seizures, bleeding from any site, uncontrolled nausea/vomiting, laboratory abnormalities which warrant dose modification; or any other clinical adverse event or laboratory abnormality occurring in therapy which is judged as serious for that patient, or which causes unexplained effects or concern.

Initiate "Bleeding Precautions" for platelet counts ≤ 50,000/mm³

Initiate "Infection Control Measures" for absolute neutrophil counts (ANC) ≤ 1000/mm³

Additional Information Not a vesicant; methotrexate derivative; incompatible with foscarnet

Trimipramine

Pronunciation (trye MI pra meen)

CAS Number 521-78-8; 739-71-9

U.S. Brand Names Surmontil®

Synonyms Trimipramine Maleate

Impairment Potential Yes

Use Treatment of various forms of depression, often in conjunction with psychotherapy

Mechanism of Action Increases the synaptic concentration of serotonin and/or norepinephrine in the central nervous system by inhibition of their reuptake by the presynaptic neuronal membrane

Adverse Reactions

Cardiovascular: Postural hypotension, cardiac arrhythmias, tachycardia, sudden death, sinus tachycardia, tachycardia (supraventricular), exacerbation of Brugada syndrome

Central nervous system: **Dizziness, drowsiness, headache**, sedation, fatigue, anxiety, impaired cognitive function, seizures have occurred occasionally, psychosis, gustatory hallucinations, hyperthermia

Dermatologic: Alopecia, urticaria, purpura, photosensitivity, pruritus, exanthem

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone, parotitis, gynecomastia

Gastrointestinal: **Xerostomia, increased appetite, nausea, unpleasant taste, weight gain, constipation**, stomatitis

Genitourinary: Urinary retention

Hematologic: Agranulocytosis, eosinophilia, may cause alterations in bleeding time, thrombocytopenia

Hepatic: Jaundice

Neuromuscular & skeletal: **Weakness**, tremors, paresthesia

Ocular: Blurred vision, increased intraocular pressure, mydriasis, nystagmus

Miscellaneous: Allergic reactions

Signs and Symptoms of Overdose Agitation, agranulocytosis, coma, confusion, dementia, granulocytopenia, hallucinations, hypotension, hypothermia, increased intraocular pressure, leukopenia, neuroleptic malignant syndrome, neutropenia, seizures, tachycardia, urinary retention

Admission Criteria/Prognosis

Admit any patient who is symptomatic 6 hours postingestion

Pharmacodynamics/Kinetics

Distribution: V_d : 17-48 L/kg

Protein binding: 95%; free drug: 3% to 7%

Metabolism: Hepatic; significant first-pass effect

Bioavailability: 18% to 63%

Half-life elimination: 16-40 hours

Excretion: Urine

Toxicodynamics/Kinetics

Absorption: Rapid from the gastrointestinal tract

Distribution: V_d : 17-48 L/kg; distributed widely in the body

Protein binding: 95%

Metabolism: Undergoes significant first-pass metabolism metabolized in the liver to desmethyl trimipramine

Half-life: 6-20 hours

Time to peak serum concentration: Within 6 hours

Elimination: Urine

Dosage Adults: Oral: 50-150 mg/day as a single bedtime dose up to a maximum of 200 mg/day outpatient and 300 mg/day inpatient

Monitoring Parameters Blood pressure and pulse rate prior to and during initial therapy; evaluate mental status; monitor weight; ECG in older adults

Contraindications Hypersensitivity to trimipramine, any component of the formulation, or other dibenzodiazepines; use of MAO inhibitors within 14 days; use in a patient during the acute recovery phase of MI

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. **Trimipramine is not FDA approved for use in children.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Trimipramine is not FDA approved for the treatment of bipolar depression.**

Often causes sedation, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Sedative effects may be additive with other CNS depressants and/or ethanol. The degree of sedation is very high relative to other antidepressants. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Therapy should not be abruptly discontinued in patients receiving high doses for prolonged periods. Use with caution in patients with hepatic or renal dysfunction and in elderly patients.

May cause orthostatic hypotension (risk is high relative to other antidepressants) - use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). The degree of anticholinergic blockade produced by this agent is very high relative to other cyclic antidepressants - use caution in patients with urinary retention, benign prostatic hyperplasia, narrow-angle glaucoma,

xerostomia, visual problems, constipation, or history of bowel obstruction. May cause alteration in glucose regulation - use with caution in patients with diabetes.

Use with caution in patients with a history of cardiovascular disease (including previous MI, stroke, tachycardia, or conduction abnormalities). The risk of conduction abnormalities with this agent is high relative to other antidepressants. Use caution in patients with a previous seizure disorder or condition predisposing to seizures such as brain damage, alcoholism, or concurrent therapy with other drugs which lower the seizure threshold. Use with caution in hyperthyroid patients or those receiving thyroid supplementation.

Dosage Forms Capsule: 25 mg, 50 mg, 100 mg

Reference Range An oral dose of 50 mg yields a peak serum level of 260 nmol/L; in the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: Do **not** induce emesis; gastric lavage (within 2-3 hours)/activated charcoal is useful

Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated. Ventricular arrhythmias often respond to systemic alkalization (sodium bicarbonate 0.5-2 mEq/kg I.V.). Arrhythmias unresponsive to this therapy may respond to lidocaine 1 mg/kg I.V. followed by a titrated infusion. Seizures usually respond to lorazepam or diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required.

Enhanced elimination: Multiple dosing of activated charcoal may be useful

Antidote(s)

- Sodium Bicarbonate [ANTIDOTE]

Test Interactions ↑ glucose; may cross react with phenothiazine assay

Drug Interactions

Substrate (major) of CYP2C19, 2D6, 3A4

Altreptamine: Concurrent use may cause orthostatic hypertension

Amphetamines: TCAs may enhance the effect of amphetamines; monitor for adverse CV effects

Anticholinergics: Combined use with TCAs may produce additive anticholinergic effects

Antihypertensives: TCAs may inhibit the antihypertensive response to betanidine, clonidine, debrisoquin, guanadrel, guanethidine, guanabenz, guanfacine; monitor BP; consider alternate antihypertensive agent

Beta-agonists: When combined with TCAs may predispose patients to cardiac arrhythmias

Bupropion: May increase the levels of tricyclic antidepressants; based on limited information; monitor response

Carbamazepine: Tricyclic antidepressants may increase carbamazepine levels; monitor

Cholestyramine and colestipol: May bind TCAs and reduce their absorption; monitor for altered response

Clonidine: Abrupt discontinuation of clonidine may cause hypertensive crisis, amitriptyline may enhance the response (also see note on antihypertensives)

CNS depressants: Sedative effects may be additive with TCAs; monitor for increased effect; includes benzodiazepines, barbiturates, antipsychotics, ethanol, and other sedative medications

CYP2D6 inhibitors: May increase the levels/effects of trimipramine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP2C19 inducers: May decrease the levels/effects of trimipramine. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of trimipramine. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of trimipramine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of trimipramine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Epinephrine (and other direct alpha-agonists): Pressor response to I.V. epinephrine, norepinephrine, and phenylephrine may be enhanced in patients receiving TCAs (**Note:** Effect is unlikely with epinephrine or levonordefrin dosages typically administered as infiltration in combination with local anesthetics).

Fenfluramine: May increase tricyclic antidepressant levels/effects

Hypoglycemic agents (including insulin): TCAs may enhance the hypoglycemic effects of tolazamide, chlorpropamide, or insulin; monitor for changes in blood glucose levels; reported with chlorpropamide, tolazamide, and insulin

TRYPTOPHAN

Levodopa: Tricyclic antidepressants may decrease the absorption (bioavailability) of levodopa; rare hypertensive episodes have also been attributed to this combination

Linezolid: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** with agents which inhibit MAO (serotonin syndrome); this combination should be avoided

Lithium: Concurrent use with a TCA may increase the risk for neurotoxicity

MAO inhibitors: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** (serotonin syndrome); this combination should be avoided

Methylphenidate: Metabolism of TCAs may be decreased

Phenothiazines: Serum concentrations of some TCAs may be increased; in addition, TCAs may increase concentration of phenothiazines; monitor for altered clinical response

QT_c-prolonging agents: Concurrent use of tricyclic agents with other drugs which may prolong QT_c interval may increase the risk of potentially fatal arrhythmias; includes type Ia and type III antiarrhythmic agents, selected quinolones (sparfloxacin, gatifloxacin, moxifloxacin, grepafloxacin), cisapride, and other agents

Ritonavir: Combined use of high-dose tricyclic antidepressants with ritonavir may cause serotonin syndrome in HIV-positive patients; monitor

Sucralfate: Absorption of tricyclic antidepressants may be reduced with coadministration

Sympathomimetics, indirect-acting: Tricyclic antidepressants may result in a decreased sensitivity to indirect-acting sympathomimetics; includes dopamine and ephedrine; also see interaction with epinephrine (and direct-acting sympathomimetics)

Valproic acid: May increase serum concentrations/adverse effects of some tricyclic antidepressants

Warfarin (and other oral anticoagulants): TCAs may increase the anticoagulant effect in patients stabilized on warfarin; monitor INR

Pregnancy Risk Factor C

Lactation Enters breast milk/contraindicated

Additional Information May cause alterations in bleeding time

Tryptophan

Related Information

- Oxitriptan

CAS Number 73-22-3

Synonyms L-Tryptophan

Use Antidepressant, insomnia, dietary supplement, postanoxic myoclonus

Mechanism of Action An essential amino acid which is a precursor to serotonin

Adverse Reactions

Eosinophilia-myalgia syndrome has been associated with L-tryptophan use manufactured by a single Japanese company (Showa-Denko). Thought to be related by presence of impurities (3-phenylaminoalanine) this syndrome is characterized by an early phase (0-2 months) which consists of **myalgia, skin rash, edema, fever, arthralgia, and dyspnea**. Tachycardia may also be present. Later manifestations may include **weight loss, muscle weakness**, progressing ascending axonal polyneuropathy, **paresthesias, alopecia, scleroderma-like cutaneous induration**, liver function abnormalities. Leukocytosis with eosinophilia (eosinophil counts ranging from 1000-36,000/mm³) usually occur. Eosinophilic fasciitis may also occur. Doses associated with development of this syndrome involve 1.2-2.4 g/day for 2 weeks to 8 years.

Cardiovascular: Vasculitis

Central nervous system: Headache, drowsiness, fever, euphoria

Endocrine & metabolic: Sexual dysfunction

Gastrointestinal: Nausea, pancreatitis

Neuromuscular & skeletal: Dyskinesias

Ocular: Nystagmus

Respiratory: Pneumonitis, pleural effusion, eosinophilic pneumonia, pulmonary vasculitis

Signs and Symptoms of Overdose Dizziness, headache, hypoglycemia, nausea (> 5 g intake)

Pharmacodynamics/Kinetics

Distribution: V_d: 0.3-3 L/kg

Protein binding: 65% to 78%

Metabolism: In the brain (to serotonin) and in the liver (via kynurenine pathway to quinolinic acid, tryptamine, niacin among other metabolites)

Half-life: 1-3 hours

Dosage Insomnia: 1-2 g at bedtime; doses up to 6 g/day in divided doses have been used to treat depression

Dosage Forms Tablet: 500 mg

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage within 1 hour if coingestion (ie, MAO inhibitors, selective serotonin reuptake inhibitors) have occurred; activated charcoal may be useful

Supportive therapy: Although its long-term benefits have not been proven, prednisone (15-60 mg/day) may provide some relief of myalgias and other acute manifestations of eosinophilia-myalgia syndrome. While total eosinophil counts may decrease following high-dose steroid therapy, no effect on neurologic or skin induration complications appear to occur. Cyproheptadine (4 mg twice daily) can be used to treat muscle spasms or cramps. (**Do not** use cyproheptadine if serotonin syndrome is present.)

Drug Interactions Fluoxetine → restlessness, agitation, nausea, diarrhea

Additional Information Usual daily dietary intake: 0.5-2 g; minimum daily requirement: ~3 mg/kg; may exacerbate Huntington's disease; 60 mg of L-tryptophan provide the equivalent of 1 mg of niacin; 1 glass of cow's milk contains ~100 mg tryptophan

Ubidecarenone

CAS Number 303-98-0

Synonyms Mitoquinone; Ubidecarenone

Unlabeled/Investigational Use In U.S.: Congestive heart failure, angina, periodontal disease, also used in treatment of warfarin-induced alopecia, breast cancer, chronic lung disease; prevention of doxorubicin-induced cardiac toxicity

Mechanism of Action A fat soluble quinone which acts as a coenzyme in mitochondrial electron transport and adenosine triphosphate (ATP) synthesis; may affect prostaglandin synthesis

Adverse Reactions

Central nervous system: Headache, agitation, dizziness

Dermatologic: Pruritus

Gastrointestinal: Nausea, diarrhea, anorexia

Pharmacodynamics/Kinetics

Half-life: 34 hours

Peak plasma level: 5-10 hours

Elimination: Biliary (fecal)

Dosage Chronic lung disease: 90 mg/day for 8 weeks

Breast cancer: 90-390 mg/day

Heart failure:

Oral: 50-150 mg/day in 2-3 divided doses

I.V.: 50-100 mg/day

Angina:

Oral: 150-600 mg/day in divided doses

I.V.: 1.5 mg/day for 1 week

Periodontal disease: Oral: 25 mg twice daily

Warfarin-induced alopecia: 30 mg/day

Prevention of doxorubicin cardiac toxicity: 50 mg/day

Contraindications Previous hypersensitivity to ubidecarenone

Warnings Use with caution in patients with diabetes mellitus, liver/biliary disease, renal insufficiency

Dosage Forms Capsule: 10 mg, 30 mg, 50 mg, 75 mg, 100 mg, 150 mg

Liquid: 30 mg/5 mL (480 mL)

Tablet: 25 mg, 60 mg, 200 mg

Tablet, chewable: 100 mg, 200 mg

Reference Range

Normal endogenous blood level of ubidecarenone: 0.3-1.6 mcg/mL

Therapeutic blood levels for congestive heart failure: 2-2.5 mcg/mL

Overdosage/Treatment

Decontamination: **Oral:** Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal. **Ocular:** Irrigate eyes copiously with saline.

Additional Information Total body ubidecarenone content is 1-1.5 g; available as a food supplement in the U.S.; not water soluble

Urapidil

CAS Number 34661-75-1; 64887-14-5

Synonyms Urapidil Hydrochloride

Use Hypertension

Mechanism of Action Alpha₁-adrenoceptor antagonist (peripheral vasodilator); a phenylpiperazine derivative of 4-aminouracil

Adverse Reactions

Cardiovascular: Palpitations, bradycardia, hypotension (orthostatic), sinus bradycardia

Central nervous system: Headache, dizziness, fatigue

Dermatologic: Allergic skin reactions, pruritus

Gastrointestinal: Nausea

Renal: Enuresis

Respiratory: Nasal congestion

Signs and Symptoms of Overdose Coagulopathy, diarrhea, drowsiness, enuresis, eosinophilia, hypotension

Pharmacodynamics/Kinetics

Protein binding: 80%

Metabolism: Hepatic to p-hydroxylated urapidil; first-pass effect (20%)

Bioavailability: 70%

Half-life elimination: Oral: 4.7 hours; I.V.: 2.7 hours

Excretion: Urine (15% to 30%) as unchanged drug

Dosage Oral: 30-90 mg twice daily
I.V.: 25 mg over 20 seconds

Reference Range Dose of 120 mg can cause a urapidil blood level of 750 ng/mL 3-5 hours postingestion

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/charcoal

Supportive therapy: Treat hypotension with fluids or Trendelenburg positioning; vasopressors may be required to support blood pressure (eg, phenylephrine or dopamine)

Drug Interactions Cimetidine modifies pharmacokinetics such that dosage reduction is necessary

Additional Information 20% as potent as prazosin; may increase plasma renin and catecholamine level

Urokinase

CAS Number 9039-53-6

U.S. Brand Names Abbokinase®

Synonyms UK

Use Thrombolytic agent for the lysis of acute massive pulmonary emboli or pulmonary emboli with unstable hemodynamics

Unlabeled/Investigational Use Thrombolytic agent used in treatment of recent severe or massive deep vein thrombosis, myocardial infarction, and occluded I.V. or dialysis cannulas

Mechanism of Action Promotes thrombolysis by directly activating plasminogen to plasmin, which degrades fibrin, fibrinogen, and other procoagulant plasma proteins

Adverse Reactions

Cardiovascular: **Arrhythmias, hypotension**

Central nervous system: Headache, chills, hyperthermia

Dermatologic: Rash, **angioneurotic edema**

Gastrointestinal: Nausea, vomiting

Hematologic: Anemia, eye hemorrhage

Local: **Bleeding at sites of percutaneous trauma**, extravasation injury

Ocular: **Periorbital edema**

Respiratory: **Bronchospasm**, epistaxis

Miscellaneous: **Anaphylaxis**, diaphoresis

Signs and Symptoms of Overdose Bleeding gums, coagulopathy, epistaxis, GI bleeding, hematoma, hematuria, hemoptysis, intracranial hemorrhage, ocular hemorrhage, oozing at catheter site, spontaneous ecchymosis

Pharmacodynamics/Kinetics

Onset of action: I.V.: Fibrinolysis occurs rapidly

Duration: ≥ 4 hours

Distribution: 11.5 L

Half-life elimination: 6.4-18.8 minutes

Excretion: Urine and feces (small amounts)

Dosage

Children and Adults: Deep vein thrombosis (unlabeled use): I.V.: Loading: 4400 units/kg over 10 minutes, then 4400 units/kg/hour for 12 hours

Adults:

Myocardial infarction (unlabeled use): Intracoronary: 750,000 units over 2 hours (6000 units/minute over up to 2 hours)

Occluded I.V. catheters (unlabeled use):

5000 units in each lumen over 1-2 minutes, leave in lumen for 1-4 hours, then aspirate; may repeat with 10,000 units in each lumen if 5000 units fails to clear the catheter; **do not infuse into the patient**; volume to instill into catheter is equal to the volume of the catheter

I.V. infusion: 200 units/kg/hour in each lumen for 12-48 hours at a rate of at least 20 mL/hour

Dialysis patients: 5000 units is administered in each lumen over 1-2 minutes; leave urokinase in lumen for 1-2 days, then aspirate

Acute pulmonary embolism: I.V.: Loading: 4400 int. units/kg over 10 minutes; maintenance: 4400 int. units/kg/hour for 12 hours. Following infusion, anticoagulation treatment is recommended to prevent recurrent thrombosis. Do not start anticoagulation until aPTT has decreased to less than twice the normal control value. If heparin is used, do not administer loading dose. Treatment should be followed with oral anticoagulants.

Stability Store in refrigerator; reconstitute by gently rolling and tilting; do not shake; contains no preservatives, should not be reconstituted until immediately before using, discard unused portion; stable at room temperature for 24 hours after reconstitution

Monitoring Parameters Blood pressure, pulse; CBC, platelet count, aPTT, urinalysis

Administration I.V. infusion: Usual concentration: 1250-1500 units/mL; maximum concentration not yet defined

Contraindications Hypersensitivity to urokinase or any component of the formulation; active internal bleeding; history of CVA; recent (within 2 months) intracranial or intraspinal surgery or trauma; intracranial neoplasm, arteriovenous malformation, or aneurysm; known bleeding diathesis; severe uncontrolled hypertension

Warnings

Concurrent heparin anticoagulation can contribute to bleeding; careful attention to all potential bleeding sites. I.M. injections and nonessential handling of the patient should be avoided. Venipunctures should be performed carefully and only when necessary. If arterial puncture is necessary, use an upper extremity vessel that can be manually compressed. If serious bleeding occurs, then the infusion of urokinase and heparin should be stopped.

For the following conditions the risk of bleeding is higher with use of thrombolytics and should be weighed against the benefits of therapy: recent (within 10 days) major surgery (eg, CABG, obstetrical delivery, organ biopsy, previous puncture of noncompressible vessels), cerebrovascular disease, recent (within 10 days) gastrointestinal or genitourinary bleeding, recent trauma (within 10 days) including CPR, hypertension (systolic BP >180 mm Hg and/or diastolic BP >110 mm Hg), high likelihood of left heart thrombus (eg, mitral stenosis with atrial fibrillation), acute pericarditis, subacute bacterial endocarditis, hemostatic defects including ones caused by severe renal or hepatic dysfunction, significant hepatic dysfunction, pregnancy, diabetic hemorrhagic retinopathy or other hemorrhagic ophthalmic conditions, septic thrombophlebitis or occluded AV cannula at seriously infected site, advanced age (eg, >75 years), patients receiving oral anticoagulants, any other condition in which bleeding constitutes a significant hazard or would be particularly difficult to manage because of location.

Coronary thrombolysis may result in reperfusion arrhythmias. Follow standard MI management. Rare anaphylactoid reactions can occur. Formulated in human albumin; products made from human sources have a theoretical risk of transmitting infectious agents. Safety and efficacy in pediatric patients have not been established.

Dosage Forms [DSC] = Discontinued product

Injection, powder for reconstitution: 250,000 int. units [contains human albumin 250 mg and mannitol 25 mg] [DSC]

Overdosage/Treatment Supportive therapy: Treat bleeding complications with transfusions of red blood cells, fresh frozen plasma, and cryoprecipitate; do not administer dextran; although human overdose data is lacking, administration of aminocaproic acid (Amicar®) at a dose of 3-5 g I.V. followed by an infusion rate of 1-1.25 g/hour may be useful

Test Interactions Earlier peaks of creatine phosphokinase isoenzyme can occur

Drug Interactions Aminocaproic acid (antifibrinolytic agent) may decrease effectiveness.

Drugs which affect platelet function (eg, aspirin, NSAIDs, dipyridamole, ticlopidine, clopidogrel, IIb/IIIa antagonists) may potentiate the risk of hemorrhage; use with caution.

Heparin: Concurrent use may increase risk of bleeding; use caution.

Warfarin or oral anticoagulants: Risk of bleeding may be increased during concurrent therapy.

Pregnancy Risk Factor B

Pregnancy Implications Urokinase was not found to be teratogenic in animal studies; it is not known if it crosses the human placenta. Placental separation and hemorrhage have been reported in one patient treated at 3 months gestation. Use during pregnancy only if clearly needed.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Use 0.22 or 0.45 micron filter during I.V. therapy

Additional Information/Note: Not currently being manufactured; contact Abbott Labs (800-615-0187) for further information.

Abbokinase® Open Cath 5000 unit product is **not** for systemic administration; it must be aspirated out of the catheter

Valacyclovir

Related Information

- Acyclovir

U.S. Brand Names Valtrex®

Synonyms Valacyclovir Hydrochloride

Use Treatment of herpes zoster (shingles) in immunocompetent patients; treatment of first-episode genital herpes; episodic treatment of recurrent genital herpes; suppression of recurrent genital herpes and reduction of heterosexual transmission of genital herpes in immunocompetent patients; suppression of genital herpes in HIV-infected individuals; treatment of herpes labialis (cold sores)

Mechanism of Action Inhibits DNA synthesis and viral replication by competing with deoxyguanosine triphosphate for viral DNA polymerase (thymidine kinase) and being incorporated into viral DNA

Adverse Reactions

Cardiovascular: Facial edema, hypertension, tachycardia

Central nervous system: **Headache** (14% to 35%), dizziness, depression, agitation, coma, confusion, consciousness decreased, encephalopathy, auditory hallucinations, visual hallucinations, mania, psychosis

Dermatologic: Alopecia, erythema multiforme, photosensitivity reaction, rash

Endocrine: Dysmenorrhea

Gastrointestinal: Abdominal pain, nausea, vomiting, diarrhea

VALPROIC ACID AND DERIVATIVES

Hematologic: Leukopenia, thrombocytopenia, anemia, aplastic anemia, hemolytic uremic syndrome (HUS), thrombotic thrombocytopenic purpura/hemolytic uremic syndrome
Hepatic: AST increased, hepatitis
Neuromuscular & skeletal: Arthralgia, tremor
Ocular: Visual disturbances
Renal: Creatinine increased, renal failure
Miscellaneous: Acute hypersensitivity reactions, anaphylaxis

Pharmacodynamics/Kinetics

Absorption: Rapid
Distribution: Acyclovir is widely distributed throughout the body including brain, kidney, lungs, liver, spleen, muscle, uterus, vagina, and CSF
Protein binding: 13.5% to 17.9%
Metabolism: Hepatic; valacyclovir is rapidly and nearly completely converted to acyclovir and L-valine by first-pass effect; acyclovir is hepatically metabolized to a very small extent by aldehyde oxidase and by alcohol and aldehyde dehydrogenase (inactive metabolites)
Bioavailability: ~55% once converted to acyclovir
Half-life elimination: Normal renal function: Adults: Acyclovir: 2.5-3.3 hours, Valacyclovir: ~30 minutes; End-stage renal disease: Acyclovir: 14-20 hours
Excretion: Urine, primarily as acyclovir (88%); **Note:** Following oral administration of radiolabeled valacyclovir, 46% of the label is eliminated in the feces (corresponding to nonabsorbed drug), while 47% of the radiolabel is eliminated in the urine.

Dosage Oral:

Adolescents and Adults: Herpes labialis (cold sores): 2 g twice daily for 1 day (separate doses by ~12 hours)
Adults:
Herpes zoster (shingles): 1 g 3 times/day for 7 days
Genital herpes:
Initial episode: 1 g twice daily for 10 days
Recurrent episode: 500 mg twice daily for 3 days
Reduction of transmission: 500 mg once daily (source partner)
Suppressive therapy:
Immunocompetent patients: 1000 mg once daily (500 mg once daily in patients with <9 recurrences per year)
HIV-infected patients (CD4 \geq 100 cells/mm³): 500 mg twice daily

Dosing interval in renal impairment:

Herpes zoster: Adults:
Cl_{cr} 30-49 mL/minute: 1 g every 12 hours
Cl_{cr} 10-29 mL/minute: 1 g every 24 hours
Cl_{cr} < 10 mL/minute: 500 mg every 24 hours
Genital herpes: Adults:
Initial episode:
Cl_{cr} 10-29 mL/minute: 1 g every 24 hours
Cl_{cr} < 10 mL/minute: 500 mg every 24 hours
Recurrent episode: Cl_{cr} < 10-29 mL/minute: 500 mg every 24 hours
Suppressive therapy: Cl_{cr} < 10-29 mL/minute:
For usual dose of 1 g every 24 hours, decrease dose to 500 mg every 24 hours
For usual dose of 500 mg every 24 hours, decrease dose to 500 mg every 48 hours
HIV-infected patients: 500 mg every 24 hours
Herpes labialis: Adolescents and Adults:
Cl_{cr} 30-49 mL/minute: 1 g every 12 hours for 2 doses
Cl_{cr} 10-29 mL/minute: 500 mg every 12 hours for 2 doses
Cl_{cr} < 10 mL/minute: 500 mg as a single dose
Hemodialysis: Dialyzable (~33% removed during 4-hour session); administer dose postdialysis
Chronic ambulatory peritoneal dialysis/continuous arteriovenous hemofiltration dialysis: Pharmacokinetic parameters are similar to those in patients with ESRD; supplemental dose not needed following dialysis

Stability Store at 15°C to 25°C (59°F to 77°F).

Monitoring Parameters Urinalysis, BUN, serum creatinine, liver enzymes, and CBC

Administration If GI upset occurs, administer with meals.

Contraindications Hypersensitivity to valacyclovir, acyclovir, or any component of the formulation

Warnings Hazardous agent - use appropriate precautions for handling and disposal. Thrombotic thrombocytopenic purpura/hemolytic uremic syndrome has occurred in immunocompromised patients (at doses of 8 g/day); use caution and adjust the dose in elderly patients or those with renal insufficiency and in patients receiving concurrent nephrotoxic agents. For genital herpes, treatment should begin as soon as possible after the first signs and symptoms (within 72 hours of onset of first diagnosis or within 24 hours of onset of recurrent episodes). For herpes zoster, treatment should begin within 72 hours of onset of rash. For cold sores, treatment should begin at with earliest symptom (tingling, itching, burning). Safety and efficacy in prepubertal patients have not been established.

Dosage Forms Caplet: 500 mg, 1000 mg

Reference Range After a 1 g oral dose, peak serum acyclovir levels were ~5.65 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal
Supportive therapy: Renal toxicity and crystalluria can be managed with I.V. fluid hydration
Enhancement of elimination: Multiple dosing of activated charcoal may be effective; hemodialysis can remove ~60% of total body burden; exchange transfusion is not useful

Drug Interactions Cimetidine: Decreased renal clearance of acyclovir; no dosage adjustment needed in patients with normal renal function
Probenecid: Decreased renal clearance of acyclovir; no dosage adjustment needed in patients with normal renal function

Pregnancy Risk Factor B

Pregnancy Implications Teratogenicity registry has shown no increased rate of birth defects than that of the general population; however, the registry is small and use during pregnancy is only warranted if the potential benefit to the mother justifies the risk of the fetus.

Lactation Enters breast milk/use caution

Additional Information Due to higher bioavailability than acyclovir, plasma acyclovir levels are 3-5 times higher with valacyclovir administration as compared with acyclovir administration

Katiyar A, Daubert GP, and Aaron C, "Acute Renal Failure Following Acute Oral Valacyclovir Overdose," *Clin Toxicol (Phila)*, 2005, 43:732.

Valproic Acid and Derivatives

CAS Number 1069-66-5; 2430-27-5; 76584-70-8; 77372-61-3; 99-66-1

U.S. Brand Names Depacon®; Depakene®; Depakote® Delayed Release; Depakote® ER; Depakote® Sprinkle®

Synonyms 2-Propylpentanoic Acid; 2-Propylvaleric Acid; Dipropylacetic Acid; Divalproex Sodium; DPA; Valproate Semisodium; Valproate Sodium; Valproic Acid

Use

Monotherapy and adjunctive therapy in the treatment of patients with complex partial seizures; monotherapy and adjunctive therapy of simple and complex absence seizures; adjunctive therapy patients with multiple seizure types that include absence seizures
Mania associated with bipolar disorder (Depakote®)
Migraine prophylaxis (Depakote®, Depakote® ER)

Unlabeled/Investigational Use Behavior disorders (eg, agitation, aggression) in patients with dementia (based on the results of several randomized, controlled trials, there is little evidence to support this use); status epilepticus

Mechanism of Action Causes increased availability of gamma-aminobutyric acid (GABA), an inhibitory neurotransmitter, to brain neurons or may enhance the action of GABA or mimic its action at postsynaptic receptor sites

Adverse Reactions

Central nervous system: Drowsiness, irritability, confusion, restlessness, hyperactivity, psychosis, malaise, visual hallucinations, extrapyramidal syndrome, headache, ataxia
Dermatologic: Alopecia, erythema multiforme
Endocrine & metabolic: Hyperammonemia, hypernatremia with sodium valproate, metabolic acidosis
Gastrointestinal: Nausea, vomiting, diarrhea, pancreatitis, abdominal cramps, anorexia, hemorrhage, weight gain, gingival hyperplasia
Hematologic: Thrombocytopenia, prolongation of bleeding time, leukopenia, pancytopenia, eosinophilia, red blood cell aplasia, factor X deficiency, transient myeloid dysplasia
Hepatic: Transient elevated liver enzymes, liver failure (especially noted in children <2 years of age), fatty degeneration of liver, cholestatic hepatitis, impaired gluconeogenesis, cholecystitis, hyperammonemic encephalopathy (in patients with UCD)
Neuromuscular & skeletal: Tremors, chorea, clonus, myoclonus, osteoporosis (long-term therapy)
Ocular: Nystagmus
Renal: Enuresis, anuria
Respiratory: Pleural effusion
Miscellaneous: Systemic lupus erythematosus

Signs and Symptoms of Overdose Agranulocytosis, cerebral edema, cholestatic jaundice, coagulopathy, coma, confusion, dementia, encephalopathy, enuresis, extrapyramidal reaction, Fanconi syndrome, granulocytopenia, hyperactivity, hyperglycemia, hyperthermia, hyporeflexia, hypothermia, hypothyroidism, ileus, irritability, jaundice, leukopenia (3%), mania, metabolic acidosis (at serum levels >50 mcg/mL), migraine headache (exacerbation), miosis, myoclonus, nephritis, neutropenia, night terrors, nystagmus, optic nerve atrophy, photophobia, pseudotumor cerebri, tachycardia (17%), thrombocytopenia (8%), tremors

Admission Criteria/Prognosis Admit any patient with central nervous system abnormality associated with the ingestion, hepatic toxicity, or ingestions > 100 mg/kg

Pharmacodynamics/Kinetics

Absorption: Nearly 100%

Distribution: Total valproate: 11 L/1.73 m²; free valproate 92 L/1.73 m²
 Protein binding (dose dependent): 80% to 90%

Metabolism: Extensively hepatic via glucuronide conjugation and mitochondrial beta-oxidation. The relationship between dose and total valproate concentration is nonlinear; concentration does not increase proportionally with the dose, but increases to a lesser extent due to saturable plasma protein binding. The kinetics of unbound drug are linear.

Bioavailability: Extended release: 90% of I.V. dose and 81% to 90% of delayed release dose

Half-life elimination: (increased in neonates and with liver disease):
 Children: 4-14 hours; Adults: 9-16 hours

Time to peak, serum: 1-4 hours; Divalproex (enteric coated): 3-5 hours

Excretion: Urine (30% to 50% as glucuronide conjugate, 3% as unchanged drug)

Dosage Seizures:

Children > 10 years and Adults:

Oral: Initial: 10-15 mg/kg/day in 1-3 divided doses; increase by 5-10 mg/kg/day at weekly intervals until therapeutic levels are achieved; maintenance: 30-60 mg/kg/day. Adult usual dose: 1000-2500 mg/day. **Note:** Regular release and delayed release formulations are usually given in 2-4 divided doses/day, extended release formulation (Depakote[®] ER) is usually given once daily. Conversion to Depakote[®] ER from a stable dose of Depakote[®] may require an increase in the total daily dose between 8% and 20% to maintain similar serum concentrations.

Children receiving more than one anticonvulsant (ie, polytherapy) may require doses up to 100 mg/kg/day in 3-4 divided doses

I.V.: Administer as a 60-minute infusion (≤ 20 mg/minute) with the same frequency as oral products; switch patient to oral products as soon as possible. Alternatively, rapid infusions have been given: ≤ 15 mg/kg over 5-10 minutes (1.5-3 mg/kg/minute).

Rectal (unlabeled): Dilute syrup 1:1 with water for use as a retention enema; loading dose: 17-20 mg/kg one time; maintenance: 10-15 mg/kg/dose every 8 hours

Status epilepticus (unlabeled use): Adults:

Loading dose: I.V.: 15-25 mg/kg administered at 3 mg/kg/minute.

Maintenance dose: I.V. infusion: 1-4 mg/kg/hour; titrate dose as needed based upon patient response and evaluation of drug-drug interactions

Mania: Adults: Oral: 750-1500 mg/day in divided doses; dose should be adjusted as rapidly as possible to desired clinical effect; a loading dose of 20 mg/kg may be used; maximum recommended dosage: 60 mg/kg/day

Migraine prophylaxis: Adults: Oral:

Extended release tablets: 500 mg once daily for 7 days, then increase to 1000 mg once daily; adjust dose based on patient response; usual dosage range 500-1000 mg/day

Delayed release tablets: 250 mg twice daily; adjust dose based on patient response, up to 1000 mg/day

Elderly: Elimination is decreased in the elderly. Studies of elderly patients with dementia show a high incidence of somnolence. In some patients, this was associated with weight loss. Starting doses should be lower and increases should be slow, with careful monitoring of nutritional intake and dehydration. Safety and efficacy for use in patients >65 years have not been studied for migraine prophylaxis.

Dosing adjustment in renal impairment: A 27% reduction in clearance of unbound valproate is seen in patients with $Cl_{cr} < 10$ mL/minute. Hemodialysis reduces valproate concentrations by 20%, therefore no dose adjustment is needed in patients with renal failure. Protein binding is reduced, monitoring only total valproate concentrations may be misleading.

Dosing adjustment/comments in hepatic impairment: Reduce dose. Clearance is decreased with liver impairment. Hepatic disease is also associated with decreased albumin concentrations and 2- to 2.6-fold increase in the unbound fraction. Free concentrations of valproate may be elevated while total concentrations appear normal.

Monitoring Parameters

Liver enzymes, CBC with platelets

Administration Depakote[®] ER: Swallow whole, do not crush or chew. Patients who need dose adjustments smaller than 500 mg/day for migraine prophylaxis should be changed to Depakote[®] delayed release tablets. Sprinkle capsules may be swallowed whole or open cap and sprinkle on small amount (1 teaspoonful) of soft food and use immediately (do not store or chew).

Depacon[®]: Following dilution to final concentration, administer over 60 minutes at a rate of ≤ 20 mg/minute. Alternatively, single doses up to 15 mg/kg have been administered as a rapid infusion over 5-10 minutes (1.5-3 mg/kg/minute).

Contraindications Hypersensitivity to valproic acid, derivatives, or any component of the formulation; hepatic dysfunction; urea cycle disorders

Warnings

[US Boxed Warning]: Hepatic failure resulting in fatalities has occurred in patients; children <2 years of age are at considerable

risk. Other risk factors include organic brain disease, mental retardation with severe seizure disorders, congenital metabolic disorders, and patients on multiple anticonvulsants. Hepatotoxicity has been reported after 3 days to 6 months of therapy. Monitor patients closely for appearance of malaise, weakness, facial edema, anorexia, jaundice, and vomiting.

[US Boxed Warning]: May cause teratogenic effects such as neural tube defects (eg, spina bifida). Use in women of childbearing potential requires that benefits of use in mother be weighed against the potential risk to fetus, especially when used for conditions not associated with permanent injury or risk of death (eg, migraine).

May cause severe thrombocytopenia, inhibition of platelet aggregation and bleeding; tremors may indicate overdose; use with caution in patients receiving other anticonvulsants. Cases of life-threatening pancreatitis, occurring at the start of therapy or following years of use, have been reported in adults and children. Some cases have been hemorrhagic with rapid progression of initial symptoms to death. Hypersensitivity reactions affecting multiple organs have been reported in association with valproic acid use; may include dermatologic and/or hematologic changes (eosinophilia, neutropenia, thrombocytopenia) or symptoms of organ dysfunction.

Hyperammonemia and/or encephalopathy, sometimes fatal, have been reported following the initiation of valproate therapy and may be present with normal transaminase levels. Ammonia levels should be measured in patients who develop unexplained lethargy and vomiting, or changes in mental status. Discontinue therapy if ammonia levels are increased and evaluate for possible urea cycle disorder (UCD). Although rare genetic disorders, UCD evaluation should be considered for the following patients, prior to the start of therapy: History of unexplained encephalopathy or coma; encephalopathy associated with protein load; pregnancy or postpartum encephalopathy; unexplained mental retardation; history of elevated plasma ammonia or glutamine; history of cyclical vomiting and lethargy; episodic extreme irritability, ataxia; low BUN or protein avoidance; family history of UCD or unexplained infant deaths (particularly male); signs or symptoms of UCD (hyperammonemia, encephalopathy, respiratory alkalosis).

In vitro studies have suggested valproate stimulates the replication of HIV and CMV viruses under experimental conditions. The clinical consequence of this is unknown, but should be considered when monitoring affected patients.

Anticonvulsants should not be discontinued abruptly because of the possibility of increasing seizure frequency; valproate should be withdrawn gradually to minimize the potential of increased seizure frequency, unless safety concerns require a more rapid withdrawal. Concomitant use with clonazepam may induce absence status.

CNS depression may occur with valproate use. Patients must be cautioned about performing tasks which require mental alertness (operating machinery or driving). Effects with other sedative drugs or ethanol may be potentiated.

Dosage Forms

Note: Strength expressed as valproic acid

Capsule, as valproic acid (Depakene[®]): 250 mg

Capsule, sprinkles, as divalproex sodium (Depakote[®] Sprinkle[®]): 125 mg
 Injection, solution, as valproate sodium (Depacon[®]): 100 mg/mL (5 mL [contains edetate disodium])

Syrup, as valproic acid: 250 mg/5 mL (480 mL)

Depakene[®]: 250 mg/5 mL (480 mL)

Tablet, delayed release, as divalproex sodium (Depakote[®]): 125 mg, 250 mg, 500 mg

Tablet, extended release, as divalproex sodium (Depakote[®] ER): 250 mg, 500 mg

Reference Range

Therapeutic: 50-100 mcg/mL (SI: 350-690 μ mol/L); seizure control may improve at levels > 100 mcg/mL (SI: > 690 μ mol/L)

Toxic: Toxicity may occur at levels of 100-150 mcg/mL (SI: 690-1040 μ mol/L)

Postmortem blood valproic acid levels from valproic acid overdoses range from 520 mg/L to 1970 mg/L.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal within 14 hours of ingestion

Supportive therapy: Supportive treatment is necessary; intubation will probably be required at serum VPA levels > 850 mcg/mL; naloxone has been used to reverse CNS depressant effects, but may block action of other anticonvulsants; carnitine (1 g 3 times/day) is useful in reducing ammonia level; L-carnitine (100 mg/kg loading dose then 250 mg every 8 hours for 4 days) has been used to treat hepatic dysfunction in children due to valproic acid overdose. Additionally, its use has been advocated in the treatment of Reye's or Reye's-like syndrome due to valproic acid

Enhancement of elimination: Multiple dosing of activated charcoal is effective; hemoperfusion and/or hemodialysis may be effective in treating persistent hypotension or acidosis; hemodialyzer clearance is ~ 23 mL/minute; not hemodialyzed in a normal dose situation due to

high protein-binding of valproic acid, but in an overdose situation, whereupon protein binding is decreased, hemodialysis may be effective. Simultaneous "in series" hemodialysis/hemoperfusion has been demonstrated to decrease valproate half-life to <2 hours; hemodialysis has been used successfully in decreasing valproic acid serum level from 949-113 mcg/mL postdialysis. Charcoal hemoperfusion has been used successfully (plasma clearance: 54.5 mL/minute); forced diuresis (4 mL/kg/hour of I.V. fluid with a urine flow of 3.5-4 mL/kg/hour) has been advocated to increase urinary valproic acid clearance 5.5 fold in massive valproic acid overdose (serum level > 1000 mcg/mL); it should be noted that this modality has not been extensively studied

Antidote(s)

- Levocarnitine [ANTIDOTE]
- Naloxone [ANTIDOTE]

Diagnostic Procedures

- Valproic Acid, Blood

Test Interactions False-positive urine ketones; ↑ sodium, glucose; ↓ calcium

Drug Interactions For valproic acid: **Substrate** (minor) of CYP2A6, 2B6, 2C9, 2C19, 2E1; **Inhibits** CYP2C9 (weak), 2C19 (weak), 2D6 (weak), 3A4 (weak); **Induces** CYP2A6 (weak)

Carbamazepine: Valproic acid may increase, decrease, or have no effect on carbamazepine levels; valproic acid may increase serum concentrations of carbamazepine - epoxide (active metabolite); valproic acid may induce the metabolism of carbamazepine; monitor.

Carbapenem antibiotics (ertapenem, imipenem, meropenem): May decrease valproic acid concentrations to subtherapeutic levels; monitor.

Felbamate: May increase the levels/effects of valproic acid; monitor.

Isoniazid: May decrease valproic acid metabolism (limited documentation).

Lamotrigine: Valproic acid inhibits the metabolism of lamotrigine; combination therapy has been proposed to increase the risk of toxic epidermal necrolysis; monitor.

Macrolide antibiotics: May decrease valproic acid metabolism (limited documentation); includes clarithromycin, erythromycin, troleandomycin; monitor.

Primidone, phenobarbital: Valproic acid appears to inhibit the metabolism of phenobarbital; monitor for increased effect.

Salicylates: May displace valproic acid from plasma proteins, leading to acute toxicity.

Topiramate: Hyperammonemia with or without encephalopathy has been reported in patients who tolerated either drug alone. These drugs may modestly decrease the serum concentrations of the other drug.

Tricyclic antidepressants: Valproate may increase serum concentrations and/or toxicity of tricyclic antidepressants.

Zidovudine: Valproic acid may increase the levels/effects of zidovudine; monitor.

Pregnancy Risk Factor D

Pregnancy Implications Crosses the placenta; 1 to 2% incidence of spina bifida

Lactation Enters breast milk/use caution (AAP considers "compatible")

Nursing Implications Do not crush enteric-coated drug product or capsules

Additional Information Tremors may indicate overdosage; monitor serum ammonium; may cause increase in alkaline phosphatase in pediatric patients; long-term or high-dose valproic acid treatment can induce hypocarnitinemia

Sodium content of valproate sodium syrup (5 mL): 23 mg (1 mEq): Divalproex sodium: Depakote®; valproate sodium: Depakene® syrup; valproic acid: Depakene® capsule

Valsartan

CAS Number 137862-53-4

U.S. Brand Names Diovan®

Use Alone or in combination with other antihypertensive agents in treating essential hypertension; treatment of heart failure (NYHA Class II-IV) in patients intolerant to angiotensin converting enzyme (ACE) inhibitors

Mechanism of Action As a prodrug, valsartan produces direct antagonism of the angiotensin II (AT2) receptors, unlike the angiotensin-converting enzyme inhibitors. It displaces angiotensin II from the AT1 receptor and produces its blood pressure lowering effects by antagonizing AT1-induced vasoconstriction, aldosterone release, catecholamine release, arginine vasopressin release, water intake, and hypertrophic responses. This action results in more efficient blockade of the cardiovascular effects of angiotensin II and fewer side effects than the ACE inhibitors.

Adverse Reactions

Hypertension:

Cardiovascular: Edema

Central nervous system: Dizziness, fatigue, headache

Endocrine & metabolic: Serum potassium increased

Gastrointestinal: Abdominal pain, diarrhea, nausea

Hematologic: Neutropenia

Neuromuscular & skeletal: Arthralgia

Respiratory: Cough, pharyngitis, rhinitis, sinusitis, upper respiratory infection

Miscellaneous: Viral infection

Heart failure:

Central nervous system: **Dizziness**

Cardiovascular: Hypotension, postural hypotension

Central nervous system: Fatigue

Endocrine & metabolic: Hyperkalemia

Gastrointestinal: Diarrhea

Neuromuscular & skeletal: Arthralgia, back pain

Renal: Creatinine elevated > 50%

All indications:

Cardiovascular: Chest pain, orthostatic effects, palpitations

Central nervous system: Anxiety, insomnia, somnolence, syncope, vertigo

Dermatologic: Angioedema, alopecia, pruritus, rash

Endocrine & metabolic: Hyperkalemia (hypertensive patients)

Gastrointestinal: Anorexia, constipation, dyspepsia, flatulence, vomiting, xerostomia

Genitourinary: Impotence

Hematologic: Anemia, hematocrit decreased, hemoglobin decreased

Hepatic: Serum transaminases increased, hepatitis

Neuromuscular & skeletal: Asthenia, back pain, muscle cramps, myalgia, paresthesia

Renal: Creatinine increased, impaired renal function; may be associated with worsening of renal function in patients dependent on renin-angiotensin-aldosterone system

Respiratory: Dyspnea

Miscellaneous: Allergic reactions

Pharmacodynamics/Kinetics

Onset of antihypertensive effect: 2 weeks (maximal: 4 weeks)

Distribution: V_d: 17 L (adults)

Protein binding: 95%, primarily albumin

Metabolism: To inactive metabolite

Bioavailability: 25% (range 10% to 35%)

Half-life elimination: 6 hours

Time to peak, serum: 2-4 hours

Excretion: Feces (83%) and urine (13%) as unchanged drug

Dosage

Adults: Oral:

Hypertension: Initial: 80 mg or 160 mg once daily (in patients who are not volume depleted); majority of effect within 2 weeks, maximal effects in 4-6 weeks; dose may be increased to achieve desired effect; maximum recommended dose: 320 mg/day

Heart failure: Initial: 40 mg twice daily; titrate dose to 80-160 mg twice daily, as tolerated; maximum daily dose: 320 mg. **Note:** Do not use with ACE inhibitors and beta blockers.

Dosing adjustment in renal impairment: No dosage adjustment necessary if Cl_{cr} > 10 mL/minute.

Dosing adjustment in hepatic impairment (mild - moderate): ≤ 80 mg/day

Dialysis: Not significantly removed

Monitoring Parameters Baseline and periodic electrolyte panels, renal and liver function tests, urinalysis; symptoms of hypotension or hypersensitivity

Administration Administer with or without food.

Contraindications Hypersensitivity to valsartan or any component of the formulation; hypersensitivity to other A-II receptor antagonists; bilateral renal artery stenosis; pregnancy (2nd and 3rd trimesters)

Warnings

[U.S. Boxed Warning]: Based on human data, drugs that act on the angiotensin system can cause injury and death to the developing fetus when used in the second and third trimesters. Angiotensin receptor blockers should be discontinued as soon as possible once pregnancy is detected. During the initiation of therapy, hypotension may occur, particularly in patients with heart failure or post-MI patients. Avoid use or use a smaller dose in patients who are volume depleted; correct depletion first.

Deterioration in renal function can occur with initiation. Use with caution in unilateral renal artery stenosis and pre-existing renal insufficiency; significant aortic/mitral stenosis. Use caution in patients with severe renal impairment or significant hepatic dysfunction. Monitor renal function closely in patients with severe heart failure; changes in renal function should be anticipated and dosage adjustments of valsartan or concomitant medications may be needed.

Dosage Forms Tablet: 40 mg, 80 mg, 160 mg, 320 mg

Overdosage/Treatment

Decontamination: Ipecac (within 30 minutes)/lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. normal saline or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam or diazepam or to phenytoin or phenobarbital. Inhaled sodium cromoglycate (total dose: 40 mg/day) can decrease ACE-inhibitor cough by 50%.

Enhanced elimination: Multiple dosing of activated charcoal may be effective

Test Interactions Increased serum potassium with potassium-sparing diuretics

Drug Interactions

Inhibits CYP2C9 (weak)

Lithium: Risk of toxicity may be increased by valsartan; monitor lithium levels.

NSAIDs: May decrease angiotensin II antagonist efficacy; effect has been seen with losartan, but may occur with other medications in this class; monitor blood pressure

Potassium-sparing diuretics (amiloride, potassium, spironolactone, triamterene): Increased risk of hyperkalemia.

Potassium supplements may increase the risk of hyperkalemia.

Trimethoprim (high dose) may increase the risk of hyperkalemia.

Pregnancy Risk Factor C/D (2nd and 3rd trimesters)

Pregnancy Implications Medications which act on the renin-angiotensin system are reported to have the following fetal/neonatal effects: Hypotension, neonatal skull hypoplasia, anuria, renal failure, and death; oligohydramnios is also reported. These effects are reported to occur with exposure during the 2nd and 3rd trimesters. Valsartan should be discontinued as soon as possible after pregnancy is detected.

Lactation Excretion in breast milk unknown/contraindicated

Additional Information Valsartan may have an advantage over losartan due to minimal metabolism requirements and consequent use in mild to moderate hepatic impairment.

• Empiric therapy of infections associated with gram-positive organisms; used orally for staphylococcal enterocolitis or for antibiotic-associated pseudomembranous colitis produced by *C. difficile*

The Centers for Disease Control and Prevention (CDC) recently published a document on the spread of vancomycin resistance with a special focus on resistant enterococci.

When vancomycin is appropriate:

- Treatment of serious infections due to β-lactam-resistant gram-positive microorganisms
- Treatment of gram-positive infections in patients with allergies to β-lactam antimicrobials
- When antibiotic-associated colitis (AAC) fails to respond to metronidazole or if it is severe and life threatening
- Prophylaxis, as recommended by the American Heart Association, for endocarditis after certain procedures in patients at high risk for endocarditis
- Prophylaxis for surgical procedures involving implantation of prosthetic materials or devices at institutions with a high rate of infections due to methicillin-resistant *Staphylococcus aureus* (MRSA) or methicillin-resistant *Staphylococcus epidermidis* (MRSE)

When use of vancomycin should be discouraged:

- Routine surgical prophylaxis
- Empiric antimicrobial therapy for a febrile neutropenic patient, unless there is strong evidence that the patient has an infection due to gram-positive microorganisms, and the prevalence of β-lactam-resistant organisms in the hospital is substantial
- Treatment in response to a single blood culture positive for coagulase-negative staphylococci, if other blood cultures drawn in the same time frame are negative
- Continued empiric use for presumed infections in patients whose cultures are negative for β-lactam-resistant gram-positive microorganisms
- Systemic or local prophylaxis for infection or colonization of indwelling central or peripheral intravascular catheters or vascular grafts
- Selective decontamination of the digestive tract
- Eradication of MRSA colonization
- Primary treatment of AAC
- Routine prophylaxis for very low-birth-weight infants
- Routine prophylaxis for patients on continuous ambulatory peritoneal dialysis

Mechanism of Action Inhibits bacterial cell wall synthesis by blocking glycopeptide polymerization through binding tightly to D-alanyl-D-alanine portion of cell wall precursor

Adverse Reactions

Rapid infusion associated with red neck or red man syndrome: Erythema multiforme-like reaction with intense pruritus, tachycardia, hypotension, rash involving face, neck, upper trunk, back and upper arms

Cardiovascular: Cardiac arrest, **hypotension, flushing**, sinus tachycardia, vasculitis, leukocytoclastic vasculitis

Central nervous system: Fever, chills, hyperthermia

Dermatologic: **Redneck or redman syndrome, rash**, macular skin rash, linear IgA bullous dermatosis, Stevens-Johnson syndrome, acute generalized exanthematous pustulosis, angioedema, bullous skin disease, toxic epidermal necrolysis, urticaria, exanthem, Henoch-Schönlein purpura, cutaneous vasculitis

Gastrointestinal: **Nausea, bitter taste, vomiting**

Genitourinary: Priapism

Hematologic: Neutropenia, eosinophilia, thrombocytopenia

Local: Phlebitis

Neuromuscular & skeletal: Lower back pain, paresthesia

Otic: Ototoxicity, tinnitus associated with prolonged serum concentration > 40 mcg/mL - may be permanent

Renal: Nephrotoxicity (higher incidence with trough concentrations > 10 mcg/mL), renal vasculitis

Miscellaneous: Hypersensitivity reactions, systemic lupus erythematosus,

Signs and Symptoms of Overdose Colitis, deafness, dermatitis, exfoliative dermatitis, lacrimation, leukopenia or neutropenia (agranulocytosis, granulocytopenia), thrombocytopenia, tubular necrosis

Pharmacodynamics/Kinetics

Absorption: Oral: Poor; I.M.: Erratic; Intraperitoneal: ~38%

Distribution: Widely in body tissues and fluids, except for CSF

Relative diffusion from blood into CSF: Good only with inflammation (exceeds usual MICs)

CSF:blood level ratio: Normal meninges: Nil; Inflamed meninges: 20% to 30%

Protein binding: 10% to 50%

Half-life elimination: Biphasic: Terminal:

Newborns: 6-10 hours

Infants and Children 3 months to 4 years: 4 hours

Children > 3 years: 2.2-3 hours

Adults: 5-11 hours; significantly prolonged with renal impairment

End-stage renal disease: 200-250 hours

Time to peak, serum: I.V.: 45-65 minutes

Vancomycin

CAS Number 1404-93-9

U.S. Brand Names Vancocin®

Synonyms Vancomycin Hydrochloride

Use

Treatment of patients with the following infections or conditions:

- Infections due to documented or suspected methicillin-resistant *S. aureus* or beta-lactam resistant coagulase-negative *Staphylococcus*
- Serious or life-threatening infections (ie, endocarditis, meningitis) due to documented or suspected staphylococcal or streptococcal infections in patients who are allergic to penicillins and/or cephalosporins

Excretion: I.V.: Urine (80% to 90% as unchanged drug); Oral: Primarily feces

Dosage Initial dosage recommendation: I.V.:

Neonates:

Postnatal age <7 days:

- <1200 g: 7.5 mg/kg/dose given every 24 hours
- 1200-2000 g: 10 mg/kg/dose given every 12 hours
- >2000 g: 15 mg/kg/dose given every 12 hours

Postnatal age >7 days:

- <1200 g: 7.5 mg/kg/dose given every 24 hours
- ≥1200 g: 10 mg/kg/dose given every 8 hours

Infants >1 month and Children: 40 mg/kg/day in divided doses every 6 hours

Infants >1 month and Children with staphylococcal central nervous system infection: 60 mg/kg/day in divided doses every 6 hours

Note: Some patients may require larger or more frequent doses if serum levels document the need (ie, febrile granulocytopenic patients)

Adults:

- <60 kg: 750 mg every 12 hours
- 60-100 kg: 1 g every 12 hours
- 100-120 kg: 1.25 g every 12 hours
- >120 kg: 1.5 g every 12 hours

Intrathecal:

- Neonates: 5-10 mg/day
- Children: 5-20 mg/day
- Adults: 20 mg/day

Oral: Pseudomembranous colitis produced by *C. difficile*:

- Neonates: 10 mg/kg/day in divided doses
- Children: 40 mg/kg/day in divided doses, added to fluids
- Adults: 250-500 mg 3 times/day in divided doses

Dosing interval in renal impairment: Following a usual loading dose, dosages and frequency of administration are best determined by measurement of serum levels and assessment of renal insufficiency

Dosing adjustments/comments in hepatic impairment: Reduce dose by 60%

Monitoring Parameters Periodic renal function tests, urinalysis, serum vancomycin concentrations, WBC, audiogram

Administration Administer vancomycin by I.V. intermittent infusion over at least 60 minutes at a final concentration not to exceed 5 mg/mL. If a maculopapular rash appears on the face, neck, trunk, and/or upper extremities (Red man syndrome), slow the infusion rate to over 1/2 to 2 hours and increase the dilution volume. Hypotension, shock, and cardiac arrest (rare) have also been reported with too rapid of infusion. Reactions are often treated with antihistamines and steroids.

Extravasation treatment: Monitor I.V. site closely; extravasation will cause serious injury with possible necrosis and tissue sloughing. Rotate infusion site frequently.

Contraindications Hypersensitivity to vancomycin or any component of the formulation; avoid in patients with previous severe hearing loss

Warnings Use with caution in patients with renal impairment or those receiving other nephrotoxic or ototoxic drugs; dosage modification required in patients with impaired renal function (especially elderly)

Dosage Forms Capsule (Vancocin®): 125 mg, 250 mg
Infusion [premixed in iso-osmotic dextrose] (Vancocin®): 500 mg (100 mL); 1 g (200 mL)

Injection, powder for reconstitution: 500 mg, 1 g, 5 g, 10 g

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension can respond to fluids; has responded to diphenhydramine (12.5 mg I.V.) in one case

Enhancement of elimination: Peritoneal dialysis can remove 40% of drug in 15 hours; continuous arteriovenous or intermittent hemofiltration may also be useful; multiple dosing of activated charcoal may be useful; hemodialysis (using polysulfone dialyzers) may increase elimination of vancomycin (mean clearance: 85 mL/minute with 49.5% extent of vancomycin removal); multiple dosing of activated charcoal may reduce vancomycin half-life by 2/3 (under 10 hours); charcoal hemoperfusion is **not** useful. Plasma exchange transfusions may result in clinically significant removal of vancomycin from the plasma.

Diagnostic Procedures

- Vancomycin Level

Test Interactions Fluorescence polarization immunoassay (FPIA) may result in overestimation of vancomycin in patients with renal failure. This overestimation is caused by interference of the degradation product, CDP-1, in this assay.

Drug Interactions Increased toxicity: Anesthetic agents; other ototoxic or nephrotoxic agents

Pregnancy Risk Factor C

Pregnancy Implications Can cause fetal bradycardia

Lactation Enters breast milk/use caution

Additional Information Symptoms of red man syndrome include facial flushing, urticaria (usually of upper body), chest pain, and dyspnea. It is usually related to rate of vancomycin infusion (14% incidence if one gram

is given over ten minutes) and is treated by slowing the rate of infusion, vancomycin dilution and antihistamines.

Vasopressin

CAS Number 11000-17-2; 113-79-1; 50-57-7

U.S. Brand Names Pitressin®

Synonyms 8-Arginine Vasopressin; ADH; Antidiuretic Hormone

Use

Treatment of diabetes insipidus; prevention and treatment of postoperative abdominal distention; differential diagnosis of diabetes insipidus

Useful to increase blood pressure in calcium channel blocker and caffeine overdose

Unlabeled/Investigational Use Adjunct in the treatment of GI hemorrhage and esophageal varices; pulseless arrest (ventricular tachycardia [VT]/ventricular fibrillation [VF], asystole/pulseless electrical activity [PEA]); vasodilatory shock (septic shock)

Mechanism of Action Increases cyclic adenosine monophosphate (cAMP) which increases water permeability at the renal tubule resulting in decreased urine volume and increased osmolality; causes peristalsis by directly stimulating the smooth muscle in the GI tract

Adverse Reactions

Cardiovascular: Elevated blood pressure, bradycardia, arrhythmias, venous thrombosis, vasoconstriction with higher doses, angina, myocardial infarction, tachycardia (ventricular), torsade de pointes, chest pain, peripheral gangrene, superior mesenteric artery thrombosis, arrhythmias (ventricular), sinus bradycardia

Central nervous system: Pounding in the head, fever, headache, vertigo
Dermatologic: Urticaria, cutaneous gangrene, circumoral pallor, bullous lesions, skin necrosis

Endocrine & metabolic: Hyponatremia, water intoxication, hyperprolactinemia

Gastrointestinal: Flatulence, abdominal cramps, nausea, vomiting, mesenteric occlusion, ischemic colitis, diarrhea, colonic ischemia

Hepatic: Hepatic steatosis

Neuromuscular & skeletal: Tremor, rhabdomyolysis

Miscellaneous: Diaphoresis, anaphylaxis, allergic reaction, anaphylactic shock

Pharmacodynamics/Kinetics

Onset of action: Nasal: 1 hour

Duration: Nasal: 3-8 hours; I.M., SubQ: 2-8 hours

Metabolism: Nasal/Parenteral: Hepatic, renal

Half-life elimination: Nasal: 15 minutes; Parenteral: 10-20 minutes

Excretion: Nasal: Urine; SubQ: Urine (5% as unchanged drug) after 4 hours

Dosage

Diabetes insipidus (highly variable dosage; titrated based on serum and urine sodium and osmolality in addition to fluid balance and urine output):

I.M., SubQ:

Children: 2.5-10 units 2-4 times/day as needed

Adults: 5-10 units 2-4 times/day as needed (dosage range 5-60 units/day)

Continuous I.V. infusion: Children and Adults: 0.5 milliunit/kg/hour (0.0005 unit/kg/hour); double dosage as needed every 30 minutes to a maximum of 0.01 unit/kg/hour

Intranasal: Administer on cotton pledget, as nasal spray, or by dropper

Abdominal distention: Adults: I.M.: 5 units stat, 10 units every 3-4 hours

GI hemorrhage (unlabeled use): I.V. infusion: Dilute in NS or D₅W to 0.1-1 unit/mL

Children: Initial: 0.002-0.005 units/kg/minute; titrate dose as needed; maximum: 0.01 unit/kg/minute; continue at same dosage (if bleeding stops) for 12 hours, then taper off over 24-48 hours

Adults: Initial: 0.2-0.4 unit/minute, then titrate dose as needed, if bleeding stops; continue at same dose for 12 hours, taper off over 24-48 hours

Pulseless arrest (unlabeled use) [ACLS protocol]: Adults: I.V.; I.O.: 40 units; may give one dose to replace first or second dose of epinephrine. I.V./I.O. drug administration is preferred, but if no access, may give endotracheally at 2 to 2 1/2 times the I.V. dose. Mix with 5-10 mL of water or normal saline, and administer down the endotracheal tube.

Vasodilatory shock/septic shock (unlabeled use): Adults: I.V.: 0.01-0.04 units/minute for the treatment of septic shock. Doses >0.04 units/minute may have more cardiovascular side effects. Most case reports have used 0.04 units/minute continuous infusion as a fixed dose.

Dosing adjustment in hepatic impairment: Some patients respond to much lower doses with cirrhosis for calcium channel blocker

Stability Store injection at room temperature; protect from heat and from freezing; use only clear solutions

Monitoring Parameters Serum and urine sodium, urine specific gravity, urine and serum osmolality; urine output, fluid input and output, blood pressure, heart rate

Administration I.V.: Use extreme caution to avoid extravasation because of risk of necrosis and gangrene. In treatment of varices, infusions are often supplemented with nitroglycerin infusions to minimize cardiac effects.

GI hemorrhage: Administration requires the use of an infusion pump and should be administered in a peripheral line.

Vasodilatory shock: Administration through a central catheter is recommended.

Infusion rates: 100 units in 500 mL D₅W rate

0.1 unit/minute: 30 mL/hour

0.2 unit/minute: 60 mL/hour

0.3 unit/minute: 90 mL/hour

0.4 unit/minute: 120 mL/hour

0.5 unit/minute: 150 mL/hour

0.6 unit/minute: 180 mL/hour

Intranasal (topical administration on nasal mucosa): Administer injectable vasopressin on cotton plugs, as nasal spray, or by dropper. Should not be inhaled.

Contraindications Hypersensitivity to vasopressin or any component of the formulation

Warnings Use with caution in patients with seizure disorders, migraine, asthma, vascular disease, renal disease, cardiac disease; chronic nephritis with nitrogen retention. Goiter with cardiac complications, arteriosclerosis; I.V. infiltration may lead to severe vasoconstriction and localized tissue necrosis; also, gangrene of extremities, tongue, and ischemic colitis. Elderly patients should be cautioned not to increase their fluid intake beyond that sufficient to satisfy their thirst in order to avoid water intoxication and hyponatremia; under experimental conditions, the elderly have shown to have a decreased responsiveness to vasopressin with respect to its effects on water homeostasis

Dosage Forms Injection, solution: 20 units/mL (0.5 mL, 1 mL, 10 mL) Pitressin®: 20 units/mL (1 mL)

Reference Range Plasma: 0-2 pg/mL (SI: 0-2 ng/L) if osmolality <285 mOsm/L; 2-12 pg/mL (SI: 2-12 ng/L) if osmolality >290 mOsm/L

Overdosage/Treatment 20 IU bolus IV and titrate to blood pressure (about 4 to 5 IU per hour IV)

Drug Interactions Decreased effect: Lithium, epinephrine, demeclocycline, heparin, and ethanol block antidiuretic activity to varying degrees. Increased effect: Chlorpropamide, phenformin, urea and fludrocortisone potentiate antidiuretic response

Pregnancy Risk Factor B

Pregnancy Implications Animal reproduction studies have not been conducted. Vasopressin and desmopressin have been used safely during pregnancy and nursing based on case reports.

Lactation Enters breast milk/use caution

Nursing Implications Watch for signs of I.V. infiltration and gangrene; elderly patients should be cautioned not to increase their fluid intake beyond that sufficient to satisfy their thirst in order to avoid water intoxication and hyponatremia; under experimental conditions, the elderly have shown to have a decreased responsiveness to vasopressin with respect to its effects on water homeostasis

Additional Information Due to prolongation of QT_c interval on ECG, avoid vasopressin in arsenic poisoning; not useful in treating lithium-induced diabetes insipidus

Venlafaxine

CAS Number 99300-78-4

U.S. Brand Names Effexor® XR; Effexor®

Impairment Potential Yes

Use Treatment of major depressive disorder; generalized anxiety disorder (GAD), social anxiety disorder (social phobia), panic disorder

Unlabeled/Investigational Use Obsessive-compulsive disorder (OCD); hot flashes; neuropathic pain; attention-deficit/hyperactivity disorder (ADHD)

Mechanism of Action Venlafaxine and its active metabolite o-desmethylvenlafaxine (ODV) are potent inhibitors of neuronal serotonin and norepinephrine reuptake and weak inhibitors of dopamine reuptake. Venlafaxine and ODV have no significant activity for muscarinic cholinergic, H₁-histaminergic, or alpha₂-adrenergic receptors. Venlafaxine and ODV do not possess MAO-inhibitory activity.

Adverse Reactions

Cardiovascular: Vasodilation, hypertension (dose-related; 3% in patients receiving <100 mg/day, up to 13% in patients receiving >300 mg/day), tachycardia, chest pain, postural hypotension, ventricular tachycardia

Central nervous system: **Headache (25%), somnolence (23%), dizziness, insomnia, nervousness**, anxiety, abnormal dreams, yawning, agitation, confusion, abnormal thinking, depersonalization, depression, akathisia, catatonia, delirium, emotional lability, extrapyramidal symptoms, hallucinations, manic reaction, psychosis, seizure, tardive dyskinesia, vertigo, hostility (up to 1% in children/adolescents), suicidal ideation (reported at a frequency of 2% in children/adolescents with major depressive disorder)

Dermatologic: Rash, pruritus, epidermal necrolysis, erythema multiforme, erythema nodosum, exfoliative dermatitis, hirsutism, rash (maculopapular, pustular, or vesiculobullous), Stevens-Johnson syndrome, ecchymosis

Endocrine & metabolic: Decreased libido, increased transaminases/GGT, metrorrhagia, serotonin syndrome, SIADH, hyponatremia

Gastrointestinal: **Nausea (37%), xerostomia (22%), constipation, anorexia**, diarrhea, vomiting, dyspepsia, flatulence, taste perversion, weight loss, hemorrhage, pancreatitis

Genitourinary: **Abnormal ejaculation/orgasm**, impotence, urinary frequency, impaired urination, orgasm disturbance, urinary retention, prostatitis, vaginitis

Hematologic: Agranulocytosis, aplastic anemia, abnormal bleeding

Hepatic: Hepatic failure, hepatic necrosis

Neuromuscular & skeletal: **Weakness**, tremor, hypertonia, paresthesia, twitching, torticollis, dyskinesias, rhabdomyolysis

Ocular: Blurred vision, mydriasis, abnormal vision, ophthalmic hemorrhage

Otic: Tinnitus

Respiratory: Asthma, bronchitis, dyspnea

Miscellaneous: **Diaphoresis**, infection, chills, trauma, anaphylaxis

Signs and Symptoms of Overdose Profound CNS depression can occur with concomitant ingestions of other CNS depressants. Sedation, seizures (7%), tachycardia (sinus)

Admission Criteria/Prognosis Monitor asymptomatic immediate release and sustained release overdoses for 6 and 18 hours, respectively, before discharge.

Pharmacodynamics/Kinetics

Absorption: Oral: 92% to 100%; food has no significant effect on the absorption of venlafaxine or formation of the active metabolite O-desmethylvenlafaxine (ODV)

Distribution: At steady state: Venlafaxine 7.5 ± 3.7 L/kg, ODV 5.7 ± 1.8 L/kg

Protein binding: Bound to human plasma protein: Venlafaxine 27%, ODV 30%

Metabolism: Hepatic via CYP2D6 to active metabolite, O-desmethylvenlafaxine (ODV); other metabolites include N-desmethylvenlafaxine and N,O-didesmethylvenlafaxine

Bioavailability: Absolute: ~45%

Half-life elimination: Venlafaxine: 3-7 hours; ODV: 9-13 hours; Steady-state, plasma: Venlafaxine/ODV: Within 3 days of multiple-dose therapy; prolonged with cirrhosis (Adults: Venlafaxine: ~30%, ODV: ~60%) and with dialysis (Adults: Venlafaxine: ~180%, ODV: ~142%)

Time to peak:

Immediate release: Venlafaxine: 2 hours, ODV: 3 hours

Extended release: Venlafaxine: 5.5 hours, ODV: 9 hours

Excretion: Urine (~87%, 5% as unchanged drug, 29% as unconjugated ODV, 26% as conjugated ODV, 27% as minor inactive metabolites) within 48 hours

VENLAFAXINE

Clearance at steady state: Venlafaxine: 1.3 ± 0.6 L/hour/kg, ODV: 0.4 ± 0.2 L/hour/kg

Clearance decreased with:

Cirrhosis: Adults: Venlafaxine: ~50%, ODV: ~30%

Severe cirrhosis: Adults: Venlafaxine: ~90%

Renal impairment (Cl_{cr} 10-70 mL/minute): Adults: Venlafaxine: ~24%

Dialysis: Adults: Venlafaxine: ~57%, ODV: ~56%; due to large volume of distribution, a significant amount of drug is not likely to be removed.

Dosage Oral:

Children and Adolescents:

ADHD (unlabeled use): Initial: 12.5 mg/day

Children <40 kg: Increase by 12.5 mg/week to maximum of 50 mg/day in 2 divided doses

Children \geq 40 kg: Increase by 25 mg/week to maximum of 75 mg/day in 3 divided doses.

Mean dose: 60 mg or 1.4 mg/kg administered in 2-3 divided doses

Adults:

Depression:

Immediate-release tablets: 75 mg/day, administered in 2 or 3 divided doses, taken with food; dose may be increased in 75 mg/day increments at intervals of at least 4 days, up to 225-375 mg/day

Extended-release capsules: 75 mg once daily taken with food; for some new patients, it may be desirable to start at 37.5 mg/day for 4-7 days before increasing to 75 mg once daily; dose may be increased by up to 75 mg/day increments every 4 days as tolerated, up to a maximum of 225 mg/day

GAD, social anxiety disorder: Extended-release capsules: 75 mg once daily taken with food; for some new patients, it may be desirable to start at 37.5 mg/day for 4-7 days before increasing to 75 mg once daily; dose may be increased by up to 75 mg/day increments every 4 days as tolerated, up to a maximum of 225 mg/day

Panic disorder: Extended-release capsules: 37.5 mg once daily for 1 week; may increase to 75 mg daily, with subsequent weekly increases of 75 mg/day up to a maximum of 225 mg/day

Obsessive-compulsive disorder (unlabeled use): Titrate to usual dosage range of 150-300 mg/day; however, doses up to 375 mg daily have been used; response may be seen in 4 weeks

Neuropathic pain (unlabeled use): Dosages evaluated varied considerably based on etiology of chronic pain, but efficacy has been shown for many conditions in the range of 75-225 mg/day; onset of relief may occur in 1-2 weeks, or take up to 6 weeks for full benefit.

Hot flashes (unlabeled use): Doses of 37.5-75 mg/day have demonstrated significant improvement of vasomotor symptoms after 4-8 weeks of treatment; in one study, doses >75 mg/day offered no additional benefit; however, higher doses (225 mg/day) may be beneficial in patients with perimenopausal depression.

Attention-deficit disorder (unlabeled use): Initial: Doses vary between 18.75 to 75 mg/day; may increase after 4 weeks to 150 mg/day; if tolerated, doses up to 225 mg/day have been used

Note: When discontinuing this medication after more than 1 week of treatment, it is generally recommended that the dose be tapered. If venlafaxine is used for 6 weeks or longer, the dose should be tapered over 2 weeks when discontinuing its use.

Dosing adjustment in renal impairment: Cl_{cr} 10-70 mL/minute: Decrease dose by 25%; decrease total daily dose by 50% if dialysis patients; dialysis patients should receive dosing after completion of dialysis

Dosing adjustment in moderate hepatic impairment: Reduce total daily dosage by 50%

Monitoring Parameters Blood pressure should be regularly monitored, especially in patients with a high baseline blood pressure; may cause mean increase in heart rate of 4-9 beats/minute; cholesterol; mental status for depression, suicidal ideation (especially at the beginning of therapy or when doses are increased or decreased), anxiety, social functioning, mania, panic attacks; height and weight should be monitored in children

Administration Administer with food.

Extended release capsule: Swallow capsule whole; do not crush or chew. Alternatively, contents may be sprinkled on a spoonful of applesauce and swallowed immediately without chewing; followed with a glass of water to ensure complete swallowing of the pellets.

Contraindications Hypersensitivity to venlafaxine or any component of the formulation; use of MAO inhibitors within 14 days; should not initiate MAO inhibitor within 7 days of discontinuing venlafaxine

Warnings Major psychiatric warnings:

* [U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and

communicate condition with healthcare provider. A medication guide concerning the use of antidepressants in children and teenagers should be dispensed with each prescription. **Venlafaxine is not FDA approved for use in children.**

• The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Patients treated with antidepressants should be observed for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy.

• Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression or psychosis occur.

• May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Venlafaxine is not FDA approved for the treatment of bipolar depression.**

Key adverse effects:

• CNS depression: Has a low potential to impair cognitive or motor performance; caution operating hazardous machinery or driving.

• SIADH and hyponatremia: Has been associated with the development of SIADH; hyponatremia has been reported rarely, predominantly in the elderly

• Weight loss and anorectic effects: Have been observed in both pediatric and adult patients; weight loss was not limited to those experiencing reduced appetite

• Reduced growth rate (pediatric): Small differences in height have been observed in pediatric patients receiving venlafaxine, particularly those <12 years of age, compared to placebo

Concurrent disease:

• Anxiety/Insomnia: May cause increase in anxiety, nervousness, and insomnia.

• Hepatic impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.

• Hypercholesterolemia: May cause increases to serum cholesterol.

• Hypertension/Tachycardia: May cause sustained increase in blood pressure or tachycardia. Control pre-existing hypertension prior to initiation of venlafaxine. Use caution in patients with recent history of MI, unstable heart disease, or hyperthyroidism. Effect is dose related and increases are generally modest (12-15 mm Hg diastolic).

• Narrow-angle glaucoma: May cause mydriasis; use caution in patients with increased intraocular pressure or at risk of acute narrow-angle glaucoma.

• Platelet aggregation: May impair platelet aggregation, resulting in bleeding.

• Renal impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.

• Seizure disorders: Use caution with a previous seizure disorder or condition predisposing to seizures such as brain damage or alcoholism.

• Sexual dysfunction: May cause or exacerbate sexual dysfunction.

• Weight loss: May cause weight loss; use caution in patients where weight loss is undesirable.

Concurrent drug therapy:

• Agents which lower seizure threshold: Concurrent therapy with other drugs which lower the seizure threshold.

• Anticoagulants/Antiplatelets: Use caution with concomitant use of NSAIDs, ASA, or other drugs that affect coagulation; the risk of bleeding is potentiated.

• CNS depressants: Use caution with concomitant therapy.

• MAO inhibitors: Potential for severe reaction when used with MAO inhibitors; autonomic instability, coma, death, delirium, diaphoresis, hyperthermia, mental status changes/agitation, muscular rigidity, myoclonus, neuroleptic malignant syndrome features, and seizures may occur.

• Agents causing weight loss or anorectic effects should be avoided.

Special notes:

• Electroconvulsive therapy: May increase the risks associated with electroconvulsive therapy; consider discontinuing, when possible, prior to ECT treatment.

• Withdrawal syndrome: May cause dysphoric mood, irritability, agitation, dizziness, sensory disturbances, anxiety, confusion, headache, lethargy, emotional lability, insomnia, hypomania, tinni-

tus, and seizures. Upon discontinuation of venlafaxine therapy, gradually taper dose. If intolerable symptoms occur following a decrease in dosage or upon discontinuation of therapy, then resuming the previous dose with a more gradual taper should be considered.

Dosage Forms Capsule, extended release:

Effexor[®] XR: 37.5 mg, 75 mg, 150 mg

Tablet: 25 mg, 37.5 mg, 50 mg, 75 mg, 100 mg

Effexor[®]: 25 mg, 37.5 mg, 50 mg, 75 mg, 100 mg

Reference Range Peak serum level of 163 ng/mL (325 ng/mL of ODV metabolite) obtained after a 150 mg oral dose; 4-hour postingestion serum level of 6100 ng/mL (1800 ng/mL of ODV metabolite) associated with coma; a venlafaxine plasma level of 7040 ng/mL (ODV of 1000 ng/mL) was associated with seizures

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Sodium bicarbonate (1-2 mEq/kg) can be given for cardiac conduction disturbances; lidocaine can be used for ventricular arrhythmias; lorazepam can be helpful for seizure control while benzotropine (0.5 mg twice daily) can be useful to treat hot flashes and excessive sweating caused by venlafaxine; night sweats can be treated with 0.5 mg benztropine at bedtime

Enhancement of elimination: Multiple dosing of activated charcoal may be of some benefit; forced diuresis/extracorporeal removal is not expected to be of any benefit

Test Interactions ↑ serum cholesterol

Drug Interactions

Substrate of CYP2C9 (minor), 2C19 (minor), 2D6 (major), 3A4 (major); **Inhibits** CYP2B6 (weak), 2D6 (weak), 3A4 (weak)

Bupirone: Concurrent use may result in serotonin syndrome; these combinations are best avoided

Clozapine: Addition of venlafaxine has been associated with case reports of increased clozapine serum concentrations and seizures.

CYP2D6 inhibitors: May increase the levels/effects of venlafaxine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of venlafaxine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of venlafaxine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nocardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Haloperidol: Serum levels may be increased during concurrent administration; AUC may be increased by as much as 70%

Indinavir: Serum levels may be reduced by venlafaxine (AUC reduced by 28%); clinical significance unknown

Lithium: Concurrent use may increase risk of serotonin syndrome.

MAO inhibitors: Serotonin syndrome may result when venlafaxine is used in combination or within 2 weeks of an MAO inhibitor; these combinations should be avoided

Meperidine: Concurrent use may increase risk of serotonin syndrome

Mirtazapine: Concurrent use may increase risk of serotonin syndrome

Nefazodone: Concurrent use may increase risk of serotonin syndrome; in addition, nefazodone may inhibit the metabolism of venlafaxine

Selegiline: Concurrent use may predispose to serotonin syndrome; avoid concurrent use.

Serotonin agonists: Theoretically, may increase the risk of serotonin syndrome; includes sumatriptan, naratriptan, rizatriptan, and zolmitriptan

Sibutramine: Concurrent use may increase risk of serotonin syndrome; avoid concomitant use.

SSRIs: Concurrent use may increase risk of serotonin syndrome.

Tramadol: Concurrent use may increase risk of serotonin syndrome.

Trazodone: Concurrent use may increase risk of serotonin syndrome.

Tricyclic antidepressants: Concurrent use may increase risk of serotonin syndrome

Warfarin: Case reports of increased INR when venlafaxine was added to therapy.

Pregnancy Risk Factor C

Pregnancy Implications There are no adequate or well-controlled studies in pregnant women. Use only in pregnancy if clearly needed. If used during pregnancy (until or shortly before birth), monitor newborn for discontinuation effects.

Lactation Enters breast milk/not recommended

Additional Information Avoid ethanol (may increase CNS effects). Avoid valerian, St John's wort, SAMe, kava kava, tryptophan (may increase risk of serotonin syndrome and/or excessive sedation).

Verapamil

Related Information

● Calcium Channel Blockers

CAS Number 152-11-4; 52-53-9

U.S. Brand Names Calan[®] SR; Calan[®]; Covera-HS[®]; Isoptin[®] SR; Verelan[®] PM; Verelan[®]

Synonyms Iproveratril Hydrochloride; Verapamil Hydrochloride

Use Orally for treatment of angina pectoris (vasospastic, chronic stable, unstable) and hypertension; I.V. for supraventricular tachyarrhythmias (PSVT, atrial fibrillation, atrial flutter)

Unlabeled/Investigational Use Migraine; hypertrophic cardiomyopathy; bipolar disorder (manic manifestations)

Mechanism of Action Inhibits calcium ion from entering the "slow channels" or select voltage-sensitive areas of vascular smooth muscle and myocardium during depolarization; produces a relaxation of coronary vascular smooth muscle and coronary vasodilation; increases myocardial oxygen delivery in patients with vasospastic angina

Adverse Reactions

Cardiovascular: Hypotension, bradycardia; first, second, or third degree AV block; worsening heart failure, fibrillation (atrial), flutter (atrial), myocardial depression, tachycardia (supraventricular), sinus bradycardia, vasculitis

Central nervous system: Dizziness, psychosis, fatigue, seizures, (occasionally with I.V. use), headache, parkinsonism

Dermatologic: Hypertrichosis, exfoliative dermatitis, erythema multiforme, alopecia, angioedema, urticaria, purpura, Stevens-Johnson syndrome, photosensitivity, pruritus, licheniform eruptions, exanthem

Endocrine & metabolic: Polydipsia, hyperkalemia, hyperprolactinemia, hypokalemia, nephrogenic diabetes insipidus

Gastrointestinal: Constipation, nausea, abdominal pain, abdominal discomfort, vomiting, GI bleeding (relative risk: 2.39), decreased esophageal sphincter tone, xerostomia

Hepatic: Elevated hepatic enzymes, cholestasis

Neuromuscular & skeletal: Erythromelalgia, paresthesia

Respiratory: May precipitate insufficiency of respiratory muscle function in Duchenne muscular dystrophy

Signs and Symptoms of Overdose Acidosis, asthenia, asystole, AV block, bundle-branch block, cardiac arrhythmias, cholestatic jaundice, coagulopathy, colonic ischemia, colon perforation, coma, confusion, constipation, drowsiness, dyspnea, eosinophilia, esophageal ulceration, extrapyramidal reaction, flatulence, gingival hyperplasia, gynecomastia, hyperkalemia, hypoglycemia, heart block, hyperglycemia, hypotension, impotence, junctional bradycardia, myoglobinuria, nausea, possible bezoars with resultant bowel infarction, rhabdomyolysis, seizures, skin flushing, syncope

Pharmacodynamics/Kinetics

Onset of action: Peak effect: Oral: Immediate release: 1-2 hours; I.V.: 1-5 minutes

Duration: Oral: Immediate release tablets: 6-8 hours; I.V.: 10-20 minutes

Protein binding: 90%

Metabolism: Hepatic via multiple CYP isoenzymes; extensive first-pass effect

VERAPAMIL

Bioavailability: Oral: 20% to 35%
Half-life elimination: Infants: 4.4-6.9 hours; Adults: Single dose: 2-8 hours, Multiple doses: 4.5-12 hours; prolonged with hepatic cirrhosis
Excretion: Urine (70%, 3% to 4% as unchanged drug); feces (16%)

Dosage

Children: SVT:
I.V.:
< 1 year: 0.1-0.2 mg/kg over 2 minutes; repeat every 30 minutes as needed
1-15 years: 0.1-0.3 mg/kg over 2 minutes; maximum: 5 mg/dose, may repeat dose in 15 minutes if adequate response not achieved; maximum for second dose: 10 mg/dose
Oral (dose not well established):
1-5 years: 4-8 mg/kg/day in 3 divided doses or 40-80 mg every 8 hours
> 5 years: 80 mg every 6-8 hours

Adults:

SVT: I.V.: 2.5-5 mg (over 2 minutes); second dose of 5-10 mg (~0.15 mg/kg) may be given 15-30 minutes after the initial dose if patient tolerates, but does not respond to initial dose; maximum total dose: 20 mg
Angina: Oral: Initial dose: 80-120 mg 3 times/day (elderly or small stature: 40 mg 3 times/day); range: 240-480 mg/day in 3-4 divided doses
Hypertension: Oral:
Immediate release: 80 mg 3 times/day; usual dose range (JNC 7): 80-320 mg/day in 2 divided doses
Sustained release: 240 mg/day; usual dose range (JNC 7): 120-360 mg/day in 1-2 divided doses; 120 mg/day in the elderly or small patients (no evidence of additional benefit in doses > 360 mg/day).
Extended release:
Covera-HS®: Usual dose range (JNC 7): 120-360 mg once daily (once-daily dosing is recommended at bedtime)
Verelan® PM: Usual dose range: 200-400 mg once daily at bedtime

Dosing adjustment in renal impairment: $Cl_{cr} < 10$ mL/minute: Administer at 50% to 75% of normal dose.

Dialysis: Not dialyzable (0% to 5%) via hemo- or peritoneal dialysis; supplemental dose is not necessary.

Dosing adjustment/comments in hepatic disease: Reduce dose in cirrhosis, reduce dose to 20% to 50% of normal and monitor ECG.

Stability Store injection at room temperature; protect from heat and from freezing; use only clear solutions; **compatible** in solutions of pH of 3-6, but may precipitate in solutions having a pH of ≥ 6

Monitoring Parameters Monitor blood pressure closely

Administration Oral: Do not crush or chew sustained or extended release products.

Calan® SR, Isoptin® SR: Administer with food.
Verelan®, Verelan® PM: Capsules may be opened and the contents sprinkled on 1 tablespoonful of applesauce, then swallowed without chewing.

I.V.: Rate of infusion: Over 2 minutes.

Contraindications Hypersensitivity to verapamil or any component of the formulation; severe left ventricular dysfunction; hypotension (systolic pressure < 90 mm Hg) or cardiogenic shock; sick sinus syndrome (except in patients with a functioning artificial pacemaker); second- or third-degree AV block (except in patients with a functioning artificial pacemaker); atrial flutter or fibrillation and an accessory bypass tract (WPW, Lown-Ganong-Levine syndrome)

Warnings Avoid use in heart failure; can exacerbate condition. Can cause hypotension. Rare increases in liver function tests can be observed. Can cause first-degree AV block or sinus bradycardia. Other conduction abnormalities are rare. Use caution when using verapamil together with a beta-blocker. Avoid use of I.V. verapamil with an I.V. beta-blocker; can result in asystole. Use caution in patients with hypertrophic cardiomyopathy (IHSS). Use with caution in patients with attenuated neuromuscular transmission (Duchenne's muscular dystrophy, myasthenia gravis). Adjust the dose in severe renal dysfunction and hepatic dysfunction. Verapamil significantly increases digoxin serum concentrations (adjust digoxin's dose). May prolong recovery from nondepolarizing neuromuscular-blocking agents.

Dosage Forms Caplet, sustained release: 120 mg, 180 mg, 240 mg
Calan® SR: 120 mg, 180 mg, 240 mg
Capsule, extended release, controlled onset, as hydrochloride:
Verelan® PM: 100 mg, 200 mg, 300 mg
Capsule, sustained release, as hydrochloride: 120 mg, 180 mg, 240 mg, 360 mg
Verelan®: 120 mg, 180 mg, 240 mg, 360 mg
Injection, solution, as hydrochloride: 2.5 mg/mL (2 mL, 4 mL)
Tablet, as hydrochloride: 80 mg, 120 mg
Calan®: 40 mg, 80 mg, 120 mg
Tablet, extended release: 120 mg, 180 mg, 240 mg
Tablet, extended release, controlled onset, as hydrochloride:
Covera-HS®: 180 mg, 240 mg

Tablet, sustained release, as hydrochloride: 120 mg, 180 mg, 240 mg
Isoptin® SR: 120 mg, 180 mg, 240 mg

Reference Range

A ratio of verapamil/norverapamil > 2.3 may be a predictor for fatal outcome

Therapeutic: 50-200 ng/mL (SI: 100-410 nmol/L) for parent; under normal conditions norverapamil concentration is the same as parent drug

Toxic: > 845 ng/mL

Fatal: > 2000 ng/mL

Levels of 2200 ng/mL and 2700 ng/mL associated with ingestions of 3.2 and 4 g, respectively

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: Ipecac-induced emesis can hypothetically worsen calcium antagonist toxicity, since it can produce vagal stimulation. The potential for seizures precipitously following acute ingestion of large doses of a calcium antagonist may also contraindicate the use of ipecac. Lavage (within 1 hour)/activated charcoal; whole bowel irrigation may be effective for sustained release preparations

Supportive therapy: Supportive and symptomatic treatment, including I.V. fluids and Trendelenburg positioning, should be initiated as intoxication may cause hypotension. Although calcium (calcium chloride I.V. 1-3 g in adults or 10-30 mg/kg in children over 5-10 minutes with repeats as needed) has been used as an "antidote" for acute intoxications, inamrinone or dopamine may be needed for hypotension and traditional use of vasopressors is the first-line therapy for shock, with calcium chloride being the second-line agent. Hyperinsulinemic therapy with 0.5-1.0 unit I.V. insulin bolus with an infusion of 0.2-1 unit/kg/hour plus a glucose bolus of 25 g I.V. and dextrose infusion to maintain a serum glucose > 100 mg/dL may reverse cardiogenic shock due to calcium blockers. Heart block may respond to isoproterenol, glucagon, atropine and/or calcium, although a temporary pacemaker may be required; sodium bicarbonate should be given for acidosis. Glucagon may increase myocardial contractility. In an animal model, the therapy of hyperinsulinemia with euglycemia allowed for larger increases in myocardial contractility than calcium chloride, epinephrine, and glucagon. In a swine model, hypertonic sodium bicarbonate (4 mEq/kg over 4 minutes) reversed myocardial depression and increased mean arterial pressure.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; not dialyzable (0% to 5%); charcoal hemoperfusion (mean plasma clearance: 73 mL/minute) is ~10 times more efficient than hemodialysis (mean plasma clearance: 8.3 mL/minute) in removal of verapamil; even so, hemoperfusion clearance is only ~1% that of normal hepatic clearance. Thus, the only indication for prolonged charcoal hemoperfusion in verapamil overdose is in the setting of concomitant hepatic dysfunction.

Antidote(s)

● Glucagon [ANTIDOTE]

Test Interactions

↑ glucose (S)

Drug Interactions Substrate of CYP1A2 (minor), 2B6 (minor), 2C9 (minor), 2C18 (minor), 2E1 (minor), 3A4 (major); **Inhibits** CYP1A2 (weak), 2C9 (weak), 2D6 (weak), 3A4 (moderate)

Alfentanil's plasma concentration is increased. Fentanyl and sufentanil may be affected similarly.

Amiodarone use may lead to bradycardia and decreased cardiac output. Monitor closely if using together.

Aspirin and concurrent verapamil use may increase bleeding times; monitor closely, especially if on other antiplatelet agents or anticoagulants.

Azole antifungals may inhibit the calcium channel blocker's metabolism; avoid this combination. Try an antifungal like terbinafine (if appropriate) or monitor closely for altered effect of the calcium channel blocker.

Barbiturates reduce the plasma concentration of verapamil. May require much higher dose of verapamil.

Beta-blockers may have increased pharmacodynamic interactions with verapamil (see Warnings/Precautions).

Buspiron's serum concentration may increase. May require dosage adjustment.

Calcium may reduce the calcium channel blocker's effects, particularly hypotension.

Carbamazepine's serum concentration is increased and toxicity may result; avoid this combination.

Cimetidine reduced verapamil's metabolism; consider an alternative H₂ antagonist.

Colchicine: Verapamil may increase colchicine toxicity (especially nephrotoxicity).

Cyclosporine's serum concentrations are increased by verapamil; avoid this combination. Use another calcium channel blocker or monitor cyclosporine trough levels and renal function closely.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of verapamil. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of verapamil. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, telithromycin, and quinidine.

CYP3A4 substrates: Verapamil may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Digoxin's serum concentration is increased; reduce digoxin's dose when adding verapamil.

Doxorubicin's clearance was reduced; monitor for altered doxorubicin's effect.

Erythromycin may increase verapamil's effects; monitor altered verapamil effect.

Ethanol's effects may be increased by verapamil; reduce ethanol consumption.

Flecainide may have additive negative effects on conduction and inotropy.

Grapefruit juice: Verapamil serum concentrations may be increased by grapefruit juice. Avoid concurrent use.

HMG-CoA reductase inhibitors (atorvastatin, cerivastatin, lovastatin, simvastatin): Serum concentration will likely be increased; consider pravastatin/fluvastatin or a dihydropyridine calcium channel blocker. If concurrent use with lovastatin is unavoidable, dose of lovastatin should not exceed 40 mg/day.

Lithium neurotoxicity may result when verapamil is added; monitor lithium levels.

Midazolam's plasma concentration is increased by verapamil; monitor for prolonged CNS depression.

Nafcillin decreases plasma concentration of verapamil; avoid this combination.

Nondepolarizing muscle relaxant: Neuromuscular blockade may be prolonged. Monitor closely.

Prazosin's serum concentration increases; monitor blood pressure.

Quinidine's serum concentration is increased; adjust quinidine's dose as necessary.

Rifampin increases the metabolism of calcium channel blockers; adjust the dose of the calcium channel blocker to maintain efficacy.

Risperidone: Verapamil may increase the levels and effects of risperidone.

Sildenafil, tadalafil, vardenafil: Blood pressure-lowering effects may be additive; use caution.

Tacrolimus's serum concentrations are increased by verapamil; avoid the combination. Use another calcium channel blocker or monitor tacrolimus trough levels and renal function closely.

Theophylline's serum concentration may be increased by verapamil. Those at increased risk include children and cigarette smokers.

Pregnancy Risk Factor C

Pregnancy Implications Use in pregnancy only when clearly needed and when the benefits outweigh the potential risk to the fetus. Crosses the placenta. One report of suspected heart block when used to control fetal supraventricular tachycardia. May exhibit tocolytic effects.

Lactation Enters breast milk (small amounts)/not recommended

Nursing Implications Help patient with ambulation; monitor blood pressure closely; I.V. rate of infusion is over 2 minutes; do not crush sustained release drug product

Additional Information Incidence of adverse reactions is most common with I.V. administration; discontinue disopyramide 48 hours before starting therapy, do not restart therapy until 24 hours after verapamil has been discontinued; response to atropine may not be observed until after I.V. calcium administration; largest survivable ingestion: 24 g (slow-release capsules)

Vigabatrin

CAS Number 60643-86-9

Impairment Potential Yes

Use Active management of partial or secondary generalized seizures not controlled by usual treatments; treatment of infantile spasms

Unlabeled/Investigational Use Spasticity, tardive dyskinesias

Mechanism of Action Irreversible inhibitor of GABA transaminase - a structural analog of GABA

Adverse Reactions

Cardiovascular: Facial flushing

Central nervous system: Lethargy, mania, confusion, CNS depression, insomnia, fatigue, dizziness, sedation (at onset of therapy), psychosis (especially in patients with behavioral abnormalities, acute and reversible), headache, mania, paranoia, aggressive behavior

Dermatologic: Alopecia

Gastrointestinal: Xerostomia, gingival hyperplasia

Hepatic: Liver failure, hepatic necrosis

Neuromuscular & skeletal: Myoclonus

Ocular: Diplopia

Signs and Symptoms of Overdose Delirium

Pharmacodynamics/Kinetics

Duration (rate of GABA-T resynthesis dependent): Variable (not strictly correlated to serum concentrations)

VINBLASTINE

Absorption: Rapid
Metabolism: Minimal
Half-life elimination: 5-8 hours; Elderly: Up to 13 hours
Time to peak: 2 hours
Excretion: Urine (70%, as unchanged drug)

Dosage

Initial dose: 1-2 g/day then titrate to maintenance dose of 2-4 g/day in 1-2 divided doses (lower initial doses in the elderly, patients with renal insufficiency, or patients with psychiatric illnesses)
Infantile spasm: 50-200 mg/kg/day
Spasticity: 2-3 g/day
Tardive dyskinesia: 2-8 g/day

Monitoring Parameters Ophthalmologic examination at baseline and periodically during therapy (every 3 months); including mydriatic peripheral fundus examination and visual field perimetry. Observe patient for excessive sedation, especially when instituting or increasing therapy.

Administration May be administered with or without food.

Sachet: Dissolve powder in 10 mL of water, juice, infant formula, or milk immediately before administration. The appropriate aliquot may be administered using an oral syringe.

Contraindications Hypersensitivity to vigabatrin of any component of the formulation; pregnancy or breast-feeding

Warnings May be associated with ophthalmologic toxicities, which may be permanent; baseline and periodic monitoring is required. Patients must be instructed to report changes in vision. Patients must be closely monitored for potential neurotoxicity (observed in animal models but not established in humans). Use caution in patients with a history of psychosis (psychotic/agitated reactions may occur more frequently), depression, or behavioral problems. Use caution in elderly patients and in patients with renal impairment ($Cl_{cr} < 60$ mL/minute). May cause an increase in seizure frequency in some patients, use particular caution in patients with myoclonic seizures, which may be more prone to this effect. Do not discontinue abruptly; gradually reduce dose over a 2- to 4-week period.

Dosage Forms Powder for oral suspension [sachets]: 0.5 g [contains povidone]

Tablet: 500 mg

Reference Range

Peak S+ enantiomer: 93 nmol/mL after 1.5 g dose
Peak R- enantiomer: 169 nmol/mL after 1.5 g dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Enhancement of elimination: Multiple dosing of activated charcoal may be useful; hemodialysis may be useful

Drug Interactions

Phenobarbital: Serum concentrations of phenobarbital may be decreased by vigabatrin (9% to 21%).
Phenytoin: Serum concentrations of phenytoin may be decreased by vigabatrin (16% to 33%).

Pregnancy Risk Factor Not assigned; contraindicated per manufacturer
Pregnancy Implications Cleft palate observed in rabbit studies

Lactation Excretion in breast milk unknown/contraindicated

Additional Information Water soluble; may worsen myoclonic seizures; rodent studies showed intramyelinic edema (reversible on cessation of treatment)

Onset: 4-7 days
Nadir: 5-10 days
Recovery: 4-21 days
Neuromuscular & skeletal: Jaw pain, myalgia, paresthesia
Respiratory: Bronchospasm

VLB rarely produces neurotoxicity at clinical doses; however, neurotoxicity may be seen, especially at high doses; if it occurs, symptoms are similar to VCR toxicity (ie, peripheral neuropathy, loss of deep tendon reflexes, headache, weakness, urinary retention, and GI symptoms, tachycardia, orthostatic hypotension, convulsions); hemorrhagic colitis

Signs and Symptoms of Overdose Agranulocytosis, ataxia, bleeding, colitis, deafness, diarrhea, fever, granulocytopenia, hypertension, hyperuricemia, hyponatremia, leukopenia, neutropenia, paresthesia, Parkinson's-like symptoms, ptosis, tachycardia, thrombocytopenia

Pharmacodynamics/Kinetics

Distribution: V_d : 27.3 L/kg; binds extensively to tissues; does not penetrate CNS or other fatty tissues; distributes to liver
Protein binding: 99%
Metabolism: Hepatic to active metabolite
Half-life elimination: Biphasic: Initial: 0.164 hours; Terminal: 25 hours
Excretion: Feces (95%); urine (<1% as unchanged drug)

Dosage Refer to individual protocols.

Children and Adults: I.V.: 4-20 mg/m² (0.1-0.5 mg/kg) every 7-10 days or 5-day continuous infusion of 1.5-2 mg/m²/day or 0.1-0.5 mg/kg/week

Dosing adjustment in hepatic impairment:

Serum bilirubin 1.5-3.0 mg/dL or AST 60-180 units: Administer 50% of normal dose
Serum bilirubin 3.0-5.0 mg/dL: Administer 25% of dose
Serum bilirubin >5.0 mg/dL or AST >180 units: Omit dose

Monitoring Parameters CBC with differential and platelet count, serum uric acid, hepatic function tests

Administration FATAL IF GIVEN INTRATHECALLY. Administer vinblastine I.V., usually as a slow (2-3 minutes) push, or a bolus (5- to 15-minute) infusion. It is occasionally given as a 24-hour continuous infusion. Avoid extravasation; may cause sloughing. Solution should be administered only by qualified personnel. Do not allow to come in contact with skin; if contact occurs, wash well with soap and water.

Extravasation management: Mix 250 units hyaluronidase with 6 mL of NS. Inject the hyaluronidase solution subcutaneously through 6 clockwise injections into the infiltrated area using a 25-gauge needle; change the needle with each new injection. Apply heat immediately for 1 hour. Repeat 4 times/day for 3-5 days. Elevate extremity. Application of cold or hydrocortisone is contraindicated. Aspirate infusate from IV site.

Contraindications For I.V. use only; I.T. use may result in death; hypersensitivity to vinblastine or any component of the formulation; pregnancy

Warnings

Hazardous agent - use appropriate precautions for handling and disposal.
[U.S. Boxed Warning]: Vinblastine is a moderate vesicant; avoid extravasation. Dosage modification required in patients with impaired liver function and neurotoxicity. Using small amounts of drug daily for long periods may cause neurotoxicity and is therefore not advised. **[U.S. Boxed Warning]: For I.V. use only. Intrathecal administration may result in death.** Monitor closely for shortness of breath or bronchospasm in patients receiving mitomycin C. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.**

Dosage Forms Injection, powder for reconstitution, as sulfate: 10 mg
Injection, solution, as sulfate: 1 mg/mL (10 mL) [contains benzyl alcohol]

Overdosage/Treatment

Supportive therapy: Seizures can be treated with diazepam, lorazepam, or barbiturates; extravasation can be treated with warm compresses with infiltration of hyaluronidase (150 units in saline in a concentration of 15 units/mL); surgical debridement may be necessary. Ocular exposure should be treated with oral prednisone and dexamethasone eye drops.
Intrathecal overdose: Maintain upright posture for gravitational protection. Maintain lumbar puncture site for CSF exchange/drainage. Give 30 ml of Lactated Ringers per 30 ml of CSF for three exchanges.
Enhancement of elimination: Exchange transfusion (2 volume) has been performed in a child 3 years of age who received ten times the therapeutic dose; not removed by hemodialysis

Drug Interactions

Substrate of CYP2D6 (minor), 3A4 (major); **Inhibits** CYP2D6 (weak), 3A4 (weak)
CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of vinblastine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.
CYP3A4 inhibitors: May increase the levels/effects of vinblastine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nocardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.
Mitomycin-C: Previous or simultaneous use with mitomycin-C has resulted in acute shortness of breath and severe bronchospasm within minutes or several hours after vinca alkaloid injection and may occur up to 2 weeks

VinBLASTine

CAS Number 143-67-9; 865-21-4

U.S. Brand Names Velban® [DSC]

Synonyms NSC-49842; Vinblastine Sulfate; VLB

Use Treatment of Hodgkin's and non-Hodgkin's lymphoma, testicular, lung, head and neck, breast, and renal carcinomas, Mycosis fungoides, Kaposi's sarcoma, histiocytosis, choriocarcinoma, and idiopathic thrombocytopenic purpura

Mechanism of Action Vinblastine binds to tubulin and inhibits microtubule formation, therefore, arresting the cell at metaphase by disrupting the formation of the mitotic spindle; it is specific for the M and S phases. Vinblastine may also interfere with nucleic acid and protein synthesis by blocking glutamic acid utilization; extracted from *Vinca rosea* (periwinkle)

Adverse Reactions

Cardiovascular: Hypertension, Raynaud's phenomenon
Central nervous system: Depression, malaise, headache, seizures
Dermatologic: **Alopecia**, rash, photosensitivity, dermatitis
Endocrine & metabolic: **SIADH**, hyperuricemia
Gastrointestinal: **Diarrhea** (less common), **stomatitis**, **anorexia**, **metallic taste**, constipation, abdominal pain, nausea (mild), vomiting (mild), paralytic ileus, stomatitis
Genitourinary: Urinary retention
Hematologic: May cause severe **bone marrow suppression** and is the dose-limiting toxicity of VLB (unlike vincristine); severe **granulocytopenia** and **thrombocytopenia** may occur following the administration of VLB and nadir 5-10 days after treatment

Myelosuppression (primarily **leukopenia**, may be dose limiting)

after the dose of mitomycin. Mitomycin-C, in combination with administration of VLB, may cause acute shortness of breath and severe bronchospasm, onset may be within minutes or several hours after VLB injection. Phenytoin may reduce vincristine serum concentrations.

Pregnancy Risk Factor D

Lactation Enters breast milk/not recommended

Additional Information Urine (for 4 days) and feces (for 7 days) should be handled with care

Myelosuppressive effects: Onset (days): 4-7. Nadir (days): 10. Recovery (days): 17

VinCRISTine

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 2068-78-2; 57-22-7

U.S. Brand Names Oncovin® [DSC]; Vincasar PFS®

Synonyms LCR; Leurocristine Sulfate; NSC-67574; VCR; Vincristine Sulfate

Use Treatment of leukemias, Hodgkin's disease, non-Hodgkin's lymphomas, Wilms' tumor, neuroblastoma, rhabdomyosarcoma

Mechanism of Action Binds to microtubular protein of the mitotic spindle causing metaphase arrest; cell-cycle phase specific in the M and S phases; extracted from *Vinca rosea* (periwinkle)

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), myocardial infarction, Central nervous system: Neurotoxicity, seizures, CNS depression, psychosis, hallucinations, cranial nerve paralysis, visual hallucinations, fever, ataxia, dysphoria, axonopathy (ascending)

Dermatologic: Alopecia (occurs in 20% to 70% of patients and is reversible), rash, radiation recall dermatitis

Endocrine & metabolic: Hyperuricemia, syndrome of inappropriate antidiuretic hormone, parotitis

Gastrointestinal: Constipation (at doses of 12.5-75 mcg/kg), paralytic ileus secondary to neurologic toxicity (particularly in the elderly), nausea, vomiting, diarrhea, stomatitis

Local: Pain, cellulitis and tissue necrosis if infiltrated; phlebitis

Neuromuscular & skeletal: Jaw pain, leg pain, myalgias, cramping, motor difficulties, numbness, Charcot-Marie-Tooth disease, weakness

Neurologic: Effects of VCR may be additive with those of other neurotoxic agents and spinal cord irradiation. Dose related: Begins at 5-6 g and is significant at 15-20 g

Ocular: Optic atrophy with cortical blindness has been reported, **ptosis/diplopia**

Respiratory: Dyspnea

Signs and Symptoms of Overdose Ascending paralysis, coma with intrathecal injection, confusion, deafness, fever, hypertension, hyperuricemia, leukopenia, Mees' lines, migraine headache (exacerbation), muscle atrophy, myopathy, numbness, occipital headache, paresthesia, thrombocytosis, thrombocytopenia

Pharmacodynamics/Kinetics

Absorption: Oral: Poor

Distribution: V_d : 163-165 L/m²; Poor penetration into CSF; rapidly removed from bloodstream and tightly bound to tissues; penetrates blood-brain barrier poorly

Protein binding: 75%

Metabolism: Extensively hepatic

Half-life elimination: Terminal: 24 hours

Excretion: Feces (~80%); urine (<1% as unchanged drug)

Dosage

I.V.: Refer to individual protocols; orders for single doses > 2.5 mg or > 5 mg/treatment cycle should be verified with the specific treatment regimen and/or an experienced oncologist prior to dispensing. Doses are often capped at 2 mg; however, this may reduce the efficacy of the therapy, and may not be advisable.

Children ≤ 10 kg or BSA < 1 m²: Initial therapy: 0.05 mg/kg once weekly then titrate dose; maximum single dose: 2 mg

Children > 10 kg or BSA ≥ 1 m²: 1-2 mg/m², may repeat once weekly for 3-6 weeks; maximum single dose: 2 mg

Neuroblastoma: I.V. continuous infusion with doxorubicin: 1 mg/m²/day for 72 hours

Adults: 0.4-1.4 mg/m², may repeat every week or 0.4-0.5 mg/day continuous infusion for 4 days every 4 weeks or 0.25-0.5 mg/m²/day for 5 days every 4 weeks

Dosing adjustment in hepatic impairment:

Serum bilirubin 1.5-3.0 mg/dL or AST 60-180 units: Administer 50% of normal dose

Serum bilirubin 3.0-5.0 mg/dL: Administer 25% of dose

Serum bilirubin > 5.0 mg/dL or AST > 180 units: Omit dose

Monitoring Parameters Serum electrolytes (sodium), hepatic function tests, neurologic examination, CBC, serum uric acid

Administration FATAL IF GIVEN INTRATHECALLY.

I.V.: Usually administered as slow (1-2 minutes) push or as short (10-15 minutes) infusion; 24-hour continuous infusions are occasionally used. Intrathecal injection has been reported for Kaposi's sarcoma.

Extravasation management: Mix 250 units hyaluronidase with 6 mL of NS. Inject the hyaluronidase solution subcutaneously through 6 clockwise injections into the infiltrated area using a 25-gauge needle. Change the needle with each new injection. Elevate extremity. Apply heat immediately for 1 hour. Repeat 4 times/day for 3-5 days. Application of cold or hydrocortisone is contraindicated.

Contraindications Hypersensitivity to vincristine or any component of the formulation; **for I.V. use only, fatal if given intrathecally**; patients with demyelinating form of Charcot-Marie-Tooth syndrome; pregnancy

Warnings

Hazardous agent – use appropriate precautions for handling and disposal. **[U.S. Boxed Warning]: Vincristine is a vesicant; avoid extravasation. (Individuals administering should be experienced in vincristine administration.)**

Dosage modification required in patients with impaired hepatic function or who have pre-existing neuromuscular disease. Use with caution in the elderly; avoid eye contamination; observe closely for shortness of breath, bronchospasm, especially in patients treated with mitomycin C. Alterations in mental status such as depression, confusion, or insomnia; constipation, paralytic ileus, and urinary tract disturbances may occur. All patients should be on a prophylactic bowel management regimen.

[U.S. Boxed Warning]: Intrathecal administration of vincristine has uniformly caused death; vincristine should never be administered by this route. For I.V. use only. Neurologic effects of vincristine may be additive with those of other neurotoxic agents and spinal cord irradiation.

Dosage Forms Injection, solution, as sulfate: 1 mg/mL (1 mL, 2 mL)

Reference Range 5-day continuous infusion (total dose: 4 mg/m²) produced plasma level of 1.8-10.9 ng/mL at 1 hour and <0.25 ng/mL at 24 hours after discontinuation of therapy

Overdosage/Treatment

Supportive therapy: Constipation resolves after 2 weeks; neurotoxicity can be decreased with pretreatment during induction period with glutamic acid (1.5 g/day); folinic acid has been utilized but efficacy is not known (100 mg every 3 hours for 1 day, then 100 mg every 6 hours for 2 days); seizures can be treated with benzodiazepines or barbituates.

Intrathecal overdose: Maintain upright posture for gravitational protection. Maintain lumbar puncture site for CSF exchange/drainage. Give 30 ml of Lactated Ringers per 30 ml of CSF for three exchanges.

Enhancement of elimination: For intrathecal route, remove contaminated CNS fluid and flush with lactated Ringer's solution with fresh frozen plasma to maintain a protein level of 150 mg/dL; glutamic acid 10 g I.V. over 1 day followed by 500 mg/day orally until neurotoxicity is stabilized

Extravasation treatment: Inject 3-5 mL of hyaluronidase (10 units/mL) SubQ clockwise into the infiltrated area using a 25-gauge needle; change the needle with each injection; apply heat immediately for 1 hour, repeat 4 times/day for 3-5 days (application of cold and injection of hydrocortisone is contraindicated). Use warm, drug compresses. Aspirate infusate from i.v. site. Elevate extremity.

Drug Interactions

Substrate of CYP3A4 (major); Inhibits CYP3A4 (weak)

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of vincristine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of vincristine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Digoxin plasma levels and renal excretion may decrease with combination chemotherapy including vincristine

Mitomycin-C: Acute pulmonary reactions may occur with mitomycin-C. Previous or simultaneous use with mitomycin-C has resulted in acute shortness of breath and severe bronchospasm within minutes or several hours after vinca alkaloid injection and may occur up to 2 weeks after the dose of mitomycin.

Nifedipine: May increase the levels/effects of vincristine; monitor.

Phenytoin levels may decrease with combination chemotherapy.

Vincristine should be given 12-24 hours before asparaginase to minimize toxicity (may decrease the hepatic clearance of vincristine)

Pregnancy Risk Factor D

Lactation Enters breast milk/not recommended

Nursing Implications Maintain adequate hydration; allopurinol may be given to prevent uric acid nephropathy; observe for life-threatening wheezing after administration; use of rectal thermometer or rectal tubing should be avoided to prevent injury to rectal mucosa

Additional Information Urine (for 4 days) and feces (for 1 week) must be handled with care

Vinorelbine

CAS Number 71486-22-1

U.S. Brand Names Navelbine®

Synonyms Dihydroxydeoxynorvinkaleukoblastine; NVB; Vinorelbine Tartrate

Use Treatment of nonsmall cell lung cancer

Unlabeled/Investigational Use Treatment of breast cancer, ovarian carcinoma, Hodgkin's disease, non-Hodgkin's lymphoma

Mechanism of Action Semisynthetic vinca alkaloid which binds to tubulin and inhibits microtubule formation, therefore, arresting the cell at metaphase by disrupting the formation of the mitotic spindle; it is specific for the M and S phases. Vinorelbine may also interfere with nucleic acid and protein synthesis by blocking glutamic acid utilization.

Adverse Reactions

Cardiovascular: Chest pain, deep vein thrombosis, flushing, hypertension, hypotension, vasodilation, tachycardia

Central nervous system: **Fatigue (27%)**, headache

Dermatologic: **Alopecia (12%)**, angioedema, radiation recall (dermatitis, esophagitis)

Endocrine & metabolic: Syndrome of inappropriate ADH secretion, hyponatremia

Gastrointestinal: **Nausea (44%, severe <2%) and vomiting (20%) are most common and are easily controlled with standard antiemetics; constipation (35%), diarrhea (17%),** paralytic ileus, abdominal pain, dysphagia, esophagitis, mucositis, pancreatitis

Emetic potential: Moderate (30% to 60%)

Genitourinary: Hemorrhagic cystitis

Hematologic: **May cause severe bone marrow suppression and is the dose-limiting toxicity of vinorelbine; severe granulocytopenia (90%) may occur following the administration of vinorelbine; leukopenia (92%), anemia (83%), thrombocytopenia**

Myelosuppressive:

WBC: Moderate - severe

Onset (days): 4-7

Nadir (days): 7-10

Recovery (days): 14-21

Hepatic: **Elevated AST (SGOT) (67%), elevated total bilirubin (13%)**

Local: **Injection site reaction (28%), injection site pain (16%),** vesicant and can cause tissue irritation and necrosis if infiltrated (if extravasation occurs, follow institutional policy, which may include hyaluronidase and hot compresses), phlebitis

Neuromuscular & skeletal: **Weakness (36%), peripheral neuropathy (20% to 25%);** mild to moderate peripheral neuropathy manifested by paresthesia and hyperesthesia, loss of deep tendon reflexes (<5%); severe peripheral neuropathy (generally reversible); myalgia (<5%), arthralgia (<5%), jaw pain (<5%), back pain, gait instability, muscle weakness

Respiratory: Dyspnea, pneumonia, pulmonary edema, pulmonary embolus

Miscellaneous: Anaphylaxis, tumor pain

Pharmacodynamics/Kinetics

Absorption: Unreliable; must be given I.V.

Distribution: V_d : 25.4-40.1 L/kg; binds extensively to human platelets and lymphocytes (79.6% to 91.2%)

Protein binding: 80% to 90%

Metabolism: Extensively hepatic to two metabolites, deacetylvinorelbine (active) and vinorelbine N-oxide

Bioavailability: Oral: 26% to 45%

Half-life elimination: Triphasic: Terminal: 27.7-43.6 hours

Excretion: Feces (46%); urine (18%, 10% to 12% as unchanged drug)

Clearance: Plasma: Mean: 0.97-1.26 L/hour/kg

Dosage Refer to individual protocols.

Adults: I.V.:

Single-agent therapy: 30 mg/m² every 7 days

Combination therapy with cisplatin: 25 mg/m² every 7 days (with cisplatin 100 mg/m² every 4 weeks); **Alternatively:** 30 mg/m² in combination with cisplatin 120 mg/m² on days 1 and 29, then every 6 weeks

Dosage adjustment in hematological toxicity: Granulocyte counts should be ≥ 1000 cells/mm³ prior to the administration of vinorelbine. Adjustments in the dosage of vinorelbine should be based on granulocyte counts obtained on the day of treatment as follows:

Granulocytes ≥ 1500 cells/mm³ on day of treatment: Administer 100% of starting dose

Granulocytes 1000-1499 cells/mm³ on day of treatment: Administer 50% of starting dose

Granulocytes < 1000 cells/mm³ on day of treatment: Do not administer. Repeat granulocyte count in one week; if 3 consecutive doses are held because granulocyte count is < 1000 cells/mm³, discontinue vinorelbine

For patients who, during treatment, have experienced fever and/or sepsis while granulocytopenic or had 2 consecutive weekly doses held due to granulocytopenia, subsequent doses of vinorelbine should be:

75% of starting dose for granulocytes ≥ 1500 cells/mm³

37.5% of starting dose for granulocytes 1000-1499 cells/mm³

Dosage adjustment in renal impairment: No dose adjustments are required for renal insufficiency.

Dosing adjustment in hepatic impairment: Vinorelbine should be administered with caution in patients with hepatic insufficiency. In patients who develop hyperbilirubinemia during treatment with vinorelbine, the dose should be adjusted for total bilirubin as follows:

Serum bilirubin ≤ 2 mg/dL: Administer 100% of starting dose

Serum bilirubin 2.1-3 mg/dL: Administer 50% of starting dose

Serum bilirubin > 3 mg/dL: Administer 25% of starting dose

Dosing adjustment in patients with concurrent hematologic toxicity and hepatic impairment: Administer the lower doses determined from the above recommendations

Monitoring Parameters CBC with differential and platelet count, hepatic function tests

Administration FATAL IF GIVEN INTRATHECALLY. Administer as a direct intravenous push or rapid bolus, over 6-10 minutes (up to 30 minutes). Longer infusions may increase the risk of pain and phlebitis. Intravenous doses should be followed by 150-250 mL of saline or dextrose to reduce the incidence of phlebitis and inflammation. **CENTRAL LINE ONLY** for IVPB administration. Avoid extravasation; may cause sloughing.

Extravasation management: Mix 250 units hyaluronidase with 6 mL of NS. Inject the hyaluronidase solution subcutaneously through 6 clockwise injections into the infiltrated area using a 25-gauge needle. Change the needle with each new injection. Elevate extremities. Apply heat immediately for 1 hour. Repeat 4 times/day for 3-5 days. Application of cold or hydrocortisone is contraindicated.

Contraindications For I.V. use only; I.T. use may result in death; hypersensitivity to vinorelbine or any component of the formulation; pregnancy

Warnings

Hazardous agent - use appropriate precautions for handling and disposal.

[U.S. Boxed Warning]: Avoid extravasation; dosage modification required in patients with impaired liver function and neurotoxicity. Frequently monitor patients for myelosuppression both during and after therapy. **[U.S. Boxed Warnings]: Granulocytopenia is dose-limiting. Intrathecal administration may result in death.** Use with caution in patients with cachexia or ulcerated skin.

Acute shortness of breath and severe bronchospasm have been reported, most commonly when administered with mitomycin. Fatal cases of interstitial pulmonary changes and ARDS have also been reported. May cause severe constipation (grade 3-4), paralytic ileus, intestinal obstruction, necrosis, and/or perforation. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.**

Dosage Forms Injection, solution [preservative free]: 10 mg/mL (1 mL, 5 mL)

Reference Range Peak serum level of 1130 ng/mL achieved 15 minutes after a 30 mg/m² I.V. dose

Overdosage/Treatment

Supportive therapy: Seizures can be treated with diazepam, lorazepam, phenytoin, or barbiturates; extravasation can be treated with warm compresses with infiltration of hyaluronidase (150 units in saline in a concentration of 15 units/mL); surgical debridement may be necessary. Enhancement of elimination: Not dialyzable

Drug Interactions

Substrate of CYP2D6 (minor), 3A4 (major); **Inhibits** CYP2D6 (weak), 3A4 (weak)

Cisplatin: Incidence of granulocytopenia is significantly higher than with single-agent vinorelbine.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of vinorelbine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of vinorelbine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nocardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Mitomycin-C: Previous or simultaneous use with mitomycin-C has resulted in acute shortness of breath and severe bronchospasm within minutes or several hours after vinca alkaloid injection and may occur up to 2 weeks after the dose of mitomycin.

Pregnancy Risk Factor D

Lactation Excretion in breast milk unknown/contraindicated

Additional Information Not useful in renal cell carcinoma; metoclopramide (20-40 mg) can be given prophylactically as an antiemetic agent; I.V. route usually utilized, although oral weekly doses of 50-160 mg have been used in patients with advanced breast cancer; less neurotoxic than vincristine or vinblastine

Vitamin A

Related Information

- Isotretinoin

CAS Number 68-26-8

U.S. Brand Names Aquasol A®; Palmitate-A® [OTC]

Synonyms Oleovitamin A

Use Treatment and prevention of vitamin A deficiency

Mechanism of Action Needed for bone development, growth, visual adaptation to darkness, testicular and ovarian function, and as a cofactor in many biochemical processes

Adverse Reactions

Reactions are only seen with doses exceeding physiologic replacement
Central nervous system: Irritability, sedation, drowsiness, dizziness, delirium, headache due to increased intracranial pressure, coma, psychosis, ataxia (truncal), insomnia

Dermatologic: Erythema, peeling skin, alopecia, yellow pigmentation (increased)

Gastrointestinal: Vomiting, diarrhea

Hematologic: Normochromic macrocytic anemia

Hepatic: Hepatomegaly

Ocular: Visual disturbances, papilledema

Otic: Ototoxicity, tinnitus

Miscellaneous: Perioral fissures

Signs and Symptoms of Overdose Anorexia, ascites, coagulopathy, diplopia, dizziness, erythema, fatigue, hypercalcemia, hypoprothrombinemia, increased intracranial pressure, low grade fever, myoglobinuria, nausea, nystagmus, portal hypertension, pruritus, pseudotumor cerebri, rhabdomyolysis, skin desquamation over hands and feet, vomiting

Pharmacodynamics/Kinetics

Absorption: Vitamin A in dosages **not** exceeding physiologic replacement is well absorbed after oral administration; water miscible preparations are absorbed more rapidly than oil preparations; large oral doses, conditions of fat malabsorption, low protein intake, or hepatic or pancreatic disease reduces oral absorption

Distribution: Large amounts concentrate for storage in the liver; enters breast milk

Metabolism: Conjugated with glucuronide; undergoes enterohepatic recirculation

Excretion: Feces

Dosage RDA:

< 1 year: 375 mcg

1-3 years: 400 mcg

4-6 years: 500 mcg*

7-10 years: 700 mcg*

> 10 years: 800-1000 mcg*

Supplementation in measles: Children: Oral:

< 1 year: 100,000 units/day for 2 days

> 1 year: 200,000 units/day for 2 days

Severe deficiency with xerophthalmia:

Children 1-8 years:

Oral: 5000-10,000 units/kg/day for 5 days or until recovery occurs

I.M.: 5000-15,000 units/day for 10 days

Children > 8 years and Adults:

Oral: 500,000 units/day for 3 days, then 50,000 units/day for 14 days, then 10,000-20,000 units/day for 2 months

I.M.: 50,000-100,000 units/day for 3 days, 50,000 units/day for 14 days

Deficiency (without corneal changes): Oral:

Infants < 1 year: 10,000 units/kg/day for 5 days, then 7500-15,000 units/day for 10 days

Children 1-8 years: 5000-10,000 units/kg/day for 5 days, then 17,000-35,000 units/day for 10 days

Children > 8 years and Adults: 100,000 units/day for 3 days then 50,000 units/day for 14 days

Malabsorption syndrome (prophylaxis): Children > 8 years and Adults:

Oral: 10,000-50,000 units/day of water miscible product

Dietary supplement: Oral:

Infants up to 6 months: 1500 units/day

Children:

6 months to 3 years: 1500-2000 units/day

4-6 years: 2500 units/day

7-10 years: 3300-3500 units/day

Children > 10 years and Adults: 4000-5000 units/day

Hepatotoxic dose: 600,000 units (acute); 25,000-50,000 units/day (chronic)

Stability Protect from light

Monitoring Parameters Monitor calcium; serum alkaline phosphatase, bilirubin, and prothrombin time may be elevated

Administration Do not give by I.V. push.

Contraindications Hypersensitivity to vitamin A or any component of the formulation; hypervitaminosis A; pregnancy (dose exceeding RDA)

Warnings Evaluate other sources of vitamin A while receiving this product; patients receiving > 25,000 units/day should be closely mon-

itored for toxicity. Parenteral vitamin A: In low birth weight infants, polysorbates have been associated with thrombocytopenia, renal dysfunction, hepatomegaly, cholestasis, ascites, hypotension, and metabolic acidosis (E-Ferol syndrome).

Dosage Forms Capsule [softgel]: 10,000 units; 25,000 units

Injection, solution (Aquasol A®): 50,000 units/mL (2 mL) [contains polysorbate 80]

Tablet (Palmitate-A®): 5000 units, 15,000 units

Reference Range

RDA: Male: 1000 mcg retinol equivalent (RE); Female: 800 mcg RE; 1 RE

= 1 retinol equivalent; 1 RE = 1 mcg retinol or 6 mg beta-carotene

Normal levels: > 0.67 units/mL or 20-60 mcg/dL; levels > 100 mcg/dL are associated with the toxic state

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour) if ingestion is acute and > 12,000 units/kg in children or > 840,000 units in adults/cholestyramine or activated charcoal

Supportive therapy: Hypercalcemia can be treated with furosemide (20-40 mg I.V.), saline hydration and prednisone (10-40 mg orally)

Drug Interactions Decreased effect: Cholestyramine decreases absorption of vitamin A; neomycin and mineral oil may also interfere with vitamin A absorption

Increased toxicity: Retinoids may have additive adverse effects

Pregnancy Risk Factor A/X (dose exceeding RDA recommendation)

Pregnancy Implications Excessive use of vitamin A shortly before and during pregnancy could be harmful to babies. Facial/ear deformities can occur.

Lactation Enters breast milk/compatible at normal daily doses

Nursing Implications Do not give by I.V. push; patients receiving

> 25,000 units/day should be closely monitored for toxicity

Additional Information 1 mg equals 3333 units

Vitamin D

CAS Number 19356-17-3; 32222-06-3; 41294-56-8; 50-14-6; 63283-36-3; 67-96-9; 67-97-0

Synonyms Activated Ergosterol; Alfacalcidol; Calcifediol; Calcitriol; Cholecalciferol; Dihydroxycholesterol; Ergocalciferol; Viosterol

Use Treatment of refractory rickets, hypophosphatemia, hypoparathyroidism; vitamin D-deficient states

Mechanism of Action Fat soluble vitamin; stimulates calcium and phosphate absorption from the small intestine, promotes secretion of calcium from bone to blood

Adverse Reactions

Cardiovascular: Hypertension, arrhythmias, cardiomyopathy, cardiomegaly

Central nervous system: Drowsiness, irritability, headache

Dermatologic: Pruritus

Endocrine & metabolic: Acidosis

Gastrointestinal: Nausea, diarrhea, vomiting, anorexia, xerostomia, metallic taste

Neuromuscular & skeletal: Weakness, muscle and bone pain

Renal: Polyuria, nephrocalcinosis, renal tubular acidosis type I

Signs and Symptoms of Overdose Albuminuria, anemia, anorexia, azotemia, confusion, drowsiness, dysosmia, ectopic calcification, headache, hypercalcemia, hyperphosphatemia, hypertension, hypomagnesemia, muscle asthenia, nausea, nystagmus, pancreatitis, renal failure, vomiting

Pharmacodynamics/Kinetics

Peak effect: In \approx 1 month following daily doses

Absorption: Readily absorbed from gastrointestinal tract; absorption requires intestinal presence of bile

Metabolism: Inactive until hydroxylated in the liver and the kidney to calcifediol and then to calcitriol (most active form)

Dosage Dietary supplementation: Oral:

Infants, premature: 10-20 mcg/day (400-800 units), up to 750 mcg/day (30,000 units)

Infants and healthy Children: 10 mcg/day (400 units)

Adults:

< 25 years: 400 units

> 25 years: 200 units

Renal failure: Oral:

Children: 0.1-1 mg/day (4000-40,000 units)

Adults: 0.5 mg/day (20,000 units)

Hypoparathyroidism: Oral:

VITAMIN E

Children: 1.25-5 mg/day (50,000-200,000 units) and calcium supplements (500 mg elemental calcium 6 times/day)

Adults: 625 mcg to 5 mg/day (25,000-200,000 units) and calcium supplements (500 mg elemental calcium 6 times/day)

Vitamin D-dependent rickets: Oral:

Children: 75-125 mcg/day (3000-5000 units)

Adults: 250 mcg to 1.5 mg/day (10,000-60,000 units)

Nutritional rickets and osteomalacia:

Children and Adults (with normal absorption): Oral: 25 mcg/day (1000 units)

Children with malabsorption: Oral: 250-625 mcg/day (10,000-25,000 units)

Adults: I.M.: 250 mcg/day

Monitoring Parameters Serum calcium and phosphorous levels, BUN, renal status

Dosage Forms Capsule (Drisdol®): 50,000 units [1.25 mg]

Injection (Calciferol™): 500,000 units/mL [12.5 mg/mL] (1 mL)

Liquid (Calciferol™, Drisdol®): 8000 units/mL [200 mcg/mL] (60 mL)

Tablet (Calciferol™): 50,000 units [1.25 mg]

Reference Range

Normal serum range of vitamin D and 25-hydroxy D₃: 10-50 pg/mL

Normal serum range of 1,25-dihydroxy D₃: 10-20 pg/mL; free 1,25-dihydroxy vitamin D levels that are elevated (mean level 852 fmol/L with a reference range of 305-523 fmol/L) may contribute to pathogenesis of hypercalcemia

Toxicity is associated with serum 25-hydroxy D₃ >850 nmol/L and free 1,25-dihydroxy D₃ >280 fmol/L; overdosage is associated with normal serum total 1,25-dihydroxy D₃ and elevated serum 25-hydroxy D₃ and free 1,25-dihydroxy D₃ due to protein binding interaction

Overdosage/Treatment Supportive therapy: Hypercalcemia can be treated with saline, diuresis, furosemide (20-40 mg I.V.) and hydrocortisone (100 mg I.V. every 6 hours); calcitonin (4-8 int. units/kg I.M. every 6-12 hours) can be used for persistent or severe hypercalcemia; hemodialysis can also be used for severe hypercalcemia; pamidronate disodium (90 mg I.V.) can be given to treat hypercalcemia due to vitamin D intoxication

Test Interactions Serum cholesterol may be falsely elevated by vitamin D

Drug Interactions Hepatic metabolism is increased with glutethimide/phenytoin; effects of vitamin D are decreased with concomitant administration of phenobarbital

Pregnancy Risk Factor A (D if dose exceeds RDA recommendation)

Pregnancy Implications Large doses (10,000 int. units/kg) can produce arterial stenosis, abnormal bone mineralization, elfin facies, and nephrocalcinosis in the neonate

Additional Information Cholecalciferol (vitamin D₃) is a potent rodenticide containing 13,000 int. units of vitamin D per g; marketed as Rampage or Quintox; present in fish, cod liver oils, butter, eggs, liver; 1.25 mg ergocalciferol provides 50,000 units of vitamin D activity; elimination of vitamin D metabolites delayed in hypothyroid individuals; insoluble in water; increased milk consumption is associated with increased serum levels of 25-hydroxy-vitamin D and increased urinary calcium

Vitamin E

CAS Number 10191-41-0; 17407-37-3; 4345-03-3; 58-95-7; 59-02-9; 7695-91-2

U.S. Brand Names Aqua Gem E® [OTC]; Aquasol E® [OTC]; E-Gems® [OTC]; Key-E® Kaps [OTC]; Key-E® [OTC]

Synonyms *d*-Alpha Tocopherol; *dl*-Alpha Tocopherol

Use Prevention and treatment of hemolytic anemia secondary to vitamin E deficiency, dietary supplement

Unlabeled/Investigational Use To reduce the risk of bronchopulmonary dysplasia or retrolental fibroplasia in infants exposed to high concentrations of oxygen; prevention and treatment of tardive dyskinesia and Alzheimer's disease; prevention and treatment of hemolytic anemia secondary to vitamin E deficiency

Mechanism of Action Prevents oxidation of vitamin A and C; protects polyunsaturated fatty acids in membranes from attack by free radicals and protects red blood cells against hemolysis

Adverse Reactions

Central nervous system: Headache

Dermatologic: Rash, contact dermatitis and erythema multiforme with topical preparation

Endocrine & metabolic: Creatinuria, gonadal dysfunction, decreased serum thyroxine and triiodothyronine

Gastrointestinal: Nausea, diarrhea, abdominal pain, intestinal cramps

Genitourinary: Increased urinary estrogens and androgens

Hepatic: Increased cholesterol and hypertriglyceridemia

Neuromuscular & skeletal: Weakness

Ocular: Blurred vision

Signs and Symptoms of Overdose Abdominal pain, asthenia, azotemia, cholestatic jaundice, diarrhea, nausea

Pharmacodynamics/Kinetics

Absorption: Oral: Depends on presence of bile; reduced in conditions of malabsorption, in low birth weight premature infants, and as dosage increases; water miscible preparations are better absorbed than oil preparations

Distribution: To all body tissues, especially adipose tissue, where it is stored

Metabolism: Hepatic to glucuronides

Excretion: Feces

Dosage RDA: Oral:

Infants:

Premature, ≤3 months: 25 units/day

≤6 months: 4.5 units/day

6-12 months: 6 units/day

Children:

1-3 years: 9 units/day

4-10 years: 10.5 units/day

Children > 11 years and Adults:

Male: 15 units/day

Female: 12 units/day

Prevention of vitamin E deficiency: Neonates, premature, low birthweight (results in normal levels within 1 week): Oral: 25-50 units/24 hours until 6-10 weeks of age or 125-150 units/kg total in 4 doses on days 1, 2, 7, and 8 of life

Vitamin E deficiency treatment: Adults: Oral: 50-200 units/24 hours for 2 weeks

Topical: Apply a thin layer over affected areas as needed

Stability Protect from light

Monitoring Parameters Monitor plasma tocopherol concentrations (normal range: 6-14 mcg/mL)

Administration Swallow capsules whole, do not crush or chew.

Contraindications Hypersensitivity to vitamin E or any component of the formulation

Warnings May induce vitamin K deficiency; necrotizing enterocolitis has been associated with oral administration of large dosages (eg, >200 units/day) of a hyperosmolar vitamin E preparation in low birth weight infants

Dosage Forms Capsule: 400 int. units, 1000 int. units

Key-E® Kaps: 200 int. units, 400 int. units

Capsule, softgel: 200 int. units, 400 int. units, 600 int. units, 1000 int. units

Alpha-E: 200 int. units, 400 int. units

Alpha-E-Mixed: 200 int. units [contains mixed tocopherols]; 400 int. units [contains mixed tocopherols], 1000 int. units [sugar free; contains mixed tocopherols]

Aqua Gem E®: 200 units, 400 units

d-Alpha-Gems™: 400 int. units [derived from soybean oil]

E-Gems®: 30 int. units, 100 int. units, 200 int. units, 400 int. units, 600 int. units, 800 int. units, 1000 int. units, 1200 int. units [derived from soybean oil]

E-Gems Plus®: 200 int. units, 400 int. units, 800 int. units [contains mixed tocopherols]

E-Gems Elite®: 400 int. units [contains mixed tocopherols]

Ester-E™: 400 int. units

Gamma E-Gems®: 90 int. units [also contains mixed tocopherols]

Gamma-E Plus: 200 int. units [contains soybean oil]

High Gamma Vitamin E Complete™: 200 int. units [contains soybean oil, mixed tocopherols]

Cream: 50 int. units/g (60 g), 100 int. units/g (60 g), 1000 int. units/120 g (120 g), 30,000 int. units/57 g (57 g)

Key-E®: 30 int. units/g (60 g, 120 g, 600 g)

Lip balm (E-Gem® Lip Care): 1000 int. units/tube [contains vitamin A and aloe]

Oil, oral/topical: 100 int. units/0.25 mL (60 mL, 75 mL); 1150 units/0.25 mL (30 mL, 60 mL, 120 mL); 28,000 int. units/30 mL (30 mL)

Alpha-E: 28,000 int. units/30 mL (30 mL) [topical]

E-Gems®: 100 units/10 drops (15 mL, 60 mL)

Ointment, topical (Key-E®): 30 units/g (60 g, 120 g, 480 g)

Powder (Key-E®): 700 int. units per 1/4 teaspoon (15 g, 75 g, 1000 g) [derived from soybean oil]

Solution, oral drops: 15 int. units/0.3 mL (30 mL)

Aquasol E®: 15 int. units/0.3 mL (12 mL, 30 mL) [latex free]

Aquavit-E: 15 int. units/0.3 mL (30 mL) [butterscotch flavor]

Suppository, rectal/vaginal (Key-E®): 30 int. units (12s, 24s) [contains coconut oil]

Tablet: 100 int. units, 200 int. units, 400 int. units, 500 int. units

Key-E®: 200 int. units, 400 int. units

Reference Range

Therapeutic: 0.8-2.5 mg/dL (SI: 19-35 μmol/L), some method variation

Toxic: >3.5 mg/dL; levels >4.5 mg/dL associated with necrotizing enterocolitis

Overdosage/Treatment Decontamination: Oral: Activated charcoal
Drug Interactions Cholestyramine (and colestipol): May reduce absorption of vitamin E
 Iron: Vitamin E may impair the hematologic response to iron in children with iron-deficiency anemia; monitor
 Orlistat: May reduce absorption of vitamin E
 Warfarin: Vitamin E may alter the effect of vitamin K actions on clotting factors resulting in an increase hypoprothrombinemic response to warfarin; monitor

Pregnancy Risk Factor A/C (dose exceeding RDA recommendation)

Lactation Enters breast milk/compatible

Additional Information Cluster of deaths in low-birth-weight infants in 1984 (~38) secondary to injectable vitamin E (E-Ferol); ascribed to large amount of polysorbates injected; found in sunflower oil, vegetable oils, eggs, wheat germ oil

Warfarin

Related Information

- Dicumarol

CAS Number 129-06-6; 2610-86-8; 81-81-2

U.S. Brand Names Coumadin®; Jantoven™

Synonyms Warfarin Sodium

Use Prophylaxis and treatment of venous thrombosis, pulmonary embolism and thromboembolic disorders; atrial fibrillation with risk of embolism and as an adjunct in the prophylaxis of systemic embolism after myocardial infarction

Unlabeled/Investigational Use Prevention of recurrent transient ischemic attacks and to reduce risk of recurrent myocardial infarction

Mechanism of Action Interferes with hepatic synthesis of vitamin K-dependent coagulation factors (II, VII, IX, X)

Adverse Reactions

As with all anticoagulants, bleeding is the major adverse effect of warfarin. Hemorrhage may occur at virtually any site. Risk is dependent on multiple variables, including the intensity of anticoagulation and patient susceptibility.

Additional adverse effects are often related to idiosyncratic reactions, and the frequency cannot be accurately estimated.

Cardiovascular: Vasculitis, edema, hemorrhagic shock

Central nervous system: Fever, lethargy, malaise, asthenia, pain, headache, dizziness, stroke

Dermatologic: Rash, dermatitis, bullous eruptions, urticaria, pruritus, alopecia

Gastrointestinal: Anorexia, nausea, vomiting, stomach cramps, abdominal pain, diarrhea, flatulence, gastrointestinal bleeding, taste disturbance, mouth ulcers

Genitourinary: Priapism, hematuria

Hematologic: Hemorrhage, leukopenia, unrecognized bleeding sites (eg, colon cancer) may be uncovered by anticoagulation, retroperitoneal hematoma, agranulocytosis

Hepatic: Increased transaminases, hepatic injury, jaundice

Neuromuscular & skeletal: Paresthesia, osteoporosis

Respiratory: Hemoptysis, epistaxis, pulmonary hemorrhage, tracheobronchial calcification

Miscellaneous: Hypersensitivity/allergic reactions

Skin necrosis/gangrene, due to paradoxical local thrombosis, is a known but rare risk of warfarin therapy. Its onset is usually within the first few days of therapy and is frequently localized to the limbs, breast or penis. The risk of this effect is increased in patients with protein C or S deficiency.

"Purple toes syndrome," caused by cholesterol microembolization, also occurs rarely. Typically, this occurs after several weeks of therapy, and may present as a dark, purplish, mottled discoloration of the plantar and lateral surfaces. Other manifestations of cholesterol microembolization may include rash; livedo reticularis; gangrene; abrupt and intense pain in lower extremities; abdominal, flank, or back pain; hematuria; renal insufficiency; hypertension; cerebral ischemia; spinal cord infarction; or other symptom of vascular compromise.

Signs and Symptoms of Overdose Alopecia, bleeding gums, cholelithiasis, circulatory collapse, coagulopathy, esophageal ulceration, eosinophilia, feces discoloration (black; light brown; pink; red; tarry), hematuria, hepatitis, intracranial hemorrhage, numbness, ocular hemorrhage, pericardial effusion/pericarditis, urine discoloration (orange)

Admission Criteria/Prognosis Patients with bleeding, prolonged prothrombin time, or history of a large ingestion (>0.5 mg/kg) should be considered for admission.

Pharmacodynamics/Kinetics

Onset of action: Anticoagulation: Oral: 36-72 hours

Peak effect: Full therapeutic effect: 5-7 days; INR may increase in 36-72 hours

Peak effect after one dose - 3 hours

Duration: 2-5 days

Absorption: Oral: Rapid

Metabolism: Hepatic

Half-life elimination: 20-60 hours; Mean: 40 hours; highly variable among individuals

Protein Binding - 98%

Dosage

Infants and Children: 0.05-0.34 mg/kg/day; infants <12 months of age may require doses at or near the high end of this range; consistent anticoagulation may be difficult to maintain in children <5 years of age

Adults: Initial dosing must be individualized. Consider the patient (hepatic function, cardiac function, age, nutritional status, concurrent therapy, risk of bleeding) in addition to prior dose response (if available) and the clinical situation. Start 5-10 mg daily for 2 days. Adjust dose according to INR results; usual maintenance dose ranges from 2-10 mg daily (individual patients may require loading and maintenance doses outside these general guidelines).

Note: Lower starting doses may be required for patients with hepatic impairment, poor nutrition, CHF, elderly, or a high risk of bleeding. Higher initial doses may be reasonable in selected patients (ie, receiving enzyme-inducing agents and with low risk of bleeding).

I.V. (administer as a slow bolus injection): 2-5 mg/day

Dosing adjustment/comments in hepatic disease: Monitor effect at usual doses; the response to oral anticoagulants may be markedly enhanced in obstructive jaundice (due to reduced vitamin K absorption) and also in hepatitis and cirrhosis (due to decreased production of vitamin K-dependent clotting factors); prothrombin index should be closely monitored

Monitoring Parameters Prothrombin time, hematocrit, INR

Administration Oral: Do not take with food. Take at the same time each day.

I.V.: Administer as a slow bolus injection over 1-2 minutes; avoid all I.M. injections

Contraindications Hypersensitivity to warfarin or any component of the formulation; hemorrhagic tendencies; hemophilia; thrombocytopenia purpura; leukemia; recent or potential surgery of the eye or CNS; major regional lumbar block anesthesia or surgery resulting in large, open surfaces; patients bleeding from the GI, respiratory, or GU tract; threatened abortion; aneurysm; ascorbic acid deficiency; history of bleeding diathesis; prostatectomy; continuous tube drainage of the small intestine; polyarthritis; diverticulitis; emaciation; malnutrition; cerebrovascular hemorrhage; eclampsia/pre-eclampsia; blood dyscrasias; severe uncontrolled or malignant hypertension; severe hepatic disease; pericarditis or pericardial effusion; subacute bacterial endocarditis; visceral carcinoma; following spinal puncture and other diagnostic or therapeutic procedures with potential for significant bleeding; history of warfarin-induced necrosis; an unreliable, noncompliant patient; alcoholism; patient who has a history of falls or is a significant fall risk; pregnancy

Warnings

Use care in the selection of patients appropriate for this treatment. Ensure patient cooperation especially from the alcoholic, illicit drug user, demented, or psychotic patient. Use with caution in trauma, acute infection (antibiotics and fever may alter affects), renal insufficiency, prolonged dietary insufficiencies (vitamin K deficiency), moderate-severe hypertension, polycythemia vera, vasculitis, open wound, active TB, history of PUD, anaphylactic disorders, indwelling catheters, severe diabetes, thyroid disease, severe renal disease, and menstruating and postpartum women. Use with caution in protein C deficiency.

Hemorrhage is the most serious risk of therapy. Patient must be instructed to report bleeding, accidents, or falls. Patient must also report any new or discontinued medications, herbal or alternative products used, significant changes in smoking or dietary habits. Necrosis or gangrene of the skin and other tissues can occur (rarely) due to early hypercoagulability. "Purple toes syndrome," due to cholesterol microembolization, may rarely occur (often after several weeks of therapy). Women may be at risk of developing ovarian hemorrhage at the time of ovulation. The elderly may be more sensitive to anticoagulant therapy.

Dosage Forms Injection, powder for reconstitution, as sodium (Coumadin®): 5 mg

Tablet, as sodium (Coumadin®, Jantoven™): 1 mg, 2 mg, 2.5 mg, 3 mg, 4 mg, 5 mg, 6 mg, 7.5 mg, 10 mg

WARFARIN

Reference Range

Therapeutic serum warfarin levels: 2-5 mcg/mL (SI: 6.5-16.2 μ mol/L)
 Prothrombin time should be $1\frac{1}{2}$ to 2 times the control or INR should be \uparrow
 2 to 3 times based upon indication
 Normal prothrombin time: 10-13 seconds
INR ranges based upon indication: See table.

INR Ranges Based Upon Indication		
Indication	Targeted INR Range	Targeted INR
Acute myocardial infarction with risk factor ¹	2.0-3.0	2.5
Atrial fibrillation (moderate- to high-risk patients)	2.0-3.0	2.5
Bileaflet or tilting disk mechanical aortic valve (NSR, NL LA)	2.0-3.0	2.5
Bileaflet mechanical aortic valve with atrial fibrillation	2.5-3.5	3
Bileaflet mechanical aortic valve with atrial fibrillation with ASA 80-100 mg/day	2.0-3.0	2.5
Bileaflet or tilting disk mechanical mitral valve	2.5-3.5	3
Bileaflet or tilting disk mechanical mitral valve with ASA 80-100 mg/day	2.0-3.0	2.5
Bioprosthetic mitral or aortic valve ²	2.0-3.0	2.5
Bioprosthetic mitral or aortic valve with atrial fibrillation	2.0-3.0	2.5
Cardioembolic cerebral ischemic events	2.0-3.0	2.5
Mechanical heart valve (caged ball, caged disk) with ASA 80-100 mg/day	2.5-3.5	3
Mechanical prosthetic valve with systemic embolism despite adequate anticoagulation ³	2.5-3.5	3
Rheumatic mitral valve disease and NSR (left atrial diameter >5.5 cm)	2.0-3.0	2.5
Venous thromboembolism	2.0-3.0	2.5

¹Up to 3 months of therapy following heparin or LMWH in patients with anterior Q-wave infarction, severe left-ventricular dysfunction, mural thrombus on 2D echo, atrial fibrillation, history of systemic or pulmonary embolism, congestive heart failure.

²Maintained for 3 months; chronic low-dose aspirin (80 mg/day) after warfarin therapy.

³Add ASA 80-100 mg/day.

For complete discussion, See *Chest*, 2001, 119(Suppl):1S-370S

Warfarin levels are not used for monitoring degree of anticoagulation. They may be useful if a patient with unexplained coagulopathy is using the drug surreptitiously or if it is unclear whether clinical resistance is due to true drug resistance or lack of drug intake.

Normal prothrombin time (PT): 10.9-12.9 seconds. Healthy premature newborns have prolonged coagulation test screening results (eg, PT, aPTT, TT) which return to normal adult values at approximately 6 months of age. Healthy prematures, however, do not develop spontaneous hemorrhage or thrombotic complications because of a balance between procoagulants and inhibitors.

The World Health Organization (WHO), in cooperation with other regulatory-advisory bodies, has developed system of standardizing the reporting of PT values through the determination of the International

Normalized Ratio (INR). The INR involves the standardization of the PT by the generation of two pieces of information: the PT ratio and the International Sensitivity Index (ISI)

Therapeutic ranges are now available or being developed to assist practicing physicians in their treatment of patients with a wide variety of thrombotic disorders

Overdosage/Treatment

Decontamination: Activated charcoal should be given for ingestions >4 mg/kg

Supportive therapy: Critically prolonged INR and bleeding complications can be treated successfully with recombinant factor (dose range: 15-90 mcg/kg body weight). Indications for use of rFVIIa have included an INR > 10 in high-risk persons or clinical hemorrhage. Check urine and stool for blood; fresh frozen plasma (15 mL/kg) should be administered; vitamin K₁ should be given in doses as outlined: See table.

For active bleeding: Prothrombin complex concentrate (which contains Factors II, VII, IX and X) at 50 units per kg IV can be given. Alternatively recombinant coagulation activated factor VII at doses of 70 to 90 mcg/kg or 1.2 to 4.8 mg total can also be given. Either complex should be given in conjunction with Vitamin K.

Management of Elevated INR		
INR	Patient Situation	Action
>3 and <5	No bleeding or need for rapid reversal (ie, no need for surgery)	Omit next few warfarin doses and/or restart at lower dose when INR approaches desired range. If only minimally above range, then no dosage reduction may be required.
>5 and <9.0	No bleeding or need for rapid reversal	Omit next 1-2 doses, monitor INR more frequently, and restart at lower dose when INR approaches target range or omit dose and give 1-2.5 mg vitamin K orally (use this if patient has risk factors for bleeding).
	No bleeding but reversal needed for surgery or dental extraction within 24 hours	Vitamin K 2-4 mg orally (expected reversal within 24 hours); give additional 1-2 mg if INR remains high at 24 hours.
>9.0 and <20.0	No bleeding	Stop warfarin, give vitamin K 3-5 mg orally; follow INR closely; repeat vitamin K if needed. Reassess need and dose of warfarin when INR approaches desirable range.
Rapid reversal required (ie, INR >20)	Serious bleeding or major warfarin overdose	Stop warfarin, give vitamin K 10 mg by slow I.V. infusion. May repeat vitamin K every 12 hours and give fresh plasma transfusion or prothrombin complex concentrate as needed. When appropriate, heparin can be given until the patient becomes responsive to warfarin.

Enhancement of elimination: Cholestyramine or multiple dosing of activated charcoal may be useful

Antidote(s)

- Cholestyramine Resin [ANTIDOTE]
- Phytonadione [ANTIDOTE]

Diagnostic Procedures

- Warfarin, Blood

Test Interactions \uparrow aPTT

Drug Interactions **Substrate** of CYP1A2 (minor), 2C9 (major), 2C19 (minor), 3A4 (minor); **Inhibits** CYP2C9 (moderate), 2C19 (weak)

Acetaminophen: May enhance the anticoagulant effect of warfarin. Most likely to occur with daily acetaminophen doses > 1.3 g for > 1 week.

Allopurinol: May enhance the anticoagulant effect of warfarin. Reductions in warfarin will likely be required.

Aminoglutethimide: May increase the metabolism, via CYP isoenzymes, of warfarin. Monitor therapy for decreased warfarin effect.

- Amiodarone: May enhance the anticoagulant effect of warfarin. An empiric warfarin dosage reduction of 30% to 50% at the initiation of warfarin may be considered.
- Androgens: May enhance the anticoagulant effect of warfarin. Significant reductions in warfarin dosage may be needed during concomitant therapy.
- Antifungal agents (imidazole): May decrease the metabolism, via CYP isoenzymes, of warfarin. Monitor for increased therapeutic/toxic effects of warfarin.
- Antithyroid agents: May diminish the anticoagulant effects of warfarin. Monitor for decreased therapeutic effects.
- Aprepitant: May decrease the serum concentration of warfarin. Monitor closely for 2 weeks following each course of aprepitant.
- Azathioprine: May decrease the anticoagulant effect of warfarin. An adjustment in warfarin dose may be needed.
- Barbiturates: May increase the metabolism, via CYP isoenzymes, of warfarin. Monitor for decreased therapeutic effect of warfarin. Anticoagulation dosage increase of 30% to 60% may be needed based upon monitored PT.
- Bile acid sequestrants: May decrease absorption of warfarin. Separating the administration of doses by >2 hours may reduce the risk of interaction.
- Bosentan: May increase metabolism, via CYP isoenzymes, of warfarin. Monitor for decreased effects.
- Capecitabine: May decrease metabolism of warfarin. Monitor for evidence of excess anticoagulation.
- Carbamazepine: May increase the metabolism, via CYP isoenzymes, of warfarin. Monitor for decreased therapeutic effect of warfarin.
- Cephalosporins: May enhance the anticoagulant effect of warfarin. Monitor for increased evidence of bleeding especially in cephalosporins that have NMTT side chain.
- Cimetidine: May enhance the anticoagulant effect of warfarin. Monitor for increased therapeutic effects of warfarin.
- Contraceptives, hormonal (estrogens and progestins): May diminish the anticoagulant effect of warfarin. Monitor for changes in coagulation status.
- COX-2 inhibitor: May enhance the anticoagulant effect of warfarin. Monitor for increased signs and symptoms of bleeding.
- CYP2C9 inducers (strong): May increase the metabolism of warfarin. Examples of inducers include: Carbamazepine, fosphenytoin, phenobarbital, phenytoin, primidone, rifampin, rifapentine, secobarbital. Monitor for decreased effect of warfarin.
- CYP2C9 Inhibitors may increase the levels/effects of warfarin. Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nicardipine, NSAIDs, sulfonamides and tolbutamide.
- Dicloxacillin: May increase the metabolism, via CYP isoenzymes, of warfarin. Monitor for decreased therapeutic effect of warfarin.
- Disulfiram: May increase the serum concentration of warfarin. Monitor for increased therapeutic effects of warfarin.
- Drotrecogin Alfa: Warfarin may enhance the adverse/toxic effect of drotrecogin alfa. Monitor for increased risk of bleeding during concomitant therapy. If possible, avoid use of drotrecogin within 7 days of warfarin therapy, or if INR ≥ 3 .
- Etoposide: May enhance the anticoagulant effect of warfarin. Monitor for increased effects of warfarin.
- Fibric acid derivatives: May enhance the anticoagulant effect of warfarin. Monitor for toxic effects of warfarin; may warrant a 25% to 33% reduction in the warfarin dosage.
- Fluconazole: May decrease the metabolism, via CYP isoenzymes, of warfarin. Monitor for increased therapeutic/toxic effects warfarin.
- Fluorouracil: May enhance the anticoagulant effect of warfarin. Monitor for increased effects of warfarin.
- Glucagon: May enhance the anticoagulant effect of warfarin. Monitor for toxic effects of warfarin, especially if glucagon is administered in high doses.
- Glutethimide: May increase the metabolism, via CYP isoenzymes, of warfarin. Consider alternative sedative-hypnotic. Monitor for decreased therapeutic effects of warfarin.
- Griseofulvin: May increase the metabolism, via CYP isoenzymes, of warfarin. Monitor for decreased therapeutic effects of warfarin.
- HMG-CoA reductase inhibitors: May enhance the anticoagulant effect of warfarin. Monitor for increased effects of warfarin.
- Ifosfamide: May enhance the anticoagulant effect of warfarin. Monitor for increased effects of warfarin.
- Leflunomide: May enhance the anticoagulant effect of warfarin. Monitor for increased effects of warfarin.
- Macrolide antibiotics: May decrease the metabolism, via CYP isoenzymes, of warfarin. Monitor for increased therapeutic effects of warfarin. CYP inhibitors (eg, clarithromycin, erythromycin, and troleandomycin) appear to pose the greatest risk. Azithromycin and telithromycin have also been implicated in a few cases.
- Mercaptopurine: May diminish the anticoagulant effect of warfarin. Monitor for decreased therapeutic effects of warfarin.
- Metronidazole: May decrease the metabolism, via CYP isoenzymes, of warfarin. If concomitant therapy is necessary, consider an empiric reduction in warfarin dosage of approximately one-third. Monitor for increased therapeutic/toxic effects of warfarin.
- Nafcillin: May increase the metabolism of warfarin. Consider choosing an alternative antibiotic if available. Monitor for decreased therapeutic effect of warfarin if nafcillin is initiated. The effects on warfarin dosing may persist long after the nafcillin is discontinued. Close monitoring is required even after nafcillin is discontinued.
- NSAID (nonselective): May enhance the anticoagulant effect of warfarin. Monitor for increased signs and symptoms of bleeding.
- Orlistat: May enhance the anticoagulant effect of warfarin. Monitor for changes in effects of warfarin.
- Phenytoin: May enhance the anticoagulant effect of warfarin. Warfarin may increase the serum concentration of phenytoin. Monitor for increased effects of warfarin and for increased serum concentrations/toxic effects of phenytoin.
- Phytonadione: May antagonize the effects of warfarin. Monitor for decreased therapeutic effect of warfarin.
- Propafenone: May increase the serum concentration of warfarin. Monitor for increased prothrombin times (PT)/therapeutic effects of warfarin.
- Propoxyphene: May decrease the metabolism, via CYP isoenzymes, of warfarin. Monitor for increased prothrombin time/toxic effects of warfarin.
- Proton pump inhibitors (omeprazole): May increase the serum concentration of warfarin. Monitor for increased effects of warfarin.
- Quinidine: May enhance the anticoagulant effect of warfarin. Monitor for increased prothrombin times (PT)/therapeutic effects of warfarin.
- Quinolone antibiotics: May enhance the anticoagulant effect of warfarin. Monitor for increased prothrombin time/toxic effects of warfarin.
- Rifamycin derivatives: May increase the metabolism, via CYP isoenzymes, of warfarin. Monitor for decreased prothrombin times (PT)/therapeutic effects of warfarin.
- Ropinirole: May enhance the anticoagulant effect of warfarin. Monitor for increased INR/effects of warfarin.
- Salicylates: May enhance the anticoagulant effect of warfarin. Monitor for increased signs and symptoms of bleeding if used concomitantly.
- Selective serotonin reuptake inhibitors (SSRIs): May enhance the anticoagulant effect of warfarin. Monitor for increased therapeutic/toxic effects of warfarin.
- Sulfasalazine: May diminish the anticoagulant effect of warfarin. Monitor for decreased INR/effects of warfarin.
- Sulfapyrazone: May decrease the metabolism, via CYP isoenzymes, of warfarin and may decrease the protein binding of warfarin. Monitor for increased prothrombin time (PT)/toxic effects of warfarin.
- Sulfonamide derivatives: May enhance the anticoagulant effect of warfarin. Monitor for increased prothrombin time (PT)/toxic effects of warfarin.
- Tetracycline derivatives: May enhance the anticoagulant effect of warfarin. Monitor for toxic effects of warfarin.
- Thyroid products: May enhance the anticoagulant effect of warfarin. Monitor for increased hypoprothrombinemic effects of warfarin.
- Tigecycline: May increase the serum concentration of warfarin. Monitor for increased effects of warfarin.
- Tolterodine: May increase the effects of warfarin.
- Treprostinil: May enhance the adverse/toxic effect of warfarin. Monitor for increased risk of bleeding when used concomitantly.
- Tricyclic antidepressants: May enhance the anticoagulant effect of warfarin. Monitor for increased prothrombin times (PT)/toxic effects of warfarin.
- Vitamin A: May enhance the anticoagulant effect of warfarin. Monitor for increased prothrombin time (PT)/effects of warfarin.
- Vitamin E: May enhance the anticoagulant effect of warfarin. Monitor for increased prothrombin time (PT)/effects of warfarin. Likely only of significant concern with higher doses of vitamin E (eg, 1200 int. units/day).
- Voriconazole: May increase the serum concentration of warfarin. Monitor for increased effects (eg, INR, bleeding) of warfarin.
- Zafirlukast: May decrease the metabolism, via CYP isoenzymes, of warfarin. Monitor for increased prothrombin time (PT)/effects of warfarin.
- Zileuton: May increase the serum concentration of warfarin. Monitor for increased effects of warfarin.

Pregnancy Risk Factor D

Pregnancy Implications Oral anticoagulants cross the placenta and produce fetal abnormalities. Warfarin should not be used during pregnancy because of significant risks. Adjusted-dose heparin can be given safely throughout pregnancy in patients with venous thromboembolism.

Lactation Does not enter breast milk, only metabolites are excreted (AAP rates "compatible")

Additional Information High intensity warfarin therapy (titrated to an internal normalized ratio ≥ 3) can prevent thrombosis in patients with

WARFARIN

antiphospholipid antibody syndrome; for I.V. injection, reconstitute with 2.7 mL of sterile water to yield 2 mg/mL.

The chart provides information about the amount of reconstituted solution of Coumadin® for injection that corresponds to a specific dose

Warfarin Dosage	
Desired Dose of Coumadin® (mg)	Coumadin® for Injection Administration Volume (mL)
0.5	0.25
1	0.50
1.5	0.75
2	1
2.5	1.25
3	1.50
3.5	1.75
4	2
4.5	2.25
5	2.50
5.5	2.75*
6	3*
6.5	3.25*
7	3.50*
7.5	3.75*
8	4*
8.5	4.25*
9	4.50*
9.5	4.75*
10	5*

*More than 1 vial required for this dose.

Further information can be obtained by calling Bristol-Myers Squibb: 800-321-1335

TLV-TWA: 0.1 mg/m³; IDLH: 200 mg/m³ (industrial exposure)

The first month of therapy appears to be the period of highest risk of bleeding (1.6% incidence).

Onset of coagulopathy after an acute ingestion (over 4 mg/kg) is 18 to 48 hours. Skin Necrosis due to Protein C deficiency occurs within ten days of use with a female predominance. Starts as painful red patches (hemorrhage) in high fat areas (Breasts, Buttocks). Purple toe syndrome is due to cholesterol crystal emboli from bleeding into atherosclerotic plaques. It occurs 3 to ten weeks after start of therapy and usually appears as a purple discoloration of the plantar surface of the toes.

Xylazine

CAS Number 7361-61-7

Use Animal tranquilizing agent

Mechanism of Action Structurally similar to clonidine and phenothiazines, this agent acts by stimulation of α_2 receptors in the central and peripheral nervous systems

Signs and Symptoms of Overdose Apnea, bradycardia, coma (at doses >1 g), drowsiness, hyperglycemia (mild), hyporeflexia, hypotension (although transient paradoxical hypertension has been described), hypotonia, incontinence, miosis

Admission Criteria/Prognosis Admit any symptomatic patient or exposure to concentrations >0.5 mg/kg

Toxicodynamics/Kinetics

Onset of action: Within 30 minutes

Absorption: Well-absorbed orally

Metabolism: Hepatic; primary metabolite is 2,6-dimethylaniline

Half-life: 4.9 hours (after I.M. overdose)

Elimination: Primarily renal

Dosage Animals: I.V./I.M.: 0.5-5 mg/kg

Reference Range Following injection (I.M.) of 1.5 g xylazine and resultant coma, serum and urinary concentrations were 4.6 mg/L and 194 mg/L, respectively

Overdosage/Treatment

Decontamination: Oral: Activated charcoal

Supportive therapy: Hypotension can initially be treated with I.V. isotonic saline (10-20 mL/kg) and Trendelenburg positioning. Dopamine or norepinephrine can be used for refractory hypotension. Tolazoline (10 mg I.V. repeated every 5-10 minutes to a maximum of 40 mg I.V.) may also be useful. Atropine is useful in treatment of bradycardia. For treatment of nontransient hypertension, phentolamine is the drug of choice. Naloxone is **not** useful in reversing coma.

Yohimbine

CAS Number 146-48-5; 65-19-0

U.S. Brand Names Aphrodyne®; Yocon®

Synonyms Yohimbine Hydrochloride

Impairment Potential Yes. Doses of 10-30 mg can produce central nervous system stimulation including mydriasis; dissociative state similar to phencyclidine can occur with excessive dosages (~250 mg). (Linden CH, Vellman WP, and Rumack B, "Yohimbine: A New Street Drug," *Ann Emerg Med*, 1985, 14(10):1002-4.)

Unlabeled/Investigational Use Treatment of SSRI-induced sexual dysfunction; weight loss; impotence; sympatholytic and mydriatic; may have activity as an aphrodisiac; used in veterinary medicine as a reversal agent for xylazine

Mechanism of Action Derived from the bark of the yohimbe tree (*Pausinystalia yohimbe*), this indole alkaloid produces an α_2 -adrenergic blockade; also is a weak MAO inhibitor; parasympathetic tone is also decreased

Adverse Reactions

Cardiovascular: Tachycardia, bradycardia, hypertension, hypotension (orthostatic), flushing, shock, sinus tachycardia, vasodilation, sinus bradycardia

Central nervous system: Anxiety, mania, hallucinations, irritability, dizziness, psychosis, insomnia, headache, panic attacks

Gastrointestinal: Nausea, vomiting, anorexia

Hematologic: Neutropenia, agranulocytosis

Neuromuscular & skeletal: Tremors, paresthesia

Ocular: Lacrimation, mydriasis

Respiratory: Bronchospasm, sinusitis

Miscellaneous: Antidiuretic action, salivation, diaphoresis, systemic lupus erythematosus

Pharmacodynamics/Kinetics

Duration of action: Usually 3-4 hours, but may last 36 hours

Absorption: 33%

Distribution: V_d : 0.3-3 L/kg

Half-life elimination: 0.6 hour

Dosage Adults: Oral: Impotence: 5.4 mg 3 times/day

Contraindications Hypersensitivity to yohimbine or any component of the formulation; renal disease

Warnings Do not use in pregnancy; do not use in children; not for use in geriatric, psychiatric, or cardio-renal patients with a history of gastric or duodenal ulcer; generally not for use in females. Should not be used in kidney disease or psychiatric disorders; can cause high blood pressure and anxiety, tachycardia, nausea, or vomiting.

Dosage Forms Tablet, as hydrochloride: 5.4 mg

Reference Range After a 10 mg oral dose, peak plasma yohimbine level achieved was ~75 mcg/L after 45 minutes

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: For hypertension, nifedipine or labetalol may be useful; for hypertensive emergencies, phentolamine with nitroprusside is useful; benzodiazepines can be used for agitation; clonidine (5 mcg/kg) may be particularly useful in treating hypertension or anxiety; phenothiazines and tricyclic antidepressants can potentiate psychic effects and thus should be avoided

Test Interactions Possible \uparrow catecholamine levels

Drug Interactions

Substrate of CYP2D6 (minor); **Inhibits** CYP2D6 (weak)

Antihypertensives: Effect of antihypertensives may be reduced by yohimbine

CNS active agents: Caution with other CNS acting drugs

Linezolid: Due to MAO inhibition (see note on MAO inhibitors), combinations with this agent should generally be avoided

MAO inhibitors: Theoretically may increase toxicity or adverse effects

Additional Information Also a street drug of abuse that can be smoked; has a bitter taste; dissociative state may resemble phencyclidine intoxication

Specific References

Dargan PI, Shiew CM, Greene SL, et al, "Yohimbine Poisoning from Slimming Pills Bought over the Internet," *Clin Toxicol (Phila)*, 2005, 43:661.

Zafirlukast

U.S. Brand Names Accolate®

Synonyms ICI-204,219

Use Prophylaxis and chronic treatment of asthma in adults and children ≥ 5 years of age

Mechanism of Action An inhibitor of the sulfidopeptide leukotrienes which can cause bronchoconstriction

Adverse Reactions

Central nervous system: **Headache**

Dermatologic: Alopecia, cutaneous vasculitis

Gastrointestinal: Xerostomia

Hepatic: Elevation of hepatic enzymes

Neuromuscular & skeletal: Weakness

Respiratory: **Pharyngitis**, rhinitis, pulmonary vasculitis

Miscellaneous: Churg-Strauss syndrome (rare), lupus

Pharmacodynamics/Kinetics

Protein binding: >99%, primarily to albumin

Metabolism: Extensively hepatic via CYP2C9

Bioavailability: Reduced 40% with food

Half-life elimination: 10 hours

Time to peak, serum: 3 hours

Excretion: Urine (10%); feces

Dosage

Oral:

Children <5 years: Safety and effectiveness have not been established

Children 5-11 years: 10 mg twice daily

Children ≥ 12 years and Adults: 20 mg twice daily

Elderly: The mean dose (mg/kg) normalized AUC and C_{max} increase and plasma clearance decreases with increasing age. In patients >65 years of age, there is a two- to threefold greater C_{max} and AUC compared to younger adults.

Dosing adjustment in renal impairment: There are no apparent differences in the pharmacokinetics between renally impaired patients and normal subjects.

Dosing adjustment in hepatic impairment: In patients with hepatic impairment (ie, biopsy-proven cirrhosis), there is a 50% to 60% greater C_{max} and AUC compared to normal subjects.

Monitoring Parameters Monitor for improvements in air flow; monitor closely for sign/symptoms of hepatic injury; periodic monitoring of LFTs may be considered (not proved to prevent serious injury, but early detection may enhance recovery)

Administration Administer at least 1 hour before or 2 hours after a meal
Contraindications Hypersensitivity to zafirlukast or any component of the formulation

Warnings

Zafirlukast is not indicated for use in the reversal of bronchospasm in acute asthma attacks, including status asthmaticus. Therapy with zafirlukast can be continued during acute exacerbations of asthma.

Hepatic adverse events (including hepatitis, hyperbilirubinemia, and hepatic failure) have been reported; female patients may be at greater risk. Discontinue immediately if liver dysfunction is suspected. Periodic testing of liver function may be considered (early detection is generally believed to improve the likelihood of recovery). If hepatic dysfunction is suspected (due to clinical signs/symptoms), liver function tests should be measured immediately. Do not resume or restart if hepatic function studies are consistent with dysfunction. Use caution in patients with alcoholic cirrhosis; clearance is reduced.

Rare cases of eosinophilic vasculitis (Churg-Strauss) have been reported in patients receiving zafirlukast (usually, but not always, associated with reduction in concurrent steroid dosage). No causal relationship established. Monitor for eosinophilic vasculitis, rash, pulmonary symptoms, cardiac symptoms, or neuropathy.

An increased proportion of zafirlukast patients >55 years of age reported infections as compared to placebo-treated patients. These infections were mostly mild or moderate in intensity and predominantly affected the respiratory tract. Infections occurred equally in both sexes, were dose-proportional to total milligrams of zafirlukast exposure, and were associated with coadministration of inhaled corticosteroids.

Dosage Forms Tablet: 10 mg, 20 mg

Reference Range Peak serum levels after a 20 mg and 40 mg oral dose: ~150 ng/mL and 250 ng/mL, respectively; plasma zafirlukast levels >5 ng/mL are associated with inhibition of leukotriene D_4 -induced bronchoconstriction

Overdosage/Treatment

Decontamination: Activated charcoal

Enhanced elimination: Multiple dosing of activated charcoal may be effective

Test Interactions May interfere with plasma bilirubin assay

Drug Interactions **Substrate** of CYP2C9 (major); **Inhibits** CYP1A2 (weak), 2C8 (weak), 2C9 (moderate), 2C19 (weak), 2D6 (weak), 3A4 (weak)

Aspirin: Coadministration of zafirlukast with aspirin results in mean increased plasma levels of zafirlukast by 45%

CYP2C9 inducers: May decrease the levels/effects of zafirlukast. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C9 substrates: Zafirlukast may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapson, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

Erythromycin: Coadministration of a single dose of zafirlukast with erythromycin to steady state results in decreased mean plasma levels of zafirlukast by 40% due to a decrease in zafirlukast bioavailability.

Theophylline: Coadministration of zafirlukast at steady state with a single dose of liquid theophylline preparations results in decreased mean plasma levels of zafirlukast by 30%, but no effects on plasma theophylline levels were observed. Cases of increased theophylline serum concentrations have been reported.

Warfarin: Coadministration of zafirlukast with warfarin results in a clinically significant increase in prothrombin time (PT). Closely monitor prothrombin times of patients on oral warfarin anticoagulant therapy and zafirlukast, and adjust anticoagulant dose accordingly.

Pregnancy Risk Factor B

Pregnancy Implications There are no adequate and well-controlled trials in pregnant women. Teratogenic effects not observed in animal studies; fetal defects were observed when administered in maternally toxic doses.

Lactation Enters breast milk/contraindicated

Additional Information Food decreases bioavailability of zafirlukast by 40%. Questions regarding use can be directed to AstraZeneca Pharmaceuticals, Wilmington, Delaware; (800) 456-3669

Zalcitabine

CAS Number 7481-89-2

U.S. Brand Names Hivid®

Synonyms ddC; Dideoxycytidine

Use Orphan drug use in the treatment of AIDS

Mechanism of Action Purine nucleoside (cytosine) analog, zalcitabine or 2',3'-dideoxycytidine (ddC) is converted to active metabolite ddCTP; lack the presence of the 3'-hydroxyl group necessary for phosphodiester linkages during DNA replication. As a result viral replication is prematurely terminated. ddCTP acts as a competitor for binding sites on the HIV-RNA dependent DNA polymerase (reverse transcriptase) to further contribute to inhibition of viral replication.

Adverse Reactions

Cardiovascular: Fibrillation (atrial), flutter (atrial), cardiomegaly, cardiomyopathy, palpitations, sinus tachycardia, arrhythmias (ventricular)

Central nervous system: Fever, malaise, amnesia

Dermatologic: Pruritus, urticaria, angioedema

Endocrine & metabolic: Hypoglycemia, hyperglycemia, hypophosphatemia, hypernatremia, hyponatremia, hypocalcemia, hypomagnesemia

Gastrointestinal: **Oral ulcers**, anorexia, pancreatitis, diarrhea, nausea, vomiting, aphthous stomatitis

Hematologic: **Neutropenia**, eosinophilia, anemia, thrombocytopenia

Hepatic: Hepatotoxicity

Neuromuscular & skeletal: Distal neuropathy (peripheral), arthralgias

Otic: Tinnitus

Miscellaneous: Night sweats

Pharmacodynamics/Kinetics

Absorption: Well, but variable; decreased 39% with food

Distribution: Minimal data available; variable CSF penetration

Protein binding: <4%

Metabolism: Intracellularly to active triphosphorylated agent

Bioavailability: >80%

Half-life elimination: 2.9 hours; Renal impairment: ≤8.5 hours

Excretion: Urine (>70% as unchanged drug)

Dosage

Oral:

Neonates: Dose unknown

Infants and Children <13 years: Safety and efficacy have not been established; investigational dose: 0.01 mg/kg every 8 hours

Adolescents and Adults: 0.75 mg 3 times/day

Dosing adjustment in renal impairment: Adults:

Cl_{cr} 10-40 mL/minute: 0.75 mg every 12 hours

Cl_{cr} <10 mL/minute: 0.75 mg every 24 hours

Moderately dialyzable (20% to 50%)

Monitoring Parameters Renal function, viral load, liver function tests, CD4 counts, CBC, serum amylase, triglycerides, calcium

Administration Food decreases absorption; take on an empty stomach.

Administer around-the-clock. Do not take at the same time with dapsone.

Contraindications Hypersensitivity to zalcitabine or any component of the formulation

Warnings Careful monitoring of pancreatic enzymes and liver function tests in patients with a history of pancreatitis, increased amylase, those on parenteral nutrition or with a history of ethanol abuse. **[U.S. Boxed Warning]: Discontinue use immediately if pancreatitis is suspected.**

[U.S. Boxed Warning]: Lactic acidosis and severe hepatomegaly and failure have rarely occurred with zalcitabine resulting in fatality (stop treatment if lactic acidosis or hepatotoxicity occur); some cases may possibly be related to underlying hepatitis B; use with caution in patients on digitalis, or with CHF, renal failure, or hyperphosphatemia. **[U.S. Boxed Warning]: Zalcitabine can cause severe peripheral neuropathy;** avoid use, if possible, in patients with pre-existing neuropathy or at risk of developing neuropathy. Risk factors include CD4 counts <50 cells/mm³, diabetes mellitus, weight loss, other drugs known to cause peripheral neuropathy.

Dosage Forms [DSC] = Discontinued product

Tablet:

Hivid®: 0.375 mg [DSC], 0.75 mg

Reference Range Therapeutic blood level: ~0.5 μmol/L

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; dialysis may be effective, although there is no data in an overdosage setting

Drug Interactions Antacids: Magnesium/aluminum-containing antacids may reduce zalcitabine absorption.

Doxorubicin: Decreases zalcitabine phosphorylation *in vitro*; clinical relevance unknown.

Metoclopramide: May reduce zalcitabine absorption.

Nephrotoxic drugs: Amphotericin, foscarnet, cimetidine, probenecid, and aminoglycosides may potentiate the risk of developing peripheral neuropathy or other toxicities associated with zalcitabine by interfering with the renal elimination of zalcitabine.

Neurotoxic drugs: Drugs associated with peripheral neuropathy which should be avoided, if possible; includes chloramphenicol, cisplatin, dapsone, disulfiram, ethionamide, glutethimide, didanosine, gold, hydralazine, iodoquinol, isoniazid, metronidazole, nitrofurantoin, phenytoin, ribavirin, and vincristine.

Reverse transcriptase inhibitors: It is not recommended that zalcitabine be given in combination with didanosine, stavudine, or lamivudine due to overlapping toxicities, virologic interactions, or lack of clinical data. Lamivudine has also been shown to decrease zalcitabine phosphorylation *in vitro*.

Ribavirin: Concomitant use of ribavirin and nucleoside analogues may increase the risk of developing hepatic decompensation or other signs of mitochondrial toxicity, including pancreatitis or lactic acidosis.

Pregnancy Risk Factor C

Pregnancy Implications It is not known if zalcitabine crosses the human placenta. Animal studies have shown zalcitabine to be teratogenic, developmental toxicities were also observed. Cases of lactic acidosis/hepatic steatosis syndrome have been reported in pregnant women receiving nucleoside analogue drugs. It is not known if pregnancy itself potentiates this known side effect; however, pregnant women may be at increased risk of lactic acidosis and liver damage. Hepatic enzymes and electrolytes should be monitored frequently during the 3rd trimester of pregnancy in women receiving nucleoside analogues. Health professionals are encouraged to contact the antiretroviral pregnancy registry to monitor outcomes of pregnant women exposed to antiretroviral medications (1-800-258-4263 or www.APRRegistry.com).

Lactation Excretion in breast milk unknown/contraindicated

Additional Information Can be combined with zidovudine (at a zidovudine dose of 200 mg every 8 hours); limiting dosage for distal, symmetrical neuropathy (peripheral) is 0.01 mg/kg every 8 hours; less bone marrow suppression than with zidovudine

Zaleplon

CAS Number 151319-34-5

U.S. Brand Names Sonata®

Impairment Potential Yes: Doses exceeding 10 mg

Use Short-term (7-10 days) treatment of insomnia (has been demonstrated to be effective for up to 5 weeks in controlled trial)

Mechanism of Action Zaleplon is unrelated to benzodiazepines, barbiturates, or other hypnotics. However, it interacts with the benzodiazepine GABA receptor complex. Nonclinical studies have shown that it binds selectively to the brain omega-1 receptor situated on the alpha subunit of the GABA-A receptor complex.

Adverse Reactions

Cardiovascular: Peripheral edema, chest pain, angina, bundle branch block, pericardial effusion, syncope, ventricular tachycardia

Central nervous system: Amnesia, anxiety, depersonalization, dizziness, hallucinations, hypesthesia, somnolence, vertigo, malaise, depression, lightheadedness, impaired coordination, fever, migraine, ataxia, dystonia

Dermatologic: Photosensitivity reaction, rash, pruritus, alopecia

Gastrointestinal: Abdominal pain, anorexia, colitis, dyspepsia, nausea, constipation, xerostomia, intestinal obstruction

Genitourinary: Dysmenorrhea, urinary retention

Hematologic: Eosinophilia

Neuromuscular & skeletal: Paresthesia, tremor, myalgia, weakness, back pain, arthralgia, dysarthria, facial paralysis, circumoral paresthesia

Ocular: Abnormal vision (at doses over 40 mg), eye pain, glaucoma, ptosis

Otic: Hyperacusis

Respiratory: Epistaxis, pulmonary embolus

Miscellaneous: Parosmia

Signs and Symptoms of Overdose CNS depression, ranging from drowsiness to coma. Mild overdose is associated with drowsiness, confusion, and lethargy. Serious case may result in ataxia, respiratory depression, hypotension, hypotonia, coma, and rarely death.

Pharmacodynamics/Kinetics

Onset of action: Rapid

Peak effect: ~1 hour

Duration: 6-8 hours

Absorption: Rapid and almost complete

Distribution: V_d : 1.4 L/kg

Protein binding: 60% ± 15%

Metabolism: Extensive, primarily via aldehyde oxidase to form 5-oxo-zaleplon and to a lesser extent by CYP3A4 to desethylzaleplon; all metabolites are pharmacologically inactive

Bioavailability: 30%

Half-life elimination: 1 hour

Time to peak, serum: 1 hour

Excretion: Urine (primarily metabolites, <1% as unchanged drug)

Clearance: Plasma: Oral: 3 L/hour/kg

Dosage Oral:

Adults: 10 mg at bedtime (range: 5-20 mg); has been used for up to 5 weeks of treatment in controlled trial setting

Elderly: 5 mg at bedtime

Dosage adjustment in renal impairment: No adjustment for mild to moderate renal impairment; use in severe renal impairment has not been adequately studied

Dosage adjustment in hepatic impairment: Mild to moderate impairment: 5 mg; not recommended for use in patients with severe hepatic impairment

Administration Immediately before bedtime or when the patient is in bed and cannot fall asleep

Contraindications Hypersensitivity to zaleplon or any component of the formulation

Warnings

Symptomatic treatment of insomnia should be initiated only after careful evaluation of potential causes of sleep disturbance. Failure of sleep disturbance to resolve after 7-10 days may indicate psychiatric and/or medical illness.

Use with caution in patients with depression, particularly if suicidal risk may be present. Use with caution in patients with a history of drug dependence. Abrupt discontinuance may lead to withdrawal symptoms. May impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive medications. Effects with other sedative drugs or ethanol may be potentiated.

Use with caution in the elderly, those with compromised respiratory function, or renal and hepatic impairment. Because of the rapid onset of action, zaleplon should be administered immediately prior to bedtime or after the patient has gone to bed and is having difficulty falling asleep. Capsules contain tartrazine (FDC yellow #5); avoid in patients with sensitivity (caution in patients with asthma).

Dosage Forms Capsule: 5 mg, 10 mg [contains tartrazine]

Reference Range Single oral zaleplon doses of 10 mg or 20 mg give an average zaleplon peak serum level of 26 mcg/L and 49 mcg/L, respectively, at 1.1 hours

Overdosage/Treatment

Decontamination: Activated charcoal or lavage within one hour at doses exceeding 1 mg/kg

Supportive therapy: Treatment is supportive. Flumazenil use is of uncertain benefit.

Drug Interactions

Substrate of CYP3A4 (minor)

Cimetidine: May increase zaleplon levels/effects; use 5 mg zaleplon as starting dose in patients receiving cimetidine

CNS depressants: Sedative effects may be additive with psychotropics; monitor for increased effect; includes anticonvulsants, antipsychotics, barbiturates, benzodiazepines, narcotic analgesics, and other sedative agents

Flumazenil: May diminish the sedative effect of zaleplon.

Rifamycin Derivatives: May decrease the levels/effects of zaleplon.

Pregnancy Risk Factor C

Pregnancy Implications Not recommended for use during pregnancy

Lactation Enters breast milk/not recommended

Additional Information Prescription quantities should not exceed a 1-month supply.

Zanamivir

Pronunciation (za NA mi veer)

CAS Number 139110-80-8

U.S. Brand Names Relenza®

Use Treatment of uncomplicated acute illness due to influenza virus A and B; treatment should only be initiated in patients who have been symptomatic for no more than 2 days. Prophylaxis against influenza virus A and B

Mechanism of Action Zanamivir inhibits influenza virus neuraminidase enzymes (sialidase), potentially altering virus particle aggregation and release. It is effective against influenza A and B replication.

Adverse Reactions

Most adverse reactions occurred at a frequency which was less than or equal to the control (lactose vehicle).

> 10%:

Central nervous system: Headache (prophylaxis 13% to 24%; treatment 2%)

Gastrointestinal: Throat/tonsil discomfort/pain (prophylaxis 8% to 19%)

Respiratory: Cough (prophylaxis 7% to 17%; treatment ≤2%), nasal signs and symptoms (prophylaxis 12%; treatment 2%)

Miscellaneous: Viral infection (prophylaxis 3% to 13%)

1% to 10%:

Central nervous system: Fever/chills (prophylaxis 5% to 9%; treatment <1.5%), fatigue (prophylaxis 5% to 8%; treatment

<1.5%), malaise (prophylaxis 5% to 8%; treatment <1.5%), dizziness (treatment 1% to 2%)

Dermatologic: Urticaria (treatment <1.5%)

Gastrointestinal: Anorexia/appetite decreased (prophylaxis 2% to 4%), nausea (prophylaxis 1% to 2%; treatment ≤3%), diarrhea (prophylaxis 2%; treatment 2% to 3%), vomiting (prophylaxis 1% to 2%; treatment 1% to 2%) abdominal pain (treatment <1.5%)

Hepatic: Liver function test, enzyme elevation

Neuromuscular & skeletal: Muscle pain (prophylaxis 3% to 8%), musculoskeletal pain (prophylaxis 6%), arthralgia/articular rheumatism (prophylaxis 2%), arthralgia (treatment <1.5%), myalgia (treatment <1.5%)

Respiratory: Infection (ear/nose/throat; prophylaxis 2%; treatment 2% to 5%), sinusitis (treatment 3%), bronchitis (treatment 2.3%), nasal inflammation (prophylaxis 1%)

<1%: Asthma (worsening bronchospasm), transient lymphopenia, hemorrhage (ear/nose/throat)

Postmarketing and/or case reports: Allergic or allergic-like reaction (including oropharyngeal edema), arrhythmia, syncope, seizure, bronchospasm, dyspnea, facial edema, rash (including serious cutaneous reactions)

Pharmacodynamics/Kinetics

Absorption: Inhalation: 4% to 17%; oral: 2%

Protein binding, plasma: <10%

Metabolism: None

Half-life elimination, serum: 1.6-5.1 hours

Intravenous: 1.6 hours

Inhalation: 2.9 hours

Intranasal: 3.4 hours

Excretion: Urine (as unchanged drug); feces (unabsorbed drug)

Dosage

Oral inhalation:

Children ≥5 years and Adults: Prophylaxis (household setting): Two inhalations (10 mg) once daily for 10 days. Begin within 1½ days following onset of signs or symptoms of index case.

Children ≥7 years and Adults: Treatment: Two inhalations (10 mg total) twice daily for 5 days. Doses on first day should be separated by at least 2 hours; on subsequent days, doses should be spaced by ~12 hours. Begin within 2 days of signs or symptoms.

Adolescents and Adults: Prophylaxis (community outbreak): Two inhalations (10 mg) once daily for 28 days. Begin within 5 days of outbreak.

Stability Store at room temperature (25°C) 77°F; do not puncture blister until taking a dose using the Diskhaler®

Administration Inhalation: Must be used with Diskhaler® delivery device. Patients who are scheduled to use an inhaled bronchodilator should use their bronchodilator prior to zanamivir. With the exception of the initial dose when used for treatment, administer at the same time each day.

Contraindications Hypersensitivity to zanamivir or any component of the formulation

Warnings Patients must be instructed in the use of the delivery system. No data are available to support the use of this drug in patients who begin use for treatment after 48 hours of symptoms. Effectiveness has not been established in patients with significant underlying medical conditions or for prophylaxis of influenza in nursing home patients. Not recommended for use in patients with underlying respiratory disease, such as asthma or COPD, due to lack of efficacy and risk of serious adverse effects. Bronchospasm, decreased lung function, and other serious adverse reactions, including those with fatal outcomes, have been reported in patients with and without airway disease; discontinue with bronchospasm or signs of decreased lung function. For a patient with an underlying airway disease where a medical decision has been made to use zanamivir, a fast-acting bronchodilator should be made available, and used prior to each dose. Not a substitute for the flu vaccine. Consider primary or concomitant bacterial infections. Powder for oral inhalation contains lactose. Safety and efficacy of repeated courses or use with severe renal impairment have not been established; efficacy in children <5 years of age have not been established.

Dosage Forms Powder for oral inhalation: 5 mg/blister (20s) [4 blisters per Rotadisk® foil pack, 5 Rotadisk® per package; packaged with Diskhaler® inhalation device; contains lactose]

Reference Range Median serum zanamivir concentration from 3.6 mg twice daily to 16 mg 6 times/day (intranasal) range from 46-67 ng/mL

Overdosage/Treatment

Supportive therapy: Treatment is limited, and symptoms appear similar to reported adverse events from clinical studies.

Treatment: Symptom-directed and supportive. I.V. doses of 600 mg have been well tolerated in adults. Bronchospasm can be treated with beta₂ inhaled adrenergic agonists.

Drug Interactions Influenza virus vaccine: Zanamivir may diminish the therapeutic effect of live, attenuated influenza virus vaccine (FluMist™). The manufacturer of FluMist™ recommends that the administration of anti-influenza virus medications be avoided during the period beginning

48 hours prior to vaccine administration and ending 2 weeks after vaccine.

Pregnancy Risk Factor C

Pregnancy Implications Zanamivir has been shown to cross the placenta in animal models, however, no evidence of fetal malformations has been demonstrated. There are no adequate and well-controlled studies in pregnant women; not mutagenic

Lactation Excretion in breast milk unknown/use caution

Additional Information Majority of patients included in clinical trials were infected with influenza A, however, a number of patients with influenza B infections were also enrolled. Patients with lower temperature or less severe symptoms appeared to derive less benefit from therapy. No consistent treatment benefit was demonstrated in patients with chronic underlying medical conditions.

Ziconotide

CAS Number 107452-89-1

U.S. Brand Names Ziconal

Use Management of severe chronic pain in patients requiring intrathecal (I.T.) therapy and are intolerant or refractory to other therapies

Unlabeled/Investigational Use Pain management (especially neuro-pathic or cancer)

Mechanism of Action A peptide derived from sea snails that is a neuronal calcium antagonist

Adverse Reactions

Cardiovascular: Orthostatic hypotension, syncope (within 6 hours of dose), bradycardia, tachycardia, nonspecific T-wave changes

Central nervous system: Vestibular toxicity, ataxia, auditory hallucinations, sedation, dizziness at doses of 10 mcg/kg/hour; agitation seen at lower doses

Dermatologic: Rash

Gastrointestinal: Nausea, diarrhea

Ocular: Nystagmus

Respiratory: Cough, nasal congestion

Pharmacodynamics/Kinetics

Distribution: I.T.: V_d: ~140 mL

Protein binding: 50%

Metabolism: Metabolized via endopeptidases and exopeptidases present on multiple organs including kidney, liver, lung; degraded to peptide fragments and free amino acids

Half-life elimination: I.V.: 1-1.6 hours (plasma); I.T.: 2.9-6.5 hours (CSF)

Excretion: I.V.: Urine (<1%)

Dosage Administered intrathecally (careful dose titration needed):

Neuropathic/malignant pain: 0.3-300 ng/kg/hr

Head trauma: 60 mg over 3 hours

Monitoring Parameters Monitor for psychiatric or neurological impairment; signs and symptoms of meningitis or other infection; serum CPK (every other week for first month then monthly); pain relief

Administration Not for I.V. administration. For I.T. administration only using Medtronic SynchroMed® EL, SynchroMed® II Infusion System, or CADD-Micro® ambulatory infusion pump.

Medtronic SynchroMed® EL or SynchroMed® II Infusion Systems:

Naive pump priming (first time use with ziconotide): Use 2 mL of undiluted ziconotide 25 mcg/mL solution to rinse the internal surfaces of the pump; repeat twice for a total of 3 rinses

Initial pump fill: Use only undiluted 25 mcg/mL solution and fill pump after priming. Following the initial fill only, adsorption on internal device surfaces will occur, requiring the use of the undiluted solution and refill within 14 days.

Pump refills: Contents should be emptied prior to refill. Subsequent pump refills should occur at least every 40 days if using diluted solution or every 60 days if using undiluted solution

CADD-Micro® ambulatory infusion pump: Refer to manufacturers' manual for initial fill and refill instructions

Contraindications Hypersensitivity to ziconotide or any component of the formulation; history of psychosis; I.V. administration

I.T. administration is contraindicated in patients with infection at the injection site, uncontrolled bleeding, or spinal canal obstruction that impairs CSF circulation

Warnings [U.S. Boxed Warning]: Severe psychiatric symptoms and neurological impairment have been reported; interrupt or discontinue therapy if cognitive impairment, hallucinations, mood changes, or changes in consciousness occur. Cognitive impairment may appear gradually during treatment and is generally reversible after discontinuation. Use caution in the elderly; may experience confusion. Patients should be instructed to use caution in performing tasks which require alertness (eg, operating machinery or driving). May have additive effects with opiates or other CNS-depressant medications. Does not potentiate opiate-induced respiratory depression. Will not prevent or relieve symptoms associated with opiate withdrawal and opiates should not be abruptly discontinued. Unlike opioids, ziconotide therapy can be interrupted abruptly or discontinued without evidence of withdrawal. Meningitis

may occur with use of I.T. pumps and treatment may require removal of system and discontinuation of therapy. Safety and efficacy have not been established with renal or hepatic dysfunction, or in pediatric patients.

Dosage Forms Injection, solution, as acetate [preservative free]: 25 mcg/mL (20 mL); 100 mcg/mL (1 mL, 2 mL, 5 mL)

Overdosage/Treatment Supportive therapy: Symptomatic treatment upon drug discontinuation

Drug Interactions CNS depressants: Ziconotide may enhance the adverse/toxic effects of other CNS depressants.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic effects were not observed in animal studies, but increased postimplantation pup loss was reported. Maternal toxicity was also noted. There are no adequate and well-controlled studies in pregnant women.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Ziconotide is a synthetic form of sea snail venom found in the piscivorous marine snail *Congus magus*, which lives in shallow, tropical salt water

Zidovudine

CAS Number 30516-87-1

U.S. Brand Names Retrovir®

Synonyms Azidothymidine; AZT (error-prone abbreviation); Compound S; ZDV

Use Management of patients with HIV infections in combination with at least two other antiretroviral agents; for prevention of maternal/fetal HIV transmission as monotherapy

Unlabeled/Investigational Use Postexposure prophylaxis for HIV exposure as part of a multidrug regimen

Mechanism of Action Zidovudine is a thymidine analog which interferes with the HIV viral RNA dependent DNA polymerase by competing with thymidine triphosphate resulting in inhibition of viral replication

Adverse Reactions

Cardiovascular: Cardiomyopathy, chest pain, syncope, vasculitis

Central nervous system: **Severe headache** (42%), **fever**, malaise, dizziness, insomnia, somnolence, anxiety, confusion, depression, dizziness, loss of mental acuity, mania, seizures, somnolence, vertigo

Dermatologic: **Rash**, hyperpigmentation of nails (bluish-brown), pruritus, angioedema, skin and nail pigmentation changes, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Endocrine & metabolic: Gynecomastia, lactic acidosis

Gastrointestinal: **Nausea** (46% to 61%), **anorexia**, **diarrhea**, **pain**, **vomiting**, dyspepsia, constipation, dysphagia, flatulence, mouth ulcer, oral mucosal pigmentation, pancreatitis, taste perversion

Genitourinary: Urinary frequency, urinary hesitancy

Hematologic: **Anemia** (23% in children), **leukopenia**, **granulocytopenia** (39% in children), changes in platelet count, aplastic anemia, hemolytic anemia, leukopenia, pancytopenia with marrow hypoplasia, pure red cell aplasia

Hepatic: Hepatitis, hepatomegaly with steatosis, jaundice, LDH increased

Neuromuscular & skeletal: **Weakness**, paresthesia, back pain, CPK increased, muscle spasm, myopathy and myositis with pathological changes (similar to that produced by HIV disease), paresthesia, rhabdomyolysis, tremor

Ocular: Amblyopia, macular edema, photophobia

Otic: Hearing loss

Respiratory: Cough, dyspnea, rhinitis, sinusitis

Miscellaneous: Diaphoresis, flu-like syndrome, generalized pain, lymphadenopathy, sensitization reactions, anaphylaxis

Signs and Symptoms of Overdose Agranulocytosis, ataxia, cardiomyopathy, cholestatic jaundice, drowsiness (after 20 g ingestion), generalized seizures, granulocytopenia, gynecomastia, headache, insomnia, leukopenia, lymphoma, mania, nausea, neutropenia, nystagmus

Pharmacodynamics/Kinetics

Distribution: Significant penetration into the CSF; crosses placenta

V_d : 1-2.2 L/kg

Relative diffusion from blood into CSF: Adequate with or without inflammation (exceeds usual MICs)

CSF:blood level ratio: Normal meninges: ~60%

Protein binding: 25% to 38%

Metabolism: Hepatic via glucuronidation to inactive metabolites; extensive first-pass effect

Bioavailability: 54% to 74%

Half-life elimination: Terminal: 0.5-3 hours

Time to peak, serum: 30-90 minutes

Excretion:

Oral: Urine (72% to 74% as metabolites, 14% to 18% as unchanged drug)

I.V.: Urine (45% to 60% as metabolites, 18% to 29% as unchanged drug)

Dosage

Prevention of maternal-fetal HIV transmission:

Neonatal: Note: Dosing should begin 8-12 hours after birth and continue for the first 6 weeks of life.

Oral:

Full-term infants: 2 mg/kg/dose every 6 hours

Infants ≥ 30 weeks and < 35 weeks gestation at birth: 2 mg/kg/dose every 12 hours; at 2 weeks of age, advance to 2 mg/kg/dose every 8 hours

Infants < 30 weeks gestation at birth: 2 mg/kg/dose every 12 hours; at 4 weeks of age, advance to 2 mg/kg/dose every 8 hours

I.V.: Infants unable to receive oral dosing:

Full term: 1.5 mg/kg/dose every 6 hours

Infants ≥ 30 weeks and < 35 weeks gestation at birth: 1.5 mg/kg/dose every 12 hours; at 2 weeks of age, advance to 1.5 mg/kg/dose every 8 hours

Infants < 30 weeks gestation at birth: 1.5 mg/kg/dose every 12 hours; at 4 weeks of age, advance to 1.5 mg/kg/dose every 8 hours

Maternal: Oral (per AIDSinfo guidelines): 100 mg 5 times/day or 200 mg 3 times/day or 300 mg twice daily. Begin at 14-34 weeks gestation and continue until start of labor.

During labor and delivery, administer zidovudine I.V. at 2 mg/kg over 1 hour followed by a continuous I.V. infusion of 1 mg/kg/hour until the umbilical cord is clamped

Treatment of HIV infection:

Children 3 months to 12 years:

Oral: 160 mg/m²/dose every 8 hours; dosage range: 90 mg/m²/dose to 180 mg/m²/dose every 6-8 hours; some Working Group members use a dose of 180 mg/m² to 240 mg/m² every 12 hours when using in drug combinations with other antiretroviral compounds, but data on this dosing in children is limited

I.V. continuous infusion: 20 mg/m²/hour

I.V. intermittent infusion: 120 mg/m²/dose every 6 hours

Adults:

Oral: 300 mg twice daily or 200 mg 3 times/day

I.V.: 1-2 mg/kg/dose (infused over 1 hour) administered every 4 hours around-the-clock (6 doses/day)

Prevention of HIV following needlesticks (unlabeled use): Oral: Adults: 200 mg 3 times/day plus lamivudine 150 mg twice daily; a protease inhibitor (eg, indinavir) may be added for high risk exposures; begin therapy within 2 hours of exposure if possible

Patients should receive I.V. therapy only until oral therapy can be administered

Dosing interval in renal impairment: $Cl_{cr} < 10$ mL/minute: May require minor dose adjustment

Hemodialysis: At least partially removed by hemo- and peritoneal dialysis; administer dose after hemodialysis or administer 100 mg supplemental dose; during CAPD, dose as for $Cl_{cr} < 10$ mL/minute

Continuous arteriovenous or venovenous hemodiafiltration effects: Administer 100 mg every 8 hours

Dosing adjustment in hepatic impairment: Reduce dose by 50% or double dosing interval in patients with cirrhosis

Monitoring Parameters Monitor CBC and platelet count at least every 2 weeks, MCV, serum creatinine kinase, viral load, and CD4 count; observe for appearance of opportunistic infections

Administration Oral: Administer around-the-clock to promote less variation in peak and trough serum levels; may be administered without regard to food

I.M.: Do not administer I.M.

I.V.: Avoid rapid infusion or bolus injection

Neonates: Infuse over 30 minutes

Adults: Infuse over 1 hour

Contraindications Life-threatening hypersensitivity to zidovudine or any component of the formulation

Warnings [U.S. Boxed Warning]: Often associated with hematologic toxicity including granulocytopenia, severe anemia requiring transfusions, or (rarely) pancytopenia. Use with caution in patients with bone marrow compromise (granulocytes < 1000 cells/mm³ or hemoglobin < 9.5 mg/dL); dosage adjustment may be required in patients who develop anemia or neutropenia. **[U.S. Boxed Warning]: Lactic acidosis and severe hepatomegaly with steatosis have been reported, including fatal cases;** use with caution in patients with risk factors for liver disease (risk may be increased in obese patients or prolonged exposure) and suspend treatment with zidovudine in any patient who develops clinical or laboratory findings suggestive of lactic acidosis (transaminase elevation may/may not accompany hepatomegaly and steatosis). Use caution in combination with interferon alfa with or without ribavirin in HIV/HBV coinfecting patients; monitor closely for hepatic decompensation, anemia, or neutropenia; dose reduction or discontinuation of interferon and/or ribavirin may be required if toxicity evident. **[U.S. Boxed Warning]: Prolonged use has been associated with symptomatic myopathy and myositis.** Immune reconstitution syndrome may develop resulting in the occurrence of an inflammatory response to an indolent or residual opportunistic infection; further evaluation and treatment may be required. Reduce dose in patients with severe renal impairment.

ZILEUTON

Dosage Forms Capsule:

Retrovir®: 100 mg

Injection, solution [preservative free]:

Retrovir®: 10 mg/mL (20 mL)

Syrup:

Retrovir®: 50 mg/5 mL (240 mL) [contains sodium benzoate; strawberry flavor]

Tablet: 300 mg

Retrovir®: 300 mg

Reference Range Peak serum level after 200 mg dose: ~0.9 mcg/mL; serum level taken 12 hours after a 20 g overdose: 49.4 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Transfusions with blood component; vitamin B₁₂ administration may assist in preventing anemia; seizures can be treated with diazepam or lorazepam

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; while hemodialysis may remove its metabolites, it has no effect on the parent compound and cannot be routinely recommended

Antidote(s)

- Filgrastim [ANTIDOTE]

Diagnostic Procedures

- Zidovudine, Blood

Drug Interactions Substrate (minor) of CYP2A6, 2C9, 2C19, 3A4

Acyclovir, valacyclovir: May increase CNS depression of zidovudine; monitor.

Bone marrow suppressants/cytotoxic agents: Concomitant use may increase risk of hematologic toxicity. (May be seen with adriamycin, dapson, flucytosine, vincristine, vinblastine.)

Fluconazole: Fluconazole may increase levels/effects of zidovudine.

Ganciclovir, valganciclovir: Concomitant use may increase risk of hematologic toxicities; monitor hemoglobin, hematocrit, and white blood cell count with differential frequently; dose reduction or interruption of either agent may be needed

Interferon-alfa: Concomitant use may increase risk of hepatic decompensation or hematologic toxicities; monitor hemoglobin, hematocrit, and white blood cell count with differential frequently; dose reduction or interruption of either agent may be needed.

Methadone: May increase serum levels/effects of zidovudine; monitor.

Probenecid: Probenecid may increase zidovudine levels/effects. Myalgia, malaise, and/or fever and maculopapular rash have been reported with concomitant use.

Ribavirin: Concomitant use of ribavirin and nucleoside analogues may increase the risk of developing hepatic decompensation or other signs of mitochondrial toxicity, including pancreatitis or lactic acidosis. May decrease the antiviral activity of zidovudine (based on *in vitro* data); monitor closely.

Rifampin: May decrease levels of zidovudine; monitor.

Stavudine: Zidovudine may decrease the antiviral activity of stavudine (based on *in vitro* data). Avoid concurrent use.

Trimetrexate: Zidovudine may increase the myelosuppressive effects of trimetrexate; avoid concomitant use.

Valproic acid: Valproic acid may increase plasma levels of zidovudine; monitor for possible increase in side effects (AUC increased by 80%)

Pregnancy Risk Factor C

Pregnancy Implications Zidovudine crosses the placenta. The use of zidovudine reduces the maternal-fetal transmission of HIV by ~70% and should be considered for antenatal and intrapartum therapy whenever possible. In HIV infected mothers not previously on antiretroviral therapy, treatment may be delayed until after 10-12 weeks gestation. Cases of lactic acidosis/hepatic steatosis syndrome have been reported in pregnant women receiving nucleoside analogues. It is not known if pregnancy itself potentiates this known side effect; however, pregnant women may be at increased risk of lactic acidosis and liver damage. Hepatic enzymes and electrolytes should be monitored frequently during the 3rd trimester of pregnancy in women receiving nucleoside analogues. Health professionals are encouraged to contact the antiretroviral pregnancy registry to monitor outcomes of pregnant women exposed to antiretroviral medications (1-800-258-4263).

Lactation Enters breast milk/not recommended

Pregnancy Implications Monitor complete blood count and platelet count at least every 2 weeks; observe for appearance of opportunistic infections; give around-the-clock to promote less variation in peak and trough serum levels

Specific References

De Santis M, Cavaliere AF, Caruso A, et al, "Hemangiomas and Other Congenital Malformations in Infants Exposed to Antiretroviral Therapy *In Utero*," *JAMA*, 2004, 291(3):305.

Use Prophylaxis and chronic treatment of asthma in children ≥ 12 years of age and adults

Mechanism of Action Specific inhibitor of 5-lipoxygenase and thus inhibits leukotriene (LTB₄, LTC₄, LTD₄ and LTE₄) formation. Leukotrienes are substances that induce numerous biological effects including augmentation of neutrophil and eosinophil migration, neutrophil and monocyte aggregation, leukocyte adhesion, increased capillary permeability and smooth muscle contraction.

Adverse Reactions

Central nervous system: Insomnia, dizziness, **headache**

Dermatologic: Urticaria

Gastrointestinal: diarrhea, dyspepsia, abdominal pain

Ocular: Increased intraocular pressure

Hepatic: Reversible transaminase increases, **ALT elevation**

Pharmacodynamics/Kinetics

Absorption: Rapid

Distribution: 1.2 L/kg

Protein binding: 93%

Metabolism: Several metabolites in plasma and urine; metabolized by CYP1A2, 2C9, and 3A4

Bioavailability: Unknown

Half-life elimination: 2.5 hours

Time to peak, serum: 1.7 hours

Excretion: Urine (~95% primarily as metabolites); feces (~2%)

Dosage Oral:

Children < 12 years: Safety and effectiveness have not been established

Children ≥ 12 years and Adults: 600 mg 4 times/day

Monitoring Parameters Evaluate hepatic transaminases at initiation of and during therapy with zileuton. Monitor serum ALT before treatment begins, once-a-month for the first 3 months, every 2-3 months for the remainder of the first year, and periodically thereafter for patients receiving long-term zileuton therapy. If symptoms of liver dysfunction (right upper quadrant pain, nausea, fatigue, lethargy, pruritus, jaundice or "flu-like" symptoms) develop or transaminase elevations > 5 times ULN occur, discontinue therapy and follow transaminase levels until normal.

Administration May be administered without regard to meals (eg, with or without food)

Contraindications Hypersensitivity to zileuton or any component of the formulation; active liver disease or transaminase elevations greater than or equal to three times the upper limit of normal (≥ 3 times ULN)

Warnings Not indicated for the reversal of bronchospasm in acute asthma attacks; therapy may be continued during acute asthma exacerbations. Hepatic adverse effects have been reported (elevated transaminase levels); females > 65 years and patients with pre-existing elevated transaminases may be at greater risk. Serum ALT should be monitored. Discontinue zileuton and follow transaminases until normal if patients develop clinical signs/symptoms of liver dysfunction or with transaminase levels > 5 times ULN (use caution with history of liver disease and/or in those patients who consume substantial quantities of ethanol.)

Dosage Forms Tablet: 600 mg

Reference Range Peak plasma level after an 800 mg dose: 3.4-4.5 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Urticaria can be treated with epinephrine and antihistamines

Antidote(s)

- Epinephrine [ANTIDOTE]

Drug Interactions Substrate (minor) of CYP1A2, 2C9, 3A4; Inhibits CYP1A2 (moderate)

CYP1A2 Substrates: Zileuton may increase the levels/effects of CYP1A2 substrates. Example substrates include aminopylline, fluvoxamine, mexiletine, mirtazapine, ropinirole, theophylline, and trifluoperazine.

Propranolol: Concomitant use results in a doubling of propranolol AUC and increased beta-blocker activity. Monitor patient closely; reduce propranolol dose if necessary.

Theophylline: Concomitant use results in an approximate doubling of serum theophylline concentrations. Monitor concentrations closely; reduce theophylline dose.

Warfarin: Concomitant use results in a significant increase in prothrombin time. PT/INR should be closely monitored; adjust warfarin dose.

Pregnancy Risk Factor C

Pregnancy Implications Clinical effects on the fetus: Developmental studies indicated adverse effects (reduced body weight and increased skeletal variations) in rats at an oral dose of 300 mg/kg/day. There are no adequate and well-controlled studies in pregnant women.

Lactation Excretion in breast milk unknown/not recommended

Additional Information No effect on release of prostaglandin D₂ or histamine; in April, 1995, the Advisory Committee of the FDA Division of Pulmonary and Allergy Drugs unanimously voted to recommend that zileuton be approved for marketing; zileuton (600 mg 4 times/day orally) can protect asthmatics from idiosyncratic reactions (ie, bronchoconstriction) due to aspirin

Zileuton

CAS Number 11406-87-2

U.S. Brand Names Zylflo™ [DSC]

Zinc Chloride

Pronunciation (zink KLOR ide)

Related Information

- Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 7440-66-6

UN Number 1436

Adverse Reactions Respiratory, gastrointestinal, ocular, pancreatic

Signs and Symptoms of Overdose Hypertension, metal fume fever, nephritis (hematuria), pancreatic insufficiency, pancreatitis. Inhalation of zinc chloride fumes from soldering has also caused asthma. Ingestion of zinc salts has produced gastritis, diarrhea, hyperthermia, shock, vomiting, and death. Eye exposure may result in corneal damage, cough, and lens opacification. Zinc chloride is highly corrosive.

Toxicodynamics/Kinetics

Absorption: In small intestine (20% to 30%); iron and dairy products decrease absorption

Protein binding: Highly protein bound

Elimination: Primarily fecal; urinary excretion is 0.3-0.4 mg/day

Injection, solution: 1 mg/mL (10 mL, 50 mL)

Dosage Forms Injection, solution: 1 mg/mL (10 mL, 50 mL)

Reference Range Normal blood levels of zinc: 68-136 mcg/dL; plasma zinc concentration following ingestion of ~193 g zinc chloride was 3915 mcg/dL (599 µmol/L), resulting in gastric necrotic lesions

Overdosage/Treatment

Decontamination: **Do not** evacuate gastric contents with zinc chloride or phosphide because they are corrosive. Dilute with milk.

Ocular: Copious irrigation, especially if zinc concentration exceeds 10%.

Enhancement elimination: Calcium disodium, ethylene diaminetetraacetate, or dimercaprol has been used with success. N-acetylcysteine has been used to increase urinary excretion of zinc sulfate.

Pregnancy Risk Factor C

Nursing Implications Patients on TPN therapy should have periodic serum copper and serum zinc levels

Additional Information Toxic dose of zinc chloride in a child: 1 g/kg or zinc concentrations >20%

Radiopaque. Taste threshold: 15 ppm. Opacification of water: 30 ppm. Zinc chloride is the most toxic form.

Average ambient air zinc concentration: <1 mcg/m³. Average concentration of surface water: <50 mcg/L.

Average daily intake in diet: 0.14-0.21 mg/kg

Zinc chloride fume: TLV-TWA: 1 mg/m³; TLV-STEL: 2 mg/m³. Zinc oxide fume: TLV-TWA: 5 mg/m³; TLV-STEL: 10 mg/m³. Zinc oxide dust: TLV-TWA: 10 mg/m³

Zinc Oxide

Related Information

- Metal Fume Fever

CAS Number 1314-13-2; 8051-03-4

U.S. Brand Names Ammens[®] Medicated Deodorant [OTC]; Balmex[®] [OTC]; Boudreaux's[®] Butt Paste [OTC]; Critic-Aid Skin Care[®] [OTC]; Desitin[®] Creamy [OTC]; Desitin[®] [OTC]

Synonyms Base Ointment; Lassar's Zinc Paste

Use Protective coating for mild skin irritations and abrasions, soothing and protective ointment to promote healing of chapped skin, diaper rash, and superficial (but not deep) skin ulcers; used with coal tar in treatment of eczema; also used in sunscreens; used in dental cements as a temporary filling

Mechanism of Action Mild astringent with weak antiseptic properties; blocks ultraviolet A and B along with long-wave light; when heated over 900°F, can be a cause of metal fume fever (at an exposure of 5 mg/m³ for 2 hours)

Adverse Reactions

Central nervous system: Chills

Dermatologic: Skin sensitivity, dermal irritation

Miscellaneous: Solitary aspergillosis of maxillary sinus associated with zinc oxide from overfilled teeth

Toxicodynamics/Kinetics Absorption: May be absorbed dermally in burns

Dosage Infants, Children, and Adults: Topical: Apply as required to affected areas several times/day

Stability Avoid prolonged storage at temperatures >30°C

Contraindications Hypersensitivity to zinc oxide or any component of the formulation

Dosage Forms Cream:

Balmex[®]: 11.3% (60 g, 120 g, 480 g) [contains aloe and vitamin E]

Ointment, topical: 20% (30 g, 60 g, 480 g); 40% (120 g)

Desitin[®]: 40% (30 g, 60 g, 90 g, 120 g, 270 g, 480 g) [contains cod liver oil and lanolin]

Desitin[®] Creamy: 10% (60 g, 120 g)

Paste, topical:

Boudreaux's[®] Butt Paste: 16% (30 g, 60 g, 120 g, 480 g) [contains castor oil, boric acid, mineral oil, and Peruvian balsam]

Critic-Aid Skin Care[®]: 20% (71 g, 170 g)

Powder, topical (Ammens[®] Medicated Deodorant): 9.1% (187.5 g, 330 g) [original and shower fresh scent]

Overdosage/Treatment Decontamination: Dermal: Irrigate with soap and water. For treatment of metal fume fever see Metal Fume Fever.

Do not evacuate gastric contents with zinc oxide or phosphide because they are corrosive. Dilute with milk.

Additional Information Black discoloration when exposed to light can accelerate growth of *Aspergillus fumigatus*, calamine is a combination of zinc oxide with ferric oxide; may result in a radiopacity on a KUB

Specific References

Liu CH, Lee CT, Tsai FC, et al, "Gastrointestinal Corrosive Injury After Oral Zinc Oxide," *Ann Emerg Med*, 2006, 47(3):296.

Zinc Sulfate

Pronunciation (zink SUL fate)

CAS Number 4468-02-4 (zinc gluconate); 7440-66-6; 7446-20-0 (zinc sulfate); 7733-02-0 (zinc sulfate)

U.S. Brand Names Orazinc[®] [OTC]; Zincate[®]

Synonyms ZnSO₄ (error-prone abbreviation)

Use Supplement for correction of zinc deficiency; used in treatment of acrodermatitis enteropathica

Mechanism of Action Needed for DNA and RNA synthesis and other enzyme symptoms

Adverse Reactions

Central nervous system: Lethargy, chills

Gastrointestinal: Vomiting, pancreatitis, metallic taste

Hematologic: Sideroblastic anemia (due to zinc-induced copper deficiency), thrombocytopenia, leukopenia

Signs and Symptoms of Overdose Blurred vision, decreased consciousness, diarrhea, hyperamylasemia, hypotension, hypothermia, jaundice, profuse sweating, pulmonary edema, oliguria, tachycardia, vomiting

Toxicodynamics/Kinetics

Absorption: Zinc sulfate: 20% to 30%

Protein binding: 99%

Half-life: 3 hours

Elimination: Through small bowel excretion

Dosage Maximum daily dose:

Zinc gluconate: 230 mg

Zinc sulfate: 660 mg

Stability Store oral liquid (injectable used orally) in refrigerator

Monitoring Parameters Patients on TPN therapy should have periodic serum copper and serum zinc levels

Dosage Forms Capsule (Orazinc[®], Zincate[®]): 220 mg [elemental zinc 50 mg]

Injection, solution [preservative free]: 1 mg elemental zinc/mL (10 mL); 5 mg elemental zinc/mL (5 mL)

Tablet (Orazinc[®]): 110 mg [elemental zinc 25 mg]

Reference Range Normal serum zinc: 9.2-23.0 µmol/L; levels >30.0 µmol/L associated with bone marrow suppression; normal urinary zinc levels: 0.3-0.4 mg/day (increased to 2.1 mg/day in patients with proteinuria)

Overdosage/Treatment

Decontamination:

Dermal: Wash with soap and water

Ocular: Irrigate copiously with saline following exposure to zinc salt concentrations >0.5%; for zinc chloride exposure following water irrigating, irrigation with 0.5 molar (1.7%) edetate disodium solution for 15 minutes within 2 minutes of exposure may be helpful

Oral: Lavage within 1 hour may be useful; dilute with milk; whole bowel irrigation has been utilized

Supportive therapy: Removal of excess zinc will eventually lead to normal hematopoiesis, although copper levels should be monitored and copper replaced as needed

Enhancement of elimination: Calcium disodium, ethylene diamine tetraacetate, dimercaprol or BAL has been used with some success; acetylcysteine has been used to increase the urinary excretion of zinc sulfate

Antidote(s)

- Succimer [ANTIDOTE]

- Unithiol [ANTIDOTE]

Pregnancy Risk Factor C

Pregnancy Implications Zinc deficiency during pregnancy can lead to intrauterine growth retardation during last trimester of pregnancy; has been associated with increased incidence of premature deliveries and stillborns at zinc ingestion of 0.6 mg/kg/day

ZIPEPROL

Nursing Implications Do not give undiluted by direct injection into a peripheral vein because of potential for phlebitis, tissue irritation, and potential to increase renal loss of minerals from a bolus injection

Additional Information Lethal dose: Zinc sulfate: I.V.: 7.4 g
Daily consumption of 100-150 mg of zinc results in a negative copper balance; can cause a decrease in HDL cholesterol
RDA requirement of zinc: Infants: 5 mg; Children: 10 mg; Adults: Male: 15 mg; Female: 12 mg; During pregnancy: 15 mg; Lactating females: 16-19 mg

Historically, zinc sulfate was used as an emetic agent and is radiopaque; may result in radiopacity on KUB with oral ingestion; elevated zinc levels can occur from chronic ingestion of coins (especially pennies); zinc gluconate (20 mg of elemental zinc) may decrease duration and severity of infant diarrhea; >20 mg/day can be twice as likely in resulting in faster progression of HIV illness

Specific References

Bobat R, Coovadia H, Stephen C, et al, "Safety and Efficacy of Zinc Supplementation for Children with HIV-1 Infection in South Africa: A Randomised Double-Blind Placebo-Controlled Trial," *Lancet*, 2005, 366(9500):1862-7

Zipeprol

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 34758-83-3; 34758-84-4

Impairment Potential Yes

Unlabeled/Investigational Use Cough suppressant; often used as a drug of abuse (not FDA approved in U.S.)

Mechanism of Action A substituted, nonopioid piperazine with centrally acting antitussive action and peripheral actions on bronchospasm; also has antihistaminic and antiserotonin properties

Adverse Reactions

Central nervous system: Drowsiness, dizziness, auditory and visual hallucinations, ataxia, retrograde amnesia (with doses >300 mg), CNS depression, pseudotumor cerebri, extrapyramidal reactions, amnesia, opisthotonos, cognitive dysfunction

Gastrointestinal: Nausea, constipation

Neuromuscular & skeletal: Chorea

Respiratory: Apnea

Miscellaneous: Abuse potential

Signs and Symptoms of Overdose Ataxia, coma, headache, lethargy, opisthotonic crisis, respiratory depression, restlessness, seizures, tremor

Admission Criteria/Prognosis Admit any ingestion >600 mg; admit any ingestion >1 g in an adult

Toxicodynamics/Kinetics

Absorption: 15 minutes

Metabolism: Hepatic

Half-life: 6 hours

Elimination: Renal (1% to 5% excreted unchanged)

Dosage

Children:
Oral: 3-5 mg/kg/day in divided doses

Rectal: 100-150 mg/day

Adults:

Oral: 150-300 mg/day in divided doses

Rectal: 150 mg 1-2 times/day

Monitoring Parameters Respiratory states, arterial blood gases

Reference Range Postmortem blood zipeprol level after ~1.5 g ingestion ranges from 2 mcg/mL to 20.5 mcg/mL; liver to blood postmortem distribution ranges from 2.5-6.3; after a 175 mg oral dose, peak serum level approximates 0.75 mcg/mL

Overdosage/Treatment

Decontamination: Do not induce emesis; lavage (within 1 hour)/activated charcoal

Supportive therapy: Benzodiazepines or barbiturates can be used for seizure although human data is lacking, pyridoxine may be useful in treating seizures; high doses of naloxone (>6 mg) may antagonize CNS depressant effects

Antidote(s)

- Naloxone [ANTIDOTE]
- Pyridoxine [ANTIDOTE]

Additional Information Minimum lethal dose: 2 g

Abusers use 750 mg to 1 g for euphoric effect. Seizuregenic dose is 1.5 g in adults or 25 mg/kg in children; mechanism for seizures may be GABA inhibition; cerebral edema can occur

Ziprasidone

CAS Number 138982-67-9; 146939-27-7

U.S. Brand Names Geodon®

Synonyms Zeldox; Ziprasidone Hydrochloride; Ziprasidone Mesylate

Use Treatment of schizophrenia

Unlabeled/Investigational Use Tourette's syndrome

Mechanism of Action The exact mechanism of action is unknown. However, *in vitro* radioligand studies show that ziprasidone has high affinity for D₂, 5-HT_{2a}, 5-HT_{1A}, 5-HT_{2c} and 5-HT_{1d}; moderate affinity for alpha₁, adrenergic and histamine H₁ receptors, and low affinity for alpha₂ adrenergic, beta adrenergic, 5-HT₃, 5-HT₄, cholinergic, mu, sigma, or benzodiazepine receptors. Ziprasidone moderately inhibits the reuptake of serotonin and norepinephrine.

Adverse Reactions

Note: Although minor QT_c prolongation (mean 10 msec at 160 mg/day) may occur more frequently (incidence not specified), clinically relevant prolongation (>500 msec) was rare (0.06%).

Cardiovascular: Angina, atrial fibrillation, AV block (first degree), bradycardia, bundle branch block, cardiomegaly, facial edema, hypertension, myocarditis, peripheral edema, postural hypotension, QT prolongation, syncope, tachycardia, vasodilation

Central nervous system: Abnormal gait, accidental fall, agitation, akinesia, akathisia, amnesia, anxiety, ataxia, buccoglossal syndrome, cerebral infarction, chills, circumoral paresthesia, confusion, delirium, dizziness, dystonia, extrapyramidal symptoms, fever, hostility, hypertonia, hypesthesia, incoordination, insomnia, opisthotonos, psychosis, seizures, speech disorder, **somnolence (13% at 2 mg doses and 20% at 20 mg doses)**, stroke, vertigo

Dermatologic: Alopecia, contact dermatitis, eczema, exfoliative dermatitis, ecchymosis, fungal dermatitis, furunculosis, maculopapular rash, photosensitivity reaction, rash, urticaria, vesiculobullous rash

Endocrine & metabolic: Amenorrhea, anorgasmia, dehydration, dysmenorrhea, gout, gynecomastia, hypercholesterolemia, hyperglycemia, hyperkalemia, hyperlipemia, hyperthyroidism, hyperuricemia, hypocalcemia, hypoglycemia, hypokalemia, hypomagnesemia, hyponatremia, hypoproteinemia, hypothyroidism, ketosis, lactation (female), menorrhagia, metrorrhagia, sexual dysfunction (male and female), thirst, thyroiditis

Gastrointestinal: Anorexia, abdominal pain, constipation, dyspepsia, diarrhea, flank pain, dysphagia, fecal impaction, gingival bleeding, hematemesis, leukoplakia (mouth), nausea, melena, rectal hemorrhage, tongue edema, vomiting, weight gain, xerostomia

Genitourinary: Abnormal ejaculation, impotence, nocturia, polyuria, priapism, uterine hemorrhage, vaginal hemorrhage

Hematologic: Anemia, basophilia, eosinophilia, leukocytosis, lymphocytosis, monocytosis, polycythemia, thrombocytopenia, thrombocytopenia, thrombocytopenia

Hepatic: Cholestatic jaundice, fatty liver, hepatitis, hepatomegaly, increased alkaline phosphatase, increased GGT, increased LDH, increased transaminases, jaundice

Local: Phlebitis, thrombophlebitis, pain at injection site

Neuromuscular & skeletal: Cogwheel rigidity, choreoathetosis, dyskinesia, hypokinesia, hypotonia, increased CPK myalgia, myoclonus, myopathy, neuropathy, paresthesia, tenosynovitis, torticollis, tremor, trismus, weakness

Ocular: Abnormal vision, blepharitis, cataract, conjunctivitis, diplopia, dry eyes, keratitis, keratoconjunctivitis, nystagmus, ocular hemorrhage, oculogyric crisis, photophobia, visual field defect

Otic: Tinnitus

Renal: Albuminuria, hematuria, increased BUN, increased creatinine (serum), oliguria, urinary retention

Respiratory: Dyspnea, epistaxis, hemoptysis, increased cough, laryngismus, pneumonia, pulmonary embolism, respiratory alkalosis, respiratory disorder (primarily cold symptoms, upper respiratory infection), rhinitis

Miscellaneous: Accidental injury, diaphoresis, flu syndrome, lactate dehydrogenase elevated, lymphadenopathy, lymphedema, motor vehicle accident, withdrawal syndrome

Pharmacodynamics/Kinetics

Absorption: Well absorbed

Distribution: V_d: 1.5 L/kg

Protein binding: 99%, primarily to albumin and alpha₁-acid glycoprotein

Metabolism: Extensively hepatic, primarily via aldehyde oxidase; less than 1/3 of total metabolism via CYP3A4 and CYP1A2 (minor)

Bioavailability: Oral (with food): 60% (up to twofold increase with food); I.M.: 100%

Half-life elimination: Oral: 7 hours; I.M.: 2-5 hours

Time to peak: Oral: 6-8 hours; I.M.: ≤60 minutes

Excretion: Feces (66%) and urine (20%) as metabolites; little as unchanged drug (1% urine, 4% feces)

Clearance: 7.5 mL/minute/kg

Dosage

Children and Adolescents: Tourette's syndrome (unlabeled use): 5-40 mg/day

Adults: Psychosis: Initial: 20 mg twice daily (with food)

Adjustment: Increases (if indicated) should be made no more frequently than every 2 days; ordinarily patients should be observed for improvement over several weeks before adjusting the dose

Maintenance: Range 20-100 mg twice daily; however, dosages >80 mg twice daily are generally not recommended

I.M.: Adults: Psychosis: 10 mg every 2 hours or 20 mg every 4 hours; maximum: 40 mg/day; oral therapy should replace I.M. administration as soon as possible

Elderly: No dosage adjustment is recommended; consider initiating at a low end of the dosage range, with slower titration

Dosage adjustment in renal impairment:

Oral: No dosage adjustment is recommended

I.M.: Cyclodextrin, an excipient in the I.M. formulation, is cleared by renal filtration; use with caution.

Dosage adjustment in hepatic impairment: No dosage adjustment is recommended

Stability Store at controlled room temperature of 15°C to 30°C (59°F to 86°F)

Monitoring Parameters Vital signs; serum potassium and magnesium; fasting lipid profile and fasting blood glucose/Hgb A_{1c} (prior to treatment, at 3 months, then annually); BMI, personal/family history of obesity, waist circumference; blood pressure; mental status, abnormal involuntary movement scale (AIMS), extrapyramidal symptoms. Weight should be assessed prior to treatment, at 4 weeks, 8 weeks, 12 weeks, and then at quarterly intervals. Consider titrating to a different antipsychotic agent for a weight gain $\geq 5\%$ of the initial weight. The value of routine ECG screening or monitoring has not been established.

Administration Administer with food

Contraindications Hypersensitivity to ziprasidone or any component of the formulation; history (or current) prolonged QT; congenital long QT syndrome; recent myocardial infarction; history of arrhythmias; uncompensated heart failure; concurrent use of other QT_c-prolonging agents including amiodarone, arsenic trioxide, bretylium, chlorpromazine, cisapride, class Ia antiarrhythmics (quinidine, procainamide), dofetilide, dolasetron, droperidol, halofantrine, ibutilide, levomethadyl, mefloquine, mesoridazine, pentamidine, pimozone, probucol, some quinolone antibiotics (moxifloxacin, sparfloxacin, gatifloxacin), sotalol, tacrolimus, and thioridazine

Warnings

[U.S. Boxed Warning]: Patients with dementia-related behavioral disorders treated with atypical antipsychotics are at an increased risk of death compared to placebo. Ziprasidone is not approved for this indication.

May result in QT_c prolongation (dose-related), which has been associated with the development of malignant ventricular arrhythmias (torsade de pointes) and sudden death. Observed prolongation was greater than with other atypical antipsychotic agents (risperidone, olanzapine, quetiapine), but less than with thioridazine. Avoid hypokalemia, hypomagnesemia. Use caution in patients with bradycardia. Discontinue in patients found to have persistent QT_c intervals >500 msec. Patients with symptoms of dizziness, palpitations, or syncope should receive further cardiac evaluation.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia. Disturbances of temperature regulation have been reported with antipsychotics (not reported in premarketing trials of ziprasidone). Antipsychotic use may also be associated with neuroleptic malignant syndrome (NMS). Use with caution in patients at risk of seizures, including those with a history of seizures, head trauma, brain damage, alcoholism, or concurrent therapy with medications which may lower seizure threshold. Elderly patients may be at increased risk of seizures due to an increased prevalence of predisposing factors.

May cause orthostatic hypotension; use with caution in patients at risk of this effect or in those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, hypovolemia, or other medications which may predispose).

Atypical antipsychotics have been associated with development of hyperglycemia; in some cases, may be extreme and associated with ketoacidosis, hyperosmolar coma, or death. There is limited documentation with ziprasidone and specific risk associated with this agent is not known. Use caution in patients with diabetes or other disorders of glucose regulation; monitor for worsening of glucose control.

Cognitive and/or motor impairment (sedation) is common with ziprasidone, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use; use with caution in patients at risk of aspiration pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). Use caution in patients with renal or hepatic impairment. Ziprasidone has been associated with a fairly high incidence of rash (5%); discontinue if alternative etiology is not identified. Safety and efficacy have not been established in pediatric patients.

The possibility of a suicide attempt is inherent in psychotic illness or bipolar disorder; use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care.

Dosage Forms Capsule, as hydrochloride: 20 mg, 40 mg, 60 mg, 80 mg
Injection, powder for reconstitution, as mesylate: 20 mg

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Reported symptoms include somnolence, slurring of speech, and hypertension. Acute extrapyramidal reactions may also occur, and should be treated with benztrapine or diphenhydramine. Akathisia should be treated with beta adrenergic blocking agents. Not removed by dialysis.

Test Interactions \downarrow cholesterol, triglycerides; may cause transient elevation of prolactin levels

Drug Interactions **Substrate** (minor) of CYP1A2, 3A4; **Inhibits** CYP2D6 (weak), 3A4 (weak)

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Amphetamines: Efficacy may be diminished by antipsychotics; in addition, amphetamines may increase psychotic symptoms; avoid concurrent use

Antihypertensives: Concurrent use of ziprasidone with an antihypertensive may produce additive hypotensive effects (particularly orthostasis)

Carbamazepine: May decrease serum concentrations of ziprasidone (AUC is decreased by 35%); other enzyme-inducing agents may share this potential

CNS depressants: Sedative effects may be additive with ziprasidone; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents

Ketoconazole: May increase serum concentrations of ziprasidone (AUC is increased by 35% to 40%); other CYP3A4 inhibitors may share this potential. QT_c prolongation was not demonstrated.

Levodopa: Ziprasidone may inhibit the antiparkinsonian effect of levodopa; avoid this combination

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk.

Potassium- or magnesium-depleting agents: May increase the risk of serious arrhythmias with ziprasidone; includes many diuretics, aminoglycosides, cyclosporine, and amphotericin; monitor serum potassium and magnesium levels closely

QT_c-prolonging agents: May result in additive effects on cardiac conduction, potentially resulting in malignant or lethal arrhythmias; concurrent use is contraindicated. Includes amiodarone, arsenic trioxide, bretylium, chlorpromazine, cisapride; class Ia antiarrhythmics (quinidine, procainamide); dofetilide, dolasetron, droperidol, halofantrine, ibutilide, levomethadyl, mefloquine, mesoridazine, pentamidine, pimozone, probucol; some quinolone antibiotics (moxifloxacin, sparfloxacin, gatifloxacin); sotalol, tacrolimus, and thioridazine.

Pregnancy Risk Factor C

Pregnancy Implications Developmental toxicity demonstrated in animals. There are no adequate and well-controlled studies in pregnant women. Use only if potential benefit justifies risk to the fetus.

Lactation Excretion in breast milk unknown/not recommended

Additional Information The increased potential to prolong QT_c, as compared to other available antipsychotic agents, should be considered in the evaluation of available alternatives.

Zolpidem

CAS Number 82626-48-0; 99294-93-6

U.S. Brand Names Ambien®

Synonyms Zolpidem Tartrate

Impairment Potential Yes. Serum zolpidem levels >100 mcg/L are associated with driving impairment. (Baselt RC and Cravey RH, *Disposition of Toxic Drugs and Chemicals in Man*, 4th ed, Foster City, CA: Chemical Toxicology Institute, 1995, 788.)

Use Hypnotic for short-term management of insomnia

Mechanism of Action Selective agonist of the omega-1 receptor at the CNS gamma amino butyric acid (GABA)/chloride channel complex; not a benzodiazepine, but an imidazopyridin

Adverse Reactions

Cardiovascular: Bradycardia, sinus bradycardia

Central nervous system: Headache, drowsiness, dizziness, slurred speech, hallucinations, anterograde amnesia, headache, night terrors, confusion, drowsiness, coma, ataxia, visual hallucinations, auditory hallucinations, paranoia, psychosis, somnolence, delirium

Dermatologic: Pruritus, bullous skin disease, urticaria, purpura, photosensitivity

Gastrointestinal: Nausea, vomiting, diarrhea, xerostomia

Hepatic: Hepatitis

Neuromuscular & skeletal: Myalgia, hyporeflexia

Ocular: Miosis

Respiratory: Apnea, respiratory depression

Signs and Symptoms of Overdose Coma, diplopia, esophageal ulceration, hypotension, miosis, night terrors, respiratory depression

Pharmacodynamics/Kinetics

Onset of action: 30 minutes

Duration: 6-8 hours

Absorption: Rapid

Distribution: Very low amounts enter breast milk

Protein binding: 92%

Metabolism: Hepatic, primarily via CYP3A4 (~60%), to inactive metabolites

Half-life elimination: 2.5-2.8 hours (range 1.4-4.5 hours); Cirrhosis: Up to 9.9 hours

Time to peak, plasma: 2 hours; 4 hours with food

Excretion: As metabolites in urine, bile, feces

Dosage Adults: Oral: 10 mg immediately before bedtime; 5 mg in elderly patients or patients with renal/liver disease; maximum dose: 20 mg

Monitoring Parameters Daytime alertness; respiratory and cardiac status

Administration Ingest immediately before bedtime due to rapid onset of action. Ambien CR™ tablets should not be divided, crushed, or chewed.

Contraindications Hypersensitivity to zolpidem or any component of the formulation

Warnings Should be used only after evaluation of potential causes of sleep disturbance. Failure of sleep disturbance to resolve after 7-10 days may indicate psychiatric or medical illness. Use with caution in patients with depression. Abnormal thinking and behavioral changes have been associated with sedative-hypnotics. Sedative/hypnotics may produce withdrawal symptoms following abrupt discontinuation. Causes CNS depression, which may impair physical and mental capabilities. Effects with other sedative drugs or ethanol may be potentiated. Use caution in the elderly; dose adjustment recommended. Closely monitor elderly or debilitated patients for impaired cognitive or motor performance. Avoid use in patients with sleep apnea or a history of sedative-hypnotic abuse. Use caution with hepatic impairment; dose adjustment required. Prescriptions should be written for the smallest effective dose (especially in the elderly) and for the smallest quantity consistent with good patient care (especially with depression). Safety and efficacy have not been established in pediatric patients.

Dosage Forms [DSC] = Discontinued product

Tablet, as tartrate:

Ambien®: 5 mg, 10 mg

Ambien® PAK™ [dose pack]: 5 mg (30s); 10 mg (30s) [DSC]

Tablet, extended release, as tartrate (Ambien CR™): 6.25 mg, 12.5 mg

Reference Range

Therapeutic: 80-150 ng/mL; serum levels of 500 ng/mL associated with coma

Autopsy blood zolpidem level of 4.1 mcg/mL associated with fatality

Postmortem blood and urine levels: 7.9 mcg/mL and 4.41 mcg/mL, respectively, following zolpidem overdose

Overdosage/Treatment

Decontamination: Activated charcoal for adult ingestions > 100 mg

Supportive therapy: Flumazenil effectively antagonizes CNS depressant effects

Enhancement of elimination: Not dialyzable; multiple dosing of activated charcoal may be effective

Antidote(s)

- Flumazenil [ANTIDOTE]

Drug Interactions

Substrate of CYP1A2 (minor), 2C9 (minor), 2C19 (minor), 2D6 (minor), 3A4 (major)

Antipsychotics: Sedative effects may be additive with antipsychotics, including phenothiazines; monitor for increased effect

CNS depressants: Sedative effects may be additive with other CNS depressants; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents
CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of zolpidem. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of zolpidem. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, troleanomycin, and verapamil.

Rifamycin derivatives: May decrease levels/effects of zolpidem.

Pregnancy Risk Factor B

Pregnancy Implications Incomplete calcification of fetal skull bones in rats at levels of 20-100 mg/kg

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Nursing Implications Patients may require assistance with ambulation; lower doses in the elderly are usually effective; institute safety measures

Zopiclone

CAS Number 43200-80-2

Impairment Potential Yes

Use Symptomatic relief of transient and short-term insomnia

Unlabeled/Investigational Use In U.S.: Insomnia (<1-month duration)

Mechanism of Action A nonbenzodiazepine sedative hypnotic agent which facilitates gamma aminobutyric acid function

Adverse Reactions

Cardiovascular: Palpitations

Central nervous system: Dizziness, headache, confusion, slurred speech, ataxia, nightmares, memory disturbance, psychosis, drowsiness, lethargy, insomnia, aggressive behavior

Gastrointestinal: **Bitter taste**, xerostomia, nausea, vomiting, loss of taste perception, bitter taste

Genitourinary: Urinary retention

Neuromuscular & skeletal: Dysarthria, tremor

Ocular: Blurred vision

Miscellaneous: Dependence

Signs and Symptoms of Overdose CNS depression, coma, hyperglycemia, hyperkalemia, respiratory depression

Admission Criteria/Prognosis Asymptomatic patients may be discharged 8 hours postingestion; admit any ingestion >30 mg

Pharmacodynamics/Kinetics

Absorption: Elderly: 75% to 94%

Distribution: Rapidly from vascular compartment

Protein binding: ~45%

Metabolism: Extensively hepatic

Half-life elimination: 5 hours; Elderly: 7 hours; Hepatic impairment: 11.9 hours

Time to peak, serum: <2 hours; Hepatic impairment: 3.5 hours

Excretion: Urine (75%); feces (16%)

Dosage Oral: 7.5 mg 30-60 minutes before bedtime

Monitoring Parameters Monitor for confusion, excessive drowsiness especially in elderly, and monitor patients with hepatic insufficiency closely

Administration Administer just before bedtime.

Contraindications Hypersensitivity to zopiclone or any component of the formulation; patients with severe respiratory impairment (eg, sleep apnea); pregnancy (similar agents)

Warnings Causes CNS depression; use with caution in patients who previously manifested paradoxical reactions to ethanol or other sedatives. Should not be administered for more than 7-10 days consecutively, failure of insomnia to remit after 7-10 days may indicate presence of a primary psychiatric or mental illness. Use with caution in elderly patients and in patients with myasthenia gravis, hepatic dysfunction, renal dysfunction, severe pulmonary insufficiency, and depression. Anterograde amnesia can occur, do not take unless a full night's sleep and clearance of the drug from the body are possible. Abnormal thinking and psychotic behaviors may occur with use; confusion may occur, especially in the elderly. Elderly are more susceptible to adverse reactions. Increased daytime anxiety and/or restlessness have been observed with use. May cause dependence; withdrawal symptoms can occur with abrupt discontinuation; the risk of dependence is increased in patients with a history of alcoholism and drug abuse. Not recommended for use in patients <18 years of age.

Dosage Forms Tablet: 5 mg, 7.5 mg

Reference Range After a 7.5 mg oral dose, peak serum levels are ~60-70 mcg/L at 1-1.5 hours and decline to 3 mcg/L at 24 hours; postmortem levels associated with fatal overdoses of zopiclone: 1.4-3.9 mg/L

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Monitor respiratory status; rarely is mechanical ventilation required; flumazenil has been used successfully in one case; flumazenil has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression and respiratory depression

Enhancement of elimination: Hemodialysis/hemoperfusion are not expected to be useful; multiple dosing of activated charcoal may be effective

Antidote(s)

- Flumazenil [ANTIDOTE]

Drug Interactions

Substrate (major) of CYP2C9, 3A4

CNS depressants: Zopiclone may produce additive CNS depressant effects when coadministered with ethanol; sedatives, antihistamines, anticonvulsants, or psychotropic medications.

CYP2C9 inducers: May decrease the levels/effects of zopiclone. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C9 inhibitors may increase the levels/effects of zopiclone. Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nifedipine, NSAIDs, sulfonamides and tolbutamide.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of zopiclone. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of zopiclone. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nifedipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Pregnancy Risk Factor Not assigned; similar agents rated D

Pregnancy Implications There is insufficient data on safety in pregnancy, however, benzodiazepines may cause congenital malformations during the 1st trimester and neonatal CNS depression during the last few weeks of pregnancy; it is expected zopiclone may do the same.

Lactation Enters breast milk/not recommended

Nursing Implications Monitor for effectiveness and excessive drowsiness or confusion the next day; administer just prior to sleep

Zuclopenthixol

CAS Number 633-59-0; 64053-00-5; 85721-05-7

Synonyms Z-Chlopenthixol; Zuclopenthixol Acetate; Zuclopenthixol Decanoate; Zuclopenthixol Dihydrochloride

Use Management of schizophrenia; acetate injection is intended for short-term acute treatment; decanoate injection is for long-term management; dihydrochloride tablets may be used in either phase

Unlabeled/Investigational Use Bipolar disorder, psychoses; agitated states

Mechanism of Action A thioxanthene with a piperazine sidechain; related to fluphenazine, the cis(z)-clopenthixol is the active isomer of this neuroleptic; blocks postsynaptic dopaminergic brain receptors

Adverse Reactions

Cardiovascular: Palpitations

Central nervous system: Dystonia, akinesia, sedation, extrapyramidal effects

Endocrine & metabolic: Elevated serum triglyceride levels

Gastrointestinal: Reduced salivation, weight gain, constipation, xerostomia

Genitourinary: Uricosuric, priapism

Hematologic: Eosinophilia

Hepatic: Liver enzyme elevation

Neuromuscular & skeletal: Rigidity, tremors

Ocular: Blurred vision

Signs and Symptoms of Overdose Dry mouth, extrapyramidal effects, hypotension, respiratory depression, sedation, seizures, tachycardia

Admission Criteria/Prognosis Admit any ingestion > 1 g or any patient exhibiting neurologic symptoms

Pharmacodynamics/Kinetics

Onset: Acetate injection: Sedation within 2 hours

Duration of action: Acetate injection: 2-3 days; Decanoate injection: 2 weeks

Distribution: V_d : 15-20 L/kg

Metabolism: Hepatic via N-dealkylation

Half-life elimination: Terminal: Oral: 20 hours; Depot: 19 days

Time to peak: Acetate injection: 24-36 hours; Dihydrochloride tablet: 3 hours; Depot: 3-7 days

Dosage Oral: Zuclopenthixol hydrochloride: Initial: 20-30 mg/day in divided doses; usual maintenance dose: 20-75 mg/day; maximum daily dose: 150 mg

I.M.:

Zuclopenthixol acetate: 50-150 mg; may be repeated in 2-3 days; no more than 4 injections should be given in the course of treatment; maximum dose during course of treatment: 400 mg

Zuclopenthixol decanoate: 100 mg by deep I.M. injection; additional doses of 100-200 mg (I.M.) may be given over the following 1-4 weeks; maximum weekly dose: 600 mg

Monitoring Parameters Vital signs; lipid profile, fasting blood glucose/Hgb A_{1c}; BMI; mental status, abnormal involuntary movement scale (AIMS), extrapyramidal symptoms (EPS)

Contraindications Hypersensitivity to zuclopenthixol, thioxanthenes, or any component of the formulation; acute intoxication (ethanol, barbiturate, or opioid); severe CNS depression; coma; suspected or established subcortical brain damage; circulatory collapse; blood dyscrasias; pheochromocytoma

Warnings

May be sedating, use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Caution in patients with hemodynamic instability; predisposition to seizures; bone marrow suppression; severe cardiac, hepatic, renal, or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use - use with caution in patients at risk of pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May alter cardiac conduction - life-threatening arrhythmias have occurred with therapeutic doses of neuroleptics. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications which may predispose). Safety and efficacy in children <18 years of age have not been established.

May cause anticholinergic effects (confusion, agitation, constipation, dry mouth, blurred vision, urinary retention); therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other neuroleptics, zuclopenthixol has a low potency of cholinergic blockade.

May cause extrapyramidal reactions, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is high relative to other neuroleptics). May be associated with neuroleptic malignant syndrome (NMS) or pigmentary retinopathy.

ZUCLOPENTHIXOL

Dosage Forms [CAN] = Canadian brand name

Injection, as acetate:

Clopixol Acuphase® [CAN]: 50 mg/mL [zuclopenthixol 42.5 mg/mL] (1 mL, 2 mL) [not available in the U.S.]

Injection, as decanoate:

Clopixol® Depot [CAN]: 200 mg/mL [zuclopenthixol 144.4 mg/mL] (10 mL) [not available in the U.S.]

Tablet, as dihydrochloride:

Clopixol® [CAN]: 10 mg, 25 mg, 40 mg [not available in the U.S.]

Reference Range Therapeutic z-clopenthixol serum levels are 2-12 ng/mL; ingestion of 2.5 g resulted in a peak blood level of 900 ng/mL

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage (within 6 hours) with activated charcoal may be useful

Supportive therapy: Benzodiazepines can be useful to control agitation or seizures

Drug Interactions Substrate of CYP2D6 (major)

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Aluminum salts: May decrease the absorption of antipsychotics; monitor.

Amphetamines: Efficacy may be diminished by antipsychotics; in addition, amphetamines may increase psychotic symptoms. Avoid concurrent use.

Anticholinergics: May inhibit the therapeutic response to antipsychotics and excess anticholinergic effects may occur; includes benztrapine, trihexyphenidyl, biperiden, and drugs with significant anticholinergic activity (TCAs, antihistamines, disopyramide).

Antihypertensives: Concurrent use of antipsychotics with an antihypertensive may produce additive hypotensive effects (particularly orthostasis).

Bromocriptine: Antipsychotics inhibit the ability of bromocriptine to lower serum prolactin concentrations.

CNS depressants: Sedative effects may be additive with antipsychotics; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents.

CYP2D6 inhibitors: May increase the levels/effects of zuclopenthixol. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Epinephrine: Chlorpromazine (and possibly other low potency antipsychotics) may diminish the pressor effects of epinephrine.

Guanethidine and guanadrel: Antihypertensive effects may be inhibited by antipsychotics.

Levodopa: Antipsychotics may inhibit the antiparkinsonian effect of levodopa; avoid this combination.

Lithium: Antipsychotics may produce neurotoxicity with lithium; this is a rare effect.

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk.

Phenytoin: May reduce serum levels of antipsychotics; phenothiazines may increase phenytoin serum levels.

Polypeptide antibiotics (polymyxin): Rare cases of respiratory paralysis have been reported with concurrent use of antipsychotics.

Propranolol: Serum concentrations of antipsychotics may be increased; propranolol also increases some antipsychotic concentrations.

Sulfadoxine/pyrimethamine: May increase antipsychotic concentrations.

Tricyclic antidepressants: Concurrent use may produce increased toxicity or altered therapeutic response.

Trazodone: Antipsychotics and trazodone may produce additive hypotensive effects.

Valproic acid: Serum levels may be increased by antipsychotics.

Pregnancy Risk Factor C

Lactation Enters breast milk/not recommended

SECTION II
NONMEDICINAL AGENTS

ACIDS AND ALKALIS

Jack C. Clifton II, MD and Steven E. Aks, DO, FACMT

Description

Acids and alkalis are ubiquitous in the household and the workplace. Acids commonly stored and shipped in bulk include the inorganic acids: hydrochloric, sulfuric, phosphoric, and nitric acid. Commonly encountered inorganic alkalis are sodium hydroxide and ammonium hydroxide. Common organic acids and bases include such agents as acetic acid and diethylamine (Table 1).

Class	Common Examples	Chemical Formula
Inorganic Acids and Bases		
Strong acids	Sulfuric	H ₂ SO ₄
	Hydrochloric	HCl
Weak acids	Phosphoric	H ₃ PO ₄
	Carbonic	H ₂ CO ₃
Weak bases	Ammonia	NH ₃
	Magnesium hydroxide	Mg(OH) ₂
Strong bases	Potassium hydroxide	KOH
	Sodium hypochlorite	NaClO
Organic Acids and Bases		
Saturated acids	Acetic (ethanoic) acid	C ₂ H ₄ O ₂
	Butyric (butanoic) acid	C ₄ H ₈ O ₂
Unsaturated acids	Valeric (pentanoic) acid	C ₅ H ₁₀ O ₂
	Acrylic acid	C ₃ H ₄ O ₂
Alkylamine bases	Diethylamine	C ₄ H ₁₁ N
Alkanolamine bases	Ethanolamine	C ₂ H ₇ NO

Since these agents can be so familiar, great care must be taken to identify these agents using identification numbers (CAS; UN/D.O.T.) or by precisely spelling the commonly used identifiers; in particular, it is important to avoid confusing hydrochloric and hydrofluoric acids — as the latter has a specific antidote. The toxicity of standard acids and bases is through contact (dermal and ocular), and respiratory irritation, typically through mists.

The concentration, form, and quantity of acids and bases are critical when assessing the significance of a spill or exposure. Acids and bases may exist in pure form, as salts (partial replacement of H⁺ or ⁻OH ions with another ion), or as an anhydride (metal or metalloid oxide), though properties are generally similar across forms.

Strong acids and bases, particularly anhydrides, can be strongly exothermic when neutralized, especially when water is added to a larger quantity of product. Heated acids can also release potent fumes. While this is a concern in fire suppression, this should not deter use of water decontamination of patients exposed to corrosives, once clothes are removed and most of the product has been gently brushed or blotted away. Copious tepid fluids will keep exothermic reactions manageable, and most quickly restore tissue pH toward normal.

Acids in particular are also a threat because of their propensity to cause generation of toxic gases when mixed with salts and other compounds (Table 2). A number of the organic bases are notable for their flammability and may release toxic nitrous oxides when heated. Incidents involving poorly managed chemical warehouses can be a hazardous material nightmare because of the proximity of so many incompatible substances.

Table 2. Selected Important Chemical Reactions Involving Acids and Bases

Agent Exposed	Toxic Product Generated
Cyanide salts with acids	Hydrocyanic gas
Metals with acids	Hydrogen gas
Arsenic with acids	Arsine gas
Metal phosphides	Phosphine gas
Bleach (NaClO) with acid	Chlorine gas
Bleach (NaClO) with ammonia	Chloramine gas

With the preceding as background, this section will focus on a few of the very common acids and bases.

Sources of Exposure

Hydrochloric acid (CAS #7647-01-0) is used for metal etching, as a bleach, and for various industrial uses in chemical synthesis. Hydrochloric acid is a nonflammable, colorless gas or fuming liquid with a characteristic suffocating odor. After reacting with metals, it can form hydrogen gas, which is highly flammable. A concentration of 100 ppm is considered immediately life-threatening due to its ability to cause asphyxiation and chemical injury. Its vapor pressure is 3240 mm Hg at 18°C (64°F), nearly 70 times the vapor pressure of water at these conditions.

Hydrofluoric acid (CAS #7664-39-3) in a concentration of 1% to 100% is commonly utilized in industrial settings for etching (ceramics, microchips, and glass), electroplating, and rust removal. Commercial products (1% to 12%) for home use include rust removers and chrome cleaners. Anhydrous HF (100%) is a colorless liquid with a boiling point of 19.4°C (67°F) and a vapor pressure of 400 mm Hg at 2.5°C (36.5°F) that fumes at concentrations >48%; therefore, vapor formation at a spill site may be hazardous to workers. A concentration of 20 ppm may be immediately dangerous to life and health.

Sulfuric acid (CAS #7664-93-9) is utilized in chemical and fertilizer manufacturing. It represents the most commonly used chemical in the United States. Two examples of sulfuric acid's use in common products are battery acid (30% solution) and toilet bowl cleaners (10% solution). Sulfuric acid is a clear, colorless, nonflammable liquid when pure. Although nonflammable by itself, this acid can ignite other combustible materials, such as wood or paper. A concentration of 10-20 ppm is nearly unbearable because of its extreme irritant effect. Sulfuric acid has a vapor pressure of 1 mm Hg at 146°C (295°F).

Nitric acid (CAS #7697-37-2; fuming, CAS #52583-42-3) is used in the engraving process, metal refining, and electroplating. Nitric acid is a transparent, colorless, or yellowish fuming liquid. It is nonflammable, but when combined with other materials, can accelerate their burning. Its vapor pressure is 760 mm Hg at 25°C (77°F). Mists of nitric acid cannot be tolerated – even at low concentrations. A concentration of 100 ppm is considered immediately life-threatening because of its potential to cause asphyxiation.

Phosphoric acid (CAS #7664-38-2) is utilized for metal cleaning and rustproofing. In low concentrations, it can be used as a disinfectant. In very low concentrations it can have a pleasant taste, and is in fact found in Coca Cola™. Phosphoric acid is a colorless liquid or rhombic crystal as a solid. It becomes anhydrous when heated to 150°C (302°F). Phosphoric acid has a low vapor pressure [0.0285 mm Hg at 20°C (68°F)]. When used as an agent for metal cleaning, phosphoric acid may react with impurities in the metal and release phosphine gas, which is highly flammable. Phosphine gas may explode in the presence of high temperatures; rescue workers must therefore use extreme caution if fires are burning at an accident site. In addition to its flammability, phosphine is a noncompetitive inhibitor of cytochrome oxidase resulting in the subsequent blockade of electron transfer and oxidative phosphorylation, particularly in the myocardium where cardiac arrhythmias and cardiovascular collapse may result.

Sodium hydroxide (CAS #1310-73-2) is used as a drain cleaner and as lye (96% to 100% solution). It is available commercially in Drano® (56% solution) and in Clintest® tablets (54.2% sodium hydroxide). Sodium hydroxide is usually in the form of a whitish, lumpy solid that is easily liquefied. It is a prototype of alkaline caustics. This base can react violently with other chemical products (eg, acetic acid). By itself it is corrosive. It has a vapor pressure of 1 mm Hg at 739°C (1362°F).

Ammonium hydroxide (CAS #1336-21-6) can be found in common household cleaning products in concentrations ranging from 3% to 10%. It is also used in industry in the production of fertilizers, fibers, and

other chemicals. Ammonium hydroxide is a colorless, alkaline liquid with a very pungent odor. In its anhydrous form (NH_3) it is a colorless alkaline gas.

Given the wide range of uses for these agents, it is hardly surprising that over 57,000 exposures to acidic and alkaline compounds are reported annually to reporting poison control centers.⁵⁸ Large quantities of these agents are produced yearly in the U.S. According to 1999 data reported in *Chemical and Engineering News*,⁹⁴ the following amounts of chemicals were produced in the U.S. that year (Table 3).

Chemical	Amount (thousand tons)
Sulfuric acid	37,515
Hydrochloric acid	5,012
Nitric acid	6,703
Phosphoric acid	11,463
Sodium hydroxide	9,508
Anhydrous ammonia	10,762

Target Organs and Mechanisms of Action

Exposure is possible via ocular, dermal, inhalational, and oral routes; the eye, skin, and mucous membranes of the gastrointestinal and respiratory tracts constitute the major sites for caustic damage. The clinical syndrome observed will reflect the route, concentration, amount, and duration of exposure. Low concentrations of acids or alkalis act as irritants to the skin, eyes, and mucous membranes when exposure is brief. At higher concentrations or with prolonged exposure, these substances are corrosive. Systemic effects of caustic exposure may be manifested following severe burns, inhalation of fumes, or ingestion.

By definition, an acid is a proton donor while a base is a proton acceptor.^{11,60} There are important differences between the burns induced by acidic and alkaline compounds. Alkali burns cause more significant and persistent changes in corneal, mucous membrane (GI and respiratory tract), and skin pH than do acid burns. Through the process of liquefactive necrosis, alkalis penetrate and destroy tissue to deeper levels via protein hydrolysis and lipid saponification. In contrast, acid burns tend to be dryer and more superficial since the affected tissue proteins upon desiccation and denaturation coagulate into an eschar which prevents deeper tissue damage.^{6,8,14,15,24,81,83}

Deserving special attention, HF, a relatively weak inorganic acid ($\text{pK}_a = 3.8$) that is desiccating and corrosive like other acids, will produce coagulation necrosis of tissues; however, unique to HF is its ability to deeply penetrate tissues in a manner similar to alkalis where it exerts additional toxicity resulting in hypocalcemia, hypomagnesemia, and hyperkalemia.

Clinical Presentation

Common symptoms after exposure to caustic mists include tearing and burning of mucous membranes. Inhalation of acid mists can cause cough, dyspnea, choking, bronchoconstriction, and even pulmonary edema, sometimes delayed for 6-12 hours after the exposure. A chemical pneumonitis may also develop with many similarities to that caused by the nitrogen oxides.

Ocular and dermal exposure are painful, with erythema and vesicle formation initially, followed by obvious burns. Dermal burns progress rapidly within minutes necessitating rapid intervention, particularly for the more deeply penetrating alkali injuries. Tearing is noted initially after ocular injuries, and is followed by development of corneal erosions.

Acid or alkali ingestion may produce a variety of signs and/or symptoms including stridor, dyspnea, drooling, vomiting, dysphagia, odynophagia, perioral or oral burns, and pain in the chest, epigastrium, or abdomen. However, in a patient with a caustic ingestion history, the absence of these signs and/or symptoms, including oropharyngeal pain or burns, does not preclude serious injury to GI tract.^{16,24,26,32,76,84,101,114-116} In adults, the most severe injuries are reported after suicidal ingestions. Acids are thought not to result in esophageal injury as often as with alkaline ingestions.^{31,109} However, many studies have demonstrated

acid-induced esophageal damage to be as frequent and severe as alkaline-induced esophageal damage.^{27,43,63,115} Gastric and duodenal burns secondary to caustic ingestion are also quite common.^{7,9,14,19,21,29,42,46,54,66,75,77,93,96,100,111,115} In either case, extensive tissue involvement may lead to perforation anywhere along the upper GI tract with life-threatening complications.^{4,9,27,40,43,53,77,83,115} Respiratory distress in the patient following a caustic ingestion may be due to aspiration of the caustic, perforation of the GI tract resulting in mediastinitis, air, and/or fluid in the chest, or edema of the larynx and/or epiglottis.^{21,23,52,71,73,83,92,99} There is generally little systemic absorption of these chemicals except infrequently in the case of severe nitric acid exposure associated with methemoglobinemia presenting clinically with cyanosis and respiratory distress.³⁶ Sulfuric acid and hydrochloric acid through their gastric absorption may also lead to a more severe metabolic acidosis accompanied by an increased anion gap or normal anion gap, respectively. More serious presentations subsequent to caustic ingestion may include signs and/or symptoms related to GI bleeding, DIC, or shock.^{16,20,21,35,40,44,47,48,93,116}

Management Guidelines

Field Stabilization and Triage

In incidents with multiple casualties and/or limited transport or treatment facilities, some triage will be required.⁹⁵ At the site of a spill, rescue workers must be careful to wear protective clothing so they do not become secondarily contaminated by the caustic; polyvinylchloride or natural rubber gloves will protect the hands from serious HF dermal exposure. Respiratory protection should also be worn if mists are present.

The patient should be removed from the source of exposure. Assuming no traumatic or other injuries, serious extensive chemical burns will be evident if each victim's clothes are removed. All clothing must be removed to uncover any traumatic injuries or chemical burns.

Inhalational injury is an important consideration. Acid mists are heavier than air, but tend to disperse rapidly. If the patient's exposure is by inhalation, he or she should be moved into fresh air and given 100% oxygen. Attention to basic resuscitation principles is essential. Airway control (bag-valve-mask or intubation) is necessary if the patient has inadequate ventilatory effort or poor air exchange. Immediate transport is mandated if the patient is exhibiting signs of respiratory distress or is hypotensive.

For ocular or dermal exposure, the affected area should be copiously irrigated with water for at least 15 minutes; alkali burns require longer periods of irrigation.^{15,97,102} Burns may become more severe if flushing is delayed for more than 1-2 minutes;¹¹² the final outcome of any chemically induced ocular injury is directly related to the duration of contact between the eye and the caustic substance.^{97,102} Using a base to neutralize an acid (or vice versa) is not advised, because the heat of reaction may exacerbate the burn.⁹¹ Contact lenses, rings, and other jewelry should be removed. Timely transport of the patient to an emergency department after decontamination and irrigation of external burns is essential. If only minor eye irritation is present without other symptoms, once adequate ocular irrigation is complete, evacuation may be delayed in deference to more seriously injured patients.

The history of exposure, vital signs, and predisposing medical conditions must be considered; if doubt remains, prompt emergency department observation is optimal. Patients with no evidence of respiratory distress, dermal, or ocular irritation are unlikely to have received a serious exposure at the spill site.

Emergency Department Management

The adequacy of field decontamination will usually be apparent – keys are removal of clothes, removal of gross contamination, and then copious irrigation with tepid water to stop the burning. The potential for secondary contamination is limited, but appropriate gloves (rubber or nitrile) and goggles are useful during gross decontamination.

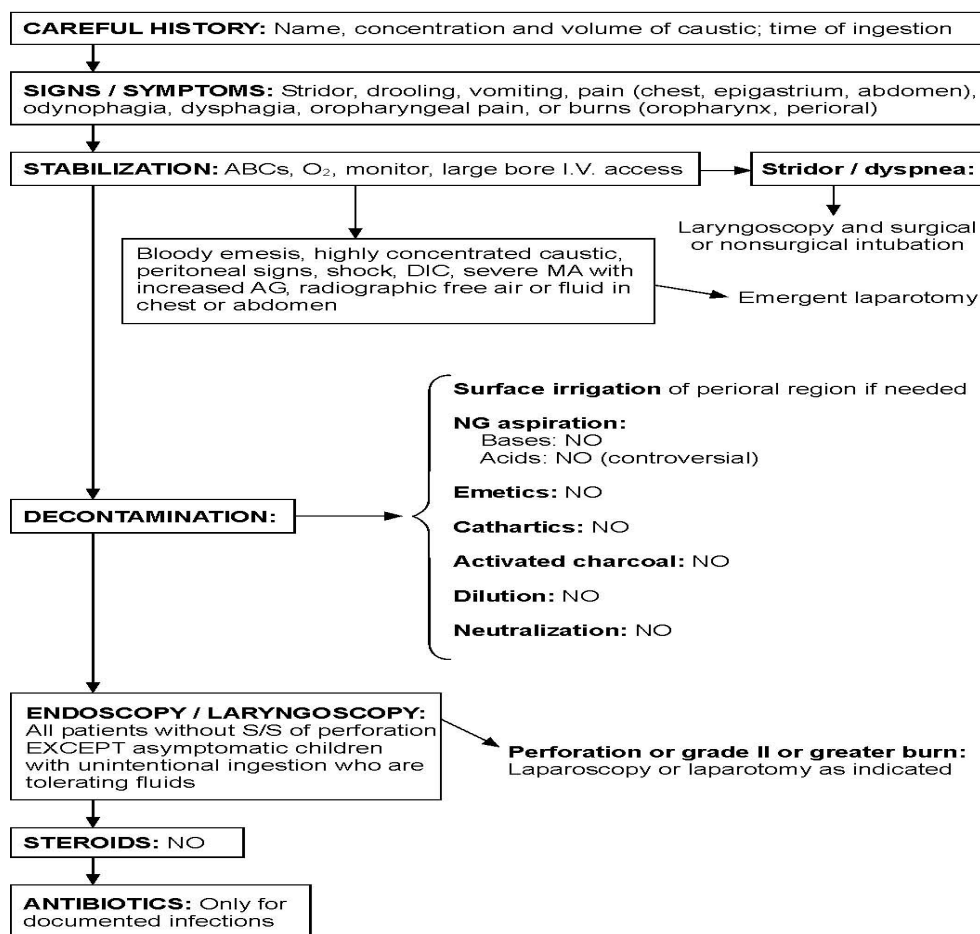

In the emergency department, the physician should assume any dermal or ocular irrigation administered at the time of the injury to be inadequate. Immediate copious irrigation should be initiated for any acid or alkali burn. Ideally, this should be done in a decontamination room to minimize exposure to healthcare workers and other patients. Testing of dermal or ocular pH may be helpful after irrigation, which should continue until the pH is normalized.^{15,17,97,102} Ocular findings may range from mere erythema of the conjunctivae in mild acid exposure to complete corneal opacification with permanent visual impairment and increased intraocular pressure in severe acid and alkali exposures. Ophthalmologic consultation is necessary for significant ocular burns.

Alkali burns of the skin and mucous membranes may range from white or gray areas with erythematous borders to complete tissue loss. Acid-induced dermal injuries appear as thermal burns with erythema, blistering, or full-thickness loss of skin.¹⁰⁸ Dermal injuries require standard burn management, except some would favor draining the acid-containing fluid from the acid-induced blisters. Patients with extensive dermal involvement require meticulous attention to the judiciously aggressive replacement of fluids.⁷⁸

For patients with documented inhalational injuries or those presenting with stridor, rales, rhonchi, or dyspnea, chest x-rays and arterial blood gas level determinations are useful; however, changes may not be evident for several hours after exposure. One-hundred percent oxygen should be administered and airway intervention should be performed as necessary. Bronchodilators may be of some benefit in patients with bronchospasm. For HF inhalation, nebulized calcium gluconate (2.5%) may also be considered.

The clinician must view all caustic ingestions as life-threatening. A methodical strategy in the evaluation and treatment of the patient with a caustic ingestion must be followed (see Figure). The history must include the caustic's name and concentration along with the amount ingested and the time of ingestion. The signs and symptoms listed in the figure below should be sought. However, the clinician must remember that the absence of the signs and/or symptoms in a patient with a caustic ingestion does not necessarily indicate the absence of severe or life-threatening GI injury.

Emergency Management of Ingested Caustics

Stabilization: An aggressive approach to airway stabilization in the symptomatic patient must be executed. Laryngoscopy with surgical or nonsurgical airway placement may be required. Continual monitoring of the respiratory and cardiovascular status of all caustic ingestion patients is essential. Immediate I.V. access should be established for fluid administration. Emergent surgical consultation is necessary in any ingestion patient with bloody emesis, peritoneal signs, metabolic acidosis (pH < 7.2) with an increased anion gap or air, and/or fluid in the chest or abdomen.^{18,29,48,61,64,69,110,113}

Decontamination: Dermal irrigation of the perioral region may be necessary in the caustic ingestion patient with facial burns. Decontamination procedures should not include emetics which may result in esophageal re-exposure to the caustic, cathartics which may actually extend the area of injury along the GI tract, or

activated charcoal which does not adsorb caustics and will interfere with subsequent endoscopy. Even though nasogastric suction of alkali from the stomach is contraindicated, some authors advocate gentle suction of acid which has pooled in the stomach.^{20,30,31,50,74} This practice remains controversial due to the risk of perforation within the GI tract.

Dilution: Dilutional techniques in the caustic ingestion patient are unproven since they have never been adequately studied in humans.^{21,30,39,51,104} In that dilutional therapy increases the risk of vomiting in the poisoned patient resulting in esophageal re-exposure to the caustic and possible aspiration and perforation, diluents should be utilized very cautiously, if at all.

Neutralization: Neutralization therapy is controversial and should not be utilized in the routine ED management of patients with caustic ingestions.^{24,80,84,91,98,104}

Endoscopy/Laryngoscopy: Unless signs of GI tract perforation are present which mandate emergent surgical intervention, immediate laryngoscopy/endoscopy is necessary in all patients who have ingested acidic or alkaline compounds, except for the child with an unintentional ingestion who is asymptomatic and tolerating liquids.^{3,4,9,16,18,32,39,40,48,49,55,56,59,66,76,79,82,83,93,100,106,113,115,116} The majority of studies involving caustic ingestions have demonstrated that the presence or absence of a patient's signs and/or symptoms at presentation does not reliably predict the presence or absence of serious injury to the GI tract.^{21,22,26,29,33,43,70,80,84,87,101,111,114,116} A qualified endoscopist should evaluate the laryngeal region as well as the esophagus, stomach, and duodenum utilizing Zargar's classification of any observed burns (Table 4).¹¹⁶ Any necrotic areas or perforations of the GI tract noted during endoscopy should result in an immediate surgical consultation.

Corticosteroid administration: The use of corticosteroids may prevent the recognition of gastrointestinal tract perforation.^{20,31} Patient studies of caustic ingestions have also revealed that first degree burns (grade 1) do not progress to stricture formation in the esophagus, while all third degree burns (grade 3) progress to stricture formation in patients receiving or not receiving corticosteroids. No study has appropriately evaluated the effect of steroids in patients with grade 2 (a or b) burns. Therefore, corticosteroid administration to the patient with a caustic ingestion can not be recommended.^{1,2,10,12-14,29,41,43,65,67,85,105,116}

Antibiotics: Antibiotic therapy should be reserved only for documented infections.

Routine labs should include a complete blood cell count, electrolytes, blood urea nitrogen, creatinine, coagulation studies, liver function tests, arterial blood gas, chest and abdominal radiographs (rule out aspiration pneumonitis, free air, or effusion), and stool for Hemocult[®]. Methemoglobin levels should be obtained in patients with known nitric acid exposure and in those patients presenting with cyanosis.

The assessment of HF exposure deserves special mention. The patient's presentation depends on the amount and concentration of HF as well as the route and duration of exposure. Patients exposed to <20% HF may not be symptomatic for up to 24 hours postexposure; 20% to 50% HF usually produces symptoms within 8 hours, while >50% HF results in immediate symptoms. Dermal exposure constitutes the most common route with the majority of HF injuries involving the hands. Progressive itching, burning, and pain with signs ranging from early erythema to blisters and necrotic (eschar) areas occur. Topical application of a 2.5% calcium gluconate gel (3.5 g calcium gluconate powder in 150 mL of K-Y[®] jelly) should be initiated with pain elimination as the goal. Should the calcium gluconate gel fail, then subcutaneous injection of 10% calcium gluconate should follow. The area of injured tissue may be infiltrated subcutaneously with a small gauge needle utilizing 0.5 mL/cm². Use of subcutaneous injection in digits is limited because of the potential to compromise local circulation. In the case of more severe burns to the hands or feet, intra-arterial (radial, brachial, posterior tibial, femoral) calcium gluconate infusion may be required. 10 mL of 10% calcium gluconate solution added to 40 mL of NS or 5W may be infused into the artery over 4 hours with pain resolution as the goal. Tissues of the eye are very sensitive to HF. Symptoms include tearing, injection of the conjunctivae, and pain. Corneal denudation and scarring may result. HF is a mucosal irritant of both the upper and lower respiratory tract. Mild, non-life-threatening irritation of the upper airway to florid pulmonary edema ending in death may be observed. In HF ingestions, abdominal pain associated with nausea and vomiting are commonly observed. Erosions of the upper GI tract to severe colitis with perforation may occur. Theoretically, HF's systemic effects can be seen following any route of exposure, but are rare after ocular exposure. Most commonly, hypocalcemia, hypomagnesemia, and hyperkalemia may lead to respiratory failure, hypotension, and cardiac arrhythmias.

Sequelae

The short term complications of serious chemical burns to be cognizant of are similar to those of thermal burns, including pneumonia, cellulitis, sepsis, gastrointestinal bleeding, renal failure, and thromboembolism. Possible systemic effects of ingestion to be anticipated include metabolic acidosis, hypotension, disseminated intravascular coagulation, shock, and potentially death.

The long-term effects of caustic exposure that may be observed are numerous. Severe caustic burns to the eye may result in corneal scarring, cataracts, glaucoma, or blindness. Dermal burns may persist as indolent ulcers or permanent scars. Inhalational caustic injuries may produce long-term morbidity ranging from pulmonary fibrosis and bronchiectasis to chronic obstructive airway disease. Ingestion of caustics resulting in severe gastrointestinal burns may lead to strictures of the esophagus, stomach, and duodenum.^{19,25,46,96,111} Esophageal shortening and motility dysfunction as well as a gastric dumping syndrome or achlorhydria with a resultant pernicious anemia may also result from caustic ingestions.^{8,37,38,47,62,68,89,90} Caustic-induced injury to the laryngeal region may result in dysphonia, aphonia, and aspiration-related problems in the patient.^{23,34,52,71,86,88,92,99,103,107} There are no reported teratogenic properties associated with either acids or bases; however, squamous cell carcinoma and adenocarcinoma of the esophagus and stomach have been reported up to 40 years after the ingestion of corrosives.^{5,28,45,57,72}

Disposition

Patients should be admitted to the hospital for evidence of functionally significant burns to the hand, foot, or perineum, any circumferential burn where vascular compromise may occur, or for a burn with >25% involvement of body surface area. The patient should be admitted at a center where there are qualified burn specialists, or plastic and hand surgeons. Parenteral antibiotics should not be initiated until positive cultures document the presence of an infection. Also, a patient with significant inhalation injury with evidence of an elevated arterial-alveolar gradient should be kept for observation. Appropriate disposition of the caustic ingestion patient may be based on the burn grade discovered during endoscopic evaluation (Table 4).¹¹⁶ Grade 0 (normal exam) or grade 1 burns: admit to the regular floor, allow P.O. intake as tolerated, prescribe antacids, and administer analgesics as needed. Most of these patients will return home within 48 hours on antacids. Grade 2a burns: hospital management is identical to the grade 0 and grade 1 burns, but the patient's discharge home on antacids occurs somewhat later (5-11 days). Grade 2b and grade 3 (a or b) burns: these patients require a much more prolonged hospitalization in the ICU, NPO status with I.V. hydration, and appropriate nutritional support. Close monitoring for possible complications such as perforation, airway obstruction, and shock is essential.

Table 4. Endoscopic Caustic Burn Classification

Grade 0	Normal exam
Grade 1	Edema and hyperemia of the mucosa
Grade 2a	Mucosal friability, blisters, hemorrhages, erosions, whitish membranes, exudates, superficial ulcerations
Grade 2b	Grade 2a plus deep discrete or circumferential ulceration
Grade 3a	Small scattered areas of multiple ulcerations and necrosis
Grade 3b	Extensive necrosis

EXAMPLES OF MASS EXPOSURES INVOLVING THE PEDIATRIC POPULATION

Carl R. Baum, MD, FAAP, FACMT

The Case of the Hapless Hyperventilating Hockey Players

In Massachusetts, 12 school-age children and some of their family members went to an away peewee league hockey tournament in the western part of the state, where they stayed in a local hotel, swam in the hotel pool, and had meals within the town. Over the course of the next 2-5 weeks, 16 of the children, 12 boys and 4 girls, some hockey players, and some siblings of the players, presented to a regional toxicology clinic on referral from their pediatricians with a similar constellation of symptoms, most noting fatigue as well as skin and respiratory problems, and most of the symptoms had persisted since the hockey weekend. The children, whose ages ranged from 7 to 14 years, had some or all of the following: fatigue with significantly decreased tolerance for exercise; a subtle white or ashy-appearing rash; a dry, nonproductive hacking cough; chest tightness; wheezing; irritated mucous membranes, mostly involving the eyes with some nasal irritation; diffuse abdominal pain; nausea; and some emesis. The patients were afebrile, with vital signs within the normal ranges, and their physical exams were otherwise unremarkable, other than the aforementioned rash and irritated mucous membranes. With the exception of one child who had asthma, none of the others had significant medical histories, and all were healthy and active prior to the hockey weekend. Some of the children experienced onset of symptoms during the hockey weekend, and some within 1-2 days after the weekend. None of the adults who attended the hockey tournament were known to have any of these symptoms.¹

Consider the following:

1. How would you plan and organize the assessment and evaluation of multiple patients with multiple symptoms?
2. What further information and what laboratory evaluations, if any, would you need to obtain?
3. What would you tell the patients, their parents, and their pediatricians?

This article describes a series of incidents in this century during which large numbers of people have become ill or even died because of the exposures to a variety of toxins. This “world tour” will bring us to a number of sites, beginning in the United States (1937); Minamata Bay, Japan (1956); Seveso, Italy (1976); Port Pirie, S. Australia (1979-82); New Orleans, LA (1981); Bhopal, India (1984); Chernobyl, Ukraine (1986); Tokyo, Japan (1995); and Haiti (1996).

What can be learned from mass exposures? While these events may not reflect the day-to-day experiences of physicians in the clinic or emergency room, much can be learned from the way the incidents are reported and studied, which helps us describe and understand the effect of these toxins over the very long term, the importance of regulatory agencies, and the elements of an environmental history. Finally, mass exposures remind us that there are no accidents; rather, series of errors occur, sometimes over many years, that go unnoticed and culminate in catastrophic events.

United States (1937)

This was an important year in infectious diseases because the antibiotic sulfanilamide was introduced. Pharmaceutical companies rushed to produce this miracle drug. Among them was the Massengill Company, which anticipated a need, especially among children, for a liquid preparation. The company knew that the drug could not simply be dissolved without the use of a solvent. In this case, they chose diethylene glycol (DEG) to help develop the elixir of sulfanilamide. DEG, like ethylene glycol, is an antifreeze and solvent and was an inexpensive and effective solvent for the elixir. The elixir was subjected to and passed Massengill's tests for appearance, flavor, and fragrance. The company did not test the safety of the new product.

DEG, discovered in 1869, is a condensation product of ethylene glycol manufacture. It did not become commercially available until 1928. By 1937, the entire world literature on DEG consisted of a few rodent studies that suggested probable toxicity. These data were ignored, and production of 228 gallons of the DEG-based elixir proceeded. Over the subsequent 4 weeks, 353 patients received the elixir for a variety of indications, such as gonorrhea, tonsillitis, otitis, and soft-tissue infections. The instructions read as follows:

... begin with 2-3 teaspoonfuls in water every 4 hours. Decrease in 24-48 hours to 1-2 teaspoonfuls and continue at this dose until recovery.

Many did not recover. In fact, a number of patients taking the elixir developed new symptoms, including nausea and emesis, followed by flank pain, anuria, coma, and seizures. Gastrointestinal disturbances may have limited absorption of the elixir. Some died. It was estimated that a fatal cumulative dose was 10 teaspoonfuls for children or 20 teaspoonfuls for adults. Mean survival after the first dose was 9 days (range 2-22 days). There were clusters of cases around the country, in East St Louis, Tulsa, and Charleston. Only 6 gallons of elixir were eventually distributed, but the death toll was 34 children and 71 adults. Postmortem examination revealed "hydropic tubular nephrosis," or vacuolar nephropathy. Unlike ethylene glycol poisoning, no calcium oxalate deposition was observed in the renal tubules. A centrilobular hepatic degeneration was seen.

The disaster did have some beneficial effects. Until this time, federal regulation of pharmaceuticals was limited to the 1906 Pure Food and Drug Act, which prohibited misbranding and adulteration of food, beverages, and drugs. There were no safety requirements. Planned revision of the Act was stalled in Congress, but the emotion aroused by this disaster led to the 1938 Food, Drug, and Cosmetic Act, which led to the modern Food and Drug Administration.²

Minamata Bay, Japan (1956)

Like the events described above, this story actually begins many years before and represents a typical pattern of errors which culminate in disaster. In 1932, the Chisso Corporation began using mercury as a catalyst in the synthesis of acetaldehyde. This reaction produced a toxic organic form of mercury, methyl mercury chloride, which was discharged into Minamata Bay. Fish living in the contaminated waters of the Bay were consumed by larger fish. Over the years, through a process known as bioaccumulation, methyl mercury was incorporated progressively into animal tissues and the food chain. By the 1950s, small animals, such as cats, were dying mysteriously, and in 1956, humans began presenting to hospitals with a variety of neurologic symptoms. Within 5 months, methyl mercury was implicated as the cause for what became known as "Minamata Disease." In the 1960s, methyl mercury levels in fish peaked at 60 times normal background levels. Cases of intrauterine intoxication became known as "fetal Minamata disease."³ Masumoto⁴ described this toxic encephalopathy which was acquired prenatally and resulted in cerebral palsy. Harada⁵ examined EEGs in 32 children; in 19 with congenital disease, 10 had abnormal findings; among 13 with acquired disease, 8 had abnormal studies. No focal abnormalities were seen on the EEGs. Methyl mercury is postulated to interfere with migration of neural cells from the neural tubule during embryogenesis. A syndrome of microcephaly, cerebral palsy, and contractures resulted, portrayed in the famous *Life* magazine photograph depicting a Japanese mother cradling an affected child.

An expert panel convened to assess the net impact of fish consumption on cognitive development concluded that prenatal exposure to methyl mercury might account for a loss of up to 1.5 intelligence-quotient (IQ) points.⁶

Seveso, Italy (1976)

In this story, a disinfectant, trichlorophenol, was produced from a variety of starting materials at a Roche plant. On July 9, a Friday, the night shift arrived at the plant and went to work around 10:00 in the evening. On Saturday at 4:45 AM, a foreman shut down the heat in a reaction vessel in an attempt to interrupt the distillation. His shift ended at 6:00 AM, but the reaction did not. The last recorded temperature in the vessel was 158°C, and pressure continued to build until just after noon that day. With only the cleaning staff on hand, the excessive pressure burst a safety valve, and an aerosol cloud escaped toward the southeast. Inhabitants of the surrounding area were warned not to touch fruits and vegetables, although the warning efforts were delayed because it was now the weekend. Within 5 days, obvious skin inflammation was noted among some inhabitants, particularly in children. Ultimately, dioxin was found in the plant and from the surrounding areas. Children began presenting with a late-occurring acne, known as chloracne.⁷ Later studies revealed indirect markers of hepatic microsomal enzyme activity, as well as modest elevations of liver function tests (GGT and ALT), which persisted for up to 6 years after the accident.⁸

Dioxin is actually a family of chemicals. The particular species was identified as tetrachlorodibenzo-p-dioxin, a contaminant of herbicide and germicide production. Most of the childhood exposures around Seveso resulted from consumption of contaminated foods or contact with soil. The U.S. Environmental Protection Agency estimates that a lifetime exposure of 1 ng/kg/day could result in 1560 additional cases of cancer per 10,000

population. Children, therefore, may bear out this legacy in years to come.⁹ A study conducted in Seveso, approximately 20 years after the accident, revealed that dioxin toxicity was confined to acute dermatological effects, and that chloracne occurrence was related to younger age and light hair color.¹⁰

Port Pirie, S. Australia (1979-82)

This exposure occurred over many years. This industrial town, with a population of 16,000, was situated immediately downwind of a large lead-smelting factory. There was extensive lead contamination in the town's topsoil and yard and house dust. McMichael et al¹¹ undertook a large, prospective study of inhabitants. They followed over 500 children who were born in the period 1979-82, and measured blood lead levels in both the birth mothers, antenatally and at delivery, and in the children at birth, at 6, 15, and 24 months, and then annually. The investigators used one of the well-known instruments for assessing childhood development, the McCarthy Scales of Children's Abilities. They found that mean lead levels in midpregnancy among the mothers was 9 g/dL; the peak at age 2 years among the children was 21 g/dL. At that time, the CDC's "cut-off" level for lead in the United States was 30 g/dL. McMichael and coworkers found that the blood lead was inversely related to development at age 4 years. This study was one of a series that suggested even low levels of lead had adverse effects on development and helped provide impetus to further lower "acceptable" lead levels subsequently, to 25 g/dL in 1985 and to 10 g/dL in 1991.

New Orleans, Louisiana (1981)

In the spring of 1981, a neonatologist named Juan Gershanik joined the staff of a small Louisiana hospital, where he cared for a 750 g infant who suddenly died. This was a child who otherwise had been doing quite well and had every reason to survive. Gershanik thought that a poison might have been responsible. His colleagues did not agree with this theory, but Gershanik persisted and noticed a pattern with other deaths: the victims were small and ill, but many had been improving before a rapid demise. He described a syndrome of multi-system disease, characterized by severe metabolic acidosis and gasps that signaled impending death. This became known as the gasping syndrome, or "gasping baby syndrome."¹² A postmortem urinalysis for organic acids on a GC-MS revealed large amounts of benzoic acid and hippuric acid. That same evening Gershanik returned to the nursery and discovered, to his horror, a vial of bacteriostatic water atop one of the isolettes contained 0.9% benzyl alcohol, a preservative. He realized that benzyl alcohol was converted via alcohol dehydrogenase to benzoic acid and hippuric acid. He immediately removed these vials (and others) containing benzyl alcohol from the nursery and, abruptly, there were no new cases of the syndrome. Gershanik corresponded with the manufacturer of the bacteriostatic water and with the FDA. Both largely ignored his concerns about its safety. In January of 1982, he reported his findings, and other institutions began to corroborate the pattern of unexpected deaths. Similar urinary organic acid profiles were found among these victims. Nearly 1 year after Gershanik removed the offending vials from his nursery, the FDA issued a "Dear Doctor" letter warning of the association between benzyl alcohol and the syndrome, and in September 1983, the AAP issued a position statement warning of the dangers of benzyl alcohol as a preservative in very sick children. After knowledge of the association became widespread, there were dramatic falls in mortality and intraventricular hemorrhage; overall, benzyl alcohol was blamed for about 3000 deaths and countless permanent disabilities. During the period in which its use was limited, there were dramatic falls in the incidence of cerebral palsy, kernicterus, especially significant among small (< 1000 g) and premature (< 27 weeks gestation) infants.

Why did these events occur in 1981? This was a period of aggressive respiratory therapy. With limited transcutaneous monitoring available, therapists performed frequent blood gas testing, which required frequent flushing of arterial lines. Ironically, as an infant became more ill, more blood gases were obtained, leading to greater benzyl alcohol exposure and risk for the syndrome.

Bhopal, India (1984)

Once again, a large corporation was involved in this story. Years before, in 1969, Union Carbide built a plant in Bhopal to package U.S.-produced pesticides. In 1980, expansion allowed for production of carbamate insecticides, requiring a chemical known as methyl isocyanate, or MIC. By 1984, squatters' rights had been granted to inhabitants of the area, and 100,000 of the city's population of 900,000 lived within 1 km of the plant. Shortly after midnight on December 3, water inadvertently entered a tank containing 41,000 kg of liquid MIC. This led to an exothermic reaction, and a cloud of MIC gas, an irritant that causes an obstructive pattern in the lung, was explosively released. A total of 1000 were dead by morning. A number of studies were done on victims in the area. In one, the death rate among 1337 affected children was 8.9% (119 dead);¹³ another

study of 211 victims found that respiratory symptoms at 100 days were persistent among over 50% of those within 2 km of the plant compared to 8.5% of those beyond 8 km of the plant. Apprehension and depression was noted among older children, some of whom awoke after the accident to find themselves on a pile of dead bodies.¹⁴ A follow-up study 3 years later revealed persistent eye complaints among those exposed to MIC.¹⁵

Chernobyl, Ukraine (1986)

In the former Soviet Union, one of the nuclear power reactors in use was known as an RBMK type. This particular design, which was used to produce both electrical power and weapon-grade plutonium, required a tall structure that precluded the usual containment shell. This resulted in a somewhat unforgiving design, because production of steam increased plant reactivity, unlike other reactors, in which steam inhibited the nuclear reaction. Xenon, another reactor product, tended to shut down the reactor if control rods were in place. In a test designed to prevent plant shutdown, the control rods were removed. But the control rods were also required as a safety feature to prevent a runaway nuclear reaction. Needless to say, steam accumulated, causing an enormous increase in the nuclear reaction. This caused a steam explosion that blew the top off the reactor. The story might have ended at this point, because the reaction stopped, but another design feature, a graphite moderator, caught fire and burned for 9 days. This helped spread radionuclides, resulting in the largest known release of radioactive material. The reactor was subsequently encased in a concrete tomb, but not before over 21,000 km² of soil were contaminated. In the first few months, the radioisotope iodine-131 (half-life 8 days) was most responsible for exposures and is blamed for causing thyroid cancers. Cesium-137 was responsible for longer-term exposures. Much of the radiation was spread to the northwest, as far as Scandinavia. Overall, an estimated 17 million people were exposed; 2.5 million were younger than 5 years of age. Delayed acknowledgment of the disaster complicated the aftermath and resulted in needless exposures. Most at risk were the so-called liquidators, who went to the scene to clean up the site and encase the reactor. Also at risk were inhabitants of the area living within 30 km, and children, whose rapidly growing bodies and long lives leave them especially susceptible to both immediate and latent effects of radiation.¹⁶

Most of the research done in the first decade following the accident looked at short- and medium-term effects. Language barriers and the fact that few studies appeared in western journals hampered interpretation of these studies. Furthermore, the breakup of the Soviet Union led to many small republics that guarded their data, which did not facilitate progress. An overdiagnosis bias resulted from poor monitoring, especially among liquidators. Baseline levels of radiation and rates of cancers were not well known for the region. Weinberg et al¹⁶ examined the plight of numerous groups who have emigrated from the Soviet Union, including 250,000 Soviet Jews. These investigators note that many émigrés are seeking, to this day, healthcare for perceived long-term illness. How do we assess these problems? The Japanese model of radiation released at Hiroshima and Nagasaki cannot be applied because different radionuclides were released at Chernobyl. Furthermore, the above-noted fire in the graphite moderator sustained the release of radionuclides over a 9-day period, leading to more significant exposures via inhalation and ingestion. A U.S. National Chernobyl Registry has been established to sort out the details of the exposure and has recommended regular physical examinations in exposed children, with attention to the thyroid gland and overall body growth. If clinically indicated, complete blood counts, thyroid function tests, and neuropsychiatric evaluations are recommended. Another study by Dubrova¹⁷ found a higher-than-normal mutation rate in the genome of children born in the region near the reactor after the accident compared to a control group in the United Kingdom. This difference could not be attributed to either parent or to genetic differences. A follow-up study of thyroid cancer incidence revealed significant radiation risk only for those exposed at an age of 0-9 years, with higher risk associated with younger age.¹⁸

Tokyo, Japan (1995)

In the mid-1990s, this populous city of 12 million had 3 million commuters per day. During the rush hour on the morning of March 20, 1995, the group Aum Shinrikyo planted a toxic substance on five subway cars on 3 different lines that converged beneath the government offices. Okamura¹⁹ reported the events: 11 people died in this exposure, and 5000 required emergency evaluation. At St Luke's Hospital, 640 patients were seen in the Emergency Department within a few hours. Five patients were pregnant, and 3 presented in cardiac arrest. The gaseous chemical agent was quickly identified as sarin, developed in the 1930s as a potent organophosphate insecticide, which blocks the effect of the enzyme acetylcholinesterase at the myoneural junction, leading to a cholinergic crisis. Lethal effects result from respiratory insufficiency, with a lethal dose estimated at 1 mg. Treatment strategy revolves around blocking cholinergic activity with atropine, as well as regeneration of acetylcholinesterase with 2-pyridine aldoxime methiodide (2-PAM). Decontamination and

supportive care are essential, along with prevention of secondary contamination among healthcare providers. In the post-9/11 era, terrorism preparedness has included a focus on sarin and other “nerve” agents.

Haiti (1996)

During an epidemic of renal failure, Haiti’s Ministry of Health called upon the U.S. Centers for Disease Control to investigate the situation. Many children were found to have had emesis, abdominal pain, lethargy, and malaise. Some children were flown to the centers in the U.S. for renal dialysis. Parents of two of the deceased children provided samples of antipyretic elixirs, sold under the brand names “Afebril” and “Valodon.” These elixirs were found to contain acetaminophen as an active ingredient, with DEG as an excipient. One 7-year-old transferred to the U.S. had a renal ultrasound which revealed enlarged, swollen kidneys consistent with classic DEG changes. In this case, investigators learned DEG had been inappropriately substituted for propylene glycol as a diluent. Ultimately, 30 children died.²⁰

In another occurrence, 33 children died following treatment with a DEG-containing cough expectorant in Gurgaon, India.²¹

There have been other fatal DEG contaminations of pharmaceutical products since the 1937 elixir of sulfanilamide disaster; sedative mixtures in South Africa (1969), glycerine in India (1986), and acetaminophen in Nigeria (1990) and Bangladesh (1990-2). In each case, deliberate or accidental substitution of a diluent with the less expensive DEG was responsible.²

The Case of the Hapless Hyperventilating Hockey Players, Revisited (1996)

The children presented in the first case had played in a hotel swimming pool that, in fact, had been excessively brominated. Bromine is used as a pool disinfectant and is generally less irritating than chlorine to mucous membranes. Adults exposed to excessive bromine have developed a constellation of findings known as reactive airways dysfunction syndrome (RADS), which includes asthma-like symptoms and rash. In order to sort out these hockey players, data obtained on each patient included a complete history, a standardized patient inventory of symptoms consistent with RADS, a physical examination, and a laboratory evaluation. The latter included a complete blood count, tests of renal function, quantitative immunoglobulins, and pulmonary function testing

On physical examination, a few had dry, excoriated skin; examinations were otherwise unremarkable. One boy had an IgE that was marginally elevated, and in 3 (19%) children, PFTs were abnormal, with bronchial hyperactivity to cold-air challenge. This hyperactivity was consistent with RADS. All of the children had follow-up visits at least 3 months later. The one boy with past medical history significant for asthma remained asymptomatic, while the patient with elevated IgE at the first visit demonstrated persistent RADS, despite use of inhaled β_2 agonists and steroids.¹

The Environmental History

What are the elements of an environmental history? Questions about home, occupation, tobacco smoke, food, and lead should be included when interviewing parents, other caregivers, and older children themselves. The timing of questions varies; in the prenatal months, ask about renovations, smoking, and feeding. When the child is 6 months of age, ask about possible poison exposures; in preschool, arts and crafts. In the teenage years, ask about hobbies and occupational exposures. Other timing issues concern the season of the year; lawn, garden, and other chemical applications in the spring and summer; wood and gas stoves and fireplaces in the fall and winter.²²

Conclusion

In summary, much can be learned from mass exposures. We learn how to report these events and conduct research in the aftermath. Regulatory agencies may play a role in investigating these disasters and preventing their recurrence. A properly obtained environmental history may help sort out the details of an exposure. Finally, we learn something about the nature of “accidents”; most of these events occur not because of an isolated catastrophic failure but because of a series of less significant failures that may go unnoticed.

TOXICOLOGY BASICS OF NONMEDICINAL AGENT EXPOSURES

Edward P. Krenzelok, PharmD, FAACT, DABAT

Introduction

New chemical compounds, mixtures, and products are produced throughout the world at an astounding rate. Production of a substance often precedes adequate toxicological testing to fully assess its hazards to man and the environment. Even for chemicals used in commerce for decades, there may be surprisingly little data to help clinicians plan immediate treatment and answer exposed patients' questions about long-term effects. Following a chemical exposure incident, this lack of information may produce confusion, anxiety, and anger in patients, caregivers, and the public. Rarely are there absolute answers to all the health-related questions that arise from such incidents. Health care providers, however, can obtain valuable assistance from poison information centers, toxicologists, and occupational medicine experts, and through the use of toxicology references and databases. Physicians charged with acute treatment and subsequent management need to understand certain toxicological principles as well as the strengths and limitations of the toxicology literature. This chapter is intended to aid clinicians in applying this knowledge to patient care.

What is Toxicity?

Stedman's Medical Dictionary defines toxicity as "the state of being poisonous" and toxin as a "noxious or poisonous substance..."¹ These definitions are nonspecific and reflect the ambiguity and art that exists within the field of toxicology. It is important to remember that everything is potentially toxic. Dose is the factor that principally determines whether a chemical exposure produces obvious harm to health, no demonstrable effect, or even beneficial effects. Exposure level, duration of exposure, and rate of absorption determine dose; tissue and plasma binding, excretion, and metabolism of an agent all modify its toxicity. Other potential modifying factors are listed in Table 1. Toxins also come in a variety of physical forms (Table 2).

Host factors (age, sex, genomics, body fat, nutritional status)
Health behaviors (EtOH, smoking)
Other medical conditions, medications
Reproductive status
Repair
Biotransformation and excretion
Incident factors
Route of entry
Environmental factors

Solid	Gas
Liquid	Mist
Aerosol	Vapor
Dust	Fumes
Smoke	Fog

Every individual has a unique threshold that must be attained after exposure to most agents for an adverse effect to become manifest. Adverse effects can be overly clinical, damaging but not apparent clinically, or cumulative. This dose-response relationship for a chemical can be altered by many factors (Table 1); subclinical, latent, and idiosyncratic nondose-related effects must also be considered. Published acceptable exposure limits are not absolute; even when they have safety margins added, they are often designed for average groups of healthy workers. Furthermore, data may be based upon *in vitro* or animal testing models.

These models are frequently controversial and their validity must be considered when the data are extrapolated to human exposures.

In addition, these exposure limits are designed for workplace exposures by adults. Brief, acute, high-dose exposures, exposures to children, women, or the elderly, and continuous low-level residential exposures are less well understood. Limits for these variables are less common and less applicable.

Dose-response relationships are based upon bell-shaped curves with intense and minimal responses at the tails of the curves. While the majority of individuals in a population respond within two standard deviations of the mean dose of an agent, it is imperative that clinicians use reported toxic doses and air concentrations merely as guidelines. They are but one more factor to be added to the history, physical examination, and other laboratory data in planning patient evaluation and treatment.

The word hazard in the context of a chemical exposure incident is used commonly, but often inappropriately. Whereas toxicity reflects the ability of a substance to cause injury in an exposed individual, hazard to responders and the public depends on many factors beyond its simple toxicity (Table 3). If one can be confident that there will be no exposure to a highly toxic substance, then there is little hazard. Conversely, an agent of low toxicity can be very harmful, given sufficient exposure—consider prolonged painting in the confined space of an unventilated room. Conveying these concepts is especially important when communicating with the “worried well” and the media.

Table 3: Contributors to the Hazard Factor

Agent and Release Factors

- Amount, concentration, physical state, and density
- Volatility and reactivity under accident conditions
- Potential for explosion, thermal and corrosive injury
- Presence of ignition sources or fire
- Weather, terrain, and ventilation conditions

Exposure Factors

- Number, age, and health of potentially exposed populations
- Robustness of storage and containment structures
- Adequacy of identification, monitoring, and warning
- Adequacy of shelter and evacuation
- Threat to water supplies and environment

Human and Planning Factors

- Maintenance of equipment and facilities for the agent and response
- Adequacy of pre-planning and coordination
- Adequacy of emergency response and medical services
- Training, number, and quality of operational and response personnel
- Adequacy of actions for containment, mitigation, and medical care

Finally, it is useful for health care providers to have some knowledge of the physicochemical properties of a chemical involved in an incident. Vapor density indicates the weight of a gas or vapor relative to dry air and provides clues as to the degree of patient exposure in inhalation injuries. For example, chlorine is heavier than air and anhydrous ammonia is lighter. This has obvious, though imperfect, exposure implications for a victim who remained flat on the ground until rescued. A liquid with a high vapor pressure will volatilize easily into the air from a contaminated patient; inadequate decontamination of the patient may pose a threat to health care providers in a poorly ventilated ambulance or decontamination room. Lipid and water solubility bear on absorption and decontamination methods. Other physicochemical properties such as boiling point, ignition point, and upper and lower explosive limits help define hazard, particularly to workers, first responders, and the public near an incident scene. Fire services, and especially their hazardous materials units, are usually very knowledgeable in this area.

Acute vs Chronic Toxicity

There are three types of exposures that can lead to toxicity: acute, subchronic, and chronic. Acute exposure is a single exposure to a chemical that may occur momentarily, briefly over several minutes, or for up to approximately 8 hours. Inhalations or dermal exposures occurring over the course of a workday or a single

exposure episode can be classified in this manner. Toxic manifestations that develop secondary to short, nonrepeated exposures are classified as acute toxicity. Subchronic exposures are intermittent acute exposures that do not exceed 90 days. The terms subchronic or subacute are applied rarely to toxicity in the clinical setting, and such exposures are usually labeled inappropriately as chronic exposures. It is important to properly characterize the temporal nature of a toxic exposure, since the literature differentiates carefully between the toxic manifestations that may ensue from acute, subchronic, and chronic exposures to poisons and toxins. Misinterpretation of these classifications and the information regarding them can lead to inaccurate diagnosis and prognosis. For example, an acute exposure to toluene may produce narcosis but not the renal and hepatic pathology that is associated with chronic toluene exposure. There are significant medical, psychological, and financial consequences to such errors. Chronic exposures are repeated acute or continuous exposures that occur over an extended temporal period, which may be days, weeks, or years. Lead poisoning in bridge painters, silicosis in miners, and neuropathies secondary to prolonged solvent exposure are examples of chronic toxicity.

Toxin Identification and Toxicity Rating Systems

The toxicology and industrial hygiene literature is replete with abbreviations, numeric, and alpha-numeric codes that serve as identifiers and indicators of safety as well as toxicity. What is a TLV? How are CAS numbers used? Can an LD₅₀ be used prognostically in humans? Awareness of the most clinically relevant terms will help the clinician identify toxins, assess toxicity, and perform hazard risk assessments.

Toxin Descriptors

Community and worker right to know legislation as well as SARA Title III regulations have spawned the wide distribution of Material Safety Data Sheets (MSDS). These documents contain limited information about an individual product's composition, adverse health effects and their treatment, physicochemical properties, and provide guidance on spill containment and clean-up. MSDS may be inaccurate and are usually inadequate for comprehensive medical care. However, they are useful in product identification and frequently accompany exposed patients to the emergency department. Chemical ingredients are listed usually by name and by the Chemical Abstracts Service (CAS) Registry number, the most common numeric code used to identify toxins in the United States. The CAS number is a unique identifier that enables immediate identification of the substance, and helps avoid the confusion inherent in the many synonyms, closely related compounds, and "sound-alikes" present in chemical nomenclature. For instance, the CAS number of nitric acid is 7697-37-2. A call to a regional poison information center with this number allows their personnel to identify immediately the toxin and to provide toxicity and hazard information. Another commonly used identifier is the Registry of Toxic Effects of Chemical Substances (RTECS) number, which also uniquely identifies chemicals. It is found rarely on Material Safety Data Sheets; its primary use is to search databases for the toxicity literature. Field information such as data from truck placards and shipping labels may provide general hazard classifications (eg, poisonous versus corrosive chemicals) and tentative identification of a substance. However, these numbers are often not specific and must be used with caution. Again, using the example of nitric acid, its placard (for some forms and concentrations) is United Nations number 1760. This number is shared by some 30 other product groups, including aluminum sulfate solution, some weed killers, and some cosmetics!

When possible, it is judicious to use one of the specific numbers (especially the CAS number) to identify what chemicals may have been implicated in an exposure. Synonyms should be avoided since they may be regional or colloquial terms that are inadequate and possibly dangerous in decision-making and treatment. For example, an exposure to "alcohol" could involve ethanol, methanol, or isopropanol, all of which have unique chemical and toxicological properties.

Toxicity Rating

A variety of descriptive terms are used to describe dose-response relationships in the literature. These terms usually reflect animal mortality data and may be based upon acute, subchronic, or chronic exposures. The term used most commonly is the Lethal Dose 50 (LD₅₀). This is the amount of chemical required to kill 50% of an experimental animal population and is commonly referred to simply as the "lethal dose." The limitation of this value lies in the uncertainty of extrapolating it to a human exposure. However, if the value is either very low or very high, an assumption is generally made that a given chemical is either relatively safe or toxic to humans. This assumption must be tempered by existing human data, usually in the form of case reports, and even then, caution must be exercised. For example, the LD₅₀'s of the organophosphate insecticides, parathion and malathion, in rats are 5 mg/kg and 1000 mg/kg, respectively. This means that considerably smaller amounts of parathion caused 50% of the rats to die. However, exposure to either of these can produce significant human cholinergic toxicity, though it may require a larger amount of malathion to do so. Similarly,

the Lethal Dose Low (LD_{LO}) is the lowest amount known to be fatal when dose-response testing is conducted. Human toxicity data is reported as the Toxic Dose Low (TD_{LO}). This is the lowest amount that has actually been reported to produce toxicity in a human. Unfortunately, there is a conspicuous absence of this information in the literature. Inhalation toxicity is described by similar terminology – Lethal Concentration- $_{50}$, Lethal Concentration- $_{LOW}$, Toxic Concentration- $_{LOW}$, etc.

Modifications of the Hodge-Sterner Toxicity Table are published in many toxicology references and rate the degree of toxicity from “Dangerously Toxic” ($LD_{50} < 1$ mg/kg) in six gradations to “Practically Nontoxic” ($LD_{50} > 15$ g/kg). These data are supposed to be applicable to a 70 kg male. This type of rating system provides limited insight into the potential toxicity of an agent, but it does not consider the acute or chronic nature of the exposure, has rather broad ranges, and is supported by neither scientific nor clinical data. Reliance solely upon this system may result in either complacency or inappropriate therapy.

Exposure Standards

What is a permissible exposure level? Ideally, there should be no exposures to potentially noxious chemicals. However, given the ubiquity of noxious chemicals in industrialized society, reality dictates that a risk to benefit ratio exists for most products. Levels of acceptable exposure have been established by both the Occupational Safety and Health Administration (OSHA) and the American Conference of Governmental Industrial Hygienists (ACGIH). It is of paramount importance to understand that these values are arbitrary, and are designed to protect nearly all workers. Some individuals are more sensitive than others, that is, dose-response relationships vary within similar populations. The values, unless otherwise specified, reflect the air concentrations to which an individual can be exposed over a specific period of time and are customarily reported in parts per million (ppm). Caution must be exercised when interpreting OSHA and ACGIH exposure limits, since these values do not take into consideration factors such as underlying health problems or performance of demanding work (which may increase respiration and accordingly increase the amount of inhaled toxin). The most commonly used exposure standard is referred to as the Threshold Limit Value (TLV), which reflects the maximum allowable exposure over a specific period of time. The TLV-Time-Weighted Average (TWA) (also referred to as the Permissible Exposure Limit (PEL)) is the average concentration to which an individual can be exposed in the workplace over a standard 8-hour day or 40-hour work week without developing any adverse effects. For example, the TLV-TWA for formaldehyde is 3 ppm. However, sensitive individuals may develop mucosal irritation at air concentrations of < 0.5 ppm. The TLV-Short-Term Exposure Limit (STEL) is the maximum concentration to which a worker can be exposed for 15 continuous minutes without developing intolerable irritation, chronic or irreversible tissue damage, or narcosis that may impair work efficiency or endanger the worker. This standard allows an individual to have four such exposures separated by at least 60 minutes per day. The TLV-Ceiling (TLV-C) is the concentration that should never be exceeded, even instantaneously. Special attention should be paid to the Immediately Dangerous to Life or Health (IDLH) Level. The IDLH is the maximum concentration from which one could escape without impairment of judgment or the development of irreversible health effects. These values are rarely available when patients with toxic effects are being treated in an emergency department or when first responders are at a hazardous materials incident. However, if the values are known, they can assist the health care provider in making both diagnostic and prognostic decisions regarding the patient.

Toxicokinetics

The absorption, distribution, metabolism, and elimination of drugs is called pharmacokinetics. The application of those principles to toxicology is referred to as toxicokinetics. An appreciation of the basic principles of toxicokinetics can facilitate patient assessment and management. Only factors that affect the route of absorption are addressed here.

Routes of Exposure

- Oral
- Ocular
- Dermal
- Inhalation
- Injection

Due to the nature of hazardous materials incidents, many of the exposures to noxious agents are inhalational and can result in both local and systemic toxicity. A variety of factors dictate how well a chemical is absorbed via the inhalational route; of considerable importance is particle size. Particulate matter with particle diameters > 10 microns tend to lodge in the pharynx or nasal cavity; they generally do not produce effects in the lower

respiratory tract. Particles smaller than 10 microns are respirable and, depending upon their size and shape, tend to gain access to the lower respiratory tract. If the diameter of a particle is in the range of 1-5 microns, it may be deposited in the bronchioles; those particles < 1 micron may reach the alveoli.

Solubility also plays an important role in the inhalational absorption of chemicals. Respirable particles that are water-soluble may be scrubbed out partially by the mucous membranes of the upper respiratory tract. This tends to limit an injury to the upper respiratory tract. In contrast, respirable substances that have lower water solubility, such as nitrogen dioxide (Silo Filler's Disease), can be inspired into the alveoli. There they may be converted to nitrous acid and lead to the development of pulmonary edema.

The skin is not impervious to the absorption of toxins. Lipid-soluble chemicals such as solvents can penetrate the dermis and cause systemic toxicity. It is important to know the solubility and corrosive characteristics of a chemical, as well as the duration of contact, to determine its potential for toxicity. Skin damaged by abrasions, burns, or wounds permits greater absorption and requires special attention during decontamination.

Summary

As stated previously, toxicology is more of an art than a science. However, some of the mystery of toxicology can be eliminated by understanding terminology and a few basic concepts. A considerable amount of knowledge exists about the toxicology of drug overdoses but there is a paucity of human data regarding hazardous materials. Common sense, basic life support considerations, and the incorporation of toxicological principles allows health care providers to make informed decisions in patient management and to contribute to important community decisions such as evacuation.

Footnote

1. *Stedman's Medical Dictionary*, Philadelphia, PA: Lippincott Williams and Wilkins, 2006.

1-Propanol

Applies to Antiseptic Agents; Cleaners; Cosmetics; Lacquer; Polishes
CAS Number 71-23-8

UN Number 1274

Synonyms n-Propyl Alcohol; Optal; Propanol; Propyl Alcohol; Propyl Alcohol

Use In lacquers, cosmetics, cleaners, polishes, and antiseptic agents

Mechanism of Toxic Action Central nervous system depression

Adverse Reactions

Central nervous system: Delirium, coma, personality changes
 Dermatologic: Dermal irritation
 Gastrointestinal: Nausea, vomiting, mucous membrane irritation
 Ocular: Eye irritation

Signs and Symptoms of Overdose Cutaneous erythema, diarrhea, feces discoloration (black), GI irritation, hypotension, nausea, porphyria, vomiting; seizures and coma may develop

Toxicodynamics/Kinetics Absorption: Quick from GI tract; can be absorbed dermally

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Enhancement of elimination: Hemodialysis for patients in deep and persistent coma

Diagnostic Procedures

- Glucose, Random
- Osmolality, Serum

Additional Information More toxic than isopropyl alcohol; 20 mL of 1-propanol with water can cause hypotension

1,1-Dichloroethene

Applies to Coating (Steel Pipes); Packaging Materials/Food Wraps; Retardant Coating (Carpet Backing)

CAS Number 75-35-4

UN Number 1303

Synonyms 1,1 DCE; VCD; Vinylidene Chloride

Use Chemical intermediate in polyvinylidene chloride production; found in food wraps and other packaging materials; also as a coating for steel pipes, retardant coating in carpet backing, and adhesives

Mechanism of Toxic Action Mucosal irritant and CNS depressant

Adverse Reactions

Central nervous system: Narcosis, cranial nerve palsies
 Dermatologic: Leukoderma
 Endocrine & metabolic: Hypoglycemia
 Hepatic: Elevated liver enzymes
 Ocular: Eye irritant

Signs and Symptoms of Overdose Lethargy

Toxicodynamics/Kinetics

Metabolism: By way of oxidation
 Elimination: Renal

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage (within 1 hour)/activated charcoal; dilute with water or milk
 Enhancement of elimination: Forced diuresis may be beneficial (although there is no human data).

Additional Information Levels of 4000 ppm associated with narcosis; possible increased toxicity with acetaminophen, ethanol, or phenobarbital. TLV-TWA: 5 ppm

1,2-Dibromoethane

Applies to Fire Extinguishers; Flue Gases; Gasoline (Antiknocking Additive); Mechanical Gauge Fluid; Soil Fumigant (Europe)

CAS Number 106-93-4

UN Number 1605

Synonyms Bromofume; DBE; EDB; Ethylene Dibromide; Glycol Dibromide

Use Acts as a lead scavenger in gasoline (at a level of ~179 mg/dL); therefore, its use is as an antiknocking additive. It has also been used as a soil fumigant (for nematode removal) in Europe, but this use was banned in the U.S. in 1994; also used as a chemical intermediate for bromide synthesis and is an ingredient in fire extinguishers and mechanical gauge fluid; found as a contaminant in flue gases.

Mechanism of Toxic Action Cytotoxic metabolites (bromoacetaldehyde and free bromide ions) can cause lipid peroxidation and result in tissue lesions. Bromide toxicity can also occur resulting in cell membrane damage and displacement of body chloride ions. Glutathione depletion can result. Binds directly to DNA.

Adverse Reactions

Central nervous system: CNS depression
 Dermatologic: Vesiculation, rash
 Endocrine & metabolic: Metabolic acidosis
 Gastrointestinal: GI ulceration
 Hepatic: Hepatic failure within 2 days

Local: Inflammation

Neuromuscular & skeletal: Muscle necrosis

Renal: Renal failure within 2 days

Respiratory: Pulmonary edema, respiratory depression

Signs and Symptoms of Overdose Agitation, anorexia, bradycardia, CNS depression, cough, dermal blisters, dermal blisters, diarrhea, dizziness, drowsiness, GI upset, hepatic necrosis (centrilobular hepatic necrosis), hepatomegaly, hypotension, jaundice, mydriasis, ocular irritation, skin erythema and pruritus, tachycardia, tachypnea, thirst, vomiting

Toxicodynamics/Kinetics

Absorption: By inhalation, ingestion of dermal routes. Inhalation absorption is 58% in rodents.

Metabolism: Oxidized in hepatic cytochrome P450 enzymes to 2-bromoacetaldehyde and free bromide ions.

Elimination: Renal, as glutathione conjugates, bromide or bromoacetic acids. Slight amounts are excreted as carbon dioxide (by inhalation) interactions.

Reference Range

Normal bromide levels are <40 mg/L. Moderate toxicity is encountered at bromide levels of 200 mg/L, while fatalities can occur at levels >330 mg/L.

Serum bromide levels of 830 mg/L and 380 mg/L have been correlated with fatalities.

Overdosage/Treatment

Decontamination:

Oral: Lavage/administer activated charcoal within 2 hours of exposure.

Dermal: **Note:** 1,2-dibromoethane can penetrate polyvinyl chloride, surgical rubber or leather gloves. Nylon appears somewhat protective. Remove all contaminated clothing. Wash the skin with soap and water for 15-20 minutes.

Inhalation: Administer high flow humidified 100% oxygen.

Ocular: Irrigate with saline or water for at least 15-20 minutes.

Supportive therapy: Corticosteroids can be used to treat symptomatic bradycardia; intravenous bicarbonate for metabolic acidosis.

Enhancement of elimination: Multiple dosing of activated charcoal may be useful in enhancing elimination.

Diagnostic Procedures

- Bromide, Serum
- Glucose, Random

Drug Interaction

Ethanol can potentiate the cytotoxic effect of 1,2-dibromoethane. Disulfiram, cyanamide, and chloral hydrate, which are aldehyde dehydrogenase inhibitors, can also potentiate the toxicity of DBE.

Additional Information A probable carcinogen (lymphoma). A brownish liquid with a sweet chloroform-like odor. Cooking of food with DBE causes decomposition to ethylene glycol and bromide. Air DBE concentrations >75 ppm are associated with gastrointestinal and respiratory irritation. IDLH: 400 ppm. PEL-TWA: 20 ppm have been implicated as causing male sterility with reduction in sperm count

1,2-Dibromo-3-Chloropropane

Applies to Fumigant (Soil); Nematocide (Soil)

CAS Number 96-12-8

UN Number 2872

U.S. Brand Names Fumagon®; Fumazone®; Nemaflume®; Nemapax®; Nemapax®; Nemazon®

Synonyms BBC12; DBCP

Use Soil fumigant and nematocide to protect field crops; also used as an intermediate in organic chemical synthesis; was the preferred fumigant for pineapples in Hawaii, although this practice was stopped by the EPA in 1985

Mechanism of Toxic Action Possibly inhibits carbohydrate metabolism of sperm at the level of nicotinamide adenine dinucleotide dehydrogenase

Adverse Reactions

Endocrine & metabolic: Spermatogenesis preponderate of female offspring to male workers; sterilization may occur due to necrosis of seminiferous tubule cells

Gastrointestinal: Abdominal pain

Ocular: Eye irritant

Respiratory: Pulmonary edema

Signs and Symptoms of Overdose Azoospermia, epigastric pain, eye irritation, headache, lightheadedness, nausea

Toxicodynamics/Kinetics

Absorption: Can be absorbed by dermal, GI, or inhalation

Elimination: Inhalation: Feces (14%)

Overdosage/Treatment Decontamination: **Oral:** Dilute with milk or water; **do not** induce emesis. Activated charcoal may be useful. **Dermal:** Wash with soap and water. **Ocular:** Irrigate with saline.

Additional Information FSH and LH elevations may occur. Azoospermia correlates with elevated FSH levels and usually is reversible. Pungent odor. Taste threshold: 0.01 mg/L. TLV: 0.01 ppm.

1,2,3-TRICHLOROPROPANE

1,2,3-Trichloropropane

CAS Number 96-18-4

Synonyms Allyl Trichloride; Glycerol Trichlorohydrin; Trichlorohydrin

Use Primarily as a paint or varnish remover, cleaning or degreasing agent

Mechanism of Toxic Action Metabolites may lead to DNA/protein adducts or lipid peroxidation; a respiratory irritant

Adverse Reactions Throat and ocular irritation at levels ~100 ppm; has caused squamous cell carcinomas in rodent models

Toxicodynamics/Kinetics

Absorption: Probably by inhalation, oral (up to 80%), and dermal routes

Metabolism: To carbon dioxide (which is expired) and glutathione conjugated (mercapturic acid)

Elimination: Urine and fecal

Overdosage/Treatment Decontamination: **Oral:** Dilute with milk or water; activated charcoal may be used with a cathartic. **Dermal:** Wash with soap and water. **Ocular:** Irrigate with saline.

Additional Information Found in soil in California and Hawaii at levels ranging from 0.2-2 ppb. Combustion products include chloride fumes. Drinking water concentrations: <0.2 mcg/L. Atmospheric half-life: 15.3 days. Water half-life: 44 days (hydrolysis). TLV-TWA (skin): 10 ppm

1,3-Butadiene

Applies to Carpet Backing; Foams; Fungicides (Production); Paper Coating

CAS Number 106-99-0

UN Number 1010

Synonyms Biethylene; Bivinyll; Butadiene Divinyl

Use In the manufacture of foams, carpet backing, paper coating, production of fungicides

Mechanism of Toxic Action Asphyxiant - anesthesia at high concentrations; no cumulative toxicity

Adverse Reactions

Cardiovascular: Bradycardia, hypotension, sinus bradycardia

Central nervous system: CNS depression

Endocrine & metabolic: Ovotoxic

Hematologic: Possibly leukemogenic

Signs and Symptoms of Overdose Blurred vision, cough, drowsiness, hallucinations, headache, skin irritation, upper airway irritation

Toxicodynamics/Kinetics

Metabolism: Though not studied in humans, major metabolites appear to be diepoxybutane and 3,4-epoxy-1,2-butanediol; glutathione-S-transferase appears to be one detoxifying pathway

Half-life (animal model): 2-10 hours

Monitoring Parameters Blood glucose

Overdosage/Treatment

Although there is no experimental data, there is a theoretical basis to utilize acetylcysteine to help detoxify this substance

Decontamination: **Oral:** Basic poison management. **Inhalation:** Move patient to fresh air; treat with 100% humidified oxygen.

Diagnostic Procedures

- Glucose, Random

Additional Information

Colorless; mild aromatic odor at > 1.3 ppm; carcinogenic and genotoxic; metabolites are active alkylating agents

TLV-TWA: 10 ppm; IDLH: 20,000 ppm; PEL-TWA: 1000 ppm

Organic vapor cartridges can adsorb up to 1000 ppm of butadiene.

Atmospheric half-life: 6 hours

Median 1,3-butadiene concentration in ambient air: 0.3 ppb in urban areas and 0.1 ppb in rural areas; indoor air concentrations may be higher (1-9 ppb) due to cigarette smoke, thus leading to an estimated daily intake of ~13 mcg per person

Specific References

McDonald JD, Bechtold WE, Krone JR, et al, "Analysis of Butadiene Urinary Metabolites by Liquid Chromatography-Triple Quadrupole Mass Spectrometry," *J Anal Toxicol*, 2004, 28:168-73.

1,3-Dichloropropene

Applies to DD-92; Fumigant (Soil)

CAS Number 10061-01-5; 10061-02-6; 542-75-6

U.S. Brand Names Telone®; Terr-o-cide® 15-D; Terr-O-Gas® 57/43T

Synonyms 1,3-Dichloropropylene

Use Soil fumigant for nematodes used primarily on soil of vegetable or tobacco crops (preplanting); also used as a solvent

Mechanism of Toxic Action Mucous membrane irritant; chemical structure is similar to vinyl chloride

Adverse Reactions

Dermatologic: Skin vesicant

Respiratory: Respiratory irritant, bronchospasm

Miscellaneous: Hypersensitivity (delayed)

Signs and Symptoms of Overdose Cough, dizziness, diarrhea, dyspnea, headache, hypotension, malaise, metabolic acidosis, nausea, neck pain, pancreatitis, pleuritic chest pain, pruritus (dermal contact), vomiting

Toxicodynamics/Kinetics

Absorbed by inhalation and/or dermal exposure

Metabolism: Hepatic to an N-acetyl cysteine conjugate through glutathione pathway

Reference Range Excretion of N-acetyl glucosaminidase (NAG) > 1.5 mg/day is considered elevated

Overdosage/Treatment Decontamination: **Oral: Do not** induce emesis; dilute with milk or water; lavage (within 1 hour)/activated charcoal.

Dermal: Wash with soap and water. **Inhalation:** Administer 100% oxygen. **Ocular:** Irrigate with normal saline.

Additional Information Possible association with development of histiocytic lymphoma and acute myelomonocytic leukemia; lung tumors noted in rodents; penetrates rubber protective gear. Odor threshold: 1-3 ppm (garlic-like). PEL-TWA (skin): 1 ppm; TWA-TLV: 1 ppm

1,3-Dinitrobenzene

CAS Number 99-65-0

UN Number 1597

Synonyms 1,3 DNB; Dinitrobenzene; Meta-Dinitrobenzene

Use Primarily used as an explosive, as a camphor substitute in nitrocellulose; medicinally, has been used as an indicator for 17-ketosteroid detection

Mechanism of Toxic Action Causes methemoglobinemia through oxidation of ferrous hemoglobin to ferric derivative

Adverse Reactions

Dermal: Skin/hair yellowing

No apparent long-term effects

Cardiovascular: Hypotension, tachycardia, cyanosis, sinus tachycardia

Central nervous system: Dizziness, headache, fatigue, ataxia, fever, hyperthermia

Gastrointestinal: Nausea, vomiting, bitter almond smell

Hematologic: Anemia, methemoglobinemia, Aplastic anemia

Ocular: Nystagmus, optic neuropathy

Respiratory: Dyspnea

Hepatic: Subacute hepatic necrosis

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Toxicodynamics/Kinetics Absorption: Oral, inhalation, and dermal (well absorbed)

Monitoring Parameters Methemoglobinemia

Overdosage/Treatment

Decontamination: **Dermal:** Wash with soap and water. **Ocular:** Irrigate copiously with saline.

Supportive therapy: Treat symptomatic methemoglobinemia with methylene blue. Ascorbic acid (3 g/day during periods of cyanosis) has been used to improve oxygen delivery, although its efficacy is not proven. Administer 100% humidified oxygen.

Antidote(s)

- Methylene Blue [ANTIDOTE]

Additional Information Penetrates latex gloves; odor of bitter almonds in vomitus or urine may be noted: IDLH-50 mg/m³

1,4-Dioxane

CAS Number 123-91-1

UN Number 1165

Synonyms 1,4-Diethylene Dioxide

Use A solvent for chemical processing (adhesives, cosmetics, deodorants, lacquers, pulping of wood, waxes); laboratory reagent; chemical intermediate used in pharmaceuticals/pesticides. Formerly used as a stabilizer of 1,1,1-trichloroethane, 1,4-dioxane is manufactured by acid catalyzed conversion of diethylene glycol; it is formed by ethylene glycol breakdown

Adverse Reactions Ocular irritation (50 ppm for 6 hours); nose/throat irritation (300 ppm for 15 minutes), vomiting, abdominal pain, elevated liver function tests, cerebral edema

Reference Range Following inhalation exposure of 1.6 ppm for 7.5 hours, urinary 1,4-dioxane and HEAA levels were 3.5 umol/L and 414 umol/L, respectively

Overdosage/Treatment

Inhalation: Give 100% humidified oxygen

Ocular: Irrigate with copious amounts of water or saline

Additional Information

A colorless, volatile liquid which is miscible in water; considered possibly carcinogenic in humans

Odor threshold: 24 ppm (ethereal odor)

Ambient atmospheric levels: 0.1-0.4 mcg/m³

Ambient water level: 1 mcg/L

Atmospheric half-life: 1-3 days

TLV (8-hour TWA): 20 ppm (skin)

IDLH: 500 ppm; minimal lethal exposure: 470 ppm for 3 days

PEL: 100 ppm

Maximum permitted concentration in food/spermicidal/medicinal products: 10 ppm

Half-life in soils: 4 weeks to 6 months; does not bioconcentrate in aquatic organisms

Specific References

CDC/ATSDR: Toxicological Profile for 1,4-Dioxane, U.S. Department of Health and Human Services, Sept 2004.

2-Butoxyethanol

Applies to Butyl Cellulosolve

CAS Number 111-76-2

UN Number 2369

Synonyms 2-Butoxy-1-Ethanol; BUCS; Ethylene Glycol Monobutyl Ether

Use Solvent/cleaning agent; dry cleaning, textile (dyeing), in inks, paint thinners, and protective coatings; often found in window/glass cleaners (usually 9% to 12% concentrations)

Mechanism of Toxic Action Both 2-butoxyethanol and its metabolite 2-butoxyacetic acid cause elevated osmotic fragility of red blood cells resulting in hemolysis; butoxyacetic acid is responsible for the metabolic acidosis.

Adverse Reactions

Cardiovascular: Tachycardia, hypotension

Central nervous system: Headache, coma

Dermatologic: Photo-onycholysis, cherry angiomas

Endocrine & metabolic: Metabolic acidosis, hypokalemia

Gastrointestinal: Eructation

Hematologic: Hemolytic anemia

Ocular: Eye irritation, mydriasis (reacts to light)

Renal: Hematuria, albuminuria, oxaluria

Respiratory: Nasal/pharyngeal irritation

Admission Criteria/Prognosis For oral ingestions of liquids containing > 10% ethyl glycol butyl ether, admit any child who ingests > 10 mL

Toxicodynamics/Kinetics

Absorption: Inhalation (57%), oral and dermal (within two hours)

Distribution: V_d : 54 L

Metabolism: Hepatic oxidation via alcohol dehydrogenase to butoxyacetaldehyde with further oxidation to 2-butoxyacetic acid

Half-life: Oral: 210 minutes. Dermal: 34 minutes. Elimination: Renal

Overdosage/Treatment

Decontamination: Oral: Lavage within 1 hour. Activated charcoal has not been demonstrated to be useful.

Supportive therapy: Use of ethanol or 4-methylpyrazole as an inhibitor of alcohol dehydrogenase has been useful in animal models, but human data are lacking. Acidosis can be treated with 1-2 mEq/kg of sodium bicarbonate. Dopamine can be used to treat hypotension. Fomepizole (15 mg/kg I.V., then 10 mg/kg I.V. in twelve hours) may assist in resolving metabolic acidosis, if administered within six hours.

Enhanced elimination: Hemodialysis is of unknown effectiveness, it should be considered in patients with acidosis or renal failure.

Additional Information

A colorless liquid with a faint odor; does not produce osmolar gap.

Irritant symptoms occur at air concentrations of 200 ppm, while levels > 300 ppm can cause narcosis, renal or hepatic injury

Density: 0.9 g/mL; does not affect serum osmolarity. Average indoor air concentration: 0.2 ppb. Odor threshold: 0.1-0.4 ppm. Atmospheric half-life: < 1 day. Water half-life: ~5 days. Soil half-life: 1 week to 1 month. TWA-TLV: 25 ppm; PEL-TWA: 50 ppm (skin)

2-Hexanone

CAS Number 591-78-6

Synonyms 2-Oxohexane; Butyl Methyl Ketone; MBK; Methyl-n-Butyl Ketone; Propylacetone

Commonly Found In Coated fabrics, paints, solvents

Mechanism of Toxic Action Metabolite 2,5-hexanedione can cause distal neuronal swelling and axonal degeneration

Adverse Reactions

Cardiovascular: Tachycardia, sinus tachycardia

Central nervous system: Polyneuropathy (distal sensory), CNS depression, axonopathy

Respiratory: Respiratory depression

Signs and Symptoms of Overdose Asthenia, dyspnea, lacrimation, nausea, ocular irritation, paresthesia, upper airway irritation, vomiting

Admission Criteria/Prognosis Symptomatic patients or patients with abnormal chest x-rays should be admitted

Toxicodynamics/Kinetics

Absorption: Through lungs (75% to 92%), oral (66%), and dermal (rate of 4.8-8.0 mcg/cm²/minute)

Metabolism: To 2,5-hexanedione (neurotoxic agent)

Elimination: Through lungs, in urine

Reference Range 2,5-hexanedione: urine: < 5.0 mg/L; blood: < 10.0 mcg/L

Overdosage/Treatment Decontamination: Lavage within 1 hour; dilute with 4-8 oz milk or water. Irrigate skin with soap and water.

Additional Information Very soluble in water; has been found in milk and cream at levels of 7-18 ppb. Odor threshold: 0.076 ppm (acetone). TLV-TWA: 5 ppm; PEL-TWA: 5 ppm; IDLH: 1000 ppm. Atmospheric half-life: 36 hours. River water half-life: 10-15 days

2-Methyl-4-Chlorophenoxyacetic Acid

CAS Number 94-74-6

U.S. Brand Names Agritox®; Agroxone®; Chiptox®; Cornex®; Dedweed®; Empal®; Hedonal® M; Homotuh®; Kilsen®; Mephanac®; Phenoxylene®; Ruonox®; Shamrok®; Weed Control; Weedar®; Weedone®

Synonyms MCP; MCPA; Methylchlorophenoxy Acetic Acid

Use Controls annual/perennial weeds in cereals, grasslands and turf

Mechanism of Toxic Action A chlorophenoxy herbicide used to control broadleaf weeds; an auxin which causes abnormal plant growth

Signs and Symptoms of Overdose Vomiting is usually the first symptom, followed by oropharyngeal burning and hypotension. Agitation, coma, lethargy, leukocytosis, mild rhabdomyolysis, miosis, muscle spasms, proteinuria, seizures, tachycardia, and twitching can occur.

Toxicodynamics/Kinetics

Half-life: 133 hours (12.6 hours with forced alkaline diuresis)

Elimination: Renal

Reference Range Fatal MCPA serum level (after a 0.25 g/kg ingestion): ~180 mg/L; recovery has occurred following ingestion of 0.8-1.67 g/kg (and associated serum MCPA level of 546 mg/L)

Overdosage/Treatment

Decontamination: Oral: Do not administer syrup of ipecac. Gastric lavage should be performed and activated charcoal should be administered.

Supportive therapy: Hypotension can be treated with isotonic saline (10-20 mL/kg) and placement in Trendelenburg position. Dopamine or norepinephrine can be given for refractory cases. Seizures can be treated with diazepam.

Enhanced elimination: Forced alkaline diuresis can decrease the half-life of MCPA. Sodium bicarbonate (1-2 mEq/kg) with potassium chloride (20-40 mEq/L) can be used to maintain alkaline urine. Furosemide or mannitol can be used to maintain diuresis. Hemodialysis is not expected to be useful.

Additional Information Colorless crystals

2-Octyl Cyanoacrylate

Pronunciation (too ok til sye AN oh ah kril ate)

Use Topical skin adhesive

Mechanism of Action Polymerizes on skin in an exothermic reaction to form a strong flexible bond

Adverse Reactions Local: Burning sensation

Dosage Topical: Apply to affected area on skin in three layers; wound should be clean and dry before application; wound should be held in a horizontal position

Contraindications Use is contraindicated in any infected wound, decubiti, on mucous membranes or mucocutaneous junction, skin which is exposed to body fluids or dense hair, or patients allergic to cyanoacrylate or formaldehyde; do not apply to wet or actively bleeding wounds, or below the skin surface; should also not be utilized in wounds of high tension area

Dosage Forms Liquid: 0.5 ml in a sterile, prefilled, single-use applicator (with colorant: D and C violet #2)

Overdosage/Treatment Decontamination: **Dermal:** Bond is active within 15-20 seconds; petroleum jelly or acetone may help loosen the bond; water, soap, Betadine®, or saline would not be expected to have any effect. **Ocular:** Immediately flush eye with copious amounts of water or normal saline

Additional Information Should be stored under 30°C; more information can be obtained at 1-877-337-6226; as effective as 5-0 monofilament sutures; adhesive sloughs off in 1-2 weeks; avoid washing or soaking the affected area; wound should be held for 30-40 seconds for full polymerization to occur; full tensile strength occurs in 2 minutes

2,3-Benzofuran

Applies to Adhesives (Food Container); Asphalt Floor Tiles; Cigarette Smoke; Coating on Citrus Fruits; Paint Production

CAS Number 271-89-6

Synonyms Benzofuran; Benzofurfuran; Coumarone; Cumaron

2,4-D

Use Found in cigarette smoke, as a coating on citrus fruits, asphalt floor tiles, food container adhesives; used in paint production

Mechanism of Toxic Action Produced by destructive distillation of coal (naphtha fraction) and fossil fuels

Adverse Reactions Little human adverse effect experience

Overdosage/Treatment

Decontamination: Flush skin or eyes with copious amounts of water.
Supportive therapy: Give oxygen if the patient is exposed to heated decomposition products; monitor pulmonary status.

Additional Information Aromatic odor, colorless liquid, insoluble in water. FDA regulation for protective coating on citrus fruits: maximum: 200 ppm. When heated, can emit acrid fumes

2,4-D

Related Information

- 2-Methyl-4-Chlorophenoxyacetic Acid

CAS Number 94-75-7

UN Number 2765

Synonyms 2,4-Dichlorophenoxyacetic Acid

Commonly Found In Choroxone®; Esteron®; Salvo®; Weedar®; Weedone®

Mechanism of Toxic Action A chlorophenoxy herbicide used to control broadleaf weeds; an auxin which causes abnormal plant growth; a weak uncoupler of oxidative phosphorylation

Adverse Reactions

Cardiovascular: Cardiac arrhythmias, bradycardia, sinus bradycardia, sinus tachycardia
Dermatologic: Concentrated solutions (> 12%) can cause dermal burns
Endocrine: Hypokalemia
Gastrointestinal: Acute nausea, diarrhea, vomiting
Hematologic: Thrombocytopenia
Neuromuscular & skeletal: Myoclonus, peripheral (sensory) neuropathy, myotonia, hyperthermia
Respiratory: Pulmonary edema

Signs and Symptoms of Overdose Elevated liver function tests, hypophosphatemia, miosis, myoglobinuria, myotonia (rare), rhabdomyolysis, tachycardia

Admission Criteria/Prognosis Any ingestion >50 mg/kg should be admitted

Toxicodynamics/Kinetics

Absorption: Absorbed through skin/oral/inhalation routes
Distribution: V_d : 0.1 L/kg; 10 L/kg in overdose
Protein binding: Extensive
Half-life: 4-140 hours - prolonged in acidic urine
Peak effect: 4-24 hours
Elimination: Urine; does not bioaccumulate

Reference Range

At an oral ingested dose of 5 mg/kg, peak plasma level was 35 mg/L at 24 hours; plasma levels > 100 mg/L associated with coma
Urine 2,4-D concentration of 314 mg/L (range 111-670 mg/L) associated with fatal poisoning

Overdosage/Treatment

Decontamination: **Oral:** Lavage/activated charcoal for ingestions within 4 hours exceeding 40 mg/kg. **Dermal:** Irrigate with saline. **Ocular:** Flush eyes with water or saline for 10-15 minutes.

Supportive therapy: Hypotension can be treated with 10-20 mL/kg of isotonic saline and Trendelenburg positioning; dopamine or norepinephrine can be used. Quinidine may be helpful for cardiac arrhythmias.

Enhancement of elimination: Alkaline diuresis for patients with metabolic acidosis, mental status changes, or a serum level >500 mg/L. Keep urine pH >7.6 by use of sodium bicarbonate (I.V.: 44-88 mEq/L). Alkaline diuresis can enhance elimination by decreasing 2,4-D half-life by 90%. Clearance by hemodialysis is 64 mL/minute. Renal clearance with a pH of 8.3 (urinary) is 63 mL/minute. Furosemide can be given to maintain diuresis.

Additional Information Minimum lethal dose: 80 mg/kg. Slight phenol odor when heated; does not contain tetrachlorodibenzoparadioxin (TCDD); does not accumulate in food chain

2,4-Dichlorophenol

Applies to Antiseptics (Production); Bactericides (Production); Disinfectant (Production); Fungicides (Production); Mothproofing

CAS Number 120-83-2

UN Number 2020 (solid)

Synonyms 2,4-DCP; 4,6-Dichlorophenol

Use Intermediate in production of 2,4-dichlorophenoxy acetic acid (2,4-D), bifenoxy, and dichloroprop herbicides; also used in production of pentachlorophenol and other disinfectants, fungicides, bactericides, and antiseptics; a waterborne contaminant of the kraft pulping process; also used as a miticide and for mothproofing

Mechanism of Toxic Action Interferes with cell division by disrupting spindle formation and interfering with oxidative phosphorylation; can cause CNS depression

Adverse Reactions

Dermatologic: Chloracne, hyperpigmentation, hirsutism
Hematologic: Porphyria cutanea tarda
Miscellaneous: Sarcoma

Signs and Symptoms of Overdose CNS depression, lethargy, seizures, tremors

Admission Criteria/Prognosis Admit any patient exhibiting neurologic changes

Toxicodynamics/Kinetics

Absorption: Dermal, orally, and by inhalation

Half-life: ~10 minutes

Metabolism: Hepatic sulfation and glucuronidation

Reference Range Death due to dermal exposure (~10% total body surface area); postmortem blood, urine, bile, and stomach levels were 24.3 mg/L, 5.3 mg/L; 18.7 mg/L, and 1.2 mg/L, respectively

Overdosage/Treatment

Decontamination: **Oral:** Do not induce emesis; lavage (within 1 hour)/activated charcoal. **Dermal:** Wash with soap and water. **Inhalation:** Give 100% humidified oxygen. **Ocular:** Irrigate with saline or water; anesthetic use may follow copious irrigation

Supportive therapy: Seizures can be treated with benzodiazepines, phenobarbital, or phenytoin.

Additional Information

Human exposure may occur from drinking contaminated water.

Human water quality criteria (EPA): 0.3 mcg/L

Half-life in water: 62 hours at a pH of 8 with a mean concentration of 0.2 mcg/L

Average daily intake of 2,3-dichlorophenol: ~0.4 mcg

Taste threshold (medicinal): ~2-8 mcg/L. Odor threshold in water: 0.0003 to 0.04 mg/L

Solid at room temperature; photolytic degradation is 0.11% per hour; decomposition rate in neutral clay-loam soil at 20°C is 81% in 40 days.

Average atmospheric concentration (during rain) in Portland, Oregon, is ~0.23 ppt.

Combustion products can contain hydrochloric acid.

2,4-Dinitrotoluene

CAS Number 121-14-2

UN Number 1600 (molten); 2038 (solid or liquid)

Synonyms 2,4-DNT

Use In the production of polyurethane polymers, explosives, and automobile air bags; an isomer of DNT

Mechanism of Toxic Action Producer of methemoglobin in rodent studies; not reported in humans; cytotoxic to hepatocytes

Adverse Reactions

Cardiovascular: Cyanosis
Central nervous system: Headache, vertigo, dizziness
Dermatologic: Dermatitis, turns skin yellow

Gastrointestinal: Nausea, vomiting

Hematologic: Anemia, hemolysis, although not described in humans, methemoglobinemia may occur (onset may be delayed for 4 hours)

Hepatic: Hepatitis

Neuromuscular & skeletal: Arthralgia (especially in the knees)

Miscellaneous: Cutaneous T-cell lymphoma

Toxicodynamics/Kinetics

Absorption: By oral (rapid and complete) and inhalation routes

Elimination: Renal

Monitoring Parameters CBC, methemoglobin

Reference Range Urinary 2,4 DNT levels in ammunition plant workers range from 2-9 mcg/L

Overdosage/Treatment

Decontamination: **Oral:** Do not induce emesis. Lavage within 4 hours. Activated charcoal may be useful. **Dermal:** Wash with soap and water. **Ocular:** Irrigate with water and saline.

Supportive therapy: Symptomatic methemoglobinemia (or methemoglobin levels >30%) can be treated with methylene blue.

Antidote(s)

- Methylene Blue [ANTIDOTE]

Drug Interaction Reduced tolerance to ethanol; ethanol may intensify symptoms of 2,4-dinitrotoluene: IDLH-50 mg/m³

Additional Information

Water soluble; mean concentration in U.S. waters is <10 mcg/L. TWA (skin): 1.5 mg/m³; IDLH: 200 ng/m³
Boiling point: 300°C; An oily liquid

2,4,5-T

CAS Number 93-76-5

Synonyms 2,4,5-Trichlorophenoxyacetic Acid

Mechanism of Toxic Action Has been banned by the EPA in 1979

Adverse Reactions

Dermatologic: More irritating to the skin and mucous membranes than 2,4-D

Neuromuscular & skeletal: Paresthesia

Signs and Symptoms of Overdose Paresthesia

Toxicodynamics/Kinetics Half-life: 23-33 hours, 90 hours in acidic urine

Overdosage/Treatment

Decontamination: Irrigate with saline; lavage (within 1 hour)/activated charcoal for ingestions >400 mg/kg

Supportive therapy: Hypotension can be treated with 10-20 mL/kg of isotonic saline and Trendelenburg positioning; dopamine or norepinephrine can be used; quinidine may be helpful for cardiac arrhythmias
Enhancement of elimination: Alkaline diuresis for patients with metabolic acidosis, mental status changes, or a serum level >500 mg/L; keep urine pH between 7.6-8.8; furosemide can be given to maintain diuresis

Additional Information 2,3,7,8-tetrachlorodibenzoparadiioxin (TCDD) is a contaminant of 2,4,5-T. 2,3,5-T and 2,3-D was used as a 50:50 mixture in agent orange. 2,4,5-T alone usually contains <0.1 ppm of TCDD; does not affect cholinesterase level

2,4,6-Trichlorophenol

CAS Number 25167-82-2; 88-06-2

UN Number 2020

U.S. Brand Names Caswell No 880C®; Dovicide 2S®; Omal®; Phenachlor®

Use Antiseptic and pesticide; used as a wood and glue preservative; antimildew agent in textile manufacture

Mechanism of Toxic Action Chemical which is actually a metabolite of lindane, 2,4,6-trichlorophenol is a respiratory irritant

Adverse Reactions

Respiratory: Bronchospasm and cough on inhalation

Miscellaneous: Chronic oral exposure has produced liver cancer and leukemia in rodent models

Toxicodynamics/Kinetics

Absorption: Probably by oral or dermal (9.9 × 10⁻⁴ cm/minute) routes

Metabolism: Hepatic

Elimination: Urine

Overdosage/Treatment Decontamination: **Ocular:** Irrigate with saline. **Dermal:** Wash with soap and water. **Inhalation:** Administer 100% humidified oxygen.

Additional Information

Fish and shellfish may concentrate 2,4,6-trichlorophenol and it has been estimated that a daily ingestion of 21 g of fish can result in an intake of 95 mcg of this agent.

Daily intake from drinking water: 0.4-100 mcg. Taste threshold: 2 ppb. Odor threshold: 2.6 ppb. Atmospheric half-life: 1 day to 3 weeks. Water half-life: 1-19 days

2,4,6-Trinitrotoluene

CAS Number 118-96-7

UN Number 0209 (<30% water); 1356 (>30% water)

Synonyms Alpha TNT; TNT; Toltit; Trilit; Tritol; Triton

Use High explosive agent used in military or civilian blasting procedures; chemical intermediate in production of dyes and photographic chemicals

Mechanism of Toxic Action Cause of methemoglobin; dermal irritant

Adverse Reactions Hematologic: Glucose-6-phosphate dehydrogenase deficiency-induced hemolytic anemia

Signs and Symptoms of Overdose Altered taste, anemia (aplastic), cataract, constipation, dermal burns, elevated liver enzymes, hemolytic anemia (especially in individuals deficient in G6PD enzyme), methemoglobinemia, paresthesia, red color to urine, toxic hepatitis

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted. Asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%.

Toxicodynamics/Kinetics

Absorption: Inhalation, oral, and dermal exposure

Metabolism: Hepatic to nitro reduction to 2,6-dinitro-4-aminotoluene (DNAT)

Elimination: Renal

Overdosage/Treatment

Decontamination: **Dermal:** Wash with soap and water. **Ocular:** Irrigate with saline.

Supportive therapy: Methylene blue for symptomatic methemoglobinemia

Antidote(s)

- Methylene Blue [ANTIDOTE]

Additional Information Combustible, pale yellow solid. Atmospheric half-life: 18-184 days. Water half-life: 14-84 hours. PEL-TWA (skin designation): 0.5 mg/m³. TLV-TWA (skin designation): 0.5 mg/m³

Specific References

3-3'-Dichlorobenzidine

CAS Number 91-94-1

U.S. Brand Names Curithane®

Synonyms Dichlorobenzidine

Use Production of pigments (primarily yellow and red) for ink, paper, paint, textiles, and plastics

Mechanism of Toxic Action Can cause DNA and protein adduction resulting in genotoxicity

Signs and Symptoms of Overdose Bladder cancer, dermatitis, dizziness, headache, pharyngitis

Toxicodynamics/Kinetics

Absorption: By inhalation and oral routes

Metabolism: Hepatic N-acetylation

Elimination: Renal

Overdosage/Treatment Decontamination: **Dermal:** Remove clothing, wash skin with soap and water. **Ocular:** Irrigate with copious amounts of water. **Inhalation:** Administer 100% humidified oxygen.

Additional Information Slightly soluble in water; not volatile

Atmospheric half-life: 2 hours to 60 days

Average air concentration in Canada: ~7.6 × 10⁻¹⁶ mcg/m³

Estimated water level in Canada: 3.4 × 10⁻⁷ ng/L

Estimated soil concentration in Canada: ~1.1 × 10⁻¹⁶ mcg/g

Average daily intake of Canadian infants and adults: 3.6 × 10⁻⁸ ng/kg and 7.4 × 10⁻⁹ ng/kg respectively

EPA ambient water quality criteria for human health: 0.01 mcg/L for water and fish and 0.02 mcg/L for fish only

3,4-Methylenedioxymethamphetamine**Related Information**

- Highlights of Recent Reports (2006) on Substance Abuse and Mental Health

CAS Number 4764-17-4; 51497-09-7

Synonyms Ecstasy; MDMA

Use Originally used as an appetite suppressant in 1913; also has been utilized in psychotherapy

Mechanism of Toxic Action A sympathomimetic that is structurally related to amphetamine and mescaline; this drug blocks serotonin reuptake while causing serotonin release, which is calcium mediated; exhibits ~10% of the CNS stimulant effect as amphetamine

Adverse Reactions

Cardiovascular: Tachycardia; hypertension, chest pain, ventricular fibrillation, ventricular tachycardia

Central nervous system: Euphoria, headache, hyperthermia, seizures, coma, fatigue, serotonin syndrome, paranoia, cognitive impairment, depression, insomnia, dystonia, hallucinations, leukoencephalopathy

Endocrine & metabolic: Hyponatremia due to SIADH, hypoglycemia

Gastrointestinal: Dry mouth, anorexia, diarrhea, nausea, vomiting

Hematologic: Disseminated intravascular coagulation, thrombocytopenia,

Hepatic: Hepatitis, aminotransferase level elevation (asymptomatic)

Neuromuscular & skeletal: Trismus, muscle rigidity, rhabdomyolysis, piloerection, clonus

Ocular: Mydriasis

Renal: Acute renal failure

Miscellaneous: Sweating, bruxism, thirst

Signs and Symptoms of Overdose Agitation, hyperthermia

Toxicodynamics/Kinetics

Onset of effect: 30-45 minutes (oral)

Duration of effect: 4-6 hours

3,4-METHYLENEDIOXY-N-METHYL-BUTANAMINE

Metabolism: Hepatic, through cytochrome P450 isoenzyme CYP2D6 into 3,4-methylenedioxyamphetamine (MDA)

Half-life: MDMA: 7.6-9 hours; MDA: 16-38 hours

Elimination: Renal

Reference Range MDMA serum concentrations > 1 mg/L are associated with fatality; peak serum MDMA and MDA concentrations following an oral dose of 1.5 mg/kg: ~0.33 mg/L and 0.015 mg/L, respectively

Overdosage/Treatment

Supportive therapy: Severe hyponatremia (serum sodium < 120 mM/L) can be treated with either continuous infusion of 0.9% normal saline or 3% normal saline at 50 mL/hour, with furosemide 40 mg twice daily. Seizures should be treated with a benzodiazepine or barbiturate. Hyperthermia should be aggressively treated with cooling blankets, ice packs, and cooling fans. The role of chlorpromazine, cyproheptadine, dantrolene, or beta-adrenergic blockers is uncertain in treating hyperthermia. Ventricular arrhythmias may respond to lidocaine. Benzodiazepines can be given for agitation. Nitroprusside or phentolamine can be given for hypertensive emergency. Hypotension should be treated with crystalloid fluids.

Test Interactions Positive amphetamine result on urinary immunoassay
Drug Interaction Hypertension, diaphoresis, and hypertonicity lasting for 6 hours has occurred with concomitant use of phenelzine.

Additional Information Psychotherapy dose: 2 mg/kg initially with a booster dose of 0.5 mg/kg to 1 mg/kg in 3-4 hours. Recreational dose: 75-160 mg with a booster dose of 50-75 mg after 3-4 hours

3,4-Methylenedioxy-N-Methyl-Butanamine

Synonyms MBDB

Use Similar to hallucinogenic amphetamines, less hallucinogenic: an "entactogen"

Mechanism of Toxic Action Central nervous system stimulant

Adverse Reactions

- (+)-isomer is probably more potent
Cardiovascular: Tachycardia, hypertension
Central nervous system: Seizures
Miscellaneous: Diaphoresis

Toxicodynamics/Kinetics

Metabolism: Hepatic demethylation to 3,4-methylene-dioxybutanamine (BDB)

Elimination: Urinary, as parent compound and as 3,4-methylene-dioxybutanamine (BDB) within 36 hours; also eliminated via saliva and sweat

Dosage 100 mg

Overdosage/Treatment

Decontamination: Oral: Gastric lavage within 1 hour with activated charcoal

Supportive therapy: Treat agitation with diazepam (0.1 mg/kg I.V. or 0.3 mg/kg orally in children; 5 mg I.V. or 10 mg orally in adults). Seizures can be treated with benzodiazepines or barbiturate. Nitroprusside can be used to treat hypertension. Monitor for rhabdomyolysis.

Additional Information A controlled substance in U.S. and France.

4-Aminopyridine

CAS Number 504-24-5

UN Number 2671

Use In Europe: Bird repellent and as a pesticide. Has possible utility as an antagonist of nondepolarizing neuromuscular blocking agents, verapamil overdose, botulism, and aminoglycoside neuromuscular blockade

Unlabeled/Investigational Use In the United States: Multiple sclerosis, Eaton-Lambert syndrome, Alzheimer's disease, myasthenia gravis, and spinal cord trauma

Mechanism of Action Enhances transmembrane calcium in flux which thus facilitates synaptic transmission; also blocks neuronal potassium channels which results in acetylcholine release

Adverse Reactions

- Neurological effects are dose related occurring at daily doses > 0.5 mg/kg
Cardiovascular: Tachycardia
Central nervous system: **Dizziness**, insomnia, generalized seizures (within 15 minutes of exposure), psychosis, headache, confusion, extrapyramidal symptoms
Gastrointestinal: **Nausea**, thirst, xerostomia, vomiting
Hepatic: Elevated liver enzymes
Neuromuscular & skeletal: Weakness, tremors, **paresthesias**, **gait instability**
Respiratory: Dyspnea
Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Choreoathetoid movements, confusion, diaphoresis, dizziness, dyspnea, dystonia, extrapyramidal effects, metabolic acidosis, seizures, tremor, weakness

Admission Criteria/Prognosis Admit any symptomatic patient or ingestion > 0.5 mg/kg

Toxicodynamics/Kinetics

Distribution: V_d : 2.6 L/kg
Protein binding: Negligible; < 5%
Bioavailability: Oral: 95%; poorly absorbed dermally
Half-life: 3.6 hours
Total serum clearance: 0.6 L/hour/kg
Elimination: Renal (87% to 91% of the drug is eliminated unchanged)

Dosage

Botulism: I.V.: 0.5 mg/kg; continuous infusion of 0.25 mg/kg/hour (monitor for seizures; will not improve respiratory parameters; may improve peripheral paralysis)

Eaton-Lambert syndrome:

Oral: 40-200 mg/day in divided doses

I.V.: 0.3-0.6 mg/kg

Multiple sclerosis:

Oral: 10-50 mg in 2-4 divided doses

I.V.: 1-5 mg every 10-60 minutes, over 1.5-3.5 hours to a maximum dose of 35 mg

Myasthenia gravis:

Oral: 40-200 mg/day in 2 to 4 divided doses

I.V.: 10-20 mg

Reversal of neuromuscular blockade: Oral: 0.3-0.6 mg/kg

Verapamil overdose: I.V. (separated by a 10-minute interval): 2 doses of 10 mg I.V. slowly dose: 18-33.5 mg

Spinal cord injury: Acute: Continuous I.V. infusion: 9-15 mg/hour; total

Spinal cord injury: Chronic: Investigational: Oral: 10 mg

Reference Range Peak serum 4-aminopyridine level after a 20 mg I.V. and oral dose: ~300 ng/mL and 62 ng/mL, respectively. Therapeutic serum 4-AP: 30-59 ng/mL. A 266 ng/mL serum level has been associated with severe toxicity in an infant.

Overdosage/Treatment

Decontamination: Do not induce emesis; lavage (within 1 hour)/activated charcoal

Supportive therapy: Seizures can be initially managed with diazepam; phenobarbital or phenytoin can be used as second-line therapy. Nondepolarizing neuromuscular blocking agents can be used if seizures persist (after the patient is intubated with assisted ventilation). d-Tubocurarine (10-15 mg slowly I.V. followed by additional doses up to 5 mg every 25 minutes in adults or 0.4 mg/kg bolus in children with additional doses of 15% to 20% of the initial dose used as needed to maintain muscle relaxation) or metocurine (1.5-8 mg slow I.V. push in adults with 0.5-1 mg as needed or 0.2 mg/kg in children with additional doses of 15% to 20% of the initial dose) can be used to counteract skeletal muscle effects of prolonged seizures. Due to its cardiac effects, avoid pancuronium. Sodium bicarbonate (1-3 mEq/kg) can be used to treat metabolic acidosis. Propranolol can be used for cardiac toxicity while atropine (0.01 mg/kg/dose slow I.V. up to 0.4 mg/dose) can be used to treat abdominal cramps and diarrhea.

Enhanced elimination: Although human data are lacking, charcoal hemoperfusion may be useful for ingestion of >500 mg. Since enterohepatic recirculation may take place, multiple dosing of activated charcoal may be useful.

Additional Information

Toxic dose: 0.6 mg/kg

Transiently beneficial for peripheral paralysis (but not respiratory paralysis) in botulism; may be a competitive antagonist for verapamil hypotension

4-Bromo-2,5-Dimethoxyphenylethylamine

Related Information

- Mescaline

Synonyms

2C-B

Impairment Potential

Use Psychoactive drug often combined with ecstasy and ketamine

Mechanism of Toxic Action Structurally related to mescaline; binds to central nervous system serotonin receptors

Adverse Reactions Central nervous system: Visual, auditory, olfactory, tactile hallucinations (dose related), euphoria

Toxicodynamics/Kinetics

Duration of action: 4-8 hours

Metabolism, hepatic: 2-(4-bromo-2,5-dimethoxyphenyl)-ethanol, 4-bromo-2,5-dimethoxyphenylacetic acid, 2-(2-hydroxy-4-bromo-5-methoxyphenyl)-ethylamine, 2-(2-methoxy-4-bromo-5-hydroxyphenyl)-ethylamine, 1-acetamino-2-(2-hydroxy-4-bromo-5-methoxyphenyl)-ethane, and 1-acetamino-2-(2-methoxy-4-bromo-5-hydroxyphenyl)-ethane

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic

Supportive therapy: Benzodiazepines are useful for agitation. Haloperidol or chlorpromazine can be used if psychiatric symptoms are not responsive to benzodiazepines. Do not use phenothiazines for treatment of flashback.

Additional Information Supplied as white tablets (3-8 mg). Hallucinogenic doses range from 4-30 mg.

4-Methylthioamphetamine

Use Drug of abuse in Europe

Mechanism of Action A dose-dependent releasing agent of serotonin; a reversible inhibitor of rodent monoamine-oxidase A (MAO-A)

Adverse Reactions

Central nervous system: Tremors, ataxia, seizures

Gastrointestinal: Abdominal cramps, nausea

Miscellaneous: Diaphoresis

Admission Criteria/Prognosis Admit any patient who ingests > 300 mg.

Dosage Tablets are 100 mg

Reference Range Blood levels of 4-MTA > 4 mg/L are consistent with an overdose. No postmortem redistribution is noted.

Overdosage/Treatment

Decontamination: Oral: Lavage any ingestion in children or ingestion > 300 mg in adults. Activated charcoal may be utilized.

Supportive therapy: Benzodiazepines can be given to treat seizures.

4,4'-Methylenebis (2-Chloroaniline)

Applies to DAC; MOCA

CAS Number 191-14-4

U.S. Brand Names Activator-M®; Bis-Amine A®; CA-800®; Cuamine-M®; Curene® 442

Synonyms DACPM; MCOVA

Use Primarily as a curing agent in polymers containing isocyanate; also used in manufacture of epoxy resins; involved in manufacture of belt drives in computers, elevator or escalator wheels, gun mounts, radar systems, and shoe soles

Mechanism of Toxic Action Forms adducts with hemoglobin, serum albumin, and tissue DNA; may be tumor promoter similar to benzidine

Adverse Reactions Cutaneous T-cell lymphoma and proteinuria in humans; carcinogenic in animals with lungs, liver, breast, and bladder being the target organs in a dose-dependent manner

Toxicodynamics/Kinetics

Absorption: Inhalation, oral (40% in animal models), and dermal

Metabolism: Hepatic N-hydroxylation and N-acetylation to toxic metabolites

Half-life: 23 hours

Elimination: Renal and fecal

Overdosage/Treatment Decontamination: **Dermal:** Remove contaminated clothing; wash with soap and water. Penetration of gloves is concentration-dependent and can occur from 2-35 hours, with natural latex gloves appearing to be most effective. **Ocular:** Irrigate copiously with saline.

Drug Interaction Phenobarbital can accelerate metabolism (hydroxylation)

Additional Information Atmospheric half-life: 0.3-2.9 hours (photooxidation). Water half-life: 1-72 days (surface); 8 weeks to 1 year (groundwater). PEL-TWA (skin designation): 0.2 ppm. TLV-TWA (skin designation): 0.2 ppm

5-Methoxy-N,N-Diisopropyltryptamine

Synonyms 5-OMe-DIPT; Foxy

Use A designer hallucinogen and aphrodisiac

Mechanism of Toxic Action An indolealkylamine which stimulates dopaminergic and tryptaminergic receptors

Signs and Symptoms of Overdose Visual hallucinations, mydriasis, muscle spasms, agitation

Toxicodynamics/Kinetics

Absorption: Well absorbed orally

Metabolism: Degraded by monoamine oxidase (oxidative deamination)

Peak effect: 1-1.5 hours

Elimination: Renal

Reference Range Following oral dose of 4 mg, urine level (obtained 4 hours post-ingestion in a symptomatic male) of 5-methoxy-N, N-diisopropyltryptamine and its metabolite (5-methoxy-indole acetic acid) was 1.7 mcg/mL and 1.3 mcg/mL, respectively

Overdosage/Treatment

Decontamination: Oral: Activated charcoal within 1 hour

Supportive therapy: Anxiety/agitation can be treated with benzodiazepines (such as lorazepam 0.05 mg I.M. or I.V.; up to 4 mg total in adults)

Drug Interaction Synergistic with cannabinoid

Additional Information Threshold hallucinogenic dose: 4 mg; usual dosage range: 6-10 mg. Recovery usually seen within 6 hours.

Abciximab**U.S. Brand Names** ReoPro®**Synonyms** 7E3; C7E3

Use Prevention of acute cardiac ischemic complications in patients at high risk for abrupt closure of the treated coronary vessel and patients at risk of restenosis; an adjunct with heparin to prevent cardiac ischemic complications in patients with unstable angina not responding to conventional therapy when a percutaneous coronary intervention is scheduled within 24 hours

Unlabeled/Investigational Use Acute MI – combination regimen of abciximab (full dose), tenecteplase (half dose), and heparin (unlabeled dose)

Mechanism of Action Fab antibody fragment of the chimeric human-murine monoclonal antibody 7E3; this agent binds to platelets resulting in steric hindrance, thus inhibiting platelet aggregation

Adverse Reactions

Cardiovascular: Hypotension, fibrillation (atrial) or flutter (atrial), tachycardia (ventricular), complete AV block

Central nervous system: Dizziness, coma, insomnia, hyperesthesia, dysphonia

Dermatologic: Pruritus

Gastrointestinal: Diarrhea, ileus

Genitourinary: Urinary retention, urinary tract infection

Hematologic: Bleeding, thrombocytopenia (0.5%)

Neuromuscular & skeletal: Myopathy

Miscellaneous: Anaphylaxis

Signs and Symptoms of Overdose Thrombocytopenia

Pharmacodynamics/Kinetics Half-life elimination: ~30 minutes

Dosage

I.V.: 0.25 mg/kg bolus administered 10-60 minutes before the start of intervention followed by an infusion of 0.125 mcg/kg/minute (to a maximum of 10 mcg/minute) for 12 hours

Patients with unstable angina not responding to conventional medical therapy and who are planning to undergo percutaneous coronary intervention within 24 hours may be treated with abciximab 0.25 mg/kg intravenous bolus followed by an 18- to 24-hour intravenous infusion of 10 mcg/minute, concluding 1 hour after the percutaneous coronary intervention.

Monitoring Parameters Prothrombin time, activated partial thromboplastin time, hemoglobin, hematocrit, platelet count, fibrinogen, fibrin split products, transfusion requirements, signs of hypersensitivity reactions, guaiac stools, and Hemastix® urine

Administration

Abciximab is intended for coadministration with aspirin postangioplasty and heparin infused and weight adjusted to maintain a therapeutic bleeding time (eg, ACT 300-500 seconds). Solution must be filtered prior to administration. Do not shake the vial.

Bolus dose: Aseptically withdraw the necessary amount of abciximab for the bolus dose into a syringe using a 0.2 or 5 micron low protein-binding syringe filter (or equivalent); the bolus should be administered 10-60 minutes before the procedure.

Continuous infusion: Aseptically withdraw 4.5 mL (9 mg) of abciximab for the infusion through a 0.2 or 5 micron low protein-binding syringe filter into a syringe; inject this into 250 mL of NS or D₅W to make a solution with a final concentration of 35 mcg/mL. Infuse at a rate of 17 mL/hour (10 mcg/minute) for 12 hours via pump. If a syringe filter was not used when preparing the infusion, administer using an in-line 0.02 or 0.22 low protein-binding filter.

Contraindications Hypersensitivity to abciximab, to murine proteins, or any component of the formulation; active internal hemorrhage or recent (within 6 weeks) clinically-significant GI or GU bleeding; history of cerebrovascular accident within 2 years or cerebrovascular accident with significant neurological deficit; clotting abnormalities or administration of oral anticoagulants within 7 days unless prothrombin time (PT) is ≤1.2 times control PT value; thrombocytopenia (<100,000 cells/μL); recent (within 6 weeks) major surgery or trauma; intracranial tumor, arteriovenous malformation, or aneurysm; severe uncontrolled hypertension; history of vasculitis; use of dextran before PTCA or intent to use dextran during PTCA; concomitant use of another parenteral GP IIb/IIIa inhibitor

Warnings

Administration of abciximab is associated with increased frequency of major bleeding complications, including retroperitoneal bleeding, pul-

monary bleeding, spontaneous GI or GU bleeding, and bleeding at the arterial access. Risk may be increased with patients weighing <75 kilograms, elderly patients (>65 years of age), history of previous GI disease, and recent thrombolytic therapy. Avoid the creation of venous access at noncompressible sites.

The risk of major bleeds may increase with concurrent use of thrombolytics. Anticoagulation, such as with heparin, may contribute to the risk of bleeding. In serious, uncontrolled bleeding, abciximab and heparin should be stopped. Increased risk of hemorrhage during or following angioplasty is associated with unsuccessful PTCA, PTCA procedure >70 minutes duration, or PTCA performed within 12 hours of symptom onset for acute myocardial infarction.

Administration of abciximab may result in human antichimeric antibody formation that can cause hypersensitivity reactions (including anaphylaxis), thrombocytopenia, or diminished efficacy. Readministration of abciximab within 30 days or in patients with human antichimeric antibodies (HACA) increases the incidence and severity of thrombocytopenia.

Dosage Forms Injection, solution: 2 mg/mL (5 mL)

Overdosage/Treatment Supportive therapy: Essentially no overdose experience; anaphylaxis may be treated with standard treatment; discontinue heparin; use pressure techniques if bleeding develops; consider platelet transfusion for patients with serious, uncontrolled bleeding and if bleeding time is >10 minutes

Drug Interactions

Heparin and aspirin: Use with aspirin and heparin may increase bleeding over aspirin and heparin alone. However, aspirin and heparin were used concurrently in the majority of patients in the major clinical studies of abciximab.

Monoclonal antibodies: Allergic reactions may be increased in patients who have received diagnostic or therapeutic monoclonal antibodies due to the presence of HACA antibodies.

Thrombolytic agents theoretically may increase the risk of bleeding; use with caution.

Warfarin and oral anticoagulants: Risk of bleeding may be increased during concurrent therapy.

Other IIb/IIIa antagonists: Avoid concomitant use of other glycoprotein IIb/IIIa antagonists (see Contraindications).

Pregnancy Risk Factor C

Pregnancy Implications Animal reproduction studies have not been conducted. *In vitro* studies have shown only small amounts of abciximab to cross the placenta. It is not known whether abciximab can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity.

Lactation Excretion in breast milk unknown/use caution

Additional Information Platelet aggregation returns to ≥50% of baseline within 24 hours in 62% of patients and within 48 hours in 88% of patients; bleeding time falls to <12 minutes within 12 hours in 75% of patients and within 24 hours in 90% of patients; may reduce restenosis rate. Risk factors for major bleeding episodes: Female gender, increasing age, low body weight

Acetaldehyde**CAS Number** 75-07-0**UN Number** 1089**Synonyms** Acetic Aldehyde; Ethanal; Ethyl Aldehyde

Use Production of plastics, mirrors, aniline, disinfectants, explosives, varnishes, synthetics, acetic acid, acetic anhydride, food flavorings; also a combustion product of wood and fuels; found in tobacco smoke and car exhaust; found as a fermentation product in beer or wine; a metabolite of ethanol

Mechanism of Toxic Action Pulmonary/mucosal irritant ($\sim 1/10$ of an irritant as formaldehyde); can cause CNS depression; also may affect mitochondrial phosphorylation and inhibit myocardial protein synthesis

Adverse Reactions Gastrointestinal: Metallic taste

Signs and Symptoms of Overdose Hypertension/tachycardia at low concentrations; hypotension/bradycardia at high concentrations; ocular irritation (at 50 ppm) with photophobia and lacrimation; bronchitis, cough, dermal burns, dyspnea, vomiting (when ingested as a liquid), erythema, pulmonary edema

Toxicodynamics/Kinetics

Absorption: Oral/dermal/inhalation routes

Metabolism: Hepatic oxidation by aldehyde dehydrogenase to acetate

Overdosage/Treatment Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal. **Dermal:** Wash with soap and water. **Inhalation:** Administer 100% humidified oxygen.

Additional Information A colorless liquid with a fruity taste. Specific gravity: 0.78 as a liquid and 1.52 as a gas. In cigarette smoke, acetaldehyde content may approach 1 mg. TLA-TWA: 100 ppm; IDLH: 10,000 ppm. Odor threshold: 0.21 ppm

Acetic Acid**Pronunciation** (a SEE tik AS id)**CAS Number** 64-19-7**U.S. Brand Names** VoSol®**Synonyms** Ethanoic Acid**Use** Continuous or intermittent irrigation of the bladder; treatment of superficial bacterial infections of the external auditory canal; may be useful in jellyfish sting**Adverse Reactions**

Dermatologic: Erythema/edema may occur, nonimmunologic contact urticaria

Endocrine & metabolic: Systemic acidosis

Gastrointestinal (ingestion): Epigastric pain, abdominal pain, pyloric stenosis, gastric perforation, achlorhydria

Ocular: Corneal irritation

Renal: Urologic pain; hematuria has occurred in patients receiving irrigation

Respiratory: Reactive airways disease syndrome

Signs and Symptoms of Overdose Hemolysis, disseminated intravascular coagulopathy

Inhalation: Coagulopathy, cough, hematuria, tachypnea, wheezing

Ingestion: Headache, nausea, vomiting

Dosage

Irrigation: For continuous irrigation of the urinary bladder with 0.25% acetic acid irrigation, the rate of administration will approximate the rate of urine flow; usually 500-1500 mL/24 hours; for periodic irrigation of an indwelling urinary catheter to maintain patency, approximately 50 mL of 0.25% acetic acid irrigation is required. (Note: Dosage of an irrigating solution depends on the capacity or surface area of the structure being irrigated.)

Otic: Insert saturated wick, keep moist 24 hours; remove wick and instill 5 drops 3-4 times/day

Administration Not for internal intake or I.V. infusion; topical use or irrigation use only.**Contraindications** Hypersensitivity to acetic acid or any component of the formulation; during transurethral procedures**Warnings** Not for internal intake or I.V. infusion; topical use or irrigation use only. Use of irrigation in patients with mucosal lesions of urinary bladder may cause irritation. Systemic acidosis may result from absorption.**Dosage Forms**

[DSC] = Discontinued product

Solution for irrigation: 0.25% (250 mL, 500 mL, 1000 mL)

Solution, otic (VéSol® [DSC]): 2% (15 mL)

Overdosage/TreatmentDecontamination: Dilution of affected area; **do not** use ipecac or induce emesis

Supportive therapy: Inhalation 100% oxygen

Pregnancy Risk Factor C**Nursing Implications** For continuous or intermittent irrigation of the urinary bladder, urine pH should be checked at least 4 times/day and the irrigation rate adjusted to maintain a pH of 4.5-5; topical use or irrigation use only**Additional Information** Clear liquid with pungent odor; similar effects as hydrochloric acid but less corrosive

The frequency of pneumonia cases is about 8%. Lethality in the case of pneumonia development was 50%.

Specific ReferencesSarmanaev SK, "Risk Factors of Pneumonia Development in Cases of Poisonings by Acetic Acid (AAP)," *J Toxicol Clin Toxicol*, 2003, 41(5):664.Sarmanaev SK and Akhmetov IR, "The Use of Tables for Prognosis of Life-Threatening States Requiring ICU Hospitalization in Cases of Acetic Acid Poisonings (AAP)," *J Toxicol Clin Toxicol*, 2003, 41(5): 661.**Acetone****Pronunciation** (A se tone)**Applies to** Defatting Agent; Solvent**CAS Number** 67-64-1**UN Number** 1090**Synonyms** 2-Propanone; Dimethyl Formaldehyde; Dimethyl Ketone**Use** Volatile solvent (ie, fingernail polish remover, glues, rubber cement); defatting agent in semiconductor industry**Mechanism of Toxic Action** Release of norepinephrine on heart; narcotic properties**Adverse Reactions**

Cardiovascular: Tachycardia, sinus tachycardia

Central nervous system: Depression

Ocular: Eye irritation, lacrimation

Respiratory: Respiratory depression

Signs and Symptoms of Overdose Ataxia, bronchial irritation, cough, coma, headache, hyperglycemia, hypoglycemia, hypotension, narcosis, sedation, seizures (in children), vomiting**Admission Criteria/Prognosis** Patients with mental status or respiratory abnormalities or blood acetone levels >330 mg/L should be admitted; any patient with change in mental status or cardiopulmonary complaints should be admitted**Toxicodynamics/Kinetics**

Absorption: Readily through the lungs (75% to 80%) and skin (more slowly) and the GI tract (74% to 83%)

Distribution: V_d : 0.8 L/kg

Metabolism: Hepatic oxidation to acetate and formate at a rate of 1-3 mg/kg/hour

Half-life, elimination: 17-24 hours

Elimination: Excreted through the lungs and urine

Monitoring Parameters Blood glucose, serum/urine acetone, arterial pH**Dosage Forms** Liquid: 120 mL, 480 mL**Reference Range** Toxic: Blood levels > 330 mg/L; urinary acetone levels correlating to air acetone levels of 200 ppm and 750 ppm are 21.6 mg/L and 76.6 mg/L, respectively; blood acetone levels associated with air acetone levels of 200 ppm and 750 ppm are 41.4 mg/L and 118 mg/L respectively; average amount of acetone in expired air of a healthy subject is ~1 mcg/L**Overdosage/Treatment**Decontamination: Oral: **Do not** induce vomiting. Activated charcoal can adsorb 42% to 44% of acetone.

Supportive therapy: Inhalation: Airway support and 100% humidified oxygen

Diagnostic Procedures

● Glucose, Random

Test Interactions May cause a false elevation of serum creatinine through interference with laboratory determination**Additional Information**

Ingestion: Toxic dose: 2-3 mL/kg

Fruity odor, sweet taste. Acetone is a metabolite of isopropyl alcohol.

Cigarette smoke contains <0.5 mg acetone per cigarette; no increased cancer risk; very water soluble; potentiates CNS toxicity of ethanol

Odor threshold: 13-20 ppm. Atmospheric half-life: ~22 days. Inhalation:

TLV-TWA: 750 ppm; IDLH: 20,000 ppm; PEL-TWA: 1000 ppm

Estimated inhalational dose of acetone in an adult: ~0.37 mg/day

Average acetone levels in urban areas: ~7 ppb in the troposphere.

Average amount in drinking water: ~1 ppb

Absorption: Dermal, oral, and inhalation

Distribution: V_d : 0.7 L/kg

Protein binding: 0%

Metabolism: Hepatic hydrolysis to hydrogen cyanide

Half-life: Acetonitrile: 32 hours. Cyanide: 15 hours

Reference Range Whole blood cyanide level of 6 mcg/mL (2310 μ mol/L) reported 12 hours after exposure in a 16-month-old age boy**Overdosage/Treatment**

Decontamination:

Oral: Basic poison management. Emesis is contraindicated due to the rapid course of neurologic symptoms. Activated charcoal may be useful.

Inhalation: Give 100% oxygen.

Supportive therapy: Give sodium bicarbonate for acidosis, otherwise treat as cyanide exposures.

Enhancement of elimination: Hemodialysis and charcoal hemoperfusion have been utilized; hyperbaric oxygen may also be utilized. Hydroxocobalamin and dicobalt-EDTA are used for chelation in Europe.

Antidote(s)

- Amyl Nitrite [ANTIDOTE]
- Sodium Nitrite [ANTIDOTE]
- Sodium Thiosulfate [ANTIDOTE]

Diagnostic Procedures

- Anion Gap, Blood
- Electrolytes, Blood
- Methemoglobin, Blood

Additional Information Decomposes to hydrogen cyanide gas at 120°C

ACETYLENE

Specific References

Acetylene

CAS Number 74-86-2

Synonyms Ethyne; Welding Gas

Use Primarily used for welding when mixed with oxygen

Mechanism of Toxic Action Central nervous system depressant combined with asphyxiation

Signs and Symptoms of Overdose Coma, dizziness, garlic-like odor, headache, incoordination, lethargy

Overdosage/Treatment Decontamination: Remove from site of exposure; administer 100% humidified oxygen; monitor carboxyhemoglobin level and if significantly elevated, treat as per carbon monoxide exposure

Additional Information May cause elevation of urine and serum acetone; may present as diabetic coma; contaminants may include phosphine (<95 ppm), arsine (<3 ppm), and hydrogen sulfide. See table.

Air Concentration Levels and Symptoms
10%: Intoxication
20%: Staggering gait
30%: Incoordination
33% (at 7 minutes): Coma

Acetylene Dichloride

Applies to Dye (Production); Perfume (Production); Thermoplastics (Production)

CAS Number 156-59-2; 156-60-5; 540-59-0

UN Number 1150

U.S. Brand Names Dioform®

Synonyms 1,2 DCE; 1,2-Dichloroethene

Use Chemical intermediate in the production of chlorinated solvents; used in production of dyes, perfumes, and thermoplastics

Mechanism of Toxic Action Mucosal irritant and CNS depressant

Adverse Reactions

Central nervous system: CNS depression

Dermatologic: Dermal irritation

Ocular: Eye irritation at concentrations of 1000 ppm

Signs and Symptoms of Overdose Dizziness, lethargy, nausea (at concentrations of ~2000 ppm), muscle cramps, tremor

Toxicodynamics/Kinetics

Absorption: Through inhalation (75%)

Metabolism: Hepatic (cytochrome P450) epoxidation to dichloroethanol and dichloroacetic acid

Overdosage/Treatment

Decontamination: **Oral:** Lavage within 1 hour of ingestion. **Dermal:** Wash with soap and water. **Inhalation:** Remove from source and administer 100% humidified oxygen.

Supportive therapy: Calcium gluconate may relieve muscle cramping.

Additional Information Very flammable. Odor threshold: 17 ppm (acid). TLV-TWA: 200 ppm. Usual general population exposure: 0.013 to 0.076 ppb (1-6 mcg/day). EPA water maximum containment level: 0.07 mg/L (cis-isomer); 0.1 mg/L (trans-isomer). Half-life: Atmospheric: 8.3 days (cis-isomer); 3.6 days (trans-isomer). Water: 3-6 hours

Acrolein

Related Information

- Allyl Alcohol

Applies to Biocide (Paper Industry); Herbicides (Manufacture); Pharmaceuticals (Manufacture); Slimicide (Paper Industry); Tear Gas; Textiles (Manufacture); Tissue Fixative (Paper Industry)

CAS Number 100-73-2; 107-02-8; 869-29-4

UN Number 1092; 2607

U.S. Brand Names Aqualin®; Magnacide H®

Synonyms Propylene Aldehyde; Pyran Aldehyde; 2-Propenal

Use Manufacture of pharmaceuticals, herbicides, textiles, and as a tear gas; found as an irritant gas generated by fire; production of acrylic acid; as a tissue fixative, biocide, and slimicide in paper industry

Mechanism of Toxic Action Irritation of mucous membranes; suppresses glycolysis and reacts with sulfhydryl groups of proteins; release of catecholamines is noted; high water stability can lead to primary upper airway damage

Adverse Reactions

Eye: Irritation

Cardiovascular: Sinus tachycardia

Respiratory: Pulmonary edema

Signs and Symptoms of Overdose Bronchial constriction, coma, cough, dyspnea, erythema, hypertension, lacrimation, tachycardia, tachypnea at air levels of 0.6 ppm

Admission Criteria/Prognosis Patients with persistent respiratory symptoms or elevation of liver alkaline phosphatase (which may be a biomarker of exposure) should be considered for hospital admission

Toxicodynamics/Kinetics

Absorption: Through ingestion and inhalation

Metabolism: Hepatic to S-carboxy ethyl mercapturic acid methyl ester

Overdosage/Treatment

Decontamination: Oral: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Inhalation: Humidified oxygen, inhaled beta-adrenergic agonist agents for wheezing; treat for pulmonary edema

Additional Information

Toxic dose for irritation: 10 ppm

One of the major irritants in smog; yellow liquid with pungent odor (acid)

Acrolein is present in cigarette smoke: 3-220 mcg/cigarette and marijuana: 92-145 mcg/joint

Odor threshold: Water: 0.11 ppm. Air: 0.16 ppm. TLV-TWA: 0.1 ppm;

IDLH: 2 ppm; PEL-TWA: 0.1 ppm. Atmospheric half-life: 15-20 hours.

Ambient air level: ~0.3 ppb

Newer concepts: N-acetylcysteine protected against hepatitis in laboratory animals

Acrylamide

CAS Number 79-06-1

UN Number 2074

U.S. Brand Names Nyloprint®

Synonyms 2-Propenamide; Acrylic Amide; Ethylene Carboxamide; Propenamide

Use Vinyl monomer synthesized from acetonitrile; it is polymerized to produce flocculants used in waste water treatment, paper strengtheners, grouting agents, gels, and adhesive agents

Mechanism of Toxic Action Causes progressive degeneration by sensory neurons ("dying back"), starting distally and progressing proximally; thought to be due to activation of activity of sulfhydryl-dependent glycolytic enzymes inhibiting axonal energy production

Adverse Reactions

Central nervous system: Ataxia, axonopathy

Dermatologic: Dermal irritation, desquamation of palms and soles

Gastrointestinal: Anorexia

Neuromuscular & skeletal: Hyporeflexia, neuritis, paresthesia

Respiratory: Cough

Miscellaneous: Palm diaphoresis

Signs and Symptoms of Overdose

Dependent on time and duration, total dose, and rate of exposure

High-dose:

Acute: Ataxia, cardiovascular collapse, confusion, disorientation,

hallucinations, hypothermia, possible seizures, somnolence, tremor

Subacute (days/weeks): Decreased concentration, drowsiness, dysarthria, nystagmus, paresthesia (may follow in 2-3 weeks), somnolence, truncal ataxia, urinary retention

Chronic: Sensorimotor and proprioceptive neuropathy

Complete recovery over weeks to months in mild exposure but in severe exposure, recovery may be incomplete. Elevated liver transaminases

and decreased urinary output have been reported. Severe thrombocytopenia has been reported. Exfoliated erythematous rash (especially on hands) occurs with chronic exposure.

Toxicodynamics/Kinetics

Absorption: Rapid through oral, dermal, and inhalation

Distribution: Rapid to blood and then tissue

Metabolism: Hepatic

Half-life: 2 hours

Time to peak blood levels: 1 hour

Elimination: Renal

Warnings/Precautions

When vapors are present, must use impervious body protector as significant toxicity may occur through dermal absorption

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Pyridoxine (vitamin B₆) 3-10 g of 10% solution in D₅W over 30-60 minutes; may delay neurotoxic effect. N-acetylcysteine has been utilized, but it is of unproven benefit.

Antidote(s)

- Pyridoxine [ANTIDOTE]

Additional Information Acrylamide may be measured in tissue and blood by HPLC; considered a suspected human skin carcinogen. Odorless, colorless, white flake-like powder

Specific References

Mucci LA, Sandin S, Balter K, et al, "Acrylamide Intake and Breast Cancer Risk in Swedish Women," *JAMA*, 2005, 293(11):1326-7.

Acrylonitrile

Applies to Acrylic/Modacrylic Fibers; Acrylics; Adhesives; Fumigant; Pesticide; Plastics; Rubber

CAS Number 107-13-1

UN Number 1093

Synonyms 2-Propenenitrile; Cyanoethylene; Vinyl Cyanide

Use Raw material in acrylic/modacrylic fibers; also used in the manufacture of plastics, rubber, acrylics, and adhesives; used as a fumigant and pesticide

Mechanism of Toxic Action Produced through the process of propylene amoxidation; hepatic conversion to cyanide can produce signs and symptoms of cyanide

Adverse Reactions

Cardiovascular: Tachycardia

Central nervous system: Dizziness, headache, seizures

Dermatologic: Dermal irritation, desquamation, toxic epidermal necrosis may develop in 3 weeks

Endocrine & metabolic: Lactic acidosis

Gastrointestinal: Nausea, diarrhea, vomiting

Hematologic: Anemia

Hepatic: Jaundice, hepatic injury

Neuromuscular & skeletal: Limb weakness

Ocular: Conjunctivitis

Respiratory: Irregular breathing, dyspnea

Admission Criteria/Prognosis All symptomatic patients should probably be admitted to an intensive care unit for 1-2 days; asymptomatic patients should be observed for at least 2 hours and then can be discharged; survival after 4 hours (in an acute exposure) is usually associated with recovery

Toxicodynamics/Kinetics

Absorption: Inhalation: 52%. Dermal: 0.6 mg/cm²/hour

Metabolism: To 2-cyanoethylene oxide then converted to cyanide

Half-life: 7-8 hours

Elimination: Renal (68%)

Reference Range Plasma thiocyanate level >20 mg/L in nonsmokers or 30 mg/L in smokers is consistent with exposure to acrylonitrile; exposure to an average air level of 4.2 ppm of acrylonitrile over an 8-hour day produces a urine acrylonitrile level of 360 mcg/L and a urinary thiocyanate level of 11.4 mg/L

Overdosage/Treatment

Decontamination: Basic poison management (lavage within 1 hour/activated charcoal). Emesis is contraindicated due to the rapid course of neurologic symptoms. Give 100% oxygen.

Supportive therapy: Give sodium bicarbonate for acidosis; cyanide antidote kit (amyl nitrate, sodium nitrate followed by sodium thiosulfate); N-acetylcysteine has been effective in rodent models

Enhancement of elimination: Hemodialysis and charcoal hemoperfusion have been utilized; hyperbaric oxygen may also be utilized. Hydroxocobalamin, dicobalt-EDTA, and 4-dimethylaminophenol used for chelation in Europe

Antidote(s)

- Amyl Nitrite [ANTIDOTE]
- Cyanide Antidote Kit [ANTIDOTE]
- Hydroxocobalamin [ANTIDOTE]
- Oxygen (Hyperbaric) [ANTIDOTE]
- Sodium Nitrite [ANTIDOTE]
- Sodium Thiosulfate [ANTIDOTE]

Diagnostic Procedures

- Anion Gap, Blood
- Cyanide, Blood
- Electrolytes, Blood
- Methemoglobin, Blood
- Thiocyanate, Blood or Urine

Additional Information

Levels of 16-100 ppm for 20-45 minutes can produce symptoms.

Children are more susceptible than adults.

Associated with increase in prostate, colon, lung, and stomach cancer.

Full recovery will usually occur if the patient survives for 4 hours.

Pungent odor (onion/garlic-like).

Odor threshold in water: 19 ppm. Atmospheric half-life: 12 hours.

TLV-TWA: 2 ppm; IDLH: 4000 ppm

Typical acrylonitrile level in margarine: 25 mcg/kg; in cigarettes: 1-2 mg/cigarette.

Acrylonitrile can be absorbed through leather products.

Acyclovir

Pronunciation (ay SYE kloe veer)

Related Information

- Famciclovir
- Therapeutic Drugs Associated with Hallucinations
- Valacyclovir

CAS Number 59277-89-3; 69657-51-8

U.S. Brand Names Zovirax®

Synonyms Aciclovir; ACV; Acycloguanosine

Use Treatment of genital herpes simplex virus (HSV), herpes labialis (cold sores), herpes zoster (shingles), HSV encephalitis, neonatal HSV, mucocutaneous HSV, varicella-zoster (chickenpox)

Unlabeled/Investigational Use Prevention of HSV reactivation in HIV-positive patients; prevention of HSV reactivation in hematopoietic stem-cell transplant (HSCT); prevention of HSV reactivation during periods of neutropenia in patients with acute leukemia

Mechanism of Action Inhibits DNA synthesis and viral replication by competing with deoxyguanosine triphosphate for viral DNA polymerase (thymidine kinase) and by being incorporated into viral DNA

Adverse Reactions**Systemic: Oral:**

Central nervous system: Lightheadedness, headache

Gastrointestinal: Diarrhea, nausea, vomiting, abdominal pain

Systemic: Parenteral:

Central nervous system: **Lightheadedness**

Dermatologic: Hives, itching, rash

Gastrointestinal: **Anorexia**, nausea, vomiting

Hepatic: Liver function tests increased

Local: Inflammation at injection site or phlebitis

Renal: Acute renal failure, BUN increased, creatinine increased

Topical:

Dermatologic: **Mild pain, burning, stinging, itching**

All forms: Postmarketing and/or case reports (<1%): Aggression, agitation, alopecia, anaphylaxis, anemia, angioedema, anorexia, ataxia, coma, confusion, consciousness decreased, delirium, diarrhea, dizziness, encephalopathy, erythema multiforme, fever, gastrointestinal distress, hallucinations, hematuria, hepatitis, hyperbilirubinemia, insomnia, jaundice, leukocytoclastic vasculitis, leukopenia, local tissue necrosis (following extravasation), mental depression, myalgia, paresthesia, peripheral edema, photosensitization, pruritus, psychosis, renal failure, seizures, somnolence, sore throat, Stevens-Johnson syndrome, thrombocytopenia, thrombocytopenic purpura/hemolytic uremic syndrome (TTP/HUS), toxic epidermal necrolysis, tremor, urticaria, visual disturbances

Pharmacodynamics/Kinetics

Absorption: Oral: 15% to 30%

Distribution: V_d: 0.8 L/kg (63.6 L): Widely (eg, brain, kidney, lungs, liver, spleen, muscle, uterus, vagina, CSF)

Protein binding: 9% to 33%

Metabolism: Converted by viral enzymes to acyclovir monophosphate, and further converted to diphosphate then triphosphate (active form) by cellular enzymes

Bioavailability: Oral: 10% to 20% with normal renal function (bioavailability decreases with increased dose)

Half-life elimination: Terminal: Neonates: 4 hours; Children 1-12 years: 2-3 hours; Adults: 3 hours

Time to peak, serum: Oral: Within 1.5-2 hours

Excretion: Urine (62% to 90% as unchanged drug and metabolite)

Dosage

Note: Obese patients should be dosed using ideal body weight

Genital HSV:

I.V.: Children ≥ 12 years and Adults (immunocompetent): Initial episode, severe: 5 mg/kg every 8 hours for 5-7 days

Oral:

Children:

Initial episode (unlabeled use): 40-80 mg/kg/day divided into 3-4 doses for 5-10 days (maximum: 1 g/day)

Chronic suppression (unlabeled use; limited data): 80 mg/kg/day in 3 divided doses (maximum: 1 g/day), re-evaluate after 12 months of treatment

Adults:

Initial episode: 200 mg every 4 hours while awake (5 times/day) for 10 days (per manufacturer's labeling); 400 mg 3 times/day for 5-10 days has also been reported

Recurrence: 200 mg every 4 hours while awake (5 times/day) for 5 days (per manufacturer's labeling); begin at earliest signs of disease); 400 mg 3 times/day for 5 days has also been reported
Chronic suppression: 400 mg twice daily or 200 mg 3-5 times/day, for up to 12 months followed by re-evaluation (per manufacturer's labeling); 400-1200 mg/day in 2-3 divided doses has also been reported

Topical: Adults (immunocompromised): Ointment: Initial episode: 1/2" ribbon of ointment for a 4" square surface area every 3 hours (6 times/day) for 7 days

Herpes labialis (cold sores): Topical: Children ≥ 12 years and Adults: Cream: Apply 5 times/day for 4 days

Herpes zoster (shingles):

Oral: Adults (immunocompetent): 800 mg every 4 hours (5 times/day) for 7-10 days

I.V.:

Children < 12 years (immunocompromised): 20 mg/kg/dose every 8 hours for 7 days

Children ≥ 12 years and Adults (immunocompromised): 10 mg/kg/dose or 500 mg/m²/dose every 8 hours for 7 days

HSV encephalitis: I.V.:

Children 3 months to 12 years: 20 mg/kg/dose every 8 hours for 10 days (per manufacturer's labeling); dosing for 14-21 days also reported

Children ≥ 12 years and Adults: 10 mg/kg/dose every 8 hours for 10 days (per manufacturer's labeling); 10-15 mg/kg/dose every 8 hours for 14-21 days also reported

Mucocutaneous HSV:

I.V.:

Children < 12 years (immunocompromised): 10 mg/kg/dose every 8 hours for 7 days

Children ≥ 12 years and Adults (immunocompromised): 5 mg/kg/dose every 8 hours for 7 days (per manufacturer's labeling); dosing for up to 14 days also reported

Oral: Adults (immunocompromised, unlabeled use): 400 mg 5 times a day for 7-14 days

Topical: Ointment: Adults (nonlife-threatening, immunocompromised): 1/2" ribbon of ointment for a 4" square surface area every 3 hours (6 times/day) for 7 days

Neonatal HSV: I.V.: Neonate: Birth to 3 months: 10 mg/kg/dose every 8 hours for 10 days (manufacturer's labeling); 15 mg/kg/dose or 20 mg/kg/dose every 8 hours for 14-21 days has also been reported

Varicella-zoster (chickenpox): Begin treatment within the first 24 hours of rash onset:

Oral:

Children ≥ 2 years and ≤ 40 kg (immunocompetent): 20 mg/kg/dose (up to 800 mg/dose) 4 times/day for 5 days

Children > 40 kg and Adults (immunocompetent): 800 mg/dose 4 times a day for 5 days

I.V.:

Children < 1 year (immunocompromised, unlabeled use): 10 mg/kg/dose every 8 hours for 7-10 days

Children ≥ 1 year and Adults (immunocompromised, unlabeled use): 1500 mg/m²/day divided every 8 hours or 10 mg/kg/dose every 8 hours for 7-10 days

Prevention of HSV reactivation in HIV-positive patients, for use only when recurrences are frequent or severe (unlabeled use): Oral:

Children: 80 mg/kg/day in 3-4 divided doses

Adults: 200 mg 3 times/day or 400 mg 2 times/day

Prevention of HSV reactivation in HSCT (unlabeled use): Note: Start at the beginning of conditioning therapy and continue until engraftment or until mucositis resolves (~30 days)

Oral: Adults: 200 mg 3 times/day

I.V.:

Children: 250 mg/m²/dose every 8 hours or 125 mg/m²/dose every 6 hours

Adults: 250 mg/m²/dose every 12 hours

Bone marrow transplant recipients (unlabeled use): I.V.: Children and Adults: Allogeneic patients who are HSV and CMV seropositive: 500 mg/m²/dose (10 mg/kg) every 8 hours; for clinically-symptomatic CMV infection, consider replacing acyclovir with ganciclovir

Dosing adjustment in renal impairment:

Oral:

Cl_{cr} 10-25 mL/minute: Normal dosing regimen 800 mg every 4 hours: Administer 800 mg every 8 hours

Cl_{cr} < 10 mL/minute:

Normal dosing regimen 200 mg every 4 hours, 200 mg every 8 hours, or 400 mg every 12 hours: Administer 200 mg every 12 hours

Normal dosing regimen 800 mg every 4 hours: Administer 800 mg every 12 hours

I.V.:

Cl_{cr} 25-50 mL/minute: Administer recommended dose every 12 hours

Cl_{cr} 10-25 mL/minute: Administer recommended dose every 24 hours

Cl_{cr} < 10 mL/minute: Administer 50% of recommended dose every 24 hours

Hemodialysis: Administer dose after dialysis

Peritoneal dialysis: No supplemental dose needed

CAVH: 3.5 mg/kg/day

CVVHD/CVVH: Adjust dose based upon Cl_{cr} 30 mL/minute

Monitoring Parameters Urinalysis, BUN, serum creatinine, liver enzymes, CBC

Administration

Oral: May be administered with or without food.

I.V.: Avoid rapid infusion; infuse over 1 hour to prevent renal damage; maintain adequate hydration of patient; check for phlebitis and rotate infusion sites

Topical: Not for use in the eye. Apply using a finger cot or rubber glove to avoid transmission to other parts of the body or to other persons.

Contraindications Hypersensitivity to acyclovir, valacyclovir, or any component of the formulation

Warnings

Use with caution in immunocompromised patients; thrombocytopenic purpura/hemolytic uremic syndrome (TTP/HUS) has been reported. Use caution in the elderly, pre-existing renal disease, or in those receiving other nephrotoxic drugs. Maintain adequate hydration during oral or intravenous therapy. Use I.V. preparation with caution in patients with underlying neurologic abnormalities, serious hepatic or electrolyte abnormalities, or substantial hypoxia.

Safety and efficacy of oral formulations have not been established in pediatric patients < 2 years of age.

Chickenpox: Treatment should begin within 24 hours of appearance of rash; oral route not recommended for routine use in otherwise healthy children with varicella, but may be effective in patients at increased risk of moderate to severe infection (> 12 years of age, chronic cutaneous or pulmonary disorders, long-term salicylate therapy, corticosteroid therapy).

Genital herpes: Physical contact should be avoided when lesions are present; transmission may also occur in the absence of symptoms. Treatment should begin with the first signs or symptoms.

Herpes labialis: For external use only to the lips and face; do not apply to eye or inside the mouth or nose. Treatment should begin with the first signs or symptoms.

Herpes zoster: Acyclovir should be started within 72 hours of appearance of rash to be effective.

Dosage Forms

[DSC] = Discontinued product

Capsule: 200 mg

Zovirax®: 200 mg

Cream, topical:

Zovirax®: 5% (2 g, 5 g)

Injection, powder for reconstitution, as sodium: 500 mg, 1000 mg

Zovirax®: 500 mg [DSC]

Injection, solution, as sodium [preservative free]: 25 mg/mL (20 mL, 40 mL); 50 mg/mL (10 mL, 20 mL)

Ointment, topical:

Zovirax®: 5% (15 g)

Suspension, oral: 200 mg/5 mL (480 mL)

Zovirax®: 200 mg/5 mL (480 mL) [banana flavor]

Tablet: 400 mg, 800 mg

Zovirax®: 400 mg, 800 mg

Reference Range Neurotoxicity is associated with plasma levels of 470 μmol/mL

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Renal toxicity and crystalluria can be managed with I.V. fluid hydration

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; hemodialysis can remove ~60% of total body burden; exchange transfusion is not useful

Pregnancy Risk Factor B B

Pregnancy Implications Teratogenic effects were not observed in animal studies. Acyclovir has been shown to cross the human placenta. Results from a pregnancy registry, established in 1984 and closed in 1999, did not find an increase in the number of birth defects with exposure to acyclovir when compared to those expected in the general population. However, due to the small size of the registry and lack of long-term data, the manufacturer recommends using during pregnancy with caution and only when clearly needed. Data from the pregnancy registry may be obtained from GlaxoSmithKline.

Lactation Enters breast milk/use with caution (AAP rates "compatible")

Nursing Implications Infuse over 1 hour; maintain adequate hydration of patient; check infusion site for phlebitis, rotate site to prevent phlebitis; wear gloves when applying ointment for self-protection

Additional Information Not effective against cytomegalovirus. Injection formulations: Sodium content of 1 g: 96.6 mg (4.2 mEq)

Aldicarb

CAS Number 116-06-3

U.S. Brand Names Temik®

Use Marketed in solutions of up to 100% aldicarb; insecticide

Mechanism of Toxic Action Potent, reversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, edema, QT prolongation, sinus bradycardia, sinus tachycardia

Central nervous system: Toxicity is limited because carbamates do not significantly cross the blood-brain barrier; CNS changes occur with most severe intoxications, hyperactivity, hypothermia

Genitourinary: Incontinence

Neuromuscular & skeletal: Weakness, paralysis

Respiratory: Respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose Abdominal pain, agitation, generalized asthenia, AV block, asystole, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsy, decreased hemoglobin, decreased red blood cell count, decreased platelet count, diaphragmatic paralysis, dysarthria, fecal incontinence, flaccid paralysis, excessive sweating, headache, heart block, hyperglycemia (severe intoxication), hypertension, hypotension, lacrimation, metabolic acidosis (severe intoxication), miosis (unreactive to light), mydriasis (rarely), skeletal muscle fasciculation, nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, tachycardia, tachypnea, urinary incontinence, vomiting

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure

Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways, and may undergo enterohepatic recirculation

Half-life: 5.75 hours

Elimination: Metabolites are excreted in urine

Warnings/Precautions Aldicarb translocates from soil into food sources in significant quantity; readily absorbed through intact skin; risk of aspiration pneumonitis exists with agents having a hydrocarbon vehicle

Reference Range

Highest survivable aldicarb concentrations: Serum: 3.22 mcg/mL; Urine: 1 mcg/mL

Following a 10 g ingestion, peak serum aldicarb level was 3.22 mcg/L (at 3 hours) and associated with severe toxicity; serum aldicarb >0.1 mcg/mL is associated with symptoms

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. Do not utilize cathartics.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach may also be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses >100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or ~¹/₂ the dose of atropine).

2-PAM: Although not specifically indicated, 2-PAM may be considered in the following situations:

Life-threatening symptoms such as respiratory paralysis
Continued excessive atropine requirements

Concomitant organophosphate and carbamate exposure

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed treatment and large volumes of distribution of organophosphates.

Antidote(s)

- Atropine [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information

Red blood cell cholinesterase and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure and are theoretically useful for differentiating between carbamate and organophosphate exposures; RBC cholinesterase is typically not analyzed by in-house laboratories and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition, thus they may not be useful in ruling out carbamate exposure.

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Spray solutions are balanced to pH = 7.0 and also contain dichloromethane and methyl isocyanate;

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Aldrin

Related Information

- Dieldrin

CAS Number 309-00-2

U.S. Brand Names Aldrec®; Aldrex®; Aldrite®; Compound 118®; Drinox®; Octalene®; Seedrin®

Synonyms HHDN

Use Insecticide - general crop protection, used against termites, EPA discontinued use in 1970s

Mechanism of Toxic Action Cyclodiene organochlorine agent which may be a competitive inhibitor of the inhibitory neurotransmitter GABA at the GABA A receptor

Adverse Reactions

Central nervous system: Convulsions, headache, dizziness, seizures

Gastrointestinal: Nausea, vomiting, anorexia

Hematologic: Hemolysis

Neuromuscular & skeletal: Muscle twitching

Renal: Hematuria, albuminuria, elevated blood urea nitrogen

Toxicodynamics/Kinetics

Absorption: Absorbed by oral or dermal routes; also by inhalation

Metabolism: Epoxidized to dieldrin (by mono-oxygenase) then to pentachloroketone and aldrin dicarboxylic acid (among other metabolites)

Elimination: Feces

Reference Range Blood aldrin levels taken from general population in El Paso, TX (1982-3) demonstrated presence of aldrin in 34% of subjects at a mean level of 4.6 ppb

Overdosage/Treatment

Decontamination: **Oral:** Activated charcoal. **Dermal:** Soap and water wash. **Ocular:** Irrigate with saline.

Supportive therapy: Beta-adrenergic blocking agents may be used for tachycardia or hypertension. Benzodiazepines, phenobarbital, or phenytoin can be used for seizures.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective.

Additional Information Lethal dose: Oral: 71 mg/kg. Odor threshold: 0.02 mg/kg

Allyl Alcohol

Related Information

- Acrolein

CAS Number 107-18-6

UN Number 1098

Synonyms Propenol; Vinylcarbinol

Use

Industrial: Synthetic chemical intermediate

Agriculture: Weed killer

Mechanism of Toxic Action A mucosal and skin irritant; the metabolite acrolein can produce cardiotoxicity and rapid onset of coma

ALUMINUM

Adverse Reactions

Central nervous system: Headache, rapid onset of coma
Dermatologic: Dermal irritation, bullous eruption
Gastrointestinal: Nausea, vomiting
Ocular: Lacrimation, irritation, photophobia, corneal ulceration
Renal: Hematuria
Respiratory: Cough, dyspnea, hemoptysis

Toxicodynamics/Kinetics Hepatic metabolism to acrolein through alcohol dehydrogenase enzyme (ADH)

Reference Range Postmortem blood allyl alcohol level of 309 mg/L and acrolein level of 7.2 mg/L were noted in a suicide fatality after an ~200 g allyl alcohol ingestion.

Overdosage/Treatment

Decontamination: **Oral:** Dilute with 4-8 ounces of milk or water; activated charcoal may be helpful. Consider gastric lavage if patient presents within 2 hours. **Dermal:** Irrigate and wash with soap and water.

Inhalation: Administer 100% humidified oxygen. **Ocular:** Administer copious amounts of saline in water through irrigation.

Supportive therapy: Although no human studies exist, fomepizole or ethanol therapy to inhibit ADH enzyme and acrolein formation may be useful. *N*-acetylcysteine administration may also be helpful (no human data).

Enhancement of elimination: Hemodialysis may enhance elimination (no human data).

Additional Information

Oral lethal dose: 50-500 mg/kg
Odor threshold: 0.8 ppm. Eye irritation can occur at 5 ppm. IDLH: 20 ppm.
Atmospheric half-life: 6 hours.
A colorless liquid with a mustard-like odor; soluble with water

aluminum is 5 mg/day with ~15 mcg absorbed, thus the total body burden of aluminum is ~30-50 mg (50% in bone, 25% in lungs). Atmospheric aluminum levels range from 0.005-0.18 ng/mg (higher in the summer). Typical aluminum soil concentration is 71,000 mg/kg. See table.

Estimated Number of Workers Potentially Exposed to Aluminum and Compounds in the Workplace

Aluminum Compound	Number of Potentially Exposed Workers
Aluminum — pure	31,369
Aluminum dust	1833
Aluminum — unknown	1,033,235
Aluminum oxide	1,345,659
Aluminum oxide, powder	172,756
Aluminum hydroxide	325,788
Aluminum hydroxide, gel	37,772
Dried aluminum hydroxide gel	7006
Aluminum chloride	49,913
Aluminum chloride hydroxide	1579
Aluminum sulfate	212,239
Aluminum sulfate, liquid	23,354
Aluminum sulfate, powder	1496
Aluminum nitrate	34,929
Aluminum phosphide	622
Aluminum phosphate	19,526
Aluminum phosphate, gel	4228
Aluminum fluoride	175
Aluminum, calcined	27,670

Source: National Occupational Exposure Study (NOES); NIOSH 1991 Reference: U.S. Department of Health and Human Services, "Toxicological Profile for Aluminum," Agency for Toxic Substances and Disease Registry, September 1997.

Aluminum

CAS Number 7429-90-5

UN Number 1309; 1383; 1396

Commonly Found In Packaging, building, transportation, and electrical applications

Use Primarily used in metallurgical purposes (ie, production of alloy castings)

Mechanism of Toxic Action Can cause neurotoxicity through an unknown mechanism. Proposed mechanisms include inhibition of neuronal microtubule formation and competition with cations (especially magnesium).

Signs and Symptoms of Overdose Asterixis, asthma, dialysis dementia (dysarthria, stammering, seizures, and motor disturbances), encephalopathy, microcytic anemia, myoclonus, osteomalacia, pulmonary fibrosis, seizures, slurred speech

Toxicodynamics/Kinetics

Absorption: Oral: 0.1% to 0.3%
Elimination: Renal (up to 0.5 mg/24 hours)

Reference Range Normal serum level: 0.35-0.85 mcg/dL (0.13-0.32 µmol/L). Aluminum bone disease occurs with aluminum levels >3 mcg/dL.

Overdosage/Treatment

Decontamination: Oral: Ranitidine (300 mg/day) may decrease aluminum absorption

Supportive therapy: Benzodiazepines should be utilized for seizure control. Deferoxamine is the chelator of choice. Aluminum neurotoxicity in dialysis patients can be treated with deferoxamine 1 g I.M. on the evening prior to dialysis and a high-flux dialyzer or charcoal cartridge to remove DFO-aluminum complex during dialysis. Anemia can be treated with a 3-month course of deferoxamine (30 mg/kg I.V. over the last 2 hours of dialysis 3 times per week).

Additional Information

Insoluble in water and alcohol; iron deficiency may increase aluminum absorption, possible association with dialysis, dementia, and renal osteodystrophy

Aluminum is the most abundant metallic component (~8%) of the Earth's crust. Bauxite is the main source of environmental aluminum.

Aluminum content of tobacco and cannabis is about 0.4% by weight
Aluminum only has one oxidation state (+3); background atmospheric aluminum levels range from 0.005-0.2 mg/m³; baseline drinking water aluminum levels range from 0.003-1.6 mg/L; soil aluminum levels range from 700 mg/kg to over 100,000 mg/kg

Foods containing highest aluminum levels are ground coffee beans (52 mg/kg), salt (31-37 mg/kg), natural peanut butter (26-94 mg/kg), pumpernickel bread (13.2 mg/kg), chocolate cookie, Oreo® (12.7 mg/kg), spinach (8.7 mg/kg), and lettuce (7.2 mg/kg). Calcium gluconate contains 38.8 mcg aluminum per 8 mL volume; potassium acid phosphate contains 2.8 mcg aluminum per 1.3 mL total volume.

Aluminum is not bioconcentrated in plants or terrestrial food chain; antacids/buffered aspirin can contain from 4-562 mg/kg of aluminum. Daily intake of aluminum is ~2-14 mg by food ingestion, 0.2 mg through drinking water, and 0.2 mg by inhalation. Normal dietary

Aluminum Phosphide

Related Information

- Phosphine
- Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 20859-73-8; 7803-51-2

UN Number 1397; 3048

U.S. Brand Names Al-Phos®, Celphos®, Delicia®, Detia®, Phostoxin®, Quickphos®

Synonyms Aluminum Monophosphide

Use Fumigation of grain, rodenticide

Mechanism of Toxic Action Liberates phosphine gas in the GI tract which blocks cytochrome C thus uncoupling oxidative phosphorylation and electron transport in the mitochondria

Adverse Reactions

Cardiovascular: Hypotension (within 6 hours), myocardial injury with widening of QRS complex on ECG, fibrillation (atrial), tachycardia (ventricular), cyanosis, pericarditis, edema, tachycardia, arrhythmias (ventricular)

Central nervous system: Headache, ataxia, dizziness, Endocrine & metabolic: Hyperkalemia, metabolic acidosis, adrenal dysfunction may occur, hypomagnesemia and hypermagnesemia have been reported

Gastrointestinal: Stomach pain, vomiting, watery diarrhea

Hematologic: Bleeding, intravascular hemolysis, methemoglobinemia

Hepatic: Hepatic failure

Ocular: Diplopia

Neuromuscular & skeletal: Tremors, paresthesia

Renal: Renal failure, oliguria

Respiratory: Tachypnea, pulmonary edema

Miscellaneous: Diathesis

Toxicodynamics/Kinetics Protein binding: 60% to 70%

Overdosage/Treatment

Decontamination: Gastric lavage within 1 hour with 1:5000 potassium permanganate to oxidize unabsorbed toxin. Sodium bicarbonate (2% solution) can also be utilized to neutralize gastric hydrochloric acid, thus inhibiting release of phosphine.

Supportive therapy: Sodium bicarbonate should be used to treat acidosis. Dopamine can be used to treat hypotension. If hypotension does not respond to vasopressors, hydrocortisone (400 mg every 4-6 hours) or dexamethasone (4 mg I.V. every 4 hours) can be used to treat adrenal dysfunction. Magnesium should be administered in order to prevent cardiac arrhythmia; suggested dose: 3 g (I.V. continuous infusion) over 3 hours followed by 6 g I.V. over 24 hours for the next 3 to 5 days. Ventricular arrhythmias can be treated successfully with trimetazidine (20 mg orally twice daily). Treat symptomatic methemoglobinemia with 1-2 mL/kg of 1% methylene blue. Endoscopic dilation may be required to treat esophageal structures (which can develop two weeks post ingestion).

Additional Information Decomposes in water; dark gray or dark yellow crystals; oral estimate of daily human exposure that is likely to be without risk of deleterious effects during a lifetime: 0.0004 mg/kg/day.

Americum**CAS Number** 7440-35-9

Use In ionization smoke detectors (0.9 microcuries of ²⁴¹Am in household detectors). No stable isotopes. Also used in diagnosis of thyroid disorders.

Mechanism of Toxic Action Emission of alpha particles during radioactive decay. Since there is very limited alpha particle penetration, cellular damage is located over the immediate vicinity of exposure.

Adverse Reactions Hematologic: Lymphopenia/thrombocytopenia from inhalation of 100 g of ¹²⁴Am exposure

Toxicodynamics/Kinetics

Absorption: By inhalation; <0.1% absorbed orally; <20% absorbed dermally

Elimination: Fecal (>50%)

Overdosage/Treatment

Decontamination: Inhalation: Administer 100% humidified oxygen.

Supportive therapy: Enhanced urinary excretion may be accomplished with DTPA (diethylenetriamine pentacetic acid) (1 g I.V. in 250 mL isotonic saline or D₅W).

Additional Information Ambient air concentration: <1 aCi/m³. Surface seawater concentration: 270 pCi/m³. Primarily taken up in skeleton and liver. Total skeletal burden is 0.27 pCi; found in shellfish, grain, fruits, and vegetables. Call Radiation Emergency Assistance Center/Training Site in Oak Ridge, Tennessee (800) 576-1004 for exposure information.

Amikacin**CAS Number** 39831-55-5

U.S. Brand Names Amikin®

Synonyms Amikacin Sulfate

Use Treatment of documented gram-negative enteric infection resistant to gentamicin and tobramycin; documented infection of mycobacterial organisms susceptible to amikacin

Mechanism of Action Inhibits protein synthesis in susceptible bacteria by binding to ribosomal subunits

Adverse Reactions

Cardiovascular: Chest pain

Central nervous system: Anxiety

Dermatologic: Rash

Neuromuscular & skeletal: Neuromuscular blockade, myasthenia gravis (exacerbation or precipitation of)

Otic: Ototoxicity, deafness, tinnitus

Renal: Nephrotoxicity, Fanconi-like syndrome

Signs and Symptoms of Overdose Hypomagnesemia

Pharmacodynamics/Kinetics

Absorption:

I.M.: Rapid

Oral: Poorly absorbed

Distribution: Primarily into extracellular fluid (highly hydrophilic); penetrates blood-brain barrier when meninges inflamed; crosses placenta
Relative diffusion of antimicrobial agents from blood into CSF: Good only with inflammation (exceeds usual MICs)

CSF: blood level ratio: Normal meninges: 10% to 20%; Inflamed meninges: 15% to 24%

Protein-binding: 0% to 11%

Half-life elimination (renal function and age dependent):

Infants: Low birth weight (1-3 days): 7-9 hours; Full-term >7 days: 4-5 hours

Children: 1.6-2.5 hours

Adults: Normal renal function: 1.4-2.3 hours; Anuria/end-stage renal disease: 28-86 hours

Time to peak, serum: I.M.: 45-120 minutes

Excretion: Urine (94% to 98%)

Dosage

Individualization is critical because of the low therapeutic index. Use of ideal body weight (IBW) for determining the mg/kg/dose appears to be more accurate than dosing on the basis of total body weight (TBW). In morbid obesity, dosage requirement may best be estimated using a dosing weight of IBW + 0.4 (TBW - IBW). Initial and periodic peak and trough plasma drug levels should be determined, particularly in critically ill patients with serious infections or in disease states known to significantly alter aminoglycoside pharmacokinetics (eg, cystic fibrosis, burns, or major surgery).

Neonates: I.V.:

<1200 g, 0-4 weeks: 7.5 mg/kg/dose every 12 hours

Postnatal age <7 days:

1200-2000 g: 7.5 mg/kg/dose every 12 hours

>2000 g: 10 mg/kg/dose every 12 hours

Postnatal age >7 days:

1200-2000 g: 7 mg/kg/dose every 8 hours

>2000 g: 7.5-10 mg/kg/dose every 8 hours

Infants, Children, and Adults: I.M., I.V.: 7.5 mg/kg/dose every 8 hours

Dosing interval in renal impairment: Loading dose: 5-7.5 mg/kg; subsequent dosages and frequency of administration are best determined by measurement of serum levels and assessment of renal insufficiency

Some patients may require larger or more frequent doses if serum levels document the need (ie, cystic fibrosis or febrile granulocytopenic patients)

Stability Stable for 24 hours at room temperature when mixed in D₅W, D₅¹/₄NS, D₅¹/₂NS, NS, LR

Monitoring Parameters Urinalysis, BUN, serum creatinine, appropriately timed peak and trough concentrations, vital signs, temperature, weight, I & O, hearing parameters

Administration Administer by intermittent I.V. infusion over 30 minutes at a final concentration not to exceed 5 mg amikacin/mL

Contraindications Hypersensitivity to amikacin sulfate or any component of the formulation; cross-sensitivity may exist with other aminoglycosides

Warnings [U.S. Boxed Warning]: Amikacin may cause neurotoxicity, nephrotoxicity, and/or neuromuscular blockade and respiratory paralysis; usual risk factors include pre-existing renal impairment, concomitant neuro/nephrotoxic medications, advanced age and dehydration. Dose and/or frequency of administration must be monitored and modified in patients with renal impairment. Drug should be discontinued if signs of ototoxicity, nephrotoxicity, or hypersensitivity occur. Ototoxicity is proportional to the amount of drug given and the duration of treatment. Tinnitus or vertigo may be indications of vestibular injury and impending bilateral irreversible damage. Renal damage is usually reversible.

Dosage Forms

[DSC] = Discontinued product

Injection, solution, as sulfate: 50 mg/mL (2 mL, 4 mL); 62.5 mg/mL (8 mL)

[DSC]; 250 mg/mL (2 mL, 4 mL)

Amikin®: 50 mg/mL (2 mL); 250 mg/mL (2 mL, 4 mL) [contains metabisulfite]

Reference Range

Therapeutic: Peak: 25-30 mcg/mL, trough: 4-8 mcg/mL

Toxic: Peak: >35 mcg/mL; trough: >10 mcg/mL

Overdosage/Treatment Enhancement of elimination: Ticarcillin complexation or exchange transfusion does not appear to be of added benefit; saline diuresis may be of benefit; dialyzable (50% to 100%)

Drug Interactions

Decreased effect of aminoglycoside: High concentrations of penicillins and/or cephalosporins (*in vitro* data)

Increased toxicity of aminoglycoside: Indomethacin I.V., amphotericin, loop diuretics, vancomycin, enflurane, methoxyflurane; increased effect of neuromuscular-blocking agents and polypeptide antibiotics with administration of aminoglycosides

Pregnancy Risk Factor C

Lactation Enters breast milk/compatible

Nursing Implications Aminoglycoside levels measured from blood taken from Silastic® central catheters can sometimes give falsely high readings; administer I.M. injection in large muscle mass; obtain culture for culture and sensitivity before first dose; weigh patient and obtain baseline renal function before therapy begins; monitor vital signs, serum levels are reportedly lower in patients with fever. Give around-the-clock rather than 3 times/day, to promote less variation in peak and trough serum levels; give other antibiotics at least 1 hour before or after amikacin.

Additional Information

Sodium content of 1 g: 29.9 mg (1.3 mEq)

AMITRAZ

Incidence of cochleotoxicity is ~10% to 63% with loop diuretics; noise exposure is ototoxic synergistic. Inhaled tobramycin appears to exhibit minimal ototoxic effects. There may be a genetic basis (in the mitochondrial 12 S ribosomal RNA gene) for ototoxicity in 17% to 33% of cases. Suggested evaluation for ototoxicity with aminoglycoside treatment includes:

- baseline audiometric evaluation (tonal air conduction thresholds from 250-20,000 Hz)
- monitoring during aminoglycoside treatment (to a tonal-air conduction threshold at frequency > 8000 Hz)
- follow-up audiometric assessment (tonal air conduction thresholds at frequencies > 8000 Hz) until the threshold stabilizes

Corpus KA, Weber KB, and Zimmerman CR, "Intrathecal Amikacin for the Treatment of Pseudomonas Meningitis," *Ann Pharmacother*, 2004, 38(6):992-5.

Amitraz

Related Information

- Xylene

CAS Number 33089-61-1

U.S. Brand Names BAAM[®]; Ectodex[®]; Mitac[®]; Taktic[®]; Triatox[®]

Synonyms U-36059

Use A topical ectoparasiticide in veterinary practice; effective against lice, mites, and ticks; used on fruit, trees, cattle, sheep, pigs, and honey bee hives; an acaricide and insect repellent

Mechanism of Toxic Action An α_2 adrenoceptor agonist (similar to clonidine). Reduces insulin secretion and heat production. Often combined with various solvents which contribute to CNS toxicity (particularly xylene).

Adverse Reactions Ocular: Visual evoked potential abnormalities

Signs and Symptoms of Overdose Onset of symptoms is usually within 4 hours. Coma (55% to 100%), bradycardia (10% to 62%), seizures (7% to 14%), CNS depression, drowsiness, vomiting (50% to 62%), flushing, headache, hyperglycemia (48% to 72%), hypokalemia, hypotonia, hypotension (42% to 67%), miosis, hypothermia (9% to 33%), respiratory depression (17% to 43%), glycosuria (21% to 42%), minor elevations in liver transaminases, polyuria, ataxia

Admission Criteria/Prognosis Admit any symptomatic patient or ingestion over 0.2 mg/kg to a cardiac monitored bed

Toxicodynamics/Kinetics

Absorption: Oral: 2 hours; dermal absorption may occur

Metabolism: Hepatic to an aromatic amine (2,4-dimethyl aniline)

Half-life: 4 hours

Elimination: Renal

Monitoring Parameters Glucose, potassium, ECG

Reference Range Blood amitraz concentration of 3.7 mg/L associated with deep coma following an ingestion of up to 12.5 g of amitraz; CNS symptoms may occur at plasma amitraz concentrations over 500 mcg/L; plasma amitraz level under 100 mcg/L not associated with symptoms

Overdosage/Treatment

Decontamination: **Oral:** Lavage/activated charcoal within 2 hours. **Dermal:** Remove contaminated clothing and wash thoroughly with soap and water. **Ocular:** Irrigate copiously with saline.

Supportive therapy: Diazepam or lorazepam for seizure control. Atropine for bradycardia (multiple doses may be needed). Isotonic crystalloid fluid 10-20 mL/kg I.V. and Trendelenburg positioning for hypotension. Dopamine or norepinephrine are vasopressors of choice. Hyperglycemia is usually transient and does not require specific treatment.

Antidote(s)

- Atropine [ANTIDOTE]

Additional Information

First marketed in 1974; concentrations (emulsifiable) solutions contain 20-200 g/L. Usually associated with a xylene vehicle; found in concentrations of 1 g of amitraz/5 mL of solution. When heated can decompose to nitrogen oxide fumes. LD50 in dogs: 100 mg/kg. Ingestion of 2.5 mg/kg can produce severe symptoms.

How supplied: Emulsifiable concentrate: 50-200 g/L; Powder: Wettable: 500 g/L; Dog shampoo (dispersal powder): 250 or 500 g/L

Synonyms Spirit of Hartshorn

Commonly Found In Household cleaners (5% to 10%) and bleach

Use Primarily in fertilizers; manufacture of nitrous oxide; petroleum refining

Mechanism of Toxic Action Tissue injury of moist mucosal membranes caused by reaction with water to form ammonia hydroxide; can cause burns by liquefaction necrosis

Adverse Reactions

Cardiovascular: Chest pain

Dermatologic: Immunologic contact urticaria

Gastrointestinal: Salivation

Respiratory: Reactive airways disease syndrome, hyposmia

Miscellaneous: Mucosal irritation

Signs and Symptoms of Overdose Burns, chest pain, coma, conjunctivitis, corneal defects, cough, dyspnea, GI irritation, headache, lacrimation, nausea, pulmonary edema, salivation, swelling, upper airway irritation, urticaria, wheezing, vomiting. Long-term sequelae include bronchiolitis obliterans and peribronchial fibrosis.

Admission Criteria/Prognosis Patient may be discharged if asymptomatic 6-8 hours postexposure

Toxicodynamics/Kinetics

Absorption: Not well absorbed

Metabolism: Hepatic to urea and glutamine

Overdosage/Treatment

Decontamination:

Oral: **Do not** induce emesis or perform gastric lavage; dilute with water or milk (4 oz in children, 8 oz in adults).

Ocular: Irrigate eyes copiously with normal saline.

Inhalation: Administer 100% humidified oxygen.

Supportive therapy: Flush injured surfaces with water. Treat for pulmonary edema. Use steroids for third degree esophageal burns. Inverse-ratio ventilation using lower tidal volume mechanical ventilation (6 mL/kg) and plateau pressures of 30 cm water may decrease mortality. While positive end expiratory pressures should be considered, oxygen toxicity should be monitored. Use of perfluorocarbon partial liquid ventilation and exogenous surfactant in chemical-induced ARDS is investigational.

Additional Information Irritation can occur at 400 ppm. Stomatitis can occur at ammonia concentrations of 50 ppm. The mixture of ammonia with hypochlorite bleach can result in chloramine which can produce pulmonary edema.

Colorless liquid; penetrating pungent odor; stable, colorless gas; highly water soluble; alkali (pH 11.6). Odor threshold: 25-48 ppm (air); 1.5 ppm (water). Atmospheric half-life: 2-3 days. TLV-TWA: 25 ppm; IDLH: 500 ppm

Ammonium Bifluoride

CAS Number 1341-49-7

UN Number 1727 (solid); 2817 (solution)

Use Magnesium manufacture, wheel cleaner, herbicide enhancer

Mechanism of Toxic Action Since approximately two-thirds of this agent is fluoride, most of its toxicity is related to fluoride at a cellular level; fluoride binds serum calcium (thus causing hypocalcemia) and decreases oxygen consumption; also causes direct mucosal damage

Adverse Reactions Cardiovascular: Fibrillation (ventricular), arrhythmias (ventricular)

Signs and Symptoms of Overdose Abdominal pain, choking, CNS depression, diarrhea, disconjugate eye movements, dyspnea, gastric ulcer, hyperkalemia, hyperreflexia, hypocalcemia, hypomagnesemia, metabolic acidosis, muscle spasms, muscle weakness, nausea, ocular irritation, prolonged QT interval on ECG, pustular skin rash, vomiting (hematemesis), salivation, seizures, tachycardia, ventricular fibrillation

Admission Criteria/Prognosis Admit any ingestion of this agent

Toxicodynamics/Kinetics

Distribution: V_d (fluoride): 0.5-0.7 L/kg

Half-life: 2-9 hours

Elimination: Primarily renal (fecal elimination is up to 10%)

Monitoring Parameters ECG, electrolytes, calcium, magnesium

Ammonia

CAS Number 7664-41-7

UN Number 1005; 2073; 2672

Reference Range Normal plasma fluoride range: 0.01-0.2 mg/L; urine fluoride following an ingestion resulting in cardiac arrest was 110 mg/L (toxic > 10 mg/L)

Overdosage/Treatment

Decontamination:

Oral: Dilute with milk. Calcium carbonate tablets or milk of magnesia may inhibit absorption by binding fluoride. Lavage (within 1 hour) with a soft nasogastric tube (with 10% calcium gluconate) may be useful. Do not induce emesis.

Dermal/ocular: As first aid, the affected extremity can be irrigated with water and bathed in an iced solution of 25% magnesium sulfate. Calcium gluconate gel 2.5% can also be utilized.

Supportive therapy: Monitor electrolytes, calcium and magnesium. Benzodiazepines should be used to control seizures.

Additional Information Density: 1.5 g/mL

Ammonium Chloride

Pronunciation (a MOE nee um KLOR ide)

CAS Number 12125-02-9

Use Treatment of hypochloremic states or metabolic alkalosis; industrial use: galvanizing procedures, fertilizer, electroplating, soldering, manufacture of dry batteries, deodorizer cleaners (Lysol[®], Swish Toilet Bowl Cleaner[®]); may be useful in bromide toxicity

Mechanism of Action Increases acidity by increasing free hydrogen ion concentration; as an expectorant by irritating, the mucosa, causing reflex stimulation of the bronchial mucosal glands

Adverse Reactions

Frequency not defined.

Central nervous system: Headache, coma, drowsiness, EEG abnormalities, mental confusion, seizures

Dermatologic: Rash

Endocrine & metabolic: Calcium-deficient tetany, hyperchloremia, hypokalemia, metabolic acidosis, potassium and sodium may be decreased

Gastrointestinal: Abdominal pain, gastric irritation, nausea, vomiting

Hepatic: Ammonia may be increased

Local: Pain at site of injection

Neuromuscular & skeletal: Twitching

Respiratory: Hyperventilation

Signs and Symptoms of Overdose Apnea, bradycardia, diuresis, headache, hyperchloremic hypokalemic metabolic acidosis, hyperventilation, hypomagnesemia, nausea, pulmonary edema, vomiting

Pharmacodynamics/Kinetics

Metabolism: Hepatic; forms urea and hydrochloric acid

Excretion: Urine

Toxicodynamics/Kinetics

Absorption: Rapid from the GI tract with absorption being complete in 3-6 hours

Distribution: Unknown

Elimination: In urine (1% to 3% in feces)

Dosage

Metabolic alkalosis: The following equations represent different methods of correction utilizing either the serum HCO₃⁻, the serum chloride, or the base excess

Dosing of mEq NH₄Cl via the chloride-deficit method (hypochloremia):

Dose of mEq NH₄Cl = [0.2 L/kg × body weight (kg)] × [103 - observed serum chloride]; administer 50% of dose over 12 hours, then re-evaluate

Note: 0.2 L/kg is the estimated chloride volume of distribution and 103 is the average normal serum chloride concentration (mEq/L)

Dosing of mEq NH₄Cl via the bicarbonate-excess method (refractory hypochloremic metabolic alkalosis):

Dose of NH₄Cl = [0.5 L/kg × body weight (kg)] × (observed serum HCO₃⁻ - 24); administer 50% of dose over 12 hours, then re-evaluate

Note: 0.5 L/kg is the estimated bicarbonate volume of distribution and 24 is the average normal serum bicarbonate concentration (mEq/L)

These equations will yield different requirements of ammonium chloride

Monitoring Parameters Serum bicarbonate; signs and symptoms of ammonia toxicity

Administration Administer by slow intravenous infusion to avoid local irritation and adverse effects. Rate of infusion should not exceed 5 mL/minute in an adult.

Contraindications Severe hepatic or renal dysfunction

Warnings Use caution in patients with primary respiratory acidosis or pulmonary insufficiency. Safety and efficacy have not been established in children.

Dosage Forms Injection, solution: Ammonium 5 mEq/mL and chloride 5 mEq/mL (20 mL) [equivalent to ammonium chloride 267.5 mg/mL]

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: I.V. sodium bicarb for acidosis; replenish potassium

Test Interactions ↑ ammonia (B), glucose (S); ↓ potassium (S), sodium (S), urine pH

Pregnancy Risk Factor C

Pregnancy Implications Reproduction studies have not been conducted.

Nursing Implications Rapid I.V. injection may increase the likelihood of ammonia toxicity; rate should not exceed 1 mEq/kg/hour; 26.75% solution must be diluted prior to administration

Additional Information Odorless, may produce an explosive reaction (with potassium chlorate, nitrates, hydrogen cyanide); TLV-TWA: 10 mg/m³; PEL-TWA: 10 mg/m³

Aniline

Related Information

- Methemoglobin, Blood

CAS Number 62-53-3

UN Number 1547

Synonyms Aminobenzene; Aminophen; Aniline; Aniline Oil; Benzeneamine; Blue Oil; Krystalline; Kyanor; Phenylamine

Use Prepared from indigo and potash; used in manufacture of dyes, resins, varnishes, perfumes, shoe blacks, vulcanizing rubber, paint removers, herbicides, fungicides, explosives, photographic chemicals, isocyanates, rigid polyurethane, and as a solvent

Adverse Reactions

Hematologic: Methemoglobinemia followed by hemolysis

Miscellaneous: Cutaneous T-cell lymphoma

Signs and Symptoms of Overdose Mild skin and eye irritant. Inducement of methemoglobinemia causing headache, tinnitus, confusion, seizures, dizziness, drowsiness, loss of consciousness, and coma in the absence of respiratory compromise. Methemoglobinemia may be followed by hemolysis. Central cyanosis is evident which does not improve with 100% oxygen. Blood is noted to be "chocolate brown" and will not become red while bubbling in 100% oxygen. Hemolysis may also occur causing heart, kidney, and liver damage; renal failure may ensue.

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Toxicodynamics/Kinetics

Absorption: Readily through all routes; delay rate up to 4 hours, the development of methemoglobinemia; methemoglobin is caused by oxidation of iron in hemoglobin Fe²⁺ to Fe⁺³ which is incapable of transporting oxygen; hemolysis then occurs 2-7 days after exposure

Metabolism: By ring hydroxylation and then conjugated to glucuronides and sulfates

Half-life: 2-7 hours

Elimination: Metabolites are renally cleared

Monitoring Parameters Methemoglobin levels; aniline levels have not been measured in blood or serum; urinary p-aminophenol can be measured by colorimetry; CBC, WBC smear, renal function, myoglobin, urinalysis and other indices of hemolysis may be required

Warnings/Precautions Persons with hemoglobin M, G6PD deficiency or NADH-cytochrome B₅ reductase deficiency may be more sensitive; patients exposed to other methemoglobin inducers are at increased risks; patients with cardiovascular disease are at greater risk from consequences; when vapors are present, must use impervious body protector as significant toxicity may occur through dermal absorption

Reference Range Urinary p-aminophenol >10 mg/L may indicate potential toxic dose with 20 mg/L indicating the need for medical intervention; as little as 1 g can be fatal in human; aniline vapor concentrations >100-160 ppm cause serious disturbances

Overdosage/Treatment

Decontamination: Emesis within 30 minutes, lavage (within 1 hour)/activated charcoal; remove patient from inhalation and administer 100% humidified air; exposed skin and eyes should be irrigated with water

Supportive therapy: Methemoglobinemia: Treat symptomatic patients or if level is >20%, administer 100% oxygen. If required, methylene blue: 1-2 mg/kg/dose I.V. over a few minutes; may repeat in 4 hours if needed; doses >15 mg/kg may cause hemolysis. High doses of methylene blue may precipitate Heinz body formation and hemolysis. Transfusion of PRBCs may be needed. Treatment for myoglobinuria may require urine alkalization and maintenance of adequate urinary output to prevent renal damage.

Enhanced elimination: One reported case of hemodialysis was used in an aniline exposure which was refractory to supportive care. Hemodialysis should be instituted for those who develop renal failure. Exchange transfusion has been used after unsuccessful treatment with methylene blue.

Antidote(s)

- Methylene Blue [ANTIDOTE]

ANISOLE

Diagnostic Procedures

- Methemoglobin, Blood
- N,N-Dimethyl-P-Toluidine

Additional Information

Estimated lethal dose: 15-30 g

Inadequate information concerning human carcinogenicity (bladder cancer); limited evidence that has been carcinogenic in animals (splenic sarcomas, bladder carcinoma)

How supplied: Colorless to brown, oil, combustible liquid with a characteristic amine-like odor; turns brown when exposed to air and light; when heated, forms toxic fumes of nitrogen oxide

Specific References

Bomhard EM and Herbold BA., "Genotoxic Activities of Aniline and Its Metabolites and Their Relationship to the Carcinogenicity of Aniline in the Spleen of Rats," *Crit Rev Toxicol*. 2005, 35(10):783-835 (review).

Katz K, Ruha AM, Curry S, et al, "Aniline and Methanol Toxicity After Shoe Dye Ingestion," *J Toxicol Clin Toxicol*, 2003, 41(5):644.

Elimination: Extensive renal elimination of metabolites, with some biliary excretion

Monitoring Parameters Hemoglobin, hematocrit, INR, partial thromboplastin time (PTT), prothrombin time (PT), stool guaiac

Reference Range Serum brodifacoum level of 254 ng/mL associated with prothrombin and partial thromboplastin times of 189 seconds, along with bleeding; plasma difenacoum levels of 0.97 mg/L associated with severe bleeding; low factor II, VII, IX and X levels are diagnostic. Serum bromadiolone level of 440 mcg/L associated with INr value > 10.

Overdosage/Treatment

Decontamination is usually not required for one-time acute ingestions in pediatric patients. In suicide attempts, decontamination should be performed.

Decontamination:

Emesis is contraindicated in patients who may experience alterations in consciousness, or who have prolonged PT values. In anticoagulated patients, intracranial hemorrhage may follow vomiting-induced elevations in intracranial pressures.

Activated charcoal administration should follow large ingestions of long-acting anticoagulants, unless otherwise contraindicated.

Supportive therapy:

Consider treatment if INR>4.

Obtain PT values immediately postingestion, then 24 and 48 hours postingestion. If significant prolongation occurs, obtain PT values every 6-12 hours thereafter; repeat PT may be obtained 4-5 days postevent. The patient should be closely monitored for signs and symptoms of bleeding for several weeks postingestion.

Vitamin K₁: Oral, SubQ, I.M., I.V.: Children: 1-5 mg; Adults: 15 mg
Up to 600 mg per day divided every 6 to 12 hours may be required in adults. If INR >5, begin with an oral dose of 50 mg and then titrate 9-12 hours dosing.

I.V. doses of up to 0.6 mg/kg diluted in saline or dextrose may be administered to refractory cases. I.V. infusion rates should not exceed 1 mg/minute or 5% of total dose/minute. I.M. administration of phytonadione may lead to significant hematoma formation. I.V. administration may elicit a hypotensive anaphylactoid reaction, and steps should be taken to anticipate hemodynamic and ventilatory support, as well as decreasing or discontinuation of the infusion.

Prophylactic oral vitamin K₁ is not indicated for accidental non-suicidal ingestions because it may further delay the onset of PT prolongation thereby masking the need for long-term vitamin K₁ therapy

Packed red blood cells (PRBCs) and intravenous crystalloids and colloids will provide immediate hemodynamic support in hypovolemia and hemorrhage. Fresh frozen plasma (FFP) (15 ml per kg), and in extreme cases pooled clotting factors, may be used for cases of refractory hemorrhage.

If active bleeding occurs: Recombinant coagulation activated factor VII at doses of 70 to 90 mcg/kg or 1.2 to 4.8 mg total with vitamin K (10 mg or 100 mcg/kg IV) can also be considered. Alternatively, Prothrombin complex concentrate (which contains factors II, VII, IX and X) at 50 units per kg IV can be given.

Enhancement of elimination: Plasmapheresis has been used to increase brodifacoum clearance

Antidote(s)

- Charcoal [ANTIDOTE]
- Ipecac Syrup [ANTIDOTE]
- Phytonadione [ANTIDOTE]

Diagnostic Procedures

- Urinalysis

Additional Information Single small ingestions of long-acting agents rarely lead to clinically significant anticoagulation and bleeding. Prolonged PT values will identify chronic ingestions, massive ingestions, or patients who were previously anticoagulated. Anticoagulant ingestion may exacerbate underlying diseases such as peptic ulceration. These agents may be absorbed through intact skin, or by inhalation of powders, sprays, or concentrates. Rodent baits and pellets are usually colored with water-soluble blue or green dye to facilitate recognition of oral exposure. No deaths reported in the American Association of Poison Control Centers annual data reports from 1987 to 1993 among children <6 years of age (encompassing ~72,060 warfarin-related exposures in rodenticides).

How supplied: Rodent bait (corn or grain pellets), cake, powder, or liquid concentrate

For comparison: See table.

For Brodifacoum, the toxic dose is about 1 mg (or 0.01 mg/kg) and duration of INR increase of at least 6 weeks.

Anisole

Synonyms Methoxybenzene; Methyl Phenyl Ether; Phenyl Methyl Ether

Use As a food additive, solvent; in perfumes, detergents

Mechanism of Toxic Action Mucosal irritation

Signs and Symptoms of Overdose Erythema, conjunctivitis

Overdosage/Treatment Decontamination: **Oral:** Lavage within 1 hour with activated charcoal; **Dermal:** Irrigate with water; **Ocular:** Irrigate with water

Additional Information Pleasant aromatic odor

Anticoagulant Rodenticide

CAS Number 117-52-2; 56073-07-5; 56073-10-1; 82-66-6; 83-26-1

U.S. Brand Names Bromone®; Caid®; d-Con®; Dipazin®; Diphacin®; Drat®; Endox®; Endrocide®; Foumarin®; Havoc®; Krumkil®; Lurat®; Maki®; Microzul®; Pivacin®; Pival®; Racumin®; Ramucide®; Ratafin®; Ratak®; Ratimus®; Ratindan®; Raviac®; Rodentin®; SuperCaid®; Talon-G®; Talon®; Topitox®; Tri-Bar®

Synonyms Brodifacoum; Bromadiolone; Chlorphacinone; Coumafuryl; Coumatetralyl; Difenacoum; Diphacinone; Hydroxycoumarin; Indanedione; Phytonadione; Pindone; Pivaldione

Mechanism of Toxic Action Inhibition of synthesis of vitamin K₁-dependent clotting factors II, VII, IX, and X through potent inhibition of vitamin K₁-2,3-epoxide reductase; resulting hypoprothrombinemia and decreased coagulability predisposes toward hemorrhage; benzylacetone metabolite of hydroxycoumarins also induces direct capillary injury, further predisposing toward hemorrhage

Adverse Reactions

Cardiovascular: Hypovolemic/hemorrhagic hypotension and shock, pericardial effusion/pericarditis

Central nervous system: Dizziness, subarachnoid, intracerebral and intraventricular hemorrhage

Dermatologic: Easy bruising, petechial rash, ecchymosis, skin necrosis, "purple toe" syndrome

Gastrointestinal: Bleeding gums, punctate or frank hemorrhage of oral mucosal surfaces, abdominal pain, hematemesis, hematochezia, melena

Genitourinary: Uterine bleed, cystitis

Hepatic: Cholestasis

Renal: Hematuria

Respiratory: Hemoptysis, epistaxis

Signs and Symptoms of Overdose Easy bruising, ecchymosis, bleeding gums, epistaxis, and mucosal hemorrhage progressing to symptoms of upper and lower GI bleeding; hypotension and hypovolemic shock may follow hemorrhage. Intracranial hemorrhage may occur, especially following trauma. Indanediones may also cause neurologic and cardiopulmonary symptoms independent of anticoagulant activity.

Admission Criteria/Prognosis Patients with bleeding, prolonged prothrombin time, or a history of a large ingestion (warfarin >0.5 mg/kg ingested, hydroxycoumarin >0.05 mg ingested, or indanedione >5 mg ingested) should be considered for admission; usually a few mouthfuls of this product does not require hospitalization

Toxicodynamics/Kinetics

Onset of anticoagulation: Typically within 24-48 hours

Maximum effect: 36-72 hours

Duration: Following repeated doses, may persist up to 45-300 days

Absorption: Complete and rapid following oral exposure

Distribution: V_d of 0.12-0.9 L/kg; rapid tissue distribution

Protein binding: Extensive plasma protein binding (97% to 99%)

Metabolism: Hepatic microsomal hydroxylation and conjugation of the inactive metabolites

Half-life: Brodifacoum: 25 days. Difenacoum: 12 days; Bromadiolone: 140 hours

Anticoagulant Rodenticides		
Class	Drug	Notes
Hydroxycoumarins		
Short-acting	Coumafuryl (Foumarin, [®] Lurat, [®] Krumkil, [®] Ratafin [®])	
Long-acting	Brodifacoum (d-Con, [®] Talon, [®] Talon-G, [®] Havoc [®])	t _{1/2} = 120 d (dogs) t _{1/2} = 156 h (rats) 0.005% grain-based pellets
	Bromadiolone (Bromone, [®] Super-Caid, [®] Ratimus, [®] Maki [®])	Grain-based pellets
	Coumatetralyl (Endox, [®] Endroside, [®] Racumin, [®] Rodentin [®])	Little human experience
	Difenacoum (Ratak [®])	0.005% grain-based pellets
Indanediones (may be considered long-acting)	Chlorphacinone (Caid, [®] Drat, [®] Microzul, [®] Ramucide, [®] Raviac, [®] Topitox [®])	t _{1/2} = 5.9-11 d (human) 0.005%, 0.25%, or 2.5% bait, solution, or concentrate
	Diphacinone (Dipazin, [®] Diphacin, [®] Ratindan [®])	0.005%, 0.05%, 0.1%, 0.2%, or 2% cake, bait, or concentrate
	Pindone/pivaldione (Pival, [®] Pivacin, [®] Tri-Ban [®])	0.025%, 0.1%, 0.2%, 0.5%, 1.5%, or 2% powder or concentrate

Antimony

CAS Number 10025-91-9; 1309-64-4; 1314-60-9; 1315-04-4; 1345-04-6; 28300-74-5; 7440-36-0; 7803-52-3

UN Number 1549; 1551; 1733; 2676; 2871

Synonyms Sb(+3); Sb(+5); Sb(-3); Sb(0)

Use Naturally brittle metal usually alloyed with lead or other metals; used in grid metal for lead storage batteries, solder, sheet/pipe metal, castings, ammunition, cable sheathing, pewter; antimony trioxide is used as a fire retardant; trivalent organic antimony was used in therapy for schistosomiasis

Mechanism of Toxic Action Primarily an irritant, inhibits the enzyme phosphofructokinase

Adverse Reactions

Cardiovascular: High blood pressure, AV block, cardiomegaly, cardiomyopathy, angina, chest pain, QT prolongation, torsade de pointes, arrhythmias (ventricular)

Central nervous system: Dementia

Dermatological: Dermal irritation

Endocrine & metabolic: Menstruation disturbances

Gastrointestinal: Abdominal pain, vomiting, diarrhea, peptic ulceration

Genitourinary: Crystalluria

Hematologic: Hemolytic anemia, leukopenia, thrombocytopenia, anemia

Neuromuscular & skeletal: Myalgia

Ocular: Eye irritation

Renal: Proteinuria, renal failure

Respiratory: Inhalation can cause pneumoconiosis, cough

Miscellaneous: Thirst

Signs and Symptoms of Overdose ECG abnormalities (elevation of S-T segment, flat T waves). Vomiting can occur with oral ingestion of 0.5 mg/kg antimony tartrate.

Toxicodynamics/Kinetics

Absorption: Oral: 2% to 7% (antimony tartrate/antimony trichloride)

Half-life: 38 days

Elimination: Renal (faster with pentavalent than trivalent compounds)

Reference Range Baseline antimony levels: 0.4 mcg/L (blood); 0.096-0.12 mcg/g (hair); 0.6 mcg/L (urine)

Overdosage/Treatment

Decontamination: Oral: Dilute with milk or water.

Enhancement of elimination: Chelation therapy with BAL may mitigate the toxicity of trivalent antimony compounds. Hemodialysis may be useful in increasing clearance of pentavalent (but not trivalent) antimony, although human experience in this modality is lacking.

Antidote(s)

- Dimercaprol [ANTIDOTE]

Additional Information Silvery white powder. OSHA-PEL-TWA: 0.5 mg/m³ (air). Water standard: 145 mcg/L. Average daily intake: Ingestion: ~5 mcg; inhalation: ~0.04 mcg

Arsenic

Related Information

- Copper
- Lewisite

CAS Number 7440-38-2

UN Number 1554; 1558; 1573

Synonyms Arsenate; Arsenite

Commonly Found In Pesticides, rodenticides, ant poisons, wood preservative, microchips, well water, seafood

Mechanism of Toxic Action Multisystem disease secondary to inhibition of oxidative phosphorylation

Enzymes inhibited by As⁺³ include pyruvate dehydrogenase complex, alpha-ketoglutarate dehydrogenase complex, thiolase, Glucose 6-phosphate dehydrogenase and glutathione synthetase and reductase

Adverse Reactions

Cardiovascular: Cardiotoxicity, tachycardia, acrocyanosis, Raynaud's phenomenon, congestive heart failure, myocardial depression, myocarditis, pericardial effusion/pericarditis, sinus tachycardia, tachycardia (supraventricular), vasodilation

Central nervous system: Neurotoxicity, axonopathy (peripheral), fever, hyperthermia, memory disturbance, Jarisch-Herxheimer reaction, delirium, psychosis, leukoencephalopathy

Dermatologic: Desquamation (scaling), hyperpigmentation, alopecia (patchy); airborne contact dermatitis, exanthem; dermal effects are usually not seen with inhalation exposure, lichen planus

Gastrointestinal: Gastrointestinal pathology, nausea, vomiting, metallic taste, salivation, feces discoloration (black), bloody diarrhea, abdominal pain, garlic odor

Hematologic: Bone marrow suppression, neutropenia, pancytopenia (leukopenia, thrombocytopenia, aplastic anemia)

Renal: Tubular necrosis (acute), hematuria

Miscellaneous: Basal cell carcinoma, cutaneous T-cell lymphoma

Signs and Symptoms of Overdose Agranulocytosis, alopecia, blindness, cough, encephalopathy, fasciculations, fever, garlic-like breath, hematuria, hemolytic anemia, hypotension, lacrimation, leukopenia, Mees' lines (on nail beds; forms at 4-6 weeks postexposure), myoglobinuria, neuritis, nystagmus, pancytopenia, paresthesia, radiopacity, seizures, stocking-glove sensory neuropathy, sweating, tachycardia, torsade de pointes, tremor

Admission Criteria/Prognosis All suspected patients should be admitted; survival > 1 week after an acute exposure is usually associated with recovery, although peripheral neuropathy may be long term

Toxicodynamics/Kinetics

Absorption: Oral, inhalation (60% to 90%), and dermal (most arsenic compounds absorption is low except for arsenic trichloride and arsenic acid)

Distribution: V_d: 0.2 L/kg

Metabolism: Reduction/oxidation reactions that interconvert arsenate and arsenite and methylation reactions to monomethyl arsonic acid and cacodylic acid

Half-life: 4-5 days

Elimination: Renal, degree of metabolism is ingestant dependent

ARSINE

Absorption: Oral, inhalation (60 to 90%) and dermal (most arsenic compounds, absorption is low except for arsenic trichloride and arsenic acid)

Reference Range

Urine concentrations in nonexposed individuals ≤ 50 mcg/L; hair concentrations detectable 30 hours postingestion; urine ≥ 100 mcg/L is suggestive for chronic exposure; blood not usually helpful, although blood arsenic levels > 1000 mcg/L are usually associated with fatality; background whole blood arsenic level is usually < 1 mcg/dl

Mean urine concentration of arsenic 0.2 mg/L associated with fatal poisoning

Seafood (methylated arsenic) can elevate, urinary arsenic levels for 2 to 3 days

Hair/nail arsenic levels in unexposed individuals < 1 ppm

Overdosage/Treatment

Decontamination:

Oral: Lavage (within 1 hour)/activated charcoal. Aluminum hydroxide may prevent absorption of pentavalent arsenic compounds (due to its phosphate-binding abilities), although this has not been investigated in humans. Whole bowel irrigation is effective.

Dermal: Remove contaminated clothing; wash with soap and water.

Ocular: Copious irrigation with saline

Supportive therapy: Succimer (at standard doses to treat lead poisoning) is probably the treatment of choice. 2,3-Dimercaptopropane sulphonate (DMPS or unithiol) is also useful to enhance this metal's elimination at a dose of 100 mg 3 times/day orally for 5 days. 2,3-Dimercaptopropane-sulphonate (DMPS), a water soluble derivative of dimercaprol, has been recently demonstrated to prevent polyneuropathy when started within 48 hours of exposure at a dose of 5 mg/kg I.V. every 4 hours for 24 hours, and then 400 mg orally every 4 hours for 5-7 days. BAL should be utilized for severe acute exposures except for arsine gas. Penicillamine provides long-term therapy or alternatives to BAL. Oral spirulina extract (250 mg) plus zinc (2 mg) twice daily for 16 weeks may be useful in treating chronic arsenic poisoning (with melanosis and keratosis).

Enhanced elimination: Hemodialysis clearance of arsenic ranges from 76-87 mL/minute; the clinical utility of this modality is unknown. No studies have been performed regarding hemodialysis with metal-chelate compound. Clearance of arsenic through hemodialysis is estimated to range from 76-87 mL/minute. Due to tissue binding of arsenic, this is not felt to be a useful modality for removal of arsenic. No current studies exist on the use of chelation with extracorporeal removal methods.

Antidote(s)

- Dimercaprol [ANTIDOTE]
- Penicillamine [ANTIDOTE]
- Succimer [ANTIDOTE]
- Unithiol [ANTIDOTE]

Diagnostic Procedures

- Arsenic, Blood
- Arsenic, Hair, Nails
- Arsenic, Urine
- Electrolytes, Blood
- Heavy Metal Screen, Blood

Additional Information

Toxic oral dose: 120-200 mg

Causes garlic odor; seafood contains arsenobetaine and arsenocholine; dietary history is important.

A radiopaque compound, but rapid absorption makes observation unlikely. Arsine gas is the most toxic, then trivalent arsenite, then pentavalent arsenate. Acute exposure can cause chronic symptoms. Bone marrow, skin, and peripheral nervous system are usual targets of chronic exposure.

Found in some homeopathic medications; Chinese herbal balls may contain from 7.8-621.3 mg of mercury and from 0.1-36.6 mg of arsenic. TLV-TWA: 0.2 mg/m³

Urban arsenic levels of ambient air: 20-30 ng/m³. Arsenic levels in groundwater: 1-2 ppb; found in the earth's crust at an arsenic level of 2 ppm.

Arsenic levels in selected media: Grains: 0.22 ppm; Meat: 0.14 ppm; Seafood: 4-5 ppm; Cigarette: 1.5 ppm

Estimated daily intake of arsenic (adult): Nonsmoker: 51.5 mcg; smoker (2 packs/day): 63.5 mcg; Drinking water: 10 mcg; Food: 45 mcg

Cancers associated with inorganic arsenic exposure: Lung (oat cell, adenocarcinoma), Skin (Basal cell, Bower's disease), Bladder and hepatic angiosarcoma

Arsine

Applies to Etchers; Jewelry; Lead Burners; Silicone Chips

CAS Number 7784-42-1

UN Number 2188

Synonyms Arsenic Trihydride; Arsenous Hydride; Hydrogen Arsenide; AsH₃

Use Produced when water comes into contact with molten arsenic; used in the semiconductor industry; also found in jewelry, lead burners, etchers, silicone chips, fertilizer makers, aniline workers

Mechanism of Toxic Action Decline of erythrocyte glutathione concentrations after arsine binds to hemoglobin

Signs and Symptoms of Overdose Abdominal cramping, abdominal tenderness, asthenia, dizziness, headache, hemolysis (potent), hypotension, jaundice (2-24 hrs. postexposure), pulmonary edema, nausea, oliguria may occur later, painless hemoglobinuria, seizures, shivering, vomiting, bone marrow depression has been reported. Renal failure within 72 hours.

Admission Criteria/Prognosis Any symptomatic patient or evidence of hemolysis should be admitted; patients may be discharged after 24 hours if the patient is asymptomatic without signs of hemolysis

Toxicodynamics/Kinetics

Absorption: Inhalation: Well absorbed

Metabolism: To arsenic and trimethylarsine

Elimination: Excreted as arsenic in urine, feces, hair, fingernails, and by the lungs

Reference Range Toxic: Blood: >200 mcg/dL; urine: >1000 mcg/L. A plasma free hemoglobin level >1.5 g/dL indicates the need for definitive treatment (possibly exchange transfusion).

Overdosage/Treatment

Decontamination: **Dermal:** Wash with soap and water. **Inhalation:** Administer 100% humidified oxygen.

Supportive therapy: Immediate removal from victim; alkalization of urine to prevent renal failure; exchange transfusions helpful in severe hemolysis with a free plasma hemoglobin over 1.5 g/dL; heavy metal chelators are ineffective. Maintain good urine output.

Elimination: Hemodialysis may be required for renal failure but will not remove the arsine-hemoglobin complex.

Additional Information One of the most potent hemolytic toxins known; odorless, colorless, nonirritating at low concentrations (<2 ppm); garlic-like odor at higher concentrations. Immediate lethal air concentration: 250 ppm. Case fatality rate: 25%. Potential human carcinogen. Hemolysis is blocked by carbon monoxide and partially blocked by methemoglobin. One hour exposure: 5 ppm TLV-TWA: 0.05 ppm; IDLH: 6 ppm; PEL-TWA: 0.05 ppm

Asbestos

Related Information

- Gastrointestinal Cancer Risks from Asbestos

Applies to Auto Repair; Brake/Clutch Linings; Building Demolition; Cement Pipe; Chemical Filters; Electrical Insulation; Fireproof Clothing; Gaskets; Locomotive Repair; Power Plants

CAS Number 1332-21-4

UN Number 2212; 2590

U.S. Brand Names Avibest® (Chrysotile type)

Synonyms Magnesium Silicate

Use Found in manufacture of cement pipe or panels, electrical insulation, fireproof clothing, locomotive repair, power plants, building demolition, car repair, chemical filters, gaskets, brake/clutch linings, transmission component

Mechanism of Toxic Action

Not well delineated; asbestos is fibrogenic with accumulation of macrophage and fiber phagocytosis occurring; it is unclear whether asbestos fibers induce carcinogenesis or are tumor promoting agents; lipid peroxidation can occur with chrysotile agents

Half-life (fibers > 10 µm): 7.9 years (chrysotile); 150 years (tremolite)

Adverse Reactions

Cardiovascular: Chest pain, angina

Renal: Renal cell cancer

Respiratory: Cough, Bronchogenic Carcinoma (Risk is over tenfold for smokers), Mesothelioma

Signs and Symptoms of Overdose Asbestosis: Bilateral interstitial fibrosis affecting lower $\frac{2}{3}$ of lung; symptoms include dyspnea, rales (usually occur 10-40 years after exposure), renal failure, acute myelocytic leukemia, and skin warts

Toxicodynamics/Kinetics

Fibers >3 µm in diameter or longer than 100 µm are not rapidly cleared from pulmonary tract

Absorption: No dermal or GI absorption

Elimination: Mucociliary transport through lung

Clearance: Upper airways: 2-3 hours. Lower airways: 10-160 days

Overdosage/Treatment Supportive therapy: There is no specific treatment for asbestosis. Traditional antineoplastic therapy for tumors is the mainstay of treatment. Certainly, patients with asbestos exposure should avoid cigarette smoking.

Additional Information

Levels of airborne asbestos (fibers measured by phase contrast microscopy/L of air): School: 0.00024; Rural: 0.000002; Urban: 0.003-0.000003; Industrial operations: 0.15-0.0015

Chrysotile exposures do not appear to increase the risk of mesothelioma; risk of mesiothelioma to amphiboles exposure is about 1.23%.

Serpentine asbestos (extended sheet polysilicate structure): Chrysotile (white asbestos)* - TLV: 2 fibers/mL of air

Amphibole group (linear double chain polysilicate structure): Actinolite TLV: 2 fibers/mL of air; Amosite (brown asbestos)* - TLV: 0.5 fibers/mL of air; Anthophyllite (gray asbestos)* - TLV: 2 fibers/mL of air; Crocidolite (blue asbestos)* - TLV: 0.2 fibers/mL of air; Mullite - TLV: 2 fibers/mL of air; Tremolite (silicic acid: calcium magnesium salt) - TLV: 2 fibers/mL of air

*Associated with high fibrogenic potential

OSHA-PEL: 0.2 fibers/nL of air

Carcinomas associated with asbestos include lung (especially in smokers), pleural mesothelioma (not increased in smokers), peritoneum mesothelioma, laryngeal carcinoma; carcinomas of questionable association with asbestos include colon, renal, pancreas, ovary, esophagus, and lymphomas

While all types of fibers can cause lung cancer, amphibole group fibers are more potent for inducing mesotheliomas than serpentine fibers; EPA estimates that lifetime exposure of asbestos dust (0.001 fiber >5 µm in length per mL of air) could result in 2-4 excess lung cancer or mesothelioma deaths per 100,000 individuals.

Pulmonary function tests may show restrictive pattern; open lung biopsy may be required; gallium scanning or bronchoalveolar lavage may be helpful

In older homes (built from 1920s to 1970s), asbestos may be located around boilers, steam pipes, ductwork, floor coverings (especially 9" vinyl tiles), "popcorn" ceiling finishes, exterior siding, roofing shingles, and acoustical ceiling tiles

Asphalt

CAS Number 8052-42-4

UN Number 1999

Synonyms Road Tar

Use Road surfacing or roof sealant agent; also used in paints, electrical adhesive, radioactive waste disposal

Mechanism of Toxic Action Can cause thermal injury; generally exhibits high viscosity, low volatility and high surface tension

Adverse Reactions

Central nervous system: Headache, hyperthermia

Dermatologic: Thermal burns, oil acne, hyperpigmentation, fingernail discoloration (black)

Gastrointestinal: Upon ingestion, concretions and bezoars can develop

Ocular: Eye irritation

Respiratory: Cough

Monitoring Parameters Carboxyhemoglobin (inhalation)

Overdosage/Treatment

Decontamination:

Dermal: Initially immerse affected area in cool water; emulsifying agents can assist in debridement. Bacitracin can be used as a topical antibiotic. Liquid Tween® 80 (polysorbate 80), can be applied to affected area; cover with wet dressings for 6 hours and then irrigate with saline. This procedure may be repeated until tar is removed. Alternatively a neosporin-based cream (Neosporin®-G-Cream) can be used in the above manner, while covering the affected area with sterile wet dressing for 24 hours, then irrigate with saline (complete removal may take 3 days). Other, less

BARIUM

effective agents include Neosporin[®] ointment, mineral oil, petrolatum, or lanolin. Additionally, butter or mayonnaise has been used as an emulsifier with some success. Medi-Sol (De-Solv-it; Orange-Sol) or Unibase[®] with triple-antibiotic ointments can also be used. Thermal burns should be treated in the traditional manner after removal. Do not debride tar mechanically without using an emulsifying agent. Do not use gasoline, kerosene, or acetone to irrigate.

Inhalation: Administer 100% humidified oxygen.

Ocular: Initially copiously irrigate with saline. Irrigation can also include sterile surface active solvents (ie, Shur-Clens[®]) with saline to facilitate tar removal. Additionally, a polysorbate with neomycin sulfate can be used to remove tar from conjunctivae.

Additional Information TLV-TWA (Fume): 5 mg/m³; fumes from asphalt may contain carbon monoxide, hydrocarbons or hydrogen sulfide; specific gravity: 0.95-1.1

Specific References

Schultz OE and Stephens TL, "Don't Hold the Mayo," *Clin Toxicol (Phila)*, 2005, 43:678.

Barium

Pronunciation (BA ree um)

Related Information

- Barium Nitrate
- Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 7440-39-3

UN Number 1339; 1400; 1854

U.S. Brand Names Anatrast; Baricon[™]; Baro-Cat[®]; Barobag[®]; Barospense[®]; Bear-E-Yum[®] CT; Bear-E-Yum[®] GI; CheeTah[®]; Digital HD; Enhancer; Entrobar[®]; EntroEase[®]; Flo-Coat; HD 200[®] Plus; HD 85[®]; Intropaste; Liqui-Coat HD[®]; Liquid Barospense[®]; Medebar[®] Plus; Medescan; Prepcat; Tomocat[®] 1000; Tomocat[®]; Tonopaque

Synonyms Ba, Barium Sulfate

Mechanism of Toxic Action Barium can sequester potassium (thus producing potassium redistribution) within muscle cells resulting in decreased ionic potential (under 60 mV) and paralysis. Potassium efflux is blocked by barium.

Adverse Reactions

Cardiovascular: Hypertension, tachycardia (ventricular), sinus bradycardia, sinus tachycardia, arrhythmias (ventricular), vasoconstriction
Central nervous system: Hypothermia, bilateral putaminal involvement
Dermatologic: Angioedema
Endocrine and metabolic: Hypokalemia, hypophosphatemia
Gastrointestinal: Abdominal pain, diarrhea, nausea, vomiting, feces discoloration (black), feces discoloration (clay/putty), feces discoloration (red), feces discoloration (white/speckling), xerostomia, appendicitis
Neuromuscular & skeletal: Muscle paralysis, myopathy, paresthesia, rhabdomyolysis areflexic flaccid quadriplegia
Ocular: Mydriasis,
Respiratory: Wheezing, apnea, allergic rhinitis (benign pneumoconiosis)

Signs and Symptoms of Overdose Abdominal pain, allergic rhinitis, angioedema, apnea, areflexia, AV block, dermal burns, diaphoresis, diarrhea, fasciculations, feces discoloration (black; clay/putty; red; white/speckling), flaccid muscle paralysis, hypertension, hypokalemia, hypophosphatemia, hyporeflexia, hypothermia, mydriasis, nausea, paresthesia, rhabdomyolysis, tachycardia (ventricular), vomiting, wheezing

Admission Criteria/Prognosis Patients who are symptomatic or develop hypokalemia should be admitted; asymptomatic patients can be discharged after 8 hours postexposure

Toxicodynamics/Kinetics

Absorption: Oral absorption from food sources: 1% to 15% (average 6%)
Distribution: Primarily to skeleton and teeth
Half-life: 3.6 days (2 hours on dialysis)
Elimination: Primarily fecal

Contraindications

Hypersensitivity to barium or any component of the formulation; known or suspected obstruction of the colon, known or suspected GI tract perforation, suspected tracheoesophageal fistula, obstructing lesions of small intestine, pyloric stenosis

Specific agents may also be contraindicated with inflammation or neoplastic lesions of the rectum, recent rectal biopsy; use in infants with swallowing disorders; newborns with complete duodenal or jejunal obstruction with suspected distal small bowel or colon obstruction; very small preterm infants and young babies requiring small volumes of contrast media; infants and young children with possible leakage from GI tract (eg, necrotizing enterocolitis, unexplained pneumoperitoneum, gasless abdomen, bowel or esophageal perforation, postoperative anastomoses)

Dosage Forms

Suspension, oral, as sulfate:

- Bear-E-Yum[®] CT: 1.5% (200 mL) [bubble gum flavor]
- Bear-E-Yum[®] GI: 60% (200 mL, 1900 mL) [bubble gum flavor]
- EntroEase[®]: 13% (600 mL) [marshmallow flavor]

Intropaste: 44% (454 g) [suspension paste; raspberry flavor]
Liqui-Coat HD[®]: 210% (150 mL) [vanilla-raspberry flavor]
Suspension, oral/rectal, as sulfate:
Baro-Cat[®]: 1.5% (300 mL, 900 mL, 1900 mL) [banana-pineapple flavor]
CheeTah[®]: 2.2% (250 mL, 450 mL, 900 mL, 1900 mL) [butterscotch vanilla flavor]
Liquid Barospense[®]: 60% (355 mL, 1900 mL) [vanilla flavor]
Medescan: 2.2% (250 mL, 450 mL, 1900 mL) [raspberry flavor]
Prepcat: 1.5% (450 mL) [strawberry flavor]
Tomocat[®]: 5% (145 mL) [concentrate to make a 1.5% solution; strawberry flavor]
Tomocat[®] 1000: 5% (225 mL) [concentrate; strawberry flavor]
Suspension, rectal, as sulfate:
Anatrast: 100% (500 g) [suspension paste; packaged with enema tips]
Entrobar[®]: 50% (500 mL) [packaged in administration kit]
Flo-Coat: 100% (1850 mL)
Medebar[®] Plus: 100% (1900 mL)
Powder for suspension, oral, as sulfate:
Baricon[™]: 98% (340 g) [lemon-vanilla flavor]
Digital HD: 96% (245 g) [citrus flavor]
Enhancer: 98% (312 g) [lemon-vanilla flavor]
HD 200[®] Plus: 98% (312 g) [strawberry flavor]
Tonopaque: 95% (180 g) [cherry flavor]
Powder for suspension, oral/rectal, as sulfate:
Barospense[®]: 95% (225 g, 900 g) [vanilla flavor]
HD 85[®]: 85% (1900 mL) [raspberry flavor]
Powder for suspension, rectal, as sulfate (Barobag[®]): 97% (340 g, 454 g) [packaged as an enema kit]

Reference Range Ingestion of barium carbonate resulting in muscle paralysis was associated with a peak barium level of 150 mEq/L; normal serum barium levels: 3-29 mcg/dL; normal urinary excretion of barium in unexposed patients: 26 mcg of barium daily; serum and urine barium levels following a symptomatic inhalation injury were 370 mcg/dL and 1600 mcg/dL, respectively. Serum barium level of 133 mcg/dL is associated with severe symptoms.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal will not bind barium. Magnesium sulfate or sodium sulfate is the preferred cathartic in order to convert barium to inabsorbable barium sulfate.

Supportive therapy: Monitor potassium. Paralysis and ventricular arrhythmia will respond to large doses of potassium (may require 120 mEq IV over 30 minutes or 400 mEq per day). Rebound hyperkalemia (upto 9 MEq/L) may occur without cardiac effects. Avoid the use of I.V. sulfate or magnesium salts since this may cause precipitation of barium in the kidneys. Hypertension can be treated with nitroglycerin.

Enhancement of elimination: Forced diuresis with I.V. saline solution with furosemide (1 mg/kg I.V.) to keep a urine flow of 3-6 mL/kg/hour will hasten elimination. Hemodialysis with a high flux filter and a sodium bicarbonate/potassium dialysate may also be useful.

Pregnancy Implications Safety and efficacy for use during pregnancy have not been established. In general, elective radiography of the abdomen is avoided during pregnancy unless essential for diagnosis.

Additional Information

Found in most soils ranging from 15-3000 ppm; average atmospheric barium concentration in North America is 0.012 mcg/m³; in seawater it is ~ 13 mcg/L. Brazil nuts have high concentrations of barium (3000-4000 ppm).

TLV-TWA: Barium: 0.5 mg/m³; Barium sulfate: 10 mg/m³

Total daily barium intake: 650-1770 mg

Average amount of barium ingested through drinking water: 1-2 mg/kg/day

Average amount of barium intake through inhalation: 1-30 mg/day (75% absorbed)

Barium Nitrate

CAS Number 10022-31-8

UN Number 1446

Synonyms Barium Dinitrate; Nitrobarite

Use Sparklers, fireworks; incendiaries, ceramic glazes

Mechanism of Toxic Action A soluble barium salt; a direct muscle stimulant which produces nitrogen oxides upon combustion

Adverse Reactions

Cardiovascular: Hypertension, tachyarrhythmias (ventricular)
 Central nervous system: Headache
 Endocrine & metabolism: May cause hypokalemia
 Gastrointestinal: Nausea, vomiting, diarrhea, abdominal cramping
 Hematologic: Leukocytosis
 Neuromuscular & skeletal: Motor weakness
 Respiratory: Hypoventilation

Admission Criteria/Prognosis Admit any symptomatic patient or any ingestion > 10 g.

Monitoring Parameters Serum electrolytes

Reference Range Normal serum barium levels: 0.08-0.4 mg/L; normal urinary excretion of barium in unexposed patients: 26 mcg of barium daily

Overdosage/Treatment

Decontamination: **Oral:** Emesis within 30 minutes or lavage within 1 hour; activated charcoal. **Dermal:** Wash the exposed area with soap and water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate copiously with saline or water.

Supportive therapy: Lidocaine or procainamide can be used to treat ventricular arrhythmias.

Additional Information TLV-TWA: 0.5 mg/m³; IDLH: 250 mg/m³. Specific gravity: 3.24

Benomyl

Applies to 50 DF; Fungicide

CAS Number 17804-35-2

U.S. Brand Names Benex®; Benlate®; Tersan® 1991

Synonyms BBC; MBC

Use A fungicide used on ornamental plants, vegetables, fruits

Mechanism of Toxic Action A benzimidazole carbamate which has no effect on cholinesterase; a dermal irritant

Adverse Reactions

Cardiovascular: Edema
 Dermatologic: Contact dermatitis, eczema, photosensitization, hyperpigmentation, dermal erythema
 Ocular: Conjunctivitis
 Respiratory: Cough
 Miscellaneous: Aneuploidy induction

Signs and Symptoms of Overdose Lethargy, somnolence

Toxicodynamics/Kinetics

Absorption: Poor
 Metabolism: Carbendazim and methyl 5-hydroxy-2-benzimidazole (or 5-HBC)
 Elimination: Primarily renal (within 72 hours)

Reference Range Exposed, asymptomatic nursery workers had 5-HBC urine levels ranging from 3-87 µmol/mol creatinine

Overdosage/Treatment

Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal. **Dermal:** Wash copiously with soap and water; remove all clothing (especially leather clothing). **Ocular:** Irrigate with saline copiously.
 Supportive therapy: Topical steroid preparations can be used for contact dermatitis.

Additional Information TLV-TWA: 0.84 ppm; a white powder with an acrid odor; no evidence for human carcinogenicity; does not accumulate in soil

Bentazon

Applies to Herbicide

CAS Number 25057-89-0

Synonyms Basagran; Bentazone

Use Selective contact postemergent herbicide used on growing grains such as rice, corn, peanuts, beans, peas, and peppers

Mechanism of Toxic Action Irritant

Signs and Symptoms of Overdose Vomiting, diarrhea, tachycardia, dyspnea, weakness, tremors, muscle rigidity, rhabdomyolysis, coma, diaphoresis have all been noted on ingestion

Reference Range Following a 240 g ingestion in a fatal suicide attempt, plasma and urine levels of bentazon was 1500 mg/L and 1000 mg/L respectively

Overdosage/Treatment

Decontamination: **Oral:** Activated charcoal; consider gastric lavage for ingestions over 50 g. **Respiratory:** Administer 100% oxygen
 Supportive therapy: Bromocriptine (2.5 mg 3 times/day for 3 days) has been used to treat muscle rigidity and signs of neuroleptic malignant syndrome; otherwise, therapy is supportive

Additional Information An odorless, white/colorless crystalline powder usually diluted in water. Water half-life < 1 day; soil half-life < 1 month

Benzene

Applies to Dyes; Lacquer; Oil Cloths; Varnishes

CAS Number 71-43-2

UN Number 1114

U.S. Brand Names Polystream®

Synonyms (6)-Annulene; Carbon Oil; Mineral Naphtha; Phene; Phenyl Hydride

Commonly Found In Industrial solvent, gasoline (0.81% to 1.35%, higher percentage in Europe)

Use In lacquers, manufacture of dyes, oil cloths, varnishes, gasoline additive, natural rubber

Mechanism of Toxic Action Hematotoxicity, CNS depression, leukemogenic

Adverse Reactions

Cardiovascular: Cardiac toxicity
 Central nervous system: CNS depression, euphoria
 Gastrointestinal: Feces discoloration (black), burning sensation of mucous membranes
 Hematologic: Acute Myelogenous Leukemia, usually after chronic exposure, aplastic anemia, neutropenia, megaloblastic anemia, agranulocytosis, malignant lymphoma
 Hepatic: Hepatotoxicity
 Respiratory: Bronchial irritation, pulmonary edema
 Miscellaneous: Aneuploidy induction, cutaneous T-cell lymphoma
