Supportive therapy: Treatment is symptomatic with captopril, nifedipine, prazosin, vasodilators (nitroprusside) or nitroglycerin for hypertension. Intra-arterial bolus of phentolamine (5-25 mg) or tolazoline (25-100 mg) followed by infusions are effective for arterial vasodilatation. Aspirin (325 mg) should be used for antiplatelet effect. Prostaglandins (alprostadil at doses of 1-20 ng/kg/minute or epoprostenol at 20 ng/kg/minute) are also effective treatment. Diazepam can be utilized for seizures. Heparin can be used for hypercoagulable state; titrate to a PTT of 70-90 seconds. Hyperbaric oxygen can be used to treat peripheral ischemia. Cyproheptadine (4 mg 3 times/day orally) can be used to reverse ergot-induced vasoconstriction. Enhancement of elimination: Multiple dosing of activated charcoal may be effective.

Drug Interactions

Substrate of CYP3A4 (major); Inhibits CYP3A4 (weak)

Antifungals, azole derivatives (itraconazole, ketoconazole) increase levels of ergot alkaloids by inhibiting CYP3A4 metabolism, resulting in toxicity; concomitant use is contraindicated.

Antipsychotics: May diminish the effects of ergotamine (due to dopamine antagonism); these combinations should generally be avoided.

Beta blockers: Severe peripheral vasoconstriction has been reported with concomitant use of beta blockers and ergot derivatives; monitor.

CYP3A4 inhibitors: May increase the levels/effects of ergotamine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine,

Ergotamine

CAS Number 379-79-3

U.S. Brand Names Ergomar®

Synonyms Ergotamine Tartrate

Use Abort or prevent vascular headaches, such as migraine, migraine variants, or so-called "histaminic cephalalgia"

ERYTHROMYCIN

propofol, protease inhibitors, quinidine, telithromycin, and verapamil. Ergot alkaloids are contraindicated with potent CYP3A4 inhibitors.

Macrolide antibiotics: Erythromycin, clarithromycin, and troleandomycin may increase levels of ergot alkaloids by inhibiting CYP3A4 metabolism, resulting in toxicity (ischemia, vasospasm); concomitant use is contraindicated.

MAO inhibitors: The serotonergic effects of ergot derivatives may be increased by MAO inhibitors. Monitor for signs and symptoms of serotonin syndrome.

Metoclopramide: May diminish the effects of ergotamine (due to dopamine antagonism); concurrent therapy should generally be avoided.

Protease inhibitors (ritonavir, amprenavir, atazanavir, indinavir, nelfinavir, and saquinavir) increase blood levels of ergot alkaloids by inhibiting CYP3A4 metabolism, acute ergot toxicity has been reported; concomitant use is contraindicated.

Sibutramine: May cause serotonin syndrome; concurrent use with ergot alkaloids is contraindicated.

Serotonin agonists: Concurrent use with ergotamine may increase the risk of serotonin syndrome (includes buspirone, SSRIs, TCAs, nefazodone, sumatriptan, and trazodone).

Sumatriptan and other serotonin 5-HT₁ receptor agonists: Prolong vasospastic reactions; do not use sumatriptan or ergot-containing drugs within 24 hours of each other.

Vasoconstrictors: Concomitant use of some ergot derivatives and peripheral vasoconstrictors may cause synergistic elevation of blood pressure; use is contraindicated.

Pregnancy Risk Factor X

Pregnancy Implications May cause prolonged constriction of the uterine vessels and/or increased myometrial tone leading to reduced placental blood flow. This has contributed to fetal growth retardation in animals. Ergotamine also has oxytocic effects.

Lactation Enters breast milk/not recommended

Nursing Implications Do not crush sublingual drug product

Erythromycin

Related Information

- Clarithromycin

CAS Number 114-07-8; 134-36-1; 23067-13-2; 304-63-2; 3521-62-8; 3847-29-8; 41342-53-4; 643-22-1; 96128-89-1

U.S. Brand Names A/T/S[®]; Akne-Mycin[®]; E.E.S.[®]; Emgel[®]; Ery-Tab[®]; Erycette[®]; Eryc[®]; Eryderm[®]; Erygel[®]; EryPed[®]; Erythra-Derm[™]; Erythrasma, N. gonorrhoeae, E. histolytica, syphilis and nongonococcal urethritis, and *Campylobacter* gastroenteritis; used in conjunction with neomycin for decontaminating the bowel

Synonyms Erythromycin Base; Erythromycin Estolate; Erythromycin Ethylsuccinate; Erythromycin Gluceptate; Erythromycin Lactobionate; Erythromycin Stearate

Use

Systemic: Treatment of susceptible bacterial infections including *S. pyogenes*, some *S. pneumoniae*, some *S. aureus*, *M. pneumoniae*, *Legionella pneumophila*, diphtheria, pertussis, chancre, *Chlamydia*, erythrasma, *N. gonorrhoeae*, *E. histolytica*, syphilis and nongonococcal urethritis, and *Campylobacter* gastroenteritis; used in conjunction with neomycin for decontaminating the bowel

Ophthalmic: Treatment of superficial eye infections involving the conjunctiva or cornea; neonatal ophthalmia

Topical: Treatment of acne vulgaris

Unlabeled/Investigational Use Systemic: Treatment of gastroparesis

Mechanism of Action Inhibits RNA-dependent protein synthesis at the chain elongation step; binds to the 50S ribosomal subunit resulting in blockage of transpeptidation

Adverse Reactions

Cardiovascular: Ventricular arrhythmias, QT_c prolongation, torsade de pointes (rare), ventricular tachycardia (rare)

Central nervous system: Headache, pain, fever, seizures

Dermatitis: Rash, erythema, desquamation, dryness, pruritus

Gastrointestinal: Abdominal pain, cramping, nausea, oral candidiasis, vomiting, diarrhea, dyspepsia, flatulence, anorexia, pseudomembranous colitis, hypertrophic pyloric stenosis (including cases in infants or IHPS), pancreatitis

Hematologic: Eosinophilia

Hepatic: Cholestatic jaundice (most common with estolate), elevated liver function tests

Local: Phlebitis at the injection site, thrombophlebitis

Neuromuscular & skeletal: Weakness

Respiratory: Dyspnea, cough

Miscellaneous: Hypersensitivity reactions, allergic reactions

Admission Criteria/Prognosis Admit ingestions > 5 g

Pharmacodynamics/Kinetics

Absorption: Oral: Variable but better with salt forms than with base form; 18% to 45%; ethylsuccinate may be better absorbed with food

Distribution: Crosses placenta; enters breast milk

Relative diffusion from blood into CSF: Minimal even with inflammation
CSF: blood level ratio: Normal meninges: 1% to 12%; Inflamed meninges: 7% to 25%

Protein binding: 75% to 90%

Metabolism: Hepatic via demethylation

Half-life elimination: Peak: 1.5-2 hours; End-stage renal disease: 5-6 hours

Time to peak, serum: Base: 4 hours; Ethylsuccinate: 0.5-2.5 hours; delayed with food due to differences in absorption

Excretion: Primarily feces; urine (2% to 15% as unchanged drug)

Dosage Neonates: Ophthalmic: Prophylaxis of neonatal gonococcal or chlamydial conjunctivitis: 0.5-1 cm ribbon of ointment should be instilled into each conjunctival sac

Infants and Children:

Usual dosage range:

Oral: (**Note:** Due to differences in absorption, 400 mg erythromycin ethylsuccinate produces the same serum levels as 250 mg erythromycin base, stearate or estolate)

Base: 30-50 mg/kg/day in 2-4 divided doses; do not exceed 2 g/day

Estolate: 30-50 mg/kg/day in 2-4 divided doses; do not exceed 2 g/day

Ethylsuccinate: 30-50 mg/kg/day in 2-4 divided doses; do not exceed 3.2 g/day

Stearate: 30-50 mg/kg/day in 2-4 divided doses; do not exceed 2 g/day

I.V.: Lactobionate: 15-50 mg/kg/day divided every 6 hours, not to exceed 4 g/day

Indication-specific dosing: Oral:

Acne vulgaris (unlabeled use): Adolescents: 250-1500 mg/day in 2 divided doses; therapy may be continued for 4-6 weeks at lowest possible dose

Pharyngitis: 40 mg/kg/day in 2 doses; maximum: 1600 mg/day; short-course therapy for 5 days may be considered

Pertussis (CDC guidelines): 40-50 mg/kg/day in 4 divided doses for 14 days; maximum 2 g/day (not preferred agent for infants <1 month)

Preop bowel preparation: 20 mg/kg erythromycin base at 1, 2, and 11 PM on the day before surgery combined with mechanical cleansing of the large intestine and oral neomycin

Children and Adults:

Ophthalmic: Instill 1/2" (1.25 cm) 2-6 times/day depending on the severity of the infection

Topical: Apply over the affected area twice daily after the skin has been thoroughly washed and patted dry

Adults:

Usual dosage range:

Oral:

Base: 250-500 mg every 6-12 hours

Ethylsuccinate: 400-800 mg every 6-12 hours

I.V. (lactobionate): 15-20 mg/kg/day divided every 6 hours or 500 mg to 1 g every 6 hours, or given as a continuous infusion over 24 hours (maximum: 4 g/24 hours)

Indication-specific dosing:

Cervicitis: Oral: 500 mg 4 times/day for 7 days

Chancroid (unlabeled use; not a preferred agent): Oral: 500 mg 4 times/day for 7 days

Community-acquired pneumonia, bronchitis: Oral, I.V.: 500-1000 mg 4 times/day for 10-14 days. If *Legionella* is suspected/confirmed, 750-1000 mg 4 times/day for 21 days or more may be recommended. **Note:** Other macrolides and/or fluoroquinolones may be preferred and better tolerated.

Lymphogranuloma venereum: Oral: 500 mg 4 times/day for 21 days

Nongonococcal urethritis (recurrent): Oral: CDC Guidelines for the Treatment of Sexually Transmitted Diseases recommendation: Metronidazole (2 g as a single dose) plus 7 days of erythromycin base (500 mg 4 times/day) or erythromycin ethylsuccinate (800 mg 4 times/day)

Pertussis (CDC guidelines): 500 mg every 6 hours for 14 days

Preop bowel preparation (unlabeled use): Oral: 1 g erythromycin base at 1, 2, and 11 PM on the day before surgery combined with mechanical cleansing of the large intestine and oral neomycin

Gastrointestinal prokinetic (unlabeled use): Oral: Erythromycin has been used as a prokinetic agent to improve gastric emptying time and intestinal motility. In adults, 200 mg was infused I.V. initially followed by 250 mg orally 3 times/day 30 minutes before meals. Lower dosages have been used in some trials.

Dosage adjustment in renal impairment: Dialysis: Slightly dialyzable (5% to 20%); no supplemental dosage necessary in hemo- or peritoneal dialysis or in continuous arteriovenous or venovenous hemofiltration

Stability Erythromycin lactobionate should be reconstituted with sterile water for injection without preservatives to avoid gel formation; the reconstituted solution is stable for 2 weeks when refrigerated or 24 hours at room temperature. Erythromycin I.V. infusion solution is stable at pH 6-8. Do not use D₅W as a diluent unless sodium bicarbonate is added to solution.

Monitoring Parameters Liver function tests

Administration Oral: Do not crush enteric coated drug product. GI upset, including diarrhea, is common. May be administered with food to decrease GI upset. Do not give with milk or acidic beverages.

I.V.: Infuse 1 g over 20-60 minutes. I.V. infusion may be very irritating to the vein. If phlebitis/pain occurs with used dilution, consider diluting further (eg, 1:5) if fluid status of the patient will tolerate, or consider administering in larger available vein. The addition of lidocaine or bicarbonate does not decrease the irritation of erythromycin infusions.

Ophthalmic: Avoid contact of tip of ophthalmic ointment tube with affected eye

Contraindications Hypersensitivity to erythromycin or any component of the formulation

Systemic: Pre-existing liver disease (erythromycin estolate); concomitant use with ergot derivatives, pimozide, or cisapride

Warnings Systemic: Use caution with hepatic impairment with or without jaundice has occurred, it may be accompanied by malaise, nausea, vomiting, abdominal colic, and fever; discontinue use if these occur; avoid using erythromycin lactobionate in neonates since formulations may contain benzyl alcohol which is associated with toxicity in neonates; observe for superinfections. Use in infants has been associated with infantile hypertrophic pyloric stenosis (IHPS). Macrolides have been associated with rare QT prolongation and ventricular arrhythmias, including torsade de pointes. Elderly may be at increased risk of adverse events, including hearing loss and/or torsade de pointes when dosage ≥ 4 g/day, particularly if concurrent renal/hepatic impairment.

Dosage Forms

[DSC] = Discontinued product; [CAN] = Canadian brand name

Capsule, delayed release, enteric-coated pellets, as base (Eryc®): 250 mg

Gel, topical: 2% (30 g, 60 g)

A/T/S®: 2% (30 g) [contains alcohol 92%]

Erygel®: 2% (30 g, 60 g) [contains alcohol 92%]

Granules for oral suspension, as ethylsuccinate (E.E.S.®): 200 mg/5 mL (100 mL, 200 mL) [cherry flavor]

Injection, powder for reconstitution, as lactobionate (Erythrocin®): 500 mg, 1 g

Ointment, ophthalmic: 0.5% [5 mg/g] (1 g, 3.5 g)

Romycin®: 0.5% [5 mg/g] (3.5 g)

Ointment, topical (Akne-Mycin®): 2% (25 g)

Powder for oral suspension, as ethylsuccinate (EryPed®): 200 mg/5 mL (100 mL, 200 mL) [fruit flavor]; 400 mg/5 mL (100 mL, 200 mL) [banana flavor]

Powder for oral suspension, as ethylsuccinate [drops] (EryPed®): 100 mg/2.5 mL (50 mL) [fruit flavor]

Solution, topical: 2% (60 mL)

A/T/S®: 2% (60 mL) [contains alcohol 66%]

Eryderm®, T-Stat® [DSC], Theramycin Z®: 2% (60 mL) [contain alcohol]

Sans Acne® [CAN]: 2% (60 mL) [contains ethyl alcohol 44%; not available in U.S.]

Staticin®: 1.5% (60 mL) [DSC]

Suspension, oral, as estolate: 125 mg/5 mL (480 mL); 250 mg/5 mL (480 mL)

Suspension, oral, as ethylsuccinate: 200 mg/5 mL (480 mL); 400 mg/5 mL (480 mL)

E.E.S.®: 200 mg/5 mL (100 mL, 480 mL) [fruit flavor]; 400 mg/5 mL (100 mL, 480 mL) [orange flavor]

Swab (T-Stat® [DSC]): 2% (60s)

Tablet, chewable, as ethylsuccinate (EryPed®): 200 mg [fruit flavor] [DSC]

Tablet, delayed release, enteric coated, as base (Ery-Tab®): 250 mg, 333 mg, 500 mg

Tablet, as base: 250 mg, 500 mg

Tablet, as ethylsuccinate (E.E.S.®): 400 mg

Tablet, as stearate: 250 mg

Erythrocin®: 250 mg, 500 mg

Tablet [polymer-coated particles], as base (PCE®): 333 mg, 500 mg

Reference Range Peak plasma level after 500 mg dose: 2-20 mg/L

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Acute gastrointestinal irritation can be treated with milk or bismuth subsalicylate; QT prolongation, hypotension, or ventricular arrhythmias can be treated with sodium bicarbonate; lidocaine can be useful for ventricular tachycardia; magnesium sulfate can be useful in treating torsade de pointes

Enhanced elimination: Slightly dialyzable

Test Interactions False-positive urinary catecholamines and 17-hydroxycorticosteroids; estolate salt may result in false-positive elevation of serum AST when assayed colorimetrically

Drug Interactions

Substrate of CYP2B6 (minor), 3A4 (major); **Inhibits** CYP1A2 (weak), 3A4 (moderate)

Alfentanil (and possibly other narcotic analgesics): Serum levels may be increased by erythromycin; monitor for increased effect.

Antipsychotic agents (particularly mesoridazine and thioridazine): Risk of QT_c prolongation and malignant arrhythmias may be increased.

Benzodiazepines (those metabolized by CYP3A4, including alprazolam and triazolam): Serum levels may be increased by erythromycin; somnolence and confusion have been reported.

Bromocriptine: Serum levels may be increased by erythromycin; monitor for increased effect.

Bupirone: Serum levels may be increased by erythromycin; monitor.

Calcium channel blockers (felodipine, verapamil, and potentially others metabolized by CYP3A4): Serum levels may be increased by erythromycin; monitor.

Carbamazepine: Serum levels may be increased by erythromycin; monitor.

Cilostazol: Serum levels may be increased by erythromycin.

Cisapride: Serum levels may be increased by erythromycin; serious arrhythmias have occurred; concurrent use contraindicated.

Clindamycin (and lincomycin): Use with erythromycin may result in pharmacologic antagonism; manufacturer recommends avoiding this combination.

Clozapine: Serum levels may be increased by erythromycin; monitor.

Colchicine: serum levels/toxicity may be increased by erythromycin; monitor. Avoid use, if possible.

Cyclosporine: Serum levels may be increased by erythromycin; monitor serum levels.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of erythromycin. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of erythromycin. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, imatinib, isoniazid, nefazodone, nocardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

CYP3A4 substrates: Erythromycin may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Delavirdine: Serum levels of erythromycin may be increased; also, serum levels of delavirdine may be increased by erythromycin (low risk); monitor.

Digoxin: Serum levels may be increased by erythromycin; monitor digoxin levels.

Disopyramide: Serum levels may be increased by erythromycin; in addition, QT_c prolongation and risk of malignant arrhythmia may be increased; avoid combination.

Ergot alkaloids: Concurrent use may lead to acute ergot toxicity (severe peripheral vasospasm and dysesthesia).

HMG-CoA reductase inhibitors (atorvastatin, lovastatin, and simvastatin): Erythromycin may increase serum levels of "statins" metabolized by CYP3A4, increasing the risk of myopathy/rhabdomyolysis (does not include fluvastatin and pravastatin). Switch to pravastatin/fluvastatin or suspend treatment during course of erythromycin therapy.

Loratadine: Serum levels may be increased by erythromycin; monitor.

Methylprednisolone: Serum levels may be increased by erythromycin; monitor.

Neuromuscular-blocking agents: May be potentiated by erythromycin (case reports).

Phenytoin: Serum levels may be increased by erythromycin; other evidence suggested phenytoin levels may be decreased in some patients; monitor.

Pimozide: Serum levels may be increased, leading to malignant arrhythmias; concomitant use is contraindicated.

Protease inhibitors (amprenavir, nelfinavir, and ritonavir): May increase serum levels of erythromycin.

QT_c-prolonging agents: Concomitant use may increase the risk of malignant arrhythmias.

Quinidine: Serum levels may be increased by erythromycin; in addition, the risk of QT_c prolongation and malignant arrhythmias may be increased during concurrent use.

Quinolone antibiotics (sparfloxacin, gatifloxacin, and moxifloxacin): Concurrent use may increase the risk of malignant arrhythmias.

Rifabutin: Serum levels may be increased by erythromycin; monitor.

Sildenafil, tadalafil, vardenafil: Serum concentration may be substantially increased by erythromycin. Do not exceed single sildenafil doses of 25 mg in 48 hours, a single tadalafil dose of 10 mg in 72 hours, or a single vardenafil dose of 2.5 mg in 24 hours.

Tacrolimus: Serum levels may be increased by erythromycin; monitor serum concentration.

Theophylline: Serum levels may be increased by erythromycin; monitor.

Valproic acid (and derivatives): Serum levels may be increased by erythromycin; monitor.

Vinblastine (and vincristine): Serum levels may be increased by erythromycin.

Warfarin: Effects may be potentiated; monitor INR closely and adjust warfarin dose as needed or choose another antibiotic.

Zafirlukast: Serum levels may be decreased by erythromycin; monitor.

Zopiclone: Serum levels may be increased by erythromycin; monitor.

Pregnancy Risk Factor B

Pregnancy Implications Crosses the placenta; avoid erythromycin estolate in that elevated serum aspartate aminotransferase can occur in 14% of patients (not a false-positive)

Lactation Enters breast milk/use caution (AAP considers "compatible")

Nursing Implications Gastrointestinal upset, including diarrhea, is common; can give with food to decrease gastritis; some formulations may contain benzyl alcohol as a preservative; use with extreme care in neonates

Additional Information Sodium content of oral suspension (ethylsuccinate) 200 mg/5 mL: 29 mg (1.3 mEq); sodium content of base Filmtab® 250 mg: 70 mg (3 mEq)

Escitalopram

Pronunciation (es sye TAL oh pram)

Related Information

- Antidepressant Agents
- Citalopram

CAS Number 128196-01-0; 219861-08-2

U.S. Brand Names Lexapro®

Synonyms Escitalopram Oxalate; Lu-26-054; S-Citalopram

Use Treatment of major depressive disorder; generalized anxiety disorders (GAD)

Mechanism of Action Escitalopram is the S-enantiomer of the racemic derivative (bicyclic) citalopram, which selectively inhibits the reuptake of serotonin with little to no effect on norepinephrine or dopamine reuptake. It has no or very low affinity for 5-HT₁₋₇, alpha- and beta-adrenergic, D₁₋₅, H₁₋₃, M₁₋₅, and benzodiazepine receptors. Escitalopram does not bind or has low affinity for Na⁺, K⁺, Cl⁻, and Ca⁺⁺ ion channels.

Adverse Reactions

> 10%:

- Central nervous system: Headache (24%), somnolence (6% to 13%), insomnia (9% to 12%)
- Gastrointestinal: Nausea (15%)
- Genitourinary: Ejaculation disorder (9% to 14%)

1% to 10%:

- Cardiovascular: Chest pain, hypertension, palpitation
- Central nervous system: Dizziness (5%), fatigue (5% to 8%), dreaming abnormal, concentration impaired, fever, irritability, lethargy, lightheadedness, migraine, vertigo, yawning
- Dermatologic: Rash
- Endocrine & metabolic: Libido decreased (3% to 7%), anorgasmia (2% to 6%), hot flashes, menstrual cramps, menstrual disorder
- Gastrointestinal: Diarrhea (8%), xerostomia (6% to 9%), appetite decreased (3%), constipation (3% to 5%), indigestion (3%), abdominal pain (2%), abdominal cramps, appetite increased, flatulence, gastroenteritis, gastroesophageal reflux, heartburn, toothache, vomiting, weight gain/loss
- Genitourinary: Impotence (3%), urinary tract infection, urinary frequency
- Neuromuscular & skeletal: Arthralgia, limb pain, muscle cramp, myalgia, neck/shoulder pain, paresthesia, tremor
- Ocular: Blurred vision
- Otic: Earache, tinnitus
- Respiratory: Rhinitis (5%), sinusitis (3%), bronchitis, cough, nasal sinus congestion, sinus headache
- Miscellaneous: Diaphoresis (4% to 5%), flu-like syndrome (5%), allergy

< 1%: Abdominal discomfort, acne, agitation, alopecia, amnesia, anaphylaxis, anemia, anxiety attack, apathy, arthritis, arthropathy, asthma, auditory hallucination, back discomfort, belching, bilirubin increased, bloating, bradycardia, bruise, bruxism, carbohydrate craving, carpal tunnel syndrome, chest tightness, chills, confusion, conjunctivitis, crying abnormal, depersonalization, depression aggravated, depression, dermatitis, dry eyes, dry skin, dysequilibrium, dyspepsia, dysuria, ECG abnormal, eczema, edema, emotional lability, excitability, eye infection, eye irritation, faintness, feeling unreal, flushing, folliculitis, forgetfulness, furunculosis, gagging, gastritis, gout, hematoma, hemorrhoids, hypercholesterolemia, hyperglycemia, hyper-reflexia, jaw pain, jaw stiffness,

jitteriness, joint stiffness, kidney stone, laryngitis, leg pain, lipoma, malaise, menorrhagia, muscle contractions (involuntary), muscle stiffness, muscle weakness, muscular tone increased, nervousness, nose-bleed, panic reaction, pelvic inflammation, pneumonia, pruritus, pupils dilated, restless legs, restlessness aggravated, shaking, shortness of breath, spotting between menses, stool frequency increased, suicidal tendency, suicide attempt, syncope, tachycardia, taste alteration, tics, tracheitis, tremulousness nervous, twitching, urinary frequency, varicose vein, vision abnormal, visual disturbance, weakness

Postmarketing and/or case reports: Acute renal failure, aggression, akathisia, allergic reaction, angioedema, atrial fibrillation, choreoathetosis, delirium, dyskinesia, ecchymosis, epidermal necrolysis, erythema multiforme, grand mal seizure, hallucination, hemolytic anemia, hepatic necrosis, hepatitis, nystagmus, pancreatitis, priapism, prolactinemia, prothrombin decreased, pulmonary embolism, QT prolonged, rhabdomyolysis, serotonin syndrome, SIADH, spontaneous abortion, thrombocytopenia, thrombosis, torsade de pointes, ventricular arrhythmia, withdrawal syndrome

Signs and Symptoms of Overdose Seizure, QT prolongation, serotonin syndrome, drowsiness, agitation, fever, clonus

Pharmacodynamics/Kinetics

Protein binding: 56% to plasma proteins

Metabolism: Hepatic via CYP2C19 and 3A4 to an active metabolite, S-desmethylcitalopram (S-DCT; 1/7 the activity); S-DCT is metabolized to S-didesmethylcitalopram (S-DDCT; active; 1/27 the activity) via CYP2D6

Volume of distribution: 12-26 L/kg

Half-life elimination: Escitalopram: 27-32 hours; S-desmethylcitalopram:

59 hours

Time to peak: Escitalopram: 5 ± 1.5 hours; S-desmethylcitalopram:

14 hours

Excretion: Urine (Escitalopram: 8%; S-DCT: 10%)

Clearance: Total body: 37-40 L/hour; Renal: Escitalopram: 2.7 L/hour;

S-desmethylcitalopram: 6.9 L/hour

Dosage Oral:

Adults: Depression, GAD: Initial: 10 mg/day; dose may be increased to

20 mg/day after at least 1 week

Elderly: 10 mg/day; bioavailability and half-life are increased by 50% in

the elderly

Dosage adjustment in renal impairment:

Mild to moderate impairment: No dosage adjustment needed

Severe impairment: Cl_{cr} < 20 mL/minute: Use caution

Dosage adjustment in hepatic impairment: 10 mg/day

Stability Store at 25°C (77°F).

Monitoring Parameters Mental status for depression, suicidal ideation (especially at the beginning of therapy or when doses are increased or decreased), anxiety, social functioning, mania, panic attacks; akathisia

Administration Administer once daily (morning or evening), with or without food.

Contraindications Hypersensitivity to escitalopram, citalopram, or any component of the formulation; concomitant use or within 2 weeks of MAO inhibitors

Warnings

Major psychiatric warnings:

- **[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders;** consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. A medication guide concerning the use of antidepressants in children and teenagers should be dispensed with each prescription. **Escitalopram is not FDA approved for use in children.**
- The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Patients treated with antidepressants should be observed for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy.
- Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression or psychosis occur.
- May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder.

Escitalopram is not FDA approved for the treatment of bipolar depression.

Key adverse effects:

- Anticholinergic effects: Relatively devoid of these side effects.
- CNS depression: Has a low potential to impair cognitive or motor performance; caution operating hazardous machinery or driving.
- SIADH and hyponatremia: Has been associated with the development of SIADH; hyponatremia has been reported rarely, predominantly in the elderly

Concurrent disease:

- Hepatic impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.
- Platelet aggregation: May impair platelet aggregation, resulting in bleeding.
- Renal impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.
- Seizure disorders: Use caution with a previous seizure disorder or condition predisposing to seizures such as brain damage or alcoholism.
- Sexual dysfunction: May cause or exacerbate sexual dysfunction.

Concurrent drug therapy:

- Agents which lower seizure threshold: Concurrent therapy with other drugs which lower the seizure threshold.
- Anticoagulants/Antiplatelets: Use caution with concomitant use of NSAIDs, ASA, or other drugs that affect coagulation; the risk of bleeding is potentiated.
- CNS depressants: Use caution with concomitant therapy.
- MAO inhibitors: Potential for severe reaction when used with MAO inhibitors; autonomic instability, coma, death, delirium, diaphoresis, hyperthermia, mental status changes/agitation, muscular rigidity, myoclonus, neuroleptic malignant syndrome features, and seizures may occur.

Special populations:

- Elderly: Use caution in elderly patients.
- Pregnancy: Use caution in pregnant patients; high doses of citalopram have been associated with teratogenicity in animals.

Special notes:

- Electroconvulsive therapy: May increase the risks associated with electroconvulsive therapy; consider discontinuing, when possible, prior to ECT treatment.
- Withdrawal syndrome: May cause dysphoric mood, irritability, agitation, dizziness, sensory disturbances, anxiety, confusion, headache, lethargy, emotional lability, insomnia, hypomania, tinnitus, and seizures. Upon discontinuation of escitalopram therapy, gradually taper dose. If intolerable symptoms occur following a decrease in dosage or upon discontinuation of therapy, then resuming the previous dose with a more gradual taper should be considered.

Dosage Forms

Solution, oral: 1 mg/mL (240 mL) [peppermint flavor]
Tablet: 5 mg, 10 mg, 20 mg

Note: Cipralox® [CAN] is available only in 10 mg and 20 mg strengths.

Reference Range Daily dose of 10 mg achieves steady state escitalopram plasma levels of 20-125 nmol/L

Overdosage/Treatment

Decontamination: Lavage/activated charcoal

Treatment should be symptom-directed and supportive. Hypertension can be treated with nitroprusside. Seizures can be treated with benzodiazepine or phenobarbital.

Drug Interactions **Substrate** (major) of CYP2C19, 3A4; **Inhibits** CYP2D6 (weak)

Aspirin: Concomitant use of escitalopram and NSAIDs, aspirin, or other drugs affecting coagulation has been associated with an increased risk of bleeding; monitor.

Buspirone: Concurrent use of citalopram with buspirone may cause serotonin syndrome; avoid concurrent use.

Cimetidine: May inhibit the metabolism of citalopram.

CYP2C19 inducers: May decrease the levels/effects of escitalopram. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of escitalopram. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of escitalopram. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of escitalopram. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Desipramine: Escitalopram may increase desipramine levels.

Linezolid: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and deaths have been reported with agents which inhibit MAO (serotonin syndrome); this combination should be avoided.

MAO inhibitors: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and deaths have been reported with MAO inhibitors (serotonin syndrome); this combination should be avoided.

Meperidine: Combined use theoretically may increase the risk of serotonin syndrome.

Metoprolol: Escitalopram may increase plasma levels of metoprolol; monitor for increased effect.

Moclobemide: Concurrent use of citalopram with moclobemide may cause serotonin syndrome; avoid concurrent use.

Nefazodone: Concurrent use of citalopram with nefazodone may cause serotonin syndrome.

NSAIDs: Concomitant use of escitalopram and NSAIDs, aspirin, or other drugs affecting coagulation has been associated with an increased risk of bleeding; monitor.

Selegiline: Concurrent use with citalopram has been reported to cause serotonin syndrome; as an MAO type B inhibitor, the risk of serotonin syndrome may be less than with nonselective MAO inhibitors, and reports indicate that this combination has been well tolerated in Parkinson's patients.

SSRIs: Concurrent use with other reuptake inhibitors may increase the risk of serotonin syndrome.

Sibutramine: May increase the risk of serotonin syndrome with SSRIs.

Sumatriptan (and other serotonin agonists): Concurrent use may result in toxicity; weakness, hyper-reflexia, and incoordination have been observed with sumatriptan and SSRIs. In addition, concurrent use may theoretically increase the risk of serotonin syndrome; includes sumatriptan, naratriptan, rizatriptan, and zolmitriptan.

Tramadol: Concurrent use of citalopram with tramadol may cause serotonin syndrome; avoid concurrent use.

Trazodone: Concurrent use of citalopram with trazodone may cause serotonin syndrome.

Venlafaxine: Combined use with citalopram may increase the risk of serotonin syndrome.

Warfarin: Use with caution; may increase risk of bleeding.

Pregnancy Risk Factor C

Teratogenic effects have been reported in animal studies. Nonteratogenic effects including respiratory distress, cyanosis, apnea, seizures, temperature instability, feeding difficulty, vomiting, hypoglycemia, hypo- or hypertonia, hyper-reflexia, jitteriness, irritability, constant crying, and tremor have been reported in the neonate immediately following delivery after exposure late in the third trimester. Adverse effects may be due to toxic effects of SSRI or drug discontinuation. In some cases, may present clinically as serotonin syndrome. There are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if the potential benefit to the mother outweighs the possible risk to the fetus. If treatment during pregnancy is required, consider tapering therapy during the third trimester.

Pregnancy Implications Teratogenic effects have been reported in animal studies. Nonteratogenic effects including respiratory distress, cyanosis, apnea, seizures, temperature instability, feeding difficulty, vomiting, hypoglycemia, hypo- or hypertonia, hyper-reflexia, jitteriness, irritability, constant crying, and tremor have been reported in the neonate immediately following delivery after exposure late in the third trimester.

Adverse effects may be due to toxic effects of SSRI or drug discontinuation. In some cases, may present clinically as serotonin syndrome. There are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if the potential benefit to the mother outweighs the possible risk to the fetus. If treatment during pregnancy is required, consider tapering therapy during the third trimester.

Lactation Enters breast milk/not recommended

Additional Information The tablet and oral solution dosage forms are bioequivalent. Clinically, escitalopram 20 mg is equipotent to citalopram 40 mg. Do not coadminister with citalopram.

Esmolol

Related Information

- Selected Properties of Beta-Adrenergic Blocking Drugs

CAS Number 103598-03-4; 81161-17-3; 84057-94-3

U.S. Brand Names Brevibloc®

Synonyms Esmolol Hydrochloride

Use Treatment of tachycardia (ventricular), fibrillation (atrial)/flutter (primarily to control ventricular rate), and hypertension (especially perioperatively); may be effective for thyrotoxic crisis; has been used to treat tachycardia due to neonatal tetanus

Unlabeled/Investigational Use In children, for SVT and postoperative hypertension

Mechanism of Action Class II antiarrhythmic: Competitively blocks response to beta₁ stimulation with little or no effect of beta₂ receptors except at high doses, no intrinsic sympathomimetic activity, no membrane stabilizing activity

Adverse Reactions

Cardiovascular: Hypotension (especially with doses >200 mcg/kg/minute), bradycardia, exacerbation of Raynaud's phenomenon, sinus bradycardia, QRS prolongation

Central nervous system: Dizziness, somnolence, confusion, drowsiness, CNS depression, headache, seizures

Gastrointestinal: Nausea, vomiting, dyspepsia, constipation

Local: Phlebitis (at concentrations >20 mg/mL), skin necrosis after extravasation

Otic: Ototoxicity, tinnitus

Respiratory: Bronchoconstriction (less than propranolol, but more likely with higher doses), bronchospasm

Miscellaneous: Other adverse reactions similar to other beta-blockers may occur, diaphoresis

Signs and Symptoms of Overdose Abdominal pain, ataxia, AV block, depression, dizziness, dose-related hypotension, dry mouth, dyspnea, headache, heart block, hypoglycemia, lightheadedness, wheezing

Pharmacodynamics/Kinetics

Onset of action: Beta-blockade: I.V.: 2-10 minutes (quickest when loading doses are administered)

Duration of hemodynamic effects: 10-30 minutes; prolonged following higher cumulative doses, extended duration of use

Protein binding: 55%

Metabolism: In blood by red blood cell esterases

Half-life elimination: Adults: 9 minutes; elimination of metabolite decreases with end stage renal disease

Excretion: Urine (~69% as metabolites, 2% unchanged drug)

Dosage

I.V. (Must be adjusted to individual response and tolerance):

Children: An extremely limited amount of information regarding esmolol use in pediatric patients is currently available. Some centers have utilized doses of 100-500 mcg/kg given over 1 minute for control of tachycardia (ventricular). Loading doses of 500 mcg/kg/minute over 1 minute with maximal doses of 50-250 mcg/kg/minute (mean 173) have been used in addition to nitroprusside in a small number of patients (7 patients, 7-19 years of age, median 13 years) to treat postoperative hypertension after coarctation of aorta repair.

Adults: Loading dose: 500 mcg/kg over 1 minute; follow with a 50 mcg/kg/minute infusion for 4 minutes; if response is inadequate, rebolus with another 500 mcg/kg loading dose over 1 minute, and increase the maintenance infusion to 100 mcg/kg/minute. Repeat this process until a therapeutic effect has been achieved or to a maximum recommended maintenance dose of 200 mcg/kg/minute. Usual dosage range: 50-200 mcg/kg/minute with average dose of 100 mcg/kg/minute.

Monitoring Parameters Blood pressure, heart rate, MAP, ECG, respiratory rate, I.V. site; cardiac monitor and blood pressure monitor required

Administration Infusions must be administered with an infusion pump. The concentrate (250 mg/mL ampul) is **not** for direct I.V. injection, but rather must first be diluted to a final concentration of 10 mg/mL (ie, 2.5 g in 250 mL or 5 g in 500 mL). Concentrations >10 mg/mL or infusion into small veins or through a butterfly catheter should be avoided (can cause thrombophlebitis). Decrease or discontinue infusion if hypotension or congestive heart failure occur. Medication port of premixed bags should be used to withdraw only the initial bolus, if necessary (not to be used for withdrawal of additional bolus doses).

Contraindications Hypersensitivity to esmolol or any component of the formulation; sinus bradycardia; heart block greater than first degree (except in patients with a functioning artificial pacemaker); cardiogenic shock; bronchial asthma (relative); uncompensated cardiac failure; hypotension; pregnancy (2nd and 3rd trimesters)

Warnings Hypotension is common; patients need close blood pressure monitoring. Administer cautiously in compensated heart failure and monitor for a worsening of the condition. Use caution in patients with PVD (can aggravate arterial insufficiency). Use caution with concurrent use of beta-blockers and either verapamil or diltiazem; bradycardia or heart block can occur. Avoid concurrent I.V. use of both agents. Use beta-blockers cautiously in patients with bronchospastic disease; monitor

pulmonary status closely. Use cautiously in diabetics because it can mask prominent hypoglycemic symptoms. Can mask signs of thyrotoxicosis. Can cause fetal bradycardia when administered in the 3rd trimester of pregnancy or at delivery. Use caution in patients with renal dysfunction (active metabolite retained). Do not use in the treatment of hypertension associated with vasoconstriction related to hypothermia. Concentrations >10 mg/mL or infusion into small veins or through a butterfly catheter should be avoided (can cause thrombophlebitis). Extravasation can lead to skin necrosis and sloughing.

Dosage Forms Infusion [premixed in sodium chloride; preservative free]: Brevibloc®: 2000 mg (100 mL) [20 mg/mL; double strength]; 2500 mg (250 mL) [10 mg/mL]

Injection, solution, as hydrochloride: 10 mg/mL (10 mL) [premixed in sodium chloride]

Brevibloc®: 10 mg/mL (10 mL) [alcohol free; premixed in sodium chloride]; 20 mg/mL (5 mL, 100 mL) [alcohol free; double strength; premixed in sodium chloride]; 250 mg/mL (10 mL) [contains alcohol 25%, propylene glycol 25%; concentrate]

Reference Range Therapeutic: 1.0-1.5 mg/L (3.4-5.1 μmol/L); note that arterial esmolol levels are sevenfold higher than venous levels

Overdosage/Treatment Supportive therapy: Usually discontinuation of the infusion will result in resolution of adverse effects within 30 minutes; hypotension can be treated with crystalloid infusion; beta agonist agents or aminophylline can be used for bronchoconstriction

Drug Interactions

Acetylcholinesterase Inhibitors: May enhance the bradycardic effect of beta-blockers.

Alpha/beta agonists (direct acting): Beta blockers may enhance the vasopressor effect of alpha/beta agonists (direct-acting). Epinephrine used as a local anesthetic for dental procedures will not likely cause clinically-relevant problems.

α₁-blockers: Beta blockers may enhance the orthostatic effect of α₁ blockers. The risk associated with ophthalmic products is probably less than systemic products.

α₂ agonists: Beta blockers may enhance the rebound hypertensive effect of α₂ agonists. This effect can occur when the α₂ agonist is abruptly withdrawn.

Amiodarone: May enhance the bradycardic effect of beta-blockers. Possibly to the point of cardiac arrest. Consider therapy modification.

β₂ agonists: May diminish the bradycardic effect of beta-blockers (β₁ selective); of concern with high doses of some beta-blockers.

Calcium channel blockers (nondihydropyridine): May enhance the hypotensive effect of beta-blockers. Bradycardia and signs of heart failure have also been reported.

Cardiac glycosides: Beta-blockers may enhance the bradycardic effect of cardiac glycosides.

Disopyramide: May enhance the bradycardic effect of beta-blockers. Use caution if coadministering disopyramide and a beta-blocker (especially if both are I.V.).

Insulin preparations: Beta-blockers may mask the hypoglycemic effect of insulin preparations.

NSAIDs: May diminish the antihypertensive effect of beta-blockers.

Sulfonylureas: Beta-blockers may enhance the hypoglycemic effect of sulfonylureas. Cardioselective beta-blockers (eg, esmolol) may be safer than nonselective beta-blockers. All beta-blockers appear to mask tachycardia as an initial symptom of hypoglycemia.

Pregnancy Risk Factor C (manufacturer); D (2nd and 3rd trimesters - expert analysis)

Pregnancy Implications Teratogenic effects are not noted in animal studies. Fetal bradycardia can occur when administered in the 3rd trimester of pregnancy or at delivery.

Lactation Excretion in breast milk unknown/use with caution

Additional Information 1.3 g overdose of esmolol associated with asystole and seizures; propylene glycol level in this case was 4 mg/dL (note that the more concentrated solution contains 25% propylene glycol)

Esomeprazole

Pronunciation (es oh ME pray zol)

U.S. Brand Names Nexium®

Synonyms Esomeprazole Magnesium

Use

Oral: Short-term (4-8 weeks) treatment of erosive esophagitis; maintaining symptom resolution and healing of erosive esophagitis; treatment of symptomatic gastroesophageal reflux disease (GERD); as part of a multidrug regimen for *Helicobacter pylori* eradication in patients with duodenal ulcer disease (active or history of within the past 5 years); prevention of gastric ulcers in patients at risk (age ≥60 years and/or history of gastric ulcer) associated with continuous NSAID therapy

I.V.: Short-term (≤10 weeks) treatment of gastroesophageal reflux disease (GERD) when oral therapy is not possible or appropriate

Mechanism of Action Proton pump inhibitor suppresses gastric acid secretion by inhibition of the H⁺/K⁺-ATPase in the gastric parietal cell

Adverse Reactions

Unless otherwise specified, percentages represent adverse reactions identified in clinical trials evaluating the intravenous formulation.

>10%: Central nervous system: Headache (I.V. 11%; oral 4% to 8%)

1% to 10%:

Central nervous system: Dizziness (3%)

Dermatologic: Pruritus (\leq 1%)

Gastrointestinal: Flatulence (10%), nausea (2% to 6%), abdominal pain (6%; oral 3% to 4%), diarrhea (4%), xerostomia (2% to 4%), dyspepsia (<1% to 6%), constipation (3%)

Local: Injection site reaction (2%)

Respiratory: Sinusitis (\leq 2%), respiratory infection (1%)

<1% (Limited to important or life-threatening): Albuminuria, alkaline phosphatase increased, allergic reactions, anemia, angioedema, arthritis exacerbation, arthropathy, asthenia, asthma exacerbation, Barrett's esophagus, benign polyps/nodules, bilirubinemia, cervical lymphadenopathy, chest pain, confusion, creatinine increased, cystitis, depression exacerbation, dermatitis, duodenitis, dysmenorrhea, dysphagia, dyspnea, epigastric pain, epistaxis, esophageal stricture, esophageal ulceration, esophageal varices, esophagitis, facial edema, fever, fibromyalgia syndrome, flu-like syndrome, flushing, fungal infection, gastric ulcer, gastritis, gastroenteritis, genital moniliasis, GI dysplasia, GI hemorrhage, glycosuria, goiter, hematuria, hepatic enzymes increased, hernia, hot flushes, hypertension, hypertonia, hyperuricemia, hypochromic anemia, hypoesthesia, hyponatremia, larynx edema, leukocytosis, leukopenia, maculopapular rash, migraine, pain, paresthesia, parosmia, peripheral edema, polymyalgia rheumatica, polyuria, pruritus ani, rash, rigors, serum gastrin increased, substernal chest pain, tachycardia, thrombocytopenia, thyroid stimulating hormone increased, tinnitus, tongue edema, total bilirubin increased, tremor, ulcerative stomatitis, urticaria, vaginitis, vertigo, vision change, vitamin B₁₂ deficiency, vomiting

Postmarketing and/or case reports: Agranulocytosis, alopecia, anaphylaxis, anaphylactic shock, blurred vision, depression, erythema multiforme, hepatitis, jaundice, myalgia, pancreatitis, pancytopenia, Stevens-Johnson syndrome, toxic epidermal necrolysis

Pharmacodynamics/Kinetics

Distribution: V_{dss}: 16 L

Protein binding: 97%

Metabolism: Hepatic via CYP2C19 and 3A4 enzymes to hydroxy, desmethyl, and sulfone metabolites (all inactive)

Bioavailability: 90% with repeat dosing

Half-life elimination: 1-1.5 hours

Time to peak: 1.5 hours

Excretion: Urine (80%); feces (20%)

Dosage Note: Delayed-release capsules should be swallowed whole and taken at least 1 hour before eating

Adolescents 12-17 years: Oral: GERD: 20-40 mg once daily for up to 8 weeks

Adults:

Oral:

Erosive esophagitis (healing): Initial: 20-40 mg once daily for 4-8 weeks; if incomplete healing, may continue for an additional 4-8 weeks; maintenance: 20 mg once daily

Symptomatic GERD: 20 mg once daily for 4 weeks; may continue an additional 4 weeks if symptoms persist

Helicobacter pylori eradication: 40 mg once daily for 10 days; requires combination therapy

Prevention of NSAID-induced gastric ulcers: 20-40 mg once daily for up to 6 months

I.V.: GERD: 20 mg or 40 mg once daily for \leq 10 days; change to oral therapy as soon as appropriate

Elderly: No dosage adjustment needed

Dosage adjustment in renal impairment: No dosage adjustment needed

Dosage adjustment in hepatic impairment:

Mild-to-moderate hepatic impairment (Child-Pugh Class A or B): No dosage adjustment needed

Severe hepatic impairment (Child-Pugh Class C): Dose should not exceed 20 mg/day

Stability

Capsule: Store at 15°C to 30°C (59°F to 86°F); keep container tightly closed

Powder for injection: Store at 15°C to 30°C (59°F to 86°F); protect from light.

For I.V. injection: Reconstitute powder with 5 mL NS.

For I.V. infusion: Initially reconstitute powder with 5 mL of NS, LR, or D₅W, then further dilute to a final volume of 50 mL.

Following reconstitution, solution for injection prepared in NS, and solution for infusion prepared in NS or LR should be used within 12 hours. Following reconstitution, solution for infusion prepared in D₅W should be used within 6 hours. Refrigeration is not required following reconstitution.

Monitoring Parameters Susceptibility testing recommended in patients who fail *H. pylori* eradication regimen (esomeprazole, clarithromycin, and amoxicillin)

Administration

Oral: Capsule should be swallowed whole and taken at least 1 hour before eating (best if taken before breakfast). For patients with difficulty swallowing, open capsule and mix contents with 1 tablespoon of applesauce. Swallow immediately; mixture should not be chewed or warmed. The mixture should not be stored for future use.

I.V.: May be administered by injection (\geq 3 minutes) or infusion (10-30 minutes). Flush line prior to and after administration with NS, LR, or D₅W.

Nasogastric tube: Open capsule and place intact granules into a 60 mL syringe; mix with 50 mL of water. Replace plunger and shake vigorously for 15 seconds. Ensure that no granules remain in syringe tip. Do not administer if pellets dissolve or disintegrate. After administration, flush nasogastric tube with additional water. Use suspension immediately after preparation.

Contraindications Hypersensitivity to esomeprazole, substituted benzimidazoles (ie, lansoprazole, omeprazole, pantoprazole, rabeprazole), or any component of the formulation

Warnings Relief of symptoms does not preclude the presence of a gastric malignancy. Atrophic gastritis (by biopsy) has been noted with long-term omeprazole therapy; this may also occur with esomeprazole. No reports of enterochromaffin-like (ECL) cell carcinoids, dysplasia, or neoplasia has occurred. No reports of enterochromaffin-like (ECL) cell carcinoids, dysplasia, or neoplasia has occurred. Safety and efficacy in children <12 years of age have not been established.

Dosage Forms Capsule, delayed release:

Nexium®: 20 mg, 40 mg

Injection, powder for reconstitution:

Nexium®: 20 mg, 40 mg [contains edetate sodium]

Drug Interactions

Substrate of CYP2C19 (major), 3A4 (minor); **Inhibits CYP2C19** (moderate)

Benzodiazepines metabolized by oxidation (eg, diazepam, midazolam, triazolam): Esomeprazole and omeprazole may increase levels of benzodiazepines metabolized by oxidation.

Carbamazepine: Esomeprazole and omeprazole may increase carbamazepine levels. Carbamazepine may decrease the effects of esomeprazole.

CYP2C19 inducers: May decrease the levels/effects of esomeprazole. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 substrates: Esomeprazole may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

HMG-CoA reductase inhibitors: Esomeprazole may increase the levels/effects; monitor.

Iron salts: Esomeprazole may decrease the absorption of orally-administered iron salts.

Itraconazole and ketoconazole: Proton pump inhibitors may decrease the absorption of itraconazole and ketoconazole.

Protease inhibitors: Proton pump inhibitors may decrease absorption of some protease inhibitors (atazanavir and indinavir).

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic effects were not observed in animal studies. However, there are no adequate and well-controlled studies in pregnant women. Congenital abnormalities have been reported sporadically following omeprazole use during pregnancy.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Esomeprazole is the S-isomer of omeprazole.

Specific References

Li X-Q, Anderson TB, Ahlstrom M, et al, "Comparison of Inhibitory Effects of the Proton Pump-Inhibiting Drugs Omeprazole, Esomeprazole, Lansoprazole, Pantoprazole, and Rabeprazole on Human Cytochrome P450 Activities," *Drug Metab Disp*, 2004, 32(8):821-7.

Estazolam

CAS Number 29975-16-4

U.S. Brand Names ProSom®

Impairment Potential Yes

Use Short-term management of insomnia

Mechanism of Action Has not been fully elucidated in humans; the most promising hypothesis involves GABA transmission. GABA is a major inhibitory transmitter in the CNS. Benzodiazepines may exert their pharmacologic effect through potentiation of the inhibitory activity of GABA. Specific benzodiazepine receptors have been identified in the rat brain located in proximity to dense areas of GABA receptors, primarily in the frontal and occipital cortex. Benzodiazepines do not alter the synthesis, release, reuptake, or enzymatic degradation of GABA.

Adverse Reactions

Cardiovascular: Syncope
 Central nervous system: **Somnolence** (42%), agitation (4%), amnesia (4%), apathy (4%), emotional lability (4%), hostility seizures (4%), sleep disorder (4%), stupor (4%), ataxia (4%), anxiety (1%), "hangover effect" (3%), abnormal thinking (2%), hypokinesia (8%), neuritis (4%)
 Dermatologic: Urticaria, acne, dry skin, photosensitivity, xerosis, purpura, pruritus
 Endocrine & metabolic: Decreased libido, gynecomastia
 Gastrointestinal: Dyspepsia, increased or decreased appetite, flatulence, gastritis, enterocolitis, melena, mouth ulcerations, xerostomia
 Genitourinary: Urinary incontinence, nocturia
 Hematologic: Agranulocytosis
 Hepatic: Elevated AST
 Neuromuscular & skeletal: **Weakness** (11%), twitching (4%), decreased reflexes (4%), paresthesia
 Renal: Hematuria, oliguria
 Respiratory: Cold symptoms, pharyngitis, asthma, cough, dyspnea, rhinitis, epistaxis, laryngitis

Signs and Symptoms of Overdose Confusion, coma, diminished reflexes, mydriasis, respiratory depression, somnolence

Admission Criteria/Prognosis Admit any patient with CNS depression or ingestions > 3 mg

Pharmacodynamics/Kinetics

Onset of action: ~1 hour
 Duration: Variable
 Metabolism: Extensively hepatic
 Half-life elimination: 10-24 hours (no significant changes in elderly)
 Time to peak, serum: 0.5-1.6 hours
 Excretion: Urine (<5% as unchanged drug)

Dosage Adults: Oral: 1 mg at bedtime, some patients may require 2 mg; start at doses of 0.5 mg in debilitated or small elderly patients

Dosing adjustment in hepatic impairment: May be necessary

Monitoring Parameters Respiratory and cardiovascular status

Contraindications Hypersensitivity to estazolam or any component of the formulation (cross-sensitivity with other benzodiazepines may exist); pregnancy

Note: Manufacturer states concurrent therapy with itraconazole or ketoconazole is contraindicated.

Warnings

As a hypnotic, should be used only after evaluation of potential causes of sleep disturbance. Failure of sleep disturbance to resolve after 7-10 days may indicate psychiatric or medical illness. Use is not recommended in patients with depressive disorders or psychoses. Avoid use in patients with sleep apnea. Use with caution in patients receiving concurrent CYP3A4 inhibitors, particularly when these agents are added to therapy. Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics), renal impairment, respiratory disease, impaired gag reflex, or obese patients.

Causes CNS depression (dose related) which may impair physical and mental capabilities. Use with caution in patients receiving other CNS depressants or psychoactive agents. Benzodiazepines have been associated with falls and traumatic injury and should be used with extreme caution in patients who are at risk of these events (especially the elderly). May cause physical or psychological dependence - use with caution in patients with a history of drug dependence.

Benzodiazepines have been associated with anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior, have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Dosage Forms Tablet: 1 mg, 2 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Treatment for benzodiazepine overdose is supportive; rarely is mechanical ventilation required. Flumazenil (Romazicon™) has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression. Do not use in concomitant tricyclic ingestion; treat hypotension with isotonic crystalloids, place in Trendelenburg position or give dopamine or norepinephrine.

Enhancement of elimination: Multiple dose of activated charcoal may enhance elimination

Antidote(s)

● Flumazenil [ANTIDOTE]

Test Interactions Visine®, Drano®, and bleach may result in false-negative urine tests

Drug Interactions

Substrate of CYP3A4 (minor)

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect.

Itraconazole, ketoconazole: Concurrent use is contraindicated (per manufacturer); however, estazolam is a minor CYP3A4 substrate and an effect has not been documented in clinical studies.

Levodopa: Therapeutic effects may be diminished in some patients following the addition of a benzodiazepine; limited/inconsistent data.

Oral contraceptives: May decrease the clearance of some benzodiazepines (those which undergo oxidative metabolism); monitor for increased benzodiazepine effect.

Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation.

Pregnancy Risk Factor X

Pregnancy Implications Suggested to be teratogenic in animal and human data; can precipitate neonatal respiratory depression when given during delivery

Lactation Enters breast milk/contraindicated

Nursing Implications Provide safety measures (ie, side rails, night light, and call button); remove smoking materials from area; supervise ambulation; avoid abrupt discontinuance in patients with prolonged therapy or seizure disorders

Estrogens, Conjugated

U.S. Brand Names Premarin®

Synonyms C.E.S.; CEE; Estrogenic Substances, Conjugated

Use Treatment of moderate to severe vasomotor symptoms associated with menopause; treatment of vulvar and vaginal atrophy; hypoestrogenism (due to hypogonadism, castration, or primary ovarian failure); prostatic cancer (palliation); breast cancer (palliation); osteoporosis (prophylaxis, postmenopausal women at significant risk only); abnormal uterine bleeding

Unlabeled/Investigational Use Uremic bleeding

Mechanism of Action Conjugated estrogens contain a mixture of estrone sulfate, equilin sulfate, 17 alpha-dihydroequilin, 17 alpha-estradiol and 17 beta-dihydroequilin. Estrogens are responsible for the development and maintenance of the female reproductive system and secondary sexual characteristics. Estradiol is the principle intracellular human estrogen and is more potent than estrone and estril at the receptor level; it is the primary estrogen secreted prior to menopause. Following menopause, estrone and estrone sulfate are more highly produced. Estrogens modulate the pituitary secretion of gonadotropins, luteinizing hormone, and follicle-stimulating hormone through a negative feedback system; estrogen replacement reduces elevated levels of these hormones in postmenopausal women.

Adverse Reactions

Cardiovascular: Edema, hypertension, venous thromboembolism, myocardial infarction, stroke

Central nervous system: Dizziness, **headache (26% to 32%)**, mental depression, migraine, epilepsy exacerbation, irritability, mood disturbances, nervousness

Dermatologic: Chloasma, erythema multiforme, erythema nodosum, hemorrhagic eruption, hirsutism, loss of scalp hair, melasma, angioedema, pruritus, rash, urticaria

Endocrine & metabolic: Breast cancer, breast enlargement, breast tenderness, changes in libido, increased thyroid-binding globulin, increased total thyroid hormone (T₄), increased serum triglycerides/phospholipids, increased HDL-cholesterol, decreased LDL-cholesterol, impaired glucose tolerance, hypercalcemia, hypocalcemia

Gastrointestinal: Abdominal cramps, bloating, cholecystitis, cholelithiasis, gallbladder disease, nausea, pancreatitis, vomiting, weight gain/loss

Genitourinary: Alterations in frequency and flow of menses, changes in cervical secretions, endometrial cancer, increased size of uterine leiomyomata, vaginal candidiasis, endometrial hyperplasia

Hematologic: Aggravation of porphyria, decreased antithrombin III and antifactor Xa, increased levels of fibrinogen, increased platelet aggregability and platelet count; increased prothrombin and factors VII, VIII, IX, X

Hepatic: Cholestatic jaundice, hepatic hemangiomas enlarged

Local: Thrombophlebitis

Neuromuscular & skeletal: Chorea, arthralgias, leg cramps

Ocular: Intolerance to contact lenses, steepening of corneal curvature, retinal vascular thrombosis

Respiratory: Pulmonary thromboembolism, asthma exacerbation

Miscellaneous: Carbohydrate intolerance, anaphylactoid/anaphylactic reactions

Signs and Symptoms of Overdose Depression, dizziness, ectopic pregnancy, fluid retention, gynecomastia, hypophosphatemia, impotence, jaundice, sexual dysfunction, thrombophlebitis

Pharmacodynamics/Kinetics

Absorption: Well absorbed

Metabolism: Hepatic via CYP3A4; estradiol is converted to estrone and estril; also undergoes enterohepatic recirculation; estrone sulfate is the main metabolite in postmenopausal women

Excretion: Urine (primarily estril, also as estradiol, estrone, and conjugates)

Dosage Adults:

Male: Androgen-dependent prostate cancer: Oral: 1.25-2.5 mg 3 times/day

Female:

Prevention of osteoporosis in postmenopausal women: Oral: Initial: 0.3 mg/day cyclically* or daily, depending on medical assessment of patient. Dose may be adjusted based on bone mineral density and clinical response. The lowest effective dose should be used.

Moderate to severe vasomotor symptoms associated with menopause: Oral: Initial: 0.3 mg/day, cyclically* or daily, depending on medical assessment of patient. The lowest dose that will control symptoms should be used. Medication should be discontinued as soon as possible.

Vulvar and vaginal atrophy:

Oral: Initial: 0.3 mg/day; the lowest dose that will control symptoms should be used. May be given cyclically* or daily, depending on medical assessment of patient. Medication should be discontinued as soon as possible.

Vaginal cream: Intravaginal: $\frac{1}{2}$ to 2 g/day given cyclically*

Abnormal uterine bleeding:

Acute/heavy bleeding:

Oral (unlabeled route): 1.25 mg, may repeat every 4 hours for 24 hours, followed by 1.25 mg once daily for 7-10 days

I.V.: 25 mg, may repeat in 6-12 hours if needed

Note: Oral/I.V.: Treatment should be followed by a low-dose oral contraceptive; medroxyprogesterone acetate along with or following estrogen therapy can also be given

Nonacute/lesser bleeding: Oral (unlabeled route): 1.25 mg once daily for 7-10 days

Female hypogonadism: Oral: 0.3-0.625 mg/day given cyclically*; dose may be titrated in 6- to 12-month intervals; progestin treatment should be added to maintain bone mineral density once skeletal maturity is achieved.

Female castration, primary ovarian failure: Oral: 1.25 mg/day given cyclically*; adjust according to severity of symptoms and patient response. For maintenance, adjust to the lowest effective dose.

***Cyclic administration:** Either 3 weeks on, 1 week off or 25 days on, 5 days off

Male and Female:

Breast cancer palliation, metastatic disease in selected patients: Oral: 10 mg 3 times/day for at least 3 months

Uremic bleeding (unlabeled use): I.V.: 0.6 mg/kg/day for 5 days

Elderly: Refer to Adults dosing; a higher incidence of stroke and invasive breast cancer was observed in women >75 years in a WHI substudy.

Stability

Injection: Refrigerate at 2°C to 8°C (36°F to 46°F) prior to reconstitution. Reconstitute using provided diluent; do not shake violently. Following reconstitution, solution is stable for 60 days under refrigeration.

Compatible with normal saline, dextrose

Incompatible with ascorbic acid

Tablets, vaginal cream: Store at room temperature (25°C)

Monitoring Parameters Yearly physical examination that includes blood pressure and Papanicolaou smear, breast exam, mammogram. Monitor for signs of endometrial cancer in female patients with uterus. Adequate diagnostic measures, including endometrial sampling, if indicated, should be performed to rule out malignancy in all cases of undiagnosed abnormal vaginal bleeding.

Menopausal symptoms: Assess need for therapy at 3- to 6-month intervals

Prevention of osteoporosis: Bone density measurement

Administration Injection: May also be administered intramuscularly; when administered I.V., drug should be administered slowly to avoid the occurrence of a flushing reaction

Oral tablet, vaginal cream: Administer at bedtime to minimize adverse effects.

Contraindications Hypersensitivity to estrogens or any component of the formulation; undiagnosed abnormal vaginal bleeding; history of or current thrombophlebitis or venous thromboembolic disorders (including DVT, PE); active or recent (within 1 year) arterial thromboembolic disease (eg, stroke, MI); carcinoma of the breast (except in appropriately selected patients being treated for metastatic disease); estrogen-dependent tumor; hepatic dysfunction or disease; pregnancy

Warnings

Cardiovascular-related considerations: **[U.S. Boxed Warning]: Estrogens with or without progestin should not be used to prevent coronary heart disease.** Use caution with cardiovascular disease or dysfunction. May increase the risks of hypertension, myocardial infarction (MI), stroke, pulmonary emboli (PE), and deep vein thrombosis; incidence of these effects was shown to be significantly increased in postmenopausal women using conjugated equine estrogens (CEE) in combination with medroxyprogesterone acetate (MPA). Nonfatal MI, PE, and thrombophlebitis have also been reported in males taking high doses of CEE (eg, for prostate cancer). Estrogen compounds are generally associated with lipid effects such as increased HDL-cholesterol and decreased LDL-cholesterol. Triglycerides may also be in-

creased; use with caution in patients with familial defects of lipoprotein metabolism. Whenever possible, estrogens should be discontinued at least 4 weeks prior to and for 2 weeks following elective surgery associated with an increased risk of thromboembolism or during periods of prolonged immobilization.

Neurological considerations: **[U.S. Boxed Warning]: The risk of dementia may be increased in postmenopausal women;** increased incidence was observed in women ≥ 65 years of age taking CEE alone or in combination with MPA.

Cancer-related considerations: **[U.S. Boxed Warning]: Unopposed estrogens may increase the risk of endometrial carcinoma in postmenopausal women.** Estrogens may exacerbate endometriosis. Malignant transformation of residual endometrial implants has been reported posthysterectomy with estrogen only therapy. Consider adding a progestin in women with residual endometriosis posthysterectomy. Estrogens may increase the risk of breast cancer. An increased risk of invasive breast cancer was observed in postmenopausal women using CEE in combination with MPA; a smaller increase in risk was seen with estrogen therapy alone in observational studies. An increase in abnormal mammograms has also been reported with estrogen and progestin therapy. Estrogen use may lead to severe hypercalcemia in patients with breast cancer and bone metastases; discontinue estrogen if hypercalcemia occurs.

Estrogens may cause retinal vascular thrombosis; discontinue permanently if papilledema or retinal vascular lesions are observed on examination. Use with caution in patients with diseases which may be exacerbated by fluid retention, including asthma, epilepsy, migraine, diabetes or renal dysfunction. Use with caution in patients with a history of severe hypocalcemia, SLE, hepatic hemangiomas, porphyria, endometriosis, and gallbladder disease. Use caution with history of cholestatic jaundice associated with past estrogen use or pregnancy. Safety and efficacy in pediatric patients have not been established. Prior to puberty, estrogens may cause premature closure of the epiphyses, premature breast development in girls or gynecomastia in boys. Vaginal bleeding and vaginal cornification may also be induced in girls.

Before prescribing estrogen therapy to postmenopausal women, the risks and benefits must be weighed for each patient. Women should be informed of these risks and benefits, as well as possible effects of progestin when added to estrogen therapy. Estrogens with or without progestin should be used for shortest duration possible consistent with treatment goals. Conduct periodic risk:benefit assessments.

When used solely for prevention of osteoporosis in women at significant risk, nonestrogen treatment options should be considered. When used solely for the treatment of vulvar and vaginal atrophy, topical vaginal products should be considered. Use caution applying topical products to severely atrophic vaginal mucosa.

Dosage Forms Cream, vaginal: 0.625 mg/g (42.5 g)

Injection, powder for reconstitution: 25 mg [contains lactose 200 mg; diluent contains benzyl alcohol]

Tablet: 0.3 mg, 0.45 mg, 0.625 mg, 0.9 mg, 1.25 mg

Reference Range

Children: <10 mcg/24 hours (SI: <35 $\mu\text{mol/day}$) (values at Mayo Medical Laboratories)

Adults:

Male: 15-40 mcg/24 hours (SI: 52-139 $\mu\text{mol/day}$)

Female:

Menstruating: 15-80 mcg/24 hours (SI: 52-277 $\mu\text{mol/day}$)

Postmenopausal: <20 mcg/24 hours (SI: <69 $\mu\text{mol/day}$)

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage within 1 hour; activated charcoal

Enhancement of elimination: Due to enterohepatic recirculation of drug, multiple dosing of activated charcoal may be effective

Test Interactions Pathologist should be advised of estrogen/progesterone therapy when specimens are submitted. Reduced response to metyrapone test.

Drug Interactions

Based on estradiol and estrone: **Substrate** of CYP1A2 (major), 2A6 (minor), 2B6 (minor), 2C9 (minor), 2C19 (minor), 2D6 (minor), 2E1 (minor), 3A4 (major); **Inhibits** CYP1A2 (weak), 2C8 (weak); **Induces** CYP3A4 (weak)

Anticoagulants: Increase potential for thromboembolic events

Cyclosporine: Estrogen derivatives may enhance the hepatotoxic effect of cyclosporine. Estrogen derivatives may increase the serum concentration of cyclosporine.

CYP1A2 inducers: May decrease the levels/effects of estrogens. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of estrogens. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

Thyroid products: Estrogen derivatives may diminish the therapeutic effect of thyroid products; monitor.

Pregnancy Risk Factor X

Pregnancy Implications Increased risk of fetal reproductive tract disorders and other birth defects; do not use during pregnancy

Lactation Enters breast milk/use caution

Nursing Implications May also be administered intramuscularly; give at bedtime to minimize occurrence of adverse effects; when administered I.V., drug should be administered slowly to avoid the occurrence of a flushing reaction

Additional Information

The use of estrogens for the prevention of other chronic diseases, as well as their potential negative effects on women's health, has been debated. Data published from the Women's Health Initiative (WHI) has provided some additional insight on this controversial topic. In the WHI, one arm of the study compared postmenopausal women with an intact uterus using CEE 0.625 mg in combination with MPA 2.5 mg daily, versus placebo. This arm of the study was stopped in 2002. In March, 2004, it was announced that the arm of the study comparing placebo to CEE alone in postmenopausal women without a uterus was ended.

Based on preliminary findings, the FDA has requested labeling changes be made to estrogen products used in postmenopausal women. The updates include information from the Women's Health Initiative Memory Study (WHIMS) as well as information collected from the completed CEE/MPA arm of the WHI study. Complete analysis of the WHI data is forthcoming, and will include all information collected through February, 2004.

Pharmacodynamics/Kinetics

Absorption: Readily

Metabolism: Rapidly hepatic to estrone sulfate, conjugated and unconjugated metabolites; first-pass effect

Excretion: Urine (as unchanged drug and as glucuronide and sulfate conjugates)

Dosage

Oral: Adults:

Prostate cancer (palliation): 1.25-2.5 mg 3 times/day

Female hypogonadism: 2.5-7.5 mg of estrogen daily for 20 days followed by a 10-day rest period. Administer cyclically (3 weeks on and 1 week off). If bleeding does not occur by the end of the 10-day period, repeat the same dosing schedule; the number of courses is dependent upon the responsiveness of the endometrium. If bleeding occurs before the end of the 10-day period, begin an estrogen-progestin cyclic regimen of 2.5-7.5 mg esterified estrogens daily for 20 days. During the last 5 days of estrogen therapy, give an oral progestin. If bleeding occurs before regimen is concluded, discontinue therapy and resume on the fifth day of bleeding.

Moderate to severe vasomotor symptoms associated with menopause: 1.25 mg/day administered cyclically (3 weeks on and 1 week off). If patient has not menstruated within the last 2 months or more, cyclic administration is started arbitrary. If the patient is menstruating, cyclic administration is started on day 5 of the bleeding. For short-term use only and should be discontinued as soon as possible. Re-evaluate at 3- to 6-month intervals for tapering or discontinuation of therapy.

Atopic vaginitis and kraurosis vulvae: 0.3 to \geq 1.25 mg/day, depending on the tissue response of the individual patient. Administer cyclically. For short-term use only and should be discontinued as soon as possible. Re-evaluate at 3- to 6-month intervals for tapering or discontinuation of therapy.

Breast cancer (palliation): 10 mg 3 times/day for at least 3 months

Osteoporosis in postmenopausal women: Initial: 0.3 mg/day and increase to a maximum daily dose of 1.25 mg/day; initiate therapy as soon as possible after menopause; cyclically or daily, depending on medical assessment of patient. Monitor patients with an intact uterus for signs of endometrial cancer; rule out malignancy if unexplained vaginal bleeding occurs

Female castration and primary ovarian failure: 1.25 mg/day, cyclically. Adjust dosage upward or downward, according to the severity of symptoms and patient response. For maintenance, adjust dosage to lowest level that will provide effective control.

Elderly: Refer to Adults dosing. A higher incidence of stroke and invasive breast cancer were observed in women >75 years in a Women's Health Initiative (WHI) substudy using conjugated equine estrogen.

Dosing adjustment in hepatic impairment:

Mild to moderate liver impairment: Dosage reduction of estrogens is recommended

Severe liver impairment: **Not recommended**

Monitoring Parameters

Yearly physical examination that includes blood pressure and Papanicolaou smear, breast exam, mammogram. Monitor for signs of endometrial cancer in female patients with uterus. Adequate diagnostic measures, including endometrial sampling, if indicated, should be performed to rule out malignancy in all cases of undiagnosed abnormal vaginal bleeding.

Menopausal symptoms: Assess need for therapy at 3- to 6-month intervals

Prevention of osteoporosis: Bone density measurement

Contraindications Hypersensitivity to estrogens or any component of the formulation; undiagnosed abnormal vaginal bleeding; history of or current thrombophlebitis or venous thromboembolic disorders (including DVT, PE); active or recent (within 1 year) arterial thromboembolic disease (eg, stroke, MI); carcinoma of the breast, except in appropriately selected patients being treated for metastatic disease; estrogen-dependent tumor; hepatic dysfunction or disease; pregnancy

Warnings

Cardiovascular-related considerations: **[U.S. Boxed Warning]: Estrogens with or without progestin should not be used to prevent coronary heart disease.** Use caution with cardiovascular disease or dysfunction. May increase the risks of hypertension, myocardial infarction (MI), stroke, pulmonary emboli (PE), and deep vein thrombosis; incidence of these effects was shown to be significantly increased in postmenopausal women using conjugated equine estrogens (CEE) in combination with medroxyprogesterone acetate (MPA). Nonfatal MI, PE, and thrombophlebitis have also been reported in males taking high doses of CEE (eg, for prostate cancer). Estrogen compounds are generally associated with lipid effects such as increased HDL-cholesterol and decreased LDL-cholesterol. Triglycerides may also be increased; use with caution in patients with familial defects of lipoprotein metabolism. Whenever possible, estrogens should be discontinued at least 4 weeks prior to and for 2 weeks following elective surgery associated with an increased risk of thromboembolism or during periods of prolonged immobilization.

Estrogens (Esterified)**U.S. Brand Names** Menest®**Synonyms** Esterified Estrogens

Use Treatment of moderate to severe vasomotor symptoms associated with menopause; treatment of vulvar and vaginal atrophy; hypoestrogenism (due to hypogonadism, castration, or primary ovarian failure); prostatic cancer (palliation); breast cancer (palliation); osteoporosis (prophylaxis, in women at significant risk only)

Mechanism of Action All estrogens, including esterified estrogens, act in a similar manner. Estrogens exert their primary effects on the interphase DNA-protein complex (chromatin) by binding to a receptor (usually located in the cytoplasm of a target cell) and initiating translocation of the hormone-receptor complex to the nucleus. The specificity of estrogen action depends upon the presence and concentration of estrogen targets, which are defined as tissues containing a high concentration of estrogen receptors.

Adverse Reactions

Cardiovascular: Edema, hypertension, venous thromboembolism

Central nervous system: Dizziness, headache, mental depression, migraine

Dermatologic: Chloasma, erythema multiforme, erythema nodosum, hemorrhagic eruption, hirsutism, loss of scalp hair, melasma

Endocrine & metabolic: Breast enlargement, breast tenderness, changes in libido, increased thyroid-binding globulin, increased total thyroid hormone (T₄), increased serum triglycerides/phospholipids, increased HDL cholesterol, decreased LDL cholesterol, impaired glucose tolerance, hypercalcemia

Gastrointestinal: Abdominal cramps, bloating, cholecystitis, cholelithiasis, gallbladder disease, nausea, pancreatitis, vomiting, weight gain/loss

Genitourinary: Alterations in frequency and flow of menses, changes in cervical secretions, endometrial cancer, increased size of uterine leiomyomata, vaginal candidiasis

Hematologic: Aggravation of porphyria, decreased antithrombin III and antifactor Xa, increased levels of fibrinogen, increased platelet aggregability and platelet count; increased prothrombin and factors VII, VIII, IX, X

Hepatic: Cholestatic jaundice

Neuromuscular & skeletal: Chorea

Ocular: Intolerance to contact lenses, steepening of corneal curvature

Respiratory: Pulmonary thromboembolism

Miscellaneous: Carbohydrate intolerance

Signs and Symptoms of Overdose Toxicity is unlikely following single exposures of excessive doses. Fluid retention, gynecomastia, hypophosphatemia, impotence, jaundice, migraine headache (exacerbation), sexual dysfunction, thrombophlebitis

Neurological considerations: **[U.S. Boxed Warning]: The risk of dementia may be increased in postmenopausal women;** increased incidence was observed in women ≥ 65 years of age taking CEE alone or in combination with MPA.

Cancer-related considerations: **[U.S. Boxed Warning]: Unopposed estrogens may increase the risk of endometrial carcinoma in postmenopausal women.** Estrogens may exacerbate endometriosis. Malignant transformation of residual endometrial implants has been reported post-hysterectomy with estrogen only therapy. Consider adding a progestin in women with residual endometriosis post-hysterectomy. Estrogens may increase the risk of breast cancer. An increased risk of invasive breast cancer was observed in postmenopausal women using CEE in combination with MPA; a smaller increase in risk was seen with estrogen therapy alone in observational studies. An increase in abnormal mammograms has also been reported with estrogen and progestin therapy. Estrogen use may lead to severe hypercalcemia in patients with breast cancer and bone metastases; discontinue estrogen if hypercalcemia occurs.

Estrogens may cause retinal vascular thrombosis; discontinue permanently if papilledema or retinal vascular lesions are observed on examination. Use with caution in patients with diseases which may be exacerbated by fluid retention, including asthma, epilepsy, migraine, diabetes or renal dysfunction. Use with caution in patients with a history of severe hypocalcemia, SLE, hepatic hemangiomas, porphyria, endometriosis, and gallbladder disease. Use caution with history of cholestatic jaundice associated with past estrogen use or pregnancy. Safety and efficacy in pediatric patients have not been established. Prior to puberty, estrogens may cause premature closure of the epiphyses, premature breast development in girls or gynecomastia in boys. Vaginal bleeding and vaginal cornification may also be induced in girls.

Before prescribing estrogen therapy to postmenopausal women, the risks and benefits must be weighed for each patient. Women should be informed of these risks and benefits, as well as possible effects of progestin when added to estrogen therapy. Estrogens with or without progestin should be used for shortest duration possible consistent with treatment goals. Conduct periodic risk/benefit assessments.

When used solely for prevention of osteoporosis in women at significant risk, nonestrogen treatment options should be considered. When used solely for the treatment of vulvar and vaginal atrophy, topical vaginal products should be considered.

Dosage Forms Tablet: 0.3 mg, 0.625 mg, 1.25 mg, 2.5 mg

Reference Range

Children: < 10 mcg/24 hours (SI: < 35 $\mu\text{mol/day}$) (values at Mayo Medical Laboratories)

Adults:

Male: 15-40 mcg/24 hours (SI: 52-139 $\mu\text{mol/day}$)

Female:

Menstruating: 15-80 mcg/24 hours (SI: 52-277 $\mu\text{mol/day}$)

Postmenopausal: < 20 mcg/24 hours (SI: < 69 $\mu\text{mol/day}$)

Overdose/Treatment Toxicity is unlikely following single exposures of excessive doses, any treatment following emesis and charcoal administration should be supportive and symptomatic. Effects noted after large doses include headache, nausea, and vomiting. Bleeding may occur in females.

Test Interactions Pathologist should be advised of estrogen/progestin therapy when specimens are submitted. Reduced response to metyrapone test.

Drug Interactions

Based on estrone: **Substrate** of CYP1A2 (major), 2B6 (minor), 2C9 (minor), 2E1 (minor), 3A4 (major)

Anticoagulants: Increases potential for thromboembolic events with anticoagulants

Corticosteroids: Estrogens may enhance the effects of hydrocortisone and prednisone.

Cyclosporine: Estrogen derivatives may enhance the hepatotoxic effect of cyclosporine. Estrogen derivatives may increase the serum concentration of cyclosporine.

CYP1A2 inducers: May decrease the levels/effects of estrogens. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of estrogens. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

Thyroid products: Estrogen derivatives may diminish the therapeutic effect of thyroid products; monitor.

Pregnancy Risk Factor X

Pregnancy Implications Increased risk of fetal reproductive tract disorders and other birth defects; do not use during pregnancy

Lactation Enters breast milk/use caution

Additional Information

The use of estrogens for the prevention of other chronic diseases, as well as their potential negative effects on women's health, has been debated. Data published from the Women's Health Initiative (WHI) has provided

some additional insight on this controversial topic. In the WHI, one arm of the study compared postmenopausal women with an intact uterus using CEE 0.625 mg in combination with MPA 2.5 mg daily, versus placebo. This arm of the study was stopped in 2002. In March, 2004, it was announced that the arm of the study comparing placebo to CEE alone in postmenopausal women without a uterus was ended.

Based on preliminary findings, the FDA has requested labeling changes be made to estrogen products used in postmenopausal women. The updates include information from the Women's Health Initiative Memory Study (WHIMS) as well as information collected from the completed CEE/MPA arm of the WHI study. Complete analysis of the WHI data is forthcoming, and will include all information collected through February, 2004.

Ethacrynic Acid

CAS Number 58-54-8

U.S. Brand Names Edecrin®

Synonyms Ethacrynate Sodium

Use Management of edema secondary to congestive heart failure; hepatic or renal disease, hypertension

Mechanism of Action Inhibits reabsorption of sodium and chloride in the ascending loop of Henle and distal renal tubule, interfering with the chloride-binding cotransport system, thus causing increased excretion of water, sodium, chloride, magnesium, and calcium

Adverse Reactions

Cardiovascular: Hypotension, diuresis

Dermatologic: Rash

Endocrine & metabolic: Fluid and electrolyte imbalances (fluid depletion, hypokalemia, hyponatremia, hyperglycemia), hyperuricemia

Gastrointestinal: GI irritation, **diarrhea**, GI bleeding (especially when used with warfarin); feces discoloration (black)

Hematologic: Thrombocytopenia, leukopenia, neutropenia, agranulocytosis, granulocytopenia

Hepatic: Abnormal liver function tests

Otic: Ototoxicity, tinnitus, deafness

Renal: Renal injury

Signs and Symptoms of Overdose Agranulocytosis, dizziness, dysosmia, gout, granulocytopenia, hyperglycemia, hyperuricemia, hypocalcemia, hypoglycemia, hypokalemia, hypomagnesemia, hyponatremia, hypotension, leukopenia, myasthenia gravis (exacerbation or precipitation), thrombocytopenia, neutropenia, nocturia, nystagmus, pancreatitis

Pharmacodynamics/Kinetics

Onset of action: Diuresis: Oral: ~ 30 minutes; I.V.: 5 minutes

Peak effect: Oral: 2 hours; I.V.: 30 minutes

Duration: Oral: 12 hours; I.V.: 2 hours

Absorption: Oral: Rapid

Protein binding: $> 90\%$

Metabolism: Hepatic (35% to 40%) to active cysteine conjugate

Half-life elimination: Normal renal function: 2-4 hours

Excretion: Feces and urine (30% to 60% as unchanged drug)

Dosage

Children:

Oral: 25 mg/day to start, increase by 25 mg/day at intervals of 2-3 days as needed, to a maximum of 3 mg/kg/day

I.V.: 1 mg/kg/dose, (maximum: 50 mg/dose); repeat doses not recommended

Adults:

Oral: 50-100 mg/day in 1-2 divided doses; may increase in increments of 25-50 mg at intervals of several days to a maximum of 400 mg/24 hours

I.V.: 0.5-1 mg/kg/dose (maximum: 100 mg/dose); repeat doses not recommended

Dosing adjustment/comments in renal impairment: $\text{Cl}_{\text{cr}} < 10$ mL/minute: Avoid use

Monitoring Parameters Blood pressure, renal function, serum electrolytes, and fluid status closely, including weight and I & O daily; hearing

Administration Injection should **not** be given SubQ or I.M. due to local pain and irritation; single I.V. doses should not exceed 100 mg; if a second dose is needed, use a new injection site to avoid possible thrombophlebitis

Contraindications Hypersensitivity to ethacrynic acid or any component of the formulation; anuria; history of severe watery diarrhea caused by this product; infants

Warnings Adjust dose to avoid dehydration. In cirrhosis, avoid electrolyte and acid/base imbalances that might lead to hepatic encephalopathy. Ototoxicity is associated with rapid I.V. administration, renal impairment, excessive doses, and concurrent use of other ototoxins. Has been associated with a higher incidence of ototoxicity than other loop diuretics. Hypersensitivity reactions can rarely occur, however, ethacrynic acid has no cross-reactivity to sulfonamides or sulfonyleureas. Monitor fluid status and renal function in an attempt to prevent oliguria, azotemia, and reversible increases in BUN and creatinine. Close medical supervision of aggressive diuresis required. Watch for and correct electrolyte disturbances. Coadministration of antihypertensives may increase the risk of

ETHAMBUTOL

hypotension. Increased risk of gastric hemorrhage associated with corticosteroid therapy.

Dosage Forms

Injection, powder for reconstitution, as ethacrynic acid sodium: 50 mg
Tablet: 25 mg

Overdosage/Treatment

Decontamination: Activated charcoal for gastric decontamination
Supportive therapy: I.V. hydration with 0.9% saline; replace electrolyte deficiency

Drug Interactions

ACE inhibitors: Hypotensive effects and/or renal effects are potentiated by hypovolemia.
Antidiabetic agents: Glucose tolerance may be decreased.
Antihypertensive agents: Hypotensive effects may be enhanced.
Cephaloridine or cephalexin: Nephrotoxicity may occur.
Cholestyramine or colestipol may reduce bioavailability of ethacrynic acid.
Clofibrate: Protein binding may be altered in hypoalbuminemic patients receiving ethacrynic acid, potentially increasing toxicity.
Digoxin: Ethacrynic acid-induced hypokalemia may predispose to digoxin toxicity; monitor potassium.
Indomethacin (and other NSAIDs) may reduce natriuretic and hypotensive effects of diuretics.
Lithium: Renal clearance may be reduced. Isolated reports of lithium toxicity have occurred; monitor lithium levels.
NSAIDs: Risk of renal impairment may increase when used in conjunction with diuretics.
Ototoxic drugs (aminoglycosides, cis-platinum): Concomitant use of ethacrynic acid may increase risk of ototoxicity, especially in patients with renal dysfunction.
Peripheral adrenergic-blocking drugs or ganglionic blockers: Effects may be increased.
Salicylates (high-dose) with diuretics may predispose patients to salicylate toxicity due to reduced renal excretion or alter renal function.
Thiazides: Synergistic diuretic effects occur.

Pregnancy Risk Factor B

Pregnancy Implications No data available. Generally, use of diuretics during pregnancy is avoided due to risk of decreased placental perfusion.

Lactation

Contraindicated
Nursing Implications Tissue irritant; not to be administered I.M. or SubQ; dilute injection with 50 mL dextrose 5% or normal saline (1 mg/mL concentration resulting); may be injected without further dilution over a period of several minutes or infused over 20-30 minutes
Monitor blood pressure, serum electrolytes, renal function, hearing

Additional Information Injection contains thimerosal

Specific References

Wall GC, Bigner D, and Craig S, "Ethacrynic Acid and the Sulfa-Sensitive Patient," *Arch Intern Med*, 2003, 163(1):116-7.

Admission Criteria/Prognosis Admit any patient with CNS abnormalities or ingestions >8 g in adults

Pharmacodynamics/Kinetics

Absorption: ~80%
Distribution: Widely throughout body; concentrated in kidneys, lungs, saliva, and red blood cells
Relative diffusion from blood into CSF: Adequate with or without inflammation (exceeds usual MICs)
CSF:blood level ratio: Normal meninges: 0%; Inflamed meninges: 25%
Protein binding: 20% to 30%
Metabolism: Hepatic (20%) to inactive metabolite
Half-life elimination: 2.5-3.6 hours; End-stage renal disease: 7-15 hours
Time to peak, serum: 2-4 hours
Excretion: Urine (~50%) and feces (20%) as unchanged drug

Dosage

Oral:

Ethambutol is generally not recommended in children whose visual acuity cannot be monitored. However, ethambutol should be considered for all children with organisms resistant to other drugs, when susceptibility to ethambutol has been demonstrated, or susceptibility is likely.

Note: A four-drug regimen (isoniazid, rifampin, pyrazinamide, and either streptomycin or ethambutol) is preferred for the initial, empiric treatment of TB. When the drug susceptibility results are available, the regimen should be altered as appropriate.

Children and Adults:

Daily therapy: 15-25 mg/kg/day (maximum: 2.5 g/day)
Directly observed therapy (DOT): Twice weekly: 50 mg/kg (maximum: 2.5 g)

DOT: 3 times/week: 25-30 mg/kg (maximum: 2.5 g)

Adults: Treatment of disseminated *Mycobacterium avium* complex (MAC) in patients with advanced HIV infection: 15 mg/kg ethambutol in combination with azithromycin 600 mg daily

Dosing interval in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer every 24-36 hours

Cl_{cr} <10 mL/minute: Administer every 48 hours

Hemodialysis: Slightly dialyzable (5% to 20%); Administer dose post-dialysis

Peritoneal dialysis: Dose for Cl_{cr} <10 mL/minute

Continuous arteriovenous or venovenous hemofiltration: Administer every 24-36 hours

Monitoring Parameters Baseline and periodic (monthly) visual testing (each eye individually, as well as both eyes tested together) in patients receiving >15 mg/kg/day; baseline and periodic renal, hepatic, and hematopoietic tests

Contraindications Hypersensitivity to ethambutol or any component of the formulation; optic neuritis; use in children, unconscious patients, or any other patient who may be unable to discern and report visual changes

Warnings May cause optic neuritis, resulting in decreased visual acuity or other vision changes. Discontinue promptly in patients with changes in vision, color blindness, or visual defects (effects normally reversible, but reversal may require up to a year). Use only in children whose visual acuity can accurately be determined and monitored (not recommended for use in children <13 years of age unless the benefit outweighs the risk). Dosage modification is required in patients with renal insufficiency. Hepatic toxicity has been reported, possibly due to concurrent therapy.

Dosage Forms Tablet, as hydrochloride: 100 mg, 400 mg

Reference Range Peak plasma ethambutol level after a dose of 25 mg/kg: ~5 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal/lavage within 1 hour
Supportive therapy: Replace potassium/sodium losses
Enhancement of elimination: Slightly dialyzable (5% to 20%) and possibly effective

Test Interactions ↑ uric acid (S)

Drug Interactions Decreased absorption with aluminum hydroxide. Avoid concurrent administration of aluminum-containing antacids for at least 4 hours following ethambutol.

Pregnancy Risk Factor B

Pregnancy Implications There are no adequate and well-controlled studies in pregnant women; teratogenic effects have been seen in animals. Ethambutol has been used safely during pregnancy.

Lactation Enters breast milk/use caution (AAP considers "compatible")
Additional Information Incidence of optic neuropathy increases significantly with dosages above 15 mg/kg/day but may be idiosyncratic

Ethchlorvynol

Related Information

• Therapeutic Drugs Associated with Hallucinations

CAS Number 113-18-8

Impairment Potential Yes

Use Short-term management of insomnia

Mechanism of Action A chlorinated acetylenic carbinol which causes nonspecific depression of the reticular activating system

Ethambutol

Related Information

• Therapeutic Drugs Associated with Hallucinations

CAS Number 1070-11-7

U.S. Brand Names Myambutol®

Synonyms Ethambutol Hydrochloride

Use Treatment of tuberculosis and other mycobacterial diseases in conjunction with other antituberculosis agents

Mechanism of Action Suppresses mycobacteria multiplication by interfering with RNA synthesis

Adverse Reactions

Cardiovascular: Myocarditis, pericarditis
Central nervous system: Headache, confusion, disorientation, malaise, mental confusion, fever, dizziness, hallucinations
Dermatologic: Rash, pruritus, dermatitis, exfoliative dermatitis
Endocrine & metabolic: Acute gout or hyperuricemia
Gastrointestinal: Abdominal pain, anorexia, nausea, vomiting
Hematologic: Leukopenia, thrombocytopenia, eosinophilia, neutropenia, lymphadenopathy
Hepatic: Abnormal LFTs, hepatotoxicity (possibly related to concurrent therapy), hepatitis
Neuromuscular & skeletal: Peripheral neuritis, arthralgia
Ocular: Optic neuritis; symptoms may include decreased acuity, scotoma, color blindness, or visual defects (usually reversible with discontinuation, irreversible blindness has been described)
Renal: Nephritis
Respiratory: Infiltrates (with or without eosinophilia), pneumonitis
Miscellaneous: Anaphylaxis, anaphylactoid reaction; hypersensitivity syndrome (rash, eosinophilia, and organ-specific inflammation)

Signs and Symptoms of Overdose Alopecia, anorexia, arthralgia, blindness, disorientation, eosinophilia, fever, hallucinations, hyperuricemia, jaundice, mental confusion, nausea, neuropathy (peripheral), neutropenia, numbness of the extremities, optic neuropathy, purpura, toxic epidermal necrolysis, visual changes, vomiting

Adverse Reactions

Cardiovascular: Bradycardia, sinus bradycardia
 Central nervous system: Facial numbness, residual sedation, headache, **dizziness**, psychosis, nervousness, excitation, clumsiness, confusion, drowsiness (daytime), visual hallucinations, slurred speech, retrograde amnesia, gustatory hallucinations
 Dermatologic: Rash
 Gastrointestinal: **Nausea, indigestion, stomach pain, unpleasant aftertaste**, vomiting
 Genitourinary: Urinary retention
 Hematologic: Thrombocytopenia, porphyria, pancytopenia
 Hepatic: Jaundice
 Neuromuscular & skeletal: **Weakness**, trembling
 Ocular: **Blurred vision**, diplopia, mydriasis, nystagmus
 Renal: Myoglobinuria
 Respiratory: Dyspnea
 Miscellaneous: **Unpleasant aftertaste** (mint-like)

Signs and Symptoms of Overdose Ataxia, bradycardia, bullous skin lesions, cough, hypotension, hypothermia, myopathy, numbness, pleural effusion, prolonged coma lasting over 100 hours, pulmonary edema, respiratory depression, rhabdomyolysis

Pharmacodynamics/Kinetics

Onset of action: 15-60 minutes
 Duration: 5 hours
 Absorption: Rapidly
 Metabolism: Hepatic
 Half-life elimination: 10-20 hours
 Time to peak, serum: 2 hours
 Excretion: Urine

Dosage Adults: Oral: 500-1000 mg at bedtime

Dosing adjustment in renal impairment: $Cl_{cr} < 50$ mL/minute: Avoid use

Monitoring Parameters Cardiac and respiratory function and abuse potential

Contraindications Hypersensitivity to ethchlorvynol or any component of the formulation; porphyria

Warnings Administer with caution to depressed or suicidal patients or to patients with a history of drug abuse; intoxication symptoms may appear with prolonged daily doses of as little as 1 g; withdrawal symptoms may be seen upon abrupt discontinuation; use with caution in the elderly and in patients with hepatic or renal dysfunction; use with caution in patients who have a history of paradoxical restlessness to barbiturates or alcohol; some products may contain tartrazine

Dosage Forms Capsule: 200 mg, 500 mg, 750 mg

Reference Range

Therapeutic: 2-8 mcg/mL
 Toxic: >20 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Hypotension can be treated with isotonic saline infusion (10-20 mL/kg), and/or dopamine or norepinephrine
 Enhancement of elimination: Multiple dosing of activated charcoal is effective for ingestions > 10 g (or over 100 mg/kg); or for prolonged coma; hemodialysis (or preferably hemoperfusion) should be initiated; consider hemodialysis/hemoperfusion if ethchlorvynol serum levels are > 10 mcg/mL; monitor for rebound effect with redistribution of drug from fat storage; thus prolonged or repeated hemoperfusion may be needed; ~17% to 23% of the drug can be removed during 4 hours of hemodialysis or hemoperfusion

Antidote(s)

- DOPamine [ANTIDOTE]
- Norepinephrine [ANTIDOTE]

Drug Interactions

CNS depressants: Sedative effects may be additive with other CNS depressants; monitor for increased effect; includes benzodiazepines, barbiturates, antipsychotics, ethanol, and other sedative medications
 Warfarin: May inhibit the hypoprothrombinemic response to warfarin via an unknown mechanism; monitor for altered anticoagulant effect or consider using a benzodiazepine

Pregnancy Risk Factor C

Nursing Implications Raise bed rails, institute safety measures, assist with ambulation

Ethionamide

CAS Number 536-33-4

U.S. Brand Names Trecator®-SC

Use In conjunction with other antituberculosis agents in the treatment of tuberculosis and other mycobacterial diseases

Mechanism of Action Inhibits peptide synthesis

Adverse Reactions

Cardiovascular: Postural hypotension
 Central nervous system: Drowsiness, psychosis, dizziness, seizures, headache, peripheral neuritis (sensory neuropathy)
 Dermatologic: Rash

Endocrine & metabolic: Hypoglycemia, goiter, gynecomastia
 Gastrointestinal: **Nausea, vomiting**, abdominal pain, diarrhea, **anorexia**, metallic taste, stomatitis

Hematologic: Thrombocytopenia, porphyria

Hepatic: Hepatitis

Ocular: Optic neuritis, photophobia, diplopia

Signs and Symptoms of Overdose Anorexia, arthralgia, extensor plantar response, hypoglycemia, impotence, neuropathy (peripheral), paresthesias, personality changes, stomatitis, vision color changes (increased color perception)

Pharmacodynamics/Kinetics

Absorption: Rapid, complete
 Distribution: Crosses placenta; V_d : 93.5 L
 Protein binding: ~30%
 Metabolism: Extensively hepatic to active and inactive metabolites
 Bioavailability: 80%
 Half-life elimination: 2-3 hours
 Time to peak, serum: 1 hour
 Excretion: Urine (<1% as unchanged drug; as active and inactive metabolites)

Dosage

Oral:

Children: 15-20 mg/kg/day in 2 divided doses, not to exceed 1 g/day

Adults: 500-1000 mg/day in 1-3 divided doses

Dosing adjustment in renal impairment: $Cl_{cr} < 50$ mL/minute: Administer 50% of dose

Monitoring Parameters Initial and periodic serum ALT and AST

Administration

Neurotoxic effects may be relieved by the administration of pyridoxine (6-100 mg daily, lower doses are more common). May be taken with or without meals. Gastrointestinal adverse effects may be decreased by administration at bedtime, decreased dose, or giving antiemetics.

Contraindications Hypersensitivity to ethionamide or any component of the formulation; severe hepatic impairment

Warnings Use with caution in patients with diabetes mellitus; use with caution in patients receiving cycloserine or isoniazid. Use caution when switching patients from the sugar-coated tablet formulation (Trecator®-SC) to film-coated tablet (Trecator®); the dosage may need retitrated in order to avoid intolerance.

Dosage Forms Tablet: 250 mg

Reference Range Peak serum concentration: 2 mcg/mL after an oral dose of 250 mg

Overdosage/Treatment

Decontamination: Charcoal/lavage within 1 hour as indicated
 Supportive therapy: Neurologic symptoms may resolve with pyridoxine or nicotinamide therapy

Test Interactions ↓ thyroxine (S)

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Lactation Excretion in breast milk unknown/use caution

Ethosuximide**Related Information**

- Therapeutic Drugs Associated with Hallucinations

CAS Number 77-67-8

U.S. Brand Names Zarontin®

Impairment Potential Yes

Use Management of absence (petit mal) seizures, myoclonic seizures, and akinetic epilepsy

Mechanism of Action Increases the seizure threshold and suppresses paroxysmal spike-and-wave pattern in absence seizures; depresses nerve transmission in the motor cortex

Adverse Reactions

Cardiovascular: Raynaud's phenomenon
 Central nervous system: **Sedation, dizziness, drowsiness, euphoria**, visual hallucinations, **insomnia**, psychosis (especially in pediatric patients), **agitation, behavioral changes**, parkinsonism, **headache, ataxia, lethargy, hallucinations**
 Dermatologic: Rashes, **Stevens-Johnson syndrome**, hypertrichosis, alopecia, urticaria, scleroderma, pruritus, exanthem
 Gastrointestinal: **Nausea, vomiting, anorexia** (dose related), **abdominal pain** (epigastric), **weight loss**, gingival hyperplasia
 Hematologic: Leukopenia, aplastic anemia, thrombocytopenia
 Hepatic: Liver enzyme elevation
 Ocular: Photophobia, diplopia
 Miscellaneous: **Hiccups, systemic lupus erythematosus**

Signs and Symptoms of Overdose Agranulocytosis, granulocytopenia, insomnia myasthenia gravis (exacerbation or precipitation), neutropenia
 Acute overdosage can cause ataxia, CNS depression, coma, hypotension, stupor
 Chronic overdose can cause albuminuria, confusion, dementia, erythema multiforme, extrapyramidal reaction, hematuria, hepatic dysfunction, leukopenia, skin rash

ETHOTOIN

Pharmacodynamics/Kinetics

Distribution: Adults: V_d : 0.62-0.72 L/kg
Metabolism: Hepatic (~80% to 3 inactive metabolites)
Half-life elimination, serum: Children: 30 hours; Adults: 50-60 hours
Time to peak, serum: Capsule: ~2-4 hours; Syrup: <2-4 hours
Excretion: Urine, slowly (50% as metabolites, 10% to 20% as unchanged drug); feces (small amounts)

Dosage

Oral:
Children 3-6 years: Initial: 250 mg/day (or 15 mg/kg/day) in 2 divided doses; increase every 4-7 days; usual maintenance dose: 15-40 mg/kg/day in 2 divided doses
Children >6 years and Adults: Initial: 250 mg twice daily; increase by 250 mg as needed every 4-7 days up to 1.5 g/day in 2 divided doses; usual maintenance dose: 20-40 mg/kg/day in 2 divided doses

Monitoring Parameters Seizure frequency, trough serum concentrations; CBC, platelets, liver enzymes, urinalysis

Administration Administer with food or milk to avoid GI upset

Contraindications Hypersensitivity to succinimides or any component of the formulation

Warnings Use with caution in patients with hepatic or renal disease; abrupt withdrawal of the drug may precipitate absence status; ethosuximide may increase tonic-clonic seizures in patients with mixed seizure disorders; ethosuximide must be used in combination with other anticonvulsants in patients with both absence and tonic-clonic seizures. Succinimides have been associated with severe blood dyscrasias and cases of systemic lupus erythematosus. Consider evaluation of blood counts in patients with signs/symptoms of infection. Safety and efficacy in patients <3 years of age have not been established.

Dosage Forms Capsule: 250 mg
Syrup: 250 mg/5 mL (473 mL) [contains sodium benzoate; raspberry flavor]

Reference Range

Therapeutic: 40-100 mcg/mL (SI: 280-710 $\mu\text{mol/L}$)
Toxic: >100 mcg/mL (SI: >710 $\mu\text{mol/L}$); at steady-state, each 1 mg/kg will result in a serum rise of 2 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: Treatment is supportive; benzodiazepine (diazepam or lorazepam) for seizures
Enhanced elimination: Hemoperfusion and hemodialysis may be useful; hemodialysis has an extraction efficiency of 61% to 100%; forced diuresis is not useful; multiple dosing of activated charcoal may be useful; hemodialyzer clearance is ~140 mL/minute

Test Interactions \uparrow alkaline phosphatase (S); positive Coombs' [direct]; \downarrow calcium (S)

Drug Interactions Substrate of CYP3A4 (major)

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, benzodiazepines, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of ethosuximide. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of ethosuximide. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Isoniazid: May inhibit hepatic metabolism of ethosuximide with a resultant increase in ethosuximide serum concentrations

Phenytoin: Ethosuximide may elevate phenytoin levels; phenytoin may decrease ethosuximide levels (see enzyme inducers)

Valproic acid: Has been reported to both increase and decrease ethosuximide levels

Pregnancy Risk Factor C

Pregnancy Implications Low teratogenicity in mice

Lactation Enters breast milk/compatible

Nursing Implications Observe patient for excess sedation

Additional Information Considered to be drug of choice for simple absence seizures

normal seizure threshold and to prevent the spread of seizure activity rather than to abolish the primary focus of seizure discharges. Ethotoin is effective in protecting against electroshock seizures and, to a lesser extent, against pentylenetetrazol-induced seizures in laboratory animals.

Adverse Reactions

Frequency not defined.
Cardiovascular: Arrhythmias, ataxia, cardiovascular collapse, venous irritation and pain
Central nervous system: Psychiatric changes, slurred speech, trembling, dizziness, drowsiness, headache, insomnia
Dermatologic: Skin rash, Stevens-Johnson syndrome
Gastrointestinal: Constipation, nausea, vomiting, gingival hyperplasia, anorexia, weight loss
Hematologic: Leukopenia, blood dyscrasias
Hepatic: Hepatitis
Local: Thrombophlebitis
Neuromuscular & skeletal: Paresthesia, peripheral neuropathy
Ocular: Nystagmus
Renal: Serum creatinine increased
Miscellaneous: Lymphadenopathy, SLE-like syndrome

Signs and Symptoms of Overdose Anemia (megaloblastic), ataxia, bradycardia, coma, diplopia, gingival hyperplasia, hypotension, insomnia, numbness

Toxicodynamics/Kinetics

Absorption: Rapidly although the extent of oral absorption is unknown
Metabolism: Exhibits saturable metabolism relative to the formation of N-diethyl and p-hydroxyethotoin which are the major metabolites
Half-life: 3-9 hours with low plasma levels (<8 mcg/mL); average: ~5 hours; above this concentration, the half-life may be prolonged because of the nonlinear kinetics

Dosage

Oral:
Children: 30-60 mg/kg/day or 250 mg twice daily, may be increased up to 2-3 g/day
Adults: 250 mg 4 times/day after meals, may be increased up to 3 g/day in divided doses 4 times/day

Contraindications Hypersensitivity to ethotoin or any component of the formulation; hepatic abnormalities; hematologic disorders; pregnancy; breast-feeding

Warnings Avoid abrupt withdrawal (can precipitate status epilepticus); hypersensitivity reactions may occur

Dosage Forms Tablet: 250 mg

Reference Range Although the therapeutic range is poorly documented, most reports indicate that therapeutic plasma concentrations fall between 15-50 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive: Bradycardia may be treated with atropine; benzodiazepine or phenobarbital for seizures
Enhancement of elimination: Multiple dosing of activated charcoal may be useful

Test Interactions \uparrow alkaline phosphatase (S); \downarrow calcium (S)

Drug Interactions Inhibits CYP2C19 (weak)

Pregnancy Risk Factor D

Pregnancy Implications Maternal ingestion of antiepileptic agents has been associated with neonatal coagulation defects/bleeding usually within 24 hours of birth.

Lactation Enters breast milk/not recommended

Ethyl Alcohol

Related Information

● Substance-Related Disorders

CAS Number 64-17-5

UN Number 1170

Impairment Potential Yes. Blood ethanol >0.03% may cause driving impairment. Most studies report significant impairment (particularly eye movement, glare resistance, visual perception, and reaction time) at blood ethanol levels of 0.05%; and 94% of studies report impairment at 0.08%. At blood ethanol levels of ~0.02%, the ability to divide attention between two or more visual stimuli is impaired. At blood ethanol levels between 0.08% and 0.10%, the relative risk of a fatal single-vehicle crash varies between 11% (for drivers 35 years of age and older) and 52% (for male drivers 16-20 years of age). See figure.

Ethotoin

Pronunciation (ETH oh toyn)

CAS Number 86-35-1

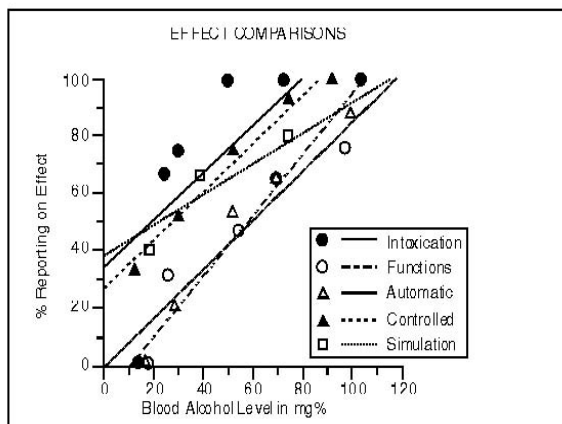

U.S. Brand Names Peganone®

Synonyms Ethylphenylhydantoin

Use Generalized tonic-clonic or complex-partial seizures

Mechanism of Action Exerts an anticonvulsant effect without causing general central nervous system depression. The mechanism of action is believed to be similar to that of phenytoin which appears to stabilize the

Comparison of Various Categories of Alcohol-Related Effects as Function of Blood Alcohol Concentrations

From Brain Information Service, Brain Research Institute, University of California, Los Angeles, CA 90002-1746.

Use Topical anti-infective; pharmaceutical aid; as an antidote for ethylene glycol overdose; as antidote for methanol overdose; may also be useful in propylene glycol. See Alcohol, Ethyl [ANTIDOTE]

Mechanism of Action Central nervous system depressant

Adverse Reactions

Cardiovascular: Tachycardia, hypertension, fibrillation (atrial), flutter (atrial), cardiomegaly, angina, chest pain, congestive heart failure, sinus tachycardia, tachycardia (supraventricular), arrhythmias (ventricular), vasodilation

Central nervous system: Ataxia, dementia, Wernicke-Korsakoff syndrome, amnesia, paranoia, hyperthermia, aggressive behavior, leukoencephalopathy

Gastrointestinal: Nausea, diarrhea, abdominal pain, dyspepsia, vomiting, GI hemorrhage, anorexia, pancreatitis, decreased esophageal sphincter tone

Hematologic: Porphyrin, megaloblastic anemia

Hepatic: Hepatic cirrhosis, fatty degeneration of liver, hepatic steatosis, impaired gluconeogenesis, aminotransferase level elevation (asymptomatic)

Neuromuscular & skeletal: Dysarthria, neuropathy (peripheral), osteoporosis

Ocular: Visual evoked potential abnormalities

Miscellaneous: Impaired judgment, hiccups, breast cancer, acute traumatic compartment syndrome; see Impairment Potential

Signs and Symptoms of Overdose Acetone breath, acidosis, apnea, atrial tachycardia, cardiomyopathy, chorea (extrapyramidal), CNS depression, dementia, depression, diplopia, dysphagia, encephalopathy, fever, gynecomastia, hyperuricemia, hyperventilation, hypocalcemia, hypoglycemia (3.4%), hypokalemia, hypomagnesemia, hyponatremia, hypophosphatemia, hyporeflexia, hypotension, hypothermia, impotence, leukocytosis, lymphopenia, mydriasis, myocardial depression, myoclonus, myoglobinuria, myopathy, numbness, nystagmus, optic neuropathy, ototoxicity, paresthesia, porphyria, rhabdomyolysis, respiratory depression, sedation, seizures, tremors, thrombocytopenia, tinnitus

Admission Criteria/Prognosis Any pediatric patient with electrolyte or acid-base disturbance or ingestion of >60 mL of cosmetic fragrances should be admitted

Toxicodynamics/Kinetics

Distribution: V_d : 0.6 L/kg

Metabolism: Hepatic to acetaldehyde by alcohol dehydrogenase at a rate of 10-30 mg/dL/hour

Dosage I.V. doses of 100-125 mg/kg/hour to maintain blood levels of 100 mg/dL are recommended after a loading dose of 0.6 g/kg; maximum dose: 400 mL of a 5% solution within 1 hour

Administration Caution must be taken to avoid extravasation; administer only by slow I.V. infusion

Reference Range Levels > 100 mg/dL can cause nausea and vomiting; levels >300 mg/dL can be associated with coma and fatalities

Overdosage/Treatment

Decontamination: Lavage within 2 hours/activated charcoal

Supportive therapy: Flumazenil (2-5 mg) or naloxone may alleviate respiratory depression but not CNS depression, there is conflicting data regarding these two agents; crystalloid infusion for hypotension (will not increase ethanol clearance); monitor glucose; thiamine (50-100 mg) should also be given; monitor magnesium level; for rate control of atrial fibrillation, digoxin or I.V. diltiazem can be used; lorazepam (2 mg I.V.) can prevent recurrent seizures due to ethanol

Enhancement of elimination: Hemodialysis removes 50% to 100%; clearance of ethanol through hemodialysis is ~300-400 mL/minute with an ethanol removal rate of 280 mg/minute

Antidote(s)

- Alcohol, Ethyl [ANTIDOTE]
- Flumazenil [ANTIDOTE]

Diagnostic Procedures

- Alcohol, Semiquantitative, Urine
- Alcohol, Serum

Test Interactions ↑ ammonia (B), creatine phosphokinase (CPK) (S), serum osmolality gap increases an average of 20 mOsm for every 100 mg/dL of ethanol; ↓ glucose, magnesium

Pregnancy Risk Factor D/X (prolonged use or high doses at term)

Pregnancy Implications Causes fetal alcohol syndrome, facial dysmorphias, growth retardation

Additional Information

Energy content of ethanol: 7.1 kcal (29.7 kg) per g

Highest serum level recorded with full recovery: 1510 mg/dL (327.8 mM/L) in an adult; in an adolescent it is 757 mg/dL; children who ingest a significant amount of alcohol should be monitored hourly for up to 6 hours; elevated serum lactate and lactate dehydrogenase levels may interfere with enzymatic ethanol assays; intravenous dexamethasone (2 mg I.V.) can impair ethyl alcohol's ability to stimulate sympathetic nerve discharge and thus suppress alcohol-induced high blood pressure in the acute state

Moderate drinking is defined as not more than 2 drinks (28 g) of ethanol daily in men and only 1 drink (14 g) daily in women. Corpus callosum atrophy can occur in the brain with chronic ethyl alcohol intake; daily ingestion of 40-60 g of ethanol in men and 20 g of ethanol in women can significantly increase the incidence of cirrhosis in individuals who are well nourished.

While the reduced risk for coronary heart disease by ethanol appears to be related to elevation of high density lipoprotein (HDL cholesterol) levels, the maximal benefit appears to be at the amount of one drink daily. Hepatic toxicity can occur at lower ethanol amounts in women as opposed to men. Serum selenium levels are significantly lower (24 ng/mL versus 39 ng/mL in control patients) in chronic alcohol abuse patients.

Odor threshold: 10 ppm; TLV-TWA: 1000 ppm.

Ethyl Chloride

Pronunciation (ETH il KLOOR ide)

CAS Number 75-00-3

UN Number 1037

U.S. Brand Names Gebauer's Ethyl Chloride®

Synonyms Chloroethane

Use

Medical: Local anesthetic in minor operative procedures and to relieve pain caused by insect stings and burns and irritation caused by myofascial and visceral pain syndromes

Industrial: Currently primarily utilized in the production of tetraethyl lead and ethyl cellulose; also used as a solvent and refrigerant

Mechanism of Action Results in tissue hypothermia (-10°C) when used topically

Adverse Reactions Gastrointestinal: Mucous membrane irritation, excessive salivation

Signs and Symptoms of Overdose Coma, laryngospasm, respiratory and cardiac arrest when taken systemically. Abdominal cramps, ataxia, chemical frostbite, coma, contact dermatitis, cyanosis, hepatomegaly, nausea, nystagmus, ocular irritation (at 40,000 ppm), unconsciousness, visual hallucinations, vomiting. Prolonged spraying may cause frostbite.

Toxicodynamics/Kinetics

Absorption: Readily through lungs; pulmonary route (82% retention); not absorbed dermally

Half-life: 1-3 minutes (when taken systemically)

Elimination: Through lungs

Dosage Dosage varies with use

Stability Refrigerate; store in airtight containers preferably hermetically sealed at a temperature not exceeding 15°C; protect from light

Administration Spray for a few seconds to the point of frost formation when the tissue becomes white; avoid prolonged spraying of skin beyond this point; avoid broken skin or mucous membranes

Dosage Forms Aerosol: 100% (103 mL) [available as a fine-point or medium spray]

Reference Range Serum ethyl chloride level of 200 mg/L associated with fatality following recreational use; postmortem ethyl chloride blood and urine levels of 423 mg/L and 35 mg/L, respectively, associated with fatality

Overdosage/Treatment Decontamination: **Dermal:** Irrigate exposed areas with soap and water; **Inhalation:** Administer 100% humidified oxygen

Pregnancy Risk Factor C

Additional Information

Spray for a few seconds to the point of frost formation when the tissue becomes white; avoid prolonged spraying of skin beyond this point. Essentially acts as a general anesthetic at air concentrations > 30,000 ppm by means of interference of calcium-mediated channels in neurons.

Highly flammable; air concentrations >5% may be explosive.

Ambient air levels of 40,000 ppm can be fatal. IDLH: 20,000 ppm

Ethyl Loflazepate

CAS Number 29177-84-2

U.S. Brand Names Meilax; Victan

Synonyms Dichlorotetrafluoroethane and Ethyl Chloride

Use Short-term treatment of anxiety disorders

Mechanism of Action Binds to stereospecific benzodiazepine receptors on the postsynaptic GABA neuron at several sites within the central nervous system, including the limbic system, reticular formation. Enhancement of the inhibitory effect of GABA on neuronal excitability results by increased neuronal membrane permeability to chloride ions. This shift in chloride ions results in hyperpolarization (a less excitable state) and stabilization.

Adverse Reactions

Frequency not defined.

Cardiovascular: Hypotension

Central nervous system: Drowsiness, ataxia, amnesia, slurred speech, paradoxical excitement or rage, fatigue, insomnia, memory impairment, headache, anxiety, depression, vertigo, confusion

Dermatologic: Rash

Endocrine & metabolic: Changes in libido

Gastrointestinal: Changes in salivation, constipation, nausea

Genitourinary: Incontinence, urinary retention

Hepatic: Jaundice

Local: Phlebitis, pain with injection

Neuromuscular & skeletal: Dysarthria, tremor

Ocular: Blurred vision, diplopia

Respiratory: Decrease in respiratory rate, apnea

Pharmacodynamics/Kinetics

Metabolism: Hepatic to active metabolites

Half-life: 75-80 hours

Protein binding: Metabolites (99%)

Dosage Oral: 1-4 mg/day in single or divided doses

Dosage Forms Aerosol: Ethyl chloride 25% and dichlorotetrafluoroethane 75% (148 mL)

Reference Range Peak ethyl loflazepate serum concentrations after 4 mg dose is about 200 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Rarely is mechanical ventilation required; flumazenil has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression and respiratory depression

Enhancement of elimination: Multiple dose activated charcoal may be effective

Pregnancy Risk Factor C

Specific References

Kamijo Y, Hayashi I, Nishikawa T, et al, "Pharmacokinetics of the Active Metabolites of Ethyl Loflazepate in Elderly Patients Who Died of Asphyxia Associated with Benzodiazepine-Related Toxicity," *J Anal Toxicol*, 2005, 29:140-4.

Etidronate Disodium

CAS Number 2809-21-4; 7414-83-7

U.S. Brand Names Didronel®

Synonyms EHDP; Sodium Etidronate

Use Symptomatic treatment of Paget's disease and heterotopic ossification due to spinal cord injury or after total hip replacement, hypercalcemia associated with malignancy

Postmenopausal osteoporosis

Mechanism of Action Decreases bone resorption by inhibiting osteocytic osteolysis; decreases mineral release and matrix or collagen breakdown in bone

Adverse Reactions

Endocrine & metabolic: Hyperphosphatemia, hypocalcemia, pseudogout

Gastrointestinal: Diarrhea, nausea, vomiting, altered taste

Hematologic: Occult blood in stools

Neuromuscular & skeletal: Risk of fractures (increased), microfractures, bone pain (increased), dose-related osteomalacia

Renal: Nephrotoxicity

Miscellaneous: Hypersensitivity reactions

Signs and Symptoms of Overdose Diarrhea, hypocalcemia, nausea

Pharmacodynamics/Kinetics

Onset of action:

Paget's disease: May be observed after 1 month of treatment; initially observed as a reduction in urinary hydroxyproline

Hypercalcemia: Reductions in urinary calcium excretion which accompany reductions in bone resorption; may become apparent after 24 hours

Duration of action: Cleared from blood in 6 hours

Absorption: Dependent upon dose administered; decreased oral absorption with calcium-rich foods

Distribution: ~1/2 absorbed dose is chemically absorbed to bone, presumably upon hydroxyapatite crystals, in areas of elevated osteogenesis

Metabolism: Not metabolized

Half-life: 5-7 hours in plasma; 90 days in bone

Elimination: Excreted as unchanged drug primarily in the urine with unabsorbed drug being eliminated in the feces

Onset of therapeutic effects: Within 1-3 months of therapy

Duration: 12 months without continuous therapy

Dosage

Adults:

Paget's disease: Oral: 5 mg/kg/day given every day for no more than 6 months; may give 10 mg/kg/day for up to 3 months; daily dose may be divided if adverse gastrointestinal effects occur

Heterotopic ossification with spinal cord injury: 20 mg/kg/day for 2 weeks, then 10 mg/kg/day for 10 weeks (this dosage has been used in children, however, treatment > 1 year has been associated with a rachitic syndrome)

Hypercalcemia associated with malignancy:

I.V. (dilute dose in at least 250 mL NS): 7.5 mg/kg/day for 3 days; there should be at least 7 days between courses of treatment

Oral: Start 20 mg/kg/day on the last day of infusion and continue for 30-90 days

Dosing adjustment in renal impairment:

S_{cr} 2.5-5 mg/dL: Use with caution

S_{cr} > 5 mg/dL: Do not use

Stability Dilute I.V. dose in at least 250 mL NS; stable for 48 hours at room temperature or refrigerated

Monitoring Parameters Serum calcium and phosphorous; serum creatinine and BUN

Administration

I.V. doses should be diluted in at least 250 mL normal saline.

Contraindications Hypersensitivity to bisphosphonates or any component of the formulation; overt osteomalacia

Warnings

Ensure adequate calcium and vitamin D intake. Etidronate may retard mineralization of bone; treatment may need delayed or interrupted until callus is present. Use caution in patients with renal impairment. Use caution with enterocolitis; diarrhea has been reported at high doses and therapy may need to be withheld.

Bisphosphonate therapy has been associated with osteonecrosis, primarily of the jaw; this has been observed mostly in cancer patients, but also in patients with postmenopausal osteoporosis and other diagnoses. Risk factors include a diagnosis of cancer, with concomitant chemotherapy, radiotherapy or corticosteroids; anemia, coagulopathy, infection or pre-existing dental disease. Symptoms included nonhealing extraction socket or an exposed jawbone. There are no data addressing whether discontinuation of therapy reduces the risk of developing osteonecrosis. However, as a precautionary measure, dental exams and preventative dentistry should be performed prior to placing patients with risk factors on chronic bisphosphonate therapy. Invasive dental procedures should be avoided during treatment.

Infrequently, severe (and occasionally debilitating) bone, joint, and/or muscle pain have been reported during bisphosphonate treatment. The onset of pain ranged from a single day to several months. Symptoms usually resolve upon discontinuation. Some patients experienced recurrence when rechallenged with same drug or another bisphosphonate; avoid use in patients with a history of these symptoms in association with bisphosphonate therapy.

Safety and efficacy in pediatric patients have not been established.

Dosage Forms Tablet: 200 mg, 400 mg

Reference Range Calcium (total): Adults: 9.0-11.0 mg/dL

Overdosage/Treatment Supportive therapy: I.V. hydration; monitor urine flow and calcium and phosphorus level

Drug Interactions

Aminoglycosides: May lower serum calcium levels with prolonged administration. Concomitant use may have an additive hypocalcemic effect.

Antacids: May decrease the absorption of bisphosphonate derivatives; should be administered at a different time of the day. Antacids containing aluminum, calcium, or magnesium are of specific concern.

Calcium salts: May decrease the absorption of bisphosphonate derivatives. Separate oral dosing in order to minimize risk of interaction.

Iron salts: May decrease the absorption of bisphosphonate derivatives. Only oral iron salts and oral bisphosphonates are of concern.

Magnesium salts: May decrease the absorption of bisphosphonate derivatives. Only oral magnesium salts and oral bisphosphonates are of concern.

Nonsteroidal anti-inflammatory drugs (NSAIDs): May enhance the gastrointestinal adverse/toxic effects (increased incidence of GI ulcers) of bisphosphonate derivatives.

Phosphate supplements: Bisphosphonate derivatives may enhance the hypocalcemic effect of phosphate supplements.

Pregnancy Risk Factor B (oral); C (parenteral)

Pregnancy Implications Teratogenic effects have been reported in some but not all animal studies. There are no adequate and well-controlled studies in pregnant women. Bisphosphonates are incorporated into the bone matrix and gradually released over time. Theoretically, there may be a risk of fetal harm when pregnancy follows the completion of therapy. Based on limited case reports with pamidronate, serum calcium levels in the newborn may be altered if administered during pregnancy.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Dilute I.V. dose in at least 250 mL NS, ensure adequate hydration; dosage modification required in renal insufficiency

Specific References

French AE, Kaplan N, Lishner M, et al, "Taking Bisphosphonates During Pregnancy," *Can Fam Physician*, 2003, 49:1281-2.

Etodolac

Related Information

- Nonsteroidal Anti-inflammatory Drugs

CAS Number 41340-25-4

U.S. Brand Names Lodine® XL; Lodine®

Synonyms Etodolic Acid

Use Acute and long-term use in the management of signs and symptoms of osteoarthritis and management of pain; rheumatoid arthritis; juvenile rheumatoid arthritis

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors

Adverse Reactions

Cardiovascular: Circulatory collapse

Central nervous system: **Dizziness**, headache, aseptic meningitis, psychosis, cognitive dysfunction, coma, seizures

Dermatologic: **Rash**, pruritus, hypersensitivity vasculitis, exfoliative dermatitis, alopecia, angioedema, urticaria, Stevens-Johnson syndrome, photosensitivity, exanthem, cutaneous vasculitis

Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, fluid retention, gynecomastia

Gastrointestinal: **Abdominal cramps, heartburn, indigestion, nausea, vomiting**, GI ulceration, constipation, diarrhea, dyspepsia, xerostomia, colitis

Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia, aplastic anemia (rare), platelet inhibition, hepatic necrosis

Hepatic: Elevated transaminases, hepatitis (fulminant)

Neuromuscular & skeletal: Paresthesia

Otic: Ototoxicity; tinnitus, deafness

Renal: Renal failure (acute), nephrotic syndrome, chronic renal failure, albuminuria

Respiratory: Wheezing, respiratory depression, rhinitis

Miscellaneous: Hypersensitivity

Signs and Symptoms of Overdose Cognitive dysfunction, conjunctivitis, drowsiness, dysuria, flatulence, gastritis, GI bleeding, hematuria, nausea, nephrotic syndrome, ototoxicity, tinnitus, wheezing, vomiting. Severe poisoning can manifest with coma, hypotension, leukocytosis, renal failure and/or hepatic failure, respiratory depression, seizures

Pharmacodynamics/Kinetics

Onset of action: Analgesic: 2-4 hours; Maximum anti-inflammatory effect:

A few days

Absorption: ≥ 80%

Distribution: V_d:

Immediate release: Adults: 0.4 L/kg

Extended release: Adults: 0.57 L/kg; Children (6-16 years): 0 .08 L/kg

Protein binding: ≥ 99%, primarily albumin

Metabolism: Hepatic

Half-life elimination: Terminal: Adults: 5-8 hours

Extended release: Children (6-16 years): 12 hours

Time to peak, serum:

Immediate release: Adults: 1-2 hours

Extended release: Extended release: 5-7 hours, increased 1.4-3.8 hours with food

Excretion: Urine 73% (1% unchanged); feces 16%

Dosage

Single dose of 76-100 mg is comparable to the analgesic effect of aspirin 650 mg; in patients ≥ 65 years, no substantial differences in the pharmacokinetics or side-effects profile were seen compared with the general population

Children 6-16 years: Oral: Juvenile rheumatoid arthritis (Lodine® XL):

20-30 kg: 400 mg once daily

31-45 kg: 600 mg once daily

46-60 kg: 800 mg once daily

> 60 kg: 1000 mg once daily

Adults: Oral:

Acute pain: 200-400 mg every 6-8 hours, as needed, not to exceed total daily doses of 1200 mg; for patients weighing < 60 kg, total daily dose should not exceed 20 mg/kg/day

Rheumatoid arthritis, osteoarthritis: Initial: 600-1200 mg/day given in divided doses: 400 mg 2 times/day; 300 mg 2 or 3 times/day; 500 mg 2 times/day; total daily dose should not exceed 1200 mg; for patients weighing < 60 kg, total daily dose should not exceed 20 mg/kg/day. Lodine® XL: 400-1000 mg once daily

Elderly: Refer to adult dosing; in patients ≥ 65 years, no dosage adjustment required based on pharmacokinetics. The elderly are more sensitive to antiprostaglandin effects and may need dosage adjustments.

Monitoring Parameters Monitor CBC, liver enzymes; in patients receiving diuretics, monitor urine output and BUN/serum creatinine

Contraindications Hypersensitivity to etodolac, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy

Warnings [U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension. Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF, or hypertension.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACE inhibitors and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Etodolac is not recommended for patients with advanced renal disease.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS), and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur. The elderly are at increased risk for adverse effects (especially peptic ulceration, CNS effects, renal toxicity) from NSAIDs even at low doses.

Withhold for at least 4-6 half-lives prior to surgical or dental procedures. Use of extended release product consisting of a nondeformable matrix should be avoided in patients with stricture/narrowing of the GI tract; symptoms of obstruction have been associated with nondeformable products.

Dosage Forms [DSC] = Discontinued product

Capsule: 200 mg, 300 mg

Lodine®: 200 mg, 300 mg [DSC]

Tablet: 400 mg, 500 mg

Tablet, extended release (Lodine® XL): 400 mg, 500 mg [DSC]

Reference Range After a 200 mg oral dose, peak plasma levels are ~12-16 mg/L; after a 400 mg oral dose, peak plasma level is ~21 mg/L

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage

Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be useful

Test Interactions False-positive for urinary bilirubin and ketone

Drug Interactions ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure. Aminoglycosides: NSAIDs may decrease the excretion of aminoglycosides.

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet agents (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatide, tirofiban) can cause an increased risk of bleeding.

Beta-blockers: NSAIDs may diminish the antihypertensive effects of beta-blockers.

Bisphosphonates: NSAIDs may increase the risk of gastrointestinal ulceration.

Cholestyramine and colestipol reduce the bioavailability of some NSAIDs; separate administration times.

Corticosteroids may increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use.

Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose. Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again.

Loop diuretics efficacy (diuretic and antihypertensive effect) is reduced. Indomethacin reduces this efficacy, however, it may be anticipated with any NSAID.

Methodretate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Pemetrexed: NSAIDs may decrease the excretion of pemetrexed. Patients with Cl_{cr} 45-79 mL/minute should avoid short acting NSAIDs for 2 days before and 2 days after pemetrexed treatment.

Thiazides antihypertensive effects are decreased; avoid concurrent use. Treprostinil: May enhance the risk of bleeding with concurrent use.

Vancomycin: NSAIDs may decrease the excretion of vancomycin. Avoid concurrent use.

Verapamil plasma concentration is decreased by some NSAIDs; avoid concurrent use.

Pregnancy Risk Factor C/D (3rd trimester)

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Do not crush tablets

Etoposide

CAS Number 33419-42-0

U.S. Brand Names Toposar®; VePesid®

Synonyms Epipodophyllotoxin; VP-16-213; VP-16

Use Treatment of refractory testicular tumors; treatment of small cell lung cancer

Unlabeled/Investigational Use Treatment of lymphomas, acute non-lymphocytic leukemia (ANLL); lung, bladder, and prostate carcinoma; hepatoma, rhabdomyosarcoma, uterine carcinoma, neuroblastoma, mycosis fungoides, Kaposi's sarcoma, histiocytosis, gestational trophoblastic disease, Ewing's sarcoma, Wilms' tumor, brain tumors

Mechanism of Action Inhibits mitotic activity; inhibits cells from entering prophase; inhibits DNA synthesis. Initially thought to be mitotic inhibitors similar to podophyllotoxin, but actually have no effect on microtubule assembly. However, later shown to induce DNA strand breakage and inhibition of topoisomerase II (an enzyme which breaks and repairs DNA); etoposide acts in late S or early G2 phases.

Adverse Reactions

Cardiovascular: Tachycardia

Hypotension: Related to drug infusion time; may be related to vehicle used in the I.V. preparation (polysorbate 80 plus polyethylene glycol). Best to administer the drug over 1 hour.

Central nervous system: Unusual tiredness, neurotoxicity, somnolence, fever, headache, dystonia

Dermatologic: **Alopecia** (reversible 66%), radiation recall dermatitis, rash, urticaria, Stevens-Johnson syndrome, onycholysis, toxic epidermal necrolysis

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone secretion

Gastrointestinal: **Emetic potential:** Moderately low (10% to 30%); occasional **diarrhea** and **infrequent nausea and vomiting** at standard doses; **severe mucositis** occurs with high (BMT) doses; **anorexia** (10% to 13%); stomatitis, abdominal pain, hepatic dysfunction, paralytic ileus

Hematologic:

Myelosuppressive: Principal dose-limiting toxicity of VP-16. White blood cell count nadir is 5-15 days after administration and is more frequent than thrombocytopenia. Recovery is usually within 24-28 days and cumulative toxicity has not been noted with VP-16 as a single agent. No difference in toxicity is seen when VP-16 is administered over a 24-hour period or over 2 hours on 5 consecutive days.

WBC: Mild to severe

Platelets: Mild

Onset (days): 10

Nadir (days): 14-16

Recovery (days): 21-28

Hepatic: Toxic hepatitis (with high-dose therapy); hepatic necrosis at doses >600 mg/m²

Local: **Irritant chemotherapy**, thrombophlebitis has been reported (0.7% to 2%), extravasation injury

Neuromuscular & skeletal: Neuropathy (peripheral) 1% to 2%

Respiratory: Dyspnea, bronchospasm, apnea, pulmonary interstitial fibrosis

Miscellaneous: Hiccups

Hypersensitivity: Reports of flushing or bronchospasm, which, in one report, did not recur if patients were pretreated with corticosteroids and antihistamines

Admission Criteria/Prognosis Admit any symptomatic patient

Pharmacodynamics/Kinetics

Absorption: Oral: 25% to 75%; significant inter- and inpatient variation
 Distribution: Average V_d : 7-17 L/m²; poor penetration across the blood-brain barrier; CSF concentrations <10% of plasma concentrations
 Protein binding: 94% to 97%
 Metabolism: Hepatic to hydroxy acid and cislactone metabolites
 Bioavailability: Oral: ~50% (range 25% to 75%)
 Half-life elimination: Terminal: 4-11 hours; Children: Normal renal/hepatic function: 6-8 hours
 Time to peak, serum: Oral: 1-1.5 hours
 Excretion:

Children: Urine (\leq 55% as unchanged drug)
 Adults: Urine (42% to 67%; 8% to 35% as unchanged drug) within 24 hours; feces (up to 44%)

Dosage Refer to individual protocols

Oral: Twice the I.V. dose rounded to the nearest 50 mg given once daily if total dose \leq 400 mg or in divided doses if >400 mg
 Children: I.V.: 60-120 mg/m²/day for 3-5 days every 3-6 weeks

AML:

Remission induction: 150 mg/m²/day for 2-3 days for 2-3 cycles
 Intensification or consolidation: 250 mg/m²/day for 3 days, courses 2-5
 Conditioning regimen for allogeneic BMT: 60 mg/kg/dose as a single dose

Adults:**Small cell lung cancer:**

I.V.: 35 mg/m²/day for 4 days or 50 mg/m²/day for 5 days every 3-4 weeks total dose \leq 400 mg/day or in divided doses if >400 mg/day
 IVPB: 200-250 mg/m² repeated every 7 weeks
 Continuous intravenous infusion: 500 mg/m² over 24 hours every 3 weeks

Testicular cancer:

IVPB: 50-100 mg/m²/day for 5 days repeated every 3-4 weeks
 I.V.: 100 mg/m² every other day for 3 doses repeated every 3-4 weeks

BMT/relapsed leukemia: I.V.: 2.4-3.5 g/m² or 25-70 mg/kg administered over 4-36 hours

Dosage adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer 75% of normal dose
 Cl_{cr} <10 mL/minute: Administer 50% of normal dose
 Hemodialysis effects: Supplemental dose is not necessary
 CAPD effects: Unknown
 CAVH effects: Unknown

Dosage adjustment in hepatic impairment:

Bilirubin 1.5-3 mg/dL or AST 60-180 units: Reduce dose by 50%
 Bilirubin >3 mg/dL or AST >180 units: Reduce by 75%

Stability

Store intact vials of injection at room temperature and protected from light; injection solution contains polyethylene glycol vehicle with absolute alcohol; store oral capsules under refrigeration

VP-16 should be further diluted in D₅W or NS for administration; diluted solutions have concentration-dependent stability: More concentrated solutions have shorter stability times

At room temperature in D₅W or NS in polyvinyl chloride, the concentration is stable as follows: 0.2 mg/mL: 96 hours; 0.4 mg/mL: 48 hours; 0.6 mg/mL: 8 hours; 1 mg/mL: 2 hours; 2 mg/mL: 1 hour; 20 mg/mL (undiluted): 24 hours

Y-site compatible with carboplatin, cytarabine, mesna, daunorubicin

Standard I.V. dilution:**Lower dose regimens (<1 g/dose):**

Doses may be diluted in 100-1000 mL of D₅W or NS
 If the concentration is less than or equal to 0.6 mg/mL, the bag should be mixed with the appropriate expiration dating
 If the concentration is >0.6 mg/mL, the concentration is highly unstable and a syringe of undiluted etoposide accompanied with the appropriate volume of diluent will be sent to the nursing unit to be mixed at the bedside just prior to administration.

High-dose regimens (>1g/dose):

Total dose should be drawn into an empty vialflex container and the appropriate amount of diluent (for a final concentration of 1 mg/mL) will be sent

Use the **2-Channel Pump Method**: Instill all of the etoposide dose into one vialflex container (concentration = 20 mg/mL). Infuse this into one channel (Baxter Flow-Guard 6300 Dual Channel Volumetric Infusion Pump - or any 2-channel infusion pump that does not require a "hard" plastic cassette). Infuse the indicated diluent (ie, D₅W or NS) at a rate of at least 20 times the infusion rate of the etoposide to simulate a 1 mg/mL concentration in the line. The etoposide should be Y-sited into the port most proximal to the patient. A 0.22 micron filter should be attached to the line after the Y-site and before entry into the patient.

Monitoring Parameters CBC with differential, platelet count, and hemoglobin, vital signs (blood pressure), bilirubin, and renal function tests

Administration

Administer lower doses IVPB over at least 30 minutes to minimize the risk of hypotensive reactions.

Administer high-doses (>1 g/dose) via the 2-channel pump method.

An in-line 0.22 micron filter should be attached to **all** etoposide infusions due to the high potential for precipitation

Contraindications Hypersensitivity to etoposide or any component of the formulation; pregnancy

Warnings Hazardous agent – use appropriate precautions for handling and disposal. **[U.S. Boxed Warning]: Severe myelosuppression with resulting infection or bleeding may occur.** Treatment should be withheld for platelets <50,000/mm³ or absolute neutrophil count (ANC) <500/mm³. May cause anaphylactic reaction manifested by chills, fever, tachycardia, bronchospasm, dyspnea, and hypotension. In children, the use of concentrations higher than recommended were associated with higher rates of anaphylactic-like reactions. Infusion should be interrupted and medications for the treatment of anaphylaxis should be available for immediate use. Must be diluted; do not give I.V. push, infuse over at least 30-60 minutes; hypotension is associated with rapid infusion. Dosage should be adjusted in patients with hepatic or renal impairment. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.** Injectable formula contains polysorbate 80; do not use in premature infants. May contain benzyl alcohol; do not use in newborn infants. Safety and efficacy in children have not been established.

Dosage Forms Capsule, softgel:

VePesid®: 50 mg

Injection, solution: 20 mg/mL (5 mL, 25 mL, 50 mL)

Toposar®: 20 mg/mL (5 mL, 25 mL, 50 mL) [contains alcohol 33% and polysorbate 80]

Reference Range 5 minutes following intravenous infusion of 100 mg/m² over 30-60 minutes, plasma etoposide level of 21 mg/L was obtained

Overdosage/Treatment

Decontamination: Oral: Emesis within 30 minutes or lavage within 2 hours of ingestion; activated charcoal

Supportive therapy: Hypotension usually responds to discontinuation of drug to I.V. fluids and diphenhydramine; bronchospasm and dystonia also respond to diphenhydramine; recombinant human erythropoietin (150-300 units/kg subcutaneously 3 times weekly) may be used to treat anemia along with red blood cell transfusions; granulocyte-macrophage colony stimulating factor or granulocyte colony stimulating factor can be used to treat bone marrow infection; diphenhydramine (1 mg/kg up to 50 mg I.V.) or benzotropine (1-2 mg/kg I.V.) can be used to treat dystonia; **extravasation treatment:** Inject 150-900 units of hyaluronidase SubQ clockwise into the infiltrated area using a 25-gauge needle; change the needle with each injection; apply heat immediately for 1 hour, repeat 4 times/day for 3-5 days; **application of cold or hydrocortisone is contraindicated**

Antidote(s)

- Thrombopoietin [ANTIDOTE]

Drug Interactions **Substrate** of CYP1A2 (minor), 2E1 (minor), 3A4 (major); **Inhibits** CYP2C9 (weak), 3A4 (weak)

Barbiturates: May increase metabolism/decrease the effects of etoposide; monitor.

Cyclosporine: May decrease the metabolism/increase the levels of etoposide; consider reducing the dose of etoposide by 50% if the patient is receiving, or has recently received, cyclosporine. Monitor for increased toxic effects of etoposide if cyclosporine is initiated, the dose is increased, or it has been recently discontinued.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of etoposide. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of etoposide. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Phenytoin: May increase metabolism/decrease effects of etoposide; monitor.

Warfarin may elevate prothrombin time with concurrent use.

Pregnancy Risk Factor D

Pregnancy Implications Fetotoxic and teratogenic in rats

Lactation Enters breast milk/contraindicated

Nursing Implications If necessary, the injection may be used for oral administration; mix with orange juice, apple juice, or lemonade to a concentration of 0.4 mg/mL or less, and use within a 3-hour period

Additional Information Derived from the May Apple plant

Famciclovir**Related Information**

- Acyclovir

CAS Number 104227-87-4

U.S. Brand Names Famvir®

Use Management of acute herpes zoster (shingles); treatment of recurrent herpes simplex (genital herpes) in immunocompetent patients

Mechanism of Action After undergoing rapid biotransformation to the active compound, penciclovir, famciclovir is phosphorylated by viral thymidine kinase in HSV-1, HSV-2, and VZV-infected cells to a monophosphate form; this is then converted to penciclovir triphosphate and competes with deoxyguanosine triphosphate to inhibit HSV-2 polymerase (ie, herpes viral DNA synthesis/replication is selectively inhibited)

Adverse Reactions

Central nervous system: **Headache**, fatigue, fever, dizziness, somnolence

Dermatologic: Pruritus

Gastrointestinal: **Nausea**, diarrhea, vomiting, constipation, anorexia, abdominal pain, pancreatitis

Neuromuscular & skeletal: Rigors, paresthesia

Pharmacodynamics/Kinetics

Absorption: Food decreases maximum peak concentration and delays time to peak; AUC remains the same

Distribution: V_{dss} : 0.91-1.25 L/kg

Protein binding: $\leq 20\%$

Metabolism: Rapidly deacetylated and oxidized to penciclovir; not via CYP

Bioavailability: 69% to 85%

Half-life elimination: Penciclovir: 2-3 hours (10, 20, and 7 hours in HSV-1, HSV-2, and VZV-infected cells, respectively); prolonged with renal impairment

Time to peak: 0.9 hours; C_{max} and T_{max} are decreased and prolonged with noncompensated hepatic impairment

Excretion: Urine (73% primarily as penciclovir); feces (27%)

Dosage Herpes zoster: Adults: Oral: 500 mg every 8 hours for 7 days

First episode genital herpes simplex: 750 mg every 8 hours for 5 days

Dosing interval in renal impairment:

$Cl_{cr} \geq 60$ mL/minute: Administer 500 mg every 8 hours

Cl_{cr} 40-59 mL/minute: Administer 500 mg every 12 hours

Cl_{cr} 20-39 mL/minute: Administer 500 mg every 24 hours

$Cl_{cr} < 20$ mL/minute: Unknown

Monitoring Parameters Periodic CBC during long-term therapy

Contraindications Hypersensitivity to famciclovir, penciclovir, or any component of the formulation

Warnings Has not been established for use in initial episodes of genital herpes, patients with ophthalmic or disseminated zoster, or in immunocompromised patients with herpes zoster. Dosage adjustment is required in patients with renal insufficiency. Tablets contain lactose; do not use with galactose intolerance, severe lactase deficiency, or glucose-galactose malabsorption syndromes. Safety and efficacy have not been established in children < 18 years of age.

Dosage Forms Tablet: 125 mg, 250 mg, 500 mg [contains lactose]

Reference Range Peak serum penciclovir levels after a 250 mg oral dose range from 1.6-1.9 mcg/mL; after a 500 mg dose, peak serum penciclovir levels are ~ 3.5 mcg/mL; peak serum penciclovir level after a 10 mg/kg I.V. dose is ~ 12 mcg/mL

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Renal toxicity and crystalluria can be managed with I.V. fluid hydration

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; while no studies have been performed, hemodialysis would appear to be an effective modality for drug removal; hemodialysis can remove as much as 76% of the drug within 4 hours

Pregnancy Risk Factor B

Pregnancy Implications Use only if the benefit to the patient clearly exceeds the potential risk to the fetus; due to potential for excretion of famciclovir in breast milk and for its associated tumorigenicity, discontinue nursing or discontinue the drug during lactation

Lactation Excretion in breast milk unknown/use caution

Additional Information Most effective if therapy is initiated within 72 hours of initial lesion; currently also being studied for chronic hepatitis B infections

Famotidine

CAS Number 76824-35-6

U.S. Brand Names Pepcid® AC [OTC]; Pepcid®

Use Therapy and treatment of duodenal ulcer, gastric ulcer, control gastric pH in critically-ill patients, symptomatic relief in gastritis, gastroesophageal reflux, active benign ulcer, and pathological hypersecretory conditions
OTC labeling: Relief of heartburn, acid indigestion, and sour stomach

Unlabeled/Investigational Use Part of a multidrug regimen for *H. pylori* eradication to reduce the risk of duodenal ulcer recurrence

Mechanism of Action Competitive inhibition of histamine at H_2 -receptors of the gastric parietal cells, which inhibits gastric acid secretion

Adverse Reactions

Note: Agitation and vomiting have been reported in up to 14% of pediatric patients < 1 year of age.

Cardiovascular: Arrhythmia, bradycardia, hypertension, palpitations, tachycardia

Central nervous system: Dizziness, headache, drowsiness, fatigue, fever, insomnia, psychiatric disturbances, seizures

Dermatologic: Acne, dry skin, pruritus, rash, urticaria

Gastrointestinal: Constipation, diarrhea, abdominal discomfort, anorexia, belching, flatulence

Hematologic: Agranulocytosis, neutropenia, thrombocytopenia

Hepatic: AST/ALT increased, jaundice

Neuromuscular & skeletal: Paresthesia, weakness

Renal: BUN/creatinine increased, proteinuria

Respiratory: Bronchospasm

Miscellaneous: Allergic reaction, anaphylaxis

Signs and Symptoms of Overdose Abdominal pain, AV block, CNS depression, confusion, depression, dry skin, hypotension, impotence, insomnia, neutropenia, seizures, tachycardia, vomiting

Pharmacodynamics/Kinetics

Onset of action: GI: Oral: Within 1-3 hour

Duration: 10-12 hours

Protein binding: 15% to 20%

Bioavailability: Oral: 40% to 50%

Half-life elimination: Injection, oral suspension, tablet: 2.5-3.5 hours; prolonged with renal impairment; Oliguria: 20 hours

Time to peak, serum: Oral: ~ 1 -3 hours

Excretion: Urine (as unchanged drug)

Dosage

Children: Treatment duration and dose should be individualized

Peptic ulcer: 1-16 years:

Oral: 0.5 mg/kg/day at bedtime or divided twice daily (maximum dose: 40 mg/day); doses of up to 1 mg/kg/day have been used in clinical studies

I.V.: 0.25 mg/kg every 12 hours (maximum dose: 40 mg/day); doses of up to 0.5 mg/kg have been used in clinical studies

GERD: Oral:

< 3 months: 0.5 mg/kg once daily

3-12 months: 0.5 mg/kg twice daily

1-16 years: 1 mg/kg/day divided twice daily (maximum dose: 40 mg twice daily); doses of up to 2 mg/kg/day have been used in clinical studies

Children ≥ 12 years and Adults: Heartburn, indigestion, sour stomach:
OTC labeling: Oral: 10-20 mg every 12 hours; dose may be taken 15-60 minutes before eating foods known to cause heartburn

Adults:

Duodenal ulcer: Oral: Acute therapy: 40 mg/day at bedtime for 4-8 weeks; maintenance therapy: 20 mg/day at bedtime

Helicobacter pylori eradication (unlabeled use): 40 mg once daily; requires combination therapy with antibiotics

Gastric ulcer: Oral: Acute therapy: 40 mg/day at bedtime

Hypersecretory conditions: Oral: Initial: 20 mg every 6 hours, may increase in increments up to 160 mg every 6 hours

GERD: Oral: 20 mg twice daily for 6 weeks

Esophagitis and accompanying symptoms due to GERD: Oral: 20 mg or 40 mg twice daily for up to 12 weeks

Patients unable to take oral medication: I.V.: 20 mg every 12 hours

Dosing adjustment in renal impairment: $Cl_{cr} < 50$ mL/minute: Manufacturer recommendation: Administer 50% of dose **or** increase the dosing interval to every 36-48 hours (to limit potential CNS adverse effects).

Monitoring Parameters ECG, CBC, electrolytes

Administration I.V. push: Inject over at least 2 minutes

Solution for infusion: Administer over 15-30 minutes

Contraindications Hypersensitivity to famotidine, other H_2 antagonists, or any component of the formulation

Warnings

Modify dose in patients with renal impairment; chewable tablets contain phenylalanine; multidose vials contain benzyl alcohol

OTC labeling: When used for self-medication, patients should be instructed not to use if they have difficulty swallowing, have vomiting with blood, or bloody or black stools. Not for use with other acid reducers.

Dosage Forms [DSC] = Discontinued product

Gelcap:

Pepcid® AC: 10 mg

Infusion [premixed in NS]: 20 mg (50 mL)

Pepcid®: 20 mg (50 mL)

Injection, solution: 10 mg/mL (4 mL, 20 mL)

Pepcid®: 10 mg/mL (20 mL) [contains benzyl alcohol]

Injection, solution [preservative free]: 10 mg/mL (2 mL)

Pepcid®: 10 mg/mL (2 mL)

Powder for oral suspension:

Pepcid®: 40 mg/5 mL (50 mL) [contains sodium benzoate; cherry-banana-mint flavor]

FELODIPINE

Tablet: 10 mg [OTC], 20 mg, 40 mg

Pepcid®: 20 mg, 40 mg

Pepcid® AC: 10 mg, 20 mg

Tablet, chewable:

Pepcid® AC: 10 mg [contains phenylalanine 1.4 mg/tablet; mint flavor]

Reference Range Serum level of 13 ng/mL will produce 50% inhibition of gastric acid secretion

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Treatment is primarily symptomatic and supportive

Enhancement of elimination: Hemodialysis may be useful (four- to sixfold increase in clearance)

Drug Interactions

Cefpodoxime: Histamine H₂ antagonists may decrease the absorption of cefpodoxime; separate oral doses by at least 2 hours. Risk: Moderate

Cefuroxime: Histamine H₂ antagonists may decrease the absorption of cefuroxime; separate oral doses by at least 2 hours. Risk: Moderate

Cyclosporine: Histamine H₂ antagonists may increase the serum concentration of cyclosporine; monitor

Delavirdine: Delavirdine's absorption is decreased; avoid concurrent use with H₂ antagonists

Itraconazole: Histamine H₂ antagonists may decrease the absorption of itraconazole; monitor

Ketoconazole: Histamine H₂ antagonists may decrease the absorption of ketoconazole; monitor

Pregnancy Risk Factor B

Pregnancy Implications Crosses the placenta; insufficient data concerning effects on the fetus

Lactation Enters breast milk/not recommended

Additional Information The expensive parenteral route should only be used when a patient is unable to take oral medication. Less antiandrogenic than cimetidine.

Reference Range Therapeutic plasma level: 5-10 nmol/L; toxic: >30 nmol/L

Overdosage/Treatment

Decontamination: Ipecac-induced emesis can hypothetically worsen calcium antagonist toxicity, since it can produce vagal stimulation. The potential for seizures precipitously following acute ingestion of large doses of a calcium antagonist may also contraindicate the use of ipecac. Lavage (within 1 hour)/activated charcoal is useful. Whole bowel irrigation for sustained release preparations.

Supportive therapy: I.V. fluids and Trendelenburg positioning should be initiated as intoxication may cause hypotension. Calcium (calcium chloride I.V. 1-3 g in adults or 10-30 mg/kg in children over 5-10 minutes with repeats as needed) has been used as an "antidote" for acute intoxications and is the second line therapy for shock next to traditional vasopressors. Heart block may respond to isoproterenol, glucagon, atropine and/or calcium, although a temporary pacemaker may be required. Inamrinone or dopamine may be required for hypotension and is the first-line treatment for shock. Glucagon may increase myocardial contractility.

Enhancement of elimination: Multiple dosing of activated charcoal is useful; ~9% of the parent drug can be removed by hemodialysis

Test Interactions May cause increased serum alkaline phosphatase, serum calcium, serum creatinine, serum gamma glutamyl transferase, serum norepinephrine, renin

Drug Interactions

Substrate of CYP3A4 (major); **Inhibits** CYP2C8 (moderate), 2C9 (weak), 2D6 (weak), 3A4 (weak)

Azole antifungals may inhibit calcium channel blocker's metabolism; avoid this combination. Try an antifungal like terbinafine (if appropriate) or monitor closely for altered effect of the calcium channel blocker.

Beta-blockers may have increased pharmacokinetic or pharmacodynamic interactions with felodipine.

Calcium may reduce the calcium channel blocker's effects, particularly hypotension.

Carbamazepine significantly reduces felodipine's bioavailability; avoid this combination.

Cimetidine may inhibit felodipine metabolism (AUC increased by 50%); use caution and monitor for potential hypotension.

Cyclosporine increases felodipine's serum concentration; avoid the combination or reduce dose of felodipine and monitor blood pressure.

CYP2C8 Substrates: Felodipine may increase the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of felodipine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of felodipine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nocardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Erythromycin decreases felodipine's metabolism; coadministration results in a twofold increase in the AUC and half-life of felodipine; monitor for hypotension.

Nafcillin decreases plasma concentration of felodipine; avoid this combination.

Rifampin increases the metabolism of the calcium channel blocker; adjust the dose of the calcium channel blocker to maintain efficacy.

Sildenafil, tadalafil, vardenafil: Blood pressure-lowering effects may be additive; use caution.

Tacrolimus: Felodipine may increase tacrolimus serum levels; monitor.

Pregnancy Risk Factor C

Pregnancy Implications Potentially, calcium channel blockers may prolong labor. There are no adequate or well-controlled studies in pregnant women.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Do not crush or chew pills; increased bioavailability when taken with grapefruit juice

Specific References

Chobanian AV, Bakris GL, Black HR, et al, "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, 289(19):2560-71.

Felodipine

Related Information

- Calcium Channel Blockers

CAS Number 72509-76-3; 86189-69-7

U.S. Brand Names Plendil®

Use Treatment of hypertension, congestive heart failure

Mechanism of Action Dihydropyridine calcium channel blocking agent similar to nifedipine; predominantly vasodilatory actions

Adverse Reactions

Cardiovascular: Peripheral edema, flushing, tachycardia, sinus bradycardia, angina, chest pain, QRS prolongation, sinus tachycardia

Central nervous system: Headache, dizziness, insomnia, night terrors, CNS depression, depression

Dermatologic: Urticaria, eczema, purpura, pruritus, exanthem

Gastrointestinal: Vomiting, xerostomia, flatulence, gingival hyperplasia, constipation

Neuromuscular & skeletal: Weakness, paresthesia, exacerbation of myasthenia gravis in elderly

Respiratory: Cough, hyposmia

Signs and Symptoms of Overdose Bradycardia, hypotension

Pharmacodynamics/Kinetics

Onset of action: Antihypertensive: 2-5 hours

Duration of antihypertensive effect: 24 hours

Absorption: 100%; Absolute: 20% due to first-pass effect

Protein binding: >99%

Metabolism: Hepatic; CYP3A4 substrate (major); extensive first-pass effect

Half-life elimination: Immediate release: 11-16 hours

Excretion: Urine (70% as metabolites); feces 10%

Dosage

Adults: Oral: 2.5-10 mg once daily; usual initial dose: 5 mg; increase by 5 mg at 2-week intervals, as needed; maximum: 10 mg

Usual dose range (JNC 7) for hypertension: 2.5-20 mg once daily

Elderly: Begin with 2.5 mg/day

Dosing adjustment/comments in hepatic impairment: May require lower dosages (initial: 2.5 mg/day); monitor blood pressure

Administration Do not crush or chew extended release tablets; swallow whole.

Contraindications Hypersensitivity to felodipine, any component of the formulation, or other calcium channel blocker

Warnings Watch for hypotension and syncope (can rarely occur). Reflex tachycardia may occur. Use caution in patients with heart failure particularly with concurrent beta-blocker use. Elderly patients and patients with hepatic impairment should start off with a lower dose. Peripheral edema is the most common side effect (occurs within 2-3 weeks of starting therapy). Use caution in hepatic impairment. Safety and efficacy in children have not been established. Dosage titration should occur after 14 days on a given dose.

Dosage Forms Tablet, extended release: 2.5 mg, 5 mg, 10 mg

Femoxetine

CAS Number 59859-58-4

Unlabeled/Investigational Use Antidepressant, narcolepsy, tension headache

Mechanism of Action A phenylpiperidine derivative which selectively inhibits reuptake of serotonin

Adverse Reactions

Cardiovascular: Palpitations

Central nervous system: Nervousness, anxiety, insomnia, dizziness, headache

Dermatologic: Urticaria
 Gastrointestinal: Nausea, xerostomia, constipation
 Genitourinary: Dysuria
 Hepatic: Hepatitis
 Neuromuscular & skeletal: Tremor
 Respiratory: Nasal congestion
 Miscellaneous: Diaphoresis

Toxicodynamics/Kinetics

Metabolism: Hepatic to active (norfemoxetine) and inactive metabolites
 Bioavailability: 5% to 10%
 Half-life: ~20 hours (norfemoxetine half-life: 4-19 hours)
 Elimination: Primarily renal (54% to 81%). Total body clearance: 8-50 L/hour/kg; Feces (6% to 11%)

Dosage

Depression: 300-600 mg in 3 divided doses; start at the lower dose
 Narcolepsy: 300 mg twice daily
 Tension headache: 100 mg 4 times/day
Dosing adjustment in hepatic impairment: Reduce initial dose to 100 mg/day

Reference Range Peak serum levels following a 500-600 mg dose: 120 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal. Consider gastric decontamination for ingestions > 1 g.
 Supportive therapy: Toxic symptoms should be treated supportively. Diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required.
 Enhancement of elimination: Multiple dosing of activated charcoal may not be useful; hemodialysis does not appear to be useful

Additional Information Does not appear to be as effective as propranolol for migraine prophylaxis

Fenoldopam

CAS Number 67227-56-9; 67227-57-0

U.S. Brand Names Corlopam®

Synonyms Fenoldopam Mesylate

Use Treatment of severe hypertension (up to 48 hours in adults), including in patients with renal compromise; short-term (up to 4 hours) blood pressure reduction in pediatric patients

Mechanism of Action A selective dopamine agonist (D₁-receptors) with vasodilatory properties; 6 times as potent as dopamine in producing vasodilatation

Adverse Reactions

Cardiovascular: Fibrillation (atrial), hypotension, edema, tachycardia, facial flushing, asymptomatic T wave flattening on ECG, flutter (atrial), chest pain, angina
 Central nervous system: Headache, dizziness
 Gastrointestinal: Nausea, vomiting, diarrhea
 Ocular: Increased intraocular pressure

Pharmacodynamics/Kinetics

Onset of action: I.V.: 10 minutes
 Duration: I.V.: 1 hour
 Distribution: V_d: 0.6 L/kg
 Half-life elimination: I.V.: Children: 3-5 minutes; Adults: ~5 minutes
 Metabolism: Hepatic via methylation, glucuronidation, and sulfation; the 8-sulfate metabolite may have some activity; extensive first-pass effect
 Excretion: Urine (90%); feces (10%)

Dosage I.V.: Hypertension, severe:

Children: Initial: 0.2 mcg/kg/minute; may be increased to dosages of 0.3-0.5 mcg/kg/minute every 20-30 minutes (maximum dose: 0.8 mcg/kg/minute); limited to short-term (4 hours) use

Adults: Initial: 0.1-0.3 mcg/kg/minute (lower initial doses may be associated with less reflex tachycardia); may be increased in increments of 0.05-0.1 mcg/kg/minute every 15 minutes until target blood pressure is reached; the maximal infusion rate reported in clinical studies was 1.6 mcg/kg/minute

Dosing adjustment in renal impairment: None required

Dosing adjustment in hepatic impairment: None published

Monitoring Parameters Blood pressure, heart rate, ECG, renal/hepatic function tests

Administration For I.V. infusion using an infusion pump.

Contraindications Hypersensitivity of fenoldopam or any component of the formulation

Warnings Use caution in patients with glaucoma or intraocular hypertension. A dose-related tachycardia can occur, especially at infusion rates > 0.1 mcg/kg/minute. Use caution in angina patients (can increase myocardial oxygen demand with tachycardia). Close monitoring of blood pressure is necessary (hypotension can occur). Monitor for hypokalemia at intervals of 6 hours during infusion. For continuous infusion only (no bolus doses). The effects of hemodialysis on the pharmacokinetics of fenoldopam have not been evaluated. Use caution with increased

intracranial pressure. Contains sulfites; may cause allergic reaction in susceptible individuals.

Dosage Forms Injection, solution: 10 mg/mL (1 mL, 2 mL) [contains sodium metabisulfite and propylene glycol]

Reference Range Mean plasma fenoldopam levels after a 2 hour infusion (at 0.5 mcg/kg/minute) and a 100 mg dose is approximately 13 ng/mL and 50 ng/mL

Overdosage/Treatment Supportive: I.V.: Usually discontinuing medication will often return blood pressure to baseline levels within 1 hour

Drug Interactions Concurrent acetaminophen may increase fenoldopam levels (30% to 70%).

Beta-blockers increase the risk of hypotension. Avoid concurrent use; if used concurrently, close monitoring is recommended.

Pregnancy Risk Factor B

Pregnancy Implications Fetal harm was not observed in animal studies; however, safety and efficacy have not been established for use during pregnancy. Use during pregnancy only if clearly needed. Fetal heart rate monitoring is recommended.

Lactation Excretion in breast milk unknown/use caution

Fenoprofen**Related Information**

- Nonsteroidal Anti-inflammatory Drugs

CAS Number 53746-45-5

U.S. Brand Names Nalfon®

Synonyms Fenoprofen Calcium

Use Symptomatic treatment of acute and chronic rheumatoid arthritis and osteoarthritis; relief of mild to moderate pain

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors; propionic acid derivative (like ibuprofen)

Adverse Reactions

Cardiovascular: Circulatory collapse, sinus tachycardia
 Central nervous system: **Dizziness**, headache, aseptic meningitis, psychosis, cognitive dysfunction, coma, seizures
 Dermatologic: **Rash**, pruritus, toxic epidermal necrolysis, exfoliative dermatitis, acne, alopecia, angioedema, urticaria, purpura, exanthem
 Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, fluid retention
 Gastrointestinal: **Abdominal cramps, heartburn, indigestion, nausea**, vomiting, GI bleeding, GI ulceration, constipation, diarrhea, dyspepsia, feces discoloration (black), aphthous stomatitis, xerostomia, stomatitis
 Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia; aplastic anemia (rare), platelet inhibition, red blood cell aplasia
 Hepatic: Elevated transaminases, hepatitis (fulminant)
 Ocular: Diplopia
 Otic: Ototoxicity, tinnitus
 Renal: Renal failure (acute), nephrotic syndrome, chronic renal failure, albuminuria, glomerulosclerosis
 Respiratory: Wheezing, respiratory depression
 Miscellaneous: Hypersensitivity

Signs and Symptoms of Overdose Azotemia, coagulopathy, cognitive dysfunction, drowsiness, erythema multiforme, gastritis, GI bleeding, nausea, nephrotic syndrome, ototoxicity, tinnitus, vomiting, wheezing
 Severe poisoning can manifest with agranulocytosis, coma, granulocytopenia, hypotension, hypothermia, leukopenia, neutropenia, renal failure and/or hepatic failure, respiratory depression, seizures, tachycardia

Pharmacodynamics/Kinetics

Onset of action: A few days
 Absorption: Rapid, 80%
 Distribution: Does not cross the placenta
 Protein binding: 99%
 Metabolism: Extensively hepatic
 Half-life elimination: 2.5-3 hours
 Time to peak, serum: ~2 hours
 Excretion: Urine (2% to 5% as unchanged drug); feces (small amounts)

Dosage

Adults: Oral:
 Rheumatoid arthritis: 300-600 mg 3-4 times/day up to 3.2 g/day
 Mild to moderate pain: 200 mg every 4-6 hours as needed

Monitoring Parameters Monitor CBC, liver enzymes; monitor urine output and BUN/serum creatinine in patients receiving diuretics

Administration

Do not crush tablets. Swallow whole with a full glass of water. Take with food to minimize stomach upset.

Contraindications Hypersensitivity to fenproporen, aspirin, or other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); significant renal dysfunction; pregnancy (3rd trimester)

Warnings [U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension. Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF, or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI, and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Not recommended for use in patients with advanced renal disease.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS), and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

The elderly are at increased risk for adverse effects (especially peptic ulceration, CNS effects, renal toxicity) from NSAIDs even at low doses. Withhold for at least 4-6 half-lives prior to surgical or dental procedures. Safety and efficacy have not been established in children < 18 years of age.

Dosage Forms

Capsule, as calcium (Nalfon®): 200 mg, 300 mg

Tablet, as calcium: 600 mg

Reference Range Therapeutic: 20-65 mcg/mL (SI: 82-268 µmol/L), not readily available

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage

Enhancement of elimination: Dialysis or hemoperfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be useful

Diagnostic Procedures

- Electrolytes, Blood
- Electrolytes, Urine
- Urinalysis

Test Interactions ↑ chloride (S), sodium (S); may yield false-positive for benzodiazepine and barbiturate assay

Drug Interactions ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet drugs (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatide, tirofiban) can cause an increased risk of bleeding.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids may increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

Gentamicin and amikacin serum concentrations are increased by indomethacin in premature infants. Results may apply to other aminoglycosides and NSAIDs.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use.

Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose. Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again.

Loop diuretics efficacy (diuretic and antihypertensive effect) is reduced. Indomethacin reduces this efficacy, however, it may be anticipated with any NSAID.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Thiazide efficacy (diuretic and antihypertensive effect) may be reduced. Indomethacin may reduce this efficacy and it may be anticipated with any NSAID.

Verapamil plasma concentration is decreased by diclofenac; avoid concurrent use.

Warfarin's INRs may be increased by piroxicam. Other NSAIDs may have the same effect depending on dose and duration. Monitor INR closely.

Use the lowest dose of NSAIDs possible and for the briefest duration.

Pregnancy Risk Factor B/D (3rd trimester)

Pregnancy Implications Does not cross the placenta

Lactation Enters breast milk/not recommended

Additional Information Generally nontoxic ingestions

Fenproporex

CAS Number 15686-61-0; 18305-29-8

Unlabeled/Investigational Use Anorectic agent (not FDA approved in U.S.)

Mechanism of Action Stimulant effects

Adverse Reactions

Cardiovascular: Palpitations, tachycardia

Central nervous system: Anxiety, headache, sleep disturbances

Gastrointestinal: Xerostomia

Toxicodynamics/Kinetics

Metabolism: Metabolized to amphetamine (both enantiomers)

Peak urine levels of amphetamine: 6-20 hours postdose

Elimination: Renal

Dosage Oral: 10-25 mg/day in divided doses before meals; long-acting preparation can be given at a dose of 20 mg before breakfast

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Seizures can be treated with lorazepam, diazepam, phenytoin, or phenobarbital; ventricular arrhythmias should be treated with lidocaine

Additional Information Will cause a positive urine amphetamine screen for up to 119 hours postdose (level of detection > 5 ng/mL). Maximal urinary amphetamine concentration after one 10 mg dose: ~2099 ng/mL. Available in Mexico (since 1972), Costa Rica, Spain, El Salvador, Panama, France, and Germany.

Fentanyl

Related Information

- Carfentanil Citrate

CAS Number 437-38-7; 990-73-8

U.S. Brand Names Actiq®; Duragesic®; Ionsys™; Sublimaze®

Synonyms Fentanyl Citrate; Fentanyl Hydrochloride

Impairment Potential

Use Sedation, relief of pain, preoperative medication, adjunct to general or regional anesthesia, management of chronic pain (transdermal product) Actiq® is indicated only for management of breakthrough cancer pain in patients who are tolerant to and currently receiving opioid therapy for persistent cancer pain.

Mechanism of Action Binds with stereospecific receptors at many sites within the CNS, increases pain threshold, alters pain reception, inhibits ascending pain pathways

Adverse Reactions

Cardiovascular: **Hypotension, bradycardia**, sinus bradycardia, angina, sinus tachycardia

Central nervous system: **CNS depression**, agitation, **drowsiness**, dizziness, **sedation**, electroencephalogram abnormalities, amnesia, paranoia

Dermatologic: Erythema, pruritus, urticaria, exanthem

Endocrine & metabolic: ADH release

Gastrointestinal: **Nausea**, dyspepsia, **vomiting, constipation**, biliary tract spasm, xerostomia, dysphagia (following intrathecal administration)

Genitourinary: Urinary tract spasm

Local: Transdermal system: Edema, erythema, pruritus

Neuromuscular & skeletal: Skeletal and thoracic muscle rigidity especially following rapid I.V. administration; dyskinesias; paresthesia

Ocular: Miosis

Respiratory: Apnea, **respiratory depression**, laryngospasm
 Miscellaneous: Physical and psychological dependence with prolonged use; chest wall rigidity can occur in neonates

Signs and Symptoms of Overdose Apnea, chest pain, coma, confusion, depression, dyspnea, exfoliative dermatitis, flatulence, hiccups, hypertension, hypertonia, hypotension, laryngospasm, pseudotumor cerebri, respiratory depression (especially with doses >200 mcg), seizures

Pharmacodynamics/Kinetics

Onset of action: Analgesic: I.M.: 7-15 minutes; I.V.: Almost immediate;
 Transmucosal: 5-15 minutes

Peak effect: Transmucosal: Analgesic: 20-30 minutes

Duration: I.M.: 1-2 hours; I.V.: 0.5-1 hour; Transmucosal: Related to blood level; respiratory depressant effect may last longer than analgesic effect
 Absorption:

Transmucosal: Rapid, ~25% from the buccal mucosa; 75% swallowed with saliva and slowly absorbed from GI tract

Iontophoretic transdermal system (Ionsys™): Fentanyl levels continue to rise for 5 minutes after the completion of each 10-minute dose

Distribution: Highly lipophilic, redistributes into muscle and fat

Metabolism: Hepatic, primarily via CYP3A4

Bioavailability: Transmucosal: ~50% (range: 36% to 71%)

Half-life elimination: 2-4 hours

Iontophoretic transdermal system (Ionsys™): 11 hours

Transdermal patch: 17 hours (half-life is influenced by absorption rate)

Transmucosal: 6.6 hours (range: 5-15 hours)

Time to peak: Transdermal patch: 24-72 hours

Excretion: Urine (primarily as metabolites, 10% as unchanged drug)

Dosage

Note: These are guidelines and do not represent the maximum doses that may be required in all patients. Doses should be titrated to pain relief/prevention. Monitor vital signs routinely. Single I.M. doses have a duration of 1-2 hours, single I.V. doses last 0.5-1 hour.

Children 1-12 years:

Sedation for minor procedures/analgesia: I.M., I.V.: 1-2 mcg/kg/dose; may repeat at 30- to 60-minute intervals.

Note: Children 18-36 months of age may require 2-3 mcg/kg/dose

Continuous sedation/analgesia: Initial I.V. bolus: 1-2 mcg/kg then 1 mcg/kg/hour; titrate upward; usual: 1-3 mcg/kg/hour

Pain control: Transdermal (limited to children >2 years who are opioid tolerant): Initial dose: 25 mcg/hour system (higher doses have been used based on equianalgesic conversion); change patch every 72 hours

Children > 12 years and Adults:

Sedation for minor procedures/analgesia: I.M., I.V.: 0.5-1 mcg/kg/dose; higher doses are used for major procedures

Pain control: Transdermal: Initial: 25 mcg/hour system; if currently receiving opiates, convert to fentanyl equivalent and administer equianalgesic dosage titrated to minimize the adverse effects and provide analgesia. Change patch every 72 hours. To convert patients from oral or parenteral opioids to Duragesic®, the previous 24-hour analgesic requirement should be calculated. This analgesic requirement should be converted to the equianalgesic oral morphine dose.

Adults:

Premedication: I.M., slow I.V.: 50-100 mcg/dose 30-60 minutes prior to surgery

Adjunct to regional anesthesia: I.M., slow I.V.: 50-100 mcg/dose; if I.V. used, give over 1-2 minutes

Severe pain: I.M.: 50-100 mcg/dose every 1-2 hours as needed; patients with prior opiate exposure may tolerate higher initial doses

Adjunct to general anesthesia: Slow I.V.:

Low dose: Initial: 2 mcg/kg/dose; Maintenance: Additional doses infrequently needed

Moderate dose: Initial: 2-20 mcg/kg/dose; Maintenance: 25-100 mcg/dose may be given slow I.V. or I.M. as needed

High dose: Initial: 20-50 mcg/kg/dose; Maintenance: 25 mcg to one-half the initial loading dose may be given as needed

General anesthesia without additional anesthetic agents: Slow I.V.: 50-100 mcg/kg with O₂ and skeletal muscle relaxant

Mechanically-ventilated patients (based on 70 kg patient): Slow I.V.: 0.35-1.5 mcg/kg every 30-60 minutes as needed; infusion: 0.7-10 mcg/kg/hour

Patient-controlled analgesia (PCA): I.V.: Usual concentration: 50 mcg/mL

Demand dose: Usual: 10 mcg; range: 10-50 mcg

Lockout interval: 5-8 minutes

Iontophoretic transdermal system: 40 mcg per activation on-demand (maximum: 6 doses/hour). Note: Patient's pain should be controlled prior to initiating system. Instruct patient how to operate system. Only the patient should initiate system. Each system operates for 24 hours or until 80 doses have been administered, whichever comes first.

Breakthrough cancer pain: Adults: Transmucosal: Actiq® dosing should be individually titrated to provide adequate analgesia with minimal side effects. It is indicated only for management of breakthrough cancer pain in patients who are tolerant to and currently receiving opioid therapy for

persistent cancer pain. An initial starting dose of 200 mcg should be used for the treatment of breakthrough cancer pain. Patients should be monitored closely in order to determine the proper dose. If redosing for the same episode is necessary, the second dose may be started 15 minutes after completion of the first dose. Dosing should be titrated so that the patient's pain can be treated with one single dose. Generally, 1-2 days is required to determine the proper dose of analgesia with limited side effects. Once the dose has been determined, consumption should be limited to 4 units/day or less. Patients needing more than 4 units/day should have the dose of their long-term opioid re-evaluated. If signs of excessive opioid effects occur before a dose is complete, the unit should be removed from the patient's mouth immediately, and subsequent doses decreased.

See tables.

Equianalgesic Doses of Opioid Agonists

Drug	Equianalgesic Dose (mg)	
	I.M.	P.O.
Codeine	75	130
Hydromorphone	1.5	7.5
Levorphanol	2 (acute)	4 (acute)
Meperidine	75	300
Methadone	10 (acute)	20 (acute)
Morphine	10	30
Oxycodone	—	20
Oxymorphone	1	10 (PR)

From "Principles of Analgesic Use," *Am Pain Soc*, 1999.

Corresponding Doses of Oral/Intramuscular Morphine and Duragesic™

P.O. 24-Hour Morphine (mg/d)	I.M. 24-Hour Morphine (mg/d)	Duragesic™ Dose (mcg/h)
45-134	8-22	25
135-224	28-37	50
225-314	38-52	75
315-404	53-67	100
405-494	68-82	125
495-584	83-97	150
585-674	98-112	175
675-764	113-127	200
765-854	128-142	225
855-944	143-157	250
945-1034	158-172	275
1035-1124	173-187	300

Product information, Duragesic™ — Janssen Pharmaceutica, January, 1991.

The dosage should not be titrated more frequently than every 3 days after the initial dose or every 6 days thereafter. The majority of patients are controlled on every 72-hour administration, however, a small number of patients require every 48-hour administration.

Elderly >65 years: Transmucosal: Actiq®: Dose should be reduced to 2.5-5 mcg/kg; elderly have been found to be twice as sensitive as younger patients to the effects of fentanyl. Patients in this age group generally require smaller doses of Actiq® than younger patients

Dosing adjustment in hepatic impairment: Actiq®: Although fentanyl kinetics may be altered in hepatic disease, Actiq® can be used successfully in the management of breakthrough cancer pain. Doses should be titrated to reach clinical effect with careful monitoring of patients with severe hepatic disease.

Stability

Protect from light; **incompatible** when mixed in the same syringe with pentobarbital; **incompatible** with thiopental sodium and methohexital sodium

Transmucosal: Store at controlled room temperature of 15°C to 30°C (59°F to 86°F)

Monitoring Parameters Respiratory and cardiovascular status, blood pressure, heart rate

Administration

I.V.: Muscular rigidity may occur with rapid I.V. administration. During prolonged administration, dosage requirements may decrease.

Transdermal: Apply to nonirritated and nonirradiated skin, such as chest, back, flank, or upper arm. Upper back is preferred location in children. Do not shave skin; hair at application site should be clipped. Prior to

application, clean site with clear water and allow to dry completely. Do not cut patch. Apply patch immediately after removing from package. Firmly press in place and hold for 30 seconds. Change patch every 72 hours. Keep transdermal product (both used and unused) out of the reach of children. Do **not** use soap, alcohol, or other solvents to remove transdermal gel if it accidentally touches skin, as they may increase transdermal absorption; use copious amounts of water. Avoid exposing application site to external heat sources (eg, heating pad, electric blanket, heat lamp, hot tub).

Transmucosal: Foil overwrap should be removed just prior to administration. Once removed, patient should place the unit in mouth and allow it to dissolve. Do **not** chew. Actiq® units may be occasionally moved from one side of the mouth to the other. The unit should be consumed over a period of 15 minutes. Unit should be removed after it is consumed or if patient has achieved an adequate response and/or shows signs of respiratory depression. For patients who have received transmucosal product within 6-12 hours, it is recommended that if other narcotics are required, they should be used at starting doses 1/4 to 1/3 those usually recommended.

Contraindications

Hypersensitivity to fentanyl or any component of the formulation; increased intracranial pressure; severe respiratory disease or depression including acute asthma (unless patient is mechanically ventilated); paralytic ileus; severe liver or renal insufficiency; pregnancy (prolonged use or high doses near term)

Iontophoretic transdermal system (lonsys™): Hypersensitivity to fentanyl, cetylpyridinium chloride (eg, Cepacol®) or any component of lonsys™ system

Transmucosal lozenges (Actiq®) or transdermal patches (eg, Duragesic®) must not be used in patients who are not opioid tolerant. Patients are considered opioid-tolerant if they are taking at least 60 mg morphine/day, 30 mg oral oxycodone/day, 8 mg oral hydromorphone/day, 25 mcg transdermal fentanyl/hour, or an equivalent dose of another opioid for ≥ 1 week. Transdermal patches are not for use in acute pain, mild pain, intermittent pain, or postoperative pain management.

Warnings

An opioid-containing analgesic regimen should be tailored to each patient's needs and based upon the type of pain being treated (acute versus chronic), the route of administration, degree of tolerance for opioids (naive versus chronic user), age, weight, and medical condition. The optimal analgesic dose varies widely among patients. Doses should be titrated to pain relief/prevention. When using with other CNS depressants, reduce dose of one or both agents. Fentanyl shares the toxic potentials of opiate agonists, and precautions of opiate agonist therapy should be observed; use with caution in patients with bradycardia; rapid I.V. infusion may result in skeletal muscle and chest wall rigidity leading to respiratory distress and/or apnea, bronchoconstriction, laryngospasm; inject slowly over 3-5 minutes. Tolerance or drug dependence may result from extended use. Use caution in patients with a history of drug dependence or abuse. The elderly may be particularly susceptible to the CNS depressant and constipating effects of narcotics. Use extreme caution in patients with COPD or other chronic respiratory conditions. Use caution with head injuries, hepatic or renal dysfunction.

Actiq®: **[U.S. Boxed Warning]: Should be used only for the care of cancer patients and is intended for use by specialists who are knowledgeable in treating cancer pain.** For patients who have received transmucosal product within 6-12 hours, it is recommended that if other narcotics are required, they should be used at starting doses 1/4 to 1/3 those usually recommended. **[U.S. Boxed Warning]: Actiq® preparations contain an amount of medication that can be fatal to children.** Keep all units out of the reach of children and discard any open units properly. Patients and caregivers should be counseled on the dangers to children including the risk of exposure to partially-consumed units. Safety and efficacy have not been established in children <16 years of age.

Transdermal patches (eg, Duragesic®): **[U.S. Boxed Warning]: Serious or life-threatening hypoventilation may occur, even in opioid-tolerant patients.** Serum fentanyl concentrations may increase approximately one-third for patients with a body temperature of 40°C secondary to a temperature-dependent increase in fentanyl release from the patch and increased skin permeability. Avoid exposure of application site to direct external heat sources. Patients who experience adverse reactions should be monitored for at least 24 hours after removal of the patch. Transdermal patch does not contain any metal-based compounds; the printed ink used to indicate strength on the outer surface of the patch does contain titanium dioxide but the amount is minimal; adverse events have not been reported while wearing during an MRI. **[U.S. Boxed Warning]: Safety and efficacy of transdermal patch have been limited to children ≥ 2 years of age who are opioid tolerant.**

Iontophoretic transdermal system (lonsys™): **[U.S. Boxed Warning]: Should only be used for the treatment of hospitalized patients. To avoid overdose, the patient should be the only one to activate the**

system. Unintended exposure to fentanyl hydrogel could lead to absorption of fatal dose; hydrogel should not come in contact with fingers or mouth. Should be used only in patients who are able to understand and follow instructions to operate the system. The error detection circuit uses a series of audible signals to alert the patient when a dose is not being delivered; use caution in patients who have high frequency hearing impairment. lonsys™ contains metal parts; remove prior to MRI procedure, cardioversion, or defibrillation. May interfere with radiographic image or CAT scan as system contains radiopaque components. Patients on chronic opioids or with a history of opioid abuse may require higher analgesic doses than lonsys™ is able to provide. Prior to patient's hospital discharge, the system must be removed and disposed of in accordance with State and Federal regulations for a C-II substance. **[U.S. Boxed Warning]: Even if all 80 doses are used, a significant amount of fentanyl remains in the iontophoretic transdermal system and requires proper removal and disposal to avoid misuse, abuse, or diversion.** Safety and efficacy of iontophoretic transdermal system have not been established in children <18 years of age.

Dosage Forms

Infusion [premixed in NS]: 0.05 mg (10 mL); 1 mg (100 mL); 1.25 mg (250 mL); 2 mg (100 mL); 2.5 mg (250 mL)

Injection, solution, as citrate [preservative free]: 0.05 mg/mL (2 mL, 5 mL, 10 mL, 20 mL, 30 mL, 50 mL)

Sublimaze®: 0.05 mg/mL (2 mL, 5 mL, 10 mL, 20 mL)

Lozenges, oral transmucosal, as citrate:

Actiq®: 200 mcg, 400 mcg, 600 mcg, 800 mcg, 1200 mcg, 1600 mcg [mounted on a plastic radiopaque handle; contains sugar 2 g/unit; raspberry flavor]

Transdermal patch: 25 mcg/hour [6.25 cm²] (5s); 50 mcg/hour [12.5 cm²] (5s); 75 mcg/hour [18.75 cm²]; 100 mcg/hour [25 cm²] (5s)

Duragesic®: 12 [delivers 12.5 mcg/hour; 5 cm²; contains alcohol 0.1 mL/10 cm²] (5s); 25 [delivers 25 mcg/hour; 10 cm²; contains alcohol 0.1 mL/10 cm²] (5s); 50 [delivers 50 mcg/hour; 20 cm²; contains alcohol 0.1 mL/10 cm²] (5s); 75 [delivers 75 mcg/hour; 30 cm²; contains alcohol 0.1 mL/10 cm²]; 100 [delivers 100 mcg/hour; 40 cm²; contains alcohol 0.1 mL/10 cm²] (5s)

Transdermal iontophoretic system:

lonsys™: Fentanyl hydrochloride 40 mcg/dose [80 doses/patch; contains 3-volt lithium battery]

Reference Range

Therapeutic: 2-200 mcg/L; opioid naive patients may exhibit CNS toxicity at serum fentanyl >3 mcg/L.

Serum level of 17.7 mcg/L has been correlated with fatality. Postmortem redistribution of drug may occur.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal for oral ingestion

Supportive therapy: Naloxone in large doses and/or a continuous infusion may be necessary; laryngospasm and masseter muscle spasm also respond to naloxone; inhaled beta adrenergic agents can be used to treat fentanyl-induced coughing; seizures can be treated with diazepam or thiopental

Enhancement of elimination: Not dialyzable

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Drug Interactions Substrate of CYP3A4 (major); Inhibits CYP3A4 (weak)

Antipsychotic agents (phenothiazines): May enhance the hypotensive effect of analgesics (narcotic).

CNS depressants: Increased sedation with CNS depressants.;

CYP3A4 inhibitors: May increase the levels/effects of fentanyl. Potentially fatal respiratory depression may occur when a potent inhibitor is used in a patient receiving chronic fentanyl (eg, transdermal patch). Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

MAO inhibitors: Not recommended to use Actiq® within 14 days. Severe and unpredictable potentiation by MAO inhibitors has been reported with opioid analgesics.

Pegvisomant: Analgesics (narcotic) may diminish the therapeutic effect of pegvisomant.

Protease inhibitors: May decrease the metabolism, via CYP isoenzymes, of fentanyl.

Selective serotonin reuptake inhibitors (SSRIs): Analgesics (narcotic) may enhance the serotonergic effect of SSRIs. This may cause serotonin syndrome.

Sibutramine: Fentanyl may enhance the serotonergic effect of sibutramine.

Pregnancy Risk Factor B/D (prolonged use or high doses at term)

Pregnancy Implications Fentanyl crosses the placenta and has been used safely during labor. Chronic use during pregnancy has shown

detectable serum levels in the newborn with mild opioid withdrawal (case report).

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Additional Information Lethal dose: Adults: I.V.: 1 mg

Half-life elimination: 14.4 hours

Time to peak, serum: ~2.6 hours

Excretion: Feces (~80%) and urine (~11%) as unchanged drug

Dosage Oral:

Children 6-11 years: 30 mg twice daily

Children ≥ 12 years and Adults:

Seasonal allergic rhinitis: 60 mg twice daily or 180 mg once daily

Chronic idiopathic urticaria: 60 mg twice daily

Dosing adjustment in renal impairment: Cl_{cr} < 80 mL/minute:

Children 6-11 years: Initial: 30 mg once daily

Children ≥ 12 years and Adults: Initial: 60 mg once daily

Stability Store capsules at controlled room temperature of 20°C to 25°C (68°F to 77°F). Protect from excessive moisture.

Monitoring Parameters Relief of symptoms

Administration Administer with water.

Contraindications Hypersensitivity to fexofenadine or any component of the formulation

Warnings Safety and effectiveness in children < 6 years of age have not been established.

Dosage Forms Tablet, as hydrochloride: 30 mg, 60 mg, 180 mg

Overdosage/Treatment

Decontamination: Lavage within 1 hour/activated charcoal

Enhancement of elimination: Hemodialysis removes <2% of dose

Drug Interactions **Substrate** of CYP3A4 (minor); **Inhibits** CYP2D6 (weak)

Antacids (containing aluminum or magnesium): AUC of fexofenadine was decreased by 41% and C_{max} by 43% with concomitant administration; separate administration is recommended.

Erythromycin: Levels of fexofenadine are increased (82% higher); not associated with increased adverse effects and no difference in QT_c intervals.

Ketoconazole: Levels of fexofenadine are increased (135% higher); not associated with increased adverse effects and no difference in QT_c intervals.

Pregnancy Risk Factor C

Pregnancy Implications There are no adequate and well-controlled studies in pregnant women; use during pregnancy only if potential benefit to mother outweighs possible risk to fetus.

Lactation Excretion in breast milk unknown/use caution (AAP rates "compatible")

Finasteride

CAS Number 98319-26-7

U.S. Brand Names Propecia®; Proscar®

Use Early data indicate that finasteride is useful in the treatment of symptomatic benign prostatic hyperplasia (BPH)

Unlabeled/Investigational Use Adjuvant monotherapy after radical prostatectomy in the treatment of prostatic cancer; female hirsutism

Mechanism of Action

Finasteride is a 4-azo analog of testosterone and is a competitive inhibitor of both tissue and hepatic 5-alpha reductase. This results in inhibition of the conversion of testosterone to dihydrotestosterone; markedly suppresses serum dihydrotestosterone levels; dependent on dose and duration, serum testosterone concentrations may or may not increase. Testosterone-dependent processes such as fertility, muscle strength, potency, and libido are not affected by finasteride.

In addition to hydrotestosterone levels, androstenediol and androsterone glucuronide are also suppressed, indicating inhibition of the formation of both unconjugated and conjugated 5-alpha reduced androgens

Adverse Reactions

Endocrine & metabolic: Decreased libido, breast tenderness, breast enlargement

Genitourinary: < 4% incidence of erectile dysfunction, decreased volume of ejaculate, testicular pain

Miscellaneous: Hypersensitivity (pruritus, urticaria, swelling of face/lips), breast cancer (males)

Admission Criteria/Prognosis Asymptomatic patients may be managed as out patients

Pharmacodynamics/Kinetics

Onset of action: 3-6 months of ongoing therapy

Duration:

After a single oral dose as small as 0.5 mg: 65% depression of plasma dihydrotestosterone levels persists 5-7 days

After 6 months of treatment with 5 mg/day: Circulating dihydrotestosterone levels are reduced to castrate levels without significant effects on circulating testosterone; levels return to normal within 14 days of discontinuation of treatment

Distribution: V_{dss}: 76 L

Protein binding: 90%

Metabolism: Hepatic via CYP3A4; two active metabolites (<20% activity of finasteride)

Bioavailability: Mean: 63%

Half-life elimination, serum: Elderly: 8 hours; Adults: 6 hours (3-16)

Fexofenadine

CAS Number 138452-21-8

U.S. Brand Names Allegra®

Synonyms Fexofenadine Hydrochloride

Impairment Potential None documented at 60 mg dose; impairment may occur at double the therapeutic dose

Use Relief of symptoms associated with seasonal allergic rhinitis; treatment of chronic idiopathic urticaria

Mechanism of Action Fexofenadine is an active metabolite of terfenadine and like terfenadine it competes with histamine for H₁-receptor sites on effector cells in the gastrointestinal tract, blood vessels, and respiratory tract; it appears that fexofenadine does not cross the blood brain barrier to any appreciable degree, resulting in a greatly reduced potential for sedation

Adverse Reactions

Central nervous system: **Headache** (with once-daily dosing) fever, dizziness, pain, drowsiness, fatigue, insomnia, nervousness, sleep disorders

Endocrine & metabolic: Dysmenorrhea

Gastrointestinal: Nausea, dyspepsia

Neuromuscular & skeletal: Back pain

Otic: Otitis media

Respiratory: Cough, upper respiratory tract infection, sinusitis

Miscellaneous: Viral infection, hypersensitivity reactions (anaphylaxis, angioedema, dyspnea, flushing, pruritus, rash, urticaria), paroniria

Pharmacodynamics/Kinetics

Onset of action: 60 minutes

Duration: Antihistaminic effect: ≥ 12 hours

Protein binding: 60% to 70%, primarily albumin and alpha₁-acid glycoprotein

Metabolism: Minimal (~5%)

FLECAINIDE

Time to peak, serum: 2-6 hours
Excretion: Feces (57%) and urine (39%) as metabolites

Dosage
Adults: Male: Benign prostatic hyperplasia: Oral: 5 mg/day as a single dose; clinical responses occur within 12 weeks to 6 months of initiation of therapy; long-term administration is recommended for maximal response
Dosing adjustment in renal impairment: No dosage adjustment is necessary

Monitoring Parameters Objective and subjective signs of relief of benign prostatic hyperplasia, including improvement in urinary flow, reduction in symptoms of urgency, and relief of difficulty in micturition

Administration Administration with food may delay the rate and reduce the extent of oral absorption. Childbearing age women should not touch or handle this medication.

Contraindications Hypersensitivity to finasteride or any component of the formulation; pregnancy; not for use in children

Warnings Hazardous agent - use appropriate precautions for handling and disposal. A minimum of 6 months of treatment may be necessary to determine whether an individual will respond to finasteride. Use with caution in those patients with hepatic dysfunction. Carefully monitor patients with a large residual urinary volume or severely diminished urinary flow for obstructive uropathy. These patients may not be candidates for finasteride therapy.

Dosage Forms Tablet: 5 mg
Propecia®: 1 mg
Proscar®: 5 mg

Reference Range Peak plasma level: 1-2 hours; peak plasma finasteride concentration after a 100 mg dose is ~835.5 (±199) mcg/L

Overdosage/Treatment Decontamination: Emesis within 30 minutes or lavage within 2 hours of ingestion; activated charcoal may be given; decontamination should be aggressive in a pregnant female

Test Interactions Finasteride does not influence plasma FSH, LH, cortisol, or estradiol levels; increases plasma testosterone levels; decreases plasma dihydrotestosterone and prostate specific antigen levels; no clinically significant effects on serum lipids

Drug Interactions Substrate of CYP3A4 (minor)

Pregnancy Risk Factor X

Pregnancy Implications Abnormalities of external male genitalia were reported in animal studies. Pregnant women are advised to avoid contact with crushed or broken tablets.

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Administration with food may delay the rate and reduce the extent of oral absorption

Additional Information May be useful in men with moderately symptomatic BPH who either refuse prostatectomy or are poor surgical candidates. The risk/benefit ratio and cost must be explained to the patient. Currently, there is no way to predict which men will respond to finasteride. The Washington Poison Control Center (206) 526-2121 can be contacted regarding toxicities of the Finasteride Study.

Flecainide

Related Information

- Lorcaïnide

CAS Number 54143-55-4
U.S. Brand Names Tambacor™
Synonyms Flecainide Acetate

Use Prevention and suppression of documented life-threatening ventricular arrhythmias (ie, sustained tachycardia (ventricular)); controlling symptomatic, disabling tachycardia (ventricular) in patients without structural heart disease (class I agent)

Mechanism of Action Class IC antiarrhythmic; slows conduction in cardiac tissue by altering transport of ions across cell membranes; causes slight prolongation of refractory periods; decreases the rate of rise of the action potential without affecting its duration; increases electrical stimulation threshold of ventricle, His-Purkinje system; possesses local anesthetic and moderate negative inotropic effects

Adverse Reactions
Cardiovascular: Bradycardia, heart block, P-R prolongation, QRS prolongation, QT_c interval prolongation is minimal; worsening arrhythmias (ventricular), congestive heart failure, palpitations, chest pain, edema, cardiac arrest, hypotension, syncope, sinus bradycardia, angina, myocardial depression, sinus tachycardia, tachycardia (supraventricular), atrial flutter, exacerbation of Brugada syndrome
Central nervous system: **Dizziness**, fatigue, nervousness, hypoesthesia, seizures, psychosis, visual hallucinations, headache
Dermatologic: Rashes
Gastrointestinal: Nausea, metallic taste, vomiting
Hematologic: Blood dyscrasias
Hepatic: Possible hepatic dysfunction
Neuromuscular & skeletal: Tremors, dysarthria, paresthesia
Ocular: **Visual disturbances**, blurred vision, photophobia, diplopia

Respiratory: **Dyspnea**
Miscellaneous: Systemic lupus-like syndrome

Signs and Symptoms of Overdose Arthralgia, AV block, blurred vision, conduction disturbances, congestive heart failure, heart block, hypotension and death, impotence, increased T-wave amplitude, neurotopenia, primary arrhythmia has been noted, P-R prolongation, polymorphous or wide-complex ventricular tachycardia (although wide-complex supraventricular arrhythmias can occur), QRS prolongation, QT prolongation, syncope, reduced heart rate and myocardial contractility, tachycardia (ventricular)

Pharmacodynamics/Kinetics
Absorption: Oral: Rapid
Distribution: Adults: V_d: 5-13.4 L/kg
Protein binding: Alpha₁ glycoprotein: 40% to 50%
Metabolism: Hepatic
Bioavailability: 85% to 90%
Half-life elimination: Infants: 11-12 hours; Children: 8 hours; Adults: 7-22 hours, increased with congestive heart failure or renal dysfunction; End-stage renal disease: 19-26 hours
Time to peak, serum: ~1.5-3 hours
Excretion: Urine (80% to 90%, 10% to 50% as unchanged drug and metabolites)

Dosage

Oral:
Children: Initial: 3 mg/kg/day in 3 divided doses; usual 3-6 mg/kg/day in 3 divided doses; up to 11 mg/kg/day for uncontrolled patients with subtherapeutic levels
Adults: Initial: 100 mg every 12 hours, increase by 100 mg/day (given in 2 doses/day) every 4 days to maximum of 400 mg/day; for patients receiving 400 mg/day who are not controlled and have trough concentrations <0.6 mcg/mL, dosage may be increased to 600 mg/day
Children and Adults:
Dosing adjustment in severe renal impairment: Cl_{cr} <10 mL/minute: Decrease usual dose by 25% to 50%
Dosing adjustment/comments in hepatic impairment: Monitoring of plasma levels is recommended because of significantly increased half-life

Monitoring Parameters ECG, blood pressure, pulse, periodic serum concentrations, especially in patients with renal or hepatic impairment

Administration Administer around-the-clock to promote less variation in peak and trough serum levels

Contraindications Hypersensitivity to flecainide or any component of the formulation; pre-existing second- or third-degree AV block or with right bundle branch block when associated with a left hemiblock (bifascicular block) (except in patients with a functioning artificial pacemaker); cardiogenic shock; coronary artery disease (based on CAST study results); concurrent use of ritonavir or amprenavir

Warnings [U.S. Boxed Warning]: In the Cardiac Arrhythmia Suppression Trial (CAST), recent (>6 days but <2 years ago) myocardial infarction patients with asymptomatic, nonlife-threatening ventricular arrhythmias did not benefit and may have been harmed by attempts to suppress the arrhythmia with flecainide or encainide. An increased mortality or nonfatal cardiac arrest rate (7.7%) was seen in the active treatment group compared with patients in the placebo group (3%). The applicability of the CAST results to other populations is unknown. The risks of class 1C agents and the lack of improved survival make use in patients without life-threatening arrhythmias generally unacceptable. Not recommended for patients with chronic atrial fibrillation; may have proarrhythmic effects. When treating atrial flutter, 1:1 atrioventricular conduction may occur; pre-emptive negative chronotropic therapy (eg, digoxin, beta-blockers) may lower the risk. Pre-existing hypokalemia or hyperkalemia should be corrected before initiation (can alter drug's effect). A worsening or new arrhythmia may occur (proarrhythmic effect). Use caution in heart failure (may precipitate or exacerbate CHF). Dose-related increases in PR, QRS, and QT intervals occur. Use with caution in sick sinus syndrome or with permanent pacemakers or temporary pacing wires (can increase endocardial pacing thresholds). Cautious use in significant hepatic impairment.

Dosage Forms Tablet, as acetate: 50 mg, 100 mg, 150 mg

Reference Range

Therapeutic: 0.2-1.0 mcg/mL (SI: 0.4-2.0 μmol/L)
Fatal: 21.3 mcg/mL associated with fatality
Postmortem flecainide blood concentration was 6.87 mcg/mL following pediatric overdose.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: Monitoring; flecainide-induced tachycardia (ventricular) should be treated with ventricular pacing, antiarrhythmic drugs and/or cardioversion; however, it is commonly refractory to these measures; isoproterenol can be used for bradyarrhythmias; sodium bicarbonate (1-2 mEq/kg) can be given for ventricular conduction delays; sotalol can be used to treat flecainide-induced atrial flutter; peripheral cardiopulmonary

bypass support can assist in hemodynamic support for improvement of drug clearance and allows time for redistribution

Enhancement of elimination: Multiple dosing of activated charcoal or charcoal hemoperfusion may be helpful; do not alkalinize the urine

Drug Interactions **Substrate** of CYP1A2 (minor), 2D6 (major); **Inhibits** CYP2D6 (weak)

Amiodarone increases in flecainide plasma levels; consider reducing flecainide dose by 25% to 33% with concurrent use.

Amprenavir and ritonavir may increase cardiotoxicity of flecainide (decrease metabolism).

Cimetidine may decrease flecainide's metabolism; monitor cardiac status or use an alternative H₂ antagonist.

CYP2D6 inhibitors: May increase the levels/effects of flecainide. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Digoxin's serum concentration may increase slightly.

Propranolol (and possibly other beta-blockers) increases flecainide blood levels, and propranolol blood levels are increased with concurrent use; monitor for excessive negative inotropic effects.

Quinidine may decrease flecainide's metabolism; monitor cardiac status. Urinary alkalinizers (antacids, sodium bicarbonate, acetazolamide) may increase flecainide blood levels.

Pregnancy Risk Factor C

Pregnancy Implications Can cause transient neonatal conjugated hyperbilirubinemia

Lactation Enters breast milk/compatible

Additional Information Based on adverse outcomes noted with flecainide in the CAST trial, the FDA recommends that use of flecainide be limited to patients with life-threatening ventricular arrhythmias; case fatality rate in overdose setting is 8%

Fleroxacin

CAS Number 79660-72-3

Unlabeled/Investigational Use Urinary tract infections, sexually transmitted diseases, skin/soft tissue infections, bone and joint infections, respiratory tract infections, chancroid, bacterial diarrhea, typhoid fever, effective against Enterobacteriaceae, *Acetobacter*, *Haemophilus*, *Neisseria*, *Moraxella*

Mechanism of Action Fluoroquinolone which inhibits bacterial DNA gyrase and thus has bactericidal activity

Adverse Reactions

Cardiovascular: Flushing

Central nervous system: Insomnia, headache, dizziness, night terrors, lethargy

Dermatologic: Photosensitivity, pruritus

Gastrointestinal: Nausea, vomiting, diarrhea, flatulence, xerostomia

Hematologic: Eosinophilia

Toxicodynamics/Kinetics

Distribution: V_d: 1.3-1.8 L/kg

Protein binding: 30%

Metabolism: Hepatic N-demethylation and N-oxidation to N-desmethyl-fleroxacin (active metabolite) and to fleroxacin-N-oxide (inactive)

Bioavailability: 96% to 100%

Half-life: 8.9-10.3 hours

Elimination: Urine

Dosage

Oral:

Uncomplicated urinary tract infection: 200 mg/day for 10 days

Complicated urinary tract infection: 400 mg/day for 10 days

Uncomplicated cervical or urethral gonorrhea: Single 400 mg dose

Bronchitis: 400 mg once daily

Skin/soft tissue infection: 400 mg/day

Typhoid fever: 400 mg/day for 7 days

I.V.: Urinary tract infection: 400 mg

Reference Range After an 800 mg oral dose, peak serum fleroxacin levels range from 7-15.6 mcg/mL; therapeutic serum levels: 1-4 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Do **not** use flumazenil; diazepam, phenobarbital; phenytoin can be used for seizures

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Additional Information Less effective than other quinolones against *Streptococcus pneumoniae*, or *Pseudomonas aeruginosa*

Floxuridine

Related Information

- Fluorouracil

CAS Number 50-91-9

U.S. Brand Names FUDR®

Synonyms 5-FUDR; Fluorodeoxyuridine; FUDR; NSC-27640

Use Antineoplastic agent usually used to treat hepatic metastasis from gastrointestinal carcinoma or other solid neoplasms.

Mechanism of Action Mechanism of action and pharmacokinetics are very similar to fluorouracil; floxuridine is the deoxyribonucleotide of fluorouracil. Floxuridine is a fluorinated pyrimidine antagonist which inhibits DNA and RNA synthesis and methylation of deoxyuridylic acid to thymidylic acid.

Adverse Reactions

Dermatologic: Alopecia, photosensitivity, hyperpigmentation of the skin, localized erythema, dermatitis

Gastrointestinal: **Stomatitis, diarrhea**; may be dose-limiting; anorexia, nausea, vomiting

Hematologic: **Myelosuppression**, may be dose-limiting; **leukopenia, thrombocytopenia, anemia**

Onset: 4-7 days

Nadir: 5-9 days

Recovery: 21 days

Hepatic: Biliary sclerosis, cholecystitis, jaundice, intrahepatic abscess

Pharmacodynamics/Kinetics

Metabolism: Hepatic; Active metabolites: Floxuridine monophosphate (FUDR-MP) and fluorouracil; Inactive metabolites: Urea, CO₂, α-fluoro-β-alanine, α-fluoro-β-guanidopropionic acid, α-fluoro-β-ureidopropionic acid, and dihydrofluorouracil

Excretion: Urine: Fluorouracil, urea, α-fluoro-β-alanine, α-fluoro-β-guanidopropionic acid, α-fluoro-β-ureidopropionic acid, and dihydrofluorouracil; exhaled gases (CO₂)

Dosage

Intra-arterial through infusion pump: 0.1-0.6 mg/kg/day. Ranitidine (150 mg twice daily) and heparin (10,000 units/50 mL of solution added to floxuridine infusate) are usually given concomitantly. Dose is usually given for 1-6 weeks.

Meningeal neoplasia: Intraventricular: 4-16 mg

Solid tumors: I.V.: 0.5-1 mg/kg/day for 6-15 days by continuous infusion.

May be administered with thymidine (30 mg/kg/day) to decrease toxicity. Bolus infusions of 30 mg/kg/day every other day for up to 11 days or until toxicity occurs have also been used to treat solid tumors.

Monitoring Parameters WBC and platelet counts. If WBC falls below 3500/mm³ or platelet count falls below 100,000/mm³, treatment should be stopped.

Administration Continuous intra-arterial or I.V. infusion (unlabeled use)

Contraindications Hypersensitivity to floxuridine, fluorouracil, or any component of the formulation; pregnancy

Warnings Hazardous agent – use appropriate precautions for handling and disposal. Use caution in impaired kidney or liver function. Discontinue if intractable vomiting, diarrhea, precipitous fall in leukocyte or platelet counts, myocardial ischemia, hemorrhage, gastrointestinal ulcer, or stomatitis occur. Use with caution in patients with poor nutritional status; depressed (leukocyte count <5000/mm³ or platelet count <100,000/mm³) bone marrow function; potentially serious infections. Use with caution in patients who have had high-dose pelvic radiation or previous use of alkylating agents. Use of floxuridine with pentostatin has been associated with a high incidence of fatal pulmonary toxicity; this combination is not recommended. [**U.S. Boxed Warnings**]: **Should be administered under the supervision of an experienced cancer chemotherapy physician. Patients should be hospitalized for initiation of the first course of therapy due to the risk for severe toxic reactions.**

Dosage Forms Injection, powder for reconstitution: 500 mg

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal for oral ingestion

Supportive therapy: Allopurinol (300 mg 3 times/day) may be useful in decreasing toxicity; for treatment of acute encephalopathy, dexamethasone (10 mg every 6 hours I.V.) and thiamine may expedite neurologic recovery. High dose prednisone can be used to treat interstitial pneumonitis.

Enhancement of elimination: Forced diuresis or hemodialysis may enhance elimination

Drug Interactions Patients may experience impaired immune response to vaccines

Possible infection after administration of live vaccines in patients receiving immunosuppressants

Pregnancy Risk Factor D

Lactation Excretion in breast milk unknown/contraindicated

Fluconazole

CAS Number 86386-73-4

U.S. Brand Names Diflucan®

Use

Treatment of oral or vaginal candidiasis unresponsive to nystatin or clotrimazole; nonlife-threatening *Candida* infections (eg, cystitis, esophagitis); treatment of hepatosplenic candidiasis; treatment of other *Candida* infections in persons unable to tolerate amphotericin B; treatment of cryptococcal infections; secondary prophylaxis for cryptococcal meningitis in persons with AIDS; antifungal prophylaxis in allogeneic bone marrow transplant recipients

Oral fluconazole should be used in persons able to tolerate oral medications; parenteral fluconazole should be reserved for patients who are both unable to take oral medications and are unable to tolerate amphotericin B (eg, due to hypersensitivity or renal insufficiency)

Mechanism of Action Interferes with cytochrome P450 activity, decreasing ergosterol synthesis (principal sterol in fungal cell membrane) and inhibiting cell membrane formation

Adverse Reactions

Cardiovascular: Pallor, torsade de pointes

Central nervous system: Dizziness, seizures, headache

Dermatologic: Skin rash, exfoliative dermatitis, alopecia, urticaria, erythema multiforme, angioedema, bullous skin disease, toxic epidermal necrolysis, purpura, Stevens-Johnson syndrome, pruritus, exanthem

Endocrine & metabolic: Hypokalemia, amenorrhea

Gastrointestinal: Nausea, abdominal pain, vomiting, diarrhea

Hematologic: Thrombocytopenia

Hepatic: Elevation of AST, ALT, or alkaline phosphatase; hepatic necrosis, aminotransferase level elevation (asymptomatic)

Neuromuscular & skeletal: Paresthesia

Renal: Renal failure

Miscellaneous: Fixed drug eruption

Signs and Symptoms of Overdose Convulsions, hepatic failure, hepatitis, hypokalemia, nausea, vomiting

Pharmacodynamics/Kinetics

Distribution: Widely throughout body with good penetration into CSF, eye, peritoneal fluid, sputum, skin, and urine

Relative diffusion blood into CSF: Adequate with or without inflammation (exceeds usual MICs)

CSF: blood level ratio: Normal meninges: 70% to 80%; Inflamed meninges: >70% to 80%

Protein binding, plasma: 11% to 12%

Bioavailability: Oral: >90%

Half-life elimination: Normal renal function: ~30 hours

Time to peak, serum: Oral: 1-2 hours

Excretion: Urine (80% as unchanged drug)

Dosage The daily dose of fluconazole is the same for oral and I.V. administration

Usual dosage ranges:

Neonates: First 2 weeks of life, especially premature neonates: Same dose as older children every 72 hours

Children: Loading dose: 6-12 mg/kg; maintenance: 3-12 mg/kg/day; duration and dosage depends on severity of infection

Adults: 200-400 mg/day; duration and dosage depends on severity of infection

Indication-specific dosing:

Children:

Candidiasis:

Oropharyngeal: Loading dose: 6 mg/kg; maintenance: 3 mg/kg/day for 2 weeks

Esophageal: Loading dose: 6 mg/kg; maintenance: 3-12 mg/kg/day for 21 days and at least 2 weeks following resolution of symptoms

Systemic infection: 6 mg/kg every 12 hours for 28 days

Meningitis, cryptococcal: Loading dose: 12 mg/kg; maintenance: 6-12 mg/kg/day for 10-12 weeks following negative CSF culture; relapse suppression: 6 mg/kg/day

Adults:

Candidiasis:

Candidemia, primary therapy, non-neutropenic: 400-800 mg/day for 14 days after last positive blood culture and resolution of signs/symptoms

Alternate therapy: 800 mg/day with amphotericin B for 4-7 days followed by 800 mg/day for 14 days after last positive blood culture and resolution of signs/symptoms

Candidemia, secondary, neutropenic: 6-12 mg/kg/day for 14 days after last positive blood culture and resolution of signs/symptoms

Chronic, disseminated: 6 mg/kg/day for 3-6 months

Oropharyngeal (long-term suppression): 200 mg/day; chronic therapy is recommended in immunocompromised patients with history of oropharyngeal candidiasis (OPC)

Osteomyelitis: 6 mg/kg/day for 6-12 months

Esophageal: 200 mg on day 1, then 100-200 mg/day for 2-3 weeks after clinical improvement

Prophylaxis in bone marrow transplant: 400 mg/day; begin 3 days before onset of neutropenia and continue for 7 days after neutrophils >1000 cells/mm³

Urinary: 200 mg/day for 1-2 weeks

Vaginal: 150 mg as a single dose

Coccidiomycosis: 400 mg/day; doses of 800-1000 mg/day have been used for meningial disease; usual duration of therapy ranges from 3-6 months for primary uncomplicated infections and up to 1 year for pulmonary (chronic and diffuse) infection

Endocarditis, prosthetic valve, early: 6-12 mg/kg/day for 6 weeks after valve replacement

Endophthalmitis: 6-12 mg/kg/day or 400-800 mg/day for 6-12 weeks after surgical intervention. Note: *C. krusei* and *C. galbrata* infection acquired exogenously should be treated with voriconazole.

Meningitis, cryptococcal: 400-800 mg/day for 10-12 weeks or with flucytosine 100-150 mg/day for 6 weeks; maintenance: 200-400 mg/day

Pneumonia, cryptococcal (mild-to-moderate): 200-400 mg/day for 6-12 months (life-long in HIV-positive patients)

Dosing adjustment/interval in renal impairment:

No adjustment for vaginal candidiasis single-dose therapy

For multiple dosing, administer usual load then adjust daily doses

Cl_{cr} ≤50 mL/minute (no dialysis): Administer 50% of recommended dose or administer every 48 hours.

Hemodialysis: 50% is removed by hemodialysis; administer 100% of daily dose (according to indication) after each dialysis treatment.

Continuous arteriovenous or venovenous hemodiafiltration effects: Dose as for Cl_{cr} 10-50 mL/minute

Stability Parenteral admixture at room temperature (25°C): Manufacturer expiration dating; do not refrigerate

Monitoring Parameters Periodic liver function tests (AST, ALT, alkaline phosphatase) and renal function tests, potassium

Administration

Parenteral fluconazole must be administered by I.V. infusion over approximately 1-2 hours; do not exceed 200 mg/hour when giving I.V. infusion

Contraindications Hypersensitivity to fluconazole, other azoles, or any component of the formulation; concomitant administration with cisapride

Warnings Should be used with caution in patients with renal and hepatic dysfunction or previous hepatotoxicity from other azole derivatives. Patients who develop abnormal liver function tests during fluconazole therapy should be monitored closely and discontinued if symptoms consistent with liver disease develop. Use caution in patients at risk of proarrhythmias.

Dosage Forms

Infusion [premixed in sodium chloride]: 2 mg/mL (100 mL, 200 mL)

Diflucan® [premixed in sodium chloride or dextrose] 2 mg/mL (100 mL, 200 mL)

Powder for oral suspension (Diflucan®): 10 mg/mL (35 mL); 40 mg/mL (35 mL) [contains sodium benzoate; orange flavor]

Tablet (Diflucan®): 50 mg, 100 mg, 150 mg, 200 mg

Reference Range Serum fluconazole trough levels >80 mcg/mL may be associated with seizures.

Overdosage/Treatment Enhancement of elimination: 3-hour hemodialysis will remove 50% (unlikely to require this procedure)

Drug Interactions

Inhibits CYP1A2 (weak), 2C9 (strong), 2C19 (strong), 3A4 (moderate) Benzodiazepines (metabolized by oxidation, eg, alprazolam, triazolam, midazolam, diazepam) serum concentrations are increased by fluconazole which may cause increased CNS sedation. Consider a benzodiazepine not metabolized by CYP3A4 or another antifungal.

Caffeine's metabolism is decreased; monitor for tachycardia, nervousness, and anxiety.

Calcium channel blockers may have increased serum concentrations; consider another agent instead of a calcium channel blocker, another antifungal, or reduce the dose of the calcium channel blocker. Monitor blood pressure.

Cisapride's serum concentration is increased which may lead to malignant arrhythmias; concurrent use is contraindicated.

Cyclosporine's serum concentration is increased; monitor cyclosporine's serum concentration and renal function.

CYP2C9 Substrates: Fluconazole may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

CYP2C19 substrates: Fluconazole may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

CYP3A4 substrates: Fluconazole may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors

(lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

HMG-CoA reductase inhibitors (except pravastatin and fluvastatin) have increased serum concentrations; switch to pravastatin/fluvastatin or monitor for development of myopathy.

Losartan's active metabolite is reduced in concentration; consider another antihypertensive agent unaffected by the azole antifungals, another antifungal, or monitor blood pressure closely.

Phenytoin's serum concentration is increased; monitor phenytoin levels and adjust dose as needed.

Rifampin decreases fluconazole's serum concentration; monitor infection status.

Tacrolimus's serum concentration is increased; monitor tacrolimus's serum concentration and renal function.

Warfarin's effects are increased; monitor INR and adjust warfarin's dose as needed.

Pregnancy Risk Factor C

Pregnancy Implications When used in high doses, fluconazole is teratogenic in animal studies. Following exposure during the first trimester, case reports have noted similar malformations in humans when used in higher doses (400 mg/day) over extended periods of time. Use of lower doses (150 mg as a single dose or 200 mg/day) may have less risk; however, additional data is needed. Use during pregnancy only if the potential benefit to the mother outweighs any potential risk to the fetus.

Lactation Enters breast/not recommended (AAP rates "compatible")

Nursing Implications Monitor renal function as dosage adjustments are required with significant changes in renal function

Additional Information Expensive oral alternative to I.V. amphotericin B infusions; in some clinical studies it has been as effective as amphotericin B, but is less likely to cause serious adverse reactions; represents a significant advancement in the treatment of systemic cryptococcosis, including meningitis

Flunitrazepam

Related Information

- Clonazepam
- Nitrazepam

CAS Number 1622-62-4

Synonyms RO5-4200

Impairment Potential Yes. Serum flunitrazepam levels >0.01 mg/L are associated with driving impairment

Use Not marketed in United States, but is encountered in the U.S. as a drug of abuse; used for insomnia and sedation (short-term therapy) and anesthesia induction or supplementation in Europe

Mechanism of Action Intermediate to long-acting benzodiazepine, this agent facilitates the gamma-aminobutyric acid-mediated neuroreceptors

Adverse Reactions

Cardiovascular: Tachycardia, myocardial depression, hypotension, shock, congestive heart failure, sinus tachycardia

Central nervous system: Lethargy, dizziness, ataxia, headache, night terrors, amnesia (anterograde), cognitive dysfunction

Gastrointestinal: Nausea, diarrhea

Hematologic: Porphyria

Neuromuscular & skeletal: Tremor

Respiratory: Cough, apnea

Miscellaneous: Hiccups

Signs and Symptoms of Overdose Apnea, ataxia, coma, hypotension

Pharmacodynamics/Kinetics

Onset: 20 minutes

Peak sedation: 1-2 hours

Duration of sedation: 8-12 hours

Absorption: Food can reduce absorption by 50%

Distribution: V_d : 3.4-5.5 L/kg

Protein binding: 80% to 90%

Metabolism: Hepatic to 7-aminoflunitrazepam and other metabolites

Bioavailability: 80% to 90%

Half-life: 19-22 hours

Elimination: Renal

Dosage

Anesthesia induction: I.V.: 0.015-0.03 mg/kg slowly over 30-60 seconds
Premedication for anesthesia: I.M.: 0.015-0.03 mg/kg slowly over 30-60 seconds

Anesthesia maintenance: I.V.: 0.2-0.5 mg (0.005-0.01 mg/kg) 2-3 hours after anesthesia induction

Insomnia: Oral: 0.5-2 mg nightly; in elderly, 0.5 mg dose should be initiated

Monitoring Parameters Blood pressure, heart rate, arterial blood gas

Contraindications Hypersensitivity to flunitrazepam, nitrazepam, or clonazepam

Warnings Use with caution in patients with porphyria, myasthenia gravis, cardiovascular disease, or hepatic/renal insufficiency; reduce dosage in elderly; dependence may occur

Dosage Forms Injection: 2 mg/mL

Tablet: 0.5 mg, 1 mg, 2 mg

Reference Range

Peak plasma levels after a 2 mg oral dose: 10-15 ng/mL

Urinary benzodiazepine micro-plate enzyme immunoassay can detect flunitrazepam and its metabolites up to 21 days after drug administration

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Flumazenil has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression and apnea; sedation also has been reversed with administration of aminophylline at a low-dose of 2 mg/kg I.V.

Enhancement of elimination: Multiple dose of activated charcoal may be effective

Antidote(s)

- Flumazenil [ANTIDOTE]

Test Interactions Urinary diazepam levels >1000 mcg/L may cross-react with flunitrazepam ELISA immunoassays.

Drug Interactions Enhances sedative effects of ethanol and general anaesthetics; with succinylcholine, increased intraocular pressure can occur; theophylline antagonizes sedative effects

Pregnancy Risk Factor D

Pregnancy Implications Can cross the placenta (no congenital malformations described) and accumulate in the fetus

Additional Information

About 10 times as potent as diazepam; insoluble in water; a growing drug of abuse in Europe and in the U.S. due to its euphoric producing qualities and low street price (\$1-\$3/tablet); usually several tablets are required for a euphoric effect; oral dose of 28 mg associated with fatality; psychomotor effects may last for 12 hours postdose; often abused in combination with heroin, ethanol, cocaine, or methamphetamine; not detectable on urine assays by EMIT for most benzodiazepine tests.

Hoffman-LaRoche can assist in analyzing urine specimens (1-800-608-6540) with a turnaround time of 1 week. General phone number for information (1-800-720-1076).

Urinary immunoassay for flunitrazepam may remain positive for up to 1 week (using an ELISA assay).

Fluoride

CAS Number 7681-49-4

UN Number 1690

U.S. Brand Names ACT[®] [OTC]; Fluor-A-Day [OTC]; Fluorigard[®] [OTC]; Fluorinse[®]; Flura-Drops[®]; Flura-Loz[®]; Gel-Kam[®] Rinse; Gel-Kam[®] [OTC]; Lozi-Flur[™]; Luride[®] Lozi-Tab[®]; Luride[®]; NeutraCare[®]; NeutraGard[®] [OTC]; Pediaflor[®]; Pharmaflur[®] 1.1; Pharmaflur[®]; Phos-Flur[®] Rinse [OTC]; Phos-Flur[®]; PreviDent[®] 5000 Plus[™]; PreviDent[®]; Stan-gard[®]; Stop[®]; Thera-Flur-N[®]

Synonyms Acidulated Phosphate Fluoride; Sodium Fluoride; Stannous Fluoride

Use Prevention of dental caries

Mechanism of Action Derived from hydrofluoric acid, reduces acid production by dental bacteria; increases tooth resistance to acid dissolution

Adverse Reactions

Cardiovascular: Arrhythmias (ventricular)

Dermatologic: Rash

Gastrointestinal: GI upset, nausea, feces discoloration (black), vomiting, stomach cramps

Neuromuscular & skeletal: Tremors, paresthesia, fasciculations

Respiratory: Asthma

Miscellaneous: Products containing stannous fluoride may stain the teeth; ulceration of mucous membranes

Signs and Symptoms of Overdose Abdominal pain, apnea, delirium, diarrhea, epigastric pain, esophageal stricture, fibrillation (ventricular), GI hemorrhage, hematuria, hyperkalemia, hypocalcemia, hypomagnesemia, hypotension, hypothyroidism, mydriasis, nausea, osteomalacia, respiratory paralysis, seizures, slurred speech, tetany, tremors, urine discoloration (milky), vomiting

FLUORIDE

Pharmacodynamics/Kinetics

Absorption: Oral: Rapid and complete; sodium fluoride; other soluble fluoride salts; calcium, iron, or magnesium may delay absorption
 Distribution: 50% of fluoride is deposited in teeth and bone after ingestion; topical application works superficially on enamel and plaque; crosses placenta; enters breast milk
 Excretion: Urine and feces

Dosage Oral:

Recommended daily fluoride supplement (2.2 mg of sodium fluoride is equivalent to 1 mg of fluoride ion): See table.

Fluoride Ion	
Fluoride Content of Drinking Water	Daily Dose, Oral (mg)
<0.3 ppm	
Birth - 6 mo	0
6 mo - 3 y	0.25
3-6 y	0.5
6 y	1.0
0.3-0.7 ppm	
Birth - 6 mo	0
6 mo - 3 y	0.125
3-6 y	0.25
6 y	0.5

Dental rinse or gel:

Children 6-12 years: 5-10 mL rinse or apply to teeth and spit daily after brushing

Adults: 10 mL rinse or apply to teeth and spit daily after brushing

Stability Store in tight plastic containers (not glass)

Contraindications Hypersensitivity to fluoride, tartrazine, or any component of the formulation; when fluoride content of drinking water exceeds 0.7 ppm; low sodium or sodium-free diets; do not use 1 mg tablets in children <3 years of age or when drinking water fluoride content is ≥ 0.3 ppm; do not use 1 mg/5 mL rinse (as supplement) in children <6 years of age

Warnings Prolonged ingestion with excessive doses may result in dental fluorosis and osseous changes; do not exceed recommended dosage; some products contain tartrazine

Dosage Forms [DSC] = Discontinued product

Cream, oral, as sodium [toothpaste]: 1.1% (51 g) [fluoride 2.5 mg/dose]

Denta 5000 Plus: 1.1% (51g) [fluoride 2.5 mg/dose; spearmint flavor]

EtheDent™: 1.1% (51g) [fluoride 2.5 mg/dose]

Gel-drops, as sodium fluoride (Thera-Flur-N®): 1.1% (24 mL) [fluoride 0.5%; neutral pH; no artificial color or flavor]

Gel, topical, as acidulated phosphate fluoride (Phos-Flur®): 1.1% (60 g) [fluoride 0.5%; cherry and mint flavors]

Gel, topical, as sodium fluoride: 1.1% (56 g) [fluoride 2 mg/dose]

DentaGel, EtheDent™: 1.1% (56 g) [fluoride 2 mg/dose; fresh mint flavor]

NeutraCare®: 1.1% (60 g) [neutral pH; grape and mint flavors]

NeutraGard® Advanced: 1.1% (60 g) [cinnamon and mint flavors]

PreviDent®: 1.1% (60 g) [fluoride 2 mg/dose; berry, cherry, and mint flavors]

Gel, topical, as stannous fluoride:

Gel-Kam®: 0.4% (129 g) [bubble gum, cinnamon, fruit/berry, and mint flavors]

Just for Kids™: 0.4% (122 g) [bubble gum, fruit punch, and grapey grape flavors]

Omnii Gel™: 0.4% (122 g) [cinnamon, grape, natural, mint, and raspberry flavors]

StanGard®: 0.4% (122 g) [bubble gum, cherry, mint, and raspberry flavors]

Stop®: 0.4% (120 g) [bubble gum, cinnamon, grape, and mint flavors]

Lozenge, as sodium [Lozi-Flur™]: 2.21 mg [fluoride 1 mg; cherry flavor]

Paste, oral, as sodium [toothpaste] (ControlRx®): 1.1% (56 g) [vanilla mint flavor]

Solution, oral drops, as sodium: 1.1 mg/mL (50 mL) [fluoride 0.5 mg/mL]

Flura-Drops®: 0.55 mg/drop (24 mL) [fluoride 0.25 mg/drop; dye free, sugar free]

Luride®: 1.1 mg/mL (50 mL) [fluoride 0.5 mg/mL; sugar free]

Pediaflor®: 1.1 mg/mL (50 mL) [fluoride 0.5 mg/mL; contains alcohol <0.5%; sugar free; cherry flavor] [DSC]

Solution, oral rinse, as sodium:

ACT®: 0.05% (530 mL) [fluoride 0.02%; bubble gum, cinnamon (contains tartrazine), and mint flavors]

ACT® Plus: 0.05% (530 mL) [fluoride 0.02%; alcohol free; icy cool mint flavor]

ACT® x2™: 0.5% (530 mL) [fluoride 0.02%; contains alcohol 11%; icy cool mint and spearmint flavors]

CaviRinse™: 0.2% (240 mL) [mint flavor]

Fluorigard®: 0.05% (480 mL) [alcohol free, sugar free; contains sodium benzoate and tartrazine; mint flavor]

Fluorinse®: 0.2% (480 mL) [alcohol free; cinnamon and mint flavors]

NeutraGard®: 0.05% (480 mL) [neutral pH; mint and tropical blast flavors]

NeutraGard® Plus: 0.2% (480 mL) [neutral pH; mint and tropical blast flavors]

Phos-Flur®: 0.44% (500 mL) [bubble gum, cherry, grape, and mint flavors]

PreviDent®: 0.2% (250 mL) [contains alcohol; mint flavor]

Solution, oral rinse concentrate, as stannous fluoride:

Gel-Kam®: 0.63% (300 mL) [fluoride 0.1%/dose; cinnamon and mint flavors]

PerioMed™: 0.63% (284 mL) [fluoride 7 mg/30 mL; alcohol free; cinnamon, mint and tropical fruit flavors]

StanGard® Perio: 0.63% (284 mL) [mint flavor]

Tablet, chewable, as sodium: 0.5 mg [fluoride 0.25 mg]; 1.1 mg [fluoride 0.5 mg]; 2.2 mg [fluoride 1 mg]

EtheDent™:
 0.55 mg [fluoride 0.25 mg; sugar free; contains aspartame; vanilla flavor]

1.1 mg [fluoride 0.5 mg; sugar free; contains aspartame; grape flavor]

2.2 mg [fluoride 1 mg; sugar free; contains aspartame; cherry flavor]

Fluor-A-Day:

0.56 mg [fluoride 0.25 mg; raspberry flavor]

1.1 mg [fluoride 0.5 mg; raspberry flavor]

2.21 mg [fluoride 1 mg; raspberry flavor]

Luride® Lozi-Tab®:

0.55 mg [fluoride 0.25 mg; sugar free; vanilla flavor]

1.1 mg [fluoride 0.5 mg; sugar free; grape flavor]

2.2 mg [fluoride 1 mg; sugar free; cherry flavor]

Pharmaflur®: 2.2 mg [fluoride 1 mg; dye free, sugar free; cherry flavor]

Pharmaflur® 1.1: 1.1 mg [fluoride 0.5 mg; dye free, sugar free; grape flavor]

Reference Range Normal serum level of fluoride: 1.9-7.6 mcg/dL (SI: 1-4 $\mu\text{mol/L}$); toxic serum fluoride level: >28.5 mcg/dL (SI: >15 $\mu\text{mol/L}$); toxic urine fluoride level is >10 mg/L

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) with 10% calcium gluconate; if <8 mg/kg is ingested, dilute with milk; **do not** induce emesis; **do not** administer sodium bicarbonate; magnesium based cathartics are preferred; calcium binds to fluoride to decrease the absorption

Supportive therapy: Calcium gluconate to reduce tetanic contractures; quinidine may be particularly effective for treatment of ventricular arrhythmias; monitor magnesium

Enhancement of elimination: Hemodialysis can be utilized; hemodialysis can remove over 80% of body stores of fluoride within 4 hours

Antidote(s)

● Calcium Gluconate [ANTIDOTE]

Test Interactions ↑ potassium; ↓ calcium

Drug Interactions Decreased effect/absorption with magnesium-, aluminum-, and calcium-containing products

Pregnancy Risk Factor C

Pregnancy Implications Crosses placenta

Nursing Implications Avoid giving with milk or dairy products

Additional Information

Fatal oral dose: 5-10 g

Odorless; not flammable; seafood can contain large amounts of fluoride (up to 28 mg/kg); tea can contain 0.5 mg/cup

PEL-TWA: 2.5 mg/m³; IDLH: 500 mg/m³

Total daily intake of fluoride: 2.1-2.4 mg (diet) and 2.8-5.9 mg (water)

In pediatrics, the therapeutic fluoride dosage is 0.05-0.07 mg/kg/day; fluorosis can develop at daily fluoride doses exceeding 0.1 mg/kg; fluoride supplementation should occur at age 6 months at a dose of 0.25 mg/day if their formulas or water contains <0.3 mg/L (0.3 ppm); this increases to daily supplementation of 0.5 mg at age 3 years and 1 mg at 6 years. Children >3 years of age require 0.25 mg/day of fluoride (0.5 mg/day at 6 years) if water fluoride ion level is 0.3-0.6 mg/L (0.3-0.6 ppm); fluoride levels in drinking water >0.6 mg/L (0.6 ppm) require no supplementation. Most fluoridated toothpastes contain ~1000 ppm of fluoride; thus, the daily dose of fluoride by brushing teeth is 0.134 mg from brushing once daily and 0.268 mg brushing twice daily. 53% of U.S. population drinks artificially fluoridated water at an optimal level of 1 mg/L (maximum allowable level 4 mg/L); carbonated beverages contain ~0.74 ppm of fluoride while tea contains ~2.6 ppm. Patients with skeletal fluorosis may exhibit lower serum testosterone levels

Fluorouracil

Related Information

- Floxuridine

CAS Number 51-21-8

U.S. Brand Names Adrucil®; Carac™; Efudex®; Fluoroplex®

Synonyms 5-Fluorouracil; 5-FU; FU

Use Treatment of carcinomas of the breast, colon, head and neck, pancreas, rectum, or stomach; topically for the management of actinic or solar keratoses and superficial basal cell carcinomas

Mechanism of Action A pyrimidine antimetabolite that interferes with DNA synthesis by blocking the methylation of deoxyuridylic acid; fluorouracil inhibits thymidylate synthetase (TS), or is incorporated into RNA. The reduced folate cofactor is required for tight binding to occur between the 5-FdUMP and TS.

Adverse Reactions

Toxicity depends on route and duration of treatment

I.V.:

- Cardiovascular: Angina, myocardial ischemia, nail changes
- Central nervous system: Acute cerebellar syndrome, confusion, disorientation, euphoria, headache, nystagmus
- Dermatologic: Alopecia, dermatitis, dry skin, fissuring, palmar-plantar erythrodysesthesia syndrome, pruritic maculopapular rash, photosensitivity, vein pigmentations
- Gastrointestinal: Anorexia, bleeding, diarrhea, esophagopharyngitis, nausea, sloughing, stomatitis, ulceration, vomiting
- Hematologic: Agranulocytosis, anemia, leukopenia, pancytopenia, thrombocytopenia

Myelosuppression:

Onset: 7-10 days

Nadir: 9-14 days

Recovery: 21-28 days

Local: Thrombophlebitis

Ocular: Lacrimation, lacrimal duct stenosis, photophobia, visual changes

Respiratory: Epistaxis

Miscellaneous: Anaphylaxis, generalized allergic reactions, loss of nails

Topical: Note: Systemic toxicity normally associated with parenteral administration (including neutropenia, neurotoxicity, and gastrointestinal toxicity) has been associated with topical use particularly in patients with a genetic deficiency of dihydropyrimidine dehydrogenase (DPD).

Central nervous system: Headache, telangiectasia

Dermatologic: Photosensitivity, pruritus, rash, scarring

Hematologic: Leukocytosis

Local: Allergic contact dermatitis, burning, crusting, dryness, edema, erosion, erythema, hyperpigmentation, irritation, pain, soreness, ulceration

Ocular: Eye irritation (burning, watering, sensitivity, stinging, itching)

Miscellaneous: Birth defects, miscarriage

Signs and Symptoms of Overdose Acrodynia, alopecia, bullous skin disease/pemphigoid, cardiogenic shock, coagulopathy, coma, dermatitis, drowsiness, encephalopathy, hypercalcemia, hyperkeratosis, hypotonia, lacrimation, myocarditis, neutropenia, pemphigus, photosensitivity

Pharmacodynamics/Kinetics

Duration: ~3 weeks

Distribution: V_d : ~22% of total body water; penetrates extracellular fluid, CSF, and third space fluids (eg, pleural effusions and ascitic fluid)

Metabolism: Hepatic (90%); via a dehydrogenase enzyme; FU must be metabolized to be active

Bioavailability: < 75%, erratic and undependable

Half-life elimination: Biphasic: Initial: 6-20 minutes; two metabolites, FdUMP and FUTP, have prolonged half-lives depending on the type of tissue

Excretion: Lung (large amounts as CO₂); urine (5% as unchanged drug) in 6 hours

Dosage Adults:

Refer to individual protocols:

I.V. bolus: 500-600 mg/m² every 3-4 hours or 425 mg/m² on days 1-5 every 4 weeks

Continuous I.V. infusion: 1000 mg/m²/day for 4-5 days every 3-4 weeks

or

2300-2600 mg/m² on day 1 every week or

300-400 mg/m²/day or

225 mg/m²/day for 5-8 weeks (with radiation therapy)

Actinic keratoses: Topical:

Carac™: Apply thin film to lesions once daily for up to 4 weeks, as tolerated

Efudex®: Apply to lesions twice daily for 2-4 weeks; complete healing may not be evident for 1-2 months following treatment

Fluoroplex®: Apply to lesions twice daily for 2-6 weeks

Basal cell carcinoma: Topical: Efudex®: Apply to affected lesions twice daily for 3-6 weeks; treatment may be continued for up to 10-12 weeks

Dosage adjustment for renal impairment: Hemodialysis: Administer dose following hemodialysis.

Dosage adjustment for hepatic impairment: Bilirubin >5 mg/dL: Omit use.

Stability Injection: Store intact vials at room temperature and protect from light; slight discoloration does not usually denote decomposition. If exposed to cold, a precipitate may form; **gentle** heating to 60°C will dissolve the precipitate without impairing the potency; solutions in 50-1000 mL NS or D₅W, or undiluted solutions in syringes are stable for 72 hours at room temperature.

Topical: Store at controlled room temperature.

Monitoring Parameters CBC with differential and platelet count, renal function tests, liver function tests

Administration

I.V.: I.V. bolus as a slow push or short (5-15 minutes) bolus infusion, or as a continuous infusion. I.V. formulation may be given orally mixed in water, grape juice, or carbonated beverage. It is generally best to drink undiluted solution, then rinse the mouth. Coca-Cola® has been recommended as the "best chaser" for oral fluorouracil.

Topical: Apply 10 minutes after washing, rinsing, and drying the affected area. Apply using fingertip (wash hands immediately after application) or nonmetal applicator. Avoid eyes, nostrils, and mouth. Do not cover area with an occlusive dressing.

Contraindications Hypersensitivity to fluorouracil or any component of the formulation; dihydropyrimidine dehydrogenase (DPD) enzyme deficiency; pregnancy

Warnings

Hazardous agent – use appropriate precautions for handling and disposal. Use with caution in patients with impaired kidney or liver function. The drug should be discontinued if intractable vomiting or diarrhea, precipitous falls in leukocyte or platelet counts, stomatitis, hemorrhage, or myocardial ischemia occurs. Use with caution in patients who have had high-dose pelvic radiation or previous use of alkylating agents. Palmar-plantar erythrodysesthesia (hand-foot) syndrome has been associated with use. Safety and efficacy have not been established in pediatric patients.

Administration to patients with a genetic deficiency of dihydropyrimidine dehydrogenase (DPD) has been associated with diarrhea, neutropenia, and neurotoxicity. Systemic toxicity normally associated with parenteral administration has also been associated with topical use, particularly in patients with DPD. Discontinue if symptoms of DPD occur. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.**

Avoid topical application to mucous membranes due to potential for local inflammation and ulceration. The use of occlusive dressings with topical preparations may increase the severity of inflammation in nearby skin areas. Avoid exposure to ultraviolet rays during and immediately following therapy.

Dosage Forms Cream, topical:

Carac™: 0.5% (30 g)

Efudex®: 5% (25 g, 40 g)

Fluoroplex®: 1% (30 g) [contains benzyl alcohol]

Injection, solution: 50 mg/mL (10 mL, 20 mL, 50 mL, 100 mL)

Adrucil®: 50 mg/mL (10 mL, 50 mL, 100 mL)

Solution, topical (Efudex®): 2% (10 mL); 5% (10 mL)

Reference Range Plasma 5-FU level of 3.37 × 10⁻⁶M with dose of 1.25 g/m²/day

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal for oral ingestion

Supportive therapy: Allopurinol (300 mg 3 times/day) may be useful in decreasing toxicity; for treatment of acute encephalopathy, dexamethasone (10 mg every 6 hours I.V.) and thiamine may expedite neurologic recovery; palmar-plantar erythrodysesthesia syndrome can be treated with pyridoxine 50-150 mg daily; hyperammonemia dissipates upon 5-FU removal.

Enhancement of elimination: Forced diuresis or hemodialysis may enhance elimination

Antidote(s)

- Thrombopoietin [ANTIDOTE]

Test Interactions Fecal discoloration; may elevate total thyroxine level

Drug Interactions Warfarin: May increase aPTT and bleeding time; monitor

Pregnancy Risk Factor D (injection); X (topical)

FLUOXETINE

Pregnancy Implications There are no adequate and well-controlled studies in pregnant women, however, fetal defects and miscarriages have been reported following use of topical and intravenous products. Use is contraindicated during pregnancy.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Warm to body temperature before using; after vial has been entered, any unused portion should be discarded within 1 hour; wash hands immediately after topical application of the 5% cream; I.V. formulation may be given orally mixed in water, grape juice, or carbonated beverage

Additional Information May be permeable to PVC gloves as opposed to latex gloves; risk factors for developing fluorouracil-induced mucositis include low salivary flow and neutrophil level <4000 cells/m³

Specific References

Weng T, Shih FF, and Chen WJ, "Unusual Causes of Hyperammonemia in the ED," *Am J Emerg Med*, 2004, 22:105-7.

Fluoxetine

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antidepressant Agents
- Citalopram

CAS Number 54910-89-3

U.S. Brand Names Prozac® Weekly™; Prozac®; Sarafem™

Synonyms Fluoxetine Hydrochloride

Use Treatment of major depressive disorder; treatment of binge-eating and vomiting in patients with moderate-to-severe bulimia nervosa; obsessive-compulsive disorder (OCD); premenstrual dysphoric disorder (PMDD); panic disorder with or without agoraphobia

Unlabeled/Investigational Use Selective mutism

Mechanism of Action Inhibits CNS neuron serotonin uptake; minimal or no effect on reuptake of norepinephrine or dopamine; does not significantly bind to alpha-adrenergic, histamine, or cholinergic receptors; may therefore be useful in patients at risk from sedation, hypotension, and anticholinergic effects of tricyclic antidepressants

Adverse Reactions

Predominant adverse effects are CNS and GI

Cardiovascular: Vasodilation, palpitations, hypertension, angina, arrhythmia, congestive heart failure, edema, heart arrest, hypotension, myocardial infarction, postural hypotension, QT prolongation, syncope, tachycardia, vasculitis, ventricular tachycardia (including torsade de pointes)

Central nervous system: Amnesia, **anxiety**, confusion, drowsiness, **headache**, emotional lability, sleep disorder, dizziness, agitation, yawning, pain, fever, abnormal dreams, chills, confusion, euphoria, **insomnia**, extrapyramidal reactions (rare), hallucinations, hostility, malaise, migraine, neuroleptic malignant syndrome, **nervousness**, serotonin syndrome, suicidal ideation, fever

Dermatologic: Rash, pruritus, cutaneous vasculitis, acne, alopecia, bruising, ecchymosis, erythema nodosum, exfoliative dermatitis, photosensitivity reaction, Stevens-Johnson syndrome

Systemic events, possibly related to vasculitis (including lupus-like syndrome), have occurred rarely in patients with rash; may include lung, kidney, and/or hepatic involvement. Death has been reported.

Endocrine & metabolic: Syndrome of inappropriate ADH secretion, hypoglycemia, hyponatremia (elderly or volume-depleted patients), dehydration, gout, hypercholesterolemia, hyperprolactinemia, hypokalemia, hypothyroidism

Gastrointestinal: **Nausea**, **diarrhea**, **xerostomia**, **anorexia**, dyspepsia, increased appetite, constipation, vomiting, flatulence, weight gain/loss, abdominal pain, dyspepsia, aphthous stomatitis, colitis, dysphagia, esophagitis, gastritis, glossitis, gynecomastia, pancreatitis, taste perversion

Genitourinary: Sexual dysfunction, urinary frequency, amenorrhea, priapism

Hematologic: Anemia, hemorrhage, immune-related hemolytic anemia, pancytopenia, thrombocytopenia, thrombocytopenic purpura

Hepatic: Cholelithiasis, cholestatic jaundice, hepatic failure/necrosis, liver function test abnormalities

Neuromuscular & skeletal: **Weakness**, **tremor**, arthritis, bone pain, bursitis, dyskinesia, leg cramps

Ocular: Abnormal vision, aggravation of glaucoma, cataract, optic neuritis
Otic: Tinnitus

Renal: Albuminuria, kidney failure

Respiratory: Pharyngitis, asthma, eosinophilic pneumonia, epistaxis, hyperventilation, laryngospasm, pulmonary embolism, pulmonary hypertension

Miscellaneous: Diaphoresis, flu syndrome, infection, abnormal thinking, allergies, anaphylactoid reactions, hiccups, lupus-like syndrome, misuse/abuse

Signs and Symptoms of Overdose Agitation, AV block, bradycardia, cognitive dysfunction, cystitis, delirium, depression, drowsiness, eosino-

philia, extrapyramidal reaction, generalized seizures, gout, hallucinations, hirsutism, hypoglycemia, hypokalemia, hypomania, hyponatremia, insomnia, leukocytosis, lightheadedness, mania, myoclonus, myoglobinuria, nausea, nystagmus, QT prolongation, rhabdomyolysis, spontaneous vomiting, tachycardia (ventricular), vasculitis

Pharmacodynamics/Kinetics

Absorption: Well absorbed; delayed 1-2 hours with weekly formulation

Protein binding: 95%

Metabolism: Hepatic to norfluoxetine (activity equal to fluoxetine)

Half-life elimination: Adults:

Parent drug: 1-3 days (acute), 4-6 days (chronic), 7.6 days (cirrhosis)

Metabolite (norfluoxetine): 9.3 days (range: 4-16 days), 12 days (cirrhosis)

Time to peak: 6-8 hours

Excretion: Urine (10% as norfluoxetine, 2.5% to 5% as fluoxetine)

Note: Weekly formulation results in greater fluctuations between peak and trough concentrations of fluoxetine and norfluoxetine compared to once-daily dosing (24% daily/164% weekly; 17% daily/43% weekly, respectively). Trough concentrations are 76% lower for fluoxetine and 47% lower for norfluoxetine than the concentrations maintained by 20 mg once-daily dosing. Steady-state fluoxetine concentrations are ~50% lower following the once-weekly regimen compared to 20 mg once daily. Average steady-state concentrations of once-daily dosing were highest in children ages 6 to <13 (fluoxetine 171 ng/mL; norfluoxetine 195 ng/mL), followed by adolescents ages 13 to <18 (fluoxetine 86 ng/mL; norfluoxetine 113 ng/mL); concentrations were considered to be within the ranges reported in adults (fluoxetine 91-302 ng/mL; norfluoxetine 72-258 ng/mL).

Dosage

Oral:

Children:

Depression: 8-18 years: 10-20 mg/day; lower-weight children can be started at 10 mg/day, may increase to 20 mg/day after 1 week if needed

OCD: 7-18 years: Initial: 10 mg/day; in adolescents and higher-weight children, dose may be increased to 20 mg/day after 2 weeks. Range: 10-60 mg/day

Selective mutism (unlabeled use):

<5 years: No dosing information available

5-18 years: Initial: 5-10 mg/day; titrate upwards as needed (usual maximum dose: 60 mg/day)

Adults: 20 mg/day in the morning; may increase after several weeks by 20 mg/day increments; maximum: 80 mg/day; doses >20 mg may be given once daily or divided twice daily. **Note:** Lower doses of 5-10 mg/day have been used for initial treatment.

Usual dosage range:

Bulimia nervosa: 60-80 mg/day

Depression: 20-40 mg/day; patients maintained on Prozac® 20 mg/day may be changed to Prozac® Weekly™ 90 mg/week, starting dose 7 days after the last 20 mg/day dose

OCD: 40-80 mg/day

Panic disorder: Initial: 10 mg/day; after 1 week, increase to 20 mg/day; may increase after several weeks; doses >60 mg/day have not been evaluated

PMDD (Sarafem™): 20 mg/day continuously, or 20 mg/day starting 14 days prior to menstruation and through first full day of menses (repeat with each cycle)

Elderly: Depression: Some patients may require an initial dose of 10 mg/day with dosage increases of 10 and 20 mg every several weeks as tolerated; should not be taken at night unless patient experiences sedation

Dosing adjustment in renal impairment:

Single dose studies: Pharmacokinetics of fluoxetine and norfluoxetine were similar among subjects with all levels of impaired renal function, including anephric patients on chronic hemodialysis

Chronic administration: Additional accumulation of fluoxetine or norfluoxetine may occur in patients with severely impaired renal function

Hemodialysis: Not removed by hemodialysis; use of lower dose or less frequent dosing is not usually necessary.

Dosing adjustment in hepatic impairment: Elimination half-life of fluoxetine is prolonged in patients with hepatic impairment; a lower or less frequent dose of fluoxetine should be used in these patients

Cirrhosis patients: Administer a lower dose or less frequent dosing interval

Compensated cirrhosis without ascites: Administer 50% of normal dose

Monitoring Parameters Mental status for depression, suicidal ideation, anxiety, social functioning, mania, panic attacks; akathisia, sleep

Contraindications Hypersensitivity to fluoxetine or any component of the formulation; patients currently receiving MAO inhibitors, pimozide, or thioridazine

Note: MAO inhibitor therapy must be stopped for 14 days before fluoxetine is initiated. Treatment with MAO inhibitors, thioridazine, or mesoridazine should not be initiated until 5 weeks after the discontinuation of fluoxetine.

Warnings**Major psychiatric warnings:**

- [U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. A medication guide concerning the use of antidepressants in children and teenagers should be dispensed with each prescription. **Fluoxetine is FDA approved for the treatment of OCD in children ≥ 7 years of age and MDD in children ≥ 8 years of age.**
- The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Patients treated with antidepressants should be observed for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy.
- Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression or psychosis occur.
- May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Fluoxetine is not FDA approved for the treatment of bipolar depression.** Safety and efficacy in children <8 years of age (major depressive disorder) and <7 years of age (OCD) have not been established.

Key adverse effects:

- Allergic events and rash: Fluoxetine use has been associated with occurrences of significant rash and allergic events, including vasculitis, lupus-like syndrome, laryngospasm, anaphylactoid reactions, and pulmonary inflammatory disease. Discontinue if underlying cause of rash cannot be identified.
- Anticholinergic effects: Relatively devoid of these side effects
- CNS depression: Has a low potential to impair cognitive or motor performance; caution operating hazardous machinery or driving.
- CNS effects: May cause insomnia, anxiety, nervousness or anorexia.
- SIADH and hyponatremia: Has been associated with the development of SIADH; hyponatremia has been reported rarely, predominantly in the elderly.

Concurrent disease:

- Diabetes: May alter glycemic control in patients with diabetes.
- Hepatic impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.
- Platelet aggregation: May impair platelet aggregation, resulting in bleeding.
- Renal impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.
- Seizure disorders: Use caution with a previous seizure disorder or condition predisposing to seizures such as brain damage or alcoholism.
- Sexual dysfunction: May cause or exacerbate sexual dysfunction.
- Weight loss: May cause weight loss. Use caution in patients where weight loss is undesirable.

Concurrent drug therapy:

- Agents which lower seizure threshold: Use caution with concurrent therapy.
- Anticoagulants/Antiplatelets: Use caution with concomitant use of NSAIDs, ASA, or other drugs that affect coagulation; the risk of bleeding is potentiated.
- Cardiovascular: Use caution with history of MI or unstable heart disease; use in these patients is limited
- CNS depressants: Use caution with concomitant therapy.
- MAO inhibitors: Potential for severe reaction when used with MAO inhibitors; autonomic instability, coma, death, delirium, diaphoresis, hyperthermia, mental status changes/agitation, muscular rigidity, myoclonus, neuroleptic malignant syndrome features, and seizures may occur.
- Thioridazine: Fluoxetine may elevate plasma levels of thioridazine; increasing risk of QTc interval prolongation; this may lead to serious ventricular arrhythmias such as torsade de pointes-type arrhythmias and sudden death. **Concurrent use is contraindicated.**

Special populations:

- Elderly: Use caution in elderly patients.

Special notes:

- Electroconvulsive therapy: May increase the risks associated with electroconvulsive therapy; consider discontinuing, when possible, prior to ECT treatment.
- Long half-life: Due to the long half-life of fluoxetine and its metabolites, the effects and interactions noted may persist for prolonged periods following discontinuation.
- Withdrawal syndrome: May cause dysphoric mood, irritability, agitation, dizziness, sensory disturbances, anxiety, confusion, headache, lethargy, emotional lability, insomnia, hypomania, tinnitus, and seizures. Upon discontinuation of fluoxetine therapy, gradually taper dose. If intolerable symptoms occur following a decrease in dosage or upon discontinuation of therapy, then resuming the previous dose with a more gradual taper should be considered.

Dosage Forms [DSC] = Discontinued product

Capsule, as hydrochloride: 10 mg, 20 mg, 40 mg

Prozac®: 10 mg, 20 mg, 40 mg

Sarafem®: 10 mg, 20 mg

Capsule, delayed release, as hydrochloride (Prozac® Weekly™): 90 mg

Solution, oral, as hydrochloride (Prozac®): 20 mg/5 mL (120 mL)

[contains alcohol 0.23% and benzoic acid; mint flavor]

Tablet, as hydrochloride: 10 mg, 20 mg

Prozac® [scored]: 10 mg [DSC]

Reference Range

Therapeutic:

Fluoxetine: 100-800 ng/mL (SI: 289-2314 nmol/L); serum level of

1956 ng/mL (norfluoxetine level of 416 ng/mL) associated with seizure

Norfluoxetine: 100-600 ng/mL (SI: 289-1735 nmol/L)

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Postmortem blood fluoxetine level of 0.63 mg/L may indicate that this drug was the cause of death.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Toxic symptoms should be treated. Seizures usually respond to lorazepam or diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required. Amantadine (100-200 mg 2 times/day) has been used successfully in treating sexual dysfunction; sildenafil (50-100 mg) can be used to treat sexual dysfunction; bruxism can be treated with buspirone (5 mg at night)

Enhancement of elimination: Multiple dosing of activated charcoal may not be useful; hemodialysis does not appear to be useful

Test Interactions Increases albumin in urine; fluoxetine can interfere with bupropion quantitation by HPLC analysis in plasma or serum**Drug Interactions Substrate** of CYP1A2 (minor), 2B6 (minor), 2C9 (major), 2C19 (minor), 2D6 (major), 2E1 (minor), 3A4 (minor); **Inhibits** CYP1A2 (moderate), 2B6 (weak), 2C9 (weak), 2C19 (moderate), 2D6 (strong), 3A4 (weak)

Amphetamines: SSRIs may increase the sensitivity to amphetamines, and amphetamines may increase the risk of serotonin syndrome.

Benzodiazepines: Fluoxetine may inhibit the metabolism of alprazolam and diazepam resulting in elevated serum levels; monitor for increased sedation and psychomotor impairment.

Beta-blockers: Fluoxetine may inhibit the metabolism of metoprolol and propranolol resulting in cardiac toxicity; monitor for bradycardia, hypotension, and heart failure if combination is used; not established for all beta-blockers (unlikely with atenolol or nadolol due to renal elimination).

Buspirone: Fluoxetine inhibits the reuptake of serotonin; combined use with a serotonin agonist (buspirone) may cause serotonin syndrome.

Carbamazepine: Fluoxetine may inhibit the metabolism of carbamazepine resulting in increased carbamazepine levels and toxicity; monitor for altered carbamazepine response.

Carvedilol: Serum concentrations may be increased; monitor carefully for increased carvedilol effect (hypotension and bradycardia).

Clozapine: Fluoxetine may increase serum levels of clozapine; levels may increase by 76%; monitor for increased effect/toxicity.

Cyclosporine: Fluoxetine may increase serum levels of cyclosporine (and possibly tacrolimus); monitor.

CYP1A2 substrates: Fluoxetine may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, fluvoxamine, mexiletine, mirtazapine, ropinirole, theophylline, and trifluoperazine.

CYP2C9 inducers: May decrease the levels/effects of fluoxetine. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C9 Inhibitors may increase the levels/effects of fluoxetine. Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nicardipine, NSAIDs, sulfonamides and tolbutamide.

CYP2C19 substrates: Fluoxetine may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

CYP2D6 inhibitors: May increase the levels/effects of fluoxetine. Example inhibitors include chlorpromazine, delavirdine, miconazole, paroxetine, pergolide, quinidine, quinidine, ritonavir, and ropinirole.

CYP2D6 substrates: Fluoxetine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Fluoxetine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

Cyproheptadine: May inhibit the effects of serotonin reuptake inhibitors (fluoxetine); monitor for altered antidepressant response; cyproheptadine acts as a serotonin agonist.

Dextromethorphan: Fluoxetine inhibits the metabolism of dextromethorphan; visual hallucinations occurred in a patient receiving this combination; monitor for serotonin syndrome.

Digoxin: Fluoxetine may increase serum levels of digoxin; monitor.

Haloperidol: Fluoxetine may inhibit the metabolism of haloperidol and cause extrapyramidal symptoms (EPS); monitor patients for EPS if combination is utilized.

HMG-CoA reductase inhibitors: Fluoxetine may inhibit the metabolism of lovastatin and simvastatin resulting in myositis and rhabdomyolysis; these combinations are best avoided.

Lithium: Reports of both increased and decreased lithium levels when used concomitantly with fluoxetine. Patients receiving fluoxetine and lithium have developed neurotoxicity. If combination is used; monitor lithium levels and for neurotoxicity.

Loop diuretics: Fluoxetine may cause hyponatremia; additive hyponatremic effects may be seen with combined use of a loop diuretic (bumetanide, furosemide, torsemide); monitor for hyponatremia.

MAO inhibitors: Combined use of fluoxetine with nonselective MAOIs (ie, isocarboxazid, phenelzine) is contraindicated; fatal reactions have been reported; wait 5 weeks after stopping fluoxetine before starting an MAO inhibitor and 2 weeks after stopping an MAO inhibitor before starting fluoxetine.

Meperidine: Combined use with fluoxetine theoretically may increase the risk of serotonin syndrome.

Nefazodone: May increase the risk of serotonin syndrome with SSRIs; monitor.

NSAIDs: Concomitant use of fluoxetine and NSAIDs, aspirin, or other drugs affecting coagulation has been associated with an increased risk of bleeding; monitor.

Phenytoin: Fluoxetine inhibits the metabolism of phenytoin and may result in phenytoin toxicity; monitor for phenytoin toxicity (ataxia, confusion, dizziness, nystagmus, involuntary muscle movement).

Pimozide: Due to potential QT_c interval prolongation, concomitant use is contraindicated.

Propafenone: Serum concentrations and/or toxicity may be increased by fluoxetine; avoid concurrent administration.

Ritonavir: Combined use of fluoxetine with ritonavir may cause serotonin syndrome in HIV-positive patients; monitor.

Selegiline: Fluoxetine has been reported to cause mania or hypertension when combined with selegiline; this combination is best avoided. Concurrent use with SSRIs has also been reported to cause serotonin syndrome. As a MAO type B inhibitor, the risk of serotonin syndrome may be less than with nonselective MAO inhibitors.

Sibutramine: May increase the risk of serotonin syndrome with SSRIs; avoid coadministration.

SSRIs: Fluoxetine inhibits the reuptake of serotonin; combined use with other drugs which inhibit the reuptake may cause serotonin syndrome.

Sumatriptan (and other serotonin agonists): Concurrent use may result in toxicity; weakness, hyper-reflexia, and incoordination have been observed with sumatriptan and SSRIs. In addition, concurrent use may theoretically increase the risk of serotonin syndrome; includes sumatriptan, naratriptan, rizatriptan, and zolmitriptan.

Sympathomimetics: May increase the risk of serotonin syndrome with SSRIs.

Thioridazine: Fluoxetine may inhibit the metabolism of thioridazine, resulting in increased plasma levels and increasing the risk of QT_c interval prolongation. This may lead to serious ventricular arrhythmias, such as torsade de pointes-type arrhythmias and sudden death. Do not use together. Wait at least 5 weeks after discontinuing fluoxetine prior to starting thioridazine.

Tramadol: Fluoxetine combined with tramadol (serotonergic effects) may cause serotonin syndrome; monitor.

Trazodone: Fluoxetine may inhibit the metabolism of trazodone resulting in increased toxicity; monitor.

Tricyclic antidepressants: Fluoxetine inhibits the metabolism of tricyclic antidepressants (amitriptyline, desipramine, imipramine, nortriptyline) resulting in elevated serum levels; if combination is warranted, a low dose of TCA (10-25 mg/day) should be utilized.

Tryptophan: Fluoxetine inhibits the reuptake of serotonin; combination with tryptophan, a serotonin precursor, may cause agitation and restlessness; this combination is best avoided.

Valproic acid: Fluoxetine may increase serum levels of valproic acid; monitor.

Venlafaxine: Fluoxetine may increase the risk of serotonin syndrome.

Warfarin: Fluoxetine may alter the hypoprothrombinemic response to warfarin; monitor.

Pregnancy Risk Factor C

Pregnancy Implications Fluoxetine crosses the placenta

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Nursing Implications Offer patient sugarless hard candy for dry mouth

Additional Information

ECG may reveal S-T segment depression; not shown to be teratogenic in rodents; 15-60 mg/day, buspirone and cyproheptadine, may be useful in treatment of sexual dysfunction during treatment with a selective serotonin reuptake inhibitor.

Weekly capsules are a delayed release formulation containing enteric-coated pellets of fluoxetine hydrochloride, equivalent to 90 mg fluoxetine. Therapeutic equivalence of weekly formulation with daily formulation for delaying time to relapse has not been established.

Fluphenazine

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antipsychotic Agents

CAS Number 146-56-5; 2746-81-8; 69-23-8

U.S. Brand Names Prolixin Decanoate®; Prolixin® [DSC]

Synonyms Fluphenazine Decanoate

Use Management of manifestations of psychotic disorders and schizophrenia; depot formulation may offer improved outcome in individuals with psychosis who are nonadherent with oral antipsychotics

Unlabeled/Investigational Use Pervasive developmental disorder

Mechanism of Action Blocks postsynaptic mesolimbic dopaminergic receptors in the brain; exhibits a strong alpha-adrenergic blocking effect and depresses the release of hypothalamic and hypophyseal hormones

Adverse Reactions

Cardiovascular: **Hypotension (especially orthostatic)**, tachycardia, **cardiac arrhythmias**, abnormal T waves with prolonged ventricular repolarization, sinus tachycardia, **hypotension**

Central nervous system: Sedation, drowsiness, fever, restlessness, anxiety, extrapyramidal reactions, **dystonic reactions**, **pseudoparkinsonian signs and symptoms**, **tardive dyskinesia**, neuroleptic malig-

nant syndrome, seizures, altered central temperature regulation, gustatory hallucinations, **akathisia**, **dizziness**

Dermatologic: Hyperpigmentation, pruritus, rash, contact dermatitis, photosensitivity (rare), exfoliative dermatitis, angioedema, toxic epidermal necrolysis, urticaria, purpura, exanthem

Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, syndrome of inappropriate antidiuretic hormone, sexual dysfunction

Gastrointestinal: **Constipation**, adynamic ileus, GI upset, xerostomia (problem for denture user), nausea, vomiting, weight gain

Genitourinary: Urinary retention, overflow incontinence, priapism

Hematologic: Leukopenia/neutropenia (agranulocytosis, granulocytopenia) usually inpatients with large doses for prolonged periods

Hepatic: Cholestatic jaundice, cholestasis

Ocular: Blurred vision, photophobia, diplopia, **retinal pigmentation**, pigmentary deposits in the lens and cornea, bilateral maculopathy

Respiratory: **Nasal congestion**

Miscellaneous: Systemic lupus erythematosus, **diaphoresis**

Signs and Symptoms of Overdose Deep sleep, depression, dystonic reactions, ejaculatory disturbances, extrapyramidal reaction, gynecomastia, enuresis, hyperthermia, hypotension or hypertension, hyponatremia, hypothermia, lactation, neuroleptic malignant syndrome, Parkinson's-like symptoms, photosensitivity, respiratory failure, seizures, QT prolongation, urine discoloration (pink; red; red-brown) vision color changes (brown tinge; yellow tinge)

Pharmacodynamics/Kinetics

Onset of action: I.M., SubQ (derivative dependent): Hydrochloride salt: ~1 hour

Peak effect: Neuroleptic: Decanoate: 48-96 hours

Duration: Hydrochloride salt: 6-8 hours; Decanoate: 24-72 hours

Absorption: Oral: Erratic and variable

Distribution: Crosses placenta; enters breast milk

Protein binding: 91% and 99%

Metabolism: Hepatic

Half-life elimination (derivative dependent): Hydrochloride: 33 hours;

Decanoate: 163-232 hours

Excretion: Urine (as metabolites)

Dosage

Children: Oral: Childhood-onset pervasive developmental disorder (unlabeled use): 0.04 mg/kg/day

Adults: Psychoses:

Oral: 0.5-10 mg/day in divided doses at 6- to 8-hour intervals; some patients may require up to 40 mg/day

I.M.: 2.5-10 mg/day in divided doses at 6- to 8-hour intervals (parenteral dose is $\frac{1}{3}$ to $\frac{1}{2}$ the oral dose for the hydrochloride salts)

I.M. (decanoate): 12.5 mg every 2 weeks

Conversion from hydrochloride to decanoate I.M. 0.5 mL (12.5 mg) decanoate every 3 weeks is approximately equivalent to 10 mg hydrochloride/day

I.M. (enanathate): 12.5-25 mg every 2 weeks

Hemodialysis: Not dialyzable (0% to 5%)

Monitoring Parameters Vital signs; lipid profile, fasting blood glucose/Hgb A_{1c}; BMI; mental status, abnormal involuntary movement scale (AIMS), extrapyramidal symptoms (EPS)

Administration Avoid contact of oral solution or injection with skin (contact dermatitis). Oral liquid should be diluted in the following **only**: Water, saline, homogenized milk, carbonated orange beverages, pineapple, apricot, prune, orange, tomato, and grapefruit juices. Do **not** dilute in beverages containing caffeine, tannins, or pectinate. Watch for hypotension when administering I.M.

Contraindications Hypersensitivity to fluphenazine or any component of the formulation (cross-reactivity between phenothiazines may occur); severe CNS depression; coma; subcortical brain damage; blood dyscrasias; hepatic disease

Warnings

May be sedating, use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Caution in patients with hemodynamic instability; bone marrow suppression; predisposition to seizures; severe cardiac, renal, or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use - use with caution in patients at risk of pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May alter cardiac conduction; life-threatening arrhythmias have occurred with therapeutic doses of phenothiazines. Hypotension may occur, particularly with I.M. administration. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications which may predispose). Adverse effects of depot injections may be prolonged.

Phenothiazines may cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention). Therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual pro-

blems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other antipsychotics, fluphenazine has a low potency of cholinergic blockade.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia and tardive dyskinesia (risk of these reactions is high relative to other antipsychotics). May be associated with neuroleptic malignant syndrome (NMS) or pigmentary retinopathy.

Dosage Forms [DSC] = Discontinued product

Elixir, as hydrochloride (Prolixin®): 2.5 mg/5 mL (60 mL) [contains alcohol 14% and sodium benzoate] [DSC]

Injection, oil, as decanoate: 25 mg/mL (5 mL) [may contain benzyl alcohol, sesame oil]

Prolixin Decanoate®: 25 mg/mL (5 mL) [contains benzyl alcohol, sesame oil]

Injection, solution, as hydrochloride (Prolixin® [DSC]): 2.5 mg/mL (10 mL) Solution, oral concentrate, as hydrochloride (Prolixin®): 5 mg/mL (120 mL) [contains alcohol 14%] [DSC]

Tablet, as hydrochloride: 1 mg, 2.5 mg, 5 mg, 10 mg

Prolixin®: 1 mg, 2.5 mg, 5 mg [contains tartrazine], 10 mg [DSC]

Reference Range Therapeutic: 5-20 ng/mL (SI: 10-40 nmol/L)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam or diazepam (I.V. 5-10 mg bolus in adults every 15 minutes if needed up to a total of 30 mg; I.V. 0.25-0.4 mg/kg/dose up to a total of 10 mg in children) or to phenytoin or phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 g), while other antiarrhythmics can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50 mg I.M. or I.V. slow push followed by a maintenance dose for 48-72 hours. When these reactions are unresponsive to diphenhydramine, benztropine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes. Ventricular arrhythmias often respond to quinidine or phenytoin; avoid quinidine or procainamide. Blepharospasm can be treated with clozapine (125-200 mg/day).

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; not dialyzable (0% to 5%)

Test Interactions ↑ cholesterol (S), glucose; ↓ uric acid (S)

Drug Interactions Substrate of CYP2D6 (major); **Inhibits** CYP1A2 (weak), 2C9 (weak), 2D6 (weak), 2E1 (weak)

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Aluminum salts: May decrease the absorption of phenothiazines; monitor Amphetamines: Efficacy may be diminished by antipsychotics; in addition, amphetamines may increase psychotic symptoms. Avoid concurrent use

Anticholinergics: May inhibit the therapeutic response to phenothiazines and excess anticholinergic effects may occur; includes benztropine, trihexyphenidyl, biperiden, and drugs with significant anticholinergic activity (TCAs, antihistamines, disopyramide)

Antihypertensives: Concurrent use of phenothiazines with an antihypertensive may produce additive hypotensive effects (particularly orthostasis)

Bromocriptine: Phenothiazines inhibit the ability of bromocriptine to lower serum prolactin concentrations

CNS depressants: Sedative effects may be additive with phenothiazines; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents

CYP2D6 inhibitors: May increase the levels/effects of fluphenazine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Epinephrine: Chlorpromazine (and possibly other low potency antipsychotics) may diminish the pressor effects of epinephrine

Guanethidine and guanadrel: Antihypertensive effects may be inhibited by phenothiazines

Levodopa: Phenothiazines may inhibit the antiparkinsonian effect of levodopa; avoid this combination

Lithium: Phenothiazines may produce neurotoxicity with lithium; this is a rare effect

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk. Phenytoin: May reduce serum levels of phenothiazines; phenothiazines may increase phenytoin serum levels

Propranolol: Serum concentrations of phenothiazines may be increased; propranolol also increases phenothiazine concentrations

Polypeptide antibiotics: Rare cases of respiratory paralysis have been reported with concurrent use of phenothiazines

FLURAZEPAM

QT_c-prolonging agents: Effects on QT_c interval may be additive with phenothiazines, increasing the risk of malignant arrhythmias; includes type Ia antiarrhythmics, TCAs, and some quinolone antibiotics (sparfloxacin, moxifloxacin and gatifloxacin)

Sulfadoxine-pyrimethamine: May increase phenothiazine concentrations
Tricyclic antidepressants: Concurrent use may produce increased toxicity or altered therapeutic response

Trazodone: Phenothiazines and trazodone may produce additive hypotensive effects

Valproic acid: Serum levels may be increased by phenothiazines

Pregnancy Risk Factor C

Pregnancy Implications Extrapyramidal reaction may develop in neonates from maternally-administered drug; crosses the placenta

Lactation Enters breast milk/not recommended

Nursing Implications Dilute oral concentrate solution in juice before administration; avoid contact of oral solution or injection with skin (contact dermatitis); watch for hypotension when administering I.M. or I.V.

Additional Information Oral liquid to be diluted in the following **only**: water, saline, 7-UP[®], homogenized milk, carbonated orange beverages, pineapple, apricot, prune, orange, V8[®] juice, tomato, and grapefruit juices. Benzotropine can be used to treat nausea/vomiting.

Flurazepam

CAS Number 1172-18-5; 17617-23-1

U.S. Brand Names Dalmane[®]

Synonyms Flurazepam Hydrochloride

Impairment Potential Yes. A 15 mg ingestion of flurazepam at bedtime has been demonstrated to result in driving impairment the next morning. A brief or extended period (up to 1 year) of use is consistent with driving impairment in the elderly; impairment is greatest in the first week of use. (Betts TA and Birtle J, "Effect of Two Hypnotic Drugs on Actual Driving Performances Next Morning," *Br Med J*, 1982, 285(6345):852.)

Use Short-term treatment of insomnia

Mechanism of Action Depresses all levels of the CNS, including the limbic and reticular formation, probably through the increased action of gamma-aminobutyric acid (GABA), which is a major inhibitory neurotransmitter in the brain

Adverse Reactions

Cardiovascular: Tachycardia

Central nervous system: **Drowsiness, ataxia, lightheadedness, dizziness, slurred speech**, euphoria, headache, mental depression, hallucinations, insomnia, convulsions, paranoid symptoms, confusion, dystonic reactions

Dermatologic: Urticaria, purpura, pruritus, exanthem

Endocrine & metabolic: Changes in libido

Gastrointestinal: Nausea, xerostomia, vomiting, diarrhea, constipation, abdominal cramps

Hematologic: Thrombocytopenia, anemia, leukopenia, neutropenia, agranulocytosis

Hepatic: Liver dysfunction

Local: Phlebitis

Neuromuscular & skeletal: Paresthesia, muscle spasm, trembling

Ocular: Blurred vision, photophobia

Miscellaneous: Allergic reaction, drug dependence, diaphoresis (excessive)

Signs and Symptoms of Overdose Adult respiratory distress syndrome, apnea, asterixis, ataxia, coma, drowsiness, hyperactivity, hypoactive reflexes, hyporeflexia, hypotension, metallic taste, mydriasis, nystagmus, respiratory depression, unsteady gait

Pharmacodynamics/Kinetics

Onset of action: Hypnotic: 15-20 minutes

Peak effect: 3-6 hours

Duration: 7-8 hours

Metabolism: Hepatic to N-desalkylflurazepam (active)

Half-life elimination: Desalkylflurazepam:

Adults: Single dose: 74-90 hours; Multiple doses: 111-113 hours

Elderly (61-85 years): Single dose: 120-160 hours; Multiple doses: 126-158 hours

Dosage

Oral:

Children:

≤ 15 years: Dose not established

> 15 years: 15 mg at bedtime

Adults: 15-30 mg at bedtime

Elderly: Oral: 15 mg at bedtime; avoid use if possible

Stability Store in light-resistant containers

Monitoring Parameters Respiratory and cardiovascular status

Administration Give 30 minutes to 1 hour before bedtime on an empty stomach with full glass of water. May be taken with food if GI distress occurs.

Contraindications Hypersensitivity to flurazepam or any component of the formulation (cross-sensitivity with other benzodiazepines may exist); narrow-angle glaucoma; pregnancy

Warnings

Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics), or renal impairment. Active metabolites with extended half-lives may lead to delayed accumulation and adverse effects. Use with caution in patients with respiratory disease, or impaired gag reflex. Avoid use in patients with sleep apnea.

Causes CNS depression (dose-related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury and should be used with extreme caution in patients who are at risk of these events (especially the elderly).

Use caution in patients with depression, particularly if suicidal risk may be present. Use with caution in patients with a history of drug dependence. Benzodiazepines have been associated with dependence and acute withdrawal symptoms on discontinuation or reduction in dose (may occur after as little as 10 days of use). Acute withdrawal, including seizures, may be precipitated in patients after administration of flumazenil to patients receiving long-term benzodiazepine therapy.

As a hypnotic, should be used only after evaluation of potential causes of sleep disturbance. Failure of sleep disturbance to resolve after 7-10 days may indicate psychiatric or medical illness. A worsening of insomnia or the emergence of new abnormalities of thought or behavior may represent unrecognized psychiatric or medical illness and requires immediate and careful evaluation.

Benzodiazepines have been associated with anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Dosage Forms Capsule, as hydrochloride: 15 mg, 30 mg

Reference Range

Therapeutic: 0-4 ng/mL (SI: 0-9 nmol/L)

Metabolite N-desalkylflurazepam: 20-110 ng/mL (SI: 43-240 nmol/L)

Toxic: 2000 ng/mL (SI: 4300 nmol/L)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Treatment for benzodiazepine overdose is supportive. Rarely is mechanical ventilation required. Flumazenil has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression. Hypotension can be treated with isotonic I.V. fluids with placement in Trendelenburg position; dopamine and norepinephrine can be used.

Enhancement of elimination: Forced diuresis or hemodialysis is not useful; multiple dosing of activated charcoal may be useful

Drug Interactions Substrate of CYP3A4 (major); **Inhibits** CYP2E1 (weak)

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect
CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of flurazepam. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.
CYP3A4 inhibitors: May increase the levels/effects of flurazepam. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nocardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Levodopa: Therapeutic effects may be diminished in some patients following the addition of a benzodiazepine; limited/inconsistent data
Oral contraceptives: May decrease the clearance of some benzodiazepines (those which undergo oxidative metabolism); monitor for increased benzodiazepine effect

Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation

Pregnancy Risk Factor X

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Provide safety measures (ie, side rails, night light, and call button); remove smoking materials from area; supervise ambulation; avoid abrupt discontinuance in patients with prolonged therapy or seizure disorders

Flurbiprofen

Related Information

- Ibuprofen
- Nonsteroidal Anti-inflammatory Drugs

CAS Number 5104-49-4

U.S. Brand Names Ansaid[®]; Ocufen[®]

Synonyms Flurbiprofen Sodium

Use

Oral: Treatment of rheumatoid arthritis and osteoarthritis
 Ophthalmic: Inhibition of intraoperative miosis

Mechanism of Action Propionic acid derivative (like ibuprofen); inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors

Adverse Reactions

Ophthalmic: Frequency not defined: Ocular: Slowing of corneal wound healing, mild ocular stinging, itching and burning, ocular irritation, fibrosis, miosis, mydriasis, bleeding tendency increased

Oral:

Cardiovascular: Edema, cerebrovascular ischemia, CHF, hypertension, vasodilation
 Central nervous system: Amnesia, anxiety, depression, dizziness, headache, insomnia, malaise, nervousness, somnolence, confusion, fever
 Dermatologic: Rash, angioedema, bruising, eczema, exfoliative dermatitis, photosensitivity, pruritus, purpura, toxic epidermal necrolysis, urticaria
 Endocrine & metabolic: Hyperuricemia
 Gastrointestinal: Abdominal pain, constipation, diarrhea, dyspepsia, flatulence, GI bleeding, nausea, vomiting, weight changes, gastric/peptic ulcer, stomatitis
 Hematologic: Anemia, eosinophilia, hematocrit decreased, hemoglobin decreased, leukopenia, thrombocytopenia
 Hepatic: Liver enzymes elevated, hepatitis, jaundice
 Neuromuscular & skeletal: Reflexes increased, tremor, vertigo, weakness, paresthesia
 Ocular: Vision changes
 Otic: Tinnitus
 Renal: Hematuria, interstitial nephritis, renal failure
 Respiratory: Rhinitis, asthma, epistaxis
 Miscellaneous: Anaphylactic reaction, parosmia

Signs and Symptoms of Overdose Cognitive dysfunction, drowsiness, gastritis, GI bleeding, nausea, nephrotic syndrome, ototoxicity, tinnitus, vomiting, wheezing. Severe poisoning can manifest with coma, renal and/or hepatic failure, hypotension, seizures, and respiratory depression.

Pharmacodynamics/Kinetics

Onset of action: ~ 1-2 hours
 Distribution: V_d : 0.12 L/kg
 Protein binding: 99%, primarily albumin
 Metabolism: Hepatic via CYP2C9; forms metabolites such as 4-hydroxy-flurbiprofen (inactive)
 Half-life elimination: 5.7 hours
 Time to peak: 1.5 hours
 Excretion: Urine (primarily as metabolites)

Dosage

Oral: Rheumatoid arthritis and osteoarthritis: 200-300 mg/day in 2-, 3-, or 4 divided doses; do not administer more than 100 mg for any single dose; maximum: 300 mg/day
 Ophthalmic: Instill 1 drop every 30 minutes, beginning 2 hours prior to surgery (total of 4 drops in each affected eye)

Administration

Tablet: Take with a full glass of water.

Contraindications Hypersensitivity to flurbiprofen, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); dendritic keratitis; pregnancy (3rd trimester)

Warnings [U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension.

Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF, or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI, and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Not recommended for use in patients with advanced renal disease.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS), and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without

prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

The elderly are at increased risk for adverse effects (especially peptic ulceration, CNS effects, renal toxicity) from NSAIDs even at low doses. Withhold for at least 4-6 half-lives prior to surgical or dental procedures. Safety and efficacy have not been established in children < 18 years of age.

Dosage Forms

[DSC] = Discontinued product

Solution, ophthalmic, as sodium (Ocufer®): 0.03% (2.5 mL) [contains thimerosal]

Tablet: 50 mg, 100 mg

Ansaid®: 50 mg, 100 mg [DSC]

Reference Range

Mean steady-state levels: ~ 6 mg/mL (not age-dependent)

Peak serum flurbiprofen levels after a single 50 mg dose: ~ 8-9.4 mg/L

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage

Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be effective

Drug Interactions

Substrate of CYP2C9 (minor); **Inhibits** CYP2C9 (strong)

ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet drugs (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamol, eptifibatid, tirofiban) can cause an increased risk of bleeding.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids may increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

CYP2C9 Substrates: Flurbiprofen may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

Gentamicin and amikacin serum concentrations are increased by indomethacin in premature infants. Results may apply to other aminoglycosides and NSAIDs.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use. Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose. Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again.

Loop diuretics efficacy (diuretic and antihypertensive effect) is reduced. Indomethacin reduces this efficacy, however, it may be anticipated with any NSAID.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Thiazides antihypertensive effects are decreased; avoid concurrent use. Warfarin's INRs may be increased by piroxicam. Other NSAIDs may have the same effect depending on dose and duration. Monitor INR closely.

Use the lowest dose of NSAIDs possible and for the briefest duration. Verapamil plasma concentration is decreased by some NSAIDs; avoid concurrent use.

Pregnancy Risk Factor C/D (3rd trimester)

Pregnancy Implications Teratogenic effects were not observed in animal studies, however, adequate and well-controlled studies have not been conducted in pregnant women. Exposure late in pregnancy may lead to premature closure of the ductus arteriosus.

Lactation Enters breast milk/not recommended

FLUTAMIDE

Nursing Implications Care should be taken to avoid contamination of the solution container tip

Flutamide

CAS Number 13311-84-7

U.S. Brand Names Eulexin®

Synonyms 4'-Nitro-3'-Trifluoromethylisobutyranide; Niftolid; NSC-147834; SCH 13521

Use Treatment of metastatic prostatic carcinoma in combination therapy with LHRH agonist analogues

Unlabeled/Investigational Use Female hirsutism

Mechanism of Action Nonsteroidal antiandrogen with properties which block the action of dihydrotestosterone on the prostatic tissue and testes

Adverse Reactions

Cardiovascular: Hypertension, edema, myocardial infarction
Central nervous system: Drowsiness, confusion, depression, anxiety, nervousness, headache, dizziness, insomnia
Dermatologic: Pruritus, ecchymosis, photosensitivity
Endocrine & metabolic: **Gynecomastia, hot flashes, breast tenderness, galactorrhea; impotence; decreased libido; tumor flare**
Gastrointestinal: **Nausea, vomiting**, anorexia, increased appetite, constipation, indigestion, upset stomach; diarrhea
Genitourinary: Discoloration of urine (yellow)
Hematologic: Anemia, leukopenia, thrombocytopenia, hepatitis, hepatic failure, jaundice, sulfhemoglobinemia
Hepatic: **Increased AST (SGOT) and LDH levels, transient, mild**
Local: Thrombophlebitis
Neuromuscular & skeletal: Weakness
Respiratory: Pulmonary embolism
Miscellaneous: Herpes zoster

Signs and Symptoms of Overdose Apnea, ataxia, hypoactivity, lacrimation, lethargy, methemoglobinemia (up to 16.2% has been described), vomiting

Pharmacodynamics/Kinetics

Absorption: Oral: Rapid and complete
Protein binding: Parent drug: 94% to 96%; 2-hydroxyflutamide: 92% to 94%
Metabolism: Extensively hepatic to more than 10 metabolites, primarily 2-hydroxyflutamide (active)
Half-life elimination: 5-6 hours (2-hydroxyflutamide)
Excretion: Primarily urine (as metabolites)

Dosage

Oral: Adults:
Prostatic carcinoma: 250 mg 3 times/day or 1.5 g once daily
Female hirsutism: 250 mg daily

Monitoring Parameters Serum transaminase levels should be measured prior to starting treatment and should be repeated monthly for the first 4 months of therapy, and periodically thereafter. LFTs should be checked at the first sign or symptom of liver dysfunction (eg, nausea, vomiting, abdominal pain, fatigue, anorexia, flu-like symptoms, hyperbilirubinuria, jaundice, or right upper quadrant tenderness). Other parameters include tumor reduction, testosterone/estrogen, and phosphatase serum levels.

Administration Usually administered orally in 3 divided doses; contents of capsule may be opened and mixed with applesauce, pudding, or other soft foods; mixing with a beverage is not recommended

Contraindications Hypersensitivity to flutamide or any component of the formulation; severe hepatic impairment; pregnancy

Warnings

[U.S. Boxed Warning]: Hospitalization and, rarely, death due to liver failure has been reported in patients taking flutamide. Elevated serum transaminase levels, jaundice, hepatic encephalopathy, and acute hepatic failure have been reported. Product labeling states flutamide is not for use in women, particularly for nonlife-threatening conditions. In some patients, the toxicity reverses after discontinuation of therapy. About 50% of the cases occur within the first 3 months of treatment. Serum transaminase levels should be measured prior to starting treatment, monthly for 4 months, and periodically thereafter. Liver function tests should be obtained at the first suggestion of liver dysfunction (nausea, vomiting, abdominal pain, fatigue, anorexia, "flu-like" symptoms, hyperbilirubinuria, jaundice, or right upper quadrant tenderness). Flutamide should be immediately discontinued any time a patient has jaundice, and/or an ALT level greater than twice the upper limit of normal. Flutamide should not be used in patients whose ALT values are greater than twice the upper limit of normal.

Patients with glucose-6 phosphate dehydrogenase deficiency or hemoglobin M disease or smokers are at risk of toxicities associated with aniline exposure, including methemoglobinemia, hemolytic anemia, and cholestatic jaundice. Monitor methemoglobin levels.

Dosage Forms Capsule: 125 mg

Reference Range At steady-state; plasma 2-hydroxyflutamide levels range from 1556-2284 ng/mL

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal
Supportive therapy: Treat symptomatic methemoglobinemia with methylene blue

Enhancement of elimination: Multiple dosing of activated charcoal may be beneficial; hemodialysis is not expected to be of benefit

Drug Interactions Substrate (major) of CYP1A2, 3A4; **Inhibits** CYP1A2 (weak)

CYP1A2 inducers: May decrease the levels/effects of flutamide. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of flutamide. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, lomefloxacin, ofloxacin, and rofecoxib.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of flutamide. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of flutamide. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Warfarin: Warfarin effects may be increased

Pregnancy Risk Factor D

Lactation Excretion in breast milk unknown/not recommended

Additional Information Diarrhea may occur due to lactose intolerance; plasma testosterone and estradiol levels may be elevated

Fluvastatin

CAS Number 93957-54-1; 93957-55-2

U.S. Brand Names Lescol® XL; Lescol®

Use

To be used as a component of multiple risk factor intervention in patients at risk for atherosclerosis vascular disease due to hypercholesterolemia. Adjunct to dietary therapy to reduce elevated total cholesterol (total-C), LDL-C, triglyceride, and apolipoprotein B (apo-B) levels and to increase HDL-C in primary hypercholesterolemia and mixed dyslipidemia (Fredrickson types IIa and IIb); to slow the progression of coronary atherosclerosis in patients with coronary heart disease; reduce risk of coronary revascularization procedures in patients with coronary heart disease

Mechanism of Action HMG-CoA reductase inhibitor, the enzyme responsible for cholesterol synthesis

Adverse Reactions

Cardiovascular: Vasculitis
Central nervous system: Headache, insomnia
Dermatologic: Rash, erythema multiforme, alopecia, angioedema, toxic epidermal necrolysis, xerosis, urticaria, purpura, Stevens-Johnson syndrome, photosensitivity, pruritus
Endocrine & metabolic: Gynecomastia
Gastrointestinal: Dyspepsia, diarrhea, nausea
Hepatic: Hepatotoxicity
Neuromuscular & skeletal: Paresthesia
Respiratory: Adult respiratory distress syndrome
Miscellaneous: Systemic lupus erythematosus

Pharmacodynamics/Kinetics

Onset: Peak effect: Maximal LDL-C reductions achieved within 4 weeks
Distribution: V_d : 0.35 L/kg
Protein binding: >98%
Metabolism: To inactive and active metabolites (oxidative metabolism via CYP2C9 [75%], 2C8 [~5%], and 3A4 [~20%] isoenzymes); active forms do not circulate systemically; extensive (saturable) first-pass hepatic extraction
Bioavailability: Absolute: Capsule: 24%; Extended release tablet: 29%
Half-life elimination: Capsule: <3 hours; Extended release tablet: 9 hours
Time to peak: Capsule: 1 hour; Extended release tablet: 3 hours
Excretion: Feces (90%); urine (5%)

Dosage Adults: Oral:

Patients requiring $\geq 25\%$ decrease in LDL-C: 40 mg capsule or 80 mg extended release tablet once daily in the evening; may also use 40 mg capsule twice daily

Patients requiring <25% decrease in LDL-C: 20 mg capsule once daily in the evening

Note: Dosing range: 20-80 mg/day; adjust dose based on response to therapy; maximum response occurs within 4-6 weeks

Dosage adjustment in renal impairment: Less than 6% excreted renally; no dosage adjustment needed with mild to moderate renal impairment; use with caution in severe impairment

Dosage adjustment in hepatic impairment: Levels may accumulate in patients with liver disease (increased AUC and C_{max}); use caution with

severe hepatic impairment or heavy ethanol ingestion; contraindicated in active liver disease or unexplained transaminase elevations; decrease dose and monitor effects carefully in patients with hepatic insufficiency

Elderly: No dosage adjustment necessary based on age

Monitoring Parameters Obtain baseline LFTs and total cholesterol profile; repeat tests at 12 weeks after initiation of therapy or elevation in dose, and periodically thereafter. Monitor LDL-C at intervals no less than 4 weeks.

Administration Patient should be placed on a standard cholesterol-lowering diet before and during treatment; fluvastatin may be taken without regard to meals; adjust dosage as needed in response to periodic lipid determinations during the first 4 weeks after a dosage change; lipid-lowering effects are additive when fluvastatin is combined with a bile-acid binding resin or niacin, however, it must be administered at least 2 hours following these drugs. Do not break, chew, or crush extended release tablets; do not open capsules.

Contraindications Hypersensitivity to fluvastatin or any component of the formulation; active liver disease; unexplained persistent elevations of serum transaminases; pregnancy; breast-feeding

Warnings Secondary causes of hyperlipidemia should be ruled out prior to therapy. Liver function must be monitored by periodic laboratory assessment. Rhabdomyolysis with acute renal failure has occurred with fluvastatin and other HMG-CoA reductase inhibitors. Risk may be increased with concurrent use of other drugs which may cause rhabdomyolysis (including gemfibrozil, fibric acid derivatives, or niacin at doses ≥ 1 g/day). Temporarily discontinue in any patient experiencing markedly elevated CPK levels, myopathy, or an acute/serious condition predisposing to renal failure secondary to rhabdomyolysis. Use caution in patients with previous liver disease or heavy ethanol use. Use caution in patients with concurrent medications or conditions which reduce steriodogenesis. Efficacy and safety in children < 10 years of age have not been established.

Dosage Forms Capsule (Lescol®): 20 mg, 40 mg
Tablet, extended release (Lescol® XL): 80 mg

Reference Range Peak plasma fluvastatin level after a 10 mg oral dose: ~ 23 ng/mL

Overdosage/Treatment Decontamination: Lavage (within 1 hour)/cholestyramine can inhibit absorption

Drug Interactions Substrate of CYP2C9 (major), 2C8 (minor), 2D6 (minor), 3A4 (minor); **Inhibits** CYP1A2 (weak), 2C8 (weak), 2C9 (moderate), 2D6 (weak), 3A4 (weak)

Cholestyramine: Cholestyramine may decrease the absorption of fluvastatin. Separate administration times by at least 4 hours. Cholestyramine may increase the therapeutic effects of fluvastatin.

CYP2C9 inhibitors: May increase the levels/effects of fluvastatin. Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nicardipine, NSAIDs, sulfonamides, and tolbutamide.

CYP2C9 substrates: Fluvastatin may increase levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

Fibric acid derivatives: May increase the risk of myopathy and rhabdomyolysis.

Fluconazole: May increase the levels/effects of fluvastatin; monitor.

Glyburide: C_{max} and AUC of both fluvastatin and glyburide may increase; half-life of glyburide may also increase; monitor

Omeprazole: Omeprazole may increase serum concentrations of fluvastatin

Phenytoin: C_{max} and AUC of both phenytoin and fluvastatin may be increased when given together; monitor phenytoin when fluvastatin is initiated, modified, or discontinued

Rifamycin derivatives: May decrease serum concentrations of fluvastatin
Warfarin: Fluvastatin may increase hypoprothrombinemic effects of warfarin; monitor INR closely when fluvastatin is initiated, modified, or discontinued

Pregnancy Risk Factor X

Pregnancy Implications Animal studies have shown delays in fetal skeletal development and fetal, neonatal, and maternal mortality. Congenital anomalies following use of other HMG-CoA reductase inhibitors in humans have been reported (rare). Use in women of childbearing potential only if they are highly unlikely to conceive; discontinue if pregnancy occurs.

Lactation Enters breast milk/contraindicated

Additional Information Food can increase absorption.

Holdaas H, Fellström B, Jardine AG, et al, "Effect of Fluvastatin on Cardiac Outcomes in Renal Transplant Recipients: A Multicentre, Randomised, Placebo-Controlled Trial," *Lancet*, 2003, 361(9374): 2024-31.

Fluvoxamine

Related Information

- Antidepressant Agents

Synonyms

 Luvox

Use Treatment of obsessive-compulsive disorder (OCD) in children ≥ 8 years of age and adults

Treatment of major depression; panic disorder; anxiety disorders in children

Mechanism of Action Serotonin reuptake inhibitor

Adverse Reactions

Cardiovascular: Syncope, Raynaud's phenomenon, sinus bradycardia, sinus tachycardia

Central nervous system: Somnolence, headache, agitation, insomnia, dizziness, psychosis, hypokinesia, akathisia, electroencephalogram abnormalities, extrapyramidal reactions

Dermatologic: Toxic epidermal necrolysis, photosensitivity, alopecia, ecchymosis, Stevens-Johnson syndrome, angioedema, urticaria, exanthem

Endocrine & metabolic: Sexual dysfunction (delayed orgasm), syndrome of inappropriate antidiuretic hormone, hyponatremia due to SIADH, anorgasmia; nephrogenic diabetes insipidus

Gastrointestinal: Xerostomia, **nausea**, vomiting, constipation

Hepatic: Elevated liver function test results

Neuromuscular & skeletal: Tremor, weakness

Ocular: Aggravation of glaucoma

Respiratory: Epistaxis

Signs and Symptoms of Overdose Amenorrhea, bradycardia, coma, death, depression, elevated liver function tests, hypotension, insomnia, mania, seizures, tachycardia, toxic epidermal necrolysis, syndrome of inappropriate antidiuretic hormone (SIADH)

Pharmacodynamics/Kinetics

Absorption: Steady-state plasma concentrations have been noted to be 2-3 times higher in children than those in adolescents; female children demonstrated a significantly higher AUC than males

Distribution: V_d : ~ 25 L/kg

Protein binding: $\sim 80\%$, primarily to albumin

Metabolism: Hepatic

Bioavailability: 53%; not significantly affected by food

Half-life elimination: ~ 15 hours

Time to peak, plasma: 3-8 hours

Excretion: Urine

Dosage

Oral: **Note:** When total daily dose exceeds 50 mg, the dose should be given in 2 divided doses:

Children 8-17 years: Initial: 25 mg at bedtime; adjust in 25 mg increments at 4- to 7-day intervals, as tolerated, to maximum therapeutic benefit:

Range: 50-200 mg/day

Maximum: Children: 8-11 years: 200 mg/day, adolescents: 300 mg/day; lower doses may be effective in female versus male patients

Adults: Initial: 50 mg at bedtime; adjust in 50 mg increments at 4- to 7-day intervals; usual dose range: 100-300 mg/day; divide total daily dose into 2 doses; administer larger portion at bedtime

Elderly: Reduce dose, titrate slowly

Dosage adjustment in hepatic impairment: Reduce dose, titrate slowly

Monitoring Parameters Mental status for depression, suicidal ideation, anxiety, social functioning, mania, panic attacks; akathisia, weight gain or loss, nutritional intake, sleep

Contraindications Hypersensitivity to fluvoxamine or any component of the formulation; concurrent use with alsetron, pimozide, thioridazine, tizanidine, mesoridazine, or cisapride; use of MAO inhibitors within 14 days

Warnings

Major psychiatric warnings:

- [U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. A medication guide concerning the use of antidepressants in children and teenagers should be dispensed with each prescription. **Fluvoxamine is not FDA approved for use in children.**

- The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Patients treated with antidepressants should be observed for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy.

- Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression or psychosis occur.

- May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder.

Fluvoxamine is not FDA approved for the treatment of bipolar depression.

Key adverse effects:

- Anticholinergic effects: Relatively devoid of these side effects
- CNS depression: Has a low potential to impair cognitive or motor performance; caution operating hazardous machinery or driving.
- SIADH and hyponatremia: Has been associated with the development of SIADH; hyponatremia has been reported rarely, predominately in the elderly

Concurrent disease:

- Cardiovascular disease: Use caution in patients with cardiovascular disease; fluvoxamine has not been systemically evaluated in patients with a recent history of MI or unstable heart disease.
- Hepatic impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.
- Platelet aggregation: May impair platelet aggregation, resulting in bleeding.
- Renal impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.
- Seizure disorders: Use caution with a previous seizure disorder or condition predisposing to seizures such as brain damage or alcoholism.
- Sexual dysfunction: May cause or exacerbate sexual dysfunction.

Concurrent drug therapy:

- Agents which lower seizure threshold: Concurrent therapy with other drugs which lower the seizure threshold.
- Anticoagulants/Antiplatelets: Use caution with concomitant use of NSAIDs, ASA, or other drugs that affect coagulation; the risk of bleeding is potentiated.
- CNS depressants: Use caution with concomitant therapy.
- MAO inhibitors: Potential for severe reaction when used with MAO inhibitors; autonomic instability, coma, death, delirium, diaphoresis, hyperthermia, mental status changes/agitation, muscular rigidity, myoclonus, neuroleptic malignant syndrome features, and seizures may occur.

Special populations:

- Elderly: Use caution in elderly patients.

Special notes:

- Electroconvulsive therapy: May increase the risks associated with electroconvulsive therapy; consider discontinuing, when possible, prior to ECT treatment.
- Withdrawal syndrome: May cause dysphoric mood, irritability, agitation, dizziness, sensory disturbances, anxiety, confusion, headache, lethargy, emotional lability, insomnia, hypomania, tinnitus, and seizures. Upon discontinuation of fluvoxamine therapy, gradually taper dose. If intolerable symptoms occur following a decrease in dosage or upon discontinuation of therapy, then resuming the previous dose with a more gradual taper should be considered.

Dosage Forms Tablet: 25 mg, 50 mg, 100 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Mianserin (15 mg at night) has been used to treat fluvoxamine-induced akathisia; akathisia can be treated with propranolol (60-120 mg/day) and trihexiphenidyl (2 mg/day)
 Enhancement of elimination: Multiple dose activated charcoal may be useful

Drug Interactions

Substrate (major) of CYP1A2, 2D6; **Inhibits** CYP1A2 (strong), 2B6 (weak), 2C9 (weak), 2C19 (strong), 2D6 (weak), 3A4 (weak)
 Alosetron: Serum concentrations may be increased by fluvoxamine; concurrent use is not recommended.
 Amphetamines: SSRIs may increase the sensitivity to amphetamines, and amphetamines may increase the risk of serotonin syndrome
 Benzodiazepines: Fluvoxamine may inhibit the metabolism of alprazolam, diazepam, and triazolam resulting in elevated serum levels; monitor for increased sedation and psychomotor impairment
 Beta-blockers: Fluvoxamine may inhibit the metabolism of metoprolol and propranolol resulting in cardiac toxicity; monitor for bradycardia, hypotension, and heart failure if combination is used; not established for all beta-blockers (unlikely with atenolol or nadolol due to renal elimination)

Bupirone: Fluvoxamine inhibits the reuptake of serotonin; combined use with a serotonin agonist (bupirone) may cause serotonin syndrome; fluvoxamine may also increase serum concentrations of bupirone
 Carbamazepine: Fluvoxamine may inhibit the metabolism of carbamazepine resulting in increased carbamazepine levels and toxicity; monitor for altered carbamazepine response
 Carvedilol: Serum concentrations may be increased; monitor carefully for increased carvedilol effect (hypotension and bradycardia)
 Cisapride: Concurrent use is contraindicated
 Clozapine: Fluvoxamine inhibits the metabolism of clozapine; adjust clozapine dosage downward or use an alternative SSRI
 CYP1A2 inducers: May decrease the levels/effects of fluvoxamine. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.
 CYP1A2 inhibitors: May increase the levels/effects of fluvoxamine. Example inhibitors include ciprofloxacin, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.
 CYP1A2 substrates: Fluvoxamine may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, mexiletine, mirtazapine, ropinirole, theophylline, and trifluoperazine.
 CYP2C19 substrates: Fluvoxamine may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.
 CYP2D6 inhibitors: May increase the levels/effects of fluvoxamine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.
 Cyproheptadine: May inhibit the effects of serotonin reuptake inhibitors (fluvoxamine); monitor for altered antidepressant response; cyproheptadine acts as a serotonin agonist
 Dextromethorphan: Fluvoxamine inhibits the metabolism of dextromethorphan; visual hallucinations occurred in a patient receiving this combination; monitor for serotonin syndrome
 Haloperidol: Fluvoxamine may inhibit the metabolism of haloperidol and cause extrapyramidal symptoms (EPS); monitor patients for EPS if combination is utilized
 HMG-CoA reductase inhibitors: Fluvoxamine may inhibit the metabolism of lovastatin and simvastatin resulting in myositis and rhabdomyolysis; these combinations are best avoided
 Lithium: Patients receiving SSRIs and lithium have developed neurotoxicity; if combination is used, monitor for neurotoxicity
 Loop diuretics: Fluvoxamine may cause hyponatremia; additive hyponatremic effects may be seen with combined use of a loop diuretic (bumetanide, furosemide, torsemide); monitor for hyponatremia
 MAO inhibitors: Fluvoxamine should not be used with nonselective MAO inhibitors (isocarboxazid, phenelzine); fatal reactions have been reported; this combination should be avoided
 Meperidine: Combined use with fluvoxamine theoretically may increase the risk of serotonin syndrome
 Methadone: Fluvoxamine may increase serum concentrations of methadone; monitor for increased effect
 Mexiletine: Clearance of mexiletine was reduced by 38% following coadministration with fluvoxamine. If used concurrently, mexiletine levels should be monitored.
 Nefazodone: May increase the risk of serotonin syndrome with SSRIs
 NSAIDs: Concomitant use of fluvoxamine and NSAIDs, aspirin, or other drugs affecting coagulation has been associated with an increased risk of bleeding; monitor.
 Pimozide: Concurrent use is contraindicated
 Phenothiazines: Fluvoxamine may inhibit metabolism of phenothiazines; **concurrent use of agents associated with QT prolongation (thioridazine, mesoridazine) is contraindicated**
 Phenytoin: Fluvoxamine inhibits the metabolism of phenytoin and may result in phenytoin toxicity; monitor for phenytoin toxicity (ataxia, confusion, dizziness, nystagmus, involuntary muscle movement)
 Propafenone: Serum concentrations and/or toxicity may be increased by fluoxetine; avoid concurrent administration
 Quinidine: Serum concentrations may be increased with fluvoxamine; avoid concurrent use
 Ritonavir: Combined use of fluvoxamine with ritonavir may cause serotonin syndrome in HIV-positive patients; monitor
 Selegiline: SSRIs have been reported to cause mania or hypertension when combined with selegiline; this combination is best avoided. In addition, use with some SSRIs has been reported to cause serotonin syndrome. As an MAO type B inhibitor, the risk of serotonin syndrome may be less than with nonselective MAO inhibitors.
 Serotonin reuptake inhibitors: Combined use with other drugs which inhibit the reuptake may cause serotonin syndrome; monitor patient for altered response with nefazodone; avoid sibutramine combination
 Sibutramine: May increase the risk of serotonin syndrome with SSRIs
 Sumatriptan (and other serotonin agonists): Concurrent use may result in toxicity; weakness, hyper-reflexia, and incoordination have been observed with sumatriptan and SSRIs. In addition, concurrent use

may theoretically increase the risk of serotonin syndrome; includes sumatriptan, naratriptan, rizatriptan, and zolmitriptan.

Sympathomimetics: May increase the risk of serotonin syndrome with SSRIs

Tacrine: Fluvoxamine inhibits the metabolism of tacrine; use alternative SSRI

Tacrolimus: Fluvoxamine may inhibit the metabolism of tacrolimus; monitor for adverse effects; consider an alternative SSRI

Theophylline: Fluvoxamine inhibits the metabolism of theophylline; monitor for theophylline toxicity or use alternative SSRI

Tizanidine: Serum concentrations may be increased by fluvoxamine; concurrent use is not recommended.

Tramadol: Fluvoxamine combined with tramadol (serotonergic effects) may cause serotonin syndrome; monitor

Trazodone: Fluvoxamine may inhibit the metabolism of trazodone resulting in increased toxicity; monitor

Tricyclic antidepressants Fluvoxamine inhibits the metabolism of tricyclic antidepressants (amitriptyline, desipramine, imipramine, nortriptyline) resulting in elevated serum levels; if combination is warranted, a low dose of TCA (10-25 mg/day) should be utilized

Tryptophan: Fluvoxamine inhibits the reuptake of serotonin; combination with tryptophan, a serotonin precursor, may cause agitation and restlessness; this combination is best avoided

Venlafaxine: Combined use with fluvoxamine may increase the risk of serotonin syndrome

Warfarin: Fluvoxamine may alter the hypoprothrombinemic response to warfarin; monitor

Pregnancy Risk Factor C

Pregnancy Implications Nonteratogenic effects including respiratory distress, cyanosis, apnea, seizures, temperature instability, feeding difficulty, vomiting, hypoglycemia, hypo- or hypertonia, hyper-reflexia, jitteriness, irritability, constant crying, and tremor have been reported in the neonate immediately following delivery after exposure to other SSRIs late in the third trimester. Adverse effects may be due to toxic effects of SSRI or drug discontinuation. In some cases, may present clinically as serotonin syndrome. There are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if the potential benefit to the mother outweighs the possible risk to the fetus. If treatment during pregnancy is required, consider tapering therapy during the third trimester.

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Additional Information Rate of serotonin syndrome-like symptoms: ~0.04-0.006/100 treatment days

Martínez MA, Sánchez de la Torre C, and Almarza E, "A Comparative Solid-Phase Extraction Study for the Simultaneous Determination of Fluvoxamine, Mianserin, Doxepin, Citalopram, Paroxetine, and Etoposide in Whole Blood by Capillary Gas-Liquid Chromatography with Nitrogen-Phosphorus Detection," *J Anal Toxicol*, 2004, 28(4):174-80.

Gastrointestinal: **Nausea, diarrhea**, dyspepsia, **vomiting**

Genitourinary: Genital ulcers

Hematologic: **Anemia**, decreases in hemoglobin and hematocrit

Hepatic: Elevated liver enzymes

Local: Thrombophlebitis

Neuromuscular & skeletal: Paresthesia

Renal: **Abnormal renal function** including renal failure, albuminuria, acidosis (renal tubular), renal tubular necrosis; **decreased creatinine clearance** at continuous dosing of 130-230 mg/kg/day,

Respiratory: Rhinitis

Miscellaneous: Penile ulceration (at 7-24 days), nephrogenic diabetes insipidus, lymphadenopathy, fixed drug eruption

Signs and Symptoms of Overdose Cough, dementia, depression, dry mouth, dysphagia, dysuria, hypercalcemia, hypocalcemia, hypokalemia, hypomagnesemia, hyponatremia, hypophosphatemia, leg cramps, leukocytosis, lymphopenia, malaise, meningitis, myalgia, nocturia, perioral or limb paresthesias, renal dysfunction, seizures, thrombocytopenia, wheezing

Pharmacodynamics/Kinetics

Distribution: Up to 28% of cumulative I.V. dose may be deposited in bone

Metabolism: Biotransformation does not occur

Half-life elimination: ~3 hours

Excretion: Urine ($\leq 28\%$ as unchanged drug)

Dosage

CMV retinitis: I.V.:

Induction treatment: 60 mg/kg/dose every 8 hours **or** 100 mg/kg every 12 hours for 14-21 days

Maintenance therapy: 90-120 mg/kg/day as a single infusion

Acyclovir-resistant HSV induction treatment: I.V.: 40 mg/kg/dose every 8-12 hours for 14-21 days

Dosage adjustment in renal impairment:

Induction and maintenance dosing schedules based on creatinine clearance (mL/kg/minute): See tables.

Maintenance Dosing of Foscarnet in Patients with Abnormal Renal Function

Cl _{cr} (mL/min/kg)	CMV	CMV
	Equivalent to 90 mg/kg q24h	Equivalent to 120 mg/kg q24h
< 0.4	Not recommended	Not recommended
≥ 0.4-0.5	50 mg/kg every 48 hours	65 mg/kg every 48 hours
> 0.5-0.6	60 mg/kg every 48 hours	80 mg/kg every 48 hours
> 0.6-0.8	80 mg/kg every 48 hours	105 mg/kg every 48 hours
> 0.8-1.0	50 mg/kg every 24 hours	65 mg/kg every 24 hours
> 1.0-1.4	70 mg/kg every 24 hours	90 mg/kg every 24 hours
> 1.4	90 mg/kg every 24 hours	120 mg/kg every 24 hours

Hemodialysis:

Foscarnet is highly removed by hemodialysis (30% in 4 hours HD) Doses of 50 mg/kg/dose posthemodialysis have been found to produce similar serum concentrations as doses of 90 mg/kg twice daily in patients with normal renal function

Doses of 60-90 mg/kg/dose loading dose (posthemodialysis) followed by 45 mg/kg/dose posthemodialysis (3 times/week) with the monitoring of weekly plasma concentrations to maintain peak plasma concentrations in the range of 400-800 μMolar has been recommended by some clinicians

Continuous arteriovenous or venovenous hemodiafiltration effects: Dose as for Cl_{cr} 10-50 mL/minute

Stability Do not admix or run with other drugs, multiple incompatibilities

Monitoring Parameters Serum creatinine, calcium, phosphorus, potassium, magnesium; hemoglobin

Administration Administer diluted to 12 mg/mL through a peripheral line; may be administered undiluted through a central line; infuse over 1 hour

Contraindications Hypersensitivity to foscarnet or any component of the formulation; Cl_{cr} < 0.4 mL/minute/kg during therapy

Warnings

Hazardous agent – use appropriate precautions for handling and disposal. **[U.S. Boxed Warning]: Indicated only for immunocompromised patients with CMV retinitis and mucocutaneous acyclovir-resistant HSV infection.** **[U.S. Boxed Warning]: Renal impairment occurs to some degree in the majority of patients treated with foscarnet; renal impairment may occur at any time and is usually reversible within 1 week following dose adjustment or discontinuation of therapy, however, several patients have died with renal failure within 4 weeks of stopping foscarnet; therefore, renal function should be closely monitored. To reduce the risk of nephrotoxicity and the potential to administer a relative overdose, always calculate the Cl_{cr} even if serum creatinine is within the normal range. Adequate hydration**

Foscarnet

CAS Number 34156-56-4; 63585-09-1

U.S. Brand Names Foscavir®

Synonyms PFA; Phosphonoformate; Phosphonoformic Acid

Use Treatment of herpes virus infections suspected to be caused by acyclovir-resistant (HSV, VZV) or ganciclovir-resistant (CMV) strains; this occurs almost exclusively in immunocompromised persons (eg, with advanced AIDS) who have received prolonged treatment for a herpes virus infection

Treatment of CMV retinitis in persons with AIDS

Unlabeled/Investigational Use Other CMV infections (eg, colitis, esophagitis, neurological disease)

Mechanism of Action Pyrophosphate analogue which acts as a non-competitive inhibitor of many viral RNA and DNA polymerases as well as HIV reverse transcriptase. Inhibitory effects occur at concentrations which do not affect host cellular DNA polymerases; however, some human cell growth suppression has been observed with high *in vitro* concentrations. Similar to ganciclovir, foscarnet is a virostatic agent. Foscarnet does not require activation by thymidine kinase.

Adverse Reactions

Cardiovascular: Cardiomyopathy, fibrillation (atrial), flutter (atrial), sinus bradycardia, cardiomegaly, palpitations

Central nervous system: Fatigue, **fever, headache, seizures**, hallucinations, electroencephalogram abnormalities, amnesia

Dermatologic: Alopecia, xerosis, urticaria, psoriasis, exanthem, toxic epidermal necrolysis

Endocrine & metabolic: Hypocalcemia, hypomagnesemia, hypokalemia, change in serum phosphorus, hypophosphatemia, hypercalcemia, nephrogenic diabetes insipidus

Induction Dosing of Foscarnet in Patients with Abnormal Renal Function				
Cl _{cr} (mL/min/kg)	HSV	HSV	CMV	CMV
	Equivalent to 40 mg/kg q12h	Equivalent to 40 mg/kg q8h	Equivalent to 60 mg/kg q8h	Equivalent to 90 mg/kg q12h
<0.4	Not recommended	Not recommended	Not recommended	Not recommended
≥0.4-0.5	20 mg/kg every 24 hours	35 mg/kg every 24 hours	50 mg/kg every 24 hours	50 mg/kg every 24 hours
>0.5-0.6	25 mg/kg every 24 hours	40 mg/kg every 24 hours	60 mg/kg every 24 hours	60 mg/kg every 24 hours
>0.6-0.8	35 mg/kg every 24 hours	25 mg/kg every 12 hours	40 mg/kg every 12 hours	80 mg/kg every 24 hours
>0.8-1.0	20 mg/kg every 12 hours	35 mg/kg every 12 hours	50 mg/kg every 12 hours	50 mg/kg every 12 hours
>1.0-1.4	30 mg/kg every 12 hours	30 mg/kg every 8 hours	45 mg/kg every 8 hours	70 mg/kg every 12 hours
>1.4	40 mg/kg every 12 hours	40 mg/kg every 8 hours	60 mg/kg every 8 hours	90 mg/kg every 12 hours

may reduce the risk of nephrotoxicity; the manufacturer makes specific recommendations regarding this (see Administration).

Imbalance of serum electrolytes or minerals occurs in at least 15% of patients (hypocalcemia, low ionized calcium, hypophosphatemia, hypomagnesemia, or hypokalemia). Patients with low ionized calcium may experience perioral tingling, numbness, paresthesias, tetany, and seizures. Correct electrolytes before initiating therapy; use caution in patients who have any underlying electrolyte imbalances, those with neurologic or cardiac abnormalities and those receiving medications that are influenced by calcium levels. Use caution when administering other medications that cause electrolyte imbalances. Patients who experience signs or symptoms of an electrolyte imbalance should be assessed immediately. **[U.S. Boxed Warning]: Seizures related to plasma electrolyte/mineral imbalance may occur;** incidence has been reported in up to 10% of AIDS patients. Risk factors for seizures include impaired baseline renal function and low total serum calcium. Some patients who have experienced seizures have been able to continue or resume foscarnet treatment after their mineral or electrolyte abnormality has been corrected, their underlying disease state treated, or their dose decreased. May cause anemia and granulocytopenia. Foscarnet has been shown to be mutagenic in animal studies. Foscarnet is deposited in teeth and bone of young, growing animals; it has adversely affected tooth enamel development in rats. Safety and efficacy in children have not been established.

Dosage Forms

Injection, solution: 24 mg/mL (250 mL, 500 mL)
Foscavir®: 24 mg/mL (500 mL)

Reference Range Therapeutic for CMV: 150 mcg/mL

Overdosage/Treatment

Supportive therapy: I.V. calcium salts for hypocalcemia; I.V. hydration is essential

Enhancement of elimination: Hemodialysis may be useful to aid in removal of the drug, although this has not been formally studied

Drug Interactions

Ciprofloxacin: May enhance the neuroexcitatory and/or seizure-potentiating effect of foscarnet.

Nephrotoxic drugs (amphotericin B, I.V. pentamidine, aminoglycosides, etc): Should be avoided, if possible, to minimize additive renal risk with foscarnet.

QT_c-prolonging agents: May enhance the adverse/toxic effect of other QT_c-prolonging agents such as foscarnet. Any electrolyte abnormalities caused by foscarnet may exacerbate the situation.

Pentamidine: Increases risk of severe hypocalcemia.

Ritonavir, saquinavir: Increased risk of renal impairment has been associated with concurrent use with foscarnet.

Thioridazine: Foscarnet may enhance the QT_c-prolonging effect of thioridazine.

Zalcitabine: Foscarnet may enhance the neurotoxic (peripheral) effect of zalcitabine.

Pregnancy Risk Factor C

Pregnancy Implications Associated with an increase in skeletal anomalies in animal studies. There are no adequate and well controlled studies in pregnant women. A single case report of use during the third trimester with normal infant outcome was observed. Monitoring of amniotic fluid volumes by ultrasound is recommended weekly after 20 weeks of gestation to detect oligohydramnios.

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Provide adequate hydration with I.V. normal saline prior to and during treatment to minimize nephrotoxicity

Fosfomycin

CAS Number 23155-02-4; 78964-85-9

U.S. Brand Names Monurol™

Synonyms Fosfomycin Tromethamine

Use Antibiotic for uncomplicated urinary tract infections

Unlabeled/Investigational Use Multiple doses have been investigated for complicated urinary tract infections in men

Mechanism of Action A phosphoric acid derivative, fosfomycin inhibits bacterial wall synthesis and thus is bactericidal

Adverse Reactions

Central nervous system: **Headache** (10.3%)

Gastrointestinal: **Diarrhea** 10.4% (diarrhea is dose related); anorexia

Hematologic: Eosinophilia

Miscellaneous: Anaphylaxis

Signs and Symptoms of Overdose Not documented in humans; animal studies at doses of 5 g/kg demonstrated little toxicity (outside of watery diarrhea)

Pharmacodynamics/Kinetics

Absorption: Well absorbed

Distribution: V_d: 2 L/kg; high concentrations in urine; well into other tissues; crosses maximally into CSF with inflamed meninges

Protein binding: <3%

Bioavailability: 34% to 58%

Half-life elimination: 4-8 hours; Cl_{cr} <10 mL/minute: 50 hours

Time to peak, serum: 2 hours

Excretion: Urine (as unchanged drug); high urinary levels (100 mcg/mL) persist for >48 hours

Dosage Oral:

Infants <1 year: 1 g single dose

Children: 2 g single dose

Adults: 3 g single dose

Doses should be taken on an empty stomach as food can impair its absorption; use in children <12 years of age has not been established

Monitoring Parameters Signs and symptoms of urinary tract infection

Administration Always mix with water before ingesting; do not administer in its dry form; pour contents of envelope into 90-120 mL of water (not hot), stir to dissolve and take immediately

Dosage Forms Powder, as tromethamine: 3 g

Reference Range Peak serum fosfomycin level ranges from 22-43 mcg/mL after a 50 mg/kg oral dose; therapeutic range: 8-32 mcg/mL

Overdosage/Treatment

Decontamination: Oral: Ipecac within 30 minutes or lavage within 1 hour/activated charcoal

Supportive therapy: Crystalloid I.V. fluids to replace watery diarrhea

Enhanced elimination: Hemodialysis can enhance fosfomycin elimination

Drug Interactions

Antacids or calcium salts may cause precipitate formation and decrease fosfomycin absorption

Metoclopramide: Increased gastrointestinal motility may lower fosfomycin tromethamine serum concentrations and urinary excretion. This drug interaction possibly could be extrapolated to other medications which increase gastrointestinal motility.

Pregnancy Risk Factor B**Lactation** Enters breast milk/not recommended**Additional Information** Cross resistance with other antibiotics does not appear to occur.**Fosinopril****Related Information**

- Angiotensin Agents

CAS Number 88889-14-9; 97825-24-6**U.S. Brand Names** Monopril®**Synonyms** Fosinopril Sodium**Use** Treatment of hypertension, either alone or in combination with other antihypertensive agents; treatment of congestive heart failure, left ventricular dysfunction after myocardial infarction**Mechanism of Action** Competitive inhibition of angiotensin I being converted to angiotensin II, a potent vasoconstrictor, through the angiotensin I-converting enzyme (ACE) activity, with resultant lower levels of angiotensin II which causes an increase in plasma renin activity and a reduction in aldosterone secretion**Adverse Reactions**

Cardiovascular: Hypotension (orthostatic), vasodilation, vasculitis

Central nervous system: Headache, fatigue, dizziness, syncope, vertigo, insomnia

Dermatologic: Angioedema, rash, scleroderma, exfoliative dermatitis, urticaria, photosensitivity, pemphigus

Endocrine & metabolic: Hypoglycemia, hyperkalemia, sexual dysfunction

Gastrointestinal: Diarrhea, nausea, vomiting, loss of taste perception, xerostomia

Genitourinary: Impotence

Hematologic: Neutropenia, agranulocytosis, anemia

Neuromuscular & skeletal: Muscle cramps, eosinophilic fasciitis, paresthesia

Renal: Deterioration in renal function, proteinuria

Respiratory: Cough

Pharmacodynamics/Kinetics

Onset of action: 1 hour

Duration: 24 hours

Absorption: 36%

Protein binding: 95%

Metabolism: Prodrug, hydrolyzed to its active metabolite fosinoprilat by intestinal wall and hepatic esterases

Bioavailability: 36%

Half-life elimination, serum (fosinoprilat): 12 hours

Time to peak, serum: ~3 hours

Excretion: Urine and feces (as fosinoprilat and other metabolites in roughly equal proportions, 45% to 50%)

Dosage

Oral:

Children > 50 kg: Hypertension: Initial: 5-10 mg once daily

Adults:

Hypertension: Initial: 10 mg/day; most patients are maintained on 20-40 mg/day. May need to divide the dose into two if trough effect is inadequate; discontinue the diuretic, if possible 2-3 days before initiation of therapy; resume diuretic therapy carefully, if needed.

Heart failure: Initial: 10 mg/day (5 mg if renal dysfunction present) and increase, as needed, to a maximum of 40 mg once daily over several weeks; usual dose: 20-40 mg/day. If hypotension, orthostasis, or azotemia occur during titration, consider decreasing concomitant diuretic dose, if any.

Dosing adjustment/comments in renal impairment: None needed since hepatobiliary elimination compensates adequately diminished renal elimination.

Hemodialysis: Moderately dialyzable (20% to 50%)

Monitoring Parameters Blood pressure (supervise for at least 2 hours after the initial dose or any increase for significant orthostasis); serum potassium, creatinine, BUN, WBC**Contraindications** Hypersensitivity to fosinopril or any component of the formulation; angioedema related to previous treatment with an ACE inhibitor; idiopathic or hereditary angioedema; bilateral renal artery stenosis; pregnancy (2nd and 3rd trimesters)**Warnings** Anaphylactic reactions can occur. Angioedema can occur at any time during treatment (especially following first dose). It may involve head and neck (potentially affecting the airway) or the intestine (presenting with abdominal pain). Prolonged monitoring may be required especially if tongue, glottis, or larynx are involved as they are associated with airway obstruction. Those with a history of airway surgery in this situation have a higher risk. Careful blood pressure monitoring (hypotension can occur especially in volume-depleted patients). [**U.S. Boxed Warning**]: Based on human data, ACEIs can cause injury and death to the developing fetus when used in the second and third trimesters. ACEIs should be discontinued as soon as possible

once pregnancy is detected. Dosage adjustment needed in severe renal impairment ($Cl_{cr} < 10$ mL/minute). Use with caution in hypovolemia; collagen vascular diseases; valvular stenosis (particularly aortic stenosis); hyperkalemia; or before, during, or immediately after anesthesia. Avoid rapid dosage escalation which may lead to renal insufficiency. Rare toxicities associated with ACE inhibitors include cholestatic jaundice (which may progress to hepatic necrosis) and neutropenia/agranulocytosis with myeloid hyperplasia. Hypersensitivity reactions may be seen during hemodialysis with high-flux dialysis membranes (eg, AN69). Hyperkalemia may rarely occur. If patient has renal impairment, then a baseline WBC with differential and serum creatinine should be evaluated and monitored closely during initial therapy. Use with caution in unilateral renal artery stenosis and pre-existing renal insufficiency.

Dosage Forms Tablet, as sodium: 10 mg, 20 mg, 40 mg

Monopril®: 10 mg, 20 mg, 40 mg

Reference Range Peak serum fosinoprilat level after a 40 mg dose: ~600 ng/mL**Overdosage/Treatment**

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to diazepam (I.V. 5-10 mg bolus in adults every 15 minutes if needed up to a total of 30 mg; I.V. 0.25-0.4 mg/kg/dose up to a total of 10 mg in children) or to phenytoin or phenobarbital. Naloxone has been shown to antagonize hypotensive effects of captopril, but routine use in an overdose situation due to this agent is uncertain. For refractory hypotension, angiotensin amide infusion may be attempted.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; hemodialysis is not effective

Test Interactions Positive Coombs' [direct]; may cause false-positive urine acetone determinations using sodium nitroprusside reagent; may cause a falsely low serum digoxin level (with Digi-Tab® RIA kit)**Drug Interactions** α_1 blockers: Hypotensive effect increased.

Antacids (aluminum hydroxide, magnesium hydroxide and simethicone): Absorption of fosinopril impaired; separate dose by 2 hours.

Aspirin: The effects of ACE inhibitors may be blunted by aspirin administration, particularly at higher dosages (see Cardiovascular Considerations) and/or increase adverse renal effects.

Diuretics: Hypovolemia due to diuretics may precipitate acute hypotensive events or acute renal failure.

Insulin: Risk of hypoglycemia may be increased.

Lithium: Risk of lithium toxicity may be increased; monitor lithium levels, especially the first 4 weeks of therapy.

Mercaptopurine: Risk of neutropenia may be increased.

NSAIDs: May attenuate hypertensive efficacy; effect has been seen with captopril and may occur with other ACE inhibitors; monitor blood pressure. May increase risk of adverse renal effects.

Potassium-sparing diuretics (amiloride, spironolactone, triamterene): Increased risk of hyperkalemia.

Potassium supplements may increase the risk of hyperkalemia.

Trimethoprim (high dose) may increase the risk of hyperkalemia.

Pregnancy Risk Factor C (1st trimester)/D (2nd and 3rd trimesters)**Pregnancy Implications** Decreased placental blood flow, low birth weight, fetal hypotension, preterm delivery, and fetal death have been noted with the use of some ACE inhibitors (ACEIs) in animal studies. Neonatal hypotension, skull hypoplasia, anuria, renal failure, oligohydramnios (associated with fetal limb contractures, craniofacial deformities, hypoplastic lung development), prematurity, intrauterine growth retardation, and patent ductus arteriosus have been reported with the use of ACEIs, primarily in the 2nd and 3rd trimesters. The risk of neonatal toxicity has been considered less when ACEIs have been used in the 1st trimester; however, major congenital malformations have been reported. The cardiovascular and/or central nervous systems are most commonly affected. Unless alternative agents are not appropriate, ACEIs should be discontinued as soon as possible once pregnancy is detected.**Lactation** Enters breast milk/not recommended**Nursing Implications** May cause depression in some patients; discontinue if angioedema of the face, extremities, lips, tongue, or glottis occurs; watch for hypotensive effects within 1-3 hours of first dose or new higher dose**Additional Information**

Some patients may have a decreased hypotensive effect between 12-16 hours; consider dividing total daily dose into 2 doses 12 hours apart. If receiving a diuretic, the potential for first-dose hypotension is increased.

To decrease this potential, stop the diuretic for 2-3 days prior to initiating fosinopril, if possible. Continue the diuretic if needed to control blood pressure.

Due to frequent decreases in glomerular filtration (also creatinine clearance) with aging, elderly patients may have exaggerated responses to ACE inhibitors; differences in clinical response due to hepatic changes are not observed. ACE inhibitors may be preferred agents in elderly patients with congestive heart failure and diabetes mellitus. Diabetic proteinuria is reduced and insulin sensitivity is enhanced. In general, the side effect profile is favorable in elderly and causes little or no CNS confusion; use lowest dose recommendations initially. Pediatric ingestion of 15 mg/kg is survivable with supportive therapy. Should not take a potassium salt supplement without the advice of healthcare provider.

Fosphenytoin

U.S. Brand Names Cerebyx®

Synonyms Fosphenytoin Sodium

Use Management of generalized tonic-clonic (grand mal), simple partial and complex partial seizures; prevention of seizures following head trauma/neurosurgery; ventricular arrhythmias, including those associated with digitalis intoxication; beneficial effects in the treatment of migraine or trigeminal neuralgia in some patients; usually used in short-term seizure management

Mechanism of Action Diphosphate ester salt of phenytoin which acts as a water soluble prodrug of phenytoin; after administration, plasma esterases convert to phenytoin as the active moiety

Adverse Reactions

- Cardiovascular:** Sinus bradycardia, facial edema
- Central nervous system:** Slurred speech, dizziness, drowsiness, fever, visual hallucinations
- Dermatologic:** Rash, exfoliative dermatitis, erythema multiforme, acne
- Endocrine & metabolic:** Folic acid depletion, hyperglycemia, reduced plasma testosterone, gynecomastia
- Gastrointestinal:** Nausea, vomiting, gingival hyperplasia
- Genitourinary:** Priapism
- Hematologic:** Neutropenia, thrombocytopenia, anemia (megaloblastic)
- Local:** Pain on injection
- Neuromuscular & skeletal:** **Sensory paresthesia** (up to 30% of patients on long-term treatment), choreoathetosis, osteomalacia
- Ocular:** Nystagmus, blurred vision, diplopia
- Renal:** Nephrotic syndrome
- Miscellaneous:** Due to the fact that fosphenytoin is water soluble and has a lower pH (8.8) than phenytoin (12), necrosis or irritation at injection site is reduced, systemic lupus erythematosus (SLE), lymphadenopathy

Signs and Symptoms of Overdose Agranulocytosis, chorea (extrapyramidal), coma, confusion, drowsiness, encephalopathy, fever, gingival hyperplasia, granulocytopenia, gynecomastia, hyperthermia, hyperglycemia, hyperreflexia, hypotension, hypothermia, leukopenia, mydriasis, myoclonus, myoglobinuria, nausea, nephrotic syndrome, neutropenia, ophthalmoplegia, respiratory depression, slurred speech, tremors, unsteady gait

Pharmacodynamics/Kinetics

- Also refer to Phenytoin monograph for additional information.
- Protein binding:** Fosphenytoin: 95% to 99% to albumin; can displace phenytoin and increase free fraction (up to 30% unbound) during the period required for conversion of fosphenytoin to phenytoin
- Metabolism:** Fosphenytoin is rapidly converted via hydrolysis to phenytoin; phenytoin is metabolized in the liver and forms metabolites
- Bioavailability:** I.M.: Fosphenytoin: 100%
- Half-life elimination:**
- Fosphenytoin: 15 minutes
 - Phenytoin: Variable (mean: 12-29 hours); kinetics of phenytoin are saturable
- Time to peak:** Conversion to phenytoin: Following I.V. administration (maximum rate of administration): 15 minutes; following I.M. administration, peak phenytoin levels are reached in 3 hours
- Excretion:** Phenytoin: Urine (as inactive metabolites)

Dosage

- I.M.:** Up to 450 mg has been used in adults
- I.V.:** 14-17 mg/kg (suggested); doses up to 3000 mg (38 mg/kg) have been used. Rates as high as 150-218 mg/minute have been administered. Usual infusion time: ~30 minutes

Monitoring Parameters Blood pressure, vital signs (with I.V. use), plasma level monitoring, CBC, liver function tests

Administration

- I.M.:** May be administered as a single daily dose using either 1 or 2 injection sites.
- I.V.:** Rates of infusion:
- Children: 1-3 mg PE/kg/minute
 - Adults: Should not exceed 150 mg PE/minute

Contraindications Hypersensitivity to phenytoin, other hydantoins, or any component of the formulation; patients with sinus bradycardia, sinoatrial block, second- and third-degree AV block, or Adams-Stokes syndrome; occurrence of rash during treatment (should not be resumed if rash is exfoliative, purpuric, or bullous); treatment of absence seizures

Warnings Doses of fosphenytoin are expressed as their phenytoin sodium equivalent (PE). Antiepileptic drugs should not be abruptly discontinued. Hypotension may occur, especially after I.V. administration at high doses and high rates of administration. Administration of phenytoin has been associated with atrial and ventricular conduction depression and ventricular fibrillation. Careful cardiac monitoring is needed when administering I.V. loading doses of fosphenytoin. Acute hepatotoxicity associated with a hypersensitivity syndrome characterized by fever, skin eruptions, and lymphadenopathy has been reported to occur within the first 2 months of treatment. Discontinue if skin rash or lymphadenopathy occurs. Use with caution in patients with hypotension, severe myocardial insufficiency, diabetes mellitus, porphyria, hypoalbuminemia, hypothyroidism, fever, or hepatic or renal dysfunction.

Dosage Forms Injection, solution, as sodium: 75 mg/mL [equivalent to phenytoin sodium 50 mg/mL] (2 mL, 10 mL)

Reference Range

- Therapeutic:** 10-20 mcg/mL (SI: 40-79 µmol/L); toxicity is measured clinically, and some patients require levels outside the suggested therapeutic range
- Toxic:** 30-50 mcg/mL (SI: 120-200 µmol/L)
- Lethal:** > 100 mcg/mL (SI: >400 µmol/L)
- Manifestations of toxicity:**
- Nystagmus: 20 mcg/mL (SI: 79 µmol/L)
 - Ataxia: 30 mcg/mL (SI: 118.9 µmol/L)
 - Decreased mental status: 40 mcg/mL (SI: 159 µmol/L)
 - Coma: 50 mcg/mL (SI: 200 µmol/L)
- Peak serum phenytoin level after a 375 mg I.M. fosphenytoin dose in healthy males: 5.7 mcg/mL
- Peak serum fosphenytoin levels and phenytoin levels after a 1.2 g infusion (I.V.) in healthy subjects over 30 minutes were 129 mcg/mL and 17.2 mcg/mL, respectively

Overdosage/Treatment

- Supportive therapy:** Treatment is supportive for hypotension; treat with I.V. fluids and place patient in Trendelenburg position; seizures may be controlled with lorazepam or diazepam 5-10 mg (0.25-0.4 mg/kg in children); I.V. albumin (25 g every 6 hours has been used to increase bound fraction of drug)
- Enhancement of elimination:** Multiple dosing of activated charcoal may be effective; peritoneal dialysis, diuresis, hemodialysis, hemoperfusion, and plasmapheresis are of little value; 4 hours of continuous venovenous hemofiltration can enhance elimination

Diagnostic Procedures

- Phenytoin, Blood

Test Interactions ↑ glucose, alkaline phosphatase (S); ↓ thyroxine (S), calcium (S); serum sodium increases in overdose setting

Drug Interactions

- As phenytoin: **Substrate** of CYP2C9 (major), 2C19 (major), 3A4 (minor); **Induces** CYP2B6 (strong), 2C8 (strong), 2C9 (strong), 2C19 (strong), 3A4 (strong)
- Acetaminophen:** Phenytoin may enhance the hepatotoxic potential of acetaminophen overdoses
- Acetazolamide:** Concurrent use with phenytoin may result in an increased risk of osteomalacia
- Acyclovir:** May decrease phenytoin serum levels; limited documentation; monitor
- Allopurinol:** May increase phenytoin serum concentrations; monitor
- Antiarrhythmics:** Phenytoin may increase the metabolism of antiarrhythmics, decreasing their clinical effect; includes disopyramide, propafenone, and quinidine; amiodarone also may increase phenytoin concentrations (see CYP inhibitors)
- Anticonvulsants:** Phenytoin may increase the metabolism of anticonvulsants; includes barbiturates, carbamazepine, ethosuximide, felbamate, lamotrigine, tiagabine, topiramate, and zonisamide; does not appear to affect gabapentin or levetiracetam; felbamate and gabapentin may increase phenytoin levels; monitor
- Antineoplastics:** Several chemotherapeutic agents have been associated with a decrease in serum phenytoin levels; includes cisplatin, bleomycin, carmustine, methotrexate, and vinblastine; monitor phenytoin serum levels. Limited evidence also suggest that enzyme-inducing

anticonvulsant therapy may reduce the effectiveness of some chemotherapy regimens (specifically in ALL). Teniposide and methotrexate may be cleared more rapidly in these patients.

Antipsychotics: Phenytoin may enhance the metabolism (decrease the efficacy) of antipsychotics; monitor for altered response; dose adjustment may be needed; also see note on clozapine

Benzodiazepines: Phenytoin may decrease the serum concentrations of some benzodiazepines; monitor for decreased benzodiazepine effect

Beta-blockers: Metabolism of beta-blockers may be increased and clinical effect decreased; atenolol and nadolol are unlikely to interact given their renal elimination

Calcium channel blockers: Phenytoin may enhance the metabolism of calcium channel blockers, decreasing their clinical effect; calcium channel blockers (diltiazem, nifedipine) have been reported to increase phenytoin levels (case report); monitor

Capecitabine: May increase the serum concentrations of phenytoin; monitor

Chloramphenicol: Phenytoin may increase the metabolism of chloramphenicol and chloramphenicol may inhibit phenytoin metabolism; monitor for altered response

Cimetidine: May increase the serum concentrations of phenytoin; monitor.

Ciprofloxacin: Case reports indicate ciprofloxacin may increase or decrease serum phenytoin concentrations; monitor

Clozapine: May decrease phenytoin serum concentrations; monitor

CNS depressants: Sedative effects may be additive with other CNS depressants; monitor for increased effect; includes ethanol, barbiturates, sedatives, antidepressants, narcotic analgesics, and benzodiazepines

Corticosteroids: Phenytoin may increase the metabolism of corticosteroids, decreasing their clinical effect; also see dexamethasone

Cyclosporine and tacrolimus: Levels may be decreased by phenytoin; monitor

CYP2B6 substrates: Phenytoin may decrease the levels/effects of CYP2B6 substrates. Example substrates include bupropion, efavirenz, promethazine, selegiline, and sertraline.

CYP2C9 inducers: May decrease the levels/effects of phenytoin. Example inducers include carbamazepine, phenobarbital, rifampin, rifapentine, and secobarbital.

CYP2C9 Inhibitors: May increase the levels/effects of phenytoin. Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nicardipine, NSAIDs, sulfonamides and tolbutamide.

CYP2C8 Substrates: Phenytoin may decrease the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP2C9 Substrates: Phenytoin may decrease the levels/effects of CYP2C9 substrates. Example substrates include bosentan, celecoxib, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, sulfonamides, trimethoprim, warfarin, and zafirlukast.

CYP2C19 inducers: May decrease the levels/effects of phenytoin. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of phenytoin. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

CYP2C19 substrates: Phenytoin may decrease the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, proton pump inhibitors, sertraline, and voriconazole

CYP3A4 substrates: Phenytoin may decrease the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, clarithromycin, cyclosporine, erythromycin, estrogens, mirtazapine, nateglinide, nefazodone, nevirapine, protease inhibitors, tacrolimus, and venlafaxine

Dexamethasone: May decrease serum phenytoin due to increased metabolism; monitor

Digoxin: Effects and/or levels of digitalis glycosides may be decreased by phenytoin

Disulfiram: May increase serum phenytoin concentrations; monitor

Dopamine: Phenytoin (I.V.) may increase the effect of dopamine (enhanced hypotension)

Doxycycline: Phenytoin may enhance the metabolism of doxycycline, decreasing its clinical effect; higher dosages may be required

Estrogens: Phenytoin may increase the metabolism of estrogens, decreasing their clinical effect; monitor

Folic acid: Replacement of folic acid has been reported to increase the metabolism of phenytoin, decreasing its serum concentrations and/or increasing seizures

HMG-CoA reductase inhibitors: Phenytoin may increase the metabolism of these agents, reducing their clinical effect; monitor

Itraconazole: Phenytoin may decrease the effect of itraconazole

Levodopa: Phenytoin may inhibit the anti-Parkinson effect of levodopa

Lithium: Concurrent use of phenytoin and lithium has resulted in lithium intoxication

Methadone: Phenytoin may enhance the metabolism of methadone resulting in methadone withdrawal

Methylphenidate: May increase serum phenytoin concentrations; monitor

Metronidazole: May increase the serum concentrations of phenytoin; monitor.

Neuromuscular-blocking agents: Duration of effect may be decreased by phenytoin

Omeprazole: May increase serum phenytoin concentrations; monitor

Oral contraceptives: Phenytoin may enhance the metabolism of oral contraceptives, decreasing their clinical effect; an alternative method of contraception should be considered

Primidone: Phenytoin enhances the conversion of primidone to phenobarbital resulting in elevated phenobarbital serum concentrations

Quetiapine: Serum concentrations may be substantially reduced by phenytoin, potentially resulting in a loss of efficacy; limited documentation; monitor

SSRIs: May increase phenytoin serum concentrations; fluoxetine and fluvoxamine are known to inhibit metabolism via CYP enzymes; sertraline and paroxetine have also been shown to increase concentrations in some patients; monitor

Theophylline: Phenytoin may increase metabolism of theophylline derivatives and decrease their clinical effect; theophylline may also increase phenytoin concentrations

Thyroid hormones (including levothyroxine): Phenytoin may alter the metabolism of thyroid hormones, reducing its effect; there is limited documentation of this interaction, but monitoring should be considered

Ticlopidine: May increase serum phenytoin concentrations and/or toxicity; monitor

Tricyclic antidepressants: Phenytoin may increase metabolism of tricyclic antidepressants and decrease their clinical effect; sedative effects may be additive; tricyclics may also increase phenytoin concentrations

Topiramate: Phenytoin may decrease serum levels of topiramate; topiramate may increase the effect of phenytoin

Trazodone: Serum levels of phenytoin may be increased; limited documentation; monitor

Trimethoprim: May increase serum phenytoin concentrations; monitor

Valproic acid (and sulfisoxazole): May displace phenytoin from binding sites; valproic acid may increase, decrease, or have no effect on phenytoin serum concentrations

Vigabatrin: May reduce phenytoin serum concentrations; monitor

Warfarin: Phenytoin transiently increased the hypothermia response to warfarin initially; this is followed by an inhibition of the hypoprothrombinemic response

Pregnancy Risk Factor D

Pregnancy Implications Crosses placenta with fetal serum concentrations equal to those of mother; eye, cardiac, cleft palate, and skeletal malformations have been noted; fetal hydantoin syndrome associated with maternal ingestion of 100-800 mg/kg during 1st trimester

Lactation Excretion in breast milk unknown/not recommended

Additional Information Infusion of 71 mg/kg in an infant resulted in cardiac arrest.

Fosphenytoin 1.5 mg is approximately equivalent to 1 mg phenytoin; equimolar fosphenytoin dose is 375 mg (75 mg/mL solution) to phenytoin 250 mg (50 mg/mL)

Water solubility: 142 mg/mL at pH of 9

Compatible with all diluents and does not require propylene glycol or ethanol for solubility; no drug interaction noted with diazepam; since there is no precipitation problem with fosphenytoin, no I.V. filter is required; antiarrhythmic effects may be similar to phenytoin; parenteral product contains no propylene sterol; this should allow for rapid intravenous bolus dosing without cardiovascular complications; formaldehyde production is not expected to be clinically consequential (~200 mg) if used for 1 week

Furosemide

CAS Number 54-31-9

U.S. Brand Names Lasix®

Synonyms Frusemide

Use Management of edema associated with congestive heart failure and hepatic or renal disease; used alone or in combination with antihypertensives in treatment of hypertension

Mechanism of Action Inhibits reabsorption of sodium and chloride in the ascending loop of Henle and distal renal tubule, interfering with the chloride-binding cotransport system, thus causing increased excretion of water, sodium, chloride, magnesium, and calcium

Adverse Reactions

Cardiovascular: Sinus bradycardia, tachycardia (supraventricular), vasodilation, **orthostatic hypotension**

Central nervous system: **Dizziness**, headache, fever, gustatory hallucinations

Dermatologic: Urticaria, Stevens-Johnson syndrome, exfoliative dermatitis, photosensitivity, lichenoid eruptions, erythema multiforme, purpura, bullous pemphigoid, acute generalized exanthematous pustulosis, pruritus, erythema nodosum, exanthem, pseudoporphyria cutanea tarda, cutaneous vasculitis

Endocrine & metabolic: Hypokalemia, hypomagnesemia, hypercalcemia, hyponatremia, hypochloremia, alkalosis, hypocalcemia, hyperglycemia, dehydration, hyperuricemia

Gastrointestinal: Pancreatitis, nausea, oral solutions may cause diarrhea due to sorbitol content, sweet dysgeusia, xerostomia

Genitourinary: Nocturia, urinary incontinence

Hematologic: Leukopenia/neutropenia (agranulocytosis, granulocytopenia), anemia, thrombocytopenia, eosinophilia

Neuromuscular & skeletal: Myasthenia gravis (exacerbation or precipitation of), paresthesia

Ocular: Phototoxic, xanthopsia

Otic: Potential ototoxicity, deafness, tinnitus

Renal: Nephrocalcinosis, proteinuria, interstitial nephritis, hypercalciuria, diuresis, prerenal azotemia, renal vasculitis

Miscellaneous: Systemic lupus erythematosus (SLE)

Signs and Symptoms of Overdose Periarthritis nodosa, photophobia, vision color changes (yellow tinge)

Pharmacodynamics/Kinetics

Onset of action: Diuresis: Oral: 30-60 minutes; I.M.: 30 minutes; I.V.: ~5 minutes

Peak effect: Oral: 1-2 hours

Duration: Oral: 6-8 hours; I.V.: 2 hours

Absorption: Oral: 60% to 67%

Protein binding: >98%

Metabolism: Minimally hepatic

Half-life elimination: Normal renal function: 0.5-1.1 hours; End-stage renal disease: 9 hours

Excretion: Urine (Oral: 50%, I.V.: 80%) within 24 hours; feces (as unchanged drug); nonrenal clearance prolonged in renal impairment

Dosage

Infants and Children:

Oral: 1-2 mg/kg/dose increased in increments of 1 mg/kg/dose with each succeeding dose until a satisfactory effect is achieved to a maximum of 6 mg/kg/dose no more frequently than 6 hours.

I.M., I.V.: 1 mg/kg/dose, increasing by each succeeding dose at 1 mg/kg/dose at intervals of 6-12 hours until a satisfactory response up to 6 mg/kg/dose.

Adults:

Oral: 20-80 mg/dose initially increased in increments of 20-40 mg/dose at intervals of 6-8 hours; usual maintenance dose interval is twice daily or every day; may be titrated up to 600 mg/day with severe edematous states.

Hypertension (JNC 7): 20-80 mg/day in 2 divided doses

I.M., I.V.: 20-40 mg/dose, may be repeated in 1-2 hours as needed and increased by 20 mg/dose until the desired effect has been obtained.

Usual dosing interval: 6-12 hours; for acute pulmonary edema, the usual dose is 40 mg I.V. over 1-2 minutes. If not adequate, may increase dose to 80 mg.

Continuous I.V. infusion: Initial I.V. bolus dose of 0.1 mg/kg followed by continuous I.V. infusion doses of 0.1 mg/kg/hour doubled every 2 hours to a maximum of 0.4 mg/kg/hour if urine output is <1 mL/kg/hour have been found to be effective and result in a lower daily requirement of furosemide than with intermittent dosing. Other studies have used a rate of ≤4 mg/minute as a continuous I.V. infusion.

Elderly: Oral, I.M., I.V.: Initial: 20 mg/day; increase slowly to desired response.

Refractory heart failure: Oral, I.V.: Doses up to 8 g/day have been used.

Dosing adjustment/comments in renal impairment: Acute renal failure: High doses (up to 1-3 g/day - oral/I.V.) have been used to initiate desired response; avoid use in oliguric states.

Dialysis: Not removed by hemo- or peritoneal dialysis; supplemental dose is not necessary.

Dosing adjustment/comments in hepatic disease: Diminished natriuretic effect with increased sensitivity to hypokalemia and volume depletion in cirrhosis; monitor effects, particularly with high doses.

Monitoring Parameters Monitor weight and I & O daily; blood pressure, serum electrolytes, renal function; in high doses, monitor hearing

Administration Replace parenteral therapy with oral therapy as soon as possible. I.V. injections should be given slowly may be administered undiluted direct I.V. at a maximum rate of 0.5 mg/kg/minute for doses <120 mg and 4 mg/minute for doses >120 mg; maximum rate of administration for IVPB or infusion: 4 mg/minute. For continuous infusion furosemide in patients with severely-impaired renal function, do not exceed 4 mg/minute.

Contraindications Hypersensitivity to furosemide, any component, or sulfonyleureas; anuria; patients with hepatic coma or in states of severe electrolyte depletion until the condition improves or is corrected

Warnings

Adjust dose to avoid dehydration. In cirrhosis, avoid electrolyte and acid/base imbalances that might lead to hepatic encephalopathy. Ototoxicity is associated with rapid I.V. administration, renal impairment, excessive doses, and concurrent use of other ototoxins. Hypersensitivity reactions can rarely occur. Monitor fluid status and renal function in an attempt to prevent oliguria, azotemia, and reversible increases in BUN and creatinine. Close medical supervision of aggressive diuresis required. Monitor closely for electrolyte imbalances particularly hypokalemia. Watch for and correct electrolyte disturbances. Coadministration of antihypertensives may increase the risk of hypotension. Avoid use of medications in which the toxicity is enhanced by hypokalemia (including quinolones with QT prolongation).

Chemical similarities are present among sulfonamides, sulfonyleureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonyleurea allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

Dosage Forms

Injection, solution: 10 mg/mL (2 mL, 4 mL, 8 mL, 10 mL)

Solution, oral: 10 mg/mL (60 mL, 120 mL) [orange flavor]; 40 mg/5 mL (5 mL, 500 mL) [pineapple-peach flavor]

Tablet (Lasix®): 20 mg, 40 mg, 80 mg

Reference Range

Therapeutic: 1-2 mcg/mL (SI: 3-6 μmol/L)

Toxic: >50 mcg/mL may be associated with toxicity

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: I.V. hydration with 0.9% saline and electrolyte replacement

Test Interactions ↑ ammonia (B), amylase (S), glucose, uric acid (S); ↓ calcium (S), chloride (S), magnesium, sodium (S). I.V. furosemide (>80 mg/day) causes a falsely increased free thyroxine level

Drug Interactions ACE inhibitors: Hypotensive effects and/or renal effects are potentiated by hypovolemia.

Antidiabetic agents: Glucose tolerance may be decreased.

Antihypertensive agents: Hypotensive effects may be enhanced.

Cephaloridine or cephalexin: Nephrotoxicity may occur.

Cholestyramine or colestipol may reduce bioavailability of furosemide.

Digoxin: Furosemide-induced hypokalemia may predispose to digoxin toxicity. Monitor potassium.

Fibric acid derivatives: Blood levels of furosemide and fibric acid derivatives (ie, clofibrate and fenofibrate) may be increased during concurrent dosing (particularly in hypoalbuminemia). Limited documentation; monitor for increased effect/toxicity.

Indomethacin (and other NSAIDs) may reduce natriuretic and hypotensive effects of furosemide.

Lithium: Renal clearance may be reduced. Isolated reports of lithium toxicity have occurred; monitor lithium levels.

Metformin may decrease furosemide concentrations.

Metformin blood levels may be increased by furosemide.

NSAIDs: Risk of renal impairment may increase when used in conjunction with furosemide.

Ototoxic drugs (aminoglycosides, cis-platinum): Concomitant use of furosemide may increase risk of ototoxicity, especially in patients with renal dysfunction.

Peripheral adrenergic-blocking drugs or ganglionic blockers: Effects may be increased.

Phenobarbital or phenytoin may reduce diuretic response to furosemide.

Salicylates (high-dose) with furosemide may predispose patients to salicylate toxicity due to reduced renal excretion or alter renal function.

Succinylcholine: Action may be potentiated by furosemide.

Sucralfate may limit absorption of furosemide, effects may be significantly decreased; separate oral administration by 2 hours.

Thiazides: Synergistic diuretic effects occur.

Tubocurarine: The skeletal muscle-relaxing effect may be attenuated by furosemide.

Pregnancy Risk Factor C

Pregnancy Implications Neonatal hyponatremia/hyperuricemia can occur; possible increase in incidence of patent ductus arteriosus

Lactation Enters breast milk/use caution

Additional Information Increased diuretic response in patients with cystic fibrosis; can cause elevation of parathyroid hormone; 40 mg furosemide is equivalent to 1 mg of bumetanide, 12 mg of piretanide, and 10-20 mg of torsemide; sodium content of 1 mL (injection): 0.162 mEq. Incidence of cochleotoxicity is 0% to 6%; aminoglycosides are ototoxic synergistic.

Gabapentin**CAS Number** 60142-96-3**U.S. Brand Names** Neurontin®**Use** Partial or secondary generalized seizures; possibly useful for pain relief due to reflex sympathetic dystrophy. Used to treat adverse effects of ciguatera fish exposure and palmitaxel toxicity.**Unlabeled/Investigational Use** Social phobia; chronic pain**Mechanism of Action** Structural analog to gamma amino butyric acid (GABA). Binds to gabapentin receptors in hippocampus. No effect on GABA system.**Adverse Reactions**

Cardiovascular: Vasodilation

Central nervous system: **Dizziness, somnolence, fatigue, ataxia, drowsiness, psychosis, slurred speech, stuttering, polyneuropathy, aggressive behavior**

Dermatologic: Eczema, Stevens-Johnson syndrome, alopecia

Endocrine & metabolic: Sexual dysfunction

Gastrointestinal: Nausea, vomiting, xerostomia, weight gain (average of 6.9 kg)

Genitourinary: Impotence, anorgasmia

Neuromuscular & skeletal: Tremors, choreoathetosis, asterixis

Ocular: Nystagmus, reversible visual field constriction

Respiratory: Cough, rhinitis

Pharmacodynamics/Kinetics**Absorption:** 50% to 60% from proximal small bowel by L-amino transport system**Distribution:** V_d : 0.6-0.8 L/kg**Protein binding:** <3%**Bioavailability:** Inversely proportional to dose due to saturable absorption:

900 mg/day: 60%

1200 mg/day: 47%

2400 mg/day: 34%

3600 mg/day: 33%

4800 mg/day: 27%

Half-life elimination: 5-7 hours; anuria 132 hours; during dialysis 3.8 hours**Excretion:** Proportional to renal function; urine (as unchanged drug)**Dosage**

If gabapentin is discontinued or if another anticonvulsant is added to therapy, it should be done slowly over a minimum of 1 week

Children > 12 years and Adults: Oral:

Initial: 300 mg on day 1 (at bedtime to minimize sedation), then 300 mg twice daily on day 2, and then 300 mg 3 times/day on day 3

Total daily dosage range: 900-1800 mg/day administered in 3 divided doses at 8-hour intervals

Pain: 300-1800 mg/day given in 3 divided doses has been the most common dosage range

Dosing adjustment in renal impairment: $Cl_{cr} > 60$ mL/minute: Administer 1200 mg/day Cl_{cr} 30-60 mL/minute: Administer 600 mg/day Cl_{cr} 15-30 mL/minute: Administer 300 mg/day $Cl_{cr} < 15$ mL/minute: Administer 150 mg/day

Hemodialysis: 200-300 mg after each 4-hour dialysis following a loading dose of 300-400 mg

Monitoring Parameters Monitor serum levels of concomitant anticonvulsant therapy**Administration** Administer first dose on first day at bedtime to avoid somnolence and dizziness. Dosage must be adjusted for renal function; when given 3 times daily, the maximum time between doses should not exceed 12 hours.**Contraindications** Hypersensitivity to gabapentin or any component of the formulation**Warnings** Avoid abrupt withdrawal, may precipitate seizures; use cautiously in patients with severe renal dysfunction; male rat studies demonstrated an association with pancreatic adenocarcinoma (clinical

implication unknown). May cause CNS depression, which may impair physical or mental abilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Effects with other sedative drugs or ethanol may be potentiated. Pediatric patients (3-12 years of age) have shown increased incidence of CNS-related adverse effects, including emotional lability, hostility, thought disorder, and hyperkinesia. Safety and efficacy in children <3 years of age have not been established.

Dosage Forms

Capsule (Neurontin®): 100 mg, 300 mg, 400 mg

Solution, oral (Neurontin®): 250 mg/5 mL (480 mL) [cool strawberry anise flavor]

Tablet: 100 mg, 300 mg, 400 mg

Neurontin®: 600 mg, 800 mg

Reference Range Peak plasma level: 2 mcg/mL 1.5-3 hours after a 200 mg dose; serum gabapentin concentration of 104.5 u/mL associated with coma, respiratory depression requiring mechanical ventilation, and hypotension.**Overdosage/Treatment**

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: In one case report flumazenil has reversed gabapentin-induced coma

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; hemodialysis will be useful; see Usual Dosage

Drug Interactions CNS depressants: Sedative effects may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents. Monitor for increased effect.**Pregnancy Risk Factor** C**Pregnancy Implications** No teratogenicity**Lactation** Enters breast milk/use caution**Additional Information** Not effective for absence seizures; benign pancreatic tumors noted in rodents administered high doses, ingestion of 48.9 g resulted in minimal symptoms; gabapentin levels 5 times over therapeutic limit result in minimal clinical effects; proposed use for amyotrophic lateral sclerosis**Specific References**

Gallium Nitrate**CAS Number** 13494-90-1; 135886-70-3**U.S. Brand Names** Ganite™**Synonyms** NSC-15200**Use** Treatment of hypercalcemia**Mechanism of Action** Gallium is a naturally occurring group IIIa heavy metal. It is the second metal, in addition to salts of platinum (group VIII metal), which has demonstrated significant clinical antitumor activity. The mechanism of hypocalcemia induced by gallium is primarily via inhibition of bone resorption with associated reduction in urinary calcium excretion. Gallium has increased the calcium content of newly mineralized bone following short-term treatment *in vitro*, and this effect combined with its ability to inhibit bone resorption has suggested the use of gallium for other disorders associated with increased bone loss. Gallium has produced significant decreases in urinary excretion of calcium and hydroxyproline in

patients with solitary or multiple lytic bone metastases, and may be useful for preventing pathologic conditions in these patients.

Adverse Reactions

Not all frequencies defined.

Cardiovascular: Hypotension, tachycardia, edema of lower extremities
Central nervous system: Lethargy, confusion, dreams, hallucinations, hypothermia, fever

Dermatologic: Rash

Endocrine & metabolic: **Hypophosphatemia** (>50%, usually asymptomatic); hypocalcemia; mild respiratory alkalosis with hyperchloremia
Gastrointestinal: **Nausea** (14%, generally mild), vomiting, diarrhea, constipation

Hematologic: Anemia, leukopenia

Neuromuscular & skeletal: Paresthesia

Renal: **Nephrotoxicity** (>10%, generally reversible and reported to be minimized with adequate hydration and urine output)

Respiratory: Dyspnea, rales, rhonchi, pleural effusion, pulmonary infiltrates. **Note:** Toxicities reported with doses higher than those used to treat hypercalcemia (ie, in trials evaluating anticancer effect): Optic neuritis, tinnitus, hearing acuity decreased, metallic taste, hypomagnesemia, encephalopathy

Pharmacodynamics/Kinetics

Onset of calcium lowering: Seen within 24-48 hours of beginning therapy, with normocalcemia achieved within 4-7 days of beginning therapy

Bioavailability: Oral: 5%

Distribution: Tissue concentrations were determined postmortem in one patient and concentrations were higher in liver and kidney than in lung, skin, muscle, heart, and cervix tumor; in dogs, tissue gallium concentrations were higher in renal cortex, bone, bone marrow, small intestine, and liver than in skeletal muscle and brain

Half-life elimination: Alpha: 1.25 hours; Beta: ~24 hours

Elimination half-life varies with method of administration (72-115 hours with prolonged intravenous infusion versus 24 hours with bolus administration); long elimination half-life may be related to slow release from tissue such as bone

Excretion: Primarily renal with no prior metabolism in the liver or kidney

Dosage

I.V.: Adults: 200 mg/m²/day for 5 days; duration may be shortened during a course if normocalcemia is achieved. If hypercalcemia is mild and with very few symptoms, 100 mg/m²/day may be used.

Dosage adjustment in renal impairment:

Serum creatinine >2.5 mg/dL: Contraindicated

Serum creatinine 2 to <2.5 mg/dL: No guidelines exist; frequent monitoring is recommended

Monitoring Parameters Renal function, serum calcium (daily), serum phosphorus (twice weekly)

Administration

I.V. infusion over 30 minutes to 24 hours

Contraindications Hypersensitivity to gallium nitrate or any component of the formulation; severe renal dysfunction (creatinine >2.5 mg/dL)

Warnings Hazardous agent - use appropriate precautions for handling and disposal. [**U.S. Boxed Warning:** Use caution with renal impairment or when administering other nephrotoxic drugs (eg, aminoglycosides, amphotericin B); consider discontinuing gallium nitrate during treatment with nephrotoxic drugs. Maintain adequate hydration. Safety and efficacy in pediatric patients have not been established.

Dosage Forms Injection, solution [preservative free]: 25 mg/mL (20 mL)

Reference Range Steady-state gallium serum levels: Generally obtained within 2 days following initiation of continuous I.V. infusions of gallium nitrate

Overdosage/Treatment Supportive therapy: Give calcium chloride for hypocalcemia

Drug Interactions

Cyclophosphamide: Concurrent use of low dose gallium nitrate has been associated with dyspnea, stomatitis, asthenia, and rarely interstitial pneumonitis.

Nephrotoxic drugs (eg, aminoglycosides, amphotericin B): Concurrent use with gallium nitrate may increase nephrotoxic effects.

Pregnancy Risk Factor C

Pregnancy Implications Reproduction studies have not been conducted

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Patients should have adequate I.V. hydration, serum creatinine levels should be monitored during gallium nitrate therapy

Additional Information Has shown to be more effective in lowering serum calcium levels in patients with cancer-related hypercalcemia than calcitonin; due to the potential for drug-induced renal dysfunction, patients receiving gallium nitrate should be adequately hydrated to minimize risk

Gallopamil

Related Information

- Calcium Channel Blockers

CAS Number 16662-47-8

Use Angina, hypertension

Mechanism of Action Second generation calcium antagonist with actions very similar to verapamil, but ~8 times as potent

Adverse Reactions

Cardiovascular: Bradycardia, palpitations, edema, flushing, sinus bradycardia, angina, chest pain

Central nervous system: Headache, drowsiness, dizziness

Gastrointestinal: Constipation

Hepatic: Cholestatic jaundice

Signs and Symptoms of Overdose Atrioventricular dissociations

Pharmacodynamics/Kinetics

Peak serum level: 1-2 hours; sustained release: 4 hours

Distribution: ~2 L/kg

Metabolism: Hepatic

Protein binding: 93%

Half-life: 4-8 hours; cirrhotic patients: 5-20 hours

Bioavailability: 25%

Dosage

Angina:

Oral: 50-75 mg 3 times/day

I.V. bolus: 0.03 mg/kg

I.V. infusion: 0.02 mg/kg/hour; can titrate up to 0.03 mg/kg/hour after 2 days

Hypertension: Oral: 50 mg 2-3 times/day; reduce dose by 50% to 75% in liver disease

Paroxysmal supraventricular tachycardia: I.V.: 0.03-0.05 mg/kg bolus

Contraindications Hypersensitivity to gallopamil, second/third degree atrioventricular block, Wolff-Parkinson-White syndrome, hypotension, cardiogenic shock

Warnings Use with caution in patients hypersensitive to verapamil, patients with bradycardia, heart failure, aortic stenosis, liver disease, patients taking calcium supplements or beta-blocking agents

Reference Range Mean serum level 2 hours after a 50 mg dose: ~40 ng/mL

Overdosage/Treatment

Decontamination: Ipecac-induced emesis can hypothetically worsen calcium antagonist toxicity, since it can produce vagal stimulation. The potential for seizures precipitously following acute ingestion of large doses of a calcium antagonist may also contraindicate the use of ipecac. Lavage (within 1 hour)/activated charcoal; whole bowel irrigation may be effective for sustained release preparations

Supportive therapy: Supportive and symptomatic treatment, including I.V. fluids and Trendelenburg positioning, should be initiated as intoxication may cause hypotension. Although calcium (calcium chloride I.V. 1-3 g in adults or 10-30 mg in children over 5-10 minutes with repeats as needed) has been used as an "antidote" for acute intoxications, although inamrinone or dopamine may be needed for hypotension and are first line agents for treatment of shock. Heart block may respond to isoproterenol, glucagon, atropine and/or calcium, although a temporary pacemaker may be required; sodium bicarbonate should be given for acidosis. Glucagon may increase myocardial contractility. In an animal model, the therapy of hyperinsulinemia with euglycemia allowed for larger increases in myocardial contractility than calcium chloride, epinephrine, and glucagon.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; not dialyzable (0% to 5%)

Drug Interactions Enhances hypotensive effects of monoxidine; can increase anti-ischemic effect of isosorbide mononitrate

Galsulfase

Pronunciation (gal SUL fase)

U.S. Brand Names Naglazyme™

Synonyms Recombinant N-Acetylglucosaminase 4-Sulfatase; rhASB

Use Replacement therapy in mucopolysaccharidosis VI (MPS VI; Maroteaux-Lamy syndrome) for improvement of walking and stair-climbing capacity

Mechanism of Action Galsulfase is a recombinant form of N-acetylglucosaminase 4-sulfatase, produced in Chinese hamster cells. A deficiency of this enzyme leads to accumulation of the glycosaminoglycan dermatan sulfate in various tissues, causing progressive disease which includes decreased growth, skeletal deformities, upper airway obstruction, clouding of the cornea, heart disease, and coarse facial features. Replacement of this enzyme has been shown to improve mobility and physical function (measured by walking and stair-climbing).

Adverse Reactions

Note: Percentages reported are from a placebo-controlled study (39 patients, 19 on galsulfase); also included are adverse effects noted during other clinical studies.

Cardiovascular: Chest pain (16%), facial edema (11%), hypertension (11%)
 Central nervous system: Pain (26%), malaise (11%), fever, headache
 Gastrointestinal: Abdominal pain (53%), gastroenteritis (11%), diarrhea, vomiting

Neuromuscular & skeletal: Rigors (21%), areflexia (11%), arthralgia
 Ocular: Conjunctivitis (21%), corneal opacification increased (11%)

Otic: ear pain (42%), otitis media

Respiratory: dyspnea (21%), pharyngitis (16%), nasal congestion (11%), cough, upper respiratory tract infections

Miscellaneous: Antigalsulfase antibodies (98%), umbilical hernia (11%)

Infusion-related reactions: angioedema, apnea, bronchospasm, chills, facial and neck urticaria, hypotension, rash, respiratory distress

Pharmacodynamics/Kinetics Half-life elimination: Week 1: Median 9 hours (range: 6-21 hours); Week 24: Median 26 hours (range: 8-40 hours)

Dosage MPS VI: Children >5 years: I.V.: 1 mg/kg once weekly

Stability

Prior to use, store vials under refrigeration at 2°C to 8°C (36°F to 46°F). Do not freeze or shake. Allow vials to reach room temperature prior to dilution. Do not keep at room temperature >24 hours. Do not heat or microwave vials.

After calculating dose, round to the nearest whole vial to prepare infusion (do not use partial vials). Dilute in NS to a final volume of 250 mL (including volume of galsulfase). Slowly add galsulfase to infusion bag (compatibility in glass containers has not been studied). Gently rotate to distribute. Do not shake or agitate, do not use filter needle. In patients <20 kg or in those who are susceptible to volume overload, dose may be diluted into 100 mL NS.

Following dilution, use immediately. May store under refrigeration if used within 48 hours from the time of preparation to the completion of infusion. Do not store solution for infusion at room temperature.

Monitoring Parameters In clinical studies, tests of mobility and physical function were monitored at baseline and every 6 weeks.

Administration Administer using infusion pump and PVC infusion set with in-line low protein binding 0.2 micrometer filter. Pretreatment with antihistamines with or without antipyretics is recommended 30-60 minutes prior to infusion. Infuse a 250 mL solution at 6 mL/hour for the first hour. If well-tolerated, increase to 80 mL/hour for the remaining 3 hours. Doses prepared in 100 mL should also be infused over at least 4 hours. In case of infusion-related reactions, decrease infusion rate or temporarily discontinue. Infusion time can be extended up to 20 hours if infusion reactions occur. Discontinue immediately if severe reaction occurs. Patients requiring supplemental oxygen or CPAP during sleep should have these treatments readily available in case of infusion-related or antihistamine-induced reaction.

Contraindications None known

Warnings Patients should be premedicated with antihistamines and/or antipyretics prior to infusion. Infusion-related reactions have been reported as late as week 55 of treatment. Evaluate airway prior to therapy (due to possible effects of antihistamine use). Consider delaying treatment in patients with an acute febrile or respiratory illness. Excess agitation of solution prior to or after dilution may denature galsulfase rendering it inactive. Studies did not include patients <5 years of age or >29 years.

Dosage Forms Injection, solution [preservative free]: 5 mg/5 mL (5 mL)

Overdosage/Treatment Supportive therapy: Treat symptomatically; Bronchospasm can be treated with beta-adrenergic agents

Pregnancy Risk Factor B

Pregnancy Implications Fetal harm was not reported in animal studies.

There are no studies in pregnant women. Pregnant women are encouraged to enroll in the Clinical Surveillance Program.

Lactation Excretion in breast milk unknown/use caution

Additional Information A Clinical Surveillance Program has been created to monitor therapeutic response, progression of disease, and adverse effects during long-term treatment; patients should be encouraged to register (866-906-6100).

Gamma Hydroxybutyric Acid

Related Information

- Highlights of Recent Reports (2006) on Substance Abuse and Mental Health

CAS Number 502-85-2

U.S. Brand Names Xyrem® (Schedule 111 drug)

Synonyms 4-Hydroxybutyrate; Gamma Hydroxybutyric Acid; GHB; Sodium 4-Hydroxybutyrate

Impairment Potential Yes. Ingestion of >100 mg/kg, urinary gamma-hydroxybutyrate level >2000 mg/L, or blood GHB level >26 mg/L is consistent with driving impairment. (Stephens BG and Baselt RC, "Driving Under the Influence of GHB?" *J Anal Toxicol*, 1994, 18(6): 357-8.) (Couper FJ and Logan BK, "Driving Under the Influence of GHB," *J Anal Toxicol*, 2001, 25:365.)

Use Treatment of cataplexy and daytime sleepiness in patients with narcolepsy

Unlabeled/Investigational Use Narcolepsy; anesthetic agent

Mechanism of Action Central nervous system depressant which has anesthetic action; possible role as a neurotransmitter particularly in the substantia nigra influencing dopamine release

Adverse Reactions

Cardiovascular: Bradycardia, hypertension, hypotension, atrial fibrillation, nonsustained ventricular tachycardia, QT prolongation

Central nervous system: Confusion, seizures, coma (1-2 hours duration), dizziness, relaxation, euphoria, amnesia, hypotonia (dose related), ataxia, extrapyramidal reaction

Gastrointestinal: Fecal incontinence, excessive salivation

Genitourinary: Urinary incontinence

Hematologic: Porphyria

Neuromuscular & skeletal: Tremors

Ocular: Nystagmus

Respiratory: Apnea, respiratory depression

Signs and Symptoms of Overdose (usually over 20 mg/kg): Coma, somnolence, dizziness, hypotonia, apnea, spontaneous emesis, seizures.

Pharmacodynamics/Kinetics

Onset: IV: 2-15 min

Oral: 15-30 min

Absorption: Rapid

Distribution: 190-384 mL/kg

Protein binding: <1%

Metabolism: Primarily via the Krebs cycle to form water and carbon dioxide; secondarily via beta oxidation; significant first-pass effect; no active metabolites; metabolic pathways are saturable

Bioavailability: 25%

Half-life elimination: 30-60 minutes

Time to peak: 30-75 minutes

Excretion: Primarily pulmonary (as carbon dioxide); urine (<5% unchanged drug)

Dosage

Analgesia/amnesia and hypotonia: 10-20 mg

General anesthesia coma, bradycardia: 50 mg/kg

Intoxicating dose: 15 mg/kg

Monitoring Parameters Respiratory status, ECG

Administration Take on an empty stomach; separate last meal (or food) and first dose by several hours; try to take at similar time each day. Doses should be administered while patient is sitting up in bed. Both doses should be prepared prior to bedtime. The first dose is taken at bedtime and the second dose is taken 2.5-4 hours later; an alarm clock may need to be set for the second dose. After taking the dose, patient is to lie down and remain in bed.

Contraindications Hypersensitivity to sodium oxybate or any component of the formulation; ethanol and other CNS depressants; semialdehyde dehydrogenase deficiency

Warnings

[U.S. Boxed Warning]: Sodium oxybate is a CNS depressant with abuse potential; it should not be used with ethanol or other CNS depressants. Seizures, respiratory depression, decreases in level of consciousness, coma, and death have been reported when used for nonprescription purposes. Due to the rapid onset of CNS depressant effects, doses should be administered only at bedtime and while the patient is sitting up in bed. May impair respiratory drive; use caution with compromised respiratory function. Most patients (~80%) in clinical trials were also treated with stimulants; therefore, an independent assessment of the effects of sodium oxybate is lacking. May cause confusion, psychosis, paranoia, hallucinations, agitation, and depression; use caution with history of depression or suicide attempt. May cause sleepwalking, urinary, and/or fecal incontinence. Use caution with hepatic dysfunction. Contains significant amounts of sodium; use caution with heart failure, hypertension, or compromised renal function.

Patients should be instructed not to engage in hazardous activities requiring mental alertness for at least 6 hours after taking this medication and that CNS effects may carryover to the next day. Tolerance to sodium oxybate, or withdrawal following its discontinuation, have not been clearly defined in controlled clinical trials, but have been reported at larger doses used for illicit purposes. Safety and efficacy have not been established in patients <16 years of age.

[U.S. Boxed Warning]: Sodium oxybate oral solution will be available only to prescribers enrolled in the Xyrem® Patient Success Program® and dispensed to the patient through the designated centralized pharmacy (1-866-997-3688).

Dosage Forms Solution, oral: 500 mg/mL (180 mL) [supplied in a kit containing two dosing cups and measuring device]

Reference Range 4-butyrolactone plasma levels >2.5 mM/L are associated with coma; oral doses (in mg/kg) approximate plasma levels (in mcg/mL); following an oral dose of 100 mg, peak urinary GHB concentrations are approximately 1100 mg/L; urinary levels are undetectable in 12 hours. Postmortem gamma-hydroxybutyric acid levels following a gamma-butyrolactone (GBL) overdose were reported as: Heart blood: 583 mg/L; vitreous: 652 mg/L; and urine: 2927 mg/L. Postmortem urine and blood levels of a 1,4-butanediol overdose fatality were 146 mcg/mL and 7.6 mcg/mL, respectively. Corresponding urine

and blood GHB levels were 6171 mcg/mL and 280 mcg/mL. Urinary GHB level >5 mg/L is reflective of GHB ingestion.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** induce emesis

Supportive therapy: Atropine can be utilized for bradycardia; naloxone or flumazenil has been effective in reversing the effect in animals, however, human experience is disappointing; pentobarbital (2.5-5 mg/kg I.V. infused over 30 minutes) can be used to treat GHB withdrawal. Supportive therapy (with possible mechanical ventilation) is the mainstay of therapy. Symptoms usually resolve in ~8 hours. Physostigmine (0.5-2 mg I.V.) has been used successfully to reverse coma.

Enhancement of elimination: Multiple dosing of charcoal may be effective

Antidote(s)

- Physostigmine [ANTIDOTE]

Test Interactions

Increases growth hormone and prolactin levels as little as a 3 g dose; sodium salt can cause hypernatremia; hypokalemia has also been reported

Drug Interactions

CNS depressants: CNS depressant effects are potentiated; concomitant use with sodium oxybate is contraindicated.

Pregnancy Risk Factor

B

Pregnancy Implications

Has been used as an obstetric anesthetic agent; while GHB crosses the placenta, no fetal effects are known; can increase uterine contractions

Lactation

Excretion in breast milk unknown/use caution

Additional Information

Lethal dose: ~4 g; Minimal lethal dose of 1,4-butanediol: Oral: 5.4 g

Recalled by the FDA in November 1990; found in certain ripe fruits such as guava; can be synthesized by titrating gamma butyryl lactone with sodium hydroxide to a pH of 6-7; withdrawal symptoms (insomnia, anxiety, tremors) may last 3-12 days; more commonly sold as a liquid form in its sodium salt form dissolved in ethanol or water. GHB can increase plasma growth hormone levels up to 40 ng/mL.

Osmolality gap determination formula: (GHB) mg/L divided by MW of GHB = (104) = calculated osmolality in mOsm/L.

Sources for GHB analysis include: Kathleen Andrews, DEA Western Laboratory, 390 Main Street, Room #700, San Francisco, CA 94105, (415) 744-7051 ext 33; Adrian Krawczeniuk, DEA Northeast Laboratory, 99 Tenth Avenue, Suite 721, New York, NY 10011, (212) 620-3684; Peter K Poole, DEA North Central Laboratory, 536 South Clark Street, Room 8, Chicago IL 60605, (312) 353-3640 ext 1601

GHB cases can be reported to the DEA through: Office of Diversion Control, Drug and Chemical Evaluation Section, Drug Enforcement Administration, Washington, DC 20537, (202) 307-7183.

GHB tolerance can occur with ingestion over 20 grams per day for over 1.5 years. Signs of withdrawal include disorientation, tremors, hallucinations, tachycardia, hypertension and nystagmus. Seizures and fever do not occur. Benzodiazepines are the mainstay of therapy.

Ganciclovir

CAS Number 107910-75-8; 82410-32-0

U.S. Brand Names Cytovene®; Vitrasert®

Synonyms DHPG Sodium; GCV Sodium; Nordeoxyguanosine

Use

Parenteral: Treatment of CMV retinitis in immunocompromised individuals, including patients with acquired immunodeficiency syndrome; prophylaxis of CMV infection in transplant patients

Oral: Alternative to the I.V. formulation for maintenance treatment of CMV retinitis in immunocompromised patients, including patients with AIDS, in whom retinitis is stable following appropriate induction therapy and for whom the risk of more rapid progression is balanced by the benefit associated with avoiding daily I.V. infusions.

Implant: Treatment of CMV retinitis

Unlabeled/Investigational Use May be given in combination with foscarnet in patients who relapse after monotherapy with either drug;

Mechanism of Action Ganciclovir is phosphorylated to a substrate which competitively inhibits the binding of deoxyguanosine triphosphate to DNA polymerase resulting in inhibition of viral DNA synthesis

Adverse Reactions

Cardiovascular: Edema, cardiac arrhythmias, hypertension, tachycardia (ventricular), sinus tachycardia, arrhythmias (ventricular), vasodilation

Central nervous system: **Headache**, seizures, confusion, nervousness, dizziness, psychosis, hallucinations, coma, fever, encephalopathy, malaise, amnesia, mania, hyperthermia

Dermatologic: Rash, alopecia, purpura, pruritus, exanthem, vitiligo

Endocrine & metabolic: Hypoglycemia, hypercalcemia

Gastrointestinal: Nausea, vomiting, diarrhea, anorexia

Hematologic: **Reversible neutropenia, granulocytopenia, thrombocytopenia**, leukopenia, anemia, eosinophilia

Hepatic: Elevated liver function tests

Local: Phlebitis

Neuromuscular & skeletal: Myalgia, trismus, paresthesia

Ocular: Retinal detachment

Renal: Hematuria, elevated BUN/serum creatinine

Respiratory: Dyspnea

Signs and Symptoms of Overdose Bone marrow depression, hematuria, hypoglycemia, leukopenia or neutropenia (agranulocytosis, granulocytopenia), myalgia, and tachycardia (ventricular)

Pharmacodynamics/Kinetics

Distribution: V_d : 15.26 L/1.73 m²; widely to all tissues including CSF and ocular tissue

Protein binding: 1% to 2%

Bioavailability: Oral: Fasting: 5%; Following food: 6% to 9%; Following fatty meal: 28% to 31%

Half-life elimination: 1.7-5.8 hours; prolonged with renal impairment; End-stage renal disease: 5-28 hours

Excretion: Urine (80% to 99% as unchanged drug)

Dosage CMV retinitis: Slow I.V. infusion (dosing is based on total body weight):

Children >3 months and Adults:

Induction therapy: 5 mg/kg/dose every 12 hours for 14-21 days followed by maintenance therapy

Maintenance therapy: 5 mg/kg/day as a single daily dose for 7 days/week or 6 mg/kg/day for 5 days/week

CMV retinitis: Oral: 1000 mg 3 times/day with food or 500 mg 6 times/day with food

Prevention of CMV disease in patients with advanced HIV infection and normal renal function: Oral: 1000 mg 3 times/day with food

Prevention of CMV disease in transplant patients: Same initial and maintenance dose as CMV retinitis except duration of initial course is 7-14 days, duration of maintenance therapy is dependent on clinical condition and degree of immunosuppression

Intravitreal implant: One implant for 5- to 8-month period; following depletion of ganciclovir, as evidenced by progression of retinitis, implant may be removed and replaced

Elderly: Refer to adult dosing; in general, dose selection should be cautious, reflecting greater frequency of organ impairment

Dosing adjustment in renal impairment:

I.V. (Induction):

Cl_{cr} 50-69 mL/minute: Administer 2.5 mg/kg/dose every 12 hours

Cl_{cr} 25-49 mL/minute: Administer 2.5 mg/kg/dose every 24 hours

Cl_{cr} 10-24 mL/minute: Administer 1.25 mg/kg/dose every 24 hours

Cl_{cr} <10 mL/minute: Administer 1.25 mg/kg/dose 3 times/week following hemodialysis

I.V. (Maintenance):

Cl_{cr} 50-69 mL/minute: Administer 2.5 mg/kg/dose every 24 hours

Cl_{cr} 25-49 mL/minute: Administer 1.25 mg/kg/dose every 24 hours

Cl_{cr} 10-24 mL/minute: Administer 0.625 mg/kg/dose every 24 hours

Cl_{cr} <10 mL/minute: Administer 0.625 mg/kg/dose 3 times/week following hemodialysis

Oral:

Cl_{cr} 50-69 mL/minute: Administer 1500 mg/day or 500 mg 3 times/day

Cl_{cr} 25-49 mL/minute: Administer 1000 mg/day or 500 mg twice daily

Cl_{cr} 10-24 mL/minute: Administer 500 mg/day

Cl_{cr} <10 mL/minute: Administer 500 mg 3 times/week following hemodialysis

Hemodialysis effects: Dialyzable (50%) following hemodialysis; administer dose postdialysis. During peritoneal dialysis, dose as for Cl_{cr} <10 mL/minute. During continuous arteriovenous or venovenous hemofiltration, administer 2.5 mg/kg/dose every 24 hours.

Stability Reconstituted solution is stable for 12 hours at room temperature; **do not refrigerate**; reconstitute with sterile water **not** bacteriostatic water because parabens may cause precipitation

Monitoring Parameters CBC with differential and platelet count, serum creatinine, ophthalmologic exams

Administration Administer by slow I.V. infusion over at least 1 hour at a final concentration for administration not to exceed 10 mg/mL

Contraindications Hypersensitivity to ganciclovir, acyclovir, or any component of the formulation; absolute neutrophil count <500/mm³; platelet count <25,000/mm³

Warnings Hazardous agent – use appropriate precautions for handling and disposal. **[U.S. Boxed Warning]: Granulocytopenia, anemia, and thrombocytopenia may occur.** Dosage adjustment or interruption of ganciclovir therapy may be necessary in patients with neutropenia and/or thrombocytopenia and patients with impaired renal function. Use with extreme caution in children since long-term safety has not been determined and **[U.S. Boxed Warning]: Animal studies have demonstrated carcinogenic and teratogenic effects, and inhibition of spermatogenesis;** contraceptive precautions for female and male patients need to be followed during and for at least 90 days after therapy with the drug; take care to administer only into veins with good blood flow. **[U.S. Boxed Warning]: Indicated only for treatment of CMV retinitis in the immunocompromised patient and CMV prevention in transplant patients at risk.**

Dosage Forms [DSC] = Discontinued product

Capsule: 250 mg, 500 mg

Cytovene®: 250 mg, 500 mg [DSC]

Implant, intravitreal (Vitrasert®): 4.5 mg [released gradually over 5-8 months]

Injection, powder for reconstitution, as sodium (Cytovene®): 500 mg

Reference Range Peak steady state serum level of 5 mg/kg/dose: 15 mcg/mL (44.5 µmol/L)

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Colony-stimulating factor may decrease hematologic toxicity

Enhancement of elimination: Multiple dosing may be effective; hemodialysis may be effective (40% to 50% removed by a 4-hour hemodialysis)

GEMFIBROZIL

Test Interactions May increase serum alkaline phosphatase and serum bilirubin

Drug Interactions

Decreased effect: Didanosine: A decrease in steady-state ganciclovir AUC may occur

Increased toxicity:

Immunosuppressive agents may increase cytotoxicity of ganciclovir
Imipenem/cilastatin may increase seizure potential
Zidovudine: Oral ganciclovir increased the AUC of zidovudine, although zidovudine decreases steady state levels of ganciclovir. Since both drugs have the potential to cause neutropenia and anemia, some patients may not tolerate concomitant therapy with these drugs at full dosage.

Probenecid: The renal clearance of ganciclovir is decreased in the presence of probenecid

Didanosine levels are increased with concurrent ganciclovir
Other nephrotoxic drugs (eg, amphotericin and cyclosporine) may have additive nephrotoxicity with ganciclovir

Pregnancy Risk Factor C

Pregnancy Implications Animal studies reveal growth retardation, cleft palate, microphthalmia, hydrocephaly

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Must be prepared in vertical flow hood; use chemotherapy precautions during administration; discard appropriately

Additional Information Sodium content of 500 mg vial: 46 mg

Questions about this drug can be directed to the Ganciclovir Study Center (301) 497-9888 or Syntex Laboratories (415) 496-3648

Gemfibrozil

CAS Number 25812-30-0

U.S. Brand Names Lopid®

Synonyms CI-719

Use Treatment of hypertriglyceridemia in types IV and V hyperlipidemia for patients who are at greater risk for pancreatitis and who have not responded to dietary intervention

Mechanism of Action Exact mechanism of action unknown, however, several theories exist regarding the VLDL effect; it can inhibit lipolysis and decrease subsequent hepatic fatty acid uptake as well as inhibit hepatic secretion of VLDL; together these actions decrease serum VLDL levels; increases HDL cholesterol; the mechanism behind HDL elevation is currently unknown

Adverse Reactions

Cardiovascular: Exacerbation of Raynaud's phenomenon, vasculitis
Central nervous system: Dizziness, drowsiness, somnolence, frontal headache, CNS depression

Dermatologic: Exacerbation of psoriasis, hypertrichosis, exfoliative dermatitis, erythema multiforme, alopecia, angioedema, xerosis, urticaria, pruritus, acanthosis nigricans, licheniform eruptions, exanthem

Gastrointestinal: **Abdominal pain, dyspepsia**, nausea, vomiting, diarrhea, constipation, flatulence, xerostomia

Genitourinary: Impotence

Hepatic: Cholelithiasis, cholecystitis

Neuromuscular & skeletal: Paresthesia, polymyositis (dermatomyositis), rhabdomyolysis

Ocular: Blurred vision

Renal: Myoglobinuria

Miscellaneous: Systemic lupus erythematosus

Pharmacodynamics/Kinetics

Onset of action: May require several days

Absorption: Well absorbed

Protein binding: 99%

Metabolism: Hepatic via oxidation to two inactive metabolites; undergoes enterohepatic recycling

Half-life elimination: 1.4 hours

Time to peak, serum: 1-2 hours

Excretion: Urine (70% primarily as conjugated drug); feces (6%)

Dosage

Adults: Oral: 1200 mg/day in 2 divided doses, 30 minutes before breakfast and dinner

Hemodialysis: Not removed by hemodialysis; supplemental dose is not necessary

Monitoring Parameters Serum cholesterol, LFTs

Contraindications Hypersensitivity to gemfibrozil or any component of the formulation; significant hepatic or renal dysfunction; primary biliary cirrhosis; pre-existing gallbladder disease

Warnings Possible increased risk of malignancy and cholelithiasis. No evidence of cardiovascular mortality benefit. Anemia and leukopenia have been reported. Elevations in serum transaminases can be seen. Discontinue if lipid response not seen. Be careful in patient selection; this is not a first- or second-line choice. Other agents may be more suitable. Adjustments in warfarin therapy may be required with concurrent use. Use caution when combining gemfibrozil with HMG-CoA reductase inhibitors (may lead to myopathy, rhabdomyolysis). Renal function

deterioration has been seen when used in patients with a serum creatinine >2.0 mg/dL. Safety and efficacy in pediatric patients have not been established.

Dosage Forms Tablet: 600 mg

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may increase clearance

Test Interactions Possible false positive urinary assay for cannabinoids utilizing the OnTrak TesTcup method (Roche Diagnostic Systems, Inc)

Drug Interactions Substrate of CYP3A4 (minor); **Inhibits** CYP1A2 (moderate), 2C8 (strong), 2C9 (strong), 2C19 (strong)

Bexarotene's serum concentration is significantly increased; avoid concurrent use.

Chlorpropamide: May increase risk of hypoglycemia.

Cyclosporine's blood levels may be reduced; monitor cyclosporine levels and renal function.

CYP1A2 substrates: Gemfibrozil may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, fluvoxamine, mexiletine, mirtazapine, ropinirole, theophylline, and trifluoperazine.

CYP2C8 substrates: Gemfibrozil may increase the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP2C9 substrates: Gemfibrozil may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

CYP2C19 substrates: Gemfibrozil may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

Furosemide: Increased blood levels of both in hypoalbuminemia.

Glyburide (and possibly other sulfonylureas): The hypoglycemic effects may be increased.

HMG-CoA reductase inhibitors (atorvastatin, fluvastatin, lovastatin, pravastatin, simvastatin) may increase the risk of myopathy and rhabdomyolysis. The manufacturer warns against the concurrent use of lovastatin (if unavoidable, limit lovastatin to <20 mg/day). Combination therapy with statins has been used in some patients with resistant hyperlipidemias (with great caution).

Repaglinide: Gemfibrozil may increase the serum concentration of repaglinide (prolonged, severe hypoglycemia has been reported). The addition of itraconazole may augment the effects of gemfibrozil on repaglinide. Consider alternative therapy.

Rifampin: Decreased gemfibrozil blood levels.

Warfarin: Hypoprothrombinemic response increased; monitor INRs closely when gemfibrozil is initiated or discontinued.

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/contraindicated

Layne RD, Sehbai AS, and Stark LJ, "Rhabdomyolysis and Renal Failure Associated with Gemfibrozil Monotherapy," *Ann Pharmacother*, 2004, 38(2):232-4.

Gentamicin

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 1405-41-0

U.S. Brand Names Garamycin® [DSC]; Genoptic®; Gentacidin®; Gentak®

Synonyms Gentamicin Sulfate

Use Treatment of susceptible bacterial infections, normally gram-negative organisms including *Pseudomonas*, *Proteus*, *Serratia*, and gram-positive *Staphylococcus*; treatment of bone infections, respiratory tract infections, skin and soft tissue infections, as well as abdominal and urinary tract infections, endocarditis, and septicemia; used topically to treat superficial infections of the skin or ophthalmic infections caused by susceptible bacteria; prevention of bacterial endocarditis prior to dental or surgical procedures

Mechanism of Action Interferes with bacterial protein synthesis by binding to 30S and 50S ribosomal subunits resulting in a defective bacterial cell membrane

Adverse Reactions

Cardiovascular: Vasoconstriction, congestive heart failure, myocardial depression

Central nervous system: Psychosis, **dizziness**, hallucinations, anxiety, **ataxia**, arachnoiditis

Dermatologic: Rash, systemic contact dermatitis, immunologic contact urticaria, toxic pustuloderma, acute generalized exanthematous pustulosis

Endocrine & metabolic: Hypomagnesemia

Hematologic: Granulocytopenia

Hepatic: Elevation of AST and ALT

Local: Thrombophlebitis

Neuromuscular & skeletal: Neuromuscular blockade, **gait instability**

Ocular: Nystagmus

Otic: **Ototoxicity** (auditory and vestibular), tinnitus (peak > 12-15 mcg/mL and high trough levels)

Renal: **Nephrotoxicity** (high trough levels) with albuminuria, reduction in glomerular filtration rate, elevated serum creatinine, decrease in urine specific gravity, casts in urine and possible electrolyte wasting, **decreased creatinine clearance**

Signs and Symptoms of Overdose Deafness, eczema, Fanconi syndrome, hypokalemia, hypomagnesemia, leukopenia or neutropenia (agranulocytosis, granulocytopenia), myasthenia gravis (exacerbation or precipitation), pseudotumor cerebri, seizures thrombocytopenia, tubular necrosis

Pharmacodynamics/Kinetics

Absorption:

Intramuscular: Rapid and complete

Oral: None

Distribution: Primarily into extracellular fluid (highly hydrophilic); crosses placenta and excreted in breast milk; high concentration in the renal cortex; minimal penetration to ocular tissues via I.V. route

V_d: Increased by edema, ascites, fluid overload; decreased with dehydration

Neonates: 0.4-0.6 L/kg

Children: 0.3-0.35 L/kg

Adults: 0.2-0.3 L/kg

Relative diffusion from blood into CSF: Minimal even with inflammation

CSF: blood level ratio: Normal meninges: Nil; Inflamed meninges: 10% to 30%

Protein binding: <30%

Half-life elimination:

Infants: <1 week: 3-11.5 hours; 1 week to 6 months: 3-3.5 hours

Adults: 1.5-3 hours; End-stage renal disease: 36-70 hours

Time to peak, serum: I.M.: 30-90 minutes; I.V.: 30 minutes after 30-minute infusion

Excretion: Urine (as unchanged drug)

Clearance: Directly related to renal function

Dosage Individualization is critical because of the low therapeutic index **Use of ideal body weight (IBW) for determining the mg/kg/dose appears to be more accurate than dosing on the basis of total body weight (TBW).**

In morbid obesity, dosage requirement may best be estimated using a dosing weight of $IBW + 0.4 (TBW - IBW)$

Initial and periodic peak and trough plasma drug levels should be determined, particularly in critically-ill patients with serious infections or in disease states known to significantly alter aminoglycoside pharmacokinetics (eg, cystic fibrosis, burns, or major surgery)

Newborns: Intrathecal: 1 mg every day

Infants >3 months: Intrathecal: 1-2 mg/day

Infants and Children <5 years: I.M., I.V.: 2.5 mg/kg/dose every 8 hours*

Cystic fibrosis: 2.5 mg/kg/dose every 6 hours

Children >5 years: I.M., I.V.: 1.5-2.5 mg/kg/dose every 8 hours*

Prevention of bacterial endocarditis: Dental, oral, upper respiratory procedures, GI/GU procedures: 2 mg/kg with ampicillin (50 mg/kg) 30 minutes prior to procedure

*Some patients may require larger or more frequent doses (eg, every 6 hours) if serum levels document the need (ie, cystic fibrosis or febrile granulocytopenic patients)

Adults: I.M., I.V.:

Severe life-threatening infections: 2-2.5 mg/kg/dose

Urinary tract infections: 1.5 mg/kg/dose

Synergy (for gram-positive infections): 1 mg/kg/dose

Prevention of bacterial endocarditis:

Dental, oral, or upper respiratory procedures: 1.5 mg/kg not to exceed 80 mg with ampicillin (1-2 g) 30 minutes prior to procedure

GI/GU surgery: 1.5 mg/kg not to exceed 80 mg with ampicillin (2 g) 30 minutes prior to procedure

Some clinicians suggest a daily dose of 4-7 mg/kg for all patients with normal renal function. This dose is at least as efficacious with similar, if not less, toxicity than conventional dosing.

Children and Adults:

Intrathecal: 4-8 mg/day

Ophthalmic:

Ointment: Instill $\frac{1}{2}$ " (1.25 cm) 2-3 times/day to every 3-4 hours

Solution: Instill 1-2 drops every 2-4 hours, up to 2 drops every hour for severe infections

Topical: Apply 3-4 times/day to affected area

Dosing interval in renal impairment:

Cl_{cr} ≥ 60 mL/minute: Administer every 8 hours

Cl_{cr} 40-60 mL/minute: Administer every 12 hours

Cl_{cr} 20-40 mL/minute: Administer every 24 hours

Cl_{cr} <20 mL/minute: Loading dose, then monitor levels

Hemodialysis: Dialyzable; removal by hemodialysis: 30% removal of aminoglycosides occurs during 4 hours of HD; administer dose after dialysis and follow levels

Removal by continuous ambulatory peritoneal dialysis (CAPD):

Administration via CAPD fluid:

Gram-negative infection: 4-8 mg/L (4-8 mcg/mL) of CAPD fluid

Gram-positive infection (ie, synergy): 3-4 mg/L (3-4 mcg/mL) of CAPD fluid

Administration via I.V., I.M. route during CAPD: Dose as for Cl_{cr} <10 mL/minute and follow levels

Removal via continuous arteriovenous or venovenous hemofiltration: Dose as for Cl_{cr} 10-40 mL/minute and follow levels

Dosing adjustment/comments in hepatic disease: Monitor plasma concentrations

Stability I.V. infusion solutions mixed in NS or D₅W solution are stable for 24 hours at room temperature; **incompatible** with penicillins

Monitoring Parameters Urinalysis, urine output, BUN, serum creatinine; hearing should be tested before, during, and after treatment; particularly in those at risk for ototoxicity or who will be receiving prolonged therapy (>2 weeks)

Administration Administer by I.V. slow intermittent infusion over 30 minutes; final concentration for administration should not exceed 10 mg/mL

Contraindications Hypersensitivity to gentamicin or other aminoglycosides

Warnings

[U.S. Boxed Warning]: Aminoglycosides may cause neurotoxicity and/or nephrotoxicity; usual risk factors include pre-existing renal impairment, concomitant neuro-/nephrotoxic medications, advanced age and dehydration. Ototoxicity may be directly proportional to the amount of drug given and the duration of treatment; tinnitus or vertigo are indications of vestibular injury and impending hearing loss; renal damage is usually reversible

Not intended for long-term therapy due to toxic hazards associated with extended administration; use caution in pre-existing renal insufficiency, vestibular or cochlear impairment, myasthenia gravis, hypocalcemia, conditions which depress neuromuscular transmission. Dosage modification required in patients with impaired renal function

Dosage Forms [DSC] = Discontinued product

Cream, topical, as sulfate: 0.1% (15 g, 30 g)

Infusion, as sulfate [premixed in NS]: 40 mg (50 mL); 60 mg (50 mL, 100 mL); 70 mg (50 mL); 80 mg (50 mL, 100 mL); 90 mg (100 mL); 100 mg (50 mL, 100 mL); 120 mg (100 mL)

Injection, solution, as sulfate [ADD-Vantage[®] vial]: 10 mg/mL (6 mL, 8 mL, 10 mL)

Injection, solution, as sulfate: 40 mg/mL (2 mL, 20 mL) [may contain sodium metabisulfite]

Injection, solution, pediatric, as sulfate: 10 mg/mL (2 mL) [may contain sodium metabisulfite]

Injection, solution, pediatric, as sulfate [preservative free]: 10 mg/mL (2 mL)

Ointment, ophthalmic, as sulfate (Gentak[®]): 0.3% [3 mg/g] (3.5 g)

Ointment, topical, as sulfate: 0.1% (15 g, 30 g)

Solution, ophthalmic, as sulfate: 0.3% (5 mL, 15 mL) [contains benzalkonium chloride]

Genoptic[®]: 0.3% (1 mL) [contains benzalkonium chloride] [DSC]

Gentak[®]: 0.3% (5 mL; 15 mL [DSC]) [contains benzalkonium chloride]

Reference Range

Therapeutic: Peak: 4-8 mcg/mL (SI: 8-17 μmol/L); Trough: <2 mcg/mL (SI: <4 μmol/L) (depends in part on the minimal inhibitory concentration of drug against organism being treated)

Toxic: Peak: >10 mcg/mL (SI: >21 μmol/L); Trough: >2 mcg/mL (SI: >4 μmol/L)

Overdosage/Treatment

Supportive therapy: 14 day-therapy with aspirin (1 g 3 times/day) may provide antioxidant protection against ototoxicity

Enhancement of elimination: While hemodialysis is of questionable benefit in those patients with normal renal function, it should be performed in patients with renal insufficiency; the addition of ticarcillin (2-5 g I.V. every 4-6 hours until gentamicin serum levels are <0.2 mcg/mL) may complex with gentamicin and decrease the half-life of gentamicin by enhancing renal excretion

Test Interactions ↑ protein, BUN, AST, GPT, alkaline phosphatase, creatinine (S); ↓ magnesium, potassium, sodium, calcium; the presence of this drug may result in decreased reactivity of urinary leukocyte esterase

Drug Interactions Increased toxicity:

Aminoglycosides may potentiate the effects of neuromuscular-blocking agents.

Penicillins, cephalosporins, amphotericin B, loop diuretics may increase nephrotoxic potential

Decreased effect: Gentamicin's efficacy reduced when given concurrently with carbenicillin, ticarcillin, or piperacillin to patients with severe renal impairment (inactivation). Separate administration.

Pregnancy Risk Factor C**Pregnancy Implications** Crosses the placenta

Lactation Enters breast milk (small amounts)/use caution (AAP rates "compatible")

Nursing Implications Slower absorption and lower peak concentrations probably due to poor circulation in the atrophic muscle, may occur following I.M. injection in paralyzed patients (suggest I.V. route); aminoglycoside levels measured in blood taken from Silastic® central catheters can sometimes give falsely high readings (draw via separate lumen or peripheral site if possible, otherwise flush very well). Monitor serum creatinine and urine output; obtain drug levels after the third dose unless otherwise directed (eg, suspected toxicity or renal dysfunction). Peak levels are drawn 30 minutes after the end of a 30-minute infusion or 60 minutes following I.M. injection; trough levels are drawn within 30 minutes before the next dose. Separate administration of extended-spectrum penicillins (eg, carbenicillin, ticarcillin, piperacillin) from gentamicin in patients with severe renal impairment; gentamicin's efficacy may be reduced if given concurrently. Hearing should be tested before, during, and after treatment in patients at risk for ototoxicity.

Additional Information Incidence of cochlear toxicity: 10% to 16%; vestibular toxicity: 5% to 15%; nephrotoxicity: 10% to 35%; ototoxicity may be related to hypovolemia, hepatic disease, and critical illness. Additionally, limiting the total dose to <2 g while limiting the duration of therapy to <10 days may limit ototoxicity, although appears idiosyncratic occurring with first dose. Nephrotoxicity is **not** related to ototoxicity.

Incidence of cochleotoxicity is ~10% to 63% with loop diuretics and noise exposure being ototoxic synergistic. Inhaled tobramycin appears to exhibit minimal ototoxic effects. There may be a genetic basis (in the mitochondrial 12 S ribosomal RNA gene) for ototoxicity in 17% to 33% of cases. Suggested evaluation for ototoxicity with aminoglycoside treatment includes:

- baseline audiometric evaluation (tonal air conduction thresholds from 250-20,000 Hz)
- monitoring during aminoglycoside treatment (to a tonal-air conduction threshold at frequency >8000 Hz)
- follow-up audiometric assessment (tonal air conduction thresholds at frequencies >8000 Hz) until the threshold stabilizes

Signs and Symptoms of Overdose Low blood sugar, tingling of lips and tongue, nausea, yawning, confusion, agitation, tachycardia, sweating, convulsions, stupor, and coma.

Admission Criteria/Prognosis Admit all intentional adult overdoses. Pediatric patients should be observed in a medical setting through an overnight sleep cycle (and for a minimum of 8 hours). No intravenous glucose or dextrose should be given prophylactically. Asymptomatic pediatric patients should have a blood glucose determination at 3-6 hours postingestion or immediately when symptoms (hunger, irritability, lethargy, tremulousness, tachycardia, diaphoresis, or seizures) develop. Any borderline blood glucose reading (about 70 mg/dL) are repeated in one hour. Consider regular 2- to 3-hour interval blood glucose measurements during sleep. If no hypoglycemic events occur and prebreakfast blood glucose levels are normal, pediatric patients can be monitored by parental observation at home.

Pharmacodynamics/Kinetics

Onset of action: Peak effect: Blood glucose reductions: 2-3 hours

Duration: 24 hours

Absorption: 100%; delayed when given with food

Distribution: V_d : 8.8 L

Protein binding: >99.5%

Metabolism: Hepatic oxidation via CYP2C9 to M1 metabolite (~33% activity of parent compound); further oxidative metabolism to inactive M2 metabolite

Half-life elimination: 5-9 hours

Time to peak, plasma: 2-3 hours

Excretion: Urine (60%, 80% to 90% M1 and M2); feces (40%, 70% M1 and M2)

Dosage

Oral (allow several days between dose titrations):

Adults: Initial: 1-2 mg once daily, administered with breakfast or the first main meal; usual maintenance dose: 1-4 mg once daily; after a dose of 2 mg once daily, increase in increments of 2 mg at 1- to 2-week intervals based upon the patient's blood glucose response to a maximum of 8 mg once daily

Combination with insulin therapy (fasting glucose level for instituting combination therapy is in the range of >150 mg/dL in plasma or serum depending on the patient): initial recommended dose: 8 mg once daily with the first main meal

After starting with low-dose insulin, upward adjustments of insulin can be done approximately weekly as guided by frequent measurements of fasting blood glucose. Once stable, combination-therapy patients should monitor their capillary blood glucose on an ongoing basis, preferably daily.

Dosing adjustment/comments in renal impairment: Cl_{cr} <22 mL/minute: Initial starting dose should be 1 mg and dosage increments should be based on fasting blood glucose levels

Dosing adjustment in hepatic impairment: No data available

Elderly: Initial: 1 mg/day; dose titration and maintenance dosing should be conservative to avoid hypoglycemia

Monitoring Parameters Urine for glucose and ketones; monitor for signs and symptoms of hypoglycemia (fatigue, excessive hunger, profuse sweating, numbness of extremities), fasting blood glucose, hemoglobin A_{1c} , fructosamine

Administration May be administered with a meal/food

Contraindications Hypersensitivity to glimepiride, any component of the formulation, or sulfonamides; diabetic ketoacidosis (with or without coma)

Warnings

All sulfonylurea drugs are capable of producing severe hypoglycemia. Hypoglycemia is more likely to occur when caloric intake is deficient, after severe or prolonged exercise, when ethanol is ingested, or when more than one glucose-lowering drug is used.

Chemical similarities are present among sulfonamides, sulfonylureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonamide allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

Product labeling states oral hypoglycemic drugs may be associated with an increased cardiovascular mortality as compared to treatment with diet alone or diet plus insulin. Data to support this association are limited, and several studies, including a large prospective trial (UKPDS) have not supported an association. Safety and efficacy in pediatric patients have not been established.

Dosage Forms Tablet: 1 mg, 2 mg, 4 mg

Reference Range Mean peak serum glimepiride concentrations after single dose of 4 mg and 8 mg were 352 ng/mL and 591 ng/mL, respectively

Overdosage/Treatment

Intoxication with sulfonylureas can cause hypoglycemia and are best managed with glucose administration (oral for milder hypoglycemia or by injection in more severe forms). Patients should be monitored for a minimum of 24-48 hours after ingestion.

Decontamination: Lavage/activated charcoal

Glimepiride

CAS Number 93479-97-1

U.S. Brand Names Amaryl®

Use Management of type 2 diabetes mellitus (noninsulin dependent, NIDDM) as an adjunct to diet and exercise to lower blood glucose or in combination with metformin; use in combination with insulin to lower blood glucose in patients whose hyperglycemia cannot be controlled by diet and exercise in conjunction with an oral hypoglycemic agent

Mechanism of Action Stimulates insulin release from the pancreatic beta cells; reduces glucose output from the liver; insulin sensitivity is increased at peripheral target sites by affecting insulin receptor binding or coupling mechanisms (especially in adipose tissue). It is structurally similar to glyburide.

Adverse Reactions

Central nervous system: Dizziness, headache

Endocrine & metabolic: Hypoglycemia

Gastrointestinal: Nausea

Neuromuscular & skeletal: Weakness

Rare but important or life-threatening: Agranulocytosis, anorexia, aplastic anemia, cholestatic jaundice, constipation, diarrhea, disulfiram-like reaction, diuretic effect, edema, epigastric fullness, gastrointestinal pain, erythema, heartburn, hemolytic anemia, hepatitis, hypoglycemia, hyponatremia, leukopenia, liver function tests abnormal, nausea, pancytopenia, photosensitivity, porphyria cutanea tarda, pruritus, rash (morbilliform or maculopapular), SIADH, thrombocytopenia, urticaria, vasculitis (allergic), visual accommodation changes (early treatment), vomiting

Supportive therapy: Glucose (25 g I.V.) is mainstay of therapy; glucagon (1-5 mg I.V., I.M., or SubQ) (0.03-0.1 mg/kg in pediatrics) will have limited benefit; diazoxide is a third-line agent (3-8 mg/kg/24 hours); octreotide (50 mcg SubQ every 12 hours) may be helpful in sulfonylurea overdose

For pediatric patients with profound sulfonylurea-induced hypoglycemia: Give 0.5 g of dextrose per kg of body weight (5 mL/kg of 10% dextrose concentration of intravenous fluid, 2 mL/kg of D₂₅ or 1 mL/kg of D₅₀).

Drug Interactions Substrate of CYP2C9 (major)

Beta blockers: Beta blockers may enhance the effects of sulfonylureas. Chloramphenicol: Chloramphenicol may increase the effects of sulfonylureas.

Cimetidine: Cimetidine may increase the effects of glimepiride.

Cyclosporine: Sulfonylureas may increase the levels of cyclosporine.

CYP2C9 inducers: May decrease the levels/effects of glimepiride.

Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C9 inhibitors: May increase the levels/effects of glimepiride.

Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nicardipine, NSAIDs, sulfonamides, and tolbutamide.

Ethanol: Sulfonylureas may induce a disulfiram-like reaction.

Fibric acid derivatives: May increase the hypoglycemic effects of sulfonylureas; monitor.

Fluconazole: Fluconazole may increase the levels of sulfonylureas.

Hyperglycemia-producing agents: Certain drugs tend to produce hyperglycemia and may lead to loss of control. These drugs include the thiazides and other diuretics, corticosteroids, phenothiazines, thyroid products, estrogens, oral contraceptives, phenytoin, nicotinic acid, sympathomimetics, and isoniazid.

Pegvisomant: Pegvisomant may increase the effects of sulfonylureas.

Rifampin: Rifampin may decrease the effects of sulfonylureas.

Salicylates: Salicylates may increase the effects of sulfonylureas.

Sulfonamides: Sulfonamides may increase the effects of sulfonylureas.

Tricyclic antidepressants: TCAs may increase the effects of sulfonylureas.

Pregnancy Risk Factor C

Pregnancy Implications Animal studies did not show any direct drug relationship with congenital malformations. Primary adverse effects are associated with maternal hypoglycemia. Abnormal blood glucose levels are associated with a higher incidence of congenital abnormalities. Insulin is the drug of choice for the control of diabetes mellitus during pregnancy.

Lactation Excretion in breast milk unknown/contraindicated

Additional Information Oral aloe, bitter melon (karela), eucalyptus, fenugreek, and ginseng may increase the effects of glimepiride. Caution with ethanol, chromium, garlic, gymnema (may cause hypoglycemia)

Specific References

Calello D, Kelly A, and Osterhoudt KC, "Case Files of the Medical Toxicology Fellowship Training Program at the Childrens Hospital of Philadelphia: A Pediatric Exploratory Sulfonylurea Ingestion," *J Med Toxicol*, 2006, 2(1):19-26.

Glipizide

CAS Number 29094-61-9

U.S. Brand Names Glucotrol® XL; Glucotrol®

Synonyms Glydiazinamide

Use Management of type 2 diabetes mellitus (noninsulin dependent, NIDDM)

Mechanism of Action Sulfonylurea which stimulates insulin release from the pancreatic beta cells; reduces glucose output from the liver; insulin sensitivity is increased at peripheral target sites

Adverse Reactions

Frequency not defined.

Cardiovascular: Edema, syncope

Central nervous system: Anxiety, depression, dizziness, headache, insomnia, nervousness

Dermatologic: Rash, urticaria, photosensitivity, pruritus

Endocrine & metabolic: Hypoglycemia, hyponatremia, SIADH (rare)

Gastrointestinal: Anorexia, nausea, vomiting, diarrhea, epigastric fullness, constipation, heartburn, flatulence

Hematologic: Blood dyscrasias, aplastic anemia, hemolytic anemia, bone marrow suppression, thrombocytopenia, agranulocytosis

Hepatic: Cholestatic jaundice, hepatic porphyria

Neuromuscular & skeletal: Arthralgia, leg cramps, myalgia, tremor

Ocular: Blurred vision

Renal: Diuretic effect (minor)

Miscellaneous: Diaphoresis, disulfiram-type reaction

Postmarketing and/or case reports: Abdominal pain

Admission Criteria/Prognosis Admit all intentional adult overdoses. Pediatric patients should be observed in a medical setting through an overnight sleep cycle (and for a minimum of 8 hours). No intravenous

glucose or dextrose should be given prophylactically. Asymptomatic pediatric patients should have a blood glucose determination at 3-6 hours postingestion or immediately when symptoms (hunger, irritability, lethargy, tremulousness, tachycardia, diaphoresis, or seizures) develop. Any borderline blood glucose reading (about 70 mg/dL) are repeated in one hour. Consider regular 2- to 3-hour interval blood glucose measurements during sleep. If no hypoglycemic events occur and prebreakfast blood glucose levels are normal, pediatric patients can be monitored by parental observation at home.

Pharmacodynamics/Kinetics

Onset of action: Peak effect: Blood glucose reductions: 1.5-2 hours

Duration: 12-24 hours

Absorption: Delayed with food

Protein binding: 92% to 99%

Metabolism: Hepatic with metabolites

Half-life elimination: 2-4 hours

Excretion: Urine (60% to 80%, 91% to 97% as metabolites); feces (11%)

Dosage

Oral (allow several days between dose titrations): Adults: Initial: 5 mg/day; adjust dosage at 2.5-5 mg daily increments as determined by blood glucose response at intervals of several days.

Immediate release tablet: Maximum recommended once-daily dose: 15 mg; maximum recommended total daily dose: 40 mg

Extended release tablet (Glucotrol® XL): Maximum recommended dose: 20 mg

When transferring from insulin to glipizide:

Current insulin requirement \leq 20 units: Discontinue insulin and initiate glipizide at usual dose

Current insulin requirement $>$ 20 units: Decrease insulin by 50% and initiate glipizide at usual dose; gradually decrease insulin dose based on patient response. Several days should elapse between dosage changes.

Elderly: Initial: 2.5 mg/day; increase by 2.5-5 mg/day at 1- to 2-week intervals

Dosing adjustment/comments in renal impairment: Cl_{cr} $<$ 10 mL/minute: Some investigators recommend not using

Dosing adjustment in hepatic impairment: Initial dosage should be 2.5 mg/day

Monitoring Parameters Urine for glucose and ketones; monitor for signs and symptoms of hypoglycemia (fatigue, excessive hunger, profuse sweating, numbness of extremities), fasting blood glucose, hemoglobin A_{1c}, fructosamine

Administration Administer immediate release tablets 30 minutes before a meal to achieve greatest reduction in postprandial hyperglycemia. Extended release tablets should be given with breakfast. Patients who are NPO may need to have their dose held to avoid hypoglycemia.

Contraindications Hypersensitivity to glipizide or any component of the formulation, other sulfonamides; type 1 diabetes mellitus (insulin dependent, IDDM)

Warnings

Use with caution in patients with severe hepatic disease.

Chemical similarities are present among sulfonamides, sulfonylureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonamide allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

The extended release formulation consists of drug within a nondeformable matrix; following drug release/absorption, the matrix/shell is expelled in the stool. The use of nondeformable products in patients with known stricture/narrowing of the GI tract has been associated with symptoms of obstruction. Avoid use of extended release tablets (Glucotrol® XL) in patients with severe gastrointestinal narrowing or esophageal dysmotility.

Product labeling states oral hypoglycemic drugs may be associated with an increased cardiovascular mortality as compared to treatment with diet alone or diet plus insulin. Data to support this association are limited, and several studies, including a large prospective trial (UKPDS) have not supported an association.

Dosage Forms Tablet (Glucotrol®): 5 mg, 10 mg

Tablet, extended release: 5 mg, 10 mg

Glucotrol® XL: 2.5 mg, 5 mg, 10 mg

Reference Range Glucose: Adults: 80-140 mg/dL; Elderly: 100-180 mg/dL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Glucose (25 g I.V.) is mainstay of therapy; glucagon (1-5 mg I.V., I.M., or SubQ) (0.03-0.1 mg/kg in pediatrics) will have limited benefit; diazoxide is a third-line agent (3-8 mg/kg/24 hours); octreotide (50 mcg SubQ every 12 hours) may be helpful in sulfonylurea overdose. For pediatric patients with profound sulfonylurea-induced hypoglycemia: Give 0.5 g of dextrose per kg of body weight (5 mL/kg of 10% dextrose concentration of intravenous fluid, 2 mL/kg of D₂₅ or 1 mL/kg of D₅₀).

GLUTAMINE

Enhancement of elimination: Multiple dosing of activated charcoal may be more effective for this agent than for other oral hypoglycemics due to enterohepatic recirculation of glipizide; peritoneal dialysis has been used with some success, but is not recommended as a routine procedure; urine alkalization is also useful

Antidote(s)

- Dextrose [ANTIDOTE]
- Glucagon [ANTIDOTE]
- Octreotide [ANTIDOTE]

Diagnostic Procedures

- Electrolytes, Blood
- Glucose, Random

Drug Interactions Substrate of 2C8/9 (major)

Anabolic steroids may increase hypoglycemic effect; monitor blood glucose.

ACE inhibitors may increase hypoglycemic effect; monitor blood glucose. Beta-blockers decrease hypoglycemic effect, mask most hypoglycemic symptoms, decrease glycogenolysis; avoid use in diabetics with frequent hypoglycemic episodes.

Cholestyramine decreases glipizide's absorption; separate administration times.

Corticosteroids cause hyperglycemia; adjustment of hypoglycemic agent may be necessary.

Cyclosporine serum concentration is increased; monitor cyclosporine levels and renal function.

CYP2C8/9 inducers: May decrease the levels/effects of glipizide. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C8/9 inhibitors: May increase the levels/effects of glipizide. Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nicardipine, NSAIDs, pioglitazone, and sulfonamides.

Ethanol (large amounts) decreases hypoglycemic effect; avoid concurrent use; rare disulfiram reaction.

H₂ antagonists, antacids, oral sodium bicarbonate may increase the hypoglycemic effect; monitor glucose response.

Rifampin may decrease hypoglycemic effects of glipizide; monitor blood glucose.

Tacrolimus serum concentrations may be increased; monitor tacrolimus serum concentrations and renal function.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta. Abnormal blood glucose levels are associated with a higher incidence of congenital abnormalities. Insulin is the drug of choice for the control of diabetes mellitus during pregnancy. If glipizide is used during pregnancy, discontinue and change to insulin at least 1 month prior to delivery to decrease prolonged hypoglycemia in the neonate.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Monitor for signs and symptoms of hypoglycemia; patients who are anorexic or NPO, may need to have their dose held to avoid hypoglycemia

Additional Information Exhibits more diuretic action than chlorpropamide

Food: A delayed release of insulin may occur if glipizide is taken with food. Immediate release tablets should be administered 30 minutes before meals to avoid erratic absorption.

Glutamine

Pronunciation (GLOO ta meen)

U.S. Brand Names Enterex[®] Glutapak-10[®] [OTC]; NutreStore[™]; Resource[®] GlutaSolve[®] [OTC]; Sympt-X G.I. [OTC]; Sympt-X [OTC]

Synonyms Gln; L-Glutamine

Use Treatment of short bowel syndrome when used in combination with nutritional support and growth hormone therapy; a medical food used to promote GI tract healing and nutritional supplementation with GI disorders, HIV/AIDS, cancer, and other critical illnesses

Mechanism of Action Glutamine regulates gastrointestinal cell growth, function, and regeneration. Considered a "conditionally essential" amino acid during metabolic stress and injury.

Adverse Reactions

Frequency not defined.

Cardiovascular: Facial edema, peripheral edema

Central nervous system: Dizziness, fever, headache, pain

Dermatologic: Pruritus, rash

Gastrointestinal: Abdominal pain, flatulence, nausea, pancreatitis, tenesmus, vomiting

Neuromuscular & skeletal: Arthralgia, back pain, hypoesthesia

Otic: Ear or hearing symptoms

Respiratory: Rhinitis

Miscellaneous: Flu-like syndrome, infection, sepsis

Pharmacodynamics/Kinetics

As reported in healthy adults; parameters may vary following oral administration in patients with short bowel syndrome.

Distribution: I.V.: V_d: 200 mL/kg

Metabolism: Via splanchnic tissue, lymphocytes, kidney, and liver to glutamate and ammonia

Half-life elimination: I.V.: 1 hour

Dosage

Oral: Adults:

Nutritional supplement (Enterex[®] Glutapak-10[®], Resource[®] GlutaSolve[®], Sympt-X, Sympt-X G.I.): Average dose: 10 g 3 times/day; dosing range: 5-30 g/day

Short bowel syndrome (NutreStore[™]): 30 g/day administered as 5 g 6 times/day (every 2-3 hours while awake) for up to 16 weeks; to be used in combination with growth hormone and nutritional support

Stability Store at controlled room temperature.

Monitoring Parameters BUN; body weight, nutritional status

Administration

Enterex[®] Glutapak-10[®]: Prior to use, mix with clear liquids or semi-solid food. If administering via feeding tube, mix each 10 g packet with ≥60 mL water. Use immediately after preparation. May also be added directly to enteral formula if used within 24 hours.

Resource[®] GlutaSolve[®]: Mix each 15 g packet with 120-240 mL of water. May also be mixed in hot or cold beverages, applesauce, or pudding. If administering via feeding tube, mix with 60-120 mL water. Use immediately after preparation.

NutreStore[™]: Mix each packet (5 g) with ~240 mL of water prior to administration. May be given with meals or snacks

Sympt-X, Sympt-X G.I.: Mix dose with 6-8 ounces of juice or another beverage, may also be mixed with applesauce or pudding. Administer with meals. If administering via feeding tube, mix with ≥60 mL water; do not add directly to feeding bag. Use immediately after preparation.

Warnings Use caution with hepatic or renal impairment. NutreStore[™] should be used with nutritional support based on individual patient requirements. Medical foods are intended to be used under the direction of a healthcare provider.

Dosage Forms Powder for oral solution:

Enterex[®] Glutapak-10[®]: 10 g/packet (50s)

NutreStore[™]: 5 g/packet

Resource[®] GlutaSolve[®]: 15 g/packet (56s)

Sympt-X, Sympt-X G.I.: 10 g/packet (60s)

Pregnancy Risk Factor C

Pregnancy Implications Reproduction studies have not been conducted.

Lactation Excretion in breast milk unknown/use caution

Glutethimide

Pronunciation (gloo TETH i mide)

Related Information

- Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 77-21-4

Impairment Potential

Yes. Blood glutethimide level >5 mg/L is associated with intoxication. (Chazan JA and Garella S, "Glutethimide Intoxication: A Prospective Study of 70 Patients Treated Conservatively Without Hemodialysis," *Arch Intern Med*, 1971, 128(2):215-9.)

Use Short-term treatment of insomnia; introduced in 1954

Mechanism of Action Central nervous system depressant with hypnotic action of phenobarbital and antimuscarinic effects

Adverse Reactions

Cardiovascular: Bradycardia, hypotension, sinus bradycardia

Central nervous system: **Daytime drowsiness**, convulsions, confusion, slurred speech, dizziness, headache, prolonged coma, fever, ataxia, hypothermia, axonopathy

Dermatologic: Skin rash; bullous eruptions

Endocrine & metabolic: Hypocalcemia (with chronic use)

Gastrointestinal: Nausea, vomiting, ileus

Genitourinary: Urinary retention

Hematologic: Blood dyscrasias, methemoglobinemia, thrombocytopenia, leukopenia (with chronic use), porphyrogenic

Neuromuscular & skeletal: Muscle spasm, rhabdomyolysis, peripheral neuropathy

Ocular: Nystagmus, mydriasis, diplopia, papilledema

Respiratory: Apnea, respiratory depression, pulmonary edema

Signs and Symptoms of Overdose Anemia (megaloblastic), apnea, bezoars, dry skin, hypocalcemia, hyporeflexia, hypothermia, leukopenia or neutropenia (agranulocytosis, granulocytopenia)

Admission Criteria/Prognosis

Admit any patient with central nervous system depression, or adult ingestion >3 g.

Toxicodynamics/Kinetics

Protein binding: 50%
Metabolism: Hepatic to an active metabolite (4-hydroxy-2-ethyl-2-phenylglutarimide); significant enterohepatic recirculation
Half-life: 5-22 hours
Elimination: ~20% of the drug is normally excreted in 4 hours in a healthy person

Dosage Oral:

Adults: 250-500 mg at bedtime, dose may be repeated but not less than 4 hours before intended awakening; maximum: 1 g/day
Elderly/debilitated patients: Total daily dose should not exceed 500 mg

Contraindications Hypersensitivity to glutethimide; porphyria

Dosage Forms Tablet: 250 mg

Reference Range

Therapeutic: 2-6 mcg/mL
Toxic: >10 mcg/mL; fatalities have occurred with serum levels between 10-100 mcg/mL (average, 50 mcg/mL)

Overdosage/Treatment

Decontamination: Aggressively lavage within 1 hour (with water or castor oil in a 1:1 mixture)/activated charcoal (1 g for every 50 g of ingested drug)

Supportive therapy: Avoid overhydration, anticholinergic

Enhancement of elimination: Multiple dosing of activated charcoal is effective; hemoperfusion is effective in removing metabolite and is preferred over hemodialysis (which is only about half as effective as charcoal hemoperfusion in removing glutethimide); considerations for extracorporeal removal of drug include ingestions >10 g (or a serum level >6 mcg/mL), prolonged coma, flat line on EEG, or progressive systemic deterioration; do not alkalinize the urine; hemoperfusion clearance ranges from 60-250 mL/minute with 32% fractional removal of drug during 4 hours

Drug Interactions Decreased effect of anticoagulants

Pregnancy Risk Factor C

Pregnancy Implications Neonatal respiratory depression/apnea have been noted as have neonatal withdrawal from chronic maternal use

Additional Information Lethal dose: 10 g. Overdose symptoms occur at 3 g ingestion. Often ingested with acetaminophen and codeine ("Fours and Doors") Not available in U.S.

GlyBURIDE

CAS Number 10238-21-8

U.S. Brand Names DiaBeta®; Glynase® PresTab®; Micronase®

Synonyms Diabeta; Glibenclamide; Glybenclamide; Glybenzcyclamide
Use Management of noninsulin-dependent diabetes mellitus (type II)

Unlabeled/Investigational Use Alternative to insulin in women for the treatment of gestational diabetes (11-33 weeks gestation)

Mechanism of Action A sulfonylurea which stimulates insulin release from the pancreatic beta cells; reduces glucose output from the liver; insulin sensitivity is increased at peripheral target sites

Adverse Reactions

Cardiovascular: Sinus tachycardia, tachycardia (supraventricular), vasculitis

Central nervous system: **Headache**, ataxia, **dizziness**

Dermatologic: Pruritus, rash, photosensitivity, hives, bullous skin disease, purpura, psoriasis, photoallergy, exanthem

Endocrine & metabolic: Hypoglycemia (12-72 hours), syndrome of inappropriate antidiuretic hormone effect, hyperinsulinemia, exanthem

Gastrointestinal: **Nausea**, **epigastric fullness**, abdominal pain, **heartburn**, **constipation**, **diarrhea**, **anorexia**

Genitourinary: Nocturia

Hematologic: Thrombocytopenia, hemolysis, aplastic anemia, leukopenia, neutropenia, agranulocytosis, granulocytopenia, bone marrow suppression

Hepatic: Cholestatic jaundice, granulomatous hepatitis, intrahepatic cholestasis, jaundice

Neuromuscular & skeletal: Arthralgia, paresthesia

Ocular: Myopia, optic atrophy (infant), diplopia

Signs and Symptoms of Overdose Coagulopathy, diuresis, enuresis, eosinophilia, exfoliative dermatitis, hypoglycemia, hyponatremia, leukopenia or neutropenia (agranulocytosis, granulocytopenia), nocturia, photosensitivity

Admission Criteria/Prognosis Admit all intentional adult overdoses. Pediatric patients should be observed in a medical setting through an overnight sleep cycle (and for a minimum of 8 hours). No intravenous glucose or dextrose should be given prophylactically. Asymptomatic pediatric patients should have a blood glucose determination at 3-6 hours postingestion or immediately when symptoms (hunger, irritability,

lethargy, tremulousness, tachycardia, diaphoresis, or seizures) develop. Any borderline blood glucose reading (about 70 mg/dL) are repeated in one hour. Consider regular 2- to 3-hour interval blood glucose measurements during sleep. If no hypoglycemic events occur and prebreakfast blood glucose levels are normal, pediatric patients can be monitored by parental observation at home.

Pharmacodynamics/Kinetics

Onset of action: Serum insulin levels begin to increase 15-60 minutes after a single dose

Duration: ≤24 hours

Protein binding, plasma: >99%

Metabolism: To one moderately active and several inactive metabolites
Half-life elimination: 5-16 hours; may be prolonged with renal or hepatic impairment

Time to peak, serum: Adults: 2-4 hours

Excretion: Feces (50%) and urine (50%) as metabolites

Dosage Oral:

Adults: 1.25-5 mg to start then increase at weekly intervals to 1.25-20 mg maintenance dose/day divided in 1-2 doses

Elderly: Initial: 1.25-2.5 mg/day, increase by 1.25-2.5 mg/day every 1-3 weeks

PresTab™: Initial: 0.75-3 mg/day, increase by 1.5 mg/day in weekly intervals, maximum: 12 mg/day

Dosing adjustment/comments in renal impairment:

Cl_{cr} 10-50 mL/minute: Use conservative initial and maintenance doses

Cl_{cr} <10 mL/minute: Avoid use

Dosing adjustment in hepatic impairment: Use conservative initial and maintenance doses and avoid use in severe disease

Monitoring Parameters Signs and symptoms of hypoglycemia, fasting blood glucose, hemoglobin A_{1c}

Administration Administer with meals at the same time each day. Patients who are anorexic or NPO may need to have their dose held to avoid hypoglycemia.

Contraindications Hypersensitivity to glyburide, any component of the formulation, or other sulfonamides; type 1 diabetes mellitus (insulin dependent, IDDM), diabetic ketoacidosis with or without coma

Warnings

Elderly: Rapid and prolonged hypoglycemia (>12 hours) despite hyper-tonic glucose injections have been reported; age and hepatic and renal impairment are independent risk factors for hypoglycemia; dosage titration should be made at weekly intervals. Use with caution in patients with renal and hepatic impairment, malnourished or debilitated conditions, or adrenal or pituitary insufficiency.

Chemical similarities are present among sulfonamides, sulfonylureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonamide allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

Product labeling states oral hypoglycemic drugs may be associated with an increased cardiovascular mortality as compared to treatment with diet alone or diet plus insulin. Data to support this association are limited, and several studies, including a large prospective trial (UKPDS) have not supported an association.

Dosage Forms [DSC] = Discontinued product

Tablet (DiaBeta®, Micronase®): 1.25 mg, 2.5 mg, 5 mg

Tablet, micronized: 1.5 mg, 3 mg, 6 mg

Glynase® PresTab®: 1.5 mg [DSC], 3 mg, 6 mg

Reference Range Normal fasting glucose: Adults: 80-140 mg/dL; Elderly: 100-180 mg/dL

Therapeutic glyburide level: 40-50 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Glucose (25 g I.V.) is mainstay of therapy; glucagon (1-5 mg I.V., I.M., or SubQ) (0.03-0.1 mg/kg in pediatrics) will have limited benefit; diazoxide is a third-line agent (3-8 mg/kg/24 hours); octreotide (50 mcg SubQ every 12 hours) may be helpful in sulfonylurea overdose

For pediatric patients with profound sulfonylurea-induced hypoglycemia: Give 0.5 g of dextrose per kg of body weight (5 mL/kg of 10% dextrose concentration of intravenous fluid, 2 mL/kg of D₂₅ or 1 mL/kg of D₅₀).

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; peritoneal dialysis has been used with some success, but is not recommended as a routine procedure; urine alkalization is also useful

Antidote(s)

- Dextrose [ANTIDOTE]
- Glucagon [ANTIDOTE]
- Octreotide [ANTIDOTE]

Diagnostic Procedures

- Electrolytes, Blood
- Glucose, Random

Drug Interactions Inhibits CYP2C8 (weak), 3A4 (weak)

Decreased effect: Thiazides may decrease effectiveness of glyburide

GLYCERIN

Increased effect: Possible interaction between glyburide and fluoroquinolone antibiotics has been reported resulting in a potentiation of hypoglycemic action of glyburide

Increased toxicity:

Since this agent is highly protein bound, the toxic potential is increased when given concomitantly with other highly protein bound drugs (ie, phenylbutazone, oral anticoagulants, hydantoins, salicylates, NSAIDs, beta-blockers, sulfonamides) - increase hypoglycemic effect

Ethanol increases disulfiram reactions

Phenylbutazone can increase hypoglycemic effects

Certain drugs tend to produce hyperglycemia and may lead to loss of control (ie, thiazides and other diuretics, corticosteroids, phenothiazines, thyroid products, estrogens, oral contraceptives, phenytoin, nicotinic acid, sympathomimetics, calcium channel blocking drugs, and isoniazid)

Possible interactions between glyburide and coumarin derivatives have been reported that may either potentiate or weaken the effects of coumarin derivatives

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta. Hypoglycemia; ear defects reported; other malformations reported but may have been secondary to poor maternal glucose control/diabetes. Insulin is the drug of choice for the control of diabetes mellitus during pregnancy.

Lactation Does not enter breast milk/ use caution

Nursing Implications Monitor for signs and symptoms of hypoglycemia; patients who are anorexic or NPO, may need to have their dose held to avoid hypoglycemia

Additional Information More diuretic effect than chlorpropamide; glyburide-microsed dust may cause hypoglycemia by inhalation

Children <6 years: 1 infant suppository 1-2 times/day as needed or 2-5 mL as an enema

Children >6 years and Adults: 1 adult suppository 1-2 times/day as needed or 5-15 mL as an enema

Children and Adults:

Oral: Maximum daily dose: 120 mg

Reduction of intraocular pressure: 1-1.8 g/kg 1-1¹/₂ hours preoperatively; additional doses may be administered at 5-hour intervals

Reduction of intracranial pressure: 1.5 g/kg/day divided every 4 hours; 1 g/kg/dose every 6 hours has also been used

Ophthalmic solution: Reduction of corneal edema: Instill 1-2 drops in eye(s) prior to examination OR for lubricant effect, instill 1-2 drops in eye(s) every 3-4 hours

Stability Refrigerate suppositories; protect from heat; freezing should be avoided

Ophthalmic: Keep bottle tightly closed; store at room temperature; discard 6 months after dropper is first placed in the solution

Administration Oral: Orange or lemon juice may be added to unflavored 50% oral solution; pour solution over crushed ice and drink through a straw to improve palatability; headache can be minimized by having the patient lie down during and after administration

Rectal: Inset suppository high in the rectum and retain 15 minutes

Dosage Forms [DSC] = Discontinued product

Solution, ophthalmic, sterile (Bausch & Lomb® Computer Eye Drops): 1% (15 mL) [contains benzalkonium chloride]

Solution, oral (Osmoglyn®): 50% (220 mL) [lime flavor] [DSC]

Solution, rectal:

Fleet® BabyLax®: 2.3 g/2.3 mL (4 mL) [6 units per box]

Fleet® Liquid Glycerin Suppositories: 5.6 g/5.5 mL (7.5 mL) [4 units per box]

Suppository, rectal: 82.5% (12s, 25s) [pediatric size]; 82.5% (12s, 24s, 25s, 50s, 100s) [adult size]

Colace® Adult/Children: 2.1 g (12s, 24s, 48s, 100s)

Colace® Infant/Children: 1.2 g (12s, 24s)

Fleet® Glycerin Suppositories: 1 g (12s) [pediatric size]; 2g (12s, 24s, 50s) [adult size]

Fleet® Glycerin Suppositories Maximum Strength: 3g (18s) [adult size]

Sani-Supp®: 82.5% (10s, 25s) [pediatric size]; 82.5% (10s, 25s, 50s) [adult size]

Reference Range 1-1.3 g/kg oral dose results in plasma glycerin levels of 1.45 mg/mL

Overdosage/Treatment

Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal.

Ocular: Irrigate with copious amounts of saline

Supportive therapy: Monitor serum electrolytes; replace fluids and electrolytes

Pregnancy Risk Factor C

Nursing Implications Apply topical anesthetic before instilling ophthalmic drops. Use caution during insertion of suppository to avoid intestinal perforation, especially in neonates; suppository needs to melt to provide laxative effect; primary use of glycerin in the elderly is as a laxative, although it is not recommended as a first-line treatment.

Glycerin

CAS Number 56-81-5

U.S. Brand Names Bausch & Lomb® Computer Eye Drops [OTC]; Fleet® BabyLax® [OTC]; Fleet® Glycerin Suppositories Maximum Strength [OTC]; Fleet® Glycerin Suppositories [OTC]; Fleet® Liquid Glycerin Suppositories [OTC]; Osmoglyn®; Sani-Supp® [OTC]

Synonyms Glycerol

Use Constipation; reduction of intraocular pressure; reduction of corneal edema; glycerin has been administered orally to reduce intracranial pressure

Mechanism of Action Osmotic dehydrating agent which increases osmotic pressure; draws fluid into colon and thus stimulates evacuation

Adverse Reactions

Cardiovascular: Arrhythmias

Central nervous system: **Headache**, dizziness, confusion, amnesia, pain

Endocrine & metabolic: Polydipsia, hyperglycemia

Gastrointestinal: **Vomiting**, diarrhea, nausea, tenesmus, xerostomia

Hematologic: Hemolytic anemia

Local: Rectal irritation, burning, cramping pain

Otic: Temporary hearing loss

Renal: Renal failure secondary to hemolysis, proteinuria

Miscellaneous: Thirst

Pharmacodynamics/Kinetics

Onset of action:

Decrease in intraocular pressure: Oral: 10-30 minutes

Reduction of intracranial pressure: Oral: 10-60 minutes

Constipation: Suppository: 15-30 minutes

Peak effect:

Decrease in intraocular pressure: Oral: 60-90 minutes

Reduction of intracranial pressure: Oral: 60-90 minutes

Duration:

Decrease in intraocular pressure: Oral: 4-8 hours

Reduction of intracranial pressure: Oral: ~2-3 hours

Absorption: Oral: Well absorbed; Rectal: Poorly absorbed

Half-life elimination, serum: 30-45 minutes

Dosage Constipation: Rectal:

Neonates: 0.5 mL/kg/dose

Gold Compounds

CAS Number 7440-57-5

Synonyms Auranofin; Aurothioglucose; Gold Sodium Thiomalate; Sodium Aurothiomalate

Use Metallic use in dentistry; food coloring agent; auric drug used for treatment of progressive rheumatoid arthritis; adjunctive treatment in adult and juvenile active rheumatoid arthritis; alternative or adjunct in treatment of pemphigus; psoriatic patients who do not respond to NSAIDs

Mechanism of Action May inhibit phagocytosis and lysosomal enzyme

Adverse Reactions

Cardiovascular: Flushing, sinus tachycardia, arrhythmias (ventricular), vasculitis

Central nervous system: Gustatory hallucinations, axonopathy

Dermatologic: Pruritus, hypersensitivity, alopecia, dermal eruption, rash, photosensitivity/phototoxicity, toxic epidermal necrolysis, exfoliative dermatitis, erythema, pemphigus, chrysiasis (total dose ~1 g), pityriasis rosea-like reaction, discoid eczema, erythema annulare centri fugum, acne, angioedema, xerosis, urticaria, purpura, erythema nodosum, exanthem, cutaneous vasculitis

Endocrine & metabolic: Gynecomastia

Gastrointestinal: Nausea, vomiting, diarrhea, gingivitis, loss of taste perception, aphthous stomatitis

Hematologic: Thrombocytopenia, eosinophilia, leukopenia, anemia, red blood cell aplasia

Hepatic: Cholestatic jaundice, hepatitis, hepatic necrosis in overdose situation, cholestatic hepatitis

Neuromuscular & skeletal: Paresthesia

Ocular: Corneal crystalline deposits that usually do not affect vision, iritis

Renal: Proteinuria (17%), tubular necrosis (acute), interstitial nephritis (oral gold is less nephrotoxic than parenteral gold administration), glomerulonephritis, nephrotic syndrome (2.6% to 5.3%)

Respiratory: Wheezing, cough, interstitial lung disease, bronchiolitis obliterans, interstitial pulmonary fibrosis, eosinophilic pneumonia

Miscellaneous: Drug-induced SLE, fixed drug eruption, elevated antineutrophilic cytoplasmic antibodies (ANCA)

Signs and Symptoms of Overdose Agranulocytosis, bleeding, blood dyscrasias, cataract, crystalluria, dementia, dysosmia, eosinophilia, feces discoloration (yellow-green), granulocytopenia, hematuria, leukopenia, lichenoid eruptions, metallic taste, pancreatitis, pemphigus, periarteritis nodosa, photosensitivity, nephrotic syndrome, neutropenia, nystagmus, toxic epidermal necrolysis, ventricular tachycardia, wheezing

Pharmacodynamics/Kinetics

Distribution: V_d : 0.1 L/kg

Protein binding: 95%

Half-life: 5-16 days

Elimination: Normal urinary excretion is 0.1-1 mg/day; 10% to 40% excreted by feces

Dosage

Auranofin: Oral:

Children: Initial: 0.1 mg/kg/day divided daily; usual maintenance: 0.15 mg/kg/day in 1-2 divided doses; maximum: 0.2 mg/kg/day in 1-2 divided doses

Adults: 6 mg/day in 1-2 divided doses; after 3 months may be increased to 9 mg/day in 3 divided doses; if still no response after 3 months at 9 mg/day, discontinue drug

Aurothioglucose: I.M.: Doses should initially be given at weekly intervals

Children 6-12 years: Initial: 0.25 mg/kg/dose first week; increment at 0.25 mg/kg/dose increasing with each weekly dose; maintenance: 0.75-1 mg/kg/dose weekly not to exceed 25 mg/dose to a total of 20 doses, then every 2-4 weeks

Adults: 10 mg first week; 25 mg second and third week; then 50 mg/week until 800 mg to 1 g cumulative dose has been given; if improvement occurs without adverse reactions, give 25-50 mg every 2-3 weeks, then every 3-4 weeks

Gold sodium thiomalate: I.M.:

Children: Initial: Test dose of 10 mg is recommended, followed by 1 mg/kg/week for 20 weeks; maintenance: 1 mg/kg/dose at 2- to 4-week intervals thereafter for as long as therapy is clinically beneficial and toxicity does not develop. Administration for 2-4 months is usually required before clinical improvement is observed.

Adults: 10 mg first week; 25 mg second week; then 25-50 mg/week until 1 g cumulative dose has been given; if improvement occurs without adverse reactions, give 25-50 mg every 2-3 weeks for 2-20 weeks, then every 3-4 weeks indefinitely

Monitoring Parameters CBC, liver function tests, renal function

Dosage Forms Capsule (Auranofin [Ridaura[®]]): 3 mg [gold 29%]

Injection (Gold Sodium Thiomalate [Myochrysin[®] Injection]): 25 mg/mL (1 mL); 50 mg/mL (1 mL, 10 mL)

Suspension, sterile (Aurothioglucose [Solganal[®]]): 50 mg/mL [gold 50%] (10 mL)

Reference Range

Gold: Normal: 0-0.1 mcg/mL (SI: 0-0.0064 μ mol/L); Therapeutic: 1-3 mcg/mL (SI: 0.06-0.18 μ mol/L)

Urine: <0.1 mcg/24 hours

Peak serum gold levels after a 50 mg injection: 6-8 mg/L; after a 450 mg I.M. injection: 29.7 mg/L

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: For thrombocytopenia refractory to chelation therapy, cyclophosphamide (100 mg/day for 6 months or until platelet count was > 100,000 with subsequent reduction of dose to 75 mg/day) can be utilized; high-dose I.V. N-acetylcysteine may be useful to treat hematologic toxicity due to gold (2-9 g in 100 mL of D₅¹/₂NS over 2-6 hours, total dose: 13-153 g); chrysiasis can be treated with corticosteroids (systemically) and topical 2% solution of hydroquinone; gold-induced pulmonary disease should be treated with prednisone (30-60 mg/day); agranulocytosis can be treated with SubQ granulocyte-colony stimulating factor (5 mcg/kg/day)

Enhancement of elimination: Chelation with BAL (dimercaprol) or D-penicillamine (250 mg 4 times/day for 11 days) can increase elimination; hemodialysis is not useful

Antidote(s)

- Dimercaprol [ANTIDOTE]
- Penicillamine [ANTIDOTE]

Diagnostic Procedures

- Gold Level

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic in animals; not proven to be teratogenic in humans; not compatible for breast-feeding since it is excreted in breast milk

Additional Information Mean cumulative dose of gold for gold-induced thrombocytopenia is 840 mg. HLA-DR3 positive individuals exhibit an 8.9 times increased risk of thrombocytopenia and a 32 times increased risk of proteinuria

Granisetron

CAS Number 109889-09-0

U.S. Brand Names Kytril[®]

Synonyms BRL 43694

Use

Prophylaxis of chemotherapy-related emesis; prophylaxis of nausea and vomiting associated with radiation therapy, including total body irradiation and fractionated abdominal radiation; prophylaxis of postoperative nausea and vomiting (PONV)

Generally **not** recommended for treatment of existing chemotherapy-induced emesis (CIE) or for prophylaxis of nausea from agents with a low emetogenic potential.

Mechanism of Action Selective 5-HT₃ receptor antagonist, blocking serotonin, both peripherally on vagal nerve terminals and centrally in the chemoreceptor trigger zone

Adverse Reactions

Cardiovascular: Transient blood pressure changes

Central nervous system: Agitation, **headache**, fever, insomnia, somnolence, extrapyramidal reactions

Endocrine & metabolic: Hot flashes

Gastrointestinal: Constipation, diarrhea, pancreatitis

Hepatic: Liver enzyme elevations

Neuromuscular & skeletal: Weakness

Signs and Symptoms of Overdose Myalgia, somnolence

Pharmacodynamics/Kinetics

Duration: Generally up to 24 hours

Absorption: Tablets and oral solution are bioequivalent

Distribution: V_d : 2-4 L/kg; widely throughout body

Protein binding: 65%

Metabolism: Hepatic via N-demethylation, oxidation, and conjugation; some metabolites may have 5-HT₃ antagonist activity

Half-life elimination: Terminal: 5-9 hours

Excretion: Urine (12% as unchanged drug, 48% to 49% as metabolites); feces (34% to 38% as metabolites)

Dosage

Oral: Adults:

Prophylaxis of chemotherapy-related emesis: 2 mg once daily up to 1 hour before chemotherapy or 1 mg twice daily; the first 1 mg dose should be given up to 1 hour before chemotherapy.

Prophylaxis of radiation therapy-associated emesis: 2 mg once daily given 1 hour before radiation therapy.

I.V.:

Children \geq 2 years and Adults: Prophylaxis of chemotherapy-related emesis:

Within U.S.: 10 mcg/kg/dose (or 1 mg/dose) administered IVPB over 5 minutes given within 30 minutes of chemotherapy; for some drugs (eg, carboplatin, cyclophosphamide) with a later onset of emetic action, 10 mcg/kg every 12 hours may be necessary.

Outside U.S.: 40 mcg/kg/dose (or 3 mg/dose); maximum: 9 mg/24 hours

Breakthrough: Repeat the dose 2-3 times within the first 24 hours as necessary (**not based on controlled trials, or generally recommended**)

Adults: PONV:

Prevention: 1 mg given undiluted over 30 seconds; administer before induction of anesthesia or before reversal of anesthesia

Treatment: 1 mg given undiluted over 30 seconds

Dosing interval in renal impairment: No dosage adjustment required.

Dosing interval in hepatic impairment: Kinetic studies in patients with hepatic impairment showed that total clearance was approximately halved, however, standard doses were very well tolerated

Monitoring Parameters Liver function tests

Administration Oral: Doses should be given up to 1 hour prior to initiation of chemotherapy/radiation

I.V.: Administer as rapid (30 second) I.V. push or a short (5-10 minutes) infusion

For prevention of PONV, administer before induction of anesthesia or before reversal of anesthesia.

For PONV, administer undiluted over 30 seconds.

Contraindications Previous hypersensitivity to granisetron, other 5-HT₃ receptor antagonists, or any component of the formulation

Warnings

Chemotherapy-related emesis: **Granisetron should be used on a scheduled basis, not on an "as needed" (PRN) basis**, since data support the use of this drug in the prevention of nausea and vomiting and not in the rescue of nausea and vomiting. Granisetron should be used only in the first 24-48 hours of receiving chemotherapy or radiation. Data do not support any increased efficacy of granisetron in delayed nausea and vomiting. May be prescribed for patients who are refractory to or have

severe adverse reactions to standard antiemetic therapy or young patients (ie, <45 years of age who are more likely to develop extrapyramidal symptoms to high-dose metoclopramide) who are to receive highly emetogenic chemotherapeutic agents. Should not be prescribed for chemotherapeutic agents with a low emetogenic potential (eg, bleomycin, busulfan, etoposide, 5-fluorouracil, vinblastine, vincristine).

Routine prophylaxis for PONV is not recommended. In patients where nausea and vomiting must be avoided postoperatively, administer to all patients even when expected incidence of nausea and vomiting is low. Use caution following abdominal surgery or in chemotherapy-induced nausea and vomiting; may mask progressive ileus or gastric distention. Use caution in patients with liver disease or in pregnancy. Safety and efficacy in children <2 years of age have not been established. Injection contains benzyl alcohol (1 mg/mL) and should not be used in neonates.

Dosage Forms Injection, solution: 1 mg/mL (1 mL, 4 mL) [contains benzyl alcohol]
Injection, solution [preservative free]: 0.1 mg/mL (1 mL)
Solution, oral: 2 mg/10 mL (30 mL) [contains sodium benzoate; orange flavor]
Tablet: 1 mg

Reference Range Peak serum levels: 11-124 ng/mL following a 40 mcg/kg dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Drug Interactions Substrate of CYP3A4 (minor)

Apomorphine: Due to reports of profound hypotension during concomitant therapy with other 5-HT3 antagonists, the manufacturer of apomorphine contraindicates its use with granisetron.

Pregnancy Risk Factor B

Pregnancy Implications There are no adequate or well-controlled studies in pregnant women. Teratogenic effects were not observed in animal studies. Injection (1 mg/mL strength) contains benzyl alcohol which may cross the placenta. Use only if benefit exceeds the risk.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Doses should be given at least 15 minutes prior to initiation of chemotherapy

Additional Information Granisetron (10 mcg/kg I.V.) can decrease nausea and emesis associated with activated charcoal/sorbitol administration; granisetron (3 mg I.V.) is effective when used with dexamethasone to prevent emesis due to chemotherapy

Griseofulvin

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 126-07-8

U.S. Brand Names Fulvicin-U/F[®]; Fulvicin[®] P/G; Grifulvin[®] V; Gris-PEG[®]

Synonyms Griseofulvin Microsize; Griseofulvin Ultramicrosized

Use Treatment of susceptible tinea infections of the skin, hair, and nails

Mechanism of Action Inhibits fungal cell mitosis at metaphase; binds to human keratin making it resistant to fungal invasion

Adverse Reactions

Central nervous system: Headache, fatigue, dizziness, insomnia, mental confusion
Dermatologic: Rash (most common), urticaria (most common), photosensitivity, erythema multiforme, angioneurotic edema (rare)
Gastrointestinal: Nausea, vomiting, epigastric distress, diarrhea, GI bleeding
Genitourinary: Menstrual irregularities (rare)
Hematologic: Leukopenia, granulocytopenia
Neuromuscular & skeletal: Paresthesia (rare)
Renal: Hepatotoxicity, proteinuria, nephrosis
Miscellaneous: Oral thrush, drug-induced lupus-like syndrome (rare)

Signs and Symptoms of Overdose Cholestatic jaundice, depression, erythema multiforme, leukopenia or neutropenia (agranulocytosis, granulocytopenia), insomnia, photosensitivity, toxic epidermal necrolysis, vision color changes (green tinge); porphyrinogenic

Pharmacodynamics/Kinetics

Absorption: Ultramicrosized griseofulvin absorption is almost complete; absorption of microsize griseofulvin is variable (25% to 70% of an oral dose); enhanced by ingestion of a fatty meal (GI absorption of ultramicrosized is ~1.5 times that of microsize)

Distribution: Crosses placenta

Metabolism: Extensively hepatic

Half-life elimination: 9-22 hours

Excretion: Urine (<1% as unchanged drug); feces; perspiration

Dosage

Oral:

Children >2 years:

Microsize: 10-20 mg/kg/day in single or 2 divided doses

Ultramicrosized: >2 years: 5-10 mg/kg/day in single or 2 divided doses
Adults:

Microsize: 500-1000 mg/day in single or divided doses

Ultramicrosized: 330-375 mg/day in single or divided doses; doses up to 750 mg/day have been used for infections more difficult to eradicate such as tinea unguium

Duration of therapy depends on the site of infection:

Tinea corporis: 2-4 weeks

Tinea capitis: 4-6 weeks or longer

Tinea pedis: 4-8 weeks

Tinea unguium: 3-6 months or longer

Monitoring Parameters Periodic renal, hepatic, and hematopoietic function tests

Administration Oral: Administer with a fatty meal (peanuts or ice cream) to increase absorption, or with food or milk to avoid GI upset

Contraindications Hypersensitivity to griseofulvin or any component of the formulation; severe liver disease; porphyria (interferes with porphyrin metabolism)

Warnings Safe use in children ≤2 years of age has not been established; during long-term therapy, periodic assessment of hepatic, renal, and hematopoietic functions should be performed; may cause fetal harm when administered to pregnant women; avoid exposure to intense sunlight to prevent photosensitivity reactions; hypersensitivity cross reaction between penicillins and griseofulvin is possible

Dosage Forms

Suspension, oral, microsize (Grifulvin[®] V): 125 mg/5 mL (120 mL) [contains alcohol 0.2%]

Tablet, microsize (Grifulvin[®] V): 500 mg

Tablet, ultramicrosized: 125 mg, 250 mg, 330 mg

Gris-PEG[®]: 125 mg, 250 mg

Reference Range Peak plasma griseofulvin level of 1 mcg/mL after a 500 mg dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: For treatment of lingua villosa nigra, discontinue causative agent. Clean the tongue with a toothbrush and rinse mouth with a half-strength solution of hydrogen peroxide or 10% carbamide peroxide. Symptoms should subside in a few days.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Test Interactions False-positive urinary VMA levels

Drug Interactions Induces CYP1A2 (weak), 2C8 (weak), 2C9 (weak), 3A4 (weak)

Decreased effect:

Barbiturates may decrease levels of griseofulvin

Decreased warfarin, cyclosporine, and salicylate activity with griseofulvin

Griseofulvin decreases oral contraceptive effectiveness

Increased toxicity: With ethanol, may cause tachycardia and flushing

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Additional Information Microsize: Fulvicin-U/F[®], Grifulvin[®] V, Grisactin[®]: 66% effective for treating pediatric tinea capitis
Ultramicrosized: Fulvicin[®] P/G, Grisactin[®] Ultra, Gris-PEG[®]; gastrointestinal absorption of ultramicrosized is ~1.5 times that of microsize

Specific References

Guaifenesin

CAS Number 93-14-1

U.S. Brand Names Allfen Jr; Amibid LA [DSC]; Diabetic Tussin[®] EX [OTC]; Ganidin NR; Guaiatuss[™] [OTC]; Humibid[®] LA [DSC]; Humibid[®] Pediatric [DSC]; Iophen NR; Liquibid[®] 1200 [DSC]; Liquibid[®] [DSC]; Mucinex[®] [OTC]; Naldecon Senior EX[®] [OTC]; Organ-1 NR; Organidin[®] NR; Phanasin [OTC]; Phanasin[®] Diabetic Choice [OTC]; Q-Tussin [OTC]; Respa-GF[®] [DSC]; Robitussin[®] [OTC]; Scot-Tussin[®] Expectorant [OTC]; Siltussin DAS [OTC]; Siltussin SA [OTC]; Touro Ex[®] [DSC]; Tussin [OTC]

Synonyms GG; Glycerol Guaiacolate

Use Help loosen phlegm and thin bronchial secretions to make coughs more productive

Mechanism of Action Thought to act as an expectorant by irritating the gastric mucosa and stimulating respiratory tract secretions, thereby increasing respiratory fluid volumes and decreasing phlegm viscosity

Adverse Reactions

Frequency not defined.

Central nervous system: Dizziness, drowsiness, headache

Dermatologic: Rash

Endocrine & metabolic: Uric acid levels decreased

Gastrointestinal: Nausea, vomiting, stomach pain

Renal: Kidney stone formation (with consumption of large quantities)

Signs and Symptoms of Overdose Coma, lethargy, nausea, respiratory depression, vomiting

Pharmacodynamics/Kinetics

Absorption: Well absorbed
 Half-life elimination: ~1 hour
 Excretion: Urine (as unchanged drug and metabolites)

Dosage

Oral:
 Children:
 6 months to 2 years: 25-50 mg every 4 hours, not to exceed 300 mg/day
 2-5 years: 50-100 mg every 4 hours, not to exceed 600 mg/day
 6-11 years: 100-200 mg every 4 hours, not to exceed 1.2 g/day
 Children > 12 years and Adults: 200-400 mg every 4 hours to a maximum of 2.4 g/day
 Extended release tablet: 600-1200 mg every 12 hours, not to exceed 2.4 g/day

Monitoring Parameters Cough, sputum consistency and volume

Administration Do not crush, chew, or break extended release tablets; administer with a full glass of water

Contraindications Hypersensitivity to guaifenesin or any component of the formulation

Warnings Not for persistent cough such as occurs with smoking, asthma, chronic bronchitis, or emphysema or cough accompanied by excessive secretions. When used for self-medication (OTC), contact healthcare provider if needed for >7 days or for a cough with a fever, rash, or persistent headache.

Dosage Forms [DSC] = Discontinued product

Liquid: 100 mg/5 mL (120 mL, 480 mL)
 Diabetic Tussin EX®: 100 mg/5 mL (120 mL) [alcohol free, sugar free, dye free; contains phenylalanine 8.4 mg/5 mL]
 Ganidin NR: 100 mg/5 mL (480 mL) [raspberry flavor]
 Iphen NR: 100 mg/5 mL (480 mL)
 Organidin® NR: 100 mg/5 mL (480 mL) [contains sodium benzoate; raspberry flavor]
 Q-Tussin: 100 mg/5 mL (120 mL, 240 mL, 480 mL, 3840 mL) [alcohol free; cherry flavor]
 Siltussin DAS: 100 mg/5 mL (120 mL) [alcohol free, dye free, sugar free; strawberry flavor]
 Syrup: 100 mg/5 mL (120 mL, 480 mL)
 Guiatuss™: 100 mg/5 mL (120 mL, 480 mL) [alcohol free; fruit-mint flavor]
 Phanasin®: 100 mg/5 mL (120 mL, 240 mL) [alcohol free, sugar free; mint flavor]
 Phanasin® Diabetic Choice: 100 mg/5 mL (120 mL) [alcohol free, sugar free; mint flavor]
 Robitussin®: 100 mg/5 mL (5 mL, 10 mL, 15 mL, 30 mL, 120 mL, 240 mL, 480 mL) [alcohol free; contains sodium benzoate]
 Scot-Tussin® Expectorant: 100 mg/5 mL (120 mL) [alcohol free, dye free, sugar free; contains benzoic acid; grape flavor]
 Siltussin SA: 100 mg/5 mL (120 mL, 240 mL, 480 mL) [alcohol free, sugar free; strawberry flavor]
 Tussin: 100 mg/5 mL (120 mL, 240 mL)
 Vicks® Casero™: 100 mg/6.25 mL (120 mL, 480 mL) [contains phenylalanine 5.5 mg/12.5 mL, sodium 32 mg/12.5 mL, and sodium benzoate; honey menthol flavor]
 Syrup, oral drops (Phanasin®): 50 mg/mL (50 mL) [alcohol free, sugar free; fruit flavor]
 Tablet: 200 mg
 Allfen Jr: 400 mg [dye free]
 Humibid® e: 400 mg [DSC]
 Organ-1 NR, Organidin® NR: 200 mg
 XPECT™: 400 mg
 Tablet, extended release:
 Humibid® Maximum Strength: 1200 mg
 Mucinex®: 600 mg

Reference Range 600 mg oral dose results in a peak guaifenesin blood level of 1.4 mg/L

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Test Interactions Possible color interference with determination of 5-HIAA and VMA; ↓ serum uric acid (uricosuric)

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/use caution

Guanabenz

CAS Number 23256-50-0; 5051-62-7
U.S. Brand Names Wytensin® [DSC]
Synonyms Guanabenz Acetate
Impairment Potential Yes
Use Management of mild to moderate hypertension

Mechanism of Action Stimulates alpha₂-adrenoreceptors in the brain stem, thus activating an inhibitory neuron, resulting in reduced sympathetic outflow, producing a decrease in vasomotor tone and heart rate

Adverse Reactions

Cardiovascular: Bradycardia, chest pain, sinus bradycardia, angina, palpitations, vasodilation
 Central nervous system: **Drowsiness, dizziness**, hypothermia, headache
 Gastrointestinal: Nausea, **xerostomia**
 Neuromuscular & skeletal: **Weakness**
 Ocular: Miosis

Signs and Symptoms of Overdose Apnea, bradycardia, CNS depression, depression, diarrhea, drowsiness, dyspnea, gynecomastia, hyperglycemia, hypoglycemia, hypotension, hypothermia, impotence, miosis, myalgia

Pharmacodynamics/Kinetics

Onset of action: Antihypertensive effects occur within 60 minutes
 Duration: 12 hours
 Absorption: Oral: ~75% from gastrointestinal tract
 Distribution: V_d: 7.4-17 L/kg; widely distributed into body
 Protein binding: 90%
 Metabolism: Extensive
 Bioavailability: Very low because of extensive first-pass metabolism
 Half-life: 7-10 hours
 Time to peak serum concentration: 2-5 hours
 Elimination: < 1% excreted as unchanged drug in urine

Dosage

Adults: Oral: Initial: 4 mg twice daily, increase in increments of 4-8 mg/day every 1-2 weeks to a maximum of 32 mg twice daily

Dosing adjustment in hepatic impairment: Probably necessary

Stability Protect from light

Monitoring Parameters Blood pressure, standing and sitting/supine

Contraindications Hypersensitivity to guanabenz or any component of the formulation

Warnings Use with caution in severe hepatic or renal failure. Avoid in pregnancy and breast-feeding. Safety and efficacy for use in children < 12 years of age have not been demonstrated. Use with caution in patients with severe coronary insufficiency, recent MI or cerebrovascular disease. Abrupt discontinuation can result in rebound hypertension. Avoid use in CNS disease, elderly or with other CNS depressants (can cause sedation and drowsiness alone). May cause significant orthostasis.

Dosage Forms Tablet: 4 mg, 8 mg

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal
 Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral vasoconstrictor may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Naloxone may be utilized in treating the hypotension, CNS depression, and/or apnea and should be given I.V. 0.4-2 mg, with repeats as needed. Atropine 15 mcg/kg I.V. or I.M. may be needed for symptomatic bradycardia.
 Enhancement of elimination: Multiple dosing of activated charcoal would not be useful; hemodialysis is not useful

Test Interactions ↑ sodium (S)

Drug Interactions Substrate of CYP1A2 (major)

CYP1A2 inducers: May decrease the levels/effects of guanabenz. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.
 CYP1A2 inhibitors: May increase the levels/effects of guanabenz. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.
 Hypoglycemic symptoms may be reduced. Educate patient about decreased signs and symptoms of hypoglycemia or avoid use in patients with frequent episodes of hypoglycemia.
 Nitroprusside and guanabenz have additive hypotensive effects.
 Noncardioselective beta-blockers (nadolol, propranolol, timolol) may exacerbate rebound hypertension when guanabenz is withdrawn. The beta-blocker should be withdrawn first. The gradual withdrawal of guanabenz or a cardioselective beta-blocker could be substituted.
 TCAs decrease the hypotensive effect of guanabenz.

Pregnancy Risk Factor C

Additional Information Guanabenz is considered an alternate to clonidine; it causes less sodium retention than clonidine or methyl dopa.

Guanadrel

CAS Number 22195-34-2; 40580-59-4
U.S. Brand Names Hyloriel®
Synonyms Guanadrel Sulfate
Impairment Potential Yes
Use Step 2 agent in stepped-care treatment of hypertension, usually with a diuretic

Mechanism of Action Acts as a false neurotransmitter that blocks the adrenergic actions of norepinephrine; it displaces norepinephrine from its presynaptic storage granules and thus exposes it to degradation; it thereby produces a reduction in total peripheral resistance and therefore blood pressure

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), **palpitations, chest pain, angina, peripheral edema**
 Central nervous system: **Fatigue, dizziness, headache, faintness, drowsiness, confusion**
 Gastrointestinal: Diarrhea, **increased bowel movements, constipation, gas pain, anorexia, weight gain or loss**
 Genitourinary: **Ejaculatory disturbances, nocturia**
 Neuromuscular & skeletal: Weakness, **paresthesia, aching limbs, leg cramps, backache, arthralgia**
 Ocular: Blurred vision, **visual disturbances**
 Renal: **Polyuria**
 Respiratory: **Dyspnea, coughing**

Signs and Symptoms of Overdose Blurred vision, ejaculatory disturbances, dizziness, hypotension, nausea, nocturia, vomiting

Pharmacodynamics/Kinetics

Onset of action: Peak effect: 4-6 hours
 Duration: 4-14 hours
 Absorption: Rapid
 Half-life elimination, serum: Biphasic: Initial: 1-4 hours; Terminal: 5-45 hours
 Time to peak, serum: 1.5-2 hours

Dosage Adults: Oral: Initial: 10 mg/day (5 mg twice daily); adjust dosage until blood pressure is controlled, usual dosage: 20-75 mg/day, given twice daily

Dosing in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer every 12-24 hours
 Cl_{cr} < 10 mL/minute: Administer every 24-48 hours

Monitoring Parameters Blood pressure, standing and sitting/supine

Contraindications Hypersensitivity to guanadrel or any component of the formulation; known or suspected pheochromocytoma; concurrent use or within 1 week of any MAO inhibitor; exacerbation of CHF

Warnings Orthostatic hypotension is common. Avoid using other drugs that cause orthostatic hypotension (alpha-blocking agents or reserpine). Discontinue 48-72 hours before elective surgery (reduces potential for vascular collapse). If emergency surgery required, notify anesthesiologist of the drug regimen. Avoid using tricyclic antidepressants and indirect-acting sympathomimetics (can reverse the blood pressure lowering effects). Use cautiously in asthma (may aggravate condition), CHF (sodium and water retention), and PUD (may aggravate condition). Safety and efficacy have not been established in pediatric patients. Dosage adjustment required with renal dysfunction.

Dosage Forms Tablet, as sulfate: 10 mg, 25 mg

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal
 Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral vasoconstrictor may be required (eg, dopamine 2-5 mcg/kg/minute titrated to 10 mcg/kg/minute). Naloxone may be utilized in treating hypotension, CNS depression, and/or apnea and should be given I.V. 0.4-2 mg, with repeats as needed. Atropine 15 mcg/kg I.V. or I.M. may be needed for symptomatic bradycardia.
 Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Test Interactions ↑ sodium (S)

Drug Interactions TCAs decrease hypotensive effect of guanadrel.

Increased toxicity of direct-acting amines (epinephrine, norepinephrine) by guanadrel; the hypotensive effect of guanadrel may be potentiated. Increased effect of beta-blockers, vasodilators.
 Phenothiazines may inhibit the antihypertensive response to guanadrel; consider an alternative antihypertensive with different mechanism of action.
 Amphetamines, related sympathomimetics, and methylphenidate decrease the antihypertensive response to guanadrel; consider an alternative antihypertensive with different mechanism of action. Reassess the need for amphetamine, related sympathomimetic, or methylphenidate; consider alternatives.
 Ephedrine may inhibit the antihypertensive response to guanadrel; consider an alternative antihypertensive with different mechanism of action. Reassess the need for ephedrine.
 Norepinephrine/phenylephrine have exaggerated pressor response; monitor blood pressure closely.
 MAO inhibitors may cause severe hypertension; give at least 1 week apart.

Pregnancy Risk Factor B

Pregnancy Implications Crosses the placenta

Nursing Implications Tablet may be crushed; assist patient with rising and ambulation

Additional Information Considered an alternative to guanethidine

Guanethidine

CAS Number 55-65-2; 645-43-2

Synonyms Guanethidine Monosulfate

Impairment Potential Yes

Use Treatment of moderate to severe hypertension; also useful in treating vasopressin extravasation

Mechanism of Action Acts as a false neurotransmitter that blocks the adrenergic actions of norepinephrine; it displaces norepinephrine from its presynaptic storage granules and thus exposes it to degradation; it thereby produces a reduction in total peripheral resistance and therefore blood pressure

Adverse Reactions

Cardiovascular: **Palpitations, chest pain**, hypotension (orthostatic), vasculitis, hypertension in patients with pheochromocytoma, AV block, sinus bradycardia, angina, vasodilation, **peripheral edema**
 Central nervous system: **Fatigue, dizziness, drowsiness, faintness, headache, confusion**
 Dermatologic: Cutaneous vasculitis
 Endocrine & metabolic: Parotitis, hypoglycemia
 Gastrointestinal: Diarrhea, **increased bowel movements, gas pain, constipation, anorexia, weight gain or loss**
 Genitourinary: **Ejaculatory disturbances, nocturia, impotence**
 Neuromuscular & skeletal: Weakness, **paresthesia, aching limbs, leg cramps, backache, arthralgia**
 Ocular: Blurred vision, diplopia, **visual disturbances**
 Renal: **Polyuria**, renal vasculitis
 Respiratory: **Dyspnea, coughing**

Signs and Symptoms of Overdose Blurred vision, dizziness, ejaculatory disturbances, hypotension, impotence, nausea, nocturia, periarthritis nodosa, ptosis, syncope, vomiting

Pharmacodynamics/Kinetics

Onset of action: 0.5-2 hours
 Peak effect: Antihypertensive: 6-8 hours
 Duration: 24-48 hours
 Absorption: Irregular (3% to 55%)
 Half-life elimination, serum: 5-10 days

Dosage Oral:

Children: Initial: 0.2 mg/kg/day, increase by 0.2 mg/kg/day at 7- to 10-day intervals to a maximum of 3 mg/kg/day
 Adults:
 Ambulatory patients: Initial: 10 mg/day, increase at 5- to 7-day intervals to a maximum of 25-50 mg/day
 Hospitalized patients: Initial: 25-50 mg/day, increase by 25-50 mg/day or every other day to desired therapeutic response
 Vasopressin extravasation: 10 mg in 0.9% saline (10 mL) with 1000 units of heparin either through offending I.V. cannulas or through multiple SubQ injections after removal of catheter; apply ice to affected area
Dosing interval in renal impairment: Cl_{cr} < 10 mL/minute: Administer every 24-36 hours

Monitoring Parameters Blood pressure, standing and sitting/supine

Contraindications Hypersensitivity to guanethidine or any component of the formulation; known or suspected pheochromocytoma; concurrent use or within 1 week of any MAO inhibitor; exacerbation of CHF (unrelated to HTN)

Warnings Orthostatic hypotension is common. Avoid using other drugs that cause orthostatic hypotension (alpha-blocking agents or reserpine). Discontinue 2 weeks before elective surgery (reduces potential for vascular collapse). If emergency surgery required, notify anesthesiologist of the drug regimen. Fever reduces dosage requirements. Avoid using tricyclic antidepressants and indirect-acting sympathomimetics (can reverse the blood pressure lowering effects). Use cautiously in asthma (may aggravate condition), CHF (sodium and water retention), renal dysfunction (can worsen renal function), recent MI, cerebrovascular disease with encephalopathy, and PUD (may aggravate condition). Safety and efficacy have not been established in pediatric patients. Dosage adjustment required with severe renal dysfunction.

Dosage Forms Tablet, as monosulfate: 10 mg, 25 mg

Reference Range Adrenergic blockade at plasma concentrations of 8 ng/mL

Overdosage/Treatment Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral vasoconstrictor may be required (eg, dopamine at 2-5 mcg/kg/minute titrated to 10 mcg/kg/minute). Treatment is primarily supportive and symptomatic; overdose symptoms usually last for 72 hours.

Test Interactions ↑ sodium (S); ↓ catecholamines (S)

Drug Interactions TCAs decrease hypotensive effect of guanethidine. Phenothiazines may inhibit the antihypertensive response to guanethidine consider an alternative antihypertensive with different mechanism of action.

Amphetamines, related sympathomimetics, and methylphenidate decrease the antihypertensive response to guanethidine; consider an alternative antihypertensive with different mechanism of action. Reas-

less the need for amphetamine, related sympathomimetic, or methylphenidate; consider alternatives.
 Ephedrine may inhibit the antihypertensive response to guanethidine; consider an alternative antihypertensive with different mechanism of action. Reassess the need for ephedrine.
 Norepinephrine/phenylephrine have exaggerated pressor response; monitor blood pressure closely.
 Oral contraceptives may decrease hypotensive effect; avoid concurrent use.
 Minoxidil may cause severe orthostatic hypotension; avoid concurrent use.
 Enflurane may cause hypotension; avoid concurrent use.

Pregnancy Risk Factor C

Nursing Implications Tablet may be crushed

Guanfacine

CAS Number 29110-47-2

U.S. Brand Names Tenex®

Synonyms Guanfacine Hydrochloride

Use Management of hypertension

Unlabeled/Investigational Use ADHD, tic disorder, aggression

Mechanism of Action False neurotransmitter (alpha₂-adrenoceptor agonist) that blocks the adrenergic actions of norepinephrine; displaces norepinephrine from its presynaptic storage granules and thus exposes it to degradation and, thereby, produces a reduction in total peripheral resistance and, therefore, blood pressure; structurally related to guanabenz, methyllopa, and clonidine

Adverse Reactions

Cardiovascular: Bradycardia, chest pain, edema, hypotension, orthostasis, palpitations, rebound hypertension, syncope
 Central nervous system: Agitation, amnesia, confusion, depression, **dizziness, headache**, fatigue, insomnia, malaise, nervousness, **somnolence**, vertigo
 Dermatologic: Alopecia, dermatitis, exfoliative dermatitis, pruritus, rash
 Endocrine & metabolic: Impotence
 Gastrointestinal: **Xerostomia, constipation**, dysphagia
 Genitourinary: Urinary incontinence
 Neuromuscular & skeletal: Hypokinesia, leg cramps, paresthesia
 Ocular: Blurred vision
 Otic: Tinnitus
 Respiratory: Dyspnea
 Miscellaneous: Diaphoresis

Note: Mania and aggressive behavior have been reported in pediatric patients with ADHD who received guanfacine.

Signs and Symptoms of Overdose Apnea, bradycardia (within 2 hours of ingestion), CNS depression, dermatitis, diarrhea, drowsiness, dysphagia, hypomagnesemia, hypotension (4-8 hours postingestion), hypothermia, impotence, insomnia, leg cramps, myalgia. Paradoxical hypertension can occur.

Admission Criteria/Prognosis Admit ingestions >3 mg in children or 30 mg in adults

Pharmacodynamics/Kinetics

Onset of action: Peak effect: 8-11 hours
 Duration: 24 hours following single dose
 Half-life elimination, serum: 17 hours
 Time to peak, serum: 1-4 hours

Dosage

Adults: Oral: Hypertension: 1 mg usually at bedtime, may increase if needed at 3- to 4-week intervals; usual dose range (JNC 7): 0.5-2 mg once daily

Monitoring Parameters Blood pressure, standing and sitting/supine, ECG

Contraindications Hypersensitivity to guanfacine or any component of the formulation

Warnings Use caution with severe coronary insufficiency, recent MI, cerebrovascular disease, or chronic renal or hepatic disease. Abrupt discontinuation can result in nervousness, anxiety and rarely, rebound hypertension (occurs 2-4 days after withdrawal). Avoid use in CNS disease, elderly, or with other CNS depressants (can cause sedation and drowsiness alone). Caution in diabetes; may mask signs of hypoglycemia. Safety and efficacy in children <12 years of age have not been demonstrated. May cause orthostasis.

Dosage Forms Tablet: 1 mg, 2 mg

Reference Range Adult therapeutic effect at serum levels of 1.5-2.0 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral vasoconstrictor may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Naloxone may be utilized in treating the hypotension, CNS depression and/or apnea and should be given I.V. 0.4-2 mg, with repeats as needed. Atropine 15 mcg/kg I.V. or I.M. may be needed for symptomatic bradycardia.

Enhancement of elimination: Hemodialysis is not useful due to its large volume of distribution.

Antidote(s)

● Naloxone [ANTIDOTE]

Test Interactions ↑ cholesterol, sodium (S), triglycerides, AST, GPT

Drug Interactions

Nitroprusside and guanfacine have additive hypotensive effects.
 Noncardioselective beta-blockers (nadolol, propranolol, timolol) may exacerbate rebound hypertension when guanfacine is withdrawn. The beta-blocker should be withdrawn first. The gradual withdrawal of guanfacine or a cardioselective beta-blocker could be substituted.
 TCAs decrease the hypotensive effect of guanfacine.

Pregnancy Risk Factor B

Nursing Implications Tablet may be crushed; assist patient with rising and ambulation

Additional Information Usually given with a thiazide diuretic

Specific References

Chobanian AV, Bakris GL, Black HR, et al, "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, 289(19):2560-71.

Guanidine

Pronunciation (GWAHN i deen)

CAS Number 113-00-8; 50-01-1

Synonyms Guanidine Hydrochloride

Use Reduction of symptoms of muscle weakness associated with the myasthenic syndrome of Eaton-Lambert, not for myasthenia gravis; has been used in botulism (type B) to reverse neuromuscular blockade with disappointing results

Adverse Reactions

Cardiovascular: Bradycardia, AV block, chest pain, sinus bradycardia, angina
 Central nervous system: Headache, seizures, dysphoria, drowsiness, ataxia
 Endocrine & metabolic: Hypoglycemia
 Gastrointestinal: **Diarrhea, nausea**, abdominal pain, **stomach cramps**
 Genitourinary: Urge to urinate
 Hematologic: Aplastic anemia
 Local: Thrombophlebitis
 Neuromuscular & skeletal: Muscle spasm, tremors, weakness
 Ocular: Lacrimation, miosis, diplopia
 Respiratory: Increased bronchial secretions, respiratory paralysis, laryngospasm
 Miscellaneous: **Diaphoresis and mouth watering (increased)**, hypersensitivity, hyper-reactive cholinergic responses

Dosage Adults: Oral: Initial: 10-15 mg/kg/day in 3-4 divided doses, gradually increase to 40 mg/kg/day

Dosage Forms Tablet, as hydrochloride: 125 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Treat symptomatic bradycardia with atropine

Test Interactions ↑ creatinine; ↓ glucose

Additional Information Primary effect on botulism is on improvement in ocular muscles; little effect on respiratory function

Haloperidol

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antipsychotic Agents

CAS Number 52-86-8; 74050-97-8

U.S. Brand Names Haldol® Decanoate; Haldol®

Synonyms Haloperidol Decanoate; Haloperidol Lactate

Impairment Potential Yes

Use Management of schizophrenia; control of tics and vocal utterances of Tourette's disorder in children and adults; severe behavioral problems in children

Unlabeled/Investigational Use Treatment of psychosis; may be used for the emergency sedation of severely-agitated or delirious patients; adjunctive treatment of ethanol dependence; antiemetic

Mechanism of Action Competitive blockade of postsynaptic dopamine receptors in the mesolimbic dopaminergic system; depresses cerebral cortex and hypothalamus; exhibits a strong alpha-adrenergic and anticholinergic-blocking activity

Adverse Reactions

Sedation and anticholinergic effects are more pronounced than extrapyramidal effects; ECG changes, retinal pigmentation are more common than with chlorpromazine; concomitant therapy with perazine can cause agranulocytosis and hepatotoxicity
 Cardiovascular: Arrhythmias (especially orthostatic hypotension), tachycardia, cardiac arrhythmias, abnormal T waves with prolonged ven-

tricular repolarization, sinus bradycardia, sinus tachycardia, arrhythmias (ventricular), torsade de pointes (case-control study ~4%)

Central nervous system: Sedation, drowsiness, **restlessness, anxiety, extrapyramidal reactions, dystonic reactions, pseudoparkinsonian signs and symptoms, tardive dyskinesia, neuroleptic malignant syndrome, seizures, altered central temperature regulation**, electroencephalogram abnormalities, memory disturbance, **akathisia**

Dermatologic: Hyperpigmentation, pruritus, rash, contact dermatitis, photosensitivity (rare), alopecia, exfoliative dermatitis, acne, urticaria, purpura, exanthem

Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, syndrome of inappropriate antidiuretic hormone, sexual dysfunction, **edema of the breasts**

Gastrointestinal: **Constipation**, adynamic ileus, dyspepsia, GI upset, xerostomia (problem for denture user), **weight gain**

Genitourinary: Urinary retention, overflow incontinence, priapism

Hematologic: Leukopenia/neutropenia (agranulocytosis, granulocytopenia) (usually inpatients with large doses for prolonged periods), thrombocytopenia

Hepatic: Cholestatic jaundice

Neuromuscular & skeletal: Trismus, rhabdomyolysis, Meige syndrome

Ocular: **Blurred vision**, retinal pigmentation, decreased visual acuity (may be irreversible)

Renal: Myoglobinuria

Miscellaneous: Bruxism, systemic lupus erythematosus

Signs and Symptoms of Overdose Agitation, alopecia, arrhythmias, bradycardia, chorea (extrapyramidal), confusion, deep sleep, dementia, disorientation, dry mouth, dysphagia, dystonic reactions, ejaculatory disturbances, extrapyramidal reaction, fever, gynecomastia, hyperglycemia, hyperprolactinemia, hyperreflexia, hyperthermia, hypoglycemia, hypokalemia, hypopigmented hair, hypothermia, impotence, lactation, memory loss, neuroleptic malignant syndrome, myasthenia gravis (exacerbation or precipitation), Parkinson's-like symptoms, ptosis, pulmonary edema, QT prolongation, urine discoloration (pink; red; red-brown). Cardiac conduction abnormalities can occur if daily I.V. dose exceeds 50 mg

Pharmacodynamics/Kinetics

Onset of action: Sedation: I.V.: ~1 hour

Duration: Decanoate: ~3 weeks

Distribution: Crosses placenta; enters breast milk

Protein binding: 90%

Metabolism: Hepatic to inactive compounds

Bioavailability: Oral: 60%

Half-life elimination: 20 hours

Time to peak, serum: 20 minutes

Excretion: Urine (33% to 40% as metabolites) within 5 days; feces (15%)

Dosage Children: 3-12 years (15-40 kg): Oral:

Initial: 0.05 mg/kg/day or 0.25-0.5 mg/day given in 2-3 divided doses; increase by 0.25-0.5 mg every 5-7 days; maximum: 0.15 mg/kg/day Usual maintenance:

Agitation or hyperkinesia: 0.01-0.03 mg/kg/day once daily

Nonpsychotic disorders: 0.05-0.075 mg/kg/day in 2-3 divided doses

Psychotic disorders: 0.05-0.15 mg/kg/day in 2-3 divided doses

Children 6-12 years: Sedation/psychotic disorders: I.M. (as lactate):

1-3 mg/dose every 4-8 hours to a maximum of 0.15 mg/kg/day; change over to oral therapy as soon as able

Adults:

Psychosis:

Oral: 0.5-5 mg 2-3 times/day; usual maximum: 30 mg/day

I.M. (as lactate): 2-5 mg every 4-8 hours as needed

I.M. (as decanoate): Initial: 10-20 times the daily oral dose administered at 4-week intervals

Maintenance dose: 10-15 times initial oral dose; used to stabilize psychiatric symptoms

Delirium in the intensive care unit (unlabeled use, unlabeled route):

I.V.: 2-10 mg; may repeat bolus doses every 20-30 minutes until calm achieved then administer 25% of the maximum dose every 6 hours; monitor ECG and QT_c interval

Intermittent I.V.: 0.03-0.15 mg/kg every 30 minutes to 6 hours

Oral: Agitation: 5-10 mg

Continuous intravenous infusion (100 mg/100 mL D₅W): Rates of 3-25 mg/hour have been used

Rapid tranquilization of severely-agitated patient (unlabeled use): Administer every 30-60 minutes:

Oral: 5-10 mg

I.M.: 5 mg

Average total dose (oral or I.M.) for tranquilization: 10-20 mg

Elderly: Initial: Oral: 0.25-0.5 mg 1-2 times/day; increase dose at 4- to 7-day intervals by 0.25-0.5 mg/day; increase dosing intervals (twice daily, 3 times/day, etc) as necessary to control response or side effects

Hemodialysis/peritoneal dialysis: Supplemental dose is not necessary

Stability Protect oral dosage forms from light; insoluble in water

Monitoring Parameters Vital signs; lipid profile, fasting blood glucose/Hgb A_{1c}; BMI; mental status, abnormal involuntary movement scale (AIMS), extrapyramidal symptoms (EPS)

Administration The decanoate injectable formulation should be administered I.M. only, **do not administer decanoate I.V.** Dilute the oral concentrate with water or juice before administration. Avoid skin contact with oral suspension or solution; may cause contact dermatitis.

Contraindications Hypersensitivity to haloperidol or any component of the formulation; Parkinson's disease; severe CNS depression; bone marrow suppression; severe cardiac or hepatic disease; coma

Warnings

Hypotension may occur, particularly with parenteral administration. Decanoate form should never be administered I.V. Avoid in thyrotoxicosis. May be sedating, use with caution in disorders where CNS depression is a feature. Caution in patients with hemodynamic instability, predisposition to seizures, subcortical brain damage, renal or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use - use with caution in patients at risk of pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May alter cardiac conduction - life-threatening arrhythmias have occurred with therapeutic doses of antipsychotics. Adverse effects of decanoate may be prolonged. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications which may predispose). Some tablets contain tartrazine.

May cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention). Therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other neuroleptics, haloperidol has a low potency of cholinergic blockade.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is high relative to other neuroleptics). May be associated with neuroleptic malignant syndrome (NMS) or pigmentary retinopathy.

Dosage Forms [DSC] = Discontinued product

Note: Strength expressed as base.

Injection, oil, as decanoate: 50 mg/mL (1 mL, 5 mL); 100 mg/mL (1 mL, 5 mL)

Haldol® Decanoate: 50 mg/mL (1 mL; 5 mL [DSC]); 100 mg/mL (1 mL; 5 mL [DSC]) [contains benzyl alcohol, sesame oil]

Injection, solution, as lactate: 5 mg/mL (1 mL, 10 mL)

Haldol®: 5 mg/mL (1 mL)

Solution, oral concentrate, as lactate: 2 mg/mL (15 mL, 120 mL)

Tablet: 0.5 mg, 1 mg, 2 mg, 5 mg, 10 mg, 20 mg

Reference Range

Therapeutic: 5-15 ng/mL (SI: 10-30 nmol/L) (psychotic disorders - less for Tourette's and mania)

Toxic: >28 ng/mL (SI: >56 nmol/L)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam or diazepam (I.V. 5-10 mg bolus in adults every 15 minutes if needed up to a total of 30 mg; I.V. 0.25-0.4 mg/kg/dose up to a total of 10 mg in children) or to phenytoin or phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 g), while other antiarrhythmics (ie, lidocaine) can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50 mg I.M. or I.V. slow push followed by a maintenance dose for 48-72 hours. When these reactions are unresponsive to diphenhydramine, benztrapine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes. Propranolol can be used to treat haloperidol-related nocturnal bruxism.

Enhancement of elimination: Multiple dosing of activated charcoal would not be expected to be useful

Test Interactions ↓ cholesterol (S)

Drug Interactions Substrate of CYP1A2 (minor), 2D6 (major), 3A4 (major); **Inhibits** CYP2D6 (moderate), 3A4 (moderate)

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Anticholinergics: May inhibit the therapeutic response to haloperidol and excess anticholinergic effects may occur; tardive dyskinesias have also been reported; includes benztrapine and trihexyphenidyl

Antihypertensives: Concurrent use of haloperidol with an antihypertensive may produce additive hypotensive effects (particularly orthostasis)

Bromocriptine: Antipsychotics inhibit the ability of bromocriptine to lower serum prolactin concentrations

Chloroquine: Serum concentrations of haloperidol may be increased by chloroquine

CNS depressants: Sedative effects may be additive; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol and other sedative agents

CYP2D6 inhibitors: May increase the levels/effects of haloperidol. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP2D6 substrates: Haloperidol may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Haloperidol may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of haloperidol. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of haloperidol. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nocardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

CYP3A4 substrates: Haloperidol may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Indomethacin: Haloperidol in combination with indomethacin may result in drowsiness, tiredness, and confusion; monitor for adverse effects

Inhalation anesthetics: Haloperidol in combination with certain forms of induction anesthesia may produce peripheral vasodilation and hypotension

Levodopa: Haloperidol may inhibit the antiparkinsonian effect of levodopa; avoid this combination

Lithium: Haloperidol may produce neurotoxicity with lithium; this is a rare effect

Methylodopa: Effect of haloperidol may be altered; enhanced effects, as well as reduced efficacy have been reported

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk.

Nefazodone: Haloperidol and nefazodone may produce additive CNS toxicity, including sedation

Propranolol: Serum concentrations of haloperidol may be increased

Quinidine: May increase haloperidol concentrations; monitor for EPS and/or QT_c prolongation

SSRIs: Fluoxetine, fluvoxamine, and paroxetine may inhibit the metabolism of haloperidol resulting in EPS; monitor for EPS

Sulfadoxine-pyrimethamine: May increase fluphenazine concentrations

Tricyclic antidepressants: Concurrent use may produce increased toxicity or altered therapeutic response

Trazodone: Haloperidol and trazodone may produce additive hypotensive effects

Pregnancy Risk Factor C

Pregnancy Implications Decline in developmental scores may be seen in nursing infants

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Nursing Implications Observe for extrapyramidal effects

Additional Information 5 mg of haloperidol (I.V.) followed by a bolus of 1 L of normal saline has been used to treat migraine headaches; may be used for the emergency sedation of severely psychotic agitated patients (5 mg I.M. With 2 mg of lorazepam I.M.); hyperprolactinemia can develop during the first week of haloperidol therapy

Heparin

CAS Number 37270-89-6; 9005-49-6; 9041-08-1

U.S. Brand Names Hep-Lock®

Synonyms Heparin Calcium; Heparin Lock Flush; Heparin Sodium

Use Prophylaxis and treatment of thromboembolic disorders

Unlabeled/Investigational Use Acute MI – combination regimen of heparin (unlabeled dose), tenecteplase (half dose), and abciximab (full dose)

Mechanism of Action Potentiates the action of antithrombin III and thereby inactivates thrombin (as well as activated coagulation factors IX, X, XI, XII, and plasmin) and prevents the conversion of fibrinogen to fibrin; heparin also stimulates release of lipoprotein lipase (lipoprotein lipase hydrolyzes triglycerides to glycerol and free fatty acids)

Adverse Reactions

Cardiovascular: Cardiac tamponade, pericardial effusion/pericarditis,

vasoconstriction, vasculitis

Central nervous system: Fever, headache, chills, hallucinations, amnesia, transient global amnesia (TGA), intracranial hemorrhage

Dermatologic: Urticaria, pruritus, eczema, alopecia, skin necrosis, purpura, unexplained bruising, angioedema, toxic epidermal necrolysis, cutaneous vasculitis, exanthem

Endocrine & metabolic: Hyperkalemia with prolonged therapy from hypoadosteronism, nephrogenic diabetes insipidus

Gastrointestinal: Nausea, vomiting, fecal discoloration (black), fecal discoloration (pink), fecal discoloration (red), **constipation, vomiting of blood**

Genitourinary: Priapism, urine discoloration (orange), urine discoloration (red)

Hematologic: **Hemorrhage** (risk is threefold with APTT between 2-2.9 times control and eightfold when APTT is over 3 times control); thrombocytopenia; incidence of thrombocytopenia is greater with bovine than porcine heparin preparations; begins 1 week after therapy ocular hemorrhage, coagulopathy, eosinophilia, spontaneous splenic rupture

Hepatic: Elevated liver enzymes

Local: Irritation, ulceration, cutaneous necrosis have been rarely reported with deep SubQ injections, extravasation injury

Neuromuscular & skeletal: Osteoporosis with doses > 15,000 units/day or therapy of over 5 months

Ocular: Conjunctivitis

Renal: Hematuria

Miscellaneous: Bleeding from gums, fixed drug eruption, anaphylaxis (0.2%)

Pharmacodynamics/Kinetics

Onset of action: Anticoagulation: I.V.: Immediate; SubQ: ~20-30 minutes

Absorption: Oral, rectal, I.M.: Erratic at best from all these routes of administration; SubQ absorption is also erratic, but considered acceptable for prophylactic use

Distribution: Does not cross placenta; does not enter breast milk

Metabolism: Hepatic; may be partially metabolized in the reticuloendothelial system

Half-life elimination: Mean: 1.5 hours; Range: 1-2 hours; affected by obesity, renal function, hepatic function, malignancy, presence of pulmonary embolism, and infections

Excretion: Urine (small amounts as unchanged drug)

Dosage

Children:

Intermittent I.V.: Initial: 50-100 units/kg, then 50-100 units/kg every 4 hours

I.V. infusion: Initial: 50 units/kg, then 15-25 units/kg/hour; increase dose by 2-4 units/kg/hour every 6-8 hours as required

Adults:

Prophylaxis (low-dose heparin): SubQ: 5000 units every 8-12 hours
Intermittent I.V.: Initial: 10,000 units, then 50-70 units/kg (5000-10,000 units) every 4-6 hours

I.V. infusion (weight-based dosing per institutional nomogram recommended):

Acute coronary syndromes: MI: Fibrinolytic therapy:

Alteplase or reteplase with first or second bolus: Concurrent bolus of 60 units/kg (maximum: 4000 units), then 12 units/kg/hour (maximum: 1000 units/hour) as continuous infusion. Check aPTT every 4-6 hours; adjust to target of 1.5-2 times the upper limit of control (50-70 seconds in clinical trials); usual range 10-30 units/kg/hour. Duration of heparin therapy depends on concurrent therapy and the specific patient risks for systemic or venous thromboembolism.

Streptokinase: Heparin use optional depending on concurrent therapy and specific patient risks for systemic or venous thromboembolism (anterior MI, CHF, previous embolus, atrial fibrillation, LV thrombus): If heparin is administered, start when aPTT <2 times the upper limit of control; do not use a bolus, but initiate infusion adjusted to a target aPTT of 1.5-2 times the upper limit of control (50-70 seconds in clinical trials). If heparin is not administered by infusion, 7500-12,500 units SubQ every 12 hours (when aPTT <2 times the upper limit of control) is recommended.

Percutaneous coronary intervention: Heparin bolus and infusion may be administered to an activated clotting time (ACT) of 300-350 seconds if no concurrent GPIIb/IIIa receptor antagonist is administered or 200-250 seconds if a GPIIb/IIIa receptor antagonist is administered.

Treatment of unstable angina (high-risk and some intermediate-risk patients): Initial bolus of 60-70 units/kg (maximum: 5000 units), followed by an initial infusion of 12-15 units/kg/hour (maximum: 1000 units/hour).

The American College of Chest Physicians consensus conference has recommended dosage adjustments to correspond to a therapeutic range equivalent to heparin levels of 0.3-0.7 units/mL by antifactor Xa determinations, which correlates with aPTT values between 60 and 80 seconds

Treatment of venous thromboembolism (DVT/PE): 80 units/kg I.V. push followed by continuous infusion of 18 units/kg/hour

Line flushing: When using daily flushes of heparin to maintain patency of single and double lumen central catheters, 10 units/mL is commonly used for younger infants (eg, <10 kg) while 100 units/mL is used for older infants, children, and adults. Capped PVC catheters and peripheral heparin locks require flushing more frequently (eg, every 6-8 hours). Volume of heparin flush is usually similar to volume of catheter (or slightly greater). Additional flushes should be given when stagnant blood is observed in catheter, after catheter is used for drug or blood administration, and after blood withdrawal from catheter.

Addition of heparin (0.5-3 unit/mL) to peripheral and central parenteral nutrition has not been shown to decrease catheter-related thrombosis. The final concentration of heparin used for TPN solutions may need to be decreased to 0.5 units/mL in small infants receiving larger amounts of volume in order to avoid approaching therapeutic amounts. Arterial lines are heparinized with a final concentration of 1 unit/mL.

Using a standard heparin solution (25,000 units/500 mL D₅W), the following infusion rates can be used to achieve the listed doses.

For a dose of:

- 400 units/hour: Infuse at 8 mL/hour
- 500 units/hour: Infuse at 10 mL/hour
- 600 units/hour: Infuse at 12 mL/hour
- 700 units/hour: Infuse at 14 mL/hour
- 800 units/hour: Infuse at 16 mL/hour
- 900 units/hour: Infuse at 18 mL/hour
- 1000 units/hour: Infuse at 20 mL/hour
- 1100 units/hour: Infuse at 22 mL/hour
- 1200 units/hour: Infuse at 24 mL/hour
- 1300 units/hour: Infuse at 26 mL/hour
- 1400 units/hour: Infuse at 28 mL/hour
- 1500 units/hour: Infuse at 30 mL/hour
- 1600 units/hour: Infuse at 32 mL/hour
- 1700 units/hour: Infuse at 34 mL/hour
- 1800 units/hour: Infuse at 36 mL/hour
- 1900 units/hour: Infuse at 38 mL/hour
- 2000 units/hour: Infuse at 40 mL/hour

Dosing adjustments in the elderly: Patients >60 years of age may have higher serum levels and clinical response (longer aPTTs) as compared to younger patients receiving similar dosages; lower dosages may be required

Stability Stable at room temperature; protect from freezing

Monitoring Parameters

Platelet counts, aPTT, hemoglobin, hematocrit, signs of bleeding

For intermittent I.V. injections, aPTT is measured 3.5-4 hours after I.V. injection

Note: Continuous I.V. infusion is preferred over I.V. intermittent injections. For full-dose heparin (ie, nonlow-dose), the dose should be titrated according to aPTT results. For anticoagulation, an aPTT 1.5-2.5 times normal is usually desired. Because of variation among hospitals in the control aPTT values, nomograms should be established at each institution, designed to achieve aPTT values in the target range (eg, for a control aPTT of 30 seconds, the target range [1.5-2.5 times control] would be 45-75 seconds). Measurements should be made prior to heparin therapy, 6 hours after initiation, and 6 hours after any dosage change, and should be used to adjust the heparin infusion until the aPTT exhibits a therapeutic level. When two consecutive aPTT values are therapeutic, the measurements may be made every 24 hours, and if necessary, dose adjustment carried out. In addition, a significant change in the patient's clinical condition (eg, recurrent ischemia, bleeding, hypotension) should prompt an immediate aPTT determination, followed by dose adjustment if necessary. Increase or decrease infusion by 2-4 units/kg/hour dependent upon aPTT.

Heparin infusion dose adjustment:

- aPTT >3x control: Decrease infusion rate 50%
- aPTT 2-3x control: Decrease infusion rate 25%
- aPTT 1.5-2x control: No change
- aPTT <1.5x control: Increase rate of infusion 25%; max 2500 units/hour

Administration

Do not administer I.M. due to pain, irritation, and hematoma formation; central venous catheters must be flushed with heparin solution when newly inserted, daily (at the time of tubing change), after blood

withdrawal or transfusion, and after an intermittent infusion through an injectable cap. A volume of at least 10 mL of blood should be removed and discarded from a heparinized line before blood samples are sent for coagulation testing.

Using a standard heparin solution (25,000 units/500 mL D₅W), the following infusion rates can be used to achieve the listed doses.

For a dose of:

- 400 units/hour: Infuse at 8 mL/hour
- 500 units/hour: Infuse at 10 mL/hour
- 600 units/hour: Infuse at 12 mL/hour
- 700 units/hour: Infuse at 14 mL/hour
- 800 units/hour: Infuse at 16 mL/hour
- 900 units/hour: Infuse at 18 mL/hour
- 1000 units/hour: Infuse at 20 mL/hour
- 1100 units/hour: Infuse at 22 mL/hour
- 1200 units/hour: Infuse at 24 mL/hour
- 1300 units/hour: Infuse at 26 mL/hour
- 1400 units/hour: Infuse at 28 mL/hour
- 1500 units/hour: Infuse at 30 mL/hour
- 1600 units/hour: Infuse at 32 mL/hour
- 1700 units/hour: Infuse at 34 mL/hour
- 1800 units/hour: Infuse at 36 mL/hour
- 1900 units/hour: Infuse at 38 mL/hour
- 2000 units/hour: Infuse at 40 mL/hour

Contraindications Hypersensitivity to heparin or any component of the formulation; severe thrombocytopenia; uncontrolled active bleeding except when due to DIC; suspected intracranial hemorrhage; not for I.M. use; not for use when appropriate monitoring parameters cannot be obtained

Warnings

Use cautiously in patients with a documented hypersensitivity reaction and only in life-threatening situations. Hemorrhage is the most common complication. Monitor for signs and symptoms of bleeding. Certain patients are at increased risk of bleeding. Risk factors include bacterial endocarditis; congenital or acquired bleeding disorders; active ulcerative or angiodyplastic GI diseases; severe uncontrolled hypertension; hemorrhagic stroke; or use shortly after brain, spinal, or ophthalmology surgery; patient treated concomitantly with platelet inhibitors; conditions associated with increased bleeding tendencies (hemophilia, vascular purpura); recent GI bleeding; thrombocytopenia or platelet defects; severe liver disease; hypertensive or diabetic retinopathy; or in patients undergoing invasive procedures. A higher incidence of bleeding has been reported in patients >60 years of age, particularly women. They are also more sensitive to the dose.

Patients who develop thrombocytopenia on heparin may be at risk of developing a new thrombus ("White-clot syndrome"). Hypersensitivity reactions can occur. Osteoporosis can occur following long-term use (>6 months). Monitor for hyperkalemia. Discontinue therapy and consider alternatives if platelets are <100,000/mm³. Patients >60 years of age may require lower doses of heparin.

Some preparations contain benzyl alcohol as a preservative. In neonates, large amounts of benzyl alcohol (>100 mg/kg/day) have been associated with fatal toxicity (gasping syndrome). The use of preservative-free heparin is, therefore, recommended in neonates. Some preparations contain sulfite which may cause allergic reactions.

Heparin does not possess fibrinolytic activity and, therefore, cannot lyse established thrombi; discontinue heparin if hemorrhage occurs; severe hemorrhage or overdosage may require protamine

Dosage Forms [DSC] = Discontinued product

Infusion, as sodium [premixed in NaCl 0.45%]; porcine intestinal mucosa source]: 12,500 units (250 mL); 25,000 units (250 mL, 500 mL)

Infusion, as sodium [preservative free; premixed in D₅W; porcine intestinal mucosa source]: 10,000 units (100 mL) [contains sodium metabisulfite]; 12,500 units (250 mL) [contains sodium metabisulfite]; 20,000 units (500 mL) [contains sodium metabisulfite]; 25,000 units (250 mL, 500 mL) [contains sodium metabisulfite]

Infusion, as sodium [preservative free; premixed in NaCl 0.9%]; porcine intestinal mucosa source]: 1000 units (500 mL); 2000 units (1000 mL)

Injection, solution, as sodium [lock flush preparation; porcine intestinal mucosa source; multidose vial]: 10 units/mL (1 mL, 10 mL, 30 mL) [contains parabens]; 100 units/mL (1 mL, 5 mL) [contains parabens]

Injection, solution, as sodium [lock flush preparation; porcine intestinal mucosa source; multidose vial]: 10 units/mL (10 mL, 30 mL); 100 units/mL (10 mL, 30 mL) [contains benzyl alcohol]

Hep-Lock[®]: 10 units/mL (1 mL, 2 mL, 10 mL, 30 mL); 100 units/mL (1 mL, 2 mL, 10 mL, 30 mL) [contains benzyl alcohol]

Injection, solution, as sodium [lock flush preparation; porcine intestinal mucosa source; prefilled syringe]: 10 units/mL (1 mL, 2 mL, 3 mL, 5 mL); 100 units/mL (1 mL, 2 mL, 3 mL, 5 mL) [contains benzyl alcohol]

Injection, solution, as sodium [preservative free; lock flush preparation; porcine intestinal mucosa source; prefilled syringe]: 100 units/mL (5 mL)

Injection, solution, as sodium [preservative free; lock flush preparation; porcine intestinal mucosa source; vial]:

HepFlush[®]-10: 10 units/mL (10 mL)

Hep-Lock U/P: 10 units/mL (1 mL); 100 units/mL (1 mL)
 Injection, solution, as sodium [porcine intestinal mucosa source; multi-dose vial]: 1000 units/mL (1 mL, 10 mL, 30 mL) [contains benzyl alcohol]; 1000 units/mL (1 mL, 10 mL, 30 mL) [contains methylparabens]; 5000 units/mL (1 mL, 10 mL) [contains benzyl alcohol]; 5000 units/mL (1 mL) [contains methylparabens]; 10,000 units/mL (1 mL, 4 mL) [contains benzyl alcohol]; 10,000 units/mL (1 mL, 5 mL) [contains methylparabens]; 20,000 units/mL (1 mL) [contains methylparabens]
 Injection, solution, as sodium [porcine intestinal mucosa source; prefilled syringe]: 5000 units/mL (1 mL) [contains benzyl alcohol]
 Injection, solution, as sodium [preservative free; porcine intestinal mucosa source; prefilled syringe]: 10,000 units/mL (0.5 mL)
 Injection, solution, as sodium [preservative free; porcine intestinal mucosa source; vial]: 1000 units/mL (2 mL); 2000 units/mL (5 mL); 2500 units/mL (10 mL)

Reference Range Therapeutic: 0.3-0.5 units/mL

Overdosage/Treatment

Supportive therapy: Protamine can be used for severe bleeding upon withdrawal of heparin (1 mg of protamine for every 80-100 units of heparin by slow I.V. push); Effect on PTT can be seen within 15 minutes
 recombinant hirudin lepirudin or argatroban (both direct thrombin inhibitors) have been used successfully in treating heparin-induced thrombocytopenia. Danaparoid sodium or recombinant hirudin can be given if heparin-induced thrombocytopenia develops. Heparin should be discontinued once the clinical diagnosis is made. Do not wait for confirmatory test results (platelet aggregometry assay or enzyme-linked immunosorbent assay for heparin-induced thrombocytopenia IgG antibody). Do not start warfarin until thrombotic event is controlled and thrombocytopenia has resolved. Oral fludrocortisone (0.1 mg/day) can help resolve heparin-induced hyperkalemia.

Enhancement of elimination: While hemodialysis is not beneficial, exchange transfusion has been used successfully in a neonate and plasma exchange has been used successfully in four older patients for thrombocytopenia

Antidote(s)

- Protamine Sulfate [ANTIDOTE]

Test Interactions Increases thyroxine (S) (false elevation with competitive protein binding methods), PT, PTT, bleeding time; interferes with calcium assay techniques leading to false depression of calcium. Note that serum electrolyte assays obtained through heparin-based cannulas may result in factitious hyperkalemia and/or hypernatremia. Heparin may cause falsely elevated free thyroxine levels when measured by direct equilibrium dialysis method; I.V. heparin may produce a fivefold increase in free thyroxine

Drug Interactions Cephalosporins which contain the MTT side chain may increase the risk of hemorrhage.

Drugs which affect platelet function (eg, aspirin, NSAIDs, dipyridamole, ticlopidine, clopidogrel, IIb/IIIa antagonists) may potentiate the risk of hemorrhage.

Nitroglycerin (I.V.) may decrease heparin's anticoagulant effect. This interaction has not been validated in some studies, and may only occur at high nitroglycerin dosages.

Penicillins (parenteral) may prolong bleeding time via inhibition of platelet aggregation, potentially increasing the risk of hemorrhage.

Thrombolytic agents increase the risk of hemorrhage.

Warfarin: Risk of bleeding may be increased during concurrent therapy. Heparin is commonly continued during the initiation of warfarin therapy to assure anticoagulation and to protect against possible transient hypercoagulability.

Other drugs reported to increase heparin's anticoagulant effect include antihistamines, tetracycline, quinine, nicotine, and cardiac glycosides (digoxin).

Pregnancy Risk Factor C

Pregnancy Implications Does not cross placenta; while maternal thrombocytopenia and bleeding must be monitored, no congenital defects have been documented; heparin is probably safer than warfarin during pregnancy

Lactation Does not enter breast milk/compatible

Nursing Implications Do not administer I.M. due to pain, irritation, and hematoma formation

Additional Information Low molecular weight heparin agents carry a lower risk of thrombocytopenia; thrombocytopenia is more likely to occur with unfractionated heparin than low molecular weight heparin; thrombocytopenia can occur in patients given heparin with lupus anticoagulant; a value of 300-500 seconds (with control of 150-180 seconds) of activated clotting time is an appropriate target during heparin therapy. When patients present with thrombocytopenia and thrombosis up to 3 weeks after exposure to heparin, delayed-onset heparin-induced thrombocytopenia should be suspected.

A 50% or greater fall in the platelet count from the postoperative peak is a sensitive definition indicating possible heparin-induced thrombocytopenia that is associated with an increased risk of thrombosis.

Heroin

Related Information

- Highlights of Recent Reports (2006) on Substance Abuse and Mental Health
- Morphine Sulfate

CAS Number 1502-95-0; 561-27-3

Synonyms Acetomorphine; Diacetylmorphine; Diamorphine Hydrochloride; Heroin Hydrochloride

Impairment Potential Yes. Urine 6-acetylmorphine levels > 10 ng/mL are consistent with recent use. (Jones AW, "Heroin Use by Motorists in Sweden Confirmed by Analysis of 6-Acetylmorphine in Urine," *J Anal Toxicol*, 2001, 25:353-5.)

Use Most commonly a drug of abuse in the United States; used as an analgesic agent or cough suppressant in Britain

Mechanism of Action Acetylated morphine derivative with CNS depressant effects

Adverse Reactions

Cardiovascular: Hypotension, congestive heart failure, vasculitis
 Central nervous system: Lethargy, coma, euphoria, hallucinations, CNS depression, depression, paranoia, aggressive behavior, leukoencephalopathy, progressive spongiform leukoencephalopathy
 Dermatologic: Pemphigus, acne, angioedema, toxic epidermal necrolysis, purpura, photosensitivity, pruritus, acanthosis nigricans, exanthem
 Gastrointestinal: Constipation, xerostomia, nausea, vomiting, Ogilvie's syndrome, decreased esophageal sphincter tone
 Genitourinary: Urinary retention, priapism
 Hematologic: Thrombocytopenia,
 Neuromuscular & skeletal: Myoclonus, rhabdomyolysis
 Ocular: Miosis, photophobia
 Renal: Renal failure, proteinuria
 Respiratory: Apnea, respiratory depression, bronchospasm (upon nasal insufflation), pulmonary edema, aspiration, asthma, acute respiratory distress syndrome, eosinophilic pneumonia, bronchiectasis
 Miscellaneous: Fixed drug eruption, acute atraumatic compartment syndrome

Signs and Symptoms of Overdose Amenorrhea, constipation, delirium, disorientation, dry mouth, dysphoria, encephalopathy, extrapyramidal reaction, hypothermia, impotence, myocardial depression, myopathy, nephrotic syndrome, pemphigus, photophobia, tongue discoloration

Admission Criteria/Prognosis

Ongoing respiratory depression after 4 hours postexposure should be admitted for 24-48 hours in the hospital; admit any hypoxemic patient (these patients are at risk for development of noncardiogenic pulmonary edema)

Patients with presumed opioid overdose can be safely discharged 1 hour after naloxone administration if they - 1) can mobilize as usual; 2) have oxygen saturation on room air of >92%; 3) have a respiratory rate > 10 breaths per minute and <20 breaths per minute; 4) have a temperature of >35.0°C and <37.5°C; 5) have a heart rate >50 beats per minute, and <100 beats per minute; and 6) have a Glasgow Coma Scale score of 15.

Pharmacodynamics/Kinetics

Peak plasma level: 10 minutes after I.M. absorption

Distribution: V_d : 25 L/kg

Protein binding: 40%

Metabolism: Deacetylation to 6-acetylmorphine and then to morphine in the liver (both active metabolites)

Half-life: 3-20 minutes

Elimination: Urine (as morphine glucuronides); total clearance: 31 mL/kg/minute

Dosage Analgesia (in Europe):

Oral: 5-10 mg

I.M., SubQ: 5 mg (usually I.V. dose)

As a drug of abuse:

Nasal insufflation, I.V., SubQ: Up to 200 mg; usual dose: ~2 mg

Contraindications Hypersensitivity to morphine or diamorphine, acute respiratory depression

Warnings May provoke hypertension and tachycardia in patients with pheochromocytoma; use with caution in renal/liver insufficiency, diarrhea associated with antibiotics; pulmonary disease, gallbladder disease, hypothyroidism, inflammatory bowel disease, prostatic hypertrophy, increased intracranial pressure

Reference Range

Heroin doses of 150-200 mg can produce plasma morphine levels of 300 ng/mL; analgesic level: 20-65 ng/mL

Screening cutoffs for 6-Monoacetyl Morphine

- Urine - 10 ng/ml
- Hair 200 pg/mg
- Oral Fluid 4 ng/ml
- Sweat 25 ng/patch

Overdosage/Treatment

Decontamination: Oral: Activated charcoal; for asymptomatic body packers, whole bowel irrigation with polyethylene glycol (PEG) solution is recommended

Supportive therapy: Antidote of choice is naloxone (bolus: 0.4-2 mg I.V.); a continuous infusion may be required, especially in the management of a body stuffer/packer

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Diagnostic Procedures

- Morphine, Urine

Drug Interactions Subcutaneous absorption may be delayed when coadministered with cocaine

Pregnancy Risk Factor B; D (if used for prolonged periods or near term)

Pregnancy Implications Associated with increased incidence of congenital abnormalities; higher rates of neonatal jaundice (due to accelerated liver maturity), lower birth rates, and perinatal mortality have been reported; narcotic withdrawal (incidence of 85% usually appearing within 48 hours) with associated elevated neonatal serum magnesium levels must be monitored; withdrawal is related to dose and length of exposure

Additional Information Use and purity has been increasing; purity ranges from 3% to 30%; often combined with cocaine ("speedball") or phenobarbital/methaqualone ("karachi"); annual prevalence according to 1991 NIDA survey in U.S. population is ~0.3%

It appears that older users are more likely to inject while younger users are more likely to snort or smoke. Dark (Mexican) heroin is usually less potent than white (Asian) heroin. Urine drug screen will remain positive for ~40 hours; adulterants include talc, cornstarch, quinine, lead, mannitol, sodium bicarbonate, and lidocaine. Delayed encephalopathy (after 4 days) can occur.

Heroin-associated renal disease has been declining since 1990 in New York City and Miami, Florida. With the average purity of New York street heroin increasing, this has led to the speculation that it was the impurities associated with heroin injection that led to the development of heroin-associated renal disease.

Wound botulism has been associated with black tar heroin use (through skin popping)

Thallium contaminated heroin has been documented in France

Behavioral and psychological effects of 12 mg intranasal heroin are equivalent to 6 mg intramuscular heroin. See table.

Celebrities in Whom Heroin Was Involved in Their Deaths

Matthew Ansara (Barbara Eden's son)
 Chet Baker (Jazz musician)
 Francisco Javier Barrios (Baseball Pitcher)
 Jean-Michel Basquiat (Graffiti artist)
 John Belushi (Comedian/actor)
 Mike Bloomfield (Guitarist)
 Tommy Bolin (Guitarist - Deep Purple)
 Graham Bond (Musician)
 Lenny Bruce (Comedian)
 Tim Buckley (Guitarist, composer)
 John Coltrane (Tenor saxophonist)
 Raphael de Rothschild (Banking heir)
 Chris Farley (Comedian)
 Trevor Goddard (Actor)
 Rodney Harvey (Actor)
 Mitch Hedberg (Comedian)
 Billie Holiday (Jazz singer)
 Shannon Hoon (Singer - Blind Melon)
 Janis Joplin (Rock/blues singer)
 "Big Daddy" Lipscombe (Football star)
 Frankie Lymon (Singer)
 Phil Lynott (Guitarist - Thin Lizzy)
 James D McElroy (Baseball Pitcher)
 Robbie McIntosh (Drummer - Average White Band)
 Johnathan Melvoin (Keyboard - Smashing Pumpkins)
 Pamela Morrison (Widow of Jim Morrison - Lead singer of the Doors)
 Gram Parsons (Guitarist - Byrds and Flying Burrito Brothers)
 Kristine Pfaff (Bassist - Hole)
 River Phoenix (Actor)
 Robert Quine (Guitarist)
 Oscar Scaggs (Son of singer Boz Scaggs)
 Eddy Shaver (Country-rock guitarist)
 Hillel Slovek (Red Hot Chili Peppers)
 Eric Vaughn Show (Baseball Pitcher - San Diego Padres)
 Daride Sorrenti (Fashion photographer)
 Layne Staley (Frontman - Alice in Chains)
 Mark Tuinei (Football player)
 Sid Vicious (Bassist - Sex Pistols)
 Danny Whitten (Guitarist - Crazy Horse)
 Andrew Wood (Band member - Mother Love Bone)

Primary source: Caro M, "Heroin Leaves FreshTrack in Entertainment World," *Chicago Tribune*, July 14, 1996, 1-6.

Injection of "black tar" heroin (which has been the predominant form of heroin in the western United States during the 1990s) either intramuscularly or subcutaneously is the primary risk factor for development of wound botulism (46 cases in California from 1988 to 1995).

Combining lemon juice to solubilize heroin can reduce its pH to 2.8 and predispose the user to *Candida* septicemia.

Seven times as toxic as morphine; average yearly mortality rate among heroin injectors is 2%

● Heroin/morphine mentions increased 22% from the first half of 1999 (38,565 mentions) to the first half of 2000 (47,008).

● From the first half of 1999 to the first half of 2000, heroin/morphine mentions increased:

U.S. retail price per pure gram: About \$1,000. Opium production in certain countries in 2000: Afghanistan: 3276 tons; Myanmar: 1087 tons; Laos: 167 tons; Columbia: 88 tons; Mexico: 21 tons; Pakistan: 8 tons; Thailand: 6 tons; Vietnam: 2 tons. U.S. spending on illicit heroin in 2000: About 12 billion dollars. Recovery rate from addiction is 40% to 50%; 33% of all drug users in the U.S. are addicted to heroin (1999 data).

According to the Drug Abuse warning Network in 2004:

● Heroin was involved in an estimated 162,137 Emergency Department (ED) Visits

● Heroin and alcohol combination was involved in an estimated 14,669 ED visits

● Heroin was involved in about 2% of visits involving suicide attempts and in 30% of visits seeking detox in ED.

● Peak age of ED visit for heroin abuse was 25 to 29 years.

U.S. retail price per pure gram: About \$1,000. Opium production in certain countries in 2000: Afghanistan: 3276 tons; Myanmar: 1087 tons; Laos: 167 tons; Columbia: 88 tons; Mexico: 21 tons; Pakistan: 8 tons; Thailand: 6 tons; Vietnam: 2 tons. U.S. spending on illicit heroin in 2000: About 12 billion dollars. Recovery rate from addiction is 40% to 50%; 33% of all drug users in the U.S. are addicted to heroin (1999 data).

Hexachlorophene

CAS Number 70-30-4

UN Number 2875

U.S. Brand Names pHisoHex®

Use Surgical scrub and as a bacteriostatic skin cleanser; control an outbreak of gram-positive infection when other procedures have been unsuccessful

Mechanism of Action Bacteriostatic polychlorinated biphenyl which inhibits membrane-bound enzymes and disrupts the cell membrane

Adverse Reactions

Cardiovascular: Hypotension, bradycardia, sinus bradycardia, cerebral edema

Central nervous system: Convulsions, irritability, fever, pseudotumor cerebri, vascular encephalopathy, dementia, confusion, drowsiness, coma, myelinopathy, leukoencephalopathy

Dermatologic: Dermatitis, erythema, dry skin, photosensitivity

Gastrointestinal: Anorexia, nausea, vomiting, diarrhea

Ocular: Optic neuropathy, blindness, diplopia

Respiratory: Wheezing upon exposure to hexachlorophene powder; respiratory failure, respiratory arrest

Admission Criteria/Prognosis Admit any patient with nervous system or cardiac toxicity or ingestions > 20 mg/kg

Pharmacodynamics/Kinetics

Absorption: Percutaneously through inflamed, excoriated, and intact skin

Distribution: Crosses placenta

Half-life elimination: Infants: 6.1-44.2 hours

Dosage Children and Adults: Topical: Apply 5 mL cleanser and water to area to be cleansed; lather and rinse thoroughly under running water

Stability Store in nonmetallic container (**incompatible** with many metals)

Contraindications Hypersensitivity to halogenated phenol derivatives or hexachlorophene; use in premature infants; use on burned or denuded skin; occlusive dressing; application to mucous membranes

Warnings Discontinue use if signs of cerebral irritability occur; exposure of preterm infants or patients with extensive burns has been associated with apnea, convulsions, agitation and coma; do not use for bathing infants, premature infants are particularly susceptible to hexachlorophene topical absorption

Dosage Forms Liquid, topical: 3% (150 mL, 500 mL, 3840 mL)

Reference Range Lethal oral dose: 2-10 g; Death in a child associated with a serum hexachlorophene level of 0.78 mcg/mL

Overdosage/Treatment

Decontamination: **Oral:** Lavage (within 4 hours) > 10 mg/kg; activated charcoal may not be useful. **Dermal:** Vigorous irrigation with soap and water; olive oil or castor oil can dissolve hexachlorophene and also be utilized

Enhancement of elimination: Peritoneal dialysis is not useful

Drug Interactions No data reported

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta; spongiform encephalopathy in low birth weight infants

Nursing Implications Do not use for bathing infants; premature infants are particularly susceptible to hexachlorophene topical absorption

Additional Information In cosmetics, usually not at a concentration > 0.1%

HIRUDIN

Hirudin

Unlabeled/Investigational Use Thrombolysis in acute myocardial infarction to prevent reocclusion

Mechanism of Action Derived from the leech (*Hirudo medicinalis*), hirudin is a specific thrombin inhibitor; inhibits conversion of fibrinogen to fibrin

Adverse Reactions Hematologic: Bleeding, hemorrhage, disseminated intravascular coagulation

Toxicodynamics/Kinetics

Absorption: SubQ: 36%

Distribution: V_d : 0.2 L/kg

Half-life: I.V.: 0.6-1.6 hours; SubQ: 0.6-3 hours

Elimination: Renal

Dosage I.V.:

Bolus: 0.1-0.4 mg/kg

Infusion: 0.06-0.15 mg/kg/hour

Monitoring Parameters Activated PTT, CBC

Overdosage/Treatment

Supportive therapy: Monitor APTT; bleeding is dose related; treat hemorrhage with local therapy; prothrombin complex concentrate can aid in decreasing bleeding

Enhanced elimination: Hemodiafiltration using a high-flux capillary dialyzer can assist in enhancing hirudin elimination

Additional Information Not available in U.S.

1 mcg of hirudin inhibits ~10 units of human thrombin. Risk of bleeding increases with bolus >0.6 mg/kg and infusion >0.2 mg/kg.

Histoplasmin

Pronunciation (hiss toe PLAZ min)

CAS Number 9008-05-3

U.S. Brand Names Histolyn-CYL®

Synonyms Histoplasmosis Skin Test Antigen

Use Diagnosing histoplasmosis; to assess cell-mediated immunity

Mechanism of Action In persons that have become sensitized to histoplasmin fungus, intradermal administration of histoplasmin skin test antigen evokes a delayed hypersensitivity reaction at the site of administration, if the T-cell immune system is intact

Adverse Reactions Local: Vesiculation, ulceration, or necrosis at site of administration

Signs and Symptoms of Overdose Excessive dosage may result in severe erythema and induration, followed by necrosis and ulceration which may last for several weeks.

Dosage Adults: Intradermally: 0.1 mL of 1:100 dilution into volar surface of forearm; induration of ≥ 5 mm in diameter indicates a positive reaction

Stability Store in refrigerator (2°C to 8°C)

Administration Use a $\frac{3}{8}$ " to $\frac{1}{2}$ " 26- or 27-gauge needle

Contraindications Known hypersensitivity to phenol or polysorbate 80

Warnings Epinephrine should be available for immediate treatment of anaphylactic reaction; use with caution in patients with coccidioid erythema nodosum; a dilution of 1:10,000 should be used for the initial skin test; resuscitative equipment and drugs should be available

Dosage Forms Injection: 1:100 (0.1 mL, 1.3 mL)

Overdosage/Treatment Treatment is dilution of site of exposure

Drug Interactions Any live virus vaccine, corticosteroids, immunosuppressive agents may inhibit the immune response to the skin test

Pregnancy Risk Factor C

Nursing Implications Examine reaction site at 24-48 hours for cell-mediated immunity and 48-72 hours for histoplasmosis; use a $\frac{3}{8}$ " to $\frac{1}{2}$ " 26- or 27-gauge needle

Additional Information Some formulations may contain phenol.

Histrelin

Pronunciation (his TREL in)

U.S. Brand Names Vantas™

Synonyms GnRH Agonist; Histrelin Acetate; LH-RH Agonist

Use Palliative treatment of advanced prostate cancer

Mechanism of Action Potent inhibitor of gonadotropin secretion; continuous administration results in, after an initiation phase, the suppression of luteinizing hormone (LH), follicle-stimulating hormone (FSH), and a subsequent decrease in testosterone.

Adverse Reactions

>10%: Endocrine & metabolic: Expected pharmacological consequence of testosterone suppression: Hot flashes (66%)

2% to 10%:

Central nervous system: Fatigue (10%), headache (3%), insomnia (3%)

Endocrine & metabolic: Expected pharmacological consequences of testosterone suppression: Gynecomastia (4%), sexual dysfunction (4%), libido decreased (2%)

Gastrointestinal: Constipation (4%), weight gain (2%)

Genitourinary: Expected pharmacological consequence of testosterone suppression: Testicular atrophy (5%)

Local: Implant site reaction (6%)

Renal: Renal impairment (5%)

<2%: Abdominal discomfort, alopecia, anemia, appetite increased, arthralgia, AST increased, back pain, bone density decreased, bone pain, breast pain, breast tenderness, contusion, craving food, creatinine increased, depression, diaphoresis, dizziness, dyspnea (exertional), dysuria, feeling cold, fluid retention, genital pruritus, hematuria, hypercalcemia, hypercholesterolemia, hyperglycemia, irritability, LDH increased, lethargy, liver disorder, malaise, muscle twitching, nausea, neck pain, palpitation, peripheral edema, prostatic acid phosphatase increased, renal calculi, renal failure, stent occlusion, testosterone increased, tremor, urinary frequency, urinary retention, ventricular asystoles, weight loss

Pharmacodynamics/Kinetics

Onset: Chemical castration: 14 days

Duration: 1 year

Distribution: V_d : ~58 L

Protein binding: 70% \pm 9%

Metabolism: Hepatic via C-terminal dealkylation and hydrolysis

Bioavailability: 92%

Half-life elimination: Terminal: ~4 hours

Time to peak, serum: 12 hours

Dosage SubQ:

Adults: 50 mg implant surgically inserted every 12 months

Elderly: See Adults dosing

Dosage adjustment in renal impairment: Cl_{cr} : 15-60 mL/minute: Adjustment not needed

Stability Vantas™: Upon delivery, separate contents of implant carton. Store implant under refrigeration at 2°C to 8°C (36°F to 46°F), wrapped in the amber pouch for protection from light; do not freeze. The implantation kit does not require refrigeration.

Monitoring Parameters LH and FSH levels, serum testosterone levels, prostate specific antigen (PSA), bone mineral density; weakness, paresthesias, and urinary tract obstruction (especially during first few weeks of therapy)

Administration SubQ: The implant must be removed from within the glass vial prior to implantation. Surgical implantation into the inner portion of the upper arm requires the use of the implantation device provided. Use the patient's nondominant arm for placement. Removal must occur after 12 months; a replacement implant may be required.

Contraindications Hypersensitivity to histrelin acetate, GnRH, GnRH-agonist analogs, or any component of the formulation; children; females

Warnings Transient increases in testosterone serum levels occur during the first week of use. Worsening symptoms such as bone pain, neuropathy, ureteral or bladder outlet obstruction, and spinal cord compression have been reported. Spinal cord compression and ureteral obstruction may contribute to paralysis; close attention should be given during the first few weeks of therapy to both patients having metastatic vertebral lesions and/or urinary tract obstructions, and to any patients reporting weakness, paresthesias or poor urine output. Safety and efficacy have not been established in patients with hepatic dysfunction.

Dosage Forms Implant: 50 mg [released over 12 months; packaged with implantation kit]

Reference Range

Testosterone level: Expected to rise during the first few days and decline to below initiation level by week 2 before reaching ≤ 50 ng/dL (castrate level)

PSA: Expected to decrease to normal levels after 6 months of therapy

Note: Lack of response (testosterone and PSA decreases) should prompt suspicion that the implant has been expelled.

Test Interactions Results of diagnostic test of pituitary gonadotropic and gonadal functions may be affected during and after therapy

Drug Interactions Not studied

Pregnancy Risk Factor X

Pregnancy Implications Fetal harm and an increase in fetal mortalities have been noted in animal studies. Histrelin is contraindicated for use in females.

Lactation Excretion in breast milk unknown/contraindicated

HydrALAZINE

CAS Number 304-20-1; 86-54-5

Synonyms Apresoline [DSC]; Hydralazine Hydrochloride

Use Management of moderate to severe hypertension, congestive heart failure, hypertension secondary to pre-eclampsia/eclampsia; treatment of primary pulmonary hypertension

Mechanism of Action Direct vasodilation of arterioles (with little effect on veins) with decreased systemic resistance

Adverse Reactions

Cardiovascular: **Palpitations, flushing, tachycardia**, edema, myocardial ischemia, pericardial effusion/pericarditis, pulmonary hypertension, sinus tachycardia, vasodilation, **angina pectoris**, vasculitis

Central nervous system: Malaise, dizziness, fever, **headache**, depression, CNS depression, axonopathy

Dermatologic: Rash, pruritus, neutrophilic dermatosis (Sweet's syndrome), Stevens-Johnson syndrome, angioedema, bullous skin disease, urticaria, purpura, photosensitivity, erythema nodosum, exanthem, cutaneous vasculitis

Endocrine & metabolic: Nephrogenic diabetes insipidus

Gastrointestinal: **Anorexia, nausea, vomiting, diarrhea**, feces discoloration (black), loss of taste perception

Hepatic: Granulomatous hepatitis

Neuromuscular & skeletal: Arthralgia, peripheral neuritis, paresthesia, weakness

Ocular: Lacrimation, blurred vision, eyelid edema

Renal: Glomerulonephritis, renal vasculitis

Respiratory: Asthma, eosinophilic pneumonia, pulmonary vasculitis

Miscellaneous: Positive ANA, positive LE cells, systemic lupus erythematosus, fixed drug eruption, elevated antineutrophilic cytoplasmic antibodies (ANCA)

Signs and Symptoms of Overdose Agranulocytosis, arrhythmias, cholestatic jaundice, erythema multiforme, granulocytopenia, hyperthermia, hypokalemia, hypotension, impotence, lacrimation, lactic acidosis, leukopenia, neuropathy (peripheral), neutropenia, shock, tachycardia, thrombocytopenia, wheezing

Pharmacodynamics/Kinetics

Onset of action: Oral: 20-30 minutes; I.V.: 5-20 minutes

Duration: Oral: Up to 8 hours; I.V.: 1-4 hours; **Note:** May vary depending on acetylator status of patient

Distribution: Crosses placenta; enters breast milk

Protein binding: 85% to 90%

Metabolism: Hepatically acetylated; extensive first-pass effect (oral)

Bioavailability: 30% to 50%; increased with food

Half-life elimination: Normal renal function: 2-8 hours; End-stage renal disease: 7-16 hours

Excretion: Urine (14% as unchanged drug)

Dosage

Children:

Oral: Initial: 0.75-1 mg/kg/day in 2-4 divided doses; increase over 3-4 weeks to maximum of 7.5 mg/kg/day in 2-4 divided doses; maximum daily dose: 200 mg/day

I.M., I.V.: 0.1-0.2 mg/kg/dose (not to exceed 20 mg) every 4-6 hours as needed, up to 1.7-3.5 mg/kg/day in 4-6 divided doses

Adults:

Oral: Hypertension:

Initial dose: 10 mg 4 times/day for first 2-4 days; increase to 25 mg 4 times/day for the balance of the first week

Increase by 10-25 mg/dose gradually to 50 mg 4 times/day (maximum: 300 mg/day); usual dose range (JNC 7): 25-100 mg/day in 2 divided doses

Oral: Congestive heart failure:

Initial dose: 10-25 mg 3-4 times/day

Adjustment: Dosage must be adjusted based on individual response

Target dose: 225-300 mg/day; use in combination with isosorbide dinitrate

I.M., I.V.:

Hypertension: Initial: 10-20 mg/dose every 4-6 hours as needed, may increase to 40 mg/dose; change to oral therapy as soon as possible.

Pre-eclampsia/eclampsia: 5 mg/dose then 5-10 mg every 20-30 minutes as needed.

Elderly: Oral: Initial: 10 mg 2-3 times/day; increase by 10-25 mg/day every 2-5 days.

Dosing interval in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer every 8 hours.

Cl_{cr} < 10 mL/minute: Administer every 8-16 hours in fast acetylators and every 12-24 hours in slow acetylators.

Hemodialysis: Supplemental dose is not necessary.

Peritoneal dialysis: Supplemental dose is not necessary.

Stability Changes color after contact with a metal filter; do not store intact ampuls in refrigerator

Monitoring Parameters Blood pressure (monitor closely with I.V. use), standing and sitting/supine, heart rate, ANA titer

Administration Inject over 1 minute. Hypotensive effect may be delayed and unpredictable in some patients.

Contraindications Hypersensitivity to hydralazine or any component of the formulation; mitral valve rheumatic heart disease

Warnings May cause a drug-induced lupus-like syndrome (more likely on larger doses, longer duration). Adjust dose in severe renal dysfunction. Use with caution in CAD (increase in tachycardia may increase myocardial oxygen demand). Use with caution in pulmonary hypertension (may cause hypotension). Patients may be poorly compliant because of frequent dosing.

Monitor blood pressure closely following I.V. administration. Response may be delayed and unpredictable in some patients. Titrate cautiously

to response. Hydralazine-induced fluid and sodium retention may require addition or increased dosage of a diuretics.

Dosage Forms Injection, solution, as hydrochloride: 20 mg/mL (1 mL)

Tablet, as hydrochloride: 10 mg, 25 mg, 50 mg, 100 mg

Overdose/Treatment

Decontamination: Ipecac (within 30 minutes)/lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral vasoconstrictor may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Treatment is primarily supportive and symptomatic. Verapamil, esmolol, or propranolol may be used to treat tachycardia. Polyneuropathy may respond to pyridoxine.

Enhancement of elimination: Multiple dosing of activated charcoal may be useful

Test Interactions ↑ calcium (S)

Drug Interactions/Inhibits CYP3A4 (weak)

Beta-blockers (metoprolol, propranolol) serum concentrations and pharmacologic effects may be increased. Monitor cardiovascular status.

Propranolol increases hydralazine's serum concentrations. Acetubolol, atenolol, and nadolol (low hepatic clearance or no first-pass metabolism) are unlikely to be affected.

NSAIDs may decrease the hemodynamic effects of hydralazine; avoid use if possible or closely monitor cardiovascular status.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta. One report of fetal arrhythmia; transient neonatal thrombocytopenia and fetal distress reported following late 3rd trimester use. A large amount of clinical experience with the use of this drug for management of hypertension during pregnancy is available. Available evidence suggests safe use during pregnancy.

Lactation Enters breast milk/compatible

Nursing Implications Monitor blood pressure closely with I.V. use; dextrose solutions suggested

Additional Information Slow acetylators, patients with decreased renal function and patients receiving >200 mg/day (chronically) are at higher risk for systemic lupus erythematosus (SLE). Usually administered with diuretic and a beta-blocker to counteract side effects of sodium and water retention and reflex tachycardia although the beta-blocker may not be necessary in the elderly; odorless, bitter-tasting powder.

Hydrochlorothiazide

CAS Number 58-93-5

U.S. Brand Names Aquazide® H; Microzide™; Oretic®

Synonyms HCTZ (error-prone abbreviation)

Use Management of mild to moderate hypertension; treatment of edema in congestive heart failure and nephrotic syndrome

Unlabeled/Investigational Use Treatment of lithium-induced diabetes insipidus

Mechanism of Action Inhibits sodium reabsorption in the distal tubules causing increased excretion of sodium and water as well as potassium and hydrogen ions; at high doses may inhibit carbonic anhydrase

Adverse Reactions

Cardiovascular: Myocarditis (hypersensitivity), postural hypotension

Central nervous system: Drowsiness, hyperthermia, fever

Dermatologic: Photosensitivity, exfoliative dermatitis, erythema multiforme, bullous skin disease, toxic epidermal necrolysis, urticaria, purpura, pruritus, licheniform eruptions, exanthem, photoallergic reaction

Endocrine & metabolic: Hypokalemia, hypercalcemia, hyperglycemia, hypochloremic metabolic alkalosis, hyperlipidemia, hyperuricemia, syndrome of inappropriate antidiuretic hormone, hypophosphatemia, hyponatremia, hypomagnesemia

Gastrointestinal: Nausea, vomiting, anorexia, loss of taste perception, xerostomia, pancreatitis

Hematologic: Aplastic anemia, hemolysis, leukopenia, neutropenia, agranulocytosis, granulocytopenia, thrombocytopenia

Hepatic: Hepatitis, intrahepatic cholestasis

Neuromuscular & skeletal: Paresthesia, weakness

Ocular: Acute angle-closure glaucoma, color vision abnormalities, phototoxic

Renal: Polyuria, prerenal azotemia

Miscellaneous: Systemic lupus erythematosus, fixed drug eruption, zinc depletion

Signs and Symptoms of Overdose Agranulocytosis, AV block, cystitis, diabetes insipidus, diuresis, fever, granulocytopenia, hypercalcemia,

hyperglycemia, hyperperistalsis, hyperuricemia, hypokalemia, hyponatremia, impotence, leukopenia, myalgia, myasthenia gravis (exacerbation or precipitation), myocarditis, neutropenia, nocturia, pancreatitis, photosensitivity, vision color changes (yellow tinge)

Pharmacodynamics/Kinetics

Onset of action: Diuresis: ~2 hours
 Peak effect: 4-6 hours
 Duration: 6-12 hours
 Absorption: ~50% to 80%
 Distribution: 3.6-7.8 L/kg
 Protein binding: 68%
 Metabolism: Not metabolized
 Bioavailability: 50% to 80%
 Half-life elimination: 5.6-14.8 hours
 Time to peak: 1-2.5 hours
 Excretion: Urine (as unchanged drug)

Dosage Oral (effect of drug may be decreased when used every day):

Children (in pediatric patients, chlorothiazide may be preferred over hydrochlorothiazide as there are more dosage formulations [eg, suspension] available):

<6 months: 2-3 mg/kg/day in 2 divided doses
 >6 months: 2 mg/kg/day in 2 divided doses

Adults:

Edema: 25-100 mg/day in 1-2 doses; maximum: 200 mg/day
 Hypertension: 12.5-50 mg/day; minimal increase in response and more electrolyte disturbances are seen with doses >50 mg/day

Elderly: 12.5-25 mg once daily

Dosing adjustment/comments in renal impairment: Cl_{cr} , 25-50 mL/minute: Not effective

Monitoring Parameters Assess weight, I & O reports daily to determine fluid loss; blood pressure, serum electrolytes, BUN, creatinine

Administration May be taken with food or milk. Take early in day to avoid nocturia. Take the last dose of multiple doses no later than 6 PM unless instructed otherwise.

Contraindications Hypersensitivity to hydrochlorothiazide or any component of the formulation, thiazides, or sulfonamide-derived drugs; anuria; renal decompensation; pregnancy

Warnings

Avoid in severe renal disease (ineffective). Electrolyte disturbances (hypokalemia, hypochloremic alkalosis, hyponatremia) can occur. Use with caution in severe hepatic dysfunction; hepatic encephalopathy can be caused by electrolyte disturbances. Gout can be precipitated in certain patients with a history of gout, a familial predisposition to gout, or chronic renal failure. Cautious use in diabetics; may see a change in glucose control. Hypersensitivity reactions can occur. Can cause SLE exacerbation or activation. Use with caution in patients with moderate or high cholesterol concentrations. Photosensitization may occur. Correct hypokalemia before initiating therapy.

Chemical similarities are present among sulfonamides, sulfonyleureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonamide allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

Dosage Forms Capsule (Microzide™): 12.5 mg

Tablet: 25 mg, 50 mg

Reference Range Serum level of 2 mcg/mL associated with peak diuretic effect

Overdosage/Treatment

Decontamination: Activated charcoal
 Supportive therapy: I.V. hydration with 0.9% saline with electrolyte replacement; diuresis is usually short-lived
 Enhancement of elimination: Hemodialysis may be effective

Test Interactions ↑ creatine phosphokinase (S), ammonia (B), amylase (S), calcium (S), cholesterol (S), glucose, acid (S); ↓ chloride (S), magnesium, potassium (S), sodium (S); hydrochlorothiazide may cause false increase in acetaminophen assay by HPLC

Drug Interactions ACE inhibitors: Increased hypotension if aggressively diuresed with a thiazide diuretic.

Beta-blockers increase hyperglycemic effects in type 2 diabetes mellitus (noninsulin dependent, NIDDM)

Cholestyramine: Hydrochlorothiazide absorption may be decreased.

Colestipol: Hydrochlorothiazide absorption may be decreased.

Cyclosporine and thiazides can increase the risk of gout or renal toxicity; avoid concurrent use.

Digoxin toxicity can be exacerbated if a thiazide induces hypokalemia or hypomagnesemia.

Lithium toxicity can occur by reducing renal excretion of lithium; monitor lithium concentration and adjust as needed.

Neuromuscular blocking agents can prolong blockade; monitor serum potassium and neuromuscular status.

NSAIDs can decrease the efficacy of thiazides reducing the diuretic and antihypertensive effects.

Pregnancy Risk Factor B (manufacturer); D (expert analysis)

Pregnancy Implications Although there are no adequate and well-controlled studies using hydrochlorothiazide in pregnancy, thiazide diuretics may cause an increased risk of congenital defects. Hypoglycemia, hypokalemia, hyponatremia, jaundice, and thrombocytopenia are also reported as possible complications to the fetus or newborn.

Lactation Enters breast milk/use caution (AAP rates "compatible")

Additional Information Inhibits insulin secretion/vitamin D synthesis

Hydrocodone and Acetaminophen

U.S. Brand Names Anexsia®; Bancap HC®; Ceta-Plus®; Co-Gesic®; hycet™; Lorcet® 10/650; Lorcet® Plus; Lorcet®-HD; Lortab®; Magesic® H; Maxidone™; Norco®; Stagesic®; Vicodin® ES; Vicodin® \tf="DM8"char178}}HP; Vicodin{\^{\tf="DM8"char178}}; Zydone{\^{\tf="-Vicodin®; Zydone®

Synonyms Acetaminophen and Hydrocodone

Use Relief of moderate to severe pain; antitussive (hydrocodone)

Mechanism of Action Hydrocodone, as with other narcotic (opiate) analgesics, blocks pain perception in the cerebral cortex by binding to specific receptor molecules (opiate receptors) within the neuronal membranes of synapses. This binding results in a decreased synaptic chemical transmission throughout the CNS thus inhibiting the flow of pain sensations into the higher centers. Mu and kappa are the two subtypes of the opiate receptor which hydrocodone binds to cause analgesia. Acetaminophen inhibits the synthesis of prostaglandins in the CNS and peripherally blocks pain impulse generation; produces antipyresis from inhibition of hypothalamic heat-regulating center.

Adverse Reactions

Cardiovascular: Hypotension, bradycardia, hypertension
 Central nervous system: Lightheadedness, dizziness, sedation, drowsiness, fatigue, confusion, hallucinations
 Gastrointestinal: Nausea, vomiting, xerostomia, anorexia, biliary tract spasm
 Genitourinary: Decreased urination
 Neuromuscular & skeletal: Weakness
 Ocular: Diplopia, miosis
 Respiratory: Dyspnea
 Miscellaneous: Histamine release, physical and psychological dependence with prolonged use

Signs and Symptoms of Overdose Blood dyscrasias, hepatic necrosis, respiratory depression

Pharmacodynamics/Kinetics

Acetaminophen: See Acetaminophen monograph.

Hydrocodone:

Onset of action: Narcotic analgesic: 10-20 minutes
 Duration: 4-8 hours
 Distribution: Crosses placenta
 Metabolism: Hepatic; O-demethylation; N-demethylation and 6-ketosteroid reduction
 Half-life elimination: 3.3-4.4 hours
 Excretion: Urine

Dosage

Oral (doses should be titrated to appropriate analgesic effect); for children ≥ 12 years of age and adults, the dosage of acetaminophen should be limited to ≤4 g/day (and possibly less in patients with hepatic impairment or ethanol use)

Children:

Antitussive (hydrocodone): 0.6 mg/kg/day in 3-4 divided doses; even though dosing by hydrocodone, make sure to keep within age-specific acetaminophen doses as well

A single dose should not exceed 10 mg in children >12 years, 5 mg in children 2-12 years, and 1.25 mg in children <2 years of age

Analgesic (acetaminophen): Refer to Acetaminophen

Adults: Analgesic: 1-2 tablets or capsules every 4-6 hours or 5-10 mL solution every 4-6 hours as needed for pain; do not exceed 4 g/day of acetaminophen

Hydrocodone 2.5-5 mg and acetaminophen 400-500 mg; maximum: 8 tablets/capsules per day

Hydrocodone 7.5 mg and acetaminophen: 400-650 mg; maximum: 6 tablets/capsules per day

Hydrocodone 2.5 mg and acetaminophen: 167 mg/5 mL (elixir/solution); maximum: 6 Tbsp/day

Hydrocodone 7.5 mg and acetaminophen 750 mg; maximum: 5 tablets/capsules per day

Hydrocodone 10 mg and acetaminophen: 350-660 mg; maximum: 6 tablets/day per product labeling

Do not exceed 4 g/day of acetaminophen

Monitoring Parameters Pain relief, respiratory and mental status, blood pressure

Contraindications Hypersensitivity to hydrocodone, acetaminophen, or any component of the formulation; CNS depression; severe respiratory depression

Warnings

Use with caution in patients with hypersensitivity reactions to other phenanthrene derivative opioid agonists (morphine, hydromorphone, levorphanol, oxycodone, oxymorphone); tolerance or drug dependence may result from extended use.

Respiratory depressant effects may be increased with head injuries. Use caution with acute abdominal conditions; clinical course may be obscured. Use caution with thyroid dysfunction, prostatic hyperplasia, hepatic or renal disease, and in the elderly. Causes sedation; caution must be used in performing tasks which require alertness (eg, operating machinery or driving).

Limit acetaminophen to <4 g/day. May cause severe hepatic toxicity in acute overdose; in addition, chronic daily dosing in adults has resulted in liver damage in some patients. Use with caution in patients with alcoholic liver disease; consuming ≥ 3 alcoholic drinks/day may increase the risk of liver damage. Use caution in patients with known G6PD deficiency.

Dosage Forms

Capsule:
Bancap HC[®], Ceta-Plus[®], Margesic[®] H, Stagesic[®]: Hydrocodone bitartrate 5 mg and acetaminophen 500 mg

Elixir: Hydrocodone bitartrate 7.5 mg and acetaminophen 500 mg per 15 mL (480 mL)

Lortab[®]: Hydrocodone bitartrate 7.5 mg and acetaminophen 500 mg per 15 mL (480 mL) [contains alcohol 7%; tropical fruit punch flavor]

Solution, oral:

hycet[™]: Hydrocodone bitartrate 7.5 mg and acetaminophen 325 mg per 15 mL (480 mL) [contains alcohol 7%; tropical fruit punch flavor]

Tablet:

Hydrocodone bitartrate 2.5 mg and acetaminophen 500 mg

Hydrocodone bitartrate 5 mg and acetaminophen 325 mg

Hydrocodone bitartrate 5 mg and acetaminophen 500 mg

Hydrocodone bitartrate 7.5 mg and acetaminophen 325 mg

Hydrocodone bitartrate 7.5 mg and acetaminophen 500 mg

Hydrocodone bitartrate 7.5 mg and acetaminophen 650 mg

Hydrocodone bitartrate 7.5 mg and acetaminophen 750 mg

Hydrocodone bitartrate 10 mg and acetaminophen 325 mg

Hydrocodone bitartrate 10 mg and acetaminophen 500 mg

Hydrocodone bitartrate 10 mg and acetaminophen 650 mg

Hydrocodone bitartrate 10 mg and acetaminophen 660 mg

Anxesia[®]:

5/500: Hydrocodone bitartrate 5 mg and acetaminophen 500 mg [DSC]

7.5/650: Hydrocodone bitartrate 7.5 mg and acetaminophen 650 mg

Co-Gesic[®] 5/500: Hydrocodone bitartrate 5 mg and acetaminophen 500 mg

Lorcet[®] 10/650: Hydrocodone bitartrate 10 mg and acetaminophen 650 mg

Lorcet[®] Plus: Hydrocodone bitartrate 7.5 mg and acetaminophen 650 mg

Lortab[®]:

2.5/500: Hydrocodone bitartrate 2.5 mg and acetaminophen 500 mg

5/500: Hydrocodone bitartrate 5 mg and acetaminophen 500 mg

7.5/500: Hydrocodone bitartrate 7.5 mg and acetaminophen 500 mg

10/500: Hydrocodone bitartrate 10 mg and acetaminophen 500 mg

Maxidone[™]: Hydrocodone bitartrate 10 mg and acetaminophen 750 mg

Norco[®]:

Hydrocodone bitartrate 5 mg and acetaminophen 325 mg

Hydrocodone bitartrate 7.5 mg and acetaminophen 325 mg

Hydrocodone bitartrate 10 mg and acetaminophen 325 mg

Vicodin[®]: Hydrocodone bitartrate 5 mg and acetaminophen 500 mg

Vicodin[®] ES: Hydrocodone bitartrate 7.5 mg and acetaminophen 750 mg

Vicodin[®] HP: Hydrocodone bitartrate 10 mg and acetaminophen 660 mg

Zydone[®]:

Hydrocodone bitartrate 5 mg and acetaminophen 400 mg

Hydrocodone bitartrate 7.5 mg and acetaminophen 400 mg

Hydrocodone bitartrate 10 mg and acetaminophen 400 mg

Overdosage/Treatment

Treatment consists of acetylcysteine 140 mg/kg orally (loading) followed by 70 mg/kg every 4 hours for 17 doses; therapy should be initiated based upon laboratory analysis suggesting a high probability for hepatotoxic potential or I.V. Prescott Protocol. See Acetaminophen. Naloxone, 2 mg I.V. With repeat administration as necessary up to a total of 10 mg, can also be used to reverse toxic effects of the opiate. Decontamination: Oral: Activated charcoal is effective at binding certain chemicals, and this is especially true for acetaminophen.

Drug Interactions Hydrocodone: **Substrate** of CYP2D6 (major)

Acetaminophen: **Substrate** (minor) of CYP1A2, 2A6, 2C9, 2D6, 2E1, 3A4; **Inhibits** CYP3A4 (weak)

Acetaminophen component: Refer to Acetaminophen monograph.

Hydrocodone component:

CYP2D6 inhibitors may decrease the effects of hydrocodone. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CNS depressants (including antianxiety agents, antihistamines, anti-psychotics, narcotics): CNS depression is additive; dose adjustment may be needed

MAO inhibitors: May see increased effects of MAO inhibitor and hydrocodone.

Tricyclic antidepressants (TCAs): May see increased effects of TCA and hydrocodone.

Pregnancy Risk Factor C

Pregnancy Implications Animal reproduction studies have not been conducted with this combination product. Opioid analgesics are considered FDA risk category D if used for prolonged periods or in large doses near term. Withdrawal symptoms may be observed in babies born to mothers taking opioids regularly during pregnancy. Respiratory depression may be observed in the newborn if opioids are given close to delivery.

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Observe patient for excessive sedation, respiratory depression

Additional Information Acetaminophen dosing for pediatric patients: 10-15 mg/kg/dose or alternatively,

Up to 3 months: 40 mg

4-11 months: 80 mg

1-2 years: 120 mg

2-3 years: 160 mg

4-5 years: 240 mg

6-8 years: 320 mg

9-10 years: 400 mg

11 years: 480 mg

Mid-Year 2000 Emergency Department Drug Abuse Warning Network (DAWN) data:

A comparison of the first half of 1999 and the first half of 2000 revealed significant increases in mentions of hydrocodone (51% from 6341 to 9549).

Hydrocortisone

Related Information

• Corticosteroids

CAS Number 125-04-2; 13609-67-1; 2203-97-6; 50-03-3; 50-23-7; 508-99-6; 57524-89-7; 6000-74-4; 83784-20-7

U.S. Brand Names A-hydroCort[®]; Anucort-HC[®]; Anusol-HC[®]; Anusol[®] HC-1 [OTC]; Aquanil[™] HC [OTC]; CaldeCORT[®] [OTC]; Cetacort[®]; Colocort[™]; CortaGel[®] Maximum Strength [OTC]; Cortaid[®] Intensive Therapy [OTC]; Cortaid[®] Maximum Strength [OTC]; Cortaid[®] Sensitive Skin with Aloe [OTC]; Cortef[®]; Corticool[®] [OTC]; Cortifoam[®]; Cortizone[®] 10 Quick Shot [OTC]; Cortizone[®] for Kids [OTC]; Cortizone[®]-10 Maximum Strength [OTC]; Cortizone[®]-10 Plus Maximum Strength [OTC]; Cortizone[®]-5 [OTC]; Dermarest Dricort[®] [OTC]; Dermtex[®] HC [OTC]; EarSol[®] HC; Hemril-HC[®]; Hydrocortone[®] Phosphate; Hydrocortone[®] [DSC]; Hytone[®]; LactiCare-HC[®]; Locoid Lipocream[®]; Locoid[®]; Nupercainal[®] Hydrocortisone Cream [OTC]; Nutracort[®]; Pandel[®]; Post Peel Healing Balm [OTC]; Preparation H[®] Hydrocortisone [OTC]; ProctoCort[®]; ProctoCream[®] HC; Proctosol-HC[®]; Sarnol[®]-HC [OTC]; Solu-Cortef[®]; Summer's Eve[®] SpecialCare[™] Medicated Anti-Itch Cream [OTC]; Texacort[®]; Theracort[®] [OTC]; Westcort[®]

Synonyms A-hydroCort; Compound F; Cortisol; Hemorrhoidal HC; Hydrocortisone Acetate; Hydrocortisone Butyrate; Hydrocortisone Probutate; Hydrocortisone Sodium Succinate; Hydrocortisone Valerate

Use Management of adrenocortical insufficiency; relief of inflammation of corticosteroid-responsive dermatoses (low and medium potency topical corticosteroid); adjunctive treatment of ulcerative colitis

Mechanism of Action Decreases inflammation by suppression of migration of polymorphonuclear leukocytes and reversal of increased capillary permeability

Adverse Reactions

Systemic:

Cardiovascular: Hypotension, edema

Central nervous system: **Insomnia, nervousness**, euphoria, headache, delirium, hallucinations, seizures, mood swings

HYDROCORTISONE

Dermatologic: Hirsutism, acne, dermatitis, skin atrophy, bruising, hyperpigmentation
Endocrine & metabolic: Diabetes mellitus, hypokalemia, hyperglycemia, Cushing's syndrome, sodium and water retention, bone growth suppression, amenorrhea
Gastrointestinal: **Increased appetite, indigestion**, peptic ulcer, abdominal distention, ulcerative esophagitis, pancreatitis
Neuromuscular & skeletal: Arthralgia, muscle wasting
Ocular: Cataracts
Respiratory: Epistaxis
Miscellaneous: Hypersensitivity reactions, immunosuppression
Topical:
Dermatologic: **Eczeema**, pruritus, stinging, dry skin, allergic contact dermatitis, hypopigmentation, striae dermal atrophy, folliculitis
Endocrine & metabolic: HPA axis suppression, hyperglycemia, hypokalemia
Local: Burning
Signs and Symptoms of Overdose Cushingoid appearance, muscle weakness, osteoporosis (with systemic long-term use only). When consumed in excessive quantities for prolonged periods, systemic hypercorticism and adrenal suppression may occur. In those cases, discontinuation and withdrawal of the corticosteroid should be done judiciously.
Pharmacodynamics/Kinetics
Onset of action:
Hydrocortisone acetate: Slow
Hydrocortisone sodium succinate (water soluble): Rapid
Duration: Hydrocortisone acetate: Long
Absorption: Rapid by all routes, except rectally
Metabolism: Hepatic
Half-life elimination: Biologic: 8-12 hours
Excretion: Urine (primarily as 17-hydroxysteroids and 17-ketosteroids)
Dosage
Dose should be based on severity of disease and patient response
Acute adrenal insufficiency: I.M., I.V.:
Infants and young Children: Succinate: 1-2 mg/kg/dose bolus, then 25-150 mg/day in divided doses every 6-8 hours
Older Children: Succinate: 1-2 mg/kg bolus then 150-250 mg/day in divided doses every 6-8 hours
Adults: Succinate: 100 mg I.V. bolus, then 300 mg/day in divided doses every 8 hours or as a continuous infusion for 48 hours; once patient is stable change to oral, 50 mg every 8 hours for 6 doses, then taper to 30-50 mg/day in divided doses
Chronic adrenal corticoid insufficiency: Adults: Oral: 20-30 mg/day
Anti-inflammatory or immunosuppressive:
Infants and Children:
Oral: 2.5-10 mg/kg/day or 75-300 mg/m²/day every 6-8 hours
I.M., I.V.: Succinate: 1-5 mg/kg/day or 30-150 mg/m²/day divided every 12-24 hours
Adolescents and Adults: Oral, I.M., I.V.: Succinate: 15-240 mg every 12 hours
Congenital adrenal hyperplasia: Oral: Initial: 10-20 mg/m²/day in 3 divided doses; a variety of dosing schedules have been used. **Note:** Inconsistencies have occurred with liquid formulations; tablets may provide more reliable levels. Doses must be individualized by monitoring growth, bone age, and hormonal levels. Mineralocorticoid and sodium supplementation may be required based upon electrolyte regulation and plasma renin activity.
Physiologic replacement: Children:
Oral: 0.5-0.75 mg/kg/day or 20-25 mg/m²/day every 8 hours
I.M.: Succinate: 0.25-0.35 mg/kg/day or 12-15 mg/m²/day once daily
Shock: I.M., I.V.: Succinate:
Children: Initial: 50 mg/kg, then repeated in 4 hours and/or every 24 hours as needed
Adolescents and Adults: 500 mg to 2 g every 2-6 hours
Status asthmaticus: Children and Adults: I.V.: Succinate: 1-2 mg/kg/dose every 6 hours for 24 hours, then maintenance of 0.5-1 mg/kg every 6 hours
Adults:
Rheumatic diseases:
Intralesional, intra-articular, soft tissue injection: Acetate:
Large joints: 25 mg (up to 37.5 mg)
Small joints: 10-25 mg
Tendon sheaths: 5-12.5 mg
Soft tissue infiltration: 25-50 mg (up to 75 mg)
Bursae: 25-37.5 mg
Ganglia: 12.5-25 mg
Stress dosing (surgery) in patients known to be adrenally-suppressed or on chronic systemic steroids: I.V.:
Minor stress (ie, inguinal herniorrhaphy): 25 mg/day for 1 day
Moderate stress (ie, joint replacement, cholecystectomy): 50-75 mg/day (25 mg every 8-12 hours) for 1-2 days

Major stress (pancreatoduodenectomy, esophagogastrectomy, cardiac surgery): 100-150 mg/day (50 mg every 8-12 hours) for 2-3 days
Dermatosis: Children >2 years and Adults: Topical: Apply to affected area 2-4 times/day (Buteprate: Apply once or twice daily). Therapy should be discontinued when control is achieved; if no improvement is seen, reassessment of diagnosis may be necessary.
Ulcerative colitis: Adults: Rectal: 10-100 mg 1-2 times/day for 2-3 weeks
Stability Hydrocortisone sodium phosphate and hydrocortisone sodium succinate are clear, light yellow solutions which are heat labile
After initial reconstitution, hydrocortisone sodium succinate solutions are stable for 3 days at room temperature and refrigeration if protected from light
Stability of parenteral admixture (Solu-Cortef®) at room temperature (25°C) and at refrigeration temperature (4°C) is concentration dependent
Minimum volume: Concentration should not exceed 1 mg/mL
Stability of concentration ≤1 mg/mL: 24 hours
Stability of concentration >1 mg/mL to <25 mg/mL: Unpredictable, 4-6 hours
Stability of concentration ≥25 mg/mL: 3 days
Standard diluent (Solu-Cortef®): 50 mg/50 mL D₅W; 100 mg/100 mL D₅W
Comments: Should be administered in a 0.1-1 mg/mL concentration due to stability problems
Monitoring Parameters Blood pressure, weight, serum glucose, and electrolytes
Administration Oral: Administer with food or milk to decrease GI upset
Parenteral: Hydrocortisone sodium succinate may be administered by I.M. or I.V. routes
I.V. bolus: Dilute to 50 mg/mL and give over 30 seconds to several minutes (depending on the dose)
I.V. intermittent infusion: Dilute to 1 mg/mL and give over 20-30 minutes
Topical: Apply a thin film to clean, dry skin and rub in gently
Contraindications Hypersensitivity to hydrocortisone or any component of the formulation; serious infections, except septic shock or tuberculous meningitis; viral, fungal, or tubercular skin lesions
Warnings
Use with caution in patients with hyperthyroidism, cirrhosis, nonspecific ulcerative colitis, hypertension, osteoporosis, thromboembolic tendencies, CHF, convulsive disorders, myasthenia gravis, thrombophlebitis, peptic ulcer, diabetes, glaucoma, cataracts, or tuberculosis. Use caution in hepatic impairment.
May cause HPA axis suppression. Acute adrenal insufficiency may occur with abrupt withdrawal after long-term therapy or with stress; young pediatric patients may be more susceptible to adrenal axis suppression from topical therapy. Avoid use of topical preparations with occlusive dressings or on weeping or exudative lesions.
Because of the risk of adverse effects, systemic corticosteroids should be used cautiously in the elderly, in the smallest possible dose, and for the shortest possible time
Dosage Forms [DSC] = Discontinued product
Aerosol, rectal, as acetate (Cortifoam®): 10% (15 g) [90 mg/applicator]
Cream, rectal, as acetate (Nupercainal® Hydrocortisone Cream): 1% (30 g) [strength expressed as base]
Cream, rectal, as base:
Cortizone®-10: 1% (30 g) [contains aloe]
Preparation H® Hydrocortisone: 1% (27 g)
Cream, topical, as acetate: 0.5% (9 g, 30 g, 60 g) [available with aloe]; 1% (30 g, 454 g) [available with aloe]
Cream, topical, as base: 0.5% (30 g); 1% (1.5 g, 30 g, 114 g, 454 g); 2.5% (20 g, 30 g, 454 g)
Anusol-HC®: 2.5% (30 g) [contains benzyl alcohol]
Caldecort®: 1% (30 g) [contains aloe vera gel]
Cortaid® Intensive Therapy: 1% (60 g)
Cortaid® Maximum Strength: 1% (15 g, 30 g, 40 g, 60 g) [contains aloe vera gel and benzyl alcohol]
Cortaid® Sensitive Skin: 0.5% (15 g) [contains aloe vera gel]
Cortizone®-10 Maximum Strength: 1% (15 g, 30 g, 60 g) [contains aloe]
Cortizone®-10 Plus Maximum Strength: 1% (30 g, 60 g) [contains vitamins A, D, E and aloe]
Dermarest® Dricort®: 1% (15 g, 30 g)
HydroZone Plus, Proctocort®, Procto-Pak™: 1% (30 g)
Hytone®: 2.5% (30 g, 60 g)
IvySoothe®: 1% (30 g) [contains aloe]
Post Peel Healing Balm: 1% (23 g)
ProctoCream® HC: 2.5% (30 g) [contains benzyl alcohol]
Procto-Kit™: 1% (30 g) [packaged with applicator tips and finger cots]; 2.5% (30 g) [packaged with applicator tips and finger cots]
Proctosol-HC®, Proctozone-HC™: 2.5% (30 g)
Summer's Eve® SpecialCare™ Medicated Anti-Itch Cream: 1% (30 g)
Cream, topical, as butyrate (Locoid®, Locoid Lipocream®): 0.1% (15 g, 45 g)

Cream, topical, as probutate (Pandel[®]): 0.1% (15 g, 45 g, 80 g)
 Cream, topical, as valerate (Westcort[®]): 0.2% (15 g, 45 g, 60 g)
 Gel, topical, as base (Corticoal[®]): 1% (45 g)
 Injection, powder for reconstitution, as sodium succinate (Solu-Cortef[®]): 100 mg, 250 mg, 500 mg, 1 g [diluent contains benzyl alcohol; strength expressed as base]
 Lotion, topical, as base: 1% (120 mL); 2.5% (60 mL)
 Aquanil[™] HC: 1% (120 mL)
 Beta-HC[®], Cetacort[®], Sarnol[®]-HC: 1% (60 mL)
 HydroZone Plus: 1% (120 mL)
 Hytone[®]: 2.5% (60 mL)
 Nutracort[®]: 1% (60 mL, 120 mL); 2.5% (60 mL, 120 mL)
 Ointment, topical, as acetate: 1% (30 g) [strength expressed as base; available with aloe]
 Anusol[®] HC-1: 1% (21 g) [strength expressed as base]
 Cortaid[®] Maximum Strength: 1% (15 g, 30 g) [strength expressed as base]
 Ointment, topical, as base: 0.5% (30 g); 1% (30 g, 454 g); 2.5% (20 g, 30 g, 454 g)
 Cortizone[®]-10 Maximum Strength: 1% (30 g, 60 g)
 Hytone[®]: 2.5% (30 g) [DSC]
 Ointment, topical, as butyrate (Locoid[®]): 0.1% (15 g, 45 g)
 Ointment, topical, as valerate (Westcort[®]): 0.2% (15 g, 45 g, 60 g)
 Solution, otic, as base (EarSol[®] HC): 1% (30 mL) [contains alcohol 44%, benzyl benzoate, yerba santa]
 Solution, topical, as base (Texacort[®]): 2.5% (30 mL) [contains alcohol]
 Solution, topical, as butyrate (Locoid[®]): 0.1% (20 mL, 60 mL) [contains alcohol 50%]
 Solution, topical spray, as base:
 Cortaid[®] Intensive Therapy: 1% (60 mL) [contains alcohol]
 Cortizone[®]-10 Quick Shot: 1% (44 mL) [contains benzyl alcohol]
 Dermtex[®] HC: 1% (52 mL) [contains menthol 1%]
 Suppository, rectal, as acetate: 25 mg (12s, 24s, 100s)
 Anucort-HC[®], Tucks[®] Anti-Itch: 25 mg (12s, 24s, 100s) [strength expressed as base; Anucort-HC[®] renamed Tucks[®] Anti-Itch]
 Anusol-HC[®], Proctosol-HC[®]: 25 mg (12s, 24s)
 Encort[™]: 30 mg (12s)
 Hemril[®]-30, Proctocort[®], Proctosert: 30 mg (12s, 24s)
 Suspension, rectal, as base: 100 mg/60 mL (7s)
 Colocort[®]: 100 mg/60 mL (1s, 7s)
 Tablet, as base: 20 mg
 Cortef[®]: 5 mg, 10 mg, 20 mg

Reference Range Therapeutic: AM: 5-25 mcg/dL (SI: 138-690 nmol/L), PM: 2-9 mcg/dL (SI: 55-248 nmol/L) depending on test, assay

Overdosage/Treatment Decontamination: Emesis or lavage within 1 hour; activated charcoal or cholestyramine (4 g) can decrease absorption

Test Interactions

> 100 mg/day may interfere with the TSH assay resulting in falsely low TSH levels

Drug Interactions Substrate of CYP3A4 (minor); Induces CYP3A4 (weak)

Decreased effect:

Insulin decreases hypoglycemic effect
 Phenytoin, phenobarbital, ephedrine, and rifampin increase metabolism of hydrocortisone and decrease steroid blood level

Increased toxicity:

Oral anticoagulants change prothrombin time
 Potassium-depleting diuretics increase risk of hypokalemia
 Cardiac glucosides increase risk of arrhythmias or digitalis toxicity secondary to hypokalemia

Pregnancy Risk Factor C

Pregnancy Implications No adequate studies in pregnant women. Corticosteroid use has been associated with cleft palate, neonatal adrenal suppression, low birth weight, and cataracts in the infant; including cases associated with topical administration. Use only if potential benefit to the mother exceeds the potential risk to the fetus. Avoid high doses or prolonged use.

Lactation Excretion in breast milk unknown/use caution

Additional Information Sodium content of 1 g (sodium succinate injection): 47.5 mg (2.07 mEq)

Hydrocortisone base topical cream, lotion, and ointments in concentrations of 0.25%, 0.5%, and 1% may be OTC or prescription depending on the product labeling

Food reduces absorption

Hydrogen Peroxide

CAS Number 7722-84-1

UN Number 2015

Synonyms H₂O₂; Hydrogen Dioxide; Peroxide

Commonly Includes Bleaching textiles, antiseptics, hair bleaching agents, loosens ear cerumen, recent intravenous use by AIDS patients to "cleanse blood." Household concentrations: 3%; industrial concentrations: 35%.

Use Cleanse wounds, suppurating ulcers, and local infections; used in the treatment of inflammatory conditions of the external auditory canal and as a mouthwash or gargle

Mechanism of Action Antiseptic oxidant that slowly releases oxygen and water upon contact with serum or tissue catalase; potent oxidizing agent

Adverse Reactions

Cardiovascular: Gas embolism, angina

Dermatologic: Bleaching effect on hair

Gastrointestinal: Rupture of the colon, proctitis, abdominal pain, ulcerative colitis, small bowel perforation, GI bleeding

Hematologic: Hemolysis

Local: Irritation of the buccal mucous membrane

Respiratory: Interstitial lung disease

Renal: Myoglobinuria, renal failure

Signs and Symptoms of Overdose Abdominal pain, chest pain, colitis, coma, dyspnea, gastric distention, gingival ulceration, metabolic acidosis, oropharyngeal burns, seizures (35% hydrogen peroxide), vomiting. Inhalation can cause cough and interstitial lung disease. Ocular exposure causes corneal ulceration, irritation, and lacrimation. Systemic embolization can produce cardiac arrest.

Admission Criteria/Prognosis Asymptomatic patients 6 hours post-exposure may be released; any patient with cardiopulmonary complaint should be admitted for 24-72 hours observation. Admit any pediatric ingestion of > 10% concentration of hydrogen peroxide.

Pharmacodynamics/Kinetics Duration of action: Only while bubbling action occurs

Dosage Children and Adults:

Mouthwash or gargle: Dilute the 3% solution with an equal volume of water; swish around in the mouth over the affected area for at least 1 minute and then expel; use up to 4 times/day (after meals and at bedtime)

Topical: 1.5% to 3% solution for cleansing wounds

Stability Keep tightly covered; decomposition is accelerated by metals and metallic salts; protect from heat and light

Monitoring Parameters CBC, renal status, x-rays

Contraindications Should not be used in abscesses

Warnings Repeat use as a mouthwash or gargle may produce irritation of the buccal mucous membrane or "hairy tongue"; bandages should not be applied too quickly after its use; 10% and 30% solutions must be diluted prior to use

Dosage Forms Gel, oral: 1.5% (15 g)

Solution:

Concentrate: 30.5% (480 mL)

Topical: 3% (120 mL, 480 mL)

Overdosage/Treatment

Decontamination: Dilute with water; use nasogastric tube for gastric decompression or removal of hydrogen peroxide

Supportive therapy: Hyperbaric oxygen advocated for reducing size of gas emboli; cerebral gas embolism can be treated with hyperbaric oxygen (3 ATA); avoid use of the Trendelenburg positioning in that it may trap air in the right ventricle; endoscopy and abdominal x-rays should be obtained within 48 hours if ingested hydrogen peroxide concentration exceeds 10% to examine local mucosal burns and abdominal distention; seizures can be treated with benzodiazepines

Additional Information Clear, colorless fluid; bitter acid taste. Intravenous use is associated with hemolytic anemia and subsequent renal failure. 1 mL of 3% hydrogen peroxide liberates 10 mL of oxygen. TLV-TWA: 1 ppm; IDLH: 75 ppm; PEL-TWA: 1 ppm

Hydromorphone

CAS Number 466-99-9; 71-68-1

U.S. Brand Names Dilaudid-HP®; Dilaudid®

Synonyms Dihydromorphinone; Hydromorphone Hydrochloride

Impairment Potential Yes

Use Management of moderate to severe pain

Unlabeled/Investigational Use Antitussive

Mechanism of Action Binds to opiate receptors in the CNS, causing inhibition of ascending pain pathways, altering the perception of and response to pain; causes cough suppression by direct central action in the medulla; produces generalized CNS depression

Adverse Reactions

Cardiovascular: **Palpitations, hypotension, bradycardia, peripheral vasodilation, sinus bradycardia**

Central nervous system: CNS depression, agitation, increased intracranial pressure, **drowsiness, dizziness, sedation, lightheadedness**

Dermatologic: Pruritus, systemic contact dermatitis

Endocrine & metabolic: Antidiuretic hormone release

Gastrointestinal: Nausea, vomiting, constipation, biliary tract spasm, **anorexia**

Genitourinary: Urinary tract spasm

Ocular: Miosis

Respiratory: Apnea, respiratory depression

Miscellaneous: Physical and psychological dependence, histamine release, Myoclonus

Signs and Symptoms of Overdose Apnea, bradycardia, confusion, coma, flaccidity, hypotension, myasthenia gravis (exacerbation or precipitation), respiratory depression, syndrome of inappropriate antidiuretic hormone (SIADH).

Pharmacodynamics/Kinetics

Onset of action: Analgesic: Immediate release formulations:

Oral: 15-30 minutes

Peak effect: Oral: 30-60 minutes

Duration: Immediate release formulations: 4-5 hours

Absorption: I.M.: Variable and delayed

Distribution: V_d : 4 L/kg

Protein binding: ~8% to 19%

Metabolism: Hepatic via glucuronidation; to inactive metabolites

Bioavailability: 62%

Half-life elimination: Immediate release formulations: 1-3 hours

Excretion: Urine (primarily as glucuronide conjugates)

Dosage

Acute pain (moderate to severe): **Note:** These are guidelines and do not represent the maximum doses that may be required in all patients.

Doses should be titrated to pain relief/prevention.

Young Children ≥ 6 months and < 50 kg:

Oral: 0.03-0.08 mg/kg/dose every 3-4 hours as needed

I.V.: 0.015 mg/kg/dose every 3-6 hours as needed

Elder Children > 50 kg and Adults:

Oral: Initial: Opiate-naïve: 2-4 mg every 3-4 hours as needed; patients with prior opiate exposure may require higher initial doses; usual dosage range: 2-8 mg every 3-4 hours as needed

I.V.: Initial: Opiate-naïve: 0.2-0.6 mg every 2-3 hours as needed; patients with prior opiate exposure may tolerate higher initial doses

Note: More frequent dosing may be needed.

Mechanically-ventilated patients (based on 70 kg patient): 0.7-2 mg every 1-2 hours as needed; infusion (based on 70 kg patient): 0.5-1 mg/hour

Patient-controlled analgesia (PCA): (Opiate-naïve: Consider lower end of dosing range)

Usual concentration: 0.2 mg/mL

Demand dose: Usual: 0.1-0.2 mg; range: 0.05-0.5 mg

Lockout interval: 5-15 minutes

4-hour limit: 4-6 mg

Epidural:

Bolus dose: 1-1.5 mg

Infusion concentration: 0.05-0.075 mg/mL

Infusion rate: 0.04-0.4 mg/hour

Demand dose: 0.15 mg

Lockout interval: 30 minutes

I.M., SubQ: **Note:** I.M. use may result in variable absorption and a lag time to peak effect.

Initial: Opiate-naïve: 0.8-1 mg every 4-6 hours as needed; patients with prior opiate exposure may require higher initial doses; usual dosage range: 1-2 mg every 3-6 hours as needed

Rectal: 3 mg every 4-8 hours as needed

Chronic pain: Patients taking opioids chronically may become tolerant and require doses higher than the usual dosage range to maintain the desired effect. Tolerance can be managed by appropriate dose titration. There is no optimal or maximal dose for hydromorphone in chronic pain.

The appropriate dose is one that relieves pain throughout its dosing interval without causing unmanageable side effects.

Adults: Oral, controlled release formulation (Hydromorph Contin®; not available in U.S.): 3-30 mg every 12 hours. **Note:** A patient's hydromorphone requirement should be established using prompt release formulations; conversion to long acting products may be considered when chronic, continuous treatment is required. Higher dosages should be reserved for use only in opioid-tolerant patients.

Antitussive: Oral:

Children 6-12 years: 0.5 mg every 3-4 hours as needed

Children > 12 years and Adults: 1 mg every 3-4 hours as needed

Dosing adjustment in hepatic impairment: Should be considered

Stability Protect tablets from light; do not store intact ampuls in refrigerator; a slightly yellowish discoloration has not been associated with a loss of potency; I.V. is **incompatible** when mixed with minocycline, prochlorperazine, sodium bicarbonate, tetracycline, thiopental, dexamethasone

Monitoring Parameters Pain relief, respiratory and mental status, blood pressure

Administration Parenteral: May be given SubQ or I.M.; vial stopper contains latex

I.V.: For IVP, must be given slowly over 2-3 minutes (rapid IVP has been associated with an increase in side effects, especially respiratory depression and hypotension)

Oral: Hydromorph Contin®: Capsule should be swallowed whole; do not crush or chew; contents may be sprinkled on soft food and swallowed

Contraindications Hypersensitivity to hydromorphone, any component of the formulation; acute or severe asthma, severe respiratory depression (in absence of resuscitative equipment or ventilatory support); severe CNS depression; pregnancy (prolonged use or high doses at term); obstetrical analgesia

Warnings Hydromorphone shares toxic potential of opiate agonists, including CNS depression and respiratory depression. Precautions associated with opiate agonist therapy should be observed. Critical respiratory depression may occur, even at therapeutic dosages, particularly in elderly or debilitated patients or in patients with pre-existing respiratory compromise (hypoxia and/or hypercapnia). Use caution in COPD or other obstructive pulmonary disease. Use with caution in patients with hypersensitivity to other phenanthrene opiates, biliary tract disease, acute pancreatitis, adrenocortical insufficiency, hypothyroidism, acute alcoholism, toxic psychoses, or severe liver or renal failure. Use extreme caution in patients with head injury, intracranial lesions, or elevated intracranial pressure; exaggerated elevation of ICP may occur (in addition, hydromorphone may complicate neurologic evaluation due to pupillary dilation and CNS depressant effects). Use with caution in patients with depleted blood volume or drugs which may exaggerate hypotensive effects (including phenothiazines or general anesthetics).

[U.S. Boxed Warning]: Hydromorphone has a high potential for abuse. Those at risk for opioid abuse include patients with a history of substance abuse or mental illness. Tolerance or drug dependence may result from extended use; however, concerns for abuse should not prevent effective management of pain. In general, abrupt discontinuation of therapy in dependent patients should be avoided.

An opioid-containing analgesic regimen should be tailored to each patient's needs and based upon the type of pain being treated (acute versus chronic), the route of administration, degree of tolerance for opioids (naïve versus chronic user), age, weight, and medical condition. The optimal analgesic dose varies widely among patients. Doses should be titrated to pain relief/prevention. I.M. use may result in variable absorption and a lag time to peak effect.

Dosage form-specific warnings:

[U.S. Boxed Warning]: Dilaudid-HP®: Extreme caution should be taken to avoid confusing the highly-concentrated (Dilaudid-HP®) injection with the less-concentrated (Dilaudid®) injectable product. Dilaudid-HP® should only be used in patients who are opioid-tolerant.

Controlled release: Capsules should only be used when continuous analgesia is required over an extended period of time. Controlled release products are not to be used on an "as needed" (PRN) basis. Some dosage forms contain trace amounts of sodium metabisulfite which may cause allergic reactions in susceptible individuals.

Dosage Forms [CAN] = Canadian brand name

Capsule, controlled release (Hydromorph Contin®) [CAN]: 3 mg, 6 mg, 12 mg, 18 mg, 24 mg, 30 mg [not available in U.S.]

Injection, powder for reconstitution, as hydrochloride (Dilaudid-HP®): 250 mg

Injection, solution, as hydrochloride: 1 mg/mL (1 mL); 2 mg/mL (1 mL, 20 mL); 4 mg/mL (1 mL); 10 mg/mL (1 mL, 5 mL, 10 mL)

Dilaudid®: 1 mg/mL (1 mL); 2 mg/mL (1 mL, 20 mL) [20 mL size contains edetate sodium; vial stopper contains latex]; 4 mg/mL (1 mL)

Dilaudid-HP®: 10 mg/mL (1 mL, 5 mL, 50 mL)

Liquid, oral, as hydrochloride (Dilaudid®): 1 mg/mL (480 mL) [may contain trace amounts of sodium bisulfite]

Suppository, rectal, as hydrochloride (Dilaudid®): 3 mg (6s)
 Tablet, as hydrochloride (Dilaudid®): 2 mg, 4 mg, 8 mg (8 mg tablets may contain trace amounts of sodium bisulfite)

Reference Range Serum therapeutic (pain control): 0.001-0.032 mg/L; fatalities due to hydromorphone can occur at postmortem levels (blood) over 51 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at $\frac{2}{3}$ the response dose/hour) may be required

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Test Interactions ↑ aminotransferases (ALT, AST) (S)

Drug Interactions Ammonium chloride: May decrease the levels/effects of hydromorphone.

CNS depressants: Effects with hydromorphone may be additive.

General anesthetics: May enhance the hypotensive and CNS depressant effects of hydromorphone.

Pegvisomant: Analgesics (narcotic) may diminish the therapeutic effect of pegvisomant; increased pegvisomant doses may be needed.

Phenothiazines: May enhance the hypotensive and CNS depressant effects of hydromorphone.

Selective serotonin reuptake inhibitors (SSRIs): Serotonergic effects may be additive, leading to serotonin syndrome.

Pregnancy Risk Factor B/D (prolonged use or high doses at term)

Pregnancy Implications Crosses the placenta

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Observe patient for oversedation, respiratory depression, implement safety measures

Additional Information Equianalgesic doses: Morphine 10 mg I.M. = hydromorphone 1.5 mg I.M.; no cough suppressant effects

Hydroquinone

CAS Number 123-31-9

UN Number 2662

U.S. Brand Names Alphaquin HP; Alustra™; Claripel™; Eldopaque Forte®; Eldopaque® [OTC]; Eldoquin Forte®; Eldoquin® [OTC]; EpiQuin™ Micro; Esoterica® Regular [OTC]; Glyquin®; Lustra-AF™; Lustra®; Melanex®; Melpaque HP®; Melquin HP®; Melquin-3®; NeoStrata AHA [OTC]; Nuquin HP®; Palmer's® Skin Success Fade Cream™ [OTC]; Solaquin Forte®; Solaquin® [OTC]

Synonyms Hydroquinol; Quinol

Use Gradual bleaching of hyperpigmented skin conditions

Mechanism of Action Produces reversible depigmentation of the skin by suppression of melanocyte metabolic processes, in particular the inhibition of the enzymatic oxidation of tyrosine to DOPA (3,4-dihydroxyphenylalanine); sun exposure reverses this effect and will cause repigmentation.

Adverse Reactions

Central nervous system: Dizziness, headache, delirium

Dermatologic: Dermatitis, dry skin, erythema, stinging, inflammatory reaction, sensitization, leukoderma, hair discoloration (red), nail discoloration (brown), hypopigmentation

Genitourinary: Discoloration of urine (black) after 12 g ingestion

Hematologic: Methemoglobinemia, hemolysis

Local: Irritation

Ocular: Keratitis, corneal ulceration

Admission Criteria/Prognosis Admit any oral ingestion > 1 g

Pharmacodynamics/Kinetics Onset and duration of depigmentation produced by hydroquinone varies among individuals

Dosage Children > 12 years and Adults: Topical: Apply thin layer and rub in twice daily

Administration For external use only; avoid contact with eyes

Contraindications Hypersensitivity to hydroquinone or any component of the formulation; sunburn, depilatory usage

Warnings Limit application to area no larger than face and neck or hands and arms

Dosage Forms

Cream, topical: 4% (30 g) [may contain sodium metabisulfite]

Alphaquin HP®: 4% (30 g, 60 g)

Eldoquin®: 2% (15 g, 30 g)

Eldoquin Forte®: 4% (30 g) [contains sodium metabisulfite]

EpiQuin™ Micro: 4% (30 g) [contains benzyl alcohol and sodium metabisulfite]

Esoterica® Regular: 2% (85 g) [contains sodium bisulfite]

Lustra®: 4% (30 g) [contains sodium metabisulfite]

Melquin HP®: 4% (15 g, 30 g) [contains sodium metabisulfite]

Cream, topical [with sunscreen]: 4% (30 g) [may contain sodium metabisulfite]

Claripel™: 4% (30 g, 45 g) [contains sodium metabisulfite]

Dermarest® Skin Correcting Cream Plus: 2% (85 g) [contains aloe vera, sodium bisulfite]

Eldopaque®: 2% (15 g, 30 g)

Eldopaque Forte®: 4% (30 g) [contains sodium metabisulfite]

Glyquin®: 4% (30 g)

Glyquin-XM™: 4% (30 g)

Lustra-AF™: 4% (30 g, 60 g) [contains sodium metabisulfite]

Melpaque HP®: 4% (15 g, 30 g) [contains sodium metabisulfite; sunblocking cream base]

Nuquin HP®: 4% (15 g, 30 g, 60 g) [contains sodium metabisulfite]

Palmer's® Skin Success Eventone® Fade Cream: 2% (81 g, 132 g) [contains sodium sulfite; available in regular, oily skin, and dry skin formulas]

Solaquin®: 2% (30 g)

Solaquin Forte®: 4% (30 g) [contains sodium metabisulfite]

Gel, topical (NeoStrata® AHA): 2% (45 g) [contains glycolic acid 10%, sodium bisulfite, and sodium sulfite]

Gel, topical [with sunscreen]: 4% (30 g)

Nuquin HP: 4% (15 g, 30 g) [contains sodium bisulfite]

Solaquin Forte®: 4% (30 g) [contains sodium metabisulfite]

Solution, topical (Melanex®, Melquin-3®): 3% (30 mL) [contains alcohol]

Reference Range Acute GI symptoms associated with serum hydroquinone levels > 0.1 mcg/mL

Overdosage/Treatment Decontamination: **Oral:** Dilute with milk or water; lavage (within 1 hour)/activated charcoal **Dermal:** Wash with soap and water. **Ocular:** Irrigate with copious amounts of saline

Test Interactions May result in positive urinary test for phenol

Drug Interactions No data reported

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Additional Information Lethal oral dose: Adults: 5 g

Specific gravity: 1.332; vapor density: 3.81; has a sweet taste

Hydroxychloroquine

Related Information

- Chloroquine

CAS Number 118-42-3; 747-36-4

U.S. Brand Names Plaquenil®

Synonyms Hydroxychloroquine Sulfate

Use Suppresses and treats acute attacks of malaria; treatment of systemic lupus erythematosus and rheumatoid arthritis

Unlabeled/Investigational Use Porphyrria cutanea tarda, polymorphous light eruptions; nonbronchodilating antiasthmatic drug with potential steroid sparing effects due to immunomodulation

Mechanism of Action Interferes with digestive vacuole function within sensitive malarial parasites by increasing the pH and interfering with lysosomal degradation of hemoglobin; inhibits locomotion of neutrophils and chemotaxis of eosinophils; impairs complement-dependent antigen-antibody reactions

Adverse Reactions

Cardiovascular: Hypotension, arrhythmia (ventricular), torsade de pointes, bradycardia, sinus bradycardia

Central nervous system: Insomnia, nervousness, night terrors, psychosis, headache, confusion, agitation, seizures, dizziness, ataxia, global amnesia, extrapyramidal reactions

Dermatologic: Lichenoid dermatitis, exfoliative dermatitis, bleaching of the hair, hypopigmented hair, pruritus, phototoxicity, pustulosis

Endocrine & metabolic: Hypokalemia, hypoglycemia

Gastrointestinal: GI irritation, anorexia, nausea, vomiting, diarrhea, dysgeusia, loss of appetite, stomach cramps

Hematologic: Bone marrow suppression, hemolysis, thrombocytopenia, leukopenia, neutropenia, agranulocytosis, granulocytopenia, aplastic anemia, porphyria, porphyrinogenic

Neuromuscular & skeletal: Weakness

Ocular: Visual field defects, vision color changes (blue tinge); vision color changes (green tinge); vision color changes (yellow tinge); photophobia, blindness, diplopia, retinitis, retinopathy threshold dose is 7.8 mg/kg/day (less ocular toxicity than chloroquine), ciliary muscle dysfunction

Otic: Hearing loss

HYDROXYUREA

Signs and Symptoms of Overdose

Lymphocytosis
Admission Criteria/Prognosis Admit any symptomatic patient, or ingestion > 10 mg/kg; asymptomatic patients should be observed on an ECG monitor for 8 hours.

Pharmacodynamics/Kinetics

Onset of action: Rheumatic disease: May require 4-6 weeks to respond
Absorption: Complete
Protein binding: 55%
Metabolism: Hepatic
Half-life elimination: 32-50 days
Time to peak: Rheumatic disease: Several months
Excretion: Urine (as metabolites and unchanged drug); may be enhanced by urinary acidification

Dosage

Oral:

Children:

Chemoprophylaxis of malaria: 5 mg/kg (base) once weekly; should not exceed the recommended adult dose; begin 2 weeks before exposure; continue for 4-6 weeks after leaving endemic area
Acute attack: 10 mg/kg (base) initial dose; followed by 5 mg/kg in 6 hours on day 1; 5 mg/kg in 1 dose on day 2 and on day 3
JRA or SLE: 3-5 mg/kg/day divided 1-2 times/day to a maximum of 400 mg/day; not to exceed 7 mg/kg/day

Adults:

Chemoprophylaxis of malaria: 2 tablets/week on same day each week; begin 2 weeks before exposure; continue for 4-6 weeks after leaving endemic area
Acute attack: 4 tablets first dose day 1; 2 tablets in 6 hours day 1; 2 tablets in 1 dose day 2; and 2 tablets in 1 dose on day 3
Rheumatoid arthritis: 2-3 tablets/day to start taken with food or milk; increase dose until optimum response level is reached; usually after 4-12 weeks dose should be reduced by $1/2$ and a maintenance dose of 1-2 tablets/day given
Lupus erythematosus: 2 tablets every day or twice daily for several weeks depending on response; 1-2 tablets/day for prolonged maintenance therapy

Asthma: 300-600 mg/day up to 3 years

To limit incidence of retinopathy, do not give more than 400 mg/day

Monitoring Parameters Ophthalmologic exam, CBC

Administration Administer with food or milk

Contraindications Hypersensitivity to hydroxychloroquine, 4-aminoquinoline derivatives, or any component of the formulation; retinal or visual field changes attributable to 4-aminoquinolines

Warnings Use with caution in patients with hepatic disease, G6PD deficiency, psoriasis, and porphyria; long-term use in children is not recommended; perform baseline and periodic (6 months) ophthalmologic examinations; test periodically for muscle weakness. **[U.S. Boxed Warning]: Should be prescribed by physicians familiar with its use.**

Dosage Forms Tablet, as sulfate: 200 mg [equivalent to 155 mg base]

Reference Range Peak serum level of 427 ng/mL after an oral dose of 200 mg (155 mg base); plasma level after ingestion of 20 g, with severe symptoms, was reported as 9.9 mg/L (29.4 μ mol/L)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: Electrolyte balance should be monitored and treated, especially when refractory arrhythmias develop. Sodium bicarbonate 1-2 mEq/kg I.V. (or 0.5-1 mEq/kg in children) may decrease conduction defects. Phenytoin or lidocaine are often effective at controlling drug-induced arrhythmias, while phenytoin is preferred due to its beneficial effects on AV conduction velocity. Diazepam should also be administered to treat cardiac toxicity. Epinephrine is useful in treating hypotension or cardiac dysrhythmias. Monitor for hypokalemia and replace potassium as necessary. Treatment is similar to that of chloroquine toxicity. Torsade de pointes can be treated with magnesium sulfate or overdrive pacemaker. Avoid class I antiarrhythmic agents; avoid administration of thiopentone.

Enhancement of elimination: Multiple dosing of activated charcoal is effective; exchange transfusion can be utilized to remove toxic metabolites; hemodialysis or charcoal hemoperfusion have little effect; slightly dialyzable (5% to 20%). Plasmapheresis is not useful.

Drug Interactions Chloroquine and other 4-aminoquinolones may be decreased due to GI binding with kaolin or magnesium trisilicate
Increased effect: Cimetidine increases levels of chloroquine and probably other 4-aminoquinolones

Pregnancy Risk Factor C

Pregnancy Implications No evidence of teratogenesis

Lactation Enters breast milk/compatible

Nursing Implications Periodic blood counts and eye examinations are recommended when patient is on chronic therapy; give with food or milk

Hydroxyurea

CAS Number 127-07-1

U.S. Brand Names DroxiaTM; Hydrea[®]; MylocelTM

Synonyms Hydroxycarbamide

Use Treatment of melanoma, refractory chronic myelocytic leukemia (CML), relapsed and refractory metastatic ovarian cancer; radiosensitizing agent in the treatment of squamous cell head and neck cancer (excluding lip cancer); adjunct in the management of sickle cell patients who have had at least three painful crises in the previous 12 months (to reduce frequency of these crises and the need for blood transfusions)

Unlabeled/Investigational Use Treatment of HIV; treatment of psoriasis, treatment of hematologic conditions such as essential thrombocytopenia, polycythemia vera, hypereosinophilia, and hyperleukocytosis due to acute leukemia; treatment of uterine, cervix and nonsmall cell lung cancers; radiosensitizing agent in the treatment of primary brain tumors; has shown activity against renal cell cancer and prostate cancer

Mechanism of Action Interferes with synthesis of DNA, during the S phase of cell division, without interfering with RNA synthesis; inhibits ribonucleoside diphosphate reductase, preventing conversion of ribonucleotides to deoxyribonucleotides; cell-cycle specific for the S phase and may hold other cells in the G₁ phase of the cell cycle.

Adverse Reactions

Central nervous system: Drowsiness (with high doses), hallucinations, headache, neurotoxicity, seizures

Dermatologic: Erythema of the hands and face, maculopapular rash, pruritus or dry skin, skin cancer, alopecia is rare. Hyperpigmentation with radiation exposure.

Endocrine & metabolic: Hyperuricemia

Gastrointestinal: Mild nausea and vomiting may occur, as well as diarrhea, constipation, stomatitis, anorexia, pancreatitis

Emetic potential: Low

Hematologic: Myelosuppression (primarily leukopenia); Dose-limiting toxicity, causes a rapid drop in leukocyte count (seen in 4-5 days in nonhematologic malignancy and more rapidly in leukemia); thrombocytopenia and anemia occur less often; reversal of WBC count occurs rapidly, but the platelet count may take 7-10 days to recover

Onset: 24-48 hours; Nadir: 10 days; Recovery: 7 days after stopping drug

Hepatic: Elevation of hepatic enzymes, hepatotoxicity

Neuromuscular & skeletal: Peripheral neuropathy

Renal: Increased creatinine and BUN due to impairment of renal tubular function

Respiratory: Acute diffuse pulmonary infiltrates (rare)

Miscellaneous: Nail banding

Pharmacodynamics/Kinetics

Absorption: Readily ($\geq 80\%$)

Distribution: Readily crosses blood-brain barrier; distributes into intestine, brain, lung, kidney tissues, effusions, and ascites

Metabolism: 60% via hepatic and GI tract

Half-life elimination: 3-4 hours

Time to peak: 1-4 hours

Excretion: Urine (80%, 50% as unchanged drug, 30% as urea); exhaled gases (as CO₂)

Dosage

Oral (refer to individual protocols): All dosage should be based on ideal or actual body weight, whichever is less:

Children:

No FDA-approved dosage regimens have been established; dosages of 1500-3000 mg/m² as a single dose in combination with other agents every 4-6 weeks have been used in the treatment of pediatric astrocytoma, medulloblastoma, and primitive neuroectodermal tumors

CML: Initial: 10-20 mg/kg/day once daily; adjust dose according to hematologic response

Adults: Dose should always be titrated to patient response and WBC counts; usual oral doses range from 10-30 mg/kg/day or 500-3000 mg/day; if WBC count falls to <2500 cells/mm³, or the platelet count to <100,000/mm³, therapy should be stopped for at least 3 days and resumed when values rise toward normal

Solid tumors:

Intermittent therapy: 80 mg/kg as a single dose every third day

Continuous therapy: 20-30 mg/kg/day given as a single dose/day

Concomitant therapy with irradiation: 80 mg/kg as a single dose every third day starting at least 7 days before initiation of irradiation

Resistant chronic myelocytic leukemia: Continuous therapy: 20-30 mg/kg as a single daily dose

HIV (unlabeled use; in combination with antiretroviral agents): 1000-1500 mg daily in a single dose or divided doses

Psoriasis (unlabeled use): 1000-1500 mg/day in a single dose or divided doses

Sickle cell anemia (moderate/severe disease): Initial: 15 mg/kg/day, increased by 5 mg/kg every 12 weeks if blood counts are in an acceptable range until the maximum tolerated dose of 35 mg/kg/day is achieved or the dose that does not produce toxic effects

Acceptable range:

Neutrophils ≥ 2500 cells/mm³

Platelets $\geq 95,000$ /mm³

Hemoglobin > 5.3 g/dL, and

Reticulocytes $\geq 95,000$ /mm³ if the hemoglobin concentration is < 9 g/dL

Toxic range:

Neutrophils < 2000 cells/mm³

Platelets $< 80,000$ /mm³

Hemoglobin < 4.5 g/dL

Reticulocytes $< 80,000$ /mm³ if the hemoglobin concentration is < 9 g/dL

Monitor for toxicity every 2 weeks; if toxicity occurs, stop treatment until the bone marrow recovers; restart at 2.5 mg/kg/day less than the dose at which toxicity occurs; if no toxicity occurs over the next 12 weeks, then the subsequent dose should be increased by 2.5 mg/kg/day; reduced dosage of hydroxyurea alternating with erythropoietin may decrease myelotoxicity and increase levels of fetal hemoglobin in patients who have not been helped by hydroxyurea alone

Dosing adjustment in renal impairment:

Sickle cell anemia: $Cl_{cr} < 60$ mL/minute or ESRD: Reduce initial dose to 7.5 mg/kg; titrate to response/avoidance of toxicity (refer to usual dosing)

Other indications:

Cl_{cr} 10-50 mL/minute: Administer 50% of normal dose

$Cl_{cr} < 10$ mL/minute: Administer 20% of normal dose

Hemodialysis: Supplemental dose is not necessary. Hydroxyurea is a low molecular weight compound with high aqueous solubility that may be freely dialyzable, however, clinical studies confirming this hypothesis have not been performed; peak serum concentrations are reached within 2 hours after oral administration and by 24 hours, the concentration in the serum is zero

CAPD effects: Unknown

CAVH effects: Dose for GFR 10-50 mL/minute

Stability Store capsules at room temperature; capsules may be opened and emptied into water (will not dissolve completely)

Monitoring Parameters CBC with differential, platelets, hemoglobin, renal function and liver function tests, serum uric acid

Administration Capsules may be opened and emptied into water (will not dissolve completely); observe proper handling procedures

Contraindications Hypersensitivity to hydroxyurea or any component of the formulation; severe anemia; severe bone marrow suppression; WBC < 2500 /mm³ or platelet count $< 100,000$ /mm³; pregnancy

Warnings Hazardous agent – use appropriate precautions for handling and disposal. Patients with a history of prior cytotoxic chemotherapy and radiation therapy are more likely to experience bone marrow depression. Patients with a history of radiation therapy are also at risk for exacerbation of post irradiation erythema. Megaloblastic erythropoiesis may be seen early in hydroxyurea treatment; plasma iron clearance may be delayed and the rate of utilization of iron by erythrocytes may be delayed. HIV-infected patients treated with hydroxyurea and didanosine (with or without stavudine) are at higher risk for pancreatitis, hepatotoxicity, hepatic failure, and severe peripheral neuropathy. **[U.S. Boxed Warning]: Hydroxyurea is mutagenic and clastogenic. Treatment of myeloproliferative disorders (polycythemia vera and thrombocytopenia) with long-term hydroxyurea is associated with secondary leukemia; it is unknown if this is drug-related or disease-related.** Cutaneous vasculitic toxicities (vasculitic ulceration and gangrene) have been reported with hydroxyurea treatment, most often in patients with a history of or receiving concurrent interferon therapy; discontinue hydroxyurea and consider alternate cytoreductive therapy if cutaneous vasculitic toxicity develops. Use caution with renal dysfunction; may require dose reductions. Safety and efficacy in children have not been established. **[U.S. Boxed Warning]: Should be administered under the supervision of a physician experienced in cancer chemotherapy or in the treatment of sickle cell anemia.**

Dosage Forms Capsule: 500 mg

Droxia®: 200 mg, 300 mg, 400 mg

Hydrea®: 500 mg

Tablet (Mylocel™): 1000 mg

Overdosage/Treatment

Supportive therapy: Leg ulcers can be treated with a single application of Apligraf.

Decontamination: Lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be useful

Test Interactions ↑ uric acid, BUN, creatinine

Drug Interactions Didanosine: Hydroxyurea may increase risk of didanosine-induced pancreatitis, hepatotoxicity, or neuropathy; concomitant use is not recommended

Pregnancy Risk Factor D

Pregnancy Implications Hydroxyurea is teratogenic and fetotoxic in animals; data on use during human pregnancy is limited. Effective contraception is recommended in women of childbearing potential.

Lactation Enters breast milk/contraindicated

Additional Information Handle urine from patients taking hydroxyurea with care. Myelosuppressive effects: **WBC:** Moderate. **Platelets:** Moderate. Onset (days): 7. Nadir (days): 10. Recovery (days): 21

HydroXYzine

Related Information

• Cetirizine

CAS Number 10246-75-0; 2192-20-3; 68-88-2

U.S. Brand Names Atarax®; Vistaril®

Synonyms Hydroxyzine Hydrochloride; Hydroxyzine Pamoate

Impairment Potential Yes. Impairment occurs (over about a 6-hour period) at doses of 25 mg. (Gengo FM and Manning C, "A Review of the Effects of Antihistamines on Mental Processes Related to Automobile Driving," *J Allergy Clin Immunol*, 1990 86(2):1034-9.)

Use Treatment of anxiety, as a preoperative sedative, an antipruritic

Unlabeled/Investigational Use Antiemetic; ethanol withdrawal symptoms

Mechanism of Action A piperazine compound which competes with histamine for H₁-receptor sites on effector cells in the gastrointestinal tract, blood vessels, and respiratory tract

Adverse Reactions

Cardiovascular: Palpitations, hypotension, sinus bradycardia, sinus tachycardia

Central nervous system: **Slight to moderate drowsiness**, headache, fatigue, nervousness, dizziness, CNS depression, sedation, paradoxical excitement, insomnia, fever, hyperthermia, ataxia

Dermatologic: Photosensitivity, rash, angioedema, fixed drug eruption, erythema multiforme, urticaria, purpura, exanthem

Gastrointestinal: Increased appetite, increased weight, nausea, diarrhea, abdominal pain, xerostomia

Genitourinary: Urinary retention

Hematologic: Hemolysis (I.V. administration), porphyrinogenic

Hepatic: Hepatitis

Neuromuscular & skeletal: Arthralgia, myalgia, tremors, paresthesia, rhabdomyolysis

Ocular: Blurred vision

Respiratory: **Thickening of bronchial secretions**, bronchospasm, pharyngitis, epistaxis

Signs and Symptoms of Overdose Depression, hypotension, impotence, insomnia, myalgia, seizures, sedation

Admission Criteria/Prognosis Observe ingestions for 12 hours; admit ingestions > 300 mg

Pharmacodynamics/Kinetics

Onset of action: 15-30 minutes

Duration: 4-6 hours

Absorption: Oral: Rapid

Metabolism: Exact fate unknown

Half-life elimination: 3-7 hours

Time to peak: ~2 hours

Dosage

Children:

Oral: 0.6 mg/kg/dose every 6 hours

I.M.: 0.5-1 mg/kg/dose every 4-6 hours as needed

Adults:

Antiemetic: I.M.: 25-100 mg/dose every 4-6 hours as needed

Anxiety: Oral: 25-100 mg 4 times/day; maximum dose: 600 mg/day

Preoperative sedation:

Oral: 50-100 mg

I.M.: 25-100 mg

Management of pruritus: Oral: 25 mg 3-4 times/day

Dosing interval in hepatic impairment: Change dosing interval to every 24 hours in patients with primary biliary cirrhosis

Stability Protect from light; I.V. is **incompatible** when mixed with aminophylline, amobarbital, chloramphenicol, dimenhydrinate, heparin, penicillin G, pentobarbital, phenobarbital, phenytoin, ranitidine, sulfisoxazole, thioridazine, vitamin B complex with C

Monitoring Parameters Relief of symptoms, mental status, blood pressure

HYOSCYAMINE

Administration

Do not administer SubQ or intra-arterially.

I.M.: For administration in children, injections should be made into the midlateral muscles of the thigh.

I.V.: Not generally recommended; may be given as a short (30-60 minute) infusion.

Contraindications Hypersensitivity to hydroxyzine or any component of the formulation; early pregnancy

Warnings

Causes sedation, caution must be used in performing tasks which require alertness (eg, operating machinery or driving). Sedative effects of CNS depressants or ethanol are potentiated. SubQ and intra-arterial administration are not recommended since thrombosis and digital gangrene can occur; should be used with caution in patients with narrow-angle glaucoma, prostatic hyperplasia, and bladder neck obstruction; should also be used with caution in patients with asthma or COPD.

Anticholinergic effects are not well tolerated in the elderly. Hydroxyzine may be useful as a short-term antipruritic, but it is not recommended for use as a sedative or anxiolytic in the elderly.

Dosage Forms

Capsule, as pamoate: 25 mg, 50 mg, 100 mg

Vistaril®: 25 mg, 50 mg

Injection, solution, as hydrochloride: 25 mg/mL (1 mL); 50 mg/mL (1 mL, 2 mL, 10 mL)

Suspension, oral, as pamoate:

Vistaril®: 25 mg/5 mL (120 mL, 480 mL) [lemon flavor]

Syrup, as hydrochloride: 10 mg/5 mL (120 mL, 480 mL)

Tablet, as hydrochloride: 10 mg, 25 mg, 50 mg

Reference Range Plasma hydroxyzine level of 5.6-41.8 mcg/dL (13.2-102.0 nmol/L) therapeutic for pruritus in children; peak plasma level is 73 mcg/L after 0.7 mg/kg dose in adults

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Physostigmine should be utilized in severe life-threatening anticholinergic crisis; norepinephrine or metaraminol are the vasopressors of choice; epinephrine is **not** useful

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Test Interactions Can suppress wheal and flare of antigen skin testing for 4 days

Drug Interactions

Inhibits CYP2D6 (weak)
Acetylcholinesterase Inhibitors (Central): May diminish the anticholinergic effect of hydroxyzine. If the anticholinergic effect is a side effect of the agent, as is the case with hydroxyzine, the result may be beneficial.

Anticholinergic agents: Central and/or peripheral anticholinergic syndrome can occur when administered with narcotic analgesics, phenothiazines and other antipsychotics (especially with high anticholinergic activity), tricyclic antidepressants, quinidine and some other antiarrhythmics, and antihistamines

CNS depressants: Sedative effects of hydroxyzine may be additive with CNS depressants; includes ethanol, benzodiazepines, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect
Pramlintide: May enhance the GI-related anticholinergic effect of hydroxyzine.

Pregnancy Risk Factor C

Pregnancy Implications Neonatal withdrawal syndrome may occur

Lactation Enters breast milk/contraindicated

Nursing Implications Extravasation can result in sterile abscess and marked tissue induration; provide safety measures (ie, side rails, night light, and call button); remove smoking materials from area; supervise ambulation

Additional Information Estimated lethal dose: 25-250 mg/kg

Hydroxyzine hydrochloride: Atarax®, Vistaril® injection

Hydroxyzine pamoate: Vistaril® capsule and suspension

Hyoscyamine

CAS Number 101-31-5; 620-61-1; 6835-16-1

U.S. Brand Names Anaspaz®, Cystospaz-M®, Cystospaz®, Hyosine; Levbid®; Levsin/SL®; Levsinex®; Levsin®; NuLev™; Spacol T/S; Spacol; Symax SL; Symax SR

Synonyms *l*-Hyoscyamine Sulfate; Hyoscyamine Sulfate

Use

Oral: Adjunctive therapy for peptic ulcers, irritable bowel, neurogenic bladder/bowel; treatment of infant colic, GI tract disorders caused by spasm; to reduce rigidity, tremors, sialorrhea, and hyperhidrosis associated with parkinsonism; as a drying agent in acute rhinitis

Injection: Preoperative antimuscarinic to reduce secretions and block cardiac vagal inhibitory reflexes; to improve radiologic visibility of the kidneys; symptomatic relief of biliary and renal colic; reduce GI motility to facilitate diagnostic procedures (ie, endoscopy, hypotonic duodenography); reduce pain and hypersecretion in pancreatitis, certain cases of partial heart block associated with vagal activity; reversal of neuromuscular blockade

Mechanism of Action Blocks the action of acetylcholine at parasympathetic sites in smooth muscle, secretory glands and the CNS; increases cardiac output, dries secretions, antagonizes histamine and serotonin, antimuscarinic agent; found in the plant *Hyoscyamus niger*

Adverse Reactions

Cardiovascular: Tachycardia, palpitations, hypotension (orthostatic), sinus tachycardia, tachycardia (supraventricular)

Central nervous system: Fatigue, delirium, restlessness, headache, lightheadedness, anxiety, memory disturbance, ataxia, mania, paranoia, psychosis

Dermatologic: **Dry skin**, hot skin; photosensitivity, skin rash, urticaria

Gastrointestinal: Impaired gastrointestinal motility, constipation, dysphagia, **xerostomia and dry throat**, loss of taste perception, impotence, urinary retention

Genitourinary: Dysuria

Local: **Irritation at injection site**

Neuromuscular & skeletal: Tremors

Ocular: Mydriasis, blurred vision, increased intraocular pressure

Respiratory: **Dry nose**

Miscellaneous: **Diaphoresis (decreased)**

Signs and Symptoms of Overdose Ataxia, blurred vision, coma, dilated unreactive pupils, diminished or absent bowel sounds, dryness of mucous membranes, dysphagia, facial flushing, foul breath, hallucinations (lilliputian), hypertension, hyperthermia, ileus, impotence, increased intraocular pressure, increased respiratory rate, lightheadedness, memory loss, myoglobinuria, photophobia, rhabdomyolysis, seizures, tachycardia, urinary retention

Pharmacodynamics/Kinetics

Onset of action: 2-3 minutes

Duration: 4-6 hours

Absorption: Well absorbed

Distribution: Crosses placenta; small amounts enter breast milk

Protein binding: 50%

Metabolism: Hepatic

Half-life elimination: 3-5 hours

Excretion: Urine

Dosage

Oral: Children: Gastrointestinal disorders: Dose as listed, based on age and weight (kg) using 0.125 mg/mL drops; repeat dose every 4 hours as needed:

Children <2 years:

3.4 kg: 4 drops; maximum: 24 drops/24 hours

5 kg: 5 drops; maximum: 30 drops/24 hours

7 kg: 6 drops; maximum: 36 drops/24 hours

10 kg: 8 drops; maximum: 48 drops/24 hours

Oral, S.L.:

Children 2-12 years: Gastrointestinal disorders: Dose as listed, based on age and weight (kg); repeat dose every 4 hours as needed:

10 kg: 0.031-0.033 mg; maximum: 0.75 mg/24 hours

20 kg: 0.0625 mg; maximum: 0.75 mg/24 hours

40 kg: 0.0938 mg; maximum: 0.75 mg/24 hours

50 kg: 0.125 mg; maximum: 0.75 mg/24 hours

Children >12 years and Adults: Gastrointestinal disorders: 0.125-0.25 mg every 4 hours or as needed (before meals or food); maximum: 1.5 mg/24 hours

Cystospaz®: 0.15-0.3 mg up to 4 times/day

Oral (timed release): Children >12 years and Adults: Gastrointestinal disorders: 0.375-0.75 mg every 12 hours; maximum: 1.5 mg/24 hours

I.M., I.V., SubQ: Children >12 years and Adults: Gastrointestinal disorders: 0.25-0.5 mg; may repeat as needed up to 4 times/day, at 4-hour intervals

I.V.: Children >2 year and Adults: I.V.: Preanesthesia: 5 mcg/kg given 30-60 minutes prior to induction of anesthesia or at the time preoperative narcotics or sedatives are administered

I.V.: Adults: Diagnostic procedures: 0.25-0.5 mg given 5-10 minutes prior to procedure

To reduce drug-induced bradycardia during surgery: 0.125 mg; repeat as needed

To reverse neuromuscular blockade: 0.2 mg for every 1 mg neostigmine (or the physostigmine/pyridostigmine equivalent)

Stability Insoluble in ether; soluble in water

Administration

Oral: Tablets should be administered before meals or food.

Levbid®: Tablets are scored and may be broken in half for dose titration; do not crush or chew.

Levsin/SL®: Tablets may be used sublingually, chewed, or swallowed whole.

NuLev™: Tablet is placed on tongue and allowed to disintegrate before swallowing; may take with or without water.

Symax SL: Tablets may be used sublingually or swallowed whole.

I.M.: May be administered without dilution.

Inject over at least 1 minute. May be administered without dilution.

Contraindications Hypersensitivity to belladonna alkaloids or any component of the formulation; glaucoma; obstructive uropathy; myasthenia gravis; obstructive GI tract disease, paralytic ileus, intestinal atony of

elderly or debilitated patients, severe ulcerative colitis, toxic megacolon complicating ulcerative colitis; unstable cardiovascular status in acute hemorrhage, myocardial ischemia

Warnings Heat prostration may occur in hot weather. Diarrhea may be a sign of incomplete intestinal obstruction, treatment should be discontinued if this occurs. May produce side effects as seen with other anticholinergic medications including drowsiness, dizziness, blurred vision, or psychosis. Children and the elderly may be more susceptible to these effects. Use with caution in children with spastic paralysis. Use with caution in patients with autonomic neuropathy, coronary heart disease, CHF, cardiac arrhythmias, prostatic hyperplasia, hyperthyroidism, hypertension, chronic lung disease, renal disease, and hiatal hernia associated with reflux esophagitis. Use with caution in the elderly, may precipitate undiagnosed glaucoma and/or severely impair memory function (especially in those patients with previous memory problems). NuLev™: Contains phenylalanine

Dosage Forms [DSC] = Discontinued product

Capsule, timed release, as sulfate (Cystospaz-M® [DSC], Levsinex®): 0.375 mg

Elixir, as sulfate: 0.125 mg/5 mL (480 mL)

Hyosine: 0.125 mg/5 mL (480 mL) [contains alcohol 20% and sodium benzoate; orange flavor]

Levsin®: 0.125 mg/5 mL (480 mL) [contains alcohol 20%; orange flavor]

Injection, solution, as sulfate (Levsin®): 0.5 mg/mL (1 mL)

Liquid, as sulfate (Spacol [DSC]): 0.125 mg/5 mL (120 mL) [sugar free, alcohol free, simethicone based, bubble gum flavor]

Solution, oral drops, as sulfate: 0.125 mg/mL (15 mL)

Hyosine: 0.125 mg/mL (15 mL) [contains alcohol 5% and sodium benzoate; orange flavor]

Levsin®: 0.125 mg/mL (15 mL) [contains alcohol 5%; orange flavor]

Tablet (Cystospaz®): 0.15 mg

Tablet, as sulfate (Anaspaz®, Levsin®, Spacol [DSC]): 0.125 mg

Tablet, extended release, as sulfate (Levbid®, Symax SR, Spacol T/S [DSC]): 0.375 mg

Tablet, orally disintegrating, as sulfate (NuLev™): 0.125 mg [contains phenylalanine 1.7 mg/tablet, mint flavor]

Tablet, sublingual, as sulfate: 0.125 mg

Levsin/SL®: 0.125 mg [peppermint flavor]

Symax SL: 0.125 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** induce emesis

Supportive therapy: Physostigmine should be used as a last resort for life-threatening seizures, arrhythmias, or hypertension that is refractory to standard supportive therapy; rhabdomyolysis can be treated with alkaline diuresis and mannitol; esmolol can be used for tachyarrhythmias; bethanechol (5-10 mg 3 times/day) can be given for peripheral anticholinergic signs

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Antidote(s)

- Mannitol [ANTIDOTE]
- Physostigmine [ANTIDOTE]

Drug Interactions Amantadine: Additive adverse effects may occur due to cholinergic blockade.

Antacids: Antacids may decrease absorption of hyoscyamine; administer hyoscyamine before meals and give antacids after meals.

Antihistamines: Additive adverse effects may occur with some antihistamines due to cholinergic blockade.

Antimuscarinics: Additive adverse effects may occur due to cholinergic blockade.

Haloperidol: Additive adverse effects may occur due to cholinergic blockade.

MAO inhibitors: Additive adverse effects may occur due to cholinergic blockade.

Phenothiazines: Additive adverse effects may occur due to cholinergic blockade.

Tricyclic antidepressants: Additive adverse effects may occur due to cholinergic blockade.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta, effects to the fetus not known; use during pregnancy only if clearly needed

Lactation Enters breast milk/not recommended

Nursing Implications Observe for tachycardia if the patient has cardiac problems.

Ibuprofen

Related Information

- Flurbiprofen
- Nonsteroidal Anti-inflammatory Drugs

CAS Number 15687-27-1

U.S. Brand Names Advil® Children's [OTC]; Advil® Infants' [OTC]; Advil® Junior [OTC]; Advil® Migraine [OTC]; Advil® [OTC]; ElixSure™ IB [OTC]; Genpril® [OTC]; I-Prin [OTC]; Ibu-200 [OTC]; Midol® Cramp and Body Aches [OTC]; Motrin® Children's [OTC]; Motrin® IB [OTC]; Motrin® Infants' [OTC]; Motrin® Junior Strength [OTC]; Motrin®; NeoProfen®; Propinal® [OTC]; Ultraprin [OTC]

Synonyms *p*-Isobutylhydratropic Acid; Ibuprofen Lysine
Use

Oral: Inflammatory diseases and rheumatoid disorders including juvenile rheumatoid arthritis, mild-to-moderate pain, fever, dysmenorrhea

Injection: Ibuprofen lysine is for use in premature infants weighing between 500-1500 g and who are ≤32 weeks gestational age (GA) to induce closure of a clinically-significant patent ductus arteriosus (PDA) when usual treatments are ineffective

Cystic fibrosis, gout, ankylosing spondylitis, acute migraine headache

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors

Adverse Reactions

Cardiovascular: Circulatory collapse, arrhythmias (ventricular), vasculitis
Central nervous system: **Dizziness, fatigue**, headache, aseptic meningitis, psychosis, cognitive dysfunction, coma, seizures

Dermatologic: **Rash, urticaria**, pruritus, Stevens-Johnson syndrome, erythema multiforme, angioedema, toxic epidermal necrolysis, onycholysis, psoriasis, erythema nodosum, exanthem, photoallergic reaction, lichen planus, cutaneous vasculitis

Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, fluid retention, gynecomastia

Gastrointestinal: **Abdominal cramps, heartburn, indigestion, nausea**, vomiting, GI ulceration, constipation, diarrhea, dyspepsia, fecal discoloration (black), vanishing bile duct syndrome, esophagitis, aphthous stomatitis, xerostomia, stomatitis

Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia; aplastic anemia (rare), platelet inhibition, hemolytic anemia (Coombs' positive)

Hepatic: Elevated transaminases, hepatitis (fulminant), aminotransferase level elevation (asymptomatic)

Neuromuscular & skeletal: Paresthesia

Ocular: Diplopia, vortex keratopathy, amblyopia, color vision abnormalities

Otic: Ototoxicity, tinnitus

Renal: Renal failure (acute), nephrotic syndrome, chronic renal failure, albuminuria

Respiratory: Wheezing, respiratory depression, aspiration

Miscellaneous: Hypersensitivity, systemic lupus erythematosus (SLE), fixed drug eruption

Signs and Symptoms of Overdose Azotemia, coagulopathy, cognitive dysfunction, depression, drowsiness, flatulence, GI bleeding, hyperthermia, gastritis, hypoglycemia, hyponatremia, leukocytosis, lightheadedness, mental confusion, nausea, nephrotic syndrome, ototoxicity, photosensitivity, purpura, vomiting, thrombocytopenia, tinnitus, wheezing
Severe poisoning can manifest with apnea, coma, hepatic failure, hypotension, hypothermia, metabolic acidosis, nystagmus, respiratory depression, and seizures. More significant exposures have been associated with ingestions >400 mg/kg. Alopecia, feces discoloration (tarry), fever, hypocalcemia, hypophosphatemia, hypomagnesemia, urine discoloration (red; red-purple). Acute renal papillary necrosis and renal failure at ingestions >6 g.

Admission Criteria/Prognosis Admit any patient with acidosis, symptoms occurring over 4 hours postingestion, or ingestions >400 mg/kg

Pharmacodynamics/Kinetics

Onset of action: Analgesic: 30-60 minutes; Anti-inflammatory: ≤7 days

Peak effect: 1-2 weeks

Duration: 4-6 hours

Absorption: Oral: Rapid (85%)

Distribution: Premature infants with ductal closure (highly variable between studies):

Day 3: 145-349 mL/kg

Day 5: 72-222 mL/kg

Protein binding: 90% to 99%

Metabolism: Hepatic via oxidation

Half-life elimination:

Premature infants (highly variable between studies):

Day 3: 35-51 hours

Day 5: 20-33 hours

Children 3 months to 10 years: 1.6 ± 0.7 hours

Adults: 2-4 hours; End-stage renal disease: Unchanged

Time to peak: ~1-2 hours

Excretion: Urine (1% as free drug); some feces

Dosage

I.V.: Infants between 500-1500 g and ≤32 weeks GA: Patent ductus arteriosus: Initial dose: Ibuprofen 10 mg/kg, followed by two doses of 5 mg/kg at 24 and 48 hours. Dose should be based on birth weight.

Oral:

Children:

Antipyretic: 6 months to 12 years: Temperature < 102.5°F (39°C): 5 mg/kg/dose; temperature > 102.5°F: 10 mg/kg/dose given every 6-8 hours (maximum daily dose: 40 mg/kg/day)
 Juvenile rheumatoid arthritis: 30-50 mg/kg/24 hours divided every 8 hours; start at lower end of dosing range and titrate upward (maximum: 2.4 g/day)
 Analgesic: 4-10 mg/kg/dose every 6-8 hours
 Cystic fibrosis (unlabeled use): Chronic (> 4 years) twice daily dosing adjusted to maintain serum levels of 50-100 mcg/mL has been associated with slowing of disease progression in younger patients with mild lung disease
 OTC labeling (analgesic, antipyretic):
 Children 6 months to 11 years: See table; use of weight to select dose is preferred; doses may be repeated every 6-8 hours (maximum: 4 doses/day)
 Children ≥ 12 years: 200 mg every 4-6 hours as needed (maximum: 1200 mg/24 hours)

Ibuprofen Dosing		
Weight (lbs)	Age	Dosage (mg)
12-17	6-11 mo	50
18-23	12-23 mo	75
24-35	2-3 y	100
36-47	4-5 y	150
48-59	6-8 y	200
60-71	9-10 y	250
72-95	11 y	300

Adults:
 Inflammatory disease: 400-800 mg/dose 3-4 times/day (maximum dose: 3.2 g/day)
 Analgesia/pain/fever/dysmenorrhea: 200-400 mg/dose every 4-6 hours (maximum daily dose: 1.2 g, unless directed by physician)
 OTC labeling (analgesic, antipyretic): 200 mg every 4-6 hours as needed (maximum: 1200 mg/24 hours)

Dosing adjustment/comments in severe hepatic impairment: Avoid use

Monitoring Parameters CBC; occult blood loss and periodic liver function tests; monitor response (pain, range of motion, grip strength, mobility, ADL function), inflammation; observe for weight gain, edema; monitor renal function (urine output, serum BUN and creatinine); observe for bleeding, bruising; evaluate gastrointestinal effects (abdominal pain, bleeding, dyspepsia); mental confusion, disorientation; with long-term therapy, periodic ophthalmic exams

Administration

Oral: Administer with food
 I.V.: For I.V. administration only; administration via umbilical line has not been evaluated. Infuse over 15 minutes through port closest to insertion site. Avoid extravasation. Do not administer simultaneously via same line with TPN. If needed, interrupt TPN for 15 minutes prior to and after ibuprofen administration, keeping line open with dextrose or saline.

Contraindications

Hypersensitivity to ibuprofen, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy (3rd trimester)
 Ibuprofen lysine is contraindicated in preterm infants with untreated proven or suspected infection; congenital heart disease where patency of the PDA is necessary for pulmonary or systemic blood flow; bleeding (especially with active intracranial hemorrhage or GI bleed); thrombocytopenia; coagulation defects; proven or suspected necrotizing enterocolitis (NEC); significant renal dysfunction

Warnings [U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension.

Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Ibuprofen is not recommended for patients with advanced renal disease.

NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

The elderly are at increased risk for adverse effects (especially peptic ulceration, CNS effects, renal toxicity) from NSAIDs even at low doses. Withhold for at least 4-6 half-lives prior to surgical or dental procedures.

Injection: Hold second or third doses if urinary output is < 0.6 mL/kg/hour. May alter signs of infection. May inhibit platelet aggregation; monitor for signs of bleeding. May displace bilirubin; use caution when total bilirubin is elevated. Long-term evaluations of neurodevelopment, growth, or diseases associated with prematurity following treatment have not been conducted. A second course of treatment, alternative pharmacologic therapy or surgery may be needed if the ductus arteriosus fails to close or reopens following the initial course of therapy.

OTC labeling: Prior to self-medication, patients should contact health care provider if they have had recurring stomach pain or upset, ulcers, bleeding problems, high blood pressure, heart or kidney disease, other serious medical problems, are currently taking a diuretic, or are ≥ 60 years of age. Recommended dosages should not be exceeded, due to an increased risk of GI bleeding. Consuming ≥ 3 alcoholic beverages/day or taking longer than recommended may increase the risk of GI bleeding. When used for self-medication, patients should contact healthcare provider if used for fever lasting > 3 days or for pain lasting > 10 days in adults or > 3 days in children. In children with a sore throat, do not use for > 2 days or administer to children < 3 years of age unless instructed by healthcare provider. Consult healthcare provider when sore throat pain is severe, persistent, or accompanied by fever, headache, nausea, and/or vomiting. Notify healthcare provider of worsening stomach pain, feeling faint, vomiting of blood or bloody black stools.

Dosage Forms

- Caplet: 200 mg [OTC]
 Advil®: 200 mg [contains sodium benzoate]
 Ibu-200, Motrin® IB: 200 mg
 Motrin® Junior Strength: 100 mg
- Capsule, liqui-gel:
 Advil®: 200 mg
 Advil® Migraine: 200 mg [solubilized ibuprofen; contains potassium 20 mg]
- Gelcap:
 Advil®: 200 mg [contains coconut oil]
- Injection, solution, as lysine [preservative free]:
 NeoProfen®: 17.1 mg/mL (2 mL) [equivalent to ibuprofen 10 mg/mL]
 Suspension, oral: 100 mg/5 mL (5 mL, 120 mL, 480 mL)
 Advil® Children's: 100 mg/5 mL (60 mL, 120 mL) [contains sodium benzoate; blue raspberry, fruit, and grape flavors]
 ElixSure™ IB: 100 mg/5 mL (120 mL) [berry flavor]
 Motrin® Children's: 100 mg/5 mL (60 mL, 120 mL) [contains sodium benzoate; berry, dye free berry, bubble gum, and grape flavors]
- Suspension, oral drops: 40 mg/mL (15 mL)
 Advil® Infants': 40 mg/mL (15 mL) [contains sodium benzoate; fruit and grape flavors]
 Motrin® Infants': 40 mg/mL (15 mL, 30 mL) [contains sodium benzoate; berry and dye-free berry flavors]
- Tablet: 200 mg [OTC], 400 mg, 600 mg, 800 mg
 Advil®: 200 mg [contains sodium benzoate]
 Advil® Junior: 100 mg [contains sodium benzoate; coated tablets]
 Genpril®, I-Prin, Midol® Cramp and Body Aches, Motrin® IB, Proprinal, Ultraprin: 200 mg
 Motrin®: 400 mg, 600 mg, 800 mg
- Tablet, chewable:
 Advil® Children's: 50 mg [contains phenylalanine 2.1 mg; grape flavors]
 Advil® Junior: 100 mg [contains phenylalanine 4.2 mg; grape flavors]
 Motrin® Children's: 50 mg [contains phenylalanine 1.4 mg; grape and orange flavor]
 Motrin® Junior Strength: 100 mg [contains phenylalanine 2.1 mg; grape and orange flavors]

Reference Range Plasma concentrations > 200 mcg/mL (971 µmol/L) may be associated with severe toxicity; serum levels are not readily

available, thus not recommended routinely; antipyretic effect can occur at plasma concentrations of 10 mcg/mL (48 μmol/L)

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal at ingestions >200 mg/kg; whole bowel irrigation is effective but usually not required

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage; famotidine (40 mg 2 times/day) can decrease incidence of gastric or duodenal ulcers in patients receiving long-term therapy of this drug. Monitor renal function with ingestions >6 g.

Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be effective.

Diagnostic Procedures

- Anion Gap, Blood
- Stool Culture
- Urinalysis

Test Interactions ↑ chloride (S), sodium (S); may cause false-positive on benzodiazepine assay

Drug Interactions **Substrate** (minor) of CYP2C9, 2C19; **Inhibits** CYP2C9 (strong)

ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Aminoglycosides: NSAIDs may decrease the excretion of aminoglycosides; this is of particular concern in preterm infants.

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet drugs (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatid, tirofiban) can cause an increased risk of bleeding.

Aspirin: Ibuprofen and other COX-1 inhibitors may reduce the cardioprotective effects of aspirin. Avoid giving prior to aspirin therapy or on a regular basis in patients with CAD.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Bisphosphonate derivatives: NSAIDs may enhance the adverse/toxic effect of bisphosphonate derivatives. An increased incidence of gastrointestinal ulceration is of concern.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids: May increase the risk of GI ulceration; avoid concurrent use

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

CYP2C9 Substrates: Ibuprofen may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use. Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose. Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again.

Loop diuretics efficacy (diuretic and antihypertensive effect) is reduced. Indomethacin reduces this efficacy, however, it may be anticipated with any NSAID.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Pemetrexed: NSAIDs may decrease the excretion of pemetrexed.

Probenecid: Probenecid may increase the serum concentration of NSAIDs.

Vancomycin: NSAIDs may decrease the excretion of vancomycin; this is of particular concern in preterm infants.

Warfarin's INRs may be increased by piroxicam. Other NSAIDs may have the same effect depending on dose and duration. Monitor INR closely. Use the lowest dose of NSAIDs possible and for the briefest duration. May alter the anticoagulant effects of warfarin; concurrent use with other antiplatelet agents or anticoagulants may increase risk of bleeding.

Pregnancy Risk Factor B/D (3rd trimester)

Lactation Enters breast milk/use caution (AAP rates "compatible")

Additional Information Largest ibuprofen ingestion reported was 72 g in an adult; while hyperkalemia, metabolic acidosis, and rhabdomyolysis was noted, the patient did well with supportive therapy and did not require dialysis

Ibutilide

U.S. Brand Names Corvert®

Synonyms Ibutilide Fumarate

Use Rapid conversion of atrial fibrillation or flutter of recent (<90 days) onset to sinus rhythm

Mechanism of Action A class III antiarrhythmic agent which prolongs action potential in atrium and ventricular myocytes; slow inward sodium current is activated and thus atrial and ventricular action potential refractoriness and duration are prolonged

Adverse Reactions

Cardiovascular: **Torsade de pointes** (1.7%), tachycardia (ventricular) (7.5%), hypotension (orthostatic), syncope, bundle branch block, premature ventricular contractions, atrioventricular block (1.7%), congestive heart failure, myocardial depression, sinus arrest

Central nervous system: Headache

Gastrointestinal: Nausea (2%)

Renal: Renal failure

Signs and Symptoms of Overdose Third degree AV block, torsade de pointes, ventricular ectopy

Pharmacodynamics/Kinetics

Onset of action: ~90 minutes after start of infusion (¹/₂ of conversions to sinus rhythm occur during infusion)

Distribution: V_d: 11 L/kg

Protein binding: 40%

Metabolism: Extensively hepatic; oxidation

Half-life elimination: 2-12 hours (average: 6 hours)

Excretion: Urine (82%, 7% as unchanged drug and metabolites); feces (19%)

Dosage

Acute conversion of atrial fibrillation and flutter:

Weight <60 kg: 0.01 mg/kg

Weight >60 kg: 0.1 mg/kg

A second dose may be given 10 minutes after the first infusion if arrhythmia persists

Monitoring Parameters Observe patient with continuous ECG monitoring for at least 4 hours following infusion or until QT_c has returned to baseline; skilled personnel and proper equipment should be available during administration of ibutilide and subsequent monitoring of the patient

Administration May be administered undiluted or diluted in 50 mL diluent (0.9% NS or D₅W); infuse over 10 minutes

Contraindications Hypersensitivity to ibutilide or any component of the formulation; QT_c >440 msec

Warnings [U.S. Boxed Warning]: Potentially fatal arrhythmias (eg, polymorphic ventricular tachycardia) can occur with ibutilide, usually in association with torsade de pointes (QT prolongation).

Studies indicate a 1.7% incidence of arrhythmias in treated patients. The drug should be given in a setting of continuous ECG monitoring and by personnel trained in treating arrhythmias particularly polymorphic ventricular tachycardia. **[U.S. Boxed Warning]: Patients with chronic atrial fibrillation may not be the best candidates for ibutilide since they often revert after conversion and the risks of treatment may not be justified when compared to alternative management.** Dosing adjustments are not required in patients with renal or hepatic dysfunction since a maximum of only two 10-minute infusions are utilized. Drug distribution, rather than administration, is one of the primary mechanisms responsible for termination of the pharmacologic effect. Use caution in elderly patients. Safety and efficacy in children have not been established. Avoid any drug that can prolong QT interval. Correct hyperkalemia and hypomagnesemia before using. Monitor for heart block.

Dosage Forms Injection, solution, as fumarate: 0.1 mg/mL (10 mL)

Reference Range Peak serum levels after infusion of 0.01 mg/kg: ~10 ng/mL

Overdosage/Treatment Supportive therapy: Polymorphic ventricular tachycardia should be treated with discontinuation of drug, monitoring of potassium and magnesium and correction of electrolyte abnormalities, overdrive pacing, electrical cardioversion, or magnesium sulfate; monitor ECG for at least 4 hours postinfusion

Drug Interactions Antiarrhythmics: Class I antiarrhythmic drugs (disopyramide, quinidine, and procainamide) and other class III drugs such as amiodarone and sotalol, should not be given concomitantly with ibutilide due to their potential to prolong refractoriness.

Other drugs which may prolong QT interval: Phenothiazines, tricyclic and tetracyclic antidepressants, and cisapride, sparfloxacin, gatifloxacin, moxifloxacin, erythromycin may increase risk of toxicity; avoid concurrent use.

Digoxin: Signs of digoxin toxicity may be masked when coadministered with ibutilide.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic in rodents (adactyly, cleft palate, scoliosis)

Lactation Enters breast milk/contraindicated

Additional Information Overall efficacy rate is 43% to 58% (conversion rate of atrial fibrillation ranges from 30% to 51% while conversion rate for atrial flutter ranges from 55% to 76%); termination rate is higher with recent onset of arrhythmia (<30 days); mean time to conversion is 13-21 minutes; patients with atrial arrhythmias over 2- to 3- day duration should be anticoagulated before conversion. Torsade de pointes usually occurs within 30 minutes of infusion but recurrent polymorphic ventricular tachycardia may occur as long as 3 hours postinfusion. Patients with congestive heart failure, bradycardia, prolonged QT interval or hypokalemia are at risk for torsade de pointes.

Ifosfamide

CAS Number 3778-73-2

U.S. Brand Names Ifex®

Synonyms Isophosphamide; NSC-109724; Z4942

Use Treatment of lung cancer, Hodgkin's and non-Hodgkin's lymphoma, breast cancer, acute and chronic lymphocytic leukemias, ovarian cancer, sarcomas, pancreatic and gastric carcinomas

Orphan drug: Treatment of testicular cancer

Mechanism of Action Causes cross-linking of strands of DNA by binding with nucleic acids and other intracellular structures; inhibits protein synthesis and DNA synthesis

Adverse Reactions

Cardiovascular: Cardiotoxicity

Central nervous system: Somnolence, confusion, hallucinations in 12% and coma (rare) have occurred and are usually reversible; usually occur with higher doses or in patients with reduced renal function; depressive psychoses, polyneuropathy

Dermatologic: Alopecia occurs in 50% to 83% of patients 2-4 weeks after initiation of therapy; may be as high as 100% in combination therapy; phlebitis, dermatitis, nail ridging, skin hyperpigmentation, impaired wound healing

Endocrine & metabolic: SIADH, metabolic acidosis

Gastrointestinal: Nausea and vomiting in 58% of patients is dose and schedule related (more common with higher doses and after bolus regimens); nausea and vomiting can persist up to 3 days after therapy; also anorexia, diarrhea, constipation, transient increase in liver function test results and stomatitis noted, pancreatitis

Emetic potential: Moderate (58%)

Time course of nausea/vomiting: Onset: 2-3 hours; Duration: 12-72 hours

Genitourinary: Hemorrhagic cystitis has been frequently associated with the use of ifosfamide. A urinalysis prior to each dose should be obtained. **Ifosfamide should never be administered without a uroprotective agent (mesna).** Hematuria has been reported in 6% to 92% of patients.

Hematologic: Myelosuppression: Less of a problem than with cyclophosphamide if used alone. Leukopenia is mild to moderate, thrombocytopenia and anemia are rare. However, myelosuppression can be severe when used with other chemotherapeutic agents or with high-dose therapy. Be cautious with patients with compromised bone marrow reserve. Methemoglobinemia.

WBC: Moderate; Platelets: Mild; Onset (days): 7; Nadir (days): 10-14

Hepatic: Elevated liver enzymes

Renal: Fanconi-like syndrome; renal toxicity occurs in 6% of patients and is manifested as an increase in BUN or serum creatinine and is most likely related to tubular damage. Renal toxicity, including ARF, may occur more frequently with high-dose ifosfamide. Metabolic acidosis may occur in up to 31% of patients.

Respiratory: Nasal congestion, pulmonary fibrosis, pulmonary toxicity

Miscellaneous: Immunosuppression, sterility, possible secondary malignancy, allergic reactions

Signs and Symptoms of Overdose Symptoms of overdose include alopecia, diarrhea, myelosuppression, nausea, vomiting. Direct extension of the drug's pharmacologic effect: Myocardial depression at doses > 15 g/m²

Pharmacodynamics/Kinetics

Pharmacokinetics are dose dependent

Distribution: V_d: 5.7-49 L; does not penetrate CNS, but not in therapeutic levels

Protein binding: Negligible

Metabolism: Hepatic to active metabolites phosphoramidate mustard, acrolein, and inactive dichloroethylated and carboxy metabolites; acrolein is the agent implicated in development of hemorrhagic cystitis

Bioavailability: Estimated at 100%

Half-life elimination: Beta: High dose: 11-15 hours (3800-5000 mg/m²); Lower dose: 4-7 hours (1800 mg/m²)

Time to peak, plasma: Oral: Within 1 hour

Excretion: Urine (15% to 50% as unchanged drug, 41% as metabolites)

Dosage Refer to individual protocols. To prevent bladder toxicity, ifosfamide should be given with the urinary protector mesna and hydration of at least 2 L of oral or I.V. fluid per day. I.V.:

Children:

1200-1800 mg/m²/day for 3-5 days every 21-28 days or

5 g/m² once every 21-28 days or

3 g/m²/day for 2 days every 21-28 days

Adults:

50 mg/kg/day or 700-2000 mg/m² for 5 days every 3-4 weeks

Alternatives: 2400 mg/m²/day for 3 days or 5000 mg/m² as a single dose every 3-4 weeks

Dosing adjustment in renal impairment:

S_{cr} 2.1-3.0 mg/dL: Reduce dose by 25% to 50%

S_{cr} > 3.0 mg/dL: Withhold drug

Dosing adjustment in hepatic impairment: Although no specific

guidelines are available, it is possible that adjusted doses are indicated in hepatic disease. Falkson G, et al (*Invest New Drugs*, 1992, 10:337-43) recommended the following dosage adjustments:

AST > 300 or bilirubin > 3.0 mg/dL: Decrease ifosfamide dose by 75%

Stability Store intact vials at room temperature. Dilute powder with SWI or NS to a concentration of 50 mg/mL. Further dilution in 50-1000 mL D₅W or NS is recommended for I.V. infusion. Reconstituted solutions may be stored under refrigeration for up to 21 days. Solutions diluted for administration are stable for 7 days at room temperature and for 6 weeks under refrigeration.

Monitoring Parameters CBC with differential, hemoglobin, and platelet count, urine output, urinalysis, liver function, and renal function tests

Administration Administer slow I.V. push, IVPB over 30 minutes to several hours or continuous I.V. over 5 days

Contraindications Hypersensitivity to ifosfamide or any component of the formulation; patients with severely depressed bone marrow function; pregnancy

Warnings Hazardous agent – use appropriate precautions for handling and disposal. **[U.S. Boxed Warning]: Urotoxic side effects, primarily hemorrhagic cystitis, may occur.** Hydration and/or mesna administration will protect against hemorrhagic cystitis. **[U.S. Boxed Warning]: Severe bone marrow suppression may occur. May cause CNS toxicity, including confusion and coma;** reversible upon discontinuation of treatment. Use with caution in patients with impaired renal function or those with compromised bone marrow reserve. May interfere with wound healing. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.** Safety and efficacy in children have not been established.

Dosage Forms

Injection, powder for reconstitution: 1 g
Ifex®: 1 g, 3 g

Overdosage/Treatment Supportive therapy: Ifosfamide neurotoxicity has been successfully treated with methylene blue (1-2 mg/kg in children or 50 mg in 1% aqueous solution administered over 5 minutes in adults). Adequate hydration is also suggested. Congestive heart failure can be treated with diuretics, inotropic and vasodilator agents.

Antidote(s)

- Methylene Blue [ANTIDOTE]

Drug Interactions **Substrate** of CYP2A6 (minor), 2B6 (minor), 2C8 (minor), 2C9 (minor), 2C19 (minor), 3A4 (major); **Inhibits** CYP3A4 (weak); **Induces** CYP2C8 (weak), 2C9 (weak)

CYP3A4 inducers: CYP3A4 inducers may increase the levels/effects of acrolein (the active metabolite of ifosfamide). Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May decrease the levels/effects of acrolein (the active metabolite of ifosfamide). Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Pregnancy Risk Factor D

Lactation Enters breast milk/contraindicated

Nursing Implications Mesna to be used concomitantly for prophylaxis against hemorrhagic cystitis

Additional Information Development of ifosfamide neurotoxicity appears to be related to low serum albumin (<3 g/dL), dehydration, extremes of age, renal dysfunction, and previous therapy with cisplatin. Encephalopathy occurs in 9% of patients receiving doses of 5 g/m².

Killickap S, Cakar M, Onal IK, et al, "Nonconvulsive Status Epilepticus Due to Ifosfamide," *Ann Pharmacother*, 2006, 40(2):332-5.

Imipenem and Cilastatin

Related Information

- Meropenem

CAS Number 64221-86-9; 74431-23-5; 81129-83-1; 82009-34-5

U.S. Brand Names Primaxin®

Synonyms Imipemide

Use Treatment of documented multidrug-resistant gram-negative infection due to organisms proven or suspected to be susceptible to imipenem/cilastatin; treatment of multiple organism infection in which other agents have an insufficient spectrum of activity or are contraindicated due to toxic potential; imipenem is usually given with a dehydropeptidase I inhibitor cilastatin sodium which inhibits renal breakdown of imipenem

Mechanism of Action Inhibits bacterial cell wall synthesis by binding to one or more of the penicillin binding proteins (PBPs); which in turn inhibits the final transpeptidation step of peptidoglycan synthesis in bacterial cell walls, thus inhibiting cell wall biosynthesis. Bacteria eventually lyse due to ongoing activity of cell wall autolytic enzymes (autolysins and murein hydrolases) while cell wall assembly is arrested.

Adverse Reactions

Cardiovascular: Hypotension, palpitations, tachycardia, sinus tachycardia
Central nervous system: Seizures, dizziness, confusion
Dermatologic: Rash, pruritus, urticaria
Gastrointestinal: Nausea, diarrhea, vomiting, pseudomembranous colitis, dental staining
Hematologic: Neutropenia, eosinophilia, thrombocytosis, aplastic anemia, leukopenia
Hepatic: Hepatotoxicity
Local: Phlebitis, pain at injection site
Neuromuscular & skeletal: Myasthenia gravis may worsen
Miscellaneous: Emergence of resistant strains of *P. aeruginosa*, anaphylactic reaction

Signs and Symptoms of Overdose Myasthenia gravis (exacerbation or precipitation), seizures, tremors

Pharmacodynamics/Kinetics

Absorption: I.M.: Imipenem: 60% to 75%; cilastatin: 95% to 100%
Distribution: Rapidly and widely to most tissues and fluids including sputum, pleural fluid, peritoneal fluid, interstitial fluid, bile, aqueous humor, reproductive organs, and bone; highest concentrations in pleural fluid, interstitial fluid, peritoneal fluid, and reproductive organs; low concentrations in CSF; crosses placenta; enters breast milk
Protein binding: Imipenem: 20%; cilastatin: 40%
Metabolism: Renally by dehydropeptidase; activity is blocked by cilastatin; cilastatin is partially metabolized renally
Half-life elimination: I.V.: Both drugs: 60 minutes; prolonged with renal impairment; I.M.: Imipenem: 2-3 hours
Time to peak: I.M.: 3.5 hours
Excretion: Both drugs: Urine (~70% as unchanged drug)

Dosage

I.V. infusion (dosage recommendation based on imipenem component):
Children: 25 mg/kg every 6 hours

Adults: 1-4 g/day not to exceed 50 mg/kg/day; reduce dose in renal failure; usually given twice daily

Stability Stable for 10 hours at room temperature following reconstitution with 100 mL of 0.9% sodium chloride injection; up to 48 hours when refrigerated at 5°C. If reconstituted with 5% or 10% dextrose injection, 5% dextrose and sodium bicarbonate, 5% dextrose and 0.9% sodium chloride, is stable for 4 hours at room temperature and 24 hours when refrigerated.

Monitoring Parameters Periodic renal, hepatic, and hematologic function tests; monitor for signs of anaphylaxis during first dose

Administration

I.M.: **Note:** I.M. administration is not intended for severe or life-threatening infections (eg, septicemia, endocarditis, shock). Administer by deep injection into a large muscle (gluteal or lateral thigh). **Only the I.M. formulation can be used for I.M. administration.**

I.V.: Do not administer I.V. push. Infuse doses ≤500 mg over 20-30 minutes; infuse doses ≥750 mg over 40-60 minutes. **Only the I.V. formulation can be used for I.V. administration.**

Contraindications Hypersensitivity to imipenem/cilastatin or any component of the formulation

Warnings Dosage adjustment required in patients with impaired renal function; elderly patients often require lower doses (adjust carefully to renal function); Prolonged use may result in superinfection, including pseudomembranous colitis. Has been associated with CNS adverse effects, including confusional states and seizures; use with caution in patients with a history of seizures or hypersensitivity to beta-lactams (including penicillins and cephalosporins); patients with impaired renal function are at increased risk of seizures if not properly dose adjusted. Not recommended in pediatric CNS infections due to seizure potential. Serious hypersensitivity reactions, including anaphylaxis, have been reported (some without a history of previous allergic reactions to beta-lactams). Doses for I.M. administration are mixed with lidocaine, consult information on lidocaine for associated warnings/precautions. Two different imipenem/cilastatin products are available; due to differences in formulation, the I.V. and I.M. preparations **cannot** be interchanged. Safety and efficacy of I.M. administration in children < 12 years have not been established.

Dosage Forms

Injection, powder for reconstitution [I.M.]: Imipenem 500 mg and cilastatin 500 mg [contains sodium 32 mg (1.4 mEq)]

Injection, powder for reconstitution [I.V.]: Imipenem 250 mg and cilastatin 250 mg [contains sodium 18.8 mg (0.8 mEq)]; imipenem 500 mg and cilastatin 500 mg [contains sodium 37.5 mg (1.6 mEq)]

Reference Range Peak plasma imipenem concentration following a 500 mg I.V. dose of imipenem/cilastatin: ~40-50 mcg/mL

Overdosage/Treatment

Supportive therapy: Diazepam or phenytoin may be useful for treatment of seizures; fentanyl (100 mcg in adults) has been used with diazepam (5 mg) to treat tremors and seizures

Enhancement of elimination: Hemodialysis is particularly useful to increase clearance of imipenem and cilastatin; ~73% of imipenem and 82% of cilastatin are cleared by a 4-hour dialysis; peritoneal dialysis is not useful in enhancing elimination

Test Interactions Interferes with urinary glucose determination using Clinitest®; can cause false elevations of amylase and lipase

Drug Interactions

Cyclosporine: May increase neurotoxicity of imipenem; conversely, imipenem may increase the serum levels/effects of cyclosporine; monitor.

Ganciclovir: May increase the risk of seizures; concomitant use not recommended.

Typhoid vaccine: Concomitant antibiotics may decrease the effectiveness of live, attenuated Ty21a typhoid vaccine; delay vaccination for >24 hours after administration of antibiotic.

Uricosuric agents: May increase the levels/effects imipenem; monitor.

Valproic acid: Imipenem may decrease valproic acid concentrations to subtherapeutic levels; monitor.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic effects were not observed in animal studies; however, maternal toxicity was noted. There are no well-controlled or adequate studies in pregnant women. Use during pregnancy only if the potential benefits outweigh the potential risks to mother and fetus.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Not for direct infusion; vial contents must be transferred to 100 mL of infusion solution; final concentration should not exceed 5 mg/mL; infuse over 30-60 minutes; watch for seizures; do not mix with or physically add to other antibiotics; however, may administer concomitantly

Additional Information

Seizure frequency is ~1.5% to 2% and usually occurs ~7 days after initiation of therapy; risk factors include brain lesions, epilepsy or

previous seizure disorder, and renal insufficiency; the mechanism of action for seizures may be due to binding of imipramine to gamma-aminobutyric acid (GABA) receptors in the central nervous system
Sodium content of 1 g injection: I.M.: 64.4 mg (2.8 mEq); I.V.: 73.6 mg (3.2 mEq)

Imipramine

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antidepressant Agents
- Dibenzepin
- Therapeutic Drugs Associated with Hallucinations

CAS Number 10075-24-8; 113-52-0; 50-49-7

U.S. Brand Names Tofranil-PM®; Tofranil®

Synonyms Imipramine Hydrochloride; Imipramine Pamoate

Use Treatment of various forms of depression, often in conjunction with psychotherapy; enuresis in children

Unlabeled/Investigational Use Analgesic for certain chronic and neuropathic pain; panic disorder; attention-deficit/hyperactivity disorder (ADHD)

Mechanism of Action Increases the synaptic concentration of serotonin, norepinephrine, and/or dopamine in the central nervous system by inhibition of their reuptake by the presynaptic neuronal membrane; peripheral alpha-receptor blockade may be the cause of hypotension (orthostatic).

Adverse Reactions

Cardiovascular: Cardiac arrhythmias, cardiomyopathy; hypotension has been associated with falls; hypotension (orthostatic), cardiomegaly, myocarditis, tachycardia (supraventricular), torsade de pointes, vasoconstriction, vasculitis, exacerbation of Brugada syndrome

Central nervous system: **Drowsiness, headache,** sedation, confusion, **dizziness,** psychosis, restlessness, fatigue, anxiety, nervousness, sleep disorders, seizures, delirium, hyperthermia, visual hallucinations, paranoia, extrapyramidal reactions

Dermatologic: Rash, photosensitivity, exfoliative dermatitis, angioedema, urticaria, purpura, pruritus, bullous eruptions, licheniform eruptions, exanthem, photoallergic reaction

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone, gynecomastia

Gastrointestinal: **Nausea, vomiting, constipation, xerostomia,** Ogilvie's syndrome, **increased appetite, weight gain, unpleasant taste,** stomatitis, lingua villosa nigra

Genitourinary: **Urinary retention**

Hematologic: Blood dyscrasias

Hepatic: Hepatitis, liver failure, liver necrosis, cholestasis

Neuromuscular & skeletal: Clonus, myoclonus, **weakness,** paresthesia

Ocular: Blurred vision, photophobia, diplopia, intraocular pressure (increased), mydriasis

Respiratory: Pulmonary edema, eosinophilic pneumonia

Miscellaneous: Hypersensitivity reactions, systemic lupus erythematosus (SLE), fixed drug eruption

Signs and Symptoms of Overdose Agranulocytosis, alopecia, ataxia, cardiac arrhythmias, colitis, coma (mean duration: 6 hours), conduction defects, confusion, constipation, cyanosis, dementia, dental erosion, depression, disorientation, ejaculatory disturbances, eosinophilia, galactorrhea, granulocytopenia, hallucinations, hyperthyroidism, hypoglycemia, hyponatremia, hypotension, impotence, increased intraocular pressure, jaundice, lactation, leukopenia, mania, myasthenia gravis (exacerbation or precipitation), myoclonus, neutropenia, nystagmus, ototoxicity, pulmonary edema, QT prolongation, respiratory depression, seizures (within 3 hours of ingestion), tachycardia (sinus), tinnitus; QRS prolongation (with rightward terminal 40 millisecond frontal plane of QRS vector)

Admission Criteria/Prognosis Admit any symptomatic patient (including persistent tachycardia) following 6 hours of ER observation; admit any pediatric ingestion > 5 mg/kg

Pharmacodynamics/Kinetics

Onset of action: Peak antidepressant effect: Usually after ≥ 2 weeks

Absorption: Well absorbed

Distribution: Crosses placenta

Metabolism: Hepatic via CYP to desipramine (active) and other metabolites; significant first-pass effect

Half-life elimination: 6-18 hours

Excretion: Urine (as metabolites)

Dosage Maximum antidepressant effect may not be seen for 2 or more weeks after initiation of therapy

Children: Oral:

Depression: 1.5 mg/kg/day with dosage increments of 1 mg/kg every 3-4 days to a maximum dose of 5 mg/kg/day in 1-4 divided doses; monitor carefully especially with doses ≥ 3.5 mg/kg/day

Enuresis: ≥ 6 years: Initial: 10-25 mg at bedtime, if inadequate response still seen after 1 week of therapy, increase by 25 mg/day; dose should not exceed 2.5 mg/kg/day or 50 mg at bedtime if 6-12 years of age or 75 mg at bedtime if ≥ 12 years of age

Adjunct in the treatment of cancer pain: Initial: 0.2-0.4 mg/kg at bedtime; dose may be increased by 50% every 2-3 days up to 1-3 mg/kg/dose at bedtime

Adolescents: Oral: Initial: 25-50 mg/day; increase gradually; maximum: 100 mg/day in single or divided doses

Adults:

Oral: Initial: 25 mg 3-4 times/day, increase dose gradually, total dose may be given at bedtime; maximum: 300 mg/day

I.M.: Initial: Up to 100 mg/day in divided doses; change to oral as soon as possible

Stability Solutions stable at a pH of 4-5; turns yellowish or reddish on exposure to light. Slight discoloration does not affect potency; marked discoloration is associated with loss of potency. Capsules stable for 3 years following date of manufacture.

Monitoring Parameters Monitor blood pressure and pulse rate prior to and during initial therapy; ECG in older adults; evaluate mental status; blood levels are useful for therapeutic monitoring

Contraindications Hypersensitivity to imipramine (cross-reactivity with other dibenzodiazepines may occur) or any component of the formulation; concurrent use of MAO inhibitors (within 14 days); in a patient during acute recovery phase of MI; pregnancy

Warnings[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. **Imipramine is FDA approved for the treatment of nocturnal enuresis in children ≥ 6 years of age.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur. May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Imipramine is not FDA approved for the treatment of bipolar depression.**

May cause sedation, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Sedative effects may be additive with other CNS depressants and/or ethanol. The degree of sedation is high relative to other antidepressants. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Therapy should not be abruptly discontinued in patients receiving high doses for prolonged periods.

May cause orthostatic hypotension (risk is very high relative to other antidepressants) - use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). The degree of anticholinergic blockade produced by this agent is high relative to other cyclic antidepressants - use caution in patients with urinary retention, benign prostatic hyperplasia, narrow-angle glaucoma, xerostomia, visual problems, constipation, or history of bowel obstruction.

Use with caution in patients with a history of cardiovascular disease (including previous MI, stroke, tachycardia, or conduction abnormalities). The risk of conduction abnormalities with this agent is high relative to other antidepressants. ECG monitoring is recommended if high dosages are used. Use caution in patients with a previous seizure disorder or condition predisposing to seizures such as brain damage, alcoholism, or concurrent therapy with other drugs which lower the seizure threshold. Use with caution in hyperthyroid patients or those receiving thyroid supplementation. Use with caution in patients with hepatic or renal dysfunction and in elderly patients. Has been associated with photosensitization.

Dosage Forms

Capsule, as pamoate (Tofranil-PM®): 75 mg, 100 mg, 125 mg, 150 mg
Tablet, as hydrochloride (Tofranil®): 10 mg, 25 mg, 50 mg [generic tablets may contain sodium benzoate]

Reference Range**Therapeutic:**

Imipramine and desipramine 150-250 ng/mL (SI: 530-890 nmol/L)
Desipramine 150-300 ng/mL (SI: 560-1125 nmol/L)

Metabolism may be impaired in elderly patients; toxic: >300 ng/mL (SI: >1070 nmol/L); serious symptoms are associated with levels >1000 ng/mL (SI: >3566 nmol/L)

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage within 2-3 hours/activated charcoal; multiple dosing of activated charcoal would be expected to be useful

Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated. Ventricular arrhythmias and ventricular conduction defects often respond to concurrent systemic alkalinization (sodium bicarbonate 0.5-2 mEq/kg I.V.). Titrate to a serum pH of 7.45-7.55. Arrhythmias unresponsive to this therapy may respond to lidocaine 1 mg/kg I.V. followed by a titrated infusion. Phenytoin is also useful in treating ventricular dysrhythmias (15 mg/kg up to 1 g I.V.). Physostigmine (1-2 mg I.V. slowly for adults or 0.5 mg I.V. slowly for children) may be indicated for seizures or movement disorders but only as a **last resort**. Propranolol may also be utilized for supraventricular arrhythmias (rate: >160) at 1 mg/minute to a maximum of 5 mg in adults; pediatric dosage of 0.1 mg/kg/dose to 1 mg I.V.. Seizures usually respond to lorazepam or diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required. Patients must be monitored for at least 24 hours if any signs or symptoms are exhibited. Dobutamine is preferred over dopamine for hypotension, although there is conflicting animal data. Norepinephrine appears effective in treating hypotension; glucagon (10 mg I.V.) can be given to treat hypotension. Flumazenil is contraindicated; magnesium has potentiated adverse cardiac effects (ie, asystole, decreased left ventricular pressure) in an animal model, although it was used successfully in treating refractory ventricular fibrillation at a dose of 20 nmol I.V. (a total of 2 doses). For treatment of lingua villosa nigra, discontinue causative agent. Clean the tongue with a toothbrush and rinse mouth with a half-strength solution of hydrogen peroxide or 10% carbamide peroxide. Oral symptoms should subside in a few days.

TCA ovine antibody fragments (TCA Fab, Protherics Inc) have been developed and used investigational at a dose of 1-2 g over 30 minutes I.V.; if QRS was >100 msec or terminal deflection of QRS in lead aVR was >3 mm, a second dose (2 g over 30 min or 4 g over 1 hour) was given. If no response, a third infusion (4 g over 60 minutes or 8 g over 2 hours) was given.

Antidote(s)

- Sodium Bicarbonate [ANTIDOTE]

Test Interactions

Increases glucose, increases plasma norepinephrine levels and plasma epinephrine levels threefold to fivefold; EMIT assays may be false-positive in the presence of diphenhydramine, thioridazine, chlorpromazine, alimemazine, carbamazepine, cyclobenzaprine, or perphenazine

Drug Interactions Substrate of CYP1A2 (minor), 2B6 (minor), 2C19 (major), 2D6 (major), 3A4 (minor); **Inhibits** CYP1A2 (weak), 2C19 (weak), 2D6 (moderate), 2E1 (weak)

Altretamine: Concurrent use may cause orthostatic hypertension

Amphetamines: TCAs may enhance the effect of amphetamines; monitor for adverse CV effects

Anticholinergics: Combined use with TCAs may produce additive anticholinergic effects

Antihypertensives: TCAs may inhibit the antihypertensive response to bethanidine, clonidine, debrisoquin, guanadrel, guanethidine, guanabenz, guanfacine; monitor BP; consider alternate antihypertensive agent

Beta-agonists: When combined with TCAs may predispose patients to cardiac arrhythmias

Bupropion: May increase the levels of tricyclic antidepressants; based on limited information; monitor response

Carbamazepine: Tricyclic antidepressants may increase carbamazepine levels; monitor

Cholestyramine and colestipol: May bind TCAs and reduce their absorption; monitor for altered response

Clonidine: Abrupt discontinuation of clonidine may cause hypertensive crisis, amitriptyline may enhance the response

CNS depressants: Amitriptyline may be additive with or may potentiate sedation; sedative effects may be additive with TCAs; monitor for increased effect; includes benzodiazepines, barbiturates, antipsychotics, ethanol, and other sedative medications

CYP2C19 inducers: May decrease the levels/effects of imipramine. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of imipramine. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

CYP2D6 inhibitors: May increase the levels/effects of imipramine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Epinephrine (and other direct alpha-agonists): The pressor response to I.V. epinephrine, norepinephrine, and phenylephrine may be enhanced in patients receiving TCAs; this combination is best avoided

Fenfluramine: May increase tricyclic antidepressant levels/effects
Hypoglycemic agents (including insulin): TCAs may enhance the hypoglycemic effects of tolazamide, chlorpropamide, or insulin; monitor for changes in blood glucose levels; reported with chlorpropamide, tolazamide, and insulin

Levodopa: Tricyclic antidepressants may decrease the absorption (bioavailability) of levodopa; rare hypertensive episodes have also been attributed to this combination

Linezolid: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** with agents which inhibit MAO (serotonin syndrome); this combination should be avoided

Lithium: Concurrent use with a TCA may increase the risk for neurotoxicity

MAO inhibitors: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** (serotonin syndrome); this combination should be avoided

Methylphenidate: Metabolism of TCAs may be decreased

Phenothiazines: Serum concentrations of some TCAs may be increased; in addition, TCAs may increase concentration of phenothiazines; monitor for altered clinical response

QT_c-prolonging agents: Concurrent use of tricyclic agents with other drugs which may prolong QT_c interval may increase the risk of potentially fatal arrhythmias; includes type Ia and type III antiarrhythmics agents, selected quinolones (sparfloxacin, gatifloxacin, moxifloxacin, grepafloxacin), cisapride, and other agents

Ritonavir: Combined use of high-dose tricyclic antidepressants with ritonavir may cause serotonin syndrome in HIV-positive patients; monitor

Sucralfate: Absorption of tricyclic antidepressants may be reduced with coadministration

Sympathomimetics, indirect-acting: Tricyclic antidepressants may result in a decreased sensitivity to indirect-acting sympathomimetics; includes dopamine and ephedrine; also see interaction with epinephrine (and direct-acting sympathomimetics)

Tramadol: Tramadol's risk of seizures may be increased with TCAs

Valproic acid: May increase serum concentrations/adverse effects of some tricyclic antidepressants

Warfarin (and other oral anticoagulants): TCAs may increase the anticoagulant effect in patients stabilized on warfarin; monitor INR

Pregnancy Risk Factor D

Pregnancy Implications Has been known to cause neonatal withdrawal consisting of tachypnea, restlessness, and insomnia; crosses the placenta

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Nursing Implications May increase appetite

Additional Information Imipramine hydrochloride: Tofranil®, Janimine® Imipramine Pamoate: Tofranil-PM®; monoclonal anti-imipramine antibodies are investigational

Hypericum extract ZE, 250 mg twice daily, appears to be as effective as imipramine, 75 mg twice daily, for treatment of mild to moderate depression for 6 weeks.

Inamrinone

CAS Number 60719-84-8

Synonyms Amrinone Lactate

Use Treatment of low cardiac output states (sepsis, congestive heart failure); adjunctive therapy of pulmonary hypertension; normally prescribed for patients who have not responded well to therapy with digitalis, diuretics, and vasodilators; effective for calcium channel blocker toxicity

Mechanism of Action Inhibits myocardial cyclic adenosine monophosphate (cAMP) phosphodiesterase activity and increases cellular levels of cAMP resulting in a positive inotropic effect; also possesses systemic and pulmonary vasodilator effects

Adverse Reactions

Cardiovascular: Hypotension, ventricular and arrhythmias (supraventricular); may be related to infusion rate, angina, tachycardia (sinus); tachycardia (supraventricular)
 Central nervous system: Headache, fever, mania
 Dermatologic: Yellow fingernail discoloration
 Endocrine & metabolic: Nephrogenic diabetes insipidus
 Gastrointestinal: Nausea, vomiting, abdominal pain, anorexia, hypogeusia, splenomegaly, stomatitis, altered taste
 Hematologic: Thrombocytopenia
 Hepatic: Hepatotoxicity: Discontinue inamrinone if significant elevation in liver enzymes (serum lactic dehydrogenase or glutamic oxaloacetic transaminase) with symptoms of idiosyncratic hypersensitivity reaction (eg, eosinophilia) occurs
 Neuromuscular & skeletal: Myalgia
 Renal: Diuresis
 Respiratory: Hyposmia

Signs and Symptoms of Overdose Chest pain, diabetes insipidus, hyperthermia, hypotension, lightheadedness, myalgia, tachycardia

Pharmacodynamics/Kinetics

Onset of action: I.V.: 2-5 minutes
 Peak effect: ~10 minutes
 Duration (dose dependent): Low dose: ~30 minutes; Higher doses: ~2 hours
 Half-life elimination, serum: Adults: Healthy volunteers: 3.6 hours, Congestive heart failure: 5.8 hours

Dosage

Dosage is based on clinical response. **Note:** Dose should not exceed 10 mg/kg/24 hours
 Neonates: 0.75 mg/kg I.V. bolus over 2-3 minutes followed by maintenance infusion 3-5 mcg/kg/minute; I.V. bolus may need to be repeated in 30 minutes
 Children and Adults: 0.75 mg/kg I.V. bolus over 2-3 minutes followed by maintenance infusion 5-10 mcg/kg/minute; I.V. bolus may need to be repeated in 30 minutes

Dosing adjustment in renal failure: $Cl_{cr} < 10$ mL/minute: Administer 50% to 75% of dose

Stability May be administered undiluted for I.V. bolus doses. For continuous infusion: Dilute with 0.45% or 0.9% sodium chloride to final concentration of 1-3 mg/mL; use within 24 hours; do not directly dilute with dextrose-containing solutions, chemical interaction occurs; may be administered I.V. into running dextrose infusions. Furosemide forms a precipitate when injected in I.V. lines containing amrinone.

Monitoring Parameters Cardiac index, stroke volume, systemic vascular resistance, and pulmonary vascular resistance (if Swan-Ganz catheter available); CVP, SBP, DBP, heart rate; platelet count, CBC, liver function and renal function tests

Administration Should be administered solely via an I.V. pump

Contraindications Hypersensitivity to inamrinone, any component of the formulation, or bisulfites (contains sodium metabisulfite); patients with severe aortic or pulmonic valvular disease

Warnings Due to a slight effect on AV conduction, may increase ventricular response rate in atrial fibrillation/atrial flutter; prior treatment with digoxin is recommended. Monitor liver function. Discontinue therapy if alteration in LFTs and clinical symptoms of hepatotoxicity occur. Observe for arrhythmias in this very high-risk patient population. Not recommended in acute MI treatment. Monitor fluid status closely; patients may require adjustment of diuretic and electrolyte replacement therapy. Can cause thrombocytopenia (dose dependent). Correct hypokalemia before initiating therapy. Increase risk of hospitalization and death with long-term therapy.

Dosage Forms Injection, solution, as lactate: 5 mg/mL (20 mL) [contains sodium metabisulfite]

Reference Range Therapeutic range: 2-7 mcg/mL (serum) serum level of 75.9 mcg/mL correlated with dose of 180-198 mcg/kg/minute refractory hypotension and death

Overdosage/Treatment Supportive therapy: There is no specific antidote for inamrinone intoxication. Overdosage with inamrinone has caused severe hypotension by vasodilation; if this occurs, general measures for circulatory support should be taken (isotonic saline, dopamine)

Test Interactions ↓ potassium

Drug Interactions Furosemide: A precipitate forms on admixture with inamrinone.

Diuretics may cause significant hypovolemia and decrease filling pressure.

Digitalis: Inotropic effects are additive.

Pregnancy Risk Factor C

Nursing Implications Patients should be carefully monitored for hemodynamic response (hypotension) and potential adverse effects (ie, thrombocytopenia, hepatitis, and GI effects)

Additional Information To avoid confusion with amiodarone, the generic name "amrinone" was changed to "inamrinone" in July, 2000. Normally prescribed for patients who have not responded well to therapy with digitalis, diuretics, and vasodilators

Indapamide

CAS Number 26807-65-8

U.S. Brand Names Lozol®

Use Hypertension; edema due to congestive heart failure, renal calculi due to hypercalciuria, Raynaud's disease

Mechanism of Action Similar diuretic action as with thiazide diuretics with additional action on blood vessels resulting in decreased peripheral vascular resistance (possibly due to a calcium channel blocking effect)

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), palpitations, vasculitis
 Central nervous system: Vertigo, headache
 Dermatologic: Hives, pruritus, epidermal necrolysis, erythema multiforme, angioedema, Stevens-Johnson syndrome, exanthem
 Endocrine & metabolic: **Hypokalemia** (12% on 2.5 mg/day, 27% on 5 mg/day), uric acid levels (increased), hypochloremia, hyponatremia (rare), toxic epidermal necrolysis, hypercalcemia
 Gastrointestinal: Nausea, vomiting, constipation, anorexia, xerostomia, pancreatitis
 Genitourinary: Nocturia, impotence
 Hepatic: Hepatotoxicity (cirrhosis)
 Neuromuscular & skeletal: Paresthesias
 Renal: Azotemia, interstitial nephritis
 Respiratory: Rhinorrhea
 Miscellaneous: Fixed drug eruption

Pharmacodynamics/Kinetics

Onset of action: 1-2 hours
 Duration: ≤36 hours
 Absorption: Complete
 Protein binding, plasma: 71% to 79%
 Metabolism: Extensively hepatic
 Half-life elimination: 14-18 hours
 Time to peak: 2-2.5 hours
 Excretion: Urine (~60%) within 48 hours; feces (~16% to 23%)

Dosage Oral: 2.5-5 mg once daily

Monitoring Parameters Blood pressure (both standing and sitting/supine), serum electrolytes, renal function, assess weight, I & O reports daily to determine fluid loss

Administration May be taken with food or milk. Administer early in day to avoid nocturia. Administer the last dose of multiple doses no later than 6 PM unless instructed otherwise.

Contraindications Hypersensitivity to indapamide or any component of the formulation, thiazides, or sulfonamide-derived drugs; anuria; renal decompensation; pregnancy (based on expert analysis)

Warnings Use with caution in severe renal disease. Electrolyte disturbances (hypokalemia, hypochloremic alkalosis, hyponatremia) can occur. Use with caution in severe hepatic dysfunction; hepatic encephalopathy can be caused by electrolyte disturbances. Gout can be precipitated in certain patients with a history of gout, a familial predisposition to gout, or chronic renal failure. Cautious use in diabetics; may see a change in glucose control. I.V. use is generally not recommended (but is available). Hypersensitivity reactions can occur. Can cause SLE exacerbation or activation. Use with caution in patients with moderate or high cholesterol concentrations. Photosensitization may occur. Correct hypokalemia before initiating therapy.

Chemical similarities are present among sulfonamides, sulfonylureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with thiazide or sulfonamide allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

Dosage Forms

Tablet: 1.25 mg, 2.5 mg
 Lozol®: 1.25 mg

Reference Range After a 5 mg oral dose, peak serum indapamide levels of 221 ng/mL are achieved (after 3 hours)

Overdosage/Treatment

Decontamination: Activated charcoal
 Supportive therapy: I.V. hydration with 0.9% saline and electrolyte replacement
 Enhancement of elimination: Hemodialysis may be effective; not dialyzable

Drug Interactions

ACE inhibitors: Increased hypotension if aggressively diuresed with a thiazide diuretic.
 Beta-blockers increase hyperglycemic effects in type 2 diabetes mellitus (noninsulin dependent, NIDDM)
 Cyclosporine and thiazides can increase the risk of gout or renal toxicity; avoid concurrent use.
 Digoxin toxicity can be exacerbated if a thiazide induces hypokalemia or hypomagnesemia.
 Lithium toxicity can occur by reducing renal excretion of lithium; monitor lithium concentration and adjust as needed.

Neuromuscular blocking agents can prolong blockade; monitor serum potassium and neuromuscular status.

NSAIDs can decrease the efficacy of thiazides reducing the diuretic and antihypertensive effects.

Pregnancy Risk Factor B (manufacturer); D (expert analysis)

Lactation Excretion in breast milk unknown

Indinavir

U.S. Brand Names Crixivan®

Synonyms Indinavir Sulfate

Use Treatment of HIV infection; should always be used as part of a multidrug regimen (at least three antiretroviral agents)

Mechanism of Action Indinavir is a human immunodeficiency virus protease inhibitor, binding to the protease activity site and inhibiting the activity of this enzyme. HIV protease is an enzyme required for the cleavage of viral polyprotein precursors into individual functional proteins found in infectious HIV. Inhibition prevents cleavage of these polyproteins resulting in the formation of immature noninfectious viral particles.

Adverse Reactions

Protease inhibitors cause dyslipidemia which includes elevated cholesterol and triglycerides and a redistribution of body fat centrally to cause "protease paunch", buffalo hump, facial atrophy, and breast enlargement. These agents also cause hyperglycemia (exacerbation or new-onset diabetes).

Cardiovascular: Myocardial infarction

Central nervous system: Headache, insomnia, malaise, dizziness, somnolence, depression, fever

Dermatologic: Urticaria, alopecia, erythema multiforme, Stevens-Johnson syndrome

Endocrine & metabolic: Increased serum cholesterol, hyperglycemia, new-onset diabetes

Gastrointestinal: **Nausea**, abdominal pain, diarrhea/vomiting, taste perversion, anorexia, pancreatitis

Genitourinary: Leukocyturia (severe and asymptomatic)

Hematologic: Decreased hemoglobin

Hepatic: **Hyperbilirubinemia (14%)**, hepatic failure, hepatitis

Neuromuscular & skeletal: Weakness, flank pain

Ocular: Photophobia

Renal: **Nephrolithiasis/uroolithiasis (29%, pediatric patients; 12%, adult patients)**, hematuria, acute renal failure, crystalluria, pyelonephritis, interstitial nephritis (with medullary calcification and cortical atrophy)

Miscellaneous: Anaphylactoid reactions

Signs and Symptoms of Overdose Dizziness, drowsiness, nausea, paresthesias

Admission Criteria/Prognosis Admit any ingestion > 5 g.

Pharmacodynamics/Kinetics

Absorption: Administration with a high fat, high calorie diet resulted in a reduction in AUC and in maximum serum concentration (77% and 84% respectively); lighter meal resulted in little or no change in these parameters.

Protein binding, plasma: 60%

Metabolism: Hepatic via CYP3A4; seven metabolites of indinavir identified

Bioavailability: Good

Half-life elimination: 1.8 ± 0.4 hour

Time to peak: 0.8 ± 0.3 hour

Excretion: Urine and feces

Dosage

Children 4-15 years (investigational): 500 mg/m² every 8 hours

Adults: Oral:

Unboosted regimen: 800 mg every 8 hours

Ritonavir-boosted regimens:

Ritonavir 100-200 mg twice daily plus indinavir 800 mg twice daily or

Ritonavir 400 mg twice daily plus indinavir 400 mg twice daily

Dosage adjustments for indinavir when administered in combination therapy:

Delavirdine, itraconazole, or ketoconazole: Reduce indinavir dose to 600 mg every 8 hours

Efavirenz: Increase indinavir dose to 1000 mg every 8 hours

Lopinavir and ritonavir (Kaletra™): Indinavir 600 mg twice daily

Nelfinavir: Increase indinavir dose to 1200 mg twice daily

Nevirapine: Increase indinavir dose to 1000 mg every 8 hours

Rifabutin: Reduce rifabutin to 1/2 the standard dose plus increase indinavir to 1000 mg every 8 hours

Dosage adjustment in hepatic impairment: Mild-moderate impairment due to cirrhosis: 600 mg every 8 hours or with ketoconazole coadministration

Monitoring Parameters Monitor viral load, CD4 count, triglycerides, cholesterol, glucose, liver function tests, CBC, urinalysis (severe leukocyturia should be monitored frequently).

Administration Drink at least 48 oz of water daily. Administer with water, 1 hour before or 2 hours after a meal. Administer around-the-clock to avoid significant fluctuation in serum levels. May be taken with food when administered in combination with ritonavir.

Contraindications Hypersensitivity to indinavir or any component of the formulation; concurrent use of amiodarone, cisapride, triazolam, midazolam, pimozone, or ergot alkaloids

Warnings Because indinavir may cause nephrolithiasis/uroolithiasis the drug should be discontinued if signs and symptoms occur; risk is substantially higher in pediatric patients versus adults. Adequate hydration is recommended. May cause tubulointerstitial nephritis (rare); severe asymptomatic leukocyturia may warrant evaluation. Indinavir should not be administered concurrently with lovastatin or simvastatin (caution with atorvastatin and cerivastatin) because of competition for metabolism of these drugs through the CYP3A4 system, and potential serious or life-threatening events. Use caution with other drugs metabolized by this enzyme (particular caution with phosphodiesterase-5 inhibitors, including sildenafil). Avoid concurrent use of St John's wort (may lead to loss of virologic response and/or resistance). Patients with hepatic insufficiency due to cirrhosis should have dose reduction. Warn patients about fat redistribution that can occur. Indinavir has been associated with hemolytic anemia (discontinue if diagnosed), hepatitis, and hyperglycemia (exacerbation or new-onset diabetes). Treatment may result in immune reconstitution syndrome (acute inflammatory response to indolent or residual opportunistic infections). Use caution in patients with hemophilia; spontaneous bleeding has been reported.

Dosage Forms Capsule: 100 mg, 200 mg, 333 mg, 400 mg

Reference Range Therapeutic drug concentration (serum) is 251-12,617 nmol

Overdosage/Treatment

Decontamination: Lavage any ingestion >3 g in adults within 1 hour; activated charcoal should be given.

Supportive therapy: Aggressively hydrate (200 mL/hour normal saline in adults) to prevent nephrolithiasis.

Drug Interactions **Substrate** of CYP2D6 (minor), 3A4 (major); **Inhibits** CYP2C9 (weak), 2C19 (weak), 2D6 (weak), 3A4 (strong)

Amiodarone: Serum levels/toxicity may be increased by indinavir; serious and/or life-threatening reactions may occur; concurrent use is contraindicated.

Anticonvulsants: Phenobarbital, and carbamazepine may decrease serum levels and consequently effectiveness of indinavir.

Benzodiazepines: An increase in midazolam and triazolam serum levels may occur resulting in significant oversedation when administered with indinavir. Concurrent use is contraindicated. Use caution with other benzodiazepines.

Calcium channel blockers: Indinavir may increase the serum concentrations of calcium channel blockers.

Cisapride: Indinavir inhibits the metabolism of cisapride and should not be administered concurrently due to risk of life-threatening cardiac arrhythmias.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of indinavir. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins. Dosage adjustment may be recommended; see individual agents.

CYP3A4 inhibitors: May increase the levels/effects of indinavir. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

CYP3A4 substrates: Indinavir may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, and tacrolimus. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozone are generally contraindicated with strong CYP3A4 inhibitors.

Didanosine: Separate administration of indinavir from buffered formulations by at least 1 hour.

Ergot alkaloids: Serum levels/toxicity may be increased by indinavir; serious and/or life-threatening reactions may occur; concurrent use is contraindicated.

HMG-CoA reductase inhibitors: Indinavir may increase levels of HMG-CoA reductase inhibitors, increasing the risk of myopathy. Lovastatin and simvastatin should not be coadministered with indinavir (per manufacturer). Atorvastatin may be used with careful monitoring, in the lowest dose possible. Fluvastatin and pravastatin may have lowest risk.

Immunosuppressants: Indinavir may increase the serum levels of cyclosporine, sirolimus or tacrolimus.

Itraconazole or ketoconazole: May increase the serum concentrations of indinavir. Dosage adjustment of indinavir is recommended.

Non-nucleoside reverse transcriptase inhibitors: When used with delavirdine, serum levels of indinavir are increased. The serum concentrations of indinavir may be decreased by efavirenz or nevirapine. Dosage adjustment of indinavir may be required for these combinations.

Phosphodiesterase-5 (PDE-5) inhibitors (sildenafil, tadalafil, vardenafil): Serum concentrations/effects may be substantially increased by indinavir. Dosage restriction/limitation is recommended.

Pimozide: Serum levels/toxicity may be increased by indinavir; serious and/or life-threatening reactions may occur; concurrent use is contraindicated.

Protease inhibitors: Serum levels of both nelfinavir and indinavir are increased with concurrent use. Serum concentrations of indinavir may be increased by ritonavir. Serum levels of ritonavir and saquinavir may be increased. Dosage adjustments of both agents may be required during concurrent therapy. Concurrent use of atazanavir may increase the risk of hyperbilirubinemia.

Quinidine: Serum levels/toxicity may be increased by indinavir; serious and/or life-threatening reactions may occur; concurrent use is contraindicated.

Rifabutin: A 200% increase in rifabutin plasma AUC has been observed when coadministered with indinavir. Rifabutin may decrease the serum concentrations of indinavir. Dosage adjustment of both agents required.

Rifampin: Rifampin decreases indinavir's serum concentrations; loss of virologic response and resistance may occur; the two drugs should not be administered together.

St John's wort (*Hypericum perforatum*): Appears to induce CYP3A enzymes and may lead to reduction in trough serum concentrations, which may lead to treatment failures. Alternatively, changes may involve P-glycoprotein. The two drugs should not be used together.

Venlafaxine: May decrease indinavir levels/effects; use caution.

Pregnancy Risk Factor C

Pregnancy Implications Safety and pharmacokinetic studies are currently underway in pregnant women; hyperbilirubinemia may be exacerbated in neonates. Pregnancy and protease inhibitors are both associated with an increased risk of hyperglycemia. Glucose levels should be closely monitored. Healthcare professionals are encouraged to contact the antiretroviral pregnancy registry to monitor outcomes of pregnant women exposed to antiretroviral medications (1-800-258-4263).

Lactation Enters breast milk/contraindicated

Nursing Implications Administer around-the-clock to avoid significant fluctuation in serum levels; administer with plenty of water

Indomethacin

Related Information

- Nonsteroidal Anti-inflammatory Drugs
- Therapeutic Drugs Associated with Hallucinations

CAS Number 53-86-1 (Base); 74252-25-8 (Sodium)

U.S. Brand Names Indocin® I.V.; Indocin® SR; Indocin®

Synonyms Indometacin; Indomethacin Sodium Trihydrate

Use Management of inflammatory diseases and rheumatoid disorders; moderate pain; acute gouty arthritis, acute bursitis/tendonitis, moderate to severe osteoarthritis, rheumatoid arthritis, ankylosing spondylitis; I.V. form used as alternative to surgery for closure of patent ductus arteriosus in neonates

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors

Adverse Reactions

Cardiovascular: Tachycardia

Central nervous system: Arrhythmias, aseptic meningitis, confusion, depression, dizziness, drowsiness, fatigue, hallucinations, **headache**, hypertension, malaise, psychic disturbances, psychosis, shock, somnolence, vertigo

Dermatologic: Angioedema, erythema multiforme, exfoliative dermatitis, itching, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Endocrine & metabolic: Hot flashes, hyperkalemia, dilutional hyponatremia (I.V.), hypoglycemia (I.V.), polydipsia

Gastrointestinal: Abdominal pain, abdominal cramps, abdominal distress, anorexia, constipation, diarrhea, dyspepsia, epigastric pain, flatulence, gastritis, GI bleeding, GI ulceration, heartburn, indigestion, perforation, proctitis, nausea, stomatitis

Genitourinary: Cystitis

Hematologic: Agranulocytosis, anemia, bone marrow suppression, hemolytic anemia, inhibition of platelet aggregation, leukopenia, thrombocytopenia

Hepatic: Cholestatic jaundice, hepatitis (including fatal cases)

Ocular: Blurred vision, conjunctivitis, corneal opacities, dry eyes, retinal/macular disturbances, toxic amblyopia

Otic: Decreased hearing, tinnitus

Neuromuscular & skeletal: Peripheral neuropathy

Renal: Interstitial nephritis, nephrotic syndrome, oliguria, polyuria, renal failure

Respiratory: Acute respiratory distress, allergic rhinitis, asthma, bronchospasm, CHF, dyspnea, epistaxis

Miscellaneous: Anaphylaxis, hypersensitivity reactions

Signs and Symptoms of Overdose Azotemia, cholestatic jaundice, coagulopathy, colitis, corneal microdeposits, dementia, drowsiness, esophageal ulceration, gastrointestinal upset, GI bleeding, hematuria, hypoglycemia, hyponatremia, impotence, nausea, ototoxicity, photosensitivity, pseudotumor cerebri, syndrome of inappropriate antidiuretic hormone (SIADH), tinnitus, vomiting, wheezing

Severe poisoning can manifest with blindness, blurred vision, coma, feces discoloration (green), hyperglycemia, hypotension, renal and/or hepatic failure, respiratory depression, seizures, thrombocytopenia, urine discoloration (green)

Pharmacodynamics/Kinetics

Onset of action: ~30 minutes

Duration: 4-6 hours

Absorption: Prompt and extensive

Distribution: V_d: 0.34-1.57 L/kg; crosses blood brain barrier and placenta; enters breast milk

Protein binding: 99%

Metabolism: Hepatic; significant enterohepatic recirculation

Bioavailability: 100%

Half-life elimination: 4.5 hours; prolonged in neonates

Time to peak: Oral: 2 hours

Excretion: Urine (60%, primarily as glucuronide conjugates); feces (33%, primarily as metabolites)

Dosage

Patent ductus arteriosus:

Neonates: I.V.: Initial: 0.2 mg/kg, followed by 2 doses depending on postnatal age (PNA):

PNA at time of first dose <48 hours: 0.1 mg/kg at 12- to 24-hour intervals

PNA at time of first dose 2-7 days: 0.2 mg/kg at 12- to 24-hour intervals

PNA at time of first dose >7 days: 0.25 mg/kg at 12- to 24-hour intervals

In general, may use 12-hour dosing interval if urine output > 1 mL/kg/hour after prior dose; use 24-hour dosing interval if urine output is < 1 mL/kg/hour but > 0.6 mL/kg/hour; doses should be withheld if patient has oliguria (urine output < 0.6 mL/kg/hour) or anuria

Inflammatory/rheumatoid disorders: Oral:

Children: 1-2 mg/kg/day in 2-4 divided doses; maximum dose: 4 mg/kg/day; not to exceed 150-200 mg/day

Adults: 25-50 mg/dose 2-3 times/day; maximum dose: 200 mg/day; extended release capsule should be given on a 1-2 times/day schedule

Stability Protect from light; not stable in alkaline solution; reconstitute just prior to administration; discard any unused portion; do not use preservative containing diluents for reconstitution

Monitoring Parameters Monitor response (pain, range of motion, grip strength, mobility, ADL function), inflammation; observe for weight gain, edema; monitor renal function (serum creatinine, BUN); observe for bleeding, bruising; evaluate gastrointestinal effects (abdominal pain, bleeding, dyspepsia); mental confusion, disorientation, CBC, liver function tests

Administration

Oral: Administer with food, milk, or antacids to decrease GI adverse effects; extended release capsules must be swallowed whole, do not crush

I.V.: Administer over 20-30 minutes at a concentration of 0.5-1 mg/mL in preservative-free sterile water for injection or normal saline. Reconstitute I.V. formulation just prior to administration; discard any unused portion; avoid I.V. bolus administration or infusion via an umbilical catheter into vessels near the superior mesenteric artery as these may cause vasoconstriction and can compromise blood flow to the intestines. Do not administer intra-arterially.

Contraindications Hypersensitivity to indomethacin, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy (3rd trimester)

Neonates: Necrotizing enterocolitis, impaired renal function, active bleeding, thrombocytopenia, coagulation defects, untreated infection

Warnings [U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension. Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI and the elderly. Rehydrate patient before starting therapy. Monitor renal function

closely. Indomethacin is not recommended for patients with advanced renal disease.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

Withhold for at least 4-6 half-lives prior to surgical or dental procedures.

Dosage Forms

Capsule (Indocin®): 25 mg, 50 mg

Capsule, sustained release (Indocin® SR): 75 mg

Injection, powder for reconstitution, as sodium trihydrate (Indocin® I.V.): 1 mg

Suspension, oral (Indocin®): 25 mg/5 mL (237 mL) [contains alcohol 1%; pineapple-coconut-mint flavor]

Reference Range Therapeutic: 0.3-3.0 mg/L (0.8-8.0 μmol/L)

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 4 hours) for ingestions > 10 mg/kg; activated charcoal can be utilized

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; dopamine is vasopressor of choice; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage; famotidine (40 mg 2 times/day) can decrease incidence of gastric or duodenal ulcers in patients receiving long-term therapy of this drug

Enhancement of elimination: Multiple doses of activated charcoal; dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone

Test Interactions Positive Coombs' [direct]

Drug Interactions **Substrate** (minor) of CYP2C9, 2C19; **Inhibits** CYP2C9 (strong), 2C19 (weak)

ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Aminoglycosides: NSAIDs may decrease the excretion of aminoglycosides.

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet drugs (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatid, tirofiban) can cause an increased risk of bleeding.

Beta-blockers: NSAIDs may diminish the antihypertensive effects of beta blockers.

Bisphosphonates: NSAIDs may increase the risk of gastrointestinal ulceration.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids may increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

CYP2C9 Substrates: Indomethacin may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapson, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

Gentamicin and amikacin serum concentrations are increased by indomethacin in premature infants. Results may apply to other aminoglycosides and NSAIDs.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use. Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose. Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again.

Loop diuretics efficacy (diuretic and antihypertensive effect) is reduced. Indomethacin reduces this efficacy, however, it may be anticipated with any NSAID.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Pemetrexed: NSAIDs may decrease the excretion of pemetrexed. Patients with Cl_{cr} 45-79 mL/minute should avoid short acting NSAIDs for 2 days before and 2 days after pemetrexed treatment.

Thiazides antihypertensive effects are decreased; avoid concurrent use. Tiludronate: Indomethacin may increase serum concentration of tiludronate.

Treprostinil: May enhance the risk of bleeding with concurrent use.

Vancomycin: NSAIDs may decrease the excretion of vancomycin.

Pregnancy Risk Factor B/D (3rd trimester)

Pregnancy Implications May have adverse effects on fetus; crosses the placenta; anhydramnios without adverse fetal effects has been associated with 100 mg/day ingestion; renal failure, metabolic acidosis, patent ductus arteriosus and tricuspid regurgitation in neonates can follow *in utero* exposure; dramatic increase in the incidence of indomethacin-induced ductal constriction occurs at 31 weeks gestation

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications Reconstitute just prior to administration; discard any unused portion; inject I.V. over 5-10 seconds; extended release capsules must be swallowed intact

Additional Information May affect platelet and renal function in neonates; misoprostol (200 mcg) can reverse indomethacin-induced renal dysfunction in patients with stable alcoholic cirrhosis

Insulin Lispro

CAS Number 133107-64-9

U.S. Brand Names Humalog®

Synonyms Lispro Insulin

Use Treatment of insulin-dependent diabetes mellitus, also noninsulin-dependent diabetes mellitus unresponsive to treatment with diet and/or oral hypoglycemics; to assure proper utilization of glucose and reduce glucosuria in nondiabetic patients receiving parenteral nutrition whose glucosuria cannot be adequately controlled with infusion rate adjustments or those who require assistance in achieving optimal caloric intakes; used to treat hyperkalemia

Mechanism of Action Equipotent to regular insulin, insulin lispro is a human insulin analog which is more rapidly adsorbed

Pharmacodynamics/Kinetics

Onset of action: 0.2-0.5 hours

Duration: 3-4 hours

Distribution: 0.26-0.36 L/kg

Bioavailability: 55% to 77%

Time to peak: 30-90 minutes

Excretion: Urine

Dosage 100 units/mL

Monitoring Parameters Urine sugar and acetone, serum glucose, electrolytes

Administration Insulin lispro (Humalog®): SubQ administration: May be administered within 15 minutes before or immediately after a meal. Cold injections should be avoided. SubQ administration is usually made into the thighs, arms, buttocks, or abdomen, with sites rotated. Can be infused SubQ by external insulin pump; however, when used in an external pump, should not be diluted or mixed with other insulins.

Note: May be mixed in the same syringe as Humulin® N or Humulin® U, but Humalog® should be drawn into the syringe first.

Contraindications Hypersensitivity to any component of the formulation

Warnings In type 1 diabetes mellitus (insulin dependent, IDDM), insulin lispro (Humalog®) and insulin glulisine (Apidra™) should be used in combination with a long-acting insulin. However, in type 2 diabetes mellitus (noninsulin dependent, NIDDM), insulin lispro (Humalog®) may be used without a long-acting insulin when used in combination with a sulfonylurea.

Dosage Forms Injection, solution (Humalog®): 100 units/mL (3 mL) [prefilled cartridge or prefilled disposable pen]; (10 mL) [vial]

Reference Range Peak serum insulin level of 4.1 ng/mL obtained 1 hour after subcutaneous injection of 10 units of insulin lispro

Overdosage/Treatment

Decontamination: Excision of tissue near insulin injection site can be performed

Supportive therapy: 50 mL D₅W given I.V.; if no I.V. is available, glucagon 0.5-1 mg SubQ or I.M.; give 300 g of carbohydrates orally when patient awakens; insulin-induced peripheral and sacral edema has been successfully treated with oral ephedrine (15 mg every 8 hours); for most insulin overdoses, anticipate a need of 400-600 mg of glucose/kg/hour; continuous infusions of glucose with concentrations exceeding 20% should be given by central venous line

INSULIN PREPARATIONS

Drug Interactions Refer to Insulin Preparations - Regular

Pregnancy Risk Factor B

Pregnancy Implications Does not cross the placenta. Insulin is the drug of choice for control of diabetes mellitus during pregnancy.

Lactation Excretion in breast milk unknown/compatible

Additional Information Less late hypoglycemia and better postprandial glucose control than with regular insulin. NPH insulin should be added to insulin lispro at any meal when the next insulin injection is due no sooner than 3-4 hours later. Insulin lispro costs ~30% more than regular human insulin.

CAS Number 11061-68-0; 11070-73-8; 11091-62-6; 12584-58-6; 51798-72-2; 53027-39-7; 68859-20-1; 8049-62-5; 8063-29-4; 9004-10-8; 9004-12-0; 9004-21-1

U.S. Brand Names Apidra™, Humalog® Mix 75/25™, Humalog®; Humulin® 50/50; Humulin® 70/30; Humulin® L; Humulin® N; Humulin® R (Concentrated) U-500; Humulin® R; Humulin® U; Lantus®; Lente® Iletin® II [DSC]; Novolin® 70/30; Novolin® L [DSC]; Novolin® N; Novolin® R; NovoLog® Mix 70/30; NovoLog®; NPH Iletin® II; Regular Iletin® II; Velosulin® BR (Buffered) [DSC]

Use Treatment of type 1 diabetes mellitus (insulin dependent, IDDM); type 2 diabetes mellitus (noninsulin dependent, NIDDM) unresponsive to treatment with diet and/or oral hypoglycemics; adjunct to parenteral nutrition

Unlabeled/Investigational Use Hyperkalemia (regular insulin only; use with glucose to shift potassium into cells to lower serum potassium levels); therapy of severe calcium channel blocker poisoning

Mechanism of Action Replacement therapy for persons unable to produce the hormone naturally or in insufficient amounts to maintain glycemic control

Adverse Reactions

Primarily symptoms of hypoglycemia

Cardiovascular: Palpitations, tachycardia, pallor, sinus tachycardia, vasodilation, vasculitis

Central nervous system: Fatigue, tingling of fingers, mental confusion, loss of consciousness, headache, hypothermia

Dermatologic: Urticaria, angioedema, bullous skin disease, purpura, exanthem

Endocrine & metabolic: Hypoglycemia, hypokalemia, parotitis, insulin antibody formation

Gastrointestinal: Hunger, nausea, numbness of mouth, loss of taste perception

Local: Itching, redness, edema, stinging, or warmth at injection site; atrophy or hypertrophy of SubQ fat tissue

Neuromuscular & skeletal: Tremors, fasciculations, weakness

Ocular: Transient presbyopia or blurred vision, nystagmus

Miscellaneous: Anaphylactoid reactions, diaphoresis, hiccups

Signs and Symptoms of Overdose Apnea, ataxia, coma, dysarthria, hepatomegaly, hyperglycemia, hypoglycemia, hypokalemia, hypothermia, mydriasis, noncardiogenic pulmonary edema, numbness, nystagmus, parotid pain, periarthritis nodosa, seizures

Admission Criteria/Prognosis Admit any patient who has taken a massive insulin overdose or any child in whom insulin was given without any indication.

Toxicodynamics/Kinetics

Onset of action and duration: Biosynthetic NPH human insulin shows a more rapid onset and shorter duration of action than corresponding porcine insulins; human insulin and purified porcine regular insulin are similarly efficacious following SubQ administration. The duration of action of highly purified porcine insulins is shorter than that of conventional insulin equivalents. Duration depends on type of preparation and route of administration as well as patient-related variables. In general, the larger the dose of insulin, the longer the duration of activity.

Absorption: Biosynthetic regular human insulin is absorbed from the SubQ injection site more rapidly than insulins of animal origin (60-90 minutes peak vs 120-150 minutes peak respectively) and lowers the initial blood glucose much faster. Human Ultralente® insulin is absorbed about twice as quickly as its bovine equivalent, and bioavailability is also improved. Human Lente® insulin preparations are also absorbed more quickly than their animal equivalents. Insulin glargine (Lantus®) is designed to form microprecipitates when injected subcutaneously. Small amounts of insulin glargine are then released over a 24-hour period, with no pronounced peak. Insulin glargine (Lantus®) for the treatment of type 1 diabetes (insulin dependent, IDDM) and type 2 diabetes mellitus (noninsulin dependent, NIDDM) in patients who require basal (long-acting) insulin.

Bioavailability: Medium-acting SubQ Lente®-type human insulins did not differ from the corresponding porcine insulins

Insulin aspart (NovoLog®):

Onset: 0.17-0.33 hours; Peak effect: 1-3 hours; Duration: 3-5 hours

Lispro (Humalog®):

Onset: 0.25 hours; Peak effect: 0.5-1.5 hours; Duration: 6-8 hours

Insulin, regular (Novolin® R):

Onset: 0.5-1 hours; Peak effect: 2-3 hours; Duration: 8-12 hours

Isoophane insulin suspension (NPH) (Novolin® N):

Onset: 1-1.5 hours; Peak effect: 4-12 hours; Duration: 24 hours

Insulin zinc suspension (Lente®):

Onset: 1-2.5 hours; Peak effect: 8-12 hours; Duration: 18-24 hours

Isoophane insulin suspension and regular insulin injection (Novolin® 70/30):

Onset: 0.5 hours; Peak effect: 2-12 hours; Duration: 24 hours

Extended insulin zinc suspension (Ultralente®):

Onset: 4-8 hours; Peak effect: 16-18 hours; Duration: >36 hours

Insulin glargine (Lantus®):

Duration: 24 hours

Dosage

Dose requires continuous medical supervision; may administer I.V. (regular), I.M., or SubQ; regular insulin may also be administered I.V.

Diabetes mellitus: The number and size of daily doses, time of administration, and diet and exercise require continuous medical supervision. In addition, specific formulations may require distinct administration procedures (see Administration).

Children and Adults: 0.5-1 unit/kg/day in divided doses

Adolescents (growth spurts): 0.8-1.2 units/kg/day in divided doses

Adjust dose to maintain premeal and bedtime blood glucose of 80-140 mg/dL (children <5 years: 100-200 mg/dL)

Insulin glargine (Lantus®): SubQ:

Type 2 diabetes (patient not already on insulin): 10 units once daily, adjusted according to patient response (range in clinical study 2-100 units/day)

Patients already receiving insulin: In clinical studies, when changing to insulin glargine from once-daily NPH or Ultralente® insulin, the initial dose was not changed; when changing from twice-daily NPH to once-daily insulin glargine, the total daily dose was reduced by 20% and adjusted according to patient response

Hyperkalemia (unlabeled use): Administer dextrose at 0.5-1 mL/kg and regular insulin 1 unit for every 4-5 g dextrose given

Diabetic ketoacidosis: Children and Adults: Regular insulin: I.V. loading dose: 0.1 unit/kg, then maintenance continuous infusion: 0.1 unit/kg/hour (range: 0.05-0.2 units/kg/hour depending upon the rate of decrease of serum glucose - too rapid decrease of serum glucose may lead to cerebral edema).

Optimum rate of decrease (serum glucose): 80-100 mg/dL/hour

Note: Newly-diagnosed patients with IDDM presenting in DKA and patients with blood sugars <800 mg/dL may be relatively "sensitive" to insulin and should receive loading and initial maintenance doses approximately 1/2 of those indicated above.

Dosing adjustment in renal impairment (regular): Insulin requirements are reduced due to changes in insulin clearance or metabolism

Cl_{cr} 10-50 mL/minute: Administer at 75% of normal dose

Cl_{cr} <10 mL/minute: Administer at 25% to 50% of normal dose and monitor glucose closely

Hemodialysis: Because of a large molecular weight (6000 daltons), insulin is not significantly removed by either peritoneal or hemodialysis

Supplemental dose is not necessary

Peritoneal dialysis: Supplemental dose is not necessary

Continuous arteriovenous or venovenous hemofiltration effects: Supplemental dose is not necessary

Monitoring Parameters Urine sugar and acetone, serum glucose, electrolytes, Hb A_{1c}, lipid profile

Administration

SubQ administration: Cold injections should be avoided. SubQ administration is usually made into the thighs, arms, buttocks, or abdomen, with sites rotated. When mixing regular insulin with other preparations of insulin, regular insulin should be drawn into syringe first. Buffered insulin (Velosulin® BR) should not be mixed with any other form of insulin.

Insulin lispro (Humalog®): May be administered within 15 minutes before or immediately after a meal.

Insulin aspart (NovoLog®): Should be administered immediately before a meal (within 5-10 minutes of the start of a meal). Can be infused SubQ by external insulin pump; do not dilute or mix with other insulins when used in an external pump for SubQ infusion; should replace insulin in reservoir every 48 hours.

Human regular insulin: Should be administered within 30-60 minutes before a meal.

Intermediate-acting insulins (such as NPH): May be administered 1-2 times/day.

Long-acting insulins (such as Ultralente®, Lantus®): May be administered once daily.

Insulin glargine (Lantus®): Should be administered once daily, at any time of day, but should be administered at the same time each day. Cannot be diluted or mixed with any other insulin or solution.

Regular insulin may be administered by SubQ, I.M., or I.V. routes
I.V. administration (requires use of an infusion pump): **Only regular insulin** may be administered I.V.

I.V. infusions: To minimize adsorption problems to I.V. solution bag:
If new tubing is **not** needed: Wait a minimum of 30 minutes between the preparation of the solution and the initiation of the infusion
If new tubing is needed: After receiving the insulin drip solution, the administration set should be attached to the I.V. container and the line should be flushed with the insulin solution. The nurse should then wait 30 minutes, then flush the line again with the insulin solution prior to initiating the infusion

If insulin is required prior to the availability of the insulin drip, regular insulin should be administered by I.V. push injection

Because of adsorption, the actual amount of insulin being administered could be substantially less than the apparent amount. Therefore, adjustment of the insulin drip rate should be based on effect and not solely on the apparent insulin dose. Furthermore, the apparent dose should not be used as the basis for determining the subsequent insulin dose upon discontinuing the insulin drip. Dose requires continuous medical supervision.

To be ordered as units/hour

Example: Standard diluent of regular insulin only: 100 units/100 mL NS
(can be administered as a more diluted solution, ie, 100 units/250 mL NS)

Insulin rate of infusion (100 units regular/100 mL NS)

- 1 unit/hour: 1 mL/hour
- 2 units/hour: 2 mL/hour
- 3 units/hour: 3 mL/hour
- 4 units/hour: 4 mL/hour
- 5 units/hour: 5 mL/hour, etc

Reference Range

Therapeutic, serum insulin (fasting): 5-20 μ IU/mL (SI: 35-145 pmol/L)
Glucose: Newborns: 20-80 mg/dL; Adults: 60-115 mg/dL; Elderly: 100-180 mg/dL
Peptide fragments are low (<0.5 ng/mL) in cases of exogenous insulin administration but high in insulinoma or sulfonylurea ingestion
Plasma insulin levels which are very high (>10,000 pmol/L), consistent with exogenous administration

Overdosage/Treatment

Decontamination: Excision of tissue near insulin injection site can be performed

Supportive therapy: 50 mL D₅W given I.V.; if no I.V. is available, glucagon 0.5-1 mg SubQ or I.M.; give 300 g of carbohydrates orally when patient awakens; insulin-induced peripheral and sacral edema has been successfully treated with oral ephedrine (15 mg every 8 hours); for most insulin overdoses, anticipate a need of 400-600 mg of glucose/kg/hour; continuous infusions of glucose with concentrations exceeding 20% should be given by central venous line

Antidote(s)

- Dextrose [ANTIDOTE]
- Glucagon [ANTIDOTE]

Nursing Implications Patients using human insulin may be less likely to recognize hypoglycemia than if they use pork insulin; patients on pork insulin that have low blood sugar exhibit hunger and sweating; regular insulin is the only form for I.V. use; patients who are unable to accurately draw up their dose will need assistance such as prefilled syringes

Additional Information The term "purified" refers to insulin preparations containing no more than 10 ppm proinsulin (purified and human insulins are less immunogenic). Insulin abuse can be identified by presence of anti-insulin antibodies or decreased plasma C-peptide concentration; aspirin may be useful in alleviating hypersensitivity reactions; gas gangrene may occur secondary to SubQ insulin injection; buffering agent in Velosulin[®] BR may alter the activity of other insulin products

Interferon Alfa-2a

CAS Number 76543-88-9

U.S. Brand Names Roferon-A[®]

Synonyms IFLrA; rIFN-A

Use Patients >18 years of age: Hairy cell leukemia, AIDS-related Kaposi's sarcoma, chronic hepatitis C

Children and Adults: Chronic myelogenous leukemia (CML), Philadelphia chromosome positive, within 1 year of diagnosis (limited experience in children)

Unlabeled/Investigational Use Adjuvant therapy for malignant melanoma, AIDS-related thrombocytopenia, cutaneous ulcerations of Behçet's disease, brain tumors, metastatic ileal carcinoid tumors, cervical and colorectal cancers, genital warts, idiopathic mixed cryoglobulinemia, hemangioma, hepatitis D, hepatocellular carcinoma, idiopathic hypereosinophilic syndrome, mycosis fungoides, Sézary syndrome, low-grade non-Hodgkin's lymphoma, macular degeneration, multiple myeloma, renal cell carcinoma, basal and squamous cell skin cancer, essential thrombocythemia, cutaneous T-cell lymphoma

Mechanism of Action Following activation, multiple effects can be detected including induction of gene transcription. Inhibits cellular growth, alters the state of cellular differentiation, interferes with oncogene expression, alters cell surface antigen expression, increases phagocytic activity of macrophages, and augments cytotoxicity of lymphocytes for target cells

Adverse Reactions

Flu-like symptoms (fever, fatigue/malaise, myalgia, chills, headache, arthralgia, rigors) begin ~2-6 hours after the dose is given and may persist as long as 24 hours; usually patient can build up a tolerance to side effects

Cardiovascular: Tachycardia, cardiac arrhythmias, hypotension, edema, chest pain, cardiomegaly, cardiomyopathy, angina, congestive heart failure, myocardial depression, sinus tachycardia, acrocyanosis

Central nervous system: **Fatigue/malaise, dizziness,** CNS depression, confusion, sensory neuropathy, psychiatric effects, headache, EEG abnormalities, **chills,** abducent nerve paralysis, psychosis, **fever**

Dermatologic: **Alopecia, rash,** lichen planus, vitiligo

Endocrine & metabolic: Increased uric acid level, Graves' disease, thyroid dysfunction, autoimmune thyroiditis

Gastrointestinal: Anorexia, **xerostomia, nausea, vomiting, diarrhea, abdominal cramps, weight loss,** change in taste, **metallic taste**

Genitourinary: Impotence

Hematologic: **Leukopenia** (mainly neutropenia), **anemia, thrombocytopenia; decreased hemoglobin, hematocrit, platelets;** neutralizing antibodies

Hepatic: Elevation of ALT and AST

Neuromuscular & skeletal: **Rigors,** myasthenia gravis, chorea, **arthralgia,** myopathy

Ocular: Blurred vision

Renal: Proteinuria, creatinine/BUN (elevated)

Respiratory: Coughing, nasal congestion, pneumonitis, pneumonia

Miscellaneous: **Diaphoresis,** subacute thyroiditis, psoriatic arthritis, systemic lupus erythematosus-like syndrome, herpes labialis

Signs and Symptoms of Overdose Agranulocytosis, AV block, coma, encephalopathy, granulocytopenia, hyperglycemia, impotence, leukopenia, mania, Mees' lines, neutropenia

Pharmacodynamics/Kinetics

Absorption: Filtered and absorbed at the renal tubule

Distribution: V_d: 0.223-0.748 L/kg

Metabolism: Primarily renal; filtered through glomeruli and undergoes rapid proteolytic degradation during tubular reabsorption

Bioavailability: I.M.: 83%; SubQ: 90%

Half-life elimination: I.V.: 3.7-8.5 hours (mean ~5 hours)

Time to peak, serum: I.M., SubQ: ~6-8 hours

Dosage Refer to individual protocols

Children (limited data):

Chronic myelogenous leukemia (CML): I.M.: 2.5-5 million units/m²/day;

Note: In juveniles, higher dosages (30 million units/m²/day) have been associated with severe adverse events, including death

Adults:

Hairy cell leukemia: SubQ, I.M.: 3 million units/day for 16-24 weeks, then 3 million units 3 times/week for up to 6-24 months

Chronic myelogenous leukemia (CML): SubQ, I.M.: 9 million units/day, continue treatment until disease progression

AIDS-related Kaposi's sarcoma: SubQ, I.M.: 36 million units/day for 10-12 weeks, then 36 million units 3 times/week; to minimize adverse reactions, can use escalating dose (3-, 9-, then 18 million units each day for 3 days, then 36 million units daily thereafter).

Hepatitis C: SubQ, I.M.: 3 million units 3 times/week for 12 months

Dosage adjustment in renal impairment: Not removed by hemodialysis
Stability Refrigerate (2°C to 8°C/36°F to 46°F); do not freeze; do not shake. Reconstitute vial with the diluent provided, or SWFI, NS, or D₅W; concentrations $\geq 3 \times 10^6$ units/mL are hypertonic. After reconstitution, the solution is stable for 24 hours at room temperature and for 1 month when refrigerated.

Monitoring Parameters Chronic hepatitis C: Monitor ALT and HCV-RNA to assess response (particularly in first 3 months of therapy)

CML/hairy cell leukemia: Hematologic monitoring should be performed monthly

Administration SubQ administration is suggested for those who are at risk for bleeding or are thrombocytopenic; rotate SubQ injection site; patient should be well hydrated

Contraindications Hypersensitivity to alfa interferon, benzyl alcohol, or any component of the formulation; autoimmune hepatitis; hepatic decompensation (Child-Pugh class B or C)

Warnings Use caution in patients with a history of depression. May cause severe psychiatric adverse events (psychosis, mania, depression, suicidal behavior/ideation) in patients with and without previous psychiatric symptoms; careful neuropsychiatric monitoring is required during therapy. Use with caution in patients with seizure disorders, brain metastases, or compromised CNS function. Higher doses in the elderly or in malignancies other than hairy cell leukemia may result in severe obtundation.

Use caution in patients with autoimmune diseases; development or exacerbation of autoimmune diseases has been reported. Use caution in patients with pre-existing cardiac disease (ischemic or thromboembolic), arrhythmias, renal impairment ($Cl_{Cr} < 50$ mL/minute), mild hepatic impairment, or myelosuppression. Also use caution in patients receiving therapeutic immunosuppression. May cause thyroid dysfunction or hyperglycemia, use caution in patients with diabetes or pre-existing thyroid disease. Pulmonary dysfunction may be induced or aggravated by interferon alfa; discontinue if persistent unexplained pulmonary infiltrates are noted. Gastrointestinal ischemia, ulcerative colitis and hemorrhage have been associated rarely with alfa interferons; some cases are severe and life-threatening. Ophthalmologic disorders (including retinal hemorrhages, cotton wool spots, and retinal artery or vein obstruction) have occurred in patients receiving alfa interferons; close monitoring is warranted.

[U.S. Boxed Warning]: Treatment should be discontinued in patients with worsening or persistently severe signs/symptoms of autoimmune, infectious, ischemic, or neuropsychiatric disorders (including depression and/or suicidal thoughts/behavior). Discontinue treatment if neutrophils $< 0.5 \times 10^9/L$ or platelets $< 25 \times 10^9/L$. **Due to differences in dosage, patients should not change brands of interferons.** Injection solution contains benzyl alcohol; do not use in neonates or infants. Safety and efficacy in children < 18 years of age have not been established.

Dosage Forms Injection, solution [single-dose prefilled syringe; SubQ use only]: 3 million units/0.5 mL (0.5 mL); 6 million units/0.5 mL (0.5 mL); 9 million units/0.5 mL (0.5 mL) [contains benzyl alcohol]

Reference Range

Peak serum concentration following an I.V. dose of 36 million units: 10,400-17,470 pg/mL

Overdosage/Treatment

Supportive therapy: Indomethacin or acetaminophen can be given for fever; avoid glucocorticoids; I.V. crystalloid therapy is usually adequate to treat hypotension

Enhancement of elimination: Hemodialysis is not useful

Test Interactions Increases norepinephrine plasma levels

Drug Interactions Inhibits CYP1A2 (weak)

Note: May exacerbate the toxicity of other agents with respect to CNS, myelotoxicity, or cardiotoxicity.

ACE inhibitors: Interferons may increase the adverse/toxic effects of ACE inhibitors, specifically the development of granulocytopenia. Risk: Monitor

Clozapine: A case report of agranulocytosis with concurrent use.

Erythropoietin: Case reports of decreased hematopoietic effect

Melphalan: Interferon alfa may decrease the serum concentrations of melphalan; this may or may not decrease the potential toxicity of melphalan. Risk: Monitor

Prednisone: Prednisone may decrease the therapeutic effects of interferon alfa. Risk: Moderate

Ribavirin: Concurrent therapy may increase the risk of hemolytic anemia.

Theophylline: Interferon alfa may decrease the P450 isoenzyme metabolism of theophylline. Risk: Moderate

Warfarin: Interferons may increase the anticoagulant effects of warfarin. Risk: Monitor

Zidovudine: Interferons may decrease the metabolism of zidovudine. Risk: Monitor

Pregnancy Risk Factor C

Pregnancy Implications Safety and efficacy for use during pregnancy have not been established. Interferon alfa has been shown to decrease serum estradiol and progesterone levels in humans. Menstrual irregularities and abortion have been reported in animals. Effective contraception is recommended during treatment.

Lactation Enters breast milk/contraindicated (AAP rates "compatible")

Nursing Implications Flu-like syndrome (fever, chills) occurs in the majority of patients 2-6 hours after a dose; use acetaminophen to prevent or partially alleviate headache and fever

Additional Information Indications and dosage regimens are specific for a particular brand of interferon; other brands of interferon (ie, Intron® A) have different indications and dosage guidelines; do not change brands of interferon as changes in dosage may result. Women with hepatitis C should be instructed that there is a theoretical risk the virus may be transmitted in breast milk. HIV-infected mothers are discouraged from breast-feeding to decrease potential transmission of HIV.

Interferon Alfa-2b

CAS Number 99210-65-8

U.S. Brand Names Intron® A

Synonyms INF-alpha 2; rLFN- $\alpha 2$; α -2-interferon

Use

Patients ≥ 1 year of age: Chronic hepatitis B

Patients ≥ 18 years of age: Condyloma acuminata, chronic hepatitis C, hairy cell leukemia, malignant melanoma, AIDS-related Kaposi's sarcoma, follicular non-Hodgkin's lymphoma

Unlabeled/Investigational Use AIDS-related thrombocytopenia, cutaneous ulcerations of Behçet's disease, carcinoid syndrome, cervical cancer, lymphomatoid granulomatosis, genital herpes, hepatitis D, chronic myelogenous leukemia (CML), non-Hodgkin's lymphomas (other than follicular lymphoma, see approved use), polycythemia vera, medullary thyroid carcinoma, multiple myeloma, renal cell carcinoma, basal and squamous cell skin cancers, essential thrombocytopenia, thrombocytopenic purpura

Investigational: West Nile virus

Mechanism of Action Following activation, multiple effects can be detected including induction of gene transcription. Inhibits cellular growth, alters the state of cellular differentiation, interferes with oncogene expression, alters cell surface antigen expression, increases phagocytic activity of macrophages, and augments cytotoxicity of lymphocytes for target cells

Adverse Reactions

Flu-like symptoms (fever, fatigue/malaise, myalgia, chills, headache, arthralgia, rigors) begin ~2-6 hours after the dose is given and may persist as long as 24 hours; usually patient can build up a tolerance to side effects

Cardiovascular: Tachycardia, cardiac arrhythmias, hypotension, edema, chest pain, Raynaud's disease, cardiomyopathy, cardiomegaly, angina, congestive heart failure, myocardial infarction, sinus tachycardia

Central nervous system: **Fatigue/malaise, dizziness,** CNS depression, confusion, sensory neuropathy, psychiatric effects, **fever,** headache, EEG abnormalities, **chills,** psychosis, hallucinations

Dermatologic: Partial alopecia, **rash,** purpura, skin necrosis

Endocrine & metabolic: Increased uric acid level, thyroid dysfunction, impaired spermatogenesis, thyroiditis

Gastrointestinal: **Anorexia, xerostomia, nausea, vomiting, diarrhea, abdominal cramps, weight loss,** change in taste, **metallic taste,** pancreatitis

Hematologic: **Leukopenia** (mainly neutropenia), agranulocytosis, **anemia,** thrombocytopenic purpura, **thrombocytopenia; decreased hemoglobin, hematocrit, platelets;** neutralizing antibodies, hemolytic anemia

Hepatic: Elevation of ALT and AST, primary biliary cirrhosis, hepatotoxic reaction

Local: Injection site alopecia

Neuromuscular & skeletal: Myalgia, **arthralgia, rigors,** myasthenia gravis, polymyositis (dermatomyositis), poliomyositis, rhabdomyolysis

Ocular: Blurred vision

Renal: Proteinuria, elevated creatinine/BUN, glomerulonephritis, nephrotic syndrome, renal failure

Respiratory: Coughing, nasal congestion, exacerbation of asthma

Miscellaneous: **Diaphoresis,** digital necrosis, Sjögren's syndrome, psoriatic arthritis, lupus erythematosus

Signs and Symptoms of Overdose Agranulocytosis, AV block, encephalopathy, granulocytopenia, hyperglycemia, leukopenia, lymphopenia, Mees' lines, neutropenia

Pharmacodynamics/Kinetics

Distribution: V_d : 31 L; but has been noted to be much greater (370-720 L) in leukemia patients receiving continuous infusion IFN; IFN does not penetrate the CSF

Metabolism: Primarily renal

Bioavailability: I.M.: 83%; SubQ: 90%

Half-life elimination: I.M., I.V.: 2 hours; SubQ: 3 hours

Time to peak, serum: I.M., SubQ: ~3-12 hours

Dosage

Refer to individual protocols

Children 1-17 years: Chronic hepatitis B: SubQ: 3 million units/m² 3 times/week for 1 week; then 6 million units/m² 3 times/week; maximum: 10 million units 3 times/week; total duration of therapy 16-24 weeks

Adults:

Hairy cell leukemia: I.M., SubQ: 2 million units/m² 3 times/week for 2-6 months

Lymphoma (follicular): SubQ: 5 million units 3 times/week for up to 18 months

Malignant melanoma: 20 million units/m² I.V. for 5 consecutive days per week for 4 weeks, then 10 million units/m² SubQ 3 times/week for 48 weeks
 AIDS-related Kaposi's sarcoma: I.M., SubQ: 30 million units/m² 3 times/week
 Chronic hepatitis B: I.M., SubQ: 5 million units/day or 10 million units 3 times/week for 16 weeks
 Chronic hepatitis C: I.M., SubQ: 3 million units 3 times/week for 16 weeks. In patients with normalization of ALT at 16 weeks, continue treatment for 18-24 months; consider discontinuation if normalization does not occur at 16 weeks. **Note:** May be used in combination therapy with ribavirin in previously untreated patients or in patients who relapse following alpha interferon therapy; refer to Interferon Alfa-2b and Ribavirin Combination Pack monograph.
 Condyloma acuminata: Intralesionally: 1 million units/lesion (maximum: 5 lesions/treatment) 3 times/week (on alternate days) for 3 weeks. Use 1 million unit per 0.1 mL concentration.

Dosage adjustment in renal impairment: Not removed by peritoneal or hemodialysis

Dosage adjustment for toxicity: Manufacturer-recommended adjustments, listed according to indication:

- Follicular lymphoma:
 - Severe toxicity (neutrophils <1000 cells/mm³ or platelets <50,000 cells/mm³): Reduce dose by 50% or temporarily discontinue
 - AST/ALT >5 times ULN: Permanently discontinue
 - Hairy cell leukemia:
 - Severe toxicity: Reduce dose by 50% or temporarily discontinue; permanently discontinue if persistent or recurrent severe toxicity is noted
 - Hepatitis B or C:
 - WBC <1500 cells/mm³, granulocytes <750 cells/mm³, or platelet count <50,000 cells/mm³: Reduce dose by 50%
 - WBC <1000 cells/mm³, granulocytes <500 cells/mm³, or platelet count <25,000 cells/mm³: Permanently discontinue
 - Kaposi sarcoma: Severe toxicity: Reduce dose by 50% or temporarily discontinue
 - Malignant melanoma:
 - Severe toxicity (neutrophils <500 cells/mm³ or AST/ALT >5 times ULN): Reduce dose by 50% or temporarily discontinue
 - Neutrophils <250 cells/mm³ or AST/ALT >10 times ULN: Permanently discontinue
- See table.

Effects of Interferon Alpha-2b on Cell Counts		
Granulocyte Count	Platelet Count	Interferon 2b dose
<750/mm ³	<50,000/mm ³	Decrease by 50%
<500/mm ³	<30,000/mm ³	Interrupt

When platelet/granulocyte count returns to normal, reinstitute therapy
Monitoring Parameters Baseline chest x-ray, ECG, CBC with differential, liver function tests, electrolytes, thyroid function tests, platelets, weight; patients with pre-existing cardiac abnormalities, or in advanced stages of cancer should have ECGs taken before and during treatment.

Administration Injection: Do not use 3-, 5-, 18-, and 25 million unit strengths intralesionally, solutions are hypertonic; 50 million unit strength is not for use in condylomata, hairy cell leukemia, or chronic hepatitis. Patients with platelet count <50,000/mm³ should receive doses SubQ, not I.M.
 Oral: Capsules should not be crushed, chewed, or opened.

Contraindications Hypersensitivity to interferon alfa or any component of the formulation; decompensated liver disease; autoimmune hepatitis; history of autoimmune disease; immunosuppressed transplant patients

Warnings
 Suicidal ideation or attempts may occur more frequently in pediatric patients when compared to adults. May cause severe psychiatric adverse events (psychosis, mania, depression, suicidal behavior/ideation) in patients with and without previous psychiatric symptoms, avoid use in severe psychiatric disorders or in patients with a history of depression; careful neuropsychiatric monitoring is required during therapy. Use with caution in patients with a history of seizures, brain metastases, multiple sclerosis, cardiac disease (ischemic or thromboembolic), arrhythmias, myelosuppression, hepatic impairment, or renal dysfunction (use is not recommended if Cl_{cr} <50 mL/minute). Use caution in patients with a history of pulmonary disease, coagulopathy, thyroid disease (monitor thyroid function), hypertension, or diabetes mellitus (particularly if prone to DKA). Caution in patients receiving drugs that may cause lactic acidosis (eg, nucleoside analogues).

Avoid use in patients with autoimmune disorders; worsening of psoriasis and/or development of autoimmune disorders has been associated with alpha interferons. Higher doses in elderly patients, or diseases other than hairy cell leukemia, may result in increased CNS toxicity. **[U.S.**

Boxed Warning: Treatment should be discontinued in patients who develop severe pulmonary symptoms with chest x-ray changes, autoimmune disorders, worsening of hepatic function, psychiatric symptoms (including depression and/or suicidal thoughts/behaviors), ischemic and/or infectious disorders. Ophthalmologic disorders (including retinal hemorrhages, cotton wool spots and retinal artery or vein obstruction) have occurred in patients receiving alpha interferons. Hypertriglyceridemia has been reported (discontinue if severe).

Safety and efficacy in children <1 year of age have not been established. Do not treat patients with visceral AIDS-related Kaposi's sarcoma associated with rapidly-progressing or life-threatening disease. A transient increase in SGOT (>2x baseline) is common in patients treated with interferon alfa-2b for chronic hepatitis. Therapy generally may continue, however, functional indicators (albumin, prothrombin time, bilirubin) should be monitored at 2-week intervals. **Due to differences in dosage, patients should not change brands of interferons without the prescribers knowledge.**

Intron® A may cause bone marrow suppression, including very rarely, aplastic anemia. Hemolytic anemia (hemoglobin <10 g/dL) was observed in up to 10% of treated patients in clinical trials when combined with ribavirin; anemia occurred within 1-2 weeks of initiation of therapy.

Dosage Forms

- Injection, powder for reconstitution: 10 million units; 18 million units; 50 million units [contains human albumin]
- Injection, solution [multidose prefilled pen]:
 - Delivers 3 million units/0.2 mL (1.5 mL) [delivers 6 doses; 18 million units]
 - Delivers 5 million units/0.2 mL (1.5 mL) [delivers 6 doses; 30 million units]
 - Delivers 10 million units/0.2 mL (1.5 mL) [delivers 6 doses; 60 million units]
- Injection, solution [multidose vial]: 6 million units/mL (3 mL); 10 million units/mL (2.5 mL)
- Injection, solution [single-dose vial]: 10 million units/ mL (1 mL)

See also Interferon Alfa-2b and Ribavirin Combination Pack monograph.

Reference Range Peak serum level after I.V. infusion of 10 million units: 546 units/mL

Overdosage/Treatment

Supportive therapy: Indomethacin or acetaminophen can be given for fever; avoid glucocorticoids
 Enhancement of elimination: Hemodialysis is not useful

Drug Interactions

- Inhibits** CYP1A2 (weak)
- ACE inhibitors: Interferons may increase the adverse/toxic effects of ACE inhibitors, specifically the development of granulocytopenia; monitor.
- Clozapine: A case report of agranulocytosis with concurrent use.
- Erythropoietin: Case reports of decreased hematopoietic effect.
- Melphalan: Interferon alfa may decrease the serum concentrations of melphalan; this may or may not decrease the potential toxicity of melphalan; monitor.
- Prednisone: Prednisone may decrease the therapeutic effects of interferon alfa. Risk: Moderate
- Ribavirin: Concurrent therapy may increase the risk of hemolytic anemia.
- Theophylline: Interferon alfa may decrease the P450 isoenzyme metabolism of theophylline. Risk: Moderate
- Warfarin: Interferons may increase the anticoagulant effects of warfarin; monitor.
- Zidovudine: Interferons may decrease the metabolism of zidovudine; monitor.

Pregnancy Risk Factor C

Pregnancy Implications Safety and efficacy for use during pregnancy have not been established. Interferon alpha has been shown to decrease serum estradiol and progesterone levels in humans. Menstrual irregularities and abortion have been reported in animals. Effective contraception is recommended during treatment.

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Nursing Implications Use acetaminophen to prevent or partially alleviate headache and fever; do not use 3, 5, and 25 million unit strengths intralesionally, solutions are hypertonic; 50 million unit strength is not for use in condylomata

Additional Information Induction of insulin antibodies may result Myelosuppressive effects: **WBC:** Mild. **Platelets:** Mild. Onset (days): 7-10. Nadir (days): 14. Recovery (days): 21

Interferon Alfa-n3

Pronunciation (in ter FEER on AL fa en three)

U.S. Brand Names Alferon® N

Use FDA approved: Condylomata acuminata, intralesional treatment of refractory or recurring genital or venereal warts; useful in patients who do not respond or are not candidates for usual treatments; indications and dosage regimens are specific for a particular brand of interferon

Mechanism of Action Alpha interferons are a family of proteins, produced by nucleated cells, that have antiviral, antiproliferative, and immune-regulating activity. There are 16 known subtypes of alpha interferons. Interferons interact with cells through high affinity cell surface receptors. Following activation, multiple effects can be detected including induction of gene transcription. Inhibits cellular growth, alters the state of cellular differentiation, interferes with oncogene expression, alters cell surface antigen expression, increases phagocytic activity of macrophages, and augments cytotoxicity of lymphocytes for target cells.

Adverse Reactions

Cardiovascular: Tachycardia, cardiac arrhythmias, chest pain, hypotension, SVT, edema, cardiomyopathy, cardiomegaly, angina, congestive heart failure, myocardial depression, sinus tachycardia

Central nervous system: **Dizziness, tiredness, fatigue, malaise, fever, chills,** lightheadedness, confusion, CNS depression, sensory neuropathy, psychiatric effects, EEG abnormalities, neurotoxicity, psychosis

Dermatologic: **Skin rash,** dry skin, alopecia

Endocrine & metabolic: Increased uric acid level

Gastrointestinal: **Nausea, anorexia, vomiting, xerostomia, diarrhea, abdominal cramps, weight loss, metallic tastes,** stomatitis

Hematologic: Mildly myelosuppressive and well tolerated if used without adjunct antineoplastic agents; **thrombocytosis** has been reported, **leukopenia** (mainly neutropenia), **anemia, thrombocytopenia, decreased hemoglobin, hematocrit, platelets**

Hepatic: Hepatotoxicity; hepatic transaminase, elevation of ALT and AST

Local: Sensitivity to injection

Neuromuscular & skeletal: **Rigors, arthralgia,** leg cramps, paresthesia

Ocular: Blurred vision

Renal: Creatinine/BUN (elevated), albuminuria

Respiratory: Cough, nasal congestion, dyspnea

Miscellaneous: **Flu-like syndrome,** neutralizing antibodies; usually patient can build up a tolerance to side effects, **diaphoresis**

Signs and Symptoms of Overdose Agranulocytosis, coagulopathy, encephalopathy, granulocytopenia, hyperglycemia, leukopenia, lightheadedness, neutropenia, syndrome of inappropriate antidiuretic hormone (SIADH)

Toxicodynamics/Kinetics Elimination: Renal

Dosage Adults: Inject 250,000 units (0.05 mL) in each wart twice weekly for a maximum of 8 weeks; therapy should not be repeated for at least 3 months after the initial 8-week course of therapy

Stability Store solution at 2°C to 8°C (36°F to 46°F); do not freeze or shake solution

Administration Inject into base of wart with a small 30-gauge needle

Contraindications Hypersensitivity to alpha interferon or any component of the formulation; anaphylactic sensitivity to mouse immunoglobulin, egg protein, or neomycin

Warnings Use with caution in patients with pre-existing cardiac disease, including unstable angina, uncontrolled CHF, or arrhythmias; severe pulmonary disease; diabetes with ketoacidosis; coagulation disorders (such as thrombophlebitis, pulmonary embolism, hemophilia); severe myelosuppression; or seizure disorder. **Due to differences in dosage, patients should not change brands of interferons.** Safety and efficacy in patients <18 years of age have not been established.

Dosage Forms Injection, solution: 5 million int. units (1 mL) [contains albumin]

Overdosage/Treatment

Supportive therapy: Indomethacin or acetaminophen can be given for fever; avoid glucocorticoids

Enhancement of elimination: Hemodialysis is not useful

Drug Interactions

ACE inhibitors: Interferons may increase the adverse/toxic effects of ACE inhibitors, specifically the development of granulocytopenia. Risk: Monitor

Clozapine: A case report of agranulocytosis with concurrent use.

Erythropoietin: Case reports of decreased hematopoietic effect

Melphalan: Interferon alpha may decrease the serum concentrations of melphalan; this may or may not decrease the potential toxicity of melphalan. Risk: Monitor

Prednisone: Prednisone may decrease the therapeutic effects of Interferon alpha. Risk: Moderate

Theophylline: Interferon alpha may decrease the P450 isoenzyme metabolism of theophylline. Risk: Moderate

Warfarin: Interferons may increase the anticoagulant effects of warfarin. Risk: Monitor

Zidovudine: Interferons may decrease the metabolism of zidovudine. Risk: Monitor

Pregnancy Risk Factor C

Pregnancy Implications Safety and efficacy for use during pregnancy have not been established. Interferon alpha has been shown to decrease serum estradiol and progesterone levels in humans. Menstrual irregularities and abortion have been reported in animals. Effective contraception is recommended during treatment.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Inject into base of wart with a small 30-gauge needle

Interferon Beta-1a

CAS Number 145258-61-3

U.S. Brand Names Avonex®; Rebif®

Synonyms rIFN beta-1a

Use Treatment of relapsing forms of multiple sclerosis (MS)

Mechanism of Action Interferon beta differs from naturally occurring human protein by a single amino acid substitution and the lack of carbohydrate side chains; alters the expression and response to surface antigens and can enhance immune cell activities. Properties of interferon beta that modify biologic responses are mediated by cell surface receptor interactions; mechanism in the treatment of MS is unknown.

Adverse Reactions

Cardiovascular: Chest pain, vasodilation, cardiomyopathy, CHF

Central nervous system: **Headache** (Avonex® 58%; Rebif® 65% to 70%), **fatigue** (Rebif® 33% to 41%), **fever** (Avonex® 20%; Rebif® 25% to 28%), convulsions, malaise, migraine, somnolence **pain** (Avonex® 23%), **chills** (Avonex® 19%), **depression** (Avonex® 18%), **dizziness** (Avonex® 14%), psychiatric disorders (new or worsening)

Dermatologic: Alopecia, rash

Endocrine & metabolic: Thyroid disorder, menorrhagia, metrorrhagia

Gastrointestinal: **Nausea** (Avonex® 23%), **abdominal pain** (Avonex® 8%; Rebif® 20% to 22%), toothache, xerostomia

Genitourinary: **Urinary tract infection** (Avonex® 17%), micturition frequency, urinary incontinence

Hematologic: **Leukopenia** (Rebif® 28% to 36%), anemia, thrombocytopenia, idiopathic thrombocytopenia, pancytopenia

Hepatic: **ALT increased** (Rebif® 20% to 27%), **AST increased** (Rebif® 10% to 17%), bilirubinemia, hepatic function abnormal, autoimmune hepatitis, hepatitis,

Local: **Injection site reaction** (Avonex® 3%; Rebif® 89% to 92%)

Neuromuscular & skeletal: **Myalgia** (Avonex® 29%; Rebif® 25%), **back pain** (Rebif® 23% to 25%), **weakness** (Avonex® 24%), **skeletal pain** (Rebif® 10% to 15%), **rigors** (Rebif® 6% to 13%), arthralgia, coordination abnormal, hypertonia

Ocular: **Vision abnormal** (Rebif® 7% to 13%), eye disorder, xerophthalmia

Respiratory: **Sinusitis** (Avonex® 14%), **upper respiratory tract infection** (Avonex® 14%), bronchitis

Miscellaneous: **Flu-like symptoms** (Avonex® 49%; Rebif® 56% to 59%), **neutralizing antibodies** (significance not known; Avonex® 5%; Rebif® 24%), **lymphadenopathy** (Rebif® 11% to 12%), infection, anaphylaxis

Signs and Symptoms of Overdose CNS depression, flu-like symptoms, myelosuppression, obtundation

Pharmacodynamics/Kinetics

Limited data due to small doses used

Half-life elimination: Avonex®: 10 hours; Rebif®: 69 hours

Time to peak, serum: Avonex® (I.M.): 3-15 hours; Rebif® (SubQ): 16 hours

Dosage Adults:

I.M. (Avonex®): 30 mcg once weekly

SubQ (Rebif®): Initial: 8.8 mcg 3 times/week, increasing over a 4-week period to the recommended dose of 44 mcg 3 times/week; doses should be separated by at least 48 hours

Dosage adjustment in hepatic impairment: Rebif®: If liver function tests increase or in case of leukopenia: Decrease dose 20% to 50% until toxicity resolves.

Monitoring Parameters Monitor for signs and symptoms of thyroid abnormalities, hematologic suppression, liver functions tests, symptoms of autoimmune disorders

Avonex®: Frequency of monitoring for patients receiving Avonex® has not been specifically defined; in clinical trials, monitoring was at 6-month intervals.

Rebif®: CBC and liver function testing at 1-, 3-, and 6 months, then periodically thereafter. Thyroid function every 6 months (in patients with pre-existing abnormalities and/or clinical indications)

Administration Avonex®: Must be administered by I.M. injection

Rebif®: Administer SubQ at the same time of day on the same 3 days each week (ie, late afternoon/evening Mon, Wed, Fri)

Contraindications Hypersensitivity to natural or recombinant interferons, human albumin, or any other component of the formulation

Warnings Interferons have been associated with severe psychiatric adverse events (psychosis, mania, depression, suicidal behavior/ideation) in patients with and without previous psychiatric symptoms, avoid use in severe psychiatric disorders and use caution in patients with a history of depression; patients exhibiting depressive symptoms should be closely monitored and discontinuation of therapy should be considered.

Allergic reactions, including anaphylaxis, have been reported. Caution should be used in patients with hepatic impairment or in those who abuse alcohol. Rare cases of severe hepatic injury, including hepatic failure, have been reported in patients receiving interferon beta-1a; risk may be increased by ethanol use or concurrent therapy with hepatotoxic drugs. Treatment should be suspended if jaundice or symptoms of hepatic dysfunction occur. Some reports indicate symptoms began after

1-6 months of treatment. Hematologic effects, including pancytopenia (rare) and thrombocytopenia, have been reported. Associated with a high incidence of flu-like adverse effects; use of analgesics and/or antipyretics on treatment days may be helpful. Use caution in patients with pre-existing cardiovascular disease, pulmonary disease, seizure disorders, myelosuppression, or renal impairment. Some formulations contain albumin, which may carry a remote risk of transmitting Creutzfeldt-Jakob or other viral diseases. Safety and efficacy in patients < 18 years of age have not been established.

Dosage Forms Combination package [preservative free] (Rebif® Titration Pack):

Injection, solution: 8.8 mcg/0.2 mL (0.2 mL) [6 prefilled syringes; contains albumin]

Injection, solution: 22 mcg/0.5 mL (0.5 mL) [6 prefilled syringes; contains albumin]

Injection, powder for reconstitution (Avonex®): 33 mcg [6.6 million units; provides 30 mcg/mL following reconstitution] [contains albumin; packaged with SWFI, alcohol wipes, and access pin and needle]

Injection, solution (Avonex®): 30 mcg/0.5 mL (0.5 mL) [albumin free; prefilled syringe; syringe cap contains latex; packaged with alcohol wipes, gauze pad, and adhesive bandages]

Injection, solution [preservative free] (Rebif®): 22 mcg/0.5 mL (0.5 mL) [prefilled syringe; contains albumin]; 44 mcg/0.5 mL (0.5 mL) [prefilled syringe; contains albumin]

Reference Range Mean serum interferon beta-1a levels during therapy range from 76.8 int. unit/mL to 94.8 int. unit/mL

Overdosage/Treatment Treatment is supportive

Drug Interactions

ACE inhibitors: Interferons may increase the adverse/toxic effects of ACE inhibitors, specifically the development of granulocytopenia; monitor.

Hepatotoxic drugs: May increase the risk of hepatic injury in patients receiving interferon beta-1a.

Warfarin: Interferons may increase the anticoagulant effects of warfarin; monitor.

Zidovudine: Interferons may decrease the metabolism of zidovudine; monitor.

Pregnancy Risk Factor C

Pregnancy Implications There are no adequate and well-controlled studies in pregnant women. Consideration should be given to discontinue treatment if a woman becomes pregnant, or plans to become pregnant during therapy. A dose-related abortifacient activity was reported in Rhesus monkeys. Healthcare providers are encouraged to register pregnant women receiving Rebif® during pregnancy online at www.rebifpregnancyregistry.com or by telephone at MS LifeLines 1-877-44-REBIF. A registry has been established for women who become pregnant while receiving Avonex®. Women may be enrolled in the registry by calling 1-800-456-2255.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Suicidal ideations, and the risk of abortion; flu-like symptoms such as chills, fever, malaise, diaphoresis, and myalgia are common

Interferon Beta-1b

CAS Number 9008-11-1

U.S. Brand Names Betaseron®

Synonyms rIFN beta-1b

Use Treatment of relapsing forms of multiple sclerosis (MS)

Mechanism of Action Interferon beta-1b differs from naturally occurring human protein by a single amino acid substitution and the lack of carbohydrate side chains; alters the expression and response to surface antigens and can enhance immune cell activities. Properties of interferon beta-1b that modify biologic responses are mediated by cell surface receptor interactions; mechanism in the treatment of MS is unknown.

Adverse Reactions

Note: Flu-like symptoms (including at least two of the following - headache, fever, chills, malaise, diaphoresis, and myalgias) are reported in the majority of patients (60%) and decrease over time (average duration ~1 week).

Cardiovascular: **Peripheral edema, chest pain**, palpitation, vasodilation, hypertension, tachycardia, peripheral vascular disorder, arrhythmia, cardiac arrest, cardiomegaly, cerebral hemorrhage, heart failure, MI, pericardial effusion, shock, syncope, DVT, capillary leak syndrome

Central nervous system: **Headache (57%), fever (36%), pain (51%), chills (25%), dizziness (24%), insomnia (24%), anxiety**, malaise, nervousness, coma, delirium, hallucinations, hypothermia, manic reaction, psychosis, ataxia, confusion, convulsion, depersonalization, emotional lability

Dermatologic: **Rash (24%), skin disorder**, alopecia, erythema nodosum, exfoliative dermatitis, skin necrosis, photosensitivity, psoriasis, rash

(maculopapular and vesiculobullous), pruritus, skin discoloration, urticaria

Endocrine & metabolic: **Metrorrhagia**, menorrhagia, dysmenorrhea, diabetes mellitus, diabetes insipidus, hypercalcemia, hyperglycemia, hypoglycemia, hypothyroidism, SIADH, hyperthyroidism, hyperuricemia, hypocalcemia, thyroid dysfunction, triglyceride increased

Gastrointestinal: **Nausea (27%), diarrhea (19%), abdominal pain (19%), constipation (20%), dyspepsia**, esophagitis, gastrointestinal hemorrhage, hematemesis, pancreatitis, vomiting

Genitourinary: **Urinary urgency**, impotence, pelvic pain, cystitis, urinary frequency, weight gain, prostatic disorder, vaginal hemorrhage, urosepsis, urinary tract infection

Hematologic: **Lymphopenia (88%), neutropenia, leukopenia**, lymphadenopathy, anemia, thrombocytopenia,

Hepatic: **SGPT increased >5x baseline**, SGOT increased >5x baseline, cholecystitis, hepatitis, hepatomegaly, gamma GT increase

Local: **Injection site reaction (85%), inflammation (53%), pain**, injection site necrosis, edema, mass

Neuromuscular & skeletal: **Weakness (61%), myalgia (27%), hypertension (50%), myasthenia (46%), arthralgia (31%), incoordination (21%)**, leg cramps, tremor, paresthesia

Ocular: Blindness

Renal: Renal calculus

Respiratory: Dyspnea, apnea, asthma, pulmonary embolism, bronchospasm, pneumonia

Miscellaneous: **Flu-like symptoms (60%)**, diaphoresis, hypersensitivity, anaphylactoid reaction, ethanol intolerance, sepsis

Signs and Symptoms of Overdose No human cases; probable response would be atrial tachycardia, confusion, cough, depression, disorientation, dry mouth, fever, hyperkalemia, hypocalcemia, hypotension, pemphigus, personality changes, nausea, vomiting

Pharmacodynamics/Kinetics

Limited data due to small doses used

Half-life elimination: 8 minutes to 4.3 hours

Time to peak, serum: 1-8 hours

Dosage

SubQ:

Children < 18 years: Not recommended

Adults > 18 years: 0.25 mg (8 million units) every other day

Monitoring Parameters Hemoglobin, liver function, and blood chemistries

Administration Withdraw 1 mL of reconstituted solution from the vial into a sterile syringe fitted with a 27-gauge needle and inject the solution subcutaneously; sites for self-injection include arms, abdomen, hips, and thighs

Contraindications Hypersensitivity to *E. coli*-derived products, natural or recombinant interferon beta, albumin human, or any other component of the formulation

Warnings Hepatotoxicity has been reported with all beta interferons, including rare reports of hepatitis (autoimmune) and hepatic failure requiring transplant. Interferons have been associated with severe psychiatric adverse events (psychosis, mania, depression, suicidal behavior/ideation) in patients with and without previous psychiatric symptoms, avoid use in severe psychiatric disorders and use caution in patients with a history of depression; patients exhibiting symptoms of depression should be closely monitored and discontinuation of therapy should be considered. Due to high incidence of flu-like adverse effects, use caution in patients with pre-existing cardiovascular disease, pulmonary disease, seizure disorders, myelosuppression, renal impairment or hepatic impairment. Severe injection site reactions (necrosis) may occur, which may or may not heal with continued therapy; patient and/or caregiver competency in injection technique should be confirmed and periodically re-evaluated. Safety and efficacy in patients < 18 years of age have not been established.

Dosage Forms Injection, powder for reconstitution [preservative free]: 0.3 mg [9.6 million units] [contains albumin; packaged with prefilled syringe containing diluent]

Overdosage/Treatment

Decontamination: Not necessary

Supportive therapy: Fever/chills can be treated with acetaminophen or nonsteroidal anti-inflammatory agent (indomethacin); hypotension can be treated with crystalloid infusion

Enhancement of elimination: Hemodialysis is not useful

Drug Interactions

ACE inhibitors: Interferons may increase the adverse/toxic effects of ACE inhibitors, specifically the development of granulocytopenia. Risk: Monitor

Warfarin: Interferons may increase the anticoagulant effects of warfarin. Risk: Monitor

Zidovudine: Interferons may decrease the metabolism of zidovudine. Risk: Monitor

Pregnancy Risk Factor C

Pregnancy Implications A dose-related abortifacient activity was reported in Rhesus monkeys. There are no adequate and well-controlled

INTERFERON GAMMA-1B

studies in pregnant women. Treatment should be discontinued if a woman becomes pregnant, or plans to become pregnant during therapy.

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Patient should be informed of possible side effects, especially depression, suicidal ideations, and the risk of abortion; flu-like symptoms such as chills, fever, malaise, sweating, and myalgia are common

Additional Information May be available only in small supplies

Interferon Gamma-1b

CAS Number 98059-61-1

U.S. Brand Names Actimmune®

Use Reduce frequency and severity of serious infections associated with chronic granulomatous disease; delay time to disease progression in patients with severe, malignant osteopetrosis

Unlabeled/Investigational Use Chronic lymphocytic leukemia, Hodgkin's disease, rheumatoid arthritis; may be useful in treatment for congenital osteopetrosis, toxoplasmosis, hyper-IgE states

Mechanism of Action Increases bone resorption in osteopetrosis

Adverse Reactions

Similar neurotoxic effects (neurobehavioral changes) as with interferon alfa
Cardiovascular: Tachycardia, cardiac arrhythmias, hypotension, edema, syncope, cardiac ectopy, chest pain, fibrillation (atrial), flutter (atrial), sinus tachycardia, tachycardia (supraventricular)

Central nervous system: **Fatigue/malaise, fever, headache, chills, dizziness, CNS depression, confusion, sensory neuropathy, psychiatric effects, seizures, in patients with brain metastasis, EEG abnormalities, parkinsonian syndrome, memory disturbance, multiple sclerosis**

Dermatologic: **Rash, partial alopecia, pruritus, erythema nodosum leprosum, exacerbation of psoriasis**

Endocrine & metabolic: Uric acid level (elevated)

Gastrointestinal: **Nausea, vomiting, diarrhea, anorexia, xerostomia, abdominal cramps, stomatitis, sore throat, weight loss, flatulence, change in taste, flatulence**

Hematologic: Leukopenia (mainly neutropenia), anemia, thrombocytopenia, decreased hemoglobin, hematocrit, platelets

Hepatic: Elevation of ALT and AST

Neuromuscular & skeletal: Myalgia, arthralgia, rigors, polymyositis (dermatomyositis)

Ocular: Blurred vision

Renal: Proteinuria, creatinine/BUN (elevated), oliguric or nonoliguric renal failure

Respiratory: Coughing, nasal congestion

Miscellaneous: Neutralizing antibodies, diaphoresis, systemic lupus erythematosus (SLE)

Signs and Symptoms of Overdose AV block, depression, hyperglycemia, hypertriglyceridemia, hypocalcemia, leukopenia or neutropenia (agranulocytosis, granulocytopenia), metallic taste, memory loss, wheezing

Pharmacodynamics/Kinetics

Absorption: I.M., SubQ: Slowly

Half-life elimination: I.V.: 38 minutes; I.M., SubQ: 3-6 hours

Time to peak, plasma: I.M.: 4 hours (1.5 ng/mL); SubQ: 7 hours (0.6 ng/mL)

Dosage

If severe reactions occur, modify dose (50% reduction) or therapy should be discontinued until adverse reactions abate.

Chronic granulomatous disease: Children > 1 year and Adults: SubQ:

BSA ≤ 0.5 m²: 1.5 mcg/kg/dose 3 times/week

BSA > 0.5 m²: 50 mcg/m² (1 million int. units/m²) 3 times/week

Severe, malignant osteopetrosis: Children > 1 year: SubQ:

BSA ≤ 0.5 m²: 1.5 mcg/kg/dose 3 times/week

BSA > 0.5 m²: 50 mcg/m² (1 million int. units/m²) 3 times/week

Note: Previously expressed as 1.5 million units/m²; 50 mcg is equivalent to 1 million int. units/m².

Monitoring Parameters CBC with differential, platelets, LFTs, electrolytes, BUN, creatinine, and urinalysis prior to therapy and at 3-month intervals

Contraindications Hypersensitivity to interferon gamma, *E. coli* derived proteins, or any component of the formulation

Warnings Patients with pre-existing cardiac disease, seizure disorders, CNS disturbances, or myelosuppression should be carefully monitored; long-term effects on growth and development are unknown; safety and efficacy in children < 1 year of age have not been established.

Dosage Forms Injection, solution [preservative free]: 100 mcg [2 million int. units] (0.5 mL)

Previously, 100 mcg was expressed as 3 million units. This is equivalent to 2 million int. units.

Reference Range Peak serum level after an I.V. dose of 3000 mcg/m²: 7.4-9.6 ng/mL

Overdosage/Treatment

Supportive therapy: Indomethacin or acetaminophen can be given for fever; avoid glucocorticoids

Enhancement of elimination: Hemodialysis is not useful

Test Interactions

Hypertriglyceridemia; rarely causes hyponatremia, hyperglycemia, hypocalcemia

Drug Interactions Inhibits CYP1A2 (weak), 2E1 (weak)

Pregnancy Risk Factor C

Pregnancy Implications Safety and efficacy in pregnant women has not been established. Treatment should be discontinued if a woman becomes pregnant, or plans to become pregnant during therapy. A dose-related abortifacient activity was reported in Rhesus monkeys.

Lactation Excretion in breast milk unknown/contraindicated

Additional Information More heat- and acid-labile than alfa interferons

Iodine

Pronunciation (EYE oh dyne)

Related Information

• Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 7553-56-2

U.S. Brand Names Iodex [OTC]; Iodoflex™; Iodosorb®

Use Preoperatively to reduce vascularity of the thyroid gland prior to thyroidectomy; management of thyrotoxic crisis or recurrent hyperthyroidism; venous sclerosing agent; topical disinfectant; also found in marine life; as a water disinfectant

Mechanism of Action Free iodine oxidizes microbial protoplasm making it effective against bacteria, fungi, yeasts, protozoa, and viruses; complexes with amino groups in tissue compounds to form iodophors from which the iodine is slowly released causing a sustained action

Adverse Reactions

Cardiovascular: Sinus tachycardia

Central nervous system: Fever, headache, hyperthermia

Dermatologic: Skin rash, angioedema, acne, contact dermatitis, erythema, nonimmunologic contact urticaria

Endocrine & metabolic: Hypothyroidism, hypercalcemia, Hashimoto's disease, Graves' disease, autoimmune thyroid disease, thyroiditis, thyrotoxic periodic paralysis

Gastrointestinal: Diarrhea, metallic taste, fecal discoloration (black),

Hematologic: Eosinophilia, hemorrhage (mucosal)

Hepatic: Elevation of serum transaminases and bilirubin

Neuromuscular & skeletal: Arthralgia

Ocular: Edema of eyelids

Respiratory: Pulmonary edema

Miscellaneous: Lymph node enlargement, hypersalivation, lymphadenopathy

Signs and Symptoms of Overdose Acneiform rash, agranulocytosis, circulation collapse, cough, dysphagia, elevated serum osmolarity, fever, gastroenteritis, granulocytopenia, hypercalcemia, hypernatremia, hypotension, hypothyroidism, leukopenia, metabolic acidosis with increased lactic acid, nausea, neutropenia, periarteritis nodosa, renal failure (acute), sexual dysfunction, swelling of glottis or larynx, tachycardia, urine discoloration (blue-green), vomiting

Admission Criteria/Prognosis Any evidence of gastrointestinal or systemic toxicity, or any symptomatic patient should be admitted; asymptomatic patients after 6 hours of observation may be discharged if electrolyte status is normal

Pharmacodynamics/Kinetics

Absorption: Topical: Amount absorbed systemically depends upon concentration and characteristics of skin

Distribution: Primarily trapped by the thyroid

Bioavailability: Oral: > 90%

Excretion: Urine (> 90%)

Dosage Adults: RDA: 150 mg; apply topically as necessary to affected areas of skin

Monitoring Parameters Renal function, acid base status, electrolytes, CBC

Administration Topical: Iodosorb®: Apply 1/8" to 1/4" thickness to dry sterile gauze, then place prepared gauze onto clean wound. Change dressing when gel changes color from brown to yellow/gray (~3 times/week). Remove with sterile water, saline, or wound cleanser; gently blot fluid from surface leaving wound slightly moist before reapplying gel.

Contraindications Hypersensitivity to iodine or any component of the formulation

Iodosorb®, Iodoflex™: Hashimoto thyroiditis, history of Grave's disease, or nontoxic nodular goiter; pregnancy; breast-feeding

Warnings Not for application to large areas of the body or for use with tight or air-excluding bandages. Use caution with renal dysfunction. When used for self-medication (OTC), do not use on deep wounds, puncture wounds, animal bites, or serious burns without consulting with healthcare provider. Notify healthcare provider if condition does not improve within 7 days. Iodosorb® is for use as topical application to wet wounds only.

Dosage Forms

Dressing, topical [gel pad] (Iodoflex™): 0.9% (5 g, 10 g)

Gel, topical (Iodosorb®): 0.9% (40 g)

Ointment, topical (Iodex): 4.7% (30 g, 720 g)
Tincture, topical: 2% (30 mL, 480 mL); 7% (30 mL, 480 mL)

Reference Range

Iodide levels >200 mcg/L (1.6 µmol/L) can inhibit iodide uptake in the normal thyroid gland (Note: iodide refers to the reduced form of iodine); postmortem blood iodine level of 146,000 mcg/L associated with fatality due to iodine overdose

Approximate normal range: Total blood iodine: 5-8 mcg/dL

Protein bound iodine: 3-6 mcg/dL

Postmortem protein bound iodine levels >1000 mcg/dL associated with suicidal fatalities due to iodine

Overdosage/Treatment

Decontamination: **Do not** use ipecac; activated charcoal is useful; gastric lavage (within 1 hour) with starch or 1% to 5% sodium thiosulfate will aid in removal (purple color of effluent)

Dermal: Wash skin with soap and water

Ocular: Irrigate copiously with saline

Supportive therapy: Endoscopy may be required to evaluate gastrointestinal hemorrhage or burns. Systemic corticosteroids may be useful in treating fungating iodema, or gastrointestinal stricture formation.

Enhancement of elimination: Can be enhanced with sodium chloride induced diuresis

Antidote(s)

- Potassium Iodide [ANTIDOTE]
- Sodium Thiosulfate [ANTIDOTE]

Test Interactions Interferes with thyroid function tests; falsely elevates chloride concentrations; may cause false-positive urinary dipstick for hematuria

Pregnancy Risk Factor D

Pregnancy Implications May lead to cretinism

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications Avoid tight bandages because iodine may cause burns on occluded skin

Additional Information IDLH - 10 ppm; iodophors/iodoform have low toxicity; acrid odor with sharp taste; taste threshold: 1.5-2 mg/L; vapor is violet when heated; lithium blood levels increase during caffeine withdrawal; amount of iodine required for water disinfectant: 2-8 ppm

Iopanoic Acid

Pronunciation (eye oh pa NOE ik AS id)

CAS Number 96-83-3

U.S. Brand Names Biliopaco[®]; Cistobil[®]; Neocontrast[®]; Telepaque[®]

Synonyms Acidum Iopanoicum; Iodopanoic Acid

Use Radiocontrast agent for biliary tract

Mechanism of Toxic Action Contains ~66% iodine which is radio-paque

Adverse Reactions

Cardiovascular: Flushing

Central nervous system: Dizziness, headache

Dermatologic: Urticaria, pruritus

Endocrine & metabolic: Thyroid storm

Genitourinary: Dysuria

Hematologic: Thrombocytopenia

Renal: Renal failure, oliguria, proximal tubular necrosis

Miscellaneous: Anaphylactoid reactions, serum sickness

Signs and Symptoms of Overdose Diarrhea, hypotension, nausea, tachycardia, syncope, vomiting

Toxicodynamics/Kinetics

Absorption: 10 hours

Protein binding: 97%

Metabolism: Hepatic glucuronidation

Half-life: 12-20 hours

Elimination: Renal: 35%. Fecal: 22% to 65%

Peak opacification: 14-19 hours

Monitoring Parameters Kidney function, blood pressure, uric acid

Contraindications Known hypersensitivity to iopanoic acid

Use with caution in patients who have hyperthyroidism, hyperuricemia, cholangitis, renal impairment (maximum dose for renal impairment: 3 g), and coronary artery disease

Dosage Forms Tablet: 500 mg (6/package)

Reference Range Iodide levels >200 mcg/L (1.6 µmol/L) can inhibit iodide uptake in the normal thyroid gland. (Note that iodide refers to the

reduced form of iodine.) Postmortem blood iodine level of 146,000 mcg/L associated with fatality due to iodine overdose.

Overdosage/Treatment

Decontamination: Lavage within 1 hour. Cholestyramine may aid in preventing absorption. **Do not** induce emesis. Activated charcoal may be useful in lieu of cholestyramine to prevent iodine absorption.

Supportive therapy: Corticosteroids can be utilized to treat thrombocytopenia; however, thrombocytopenia will usually resolve in 6-9 days.

Enhanced elimination: Urine output should be monitored to prevent renal blockage from uric acid. Alkalinization of the urine has been advocated to increase iopanoic acid solubility; however, this modality has not been proven in an overdose setting. Due to its glucuronide conjugate undergoing enterohepatic recirculation, multiple doses of activated charcoal or cholestyramine may be effective.

Test Interactions May produce falsely elevated TSH values (usually <10 units/L); causes a falsely increased free thyroxine level

Drug Interaction Aspirin can inhibit uricosuric effect of iopanoic acid as can pyrazinamide

Pregnancy Risk Factor D

Additional Information

Oral ingestions up to 75 g have been documented with complete recovery. Radiopaque; insoluble in water; contains 333 mg of iodine per tablet; has uricosuric and anticholinesterase effects agent.

How supplied: Tablets: 500 mg

Ipratropium

CAS Number 22254-24-6; 66985-17-9

U.S. Brand Names Atrovent[®]

Synonyms Ipratropium Bromide

Use Anticholinergic bronchodilator used in bronchospasm associated with COPD, bronchitis, and emphysema; symptomatic relief of rhinorrhea associated with the common cold and allergic and nonallergic rhinitis

Mechanism of Action Blocks the action of acetylcholine at parasympathetic sites in bronchial smooth muscle causing bronchodilation

Adverse Reactions

Cardiovascular: Palpitations, sinus tachycardia, tachycardia (supraventricular)

Central nervous system: **Nervousness**, anxiety, **dizziness**, **headache**, **fatigue**, insomnia, mania, paranoia

Dermatologic: Rash

Gastrointestinal: **Nausea**, **xerostomia**, **bitter taste**, buccal ulceration, paralytic ileus, **stomach upset**

Ocular: Blurred vision, exacerbation of closed-angle glaucoma, mydriasis

Respiratory: **Cough**, paradoxical wheezing

Pharmacodynamics/Kinetics

Onset of action: Bronchodilation: 1-3 minutes

Peak effect: 1.5-2 hours

Duration: ≤4 hours

Absorption: Negligible

Distribution: Inhalation: 15% of dose reaches lower airways

Dosage

Children >12 years and Adults: 2 inhalations 4 times/day up to 12 inhalations/24 hours

Rhinorrhea and sneezing due to the common cold: Ipratropium bromide nasal spray (0.06%) in buffered salt solution; two 42 mcg sprays/nosril

Administration Atrovent[®]: Shake inhaler before each use; rinsing mouth after each use decreases dry mouth side effect

Atrovent[®] HFA: Prime inhaler by releasing 2 test sprays into the air. If the inhaler has not been used for >3 days, reprime.

Contraindications Hypersensitivity to ipratropium, atropine, its derivatives, or any component of the formulation

In addition, Atrovent[®] inhalation aerosol is contraindicated in patients with hypersensitivity to soya lecithin or related food products (eg, soybean and peanut). **Note:** Other formulations may include these components; refer to product-specific labeling.

Warnings Not indicated for the initial treatment of acute episodes of bronchospasm; use with caution in patients with myasthenia gravis, narrow-angle glaucoma, benign prostatic hyperplasia (BPH), or bladder neck obstruction

Dosage Forms

[DSC] = Discontinued product

Aerosol for oral inhalation, as bromide (Atrovent[®]): 18 mcg/actuation (14 g) [contains soya lecithin and chlorofluorocarbons] [DSC]

Aerosol for oral inhalation, as bromide (Atrovent[®] HFA): 17 mcg/actuation (12.9 g)

Solution for nebulization, as bromide: 0.02% (2.5 mL)

Solution, intranasal, as bromide [spray] (Atrovent[®]): 0.03% (30 mL); 0.06% (15 mL)

Reference Range Inhalation of 555 mcg of ipratropium results in peak plasma concentration of 0.06 ng/mL (0.03% of inhaled dose)

Overdosage/Treatment Supportive therapy: Physostigmine should be administered for life-threatening anticholinergic poisoning, although for-

IRINOTECAN

mal studies are lacking; bethanechol (5-10 mg 3 times/day) can be given for peripheral anticholinergic side effects; esmolol can be used for tachyarrhythmia

Antidote(s)

- Physostigmine [ANTIDOTE]

Drug Interactions Anticholinergics: Concurrent use with ipratropium may increase risk of adverse events.

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic effects were not observed in animal studies.

Lactation Excretion in breast milk unknown/use caution

Specific References

Peterson GM, Boyles PJ, Bleasel MD, et al, "Ipratropium Treatment of Acute Airways Disease," *Ann Pharmacother*, 2003, 37(3):339-44.

Irinotecan

U.S. Brand Names Camptosar®

Synonyms Camptothecin-11; CPT-11; NSC-616348

Use Treatment of metastatic carcinoma of the colon or rectum

Unlabeled/Investigational Use Lung cancer (small cell and nonsmall cell), cervical cancer, gastric cancer, pancreatic cancer, leukemia, lymphoma, breast cancer

Mechanism of Action A derivative of camptothecin from the Oriental tree *Camptotheca acuminata*; irinotecan inhibits the enzyme topoisomerase I which is involved in structural maintenance of DNA

Adverse Reactions

Cardiovascular: Flushing, sinus bradycardia, **vasodilation**

Central nervous system: **Insomnia, dizziness, fever**

Dermatologic: **Alopecia, rash**

Gastrointestinal: **Diarrhea** (may be severe), nausea, vomiting, **abdominal pain or cramps, anorexia, constipation, flatulence, stomatitis, dyspepsia**

Hematologic: **Myelosuppression**, anemia, thrombocytopenia, **neutropenia**

Neuromuscular & skeletal: **Weakness**

Ocular: Lacrimation

Respiratory: **Dyspnea, coughing, rhinitis**

Miscellaneous: **Diaphoresis**

Pharmacodynamics/Kinetics

Distribution: V_d : 33-150 L/m²

Protein binding, plasma: Predominantly albumin; Parent drug: 30% to 68%, SN-38 (active drug): ~95%

Metabolism: Primarily hepatic to SN-38 (active metabolite) by carboxylesterase enzymes; SN-38 undergoes conjugation by UDP-glucuronosyl transferase 1A1 (UGT1A1) to form a glucuronide metabolite. SN-38 is increased by UGT1A1*28 polymorphism (10% of North Americans are homozygous for UGT1A1*28 allele). The lactones of both irinotecan and SN-38 undergo hydrolysis to inactive hydroxy acid forms.

Half-life elimination: SN-38: Mean terminal: 10-20 hours

Time to peak: SN-38: Following 90-minute infusion: ~1 hour

Excretion: Within 24 hours: Urine: Irinotecan (11% to 20%), metabolites (SN-38 <1%, SN-38 glucuronide, 3%)

Dosage Dosing regimens vary with usual dosage range of 40 mg/m²/day to 250 mg/m²/day up to a maximum of 750 mg/m²/day; infusions are from 30-90 minutes and may vary from 3 times/week to weekly to every 3 weeks. See table.

Single-Agent Schedule: Recommended Dosage Modifications ¹			
Toxicity NCI Grade ² (Value)	During a Cycle of Therapy	At Start of Subsequent Cycles of Therapy (After Adequate Recovery), Compared to Starting Dose in Previous Cycle ¹	
		Weekly	Once Every 3 Weeks
No toxicity	Maintain dose level	↑ 25 mg/m ² up to a maximum dose of 150 mg/m ²	Maintain dose level
Neutropenia			
1 (1500-1999/mm ³)	Maintain dose level	Maintain dose level	Maintain dose level
2 (1000-1499/mm ³)	↓ 25 mg/m ²	Maintain dose level	Maintain dose level

Table (Continued)			
Toxicity NCI Grade ² (Value)	During a Cycle of Therapy	At Start of Subsequent Cycles of Therapy (After Adequate Recovery), Compared to Starting Dose in Previous Cycle ¹	
		Weekly	Once Every 3 Weeks
3 (500-999/mm ³)	Omit dose until resolved to ≤ grade 2, then ↓ 25 mg/m ²	↓ 25 mg/m ²	↓ 50 mg/m ²
4 (<500/mm ³)	Omit dose until resolved to ≤ grade 2, then ↓ 50 mg/m ²	↓ 50 mg/m ²	↓ 50 mg/m ²
Neutropenic Fever (grade 4 neutropenia and ≥ grade 2 fever)	Omit dose until resolved, then ↓ 50 mg/m ²	↓ 50 mg/m ²	↓ 50 mg/m ²
Other Hematologic Toxicities	Dose modifications for leukopenia, thrombocytopenia, and anemia during a course of therapy and at the start of subsequent courses of therapy are also based on NCI toxicity criteria and are the same as recommended for neutropenia above.		
Diarrhea			
1 (2-3 stools/day > pretreatment)	Maintain dose level	Maintain dose level	Maintain dose level
2 (4-6 stools/day > pretreatment)	↓ 25 mg/m ²	Maintain dose level	Maintain dose level
3 (7-9 stools/day > pretreatment)	Omit dose until resolved to ≤ grade 2, then ↓ 25 mg/m ²	↓ 25 mg/m ²	↓ 50 mg/m ²
4 (≥ 10 stools/day > pretreatment)	Omit dose until resolved to ≤ grade 2, then ↓ 50 mg/m ²	↓ 50 mg/m ²	↓ 50 mg/m ²
Other Nonhematologic Toxicities³			
1	Maintain dose level	Maintain dose level	Maintain dose level
2	↓ 25 mg/m ²	↓ 25 mg/m ²	↓ 50 mg/m ²
3	Omit dose until resolved to ≤ grade 2, then ↓ 25 mg/m ²	↓ 25 mg/m ²	↓ 50 mg/m ²
4	Omit dose until resolved to ≤ grade 2, then ↓ 50 mg/m ²	↓ 50 mg/m ²	↓ 50 mg/m ²

¹All dose modifications should be based on the worst preceding toxicity.

²National Cancer Institute Common Toxicity Criteria (version 1.0).

³Excludes alopecia, anorexia, asthenia.

Monitoring Parameters CBC with differential, platelet count, and hemoglobin with each dose

Administration Administer by I.V. infusion, usually over 90 minutes.

Contraindications Hypersensitivity to irinotecan or any component of the formulation; concurrent use of atazanavir, ketoconazole, St John's wort; pregnancy

Warnings

Hazardous agent – use appropriate precautions for handling and disposal. Severe hypersensitivity reactions have occurred.

[U.S. Boxed Warning]: May cause severe myelosuppression. Deaths due to sepsis following severe myelosuppression have been reported. Therapy should be temporarily discontinued if neutropenic fever occurs or if the absolute neutrophil count is <1000/mm³. The dose of irinotecan should be reduced if there is a clinically significant decrease in the total WBC (<200/mm³), neutrophil count (<1500/mm³), hemoglobin (<8 g/dL), or platelet count (<100,000/mm³). Routine administration of a colony-stimulating factor is generally not necessary, but may be considered for patients experiencing significant neutropenia.

Patients homozygous for the UGT1A1*28 allele are at increased risk of neutropenia; initial one-level dose reduction should be considered for both single-agent and combination regimens. Heterozygous carriers of the UGT1A1*28 allele may also be at increased risk; however, most patients have tolerated normal starting doses.

Patients with even modest elevations in total serum bilirubin levels (1.0-2.0 mg/dL) have a significantly greater likelihood of experiencing first-course grade 3 or 4 neutropenia than those with bilirubin levels that were <1.0 mg/dL. Patients with abnormal glucuronidation of bilirubin, such as those with Gilbert's syndrome, may also be at greater risk of myelosuppression when receiving therapy with irinotecan. Use caution when treating patients with known hepatic dysfunction or hyperbilirubinemia. Dosage adjustments should be considered.

Patients with diarrhea should be carefully monitored and treated promptly. **[U.S. Boxed Warning]: Severe diarrhea may be dose-limiting and potentially fatal; two severe (life-threatening) forms of diarrhea may occur.** Early diarrhea occurs during or within 24 hours of receiving irinotecan and is characterized by cholinergic symptoms (eg, increased salivation, diaphoresis, abdominal cramping); it is usually responsive to atropine. Late diarrhea occurs more than 24 hours after treatment which may lead to dehydration, electrolyte imbalance, or sepsis; it should be promptly treated with loperamide.

Patients should receive fluid and electrolyte replacement as indicated, or antibiotics if ileus, fever, or neutropenia develop. Hold diuretics during dosing due to potential risk of dehydration secondary to vomiting and/or diarrhea induced by irinotecan.

Use caution in patients who previously received pelvic/abdominal radiation, elderly patients with comorbid conditions, or baseline performance status of 2; close monitoring and dosage adjustments are recommended. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.**

Dosage Forms Injection, solution, as hydrochloride: 20 mg/mL (2 mL, 5 mL)

Camptosar®: 20 mg/mL (2 mL, 5 mL)

Overdosage/Treatment

Supportive therapy: Ondansetron (0.15 mg/kg I.V. or oral) with a corticosteroid is effective in preventing emesis; diphenhydramine can be used to decrease cholinergic reactions (lacrimation, sweating, flushing); loperamide (2 mg doses) is effective in treating diarrhea. Enhancement of elimination: Due to enterohepatic recirculation, multiple dosing of activated charcoal may be useful in enhancing clearance.

Drug Interactions

Substrate (major) of CYP2B6, 3A4

Anticonvulsants (carbamazepine, phenobarbital, phenytoin): Decreases the therapeutic effect of irinotecan. Consider replacement of anticonvulsant with a nonenzyme-inducing agent ≥ 2 weeks prior to irinotecan therapy.

Atazanavir: May increase the levels/effects of irinotecan (SN-38) by CYP3A4 and UGT1A1 inhibition; avoid concurrent use.

Bevacizumab: May increase the adverse effects of irinotecan (eg, diarrhea, neutropenia).

CYP2B6 inducers: May decrease the levels/effects of irinotecan. Example inducers include carbamazepine, nevirapine, phenobarbital, phenytoin, and rifampin.

CYP2B6 inhibitors: May increase the levels/effects of irinotecan. Example inhibitors include desipramine, paroxetine, and sertraline.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of irinotecan. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of irinotecan. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Ketoconazole: Increases the levels/effects of irinotecan and active metabolite. Discontinue ketoconazole 1 week prior to irinotecan therapy; **concurrent use is contraindicated.**

St John's wort: Decreases the therapeutic effect of irinotecan. Discontinue St John's wort ≥ 2 weeks prior to irinotecan therapy; **concurrent use is contraindicated.**

Pregnancy Risk Factor D

Pregnancy Implications Has shown to be teratogenic in animals. Teratogenic effects include a variety of external, visceral, and skeletal abnormalities. The patient should be warned of potential hazards to the fetus. Women of childbearing potential should avoid becoming pregnant while receiving treatment.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Diarrhea is dose related; high doses of loperamide can increase tolerated dose of irinotecan; used in combination with fluorouracil and etoposide

Herb/Nutraceutical interaction: St John's wort may decrease the efficacy of irinotecan.

Specific References

Richards S, Umbreit JN, Fanucchi MP, et al, "Selective Serotonin Reuptake Inhibitor-Induced Rhabdomyolysis Associated with Irinotecan," *South Med J*, 2003, 96(10):1031-3.

Iron

CAS Number 1439-89-6

Synonyms Ferrous Fumarate; Ferrous Gluconate; Ferrous Sulfate; Iron Dextran Complex

Commonly Includes Ferrous sulfate, ferrous gluconate, ferrous fumarate, ferrous chloride, ferrous carbonate, ferrous chloride

Use Prevention and/or treatment of iron deficiency anemias; prenatal supplementation

Mechanism of Action Essential component of hemoglobin, myoglobin, and multiple enzymes; supplementation is given to replenish lost iron stores

Adverse Reactions

Anaphylactoid reactions: Respiratory difficulties and cardiovascular collapse have been reported and occur most frequently within the first several minutes of administration

Cardiovascular: Hypotension, myocardial depression, **flushing**, tachycardia, congestive heart failure, sinus tachycardia, vasodilation

Central nervous system: **Dizziness, fever, headache, chills**

Dermatologic: Urticaria, pustular drug eruption

Gastrointestinal: **Nausea, metallic taste, vomiting**, GI irritation, abdominal pain, diarrhea, dark stools, heartburn, esophagitis

Hematologic: Leukocytosis

Hepatic: Steatosis

Local: **Pain, staining of skin at the site of I.M. injection, phlebitis**

Neuromuscular & skeletal: Arthralgia

Renal: Hematuria

Respiratory: Aspiration

Miscellaneous: Lymphadenopathy, liquid preparations may temporarily stain the teeth, **diaphoresis**

Note: Diaphoresis, rash, arthralgia, fever, chills, dizziness, headache, and nausea may be delayed 24-48 hours after I.V. administration or 3-4 days after I.M. administration

Signs and Symptoms of Overdose Acidosis, acute GI irritation, bezoars, coagulopathy, coma, drowsiness, erosion of GI mucosa, esophageal ulceration, feces discoloration (black; green), fever, hematemesis, hematuria, hepatic and renal impairment, hyperthermia, hyperventilation, hypoglycemia, sedation, sweating, urine discoloration (black)

There are essentially five stages of iron poisoning:

Stage I (30 minutes to 6 hours): Predominately GI irritation, due primarily to the corrosive effect of iron; drowsiness, epigastric pain, GI bleeding, hypotension, nausea, and vomiting may occur. Hyperglycemia, leukocytosis, or metabolic acidosis may be present (due to vasodilatation).

Stage II (6-24 hours): A latent period of symptom quiescence during which symptomatic improvement may be noted; in severe poisonings, there may be no latent period

Stage III (6-48 hours): Metabolic and systemic derangement occur with cardiovascular collapse, coagulopathy (inhibition of thrombin and fibrinogen), coma, and seizures. Pulmonary edema may occur due to cardiac failure.

Stage IV (2-7 days): Hepatotoxicity (jaundice) and coagulopathy occur; metabolic acidosis is present, and renal insufficiency may occur

Stage V (1-8 weeks): Primarily delayed GI complications, including gastric/duodenal fibrosis resulting in obstructive pattern; achlorhydria may develop

Admission Criteria/Prognosis Admit patients with hypotension, abdominal pain, acidosis, nervous system abnormalities, serum iron levels >350 mcg/dL, positive abdominal radiographs, or ingestions >60 mg/kg of elemental iron

Pharmacodynamics/Kinetics

Total body stores are 3-4 g

Absorption: In ferrous state (Fe²⁺) in duodenum and jejunum

Distribution: 70% as ferrous state in hemoglobin, 25% in ferric state as ferritin or hemosiderin, 0.1% in ferric state in plasma

Elimination: ≈ 1 mg/day of iron is lost via urinary excretion, skin desquamation; this may increase to 2 mg/day when iron accumulates

Dosage

Oral (dose expressed in terms of elemental iron):

Recommended daily allowance:

Male: 10 mg

Female: 18 mg

Pregnancy and lactation: 30-60 mg

Iron replacement:

Infants: 10-25 mg/day in 3-4 divided doses

Children:

6 months to 2 years: Up to 6 mg/kg/day in 3-4 divided doses

2-12 years: 3 mg/kg/day given 3-4 times/day

Adults: 2-3 mg/kg/day given 3 times/day

I.M. (Z-track method should be used for I.M. injection), I.V.:
 A 0.5 mL test dose (0.25 mL in infants) should be given prior to starting iron dextran therapy; total dose should be divided into a daily schedule for I.M., total dose may be given as a single continuous infusion

Contraindications Hemosiderosis, hemochromatosis, hemolytic anemia, peptic ulcer disease, ulcerative colitis

Warnings Some products contain tartrazine which may cause allergic reactions

Dosage Forms

Amount of elemental iron is listed in brackets

Ferrous fumarate:

- Capsule, controlled release (Span-FF®): 325 mg [106 mg]
- Drops (Feostat®): 45 mg/0.6 mL [15 mg/0.6 mL] (60 mL)
- Suspension, oral (Feostat®): 100 mg/5 mL [33 mg/5 mL] (240 mL)
- Tablet: 325 mg [106 mg]
 - Chewable (chocolate flavor) (Feostat®): 100 mg [33 mg]
 - Femiron®: 63 mg [20 mg]
 - Fumerin®: 195 mg [64 mg]
 - Fumasorb®, Iron®: 200 mg [66 mg]
 - Hemocyte®: 324 mg [106 mg]
 - Nephro-Fer™: 350 mg [115 mg]
 - Timed release (Ferro-Sequels®): Ferrous fumarate 150 mg [50 mg] and docusate sodium 100 mg

Ferrous gluconate:

- Capsule, soft gelatin (Simron®): 86 mg [10 mg]
- Elixir (Fergon®): 300 mg/5 mL [34 mg/5 mL] with alcohol 7% (480 mL)
- Tablet: 300 mg [34 mg]; 325 mg [38 mg]
 - Fergon®, Ferralet®: 320 mg [37 mg]
 - Sustained release (Feralet® Slow Release): 320 mg [37 mg]

Ferrous sulfate:

- Capsule:
 - Exsiccated (Fer-In-Sol®): 190 mg [60 mg]
 - Exsiccated, timed release (Feosol®): 159 mg [50 mg]
 - Exsiccated, timed release (Ferralyne® Lanacaps®, Ferra-TD®): 250 mg [50 mg]
 - Ferospace®: 250 mg [50 mg]
- Drops, oral:
 - Fer-In-Sol®: 75 mg/0.6 mL [15 mg/0.6 mL] (50 mL)
 - Fer-Iron®: 125 mg/mL [25 mg/mL] (50 mL)
- Elixir (Feosol®): 220 mg/5 mL [44 mg/5 mL] with alcohol 5% (473 mL, 4000 mL)
- Powder for injection: Deferoxamine: 500 mg vials
- Syrup (Fer-In-Sol®): 90 mg/5 mL [18 mg/5 mL] with alcohol 5% (480 mL)
- Tablet: 324 mg [65 mg]
 - Exsiccated (Feosol®) 200 mg [65 mg]
 - Exsiccated, timed release (Slow FE®): 160 mg [50 mg]
 - Feratab®: 300 mg [60 mg]
 - Mol-Iron®: 195 mg [39 mg]
 - Timed release (Fero-Gradumet®): 525 mg [105 mg]

Iron dextran complex: InFem™ injection: 50 mg/mL (2 mL, 10 mL)

Reference Range

Levels >500 mcg/dL associated with toxicity; consider treatment with symptomatic levels ≥350 mcg/dL; peak values are 2-4 hours after ingestion; standard measurement of total iron binding capacity (TIBC) are unreliable and should not be used to assess the patient
 Therapeutic: Male: 75-175 mcg/dL (SI: 13.4-31.3 μmol/L). Female: 65-165 mcg/dL (SI: 11.6-29.5 μmol/L); iron levels >300 mcg/dL can be considered toxic and should be treated as an overdose

Overdosage/Treatment

Determine amount of drug ingested based on mg/kg of elemental iron; doses <20 mg/kg are minimal to no toxicity; 20-60 mg/kg are mild to moderate; >60 mg/kg are potentially serious. See table.

Iron	
Overdosage	Elemental Iron
Ferrous sulfate (hydrated)	20%
Ferrous fumarate	33%
Ferrous gluconate	12%
Ferrous chloride (hydrated)	28%
Ferric chloride (hydrated)	20%

Decontamination: Lavage within 1 hour with normal saline and/or whole bowel irrigation with polyethylene glycol electrolyte solution (GoLYTELY®); use WBI if radiopaque tablets present on KUB; charcoal is ineffective unless it is a multiple drug ingestion; oral deferoxamine is not effective

Supportive therapy: Shock can be treated with I.V. crystalloid fluids, blood products may be necessary; following treatment for fluid losses, metabolic acidosis, and shock, a severe iron overdose may be treated with deferoxamine. Deferoxamine may be administered I.V. (10-15 mg/kg/hour) or I.M. (40-90 mg/kg every 8 hours). Lethal dose of elemental iron is 180-300 mg/kg.

Antidote: Deferoxamine is a chelating agent for iron; it binds free iron and some iron bound to ferritin and hemosiderin; the complex of iron and deferoxamine (ferrioxamine) is then excreted renally with a "vin rosé" color; color change is dependent on pH and concentrations with basic pH and higher concentrations being positively associated with the change in color. Indications for deferoxamine therapy include asymptomatic serum iron concentrations >500 mcg/dL, radiopaque tablets on abdominal x-ray; symptomatic patients with iron levels >350 mcg/dL, persistent symptoms, acidosis, hypovolemia, mental status changes or abdominal pain.

Obtain baseline serum iron level and urine sample. Administration via I.V. route is preferred; give at 15 mg/kg/hour by continuous infusion. Doses up to 50 mg/kg/hour have been used for severe ingestion. Maximum recommended dose is 6 g/day; however, higher doses have been given. Continuous infusion of 15 mg/kg/hour should not be continued for longer than 24 hours without a "drug holiday." Monitor urine for "vin rosé" color change compared to baseline.

Endpoints of therapy include change in urine color back to baseline, serum concentrations of iron <100 mg/dL, and/or resolution of symptoms; chelation therapy typically requires <24-hour duration

Antidote(s)

- Deferoxamine [ANTIDOTE]
- Polyethylene Glycol - High Molecular Weight [ANTIDOTE]

Diagnostic Procedures

- Iron and Total Iron Binding Capacity/Transferrin

Test Interactions Measured serum iron concentrations will be lowered in face of deferoxamine therapy; high serum iron may falsely increase total iron binding capacity (TIBC) for most common assay. Hemoccult® and Gastrocult® tests may be unreliable in detecting GI bleeding in iron overdose treated with whole bowel irrigation (ferrous sulfate/ferrous gluconate: false-positive; ascorbic acid: false-negative)

Drug Interactions Antacids decrease iron absorption; vitamin C increases gastrointestinal absorption; iron can inhibit tetracycline and penicillamine absorption

Pregnancy Risk Factor A; Deferoxamine: C

Pregnancy Implications Although placental transport is poor and treatment of iron overdose in pregnancy should not be harmful, untreated patients may result in fetal and/or maternal morbidity and mortality

Nursing Implications Always obtain baseline urine before administration of deferoxamine; I.V. infusion may be prepared in saline or glucose

Additional Information Lethal dose: Elemental iron: 180-300 mg/kg. Oral chelation with deferoxamine is not recommended; chelation with deferoxamine in parenteral overdoses of iron dextran solutions may not be as necessary as compared to oral ingestions at similar dosages since the elemental iron binds directly to dextran; liver transplantation has been used for iron-induced hepatic failure 5 days after ingestion; largest reported volume of polyethylene glycol electrolyte solution for use for whole bowel irrigation in a toxic ingestion was 44.3 L (2953 mL/kg) over a 5-day period in a 33-month old boy who ingested at least 160 mg/kg elemental iron (initial serum iron level: 367 mcg/dL); optimal bowel cleansing in pediatric patients (age 0.5-12 years): 6-10 hours of therapy at a rate of 25-35 mL/kg/hour of polyethylene glycol

Representative Iron Products		
Iron Product	Dosage Form(s)	Approximate Elemental Iron per Dosage Unit
Ferrous sulfate	250 mg tablets	50 mg/tablet
	325 mg tablets	65 mg/tablet
	Timed-release tablets	65-105 mg/tablet
	Elixir 220 mg/5 mL	44 mg/5 mL
	Drops 75 mg/0.6 mL	15 mg/0.6 mL
Ferrous gluconate	240 mg tablets	28 mg tablet
	300 mg/tablets	36 mg/tablet
	325 mg tablets	40 mg/tablet
	100 mg chewable tablets	33 mg/tablet
Ferrous fumarate	Timed-release tablets	50-110 mg/tablet
	200 mg tablets	65 mg/tablet
	325 mg tablets	107 mg/tablet
	350 mg tablets	115 mg/tablet
	Suspension 350 mg/5 mL	33 mg/5 mL
Multivitamin hematonic products	Tablet or capsule	65-150 mg/tablet
Prenatal vitamins with iron	Tablet or capsule	9-106 mg/tablet

Iron Product	Dosage Form(s)	Approximate Elemental Iron per Dosage Unit
Adult multiple vitamin plus iron	Tablet or capsule	3-110 mg/tablet
Pediatric multiple vitamin plus iron	Chewable tablet	10-18 mg/tablet
	Drops	10 mg/mL
	Liquid	10 mg/5 mL
Carbonyl iron	Tablets and capsules	50-66 mg/tablet or capsule
	Liquid	15 mg/1.25 mL
Polysaccharide-iron complex	Tablets	50-150 mg/tablet
	Capsules	150 mg/capsule
	Elixir	100 mg/5 mL

Summary of Iron Deaths Reported to TESS 1985-2002

Age	Stated Iron Product Ingested	Stated Dose	Serum Iron Concentrations mcg/dL (mmol/L)	Time Serum Iron Drawn After Ingestion
3 y	Ferrous sulfate 325 mg tablets	Unknown	3805 (681)	3 h
18 mo	Ferrous sulfate	Unknown	23,000 (4119)	6 h
10 mo	Ferrous sulfate	22 g	>7000 (>1254)	Unknown
15 mo	Ferrous sulfate 325 mg tablets	Unknown	1200 (215)	1 h
17 mo	Prenatal iron tablets	Unknown	25,000 (4477)	6 h
17 mo	Ferrous sulfate 325 mg tablets	Unknown	1400 (251)	4 h
22 mo	Iron tablets	Unknown	4674 (837)	Unknown
10 mo	Ferrous sulfate tablets	Unknown	18,930 (3390)	Unknown
11 mo	Ferrous sulfate tablets	Unknown	>10,000 (>1790)	2 h?
14 mo	Ferrous sulfate tablets	Unknown	>10,000 (>1790)	2 h
15 mo	Iron tablets	Unknown	383 (68)	>10 h
16 mo	Ferrous sulfate 325 mg tablets	>30 tablets	8500 (1522)	Unknown
9 mo	Ferrous sulfate 325 mg tablets	>20 tablets	3730 (668)	>6 h
12 mo	Ferrous sulfate 325 mg tablets	35-40 tablets	4023 (720)	4 h
14 mo	Ferrous sulfate 325 mg tablets	Unknown	2088 (374)	3-4 h
18 mo	Ferrous sulfate 325 mg tablets	40 tablets	1651 (296)	9 h
2 y	Ferrous sulfate	90 tablets	14,000 (2507)	Unknown
2 y	Ferrous sulfate	35 tablets	6350 (1137)	4 h
3 y	Ferrous sulfate 325 mg tablets	30 tablets	>10,000 (>1790)	4 h
3 y	Ferrous sulfate	Unknown	377 (68)	3 h
15 mo	Iron tablets	Unknown	>400 (>72)	>24 h
17 mo	Prenatal vitamins with iron (65 mg Fe/tab)	"Whole bottle"	18,150 (3250)	Unknown
18 mo	Prenatal vitamins with iron (65 mg Fe/tab)	"4-5 tablets" (likely an underestimation)	>1000 (>179)	4.5 h
12 mo	Iron tablets	Unknown	1555 (278)	30 min
19 mo	Iron tablets (65 mg Fe)	35 tablets	6000 (1074)	1 h
15 mo	Prenatal vitamins with iron (325 mg ferrous sulfate/tab)	50 tablets	4500 (806)	6 h
16 mo	Prenatal vitamins with iron	Unknown	1200 (215)	Unknown

Age	Stated Iron Product Ingested	Stated Dose	Serum Iron Concentrations mcg/dL (mmol/L)	Time Serum Iron Drawn After Ingestion
16 mo	Prenatal vitamins with iron (325 mg ferrous sulfate/tab)	50 tablets	1440 (258)	Unknown
21 mo	Prenatal vitamins with iron (65 mg Fe/tab)	90 tablets	1858 (333)	10 h
20 mo	Ferrous sulfate 325 mg tablets	Unknown	1080 (193)	Unknown
11 mo	Iron tablets	50-70 tablets	8800 (1576)	2 h
23 mo	Prenatal vitamins with iron	Unknown	251 (45)	36 h
18 mo	Ferrous sulfate 325 mg tablets	Unknown	Not done	
22 mo	Ferrous sulfate 325 mg tablets	96 tablets	2583 (463)	6.5 h
1 y	Prenatal vitamins with iron	Unknown	5900 (1057)	12-14 h
16 mo	Prenatal vitamins with iron	Unknown	397 (71)	>3 days
17 mo	Prenatal vitamins with iron	>25 tablets	1055 (189)	6 h
16 mo	Ferrous sulfate	Unknown	12,000 (2149)	>4 h
14 mo	Iron tablets	Unknown	18,750 (3358)	3 h
36 y	Unknown iron preparation	Unknown	345 (62)	Unknown
14 y	Iron tablets	140 mg/kg	476 (85)	Unknown
34 y	Prenatal vitamins with iron	Unknown	92 (17)	Unknown

Isocarboxazid

Pronunciation (eye soe kar BOKS a zid)

CAS Number 59-63-2

U.S. Brand Names Marplan®

Use Symptomatic treatment of atypical, nonendogenous, or neurotic depression

Mechanism of Action Thought to act by increasing endogenous concentrations of epinephrine, norepinephrine, dopamine, and serotonin through inhibition of the enzyme (monoamine oxidase) responsible for the breakdown of these neurotransmitters

Adverse Reactions

Cardiovascular: Hypotension, hypertension, edema, ECG changes (peaked T waves), palpitations, vasoconstriction
Central nervous system: Drowsiness, excitement, mania, coma, hallucinations, seizures, delirium, hyperthermia
Dermatologic: Skin rash, hyperhidrosis
Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone
Gastrointestinal: Xerostomia, constipation, nausea
Genitourinary: Urinary retention, ejaculatory disturbances
Ocular: Blurred vision, photophobia, ptosis, diplopia, mydriasis, "ping-pong" gaze, nystagmus
Neuromuscular & skeletal: Muscle rigidity, hyperreflexia
Renal: Myoglobinuria leading to renal failure
Respiratory: Tachypnea
Miscellaneous: Diaphoresis

Dosage Adults: Oral: 10 mg 3 times/day; reduce to 10-20 mg/day in divided doses when condition improves

Monitoring Parameters Blood pressure

Contraindications Hypersensitivity to isocarboxazid or any component of the formulation; uncontrolled hypertension; pheochromocytoma; hepatic or renal disease; cerebrovascular defect; cardiovascular disease (CHF); CNS depressants, ethanol, meperidine, bupropion, buspirone, guanethidine, and serotonergic drugs (including SSRIs) - do not use within 5 weeks of fluoxetine discontinuation or 2 weeks of other antidepressant discontinuation; general anesthesia, local vasoconstrictors; spinal anesthesia (hypotension may be exaggerated); sympathomimetics (and related compounds); foods high in tyramine content; supplements containing tyrosine, phenylalanine, tryptophan, or caffeine

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. **Isocarboxazid is FDA approved for the treatment of depression in children ≥ 16 years of age.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Isocarboxazid is not FDA approved for the treatment of bipolar depression.**

Use with caution in patients who are hyperactive, hyperexcitable, or who have glaucoma, hyperthyroidism, or diabetes; avoid use of meperidine within 2 weeks of isocarboxazid use. Toxic reactions have occurred with dextromethorphan. Hypertensive crisis may occur with foods/supplements high in tyramine, tryptophan, phenylalanine, or tyrosine content.

Should not be used in combination with other antidepressants. Hypotensive effects of antihypertensives (beta-blockers, thiazides) may be exaggerated. May cause orthostatic hypotension (especially at dosages > 30 mg/day) - use with caution in patients with hypotension or patients who would not tolerate transient hypotensive episodes - effects may be additive when used with other agents known to cause orthostasis (phenothiazines).

Discontinue at least 48 hours prior to myelography. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Use with caution in patients receiving disulfiram. Use with caution in patients with renal impairment. The MAO inhibitors are effective and generally well tolerated by older patients. It is the potential interactions with tyramine-containing foods and other drugs, and their effects on blood pressure that have limited their use.

Dosage Forms Tablet: 10 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Diazepam or lorazepam can be used for agitation/seizures; dantrolene (2.5 mg/kg every 6 hours) can be used for muscle rigidity and hyperthermia; norepinephrine is the preferred agent for treatment of hypotension. Avoid bretylium for ventricular dysrhythmia, lidocaine or procainamide are preferred. Hypertensive crisis can be treated with nitroprusside, phentolamine (2-10 mg slow I.V. injection in adults), diazoxide (50-100 mg I.V.). Dantrolene (2.5 mg/kg every 6 hours I.V.) can be used to treat hypermetabolic crisis; avoid use of succinylcholine and bretylium.

Diagnostic Procedures

• Electrolytes, Blood

Test Interactions ↓ glucose

Drug Interactions

Amphetamines: MAO inhibitors in combination with amphetamines may result in severe hypertensive reaction; these combinations are best avoided.

Anorexiant: Concurrent use of anorexiant may result in serotonin syndrome; these combinations are best avoided; includes dexfenfluramine, fenfluramine, or sibutramine.

Barbiturates: MAO inhibitors may inhibit the metabolism of barbiturates and prolong their effect.

CNS stimulants: MAO inhibitors in combination with stimulants (methylphenidate) may result in severe hypertensive reaction; these combinations are best avoided

Dextromethorphan: Concurrent use of MAO inhibitors may result in serotonin syndrome; these combinations are best avoided.

Disulfiram: MAO inhibitors may produce delirium in patients receiving disulfiram; monitor.

Guanadrel and guanethidine: MAO inhibitors inhibit the antihypertensive response to guanadrel or guanethidine; use an alternative antihypertensive agent.

Hypoglycemic agents: MAO inhibitors may produce hypoglycemia in patients with diabetes; monitor.

Levodopa: MAO inhibitors in combination with levodopa may result in hypertensive reactions; monitor.

Lithium: MAO inhibitors in combination with lithium have resulted in malignant hyperpyrexia; this combination is best avoided.

Meperidine: May cause serotonin syndrome when combined with an MAO inhibitor; avoid this combination.

Nefazodone: Concurrent use of MAO inhibitors may result in serotonin syndrome; these combinations are best avoided.

Norepinephrine: MAO inhibitors may increase the pressor response of norepinephrine (effect is generally small); monitor.

Reserpine: MAO inhibitors in combination with reserpine may result in hypertensive reactions; monitor.

Serotonin agonists: Theoretically, may increase the risk of serotonin syndrome; includes sumatriptan, naratriptan, rizatriptan, and zolmitriptan.

SSRIs: May cause serotonin syndrome when combined with an MAO inhibitor; avoid this combination.

Succinylcholine: MAO inhibitors may prolong the muscle relaxation produced by succinylcholine via decreased plasma pseudocholinesterase.

Sympathomimetics (indirect-acting): MAO inhibitors in combination with sympathomimetics such as dopamine, metaraminol, phenylephrine, and decongestants (pseudoephedrine) may result in severe hypertensive reaction; these combinations are best avoided.

Tramadol: May increase the risk of seizures and serotonin syndrome in patients receiving an MAO inhibitor.

Trazodone: Concurrent use of MAO inhibitors may result in serotonin syndrome; these combinations are best avoided.

Tricyclic antidepressants: May cause serotonin syndrome when combined with an MAO inhibitor; avoid this combination.

Venlafaxine: Concurrent use of MAO inhibitors may result in serotonin syndrome; these combinations are best avoided.

Pregnancy Risk Factor C

Nursing Implications Watch for hypotension (orthostatic); monitor blood pressure carefully, especially at therapy onset or if other CNS drugs or cardiovascular drugs are added; check for dietary and drug restriction

Additional Information Avoid tyramine-containing foods: red wine, cheese (except cottage, ricotta, and cream), smoked or pickled fish, beef or chicken liver, dried sausage, fava or broad bean pods, yeast vitamin supplements

Isoniazid

Related Information

● Therapeutic Drugs Associated with Hallucinations

CAS Number 54-85-3

U.S. Brand Names Nydrazid®

Synonyms INH; Isonicotinic Acid Hydrazide

Use Treatment of susceptible tuberculosis infections and prophylactically to those individuals exposed to tuberculosis

Mechanism of Action Inhibits mycolic acid synthesis resulting in disruption of the bacterial cell wall; inhibits pyridoxine use as a cofactor in production of gamma-aminobutyric acid (GABA), an inhibitory neurotransmitter. Structurally related to nicotinic acid

Adverse Reactions

Cardiovascular: Myocarditis (hypersensitivity), pericardial effusion/pericarditis, sinus tachycardia, vasculitis

Central nervous system: Peripheral neuritis, vascular encephalopathy, seizures, stupor, dizziness, psychosis, fever, auditory and visual hallucinations, ataxia, memory disturbance, CNS depression, depression, mania, axonopathy

Dermatologic: Skin eruptions, angioedema, Stevens-Johnson syndrome, acute generalized exanthematous pustulosis, alopecia, toxic epidermal necrolysis, purpura, onycholysis, photosensitivity, pruritus, licheniform eruptions, exanthem

Endocrine & metabolic: Hyperglycemia

Gastrointestinal: Nausea, vomiting, stomach pain, loss of appetite, constipation, pancreatitis

Genitourinary: Urinary retention

Hematologic: Blood dyscrasias, hemolysis, eosinophilia, agranulocytosis, red blood cell aplasia, thrombocytopenia, aplastic anemia

Hepatic: Hepatitis, elevated liver transaminase levels, aminotransferase level elevation (asymptomatic)

Neuromuscular & skeletal: Weakness, peripheral neuritis, rhabdomyolysis

Ocular: Optic neuritis, photophobia, diplopia

Otic: Ototoxicity (deafness), tinnitus

Miscellaneous: Systemic lupus erythematosus

Signs and Symptoms of Overdose Arthralgia, blurred vision, coma, deafness, dizziness, encephalopathy, eosinophilia, exfoliative dermatitis, fever, hallucinations, hyperglycemia, hyperkalemia, hyperreflexia, hyperthermia, hypoglycemia, intractable seizures in acute overdose (>40 mg/kg), memory loss, meningitis, metabolic acidosis, myoclonus, myoglobinuria, nausea, neuropathy (peripheral), nystagmus, paresthesia, rhabdomyolysis, slurred speech, stupor, vomiting

Chronic overdosage has similar toxicities, though early signs of acute overdosage (nausea, vomiting) may not occur. Agranulocytosis, granulocytopenia, hypotension, leukocytosis, leukopenia, neutropenia, tachycardia

Admission Criteria/Prognosis Admit any patient who is symptomatic 6 hours postingestion or ingestions >20 mg/kg

Pharmacodynamics/Kinetics

Absorption: Rapid and complete; rate can be slowed with food

Distribution: All body tissues and fluids including CSF; crosses placenta; enters breast milk

Protein binding: 10% to 15%

Metabolism: Hepatic with decay rate determined genetically by acetylation phenotype

Half-life elimination: Fast acetylators: 30-100 minutes; Slow acetylators: 2-5 hours; may be prolonged with hepatic or severe renal impairment

Time to peak, serum: 1-2 hours

Excretion: Urine (75% to 95%); feces; saliva

Dosage

Oral, I.M. (recommendations often change due to resistant strains and newly developed information; consult *MMWR Morb Mortal Wkly Rep* for current CDC recommendations):

Children: 10-20 mg/kg/day in 1-2 divided doses (maximum: 300 mg total dose)

Prophylaxis: 10 mg/kg/day (up to 300 mg total dose) for 12 months

Adults: 5 mg/kg/day (usual dose is 300 mg)

Disseminated disease: 10 mg/kg/day in 1-2 divided doses

Treatment should be continued for 9 months with rifampin or for 6 months with rifampin and pyrazinamide

Prophylaxis: 300 mg/day for 12 months

American Thoracic Society and CDC currently recommend twice weekly therapy as part of a short-course regimen which follows 1-2 months of daily treatment for uncomplicated pulmonary tuberculosis in compliant patients

Children: 20-40 mg/kg/dose (up to 900 mg) twice weekly

Adults: 15 mg/kg/dose (up to 900 mg) twice weekly

Dosing adjustment in hepatic impairment: Dose should be reduced in severe hepatic disease

Stability Protect oral dosage forms from light

Monitoring Parameters Periodic liver function tests; monitoring for prodromal signs of hepatitis

Administration

Should be administered 1 hour before or 2 hours after meals on an empty stomach.

Contraindications Hypersensitivity to isoniazid or any component of the formulation; acute liver disease; previous history of hepatic damage during isoniazid therapy

Warnings Use with caution in patients with renal impairment and chronic liver disease. **[U.S. Boxed Warning]: Severe and sometimes fatal hepatitis may occur or develop even after many months of treatment.** Patients must report any prodromal symptoms of hepatitis, such as fatigue, weakness, malaise, anorexia, nausea, or vomiting. Malnourished patients should receive concomitant pyridoxine therapy. Periodic ophthalmic examinations are recommended even when usual symptoms do not occur; pyridoxine (10-50 mg/day) is recommended in individuals likely to develop peripheral neuropathies.

Dosage Forms

[DSC] = Discontinued product

Injection, solution (Nydrazid®): 100 mg/mL (10 mL) [DSC]

Syrup: 50 mg/5 mL (473 mL) [orange flavor]

Tablet: 100 mg, 300 mg

Reference Range

Therapeutic: 1-7 mcg/mL (SI: 7-51 µmol/L)

Toxic: >20 mcg/mL (SI: 146 µmol/L)

Overdosage/Treatment

Decontamination: **Do not** use ipecac; gastric lavage within 1 hour (protect airway if gag reflex is negative) with activated charcoal (lavage if obtunded)

Supportive therapy: Treat seizures with diazepam while awaiting pyridoxine; refractory seizures should be treated with thiopental or other short-acting barbiturates, phenytoin is **not** useful in treating isoniazid induced seizures; acidosis should be appropriately treated with sodium bicarbonate; early consideration of intubation is recommended. Pyridoxine has been shown to be effective in the treatment of intoxication, especially when seizures occur. Pyridoxine I.V. is administered on a milligram to milligram dose. If the amount of isoniazid ingested is unknown, 5 g of pyridoxine should be given over 3-5 minutes (70 mg/kg in children) and may be followed by an additional 5 g in 30 minutes; phenytoin is not useful; pyridoxine can also be useful for coma or optic neuropathy. Propofol use has not been studied. Because of the severe morbidity and high mortality rates with isoniazid overdose, patients who are asymptomatic after an overdose, should be monitored for 4-6 hours. Acute ingestions over 80 mg/kg should be given pyridoxine.

Enhancement of elimination: Dialysis may be useful (dialyzable 50% to 100%) as is hemoperfusion in refractory cases; exchange transfusion has been used successfully

Antidote(s)

● Pyridoxine [ANTIDOTE]

Test Interactions False-positive urinary glucose with Clinitest®

Drug Interactions

Substrate of CYP2E1 (major); Inhibits CYP1A2 (weak), 2A6 (moderate), 2C9 (weak), 2C19 (strong), 2D6 (moderate), 2E1 (moderate), 3A4 (strong); Induces CYP2E1 (after discontinuation) (weak)

Acetaminophen: Isoniazid may enhance the adverse/toxic effect of acetaminophen.

Antacids: Antacids may decrease the absorption of isoniazid.

Benzodiazepines (metabolized by oxidation): Isoniazid may decrease the metabolism, via CYP isoenzymes, of benzodiazepines (metabolized by oxidation).

Carbamazepine: Isoniazid may decrease the metabolism of carbamazepine.

Cycloserine: Cycloserine may enhance the CNS depressant effect of isoniazid.

CYP2A6 substrates: Isoniazid may increase the levels/effects of CYP2A6 substrates. Example substrates include dexmedetomidine and ifosfamide.

CYP2C19 substrates: Isoniazid may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

CYP2D6 substrates: Isoniazid may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Isoniazid may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP2E1 substrates: Isoniazid may increase the levels/effects of CYP2E1 substrates. Example substrates include inhalational anesthetics, theophylline, and trimethadione.

ISOSORBIDE DINITRATE

CYP3A4 substrates: Isoniazid may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Disulfiram: Isoniazid may enhance the adverse/toxic effect of disulfiram. Phenytoin: Isoniazid may decrease the metabolism, via CYP isoenzymes, of phenytoin.

Theophylline: Isoniazid may decrease the metabolism, via CYP isoenzymes, of theophylline derivatives.

Valproic Acid: Isoniazid may increase the serum concentration of valproic acid.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk/compatible

Additional Information Lethal dose: 80-150 mg/kg; Toxic dose: 1.5 g
Due to mild inhibition of monoamine oxidase by isoniazid, an interaction with tyramine containing foods may occur; children with low milk and low meat intake should receive concomitant pyridoxine therapy; most combination antituberculin products contain INH which generally should be regarded as the more significant toxin.

Isosorbide Dinitrate

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 87-33-2

U.S. Brand Names Dilatrate®-SR; Isordil®

Synonyms ISD; ISDN

Use Prevention and treatment of angina pectoris; for congestive heart failure; to relieve pain, dysphagia, and spasm in esophageal spasm with GE reflux

Unlabeled/Investigational Use Esophageal spastic disorders

Mechanism of Action Reduces cardiac oxygen demand by decreasing left ventricular pressure and systemic vascular resistance by dilating coronary arteries and improving collateral flow to ischemic regions

Adverse Reactions

Cardiovascular: **Postural hypotension, cutaneous flushing of head, neck, and clavicular area**; tachycardia, sinus tachycardia, tachycardia (supraventricular)

Central nervous system: **Dizziness, headache, lightheadedness**, psychosis, visual hallucinations, seizures

Dermatologic: Rash, exfoliative dermatitis

Gastrointestinal: Nausea, GI upset, diarrhea, vomiting

Neuromuscular & skeletal: **Weakness**

Signs and Symptoms of Overdose Cough, cyanosis, dyspepsia, heart palpitations, hypotension, methemoglobin formation, ptosis, throbbing headache, urinary frequency, visual disturbances

Pharmacodynamics/Kinetics

Onset of action: Sublingual tablet: 2-10 minutes; Chewable tablet: 3 minutes; Oral tablet: 45-60 minutes

Duration: Sublingual tablet: 1-2 hours; Chewable tablet: 0.5-2 hours; Oral tablet: 4-6 hours

Metabolism: Extensively hepatic to conjugated metabolites, including isosorbide 5-mononitrate (active) and 2-mononitrate (active)

Half-life elimination: Parent drug: 1-4 hours; Metabolite (5-mononitrate): 4 hours

Excretion: Urine and feces

Dosage

Adults:

Oral: 5-40 mg every 6 hours or 40-80 mg every 8-12 hours in sustained release dosage form

Chewable: 5-10 mg every 2-3 hours

Sublingual: 2.5-10 mg every 4-6 hours

Monitoring Parameters Monitor for orthostasis

Administration Do not administer around-the-clock; the first dose of nitrates should be administered in a physician's office to observe for maximal cardiovascular dynamic effects and adverse effects (orthostatic blood pressure drop, headache); when immediate release products are

prescribed twice daily (recommend 7 AM and noon); for 3 times/day dosing (recommend 7 AM, noon, and 5 PM); when sustained-release products are indicated, suggest once a day in morning or via twice daily dosing at 8 AM and 2 PM. Do not crush sublingual tablets.

Contraindications Hypersensitivity to isosorbide dinitrate or any component of the formulation; hypersensitivity to organic nitrates; concurrent use with phosphodiesterase-5 (PDE-5) inhibitors (sildenafil, tadalafil, or vardenafil); angle-closure glaucoma (intraocular pressure may be increased); head trauma or cerebral hemorrhage (increase intracranial pressure); severe anemia

Warnings Severe hypotension can occur. Use with caution in volume depletion, hypotension, and right ventricular infarctions. Paradoxical bradycardia and increased angina pectoris can accompany hypotension. Postural hypotension can also occur. Tolerance does develop to nitrates and appropriate dosing is needed to minimize this. Safety and efficacy have not been established in pediatric patients. Nitrate may aggravate angina caused by hypertrophic cardiomyopathy. Avoid concurrent use with sildenafil.

Dosage Forms

[DSC] = Discontinued product

Capsule, sustained release (Dilatrate®-SR): 40 mg

Tablet: 5 mg, 10 mg, 20 mg, 30 mg

Isordil®: 5 mg, 10 mg [DSC], 20 mg [DSC], 30 mg [DSC], 40 mg

Tablet, extended release (Isochron™): 40 mg

Tablet, sublingual: 2.5 mg, 5 mg

Isordil®: 2.5 mg, 5 mg, 10 mg [DSC]

Reference Range Peak isosorbide plasma levels after a 5 mg oral and sublingual dose: 3.1 mcg/L and 8.9 mcg/L, respectively

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Formation of methemoglobinemia is dose related and unusual in normal doses; high levels can cause signs and symptoms of hypoxemia; treatment consists of placing patient in recumbent position and administering fluids; alpha-adrenergic vasopressors may be required; treat methemoglobinemia with oxygen and methylene blue at a dose of 1-2 mg/kg slow I.V.; treat hypotension with isotonic fluid and Trendelenburg positioning; pressors are rarely necessary unless ingestion is severe

Enhancement of elimination: Hemodialysis is not useful

Antidote(s)

- Methylene Blue [ANTIDOTE]

Diagnostic Procedures

- Methemoglobin, Blood

Test Interactions ↓ cholesterol (S)

Drug Interactions

Substrate of CYP3A4 (major)

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of isosorbide dinitrate. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of isosorbide dinitrate.

Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Sildenafil, tadalafil, vardenafil: Significant reduction of systolic and diastolic blood pressure with concurrent use (contraindicated). Do not administer sildenafil, tadalafil, or vardenafil within 24 hours of a nitrate preparation.

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Isosorbide Mononitrate

CAS Number 16051-77-7

U.S. Brand Names Imdur®; Ismo®; Monoket®

Synonyms ISMN

Use Long-acting metabolite of the vasodilator isosorbide dinitrate used for the prophylactic treatment of angina pectoris

Unlabeled/Investigational Use To prevent esophageal variceal bleeding

Mechanism of Action Prevailing mechanism of action for nitroglycerin (and other nitrates) is systemic venodilation, decreasing preload as measured by pulmonary capillary wedge pressure and left ventricular end diastolic volume and pressure; the average reduction in LVEDV is 25% at rest, with a corresponding increase in ejection fractions of 50% to 60%. This effect improves congestive symptoms in heart failure and improves the myocardial perfusion gradient in patients with coronary artery disease.

Adverse Reactions

Cardiovascular: Angina pectoris, arrhythmias, fibrillation (atrial), hypotension, palpitations, postural hypotension, premature ventricular contractions, supraventricular tachycardia, syncope, edema, sinus bradycardia, bundle branch block, flutter (atrial), chest pain, tachycardia (supraventricular)

Central nervous system: Headache (duration 2-3 hours), dizziness, malaise, agitation, anxiety, confusion, hypoesthesia, insomnia, nervousness, nightmares, vertigo
 Dermatologic: Pruritus, rash
 Gastrointestinal: Nausea, vomiting, abdominal pain, diarrhea, dyspepsia, tenesmus, increased appetite, tooth disorder, hemorrhoids
 Genitourinary: Impotence, urinary frequency, dysuria
 Hematologic: Methemoglobinemia (rarely), thrombocytopenia
 Neuromuscular & skeletal: Neck stiffness, rigors, arthralgia, dyscoordination, weakness
 Ocular: Blurred vision, diplopia
 Respiratory: Bronchitis, pneumonia, upper respiratory tract infection, rhinitis
 Miscellaneous: Cold sweat

Signs and Symptoms of Overdose Coma, diaphoresis, flushing, hypotension, metabolic acidosis, methemoglobinemia, palpitations, tachycardia, throbbing headache, visual disturbances. High levels of methemoglobinemia can cause signs and symptoms of hypoxemia.

Pharmacodynamics/Kinetics

Onset of action: 30-60 minutes
 Absorption: Nearly complete and low intersubject variability in its pharmacokinetic parameters and plasma concentrations
 Metabolism: Hepatic
 Half-life elimination: Mononitrate: ~4 hours
 Excretion: Urine and feces

Dosage

Adults: Oral:
 Regular tablet: 20 mg twice daily separated by 7 hours
 Extended release tablet (Imdur[®]): Initial: 30-60 mg once daily; after several days the dosage may be increased to 120 mg/day (given as two 60 mg tablets); daily dose should be taken in the morning upon arising; maximum: 240 mg/day
 Asymmetrical dosing regimen of 7 AM and 3 PM or 9 AM and 5 PM to allow for a nitrate-free dosing interval to minimize nitrate tolerance
 Esophageal variceal rebleeding: 80 mg once daily of nadolol (titrate until resting heart is reduced by 25% or at 55 beats/minute over a period of 5 days); following nadolol adjustment, isosorbide mononitrate can be added to a maximum oral dose of 40 mg twice daily
 Dosing adjustment in renal impairment: Not necessary for elderly or patients with altered renal or hepatic function

Stability Tablets should be stored in a tight container at room temperature of 15°C to 30°C (59°F to 86°F)

Monitoring Parameters Monitor for orthostasis, increased hypotension
Administration Do not administer around-the-clock; Monoket[®] and Ismo[®] should be scheduled twice daily with doses 7 hours apart (8 AM and 3 PM); Imdur[®] may be administered once daily. Extended release tablets should not be chewed or crushed. Should be swallowed with a half-glassful of fluid.

Contraindications Hypersensitivity to isosorbide or any component of the formulation; hypersensitivity to organic nitrates; concurrent use with phosphodiesterase-5 (PDE-5) inhibitors (sildenafil, tadalafil, or vardenafil); angle-closure glaucoma (intraocular pressure may be increased); head trauma or cerebral hemorrhage (increase intracranial pressure); severe anemia

Warnings Severe hypotension can occur. Use with caution in volume depletion, hypotension, and right ventricular infarctions. Paradoxical bradycardia and increased angina pectoris can accompany hypotension. Orthostatic hypotension can also occur. Ethanol can accentuate this. Tolerance does develop to nitrates and appropriate dosing is needed to minimize this (drug-free interval). Safety and efficacy have not been established in pediatric patients. Nitrates may aggravate angina caused by hypertrophic cardiomyopathy. Avoid concurrent use with sildenafil.

Dosage Forms Tablet: 10 mg, 20 mg

Ismo[®]: 20 mg
 Monoket[®]: 10 mg, 20 mg

Tablet, extended release (Imdur[®]): 30 mg, 60 mg, 120 mg

Reference Range Peak serum isosorbide mononitrate level after a 40 mg dose: ~706 ng/mL; serum levels of 100-500 ng/mL are considered therapeutic

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Formation of methemoglobinemia is dose related and unusual in normal doses; high levels can cause signs and symptoms of hypoxemia; treatment consists of placing patient in recumbent position and administering fluids; alpha-adrenergic vasopressors may be required; treat methemoglobinemia with oxygen and methylene blue at a dose of 1-2 mg/kg I.V. slowly; treat hypotension with isotonic fluid and Trendelenburg position; pressors rarely necessary unless ingestion is severe

Enhancement of elimination: Hemodialysis is not useful; hemodialysis can decrease peak levels by 20% to 30% and result in plasma clearance of 81 mL/minute

Test Interactions May interfere with colorimetric cholesterol determinations resulting in falsely low cholesterol levels

Drug Interactions Substrate of CYP3A4

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of isosorbide mononitrate. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of isosorbide mononitrate. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nifedipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Sildenafil, tadalafil, vardenafil: Significant reduction of systolic and diastolic blood pressure with concurrent use (contraindicated). Do not administer sildenafil, tadalafil, or vardenafil within 24 hours of a nitrate preparation.

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Additional Information Methemoglobin levels >10% may occur with ingestions >2 mg/kg; it appears that age and serum creatinine levels are inversely associated with development of vascular headache due to nitrates; risk for headache decreases by ~40% for at 10 year increase in age and is 5 times less likely in patients with serum creatinine levels >133 µmol/L as opposed to levels <97 µmol/L

Isotretinoin

Related Information

• Vitamin A

CAS Number 4759-48-2

U.S. Brand Names Accutane[®], Amnesteem[™], Claravis[™], Sotret[®]

Synonyms 13-*cis*-Retinoic Acid

Use Treatment of severe recalcitrant nodular acne unresponsive to conventional therapy

Unlabeled/Investigational Use Investigational: Treatment of children with metastatic neuroblastoma or leukemia that does not respond to conventional therapy

Mechanism of Action Reduces sebaceous gland size and reduces sebum production; regulates cell proliferation and differentiation

Adverse Reactions

Cardiovascular: Vasculitis

Central nervous system: CNS depression, headache, tiredness, mood changes, psychosis, pseudotumor cerebri

Dermatologic: **Dry skin**, skin rash, skin peeling on hands or soles of feet, **pruritus**, alopecia, **photosensitivity**, desquamation (scaling), pemphigus, Beau's lines, brittle fingernails, fingernail dystrophy, **cheilitis**, hypertrichosis, erythema multiforme, acne, toxic epidermal necrolysis, xerosis, erythema nodosum, exanthem, cutaneous vasculitis

Endocrine & metabolic: Growth suppression, hypertriglyceridemia, hypercalcemia, **increased serum concentration of triglycerides**, thyrotoxicosis, gynecomastia

Gastrointestinal: Stomach upset, abdominal pain, inflammatory bowel disease, anorexia, nausea, vomiting, ageusia, **xerostomia**, loss of sour taste, bleeding of gums, gastrointestinal vasculitis

Hematologic: Thrombocytopenia, agranulocytosis, hemolysis, decreased hemoglobin and hematocrit

Hepatic: Hepatitis

Local: **Burning**

Neuromuscular & skeletal: **Myalgia**, skeletal hyperostosis, acute myopathy, rhabdomyolysis (rare), **back pain** (29% in pediatric patients), decreased bone mineral density, acute arthritis, **bone pain**, **arthralgia**

Ocular: **Burning eyes**, conjunctivitis, **redness**, **itching of eye**, dry eyes, photophobia, optic neuropathy, cataract, blepharoconjunctivitis (dose related)

Renal: Hypercalciuria, renal vasculitis

Respiratory: **Epistaxis**, **dry nose**, pleural effusion, pulmonary vasculitis

Miscellaneous: Increased erythrocyte sedimentation rate, polyarteritis-nodosa-like vasculitis, fixed drug eruption, thyroglossal duct cyst, keloid formation, diaphoresis

Signs and Symptoms of Overdose All signs and symptoms have been transient. Abdominal pain, acro-dynia, ataxia, cheilosis, depression, dermatitis, desquamation, dizziness, dry eyes, eczema, ejaculatory disturbances, flushing, headache, hematuria, hypercalcemia, hyperthyroidism, hyperuricemia, neutropenia, photophobia, tachypnea, vomiting

Pharmacodynamics/Kinetics

Distribution: Crosses placenta

Protein binding: 99% to 100%; primarily albumin

Metabolism: Hepatic via CYP2B6, 2C8, 2C9, 2D6, 3A4; forms metabolites; major metabolite: 4-oxo-isotretinoin (active)

Half-life elimination: Terminal: Parent drug: 21 hours; Metabolite: 21-24 hours

Time to peak, serum: 3-5 hours

Excretion: Urine and feces (equal amounts)

Dosage

Oral:

Children: Maintenance therapy for neuroblastoma (investigational): 100-250 mg/m²/day in 2 divided doses

Children and Adults: Severe recalcitrant nodular acne: 0.5-2 mg/kg/day in 2 divided doses (dosages as low as 0.05 mg/kg/day have been reported to be beneficial) for 15-20 weeks or until the total cyst count decreases by 70%, whichever is sooner. A second course of therapy may be initiated after a period of ≥ 2 months off therapy.

Dosing adjustment in hepatic impairment: Dose reductions empirically are recommended in hepatitis disease

Stability Store at room temperature and protect from light

Monitoring Parameters CBC with differential and platelet count, baseline sedimentation rate, glucose, CPK

Pregnancy test (for all female patients of childbearing potential): Two negative tests with a sensitivity of at least 25 mIU/mL prior to beginning therapy (the second performed during the first five days of the menstrual period immediately preceding the start of therapy); monthly tests to rule out pregnancy prior to refilling prescription.

Lipids: Prior to treatment and at weekly or biweekly intervals until response to treatment is established. Test should not be performed <36 hours after consumption of ethanol.

Liver function tests: Prior to treatment and at weekly or biweekly intervals until response to treatment is established.

Administration Administer with food. Capsules can be swallowed, or chewed and swallowed. The capsule may be opened with a large needle and the contents placed on applesauce or ice cream for patients unable to swallow the capsule. Whole capsules should be swallowed with a full glass of liquid.

Contraindications Hypersensitivity to isotretinoin or any component of the formulation; sensitivity to parabens, vitamin A, or other retinoids; pregnancy

Warnings This medication should only be prescribed by prescribers competent in treating severe recalcitrant nodular acne, are experienced in the use of systemic retinoids, and are participating in the pregnancy prevention programs authorized by the FDA and product manufacturer. Use with caution in patients with diabetes mellitus, hypertriglyceridemia; acute pancreatitis and fatal hemorrhagic pancreatitis (rare) have been reported. Not to be used in women of childbearing potential unless woman is capable of complying with effective contraceptive measures. Patients must select and commit to two forms of contraception. Therapy is begun after two negative pregnancy tests; effective contraception must be used for at least 1 month before beginning therapy, during therapy, and for 1 month after discontinuation of therapy. Prescriptions should be written for no more than a 1-month supply, and pregnancy testing and counseling should be repeated monthly. **[U.S. Boxed Warning]: Because of the high likelihood of teratogenic effects (~20%), do not prescribe isotretinoin for women who are or who are likely to become pregnant while using the drug (see Additional Information for details).** Male and female patients must be enrolled in the manufacturer-sponsored and FDA-approved monitoring programs.

Depression, psychosis, aggressive or violent behavior, and changes in mood. Rarely, suicidal thoughts and actions have been reported during isotretinoin usage. All patients should be observed closely for symptoms of depression or suicidal thoughts. Discontinuation of treatment alone may not be sufficient, further evaluation may be necessary. Cases of pseudotumor cerebri (benign intracranial hypertension) have been reported, some with concomitant use of tetracycline (avoid using together). Patients with papilledema, headache, nausea, vomiting, and visual disturbances should be referred to a neurologist and treatment with isotretinoin discontinued. Hearing impairment, which can continue after therapy is discontinued, may occur. Clinical hepatitis, elevated liver enzymes, inflammatory bowel disease, skeletal hyperostosis, premature epiphyseal closure, vision impairment, corneal opacities, and decreased night vision have also been reported with the use of isotretinoin. Bone mineral density may decrease; use caution in patients with a genetic predisposition to bone disorders (ie osteoporosis, osteomalacia) and with disease states or concomitant medications that can induce bone disorders. Patients may be at risk when participating in activities with repetitive impact (such as sports). Safety of long-term use is not established and is not recommended.

Dosage Forms

Capsule:

Accutane®: 10 mg, 20 mg, 40 mg [contains soybean oil and parabens]

Amnesteem™: 10 mg, 20 mg, 40 mg [contains soybean oil]

Claravis™: 10 mg, 20 mg, 40 mg

Sotret®: 10 mg, 20 mg, 30 mg, 40 mg [contains soybean oil]

Reference Range Therapeutic blood levels: 141-179 ng/mL

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hyperventilation, furosemide or mannitol (0.25-2 g/kg every 3-4 hours) for increased intracranial pressure

Enhancement of elimination: Due to enterohepatic recirculation, multiple dosing of activated charcoal may be effective

Drug Interactions

Carbamazepine: Clearance of carbamazepine may be increased, leading to decreased levels.

Corticosteroids: Corticosteroids may cause osteoporosis. Interactive effect with isotretinoin unknown; use with caution.

Oral contraceptives: Retinoic acid derivatives may diminish the therapeutic effect of oral contraceptives. Two forms of contraception are recommended in females of childbearing potential during retinoic acid therapy.

Phenytoin: Phenytoin may cause osteomalacia. Interactive effect with isotretinoin unknown; use with caution.

Tetracycline: Cases of pseudotumor cerebri have been reported with concurrent use; avoid combination.

Pregnancy Risk Factor X

Pregnancy Implications Major fetal abnormalities (both internal and external), spontaneous abortion, premature births and low IQ scores in surviving infants have been reported. This medication is contraindicated in females of childbearing potential unless they are able to comply with the guidelines of pregnancy prevention programs put in place by the FDA and the manufacturer of isotretinoin.

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Capsules can be swallowed, or chewed and swallowed. The capsule may be opened with a large needle and the contents placed on apple sauce or ice cream for patients unable to swallow the capsule; administer with meals

Additional Information

Females of childbearing potential must receive oral and written information reviewing the hazards of therapy and the effects that isotretinoin can have on a fetus. Therapy should not begin without two negative pregnancy tests, one to be performed in the physician's office when qualifying the patient for treatment, the second test performed on the second day of the next normal menstrual period or 11 days after the last unprotected intercourse, whichever is last. Two forms of contraception (a primary and secondary form as described in the pregnancy prevention program materials) must be used during treatment and limitations to their use must be explained. Prescriptions should be written for no more than a 1-month supply, and pregnancy testing and counseling should be repeated monthly. Urine pregnancy test kits (for monthly pregnancy testing) and a Pregnancy Prevention Program kit (to be given to the patient prior to therapy) are provided by the manufacturer. Any cases of accidental pregnancy should be reported to the manufacturer or the FDA MedWatch Program. All patients (male and female) must read and sign the informed consent material provided in the pregnancy prevention program. Prescriptions will not be honored unless they have the yellow qualification sticker affixed.

The manufacturers of isotretinoin have developed comprehensive educational programs for healthcare providers and patients. Prior to prescribing isotretinoin, healthcare providers must be registered in one of these programs. Additional information for Accutane® and the corresponding S.M.A.R.T. (System To Manage Accutane®-Related Teratogenicity) program may be obtained from Roche Laboratories. Additional information for Amnesteem™ and the S.P.I.R.I.T.™ (System To Prevent Isotretinoin-Related Issues of Teratogenicity) program may be obtained from Bertek Pharmaceuticals. Additional information for Sotret® and I.M.P.A.R.T.™ (Isotretinoin Medication Program: Alerting you to the Risks of Teratogenicity) may be obtained from Ranbaxy Pharmaceuticals.

Itraconazole

CAS Number 84625-61-6

U.S. Brand Names Sporanox®

Use

Treatment of susceptible fungal infections in immunocompromised and immunocompetent patients including blastomycosis and histoplasmosis; indicated for aspergillosis, and onychomycosis of the toenail; treatment of onychomycosis of the fingernail without concomitant toenail infection via a pulse-type dosing regimen; has activity against *Aspergillus*, *Candida*, *Coccidioides*, *Cryptococcus*, *Sporothrix*, tinea unguium

Oral: Useful in superficial mycoses including dermatophytoses (eg, tinea capitis), pityriasis versicolor, seborrheic dermatitis, vaginal and chronic mucocutaneous candidiasis; systemic mycoses including candidiasis, meningococcal and disseminated cryptococcal infections, paracoccidioidomycosis, coccidioidomycosis; miscellaneous mycoses such as sporotrichosis, chromomycosis, leishmaniasis, fungal keratitis, alternariosis, zygomycosis

Oral solution: Treatment of oral and esophageal candidiasis

Intravenous solution: Indicated in the treatment of blastomycosis, histoplasmosis (nonmeningeal), and aspergillosis (in patients intolerant or refractory to amphotericin B therapy); empiric therapy of febrile neutropenic fever

Mechanism of Action Interferes with cytochrome P450 activity, decreasing ergosterol synthesis (principal sterol in fungal cell membrane) and inhibiting cell membrane formation

Adverse Reactions

Listed incidences are for higher doses appropriate for systemic fungal infections.

Cardiovascular: Edema, hypertension, arrhythmia, CHF

Central nervous system: Headache, fatigue, malaise, fever, dizziness, somnolence

Dermatologic: Rash, pruritus, angioedema, urticaria, alopecia, photosensitivity, Stevens-Johnson syndrome

Endocrine & metabolic: Decreased libido, hypertriglyceridemia, hypokalemia, adrenal suppression, gynecomastia, menstrual disorders

Gastrointestinal: **Nausea**, abdominal pain, anorexia, vomiting, diarrhea, constipation, gastritis

Genitourinary: Impotence

Hematologic: Neutropenia

Hepatic: Abnormal LFTs, hepatitis, hepatic failure

Neuromuscular & skeletal: Peripheral neuropathy

Otic: Tinnitus

Renal: Albuminuria

Respiratory: Pulmonary edema

Miscellaneous: Allergic reactions, anaphylactoid reactions, anaphylaxis

Pharmacodynamics/Kinetics

Absorption: Requires gastric acidity; capsule better absorbed with food, solution better absorbed on empty stomach

Distribution: V_d (average): 796 ± 185 L or 10 L/kg; highly lipophilic and tissue concentrations are higher than plasma concentrations. The highest concentrations: adipose, omentum, endometrium, cervical and vaginal mucus, and skin/nails. Aqueous fluids (eg, CSF and urine) contain negligible amounts.

Protein binding, plasma: 99.9%; metabolite hydroxy-itraconazole: 99.5%

Metabolism: Extensively hepatic via CYP3A4 into >30 metabolites including hydroxy-itraconazole (major metabolite); appears to have *in vitro* antifungal activity. Main metabolic pathway is oxidation; may undergo saturation metabolism with multiple dosing.

Bioavailability: Variable, ~55% (oral solution) in 1 small study; **Note:** Oral solution has a higher degree of bioavailability ($149\% \pm 68\%$) relative to oral capsules; should not be interchanged

Half-life elimination: Oral: After single 200 mg dose: 21 ± 5 hours; 64 hours at steady-state; I.V.: steady-state: 35 hours; steady-state concentrations are achieved in 13 days with multiple administration of itraconazole 100-400 mg/day.

Excretion: Feces (~3% to 18%); urine (~0.03% as parent drug, 40% as metabolites)

Dosage Note: Capsule: Absorption is best if taken with food, therefore, it is best to administer itraconazole after meals; Solution: Should be taken on an empty stomach.

Children: Efficacy and safety have not been established; a small number of patients 3-16 years of age have been treated with 100 mg/day for systemic fungal infections with no serious adverse effects reported. A dose of 5 mg/kg once daily was used in a pharmacokinetic study using the oral solution in patients 6 months-12 years; duration of study was 2 weeks.

Adults:

Oral:

Blastomycosis/histoplasmosis: 200 mg once daily, if no obvious improvement or there is evidence of progressive fungal disease, increase the dose in 100 mg increments to a maximum of 400 mg/day; doses >200 mg/day are given in 2 divided doses; length of therapy varies from 1 day to >6 months depending on the condition and mycological response

Aspergillosis: 200-400 mg/day

Onychomycosis: 200 mg once daily for 12 consecutive weeks

Life-threatening infections: Loading dose: 200 mg 3 times/day (600 mg/day) should be given for the first 3 days of therapy

Oropharyngeal candidiasis: Oral solution: 200 mg once daily for 1-2 weeks; in patients unresponsive or refractory to fluconazole: 100 mg twice daily (clinical response expected in 1-2 weeks)

Esophageal candidiasis: Oral solution: 100-200 mg once daily for a minimum of 3 weeks; continue dosing for 2 weeks after resolution of symptoms

I.V.: 200 mg twice daily for 4 doses, followed by 200 mg daily

Dosing adjustment in renal impairment: Not necessary; itraconazole injection is not recommended in patients with $Cl_{Cr} < 30$ mL/minute

Hemodialysis: Not dialyzable

Dosing adjustment in hepatic impairment: May be necessary, but specific guidelines are not available. Risk-to-benefit evaluation should be undertaken in patients who develop liver function abnormalities during treatment.

Monitoring Parameters Liver function in patients with pre-existing hepatic dysfunction, and in all patients being treated for longer than 1 month

Administration

Oral: Doses >200 mg/day are given in 2 divided doses; do not administer with antacids. Capsule absorption is best if taken with food, therefore, it is best to administer itraconazole after meals; solution should be taken on an empty stomach. When treating oropharyngeal and esophageal candidiasis, solution should be swished vigorously in mouth, then swallowed.

I.V.: Infuse 60 mL of the dilute solution (3.33 mg/mL = 200 mg itraconazole, pH ~4.8) over 60 minutes; flush with 15-20 mL of 0.9% sodium chloride over 30 seconds to 15 minutes

Contraindications Hypersensitivity to itraconazole, any component of the formulation, or to other azoles; concurrent administration with cisapride, dofetilide, ergot derivatives, levomethadyl, lovastatin, midazolam, pimozide, quinidine, simvastatin, or triazolam; treatment of onychomycosis in patients with evidence of left ventricular dysfunction, CHF, or a history of CHF

Warnings Discontinue if signs or symptoms of CHF or neuropathy occur during treatment. **[U.S. Boxed Warning]: Rare cases of serious cardiovascular adverse events (including death), ventricular tachycardia, and torsade de pointes have been observed due to increased cisapride, pimozide, quinidine, dofetilide or levomethadyl concentrations induced by itraconazole; concurrent use contraindicated. Use with caution in patients with left ventricular dysfunction or a history of CHF; not recommended for treatment of onychomycosis in these patients.** Not recommended for use in patients with active liver disease, elevated liver enzymes, or prior hepatotoxic reactions to other drugs. Itraconazole has been associated with rare cases of serious hepatotoxicity (including fatal cases and cases within the first week of treatment); treatment should be discontinued in patients who develop clinical symptoms of liver dysfunction or abnormal liver function tests during itraconazole therapy except in cases where expected benefit exceeds risk. Large differences in itraconazole pharmacokinetic parameters have been observed in cystic fibrosis patients receiving the solution; if a patient with cystic fibrosis does not respond to therapy, alternate therapies should be considered. Due to differences in bioavailability, oral capsules and oral solution **cannot be used interchangeably.** Intravenous formulation should be used with caution in renal impairment; consider conversion to oral therapy if renal dysfunction/toxicity is noted. Initiation of treatment with oral solution is not recommended in patients at immediate risk for systemic candidiasis (eg, patients with severe neutropenia).

Dosage Forms

Capsule: 100 mg

Injection, solution: 10 mg/mL (25 mL) [packaged in a kit containing sodium chloride 0.9% (50 mL); filtered infusion set (1)]

Solution, oral: 100 mg/10 mL (150 mL) [cherry flavor]

Reference Range Antifungal activity associated with serum itraconazole levels >500 mcg/L

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal would not be expected to be helpful

Drug Interactions **Substrate** of CYP3A4 (major); **Inhibits** CYP3A4 (strong)

Antacids: May decrease serum concentration of itraconazole. Administer antacids 1 hour before or 2 hours after itraconazole capsules.

Alfentanil: Serum concentrations may be increased; monitor.

Anticonvulsants: Itraconazole may increase the serum concentration of carbamazepine; carbamazepine, phenobarbital, and phenytoin may decrease the serum concentration of itraconazole.

Benzodiazepines: Alprazolam, diazepam, temazepam, triazolam, and midazolam serum concentrations may be increased; consider a benzodiazepine not metabolized by CYP3A4 (such as lorazepam) or another antifungal that is metabolized by CYP3A4

Bupirone: Serum concentrations may be increased; monitor for sedation

Busulfan: Serum concentrations may be increased; avoid concurrent use Calcium channel blockers: Serum concentrations may be increased (applies to those agents metabolized by CYP3A4, including felodipine, nifedipine, and verapamil); consider another agent instead of a calcium channel blocker, another antifungal, or reduce the dose of the calcium channel blocker; monitor blood pressure

Cisapride: Serum concentration is increased which may lead to malignant arrhythmias; concurrent use is contraindicated

Corticosteroids: Serum levels/effects of the corticosteroid may be increased; use caution.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of itraconazole. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 substrates: Itraconazole may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozone are generally contraindicated with strong CYP3A4 inhibitors.

Didanosine: May decrease absorption of itraconazole (due to buffering capacity of oral solution); applies only to oral solution formulation of didanosine

Digoxin: Serum concentrations may be increased; monitor.

Disopyramide: Serum levels/effects (including QT_c prolongation) may be increased; use caution.

Docetaxel: Serum concentrations may be increased; avoid concurrent use

Dofetilide: Serum levels/toxicity may be increased; concurrent use is contraindicated.

Eletriptan: Serum level/toxicity of eletriptan may be increased; use caution.

Ergot alkaloids: Toxicity (vasospasm, ischemia) may be significantly increased by itraconazole; concurrent use is contraindicated.

Erythromycin (and clarithromycin): May increase serum concentrations of itraconazole.

H₂ blockers: May decrease itraconazole absorption. Itraconazole depends on gastric acidity for absorption. Avoid concurrent use.

Halofantrine: Serum levels/effects (including QT_c prolongation) may be increased; use caution.

HMG-CoA reductase inhibitors (except pravastatin and fluvastatin): Serum concentrations may be increased. The risk of myopathy/rhabdomyolysis may be increased. Switch to pravastatin/fluvastatin or suspend treatment during course of itraconazole therapy.

Hypoglycemic agents, oral: Serum concentrations may be increased; monitor.

Immunosuppressants: Cyclosporine, sirolimus, and tacrolimus: Serum concentrations may be increased; monitor serum concentrations and renal function.

Levomethadyl: Serum levels/effects may be increased by itraconazole, potentially resulting in malignant arrhythmia; concurrent use is contraindicated.

Nevirapine: May decrease serum concentrations of itraconazole; monitor

Oral contraceptives: Efficacy may be reduced by itraconazole (limited data); use barrier birth control method during concurrent use

Pimozone: Serum levels/toxicity may be increased; concurrent use is contraindicated.

Protease inhibitors: May increase serum concentrations of itraconazole. Includes amprenavir, indinavir, nelfinavir, ritonavir, and saquinavir may be increased by itraconazole.

Proton pump inhibitors: May decrease itraconazole absorption. Itraconazole depends on gastric acidity for absorption. Avoid concurrent use (includes omeprazole, lansoprazole).

Quinidine: Serum levels may be increased. Concurrent use is contraindicated.

Rifabutin: Serum concentrations may be increased; monitor.

Sildenafil: Serum concentrations may be increased by itraconazole; consider dosage reduction. A maximum sildenafil dose of 25 mg in 48 hours is recommended with other strong CYP3A4 inhibitors.

Tadalafil: Serum concentrations may be increased by itraconazole. A maximum tadalafil dose of 10 mg in 72 hours is recommended with strong CYP3A4 inhibitors.

Trimetrexate: Serum concentrations may be increased; monitor

Vardenafil: Serum concentrations may be increased by itraconazole. If itraconazole dose is 200 mg/day, limit vardenafil dose to a maximum of 5 mg/24 hours. If itraconazole dose is 400 mg/day, limit vardenafil dose to a maximum of 2.5 mg/24 hours.

Warfarin: Anticoagulant effects may be increased; monitor INR and adjust warfarin's dose as needed

Vinca alkaloids: Serum concentrations may be increased; avoid concurrent use

Zolpidem: Serum levels may be increased; monitor

Pregnancy Risk Factor C

Pregnancy Implications Should not be used to treat onychomycosis during pregnancy. Effective contraception should be used during treatment and for 2 months following treatment. Congenital abnormalities have been reported during postmarketing surveillance, but a causal relationship has not been established.

Lactation Enters breast milk/not recommended

Ivermectin

CAS Number 70161-11-4; 70209-81-3; 70288-86-7

U.S. Brand Names Stromectol®

Use Treatment of the following infections: Strongyloidiasis of the intestinal tract due to the nematode parasite *Strongyloides stercoralis*. Onchocerciasis due to the nematode parasite *Onchocerca volvulus*. Ivermectin is only active against the immature form of *Onchocerca volvulus*, and the intestinal forms of *Strongyloides stercoralis*.

Unlabeled/Investigational Use Has been used for other parasitic infections including *Ascaris lumbricoides*, Bancroftian filariasis, *Brugia malayi*, scabies, *Enterobius vermicularis*, *Mansonella ozzardi*, *Trichuris trichiura*.

Mechanism of Action Ivermectin is a semisynthetic antihelminthic agent; it binds selectively and with strong affinity to glutamate-gated chloride ion channels which occur in invertebrate nerve and muscle cells. This leads to increased permeability of cell membranes to chloride ions then hyperpolarization of the nerve or muscle cell, and death of the parasite.

Adverse Reactions

Frequency not defined.

Cardiovascular: Hypotension, mild ECG changes, orthostasis, peripheral and facial edema, transient tachycardia

Central nervous system: Dizziness, headache, hyperthermia, insomnia, somnolence, vertigo

Dermatologic: Pruritus, rash, urticaria, toxic epidermal necrolysis

Gastrointestinal: Abdominal pain, anorexia, constipation, diarrhea, nausea, vomiting

Hematologic: Anemia, eosinophilia, leukopenia

Hepatic: ALT/AST increased

Neuromuscular & skeletal: Myalgia, tremor, weakness

Ocular: Blurred vision, mild conjunctivitis, punctate opacity

Respiratory: Asthma exacerbation

Mazzotti reaction (with onchocerciasis): Arthralgia, edema, fever, lymphadenopathy, ocular damage, pruritus, rash, synovitis

Signs and Symptoms of Overdose Abdominal pain, hypotension, lethargy, pallor, pruritus, tachycardia, urticaria, vomiting

Pharmacodynamics/Kinetics

Onset of action: Peak effect: 3-6 months

Absorption: Well absorbed

Distribution: Does not cross blood-brain barrier

Half-life elimination: 16-35 hours

Metabolism: Hepatic (>97%)

Excretion: Urine (<1%); feces

Dosage

Oral: Children ≥ 15 kg and Adults:

Strongyloidiasis: 200 mcg/kg as a single dose; follow-up stool examinations

Onchocerciasis: 150 mcg/kg as a single dose; retreatment may be required every 3-12 months until the adult worms die

Monitoring Parameters Skin and eye microfilarial counts, periodic ophthalmologic exams

Administration Administer on an empty stomach with water.

Contraindications Hypersensitivity to ivermectin or any component of the formulation

Warnings Data have shown that antihelminthic drugs like ivermectin may cause cutaneous and/or systemic reactions (Mazzotti reaction) of varying severity including ophthalmological reactions in patients with onchocerciasis. These reactions are probably due to allergic and inflammatory responses to the death of microfilariae. Patients with hyper-reactive onchodermatitis may be more likely than others to experience severe adverse reactions, especially edema and aggravation of the onchodermatitis. Repeated treatment may be required in immunocompromised patients (eg, HIV); control of extraintestinal strongyloidiasis may necessitate suppressive (once monthly) therapy. Pretreatment assessment for *Loa loa* infection is recommended in any patient with significant exposure to endemic areas (West and Central Africa); serious and/or fatal encephalopathy has been reported during treatment in patients with loiasis. Safety and efficacy in children < 15 kg have not been established.

Dosage Forms Tablet [scored]: 3 mg

Reference Range Doses of 50 mcg/kg can result in blood ivermectin levels of 9-13 ng/mL; adverse effects do not correlate with serum concentrations

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension can be treated with I.V. fluids (ie, saline) and placement in Trendelenburg position; dopamine or norepinephrine can be used for refractory hypotension; antihistamines can be used for urticaria or pruritus

Drug Interactions Substrate of CYP3A4 (minor)

Pregnancy Risk Factor C

Pregnancy Implications Safety and efficacy have not been established in pregnant women. The WHO considers use after the first trimester as "probably acceptable."

Lactation Enters breast milk/not recommended

Additional Information Often used for prophylaxis against heartworm (*Dirofilaria immitis*) in dogs

Ketamine

Related Information

- Highlights of Recent Reports (2006) on Substance Abuse and Mental Health
- Phencyclidine
- Therapeutic Drugs Associated with Hallucinations

CAS Number 1867-66-9; 6740-88-1

U.S. Brand Names Ketalar®

Synonyms Ketamine Hydrochloride

Impairment Potential Yes

Use Induction of anesthesia; short surgical procedures; dressing changes

Mechanism of Action An N-methyl-D-aspartate (NMDA) neuroreceptor antagonist; some opiate agonist effect; while analgesic effect is rapid, laryngeal reflexes, muscle tone, and cardiopulmonary function is usually not affected; structurally related to phencyclidine

Adverse Reactions

Cardiovascular: **Tachycardia, increased cardiac output, paradoxical direct myocardial depression, hypertension**, edema, sinus tachycardia

Central nervous system: **Visual hallucinations, increased intracranial pressure, vivid dreams**, delirium, dysphoric states, dystonic reactions, psychosis, dizziness, insomnia, ataxia, malignant hyperthermia, electroencephalogram abnormalities, aggressive behavior

Gastrointestinal: Increased salivation, nausea, vomiting

Neuromuscular & skeletal: **Tonic-clonic movements, tremors**, clonus, myoclonus, muscle rigidity, hypertonus

Ocular: Diplopia, lacrimation, increased intraocular pressure, nystagmus

Respiratory: Bronchodilatation, laryngospasm

Miscellaneous: **Emergency reactions, vocalization**

Signs and Symptoms of Overdose Apnea, cardiac arrest, delirium, extrapyramidal reaction, fasciculations, hyperglycemia, insomnia, lacrimation, laryngospasm, polyneuropathy, seizures

Pharmacodynamics/Kinetics

Onset of action:

I.V.: General anesthesia: 1-2 minutes; Sedation: 1-2 minutes

I.M.: General anesthesia: 3-8 minutes

Duration: I.V.: 5-15 minutes; I.M.: 12-25 minutes

Metabolism: Hepatic via hydroxylation and N-demethylation; the metabolite norketamine is 25% as potent as parent compound

Half-life elimination: 11-17 minutes; Elimination: 2.5-3.1 hours

Excretion: Clearance: 18 mL/kg/minute

Dosage Illicit dose "snorted" by drug abusers: 50-100 mg

Anesthetic induction dose:

Oral: 4-5 mg/kg

I.M.: 5-10 mg/kg

I.V.: 1-2 mg/kg

Maintenance dose is $1/2$, up to total induction dose as needed to maintain anesthesia

Stability Do not mix with barbiturates or diazepam → precipitation may occur

Monitoring Parameters Cardiovascular effects, heart rate, blood pressure, respiratory rate, transcutaneous O₂ saturation

Administration Relative exclusion criteria to minimize the risk of sympathomimetic adverse events in adults:

- Avoid ketamine in patients with poorly controlled hypertension or ED blood pressures 140/90 or above.
- Avoid ketamine in patients with known coronary artery disease, or in older patients with risk factors for coronary artery disease

Relative exclusion criteria to minimize risk of emergence reactions in adults:

- Avoid ketamine in patients with known or suspected psychosis, even if currently stable or controlled with medications.

Drug administration in adults:

- The recommended ketamine dose is 1.5-2.0 mg/kg I.V., administered over at least 1 minute; 100 mg is a typical adult dose. There is no evidence of any greater safety or other advantage at lower doses.

- Consider prophylactic coadministration of midazolam (2-4 mg I.V.) to reduce the risk of emergence reactions and to enhance cardiovascular stability.

- I.V. access is desirable so that additional midazolam can be promptly administered in the rare event of a clinically important emergence reaction.

- Whenever possible, minimize lighting, noise, and physical contact during recovery until wakefulness is well established.

Contraindications Hypersensitivity to ketamine or any component of the formulation; elevated intracranial pressure; hypertension, aneurysms, thyrotoxicosis, congestive heart failure, angina, psychotic disorders; pregnancy

Warnings Use with caution in patients with coronary artery disease, catecholamine depletion, and tachycardia. **[U.S. Boxed Warning]: Postanesthetic emergence reactions which can manifest as vivid dreams, hallucinations, and/or frank delirium occur in 12% of patients; these reactions are less common in patients > 65 years of age and when given I.M.** Emergence reactions, confusion, or irrational behavior may occur up to 24 hours postoperatively and may be reduced by pretreatment with a benzodiazepine. May cause dependence (withdrawal symptoms on discontinuation) and tolerance with prolonged use.

Dosage Forms

Injection, solution: 50 mg/mL (10 mL); 100 mg/mL (5 mL)

Ketalar®: 10 mg/mL (20 mL); 50 mg/mL (10 mL); 100 mg/mL (5 mL)

Reference Range

An I.V. dose of 2.5 mg/kg produces an average serum ketamine concentration of 1 mg/L at 12 minutes and 0.5 mg/L at 30 minutes, while doses of 4 mg/kg can produce a peak serum ketamine level of 6.3 mg/L

Postmortem blood and urine levels from a mixed-drug fatality were reported as 1.8 mg/L and 2 mg/L, respectively

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Benzodiazepines can be utilized for delirium, dysphoric reactions, or hallucinations; extrapyramidal reaction can be treated with diphenhydramine and/or benztropine. Benzodiazepines, alpha- and beta-adrenergic blockers, or verapamil can decrease cardiac stimulation; benzodiazepines are initial choice for seizure management and adverse cardiovascular events. Cardiovascular response to labetalol may not be predictable. Atropine can be used to prevent excess salivation; positive end expiratory pressure can be used to treat laryngospasm.

Test Interactions Except for ToxiLab™ system, commercial immunoassay urine screening tests do **not** detect ketamine as phencyclidine even though it is structurally related to PCP.

Drug Interactions

Substrate (major) of CYP2B6, 2C9, 3A4

CYP2B6 inhibitors: May increase the levels/effects of ketamine. Example inhibitors include desipramine, paroxetine, and sertraline.

CYP2C9 Inhibitors may increase the levels/effects of ketamine. Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nicardipine, NSAIDs, sulfonamides and tolbutamide.

CYP3A4 inhibitors: May increase the levels/effects of ketamine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Increased effect: Barbiturates, narcotics, hydroxyzine increase prolonged recovery; nondepolarizing may increase effects

Increased toxicity: Muscle relaxants, thyroid hormones may increase blood pressure and heart rate; halothane may decrease BP

Pregnancy Risk Factor

Pregnancy Implications Crosses the placenta; fetal respiratory depression can occur

Additional Information Elevation of catecholamine levels occur. Illicit use is usually by intranasal insufflation.

Ketobemidone

CAS Number 469-79-4

Use Pain relief in the postoperative period and during acute myocardial infarction; premedication for anesthesia

Mechanism of Action Opioid compound similar to meperidine structurally

Adverse Reactions

Central nervous system: Lethargy, headache, confusion, sedation, dizziness, euphoria

Gastrointestinal: Ileus, nausea, vomiting, xerostomia, obstipation, constipation

Genitourinary: Urinary retention

Neuromuscular & skeletal: Smooth muscle spasm

Ocular: Blurred vision

Respiratory: Cough, apnea

Signs and Symptoms of Overdose Apnea, coma

Toxicodynamics/Kinetics

Duration of effect: 4-5 hours

Distribution: V_d : 2-7.8 L/kg

Metabolism: Hepatic to norketobemidone and 4'-hydroxyketobemidone

Bioavailability: Oral (34%), rectal (44%)

Half-life: 2-2.4 hours

Elimination: Renal

Dosage

I.M.: 5-7.5 mg every 6 hours

I.V.:

Patient-controlled analgesia: 2-3 mg over one minute with each dose allowable per 15 minutes

Postoperative pain: 3 mg/hour decreasing to 0.75 mg/hour after shivering cessation

Oral: 5-15 mg every 3-6 hours

Rectal: 10 mg every 3-4 hours

Reference Range Following a 10 mg I.V. dose, peak serum levels are > 500 ng/mL; following a 10 mg rectal dose, peak plasma levels range from 10-15 ng/mL; after a 10 mg oral dose, peak serum levels range from 10-30 ng/mL

Overdosage/Treatment Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at $\frac{2}{3}$ the response dose/hour) may be required

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Additional Information Often combined with a spasmolytic agent W-N-dimethyl-3,3-diphenyl 1-methylallylamine (A-29) due to its effects on smooth muscle spasm

Ketoconazole

CAS Number 65277-42-1

U.S. Brand Names Nizoral® A-D [OTC]; Nizoral®

Use Treatment of susceptible fungal infections, including candidiasis, oral thrush, blastomycosis, histoplasmosis, paracoccidioidomycosis, chronic mucocutaneous candidiasis, as well as certain recalcitrant cutaneous dermatophytoses; used topically for treatment of tinea corporis, tinea cruris, tinea versicolor and cutaneous candidiasis

Treatment of prostate cancer (androgen synthesis inhibitor)

Mechanism of Action Alters permeability of the cell wall; inhibits biosynthesis of triglycerides and phospholipids by fungi; inhibits several fungal enzymes that results in a build-up of toxic concentrations of hydrogen peroxide

Adverse Reactions

Cardiovascular: QT prolongation, vasculitis

Central nervous system: Psychosis, paranoid ideation

Dermatologic: Pruritus, rash, exfoliative dermatitis, alopecia, angioedema, xerosis, purpura, photosensitivity, exanthem, lichen planus

Endocrine & metabolic: Adrenal cortical insufficiency, gynecomastia

Gastrointestinal: Nausea, vomiting, abdominal pain, GI bleeding, anorexia, gingival hyperplasia

Hematologic: Thrombocytopenia

Hepatic: Hepatotoxicity, aminotransferase level elevation (asymptomatic)

Local: Irritation, stinging, phlebitis

Miscellaneous: Fixed drug eruption

Signs and Symptoms of Overdose Diarrhea, dizziness, headache, hypertriglyceridemia, hyperuricemia, hypothyroidism, myalgia, nausea, paresthesias, photophobia, sexual dysfunction, thrombocytopenia, vomiting

Pharmacodynamics/Kinetics

Absorption: Oral: Rapid (~75%); Shampoo: None; Gel: Minimal

Distribution: Well into inflamed joint fluid, saliva, bile, urine, breast milk, sebum, cerumen, feces, tendons, skin and soft tissues, and testes;

crosses blood-brain barrier poorly; only negligible amounts reach CSF

Protein binding: 93% to 96%

Metabolism: Partially hepatic via CYP3A4 to inactive compounds

Bioavailability: Decreases as gastric pH increases

Half-life elimination: Biphasic: Initial: 2 hours; Terminal: 8 hours

Time to peak, serum: 1-2 hours

Excretion: Feces (57%); urine (13%)

Dosage

Oral:

Children \geq 2 years: 3.3-6.6 mg/kg/day as a single dose for 1-2 weeks for candidiasis, for at least 4 weeks in recalcitrant dermatophyte infections, and for up to 6 months for other systemic mycoses

Adults: 200-400 mg/day as a single daily dose for durations as stated above

Shampoo: Apply twice weekly for 4 weeks with at least 3 days between each shampoo

Topical: Rub gently into the affected area once daily to twice daily

Dosing adjustment in hepatic impairment: Dose reductions should be considered in patients with severe liver disease

Hemodialysis: Not dialyzable (0% to 5%)

Monitoring Parameters Liver function tests

Administration

Administer oral tablets 2 hours prior to antacids to prevent decreased absorption due to the high pH of gastric contents. Cream, gel, and shampoo are for external use only.

Contraindications Hypersensitivity to ketoconazole or any component of the formulation; CNS fungal infections (due to poor CNS penetration); coadministration with ergot derivatives or cisapride is contraindicated due to risk of potentially fatal cardiac arrhythmias

Warnings

[U.S. Boxed Warning]: Ketoconazole has been associated with hepatotoxicity, including some fatalities; use with caution in patients with impaired hepatic function and perform periodic liver function tests.

[U.S. Boxed Warning]: Concomitant use with cisapride is contraindicated due to the occurrence of ventricular arrhythmias. High doses of ketoconazole may depress adrenocortical function.

Topical: Formulations may contain sulfites. Avoid exposure of gel to open flames during or immediately after application.

Dosage Forms

Cream, topical: 2% (15 g, 30 g, 60 g)

Kuric™: 2% (25 g, 75 g)

Gel, topical:

Xolegel™: 2% (15 g)

Shampoo, topical: 1% (120 mL)

Nizoral® A-D: 1% (120 mL, 210 mL)

Tablet: 200 mg

Nizoral®: 200 mg

Reference Range Therapeutic: Peak: 1-4 mg/L; Trough: \leq 1 mg/L

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal would not be expected to be helpful; not dialyzable (0% to 5%)

Drug Interactions Substrate of CYP3A4 (major); **Inhibits** CYP1A2 (strong), 2A6 (moderate), 2B6 (weak), 2C8 (weak), 2C9 (strong), 2C19 (moderate), 2D6 (moderate), 3A4 (strong)

Benzodiazepines: Alprazolam, diazepam, temazepam, triazolam, and midazolam serum concentrations may be increased; consider a benzodiazepine not metabolized by CYP3A4 (such as lorazepam) or another antifungal that is metabolized by CYP3A4. Concurrent use is contraindicated.

Bupirone: Serum concentrations may be increased; monitor for sedation

Busulfan: Serum concentrations may be increased; avoid concurrent use
Calcium channel blockers: Serum concentrations may be increased (applies to those agents metabolized by CYP3A4, including felodipine, nifedipine, and verapamil); consider another agent instead of a calcium channel blocker, another antifungal, or reduce the dose of the calcium channel blocker; monitor blood pressure

Cisapride: Serum concentration is increased which may lead to malignant arrhythmias; concurrent use is contraindicated

CYP1A2 substrates: Ketoconazole may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, fluvoxamine, mexiletine, mirtazapine, ropinirole, theophylline, and trifluoperazine.

CYP2A6 substrates: Ketoconazole may increase the levels/effects of CYP2A6 substrates. Example substrates include dexmedetomidine and ifosfamide.

CYP2C9 substrates: Ketoconazole may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

CYP2C19 substrates: Ketoconazole may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

CYP2D6 substrates: Ketoconazole may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Ketoconazole may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of ketoconazole. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 substrates: Ketoconazole may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Didanosine: May decrease absorption of ketoconazole (due to buffering capacity of oral solution); applies only to oral solution formulation of didanosine

Docetaxel: Serum concentrations may be increased; avoid concurrent use

Erythromycin (and clarithromycin): May increase serum concentrations of ketoconazole.

H₂ blockers: May decrease ketoconazole absorption. Ketoconazole depends on gastric acidity for absorption. Avoid concurrent use.

HMG-CoA reductase inhibitors (except pravastatin and fluvastatin): Serum concentrations may be increased. The risk of myopathy/rhabdomyolysis may be increased. Switch to pravastatin/fluvastatin or suspend treatment during course of ketoconazole therapy.

Immunosuppressants: Cyclosporine, sirolimus, and tacrolimus: Serum concentrations may be increased; monitor serum concentrations and renal function

Methylprednisolone: Serum concentrations may be increased; monitor

Nevirapine: May decrease serum concentrations of ketoconazole; monitor

Oral contraceptives: Efficacy may be reduced by ketoconazole (limited data); use barrier birth control method during concurrent use

Phenytoin: Serum concentrations may be increased; monitor phenytoin levels and adjust dose as needed

Protease inhibitors: May increase serum concentrations of ketoconazole. Includes amprenavir, indinavir, nelfinavir, ritonavir, and saquinavir; monitor

Proton pump inhibitors: May decrease ketoconazole absorption. Ketoconazole depends on gastric acidity for absorption. Avoid concurrent use (includes omeprazole, lansoprazole).

Quinidine: Serum levels may be increased; monitor

Rifampin: Rifampin decreases ketoconazole's serum concentration to levels which are no longer effective; avoid concurrent use.

Sildenafil: Serum concentrations may be increased by ketoconazole; consider dosage reduction. A maximum sildenafil dose of 25 mg in 48 hours is recommended with other strong CYP3A4 inhibitors.

Tadalafil: Serum concentrations may be increased by ketoconazole. A maximum tadalafil dose of 10 mg in 72 hours is recommended with strong CYP3A4 inhibitors.

Trimetrexate: Serum concentrations may be increased; monitor

Vardenafil: Serum concentrations may be increased by ketoconazole. If ketoconazole dose is 200 mg/day, limit vardenafil to a maximum of 5 mg/24 hours. If ketoconazole dose is 400 mg/day, limit vardenafil dose to a maximum of 2.5 mg/24 hours.

Warfarin: Anticoagulant effects may be increased; monitor INR and adjust warfarin's dose as needed

Vinca alkaloids: Serum concentrations may be increased; avoid concurrent use

Zolpidem: Serum levels may be increased; monitor

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic effects were noted in animal studies. There are no adequate and well-controlled studies in pregnant women.

Lactation Enters breast milk/not recommended

Nursing Implications Administer 2 hours prior to antacids H₂-receptor antagonist to prevent decreased absorption due to the high pH of gastric contents

Ketoprofen

Related Information

- Nonsteroidal Anti-inflammatory Drugs

CAS Number 22071-15-4 (Base); 57469-78-0 (Lysine); 57495-14-4 (Sodium)

U.S. Brand Names Orudis® KT [OTC]; Oruvail®

Use Acute or long-term treatment of rheumatoid arthritis and osteoarthritis; primary dysmenorrhea; mild to moderate pain

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors

Adverse Reactions

Cardiovascular: Arrhythmias, congestive heart failure, hypertension, tachycardia

Central nervous system: Headache, nervousness, dizziness, somnolence, insomnia, malaise, depression, aseptic meningitis, confusion, drowsiness, hallucinations

Dermatologic: Rash, itching, angioedema, erythema multiforme, photosensitivity, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Endocrine & metabolic: Fluid retention, hot flashes, polydipsia

Gastrointestinal: **Dyspepsia**, vomiting, diarrhea, nausea, constipation, abdominal distress/cramping/pain, flatulence, anorexia, stomatitis, gastritis, GI ulceration

Genitourinary: Urinary tract infection, cystitis

Hematologic: Agranulocytosis, anemia, bone marrow suppression, hemolytic anemia, leukopenia, thrombocytopenia

Hepatic: Hepatitis

Neuromuscular & skeletal: Peripheral neuropathy

Ocular: Visual disturbances, blurred vision, conjunctivitis, dry eyes, toxic amblyopia

Otic: Tinnitus, hearing decreased

Renal: Acute renal failure, renal function impairment, polyuria

Respiratory: Allergic rhinitis, dyspnea, epistaxis

Miscellaneous: Allergic reaction, anaphylaxis

Signs and Symptoms of Overdose Cognitive dysfunction, confusion, conjunctivitis, depression, drowsiness, dyspnea, eczema, exfoliative dermatitis, gastritis, GI bleeding, impotence, insomnia, myalgia, nausea, nephrotic syndrome, ototoxicity, photosensitivity, pseudotumor cerebri, purpura, tinnitus, vomiting, wheezing

Severe poisoning can manifest with apnea, coma, hypotension, leukocytosis, metabolic acidosis, nystagmus, renal and/or hepatic failure, respiratory depression, seizures

Pharmacodynamics/Kinetics

Absorption: Almost complete

Protein binding: > 99%, primarily albumin

Metabolism: Hepatic via glucuronidation; metabolite can be converted back to parent compound; may have enterohepatic recirculation

Half-life elimination:

 Capsule: 2-4 hours; moderate-severe renal impairment: 5-9 hours

 Capsule, extended release: ~3-7.5 hours

Time to peak, serum:

 Capsule: 0.5-2 hours

KETOROLAC

Capsule, extended release: 6-7 hours

Excretion: Urine (~80%, primarily as glucuronide conjugates)

Dosage

Oral:

Children ≥ 16 years and Adults:

Rheumatoid arthritis or osteoarthritis:

Capsule: 50-75 mg 3-4 times/day up to a maximum of 300 mg/day

Capsule, extended release: 200 mg once daily

Mild to moderate pain: Capsule: 25-50 mg every 6-8 hours up to a maximum of 300 mg/day

OTC labeling: 12.5 mg every 4-6 hours, up to a maximum of 6 tablets/24 hours

Elderly: Initial dose should be decreased in patients >75 years; use caution when dosage changes are made

Dosage adjustment in renal impairment:

Mild impairment: Maximum dose: 150 mg/day

Severe impairment: Maximum dose: 100 mg/day

Dosage adjustment in hepatic impairment and serum albumin <3.5 g/dL: Maximum dose: 100 mg/day

Administration

May take with food to reduce GI upset. Do not crush or break extended release capsules.

Contraindications Hypersensitivity to ketoprofen, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy (3rd trimester)

Warnings [U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension.

Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Ketoprofen is not recommended for patients with advanced renal disease.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

Withdraw for at least 4-6 half-lives prior to surgical or dental procedures.

Safety and efficacy have not been established in pediatric patients.

Dosage Forms

[DSC] = Discontinued product

Capsule: 50 mg, 75 mg

Capsule, extended release: 200 mg

Tablet (Orudis® KT): 12.5 mg [contains tartrazine and sodium benzoate] [DSC]

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage; famotidine (40 mg 2 times/day) can decrease incidence of gastric or duodenal ulcers in patients receiving long-term therapy of this drug

Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be effective

Test Interactions ↑ chloride (S), sodium (S)

Drug Interactions

Inhibits CYP2C9 (weak)

ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure

Aminoglycosides: NSAIDs may decrease the excretion of aminoglycosides.

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants (warfarin, heparin, LMWHs): In combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet agents (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamol, eptifibatide, tirofiban): In combination with NSAIDs can cause an increased risk of bleeding.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Bisphosphonates: NSAIDs may increase the risk of gastrointestinal ulceration.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids: May increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

Hydralazine: Antihypertensive effect is decreased; avoid concurrent use. Lithium: Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose. Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again.

Loop diuretics: Antihypertensive and diuretic effects may be diminished. Indomethacin reduces this efficacy, however, it may be anticipated with any NSAID.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Pemetrexed: NSAIDs may decrease the excretion of pemetrexed. Patients with Cl_{cr} 45-79 mL/minute should avoid long acting NSAIDs for 5 days before and 2 days after pemetrexed treatment.

Probenecid: May increase the serum concentration of ketoprofen.

Thiazides: Antihypertensive effects may be decreased; avoid concurrent use.

Treprostiniol: May enhance the risk of bleeding with concurrent use.

Vancomycin: NSAIDs may decrease the excretion of vancomycin.

Pregnancy Risk Factor B/D (3rd trimester)

Pregnancy Implications Teratogenic effects were not observed in animal studies. Embryotoxicity was observed in some, but not all, animal studies. Renal insufficiency and pulmonary hypertension have been noted in premature infants (case reports). Accumulation of the active enantiomer of ketoprofen has also been reported in premature neonates with renal insufficiency. Exposure to NSAIDs late in pregnancy may lead to premature closure of the ductus arteriosus and may inhibit uterine contractions.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Do not crush capsule

Ketorolac

Related Information

• Nonsteroidal Anti-inflammatory Drugs

CAS Number 74103-06-3 (Base); 74103-07-4 (Tromethamine)

U.S. Brand Names Acular LS™; Acular® PF; Acular®; Toradol®

Synonyms Ketorolac Tromethamine

Use

Oral, injection: Short-term (≤ 5 days) management of moderately-severe acute pain requiring analgesia at the opioid level

Ophthalmic: Temporary relief of ocular itching due to seasonal allergic conjunctivitis; postoperative inflammation following cataract extraction; reduction of ocular pain and photophobia following incisional refractive surgery, reduction of ocular pain, burning and stinging following corneal refractive surgery

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors

Adverse Reactions

Systemic:

Cardiovascular: Edema, hypertension, pallor, palpitation, syncope, flushing, hypotension

Central nervous system: **Headache**, dizziness, drowsiness, abnormal dreams, abnormal thinking, depression, euphoria, extrapyramidal symptoms, fever, hallucinations, inability to concentrate, insomnia, nervousness, stupor, aseptic meningitis, convulsions, psychosis

Dermatologic: Pruritus, purpura, rash, urticaria, exfoliative dermatitis, Lyell's syndrome, maculopapular rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

Endocrine & metabolic: Hyperkalemia, hyponatremia

Gastrointestinal: **Gastrointestinal pain, dyspepsia, nausea, diarrhea, constipation, flatulence, gastrointestinal fullness, vomiting, stomatitis, abnormal taste, anorexia, appetite increased, dry mouth, eructation, gastritis, rectal bleeding, weight gain, acute pancreatitis, esophagitis, GI hemorrhage, GI perforation, hematemesis, melena, peptic ulceration, tongue edema**

Genitourinary: Urinary frequency increased, urinary retention

Hematologic: Anemia, eosinophilia, hemolytic uremic syndrome, leukopenia, thrombocytopenia, wound hemorrhage (postoperative)

Hepatic: Cholestatic jaundice, hepatitis, liver failure

Local: Injection site pain

Neuromuscular & skeletal: Hyperkinesia, paresthesia, tremors, weakness, flank pain, myalgia

Ocular: Abnormal vision, blurred vision

Otic: Hearing loss, tinnitus

Renal: Hematuria, oliguria, polyuria, proteinuria, acute renal failure, azotemia, nephritis

Respiratory: Cough, dyspnea, epistaxis, pulmonary edema, rhinitis, asthma, bronchospasm, laryngeal edema

Miscellaneous: Diaphoresis, excessive thirst, infections, anaphylactoid reaction, anaphylaxis, hypersensitivity reactions

Ophthalmic solution:

Central nervous system: Headache

Ocular: **Transient burning/stinging (Acular®: 40%; Acular® PF: 20%), conjunctival hyperemia, corneal infiltrates, iritis, ocular edema, ocular inflammation, ocular irritation, ocular pain, superficial keratitis, superficial ocular infection, dry eyes, corneal ulcer, blurred vision, corneal erosion, corneal perforation, corneal thinning, epithelial breakdown**

Miscellaneous: Allergic reactions

Chills, coagulopathy, cognitive dysfunction, drowsiness, dry mouth, GI bleeding, nausea, nephrotic syndrome, ototoxicity, tinnitus, vomiting, wheezing

Severe poisoning can manifest with coma, hypotension, renal and/or hepatic failure, respiratory depression, seizures

Pharmacodynamics/Kinetics

Onset of action: Analgesic: I.M.: ~ 10 minutes

Peak effect: Analgesic: 2-3 hours

Duration: Analgesic: 6-8 hours

Absorption: Oral: Well absorbed

Distribution: Poor penetration into CSF; crosses placenta; enters breast milk

Protein binding: 99%

Metabolism: Hepatic

Half-life elimination: 2-8 hours; prolonged 30% to 50% in elderly

Time to peak, serum: I.M.: 30-60 minutes

Excretion: Urine (61% as unchanged drug)

Dosage

Children 2-16 years: **Do not exceed adult doses**

Single-dose treatment:

I.M.: 1 mg/kg (maximum: 30 mg)

I.V.: 0.5 mg/kg (maximum: 15 mg)

Oral (unlabeled): 1 mg/kg as a single dose reported in one study

Multiple-dose treatment (unlabeled): Limited pediatric studies. The maximum combined duration of treatment (for parenteral and oral) is 5 days.

I.V.: Initial dose: 0.5 mg/kg, followed by 0.25-1 mg/kg every 6 hours for up to 48 hours (maximum daily dose: 90 mg)

Oral: 0.25 mg/kg every 6 hours

Adults (pain relief usually begins within 10 minutes with parenteral forms): **Note:** The maximum combined duration of treatment (for parenteral and oral) is 5 days; do not increase dose or frequency; supplement with low-dose opioids if needed for breakthrough pain. For patients <50 kg and/or ≥ 65 years, see Elderly dosing.

I.M.: 60 mg as a single dose or 30 mg every 6 hours (maximum daily dose: 120 mg)

I.V.: 30 mg as a single dose or 30 mg every 6 hours (maximum daily dose: 120 mg)

Oral: 20 mg, followed by 10 mg every 4-6 hours; do not exceed 40 mg/day; oral dosing is intended to be a continuation of I.M. or I.V. therapy only

Ophthalmic: Children ≥3 years and Adults:

Allergic conjunctivitis (relief of ocular itching) (Acular®): Instill 1 drop (0.25 mg) 4 times/day for seasonal allergic conjunctivitis

Inflammation following cataract extraction (Acular®): Instill 1 drop (0.25 mg) to affected eye(s) 4 times/day beginning 24 hours after surgery; continue for 2 weeks

Pain and photophobia following incisional refractive surgery (Acular® PF): Instill 1 drop (0.25 mg) 4 times/day to affected eye for up to 3 days

Pain following corneal refractive surgery (Acular LS™): Instill 1 drop 4 times/day as needed to affected eye for up to 4 days

Elderly >65 years: Renal insufficiency or weight <50 kg: **Note:** Ketorolac has decreased clearance and increased half-life in the elderly. In addition, the elderly have reported increased incidence of GI bleeding, ulceration, and perforation. The maximum combined duration of treatment (for parenteral and oral) is 5 days.

I.M.: 30 mg as a single dose or 15 mg every 6 hours (maximum daily dose: 60 mg)

I.V.: 15 mg as a single dose or 15 mg every 6 hours (maximum daily dose: 60 mg)

Oral: 10 mg every 4-6 hours; do not exceed 40 mg/day; oral dosing is intended to be a continuation of I.M. or I.V. therapy only

Dosage adjustment in renal impairment: Do not use in patients with advanced renal impairment. Patients with moderately-elevated serum creatinine should use half the recommended dose, not to exceed 60 mg/day I.M./I.V.

Dosage adjustment in hepatic impairment: Use with caution, may cause elevation of liver enzymes

Stability Do not mix with morphine sulfate, meperidine hydrochloride, promethazine hydrochloride, or hydroxyzine hydrochloride in that precipitation may occur

Monitoring Parameters Monitor response (pain, range of motion, grip strength, mobility, ADL function), inflammation; observe for weight gain, edema; monitor renal function (serum creatinine, BUN, urine output); observe for bleeding, bruising; evaluate gastrointestinal effects (abdominal pain, bleeding, dyspepsia); mental confusion, disorientation, CBC, liver function tests

Administration Oral: May take with food to reduce GI upset

I.M.: Administer slowly and deeply into the muscle. Analgesia begins in 30 minutes and maximum effect within 2 hours

I.V.: Administer I.V. bolus over a minimum of 15 seconds; onset within 30 minutes; peak analgesia within 2 hours

Ophthalmic solution: Contact lenses should be removed before instillation.

Contraindications Hypersensitivity to ketorolac, aspirin, other NSAIDs, or any component of the formulation; active or history of peptic ulcer disease; recent or history of GI bleeding or perforation; patients with advanced renal disease or risk of renal failure; labor and delivery; nursing mothers; prophylaxis before major surgery; suspected or confirmed cerebrovascular bleeding; hemorrhagic diathesis; concurrent ASA or other NSAIDs; epidural or intrathecal administration; concomitant probenecid; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy (3rd trimester)

Warnings

Systemic: Treatment should be started with I.V./I.M. administration then changed to oral only as a continuation of treatment. Total therapy is not to exceed 5 days. Should not be used for minor or chronic pain.

May prolong bleeding time; do not use when hemostasis is critical. Patients should be euvolemic prior to treatment. Low doses of narcotics may be needed for breakthrough pain.

[U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension. Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Ketorolac is not recommended for patients with advanced renal disease.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely;

discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

The elderly are at increased risk for adverse effects (especially peptic ulceration, CNS effects, renal toxicity) from NSAIDs even at low doses. Withhold for at least 4-6 half-lives prior to surgical or dental procedures.

Ophthalmic: May increase bleeding time associated with ocular surgery. Use with caution in patients with known bleeding tendencies or those receiving anticoagulants. Healing time may be slowed or delayed. Corneal thinning, erosion, or ulceration have been reported with topical NSAIDs; discontinue if corneal epithelial breakdown occurs. Use caution with complicated ocular surgery, corneal denervation, corneal epithelial defects, diabetes, rheumatoid arthritis, ocular surface disease, or ocular surgeries repeated within short periods of time; risk of corneal epithelial breakdown may be increased. Use for >24 hours prior to or for >14 days following surgery also increases risk of corneal adverse effects. Do not administer while wearing soft contact lenses. Safety and efficacy in pediatric patients <3 years of age have not been established.

Dosage Forms[DSC] = Discontinued product

Injection, solution, as tromethamine: 15 mg/mL (1 mL); 30 mg/mL (1 mL, 2 mL, 10 mL) [contains alcohol]

Solution, ophthalmic, as tromethamine:

Acular®: 0.5% (3 mL, 5 mL, 10 mL) [contains benzalkonium chloride]

Acular LS™: 0.4% (5 mL) [contains benzalkonium chloride]

Acular® P.F. [preservative free]: 0.5% (0.4 mL)

Tablet, as tromethamine: 10 mg

Toradol®: 10 mg [DSC]

Reference Range

Peak plasma level after a 60 mg dose (I.M.): 4-4.5 mcg/mL

Serum concentration:

Therapeutic: 0.3-5.0 mcg/mL

Toxic: >5.0 mcg/mL

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; dopamine is vasopressor of choice; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage

Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone

Test Interactions ↑ chloride (S), sodium (S), bleeding time

Drug Interactions ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants: Increased risk of bleeding complications with concomitant use; monitor closely.

Antiepileptic drugs (carbamazepine, phenytoin): Sporadic cases of seizures have been reported with concomitant use.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Diuretics: May see decreased effect of diuretics.

Hydralazine's antihypertensive effect may be reduced; monitor.

Lithium: May increase lithium levels; monitor.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Nondepolarizing muscle relaxants: Concomitant use has resulted in apnea.

NSAIDs, salicylates: Concomitant use increases NSAID-induced adverse effects; contraindicated.

Probenecid: Probenecid significantly decreases ketorolac clearance, increases ketorolac plasma levels, and doubles the half-life of ketorolac; concomitant use is contraindicated.

Psychoactive drugs (alprazolam, fluoxetine, thiothixene): Hallucinations have been reported with concomitant use.

Pregnancy Risk Factor C/D (3rd trimester)

Pregnancy Implications Ketorolac is contraindicated during labor and delivery (may inhibit uterine contractions and adversely affect fetal circulation). Avoid use of ketorolac ophthalmic solution during late pregnancy.

Lactation Enters breast milk/contraindicated (AAP rates "compatible")

Additional Information 30 mg provides the analgesia comparable to 12 mg of morphine or 100 mg of meperidine; postmarketing surveillance of ketorolac indicated that the risk of clinically serious GI bleeding was dose-dependent, particularly in elderly patients, who received doses >60 mg/day

Labetalol

CAS Number 32780-64-6; 36894-69-6

U.S. Brand Names Normodyne®; Trandate®

Synonyms Ibdomide Hydrochloride; Labetalol Hydrochloride

Use Treatment of mild to severe hypertension; I.V. for hypertensive emergencies

Mechanism of Action Blocks alpha-, beta₁-, and beta₂-adrenergic receptor sites; elevated renins are reduced; roughly 80% beta-blocker and 20% alpha-blocker; beta- to alpha-blocking ratio is 7:1 (I.V.) and 3:1 (oral)

Adverse Reactions

Cardiovascular: Hypotension (orthostatic) especially with I.V. administration, edema, congestive heart failure, AV conduction disturbances, bradycardia, sinus bradycardia, myocardial depression, arrhythmias (ventricular)

Central nervous system: Drowsiness, fatigue, dizziness, behavior disorders, headache

Dermatologic: Tingling in scalp or skin (transient with initiation of therapy), rash, alopecia, angioedema, urticaria, purpura, pruritus, psoriasis, licheniform eruptions, exanthem

Endocrine & metabolic: Sexual dysfunction

Gastrointestinal: Nausea, xerostomia, vomiting, diarrhea

Genitourinary: Urinary problems

Hematologic: Leukopenia

Hepatic: Hepatotoxicity (usually mild and reversible), cholestasis

Neuromuscular & skeletal: Paresthesia, reversible myopathy

Ocular: Diplopia (dose-related)

Respiratory: Wheezing, nasal congestion

Miscellaneous: Systemic lupus erythematosus

Signs and Symptoms of Overdose Agranulocytosis, bradycardia, cholestatic jaundice, claudication, depression, dyspepsia, ejaculatory disturbances, granulocytopenia, heart failure, hypoglycemia, hypotension, impotence, leukopenia, lightheadedness, neutropenia, night terrors, oliguric renal failure, priapism, wheezing

Admission Criteria/Prognosis Admit any hypotensive patient or adult ingestions >3.5 g

Pharmacodynamics/Kinetics

Onset of action: Oral: 20 minutes to 2 hours; I.V.: 2-5 minutes

Peak effect: Oral: 1-4 hours; I.V.: 5-15 minutes

Duration: Oral: 8-24 hours (dose dependent); I.V.: 2-4 hours

Distribution: V_d: Adults: 3-16 L/kg; mean: <9.4 L/kg; moderately lipid soluble, therefore, can enter CNS; crosses placenta; small amounts enter breast milk

Protein binding: 50%

Metabolism: Hepatic, primarily via glucuronide conjugation; extensive first-pass effect

Bioavailability: Oral: 25%; increased with liver disease, elderly, and concurrent cimetidine

Half-life elimination: Normal renal function: 2.5-8 hours

Excretion: Urine (<5% as unchanged drug)

Clearance: Possibly decreased in neonates/infants

Dosage

Due to limited documentation of its use, labetalol should be initiated cautiously in pediatric patients with careful dosage adjustment and blood pressure monitoring.

Children:

Oral: Limited information regarding labetalol use in pediatric patients is currently available in literature. Some centers recommend initial oral doses of 4 mg/kg/day in 2 divided doses. Reported oral doses have started at 3 mg/kg/day and 20 mg/kg/day and have increased up to 40 mg/kg/day.

I.V., intermittent bolus doses of 0.3-1 mg/kg/dose have been reported.

For treatment of pediatric hypertensive emergencies, initial continuous infusions of 0.4-1 mg/kg/hour with a maximum of 3 mg/kg/hour have been used. Administration requires the use of an infusion pump.

Adults:

Oral: Initial: 100 mg twice daily, may increase as needed every 2-3 days by 100 mg until desired response is obtained; usual dose: 200-400 mg twice daily; may require up to 2.4 g/day.

Usual dose range (JNC 7): 200-800 mg/day in 2 divided doses

I.V.: 20 mg (0.25 mg/kg for an 80 kg patient) IVP over 2 minutes; may administer 40-80 mg at 10-minute intervals, up to 300 mg total dose.

I.V. infusion: Initial: 2 mg/minute; titrate to response up to 300 mg total dose, if needed. Administration requires the use of an infusion pump.

I.V. infusion (500 mg/250 mL D₅W) rates:

- 1 mg/minute: 30 mL/hour
- 2 mg/minute: 60 mL/hour
- 3 mg/minute: 90 mL/hour
- 4 mg/minute: 120 mL/hour
- 5 mg/minute: 150 mL/hour
- 6 mg/minute: 180 mL/hour

Dialysis: Not removed by hemo- or peritoneal dialysis; supplemental dose is not necessary.

Dosage adjustment in hepatic impairment: Dosage reduction may be necessary.

Stability Stable in D₅W, saline for 24 hours; **incompatible** with alkaline solutions, NaHCO₃; use only solutions that are clear or slightly yellow; may cause a precipitate if exposed to alkaline admixture; parenteral admixture at room temperature (25°C) or refrigeration (4°C): 24 hours

Monitoring Parameters Blood pressure, standing and sitting/supine, pulse, cardiac monitor and blood pressure monitor required for I.V. administration

Administration Bolus administered over 2 minutes. Loading infusions (2 mg/minute) require close monitoring of heart rate and blood pressure and are usually terminated after response or cumulative dose of 300 mg. There is limited documentation of prolonged continuous infusions. In clinical experience, prolonged continuous infusions have been used. In rare clinical situations, higher dosages (up to 6 mg/minute) have been used in the critical care setting (eg, aortic dissection). At the other extreme, continuous infusions at relatively low doses (2-6 mg/hour; note difference in units) have been used in some settings (following loading infusion in patients who are unable to be converted to oral regimens or in some cases as a continuation of outpatient oral regimens). These prolonged infusions should not be confused with loading infusions. Because of wide variation in the use of infusions, an awareness of institutional policies and practices is extremely important. Careful clarification of orders and specific infusion rates/units is required to avoid confusion. Due to the prolonged duration of action, careful monitoring should be extended for the duration of the infusion and for several hours after the infusion. Excessive administration may result in prolonged hypotension and/or bradycardia.

Contraindications Hypersensitivity to labetalol or any component of the formulation; sinus bradycardia; heart block greater than first degree (except in patients with a functioning artificial pacemaker); cardiogenic shock; bronchial asthma; uncompensated cardiac failure; pregnancy (2nd and 3rd trimesters)

Warnings Use only with extreme caution in compensated heart failure and monitor for a worsening of the condition. Avoid abrupt discontinuation in patients with a history of CAD; slowly wean while monitoring for signs and symptoms of ischemia. Use caution with concurrent use of beta-blockers and either verapamil or diltiazem; bradycardia or heart block can occur. Avoid concurrent I.V. use of both agents. Patients with bronchospastic disease should not receive beta-blockers. Labetalol may be used with caution in patients with nonallergic bronchospasm (chronic bronchitis, emphysema). Use cautiously in diabetics because it can mask prominent hypoglycemic symptoms. Can mask signs of thyrotoxicosis. Can cause fetal harm when administered in pregnancy. Use cautiously in the hepatically impaired. Use caution when using I.V. labetalol and inhalational anesthetics concurrently (significant myocardial depression).

Dosage Forms

Injection, solution, as hydrochloride: 5 mg/mL (4 mL, 20 mL, 40 mL)

Trandate®: 5 mg/mL (20 mL, 40 mL)

Tablet, as hydrochloride: 100 mg, 200 mg, 300 mg

Trandate®: 100 mg, 200 mg [contains sodium benzoate], 300 mg

Reference Range Toxic: Serum levels >500 ng/mL

Overdosage/Treatment

Decontamination: Gastric lavage (within 1 hour) with activated charcoal is recommended; **do not** use ipecac

Supportive therapy: Sympathomimetics (eg, epinephrine or dopamine), atropine, glucagon, or a pacemaker can be used to treat the toxic bradycardia, asystole, and/or hypotension; inamrinone may also be effective for labetalol-induced hypotension; initially fluids may be the best treatment for toxic hypotension with norepinephrine being used for second-line therapy

Enhancement of elimination: Multiple dosing of activated charcoal may be useful

Test Interactions False-positive urine catecholamines and VMA if measured by fluorometric or photometric methods; use HPLC or specific catecholamine radioenzymatic technique; can cause positive antinuclear antibody; a labetalol metabolite (3-amino-1-phenylbutane or APB) may cause a false-positive result with amphetamine/methamphetamine by thin-layer chromatography or immunoassay

Drug Interactions **Substrate** of CYP2D6 (major); **Inhibits** CYP2D6 (weak)

Alpha-blockers (prazosin, terazosin): Concurrent use of beta-blockers may increase risk of orthostasis.

Cimetidine increases the bioavailability of labetalol.

CYP2D6 inhibitors: May increase the levels/effects of labetalol. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Halothane, isoflurane, enflurane (possibly other inhalational anesthetics): Excessive hypotension may occur.

NSAIDs may reduce antihypertensive efficacy of labetalol.

Salicylates may reduce the antihypertensive effects of beta-blockers.

Sulfonylureas: Effects may be decreased by beta-blockers.

Verapamil or diltiazem may have synergistic or additive pharmacological effects when taken concurrently with beta-blockers; avoid concurrent I.V. use.

Pregnancy Risk Factor C (manufacturer); D (2nd and 3rd trimesters - expert analysis)

Pregnancy Implications Labetalol crosses the placenta. Beta-blockers have been associated with persistent bradycardia, hypotension, and IUGR; IUGR is probably related to maternal hypertension. Available evidence suggests beta-blockers are generally safe during pregnancy (JNC-7). Cases of neonatal hypoglycemia have been reported following maternal use of beta-blockers at parturition or during breast-feeding.

Lactation Enters breast milk/use caution (AAP rates "compatible")

Additional Information Not shown to be effective for cocaine-cardiovascular toxicity

Lamivudine

U.S. Brand Names Eпивir-HBV®; Eпивir®

Synonyms 3TC

Use

Eпивir®: Treatment of HIV infection when antiretroviral therapy is warranted; should always be used as part of a multidrug regimen (at least three antiretroviral agents)

Eпивir-HBV®: Treatment of chronic hepatitis B associated with evidence of hepatitis B viral replication and active liver inflammation

Unlabeled/Investigational Use Prevention of HIV following needlesticks (with or without protease inhibitor)

Mechanism of Action Lamivudine is a cytosine analog. After lamivudine is triphosphorylated, the principle mode of action is inhibition of HIV reverse transcription via viral DNA chain termination; inhibits RNA- and DNA-dependent DNA polymerase activities of reverse transcriptase. The monophosphate form of lamivudine is incorporated into the viral DNA by hepatitis B virus polymerase, resulting in DNA chain termination.

Adverse Reactions

(As reported in adults treated for HIV infection)

Central nervous system: **Headache, fatigue**; dizziness, depression, fever, chills, insomnia

Dermatologic: Rash, alopecia, pruritus, urticaria

Endocrine & metabolic: Hyperglycemia, lactic acidosis

Gastrointestinal: **Nausea, diarrhea, vomiting, pancreatitis (range: 0.5% to 18%; higher percentage in pediatric patients)**; anorexia, abdominal pain, heartburn, elevated amylase, splenomegaly, stomatitis

Hematologic: Neutropenia, anemia, thrombocytopenia, red cell aplasia

Hepatic: Elevated AST/ALT, hepatomegaly, hyperbilirubinemia, steatosis

Neuromuscular & skeletal: **Peripheral neuropathy, paresthesia,**

musculoskeletal pain; myalgia, arthralgia, rhabdomyolysis, weakness, increased CPK

Respiratory: Nasal signs and symptoms, cough

Miscellaneous: Anaphylaxis, lymphadenopathy

Pharmacodynamics/Kinetics

Absorption: Rapid

Distribution: V_d: 1.3 L/kg

Protein binding, plasma: <36%

Metabolism: 5.2% to trans-sulfoxide metabolite

Bioavailability: Absolute; C_pmax decreased with food although AUC not significantly affected

Children: 66%

Adults: 86% to 87%

Half-life elimination: Children: 2 hours; Adults: 5-7 hours

Time to peak, plasma: Fed: 3.2 hours; Fasted: 0.9 hours

Excretion: Primarily urine (as unchanged drug)

Dosage Note: The formulation and dosage of Eпивir-HBV® are not appropriate for patients infected with both HBV and HIV. Use with at least two other antiretroviral agents when treating HIV

Oral:

Children 3 months to 16 years: HIV: 4 mg/kg twice daily (maximum: 150 mg twice daily)
 Children 2-17 years: Treatment of hepatitis B (Epivir-HBV®): 3 mg/kg once daily (maximum: 100 mg/day)
 Adolescents and Adults: Prevention of HIV following needlesticks (unlabeled use): 150 mg twice daily (with zidovudine with or without a protease inhibitor, depending on risk)

Adults:

HIV: 150 mg twice daily or 300 mg once daily
 <50 kg: 4 mg/kg twice daily (maximum: 150 mg twice daily)
 Treatment of hepatitis B (Epivir-HBV®): 100 mg/day

Dosing interval in renal impairment in pediatric patients: Insufficient data; however, dose reduction should be considered.

Dosing interval in renal impairment in patients > 16 years for HIV:

Cl_{cr} 30-49 mL/minute: Administer 150 mg once daily
 Cl_{cr} 15-29 mL/minute: Administer 150 mg first dose, then 100 mg once daily
 Cl_{cr} 5-14 mL/minute: Administer 150 mg first dose, then 50 mg once daily
 Cl_{cr} <5 mL/minute: Administer 50 mg first dose, then 25 mg once daily

Dosing interval in renal impairment in adult patients with hepatitis B:

Cl_{cr} 30-49: Administer 100 mg first dose then 50 mg once daily
 Cl_{cr} 15-29: Administer 100 mg first dose then 25 mg once daily
 Cl_{cr} 5-14: Administer 35 mg first dose then 15 mg once daily
 Cl_{cr} <5: Administer 35 mg first dose then 10 mg once daily

Dialysis: Negligible amounts are removed by 4-hour hemodialysis or peritoneal dialysis. Supplemental dosing is not required.

Stability Store at 2°C to 25°C (68°F to 77°F) tightly closed.

Monitoring Parameters Amylase, bilirubin, liver enzymes, hematologic parameters, viral load, and CD4 count; signs and symptoms of pancreatitis

Administration May be taken with or without food. Adjust dosage in renal failure.

Contraindications Hypersensitivity to lamivudine or any component of the formulation

Warnings

Use caution with renal impairment; dosage reduction recommended. Use with extreme caution in children with history of pancreatitis or risk factors for development of pancreatitis. Do not use as monotherapy in treatment of HIV. Treatment of HBV in patients with unrecognized/untreated HIV may lead to rapid HIV resistance. In addition, treatment of HIV in patients with unrecognized/untreated HBV may lead to rapid HBV resistance. **[U.S. Boxed Warning]: Do not use Epivir-HBV® tablets or Epivir-HBV® oral solution for the treatment of HIV.**

[U.S. Boxed Warning]: Lactic acidosis and severe hepatomegaly with steatosis have been reported, including fatal cases. Use caution in hepatic impairment. Pregnancy, obesity, and/or prolonged therapy may increase the risk of lactic acidosis and liver damage.

Immune reconstitution syndrome may develop resulting in the occurrence of an inflammatory response to an indolent or residual opportunistic infection; further evaluation and treatment may be required. May be associated with fat redistribution (buffalo hump, increased abdominal girth, breast engorgement, facial atrophy, and dyslipidemia).

[U.S. Boxed Warning]: Monitor patients closely for several months following discontinuation of therapy for chronic hepatitis B; clinical exacerbations may occur.

Dosage Forms

Solution, oral:

Epivir®: 10 mg/mL (240 mL) [strawberry-banana flavor]
 Epivir-HBV®: 5 mg/mL (240 mL) [strawberry-banana flavor]

Tablet:

Epivir®: 150 mg, 300 mg
 Epivir-HBV®: 100 mg

Reference Range Peak serum concentrations after a 8 mg/kg I.V. and oral dose: 10,560 ng/mL and 5815 ng/mL, respectively

Overdosage/Treatment Decontamination: Emesis with ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal; monitor hematologic parameters

Drug Interactions

Interferon alfa: Concomitant use of interferon alfa and nucleoside analogues may increase the risk of developing hepatic decompensation or other signs of mitochondrial toxicity, including pancreatitis or lactic acidosis.

Ganciclovir/valganciclovir: May increase the adverse effects/toxicity (eg, hematologic) of nucleoside reverse transcriptase inhibitors

Ribavirin: Concomitant use of ribavirin and nucleoside analogues may increase the risk of developing hepatic decompensation or other signs of mitochondrial toxicity, including pancreatitis or lactic acidosis.

Sulfamethoxazole/trimethoprim: Increased AUC and decreased clearance of lamivudine with concomitant use

Trimethoprim (and other drugs excreted by organic cation transport): May increase serum levels/effects of lamivudine.

Zalcitabine: Intracellular phosphorylation of lamivudine and zalcitabine may be inhibited if used together; concomitant use should be avoided.

Zidovudine: Plasma levels of zidovudine are increased by ~39% with concomitant use.

Pregnancy Risk Factor C

Pregnancy Implications Lamivudine crosses the placenta. It may be used in combination with zidovudine in HIV-infected women who are in labor, but have had no prior antiretroviral therapy, in order to reduce the maternal-fetal transmission of HIV. Cases of lactic acidosis/hepatic steatosis syndrome have been reported in pregnant women receiving nucleoside analogues. It is not known if pregnancy itself potentiates this known side effect; however, pregnant women may be at increased risk of lactic acidosis and liver damage. Hepatic enzymes and electrolytes should be monitored frequently during the 3rd trimester of pregnancy in women receiving nucleoside analogues. Health professionals are encouraged to contact the antiretroviral pregnancy registry to monitor outcomes of pregnant women exposed to antiretroviral medications (1-800-258-4263).

Lactation Enters breast milk/not recommended

Nursing Implications Monitor children for signs and symptoms of pancreatitis; evaluate frequently for opportunistic infection and other complications of HIV; administer on an empty stomach, if possible; adjust dosage in renal failure

Additional Information There are, as yet, no results from clinical trials evaluating the effect of lamivudine, in combination with zidovudine, on progression of HIV infection (eg, incidence of opportunistic infections or survival). Patients may continue to develop infections and other complications of HIV infection and should remain under close physician observation.

Lamotrigine

CAS Number 84057-84-1

U.S. Brand Names Lamictal®

Synonyms BW-430C; LTG

Use Adjunctive therapy in the treatment of generalized seizures of Lennox-Gastaut syndrome and partial seizures in adults and children ≥2 years of age; conversion to monotherapy in adults with partial seizures who are receiving treatment with valproate or a single enzyme-inducing antiepileptic drug; maintenance treatment of bipolar disorder

Mechanism of Action Triazine derivative which inhibits release of glutamate (an excitatory amino acid)

Adverse Reactions

Reported in adults receiving adjunctive therapy:

Cardiovascular: Angina, atrial fibrillation, facial edema, hypertension, palpitations, postural hypotension, vasculitis, peripheral edema

Central nervous system: **Headache** (29%), **dizziness** (38%), **ataxia** (22%), **somnolence**, depression, anxiety, irritability, confusion, speech disorder, difficulty concentrating, malaise, mania, migraine, movement disorder, stroke, suicidal ideation, Parkinson's disease exacerbation

Dermatologic: **Hypersensitivity rash** (10%; serious rash requiring hospitalization - adults 0.3%, children 0.8%), pruritus, acne, alopecia, angioedema, bruising, erythema multiforme, maculopapular rash, photosensitivity (rare), rash, Stevens-Johnson syndrome, urticaria, vesiculobullous rash, toxic epidermal necrolysis

Endocrine & metabolic: Hot flashes

Gastrointestinal: **Nausea**, abdominal pain, vomiting, diarrhea, dyspepsia, constipation, anorexia, tooth disorder, dysphagia, GI hemorrhage, gingival hyperplasia, halitosis, esophagitis, pancreatitis, xerostomia

Genitourinary: Vaginitis, dysmenorrhea, amenorrhea, impotence

Hematologic: Anemia, eosinophilia, hemorrhage, leukopenia, agranulocytosis, aplastic anemia, disseminated intravascular coagulation (DIC), hemolytic anemia, neutropenia, pancytopenia, red cell aplasia, thrombocytopenia

Hepatic: Hepatitis

Neuromuscular & skeletal: Tremor, arthralgia, neck pain, back pain, dysarthria, paralysis, tics

Ocular: **Diplopia** (28%), **blurred vision**, nystagmus, visual abnormality

Renal: Acute renal failure

Respiratory: **Rhinitis**, bronchospasm, dyspnea, apnea, epistaxis, bronchitis

Miscellaneous: Flu syndrome, fever, allergic reactions, hypersensitivity reactions (including rhabdomyolysis), immunosuppression (progressive), lupus-like reaction, multiorgan failure

Signs and Symptoms of Overdose QRS prolongation on ECG

Admission Criteria/Prognosis Admit any patient with nervous system or cardiac abnormalities (especially QRS prolongation over 100 msec on ECG), ingestions > 1 g, or serum lamotrigine levels > 10 mcg/mL

Pharmacodynamics/Kinetics

Distribution: V_d : 1.1 L/kg

Protein binding: 55%

Metabolism: Hepatic and renal; metabolized by glucuronic acid conjugation to inactive metabolites

Bioavailability: 98%

Half-life elimination: Adults: 25-33 hours; Concomitant valproic acid therapy: 59-70 hours; Concomitant phenytoin or carbamazepine therapy: 13-14 hours

Time to peak, plasma: 1-4 hours

Excretion: Urine (94%, ~90% as glucuronide conjugates and ~10% unchanged); feces (2%)

Dosage Note: Only whole tablets should be used for dosing, round calculated dose down to the nearest whole tablet: Oral:

Children 2-12 years: Lennox-Gastaut (adjunctive) or partial seizures (adjunctive): **Note:** Children 2-6 years will likely require maintenance doses at the higher end of recommended range:

Patients receiving AED regimens containing valproic acid:

Weeks 1 and 2: 0.15 mg/kg/day in 1-2 divided doses; round dose down to the nearest whole tablet. For patients > 6.7 kg and < 14 kg, dosing should be 2 mg every other day.

Weeks 3 and 4: 0.3 mg/kg/day in 1-2 divided doses; round dose down to the nearest whole tablet; may use combinations of 2 mg and 5 mg tablets. For patients > 6.7 kg and < 14 kg, dosing should be 2 mg/day.

Maintenance dose: Titrate dose to effect; after week 4, increase dose every 1-2 weeks by a calculated increment; calculate increment as 0.3 mg/kg/day rounded down to the nearest whole tablet; add this amount to the previously administered daily dose; usual maintenance: 1-5 mg/kg/day in 1-2 divided doses; maximum: 200 mg/day given in 1-2 divided doses

Patients receiving enzyme-inducing AED regimens without valproic acid:

Weeks 1 and 2: 0.6 mg/kg/day in 2 divided doses; round dose down to the nearest whole tablet

Weeks 3 and 4: 1.2 mg/kg/day in 2 divided doses; round dose down to the nearest whole tablet

Maintenance dose: Titrate dose to effect; after week 4, increase dose every 1-2 weeks by a calculated increment; calculate increment as 1.2 mg/kg/day rounded down to the nearest whole tablet; add this amount to the previously administered daily dose; usual maintenance: 5-15 mg/kg/day in 2 divided doses; maximum: 400 mg/day

Children > 12 years: Lennox-Gastaut (adjunctive) or partial seizures (adjunctive): Refer to Adults dosing

Children ≥ 16 years: Conversion from single enzyme-inducing AED regimen to monotherapy: Refer to Adults dosing

Adults:

Lennox-Gastaut (adjunctive) or treatment of partial seizures (adjunctive):

Patients receiving AED regimens containing valproic acid: Initial dose: 25 mg every other day for 2 weeks, then 25 mg every day for 2 weeks. Dose may be increased by 25-50 mg every day for 1-2 weeks in order to achieve maintenance dose. Maintenance dose: 100-400 mg/day in 1-2 divided doses (usual range 100-200 mg/day).

Patients receiving enzyme-inducing AED regimens without valproic acid: Initial dose: 50 mg/day for 2 weeks, then 100 mg in 2 doses for 2 weeks; thereafter, daily dose can be increased by 100 mg every 1-2 weeks to be given in 2 divided doses. Usual maintenance dose: 300-500 mg/day in 2 divided doses; doses as high as 700 mg/day have been reported

Conversion to monotherapy (partial seizures in patients ≥ 16 years of age):

Adjunctive therapy with valproate: Initiate and titrate as per recommendations to a lamotrigine dose of 200 mg/day. Then taper valproate dose in decrements of not more than 500 mg/day at intervals of one week (or longer) to a valproate dosage of 500 mg/day; this dosage should be maintained for one week. The lamotrigine dosage should then be increased to 300 mg/day while valproate is decreased to 250 mg/day; this dosage should be maintained for one week. Valproate may then be discontinued, while the lamotrigine dose is increased by 100 mg/day at weekly intervals to achieve a lamotrigine maintenance dose of 500 mg/day.

Adjunctive therapy with enzyme-inducing AED: Initiate and titrate as per recommendations to a lamotrigine dose of 500 mg/day.

Concomitant enzyme-inducing AED should then be withdrawn by 20% decrements each week over a 4-week period. Patients should be monitored for rash.

Adjunctive therapy with non-enzyme inducing AED: No specific guidelines available

Bipolar disorder: 25 mg/day for 2 weeks, followed by 50 mg/day for 2 weeks, followed by 100 mg/day for 1 week; thereafter, daily dosage may be increased to 200 mg/day

Patients receiving valproic acid: Initial: 25 mg every other day for 2 weeks, followed by 25 mg/day for 2 weeks, followed by 50 mg/day for 1 week, followed by 100 mg/day (target dose) thereafter. **Note:** If valproate is discontinued, increase daily lamotrigine dose in 50 mg increments at weekly intervals until daily dosage of 200 mg is attained.

Patients receiving enzyme-inducing drugs (eg, carbamazepine): Initial: 50 mg/day for 2 weeks, followed by 100 mg/day (in divided doses) for 2 weeks, followed by 200 mg/day (in divided doses) for 1 week, followed by 300 mg/day (in divided doses) for 1 week. May increase to 400 mg/day (in divided doses) during week 7 and thereafter. **Note:** If carbamazepine (or other enzyme-inducing drug) is discontinued, decrease daily lamotrigine dose in 100 mg increments at weekly intervals until daily dosage of 200 mg is attained.

Discontinuing therapy: Children and Adults: Decrease dose by ~50% per week, over at least 2 weeks unless safety concerns require a more rapid withdrawal.

Restarting therapy after discontinuation: If lamotrigine has been withheld for > 5 half-lives, consider restarting according to initial dosing recommendations.

Dosage adjustment in renal impairment: Decreased dosage may be effective in patients with significant renal impairment; use with caution

Dosage adjustment in hepatic impairment:

Child-Pugh Grade B: Reduce initial, escalation, and maintenance doses by 50%

Child-Pugh Grade C: Reduce initial, escalation, and maintenance doses by 75%

Monitoring Parameters Seizure, frequency and duration, serum levels of concurrent anticonvulsants, hypersensitivity reactions, especially rash

Administration Doses should be rounded down to the nearest whole tablet. Dispersible tablets may be chewed, dispersed in water, or swallowed whole. To disperse tablets, add to a small amount of liquid (just enough to cover tablet); let sit ~1 minute until dispersed; swirl solution and consume immediately. Do not administer partial amounts of liquid. If tablets are chewed, a small amount of water or diluted fruit juice should be used to aid in swallowing.

Contraindications Hypersensitivity to lamotrigine or any component of the formulation

Warnings [U.S. Boxed Warning]: Severe and potentially life-threatening skin rashes requiring hospitalization have been reported (children 0.8%, adults 0.3%); risk may be increased by coadministration with valproic acid, higher than recommended starting doses, and rapid dose titration. The majority of cases occur in the first 8 weeks; however, isolated cases may occur after prolonged treatment. Discontinue at first sign of rash unless rash is clearly not drug related. Use caution in patients with impaired renal, hepatic, or cardiac function. Avoid abrupt cessation, taper over at least 2 weeks if possible. May cause CNS depression, which may impair physical or mental abilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Effects with other sedative drugs or ethanol may be potentiated. Binds to melanin and may accumulate in the eye and other melanin-rich tissues; the clinical significance of this is not known. Safety and efficacy has not been established for use as initial monotherapy, conversion to monotherapy from nonenzyme-inducing antiepileptic drugs (AED) except valproate, or conversion to monotherapy from two or more AEDs. **Use caution in writing and/or interpreting prescriptions/orders; medication dispensing errors have occurred with similar-sounding medications (Lamisil[®], ludiomil, lamivudine, labetalol, and Lomitol[®]).**

Dosage Forms

Tablet: 25 mg, 100 mg, 150 mg, 200 mg [contains lactose]

Tablet, combination package [each unit-dose starter kit contains]:

Lamictal[®] (blue kit; for patients taking valproate):

Tablet: Lamotrigine 25 mg (35s)

Lamictal[®] (green kit; for patients taking carbamazepine, phenytoin, phenobarbital, primidone, or rifampin and **not** taking valproate):

Tablet: Lamotrigine 25 mg (84s)

Tablet: Lamotrigine 100 mg (14s)

Lamictal[®] (orange kit; for patients **not** taking carbamazepine, phenytoin, phenobarbital, primidone, rifampin, or valproate; for use in bipolar patients only):

Tablet: Lamotrigine 25 mg (42s)

Tablet: Lamotrigine 100 mg (7s)

Tablet, dispersible/chewable: 2 mg, 5 mg, 25 mg [black currant flavor]

Reference Range

Not established
 Postmortem levels in a related fatality were: Cardiac blood: 52 mg/L; liver: 220 mg/kg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Cardiac monitoring should occur for 24 to 48 hours in the setting of acute overdose. Although no formal studies exist, I.V. sodium bicarbonate (1-2 mEq/kg) should be considered in treating wide complex tachycardia.
 Enhancement of elimination: Multiple dosing of activated charcoal may be useful

Drug Interactions

Acetaminophen: May reduce serum concentrations of lamotrigine; mechanism not defined; of clinical concern only with chronic acetaminophen dosing (not single doses).
 Carbamazepine: Lamotrigine may increase the epoxide metabolite of carbamazepine resulting in toxicity. Carbamazepine may decrease plasma levels of lamotrigine. Dosage adjustments may be needed when adding or withdrawing agents; monitor.
 Oral contraceptives (estrogens): Oral contraceptives may decrease the serum concentration of lamotrigine; monitor. Dosage adjustment of lamotrigine may be required when starting/stopping oral contraceptives.
 Phenytoin: May decrease plasma levels of lamotrigine. Dosage adjustments may be needed when adding or withdrawing agents; monitor.
 Phenobarbital (barbiturates): May increase the metabolism of lamotrigine. Dosage adjustment may be needed when adding or withdrawing agent; monitor.
 SSRIs (sertraline): Toxicity has been reported following the addition of sertraline; limited documentation; monitor.
 Valproic acid: Inhibits the clearance of lamotrigine, dosage adjustment required when adding or withdrawing valproic acid. Inhibition appears maximal at valproic acid 250-500 mg/day. The incidence of serious rash may be increased by valproic acid.

Pregnancy Risk Factor C

Pregnancy Implications Lamotrigine has been found to decrease folate concentrations in animal studies. Teratogenic effects in animals were not observed. Safety and efficacy in pregnant women have not been established. Healthcare providers may enroll patients in the Lamotrigine Pregnancy Registry by calling (800) 336-2176. Patients may enroll themselves in the North American Antiepileptic Drug Pregnancy Registry by calling (888) 233-2334. Dose of lamotrigine may need adjusted during pregnancy to maintain clinical response; lamotrigine serum levels may decrease during pregnancy and return to prepregnancy levels following delivery.

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Additional Information Low water solubility; not indicated for patients <16 years of age; when having the prescription refilled, patients should be advised to contact the prescriber if the medicine looks different or the label name has changed (see Warnings)

Adverse Reactions

Cardiovascular: Angina, arrhythmia, bradycardia, cardiospasm, cerebrovascular accident, cerebral infarction, chest pain, edema, hypertension, hypotension, myocardial infarction, palpitations, peripheral edema, shock, syncope, tachycardia, vasodilation
Central nervous system: Abnormal dreams, agitation, amnesia, anxiety, apathy, chills, confusion, convulsion, depersonalization, depression, dizziness, emotional lability, fever, hallucinations, hostility aggravated, hypesthesia, insomnia, malaise, migraine, nervousness, neurosis, pain, sleep disorder, thinking abnormality, vertigo, dizziness, speech disorder
Dermatologic: Acne, alopecia, contact dermatitis, dry skin, maculopapular rash, photophobia, pruritus, skin carcinoma, urticaria, erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis (some fatal)
Endocrine & metabolic: Breast enlargement, breast pain, breast tenderness, cholesterol increased, cholesterol decreased, dehydration, diabetes mellitus, electrolyte imbalance, glucocorticoids increased, goiter, gout, gynecomastia, hyperglycemia, hyperlipemia, hypoglycemia, hypothyroidism, menorrhagia, menstrual disorder
Gastrointestinal: Abdominal pain, diarrhea (4%, more likely at doses of 60 mg/day), constipation, nausea, enlarged abdomen, anorexia, appetite increased, bezoar, colitis, dry mouth, dyspepsia, dysphagia, enteritis, eructation, esophageal ulcer, esophagitis, fecal discoloration, flatulence, fundic gland polyps, gastric nodules, gastrin levels increased, gastritis, gastroenteritis, gastrointestinal anomaly, gastrointestinal disorder, gastrointestinal hemorrhage, glossitis, gum hemorrhage, halitosis, hematemesis, melena, mouth ulceration, pancreatitis, rectal disorder, rectal hemorrhage, salivation increased, stomatitis, taste loss, taste perversion, tenesmus, tongue disorder, ulcerative stomatitis, ulcerative colitis, vomiting, weight gain/loss, abnormal stools
Genitourinary: Abnormal menses, dysmenorrhea, dysuria, glycosuria, impotence, leukorrhea, libido decreased, pelvic pain, penis disorder, testis disorder, urethral pain, urinary frequency, urination impaired, vaginitis, urinary retention, increased libido
Hematologic: Anemia, eosinophilia, hemolysis, platelet abnormalities, RBC abnormal, WBC abnormal, agranulocytosis, aplastic anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia, thrombotic thrombocytopenic purpura
Hepatic: Increased alkaline phosphatase, increased ALT, AST increased, bilirubinemia, cholelithiasis, GGTP increased, GGTP decreased, globulins increased, abnormal liver function test, hepatotoxicity, LDH increased
Neuromuscular & skeletal: Asthenia, arthralgia, arthritis, back pain, bone disorder, hemiplegia, hyperkinesia, hypertonia, joint disorder, leg cramps, musculoskeletal pain, myalgia, myasthenia, neck pain, neck rigidity, paresthesia, synovitis, tremor
Ocular: Abnormal vision, blurred vision, conjunctivitis, diplopia, dry eyes, eye pain, retinal degeneration, visual field defect
Otic: Deafness, ear disorder, otitis media, parosmia, tinnitus
Renal: Creatinine increased, hematuria, kidney calculus, kidney pain, polyuria, albuminuria
Respiratory: Asthma, bronchitis, cough increased, dyspnea, epistaxis, hemoptysis, laryngeal neoplasia, pharyngitis, pleural disorder, pneumonia, respiratory disorder, rhinitis, sinusitis, stridor, upper respiratory inflammation, upper respiratory infection
Miscellaneous: Allergic reaction, candidiasis, carcinoma, fixed eruption, flu-like syndrome, hair disorder, hiccups, infection, moniliasis (oral), nail disorder, anaphylactoid reaction, lymphadenopathy, sweating, thirst

Pharmacodynamics/Kinetics

Duration: >1 day
 Absorption: Rapid
 Protein binding: 97%
 Metabolism: Hepatic via CYP2C19 and 3A4, and in parietal cells to two inactive metabolites
 Bioavailability: 80%; decreased 50% to 70% if given 30 minutes after food
 Half-life elimination: 2 hours; Elderly: 2-3 hours; Hepatic impairment: ≤7 hours
 Time to peak, plasma: 1.7 hours
 Excretion: Feces (67%); urine (33%)

Dosage

Oral:
 Children 1-11 years: GERD, erosive esophagitis:
 ≤30 kg: 15 mg once daily
 >30 kg: 30 mg once daily
Adults:
 Duodenal ulcer: Short-term treatment: 15 mg once daily for 4 weeks; maintenance therapy: 15 mg once daily
 Gastric ulcer: Short-term treatment: 30 mg once daily for up to 8 weeks
 NSAID-associated gastric ulcer (healing): 30 mg once daily for 8 weeks; controlled studies did not extend past 8 weeks of therapy
 NSAID-associated gastric ulcer (to reduce risk): Oral: 15 mg once daily for up to 12 weeks; controlled studies did not extend past 12 weeks of therapy
 Symptomatic GERD: Short-term treatment: 15 mg once daily for up to 8 weeks

Lansoprazole

CAS Number 103577-45-3

U.S. Brand Names Prevacid® SoluTab™; Prevacid®

Use Short-term treatment of active duodenal ulcers; maintenance treatment of healed duodenal ulcers; as part of a multidrug regimen for *H. pylori* eradication to reduce the risk of duodenal ulcer recurrence; short-term treatment of active benign gastric ulcer; treatment of NSAID-associated gastric ulcer; to reduce the risk of NSAID-associated gastric ulcer in patients with a history of gastric ulcer who require an NSAID; short-term treatment of symptomatic GERD; short-term treatment for all grades of erosive esophagitis; to maintain healing of erosive esophagitis; long-term treatment of pathological hypersecretory conditions, including Zollinger-Ellison syndrome

Unlabeled/Investigational Use Active ulcer bleeding (parenteral formulation)

Mechanism of Action Similar to omeprazole; a proton pump inhibitor which decreases acid secretion in gastric parietal cells

Erosive esophagitis: Short-term treatment: 30 mg once daily for up to 8 weeks; continued treatment for an additional 8 weeks may be considered for recurrence or for patients that do not heal after the first 8 weeks of therapy; maintenance therapy: 15 mg once daily

Hypersecretory conditions: Initial: 60 mg once daily; adjust dose based upon patient response and to reduce acid secretion to <10 mEq/hour (5 mEq/hour in patients with prior gastric surgery); doses of 90 mg twice daily have been used; administer doses >120 mg/day in divided doses

Helicobacter pylori eradication: Currently accepted recommendations (may differ from product labeling): Dose varies with regimen: 30 mg once daily or 60 mg/day in 2 divided doses; requires combination therapy with antibiotics

Elderly: No dosage adjustment is needed in elderly patients with normal hepatic function

Dosage adjustment in renal impairment: No dosage adjustment is needed

Dosing adjustment in hepatic impairment: Dose reduction is necessary for severe hepatic impairment

Monitoring Parameters Patients with Zollinger-Ellison syndrome should be monitored for gastric acid output, which should be maintained at ≤ 10 mEq/hour during the last hour before the next lansoprazole dose; lab monitoring should include CBC, liver function, renal function, and serum gastrin levels

Administration

Oral: Administer before food; best if taken before breakfast. The intact granules should not be chewed or crushed; however, in addition to oral suspension, several options are available for those patients unable to swallow capsules:

Capsules may be opened and the intact granules sprinkled on 1 tablespoon of applesauce, Ensure[®] pudding, cottage cheese, yogurt, or strained pears. The granules should then be swallowed immediately.

Capsules may be opened and emptied into ~60 mL orange juice, apple juice, or tomato juice; mix and swallow immediately. Rinse the glass with additional juice and swallow to assure complete delivery of the dose.

Capsule granules may be mixed with apple, cranberry, grape, orange, pineapple, prune, tomato and V-8[®] juice and stored for up to 30 minutes.

Delayed release oral suspension granules should be mixed with 2 tablespoonfuls (30 mL) of water; no other liquid should be used; should not be administered through enteral administration tubes

Orally-disintegrating tablets: Should not be swallowed whole or chewed. Place tablet on tongue; allow to dissolve (with or without water) until particles can be swallowed.

Nasogastric tube administration: Capsules can be opened, the granules mixed (not crushed) with 40 mL of apple juice and then injected through the NG tube into the stomach, then flush tube with additional apple juice.

Contraindications Hypersensitivity to lansoprazole, substituted benzimidazoles (ie, esomeprazole, omeprazole, pantoprazole, rabeprazole), or any component of the formulation

Warnings Severe liver dysfunction may require dosage reductions. Symptomatic response does not exclude malignancy. Safety and efficacy have not been established in children < 1 year of age.

Dosage Forms Capsule, delayed release (Prevacid[®]): 15 mg, 30 mg Granules, for oral suspension, delayed release (Prevacid[®]): 15 mg/packet (30s), 30 mg/packet (30s) [strawberry flavor] Injection, powder for reconstitution (Prevacid[®]): 30 mg Tablet, orally disintegrating (Prevacid[®] SoluTab[™]): 15 mg [contains phenylalanine 2.5 mg; strawberry flavor]; 30 mg [contains phenylalanine 5.1 mg; strawberry flavor]

Reference Range Peak serum level after a 60 mg oral dose: 2.2 mcg/mL

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Not dialyzable

Test Interactions Possible increased plasma gastrin levels

Drug Interactions **Substrate** of CYP2C9 (minor), 2C19 (major), 3A4 (major); **Inhibits** CYP2C9 (weak), 2C19 (moderate), 2D6 (weak), 3A4 (weak); **Induces** CYP1A2 (weak)

CYP2C19 inducers: May decrease the levels/effects of lansoprazole. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 substrates: Lansoprazole may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of lansoprazole. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

Itraconazole and ketoconazole: Proton pump inhibitors may decrease the absorption of itraconazole and ketoconazole.

Protease inhibitors: Proton pump inhibitors may decrease absorption of some protease inhibitors (atazanavir and indinavir).

Pregnancy Risk Factor B

Pregnancy Implications Animal studies have not shown teratogenic effects to the fetus. However, there are no adequate and well-controlled studies in pregnant women; use during pregnancy only if clearly needed.

Lactation Excretion in breast milk unknown/not recommended

Additional Information May have activity against *Helicobacter pylori*

Latanoprost

CAS Number 130209-82-4

U.S. Brand Names Xalatan[®]

Use Reduction of elevated intraocular pressure in patients with open-angle glaucoma and ocular hypertension

Mechanism of Action Latanoprost is a prostaglandin F₂-alpha analog of dinoprost believed to reduce intraocular pressure by increasing the outflow of the aqueous humor

Adverse Reactions

Cardiovascular: Chest pain, angina pectoris

Dermatologic: Rash, allergic skin reaction, toxic epidermal necrolysis

Neuromuscular & skeletal: Myalgia, arthralgia, back pain

Ocular: **Blurred vision, burning and stinging, conjunctival hyperemia, foreign body sensation, itching, increased pigmentation of the iris, punctate epithelial keratopathy**, dry eye, excessive tearing, eye pain, lid crusting, lid edema, lid erythema, lid discomfort/pain, photophobia, conjunctivitis, diplopia, eye discharge, retinal artery embolus, retinal detachment, vitreous hemorrhage from diabetic retinopathy, corneal edema, corneal erosion, eyelash change, eyelid skin darkening, herpes keratitis, iritis, keratitis, macular edema, uveitis
Respiratory: Upper respiratory tract infection, cold, flu, asthma, dyspnea

Pharmacodynamics/Kinetics

Onset of action: 3-4 hours

Peak effect: Maximum: 8-12 hours

Absorption: Through the cornea where the isopropyl ester prodrug is hydrolyzed by esterases to the biologically active acid. Peak concentration is reached in 2 hours after topical administration in the aqueous humor.

Distribution: V_d: 0.16 L/kg

Metabolism: Primarily hepatic via fatty acid beta-oxidation

Half-life elimination: 17 minutes

Excretion: Urine (as metabolites)

Dosage Adults: Ophthalmic: 1 drop (1.5 mcg) in the affected eye(s) once daily in the evening; do not exceed the once daily dosage because it has been shown that more frequent administration may decrease the IOP lowering effect

Stability Protect from light; store intact bottles under refrigeration (2°C to 8°C/36°F to 46°F). Once opened, the container may be stored at room temperature up to 25°C (77°F) for 6 weeks.

Administration If more than one topical ophthalmic drug is being used, administer the drugs at least 5 minutes apart

Contraindications Hypersensitivity to latanoprost or any component of the formulation

Warnings

Latanoprost may gradually change eye color, increasing the amount of brown pigment in the iris by increasing the number of melanosome in melanocytes. The long-term effects on the melanocytes and the consequences of potential injury to the melanocytes or deposition of pigment granules to other areas of the eye is currently unknown. Patients should be examined regularly, and depending on the clinical situation, treatment may be stopped if increased pigmentation ensues. There have been reports of bacterial keratitis associated with the use of multiple-dose containers of topical ophthalmic products. Do not administer while wearing contact lenses.

Dosage Forms Solution, ophthalmic: 0.005% (2.5 mL) [contains benzalkonium chloride]

Overdosage/Treatment Decontamination: Ocular: Irrigate with saline

Drug Interactions May be used concomitantly with other topical ophthalmic drugs if administration is separated by at least 5 minutes.

Bimatoprost: Combination therapy may result in higher IOP than either agent alone.

Thimerosal-containing eye drops: Precipitation occurs when eye drops containing thimerosal are mixed with latanoprost. If such drugs are used, administer with an interval of at least 5 minutes between applications.

Pregnancy Risk Factor C

Additional Information Irreversible brown eye color change in individuals with blue-green eyes

Leflunomide

U.S. Brand Names Arava®

Use Treatment of active rheumatoid arthritis: indicated to reduce signs and symptoms, and to retard structural damage and improve physical function
Unlabeled/Investigational Use Treatment of cytomegalovirus (CMV) disease

Mechanism of Action An isoxazole derivative which inhibits pyrimidine synthesis, resulting in antiproliferative and anti-inflammatory effects; attenuates the immune response

Adverse Reactions

Cardiovascular: Hypertension, chest pain, palpitations, tachycardia, vasculitis, vasodilation, varicose veins, peripheral edema
Central nervous system: Headache, dizziness, pain, fever, malaise, migraine, anxiety, depression, insomnia, sleep disorder
Dermatologic: **Alopecia** (10%), rash, pruritus, dry skin, eczema, acne, dermatitis, hair discoloration, hematoma, nail disorder, skin disorder/dyscoloration, skin ulcer, bruising, urticaria, toxic epidermal necrolysis, urticaria, Stevens-Johnson syndrome, angioedema, erythema multiforme
Endocrine & metabolic: Hypokalemia, diabetes mellitus, hyperglycemia, hyperlipidemia, hyperthyroidism, menstrual disorder
Gastrointestinal: **Diarrhea**, nausea, abdominal pain, dyspepsia, weight loss, anorexia, gastroenteritis, stomatitis, vomiting, cholelithiasis, colitis, constipation, esophagitis, flatulence, gastritis, gingivitis, melena, enlarged salivary gland, tooth disorder, xerostomia, taste disturbance, pancreatitis
Genitourinary: Urinary tract infection, cystitis, dysuria, vaginal candidiasis, prostate disorder, urinary frequency, pelvic pain
Hematologic: Anemia, eosinophilia, thrombocytopenia, leukopenia, pancytopenia, agranulocytosis
Hepatic: Abnormal liver function test results, hepatotoxicity, hepatic failure, cholestasis, hepatic necrosis
Neuromuscular & skeletal: Back pain, joint disorder, weakness, tenosynovitis, synovitis, arthralgia, paresthesia, muscle cramps, neck pain, arthrosis, bursitis, myalgia, bone necrosis, bone pain, tendon rupture, neuralgia, neuritis, increased CPK, peripheral neuropathy
Ocular: Blurred vision, cataract, conjunctivitis, eye disorder
Renal: Albuminuria, hematuria
Respiratory: **Respiratory tract infection**, bronchitis, cough, pharyngitis, pneumonia, rhinitis, sinusitis, asthma, dyspnea, epistaxis, interstitial lung disease
Miscellaneous: Infection, accidental injury, allergic reactions, diaphoresis, anaphylaxis, herpes infection, subcutaneous nodule, oral candidiasis, sepsis, opportunistic infection

Pharmacodynamics/Kinetics

Distribution: V_d : 0.13 L/kg
Metabolism: Hepatic to A77 1726 (MI) which accounts for nearly all pharmacologic activity; further metabolism to multiple inactive metabolites; undergoes enterohepatic recirculation
Bioavailability: 80%
Half-life elimination: Mean: 14-15 days; enterohepatic recycling appears to contribute to the long half-life of this agent, since activated charcoal and cholestyramine substantially reduce plasma half-life
Time to peak: 6-12 hours
Excretion: Feces (48%); urine (43%)

Dosage

Oral:

Adults: Initial: 100 mg/day for 3 days, followed by 20 mg/day; dosage may be decreased to 10 mg/day in patients who have difficulty tolerating the 20 mg dose. Due to the long half-life of the active metabolite, plasma levels may require a prolonged period to decline after dosage reduction.
Elderly: Although hepatic function may decline with age, no specific dosage adjustment is recommended. Patients should be monitored closely for adverse effects which may require dosage adjustment.

Dosing adjustment in renal impairment: No specific dosage adjustment is recommended. There is no clinical experience in the use of leflunomide in patients with renal impairment. The free fraction of MI is doubled in dialysis patients. Patients should be monitored closely for adverse effects requiring dosage adjustment.

Dosing adjustment in hepatic impairment: No specific dosage adjustment is recommended. Since the liver is involved in metabolic activation and subsequent metabolism/elimination of leflunomide, patients with hepatic impairment should be monitored closely for adverse effects requiring dosage adjustment.

Dosing adjustment in hepatic toxicity: Guidelines for dosage adjustment or discontinuation based on the severity and persistence of ALT elevation secondary to leflunomide have been developed. If ALT elevations >2 times but ≤3 times ULN are noted, reduce dose to 10 mg/day, and monitor closely. If elevations persist or if elevations >3 times ULN are observed, discontinue leflunomide and initiate protocol to accelerate elimination. Cholestyramine (8 g 3 times/day for 1-3 days) or activated charcoal (50 g every 6 hours for 24 hours) may be administered

to decrease leflunomide concentrations rapidly. If elevations >3 times ULN persist additional cholestyramine and/or activated charcoal may be required.

Stability Protect from light; store at 25°C (77°F)

Monitoring Parameters A complete blood count (WBC, hemoglobin, hematocrit, and platelet count) as well as serum transaminase determinations should be monitored at baseline and monthly during the initial 6 months of treatment; if stable, monitoring frequency may be decreased to every 6-8 weeks thereafter (continue monthly when used in combination with other immunosuppressive agents). In addition, monitor for signs/symptoms of severe infection, abnormalities in hepatic function tests, or symptoms of hepatotoxicity.

Contraindications Hypersensitivity to leflunomide or any component of the formulation; pregnancy

Warnings Leflunomide has been associated with rare reports of hepatotoxicity, hepatic failure, and death. Multiple risk factors for hepatotoxicity including hepatic disease (including seropositive hepatitis B or C patients) and/or concurrent exposure to other hepatotoxins may increase the risk of hepatotoxicity. Most severe cases occur within 6 months of initiation. Monitoring of hepatic function is required.

Not recommended for patients with severe immune deficiency, bone marrow dysplasia, or uncontrolled infection. Has been associated with rare pancytopenia, agranulocytosis, and thrombocytopenia, particularly when given in combination with methotrexate or other immunosuppressive agents. Monitoring of hematologic function is required. Use with caution in patients with a prior history of significant hematologic abnormalities. Discontinue if evidence of bone marrow suppression or severe dermatologic reaction occurs, and begin procedure to accelerate elimination (cholestyramine or activated charcoal, see Overdosage/Toxicology). Interstitial lung disease has been associated (rarely) with leflunomide use. Discontinue in patients who develop new onset or worsening of pulmonary symptoms; accelerated elimination procedures should be considered if interstitial lung disease occurs; fatal outcomes have been reported. Consider interruption of therapy and accelerated elimination in patients who develop serious infections while receiving leflunomide. The use of live vaccines is not recommended.

[U.S. Boxed Warning]: Women of childbearing potential should not receive leflunomide until pregnancy has been excluded. Patients have been counseled concerning fetal risk and reliable contraceptive measures have been confirmed. Caution in renal impairment. Leflunomide will increase uric acid excretion. Immunosuppression may increase the risk of lymphoproliferative disorders or other malignancies.

Dosage Forms Tablet (Arava®): 10 mg, 20 mg

Overdosage/Treatment

Decontamination: Lavage within 1 hour. Activated charcoal without sorbitol or cholestyramine should then be given.

Enhanced elimination: Multiple dosing of activated charcoal without sorbitol (50 g every 6 hours for 24 hours) or cholestyramine (8 g every 8 hours for 1-3 days) may be useful. Cholestyramine and/or activated charcoal enhance elimination of leflunomide's active metabolite (MI). Cholestyramine reduces plasma levels by approximately 40% in 24 hours and 49% to 65% after 48 hours of dosing. Activated charcoal reduces plasma levels by 37% after 24 hours and 48% after 48 hours of continuous dosing.

Drug Interactions Inhibits CYP2C9 (weak)

Bile acid sequestrants (cholestyramine): May interfere with enterohepatic recycling of leflunomide. This is used emergently to remove drug from the circulation, but may decrease levels inadvertently if used concomitantly.

Hepatotoxic agents: Leflunomide may increase the risk of hepatotoxicity when combined with drugs which may cause hepatic injury; use caution.

Methotrexate: Concomitant treatment with leflunomide may increase the risk of hepatotoxicity or hematologic toxicity; monitor.

Rifampin: May increase the serum concentration of leflunomide's active metabolite; use caution.

Warfarin: Leflunomide may increase the effects of warfarin; monitor.

Pregnancy Risk Factor X

Pregnancy Implications Has been associated with teratogenic and embryolethal effects in animal models at low doses. Leflunomide is contraindicated in pregnant women or women of childbearing potential who are not using reliable contraception. Pregnancy must be excluded prior to initiating treatment. Following treatment, pregnancy should be avoided until undetectable plasma levels (< 0.02 mcg/mL) are verified. This may be accomplished by an extended drug elimination procedure: Administer cholestyramine 8 g 3 times/day for 11 days (the 11 days do not need to be consecutive). Plasma levels <0.02 mg/L should be verified by two separate tests performed at least 14 days apart. If plasma levels are >0.02 mg/L, additional cholestyramine treatment should be considered. Without this procedure, it may take up to 2 years to reach acceptable plasma concentrations.

Lactation Excretion in breast milk unknown/contraindicated

Additional Information Smoking increases plasma clearance by 38%.

Levetiracetam

CAS Number 102767-28-2

U.S. Brand Names Keppra®

Use Indicated as adjunctive therapy in the treatment of partial onset seizures in adults with epilepsy

Unlabeled/Investigational Use Bipolar disorder; partial onset seizures in children with epilepsy

Mechanism of Action The precise mechanism by which levetiracetam exerts its antiepileptic effect is unknown and does not appear to derive from any interaction with known mechanisms involved in inhibitory and excitatory neurotransmission.

Adverse Reactions

Cardiovascular: Chest pain

Central nervous system: **Somnolence, headache,** pain, psychotic symptoms, amnesia, ataxia, depression, dizziness, emotional lability, nervousness, vertigo, agitation, anger, aggression, irritability, hostility, anxiety, apathy, depersonalization, confusion, convulsion, fever, insomnia, thinking abnormal

Dermatologic: Bruising, rash

Gastrointestinal: Anorexia, abdominal pain, constipation, diarrhea, dyspepsia, gastroenteritis, gingivitis, nausea, vomiting, weight gain

Hematologic: Decreased erythrocyte counts, decreased leukocytes, leukopenia, neutropenia, pancytopenia, thrombocytopenia

Neuromuscular & skeletal: **Weakness,** ataxia and other coordination difficulties, paresthesia, arthralgia, back pain, tremor

Ocular: Diplopia, amblyopia, otitis media

Respiratory: Pharyngitis, rhinitis, cough, sinusitis, bronchitis

Miscellaneous: **Infection,** flu-like symptoms

Signs and Symptoms of Overdose Coma, lethargy, respiratory depression, sedation

Admission Criteria/Prognosis Admit if somnolent, exhibiting respiratory depression, or if ingestion exceeds 10 g

Pharmacodynamics/Kinetics

Onset of action: Oral: Peak effect: 1 hour

Absorption: Oral: Rapid and complete

Distribution: V_d : Similar to total body water

Protein binding: < 10%

Metabolism: Not extensive; primarily by enzymatic hydrolysis; forms metabolites (inactive)

Bioavailability: 100%

Half-life elimination: 6-8 hours

Excretion: Urine (66% as unchanged drug)

Dosage

Oral:

Children 4-16 years: Partial onset seizures (unlabeled use): 10-20 mg/kg/day in 2 divided doses; may increase weekly by 10-20 mg/kg, up to a maximum of 60 mg/kg

Children \geq 16 years and Adults:

Partial onset seizure: Initial: 500 mg twice daily; additional dosing increments may be given (1000 mg/day additional every 2 weeks) to a maximum recommended daily dose of 3000 mg

Bipolar disorder (unlabeled use): Initial: 500 mg twice daily; if tolerated, increase to 500 mg twice daily; dose may be increased every 3 days until target dose of 3000 mg/day is reached; maximum: 4000 mg/day

Dosing adjustment in renal impairment:

Cl_{cr} > 80 mL/minute: 500-1500 mg every 12 hours

Cl_{cr} 50-80 mL/minute: 500-1000 mg every 12 hours

Cl_{cr} 30-50 mL/minute: 250-750 mg every 12 hours

Cl_{cr} < 30 mL/minute: 250-500 mg every 12 hours

End-stage renal disease patients using dialysis: 500-1000 mg every 24 hours; a supplemental dose of 250-500 mg following dialysis is recommended hours

Administration Tablets may be crushed and placed in food if unable to swallow whole (bitter taste may be expected).

Contraindications Hypersensitivity to levetiracetam or any component of the formulation

Warnings Psychotic symptoms (psychosis, hallucinations) and behavioral symptoms (including aggression, anger, anxiety, depersonalization, depression, personality disorder) may occur; incidence may be increased in children. Dose reduction may be required. Levetiracetam should be withdrawn gradually to minimize the potential of increased seizure frequency. Use caution with renal impairment; dosage adjustment may be necessary. Weakness, dizziness, and somnolence occur mostly during the first month of therapy. Safety and efficacy in children < 4 years (oral formulation) or < 16 years (I.V. formulation) have not been established.

Dosage Forms Injection, solution:

Keppra®: 100 mg/mL (5 mL)

Solution, oral:

Keppra®: 100 mg/mL (480 mL) [dye free; grape flavor]

Tablet:

Keppra®: 250 mg, 500 mg, 750 mg, 1000 mg

Reference Range Steady state serum levels following a 3000 mg daily dose: 10-37 mcg/mL. Peak serum levetiracetam after 5000 mg dose: 118 mcg/mL. Serum level after 30,000 mg overdose with resultant coma: 400 mcg/mL

Overdosage/Treatment

Decontamination: Lavage within 1 hour of ingestion with activated charcoal. Consider gastric decontamination if ingestion exceeds 10 g.

Supportive therapy: May require respiratory support for respiratory depression

Enhanced elimination: Multiple dosing of activated charcoal may be useful; hemodialysis can remove 50% of dose in 4 hours

Drug Interactions CNS depressants: May enhance the adverse/toxic effect of levetiracetam.

Pregnancy Risk Factor C

Pregnancy Implications Developmental toxicities were observed in animal studies. There are no adequate and well-controlled studies in pregnant women. Pregnant women exposed to levetiracetam may be enrolled in the Antiepileptic Drug Pregnancy Registry by calling 888-233-2334.

Lactation Enters breast milk/not recommended

Levodopa

Related Information

• Therapeutic Drugs Associated with Hallucinations

CAS Number 59-92-7

U.S. Brand Names Dopar®; Larodopa®

Synonyms L-3-Hydroxytyrosine; L-Dopa

Use Treatment of Parkinson's disease

Diagnostic agent for growth hormone deficiency

Mechanism of Action Increases dopamine levels in the brain, then stimulates dopaminergic receptors in the basal ganglia to improve the balance between cholinergic and dopaminergic activity

Adverse Reactions

Cardiovascular: **Cardiac arrhythmias, hypotension (orthostatic),** flutter (atrial), myocardial depression, tachycardia (supraventricular), palpitations

Central nervous system: **Anxiety, dizziness, confusion, nightmares,** memory loss, nervousness, insomnia, fatigue, psychosis, auditory and visual hallucinations, dystonic reactions, ataxia, electroencephalogram abnormalities, gustatory hallucinations, hyperthermia

Dermatologic: Urticaria, purpura, exanthem

Endocrine & metabolic: Hypoprolactinemia

Gastrointestinal: **Nausea, anorexia, constipation, vomiting,** GI bleeding, xerostomia, metallic taste

Genitourinary: **Dysuria**

Hematologic: Hemolytic anemia with positive direct and indirect Coombs' tests, leukopenia, neutropenia, agranulocytosis, granulocytopenia

Neuromuscular & skeletal: **Choreiform and involuntary movements,** clonus, myoclonus

Ocular: **Blepharospasm,** blurred vision

Miscellaneous: Bruxism, systemic lupus erythematosus

Signs and Symptoms of Overdose Agranulocytosis, alopecia, arrhythmias, chorea (extrapyramidal), congestive heart failure, confusion, delirium, dementia, depression, dysosmia, eosinophilia, euphoria, extrapyramidal reaction including choreoathetosis, feces discoloration (black), fibrillation (atrial), granulocytopenia, gout, hyperpigmented hair, hypertension, hyperuricemia, hypokalemia, hyponatremia, insomnia, leukocytosis, leukopenia, malignant hyperthermia (reported), mania, memory loss, myoclonus, nausea, neutropenia, night terrors, palpitations, Parkinson's-like symptoms, paroxysmal tachycardia (ventricular), pemphigus, respiratory dyskinesias, restlessness, pseudotumor cerebri, spasm, thrombocytopenia, urine discoloration (black; brown), vomiting

Pharmacodynamics/Kinetics

Duration: Variable, usually 6-12 hours

Absorption: May be decreased if given with a high protein meal

Metabolism: Peripheral decarboxylation to dopamine; small amounts reach brain and are decarboxylated to active dopamine

Half-life elimination: 1.2-2.3 hours

Time to peak, serum: 1-2 hours

Excretion: Primarily urine (80% as dopamine, norepinephrine, and homovanillic acid)

Dosage

Oral:

Children (given as a single dose to evaluate growth hormone deficiency):

0.5 g/m² or

< 30 lbs: 125 mg

30-70 lbs: 250 mg

> 70 lbs: 500 mg

LEVOFLOXACIN

Adults (administer with food): 500-1000 mg/day in divided doses every 6-12 hours; increase by 100-750 mg/day every 3-7 days until response or total dose of 8000 mg is reached

Significant therapeutic response may not be obtained for 6 months

Monitoring Parameters Serum growth hormone concentration

Administration

Administer with meals to decrease GI upset

Contraindications Hypersensitivity to levodopa or any component of the formulation; narrow-angle glaucoma; use of MAO inhibitors within prior 14 days (however, may be administered concomitantly with the manufacturer's recommended dose of an MAO inhibitor with selectivity for MAO type B); history of melanoma or any undiagnosed skin lesions

Warnings Use with caution in patients with history of cardiovascular disease (including myocardial infarction and arrhythmias); pulmonary diseases such as asthma, psychosis, wide-angle glaucoma, peptic ulcer disease; as well as in renal, hepatic, or endocrine disease. Sudden discontinuation of levodopa may cause a worsening of Parkinson's disease. Elderly may be more sensitive to CNS effects of levodopa. May cause or exacerbate dyskinesias. May cause orthostatic hypotension; Parkinson's disease patients appear to have an impaired capacity to respond to a postural challenge. Use with caution in patients at risk of hypotension (such as those receiving antihypertensive drugs) or where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). Observe patients closely for development of depression with concomitant suicidal tendencies. Safety and effectiveness in pediatric patients have not been established. Some products may contain tartrazine. Dopaminergic agents have been associated with a syndrome resembling neuroleptic malignant syndrome on withdrawal or significant dosage reduction after long-term use. Pyridoxine may reverse effects of levodopa. Toxic reactions have occurred with dextromethorphan.

Dosage Forms Capsule: 100 mg, 250 mg, 500 mg

Tablet: 100 mg, 250 mg, 500 mg

Reference Range Peak serum level of 3.2 mg/L occurs after ingestion of 200 mg levodopa

Overdosage/Treatment

Decontamination: Emesis (within 30 minutes) may be of value in only very early ingestions; lavage (within 1 hour); activated charcoal of use

Supportive therapy: Deanol and pyridoxine of questionable use for dyskinesias, but have been tried; dantrolene and/or bromocriptine has been used in malignant hyperthermia; choreo-ballistic dyskinesia due to levodopa can improve with low dose propranolol (30-60 mg/day); levodopa-induced psychosis can be treated with remoxipride; amantadine at doses of 200-300 mg/day can help improve dyskinesia

Enhancement of elimination: Multiple dose activated charcoal has not been addressed

Test Interactions False-positive reaction for urinary glucose with Clinistix®; false-negative reaction using Clinistix®; false-positive urine ketones with Acetest®, Ketostix®, Labstix®; serum uric acid may be elevated; may cause false elevation of serum creatinine through interference with laboratory determination; may interfere with the TSH assay resulting in falsely low TSH levels

Drug Interactions

Antacids: Levodopa absorption may be increased; monitor

Anticholinergics: May reduce the efficacy of levodopa, possibly due to reduced gastrointestinal absorption (also see tricyclic antidepressants); limited evidence of clinical significance; monitor

Antipsychotics: May inhibit the antiparkinsonian effects of levodopa via dopamine receptor blockade; use antipsychotics with low dopamine blockade (clozapine, olanzapine, quetiapine)

Benzodiazepines: May inhibit the antiparkinsonian effects of levodopa; monitor for reduced effect

Clonidine: May reduce the efficacy of levodopa; monitor

Furazolidone: May increase the effect/toxicity of levodopa; hypertensive episodes have been reported; monitor

Iron salts: Binds levodopa and reduces its bioavailability; separate doses of iron and levodopa

Linezolid: Due to MAO inhibition (see note on MAO inhibitors), this agent is best avoided

MAO inhibitors: Concurrent use of levodopa with nonselective MAO inhibitors may result in hypertensive reactions via an increased storage and release of dopamine, norepinephrine, or both; use with carbidopa to minimize reactions if combination is necessary; otherwise avoid combination

L-methionine: May inhibit levodopa's antiparkinsonian effects; monitor for reduced effect

Metoclopramide: May increase the absorption/efficacy of levodopa; hypertensive episodes have been reported. Levodopa antagonizes metoclopramide's effects on lower esophageal sphincter pressure; avoid use of metoclopramide for reflux, monitor response to levodopa carefully if used.

Methyldopa: May potentiate the effects of levodopa; levodopa may increase the hypotensive response to methyldopa; monitor

Papaverine: May decrease the efficacy of levodopa; includes other similar agents (ethaverine); monitor

Penicillamine: May increase serum concentrations of levodopa; monitor for increased effect

Phenytoin: May inhibit levodopa's antiparkinsonian effects; monitor for reduced effect

Pyridoxine: May inhibit levodopa's antiparkinsonian effects; monitor for reduced effect (pyridoxine in doses >10-25 mg for levodopa alone, higher doses >200 mg/day may be a problem for levodopa/carbidopa)

Spiramycin: May inhibit levodopa's antiparkinsonian effects; monitor for reduced effect

Tacrine: May inhibit the effects of levodopa via enhanced cholinergic activity; monitor for reduced effect

Tricyclic antidepressants: May decrease the absorption (bioavailability) of levodopa; rare hypertensive episodes have also been attributed to this combination

Pregnancy Risk Factor C

Nursing Implications Sustained release product should not be crushed

Levofloxacin

Related Information

● Ciprofloxacin

CAS Number 100986-85-4; 138199-71-0

U.S. Brand Names Iquix®, Levaquin®, Quixin™

Use

Systemic: Treatment of mild, moderate, or severe infections caused by susceptible organisms. Includes the treatment of community-acquired pneumonia (including penicillin-resistant strains of *S. pneumoniae*); nosocomial pneumonia; chronic bronchitis (acute bacterial exacerbation); acute maxillary sinusitis; urinary tract infection (uncomplicated or complicated), including acute pyelonephritis caused by *E. coli*; prostatitis (chronic bacterial); skin or skin structure infections (uncomplicated or complicated)

Ophthalmic: Treatment of bacterial conjunctivitis caused by susceptible organisms (Quixin™ 0.5% ophthalmic solution); treatment of corneal ulcer caused by susceptible organisms (Iquix® 1.5% ophthalmic solution)

Unlabeled/Investigational Use Diverticulitis, enterocolitis, (*Shigella* sp), gonococcal infections, Legionnaires' disease, peritonitis, PID

Mechanism of Action As the S (-) enantiomer of the fluoroquinolone, ofloxacin, levofloxacin, inhibits DNA-gyrase in susceptible organisms thereby inhibiting relaxation of supercoiled DNA and promoting breakage of DNA strands. DNA gyrase (topoisomerase II), is an essential bacterial enzyme that maintains the superhelical structure of DNA and is required for DNA replication and transcription, DNA repair, recombination, and transposition.

Adverse Reactions

Systemic:

Cardiovascular: Cardiac failure, hypertension, bradycardia, tachycardia, arrhythmias (including ventricular tachycardia and torsade de pointes), QTc prolongation

Central nervous system: Dizziness, fever, headache, insomnia, seizures, dysphonia

Dermatologic: Photosensitivity (<0.1%), erythema multiforme, rash, Stevens-Johnson syndrome

Genitourinary: Leukorrhea

Gastrointestinal: Nausea, vomiting, diarrhea, constipation, pseudomembranous colitis

Hematologic: Granulocytopenia, leukopenia, leukocytosis, thrombocytopenia, eosinophilia, hemolytic anemia, autoimmune hemolytic anemia (AIHA)

Hepatic: Elevated transaminases, hepatic failure, jaundice

Neuromuscular & skeletal: Tremor, arthralgia, tendon rupture

Renal: Acute renal failure

Respiratory: Pharyngitis, pulmonary embolism

Miscellaneous: Allergic reaction (including pneumonitis and anaphylaxis)

Ophthalmic solution:

Ocular: Decreased vision (transient), foreign body sensation, transient ocular burning, ocular pain or discomfort, photophobia, lid edema, ocular dryness, ocular itching

Miscellaneous: Allergic reaction

Signs and Symptoms of Overdose Acute renal failure, dizziness, diarrhea, seizures

Pharmacodynamics/Kinetics

Absorption: Rapid and complete

Distribution: V_d: 1.25 L/kg; CSF concentrations ~15% of serum levels; high concentrations are achieved in prostate, lung, and gynecological tissues, sinus, saliva

Protein binding: 50%

Metabolism: Minimally hepatic

Bioavailability: 99%

Half-life elimination: 6-8 hours
 Time to peak, serum: 1-2 hours
 Excretion: Primarily urine (as unchanged drug)

Dosage

Oral, I.V. (infuse I.V. solution over 60 minutes): Adults:

Chronic bronchitis (acute bacterial exacerbation): 500 mg every 24 hours for at least 7 days

Maxillary sinusitis (acute): 500 mg every 24 hours for 10-14 days

Pneumonia:

Community-acquired: 500 mg every 24 hours for 7-14 days or 750 mg every 24 hours for 5 days

Nosocomial: 750 mg every 24 hours for 7-14 days

Prostatitis (chronic bacterial): 500 mg every 24 hours for 28 days

Skin infections:

Uncomplicated: 500 mg every 24 hours for 7-10 days

Complicated: 750 mg every 24 hours for 7-14 days

Urinary tract infections:

Uncomplicated: 250 mg once daily for 3 days

Complicated, including acute pyelonephritis: 250 mg every 24 hours for 10 days

Ophthalmic:

Conjunctivitis (0.5% ophthalmic solution): Children \geq 1 year and Adults:

Treatment day 1 and day 2: Instill 1-2 drops into affected eye(s) every 2 hours while awake, up to 8 times/day

Treatment day 3 through day 7: Instill 1-2 drops into affected eye(s) every 4 hours while awake, up to 4 times/day

Corneal ulceration (1.5% ophthalmic solution): Children \geq 6 years and Adults:

Treatment day 1 through day 3: Instill 1-2 drops into affected eye(s) every 30 minutes to 2 hours while awake and ~4-6 hours after retiring.

Treatment day 4 to treatment completion: Instill 1-2 drops into affected eye(s) every 1-4 hours while awake.

Dosing adjustment in renal impairment:

Chronic bronchitis, acute maxillary sinusitis, uncomplicated skin infection, community-acquired pneumonia, chronic bacterial prostatitis, complicated UTI, or acute pyelonephritis: First dose as indicated in patients with normal renal function (250 mg or 500 mg), followed by:

Cl_{cr} 20-49 mL/minute: 250 mg every 24 hours

Cl_{cr} 10-19 mL/minute: 250 mg every 48 hours

Uncomplicated UTI: No dosage adjustment required

Complicated skin infection, community-acquired pneumonia, or nosocomial pneumonia:

Cl_{cr} 20-49 mL/minute: Administer 750 mg every 48 hours

Cl_{cr} 10-19 mL/minute: Administer 500 mg every 48 hours (initial: 750 mg)

Hemodialysis/CAPD: 250 mg every 48 hours (initial: 500 mg for most infections; initial: 750 mg for complicated skin/soft tissue infections followed by 500 mg every 48 hours)

Stability Injection: Stable for 72 hours when diluted to 5 mg/mL in a compatible I.V. fluid and stored at room temperature; stable for 14 days when stored under refrigeration; stable for 6 months when frozen, do not refreeze; do not thaw in microwave or by bath immersion; **incompatible** with mannitol and sodium bicarbonate

Ophthalmic solution: Store at 15°C to 25°C (59°F to 77°F)

Monitoring Parameters Evaluation of organ system functions (renal, hepatic, ophthalmologic, and hematopoietic) is recommended periodically during therapy; the possibility of crystalluria should be assessed; WBC and signs of infection

Administration

Oral: May be administered without regard to meals.

I.V.: Infuse I.V. solution over 60 minutes. Too rapid of infusion can lead to hypotension. Avoid administration through an intravenous line with a solution containing multivalent cations (ie, magnesium, calcium).

Contraindications Hypersensitivity to levofloxacin, any component of the formulation, or other quinolones

Warnings

Systemic: Not recommended in children <18 years of age; CNS stimulation may occur (tremor, restlessness, confusion, and very rarely hallucinations or seizures). Potential for seizures, although very rare, may be increased with concomitant NSAID therapy. Use with caution in individuals at risk of seizures, with known or suspected CNS disorders or renal dysfunction; use caution to avoid possible photosensitivity reactions during and for several days following fluoroquinolone therapy. Rare cases of torsade de pointes have been reported in patients receiving levofloxacin. Risk may be minimized by avoiding use in patients with known prolongation of QT interval, bradycardia, hypokalemia, hypomagnesemia, cardiomyopathy, or in those receiving concurrent therapy with Class Ia or Class III antiarrhythmics.

Severe hypersensitivity reactions, including anaphylaxis, have occurred with quinolone therapy. If an allergic reaction occurs (itching, urticaria, dyspnea or facial edema, loss of consciousness, tingling, cardiovascular collapse), discontinue drug immediately. Prolonged use may result

in superinfection; pseudomembranous colitis may occur and should be considered in all patients who present with diarrhea. Tendon inflammation and/or rupture has been reported; risk may be increased with concurrent corticosteroids, particularly in the elderly. Discontinue at first sign of tendon inflammation or pain. Peripheral neuropathies have been linked to levofloxacin use; discontinue if numbness, tingling, or weakness develops. Quinolones may exacerbate myasthenia gravis; use with caution (rare, potentially life-threatening weakness of respiratory muscles may occur).

Ophthalmic solution: For topical use only. Do not inject subconjunctivally or introduce into anterior chamber of the eye. Contact lenses should not be worn during treatment for bacterial conjunctivitis. Safety and efficacy in children <1 year of age (Quixin™) or <6 years of age (Iquix®) have not been established. **Note:** Indications for ophthalmic solutions are product concentration-specific and should not be used interchangeably.

Dosage Forms Infusion [premixed in D₅W] (Levaquin®): 250 mg (50 mL); 500 mg (100 mL); 750 mg (150 mL)

Injection, solution [preservative free] (Levaquin®): 25 mg/mL (20 mL, 30 mL)

Solution, ophthalmic:

Iquix®: 1.5% (5 mL)

Quixin™: 0.5% (5 mL) [contains benzalkonium chloride]

Solution, oral (Levaquin®): 25 mg/mL (480 mL) [contains benzyl alcohol]

Tablet (Levaquin®): 250 mg, 500 mg, 750 mg

Levaquin® Leva-Pak: 750 mg (5s)

Overdosage/Treatment Treatment should include GI decontamination (for ingestions >5 g) and supportive care; not removed by peritoneal or hemodialysis

Test Interactions Can give a false-positive result for opiates by urine immunoassay screening

Drug Interactions Corticosteroids: Concurrent use may increase the risk of tendon rupture, particularly in elderly patients (overall incidence rare).

Glyburide: Quinolones may increase the effect of glyburide; monitor Metal cations (aluminum, calcium, iron, magnesium, and zinc) bind quinolones in the gastrointestinal tract and inhibit absorption. Concurrent administration of most antacids, oral electrolyte supplements, quinapril, sucralfate, some didanosine formulations (chewable/buffered tablets and pediatric powder for oral suspension), and other highly-buffered oral drugs, should be avoided. Levofloxacin should be administered 2 hours before or 2 hours after these agents.

Probenecid: May decrease renal secretion of levofloxacin.

QT_c-prolonging agents: Effects may be additive with levofloxacin. Avoid concurrent use with Class Ia and Class III antiarrhythmics, erythromycin, cisapride, antipsychotics, and cyclic antidepressants.

Warfarin: The hypoprothrombinemic effect of warfarin may be enhanced by some quinolone antibiotics; monitor INR.

Pregnancy Risk Factor C

Pregnancy Implications Avoid use in pregnant women unless the benefit justifies the potential risk to the fetus

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Infuse I.V. solutions over 60 minutes

Additional Information Ophthalmic solution contains benzalkonium chloride 0.005% as a preservative.

Levonorgestrel

CAS Number 797-63-7

U.S. Brand Names Mirena®; Plan B®

Synonyms LNG 20

Use Prevention of pregnancy

Mechanism of Action Pregnancy may be prevented through several mechanisms: Thickening of cervical mucus, which inhibits sperm passage through the uterus and sperm survival; inhibition of ovulation, from a negative feedback mechanism on the hypothalamus, leading to reduced secretion of follicle stimulating hormone (FSH) and luteinizing hormone (LH); inhibition of implantation. Levonorgestrel is not effective once the implantation process has begun.

Adverse Reactions

Intrauterine system:

Cardiovascular: Hypertension
 Central nervous system: Headache, depression, nervousness, migraine
 Dermatologic: Acne, alopecia, eczema, induration
 Endocrine & metabolic: Breast pain, dysmenorrhea, decreased libido, abnormal Pap smear, **amenorrhea, enlarged follicles**
 Gastrointestinal: Abdominal pain, nausea, weight gain, vomiting
 Genitourinary: Leukorrhea, vaginitis, cervicitis, dyspareunia
 Hematologic: Anemia
 Neuromuscular & skeletal: Back pain
 Respiratory: Upper respiratory tract infection, sinusitis
 Miscellaneous: Failed insertion, sepsis

Oral tablets:

Central nervous system: **Fatigue, headache, dizziness**
 Endocrine & metabolic: **Heavier menstrual bleeding, lighter menstrual bleeding, breast tenderness**
 Gastrointestinal: **Nausea, abdominal pain**, vomiting, diarrhea

Subdermal capsules:

Cardiovascular: Deep vein thrombosis, idiopathic intracranial hypertension, myocardial infarction, superficial venous thrombosis
 Central nervous system: Anxiety, depression, dizziness, emotional lability, fatigue, headache, migraine, nervousness, stroke
 Dermatologic: Acne, alopecia, blistering, bruising, cellulitis, dermatitis, hirsutism, hyperpigmentation, pruritus, rash, sloughing, ulcerations, urticaria
 Endocrine & metabolic: **Increased/prolonged bleeding, spotting**, breast discharge, menstrual irregularities, dysmenorrhea, mastalgia
 Gastrointestinal: Abdominal discomfort, appetite change, vomiting, weight gain
 Genitourinary: Cervicitis, leukorrhea, vaginitis
 Hematologic: Thrombotic thrombocytopenic purpura (TTP)
 Local: Pain/itching at implant site (usually transient), infection at implant site, phlebitis
 Neuromuscular & skeletal: Musculoskeletal pain, arm pain, nerve injury, numbness, tingling, weakness
 Respiratory: Pulmonary embolism
 Miscellaneous: Removal difficulties; these may include multiple incisions, remaining capsule fragments, pain, multiple visits, deep placement, lengthy procedure; abscess, adnexal enlargement, breast cancer, congenital anomalies, excessive scarring

Signs and Symptoms of Overdose Can result if >6 capsules are *in situ*; symptoms include uterine bleeding irregularities and fluid retention; benign intracranial hypertension

Pharmacodynamics/Kinetics

Duration: Intrauterine system: Up to 5 years
 Absorption: Oral: Rapid and complete
 Protein binding: Highly bound to albumin (~50%) and sex hormone-binding globulin (~47%)
 Metabolism: To inactive metabolites
 Half-life elimination: Oral: ~24 hours
 Excretion: Primarily urine

Dosage Adults:

Long-term prevention of pregnancy: Intrauterine system: To be inserted into uterine cavity; should be inserted within 7 days of onset of menstruation or immediately after 1st trimester abortion; releases 20 mcg levonorgestrel/day over 5 years. May be removed and replaced with a new unit at anytime during menstrual cycle; do not leave any one system in place for >5 years

Emergency contraception: Oral tablet: One 0.75 mg tablet as soon as possible within 72 hours of unprotected sexual intercourse; a second 0.75 mg tablet should be taken 12 hours after the first dose; may be used at any time during menstrual cycle

Dosage adjustment in renal impairment: Safety and efficacy have not been established

Dosage adjustment in hepatic impairment: Safety and efficacy have not been established

Elderly: Not intended for use in postmenopausal women

Monitoring Parameters Monitor for prolonged menstrual bleeding, amenorrhea, irregularity of menses, Pap smear, blood pressure, serum glucose in patients with diabetes, LDL levels in patients with hyperlipidemias

Administration Intrauterine system: Inserted in the uterine cavity, to a depth of 6-9 cm, with the provided insertion device; should not be forced into the uterus

Contraindications Hypersensitivity to levonorgestrel or any component of the formulation; undiagnosed abnormal uterine bleeding, active hepatic disease or malignant tumors, known or suspected carcinoma of the breast; pregnancy

Additional product-specific contraindications: Intrauterine system: Congenital or acquired uterine anomaly, acute pelvic inflammatory disease, history of pelvic inflammatory disease (unless there has been a subsequent intrauterine pregnancy), postpartum endometritis, infected abortion within past 3 months, known or suspected uterine or cervical neoplasia, unresolved/abnormal Pap smear, untreated acute cervicitis or vaginitis, patient or partner with multiple sexual partners, conditions which increase susceptibility to infections (ie, leukemia, AIDS, I.V. drug abuse), unremoved IUD, history of ectopic pregnancy, conditions which predispose to ectopic pregnancy; genital actinomycosis

Note: A previously available levonorgestrel product also had the following contraindications: Active thrombophlebitis, or thromboembolic disorders (current or history of); history of intracranial hypertension

Warnings

Menstrual bleeding patterns may be altered, missed menstrual periods should not be used to identify early pregnancy. These products do not protect against HIV infection or other sexually-transmitted diseases. Patients presenting with lower abdominal pain should be evaluated for follicular atresia and ectopic pregnancy. Patients receiving enzyme-inducing medications should be evaluated for an alternative method of contraception. Levonorgestrel may affect glucose tolerance, monitor serum glucose in patients with diabetes. Safety and efficacy for use in renal or hepatic impairment have not been established. Use with caution in conditions that may be aggravated by fluid retention, depression, or history of migraine. Only for use in women of reproductive age.

Use of combination hormonal contraceptives increases the risk of cardiovascular side effects in women who smoke cigarettes, especially those who are >35 years of age; although this may be an estrogen-related effect, the risk with progestin-only contraceptives is not known and women should be strongly advised not to smoke. Combination hormonal contraceptives may lead to increased risk of myocardial infarction and should be used with caution in patients with risk factors for coronary artery disease; the actual risk with progestin-only contraceptives is not known, however, there have been postmarketing reports of myocardial infarction in women using levonorgestrel-only contraception. May increase the risk of thromboembolism; discontinue therapy if this occurs. Combination hormonal contraceptives may have a dose-related risk of vascular disease and hypertension; strokes have also been reported with postmarketing use of levonorgestrel-only contraception. Women with hypertension should be encouraged to use a nonhormonal form of contraception. The use of combination hormonal contraceptives has been associated with a slight increase in frequency of breast cancer (studies are not consistent); studies with progestin only contraceptives have been similar. Retinal thrombosis has been reported (rarely) with combination hormonal contraceptives and may be related to the estrogen component, however, progestin-only therapy should also be discontinued with unexplained partial or complete loss of vision.

Additional formulation-specific warnings:

Intrauterine system: Increased incidence of group A streptococcal sepsis and pelvic inflammatory disease (may be asymptomatic). May perforate uterus or cervix; risk of perforation is increased in lactating women. Partial penetration or embedment in the myometrium may decrease effectiveness and lead to difficult removal. Postpartum insertion should be delayed for 6 weeks or until uterine involution is complete. Use caution in patients with coagulopathy or receiving anticoagulants

Oral tablet: Not intended to be used for routine contraception and will not terminate an existing pregnancy

Dosage Forms Intrauterine device:

Mirena®: 52 mg levonorgestrel/unit [releases levonorgestrel 20 mcg/day]

Tablet:

Plan B®: 0.75 mg

Reference Range Contraceptive protection usually with plasma levonorgestrel concentrations of 0.29-0.35 ng/mL

Overdosage/Treatment Treatment includes removal of all implanted capsules. In single acute ingestion, acute toxic effects are unlikely. In pregnancy exposure, suggest decontamination by emesis within 30 minutes or lavage within 1 hour followed by activated charcoal.

Drug Interactions Substrate of CYP3A4 (major)

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of levonorgestrel. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

Pregnancy Risk Factor X

Pregnancy Implications Epidemiologic studies have not shown an increased risk of birth defects when used prior to pregnancy or inadvertently during early pregnancy, although rare reports of congenital anomalies have been reported. Intrauterine system: Women who become pregnant with an IUD in place risk septic abortion (septic shock and death may occur), removal of IUD may result in pregnancy loss. In addition, miscarriage, premature labor, and premature delivery may occur if pregnancy is continued with IUD in place.

Lactation Enters breast milk/use caution (AAP rates "compatible")

Levorphanol

CAS Number 125-72-4; 5985-38-6; 77-07-6

U.S. Brand Names Levo-Dromoran®

Synonyms Levorphan Tartrate; Levorphanol Tartrate

Impairment Potential Yes

Use Relief of moderate to severe pain; also used parenterally for preoperative sedation and an adjunct to nitrous oxide/oxygen anesthesia; 2 mg levorphanol produces analgesia comparable to that produced by 10 mg of morphine

Mechanism of Action Levorphanol is a synthetic opioid agonist that is classified as a morphinan derivative. Opioids interact with stereospecific opioid receptors in various parts of the central nervous system and other tissues. Analgesic potency parallels the affinity for these binding sites. These drugs do not alter the threshold or responsiveness to pain, but the perception of pain.

Adverse Reactions

Cardiovascular: **Palpitations, hypotension, bradycardia, peripheral vasodilation**

Central nervous system: **CNS depression**, agitation, increased intracranial pressure, **fatigue, drowsiness, dizziness**

Dermatologic: **Pruritus**

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone

Gastrointestinal: **Nausea, vomiting**, constipation, biliary tract spasm

Genitourinary: Urinary tract spasm

Neuromuscular & skeletal: **Weakness**

Ocular: Miosis

Respiratory: Apnea, respiratory depression

Miscellaneous: Physical and psychological dependence, histamine release

Pharmacodynamics/Kinetics

Onset of action: Oral: 10-60 minutes

Duration: 4-8 hours

Metabolism: Hepatic

Half-life elimination: 11-16 hours

Excretion: Urine (as inactive metabolite)

Dosage

Adults: Note: These are guidelines and do not represent the maximum doses that may be required in all patients. Doses should be titrated to pain relief/prevention.

Acute pain (moderate to severe):

Oral: Initial: Opiate-naïve: 2 mg every 6-8 hours as needed; patients with prior opiate exposure may require higher initial doses; usual dosage range: 2-4 mg every 6-8 hours as needed

I.M., SubQ: Initial: Opiate-naïve: 1 mg every 6-8 hours as needed; patients with prior opiate exposure may require higher initial doses; usual dosage range: 1-2 mg every 6-8 hours as needed

Slow I.V.: Initial: Opiate-naïve: Up to 1 mg/dose every 3-6 hours as needed; patients with prior opiate exposure may require higher initial doses

Chronic pain: Patients taking opioids chronically may become tolerant and require doses higher than the usual dosage range to maintain the desired effect. Tolerance can be managed by appropriate dose titration. There is no optimal or maximal dose for levorphanol in chronic pain. The appropriate dose is one that relieves pain throughout its dosing interval without causing unmanageable side effects.

Premedication: I.M., SubQ: 1-2 mg/dose 60-90 minutes prior to surgery; older or debilitated patients usually require less drug

Dosing adjustment in hepatic disease: Reduction is necessary in patients with liver disease

Stability Store at room temperature, protect from freezing; I.V. is incompatible when mixed with aminophylline, barbiturates, heparin, methicillin, phenytoin, sodium bicarbonate

Monitoring Parameters Pain relief, respiratory and mental status, blood pressure

Administration I.V.: Inject 3 mg over 4-5 minutes

Contraindications Hypersensitivity to levorphanol or any component of the formulation; pregnancy (prolonged use or high doses at term)

Warnings

An opioid-containing analgesic regimen should be tailored to each patient's needs and based upon the type of pain being treated (acute versus chronic), the route of administration, degree of tolerance for opioids (naïve versus chronic user), age, weight, and medical condition. The optimal analgesic dose varies widely among patients. Doses should be titrated to pain relief/prevention.

Use with caution in patients with hypersensitivity reactions to other phenanthrene derivative opioid agonists (morphine, hydrocodone, hydromorphone, levorphanol, oxycodone, oxymorphone); respiratory diseases including asthma, emphysema, COPD or severe liver or renal insufficiency; some preparations contain sulfites which may cause allergic reactions; tolerance or dependence may result from extended use; dextromethorphan has equivalent antitussive activity but has much lower toxicity in accidental overdose. Elderly may be particularly susceptible to the CNS depressant and constipating effects of narcotics.

Dosage Forms Injection, solution, as tartrate: 2 mg/mL (1 mL, 10 mL)

Tablet, as tartrate: 2 mg

Overdosage/Treatment Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at $\frac{2}{3}$ the response dose/hour) may be required

Antidote(s)

● Nalmefene [ANTIDOTE]

● Naloxone [ANTIDOTE]

Drug Interactions Increased toxicity: CNS depressants increase CNS depression

Pregnancy Risk Factor B/D (prolonged use or high doses at term)

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Observe patient for excessive sedation, respiratory depression, implement safety measures, assist with ambulation

Levothyroxine

Related Information

● Liothyronine

● Therapeutic Drugs Associated with Hallucinations

CAS Number 25416-65-3; 51-48-9; 55-03-8; 8065-29-0

U.S. Brand Names Levothroid®; Levoxyl®; Novothyrox; Synthroid®; Unithroid®

Synonyms L-Thyroxine Sodium; Levothyroxine Sodium; T₄

Use Replacement or supplemental therapy in hypothyroidism; pituitary TSH suppression

Mechanism of Action Exact mechanism of action is unknown; however, it is believed the thyroid hormone exerts its many metabolic effects through control of DNA transcription and protein synthesis; involved in normal metabolism, growth, and development; promotes gluconeogenesis, increases utilization and mobilization of glycogen stores, and stimulates protein synthesis, increases basal metabolic rate

Adverse Reactions

Cardiovascular: Angina, arrhythmias, blood pressure increased, cardiac arrest, flushing, heart failure, MI, palpitations, pulse increased, tachycardia

Central nervous system: Anxiety, emotional lability, fatigue, fever, headache, hyperactivity, insomnia, irritability, nervousness, pseudotumor cerebri (children), seizures (rare)

Dermatologic: Alopecia

Endocrine & metabolic: Fertility impaired, menstrual irregularities

Gastrointestinal: Abdominal cramps, appetite increased, diarrhea, vomiting, weight loss

Hepatic: Elevated liver function tests

Neuromuscular & skeletal: Bone mineral density decreased, muscle weakness, tremors, slipped capital femoral epiphysis (children)

Respiratory: Dyspnea

Miscellaneous: Diaphoresis, heat intolerance, hypersensitivity (to inactive ingredients - symptoms include urticaria, pruritus, rash, flushing, angioedema, GI symptoms, fever, arthralgia, serum sickness, wheezing)

Signs and Symptoms of Overdose Overdose may cause agitation, congestive heart failure, coma, fever, heat intolerance, hypertension, hyperthyroidism, hypoglycemia, insomnia, menstrual irregularities, nervousness, palpitations, psychosis, pseudotumor cerebri, seizures (may occur up to 1 week postingestion), sweating, tachycardia (may last 3 days), unrecognized adrenal insufficiency, and weight loss. Overtreatment of children may result in premature closure of epiphyses or craniosynostosis (infants). Acute massive overdose may be life-threatening.

Admission Criteria/Prognosis Admit any symptomatic patient, ingestion > 4 mg, or serum total T₄ > 75 mcg/dL

Pharmacodynamics/Kinetics

Onset of action: Therapeutic: Oral: 3-5 days; I.V. 6-8 hours

Peak effect: I.V.: ~24 hours

Absorption: Oral: Erratic (40% to 80%); decreases with age

Protein binding: >99%

Metabolism: Hepatic to triiodothyronine (active)

Time to peak, serum: 2-4 hours

Half-life elimination: Euthyroid: 6-7 days; Hypothyroid: 9-10 days;

Hyperthyroid: 3-4 days

Excretion: Urine and feces; decreases with age

Dosage Doses should be adjusted based on clinical response and laboratory parameters.

Oral:

Children: Hypothyroidism:

Newborns: Initial: 10-15 mcg/kg/day. Lower doses of 25 mcg/day should be considered in newborns at risk for cardiac failure.

Newborns with T₄ levels < 5 mcg/dL should be started at 50 mcg/day. Adjust dose at 4- to 6-week intervals.

Infants and Children: Dose based on body weight and age as listed below. Children with severe or chronic hypothyroidism should be started at 25 mcg/day; adjust dose by 25 mcg every 2-4 weeks. In older children, hyperactivity may be decreased by starting with $\frac{1}{4}$ of the recommended dose and increasing by $\frac{1}{4}$ dose each week

until the full replacement dose is reached. Refer to adult dosing once growth and puberty are complete.

0-3 months: 10-15 mcg/kg/day
3-6 months: 8-10 mcg/kg/day
6-12 months: 6-8 mcg/kg/day
1-5 years: 5-6 mcg/kg/day
6-12 years: 4-5 mcg/kg/day
> 12 years: 2-3 mcg/kg/day

Adults:

Hypothyroidism: 1.7 mcg/kg/day in otherwise healthy adults < 50 years old, children in whom growth and puberty are complete, and older adults who have been recently treated for hyperthyroidism or who have been hypothyroid for only a few months. Titrate dose every 6 weeks. Average starting dose ~100 mcg; usual doses are ≤ 200 mcg/day; doses ≥ 300 mcg/day are rare (consider poor compliance, malabsorption, and/or drug interactions). **Note:** For patients > 50 years or patients with cardiac disease, refer to Elderly dosing.

Severe hypothyroidism: Initial: 12.5-25 mcg/day; adjust dose by 25 mcg/day every 2-4 weeks as appropriate; **Note:** Oral agents are not recommended for myxedema (see I.V. dosing).

Subclinical hypothyroidism (if treated): 1 mcg/kg/day
TSH suppression:

Well-differentiated thyroid cancer: Highly individualized; Doses > 2 mcg/kg/day may be needed to suppress TSH to < 0.1 mIU/L.

Benign nodules and nontoxic multinodular goiter: Goal TSH suppression: 0.1-0.3 mIU/L

Elderly: Hypothyroidism:

> 50 years without cardiac disease **or** < 50 years with cardiac disease: Initial: 25-50 mcg/day; adjust dose at 6- to 8-week intervals as needed

> 50 years with cardiac disease: Initial: 12.5-25 mcg/day; adjust dose by 12.5-25 mcg increments at 4- to 6-week intervals

Note: Elderly patients may require < 1 mcg/kg/day

I.M., I.V.: Children, Adults, Elderly: Hypothyroidism: 50% of the oral dose I.V.:

Adults: Myxedema coma or stupor: 200-500 mcg, then 100-300 mcg the next day if necessary; smaller doses should be considered in patients with cardiovascular disease

Elderly: Myxedema coma: Refer to Adults dosing; lower doses may be needed

Stability Protect tablets from light; do not mix I.V. solution with other I.V. infusion solutions; reconstituted solutions should be used immediately and any unused portions discarded

Monitoring Parameters Thyroid function test (serum thyroxine, thyrotropin concentrations), resin triiodothyronine uptake (rT₃U), free thyroxine index (FTI), T₄, TSH, heart rate, blood pressure, clinical signs of hypo- and hyperthyroidism; TSH is the most reliable guide for evaluating adequacy of thyroid replacement dosage. TSH may be elevated during the first few months of thyroid replacement despite patients being clinically euthyroid. In cases where T₄ remains low and TSH is within normal limits, an evaluation of "free" (unbound) T₄ is needed to evaluate further increase in dosage

Infants: Monitor closely for cardiac overload, arrhythmias, and aspiration from avid suckling

Infants/children: Monitor closely for under/overtreatment. Undertreatment may decrease intellectual development and linear growth, and lead to poor school performance due to impaired concentration and slowed mentation. Overtreatment may adversely affect brain maturation, accelerate bone age (leading to premature closure of the epiphyses and reduced adult height); craniosynostosis has been reported in infants. Treated children may experience a period of catch-up growth. Monitor TSH and total or free T₄ at 2 and 4 weeks after starting treatment; every 1-2 months for first year of life; every 2-3 months during years 1-3; every 3-12 months until growth completed.

Adults: Monitor TSH every 6-8 weeks until normalized; 8-12 weeks after dosage changes; every 6-12 months throughout therapy

Administration Dilute vial with 5 mL normal saline; use immediately after reconstitution; give by direct I.V. infusion over 2- to 3-minute period

Contraindications Hypersensitivity to levothyroxine sodium or any component of the formulation; recent MI or thyrotoxicosis; uncorrected adrenal insufficiency

Warnings [U.S. Boxed Warning]: Ineffective and potentially toxic for weight reduction. High doses may produce serious or even life-threatening toxic effects particularly when used with some anorectic drugs. Use with caution and reduce dosage in patients with angina pectoris or other cardiovascular disease; use cautiously in elderly since they may be more likely to have compromised cardiovascular functions. Patients with adrenal insufficiency, myxedema, diabetes mellitus and insipidus may have symptoms exaggerated or aggravated; thyroid replacement requires periodic assessment of thyroid status. Chronic hypothyroidism predisposes patients to coronary artery disease. Levoxy[®] may rapidly swell and disintegrate causing choking or gagging

(should be administered with a full glass of water); use caution in patients with dysphagia or other swallowing disorders.

Dosage Forms Injection, powder for reconstitution, as sodium: 0.2 mg, 0.5 mg

Tablet, as sodium: 25 mcg, 50 mcg, 75 mcg, 88 mcg, 100 mcg, 112 mcg, 125 mcg, 150 mcg, 175 mcg, 200 mcg, 300 mcg
Levothroid[®]: 25 mcg, 50 mcg, 75 mcg, 88 mcg, 100 mcg, 112 mcg, 125 mcg, 150 mcg, 175 mcg, 200 mcg, 300 mcg
Levoxy[®], Synthroid[®]: 25 mcg, 50 mcg, 75 mcg, 88 mcg, 100 mcg, 112 mcg, 125 mcg, 137 mcg, 150 mcg, 175 mcg, 200 mcg, 300 mcg
Unithroid[®]: 25 mcg, 50 mcg, 75 mcg, 88 mcg, 100 mcg, 112 mcg, 125 mcg, 150 mcg, 175 mcg, 200 mcg, 300 mcg

Reference Range

Correlation is poor with symptomatology in acute overdose

Pediatrics: Cord T₄ and values in the first few weeks are much higher, falling over the first months and years

≥ 10 years: ~5.8-11.0 mcg/dL (SI: 75-142 nmol/L)

Borderline low: 4.5-5.7 mcg/dL (SI: 58-73 nmol/L) or less

Low: ≤ 4.4 mcg/dL (SI: ≤ 57 nmol/L); results < 2.5 mcg/dL (SI: < 32 nmol/L) are strong evidence for hypothyroidism

Adults:

Approximate normal range: 4.0-12.0 mcg/dL (SI: 51-154 nmol/L)

Borderline high: 11.1-13.0 mcg/dL (SI: 143-167 nmol/L)

High: ≥ 13.1 mcg/dL (SI: ≥ 169 nmol/L)

Normal range is increased in women on birth control pills (5.5-12.0 mcg/dL)

Normal range in pregnancy: ~5.5-16.0 mcg/dL (SI: ~71-206 nmol/L)

TSH: 0.4-10.0 (for those ≥ 80 years) mIU/L

T₄: 4.0-12.0 mcg/dL (51-154 nmol/L)

T₃ (RIA) (total T₃): 80-230 ng/dL (1.2-3.5 nmol/L)

T₄, free: 0.7-1.8 ng/dL (9-23 pmol/L)

Overdosage/Treatment

Decontamination: Gastric emptying indicated for ingestions > 5 mg; lavage within 1 hour with activated charcoal; cholestyramine is an effective agent to decrease T₄ absorption; 50 mg of cholestyramine can bind at least 3 mg of thyroxine, therefore, 4 g of cholestyramine given 4 times/day should be administered in order to interrupt enterohepatic recirculation

Supportive therapy: Propranolol may be used for hyperadrenergic signs (1 mg I.V. in adults, 0.01-0.1 mg/kg in pediatrics); sodium ipodate (3 g/1.7 m²) has been used in acute ingestion to prevent T₄ to T₃ conversion
Enhancement of elimination: Plasmapheresis increases elimination 30-fold while charcoal hemoperfusion enhances T₄ elimination fivefold; plasmapheresis (36 minutes using 1 L of 5% human serum albumin and 1 L of fresh frozen plasma) has been utilized following thyroxine overdose with poor results (nearly complete rebound of thyroid hormone levels) and thus is not recommended

Test Interactions Many drugs may have effects on thyroid function tests (see Additional Information). Pregnancy, infectious hepatitis, and acute intermittent porphyria may increase thyroxine-binding globulin; nephrosis, severe hypoproteinemia, severe liver disease, and acromegaly may decrease thyroxine-binding globulin.

Drug Interactions Also refer to Additional Information.

Aluminum- and magnesium-containing antacids, calcium carbonate, simethicone, or sucralfate: May decrease T₄ absorption; separate dose from levothyroxine by at least 4 hours.

Antidiabetic agents (biguanides, meglitinides, sulfonylureas, thiazolidinediones, insulin): Changes in thyroid function may alter requirements of antidiabetic agent. Monitor closely at initiation of therapy, or when dose is changed or discontinued.

Cholestyramine and colestipol: Decrease T₄ absorption; separate dose from levothyroxine by at least 2 hours.

Digoxin: Digoxin levels may be reduced in hyperthyroidism; therapeutic effect may be reduced. Impact of thyroid replacement should be monitored.

Estrogens: May decrease serum free thyroxine concentrations.

Imatinib: May decrease the effects of thyroid replacement therapy; monitor.

Iron: Decreases T₄ absorption; separate dose from levothyroxine by at least 4 hours.

Kayexalate[®]: Decreases T₄ absorption; separate dose from levothyroxine by at least 4 hours.

Ketamine: May cause marked hypertension and tachycardia; monitor.

Theophylline, caffeine: Decreased theophylline clearance in hypothyroid patients; monitor during thyroid replacement.

Tricyclic and tetracyclic antidepressants: Therapeutic and toxic effects of levothyroxine and the antidepressant are increased.

Warfarin (and other oral anticoagulants): The hypoprothrombinemic response to warfarin may be altered by a change in thyroid function or replacement. Replacement may dramatically increase response to warfarin. However, initiation of warfarin in a patient stabilized on a dose of levothyroxine does not appear to require a significantly different approach.

Pregnancy Risk Factor A

Pregnancy Implications Untreated maternal hypothyroidism may have adverse effects on fetal growth and development and is associated with higher rate of complications (spontaneous abortion, pre-eclampsia, stillbirth, premature delivery). Treatment should not be discontinued during pregnancy. TSH levels should be monitored during each trimester and 6-8 weeks postpartum. Increased doses may be needed during pregnancy.

Lactation Enters breast milk/compatible

Nursing Implications I.V. form must be prepared immediately prior to administration; should not be admixed with other solutions

Additional Information Levothroid® tablets contain lactose; levothyroxine is soluble in water; horseradish can depress thyroid function
Equivalent doses: Thyroid USP 60 mg ~ levothyroxine 0.05-0.06 mg ~ liothyronine 0.015-0.0375 mg
50-60 mg thyroid ~ 50-60 mcg levothyroxine and 12.5-15 mcg liothyronine Liotrix®

Note: Several medications have effects on thyroid production or conversion. The impact in thyroid replacement has not been specifically evaluated, but patient response should be monitored:

Methimazole: Decreases thyroid hormone secretion, while propylthiouracil decreases thyroid hormone secretion and decreases conversion of T₄ to T₃.

Beta-adrenergic antagonists: Decrease conversion of T₄ to T₃ (dose related, propranolol ≥ 160 mg/day); patients may be clinically euthyroid.

Iodide, iodine-containing radiographic contrast agents may decrease thyroid hormone secretion; may also increase thyroid hormone secretion, especially in patients with Graves' disease.

Other agents reported to impact on thyroid production/conversion include aminoglutethimide, amiodarone, chloral hydrate, diazepam, ethionamide, interferon-alpha, interleukin-2, lithium, lovastatin (case report), glucocorticoids (dose-related), mercaptopurine, sulfonamides, thiazide diuretics, and tolbutamide.

In addition, a number of medications have been noted to cause transient depression in TSH secretion, which may complicate interpretation of monitoring tests for levothyroxine, including corticosteroids, octreotide, and dopamine. Metoclopramide may increase TSH secretion

Siraj ES, Gupta MK, and Reddy SS, "Raloxifene Causing Malabsorption of Levothyroxine," *Arch Intern Med*, 2003, 163(11):1367-70.

Lidocaine

CAS Number 6108-05-0; 73-78-9

U.S. Brand Names Anestacon®; Band-Aid® Hurt-Free™ Antiseptic Wash [OTC]; Burn Jel [OTC]; Burn-O-Jel [OTC]; Burnamycin [OTC]; L-M-X™ 4 [OTC]; L-M-X™ 5 [OTC]; LidaMantle®; Lidoderm®; Premjact® [OTC]; Solarcaine® Aloe Extra Burn Relief [OTC]; Topicaine® [OTC]; Xylocaine® MPF; Xylocaine® Viscous; Xylocaine®; Zilactin-L® [OTC]

Synonyms Lidocaine Hydrochloride; Lignocaine Hydrochloride

Use

Local anesthetic and acute treatment of ventricular arrhythmias from myocardial infarction, cardiac manipulation, digitalis intoxication; drug of choice for ventricular ectopy, ventricular tachycardia (VT), ventricular fibrillation (VF); for pulseless VT or VF preferably administer **after** defibrillation and epinephrine; control of premature ventricular contractions, wide-complex paroxysmal supraventricular tachycardia (PSVT); control of hemodynamically compromising PVCs; hemodynamically stable VT

Rectal: Temporary relief of pain and itching due to anorectal disorders
Topical: Local anesthetic for use in laser, cosmetic, and outpatient surgeries; minor burns, cuts, and abrasions of the skin

Orphan drug: Lidoderm® Patch: Relief of allodynia (painful hypersensitivity) and chronic pain in postherpetic neuralgia

Unlabeled/Investigational Use ACLS guidelines (not considered drug of choice): Stable monomorphic VT (preserved ventricular function), polymorphic VT (preserved ventricular function), drug-induced monomorphic VT

Mechanism of Action Class IB antiarrhythmic; suppresses automaticity of conduction tissue, by increasing electrical stimulation threshold of ventricle, His-Purkinje system, and spontaneous depolarization of the ventricles during diastole by a direct action on the tissues; blocks both the initiation and conduction of nerve impulses by decreasing the neuronal membrane's permeability to sodium ions, which results in inhibition of depolarization with resultant blockade of conduction

Adverse Reactions

Cardiovascular: Bradycardia, hypotension, heart block with sinus arrest, cardiac arrhythmias (tachycardia [ventricular]), cardiovascular collapse, torsade de pointes, sinus bradycardia, sinus tachycardia, arrhythmias (ventricular), vasoconstriction

Central nervous system: Lethargy, coma, agitation, slurred speech, seizures, psychosis, anxiety, euphoria, hallucinations, circumoral numbness, fever, hyperthermia, acute aphasia

Gastrointestinal: Nausea, vomiting

Hematologic: Porphyria, porphyrinogenic, methemoglobinemia, thrombocytopenia

Neuromuscular & skeletal: Paresthesia, clonus, myoclonus

Ocular: Blurred vision, diplopia, miosis

Otic: Ototoxicity, tinnitus

Respiratory: Depression or arrest

Miscellaneous: Fixed drug eruption, acute atraumatic compartment syndrome

Signs and Symptoms of Overdose Agitation, asystole, AV block, bradycardia, cardiovascular collapse, coma, convulsions, delirium, diplopia, disorientation, euphoria, heart block, hypokalemia, hypotension, methemoglobinemia, myasthenia gravis (exacerbation or precipitation), mydriasis, myoclonus, numbness, nystagmus, ototoxicity, ptosis, respiratory failure, slurred speech, tachycardia (ventricular), tinnitus, tremors

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Pharmacodynamics/Kinetics

Onset of action: Single bolus dose: 45-90 seconds

Duration: 10-20 minutes

Distribution: V_d: 1.1-2.1 L/kg; alterable by many patient factors; decreased in CHF and liver disease; crosses blood-brain barrier

Protein binding: 60% to 80% to alpha₁ acid glycoprotein

Metabolism: 90% hepatic; active metabolites monoethylglycinexylidide (MEGX) and glycinexylidide (GX) can accumulate and may cause CNS toxicity

Half-life elimination: Biphasic: Prolonged with congestive heart failure, liver disease, shock, severe renal disease; Initial: 7-30 minutes; Terminal: Infants, premature: 3.2 hours, Adults: 1.5-2 hours

Dosage

Topical: Apply to affected area as needed; maximum: 3 mg/kg/dose; do not repeat within 2 hours.

L-M-X™ 4 cream: Apply 1/4 inch thick layer to intact skin. Leave on until adequate anesthetic effect is obtained. Remove cream and cleanse area before beginning procedure.

Rectal: Relief of pain and itching (L-M-X™ 5): Children ≥ 12 years and Adults: Apply topically to clean, dry area **or** using applicator insert rectally, up to 6 times/day

Injectable local anesthetic: Varies with procedure, degree of anesthesia needed, vascularity of tissue, duration of anesthesia required, and physical condition of patient; maximum: 4.5 mg/kg/dose; do not repeat within 2 hours.

Patch: Postherpetic neuralgia: Apply patch to most painful area. Up to 3 patches may be applied in a single application. Patch may remain in place for up to 12 hours in any 24-hour period.

Antiarrhythmic:

I.V.: 1-1.5 mg/kg bolus over 2-3 minutes; may repeat doses of 0.5-0.75 mg/kg in 5-10 minutes up to a total of 3 mg/kg; continuous infusion: 1-4 mg/minute

I.V. (2 g/250 mL D₅W) infusion rates (infusion pump should be used for I.V. infusion administration):

1 mg/minute: 7.5 mL/hour

2 mg/minute: 15 mL/hour

3 mg/minute: 22.5 mL/hour

4 mg/minute: 30 mL/hour

Ventricular fibrillation (after defibrillation and epinephrine): Initial: 1-1.5 mg/kg. Repeat 0.5-0.75 mg/kg bolus may be given 3-5 minutes after initial dose. Total dose should not exceed 200-300 mg during a 1-hour period or 3 mg/kg total dose. Follow with continuous infusion after return of perfusion.

Endotracheal: 2-2.5 times the I.V. dose (2-4 mg/kg diluted with NS to a total volume of 10 mL)

Decrease dose in patients with CHF, shock, or hepatic disease.

Dosage adjustment in renal impairment: Not dialyzable (0% to 5%) by hemo- or peritoneal dialysis; supplemental dose is not necessary.

Dosage adjustment in hepatic impairment: Reduce dose in acute hepatitis and decompensated cirrhosis by 50%.

Monitoring Parameters Monitor ECG continuously, serum lidocaine concentration, obtain methemoglobin level

Administration Intratracheal: Dilute in NS or distilled water. Absorption is greater with distilled water, but causes more adverse effects on PaO₂. Pass catheter beyond tip of tracheal tube, stop compressions, spray drug quickly down tube. Follow immediately with several quick insufflations and continue chest compressions.

I.V.: Use microdrip (60 gtt/mL) or infusion pump to administer an accurate dose

Infusion rates: 2 g/250 mL D₅W (infusion pump should be used):

1 mg/minute: 7.5 mL/hour

2 mg/minute: 15 mL/hour

3 mg/minute: 22.5 mL/hour

4 mg/minute: 30 mL/hour

LIDOCAINE

Buffered lidocaine for injectable local anesthetic: Add 2 mL of sodium bicarbonate 8.4% to 18 mL of lidocaine 1%

Topical:

Gel (Topicaine®): Avoid mucous membranes; remove prior to laser treatment.

Transdermal: Apply to painful area of skin immediately after removal from protective envelope. May be cut to appropriate size. After removal from skin, fold used transdermal systems so the adhesive side sticks to itself. Remove immediately if burning sensation occurs. Wash hands after application.

Contraindications Hypersensitivity to lidocaine or any component of the formulation; hypersensitivity to another local anesthetic of the amide type; Adam-Stokes syndrome; severe degrees of SA, AV, or intraventricular heart block (except in patients with a functioning artificial pacemaker); premixed injection may contain corn-derived dextrose and its use is contraindicated in patients with allergy to corn-related products

Warnings

Intravenous: Constant ECG monitoring is necessary during I.V. administration. Use cautiously in hepatic impairment, any degree of heart block, Wolff-Parkinson-White syndrome, CHF, marked hypoxia, severe respiratory depression, hypovolemia, history of malignant hyperthermia, or shock. Increased ventricular rate may be seen when administered to a patient with atrial fibrillation. Correct any underlying causes of ventricular arrhythmias. Monitor closely for signs and symptoms of CNS toxicity. The elderly may be prone to increased CNS and cardiovascular side effects. Reduce dose in hepatic dysfunction and CHF.

Injectable anesthetic: Follow appropriate administration techniques so as not to administer any intravascularly. Solutions containing antimicrobial preservatives should not be used for epidural or spinal anesthesia. Some solutions contain a bisulfite; avoid in patients who are allergic to bisulfite. Resuscitative equipment, medicine and oxygen should be available in case of emergency. Use products containing epinephrine cautiously in patients with significant vascular disease, compromised blood flow, or during or following general anesthesia (increased risk of arrhythmias). Adjust the dose for the elderly, pediatric, acutely ill, and debilitated patients.

Topical: L-M-X™ 4 cream: Do not leave on large body areas for > 2 hours.

Observe young children closely to prevent accidental ingestion. Not for use ophthalmic use or for use on mucous membranes.

Transdermal patch: May contain conducting metal (eg, aluminum); remove patch prior to MRI.

Dosage Forms [DSC] = Discontinued product

Cream, rectal (L-M-X™ 5): 5% (15 g) [contains benzyl alcohol; packaged with applicator]; (30 g) [contains benzyl alcohol]

Cream, topical (L-M-X™ 4): 4% (5 g) [contains benzyl alcohol; packaged with Tegaderm™ dressing]; (15 g, 30 g) [contains benzyl alcohol]

Cream, topical, as hydrochloride: 3% (30 g)

LidaMantle®: 3% (30 g, 85 g)

Gel, topical:

Burn-O-Jel: 0.5% (90 g)

Topicaine®: 4% (10 g, 30 g, 113 g) [contains alcohol 35%, benzyl alcohol, aloe vera, and jojoba]

Gel, topical, as hydrochloride:

Burn Jel: 2% (3.5 g, 120 g)

Solarcaine® Aloe Extra Burn Relief: 0.5% (113 g, 226 g) [contains aloe vera gel and tartrazine]

Infusion, as hydrochloride [premixed in D₅W]: 0.4% [4 mg/mL] (250 mL, 500 mL); 0.8% [8 mg/mL] (250 mL, 500 mL)

Injection, solution, as hydrochloride: 0.5% [5 mg/mL] (50 mL); 1% [10 mg/mL] (2 mL, 10 mL, 20 mL, 30 mL, 50 mL); 2% [20 mg/mL] (2 mL, 5 mL, 20 mL, 50 mL)

Xylocaine®: 0.5% [5 mg/mL] (50 mL); 1% [10 mg/mL] (10 mL, 20 mL, 50 mL); 2% [20 mg/mL] (1.8 mL, 10 mL, 20 mL, 50 mL)

Injection, solution, as hydrochloride [preservative free]: 0.5% [5 mg/mL] (50 mL); 1% [10 mg/mL] (2 mL, 5 mL, 30 mL); 1.5% [15 mg/mL] (20 mL); 2% [20 mg/mL] (2 mL, 5 mL, 10 mL); 4% [40 mg/mL] (5 mL)

Xylocaine®: 10% [100 mg/mL] (5 mL) [for ventricular arrhythmias]

Xylocaine® MPF: 0.5% [5 mg/mL] (50 mL); 1% [10 mg/mL] (2 mL, 5 mL, 10 mL, 30 mL); 1.5% [15 mg/mL] (10 mL, 20 mL); 2% [20 mg/mL] (2 mL, 5 mL, 10 mL); 4% [40 mg/mL] (5 mL)

Injection, solution, as hydrochloride [premixed in D_{7.5}W, preservative free]: 5% (2 mL)

Xylocaine® MPF: 1.5% (2 mL) [DSC]

Jelly, topical, as hydrochloride: 2% (5 mL, 30 mL)

Anestacon®: 2% (15 mL) [contains benzalkonium chloride]

Xylocaine®: 2% (5 mL, 30 mL)

Liquid, topical (Zilactin®-L): 2.5% (7.5 mL)

Lotion, topical, as hydrochloride (LidaMantle®): 3% (177 mL)

Ointment, topical: 5% (37 g, 50 g)

Solution, topical, as hydrochloride: 4% [40 mg/mL] (50 mL)

Band-Aid® Hurt-Free™ Antiseptic Wash: 2% (180 mL)

LTA® 360: 4% [40 mg/mL] (4 mL) [packaged with cannula for laryngotracheal administration]

Xylocaine®: 4% [40 mg/mL] (50 mL)

Solution, viscous, as hydrochloride: 2% [20 mg/mL] (20 mL, 100 mL)

Xylocaine® Viscous: 2% [20 mg/mL] (100 mL, 450 mL)

Spray, topical:

Burnamycin: 0.5% (60 mL) [contains aloe vera gel and menthol]

Premjact®: 9.6% (13 mL)

Solarcaine® Aloe Extra Burn Relief: 0.5% (127 g) [contains aloe vera]

Transdermal system, topical (Lidoderm®): 5% (30s)

Reference Range

Therapeutic: 1.5-4.0 mcg/mL (SI: 6.4-17.1 µmol/L), up to 6.0 mcg/mL (SI: 25.6 µmol/L) if necessary

Therapeutic level for tinnitus: 1.5-2.5 mcg/mL

Toxic: > 6.0 mcg/mL (SI: > 25.6 µmol/L)

Fatal: > 15.0 mcg/mL

Overdosage/Treatment

Decontamination: Oral: **Do not** use ipecac due to possible development of seizures; lavage (within 1 hour)/activated charcoal

Supportive therapy: Termination of anesthesia by pneumatic tourniquet inflation should be attempted when the agent is administered by infiltration or regional injection. Seizures commonly respond to diazepam or lorazepam, while hypotension responds to I.V. fluids and Trendelenburg positioning. Refractory hypotension can be treated with norepinephrine, dopamine, dobutamine, or intra-aortic balloons. Bradyarrhythmias (when the heart rate is less than 60) can be treated with I.V. atropine 15 mcg/kg, isoproterenol, or a pacemaker. With the development of metabolic acidosis, I.V. sodium bicarbonate 0.5-2 mEq/kg and ventilatory assistance should be instituted. Methemoglobinemia should be treated with methylene blue 1-2 mg/kg in a 1% sterile aqueous solution I.V. push over 4-6 minutes repeated up to a total dose of 7 mg/kg. Cardiopulmonary bypass and cardiac pacing has been utilized. Phenobarbital can be also utilized for seizure treatment. Avoid use of phenytoin in that sinoatrial arrest may occur. Peripheral cardiopulmonary bypass support can be used to support hemodynamic compromise. Epidural phenylephrine 200 mcg reduces the incidence of hypotension induced by epidural lidocaine.

Enhancement of elimination: Arteriovenous hemofiltration is also not useful; not dialyzable (0% to 5%)

Diagnostic Procedures

- Lidocaine, Blood

Test Interactions Falsely lowered if blood makes contact with stopper of tube

Drug Interactions

Substrate of CYP1A2 (minor), 2A6 (minor), 2B6 (minor), 2C9 (minor), 2D6 (major), 3A4 (major); **Inhibits** CYP1A2 (strong), 2D6 (moderate), 3A4 (moderate)

Cimetidine increases lidocaine blood levels; monitor levels or use an alternative H₂ antagonist.

CYP1A2 substrates: Lidocaine may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, fluvoxamine, mexiletine, mirtazapine, ropinirole, theophylline, and trifluoperazine.

CYP2D6 inhibitors: May increase the levels/effects of lidocaine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP2D6 substrates: Lidocaine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Lidocaine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of lidocaine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of lidocaine. Example inhibitors include amiodarone (doses > 400 mg/day), azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

CYP3A4 substrates: Lidocaine may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozone are generally contraindicated with strong CYP3A4 inhibitors.

Propranolol: Increases lidocaine blood levels.

Protease inhibitors (eg, amprenavir, ritonavir): May increase lidocaine blood levels.

Pregnancy Risk Factor B (manufacturer); C (expert analysis)

Pregnancy Implications Animal studies with lidocaine have not shown teratogenic effects.

Lactation Enters breast milk (small amounts)/use caution (AAP rates "compatible")

Nursing Implications Local thrombophlebitis may occur in patients receiving prolonged I.V. infusions

Additional Information Odorless, bitter taste; intranasal use of 4% solution is 55% effective for migraine; child-resistant packaging ordered by the U.S. Consumer Product Safety Commission for products containing more than 5 mg of lidocaine

Lindane

CAS Number 58-89-9

UN Number 2761

Synonyms Benzene Hexachloride; Gamma Benzene Hexachloride; Hexachlorocyclohexane

Use Treatment of *Sarcoptes scabiei* (scabies), *Pediculus capitis* (head lice), and *Phthirus pubis* (crab lice); FDA recommends reserving lindane as a second-line agent or with inadequate response to other therapies

Mechanism of Action Directly absorbed by parasites and ova through the exoskeleton; stimulates the nervous system resulting in seizures and death of parasitic arthropods; interferes with the gamma-aminobutyric acid A receptor chloride channel complex in the synapse

Adverse Reactions

Frequency not defined (includes postmarketing and/or case reports).

Cardiovascular: Cardiac arrhythmia

Central nervous system: Ataxia, dizziness, headache, restlessness, seizures, pain

Dermatologic: Alopecia, contact dermatitis, skin and adipose tissue may act as repositories, eczematous eruptions, pruritus, urticaria

Gastrointestinal: Nausea, vomiting

Hematologic: Aplastic anemia

Hepatic: Hepatitis

Local: Burning and stinging

Neuromuscular & skeletal: Paresthesias

Renal: Hematuria

Respiratory: Pulmonary edema

Signs and Symptoms of Overdose Agitation, arrhythmia, ataxia, blindness, disseminated intravascular coagulation, hematuria, hepatitis, lactic acidosis, muscle necrosis, myoglobinuria, nausea, neutropenia, pulmonary edema, respiratory depression, restlessness, rhabdomyolysis, seizures, thrombocytopenia, vomiting

Pharmacodynamics/Kinetics

Absorption: $\leq 13\%$ systemically

Distribution: Stored in body fat; accumulates in brain; skin and adipose tissue may act as repositories

Metabolism: Hepatic

Half-life elimination: Children: 17-22 hours

Time to peak, serum: Children: 6 hours

Excretion: Urine and feces

Dosage Children and Adults: Topical:

Scabies: Apply a thin layer of lotion and massage it on skin from the neck to the toes; after 8-12 hours, bathe and remove the drug

Head lice, crab lice: Apply shampoo to dry hair and massage into hair for 4 minutes; add small quantities of water to hair until lather forms, then rinse hair thoroughly and comb with a fine tooth comb to remove nits. Amount of shampoo needed is based on length and density of hair; most patients will require 30 mL (maximum: 60 mL).

Administration

For topical use only; never administer orally. Caregivers should apply with gloves (avoid natural latex, may be permeable to lindane). Rinse off with warm (not hot) water.

Lotion: Apply to dry, cool skin; do not apply to face or eyes. Wait at least 1 hour after bathing or showering (wet or warm skin increases absorption). Skin should be clean and free of any other lotions, creams, or oil prior to lindane application.

Shampoo: Apply to clean, dry hair. Wait at least 1 hour after washing hair before applying lindane shampoo. Hair should be washed with a shampoo not containing a conditioner; hair and skin of head and neck should be free of any lotions, oils, or creams prior to lindane application.

Contraindications Hypersensitivity to lindane or any component of the formulation; uncontrolled seizure disorders; crusted (Norwegian) scabies, acutely-inflamed skin or raw, weeping surfaces or other skin conditions which may increase systemic absorption

Warnings

[U.S. Boxed Warning]: Not considered a drug of first choice; use only in patients who have failed first-line treatments, or in patients who cannot tolerate these agents. Because of the potential for systemic absorption and CNS side effects, lindane should be used with caution; consider permethrin or crotamiton agent first. Oil-based hair dressing may increase toxic potential.

[U.S. Boxed Warning]: May be associated with severe neurologic toxicities (contraindicated in premature infants and uncontrolled seizure disorders). Seizures and death have been reported with use; use with caution in infants, small children, patients < 50 kg, or patients with a history of seizures; use caution with conditions which may increase risk of seizures or medications which decrease seizure threshold; use caution with hepatic impairment; avoid contact with face, eyes, mucous membranes, and urethral meatus.

[U.S. Boxed Warning]: A lindane medication use guide must be given to all patients along with instructions for proper use. Patients should be informed that itching may occur following successful killing of lice and re-treatment may not be indicated. Should be used as a part of an overall lice management program

Dosage Forms Lotion, topical: 1% (60 mL)

Shampoo, topical: 1% (60 mL) [contains alcohol 0.5%]

Reference Range

In lindane-exposed workers, chronic symptoms can occur at blood levels > 0.02 mcg/mL.

After acute ingestion: Blood levels > 0.12 mcg/mL are correlated with sedation, seizures can occur at blood levels > 0.2 mcg/mL (0.13 mcg/mL in patients with pre-existing seizure disorder), myonecrosis can occur at blood levels > 0.6 mcg/mL and death can occur at blood levels exceeding 1.3 mcg/mL

Fatal oral dose: Adults: 28 g

Overdosage/Treatment

Decontamination:

Oral: Emesis should not be induced since seizures can occur within 15 minutes of ingestion; activated charcoal is effective; do not give with milk, oil, or fatty food since it may enhance absorption

Dermal: Use soap and water to decontaminate the skin; cholestyramine may be effective in hastening elimination; absorbed through skin and mucous membranes and gastrointestinal tract; has occasionally caused serious CNS, hepatic and renal toxicity when used excessively for prolonged periods, or when accidental ingestion has occurred

Supportive therapy: Diazepam and/or phenobarbital can be used to treat seizures

Enhancement of elimination: Hemoperfusion may be effective if performed early. Although it has not been formally studied, cholestyramine (4 g every 8 hours) may enhance the elimination of lindane.

Antidote(s)

- Cholestyramine Resin [ANTIDOTE]

Drug Interactions Increased toxicity: Drugs which lower seizure threshold

Pregnancy Risk Factor B

Pregnancy Implications There are no well-controlled studies in pregnant women

Lactation Enters breast milk/contraindicated

Nursing Implications Drug should not be administered orally

Additional Information Mean fatal oral dose: Adults: 28 g.

Consider alternative therapies (ie, crotamiton) for treatment of scabies in infants and children < 10 years; drug has a bitter taste. TLV-TWA: 0.5 mg/m³; IDLH: 1000 ppm; OSHA PEL-TWA: 0.5 mg/m²

Linezolid

CAS Number 165800-03-3

U.S. Brand Names Zyvox™

Use Treatment of vancomycin-resistant *Enterococcus faecium* (VRE) infections, nosocomial pneumonia caused by *Staphylococcus aureus* including MRSA or *Streptococcus pneumoniae* (penicillin-susceptible strains only), complicated and uncomplicated skin and skin structure infections (including diabetic foot infections without concomitant osteomyelitis), and community-acquired pneumonia caused by susceptible gram-positive organisms.

Mechanism of Action Inhibits bacterial protein synthesis by binding to bacterial 23S ribosomal RNA of the 50S subunit. This prevents the formation of a functional 70S initiation complex that is essential for the bacterial translation process. Linezolid is bacteriostatic against enterococci and staphylococci and bactericidal against most strains of streptococci.

Adverse Reactions

Cardiovascular: Hypertension
 Central nervous system: **Headache** (27%), insomnia, dizziness, fever
 Dermatologic: Rash, pruritus
 Endocrine & metabolic: Lactic acidosis, serotonin syndrome
 Gastrointestinal: **Nausea, diarrhea**, vomiting, constipation, taste alteration, **brownish tongue discoloration** (33%), oral moniliasis, pancreatitis, localized abdominal pain, dyspepsia
 Genitourinary: **Vaginal yeast infection** (36% in a 5 day treatment course)
 Hematologic: **Thrombocytopenia**, anemia, leukopenia, neutropenia;
Note: Myelosuppression (including anemia, leukopenia, pancytopenia, and thrombocytopenia; may be more common in patients receiving linezolid for >2 weeks)
 Hepatic: Abnormal LFTs
 Neuromuscular & skeletal: Peripheral neuropathy
 Ocular: Optic neuropathy
 Renal: Increase in creatinine
 Miscellaneous: *C. difficile*-related complications

Pharmacodynamics/Kinetics

Absorption: Rapid and extensive
 Distribution: V_{dss} : Adults: 40-50 L
 Protein binding: Adults: 31%
 Metabolism: Hepatic via oxidation of the morpholine ring, resulting in two inactive metabolites (aminoethoxyacetic acid, hydroxyethyl glycine); does not involve CYP
 Bioavailability: 100%
 Half-life elimination: Children ≥ 1 week (full-term) to 11 years: 1.5-3 hours; Adults: 4-5 hours
 Time to peak: Adults: Oral: 1-2 hours
 Excretion: Urine (30% as parent drug, 50% as metabolites); feces (9% as metabolites)
 Nonrenal clearance: 65%; increased in children ≥ 1 week to 11 years

Dosage VRE infections: Oral, I.V.:

Infants (excluding preterm neonates <1 week) and Children ≤ 11 years: 10 mg/kg every 8 hours for 14-28 days
 Children ≥ 12 years and Adults: 600 mg every 12 hours for 14-28 days
 Nosocomial pneumonia, complicated skin and skin structure infections, community acquired pneumonia including concurrent bacteremia: Oral, I.V.:

Infants (excluding preterm neonates <1 week) and Children ≤ 11 years: 10 mg/kg every 8 hours for 10-14 days
 Children ≥ 12 years and Adults: 600 mg every 12 hours for 10-14 days
 Uncomplicated skin and skin structure infections: Oral:

Infants (excluding preterm neonates <1 week) and Children <5 years: 10 mg/kg every 8 hours for 10-14 days
 Children 5-11 years: 10 mg/kg every 12 hours for 10-14 days
 Children ≥ 12 -18 years: 600 mg every 12 hours for 10-14 days
 Adults: 400 mg every 12 hours for 10-14 days

Elderly: No dosage adjustment required

Dosage adjustment in hepatic impairment: No dosage adjustment required for mild to moderate hepatic insufficiency (Child-Pugh Class A or B). Use in severe hepatic insufficiency has not been adequately evaluated.

Monitoring Parameters Weekly CBC and platelet counts, particularly in patients at increased risk of bleeding, with pre-existing myelosuppression, on concomitant medications that cause bone marrow suppression, in those who require >2 weeks of therapy, or in those with chronic infection who have received previous or concomitant antibiotic therapy.

Administration I.V.: Administer intravenous infusion over 30-120 minutes. Do not mix or infuse with other medications. When the same intravenous line is used for sequential infusion of other medications, flush line with D₅W, NS, or LR before and after infusing linezolid. The

yellow color of the injection may intensify over time without affecting potency.

Oral suspension: Invert gently to mix prior to administration, do not shake.

Contraindications Hypersensitivity to linezolid or any other component of the formulation

Warnings

Myelosuppression has been reported and may be dependent on duration of therapy (generally >2 weeks of treatment); use with caution in patients with pre-existing myelosuppression, in patients receiving other drugs which may cause bone marrow suppression, or in chronic infection (previous or concurrent antibiotic therapy). Weekly CBC monitoring is recommended. Discontinue linezolid in patients developing myelosuppression (or in whom myelosuppression worsens during treatment).

Lactic acidosis has been reported with use. Patients who develop recurrent nausea and vomiting, unexplained acidosis, or low bicarbonate levels need immediate evaluation.

Linezolid exhibits mild MAO inhibitor properties and has the potential to have the same interactions as other MAO inhibitors; use with caution in uncontrolled hypertension, pheochromocytoma, carcinoid syndrome, or untreated hyperthyroidism; avoid use with serotonergic agents such as TCAs, venlafaxine, trazodone, sibutramine, mepredine, dextromethorphan, and SSRIs; concomitant use has been associated with the development of resistance to linezolid; consider alternatives before initiating outpatient treatment.

Peripheral and optic neuropathy (with vision loss) has been reported and may occur primarily with extended courses of therapy >28 days; any symptoms of visual change or impairment warrant immediate ophthalmic evaluation and possible discontinuation of therapy.

Due to inconsistent therapeutic concentrations in the CSF, empiric use in pediatric patients with CNS infections is not recommended.

Dosage Forms Infusion [premixed]: 200 mg (100 mL) [contains sodium 1.7 mEq]; 400 mg (200 mL) [contains sodium 3.3 mEq]; 600 mg (300 mL) [contains sodium 5 mEq]

Powder for oral suspension: 20 mg/mL (150 mL) [contains phenylalanine 20 mg/5 mL, sodium benzoate, and sodium 0.4 mEq/5 mL; orange flavor]

Tablet: 600 mg [contains sodium 0.1 mEq/tablet]

Reference Range Treatment serum range: 0.5-4 mcg/mL

Overdosage/Treatment

Decontamination: Oral: Activated charcoal

Supportive therapy: Metronidazole (250 mg 4 times/day for 10 days) can be used to treat pseudomembranous colitis

Enhanced elimination: Eliminated by dialysis (38% dialysis extraction ratio). Dialysis (along with sodium bicarbonate 1-2 meq/kg I.V.) should be used for severe lactic acidosis

Drug Interactions Adrenergic agents (eg, phenylpropranolamine, pseudoephedrine, sympathomimetic agents, vasopressor or dopaminergic agents) may cause hypertension.

Myelosuppressive medications: Concurrent use may increase risk of myelosuppression with linezolid.

Serotonergic agents (eg, TCAs, venlafaxine, trazodone, sibutramine, mepredine, dextromethorphan, and SSRIs) may cause a serotonin syndrome (eg, hyperpyrexia, cognitive dysfunction) when used concomitantly.

Tramadol: Concurrent use may increase risk of seizures.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic effects were not observed in animal studies. There are no adequate and well-controlled studies in pregnant women. Should be used in pregnancy only if the potential benefit justifies the risk to the fetus.

Lactation Excretion in breast milk unknown/use caution

Additional Information Avoid alcohol and foods (eg, cheese) containing tyramine (hypertensive crisis may result)

Liothyronine

Related Information

- Levothyroxine

CAS Number 55-06-1; 6893-03-3

U.S. Brand Names Cytomel®; Triostat®

Synonyms Liothyronine Sodium; Sodium *L*-Triiodothyronine; T₃ Sodium (error-prone abbreviation)

Use

Oral: Replacement or supplemental therapy in hypothyroidism; management of nontoxic goiter; a diagnostic aid

I.V.: Treatment of myxedema coma/precoma

Mechanism of Action Primary active compound is T₃ (triiodothyronine), which may be converted from T₄ (thyroxine) and then circulates throughout the body to influence growth and maturation of various tissues; exact mechanism of action is unknown; however, it is believed the thyroid hormone exerts its many metabolic effects through control of DNA transcription and protein synthesis; involved in normal metabolism, growth, and development; promotes gluconeogenesis, increases utilization and mobilization of glycogen stores, and stimulates protein synthesis, increases basal metabolic rate

Adverse Reactions

Cardiovascular: Angina, arrhythmia, cardiopulmonary arrest, congestive heart failure, hypertension, hypotension, myocardial infarction, phlebitis, tachycardia

Central nervous system: Fever

Dermatologic: Allergic skin reactions

Neuromuscular & skeletal: Twitching

Signs and Symptoms of Overdose Hyperthyroidism, insomnia sweating, tachycardia

Admission Criteria/Prognosis Admit any symptomatic patient or serum total T₄ > 75 mcg/dL

Pharmacodynamics/Kinetics

Onset of action: 2-4 hours

Peak response: 2-3 days

Absorption: Oral: Well absorbed (95% in 4 hours)

Half-life elimination: 2.5 days

Excretion: Urine

Dosage

Doses should be adjusted based on clinical response and laboratory parameters.

Children: Congenital hypothyroidism: Oral: 5 mcg/day increase by 5 mcg every 3-4 days until the desired response is achieved. Usual maintenance dose: 20 mcg/day for infants, 50 mcg/day for children 1-3 years of age, and adult dose for children > 3 years.

Adults:

Hypothyroidism: Oral: 25 mcg/day increase by increments of 12.5-25 mcg/day every 1-2 weeks to a maximum of 100 mcg/day; usual maintenance dose: 25-75 mcg/day.

Patients with cardiovascular disease: Refer to Elderly dosing.

T₃ suppression test: Oral: 75-100 mcg/day for 7 days; use lowest dose for elderly

Myxedema: Oral: Initial: 5 mcg/day; increase in increments of 5-10 mcg/day every 1-2 weeks. When 25 mcg/day is reached, dosage may be increased at intervals of 5-25 mcg/day every 1-2 weeks. Usual maintenance dose: 50-100 mcg/day.

Myxedema coma: I.V.: 25-50 mcg

Patients with known or suspected cardiovascular disease: 10-20 mcg

Note: Normally, at least 4 hours should be allowed between doses to adequately assess therapeutic response and no more than 12 hours should elapse between doses to avoid fluctuations in hormone levels. Oral therapy should be resumed as soon as the clinical situation has been stabilized and the patient is able to take oral medication. If levothyroxine rather than liothyronine sodium is used in initiating oral therapy, the physician should bear in mind that there is a delay of several days in the onset of levothyroxine activity and that I.V. therapy should be discontinued gradually.

Simple (nontoxic) goiter: Oral: Initial: 5 mcg/day; increase by 5-10 mcg every 1-2 weeks; after 25 mcg/day is reached, may increase dose by 12.5-25 mcg. Usual maintenance dose: 75 mcg/day

Elderly: Oral: 5 mcg/day; increase by 5 mcg/day every 2 weeks

Stability Store between 2°C and 8°C (36°F to 46°F)

Monitoring Parameters T₃, TSH, heart rate, blood pressure, renal function, clinical signs of hypo- and hyperthyroidism; TSH is the most reliable guide for evaluating adequacy of thyroid replacement dosage. TSH may be elevated during the first few months of thyroid replacement despite patients being clinically euthyroid. In cases where T₄ remains low

and TSH is within normal limits, an evaluation of "free" (unbound) T₄ is needed to evaluate further increase in dosage.

Administration I.V. form must be prepared immediately prior to administration; dilute 200 mcg/mL vial with 2 mL of 0.9% sodium chloride injection and shake well until a clear solution is obtained; should not be admixed with other solutions

Contraindications Hypersensitivity to liothyronine sodium or any component of the formulation; undocumented or uncorrected adrenal insufficiency; recent myocardial infarction or thyrotoxicosis; artificial rewarming (injection)

Warnings [U.S. Boxed Warning]: Ineffective for weight reduction.

High doses may produce serious or even life-threatening toxic effects particularly when used with some anorectic drugs. Use with extreme caution in patients with angina pectoris or other cardiovascular disease (including hypertension) or coronary artery disease; use with caution in elderly patients since they may be more likely to have compromised cardiovascular function. Patients with adrenal insufficiency, myxedema, diabetes mellitus and insipidus may have symptoms exaggerated or aggravated; thyroid replacement requires periodic assessment of thyroid status. Chronic hypothyroidism predisposes patients to coronary artery disease.

Dosage Forms Injection, solution, as sodium (Triostat®): 10 mcg/mL (1 mL) [contains alcohol 6.8%]

Tablet, as sodium (Cytomel®): 5 mcg, 25 mcg, 50 mcg

Reference Range Free T₃, serum: 250-390 pg/dL; TSH: 0.4 up to 10.0 (for those ≥ 80 years of age) mIU/L; remains normal in pregnancy

Overdosage/Treatment

Decontamination: Gastric emptying indicated for ingestions > 2 mg; ipecac within 30 minutes or lavage within 1 hour with activated charcoal; 50 mg of cholestyramine can bind at least 3 mg of thyroxine, therefore, 4 g of cholestyramine given 4 times/day should be administered in order to interrupt enterohepatic recirculation

Supportive therapy: Propranolol may be used for hyperadrenergic signs (1 mg I.V. in adults, 0.01-0.1 mg/kg in pediatrics)

Enhancement of elimination: Plasmapheresis increases elimination 30-fold while charcoal hemoperfusion enhances T₄ elimination fivefold.

Test Interactions Many drugs may have effects on thyroid function tests; para-aminosalicylic acid, aminoglutethimide, amiodarone, barbiturates, carbamazepine, chloral hydrate, clofibrate, colestipol, corticosteroids, danazol, diazepam, estrogens, ethionamide, fluorouracil, I.V. heparin, insulin, lithium, methadone, methimazole, mitotane, nitroprusside, oxyphenbutazone, phenylbutazone, propylthiouracil, perphenazine, phenytoin, propranolol, salicylates, sulfonyleureas, and thiazides

Drug Interactions Aluminum- and magnesium-containing antacids, calcium carbonate, simethicone, or sucralfate: May decrease T₄ absorption; separate dose from thyroid hormones by at least 4 hours.

Antidiabetic agents (biguanides, meglitinides, sulfonylureas, thiazolidinediones, insulin): Changes in thyroid function may alter requirements of antidiabetic agent. Monitor closely at initiation of therapy, or when dose is changed or discontinued.

Cholestyramine and colestipol: Decrease T₄ absorption; separate dose from thyroid hormones by at least 2 hours.

Digoxin: Digoxin levels may be reduced in hyperthyroidism; therapeutic effect may be reduced. Impact of thyroid replacement should be monitored.

Estrogens: May decrease serum free-thyroxine concentrations.

Iron: Decreases T₄ absorption; separate dose from thyroid hormones by at least 4 hours

Kayexalate®: Decreases T₄ absorption; separate dose from thyroid hormones by at least 4 hours

Ketamine: May cause marked hypertension and tachycardia; monitor

Theophylline, caffeine: Decreased theophylline clearance in hypothyroid patients; monitor during thyroid replacement.

Tricyclic and tetracyclic antidepressants: Therapeutic and toxic effects of thyroid hormones and the antidepressant are increased.

Warfarin (and other oral anticoagulants): The hypoprothrombinemic response to warfarin may be altered by a change in thyroid function or replacement. Replacement may dramatically increase response to warfarin. However, initiation of warfarin in a patient stabilized on a dose of thyroid hormones does not appear to require a significantly different approach.

Pregnancy Risk Factor A

Pregnancy Implications Untreated hypothyroidism may have adverse effects on fetal growth and development, and is associated with higher rate of complications; treatment should not be discontinued during pregnancy.

Lactation Enters breast milk (small amounts)/compatible

Additional Information Equivalent doses: Thyroid USP 60 mg ~ levothyroxine 0.05-0.06 mg ~ liothyronine 0.015-0.0375 mg
50-60 mg thyroid ~ 50-60 mcg levothyroxine and 12.5-15 mcg liothyronine

A synthetic form of *L*-Triiodothyronine (T₃) can be used in patients allergic to products derived from pork or beef.

Note: Several medications have effects on thyroid production or conversion. The impact in thyroid replacement has not been specifically evaluated, but patient response should be monitored:

Methimazole: Decreases thyroid hormone secretion, while propylthiouracil decreases thyroid hormone secretion and decreases conversion of T_4 to T_3 .

Beta-adrenergic antagonists: Decrease conversion of T_4 to T_3 (dose related, propranolol ≥ 160 mg/day); patients may be clinically euthyroid.

Iodide, iodine-containing radiographic contrast agents may decrease thyroid hormone secretion; may also increase thyroid hormone secretion, especially in patients with Graves' disease.

Other agents reported to impact on thyroid production/conversion include aminoglutethimide, amiodarone, chloral hydrate, diazepam, ethionamide, interferon-alpha, interleukin-2, lithium, lovastatin (case report), glucocorticoids (dose-related), mercaptopurine, sulfonamides, thiazide diuretics, and tolbutamide.

In addition, a number of medications have been noted to cause transient depression in TSH secretion, which may complicate interpretation of monitoring tests for thyroid hormones, including corticosteroids, octreotide, and dopamine. Metoclopramide may increase TSH secretion.

Liotrix

CAS Number 8065-29-0

U.S. Brand Names Thyrolar®

Synonyms T_3/T_4 Liotrix

Use Replacement or supplemental therapy in hypothyroidism (uniform mixture of $T_4:T_3$ in 4:1 ratio by weight); little advantage to this product exists and cost is not justified

Mechanism of Action The primary active compound is T_3 (triiodothyronine), which may be converted from T_4 (thyroxine) and then circulates throughout the body to influence growth and maturation of various tissues. Liotrix is uniform mixture of synthetic T_4 and T_3 in 4:1 ratio; exact mechanism of action is unknown; however, it is believed the thyroid hormone exerts its many metabolic effects through control of DNA transcription and protein synthesis; involved in normal metabolism, growth, and development; promotes gluconeogenesis, increases utilization and mobilization of glycogen stores and stimulates protein synthesis, increases basal metabolic rate.

Adverse Reactions

Cardiovascular: Palpitations, tachycardia, cardiac arrhythmias, sinus tachycardia

Central nervous system: Nervousness, insomnia, fever, headache

Dermatologic: Hair loss

Gastrointestinal: Weight loss, increased appetite, diarrhea, abdominal cramps

Neuromuscular & skeletal: Tremors

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Agitation, coma, hypertension, insomnia, seizures (may occur up to 1 week postingestion), tachycardia

Pharmacodynamics/Kinetics

Absorption: 50% to 95%

Metabolism: Partially hepatic, renal, and in intestines

Half-life elimination: 6-7 days

Time to peak, serum: 12-48 hours

Excretion: Partially feces (as conjugated metabolites)

Dosage

Oral:

Congenital hypothyroidism:

Children (dose/day):

0-6 months: 8-10 mcg/kg

6-12 months: 6-8 mcg/kg

1-5 years: 5-6 mcg/kg

6-12 years: 4-5 mcg/kg

> 12 years: 2-3 mcg/kg

Hypothyroidism:

Adults: 30 mg/day, increasing by 15 mg/day at 2- to 3-week intervals to a maximum of 180 mg/day (usual maintenance dose: 60-120 mg/day)

Elderly: Initial: 15 mg, adjust dose at 2- to 4-week intervals by increments of 15 mg

Monitoring Parameters T_4 , TSH, heart rate, blood pressure, clinical signs of hypo- and hyperthyroidism; TSH is the most reliable guide for evaluating adequacy of thyroid replacement dosage. TSH may be elevated during the first few months of thyroid replacement despite patients being clinically euthyroid. In cases where T_4 remains low and TSH is within normal limits, an evaluation of "free" (unbound) T_4 is needed to evaluate further increase in dosage.

Contraindications Hypersensitivity to liotrix or any component of the formulation; recent myocardial infarction or thyrotoxicosis, uncomplicated by hypothyroidism; uncorrected adrenal insufficiency, hypersensitivity to active or extraneous constituents

Warnings [U.S. Boxed Warning]: Ineffective for weight reduction; high doses may produce serious or even life-threatening toxic effects particularly when used with some anorectic drugs. Use cautiously in patients with pre-existing cardiovascular disease (angina, CHD), elderly since they may be more likely to have compromised cardiovascular function

Dosage Forms Tablet:

$1/4$ [levothyroxine sodium 12.5 mcg and liothyronine sodium 3.1 mcg]

$1/2$ [levothyroxine sodium 25 mcg and liothyronine sodium 6.25 mcg]

1 [levothyroxine sodium 50 mcg and liothyronine sodium 12.5 mcg]

2 [levothyroxine sodium 100 mcg and liothyronine sodium 25 mcg]

3 [levothyroxine sodium 150 mcg and liothyronine sodium 37.5 mcg]

Reference Range

TSH: 0.4-10.0 (for those ≥ 80 years) mIU/L

T_4 : 4.0-12.0 mcg/dL (SI: 51-154 nmol/L)

T_3 (RIA) (total T_3): 80-230 ng/dL (SI: 1.2-3.5 nmol/L)

Free T_4 : 0.7-1.8 ng/dL (SI: 9-23 pmol/L)

Overdosage/Treatment

Decontamination: Gastric emptying indicated for ingestions > 2 mg; ipecac within 30 minutes or lavage within 1 hour with activated charcoal; 50 mg of cholestyramine can bind at least 3 mg of thyroxine, therefore, 4 g of cholestyramine given 4 times/day should be administered in order to interrupt enterohepatic recirculation

Supportive therapy: Propranolol may be used for hyperadrenergic signs (1 mg I.V. in adults, 0.01-0.1 mg/kg in pediatrics); sodium ipodate (3 g/1.7 m²) has been used in acute ingestion to prevent T_4 to T_3 conversion.

Enhancement of elimination: Plasmapheresis increases elimination 30-fold while charcoal hemoperfusion enhances T_4 elimination fivefold

Test Interactions Many drugs may have effects on thyroid function tests; para-aminosalicylic acid, aminoglutethimide, amiodarone, barbiturates, carbamazepine, chloral hydrate, clofibrate, colestipol, corticosteroids, danazol, diazepam, estrogens, ethionamide, fluorouracil, I.V. heparin, insulin, lithium, methadone, methimazole, mitotane, nitroprusside, oxyphenbutazone, phenylbutazone, PTU, perphenazine, phenytoin, propranolol, salicylates, sulfonyleureas, and thiazides

Drug Interactions Aluminum- and magnesium-containing antacids, calcium carbonate, simethicone, or sucralfate: May decrease T_4 absorption; separate dose from thyroid hormones by at least 4 hours.

Antidiabetic agents (biguanides, meglitinides, sulfonyleureas, thiazolidinediones, insulin): Changes in thyroid function may alter requirements of antidiabetic agent. Monitor closely at initiation of therapy, or when dose is changed or discontinued.

Cholestyramine and colestipol: Decrease T_4 absorption; separate dose from thyroid hormones by at least 4 hours.

Digoxin: Digoxin levels may be reduced in hyperthyroidism; therapeutic effect may be reduced. Impact of thyroid replacement should be monitored.

Iron: Decreases T_4 absorption; separate dose from thyroid hormones by at least 4 hours

Kayexalate®: Decreases T_4 absorption; separate dose from thyroid hormones by at least 4 hours

Ketamine: May cause marked hypertension and tachycardia; monitor

Ritonavir: May alter response to thyroid hormones (limited documentation/case report); monitor

Somatrem, somatropin: Excessive thyroid hormone levels lead to accelerated epiphyseal closure; inadequate replacement interferes with growth response to growth hormone. Effect of thyroid replacement not specifically evaluated; use caution.

SSRI antidepressants: May need to increase dose of thyroid hormones when SSRI is added to a previously stabilized patient.

Sympathomimetics: Effects of sympathomimetic agent or thyroid hormones may be increased. Risk of coronary insufficiency is increased in patients with coronary artery disease when these agents are used together.

Theophylline, caffeine: Decreased theophylline clearance in hypothyroid patients; monitor during thyroid replacement.

Tricyclic and tetracyclic antidepressants: Therapeutic and toxic effects of thyroid hormones and the antidepressant are increased.

Warfarin (and other oral anticoagulants): The hypoprothrombinemic response to warfarin may be altered by a change in thyroid function or replacement. Replacement may dramatically increase response to warfarin. However, initiation of warfarin in a patient stabilized on a dose of thyroid hormones does not appear to require a significantly different approach.

Note: Several medications have effects on thyroid production or conversion. The impact in thyroid replacement has not been specifically evaluated, but patient response should be monitored:

Methimazole: Decreases thyroid hormone secretion, while propylthiouracil decrease thyroid hormone secretion and decreases conversion of T_4 to T_3 .

Beta-adrenergic antagonists: Decrease conversion of T_4 to T_3 (dose related, propranolol ≥ 160 mg/day); patients may be clinically euthyroid.

Iodide, iodine-containing radiographic contrast agents may decrease thyroid hormone secretion; may also increase thyroid hormone secretion, especially in patients with Graves' disease.

Other agents reported to impact on thyroid production/conversion include aminoglutethimide, amiodarone, chloral hydrate, diazepam, ethionamide, interferon-alpha, interleukin-2, lithium, lovastatin (case report), glucocorticoids (dose-related), mercaptopurine, sulfonamides, thiazide diuretics, and tolbutamide.

In addition, a number of medications have been noted to cause transient depression in TSH secretion, which may complicate interpretation of monitoring tests for thyroid hormones, including corticosteroids, octreotide, and dopamine. Metoclopramide may increase TSH secretion.

Pregnancy Risk Factor A

Pregnancy Implications Untreated hypothyroidism may have adverse effects on fetal growth and development, and is associated with higher rate of complications; treatment should not be discontinued during pregnancy.

Nursing Implications Monitor T_4 , TSH, heart rate, blood pressure, clinical signs of hypo- and hyperthyroidism; TSH is the most reliable guide for evaluating adequacy of thyroid replacement dosage. TSH may be elevated during the first few months of thyroid replacement despite patients being clinically euthyroid. In cases where T_4 remains low and TSH is within normal limits, an evaluation of "free" (unbound) T_4 is needed to evaluate further increase in dosage

Additional Information No advantage over synthetic levothyroxine sodium; 1 grain (60 mg) liotrix is equivalent to 0.05-0.06 mg levothyroxine; 60 mg thyroid USP and thyroglobulin; and 45 mg of Thyroid Strong®

Lisinopril

Related Information

- Angiotensin Agents

CAS Number 76547-98-3; 83915-83-7

U.S. Brand Names Prinivil®; Zestril®

Use Treatment of hypertension, either alone or in combination with other antihypertensive agents; adjunctive therapy in treatment of CHF (after-load reduction); treatment of acute myocardial infarction within 24 hours in hemodynamically-stable patients to improve survival; treatment of left ventricular dysfunction after myocardial infarction

Mechanism of Action Competitive inhibition of angiotensin I being converted to angiotensin II, a potent vasoconstrictor, through the angiotensin I-converting enzyme (ACE) activity, with resultant lower levels of angiotensin II which causes an increase in plasma renin activity and a reduction in aldosterone secretion

Adverse Reactions

Cardiovascular: Hypotension (maximum hypotensive effect: 6 hours), syncope, chest pain, angina, palpitations, sinus tachycardia, vasodilation

Central nervous system: Fatigue, insomnia, dizziness, headache, mania
Dermatologic: Rash, angioedema, toxic epidermal necrolysis, bullous skin disease, purpura, photosensitivity, pruritus, licheniform eruptions, exanthem, cutaneous vasculitis

Endocrine & metabolic: Hypoglycemia, hyperkalemia, inappropriate antidiuretic hormone secretion

Gastrointestinal: Nausea, diarrhea, altered taste, pancreatitis

Genitourinary: Impotence

Hematologic: Leukopenia/neutropenia (agranulocytosis, granulocytopenia), anemia, aplastic anemia

Neuromuscular & skeletal: Muscle cramps, paresthesia

Renal: Deterioration in renal function, albuminuria, type IV renal tubular acidosis, renal vasculitis

Respiratory: Cough (dry), wheezing

Miscellaneous: Elevated antineutrophilic cytoplasmic antibodies (ANCA)

Signs and Symptoms of Overdose Hypotension is usually not severe in overdose and manifests itself within 1 hour with maximal effect at 4 hours. Azotemia, bradycardia, confusion, depression, diplopia, dry mouth, dyspnea, dyspepsia, eosinophilia, gout, hyperuricemia, hypoglycemia, insomnia, photophobia, thrombocytopenia

Pharmacodynamics/Kinetics

Onset of action: 1 hour

Peak effect: Hypotensive: Oral: ~6 hours

Duration: 24 hours

Absorption: Well absorbed; unaffected by food

Protein binding: 25%

Half-life elimination: 11-12 hours

Excretion: Primarily urine (as unchanged drug)

Dosage

Oral:

Hypertension:

Children ≥ 6 years: Initial: 0.07 mg/kg once daily (up to 5 mg); increase dose at 1- to 2-week intervals; doses >0.61 mg/kg or >40 mg have not been evaluated.

Adults: Initial: 10 mg/day; increase doses 5-10 mg/day at 1- to 2-week intervals; maximum daily dose: 40 mg

Elderly: Initial: 2.5-5 mg/day; increase doses 2.5-5 mg/day at 1- to 2-week intervals; maximum daily dose: 40 mg

Patients taking diuretics should have them discontinued 2-3 days prior to initiating lisinopril if possible. Restart diuretic after blood pressure is stable if needed. If diuretic cannot be discontinued prior to therapy, begin with 5 mg with close supervision until stable blood pressure. In patients with hyponatremia (<130 mEq/L), start dose at 2.5 mg/day. Congestive heart failure: Adults: Initial: 5 mg; then increase by no more than 10 mg increments at intervals no less than 2 weeks to a maximum daily dose of 40 mg. Usual maintenance: 5-40 mg/day as a single dose. Patients should start/continue standard therapy, including diuretics, beta-blockers, and digoxin, as indicated.

Acute myocardial infarction (within 24 hours in hemodynamically stable patients): Oral: 5 mg immediately, then 5 mg at 24 hours, 10 mg at 48 hours, and 10 mg every day thereafter for 6 weeks. Patients should continue to receive standard treatments such as thrombolytics, aspirin, and beta-blockers.

Dosing adjustment in renal impairment:

Adults: Initial doses should be modified and upward titration should be cautious, based on response (maximum: 40 mg/day)

$Cl_{cr} >30$ mL/minute: Initial: 10 mg/day

$Cl_{cr} 10-30$ mL/minute: Initial: 5 mg/day

Hemodialysis: Initial: 2.5 mg/day; dialyzable (50%)

Children: Use in not recommended in pediatric patients with $GFR <30$ mL/1.73 m^2 /minute

Monitoring Parameters BUN, serum creatinine, renal function, WBC, and potassium

Administration Watch for hypotensive effects within 1-3 hours of first dose or new higher dose.

Contraindications Hypersensitivity to lisinopril or any component of the formulation; angioedema related to previous treatment with an ACE inhibitor; bilateral renal artery stenosis; pregnancy (2nd and 3rd trimesters)

Warnings Anaphylactic reactions can occur. Angioedema can occur at any time during treatment (especially following first dose). It may involve head and neck (potentially affecting the airway) or the intestine (presenting with abdominal pain). Prolonged monitoring may be required especially if tongue, glottis, or larynx are involved as they are associated with airway obstruction. Those with a history of airway surgery in this situation have a higher risk. Careful blood pressure monitoring with first dose (hypotension can occur especially in volume-depleted patients).

[U.S. Boxed Warning]: Based on human data, ACEIs can cause injury and death to the developing fetus when used in the second and third trimesters. ACEIs should be discontinued as soon as possible once pregnancy is detected. Dosage adjustment needed in renal impairment. Use with caution in hypovolemia; collagen vascular diseases; valvular stenosis (particularly aortic stenosis); hyperkalemia; or before, during, or immediately after anesthesia. Avoid rapid dosage escalation, which may lead to renal insufficiency. Rare toxicities associated with ACE inhibitors include cholestatic jaundice (which may progress to hepatic necrosis) and neutropenia/agranulocytosis with myeloid hyperplasia. If patient has renal impairment then a baseline WBC with differential and serum creatinine should be evaluated and monitored closely during the first 3 months of therapy. Hypersensitivity reactions may be seen during hemodialysis with high-flux dialysis membranes (eg, AN69). Deterioration in renal function can occur with initiation. Use with caution in unilateral renal artery stenosis and pre-existing renal insufficiency. Safety and efficacy have not been established in children <6 years of age.

Dosage Forms [DSC] = Discontinued product

Tablet: 2.5 mg, 5 mg, 10 mg, 20 mg, 30 mg, 40 mg

Prinivil®: 5 mg, 10 mg, 20 mg, 30 mg; 40 mg [DSC]

Zestril®: 2.5 mg, 5 mg, 10 mg, 20 mg, 30 mg, 40 mg

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. normal saline or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam or diazepam (I.V. 5-10 mg bolus in adults every 15 minutes if needed up to a total of 30 mg; I.V. 0.25-0.4 mg/kg/dose up to a total of 10 mg in children) or to phenytoin or phenobarbital. Naloxone may antagonize hypotensive effects. Inhaled sodium cromoglycate (total dose: 40 mg/day) can decrease ACE-inhibitor cough by 50%. For refractory hypotension, angiotensin amide infusion may be attempted. Enhanced elimination: Multiple dosing of activated charcoal may be effective but not studied in an overdose setting; dialyzable (50%)

Antidote(s)

- Naloxone [ANTIDOTE]

Test Interactions ↑ BUN, creatinine, potassium; positive Coombs' [direct]; ↓ cholesterol (S); may cause false-positive urine acetone determinations using sodium nitroprusside reagent

Drug Interactions Allopurinol: Case reports (rare) indicate a possible increased risk of hypersensitivity reactions when combined with lisinopril. Alpha₁ blockers: Hypotensive effect increased.

Aspirin: The effects of ACE inhibitors may be blunted by aspirin administration, particularly at higher dosages (see Cardiovascular Considerations) and/or increase adverse renal effects.

Diuretics: Hypovolemia due to diuretics may precipitate acute hypotensive events or acute renal failure.

Insulin: Risk of hypoglycemia may be increased.

Lithium: Risk of lithium toxicity may be increased; monitor lithium levels, especially the first 4 weeks of therapy.

Mercaptopurine: Risk of neutropenia may be increased.

NSAIDs: May attenuate hypertensive efficacy; effect has been seen with captopril and may occur with other ACE inhibitors; monitor blood pressure. May increase adverse renal effects.

Potassium-sparing diuretics (amiloride, spironolactone, triamterene): Increased risk of hyperkalemia.

Potassium supplements may increase the risk of hyperkalemia.

Trimethoprim (high dose) may increase the risk of hyperkalemia.

Pregnancy Risk Factor C (1st trimester)/D (2nd and 3rd trimesters)

Pregnancy Implications Decreased placental blood flow, low birth weight, fetal hypotension, preterm delivery, and fetal death have been noted with the use of some ACE inhibitors (ACEIs) in animal studies. Neonatal hypotension, skull hypoplasia, anuria, renal failure, oligohydramnios (associated with fetal limb contractures, craniofacial deformities, hypoplastic lung development), prematurity, intrauterine growth retardation, and patent ductus arteriosus have been reported with the use of ACEIs, primarily in the 2nd and 3rd trimesters. The risk of neonatal toxicity has been considered less when ACEIs have been used in the 1st trimester; however, major congenital malformations have been reported. The cardiovascular and/or central nervous systems are most commonly affected. Unless alternative agents are not appropriate, ACEIs should be discontinued as soon as possible once pregnancy is detected.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications May cause depression in some patients; discontinue if angioedema of the face, extremities, lips, tongue, or glottis occurs; watch for hypotensive effects within 1-3 hours of first dose or new higher dose

Additional Information Conversion factor from captopril to lisinopril is 5:1

Lithium

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 554-13-2

U.S. Brand Names Eskalith CR®; Eskalith®; Lithobid®

Synonyms Lithium Carbonate; Lithium Citrate

Impairment Potential Yes

Use Management of bipolar disorders; treatment of mania in individuals with bipolar disorder (maintenance treatment prevents or diminishes intensity of subsequent episodes)

Unlabeled/Investigational Use Potential augmenting agent for antidepressants; aggression, post-traumatic stress disorder, conduct disorder in children

Mechanism of Action Alters cation transport across cell membrane in nerve and muscle cells and influences reuptake of serotonin and/or norepinephrine

Adverse Reactions

Cardiovascular: Cardiac arrhythmias, hypotension, sinus node dysfunction, flattened or inverted T waves (reversible), edema, bradycardia, syncope

Central nervous system: Dizziness, vertigo, slurred speech, blackout spells, seizures, sedation, restlessness, confusion, psychomotor retardation, stupor, coma, dystonia, fatigue, lethargy, headache, pseudotumor cerebri, slowed intellectual functioning, tics

Dermatologic: Dry or thinning of hair, folliculitis, alopecia, exacerbation of psoriasis, rash

Endocrine & metabolic: Euthyroid goiter and/or hypothyroidism, hyperthyroidism, hyperglycemia, diabetes insipidus

Gastrointestinal: Polydipsia, anorexia, nausea, vomiting, diarrhea, xerostomia, metallic taste, weight gain, salivary gland swelling, excessive salivation

Genitourinary: Incontinence, polyuria, glycosuria, oliguria, albuminuria

Hematologic: Leukocytosis

Neuromuscular & skeletal: Tremor, muscle hyperirritability, ataxia, choreoathetoid movements, hyperactive deep tendon reflexes, myasthenia gravis (rare), peripheral neuropathy

ocular: Nystagmus, blurred vision, transient scotoma, blepharospasm

Miscellaneous: Coldness and painful discoloration of fingers and toes

Signs and Symptoms of Overdose Alopecia, aphasia, arthralgia, ataxia, AV block, bradycardia, blurred vision, chorea (extrapyramidal), cognitive dysfunction, confusion, dementia, dysosmia, encephalopathy, fever, granulocytopenia, heart block, hepatic failure, hypercalcemia, hyperglycemia, hyperkalemia, hyperthyroidism, hypertonia, hypoglycemia, hypokalemia, hypotension, hypothyroidism, hypothermia, impotence, leukopenia, mania, myocardial infarction, myoglobinuria, neuroleptic malignant syndrome, neutropenia, nocturia, nystagmus, ototoxicity, Parkinson's-like symptoms, parotid pain, photophobia, polyuria, rhabdomyolysis, sedation, seizures, tinnitus, thrombocytosis, tremors, ventricular arrhythmia, visual changes. See table.

Lithium (Acute Ingestion)	
Serum Level	Symptom
1.5-2.0 mEq/L	Nausea, diarrhea
2.0-2.5 mEq/L	Polyuria, blurred vision, weakness, lethargy, dizziness, increased reflexes, fasciculations
2.5-3.0 mEq/L	Myoclonic twitching, incontinence, stupor, restlessness, coma
>3.0 mEq/L	Seizures, hypotension, cardiac arrhythmias

Admission Criteria/Prognosis For acute ingestions, admit any symptomatic patient or lithium level >2 mEq/L or acute ingestions >40 mg/kg

Pharmacodynamics/Kinetics

Absorption: Rapid and complete

Distribution: V_d : Initial: 0.3-0.4 L/kg; V_{dss} : 0.7-1 L/kg; crosses placenta; enters breast milk at 35% to 50% the concentrations in serum; distribution is complete in 6-10 hours

CSF, liver concentrations: $\frac{1}{3}$ to $\frac{1}{2}$ of serum concentration

Erythrocyte concentration: $\sim\frac{1}{2}$ of serum concentration

Heart, lung, kidney, muscle concentrations: Equivalent to serum concentration

Saliva concentration: 2-3 times serum concentration

Thyroid, bone, brain tissue concentrations: Increase 50% over serum concentrations

Protein binding: Not protein bound

Metabolism: Not metabolized

Bioavailability: Not affected by food; Capsule, immediate release tablet: 95% to 100%; Extended release tablet: 60% to 90%; Syrup: 100%

Half-life elimination: 18-24 hours; can increase to more than 36 hours in elderly or with renal impairment

Time to peak, serum: Nonsustained release: \sim 0.5-2 hours; slow release: 4-12 hours; syrup: 15-60 minutes

Excretion: Urine (90% to 98% as unchanged drug); sweat (4% to 5%); feces (1%)

Clearance: 80% of filtered lithium is reabsorbed in the proximal convoluted tubules; therefore, clearance approximates 20% of GFR or 20-40 mL/minute

Dosage

Oral: Monitor serum concentrations and clinical response (efficacy and toxicity) to determine proper dose

Children 6-12 years:

Bipolar disorder: 15-60 mg/kg/day in 3-4 divided doses; dose not to exceed usual adult dosage

Conduct disorder (unlabeled use): 15-30 mg/kg/day in 3-4 divided doses; dose not to exceed usual adult dosage

Adults: Bipolar disorder: 900-2400 mg/day in 3-4 divided doses or 900-1800 mg/day (sustained release) in 2 divided doses

Elderly; Bipolar disorder: Initial dose: 300 mg once or twice daily; increase weekly in increments of 300 mg/day, monitoring levels; rarely need > 900-1200 mg/day

Dosing adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer 50% to 75% of normal dose

Cl_{cr} <10 mL/minute: Administer 25% to 50% of normal dose

Hemodialysis: Dialyzable (50% to 100%)

Monitoring Parameters Serum lithium every 4-5 days during initial therapy; draw lithium serum concentrations 8-12 hours postdose; renal, thyroid, and cardiovascular function; fluid status; serum electrolytes; CBC with differential, urinalysis; monitor for signs of toxicity; b-HCG pregnancy test for all females not known to be sterile

Administration Administer with meals to decrease GI upset. Slow release tablets must be swallowed whole; do not crush or chew.

Contraindications Hypersensitivity to lithium or any component of the formulation; avoid use in patients with severe cardiovascular or renal disease, or with severe debilitation, dehydration, or sodium depletion; pregnancy

Warnings[U.S. Boxed Warning]: Lithium toxicity is closely related to serum levels and can occur at therapeutic doses; serum lithium determinations are required to monitor therapy. Use with caution in patients with thyroid disease, mild-moderate renal impairment, or mild-moderate cardiovascular disease. Use caution in patients receiving medications which alter sodium excretion (eg, diuretics, ACE inhibitors, NSAIDs), or in patients with significant fluid loss (protracted sweating, diarrhea, or prolonged fever); temporary reduction or cessation of therapy may be warranted. Some elderly patients may be extremely sensitive to the effects of lithium, see Dosage and Reference Range. Chronic therapy results in diminished renal concentrating ability (nephrogenic DI); this is usually reversible when lithium is discontinued. Changes in renal function should be monitored, and re-evaluation of treatment may be necessary. Use caution in patients at risk of suicide (suicidal thoughts or behavior).

Morphologic changes with glomerular and interstitial fibrosis and nephron atrophy have been reported in patients on chronic lithium therapy; morphologic changes have also been reported in manic-depressive patients never exposed to lithium. The relationship between morphologic changes and renal function, and the association with lithium therapy, have not been established.

Use with caution in patients receiving neuroleptic medications - a syndrome resembling NMS has been associated with concurrent therapy. Lithium may impair the patient's alertness, affecting the ability to operate machinery or driving a vehicle. Neuromuscular-blocking agents should be administered with caution; the response may be prolonged.

Higher serum concentrations may be required and tolerated during an acute manic phase; however, the tolerance decreases when symptoms subside. Normal fluid and salt intake must be maintained during therapy.

Safety and efficacy have not been established in children <12 years of age.

Dosage Forms [DSC] = Discontinued product

Capsule, as carbonate: 150 mg, 300 mg, 600 mg

Eskalith®: 300 mg [contains benzyl alcohol] [DSC]

Solution, as citrate: 300 mg/5 mL (5 mL, 500 mL) [equivalent to amount of lithium in lithium carbonate]

Syrup, as citrate: 300 mg/5 mL (480 mL) [equivalent to amount of lithium in lithium carbonate]

Tablet, as carbonate: 300 mg

Tablet, controlled release, as carbonate: 450 mg

Eskalith CR®: 450 mg [DSC]

Tablet, slow release, as carbonate: 300 mg

Lithobid®: 300 mg

Reference Range

Levels should be obtained twice weekly until both patient's clinical status and levels are stable then levels may be obtained every 1-3 months

Timing of serum samples: Draw trough just before next dose (8-12 hours after previous dose)

Therapeutic levels:

Acute mania: 0.6-1.2 mEq/L (SI: 0.6-1.2 mmol/L)

Protection against future episodes in most patients with bipolar disorder: 0.8-1 mEq/L (SI: 0.8-1.0 mmol/L); a higher rate of relapse is described in subjects who are maintained at <0.4 mEq/L (SI: 0.4 mmol/L)

Elderly patients can usually be maintained at lower end of therapeutic range (0.6-0.8 mEq/L)

Toxic concentration: > 1.5 mEq/L (SI: > 2 mmol/L)

Adverse effect levels:

GI complaints/tremor: 1.5-2 mEq/L

Confusion/somnolence: 2-2.5 mEq/L

Seizures/death: > 2.5 mEq/L

Overdosage/Treatment

Decontamination: Lavage within 1 hour acute ingestions > 40 mg/kg; 30-60 g of sodium polystyrene sulfonate may prevent absorption; whole bowel irritation with polyethylene glycol (2 L/hour for 5 hours in adults),

may cause a 67% decrease in absorption; activated charcoal may not be effective in adsorbing lithium but is not harmful if used.

Supportive therapy: There is no specific antidote for lithium poisoning. In the acute ingestion, following initiation of essential overdose management, correction of fluid and electrolyte imbalances should be commenced. Lithium-induced tachycardia (ventricular) may respond to I.V. magnesium sulfate. Amiloride is an effective therapy in reducing lithium-induced polyuria by one-third. Lithium-induced nephrogenic diabetes insipidus can be treated with amiloride, hydrochlorothiazide, indomethacin, or I.V. ketorolac. Lithium-induced bradycardia may require transvenous pacemaker; may not respond to atropine or transcutaneous pacemaker.

Enhancement of elimination: Hemodialysis is the treatment of choice for severe intoxications; 50% to 100% dialyzable. Dialysis should be considered in a symptomatic patient with levels >4.0 mEq/L (acute ingestion), role of hemodialysis is controversial in chronic toxicity due to limited distribution out of CNS; other indications for dialysis include neurologic toxicity, renal failure, or ingestions of sustained release preparations. Four hours of hemodialysis should reduce lithium concentrations by ~1 mEq/L, but due to a rebound effect, a usual dialysis time of 10-12 hours is recommended. Dialysis using a bicarbonate bath (35 mM/L) may be more efficacious than an acetate bath in removing lithium.

Antidote(s)

- Ipecac Syrup [ANTIDOTE]
- Polyethylene Glycol - High Molecular Weight [ANTIDOTE]
- Sodium Polystyrene Sulfonate [ANTIDOTE]

Diagnostic Procedures

- Lithium RBC/Plasma Ratio
- Lithium, Blood

Test Interactions ↑ calcium (S), glucose, magnesium, potassium (S), serum bicarbonate, urea; ↓ thyroxine (S), serum bromide; causes leukopenia, thrombocytopenia

Drug Interactions ACE inhibitors: May increase the risk of lithium toxicity via sodium depletion; monitor

Angiotensin receptor antagonists (losartan): May reduce the renal clearance of lithium; monitor

Caffeine (xanthine derivatives): May lower lithium serum concentrations by increasing urinary lithium excretion; monitor.

Carbamazepine: Concurrent use of lithium with carbamazepine may increase the risk for neurotoxicity; monitor

Carbonic anhydrase inhibitors: May decrease lithium levels; includes acetazolamide; monitor

Calcium channel blockers (diltiazem and verapamil): May increase the risk for neurotoxicity (ataxia, tremors, nausea, vomiting, diarrhea, and/or tinnitus); monitor; does not appear to involve dihydropyridine class

Chlorpromazine: May lower serum concentrations of both drugs; monitor

COX-2 inhibitors (celecoxib): May increase lithium plasma concentrations (similar to NSAIDs); monitor.

Haloperidol: May increase the risk for neurotoxicity and encephalopathy; a rare encephalopathic syndrome resulting in irreversible brain damage has been reported in a few patients (causal relationship not established); monitor

Iodine salts: May enhance the hypothyroid effects of lithium; monitor

Loop diuretics: May decrease the renal excretion of lithium, leading to toxicity; monitor

MAO inhibitors: Should generally be avoided due to use reports of fatal malignant hyperpyrexia when combined with lithium

Methyldopa: May increase the risk for neurotoxicity; monitor

Metronidazole: May increase lithium toxicity (rare); monitor

Neuromuscular-blocking agents: Lithium may potentiate the response to neuromuscular blockade, resulting in prolonged blockade and possible delayed recovery

NSAIDs: Renal lithium excretion may be decreased leading to increased serum lithium concentrations; sulindac and aspirin may be the exceptions; monitor

Phenothiazines: May increase the risk for neurotoxicity; monitor

Phenytoin: May enhance lithium toxicity; monitor

Selegiline: Risk of severe reactions when combined with MAO inhibitors may be decreased when administered with selective MAO type B inhibitor, particularly at selegiline doses <10 mg/day; however, theoretical risk is still present

SSRIs: May increase the risk for neurotoxicity; monitor; effect noted with fluoxetine, fluvoxamine

Sibutramine: Combined use of lithium with sibutramine may increase the risk of serotonin syndrome; this combination is best avoided

Sodium-containing products: Bicarbonate and/or high sodium intake may reduce serum lithium concentrations via enhanced excretion; monitor.

Note: Reabsorption of lithium in the proximal convoluted tubule occurs against electrical and concentration gradients that do not distinguish between lithium and sodium. Therefore, lithium clearance may increase or decrease 30% to 50% with sodium load or depletion, respectively. Sodium depletion usually has the greater effect.

LODOXAMIDE

Sympathomimetics: Lithium may blunt the pressor response to sympathomimetics (epinephrine, phenylephrine, norepinephrine)
Tetracyclines: May increase lithium levels; monitor
Theophylline: May increase renal clearance of lithium, resulting in a decrease in serum lithium concentrations; monitor
Thiazide diuretics: May increase serum lithium concentration via sodium depletion and decreased lithium clearance; a lithium dose reduction of 50% is commonly recommended
Tricyclic antidepressants: May increase the risk for neurotoxicity; monitor
Urea: May lower lithium serum concentrations by increasing urinary excretion; monitor.

Pregnancy Risk Factor D

Pregnancy Implications Cardiac malformations in the infant, including Ebstein's anomaly, are associated with use of lithium during the first trimester of pregnancy. Nontoxic effects to the newborn include shallow respiration, hypotonia, lethargy, cyanosis, diabetes insipidus, thyroid depression, and nontoxic goiter when lithium is used near term. Efforts should be made to avoid lithium use during the first trimester; if an alternative therapy is not appropriate, the lowest possible dose of lithium should be used throughout the pregnancy. Fetal echocardiography and ultrasound to screen for anomalies should be conducted between 16-20 weeks of gestation. Lithium levels should be monitored in the mother and may need adjusted following delivery. Enters breast milk/contraindicated

Lactation Enters breast milk/contraindicated

Nursing Implications Give with meals to decrease gastrointestinal upset

Lodoxamide

CAS Number 53882-12-5; 53882-13-6; 63610-09-3

U.S. Brand Names Alomide®

Synonyms Lodoxamide Tromethamine

Use Treatment of allergic keratoconjunctivitis, allergic conjunctivitis, and allergic keratitis

Mechanism of Action Mast cell stabilizer (similar to sodium cromoglycate) that inhibits the *in vivo* type I immediate hypersensitivity reaction to increase cutaneous vascular permeability associated with IgE and antigen-mediated reactions

Adverse Reactions

Central nervous system: Headache, dizziness, somnolence
Dermatologic: Rash
Gastrointestinal: Nausea, stomach discomfort
Local: **Transient burning, stinging, discomfort**
Ocular: Blurred vision, corneal erosion/ulcer, eye pain, corneal abrasion, blepharitis, xerophthalmia
Respiratory: Sneezing, dry nose

Signs and Symptoms of Overdose Dizziness, fatigue, feeling of warmth, headache, nausea, sweating, and loose stools following oral administration.

Pharmacodynamics/Kinetics

Absorption: Topical: Negligible

Dosage Children >2 years and Adults: Instill 1-2 drops in eye(s) 4 times/day for up to 3 months

Contraindications Hypersensitivity to lodoxamide tromethamine or any component of the formulation

Warnings Safety and efficacy in children <2 years of age have not been established; not for injection; not for use in patients wearing soft contact lenses during treatment

Dosage Forms Solution, ophthalmic: 0.1% (10 mL) [contains benzalkonium chloride]

Overdosage/Treatment Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal. **Ocular:** Irrigate with normal saline through a Morgans lens

Drug Interactions No data reported

Pregnancy Risk Factor B

Loperamide

CAS Number 34552-83-5; 53179-11-6

U.S. Brand Names Imodium® A-D [OTC]

Synonyms Loperamide Hydrochloride

Use

Treatment of chronic diarrhea associated with inflammatory bowel disease; acute nonspecific diarrhea; increased volume of ileostomy discharge

OTC labeling: Control of symptoms of diarrhea, including Traveler's diarrhea

Unlabeled/Investigational Use Cancer treatment-induced diarrhea (eg, irinotecan induced); chronic diarrhea caused by bowel resection

Mechanism of Action Acts directly on intestinal muscles to inhibit peristalsis and prolong transit time

Adverse Reactions

Cardiovascular: Bradycardia

Central nervous system: Sedation, psychosis, restlessness, fatigue, dizziness, delirium

Dermatologic: Rash

Gastrointestinal: Nausea, vomiting, constipation, abdominal pain, abdominal cramping, xerostomia, appendicitis, pancreatitis

Genitourinary: Urinary retention, toxic megacolon

Signs and Symptoms of Overdose Bradycardia, CNS and respiratory depression, constipation, dry mouth, dystonic reactions, gastrointestinal cramping, headache, ileus, nausea, miosis, personality changes, vomiting

Admission Criteria/Prognosis Admit ingestions >1 mg/kg

Pharmacodynamics/Kinetics

Absorption: Poor

Distribution: Poor penetration into brain; low amounts enter breast milk

Metabolism: Hepatic via oxidative N-demethylation

Half-life elimination: 7-14 hours

Time to peak, plasma: Liquid: 2.5 hours; Capsule: 5 hours

Excretion: Urine and feces (1% as metabolites, 30% to 40% as unchanged drug)

Dosage

Oral:

Children:

Acute diarrhea: Initial doses (in first 24 hours):

2-5 years (13-20 kg): 1 mg 3 times/day

6-8 years (20-30 kg): 2 mg twice daily

8-12 years (>30 kg): 2 mg 3 times/day

Maintenance: After initial dosing, 0.1 mg/kg doses after each loose stool, but not exceeding initial dosage

Traveler's diarrhea:

6-8 years: 2 mg after first loose stool, followed by 1 mg after each subsequent stool (maximum dose: 4 mg/day)

9-11 years: 2 mg after first loose stool, followed by 1 mg after each subsequent stool (maximum dose: 6 mg/day)

≥ 12 years: See adult dosing.

Adults:

Acute diarrhea: Initial: 4 mg, followed by 2 mg after each loose stool, up to 16 mg/day

Chronic diarrhea: Initial: Follow acute diarrhea; maintenance dose should be slowly titrated downward to minimum required to control symptoms (typically, 4-8 mg/day in divided doses)

Traveler's diarrhea: Initial: 4 mg after first loose stool, followed by 2 mg after each subsequent stool (maximum dose: 8 mg/day)

Irinotecan-induced diarrhea (unlabeled use): 4 mg after first loose or frequent bowel movement, then 2 mg every 2 hours until 12 hours have passed without a bowel movement. If diarrhea recurs, then repeat administration

Dosage adjustment in hepatic impairment: No specific guidelines available.

Monitoring Parameters Stool frequency, fluid and electrolytes

Contraindications Hypersensitivity to loperamide or any component of the formulation; abdominal pain without diarrhea; children <2 years

Avoid use as primary therapy in acute dysentery, acute ulcerative colitis, bacterial enterocolitis, pseudomembranous colitis

Warnings

Should not be used if diarrhea is accompanied by high fever or blood in stool. Use caution in young children as response may be variable because of dehydration. Concurrent fluid and electrolyte replacement is often necessary in all age groups depending upon severity of diarrhea. Should not be used when inhibition of peristalsis is undesirable or dangerous. Discontinue if constipation, abdominal pain, or ileus develop. Use caution in patients with hepatic impairment because of reduced first pass metabolism. Use caution in treatment of AIDS patients; stop therapy at the sign of abdominal distention. Cases of toxic megacolon have occurred in this population. Loperamide is a symptom-directed treatment; if an underlying diagnosis is made, other disease-specific treatment may be indicated. Use caution in patients with hepatic impairment because of reduced first-pass metabolism; monitor for signs of CNS toxicity.

OTC labeling: If diarrhea lasts longer than 2 days, patient should stop taking loperamide and consult healthcare provider.

Dosage Forms Caplet, as hydrochloride: 2 mg
 Diamode, Imodium® A-D, Kao-Paverin®: 2 mg
 Capsule, as hydrochloride: 2 mg
 Liquid, oral, as hydrochloride: 1 mg/5 mL (5 mL, 10 mL, 120 mL)
 Imodium® A-D: 1 mg/5 mL (60 mL, 120 mL) [contains alcohol, sodium benzoate, benzoic acid; cherry mint flavor]
 Imodium® A-D [new formulation]: 1 mg/7.5 mL (60 mL, 120 mL, 360 mL) [contains sodium 10 mg/30 mL, sodium benzoate; creamy mint flavor]
 Tablet, as hydrochloride: 2 mg
 K-Pek II: 2 mg

Reference Range Peak plasma loperamide level: ~0.75 ng/mL after a 4 mg oral dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** use a cathartic if an ileus is present

Supportive therapy: Naloxone is useful to reverse CNS or apnea; dystonic reaction can be managed with benzotropine (1-2 mg I.V.) or diphenhydramine (1 mg/kg up to 50 mg I.V.)

Antidote(s)

- Naloxone [ANTIDOTE]

Test Interactions ↑ glucose

Drug Interactions **Substrate** (minor) of CYP2B6

P-glycoprotein inhibitors: May increase CNS depressant effects of loperamide. Examples of inhibitors include cyclosporine, ketoconazole, quinidine, quinine, and ritonavir. Monitor.

Saquinavir: Loperamide may decrease levels/effects of saquinavir.

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic effects were not observed in animal studies.

Lactation Enters breast milk/not recommended.

Additional Information Toxic dose: 2 mg/kg. If clinical improvement is not achieved after 16 mg/day for 10 days, control is unlikely with further use. Continue use if diet or other treatment does not control. Elderly are particularly sensitive to fluid and electrolyte loss. Drug therapy must be limited in order to avoid toxicity with this agent.

Loracarbef

CAS Number 121961-22-6; 76470-66-1

U.S. Brand Names Lorabid®

Use Infections caused by susceptible organisms involving the respiratory tract, acute otitis media, sinusitis, skin and skin structure, bone and joint, and urinary tract and gynecologic

Mechanism of Action Inhibits bacterial cell wall synthesis by binding to one or more of the penicillin binding proteins (PBPs); inhibits the final transpeptidation step of peptidoglycan synthesis in bacterial cell walls, thus inhibiting cell wall biosynthesis. It is thought that beta-lactam antibiotics inactivate transpeptidase via acylation of the enzyme with cleavage of the CO-N bond of the beta-lactam ring. Upon exposure to beta-lactam antibiotics, bacteria eventually lyse due to ongoing activity of cell wall autolytic enzymes (autolysins and murein hydrolases) while cell wall assembly is arrested.

Adverse Reactions

Cardiovascular: Vasodilation

Central nervous system: Headache, somnolence, nervousness, dizziness

Dermatologic: Rashes, urticaria, pruritus

Endocrine & metabolic: Menorrhagia

Gastrointestinal: Diarrhea, nausea, vomiting, abdominal pain, anorexia

Genitourinary: **Vaginitis** (15%), vaginal moniliasis

Hematologic: Transient thrombocytopenia, leukopenia, and eosinophilia

Hepatic: Transient elevations of ALT, AST, alkaline phosphatase

Renal: Transient elevations of BUN/creatinine

Pharmacodynamics/Kinetics

Absorption: Rapid

Protein binding: ~25%

Bioavailability: ~90%; decreased by food

Half-life elimination: ~1 hour

Time to peak, serum: ~1 hour

Excretion: Clearance: Plasma: ~200-300 mL/minute

Dosage

Oral:

Children:

Impetigo: 15 mg/kg/day in divided doses for 10 days

Acute otitis media: 15 mg/kg twice daily for 10 days

Pharyngitis: 7.5-15 mg/kg twice daily for 10 days

Adults:

Pharyngitis: 200 mg every 12 hours for 10 days

Bronchitis: 200-400 mg every 12 hours for 7 days

Pneumonia: 400 mg every 12 hours for 14 days

Sinusitis: 200-400 mg every 12 hours for 10 days

Uncomplicated urinary tract infections: 200 mg once daily for 7 days

Skin and soft tissue: 200-400 mg every 12-24 hours

Adults, female:

Uncomplicated pyelonephritis: 400 mg every 12 hours for 14 days

Dosing comments in renal impairment:

Cl_{cr} ≥ 50 mL/minute: Give usual dose

Cl_{cr} 10-49 mL/minute: 50% of usual dose at usual interval or usual dose given half as often

Cl_{cr} < 10 mL/minute: Give usual dose every 3-5 days

Hemodialysis: Doses should be administered after dialysis sessions

Stability Suspension may be kept at room temperature for 14 days

Administration Administer on an empty stomach at least 1 hour before or 2 hours after meals. Finish all medication. Shake suspension well before using.

Contraindications Hypersensitivity to loracarbef, any component of the formulation, or cephalosporins

Warnings Modify dosage in patients with severe renal impairment. Prolonged use may result in superinfection. Use with caution in patients with a previous history of hypersensitivity to other beta-lactam antibiotics (eg, penicillins, cephalosporins). Safety and efficacy in children < 6 months of age have not been established.

Dosage Forms Capsule: 200 mg, 400 mg

Powder for oral suspension: 100 mg/5 mL (100 mL); 200 mg/5 mL (100 mL) [strawberry bubble gum flavor]

Reference Range Peak serum loracarbef levels range from 14-15.4 mcg/mL after a 400 mg oral dose

Overdosage/Treatment Decontamination: Emesis with ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Drug Interactions Probenecid: May decrease cephalosporin elimination.

Pregnancy Risk Factor B

Pregnancy Implications Animal studies have not demonstrated teratogenicity. There are no adequate and well-controlled studies in pregnant women.

Lactation Excretion in breast milk unknown/use caution

Loratadine

CAS Number 79794-75-5

U.S. Brand Names Alavert™ [OTC]; Claritin® Hives Relief [OTC]; Claritin® [OTC]; Dimetapp® Children's ND [OTC]; Tavist® ND [OTC]

Impairment Potential Impairment may occur at double the therapeutic doses

Use Relief of nasal and non-nasal symptoms of seasonal allergic rhinitis with little sedative properties; urticaria (chronic); idiopathic chronic urticaria

Mechanism of Action Long-acting tricyclic antihistamine with selective peripheral histamine H₁ receptor antagonistic properties; derived from azatadine

Adverse Reactions

Cardiovascular: Hypotension, hypertension, palpitations, tachycardia, fibrillation (atrial), sinus tachycardia

Central nervous system: **Headache, somnolence, fatigue, anxiety, CNS depression, ataxia**

Dermatologic: Erythema multiforme, alopecia, angioedema, xerosis, urticaria, purpura, photosensitivity, pruritus, exanthem

Endocrine & metabolic: Breast pain, gynecomastia

Gastrointestinal: **Xerostomia, stomatitis**

Hepatic: Hepatotoxicity, liver necrosis

Neuromuscular & skeletal: Hyperkinesia, arthralgias, paresthesia

Respiratory: Dyspnea, pharyngitis, nasal dryness

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose

Admission Criteria/Prognosis Admit any patient with cardiac abnormalities or ingestion > 170 mg in children; admit any symptomatic patient or ingestion > 35 mg.

Pharmacodynamics/Kinetics

Onset of action: 1-3 hours

Peak effect: 8-12 hours

Duration: >24 hours

Absorption: Rapid

Distribution: Significant amounts enter breast milk

Metabolism: Extensively hepatic via CYP2D6 and 3A4 to active metabolite

Half-life elimination: 12-15 hours

Excretion: Urine (40%) and feces (40%) as metabolites

Dosage

Oral: Seasonal allergic rhinitis, chronic idiopathic urticaria:

Children 2-5 years: 5 mg once daily

LORAZEPAM

Children ≥ 6 years and Adults: 10 mg once daily
Elderly: Peak plasma levels are increased; elimination half-life is slightly increased; specific dosing adjustments are not available
Dosage adjustment in renal impairment: $Cl_{cr} \leq 30$ mL/minute:
Children 2-5 years: 5 mg every other day
Children ≥ 6 years and Adults: 10 mg every other day

Dosage adjustment in hepatic impairment: Elimination half-life increases with severity of disease
Children 2-5 years: 5 mg every other day
Children ≥ 6 years and Adults: 10 mg every other day

Administration Take on an empty stomach.

Contraindications Hypersensitivity to lorazepam or any component of the formulation

Warnings Use with caution and modify dose in patients with liver or renal impairment; safety and efficacy in children < 2 years of age have not been established

Dosage Forms Syrup: 1 mg/mL (120 mL)

Claritin[®]: 1 mg/mL (120 mL) [contains sodium benzoate; fruit flavor]; (60 mL, 120 mL) [alcohol free, dye free, sugar free; contains sodium 6 mg/5 mL and sodium benzoate; grape flavor]

Tablet: 10 mg

Alavert[®], Claritin[®], Claritin[®] Hives Relief, Claritin[®] 24 Hour Allergy, Tavist[®] ND: 10 mg

Tablet, rapidly disintegrating: 10 mg

Alavert[®]: 10 mg [contains phenylalanine 8.4 mg/tablet; mint and citrus burst flavors]

Claritin[®] RediTabs[®]: 10 mg [mint flavor]

Triaminic[®] Allerchews[™]: 10 mg

Reference Range Peak lorazepam serum level of 18 ng/mL 1 hour after a single 40 mg dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) ingestions > 150 mg/activated charcoal

Enhancement of elimination: Hemodialysis is not useful; multiple dosing of activated charcoal may be useful

Drug Interactions **Substrate** (minor) of CYP2D6, 3A4; **Inhibits** CYP2C8 (weak), 2C19 (moderate), 2D6 (weak)

CYP2C19 substrates: Lorazepam may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

Protease inhibitors (amprenavir, ritonavir, nelfinavir) may increase the serum levels of lorazepam

Increased toxicity: Other antihistamines

Pregnancy Risk Factor B

Pregnancy Implications Lorazepam was not found to be teratogenic in animal studies. There are no adequate and well-controlled studies in pregnant woman; use during pregnancy only if clearly needed.

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Specific References

Manning B, Tai W, and Kearney T, "A Four Year Review of Pediatric Lorazepam Ingestions; Implications for Poison Center Referral Guidelines," *J Toxicol Clin Toxicol*, 2003, 41(5):669.

Lorazepam

Related Information

- Seizures, Neonatal Guidelines
- Therapeutic Drugs Associated with Hallucinations

CAS Number 846-49-1

U.S. Brand Names Ativan[®]; Lorazepam Intenso[®]

Impairment Potential Yes. Cognitive and psychomotor impairment can occur in the elderly following acute single doses (0.5 and 1 mg) of oral lorazepam. (Pomara N, Tun H, DaSilva D, et al, "Benzodiazepine Use and Crash Risk in Older Patients," *JAMA*, 1998, 279(2):113-4.)

Use

Oral: Management of anxiety disorders or short-term relief of the symptoms of anxiety or anxiety associated with depressive symptoms
I.V.: Status epilepticus, preanesthesia for desired amnesia, antiemetic adjunct; pain/muscle spasm due to black widow spider bite

Unlabeled/Investigational Use Ethanol detoxification; insomnia; psychogenic catatonia; partial complex seizures; agitation (I.V.)

Mechanism of Action Depresses all levels of the CNS, including the limbic and reticular formation, probably through the increased action of gamma-aminobutyric acid (GABA), which is a major inhibitory neurotransmitter in the brain

Adverse Reactions

Cardiovascular: Hypotension

Central nervous system: **Sedation** (15.9%), headache, fatigue, depression, unsteadiness (3.4%), dizziness (6.9%), disorientation, sleep disturbances, agitation, aggressive behavior

Dermatologic: Hypertrichosis, erythema multiforme, alopecia, urticaria, purpura, Stevens-Johnson syndrome, pruritus, exanthem, lichen planus

Endocrine & metabolic: Menstrual irregularities

Gastrointestinal: Nausea, appetite changes, xerostomia, increased salivation

Hematologic: Blood dyscrasias

Neuromuscular & skeletal: Weakness (4.2%), reflex slowing

Miscellaneous: Fixed drug eruption, physical and psychological dependence with prolonged use, polyethylene glycol or propylene glycol poisoning (prolonged I.V. infusion)

Signs and Symptoms of Overdose Acute myoglobinuria, "alpha" coma (alpha frequency rhythm on EEG), ataxia, confusion, depression, disorientation, dyspnea, hypoaffective reflexes, hyporeflexia, labored breathing, myalgia, nystagmus, rhabdomyolysis, visual and auditory hallucinations. Onset of effects may be delayed as long as 7 hours in acute overdosage.

Pharmacodynamics/Kinetics

Onset of action:

Hypnosis: I.M.: 20-30 minutes

Sedation: I.V.: 5-20 minutes

Anticonvulsant: I.V.: 5 minutes, oral: 30-60 minutes

Duration: 6-8 hours

Absorption: Oral, I.M.: Prompt

Distribution:

V_d : Neonates: 0.76 L/kg, Adults: 1.3 L/kg; crosses placenta; enters breast milk

Protein binding: 85%; free fraction may be significantly higher in elderly

Metabolism: Hepatic to inactive compounds

Half-life elimination: Neonates: 40.2 hours; Older children: 10.5 hours;

Adults: 12.9 hours; Elderly: 15.9 hours; End-stage renal disease: 32-70 hours

Excretion: Urine; feces (minimal)

Dosage

Antiemetic:

Children 2-15 years: I.V.: 0.05 mg/kg (up to 2 mg/dose) prior to chemotherapy

Adults: Oral, I.V. (**Note:** May be administered sublingually; not a labeled route): 0.5-2 mg every 4-6 hours as needed

Anxiety and sedation:

Infants and Children: Oral, I.M., I.V.: Usual: 0.05 mg/kg/dose (range: 0.02-0.09 mg/kg) every 4-8 hours

I.V.: May use smaller doses (eg, 0.01-0.03 mg/kg) and repeat every 20 minutes, as needed to titrate to effect

Adults: Oral: 1-10 mg/day in 2-3 divided doses; usual dose: 2-6 mg/day in divided doses

Elderly: 0.5-4 mg/day; initial dose not to exceed 2 mg

Insomnia: Adults: Oral: 2-4 mg at bedtime

Preoperative: Adults:

I.M.: 0.05 mg/kg administered 2 hours before surgery (maximum: 4 mg/dose)

I.V.: 0.044 mg/kg 15-20 minutes before surgery (usual maximum: 2 mg/dose)

Operative amnesia: Adults: I.V.: Up to 0.05 mg/kg (maximum: 4 mg/dose)

Sedation (preprocedure): Infants and Children:

Oral, I.M., I.V.: Usual: 0.05 mg/kg (range: 0.02-0.09 mg/kg);

I.V.: May use smaller doses (eg, 0.01-0.03 mg/kg) and repeat every 20 minutes, as needed to titrate to effect

Status epilepticus: I.V.:

Infants and Children: 0.1 mg/kg slow I.V. over 2-5 minutes; do not exceed 4 mg/single dose; may repeat second dose of 0.05 mg/kg slow I.V. in 10-15 minutes if needed

Adolescents: 0.07 mg/kg slow I.V. over 2-5 minutes; maximum: 4 mg/dose; may repeat in 10-15 minutes

Adults: 4 mg/dose slow I.V. over 2-5 minutes; may repeat in 10-15 minutes; usual maximum dose: 8 mg

Rapid tranquilization of agitated patient (administer every 30-60 minutes):

Oral: 1-2 mg

I.M.: 0.5-1 mg

Average total dose for tranquilization: Oral, I.M.: 4-8 mg

Agitation in the ICU patient (unlabeled):

I.V.: 0.02-0.06 mg/kg every 2-6 hours

I.V. infusion: 0.01-0.1 mg/kg/hour

Monitoring Parameters Respiratory and cardiovascular status, blood pressure, heart rate, symptoms of anxiety

Administration May be administered by I.M., I.V., or orally

I.M.: Should be administered deep into the muscle mass

I.V.: Do not exceed 2 mg/minute or 0.05 mg/kg over 2-5 minutes; dilute I.V. dose with equal volume of compatible diluent (D₅W, NS, SW).

Contraindications Hypersensitivity to lorazepam or any component of the formulation (cross-sensitivity with other benzodiazepines may exist); acute narrow-angle glaucoma; sleep apnea (parenteral); intra-arterial injection of parenteral formulation; severe respiratory insufficiency (except during mechanical ventilation); pregnancy

Warnings

Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics) or renal impairment. Use with caution in patients with respiratory disease or impaired gag reflex. Initial doses in

elderly or debilitated patients should not exceed 2 mg. Prolonged lorazepam use may have a possible relationship to GI disease, including esophageal dilation.

The parenteral formulation of lorazepam contains polyethylene glycol and propylene glycol. Also contains benzyl alcohol - avoid in neonates. Concurrent administration with scopolamine results in an increased risk of hallucinations, sedation, and irrational behavior.

Causes CNS depression (dose-related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury and should be used with extreme caution in patients who are at risk of these events (especially the elderly).

Lorazepam may cause anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Use caution in patients with depression, particularly if suicidal risk may be present. Use with caution in patients with a history of drug dependence. Benzodiazepines have been associated with dependence and acute withdrawal symptoms on discontinuation or reduction in dose. Acute withdrawal, including seizures, may be precipitated after administration of flumazenil to patients receiving long-term benzodiazepine therapy.

As a hypnotic agent, should be used only after evaluation of potential causes of sleep disturbance. Failure of sleep disturbance to resolve after 7-10 days may indicate psychiatric or medical illness. A worsening of insomnia or the emergence of new abnormalities of thought or behavior may represent unrecognized psychiatric or medical illness and requires immediate and careful evaluation.

Dosage Forms Injection, solution (Ativan®): 2 mg/mL (1 mL, 10 mL); 4 mg/mL (1 mL, 10 mL) [contains benzyl alcohol]
Solution, oral concentrate (Lorazepam Intenso®): 2 mg/mL (30 mL) [alcohol free, dye free]

Tablet (Ativan®): 0.5 mg, 1 mg, 2 mg

Reference Range Therapeutic: Serum level: 50-240 ng/mL (SI: 156-746 nmol/L)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Treatment for benzodiazepine overdose is supportive; rarely is mechanical ventilation required. Flumazenil (Romazicon™) has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression. Do not use in concomitant tricyclic antidepressant ingestion; treat hypotension with isotonic crystalloids, place in Trendelenburg position or give dopamine or norepinephrine.

Enhancement of elimination: Multiple dose of activated charcoal may enhance elimination

Antidote(s)

- Flumazenil [ANTIDOTE]

Test Interactions May ↑ LFTs; Visine®, Drano®, and bleach can cause false-negative urine tests

Drug Interactions Clozapine: Benzodiazepines may enhance the adverse/toxic effect of Clozapine.

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect

Loxapine: There are rare reports of significant respiratory depression, stupor, and/or hypotension with concomitant use of loxapine and lorazepam; use caution if concomitant administration of loxapine and CNS drugs is required

Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation

Pregnancy Risk Factor D

Pregnancy Implications Crosses the placenta; neonatal respiratory depression or hypotonia if administered near time of delivery

Lactation Enters breast milk/contraindicated (AAP rates "of concern")

Nursing Implications Keep injectable form in the refrigerator; inadvertent intra-arterial injection may produce arteriospasm resulting in gangrene which may require amputation; emergency resuscitative equipment should be available when administering by I.V.; prior to I.V. use, Ativan® injection must be diluted with an equal amount of compatible diluent; injection must be made slowly with repeated aspiration to make sure the injection is not intra-arterial and that perivascular extravasation has not occurred; provide safety measures (ie, side rails, night light, and call button); remove smoking materials from area; supervise ambulation

Additional Information Injectable form has a longer duration of action than diazepam; provides an amnesic effect, so is useful for preop and preadministration of chemotherapy; for psychotic agitation: 2 mg I.M.

With 5 mg of haloperidol I.M. may be particularly useful. **Note:** Prolonged infusions have been associated with toxicity from propylene glycol and/or polyethylene glycol.

Lorcaïnide

Related Information

- Flecainide

CAS Number 58934-46-6; 59729-31-6

Unlabeled/Investigational Use Management of ventricular/supraventricular arrhythmias

Mechanism of Action A class IC antiarrhythmic agent with similar actions as flecainide

Adverse Reactions

Cardiovascular: Bradycardia, heart block, P-R prolongation, QRS prolongation, QT_c interval prolongation is minimal; worsening arrhythmias (ventricular), congestive heart failure, palpitations, chest pain, edema, cardiac arrest, hypotension, syncope, sinus bradycardia, angina, myocardial depression

Central nervous system: Dizziness, headache, sleep disturbance

Endocrine & metabolic: Hyponatremia

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose AV block, bradycardia, coma, hyponatremia, hypotension, insomnia, seizures, widened ventricular complexes

Toxicodynamics/Kinetics

Absorption: Oral: Well absorbed

Protein binding: 83%

Distribution: V_d: 5-10 L/kg

Metabolism: Hepatic to norlorcaïnide (active metabolite)

Bioavailability: 100%

Half-life: Lorcaïnide: 8 hours; norlorcaïnide: 27 hours

Elimination: Hepatic; clearance: 1500 mL/minute

Dosage

Oral: 100 mg twice daily; maximum daily oral dose: 400 mg

I.V.: Initial: 2 mg/kg with an infusion rate of 10 mg/minute under ECG control

Reference Range Serum therapeutic range: 150-400 ng/mL; serum lorcaïnide level of 1820 ng/mL and serum norlorcaïnide level of 450 ng/mL associated with fatality following an ingestion of 2.5 g

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Benzodiazepines can be used for seizure control; bradycardia or hypotension can be managed with catecholamines; cardiac pacing will probably not be effective; multiple dosing of activated charcoal may be effective

Losartan

U.S. Brand Names Cozaar®

Synonyms DuP 753; Losartan Potassium; MK594

Use Treatment of hypertension (HTN); treatment of diabetic nephropathy in patients with type 2 diabetes mellitus (noninsulin dependent, NIDDM) and a history of hypertension; stroke risk reduction in patients with HTN and left ventricular hypertrophy (LVH)

Mechanism of Action As a selective and competitive, nonpeptide angiotensin II receptor antagonist, losartan blocks the vasoconstrictor and aldosterone-secreting effects of angiotensin II; losartan interacts reversibly at the AT1 and AT2 receptors of many tissues and has slow dissociation kinetics; its affinity for the AT1 receptor is 1000 times greater than the AT2 receptor. Angiotensin II receptor antagonists may induce a

more complete inhibition of the renin-angiotensin system than ACE inhibitors, they do not affect the response to bradykinin, and are less likely to be associated with nonrenin-angiotensin effects (eg, cough and angioedema). Losartan increases urinary flow rate and in addition to being natriuretic and kaliuretic, increases excretion of chloride, magnesium, uric acid, calcium, and phosphate.

Adverse Reactions

Cardiovascular: Angina, arrhythmias, AV block (second degree), bradycardia, CVA, **chest pain** (diabetic nephropathy), edema, facial edema, flushing, hypotension, orthostatic hypotension (hypertension/diabetic nephropathy), first-dose hypotension (dose-related: <1% with 50 mg, 2% with 100 mg), palpitations, syncope, tachycardia, ventricular arrhythmias, vasculitis

Central nervous system: Acute psychosis with paranoid delusions, anxiety, ataxia, confusion, depression, dizziness, **fatigue** (diabetic nephropathy), fever, headache, hypoesthesia (diabetic nephropathy), insomnia, memory impairment, MI, migraine, nervousness, sleep disorder, somnolence, vertigo

Dermatology: Alopecia, angioedema, cellulitis (diabetic nephropathy), dermatitis, dry skin, ecchymosis, erythema, Henoch-Schönlein purpura, maculopapular rash, photosensitivity, pruritus, rash, urticaria

Endocrine: Gout, hyperkalemia (hypertension/diabetic nephropathy), **hypoglycemia** (diabetic nephropathy), hyponatremia, impotence, libido decreased

Gastrointestinal: Abdominal pain, ageusia, anorexia, constipation, **diarrhea** (hypertension/diabetic nephropathy), dysgeusia, dyspepsia, flatulence, gastritis (diabetic nephropathy), nausea, pancreatitis, taste perversion, weight gain (diabetic nephropathy), vomiting, xerostomia

Genitourinary: Nocturia, **urinary tract infection** (diabetic nephropathy), urinary frequency

Hematologic: **Anemia** (diabetic nephropathy), hematocrit decreased, hemoglobin decreased, hyperkalemia

Hepatic: Bilirubin increased, hepatitis, transaminases increased

Neuromuscular & skeletal: Arm pain, arthralgia, arthritis, **back pain** (hypertension/diabetic nephropathy), hip pain, joint swelling, leg pain, muscle cramps, muscular weakness (diabetic nephropathy), knee pain (diabetic nephropathy), muscle weakness, myalgia, paresthesia, **weakness** (diabetic nephropathy), peripheral neuropathy, tremor

Ocular: Blurred vision, conjunctivitis, visual acuity decreased

Otic: Tinnitus

Renal: BUN increased, serum creatinine increased

Respiratory: Bronchitis, **cough** (diabetic nephropathy; hypertension, but similar to that associated with hydrochlorothiazide or placebo therapy), dyspnea, epistaxis, nasal congestion, pharyngitis, rhinitis, sinusitis (hypertension/diabetic nephropathy), upper respiratory infection

Miscellaneous: Allergic reaction, anaphylactic reactions, dental pain, diaphoresis, infection (diabetic nephropathy), flu-like syndrome (diabetic nephropathy)

Pharmacodynamics/Kinetics

Onset of action: 6 hours

Distribution: V_d: Losartan: 34 L; E-3174: 12 L; does not cross blood brain barrier

Protein binding, plasma: High

Metabolism: Hepatic (14%) via CYP2C9 and 3A4 to active metabolite, E-3174 (40 times more potent than losartan); extensive first-pass effect

Bioavailability: 25% to 33%; AUC of E-3174 is four times greater than that of losartan

Half-life elimination: Losartan: 1.5-2 hours; E-3174: 6-9 hours

Time to peak, serum: Losartan: 1 hour; E-3174: 3-4 hours

Excretion: Urine (4% as unchanged drug, 6% as active metabolite)

Clearance: Plasma: Losartan: 600 mL/minute; Active metabolite: 50 mL/minute

Dosage

Oral:

Hypertension:

Children 6-16 years: 0.7 mg/kg once daily (maximum: 50 mg/day); adjust dose based on response; doses >1.4 mg/kg (maximum: 100 mg) have not been studied

Adults: Usual starting dose: 50 mg once daily; can be administered once or twice daily with total daily doses ranging from 25-100 mg
Patients receiving diuretics or with intravascular volume depletion:
Usual initial dose: 25 mg

Nephropathy in patients with type 2 diabetes and hypertension: Adults: Initial: 50 mg once daily; can be increased to 100 mg once daily based on blood pressure response

Stroke reduction (HTN with LVH): Adults: 50 mg once daily (maximum daily dose: 100 mg); may be used in combination with a thiazide diuretic

Dosing adjustment in renal impairment:

Children: Use is not recommended if Cl_{cr} <30 mL/minute.

Adults: No adjustment necessary.

Dosing adjustment in hepatic impairment: Reduce the initial dose to 25 mg/day; divide dosage intervals into two.

Monitoring Parameters Supine blood pressure, electrolytes, serum creatinine, BUN, urinalysis, symptomatic hypotension and tachycardia, CBC

Administration May be administered with or without food.

Contraindications Hypersensitivity to losartan or any component of the formulation; hypersensitivity to other A-II receptor antagonists; bilateral renal artery stenosis; pregnancy (2nd and 3rd trimesters)

Warnings

[U.S. Boxed Warning]: Based on human data, drugs that act on the angiotensin system can cause injury and death to the developing fetus when used in the second and third trimesters. Angiotensin receptor blockers should be discontinued as soon as possible once pregnancy is detected. Avoid use or use a smaller dose in patients who are volume depleted; correct depletion first. Deterioration in renal function can occur with initiation. May cause hyperkalemia; avoid potassium supplementation unless specifically required by healthcare provider. Use with caution in unilateral renal artery stenosis and pre-existing renal insufficiency; significant aortic/mitral stenosis. When used to reduce the risk of stroke in patients with HTN and LVH, may not be effective in the African-American population. Use caution with hepatic dysfunction, dose adjustment may be needed. Safety and efficacy in children <6 years of age have not been established.

Dosage Forms Tablet, as potassium: 25 mg, 50 mg, 100 mg

Overdosage/Treatment

Decontamination: Ipecac (within 30 minutes)/lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. normal saline or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam or diazepam or to phenytoin or phenobarbital. Inhaled sodium cromoglycate (total dose: 40 mg/day) can decrease ACE-inhibitor cough by 50%.

Enhanced elimination: Multiple dosing of activated charcoal may be effective. Not removed via hemodialysis.

Drug Interactions Substrate (major) of CYP2C9, 3A4; **Inhibits** CYP1A2 (weak), 2C8 (moderate), 2C9 (moderate), 2C19 (weak), 3A4 (weak)

CYP2C9 inducers: May decrease the levels/effects of losartan. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C8 Substrates: Losartan may increase the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP2C9 Substrates: Losartan may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapson, fluoxetine, glimepiride, glipizide, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of losartan. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

Fluconazole: Increases plasma levels of losartan via 2C8/9 inhibition (decreases the plasma levels of the active metabolite). Monitor for increased losartan efficacy.

Lithium: Risk of toxicity may be increased by losartan; monitor lithium levels.

NSAIDs: May decrease angiotensin II antagonist efficacy; effect has been seen with losartan, but may occur with other medications in this class; monitor blood pressure

Potassium-sparing diuretics (amiloride, potassium, spironolactone, triamterene): Increased risk of hyperkalemia.

Potassium supplements may increase the risk of hyperkalemia.

Rifampin may reduce antihypertensive efficacy of losartan.

Trimethoprim (high dose) may increase the risk of hyperkalemia.

Pregnancy Risk Factor C/D (2nd and 3rd trimesters)

Pregnancy Implications Discontinue as soon as possible when pregnancy is detected. Drugs which act directly on renin-angiotensin can cause fetal and neonatal morbidity and death.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Maximal antihypertensive effect seen in 3-6 weeks; lowers serum uric acid levels

Specific References

Lovastatin

CAS Number 75330-75-5

U.S. Brand Names Altacor™; Mevacor®

Synonyms Mevinolin; Monacolin K

Use

Adjunct to dietary therapy to decrease elevated serum total and LDL-cholesterol concentrations in primary hypercholesterolemia

Primary prevention of coronary artery disease (patients without symptomatic disease with average to moderately elevated total and LDL-cholesterol and below average HDL-cholesterol); slow progression of coronary atherosclerosis in patients with coronary heart disease

Adjunct to dietary therapy in adolescent patients (10-17 years of age, females >1 year post-menarche) with heterozygous familial hypercholesterolemia having LDL >189 mg/dL, or LDL >160 mg/dL with positive family history of premature cardiovascular disease (CVD), or LDL >160 mg/dL with the presence of at least two other CVD risk factors

Mechanism of Action Lovastatin acts by competitively inhibiting 3-hydroxyl-3-methylglutaryl-coenzyme A (HMG-CoA) reductase, the enzyme that catalyzes the rate-limiting step in cholesterol biosynthesis

Adverse Reactions

Cardiovascular: Chest pain

Central nervous system: Headache, dizziness, insomnia

Dermatologic: Alopecia, pruritus, dermatomyositis, rash

Gastrointestinal: Abdominal pain, acid regurgitation, constipation, diarrhea, dyspepsia, flatulence, nausea, xerostomia, vomiting

Neuromuscular & skeletal: **Increased CPK** (>2x normal), myalgia, weakness, muscle cramps, leg pain, arthralgia, paresthesia

Ocular: Blurred vision, eye irritation

Note: Additional class-related events or case reports (not necessarily reported with lovastatin therapy):

Cardiovascular: Angioedema, flushing, vasculitis

Central nervous system: Anxiety, chills, depression, fever, malaise, memory loss, psychic disturbance, vertigo

Dermatologic: Dryness of skin/mucous membranes, erythema multiforme, nail changes, nodules, photosensitivity, skin discoloration, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Endocrine & metabolic: Decreased libido, erectile dysfunction, gynecostasia, impotence, thyroid dysfunction

Gastrointestinal: Alteration in taste, anorexia, pancreatitis

Hematologic: Eosinophilia, hemolytic anemia, leukopenia, thrombocytopenia, purpura

Hepatic: Alkaline phosphatase increased, cholestatic jaundice, cirrhosis, elevated transaminases, fatty liver, fulminant hepatic necrosis, hepatitis, hepatoma, hyperbilirubinemia, increased GGT

Neuromuscular & skeletal: Arthritis, facial palsy, increased CPK (>10x normal), myopathy, peripheral nerve palsy, peripheral neuropathy, polymyalgia rheumatica, rhabdomyolysis, tremor

Renal: Renal failure (secondary to rhabdomyolysis)

Ocular: Cataracts, impaired extraocular muscle movement, ophthalmoplegia

Respiratory: Dyspnea

Miscellaneous: Anaphylaxis, hypersensitivity reaction, increased ESR, positive ANA, systemic lupus erythematosus-like syndrome

Signs and Symptoms of Overdose Cholestatic jaundice, dyspepsia, gynecomastia, hyperthermia, myalgia, myoglobinuria, rhabdomyolysis

Admission Criteria/Prognosis Admit any ingestion >200 mg or admit any symptomatic patient

Pharmacodynamics/Kinetics

Onset of action: LDL-cholesterol reductions: 3 days

Absorption: 30%; increased with extended release tablets when taken in the fasting state

Protein binding: 95%

Metabolism: Hepatic; extensive first-pass effect; hydrolyzed to B-hydroxy acid (active)

Bioavailability: Increased with extended release tablets

Half-life elimination: 1.1-1.7 hours

Time to peak, serum: 2-4 hours

Excretion: Feces (~80% to 85%); urine (10%)

Dosage

Oral:

Adolescents 10-17 years: Immediate release tablet:

LDL reduction <20%: Initial: 10 mg/day with evening meal

LDL reduction ≥20%: Initial: 20 mg/day with evening meal

Usual range: 10-40 mg with evening meal, then adjust dose at 4-week intervals

Adults: Initial: 20 mg with evening meal, then adjust at 4-week intervals; maximum dose: 80 mg/day immediate release tablet or 60 mg/day extended release tablet; before initiation of therapy, patients should be placed on a standard cholesterol-lowering diet for 3-6 months and the diet should be continued during drug therapy. Patients receiving immunosuppressant drugs should start at 10 mg/day and not exceed 20 mg/day. Patients receiving concurrent therapy with fibrates should

not exceed 20 mg lovastatin. Patients receiving amiodarone, niacin, or verapamil should not exceed 40 mg lovastatin daily.

Monitoring Parameters Obtain baseline LFTs and total cholesterol profile. LFTs should be performed before initiation of therapy, at 6- and 12 weeks after initiation or first dose, and periodically thereafter.

Administration Administer immediate release tablet with meals. Administer extended release tablet at bedtime; do not crush or chew.

Contraindications Hypersensitivity to lovastatin or any component of the formulation; active liver disease; unexplained persistent elevations of serum transaminases; pregnancy; breast-feeding

Warnings Liver function tests should be assessed before initiation of therapy in patients with a history of liver disease, prior to upwards dosage adjustment to ≥40 mg daily or when otherwise indicated; enzyme levels should be followed periodically thereafter as clinically warranted. Rhabdomyolysis with or without acute renal failure has occurred. Risk is dose-related and is increased with concurrent use of lipid-lowering agents which may cause rhabdomyolysis (gemfibrozil, fibric acid derivatives, or niacin at doses ≥1 g/day) or during concurrent use with potent CYP3A4 inhibitors. Avoid concurrent use of azole antifungals, macrolide antibiotics, and protease inhibitors. Use caution/limit dose with amiodarone, cyclosporine, danazol, gemfibrozil (or other fibrates), lipid-lowering doses of niacin, or verapamil. Patients should be instructed to report unexplained muscle pain or weakness; lovastatin should be discontinued if myopathy is suspected/confirmed. Temporarily discontinue in any patient experiencing an acute or serious condition predisposing to renal failure secondary to rhabdomyolysis. Use with caution in patients who consume large amounts of ethanol or have a history of liver disease. Safety and efficacy of the immediate release tablet have not been evaluated in prepubertal patients, patients <10 years of age, or doses >40 mg/day in appropriately-selected adolescents; extended release tablets have not been studied in patients <20 years of age.

Dosage Forms Tablet: 10 mg, 20 mg, 40 mg

Mevacor®: 20 mg, 40 mg

Tablet, extended release:

Altoprev®: 20 mg, 40 mg, 60 mg

Reference Range NCEP classification of pediatric patients with familial history of hypercholesterolemia or premature CVD: Acceptable total cholesterol: <170 mg/dL, LDL: <110 mg/dL

Overdosage/Treatment

Decontamination: Ipecac (within 30 minutes)/lavage (within 1 hour)/activated charcoal

Supportive therapy: If rhabdomyolysis occurs, alkaline diuresis (with sodium bicarbonate) and diuretics (mannitol preferably with furosemide as a second choice) in order to maintain urine flow may be needed

Test Interactions ↑ liver transaminases (S), HDL cholesterol, CPK; ↓ VLDL and LDL levels

Drug Interactions **Substrate** of CYP3A4 (major); **Inhibits** CYP2C9 (weak), 2D6 (weak), 3A4 (weak)

Amiodarone: Inhibits metabolism of lovastatin and may increase lovastatin-induced myopathy and rhabdomyolysis. Concurrent use is not recommended, but if unavoidable, dose of lovastatin should be limited.

Antacids: Plasma concentrations may be decreased when given with magnesium-aluminum hydroxide containing antacids (reported with atorvastatin and pravastatin). Clinical efficacy is not altered, no dosage adjustment is necessary

Azole antifungals: May decrease the metabolism, via CYP isoenzymes, of HMG-CoA reductase inhibitors and may increase risk of lovastatin-induced myopathy and rhabdomyolysis. Avoid concurrent use.

Cholestyramine reduces absorption of several HMG-CoA reductase inhibitors. Separate administration times by at least 4 hours.

Cholestyramine and colestipol (bile acid sequestrants): Cholesterol-lowering effects are additive.

Clofibrate and fenofibrate may increase the risk of myopathy and rhabdomyolysis; limit dose of lovastatin

Cyclosporine: Concurrent use may increase risk of myopathy; limit dose of lovastatin

CYP3A4 inhibitors: May increase the levels/effects of lovastatin. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil. Avoid concurrent use.

Danzol: Concurrent use may increase risk of myopathy; limit dose of lovastatin.

Gemfibrozil: Increased risk of myopathy and rhabdomyolysis; limit dose of lovastatin

Grapefruit juice may inhibit metabolism of lovastatin via CYP3A4; avoid high dietary intakes of grapefruit juice.

Isradipine may decrease lovastatin blood levels.

Macrolide antibiotics: May decrease the metabolism, via CYP isoenzymes, of HMG-CoA reductase inhibitors and may increase risk of lovastatin-induced myopathy and rhabdomyolysis. Avoid concurrent use.

LOXAPINE

Nefazodone: May decrease the metabolism, via CYP isoenzymes, of HMG-CoA reductase inhibitors and may increase risk of lovastatin-induced myopathy and rhabdomyolysis. Avoid concurrent use.

Niacin (at higher dosages ≥ 1 g/day) may increase risk of myopathy and rhabdomyolysis; limit dose of lovastatin

Protease inhibitors: Concurrent use increases the risk of myopathy and rhabdomyolysis; concurrent use should be avoided.

Verapamil: Inhibits metabolism of lovastatin and may increase lovastatin-induced myopathy and rhabdomyolysis. Concurrent use is not recommended, but if unavoidable, dose of lovastatin should be limited.

Warfarin effect (hypoprothrombinemic response) may be increased; monitor INR closely when lovastatin is initiated or discontinued.

Pregnancy Risk Factor X

Pregnancy Implications Interferes with fetal steroid synthesis. Congenital abnormalities (VATER) have been associated with 1st trimester use. A case of bone deformity, tracheoesophageal fistula, and anal atresia has been noted in a fetus after first-trimester use of lovastatin and dextroamphetamine.

Lactation Excretion unknown/contraindicated

Nursing Implications Administer with meals, urge patient to adhere to cholesterol-lowering diet

Additional Information Before initiation of therapy, patients should be placed on a standard cholesterol-lowering diet for 6 weeks and the diet should be continued during drug therapy. Average length of time to development of rhabdomyolysis is one year; with an addition of a fibrate, the average time is about 32 days. Muscle pain (88%) or fatigue (74%) are the two most prominent symptoms in statin-induced rhabdomyolysis.

Duration: ~12 hours

Metabolism: Hepatic to glucuronide conjugates

Half-life elimination: Biphasic: Initial: 5 hours; Terminal: 12-19 hours

Excretion: Urine; feces (small amounts)

Dosage

Adults:

Oral: 10 mg twice daily, increase dose until psychotic symptoms are controlled; usual dose range: 60-100 mg/day in divided doses 2-4 times/day; dosages >250 mg/day are not recommended

I.M.: 12.5-50 mg every 4-6 hours or longer as needed and change to oral therapy as soon as possible

Monitoring Parameters Vital signs; lipid profile, fasting blood glucose/Hgb A_{1c}; BMI; mental status, abnormal involuntary movement scale (AIMS), extrapyramidal symptoms (EPS)

Contraindications Hypersensitivity to loxapine or any component of the formulation; severe CNS depression; coma

Warnings

May cause hypotension. Moderately sedating, use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Caution in patients with hemodynamic instability; bone marrow suppression; predisposition to seizures; subcortical brain damage; severe cardiac, hepatic, renal or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use - use with caution in patients at risk of pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May alter cardiac conduction; life-threatening arrhythmias have occurred with therapeutic doses of phenothiazines. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications which may predispose). Safety and effectiveness of loxapine in pediatric patients have not been established.

Phenothiazines may cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention); therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other antipsychotics, loxapine has a low potency of cholinergic blockade.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is moderate-high relative to other neuroleptics). May be associated with neuroleptic malignant syndrome (NMS) or pigmentary retinopathy.

Dosage Forms Capsule, as succinate: 5 mg, 10 mg, 25 mg, 50 mg

Reference Range Plasma loxapine level of 0.2 mg/L associated with stupor. Postmortem blood loxapine levels due to loxapine fatalities range from 1.2-9.5 mg/L.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam or diazepam (I.V. 5-10 mg bolus in adults every 15 minutes if needed up to a total of 30 mg; I.V. 0.25-0.4 mg/kg/dose up to a total of 10 mg in children) or to phenytoin or phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 gram), while other antiarrhythmics can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50 mg I.M. or I.V. slow push followed by a maintenance dose for 48-72 hours. When these reactions are unresponsive to diphenhydramine, benztropine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes.

Enhancement of elimination: Multiple dosing of activated charcoal would not be expected to be useful

Test Interactions Increases glucose, increases plasma norepinephrine levels and epinephrine levels threefold to fivefold; false-positives for phenylketonuria, amylase, uroporphyrins, urobilinogen; EMIT assays may be false-positive in the presence of diphenhydramine, thioridazine, chlorpromazine, alimemazine, carbamazepine, cyclobenzaprine, or perphenazine

Drug Interactions

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Aluminum salts: May decrease the absorption of antipsychotics; monitor
Amphetamines: Efficacy may be diminished by antipsychotics; in addition, amphetamines may increase psychotic symptoms; avoid concurrent use

Loxapine

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antipsychotic Agents

CAS Number 27833-64-3

U.S. Brand Names Loxitane[®] C; Loxitane[®]

Synonyms Loxapine Succinate; Oxilapine Succinate

Impairment Potential Yes

Use Management of psychotic disorders

Mechanism of Action Unclear mechanism of action; a dibenzoxazepine thought to be similar to chlorpromazine

Adverse Reactions

Cardiovascular: **Hypotension (orthostatic)**, tachycardia, cardiac arrhythmias; abnormal T-waves with prolonged ventricular repolarization, severe hypotension, arrhythmias, flutter (atrial), fibrillation (atrial)

Central nervous system: **drowsiness, extrapyramidal reactions, pseudoparkinsonian signs and symptoms, tardive dyskinesia, confusion**, CNS depression, fever, sedation, restlessness, anxiety, psychosis, dystonic reactions, seizures, altered central temperature regulation, neuroleptic malignant syndrome, hyperthermia

Dermatologic: Hyperpigmentation, pruritus, rash, photosensitivity, alopecia, urticaria, purpura, exanthem

Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, syndrome of inappropriate antidiuretic hormone, sexual dysfunction

Gastrointestinal: **Xerostomia** (problem with denture users), adynamic ileus, constipation, GI upset, nausea, weight gain

Genitourinary: Urinary retention, overflow incontinence, priapism

Hematologic: Agranulocytosis (more often in women between fourth and tenth weeks of therapy), leukopenia (usually in patients with large doses for prolonged periods)

Hepatic: Cholestatic jaundice

Neuromuscular & skeletal: Paresthesia

Ocular: **Blurred vision**, retinal pigmentation

Miscellaneous: Systemic lupus erythematosus

Signs and Symptoms of Overdose Agitation, agranulocytosis, arrhythmias, CNS depression, deep sleep, dysphagia, dystonic reactions, extrapyramidal reaction, granulocytopenia, gynecomastia, hypertension followed by hypotension, hypothermia, leukocytosis, leukopenia, myoglobinuria, neuroleptic malignant syndrome, neutropenia, Parkinson's-like symptoms, ptosis, renal failure (acute), rhabdomyolysis, seizures, sinus tachycardia, syncope

Pharmacodynamics/Kinetics

Onset of action: Neuroleptic: Oral: 20-30 minutes

Peak effect: 1.5-3 hours

Anticholinergics: May inhibit the therapeutic response to antipsychotics and excess anticholinergic effects may occur; includes benztrapine, trihexyphenidyl, biperiden, and drugs with significant anticholinergic activity (TCAs, antihistamines, disopyramide)

Antihypertensives: Concurrent use of antipsychotics with an antihypertensive may produce additive hypotensive effects (particularly orthostasis)

Bromocriptine: Antipsychotics inhibit the ability of bromocriptine to lower serum prolactin concentrations

CNS depressants: Sedative effects may be additive with antipsychotics; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents

Epinephrine: Chlorpromazine (and possibly other low potency antipsychotics) may diminish the pressor effects of epinephrine

Guanethidine and guanadrel: Antihypertensive effects may be inhibited by antipsychotics

Levodopa: Antipsychotics may inhibit the antiparkinsonian effect of levodopa; avoid this combination

Lithium: Antipsychotics may produce neurotoxicity with lithium; this is a rare effect

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk.

Phenytoin: May reduce serum levels of antipsychotics; antipsychotics may increase phenytoin serum levels

Propranolol: Serum concentrations of antipsychotics may be increased; propranolol also increases antipsychotic concentrations

QT_c-prolonging agents: Effects on QT_c interval may be additive with antipsychotics, increasing the risk of malignant arrhythmias. Other QT_c-prolonging agents include type Ia antiarrhythmics, TCAs, and some quinolone antibiotics (sparfloxacin, moxifloxacin and gatifloxacin). Concomitant use with thioridazine is contraindicated.

Sulfadoxine-pyrimethamine: May increase antipsychotic concentrations

Tricyclic antidepressants: Concurrent use may produce increased toxicity or altered therapeutic response

Trazodone: Antipsychotics and trazodone may produce additive hypotensive effects

Valproic acid: Serum levels may be increased by antipsychotics

Pregnancy Risk Factor C**Pregnancy Implications** Crosses placenta**Lactation** Excretion in breast milk unknown/not recommended**Nursing Implications** Injectable is for I.M. use only**Specific References**

Moore KA, Levine B, Korell M, et al, "An Unusual Loxapine Intoxication," *J Anal Toxicol*, 2004, 28:300.

Malathion (Topical Lotion)**CAS Number** 121-75-5**UN Number** 2783**U.S. Brand Names** Ovide®**Use** Treatment of head lice and their ova (pediculosis)**Mechanism of Action** A dimethoxy organophosphate insecticide with inherent toxicity**Adverse Reactions**

Cardiovascular: Bradycardia, AV block, sinus bradycardia

Central nervous system: Anxiety, clumsiness, confusion, dizziness, drowsiness, seizures

Dermatologic: Contact dermatitis, irritation of scalp

Gastrointestinal: Abdominal cramps, diarrhea

Ocular: Nystagmus

Renal: Acute renal insufficiency

Signs and Symptoms of Overdose Paresthesia

Dosage Sprinkle Ovide™ lotion on dry hair and rub gently until the scalp is thoroughly moistened; pay special attention to the back of the head and neck. Allow to dry naturally - use no heat and leave uncovered. After 8-12 hours, the hair should be washed with a nonmedicated shampoo; rinse and use a fine-toothed comb to remove dead lice and eggs. If required, repeat with second application in 7-9 days. Further treatment is generally not necessary. Other family members should be evaluated to determine if infested and if so, receive treatment.

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles; all emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails

Gastric: Activated charcoal can be administered either orally or via a nasogastric tube; do not induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles; do not use any cathartic

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Including airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Enhancement of elimination: Dialysis and hemoperfusion is not indicated due to effectiveness of the prescribed antidotal treatment and large volume of distribution of organophosphates

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed and should be titrated to the resolution of excess pulmonary secretions; frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures

Glycopyrrolate: May be administered if atropine is unavailable at $\sim 1/2$ the atropine dose

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Pregnancy Risk Factor B**Additional Information** Contains 78% isopropyl alcohol**Maprotiline****Related Information**

- Anticholinergic Effects of Common Psychotropics
- Therapeutic Drugs Associated with Hallucinations

CAS Number 10262-69-8; 10347-81-6**Synonyms** Ludiomil; Maprotiline Hydrochloride**Impairment Potential** Yes**Use** Treatment of depression and anxiety associated with depression

Unlabeled/Investigational Use Bulimia; duodenal ulcers; enuresis; urinary symptoms of multiple sclerosis; pain; panic attacks; tension headache; cocaine withdrawal

Mechanism of Action Increases the synaptic concentration of serotonin and/or norepinephrine in the central nervous system by inhibition of their reuptake by the presynaptic neuronal membrane

Adverse Reactions

Cardiovascular: **Hypotension (orthostatic)**, heart block, tachycardia, torsade de pointes, sinus bradycardia, QRS prolongation

Central nervous system: **Drowsiness**, convulsions (dose-dependent), sedation, hand hypotonia, psychosis, dizziness, visual hallucinations, fever, hyperthermia

Dermatologic: **Rash**, cutaneous vasculitis

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone

Gastrointestinal: **Extreme xerostomia**, constipation, increased appetite, weight gain

Genitourinary: **Urinary retention**

Hematologic: Leukocytosis, thrombocytopenia

Hepatic: Elevated liver function tests

Neuromuscular & skeletal: **Weakness**, tremor, clonus, myoclonus

Ocular: Blurred vision, increased intraocular pressure

Otic: Ototoxicity, tinnitus

Respiratory: Aspiration

Signs and Symptoms of Overdose Agitation, agranulocytosis, AV block, bradycardia, confusion, delirium, dental erosion, eosinophilia, granulocytopenia, hypnopompic hallucinations, hypotension, hypothermia, increased intraocular pressure, leukopenia, mania, neutropenia, photosensitivity, QT prolongation, respiratory depression, seizures, tachycardia, torsade de pointes, urinary retention, vasculitis

Pharmacodynamics/Kinetics

Absorption: Slow

Protein binding: 88%

Metabolism: Hepatic to active and inactive compounds

Half-life elimination, serum: 27-58 hours (mean: 43 hours)

Time to peak, serum: Within 12 hours

Excretion: Urine (70%); feces (30%)

Dosage

Oral:

Children 6-14 years: 10 mg/day, increase to a maximum daily dose of 75 mg

Adults: 75 mg/day to start, increase by 25 mg every 2 weeks up to 150-225 mg/day; given in 3 divided doses or in a single daily dose

Monitoring Parameters Monitor blood pressure and pulse rate prior to and during initial therapy; evaluate mood and somatic complaints; monitor appetite and weight; ECG in older adults

Contraindications Hypersensitivity to maprotiline or any component of the formulation; use of MAO inhibitors within 14 days; use in a patient during the acute recovery phase of MI

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. **Maprotiline is not FDA approved for use in children.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Maprotiline is not FDA approved for the treatment of bipolar depression.**

May cause sedation, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Sedative effects may be additive with other CNS depressants and/or ethanol. The degree of sedation is high relative to other antidepressants. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Therapy should not be abruptly discontinued in patients receiving high doses for prolonged periods.

May cause orthostatic hypotension (risk is moderate relative to other antidepressants) - use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). The degree of anticholinergic blockade produced by this agent is moderate relative to other cyclic antidepressants, however, caution should still be used in patients with urinary retention, benign prostatic hyperplasia, narrow-angle glaucoma, xerostomia, visual problems, constipation, or history of bowel obstruction.

Use with caution in patients with a history of cardiovascular disease (including previous MI, stroke, tachycardia, or conduction abnormalities). The risk conduction abnormalities with this agent is moderate relative to other antidepressants. Use caution in patients with a previous seizure disorder or condition predisposing to seizures such as brain damage, alcoholism, or concurrent therapy with other drugs which lower the seizure threshold. Use with caution in hyperthyroid patients or those receiving thyroid supplementation. Use with caution in patients with hepatic or renal dysfunction and in elderly patients.

Dosage Forms Tablet, as hydrochloride: 25 mg, 50 mg, 75 mg

Reference Range

Therapeutic: 100-150 ng/mL (SI: 361-540 nmol/L); levels >237 ng/mL can be associated with seizures

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdose/Treatment

Decontamination: Emesis is contraindicated, lavage (within 1 hour)/activated charcoal can be useful; multiple dosing of activated charcoal may be useful

Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated. Ventricular arrhythmias may respond to systemic alkalinization (sodium bicarbonate 0.5-2 mEq/kg I.V.). Arrhythmias unresponsive to this therapy may respond to lidocaine 1 mg/kg I.V. followed by a titrated infusion. Seizures usually respond to benzodiazepines. If seizures are unresponsive or recur, phenytoin or phenobarbital may be required. For hypotension, isotonic saline is effective; norepinephrine (adults: 8-12 mcg/minute or children 0.1-0.2 mcg/kg/minute) is most effective pressor.

Antidote(s)

- Sodium Bicarbonate [ANTIDOTE]

Drug Interactions Substrate of CYP2D6 (major)

Altretamine: Concurrent use may cause orthostatic hypertension

Amphetamines: Cyclic antidepressants may enhance the effect of amphetamines; monitor for adverse CV effects

Anticholinergics: Combined use with cyclic antidepressants may produce additive anticholinergic effects

Antihypertensives: Cyclic antidepressants may inhibit the antihypertensive response to bethanidine, clonidine, debrisoquin, guanadrel, guanethidine, guanabenz, guanfacine; monitor BP; consider alternate antihypertensive agent

Beta-agonists: When combined with cyclic antidepressants may predispose patients to cardiac arrhythmias

Bupropion: May increase the levels of cyclic antidepressants; based on limited information; monitor response

Carbamazepine: Cyclic antidepressants may increase carbamazepine levels; monitor

Cholestyramine and colestipol: May bind cyclic antidepressants and reduce their absorption; monitor for altered response

Clonidine: Abrupt discontinuation of clonidine may cause hypertensive crisis, cyclic antidepressants may enhance the response

CNS depressants: Sedative effects may be additive with cyclic antidepressants; monitor for increased effect; includes benzodiazepines, barbiturates, antipsychotics, ethanol and other sedative medications

CYP2D6 inhibitors: May increase the levels/effects of maprotiline. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and rofinirole.

Epinephrine (and other direct alpha-agonists): The pressor response to I.V. epinephrine, norepinephrine, and phenylephrine may be enhanced in patients receiving cyclic antidepressants; this combination is best avoided

Fenfluramine: May increase cyclic antidepressant levels/effects

Hypoglycemic agents (including insulin): Hypoglycemic effects may be enhanced, profound hypoglycemia has been reported; monitor for changes in blood glucose levels; reported with chlorpropamide, tolazamide, and insulin

Levodopa: Cyclic antidepressants may decrease the absorption (bioavailability) of levodopa; rare hypertensive episodes have also been attributed to this combination

Linezolid: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** with agents which inhibit MAO (serotonin syndrome); this combination should be avoided

Lithium: Concurrent use with a cyclic antidepressant may increase the risk for neurotoxicity

MAO inhibitors: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** (serotonin syndrome); this combination should be avoided

Methylphenidate: Metabolism of maprotiline may be decreased

Phenothiazines: Serum concentrations of some TCAs may be increased; in addition, TCAs may increase concentration of phenothiazines; monitor for altered clinical response

QT_c-prolonging agents: Concurrent use of cyclic agents with other drugs which may prolong QT_c interval may increase the risk of potentially fatal arrhythmias; includes type Ia and type III antiarrhythmic agents, selected quinolones (sparfloxacin, gatifloxacin, moxifloxacin, grepafloxacin), cisapride, and other agents

Sucralfate: Absorption of cyclic antidepressants may be reduced with coadministration.

Sympathomimetics, indirect-acting: Cyclic antidepressants may result in a decreased sensitivity to indirect-acting sympathomimetics; includes dopamine and ephedrine; also see interaction with epinephrine (and direct-acting sympathomimetics)

Tramadol: Tramadol's risk of seizures may be increased with TCAs

Valproic acid: May increase serum concentrations/adverse effects of some cyclic antidepressants

Warfarin (and other oral anticoagulants): Cyclic antidepressants may increase the anticoagulant effect in patients stabilized on warfarin; monitor INR

Pregnancy Risk Factor B

Nursing Implications Monitor blood pressure and pulse rate prior to and during initial therapy; evaluate mental status; monitor weight, may increase appetite and possibly a craving for sweets

Additional Information Odorless, bitter tasting; seizures rarely seen 5-30 hours postdrug ingestion

Mecamylamine

Pronunciation (mek a MIL a meen)

CAS Number 60-40-2; 826-39-1

U.S. Brand Names Inversine®

Synonyms Mecamylamine Hydrochloride

Use Treatment of moderately severe to severe hypertension and in uncomplicated malignant hypertension

Unlabeled/Investigational Use Tourette's syndrome

Mechanism of Action Mecamylamine is a ganglionic blocker. This agent inhibits acetylcholine at the autonomic ganglia, causing a decrease in blood pressure. Mecamylamine also blocks central nicotinic cholinergic receptors, which inhibits the effects of nicotine and may suppress the desire to smoke.

Adverse Reactions

Cardiovascular: **Postural hypotension**, tachycardia, syncope, sinus tachycardia
 Central nervous system: **Drowsiness**, dizziness, fatigue, hallucinations, confusion, sedation, psychosis
 Endocrine & metabolic: **Decreased sexual ability**
 Gastrointestinal: **Xerostomia**, loose stools, nausea, vomiting, anorexia, constipation,
 Genitourinary: Impotence, urinary retention
 Neuromuscular & skeletal: Tremors, choreiform movements, weakness
 Ocular: **Blurred vision, mydriasis**

Signs and Symptoms of Overdose Constipation, diarrhea, hypotension, impotence, nausea, seizures, urinary retention, vomiting

Toxicodynamics/Kinetics

Absorption: Completely through gastrointestinal tract
 Half-life, elimination: 6-8 hours
 Time to peak plasma concentration: 1-2 hours
 Elimination: 50% excreted renally within 1 day

Dosage Adults: Oral: 2.5 mg twice daily after meals for 2 days; increased by increments of 2.5 mg at intervals of ≥ 2 days until desired blood pressure response is achieved; average daily dose: 25 mg

Dosing adjustment/comments in renal impairment: Use with caution, if at all, although no specific guidelines are available

Monitoring Parameters Monitor for orthostatic hypotension; aid with ambulation

Contraindications Coronary insufficiency, pyloric stenosis, glaucoma, uremia, recent myocardial infarction, unreliable, uncooperative patients

Warnings Use with caution in patients receiving sulfonamides or antibiotics that cause neuromuscular blockade; use with caution in patients with impaired renal function, previous CNS abnormalities, prostatic hyperplasia, bladder obstruction, or urethral stricture; do not abruptly discontinue

Dosage Forms Tablet, as hydrochloride: 2.5 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Signs and symptoms are a direct result of ganglionic blockade; pressor amines may be used to correct hypotension; use caution as patients will be unusually sensitive to these agents. Physostigmine (0.5-1 mg I.V.) may be utilized to reverse adverse effects
 Enhancement of elimination: Multiple dosing of activated charcoal may be useful

Antidote(s)

- Physostigmine [ANTIDOTE]

Drug Interactions Increased effect with sulfonamides and antibiotics that cause neuromuscular blockade; action of mecamylamine may be increased by anesthesia, other antihypertensives, and ethanol

Pregnancy Risk Factor C

Nursing Implications Check frequently for hypotension (orthostatic); aid with ambulation

Mechlorethamine

CAS Number 51-75-2; 55-86-7

U.S. Brand Names Mustargen®

Synonyms Chlorethazine Mustard; Chlorethazine; HN₂; Mechlorethamine Hydrochloride; Mustine; Nitrogen Mustard; NSC-762

Use Combination therapy of Hodgkin's disease and malignant lymphomas; non-Hodgkin's lymphoma; may be used by intracavitary injection for treatment of metastatic tumors; pleural and other malignant effusions; topical treatment of mycosis fungoides

Mechanism of Action Bischloroethylamine which alkylates the N⁷ position of guanine in DNA and RNA thus resulting in depurination of DNA-causing breakage

Adverse Reactions

Central nervous system: Headache, seizures
 Dermatologic: Keratoacanthoma, hyperpigmentation
 Endocrine & metabolic: Ovotoxic, **amenorrhea, delayed menses, oligomenorrhea, impaired spermatogenesis**
 Gastrointestinal: **Nausea, vomiting**, dizziness, anorexia
 Genitourinary: **Azoospermia**
 Hematologic: **Leukopenia** (nadir: 6-8 days), **thrombocytopenia** (nadir: 10-16 days)
 Hepatic: Jaundice
 Local: Extravasation injury
 Neuromuscular & skeletal: Tremors
 Otic: Tinnitus, deafness, **ototoxicity**
 Miscellaneous: **Precipitation of herpes zoster**

Signs and Symptoms of Overdose Deafness, diarrhea, nausea, suppression of all formed elements of the blood, uric acid crystals, vomiting

Pharmacodynamics/Kinetics

Duration: Unchanged drug is undetectable in blood within a few minutes
 Absorption: Intracavitary administration: Incomplete secondary to rapid deactivation by body fluids
 Metabolism: Rapid hydrolysis and demethylation, possibly in plasma
 Half-life elimination: <1 minute
 Excretion: Urine (50% as metabolites, <0.01% as unchanged drug)

Dosage

Refer to individual protocols.

Children and Adults: I.V.: 6 mg/m² on days 1 and 8 of a 28-day cycle (MOPP regimen)

Adults:

I.V.: 0.4 mg/kg or 12-16 mg/m² for one dose or divided into 0.1 mg/kg/day for 4 days, repeated at 4- to 6-week intervals

Intracavitary: 0.2-0.4 mg/kg (10-20 mg) as a single dose; may be repeated if fluid continues to accumulate.

Intrapericardially: 0.2-0.4 mg/kg as a single dose; may be repeated if fluid continues to accumulate.

Topical: 0.01% to 0.02% solution, lotion, or ointment

Hemodialysis: Not removed; supplemental dosing is not required.

Peritoneal dialysis: Not removed; supplemental dosing is not required.

Monitoring Parameters CBC with differential, hemoglobin, and platelet count

Administration

I.V. as a slow push through the side of a freely-flowing saline or dextrose solution. Due to the limited stability of the drug, and the increased risk of phlebitis and venous irritation and blistering with increased contact time, infusions of the drug are not recommended.

Mechlorethamine may cause extravasation. Use within 1 hour of preparation. Avoid extravasation since mechlorethamine is a potent vesicant. **Extravasation management:** Sodium thiosulfate 1/6 molar solution is the specific antidote for nitrogen mustard extravasations and should be used as follows: Mix 4 mL of 10% sodium thiosulfate with 6 mL of sterile water for injection. Inject 5-6 mL of this solution into the existing I.V. line. Remove the needle. Inject 2-3 mL of the solution SubQ clockwise into the infiltrated area using a 25-gauge needle. Change the needle with each new injection. Apply ice immediately for 6-12 hours.

Contraindications Hypersensitivity to mechlorethamine or any component of the formulation; pre-existing profound myelosuppression or infection; pregnancy

Warnings [U.S. Boxed Warnings]: Hazardous agent – use appropriate precautions for handling and disposal. Mechlorethamine is a potent vesicant; if extravasation occurs, severe tissue damage (leading to ulceration and necrosis) and pain may occur. Urate precipitation should be anticipated especially with lymphomas. [U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.

Dosage Forms Injection, powder for reconstitution, as hydrochloride: 10 mg

Overdosage/Treatment

Decontamination: **Dermal:** Extravasation: Sodium thiosulfate 1/6 molar solution: Mix 4 mL of 10% sodium thiosulfate with 6 mL of sterile water injected with fine hypodermic needle into area of extravasation; apply ice packs for 6-12 hours; a 1% lidocaine solution may also be infiltrated.

Oral: Dilute with milk or water

Supportive therapy: Colony stimulating factor may be utilized to treat granulocytopenia

Test Interactions ↑ potassium (S)

Drug Interactions Patients may experience impaired immune response to vaccines; possible infection after administration of live vaccines in patients receiving immunosuppressants

Pregnancy Risk Factor D

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Use within 1 hour of preparation

Additional Information Allopurinol may be given 2-3 days prior to treatment in lymphoma patients to prevent hyperuricemia; unused solutions can be neutralized by mixing with an equal volume of a solution containing 2.5% sodium bicarbonate and 2.5% sodium thiosulfate and letting stand for 45 minutes; equipment can be soaked (needles, gloves, etc) for 45 minutes in a 10% sodium thiosulfate bath before discarding; sodium thiosulfate has no effect on central nervous system effects

Specific References

Meclizine

CAS Number 1104-22-9 (anhydrous); 31884-77-2 (monohydrate); 569-65-3

U.S. Brand Names Antivert®; Bonine® [OTC]; Dramamine® Less Drowsy Formula [OTC]

Synonyms Meclizine Hydrochloride; Meclozine Hydrochloride

Use Prevention and treatment of motion sickness; management of dizziness with diseases affecting the vestibular system

Mechanism of Action Has central anticholinergic action by blocking chemoreceptor trigger zone; decreases excitability of the middle ear labyrinth and blocks conduction in the middle ear vestibular-cerebellar pathways

Adverse Reactions

Cardiovascular: Sinus tachycardia

Central nervous system: **Drowsiness**, fatigue, sedation, dizziness, paranoia, extrapyramidal reaction, ataxia, memory disturbance

Gastrointestinal: Xerostomia, nausea, vomiting

Ocular: Blurred vision

Respiratory: **Thickening of bronchial secretions**

Signs and Symptoms of Overdose Confusion, disorientation, excitation alternating with drowsiness, flushing, hallucinations, memory loss, mydriasis, respiratory depression

Pharmacodynamics/Kinetics

Onset of action: ~1 hour

Duration: 8-24 hours

Metabolism: Hepatic

Half-life elimination: 6 hours

Excretion: Urine (as metabolites); feces (as unchanged drug)

Dosage

Children > 12 years and Adults: Oral:

Motion sickness: 25-50 mg 1 hour before travel, repeat dose every 24 hours as needed

Vertigo: 25-100 mg/day in divided doses

Contraindications Hypersensitivity to meclizine or any component of the formulation

Warnings Use with caution in patients with angle-closure glaucoma, prostatic hyperplasia, pyloric or duodenal obstruction, or bladder neck obstruction; use with caution in hot weather, and during exercise; elderly may be at risk for anticholinergic side effects such as glaucoma, prostatic hyperplasia, constipation, gastrointestinal obstructive disease; if vertigo does not respond in 1-2 weeks, it is advised to discontinue use

Dosage Forms

Tablet, as hydrochloride: 12.5 mg, 25 mg

Antivert®: 12.5 mg, 25 mg, 50 mg

Dramamine® Less Drowsy Formula: 25 mg

Tablet, chewable, as hydrochloride (Bonine®): 25 mg

Reference Range Serum level of 10 ng/mL 12 hours after an oral dose of 75 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: There is no specific treatment for an antihistamine overdose, however, most of its clinical toxicity is due to anticholinergic effects. Anticholinesterase inhibitors may be useful by reducing acetylcholinesterase. Anticholinesterase inhibitors include physostigmine for central and peripheral effects, neostigmine, pyridostigmine and edrophonium. For anticholinergic overdose with severe life-threatening symptoms, physostigmine 1-2 mg (0.5 or 0.02 mg/kg for children) I.V., slowly may be given to reverse these effects.

Drug Interactions Increased toxicity: CNS depressants, neuroleptics, anticholinergics

Pregnancy Risk Factor B

Pregnancy Implications Crosses the placenta

Lactation Excretion in breast milk unknown/not recommended

Additional Information Moderately radiopaque

Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, fluid retention

Gastrointestinal: **Abdominal cramps, heartburn, indigestion, nausea, vomiting, GI bleeding, GI ulceration, constipation, diarrhea, dyspepsia, steatorrhea, xerostomia, stomatitis**

Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia; aplastic anemia (rare), platelet inhibition, hemolytic anemia

Hepatic: Elevated transaminases, hepatitis (fulminant), hepatic necrosis

Neuromuscular & skeletal: Paresthesia

Otic: Ototoxicity, tinnitus

Renal: Renal failure (acute), nephrotic syndrome, chronic renal failure, albuminuria

Respiratory: Wheezing, respiratory depression

Miscellaneous: Hypersensitivity, systemic lupus erythematosus (SLE), fixed drug eruption

Signs and Symptoms of Overdose Cognitive dysfunction, drowsiness, gastritis, GI bleeding, nausea, nephrotic syndrome, ototoxicity, tinnitus, vomiting, wheezing. Severe poisoning can manifest with coma, hypotension, renal and/or hepatic failure, respiratory depression, seizures

Pharmacodynamics/Kinetics

Duration: 2-4 hours

Distribution: Crosses placenta

Protein binding: 99%

Half-life elimination: 2-3.3 hours

Time to peak, serum: 0.5-1.5 hours

Excretion: Primarily urine and feces (as metabolites)

Dosage

Children > 14 years and Adults: Oral:

Mild to moderate pain: 50 mg every 4-6 hours, not to exceed 400 mg/day

Rheumatoid arthritis/osteoarthritis: 200-400 mg/day in 3-4 equal doses

Contraindications Hypersensitivity to meclofenamate, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); active GI bleeding, ulcer disease; pregnancy (3rd trimester)

Warnings

[U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension. Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Use caution in patients with advanced renal disease.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

The elderly are at increased risk for adverse effects (especially peptic ulceration, CNS effects, renal toxicity) from NSAIDs even at low doses. Withhold for at least 4-6 half-lives prior to surgical or dental procedures. Safety and efficacy have not been established in children <14 years of age.

Dosage Forms Capsule, as sodium: 50 mg, 100 mg

Reference Range Steady-state meclofenamate plasma levels range from 10-20 mcg/mL at a dose of 100 mg 3 times/day; one 100 mg dose results in a peak plasma level of 8-9 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage

Meclofenamate

Related Information

● Nonsteroidal Anti-inflammatory Drugs

CAS Number 6385-02-0 (Sodium); 644-62-2 (Base)

Synonyms Meclofenamate Sodium

Use Treatment of inflammatory disorders

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors

Adverse Reactions

Cardiovascular: Circulatory collapse, vasculitis

Central nervous system: **Dizziness**, headache, aseptic meningitis, psychosis, cognitive dysfunction, coma, seizures

Dermatologic: **Rash**, pruritus, exfoliative dermatitis, erythema multiforme, alopecia, angioedema, urticaria, purpura, photosensitivity, psoriasis, exanthem

Enhancement of elimination: Dialysis is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be effective

Test Interactions ↑ chloride (S), sodium (S)

Drug Interactions ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure. Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet drugs (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatide, tirofiban) can cause an increased risk of bleeding.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids may increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

Gentamicin and amikacin serum concentrations are increased by indomethacin in premature infants. Results may apply to other aminoglycosides and NSAIDs.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use.

Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose. Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again.

Loop diuretics efficacy (diuretic and antihypertensive effect) is reduced. Indomethacin reduces this efficacy, however, it may be anticipated with any NSAID.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Thiazides antihypertensive effects are decreased; avoid concurrent use. Verapamil plasma concentration is decreased by diclofenac; avoid concurrent use.

Warfarin's INRs may be increased by piroxicam. Other NSAIDs may have the same effect depending on dose and duration. Monitor INR closely. Use the lowest dose of NSAIDs possible and for the briefest duration.

Pregnancy Risk Factor B/D (3rd trimester)

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk/not recommended

Mefenamic Acid

Related Information

- Nonsteroidal Anti-inflammatory Drugs

CAS Number 61-68-7

U.S. Brand Names Ponstel®

Use Short-term relief of mild to moderate pain including primary dysmenorrhea

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors

Adverse Reactions

Cardiovascular: Circulatory collapse, vasculitis

Central nervous system: Headache, aseptic meningitis, psychosis, cognitive dysfunction, insomnia, coma, seizures, **dizziness**, extrapyramidal reactions

Dermatologic: **Rash**, pruritus, exfoliative dermatitis, toxic epidermal necrolysis, urticaria, purpura, Stevens-Johnson syndrome, exanthem

Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, fluid retention

Gastrointestinal: **Abdominal cramps, nausea**, vomiting, GI bleeding, GI ulceration, constipation, diarrhea, dyspepsia, steatorrhea, feces discoloration (black), **heartburn, indigestion**

Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia, aplastic anemia (rare), platelet inhibition, hemolytic anemia

Hepatic: Elevated transaminases, hepatitis (fulminant)

Otic: Ototoxicity, tinnitus

Renal: Renal failure (acute), nephrotic syndrome, chronic renal failure, albuminuria, glomerulonephritis

Respiratory: Wheezing, respiratory depression

Miscellaneous: Hypersensitivity

Signs and Symptoms of Overdose Bullous skin disease/pemphigoid, cognitive dysfunction, colitis, drowsiness, gastritis, GI bleeding, insomnia, nausea, nephrotic syndrome, ototoxicity, thrombocytopenia, tinnitus, vomiting, wheezing. Severe poisoning can manifest with coma, hypotension, renal and/or hepatic failure, respiratory depression, seizures (38%, 2-12 hours postingestion)

Admission Criteria/Prognosis Admit any patient with neurologic symptoms within 12 hours postingestion; pediatric ingestion > 1 g or adult ingestion > 3 g

Pharmacodynamics/Kinetics

Onset of action: Peak effect: 2-4 hours

Duration: ≤ 6 hours

Protein binding: High

Metabolism: Conjugated hepatically

Half-life elimination: 3.5 hours

Excretion: Urine (50%) and feces as unchanged drug and metabolites

Dosage

Oral:

Children > 14 years and Adults: 500 mg to start then 250 mg every 4 hours as needed; maximum therapy: 1 week

Seizurgenic dose: Children: 2 g; Adults: 6 g

Dosing adjustment/comments in renal impairment: Not recommended for use

Administration

May be administered with food, milk, or antacids.

Contraindications Hypersensitivity to mefenamic acid, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); active ulceration or chronic inflammation of the GI tract; renal disease; pregnancy (3rd trimester)

Warnings

[U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension. Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Mefenamic acid is not recommended for patients with advanced renal disease.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

The elderly are at increased risk for adverse effects (especially peptic ulceration, CNS effects, renal toxicity) from NSAIDs even at low doses. Withhold for at least 4-6 half-lives prior to surgical or dental procedures. Safety and efficacy have not been established in children < 14 years of age.

Dosage Forms Capsule: 250 mg

Reference Range Therapeutic mefenamic acid level: Up to 10 mcg/mL; levels > 100 mcg/mL associated with severe neurological abnormalities

Overdosage/Treatment

Decontamination: Activated charcoal; **do not** induce emesis

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage

Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be effective

Test Interactions ↑ chloride (S), sodium (S); positive Coombs' [direct]

Drug Interactions

Substrate of CYP2C9 (minor); **Inhibits** CYP2C9 (strong)

ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

MEFLOQUINE

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet drugs (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatid, tirofiban) can cause an increased risk of bleeding.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids may increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

CYP2C9 Substrates: Mefenamic acid may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

Gentamicin and amikacin serum concentrations are increased by indomethacin in premature infants. Results may apply to other aminoglycosides and NSAIDs.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use.

Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose. Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again.

Loop diuretics efficacy (diuretic and antihypertensive effect) is reduced. Indomethacin reduces this efficacy, however, it may be anticipated with any NSAID.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Thiazides antihypertensive effects are decreased; avoid concurrent use. Verapamil plasma concentration is decreased by diclofenac; avoid concurrent use.

Warfarin's INRs may be increased by piroxicam. Other NSAIDs may have the same effect depending on dose and duration. Monitor INR closely. Use the lowest dose of NSAIDs possible and for the briefest duration.

Pregnancy Risk Factor C/D (3rd trimester)

Lactation Enters breast milk (trace amounts)/not recommended (AAP rates "compatible")

Specific References

Laredo P, Kupferschmidt H, Meier PJ, et al, "Acute Mefenamic Acid Poisoning in Switzerland," *Clin Toxicol (Phila)*, 2005, 43:744.

Half-life elimination: 21-22 days

Time to peak, plasma: 6-24 hours (median: ~17 hours)

Excretion: Primarily bile and feces; urine (9% as unchanged drug, 4% as primary metabolite)

Dosage

Oral (dose expressed as mg of mefloquine hydrochloride):

Children \geq 6 months and $>$ 5 kg:

Malaria treatment: 20-25 mg/kg in 2 divided doses, taken 6-8 hours apart (maximum: 1250 mg) Take with food and an ample amount of water. If clinical improvement is not seen within 48-72 hours, an alternative therapy should be used for retreatment.

Malaria prophylaxis: 5 mg/kg/once weekly (maximum dose: 250 mg) starting 1 week before, arrival in endemic area, continuing weekly during travel and for 4 weeks after leaving endemic area. Take with food and an ample amount of water.

Adults:

Malaria treatment (mild to moderate infection): 5 tablets (1250 mg) as a single dose. Take with food and at least 8 oz of water. If clinical improvement is not seen within 48-72 hours, an alternative therapy should be used for retreatment.

Malaria prophylaxis: 1 tablet (250 mg) weekly starting 1 week before, arrival in endemic area, continuing weekly during travel and for 4 weeks after leaving endemic area. Take with food and at least 8 oz of water.

Dosage adjustment in renal impairment: No dosage adjustment needed in patients with renal impairment or on dialysis.

Dosage adjustment in hepatic impairment: Half-life may be prolonged and plasma levels may be higher.

Monitoring Parameters LFTS; ocular examination

Administration Administer with food and with at least 8 oz of water.

When used for malaria prophylaxis, dose should be taken once weekly on the same day each week. If vomiting occurs within 30-60 minutes after dose, an additional half-dose should be given. Tablets may be crushed and suspended in a small amount of water, milk, or another beverage for persons unable to swallow tablets.

Contraindications Hypersensitivity mefloquine, related compounds (such as quinine and quinidine), or any component of the formulation; history of convulsions; cardiac conduction abnormalities; severe psychiatric disorder (including active or recent history of depression, generalized anxiety disorder, psychosis, or schizophrenia); use with halofantrine

Warnings Use with caution in patients with a previous history of depression (see Contraindications regarding severe psychiatric illness, including active/recent depression). May cause a range of psychiatric symptoms (anxiety, paranoia, depression, hallucinations and psychosis). Occasionally, symptoms have been reported to persist long after mefloquine has been discontinued. Rare cases of suicidal ideation and suicide have been reported (no causal relationship established). The appearance of psychiatric symptoms such as acute anxiety, depression, restlessness or confusion may be considered a prodrome to more serious events. When used as prophylaxis, substitute an alternative medication. Discontinue if unexplained neuropsychiatric disturbances occur. Use caution in patients with significant cardiac disease. If mefloquine is to be used for a prolonged period, periodic evaluations including liver function tests and ophthalmic examinations should be performed. (Retinal abnormalities have not been observed with mefloquine in humans; however, it has with long-term administration to rats.) In cases of life-threatening, serious, or overwhelming malaria infections due to *Plasmodium falciparum*, patients should be treated with intravenous antimalarial drug. Mefloquine may be given orally to complete the course. Dizziness, loss of balance, and other CNS disorders have been reported; due to long half-life, effects may persist after mefloquine is discontinued. Use caution in activities requiring alertness and fine motor coordination (driving, piloting planes, operating machinery, deep sea diving, etc).

Dosage Forms Tablet, as hydrochloride: 250 mg [equivalent to 228 mg base]

Reference Range Peak serum levels after a 250 mg oral dose in patients with malaria range from 0.7-1.4 mcg/mL (may be higher in healthy person, but lower in pregnancy)

Overdosage/Treatment Supportive therapy: Psychosis can be treated with diazepam and haloperidol

Drug Interactions **Substrate** of CYP3A4 (major); **Inhibits** CYP2D6 (weak), 3A4 (weak)

Anticonvulsants: Decreased effect of valproic acid, carbamazepine, phenobarbital, or phenytoin.

Antiarrhythmics: Chloroquine and quinidine may produce electrocardiographic changes and increase risk of convulsions. When used as initial treatment of severe malaria, delay mefloquine for 12 hours after the last dose. Use caution with other medications known to alter conduction.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of mefloquine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of mefloquine. Example inhibitors include azole antifungals, clarithromycin, diclofenac,

Mefloquine

CAS Number 51773-92-3; 53230-10-7

U.S. Brand Names Lariam®

Synonyms Mefloquine Hydrochloride

Use Treatment of acute malarial infections and prevention of malaria

Mechanism of Action Mefloquine is a quinoline-methanol compound structurally similar to quinine; mefloquine's effectiveness in the treatment and prophylaxis of malaria is due to the destruction of the asexual blood forms of the malarial pathogens that affect humans, *Plasmodium falciparum*, *P. vivax*, *P. malariae*, *P. ovale*

Adverse Reactions

Cardiovascular: Bradycardia, extrasystoles, syncope, AV block, chest pain, conduction abnormalities (transient), edema, hypotension, palpitations, tachycardia

Central nervous system: Headache, fever, chills, fatigue, neuropsychiatric events, dizziness, emotional lability, seizures, abnormal dreams, ataxia, aggressive behavior, agitation, anxiety, confusion, convulsions, depression, encephalopathy, hallucinations, insomnia, malaise, mood changes, panic attacks, paranoia, psychosis, somnolence, suicidal ideation and behavior (causal relationship not established), vertigo

Dermatologic: Rash, alopecia, pruritus, erythema multiforme, exanthema, Stevens-Johnson syndrome, urticaria

Gastrointestinal: Vomiting, diarrhea, stomach pain, nausea, appetite decreased, dyspepsia

Hematologic: Leukocytosis, thrombocytopenia

Neuromuscular & skeletal: Myalgia, arthralgia, muscle cramps/weakness, paresthesia, tremor

Ocular: Visual disturbances

Otic: Tinnitus, hearing impairment

Respiratory: Dyspnea

Miscellaneous: Anaphylaxis, diaphoresis (increased)

Pharmacodynamics/Kinetics

Absorption: Well absorbed

Distribution: V_d : 19 L/kg; blood, urine, CSF, tissues; enters breast milk

Protein binding: 98%

Metabolism: Extensively hepatic; main metabolite is inactive

Bioavailability: Increased by food

doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Halofantrine: Fatal prolongation of the QT_c interval reported; concomitant use is contraindicated.

Quinine: May produce electrocardiographic changes and increase risk of convulsions. When used as initial treatment of severe malaria, delay mefloquine for 12 hours after the last dose.

Vaccines: Vaccinations with attenuated live bacteria should be completed at least 3 days prior to first dose of mefloquine. Vaccination with oral live attenuated Ty21a vaccine should be delayed for at least 24 hours after the administration of mefloquine.

Pregnancy Risk Factor C

Pregnancy Implications Mefloquine crosses the placenta and is teratogenic in animals. There are no adequate and well-controlled studies in pregnant women, however, clinical experience has not shown teratogenic or embryotoxic effects; use with caution during pregnancy if travel to endemic areas cannot be postponed. Nonpregnant women of child-bearing potential are advised to use contraception and avoid pregnancy during malaria prophylaxis and for 3 months thereafter. In case of an unplanned pregnancy, treatment with mefloquine is not considered a reason for pregnancy termination.

Lactation Enters breast milk/not recommended

Megestrol

CAS Number 595-33-5

U.S. Brand Names Megace®

Synonyms 5071-1DL(6); Megestrol Acetate; NSC-10363

Use

Palliative treatment of breast and endometrial carcinoma

Orphan drug: Treatment of anorexia, cachexia, or significant weight loss ($\geq 10\%$ baseline body weight) and confirmed diagnosis of AIDS

Mechanism of Action A synthetic progestin with antiestrogenic properties which disrupt the estrogen receptor cycle. Megestrol interferes with the normal estrogen cycle and results in a lower LH titer. May also have a direct effect on the endometrium. Megestrol is an antineoplastic progestin thought to act through an antileutenizing effect mediated via the pituitary.

Adverse Reactions

Cardiovascular: Cardiomyopathy, edema, hypertension, palpitations

Central nervous system: Confusion, convulsions, depression, fever, headache, insomnia, pain

Dermatologic: Allergic rash with or without pruritus, alopecia

Endocrine & metabolic: Adrenal insufficiency, amenorrhea, breakthrough bleeding, changes in menstrual flow, changes in cervical erosion and secretions, spotting, Cushing's syndrome, diabetes, fluid retention, HPA axis suppression, hyperglycemia, increased breast tenderness

Gastrointestinal: Constipation, diarrhea, flatulence, nausea, vomiting, weight gain (not attributed to edema or fluid retention)

Genitourinary: Decreased libido, impotence

Hepatic: Cholestatic jaundice, hepatotoxicity, hepatomegaly

Local: Thrombophlebitis

Neuromuscular & skeletal: Carpal tunnel syndrome, paresthesia, weakness

Respiratory: Cough, dyspnea, hyperpnea

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Nausea, vomiting

Admission Criteria/Prognosis Admit any symptomatic ingestion or any ingestion > 2 g orally

Pharmacodynamics/Kinetics

Absorption: Well absorbed orally

Metabolism: Completely hepatic to free steroids and glucuronide conjugates

Time to peak, serum: 1-3 hours

Half-life elimination: 15-100 hours

Excretion: Urine (57% to 78% as steroid metabolites and inactive compound); feces (8% to 30%)

Dosage

Adults: Oral (refer to individual protocols):

Female:

Breast carcinoma: 40 mg 4 times/day

Endometrial carcinoma: 40-320 mg/day in divided doses; use for 2 months to determine efficacy; maximum doses used have been up to 800 mg/day

Uterine bleeding (unlabeled use): 40 mg 2-4 times/day

Male/Female: HIV-related cachexia: Initial dose: 800 mg/day; daily doses of 400 and 800 mg/day were found to be clinically effective

Dosing adjustment in renal impairment: No data available; however, the urinary excretion of megestrol acetate administered in doses of 4-90 mg ranged from 56% to 78% within 10 days

Hemodialysis: Megestrol acetate has not been tested for dialyzability; however, due to its low solubility, it is postulated that dialysis would not be an effective means of treating an overdose

Monitoring Parameters Observe for signs of thromboembolic phenomena

Administration Megestrol acetate (Megace®) oral suspension is compatible with water, orange juice, apple juice, or Sustacal H.C. for immediate consumption.

Contraindications Hypersensitivity to megestrol or any component of the formulation; pregnancy

Warnings Use with caution in patients with a history of thrombophlebitis. Elderly females may have vaginal bleeding or discharge. May suppress hypothalamic-pituitary-adrenal (HPA) axis during chronic administration. Consider the possibility of adrenal suppression in any patient receiving or being withdrawn from chronic therapy when signs/symptoms suggestive of hypoadrenalism are noted (during stress or in unstressed state). Laboratory evaluation and replacement/stress doses of rapid-acting glucocorticoid should be considered.

Dosage Forms Suspension, oral, as acetate: 40 mg/mL (240 mL, 480 mL)

Megace®: 40 mg/mL (240 mL) [contains alcohol 0.06% and sodium benzoate; lemon-lime flavor]

Megace® ES: 125 mg/mL (150 mL) [contains alcohol 0.06% and sodium benzoate; lemon-lime flavor]

Tablet, as acetate: 20 mg, 40 mg

Reference Range Following a single 40 mg oral dose, peak plasma levels range from 10-56 ng/mL

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Test Interactions Altered thyroid and liver function tests; increased levels of prostate-specific antigen

Drug Interactions No data reported

Pregnancy Risk Factor X

Lactation Enters breast milk/contraindicated

Additional Information Herb/Nutraceutical: Avoid black cohosh, dong quai in estrogen-dependent tumors.

Melatonin

CAS Number 73-31-4

Synonyms N-Acetyl-5-methoxytryptamine

Use Sleep disorders (insomnia), circadian rhythm disturbances (ie, jet lag); only FDA approval (as an orphan drug) is for treatment of circadian rhythm sleep disorders in blind people with no light perception

Mechanism of Action A hormone produced and secreted in the pineal gland causes an increase in hypothalamus aminobutyric acid and serotonin. Increased secretion occurs during dark hours; decreases neopterin release; counteracts apoptosis; increases thymus activity

Adverse Reactions

Central nervous system: Drowsiness, dysphoria (especially in depressed patients), giddiness

Gastrointestinal: Nausea

Miscellaneous: Fixed drug eruption

Signs and Symptoms of Overdose Ataxia, drowsiness

Pharmacodynamics/Kinetics

Absorption: Rapid

Peak plasma level: 1 hour

Dosage

Oral:

Jet lag: 5 mg/day (at 1800 hours) for 1 week starting 3 days before the flight

Hypnotic effects: Oral: 0.1-0.3 mg (daytime); 1-10 mg (nighttime)

Insomnia: 5-75 mg at night have been used

Dosage Forms Tablet: 3 mg

Tablet, sublingual: 2.5 mg

Reference Range Mean baseline melatonin serum levels 80 pg/mL (range: 0-200) between 0200-0400 hours. Elevated endogenous levels seen after 0900 hours; after a 2.5 mg oral dose, plasma melatonin level may be as high as 8.50 pg/mL.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with sorbitol may be effective

Supportive: Need to monitor respiratory status; naloxone may be useful to reduce respiratory depression

Meloxicam

Related Information

- Nonsteroidal Anti-inflammatory Drugs

CAS Number 71125-38-7

U.S. Brand Names MOBIC®

Use Relief of signs and symptoms of osteoarthritis

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors

Adverse Reactions

Cardiovascular: Angina, arrhythmia, cardiac failure, edema, hypertension, hypotension, myocardial infarction, palpitations, shock, tachycardia, vasculitis

Central nervous system: Abnormal dreams, anxiety, confusion, depression, headache and dizziness (occurred in 2% to 8% of patients, but occurred less frequently than placebo in controlled trials), malaise, nervousness, syncope, seizures, somnolence, vertigo

Dermatologic: Alopecia, angioedema, bullous eruption, erythema multiforme, photosensitivity reaction, pruritus, purpura, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Endocrine & metabolic: Hot flashes, dehydration

Gastrointestinal: Abdominal pain, colitis, diarrhea, duodenal ulcer, duodenal perforation, dyspepsia, flatulence, gastric ulcer, gastritis, gastric perforation, gastroesophageal reflux, gastrointestinal hemorrhage, hematemesis, intestinal perforation, melena, nausea, pancreatitis, taste perversion, weight changes, xerostomia, ulcerative stomatitis

Hematologic: Agranulocytosis, leukopenia, thrombocytopenia

Hepatic: Hepatitis, hepatic failure, hyperbilirubinemia, increased ALT, increased AST, increased GGT, jaundice

Neuromuscular & skeletal: Paresthesia, tremor

Ocular: Abnormal vision, conjunctivitis

Otic: Tinnitus

Renal: Albuminuria, increased BUN, increased creatinine, hematuria, interstitial nephritis, renal failure

Respiratory: Asthma, bronchospasm, cough, dyspnea, pharyngitis, upper respiratory infection

Miscellaneous: Allergic reaction, anaphylactic reaction, flu-like symptoms, falls

Signs and Symptoms of Overdose Drowsiness, epigastric pain, lethargy, nausea, vomiting

Pharmacodynamics/Kinetics

Distribution: 10 L

Protein binding: 99.4%

Metabolism: Hepatic via CYP2C9 and CYP3A4 (minor); forms 4 metabolites (inactive)

Bioavailability: 89%

Half-life elimination: Adults: 15-20 hours

Time to peak: Initial: 5-10 hours; Secondary: 12-14 hours

Excretion: Urine and feces (as inactive metabolites)

Dosage

Adult: Oral: Initial: 7.5 mg once daily; some patients may receive additional benefit from an increased dose of 15 mg once daily; maximum dose: 15 mg/day

Elderly: Increased concentrations may occur in elderly patients (particularly in females); however, no specific dosage adjustment is recommended

Dosage adjustment in renal impairment:

Mild to moderate impairment: No specific dosage recommendations

Significant impairment ($Cl_{cr} \leq 15$ mL/minute): Avoid use

Dosage adjustment in hepatic impairment:

Mild (Child-Pugh class A) to moderate (Child-Pugh class B) hepatic dysfunction: No dosage adjustment is necessary

Severe hepatic impairment: Patients with severe hepatic impairment have not been adequately studied

Stability Store at 25°C (77°F)

Monitoring Parameters CBC, periodic liver function, renal function (serum BUN, and creatinine)

Contraindications Hypersensitivity to meloxicam, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy (3rd trimester)

Warnings

[U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension. Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Meloxicam is not recommended for patients with advanced renal disease

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

The elderly are at increased risk for adverse effects (especially peptic ulceration, CNS effects, renal toxicity) from NSAIDs even at low doses. Withhold for at least 4-6 half-lives prior to surgical or dental procedures. Safety and efficacy have not been established in pediatric patients <2 years of age.

Dosage Forms

Suspension:
Mobic®: 7.5 mg/5 mL (100 mL) [contains sodium benzoate; raspberry flavor]

Tablet: 7.5 mg, 15 mg

Mobic®: 7.5 mg, 15 mg

Overdosage/Treatment

Decontamination: Activated charcoal or cholestyramine may be used for decontamination of the GI tract.

Enhancement of elimination: Since meloxicam undergoes enterohepatic cycling, multiple doses of charcoal may be needed to reduce the potential for delayed toxicities. Cholestyramine has been shown to increase meloxicam clearance.

Drug Interactions

Substrate (minor) of CYP2C9, 3A4; **Inhibits** CYP2C9 (weak)

ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet drugs (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatide, tirofiban) can cause an increased risk of bleeding. Aspirin increases serum concentrations (AUC) of meloxicam (in addition to potential for additive adverse effects); concurrent use is not recommended.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids may increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use.

Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose. When NSAID is stopped, lithium will need adjustment again.

Loop diuretic's efficacy (diuretic and antihypertensive effect) may be reduced by NSAIDs.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Thiazide diuretics: Antihypertensive effects of thiazide diuretics are decreased; avoid concurrent use.

Warfarin INRs may be increased by meloxicam. Monitor INR closely, particularly during initiation or change in dose. May increase risk of bleeding. Use lowest possible dose for shortest duration of possible.

Pregnancy Risk Factor

C/D (3rd trimester)
Pregnancy Implications May cause premature closure of the ductus arteriosus in the third trimester of pregnancy. It is not known whether meloxicam is excreted in human milk. Due to a potential for serious adverse reactions, the manufacturer recommends that a decision be

made whether to discontinue nursing or discontinue the drug, taking into account the importance of the drug to the mother.

Lactation Excretion in breast milk unknown/not recommended

Melphalan

CAS Number 148-82-3

U.S. Brand Names Alkeran®

Synonyms L-PAM; L-Sarcosylsin; NSC-8806; Phenylalanine Mustard
Use

Palliative treatment of multiple myeloma and nonresectable epithelial ovarian carcinoma; neuroblastoma, rhabdomyosarcoma, breast cancer, sarcoma; may be helpful in patients with primary amyloidosis

I.V. formulation: Use in patients in whom oral therapy is not appropriate

Unlabeled/Investigational Use Treatment of neuroblastoma, rhabdomyosarcoma, breast cancer; part of an induction regimen for marrow and stem cell transplantation

Mechanism of Action Alkylating agent which is a derivative of mechlorethamine that inhibits DNA and RNA synthesis via formation of carbonium ions; cross-links strands of DNA

Adverse Reactions

Cardiovascular: Vasculitis

Central nervous system: Fever

Dermatologic: **Alopecia, rash, pruritus**, vesiculation of skin, radiation recall dermatitis, scleroderma

Endocrine & metabolic: **Amenorrhea**, hyponatremia, ovarian failure

Gastrointestinal: Nausea, vomiting, diarrhea, stomatitis, oral ulceration, feces discoloration (black)

Genitourinary: Bladder irritation, hemorrhagic cystitis

Hematologic: **Thrombocytopenia, anemia, leukopenia**, neutropenia, **agranulocytosis**, granulocytopenia, **hemolytic anemia**

Hepatic: Increased transaminases (hepatitis, jaundice have been reported)

Local: Burning and discomfort at injection site

Respiratory: **Pulmonary fibrosis**, cough, dyspnea

Miscellaneous: Hypersensitivity

Pharmacodynamics/Kinetics

Absorption: Oral: Variable and incomplete

Distribution: V_d : 0.5-0.6 L/kg throughout total body water

Protein binding: 60% to 90%; primarily to albumin, 20% to α_1 -acid glycoprotein

Metabolism: Hepatic; chemical hydrolysis to monohydroxymelphalan and dihydroxymelphalan

Bioavailability: Unpredictable; 61% \pm 26%, decreasing with repeated doses

Half-life elimination: Terminal: I.V.: 1.5 hours; oral: 1-1.25 hours

Time to peak, serum: ~1-2 hours

Excretion: Oral: Feces (20% to 50%); urine (10% to 30% as unchanged drug)

Dosage Refer to individual protocols. Dose should always be adjusted to patient response and weekly blood counts.

Children:

Oral: 4-20 mg/m²/day for 1-21 days

Pediatric rhabdomyosarcoma: I.V.: 10-35 mg/m² bolus every 21-28 days

Bone marrow transplant for neuroblastoma: 70-140 mg/m² on days 7 and 6 before BMT or 140-220 mg/m² as a single dose before BMT

Adults:

Multiple myeloma:

Oral: 6 mg/day for 2-3 weeks or 10 mg/day for 7-10 days or 0.15 mg/kg/day for 7 days; labs should be carefully monitored during therapy and the drug may need to be discontinued after 2-3 weeks of treatment. Maintenance doses of 1-3 mg/day may be instituted after WBC recovery.

I.V.: 16 mg/m² over 15-20 minutes I.V. infusion and administered at 2-week intervals for 4 doses, then at 4-week intervals

Bone marrow transplant: I.V.: 50-60 mg/m² (up to 140 mg/m²)

Ovarian carcinoma: Oral: 0.2 mg/kg/day for 5 days, repeat every 4-5 weeks

Dosing adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer at 75% of normal dose

Cl_{cr} < 10 mL/minute: Administer at 50% of normal dose

Stability Dilute I.V. formulation with diluent (to 5 mg/mL), then immediately further dilute to \leq 0.45 mg/mL with 0.9% sodium chloride injection in a glass bottle and administer within 60 minutes; store at room temperature; protect from light; do not refrigerate reconstituted product; use within 1 hour of reconstitution

Monitoring Parameters CBC with differential and platelet count, serum electrolytes, serum uric acid

Administration Reconstitute injection with special diluent 50 mg vial with special diluent to yield a 5 mg/mL solution; filter through a 0.45 μ M Millex-HV filter; dilute the reconstituted solution with normal saline to a final concentration not to exceed 2 mg/mL; administer by I.V. infusion at a rate

not to exceed 10 mg/minute, but total infusion should be given within 1 hour

Contraindications Hypersensitivity to melphalan or any component of the formulation; severe bone marrow suppression; patients whose disease was resistant to prior melphalan therapy; pregnancy

Warnings Hazardous agent – use appropriate precautions for handling and disposal. **[U.S. Boxed Warning]: Is potentially mutagenic, leukemogenic, and carcinogenic.** Suppresses ovarian function and produces amenorrhea; may also cause testicular suppression. **[U.S. Boxed Warning]: Bone marrow suppression is common.** Use with caution in patients with prior bone marrow suppression, impaired renal function (consider dose reduction), or who have received prior chemotherapy or irradiation. Toxicity to immunosuppressives is increased in elderly; start with lowest recommended adult doses. Signs of infection, such as fever and WBC rise, may not occur. Lethargy and confusion may be more prominent signs of infection. **[U.S. Boxed Warning]: Hypersensitivity has been reported with I.V. administration** and oral melphalan; may occur after multiple treatment cycles. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.** Safety and efficacy in children have not been established.

Dosage Forms Injection, powder for reconstitution: 50 mg [diluent contains ethanol and propylene glycol]

Tablet: 2 mg

Reference Range

At 0.6 mg/kg dose of melphalan, a peak plasma level of 280 ng/mL was obtained

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: High-dose corticosteroids can be used for pulmonary fibrosis; ice pops if used during melphalan therapy can prevent oral stomatitis. Oral glutamine suspension as a swish and swallow, starting on day 7 every 4 hours around-the-clock for a total dose of 24 g daily, is effective in preventing oral mucositis. Filgrastim can be used to treat neutropenia.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Test Interactions False-positive Coombs' test [direct]

Drug Interactions Cisplatin: May decrease I.V. melphalan clearance by altering renal function.

Cyclosporine: Risk of nephrotoxicity is increased by melphalan.

Digitalis glycosides: Melphalan may decrease plasma levels of digoxin.

Nalidixic acid: Concomitant use of I.V. melphalan with nalidixic acid may increase risk of necrotic enterocolitis (reported with pediatric patients).

Vaccine (live organism): Melphalan may increase the risk of vaccinal infection.

Pregnancy Risk Factor D

Pregnancy Implications Animal studies have demonstrated embryotoxicity and teratogenicity. Therapy may suppress ovarian function leading to amenorrhea. There are no adequate and well-controlled studies in pregnant women. Women of childbearing potential should be advised to avoid pregnancy while on melphalan therapy.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Protect from light; avoid skin contact with I.V. formulation

Additional Information Myelosuppressive effects: **WBC:** Moderate. **Platelets:** Moderate. Onset (days): 7. Nadir (days): 10-18. Recovery (days): 42-50

Meperidine

CAS Number 50-13-5; 57-42-1

U.S. Brand Names Demerol®; Meperitab®

Synonyms Isonipicaine Hydrochloride; Meperidine Hydrochloride; Pethidine Hydrochloride

Impairment Potential Yes

Use Management of moderate to severe pain; adjunct to anesthesia and preoperative sedation

Unlabeled/Investigational Use Reduce postoperative shivering; reduce rigors from amphotericin

Mechanism of Action Binds to opiate receptors in the CNS, causing inhibition of ascending pain pathways, altering the perception of and response to pain; produces generalized CNS depression; a congener of atropine

Adverse Reactions

Cardiovascular: **Hypotension**, palpitations, bradycardia, peripheral vasodilation, tachycardia (with I.V. injection), hypertension, sinus bradycardia, tachycardia (sinus);

Central nervous system: **Dizziness, fatigue, drowsiness**, sedation, seizures, psychosis, agitation, increased intracranial pressure, parkinsonism especially associated with synthetic analogues (MPPP, MPTP, PEPAP), electroencephalogram abnormalities, dysphoria, fever, CNS depression, hyperthermia

Dermatologic: Pruritus, angioedema, toxic epidermal necrolysis, urticaria

Endocrine & metabolic: Antidiuretic hormone release
 Gastrointestinal: **Nausea, vomiting, constipation** (less likely than with morphine), licorice-like taste, biliary tract spasm, decreased esophageal sphincter tone, xerostomia
 Genitourinary: Urinary tract spasm, urinary incontinence
 Hematologic: Porphyria
 Neuromuscular & skeletal: **Weakness**, myoclonus, tremors, hyperreflexia
 Ocular: Miosis, mydriasis
 Respiratory: Apnea, respiratory depression
 Miscellaneous: **Histamine release**, physical and psychological dependence

Signs and Symptoms of Overdose Ejaculatory disturbances, myoglobinuria, rhabdomyolysis, seizures, syndrome of inappropriate antidiuretic hormone (SIADH)

Pharmacodynamics/Kinetics

Onset of action: Analgesic: Oral, SubQ: 10-15 minutes; I.V.: ~5 minutes
 Peak effect: SubQ.: ~1 hour; Oral: 2 hours
 Duration: Oral, SubQ.: 2-4 hours
 Absorption: I.M.: Erratic and highly variable
 Distribution: Crosses placenta; enters breast milk
 Protein binding: 65% to 75%
 Metabolism: Hepatic; hydrolyzed to meperidine acid (inactive) or undergoes N-demethylation to normeperidine (active; has 1/2 the analgesic effect and 2-3 times the CNS effects of meperidine)
 Bioavailability: ~50% to 60%; increased with liver disease
 Half-life elimination:
 Parent drug: Terminal phase: Adults: 2.5-4 hours, Liver disease: 7-11 hours
 Normeperidine (active metabolite): 15-30 hours; can accumulate with high doses or with decreased renal function
 Excretion: Urine (as metabolites)

Dosage Note: Doses should be titrated to necessary analgesic effect. When changing route of administration, note that oral doses are about half as effective as parenteral dose. Oral route not recommended for chronic pain. These are guidelines and do not represent the maximum doses that may be required in all patients.

Children: Pain: Oral, I.M., I.V., SubQ: 1-1.5 mg/kg/dose every 3-4 hours as needed; 1-2 mg/kg as a single dose preoperative medication may be used; maximum 100 mg/dose

Adults: Pain:

Oral: Initial: Opiate-naïve: 50 mg every 3-4 hours as needed; usual dosage range: 50-150 mg every 2-4 hours as needed
 I.M., SubQ: Initial: Opiate-naïve: 50-75 mg every 3-4 hours as needed; patients with prior opiate exposure may require higher initial doses; usual dosage range: 50-150 mg every 2-4 hours as needed
 Preoperatively: 50-100 mg given 30-90 minutes before the beginning of anesthesia
 Slow I.V.: Initial: 5-10 mg every 5 minutes as needed
 Patient-controlled analgesia (PCA): Usual concentration: 10 mg/mL
 Initial dose: 10 mg
 Demand dose: 1-5 mg (manufacturer recommendations); range 5-25 mg (American Pain Society, 1999).
 Lockout interval: 5-10 minutes

Elderly:

Oral: 50 mg every 4 hours
 I.M.: 25 mg every 4 hours

Dosing adjustment in renal impairment: Avoid repeated administration of meperidine in renal dysfunction:

Cl_{cr} 10-50 mL/minute: Administer at 75% of normal dose
 Cl_{cr} < 10 mL/minute: Administer at 50% of normal dose

Dosing adjustment/comments in hepatic disease: Increased narcotic effect in cirrhosis; reduction in dose more important for oral than I.V. route

Stability Protect oral dosage forms from light; **incompatible** with aminophylline, heparin, phenobarbital, phenytoin, and sodium bicarbonate

Monitoring Parameters Pain relief, respiratory and mental status, blood pressure; observe patient for excessive sedation, CNS depression, seizures, respiratory depression

Administration Meperidine may be administered I.M. (preferably), SubQ, or I.V.; I.V. push should be administered slowly, use of a 10 mg/mL concentration has been recommended. For continuous I.V. infusions, a more dilute solution (eg, 1 mg/mL) should be used.

Contraindications Hypersensitivity to meperidine or any component of the formulation; use with or within 14 days of MAO inhibitors; pregnancy (prolonged use or high doses near term)

Warnings

Meperidine is not recommended for the management of chronic pain. When used for acute pain (in patients without renal or CNS disease), treatment should be limited to 48 hours and doses should not exceed 600 mg/24 hours. Oral meperidine is not recommended for acute pain management. Normeperidine (an active metabolite and CNS stimulant) may accumulate and precipitate anxiety, tremors, or seizures; risk increases with renal dysfunction and cumulative dose.

Use only with extreme caution (if at all) in patients with head injury or increased intracranial pressure (ICP); potential to elevate ICP may be greatly exaggerated in these patients. Use caution with pulmonary, hepatic, or renal disorders, supraventricular tachycardias, acute abdominal conditions, hypothyroidism, Addison's disease, BPH, or urethral stricture.

An opioid-containing analgesic regimen should be tailored to each patient's needs and based upon the type of pain being treated (acute versus chronic), the route of administration, degree of tolerance for opioids (naïve versus chronic user), age, weight, and medical condition. The optimal analgesic dose varies widely among patients. Doses should be titrated to pain relief/prevention.

Some preparations contain sulfites which may cause allergic reaction. Tolerance or drug dependence may result from extended use.

Dosage Forms Injection, solution, as hydrochloride [ampul]: 25 mg/0.5 mL (0.5 mL); 25 mg/mL (1 mL); 50 mg/mL (1 mL, 1.5 mL, 2 mL); 75 mg/mL (1 mL); 100 mg/mL (1 mL)

Injection, solution, as hydrochloride [prefilled syringe]: 25 mg/mL (1 mL); 50 mg/mL (1 mL); 75 mg/mL (1 mL); 100 mg/mL (1 mL)

Injection, solution, as hydrochloride [for PCA pump]: 10 mg/mL (30 mL, 50 mL, 60 mL)

Injection, solution, as hydrochloride [vial]: 25 mg/mL (1 mL); 50 mg/mL (1 mL, 30 mL); 75 mg/mL (1 mL); 100 mg/mL (1 mL, 20 mL) [may contain sodium metabisulfite]

Syrup, as hydrochloride:

Demerol®: 50 mg/5 mL (480 mL) [contains benzoic acid; banana flavor]

Tablet, as hydrochloride: 50 mg, 100 mg

Demerol®, Meperitab®: 50 mg, 100 mg

Reference Range

Serum level:

Meperidine:

Therapeutic: 70-500 ng/mL (SI: 283-2020 nmol/L)

Toxic: > 1000 ng/mL (SI: > 4043 nmol/L)

Normeperidine: Toxic: > 450 ng/mL

Urinary level: Meperidine: Therapeutic: 1-10 mg/L

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at 2/3 the response dose/hour) may be required; seizures are usually self-limited and can be managed with benzodiazepines. Naloxone is not useful in treating meperidine-induced seizures.

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Test Interactions ↑ amylase (S), BSP retention, CPK (I.M. injections)

Drug Interactions **Substrate** (minor) of CYP2B6, 2C19, 3A4

Acyclovir: May increase meperidine metabolite concentrations. Use caution.

Barbiturates: May decrease analgesic efficacy and increase sedative and/or respiratory depressive effects of meperidine.

Cimetidine: May increase meperidine metabolite concentrations; use caution.

CNS depressants (including benzodiazepines): May potentiate the sedative and/or respiratory depressive effects of meperidine.

MAO inhibitors: May enhance the serotonergic effect of meperidine, which may cause serotonin syndrome. Concurrent use with or within 14 days of an MAO inhibitor is contraindicated.

Phenothiazines: May potentiate the sedative and/or respiratory depressive effects of meperidine; may increase the incidence of hypotension.

Phenytoin: May decrease the analgesic effects of meperidine

Ritonavir: May increase meperidine metabolite concentrations; use caution.

Serotonin agonists: Serotonin agonists and meperidine may enhance serotonin levels in the brain. Serotonin syndrome may occur.

Serotonin reuptake inhibitors: May potentiate the effects of meperidine, increasing serotonin levels in the brain. Serotonin syndrome may occur.

Sibutramine: May enhance the serotonergic effect of meperidine. Serotonin syndrome may occur.

Tricyclic antidepressants: May potentiate the sedative and/or respiratory depressive effects of meperidine. In addition, potentially may increase the risk of serotonin syndrome.

Pregnancy Risk Factor B/D (prolonged use or high doses at term)

Pregnancy Implications Meperidine is known to cross the placenta, which may result in respiratory or CNS depression in the newborn.

Lactation Enters breast milk/contraindicated (AAP rates "compatible")

Additional Information Decrease the dose in patients with renal or hepatic impairment; equianalgesic doses: morphine 10 mg I.M. is equivalent to meperidine 75-100 mg I.M.

I.V. incompatible with barbiturates

Risk for meperidine-induced seizures includes renal insufficiency, alkaline urine, coadministration of phenothiazines and doses of meperidine > 100 mg every 2 hours for longer than 24 hours.

Factors predisposing to normeperidine-induced seizures: Doses >100 mg every 2 hours for longer than 24 hours; renal failure; alkaline urine; coadministration of hepatic enzyme-inducing medications; coadministration of medications which can lower the seizure threshold (ie, phenothiazines); sickle cell anemia

Mephentermine

CAS Number 100-92-5; 1212-72-2; 6190-60-9

Synonyms Mephentermine Sulfate

Use Treatment of hypotension secondary to ganglionic blockade or spinal anesthesia; may be used as an emergency measure to maintain blood pressure until whole blood replacement becomes available

Mechanism of Action A sympathomimetic drug with similar properties as other paraphenylethylamines; an indirect-acting sympathomimetic that releases norepinephrine; the elevation in blood pressure is probably primarily related to an increased in cardiac output resulting from enhanced cardiac contraction and due to an increase in peripheral resistance from peripheral vasoconstriction to a lesser degree; may also stimulate beta-adrenergic receptors and the change in heart rate is variable, depending on vagal tone

Adverse Reactions

Cardiovascular: Arrhythmias

Central nervous system: Euphoria, weeping, nervousness, anxiety, convulsions, hallucinations (visual, auditory or olfactory), psychosis, paranoia, delirium

Gastrointestinal: Anorexia

Neuromuscular & skeletal: Tremor

Signs and Symptoms of Overdose Hallucinations, paranoia, seizures

Pharmacodynamics/Kinetics

Metabolism: Hepatic

Elimination: In urine

Dosage

Hypotension: I.M., I.V.:

Children: 0.4 mg/kg

Adults: 0.5 mg/kg

Hypotensive emergency: I.V. infusion: 20-60 mg

Administration May be given I.M.

Contraindications Known hypersensitivity to mephentermine, hypotension induced by drugs causing alpha blockade

Warnings Use with caution in patients with cardiovascular disease or hypertension

Dosage Forms Injection, as sulfate: 15 mg/mL (2 mL, 10 mL)

Overdosage/Treatment Supportive therapy: Agitation can be treated with diazepam (0.1 mg/kg); severe agitation can be treated with haloperidol (up to 0.1 mg/kg) or droperidol (up to 0.1 mg/kg I.V.); for treatment of distal extremity necrosis due to inadvertent intra-arterial administration, tolazoline (25 mg intra-arterial then 50 mg I.V.) may be useful; if this is not effective, stellate ganglion block may be necessary; seizures can be treated with benzodiazepines; hypertension can be treated with phentolamine or nitroprusside while ventricular arrhythmias can be treated with lidocaine

Antidote(s)

- Phentolamine [ANTIDOTE]

Drug Interactions Phenothiazines antagonize the pressor effects, MAO inhibitors potentiate the pressor effects

Pregnancy Risk Factor C

Pregnancy Implications Uterine stimulation may occur

Mephentyoin

CAS Number 50-12-4

Synonyms Methoin; Methylphenylethylhydantoin; Phenantoin

Impairment Potential Yes

Use Treatment of tonic-clonic and partial seizures in patients who are uncontrolled with less toxic anticonvulsants

Mechanism of Action Stabilizes neuronal membranes and decreases seizure activity by increasing efflux or decreasing influx of sodium ions across cell membranes in the motor cortex during generation of nerve impulses; prolongs effective refractory period and suppresses ventricular pacemaker automaticity, shortens action potential in the heart

Adverse Reactions

Cardiovascular: Hypotension, bradycardia, cardiac arrhythmias, cardiovascular collapse

Central nervous system: **Psychiatric changes, slurred speech, dizziness, drowsiness,** headache, insomnia, confusion, fever, ataxia,

psychotic episodes, complex partial epilepsy, simple partial epilepsy, tonic-clonic epilepsy

Dermatologic: Skin rash, Stevens-Johnson syndrome or SLE-like syndrome, alopecia, urticaria, purpura, toxic epidermal necrolysis, exfoliative dermatitis, acne, angioedema, bullous skin disease, pruritus, exanthem

Gastrointestinal: **Constipation, nausea, vomiting,** anorexia, weight loss, gingival hyperplasia (less common than with phenytoin)

Hematologic: Blood dyscrasias (neutropenia, thrombocytopenia, leukopenia, pancytopenia), aplastic anemia, Hodgkin's disease-like syndrome

Hepatic: Hepatitis, jaundice

Local: Venous irritation and pain, thrombophlebitis

Neuromuscular & skeletal: **Trembling,** paresthesia, neuropathy (peripheral)

Ocular: Diplopia, nystagmus, blurred vision, photophobia, conjunctivitis

Renal: Nephrotic syndrome, proteinuria, elevated serum creatinine, glomerulonephritis

Respiratory: Pulmonary fibrosis

Miscellaneous: Lymphadenopathy, serum sickness, periarteritis nodosa

Admission Criteria/Prognosis Admit any ingestion which results in a total mephentyoin serum level >50 mcg/mL

Pharmacodynamics/Kinetics

Onset of action: 30 minutes

Duration: 24-48 hours

Absorption: Oral: Rapid

Metabolism: In the liver

Half-life: 144 hours

Elimination: In urine

Dosage

Oral:

Children: 3-15 mg/kg/day in 3 divided doses; usual maintenance dose: 100-400 mg/day in 3 divided doses

Adults: Initial dose: 50-100 mg/day given daily; increase by 50-100 mg at weekly intervals; usual maintenance dose: 200-600 mg/day in 3 divided doses; maximum: 800 mg/day

Monitoring Parameters CBC and platelet count

Contraindications Hypersensitivity to mephentyoin, other hydantoins, or any component of the formulation

Warnings Fatal irreversible aplastic anemia has occurred; abrupt withdrawal may precipitate seizures; may increase frequency of petit mal seizures; use with caution in patients with liver disease or porphyria; usually listed in combination with other anticonvulsants

Dosage Forms Tablet: 100 mg

Reference Range Total mephentyoin (mephentyoin plus 5-ethyl-5-phenylhydantoin) of 25-40 mcg/mL produces optimal seizure control; serum levels >40 mcg/mL can produce central nervous system effects or exacerbate seizures

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Treatment is supportive for hypotension; treat with I.V. fluids and place patient in Trendelenburg position; seizures may be controlled with lorazepam or diazepam 5-10 mg (0.25-0.4 mg/kg in children); I.V. albumin (25 g every 6 hours has been used to increase bound fraction of drug); extravasation can be treated with compressive dressing, elevation and splinting of extremity

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; peritoneal dialysis, diuresis, hemodialysis, hemoperfusion, and plasmapheresis is of little value

Test Interactions ↑ alkaline phosphatase (S); ↓ calcium (S)

Drug Interactions

CYP2C19 enzyme substrate

Acetaminophen: Hydantoins may enhance the hepatotoxic potential of acetaminophen overdoses

Acetazolamide: Concurrent use with hydantoins may result in an increased risk of osteomalacia

Acyclovir: May decrease hydantoin serum levels; limited documentation; monitor

Allopurinol: May increase hydantoin serum concentrations; monitor

Antacids: May decrease absorption of hydantoins; separate oral doses by several hours

Antiarrhythmics: Hydantoins may increase the metabolism of antiarrhythmics, decreasing their clinical effect; includes disopyramide, propafenone, and quinidine; amiodarone also may increase hydantoin concentrations (see CYP inhibitors)

Anticonvulsants: Hydantoins may increase the metabolism of anticonvulsants; includes barbiturates, carbamazepine, ethosuximide, felbamate, lamotrigine, tiagabine, topiramate, and zonisamide; does not appear to affect gabapentin or levetiracetam; felbamate and gabapentin may increase hydantoin levels; monitor

Antineoplastics: Several chemotherapeutic agents have been associated with a decrease in serum hydantoin levels; includes cisplatin, bleomycin, carmustine, methotrexate, and vinblastine; monitor hydantoin

serum levels. Limited evidence also suggest that enzyme-inducing anticonvulsant therapy may reduce the effectiveness of some chemotherapy regimens (specifically in ALL). Teniposide and methotrexate may be cleared more rapidly in these patients.

Antipsychotics: Hydantoin may enhance the metabolism (decrease the efficacy) of antipsychotics; monitor for altered response; dose adjustment may be needed; also see note on clozapine

Benzodiazepines: Hydantoin may decrease the serum concentrations of some benzodiazepines; monitor for decreased benzodiazepine effect

Beta-blockers: Metabolism of beta-blockers may be increased and clinical effect decreased; atenolol and nadolol are unlikely to interact given their renal elimination

Calcium channel blockers: Hydantoin may enhance the metabolism of calcium channel blockers, decreasing their clinical effect; nifedipine has been reported to increase hydantoin levels (case report); monitor

Capecitabine: May increase the serum concentrations of hydantoin; monitor

Chloramphenicol: Hydantoin may increase the metabolism of chloramphenicol and chloramphenicol may inhibit hydantoin metabolism; monitor for altered response

Ciprofloxacin: Case reports indicate ciprofloxacin may increase or decrease serum hydantoin concentrations; monitor

Clozapine: May decrease hydantoin serum concentrations; monitor

CNS depressants: Sedative effects may be additive with other CNS depressants; monitor for increased effect; includes ethanol, barbiturates, sedatives, antidepressants, narcotic analgesics, and benzodiazepines

Corticosteroids: Hydantoin may increase the metabolism of corticosteroids, decreasing their clinical effect; also see dexamethasone

Cyclosporine and tacrolimus: Levels may be decreased by hydantoin; monitor

CYP2C8/9 inhibitors: Serum levels and/or toxicity of hydantoin may be increased; inhibitors include amiodarone, cimetidine, fluvoxamine, some NSAIDs, metronidazole, ritonavir, sulfonamides, troglitazone, valproic acid, and zafirlukast; monitor for increased effect/toxicity

CYP2C19 inhibitors: Serum levels of hydantoin may be increased; inhibitors include cimetidine, felbamate, fluconazole, fluoxetine, omeprazole, teniposide, tolbutamide, and troglitazone

Dexamethasone: May decrease serum hydantoin due to increased metabolism; monitor

Digoxin: Effects and/or levels of digitalis glycosides may be decreased by hydantoin

Disulfiram: May increase serum hydantoin concentrations; monitor

Dopamine: I.V. hydantoin may increase the effect of dopamine (enhanced hypotension)

Doxycycline: Hydantoin may enhance the metabolism of doxycycline, decreasing its clinical effect; higher dosages may be required

Estrogens: Hydantoin may increase the metabolism of estrogens, decreasing their clinical effect; monitor

Enzyme inducers: The serum levels of hydantoin may be reduced by barbiturates, carbamazepine, chronic ethanol, dexamethasone, and rifampin

Folic acid: Replacement of folic acid has been reported to increase the metabolism of hydantoin, decreasing its serum concentrations and/or increasing seizures

Furosemide: Diuretic effect may be blunted by hydantoin (mechanism unclear); possibly due to decreased furosemide bioavailability

HMG-CoA reductase inhibitors: Hydantoin may increase the metabolism of these agents, reducing their clinical effect; monitor

Itraconazole: Hydantoin may decrease the effect of itraconazole

Levodopa: Hydantoin may inhibit the anti-Parkinson effect of levodopa

Lithium: Concurrent use of hydantoin and lithium has resulted in lithium intoxication

Methadone: Hydantoin may enhance the metabolism of methadone resulting in methadone withdrawal

Methylphenidate: May increase serum hydantoin concentrations; monitor

Neuromuscular blocking agents: Duration of effect may be decreased by hydantoin

Omeprazole: May increase serum hydantoin concentrations; monitor

Oral contraceptives: Hydantoin may enhance the metabolism of oral contraceptives, decreasing their clinical effect; an alternative method of contraception should be considered

Phenylbutazone: May increase hydantoin concentrations; monitor and adjust dosage

Primidone: Hydantoin enhance the conversion of primidone to phenobarbital resulting in elevated phenobarbital serum concentrations

Quetiapine: Serum concentrations may be substantially reduced by hydantoin, potentially resulting in a loss of efficacy; limited documentation; monitor

SSRIs: May increase hydantoin serum concentrations; fluoxetine and fluvoxamine are known to inhibit metabolism via CYP enzymes; sertraline and paroxetine have also been shown to increase concentrations in some patients; monitor

Sucralfate: May reduce the GI absorption of hydantoin; monitor

Theophylline: Hydantoin may increase metabolism of theophylline derivatives and decrease their clinical effect; theophylline may also increase hydantoin concentrations

Thyroid hormones (including levothyroxine): Hydantoin may alter the metabolism of thyroid hormones, reducing its effect; there is limited documentation of this interaction, but monitoring should be considered

Ticlopidine: May increase serum hydantoin concentrations and/or toxicity; monitor

Tricyclic antidepressants: Hydantoin may increase metabolism of tricyclic antidepressants and decrease their clinical effect; sedative effects may be additive; tricyclics may also increase hydantoin concentrations

Topiramate: Hydantoin may decrease serum levels of topiramate; topiramate may increase the effect of hydantoin

Trazodone: Serum levels of hydantoin may be increased; limited documentation; monitor

Trimethoprim: May increase serum hydantoin concentrations; monitor

Valproic acid (and sulfisoxazole): May displace hydantoin from binding sites; valproic acid may increase, decrease, or have no effect on hydantoin serum concentrations

Vigabatrin: May reduce hydantoin serum concentrations; monitor

Warfarin: Hydantoin transiently increased the hypoprothrombinemia response to warfarin initially; this is followed by an inhibition of the hypoprothrombinemic response

Pregnancy Risk Factor C**Nursing Implications** Monitor CBC and platelet**Additional Information** Usually used in combination with other anticonvulsants; **Note:** The company that makes Mesantoin® has **discontinued manufacturing** (July, 2000); the drug is currently available from Novartis under a transition program; small quantities may be obtained while transitioning patients to other antiepileptic agents.**Mephobarbital****CAS Number** 115-38-8**U.S. Brand Names** Mebaral®**Synonyms** Methylphenobarbital**Impairment Potential** Yes**Use** Prophylactic management of tonic-clonic (grand mal) seizures and absence (petit mal) seizures**Mechanism of Action** Increases seizure threshold in the motor cortex; depresses monosynaptic and polysynaptic transmission in the CNS**Adverse Reactions**

Cardiovascular: Sinus tachycardia

Central nervous system: **Drowsiness, dizziness, lightheadedness, "hangover" effect, paradoxical excitation (especially in children), sinus bradycardia**

Dermatologic: Rash, including Stevens-Johnson syndrome or erythema multiforme

Gastrointestinal: Nausea, vomiting

Hematologic: Leukopenia/neutropenia (agranulocytosis, granulocytopenia), thrombocytopenic purpura

Miscellaneous: Psychological and physical dependence

Signs and Symptoms of Overdose CNS depression, cyclic coma, hypotension, hypothermia, nystagmus, ptosis, renal failure, respiratory depression, tachycardia, vision color changes (green tinge; yellow tinge)**Pharmacodynamics/Kinetics****Onset of action:** 20-60 minutes**Duration:** 6-8 hours**Absorption:** ~50%**Half-life elimination, serum:** 34 hours**Dosage****Oral:****Epilepsy:**

Children: 6-12 mg/kg/day in 2-4 divided doses

Adults: 200-600 mg/day in 2-4 divided doses

Sedation:

Children:

< 5 years: 16-32 mg 3-4 times/day

> 5 years: 32-64 mg 3-4 times/day

Adults: 32-100 mg 3-4 times/day

Dosing adjustment in renal or hepatic impairment: Use with caution and reduce dosages**Monitoring Parameters** Respiratory**Contraindications** Hypersensitivity to mephobarbital, other barbiturates, or any component of the formulation; pre-existing CNS depression; respiratory depression; severe uncontrolled pain; history of porphyria; pregnancy**Dosage Forms** Tablet: 32 mg, 50 mg, 100 mg**Reference Range** Phenobarbital level should be in the range of 15-40 mcg/mL; levels > 80 mcg/mL correlate with decreased mental status. Mephobarbital: therapeutic: 8-15 mg/L

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Isotonic fluids for hypotension; dopamine or norepinephrine can be used

Enhancement of elimination: Repeated oral doses of activated charcoal significantly reduce the half-life of phenobarbital resulting from an enhancement of nonrenal elimination. Assure adequate hydration and renal function. Urinary alkalinization with I.V. sodium bicarbonate also helps to enhance elimination. Hemodialysis or hemoperfusion is of uncertain value. Patients in stage four coma due to high serum barbiturate levels may require charcoal hemoperfusion.

Test Interactions ↑ alkaline phosphatase (S), ammonia (B); ↓ bilirubin (S), calcium (S)

Drug Interactions **Substrate** of CYP2B6 (minor), 2C9 (minor), 2C19 (major); **Inhibits** CYP2C19 (weak); **Induces** CYP2A6 (weak)

Acetaminophen: Barbiturates may enhance the hepatotoxic potential of acetaminophen overdoses

CNS depressants: Sedative effects and/or respiratory depression with barbiturates may be additive with other CNS depressants; monitor for increased effect; includes ethanol, sedatives, antidepressants, narcotic analgesics, and benzodiazepines

Cyclosporine: Levels may be decreased by barbiturates; monitor

CYP2C19 inducers: May decrease the levels/effects of mephobarbital. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of mephobarbital. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

Griseofulvin: Barbiturates may impair the absorption of griseofulvin, and griseofulvin metabolism may be increased by barbiturates, decreasing clinical effect

Guanfacine: Effect may be decreased by barbiturates

MAO inhibitors: Metabolism of barbiturates may be inhibited, increasing clinical effect or toxicity of the barbiturates

Methoxyflurane: Barbiturates may enhance the nephrotoxic effects of methoxyflurane

Valproic acid: Metabolism of barbiturates may be inhibited by valproic acid; monitor for excessive sedation; a dose reduction may be needed

Pregnancy Risk Factor D

Nursing Implications Observe patient for excessive sedation, apnea; raise bed rails, institute safety precautions, assist with ambulation

Additional Information Sometimes used in specific patients who have excessive sedation or hyperexcitability from phenobarbital; avoid abrupt discontinuation

Mepivacaine

CAS Number 1722-62-9; 96-88-8

U.S. Brand Names Carbocaine® [DSC]; Polocaine® MPF; Polocaine®

Synonyms Mepivacaine Hydrochloride

Use Local anesthesia by nerve block; infiltration in dental procedures

Mechanism of Action Mepivacaine is an amino amide local anesthetic similar to lidocaine; like all local anesthetics, mepivacaine acts by preventing the generation and conduction of nerve impulses

Adverse Reactions

Cardiovascular: Bradycardia, myocardial depression, hypotension, cardiovascular collapse, edema, sinus bradycardia, congestive heart failure

Central nervous system: Anxiety, restlessness, disorientation, confusion, seizures, drowsiness, unconsciousness, lightheadedness, headache, chills

Dermatologic: Urticaria

Gastrointestinal: Nausea, vomiting

Hematologic: Porphyria, porphyrinogenic

Local: Transient stinging or burning at injection site

Neuromuscular & skeletal: Tremors

Ocular: Blurred vision

Otic: Ototoxicity, tinnitus

Respiratory: Respiratory arrest

Miscellaneous: Neonatal CNS depression following paracervical blocks from delivery, shivering, anaphylactoid reactions

Signs and Symptoms of Overdose Apnea, bradycardia, bronchial spasm, cyanosis, depression, dizziness, muscle twitching, nystagmus, ototoxicity, seizures, tinnitus, tremors

Pharmacodynamics/Kinetics

Onset of action (route and dose dependent): Range: 3-20 minutes

Duration (route and dose dependent): 2-2.5 hours

Protein binding: ~75%

Metabolism: Primarily hepatic via N-demethylation, hydroxylation, and glucuronidation

Half-life elimination: Neonates: 8.7-9 hours; Adults: 1.9-3 hours

Excretion: Urine (95% as metabolites)

Dosage Children and Adults: Injectable local anesthetic: Varies with procedure, degree of anesthesia needed, vascularity of tissue, duration of anesthesia required, and physical condition of patient

Monitoring Parameters ECG, respiratory status

Administration Before injecting, withdraw syringe plunger to ensure injection is not into vein or artery

Contraindications Hypersensitivity to mepivacaine, other amide-type local anesthetics, or any component of the formulation

Warnings Use with caution in patients with cardiac disease, hepatic or renal disease, or hyperthyroidism. Local anesthetics have been associated with rare occurrences of sudden respiratory arrest; convulsions due to systemic toxicity leading to cardiac arrest have been reported presumably due to intravascular injection. A test dose is recommended prior to epidural administration and all reinforcing doses with continuous catheter technique. Do not use solutions containing preservatives for caudal or epidural block. Use caution in debilitated, elderly, or acutely ill patients; dose reduction may be required.

Dosage Forms Injection, solution, as hydrochloride [contains methylparabens]:

Carbocaine®: 1% (50 mL); 2% (50 mL)

Polocaine®: 1% (50 mL); 2% (50 mL)

Injection, solution, as hydrochloride [preservative free]:

Carbocaine®: 1% (30 mL); 1.5% (30 mL); 2% (20 mL); 3% (1.8 mL) [dental cartridge]

Polocaine® Dental: 3% (1.8 mL) [dental cartridge]

Polocaine® MPF: 1% (30 mL); 1.5% (30 mL); 2% (20 mL)

Reference Range

Therapeutic: Plasma levels are <5 mcg/mL

Fatal: Fatalities are associated with levels >10 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Termination of anesthesia by pneumatic tourniquet inflation should be attempted when the agent is administered by infiltration or regional injection. Seizures commonly respond to diazepam, lorazepam or barbiturates, while hypotension responds to I.V. fluids and Trendelenburg positioning. Bradyarrhythmias (when the heart rate is less than 60) can be treated with I.V. atropine 15 mcg/kg. With the development of metabolic acidosis, I.V. sodium bicarbonate 0.5-2 mEq/kg and ventilatory assistance should be instituted.

Enhancement of elimination: Exchange transfusion is of minimal benefit

Pregnancy Risk Factor C

Pregnancy Implications May cause neonatal depression or seizures

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Before injecting, withdraw syringe plunger to ensure injection is not into vein or artery; solution is acidic

Additional Information Numbing, bitter taste

Meprobamate**Related Information**

• Carisoprodol

CAS Number 57-53-4

U.S. Brand Names Miltown®

Synonyms Equanil

Impairment Potential Yes. Serum meprobamate level >60 mg/L has been associated with impairment. (Baselt RC and Cravey RH, *Disposition of Toxic Drugs and Chemicals in Man*, 4th ed, Foster City, CA: Chemical Toxicology Institute, 1995, 460.) Driving impairment can occur if combined serum level of carisoprodol and meprobamate exceeds 10 mg/L.

Use Management of anxiety disorders

Unlabeled/Investigational Use Demonstrated value for muscle contraction, headache, premenstrual tension, external sphincter spasticity, muscle rigidity, opisthotonos-associated with tetanus

Mechanism of Action Precise mechanisms are not yet clear, but many effects have been ascribed to its central depressant actions

Adverse Reactions

Cardiovascular: Syncope, peripheral edema, cyanosis, sinus bradycardia, palpitations, sinus tachycardia, vasculitis

Central nervous system: **Drowsiness**, slurred speech, headache, euphoria, dizziness, paradoxical excitation, **ataxia**

Dermatologic: Exfoliative dermatitis, pityriasis rosea-like reaction, toxic epidermal necrolysis, urticaria, photosensitivity, pruritus, erythema nodosum

Endocrine & metabolic: Gynecomastia

Gastrointestinal: Xerostomia

Neuromuscular & skeletal: Paresthesia

Ocular: Nystagmus, miosis, mydriasis

Miscellaneous: Systemic lupus erythematosus, fixed drug eruption

Hypersensitivity reactions: **Mild:** Rash, leukopenia, purpura, angioedema, bullous dermatitis. **Severe:** Fever, chills, wheezing, renal failure, dermatitis, stomatitis, Stevens-Johnson syndrome, agranulocytosis

MEPTAZINOL

Signs and Symptoms of Overdose Agranulocytosis, areflexia, ataxia, bezoars, bradycardia, coma, drowsiness, granulocytopenia, hyporeflexia, hypotension, leukopenia, neutropenia, porphyria, respiratory depression, stupor, syncope, tachycardia, wheezing

Pharmacodynamics/Kinetics

Onset of action: Sedation: ~1 hour
Distribution: Crosses placenta; enters breast milk
Metabolism: Hepatic
Half-life elimination: 10 hours
Excretion: Urine (8% to 20% as unchanged drug); feces (10% as metabolites)

Dosage

Oral:
Children 6-12 years: Anxiety: 100-200 mg 2-3 times/day
Adults: Anxiety: 400 mg 3-4 times/day, up to 2400 mg/day

Dosing interval in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer every 9-12 hours
 Cl_{cr} < 10 mL/minute: Administer every 12-18 hours
Hemodialysis: Moderately dialyzable (20% to 50%)

Dosing adjustment in hepatic impairment: Probably necessary in patients with liver disease

Monitoring Parameters

Contraindications Hypersensitivity to meprobamate, related compounds (including carisoprodol), or any component of the formulation; acute intermittent porphyria; pre-existing CNS depression; narrow-angle glaucoma; severe uncontrolled pain; pregnancy

Warnings Physical and psychological dependence and abuse may occur; abrupt cessation may precipitate withdrawal. Use with caution in patients with depression or suicidal tendencies, or in patients with a history of drug abuse. May cause CNS depression, which may impair physical or mental abilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Effects with other sedative drugs or ethanol may be potentiated. Not recommended in children <6 years of age; allergic reaction may occur in patients with history of dermatological condition (usually by fourth dose). Use with caution in patients with renal or hepatic impairment, or with a history of seizures. Use caution in the elderly as it may cause confusion, cognitive impairment, or excessive sedation.

Dosage Forms [DSC] = Discontinued product

Tablet: 200 mg, 400 mg
Miltown®: 200 mg, 400 mg [DSC]

Reference Range

Therapeutic: 6-12 mcg/mL (SI: 28-55 µmol/L); sedative dose 8-24 mcg/mL (SI: 37-110 µmol/L)
Toxic: > 50 mcg/mL (SI: > 229 µmol/L); coma is associated with levels > 70 mcg/mL
Fatal: Fatalities can occur with levels > 142 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: Following attempts to enhance drug elimination. Hypotension should be treated with I.V. fluids and/or Trendelenburg positioning.
Enhancement of elimination: Hemodialysis is recommended at plasma levels > 20 mg/dL; charcoal hemoperfusion increases meprobamate clearance. Multiple dosing of activated charcoal may decrease half-life by 50%; forced diuresis with saline may be useful; moderately dialyzable (20% to 50%). Clearance through hemodialysis and hemoperfusion average 60 mL/minute and 153 mL/minute respectively. Continuous arteriovenous hemoperfusion clearance rates are 198 ± 16 mL/minute.

Drug Interactions CNS depressants: Sedative effects may be additive with other CNS depressants; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents

Pregnancy Risk Factor D

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk/not recommended

Additional Information Can cause bezoars

Specific References

Daval S, Richard D, Souweine B, et al, "A One-Step and Sensitive GC-MS Assay for Meprobamate Determination in Emergency Situations," *J Anal Toxicol*, 2006, 30:302-5.

Meptazinol

CAS Number 34154-59-1; 54340-58-8; 59263-76-2

Unlabeled/Investigational Use In U.S.: Acute analgesic agent; also used to diminish Jarisch-Herxheimer reaction

Mechanism of Action A centrally acting opioid agonist-antagonist agent with cholinergic activity

Adverse Reactions

All adverse effects are seen frequently with parenteral administration as compared to oral administration

Central nervous system: Drowsiness, dizziness, euphoria, headache, amnesia, hallucinations, dysphoria

Gastrointestinal: **Nausea, vomiting**, xerostomia, dyspepsia

Ocular: Slight miosis, blurred vision

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Respiratory depression

Toxicodynamics/Kinetics

Peak effect: Oral: 1-2 hours; Parenteral: 0.5-1 hour
Distribution: V_d : 2-3 L/kg
Protein binding: 23% to 27%
Metabolism: Hepatic
Bioavailability: Oral: 4% to 10%
Half-life: Neonates: 3.4 hours; Adults: 2 hours (adult men); 1.4-1.7 hours (adult women)
Elimination: Primarily renal (plasma clearance ~100 L/hour)
Effective analgesia: Oral: 4 hours

Dosage

Children: I.M. (in lateral thigh): 1 mg/kg

Analgesia:

Oral: 200 mg every 3-6 hours
Epidural: 30-90 mg (in 10 mL of normal saline)
I.M.: 75-100 mg every 2-4 hours
I.V.: 50-100 mg slowly every 2-4 hours; continuous I.V.: Loading dose of 50 mg I.V. followed by 0.5 mg/kg/hour for up to 1 day
Herxheimer reaction: I.V.: 300-500 mg

Reference Range Peak serum level after a 200 mg oral dose: 10-110 ng/mL; peak plasma level after a 50 mg I.V. dose: ~270 ng/mL

Overdosage/Treatment Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at $\frac{2}{3}$ the response dose/hour) may be required; opioid-induced myoclonus may respond to dantrolene (50-150 mg/day); higher than usual doses of naloxone may be necessary to treat respiratory depression

Antidote(s)

● Naloxone [ANTIDOTE]

Pregnancy Implications No teratogenic effects known; can cross the placenta

Additional Information $\sim \frac{1}{10}$ as potent as morphine with miosis and constipation occurring less frequently; structurally similar to pentazocine

Merbromin

Pronunciation (mer BROE min)

CAS Number 129-16-8

U.S. Brand Names Mercurochrome®

Use Dermal antiseptic

Mechanism of Action Bacteriostatic antimicrobial activity

Adverse Reactions

Central nervous system: Dizziness
Dermatologic: Contact dermatitis
Gastrointestinal: Abdominal pain, nausea, diarrhea in less than 4% of ingestions
Miscellaneous: Application to surgical wounds and decubitus ulcers has resulted in a fatality due to aplastic anemia; anaphylaxis

Dosage Apply freely, until injury has healed

Monitoring Parameters Renal function, liver function

Warnings Prolonged use or use on extensive areas should be under physician's directions

Dosage Forms Solution, topical: 2% (30 mL)

Reference Range Urinary and whole blood levels can be obtained; normally urinary values are <10 mcg/dL and whole blood <2 mcg/dL; whole blood levels < 50 mcg/dL are usually associated with gastroenteritis and acute tubular necrosis; urinary levels for organic mercury are not useful since 90% is eliminated through bile in the feces; urinary mercury levels > 56 mcg/L can result in neurotoxic effects (due to elemental mercury)

Overdosage/Treatment

Decontamination: **Oral:** Lavage ingestions > 50 mg/kg within 1 hour/activated charcoal is probably not useful. **Dermal:** Wash thoroughly with soap and water. **Ocular:** Irrigate with normal saline.

Supportive therapy: Succimer (10 mg/kg every 8 hours for 5 days, then every 12 hours for 14 days) may be useful in severe exposures; penicillamine or N-acetyl-penicillamine can also be used; BAL may increase mercury levels in the central nervous system and is therefore contraindicated

Drug Interactions Incompatible with acids, most alkaloidal salts, many local anesthetics, metals, and sulfides

Mercaptopurine

Related Information

● Azathioprine

CAS Number 50-44-2; 6112-76-1

U.S. Brand Names Purinethol®

Synonyms 6-Mercaptopurine (error-prone abbreviation); 6-MP (error-prone abbreviation); NSC-755

Use Maintenance therapy in acute lymphoblastic leukemia (ALL); other (less common) uses include chronic granulocytic leukemia, induction therapy in ALL, and treatment of non-Hodgkin's lymphomas

Unlabeled/Investigational Use Steroid-sparing agent for corticosteroid-dependent Crohn's disease (CD) and ulcerative colitis (UC); maintenance of remission in CD; fistulizing Crohn's disease

Mechanism of Action Purine antagonist which inhibits DNA and RNA synthesis; acts as false metabolite and is incorporated into DNA and RNA, eventually inhibiting their synthesis; specific for the S phase of the cell cycle

Adverse Reactions

Central nervous system: Drug fever

Dermatologic: Hyperpigmentation, rash, alopecia, dry and scaling rash

Endocrine & metabolic: Hyperuricemia

Gastrointestinal: Nausea, vomiting, diarrhea, stomatitis, anorexia, stomach pain, mucositis, glossitis, tarry stools

Genitourinary: Oligospermia

Hematologic: **Myelosuppression; leukopenia, thrombocytopenia, anemia, eosinophilia**

Onset: 7-10 days

Nadir: 14-16 days

Recovery: 21-28 days

Hepatic: **Intrahepatic cholestasis and focal centrallobular necrosis** (40%), characterized by hyperbilirubinemia, increased alkaline phosphatase and AST, jaundice, ascites, encephalopathy; more common at doses >2.5 mg/kg/day. Usually occurs within 2 months of therapy but may occur within 1 week, or be delayed up to 8 years.

Renal: Renal toxicity

Signs and Symptoms of Overdose Immediate symptoms are nausea and vomiting. Delayed symptoms include bone marrow suppression, hepatic necrosis, and gastroenteritis.

Pharmacodynamics/Kinetics

Absorption: Variable and incomplete (16% to 50%)

Distribution: V_d = total body water; CNS penetration is poor

Protein binding: 19%

Metabolism: Hepatic and in GI mucosa; hepatically via xanthine oxidase and methylation via TPMT to sulfate conjugates, 6-thiouric acid, and other inactive compounds; first-pass effect

Half-life elimination (age dependent): Children: 21 minutes; Adults: 47 minutes

Time to peak, serum: ~2 hours

Excretion: Urine (46% as mercaptopurine and metabolites)

Dosage

Oral (refer to individual protocols):

Children:

Induction: 2.5-5 mg/kg/day or 70-100 mg/m²/day given once daily

Maintenance: 1.5-2.5 mg/kg/day or 50-75 mg/m²/day given once daily

Adults:

Induction: 2.5-5 mg/kg/day (100-200 mg)

Maintenance: 1.5-2.5 mg/kg/day or 80-100 mg/m²/day given once daily

Elderly: Due to renal decline with age, start with lower recommended doses for adults

Note: In ALL, administration in the evening (vs morning administration) may lower the risk of relapse.

Dosing adjustment in renal or hepatic impairment: Dose should be reduced to avoid accumulation, but specific guidelines are not available.

Hemodialysis: Removed; supplemental dosing is usually required

Monitoring Parameters CBC with differential and platelet count, liver function tests, uric acid, urinalysis

Contraindications Hypersensitivity to mercaptopurine or any component of the formulation; patients whose disease showed prior resistance to mercaptopurine or thioguanine; severe liver disease, severe bone marrow suppression; pregnancy

Warnings Hazardous agent – use appropriate precautions for handling and disposal. Mercaptopurine is potentially carcinogenic, and may be teratogenic; use with caution in patients with prior bone marrow suppression. Common signs of infection, such as fever and leukocytosis may not occur; lethargy and confusion may be more prominent signs of infection. Use caution with other hepatotoxic drugs or in dosages >2.5 mg/kg/day; hepatotoxicity may occur. Patients with genetic deficiency of thiopurine methyltransferase (TPMT) or concurrent therapy with drugs which may inhibit TPMT (eg, olsalazine) or xanthine oxidase (eg, allopurinol) may be sensitive to myelosuppressive effects. Azathioprine is metabolized to mercaptopurine; concomitant use may result in profound myelosuppression and should be avoided.

To avoid potentially serious dosage errors, the terms "6-mercaptopurine" or "6-MP" should be avoided; use of these terms has been associated with sixfold overdosages.

Dosage Forms Tablet [scored]: 50 mg

Overdosage/Treatment Decontamination: Efforts to minimize absorption (charcoal, gastric lavage) may be ineffective unless instituted within 60 minutes of ingestion.

Drug Interactions Allopurinol: Can cause increased levels of mercaptopurine by inhibition of xanthine oxidase; decrease dose of mercaptopurine by 75% when both drugs are used concomitantly; may potentiate effect of bone marrow suppression (reduce mercaptopurine to 25% of dose).

Aminosalicylates (olsalazine, mesalamine, sulfasalazine): May inhibit TPMT, increasing toxicity/myelosuppression of mercaptopurine. Use caution.

Azathioprine: Metabolized to mercaptopurine, concomitant use may result in profound myelosuppression and should be avoided

Doxorubicin: Synergistic liver toxicity with mercaptopurine in >50% of patients, which resolved with discontinuation of the mercaptopurine.

Hepatotoxic drugs: Any agent which could potentially alter the metabolic function of the liver could produce higher drug levels and greater toxicities from either mercaptopurine or 6-TG.

Warfarin: mercaptopurine inhibits the anticoagulation effect of warfarin by an unknown mechanism.

Pregnancy Risk Factor D

Lactation Enters breast milk/contraindicated

Nursing Implications Adjust dosage in patients with renal insufficiency

Meropenem

Related Information

- Imipenem and Cilastatin

CAS Number 96036-03-2

U.S. Brand Names Merrem® I.V.

Use Carbapenem antibiotic useful against gram-positive and gram-negative (including *Pseudomonas aeruginosa*) organisms used in meningitis, skin, and soft tissue infections and in urinary tract infections

Unlabeled/Investigational Use Febrile neutropenia, urinary tract infections

Mechanism of Action Interacts with proteins in bacterial cytoplasmic membrane; similar to imipenem

Adverse Reactions

Central nervous system: Headache

Gastrointestinal: Abdominal pain, vomiting, diarrhea, nausea

Hepatic: Elevated liver function tests

Signs and Symptoms of Overdose Convulsions

Pharmacodynamics/Kinetics

Distribution: V_d : Adults: ~0.3 L/kg, Children: 0.4-0.5 L/kg; penetrates well into most body fluids and tissues; CSF concentrations approximate those of the plasma

Protein binding: 2%

Metabolism: Hepatic; metabolized to open beta-lactam form (inactive)

Half-life elimination:

Normal renal function: 1-1.5 hours

Cl_{cr} 30-80 mL/minute: 1.9-3.3 hours

Cl_{cr} 2-30 mL/minute: 3.82-5.7 hours

Time to peak, tissue: 1 hour following infusion

Excretion: Urine (~25% as inactive metabolites)

Dosage

I.V.:

Neonates:

Preterm: 20 mg/kg/dose every 12 hours (may be increased to 40 mg/kg/dose if treating a highly resistant organism such as *Pseudomonas aeruginosa*)

Full-term (<3 months of age): 20 mg/kg/dose every 8 hours (may be increased to 40 mg/kg/dose if treating a highly resistant organism such as *Pseudomonas aeruginosa*)

Children >3 months (<50 kg):

Complicated skin and skin structure infections: 10 mg/kg every 8 hours (maximum dose: 500 mg every 8 hours)

Intra-abdominal infections: 20 mg/kg every 8 hours (maximum dose: 1 g every 8 hours)

Meningitis: 40 mg/kg every 8 hours (maximum dose: 2 g every 8 hours)

Children >50 kg:

Complicated skin and skin structure infections: 500 mg every 8 hours

Intra-abdominal infections: 1 g every 8 hours

Meningitis: 2 g every 8 hours

Adults: 1 g every 8 hours

Elderly: No differences in safety or efficacy have been reported. However, increased sensitivity may occur in some elderly patients; adjust dose based on renal function; see Warnings/Precautions

Dosing adjustment in renal impairment: Adults:

Cl_{cr} 26-50 mL/minute: Administer recommended dose based on indication every 12 hours

Cl_{cr} 10-25 mL/minute: Administer one-half recommended dose every 12 hours

Cl_{cr} <10 mL/minute: Administer one-half recommended dose every 12 hours

Dialysis: Meropenem and its metabolites are readily dialyzable

Continuous arteriovenous or venovenous hemodiafiltration effects: Dose as Cl_{cr} 10-50 mL/minute

MESALAMINE

Monitoring Parameters Monitor for signs of anaphylaxis during first dose

Administration Administer I.V. infusion over 15-30 minutes; I.V. bolus injection over 3-5 minutes

Contraindications Hypersensitivity to meropenem, any component of the formulation, or other carbapenems (eg, imipenem); patients who have experienced anaphylactic reactions to other beta-lactams

Warnings Hypersensitivity reactions, including anaphylaxis, have occurred and often require immediate drug discontinuation. Seizures and other CNS adverse reactions have occurred, most commonly in patients with renal impairment and/or underlying neurologic disorders (less frequent than with Primaxin®). Use with caution in renal impairment; dose adjustment is necessary. Thrombocytopenia has been reported in patients with significant renal dysfunction. Pseudomembranous colitis has been associated with meropenem use. Superinfection is possible with long courses of therapy. Safety and efficacy have not been established for children <3 months of age

Dosage Forms Injection, powder for reconstitution: 500 mg [contains sodium 45.1 mg as sodium carbonate (1.96 mEq)]; 1 g [contains sodium 90.2 mg as sodium carbonate (3.92 mEq)]

Reference Range Peak serum meropenem levels after a 1 g dose: 55-62 mcg/mL 30 minutes postinfusion

Overdosage/Treatment

Supportive therapy: Benzodiazepines can be used for seizure control
Enhancement of elimination: Hemodialysis can effectively remove meropenem and its metabolite; dialysis clearance: 79-81 mL/minute

Drug Interactions Probenecid: May increase meropenem serum concentrations; use caution.

Valproic acid: Meropenem may decrease valproic acid serum concentrations to subtherapeutic levels; monitor.

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic effects have not been found in animal studies; use during pregnancy only if clearly indicated.

Lactation Excretion in breast milk unknown/use caution

Mesalamine

CAS Number 89-57-6

U.S. Brand Names Asacol®; Canasa™; Pentasa®; Rowasa®

Synonyms 5-Aminosalicylic Acid; 5-ASA; Fisalmine; Mesalazine

Use

Oral: Remission and treatment of mildly to moderately active ulcerative colitis

Rectal: Treatment of active mild to moderate distal ulcerative colitis, proctosigmoiditis, or proctitis

Mechanism of Action Mesalamine (5-aminosalicylic acid) is the active component of sulfasalazine; the specific mechanism of action of mesalamine is unknown; however, it is thought that it modulates local chemical mediators of the inflammatory response, especially leukotrienes; action appears topical rather than systemic

Adverse Reactions

Adverse effects vary depending upon dosage form. Effects as reported with tablets, unless otherwise noted:

Cardiovascular: Chest pain, peripheral edema, edema, facial edema, myocarditis, pericarditis

Central nervous system: **Pain (14%)**, chills, dizziness (suppository: 3%), fever (enema: 3%; suppository: 1%), insomnia, malaise, confusion, depression, emotional lability, Guillain-Barré syndrome somnolence, transverse myelitis, T-wave abnormality, vertigo

Dermatologic: Rash (6%; suppository: 1%), pruritus (3%; enema: 1%), acne (2%; suppository: 1%), alopecia, dry skin, erythema nodosum, psoriasis, pyoderma gangrenosum, urticaria

Endocrine & metabolic: GGT elevated, gout, Kawasaki-like syndrome, menorrhagia

Gastrointestinal: **Eructation (16%)**, **abdominal pain (18%)**; enema: 8%), dyspepsia, constipation (5%), vomiting (5%), colitis exacerbation (3%; suppository: 1%), nausea (capsule: 3%), flatulence (enema: 6%), hemorrhoids (enema: 1%), nausea and vomiting (capsule: 1%), rectal pain (enema: 1%; suppository: 2%), anorexia, appetite increased, bloody diarrhea, dry mouth, gastritis, oral ulcers, pancreatitis, perforated peptic ulcer, taste perversion

Genitourinary: Epididymitis, dysuria, urinary urgency

Hematologic: Agranulocytosis, aplastic anemia, eosinophilia, leukopenia, pancytopenia, anemia

Hepatic: Elevated alkaline phosphatase, elevated ALT, AST elevated, elevated bilirubin, cholestatic jaundice, cholecystitis, hepatitis, hepatocellular damage, hepatotoxicity, jaundice, LDH elevated, liver failure, minimal change nephrotic syndrome, hepatic necrosis

Hematologic: Thrombocytopenia

Local: Pain on insertion of enema tip (enema: 1%)

Neuromuscular & skeletal: Back pain (7%; enema: 1%), arthralgia, hypertension, myalgia, arthritis, leg/joint pain (enema: 2%), hyperesthesia, neck pain, tremor, peripheral neuropathy

Ocular: Conjunctivitis, blurred vision, eye pain

Otic: Tinnitus

Respiratory: **Pharyngitis (11%)**, flu-like syndrome (3%; enema: 5%), cough increased, asthma exacerbation, eosinophilic pneumonia, fibrosing alveolitis, hypersensitivity pneumonitis, interstitial pneumonia, pleuritis

Renal: BUN elevated, hematuria, interstitial nephritis, serum creatinine elevated, urinary urgency

Miscellaneous: Lupus-like syndrome, lymphadenopathy, diaphoresis

Signs and Symptoms of Overdose Decreased motor activity, diarrhea, renal function impairment, tinnitus, vomiting

Pharmacodynamics/Kinetics

Absorption: Rectal: Variable and dependent upon retention time, underlying GI disease, and colonic pH; Oral: Tablet: ~28%, Capsule: ~20% to 30%

Metabolism: Hepatic and via GI tract to acetyl-5-aminosalicylic acid

Half-life elimination: 5-ASA: 0.5-1.5 hours; acetyl-5-ASA: 5-10 hours

Time to peak, serum: 4-7 hours

Excretion: Urine (as metabolites); feces (<2%)

Dosage

Adults (usual course of therapy is 3-6 weeks):

Oral:

Capsule: 1 g 4 times/day

Tablet: 800 mg 3 times/day

Retention enema: 60 mL (4 g) at bedtime, retained overnight, approximately 8 hours

Rectal suppository: Insert 1 suppository in rectum twice daily

Some patients may require rectal and oral therapy concurrently

Elderly: Postmarketing reports suggest an increased incidence of blood dyscrasias in patients >65 years of age; use with caution; monitor blood cell counts and renal function

Stability Unstable in presence of water or light; once foil has been removed, unopened bottles have an expiration of 1 year following the date of manufacture

Monitoring Parameters CBC and renal function, particularly in elderly patients

Administration Oral: Swallow capsules or tablets whole, do not chew or crush.

Rectal enema: Shake bottle well. Retain enemas for 8 hours or as long as practical.

Suppository: Remove foil wrapper; avoid excessive handling. Should be retained for at least 1-3 hours to achieve maximum benefit.

Contraindications Hypersensitivity to mesalamine, sulfasalazine, salicylates, or any component of the formulation; Canasa™ suppositories containing saturated vegetable fatty acid esters (contraindicated in patients with allergy to these components)

Warnings May cause an acute intolerance syndrome (cramping, acute abdominal pain, bloody diarrhea; sometimes fever, headache, rash); discontinue if this occurs. Patients with pyloric stenosis may have prolonged gastric retention of tablets, delaying the release of mesalamine in the colon. Pericarditis should be considered in patients with chest pain; pancreatitis should be considered in patients with new abdominal complaints. Symptomatic worsening of colitis/IBD may occur following initiation of therapy. Oligospermia (rare) has been reported in males. Use caution in patients with impaired renal or hepatic function. Renal impairment (including minimal change nephropathy and acute/chronic interstitial nephritis) has been reported; use caution with other medications converted to mesalamine. Postmarketing reports suggest an increased incidence of blood dyscrasias in patients >65 years of age. In addition, elderly may have difficulty administering and retaining rectal suppositories and decreased renal function; use with caution and monitor. Safety and efficacy in pediatric patients have not been established.

Rowasa® enema: Contains potassium metabisulfite; may cause severe hypersensitivity reactions (ie, anaphylaxis) in patients with sulfite allergies.

Dosage Forms Capsule, controlled release (Pentasa®): 250 mg, 500 mg
Suppository, rectal (Canasa™): 500 mg [DSC], 1000 mg [contains saturated vegetable fatty acid esters]

Suspension, rectal: 4 g/60 mL (7s, 28s) [contains potassium metabisulfite and sodium benzoate]

Rowasa®: 4 g/60 mL (7s, 28s) [contains potassium metabisulfite and sodium benzoate]

Tablet, delayed release [enteric coated] (Asacol®): 400 mg

Overdosage/Treatment

Decontamination: Oral: Activated charcoal is the preferred modality; consider decontamination for ingestions >3 g

Supportive therapy: Monitor fluid/electrolyte status along with renal function. Bradycardia may respond to I.V. fluids and atropine.

Drug Interactions Azathioprine, mercaptopurine, thioguanine: Risk of myelosuppression may be increased by aminosalicylates (due to inhibition of TPMT).

Digoxin: Mesalamine may decrease digoxin bioavailability.

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Provide patient with copy of mesalamine administration instructions

Additional Information Mesalazine 400 mg is equivalent to sulfasalazine 1 g

Mesoridazine

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antipsychotic Agents

CAS Number 32672-69-8; 5588-33-0

U.S. Brand Names Serentil® [DSC]

Synonyms Mesoridazine Besylate

Impairment Potential Yes

Use Symptomatic management of psychotic disorders, including schizophrenia, behavioral problems, alcoholism as well as reducing anxiety and tension occurring in neurosis

Unlabeled/Investigational Use Psychosis

Mechanism of Action Blockade of postsynaptic CNS dopamine receptors; a metabolite of thioridazine

Adverse Reactions

Cardiovascular: **Hypotension** (especially with I.V. use), **hypotension (orthostatic)**, tachycardia, cardiac arrhythmias, sinus tachycardia

Central nervous system: Sedation, drowsiness, restlessness, anxiety, extrapyramidal reactions, **pseudoparkinsonian signs and symptoms, tardive dyskinesia**, neuroleptic malignant syndrome, seizures, altered central temperature regulation, **akathisia, dystonias, dizziness, hyperthermia**

Dermatologic: Hyperpigmentation, pruritus, rash, photosensitivity

Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, syndrome of inappropriate antidiuretic hormone

Gastrointestinal: GI upset, xerostomia, **constipation**, weight gain

Genitourinary: Urinary retention, impotence

Hematologic: Agranulocytosis, leukopenia (usually in patients with large doses for prolonged periods), thrombocytopenia, hemolysis, eosinophilia

Hepatic: Cholestatic jaundice

Neuromuscular & skeletal: Trismus

Ocular: **Retinal pigmentation**, nystagmus, blurred vision

Respiratory: **Nasal congestion**

Miscellaneous: **Diaphoresis (decreased)**, systemic lupus erythematosus

Signs and Symptoms of Overdose Abnormal involuntary muscle movements, agranulocytosis, cardiac arrhythmias, coma, deep sleep, ejaculatory disturbances, enuresis, extrapyramidal reaction, galactorrhea, granulocytopenia, gynecomastia, hypotension, impotence, leukopenia, neuroleptic malignant syndrome, neutropenia, nystagmus, Parkinson's-like symptoms, photophobia, priapism, QRS prolongation, urine discoloration (pink; red; red-brown), vision color changes (brown tinge; yellow tinge)

Pharmacodynamics/Kinetics

Duration: 4-6 hours

Absorption: Tablet: Erratic; Liquid: More dependable

Protein binding: 91% to 99%

Half-life elimination: 24-48 hours

Time to peak, serum: 2-4 hours; Steady-state serum: 4-7 days

Excretion: Urine

Dosage

Concentrate may be diluted just prior to administration with distilled water, acidified tap water, orange or grape juice; do not prepare and store bulk dilutions

Adults:

Oral: 25-50 mg 3 times/day; maximum: 100-400 mg/day

I.M.: 25 mg initially, repeat in 30-60 minutes as needed; optimal dosage range: 25-200 mg/day

Monitoring Parameters Vital signs, orthostatic blood pressures; lipid profile, fasting blood glucose/Hgb A_{1c}, baseline (and periodic) serum potassium; BMI; mental status, abnormal involuntary movement scale (AIMS); tremors, gait changes, abnormal movement in trunk, neck, buccal area or extremities; monitor target behaviors for which the agent is given; monitor hepatic function (especially if fever with flu-like symptoms); baseline ECG, do not initiate if QT_c > 450 msec (discontinue in any patient with a QT_c > 500 msec)

Administration When administering I.M. or I.V., watch for hypotension. Dilute oral concentrate just prior to administration with distilled water, acidified tap water, orange or grape juice. Do not prepare and store bulk dilutions. Do not mix oral solutions of mesoridazine and lithium, these oral liquids are incompatible when mixed. **Note:** Avoid skin contact with oral medication; may cause contact dermatitis.

Contraindications Hypersensitivity to mesoridazine or any component of the formulation (cross-reactivity between phenothiazines may occur); severe CNS depression and coma; prolonged QT interval (> 450 msec), including prolongation due to congenital causes; history of arrhythmias; concurrent use of medications which prolong QT_c (including type Ia and type III antiarrhythmics, cyclic antidepressants, some fluoroquinolones, cisapride)

Warnings

[U.S. Boxed Warning]: Has been shown to prolong QT_c interval in a dose-dependent manner (associated with an increased risk of torsade de pointes). Patients should have a baseline ECG prior to initiation, and should not receive mesoridazine if baseline QT_c > 450 msec. Mesoridazine should be discontinued in patients with a QT_c interval > 500 msec. Potassium levels must be evaluated and normalized prior to and throughout treatment.

May cause hypotension, particularly with I.M. administration. Highly sedating, use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Caution in patients with hemodynamic instability; bone marrow suppression; predisposition to seizures; subcortical brain damage; severe cardiac, hepatic, renal, or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use; use with caution in patients at risk of pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications which may predispose).

Phenothiazines may cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention). Therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other antipsychotics, mesoridazine has a high potency of cholinergic blockade.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is low relative to other neuroleptics). May be associated with neuroleptic malignant syndrome (NMS) or pigmentary retinopathy (particularly at doses > 1 g/day).

Dosage Forms [DSC] = Discontinued product

Injection, solution, as besylate [DSC]: 25 mg/mL (1 mL)

Liquid, oral, as besylate [DSC]: 25 mg/mL (118 mL) [contains alcohol 0.61%]

Tablet, as besylate [DSC]: 10 mg, 25 mg, 50 mg, 100 mg

Overdosage/Treatment

Decontamination: Activated charcoal/lavage within 1 hour

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required. Seizures commonly respond to lorazepam or diazepam (I.V. 5-10 mg bolus in adults every 15 minutes if needed up to a total of 30 mg; I.V. 0.25-0.4 mg/kg/dose up to a total of 10 mg in children) or to phenytoin or phenobarbital. Also critical cardiac arrhythmias and prolonged QT interval on ECG often respond to I.V. phenytoin (15 mg/kg up to 1 g), while other antiarrhythmics can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with benztropine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes. Avoid use of quinidine, procainamide, or disopyramide

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; not dialyzable (0% to 5%)

Test Interactions ↑ cholesterol (S), ↑ glucose; ↓ uric acid (S), calcium (S); may result in a false-positive when testing for tricyclic antidepressants through the EMIT system

Drug Interactions Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Aluminum salts: May decrease the absorption of phenothiazines; monitor
Amphetamines: Efficacy may be diminished by antipsychotics; in addition, amphetamines may increase psychotic symptoms; avoid concurrent use

Anticholinergics: May inhibit the therapeutic response to phenothiazines and excess anticholinergic effects may occur; includes benztropine, trihexyphenidyl, biperiden, and drugs with significant anticholinergic activity (TCAs, antihistamines, disopyramide)

Antihypertensives: Concurrent use of phenothiazines with an antihypertensive may produce additive hypotensive effects (particularly orthostasis)

Bromocriptine: Phenothiazines inhibit the ability of bromocriptine to lower serum prolactin concentrations

CNS depressants: Sedative effects may be additive with phenothiazines; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents

Epinephrine: Chlorpromazine (and possibly other low potency antipsychotics) may diminish the pressor effects of epinephrine

Guanethidine and guanadrel: Antihypertensive effects may be inhibited by chlorpromazine

Levodopa: Chlorpromazine may inhibit the antiparkinsonian effect of levodopa; avoid this combination

METAPROTERENOL

Lithium: Chlorpromazine may produce neurotoxicity with lithium; this is a rare effect

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk.
Polypeptide antibiotics: Rare cases of respiratory paralysis have been reported with concurrent use of phenothiazines

QT_c-prolonging agents: Effects on QT_c interval may be additive with phenothiazines, increasing the risk of malignant arrhythmias; includes type Ia antiarrhythmics, TCAs, and some quinolone antibiotics (sparfloxacin, moxifloxacin and gatifloxacin). **Concurrent use is contraindicated.**

Sulfadoxine-pyrimethamine: May increase phenothiazine concentrations
Tricyclic antidepressants: Concurrent use may produce increased toxicity or altered therapeutic response

Trazodone: Phenothiazines and trazodone may produce additive hypotensive effects

Valproic acid: Serum levels may be increased by phenothiazines

Pregnancy Risk Factor C

Lactation Enters breast milk/contraindicated (AAP rates "of concern")

Nursing Implications Watch for hypotension when administering I.M. or I.V.

Metaproterenol

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 5874-97-5

U.S. Brand Names Alupent®

Synonyms Metaproterenol Sulfate; Orciprenaline Sulfate

Use Bronchodilator in reversible airway obstruction due to asthma or COPD; because of its delayed onset of action (one hour) and prolonged effect (4 or more hours), this may not be the drug of choice for assessing response to a bronchodilator

Mechanism of Action Relaxes bronchial smooth muscle by action on β₂-receptors with very little effect on heart rate

Adverse Reactions

Cardiovascular: **Tachycardia**, palpitations, hypertension, flushing, shortened P-R segment, lengthened QT segment, cardiac arrhythmias, chest pain, sinus tachycardia

Central nervous system: Dizziness, headache, **nervousness**, CNS stimulation, hyperactivity, insomnia, visual and gustatory hallucinations, mania

Dermatologic: Maculopapular rash, angioedema

Endocrine & metabolic: Hypokalemia, hyperglycemia

Gastrointestinal: GI upset

Neuromuscular & skeletal: **Tremors**

Signs and Symptoms of Overdose Angina, cardiac arrhythmias, dry mouth, insomnia, tremors, tachycardia, hypertension, seizures. Hypokalemia also may occur. Cardiac arrest and death may be associated with abuse of beta-agonist bronchodilators.

Pharmacodynamics/Kinetics

Onset of action: Bronchodilation: Oral: ~15 minutes; Inhalation: ~60 seconds

Peak effect: Oral: ~1 hour

Duration: ~1-5 hours

Dosage

Oral:

Children:

<2 years: 0.4 mg/kg/dose given 3-4 times/day; in infants, the dose can be given every 8-12 hours

2-6 years: 1-2.6 mg/kg/day divided every 6 hours

6-9 years: 10 mg/dose 3-4 times/day

Children >9 years and Adults: 20 mg 3-4 times/day

Elderly: Initial: 10 mg 3-4 times/day, increasing as necessary up to 20 mg 3-4 times/day

Inhalation: Children >12 years and Adults: 2-3 inhalations every 3-4 hours, up to 12 inhalations in 24 hours

Nebulizer:

Infants and Children: 0.01-0.02 mL/kg of 5% solution; minimum dose: 0.1 mL; maximum dose: 0.3 mL diluted in 2-3 mL normal saline every 4-6 hours (may be given more frequently according to need)

Adolescents and Adults: 5-20 breaths of full strength 5% metaproterenol or 0.2 to 0.3 mL 5% metaproterenol in 2.5-3 mL normal saline until nebulized every 4-6 hours (can be given more frequently according to need)

Stability Store in tight, light-resistant container

Monitoring Parameters Assess lung sounds, heart rate, and blood pressure before administration and during peak of medication; observe patient for wheezing after administration, if this occurs, call physician; monitor respiratory rate, arterial or capillary blood gases if applicable; FEV₁, peak flow, and/or other pulmonary function tests; CNS stimulation; serum glucose, serum potassium

Administration Inhalation: Do not use solutions for nebulization if they are brown or contain a precipitate. Shake inhaler well before using.

Oral: Administer around-the-clock to promote less variation in peak and trough serum levels

Contraindications Hypersensitivity to metaproterenol or any component of the formulation; pre-existing cardiac arrhythmias associated with tachycardia

Warnings

Optimize anti-inflammatory treatment before initiating maintenance treatment with metaproterenol. Do not use as a component of chronic therapy without an anti-inflammatory agent. Only the mildest form of asthma (Step 1 and/or exercise-induced) would not require concurrent use based upon asthma guidelines. Patient must be instructed to seek medical attention in cases where acute symptoms are not relieved or a previous level of response is diminished. The need to increase frequency of use may indicate deterioration of asthma, and treatment must not be delayed.

Use caution in patients with cardiovascular disease (arrhythmia or hypertension or CHF), convulsive disorders, diabetes, glaucoma, hyperthyroidism, or hypokalemia. Beta agonists may cause elevation in blood pressure, heart rate, and result in CNS stimulation/excitation. Beta₂ agonists may increase risk of arrhythmia, increase serum glucose, or decrease serum potassium.

Do not exceed recommended dose; serious adverse events including fatalities, have been associated with excessive use of inhaled sympathomimetics. Rarely, paradoxical bronchospasm may occur with use of inhaled bronchodilating agents; this should be distinguished from inadequate response. All patients should utilize a spacer device when using a metered-dose inhaler; additionally, a face mask should be used in children <4 years of age.

Metaproterenol has more beta₁ activity than beta₂-selective agents such as albuterol and, therefore, may no longer be the beta agonist of first choice. Oral use should be avoided due to the increased incidence of adverse effects.

Dosage Forms

Aerosol for oral inhalation, as sulfate (Alupent®): 0.65 mg/inhalation (14 g) [200 doses]

Solution for nebulization, as sulfate [preservative free]: 0.4% [4 mg/mL] (2.5 mL); 0.6% [6 mg/mL] (2.5 mL)

Syrup, as sulfate: 10 mg/5 mL (480 mL) [may contain sodium benzoate]

Tablet, as sulfate: 10 mg, 20 mg

Overdosage/Treatment Beta-adrenergic stimulation can cause increased heart rate, decreased blood pressure, and CNS stimulation; heart rate can be treated with beta-blockers; decreased blood pressure can be treated with pure beta-adrenergic agents; diazepam 0.07 mg/kg or lorazepam can be used for excitation, seizures

Test Interactions ↑ potassium (S)

Drug Interactions Beta-adrenergic blockers (eg, propranolol) antagonize metaproterenol's effects; avoid concurrent use.

Inhaled ipratropium may increase duration of bronchodilation.

MAO inhibitors may increase side effects; monitor heart rate and blood pressure.

TCAs may increase side effects; monitor heart rate and blood pressure. Sympathomimetics may increase side effects; monitor heart rate and blood pressure.

Halothane may increase risk of malignant arrhythmias; avoid concurrent use.

Pregnancy Risk Factor C

Pregnancy Implications No data on crossing the placenta. Reported association with polydactyly in 1 study; may be secondary to severe maternal disease or chance.

Lactation Excretion in breast milk unknown

Additional Information Because of its delayed onset of action (1 hour) and prolonged effect (4 or more hours), this may not be the drug of choice for assessing response to a bronchodilator.

Metaxalone

Pronunciation (me TAKS a lone)

CAS Number 1665-48-1

U.S. Brand Names Skelaxin®

Impairment Potential Yes

Use Relief of discomfort associated with acute, painful musculoskeletal conditions

Mechanism of Action Does not have a direct effect on skeletal muscle; most of its therapeutic effect comes from actions on the central nervous system

Adverse Reactions

Frequency not defined.

Central nervous system: Paradoxical stimulation, headache, drowsiness, dizziness, irritability

Dermatologic: Allergic dermatitis

Gastrointestinal: Nausea, vomiting, stomach cramps

Hematologic: Leukopenia, hemolytic anemia

Hepatic: Hepatotoxicity

Miscellaneous: Anaphylaxis

Signs and Symptoms of Overdose Mydriasis, muscle rigidity, CNS depression

Pharmacodynamics/Kinetics

Onset of action: ~1 hour
 Duration: ~4-6 hours
 Metabolism: Hepatic
 Bioavailability: Not established; food may increase
 Half-life elimination: 9.2 hours
 Time to peak: T_{max} : 3 hours
 Excretion: Urine (as metabolites)

Dosage Children > 12 years and Adults: Oral: 800 mg 3-4 times/day

Administration May be administered with or without food. However, serum concentrations may be increased when administered with food; clinical significance has not been established. Patients should be monitored.

Contraindications Hypersensitivity to metaxalone or any component of the formulation; impaired hepatic or renal function, history of drug-induced hemolytic anemias or other anemias

Warnings Use with caution in patients with impaired hepatic function

Dosage Forms [DSC] = Discontinued product

Tablet: 400 mg [DSC], 800 mg

Reference Range Mean peak serum metaxalone concentration (3.3 hours) after a 400 mg dose is about 856 mcg/L

Overdosage/Treatment

Decontamination: Lavage/activated charcoal with 3 hours of ingestion
 Supportive care is mainstay of treatment

Test Interactions False-positive Benedict's test for urine glucose

Drug Interactions Increased effect of alcohol, CNS depressants

Pregnancy Risk Factor C

Pregnancy Implications Does not appear to be embryotoxic

Nursing Implications Raise bed rails, institute safety measures, assist with ambulation

Nirog RS, Kandikere VN, Shukla M, et al, "Quantification of Metaxalone in Human Plasma by Liquid Chromatography Coupled to Tandem Mass Spectrometry," *J Anal Tox*, 2006, 30:245-51.

Metformin

CAS Number 657-24-9

U.S. Brand Names Glucophage® XR; Glucophage®; Riomet™

Synonyms Metformin Hydrochloride

Use Management of type 2 diabetes mellitus (noninsulin dependent, NIDDM) as monotherapy when hyperglycemia cannot be managed on diet alone. May be used concomitantly with a sulfonylurea or insulin to improve glycemic control.

Unlabeled/Investigational Use Treatment of HIV lipodystrophy syndrome

Mechanism of Action Unclear, requires some endogenous insulin to act as antidiabetic

Adverse Reactions

Cardiovascular: Vasculitis
 Dermatologic: Cutaneous vasculitis
 Endocrine & metabolic: Lactic acidosis, hyponatremia, hypoglycemia, acidosis, hyperinsulinemia, vitamin B₁₂ deficiency
 Gastrointestinal: **Diarrhea, anorexia, nausea, vomiting, constipation, heartburn, epigastric fullness, metallic taste, pancreatitis**
 Hematologic: Megaloblastic anemia, porphyrogenic, hemolytic anemia
 Hepatic: Hepatitis, jaundice
 Neuromuscular & skeletal: Fasciculations
 Respiratory: Pulmonary vasculitis
 Miscellaneous: Diaphoresis, hypersensitivity pneumonitis

Admission Criteria/Prognosis

Admit any ingestion > 1700 mg.

Pharmacodynamics/Kinetics

Onset of action: Within days; maximum effects up to 2 weeks
 Distribution: V_d : 654 ± 358 L
 Protein binding: Negligible
 Bioavailability: Absolute: Fasting: 50% to 60%
 Half-life elimination, plasma: 6.2 hours
 Excretion: Urine (90% as unchanged drug)

Dosage Note: Allow 1-2 weeks between dose titrations: Generally, clinically significant responses are not seen at doses < 1500 mg daily; however, a lower recommended starting dose and gradual increased dosage is recommended to minimize gastrointestinal symptoms

Children 10-16 years: Management of type 2 diabetes mellitus: Oral (500 mg tablet or oral solution): Initial: 500 mg twice daily (given with the morning and evening meals); increases in daily dosage should be made in increments of 500 mg at weekly intervals, given in divided doses, up to a maximum of 2000 mg/day

Adults ≥ 17 years: Management of type 2 diabetes mellitus: Oral: Immediate release tablet or oral solution: Initial: 500 mg twice daily (give with the morning and evening meals) or 850 mg once daily; increase dosage incrementally.

Incremental dosing recommendations based on dosage form:

500 mg tablet: One tablet/day at weekly intervals

850 mg tablet: One tablet/day every other week

Oral solution: 500 mg twice daily every other week

Doses of up to 2000 mg/day may be given twice daily. If a dose > 2000 mg/day is required, it may be better tolerated in three divided doses. Maximum recommended dose 2550 mg/day.

Extended release tablet: Initial: 500 mg once daily (with the evening meal); dosage may be increased by 500 mg weekly; maximum dose: 2000 mg once daily. If glycemic control is not achieved at maximum dose, may divide dose to 1000 mg twice daily. If doses > 2000 mg/day are needed, switch to regular release tablets and titrate to maximum dose of 2550 mg/day.

Elderly: The initial and maintenance dosing should be conservative, due to the potential for decreased renal function. Generally, elderly patients should not be titrated to the maximum dose of metformin. Do not use in patients ≥ 80 years of age unless normal renal function has been established.

Transfer from other antidiabetic agents: No transition period is generally necessary except when transferring from chlorpropamide. When transferring from chlorpropamide, care should be exercised during the first 2 weeks because of the prolonged retention of chlorpropamide in the body, leading to overlapping drug effects and possible hypoglycemia.

Concomitant metformin and oral sulfonylurea therapy: If patients have not responded to 4 weeks of the maximum dose of metformin monotherapy, consider a gradual addition of an oral sulfonylurea, even if prior primary or secondary failure to a sulfonylurea has occurred. Continue metformin at the maximum dose.

Failed sulfonylurea therapy: Patients with prior failure on glyburide may be treated by gradual addition of metformin. Initiate with glyburide 20 mg and metformin 500 mg daily. Metformin dosage may be increased by 500 mg/day at weekly intervals, up to a maximum of 2500 mg/day (dosage of glyburide maintained at 20 mg/day).

Concomitant metformin and insulin therapy: Initial: 500 mg metformin once daily, continue current insulin dose; increase by 500 mg metformin weekly until adequate glycemic control is achieved

Maximum dose: 2500 mg metformin; 2000 mg metformin extended release

Decrease insulin dose 10% to 25% when FPG < 120 mg/dL; monitor and make further adjustments as needed

Dosing adjustment/comments in renal impairment: The plasma and blood half-life of metformin is prolonged and the renal clearance is decreased in proportion to the decrease in creatinine clearance. Per the manufacturer, metformin is contraindicated in the presence of renal dysfunction defined as a serum creatinine > 1.5 mg/dL in males, or > 1.4 mg/dL in females and in patients with abnormal clearance. Clinically, it has been recommended that metformin be avoided in patients with Cl_{cr} < 60-70 mL/minute (DeFronzo, 1999).

Dosing adjustment in hepatic impairment: Avoid metformin; liver disease is a risk factor for the development of lactic acidosis during metformin therapy.

Monitoring Parameters Urine for glucose and ketones, fasting blood glucose, and hemoglobin A_{1c}. Initial and periodic monitoring of hematologic parameters (eg, hemoglobin/hematocrit and red blood cell indices) and renal function should be performed, at least annually. Check vitamin B₁₂ and folate if anemia is present.

Administration Extended release dosage form should be swallowed whole; do not crush, break, or chew

Contraindications Hypersensitivity to metformin or any component of the formulation; renal disease or renal dysfunction (serum creatinine ≥ 1.5 mg/dL in males or ≥ 1.4 mg/dL in females or abnormal creatinine clearance from any cause, including shock, acute myocardial infarction, or septicemia); congestive heart failure requiring pharmacological management; acute or chronic metabolic acidosis with or without coma (including diabetic ketoacidosis)

Note: Temporarily discontinue in patients undergoing radiologic studies in which intravascular iodinated contrast materials are utilized.

Warnings [U.S. Boxed Warning]: Lactic acidosis is a rare, but potentially severe consequence of therapy with metformin. Lactic acidosis should be suspected in any diabetic patient receiving metformin who has evidence of acidosis when evidence of ketoacidosis is lacking. Discontinue metformin in clinical situations predisposing to hypoxemia, including conditions such as cardiovascular collapse, respiratory failure, acute myocardial infarction, acute congestive heart failure, and septicemia.

Metformin is substantially excreted by the kidney. The risk of accumulation and lactic acidosis increases with the degree of impairment of renal function. Patients with renal function below the limit of normal for their age should not receive metformin. In elderly patients, renal function should be monitored regularly; should not be used in any patient ≥ 80 years of age unless measurement of creatinine clearance verifies normal renal function. Use of concomitant medications that may affect renal function (ie, affect tubular secretion) may also affect metformin

disposition. Metformin should be suspended in patients with dehydration and/or prerenal azotemia. Therapy should be suspended for any surgical procedures (resume only after normal intake resumed and normal renal function is verified). Metformin should also be temporarily discontinued for 48 hours in patients undergoing radiologic studies involving the intravascular administration of iodinated contrast materials (potential for acute alteration in renal function).

Avoid use in patients with impaired liver function. Patient must be instructed to avoid excessive acute or chronic ethanol use. Administration of oral antidiabetic drugs has been reported to be associated with increased cardiovascular mortality; metformin does not appear to share this risk. Safety and efficacy of metformin have been established for use in children ≥ 10 years of age; the extended release preparation is for use in patients ≥ 17 years of age.

Dosage Forms

Solution, oral, as hydrochloride:
Riomet™: 100 mg/mL (118 mL, 473 mL) [contains saccharin; cherry flavor]

Tablet, as hydrochloride: 500 mg, 850 mg, 1000 mg

Glucophage®: 500 mg, 850 mg, 1000 mg

Tablet, extended release, as hydrochloride: 500 mg, 750 mg

Fortamet®: 500 mg, 1000 mg

Glucophage® XR: 500 mg, 750 mg

Glumetza™: 500 mg

Reference Range

Therapeutic serum level: 1-2 mg/L

Peak plasma metformin level after a 1.5 g dose: ~ 3.1 mg/L; levels > 45 mg/L associated with toxicity

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Glucose for hypoglycemia; sodium bicarbonate for severe acidosis

Enhancement of elimination: Removed by hemodialysis; in presence of lactic acidosis, use nonlactate dialysate; hemodialysis with bicarbonate as the buffer can be used.

In one case report, continuous venovenous hemodialysis was performed with a blood flow of 180 mL/minute and dialysate flow of 2.5 L/hour. A Multiflow 60 kidney (Cobe) on a Prisma (Cobe) continuous renal replacement therapy machine was used. By continuous venovenous hemodialysis, an absolute clearance of 50.4 mL/minute was obtained in this case report.

Antidote(s)

- Dextrose [ANTIDOTE]
- Glucagon [ANTIDOTE]
- Sodium Bicarbonate [ANTIDOTE]

Drug Interactions Drugs which tend to produce hyperglycemia (eg, diuretics, corticosteroids, phenothiazines, thyroid products, estrogens, oral contraceptives, phenytoin, nicotinic acid, sympathomimetics, calcium channel blocking drugs, isoniazid) may lead to a loss of glycemic control

Cationic drugs (eg, amiloride, digoxin, morphine, procainamide, quinidine, quinine, ranitidine, triamterene, trimethoprim, and vancomycin) which are eliminated by renal tubular secretion could have the potential for interaction with metformin by competing for common renal tubular transport systems

Cimetidine increases (by 60%) peak metformin plasma and whole blood concentrations

Contrast agents: May increase the risk of metformin-induced lactic acidosis. Discontinue metformin prior to exposure and withhold for 48 hours.

Furosemide increased the metformin plasma and blood C_{max} without altering metformin renal clearance in a single dose study

Pregnancy Risk Factor B

Pregnancy Implications Abnormal blood glucose levels are associated with a higher incidence of congenital abnormalities. Insulin is the drug of choice for the control of diabetes mellitus during pregnancy.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Related to withdrawn phenformin; average estimated incidence of lactic acidosis is 0.03 cases per 1000 patient-years; long-term therapy is associated with decreased intestinal absorption of vitamin B₁₂ and folate

Methadone

Related Information

- Drugs Used in Addiction Treatment

CAS Number 1095-90-5; 125-56-4; 297-88-1; 76-99-3

U.S. Brand Names Dolophine®; Methadone Intenso!™; Methadose®

Synonyms Methadone Hydrochloride

Impairment Potential Yes. No apparent impairment in complex tasks noted in patients on daily methadone maintenance (60-100 mg). (Moskowitz H and Robinson CD, "Methadone Maintenance and Tracking Performance," *Alcohol Drugs and Traffic Safety*, Kaye S and Meier GW, eds, Univ Puerto Rico, 1985, 995-1004.)

Use Management of severe pain; detoxification and maintenance treatment of narcotic addiction (must be part of an FDA-approved program)

Mechanism of Action Binds to opiate receptors in the CNS, causing inhibition of ascending pain pathways, altering the perception of and response to pain; produces generalized CNS depression

Adverse Reactions

Cardiovascular: Hypotension, bradycardia, peripheral vasodilation, palpitations, sinus bradycardia, torsade de pointes (methadone dose: > 400 mg/day)

Central nervous system (toxicity may be delayed after 6 hours): CNS depression, increased intracranial pressure, agitation, psychosis, drowsiness, dizziness, sedation (marked sedation seen after repeated administration), tiredness, nervousness, headache, restlessness, malaise, confusion, hallucinations, paradoxical CNS stimulation, choreic movements

Dermatologic: Skin rash, hives, pruritus, angioedema, urticaria, purpura; bullous eruptions, exanthem

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone, hypoadrenalism

Gastrointestinal: Nausea, vomiting, constipation, xerostomia, anorexia, stomach cramps, paralytic ileus, biliary tract spasm

Genitourinary: Decreased urination, ureteral spasm, urinary tract spasm

Local: Pain at injection site

Neuromuscular & skeletal: Rhabdomyolysis, weakness

Ocular: Miosis

Respiratory: Apnea, respiratory depression, dyspnea

Miscellaneous: Histamine release, physical and psychological dependence with prolonged use

Signs and Symptoms of Overdose Coma, ejaculatory disturbances, impotence, pulmonary edema, respiratory depression

Admission Criteria/Prognosis

Admit all pediatric methadone overdoses.

Pharmacodynamics/Kinetics

Oral:

Onset of action: Within 30-60 minutes; Duration: 6-8 hours; with repeated doses, increases to 22-48 hours

Parenteral:

Onset of action: Within 10-20 minutes; Peak effect: Within 1-2 hours

Enhanced analgesia has been seen in elderly patients on therapeutic doses of narcotics; duration of action may be increased.

Absorption: Absorbed well from gastrointestinal tract

Distribution: V_d : 3.8 L/kg; distributes widely to tissues

Protein binding: 80% to 89%

Metabolism: Liver metabolism (N-demethylation)

Bioavailability, oral: 92%

Half-life: 15-25 hours, half-life may be prolonged with alkaline pH

Elimination: Urine ($< 10\%$ as unchanged drug); increased renal excretion with urine pH < 6 ; clearance: 0.08 L/hour/kg; oral clearance following one dose is 6.9 L/hour in nondrug users and 3.2 L/hour in drug addicts

Toxicodynamics/Kinetics

Oral:

Onset of action: Within 30-60 minutes; Duration: 6-8 hours; with repeated doses, increases to 22-48 hours

Parenteral:

Onset of action: Within 10-20 minutes; Peak effect: Within 1-2 hours

Enhanced analgesia has been seen in elderly patients on therapeutic doses of narcotics; duration of action may be increased.

Absorption: Absorbed well from gastrointestinal tract

Distribution: V_d : 3.8 L/kg; distributes widely to tissues

Protein binding: 80% to 89%

Metabolism: Liver metabolism (N-demethylation)

Bioavailability, oral: 92%

Half-life: 15-25 hours, half-life may be prolonged with alkaline pH

Elimination: Urine (<10% as unchanged drug); increased renal excretion with urine pH <6; clearance: 0.08 L/hour/kg; oral clearance following one dose is 6.9 L/hour in nondrug users and 3.2 L/hour in drug addicts

Dosage Note: These are guidelines and do not represent the maximum doses that may be required in all patients. Methadone accumulates with repeated doses and dosage may need reduction after 3-5 days to prevent CNS depressant effects. Some patients may benefit from every 8-12 hour dosing interval for chronic pain management. Doses should be titrated to appropriate effects.

Children:

Pain (analgesia):

Oral (unlabeled use): Initial: 0.1-0.2 mg/kg 4-8 hours initially for 2-3 doses, then every 6-12 hours as needed. Dosing interval may range from 4-12 hours during initial therapy; decrease in dose or frequency may be required (~ days 2-5) due to accumulation with repeated doses (maximum dose: 5-10 mg)

I.V. (unlabeled use): 0.1 mg/kg every 4-8 hours initially for 2-3 doses, then every 6-12 hours as needed. Dosing interval may range from 4-12 hours during initial therapy; decrease in dose or frequency may be required (~ days 2-5) due to accumulation with repeated doses (maximum dose: 5-8 mg)

iatrogenic narcotic dependency (unlabeled): Oral: General guidelines: Initial: 0.05-0.1 mg/kg/dose every 6 hours; increase by 0.05 mg/kg/dose until withdrawal symptoms are controlled; after 24-48 hours, the dosing interval can be lengthened to every 12-24 hours; to taper dose, wean by 0.05 mg/kg/day; if withdrawal symptoms recur, taper at a slower rate

Adults:

Pain (analgesia):

Oral: Initial: 5-10 mg; dosing interval may range from 4-12 hours during initial therapy; decrease in dose or frequency may be required (~days 2-5) due to accumulation with repeated doses

Manufacturer's labeling: 2.5-10 mg every 3-4 hours as needed

I.V.: Manufacturer's labeling: Initial: 2.5-10 mg every 8-12 hours in opioid-naïve patients; titrate slowly to effect; may also be administered by SubQ or I.M. injection

Conversion from oral to parenteral dose: Initial dose: Oral: parenteral: 2:1 ratio

Detoxification: Oral: 15-40 mg/day

Maintenance treatment of opiate dependence: Oral: 20-120 mg/day

Dosage adjustment in renal impairment: $Cl_{cr} < 10$ mL/minute: Administer 50% to 75% of normal dose

Dosage adjustment in hepatic impairment: Avoid in severe liver disease

Stability Highly incompatible with all other I.V. agents when mixed together

Monitoring Parameters Pain relief, respiratory and mental status, blood pressure

Administration Oral dose for detoxification and maintenance may be administered in fruit juice or water.

Contraindications Hypersensitivity to methadone or any component of the formulation; respiratory depression (in the absence of resuscitative equipment or in an unmonitored setting); acute bronchial asthma or hypercarbia; pregnancy (prolonged use or high doses near term)

Warnings

An opioid-containing analgesic regimen should be tailored to each patient's needs and based upon the type of pain being treated (acute versus chronic), the route of administration, degree of tolerance for opioids (naïve versus chronic user), age, weight, and medical condition. The optimal analgesic dose varies widely among patients. Doses should be titrated to pain relief/prevention. Patients maintained on stable doses of methadone may need higher and/or more frequent doses in case of acute pain (eg, postoperative pain, physical trauma). Methadone is ineffective for the relief of anxiety.

May prolong the QT interval; use caution in patients at risk for QT prolongation, with medications known to prolong the QT interval, or history of conduction abnormalities. QT interval prolongation and torsade de pointes may be associated with doses >200 mg/day, but have also been observed with lower doses. May cause severe hypotension; use caution with severe volume depletion or other conditions which may compromise maintenance of normal blood pressure. Use caution with cardiovascular disease or patients predisposed to dysrhythmias.

May cause respiratory depression. Use caution in patients with respiratory disease or pre-existing respiratory conditions (eg, severe obesity, asthma, COPD, sleep apnea, CNS depression). Because the respiratory effects last longer than the analgesic effects, slow titration is required. Abrupt cessation may precipitate withdrawal symptoms.

May cause CNS depression, which may impair physical or mental abilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Effects

with other sedative drugs or ethanol may be potentiated. Use with caution in patients with depression or suicidal tendencies, or in patients with a history of drug abuse. Tolerance or psychological and physical dependence may occur with prolonged use.

Use with caution in patients with head injury or increased intracranial pressure. May obscure diagnosis or clinical course of patients with acute abdominal conditions. Elderly may be more susceptible to adverse effects (eg, CNS, respiratory, gastrointestinal). Decrease initial dose and use caution in the elderly or debilitated; with hyper/hypothyroidism, prostatic hypertrophy, or urethral stricture; or with severe renal or hepatic failure. Safety and efficacy have not been established in patients <18 years of age. Tablets contain excipients to deter use by injection.

[U.S. Boxed Warning]: When used for treatment of narcotic addiction: May only be dispensed by opioid treatment programs certified by the Substance Abuse and Mental Health Services Administration (SAMHSA) and certified by the designated state authority. Exceptions include inpatient treatment of other conditions and emergency period (not >3 days) while definitive substance abuse treatment is being sought.

Dosage Forms Injection, solution, as hydrochloride: 10 mg/mL (20 mL) Solution, oral, as hydrochloride: 5 mg/5 mL (500 mL); 10 mg/5 mL (500 mL) [contains alcohol 8%; citrus flavor]

Solution, oral concentrate, as hydrochloride: 10 mg/mL (946 mL)

Methadone IntensoTM: 10 mg/mL (30 mL)

Methadose[®]: 10 mg/mL (1000 mL) [cherry flavor]

Methadose[®]: 10 mg/mL (1000 mL) [dye free, sugar free, unflavored]

Tablet, as hydrochloride (Dolophine[®], Methadose[®]): 5 mg, 10 mg

Tablet, dispersible, as hydrochloride:

Methadose[®]: 40 mg

Methadone Diskets[®]: 40 mg [orange-pineapple flavor]

Reference Range

Therapeutic (pain control), serum: 0.1-0.4 mcg/mL (SI: 0.32-1.29 µmol/L); narcotic stabilization: 0.3-1.0 mcg/mL

Toxic: >2.0 mcg/mL (SI: >6.46 µmol/L)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at $\frac{2}{3}$ the response dose/hour) may be required; opioid-induced myoclonus may respond to dantrolene (50-150 mg/day)

Antidote(s)

- Nalmefene [ANTIDOTE]

- Naloxone [ANTIDOTE]

Diagnostic Procedures

- Methadone, Urine

Test Interactions ↑ thyroxine (S), aminotransferases (ALT, AST) (S); brompheniramine, diphenhydramine, or doxylamine may cause a false-positive urinary immunoassay for methadone; disopyramide can cross react with methadone urinary immunoassays

Drug Interactions **Substrate** of CYP2C9 (minor), 2C19 (minor), 2D6 (minor), 3A4 (major); **Inhibits** CYP2D6 (moderate), 3A4 (weak)

Agonist/antagonist analgesics (buprenorphine, butorphanol, nalbuphine, pentazocine): May decrease analgesic effect of methadone and precipitate withdrawal symptoms; use is not recommended.

Antiretroviral agents, NNRTI: May decrease levels of methadone, opioid withdrawal syndrome has been reported. Effect reported with efavirenz and nevirapine.

Antiretroviral agents, NRTI: Methadone may increase bioavailability and toxic effects of zidovudine. Methadone may decrease bioavailability of didanosine and stavudine.

Antiretroviral agent, PI: Ritonavir (and combinations) may decrease levels of methadone; withdrawal symptoms have inconsistently been observed, monitor.

CNS depressants (including but not limited to opioid analgesics, general anesthetics, sedatives, hypnotics, ethanol): May cause respiratory depression, hypotension, profound sedation, or coma.

CYP2D6 substrates: Methadone may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Methadone may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of methadone. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of methadone. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Desipramine: Levels of desipramine may be increased by methadone.

QT_c interval-prolonging agents (including but may not be limited to amitriptyline, astemizole, bepridil, disopyramide, erythromycin, haloperidol, imipramine, quinidine, pimozone, procainamide, sotalol, and thioridazine): Effect/toxicity increased; use with caution.

Ritonavir: May increase levels/effects of methadone shortly after initiation. May decrease levels/effects of methadone with continued dosing. Somatostatin: Therapeutic effect of methadone may be decreased; limited documentation; monitor

Zidovudine: serum concentrations may be increased by methadone; monitor

Pregnancy Risk Factor B/D (prolonged use or high doses at term)

Pregnancy Implications Crosses the placenta; neonatal respiratory depression

Lactation Amount of Methadone in breast milk is very low with mean relative infant dose as a percentage of maternal dose generally less than 3% (less than 0.1 mg daily). American Academy of pediatrics has deemed that methadone is compatible with breastfeeding

Nursing Implications Observe patient for excessive sedation, respiratory depression, implement safety measures, assist with ambulation

Additional Information Not detected as an opioid in most urine immunoassays; although narcotic-induced respiratory abnormalities with methadone are not as severe as with heroin, as little as 80 mg can cause pulmonary edema. In pediatric methadone exposures, 5 mg can cause coma, while 10 mg may be fatal. Pupillary signs (miosis) correlate well with plasma methadone levels in acute pediatric exposures. Ingestion of a single daily adult methadone maintenance dose has resulted in fatalities in children <6 years of age.

According to the Drug Abuse Warning Network, in 2004.

- An estimated 31,874 Emergency Department (ED) visits involved Methadone.

- An estimate 1,207 ED visits due to methadone involved a suicide attempt.

Methamphetamine

Related Information

- Highlights of Recent Reports (2006) on Substance Abuse and Mental Health

CAS Number 51-57-0; 537-46-2

U.S. Brand Names Desoxyn®

Synonyms Desoxyephedrine Hydrochloride; Methamphetamine Hydrochloride

Impairment Potential Yes. Blood methamphetamine levels >0.1 mg/L have been associated with driving impairment (typical driving behaviors noted include speeding, weaving, drifting out of lane of travel, and erratic driving). (Logan BK, "Methamphetamine and Driving Impairment," *J Forensic Sci*, 1996, 41(3):457-64.)

Use Treatment of attention-deficit/hyperactivity disorder (ADHD); exogenous obesity (short-term adjunct)

Unlabeled/Investigational Use Narcolepsy

Mechanism of Action A sympathomimetic amine related to ephedrine and amphetamine

Adverse Reactions

Cardiovascular: Irregular heartbeat, cardiac arrhythmia, hypertension, chest pain, dilated cardiomyopathy, vasculitis, sinus bradycardia, cardiomegaly, angina, sinus tachycardia, tachycardia (supraventricular), cerebral edema, myocardial infarction, Raynaud's phenomenon

Central nervous system: False feeling of well being, nervousness, restlessness, insomnia, mood or mental changes, dizziness, light-headedness, headache, visual hallucinations, delusional perceptions, CNS stimulation (severe), hyperthermia, Tourette's syndrome, psychosis, irritability, seizures, paranoia, agitation, extrapyramidal reaction, bilateral putaminal involvement

Dermatologic: Skin rash, hives, licheniform eruptions, urticaria

Endocrine & metabolic: Changes in libido, growth suppression, hyponatremia, syndrome of inappropriate antidiuretic hormone

Gastrointestinal: Diarrhea, nausea, vomiting, stomach cramps, constipation, anorexia, weight loss, xerostomia, colonic ischemia, bitter dysgeusia

Hepatic: Hepatitis, jaundice, hepatomegaly, hepatic failure, centrilobular necrosis

Neuromuscular & skeletal: Tremor, choreoathetoid movements

Ocular: Blurred vision, mydriasis, cortical blindness

Miscellaneous: Tolerance and withdrawal with prolonged use, diaphoresis (increased), "washed-out" syndrome, fixed drug eruption, Pott puffy tumor (PPT)

Signs and Symptoms of Overdose Alopecia, confusion, delirium, feces discoloration (black), gynecomastia, hypertension, insomnia, mania, myoclonus, myoglobinuria, periarteritis nodosa, pulmonary edema, respiratory alkalosis, rhabdomyolysis, rigors, tachycardia or reflex bradycardia, tachypnea, tremors

Pharmacodynamics/Kinetics

Duration of action: 6-12 hours

Absorption: Rapid from GI tract

Metabolism: In liver to amphetamine (4% to 7%) and other metabolites

Half-life: 12-34 hours

Elimination: Renally

Dosage

Oral:

Children >6 years and Adults: ADHD: 2.5-5 mg 1-2 times/day; may increase by 5 mg increments at weekly intervals until optimum response is achieved, usually 20-25 mg/day

Children >12 years and Adults: Exogenous obesity: 5 mg 30 minutes before each meal; treatment duration should not exceed a few weeks

Monitoring Parameters Heart rate, respiratory rate, blood pressure, and CNS activity

Contraindications Hypersensitivity to methamphetamine, any component of the formulation, or idiosyncrasy to amphetamines or other sympathomimetic amines; patients with advanced arteriosclerosis, symptomatic cardiovascular disease, moderate to severe hypertension (stage II or III), hyperthyroidism, glaucoma, agitated states; patients with a history of drug abuse; use during or within 14 days following MAO inhibitor therapy; stimulant medications are contraindicated for use in children with attention-deficit/hyperactivity disorders and concomitant Tourette's syndrome or tics

Warnings

[U.S. Boxed Warning]: Dexamphetamine has been associated with serious cardiac cardiovascular events including sudden death in patients with pre-existing structural cardiac abnormalities or other serious heart problems. Using CNS stimulant treatment at usual doses in children and adolescents with serious heart problems and structural cardiac abnormalities has been associated with sudden death. In adults, stimulant use has been associated with sudden deaths, stroke, and myocardial infarction. Stimulant products should be avoided in the patients with known serious structural cardiac abnormalities, cardiomyopathy, serious heart rhythm abnormalities, or other serious cardiac problems that could increase the risk of sudden death that these conditions alone carry. Caution should be used in patients with hypertension and other cardiovascular conditions that might be exacerbated by increases in blood pressure or heart rate. Use of stimulants can cause an increase in blood pressure (average 2-4 mm Hg) and increases in heart rate (average 3-6 bpm), although some patients may have larger than average increases.

Use with caution in patients with bipolar disorder, cardiovascular disease, diabetes, seizure disorders, insomnia, porphyria, mild hypertension (stage I), or history of substance abuse. May exacerbate symptoms of behavior and thought disorder in psychotic patients. Stimulants may unmask tics in individuals with coexisting Tourette's syndrome. Potential for drug dependency exists - avoid abrupt discontinuation in patients who have received for prolonged periods. **[U.S. Boxed Warning]: Use in weight reduction programs only when alternative therapy has been ineffective; due to high potential for abuse and/or nontherapeutic use should be prescribed/dispensed sparingly.** Products may contain tartrazine - use with caution in potentially sensitive individuals. Stimulant use in children has been associated with growth suppression.

Dosage Forms Tablet, as hydrochloride: 5 mg

Reference Range

Therapeutic: Serum: 20-30 ng/mL

Psychosis can develop at serum levels of 150-500 ng/mL; serum levels >230 ng/mL can be fatal.

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdose/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Methamphetamine psychosis:

Haloperidol: I.V.: 5-10 mg

Diazepam: I.V.: 5-10 mg

Droperidol: I.M.: 2.5-5 mg can be used for psychosis if I.V. access is not available

Hypertension that is not responsive to sedation can be treated with phentolamine or nitroprusside

Enhancement of elimination: Multiple dosing of activated charcoal may be useful. While acid diuresis can increase excretion, it is not recommended due to renal effects.

Diagnostic Procedures

- Methamphetamines, Urine

Test Interactions A labetalol metabolite (3-amino-1-phenylbutane or APB) may cause a false-positive result with amphetamine/methamphetamine by thin-layer chromatography or immunoassay; false-positive by immunoassay may be seen with ranitidine, phenylpropranolamine, brompheniramine, chlorpromazine, fluspirilene or pipothiazine coingestion; alum (25 g/L) may elicit a false-negative urinary assay for methamphetamine; urine will be acidic in these cases. May interfere with the TSH assay resulting in falsely low TSH levels.

Drug Interactions **Substrate** of CYP2D6 (major)

Alkalinizers: Large doses of sodium bicarbonate or other alkalinizers may increase renal tubular reabsorption (decreased elimination) and enhance the effect of amphetamine; includes potassium or sodium citrate and acetate

CYP2D6 inhibitors: May increase the levels/effects of methamphetamine.

Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole. False neurotransmitters (eg, guanethidine, methylodopa): Amphetamines may inhibit the antihypertensive response to these agents; monitor.

MAO inhibitors: Severe hypertensive episodes have occurred with amphetamine when used in patients receiving MAO inhibitors; concurrent use or use within 14 days is contraindicated

Sibutramine: Concurrent use of sibutramine and amphetamines may cause severe hypertension and tachycardia; use is contraindicated (benzphetamine)

SSRIs: Amphetamines may increase the potential for serotonin syndrome when used concurrently with selective serotonin reuptake inhibitors (including fluoxetine, fluvoxamine, paroxetine, and sertraline)

Tricyclic antidepressants: Concurrent use of amphetamines with TCAs may result in hypertension and CNS stimulation; avoid this combination

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta; can cause low birth weight/premature birth; reportedly associated with increased obstetric complications and maternal death; preterm birth, intrauterine growth retardation, placental abruption

Lactation Enters breast milk/contraindicated

Additional Information Illicit methamphetamine may contain lead; alkalinizing urine can result in longer methamphetamine half-life and elevated blood level; ephedrine is a precursor in the illicit manufacture of methamphetamine

Mid-Year 2000 Emergency Department Drug Abuse Warning Network (DAWN) data: **Note:** Methamphetamine/speed is sometimes used in combination with other drugs; therefore, one Emergency Department (ED) episode can include mentions of one or more drugs.

- In the first half of 2000, methamphetamine/speed was mentioned in 2% of all drug-related episodes. This number was 48% greater than in the first half of 1999, which had 4730 mentions. It is important to remember that national estimates of methamphetamine/speed mentions tend to fluctuate substantially from year to year.

- The estimated number of amphetamine mentions rose 32% from 5668 mentions in the first half of 1999 to 7510 mentions in the first half of 2000.

- Methamphetamine/speed mentions increased 48% nationwide between the first halves of 1999 and 2000 (4730 to 6980). Among the 5 metropolitan areas with the greatest number of methamphetamine/speed mentions, there were significant increases for this period in Seattle (80%), San Diego (71%), and Phoenix (67%). Methamphetamine/speed mentions were statistically unchanged for the same period in Los Angeles-Long Beach and San Francisco.

Methaqualone

Pronunciation (meth A kwa lone)

Related Information

● Donor Victims of Poisoning in Whom Transplantation of Organs Occurred

CAS Number 340-56-7; 72-44-6

Synonyms Methaqualone Hydrochloride

Impairment Potential Yes. Plasma methaqualone levels >2 mg/L have been associated with erratic driving. (Baselt RC and Cravey RH, *Disposition of Toxic Drugs and Chemicals in Man*, 4th ed, Foster City, CA: Chemical Toxicology Institute, 1995, 484.)

Use Europeans use for insomnia; taken off the U.S. market in 1984

Mechanism of Action Nonbarbiturate hypnosedative

Adverse Reactions

Cardiovascular: Tachycardia, sinus tachycardia

Central nervous system: Euphoria, slurred speech, salivation, ataxia, electroencephalogram abnormalities

Dermatologic: Bullous lesions

Gastrointestinal: Vomiting, necrotizing cystitis

Neuromuscular & skeletal: Rhabdomyolysis

Ocular: Nystagmus

Renal: Hematuria

Respiratory: Aspiration

Signs and Symptoms of Overdose Apnea, AV block, coma, dyspnea, erythema multiforme, hematuria, hyperreflexia, hyperthermia, hypotension, myoclonus, respiratory depression, seizures, vision color changes (yellow tinge)

Pharmacodynamics/Kinetics

Absorption: Complete within 2 hours

Distribution: V_d : 2.4-6.4 L/kg

Protein binding: 70% to 90%

Metabolism: Hepatic

Half-life: 33-40 hours

Elimination: ~8% of the drug is normally excreted in 4 hours in a normal patient

Toxicodynamics/Kinetics

Absorption: Complete within 2 hours

Distribution: V_d : 2.4-6.4 L/kg

Protein binding: 70% to 90%

Metabolism: Hepatic

Half-life: 33-40 hours

Elimination: ~8% of the drug is normally excreted in 4 hours in a healthy person

Dosage Insomnia: 150-300 mg at night

Reference Range A 600 mg dose will yield a peak plasma level of 7 mg/L; plasma level of methaqualone >10 mg/L is consistent with toxicity

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Treat seizures with diazepam, phenobarbital, or phenytoin

Enhancement of elimination: Hemodialysis or resin hemoperfusion can enhance elimination; do not use forced saline diuresis; multiple dosing of activated charcoal may be effective; level >40 mg/mL is an indication for consideration of extracorporeal removal of this drug; clearance by hemodialysis is estimated to be 23 mL/minute; by charcoal hemoperfusion it is 137 mL/minute

Drug Interactions Enhances codeine analgesia

Pregnancy Risk Factor D

Additional Information Lethal dose: 8 g. Mandrax® also contains diphenhydramine.

Metharbital

CAS Number 50-11-3

Impairment Potential Yes

Use Control of grand mal, petit mal, myoclonic and mixed types of seizures

Adverse Reactions

Cardiovascular: Hypotension, circulatory collapse

Central nervous system: Drowsiness, paradoxical excitement, hyperkinetic activity, cognitive impairment, defects in general comprehension, short-term memory deficits, decreased attention span, ataxia

Dermatologic: Skin eruptions, skin rash, exfoliative dermatitis

Hematologic: Megaloblastic anemia

Hepatic: Hepatitis

Ocular: Vision color changes (yellow tinge), ptosis

Respiratory: Apnea (especially with rapid I.V. use), respiratory depression
Miscellaneous: Psychological and physical dependence

Toxicodynamics/Kinetics

Metabolism: Demethylated to barbital (active)
Elimination: Renal, 1% excreted unchanged; 9% excreted as barbital

Dosage Oral:

Children: 5-15 mg/kg/day or 50 mg 1-3 times/day
Adults: 100 mg 1-3 times/day, adjust dosage to obtain optimal effect

Reference Range Therapeutic, serum: 5-10 mcg/mL**Overdosage/Treatment**

Decontamination: Lavage (within 1 hour)/activated charcoal
Enhancement of elimination: Multiple dosing of activated charcoal may be helpful

Test Interactions ↑ alkaline phosphatase (S); ↓ calcium (S)**Pregnancy Risk Factor** D**Nursing Implications** Solution is slightly acidic**Additional Information** Faint, aromatic odor**Methimazole**

CAS Number 60-56-0

U.S. Brand Names Tapazole®

Synonyms Thiamazole

Use Palliative treatment of hyperthyroidism, to return the hyperthyroid patient to a normal metabolic state prior to thyroidectomy, and to control thyrotoxic crisis that may accompany thyroidectomy

Mechanism of Action A thiourea which inhibits the synthesis of thyroid hormones by blocking the oxidation of iodine in the thyroid gland, blocking iodine's ability to combine with tyrosine to form thyroxine and triiodothyronine (T₃), does not inactivate circulating T₄ and T₃

Adverse Reactions

Cardiovascular: Edema
Central nervous system: Headache, vertigo, drowsiness, CNS stimulation, depression
Dermatologic: Skin rash, urticaria, pruritus, erythema nodosum, skin pigmentation, exfoliative dermatitis, alopecia, cutaneous vasculitis
Endocrine & metabolic: Goiter
Gastrointestinal: Nausea, vomiting, stomach pain, abnormal taste, constipation, weight gain, salivary gland swelling
Hematologic: Leukopenia, agranulocytosis, granulocytopenia, thrombocytopenia, aplastic anemia, hypoprothrombinemia
Hepatic: Cholestatic jaundice, jaundice, hepatitis
Neuromuscular & skeletal: Arthralgia, paresthesia
Renal: Nephrotic syndrome, renal vasculitis
Respiratory: Pulmonary vasculitis
Miscellaneous: SLE-like syndrome, elevated antineutrophilic cytoplasmic antibodies (ANCA)

Pharmacodynamics/Kinetics

Onset of action: Antithyroid: Oral: 12-18 hours
Duration: 36-72 hours
Distribution: Concentrated in thyroid gland; crosses placenta; enters breast milk (1:1)
Protein binding, plasma: None
Metabolism: Hepatic
Bioavailability: 80% to 95%
Half-life elimination: 4-13 hours
Excretion: Urine (80%)

Dosage

Oral:

Children: Initial: 0.4 mg/kg/day in 3 divided doses; maintenance: 0.2 mg/kg/day in 3 divided doses up to 30 mg/24 hours maximum
Adults: Initial: 5 mg every 8 hours; maintenance dose: 5-15 mg/day up to 60 mg/day for severe hyperthyroidism
Adjust dosage as required to achieve and maintain serum T₃, T₄, and TSH levels in the normal range. An elevated T₃ may be the sole indicator of inadequate treatment. An elevated TSH indicates excessive antithyroid treatment.

Stability Protect from light

Monitoring Parameters Monitor for signs of hypothyroidism, hyperthyroidism, T₄, T₃; CBC with differential, liver function (baseline and as needed), serum thyroxine, free thyroxine index

Contraindications Hypersensitivity to methimazole or any component of the formulation; nursing mothers (per manufacturer; however, expert analysis and the AAP state this drug may be used with caution in nursing mothers); pregnancy

Warnings Use with extreme caution in patients receiving other drugs known to cause myelosuppression particularly agranulocytosis, patients >40 years of age; avoid doses > 40 mg/day (increased myelosuppression); may cause acneiform eruptions or worsen the condition of the thyroid

Dosage Forms Tablet: 5 mg, 10 mg, 20 mg

Tapazole® 5 mg, 10 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Recombinant human granulocyte-monocyte colony-stimulating factor (270 mcg SubQ/day combined with glucocorticosteroids and antibiotics) has been used successfully in order to treat methimazole agranulocytosis

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Drug Interactions Inhibits CYP1A2 (weak), 2A6 (weak), 2B6 (weak), 2C9 (weak), 2C19 (weak), 2D6 (moderate), 2E1 (weak), 3A4 (weak)
Beta-blockers: Methimazole may decrease beta-blocker clearance due to changes in thyroid function.

Digoxin: Methimazole may increase digoxin levels due to changes in thyroid function.

CYP2D6 substrates: Methimazole may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Methimazole may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

Theophylline: Methimazole may decrease theophylline clearance due to changes in thyroid function.

Warfarin: Anticoagulant effect of warfarin may be decreased.

Pregnancy Risk Factor D

Pregnancy Implications Hypothyroidism and congenital defects (rare) may occur.

Lactation Enters breast milk/contraindicated (AAP rates "compatible")

Methocarbamol

CAS Number 532-03-6

U.S. Brand Names Robaxin®

Use Treatment of muscle spasm associated with acute painful musculoskeletal conditions, supportive therapy in tetanus

Mechanism of Action Causes skeletal muscle relaxation by reducing the transmission of impulses from the spinal cord to skeletal muscle

Adverse Reactions

Frequency not defined.

Cardiovascular: Flushing of face, bradycardia, hypotension, syncope
Central nervous system: Drowsiness, dizziness, lightheadedness, convulsion, vertigo, headache, fever, amnesia, confusion, insomnia, sedation, coordination impaired (mild)

Dermatologic: Allergic dermatitis, urticaria, pruritus, rash, angioneurotic edema

Gastrointestinal: Nausea, vomiting, metallic taste, dyspepsia

Hematologic: Leukopenia

Hepatic: Jaundice

Local: Pain at injection site, thrombophlebitis

Ocular: Nystagmus, blurred vision, diplopia, conjunctivitis

Renal: Renal impairment

Respiratory: Nasal congestion

Miscellaneous: Allergic manifestations, anaphylactic reaction

Signs and Symptoms of Overdose Apnea, cardiac arrhythmias, coma, drowsiness, hypotension, nausea, urine discoloration (black; blue; brown; green), vomiting

Pharmacodynamics/Kinetics

Onset of action: Muscle relaxation: Oral: ~30 minutes

Protein binding: 46% to 50%

Metabolism: Hepatic via dealkylation and hydroxylation

Half-life elimination: 1-2 hours

Time to peak, serum: ~2 hours

Excretion: Urine (as metabolites)

Dosage Tetanus: I.V.:

Children: Recommended **only** for use in tetanus: 15 mg/kg/dose or 500 mg/m²/dose, may repeat every 6 hours if needed; maximum dose: 1.8 g/m²/day for 3 days only

Adults: Initial dose: 1-3 g; may repeat dose every 6 hours until oral dosing is possible; injection should not be used for more than 3 consecutive days

Muscle spasm: Children ≥16 years and Adults:

Oral: 1.5 g 4 times/day for 2-3 days (up to 8 g/day may be given in severe conditions), then decrease to 4-4.5 g/day in 3-6 divided doses I.M., I.V.: 1 g every 8 hours if oral not possible; injection should not be used for more than 3 consecutive days

Elderly: Muscle spasm: Oral: Initial: 500 mg 4 times/day; titrate to response

Dosing adjustment/comments in renal impairment: Do not administer parenteral formulation to patients with renal dysfunction.

Dosing adjustment in hepatic impairment: Specific dosing guidelines are not available; plasma protein binding and clearance are decreased; half-life is increased

Monitoring Parameters Cardiac/respiratory

Administration Injection: Maximum rate: 3 mL/minute; should not be used for more than 3 consecutive days; may be administered undiluted.

METHOHEXITAL

Monitor closely for extravasation. Administer I.V. while in recumbent position. Maintain position 15-30 minutes following infusion.

Tablet: May be crushed and mixed with food or liquid if needed. Avoid alcohol.

Contraindications Hypersensitivity to methocarbamol or any component of the formulation; renal impairment (injection formulation)

Warnings Oral: Use caution with renal or hepatic impairment.

Injection: Rate of injection should not exceed 3 mL/minute; solution is hypertonic; avoid extravasation. Use with caution in patients with a history of seizures. Use caution with hepatic impairment.

Dosage Forms Injection, solution: 100 mg/mL (10 mL) [in polyethylene glycol; vial stopper contains latex]

Tablet: 500 mg, 750 mg

Reference Range Peak serum level after 2 g: 25.8 mg/L; peak serum levels after 4 g: 41 mg/L; blood levels >320 mg/L have been associated with fatalities

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Following attempts to enhance drug elimination, hypotension should be treated with I.V. fluids and/or Trendelenburg positioning

Enhancement of elimination: Dialysis and hemoperfusion might be useful in reducing serum drug concentrations; patient should be observed for possible relapses due to incomplete gastric emptying

Test Interactions May cause color interference in certain screening tests for 5-HIAA using nitrosonaphthol reagent and in screening tests for urinary VMA using the Gitlow method.

Drug Interactions Increased effect/toxicity with CNS depressants; pyridostigmine (a single case of worsening myasthenia has been reported following methocarbamol administration)

Pregnancy Risk Factor C

Pregnancy Implications Animal reproduction studies have not been conducted. The manufacturer notes that fetal and congenital abnormalities have been rarely reported following *in utero* exposure. Use during pregnancy only if clearly needed.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Not recommended for SubQ administration; rate of injection should not exceed 3 mL/minute

Rectal: Preoperative/induction: 20-35 mg/kg/dose; usual: 25 mg/kg/dose; maximum dose: 500 mg/dose; give as 10% aqueous solution

Adults: I.V.:

Induction: 50-120 mg to start; 20-40 mg every 4-7 minutes

Wada test (unlabeled): 3-4 mg over 3 second; following signs of recovery, administer a second dose of 2 mg over 2 seconds

Dosing adjustment/comments in hepatic impairment: Lower dosage and monitor closely

Stability Do not dilute with solutions containing bacteriostatic agents; solutions are alkaline (pH 9.5-11) and **incompatible** with acids (eg, atropine sulfate, succinylcholine), also **incompatible** with phenol-containing solutions and silicone

Administration Dilute to a maximum concentration of 1% for I.V. use; for Wada testing, a dilution of 1 mg/mL has been reported

Contraindications Hypersensitivity to methohexital or any component of the formulation; porphyria

Warnings Use with extreme caution in patients with liver impairment, asthma, cardiovascular instability. **[U.S. Boxed Warning]: Should only be administered in hospitals or ambulatory care settings.**

Dosage Forms Injection, powder for reconstitution, as sodium: 500 mg, 2.5 g, 5 g

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Treatment is primarily supportive with mechanical ventilation if needed

Enhancement of elimination: Charcoal hemoperfusion is unlikely to be of benefit due to rapid elimination; consider with fulminant hepatic failure

Drug Interactions Acetaminophen: Barbiturates may enhance the hepatotoxic potential of acetaminophen overdoses

Antiarrhythmics: Barbiturates may increase the metabolism of antiarrhythmics, decreasing their clinical effect; includes disopyramide, propafenone, and quinidine

Anticonvulsants: Barbiturates may increase the metabolism of anticonvulsants; includes ethosuximide, felbamate (possibly), lamotrigine, phenytoin, tiagabine, topiramate, and zonisamide; does not appear to affect gabapentin or levetiracetam

Antineoplastics: Limited evidence suggests that enzyme-inducing anticonvulsant therapy may reduce the effectiveness of some chemotherapy regimens (specifically in ALL); teniposide and methotrexate may be cleared more rapidly in these patients

Antipsychotics: Barbiturates may enhance the metabolism (decrease the efficacy) of antipsychotics; monitor for altered response; dose adjustment may be needed

Beta-blockers: Metabolism of beta-blockers may be increased and clinical effect decreased; atenolol and nadolol are unlikely to interact given their renal elimination

Calcium channel blockers: Barbiturates may enhance the metabolism of calcium channel blockers, decreasing their clinical effect

Chloramphenicol: Barbiturates may increase the metabolism of chloramphenicol and chloramphenicol may inhibit barbiturate metabolism; monitor for altered response

Cimetidine: Barbiturates may enhance the metabolism of cimetidine, decreasing its clinical effect

CNS depressants: Sedative effects and/or respiratory depression with barbiturates may be additive with other CNS depressants; monitor for increased effect; includes ethanol, sedatives, antidepressants, narcotic analgesics, and benzodiazepines

Corticosteroids: Barbiturates may enhance the metabolism of corticosteroids, decreasing their clinical effect

Cyclosporine: Levels may be decreased by barbiturates; monitor

Doxycycline: Barbiturates may enhance the metabolism of doxycycline, decreasing its clinical effect; higher dosages may be required

Estrogens: Barbiturates may increase the metabolism of estrogens and reduce their efficacy

Felbamate may inhibit the metabolism of barbiturates and barbiturates may increase the metabolism of felbamate

Griseofulvin: Barbiturates may impair the absorption of griseofulvin, and griseofulvin metabolism may be increased by barbiturates, decreasing clinical effect

Guanfacine: Effect may be decreased by barbiturates

Immunosuppressants: Barbiturates may enhance the metabolism of immunosuppressants, decreasing its clinical effect; includes both cyclosporine and tacrolimus

Loop diuretics: Metabolism may be increased and clinical effects decreased; established for furosemide, effect with other loop diuretics not established

MAO inhibitors: Metabolism of barbiturates may be inhibited, increasing clinical effect or toxicity of the barbiturates

Methadone: Barbiturates may enhance the metabolism of methadone resulting in methadone withdrawal

Methoxyflurane: Barbiturates may enhance the nephrotoxic effects of methoxyflurane

Methohexital

CAS Number 309-36-4

U.S. Brand Names Brevital® Sodium

Synonyms Methohexital Sodium

Impairment Potential Yes

Use

Induction and maintenance of general anesthesia for short procedures

Can be used in pediatric patients ≥ 1 month of age as follows: For rectal or intramuscular induction of anesthesia prior to the use of other general anesthetic agents, as an adjunct to subpotent inhalational anesthetic agents for short surgical procedures, or for short surgical, diagnostic, or therapeutic procedures associated with minimal painful stimuli

Unlabeled/Investigational Use Wada test

Mechanism of Action Ultra short-acting I.V. barbiturate anesthetic

Adverse Reactions

Cardiovascular: Hypotension, peripheral vascular collapse, sinus bradycardia, sinus tachycardia

Central nervous system: Convulsions, CNS depression, headache, extrapyramidal reactions

Gastrointestinal: Nausea, vomiting

Local: **Pain on I.M. injection**, thrombophlebitis

Neuromuscular & skeletal: Involuntary muscle movement, myoclonus, rigidity, tremors

Respiratory: Apnea, respiratory depression, laryngospasm, coughing, rhinitis

Miscellaneous: Hiccups

Signs and Symptoms of Overdose Apnea, hypotension, ptosis, tachycardia, vision color changes (green tinge; yellow tinge), wheezing

Pharmacodynamics/Kinetics

Onset of action: I.V.: Immediately

Duration: Single dose: 10-20 minutes

Dosage Doses must be titrated to effect

Manufacturer's recommendations:

Infants < 1 month: Safety and efficacy not established

Infants ≥ 1 month and Children:

I.M.: Induction: 6.6-10 mg/kg of a 5% solution

Rectal: Induction: Usual: 25 mg/kg of a 1% solution

Alternative pediatric dosing:

Children 3-12 years:

I.M.: Preoperative: 5-10 mg/kg/dose

I.V.: Induction: 1-2 mg/kg/dose

Oral contraceptives: Barbiturates may enhance the metabolism of oral contraceptives, decreasing their clinical effect; an alternative method of contraception should be considered
 Theophylline: Barbiturates may increase metabolism of theophylline derivatives and decrease their clinical effect
 Tricyclic antidepressants: Barbiturates may increase metabolism of tricyclic antidepressants and decrease their clinical effect; sedative effects may be additive
 Valproic acid: Metabolism of barbiturates may be inhibited by valproic acid; monitor for excessive sedation; a dose reduction may be needed
 Warfarin: Barbiturates inhibit the hypoprothrombinemic effects of oral anticoagulants via increased metabolism; this combination should generally be avoided

Pregnancy Risk Factor C

Nursing Implications Avoid extravasation or intra-arterial administration

Additional Information Lethal dose: 1-2 g

Methotrexate

Related Information

- Trimetrexate Glucuronate

CAS Number 59-05-2

U.S. Brand Names Rheumatrex®; Trexall™

Synonyms Amethopterin; Methotrexate Sodium; MTX (error-prone abbreviation) ; NSC-740

Use Treatment of trophoblastic neoplasms; leukemias; psoriasis; rheumatoid arthritis (RA), including polyarticular-course juvenile rheumatoid arthritis (JRA); breast, head and neck, and lung carcinomas; osteosarcoma; soft-tissue sarcomas; carcinoma of gastrointestinal tract, esophagus, testes; lymphomas

Unlabeled/Investigational Use Treatment and maintenance of remission in Crohn's disease

Mechanism of Action Methotrexate is a folate antimetabolite that inhibits DNA synthesis. Methotrexate irreversibly binds to dihydrofolate reductase, inhibiting the formation of reduced folates, and thymidylate synthetase, resulting in inhibition of purine and thymidylidic acid synthesis. Methotrexate is cell cycle specific for the S phase of the cycle.

The MOA in the treatment of rheumatoid arthritis is unknown, but may affect immune function. In psoriasis, methotrexate is thought to target rapidly proliferating epithelial cells in the skin.

Adverse Reactions

Note: Adverse reactions vary by route and dosage. Hematologic and/or gastrointestinal toxicities may be common at dosages used in chemotherapy; these reactions are much less frequent when used at typical dosages for rheumatic diseases.

Cardiovascular: **Vasculitis**, pericarditis, pericardial effusion, serositis
 Central nervous system: Malaise, fatigue, dizziness, **encephalopathy, seizures**, confusion, **fever**, chills, **headache**, hyperthermia, **arachnoiditis, coma, cranial nerve palsies**, leukoencephalopathy

Dermatologic: Alopecia, rash, depigmentation or hyperpigmentation of skin, photosensitivity, bullous acral erythema, toxic epidermal necrolysis, acne, bullous skin disease, urticaria, purpura, onycholysis, pruritus, yellow fingernail, exanthem, radiation recall dermatitis, cutaneous vasculitis

Endocrine & metabolic: Hypoglycemia, diabetes, gynecomastia, **hyperuricemia, defective oogenesis or spermatogenesis**

Gastrointestinal: **Ulcerative stomatitis, nausea**, abdominal distress, **vomiting, anorexia**, stomatitis, **diarrhea**, enteritis, fecal discoloration (black), metallic taste, **mucositis, glossitis, gingivitis, intestinal perforation**

Genitourinary: Cystitis

Hematologic: Myelosuppression, **leukopenia**, hemorrhage, pancytopenia (mean cumulative dose 675 mg), **thrombocytopenia**

Hepatic: Cirrhosis (especially noted in diabetics and obese patients), hepatic steatosis

Neuromuscular & skeletal: Rarely arthralgia, osteopathy, stress fractures, osteoporosis

Ocular: Blurred vision

Renal: **Renal failure, azotemia, nephropathy**, nephrotic syndrome

Respiratory: Interstitial pneumonitis, cough, dyspnea, crepitant rales, hyposmia, **pharyngitis**, eosinophilic pneumonia

Miscellaneous: Decreased resistance to infection, anaphylactic shock, accelerated nodulosis, Fournier's gangrene

Signs and Symptoms of Overdose Agranulocytosis, alopecia, ataxia, azotemia, bone marrow depression, cirrhosis, conjunctivitis, coma, cranial nerve palsies, dementia, diarrhea, elevated AST, encephalopathy, granulocytopenia, gynecomastia, hemiplegia, leukopenia, lymphoma, melena, myalgia, nausea, neutropenia, oligospermia, pleural effusion, sexual dysfunction, stomatitis, toxic epidermal necrolysis, tubular necrosis, vomiting

Pharmacodynamics/Kinetics

Onset of action: Antirheumatic: 3-6 weeks; additional improvement may continue longer than 12 weeks

Absorption: Oral: Rapid; well absorbed at low doses (<30 mg/m²), incomplete after large doses; I.M.: Complete

Distribution: Penetrates slowly into 3rd space fluids (eg, pleural effusions, ascites), exits slowly from these compartments (slower than from plasma); crosses placenta; small amounts enter breast milk; sustained concentrations retained in kidney and liver

Protein binding: 50%

Metabolism: <10%; degraded by intestinal flora to DAMPA by carboxypeptidase; hepatic aldehyde oxidase converts methotrexate to 7-OH methotrexate; polyglutamates are produced intracellularly and are just as potent as methotrexate; their production is dose- and duration-dependent and they are slowly eliminated by the cell once formed

Half-life elimination: Low dose: 3-10 hours; High dose: 8-12 hours

Time to peak, serum: Oral: 1-2 hours; I.M.: 30-60 minutes

Excretion: Urine (44% to 100%); feces (small amounts)

Dosage Refer to individual protocols.

Note: Doses between 100-500 mg/m² may require leucovorin rescue. Doses > 500 mg/m² require leucovorin rescue.

Children:

Dermatomyositis: Oral: 15-20 mg/m²/week as a single dose once weekly or 0.3-1 mg/kg/dose once weekly

Juvenile rheumatoid arthritis: Oral, I.M.: 10 mg/m² once weekly, then 5-15 mg/m²/week as a single dose or as 3 divided doses given 12 hours apart

Antineoplastic dosage range:

Oral, I.M.: 7.5-30 mg/m²/week or every 2 weeks

I.V.: 10-18,000 mg/m² bolus dosing or continuous infusion over 6-42 hours

For dosing schedules, see table:

Methotrexate Dosing Schedules		
Dose	Route	Frequency
Conventional		
15-20 mg/m ²	P.O.	Twice weekly
30-50 mg/m ²	P.O., I.V.	Weekly
15 mg/day for 5 days	P.O., I.M.	Every 2-3 weeks
Intermediate		
50-150 mg/m ² *	I.V. push	Every 2-3 weeks
240 mg/m ² *	I.V. infusion	Every 4-7 days
0.5-1 g/m ² **	I.V. infusion	Every 2-3 weeks
High		
1-25 g/m ² *	I.V. infusion	Every 1-3 weeks

*Doses between 100-500 mg/m² may require leucovorin rescue in some patients.
 **Followed with leucovorin rescue - refer to Leucovorin monograph for details.

Pediatric solid tumors (high-dose): I.V.:

< 12 years: 12-25 g/m²

≥ 12 years: 8 g/m²

Acute lymphocytic leukemia (intermediate-dose): I.V.: Loading: 100 mg/m² bolus dose, followed by 900 mg/m²/day infusion over 23-41 hours.

Meningeal leukemia: I.T.: 10-15 mg/m² (maximum dose: 15 mg) or an age-based dosing regimen; one possible system is:

≤ 3 months: 3 mg/dose

4-11 months: 6 mg/dose

1 year: 8 mg/dose

2 years: 10 mg/dose

≥ 3 years: 12 mg/dose

Adults: I.V.: Range is wide from 30-40 mg/m²/week to 100-12,000 mg/m² with leucovorin rescue

Trophoblastic neoplasms:

Oral, I.M.: 15-30 mg/day for 5 days; repeat in 7 days for 3-5 courses

I.V.: 11 mg/m² days 1 through 5 every 3 weeks

Head and neck cancer: Oral, I.M., I.V.: 25-50 mg/m² once weekly

Mycosis fungoides (cutaneous T-cell lymphoma): Oral, I.M.: Initial (early stages):

5-50 mg once weekly or

15-37.5 mg twice weekly

Bladder cancer: I.V.:

30 mg/m² day 1 and 8 every 3 weeks or

30 mg/m² day 1, 15, and 22 every 4 weeks

Breast cancer: I.V.: 30-60 mg/m² days 1 and 8 every 3-4 weeks

Gastric cancer: I.V.: 1500 mg/m² every 4 weeks

Lymphoma, non-Hodgkin's: I.V.:

30 mg/m² days 3 and 10 every 3 weeks or

120 mg/m² day 8 and 15 every 3-4 weeks or

200 mg/m² day 8 and 15 every 3 weeks **or**
 400 mg/m² every 4 weeks for 3 cycles **or**
 1 g/m² every 3 weeks **or**
 1.5 g/m² every 4 weeks

Sarcoma: I.V.: 8-12 g/m² weekly for 2-4 weeks

Rheumatoid arthritis: Oral: 7.5 mg once weekly **or** 2.5 mg every 12 hours for 3 doses/week, not to exceed 20 mg/week

Psoriasis:

Oral: 2.5-5 mg/dose every 12 hours for 3 doses given weekly **or**

Oral, I.M.: 10-25 mg/dose given once weekly

Ectopic pregnancy: I.M., I.V.: 50 mg/m² as a single dose

Elderly: Rheumatoid arthritis/psoriasis: Oral: Initial: 5-7.5 mg/week, not to exceed 20 mg/week

Dosing adjustment in renal impairment:

Cl_{cr} 61-80 mL/minute: Reduce dose to 75% of usual dose

Cl_{cr} 51-60 mL/minute: Reduce dose to 70% of usual dose

Cl_{cr} 10-50 mL/minute: Reduce dose to 30% to 50% of usual dose

Cl_{cr} < 10 mL/minute: Avoid use

Hemodialysis: Not dialyzable (0% to 5%); supplemental dose is not necessary

Peritoneal dialysis: Supplemental dose is not necessary

Dosage adjustment in hepatic impairment:

Bilirubin 3.1-5 mg/dL **or** AST > 180 units: Administer 75% of usual dose

Bilirubin > 5 mg/dL: Do not use

Stability Store tablets and intact vials at room temperature (15°C to 25°C); protect from light. Dilute powder with D₅W or NS to a concentration of ≤25 mg/mL (20 mg and 50 mg vials) and 50 mg/mL (1 g vial). Intrathecal solutions may be reconstituted to 2.5-5 mg/mL with NS, D₅W, lactated Ringer's, or Elliott's B solution. Use preservative free preparations for intrathecal or high-dose administration. Further dilution in D₅W or NS is stable for 24 hours at room temperature (21°C to 25°C). Reconstituted solutions with a preservative may be stored under refrigeration for up to 3 months, and up to 4 weeks at room temperature. Intrathecal dilutions are stable at room temperature for 7 days, but it is generally recommended that they be used within 4-8 hours.

Monitoring Parameters For prolonged use (especially rheumatoid arthritis, psoriasis) a baseline liver biopsy, repeated at each 1-1.5 g cumulative dose interval, should be performed; WBC and platelet counts every 4 weeks; CBC and creatinine, LFTs every 3-4 months; chest x-ray

Administration Methotrexate may be administered I.M., I.V., or I.T.; I.V. administration may be as slow push, short bolus infusion, or 24- to 42-hour continuous infusion

Specific dosing schemes vary, but high dose should be followed by leucovorin calcium to prevent toxicity; refer to Leucovorin monograph

Contraindications Hypersensitivity to methotrexate or any component of the formulation; severe renal or hepatic impairment; pre-existing profound bone marrow suppression in patients with psoriasis or rheumatoid arthritis, alcoholic liver disease, AIDS, pre-existing blood dyscrasias; pregnancy (in patients with psoriasis or rheumatoid arthritis); breast-feeding

Warnings

Hazardous agent - use appropriate precautions for handling and disposal.

May cause potentially life-threatening pneumonitis (may occur at any time during therapy and at any dosage); monitor closely for pulmonary symptoms, particularly dry, nonproductive cough. Methotrexate may cause photosensitivity and/or severe dermatologic reactions which are not dose-related. Methotrexate has been associated with acute and chronic hepatotoxicity, fibrosis, and cirrhosis. Risk is related to cumulative dose and prolonged exposure. Ethanol abuse, obesity, advanced age, and diabetes may increase the risk of hepatotoxic reactions.

Methotrexate may cause renal failure, gastrointestinal toxicity, or bone marrow depression. Use with caution in patients with renal impairment, peptic ulcer disease, ulcerative colitis, or pre-existing bone marrow suppression. Diarrhea and ulcerative stomatitis may require interruption of therapy; death from hemorrhagic enteritis or intestinal perforation has been reported. Methotrexate penetrates slowly into 3rd space fluids, such as pleural effusions or ascites, and exits slowly from these compartments (slower than from plasma). Dosage reduction may be necessary in patients with renal or hepatic impairment, ascites, and pleural effusion. Toxicity from methotrexate or any immunosuppressive is increased in the elderly.

Severe bone marrow suppression, aplastic anemia, and GI toxicity have occurred during concomitant administration with NSAIDs. Use caution when used with other hepatotoxic agents (azathioprine, retinoids, sulfasalazine). Methotrexate given concomitantly with radiotherapy may increase the risk of soft tissue necrosis and osteonecrosis. Immune suppression may lead to opportunistic infections.

For rheumatoid arthritis and psoriasis, immunosuppressive therapy should only be used when disease is active and less toxic; traditional therapy is ineffective. Discontinue therapy in RA or psoriasis if a significant decrease in hematologic components is noted. Methotrexate formulations and/or diluents containing preservatives should not be

used for intrathecal or high-dose therapy. Methotrexate injection may contain benzyl alcohol and should not be used in neonates.

Dosage Forms

Injection, powder for reconstitution [preservative free]:

20 mg, 1 g

Injection, solution: 25 mg/mL (2 mL, 10 mL) [contains benzyl alcohol]

Injection, solution [preservative free]: 25 mg/mL (2 mL, 4 mL, 8 mL,

10 mL)

Tablet: 2.5 mg

Trexall™: 5 mg, 7.5 mg, 10 mg, 15 mg

Tablet, as sodium [dose pack] (Rheumatrex® Dose Pack): 2.5 mg

(4 cards with 2, 3, 4, 5, or 6 tablets each)

Reference Range

Therapeutic levels: Variable; Toxic concentration: Variable; therapeutic range is dependent upon therapeutic approach.

High-dose regimens produce drug levels that are between 10⁻⁶ Molar and 10⁻⁷ Molar 24-72 hours after drug infusion

10⁻⁶ Molar unit = 1 micro Molar unit

Toxic: Low-dose therapy: >9.1 ng/mL; high-dose therapy: >454 ng/mL

Overdosage/Treatment

Decontamination: (No cathartic) lavage (within 1 hour)/activated charcoal
 Supportive therapy: Severe bone marrow toxicity can result from overdose; leucovorin rescue can reduce the toxicity; administer as quickly as possible 10 mg/m² every 6 hours for 72 hours, follow serum methotrexate levels; leucovorin treatment should be continued until methotrexate levels in serum fall below 50 mM/L. SubQ granulocyte colony stimulating factor may improve agranulocytosis (5 mcg/kg/day); aminophylline (2.5 mg/kg) has been used to treat methotrexate neurotoxicity in children; corticosteroids may be useful to treat methotrexate pulmonary hypersensitivity reaction; accelerated nodulosis has been successfully treated with penicillamine (250-500 mg/day); ondansetron (8 mg) improves methotrexate-induced nausea

For intrathecal methotrexate overdose, cerebrospinal fluid washout procedure should be performed: Drain 30 mL of CSF as soon as possible; if >100 mg of methotrexate was administered, a neurosurgical consultation should be obtained; after a burrhole into the frontal horn of the right lateral ventricle with a Scott ventricular cannula is performed, 5 mL of warmed preservative-free normal saline is infused; simultaneously, 5 mL of CSF is drained from the lumbar puncture needle; over the next 4 hours, up to 550 mL of warmed normal saline is infused into the ventricles and subsequently removed through the lumbar puncture needle; the ventricular cannula is then attached to a intraventricular pressure transducer; leucovorin can be added to the final 100 mL of normal saline at a concentration of 0.02 mg/mL (however, its efficacy has not been determined); pentobarbital and phenytoin can be given to prevent seizures; 24 hours later, I.V. thymidylate rescue (8 g/m²/day) can be given by continuous I.V. infusion (though this is investigational); alternatively, I.V. leucovorin (high-dose ~1 g) rescue can be given until the methotrexate levels in the blood and CSF are in nontoxic range; alkalization of urine may help in enhancing elimination of methotrexate; monitor for cerebral edema; treat with mannitol if it is present. Dexamethasone can be given intravenously to limit meningeal irritation. Alternatively, a CSF exchange through the L.P. site can be performed (30 ml of Lactated Ringers in 30 ml of CSF with 3 exchanges. Maintain upright position).

Methotrexate can be precipitated in an acidic urine. The urine pH should be >6.5 by administering I.V. sodium bicarbonate (40-60 mEq/L in crystalloid fluids).

Carboxypeptidase G2 (CPG2) at a dose of 10-58 units/kg is an effective rescue treatment for patients with delayed elimination of methotrexate. It can be obtained through Dr. Matthew Boron at 301-496-5725 or page 1-888-720-0931.

Enhancement of elimination: Multiple dosing of activated charcoal is effective; renal excretion is optimized at a urinary pH over 7.0. Charcoal hemoperfusion, hydration, and urinary alkalization may enhance elimination and prevent precipitation in renal tubules; not dialyzable (0% to 5%); clearance by hemoperfusion is estimated to be 54-137 mL/minute.

Antidote(s)

● Folic Acid [ANTIDOTE]

● Leucovorin [ANTIDOTE]

Test Interactions ↑ potassium (S)

Drug Interactions Acitretin: May enhance the hepatotoxic effect of methotrexate. Avoid concurrent use.

Cholestyramine: May decrease levels of methotrexate.

Corticosteroids: May decrease uptake of methotrexate into leukemia cells. Administration of these drugs should be separated by 12 hours.

Dexamethasone has been reported to not affect methotrexate influx into cells.

Cyclosporine: Concomitant administration with methotrexate may increase levels and toxicity of each.

Cytarabine: Methotrexate, when administered prior to cytarabine, may enhance the efficacy and toxicity of cytarabine. Some combination treatment regimens (eg, hyper-CVAD) have been designed to take advantage of this interaction.

Hepatotoxic agents (azathioprine, retinoids, sulfasalazine) may increase the risk of hepatotoxic reactions

Mercaptopurine: Methotrexate may increase mercaptopurine levels. Dosage adjustment may be required.

NSAIDs: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant therapy. Should not be used during moderate or high-dose methotrexate due to increased and prolonged methotrexate levels (may increase toxicity); NSAID use during treatment of rheumatoid arthritis has not been fully explored, but continuation of prior regimen has been allowed in some circumstances, with cautious monitoring

Penicillins: May increase methotrexate concentrations (due to a reduction in renal tubular secretion). Primarily a concern with high doses of penicillins and higher dosages of methotrexate.

Probenecid: May increase methotrexate concentrations (due to a reduction in renal tubular secretion). Primarily a concern with higher dosages of methotrexate.

Salicylates: May increase the serum concentration of Methotrexate. Salicylate doses used for prophylaxis of cardiovascular events are not likely to be of concern.

Sulfonamides: May increase methotrexate concentrations (due to a reduction in renal tubular secretion). In addition, sulfonamides may reduce folate levels, increasing the risk/severity of bone marrow suppression. Particularly a concern with higher dosages of methotrexate.

Tetracyclines: May increase methotrexate toxicity; monitor

Theophylline: Methotrexate may increase theophylline levels.

Vaccines (live virus): Concurrent use with methotrexate may result in vaccinia infections.

Pregnancy Risk Factor D

Pregnancy Implications Fetal death or teratogenic effects may occur. Use is contraindicated in pregnant women with psoriasis or rheumatoid arthritis. Use for the treatment of neoplastic diseases only when the potential benefit to the mother outweighs the possible risk to the fetus. Pregnancy should be excluded prior to therapy in women of childbearing potential. Pregnancy should be avoided for ≥ 3 months following treatment in male patients and ≥ 1 ovulatory cycle in female patients.

Lactation Enters breast milk/contraindicated

Nursing Implications For intrathecal use, mix methotrexate without preservative with Elliott's B solution to concentration no greater than 2 mg/mL

Additional Information Toxic dose: I.V.: 1.5 mg/kg; Adults: I.T.: 12.5 mg Low-dose methotrexate (0.2 mg/kg/week) has been shown to be effective in treating idiopathic granulomatous hepatitis

Myelosuppressive effects: WBC: Mild; Platelets: Moderate; Onset (days): 7. Nadir (days): 10. Recovery (days): 21. Sodium content of 100 mg injection: 20 mg (0.86 mEq); Sodium content of 100 mg (low sodium) injection: 15 mg (0.65 mEq)

Risk factors for development of lung injury include older age, diabetes, rheumatoid pleuropulmonary involvement, previous use of disease modifying antirheumatic drugs, and hypoalbuminemia.

Methsuximide

CAS Number 77-41-8

U.S. Brand Names Celontin®

Impairment Potential Yes

Use Control of absence (petit mal) seizures that are refractory to other drugs

Unlabeled/Investigational Use Partial complex (psychomotor) seizures

Mechanism of Action Increases the seizure threshold and suppresses paroxysmal spike-and-wave pattern in absence seizures; depresses nerve transmission in the motor cortex

Adverse Reactions

Central nervous system: **Headache, dizziness, ataxia, drowsiness, euphoria, nervousness, hallucinations, insomnia, agitation, behavioral changes, mental confusion, Parkinson-like symptoms, sedation**

Dermatologic: **Stevens-Johnson syndrome, rashes, hypertrichosis, alopecia, urticaria, purpura, pruritus, exanthem**

Gastrointestinal: **Nausea, vomiting, anorexia, weight loss, abdominal pain, flatulence, gingival hyperplasia**

Hematologic: Leukopenia, aplastic anemia, thrombocytopenia, eosinophilia, pancytopenia, monocytosis

Ocular: Photophobia, periorbital edema

Miscellaneous: **Hiccups, SLE syndrome**

Signs and Symptoms of Overdose Agranulocytosis, ataxia, dizziness, dysarthria, granulocytopenia, hiccups, insomnia, neutropenia, leukopenia, relapsing coma, stupor

Pharmacodynamics/Kinetics

Metabolism: Hepatic; rapidly demethylated to N-desmethylnmethsuximide (active metabolite)

Half-life elimination: 2-4 hours

Time to peak, serum: Within 1-3 hours

Excretion: Urine (<1% as unchanged drug)

Dosage

Oral:

Children: Anticonvulsant: Initial: 10-15 mg/kg/day in 3-4 divided doses; increase weekly up to maximum of 30 mg/kg/day

Adults: Anticonvulsant: 300 mg/day for the first week; may increase by 300 mg/day at weekly intervals up to 1.2 g/day in 2-4 divided doses/day

Stability Protect from high temperature

Monitoring Parameters CBC, hepatic function tests, urinalysis

Contraindications Hypersensitivity to succinimides or any component of the formulation

Warnings Use with caution in patients with hepatic or renal disease; abrupt withdrawal of the drug may precipitate absence status; methsuximide may increase tonic-clonic seizures in patients with mixed seizure disorders; methsuximide must be used in combination with other anticonvulsants in patients with both absence and tonic-clonic seizures. Succinimides have been associated with severe blood dyscrasias and cases of systemic lupus erythematosus.

Dosage Forms Capsule: 150 mg, 300 mg

Reference Range

Therapeutic (normmethsuximide): 10-40 mcg/mL (SI: 53-212 $\mu\text{mol/L}$)

Toxic: > 40 mcg/mL (SI: >212 $\mu\text{mol/L}$); N-desmethylnmethsuximide levels > 150 mcg/mL (SI: > 738 $\mu\text{mol/L}$) associated with coma

Overdosage/Treatment

Decontamination: Activated charcoal

Enhancement of elimination: Charcoal hemoperfusion (useful in removal of toxic metabolite) and hemodialysis may be useful

Test Interactions \uparrow alkaline phosphatase (S); \downarrow calcium (S)

Drug Interactions **Substrate** of CYP2C19 (major); **Inhibits** CYP2C19 (weak)

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, benzodiazepines, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect

CYP2C19 inducers: May decrease the levels/effects of methsuximide. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of methsuximide. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

Phenobarbital: Methsuximide may increase phenobarbital concentration. Phenytoin: Methsuximide may increase phenytoin concentration.

Pregnancy Risk Factor C

Pregnancy Implications May be teratogenic

Nursing Implications Observe patient for excess sedation

Methyl Salicylate

CAS Number 119-36-8

Synonyms Betula Oil; Oil of Wintergreen; Sweet Birch Oil; Teaberry Oil

Use Flavoring agent in candy and rubefacient

Adverse Reactions

Cardiovascular: Circulatory collapse, pericardial effusion/pericarditis

Central nervous system: Headache, aseptic meningitis, psychosis, cognitive dysfunction, coma, seizures, electroencephalogram abnormalities

Dermatologic: Rash, pruritus, alopecia, pustular psoriasis, skin necrosis, nonimmunologic contact urticaria, Stevens-Johnson syndrome

METHYLDOPA

Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, hypouricemia, fluid retention
Gastrointestinal: Abdominal pain, **nausea**, vomiting, GI bleeding, GI ulceration, constipation, diarrhea, **dyspepsia**, bezoars/concretions
Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia, aplastic anemia (rare), platelet inhibition, hypoprothrombinemia
Hepatic: Elevated transaminases, hepatitis (fulminant)
Neuromuscular & skeletal: Rhabdomyolysis
Ocular: Diplopia
Otic: Ototoxicity, tinnitus
Renal: Renal failure (acute), albuminuria, nephrotic syndrome
Respiratory: Wheezing, adult respiratory distress syndrome, apnea, tachypnea, respiratory depression
Miscellaneous: Hypersensitivity

Signs and Symptoms of Overdose Bezoars, chest pain, coagulopathy, cognitive dysfunction, colitis, deafness, delirium, dementia, drowsiness, dry mouth, GI bleeding, gout, hematuria, hyperthermia, hypoglycemia, nausea, nephrotic syndrome, nystagmus, ototoxicity, stomatitis, tinnitus, vomiting, wheezing

Severe poisoning can manifest with agranulocytosis, confusion, coma, dizziness, feces discoloration (black; pink; red; tarry), fever, granulocytopenia, headache, hyperglycemia, hyponatremia, hypotension, leukopenia, neutropenia, metabolic acidosis, pylorospasm, respiratory depression, rhabdomyolysis, seizures, renal failure and/or hepatic failure, thirst, urine discoloration (pink)

Phases of aspirin poisoning:

Phase I (up to 12 hours after ingestion): Tachypnea and hyperventilation predominate (respiratory alkalosis) with increased renal secretion of sodium, potassium, and bicarbonate resulting in both an alkaline urine and serum pH

Phase II (12-24 hours after ingestion): Urine becomes more acidic as intracellular potassium decreases. While children <4 years of age may develop a pure metabolic acidosis, older patients will have significant respiratory compensation and thus serum pH can be alkalotic. Coagulation abnormalities may occur.

Phase III (over 24 hours after ingestion): Severe potassium and bicarbonate depletion occurs with hydrogen being excreted renally; serum pH becomes acidotic. Infants may reach this phase within 6 hours.

Admission Criteria/Prognosis Admit any child who has ingested over one "swallow" of oil of wintergreen

Pharmacodynamics/Kinetics

Absorption: Dermally can lead to systemic toxicity; absorption orally or dermally is incomplete

Distribution: V_d : $\approx 0.1-0.2$ L/kg which increases in presence of acidosis

Protein binding: Significant

Metabolism: Hepatic, converts methyl salicylate to salicylic acid

Dosage See Additional Information.

Monitoring Parameters Salicylate concentrations, electrolytes, I & O, Aa gradient

Dosage Forms Solution, topical: 240 mL

Reference Range Not available for methyl salicylate; salicylate concentrations following acute ingestions as high as 1200 mg/L have been reported in survivors with deaths occurring in chronic exposures at concentrations as low as 100 mg/L; one swallow in an infant 21 months of age of oil of wintergreen resulted in a salicylate level of 81 mg/dL 6 hours postingestion

Overdosage/Treatment

Decontamination: Dermal: Wash with soap and water

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; blood products are indicated, as appropriate, for hemorrhage; antacids may promote gastric absorption

Enhancement of elimination: Forced alkaline diuresis with I.V. sodium bicarbonate to keep urine pH at 8 should be performed for salicylate levels >40 mg/dL; dialysis is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; consider hemodialysis for acute salicylate levels >100 mg/dL; multiple dosing of activated charcoal may not hasten elimination; dialyzable (50% to 100%); exchange transfusion has been used successfully in a child 2 years of age (elimination rate estimated to be 152 mg/hour) to treat a methyl salicylate intoxication

Drug Interactions Can potentiate bleeding when given with warfarin by platelet aggregation inhibition; elevation of international normalized ratio may result

Additional Information Lethal dose: Oral: Children: 7.5 mL; Adults: 30 mL

Always consider acetaminophen serum concentration in exposures to analgesics, mandatory in suicide attempts; 1 teaspoonful contains 7 g salicylate, most potent available salicylate product

Aspirin conversion factor (ACF) of methyl salicylate: 0.679

Specific gravity: 1.18

Methyldopa

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 41372-08-1; 555-30-6

Synonyms Aldomet; Methyldopate Hydrochloride

Impairment Potential Yes

Use Management of moderate to severe hypertension

Mechanism of Action Stimulation of alpha-adrenergic receptors by a false transmitter that results in a decreased sympathetic outflow to the heart, kidneys and peripheral vasculature (similar to clonidine)

Adverse Reactions

Cardiovascular: **Peripheral edema**, hypotension (orthostatic), bradycardia, edema, myocarditis (hypersensitivity), sinus bradycardia, myocarditis, pericardial effusion/pericarditis, vasodilation

Central nervous system: Drowsiness, sedation, dizziness, headache, CNS depression, psychosis, seizures, fever, visual hallucinations, amnesia, paranoia, gustatory hallucinations, extrapyramidal reactions
Dermatologic: Rash, bullous lesions, erythema multiforme, toxic epidermal necrolysis, urticaria, purpura, seborrheic dermatitis, Stevens-Johnson syndrome, pruritus, erythema nodosum, exanthem, lichen planus

Endocrine & metabolic: Sodium retention, syndrome of inappropriate antidiuretic hormone, gynecomastia, parotitis, sexual dysfunction, nephrogenic diabetes insipidus

Gastrointestinal: Nausea, vomiting, diarrhea, xerostomia, "black" tongue, pancreatitis, metallic taste, lingua villosa nigra

Genitourinary: Retroperitoneal fibrosis, urinary incontinence

Hematologic: Hemolysis, positive Coombs' test, leukopenia, thrombocytopenia, red blood cell aplasia

Hepatic: Hepatitis, elevated liver enzymes, jaundice, cirrhosis, hepatic necrosis, hepatic vasculitis

Neuromuscular & skeletal: Weakness, paresthesia, Meige syndrome

Respiratory: Nasal congestion, asthma

Miscellaneous: Systemic lupus erythematosus, fixed drug eruption

Signs and Symptoms of Overdose Agranulocytosis, alopecia, AV block, bradycardia, cholestatic jaundice, circulatory collapse, CNS depression, cognitive dysfunction, colitis, constipation or diarrhea, delirium, dementia, depression, dermatitis, dizziness, eczema, ejaculatory disturbances, encephalopathy, flatus, galactorrhea, granulocytopenia, gynecomastia, hiccups, hyperprolactinemia, hypertension, hyperthermia, hypotension, hypothermia, impotence, leukopenia, lichenoid eruptions, memory loss, nausea, neutropenia, Parkinson's-like symptoms, parotid pain, photosensitivity, sedation, urine discoloration (black; brown; red; red-brown), vomiting

Pharmacodynamics/Kinetics

Onset of action: Peak effect: Hypotensive: Oral/parenteral: 3-6 hours

Duration: 12-24 hours

Distribution: Crosses placenta; enters breast milk

Protein binding: < 15%

Metabolism: Intestinal and hepatic

Half-life elimination: 75-80 minutes; End-stage renal disease: 6-16 hours

Excretion: Urine (85% as metabolites) within 24 hours

Dosage

Children:

Oral: Initial: 10 mg/kg/day in 2-4 divided doses; increase every 2 days as needed to maximum dose of 65 mg/kg/day; do not exceed 3 g/day.

I.V.: 5-10 mg/kg/dose every 6-8 hours up to a total dose of 65 mg/kg/24 hours or 3 g/24 hours

Adults:

Oral: Initial: 250 mg 2-3 times/day; increase every 2 days as needed (maximum dose: 3 g/day); usual dose range (JNC 7): 250-1000 mg/day in 2 divided doses

I.V.: 250-500 mg every 6-8 hours; maximum dose: 1 g every 6 hours

Dosing interval in renal impairment:

Cl_{cr} > 50 mL/minute: Administer every 8 hours.

Cl_{cr} 10-50 mL/minute: Administer every 8-12 hours.

Cl_{cr} < 10 mL/minute: Administer every 12-24 hours.

Hemodialysis: Slightly dialyzable (5% to 20%)

Stability Injectable dosage form is most stable at acid to neutral pH; parenteral admixture at room temperature (25°C): 24 hours

Monitoring Parameters Blood pressure, standing and sitting/lying down, CBC, liver enzymes, Coombs' test (direct); blood pressure monitor required during I.V. administration

Administration When methyldopa is administered with antihypertensives other than thiazides, limit initial doses to 500 mg/day

Contraindications Hypersensitivity to methyldopa or any component of the formulation; active hepatic disease; liver disorders previously associated with use of methyldopa; on MAO inhibitors; bisulfite allergy if using oral suspension or injectable

Warnings May rarely produce hemolytic anemia and liver disorders; positive Coombs' test occurs in 10% to 20% of patients (perform periodic CBCs); sedation usually transient may occur during initial therapy or whenever the dose is increased. Use with caution in patients with previous liver disease or dysfunction, the active metabolites of methyldopa accumulate in uremia. Patients with impaired renal function may respond to smaller doses. Elderly patients may experience syncope (avoid by giving smaller doses). Tolerance may occur usually between the second and third month of therapy. Adding a diuretic or increasing the dosage of methyldopa frequently restores blood pressure control. Because of its CNS effects, methyldopa is not considered a drug of first choice in the elderly. Often considered the drug of choice for treatment of hypertension in pregnancy. Do not use injectable if bisulfite allergy.

Dosage Forms Injection, solution, as methyldopate hydrochloride: 50 mg/mL (5 mL) [contains sodium bisulfite]
Tablet: 250 mg, 500 mg

Reference Range

Therapeutic: 1-5 mcg/mL (SI: 4.7-23.7 μ mol/L)

Toxic: >7 mcg/mL (SI: >33.0 μ mol/L)

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral vasoconstrictor may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Treatment is primarily supportive and symptomatic. Use atropine to treat bradycardia. For treatment of lingua villosa nigra, discontinue causative agent. Clean the tongue with a toothbrush and rinse mouth with a half-strength solution of hydrogen peroxide or 10% carbamide peroxide. Symptoms should subside in a few days.

Enhancement of elimination: Dialysis/hemoperfusion may be of some use; slightly dialyzable (5% to 20%)

Test Interactions Methyldopa interferes with urinary uric acid, serum creatinine (alkaline picrate method), AST (colorimetric method), and urinary catecholamines (falsely high levels)

Drug Interactions Barbiturates and TCAs may reduce response to methyldopa.

Beta-blockers, MAO inhibitors, phenothiazines, and sympathomimetics: Hypertension, sometimes severe, may occur.

Iron supplements can interact and cause a significant **increase** in blood pressure.

Lithium: Methyldopa may increase lithium toxicity; monitor lithium levels. Tolbutamide, haloperidol, anesthetics, and levodopa effects/toxicity are increased with methyldopa.

Pregnancy Risk Factor B

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk/compatible

Nursing Implications Transient sedation or depression may be common for first 72 hours of therapy; usually disappears over time; infuse over 30-60 minutes

Specific References

Chobanian AV, Bakris GL, Black HR, et al, "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, 289(19):2560-71.

Methylergonovine

CAS Number 113-42-8; 57432-61-8

U.S. Brand Names Methergine®

Synonyms Methylergometrine Maleate; Methylergonovine Maleate

Use Prevention and control of uterine hemorrhage postpartum, usually administered in last stage of labor

Mechanism of Action A semisynthetic ergot alkaloid that directly stimulates alpha-adrenergic receptors. Less adrenergic effect than other ergot alkaloids. Directly contracts smooth muscle cells.

Adverse Reactions

Cardiovascular: Myocardial infarction, chest pain, hypertension, vasoconstriction

Central nervous system: Headache, vertigo

Gastrointestinal: Nausea, vomiting

Genitourinary: Uterine hypertonicity

Ocular: Blurred vision

Signs and Symptoms of Overdose Usually occurs within 4 hours; intranasal administration appears to exhibit fewer toxic effects
Paresthesia, nausea, vomiting, diarrhea, hypoperfusion of digits, tachycardia, hypertension, apnea, myocardial ischemia, coma

Admission Criteria/Prognosis Admit any symptomatic patient or asymptomatic ingestion >0.02 mg/kg

Pharmacodynamics/Kinetics

Onset of action: Oxytocic: Oral: 5-10 minutes; I.M.: 2-5 minutes; I.V.: Immediately

Duration: Oral: ~3 hours; I.M.: ~3 hours; I.V.: 45 minutes

Absorption: Rapid

Distribution: V_d : 39-73 L

Rapid; primarily to plasma and extracellular fluid following I.V. administration; tissues

Metabolism: Hepatic

Bioavailability: Oral: 60%; I.M.: 78%

Half-life elimination: Biphasic: Initial: 1-5 minutes; Terminal: 0.5-2 hours

Time to peak, serum: Oral: 0.3-2 hours; I.M.: 0.2-0.6 hours

Excretion: Urine and feces

Dosage I.M.: 0.2 mg postpartum, then 0.2 mg orally 3-4 times/day up to 7 days

Administration Administer over \geq 60 seconds. Should not be routinely administered I.V. because of possibility of inducing sudden hypertension and cerebrovascular accident.

Contraindications Hypersensitivity to methylergonovine or any component of the formulation; ergot alkaloids are contraindicated with potent inhibitors of CYP3A4 (includes protease inhibitors, azole antifungals, and some macrolide antibiotics); hypertension; toxemia; pregnancy

Warnings Use caution in patients with sepsis, obliterative vascular disease, hepatic, or renal involvement, or second stage of labor; administer with extreme caution if using intravenously. Pleural and peritoneal fibrosis have been reported with prolonged daily use. Cardiac valvular fibrosis has also been associated with ergot alkaloids.

Dosage Forms Injection, solution, as maleate: 0.2 mg/mL (1 mL)

Tablet, as maleate: 0.2 mg

Reference Range Peak serum levels after a 0.2 mg dose: ~6 nmol/L

Overdosage/Treatment

Decontamination: Avoid ipecac; lavage within 1 hour/activated charcoal.

Supportive therapy: Terbutaline can be used to treat fetal bradycardia.

Treat myocardial ischemia by traditional modalities.

Drug Interactions Substrate of CYP3A4 (major)

Antifungals, azole derivatives (itraconazole, ketoconazole) increase levels of ergot alkaloids by inhibiting CYP3A4 metabolism, resulting in toxicity; concomitant use is contraindicated.

Antipsychotics: May diminish the effects of methylergonovine (due to dopamine antagonism); these combinations should generally be avoided.

Beta blockers: Severe peripheral vasoconstriction has been reported with concomitant use of beta blockers and ergot derivatives. Monitor.

CYP3A4 inhibitors: May increase the levels/effects of methylergonovine.

Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Macrolide antibiotics: Erythromycin, clarithromycin, and troleandomycin may increase levels of ergot alkaloids by inhibiting CYP3A4 metabolism, resulting in toxicity (ischemia, vasospasm); concomitant use is contraindicated.

MAO inhibitors: The serotonergic effects of ergot derivatives may be increased by MAO inhibitors. Monitor for signs and symptoms of serotonin syndrome.

Metoclopramide: May diminish the effects of methylergonovine (due to dopamine antagonism); concurrent therapy should generally be avoided.

Protease inhibitors (ritonavir, amprenavir, atazanavir, indinavir, nelfinavir, and saquinavir) increase blood levels of ergot alkaloids by inhibiting CYP3A4 metabolism, acute ergot toxicity has been reported; concomitant use is contraindicated.

Serotonin agonists: Concurrent use with methylergonovine may increase the risk of serotonin syndrome (includes buspirone, SSRIs, TCAs, nefazodone, sumatriptan, and trazodone).

Sibutramine: May cause serotonin syndrome; concurrent use with ergot alkaloids is contraindicated.

Sumatriptan and other serotonin 5-HT₁ receptor agonists: Prolong vasospastic reactions; do not use sumatriptan or ergot-containing drugs within 24 hours of each other.

Vasoconstrictors: Concomitant use with peripheral vasoconstrictors may cause synergistic elevation of blood pressure; use is contraindicated.

Pregnancy Risk Factor C

Pregnancy Implications Fetal bradycardia and fetal acidosis can occur

Lactation Enters breast milk/use caution

Methylphenidate

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 113-45-1; 298-59-9

U.S. Brand Names Concerta®; Metadate® CD; Metadate™ ER; Methylin™ ER; Methylin™; Ritalin-SR®; Ritalin® LA; Ritalin®

Synonyms Methylphenidate Hydrochloride

Impairment Potential Yes. Urine methylphenidate levels >0.8 mg/L are consistent with driving impairment

Use Treatment of attention deficit disorder and symptomatic management of narcolepsy; multiple unlabeled uses

Unlabeled/Investigational Use Depression (especially elderly or medically ill)

Mechanism of Action Blocks the reuptake mechanism of dopaminergic neurons, appears to act at the cerebral cortex and subcortical structures

Adverse Reactions

Cardiovascular: Tachycardia, hypertension, hypotension, palpitations, cardiac arrhythmias, sinus tachycardia, vasculitis

Central nervous system: Nervousness, insomnia, dizziness, drowsiness, movement disorders, agitation, precipitation of Tourette's syndrome, toxic psychosis (rare), fever, headache, visual hallucinations, euphoria, psychosis, stuttering, neuroleptic malignant syndrome, cerebral vasculitis

Dermatologic: Rash, exfoliative dermatitis, erythema multiforme, alopecia, angioedema, urticaria, purpura, photosensitivity, exanthem

Endocrine & metabolic: Growth suppression

Gastrointestinal: Anorexia, nausea, abdominal pain, weight loss, xerostomia

Hematologic: Thrombocytopenia

Hepatic: Fulminant liver failure

Neuromuscular & skeletal: Choreoathetoid movements

Ocular: Talc retinopathy

Respiratory: Bilateral lung opacities

Miscellaneous: Hypersensitivity reactions, fixed drug eruption

Signs and Symptoms of Overdose Agitation, coma, insomnia, seizures, tachypnea

Admission Criteria/Prognosis Admit any patient with coingestants involved, acute cardiac or neurological effects, or dose >2 mg/kg of sustained release product in pediatric patients <6 years of age

Pharmacodynamics/Kinetics

Onset of action: Peak effect:

Immediate release tablet: Cerebral stimulation: ~2 hours

Extended release capsule (Metadate® CD): Biphasic; initial peak similar to immediate release product, followed by second rising portion (corresponding to extended release portion)

Sustained release tablet: 4-7 hours

Osmotic release tablet (Concerta®): Initial: 1-2 hours

Transdermal: ~2 hours

Duration: Immediate release tablet: 3-6 hours; Sustained release tablet: 8 hours; Extended release tablet: Methylin® ER, Metadate® ER: 8 hours, Concerta®: 12 hours

Absorption:

Oral: Readily absorbed

Transdermal: Absorption increased when applied to inflamed skin or exposed to heat. Absorption is continuous for 9 hours after application.

Metabolism: Hepatic via de-esterification to minimally active metabolite

Half-life elimination: *d*-methylphenidate: 3-4 hours; *l*-methylphenidate: 1-3 hours

Time to peak (Concerta®): C_{max}: 6-8 hours; Daytrana™: 7.5-10.5 hours

Excretion: Urine (90% as metabolites and unchanged drug)

Dosage

ADHD:

Oral (discontinue periodically to re-evaluate or if no improvement occurs within 1 month): Children ≥6 years and Adults: Initial: 0.3 mg/kg/dose or 2.5-5 mg/dose given before breakfast and lunch; increase by 0.1 mg/kg/dose or by 5-10 mg/day at weekly intervals; usual dose: 0.5-1 mg/kg/day; maximum dose: 2 mg/kg/day or 90 mg/day

Extended release products:

Metadate® ER, Methylin® ER, Ritalin® SR: Duration of action is 8 hours. May be given in place of regular tablets, once the daily dose is titrated using the regular tablets and the titrated 8-hour dosage corresponds to sustained release tablet size.

Metadate® CD, Ritalin® LA: Initial: 20 mg once daily; may be adjusted in 10-20 mg increments at weekly intervals; maximum: 60 mg/day

Concerta®: Duration of action is 12 hours:

Initial dose:

Children not currently taking methylphenidate: 18 mg once daily in the morning

Children currently taking methylphenidate: **Note:** Dosing based on current regimen and clinical judgment; suggested dosing listed below:

Patients taking methylphenidate 5 mg 2-3 times/day or 20 mg/day sustained release formulation: 18 mg once every morning

Patients taking methylphenidate 10 mg 2-3 times/day or 40 mg/day sustained release formulation: 36 mg once every morning

Patients taking methylphenidate 15 mg 2-3 times/day or 60 mg/day sustained release formulation: 54 mg once every morning

Dose adjustment: May increase dose in increments of 18 mg; dose may be adjusted at weekly intervals. A dosage strength of 27 mg is available for situations in which a dosage between 18-36 mg is desired. Maximum dose should not exceed 2 mg/kg/day or 54 mg/day in children 6-12 years or 72 mg/day in children 13-17 years.

Transdermal (Daytrana™): Children 6-12 years: Initial: 10 mg patch once daily; remove up to 9 hours after application. Titrate based on response and tolerability; may increase to next transdermal dose no more frequently than every week. **Note:** Application should occur 2 hours prior to desired effect. Drug absorption may continue for a period of time after patch removal.

Adults:

Narcolepsy: 10 mg 2-3 times/day, up to 60 mg/day

Depression (unlabeled use): Initial: 2.5 mg every morning before 9 AM; dosage may be increased by 2.5-5 mg every 2-3 days as tolerated to a maximum of 20 mg/day; may be divided (ie, 7 AM and 12 noon), but should not be given after noon; do not use sustained release product

Monitoring Parameters Blood pressure, heart rate, signs and symptoms of depression, CBC, differential and platelet counts, growth rate in children, signs of central nervous system stimulation

Administration

Do not crush or allow patient to chew sustained release dosage form. To effectively avoid insomnia, dosing should be completed by noon.

Concerta™: Administer dose once daily in the morning. May be taken with or without food, but must be taken with water, milk, or juice.

Metadate® CD, Ritalin® LA: Capsules may be opened and the contents sprinkled onto a small amount (equal to 1 tablespoon) of applesauce. Swallow applesauce without chewing. Do not crush or chew capsule contents.

Contraindications Hypersensitivity to methylphenidate, any component of the formulation, or idiosyncratic reactions to sympathomimetic amines; marked anxiety, tension, and agitation; glaucoma; use during or within 14 days following MAO inhibitor therapy; Tourette's syndrome or tics

Warnings [U.S. Boxed Warning]: Dexamphetamine has been associated with serious cardiac cardiovascular events including sudden death in patients with pre-existing structural cardiac abnormalities or other serious heart problems. Using CNS stimulant treatment at usual doses in children and adolescents with serious heart problems and structural cardiac abnormalities has been associated with sudden death. In adults, stimulant use has been associated with sudden deaths, stroke, and myocardial infarction. Stimulant products should be avoided in the patients with known serious structural cardiac abnormalities, cardiomyopathy, serious heart rhythm abnormalities, or other serious cardiac problems that could increase the risk of sudden death that these conditions alone carry. Caution should be used in patients with hypertension and other cardiovascular conditions that might be exacerbated by increases in blood pressure or heart rate. Use of stimulants can cause an increase in blood pressure (average 2-4 mm Hg) and increases in heart rate (average 3-6 bpm), although some patients may have larger than average increases.

Has demonstrated value as part of a comprehensive treatment program for ADHD. Use with caution in patients with bipolar disorder (may induce mixed/manic episode), diabetes mellitus, hyperthyroidism, seizure disorders (may reduce seizure threshold), insomnia, or porphyria. Use caution in patients with history of ethanol or drug abuse. May exacerbate symptoms of behavior and thought disorder in psychotic patients. **[U.S. Boxed Warning]: Potential for drug dependency exists - avoid abrupt discontinuation in patients who have received for prolonged periods.** Visual disturbances have been reported (rare). Stimulant use has been associated with growth suppression. Growth should be monitored during treatment. Stimulants may unmask tics in individuals with coexisting Tourette's syndrome. Concerta® should not be used in patients with esophageal motility disorders or pre-existing severe gastrointestinal narrowing (small bowel disease, short gut syndrome, history of peritonitis, cystic fibrosis, chronic intestinal pseudo-obstruction, Meckel's diverticulum). Safety and efficacy in children <6 years of age have not been established. Transdermal system may cause allergic contact sensitization, characterized by intense local reactions (edema, papules); sensitization may subsequently manifest systemically with other routes of methylphenidate administration; monitor closely. Avoid exposure of application site to any direct external heat sources (eg, heating pads, electric blankets). Efficacy of transdermal methylphenidate therapy for >7 weeks has not been established.

Dosage Forms Capsule, extended release, as hydrochloride:
 Metadate® CD: 10 mg, 20 mg, 30 mg, 40 mg, 50 mg, 60 mg
 Ritalin® LA: 10 mg, 20 mg, 30 mg, 40 mg
 Solution, oral, as hydrochloride:
 Methylin®: 5 mg/5 mL (500 mL) [grape flavor]; 10 mg/5 mL (500 mL) [grape flavor]
 Tablet, as hydrochloride: 5 mg, 10 mg, 20 mg
 Methylin®, Ritalin®: 5 mg, 10 mg, 20 mg
 Tablet, chewable, as hydrochloride:
 Methylin®: 2.5 mg [contains phenylalanine 0.42 mg; grape flavor]; 5 mg [contains phenylalanine 0.84 mg; grape flavor]; 10 mg [contains phenylalanine 1.68 mg; grape flavor]
 Tablet, extended release, as hydrochloride: 20 mg
 Concerta®: 18 mg, 27 mg, 36 mg, 54 mg [osmotic controlled release]
 Metadate® ER, Methylin® ER: 10 mg, 20 mg
 Tablet, sustained release, as hydrochloride:
 Ritalin-SR®: 20 mg [dye free]
 Transdermal system [once-daily patch]:
 Daytrana™: 10 mg/9 hours (10s, 30s) [12.5 cm², total methylphenidate 27.5 mg]; 15 mg/9 hours (10s, 30s) [18.75 cm², total methylphenidate 41.3 mg]; 20 mg/9 hours (10s, 30s) [25 cm², total methylphenidate 55 mg]; 30 mg/9 hours (10s, 30s) [37.5 cm², total methylphenidate 82.5 mg]

Reference Range

Therapeutic: 5-40 ng/mL
 After oral administration of 20 mg/day, concentration in plasma after 1 hour is 20 ng/mL
 Toxic values (urine): 0.8-40 mcg/mL
 Serum ritolinic acid level of 0.4 mg/L has been associated with a fatality following intranasal abuse of methylphenidate

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Nitroprusside may be used for hypertension while diazepam or lorazepam can be used for agitation. Haloperidol can be used for hallucinatory behavior.
 Enhancement of elimination: Multiple dosing of activated charcoal may be useful; while acid diuresis can increase excretion, it is not recommended due to renal effects

Test Interactions False-positives by immunoassay can be seen with ranitidine, phenylpropanolamine, brompheniramine, chlorpromazine, flupiridene, or pipothiazine coingestion

Drug Interactions **Substrate** of CYP2D6 (major); **Inhibits** CYP2D6 (weak)

Antihypertensive agents: Effectiveness of antihypertensive agent may be decreased; use with caution

Carbamazepine: Carbamazepine may decrease the serum concentration of methylphenidate.

Clonidine: Severe toxic reactions have been reported in combined use with methylphenidate.

CYP2D6 inhibitors: May increase the levels/effects of methylphenidate. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Linezolid: Due to MAO inhibition (see note on MAO inhibitors), concurrent use with methylphenidate should generally be avoided.

MAO inhibitors: Severe hypertensive episodes have occurred with amphetamine when used in patients receiving nonselective MAO inhibitors; methylphenidate may be less likely to interact, or reactions may be less severe; use with caution only when warranted; wait 14 days following discontinuation of MAO inhibitor.

Phenytoin: Serum levels may be increased by methylphenidate (in some patients); monitor

Selegiline: When selegiline is used at low dosages (<10 mg/day), an interaction with methylphenidate is less likely than with nonselective MAO inhibitors (see MAO inhibitor information), but theoretically possible; monitor

Sibutramine: Potential for reactions noted with amphetamines (severe hypertension and tachycardia) appears to be low; use with caution

Tricyclic antidepressants: Methylphenidate may increase serum concentrations of some tricyclic agents; clinical reports of toxicity are limited; dosage reduction of tricyclic antidepressants may be required; monitor

Pregnancy Risk Factor C

Pregnancy Implications No increase in congenital malformations noted
Lactation Enters breast milk/use caution

Nursing Implications Do not crush or allow patient to chew sustained release dosage form

Additional Information Chewing tablets instead of swallowing can lead to decreased efficacy and increase in side effects

MethylPREDNISolone

Related Information

- Corticosteroids

CAS Number 2375-03-5; 2921-57-5; 53-36-1; 83-43-2

U.S. Brand Names A-Methapred®; Depo-Medrol®; Medrol®; Solu-Medrol®

Synonyms 6- α -Methylprednisolone; A-Methapred; Methylprednisolone Acetate; Methylprednisolone Sodium Succinate

Use

Dental: Treatment of a variety of oral diseases of allergic, inflammatory or autoimmune origin

Medical: Primarily as an anti-inflammatory or immunosuppressant agent in the treatment of a variety of diseases including those of hematologic, allergic, inflammatory, neoplastic, and autoimmune origin. Prevention and treatment of graft-versus-host disease following allogeneic bone marrow transplantation.

Mechanism of Action In a tissue-specific manner, corticosteroids regulate gene expression subsequent to binding specific intracellular receptors and translocation into the nucleus. Corticosteroids exert a wide array of physiologic effects including modulation of carbohydrate, protein, and lipid metabolism and maintenance of fluid and electrolyte homeostasis. Moreover cardiovascular, immunologic, musculoskeletal, endocrine, and neurologic physiology are influenced by corticosteroids. Decreases inflammation by suppression of migration of polymorphonuclear leukocytes and reversal of increased capillary permeability.

Adverse Reactions

Cardiovascular: Edema, hypertension, arrhythmias

Central nervous system: Insomnia, nervousness, aseptic meningitis, vertigo, seizures, psychoses, pseudotumor cerebri, headache, mood swings, delirium, hallucinations, euphoria

Dermatologic: Hirsutism, acne, skin atrophy, hyperpigmentation

Endocrine & metabolic: Diabetes mellitus, adrenal suppression, hyperlipidemia, Cushing's syndrome, pituitary-adrenal axis suppression, growth suppression, glucose intolerance, hypokalemia, alkalosis, sodium and water retention, hyperglycemia, amenorrhea

Gastrointestinal: Increased appetite, indigestion, peptic ulcer, nausea, vomiting, abdominal distention, ulcerative esophagitis, pancreatitis

Hematologic: Transient leukocytosis

Neuromuscular & skeletal: Arthralgia, muscle weakness, osteoporosis, fractures, avascular necrosis

Ocular: Cataracts, glaucoma

Miscellaneous: Infections, hypersensitivity reactions, secondary malignancy, intractable hiccups

Signs and Symptoms of Overdose Arrhythmias (atrial fibrillation) and cardiovascular collapse are possible with rapid intravenous infusion of high-dose methylprednisolone. May mask signs and symptoms of infection. When consumed in high doses for prolonged periods, systemic hypercorticism and adrenal suppression may occur. In these cases, discontinuation should be done judiciously.

Pharmacodynamics/Kinetics

Onset of action: Peak effect (route dependent): Oral: 1-2 hours; I.M.: 4-8 days; Intra-articular: 1 week; methylprednisolone sodium succinate is highly soluble and has a rapid effect by I.M. and I.V. routes

Duration (route dependent): Oral: 30-36 hours; I.M.: 1-4 weeks; Intra-articular: 1-5 weeks; methylprednisolone acetate has a low solubility and has a sustained I.M. effect

Distribution: V_d: 0.7-1.5 L/kg

Half-life elimination: 3-3.5 hours; reduced in obese

Excretion: Clearance: Reduced in obese

Dosage Dosing should be based on the lesser of ideal body weight or actual body weight

Only sodium succinate may be given I.V.; methylprednisolone sodium succinate is highly soluble and has a rapid effect by I.M. and I.V. routes. Methylprednisolone acetate has a low solubility and has a sustained I.M. effect.

Children:

Anti-inflammatory or immunosuppressive: Oral, I.M., I.V. (sodium succinate): 0.5-1.7 mg/kg/day or 5-25 mg/m²/day in divided doses every 6-12 hours; "Pulse" therapy: 15-30 mg/kg/dose over \geq 30 minutes given once daily for 3 days

Status asthmaticus: I.V. (sodium succinate): Loading dose: 2 mg/kg/dose, then 0.5-1 mg/kg/dose every 6 hours for up to 5 days

Acute spinal cord injury: I.V. (sodium succinate): 30 mg/kg over 15 minutes, followed in 45 minutes by a continuous infusion of 5.4 mg/kg/hour for 23 hours

Lupus nephritis: I.V. (sodium succinate): 30 mg/kg over \geq 30 minutes every other day for 6 doses

METHYLTESTOSTERONE

High-dose therapy for acute spinal cord injury: I.V. bolus: 30 mg/kg over 15 minutes, followed 45 minutes later by an infusion of 5.4 mg/kg/hour for 23 hours

Idiopathic thrombocytopenic purpura: Oral: 30 mg/kg daily for 3 days

Adults:

Anti-inflammatory or immunosuppressive: Oral: 2-60 mg/day in 1-4 divided doses to start, followed by gradual reduction in dosage to the lowest possible level consistent with maintaining an adequate clinical response

I.M. (sodium succinate): 10-80 mg/day once daily

I.M. (acetate): 10-80 mg every 1-2 weeks

I.V. (sodium succinate): 10-40 mg over a period of several minutes and repeated I.V. or I.M. at intervals depending on clinical response; when high dosages are needed, administer 30 mg/kg over a period of ≥ 30 minutes and may be repeated every 4-6 hours for 48 hours

Status asthmaticus: I.V. (sodium succinate): Loading dose: 2 mg/kg/dose, then 0.5-1 mg/kg/dose every 6 hours for up to 5 days

High-dose therapy for acute spinal cord injury: I.V. bolus: 30 mg/kg over 15 minutes, followed 45 minutes later by an infusion of 5.4 mg/kg/hour for 23 hours

Lupus nephritis: High-dose "pulse" therapy: I.V. (sodium succinate): 1 g/day for 3 days

Aplastic anemia: I.V. (sodium succinate): 1 mg/kg/day or 40 mg/day (whichever dose is higher), for 4 days. After 4 days, change to oral and continue until day 10 or until symptoms of serum sickness resolve, then rapidly reduce over approximately 2 weeks.

Hemodialysis: Slightly dialyzable (5% to 20%); administer dose post-hemodialysis

Intra-articular (acetate): Administer every 1-5 weeks

Large joints: 20-80 mg

Small joints: 4-10 mg

Intralesional (acetate): 20-60 mg every 1-5 weeks

Stability Intact vials of methylprednisolone sodium succinate should be stored at controlled room temperature

Reconstituted solutions of methylprednisolone sodium succinate should be stored at room temperature (15°C to 30°C) and used within 48 hours

Stability of parenteral admixture at room temperature (25°C) and at refrigeration temperature (4°C): 48 hours

Standard diluent (Solu-Medrol®): 40 mg/50 mL D₅W; 125 mg/50 mL D₅W
Minimum volume (Solu-Medrol®): 50 mL D₅W

Monitoring Parameters Blood pressure, blood glucose, electrolytes

Administration Oral: Administer after meals or with food or milk

Parenteral: Methylprednisolone sodium succinate may be administered I.M. or I.V.; I.V. administration may be IVP over one to several minutes or IVPB or continuous I.V. infusion

I.V.: Succinate:

Low dose: ≤ 1.8 mg/kg or ≤ 125 mg/dose: I.V. push over 3-15 minutes

Moderate dose: ≥ 2 mg/kg or 250 mg/dose: I.V. over 15-30 minutes

High dose: 15 mg/kg or ≥ 500 mg/dose: I.V. over ≥ 30 minutes

Doses > 15 mg/kg or ≥ 1 g: Administer over 1 hour

Do **not** administer high-dose I.V. push; hypotension, cardiac arrhythmia, and sudden death have been reported in patients given high-dose methylprednisolone I.V. push over < 20 minutes; intermittent infusion over 15-60 minutes; maximum concentration: I.V. push 125 mg/mL

Contraindications Hypersensitivity to methylprednisolone or any component of the formulation; viral, fungal, or tubercular skin lesions; administration of live virus vaccines; serious infections, except septic shock or tuberculous meningitis. Methylprednisolone formulations containing benzyl alcohol preservative are contraindicated in infants.

Warnings

Use with caution in patients with hyperthyroidism, cirrhosis, nonspecific ulcerative colitis, hypertension, osteoporosis, thromboembolic tendencies, CHF, convulsive disorders, myasthenia gravis, thrombophlebitis, peptic ulcer, diabetes, glaucoma, cataracts, or tuberculosis. Use caution in hepatic impairment. Because of the risk of adverse effects, systemic corticosteroids should be used cautiously in the elderly, in the smallest possible dose, and for the shortest possible time

Acute adrenal insufficiency may occur with abrupt withdrawal after long-term therapy or with stress; young pediatric patients may be more susceptible to adrenal axis suppression from topical therapy

Dosage Forms Injection, powder for reconstitution, as sodium succinate: 125 mg [strength expressed as base]

Solu-Medrol®: 40 mg, 125 mg, 500 mg, 1 g, 2 g [packaged with diluent; diluent contains benzyl alcohol; strength expressed as base]

Solu-Medrol®: 500 mg, 1 g

Injection, suspension, as acetate (Depo-Medrol®): 20 mg/mL (5 mL); 40 mg/mL (5 mL); 80 mg/mL (5 mL) [contains benzyl alcohol; strength expressed as base]

Injection, suspension, as acetate [single-dose vial] (Depo-Medrol®): 40 mg/mL (1 mL, 10 mL); 80 mg/mL (1 mL)

Tablet: 4 mg

Medrol®: 2 mg, 4 mg, 8 mg, 16 mg, 32 mg

Tablet, dose-pack: 4 mg (21s)

Medrol® Dosepack™: 4 mg (21s)

Overdosage/Treatment Supportive care is the primary treatment; toxic symptomatology rarely occurs with dosing of < 3 weeks duration. Promethazine can be used to treat steroid-induced psychosis.

Test Interactions Interferes with skin tests

Drug Interactions **Substrate** of CYP3A4 (minor); **Inhibits** CYP2C8 (weak), 3A4 (weak)

Decreased effect:

Phenytoin, phenobarbital, rifampin increase clearance of methylprednisolone

Potassium depleting diuretics enhance potassium depletion

Increased toxicity:

Skin test antigens, immunizations decrease response and increase potential infections

Methylprednisolone may increase circulating glucose levels and may need adjustments of insulin or oral hypoglycemics

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Nursing Implications **Acetate salt should not be given I.V.**

Additional Information Sodium content of 1 g sodium succinate injection: 2.01 mEq; 53 mg of sodium succinate salt is equivalent to 40 mg of methylprednisolone base

Methylprednisolone acetate: Depo-Medrol®

Methylprednisolone sodium succinate: Solu-Medrol®

MethylTESTOSTERone

CAS Number 58-18-4

U.S. Brand Names Android®; Methitest®; Testred®; Virilon®

Use

Male: Hypogonadism; delayed puberty; impotence and climacteric symptoms

Female: Palliative treatment of metastatic breast cancer; postpartum breast pain and/or engorgement

Mechanism of Action Stimulates receptors in organs and tissues to promote growth and development of male sex organs and maintains secondary sex characteristics in androgen-deficient males

Adverse Reactions

Cardiovascular: **Edema**

Central nervous system: Mania, paranoid psychosis

Dermatologic: **Acne (cystic), seborrheic dermatitis**; Female: Hirsutism (increase in pubic hair growth) atrophy, urticaria, purpura, pruritus, psoriasis, licheniform eruptions, exanthem

Endocrine & metabolic: Gynecomastia, amenorrhea, hypercalcemia

Male: **Virilism**

Female: **Virilism, menstrual problems (amenorrhea), breast soreness**

Gastrointestinal: GI irritation, nausea, vomiting, stomatitis

Genitourinary: Males: **Priapism**, prostatic hypertrophy, prostatic carcinoma, impotence

Hematologic: Leukopenia, polycythemia

Hepatic: Hepatic dysfunction, hepatic necrosis, cholestatic hepatitis, peliosis hepatitis, aminotransferase level elevation (asymptomatic)

Ocular: Night blindness

Miscellaneous: Hypersensitivity reactions, systemic lupus erythematosus

Pharmacodynamics/Kinetics

Metabolism: Hepatic

Excretion: Urine

Dosage Adults (buccal absorption produces twice the androgenic activity of oral tablets):

Male:

Oral: 10-40 mg/day

Buccal: 5-25 mg/day

Female:

Breast pain/engorgement:

Oral: 80 mg/day for 3-5 days

Buccal: 40 mg/day for 3-5 days

Breast cancer:

Oral: 50-200 mg/day

Buccal: 25-100 mg/day

Monitoring Parameters In prepubertal children, perform radiographic examination of the hand and wrist every 6 months to determine the rate of bone maturation and to assess the effect of treatment on the epiphyseal centers.

Contraindications Hypersensitivity to methyltestosterone or any component of the formulation; in males, known or suspected carcinoma of the breast or the prostate; pregnancy

Warnings Use with extreme caution in patients with liver or kidney disease or serious heart disease; may accelerate bone maturation without producing compensatory gain in linear growth

Dosage Forms Capsule (Android®, Testred®, Virilon®): 10 mg
Tablet (Methitest™): 10 mg

Reference Range Peak serum concentrations following a 10 mg ingestion: 24-39 ng/mL

Overdosage/Treatment Decontamination: Activated charcoal

Test Interactions Thyroxine-binding globulin levels may be decreased

Drug Interactions Anticoagulants, oral: May have increased effect; monitor INR

Cyclosporine: Toxicity may occur; avoid concurrent use

Hypoglycemics, oral: May have increased effect; monitor blood glucose

Pregnancy Risk Factor X

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications In prepubertal children, perform radiographic examination of the hand and wrist every 6 months to determine the rate of bone maturation and to assess the effect of treatment on the epiphyseal centers

Methyprylon

CAS Number 125-64-4

Impairment Potential Yes

Mechanism of Action Similar to glutethimide; it is a piperidineone which has sedative/hypnotic properties; water and lipid soluble

Adverse Reactions

Cardiovascular: Tachycardia, hypotension, sinus tachycardia

Central nervous system: Headache, coma, dementia, seizures, hypothermia, hyperthermia

Gastrointestinal: Nausea, vomiting, diarrhea

Hematologic: Thrombocytopenia, neutropenia, porphyria, porphyrinogenic

Hepatic: Jaundice, mild elevation in liver function tests

Ocular: Miosis, nystagmus

Neuromuscular & skeletal: Hyperreflexia

Respiratory: Respiratory failure, apnea, pulmonary edema

Signs and Symptoms of Overdose Hypothermia, leukopenia or neutropenia (agranulocytosis, granulocytopenia)

Toxicodynamics/Kinetics

Distribution: V_d : 1 L/kg

Protein binding: 60%; parent compound: 38% metabolites

Metabolism: Hepatic

Half-life: 4-16 hours (in overdose: 50 hours)

Elimination: Urine 60%, feces 20%; ~50% of the drug is normally excreted in 4 hours in a healthy person

Dosage Usual daily dose: 200-400 mg at night

Reference Range Therapeutic serum level is ~8-10 mcg/mL; respiratory arrest can occur at plasma levels >60 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension can be treated with isotonic saline/Trendelenburg; dopamine or norepinephrine can then be used

Enhancement of elimination: Multiple dosing of activated charcoal probably is not effective; forced diuresis does not play any role; hemodialysis can remove ~20% of the dose; charcoal hemoperfusion is not effective in enhancing elimination

Pregnancy Risk Factor B

Additional Information Minimum lethal dose: 6 g

Metoclopramide

CAS Number 364-62-5; 54143-57-6; 7232-21-5

U.S. Brand Names Reglan®

Use Prevention and/or treatment of nausea and vomiting associated with chemotherapy, radiation therapy, or postsurgery; symptomatic treatment of diabetic gastric stasis; gastroesophageal reflux; facilitation of intubation of the small intestine

Mechanism of Action Blocks dopamine receptors and (when given in higher doses) also blocks serotonin receptors in chemoreceptor trigger zone of the CNS; enhances the response to acetylcholine of tissue in upper GI tract causing enhanced motility and accelerated gastric emptying without stimulating gastric, biliary, or pancreatic secretions

Adverse Reactions

Cardiovascular: Bradycardia, hypotension/hypertension, hypertensive crisis, sinus bradycardia, palpitations, tachycardia (supraventricular)

Central nervous system: **Restlessness, drowsiness**, extrapyramidal reactions, fatigue, psychosis, anxiety, agitation, neuroleptic malignant syndrome, panic attacks, irritability, Chorea

Dermatologic: Rash

Endocrine & metabolic: Gynecomastia, hyperprolactinemia

Gastrointestinal: **Diarrhea**, constipation

Genitourinary: Priapism

Hematologic: Methemoglobinemia (particularly in neonates); leukopenia, neutropenia, agranulocytosis, granulocytopenia, sulfhemoglobinemia (especially in N-acetylcysteine therapy of acetaminophen overdose)

Neuromuscular & skeletal: **Weakness**, asterixis, trismus

Signs and Symptoms of Overdose Agitation, ataxia, AV block, chorea (extrapyramidal), cognitive dysfunction, delirium, depression, drowsiness, extrapyramidal reactions, fever, galactorrhea, gynecomastia, hyperprolactinemia, hypertension, hyperthermia, impotence, irritability, lactation, mania, metallic taste, methemoglobinemia (in infants), muscle hypertonia, neuroleptic malignant syndrome, nystagmus, Parkinson's-like symptoms, seizures, wheezing

Pharmacodynamics/Kinetics

Onset of action: Oral: 0.5-1 hour; I.V.: 1-3 minutes; I.M.: 10-15 minutes

Duration: Therapeutic: 1-2 hours, regardless of route

Distribution: V_d : 2-4 L/kg

Protein binding: 30%

Bioavailability: Oral: 65% to 95%

Half-life elimination: Normal renal function: 4-6 hours (may be dose dependent)

Time to peak, serum: Oral: 1-2 hours

Excretion: Urine (~85%)

Dosage

Children:

Gastroesophageal reflux: Oral: 0.1-0.2 mg/kg/dose up to 4 times/day; efficacy of continuing metoclopramide beyond 12 weeks in reflux has not been determined; total daily dose should not exceed 0.5 mg/kg/day

Gastrointestinal hypomotility (gastroparesis): Oral, I.M., I.V.: 0.1 mg/kg/dose up to 4 times/day, not to exceed 0.5 mg/kg/day

Antiemetic (chemotherapy-induced emesis): I.V.: 1-2 mg/kg 30 minutes before chemotherapy and every 2-4 hours, for a total of 5 doses (5-10 mg/kg) daily

Facilitate intubation: I.V.:

<6 years: 0.1 mg/kg

6-14 years: 2.5-5 mg

Adults:

Gastroesophageal reflux: Oral: 10-15 mg/dose up to 4 times/day 30 minutes before meals or food and at bedtime; single doses of 20 mg are occasionally needed for provoking situations; efficacy of continuing metoclopramide beyond 12 weeks in reflux has not been determined

Gastrointestinal hypomotility (gastroparesis):

Oral: 10 mg 30 minutes before each meal and at bedtime for 2-8 weeks

I.V. (for severe symptoms): 10 mg over 1-2 minutes; 10 days of I.V. therapy may be necessary for best response

Antiemetic (chemotherapy-induced emesis): I.V.: 1-2 mg/kg 30 minutes before chemotherapy and every 2-4 hours, for a total of 5 doses (5-10 mg/kg) daily

Postoperative nausea and vomiting: I.M.: 10 mg near end of surgery; 20 mg doses may be used

Facilitate intubation: I.V.: 10 mg

Elderly:

Gastroesophageal reflux: Oral: 5 mg 4 times/day (30 minutes before meals and at bedtime); increase dose to 10 mg 4 times/day if no response at lower dose

Gastrointestinal hypomotility:

Oral: Initial: 5 mg 30 minutes before meals and at bedtime for 2-8 weeks; increase if necessary to 10 mg doses

I.V.: Initiate at 5 mg over 1-2 minutes; increase to 10 mg if necessary

Postoperative nausea and vomiting: I.M.: 5 mg near end of surgery; may repeat dose if necessary

Dosing adjustment in renal impairment:

Cl_{cr} 10-40 mL/minute: Administer at 50% of normal dose

Cl_{cr} <10 mL/minute: Administer at 25% of normal dose

Hemodialysis: Not dialyzable (0% to 5%); supplemental dose is not necessary

Stability Injection: Store intact vial at controlled room temperature; injection is photosensitive and should be protected from light during storage; parenteral admixtures in D₅W or NS are stable for at least 24 hours, and do not require light protection if used within 24 hours.

Tablet: Store at controlled room temperature; protect from freezing

Monitoring Parameters Periodic renal function test; monitor for dystonic reactions; monitor for signs of hypoglycemia in patients using insulin and those being treated for gastroparesis; monitor for agitation and irritable confusion

Administration Injection solution may be given I.M., direct I.V. push, short infusion (15-30 minutes), or continuous infusion; lower doses (\leq 10 mg) of metoclopramide can be given I.V. push undiluted over 1-2 minutes; higher doses to be given IVPB over at least 15 minutes; continuous SubQ infusion and rectal administration have been reported

METOPROLOL

Contraindications Hypersensitivity to metoclopramide or any component of the formulation; GI obstruction, perforation or hemorrhage; pheochromocytoma; history of seizures

Warnings Use caution with a history of mental illness; has been associated with extrapyramidal symptoms (EPS) and depression. The frequency of EPS is higher in pediatric patients and adults <30 years of age; risk is increased at higher dosages. Extrapyramidal reactions typically occur within the initial 24-48 hours of treatment. Use caution with concurrent use of other drugs associated with EPS. Use caution in the elderly and with Parkinson's disease; may have increased risk of tardive dyskinesia. Use caution in patients with a history of seizures; risk of metoclopramide-associated seizures is increased. Neuroleptic malignant syndrome (NMS) has been reported (rarely) with metoclopramide. Use lowest recommended doses initially; may cause transient increase in serum aldosterone; use caution in patients who are at risk of fluid overload (CHF, cirrhosis). Use caution in patients with hypertension or following surgical anastomosis/closure. Patients with NADH-cytochrome b5 reductase deficiency are at increased risk of methemoglobinemia and/or sulfhemoglobinemia. Abrupt discontinuation may (rarely) result in withdrawal symptoms (dizziness, headache, nervousness). Use caution and adjust dose in renal impairment.

Dosage Forms Injection, solution (Reglan®): 5 mg/mL (2 mL, 10 mL, 30 mL)

Syrup: 5 mg/5 mL (10 mL, 480 mL)

Tablet (Reglan®): 5 mg, 10 mg

Reference Range Dose of 10 mg results in a mean plasma level of 65 ng/mL; following a 3 mg/kg overdose, a symptomatic infant exhibited blood metoclopramide level of 150 ng/mL

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Metoclopramide often causes extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50-100 mg I.M. or I.V. slow push followed by a maintenance dose (25-50 mg orally every 4-6 hours) for 48-72 hours. When these reactions are unresponsive to diphenhydramine, benzotropine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes. Treat methemoglobin with methylene blue.

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; hemodialysis is not useful; not dialyzable (0% to 5%)

Antidote(s)

- Methylene Blue [ANTIDOTE]

Diagnostic Procedures

- Methemoglobin, Blood

Test Interactions ↑ aminotransferases (ALT, AST) (S), amylase (S); may produce falsely elevated TSH (usually <10 units/L).

Drug Interactions **Substrate** (minor) of CYP1A2, 2D6; **Inhibits** CYP2D6 (weak)

Anticholinergic agents antagonize metoclopramide's actions

Antipsychotic agents: Metoclopramide may increase extrapyramidal symptoms (EPS) or risk when used concurrently.

Cyclosporine: Metoclopramide may increase cyclosporine levels.

Opiate analgesics may increase CNS depression

Pregnancy Risk Factor B

Pregnancy Implications Crosses the placenta; available evidence suggests safe use during pregnancy

Lactation Enters breast milk/use caution

Additional Information Structurally similar to domperidone

already receiving ACE inhibitors, diuretics, and/or digoxin (sustained-release only)

Unlabeled/Investigational Use Treatment of ventricular arrhythmias, atrial ectopy, migraine prophylaxis, essential tremor, aggressive behavior

Mechanism of Action Selective inhibitor of beta₁-adrenergic receptors; competitively blocks beta₁-receptors, with little or no effect on beta₂-receptors at doses <100 mg

Adverse Reactions

Cardiovascular: Bradycardia, palpitations, edema, CHF, reduced peripheral circulation, arrhythmias, chest pain, heart block (second- and third-degree), orthostatic hypotension

Central nervous system: **Drowsiness, insomnia**, mental depression, confusion (especially in the elderly), hallucinations, headache, depression, nervousness

Dermatologic: Photosensitivity

Endocrine & metabolic: **Decreased sexual ability**

Gastrointestinal: Diarrhea or constipation, nausea, stomach discomfort, vomiting

Hematologic: Leukopenia, thrombocytopenia

Hepatic: Jaundice, hepatic dysfunction, hepatitis

Neuromuscular & skeletal: Arthralgia, paresthesia

Respiratory: Bronchospasm, dyspnea

Miscellaneous: Cold extremities

Signs and Symptoms of Overdose Apnea, asystole, ataxia, AV block, bradycardia, confusion, cyanosis, heart failure, hyperreflexia, hypotension, impotence, insomnia, metabolic acidosis, night terrors, respiratory arrest, seizures, wheezing

Pharmacodynamics/Kinetics

Onset of action: Peak effect: Antihypertensive: Oral: 1.5-4 hours

Duration: 10-20 hours

Absorption: 95%

Protein binding: 12%

Metabolism: Extensively hepatic via CYP2D6; significant first-pass effect

Bioavailability: Oral: 40% to 50%

Half-life elimination: 3-8 hours

Excretion: Urine (3% to 10% as unchanged drug)

Dosage

Children: Oral: 1-5 mg/kg/24 hours divided twice daily; allow 3 days between dose adjustments

Adults:

Hypertension: Oral: 100-450 mg/day in 2-3 divided doses, begin with 50 mg twice daily and increase doses at weekly intervals to desired effect; usual dosage range (JNC 7): 50-100 mg/day

Extended release: Same daily dose administered as a single dose

Angina, SVT, MI prophylaxis: Oral: 100-450 mg/day in 2-3 divided doses, begin with 50 mg twice daily and increase doses at weekly intervals to desired effect

Extended release: Same daily dose administered as a single dose

Hypertension/ventricular rate control: I.V. (in patients having nonfunctioning GI tract): Initial: 1.25-5 mg every 6-12 hours; titrate initial dose to response. Initially, low doses may be appropriate to establish response; however, up to 15 mg every 3-6 hours has been employed.

Congestive heart failure: Oral (extended release): Initial: 25 mg once daily (reduce to 12.5 mg once daily in NYHA class higher than class II); may double dosage every 2 weeks as tolerated, up to 200 mg/day

Myocardial infarction (acute): I.V.: 5 mg every 2 minutes for 3 doses in early treatment of myocardial infarction; thereafter give 50 mg orally every 6 hours 15 minutes after last I.V. dose and continue for 48 hours; then administer a maintenance dose of 100 mg twice daily.

Elderly: Oral: Initial: 25 mg/day; usual range: 25-300 mg/day

Extended release: 25-50 mg/day initially as a single dose; increase at 1- to 2-week intervals.

Hemodialysis: Administer dose posthemodialysis or administer 50 mg supplemental dose; supplemental dose is not necessary following peritoneal dialysis

Dosing adjustment/comments in hepatic disease: Reduced dose probably necessary

Monitoring Parameters Acute cardiac treatment: Monitor ECG and blood pressure with I.V. administration; heart rate and blood pressure with oral administration

Administration Oral: Do not crush or chew extended release tablets.

I.V.: When administered acutely for cardiac treatment, monitor ECG and blood pressure. May administer by rapid infusion (I.V. push) over 1 minute or by slow infusion (ie, 5-10 mg of metoprolol in 50 mL of fluid) over ~30 minutes. Necessary monitoring for surgical patients who are unable to take oral beta-blockers (prolonged ileus) has not been defined. Some institutions require monitoring of baseline and postinfusion heart rate and blood pressure when a patient's response to beta-blockade has not been characterized (ie, the patient's initial dose or following a change in dose). Consult individual institutional policies and procedures.

Contraindications Hypersensitivity to metoprolol or any component of the formulation; sick sinus syndrome; sinus bradycardia; heart block greater than first degree (except in patients with a functioning artificial

Metoprolol

Related Information

- Selected Properties of Beta-Adrenergic Blocking Drugs

CAS Number 37350-58-6; 54163-88-1; 56392-17-7

U.S. Brand Names Lopressor®; Toprol-XL®

Synonyms Metoprolol Succinate; Metoprolol Tartrate

Use Treatment of hypertension and angina pectoris; prevention of myocardial infarction, atrial fibrillation, flutter, symptomatic treatment of hypertrophic subaortic stenosis; to reduce mortality/hospitalization in patients with congestive heart failure (NYHA class II or III) in patients

pacemaker); cardiogenic shock; uncompensated cardiac failure; severe peripheral arterial disease; pheochromocytoma (without alpha blockade); pregnancy (2nd and 3rd trimesters)

Warnings

[U.S. Boxed Warning]: Beta-blocker therapy should not be withdrawn abruptly (particularly in patients with CAD), but gradually tapered to avoid acute tachycardia, hypertension, and/or ischemia. Beta-blockers may increase the risk of anaphylaxis (in predisposed patients) and blunt response to epinephrine. Use caution in patients with PVD (can aggravate arterial insufficiency). Use caution with concurrent use of beta-blockers and either verapamil or diltiazem; bradycardia or heart block can occur; avoid concurrent I.V. use of both agents. In general, beta-blockers should be avoided in patients with bronchospastic disease. Metoprolol, with B₁ selectivity, should be used cautiously in bronchospastic disease with close monitoring. Use cautiously in diabetics because it can mask prominent hypoglycemic symptoms. Can mask signs of thyrotoxicosis. In pheochromocytoma, initiate an alpha blocker prior to beta-blocker; beta-blocker alone may cause a paradoxical increase in blood pressure. Can cause fetal harm when administered in pregnancy. Use caution with hepatic dysfunction. Use care with anesthetic agents which decrease myocardial function. Use of beta-blockers may unmask cardiac failure in patients without a history of dysfunction

Extended release: Use care in compensated heart failure and monitor closely for a worsening of the condition. May need to increase diuretics and wait until clinically stable to advance dose to target.

Dosage Forms

Injection, solution, as tartrate: 1 mg/mL (5 mL)
Lopressor®: 1 mg/mL (5 mL)
Tablet, as tartrate: 25 mg, 50 mg, 100 mg
Lopressor®: 50 mg, 100 mg
Tablet, extended release, as succinate: 25 mg, 50 mg, 100 mg, 200 mg [expressed as mg equivalent to tartrate]
Toprol-XL®: 25 mg, 50 mg, 100 mg, 200 mg [expressed as mg equivalent to tartrate]

Reference Range

Therapeutic: 20-340 ng/mL
Survival has occurred with levels as high as 7,140 ng/mL
In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal
Supportive therapy: Sympathomimetics (eg, epinephrine or dopamine), atropine, glucagon, or a pacemaker can be used to treat the toxic bradycardia, asystole, and/or hypotension; initially fluids may be the best treatment for toxic hypotension; enoximone (0.5 mg/kg bolus then 15 mcg/kg/minute drip) can increase cardiac output and stroke volume in metoprolol overdose
Enhancement of elimination: Charcoal hemoperfusion can be used to lower serum levels

Test Interactions

↑ cholesterol (S), glucose
Drug Interactions Substrate of CYP2C19 (minor), 2D6 (major);

Inhibits CYP2D6 (weak)

Acetylcholinesterase inhibitors (eg, donepezil, galantamine, neostigmine): May enhance the bradycardic effect of beta-blockers.

Alpha-/beta-agonists: Beta-blockers may enhance the vasopressor effect of alpha-/beta-agonists (direct-acting).

Alpha₁-blockers (prazosin, terazosin): Concurrent use of beta-blockers may increase risk of orthostasis.

Alpha₂-agonists: Beta-blockers may enhance the rebound hypertensive effect of alpha₂-agonists. This effect can occur when the alpha₂-agonist is abruptly withdrawn.

Aminoquinolines (antimalarial): May decrease the metabolism, via CYP isoenzymes, of beta-blockers.

Amiodarone: May enhance the bradycardic effect of beta-blockers.

Antipsychotic agents (phenothiazines): May enhance the hypotensive effect of beta-blockers. Beta-blockers may decrease the metabolism, via CYP isoenzymes, of antipsychotic agents (phenothiazines).

Barbiturates: May increase the metabolism, via CYP isoenzymes, of beta-blockers.

Beta₂-agonists: May diminish the bradycardic effect of beta-blockers (beta₁ selective).

Calcium channel blockers (nondihydropyridine): May enhance the hypotensive effect of beta-blockers. Bradycardia and signs of heart failure have also been reported.

Cardiac glycosides: Beta-blockers may enhance the bradycardic effect of cardiac glycosides.

CYP2D6 inhibitors: May increase the levels/effects of metoprolol. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Dipyridamole: May enhance the bradycardic effect of beta-blockers.

Disopyramide: May enhance the bradycardic effect of beta-blockers.

Insulin: Beta-blockers may enhance the hypoglycemic effect of insulin. Tachycardia may be masked as a symptom of hypoglycemia.

Lidocaine: Beta-blockers may decrease the metabolism of lidocaine.

Nonsteroidal anti-inflammatory agents (NSAIDs): May diminish the antihypertensive effect of beta-blockers.

Propafenone: May decrease the metabolism, via CYP isoenzymes, of beta-blockers. Propafenone possesses some independent beta-blocking activity.

Propoxyphene: May decrease the metabolism, via CYP isoenzymes, of beta-blockers.

Quinidine: May decrease the metabolism, via CYP isoenzymes, of beta-blockers.

Rifamycin derivatives: May increase the metabolism, via CYP isoenzymes, of beta-blockers.

Selective serotonin reuptake inhibitors (SSRIs): May enhance the bradycardic effect of beta-blockers.

Sulfonylureas: Beta-blockers may enhance the hypoglycemic effect of sulfonylureas. Tachycardia may be masked as a symptom of hypoglycemia.

Theophylline: Beta-blockers (beta₁ selective) may diminish the bronchodilatory effect of theophylline derivatives.

Pregnancy Risk Factor C (manufacturer); D (2nd and 3rd trimesters - expert analysis)

Pregnancy Implications Metoprolol crosses the placenta. Beta-blockers have been associated with bradycardia, hypotension, and IUGR; IUGR is probably related to maternal hypertension. Available evidence suggests beta-blockers are generally safe during pregnancy (JNC-7). Cases of neonatal hypoglycemia have been reported following maternal use of beta-blockers at parturition or during breast-feeding.

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications Patient's therapeutic response may be evaluated by looking at blood pressure, apical and radial pulses, fluid I & O, daily weight, respirations, and circulation in extremities before and during therapy

Metronidazole

CAS Number 13182-89-3; 443-48-1; 69198-10-3

U.S. Brand Names Flagyl ER®; Flagyl®; MetroCream®; MetroGel-Vaginal®; MetroGel®; MetroLotion®; Noritate®; Rozex™

Synonyms Metronidazole Hydrochloride

Use

Treatment of susceptible anaerobic bacterial and protozoal infections in the following conditions: Amebiasis, symptomatic and asymptomatic trichomoniasis; skin and skin structure infections; CNS infections; intra-abdominal infections (as part of combination regimen); systemic anaerobic infections; treatment of antibiotic-associated pseudomembranous colitis (AAPC), bacterial vaginosis; as part of a multidrug regimen for *H. pylori* eradication to reduce the risk of duodenal ulcer recurrence

Topical: Treatment of inflammatory lesions and erythema of rosacea

Unlabeled/Investigational Use Crohn's disease

Mechanism of Action Reduced to a product by a nitroreductase enzyme which interacts with DNA to cause a loss of helical DNA structure and strand breakage resulting in inhibition of protein synthesis and cell death in susceptible organisms

Adverse Reactions

Systemic: Frequency not defined:

Cardiovascular: Flattening of the T-wave, flushing

Central nervous system: Ataxia, confusion, coordination impaired, dizziness, fever, headache, insomnia, irritability, seizures, vertigo
Dermatologic: Erythematous rash, urticaria

Endocrine & metabolic: Disulfiram-like reaction, dysmenorrhea, libido decreased

Gastrointestinal: **Nausea** (~12%), anorexia, abdominal cramping, constipation, diarrhea, furry tongue, glossitis, proctitis, stomatitis, unusual/metallic taste, vomiting, xerostomia
 Genitourinary: Cystitis, darkened urine (rare), dysuria, incontinence, polyuria, vaginitis
 Hematologic: Neutropenia (reversible), thrombocytopenia (reversible, rare)
 Neuromuscular & skeletal: Peripheral neuropathy, weakness
 Respiratory: Nasal congestion, rhinitis, sinusitis, pharyngitis
 Miscellaneous: Flu-like syndrome, moniliasis

Topical: Frequency not defined:

Central nervous system: Headache
 Dermatologic: Burning, contact dermatitis, dryness, erythema, irritation, pruritus, rash
 Gastrointestinal: Unusual/metallic taste, nausea, constipation
 Local: Local allergic reaction
 Neuromuscular & skeletal: Tingling/numbness of extremities
 Ocular: Eye irritation

Vaginal:

Central nervous system: Headache, dizziness, depression, fatigue
 Dermatologic: Itching, rash
 Gastrointestinal: Gastrointestinal discomfort, nausea and/or vomiting, unusual/metallic taste, diarrhea, abdominal bloating, abdominal gas, xerostomia
 Genitourinary: **Vaginitis, vaginal discharge**, vulva/vaginal irritation, pelvic discomfort, darkened urine
 Hematologic: WBC increased
 Miscellaneous: Thirst

Signs and Symptoms of Overdose Ataxia, cystitis, diplopia, dry skin, dysosmia, gynecomastia, hepatotoxicity (12.5 g ingestion), insomnia, nausea, neuropathy (peripheral), neutropenia, seizures, vomiting

Pharmacodynamics/Kinetics

Absorption: Oral: Well absorbed; Topical: Concentrations achieved systemically after application of 1 g topically are 10 times less than those obtained after a 250 mg oral dose
 Distribution: To saliva, bile, seminal fluid, breast milk, bone, liver, and liver abscesses, lung and vaginal secretions; crosses placenta and blood-brain barrier
 CSF: blood level ratio: Normal meninges: 16% to 43%; Inflamed meninges: 100%
 Protein binding: <20%
 Metabolism: Hepatic (30% to 60%)
 Half-life elimination: Neonates: 25-75 hours; Others: 6-8 hours, prolonged with hepatic impairment; End-stage renal disease: 21 hours
 Time to peak, serum: Oral: Immediate release: 1-2 hours
 Excretion: Urine (20% to 40% as unchanged drug); feces (6% to 15%)

Dosage

Infants and Children:

Amebiasis: Oral: 35-50 mg/kg/day in divided doses every 8 hours for 10 days
 Trichomoniasis: Oral: 15-30 mg/kg/day in divided doses every 8 hours for 7 days
 Anaerobic infections:
 Oral: 15-35 mg/kg/day in divided doses every 8 hours
 I.V.: 30 mg/kg/day in divided doses every 6 hours
Clostridium difficile (antibiotic-associated colitis): Oral: 20 mg/kg/day divided every 6 hours
 Maximum dose: 2 g/day

Adults:

Amebiasis: Oral: 500-750 mg every 8 hours for 5-10 days
 Trichomoniasis: Oral: 250 mg every 8 hours for 7 days or 375 mg twice daily for 7 days or 2 g as a single dose
 Anaerobic infections: Oral, I.V.: 500 mg every 6-8 hours, not to exceed 4 g/day
 Antibiotic-associated pseudomembranous colitis: Oral: 250-500 mg 3-4 times/day for 10-14 days
Helicobacter pylori eradication: Oral: 250-500 mg with meals and at bedtime for 14 days; requires combination therapy with at least one other antibiotic and an acid-suppressing agent (proton pump inhibitor or H₂ blocker)
 Bacterial vaginosis:
 Oral: 750 mg (extended release tablet) once daily for 7 days
 Vaginal: 1 applicatorful (~37.5 mg metronidazole) intravaginally once or twice daily for 5 days; apply once in morning and evening if using twice daily, if daily, use at bedtime
 Acne rosacea: Topical:
 0.75%: Apply and rub a thin film twice daily, morning and evening, to entire affected areas after washing. Significant therapeutic results should be noticed within 3 weeks. Clinical studies have demonstrated continuing improvement through 9 weeks of therapy.
 1%: Apply thin film to affected area once daily
 Elderly: Use lower end of dosing recommendations for adults, do not administer as a single dose

Dosing adjustment in renal impairment: Cl_{cr} < 10 mL/minute: Administer 50% of dose or every 12 hours

Hemodialysis: Extensively removed by hemodialysis and peritoneal dialysis (50% to 100%); administer dose posthemodialysis
 Peritoneal dialysis: Dose as for Cl_{cr} < 10 mL/minute
 Continuous arteriovenous or venovenous hemofiltration: Administer usual dose

Dosing adjustment/comments in hepatic disease: Unchanged in mild liver disease; reduce dosage in severe liver disease

Stability Reconstituted solution is stable for 96 hours when refrigerated; for I.V. infusion in normal saline or D₅W and neutralized (with sodium bicarbonate), solution is stable for 24 hours at room temperature; do not refrigerate neutralized solution because a precipitate will occur

Monitoring Parameters WBC count

Administration Oral: May be taken with food to minimize stomach upset. Extended release tablets should be taken on an empty stomach (1 hour before or 2 hours after meals).

I.V.: Avoid contact between the drug and aluminum in the infusion set.

Topical: No disulfiram-like reactions have been reported after topical application, although metronidazole can be detected in the blood. Apply to clean, dry skin. Cosmetics may be used after application (wait at least 5 minutes after using lotion).

Contraindications Hypersensitivity to metronidazole, nitroimidazole derivatives, or any component of the formulation; pregnancy (1st trimester - found to be carcinogenic in rats)

Warnings Use with caution in patients with liver impairment due to potential accumulation, blood dyscrasias; history of seizures, CHF, or other sodium retaining states; reduce dosage in patients with severe liver impairment, CNS disease, and severe renal failure (Cl_{cr} < 10 mL/minute); if *H. pylori* is not eradicated in patients being treated with metronidazole in a regimen, it should be assumed that metronidazole-resistance has occurred and it should not again be used; seizures and neuropathies have been reported especially with increased doses and chronic treatment; if this occurs, discontinue therapy. **[U.S. Boxed Warning]: Possibly carcinogenic based on animal data.**

Dosage Forms [DSC] = Discontinued product

Capsule:

Flagyl®: 375 mg

Cream, topical: 0.75% (45 g)

MetroCream®: 0.75% (45 g) [contains benzyl alcohol]

Noritate®: 1% (60 g)

Gel, topical: 0.75% (45 g)

MetroGel®: 0.75% (45 g) [DSC], 1% (60 g)

Gel, vaginal:

MetroGel-Vaginal®, Vandazole™: 0.75% (70 g)

Infusion [premixed iso-osmotic sodium chloride solution]: 500 mg (100 mL)

Flagyl® I.V. RTU™: 500 mg (100 mL) [contains sodium 14 mEq]

Lotion, topical: 0.75% (60 mL)

MetroLotion®: 0.75% (60 mL) [contains benzyl alcohol]

Tablet: 250 mg, 500 mg

Flagyl®: 250 mg, 500 mg

Tablet, extended release:

Flagyl® ER: 750 mg

Reference Range 500 mg oral dose results in a peak plasma level of 12 mg/L (70 μmol/L)

Overdosage/Treatment

Decontamination: Activated charcoal; **do not** use a cathartic if an ileus is present

Supportive therapy: Benzodiazepines can be used for seizure control with phenobarbital in phenytoin used as second-line agent

Enhancement of elimination: Metronidazole and active metabolite are eliminated by hemodialysis; up to 45% of drug may be removed from 4 hours of hemodialysis; peritoneal dialysis can remove 10% of the dose (during a 7.5 hour period)

Test Interactions May cause falsely decreased AST and ALT

Drug Interactions Inhibits CYP2C9 (weak), 3A4 (moderate)

Cimetidine may increase metronidazole levels.

Cisapride: May inhibit metabolism of cisapride, causing potential arrhythmias; avoid concurrent use

CYP3A4 substrates: Metronidazole may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Ethanol: Ethanol results in disulfiram-like reactions.

Lithium: Metronidazole may increase lithium levels/toxicity; monitor lithium levels.

Phenytoin, phenobarbital may increase metabolism of metronidazole, potentially decreasing its effect.

Warfarin: Metronidazole increases P-T prolongation with warfarin.

Pregnancy Risk Factor B (may be contraindicated in 1st trimester)

Pregnancy Implications Crosses the placenta (carcinogenic in rats); contraindicated for the treatment of trichomoniasis during the first trimester of pregnancy, unless alternative treatment is inadequate. Until safety and efficacy for other indications have been established, use only during pregnancy when the benefit to the mother outweighs the potential risk to the fetus.

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Nursing Implications No disulfiram-like reactions have been reported after **topical** application, although metronidazole can be detected in the blood; avoid contact between the drug and aluminum in the infusion set

Additional Information Sodium content of 500 mg (I.V.): 322 mg (14 mEq); D-lactic acidosis may develop in patients with short bowel syndrome due to overgrowth of D-lactate producing organisms (*Lactobacillus* species, *Streptococcus bovis*, *Bifidobacterium* species, or *Eubacterium* species); peripheral neuropathy usually does not occur in daily doses <800 mg but can occur at daily doses >2 g

Mexiletine

CAS Number 31828-71-4; 5370-10-4

U.S. Brand Names Mexilitil®

Use Management of serious ventricular arrhythmias; suppression of PVCs

Unlabeled/Investigational Use Diabetic neuropathy

Mechanism of Action Class IB antiarrhythmic, structurally related to lidocaine, which may cause increase in systemic vascular resistance and decrease in cardiac output; no significant negative inotropic effect

Adverse Reactions

Excessive doses: 1.8-2.4 g: CNS depression

Cardiovascular: Palpitations, bradycardia, chest pain, syncope, hypotension, arrhythmias (atrial or ventricular), fibrillation (atrial), flutter (atrial), AV block, sinus bradycardia, angina, myocardial depression, QT prolongation

Central nervous system: **Dizziness, lightheadedness, nervousness, confusion, ataxia, memory disturbance**

Dermatologic: Rash

Gastrointestinal: Nausea, vomiting, diarrhea, esophagitis associated with oral forms

Hematologic: Rarely thrombocytopenia

Hepatic: Hepatitis progressing to hepatic necrosis

Neuromuscular & skeletal: **Trembling, unsteady gait, tremors, paresthesia**

Ocular: Diplopia

Otic: Ototoxicity, tinnitus

Respiratory: Dyspnea

Miscellaneous: Positive antinuclear antibody, hiccup

Signs and Symptoms of Overdose Asystole, bradycardia, CNS depression, congestive heart failure, dry mouth, dysphagia, esophageal ulceration, hypotension, impotence, left bundle-branch block, lightheadedness, malaise, memory loss, nausea, neutropenia, paresthesia, QRS prolongation, seizures

Pharmacodynamics/Kinetics

Absorption: Elderly have a slightly slower rate, but extent of absorption is the same as young adults

Distribution: V_d : 5-7 L/kg

Protein binding: 50% to 70%

Metabolism: Hepatic; low first-pass effect

Half-life elimination: Adults: 10-14 hours (average: elderly: 14.4 hours, younger adults: 12 hours); prolonged with hepatic impairment or heart failure

Time to peak: 2-3 hours

Excretion: Urine (10% to 15% as unchanged drug); urinary acidification increases excretion, alkalinization decreases excretion

Dosage Adults: Oral: 400 mg to start, then 200 mg in 8 hours, then 200-400 mg every 8 hours; adjust dose in 50-100 mg increments with a minimum of 2-3 days between doses; do not exceed 1200 mg/day

Dosing adjustment in renal impairment: Cl_{cr} <10 mL/minute: Administer at 50% to 75% of normal dose

Dosing adjustment/comments in hepatic disease: Reduce maintenance dose to 25% to 30% of normal dose; patients with severe liver disease may require lower dosages and must be monitored closely

Administration Administer around-the-clock rather than 3 times/day to promote less variation in peak and trough serum levels; administer with food

Contraindications Hypersensitivity to mexiletine or any component of the formulation; cardiogenic shock; second- or third-degree AV block (except in patients with a functioning artificial pacemaker)

Warnings [U.S. Boxed Warning]: In the Cardiac Arrhythmia Suppression Trial (CAST), recent (>6 days but <2 years ago) myocardial infarction patients with asymptomatic, nonlife-threatening ventricular arrhythmias did not benefit and may have been harmed by attempts to suppress the arrhythmia with flecainide or encainide. An increased mortality or non-fatal cardiac arrest rate (7.7%) was seen in the active treatment group compared with patients in the placebo group (3%). The applicability of the CAST results to other populations is unknown. Antiarrhythmic agents should be reserved for patients with life-threatening ventricular arrhythmias. Can be proarrhythmic. Electrolyte disturbances alter response; should be corrected before initiating therapy. Use cautiously in patients with first-degree block, pre-existing sinus node dysfunction, intraventricular conduction delays, significant hepatic dysfunction, hypotension, or severe CHF. Alterations in urinary pH may change urinary excretion. Rare hepatic toxicity may occur; may cause acute hepatic injury.

Dosage Forms [DSC] = Discontinued product

Capsule, as hydrochloride: 150 mg, 200 mg, 250 mg

Mexilitil®: 150 mg, 200 mg, 250 mg [DSC]

Reference Range

Therapeutic: 0.75-2.00 mcg/mL

Potentially toxic: >2.00 mcg/mL; level of 20 mcg/mL associated with seizures

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: **Do not** use ipecac; lavage (within 1 hour)/activated charcoal is useful

Supportive therapy: Treatment includes supportive measures; atropine may be used for bradycardia; dopamine or norepinephrine can be used for hypotension. Seizures can be treated with benzodiazepines and phenytoin.

Enhancement of elimination: Forced diuresis with mannitol may be useful; do not alkalinize urine, this may delay excretion; hemodialysis may be useful, although there is no overdose experience of this modality

Diagnostic Procedures

- Mexiletine, Blood

Test Interactions Abnormal LFTs, positive ANA, thrombocytopenia; may cause false-positive amphetamine by urinary fluorescence polarization immunoassay

Drug Interactions **Substrate** (major) of CYP1A2, 2D6; **Inhibits** CYP1A2 (strong)

CYP1A2 inducers: May decrease the levels/effects of mexiletine. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of mexiletine. Example inhibitors include ciprofloxacin, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

CYP1A2 substrates: Mexiletine may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, fluvoxamine, mirtazapine, ropinirole, theophylline, and trifluoperazine.

CYP2D6 inhibitors: May increase the levels/effects of mexiletine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Fluvoxamine: Clearance of mexiletine was reduced by 38% following coadministration with fluvoxamine. If used concurrently, mexiletine levels should be monitored.

Quinidine may increase mexiletine blood levels.

Theophylline blood levels are increased by mexiletine.

Urinary alkalinizers (antacids, sodium bicarbonate, acetazolamide) may increase mexiletine blood levels.

Pregnancy Risk Factor C

Lactation Enters breast milk/compatible

Additional Information I.V. form under investigation; bitter tasting

Mianserin

Related Information

- Antidepressant Agents

CAS Number 21535-47-7; 24219-97-4

Use Depression; has been used to treat fluvoxamine-induced akathisia

Mechanism of Action Tetracyclic piperazinoazepine antidepressant with few antimuscarinic effects; a central serotonin antagonist

Adverse Reactions

Cardiovascular: Bradycardia, hypotension (orthostatic), bundle branch block, sinus bradycardia, congestive heart failure, myocardial depression, sinus tachycardia, tachycardia (supraventricular)

Central nervous system: Drowsiness, seizures, restlessness

Dermatologic: Erythema multiforme, toxic epidermal necrolysis

Endocrine & metabolic: Hypokalemia, gynecomastia

Gastrointestinal: Glossitis

Hematologic: Leukopenia/neutropenia (agranulocytosis, granulocytopenia), aplastic anemia

Hepatic: Jaundice, elevated liver function tests

MICONAZOLE

Neuromuscular & skeletal: Polyarthralgia
Miscellaneous: Diaphoresis, restless legs syndrome
Signs and Symptoms of Overdose Delirium, dizziness, gynecomastia, heart block, hypokalemia, hypotension, prolonged sedation, seizures, tachycardia/bradycardia with conduction disturbances leading to complete AV block, toxic epidermal necrolysis

Toxicodynamics/Kinetics

Distribution: V_d : 16 L/kg
Protein binding: 90%
Metabolism: Hepatic to two active metabolites
Bioavailability: 70%
Half-life: 6-40 hours
Time to peak plasma levels: 1-3 hours
Elimination: Clearance: 0.5 L/hour/kg

Dosage Initial dose: 30-40 mg/day; usual dose: 30-90 mg/day; maximum dose: 200 mg/day; for fluvoxamine-induced akathisia: 15 mg at night

Reference Range Peak serum level at a dose of 60 mg/day: 100-120 mcg/L; a peak plasma level of 439 mcg/L associated with heart block

Overdosage/Treatment

Decontamination: **Do not** induce emesis; activated charcoal
Supportive therapy: Treat seizures with diazepam or lorazepam; phenobarbital is second choice; atropine or isoproterenol can be used for bradycardia

Enhancement of elimination: Multiple dosing of activated charcoal or hemodialysis is not likely to be effective

Specific References

Martínez MA, Sánchez de la Torre C, and Almarza E. Miconazole

CAS Number 22832-87-7; 22916-47-8

U.S. Brand Names Aloe Vesta[®] 2-n-1 Antifungal [OTC]; Baza[®] Antifungal [OTC]; Carrington Antifungal [OTC]; Femizol-M[™] [OTC]; Fungoid[®] Tincture [OTC]; Lotrimin[®] AF Powder/Spray [OTC]; Micaderm[®] [OTC]; Micatin[®] [OTC]; Micro-Guard[®] [OTC]; Mitrazol[™] [OTC]; Monistat-Derm[®]; Monistat[®] 1 Combination Pack [OTC]; Monistat[®] 3 [OTC]; Monistat[®] 7 [OTC]; Triple Care[®] Antifungal [OTC]; Zeasorb[®]-AF [OTC]

Synonyms Miconazole Nitrate

Use Treatment of vulvovaginal candidiasis and a variety of skin and mucous membrane fungal infections

Mechanism of Action Inhibits biosynthesis of ergosterol, damaging the fungal cell wall membrane, which increases permeability causing leaking of nutrients

Adverse Reactions

Topical: Allergic contact dermatitis, burning, maceration
Vaginal: Abdominal cramps, burning, irritation, itching

Pharmacodynamics/Kinetics

Absorption: Topical: Negligible
Distribution: Widely to body tissues; penetrates well into inflamed joints, vitreous humor of eye, and peritoneal cavity, but poorly into saliva and sputum; crosses blood-brain barrier but only to a small extent
Protein binding: 91% to 93%
Metabolism: Hepatic
Half-life elimination: Multiphasic: Initial: 40 minutes; Secondary: 126 minutes; Terminal: 24 hours
Excretion: Feces (~50%); urine (<1% as unchanged drug)

Dosage Topical: Children and Adults: **Note:** Not for OTC use in children <2 years:

Tinea pedis and tinea corporis: Apply twice daily for 4 weeks

Tinea cruris: Apply twice daily for 2 weeks

Vaginal: Adults: Vulvovaginal candidiasis:

Cream, 2%: Insert 1 applicatorful at bedtime for 7 days

Cream, 4%: Insert 1 applicatorful at bedtime for 3 days

Suppository, 100 mg: Insert 1 suppository at bedtime for 7 days

Suppository, 200 mg: Insert 1 suppository at bedtime for 3 days

Suppository, 1200 mg: Insert 1 suppository at bedtime (a one-time dose)

Note: Many products are available as a combination pack, with a suppository for vaginal instillation and cream to relieve external symptoms.

Contraindications Hypersensitivity to miconazole or any component of the formulation

Warnings For external use only; discontinue if sensitivity or irritation develop. Petrolatum-based vaginal products may damage rubber or latex condoms or diaphragms. Separate use by 3 days.

Dosage Forms [DSC] = Discontinued product

Combination products: Miconazole nitrate vaginal suppository 200 mg (3s) and miconazole nitrate external cream 2%

Monistat[®] 1 Combination Pack: Miconazole nitrate vaginal insert 1200 mg (1) and miconazole nitrate external cream 2% (5 g)

[Note: Do not confuse with 1-Day[™] (formerly Monistat[®] 1) which contains tioconazole]

Monistat[®] 3 Combination Pack:

Miconazole nitrate vaginal suppository 200 mg (3s) and miconazole nitrate external cream 2%

Miconazole nitrate vaginal cream 4% and miconazole nitrate external cream 2%

Monistat[®] 7 Combination Pack:

Miconazole nitrate vaginal suppository 100 mg (7s) and miconazole nitrate external cream 2%

Miconazole nitrate vaginal cream 2% (7 prefilled applicators) and miconazole nitrate external cream 2%

Cream, topical, as nitrate: 2% (15 g, 30 g, 45 g)

Baza[®] Antifungal: 2% (4 g, 57 g, 142 g) [zinc oxide based formula]

Carrington Antifungal: 2% (150 g)

Micaderm[®], Neosporin[®] AF, Podactin: 2% (30 g)

Micatin[®] Athlete's Foot, Micatin[®] Jock Itch: 2% (15 g)

Micro-Guard[®], Mitrazol[™]: 2% (60 g)

Monistat-Derm[®]: 2% (15 g, 30 g, 85 g)

Secura[®] Antifungal: 2% (60 g, 98 g)

Cream, vaginal, as nitrate [prefilled or refillable applicator]: 2% (45 g)

Monistat[®] 3: 4% (15 g, 25 g)

Monistat[®] 7: 2% (45 g)

Liquid, spray, topical, as nitrate:

Micatin[®] Athlete's Foot: 2% (90 mL) [contains alcohol]

Neosporin AF[®]: 2% (105 mL)

Lotion, powder, as nitrate (Zeasorb[®]-AF): 2% (56 g) [contains alcohol 36%]

Ointment, topical, as nitrate:

Aloe Vesta[®] 2-n-1 Antifungal: 2% (60 g, 150 g)

DermaFungal: 2% (113 g)

Dermagran[®] AF: (113 g) [contains vitamin A and zinc]

Powder, topical, as nitrate:

Lotrimin[®] AF: 2% (160 g)

Micro-Guard[®]: 2% (90 g)

Mitrazol[™]: 2% (30 g)

Zeasorb[®]-AF: 2% (70 g)

Powder spray, topical, as nitrate:

Lotrimin[®] AF, Lotrimin[®] AF Jock Itch: 2% (140 g)

Micatin[®] Athlete's Foot, Micatin[®] Jock Itch: 2% (90 g) [contains alcohol]

Neosporin[®] AF: 2% (85 g)

Suppository, vaginal, as nitrate: 100 mg (7s); 200 mg (3s)

Monistat[®] 3: 200 mg (3s)

Monistat[®] 7: 100 mg (7s)

Tablet, effervescent, topical, as nitrate (DiabetAid[™] Antifungal Foot Bath): 2% (10s)

Tincture, topical, as nitrate (Fungoid[®]): 2% (30 mL, 473 mL) [contains isopropyl alcohol 30%]; 30 mL size also available in a treatment kit which contains nail scrub and nail brush]

Overdosage/Treatment

Decontamination: Dermal: Wash with soap and water

Supportive therapy: Seizures and anaphylaxis can be treated with standard therapy

Enhancement of elimination: Not dialyzable (0% to 5%)

Drug Interactions **Substrate** of CYP3A4 (major); **Inhibits** CYP1A2 (moderate), 2A6 (strong), 2B6 (weak), 2C9 (strong), 2C19 (strong), 2D6 (strong), 2E1 (moderate), 3A4 (strong)

Note: The majority of reported drug interactions were observed following intravenous miconazole administration. Although systemic absorption following topical and/or vaginal administration is low, potential interactions due to CYP isoenzyme inhibition may occur (rarely). This may be particularly true in situations where topical absorption may be increased (eg, inflamed tissue).

Amphotericin B: Antifungal effects of both agents may be decreased

Cisapride: Risk of cardiotoxicity may be increased due to effect on metabolism; concurrent administration is contraindicated

CYP1A2 substrates: Miconazole may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, fluvoxamine, mexiletine, mirtazapine, ropinirole, theophylline, and trifluoperazine.

CYP2A6 substrates: Miconazole may increase the levels/effects of CYP2A6 substrates. Example substrates include dexmedetomidine and ifosfamide.

CYP2C9 Substrates: Miconazole may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

CYP2C19 substrates: Miconazole may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

CYP2D6 substrates: Miconazole may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtaza-

pine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Miconazole may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP2E1 substrates: Miconazole may increase the levels/effects of CYP2E1 substrates. Example substrates include inhalational anesthetics, theophylline, and trimethadione.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of miconazole. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 substrates: Miconazole may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Phenytoin: Serum concentration may be increased by miconazole

Sulfonylureas: Hypoglycemic effects may be increased

Warfarin: An increased anticoagulant effect may occur with coadministration, including reports associated with short-term (3-day) intravaginal miconazole therapy

Pregnancy Risk Factor C

Pregnancy Implications Benefits of use should outweigh possible risks

Lactation Excretion in breast milk unknown/use caution

Midazolam

CAS Number 59467-70-8; 59467-94-6; 59467-96-8

U.S. Brand Names Versed® [DSC]

Synonyms Midazolam Hydrochloride; Versed

Impairment Potential Yes

Use Preoperative sedation and provides conscious sedation prior to diagnostic or radiographic procedures; ICU sedation (continuous infusion); intravenous anesthesia (induction); intravenous anesthesia (maintenance)

Unlabeled/Investigational Use Anxiety, status epilepticus

Mechanism of Action A short-acting triazolobenzodiazepine which depresses all levels of the CNS, including the limbic and reticular formation, probably through the increased action of gamma-aminobutyric acid (GABA), which is a major inhibitory neurotransmitter in the brain

Adverse Reactions

Cardiovascular: Cardiac arrest, **hypotension**, bradycardia, ventricular dysrhythmia, sinus bradycardia, arrhythmias (ventricular)

Central nervous system: Drowsiness, amnesia, anxiety, dizziness, paradoxical excitation, psychosis, sedation, headache, delirium, ataxia, hypothermia, extrapyramidal reactions, aggressive behavior

Dermatologic: Angioedema, urticaria, pruritus, exanthem

Gastrointestinal: Nausea, vomiting

Local: Pain and local reactions at injection site (severity less than diazepam)

Neuromuscular & skeletal: Dysarthria, clonus, myoclonus, paresthesia

Ocular: Blurred vision, diplopia, mydriasis

Respiratory: **Apnea**, respiratory depression, laryngospasm, wheezing

Miscellaneous: Physical and psychological dependence with prolonged use, **hiccups**

Signs and Symptoms of Overdose Apnea, cardiovascular arrest, chills, coma, confusion, cough, dyspnea, encephalopathy, euphoria, hypotension, hypothermia, hyperactivity, respiratory depression, seizures, stupor

Pharmacodynamics/Kinetics

Onset of action: I.M.: Sedation: ~15 minutes; I.V.: 1-5 minutes

Peak effect: I.M.: 0.5-1 hour

Duration: I.M.: Up to 6 hours; Mean: 2 hours

Absorption: Oral: Rapid

Distribution: V_d: 0.8-2.5 L/kg; increased with congestive heart failure (CHF) and chronic renal failure

Protein binding: 95%

Metabolism: Extensively hepatic via CYP3A4

Bioavailability: Mean: 45%

Half-life elimination: 1-4 hours; prolonged with cirrhosis, congestive heart failure, obesity, and elderly

Excretion: Urine (as glucuronide conjugated metabolites); feces (~2% to 10%)

Dosage

The dose of midazolam needs to be individualized based on the patient's age, underlying diseases, and concurrent medications. Decrease dose (by ~30%) if narcotics or other CNS depressants are administered concomitantly. **Personnel and equipment needed for standard respiratory resuscitation should be immediately available during midazolam administration.**

Children <6 years may require higher doses and closer monitoring than older children; calculate dose on ideal body weight

Conscious sedation for procedures or preoperative sedation:

Oral: 0.25-0.5 mg/kg as a single dose preprocedure, up to a maximum of 20 mg; administer 30-45 minutes prior to procedure. Children <6 years or less cooperative patients may require as much as 1 mg/kg as a single dose; 0.25 mg/kg may suffice for children 6-16 years of age.

Intranasal (not an approved route): 0.2 mg/kg (up to 0.4 mg/kg in some studies), to a maximum of 15 mg; may be administered 30-45 minutes prior to procedure

I.M.: 0.1-0.15 mg/kg 30-60 minutes before surgery or procedure; range 0.05-0.15 mg/kg; doses up to 0.5 mg/kg have been used in more anxious patients; maximum total dose: 10 mg

I.V.:

Infants <6 months: Limited information is available in nonintubated infants; dosing recommendations not clear; infants <6 months are at higher risk for airway obstruction and hypoventilation; titrate dose in small increments to desired effect; monitor carefully

Infants 6 months to Children 5 years: Initial: 0.05-0.1 mg/kg; titrate dose carefully; total dose of 0.6 mg/kg may be required; usual maximum total dose: 6 mg

Children 6-12 years: Initial: 0.025-0.05 mg/kg; titrate dose carefully; total doses of 0.4 mg/kg may be required; usual maximum total dose: 10 mg

Children 12-16 years: Dose as adults; usual maximum total dose: 10 mg

Conscious sedation during mechanical ventilation: Children: Loading dose: 0.05-0.2 mg/kg, followed by initial continuous infusion: 0.06-0.12 mg/kg/hour (1-2 mcg/kg/minute); titrate to the desired effect; usual range: 0.4-6 mcg/kg/minute

Status epilepticus refractory to standard therapy (unlabeled use):

Infants >2 months and Children: Loading dose: 0.15 mg/kg followed by a continuous infusion of 1 mcg/kg/minute; titrate dose upward every 5 minutes until clinical seizure activity is controlled; mean infusion rate required in 24 children was 2.3 mcg/kg/minute with a range of 1-18 mcg/kg/minute

Adults:

Preoperative sedation:

I.M.: 0.07-0.08 mg/kg 30-60 minutes prior to surgery/procedure; usual dose: 5 mg; **Note:** Reduce dose in patients with COPD, high-risk patients, patients ≥60 years of age, and patients receiving other narcotics or CNS depressants

I.V.: 0.02-0.04 mg/kg; repeat every 5 minutes as needed to desired effect or up to 0.1-0.2 mg/kg

Intranasal (not an approved route): 0.2 mg/kg (up to 0.4 mg/kg in some studies); administer 30-45 minutes prior to surgery/procedure

Conscious sedation: I.V.: Initial: 0.5-2 mg slow I.V. over at least 2 minutes; slowly titrate to effect by repeating doses every 2-3 minutes if needed; usual total dose: 2.5-5 mg; use decreased doses in elderly

Healthy Adults <60 years: Some patients respond to doses as low as 1 mg; no more than 2.5 mg should be administered over a period of 2 minutes. Additional doses of midazolam may be administered after a 2-minute waiting period and evaluation of sedation after each dose increment. A total dose >5 mg is generally not needed. If narcotics or other CNS depressants are administered concomitantly, the midazolam dose should be reduced by 30%.

Anesthesia: I.V.:

Induction:

Unpremedicated patients: 0.3-0.35 mg/kg (up to 0.6 mg/kg in resistant cases)

Premedicated patients: 0.15-0.35 mg/kg

Maintenance: 0.05-0.3 mg/kg as needed, or continuous infusion 0.25-1.5 mcg/kg/minute

Sedation in mechanically-ventilated patients: I.V. continuous infusion: 100 mg in 250 mL D₅W or NS (if patient is fluid-restricted, may concentrate up to a maximum of 0.5 mg/mL); initial dose: 0.02-0.08 mg/kg (~1 mg to 5 mg in 70 kg adult) initially and either repeated at 5-15 minute intervals until adequate sedation is achieved or continuous infusion rates of 0.04-0.2 mg/kg/hour and titrate to reach desired level of sedation

Elderly: I.V.: Conscious sedation: Initial: 0.5 mg slow I.V.; give no more than 1.5 mg in a 2-minute period; if additional titration is needed, give no more than 1 mg over 2 minutes, waiting another 2 or more minutes to evaluate sedative effect; a total dose of >3.5 mg is rarely necessary

Dosage adjustment in renal impairment:

Hemodialysis: Supplemental dose is not necessary

Peritoneal dialysis: Significant drug removal is unlikely based on physiochemical characteristics

Stability Admixtures do not require protection from light for short-term storage

Monitoring Parameters Respiratory and cardiovascular status, blood pressure, blood pressure monitor required during I.V. administration

Administration Intranasal: Administer using a 1 mL needleless syringe into the nostrils over 15 seconds; use the 5 mg/mL injection; 1/2 of the dose may be administered to each nostril

Oral: Do not mix with any liquid (such as grapefruit juice) prior to administration

Parenteral:

I.M.: Administer deep I.M. into large muscle.

I.V.: Administer by slow I.V. injection over at least 2-5 minutes at a concentration of 1-5 mg/mL or by I.V. infusion. Continuous infusions should be administered via an infusion pump.

Contraindications Hypersensitivity to midazolam or any component of the formulation, including benzyl alcohol (cross-sensitivity with other benzodiazepines may exist); parenteral form is not for intrathecal or epidural injection; narrow-angle glaucoma; concurrent use of potent inhibitors of CYP3A4 (amprenavir, atazanavir, or ritonavir); pregnancy

Warnings [U.S. Boxed Warning]: May cause severe respiratory depression, respiratory arrest, or apnea. Use with extreme caution, particularly in noncritical care settings. Appropriate resuscitative equipment and qualified personnel must be available for administration and monitoring. Initial dosing must be cautiously titrated and individualized, particularly in elderly or debilitated patients, patients with hepatic impairment (including alcoholics), or in renal impairment, particularly if other CNS depressants (including opiates) are used concurrently. **[U.S. Boxed Warning]: Initial doses in elderly or debilitated patients should be conservative; as little as 1 mg, but not to exceed 2.5 mg.** Use with caution in patients with respiratory disease or impaired gag reflex. Use during upper airway procedures may increase risk of hypoventilation. Prolonged responses have been noted following extended administration by continuous infusion (possibly due to metabolite accumulation) or in the presence of drugs which inhibit midazolam metabolism.

Causes CNS depression (dose-related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). A minimum of 1 day should elapse after midazolam administration before attempting these tasks. Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury and should be used with extreme caution in patients who are at risk of these events (especially the elderly).

May cause hypotension - hemodynamic events are more common in pediatric patients or patients with hemodynamic instability. Hypotension and/or respiratory depression may occur more frequently in patients who have received narcotic analgesics. Use with caution in obese patients, chronic renal failure, and CHF. Does not protect against increases in heart rate or blood pressure during intubation. Should not be used in shock, coma, or acute alcohol intoxication. **[U.S. Boxed Warning]: Parenteral form contains benzyl alcohol; avoid rapid injection in neonates or prolonged infusions.** Avoid intra-arterial administration or extravasation of parenteral formulation.

Midazolam causes anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Benzodiazepines have been associated with dependence and acute withdrawal symptoms on discontinuation or reduction in dose. Acute withdrawal, including seizures, may be precipitated after administration of flumazenil to patients receiving long-term benzodiazepine therapy.

Dosage Forms

Injection, solution: 1 mg/mL (2 mL, 5 mL, 10 mL); 5 mg/mL (1 mL, 2 mL, 5 mL, 10 mL) [contains benzyl alcohol 1%]

Injection, solution [preservative free]: 1 mg/mL (2 mL, 5 mL); 5 mg/mL (1 mL, 2 mL)

Syrup: 2 mg/mL (118 mL) [contains sodium benzoate; cherry flavor]

Reference Range Intranasal dose of 0.1-0.2 mg/kg result in serum midazolam levels of between 40-70 ng/mL within 3 minutes; plasma midazolam levels >100 ng/mL associated with sedation; plasma midazolam levels >200 ng/mL associated with sleep

Overdosage/Treatment

Supportive therapy: Rarely is mechanical ventilation required. Flumazenil (Romazicon™) has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression. Resedation usually does not occur at midazolam adult doses <10 mg. Acetaminophen can be used to mask the metallic bitter taste.

Enhancement of elimination: Hemodialysis is not useful; multiple dosing of activated charcoal may be useful

Antidote(s)

● Flumazenil [ANTIDOTE]

Test Interactions Visine®, Drano®, bleach, and soap may result in a false-negative urine test

Drug Interactions Substrate of CYP2B6 (minor), 3A4 (major); Inhibits CYP2C8 (weak), 2C9 (weak), 3A4 (weak)

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect. **If narcotics or other CNS depressants are administered concomitantly, the midazolam dose should be reduced by 30% if <65 years of age, or by at least 50% if >65 years of age.**

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of midazolam. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of midazolam. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nocardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Levodopa: Therapeutic effects may be diminished in some patients following the addition of a benzodiazepine; limited/inconsistent data

Oral contraceptives: May decrease the clearance of some benzodiazepines (those which undergo oxidative metabolism); monitor for increased benzodiazepine effect

Saquinavir: A 56% reduction in clearance and a doubling of midazolam's half-life were seen with concurrent administration with saquinavir.

Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation

Pregnancy Risk Factor D

Pregnancy Implications Crosses the placenta; not recommended for use during pregnancy

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Additional Information Each mL contains 0.14 mEq of sodium.

Flumazenil (0.4 mg I.V.) has been used successfully in reversing midazolam-induced laryngospasm.

Grapefruit juice may increase serum concentrations of midazolam; avoid concurrent use with oral form

Midodrine

CAS Number 3092-17-9; 42794-76-3

U.S. Brand Names ProAmatine®

Synonyms Midodrine Hydrochloride

Use Orphan drug: Treatment of symptomatic orthostatic hypotension

Unlabeled/Investigational Use Investigational: Management of urinary incontinence

Mechanism of Action Oral sympathomimetic agent which is an alpha₁-adrenergic agonist resulting in vasoconstriction; essentially a prodrug

Adverse Reactions

Cardiovascular: Tachycardia, bradycardia, supine hypertension, flushing, sinus bradycardia, sinus tachycardia

Central nervous system: Headache, insomnia, sleep disturbance, irritability

Dermatologic: **Scalp pruritus**

Gastrointestinal: Nausea, xerostomia

Genitourinary: **Urinary urgency, retention**

Neuromuscular & skeletal: **Piloerection, paresthesia**

Renal: **Polyuria**

Miscellaneous: Diaphoresis

Pharmacodynamics/Kinetics

Onset of action: ~1 hour

Duration: 2-3 hours

Absorption: Rapid
 Distribution: V_d (desglymidodrine): <1.6 L/kg; poorly across membrane (eg, blood brain barrier)
 Protein binding: Minimal
 Metabolism: Hepatic; midodrine is a prodrug which undergoes rapid deglycination to desglymidodrine (active metabolite); metabolism occurs in many tissues and plasma
 Bioavailability: Desglymidodrine: 93%
 Half-life elimination: Desglymidodrine: ~3-4 hours; Midodrine: 25 minutes
 Time to peak, serum: Desglymidodrine: 1-2 hours; Midodrine: 30 minutes
 Excretion: Urine (2% to 4%)
 Clearance: Desglymidodrine: 385 mL/minute (predominantly by renal secretion)

Dosage

Adults: Oral: 10 mg 3 times/day during daytime hours (every 3-4 hours) when patient is upright (maximum: 40 mg/day)

Dosing adjustment in renal impairment: 2.5 mg 3 times/day, gradually increasing as tolerated

Monitoring Parameters Blood pressure, renal and hepatic parameters
Administration Doses may be given in approximately 3- to 4-hour intervals (eg, shortly before or upon rising in the morning, at midday, in the late afternoon not later than 6 PM). Avoid dosing after the evening meal or within 4 hours of bedtime. Continue therapy only in patients who appear to attain symptomatic improvement during initial treatment. Standing systolic blood pressure may be elevated 15-30 mm Hg at 1 hour after a 10 mg dose. Some effect may persist for 2-3 hours.

Contraindications Hypersensitivity to midodrine or any component of the formulation; severe organic heart disease; urinary retention; pheochromocytoma; thyrotoxicosis; persistent and significant supine hypertension

Warnings [U.S. Boxed Warning]: Indicated for patients for whom orthostatic hypotension significantly impairs their daily life despite standard clinical care. Use is not recommended with supine hypertension. Caution should be exercised in patients with diabetes, visual problems (especially if receiving fludrocortisone), urinary retention (reduce initial dose), or hepatic dysfunction; monitor renal and hepatic function prior to and periodically during therapy; safety and efficacy has not been established in children; discontinue and re-evaluate therapy if signs of bradycardia occur.

Dosage Forms Tablet, as hydrochloride: 2.5 mg, 5 mg, 10 mg

Reference Range After a 2.5 mg oral dose, peak serum level is ~11 mcg/L at 0.5 hour; serum desglymidodrine level is 5 mcg/L at 1-hour postingestion

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: There is no specific antidote for midodrine intoxication and the bulk of the treatment is supportive. Hyperactivity and agitation usually respond to reduced sensory input, however with extreme agitation haloperidol (2-5 mg I.M. for adults) may be required. Hyperthermia is best treated with external cooling measures, or when severe or unresponsive, muscle paralysis with pancuronium may be needed. Hypertension is usually transient and generally does not require treatment unless severe. For diastolic blood pressures >110 mm Hg, a nitroprusside infusion should be initiated. Seizures usually respond to diazepam or lorazepam I.V. and/or phenytoin maintenance regimens.

Drug Interactions Increased effect: Concomitant fludrocortisone results in hypernatremia or an increase in intraocular pressure and glaucoma; bradycardia may be accentuated with concomitant administration of cardiac glycosides, psychotherapeutics, and beta-blockers; alpha-agonists may increase the pressure effects and alpha-antagonists may negate the effects of midodrine

Pregnancy Risk Factor C

Pregnancy Implications Increased rate of embryo resorption and decreased fetal weight were observed in animal studies. Use during pregnancy should be avoided unless the potential benefit outweighs the risk to the fetus.

Lactation Excretion in breast milk is unknown/use caution

Specific References

Young TM and Mathias CJ, "Taste and Smell Disturbance with the Alpha-Adrenoceptor Agonist Midodrine," *Ann Pharmacother*, 2004, 38(11):1868-70.

Mifepristone

CAS Number 84371-65-3

U.S. Brand Names Mifeprex®

Synonyms RU-38486; RU-486

Use Medical termination of intrauterine pregnancy, through day 49 of pregnancy. Patients may need treatment with misoprostol and possibly surgery to complete therapy

Unlabeled/Investigational Use Treatment of unresectable meningioma; has been studied in the treatment of breast cancer, ovarian cancer, and adrenal cortical carcinoma

Mechanism of Action An antiprogesterin agent which interacts upon the decidua progesterone receptors resulting in increased release of endometrium prostaglandins and thus uterine bleeding, contraction and cervical dilation occurs thus promoting fetal evacuation

Adverse Reactions

Vaginal bleeding and uterine cramping are expected to occur when this medication is used to terminate a pregnancy; 90% of women using this medication for this purpose also report adverse reactions

Cardiovascular: Syncope, myocardial infarction

Central nervous system: **Headache, dizziness**, fatigue, fever, insomnia, anxiety, fainting

Gastrointestinal: **Abdominal pain (cramping), nausea, vomiting, diarrhea**, dyspepsia

Genitourinary: **Uterine cramping**, uterine hemorrhage, vaginitis, pelvic pain, ruptured ectopic pregnancy, leukorrhea

Hematologic: Decreased hemoglobin >2 g/dL, anemia

Hepatic: Significant SGOT, SGPT, alkaline phosphatase, and GT changes have been reported rarely

Neuromuscular & skeletal: Back pain, rigors, leg pain, weakness

Respiratory: Sinusitis

Miscellaneous: Viral infection, bacterial infection

In trials for unresectable meningioma, the most common adverse effects included fatigue, hot flashes, gynecomastia or breast tenderness, hair thinning, and rash. In premenopausal women, vaginal bleeding may be seen shortly after beginning therapy and cessation of menses is common. Thyroiditis and effects related to antigluco-corticoid activity have also been noted.

Pharmacodynamics/Kinetics

Absorption: Oral: rapid

Protein binding: 98% to albumin and α_1 -acid glycoprotein

Metabolism: Hepatic via CYP3A4 to three metabolites (may possess some antiprogesterin and antigluco-corticoid activity)

Bioavailability: Oral: 69%

Half-life elimination: Terminal: 18 hours following a slower phase where 50% eliminated between 12-72 hours

Time to peak: Oral: 90 minutes

Excretion: Feces (83%); urine (9%)

Dosage

Adults: Termination of pregnancy: Treatment consists of three office visits by the patient; the patient must read medication guide and sign patient agreement prior to treatment:

Day 1: 600 mg (three 200 mg tablets) taken as a single dose under physician supervision

Day 3: Patient must return to the healthcare provider 2 days following administration of mifepristone; if termination of pregnancy cannot be confirmed using ultrasound or clinical examination: 400 mcg (two 200 mcg tablets) of misoprostol; patient may need treatment for cramps or gastrointestinal symptoms at this time

Day 14: Patient must return to the healthcare provider ~14 days after administration of mifepristone; confirm complete termination of pregnancy by ultrasound or clinical exam. Surgical termination is recommended to manage treatment failures.

Elderly: Safety and efficacy have not been established

Dosage adjustment in renal impairment: Safety and efficacy have not been established

Dosage adjustment in hepatic impairment: Safety and efficacy have not been established; use with caution due to CYP3A4 metabolism

Unlabeled use: Refer to individual protocols. The dose used in meningioma is usually 200 mg/day, continued based on toxicity and response.

Monitoring Parameters Clinical exam and/or ultrasound to confirm complete termination of pregnancy; hemoglobin, hematocrit, and red blood cell count in cases of heavy bleeding

Contraindications Hypersensitivity to mifepristone, misoprostol, other prostaglandins, or any component of the formulation; chronic adrenal failure; porphyrias; hemorrhagic disorder or concurrent anticoagulant therapy; pregnancy termination >49 days; intrauterine device (IUD) in place; ectopic pregnancy or undiagnosed adnexal mass; concurrent long-term corticosteroid therapy; inadequate or lack of access to emergency medical services; inability to understand effects and/or comply with treatment

Warnings [U.S. Boxed Warning]: Patient must be instructed of the treatment procedure and expected effects. A signed agreement form must be kept in the patient's file. Physicians may obtain patient agreement forms, physician enrollment forms, and medical consultation directly from Danco Laboratories at 1-877-432-7596. Adverse effects (including blood transfusions, hospitalization, ongoing pregnancy, and other major complications) must be reported in writing to the medication distributor. To be administered only by physicians who can date pregnancy, diagnose ectopic pregnancies, provide access to surgical abortion (if needed), and can provide access to emergency care. Medication will be distributed directly to these physicians following signed agreement with the distributor. Must be administered under

supervision by the qualified physician. Pregnancy is dated from day 1 of last menstrual period (presuming a 28-day cycle, ovulation occurring midcycle). Pregnancy duration can be determined using menstrual history and clinical examination. Ultrasound should be used if an ectopic pregnancy is suspected or if duration of pregnancy is uncertain. Ultrasonography may not identify all ectopic pregnancies, and health-care providers should be alert for signs and symptoms which may be related to undiagnosed ectopic pregnancy in any patient who receives mifepristone

Bleeding occurs and should be expected (average 9-16 days, may be ≥ 30 days). In some cases, bleeding may be prolonged and heavy, potentially leading to hypovolemic shock. **[U.S. Boxed Warning]: Patients should be counseled to seek medical attention in cases of excessive bleeding;** the manufacturer cites soaking through two thick sanitary pads per hour for two consecutive hours as an example of excessive bleeding. Bleeding may require blood transfusion (rare), curettage, saline infusions, and/or vasoconstrictors. Use caution in patients with severe anemia. Confirmation of pregnancy termination by clinical exam or ultrasound must be made 14 days following treatment. Manufacturer recommends surgical termination of pregnancy when medical termination fails or is not complete. Prescriber should determine in advance whether they will provide such care themselves or through other providers. Preventative measures to prevent rhesus immunization must be taken prior to surgical abortion. Prescriber should also give the patient clear instructions on whom to call and what to do in the event of an emergency following administration of mifepristone.

[U.S. Boxed Warning]: Bacterial infections have been reported following use of this product. In rare cases, these infections may be serious and/or fatal, with septic shock as a potential complication. A causal relationship has not been established. Sustained fever, abdominal pain, or pelvic tenderness should prompt evaluation; however, healthcare professionals are warned that atypical presentations of serious infection without these symptoms have also been noted. Patients presenting with nausea, vomiting, diarrhea, or weakness, with or without abdominal pain or fever, should be evaluated for serious bacterial infection when symptoms occur > 24 hours after taking misoprostol. Treatment with antibiotics, including coverage for anaerobic bacteria (eg, *Clostridium sordellii*) should be initiated. **[U.S. Boxed Warning]: Patients undergoing treatment with mifepristone should be instructed to bring their Medication Guide with them when an obtaining treatment from an emergency room or healthcare provider that did not prescribe the medication initially in order to identify that they are undergoing a medical abortion.**

Safety and efficacy have not been established for use in women with chronic cardiovascular, hypertensive, hepatic, respiratory, or renal disease, insulin-dependent diabetes mellitus, severe anemia, or heavy smokers. Women > 35 years of age and smokers (> 10 cigarettes/day) were excluded from clinical trials. Safety and efficacy in pediatric patients have not been established.

Dosage Forms Tablet: 200 mg

Reference Range Peak serum mifepristone level 3 hours following a 25 mg/kg dose: ~ 7.5 $\mu\text{mol/L}$

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Transfusion and curettage may be required to treat uterine bleeding; acetaminophen can be used to treat headaches

Enhanced elimination: Multiple dosing of activated charcoal may be effective

Test Interactions May increase morning serum cortisol

Drug Interactions

Substrate of CYP3A4 (minor); **Inhibits** CYP2D6 (weak), 3A4 (weak)

There are no reported interactions. It might be anticipated that the concurrent administration of mifepristone and a progestin would result in an attenuation of the effects of one or both agents.

Pregnancy Risk Factor X

Pregnancy Implications This medication is used to terminate pregnancy; there are no approved treatment indications for its use during pregnancy. Prostaglandins (including mifepristone and misoprostol) may have teratogenic effects when used during pregnancy. It is unknown if mifepristone is excreted in human milk; breast-feeding contraindicated. Breast milk should be discarded for a few days following use of this medication.

Lactation Excretion in breast milk unknown/contraindicated

Additional Information An abortifacient approved in France in September 1988. Patients with prosthetic heart valves require chemoprophylaxis; avoid aspirin or other nonsteroidal anti-inflammatory drugs for 2 weeks

Specific Reference

Miech RP, "Pathophysiology of Mifepristone-Induced Septic Shock Due to *Clostridium sordellii*," *Ann Pharmacother*, 2005, 39(9):1483-8.

Milnacipran

Pronunciation (mil NAY ci pran)

CAS Number 101152-94-7; 17513-61-0; 92623-85-3

Impairment Potential Yes; particularly if daily dose is > 100 mg

Use Treatment of major depression

Mechanism of Action A cyclopropanecarboxylic acid derivative which inhibits reuptake of both serotonin and noradrenaline neurotransmitters.

Adverse Reactions

Cardiovascular: Orthostatic hypotension (2% to 21%), tachycardia (2%), hypotension (1% to 2%)

Central nervous system: Headache (8%), dizziness (3% to 5%), tremor (3%), fatigue (2%), lethargy (2%), insomnia (5% to 6%), mania (rare)

Gastrointestinal: Nausea (11%), dry mouth (8%), abdominal pain (7%), constipation (7%)

Genitourinary: Dysuria (2%)

Hepatic: Transient elevation of transaminases

Ocular: Visual disturbances (2%)

Miscellaneous: Diaphoresis (3% to 4%)

Signs and Symptoms of Overdose CNS depression, coma, lethargy, tachycardia, tachypnea, vomiting

Admission Criteria/Prognosis Admit any symptomatic patient or adult ingestion > 300 mg

Toxicodynamics/Kinetics

Volume of distribution: 5 L/kg

Protein binding: 13%

Metabolism: Hepatic glucuronidation to inactive metabolite

Half-life: 8 hours

Bioavailability: Oral: 85%

Time to peak concentration: 0.5-4 hours

Elimination: Renal clearance: 3.2 mL/kg/minute

Renal: 90% (50% to 60% unchanged); 20% to 30% milnacipran glucuronide

Fecal: $< 5\%$

Dosage Oral: 50 mg twice daily

Dosing adjustment in renal insufficiency: 25 mg twice daily

Dosage Forms Capsule: 25 mg, 50 mg

Reference Range Therapeutic serum milnacipran level: 100-300 ng/mL;

Lethal serum concentration: 3000 ng/mL

Overdosage/Treatment

Oral decontamination: Lavage within 1 hour with activated charcoal

Enhanced elimination: Hemodialysis is not likely to be helpful

Additional Information Brand names: Dalcipran, Ixel, Milneurion, Tole-domin

Mineral Oil

CAS Number 8012-95-1

U.S. Brand Names Fleet[®] Mineral Oil Enema [OTC]; Kondremul[®] [OTC]; Liqui-Doss[®] [OTC]

Synonyms Heavy Mineral Oil; Liquid Paraffin; White Mineral Oil

Use Temporary relief of constipation, to relieve fecal impaction, preparation for bowel studies or surgery; baby oil can be used to remove tar/asphalt burns

Mechanism of Action An emollient laxative which eases passage of stool by decreasing water absorption and lubricating the intestine; low volatility; high viscosity

Adverse Reactions

Gastrointestinal: Nausea, vomiting, diarrhea, abdominal cramps, anal itching, intestinal obstruction from bezoar formation may result

Respiratory: Lipoid pneumonitis with aspiration

Signs and Symptoms of Overdose Aspiration of oils may cause chemical pneumonitis with fever, leukocytosis, x-ray changes

Pharmacodynamics/Kinetics

Onset of action: Oral: 6-8 hours; Rectal: 2-15 minutes

Distribution: Site of action is the colon

Excretion: Feces

Dosage

Children:

Oral: 5-11 years: 5-20 mL once daily or in divided doses

Rectal: 2-11 years: 30-60 mL as a single dose

Children > 12 years and Adults:

Oral: 15-45 mL/day once daily or in divided doses

Rectal: Retention enema, contents of one enema (range 60-150 mL)/day as a single dose

Monitoring Parameters Monitor for response (stool frequency, consistency). Avoid use in patients who may aspirate.

Administration Oral: Mineral oil may be more palatable if refrigerated. Administer on an empty stomach in an upright position.

Kondremul[®]: Shake well before use.

Liqui-Doss[®]: Shake well before use. Prior to use, mix with 120 mL of any beverage; administer only at bedtime.

Rectal (Fleet[®] Mineral Oil): Gently insert enema rectally with patient lying on left side and left knee slightly bent, right knee drawn to chest.

Contraindications Patients with colostomy or an ileostomy, appendicitis, ulcerative colitis, diverticulitis

Warnings

Lipid pneumonitis results from aspiration of mineral oil. Aspiration risk increased in patients in prolonged supine position or conditions which interfere with swallowing or epiglottal function (eg, stroke, Parkinson's disease, Alzheimer's disease, esophageal dysmotility).

When used for self-medication (OTC): Healthcare provider should be contacted in case of sudden changes in bowel habits which last over 2 weeks; abdominal pain, nausea, vomiting; rectal bleeding following use; if needed for >1 week.

Dosage Forms

Liquid, oral:

Liqui-Doss®: 13.5 mL/15 mL (480 mL) [self-emulsifying oily liquid; alcohol free, sugar free]

Microemulsion, oral:

Kondremul®: 2.5 mL/5 mL (480 mL) [sugar free; mint flavor]

Oil, rectal [enema]:

Fleet® Mineral Oil: 100% (118 mL)

Oil, oral: 100% (480 mL, 3840 mL)

Overdosage/Treatment

Decontamination: **Do not** induce emesis; activated charcoal may be useful

Supportive therapy: Fluid/electrolyte replacement; pulmonary physiotherapy should be considered; corticosteroids are of unproven pulmonary benefit

Drug Interactions May impair absorption of fat-soluble vitamins (A, D, K, E), coumarin, sulfonamides; administration of surfactants (docusate) with mineral oil may increase mineral oil absorption and therefore enhance toxic potential of mineral oil resulting in a foreign body reaction in lymphoid tissue

Nursing Implications Administer on an empty stomach because of the risk of aspiration

Additional Information Associated with increased risk from bronchogenic carcinoma (from lipoid pneumonia), gastrointestinal tumors, and dermal tumors suppresses cough reflex; prolonged administration of mineral oil may decrease absorption of lipid-soluble vitamins A, D, E, and K. Light sterile mineral oils are not for injection. Gauze pads soaked with mineral oil compresses can be used to lyse eyelid adhesions due to cyanoacrylate adhesive; no ocular damage was reported over a 1¹/₂-day period.

Minocycline

CAS Number 10118-90-8; 13614-98-7

U.S. Brand Names Dynacin®; Minocin®

Synonyms Minocycline Hydrochloride

Use Treatment of susceptible bacterial infections of both gram-negative and gram-positive organisms; treatment of anthrax (inhalational, cutaneous, and gastrointestinal); acne; meningococcal carrier state; Rickettsial diseases (including Rocky Mountain spotted fever, Q fever); nongonococcal urethritis, gonorrhea; acute intestinal amebiasis

Mechanism of Action Inhibits bacterial protein synthesis by binding with the 30S and possibly the 50S ribosomal subunit(s) of susceptible bacteria; cell wall synthesis is not affected

Adverse Reactions

Cardiovascular: Pericarditis, Raynaud's phenomenon, vasculitis

Central nervous system: Increased intracranial pressure, bulging fontanelles in infants, vertigo, memory disturbance (1% to 14%), headache (1%), pseudotumor cerebri, fever, visual hallucination, lightheadedness

Dermatologic: Photosensitivity, dermatologic effects, pruritus, exfoliative dermatitis, rash, blue macular pigmentation (usually localized to legs, fingernails, and scars), pityriasis versicolor, pityriasis rosea-like reaction, onycholysis, neutrophilic dermatosis (Sweet's syndrome), erythema multiforme, angioedema, urticaria, purpura, Stevens-Johnson syndrome, yellow fingernails, erythema nodosum, licheniform eruptions, exanthem, cutaneous vasculitis

Endocrine & metabolic: Diabetes insipidus, black galactorrhea, black thyroid, thyroid dysfunction (extremely rare)

Gastrointestinal: Nausea, diarrhea, vomiting, esophagitis, anorexia, abdominal cramps, lingua villosa nigra

Genitourinary: Vaginal candidiasis

Hematologic: Leukemoid, eosinophilia, hemolytic anemia, neutropenia, thrombocytopenia

Hepatic: Hepatotoxicity, hepatitis (autoimmune), hepatic vasculitis, hepatic failure

Neuromuscular & skeletal: Paresthesia

Ocular: Scotoma

Otic: Ototoxicity, tinnitus

Renal: Acute renal failure, azotemia, interstitial nephritis, necrotizing vasculitis, renal vasculitis

Respiratory: Eosinophilic pneumonitis

Miscellaneous: **Discoloration of teeth in children**, superinfections, anaphylaxis, systemic lupus erythematosus (SLE), serum sickness-like reaction, fixed drug eruption, elevated antineutrophilic cytoplasmic antibodies (ANCA)

Pharmacodynamics/Kinetics

Absorption: Well absorbed

Distribution: Majority deposits for extended periods in fat; crosses placenta; enters breast milk

Protein binding: 70% to 75%

Half-life elimination: 16 hours (range: 11-23 hours)

Time to peak: Capsule, pellet filled: 1-4 hours; Extended release tablet: 3.5-4 hours

Excretion: Urine

Dosage

Children >8 years: Oral, I.V.: Initial: 4 mg/kg followed by 2 mg/kg/dose every 12 hours

Adults:

Infection: Oral, I.V.: 200 mg stat, 100 mg every 12 hours not to exceed 400 mg/24 hours

Acne: Oral: 50 mg 1-3 times/day

Dosage adjustment in renal impairment: Consider decreasing dose or increasing dosing interval with renal impairment.

Monitoring Parameters Culture and sensitivity testing prior to initiating therapy; LFTs, BUN, renal function with long-term treatment; if symptomatic for autoimmune disorder, include ANA, CBC

Administration Oral: May be taken with food or milk. Administer with adequate fluid to decrease the risk of esophageal irritation and ulceration. I.V.: Infuse slowly, usually over a 4- to 6-hour period.

Contraindications Hypersensitivity to minocycline, other tetracyclines, or any component of the formulation; pregnancy

Warnings May cause tissue hyperpigmentation or permanent tooth discoloration; avoid use during tooth development (children ≤8 years of age) unless other drugs are not likely to be effective or are contraindicated. May be associated with increases in BUN secondary to antianabolic effects; use caution in patients with renal impairment. Hepatotoxicity has been reported; use caution in patients with hepatic insufficiency. Autoimmune syndromes (eg, lupus-like, hepatitis, and vasculitis) have been reported; discontinue if symptoms. CNS effects (lightheadedness, vertigo) may occur; patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Has been associated (rarely) with pseudotumor cerebri. May cause photosensitivity; discontinue if skin erythema occurs. May cause overgrowth of nonsusceptible organisms, including fungi; discontinue if superinfection occurs. Avoid use in children ≤8 years of age.

Dosage Forms Capsule: 50 mg, 75 mg, 100 mg

Dynacin®: 75 mg, 100 mg

Capsule, pellet filled: 50 mg, 100 mg

Minocin®: 50 mg, 100 mg

Tablet: 50 mg, 75 mg, 100 mg

Dynacin®, myrac™: 50 mg, 75 mg, 100 mg

Tablet, extended release:

Solodyn™: 45 mg, 90 mg, 135 mg

Reference Range Maximum serum concentration after a single 200 mg oral dose: 2.7 mcg/mL; after a 200 mg I.V. dose; maximum serum concentration: 3.5 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Antacids can be given for epigastric pain; acetazolamide (500 mg twice daily) can be used to treat pseudotumor cerebri.

For treatment of lingua villosa nigra, discontinue causative agent. Clean the tongue with a toothbrush and rinse mouth with a half-strength solution of hydrogen peroxide or 10% carbamide peroxide. Symptoms should subside in a few days.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; not dialyzable (0% to 5%)

Test Interactions May cause false elevations on fluorescence test for urinary catecholamines

Drug Interactions Calcium-, magnesium-, or aluminum-containing antacids, bile acid sequestrants, bismuth, oral contraceptives, iron, zinc, sodium bicarbonate, penicillins, quinapril: May decrease absorption of tetracyclines.

Methoxyflurane anesthesia, when concurrent with tetracyclines, may cause fatal nephrotoxicity.

Penicillins: Tetracyclines may reduce bactericidal efficacy of penicillins and cephalosporins.

Retinoic acid derivatives: May increase risk of pseudotumor cerebri.

Typhoid vaccine: Antibacterial agents may decrease the therapeutic efficacy of the live, attenuated typhoid (Ty21a strain) vaccine

Warfarin: Hypoprothrombinemic response may be increased with tetracyclines; monitor INR closely during initiation or discontinuation.

Pregnancy Risk Factor D

Pregnancy Implications May cause permanent discoloration (brown-grey) of teeth. Animal studies indicate possible embryotoxicity.

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Minoxidil

CAS Number 38304-91-5

U.S. Brand Names Loniten®; Rogaine® Extra Strength for Men [OTC]; Rogaine® for Men [OTC]; Rogaine® for Women [OTC]

Use Management of severe hypertension (usually in combination with a diuretic and beta-blocker); treatment (topical formulation) of alopecia androgenetica in males and females

Mechanism of Action Produces vasodilation by directly relaxing arteriolar smooth muscle, with little effect on veins, effects may be mediated by cyclic amp; stimulation of hair growth is secondary to vasodilation, increased cutaneous blood flow and stimulation of resting hair follicles

Adverse Reactions

Cardiovascular: **Edema**, chest pain, **congestive heart failure**, **tachycardia**, angina, pericardial effusion/pericarditis, **ECG changes**, myocardial depression, pulmonary hypertension, sinus tachycardia, vasodilation

Central nervous system: Dizziness, fatigue, headache

Dermatologic: **Hypertrichosis (commonly occurs within 1-2 months of therapy)**, coarsening facial features, dermatologic reactions, rash, Stevens-Johnson syndrome, sunburn, hirsutism, bullous lesions, acne, urticaria, exanthem

Endocrine & metabolic: Sodium and water retention, gynecomastia

Gastrointestinal: Vomiting, weight gain

Local: Topical burning, itching

Neuromuscular & skeletal: Paresthesia

Ocular: Optic neuritis

Respiratory: Pulmonary edema

Miscellaneous: Lupus erythematosus

Signs and Symptoms of Overdose Coma, erythema multiforme, hair discoloration (red), hyperglycemia, hypotension, hypertrichosis, ototoxicity, pericardial effusion, pericarditis, photosensitivity, tachycardia, thrombocytopenia, tinnitus

Admission Criteria/Prognosis Admit any ingestion > 1 g

Pharmacodynamics/Kinetics

Onset of action: Hypotensive: Oral: ~30 minutes

Peak effect: 2-8 hours

Duration: 2-5 days

Protein binding: None

Metabolism: 88%, primarily via glucuronidation

Bioavailability: Oral: 90%

Half-life elimination: Adults: 3.5-4.2 hours

Excretion: Urine (12% as unchanged drug)

Dosage

Children < 12 years: Hypertension: Oral: Initial: 0.1-0.2 mg/kg once daily; maximum: 5 mg/day; increase gradually every 3 days; usual dosage: 0.25-1 mg/kg/day in 1-2 divided doses; maximum: 50 mg/day

Children > 12 years and Adults: Hypertension: Oral: Initial: 5 mg once daily, increase gradually every 3 days (maximum: 100 mg/day); usual dose range (JNC 7): 2.5-80 mg/day in 1-2 divided doses

Adults: Alopecia: Topical: Apply twice daily; 4 months of therapy may be necessary for hair growth.

Elderly: Initial: 2.5 mg once daily; increase gradually.

Note: Dosage adjustment is needed when added to concomitant therapy. Dialysis: Supplemental dose is not necessary via hemo- or peritoneal dialysis.

Monitoring Parameters Blood pressure, standing and sitting/supine; fluid and electrolyte balance and body weight should be monitored

Contraindications Hypersensitivity to minoxidil or any component of the formulation; pheochromocytoma; acute MI; dissecting aortic aneurysm

Warnings Maximum therapeutic doses of a diuretic and two antihypertensives should be used before this drug is ever added. **[U.S. Boxed Warning]: It can cause pericardial effusion, tamponade, or exacerbate angina pectoris.** Monitor patients who are receiving guanethidine concurrently (orthostasis can be problematic). May need to add a diuretic to minimize fluid gain and a beta-blocker (if no contraindications) to treat tachycardia. Rapid control of blood pressure can lead to syncope, CVA, MI, ischemia. Hypersensitivity reactions occur rarely. Avoid use for a month after acute MI. Inform patients of hair growth patterns before initiating therapy. May take 1-6 months for hypertrichosis to reverse itself after discontinuation of the drug. Use with caution in patients with pulmonary hypertension, significant renal failure, CHF, or ischemic disease. Renal failure and dialysis patients may require a smaller dose.

Dosage Forms

[DSC] = Discontinued product

Solution, topical: 2% [20 mg/metered dose] (60 mL); 5% [50 mg/metered dose] (60 mL)

Rogaine® for Men, Rogaine® for Women: 2% [20 mg/metered dose] (60 mL)

Rogaine® Extra Strength for Men: 5% [50 mg/metered dose] (60 mL)

Tablet: 2.5 mg, 10 mg

Loniten®: 2.5 mg [DSC], 10 mg

Reference Range Mean serum level (oral) for 5 mg: 59.2 ng/mL

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral vasoconstrictor may be required (eg, phenylephrine or dopamine). Treatment is primarily supportive and symptomatic.

Enhancement of elimination: Multiple dosing of activated charcoal is useful; hemodialysis may be useful; dialyzable (50% to 100%)

Test Interactions ↑ alkaline phosphatase

Drug Interactions

Antihypertensives: Effects may be additive.

Guanethidine can cause severe orthostasis; avoid concurrent use - discontinue 1-3 weeks prior to initiating minoxidil.

Pregnancy Risk Factor C

Nursing Implications May cause hirsutism

Additional Information Usually given in combination with a diuretic and beta-blocker

Specific Reference

Chobanian AV, Bakris GL, Black HR, et al, "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, 289(19):2560-71.

Mirtazapine

Related Information

• Antidepressant Agents

CAS Number 61337-67-5

U.S. Brand Names Remeron SolTab®; Remeron®

Impairment Potential Yes

Use Treatment of depression

Mechanism of Action Strong alpha₂ antagonist with similar properties to mianserin; a tetracyclic piperazinoazepine that is a presynaptic alpha₂-adrenoreceptor antagonist as well as a 5-HT₂ and 5-HT₃ antagonist thus enhancing noradrenergic and serotonergic neurotransmission; does not inhibit serotonin reuptake

Adverse Reactions

Cardiovascular: Angina pectoris, atrial arrhythmia, bigeminy, bradycardia, cardiomegaly, cerebral ischemia, chest pain, edema, facial edema, hypertension, hypotension, left heart failure, myocardial infarction, peripheral edema, syncope, vasodilatation, ventricular extrasystoles, torsade de pointes, vascular headache

Central nervous system: Abnormal dreams, abnormal thoughts, confusion, malaise, agitation, akathisia, amnesia, anxiety, apathy, aphasia, ataxia, chills, coordination abnormal, delirium, delusions, dementia, depersonalization, depression, dizziness, dystonia, emotional lability, euphoria, extrapyramidal syndrome, fever, grand mal seizure, hallucinations, hostility, hypesthesia, hypotonia, manic reaction, migraine, neurosis, paranoid reaction, psychotic depression, **somnolence** (54%), stupor, vertigo

Dermatologic: Acne, alopecia, cellulitis, dry skin, exfoliative dermatitis, petechia, photosensitivity reaction, pruritus, rash, seborrhea, skin hypertrophy, skin ulcer, urticaria

Endocrine & metabolic: Amenorrhea, breast engorgement, breast enlargement, breast pain, **cholesterol increased**, dehydration, diabetes mellitus, dysmenorrhea, goiter, gout, hypothyroidism, libido increased, menorrhagia, metrorrhagia, triglycerides increased

Gastrointestinal: Abdomen enlarged, abdominal pain, **appetite increased**, anorexia, aphthous stomatitis, colitis, constipation, eructation, gastroenteritis, gastritis, glossitis, gum hemorrhage, increased salivation, intestinal obstruction, nausea, oral moniliasis, pancreatitis, salivary gland enlargement, taste loss, tongue discoloration, tongue edema, ulcer, ulcerative stomatitis, vomiting, weight loss, **weight gain** (12%; weight gain of >7% reported in 8% of adults, ≤49% of pediatric patients) **xerostomia** (25%)

Genitourinary: Abnormal ejaculation, cystitis, dysuria, impotence, leukorrhea, urethritis, urinary frequency, urinary incontinence, urinary retention, urinary tract infection, urinary urgency, vaginitis

Hematologic: Agranulocytosis, anemia, leukopenia, pancytopenia, thrombocytopenia

Hepatic: Cholecystitis, cirrhosis, liver function tests abnormal

Local: Phlebitis

Neuromuscular & skeletal: Arthralgias, arthrosis, arthritis, back pain, bone pain, bursitis, dysarthria, dyskinesia, fracture, hypokinesia, hyperkinesias, myoclonus, myalgia, myositis, neck pain, neck rigidity, osteoporosis, paralysis, paresthesia, reflexes increased, tendon rupture, tenosynovitis, tremor, twitching, weakness

Ocular: Accommodation abnormality, blepharitis, conjunctivitis, diplopia, eye pain, glaucoma, keratoconjunctivitis, lacrimation disorder, nystagmus

Otic: Deafness, ear pain, hyperacusis, otitis media

Renal: Hematuria, kidney calculus, polyuria

Respiratory: Asphyxia, asthma, bronchitis, cough, dyspnea, epistaxis, laryngitis, pneumonia, pneumothorax, pulmonary embolus, sinusitis

Miscellaneous: Flu-like symptoms, thirst, drug dependence, hiccups, lymphadenopathy, lymphocytosis, herpes simplex, herpes zoster, parosmia, withdrawal syndrome

Signs and Symptoms of Overdose Coma, disorientation, drowsiness, sedation, lethargy, leukocytosis, somnolence, tachycardia (30%). Little or no cardiac complications.

Admission Criteria/Prognosis Admit any ingestion > 100 mg or any symptomatic patient with change in mental status; for any polydrug overdose or ingestion > 1 g, hospital admission should be considered.

Pharmacodynamics/Kinetics

Protein binding: 85%

Metabolism: Extensively hepatic via CYP1A2, 2C9, 2D6, 3A4 and via demethylation and hydroxylation

Bioavailability: 50%

Half-life elimination: 20-40 hours; hampered with renal or hepatic impairment

Time to peak, serum: 2 hours

Excretion: Urine (75%) and feces (15%) as metabolites

Dosage

Children: Safety and efficacy in children have not been established

Treatment of depression: Adults: Oral: Initial: 15 mg nightly, titrate up to 15-45 mg/day with dose increases made no more frequently than every 1-2 weeks; there is an inverse relationship between dose and sedation

Elderly: Decreased clearance seen (40% males, 10% females); no specific dosage adjustment recommended by manufacturer

Dosage adjustment in renal impairment:

Cl_{cr} 11-39 mL/minute: 30% decreased clearance

Cl_{cr} <10 mL/minute: 50% decreased clearance

Dosage adjustment in hepatic impairment: Clearance decreased by 30%

Monitoring Parameters Patients should be monitored for signs of agranulocytosis or severe neutropenia such as sore throat, stomatitis or other signs of infection or a low WBC; mental status for depression, suicidal ideation (especially at the beginning of therapy or when doses are increased or decreased), anxiety, social functioning, mania, panic attacks; lipid profile

Administration SolTab®: Open blister pack and place tablet on the tongue. Do not split tablet. Tablet is formulated to dissolve on the tongue without water.

Contraindications Hypersensitivity to mirtazapine or any component of the formulation; use of MAO inhibitors within 14 days

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. **Mirtazapine is not FDA approved for use in children.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Mirtazapine is not FDA approved for the treatment of bipolar depression.**

Discontinue immediately if signs and symptoms of neutropenia/agranulocytosis occur. May cause sedation, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Sedative effects may be additive with other CNS depressants and/or ethanol. The degree of sedation is moderate-high relative to other

antidepressants. The risks of orthostatic hypotension or anticholinergic effects are low relative to other antidepressants. The incidence of sexual dysfunction with mirtazapine is generally lower than with SSRIs. May increase appetite and stimulate weight gain. Weight gain of >7% of body weight reported in 7.5% of patients treated with mirtazapine compared to 0% for placebo; 8% of patients receiving mirtazapine discontinued treatment due to the weight gain. In an 8-week pediatric clinical trial, 49% of mirtazapine-treated patients had a weight gain of at least 7% (mean increase 4 kg) as compared to 5.7% of placebo-treated patients (mean increase 1 kg).

May increase serum cholesterol and triglyceride levels. Use caution in patients with a previous seizure disorder or condition predisposing to seizures such as brain damage, alcoholism, or concurrent therapy with other drugs which lower the seizure threshold. Use with caution in patients with hepatic or renal dysfunction and in elderly patients. SolTab® formulation contains phenylalanine.

Dosage Forms Tablet (Remeron®): 15 mg, 30 mg, 45 mg

Tablet, orally disintegrating: 15 mg, 30 mg

Remeron SolTab®:

15 mg [contains phenylalanine 2.6 mg/tablet; orange flavor]

30 mg [contains phenylalanine 5.2 mg/tablet; orange flavor]

45 mg [contains phenylalanine 7.8 mg/tablet; orange flavor]

Reference Range Following a 20 mg oral dose, peak serum levels: ~100 ng/mL; serum level of 2300 ng/mL associated with a 900 mg ingestion and somnolence

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage (within 1 hour)/activated charcoal

Supportive therapy: Treat seizures with diazepam or lorazepam; phenobarbital is second choice; atropine or isoproterenol can be used for bradycardia

Enhancement of elimination: Multiple dosing of activated charcoal or hemodialysis is not likely to be effective

Drug Interactions Substrate of CYP1A2 (major), 2C9 (minor), 2D6 (major), 3A4 (major); **Inhibits** CYP1A2 (weak), 3A4 (weak)

Clonidine: Antihypertensive effects of clonidine may be antagonized by mirtazapine (hypertensive urgency has been reported following addition of mirtazapine to clonidine); in addition, mirtazapine may potentially enhance the hypertensive response associated with abrupt clonidine withdrawal. Avoid this combination; consider an alternative agent.

CNS depressants: Sedative effects may be additive with other CNS depressants; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol and other sedative agents

CYP1A2 inducers: May decrease the levels/effects of mirtazapine. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of mirtazapine. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

CYP2D6 inhibitors: May increase the levels/effects of mirtazapine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinireole.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of mirtazapine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of mirtazapine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Linezolid: Due to MAO inhibition (see note on MAO inhibitors), this combination should be avoided

MAO inhibitors: Possibly serious or fatal reactions can occur when given with or when given within 14 days of an MAO inhibitor; use is contraindicated.

Selegiline: Interaction is less likely than with nonselective MAO inhibitors (see MAO inhibitor information), but theoretically possible; monitor

Sibutramine: Potential for serotonin syndrome when used in combination

Pregnancy Risk Factor C

Pregnancy Implications Animal studies did not show teratogenic effects, however, there was an increase in fetal loss and decrease in birth weight; use during pregnancy only if clearly needed.

Lactation Excretion in breast milk unknown/not recommended

Reference Range Peak blood misoprostol level after a 400 mcg oral dose is ~500 pg/mL

Overdosage/Treatment

Decontamination: Activated charcoal
 Supportive therapy: Psyllium hydrophobic mucilliod (3.4 g twice daily) can be used to treat misoprostol-induced diarrhea

Drug Interactions Oxytocin: Misoprostol may increase the effect of oxytocin; wait 6-12 hours after misoprostol administration before initiating oxytocin.

Pregnancy Risk Factor X

Pregnancy Implications Misoprostol is an abortifacient. During pregnancy, use to prevent NSAID-induced ulcers is contraindicated. Reports of fetal death, congenital anomalies, uterine perforation, and abortion have been received after the use of misoprostol in pregnancy. Excretion in breast milk is unknown; breast-feeding is contraindicated. See Additional Information.

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Incidence of diarrhea may be lessened by having patient take dose right after meals

Additional Information Has been utilized in self-abortion attempts; misoprostol (200 mcg) can prevent diclofenac-induced gastric ulcers (not duodenal ulcers)

When used to prevent NSAID-induced ulcers: Inform prescriber if you are pregnant. Do not get pregnant during or for 1 month following therapy. Male: Do not cause a female to become pregnant. Male/female: Consult prescriber for instruction on appropriate contraceptive measures. This drug may cause severe fetal defects, miscarriage, or abortion; do not share medication with others. Do not breast-feed.

Misoprostol

CAS Number 59122-46-2

U.S. Brand Names Cytotec®

Use Prevention of NSAID-induced gastric ulcers; medical termination of pregnancy of ≤49 days (in conjunction with mifepristone)

Unlabeled/Investigational Use Cervical ripening and labor induction; NSAID-induced nephropathy; fat malabsorption in cystic fibrosis

Mechanism of Action Misoprostol is a synthetic prostaglandin E₁ analog that replaces the protective prostaglandins consumed with prostaglandin-inhibiting therapies (eg, nonsteroidal anti-inflammatory drugs); has been shown to induce uterine contractions

Adverse Reactions

Cardiovascular: Angina, chest pain, MI, arterial thrombosis
 Central nervous system: Headache, CNS depression, depression, hyperthermia
 Endocrine & metabolic: Abortifacient
 Gastrointestinal: Diarrhea (14% to 40%), abdominal pain, constipation, flatulence, nausea, vomiting, cramps
 Genitourinary: Uterine stimulation, vaginal bleeding, uterine rupture
 Respiratory: Pulmonary embolism
 Miscellaneous: Thirst

Signs and Symptoms of Overdose Abdominal cramps, fever, hypertension, metabolic acidosis, rhabdomyolysis, tachycardia, tremor (3 g ingestion)

Admission Criteria/Prognosis Admit any adult ingestion >3 mg

Pharmacodynamics/Kinetics

Absorption: Rapid
 Metabolism: Hepatic; rapidly de-esterified to misoprostol acid (active)
 Half-life elimination: Metabolite: 20-40 minutes
 Time to peak, serum: Active metabolite: Fasting: 15-30 minutes
 Excretion: Urine (64% to 73%) and feces (15%) within 24 hours

Dosage Oral:

Children 8-16 years: Fat absorption in cystic fibrosis (unlabeled use): 100 mcg 4 times/day

Adults:

Prevention of NSAID-induced gastric ulcers: 200 mcg 4 times/day with food; if not tolerated, may decrease dose to 100 mcg 4 times/day with food or 200 mcg twice daily with food; last dose of the day should be taken at bedtime

Medical termination of pregnancy: Refer to Mifepristone.

Intravaginal: Adults: Labor induction or cervical ripening (unlabeled use): 25 mcg (1/4 of 100 mcg tablet); may repeat at intervals no more frequent than every 3-6 hours. Do not use in patients with previous cesarean delivery or prior major uterine surgery.

Administration Incidence of diarrhea may be lessened by having patient take dose right after meals. Therapy is usually begun on the second or third day of the next normal menstrual period.

Contraindications Hypersensitivity to misoprostol, prostaglandins, or any component of the formulation; pregnancy (when used to reduce NSAID-induced ulcers)

Warnings Safety and efficacy have not been established in children < 18 years of age; use with caution in patients with renal impairment and the elderly. [U.S. Boxed Warning]: Not to be used in women of child-bearing potential unless woman is capable of complying with effective contraceptive measures; therapy is normally begun on the second or third day of next normal menstrual period. Uterine perforation and/or rupture have been reported in association with intravaginal use to induce labor or with combined oral/intravaginal use to induce abortion. The manufacturer states that Cytotec® should not be used as a cervical-ripening agent for induction of labor. However, The American College of Obstetricians and Gynecologists (ACOG) continues to support this off-label use.

Dosage Forms Tablet: 100 mcg, 200 mcg

Mitoxantrone

CAS Number 65271-80-9; 70476-82-3

U.S. Brand Names Novantrone®

Synonyms DAD; DHAD; DHAQ; Dihydroxyanthracenedione Dihydrochloride; Mitoxantrone Hydrochloride CL-232315; Mitozantrone; NSC-301739

Use Treatment of acute leukemias, lymphoma, breast cancer, pediatric sarcoma, progressive or relapsing-remitting multiple sclerosis, prostate cancer

Mechanism of Action Analogue of the anthracyclines, mitoxantrone intercalates DNA; binds to nucleic acids and inhibits DNA and RNA synthesis by template disordering and steric obstruction; replication is decreased by binding to DNA topoisomerase II and seems to inhibit the incorporation of uridine into RNA and thymidine into DNA; active throughout entire cell cycle

Adverse Reactions

Cardiovascular: Arrhythmia (3% to 18%), edema, nail bed changes, CHF (2% to 3%; risk is much lower with anthracyclines, some reports suggest cumulative doses >160 mg/mL cause CHF in ~10% of patients), ECG changes, hypotension, ischemia, LVEF decreased (≤5%), tachycardia

Central nervous system: Fatigue, fever, headache (6% to 13%), chills, anxiety, depression, seizures

Dermatologic: Alopecia (20% to 61%), skin infection, irritant chemotherapy with blue skin discoloration, rash

Endocrine & metabolic: Amenorrhea, menstrual disorder, hypocalcemia, hypokalemia, hyponatremia, hyperglycemia

Gastrointestinal: Abdominal pain, anorexia, nausea (29% to 76%), constipation, diarrhea (16% to 47%), GI bleeding, mucositis (10% to 29%), stomatitis, vomiting, weight gain/loss, dyspepsia, aphthosis

Genitourinary: Abnormal urine, urinary tract infection, impotence, proteinuria, renal failure, sterility

Hematologic: Hemoglobin decreased, leukopenia, lymphopenia, petechiae/bruising, acute leukemia, anemia, granulocytopenia, hemorrhage; myelosuppressive effects of chemotherapy:

WBC: Mild
 Platelets: Mild
 Onset: 7-10 days
 Nadir: 14 days
 Recovery: 21 days

Hepatic: Increased GGT, jaundice, increased SGOT, increased SGPT

Local: Extravasation and phlebitis at the infusion site

Neuromuscular & skeletal: Weakness (24%), back pain, myalgia, arthralgia

Ocular: Blurred vision, conjunctivitis

Renal: Hematuria

Respiratory: Cough, dyspnea, upper respiratory tract infection, pneumonia, rhinitis, sinusitis, interstitial pneumonitis (has occurred during combination chemotherapy)

Miscellaneous: Fungal infections, infection, sepsis, systemic infection, sweats, development of secondary leukemia (~1% to 2%), allergic reaction, anaphylactoid reactions, anaphylaxis

Signs and Symptoms of Overdose Leukopenia, marrow hypoplasia (pancytopenia), nausea, shaking chills, tachycardia, vomiting

Pharmacodynamics/Kinetics

Absorption: Oral: Poor
 Distribution: V_d : 14 L/kg; distributes into pleural fluid, kidney, thyroid, liver, heart, and red blood cells
 Protein binding: >95%, 76% to albumin
 Metabolism: Hepatic; pathway not determined
 Half-life elimination: Terminal: 23-215 hours; may be prolonged with hepatic impairment
 Excretion: Urine (6% to 11%) and feces as unchanged drug and metabolites

Dosage Refer to individual protocols. I.V. (dilute in D₅W or NS):

Acute leukemias:
 Children ≤2 years: 0.4 mg/kg/day once daily for 3-5 days
 Children >2 years and Adults: 8-12 mg/m²/day once daily for 4-5 days
 Solid tumors:
 Children: 18-20 mg/m² every 3-4 weeks or 5-8 mg/m² every week
 Adults: 12-14 mg/m² every 3-4 weeks or 2-4 mg/m²/day for 5 days every 4 weeks
 Hormone-refractory prostate cancer: Adults: 12-14 mg/m²
 Multiple sclerosis: Adults: 12 mg/m²

Dosing adjustment in renal impairment: Safety and efficacy have not been established

Hemodialysis: Supplemental dose is not necessary
 Peritoneal dialysis: Supplemental dose is not necessary
 Elderly: Clearance is decreased in elderly patients; use with caution

Dosing adjustment in hepatic impairment: Official dosage adjustment recommendations have not been established.

Moderate dysfunction (bilirubin 1.5-3 mg/dL): Some clinicians recommend a 50% dosage reduction
 Severe dysfunction (bilirubin >3.0 mg/dL) may require a dosage adjustment to 8 mg/m²; some clinicians recommend a dosage reduction to 25% of dose

Stability Store intact vials at room temperature or refrigeration

Dilute in at least 50 mL of NS or D₅W; solution is stable for 7 days at room temperature or refrigeration

Incompatible with heparin and hydrocortisone

Standard I.V. dilution:

IVPB: Dose/100 mL D₅W or NS
 Solution is stable for 7 days at room temperature and refrigeration

Monitoring Parameters CBC, serum uric acid (for treatment of leukemia), liver function tests, signs and symptoms of CHF; evaluate LVEF prior to start of therapy and regularly during treatment. In addition, for the treatment of multiple sclerosis, monitor LVEF prior to all doses following cumulative dose of ≥100 mg/m².

Administration Administered as a short (15-30 minutes) I.V. infusion; continuous 24-hour infusions are occasionally used. Although not generally recommended, mitoxantrone has been given as a rapid bolus over 1-3 minutes. High doses for bone marrow transplant are usually given as 1- to 4-hour infusions.

Contraindications Hypersensitivity to mitoxantrone or any component of the formulation; multiple sclerosis with left ventricular ejection fraction (LVEF) <50% or clinically significant decrease in LVEF; pregnancy

Warnings

Hazardous agent – use appropriate precautions for handling and disposal.

[U.S. Boxed Warning]: Do not use if baseline neutrophil count < 1500 cells/mm³ (except for in the treatment of ANLL). Treatment may lead to severe myelosuppression; use with caution in patients with pre-existing myelosuppression.

[U.S. Boxed Warning]: May cause myocardial toxicity and potentially-fatal CHF; risk increases with cumulative dosing. Predisposing factors for mitoxantrone-induced cardiotoxicity include prior anthracycline therapy, prior cardiovascular disease, concomitant use of cardiotoxic drugs, and mediastinal/pericardial irradiation. Not recommended for use when left ventricular ejection fraction (LVEF) <50%. Use in multiple sclerosis should be limited to a cumulative dose of ≤140 mg/m², and discontinued if a significant decrease in LVEF is observed.

[U.S. Boxed Warnings]: For I.V. use only; may cause severe local tissue damage if extravasation occurs. Do not administer intrathecally; may cause serious and permanent neurologic damage. May cause urine, saliva, tears, and sweat to turn blue-green for 24 hours postinfusion. Whites of eyes may have blue-green tinge. **[U.S. Boxed Warning]: Has been associated with the development of secondary acute myelogenous leukemia and myelodysplasia.**

[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician. Dosage should be reduced in patients with impaired hepatobiliary function; not for treatment of multiple sclerosis in patients with concurrent hepatic impairment. Not for treatment of primary progressive multiple sclerosis. Safety and efficacy in children have not been established.

Dosage Forms Injection, solution: 2 mg/mL (10 mL, 12.5 mL, 15 mL)
 Novantrone®: 2 mg/mL (10 mL, 12.5 mL, 15 mL)

Overdosage/Treatment

No known antidote
 Supportive therapy: Bradycardia may respond to atropine; consider reverse isolation; pancytopenia is usually reversible

Enhanced elimination: Hemoperfusion or hemodialysis is not useful
Test Interactions May cause a 50% reduction of prostate specific antigen, which does not correlate with response

Drug Interactions Inhibits CYP3A4 (weak)

Patients may experience impaired immune response to vaccines; possible infection after administration of live vaccines in patients receiving immunosuppressants

Pregnancy Risk Factor D

Pregnancy Implications May cause fetal harm if administered to a pregnant woman. Women with multiple sclerosis and who are biologically capable of becoming pregnant should have a pregnancy test prior to each dose.

Lactation Enters breast milk/contraindicated

Nursing Implications Vesicant; avoid extravasation

Mitoxantrone is excreted in human milk and significant concentrations (180 mg/mL) have been reported for 28 days after the last administration. Because of the potential for serious adverse reactions in infants from mitoxantrone, breast-feeding should be discontinued before starting treatment.

Additional Information Indications for stopping mitoxantrone due to cardiac toxicity include endomyocardial biopsy with evidence of characteristic changes of cardiomyopathy induced by an anthracycline (ie, distention of sarcoplasmic reticulum, vacuole formation and myofibrillar dropout), and/or a ≥20% decrease in cardiac ejection fraction

Moclobemide

CAS Number 71320-77-9

Use Symptomatic relief of depressive illness

Unlabeled/Investigational Use Depression; smoking cessation

Mechanism of Action Selective and reversible monoamine oxidase (type A) inhibitor

Adverse Reactions

Cardiovascular: Hypertension, tachycardia, sinus tachycardia, vasoconstriction

Central nervous system: Agitation, dizziness, headache, hypomania, insomnia, anxiety

Dermatologic: Rash, pruritus, alopecia

Gastrointestinal: **Xerostomia**, constipation, nausea, stomach pain

Hepatic: Cholestasis

Neuromuscular & skeletal: Tremor

Ocular: Blurred vision

Miscellaneous: **Diaphoresis**

Signs and Symptoms of Overdose Disorientation, tachycardia, tachypnea

Admission Criteria/Prognosis Any symptomatic patient or adult ingestion >1 g should be considered for admission to a cardiac-monitored bed or intensive care unit (ICU)

Pharmacodynamics/Kinetics

Absorption: 98% from GI tract

Distribution: 1.2 L/kg

Protein binding: ~50% to albumin

Metabolism: Oxidative reactions

Half-life elimination: Terminal: 1-2 hours

Excretion: Urine (95%, as metabolites)

Dosage

Oral:

Depression: Initial: 100 mg 3 times/day immediately following a meal; maximum dose/day: 600 mg; reduce dosage by 30% to 50% in patients with hepatic disease

Smoking cessation: 400 mg/day for 2 months, then, 200 mg/day for 1 month

Monitoring Parameters Blood pressure, warning signs of suicide

Administration Administer immediately after meals.

Contraindications Hypersensitivity to moclobemide or any component of the formulation; uncontrolled hypertension; hepatic disease; confusional states; concurrent use of sympathomimetics (and related compounds), MAO inhibitors, meperidine, tricyclic antidepressants, serotonergic drugs (including SSRIs) - do not use within 5 weeks of fluoxetine discontinuation or 2 weeks of other antidepressant discontinuation; general anesthesia, local vasoconstrictors; spinal anesthesia (hypotension may be exaggerated). Not approved for use in patients <18 years of age.

Warnings The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. Use caution in patients with thyrotoxicosis, pheochromocytoma, and renal dysfunction. Use caution in patients receiving concurrent CNS depressants, ethanol, or buspirone. Severe reactions may occur if MAO inhibitors and

serotonergic agents, including SSRIs are used concurrently. Discontinue 2 days prior to local or general anesthesia. Use caution in hepatic impairment (dose adjustment required). Dietary restriction of tyramine does not appear to be necessary for patients receiving moclobemide (patients must be informed of signs/symptoms of reaction).

Dosage Forms Tablet: 150 mg, 300 mg

Reference Range Therapeutic serum range: 0.5-1.5 mg/L; plasma moclobemide levels as high as 62.5 mg/L associated with drowsiness

Overdosage/Treatment

Decontamination: Lavage within 2 hours of ingestion/activated charcoal
Supportive therapy: Competent supportive care is the most important treatment for an overdose with a monoamine oxidase (MAO) inhibitor. Both hypertension or hypotension can occur with intoxication. Hypotension may respond to I.V. fluids or vasopressors and hypertension usually responds to an alpha-adrenergic blocker. While treating the hypertension, care is warranted to avoid sudden drops in blood pressure, since this may worsen the MAO inhibitor toxicity. Muscle irritability and seizures often respond to diazepam or lorazepam, while hyperthermia is best treated antipyretics and cooling blankets. Cardiac arrhythmias are best treated with phenytoin or procainamide. Hypertensive crisis can be treated with nitroprusside, phentolamine (2-10 mg slow I.V. injection in adults), diazoxide (50-100 mg I.V.) or oral nifedipine (10 mg); dantrolene (2.5 mg/kg every 6 hours I.V.) can be used to treat hypermetabolic crisis.

Drug Interactions

Substrate (major) of CYP2C19, 2D6; **Inhibits** CYP1A2 (weak), 2C19 (weak), 2D6 (weak)

Anesthetics: Moclobemide should be stopped at least 2 days prior to using (local or general).

Antihypertensive agents: Moclobemide may decrease antihypertensive effect; use with caution. Monitor.

Antipsychotics: Moclobemide may exacerbate psychotic disorders.

Cimetidine: May increase moclobemide serum concentrations; consider 50% reduction in moclobemide dose.

CYP2C19 inducers: May decrease the levels/effects of moclobemide. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of moclobemide. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

CYP2D6 inhibitors: May increase the levels/effects of moclobemide. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Dextromethorphan: Concomitant use increases risk of serotonin syndrome; avoid concurrent use.

MAO inhibitors (conventional): Concomitant use increases risk of severe adverse reactions; concurrent use is contraindicated.

Meperidine: May increase the risk of severe adverse reactions; concurrent use is contraindicated.

Opiates: Moclobemide potentiates effects; avoid meperidine.

SSRIs: Concomitant use increases risk of serotonin syndrome. Do not use within 5 weeks of fluoxetine discontinuation or 2 weeks of other antidepressant discontinuation.

Sympathomimetic amines: Concomitant use may cause hypertension; concurrent use is contraindicated.

Tramadol: An increase risk of seizures and/or serotonin syndrome has been described with other MAO inhibitors; avoid concurrent use.

Tricyclic antidepressants: Concomitant use increases risk of severe adverse reactions; concurrent use is contraindicated.

Pregnancy Risk Factor Not available

Pregnancy Implications Safety has not been established, use only if benefits outweigh the risks.

Lactation Enters breast milk/use caution

Nursing Implications Monitor patients for signs of suicide risk; administer immediately after meals; monitor blood pressure

Specific Reference

Bleumink GS, van Vliet ACM, van der Tholen A, et al, "Fatal Combination of Moclobemide Overdose and Whisky," *Neth J Med*, 2003, 61(3): 88-90.

Adverse Reactions

Cardiovascular: **Hypotension (orthostatic)**, tachycardia, cardiac arrhythmias, sinus tachycardia

Central nervous system: **Extrapyramidal reactions, akathisia, persistent tardive dyskinesia**, pseudoparkinsonian signs and symptoms, seizures, altered central temperature regulation, neuroleptic malignant syndrome, restlessness, fever, sedation, drowsiness, restlessness, anxiety, hyperthermia

Dermatologic: Hyperpigmentation, pruritus, rash, photosensitivity

Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, syndrome of inappropriate antidiuretic hormone

Gastrointestinal: **Xerostomia, constipation**, GI upset, weight gain

Genitourinary: Urinary retention

Hematologic: Agranulocytosis (more often in women between fourth and tenth weeks of therapy); leukopenia (usually in patients with large doses for prolonged periods)

Hepatic: Elevated liver transaminases

Ocular: **Blurred vision**, retinal pigmentation

Miscellaneous: **Diaphoresis (decreased)**, systemic lupus erythematosus

Signs and Symptoms of Overdose Agranulocytosis, cardiac arrhythmias, deep sleep, extrapyramidal reaction, galactorrhea, granulocytopenia, gynecomastia, leukocytosis, leukopenia, myoglobinuria with oliguria, neuroleptic malignant syndrome, neutropenia, Parkinson's-like symptoms, priapism, renal failure, rhabdomyolysis

Pharmacodynamics/Kinetics

Metabolism: Hepatic

Half-life elimination: 1.5 hours

Time to peak, serum: ~1.5 hours

Excretion: Urine and feces (90%) within 24 hours

Dosage Oral:

Children: Schizophrenia/psychoses:

3-5 years: 1-2.5 mg/day in 4 divided doses

5-12 years: 0.5-1 mg/kg/day in 4 divided doses

Adults: Schizophrenia/psychoses: 50-75 mg/day increase at 3- to 4-day intervals up to 225 mg/day

Elderly: Behavioral symptoms associated with dementia: Initial: 5-10 mg 1-2 times/day; increase at 4- to 7-day intervals by 5-10 mg/day; increase dosing intervals (bid, tid, etc) as necessary to control response or side effects.

Monitoring Parameters Vital signs; lipid profile, fasting blood glucose/Hgb A_{1c}; BMI; mental status, abnormal involuntary movement scale (AIMS), extrapyramidal symptoms (EPS)

Contraindications Hypersensitivity to molindone or any component of the formulation (cross-reactivity between phenothiazines may occur); severe CNS depression; coma

Warnings

May be sedating, use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Caution in patients with hemodynamic instability; bone marrow suppression; predisposition to seizures; subcortical brain damage; severe cardiac, hepatic, renal, or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use - use with caution in patients at risk of pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May alter cardiac conduction; life-threatening arrhythmias have occurred with therapeutic doses of neuroleptics. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications which may predispose).

May cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention); therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other neuroleptics, molindone has a low potency of cholinergic blockade.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is moderate-high relative to other neuroleptics). May be associated with neuroleptic malignant syndrome (NMS) or pigmentary retinopathy.

Dosage Forms Tablet, as hydrochloride: 5 mg, 10 mg, 25 mg, 50 mg

Reference Range Antipsychotic range: 27-69 ng/mL; level of 152 ng/mL seen with rhabdomyolysis

Overdosage/Treatment

Decontamination: **Oral:** Activated charcoal or gastric lavage for ingestions > 500 mg in adults

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute)

Molindone

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antipsychotic Agents

CAS Number 15622-65-8; 7416-34-4

U.S. Brand Names Moban®

Synonyms Molindone Hydrochloride

Use Management of schizophrenia

Unlabeled/Investigational Use Management of psychotic disorders

Mechanism of Action Mechanism of action mimics that of chlorpromazine; however, it produces more extrapyramidal effects and less sedation than chlorpromazine

titrated to response). Seizures commonly respond to lorazepam or diazepam (I.V. 5-10 mg bolus in adults every 15 minutes if needed up to a total of 30 mg; I.V. 0.25-0.4 mg/kg/dose up to a total of 10 mg in children) or to phenytoin or phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 gram), while other antiarrhythmics can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50 mg I.M. or I.V. slow push followed by a maintenance dose for 48-72 hours. When these reactions are unresponsive to diphenhydramine, benzotropine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes. Lidocaine is the first line agent for treatment of ventricular arrhythmias. Amiodarone may also be useful.

Test Interactions May result in false-positive tricyclics by the EMIT® system

Drug Interactions

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Aluminum salts: May decrease the absorption of antipsychotics; monitor
Amphetamines: Efficacy may be diminished by antipsychotics; in addition, amphetamines may increase psychotic symptoms; avoid concurrent use

Anticholinergics: May inhibit the therapeutic response to antipsychotics and excess anticholinergic effects may occur; includes benzotropine, trihexyphenidyl, biperiden, and drugs with significant anticholinergic activity (TCAs, antihistamines, disopyramide)

Antihypertensives: Concurrent use of antipsychotics with an antihypertensive may produce additive hypotensive effects (particularly orthostasis)

Bromocriptine: Antipsychotics inhibit the ability of bromocriptine to lower serum prolactin concentrations

CNS depressants: Sedative effects may be additive with antipsychotics; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol and other sedative agents

Epinephrine: Chlorpromazine (and possibly other low potency antipsychotics) may diminish the pressor effects of epinephrine

Guanethidine and guanadrel: Antihypertensive effects may be inhibited by antipsychotics
Levodopa: Antipsychotics may inhibit the antiparkinsonian effect of levodopa; avoid this combination

Lithium: Antipsychotics may produce neurotoxicity with lithium; this is a rare effect

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk.
Propranolol: Serum concentrations of antipsychotics may be increased; propranolol also increases antipsychotic concentrations

QT_c-prolonging agents: Effects on QT_c interval may be additive with antipsychotics, increasing the risk of malignant arrhythmias; includes type Ia antiarrhythmics, TCAs, and some quinolone antibiotics (sparfloxacin, moxifloxacin, and gatifloxacin)

Sulfadoxine-pyrimethamine: May increase antipsychotics concentrations

Tricyclic antidepressants: Concurrent use may produce increased toxicity or altered therapeutic response

Trazodone: Antipsychotics and trazodone may produce additive hypotensive effects

Valproic acid: Serum levels may be increased by antipsychotics

Pregnancy Risk Factor C

Pregnancy Implications Not known if crosses the placenta

Lactation Excretion in breast milk unknown

Nursing Implications May increase appetite and possibly a craving for sweets; recognize signs of neuroleptic malignant syndrome and tardive dyskinesia

Moricizine

CAS Number 29560-58-5; 31883-05-3

U.S. Brand Names Ethmozine®

Synonyms Moricizine Hydrochloride

Use Life-threatening ventricular arrhythmia

Unlabeled/Investigational Use PVCs, complete and nonsustained ventricular tachycardia, atrial arrhythmias

Mechanism of Action A phenothiazine compound with class I antiarrhythmic activity (myocardial membrane stabilizing effect); reduces fast inward sodium current of the action potential

Adverse Reactions

Cardiovascular: Heart failure, fibrillation (atrial), flutter (atrial), myocardial depression, arrhythmias (ventricular)

Central nervous system: Headache, fatigue, fever, hypothermia, dizziness

Dermatologic: Skin rash

Endocrine & metabolism: Impotence

Gastrointestinal: Nausea, abdominal pain, xerostomia, vomiting

Hematologic: Thrombocytopenia

Hepatic: Hepatic dysfunction

Ocular: Blurred vision

Respiratory: Dyspnea

Signs and Symptoms of Overdose Asystole, coma, exacerbation of heart failure, hypotension, junctional bradycardia, respiratory failure, sinus arrest, ventricular fibrillation, ventricular tachycardia

Admission Criteria/Prognosis Admit any patient exhibiting cardiotoxicity or adult ingestions > 1 g

Pharmacodynamics/Kinetics

Protein binding, plasma: 95%

Metabolism: Significant first-pass effect; some enterohepatic recycling

Bioavailability: 38%

Half-life elimination: Healthy volunteers: 3-4 hours; Cardiac disease: 6-13 hours

Excretion: Feces (56%); urine (39%)

Dosage Oral: 600-900 mg/day in 2-3 divided doses

Dosing adjustment in renal/hepatic impairment: Reduce dosage in renal/hepatic insufficiency

Contraindications Hypersensitivity to moricizine or any component of the formulation; pre-existing second- or third-degree AV block (except in patients with a functioning artificial pacemaker); right bundle branch block when associated with left hemiblock or bifascicular block (unless functional pacemaker in place); cardiogenic shock

Warnings Can be proarrhythmic; watch for new rhythm disturbances or existing arrhythmias that worsen. Use cautiously in CAD, previous history of MI, CHF, and cardiomegaly. **[U.S. Boxed Warning]: The CAST II trial demonstrated a decreased trend in survival for patients receiving moricizine.** Dose-related increases in PR and QRS intervals occur. Use cautiously in patients with pre-existing conduction abnormalities, and significant hepatic impairment. Safety and efficacy have not been established in pediatric patients.

Dosage Forms Tablet, as hydrochloride: 200 mg, 250 mg, 300 mg

Overdosage/Treatment

Decontamination: **Do not** use ipecac; use lavage (within 1 hour)/activated charcoal

Supportive therapy: Avoid type IA antiarrhythmic agents (quinidine, procainamide, disopyramide); I.V. sodium bicarbonate (1-2 mEq/kg) can be used for hypotension or ventricular arrhythmia; phenytoin (15 mg/kg up to 1 g I.V. slow administration of 50 mg/minute) is antiarrhythmic of choice; magnesium sulfate, lidocaine, bretylium, or propranolol can also be used for ventricular arrhythmias

Enhancement of elimination: Hemodialysis is not useful

Drug Interactions Substrate of CYP3A4 (major); **Induces** CYP1A2 (weak), 3A4 (weak)

Cimetidine increases moricizine levels by 50%.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of moricizine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of moricizine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Digoxin may result in additive prolongation of the PR interval when combined with moricizine (but not rate of second- and third-degree AV block).

Diltiazem increases moricizine levels resulting in an increased incidence of side effects. Moricizine decreases diltiazem plasma levels and decreases its half-life.

Drugs which may prolong QT interval (including cisapride, erythromycin, phenothiazines, cyclic antidepressants, and some quinolones) are contraindicated with Type Ia antiarrhythmics. Moricizine has some type Ia activity, and caution should be used.

Theophylline levels are decreased by 50% with moricizine due to increased clearance.

Pregnancy Risk Factor B

Lactation Enters breast milk/not recommended

Additional Information Based on adverse outcomes noted with moricizine in the CAST trial, the FDA recommends that use of moricizine be limited to patients with life-threatening ventricular arrhythmias

Morphine Sulfate

Related Information

- Heroin
- Highlights of Recent Reports (2006) on Substance Abuse and Mental Health

CAS Number 57-27-2; 6009-81-0; 6211-15-0; 64-31-3

U.S. Brand Names Astramorph/PF™, Avinza™, DepoDur™, Duramorph®, Infumorph®, Kadian®, MS Contin®, MSIR®, Oramorph SR®, RMS®, Roxanol 100®; Roxanol®-T; Roxanol®

Synonyms MSO₄ (error-prone abbreviation and should not be used)

Impairment Potential Yes

Use

Relief of moderate to severe acute and chronic pain; relief of pain of myocardial infarction; relief of dyspnea of acute left ventricular failure and pulmonary edema; preanesthetic medication

Orphan drug: Infumorph™. Used in microinfusion devices for intraspinal administration in treatment of intractable chronic pain

Mechanism of Action Binds to opiate receptors in the CNS, causing inhibition of ascending pain pathways, altering the perception of and response to pain; produces generalized CNS depression

Adverse Reactions

Cardiovascular: **Palpitations, hypotension, bradycardia**, peripheral vasodilation, sinus bradycardia, congestive heart failure

Central nervous system: CNS depression, psychosis, drowsiness, **dizziness**, sedation, agitation, increased intracranial pressure, Guillain-Barré syndrome, depression, dysphoria, paranoia, aggressive behavior

Dermatologic: Pruritus (more common with epidural or intrathecal administration)

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone
Gastrointestinal: **Nausea, vomiting, constipation**, adynamic ileus, biliary tract spasm, Ogilvie's syndrome, decreased esophageal sphincter tone, intestinal obstruction

Genitourinary: Urinary retention, urinary tract spasm, urinary incontinence

Hematologic: Thrombocytopenia

Hepatic: Transaminases increased

Neuromuscular & skeletal: Clonus, myoclonus

Ocular: Miosis, nystagmus

Respiratory: Apnea, respiratory depression, aspiration, asthma, acute respiratory distress syndrome

Miscellaneous: Physical and psychological dependence, **histamine release**, anaphylaxis

Signs and Symptoms of Overdose Apnea, coma, constipation, dry mouth, dysuria, encephalopathy, hallucinations, hyponatremia, hypotension, hypothermia, impotence, miosis, myocardial depression, myoglobinuria, pulmonary edema, respiratory depression, rhabdomyolysis, seizures (in neonates), thirst

Pharmacodynamics/Kinetics

Onset of action: Oral (immediate release): ~30 minutes; I.V.: 5-10 minutes

Duration: Pain relief:

Immediate release formulations: 4 hours

Extended release epidural injection (DepoDur™): >48 hours

Toxicodynamics/Kinetics

Absorption: Oral: Variable

Distribution: V_d: 3-4 L/kg; lower in elderly patients

Protein binding: 35%

Metabolism: In the liver via glucuronide conjugation

Half-life: Neonates: Prolonged 6% to 10%; Adults: 1.5-2 hours

Elimination: Excreted unchanged in urine; renal clearance: 2 L/hour/kg

See table.

Morphine Sulfate		
Dosage Form/Route	Analgesia	
	Peak	Duration
Tablets	1 h	4-5 h
Oral solution	1 h	4-5 h
Extended release tablets	1 h	8-12 h
Suppository	20-60 min	3-7 h
Subcutaneous injection	50-90 min	4-5 h
I.M. injection	30-60 min	4-5 h
I.V. injection	20 min	4-5 h

Dosage Note: These are guidelines and do not represent the maximum doses that may be required in all patients. Doses should be titrated to pain relief/prevention.

Children > 6 months and < 50 kg: Acute pain (moderate-to-severe):

Oral (prompt release): 0.15-0.3 mg/kg every 3-4 hours as needed

I.M.: 0.1 mg/kg every 3-4 hours as needed

I.V.: 0.05-0.1 mg/kg every 3-4 hours as needed

I.V. infusion: Range: 10-30 mcg/kg/hour

Adolescents > 12 years: Sedation/analgesia for procedures: I.V.:

3-4 mg and repeat in 5 minutes if necessary

Adults: Acute pain (moderate-to-severe):

Oral: Prompt release formulations: Opiate-naive: Initial: 10 mg every 3-4 hours as needed; patients with prior opiate exposure may require higher initial doses: usual dosage range: 10-30 mg every 3-4 hours as needed

Oral: Controlled-, extended-, or sustained-release formulations: **Note:** A patient's morphine requirement should be established using prompt-release formulations. Conversion to long-acting products may

be considered when chronic, continuous treatment is required. Higher dosages should be reserved for use only in opioid-tolerant patients.

Capsules, extended release (Avinza™): Daily dose administered once daily (for best results, administer at same time each day)

Capsules, sustained release (Kadian®): Daily dose administered once daily or in 2 divided doses daily (every 12 hours)

Tablets, controlled release (MS Contin®), sustained release (Oramorph SR®), or extended release: Daily dose divided and administered every 8 or every 12 hours

I.V.: Initial: Opiate-naive: 2.5-5 mg every 3-4 hours; patients with prior opiate exposure may require higher initial doses. **Note:** Repeated doses (up to every 5 minutes if needed) in small increments (eg, 1-4 mg) may be preferred to larger and less frequent doses.

I.V., SubQ continuous infusion: 0.8-10 mg/hour; may increase depending on pain relief/adverse effects: usual range: up to 80 mg/hour although higher doses may be required

Mechanically-ventilated patients (based on 70 kg patient): 0.7-10 mg every 1-2 hours as needed; infusion: 5-35 mg/hour

Patient-controlled analgesia (PCA): (Opiate-naive: Consider lower end of dosing range):

Usual concentration: 1 mg/mL

Demand dose: Usual: 1 mg; range: 0.5-2.5 mg

Lockout interval: 5-10 minutes

Epidural: **Note:** Administer with extreme caution and in reduced dosage to geriatric or debilitated patients.

Infusion:

Bolus dose: 1-6 mg

Infusion rate: 0.1-1 mg/hour

Maximum dose: 10 mg/24 hours

Single-dose (extended release, Depo-Dur™):

Cesarean section: 10 mg

Lower abdominal/pelvic surgery: 10-15 mg

Note: Some patients may benefit from a 20 mg dose, however, the incidence of adverse effects may be increased.

Intrathecal (I.T.): One-tenth of epidural dose; **Note:** Administer with extreme caution and in reduced dosage to geriatric or debilitated patients.

Opiate-naive: 0.2-1 mg/dose (may provide adequate relief for 24 hours); repeat doses **not** recommended except to establish initial IT dose.

I.M., SubQ: **Note:** Repeated SubQ administration causes local tissue irritation, pain, and induration.

Initial: Opiate-naive: 5-10 mg every 3-4 hours as needed; patients with prior opiate exposure may require higher initial doses; usual dosage range: 5-20 mg every 3-4 hours as needed

Rectal: 10-20 mg every 3-4 hours

Chronic pain: Patients taking opioids chronically may become tolerant and require doses higher than the usual dosage range to maintain the desired effect. Tolerance can be managed by appropriate dose titration. There is no optimal or maximal dose for morphine in chronic pain. The appropriate dose is one that relieves pain throughout its dosing interval without causing unmanageable side effects.

Elderly or debilitated patients: Use with caution; may require dose reduction

Dosing adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer at 75% of normal dose

Cl_{cr} < 10 mL/minute: Administer at 50% of normal dose

Dosing adjustment/comments in hepatic disease: Unchanged in mild liver disease; substantial extrahepatic metabolism may occur; excessive sedation may occur in cirrhosis

Stability Refrigerate suppositories; do not freeze; degradation depends on pH and presence of oxygen; relatively stable in pH 4 and below; darkening of solutions indicate degradation; usual concentration for continuous I.V. infusion = 0.1-1 mg/mL in D₅W; **incompatible** with acyclovir, furosemide, heparin, pethidine, prochlorperazine, promethazine

Monitoring Parameters Pain relief, respiratory and mental status, blood pressure

Administration

Oral: Do not crush controlled release drug product, swallow whole.

Kadian® can be opened and sprinkled on applesauce. Avinza™ can also be opened and sprinkled on applesauce; do not crush or chew the beads. Administration of oral morphine solution with food may increase bioavailability (not observed with Oramorph SR®).

I.V.: When giving morphine I.V. push, it is best to first dilute in 4-5 mL of sterile water, and then to administer slowly (eg, 15 mg over 3-5 minutes)

Epidural or intrathecal: Use preservative-free solutions

Contraindications Hypersensitivity to morphine sulfate or any component of the formulation; increased intracranial pressure; severe respiratory depression; acute or severe asthma; known or suspected paralytic ileus; sustained release products are not recommended with gastrointestinal obstruction or in acute/postoperative pain; pregnancy (prolonged use or high doses at term)

Warnings

An opioid-containing analgesic regimen should be tailored to each patient's needs and based upon the type of pain being treated (acute versus chronic), the route of administration, degree of tolerance for opioids (naïve versus chronic user), age, weight, and medical condition. The optimal analgesic dose varies widely among patients. Doses should be titrated to pain relief/prevention. When used as an epidural injection, monitor for delayed sedation.

May cause respiratory depression; use with caution in patients (particularly elderly or debilitated) with impaired respiratory function or severe hepatic dysfunction and in patients with hypersensitivity reactions to other phenanthrene derivative opioid agonists (codeine, hydrocodone, hydromorphone, levorphanol, oxycodone, oxymorphone). Some preparations contain sulfites which may cause allergic reactions; infants <3 months of age are more susceptible to respiratory depression, use with caution and generally in reduced doses in this age group. Morphine shares the toxic potential of opiate agonists and usual precautions of opiate agonist therapy should be observed; may cause hypotension in patients with acute myocardial infarction, volume depletion, or concurrent drug therapy which may exaggerate vasodilation. Tolerance or drug dependence may result from extended use. Elderly may be particularly susceptible to the CNS depressant and constipating effects of narcotics.

Extended or sustained-release formulations:

[U.S. Boxed Warning]: Extended or sustained release dosage forms should not be crushed or chewed. Controlled-, extended-, or sustained-release products are not intended for "as needed (PRN)" use. MS Contin® 100 mg or 200 mg tablets are for use only in opioid-tolerant patients requiring >400 mg/day.

[U.S. Boxed Warning]: Avinza®: Do not administer with alcoholic beverages or ethanol-containing products, which may disrupt extended-release characteristic of product.

Injections: Note: Products are designed for administration by specific routes (I.V., intrathecal, epidural). Use caution when prescribing, dispensing, or administering to use formulations only by intended route(s).

[U.S. Boxed Warning]: Duramorph®: Due to the risk of severe and/or sustained cardiopulmonary depressant effects of Duramorph® must be administered in a fully equipped and staffed environment. Naloxone injection should be immediately available. Patient should remain in this environment for at least 24 hours following the initial dose. Infumorph® solutions are for use in microinfusion devices only; not for I.V., I.M., or SubQ administration.

Depo-Dur™: Freezing may adversely affect modified-release mechanism of drug; check freeze indicator within carton prior to administration.

Dosage Forms

[DSC] = Discontinued product

Capsule, extended release (Avinza®): 30 mg, 60 mg, 90 mg, 120 mg
Capsule, sustained release (Kadian®): 20 mg, 30 mg, 50 mg, 60 mg, 100 mg

Infusion [premixed in D₅W]: 1 mg/mL (100 mL, 250 mL)

Injection, extended release liposomal suspension [lumbar epidural injection, preservative free] (DepoDur™): 10 mg/mL (1 mL, 1.5 mL, 2 mL)

Injection, solution: 2 mg/mL (1 mL); 4 mg/mL (1 mL); 5 mg/mL (1 mL); 8 mg/mL (1 mL); 10 mg/mL (1 mL, 10 mL); 15 mg/mL (1 mL, 20 mL); 25 mg/mL (4 mL, 10 mL, 20 mL, 40 mL, 50 mL, 100 mL, 250 mL); 50 mg/mL (20 mL, 40 mL) [some preparations contain sodium metabisulfite]

Injection, solution [epidural, intrathecal, or I.V. infusion; preservative free]:

Astramorph/PF™: 0.5 mg/mL (2 mL, 10 mL); 1 mg/mL (2 mL, 10 mL)

Duramorph®: 0.5 mg/mL (2 mL); 1 mg/mL (10 mL)

Injection, solution [epidural or intrathecal infusion via microinfusion device; preservative free] (Infumorph®): 10 mg/mL (20 mL); 25 mg/mL (20 mL)

Injection, solution [I.V. infusion via PCA pump]: 0.5 mg/mL (30 mL); 1 mg/mL (30 mL, 50 mL); 2 mg/mL (30 mL); 5 mg/mL (30 mL, 50 mL)

Injection, solution [preservative free]: 0.5 mg/mL (10 mL); 1 mg/mL (10 mL); 25 mg/mL (4 mL, 10 mL, 20 mL)

Solution, oral: 10 mg/5 mL (5 mL, 10 mL, 100 mL, 500 mL); 20 mg/5 mL (100 mL, 500 mL); 20 mg/mL (30 mL, 120 mL, 240 mL)

Roxanol™: 20 mg/mL (30 mL, 120 mL)

Roxanol 100™: 100 mg/5 mL (240 mL) [with calibrated spoon]

Roxanol™-T: 20 mg/mL (30 mL, 120 mL) [tinted, flavored] [DSC]

Suppository, rectal (RMS®): 5 mg (12s), 10 mg (12s), 20 mg (12s), 30 mg (12s)

Tablet: 15 mg, 30 mg

Tablet, controlled release (MS Contin®): 15 mg, 30 mg, 60 mg, 100 mg, 200 mg

Tablet, extended release: 15 mg, 30 mg, 60 mg, 100 mg, 200 mg

Tablet, sustained release (Oramorph SR®): 15 mg, 30 mg, 60 mg, 100 mg

Reference Range

Therapeutic: Surgical anesthesia: 65-80 ng/mL (SI: 227-280 nmol/L)

Toxic: 200-5000 ng/mL (SI: 700-17,500 nmol/L)

Overdosage/Treatment Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at 2/3 the response dose/hour) may be required; opioid-induced myoclonus may respond to dantrolene (50-150 mg/day); ondansetron (4 mg I.V.) may be effective in treatment of morphine-induced pruritus. Severe chronic constipation may respond to oral naloxone 2-6 mg.

Antidote(s)

- Nalmefene [ANTIDOTE]

- Naloxone [ANTIDOTE]

Diagnostic Procedures

- Morphine, Urine

- Opiates, Qualitative, Urine

Test Interactions ↑ aminotransferases (ALT, AST) (S), amylase

Drug Interactions

Substrate of CYP2D6 (minor)

Antipsychotic agents: May increase hypotensive effects of morphine; monitor.

CNS depressants: May increase the effects/toxicity of morphine; monitor.

MAO inhibitors: May increase the effects/toxicity of morphine; some manufacturers recommend avoiding use within 14 days of MAO inhibitors

Pegvisomant: Therapeutic efficacy may be decreased by concomitant opiates, possibly requiring dosage adjustment of pegvisomant.

Rifamycin derivatives: May decrease levels/effects of morphine; monitor.

Selective serotonin reuptake inhibitors (SSRIs) and meperidine: Serotonergic effects may be additive, leading to serotonin syndrome.

Pregnancy Risk Factor B/D (prolonged use or high doses at term)

Pregnancy Implications Morphine crosses the placenta. The frequency of congenital malformations has not been reported to be greater than expected in children from mothers treated with morphine during pregnancy. Reduced growth and behavioral abnormalities in offspring have been observed in animal studies. Neonates born to mothers receiving chronic opioids during pregnancy should be monitored for neonatal withdrawal syndrome. DepoDur™ may be used in women undergoing cesarean section following clamping of the umbilical cord; not for use in vaginal labor and delivery.

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications Do not crush controlled release drug product, observe patient for excessive sedation, apnea; implement safety measures, assist with ambulation; use preservative-free solutions for intrathecal or epidural use

Additional Information

Stimulates prolactin release; addition of clonidine (75-150 mcg) increased duration of analgesia produced by epidural morphine (2 mg) for cesarean delivery; poppyseed use can be ruled out as a cause for a urinary morphine screen when codeine levels exceed 300 ng/mL; morphine to codeine ratio is <2 and high levels of morphine (> 1000 ng/mL) are detected without codeine being present

International Olympic Committee urinary cutoff limit for morphine: 1 mcg/mL

Notable individuals in whom morphine was involved in their deaths: King George V (Britain) - 1936; Sigmund Freud (Psychiatrist) - 1939; Chris Farley (Comedian) - 1997

Mid-Year 2000 Preliminary Emergency Department Drug Abuse Warning Network (DAWN) data: **Note:** Heroin/morphine is sometimes used in combination with other drugs; therefore, one Emergency Department (ED) episode can include mentions of one or more drugs.

- Heroin/morphine mentions increased 22% from the first half of 1999 (38,565 mentions) to the first half of 2000 (47,008).

- From the first half of 1999 to the first half of 2000, heroin/morphine mentions increased:

- 31% (from 9041 to 11,850) for adults age 26-34 and 22% (from 21,726 to 26,400) for adults age 35 and over.

- 21% for males (from 26,048 to 31,472) and females (from 12,308 to 14,842); and

- 27% for patients reported as white (from 15,364 to 19,455) and 17% for patients reported as black (from 13,292 to 15,487).

- During the same period, heroin/morphine mentions were unchanged for young adults age 18-25 and for patients reported as Hispanic.

- From the first half of 1999 to the first half of 2000, heroin/morphine mentions increased in 8 of the 21 metropolitan areas oversampled in DAWN and decreased in 1. The decrease came in Baltimore (18%). Increases were found in New Orleans (62%), Buffalo (58%), Miami-Hialeah (50%), San Francisco (34%), Detroit (33%), Boston (32%), Atlanta (25%), and San Diego (24%).

Moxonidine

CAS Number 75438-57-2

Synonyms Monoxidin

Unlabeled/Investigational Use Hypertension

Mechanism of Action Structurally similar to clonidine, moxonidine is a centrally active imidazoline and α_2 -receptor antagonist; also promotes natriuresis

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), edema, facial flushing, hypertension

Central nervous system: Drowsiness (less sedation than clonidine), dizziness, headache, insomnia, vertigo

Gastrointestinal: Xerostomia

Hepatic: Cholestatic hepatitis

Renal: Diuresis

Miscellaneous: Thirst

Signs and Symptoms of Overdose Hypotension

Pharmacodynamics/Kinetics

Absorption: 80% to 90%

Distribution: V_d : 1.8-3 L/kg

Protein binding: 6% to 8% (not changed in renal failure)

Metabolism: To 4,5-dehydromoxonidine (10% to 20%)

Bioavailability: 89%

Half-life: 2.6 hours (increased in renal insufficiency)

Peak serum levels: 30-180 minutes

Elimination: Renal

Dosage Starting dose: 0.2-0.4 mg/day; may increase after 3 weeks to 0.2-0.4 mg twice daily; maximum single dose: 0.4 mg

Contraindications Bradycardia, sick sinus syndrome, atrioventricular block, arrhythmias, severe congestive heart failure, severe coronary ischemia, unstable angina pectoris, renal insufficiency (creatinine >1.8 mg/dL), angioedema, intermittent claudication, Raynaud's disease, Par-

kinson's disease, epilepsy, glaucoma, depression, pregnancy, lactation, children <16 years of age

Warnings Use with caution in patients with mild to moderate renal impairment (serum creatinine: 1.2-1.8 mg/dL)

Dosage Forms Tablet: 0.2 mg, 0.3 mg, 0.4 mg

Reference Range Peak serum moxonidine levels after 0.2 mg oral and intravenous administration were 1495 pg/mL and 3965 pg/mL, respectively

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: For hypotension, I.V. saline administration with placement of patient in Trendelenburg position; vasopressors may also be utilized

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Drug Interactions Concomitant use with beta-adrenergic blocking agents; abrupt withdrawal of moxonidine may lead to rebound hypertension

Nabilone

CAS Number 51022-71-0

U.S. Brand Names Cesamet®

Impairment Potential Yes

Use Treatment of nausea and vomiting associated with cancer chemotherapy

Mechanism of Action Nabilone is a synthetic cannabinoid utilized as an antiemetic drug in the control of nausea and vomiting in patients receiving cancer chemotherapy; like delta-9-tetrahydrocannabinol (the active principal of marijuana), nabilone is a dibenzo(b,d)pyrans; has central CNS antiemetic action through the dopaminergic pathway

Adverse Reactions

Cardiovascular: Hypotension, hypertension, tachycardia, sinus tachycardia

Central nervous system: Changes of mood, confusion, hallucinations, CNS depression, dizziness, drowsiness, headache, euphoria, clumsiness

Gastrointestinal: Loss of appetite or increased appetite, xerostomia

Ocular: Blurred vision

Respiratory: Difficulty breathing

Pharmacodynamics/Kinetics

Absorption: Rapid and complete

Distribution: ~12.5 L/kg

Metabolism: To several active metabolites by oxidation and stereospecific enzyme reduction; CYP450 enzymes may also be involved

Half-life elimination: Parent compound: 2 hours; Metabolites: 35 hours

Time to peak, serum: Within 2 hours

Excretion: Feces (~60%); renal (~24%)

Dosage Oral:

Children >4 years:

<18 kg: 0.5 mg twice daily

18-30 kg: 1 mg twice daily

>30 kg: 1 mg 3 times/day

Adults: 1-2 mg twice daily beginning 1-3 hours before chemotherapy is administered and continuing around-the-clock until 1 dose after chemotherapy is completed; maximum daily dose: 6 mg divided in 3 doses

Monitoring Parameters Blood pressure, heart rate; signs and symptoms of excessive use, abuse, or misuse

Administration Initial dose should be given 1-3 hours before chemotherapy; may be given 2-3 times a day during the entire chemotherapy course and for up to 48 hours after the last dose of chemotherapy; a dose of 1-2 mg the night before chemotherapy may be useful.

Contraindications Hypersensitivity to nabilone, cannabinoids, tetrahydrocannabinol, or any component of the formulation

Warnings May affect CNS function; use with caution in the elderly and those with pre-existing CNS depression. May cause additive CNS effects with sedatives, hypnotics, or other psychoactive agents; patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use caution with current or previous history of mental illness; cannabinoid use may reveal symptoms of psychiatric disorders. Psychiatric adverse reactions may persist for up to 3 days after discontinuing treatment. Has potential for abuse and dependence, use caution in patients with substance abuse history or potential. May cause tachycardia and orthostatic hypotension; use caution with cardiovascular disease. Safety and efficacy in children have not been established.

Dosage Forms Capsule:

Cesamet™: 1 mg

Reference Range Peak serum levels after a 2 mg dose: 10 ng/mL

Overdosage/Treatment

Decontamination: Oral: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Benzodiazepines for agitation; hypotension can be treated with Trendelenburg/crystalloid infusion; tachycardia can be treated with beta-blockers

Drug Interactions

Anticholinergic agents (includes antihistamines, atropine, and scopolamine): Tachycardia and drowsiness may be additive.

CNS depressants (includes barbiturates, narcotic analgesics, and other sedative agents): Sedative effects may be additive with CNS depressants; monitor for increased effect.

Naltrexone: Oral cannabinoid effects may be enhanced via opioid receptor blockade.

Opioids: May have cross-tolerance and potentiation.

Sympathomimetic agents (includes amphetamines and cocaine): Hypertension, tachycardia, and cardiotoxicity may be additive.

Tricyclic antidepressants (includes amitriptyline, amoxapine, and desipramine): Tachycardia, hypertension, and drowsiness may be additive.

Pregnancy Risk Factor C

Pregnancy Implications Animal studies did not demonstrate teratogenic effects, however, dose-related decreased fetal weights and increased fetal resorptions were observed. There are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if clearly needed.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications May cause drowsiness, euphoria; institute safety precautions

Nabumetone**Related Information**

- Nonsteroidal Anti-inflammatory Drugs

CAS Number 42924-53-8

U.S. Brand Names Relafen®

Use Management of osteoarthritis and rheumatoid arthritis
Moderate pain

Mechanism of Action Nabumetone is a nonacidic, nonsteroidal anti-inflammatory drug that is rapidly metabolized after absorption to a major active metabolite, 6-methoxy-2-naphthylacetic acid. Nabumetone's active metabolite inhibits the cyclooxygenase enzyme which is indirectly responsible for the production of endoperoxides and prostaglandins E₂ and I₂ (prostacyclin). The active metabolite of nabumetone is felt to be the compound primarily responsible for therapeutic effect. Comparatively, the parent drug is a poor inhibitor of prostaglandin synthesis.

Adverse Reactions

Cardiovascular: Angina, arrhythmia, hypertension, myocardial infarction, syncope, vasculitis, congestive heart failure

Central nervous system: **Dizziness**, headache, nervousness, agitation, anxiety, confusion, depression, fever, malaise, nightmares, vertigo

Dermatologic: **Rash**, itching, acne, alopecia, angioneurotic edema, bullous eruptions, photosensitivity, urticaria, Stevens-Johnson syndrome, toxic epidermal necrolysis, erythema multiforme, pseudoporphyria cutanea tarda

Endocrine & metabolic: Fluid retention, hyperglycemia

Gastrointestinal: **Abdominal cramps, abdominal pain (12%), diarrhea (14%), dyspepsia (13%), heartburn, indigestion, nausea**, vomiting, anorexia, duodenal ulcer, dysphagia, gallstones, gastric ulcer, gastroenteritis, gingivitis, GI bleeding, melena, pancreatitis

Genitourinary: Hyperuricemia, hypokalemia, impotence

Hematologic: Anemia, granulocytopenia, leukopenia, thrombocytopenia, thrombophlebitis

Hepatic: Cholestatic jaundice, liver function abnormalities, hepatic failure, hepatitis

Neuromuscular & skeletal: Paresthesia, tremor, weakness

Ocular: Abnormal vision

Otic: Tinnitus

Renal: Albuminuria, azotemia, nephrolithiasis, interstitial nephritis, nephrotic syndrome, renal failure

Respiratory: Asthma, dyspnea, eosinophilic pneumonia, hypersensitivity pneumonitis, interstitial pneumonitis

Miscellaneous: Anaphylactoid reaction, anaphylaxis

Signs and Symptoms of Overdose Cognitive dysfunction, drowsiness, flatulence, gastritis, nausea, nephrotic syndrome, ototoxicity, photosensitivity, stomatitis, tinnitus, vomiting, wheezing. Severe poisoning can manifest with coma, hypotension, renal and/or hepatic failure, respiratory depression, and seizures.

Pharmacodynamics/Kinetics

Onset of action: Several days

Distribution: Diffusion occurs readily into synovial fluid

V_d: 6MNA: 29-82 L

Protein binding: 6MNA: >99%

Metabolism: Prodrug, rapidly metabolized in the liver to an active metabolite [6-methoxy-2-naphthylacetic acid (6MNA)] and inactive metabolites; extensive first-pass effect

Half-life elimination: 6MNA: ~24 hours

Time to peak, serum: 6MNA: Oral: 2.5-4 hours; Synovial fluid: 4-12 hours

Excretion: 6MNA: Urine (80%) and feces (9%)

Dosage

Adults: Oral: 1000 mg/day; an additional 500-1000 mg may be needed in some patients to obtain more symptomatic relief; may be administered once or twice daily

Dosing adjustment in renal impairment: None necessary; however, adverse effects due to accumulation of inactive metabolites of nabumetone that are renally excreted have not been studied and should be considered

Monitoring Parameters Patients with renal insufficiency: Baseline renal function followed by repeat test within weeks (to determine if renal function has deteriorated)

Contraindications Hypersensitivity to nabumetone, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy (3rd trimester)

Warnings

[U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension. Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Not recommended for use in patients with advanced renal disease.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

The elderly are at increased risk for adverse effects (especially peptic ulceration, CNS effects, renal toxicity) from NSAIDs even at low doses. Withhold for at least 4-6 half-lives prior to surgical or dental procedures. May cause photosensitivity reactions. Safety and efficacy have not been established in pediatric patients.

Dosage Forms

[DSC] = Discontinued product

Tablet: 500 mg, 750 mg

Relafen®: 500 mg, 750 mg [DSC]

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage

Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be effective

Drug Interactions ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure. Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet drugs (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatid, tirofiban) can cause an increased risk of bleeding.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids may increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use. Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose. Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again. Loop diuretics efficacy (diuretic and antihypertensive effect) is reduced. Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Thiazides antihypertensive effects are decreased; avoid concurrent use. Warfarin's INRs may be increased by nabumetone. Monitor INR closely. Use the lowest dose of NSAIDs possible and for the briefest duration.

Pregnancy Risk Factor C/D (3rd trimester)

Lactation Excretion in breast milk unknown/not recommended

Nadolol

Related Information

- Selected Properties of Beta-Adrenergic Blocking Drugs

CAS Number 42200-33-9

U.S. Brand Names Corgard®

Use Treatment of hypertension and angina pectoris; prophylaxis of migraine headaches

Mechanism of Action Competitively blocks response to beta-adrenergic stimulation; hydrophilic

Adverse Reactions

Cardiovascular: **Persistent bradycardia**, hypotension (orthostatic), Raynaud's syndrome, congestive heart failure, edema, sinus bradycardia, chest pain, angina, myocardial depression, QRS prolongation
 Central nervous system: Fatigue, dizziness, malaise, ataxia
 Dermatological: Rash, alopecia, toxic epidermal necrolysis, xerosis, urticaria, onycholysis, pruritus, psoriasis, licheniform eruptions
 Gastrointestinal: Gastrointestinal discomfort, abdominal pain, flatulence, nausea, diarrhea, pancreatitis, xerostomia
 Genitourinary: Impotence
 Neuromuscular & skeletal: Paresthesia
 Ocular: Optic atrophy
 Respiratory: Wheezing, hypersensitivity, pneumonitis with elevated sedimentation rate, dyspnea, cough
 Miscellaneous: Systemic lupus erythematosus

Signs and Symptoms of Overdose Ataxia, hyperglycemia, hyperkalemia, and impotence

Pharmacodynamics/Kinetics

Duration: 17-24 hours
 Absorption: 30% to 40%
 Distribution: Concentration in human breast milk is 4.6 times higher than serum
 Protein binding: 28%
 Half-life elimination: Adults: 10-24 hours; prolonged with renal impairment; End-stage renal disease: 45 hours
 Time to peak, serum: 2-4 hours
 Excretion: Urine (as unchanged drug)

Dosage Oral:

Adults: Initial: 40 mg/day, increase dosage gradually by 40-80 mg increments at 3- to 7-day intervals until optimum clinical response is obtained with profound slowing of heart rate; doses up to 160-240 mg/day in angina and 240-320 mg/day in hypertension may be necessary.
 Hypertension: Usual dosage range (JNC 7): 40-120 mg once daily
 Elderly: Initial: 20 mg/day; increase doses by 20 mg increments at 3- to 7-day intervals; usual dosage range: 20-240 mg/day.

Dosing adjustment in renal impairment:

Cl_{cr} 31-40 mL/minute: Administer every 24-36 hours or administer 50% of normal dose.
 Cl_{cr} 10-30 mL/minute: Administer every 24-48 hours or administer 50% of normal dose.
 Cl_{cr} < 10 mL/minute: Administer every 40-60 hours or administer 25% of normal dose.

Hemodialysis: Moderately dialyzable (20% to 50%); administer dose postdialysis or administer 40 mg supplemental dose.
 Peritoneal dialysis: Supplemental dose is not necessary.

Dosing adjustment/comments in hepatic disease: Reduced dose probably necessary.

Monitoring Parameters Blood pressure, heart rate, fluid input and output, weight

Contraindications Hypersensitivity to nadolol or any component of the formulation; bronchial asthma; sinus bradycardia; sinus node dysfunction; heart block greater than first degree (except in patients with a functioning artificial pacemaker); cardiogenic shock; uncompensated cardiac failure

Warnings Administer only with extreme caution in patients with compensated heart failure, monitor for a worsening of the condition. Efficacy in heart failure has not been established for nadolol. **[U.S. Boxed Warn-**

ing]: Beta-blocker therapy should not be withdrawn abruptly (particularly in patients with CAD), but gradually tapered to avoid acute tachycardia, hypertension, and/or ischemia. Use caution with concurrent use of beta-blockers and either verapamil or diltiazem; bradycardia or heart block can occur. In general, patients with bronchospastic disease should not receive beta-blockers. Nadolol, if used at all, should be used cautiously in bronchospastic disease with close monitoring. Use cautiously in diabetics because it can mask prominent hypoglycemic symptoms. Can mask signs of thyrotoxicosis. Can cause fetal harm when administered in pregnancy. Use cautiously in the renally impaired (dosage adjustments are required). Use care with anesthetic agents which decrease myocardial function.

Dosage Forms [DSC] = Discontinued product

Tablet: 20 mg, 40 mg, 80 mg, 120 mg, 160 mg
 Corgard®: 20 mg, 40 mg, 80 mg, 120 mg [DSC], 160 mg [DSC]

Reference Range Peak serum nadolol concentration of 5 ng/mL after a 2 mg dose; peak steady-state nadolol level after a 55 mg daily dose: 62 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** use ipecac

Supportive therapy: Glucagon (50-150 mcg/kg followed by continuous drip of 1-5 mg/hour) for positive chronotropic effect; atropine/isoproterenol can be utilized to increase heart rate; calcium chloride may also be effective; **do not** use epinephrine

Enhancement of elimination: Multiple dosing of activated charcoal is effective; hemodialysis has been utilized with clinical improvement and increased clearance rate from 46-102 mL/minute (30% of drug can be fractionally removed during 4 hours of hemodialysis); in a nadolol overdose (6-20 mg of total drug removed); moderately dialyzable (20% to 50%)

Drug Interactions

Albuterol (and other beta₂ agonists): Effects may be blunted by nonspecific beta-blockers.

Alpha-blockers (prazosin, terazosin): Concurrent use of beta-blockers may increase risk of orthostasis.

Clonidine: Hypertensive crisis after or during withdrawal of either agent. Drugs which slow AV conduction (digoxin): Effects may be additive with beta-blockers.

Epinephrine (including local anesthetics with epinephrine): Propranolol may cause hypertension.

Glucagon: Nadolol may blunt the hyperglycemic action of glucagon.

Insulin and oral hypoglycemics: Nadolol may mask symptoms of hypoglycemia.

Nadolol increases antipyrine's half-life.

NSAIDs (ibuprofen, indomethacin, naproxen, piroxicam) may reduce the antihypertensive effects of beta-blockers.

Salicylates may reduce the antihypertensive effects of beta-blockers.

Sulfonylureas: Beta-blockers may alter response to hypoglycemic agents. Verapamil or diltiazem may have synergistic or additive pharmacological effects when taken concurrently with beta-blockers.

Pregnancy Risk Factor C

Pregnancy Implications No data available on crossing the placenta. Beta-blockers have been associated with bradycardia, hypotension, and IUGR; IUGR is probably related to maternal hypertension. Alternative beta-blockers are preferred for use during pregnancy due to limited data and prolonged half-life. Cases of neonatal hypoglycemia have been reported following maternal use of beta-blockers at parturition or during breast-feeding.

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications Patient's therapeutic response may be evaluated by looking at blood pressure, apical and radial pulses

Specific References

Chobanian AV, Bakris GL, Black HR, et al, "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, 289(19):2560-71.

Nalbuphine

CAS Number 20594-83-6; 23277-43-2

U.S. Brand Names Nubain®

Synonyms Nalbuphine Hydrochloride

Impairment Potential Yes

Use Relief of moderate to severe pain

Mechanism of Action Binds to opiate receptors in the CNS, causing inhibition of ascending pain pathways, altering the perception of and response to pain; produces generalized CNS depression. A 14-hydroxymorphine derivative. A kappa-receptor opioid agonist but a mcg-receptor antagonist.

Adverse Reactions

Cardiovascular: Hypotension, flushing, hypertension, tachycardia, sinus bradycardia, sinus tachycardia

Central nervous system: **CNS depression, narcotic withdrawal, drowsiness**, dizziness, headache, anxiety, agitation, hallucinations, confu-

sion, nervousness, restlessness, night terrors, insomnia, paradoxical CNS stimulation

Dermatologic: Urticaria, skin rash

Gastrointestinal: Nausea, vomiting, anorexia, xerostomia, biliary tract spasm

Genitourinary: Ureteral spasm, decreased urination

Local: Pain at injection site

Neuromuscular & skeletal: Weakness

Ocular: Blurred vision

Respiratory: Apnea, respiratory depression, dyspnea, pulmonary edema

Miscellaneous: **Histamine release**, toxic megacolon, diaphoresis

Signs and Symptoms of Overdose Clammy skin, coma, depression, drowsiness, dyspepsia, dysphoria, hypotension, insomnia, miosis, night terrors

Pharmacodynamics/Kinetics

Onset of action: Peak effect: SubQ, I.M.: < 15 minutes; I.V.: 2-3 minutes

Metabolism: Hepatic

Half-life elimination: 5 hours

Excretion: Feces; urine (~7% as metabolites)

Dosage

I.M., I.V., SubQ:

Children 10 months to 14 years: Premedication: 0.2 mg/kg; maximum: 20 mg/dose

Adults: 10 mg/70 kg every 3-6 hours; maximum single dose: 20 mg; maximum daily dose: 160 mg

Dosing adjustment/comments in hepatic impairment: Use with caution and reduce dose

Stability Incompatible with nafcillin, diazepam, or pentobarbital

Monitoring Parameters Relief of pain, respiratory and mental status, blood pressure

Administration Administer I.M., SubQ, or I.V.

Contraindications Hypersensitivity to nalbuphine or any component of the formulation

Warnings Use caution in CNS depression. Sedation and psychomotor impairment are likely, and are additive with other CNS depressants or ethanol. May cause respiratory depression. Ambulatory patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in patients with recent myocardial infarction, biliary tract surgery, head trauma, or increased intracranial pressure. Use caution in patients with decreased hepatic or renal function. May result in tolerance and/or drug dependence with chronic use; use with caution in patients with a history of drug dependence. Abrupt discontinuation following prolonged use may lead to withdrawal symptoms. May precipitate withdrawal symptoms in patients following prolonged therapy with mu opioid agonists. Use with caution in pregnancy (close neonatal monitoring required when used in labor and delivery). Safety and efficacy in pediatric patients (< 18 years of age) have not been established.

Dosage Forms [DSC] = Discontinued product

Injection, solution, as hydrochloride: 10 mg/mL (10 mL); 20 mg/mL (10 mL)

Nubain®: 10 mg/mL (10 mL) [DSC]; 20 mg/mL (10 mL)

Injection, solution, as hydrochloride [preservative free]: 10 mg/mL (1 mL); 20 mg/mL (1 mL)

Nubain®: 10 mg/mL (1 mL); 20 mg/mL (1 mL)

Reference Range Peak blood nalbuphine level after a 30 mg oral dose in adults and elderly volunteers: 7 mcg/L and 49 mcg/L, respectively

Overdosage/Treatment Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at $\frac{2}{3}$ the response dose/hour) may be required. Risperidone (1 mg twice daily) can be used to treat nalbuphine-associated psychosis.

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Drug Interactions Increased toxicity: Barbiturate anesthetics may increase CNS depression

Pregnancy Risk Factor B/D (prolonged use or high doses at term)

Pregnancy Implications May cause neonatal bradycardia or respiratory depression when used during labor

Lactation Enters breast milk/use caution

Nursing Implications Observe patient for excessive sedation, apnea; implement safety measures, assist with ambulation; observe for narcotic withdrawal

Additional Information Little abuse potential

Specific Reference

Klinzing F, Vinner E, Brassart C, et al, "Hair Analysis by LC-MS as Evidence of Nalbuphine Abuse by a Nurse," *J Anal Tox*, 2007, 31: 62-5.

Nalidixic Acid

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 389-08-2

U.S. Brand Names NegGram®

Synonyms

Nalidixinic Acid

Use Urinary tract infections

Mechanism of Action Inhibits DNA polymerization in late stages of chromosomal replication; direct antagonist of gabanergic neurotransmission

Adverse Reactions

Central nervous system: Fever, chills, malaise, **drowsiness**, **dizziness**, confusion, toxic psychosis, seizures, **headache**, visual hallucinations, increased intracranial pressure, psychosis

Dermatologic: Rash, bullous eruptions, pruritus, photosensitivity reactions, exfoliative dermatitis, alopecia, angioedema, toxic epidermal necrolysis, urticaria, purpura, exanthem, photoallergic reaction

Endocrine & metabolic: Metabolic acidosis

Gastrointestinal: Nausea, vomiting, feces discoloration (greenish gray), feces discoloration (white/speckling)

Hematologic: Leukopenia, thrombocytopenia, hemolytic anemia, porphyrogenic

Hepatic: Hepatotoxicity (cholestatic)

Neuromuscular & skeletal: Paresthesia

Ocular: Visual disturbances, nystagmus, color vision abnormalities

Miscellaneous: Systemic lupus erythematosus

Signs and Symptoms of Overdose Agranulocytosis, coma, dementia, dermatitis, diplopia, eosinophilia, erythema multiforme, granulocytopenia, hyperglycemia, hyperthermia, increased intracranial pressure, leukopenia, metabolic acidosis, nausea, neutropenia, photophobia, photosensitivity, pseudotumor cerebri, seizures, thrombocytopenia, toxic psychosis, vision color changes (blue tinge; violet tinge; yellow tinge), vomiting

Pharmacodynamics/Kinetics

Distribution: Achieves significant antibacterial concentrations only in the urinary tract; crosses placenta; enters breast milk

Protein binding: 90%

Metabolism: Partially hepatic; active metabolite, hydroxynalidixic acid

Half-life elimination: 6-7 hours; significantly prolonged with renal impairment

Time to peak, serum: 1-2 hours

Excretion: Urine (as unchanged drug, 80% as metabolites); feces (small amounts)

Dosage

Oral:
Children 3 months to 12 years: 55 mg/kg/day divided every 6 hours; suppressive therapy is 33 mg/kg/day divided every 6 hours

Adults: 1 g 4 times/day for 2 weeks; then suppressive therapy of 500 mg 4 times/day

Dosing comments in renal impairment: Cl_{cr} < 50 mL/minute: Avoid use

Monitoring Parameters Urinalysis, urine culture; CBC, renal, and hepatic function tests

Administration

May be administered with or without food; drink fluids liberally

Contraindications Hypersensitivity to nalidixic acid or any component of the formulation; infants < 3 months of age; porphyria, seizures; concurrent melphalan or other alkylating agent; breast-feeding

Warnings

Use with caution in patients with impaired hepatic or renal function and prepubertal children; has been shown to cause cartilage degeneration in immature animals; may induce hemolysis in patients with G6PD deficiency; use caution in patients with seizure disorder. Potential for seizures, although very rare, may be increased with concomitant NSAID therapy. Tendon inflammation and/or rupture have been reported. Risk may be increased with concurrent corticosteroids, particularly in the elderly. Discontinue at first sign of tendon inflammation or pain. Peripheral neuropathy may rarely occur; prompt discontinuation is recommended in patients with signs and symptoms of neuropathy.

Severe hypersensitivity reactions, including anaphylaxis, have occurred with quinolone therapy. If an allergic reaction occurs (itching, urticaria, dyspnea, facial edema, loss of consciousness, tingling, cardiovascular collapse), discontinue drug immediately. Prolonged use may result in superinfection; pseudomembranous colitis may occur and should be considered in all patients who present with diarrhea. Quinolones may exacerbate myasthenia gravis, use with caution (rare, potentially life-threatening weakness of respiratory muscles may occur).

Dosage Forms

[DSC] = Discontinued product

Suspension, oral: 250 mg/5 mL (473 mL) [raspberry flavor] [DSC]

Tablet: 500 mg [DSC]

Reference Range Peak plasma level of 20-50 mcg/mL achieved 2 hours after oral dose of 1 g; urine concentration after 1 g oral dose can range from 25-250 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Diazepam/lorazepam for seizures

Test Interactions False-positive urine glucose with Clinitest®, false increase in urinary VMA

Drug Interactions

Inhibits CYP1A2 (weak)

Corticosteroids: Concurrent use may increase the risk of tendon rupture, particularly in elderly patients (overall incidence rare).

NALTREXONE

Glyburide: Quinolones may increase the effect of glyburide; monitor.
Melfalan: Concomitant use of I.V. melfalan and nalidixic acid may increase the risk of developing necrotic enterocolitis (reported in pediatric patients).

Metal cations (aluminum, calcium, iron, magnesium, and zinc) bind quinolones in the gastrointestinal tract and inhibit absorption. Concurrent administration of most antacids, oral electrolyte supplements, quinapril, sucralfate, some didanosine formulations (chewable/buffered tablets and pediatric powder for oral suspension), and other highly-buffered oral drugs, should be avoided. Nalidixic acid should be administered 2 hours before or 2 hours after these agents.

Probenecid: May decrease renal secretion of nalidixic acid.

Warfarin: The hypoprothrombinemic effect of warfarin may be enhanced by some quinolone antibiotics; monitor INR.

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic and embryocidal effects were observed in animal studies. One study suggests that use late in pregnancy may increase the risk of infantile pyloric stenosis in the newborn. However, this finding was based on a small number of cases and other causes such as chance could not be excluded. Other authors suggest that nalidixic acid is unlikely to be teratogenic at therapeutic doses, but that there is not enough data to state there is no risk.

Lactation Enters breast milk/contraindicated (AAP considers "compatible")

Naltrexone

Related Information

- Drugs Used in Addiction Treatment

CAS Number 16590-41-3; 16676-29-2

U.S. Brand Names Depade®; ReVia®; Vivitrol™

Synonyms Naltrexone Hydrochloride

Use Adjunct to the maintenance of an opioid-free state in detoxified individual; approved for use in the treatment of ethanol abuse; used in alternative medicine to treat HIV (T-cell count > 500)

Mechanism of Action Naltrexone (a pure opioid antagonist) is a cyclopropyl derivative of oxymorphone similar in structure to naloxone and nalorphine (a morphine derivative); it acts as a competitive antagonist at opioid receptor sites, showing the highest affinity for mu receptors.

Adverse Reactions

Cardiovascular: Hypertension, tachycardia, sinus tachycardia
Central nervous system: **Insomnia, nervousness, headache**, irritability, anxiety, dysphoria, dizziness, panic attacks, delirium
Dermatologic: Rash, acne, pruritus, alopecia, oily skin
Gastrointestinal: **Nausea, abdominal cramping, vomiting**, anorexia
Hematologic: Thrombocytopenia, agranulocytosis, hemolysis
Hepatic: Hepatitis
Neuromuscular & skeletal: **Arthralgia**, myalgia
Ocular: Blurred vision
Otic: Tinnitus
Miscellaneous: Narcotic withdrawal

Signs and Symptoms of Overdose Agranulocytosis, dysphoria, granulocytopenia, hepatocellular damage, insomnia, leukopenia, neutropenia

Pharmacodynamics/Kinetics

Duration: Oral: 50 mg: 24 hours; 100 mg: 48 hours; 150 mg: 72 hours; I.M.: 4 weeks

Absorption: Oral: Almost complete

Distribution: V_d : 19 L/kg; widely throughout the body but considerable interindividual variation exists

Protein binding: 21%

Metabolism: Noncytochrome-mediated dehydrogenase conversion to 6- β -naltrexol and related minor metabolites; Oral: Extensive first-pass effect

Half-life elimination: Oral: 4 hours; 6- β -naltrexol: 13 hours; I.M.: naltrexone and 6- β -naltrexol: 5-10 days

Time to peak, serum: Oral: ~60 minutes; I.M.: Biphasic: 2 hours (first peak), 2-3 days (second peak)

Excretion: Primarily urine (as metabolites and unchanged drug)

Dosage

Adults: Do not give until patient is opioid-free for 7-10 days as determined by urinalysis

Oral: Alcohol dependence, opioid antidote: 25 mg; if no withdrawal signs within 1 hour give another 25 mg; maintenance regimen is flexible, variable and individualized (50 mg/day to 100-150 mg 3 times/week for 12 weeks); up to 800 mg/day has been tolerated in a small number of healthy adults without an adverse effect

I.M.: Alcohol dependence: 380 mg once every 4 weeks

Dosage adjustment in renal impairment: Use caution. No adjustment needed in mild impairment. Not adequately studied in moderate-to-severe renal impairment.

Dosage adjustment in hepatic impairment: Use caution. An increase in naltrexone AUC of approximately five- and 10-fold in patients with compensated or decompensated liver cirrhosis respectively, compared with normal liver function has been reported. No adjustment required

with mild-to-moderate hepatic impairment. Not adequately studied in severe hepatic impairment.

Monitoring Parameters For narcotic withdrawal; liver function tests

Administration If there is any question of occult opioid dependence, perform a naloxone challenge test; do not attempt treatment until naloxone challenge is negative.

Oral: To minimize adverse gastrointestinal effects, administer with food or antacids or after meals; advise patient not to self-administer opiates while receiving naltrexone therapy.

I.M.: Vivitrol™: Administer I.M. into the upper outer quadrant of the gluteal area. Injection should alternate between the two buttocks. Do not substitute any components of the dose-pack; administer with needle provided.

Contraindications Hypersensitivity to naltrexone or any component of the formulation; narcotic dependence or current use of opioid analgesics; acute opioid withdrawal; failure to pass Narcan® challenge or positive urine screen for opioids; acute hepatitis; liver failure

Warnings[U.S. Boxed Warning]: Dose-related hepatocellular injury is possible; the margin of separation between the apparent safe and hepatotoxic doses appears to be only fivefold or less (contraindicated in acute hepatitis or hepatic failure).

May precipitate withdrawal symptoms in patients addicted to opiates, including pain, hypertension, sweating, agitation, irritability; in neonates: shrill cry, failure to feed. Patients should be opiate-free for a minimum of 7-10 days; use naloxone challenge test to confirm. Use with caution in patients with hepatic or renal impairment; not studied in severe hepatic or moderate-to-severe renal impairment.

Patients who had been treated with naltrexone may respond to lower opioid doses than previously used. This could result in potentially life-threatening opioid intoxication. Patients should be aware that they may be more sensitive to lower doses of opioids after naltrexone treatment is discontinued. Use of naltrexone does not eliminate or diminish withdrawal symptoms. Warn patients that attempts to overcome opioid blockade could lead to fatal overdose. Suicidal thoughts and depression have been reported; monitor closely.

Cases of eosinophilic pneumonia have been reported; monitor for hypoxia and dyspnea. Safety and efficacy in children have not been established.

Dosage Forms

Injection, powder for suspension [extended-release microspheres]:

Vivitrol™: 380 mg [diluent provided]

Tablet, as hydrochloride: 50 mg

Depade®: 25 mg, 50 mg, 100 mg

ReVia®: 50 mg

Reference Range Peak plasma naltrexone and 6- β -naltrexol levels after a 100 mg oral dose: 27 ng/mL and 106 ng/mL, respectively

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Dysmorphic/irritability can be treated by titrating with morphine

Test Interactions ↑ gonadotropin, cortisol (S)

Drug Interactions Narcotic analgesics: Decreased effect of narcotic analgesics; may precipitate acute withdrawal reaction in physically dependent patients; concurrent use is contraindicated

Thioridazine: Lethargy and somnolence have been reported with the combination of naltrexone and thioridazine

Pregnancy Risk Factor C

Pregnancy Implications Evidence of early fetal loss has been observed in animal studies with oral naltrexone. There are no adequate and well-controlled studies in pregnant women.

Lactation Enters breast milk/not recommended

Nursing Implications Monitor for narcotic withdrawal

Additional Information Up to 800 mg/day has been tolerated in adults without an adverse effect

Naphazoline

CAS Number 550-99-2; 835-31-4

U.S. Brand Names AK-Con™; Albalon®; Allersol®; Clear Eyes® ACR [OTC]; Clear Eyes® [OTC]; Naphcon® [OTC]; Privine® [OTC]; VasoClear® [OTC]

Synonyms Naphazoline Hydrochloride

Use Topical ocular vasoconstrictor; will temporarily relieve congestion, itching, and minor irritation, and to control hyperemia in patients with superficial corneal vascularity; also has been used to treat myopathic ptosis

Mechanism of Action Stimulates alpha-adrenergic receptors in the arterioles of the conjunctiva and the nasal mucosa to produce vasoconstriction

Adverse Reactions

Cardiovascular: **Systemic cardiovascular stimulation, premature ventricular contractions (I.V.)**

Central nervous system: **Dizziness, headache, nervousness, hypothermia**

Gastrointestinal: **Nausea**

Local: **Transient stinging, nasal mucosa irritation, dryness, rebound congestion**

Ocular: **Mydriasis, increased intraocular pressure, blurring of vision**

Respiratory: **Sneezing**

Signs and Symptoms of Overdose Apnea, bradycardia, cardiovascular collapse, CNS depression, coma, hypothermia

Admission Criteria/Prognosis Patients may be discharged if asymptomatic 6 hours postingestion

Pharmacodynamics/Kinetics

Onset of action: Decongestant: Topical: ~10 minutes

Duration: 2-6 hours

Dosage Nasal:

Children:

< 6 years: Intranasal: Not recommended (especially infants) due to CNS depression

6-12 years: 1 spray of 0.05% into each nostril every 6 hours if necessary; therapy should not exceed 3-5 days

Children > 12 years and Adults: 0.05%, instill 1-2 drops or sprays every 6 hours if needed; therapy should not exceed 3-5 days

Ophthalmic:

Children < 6 years: Not recommended for use due to CNS depression (especially in infants)

Children > 6 years and Adults: Instill 1-2 drops into conjunctival sac of affected eye(s) every 3-4 hours; therapy generally should not exceed 3-4 days

Stability Store in tight, light-resistant containers

Administration Ophthalmic: Contact lenses should be removed prior to administering products containing benzalkonium chloride.

Contraindications Hypersensitivity to naphazoline or any component of the formulation; narrow-angle glaucoma

Warnings Rebound congestion may occur with extended use. Use with caution in the presence of hypertension, diabetes, hyperthyroidism, heart disease, coronary artery disease, cerebral arteriosclerosis, local infection or injury, benign prostatic hyperplasia, or long-standing bronchial asthma. Use in children, especially infants, may cause CNS depression, coma and marked reduction in body temperature. Products may contain benzalkonium chloride which may be absorbed by soft contact lenses.

When used for self-medication (OTC): Patients should notify healthcare provider if symptoms last > 72 hours or if condition worsens. In addition with ophthalmic products, contact prescriber in case of eye pain or if changes in vision occur.

Dosage Forms Solution, intranasal drops, as hydrochloride:

Privine®: 0.05% (25 mL)

Solution, intranasal spray, as hydrochloride:

Privine®: 0.05% (20 mL)

Solution, ophthalmic, as hydrochloride:

AK-Con™, Albalon®, Allersol®: 0.1% (15 mL) [contains benzalkonium chloride]

Clear Eyes® ACR: 0.012% (15 mL, 30 mL) [contains glycerin 0.2%, zinc sulfate 0.25%, and benzalkonium chloride]

Clear Eyes® Extra Relief: 0.012% (6 mL, 15 mL, 30 mL) [contains glycerin 0.2% and benzalkonium chloride]

Naphcon®: 0.012% (15 mL) [contains benzalkonium chloride]

Overdosage/Treatment

Decontamination: **Oral:** Do not induce emesis; lavage (with airway protection) may be useful if performed within 1 hour of ingestion; activated charcoal can be given. **Ocular:** Irrigation copiously with normal saline or water

Supportive therapy: Hypotension and/or bradycardia will usually respond to isotonic I.V. fluid administration (10-20 mL/kg); atropine can cause significant hypertension if given; nitroprusside or phentolamine can be given to treat hypertension while phentolamine can be used to treat localized vasoconstriction; seizures can be treated with lorazepam or diazepam; phenytoin or phenobarbital can be used in refractory cases; naloxone and flumazenil do not appear to be useful

Drug Interactions

Guanadrel: May enhance the therapeutic effect of alpha₁-agonists, in particular the mydriatic effects of ophthalmic products.

MAO inhibitors: MAO inhibitors may enhance the hypertensive effect of alpha₁-agonists; avoid use.

Methyldopa: May enhance the therapeutic effect of alpha₁-agonists, in particular the mydriatic effects of ophthalmic products.

Tricyclic antidepressants: Tricyclic antidepressants may enhance the vasopressor effect of alpha₁-agonists; avoid use.

Pregnancy Risk Factor C

Pregnancy Implications Animal reproduction studies have not been conducted.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Rebound congestion can result with continued use

Additional Information Recovery from overdose usually occurs within 36 hours

Naproxen

Related Information

• Nonsteroidal Anti-inflammatory Drugs

CAS Number 222-53-1; 26159-34-2

U.S. Brand Names Aleve® [OTC]; Anaprox® DS; Anaprox®; EC-Naprosyn®; Midol® Extended Relief; Naprelan®; Naprosyn®; Pamprin® Maximum Strength All Day Relief [OTC]

Synonyms Naproxen Sodium

Use Management of inflammatory disease and rheumatoid disorders (including juvenile rheumatoid arthritis); acute gout; mild to moderate pain; dysmenorrhea; fever, migraine headache

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors

Adverse Reactions

Cardiovascular: Circulatory collapse, vasculitis

Central nervous system: Headache, aseptic meningitis, psychosis, cognitive dysfunction, **dizziness**, coma, seizures, exacerbation of Parkinson's disease

Dermatologic: **Rash, pruritus**, increased incidence of shallow facial scars (relative risk is 6) in children, exfoliative dermatitis, pityriasis rosea-like reaction, erythema multiforme, alopecia, angioedema, bullous skin disease, toxic epidermal necrolysis, Stevens-Johnson syndrome, erythema nodosum, exanthem, lichen planus, cutaneous vasculitis, phototoxicity

Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, parotiditis, parotitis, fluid retention

Gastrointestinal: **Abdominal discomfort, nausea**, vomiting, **GI bleeding, GI ulceration, constipation**, diarrhea, dyspepsia, pancreatitis, esophageal ulcerations, **heartburn, perforation, indigestion**, aphthous stomatitis, xerostomia, gastrointestinal vasculitis

Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia, aplastic anemia (rare), platelet inhibition, eosinophilia, thrombocytopenia

Hepatic: Elevated transaminases, hepatitis (fulminant), aminotransferase level elevation (asymptomatic)

Ocular: Vortex keratopathy

Otic: Ototoxicity, tinnitus

Renal: Renal failure (acute), nephrotic syndrome, chronic renal failure, albuminuria, renal vasculitis

Respiratory: Wheezing, pulmonary infiltrate, respiratory depression, eosinophilic pneumonia

Miscellaneous: Hypersensitivity, systemic lupus erythematosus (SLE), fixed drug eruption, leukoclastic vasculitis

Signs and Symptoms of Overdose Coagulopathy, cognitive dysfunction, colitis, depression, drowsiness, ejaculatory disturbances, gastritis, GI bleeding, gout, impotence, increased intraocular pressure, lichenoid eruptions, lightheadedness, meningitis, nausea, nephrotic syndrome, night terrors, ototoxicity, photosensitivity, purpura, stomatitis, tinnitus, vomiting, wheezing. Severe poisoning can manifest with coma, hypotension, metabolic acidosis, renal and/or hepatic failure, respiratory depression, seizures

Pharmacodynamics/Kinetics

Onset of action: Analgesic: 1 hour; Anti-inflammatory: ~2 weeks

Peak effect: Anti-inflammatory: 2-4 weeks

Duration: Analgesic: ≤ 7 hours; Anti-inflammatory: ≤ 12 hours

Absorption: Almost 100%

Protein binding: > 99%; increased free fraction in elderly

Half-life elimination: Normal renal function: 12-17 hours; End-stage renal disease: No change

Time to peak, serum: 1-4 hours

Excretion: Urine (95%)

Dosage Note: Dosage expressed as naproxen base; 200 mg naproxen base is equivalent to 220 mg naproxen sodium.

Oral:

Children > 2 years: Juvenile arthritis: 10 mg/kg/day in 2 divided doses

Adults:

Gout, acute: Initial: 750 mg, followed by 250 mg every 8 hours until attack subsides. **Note:** EC-Naprosyn® is not recommended.

Migraine, acute (unlabeled use): Initial: 500-750 mg.; an additional 250-500 mg may be given if needed (maximum: 1250 mg in 24 hours).

Note: EC-Naprosyn® is not recommended.

Pain (mild-to-moderate), dysmenorrhea, acute tendonitis, bursitis:
Initial: 500 mg, then 250 mg every 6-8 hours; maximum: 1250 mg/day naproxen base

Rheumatoid arthritis, osteoarthritis, and ankylosing spondylitis: 500-1000 mg/day in 2 divided doses; may increase to 1.5 g/day of naproxen base for limited time period

OTC labeling: Pain/fever:

Children ≥ 12 years and Adults ≤65 years: 200 mg naproxen base every 8-12 hours; if needed, may take 400 mg naproxen base for the initial dose; maximum: 600 mg naproxen base/24 hours

Adults >65 years: 200 mg naproxen base every 12 hours

Dosing adjustment in renal impairment: $Cl_{cr} < 30$ mL/minute: use is not recommended

Monitoring Parameters Occult blood loss, periodic liver function test, CBC, BUN, serum creatinine

Administration Administer with food, milk, or antacids to decrease GI adverse effects

Suspension: Shake suspension well before administration.

Tablet, extended release: Swallow tablet whole; do not break, crush, or chew.

Contraindications Hypersensitivity to naproxen, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy (3rd trimester)

Warnings

[U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension. Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF, or hypertension. Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Naproxen is not recommended for patients with advanced renal disease.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson Syndrome (SJS) and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

The elderly are at increased risk for adverse effects (especially peptic ulceration, CNS effects, renal toxicity) from NSAIDs even at low doses. Withhold for at least 4-6 half-lives prior to surgical or dental procedures. Safety and efficacy have not been established in children <2 years of age.

OTC labeling: Prior to self-medication, patients should contact health care provider if they have had recurring stomach pain or upset, ulcers, bleeding problems, high blood pressure, heart or kidney disease, other serious medical problems, are currently taking a diuretic, or are ≥60 years of age. Recommended dosages should not be exceeded, due to an increased risk of GI bleeding. Consuming ≥3 alcoholic beverages/day or taking longer than recommended may increase the risk of GI bleeding. When used for self-medication, patients should be instructed to contact healthcare provider if used for fever lasting >3 days or for pain lasting >10 days in adults or >3 days in children. Not for self-medication (OTC use) in children <12 years of age.

Dosage Forms

Caplet, as sodium (Aleve®, Midol® Extended Relief, Pamprin® Maximum Strength All Day Relief): 220 mg [equivalent to naproxen 200 mg and sodium 20 mg]

Gelcap, as sodium (Aleve®): 220 mg [equivalent to naproxen 200 mg and sodium 20 mg]

Suspension, oral (Naprosyn®): 125 mg/5 mL (480 mL) [contains sodium 0.3 mEq/mL; orange-pineapple flavor]

Tablet (Naprosyn®): 250 mg, 375 mg, 500 mg

Tablet, as sodium: 220 mg [equivalent to naproxen 200 mg and sodium 20 mg]; 275 mg [equivalent to naproxen 250 mg and sodium 25 mg]; 550 mg [equivalent to naproxen 500 mg and sodium 50 mg]

Aleve®: 220 mg [equivalent to naproxen 200 mg and sodium 20 mg]

Anaprox®: 275 mg [equivalent to naproxen 250 mg and sodium 25 mg]

Anaprox® DS: 550 mg [equivalent to naproxen 500 mg and sodium 50 mg]

Tablet, controlled release, as sodium: 550 mg [equivalent to naproxen 500 mg and sodium 50 mg]

Naprelan®: 421.5 mg [equivalent to naproxen 375 mg and sodium 37.5 mg]; 550 mg [equivalent to naproxen 500 mg and sodium 50 mg]

Tablet, delayed release (EC-Naprosyn®): 375 mg, 500 mg

Reference Range

Trough concentrations of >50 mcg/L (217 μmol/L) are therapeutic in patients with rheumatoid arthritis; serum naproxen level of 414 mg/L associated with oral ingestion of 25 g and mild toxicity

Therapeutic range: 30-90 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage; famotidine (40 mg 2 times/day) can decrease incidence of gastric or duodenal ulcers in patients receiving long-term therapy of this drug

Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be effective

Test Interactions ↑ chloride (S), sodium (S); causes a falsely increased free thyroxine

Drug Interactions

Substrate (minor) of CYP1A2, 2C9

ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet drugs (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatide, tirofiban) can cause an increased risk of bleeding.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids may increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use.

Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose. Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again.

Loop diuretics efficacy (diuretic and antihypertensive effect) is reduced. Indomethacin reduces this efficacy, however, it may be anticipated with any NSAID.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Thiazides antihypertensive effects are decreased; avoid concurrent use.

Warfarin's INRs may be increased by naproxen. Other NSAIDs may have the same effect depending on dose and duration. Monitor INR closely. Use the lowest dose of NSAIDs possible and for the briefest duration.

Pregnancy Risk Factor B/D (3rd trimester)

Pregnancy Implications Crosses the placenta; maternal overdosage has lead to neonatal distress; drowsiness, hypotonia, edema

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Nursing Implications Administer with food, milk, or antacids to decrease GI adverse effects

Additional Information Naproxen: Naprosyn® naproxen sodium: Anaprox®; 275 mg of Anaprox® equivalent to 250 mg of Naprosyn®

N-Benzylpiperazine

Related Information

- Amphetamines, Qualitative, Urine

Use Hallucinogen; has been utilized as an antidepressant

Mechanism of Action Sympathomimetic: Similar autonomic effects of S(+)-amphetamine. Triggers release of dopamine and norepinephrine, and inhibits reuptake (in the CNS) of dopamine, norepinephrine, and serotonin

Adverse Reactions

Central nervous system: Seizures, insomnia, agitation, auditory/visual hallucinations

Ocular: Mydriasis

Toxicodynamics/Kinetics

Metabolism: Hepatic to benzylamine and N-benzylethylenediamine

Elimination: Renal

Dosage Hallucinogenic: Oral: 75-250 mg

Reference Range Whole blood (postmortem) N-benzylpiperazine level of 1.7 mcg/g blood associated with fatality

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Amphetamine psychosis:

Haloperidol: I.V.: 5-10 mg

Diazepam: I.V.: 5-10 mg

Droperidol: I.M.: 2.5-5 mg can be used for psychosis if I.V. access is not available

Oral: Risperidone 4 mg and lorazepam 3 mg can aid in remission of neuropsychiatric effects

Hypertension that is not responsive to sedation can be treated with phentolamine or nitroprusside

Enhancement of elimination: Multiple dosing of activated charcoal may be useful. While acid diuresis can increase excretion, it is not recommended due to renal effects.

Additional Information Approximately 10% of the potency of S(+)-amphetamine; will test positive for amphetamines on urinary immunoassay

Specific Reference

Wikström M, Holmgren P, and Ahlner J, "A2 (N-Benzylpiperazine): A New Drug of Abuse in Sweden," *J Anal Tox*, 2004, 28(1):67-70.

Nebivolol

CAS Number 99200-09-6

Unlabeled/Investigational Use Hypertension

Mechanism of Action Selective beta₁-adrenoceptor antagonist which is mostly due to the D-isomer; L-isomer may improve left ventricular function

Adverse Reactions

Cardiovascular: Bradycardia, palpitations, sinus bradycardia

Central nervous system: Headache, dizziness, somnolence, insomnia

Endocrine & metabolic: Hypertriglyceridemia (doses > 30 mg)

Gastrointestinal: Nausea

Genitourinary: Impotence

Neuromuscular & skeletal: Myalgia

Signs and Symptoms of Overdose Hypotension, impotence

Toxicodynamics/Kinetics

Distribution: V_d: 10.1-39.4 L/kg

Protein binding: 98%

Metabolism: Hepatic (aromatic hydroxylation) to nebivolol glucuronide

Bioavailability: 12% (fast metabolizers); 96% (slow metabolizers)

Half-life: 8 hours (27 hours in slow metabolizers)

Dosage Oral: 5 mg once daily

Reference Range Peak plasma level of 1 mcg/L in fast metabolizers and ~3 mcg/L in slow metabolizers following a 5 mg oral dose; no change in plasma catecholamine levels (either at rest or during exercise)

Overdosage/Treatment

Decontamination: Activated charcoal; **do not** use ipecac

Supportive therapy: Glucagon (50-150 mcg/kg followed by continuous drip of 1-5 mg/hour) for positive chronotropic effect; atropine/isoproterenol can be utilized to increase heart rate; calcium chloride may also be effective

Enhancement of elimination: Multiple dosing of activated charcoal is not likely to be of benefit; dialysis is not useful; not dialyzable (0% to 5%)

Antidote(s)

- Glucagon [ANTIDOTE]

Nedocromil Sodium

CAS Number 101626-68-0; 69049-73-6; 69049-74-7

Use

Aerosol: Maintenance therapy in patients with mild to moderate bronchial asthma

Ophthalmic: Treatment of itching associated with allergic conjunctivitis

Mechanism of Action Disodium salt of a pyranoquinolone dicarboxylic acid which inhibits mediator release from inflammatory cells; can decrease bronchial hyper-reactivity; greater effect in inhibiting histamine release than cromolyn

Adverse Reactions

Cardiovascular: Chest pain, angina, sinus tachycardia

Central nervous system: Dizziness, headache, fatigue

Gastrointestinal: **Bitter taste**, nausea, vomiting, xerostomia, diarrhea, unpleasant taste

Respiratory: Coughing, pharyngitis, rhinitis, bronchitis, dyspnea, bronchospasm

Signs and Symptoms of Overdose Bitter taste (13%), bronchospasm, dizziness, headache, nausea, vomiting

Pharmacodynamics/Kinetics

Duration of therapeutic effect: 2 hours

Protein binding, plasma: 89%

Bioavailability: Systemic: 7% to 9% absorption

Half-life: 1.5-2 hours

Elimination: Excreted unchanged in urine

Dosage Adults: Metered dose inhaler: 4 mg twice daily, up to 4 times/day

Monitoring Parameters Use of beta agonists (oral or inhaled), peak expiratory flow rates, frequency and severity of wheezing, coughing, chest tightness, shortness of breath or dyspnea

Contraindications Hypersensitivity to nedocromil or other ingredients in the preparation

Warnings Safety and efficacy in children <6 years of age have not been established; if systemic or inhaled steroid therapy is at all reduced, monitor patients carefully; nedocromil is **not** a bronchodilator and, therefore, should not be used for reversal of acute bronchospasm

Dosage Forms Aerosol, as sodium: 1.75 mg/activation (16.2 g)

Reference Range Peak plasma level after a 4 mg dose (inhalation): ~3.3 ng/mL in healthy person and 2.8 ng/mL in asthmatic patients; levels not relatable to effect

Overdosage/Treatment

Decontamination: Oral: Activated charcoal

Supportive therapy: Treat inhalation exposure with 100% humidified oxygen; treat anaphylaxis with epinephrine and corticosteroids; albuterol can be given for bronchospasm

Pregnancy Risk Factor B

Nursing Implications Nedocromil is **not** a bronchodilator and, therefore, should not be used for reversal of acute bronchospasm; has no known therapeutic systemic activity when delivered by inhalation

Additional Information Each canister provides ~112 inhalations; 1.75 g/actuation

Nefazodone

Related Information

- Antidepressant Agents

U.S. Brand Names Serzone®

Synonyms Nefazodone Hydrochloride; Serzone

Impairment Potential Yes

Use Treatment of depression

Unlabeled/Investigational Use Post-traumatic stress disorder

Mechanism of Action Chemically related to trazodone, 5-HT₂ receptor antagonist, also alpha₁-adrenergic antagonist; acts to inhibit neuronal uptake of serotonin and norepinephrine

Adverse Reactions

Cardiovascular: Postural hypotension, AV block

Central nervous system: **Headache, drowsiness, insomnia, agitation, dizziness**, lightheadedness, confusion, memory impairment, abnormal dreams, decreased concentration, ataxia, hallucinations, seizures, serotonin syndrome

Dermatologic: Pruritus, rash, angioedema, photosensitivity, Stevens-Johnson syndrome

Endocrine & metabolic: Galactorrhea, gynecomastia, increased prolactin, hyponatremia

Gastrointestinal: **Xerostomia, nausea, constipation**, vomiting, dyspepsia, diarrhea, increased appetite, thirst, taste perversion

Genitourinary: Impotence, priapism

Hematologic: Leukopenia, thrombocytopenia

Hepatic: Hepatic failure, hepatic necrosis

Neuromuscular & skeletal: **Weakness**, arthralgia, paresthesia, tremor, rhabdomyolysis (with lovastatin/simvastatin)

Ocular: Blurred vision, abnormal vision, visual field defect, eye pain

Otic: Tinnitus

Respiratory: Cough, bronchitis, dyspnea

Miscellaneous: Flu syndrome, allergic reaction

Signs and Symptoms of Overdose Bradycardia, diaphoresis, hypotension, lethargy, nausea, vomiting

Admission Criteria/Prognosis Admit any adult ingestion > 1 g.

Pharmacodynamics/Kinetics

Onset of action: Therapeutic: Up to 6 weeks

Metabolism: Hepatic to three active metabolites: Triazolodione, hydroxynefazodone, and m-chlorophenylpiperazine (mCPP)

Bioavailability: 20% (variable)

Half-life elimination: Parent drug: 2-4 hours; active metabolites persist longer

Time to peak, serum: 1 hour, prolonged in presence of food

Excretion: Primarily urine (as metabolites); feces

Dosage Oral:

Children and Adolescents: Depression: Target dose: 300-400 mg/day (mean: 3.4 mg/kg)

Adults: Depression: 200 mg/day, administered in 2 divided doses initially, with a range of 300-600 mg/day in 2 divided doses thereafter

Monitoring Parameters If AST/ALT increase >3 times ULN, the drug should be discontinued and not reintroduced; mental status for depression, suicidal ideation (especially at the beginning of therapy or when doses are increased or decreased), anxiety, social functioning, mania, panic attacks

Administration Dosing after meals may decrease lightheadedness and postural hypotension, but may also decrease absorption and therefore effectiveness.

Contraindications Hypersensitivity to nefazodone, related compounds (phenylpiperazines), or any component of the formulation; liver injury due to previous nefazodone treatment, active liver disease, or elevated serum transaminases; concurrent use or use of MAO inhibitors within previous 14 days; use in a patient during the acute recovery phase of MI; concurrent use with carbamazepine, cisapride, or pimozide; concurrent therapy with triazolam or alprazolam is generally contraindicated (dosage must be reduced by 75% for triazolam and 50% for alprazolam; such reductions may not be possible with available dosage forms).

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. **Nefazodone is not FDA approved for use in children.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Nefazodone is not FDA approved for the treatment of bipolar depression.**

Cases of life-threatening hepatic failure have been reported (risk should be considered when choosing an agent for the treatment of depression); discontinue if clinical signs or symptoms suggest liver failure. May cause sedation, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Sedative effects may be additive with other CNS depressants. Does not potentiate ethanol but use is not advised. The degree of sedation is low relative to other antidepressants. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Therapy should not be abruptly discontinued in patients receiving high doses for prolonged periods. Rare reports of priapism have occurred. The incidence of sexual dysfunction with nefazodone is generally lower than with SSRIs.

Use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). The risk of postural

hypotension is low relative to other antidepressants. Use with caution in patients with urinary retention, benign prostatic hyperplasia, narrow-angle glaucoma, xerostomia, visual problems, constipation, or history of bowel obstruction (due to anticholinergic effects). The degree of anticholinergic blockade produced by this agent is very low relative to other cyclic antidepressants.

Use caution in patients with a previous seizure disorder or condition predisposing to seizures such as brain damage, alcoholism, or concurrent therapy with other drugs which lower the seizure threshold. Use with caution in patients with renal dysfunction and in elderly patients. Use with caution in patients with a history of cardiovascular disease (including previous MI, stroke, tachycardia, or conduction abnormalities). However, the risk of conduction abnormalities with this agent is very low relative to other antidepressants.

Dosage Forms Tablet, as hydrochloride: 50 mg, 100 mg, 150 mg, 200 mg, 250 mg

Reference Range

After a 150 mg oral dose, peak plasma nefazodone, HO-NEF, and meta-chlorophenylpiperazine levels were 1200 ng/mL, 400 ng/mL, and 25 ng/mL, respectively; serum level of 5.5 mcg/mL associated with drowsiness after a 3 g ingestion

TLC detection limit: 1 mcg/mL

HPLC detection limit: 1-10 ng/mL

Overdosage/Treatment

Decontamination: Oral: Adults with ingestions <3 g: Activated charcoal
Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated. Ventricular arrhythmias often respond to phenytoin 15-20 mg/kg (adults) with concurrent systemic alkalization (sodium bicarbonate 0.5-2 mEq/kg I.V.). Arrhythmias unresponsive to this therapy may respond to lidocaine 1 mg/kg I.V. followed by a titrated infusion. Treat bradycardia with atropine; benzotropine may be useful to treat priapism. Seizures usually respond to lorazepam or diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required. Priapism can be treated with alpha-adrenergic agonists.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; forced diuresis to remove active metabolite may not be beneficial

Drug Interactions

Substrate (major) of CYP2D6, 3A4; **Inhibits** CYP1A2 (weak), 2B6 (weak), 2C8 (weak), 2D6 (weak), 3A4 (strong)

Antiarrhythmics: Serum concentrations may be increased due to enzyme inhibition; monitor; includes amiodarone, lidocaine, propafenone, quinidine

Antipsychotics: Serum concentrations of some antipsychotics may be increased by nefazodone due to enzyme inhibition; includes clozapine, haloperidol, mesoridazine, pimozide, quetiapine, and risperidone

Benzodiazepines: Nefazodone inhibits the metabolism of triazolam (decrease dose by 75%) and alprazolam (decrease dose by 50%); triazolam is contraindicated per manufacturer

Buspiron: Concurrent use may result in serotonin syndrome; serum concentrations may be increased due to enzyme inhibition; these combinations are best avoided or limit buspiron to 2.5 mg/day

Calcium channel blockers: Serum concentrations may be increased due to enzyme inhibition; monitor for increased effect (hypotension)

Carbamazepine: Significantly reduces serum concentrations of nefazodone; coadministration is contraindicated

Cisapride: Nefazodone likely increases cisapride serum concentrations via CYP3A4 inhibition; this combination may lead to cardiac arrhythmias; concurrent use is contraindicated

Cyclosporine and tacrolimus: Serum levels and toxicity may be increased by nefazodone; monitor

CYP2D6 inhibitors: May increase the levels/effects of nefazodone. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of nefazodone. Example inducers include aminoglutethimide, carbamazepine (contraindicated), nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of nefazodone. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nateglinide, nefazodone, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

CYP3A4 substrates: Nefazodone may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Digoxin: Serum levels may be increased by nefazodone (modest increases); monitor for digoxin toxicity or increased serum levels

Donepezil: Serum concentrations may be increased due to enzyme inhibition; monitor

HMG-CoA reductase inhibitors (statins) have been associated with myositis and rhabdomyolysis when used in combination with nefazodone; this has been associated most strongly with lovastatin and simvastatin. Concomitant use of lovastatin with nefazodone should be avoided.

Linezolid: Due to MAO inhibition (see note on MAO inhibitors), this combination should be avoided

MAO inhibitors: Concurrent use may lead to serotonin syndrome; avoid concurrent use or use within 14 days

Meperidine: Combined use theoretically may increase the risk of serotonin syndrome

Methadone: Serum concentrations may be increased due to enzyme inhibition; monitor

Oral contraceptives: Serum concentrations may be increased due to enzyme inhibition; monitor

Pimozide: Serum concentrations may be increased due to enzyme inhibition; may result in life-threatening arrhythmias (also see note on antipsychotics); avoid use

Protease inhibitors: Indinavir, ritonavir, saquinavir; serum concentrations may be increased due to enzyme inhibition; monitor

Quinidine: Metabolism is likely to be inhibited by nefazodone; avoid concurrent use

Selegiline: Concurrent use with nefazodone may be associated with a risk of serotonin syndrome, particularly at higher dosages (> 10 mg/day)

Serotonin agonists: Theoretically may increase the risk of serotonin syndrome; includes sumatriptan, naratriptan, rizatriptan, and zolmitriptan

Sibutramine: Serum concentrations may be increased by nefazodone; monitor

Sildenafil, vardenafil: Serum concentrations may be increased by nefazodone via inhibition of CYP3A4; use caution. Specific dosage adjustment guidelines have not been established. Recommendations for other strong CYP3A4 inhibitors include single sildenafil dose not to exceed 25 mg in a 48-hour period, a single tadalafil dose not to exceed 10 mg in a 72-hour period, or a single vardenafil dose not to exceed 2.5 mg in a 24-hour period.

SSRIs: Combined use of nefazodone with an SSRI may produce serotonin syndrome; in addition, nefazodone may increase serum concentrations of some SSRIs due to enzyme inhibition (fluoxetine and citalopram)

Tricyclic antidepressants: Serum concentrations of some tricyclic antidepressants (amitriptyline, clomipramine) may be increased; monitor for increased effect or toxicity

Venlafaxine: Combined use with nefazodone may increase the risk of serotonin syndrome

Vinca alkaloids (vincristine and vinblastine): Serum concentrations may be increased due to enzyme inhibition; may result in increased toxicity

Zolpidem: Serum concentrations may be increased due to enzyme inhibition; monitor

Pregnancy Risk Factor C

Lactation Enters breast milk/not recommended

Additional Information May cause an increase in plasma prolactin levels; food delays absorption; inhibitor of cytochrome P450 IIIA and IID6; women and elderly receiving single doses attain significant higher peak concentrations than male volunteers

Nefopam Hydrochloride

CAS Number 13669-70-0; 23327-57-3

Use Moderate pain control - nonopiate analgesic

Mechanism of Action Nonopiate analgesic with anticholinergic effects; does not bind to opiate receptors, but appears to act at the spinal level

Adverse Reactions

Cardiovascular: Tachycardia

Central nervous system: Dizziness, drowsiness, euphoria, hallucinations, insomnia, seizures

Dermatologic: Diaphoresis, rash

Gastrointestinal: Dry mouth, nausea, vomiting

Genitourinary: Urinary retention

Respiratory: Respiratory depression

Signs and Symptoms of Overdose Deep coma with bundle branch block, fever, mydriasis, oliguria, renal failure, ventricular arrhythmia. Seizures can occur with ingestions > 1.8 g.

Admission Criteria/Prognosis Admit any symptomatic patient or adult ingestions > 300 mg.

Toxicodynamics/Kinetics

Absorption: Well absorbed

Distribution: V_d: 410-447 L

Protein binding: 71% to 76%

Metabolism: Hepatic to inactive metabolites

Half-life: 3-8 hours

Elimination: Renal: 92%; Fecal: 8%

Dosage Adults:

Oral: 30-60 mg three to four times/day; maximum daily dose: 300 mg I.V.; I.M.: 10-20 mg every 4-6 hours; slow I.V. With patient supine for at least 20 minutes following administration; maximum daily dose: 120 mg

Reference Range Oral 90 g doses result in plasma concentration range of 73-154 ng/mL. Postmortem blood level of 4380 ng/mL has been associated with self-injection of nefopam in a suicide attempt.

Overdosage/Treatment

Decontamination: Activated charcoal 50 g, can absorb up to 95% of a 10 g nefopam ingestion; lavage within 1 hour; avoid ipecac.

Supportive therapy: Naloxone is **not** expected to be useful. Seizures can be treated with benzodiazepines. Ventricular dysrhythmia can be treated with lidocaine or amiodarone. Sotalol can be used to treat monomorphic ventricular tachycardia. Atropine can be used to treat severe symptomatic bradycardia. Crystalloid fluids/vasopressors can be used to treat hypotension.

Pregnancy Risk Factor B; Animal studies have not demonstrated teratogenesis at doses up to 80 mg/kg/day

Pregnancy Implications Animal studies have not demonstrated teratogenesis at doses up to 80 mg/kg/day

Additional Information Brand names: Acupan[®]; AJAN; Nefadol; Nefam; Oxadol; Placadol; Silentan

Nesiritide

Pronunciation (ni SIR i tide)

Applies to Natrecor[®]

U.S. Brand Names Natrecor[®]

Synonyms B-type Natriuretic Peptide (Human); hBNP; Natriuretic Peptide

Use Treatment of acutely decompensated congestive heart failure (CHF) in patients with dyspnea at rest or with minimal activity

Mechanism of Action Binds to guanylate cyclase receptor on vascular smooth muscle and endothelial cells, increasing intracellular cyclic GMP, resulting in smooth muscle cell relaxation. Has been shown to produce dose-dependent reductions in pulmonary capillary wedge pressure (PCWP) and systemic arterial pressure.

Adverse Reactions

Note: Frequencies cited below were recorded in VMAC trial at dosages similar to approved labeling. Higher frequencies have been observed in trials using higher dosages of nesiritide.

> 10%:

Cardiovascular: Hypotension (total: 11%; symptomatic: 4% at recommended dose, up to 30% at higher doses)

Renal: Increased serum creatinine (28% with >0.5 mg/dL increase over baseline)

1% to 10%:

Cardiovascular: Ventricular tachycardia (3%)*, ventricular extrasystoles (3%)*, angina (2%)*, bradycardia (1%), tachycardia, atrial fibrillation, AV node conduction abnormalities

Central nervous system: Headache (8%)*, dizziness (3%)*, insomnia (2%), anxiety (3%), fever, confusion, paresthesia, somnolence, tremor

Dermatologic: Pruritus, rash

Gastrointestinal: Nausea (4%)*, abdominal pain (1%)*, vomiting (1%)*

Hematologic: Anemia

Local: Injection site reaction

Neuromuscular & skeletal: Back pain (4%), leg cramps

Ocular: Amblyopia

Respiratory: Cough (increased), hemoptysis, apnea

Miscellaneous: Increased diaphoresis

*Frequency less than or equal to placebo or other standard therapy

Signs and Symptoms of Overdose Symptoms of overdose would be expected to include excessive and/or prolonged hypotension.

Treatment is symptomatic and supportive; dopamine is the vasopressor of choice

Drug discontinuation and/or dosage reduction may be required

Pharmacodynamics/Kinetics

Onset of action: 15 minutes (60% of 3-hour effect achieved)

NEVIRAPINE

Duration: >60 minutes (up to several hours) for systolic blood pressure; hemodynamic effects persist longer than serum half-life would predict
Distribution: V_{ss} : 0.19 L/kg
Metabolism: Proteolytic cleavage by vascular endopeptidases and proteolysis following receptor binding and cellular internalization
Half-life elimination: Initial (distribution) 2 minutes; Terminal: 18 minutes
Time to peak: 1 hour
Excretion: Urine

Dosage

Adults: I.V.: Initial: 2 mcg/kg (bolus); followed by continuous infusion at 0.01 mcg/kg/minute; **Note:** Should not be initiated at a dosage higher than initial recommended dose. At intervals of ≥ 3 hours, the dosage may be increased by 0.005 mcg/kg/minute (preceded by a bolus of 1 mcg/kg), up to a maximum of 0.03 mcg/kg/minute. Increases beyond the initial infusion rate should be limited to selected patients and accompanied by hemodynamic monitoring.

Patients experiencing hypotension during the infusion: Infusion should be interrupted. May attempt to restart at a lower dose (reduce initial infusion dose by 30% and omit bolus).

Dosage adjustment in renal impairment: No adjustment required

Stability

Vials may be stored at controlled room temperature of 20°C to 25°C (68°F to 77°F) or under refrigeration at 2°C to 8°C (36°F to 46°F). Following reconstitution, vials are stable under these conditions for up to 24 hours.

Reconstitute 1.5 mg vial with 5 mL of diluent removed from a premixed plastic I.V. bag (compatible with 5% dextrose, 0.9% sodium chloride, 5% dextrose and 0.45% sodium chloride, or 5% dextrose and 0.2% sodium chloride). Do not shake vial to dissolve (roll gently). Withdraw entire contents of vial and add to 250 mL I.V. bag. Resultant concentration of solution approximately 6 mcg/mL.

Monitoring Parameters Blood pressure, hemodynamic responses (PCWP, RAP, CI)

Administration Do not administer through a heparin-coated catheter (concurrent administration of heparin via a separate catheter is acceptable, per manufacturer).

Prime I.V. tubing with 25 mL of infusion prior to connection with vascular access port and prior to administering bolus or starting the infusion. Withdraw bolus from the prepared infusion bag and administer over 60 seconds. Begin infusion immediately following administration of the bolus. Using a standard 6 mcg/mL concentration, bolus volume in mL = patient weight in kg \times 0.33.

Physically incompatible with heparin, insulin, ethacrynate sodium, bumetanide, enalaprilat, hydralazine, and furosemide. Do not administer through the same catheter. Do not administer with any solution containing sodium metabisulfite. Catheter must be flushed between administration of nesiritide and physically incompatible drugs.

Contraindications Hypersensitivity to natriuretic peptide or any component of the formulation; cardiogenic shock (when used as primary therapy); hypotension (systolic blood pressure <90 mm Hg)

Warnings

May cause hypotension; administer in clinical situations when blood pressure may be closely monitored. Use caution in patients with systolic blood pressure <100 mm Hg (contraindicated if <90 mm Hg); more likely to experience hypotension. Effects may be additive with other agents capable of causing hypotension. Hypotensive effects may last for several hours.

Should not be used in patients with low filling pressures, or in patients with conditions which depend on venous return including significant valvular stenosis, restrictive or obstructive cardiomyopathy, constrictive pericarditis, and pericardial tamponade. May be associated with development of azotemia; use caution in patients with renal impairment or in patients where renal perfusion is dependent on renin-angiotensin-aldosterone system.

Atrial natriuretic peptide (ANP), a related peptide, has been associated with increased vascular permeability and decreased intravascular volume. This has not been observed in clinical trials with nesiritide, however, patients should be monitored for this effect.

Prepared through recombinant technology using *E. coli*; monitor for allergic or anaphylactic reactions. Use caution with prolonged infusions; limited experience for infusions >48 hours. Safety and efficacy in pediatric patients have not been established.

Dosage Forms Injection, powder for reconstitution: 1.5 mg

Reference Range Therapeutic drug concentration in heart failure patients is about 8-40 pmol/L

Drug Interactions

ACE inhibitors: An increased frequency of symptomatic hypotension was observed with concurrent administration.

Diuretics: Use caution in patients who may have decreased intravascular volume due to diuretic therapy (risk of hypotension and/or renal impairment may be increased). Nesiritide should be avoided in patients with low filling pressures.

Hypotensive agents: Effects on blood pressure are likely to be additive with nesiritide.

Pregnancy Risk Factor C

Pregnancy Implications Excretion in breast milk is unknown; use caution in breast-feeding women.

Lactation Excretion in breast milk unknown/use caution

Additional Information The duration of symptomatic improvement with nesiritide following discontinuation of the infusion has been limited (generally lasting several days). Atrial natriuretic peptide, which is related to nesiritide, has been associated with increased vascular permeability. This has not been observed in clinical trials with nesiritide, but patients should be monitored for this effect.

Nevirapine

CAS Number 129618-40-2

U.S. Brand Names Viramune®

Synonyms NVP

Use In combination therapy with other antiretroviral agents for the treatment of HIV-1

Mechanism of Action As a non-nucleoside reverse transcriptase inhibitor, nevirapine has activity against HIV-1 by binding to reverse transcriptase. It consequently blocks the RNA-dependent and DNA-dependent DNA polymerase activities including HIV-1 replication. It does not require intracellular phosphorylation for antiviral activity. Cross-resistance between nevirapine and HIV protease inhibitors is unlikely although emergence of HIV strains which are cross-resistant between non-nucleoside reverse transcriptase inhibitors have been observed *in vitro*. It is not immunosuppressive.

Adverse Reactions

Central nervous system: **Headache, fever**

Dermatologic: **Rash**, Stevens-Johnson syndrome, angioedema

Gastrointestinal: **Diarrhea**, ulcerative stomatitis, nausea, abdominal pain

Hematologic: **Neutropenia**, anemia, thrombocytopenia

Hepatic: Hepatitis, increased LFTs, hepatotoxicity, hepatic necrosis, cholestatic hepatitis

Neuromuscular & skeletal: Peripheral neuropathy, paresthesia, myalgia

Miscellaneous: Anaphylaxis

Hypersensitivity (frequency not defined): Symptoms of severe hypersensitivity/dermatologic reactions may include: Severe rash (or rash with fever), blisters, oral lesions, conjunctivitis, facial edema, muscle or joint aches, general malaise, hepatitis, eosinophilia, granulocytopenia, lymphadenopathy, or renal dysfunction. Nevirapine should be permanently discontinued.

Admission Criteria/Prognosis Admit any patient with liver function abnormalities following ingestion or an acute ingestion >1 g

Pharmacodynamics/Kinetics

Absorption: >90%

Distribution: Widely; V_d : 1.2-1.4 L/kg; CSF penetration approximates 40% to 50% of plasma

Protein binding, plasma: 60%

Metabolism: Extensively hepatic via CYP3A4 (hydroxylation to inactive compounds); may undergo enterohepatic recycling

Half-life elimination: Decreases over 2- to 4-week time with chronic dosing due to autoinduction (ie, half-life = 45 hours initially and decreases to 25-30 hours)

Time to peak, serum: 2-4 hours

Excretion: Urine (~81%, primarily as metabolites, <3% as unchanged drug); feces (~10%)

Dosage

Oral:

Children 2 months to <8 years: Initial: 4 mg/kg/dose once daily for 14 days; increase dose to 7 mg/kg/dose every 12 hours if no rash or other adverse effects occur; maximum dose: 200 mg/dose every 12 hours

Children ≥ 8 years: Initial: 4 mg/kg/dose once daily for 14 days; increase dose to 4 mg/kg/dose every 12 hours if no rash or other adverse effects occur; maximum dose: 200 mg/dose every 12 hours

Note: Alternative pediatric dosing (AIDSinfo guidelines): 120-200 mg/m² every 12 hours; this dosing has been proposed due to the fact that dosing based on mg/kg may result in an abrupt decrease in dose at the 8th birthday, which may be inappropriate.

Adults: Initial: 200 mg once daily for 14 days; maintenance: 200 mg twice daily (in combination with an additional antiretroviral agent)

Note: If patient experiences a rash during the 14-day lead-in period, dose should not be increased until the rash has resolved. Discontinue if severe rash, or rash with constitutional symptoms, is noted. If therapy is interrupted for >7 days, restart with initial dose for 14 days. Use of prednisone to prevent nevirapine-associated rash is not recommended. Permanently discontinue if symptomatic hepatic events occur.

Prevention of maternal-fetal HIV transmission in women with no prior antiretroviral therapy (AIDS information guidelines):

Mother: 200 mg as a single dose at onset of labor. May be used in combination with zidovudine.

Infant: 2 mg/kg as a single dose at age 48-72 hours. If a maternal dose was given <1 hour prior to delivery, administer a 2 mg/kg dose as soon as possible after birth and repeat at 48-72 hours. May be used in combination with zidovudine.

Dosage adjustment in renal impairment:

Cl_{cr} ≥ 20 mL/minute: No adjustment required

Hemodialysis: An additional 200 mg dose is recommended following dialysis.

Dosage adjustment in hepatic impairment: Use not recommended with moderate-to-severe hepatic impairment. Permanently discontinue if symptomatic hepatic events occur.

Monitoring Parameters Liver function tests should be monitored at baseline, and intensively during the first 18 weeks of therapy (optimal frequency not established, some practitioners recommend more often than once a month, including prior to dose escalation, and at 2 weeks following dose escalation), then periodically throughout therapy; observe for CNS side effects. Assess/evaluate AST/ALT in any patients with a rash. Permanently discontinue if patient experiences severe rash, constitutional symptoms associated with rash, rash with elevated AST/ALT, or clinical hepatitis. Mild-to-moderate rash without AST/ALT elevation may continue treatment per discretion of prescriber. If mild-to-moderate urticarial rash, do not restart if treatment is interrupted.

Administration Oral: May be administered with or without food; may be administered with an antacid or didanosine; shake suspension gently prior to administration

Contraindications Hypersensitivity to nevirapine or any component of the formulation

Warnings

[U.S. Boxed Warning]: Severe hepatotoxic reactions may occur (fulminant and cholestatic hepatitis, hepatic necrosis) and, in some cases, have resulted in hepatic failure and death. The greatest risk of these reactions is within the initial 6 weeks of treatment. Patients with a history of chronic hepatitis (B or C) or increased baseline transaminase levels may be at increased risk of hepatotoxic reactions. Female gender and patients with increased CD4⁺-cell counts may be at substantially greater risk of hepatic events (often associated with rash). Therapy should not be started with elevated CD4⁺-cell counts unless the benefit of therapy outweighs the risk of serious hepatotoxicity (adult females: CD4⁺-cell counts >250 cells/mm³; adult males: CD4⁺-cell counts >400 cells/mm³).

[U.S. Boxed Warning]: Severe life-threatening skin reactions (eg, Stevens-Johnson syndrome, toxic epidermal necrolysis, hypersensitivity reactions with rash and organ dysfunction) have occurred; intensive monitoring is required during the initial 18 weeks of therapy to detect potentially life-threatening dermatologic, hypersensitivity, and hepatic reactions. Nevirapine must be initiated with a 14-day lead-in dosing period to decrease the incidence of adverse effects.

If a severe dermatologic or hypersensitivity reaction occurs, or if signs and symptoms of hepatitis occur, nevirapine should be permanently discontinued. These may include a severe rash, or a rash associated with fever, blisters, oral lesions, conjunctivitis, facial edema, muscle or joint aches, general malaise, hepatitis, eosinophilia, granulocytopenia, lymphadenopathy, or renal dysfunction.

Consider alteration of antiretroviral therapies if disease progression occurs while patients are receiving nevirapine. Safety and efficacy have not been established in neonates.

Dosage Forms Suspension, oral: 50 mg/5 mL (240 mL)

Tablet: 200 mg

Reference Range Peak serum nevirapine level after a 400 mg dose ranges from 2.9-3.4 mcg/mL

Overdosage/Treatment

Decontamination: Oral: Ipecac within 30 minutes or lavage within 1 hour/activated charcoal

Enhanced elimination: Due to enterohepatic circulation, multiple dosing of activated charcoal may be effective

Drug Interactions **Substrate** of CYP2B6 (minor), 2D6 (minor), 3A4 (major); **Inhibits** CYP1A2 (weak), 2D6 (weak), 3A4 (weak); **Induces** CYP2B6 (strong), 3A4 (strong)

Antiarrhythmics (includes amiodarone, disopyramide, lidocaine): Serum concentration/effects may be decreased by nevirapine.

Anticonvulsants (includes carbamazepine, clonazepam, ethosuximide): Serum concentration/effects may be decreased by nevirapine.

Calcium channel blockers: Serum concentration may be decreased by nevirapine.

Cimetidine may decrease the metabolism of nevirapine, potentially increasing levels/toxicity.

Clarithromycin: Serum concentration may be decreased by nevirapine; an alternative antimicrobial agent should be considered.

Cyclophosphamide: Serum concentration may be decreased by nevirapine.

CYP2B6 substrates: Nevirapine may decrease the levels/effects of CYP2B6 substrates. Example substrates include bupropion, efavirenz, promethazine, selegiline, and sertraline

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of nevirapine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 substrates: Nevirapine may decrease the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, clarithromycin, cyclosporine, erythromycin, estrogens, mirtazapine, nateglinide, nefazodone, protease inhibitors, tacrolimus, and venlafaxine

Efavirenz: Serum concentration may be decreased by nevirapine; specific adjustments not established

Immunosuppressants: Serum concentration may be decreased by nevirapine.

Ketoconazole: Nevirapine may inhibit ketoconazole absorption. Ketoconazole may inhibit metabolism of nevirapine. Avoid concurrent use.

Methadone: Plasma concentrations may be reduced by nevirapine. Acute withdrawal symptoms have been reported; monitor

Oral contraceptives: Nevirapine may decrease the clinical effect of oral contraceptives; recommend alternative form or additional method of contraception

Prednisone: Concurrent administration of prednisone for the initial 14 days of nevirapine therapy was associated with an increased incidence and severity of rash.

Protease inhibitors: Nevirapine may decrease serum concentrations of some protease inhibitors (AUC of indinavir, lopinavir, nelfinavir, and saquinavir may be decreased - no effect noted with ritonavir), specific dosage adjustments have not been recommended; no adjustment recommended for ritonavir, unless in combination with lopinavir (Kaletra™).

Rifampin, rifabutin: May decrease nevirapine concentrations; rifabutin concentrations may be increased by nevirapine; avoid concurrent use.

St John's wort: Concurrent use may reduce serum concentrations/efficacy of nevirapine. May lead to treatment failure and/or drug resistance. Avoid concurrent use.

Warfarin: Therapeutic effects may be increased; monitor.

Pregnancy Risk Factor C

Pregnancy Implications Nevirapine crosses the placenta. It may be used in combination with zidovudine in HIV-infected women who are in labor, but have had no prior antiretroviral therapy, in order to reduce the maternal-fetal transmission of HIV. Health professionals are encouraged to contact the antiretroviral pregnancy registry to monitor outcomes of pregnant women exposed to antiretroviral medications (1-800-258-4263).

Lactation Enters breast milk/contraindicated

Additional Information Potential compliance problems, frequency of administration, and adverse effects should be discussed with patients before initiating therapy to help prevent the emergence of resistance.

Niacin

CAS Number 59-67-6

U.S. Brand Names Niacor®; Niaspan®; Slo-Niacin® [OTC]

Synonyms Nicotinic Acid; Vitamin B₃

Use Adjunctive treatment of dyslipidemias (types IIa and IIb or primary hypercholesterolemia) to lower the risk of recurrent MI and/or slow progression of coronary artery disease, including combination therapy with other antidyplipidemic agents when additional triglyceride-lowering or HDL-increasing effects are desired; treatment of hypertriglyceridemia in patients at risk of pancreatitis; treatment of peripheral vascular disease and circulatory disorders; treatment of pellagra; dietary supplement

Mechanism of Action Component of two coenzymes which is necessary for tissue respiration, lipid metabolism, and glycogenolysis; inhibits the synthesis of very low density lipoproteins while increasing high density cholesterol; water soluble vitamin B complex

Adverse Reactions

Cardiovascular: Arrhythmias, atrial fibrillation, edema, flushing, hypotension, orthostasis, palpitations, syncope (rare), tachycardia

Central nervous system: Chills, dizziness, insomnia, migraine

Dermatologic: Acanthosis nigricans, dry skin, hyperpigmentation, maculopapular rash, pruritus, rash, urticaria

Endocrine & metabolic: Glucose tolerance decreased, gout, phosphorus levels decreased, uric acid level increased

Gastrointestinal: Abdominal pain, nausea, peptic ulcers, vomiting

Hepatic: Hepatic necrosis (rare), jaundice, liver enzymes elevated

Neuromuscular & skeletal: Myalgia, myopathy (with concurrent HMG-CoA reductase inhibitor), rhabdomyolysis (with concurrent HMG-CoA reductase inhibitor; rare), weakness

Ocular: Cystoid macular edema, toxic amblyopia

Respiratory: Dyspnea

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Anorexia, arrhythmias, cholelithiasis, coagulopathy, delirium, diarrhea, hepatitis, nausea, hyperglycemia, hyperuricemia, thrombocytopenia

Pharmacodynamics/Kinetics

Absorption: Rapid and extensive (60% to 76%)

Distribution: Mainly to hepatic, renal, and adipose tissue

Metabolism: Extensive first-pass effects; converted to nicotinamide adenine dinucleotide, nicotinic acid, and other metabolites

Half-life elimination: 45 minutes

NIACINAMIDE

Time to peak, serum: Immediate release formulation: ~45 minutes; extended release formulation: 4-5 hours

Excretion: Urine 60% to 88% (unchanged drug and metabolites)

Dosage Children: Oral:

Pellagra: 50-100 mg/dose 3 times/day

Recommended daily allowances:

0-0.5 years: 5 mg/day

0.5-1 year: 6 mg/day

1-3 years: 9 mg/day

4-6 years: 12 mg/day

7-10 years: 13 mg/day

Children and Adolescents: Recommended daily allowances:

Male:

11-14 years: 17 mg/day

15-18 years: 20 mg/day

19-24 years: 19 mg/day

Female: 11-24 years: 15 mg/day

Adults: Oral:

Recommended daily allowances:

Male: 25-50 years: 19 mg/day; >51 years: 15 mg/day

Female: 25-50 years: 15 mg/day; >51 years: 13 mg/day

Hyperlipidemia: Usual target dose: 1.5-6 g/day in 3 divided doses with or after meals using a dosage titration schedule; extended release: 375 mg to 2 g once daily at bedtime

Regular release formulation (Niacor®): Initial: 250 mg once daily (with evening meal); increase frequency and/or dose every 4-7 days to desired response or first-level therapeutic dose (1.5-2 g/day in 2-3 divided doses); after 2 months, may increase at 2- to 4-week intervals to 3 g/day in 3 divided doses

Extended release formulation (Niaspan®): 500 mg at bedtime for 4 weeks, then 1 g at bedtime for 4 weeks; adjust dose to response and tolerance; can increase to a maximum of 2 g/day, but only at 500 mg/day at 4-week intervals

With lovastatin: Maximum lovastatin dose: 40 mg/day

Pellagra: 50-100 mg 3-4 times/day, maximum: 500 mg/day

Niacin deficiency: 10-20 mg/day, maximum: 100 mg/day

Dosage adjustment in renal impairment: Use with caution

Dosage adjustment in hepatic impairment: Not recommended for use in patients with significant or unexplained hepatic dysfunction

Dosage adjustment for toxicity: Transaminases rise to 3 times ULN: Discontinue therapy.

Stability Injection has a pH 4-6

Monitoring Parameters Blood glucose; liver function tests (dyslipidemia, high dose, prolonged therapy) pretreatment and every 6-12 weeks for first year then periodically; lipid profile; elevated uric acid levels have been reported

Administration Administer with food. Niaspan® tablet strengths are not interchangeable. When switching from immediate release tablet, initiate Niaspan® at lower dose and titrate. Long-acting forms should not be crushed, broken, or chewed. Do not substitute long-acting forms for immediate release ones.

Contraindications Hypersensitivity to niacin, niacinamide, or any component of the formulation; active hepatic disease; active peptic ulcer; arterial hemorrhage

Warnings

Use caution in heavy ethanol users, unstable angina or MI, diabetes (interferes with glucose control), renal disease, active gallbladder disease (can exacerbate), gout, past history of hepatic disease, or with anticoagulants. Monitor glucose and liver function tests. Rare cases of rhabdomyolysis have occurred during concomitant use with HMG-CoA reductase inhibitors. With concurrent use or if symptoms suggestive of myopathy occur, monitor creatinine phosphokinase (CPK) and potassium. Immediate and extended or sustained release products should not be interchanged. Flushing is common and can be attenuated with a gradual increase in dose, and/or by taking aspirin 30-60 minutes before dosing. Compliance is enhanced with twice-daily dosing.

Note: Formulations of niacin (regular release versus extended release) are not interchangeable.

Niaspan®: 500 mg and 750 mg tablets are not interchangeable (eg, three 500 mg tablets are not equivalent to two 750 mg tablets).

Dosage Forms Capsule, extended release: 125 mg, 250 mg, 400 mg, 500 mg

Capsule, timed release: 250 mg

Tablet: 50 mg, 100 mg, 250 mg, 500 mg

Niacor®: 500 mg

Tablet, controlled release (Slo-Niacin®): 250 mg, 500 mg, 750 mg

Tablet, extended release (Niaspan®): 500 mg, 750 mg, 1000 mg

Note: 500 mg and 750 mg tablets are not interchangeable (eg, three 500 mg tablets are not equivalent to two 750 mg tablets)

Tablet, timed release: 250 mg, 500 mg, 750 mg, 1000 mg

Reference Range Serum niacin level after 11 g ingestion at 48 hours was 8.2 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Aspirin (160 mg or 325 mg) can reduce flushing due to niacin when given in a prophylactic manner; ibuprofen (200 mg) is also effective

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Diagnostic Procedures

- Glucose, Random

Test Interactions False elevations in some fluorometric determinations of urinary catecholamines; false-positive urine glucose (Benedict's reagent); ↑ LFTs, glucose, and uric acid

Drug Interactions Bile acid sequestrants: May decrease the absorption of niacin; separate administration by 4-6 hours.

Pregnancy Risk Factor A/C (dose exceeding RDA recommendation)

Lactation Enters breast milk/consult prescriber

Nursing Implications Monitor closely for signs of hepatitis and myositis

Additional Information Pretreatment with 325 mg of aspirin prevents niacin-induced flushing; >61 mg/day may result in slower progression of HIV illness (RR=0.52)

Niacinamide

CAS Number 98-92-0

U.S. Brand Names Nicomide-T™

Synonyms Nicotinamide; Nicotinic Acid Amide; Vitamin B₃

Use Prophylaxis and treatment of pellagra; treatment of N-d-pyridimethyl-N-P-nitrophenyl urea (PNU/Vacor®) toxicity

Mechanism of Action Used by the body as a source of niacin; water soluble vitamin B complex; less vasodilatory action than niacin

Adverse Reactions

Cardiovascular: Flushing, hypotension, vasodilation

Central nervous system: Headache

Dermatologic: Pruritus, acanthosis nigricans

Gastrointestinal: Vomiting

Ocular: Blurred vision

Pharmacodynamics/Kinetics

Absorption: Oral: Rapid; Topical: Absorbed systemically

Metabolism: Hepatic

Half-life elimination: 45 minutes

Time to peak, serum: 20-70 minutes

Excretion: Urine (as metabolites)

Dosage

Oral:

Children: Pellagra: 100-300 mg/day in divided doses

Adults: 50 mg 3-10 times/day

Pellagra: 300-500 mg/day

Recommended daily allowance: 13-19 mg/day

Vacor® (PNU) toxicity: 500 mg I.M. or I.V. followed by 100-200 mg I.M. or I.V. every 4 hours up to 48 hours, then 100 mg orally 3-5 times/day for 2 weeks

Administration Topical: Prior to using cream or gel, wash face with mild cleanser. Apply thin layer to affected area. May apply under make-up or other acne medications. Re-evaluate after 8-12 weeks.

Contraindications Hypersensitivity to niacin, niacinamide, or any component of the formulation; liver disease; active peptic ulcer

Warnings Use caution in heavy ethanol users, unstable angina or CAD (risk of arrhythmias at high doses), diabetes (interfere with glucose control), renal disease, active gallbladder disease (can exacerbate), gout, or allergies. Avoid large pharmacological amounts in patients with a history of liver disease. Monitor liver function tests with high doses.

Dosage Forms Cream (Nicomide-T™): 4% (30 g) [contains benzyl alcohol]

Gel (Nicomide-T™): 4% (30 g) [contains alcohol]

Tablet: 100 mg, 250 mg, 500 mg

Overdosage/Treatment

Decontamination: Ipecac (within 30 minutes)/lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Diagnostic Procedures

- Glucose, Random

Test Interactions False elevations of urinary catecholamines in some fluorometric determinations

Pregnancy Risk Factor A/C (dose exceeding RDA recommendation)

NiCARdipine

Related Information

- Calcium Channel Blockers

CAS Number 54527-84-3; 55985-32-5

U.S. Brand Names Cardene® I.V.; Cardene® SR; Cardene®

Synonyms Nicardipine Hydrochloride

Use Chronic stable angina (immediate-release product only); management of essential hypertension (immediate and sustained release; parenteral only for short time that oral treatment is not feasible)

Unlabeled/Investigational Use Congestive heart failure

Mechanism of Action Inhibits calcium ion from entering the "slow channels" or select voltage-sensitive areas of vascular smooth muscle and myocardium during depolarization, producing a relaxation of coronary vascular smooth muscle and coronary vasodilation; increases myocardial oxygen delivery in patients with vasospastic angina

Adverse Reactions

Cardiovascular: Flushing, palpitations, tachycardia, edema, syncope, abnormal ECG, chest pain, angina

Central nervous system: Headache, dizziness, somnolence, insomnia, malaise, abnormal dreams, CNS depression, depression

Dermatologic: Rash, urticaria, exanthem

Endocrine & metabolic: Parotitis

Gastrointestinal: Vomiting, constipation, dyspepsia, xerostomia, nausea

Genitourinary: Nocturia

Neuromuscular & skeletal: Tremor, erythromelalgia, weakness, paresthesia

Respiratory: Rhinitis

Miscellaneous: Pedal edema

Signs and Symptoms of Overdose Bradycardia, hypotension

Admission Criteria/Prognosis Admit any patient with cardiovascular symptoms; admit any ingestion in a child or ingestions > 100 mg in an adult; asymptomatic patients (with normal ECG and blood pressure) can be discharged after 8 hours observation for nonsustained released preparation ingestions

Pharmacodynamics/Kinetics

Onset of action: Oral: 0.5-2 hours; I.V.: 10 minutes; Hypotension: ~20 minutes

Duration: ≤ 8 hours

Absorption: Oral: ~100%

Protein binding: > 95%

Metabolism: Hepatic; CYP3A4 substrate (major); extensive first-pass effect (saturable)

Bioavailability: 35%

Half-life elimination: 2-4 hours

Time to peak, serum: 30-120 minutes

Excretion: Urine (60% as metabolites); feces (35%)

Dosage Adults:

Oral:

Immediate release: Initial: 20 mg 3 times/day; usual: 20-40 mg 3 times/day (allow 3 days between dose increases)

Sustained release: Initial: 30 mg twice daily, titrate up to 60 mg twice daily

Note: The total daily dose of immediate-release product may not automatically be equivalent to the daily sustained-release dose; use caution in converting.

I.V. (dilute to 0.1 mg/mL):

Acute hypertension: Initial: 5 mg/hour increased by 2.5 mg/hour every 15 minutes to a maximum of 15 mg/hour; consider reduction to 3 mg/hour after response is achieved. Monitor and titrate to lowest dose necessary to maintain stable blood pressure.

Substitution for oral therapy (approximate equivalents):

20 mg every 8 hours oral, equivalent to 0.5 mg/hour I.V. infusion

30 mg every 8 hours oral, equivalent to 1.2 mg/hour I.V. infusion

40 mg every 8 hours oral, equivalent to 2.2 mg/hour I.V. infusion

Dosing adjustment in renal impairment: Titrate dose beginning with 20 mg 3 times/day (immediate release) or 30 mg twice daily (sustained release). Specific guidelines for adjustment of I.V. nicardipine are not available, but careful monitoring/adjustment is warranted.

Dosing adjustment in hepatic impairment: Starting dose: 20 mg twice daily (immediate release) with titration. Specific guidelines for adjustment of I.V. nicardipine are not available, but careful monitoring/adjustment is warranted.

Stability Compatible with D₅W, D₅¹/₂NS, D₅NS, and D₅W with 40 mEq potassium chloride; 0.45% and 0.9% NS; **do not** mix with 5% sodium bicarbonate and lactated Ringer's solution; store at room temperature; protect from light; stable for 24 hours at room temperature

Monitoring Parameters ECG, blood pressure, electrolytes

Administration Oral: The total daily dose of immediate-release product may not automatically be equivalent to the daily sustained-release dose; use caution in converting. Do not chew or crush the sustained release formulation, swallow whole. Do not open or cut capsules.

I.V.: Ampuls must be diluted before use. Administer as a slow continuous infusion.

Contraindications Hypersensitivity to nicardipine or any component of the formulation; advanced aortic stenosis

Warnings

Blood pressure lowering should be done at a rate appropriate for the patient's condition. Rapid drops in blood pressure can lead to arterial insufficiency. Use with caution in CAD (can cause increase in angina), CHF (can worsen heart failure symptoms), and pheochromocytoma (limited clinical experience). Peripheral infusion sites (for I.V. therapy) should be changed ever 12 hours. Titrate I.V. dose cautiously in patients with CHF, renal, or hepatic dysfunction. Use the I.V. form cautiously in patients with portal hypertension (can cause increase in hepatic pressure gradient). Safety and efficacy have not been demonstrated in pediatric patients. Abrupt withdrawal may cause rebound angina in patients with CAD.

Dosage Forms Capsule (Cardene®): 20 mg, 30 mg

Capsule, sustained release (Cardene® SR): 30 mg, 45 mg, 60 mg

Injection, solution (Cardene® IV): 2.5 mg/mL (10 mL)

Reference Range Therapeutic blood nicardipine levels: 24-50 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: The primary cardiac symptoms of calcium blocker overdose include hypotension and bradycardia. Hypotension is caused by peripheral vasodilation, myocardial depression, and bradycardia. Bradycardia results from sinus bradycardia, second- or third-degree atrioventricular block, or sinus arrest with junctional rhythm. Intraventricular conduction is usually not affected, so QRS duration is normal (verapamil does prolong the P-R interval and bepridil prolongs the QT interval and may cause ventricular arrhythmias, including torsade de pointes).

Noncardiac symptoms include confusion, stupor, nausea, vomiting, metabolic acidosis and hyperglycemia. Following initial gastric decontamination, if possible, repeated calcium administration may promptly reverse depressed cardiac contractility (but not sinus node depression or peripheral vasodilation); glucagon, epinephrine, and inamrinone may treat refractory hypotension; calcium chloride (1-3 g slow I.V. push) is considered a second-line agent for treatment of shock; glucagon and epinephrine also increase the heart rate (outside the U.S., 4-aminopyridine may be available as an antidote).

Enhanced elimination: Multiple dosing of activated charcoal may be useful for sustained release preparations; hemodialysis or hemoperfusion is not effective

Antidote(s)

- Glucagon [ANTIDOTE]

Drug Interactions

Substrate of CYP1A2 (minor), 2C9 (minor), 2D6 (minor), 2E1 (minor), 3A4 (major); **Inhibits** CYP2C9 (strong), 2C19 (moderate), 2D6 (moderate), 3A4 (strong)

Azole antifungals may inhibit the calcium channel blocker's metabolism; avoid this combination. Try an antifungal like terbinafine (if appropriate) or monitor closely for altered effect of the calcium channel blocker.

Calcium may reduce the calcium channel blocker's effects, particularly hypotension.

Cyclosporine's serum concentrations are increased by nicardipine; avoid this combination. Use another calcium channel blocker or monitor cyclosporine trough levels and renal function closely. Tacrolimus may be affected similarly.

CYP2C9 Substrates: Nicardipine may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

CYP2C19 substrates: Nicardipine may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

CYP2D6 substrates: Nicardipine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Nicardipine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of nicardipine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of nicardipine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

CYP3A4 substrates: Nicardipine may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase

NICERGOLINE

inhibitors (lovastatin and simvastatin), and pimozone are generally contraindicated with strong CYP3A4 inhibitors.

Metoprolol: Concentration of metoprolol is increased by 25% with concurrent use.

Naficillin decreases plasma concentration of nicardipine; avoid this combination.

Propranolol: May decrease the metabolism of nicardipine.

Protease inhibitor like amprenavir and ritonavir may increase nicardipine's serum concentration.

Rifampin increases the metabolism of the calcium channel blocker; adjust the dose of the calcium channel blocker to maintain efficacy.

Sildenafil, tadalafil, vardenafil: Blood pressure-lowering effects may be additive; use caution.

Vecuronium: Clearance of vecuronium is decreased by 25% with use of I.V. nicardipine; reduce dose of muscle relaxant.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta; may exhibit tocolytic effect

Lactation Enters breast milk/not recommended

Nursing Implications Monitor closely for orthostasis; ampuls must be diluted before use; do not crush sustained release product

Nicergoline

CAS Number 27848-84-6

Use Transient ischemic attacks, cerebrovascular insufficiency, dementia

Mechanism of Action Ergot derivative with alpha-adrenergic blocking activity and vasodilatation

Adverse Reactions

Cardiovascular: Hypotension, syncope, bradycardia, flushing, sinus bradycardia

Central nervous system: Insomnia, agitation

Dermatologic: Urticaria

Gastrointestinal: Nausea, increased appetite, diarrhea

Hematologic: Inhibits platelet aggregation

Miscellaneous: Diaphoresis

Toxicodynamics/Kinetics

Onset of action: Oral: 1-1.5 hours

Protein binding: 82% to 87%

Half-life: Parent compound: 2.5 hours; MDL metabolite: 12-17 hours

Elimination: 80% renal, 20% fecal

Dosage

Oral: Initial: 10 mg 3 times/day; maintenance: 5-10 mg 3 times/day (before or during meals)

I.M.: 2-4 mg once or twice daily

I.V.: 4-8 mg diluted in 250 mL of normal saline and given over 30 minutes

Dosing adjustment in renal impairment: Reduce dose

Reference Range Oral dose of 70 mcg/kg results in plasma nicergoline level of 100-200 ng/mL

Overdosage/Treatment

Decontamination: Gastric lavage within 1 hour or induction of emesis within 30 minutes, activated charcoal; keep extremities warm

Supportive therapy: Treatment is symptomatic with captopril, nifedipine, prazosin, vasodilators (nitroprusside) or nitroglycerin for hypertension; phenolamine can also be used; diazepam can be utilized for seizures; heparin, dextran, or corticosteroids can be used for hypercoagulable state; hyperbaric oxygen can be used as an adjunct to treat localized tissue hypoxia

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Nicotine

Related Information

- Drugs Used in Addiction Treatment

- Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 54-11-5

UN Number 1654; 1655; 1656; 1657; 1658; 1659; 3144

U.S. Brand Names Commit™ [OTC]; NicoDerm® CQ® [OTC]; Nicorette® [OTC]; Nicotrol® Inhaler; Nicotrol® NS; Nicotrol® Patch [OTC]

Synonyms Habitrol

Commonly Includes Cigarettes (13-19 mg); nicotine gum (2-4 mg); cigars (15-40 mg); cigarette butt (5-7 mg); nicotine patch (8.3-114 mg); chewing tobacco (6-8 mg)

Use

Treatment to aid smoking cessation for the relief of nicotine withdrawal symptoms (including nicotine craving)

Insecticide (rarely), found in tobacco leaf (1% to 6% nicotine by weight) products.

Management of ulcerative colitis (transdermal)

Mechanism of Action Direct stimulant to nicotinic acetylcholine receptor causing either sympathetic or parasympathetic effects

Adverse Reactions

Chewing gum/lozenge:

Cardiovascular: Atrial fibrillation, **tachycardia**

Central nervous system: Dizziness, **headache (mild)**, insomnia, nervousness

Dermatologic: Erythema, itching

Endocrine & metabolic: Dysmenorrhea

Gastrointestinal: **Belching**, eructation, **excessive salivation**, GI distress, **increased appetite, indigestion, nausea, vomiting**

Neuromuscular & skeletal: Muscle pain

Respiratory: Hoarseness

Miscellaneous: Hiccups, hypersensitivity reactions, **jaw muscle ache, mouth or throat soreness**

Transdermal systems:

Cardiovascular: Atrial fibrillation, chest pain

Central nervous system: **Abnormal dreams**, anxiety, difficulty concentrating, dizziness, dysphoria, **insomnia**, nervousness, somnolence

Dermatologic: **Erythema**, itching, **pruritus**, rash

Gastrointestinal: Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, nausea, taste perversion, xerostomia

Local: **Application site reaction**

Neuromuscular & skeletal: Arthralgia, myalgia, tremor

Respiratory: **Cough, pharyngitis, rhinitis, sinusitis**

Miscellaneous: Hypersensitivity reactions, thirst

Signs and Symptoms of Overdose Abdominal pain, apnea, AV block, blurred vision, cyanosis, dementia, diarrhea (may be delayed up to 24 hours in pediatric ingestion), dry mouth, dysosmia, dyspepsia, headache (early sign), hiccups, hyperglycemia, hypertension then bradycardia, hyperreflexia, hyperthermia, hyperventilation, hyponatremia, hypotension, hypotonia, increased bronchial secretions, insomnia, lacrimation, lightheadedness, mental confusion, muscle fasciculations/paralysis, myalgia, myasthenia gravis (exacerbation or precipitation), mydriasis, myoclonus, nausea, nystagmus, ototoxicity, paresthesia, respiratory depression, salivation, seizures, tachycardia, tinnitus, vomiting

Admission Criteria/Prognosis Admit pediatric ingestions >2 whole cigarettes, 6 cigarette butts or a total of >0.5 mg/kg of nicotine; symptomatic patients or patients with tachycardia or hypertension 4 hours postexposure should be admitted; survival after 4 hours is usually associated with complete recovery; any patient with change in mental status or cardiopulmonary complaints should be admitted

Pharmacodynamics/Kinetics

Onset of action: Intranasal: More closely approximate the time course of plasma nicotine levels observed after cigarette smoking than other dosage forms

Duration: Transdermal: 24 hours

Absorption: Transdermal: Slow

Metabolism: Hepatic, primarily to cotinine (1/5 as active)

Half-life elimination: 4 hours

Time to peak, serum: Transdermal: 8-9 hours

Excretion: Urine

Clearance: Renal: pH dependent

Dosage

Smoking deterrent: Patients should be advised to completely stop smoking upon initiation of therapy.

Oral:

Gum: Chew 1 piece of gum when urge to smoke, up to 2 pieces/day. Patients who smoke <25 cigarettes/day should start with 2-mg strength; patients smoking ≥25 cigarettes/day should start with the 4-mg strength. Use according to the following 12-week dosing schedule:

Weeks 1-6: Chew 1 piece of gum every 1-2 hours; to increase chances of quitting, chew at least 9 pieces/day during the first 6 weeks

Weeks 7-9: Chew 1 piece of gum every 2-4 hours

Weeks 10-12: Chew 1 piece of gum every 4-8 hours

Inhaler: Usually 6 to 16 cartridges per day; best effect was achieved by frequent continuous puffing (20 minutes); recommended duration of treatment is 3 months, after which patients may be weaned from the inhaler by gradual reduction of the daily dose over 6-12 weeks

Lozenge: Patients who smoke their first cigarette within 30 minutes of waking should use the 4 mg strength; otherwise the 2 mg strength is recommended. Use according to the following 12-week dosing schedule:

Weeks 1-6: One lozenge every 1-2 hours

Weeks 7-9: One lozenge every 2-4 hours

Weeks 10-12: One lozenge every 4-8 hours

Note: Use at least 9 lozenges/day during first 6 weeks to improve chances of quitting; do not use more than one lozenge at a time (maximum: 5 lozenges every 6 hours, 20 lozenges/day)

Topical:

Transdermal patch: Apply new patch every 24 hours to nonhairy, clean, dry skin on the upper body or upper outer arm; each patch should be applied to a different site. **Note:** Adjustment may be required during initial treatment (move to higher dose if experiencing withdrawal symptoms; lower dose if side effects are experienced).

NicoDerm CQ®:

Patients smoking ≥ 10 cigarettes/day: Begin with **step 1** (21 mg/day) for 4-6 weeks, followed by **step 2** (14 mg/day) for 2 weeks; finish with **step 3** (7 mg/day) for 2 weeks

Patients smoking < 10 cigarettes/day: Begin with **step 2** (14 mg/day) for 6 weeks, followed by **step 3** (7 mg/day) for 2 weeks

Note: Initial starting dose for patients < 100 pounds, history of cardiovascular disease: 14 mg/day for 4-6 weeks, followed by 7 mg/day for 2-4 weeks

Note: Patients receiving > 600 mg/day of cimetidine: Decrease to the next lower patch size

Nicotrol®: One patch daily for 6 weeks

Note: Benefits of use of nicotine transdermal patches beyond 3 months have not been demonstrated.

Ulcerative colitis (unlabeled use): Transdermal: Titrated to 22-25 mg/day

Nasal: Spray: 1-2 sprays/hour; do not exceed more than 5 doses (10 sprays) per hour [maximum: 40 doses/day (80 sprays)]; each dose (2 sprays) contains 1 mg of nicotine

Monitoring Parameters Heart rate and blood pressure periodically during therapy; discontinue therapy if signs of nicotine toxicity occur (eg, severe headache, dizziness, mental confusion, disturbed hearing and vision, abdominal pain; rapid, weak and irregular pulse; salivation, nausea, vomiting, diarrhea, cold sweat, weakness); therapy should be discontinued if rash develops; discontinuation may be considered if other adverse effects of patch occur such as myalgia, arthralgia, abnormal dreams, insomnia, nervousness, dry mouth, sweating

Administration Gum: Should be chewed slowly to avoid jaw ache and to maximize benefit.

Lozenge: Allow to dissolve slowly in the mouth. Do not chew or swallow lozenge whole. Acidic foods/beverages decrease absorption of nicotine. Avoid coffee, orange juice, or soft drinks 15 minutes prior to, during, or after lozenge.

Contraindications Hypersensitivity to nicotine or any component of the formulation; patients who are smoking during the postmyocardial infarction period; patients with life-threatening arrhythmias, or severe or worsening angina pectoris; active temporomandibular joint disease (gum); pregnancy; not for use in nonsmokers

Warnings The risk versus the benefits must be weighed for each of these groups: patients with CAD, serious cardiac arrhythmias, vasospastic disease. Use caution in patients with hyperthyroidism, pheochromocytoma, or insulin-dependent diabetes. Use with caution in oropharyngeal inflammation and in patients with history of esophagitis, peptic ulcer, coronary artery disease, vasospastic disease, angina, hypertension, pheochromocytoma, severe renal dysfunction, and hepatic dysfunction. The inhaler should be used with caution in patients with bronchospastic disease (other forms of nicotine replacement may be preferred). Use of nasal product is not recommended with chronic nasal disorders (eg, allergy, rhinitis, nasal polyps, and sinusitis). Transdermal patch may contain conducting metal (eg, aluminum); remove patch prior to MRI. Cautious use of topical nicotine in patients with certain skin diseases. Hypersensitivity to the topical products can occur. Dental problems may be worsened by chewing the gum. Urge patients to stop smoking completely when initiating therapy. Safety and efficacy have not been established in pediatric patients.

Dosage Forms

Gum, chewing, as polacrilex: 2 mg (48s, 108s); 4 mg (48s, 108s)

Nicorette®:

2 mg (48s, 50s, 110s, 168s, 170s, 192s, 200s, 216s) [fruit chill flavor contains calcium 94 mg/gum and sodium 11 mg/gum; mint, fresh mint, fruit chill, orange, and original flavors]

4 mg (48s, 108s, 168s) [fruit chill flavor contains calcium 94 mg/gum and sodium 13 mg/gum; mint, fresh mint, fruit chill, orange, and original flavors]

Lozenge, as polacrilexL:

Commit®: 2 mg (48s, 72s) [contains phenylalanine 3.4 mg/lozenge, sodium 18 mg/lozenge; mint flavor]; 4 mg (48s, 72s) [contains phenylalanine 3.4 mg/lozenge, sodium 18 mg/lozenge; mint flavor]

Oral inhalation system:

Nicotrol® Inhaler: 10 mg cartridge [delivering 4 mg nicotine] (168s) [each unit consists of 5 mouthpieces, 28 storage trays each containing 6 cartridges, and 1 storage case]

Patch, transdermal: 7 mg/24 (30s); 14 mg/24 hours (30s); 21 mg/24 hours (30s)

NicoDerm® CQ®: 7 mg/24 hours (14s); 14 mg/24 hours (14s); 21 mg/24 hours (14s) [available in tan or clear patch]

Nicotrol®: 15 mg/16 hours (7s, 14s) [step 1]; 10 mg/16 hours (14s) [step 2]; 5 mg/16 hours (14s) [step 3]

Solution, intranasal spray (Nicotrol® NS): 10 mg/mL (10 mL) [delivers 0.5 mg/spray; 200 sprays]

Reference Range A serum nicotine level of 13,600 ng/mL has been associated with fatality. Mean plasma level after smoking one cigarette: 5-30 ng/mL. Mean plasma level after 6¹/₂ hours of smoking: 12-44 ng/mL. Pipe smoking can result in nicotine levels of 4-6 ng/mL. Plasma levels of

cotinine averaged 0.001 mg/L in children from nonsmoking homes and 0.004 mg/L in children from homes with smoking cohabitants. Arterial levels are ~6-8 times that of venous levels, thus leading to rapidly elevated brain levels. Cotinine serum levels as high as 800 ng/mL are associated with nausea, vomiting, and severe symptomatology. Steady state plasma nicotine level from transdermal patches: 12-17 ng/mL; steady state plasma nicotine level from chewing 4 mg nicotine gum: 23 ng/mL; urine cotinine levels in nonsmokers and smokers: < 20 and > 50 ng/mL, respectively. Therapeutic nicotine serum level for smoking cessation: 2-17 ng/mL. Accidental cigarette ingestion by children is a frequent occurrence in Japan where hundreds of cigarette brands (domestic and imported) are purchased. To evaluate the predictive value of the nicotine yield given on the label and determined by a smoking machine, measurement was done on the actual nicotine content of tobacco in 33 popular cigarette brands. See table.

Nicotine and Tobacco Content of 33 Cigarette Brands**Japanese Domestic Cigarette Brands (n=16)**

Brand Names	Nicotine Content		Nicotine*	Tobacco
	(mg)	(%)	Yield (mg)	Content (g)

From Fukumoto M, Kubo H, and Ogamo A, "Determination of Nicotine Content of Popular Cigarettes," *Vet Hum Toxicol*, 1997, 39(4):227, with permission.

Overdosage/Treatment

Decontamination: **Oral:** Emesis is not recommended due to seizure potential. For ingestions, lavage (within 1 hour) with 1:10,000 potassium permanganate (100 mg/L) is recommended after control of seizures. Use of activated charcoal for acute ingestions is not well established.

Dermal: Wash area well with cool water and dry; soap (especially alkaline soaps) may increase absorption; remove any remaining transdermal systems; nicotine will continue to be absorbed several hours after removal due to depot in skin. **Ocular:** Irrigate with saline.

Supportive therapy: Control seizures with benzodiazepines; if continuous, use phenobarbital; atropine can be utilized for cholinergic toxicity while phentolamine can be used for hypertension; avoid antacids due to increased nicotine absorption in alkali medium

Enhancement of elimination: Hemodialysis/hemoperfusion of unknown value. While acidifying the urine may enhance elimination, this modality is not recommended due to inherent dangers.

Antidote(s)

- Atropine [ANTIDOTE]

Diagnostic Procedures

- Nicotine Level

Drug Interactions Substrate (minor) of CYP1A2, 2A6, 2B6, 2C9, 2C19, 2D6, 2E1, 3A4; **Inhibits** CYP2A6 (weak), 2E1 (weak)

Adenosine: Nicotine increases the hemodynamic and AV blocking effects of adenosine; monitor

Bupropion: Monitor for treatment-emergent hypertension in patients treated with the combination of nicotine patch and bupropion

Cimetidine: May increase nicotine concentrations; therefore, may decrease amount of gum or patches needed

Pregnancy Risk Factor D (transdermal); X (chewing gum)

Pregnancy Implications Pregnant smokers are almost twice as likely to have a spontaneous abortion or a low birth weight neonate (<2500 g); prematurity, placenta previa, and abruption rates are also increased in the smoker; nicotine is present in breast milk

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Patients should be instructed to chew slowly to avoid jaw ache and to maximize benefit

Additional Information

Lethal adult dose: 40 mg

Symptoms usually do not occur in pediatric ingestions <1 mg/kg; not useful as maintenance therapy for ulcerative colitis

Nicotine withdrawal is characterized by psychological distress, difficulty concentrating, tobacco craving, and hunger; average weight gain during smoking cessation is ~4 kg; 3% annual quit rate from smoking; contact the National Capital Poison Center (1-800-498-8666) with all cases of misuse, overdose or abuse of nicotine nasal spray; each actuation of Nicotrol® NS delivers a metered 50 µL spray containing 0.5 mg of nicotine

Tobacco harvesters absorbed ~0.8 mg nicotine per day.

Use Angina, hypertrophic cardiomyopathy, hypertension (sustained release only)

Mechanism of Action Inhibits calcium ion from entering the "slow channels" or select voltage-sensitive areas of vascular smooth muscle and myocardium during depolarization, producing a relaxation of coronary vascular smooth muscle and coronary vasodilation; increases myocardial oxygen delivery in patients with vasospastic angina

Adverse Reactions

Cardiovascular: **Flushing**, hypotension, tachycardia, palpitations, syncope, peripheral edema, chest pain, sinus bradycardia, angina, myocardial depression, QRS prolongation, sinus tachycardia, torsade de pointes, vasodilation, vasculitis

Central nervous system: **Dizziness, headache, lightheadedness, giddiness**, drowsiness, fever, chills, psychosis, memory disturbance

Dermatologic: Dermatitis, rash, photosensitivity reactions, flushing, purpura, bullous lesions, erythema multiforme, acute generalized exanthematous pustulosis, alopecia, angioedema, toxic epidermal necrolysis, urticaria, Stevens-Johnson syndrome, pruritus, erythema nodosum, licheniform eruptions, exanthem, pemphigoid nodularis

Endocrine & metabolic: Gynecomastia, parotitis

Gastrointestinal: **Nausea, heartburn**, diarrhea, constipation, gingival hyperplasia, vomiting, bezoars, intestinal infarction, concretions, metallic taste, loss of taste perception, decreased esophageal sphincter tone

Hematologic: Thrombocytopenia, leukopenia, anemia, hemolytic anemia

Neuromuscular & skeletal: **Weakness**, joint stiffness, arthritis with elevated ANA, clonus, myoclonus, erythromelalgia, rhabdomyolysis, paresthesia

Ocular: Blurred vision, transient blindness

Respiratory: Dyspnea, hyposmia

Miscellaneous: **Heat sensation**, diaphoresis, systemic lupus erythematosus, fixed drug eruption

Signs and Symptoms of Overdose Agranulocytosis, AV block, bradycardia, chest pain, congestive heart failure, constipation, depression, enuresis, exfoliative dermatitis, extrapyramidal reaction, gingival hyperplasia, granulocytopenia, gynecomastia, heart block, hyperglycemia, hyperthermia, hyperkalemia, hypokalemia, hypotension, leukopenia, lightheadedness, memory loss, neutropenia, nocturia, peripheral vasodilation, pulmonary edema, QT prolongation, Raynaud's (exacerbation), reflex tachycardia, wheezing

Pharmacodynamics/Kinetics

Onset of action: Immediate release: ~20 minutes

Protein binding (concentration dependent): 92% to 98%

Metabolism: Hepatic to inactive metabolites

Bioavailability: Capsule: 40% to 77%; Sustained release: 65% to 89% relative to immediate release capsules

Half-life elimination: Adults: Healthy: 2-5 hours, Cirrhosis: 7 hours; Elderly: 6.7 hours

Excretion: Urine (as metabolites)

Dosage

Children: Oral:

Hypertensive emergencies: 0.25-0.5 mg/kg/dose

Hypertrophic cardiomyopathy: 0.6-0.9 mg/kg/24 hours in 3-4 divided doses

Adults: Oral: Initial: 10 mg 3 times/day as capsules or 30-60 mg once daily as sustained release tablet; maintenance: 10-30 mg 3-4 times/day (capsules); maximum: 180 mg/24 hours (capsules) or 120 mg/day (sustained release)

Dosing adjustment in hepatic impairment: Reduce oral dose by 50% to 60% in patients with cirrhosis

Monitoring Parameters Heart rate, blood pressure, signs and symptoms of CHF, peripheral edema

Administration Extended release tablets should be swallowed whole; do not crush or chew.

Contraindications Hypersensitivity to nifedipine or any component of the formulation; immediate release preparation for treatment of urgent or emergent hypertension; acute MI

Warnings

The use of sublingual short-acting nifedipine in hypertensive emergencies and pseudoemergencies is neither safe nor effective and SHOULD BE ABANDONED! Serious adverse events (cerebrovascular ischemia, syncope, heart block, stroke, sinus arrest, severe hypotension, acute myocardial infarction, ECG changes, and fetal distress) have been reported in relation to such use.

Blood pressure lowering should be done at a rate appropriate for the patient's condition. Rapid drops in blood pressure can lead to arterial insufficiency. Increased angina and/or MI has occurred with initiation or dosage titration of calcium channel blockers. Severe hypotension may occur in patients taking immediate release nifedipine concurrently with beta blockers when undergoing CABG with high dose fentanyl anesthesia. When considering surgery with high dose fentanyl, may consider withdrawing nifedipine (>36 hours) before surgery if possible. Use caution in severe aortic stenosis. Use caution in patients with severe hepatic impairment (may need dosage adjustment). Abrupt withdrawal may cause rebound angina in patients with CAD. Use caution in CHF (may cause worsening of symptoms).

NIFEdipine

Related Information

- Calcium Channel Blockers

CAS Number 21829-25-4

U.S. Brand Names Adalat® CC; Nifedical™ XL; Procardia XL®; Procardia®

The extended release formulation consists of drug within a nondeformable matrix; following drug release/absorption, the matrix/shell is expelled in the stool. The use of nondeformable products in patients with known stricture/narrowing of the GI tract has been associated with symptoms of obstruction. Avoid grapefruit juice during treatment with nifedipine.

Dosage Forms Capsule, softgel: 10 mg, 20 mg

Procardia®: 10 mg

Tablet, extended release: 30 mg, 60 mg, 90 mg

Adalat® CC, Procardia XL®: 30 mg, 60 mg, 90 mg

Afedital™ CR, Nifedical™ XL: 30 mg, 60 mg

Nifediac™ CC: 30 mg, 60 mg, 90 mg [90 mg tablet contains tartrazine]

Reference Range Therapeutic: 25-100 ng/mL; although levels >28 ng/mL correlate with negative inotropic effect after I.V. use; serum nifedipine level of 1290 ng/mL associated with fatality (postmortem urine nifedipine level was 130 ng/mL)

Overdosage/Treatment

Decontamination: Avoid ipecac. Lavage (within 1 hour)/activated charcoal is useful. Whole bowel irrigation for sustained release preparations.

Supportive therapy: I.V. fluids and Trendelenburg positioning should be initiated as intoxication may cause hypotension. Calcium (calcium chloride I.V. 1-3 g in adults or 10-30 mg/kg in children over 5-10 minutes with repeats as needed) has been used as an "antidote" for acute intoxications, although its effectiveness is questionable in nifedipine overdose. Hyperinsulinemic therapy with 0.5-1.0 unit I.V. insulin bolus with an infusion of 0.2-1 unit/kg/hour plus a glucose bolus of 25 g I.V. and dextrose infusion to maintain a serum glucose >100 mg/dL may reverse cardiogenic shock due to calcium blockers. Heart block may respond to isoproterenol, glucagon, atropine and/or calcium, although a temporary pacemaker may be required. Inamrinone or dopamine may be required for hypotension and is considered to be first-line therapy in the treatment of shock. Glucagon may increase myocardial contractility.

Enhancement of elimination: Multiple dosing of activated charcoal is useful

Antidote(s)

- Glucagon [ANTIDOTE]

Drug Interactions **Substrate** of CYP2D6 (minor), 3A4 (major); **Inhibits** CYP1A2 (moderate), 2C9 (weak), 2D6 (weak), 3A4 (weak)

Alpha 1-blockers: May enhance the effects of calcium channel blockers; monitor blood pressure.

Azole antifungals: May inhibit the calcium channel blocker's metabolism; monitor for the toxic effects of calcium channel blocker and adjust accordingly.

Barbiturates: May increase metabolism of calcium channel blocker. Consider therapy modification.

Calcium may reduce the calcium channel blocker's effects.

Calcium channel blocker (nondihydropyridine): May enhance the hypotensive effects of calcium channel blocker (dihydropyridine).

Carbamazepine: May decrease nifedipine serum concentration.

Cimetidine: May increase nifedipine serum concentrations; monitor for toxic effects of calcium channel blocker or choose an alternative H₂ antagonist.

Cisapride: May increase nifedipine's effects; monitor blood pressure.

Cyclosporine: May decrease metabolism of calcium channel blocker (dihydropyridine); monitor for toxic effects of calcium channel blocker.

CYP1A2 substrates: Nifedipine may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, fluvoxamine, mexiletine, mirtazapine, ropinirole, theophylline, and trifluoperazine.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of nifedipine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of nifedipine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nifedipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Erythromycin: May increase nifedipine serum concentration; monitor blood pressure and adjust if necessary.

Grapefruit juice increases the bioavailability of nifedipine; avoid grapefruit juice.

Magnesium salts: Concurrent use may enhance the adverse/toxic effects of magnesium and enhance the hypotensive effects of the calcium channel blocker.

Nafcillin decreases plasma concentration of nifedipine; avoid this combination.

Neuromuscular-blocking agent (nondepolarizing): Calcium channel blockers may enhance the neuromuscular blocking effect; monitor.

Phenobarbital reduces the plasma concentration of nifedipine. May require much higher dose of nifedipine.

Phenytoin: May decrease nifedipine serum concentration; monitor and adjust if necessary.

Protease inhibitors like amprenavir and ritonavir may increase nifedipine's serum concentration.

Quinidine's serum concentration is reduced and nifedipine's is increased; adjust doses as needed.

Quinupristin/dalfopristin: May increase nifedipine serum concentration; monitor blood pressure and adjust if necessary.

Rifamycin derivatives: Increase the metabolism of the calcium channel blocker; adjust the dose of the calcium channel blocker to maintain efficacy.

Tacrolimus's serum concentrations are increased by nifedipine; monitor tacrolimus trough levels and renal function closely.

Vincristine's half-life is increased by nifedipine; monitor closely for vincristine dose adjustment.

Pregnancy Risk Factor C

Pregnancy Implications Late decelerations of fetal heart rate can occur

Lactation Enters breast milk/compatible

Nursing Implications May cause some patients to urinate frequently at night; may cause inflamed gums

Additional Information Tasteless; response to atropine may not be observed until after I.V. calcium administration

Nilutamide

CAS Number 63612-50-0

U.S. Brand Names Nilandron®

Synonyms RU-23908

Use Treatment of metastatic prostate cancer

Mechanism of Action Nonsteroidal antiandrogen that inhibits androgen uptake or inhibits binding of androgen in target tissues. It specifically blocks the action of androgens by interacting with cytosolic androgen receptor F sites in target tissue

Adverse Reactions

Cardiovascular: Chest pain, edema, heart failure, hypertension, syncope

Central nervous system: Depression, dizziness, drowsiness, fever,

headache, hypesthesia, **insomnia**, malaise

Dermatologic: Pruritus, alopecia, dry skin, rash

Endocrine & metabolic: Disulfiram-like reaction, **gynecomastia**, **hot flashes**

Gastrointestinal: **Abdominal pain**, **anorexia**, **constipation**, diarrhea, dyspepsia, GI hemorrhage, melena, **nausea**, vomiting, weight loss, xerostomia

Genitourinary: Hematuria, **libido decreased**, nocturia, **testicular atrophy**

Hematologic: Anemia, aplastic anemia

Hepatic: Hepatitis, **transient elevation in serum transaminases**

Neuromuscular & skeletal: Arthritis, paresthesia

Ocular: Abnormal vision, cataracts, chromatopsia, **impaired dark adaptation** (usually reversible with dose reduction, may require discontinuation in 1% to 2% of patients), photophobia

Respiratory: **Dyspnea**, interstitial pneumonitis (typically exertional dyspnea, cough, chest pain, and fever; most often occurring within the first 3 months of treatment); rhinitis

Miscellaneous: Diaphoresis, flu-like syndrome

Signs and Symptoms of Overdose Nausea, vomiting, malaise, headache, dizziness, elevated liver enzymes

Pharmacodynamics/Kinetics

Absorption: Rapid and complete

Protein binding: 72% to 85%

Metabolism: Hepatic, forms active metabolites

Half-life elimination: Terminal: 23-87 hours; Metabolites: 35-137 hours

Excretion: Urine (up to 78% at 120 hours; <1% as unchanged drug); feces (1% to 7%)

Dosage 300 mg/day (100 mg every 8 hours); consider reducing dose in hepatic insufficiency

Monitoring Parameters Obtain a chest x-ray if a patient reports dyspnea; if there are findings suggestive of interstitial pneumonitis, discontinue treatment with nilutamide. Measure serum hepatic enzyme levels at baseline and at regular intervals (3 months); if transaminases increase over 2-3 times the upper limit of normal, discontinue treatment. Perform appropriate laboratory testing at the first symptom/sign of liver injury (eg, jaundice, dark urine, fatigue, abdominal pain or unexplained GI symptoms).

NILVADIPINE

Contraindications Hypersensitivity to nilutamide or any component of the formulation; severe hepatic impairment; severe respiratory insufficiency

Warnings

Hazardous agent - use appropriate precautions for handling and disposal.

[U.S. Boxed Warning]: Interstitial pneumonitis has been reported in 2% of patients exposed to nilutamide. Patients typically experienced progressive exertional dyspnea, and possibly cough, chest pain and fever. X-rays showed interstitial or alveolo-interstitial changes. The suggestive signs of pneumonitis most often occurred within the first 3 months of nilutamide treatment.

Hepatitis or marked increases in liver enzymes leading to drug discontinuation occurred in 1% of nilutamide patients. Rare cases of elevated hepatic enzymes followed by death have been reported.

Foreign postmarketing surveillance has revealed isolated cases of aplastic anemia in which a causal relationship with nilutamide could not be ascertained.

13% to 57% of patients receiving nilutamide reported a delay in adaptation to the dark, ranging from seconds to a few minutes. This effect sometimes does not abate as drug treatment is continued. Caution patients who experience this effect about driving at night or through tunnels. This effect can be alleviated by wearing tinted glasses.

Dosage Forms Tablet: 150 mg

Reference Range Peak plasma levels after a 100 mg and 300 mg oral dose: 0.8 mg/mL and 1.6 mg/mL, respectively

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Management is supportive

Enhancement of elimination: Dialysis is of no benefit

Drug Interactions **Substrate** of CYP2C19 (major); **Inhibits** CYP2C19 (weak)

CYP2C19 inducers: May decrease the levels/effects of nilutamide.

Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of nilutamide.

Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

Pregnancy Risk Factor C; Not indicated for use in women

Pregnancy Implications Not indicated for use in women

Lactation Not indicated for use in women

Additional Information Other nonapproved uses: Treatment of acne, seborrhea, and transsexual hormonal feminization

Nilvadipine

Related Information

- Calcium Channel Blockers

CAS Number 75530-68-6

Synonyms Nivadipine

Unlabeled/Investigational Use Hypertension; also may be useful in patients with cerebrovascular disease or stable exertional or variant angina pectoris

Mechanism of Action Dihydropyridine calcium channel blocking agent with properties similar to nifedipine

Adverse Reactions

Cardiovascular: Flushing, tachycardia, edema, hypotension, ectopy (ventricular), shock, chest pain, angina, palpitations, sinus tachycardia, arrhythmias (ventricular)

Central nervous system: Headache, dizziness, sleep disturbances, insomnia

Gastrointestinal: Nausea

Ocular: Oscillopsia

Pharmacodynamics/Kinetics

Distribution: V_d : 24-40 L/kg

Protein binding: 98%

Bioavailability: Oral: 14% to 19%

Half-life elimination: 9.8-18.2 hours

Excretion: Urine

Clearance: 1.08 L/kg/hour

Dosage Hypertension: 4-16 mg/day; reduce dosage to a maximum dose of 8 mg in patients with cirrhosis or with concomitant use with cimetidine

Cerebrovascular disease: 2-4 mg twice daily

Angina pectoris: 8-16 mg/day

Contraindications Hypersensitivity to nilvadipine or any component of the formulation; acute apoplectic stroke; intracranial hemorrhage; raised intracranial pressure

Overdosage/Treatment

Decontamination: Avoid ipecac. Lavage (within 1 hour)/activated charcoal is useful. Whole bowel irrigation for sustained release preparations.

Supportive therapy: I.V. fluids and Trendelenburg positioning should be initiated as intoxication may cause hypotension. Calcium (calcium chloride I.V. 1-3 g in adults or 10-30 mg/kg in children over 5-10 minutes with repeats as needed) has been used as an "antidote" for acute intoxications, although its effectiveness is questionable in nifedipine overdose. Heart block may respond to isoproterenol, gluca-

gon, atropine and/or calcium, although a temporary pacemaker may be required. Inamrinone or dopamine may be required for hypotension and are considered first-line therapy in treatment of shock. Glucagon may increase myocardial contractility.

Enhancement of elimination: Multiple dosing of activated charcoal is useful

Drug Interactions Sildenafil, tadalafil, vardenafil: Blood pressure-lowering effects may be additive; use caution.

Additional Information Not available in U.S.

Nimodipine

Related Information

- Calcium Channel Blockers

CAS Number 66085-59-4

U.S. Brand Names Nimotop®

Use Improvement of neurological deficits due to spasm following subarachnoid hemorrhage from ruptured congenital intracranial aneurysms who are in good neurological condition postictus

Mechanism of Action Nimodipine is a calcium channel blocker; animal studies indicate that nimodipine has a greater effect on cerebral arterials than other arterials; this increased specificity may be due to the drug's increased lipophilicity and cerebral distribution as compared to nifedipine indicated for patients with subarachnoid hemorrhage

Adverse Reactions

Cardiovascular: Reductions in systemic blood pressure, flushing, tachycardia, palpitations, sinus bradycardia, QRS prolongation, sinus tachycardia, vasodilation

Central nervous system: Dizziness

Dermatologic: Acne, purpura, exanthem, pruritus

Gastrointestinal: Nausea, constipation

Hematologic: Bleeding

Neuromuscular & skeletal: Rhabdomyolysis

Respiratory: Wheezing

Signs and Symptoms of Overdose Depression, diarrhea, disorientation, gingival hyperplasia, hyponatremia, hypotension, lightheadedness, myalgia, peripheral vasodilation

Pharmacodynamics/Kinetics

Protein binding: >95%

Metabolism: Extensively hepatic

Bioavailability: 13%

Half-life elimination: 1-2 hours; prolonged with renal impairment

Time to peak, serum: ~1 hour

Excretion: Urine (50%) and feces (32%) within 4 days

Dosage Note: Capsules and contents are for oral administration **ONLY**.

Adults: Oral: 60 mg every 4 hours for 21 days, start therapy within 96 hours after subarachnoid hemorrhage.

Dialysis: Not removed by hemo- or peritoneal dialysis; supplemental dose is not necessary.

Dosing adjustment in hepatic impairment: Reduce dosage to 30 mg every 4 hours in patients with liver failure.

Monitoring Parameters Blood pressure

Administration For oral administration **ONLY**. If the capsules cannot be swallowed, the liquid may be removed by making a hole in each end of the capsule with an 18-gauge needle and extracting the contents into a syringe. If administered via NG tube, follow with a flush of 30 mL NS.

Contraindications Hypersensitivity to nimodipine or any component of the formulation

Warnings

May cause reductions in blood pressure. Use caution in hepatic impairment. Intestinal pseudo-obstruction and ileus have been reported during the use of nimodipine. Use caution in patients with decreased GI motility of a history of bowel obstruction. Use caution when treating patients with increased intracranial pressure.

[U.S. Boxed Warning]: Nimodipine has inadvertently been administered I.V. when withdrawn from capsules into a syringe for subsequent nasogastric administration. Severe cardiovascular adverse events, including fatalities, have resulted; precautions should be employed against such an event.

Dosage Forms Capsule, liquid filled: 30 mg

Overdosage/Treatment

Avoid ipecac.

Supportive therapy: Supportive and symptomatic treatment, including I.V. fluids and Trendelenburg positioning, should be initiated as intoxication may cause hypotension. Although calcium (calcium chloride I.V. 1-3 g in adults or 10-30 mg/kg in children over 5-10 minutes with repeats as needed) has been used as an "antidote" for acute intoxications, there is limited experience to support its routine use and should be reserved for those cases where definite signs of myocardial depression are evident. Heart block may respond to isoproterenol, glucagon, atropine and/or calcium, although a temporary pacemaker may be required; norepinephrine, dopamine, or inamrinone for treatment of refractory hypotension is considered first-line therapy in treatment of shock

Enhancement of elimination: Multiple dosing of activated charcoal may be useful

Antidote(s)

- Calcium Gluconate [ANTIDOTE]

Drug Interactions Substrate of CYP3A4 (major)

Antihypertensive agents: May be potentiated by nimodipine.
Azole antifungals may inhibit the calcium channel blocker's metabolism; avoid this combination. Try an antifungal like terbinafine (if appropriate) or monitor closely for altered effect of the calcium channel blocker.

Calcium may reduce the calcium channel blocker's effects, particularly hypotension.

Calcium channel blockers: The effects of other calcium channel blockers may be potentiated by nimodipine.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of nimodipine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of nimodipine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Grapefruit juice increases the bioavailability of nimodipine; monitor for altered nimodipine effects.

Protease inhibitor like amprevir and ritonavir may increase nimodipine's serum concentration.

Rifampin increases the metabolism of the calcium channel blocker; adjust the dose of the calcium channel blocker to maintain efficacy.

Sildenafil, tadalafil, vardenafil: Blood pressure-lowering effects may be additive; use caution.

Valproic acid increased nimodipine's serum concentration; monitor altered effect of nimodipine.

Pregnancy Risk Factor C

Pregnancy Implications Use in pregnancy only when clearly needed and when the benefits outweigh the potential hazard to the fetus. Teratogenic and embryotoxic effects have been demonstrated in small animals. No well-controlled studies have been conducted in pregnant women.

Lactation Enters breast milk/not recommended

Nursing Implications If the capsules cannot be swallowed, the liquid may be removed by making a hole in each end of the capsule with an 18-gauge needle and extracting the contents into a syringe; if given via NG tube, follow with a flush of 30 mL NS

Nitrazepam

Related Information

- Clonazepam
- Flunitrazepam

CAS Number 146-22-5

Synonyms Nitrozepamum

Impairment Potential Yes. A brief or extended period (up to 1 year) of use is consistent with driving impairment in the elderly; impairment is greatest in the first 7 days of use.

Unlabeled/Investigational Use Short-term management of insomnia; treatment of infantile spasm and seizures

Mechanism of Action Facilitates gamma-aminobutyric acid neurotransmission; a 7-nitrobenzodiazepine derivative

Adverse Reactions

Central nervous system: Lethargy, disorientation, night terrors, opisthotonos, ataxia, headache, hypothermia

Dermatologic: Bullous eruptions

Endocrine & metabolic: Gout

Gastrointestinal: Salivation, dysphagia, anorexia

Hematologic: Porphyria

Neuromuscular & skeletal: Rhabdomyolysis

Ocular: Increased intraocular pressure

Signs and Symptoms of Overdose Apnea, aspiration

Pharmacodynamics/Kinetics

Peak serum levels: 1.4 hours

Duration of effect: 4-8 hours

Distribution: V_d : 2.4 L/kg (young patients); 4.8 L/kg (elderly)

Protein binding: 85% to 88%

Metabolism: Hepatic reduction

Bioavailability: 78%

Half-life: 24-29 hours

Elimination: Renal (80%), feces (20%)

Dosage

Oral:

Insomnia:

Children:

1-6 years: 2.5 mg

≥ 7 years: 5 mg

Adults: 5-10 mg at night

Epilepsy: Children and Adults: 1-6 mg/day; dosage should be decreased in elderly, hypothyroid patients, and cirrhosis

Children maximum dose: 60 mg

Adult maximum dose: 20 mg

Contraindications Hypersensitivity to nitrazepam, flunitrazepam, or clonazepam

Warnings Use with caution in patients with hypothyroidism, cirrhosis, elderly, pregnancy, and breast-feeding

Dosage Forms Capsule: 5 mg

Tablet: 5 mg

Reference Range Steady state plasma levels with a 5 mg/day oral dose: ~57 (± 17) ng/mL; fatalities associated with postmortem blood levels of 1.2-9 mg/L; therapeutic level: 0.035 + 0.084 mg/L

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Rarely is mechanical ventilation required; flumazenil has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression and respiratory depression

Enhancement of elimination: Multiple dose of activated charcoal is effective

Antidote(s)

- Flumazenil [ANTIDOTE]

Test Interactions Nitrazepam can cause a false elevation (~15%) of clozapine serum levels

Drug Interactions Birth control pills, probenecid, and cimetidine can result in decreased nitrazepam clearance; rifampin can result in increased clearance of nitrazepam; hallucinations with concomitant erythromycin

Additional Information Hangover can occur at 20 mg oral doses; hallucinations from withdrawal can be treated with chlorpromazine

Nitrendipine

Related Information

- Calcium Channel Blockers

CAS Number 39562-70-6

Unlabeled/Investigational Use Hypertension

Mechanism of Action Dihydropyridine calcium channel blocking agent with actions similar to nifedipine

Adverse Reactions

Cardiovascular: Flushing, edema, tachycardia, palpitations, sinus tachycardia, vasodilation

Central nervous system: **Headache**, dizziness, fatigue

Gastrointestinal: Nausea, gingival hyperplasia

Otic: Tinnitus

Pharmacodynamics/Kinetics

Distribution: 6 L/kg

Protein binding: 98%

Metabolism: Hepatic to inactive metabolites

Bioavailability: 16% to 23%

Half-life elimination: 8.6 hours

Excretion: Urine (80%); feces (8%)

Dosage 20 mg/day (in patients with liver disease or in the elderly, an initial dose of 10 mg is recommended); maximum dose: 40 mg/day

Contraindications Hypersensitivity to any component of the formulation or other calcium channel blocking agents; hypotension; advanced aortic stenosis

Warnings Reduce dosage in elderly; use with caution in patients with liver insufficiency, digital ischemia, nonobstructive hypertrophic cardiomyopathy, Duchenne muscular dystrophy, or in combination with beta-blocking agents. Blood pressure lowering must be done at a rate appropriate for the patient's clinical condition.

Reference Range Peak plasma levels after a 20 mg oral dose: 5-40 mcg/L

Overdosage/Treatment

Decontamination: Avoid ipecac. Lavage (within 1 hour)/activated charcoal is useful. Whole bowel irrigation for sustained release preparations.

Supportive therapy: I.V. fluids and Trendelenburg positioning should be initiated as intoxication may cause hypotension. Calcium (calcium chloride I.V. 1-3 g in adults or 10-30 mg/kg in children over 5-10 minutes with repeats as needed) has been used as an "antidote" for acute intoxications and is considered a second-line agent (to traditional vasopressors) for treatment of shock. Heart block may respond to isoproterenol, glucagon, atropine and/or calcium, although a temporary pacemaker may be required. Inamrinone or dopamine may be required for hypotension. Glucagon may increase myocardial contractility.

Enhancement of elimination: Multiple dosing of activated charcoal is useful

Drug Interactions

Substrate of CYP3A4 (major); Inhibits CYP3A4 (weak)

Beta-blockers: Concomitant use may increase the hypotensive effects.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of nitrendipine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of nitrendipine. Example inhibitors include azole antifungals, clarithromycin, diclofenac,

NITRIC OXIDE

doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Digoxin: At nitrendipine doses exceeding 20 mg/day, increased digoxin levels and toxicity can occur.

Sildenafil, tadalafil, vardenafil: Blood pressure-lowering effects may be additive; use caution.

Lactation Enters breast milk

Additional Information Not available in U.S.

Can cause an increase in plasma catecholamine, urinary aldosterone levels, and serum alkaline phosphatase levels. Natriuresis and diuresis may also occur on a short-term basis.

Nitric Oxide

CAS Number 10102-43-9

UN Number 1660

Use Orphan drug status for treatment of primary pulmonary hypertension in the newborn; may be useful for septic shock, ARDS, or treatment of pulmonary effects of paraquat; has been used to treat high altitude pulmonary edema (HAPE)

Mechanism of Action Produces selective pulmonary vasodilatation without systemic vasodilatation through direct effect on smooth muscle of pulmonary vasculature

Adverse Reactions

Cardiovascular: Vasodilation

Hematologic: Methemoglobinemia

Respiratory: Pulmonary fibrosis, rebound pulmonary hypertension from nitric oxide withdrawal

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Pharmacodynamics/Kinetics

Onset of action: Inhalation: 2-5 minutes

Absorption: Rapidly absorbed via lungs; blood/gas partition coefficient is 0.47

Metabolism: Body: <0.004%

Excretion: Primarily exhaled gases; skin (minimal amounts)

Dosage High altitude pulmonary edema: 40 ppm of nitric oxide with room air

Contraindications Hypersensitivity to nitrous oxide or any component of the formulation; nitrous oxide should not be administered without oxygen; should not be given to patients after a full meal

Warnings Nausea and vomiting occurs postoperatively in ≈15% of patients. Prolonged use may produce bone marrow suppression and/or neurologic dysfunction. Oxygen should be briefly administered during emergence from prolonged anesthesia with nitrous oxide to prevent diffusion hypoxia. Patients with vitamin B₁₂ deficiency (pernicious anemia) and those with other nutritional deficiencies (alcoholics) are at increased risk of developing neurologic disease and bone marrow suppression with exposure to nitrous oxide. May be addictive

Dosage Forms Supplied in blue cylinders

Reference Range Normal plasma nitrate level: 24 μmol/L (range: 19-39 μmol/L); patients with congestive heart failure 56 μmol/L (range: 41-72 μmol/L)

Overdosage/Treatment Supportive therapy: Methylene blue for symptomatic methemoglobinemia

Antidote(s)

● Methylene Blue [ANTIDOTE]

Drug Interactions No data reported

Pregnancy Risk Factor No data reported

Additional Information Flammable, can inactivate surfactant; colorless gas; paralysis (motor neuropathy) may develop in alcoholics; TLV-TWA: 25 ppm; IDLH: 100 ppm

Nitrofurantoin

CAS Number 17140-81-7; 54-87-5; 67-20-9

U.S. Brand Names Furadantin®; Macrobid®; Macrochantin®

Use Prevention and treatment of urinary tract infections caused by susceptible gram-negative and some gram-positive organisms; *Pseudomonas*, *Serratia*, and most species of *Proteus* are generally resistant to nitrofurantoin

Mechanism of Action Inhibits several bacterial enzyme systems including acetyl coenzyme A interfering with metabolism and possibly cell wall synthesis

Adverse Reactions

Frequency not defined.

Cardiovascular: Chest pain, cyanosis, ECG changes (associated with pulmonary toxicity)

Central nervous system: Chills, depression, dizziness, drowsiness, fatigue, fever, headache, pseudotumor cerebri, psychotic reactions

Dermatologic: Alopecia, erythema multiforme, exfoliative dermatitis, pruritus, rash, Stevens-Johnson syndrome

Gastrointestinal: Abdominal pain, *C. difficile*-colitis, constipation, diarrhea, dyspepsia, loss of appetite, nausea (most common), pancreatitis, sore throat, vomiting

Hematologic: Agranulocytosis, aplastic anemia, eosinophilia, hemolytic anemia, methemoglobinemia, thrombocytopenia

Hepatic: Cholestasis, hepatitis, hepatic necrosis, serum transaminases increased, jaundice (cholestatic)

Neuromuscular & skeletal: Arthralgia, numbness, paresthesia, peripheral neuropathy, weakness

Ocular: Amblyopia, nystagmus, optic neuritis (rare)

Respiratory: Cough, dyspnea, pneumonitis, pulmonary fibrosis

Miscellaneous: Hypersensitivity (including acute pulmonary hypersensitivity), lupus-like syndrome

Signs and Symptoms of Overdose Apnea, cholestatic jaundice, crystalluria, erythema multiforme, hyperthermia, jaundice, leukopenia or neutropenia (agranulocytosis, granulocytopenia), methemoglobinemia, numbness, pseudotumor cerebri, sexual dysfunction, vision color changes (yellow tinge)

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, ingestion >10 mg/kg, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Pharmacodynamics/Kinetics

Absorption: Well absorbed; macrocrystalline form absorbed more slowly due to slower dissolution (causes less GI distress)

Distribution: V_d: 0.8 L/kg; crosses placenta; enters breast milk

Protein binding: 60% to 90%

Metabolism: Body tissues (except plasma) metabolize 60% of drug to inactive metabolites

Bioavailability: Increased with food

Half-life elimination: 20-60 minutes; prolonged with renal impairment

Excretion:

Suspension: Urine (40%) and feces (small amounts) as metabolites and unchanged drug

Macrocrystals: Urine (20% to 25% as unchanged drug)

Dosage

Oral:

Children >1 month: 5-7 mg/kg/day in divided doses every 6 hours; maximum: 400 mg/day

UTI prophylaxis (chronic): 1-2 mg/kg/day in divided doses every 12-24 hours; maximum: 100 mg/day

Adults: 50-100 mg/dose every 6 hours

Macrocrystal/monohydrate: 100 mg twice daily

UTI prophylaxis (chronic): 50-100 mg/dose at bedtime

Dosing adjustment in renal impairment: Cl_{cr} <60 mL/minute: Contraindicated

Contraindicated in hemo- and peritoneal dialysis and continuous arteriovenous or venovenous hemofiltration

Monitoring Parameters Signs of pulmonary reaction, signs of numbness or tingling of the extremities, periodic liver function tests

Administration Administer with meals to slow the rate of absorption and decrease adverse effects; suspension may be mixed with water, milk, fruit juice, or infant formula

Contraindications Hypersensitivity to nitrofurantoin or any component of the formulation; renal impairment (anuria, oliguria, significantly elevated serum creatinine, or Cl_{cr} <60 mL/minute); infants <1 month (due to the possibility of hemolytic anemia); pregnancy at term (38-42 weeks gestation), during labor and delivery, or when the onset of labor is imminent

Warnings Use with caution in patients with G6PD deficiency or in patients with anemia. Therapeutic concentrations of nitrofurantoin are not attained in urine of patients with Cl_{cr} <60 mL/minute. Use with caution if prolonged therapy is anticipated due to possible pulmonary toxicity. Acute, subacute, or chronic (usually after 6 months of therapy) pulmonary reactions have been observed in patients treated with nitrofurantoin; if these occur, discontinue therapy immediately; monitor closely for malaise, dyspnea, cough, fever, radiologic evidence of diffuse interstitial pneumonitis or fibrosis. Rare, but severe hepatic reactions have been associated with nitrofurantoin (onset may be insidious); discontinue immediately if hepatitis occurs. Has been associated with peripheral neuropathy (rare); risk may be increased by renal impairment, diabetes, vitamin B deficiency, or electrolyte imbalance; use caution.

Dosage Forms Capsule, macrocrystal: 50 mg, 100 mg

Macrochantin®: 25 mg, 50 mg, 100 mg

Capsule, macrocrystal/monohydrate (Macrobid®): 100 mg

Suspension, oral (Furadantin®): 25 mg/5 mL (470 mL)

Reference Range After an oral dose of 100 mg, urinary nitrofurantoin levels range from 50-100 mcg/mL and peak plasma level: ~0.72 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Treat symptomatic methemoglobinemia with methylene blue

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Antidote(s)

- Methylene Blue [ANTIDOTE]

Diagnostic Procedures

- Methemoglobin, Blood

Test Interactions False-positive urine glucose (Benedict's and Fehling's methods); no false positives with enzymatic tests

Drug Interactions Decreased effect: Antacids, especially magnesium salts, decrease absorption of nitrofurantoin; nitrofurantoin may antagonize effects of norfloxacin

Increased toxicity: Probenecid (decreases renal excretion of nitrofurantoin); anticholinergic drugs increase absorption of nitrofurantoin

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic effects have not been observed, however, may cause hemolytic anemia in infants. Use of nitrofurantoin is contraindicated at term (38-42 weeks gestation), during labor and delivery, or when the onset of labor is imminent.

Lactation Enters breast milk/not recommended (infants < 1 month); AAP rates "compatible"

Nursing Implications Higher peak serum levels may cause increased gastritis; give with meals to slow the rate of absorption and thus decrease adverse effects

Nitroglycerin

CAS Number 55-63-0

U.S. Brand Names Minitran™; Nitrek®; Nitro-Bid®; Nitro-Dur®; Nitro-Tab®; Nitrogard®; Nitrolingual®; Nitrol® [DSC]; NitroQuick®; Nitrostat®; NitroTime®

Synonyms Glyceryl Trinitrate; Nitroglycerol; NTG

Use Angina pectoris; I.V. for congestive heart failure (especially when associated with acute myocardial infarction); hypertension due to ergotism; pulmonary hypertension; hypertensive emergencies occurring perioperatively (especially during cardiovascular surgery); industrial uses: dynamite, cordite; not FDA approved; topical use for relief of pain of anal fissures or ulcers

Unlabeled/Investigational Use Esophageal spastic disorders (sublingual)

Mechanism of Action Reduces cardiac oxygen demand by decreasing left ventricular pressure and systemic vascular resistance; dilates coronary arteries and improves collateral flow to ischemic regions

Adverse Reactions

Cardiovascular: **Flushing**, chest pain, **postural hypotension**, reflex tachycardia, severe hypotension, bradycardia, coronary vascular insufficiency, cardiac arrhythmias, palpitations, pallor, sinus bradycardia, angina, sinus tachycardia, vasodilation

Central nervous system: **Dizziness**, restlessness, **headache**, **light-headedness**

Dermatologic: Allergic contact dermatitis, exfoliative dermatitis, urticaria, purpura, exanthem

Gastrointestinal: Nausea, vomiting, colic, diarrhea, loss of taste perception, xerostomia

Hematologic: Methemoglobinemia, thrombocytopenia

Neuromuscular & skeletal: **Weakness**

Miscellaneous: Alcohol intoxication, diaphoresis and collapse

Signs and Symptoms of Overdose Bloody diarrhea, bradycardia, circulatory collapse, clonic seizures, cyanosis, hypotension, methemoglobinemia, metabolic acidosis, palpitations, throbbing headache, tissue hypoxia

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Pharmacodynamics/Kinetics Onset and duration of action is dependent upon dosage form administered. See table.

Nitroglycerin			
Dosage Form	Onset of Effect	Peak Effect	Duration
Sublingual tablet	1-3 min	4-8 min	30-60 min
Lingual spray	2 min	4-10 min	30-60 min
Buccal tablet	2-5 min	4-10 min	2 h
Sustained release	20-45 min	45-120 min	4-8 h
Topical	15-60 min	30-120 min	2-12 h
Transdermal	40-60 min	60-180 min	8-24 h
I.V. drip	Immediate	Immediate	3-5 min

Absorption: Well from gastrointestinal tract

Distribution: V_d : 2.1-4.5 L/kg; distributed widely throughout the body

Protein binding: 60%

Metabolism: Extensive first-pass to inorganic nitrite

Half-life: S.L.: 1-4 minutes

Elimination: In urine; clearance: 140-320 mL/kg/minute

Dosage

Note: Hemodynamic and antianginal tolerance often develop within 24-48 hours of continuous nitrate administration

Children: Pulmonary hypertension: Continuous infusion: Start 0.25-0.5 mcg/kg/minute and titrate by 1 mcg/kg/minute at 20- to 60-minute intervals to desired effect; usual dose: 1-3 mcg/kg/minute; maximum: 5 mcg/kg/minute

Adults:

Buccal: Initial: 1 mg every 3-5 hours while awake (3 times/day); titrate dosage upward if angina occurs with tablet in place

Oral: 2.5-9 mg 2-4 times/day (up to 26 mg 4 times/day)

I.V.: 5 mcg/minute, increase by 5 mcg/minute every 3-5 minutes to 20 mcg/minute; if no response at 20 mcg/minute increase by 10 mcg/minute every 3-5 minutes, up to 200 mcg/minute

Ointment: 1" to 2" every 8 hours up to 4" to 5" every 4 hours

Patch, transdermal: Initial: 0.2-0.4 mg/hour, titrate to doses of 0.4-0.8 mg/hour; tolerance is minimized by using a patch-on period of 12-14 hours and patch-off period of 10-12 hours

Sublingual: 0.2-0.6 mg every 5 minutes for maximum of 3 doses in 15 minutes; may also use prophylactically 5-10 minutes prior to activities which may provoke an attack

Translingual: 1-2 sprays into mouth under tongue every 3-5 minutes for maximum of 3 doses in 15 minutes, may also be used 5-10 minutes prior to activities which may provoke an attack prophylactically

Anal fissure/ulcer pain: 200 mg applied topically to anal canal 4 times daily and after each bowel movement

May need to use nitrate-free interval (10-12 hours/day) to avoid tolerance development; tolerance may possibly be reversed with acetylcysteine; gradually decrease dose in patients receiving NTG for prolonged period to avoid withdrawal reaction

Stability I.V. infusion solution in NS or D_5W , is stable for 48 hours at room temperature, mixed and stored in glass containers; maximum concentration not to exceed 400 mcg/mL; do not mix with other drugs; store sublingual tablets and ointment in tightly closed container; store at 15°C to 30°C

Monitoring Parameters Blood pressure, heart rate

Administration I.V.: I.V. must be prepared in glass bottles; use special sets intended for nitroglycerin. glass I.V. bottles and administration sets provided by manufacturer.

Sublingual: Do not crush sublingual product (tablet). Place under tongue and allow to dissolve.

Translingual spray: Prime prior to first use (5 sprays into the air). If unused for 6 weeks, a single priming spray should be completed.

Priming sprays should be directed away from patient and others. The end of the pump should be covered by the fluid in the bottle.

Contraindications

Hypersensitivity to organic nitrates; hypersensitivity to isosorbide, nitroglycerin, or any component of the formulation; concurrent use with phosphodiesterase-5 (PDE-5) inhibitors (sildenafil, tadalafil, or vardenafil); angle-closure glaucoma (intraocular pressure may be increased); head trauma or cerebral hemorrhage (increase intracranial pressure); severe anemia; allergy to adhesive (transdermal product)

Additional contraindications for I.V. product: Hypotension; uncorrected hypovolemia; inadequate cerebral circulation; constrictive pericarditis; pericardial tamponade

Warnings Severe hypotension can occur. Use with caution in volume depletion, hypotension, and right ventricular infarctions. Paradoxical bradycardia and increased angina pectoris can accompany hypotension. Orthostatic hypotension can also occur. Ethanol can accentuate this. Tolerance does develop to nitrates and appropriate dosing is needed to minimize this (drug-free interval). Safety and efficacy have not been established in pediatric patients. Avoid use of long-acting agents in acute MI or CHF; cannot easily reverse. Nitrate may aggravate angina caused by hypertrophic cardiomyopathy. Nitroglycerin transdermal patches should be removed prior to defibrillation or MRI study.

Dosage Forms Capsule, extended release: 2.5 mg, 6.5 mg, 9 mg

Nitro-Time®: 2.5 mg, 6.5 mg, 9 mg

Infusion [premixed in D_5W]: 25 mg (250 mL) [0.1 mg/mL]; 50 mg (250 mL) [0.2 mg/mL]; 50 mg (500 mL) [0.1 mg/mL]; 100 mg (250 mL) [0.4 mg/mL]; 200 mg (500 mL) [0.4 mg/mL]

Injection, solution: 5 mg/mL (5 mL, 10 mL) [contains alcohol and propylene glycol]

Ointment, topical:

Nitro-Bid®: 2% [20 mg/g] (1 g, 30 g, 60 g)

Solution, translingual spray:

Nitrolingual®: 0.4 mg/metered spray (4.9 g) [contains alcohol 20%; 60 metered sprays]; (12 g) [contains alcohol 20%; 200 metered sprays]

NITROPRUSSIDE

Tablet, sublingual:

NitroQuick[®], Nitrostat[®]: 0.3 mg, 0.4 mg, 0.6 mg

Transdermal system [once daily patch]: 0.1 mg/hour (30s); 0.2 mg/hour (30s); 0.4 mg/hour (30s); 0.6 mg/hour (30s)

Minitran[™]: 0.1 mg/hour (30s); 0.2 mg/hour (30s); 0.4 mg/hour (30s); 0.6 mg/hour (30s)

Nitrek[®]: 0.2 mg/hour (30s); 0.4 mg/hour (30s); 0.6 mg/hour (30s)

Nitro-Dur[®]: 0.1 mg/hour (30s); 0.2 mg/hour (30s); 0.3 mg/hour (30s); 0.4 mg/hour (30s); 0.6 mg/hour (30s); 0.8 mg/hour (30s)

Reference Range Concentrations of 1.2-11.0 ng/mL produce 25% decrease in capillary wedge pressure

Overdosage/Treatment

Supportive therapy: Keep patient recumbent; elevate legs if needed; hypotension is treated with fluids and alpha-adrenergic pressors if needed; methylene blue treatment for symptomatic methemoglobin; if used topically, wipe off area of application

Enhancement of elimination: Forced diuresis may enhance elimination

Antidote(s)

- Methylene Blue [ANTIDOTE]

Diagnostic Procedures

- Methemoglobin, Blood

Test Interactions

↑ catecholamines (U)

Drug Interactions Alteplase (tissue plasminogen activator) has a lesser effect when used with I.V. nitroglycerin; avoid concurrent use.

Ergot alkaloids may cause an increase in blood pressure and decrease in antianginal effects; avoid concurrent use.

Ethanol can cause hypotension when nitrates are taken 1 hour or more after ethanol ingestion.

Heparin's effect may be reduced by I.V. nitroglycerin. May affect only a minority of patients.

Sildenafil, tadalafil, vardenafil: Significant reduction of systolic and diastolic blood pressure with concurrent use (contraindicated). Do not administer sildenafil, tadalafil, or vardenafil within 24 hours of a nitrate preparation.

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/use caution

Nursing Implications I.V. must be prepared in glass bottles and use special sets intended for nitroglycerin; transdermal patches labeled as mg/hour

Additional Information I.V. preparations contain alcohol and/or propylene glycol; may need to use nitrate-free internal (10-12 hours/day) to avoid tolerance development; tolerance may possibly be reversed with acetylcysteine; gradually decrease dose in patients receiving NTG for prolonged period to avoid withdrawal reaction; monitor for ethanol toxicity due to diluent TLV-TWA 0.05 ppm; sweet, burning taste; tablets are not explosive.

Note: Nitroglycerin tabs is a slang for heroin with intravenous nitroglycerin.

It appears that age and serum creatinine levels are inversely associated with development of vascular headache due to nitrates. Risk for headache decreases by ~40% for a 10-year increase in age and is 5 times less likely in patients with serum creatinine levels > 133 μmol/L as opposed to levels < 97 μmol/L.

Lorazepam (2 mg I.V.) and nitroglycerin (I.V. infusion of 2 mg/kg/minute) have been used successfully to treat serotonin syndrome induced by sertraline.

Use of nitroglycerin patch (5 mg/day) near or distal to I.V. cannulation site may prevent intravenous infusion failure due to phlebitis or extravasation in patients requiring long-term (> 50 hours) I.V. therapy.

Nitroprusside

CAS Number 13755-38-9; 14402-89-2

U.S. Brand Names Nitropress[®]

Synonyms Nitroprusside Sodium; Sodium Nitroferricyanide; Sodium Nitroprusside

Use Management of hypertensive crisis especially due to ergotism; congestive heart failure; used for controlled hypotension to reduce bleeding during surgery

Mechanism of Action Causes peripheral vasodilation by direct action on venous and arteriolar smooth muscle, thus reducing peripheral resistance; will increase cardiac output by decreasing afterload; reduces aortal and left ventricular impedance

Adverse Reactions

Cardiovascular: Excessive hypotensive response, palpitations, tachycardia followed by bradycardia, sinus bradycardia, sinus tachycardia, vasodilation

Central nervous system: Restlessness, disorientation, psychosis, intracranial hypertension (increased), headache, delirium

Endocrine & metabolic: Thyroid suppression, hypothyroidism

Gastrointestinal: Nausea, vomiting, adynamic ileus

Hematologic: Thrombocytopenia

Local: Transient phlebitis

Neuromuscular & skeletal: Muscle spasm, weakness

Otic: Ototoxicity, tinnitus

Respiratory: Substernal distress, hypoxia, tachypnea

Miscellaneous: Diaphoresis, thiocyanate toxicity

Signs and Symptoms of Overdose Azotemia, bradycardia, confusion, hyperventilation, hypotension, hypothyroidism, metabolic acidosis, methemoglobinemia, myoclonus, vomiting

Pharmacodynamics/Kinetics

Onset of action: BP reduction < 2 minutes

Duration: 1-10 minutes

Metabolism: Nitroprusside is converted to cyanide ions in the bloodstream; decomposes to prussic acid which in the presence of sulfur donor is converted to thiocyanate (hepatic and renal rhodanase systems)

Half-life elimination: Parent drug: < 10 minutes; Thiocyanate: 2.7-7 days

Excretion: Urine (as thiocyanate)

Dosage

I.V.:

Children: Continuous infusion:

Initial: 1 mcg/kg/minute by continuous I.V. infusion; increase in increments of 1 mcg/kg/minute at intervals of 20-60 minutes; titrating to the desired response

Usual dose: 3 mcg/kg/minute; rarely need > 4 mcg/kg/minute

Maximum (short-term): 10 mcg/kg/minute. Dilute 15 mg × weight (kg) to 250 mL D₅W, then dose in mcg/kg/minute = infusion rate in mL/hour

Adults: Begin at 0.5 mcg/kg/minute; increase in increments of 2-4 mcg/kg/minute (up to 20 mcg/kg/minute), then in increments of 10-20 mcg/kg/minute; titrating to the desired hemodynamic effect or the appearance of headache or nausea. When > 500 mcg/kg is administered by prolonged infusion of > 2 mcg/kg/minute, cyanide is generated faster than an unaided patient can handle.

Cyanide risk for for nitroprusside administration:

Low risk:

Short-term (< 8 hours) administration: 1.5 mg/kg total dose

Long-term (> 8 hours) administration: 2-4 mcg/kg/minute (at a dose of 5-10 mcg/kg/minute, cyanide toxicity can result in 5-10 hours)

Thiocyanide toxicity usually does **not** occur at total nitroprusside doses < 70 mg/kg

Stability Discard solution 24 hours after reconstitution and dilution in D₅W; promptly wrap in aluminum foil or other opaque material to protect from sunlight (incandescent light is safe); reconstituted solution should be very faint brown, discard if highly colored (blue, green or red); store powder in carton until use

Monitoring Parameters Blood pressure, heart rate; monitor for cyanide and thiocyanate toxicity; monitor acid-base status as acidosis can be the earliest sign of cyanide toxicity; monitor thiocyanate levels if requiring prolonged infusion (> 3 days) or dose ≥ 4 mcg/kg/minute or patient has renal dysfunction; monitor cyanide blood levels in patients with decreased hepatic function; cardiac monitor and blood pressure monitor required

Administration I.V. infusion only, not for direct injection

Contraindications Hypersensitivity to nitroprusside or any component of the formulation; treatment of compensatory hypertension (aortic coarctation, arteriovenous shunting); high output failure; congenital optic atrophy or tobacco amblyopia

Warnings [U.S. Boxed Warning]: Continuous blood pressure monitoring is needed. Except when used briefly or at low (< 2 mcg/kg/minute) infusion rates, nitroprusside gives rise to large cyanide quantities. Do not use the maximum dose for more than 10 minutes; if blood pressure not controlled then discontinue infusion. Monitor for cyanide toxicity via acid-base balance and venous oxygen concentration. Use with extreme caution in patients with elevated intracranial pressure. Use extreme caution in patients with hepatic or renal dysfunction. Use the lowest end of the dosage range with renal impairment. Thiocyanate toxicity occurs in patients with renal impairment or those on prolonged infusions. [U.S. Boxed Warning]: Should not be administered by direct injection; must be further diluted with 5% dextrose in water.

Dosage Forms Injection, solution, as sodium: 25 mg/mL (2 mL)

Reference Range

Cyanide levels

Whole blood levels: Smoker: ≤ 0.5 mg/L

Flushing and tachycardia seen at 0.5-1.0 mg/L; obtundation at 1.0-2.5 mg/L

Coma and death occur at > 2.5 mg/L

Can also monitor thiocyanate levels if requiring prolonged infusion (> 4 days) or ≥ 4 mcg/kg/minute; therapeutic: 6-29 mcg/mL (SI: 103-499 μmol/L)

Overdosage/Treatment

Supportive therapy: Thiocyanate toxicity includes psychosis, tremor, delirium, hypothyroidism, hyperreflexia, confusion, asthenia, tinnitus, and coma; no metabolic acidosis is noted with thiocyanate toxicity; cyanide toxicity includes acidosis (decreased HCO_3^- , decreased pH, increased lactate), increase in mixed venous blood oxygen tension, tachycardia, altered consciousness, seizures, and almond smell on breath. Nitroprusside has been shown to release cyanide *in vivo* with hemoglobin. Cyanide toxicity does not usually occur because of the rapid uptake of cyanide by erythrocytes and its eventual incorporation into cyanocobalamin. However, prolonged administration of nitroprusside or its reduced elimination can lead to cyanide intoxication. In these situations, airway support with oxygen therapy is germane, followed closely with antidotal therapy of amyl nitrate perles, sodium nitrate 300 mg I.V. (10 mg/kg for children) and sodium thiosulfate 12.5 g I.V. (1.5 mL/kg for children). Sodium bicarbonate (1 mEq/kg) for treatment of acidosis; hydroxocobalamin or cobalt EDTA (Kelocyanor®) may also be effective against cyanide toxicity. Cyanide toxicity can be prevented by coadministration with hydroxocobalamin (2.4 g or 80 vials of hydroxocobalamin for every 100 mg of nitroprusside) or more practically with coadministration with sodium thiosulfate (1 g of sodium thiosulfate for every 100 mg of nitroprusside). Propranolol can block the effect of rebound hypertension when nitroprusside is discontinued.

Enhancement of elimination: Hemodialysis may be effective when used in conjunction with above therapy

Antidote(s)

- Cyanide Antidote Kit [ANTIDOTE]
- Hydroxocobalamin [ANTIDOTE]

Diagnostic Procedures

- Cyanide, Blood

Drug Interactions None noted

Pregnancy Risk Factor C

Pregnancy Implications May decrease uterine blood flow by 25% to 35%

Lactation Excretion in breast milk unknown

Nursing Implications I.V. infusion only, not for direct injection; protect from light; brownish solution is usable, discard if bluish in color

Additional Information Nitroprusside is converted to cyanide ions by the endothelium in the bloodstream; decomposes to prussic acid which in the presence of sulfur donor is converted to thiocyanate (liver and kidney rhodanase systems); thiocyanate is then renally eliminated

Specific Reference

Devlin JW, Seta ML, Kanji S, et al, "Fenoldopam Versus Nitroprusside for the Treatment of Hypertensive Emergency," *Ann Pharmacother*, 2004, 38(5):755-9.

Nizatidine

CAS Number 76963-41-3

U.S. Brand Names Axid® AR [OTC]; Axid®

Use Treatment and maintenance of duodenal ulcer; meal-induced heartburn

Unlabeled/Investigational Use Part of a multidrug regimen for *H. pylori* eradication to reduce the risk of duodenal ulcer recurrence

Mechanism of Action Nizatidine is an H_2 -receptor antagonist. In healthy volunteers, nizatidine has been effective in suppressing gastric acid secretion induced by pentagastrin infusion or food. Nizatidine reduces gastric acid secretion by 29.4% to 78.4%. This compares with a 60.3% reduction by cimetidine. Nizatidine 100 mg is reported to provide equivalent acid suppression as cimetidine 300 mg. There has been a significant correlation between plasma nizatidine concentrations and gastric acid suppression, although not always reliable. Following a single oral nighttime dose of nizatidine 300 mg, acid suppression has been shown to last at least 10 hours. Although there does appear to be a correlation between acid suppression and ulcer healing, the relationship dose not always hold. The amount of nighttime acid secretion is believed to be an important factor in the development of ulcer disease. Thus, the inhibition of nocturnal acid secretion may be an important consideration in the therapy of duodenal ulcers. In comparison with placebo, nizatidine doses of 150 mg or 300 mg at bedtime reduce nighttime hydrogen ion concentration by 70% and 79% respectively. Cimetidine 800 mg at bedtime and ranitidine 300 mg at bedtime reduce nocturnal acid secretion by 76% and 95% respectively. These differences are not significant.

Adverse Reactions

Cardiovascular: Chest pain, angina, leukocytoclastic vasculitis

Central nervous system: Somnolence, CNS depression, dizziness, headache, delirium

Dermatologic: Urticaria, pruritus, exanthem, cutaneous vasculitis

Endocrine & metabolic: Sexual dysfunction, gynecomastia

Hematologic: Leukocytosis, eosinophilia, thrombocytopenia

Hepatic: Hepatic failure

Neuromuscular & skeletal: Myalgia

Renal: Renal failure

Respiratory: Rhinitis

Miscellaneous: Diaphoresis, anaphylaxis

Signs and Symptoms of Overdose Dyspepsia, impotence, muscular tremors, rapid respiration, vomiting

Pharmacodynamics/Kinetics

Distribution: V_d : 0.8-1.5 L/kg

Protein binding: 35% to α_1 -acid glycoprotein

Metabolism: Partially hepatic; forms metabolites

Bioavailability: >70%

Half-life elimination: 1-2 hours; prolonged with renal impairment

Time to peak, plasma: 0.5-3.0 hours

Excretion: Urine (90%; ~60% as unchanged drug); feces (<6%)

Dosage

Adults: Active duodenal ulcer: Oral:

Treatment: 300 mg at bedtime or 150 mg twice daily

Maintenance: 150 mg/day

Meal-induced heartburn: 75 mg before meals twice daily

Dosing adjustment in renal impairment:

Cl_{cr} 50-80 mL/minute: Administer 75% of normal dose

Cl_{cr} 10-50 mL/minute: Administer 50% of normal dose or 150 mg/day for active treatment and 150 mg every other day for maintenance treatment

Cl_{cr} < 10 mL/minute: Administer 25% of normal dose or 150 mg every other day for treatment and 150 mg every 3 days for maintenance treatment

Contraindications Hypersensitivity to nizatidine or any component of the formulation; hypersensitivity to other H_2 antagonists (cross-sensitivity has been observed)

Warnings Use with caution in children < 12 years of age; use with caution in patients with liver and renal impairment; dosage modification required in patients with renal impairment

Dosage Forms Capsule (Axid®): 150 mg, 300 mg

Solution, oral (Axid®): 15 mg/mL (120 mL, 480 mL) [bubble gum flavor]

Tablet (Axid® AR): 75 mg

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Treatment is primarily symptomatic and supportive

Enhancement of elimination: Multiple dosing of activated charcoal may be useful

Test Interactions

False-positive urine protein using Multistix®, gastric acid secretion test, skin test allergen extracts, serum creatinine, and serum transaminase concentrations

Drug Interactions Inhibits 3A4 (weak)

Antifungal agents (imidazole): Nizatidine may decrease the absorption of itraconazole or ketoconazole.

Pregnancy Risk Factor C

Pregnancy Implications No animal teratogenic effects at 1500 mg/kg/day

Lactation Enters breast milk/may be compatible

Nursing Implications Giving dose at 6 PM may better suppress nocturnal acid secretion than 10 PM

Additional Information LD_{50} : ~80 mg/kg

Specific Reference

Morisset M, Moneret-Vautrin DA, Loppinet V, et al, "Cross-Allergy to Ranitidine and Nizatidine," *Allergy*, 2000, 55(7):682-3.

Norfloxacin

CAS Number 70458-96-7

U.S. Brand Names Noroxin®

Use Uncomplicated urinary tract infections and cystitis caused by susceptible gram-negative and gram-positive bacteria; sexually-transmitted disease (eg, uncomplicated urethral and cervical gonorrhea) caused by *N. gonorrhoeae*; prostatitis due to *E. coli*

Mechanism of Action Norfloxacin is a DNA gyrase inhibitor. DNA gyrase is an essential bacterial enzyme that maintains the superhelical structure of DNA. DNA gyrase is required for DNA replication and transcription, DNA repair, recombination, and transposition; bactericidal

Adverse Reactions

Cardiovascular: Vasculitis

Central nervous system: Anxiety, ataxia, confusion, depression, dizziness, exacerbation of myasthenia gravis, fever, Guillain-Barré syndrome, headache, insomnia, psychotic reactions, seizures, somnolence, Dermatologic: Angioedema, erythema, erythema multiforme, exfoliative dermatitis, photosensitivity, pruritus, rash, toxic epidermal necrolysis, Stevens-Johnson syndrome, urticaria

Endocrine & metabolic: Hyperhidrosis

Gastrointestinal: Abdominal pain, anorexia, bitter taste, constipation, diarrhea, dysgeusia, dyspepsia, flatulence, GI bleeding, heartburn, loose stools, nausea, pancreatitis, pseudomembranous colitis, vomiting, xerostomia

Hematologic: Hemolytic anemia (sometimes associated with G6PD deficiency), leukopenia, neutropenia, thrombocytopenia

NORTRIPTYLINE

Hepatic: Cholestatic jaundice, hepatitis, increased transaminases, jaundice

Neuromuscular & skeletal: Arthritis, arthralgia, back pain, myalgia, myoclonus, paresthesias, peripheral neuropathy, tremor, weakness; quinolones have been associated with tendonitis and tendon rupture

Ocular: Diplopia

Otic: Tinnitus, transient hearing loss

Renal: Acute renal failure, increased serum creatinine/BUN

Respiratory: Dyspnea

Miscellaneous: Anaphylactoid reactions

Pharmacodynamics/Kinetics

Absorption: Oral: Rapid, up to 40%

Distribution: Crosses placenta; small amounts enter breast milk

Protein binding: 15%

Metabolism: Hepatic

Half-life elimination: 3-4 hours; Renal impairment ($Cl_{cr} \leq 30$ mL/minute): 6.5 hours; Elderly: 4 hours

Time to peak, serum: 1-2 hours

Excretion: Urine (26% to 36%); feces (30%)

Dosage

Oral: Adults:

Urinary tract infections: 400 mg twice daily for 3-21 days depending on severity of infection or organism sensitivity; maximum: 800 mg/day

Uncomplicated gonorrhea: 800 mg as a single dose (CDC recommends as an alternative regimen to ciprofloxacin or ofloxacin)

Prostatitis: 400 mg every 12 hours for 4 weeks

Dosing interval in renal impairment: Cl_{cr} 10-30 mL/minute: Urinary tract infections: Administer 400 mg every 24 hours

Administration Hold antacids or sucralfate for 3-4 hours after giving norfloxacin; do not administer together. Best taken on an empty stomach with water (1 hour before or 2 hours after meals, milk, or other dairy products).

Contraindications Hypersensitivity to norfloxacin, quinolones, or any component of the formulation

Warnings Concurrent disease:

- Renal impairment: Use caution with renal impairment.
- Myasthenia gravis: Quinolones may exacerbate myasthenia gravis, use with caution (rare, potentially life-threatening weakness of respiratory muscles may occur).
- G6PD deficiency: Use caution in patients with glucose-6-phosphate dehydrogenase deficiency.

Key adverse reactions:

- Allergic reactions: Severe hypersensitivity reactions, including anaphylaxis, have occurred with quinolone therapy. If an allergic reaction occurs (itching, urticaria, dyspnea, facial edema, loss of consciousness, tingling, cardiovascular collapse), discontinue drug immediately.
- Tendon rupture: Tendon inflammation and/or rupture have been reported with norfloxacin and other quinolone antibiotics. Risk may be increased with concurrent corticosteroids, particularly in the elderly. Discontinue at first sign of tendon inflammation or pain.
- CNS effects: CNS stimulation may occur which may lead to tremor, restlessness, confusion, and very rarely to hallucinations or convulsive seizures. Potential for seizures, although very rare, may be increased with concomitant NSAID therapy. Use with caution in individuals at risk of seizures.
- QT_c prolongation: Use may be associated (rarely) with prolongation of QT_c interval; avoid concurrent use with class Ia and class III antiarrhythmics; use caution with other drugs which may cause QT_c prolongation.
- Photosensitization: Avoid excessive exposure to sunlight; other quinolones have been associated with phototoxicity.
- Neuropathy/paresthesia: May be associated with the development of peripheral neuropathy and/or paresthesias; discontinue in patients who develop symptoms consistent with neuropathy.
- Developmental effects: Not recommended in children <18 years of age; other quinolones have caused transient arthropathy in children; use with caution in patients with known or suspected CNS disorders.
- Superinfection: Prolonged use may result in superinfection; pseudomembranous colitis may occur and should be considered in all patients who present with diarrhea.

Dosage Forms Tablet: 400 mg

Reference Range Following a 400 mg oral dose, peak serum and urine levels: ~1.5 mcg/mL and >200 mcg/mL, respectively

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Do **not** use flumazenil; diazepam, phenobarbital, or phenytoin can be used for seizures

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; only small amounts of ciprofloxacin are removed by dialysis (<10%)

Drug Interactions Inhibits CYP1A2 (strong), 3A4 (moderate)

Corticosteroids: Concurrent use may increase the risk of tendon rupture, particularly in elderly patients (overall incidence rare).

Cyclosporine: Norfloxacin may increase serum cyclosporine concentrations; monitor

CYP1A2 substrates: Norfloxacin may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, fluvoxamine, mexiletine, mirtazapine, ropinirole, and trifluoperazine.

CYP3A4 substrates: Norfloxacin may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Glyburide: Quinolones may increase the effect of glyburide; monitor.

Metal cations (aluminum, calcium, iron, magnesium, and zinc) bind quinolones in the gastrointestinal tract and inhibit absorption. Concurrent administration of most antacids, oral electrolyte supplements, quinapril, sucralfate, some didanosine formulations (chewable/buffered tablets and pediatric powder for oral suspension), and other highly-buffered oral drugs, should be avoided. Norfloxacin should be administered 4 hours before or 8 hours after these agents.

Nitrofurantoin: May antagonize the activity of norfloxacin in treating UTIs. Probenecid: May decrease renal secretion of norfloxacin.

QT_c-prolonging agents: Effects may be additive with norfloxacin. Avoid concurrent use with Class Ia and Class III antiarrhythmics; use caution with other drugs known to prolong QT_c, including erythromycin, cisapride, antipsychotics, and cyclic antidepressants.

Theophylline: Norfloxacin may increase serum levels/effects of theophylline; monitor.

Warfarin: The hypoprothrombinemic effect of warfarin may be enhanced by some quinolone antibiotics; monitor INR.

Pregnancy Risk Factor C

Pregnancy Implications Reports of arthropathy (observed in immature animals and reported rarely in humans) have limited the use of fluoroquinolones in pregnancy. Teratogenic effects have not been reported with norfloxacin in animal studies; however, embryonic loss has been reported with one species. Norfloxacin crosses the placenta. The Teratogen Information System concluded that therapeutic doses during pregnancy are unlikely to produce substantial teratogenic risk, but data are insufficient to say that there is no risk. There are no adequate and well-controlled studies in pregnant women. When considering treatment for life-threatening infection and/or prolonged duration of therapy, the potential risk to the fetus must be balanced against the severity of the potential illness.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Hold antacids, sucralfate for 3-4 hours after giving

Specific Reference

Sahin MT, Ozturkcan S, Inanir I, et al, "Norfloxacin-Induced Toxic Epidermal Necrolysis," *Ann Pharmacother*, 2005, 39(4):768-70.

Nortriptyline

Related Information

- Anticholinergic Effects of Common Psychotropics

CAS Number 72-69-5; 894-71-3

U.S. Brand Names Aventyl® HCl; Pamelor®

Synonyms Nortriptyline Hydrochloride

Impairment Potential Yes

Use Treatment of symptoms of depression

Unlabeled/Investigational Use Chronic pain, anxiety disorders, enuresis, attention-deficit/hyperactivity disorder (ADHD); adjunctive therapy for smoking cessation

Mechanism of Action Increases the synaptic concentration of serotonin and/or norepinephrine in the central nervous system by inhibition of their reuptake by the presynaptic neuronal membrane

Adverse Reactions

Cardiovascular: Postural hypotension, cardiac arrhythmias, tachycardia, sudden death, bundle branch block, sinus tachycardia, tachycardia (supraventricular), torsade de pointes, exacerbation of Brugada syndrome

Central nervous system: **Dizziness, drowsiness, headache**, sedation, restlessness, fatigue, anxiety, psychosis, impaired cognitive function, and seizures have occurred occasionally, extrapyramidal reactions, neuroleptic malignant syndrome

Dermatologic: Alopecia, purpura, pruritus, exanthem

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone, gynecomastia

Gastrointestinal: **Xerostomia, increased appetite, nausea, unpleasant taste, weight gain, constipation**, adynamic ileus, Ogilvie's syndrome, stomatitis, lingua villosa nigra

Genitourinary: Urinary retention

Hematologic: Rarely agranulocytosis, eosinophilia, porphyria

Hepatic: Jaundice, liver failure

Neuromuscular & skeletal: **Weakness**, tremors, clonus, myoclonus, paresthesia

Ocular: Blurred vision, photophobia, increased intraocular pressure, mydriasis, nystagmus, phototoxic

Renal: Renal vasculitis

Respiratory: Hyperventilation

Miscellaneous: Allergic reactions

Signs and Symptoms of Overdose Agitation, agranulocytosis, AV block, bone marrow depression, coma, confusion, delirium, dementia, dental erosion, depression, dysphagia, ejaculatory disturbances, granulocytopenia, heart block, hyperthermia, hypoglycemia, hyponatremia, hypotension, hypothermia, impotence, insomnia, increased intraocular pressure, leukopenia, mania, memory loss, neutropenia, night terrors, photosensitivity, P-R prolongation, pulmonary edema, QRS prolongation, QT prolongation, respiratory depression, seizures (within 3 hours of ingestion), tachycardia, thrombocytopenia, urinary retention, visual hallucinations. QRS interval > 0.12 seconds may indicate significant toxicity.

Admission Criteria/Prognosis Admit any patient who is symptomatic 6 hours postingestion; admit any pediatric ingestion > 5 mg/kg

Pharmacodynamics/Kinetics

Onset of action: Therapeutic: 1-3 weeks

Distribution: V_d : 21 L/kg

Protein binding: 93% to 95%

Metabolism: Primarily hepatic; extensive first-pass effect

Half-life elimination: 28-31 hours

Time to peak, serum: 7-8.5 hours

Excretion: Urine (as metabolites and small amounts of unchanged drug); feces (small amounts)

Dosage Oral:

Nocturnal enuresis:

Children:

6-7 years (20-25 kg): 10 mg/day

8-11 years (25-35 kg): 10-20 mg/day

> 11 years (35-54 kg): 25-35 mg/day

Depression or ADHD (unlabeled use):

Children 6-12 years: 1-3 mg/kg/day or 10-20 mg/day in 3-4 divided doses

Adolescents: 30-100 mg/day in divided doses

Depression:

Adults: 25 mg 3-4 times/day up to 150 mg/day

Elderly (**Note:** Nortriptyline is one of the best tolerated TCAs in the elderly)

Initial: 10-25 mg at bedtime

Dosage can be increased by 25 mg every 3 days for inpatients and weekly for outpatients if tolerated

Usual maintenance dose: 75 mg as a single bedtime dose or 2 divided doses; however, lower or higher doses may be required to stay within the therapeutic window

Dosing adjustment in hepatic impairment: Lower doses and slower titration dependent on individualization of dosage is recommended

Stability

Protect from light

Monitoring Parameters Blood pressure and pulse rate (ECG, cardiac monitoring) prior to and during initial therapy in older adults; weight; blood levels are useful for therapeutic monitoring

Contraindications Hypersensitivity to nortriptyline and similar chemical class, or any component of the formulation; use of MAO inhibitors within 14 days; use in a patient during the acute recovery phase of MI; pregnancy

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. **Nortriptyline is not FDA approved for use in children.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for

the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Nortriptyline is not FDA approved for the treatment of bipolar depression.**

May cause sedation, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Sedative effects may be additive with other CNS depressants and/or ethanol. The degree of sedation is low-moderate relative to other antidepressants. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Therapy should not be abruptly discontinued in patients receiving high doses for prolonged periods. May alter glucose regulation - use caution in patients with diabetes.

May cause orthostatic hypotension (risk is low relative to other antidepressants) - use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). The degree of anticholinergic blockade produced by this agent is moderate relative to other cyclic antidepressants, however, caution should still be used in patients with urinary retention, benign prostatic hyperplasia, narrow-angle glaucoma, xerostomia, visual problems, constipation, or history of bowel obstruction.

Use with caution in patients with a history of cardiovascular disease (including previous MI, stroke, tachycardia, or conduction abnormalities). The risk conduction abnormalities with this agent is moderate relative to other antidepressants. Use caution in patients with a previous seizure disorder or condition predisposing to seizures such as brain damage, alcoholism, or concurrent therapy with other drugs which lower the seizure threshold. Use with caution in hyperthyroid patients or those receiving thyroid supplementation. Use with caution in patients with hepatic or renal dysfunction and in elderly patients.

Dosage Forms Capsule, as hydrochloride: 10 mg, 25 mg, 50 mg, 75 mg Pamelor[®]: 10 mg, 25 mg, 50 mg, 75 mg [may contain benzyl alcohol; 50 mg may also contain sodium bisulfite]

Solution, as hydrochloride (Pamelor[®]): 10 mg/5 mL (473 mL) [contains alcohol 4% and benzoic acid]

Reference Range

Therapeutic: 50-150 ng/mL (SI: 190-570 nmol/L)

Toxic: > 500 ng/mL (SI: > 1900 nmol/L)

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: Lavage within 3 hours/activated charcoal; multiple dosing of activated charcoal would be expected to be useful to decontaminate gut adequately

Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated. Ventricular arrhythmias and ventricular conduction defects often respond to concurrent systemic alkalization (sodium bicarbonate 0.5-2 mEq/kg I.V.). Titrate to a serum pH of 7.45-7.55. Arrhythmias unresponsive to this therapy may respond to lidocaine 1 mg/kg I.V. followed by a titrated infusion. Phenytoin is also useful in treating ventricular dysrhythmias (15 mg/kg up to 1 g I.V.). Physostigmine (1-2 mg I.V. slowly for adults or 0.5 mg I.V. slowly for children) may be indicated for seizures or movement disorders but only as a **last resort**. Propranolol may also be utilized for supraventricular arrhythmias (rate: >160) at 1 mg/minute to a maximum of 5 mg in adults; pediatric dosage of 0.1 mg/kg/dose to 1 mg I.V.. Seizures usually respond to lorazepam or diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required. Patients must be monitored for at least 24 hours if any signs or symptoms are exhibited. Dobutamine is preferred over dopamine for hypotension, although there is conflicting animal data. Norepinephrine appears effective in treating hypotension; glucagon (10 mg I.V.) can be given to treat hypotension. Flumazenil is contraindicated; magnesium has potentiated adverse cardiac effects (ie, asystole, decreased left ventricular pressure) in an animal model, although it was used successfully in treating refractory ventricular fibrillation at a dose of 20 nmol I.V. (a total of 2 doses). For treatment of lingua villosa nigra, discontinue causative agent. Clean the tongue with a toothbrush and rinse mouth with a half-strength solution of hydrogen peroxide or 10% carbamide peroxide. Oral symptoms should subside in a few days. Hypertonic saline (200 mL of 7.5% sodium chloride I.V. push) can improve antidepressant-induced cardiotoxicity that is **not** responding to other therapies.

TCA ovine antibody fragments (TCA Fab, Protherics Inc) have been developed and used investigational at a dose of 1-2 g over 30 minutes I.V.; if QRS was >100 msec or terminal deflection of QRS in lead aVR was >3 mm, a second dose (2 g over 30 min or 4 g over 1 hour) was given. If no response, a third infusion (4 g over 60 minutes or 8 g over 2 hours) was given.

Enhanced elimination: Multiple dosing of activated charcoal may be effective

Antidote(s)

- Sodium Bicarbonate [ANTIDOTE]

Diagnostic Procedures

- Nortriptyline, Blood

Test Interactions Increases glucose; increases plasma norepinephrine levels and plasma epinephrine levels threefold to fivefold; EMIT assays may be false-positive in the presence of diphenhydramine, thioridazine, chlorpromazine, alimemazine, carbamazepine, cyclobenzaprine, or perphenazine

Drug Interactions Substrate of CYP1A2 (minor), 2C19 (minor), 2D6 (major), 3A4 (minor); **Inhibits** CYP2D6 (weak), 2E1 (weak)

Altreptamine: Concurrent use may cause orthostatic hypertension

Amphetamines: TCAs may enhance the effect of amphetamines; monitor for adverse CV effects

Anticholinergics: Combined use with TCAs may produce additive anticholinergic effects

Antihypertensives: TCAs may inhibit the antihypertensive response to bethanidine, clonidine, debrisoquin, guanadrel, guanethidine, guanabenz, guanfacine; monitor BP; consider alternate antihypertensive agent

Beta-agonists: When combined with TCAs may predispose patients to cardiac arrhythmias

Bupropion: May increase the levels of tricyclic antidepressants; based on limited information; monitor response

Carbamazepine: Tricyclic antidepressants may increase carbamazepine levels; monitor

Cholestyramine and colestipol: May bind TCAs and reduce their absorption; monitor for altered response

Clonidine: Abrupt discontinuation of clonidine may cause hypertensive crisis, amitriptyline may enhance the response

CNS depressants: Sedative effects may be additive with TCAs; monitor for increased effect; includes benzodiazepines, barbiturates, antipsychotics, ethanol and other sedative medications

CYP2D6 inhibitors: May increase the levels/effects of nortriptyline. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Epinephrine (and other direct alpha-agonists): Pressor response to I.V. epinephrine, norepinephrine, and phenylephrine may be enhanced in patients receiving TCAs (**Note:** Effect is unlikely with epinephrine or levonordefrin dosages typically administered as infiltration in combination with local anesthetics)

Fenfluramine: May increase tricyclic antidepressant levels/effects

Hypoglycemic agents (including insulin): TCAs may enhance the hypoglycemic effects of tolazamide, chlorpropamide, or insulin; monitor for changes in blood glucose levels; reported with chlorpropamide, tolazamide, and insulin

Levodopa: Tricyclic antidepressants may decrease the absorption (bioavailability) of levodopa; rare hypertensive episodes have also been attributed to this combination

Linezolid: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** with agents which inhibit MAO (serotonin syndrome); this combination should be avoided

Lithium: Concurrent use with a TCA may increase the risk for neurotoxicity

MAO inhibitors: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** (serotonin syndrome); this combination should be avoided

Methylphenidate: Metabolism of TCAs may be decreased

Phenothiazines: Serum concentrations of some TCAs may be increased; in addition, TCAs may increase concentration of phenothiazines; monitor for altered clinical response

QT_c-prolonging agents: Concurrent use of tricyclic agents with other drugs which may prolong QT_c interval may increase the risk of potentially fatal arrhythmias; includes type Ia and type III antiarrhythmics agents, selected quinolones (sparfloxacin, gatifloxacin, moxifloxacin, grepafloxacin), cisapride, and other agents

Ritonavir: Combined use of high-dose tricyclic antidepressants with ritonavir may cause serotonin syndrome in HIV-positive patients; monitor

Sucralfate: Absorption of tricyclic antidepressants may be reduced with coadministration

Sympathomimetics, indirect-acting: Tricyclic antidepressants may result in a decreased sensitivity to indirect-acting sympathomimetics; includes dopamine and ephedrine; also see interaction with epinephrine (and direct-acting sympathomimetics)

Tramadol: Tramadol's risk of seizures may be increased with TCAs
Valproic acid: May increase serum concentrations/adverse effects of some tricyclic antidepressants

Warfarin (and other oral anticoagulants): TCAs may increase the anticoagulant effect in patients stabilized on warfarin; monitor INR

Pregnancy Risk Factor D

Lactation Enters breast milk/contraindicated (AAP rates "of concern")

Nursing Implications Offer patient sugarless hard candy for dry mouth

Additional Information Maximum antidepressant effect may not be seen for 2 or more weeks after initiation of therapy

Nystatin

CAS Number 1400-61-9

U.S. Brand Names Bio-Statin®; Mycostatin®; Nystat-Rx®; Nystop®; Pedi-Dri®

Use Treatment of susceptible cutaneous, mucocutaneous, and oral cavity fungal infections normally caused by the *Candida* species

Mechanism of Action Binds to sterols in fungal cell membrane, changing the cell wall permeability allowing for leakage of cellular contents

Adverse Reactions

Dose of 10,000,000/day can produce mild nausea

Dermatologic: Contact dermatitis, systemic contact dermatitis, Stevens-Johnson syndrome, acute generalized exanthematous pustulosis, urticaria, pruritus, exanthem

Gastrointestinal: Nausea, vomiting, diarrhea

Local: Irritation

Respiratory: Cough, wheezing

Miscellaneous: Fixed drug eruption

Signs and Symptoms of Overdose Diarrhea, nausea, vomiting, wheezing

Pharmacodynamics/Kinetics

Onset of action: Symptomatic relief from candidiasis: 24-72 hours

Absorption: Topical: None through mucous membranes or intact skin;

Oral: Poorly absorbed

Excretion: Feces (as unchanged drug)

Dosage

Oral candidiasis: Suspension (swish and swallow orally):

Neonates: 100,000 units 4 times/day or 50,000 units to each side of mouth 4 times/day

Infants: 200,000 units 4 times/day or 100,000 units to each side of mouth 4 times/day

Children and Adults: 400,000-600,000 units 4 times/day; troche: 200,000-400,000 units 4-5 times/day

Mucocutaneous infections: Children and Adults: Topical: Apply 2-3 times/day to affected areas; very moist topical lesions are treated best with powder

Intestinal infections: Adults: Oral tablets: 500,000-1,000,000 units every 8 hours

Vaginal infections: Adults: Vaginal tablets: Insert 1 tablet/day at bedtime for 2 weeks

Stability Keep vaginal inserts in refrigerator; protect from temperature extremes, moisture and light

Administration

Suspension: Shake well before using. Should be swished about the mouth and retained in the mouth for as long as possible (several minutes) before swallowing.

Contraindications Hypersensitivity to nystatin or any component of the formulation

Dosage Forms

Capsule (Bio-Statin®): 500,000 units, 1 million units

Cream: 100,000 units/g (15 g, 30 g)

Mycostatin®: 100,000 units/g (30 g)

Ointment, topical: 100,000 units/g (15 g, 30 g)

Powder, for prescription compounding: 50 million units (10 g); 150 million units (30 g); 500 million units (100 g); 2 billion units (400 g)
 Nystat-Rx®: 50 million units (10 g); 150 million units (30 g); 500 million units (100 g); 1 billion units (190 g); 2 billion units (350 g)
 Powder, topical:
 Mycostatin®: 100,000 units/g (15 g)
 Nyamyc™: 100,000 units/g (15 g, 30 g)
 Nystop®: 100,000 units/g (15 g, 30 g, 60 g)
 Pedi-Dri®: 100,000 units/g (56.7 g)
 Suspension, oral: 100,000 units/mL (5 mL, 60 mL, 480 mL)
 Tablet: 500,000 units
 Tablet, vaginal: 100,000 units (15s) [packaged with applicator]

Reference Range A dose of 2,700,000 units/kg produces a plasma level of 9.8 units/mL; mean salivary levels were 1000 units/mL 2 hours after dissolution of 2 nystatin pastilles (400,000 units)

Overdosage/Treatment Supportive therapy: General poison management

Drug Interactions No data reported

Pregnancy Risk Factor B/C (oral)

Lactation Does not enter breast milk/compatible (not absorbed orally)

Additional Information Very moist topical lesions are best treated with powder.

Ofloxacin

CAS Number 83380-47-6

U.S. Brand Names Floxin®; Ocuflor®

Synonyms Floxin Otic Singles

Use Quinolone antibiotic for skin and skin structure, lower respiratory, and urinary tract infections and sexually-transmitted diseases. Active against many gram-positive and gram-negative aerobic bacteria.

Ophthalmic: Treatment of superficial ocular infections involving the conjunctiva or cornea due to strains of susceptible organisms

Otic: Otitis externa, chronic suppurative otitis media, acute otitis media

Epididymitis (gonorrhea), leprosy, Traveler's diarrhea

Mechanism of Action Ofloxacin, a fluorinated quinolone, is a pyridone carboxylic acid derivative which exerts a broad spectrum antimicrobial effect. The primary target of the fluoroquinolones is DNA gyrase (topoisomerase II) an essential bacterial enzyme that maintains the superhelical structure of DNA. DNA gyrase is required for DNA replication and transcription, DNA repair, recombination, and transposition.

Adverse Reactions

Systemic:

Cardiovascular: Chest pain, syncope, vasculitis, edema, hypertension, palpitations, vasodilation, vasculitis

Central nervous system: Headache, insomnia, dizziness, fatigue, somnolence, sleep disorders, nervousness, pyrexia, pain, seizures, anxiety, cognitive changes, depression, dream abnormality, euphoria, hallucinations, vertigo, chills, malaise, Tourette's syndrome

Dermatologic: Rash/pruritus, Stevens-Johnson syndrome, photosensitivity

Gastrointestinal: Diarrhea, vomiting, GI distress, cramps, abdominal cramps, flatulence, abnormal taste, xerostomia, decreased appetite, nausea, weight loss

Genitourinary: Vaginitis, external genital pruritus in women

Hepatic: Hepatitis

Local: Pain at injection site

Neuromuscular & skeletal: Paresthesia, extremity pain, weakness; quinolones have been associated with tendonitis and tendon rupture

Ocular: Superinfection (ophthalmic), photophobia, lacrimation, dry eyes, stinging, visual disturbances

Otic: Decreased hearing acuity, tinnitus

Renal: Interstitial nephritis

Respiratory: Cough

Miscellaneous: Trunk pain, thirst

Ophthalmic:

Frequency not defined:

Central nervous system: Dizziness

Gastrointestinal: Nausea

Ocular: Blurred vision, burning, chemical conjunctivitis/keratitis, discomfort, dryness, edema, eye pain, foreign body sensation, itching, photophobia, redness, stinging, tearing

Otic:

Central nervous system: Dizziness, transient neuropsychiatric disturbances, vertigo

Dermatologic: Pruritus, rash

Gastrointestinal: Taste perversion

Neuromuscular & skeletal: Paresthesia

Otic: Application site reaction, earache

Signs and Symptoms of Overdose Nausea, photosensitivity, pseudotumor cerebri, seizures, vomiting

Pharmacodynamics/Kinetics

Absorption: Well absorbed; food causes only minor alterations

Distribution: V_d : 2.4-3.5 L/kg

Protein binding: 20%

Bioavailability: Oral: 98%

Half-life elimination: Biphasic: 5-7.5 hours and 20-25 hours (accounts for <5%); prolonged with renal impairment

Excretion: Primarily urine (as unchanged drug)

Dosage

Oral, I.V.: Adults:

Lower respiratory tract infection: 400 mg every 12 hours for 10 days

Epididymitis (gonorrhea): 300 mg twice daily for 10 days

Cervicitis due to *C. trachomatis* and/or *N. gonorrhoeae*: 300 mg every 12 hours for 7 days

Skin/skin structure: 400 mg every 12 hours for 10 days

Urinary tract infection: 200-400 mg every 12 hours for 3-10 days

Prostatitis: 300 mg every 12 hours for 6 weeks

Ophthalmic: Children > 1 year and Adults:

Conjunctivitis: Instill 1-2 drops in affected eye(s) every 2-4 hours for the first 2 days, then use 4 times/day for an additional 5 days

Corneal ulcer: Instill 1-2 drops every 30 minutes while awake and every 4-6 hours after retiring for the first 2 days; beginning on day 3, instill 1-2 drops every hour while awake for 4-6 additional days; thereafter, 1-2 drops 4 times/day until clinical cure.

Otic:

Acute otitis media with tympanostomy tubes: Children 1-12 years: Instill 5 drops into affected ear(s) twice daily for 10 days

Chronic suppurative otitis media with perforated tympanic membranes: Children > 12 years and Adults: 10 drops into affected ear twice daily for 14 days

Otitis externa:

Children 6 months to 13 years: Instill 5 drops into affected ear(s) once daily for 7 days

Children ≥ 13 years and Adults: Instill 10 drops into affected ear(s) once daily for 7 days

Dosing adjustment/interval in renal impairment: Adults: I.V., Oral:

Cl_{cr} 10-50 mL/minute: Administer 200-400 mg every 24 hours

Cl_{cr} < 10 mL/minute: Administer 100-200 mg every 24 hours

Continuous arteriovenous or venovenous hemodiafiltration effects: Administer 300 mg every 24 hours

Administration I.V.: Administer over at least 60 minutes. Infuse separately. Do not infuse through lines containing solutions with magnesium or calcium.

Ophthalmic: For ophthalmic use only; avoid touching tip of applicator to eye or other surfaces.

Oral: Do not take within 2 hours of food or any antacids which contain zinc, magnesium, or aluminum.

Otic: Prior to use, warm solution by holding bottle in hands for 1-2 minutes. Patient should lie down with affected ear upward and medication instilled. Pump tragus 4 times to ensure penetration of medication. Patient should remain in this position for 5 minutes.

Contraindications Hypersensitivity to ofloxacin or other members of the quinolone group such as nalidixic acid, oxolinic acid, cinoxacin, norfloxacin, and ciprofloxacin; hypersensitivity to any component of the formulation

Warnings

Use with caution in patients with epilepsy or other CNS diseases which could predispose seizures; potential for seizures, although very rare, may be increased with concomitant NSAID therapy. Use with caution in patients with renal or hepatic impairment. Tendon inflammation and/or rupture have been reported with quinolone antibiotics, including ofloxacin. Risk may be increased with concurrent corticosteroids, particularly in the elderly. Discontinue at first sign of tendon inflammation or pain. Peripheral neuropathies have been linked to ofloxacin use; discontinue if numbness, tingling, or weakness develops.

Rare cases of torsade de pointes have been reported in patients receiving ofloxacin and other quinolones. Risk may be minimized by avoiding use in patients with known prolongation of the QT interval, bradycardia, hypokalemia, hypomagnesemia, cardiomyopathy, or in those receiving concurrent therapy with Class Ia or Class III antiarrhythmics.

Severe hypersensitivity reactions, including anaphylaxis, have occurred with quinolone therapy. If an allergic reaction occurs (itching, urticaria, dyspnea, facial edema, loss of consciousness, tingling, cardiovascular collapse), discontinue drug immediately. Prolonged use may result in superinfection; pseudomembranous colitis may occur and should be considered in all patients who present with diarrhea. Quinolones may exacerbate myasthenia gravis, use with caution (rare, potentially life-threatening weakness of respiratory muscles may occur).

Dosage Forms

[DSC] = Discontinued product

Solution, ophthalmic (Ocuflor®): 0.3% (5 mL; 10 mL [DSC]) [contains benzalkonium chloride]

Solution, otic:

Floxin®: 0.3% (5 mL, 10 mL) [contains benzalkonium chloride]

OLANZAPINE

Floxin[®] Otic Singles™: 0.3% (0.25 mL) [contains benzalkonium chloride; packaged as 2 single-dose containers per pouch, 10 pouches per carton, total net volume 5 mL]

Tablet (Floxin[®]): 200 mg, 300 mg, 400 mg

Reference Range Overdose of 3 g ofloxacin (I.V.) yielded a peak plasma level of 39.3 mcg/mL (patient had been administered 400 mg I.V. every 12 hours for 3 days previously)

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Phenytoin has been used successfully in treatment of ofloxacin-induced seizure

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; not removed by dialysis

Test Interactions Can give a false-positive result for opiates by urine immunoassay screening

Drug Interactions

Inhibits CYP1A2 (strong)

Corticosteroids: Concurrent use may increase the risk of tendon rupture, particularly in elderly patients (overall incidence rare).

CYP1A2 substrates: Ofloxacin may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, fluvoxamine, mexiletine, mirtazapine, ropinirole, and trifluoperazine.

Glyburide: Quinolones may increase the effect of glyburide; monitor.

Metal cations (aluminum, calcium, iron, magnesium, and zinc) bind quinolones in the gastrointestinal tract and inhibit absorption. Concurrent administration of most antacids, oral electrolyte supplements, quinapril, sucralfate, some didanosine formulations (chewable/buffered tablets and pediatric powder for oral suspension), and other highly-buffered oral drugs, should be avoided. Ofloxacin should be administered 2 hours before or 2 hours after these agents.

Probenecid: May decrease renal secretion of ofloxacin.

QT_c-prolonging agents: Effects may be additive with ofloxacin. Avoid concurrent use with Class Ia and Class III antiarrhythmics; use caution with other drugs known to prolong QT_c, including erythromycin, cisapride, antipsychotics, and cyclic antidepressants.

Theophylline: Ofloxacin may increase plasma levels of theophylline. Monitor.

Warfarin: The hypoprothrombinemic effect of warfarin may be enhanced by some quinolone antibiotics; monitor INR.

Pregnancy Risk Factor C

Pregnancy Implications Reports of arthropathy (observed in immature animals and reported rarely in humans) have limited the use of fluoroquinolones in pregnancy. According to the FDA, the Teratogen Information System concluded that therapeutic doses during pregnancy are unlikely to produce substantial teratogenic risk, but data are insufficient to say that there is no risk. In general, reports of exposure have been limited to short durations of therapy in the first trimester. When considering treatment for life-threatening infection and/or prolonged duration of therapy, the potential risk to the fetus must be balanced against the severity of the potential illness.

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Olanzapine

Related Information

- Antipsychotic Agents

CAS Number 132539-06-1

U.S. Brand Names Zyprexa[®] Zydys[®]; Zyprexa[®]

Synonyms LY170053; Zyprexa Zydys

Impairment Potential Yes

Use Treatment of the manifestations of schizophrenia; treatment of acute mania episodes associated with bipolar disorder (as monotherapy or in combination with lithium or valproate); maintenance treatment of bipolar disorder; acute agitation (patients with schizophrenia or bipolar mania)

Unlabeled/Investigational Use Treatment of psychotic symptoms; chronic pain

Mechanism of Action A thienobenzodiazepine with properties similar to clozapine; exact mechanism of action is unknown; olanzapine acts primarily as a dopamine (D₁, D₂, D₄ and D₅) and 5HT₂ antagonist; also inhibits serotonin type 3 and 6, muscarinic M₁₋₅, H₁, and adrenergic alpha₁-receptors

Adverse Reactions

Cardiovascular: Postural hypotension, tachycardia, hypotension, peripheral edema, chest pain, hypertension

Central nervous system: **Headache, somnolence, insomnia, agitation, nervousness, hostility, dizziness**, dystonic reactions, parkinsonian events, amnesia, euphoria, stuttering, akathisia, anxiety, personality changes, fever, abnormal dreams, speech disorder, neuroleptic malignant syndrome, seizures, tardive dyskinesia, diabetic coma

Dermatologic: Rash, bruising, photosensitivity reaction, angioedema, pruritus, urticaria

Endocrine & metabolic: Prolactin increased, amenorrhea, diabetes mellitus, hyperglycemia

Gastrointestinal: **Dyspepsia, constipation, weight gain** (clinically and long term), xerostomia, abdominal pain, appetite increased, vomiting, salivation increased, pancreatitis

Genitourinary: Premenstrual syndrome, incontinence, priapism

Hematologic: Leukopenia, agranulocytosis, neutropenia

Neuromuscular & skeletal: **Weakness**, arthralgia, neck rigidity, twitching, hypertonia, tremor, back pain, abnormal gait, akathisia, falling (particularly in older patients)

Ocular: Amblyopia

Respiratory: Rhinitis, cough, pharyngitis, dyspnea

Miscellaneous: Diaphoresis, allergic reactions, anaphylactoid reactions

Additional significant effects reported with I.M. administration: Articulation impairment, AV block, injection site pain, syncope

Signs and Symptoms of Overdose Coma, drowsiness, extrapyramidal movements, fasciculations, hypotension (possible, though not described), miosis, respiratory depression, rhinitis (10%), slurred speech, tachycardia, trismus

Pharmacodynamics/Kinetics

Absorption:

I.M.: Rapidly absorbed

Oral: Well absorbed; not affected by food; tablets and orally-disintegrating tablets are bioequivalent

Distribution: V_d: Extensive, 1000 L

Protein binding, plasma: 93% bound to albumin and alpha₁-glycoprotein

Metabolism: Highly metabolized via direct glucuronidation and cytochrome P450 mediated oxidation (CYP1A2, CYP2D6); 40% removed via first pass metabolism

Bioavailability: > 57%

Half-life elimination: 21-54 hours; ~1.5 times greater in elderly

Time to peak, plasma: Maximum plasma concentrations after I.M. administration are 5 times higher than maximum plasma concentrations produced by an oral dose.

I.M.: 15-45 minutes

Oral: ~6 hours

Excretion: Urine (57%, 7% as unchanged drug); feces (30%)

Clearance: 40% increase in olanzapine clearance in smokers; 30% decrease in females

Dosage

Children: Schizophrenia/bipolar disorder: Oral: Initial: 2.5 mg/day; titrate as necessary to 20 mg/day (0.12-0.29 mg/kg/day)

Adults:

Schizophrenia: Oral:

Initial: 5-10 mg once daily (increase to 10 mg once daily within 5-7 days); thereafter, adjust by 5 mg/day at 1-week intervals, up to a recommended maximum of 20 mg/day. Maintenance: 10-20 mg once daily. **Note:** Doses of 30-50 mg/day have been used; however, doses >10 mg/day have not demonstrated better efficacy, and safety and efficacy of doses >20 mg/day have not been evaluated.

Bipolar I acute mixed or manic episodes: Oral:

Monotherapy: Initial: 10-15 mg once daily; increase by 5 mg/day at intervals of not less than 24 hours. Maintenance: 5-20 mg/day; recommended maximum dose: 20 mg/day

Combination therapy (with lithium or valproate): Initial: 10 mg once daily; dosing range: 5-20 mg/day

Agitation (acute, associated with bipolar I mania or schizophrenia):

I.M.: Initial dose: 5-10 mg (a lower dose of 2.5 mg may be considered when clinical factors warrant); additional doses (2.5-10 mg) may be considered; however, 2-4 hours should be allowed between doses to evaluate response (maximum total daily dose: 30 mg, per manufacturer's recommendation)

Elderly: Oral, I.M.: Consider lower starting dose of 2.5-5 mg/day for elderly or debilitated patients; may increase as clinically indicated and tolerated with close monitoring of orthostatic blood pressure

Dosage adjustment in renal impairment: No adjustment required. Not removed by dialysis

Monitoring Parameters Vital signs; fasting lipid profile and fasting blood glucose/Hgb A_{1c} (prior to treatment, at 3 months, then annually); periodic assessment of hepatic transaminases (in patients with hepatic disease); BMI, personal/family history of obesity, waist circumference; orthostatic blood pressure; mental status, abnormal involuntary movement scale (AIMS), extrapyramidal symptoms (EPS). Weight should be assessed prior to treatment, at 4 weeks, 8 weeks, 12 weeks, and then at quarterly intervals. Consider titrating to a different antipsychotic agent for a weight gain ≥5% of the initial weight.

Administration

Injection: For I.M. administration only; do not administer injection intravenously; inject slowly, deep into muscle. If dizziness and/or drowsiness are noted, patient should remain recumbent until examination indicates postural hypotension and/or bradycardia are not a problem.

Tablet: May be administered with or without food/meals.

Orally-disintegrating: Remove from foil blister by peeling back (do not push tablet through the foil); place tablet in mouth immediately upon removal; tablet dissolves rapidly in saliva and may be swallowed with or without liquid. May be administered with or without food/meals.

Contraindications Hypersensitivity to olanzapine or any component of the formulation

Warnings

[U.S. Boxed Warning]: Patients with dementia-related behavioral disorders treated with atypical antipsychotics are at an increased risk of death compared to placebo. An increased incidence of cerebrovascular adverse events (including fatalities) has been reported in elderly patients with dementia-related psychosis. Olanzapine is not approved for this indication.

Moderate to highly sedating, use with caution in disorders where CNS depression is a feature; patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in Parkinson's disease; in patients with bone marrow suppression; predisposition to seizures; subcortical brain damage; severe hepatic, renal, or respiratory disease. Life-threatening arrhythmias have occurred with therapeutic doses of some neuroleptics. May induce orthostatic hypotension, especially during titration; use caution with history of MI, heart failure, conduction abnormalities, cerebrovascular disease, or conditions/medications which predispose to hypotension and/or bradycardia. Esophageal dysmotility and aspiration have been associated with antipsychotic use; use with caution in patients at risk of pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). Significant weight gain may occur. Impaired core body temperature regulation may occur; caution with strenuous exercise, heat exposure, dehydration, and concomitant medication possessing anticholinergic effects.

May cause anticholinergic effects (constipation, xerostomia, blurred vision, urinary retention); therefore, they should be used with caution in patients with decreased gastrointestinal motility, paralytic ileus, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other neuroleptics, olanzapine has a moderate potency of cholinergic blockade.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is lower relative to other neuroleptics). May be associated with neuroleptic malignant syndrome (NMS). May cause hyperglycemia; in some cases may be extreme and associated with ketoacidosis, hyperosmolar coma, or death. Use with caution in patients with diabetes or other disorders of glucose regulation; monitor for worsening of glucose control. Olanzapine levels may be lower in patients who smoke, requiring dosage adjustment.

The possibility of a suicide attempt is inherent in psychotic illness or bipolar disorder; use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. Safety and efficacy in pediatric patients have not been established.

Dosage Forms Injection, powder for reconstitution (Zyprexa® IntraMuscular): 10 mg [contains lactose 50 mg]

Tablet (Zyprexa®): 2.5 mg, 5 mg, 7.5 mg, 10 mg, 15 mg, 20 mg

Tablet, orally disintegrating (Zyprexa® Zydis®): 5 mg [contains phenylalanine 0.34 mg/tablet], 10 mg [contains phenylalanine 0.45 mg/tablet], 15 mg [contains phenylalanine 0.67 mg/tablet], 20 mg [contains phenylalanine 0.9 mg/tablet]

Reference Range

Therapeutic serum range: 9-23 ng/mL; serum and urine olanzapine levels >600 ng/mL and 500 ng/mL, respectively, associated with coma following a 600 mg ingestion; toxicity may occur at blood olanzapine levels >100 ng/mL; death due to olanzapine toxicity can occur at postmortem blood olanzapine levels >160 ng/mL

Postmortem blood olanzapine level of 0.160 mg/L may indicate that this drug was the cause of death.

Olanzapine postmortem aorta blood concentrations of ≥ 0.8 mg/L or iliac blood values of ≥ 0.5 mg/L are sufficient to cause death. In instances of olanzapine overdose, liver concentrations can be expected to exceed 1.0 mg/kg.

Overdosage/Treatment

Decontamination: Oral: Activated charcoal

Supportive therapy: Hypotension should be treated with I.V. crystalloid fluids; avoid sympathomimetics with beta-agonist properties since this can theoretically worsen hypotension. Weight gain can be treated with nizatidine 150 mg twice daily. Ephedrine (25 mg/day) can be used to treat olanzapine-induced urinary incontinence. Physostigmine (2 mg I.V.) can reverse olanzapine-induced coma.

Enhanced elimination: Hemodialysis does not appear to be useful

Drug Interactions

Substrate of CYP1A2 (major), 2D6 (minor); **Inhibits** CYP1A2 (weak), 2C9 (weak), 2C19 (weak), 2D6 (weak), 3A4 (weak)

Acetylcholinesterase inhibitors (central): May increase the risk of anti-psychotic-related extrapyramidal symptoms; monitor.

Anticholinergics: Adverse effects/toxicity may be additive with olanzapine.

Carbamazepine: May decrease olanzapine levels/effects; monitor.

Ciprofloxacin; May increase the levels/effects of olanzapine.

CNS depressants: Sedative effects and may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect.

CYP1A2 inducers may decrease the levels/effects of olanzapine. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of olanzapine. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

Fluvoxamine: Increases olanzapine levels; consider using a lower dose of olanzapine in patients receiving concomitant treatment with fluvoxamine.

Lithium: Risk of extrapyramidal effects may be increased with concurrent therapy.

Pramlintide: Anticholinergic effects may be increased with concomitant therapy.

Pregnancy Risk Factor C

Pregnancy Implications No evidence of teratogenicity reported in animal studies. However, fetal toxicity and prolonged gestation have been observed. There are no adequate and well-controlled studies in pregnant women.

Lactation Enters breast milk/not recommended

Additional Information Antipsychotic efficacy was established in short-term (6 weeks) controlled trials of psychotic disorders; effectiveness in long-term use (>6 weeks) has not been systematically evaluated in controlled trial, therefore, the physician who uses olanzapine for extended periods should periodically re-evaluate the long-term usefulness of the drug for the individual patient; less extrapyramidal effects and adverse hematological effects as compared with clozapine. Postmortem blood olanzapine level of 0.160 mg/L may indicate that this drug was the cause of death.

Olsalazine

CAS Number 15722-48-2

U.S. Brand Names Dipentum®

Synonyms Olsalazine Sodium

Use Maintenance of remission of ulcerative colitis in patients intolerant to sulfasalazine

Mechanism of Action The mechanism of action appears to be topical rather than systemic

Adverse Reactions

- Cardiovascular: Palpitations, pericarditis
- Central nervous system: Headache, fatigue, depression, fever
- Dermatologic: Rash, itching, alopecia
- Gastrointestinal: Nausea, dyspepsia, bloating, anorexia, **diarrhea** (secretory: dose dependent), **abdominal cramps**, **abdominal pain**, bloody diarrhea, pancreatitis
- Hematologic: Blood dyscrasias
- Hepatic: Hepatitis
- Ocular: Dry eyes, blurred vision
- Neuromuscular & skeletal: Arthralgia

Signs and Symptoms of Overdose Decreased motor activity, diarrhea

Pharmacodynamics/Kinetics

- Absorption: <3%; very little intact olsalazine is systemically absorbed
- Protein binding, plasma: >99%
- Metabolism: Primarily via colonic bacteria to active drug, 5-aminosalicylic acid
- Half-life elimination: 56 minutes
- Time to peak: ~1 hour
- Excretion: Primarily feces

Dosage Adults: Oral: 1 g/day in 2 divided doses; maximum dose: 3 g/day

Monitoring Parameters Stool frequency

Administration Take with food in evenly divided doses.

Contraindications Hypersensitivity to olsalazine, salicylates, or any component of the formulation

Warnings

Diarrhea is a common adverse effect of olsalazine; use with caution in patients with hypersensitivity to salicylates, sulfasalazine, or mesalamine

Dosage Forms Capsule, as sodium: 250 mg

Reference Range Olsalazine: 0-4.3 mM/L; olsalazine sodium: 3.3-12.4 mM/L. These are not therapeutic guideline levels. These are reported levels after administration that have been observed on study. No correlation to response is known at this time.

Overdosage/Treatment

Decontamination: For ingestions >3 g: Ipecac within 30 minutes or lavage within 1 hour; activated charcoal

Supportive therapy: Replace fluid losses with I.V. crystalloid solution

Drug Interactions Azathioprine, mercaptopurine, thioguanine: Amino-salicylates may increase the risk of myelosuppression (due to TPMT inhibition).

Warfarin: Olsalazine has been reported to increase the prothrombin time in patients taking warfarin.

Pregnancy Risk Factor C

Lactation Enters breast milk/use caution (monitor for diarrhea)

Additional Information Cross-reactivity with sulfasalazine allergy is probable

Omeprazole

CAS Number 73590-58-6

U.S. Brand Names Prilosec OTC™ [OTC]; Prilosec®

Use Short-term (4-8 weeks) treatment of active duodenal ulcer disease or active benign gastric ulcer; treatment of heartburn and other symptoms associated with gastroesophageal reflux disease (GERD); short-term (4-8 weeks) treatment of endoscopically-diagnosed erosive esophagitis; maintenance healing of erosive esophagitis; long-term treatment of pathological hypersecretory conditions; as part of a multidrug regimen for *H. pylori* eradication to reduce the risk of duodenal ulcer recurrence
OTC labeling: Short-term treatment of frequent, uncomplicated heartburn occurring ≥2 days/week

Unlabeled/Investigational Use Healing NSAID-induced ulcers; prevention of NSAID-induced ulcers

Mechanism of Action A benzimidazole compound prodrug which suppresses gastric acid secretion by inhibiting the parietal cell H⁺/K⁺ ATP pump

Adverse Reactions

- Cardiovascular: Chest pain, tachycardia, bradycardia, hypertension, sinus bradycardia, angina, palpitations, sinus tachycardia
- Central nervous system: Headache, dizziness, fever, fatigue, malaise, nervousness, lethargy
- Dermatologic: Rash, dermatitis exfoliative, toxic epidermal necrolysis, alopecia, bullous skin disease, xerosis, purpura, pruritus, psoriasis, licheniform eruptions, exanthem
- Endocrine & metabolic: Acute gout, hyponatremia, erythema nodosum

- Gastrointestinal: Diarrhea, nausea, abdominal pain, vomiting, constipation, abdominal edema, anorexia, irritable colon, flatulence, xerostomia, gastric giardiasis, dysgeusia, weight gain
- Genitourinary: Urinary tract infection, pyuria
- Hematologic: Hypoglycemia, anemia, leukocytosis, pancytopenia, agranulocytosis, thrombocytopenia, neutropenia, megaloblastic anemia, hemolytic anemia
- Hepatic: Hepatitis
- Neuromuscular & skeletal: Back pain, myalgia, tremors, arthralgia, weakness, paresthesia
- Ocular: Eye irritation
- Renal: Proteinuria, interstitial nephritis (acute)
- Respiratory: Cough
- Miscellaneous: Lichen spinulosus, fixed drug eruption

Signs and Symptoms of Overdose Decreased respiratory rate has been demonstrated in animals only. Angioedema, blindness, confusion, depression, dermatitis, dry mouth, gout, gynecomastia, hematuria, hypoglycemia, hyperhidrosis, hyponatremia, hypothermia, nephritis, sedation, seizures, urinary frequency

Pharmacodynamics/Kinetics

- Onset of action: Antisecretory: ~1 hour
- Peak effect: 2 hours
- Duration: 72 hours
- Protein binding: 95%
- Metabolism: Extensively hepatic to inactive metabolites
- Bioavailability: Oral: 30% to 40%; increased in Asian patients and patients with hepatic dysfunction
- Half-life elimination: Delayed release capsule: 0.5-1 hour
- Excretion: Urine (77% as metabolites, very small amount as unchanged drug); feces

Dosage

- Oral:
- Children ≥2 years: GERD or other acid-related disorders:
 - <20 kg: 10 mg once daily
 - ≥20 kg: 20 mg once daily
- Adults:

- Active duodenal ulcer: 20 mg/day for 4-8 weeks
- Gastric ulcers: 40 mg/day for 4-8 weeks
- Symptomatic GERD: 20 mg/day for up to 4 weeks
- Erosive esophagitis: 20 mg/day for 4-8 weeks; maintenance of healing: 20 mg/day for up to 12 months total therapy (including treatment period of 4-8 weeks)
- Helicobacter pylori* eradication: Dose varies with regimen: 20 mg once daily or 40 mg/day as single dose or in 2 divided doses; requires combination therapy with antibiotics
- Pathological hypersecretory conditions: Initial: 60 mg once daily; doses up to 120 mg 3 times/day have been administered; administer daily doses >80 mg in divided doses
- Frequent heartburn (OTC labeling): 20 mg/day for 14 days; treatment may be repeated after 4 months if needed

Dosage adjustment in hepatic impairment: Specific guidelines are not available; bioavailability is increased with chronic liver disease

Monitoring Parameters Improvement in gastrointestinal symptoms

Administration Capsule should be swallowed whole. Do not chew, crush, or open. Best if taken before breakfast. May be opened and contents added to applesauce. Administration via NG tube should be in an acidic juice.

Contraindications Hypersensitivity to omeprazole, substituted benzimidazoles (ie, esomeprazole, lansoprazole, pantoprazole, rabeprazole), or any component of the formulation

Warnings In long-term (2-year) studies in rats, omeprazole produced a dose-related increase in gastric carcinoid tumors. While available endoscopic evaluations and histologic examinations of biopsy specimens from human stomachs have not detected a risk from short-term exposure to omeprazole, further human data on the effect of sustained hypochlorhydria and hypergastrinemia are needed to rule out the possibility of an increased risk for the development of tumors in humans receiving long-term therapy. Bioavailability may be increased in the elderly, Asian population, and with hepatic dysfunction. Safety and efficacy have not been established in children <2 years of age. When used for self-medication (OTC), do not use for >14 days; treatment should not be repeated more often than every 4 months; OTC and oral suspension are not approved for use in children <18 years of age.

- Dosage Forms** Capsule, delayed release: 10 mg, 20 mg
- Prilosec®: 10 mg, 20 mg, 40 mg
- Tablet, delayed release: Prilosec OTC™: 20 mg

Overdosage/Treatment

- Decontamination: Activated charcoal
- Enhancement of elimination: Multiple dosing of activated charcoal may be effective
- Not dialyzable due to high protein binding although 1 case report in an anemic, anuric patient did describe removal by hemodialysis (Roggo)

Test Interactions May result in increased gastric levels

Drug Interactions **Substrate** of CYP2A6 (minor), 2C9 (minor), 2C19 (major), 2D6 (minor), 3A4 (minor); **Inhibits** CYP1A2 (weak), 2C9 (moderate), 2C19 (strong), 2D6 (weak), 3A4 (weak); **Induces** CYP1A2 (weak)

Benzodiazepines metabolized by oxidation (eg, diazepam, midazolam, triazolam): Esomeprazole and omeprazole may increase levels of benzodiazepines metabolized by oxidation.

Carbamazepine: Esomeprazole and omeprazole may increase carbamazepine levels.

Clozapine: Omeprazole may alter the concentrations/effects of clozapine; monitor.

CYP2C9 substrates: Omeprazole may increase the levels/effects of CYP2C9 substrates. Example substrates include amiodarone, fluoxetine, glimepiride, glipizide, nateglinide, phenytoin, pioglitazone, rosiglitazone, sertraline, and warfarin.

CYP2C19 inducers: May decrease the levels/effects of omeprazole. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 substrates: Omeprazole may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

Itraconazole and ketoconazole: Proton pump inhibitors may decrease the absorption of itraconazole and ketoconazole.

Methotrexate: Concurrent use with omeprazole may decrease the excretion of methotrexate. **Note:** Antirheumatic doses of methotrexate probably hold minimal risk.

Phenytoin: Elimination of phenytoin may be prolonged; monitor. Phenytoin may decrease omeprazole levels/effects.

Protease inhibitors: Proton pump inhibitors may decrease absorption of some protease inhibitors (atazanavir and indinavir). Avoid concurrent use.

Warfarin: Elimination of warfarin may be prolonged; monitor.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta; congenital abnormalities have been reported sporadically following omeprazole use during pregnancy. The manufacturer recommends use during pregnancy only if the potential benefit to the mother outweighs the possible risk to the fetus.

Lactation Enters breast milk/not recommended

Additional Information May be effective in preventing nonsteroidal anti-inflammatory drug-induced large gastric ulcers by inhibiting acid secretion; the incidence of side effects in elderly is not different than that of younger adults (≤ 65 years) despite slight decrease in elimination and increase in bioavailability. No dosage adjustments are necessary for elderly (≥ 65 years).

Ondansetron

CAS Number 103639-04-9; 116002-70-1; 99614-02-5

U.S. Brand Names Zofran® ODT; Zofran®

Synonyms GR38032R; Ondansetron Hydrochloride

Use

Prevention of nausea and vomiting associated with moderately- to highly-emetogenic cancer chemotherapy; radiotherapy in patients receiving total body irradiation or fractions to the abdomen; prevention and treatment of postoperative nausea and vomiting

Generally **not** recommended for treatment of existing chemotherapy-induced emesis (CIE) or for prophylaxis of nausea from agents with a low emetogenic potential.

Unlabeled/Investigational Use Treatment of early-onset alcoholism; hyperemesis gravidarum

Mechanism of Action Selective 5-HT₃ receptor antagonist, blocking serotonin, both peripherally on vagal nerve terminals and centrally in the chemoreceptor trigger zone

Adverse Reactions
