TABLE OF CONTENTS

Preface.....	xxix
Acknowledgments.....	xxxi
Editors.....	xxxiii
Contributors.....	xxxv
Editorial Advisory Panel.....	xxxix
Introduction.....	1
Description of Sections and Fields Used in This Handbook.....	1
FDA Pregnancy Categories.....	2
FDA Name Differentiation Project: The Use of Tall-Man Letters.....	3
Safe Writing.....	5
General References.....	6
Poison Information Centers.....	9
General Poison Information Sources.....	20
Teratology Information Services.....	28
Section I Medicinal Agents	
Approach to Toxicology.....	35
Stabilization of the Patient.....	36
History and Physical Examination.....	37
Drugs/Toxins Causing Increased Anion Gap (> 12 mEq/L).....	39
Drugs/Toxins Causing Decreased Anion Gap (<6 mEq/L).....	40
Toxins Causing Osmolar Gap (By Freezing-Point Depression, Gap is > 10 mOsm from Baseline Value).....	41
Toxins Associated with Oxygen Saturation Gap (>5% Difference Between Measured and Calculated Value).....	41
Prevention of Absorption.....	42
Antidotes.....	44
Enhancement of Elimination.....	44
Toxins with Enhanced Elimination by Multiple Dosing of Activated Charcoal.....	44
Toxins Eliminated by Saline Diuresis.....	45
Toxins Eliminated by Urine Alkalinization.....	45
Drugs and Toxins Removed by Hemodialysis.....	46
Drugs and Toxins Removed by Hemoperfusion (Charcoal).....	48
Toxicants for Which Exchange Transfusions May Be Helpful.....	49
References.....	49
Support and Monitoring for Adverse Effects.....	50
Criteria for Admission of the Poisoned Patient to ICU.....	50
Footnotes.....	51
Clinical Toxicokinetics.....	53
Explanations for Variations Between Predicted and Observed Values.....	54
Potential Benefits in the Toxicokinetic Evaluation and/or Management of the Overdose Patient.....	55
Suggested Reading.....	55
Highlights of Recent Reports (2006) on Substance Abuse and Mental Health.....	56
Lipid Emulsion Resuscitation for Local Anesthetic and Toxic Cardiac Arrest.....	60
Background.....	60
Clinical Features of Local Anesthetic Toxicity.....	60
Animal Studies.....	60
Mechanisms.....	60
Clinical Efficacy.....	60
General Applicability of Lipid Rescue Resuscitation.....	61
Future Directions: Research and Practice.....	61
Recommendations.....	61
References.....	61
Position Statement and Practice Guidelines on the Use of Multi-Dose Activated Charcoal in the Treatment of Acute Poisoning.....	63
Summary Statement.....	63
Introduction.....	63
Rationale.....	63
Animal Studies.....	63
Volunteer Studies.....	63
Clinical Studies.....	64
Indications.....	64
Dosage Regimen.....	64
Coadministration of a Cathartic.....	64
Contraindications.....	65
Absolute.....	65
Relative.....	65
Complications of Use.....	65
Supporting Documentation.....	65
Introduction.....	65
Methodology.....	65
Rationale.....	65
Mechanisms of Action.....	66
Animal Studies.....	66
Volunteer Studies.....	67
Clinical Studies.....	71
Dosage Regimen.....	76
Coadministration of a Cathartic.....	77
Complications of Use.....	77
Gastrointestinal Complications.....	77
Respiratory Complications.....	78
Fluid, Electrolyte, and Acid-Base Abnormalities.....	78
References.....	78
Substance-Related Disorders.....	83
General Treatment Recommendations.....	83
Alcohol.....	83

Intoxication/Overdose (see Ethyl Alcohol)	83
Withdrawal	83
General Treatment	84
Cocaine	84
Intoxication/Overdose (see Cocaine)	84
Withdrawal	85
General Treatment	85
Opioids	85
Intoxication/Overdose	85
Withdrawal	85
General Treatment	86
Sedative/Hypnotic	86
Intoxication/Overdose	86
Withdrawal	86
General Treatment	87
Benzodiazepine	87
Intoxication	87
Withdrawal	87
Gamma Hydroxybutyrate (GHB)/Gamma Butyrolactone (GBL)	87
Intoxication	87
Withdrawal	87
Stimulants	88
Intoxication/Overdose	88
Withdrawal	88
General Treatment	88
Caffeine	88
Intoxication	88
Withdrawal	88
Hallucinogens	88
Intoxication	88
Withdrawal	88
General Treatment	88
Baclofen	88
Intoxication	88
Withdrawal	88
Inhalants	89
Intoxication	89
Withdrawal	89
General Treatment	89
Selective Serotonin Reuptake Inhibitors (SSRIs)	89
Intoxication/Overdose	89
Withdrawal	89
Synthesized Compounds	89
Intoxication/Overdose	89
Withdrawal	89
General Treatment	89
Marijuana	89
Intoxication	89
Withdrawal	90
General Treatment	90
Nicotine	90
Intoxication/Overdose	90
Withdrawal	90
General Treatment	91
Psychiatric Emergencies - Violence	91
Neuroleptic Malignant Syndrome	92
Catatonia	92
Acute Extrapryramidal Syndromes (Eps)	94
Acute Dystonias	94
Akathisia	94
Drug-Induced Parkinsonism	94
References	95
Acarbose	97
Acebutolol	97
Acetaminophen	98
AcetaZOLAMIDE	102
AcetoHEXAMIDE	103
Acrivastine and Pseudoephedrine	104
Adalimumab	104
Adenosine	105
Albendazole	106
Albuterol	106
Aldesleukin	108
Alendronate	109
Alfentanil	110
Alglucerase	111
Allopurinol	112
Alprazolam	113
Alteplase	114
Altretamine	116
Aluminum Hydroxide	116
Amantadine	117
Amiloride	118
Aminophylline	119
Amiodarone	120

Amisulpride	122
Amitriptyline	122
Amlodipine	125
Amoxapine	126
Amoxicillin	127
Amphotericin B	128
Ampicillin	129
Amsacrine	130
Androstenedione	131
Aprotinin	131
Arginine	132
Aripiprazole	132
Ascorbic Acid	133
Atenolol	134
Atomoxetine	135
Atorvastatin	136
Azathioprine	137
Azithromycin	138
Bacitracin	140
Baclofen	140
Belladonna	141
Benazepril	142
Benzalkonium Chloride	143
Benzbromarone	143
Benzocaine	143
Benzonatate	144
Benztropine	145
Bepridil	145
Betamethasone	146
Betaxolol	147
Bethanechol	148
Biperiden	148
Bisacodyl	149
Bismuth Subgallate	149
Bisoprolol	150
Blasticidin S	150
Bleomycin	151
Botulinum Toxin Type A	151
Bromazepam	153
Buflomedil	154
Bumetanide	154
Bunazosin	155
Bupivacaine	155
Buprenorphine	156
BuPROPion	157
BusPIRone	159
Busulfan	160
Butorphanol	161
Butriptyline	162
Caffeine	162
Calcitonin	163
Calfactant	164
Candesartan	164
Cantharidin	165
Capreomycin	165
Captopril	166
Carbamazepine	167
Carboplatin	169
Carfentanil Citrate	170
Carisoprodol	170
Carmustine	171
Carteolol	172
Carvedilol	173
Castor Oil	174
Ceftriaxone	174
Cefuroxime	175
Celecoxib	176
Celiprolol	177
Cephalexin	177
Cephradine	178
Cetirizine	178
Chloral Hydrate	179
Chlorambucil	180
Chloramphenicol	181
Chlordiazepoxide	182
Chlorhexidine Gluconate	183
Chlormezanone	184
Chloroprocaine	184
Chloroquine	185
Chlorpheniramine	186
ChlorproMAZINE	186
ChlorproPAMIDE	188
Chlorprothixene	189
Chlorthalidone	189
Chlorzoxazone	190

Cholecalciferol	190
Choline Magnesium Trisalicylate	191
Cidofovir	191
Cimetidine	192
Ciprofloxacin	194
Cisapride	196
Cisplatin	197
Citalopram	198
Cladribine	200
Clarithromycin	201
Clemastine	202
Clenbuterol	203
Clobazam	203
Clofibrate	204
ClomiPHENE	204
ClomiPRAMINE	204
Clonazepam	206
Clonidine	207
Clorazepate	209
Clotrimazole	210
Clozapine	210
Cocaine	212
Codeine	215
Colchicine	216
Cortisone	217
Cromolyn	218
Cyanocobalamin	219
Cyclizine	219
Cyclobenzaprine	220
Cyclophosphamide	221
CycloSERINE	222
CycloSPORINE	222
Cyproheptadine	226
Cytarabine	227
Dalteparin	228
Danaparoid	229
Danazol	229
Dantrolene	230
Dapsone	231
DAUNOrubicin Hydrochloride	232
Dehydroepiandrosterone	233
Desipramine	233
Deslanoside	235
Dexamethasone	235
Dexfenfluramine	237
Dextroamphetamine	237
Dextromethorphan	238
Diazepam	239
Diazoxide	241
Dibenzepin	242
Dibucaine	242
Diclofenac	243
Dicumarol	244
Dicyclomine	244
Didanosine	245
Diethylcarbamazine	246
Diethylpropion	247
Diethylstilbestrol	247
Diethyltoluamide	248
Diffunisal	248
Digitoxin	249
Digoxin	250
Diltiazem	252
DimenhyDRINATE	254
Dimethyl Sulfoxide	255
DiphenhydrAMINE	255
Diphenoxylate and Atropine	257
Dipyridamole	258
Dirithromycin	258
Disopyramide	259
Disulfiram	260
Docetaxel	260
Docusate	262
Dofetilide	262
Donepezil	263
Dornase Alfa	264
Doxazosin	264
Doxepin	265
DOXOrubicin	266
Doxycycline	268
Doxylamine	269
Droperidol	270
Duloxetine	271
Edrophonium	273
Eflornithine	273

Enalapril	274
Enfuvirtide	275
Enoxacin	276
Enoxaparin	276
Ephedrine	277
Epoetin Alfa	278
Eptifibatide	280
Ergotamine	281
Erythromycin	282
Escitalopram	284
Esmolol	286
Esomeprazole	286
Estazolam	287
Estrogens, Conjugated	288
Estrogens (Esterified)	290
Ethacrynic Acid	291
Ethambutol	292
Ethchlorvynol	292
Ethionamide	293
Ethosuximide	293
Ethotoin	294
Ethyl Alcohol	294
Ethyl Chloride	297
Ethyl Loflazepate	297
Etidronate Disodium	297
Etodolac	298
Etoposide	299
Famciclovir	300
Famotidine	301
Felodipine	302
Femoxetine	302
Fenoldopam	303
Fenoprofen	303
Fenproporex	304
Fentanyl	304
Fexofenadine	307
Finasteride	307
Flecainide	308
Fleroxacin	309
Floxuridine	309
Fluconazole	310
Flunitrazepam	311
Fluoride	311
Fluorouracil	313
Fluoxetine	314
Fluphenazine	316
Flurazepam	318
Flurbiprofen	318
Flutamide	320
Fluvastatin	320
Fluvoxamine	321
Foscarnet	323
Fosfomycin	324
Fosinopril	325
Fosphenytoin	326
Furosemide	327
Gabapentin	329
Gallium Nitrate	329
Gallopamil	330
Galsulfase	330
Gamma Hydroxybutyric Acid	331
Ganciclovir	333
Gemfibrozil	334
Gentamicin	334
Glimepiride	336
GlipiZIDE	337
Glutamine	338
Glutethimide	338
GlyBURIDE	339
Glycerin	340
Gold Compounds	340
Granisetron	341
Griseofulvin	342

Poinsettia	918
Poison Hemlock	918
Poison Ivy	918
Poison Lily	918
Poison Oak	918
Poison Sumac	919
Pokeweed	919
Portuguese Man-of-War	919
Potato (Leaves, Stems, Tubercles)	919
Privet (Berries and Leaves)	919
Puss Caterpillar	919
Rabies Virus	919
Rapeseed Oil	923
Rattlesnakes	923
Red-back Spider	924
Reduviids	924
Rhododendron	924
Rubber Vine	924
<i>Salmonella</i> Food Poisoning	925
Sand Brier	926
Schefflera	926
Scombroid Food Poisoning	926
Scorpion Fish	927
Scotch Broom	927
Sea Anemones	927
Sea Cucumber	928
Sea Urchins	928
Sea Wasp	928
<i>Sedum</i>	928
Shamrock	928
Shellfish Food Poisoning	928
<i>Shigella</i> Food Poisoning	928
Squill	929
Squirting Cucumber	929
<i>Staphylococcus</i> Food Poisoning	930
Star-of-Bethlehem (<i>Hippobroma longiflora</i>)	930
Star-of-Bethlehem (<i>Ornithogalum pyrenaicum</i>)	930
Star-of-Bethlehem (<i>Ornithogalum umbellatum</i>)	930
Starfish	931
Starfruit Food Poisoning	931
Stinging Catfish	931
Stonfish	931
<i>Streptococcus</i> Food Poisoning	931
Striped Blister Beetles	932
Sulfite Food Poisoning	932
Sweet Pea	932
<i>Tabernanthe iboga</i> Baillon	932
Tarantulas	932
Tartrazine Food Poisoning	932
Tetrodotoxin Food Poisoning	932
Tobacco	933
Tomato (Leaves and Stems)	933
<i>Trichinella spiralis</i> Food Poisoning	933
Tulip	934
Tung Nut	934
Turkey Fish	934
Tyramine Hydrochloride Food Poisoning	934
Upas Tree	934
<i>Vibrio cholerae</i> and <i>Vibrio parahaemolyticus</i> Food Poisoning	934
<i>Vibrio vulnificus</i>	935
Vietnamese Centipede	935
Water Hemlock	935
Whelk Poisoning	936
White Chameleon	936
Wild Cucumber	936
Wild Hops	936
Wild Mustard	936
Wisteria	936
Woody Nightshade	936
Yellow Sac Spider	936
<i>Yersinia enterocolitica</i> Food Poisoning	937
<i>Yersinia pestis</i>	937
Yew	938

Section IV Herbal Agents

Achyranthes Aspera	941

PREFACE

The term toxicology can today be defined as the assault, absorption, and adverse effects of foreign substances upon the human body. As such, toxicology is truly one of the most exciting and expanding fields in the medical sciences. The depth and scope of this discipline are increasing yearly with the discovery and the analysis of newer drugs, chemicals, or environmental toxins. Certainly, the areas of drug overdose, drug interactions, allergic reactions, street drug abuse, hazardous material accidents, radiation physics, industrial/occupational exposures, psychiatry, wilderness medicine, food safety, botany, virology, zoology, parasitology, mycology, teratology, analytical laboratory techniques, radiology, infectious agents, basic pharmacology, and just plain old detective investigational techniques are all encompassed within the field of toxicology.

Our sincere thanks goes out to the staff of the Illinois Poison Center, Evanston Northwestern Healthcare Omega, University of Illinois College of Pharmacy, Toxikon Consortium, and the many reviewers across the country who gave us immeasurable assistance in helping develop and enhance this book.

While preparing this reference book, we attempted to include as much information as possible. Quite often, all of the characteristics have not been delineated for every drug, chemical, or biological agent, and our clinical experience is truly in the embryonic stage for some of these toxins. Our goal is to provide the reader with our basic approach, incorporating these details to toxic management by using available pharmacological and clinical information along with our experience. Since the recent years have afforded us a literal explosion of information, the reader should realize that this reference still is representative of a beginning chapter in toxicology.

Jerrold B. Leikin, MD
Frank P. Paloucek, PharmD

ACKNOWLEDGMENTS

The *Poisoning & Toxicology Handbook* exists in its present form as the result of the concerted efforts of the following individuals: Robert D. Kerscher, publisher and president of Lexi-Comp Inc; Lynn D. Coppinger, managing editor; David C. Marcus, director of information systems; Matthew C. Kerscher, product manager; and Tracey J. Henterley, graphic designer.

Much of the material contained in this book is the result of contributions by pharmacists throughout the United States and Canada. Lexi-Comp has assisted many medical institutions to develop hospital-specific formulary manuals that contain clinical drug information as well as dosing. Working with these clinical pharmacists, hospital pharmacies and therapeutics committees, and hospital drug information centers, Lexi-Comp has developed an evolutionary drug database that reflects the practice of pharmacy in these major institutions. Information was derived from Lexi-Comp's Poisoning and Toxicology database (www.lexi.com) for this book.

The authors wish to thank their families, friends, and colleagues who supported them in their efforts to complete this book.

EDITORS

Jerrold Blair Leikin, MD, FACP, FACEP, FACMT, FAACT, FACOEM

Dr. Leikin is director of medical toxicology at Evanston Northwestern Healthcare-OMEGA, Glenbrook Hospital, located in Glenview, Illinois. He is associate director of the Toxikon Consortium based at Cook County Hospital in Chicago. He is also professor of medicine at Rush Medical College and professor of emergency medicine at Feinberg School of Medicine at Northwestern University in Chicago, Illinois.

Dr. Leikin received his medical doctorate degree from the Chicago Medical School in 1980 and completed a combined residency in internal medicine and emergency medicine at Evanston Hospital and Northwestern Memorial Hospital in 1984. He completed a fellowship in medical toxicology at Cook County Hospital in Chicago in 1987. He is also board-certified in the above specialties.

Dr. Leikin was the associate director of the emergency department from 1988 to 2001 at Rush-Presbyterian-St Luke's Medical Center in Chicago. He was medical director of the Rush Poison Control Center for 11 years and was the medical director of the United States Drug Testing Laboratory for 5 years. Dr. Leikin is also a consultant with the Illinois Poison Center and Wisconsin Poison Center. He is also medical director of PROSAR Drug Safety Call Center located in St. Paul, Minnesota.

Dr. Leikin has presented over 100 abstracts at national meetings and has published over 200 articles in peer-reviewed medical journals. He is coeditor of the *American Medical Association Handbook of First Aid and Emergency Care*. He has written chapters on the subjects of toxicology, emergency medicine, critical care medicine, internal medicine, and observational medicine in medical textbooks. Dr. Leikin is an active member of the American Academy of Clinical Toxicology, American College of Medical Toxicology, the American College of Emergency Physicians, and the American Medical Association.

Frank P. Paloucek, PharmD, DABAT, FASHP

Dr. Paloucek is a clinical associate professor of pharmacy practice and director of residency programs at the University of Illinois in Chicago. Dr. Paloucek received his BS degree in pharmacy from the University of Illinois in 1981 and his PharmD from the Philadelphia College of Pharmacy and Sciences in 1984. He completed a residency in pharmacy practice and a fellowship in clinical pharmacokinetics at the University of Illinois at Chicago.

He practices on the clinical toxicology service at the University of Illinois. He is an adjunct assistant professor in the emergency medicine program, has been a faculty member of the American Academy of Clinical Toxicology since 1989, and a Diplomate of the American Board of Applied Toxicology since 1991. He has been a director of a postdoctoral clinical toxicology fellowship program since 1991 and is now director of residency programs at the University of Illinois Hospital. In addition to numerous scientific posters and clinical toxicology publications, Dr. Paloucek is currently on the editorial board of *The Poison Review*. He is an acknowledged expert on the pharmacist's role in emergency medicine and the interpretation of drug-toxin concentrations in poisoning patients.

Dr. Paloucek is an active member of the American Society of Hospital Pharmacists and the American College of Clinical Pharmacy. His research interests are toxicokinetics of medications in overdose, drug misadventures in the emergency department, and theophylline toxicity.

CONTRIBUTORS

Steven E. Aks, DO, DABMT

Dr. Aks is the director at the Toxikon Consortium. He is an associate professor of emergency medicine at the Rush Medical College, Chicago, and an attending physician in the department of emergency medicine at John Stroger Hospital, Chicago, Illinois. He received his BA degree in biology and psychology at the University of Rochester and his DO degree from the New York College of Osteopathic Medicine. His internship was at the Brookdale Hospital Medical Center, his residency in emergency medicine at the Chicago College of Osteopathic Medicine Program in emergency medicine. He completed a fellowship in medical toxicology at the Toxikon Consortium at Cook County Hospital. Areas of interest include education, mushroom toxicity, cocaine toxicity, and clinical toxicology. He has recently completed work on drug and hallucinogenic mushroom use at rock concerts.

Anthony M. Burda, RPh, CSPI, DABAT

Anthony Burda is the chief specialist in poison information at the Illinois Poison Center in Chicago. He has become certified as a specialist in poison information through the American Association of Poison Control Centers (AAPCC) in 1983, 1988, 1993, and 2000. He became a diplomate of the American Board of Applied Toxicology in 1997. He is a 1978 graduate of the University of Illinois College of Pharmacy.

Mr. Burda is a clinical assistant professor of pharmacy practice at the University of Illinois College of Pharmacy, Chicago, and Chicago College of Pharmacy, Midwest University, Downers Grove, Illinois. He is an assistant professor in the department of pharmacology at Rush Medical College, Chicago. He serves as a rotation preceptor for a number of pharmacy colleges and emergency medicine and medical school clinical programs.

Mr. Burda's professional experiences include authoring continuing education programs for pharmacists, presenting lectures in pharmacology/medications courses for nurses, and serving as a technical advisor to the executive director of a pharmacy association.

Jack C. Clifton, MD

Following his PhD graduate study in the department of microbiology and immunology at the University of Illinois, Dr. Clifton attended medical school as a James Scholar at the University of Illinois College of Medicine. Subsequent to medical school, Dr. Clifton completed a combined internal medicine/pediatrics residency program at the University of Illinois, becoming chief resident during his final year. Having attended in the departments of pediatrics and internal medicine at the University of Chicago following his residency training, Dr. Clifton returned to graduate work in a combined PhD/pediatric critical care fellowship at the University of Chicago in the departments of pediatrics pathology and immunology. After accepting an attending position in the section of emergency medicine within the department of pediatrics at Rush Children's Hospital, Dr. Clifton then completed a fellowship in medical toxicology with the Toxikon Consortium at the University of Illinois, Cook County Hospital, and Rush-Presbyterian-St. Lukes Medical Center. In addition to being currently enrolled in a combined clinical pharmacology fellowship/master's of clinical research program at Rush, Dr. Clifton is presently an attending physician in the Toxikon Consortium at the University of Illinois, John Stroger Hospital, and Rush-Presbyterian-St. Luke's Medical Center.

Connie B. Fischbein, BA, CSPI

Connie Fischbein received her BS degree in chemistry from Northwestern University in Evanston, Illinois in 1977. She received her certification as a specialist in poison information from the AAPCC in 1985 and 1990. She has practiced as a certified specialist in poison information (CSPI) at the Intermountain Regional Poison Center in Salt Lake City, Utah, and at the Illinois Poison Center in Chicago (formerly at Rush-Presbyterian-St. Luke's Medical Center). She is an active member of the Illinois Mycological Association.

Christina E. Hantsch, MD

Dr. Hantsch is a medical director of the Illinois Poison Center and an assistant professor at Loyola University, Chicago. She practices both emergency medicine and medical toxicology at Loyola University Medical Center. She graduated from Northwestern University Medical School in Chicago in 1992. After finishing her internship at Northwestern University, she studied at the Medical College of Wisconsin for her emergency medicine residency. There, she was chief

Resident in 1995–1996. Dr. Hantsch completed a medical toxicology fellowship at the Center for Clinical Toxicology at Vanderbilt University. She is a member of several professional organizations including the American College of Medical Toxicology, the American Academy of Clinical Toxicology, and the European Association of Poisons Centres and Clinical Toxicologists.

Terry D. Jacobsen, PhD, FLS

Dr. Jacobsen received his BS degree from the College of Idaho and his MS and PhD degrees in systematic botany from Washington State University. In addition to his administrative and programmatic activities at the Institute, he teaches in the biological sciences department. He also is a research associate in the section of botany at the Carnegie Museum of Natural History and an adjunct scientist at the Pittsburgh Poison Center at Children's Hospital.

Dr. Jacobsen's main research interests include vascular taxonomy, especially *Allium* (onion, Liliaceae) in North America, and toxic plants and fungi.

Edward P. Krenzelok, PharmD, FAACT, ABAT

Dr. Krenzelok is director of the Pittsburgh Poison Center at Children's Hospital of Pittsburgh and a professor of pharmacy and pediatrics at the University of Pittsburgh. He received his BS degree in pharmacy from the University of Wisconsin in 1971 and his doctor of pharmacy degree from the University of Minnesota in 1974. Dr. Krenzelok is active in numerous professional toxicology and medically related societies and associations and is a past president of the American Academy of Clinical Toxicology. He is board certified in clinical toxicology by the American Board of Applied Toxicology and has been awarded the distinction of being a Fellow in the American Academy of Clinical Toxicology. Dr. Krenzelok is on the board of directors of the American Association of Poison Control Centers. He is a former chair of the United States Pharmacopeia Clinical Toxicology and Substance Abuse Committee, a former member of the Food and Drug Administration Nonprescription Drug Advisory Committee, on the editorial boards and review panels of numerous medical and toxicology journals, and the author of several hundred scientific publications and book chapters and the editor of three books.

Christine M. Moore, PhD

Dr. Moore is the vice president of Toxicology Research and Development for Immunalysis Corporation, a company specializing in the development of immunoassays for the testing of drugs in biological matrices. Additionally, she is the secretary of the Society of Hair Testing, and the treasurer of the Society of Forensic Toxicologists.

Following a PhD in forensic toxicology and postdoctoral work in Japan, Dr. Moore served as a research associate at the University of Illinois and as technical services manager of United Chemical Technologies, a manufacturer of solid-phases for use in clinical, drug testing, and pharmaceutical laboratories. She has also served as the associate scientific director of U.S. Drug Testing Laboratories, Chicago, a laboratory specializing in the detection of drugs in meconium, hair, and other less common sample matrices.

Lisa Sigg, BS, RPh

Lisa Sigg received her BS degree in pharmacy from Butler University in 1955 and became licensed to practice later that year. She is currently practicing community pharmacy in Chicago, Illinois.

Todd Sigg, PharmD, CSPI

Dr. Sigg received his doctor of pharmacy degree from the Purdue University College of Pharmacy in 1995. He then completed a pharmacy practice residency at Rush-Presbyterian-St. Luke's Medical Center in Chicago, Illinois. In 1998, the American Association of Poison Control Centers certified Dr. Sigg as a specialist in poison information. Presently he is employed by the Illinois Poison Center. He serves as affiliate faculty and preceptor for the University of Illinois College of Pharmacy and Midwestern University, Chicago College of Pharmacy.

Michael Wahl, MD, FACEP

Dr. Wahl received his medical degree from Case Western Reserve University in 1991. He completed residency at the University of Illinois, program in emergency medicine, in 1994. He completed a fellowship in toxicology in 1994 with the Toxikon Consortium in 1996. Dr. Wahl is board certified in both emergency medicine and toxicology. Current appointments include attending physician, Evanston and Glenbrook Hospitals, department of emergency medicine, and medical director, Illinois Poison Center since 1998.

Guy L. Weinberg, MD

Dr. Weinberg is a professor of anesthesiology at the University of Illinois at Chicago and is a diplomate of the American Boards of Internal Medicine, Medical Genetics, and Anesthesiology. He stumbled into the world of toxicology during experiments studying the effects of local anesthetics on fatty acid metabolism when he unexpectedly found that a lipid emulsion infusion prevented local anesthetic cardiac toxicity in rats. Since then, the clinical efficacy of lipid emulsion therapy for anesthetic-induced cardiac toxicity has been confirmed in many case reports. Current laboratory studies also point to its potential for treating other forms of poisoning. Dr. Weinberg's other research interests include cardiac metabolism, protection, and preservation. He has an abiding affection for intermediary metabolism and mitochondria in particular.

DESCRIPTION OF SECTIONS AND FIELDS USED IN THIS HANDBOOK

The *Poisoning & Toxicology Handbook* is divided into six sections, medicinal, nonmedicinal, biological, herbal, antidotal agents, and diagnostic tests and procedures. These sections (except for herbal agents) are introduced by essays from leaders in the field and are followed by monographs that list the numerical indices of the Chemical Abstract Services (CAS) registry numbers (internationally used) and the United Nations/United States Department of Transportation (DOT) numbers (used nationally). These monographs also contain the information described below. However, not all fields of information will appear for every monograph; only those fields that correspond to a particular type of agent will be given.

Abstract	A brief description of the test and its use
Additional Information	Information about sodium content and/or pertinent information about specific drug brands; or, additional information about a test/procedure and its uses
Administration	Specific instructions on proper procedure or information in relation to the administration of the drug
Admission Criteria/Prognosis	Clinical indicators of exposure used to determine if hospitalization is necessary (ie, symptoms, laboratory values, etc); may also include parameters that can impact on prognosis
Adverse Reactions	Side effects are listed by organ system affected. Symptoms reported in bold print have an incidence of 10% or greater.
Aftercare	Special instructions or warnings for medical personnel for the care of the patient after the procedure is performed
AHPA Botanical Safety Rating System	Relative safety rating of each herb as determined by the American Herbal Products Association (AHPA)
Antidote	Directs the reader to the drug and page where the antidote and its information can be located
Applies to	Refers to various sample sites or specimen types that follow the same procedure
Brand Names	Common trade names
CAS Number	Chemical Abstract Service Registry Number, the international nomenclature system
Causes for Rejection	Possible reasons why a specimen may be rejected by the laboratory
Collection	General and specific collection instructions that should be followed to obtain a proper and usable specimen
Container	Type of container required for acquiring and maintaining a usable specimen
Contraindications	Information pertaining to inappropriate use of a drug; or, reasons why a test should not be performed
Critical Values	Values that alert the medical staff that the patient has reached a range or value that may be hazardous
Diagnostic Tests/Procedures	Directs the reader to the page in the book for information on the tests and/or procedures which should be considered in the treatment of the patient
Dosage Forms	Information with regard to form, strength, and availability of the drug. This field is strung with the forms bolded and uses some abbreviations as follows: AERO: aerosol; AMP: ampul; CAP: capsule; CONC: concentration; CRM: cream; CRYST: crystal; ELIX: elixir; GRAN: granules; INF: infusion; INH: inhaler; INJ: injection; LIQ: liquid; LOZ: lozenge; OINT: ointment; SHAMP: shampoo; SOLN: solution; SUPP: suppository; SUSP: suspension; SYR: syrup; TOP: topical
Drug Interactions	Effects that may be potentially harmful or toxic when used with other medications
Equipment	Equipment needed to perform the named procedure
Impairment Potential	Possible effect on an individual's functional capacity; probability of increased risk of involvement in an accident
Limitations	Limits of the test/procedure
Mechanism of Action	How the drug works in the body to elicit a response
Mechanism of Toxic Action	How nontherapeutic agents elicit a toxic response
Methodology	Testing methodologies available
Minimum Volume	Minimum amount of specimen required to perform testing
Monitoring Parameters	Laboratory tests and patient physical parameters that should be monitored for safety and efficacy of drug therapy are listed when appropriate
Monograph Name	The generic (U.S. adopted) name is used for antidotes and medicinal agents. For the purpose of this publication antidotes are defined as [ANTIDOTE] after the monograph name.
Nursing Implications	Includes additional instructions for the administration of the drug and monitoring tips from the nursing perspective
Overdosage Treatment	Description of treatment modalities of adverse effects and overdosage presented in sections: Decontamination; Supportive therapy; Enhanced elimination
Pharmacodynamics/Kinetics	The magnitude of a drug's effect depends on the drug concentration at the site of action. The pharmacodynamics are expressed in terms of onset of action and duration of action. Pharmacokinetics are expressed in terms of absorption, distribution (including appearance in breast milk and crossing of the placenta), protein binding, metabolism, bioavailability, half-life, time to peak serum concentration, and elimination.
Patient Preparation	Any special preparation that the patient must undergo prior to the procedure being performed
Possible Panic Range	Values that alert the medical staff that the patient has reached a range or value that may be hazardous
Pregnancy Implications	Includes the five categories established by the FDA to indicate the potential of a systemically absorbed drug for causing birth defects, as well as, information which may be critical in the treatment of a pregnant patient
Reference Range	Serves as a general guideline. Therapeutic and toxic serum concentrations are listed when appropriate. For diagnostic tests: See specific testing facility for their ranges.
Related Information	Cross-references to other tests or procedures, or the appendix, that are related to the named test and may be helpful to the user
Sampling Time	The time frame a specimen should be collected
Scientific Name	Taxonomic name
Signs & Symptoms of Acute Overdose	Primarily clinical effects of acute toxic exposure
Slang Name	"Street names" for drugs of abuse
Special Instructions	Specific instructions for the acquisition and handling of specimens
Specific References	Specific references used in the information of the monograph published since 2003. For references published before 2003, consult the Poisoning & Toxicology database or CD-ROM online version.
Specimen	Possible specimens that can be used for testing

INTRODUCTION

Stability	Storage, refrigeration, and compatibility information
Storage Instructions	The appropriate storage of the specimen after collection but prior to testing
Technique	Explanation of how the procedure is performed
Test Commonly Includes	All laboratory tests or procedures that may occur when the named test is performed
Test Interactions	Listing of assay interferences when relevant; (B) = Blood; (S) = Serum; (U) = Urine
Toxicodynamics/Kinetics	The magnitude of a drug's effect depends on the drug concentration at the site of action. The toxicodynamics are expressed in terms of onset of action and duration of action. Toxicokinetics are expressed in terms of absorption, distribution (including appearance in breast milk and crossing of the placenta), protein binding, metabolism, bioavailability, half-life, time to peak serum concentration, and elimination.
UN Number	United Nations/United States Department of Transportation (D.O.T.) number. Identification nomenclature used for shipping in the United States; usually found on placard on side of vehicle.
U.S. Brand Names	Common United States trade names
Use	Information pertaining to appropriate indications of a drug; or common uses for a test/procedure
Usual Dosage	Information regarding the recommended final concentrations and rates for administration of the drug
Volume	Desirable amount of specimen needed for testing
Warnings	Hazardous conditions related to use of the drug and disease states or patient populations in which the drug should be cautiously used

FDA PREGNANCY CATEGORIES

In many of the drug monographs throughout this book there is a field labeled Pregnancy Implications and the letter A, B, C, D, or X immediately following which signifies a category. The FDA has established these five categories to indicate the potential of a systemically absorbed drug for causing birth defects. The key differentiation among the categories rests upon the reliability of documentation and the risk:benefit ratio. Pregnancy category X is particularly notable in that if any data exist that may implicate a drug as a teratogen and the risk:benefit ratio is clearly negative, the drug is contraindicated during pregnancy.

These categories are summarized as follows:

A	Controlled studies in pregnant women fail to demonstrate a risk to the fetus in the first trimester with no evidence of risk in later trimesters. The possibility of fetal harm appears remote.
B	Either animal-reproduction studies have not demonstrated a fetal risk but there are no controlled studies in pregnant women, or animal-reproduction studies have shown an adverse effect (other than a decrease in fertility) that was not confirmed in controlled studies in women in the first trimester and there is no evidence of a risk in later trimesters.
C	Either studies in animals have revealed adverse effects on the fetus (teratogenic or embryocidal effects or other) and there are no controlled studies in women, or studies in women and animals are not available. Drugs should be given only if the potential benefits justify the potential risk to the fetus.
D	There is positive evidence of human fetal risk, but the benefits from use in pregnant women may be acceptable despite the risk (eg, if the drug is needed in a life-threatening situation or for a serious disease for which safer drugs cannot be used or are ineffective).
X	Studies in animals or human beings have demonstrated fetal abnormalities, or there is evidence of fetal risk based on human experience, or both, and the risk of the use of the drug in pregnant women clearly outweighs any possible benefit. The drug is contraindicated in women who are or may become pregnant.

FDA NAME DIFFERENTIATION PROJECT: THE USE OF TALL-MAN LETTERS

Confusion between similar drug names is an important cause of medication errors. For years, the Institute for Safe Medication Practices (ISMP) has urged generic manufacturers use a combination of large and small letters as well as bolding (eg, chlorpro **MAZINE** and chlorpro **PAMIDE**) to help distinguish drugs with look-alike names, especially when they share similar strengths. Recently, the FDA's Division of Generic Drugs began to issue recommendation letters to manufacturers suggesting this novel way to label their products to help reduce this drug name confusion. Although this project has had marginal success, the method has successfully eliminated problems with products such as diphenhydr **AMINE** and dimenhy **DRINATE**. Hospitals should also follow suit by making similar changes on their own labels, preprinted order forms, computer screens and printouts, and drug storage location labels.

Lexi-Comp Medical Publishing, with this edition of the *Poisoning and Toxicology Handbook*, will begin using these "Tall-Man" letters for the drugs suggested by the FDA.

The following is a list of product names and recommended FDA revisions.

Drug Product	Recommended Revision
acetazolamide	aceta ZOLAMIDE
acetoexamide	aceto HEXAMIDE
bupropion	bu PROP ion
buspirone	bus PIR one
chlorpromazine	chlorpro MAZINE
chlorpropamide	chlorpro PAMIDE
clomiphene	clomi PHENE
clomipramine	clomi PRAMINE
cycloserine	cyclo SERINE
cyclosporine	cyclo SPORINE
daunorubicin	DAUNO rubicin
dimenhydrinate	dimenhy DRINATE
diphenhydramine	diphenhydr AMINE
dobutamine	DOBUT amine
dopamine	DOP amine
doxorubicin	DOXO rubicin
glipizide	glipi ZIDE
glyburide	gly BURIDE
hydralazine	hydr ALAZINE
hydroxyzine	hydr OXY zine
medroxyprogesterone	medroxy PROGESTER one
methylprednisolone	methyl PREDNIS olone
methyltestosterone	methyl TESTOSTER one
nicardipine	ni CARD ipine
nifedipine	NIFE dipine
prednisolone	predniso LONE
prednisone	predni SONE
sulfadiazine	sulfa DIAZINE
sulfisoxazole	sulfi SOXAZOLE

<i>(Continued)</i>	
Drug Product	Recommended Revision
tolazamide	TOLAZ amide
tolbutamide	TOLBUT amide
vinblastine	vin BLAS tine
vincristine	vin CRIS tine

SAFE WRITING

Health professionals and their support personnel frequently produce handwritten copies of information they see in print; therefore, such information is subjected to even greater possibilities for error or misinterpretation on the part of others. Thus, particular care must be given to how drug names and strengths are expressed when creating written healthcare documents.

The following are a few examples of safe writing rules suggested by the Institute for Safe Medication Practices, Inc.*

1. There should be a space between a number and its units as it is easier to read. There should be no periods after the abbreviations mg or mL.

Correct	Incorrect
10 mg	10mg
100 mg	100mg

2. Never place a decimal and a zero after a whole number (2 mg is correct and 2.0 mg is **incorrect**). If the decimal point is not seen because it falls on a line or because individuals are working from copies where the decimal point is not seen, this causes a tenfold overdose.
3. Just the opposite is true for numbers less than one. Always place a zero before a naked decimal (0.5 mL is correct, .5 mL is **incorrect**).
4. Never abbreviate the word unit. The handwritten U or u looks like a 0 (zero), and may cause a tenfold overdose error to be made.
5. IU is not a safe abbreviation for international units. The handwritten IU looks like IV. Write out international units or use int. units.
6. Q.D. is not a safe abbreviation for once daily, as when the Q is followed by a sloppy dot, it looks like QID which means four times daily.
7. O.D. is not a safe abbreviation for once daily, as it is properly interpreted as meaning “right eye” and has caused liquid medications such as saturated solution of potassium iodide and Lugol’s solution to be administered incorrectly. There is no safe abbreviation for once daily. It must be written out in full.
8. Do not use chemical names such as 6-mercaptopurine or 6-thioguanine, as sixfold overdoses have been given when these were not recognized as chemical names. The proper names of these drugs are mercaptopurine or thioguanine.
9. Do not abbreviate drug names (5FC, 6MP, 5-ASA, MTX, HCTZ, CPZ, PBZ, etc) as they are misinterpreted and cause error.
10. Do not use the apothecary system or symbols.
11. Do not abbreviate microgram as mic g instead use μg as there is less likelihood of misinterpretation.
12. When writing an outpatient prescription, write a complete prescription. A complete prescription can prevent the prescriber, the pharmacist, and/or the patient from making a mistake and can eliminate the need for further clarification.

The legible prescriptions should contain:

- a. patient’s full name
- b. for pediatric or geriatric patients: their age (or weight where applicable)
- c. drug name, dosage form, and strength; if a drug is new or rarely prescribed, print this information
- d. number or amount to be dispensed
- e. complete instructions for the patient, including the purpose of the medication
- f. when there are recognized contraindications for a prescribed drug, indicate to the pharmacist that you are aware of this fact (eg, when prescribing a potassium salt for a patient receiving an ACE inhibitor, write “K serum level being monitored”)

*From “Safe Writing” by Davis NM, PharmD and Cohen MR, MS, Lecturers and Consultants for Safe Medication Practices, 1143 Wright Drive, Huntington Valley, PA 19006. Phone: (215) 947-7566.

POISON INFORMATION CENTERS

Updated from the American Association of Poison Control Centers (AAPCC). Available at: <http://www.aapcc.org/certctrlst/certifie.html>

(Certified centers are printed in italics.)

Centers in each state are listed alphabetically. Telephone numbers designated “TTY” are teletype lines for the hearing-impaired. “TDD” numbers reach a telecommunication device for the deaf.

Note: As of June 2001, the National toll-free poison center number is (800) 222-1222 (automatically connects to caller’s locale).

ALABAMA

Alabama Poison Center
2503 Phoenix Drive
Tuscaloosa, AL 35405
Emergency phone: (205) 345-0600

Regional Poison Control Center

SECTION I
MEDICINAL AGENTS

APPROACH TO TOXICOLOGY

Jerrold B. Leikin, MD

Peter Mere Latham (1789-1875) is credited with the statement, "Poisons and medicines are oftentimes the same substance given with different intents." While this remark was penned in a bygone era, it is probably more true today than it was then. For confirmation of this fact, one can open any clinical pharmacology textbook (or even the *Physician's Desk Reference*) and note therapeutic agents that can lead to specific toxic syndromes or toxidromes.¹ There are few fields in medicine that demand such immediate, decisive, and definitive treatment strategy with as small an information base as in the area of toxicologic emergencies. Despite the potential for the wide range of clinical presentations due to a virtually unlimited amount of toxins, <0.05% of all poison exposures (about 2.5 million) annually called in to a Poison Control Center result in death.² In about 40% of these deaths, cardiac or respiratory arrest occurred in the prehospital setting.¹ Although this statistic may be somewhat misleading because of biased population sample, it is still evident that if one follows a consistent treatment algorithm of the poisoned patient, the outcome will be favorable in a vast majority of cases.³⁻⁸

Patterns of Mortality Risk from Drugs/Substance Overdose
A Theoretical Model

- A – High toxicity: Digoxin, tricyclic antidepressant, theophylline, carbon monoxide, cyanide
 B – Intermediate: Acetaminophen, salicylate, phenobarbital
 C – Low: Propranolol (immediate-release)
 D – Threshold for overdose effect: Atropine, phenylpropanolamine

Theoretical model of patterns of mortality risk from drug or substance overdose. A = highly toxic substances that cause mortality with a dose-effect pattern (eg, digoxin, tricyclic antidepressants, theophylline, carbon monoxide, cyanide); B = other substances that react in a similar manner but require a larger dose or more time to reach 100% mortality (eg, acetaminophen, aspirin, iron); C = less toxic substances that act in a predictable dose-response relationship (eg, nonsteroidal anti-inflammatory drugs); D = substances that may cause mortality in a less predictable fashion where a clear dose-response relationship cannot be established (eg, atropine, phenylpropanolamine). (Courtesy of Yona Amitai, MD, Hadassah Medical Organization, Jerusalem, Israel)

Mortality from poisoning often follows two distinct patterns (see figure). Those toxins that cause mortality usually through cell necrosis by a dose-dependent mechanism are demonstrated in the figure by mortality curves A, B, and C. Highly toxic substances which can cause cellular damage and necrosis in a rapid dose-effect pattern are illustrated by mortality curve A. Moderately toxic agents, for which a higher dose is required to achieve 100% mortality, are illustrated by mortality curve B. Substances that are less toxic but whose dose-effect curve is more predictable (with a slope approaching 1) are illustrated by mortality curve C. Note that a definition of an antidote is any agent that moves a toxin mortality curve to the right. A second mechanism of toxin-induced mortality is demonstrated by curve D. This can be termed the "threshold effect", which is usually demonstrated by drugs that operate through a receptor mechanism (ie, atropine, beta-agonists, phenylpropanolamine). These drugs do not demonstrate a dose-dependent mortality curve but rather a plateau following a certain threshold dose whereupon maximal target organ response is achieved but no further mortality is expected to occur. These curves do not reflect the patterns of mortality risk for drugs that are metabolized to potentially lethal substances nor do they reflect death secondary to organ system failures in susceptible patients.

The recommended treatment plan for the poisoned patient is not unlike general treatment plans taught in advanced cardiac life support (ACLS) or advanced trauma life support (ATLS) courses. In this manner, the

initial approach to the poisoned patient should be essentially similar in every case, irrespective of the toxin ingested, just as the initial approach to the trauma patient is the same irrespective of the mechanism of injury. This approach, which can be termed as routine poison management, essentially includes the following aspects:

- Stabilization: ABCs (airway, breathing, circulation); administration of glucose, thiamine, oxygen, and naloxone
- History, physical examination leading toward the identification of class of toxin (toxidrome recognition)
- Prevention of absorption (decontamination)
- Specific antidote, if available
- Removal of absorbed toxin (enhancing excretion)
- Support and monitoring for adverse effects
- If discharged, preventive education and environmental detoxification

Stabilization of the Patient

In the initial evaluation of a toxic patient, the treating physician must remember that the most common cause of airway obstruction in the unconscious patient is passive obstruction by the tongue. The neck lift with jaw thrust may be the first maneuver performed by the physician on the unconscious poisoned patient followed by endotracheal intubation. Indications for endotracheal intubation in the poisoned patient include protection of the airway in the obtunded or comatose patient with a depressed or absent gag reflex to prevent aspiration during gastric lavage; controlled ventilation in patients who demonstrate respiratory depression or failure; removal of secretions in patients who develop pulmonary edema secondary to a toxic substance; and institution of positive end-expiratory pressure (PEEP) therapy for those patients who are at risk for developing adult respiratory distress syndrome (ARDS). A chest film should be obtained to note the position of the endotracheal tube.

Following evaluation of airway and breathing, the circulatory status needs to be assessed. Hypotension in the toxic patient must be addressed as quickly as possible in order to avoid the sequelae of shock. While hypotension in this group of patients may arise from a variety of mechanisms (ranging from decreased cardiac output due to myocardial depression; to venous pooling; to decreased peripheral resistance; or to hemorrhage), the initial treatment is essentially the same: intravenous fluid administration. A fluid challenge of 100-200 mL of a crystalloid solution (10-20 mL/kg in pediatrics) is often given at this time while urine output is monitored (0.5-1 mL/kg/hour). At this time, if the patient's mental status is altered or if hypotension exists, four essentially innocuous drugs (oxygen, naloxone, glucose, and thiamine) are administered for a combination of diagnostic and therapeutic reasons. See the following table:

Drugs to Be Utilized in the Toxic Patient with Altered Mental Status		
Drug	Effect	Comment
25-50 g dextrose (D ₅₀ W) intravenously to reverse the effects of drug-induced hypoglycemia (adult) 1 mL/kg D ₅₀ W diluted 1:1 (child).	This can be especially effective in patients with limited glycogen stores (ie, neonates and patients with cirrhosis).	Extravasation into the extremity of this hyperosmolar solution can cause Volkmann's contractures.
50-100 mg intravenous thiamine	Prevent Wernicke's encephalopathy	A water-soluble vitamin with low toxicity; rare anaphylactoid reactions have been reported.
Initial dosage of naloxone should be 2 mg in adult patients preferably by the intravenous route, although intramuscular, subcutaneous, intralingual, and endotracheal routes may also be utilized. Pediatric dose is 0.1 mg/kg from birth until 5 years of age. For potentially opioid-dependent patients with altered mental status, smaller doses (0.1-0.2 mg) could initially be used to increase arousal without producing withdrawal.	Specific opioid antagonist without any agonist properties.	It should be noted that some semisynthetic opiates (such as meperidine or propoxyphene) may require higher initial doses for reversal, so that a total dose of 6-10 mg is not unusual. If the patient responds to a bolus dose and then relapses to a lethargic or comatose state, a naloxone drip can be considered. This can be accomplished by administering two-thirds of the bolus dose that revives the patient per hour or injecting 4 mg naloxone in 1 L crystalloid solution and administering at a rate of 100 mL/hour (0.4 mg/hour); pediatric infusion rate: 0.16 mg/kg/hour.
Oxygen , utilized in 100% concentration	Useful for carbon monoxide, hydrogen, sulfide, and asphyxiants	While oxygen is antidotal for carbon monoxide intoxication, the only relative toxic contraindication is in paraquat intoxication (in that it can promote pulmonary fibrosis).

History and Physical Examination

While the history and physical examination is the cornerstone of clinical patient management, it takes on special meaning with regard to the toxic patient. While taking a history may be a more direct method of the determination of the toxin, often it is not reliable. Information obtained may prove minimal in some cases and could be considered partial or inaccurate in suicide gestures and addicts. A quick physical examination often leads to important clues about the nature of the toxin. These clues can be specific symptom complexes associated with certain toxins and can be referred to as “toxidromes.” See the following table:

Examples of Toxidromes			
Toxidromes	Pattern	Example of Drugs	Treatment Approach
Anticholinergic	Fever, ileus, flushing, tachycardia, urinary retention, inability to sweat, visual blurring, and mydriasis. Central manifestations include myoclonus, choreoathetosis, toxic psychosis with lilliputian hallucinations, seizures, and coma	Antihistamines Atropine Baclofen Benztropine Jimson weed Methylpyroline Phenothiazines Propantheline Tricyclic antidepressants	Physostigmine for life-threatening symptoms*
Carbolic marasmus	Headache, dizziness, salivation, anorexia, and skin pigmentation changes	Phenol	Lavage/activated charcoal with cathartic Possible endoscopy
Cholinergic	Characterized by salivation, lacrimation, urination, defecation, gastrointestinal cramps, and emesis (“sludge”). Bradycardia and bronchoconstriction may also be seen	Carbamate Organophosphates Pilocarpine	Atropine* Pralidoxime for organophosphate insecticides*
Extrapyramidal	Choreoathetosis, hyperreflexia, trismus, opisthotonos, rigidity, and tremor	Haloperidol Phenothiazines	Diphenhydramine Benztropine
Hallucinogenic	Perceptual distortions, synesthesia, depersonalization, and derealization	Amphetamines Cannabinoids Cocaine Indole alkaloids Phencyclidine	Benzodiazepine
Metal fume fever	Pleuritic chest pain, cough, dyspnea, thirst, metallic taste, fever (temperature ranges from 102°-104°), tachycardia, chills, nausea, myalgia	Most common: Zinc and copper Also: Cadmium, mercury	Supportive (usually resolves within 2 days) Avoidance of further exposure
Monosodium glutamate symptom complex	Burning sensation of back of neck, forearm, and chest; numbness in back of neck radiating to arms and back; tingling, warmth, and weakness in facial area, temples, upper back, neck, and arms; facial pressure or tightness, chest pain, headache, nausea, tachycardia, bronchospasm, drowsiness, weakness	Monosodium glutamate	Usually self-limited; diphenhydramine may be useful
Narcotic	Altered mental status, unresponsiveness, shallow respirations, slow respiratory rate or periodic breathing, miosis, bradycardia, hypothermia	Opiates Dextromethorphan Pentazocine Propoxyphene	Naloxone*
Retinoic acid syndrome	Fever, dyspnea (60%), arrhythmias (23%), tachycardia, hypotension, cardiac failure (6%), respiratory distress, nausea, vomiting (57%), renal failure (seen in patients with acute promyelocytic leukemia treated with > 45 mg/m ² /day of tretinoin)	Tretinoin	Dexamethasone (10 mg I.M. every 12 hours for 3 or more days)
Sedative/Hypnotic	Manifested by sedation with progressive deterioration of central nervous system function. Coma, stupor, confusion, apnea, delirium, or hallucinations may accompany this pattern	Anticonvulsants Antipsychotics Barbiturates Benzodiazepines Ethanol Ethchlorvynol Fentanyl Glutethimide Meprobamate Methadone Methocarbamol Opiates Quinazolines Propoxyphene	Naloxone* (opiates) Flumazenil* (benzodiazepines) Urinary alkalization (barbiturates)

POISONING AND TOXICOLOGY

Examples of Toxidromes (Continued)			
Toxidromes	Pattern	Example of Drugs	Treatment Approach
Epileptogenic†	May mimic stimulant pattern with hyperthermia, hyperreflexia, and tremors being prominent signs	Anticholinergics Camphor Chlorinated hydrocarbons Cocaine Isoniazid Lidocaine Lindane Nicotine Phencyclidine Strychnine Xanthines	Anticonvulsants (though generally not phenytoin) Pyridoxine for isoniazid* Extracorporeal removal of drug (ie, lindane, camphor, xanthines) Physostigmine for anticholinergic agents* Avoid phenytoin
Serotonin†	Confusion, myoclonus, hyperreflexia, diaphoresis tremor, facial flushing, diarrhea, fever, trismus	Clomipramine Fluoxetine Isoniazid L-tryptophan Paroxetine Phenelzine Sertraline Tranlycypromine Drug combinations include: MAO inhibitors with L-tryptophan Fluoxetine or meperidine Fluoxetine with carbamazepine or sertraline Clomipramine and meclizemide Trazadol and buspirone Paroxetine and dextromethorphan	Withdrawal of drug/benzodiazepine Beta-blocker (?) Cyproheptadine (?)
Solvent	Lethargy, confusion, dizziness, headache, restlessness, incoordination, derealization, depersonalization	Acetone Chlorinated hydrocarbons Hydrocarbons Naphthalene Trichloroethane Toluene	Avoid catecholamines
Stimulant	Restlessness, excessive speech and motor activity, tachycardia, tremor, and insomnia — may progress to seizure. Other effects noted include euphoria, mydriasis, anorexia, and paranoia	Amphetamines Caffeine (xanthines) Cocaine Ephedrine/pseudoephedrine Methylphenidate Nicotine Phencyclidine	Benzodiazepines
Uncoupling of oxidative phosphorylation	Hyperthermia, tachypnea, diaphoresis, metabolic acidosis (usually)	Aluminum phosphide Aspirin/Salicylates Bromethalin 2,4-Dichlorophenol Di-n-Butyl Phthalate Dinitrophenols Dinitro cresols Glyphosate (?) Hexachlorobutadiene Phosphorus Pentachlorophenol Tin (?) Zinc phosphide	Sodium bicarbonate to treat metabolic acidosis Patient cooling techniques Avoidance of atropine or salicylate agents Hemodialysis may be required for acidosis treatment.

The term toxidromes was originated by Mofensen in 1974 to assist the clinician in identifying the classification of toxins by toxin-specific symptom complexes. With the clinician focusing on the patient's vital signs, sensorium, motor signs, ocular findings, and other clinical abnormalities (eg, odor on breath, discoloration of urine), clinical toxin-pattern recognition can be achieved and an initial treatment plan formalized.

Sensorium: Determine whether the patient is comatose, stuporous, lethargic, confused, or alert.

Behavior and hallucinations: Often the hallucinatory pattern of the patient can be specific for certain drugs. For example, with atropine the patient experiences lilliputian hallucinations; with cocaine, there is a simple visual hallucinatory pattern with objects appearing in the periphery of vision; with phencyclidine, complex hallucinations are often indistinguishable clinically from a paranoid psychosis; and with LSD, the

patient experiences a combination of illusions (seeing objects in altered forms), hallucination (experiencing sensations without external stimuli), and pseudohallucinations (knowing when one is hallucinating).⁹

Motor signs: Tremors, hyporeflexia and hyperreflexia, and even the nature of seizures can be useful diagnostic tools. Like hallucinations, seizures caused by specific toxins can exhibit certain specific properties. For example, strychnine is unique in that it can cause generalized seizures while the patient is alert. This can be referred to as a “spinal seizure.” Other drug-induced seizures will respond only to specific antidotal therapies and not to conventional antiseizure medication. Examples of this property include anticholinergic-induced seizures, which may respond to physostigmine, and isoniazid-induced seizures, which respond to pyridoxine. Additionally, theophylline-induced seizures rarely respond to phenytoin alone and often only to multidrug therapy.

Vital signs: Sympathomimetics and anticholinergics essentially cause an increase in all of the vital signs parameters. This is particularly true for cocaine intoxication, where it has been noted that hyperthermia may be a particularly ominous sign for mortality. Conversely, organophosphates, opiates, barbiturates, beta-blockers, benzodiazepines, alcohol, and clonidine toxicities result in hypothermia, respiratory depression, and bradycardia.

Ocular findings: This can be divided into categories: pupillary size and reactivity, and demonstration of nystagmus.

Pupillary signs: Both anticholinergic and sympathomimetic substances can result in mydriasis, but in cocaine intoxication, the pupils will respond to light, whereas with anticholinergics the pupils will not. Agents that contribute to miosis include organophosphate insecticides, narcotics, bromide, acetone, clonidine, and nicotine. Phencyclidine has been known to cause either mydriasis or miosis.

Nystagmus: Alcohols are probably the most common etiology of horizontal nystagmus, although lithium, carbamazepine, solvents, meprobamate, quinine, and primidone can also result in horizontal nystagmus. Phencyclidine can cause a combination of vertical, horizontal, and even rotary nystagmus, as can phenytoin and sedative-hypnotics.

Other findings: In addition to these physical signs, odors emanating from the patient may also provide important directions in management. For example, a garlic odor is often caused by arsenicals, phosphorus compounds, or organophosphates. A rotten egg odor can be associated with decomposition of organic materials (hydrogen sulfide) or disulfiram. Periodic gaze disturbances (“ping-pong” gaze) are associated with MAO inhibitor overdose.

Radiographs can be of some utility in toxic exposure analysis. Factors that influence radiodensity include molecular weight, atomic number, relative contrast to surrounding tissues, and compactness of the form of drug. Sustained-released medications can be more easily detected through digital enhancement of the radiograph.¹⁰ Also, specific sustained-release dosage forms (bead-filled capsules) may appear as radiolucencies. It should be pointed out that this is not a reliable method for evaluating toxic exposure and should be utilized in only specific cases. These cases include evaluation of heavy metal exposure (including leaded paint chips), concretion formation of drugs (such as aspirin, meprobamate, glutethimide, barbiturates, iron, and sustained-release theophylline), and the body packing/stuffing phenomenon.

The clinical laboratory evaluation includes the evaluation of the “three gaps of toxicology”: anion gap (usually a type A lactic acidosis due to tissue hypoxia), osmolar gap, and oxygen saturation gap. What these “gaps” have in common is that the toxic substance accounts for a difference between calculated and measured determination. The following drugs are known to cause these gaps.

Drugs/Toxins Causing Increased Anion Gap (> 12 mEq/L)

Nonacidotic

Carbenicillin

Sodium salts

Metabolic Acidosis

Acetaminophen (ingestion > 75-100 g)

Ammonium chloride

Acetazolamide

Ascorbic acid

Aluminum phosphate

Benzalkonium chloride

Amiloride

Bialaphos

4-Aminopyridine

2-Butanone

2-Butoxyethanol	Methanol
Carbon monoxide	Methenamine mandelate
Centrimonium bromide	Misoprostol
Chloramphenicol	Monochloroacetic acid
Clozapine	Nalidixic acid
Cobalt	Naproxen
Colchicine	Nefopam
Cotrimoxazole (I.V. high dose)	Niacin
Cyanide	Papaverine
Dapsone	Paraldehyde
Dimethyl sulfate	Pennyroyal oil
Dinitrophenol	Pentaborane
Endosulfan	Pentachlorophenol
Epinephrine (I.V. overdose)	Phenelzine
Ethanol	Phenformin (off the market)
Ethyl acetate	Phenol
Ethylene dibromide	Phenylbutazone
Ethylene glycol	Phosphoric acid
Fenoprofen	Polyethylene glycol (low molecular weight)
Fluoroacetate	Propofol
Formaldehyde	Propylene glycol
Fructose (I.V.)	Salicylates
Funnel web spiders	Sodium Azide
Glycol ethers	Sorbitol (I.V.)
Glyphosate	Strychnine
Hydrogen sulfide	Sublimed sulfur
Ibuprofen (ingestion > 300 mg/kg)	Sultiame
Inorganic acid	Surfactant herbicide
Iodine	Tetracycline (outdated)
Iron	Tienilic acid
Isoniazid	Toluene
Ketamine	Tranylcypromine
Ketoprofen	Vacor
Lime sulfur	Valproic acid
Margosa oil	Verapamil
Metaldehyde	Zidovudine (chronic use > 6 months)
Metformin	Zinc phosphide

Drugs/Toxins Causing Decreased Anion Gap (< 6 mEq/L)

Acidosis

Acetazolamide	Kombucha Tea
Amiloride	Lithium
Ammonium chloride	Polymyxin B
Amphotericin B	Spirolactone
Bromide	Sulindac
Fialuridine (FIAU)	Toluene
Iodide	Tromethamine

Toxins Causing Osmolar Gap (By Freezing-Point Depression, Gap is > 10 mOsm from Baseline Value)

Ethanol	Iodine (questionable)
Ethylene glycol	Mannitol
Glycerol	Methanol
Hypermagnesemia (>9.5 mEq/L)	Sorbitol
Isopropanol (acetone)	Valproic acid (minor)

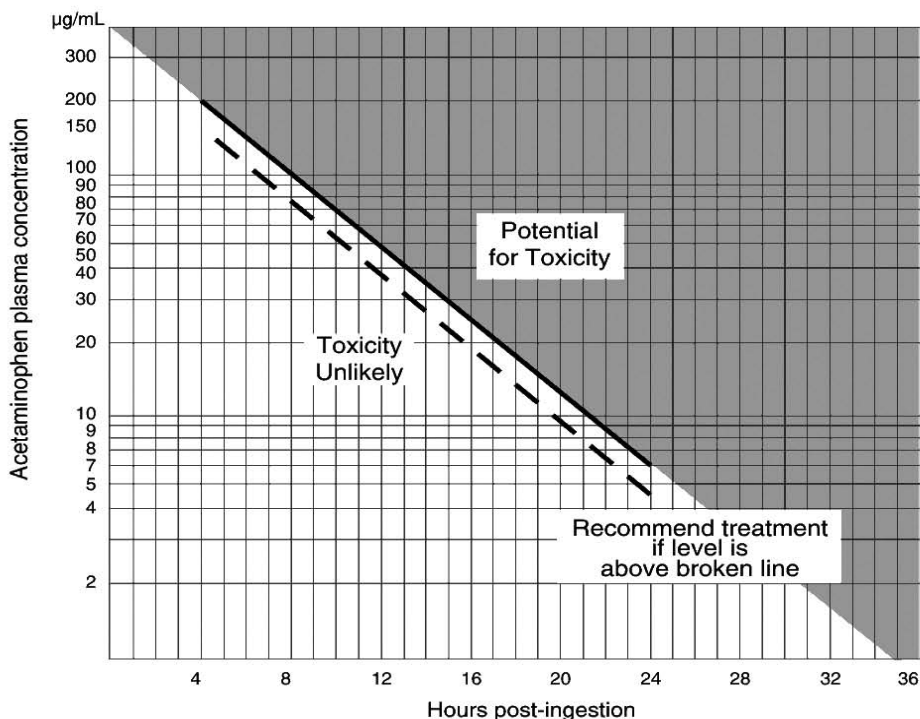

Toxins Associated With Oxygen Saturation Gap (>5% Difference Between Measured and Calculated Value)

Carbon monoxide	Methemoglobin
Cyanide (questionable)	Nitrates
Hydrogen sulfide (possible)	

The Toxicology Laboratory is also very useful for determining levels of toxin in body fluids. Often these drug levels will guide therapy. For example, use of the Rumack-Matthew nomogram for acute acetaminophen poisoning can direct N-acetylcysteine therapy if the serum acetaminophen level falls above the treatment line.

Nomogram: Plasma or Serum Acetaminophen Concentration vs Time Post Acetaminophen Ingestion

Estimating potential for hepatotoxicity:
 The following nomogram has been developed to estimate the probability that plasma levels in relation to intervals post-ingestion will result in hepatotoxicity.

From Rumack BH and Matthew H, "Acetaminophen Poisoning and Toxicity," *Pediatrics*, June 1975, 55:871-6 with permission.

If the acetaminophen level determined at least 4 hours following an overdose falls above the broken line, administer the entire course of acetylcysteine treatment.

If the acetaminophen level, determined at least 4 hours following an overdose, falls below the broken line, acetylcysteine treatment is not necessary or if already initiated may be discontinued. Serum levels drawn before 4 hours may not represent peak levels.

Cautions for Use of this Chart:

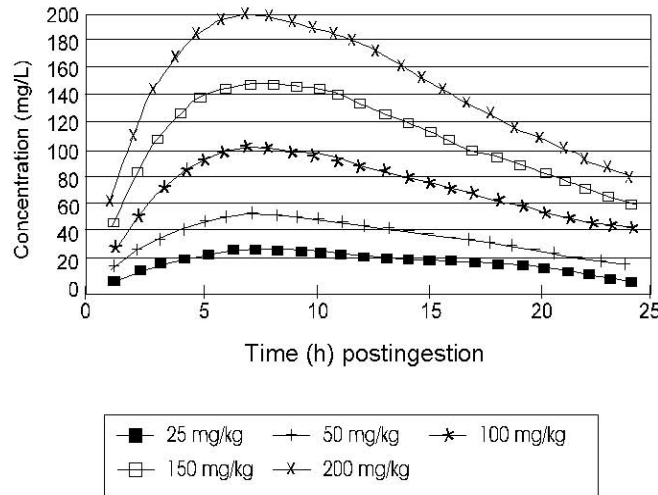

1. The time coordinates refer to time post-ingestion.
2. The graph relates only to plasma levels following a single acute overdose ingestion.
3. The broken line, which represents a 25% allowance below the solid line, is included to allow for possible errors in acetaminophen plasma assays and estimated time from ingestion of an overdose.

Similarly, the Done nomogram is somewhat useful in predicting salicylate toxicity in pediatric patients; see the Serum Salicylate Toxicity Nomogram and the Ibuprofen Toxicity Nomogram. Neither nomogram should be utilized with chronic ingestions.

A nomogram has been devised for theophylline ingestion.

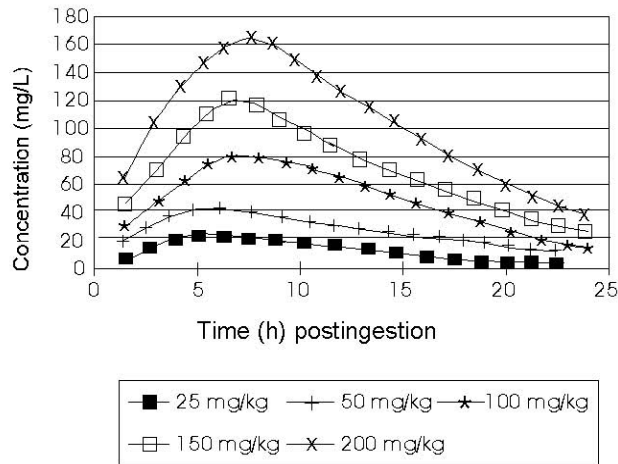

SERUM THEOPHYLLINE OVERDOSE

Nonsmokers

SERUM THEOPHYLLINE OVERDOSE

Smokers and Children

Nomogram for overdose of sustained-release theophylline in 1) nonsmoking adults, and 2) smokers and children. (Courtesy of Frank Paloucek, PharmD, College of Pharmacy, University of Illinois, Chicago.)

Additionally, certain serum levels demand immediate attention when they are obtained. For example, one should consider aggressive treatment in the setting of an acute exposure when one obtains a quantitative level of such toxins as a carboxyhemoglobin level >25% (hyperbaric oxygen), ethylene glycol >20 µg/dL (ethanol therapy with possible hemodialysis), methanol level >20 µg/dL (ethanol therapy with possible hemodialysis), lithium level >2.5 mEq/L (hemodialysis), iron level >350 µg/dL (deferoxamine), methemoglobin level >30% (methylene blue), salicylate level >100 mg/dL (hemodialysis), lead level >45 µg/dL (chelation), or mercury level >3 µg/dL (chelation).

Prevention of Absorption

Toxic substances can enter the body through the dermal, ocular, pulmonary, parenteral, and gastrointestinal routes. The basic principle of decontamination involves appropriate copious irrigation of the toxic substance

relatable to the route of exposure. For example, with ocular exposure, this can be done with normal saline for 30-40 minutes through a Morgan therapeutic lens. With alkali exposures, the pH should be checked until the runoff of the solution is either neutral or slightly acidic. Skin decontamination involves removal of the toxin with nonabrasive soap. This should especially be considered for organophosphates, methylene chloride, dioxin, radiation, hydrocarbons, and herbicide exposure. Separate drainage areas should be obtained for the contaminated runoff.

Since >80% of incidents of accidental poisoning in children occur through the gastrointestinal tract, a thorough knowledge of gastric decontamination is essential. There are essentially four modes of gastric decontamination, of which three are physical removal (emesis, gastric lavage, and whole bowel irrigation). Activated charcoal is the fourth mode for preventing absorption.

Emesis: Emesis by means of syrup of ipecac (a derivative of the plant alkaloid emetine) has been a standard of gastric decontamination; utilized at a dose of 30 mL accompanied with 16 oz of fluid for adults (repeated in 20 minutes if no emesis). Dosage of 15 mL in children 1-12 years of age accompanied with 6-8 oz fluid, or 10 mL in infants 6-12 months of age with 4 oz fluid is virtually 100% effective in producing emesis. However, it is apparent that a 100% rate of emesis is not equitable to a 100% rate of removal of toxin. In ideal circumstances, only 30% to 40% removal can be achieved within 1-2 hours postingestion, although significantly higher removal rates can be achieved if emesis is obtained within 30 minutes postingestion. For this reason, home ipecac use is being discouraged. Its use as a method of gastric decontamination in the hospital setting is virtually zero^{11,12}. The use of salt water, detergents, apomorphine, copper sulfate, and physical induction of emesis should be confined to the medical history books.

Gastric lavage: Gastric lavage through a 36- to 40-French single-use Ewald tube in adults (28- to 34-French in children) is another mode of physical removal of ingested toxin. With the patient in the left lateral decubitus position, feet elevated 20°, approximately 200-300 mL warm saline (38°C) is lavaged per run (10-15 mL/kg in children), with an additional 1-2 L used for irrigation after clearing. As with ipecac, 30% to 40% removal rate can be achieved. The contraindications are ingestion of caustic material, hydrocarbons, hemorrhagic diathesis, and seizures. Lavage should only be considered with an intubated airway with a cuffed endotracheal tube if the gag reflex is lost. Gastric lavage is not a routine procedure for all poisonings. Its use is reserved for life-threatening ingestions of selected agents within 1 hour of the ingestion. Complications of lavage include aspiration, laryngospasm, mechanical injury, and electrolyte imbalance.¹³

Activated charcoal: The use of activated charcoal has had a resurgence over the past 10 years, with several studies comparing it favorably to the other forms of physical gastric decontamination.^{14,15} An inert, nontoxic adsorbent with a surface area as high as 3000 m²/g, it is quite effective in binding high molecular weight compounds due to intermolecular attractions (van der Waals forces). The dose of activated charcoal commonly used is 0.5-1 g/kg in children and 25-100 g in adults (can be instilled through an Ewald tube), although data (with theophylline and salicylate) suggest that the optimum dose is 10 g of activated charcoal for every gram of toxin ingested. Doses in excess of 100 gms determined by a 10:1 ratio calculation must be split so that after the initial dose, no dose greater than 25 g be given every 2 hours. While children may not want to drink activated charcoal because it is black and gritty, mixing it with juice may bring a higher acceptance rate. Tablets of activated charcoal should not be used for gastric contamination.

Activated charcoal had been traditionally administered in conjunction with a cathartic to facilitate evacuation of the toxic substance. Cathartics most often administered are magnesium sulfate (15-20 g in a 10% solution), magnesium citrate (200-300 mL), sodium sulfate or sorbitol (100-150 mL in a 70% solution, or 0.5-3 mL/kg up to 50 g in pediatric patients). While cathartics may account for an additional 30% of more drug elimination, they should not be used in the presence of ileus.¹⁶ Additionally, recent reports of hypermagnesemia, in the setting of magnesium-containing cathartic administration with renal insufficiency and emesis associated with increasing amounts of sorbitol, indicate that cathartics are not a benign medication and should not be used routinely.

Whole bowel irrigation: Whole bowel irrigation with the use of GoLYTELY® has been advocated for certain intoxications, most particularly iron, lead, lithium, sustained-release or enteric-coated medications, and the body packer phenomenon.¹⁷ The patient should be seated or the head of the bed elevated 45°; the cathartic should be administered through a 12-French nasogastric tube. At an adult infusion rate of 1.5-2 L/hour (500-1000 mL/hour in children), it may take 4-6 hours (or 3 L) for complete bowel irrigation until the rectal effluent is clear. If emesis occurs, metoclopramide may be administered. Additionally, the infusion rate can be decreased by 50% for up to 1 hour and then returned to the original rate. It should be considered as a first-line decontamination procedure when one encounters a toxin that is not well adsorbed by activated charcoal within 2 hours of ingestion. Contraindications include adynamic ileus, hemorrhage, bowel obstruction, bowel perforation, unprotected airway, hemodynamic instability, or uncontrolled vomiting. Activated charcoal should not be administered with whole bowel irrigation.

Antidotes

One can use as a definition of an antidote any drug that increases the median lethal dose (LD₅₀) of a toxin. While certain drugs may modify symptoms produced by a toxin (eg, beta-blockers reducing heart rate in cocaine intoxication), only a relatively few toxins have specific antidotes. The reader should be referred to specific monographs for antidote utilization.

Enhancement of Elimination

Only recently has this aspect of poison management received more than cursory attention in practice and in the literature. The standard practice for enhancement of elimination consisted primarily of forced diuresis in order to excrete the toxin. However, the past 10 years experience has produced a radical change in the approach to this and therefore a more focused methodology to eliminating absorbed toxins. Essentially, there are three methods by which absorbed toxins may be eliminated: recurrent adsorption with multiple dosings of activated charcoal, use of forced diuresis in combination with possible alkalization of the urine, and use of dialysis, charcoal hemoperfusion, or other extracorporeal methods to support renal function. Other methods such as exchange transfusions and plasmapheresis are used rarely.

Multiple dosing of activated charcoal ("pulse dosing") has been advocated as a method for removal of absorbed drug.¹⁸ This procedure has been demonstrated to be efficacious in drugs that re-enter the gastrointestinal tract through enterohepatic circulation (eg, digitoxin, carbamazepine, glutethimide) and with drugs that diffuse from the systemic circulation into the gastrointestinal tract due to formation of a concentration gradient ("the infinite sink" hypothesis).

Toxins with Enhanced Elimination by Multiple Dosing of Activated Charcoal

Acetaminophen	Maprotiline
Amitriptyline	Methyprylon
Atrazine (?)	Nadolol
Baclofen (?)	Nortriptyline
Bupropion (?)	Phencyclidine (?)
Carbamazepine*	Phenobarbital*
Chlordecone	Phenylbutazone
Cyclosporine	Phenytoin (?)
Dapsone*	Piroxicam
Dextropropoxyphene	Propoxyphene
Diazepam (desmethyldiazepam)	Propranolol (?)
Digitoxin	Quinine*
Digoxin (with renal impairment)	Salicylates (?)
Disopyramide	Sotalol
Glutethimide	Theophylline*

* Recommended in American Academy of Clinical Toxicology Practice Guidelines.¹⁸

The following agents have been studied and have not been demonstrated to result in enhanced elimination.

Amiodarone	Meprobamate
Astemizole	Methotrexate
Chlopropamide	Sodium Valproate
Doxepin	Tobramycin
Imipramine	Vancomycin

Essentially, this can be thought of as “intestinal dialysis.” The toxins by which this method appears to be most efficacious are those with low volume of distribution (< 1.0 L/kg), uncharged, lipophilic, low protein binding, long half-life, and that undergo enterohepatic circulation (although the latter property is not essential). Note that these are similar criteria required for a toxin to be removed by hemoperfusion.

Despite the above limitations, multiple dosing of activated charcoal is utilized quite often. The literature has demonstrated that the data on phenytoin and salicylates are somewhat equivocal due primarily to their high protein binding. The usual dosage of activated charcoal is 1 g/kg as the initial dose, followed by 0.5 g/kg every 2-4 hours. Usually at least three doses are required; cathartics should not be administered more than once daily. Multiple dosing of cholestyramine (4 g every 8 hours) resin may be useful in enhancing elimination of digitoxin, phenobarbital, warfarin, lorazepam, methotrexate, lindane, or chlordecone.

The practice of blindly overloading the toxic patient with intravenous fluids to promote diuresis has not been supported in the literature and is associated with an increased risk of pulmonary edema, hyponatremia, or increased intracranial pressure.^{19,20} Patients who exhibit the syndrome of inappropriate secretion of antidiuretic hormone (SIADH) should not undergo a diuresis. Ion trapping techniques are useful to increase renal excretion of polar drugs with a dissociable group that will carry a charge at a pH that is distant from their pKa. Thus, most of the drug will be ionic (either acidic or alkali) in the distal tubular lumen and in its ionic form will not undergo tubular reabsorption and thus enhance urinary excretion. The use of this modality (with or without ion trapping) should be limited to the following drugs.

Toxins Eliminated by Saline Diuresis

Barium	Isoniazid (?)
Bromides	Meprobamate
Chromium	Methyl iodide
Cimetidine (?)	Mushrooms (Group I)
Cis-platinum	Nickel
Cyclophosphamide	Potassium chloroplatinite
Hydrazine	Thallium
Iodide	Valproic Acid (?)
Iodine	

Toxins Eliminated by Urine Alkalinization

2,4-D-chlorophenoxyacetic acid (Mecoprop)* (urine pH > 8 and urine flow of 600 mL/h)	Methotrexate*
Barbital (?)	2-Methyl-4-chlorophenoxyacetic acid (MCPA)
Chlorpropamide*	Orellanine (?)
Diflunisal* (2-fold increase)	Phenobarbital*
Fluoride	Primidone
Iopanoic Acid (?)	Quinolones antibiotic
Isoniazid (?)	Salicylates*
Mephobarbital	Sulfisoxazole
	Uranium

* Confirmed in clinical studies

A urine flow of 3-5 mL/kg/hour should be achieved with a combination of isotonic fluids or diuretics. Alkalinization can be achieved by administration of 44-88 mEq of intravenous sodium bicarbonate per liter to titrate a urine pH of 7.5-8.5; 20-40 mEq/L of intravenous potassium chloride may also be required (potassium should not be administered in patients with renal insufficiency). Arterial pH should not exceed 7.50. In a child, the dose of I.V. sodium bicarbonate is 25-50 nmol (25 mL of an 8.4% solution) over one hour. It should be noted that urine alkalinization is most often for salicylates and phenobarbital; however, it should be noted that multiple dosing of activated charcoal is more efficient in phenobarbital elimination. Complications of urine alkalinization include hypokalemia, hypocalcemia, and systemic alkalinization. Although several drugs can exhibit enhanced elimination through an acidic urine (tranylcypromine, quinine, chlorpheniramine, fenfluramine, strychnine, cathinone or khat, amphetamines, phencyclidine, nicotine, bismuth, diethylcarbamazine

citrate, ephedrine, flecainide, local anesthetics), the practice of acidifying the urine should be discouraged in that it can produce metabolic acidosis and promote renal failure in the presence of rhabdomyolysis.

Hemodialysis can be used to increase clearance with the following drugs:

Drugs and Toxins Removed by Hemodialysis

Acetaminophen	Cephapirin
Acetazolamide	Cephradine
Acyclovir	Chloral hydrate
Alkyl phosphate	Chloramphenicol (?)
Allopurinol	Chlordiazepoxide (?)
Aluminum	Chloride
<i>Amanita phalloides</i> (?)	Chlorpropamide
Amantadine (?)	Chromic acid
Amikacin	Chromium
Ammonia	Cimetidine (?)
Ammonium chloride	Ciprofloxacin (?)
Amobarbital	Colistin
Amoxicillin	Cyclobarbitol
Amphetamine	Cyclophosphamide
Ampicillin	Cycloserine
Anilines	Dapsone
Antimony (Pentavalent) (?)	Demeton-S-methyl sulfoxide
Arsenic (?)	Dextropropoxyphene
Atenolol	Diethyl pentenamide
Azathioprine	Dimethoate
Azlocillin	Dinitro-ortho-cresol
Aztreonam	Diquat
Bacitracin (?)	Disopyramide
Baclofen	Enalapril (?)
Barbital	Ergotamine
Boric acid	Erythromycin
Bretylium	Ethambutol
Bromides	Ethanol
Bromisoval	Ethchlorvynol (?)
Butalbital	Ethinamate
Calcium	Ethosuximide (?)
Captopril (?)	Ethylene glycol
Carbamazepine	Eucalyptus oil
Carbenicillin	Famciclovir (Penciclovir)
Carbromal	Famotidine (?)
Carisoprodol	Flucytosine
Cefaclor	Fluoride
Cefamandole	Fluoridem chlorate
Cefazolin	5-Fluorouracil (?)
Cefoperazone (?)	Folic acid
Cefotaxime	Formaldehyde
Cefoxitin	Foscarnet sodium
Ceftazidime	Fosfomycin
Cephalexin	Gabapentin
Cephaloridine	Gallamine triethiodide
Cephalothin	Ganciclovir

Gentamicin	Pentachlorophenol
Glufosinate Ammonium	Pentobarbital
Glutethimide (?)	Phenelzine (?)
Glycol ethers	Phenobarbital
Hydrazine (?)	Phosphate
Hydrochlorothiazide	Phosphoric acid
Imipenem/Cilastatin	Piperacillin
Iodides	Potassium Chloride
Isoniazid	Potassium Dichromate
Isopropanol	Practolol
Kanamycin	Prednisone (?)
Ketoprofen	Primidone
Lead (with EDTA)	Procainamide
Lithium	Propoxyphene
Magnesium	Quinalbital
Mannitol	Quinidine
Meprobamate	Ranitidine (?)
Meropenem	Rifabutin
Metal-chelate compounds	Salicylates
Metformin (?)	Secobarbital (?)
Methanol	Sodium chlorate
Methaqualone	Sodium chloride
Methotrexate	Sodium citrate
Methyldopa	Sotalol
Methylprednisolone (?)	Streptomycin
Methylprylone	Strychnine
4-Methylpyrazole	Succimer (?)
Metronidazole	Sulfamethoxazole
Mezlocillin	Sulfisoxazole
Monochloroacetic acid	Tetracycline (?)
Nadolol	Thallium
Nafcillin	Theophylline
Neomycin	Thiocyanates
Netilmicin	Ticarcillin
Nitrates	Tobramycin
Nitrite	Tocainide
Orellanine (?)	Topiramate
Ouabain (?)	Tranylcypromine sulfate (?)
Oxalic acid	Trimethoprim
Paraldehyde	Valproic acid (?)
Paraquat (?)	Vancomycin
Pargyline	Verapamil (?)
Penicillin G	Vidarabine

Hemodialysis is especially effective in correcting metabolic acidosis induced by certain toxins such as salicylates. Criteria utilized for hemodialysis include water solubility of the toxin, low steady state volume of distribution (< 1 L/kg), low protein binding (< 70% to 80%), polarity, and low molecular weight (< 500 daltons). Drugs in which hemodialysis is required at an early stage of intoxication include methanol, ethylene glycol, lithium, and boric acid.^{21,22} Hemodialysis also should be definitely used after heavy metal chelation in patients with renal failure.

A lipid-based dialysis (used by adding soy bean oil to an aqueous bath) may be useful in enhancing the elimination of such lipid soluble toxins as ethchlorvynol, glutethimide, camphor, or N,N-diethyltoluamide (DEET), although clinical studies with this modality are minimal. Complications of hemodialysis include hypotension, bleeding (due to systemic anticoagulation), nosocomial infection, or air embolism. Peritoneal dialysis should not be considered for the enhancement of elimination of drugs with the possible exception of vancomycin or boric acid.

Charcoal hemoperfusion can increase clearances of toxins that are absorbed by an adsorbent. Unlike hemodialysis, drug clearance through hemoperfusion is less dependent on water solubility, but on ability of the adsorbent to bind to the drug. Hemoperfusion is most efficacious for phenobarbital, glutethimide, theophylline, and paraquat. The complications of hemoperfusion are analogous to hemodialysis. Additionally, leukopenia, thrombocytopenia, or hypocalcemia may occur.²²

Drugs and Toxins Removed by Hemoperfusion (Charcoal)

<i>Amanita phalloides</i> (?)	Meprobamate
Atenolol (?)	Methaqualone
Bromisoval	Methotrexate
Bromoethylbutyramide	Methsuximide
Caffeine	Methyprylon (?)
Carbamazepine	Metoprolol (?)
Carbon tetrachloride (?)	Nadolol (?)
Carbromal	Orellanine (?)
Chloral hydrate (trichloroethanol)	Oxalic acid (?)
Chloramphenicol	Paraquat
Chlorfenvinphos (?)	Parathion (?)
Chlorpropamide	Pentamidine
Cibenzoline succinate	Phenelzine (?)
Clonidine	Phenobarbital
Colchicine (?)	Phenol
Creosote (?)	Phenytoin
Dapsone	Podophyllin (?)
Demeton-S-methyl Sulfoxide	Procainamide (?)
Diltiazem (?)	Quinidine (?)
Dimethoate	Rifabutin (?)
Disopyramide	Sotalol (?)
Ethchlorvynol	Thallium
Ethylene oxide	Thyroglobulin/Thyroid hormone
Glutethimide	Theophylline
Levothyroxine (?)	Valproic acid
Lindane	Verapamil (?)
Liotrix	

Continuous arteriovenous hemofiltration has been used to treat lithium, paraquat, N-acetyl-procainamide, and vancomycin ingestions with varying results. It is capable of filtering molecules with a molecular weight up to 500 daltons, but some substances such as thallium and formaldehyde cannot be removed by this method despite their low molecular weight. High flux dialyzers can promote clearance of larger molecules (eg, vancomycin, valproic acid) and compounds bound to proteins (eg, carbamazepine). Hemodialysis can also correct systemic acidosis induced by salicylate, toxic alcohols, and metformin. Plasmaphoresis is a method for removal of plasma in exchange for albumin or fresh frozen plasma. With plasma exchange, the plasma concentration of drugs or toxins can theoretically be lowered if they are primarily in the intravascular compartment. Thus, toxins which are highly protein bound and have a high molecular weight can be removed. In reality, multiple plasma exchanges have only been demonstrated to be marginally useful in treating life-threatening exposure to *Amanita* mushroom (Group I) poisoning, botulism, pentachlorophenol, crotalid envenomation, and thyroxine and digoxin overdose.²³

Exchange transfusion is a useful modality to enhance drug elimination in neonatal or infant drug toxicity. Usually double or triple volume exchanges are performed. It has been utilized to treat barbiturate, phenobarbital, acetaminophen, iron, caffeine, methyl salicylate, propafenone, ganciclovir, sodium nitrite, lead, phenazopyridine hydrochloride, Group I mushrooms, atropine, reserpine, pentachlorophenol, pine oil, theophylline overdose, and nitrate exposure in pediatric patients. Exchange transfusions (500-2000 mL) volume replacement have also been used to treat adults with 80-150 g ingestions of parathion.

EXCHANGE TRANSFUSIONS

Toxicants for Which Exchange Transfusions May Be Helpful

Parathion
Acetaminophen
Iron (serum levels > 1000 mcg/dL)
Caffeine
Methyl salicylate
Propafenone
Ganciclovir/acyclovir
Methemoglobin producers ¹
Lead
Phenazopyridine hydrochloride
Pine oil
Theophylline (serum levels > 90 mcg/mL)
Vancomycin
<i>Plasmodium falciparum</i> malaria
Halothane hepatitis
<i>E. coli</i> 0157:H7 associated Hemolytic-Uremic Syndrome
¹ Especially patients with G6PD or NADPH-dependent methemoglobin reductase deficiency and/or methylene blue therapy with methemoglobin levels > 70%.

Support and Monitoring for Adverse Effects

This aspect of poison management is the least studied. The usual disposition of the admitted poisoned patient is an intensive care unit bed or cardiac monitored bed to evaluate the late sequelae of the toxic agent. However, the practice of admitting the poisoned patient routinely to the intensive care unit is being questioned. A recent retrospective study identified eight clinical risk factors that predicted ICU interventions: (1) arterial carbon dioxide pressure ≥ 45 mm Hg, (2) need for emergency intubation, (3) seizures, (4) cardiac arrhythmia, (5) QRS duration ≥ 0.12 seconds, (6) systolic blood pressure < 80 mm Hg, (7) second- or third-degree atrioventricular block, and (8) unresponsiveness to verbal stimuli.²⁴ If a toxic patient did not exhibit any of these characteristics, no ICU interventions (such as intubation, antiseizure therapy, intravenous vasopressors, antiarrhythmics, and dialysis or hemoperfusion) were performed.

Additionally, other risk factors that should be considered for ICU admission include the need for emergent hemodialysis or hemoperfusion, increasing metabolic acidosis, and any tricyclic or phenothiazine overdose manifesting anticholinergic signs of cardiac abnormalities.^{25,26} While many drugs (such as ibuprofen) will manifest their toxicity within 4 hours after ingestion, tricyclic overdoses are renowned for their incidence of delayed complications.²⁷ It has been noted that most of these patients exhibited cardiac or neurologic abnormality prior to the delayed arrhythmia. The following are suggested criteria for ICU admission.

Criteria for Admission of the Poisoned Patient to ICU

Respiratory depression ($p\text{CO}_2 > 45$ mm Hg)

Emergency intubation

Seizures

Cardiac arrhythmia

Hypotension (systolic blood pressure < 80 mm Hg)

Unresponsiveness to verbal stimuli

Second- or third-degree atrioventricular block

Emergent dialysis or hemoperfusion

Increasing metabolic acidosis

Tricyclic or phenothiazine overdose manifesting anticholinergic signs, neurologic abnormality, QRS duration > 0.12 second, or QT_c duration > 0.5 seconds

Administration of pralidoxime in organophosphate toxicity

Pulmonary edema induced by drugs or toxic inhalation (ARDS)

Cerebral edema (from salicylate, lead, carbon monoxide, etc)

Drug-induced hypothermia or hyperthermia including neuroleptic malignant syndrome

Hyperkalemia secondary to digitalis overdose

Any use of digoxin-immune Fab fragments

Body packers and stuffers

Concretions secondary to drugs

Emergent surgical intervention

Monoamine oxidase inhibitor overdose

Antivenom administration in Crotalidae, coral snake, or arthropod envenomation

Significant aspiration pneumonitis in the elderly

Need for continuous infusion of naloxone

Need for extracorporeal membrane oxygenation (ECMO)

Continuous arteriovenous hemofiltration

Requirement for exchange transfusion

Sustained release beta-adrenergic blocker, calcium channel blocker overdose, bupropion, lithium, or oral hypoglycemic agent overdose

pCO₂ = carbon dioxide pressure

ARDS = adult respiratory distress syndrome

Adapted from Kulling P, Persson H, "Role of the Intensive Care Unit in the Management of the Poisoned Patient," *Med Toxicol*, 1986, 1:375-86, and Brett AS, Rothschild N, Gray R, et al, "Predicting the Clinical Course in Intentional Drug Overdose: Implication for Use of the Intensive Care Unit," *Arch Intern Med*, 1987, 147:133-7, and Callahan M, "Admission Criteria for Tricyclic Antidepressant Ingestion," *West J Med*, 1982, 137:425-9.

Extracorporeal membrane oxygenation (ECMO) has been used with varying success to treat hydrocarbon pneumonitis (primarily in pediatric exposures), tricyclic antidepressant, propranolol, paraquat, chlorine gas, or quinidine poisoning.²⁸⁻³¹ Prerequisites for its use include ability to survive until ECMO is applied (about 2 hours), high expected mortality (> 75%) from cardiac or respiratory failure if ECMO is not used, and lack of long-term toxin sequelae. Peripheral cardiopulmonary bypass support has been shown to be useful in accidental lidocaine, aconitine, flecainide, bupivacaine, propranolol, and organophosphate overdoses.³²⁻³⁴ Also, the use of partial liquid ventilation has been used successfully to treat severe pulmonary complications due to verapamil poisoning.³⁵

CLINICAL TOXICOKINETICS

Frank P. Paloucek, PharmD

The common “no calculation” approach in the assessment of the poisoned patient is to obtain a history of the dose ingested (assuming the maximum value possible), converting to a weight-based value (mg/kg), and comparing it with published standards for either prognosis or treatment decisions. A limited number of agents including, but not limited to, acetaminophen, salicylate, theophylline, lithium, digoxin, phenytoin, and the toxic alcohols have reasonable, and timely, availability of serum concentration analysis. This leads to use of the magnitude of a serum concentration at the time of presentation, or subsequent peak value to predict outcome or serve as an indication for therapeutic decisions. Unfortunately, the common practice is to apply routine serum concentration analysis and monitoring practices to the overdose population.

Ideally, predictive pharmacokinetic calculations, based on the historical data, should include considerations for the continued absorption and distribution phases of an acute ingestion. Furthermore, the use of comparative analysis of predicted vs observed data should enhance the assessment and need-to-treat decisions. The use of these formulas should not provide sole or absolute criteria in patient management issues but should be combined with overall clinical assessments, preferably with the assistance of poison control centers or clinical toxicologists.

Initial assessment of any case prior to obtaining the results of the initial serum concentration determination should include calculation of the “worst case” scenario. The following formula can be used to predict the highest magnitude concentration (“worst case”) for a specified dose and patient:

$$C_{\text{peak}} = \text{dose}/[V_d \text{ weight (kg)}] \quad (1)$$

where C_{peak} is the highest observed serum concentration, dose is the greatest possible ingested dose in mg, and V_d is the population value for the volume of distribution (in L/kg) of the ingested agent.

Observed values will vary from prediction on the basis of the accuracy of dose ingested, time between ingestion and serum sampling, and bioavailability (assumes $F = 1.0$), and ignores any reductions, or delay, in toxin dose due to the presence of a salt form ($S = 1.0$) or dosage form. Additionally, any intervening symptoms and/or treatments (vomiting or gastric decontamination) will also affect predictive performance. Thus, if the history is accurate, the calculation should nearly always be an overprediction.

Accounting for the passage of time between ingestion and serum sampling, the following formula is preferred to the formula above for a more precise prediction:

$$C_p = \{\text{dose}/[V_d \text{ weight (kg)}]\} \times e^{-(K_e \times t)} \quad (2)$$

or

$$C_p = (C_{\text{peak}}) (e^{-(K_e \times t)}) \quad (3)$$

where C_p is the serum concentration at any time (t , in hours) after an ingestion, dose and V_d are defined as above, and K_e is the population value for the elimination rate of the toxin (hr^{-1}).

Formula 3 can be generalized to:

$$C_{p2} = (C_{p1}) (e^{-(K_e \times t)}) \quad (4)$$

where C_{p1} and C_{p2} are any two consecutive serum concentrations with time interval (t) between. This allows the ability to anticipate future sampling times and/or potential windows of threat/opportunity/resolution.

Once two consecutive declining serum samples have been determined, the elimination rate might be approximated by the following formula (which is a mere rearrangement of formula 4):

$$K_e = \{\ln (C_{p1}/C_{p2})\}/t \quad (5)$$

This can be compared with a known population value to assess the competency of the patient to eliminate the toxin and provide an etiology for the presentation. It should be noted that the value determined can be falsely diminished or in “normal” range (slower or equal to normal elimination) if sampling occurs during significant drug absorption. This would be common with sustained-releases preparations or in presence of a bezoar. Also, the calculated value determined can be falsely elevated (faster than normal elimination) if sampling occurs during significant tissue distribution, especially with drugs like digoxin or lithium. This technique is useful for determining the patient-specific impairment of underlying elimination, especially with chronic

overdoses, as well as to assess the impact of intervening treatment strategies and/or the need to add or continue elimination-enhancing modalities.

Elimination rates are best determined graphically with at least three values to determine a linear plot. The use of formula 5 and its frequent adaptation to calculate half-life (formula 6 below) assumes that the absorption and distribution processes are essentially complete, which is frequently not true of initial samplings in the evaluation of a poisoning. The elimination half-life is calculated using K_e by the following formula:

$$T_{1/2} = 0.693/K_e \quad (6)$$

The formulas above assume essentially complete and instantaneous absorption and hold limited value (consistently overpredicting) for predicting values in sustained-release dosage form overdoses. While consistent with the worst-case approach to evaluating patients, accounting for the absorption process can improve accuracy of predictions and may refine evaluation and need-to-treat decisions.

The following formula provides the potentially most accurate prediction of a serum concentration at any time for any toxin for which the parameters V_d , K_a , and K_e are available.

$$C_p = [\text{dose}/(V_d \times \text{weight})] \times [K_a/(K_a + K_e)] \times (e^{-(K_e \times t)} - e^{-(K_a \times t)}) \quad (7)$$

Unfortunately, absorption rates (K_a) are rarely found in the common biomedical literature, limiting the application of this calculation and evaluation of its potential benefit in use.

In any event, when the initial prediction is compared to the actual concentration and a marked discrepancy is noted, reconsideration of the history must be undertaken. A reasonable approach would be to assume an inaccuracy of dose. Back calculation using the same formula and the observed concentration to determine the "actual" dose ingestion can be performed. Repeat calculations can be made for future serum concentration determinations based on the calculated "actual" dose ingested and assuming the time of ingestion history was accurate.

Explanations for Variations Between Predicted and Observed Values

Overpredictions for Initial Concentrations

- Inaccurate history of dose (historical dose used was too high)
- Inaccurate time interval (historical data too short)
- Early sampling with minimal time for product dissolution and absorption to occur
- Decreased absorption (positive outcomes from gastric emptying events)
- Delayed/incomplete absorption (bezoars, sustained-release, enteric-coated, highly compressed, or poorly water soluble products)

Overpredictions for Subsequent Concentrations

- Patient still in absorption-phase, or endogenous metabolism and/or elimination better than the specific average population parameter value chosen
- Calculation with V_d central compartment not postdistribution or steady-state V_d

Underpredictions for Initial Concentrations

- Inaccurate history of dose (historical data too low)
- Inaccurate time interval (historical data too long)
- Alterations in absorption (dose-dumping of sustained-release dosage forms)
- Early sampling during distribution phase, but C_p is calculated using postdistribution V_d

Overpredictions for Subsequent Concentrations

- Alterations in absorption (dose-dumping of sustained-release dosage forms)
- Bezoar dissolution endogenous metabolism and/or elimination is slower than known population values
- Calculated patient-specific K_e was peridistribution not during true elimination
- Ineffective decontamination or elimination-enhancement therapies, and/or unaccounted new administration

Potential Benefits in the Toxicokinetic Evaluation and/or Management of the Overdose Patient

- Differentiating the acute or acute-on-chronic overdose from a chronic intoxication
Acute ingestions generally require higher serum concentrations for specific morbidity or mortality than acute-on-chronic or chronic. Conversely, aggressive treatment measures are indicated at lower serum concentrations in acute-on-chronics and chronics than for acute overdoses. Specific poisonings for which this is true include theophylline, lithium, salicylate, and digoxin. Acute-on-chronic overdoses could be characterized by increases in serum concentrations greater than expected from a maintenance dose, whereas a chronic intoxication would generally have a normal increase. Chronic intoxications frequently are associated with prolonged elimination half-lives. Differentiation assist in determining the need for psychiatric consult and for etiologies in the chronic.
- Clarifying the history
Comparing predicted with observed values can lead to revised etiologies, which may reflect reversible process errors. Calculations can assist in suggesting prognosis and/or chronicity of exposure, as in the suspected acetaminophen ingestion without any history of time or dose. Calculations allow anticipation of future serum concentration changes. This could allow for prospective use of treatment measures vs traditional reactive implementation.

HIGHLIGHTS OF RECENT REPORTS (2006) ON SUBSTANCE ABUSE AND MENTAL HEALTH

Reprinted from www.oas.samhsa.gov.

SAMHSA's National Survey on Drug Use and Health found that 2.4 million persons aged 12 and older initiated nonmedical use of prescription pain relievers (analgesics) such as OxyContin[®] within the past year in 2004. Among persons who initiated nonmedical use of pain relievers in the past year, 48.0% used Vicodin[®], Lortab[®], or Lorcet[®], nonmedically; 34.3% had used Darvocet[®], Darvon[®], or Tylenol[®] with codeine nonmedically; and 20.0% had used Percocet[®], Percodan[®], or Tylox[®] nonmedically. Of the past year new users of nonmedical pain relievers, 73.8% had used another illicit drug prior to using pain relievers nonmedically. In 2004, about 615,000 persons began using OxyContin[®] nonmedically. Nearly all (99.1%) of the persons who first used OxyContin[®] nonmedically in the past year had used another illicit drug prior to using OxyContin[®] nonmedically (<http://www.oas.samhsa.gov/2k6/pain/pain.cfm>).

Based on SAMHSA's Treatment Episode Data Set (TEDS), young adults aged 18 to 25 accounted for 21% and youth aged 12 to 17 accounted for 8% of the 1.9 million admissions to substance abuse treatment reported to TEDS in 2004. Young adults aged 18-25 were less likely than youths aged 12-17 to be admitted with marijuana as their primary substance of abuse (27% vs. 64%). The criminal justice system was the principal source of referral to treatment for 47% of young adult admissions compared to 52% of youth admissions to substance abuse treatment. About 48% of all TEDS substance abuse treatment admissions in 2004 were in the 28 states that provided data on a psychiatric problem in addition to an alcohol or drug problem for their treatment admissions. Based on this TEDS supplemental data set, 17% of young adults had a psychiatric problem in addition to substance abuse compared with 20% of the youth admissions for substance abuse treatment (<http://www.oas.samhsa.gov/2k6/youngTX/youngTX.cfm>).

Based on SAMHSA's National Survey on Drug Use and Health combined data from 2002 to 2004, most of the young adults aged 18 to 25 who had used marijuana in the past year obtained their most recently used marijuana from a friend either free or by purchase. Among young adults who had used marijuana in the past year, 58.3% obtained their most recently used marijuana for free or shared someone else's and 40.0% bought their marijuana. Young adults who were daily marijuana users were more likely than nondaily marijuana users to have bought their most recently used marijuana (75.3% vs. 33.8%). Young adult users of marijuana in the past year who used marijuana daily were more likely than nondaily marijuana users to have gotten their most recently used marijuana inside a home, apartment, or dorm room and less likely to have gotten their marijuana from inside a public building or outside in a public area (<http://www.oas.samhsa.gov/2k6/MJsource/MJsource.cfm>).

SAMHSA's Drug Abuse Warning Network (DAWN) collects data on all deaths where drugs played a role, either directly (eg, overdose) or indirectly (eg, fatal car crash where drugs were involved). Drug misuse death is defined as a drug-related death caused by overmedication, all other accidental causes, homicide by drugs, and drug-related deaths where the cause could not be determined. Six states participate in the mortality component of the Drug Abuse Warning Network: Maine, Maryland, New Hampshire, New Mexico, Utah, and Vermont. The rates of opiate-related drug misuse deaths in 2003 ranged from 7.2 per 100,000 population in New Hampshire to 11.6 per 100,000 population in New Mexico. In each of these 6 states, most opiate-related drug misuse deaths involved multiple drugs. Three opiate pain medications as a group (oxycodone, hydrocodone, and methadone) were involved in 40% or more of the opiate misuse deaths in these states. The involvement of oxycodone ranged from 13% in New Mexico to 30% in Vermont; hydrocodone ranged from 3% in Maryland to 17% in Utah; and methadone ranged from 17% in New Mexico to 46% in Maine (<http://www.oas.samhsa.gov/2k6/opiateDeaths.cfm>).

Based on SAMHSA's National Survey on Drug Use & Health, 70.4% of students aged 12 to 17 reported that they had an A or B grade average in their last semester or grading period, while 29.6% had a C average or less. Younger students were more likely to report good grades than older students; for example, 75.6% of students aged 12 or 13 reported an A or B average compared with 68.3% of students aged 16 or 17. Students who did not use alcohol in the past month (72.5%) were more likely to have an A or B grade average than those who drank alcohol but did not binge (67.1%) or those who binge drank alcohol in the past month (57.7%). Students who did not use marijuana in the past month (72.2%) were more likely to have an A or B grade average than those who used marijuana on 1 to 4 days in the past month (58.0%) or those using marijuana on 5 or more days in the past month (44.9%) (<http://www.oas.samhsa.gov/2k6/academics/academics.cfm>).

Based on SAMHSA's Drug Abuse Warning Network (DAWN), of the 1.3 million drug-related visits to emergency departments in 2004 that were associated with drug misuse or abuse, 30% involved illicit drugs

only, 25% involved pharmaceuticals only, 15% involved illicit drugs and alcohol, 8% involved illicit drugs with pharmaceuticals, and 14% involved illicit drugs with pharmaceuticals and alcohol (<http://dawninfo.samhsa.gov/pubs/edpubs/default.asp>).

Among older adult admissions to substance abuse treatment reported to SAMHSA's Treatment Episode Data Set (TEDS), about half (48%) were admitted for abuse of alcohol only. Older adult alcohol-only admissions were less likely than other older adult admissions to be self/individual referrals (37% vs. 45%). Among older adult admissions alcohol-only admissions were more likely than other admissions to have entered treatment for the first time (45% vs. 33%) (<http://www.oas.samhsa.gov/2k6/olderAdultsTX/olderAdultsTX.cfm>).

Based on analysis of combined data from SAMHSA's 2002-2004 National Surveys on Drug Use & Health, 7.6% (18.2 million) persons aged 12 or older met the criteria for alcohol dependence or abuse in the past year. Alcohol abuse or dependence was more prevalent among adults aged 18 or older who were never married (16%) than adults who were divorced or separated (4.6%) or widowed (1.3%). Persons aged 12 or older who were dependent on or abused alcohol in the past year were more likely to have been treated in an emergency room at least once in the past year than those who did not meet alcohol dependence or abuse criteria (34.2% vs. 27.9%) (<http://www.oas.samhsa.gov/2k6/alcDepend/alcDepend.cfm>).

Provides latest data on treatment completion rates by type of substance abuse care (inpatient, outpatient, hospital, methadone maintenance, etc.). Among the 888,432 discharges from substance abuse treatment reported to SAMHSA's TEDS system, 42% were from outpatient treatment, 23% from detoxification, 12% were from intensive outpatient treatment, 8% from long-term residential treatment, 8% from short term residential treatment, 5% from methadone treatment, and 1% from hospital residential treatment. Overall, treatment was completed by 41% of the substance abuse treatment discharges. The treatment completion rate was highest from short-term treatment programs (69% of the discharges from hospital residential treatment completed treatment, 64% from short-term residential, and 55% from detoxification). The treatment completion rate was 41% for long-term residential treatment and 38% for outpatient treatment (<http://www.dasis.samhsa.gov/teds03/tedsdischweb2k3.pdf>).

During 2004, an estimated 192,690 patients in drug-related emergency department visits were diagnosed with co-occurring substance use and mental disorders. When emergency department visits involved co-occurring disorders, 40.4% were treated and released home or referred to detoxification or other drug treatment and 42.2% were admitted to inpatient units including chemical dependency or detoxification units. Of the emergency department visits with co-occurring diagnosis, the drug most frequently reported were cocaine (31.8%), alcohol (29.3%), opiates/opioids (18.0%), and marijuana (16.3%) (<http://dawninfo.samhsa.gov/pubs/shortreports/default.asp>).

Opiates were the primary substance of abuse for 324,000 (18%) of the 1.8 million substance abuse treatment admissions reported to SAMHSA's Treatment Episode Data Set (TEDS) in 2003. Of these, 51,000 (3% of all admissions) were for a non-heroin opiate. Non-heroin opiates include methadone, codeine, Dilaudid, morphine, Demerol, opium, oxycodone, and any other drug with morphine-like effects. Non-heroin opiate admissions (40%) were more likely than heroin admissions (22%) to be entering treatment for the first time. Non-heroin opiate admissions were less likely than heroin admissions to report cocaine as their secondary substance of abuse (17% vs. 50%) and more likely than heroin admissions to report marijuana as their secondary substance of abuse (19% vs. 10%) (<http://www.oas.samhsa.gov/2k6/opiatesTX/opiatesTX.cfm>).

This report on underaged drinking (by persons aged 12 to 20) is based on state level data combined from 2 years of data, i.e. from SAMHSA's 2003 and 2004 National Surveys on Drug Use and Health. Data are annualized estimates, that is, an average per year estimate is calculated from the combined data years. In 2003-2004, past month alcohol use rates for persons aged 12 to 20 were among the lowest in Utah (18.6%) and Tennessee (22.3%) and among the highest in North Dakota (42.7%) and South Dakota (39.1%). Between 2002-2003 and 2003-2004, past month alcohol use increased in California (from 24.7 to 26.3%) and Wisconsin (from 34.7% to 38.3%), while binge alcohol drinking increased in Iowa (from 24.7% to 27.7%) and Oklahoma (from 19.1% to 21.5%). Past month alcohol drinking decreased between 2002-2003 and 2003-2004 in South Carolina (from 27.2% to 24.1%) and Michigan (from 31.8% to 30.2%), while binge alcohol drinking decreased in South Carolina and North Carolina (both from 18.0% to 15.9%) and in Tennessee (from 15.9% to 13.1%) (<http://www.oas.samhsa.gov/2k6/StateUnderageDrinking/underageDrinking.cfm>).

Between 1993 and 2003, the number of substance abuse treatment admissions increased from 1.62 million to 1.84 million treatment admissions. This increase in substance abuse treatment admissions was almost 14%. The proportion of admissions also increased between 1993 and 2003 for those reporting as their primary substance of abuse: marijuana (increased from 7% in 1993 to 16% in 2003), opiates (increased from 13% to 18%), or stimulants (increased from 2% to 7%). The proportion of admissions decreased during this decade

for those reporting alcohol (57% to 41%) or cocaine (17% to 14%) as their primary substance of abuse. Substance abuse treatment admissions that were aged 25 to 34 decreased from 40% of admissions in 1993 to 25% of treatment admissions in 2003 (<http://www.oas.samhsa.gov/2k6/TXtrends/TXtrends.cfm>).

According to SAMHSA's Drug Abuse Warning Network (DAWN), in 2004 there were over 15,000 emergency department visits by adolescents aged 12 to 17 whose suicide attempts involved drugs. Pain medications were involved in about half of the suicide attempts. Almost three quarters of the drug, related suicide attempts were serious enough to merit the patient's admission to the same hospital or transfer to another health care facility. Antidepressants or other psychotherapeutic medications were involved in over 40% of the suicide attempts by adolescents who were admitted to the hospital (<http://dawninfo.samhsa.gov/pubs/shortreports/>).

In SAMHSA's 2002 to 2004 National Surveys on Drug Use & Health, an average of 598,000 youths aged 12 to 17 per year reported that they initiated inhalant use in the 12 months prior to being surveyed. The types of inhalants most frequently mentioned as having been used by recent initiates were: glue, shoe polish, or toluene (30.3%), gasoline or lighter fluid (24.9%), nitrous oxide or "whippets" (24.9%), and spray paints (23.4%). Among recent inhalant initiates, 19.4% used inhalants on 13 or more days in the past year. In 2002 to 2004, 59.7% of recent inhalant initiates aged 12 to 17 had used cigarettes prior to using inhalants, 67.6% had previously used alcohol, 42.4% had previously used marijuana, and 35.9% had used all three substances (cigarettes, alcohol, and marijuana) before they used inhalants (<http://www.oas.samhsa.gov/2k6/inhalants/inhalants.cfm>).

Based on SAMHSA's National Survey on Drug Use and Health (NSDUH), an estimated 43.9% of individuals who received alcohol or illicit drug use treatment in the past year paid at least a portion of the cost of their last or current treatment with their own savings or earnings. The majority (52.9%) of the individuals who received substance use treatment in the past year used two or more sources of payment for their last or current services. Among persons who received alcohol or illicit drug use treatment in the past year, females were more likely than males to have paid at least a portion of the costs for their last or current services with private insurance (30.9% vs. 23.5%), Medicaid (19.8% vs. 11.6%), and other public assistance (21.0% vs. 13.6%) (<http://www.oas.samhsa.gov/2k6/pay/pay.cfm>).

According to SAMHSA's Treatment Episode Data Set (TEDS), 47 of the 50 states distinguish between methamphetamines and amphetamines as primary substances of abuse in their reporting to TEDS. In these 47 states, methamphetamine was the primary drug in 86% of the combined methamphetamine/ amphetamine treatment admissions in 2003. Arkansas, Oregon, and Texas do not distinguish between amphetamine and methamphetamine in their reporting of primary substance of abuse in treatment admissions. Nationally, the rate of substance abuse treatment admissions for primary methamphetamine/amphetamine abuse increased between 1993 to 2003 from 13 per 100,000 to 56 admissions per 100,000 population aged 12 or older. In 2003, 18 states had rates in excess of the national rate (56 admissions per 100,000 population): 10 states were in the West, 6 were in the Midwest, and 2 were in the South; none were in the Northeast. The highest rates were in Oregon (251 admissions per 100,000), Hawaii (241 per 100,000), Iowa (213 per 100,000), California (212 per 100,000), Wyoming (209 per 100,000), Utah (186 per 100,000), Nevada (176 per 100,000), Washington State (143 per 100,000), Montana (133 per 100,000), Arkansas (130 admissions per 100,000 population), Nebraska (118 per 100,000), and Oklahoma (117 per 100,000). All the rates for the states in the Northeast were 5 or less per 100,000 population (<http://www.oas.samhsa.gov/2k6/methTx/methTX.cfm>).

Based on SAMHSA's National Survey on Drug Use and Health, an estimated 33.7% of youths aged 15 to 17 were employed either part- or full-time during the past week. Employed youths were more likely than youths who were not employed to have used alcohol (35.9% vs. 24.4%), to have engaged in binge alcohol use (24.6% vs. 15.2%), and to have used an illicit drug (19.4% vs. 15.6%) during the past month. Youths working 20 or more hours per week were more likely than those working 19 or fewer hours per week to have drunk alcohol (41.1% vs. 33.8%), to have binged on alcohol (29.0% vs. 23.1%), and to have used any illicit drug (22.3% vs. 18.5%) during the past month (<http://www.oas.samhsa.gov/2k6/employedYouth/employedYouth.cfm>).

Based on SAMHSA's Treatment Episode Data Set (TEDS) among the 29 states that reported retirement status in 2003, about twice as many substance abuse treatment admissions among retired persons (80%) than other admissions (44%) reported alcohol as the primary substance of abuse. Only 17% of substance abuse treatment admissions among retired persons reported a secondary substance of abuse compared to 52% of other admissions. Substance abuse treatment admissions who were retired persons were more likely to have some form of health insurance than other admissions (60% vs. 42%) (<http://www.oas.samhsa.gov/2k6/retiredTX/retiredTX.cfm>).

Based on SAMHSA's National Survey on Drug Use & Health, youths aged 12 to 17 who used an illicit drug in the past year were almost twice as likely to have engaged in a violent behavior as those who did not use an illicit drug (49.8% vs. 26.6%). Rates of past year violent behavior were higher among youths aged 13, 14, and 15 than those either younger or older. The likelihood of having engaged in violent behavior increased with the number of drugs used in the past year: 45.6% of youths who used one illicit drug engaged in violent behavior compared to 61.9% of youths who used three or more illicit drugs (<http://www.oas.samhsa.gov/2k6/youthViolence/youthViolence.cfm>).

Based on SAMHSA's Treatment Episode Data Set (TEDS), the average age of first illicit drug use among admissions for substance abuse treatment changed between 1993 and 2003. The average age of first use of any illicit drug among substance abuse treatment admissions showed a slight decrease from age 18.8 in 1993 to age 18.6 in 2003. Among substance abuse treatment admissions whose earliest reported drug of abuse at admission was stimulants, opiates, or cocaine, the average age of first use rose between 1993 and 2003 (for stimulants from age 18.5 to age 19.7; for opiates from age 21.0 to age 22.1; and for cocaine from age 22.5 to age 22.7). For marijuana, however, it decreased. The average age of first use among substance abuse treatment admissions whose earliest reported drug of abuse was marijuana decreased from age 15.1 in 1993 to age 14.6 in 2003. While the average age of first use of any drug remained the same or decreased between 1993 and 2003 for all age groups, the percentage of substance abuse treatment admissions starting drug use before age 13 increased for all age groups except those age 18-24 at treatment admission. Criminal justice was the only admissions referral source that had a decrease in the average age of first use of any illicit drug. The average age of first use of any illicit drug for admissions referred by the criminal justice system decreased from age 17.6 in 1993 to age 16.8 in 2003 (<http://www.oas.samhsa.gov/2k6/AgeDrugTX/AgeDrugTX.cfm>).

SAMHSA's National Survey on Drug Use and Health in 2002 through 2004 assessed whether respondents met criteria for serious psychological distress during the month in the past year when respondents were at their worst emotionally. An estimated 10.3% of males aged 18 to 25 (1.6 million persons) experienced serious psychological distress during the past year. Divorced or separated males aged 18 to 25 (20.9%) were more likely to have experienced serious psychological distress during the past year than those who were married (7.3%) or never married (10.5%). Males aged 18 to 25 with serious psychological distress during the past year were more likely than those without past year serious psychological distress to have engaged in heavy alcohol use (27.2% vs. 20.7%), binge alcohol use (56.7% vs. 49.9%), and illicit drug use (35.6% vs. 22.1%) in the past month (<http://www.oas.samhsa.gov/2k6/menMH/menMH.cfm>).

Of the 13,454 facilities that responded to SAMHSA's National Survey of Substance Abuse Treatment Services (N-SSATS), 4756 facilities (35%) had special programs or groups for clients with co-occurring psychiatric and substance use disorders in 2004. Facilities operated by state governments were most likely to offer special programs or groups for clients with co-occurring substance abuse and psychiatric disorders (50%), followed by those operated by local governments (44%), the federal government (41%) and private nonprofit organizations (36%). Facilities operated by private-for-profit organizations (31%) and tribal governments (29%) were least likely to offer special programs or groups for clients with co-occurring substance abuse and psychiatric disorders. Facilities with special programs or groups for clients with co-occurring substance abuse and psychiatric disorders were more likely than those not offering such special programs or groups to offer a number of services, including family counseling (83% vs. 73%), Hepatitis B testing (30% vs. 19%), transitional social services (65% vs. 49%), domestic violence services (40% vs. 29%), and HIV testing (38% vs. 28%) (<http://www.oas.samhsa.gov/2k6/DualTX/DualTX.cfm>).

An estimated 142,701 alcohol-related emergency department (ED) visits reported to SAMHSA's Drug Abuse Warning Network (DAWN) system were made by patients aged 12 to 20. Nearly half (42%) of drug-related ED visits among patients aged 12 to 20 involved alcohol. Patients aged 18 to 20 were approximately 3 times as likely as patients aged 12 to 17 to have an alcohol-related ED visit. ED visits involving alcohol with other drugs were almost 2 times as likely as visits involving only alcohol to result in admission to the hospital for inpatient care (19% vs. 10%) (<http://dawninfo.samhsa.gov/pubs/shortreports/default.asp>).

LIPID EMULSION RESUSCITATION FOR LOCAL ANESTHETIC AND TOXIC CARDIAC ARREST

Guy L. Weinberg, MD

Background

Recent observations that lipid infusion is effective in treating cardiac arrest due to local anesthetic toxicity have suggested that this method could have wider application in clinical toxicology (1). Cardiovascular collapse induced by local anesthetic overdose is a rare but potentially devastating complication of regional anesthesia. The problem was first publicized thirty years ago by Albright in an editorial describing several cases of intractable cardiac arrest in patients receiving large doses of bupivacaine or etidocaine for neuraxial anesthesia (2). He proposed a link between the lipid solubility of these agents and fatal arrhythmias. Bupivacaine, the canonical cardio-toxic local anesthetic, is one of the most lipophilic of local anesthetics. It is also one of the most commonly used local anesthetics, in large part because of its potency and long duration of action (3).

Clinical Features of Local Anesthetic Toxicity

Inadvertent intravascular injection or excessive absorption, particularly of the lipophilic local anesthetics (e.g., bupivacaine, levo-bupivacaine, ropivacaine), causes CNS excitation or suppression of neural activity, resulting in agitation, seizures, obtundation, or loss of consciousness (4). Signs of cardiovascular toxicity may quickly follow and are typified by progressive hypotension, bradycardia, conduction blockade, malignant arrhythmias, and asystole. Typical of bupivacaine-related cardiac arrest is its resistance to standard resuscitative measures. Cases of successful resuscitation with cardiopulmonary bypass have been reported but, until recently, other modes have proven ineffective (5).

Animal Studies

An intravascular infusion (pre-treatment) of soy oil emulsion will render laboratory rats relatively resistant to bupivacaine cardiac toxicity (6). Furthermore, when given lipid during the resuscitation phase (post-treatment) rats will survive doses of bupivacaine that are uniformly fatal to control animals. Follow-up studies in dogs confirm that lipid infusion given during open-chest cardiac massage allows successful resuscitation from an overwhelming, otherwise fatal bupivacaine overdose, even after prolonged "down-times" (7).

Mechanisms

Several mechanisms are likely to play a role in lipid reversal of bupivacaine toxicity. Bupivacaine is highly lipophilic and exhibits a lipid:aqueous partition coefficient of ~ 11 . Hence, the easiest mechanism to envision is that bupivacaine partitions into a lipemic phase, or "lipid sink", thereby lowering the concentration of free bupivacaine in the aqueous phase of blood. Weinberg et al observed in isolated rat hearts exposed to bupivacaine that adding lipid to the perfusion buffer resulted in more rapid decline of cardiac bupivacaine content than seen in controls (8). These data support the "lipid sink" mechanism. However, the rapidity of lipid reversal observed in experimental animals seems to belie a mechanism that requires bupivacaine to traverse several diffusion barriers in quickly re-establishing an equilibrium that favors the vascular space over cardiac tissue, all within minutes or less of the lipid injection. Another possible mechanism includes a positive metabolic effect of lipids (9). Cardiac lipid metabolism is strongly inhibited by bupivacaine and lipid infusion could overwhelm such inhibition (10). Lipids can also exhibit direct inotropy on isolated heart, suggesting that direct antagonism of bupivacaine contractile depression is possible. Dilution of plasma bupivacaine by volume expansion could also play a role. Elucidating the mechanism(s) of lipid rescue resuscitation remains an important goal for research on this topic.

Clinical Efficacy

The first reports of the clinical use of lipid infusion for treating local anesthetic-related cardiac arrest have recently been published. Rosenblatt et al reported a successful resuscitation from prolonged cardiac arrest after a brachial plexus block with bupivacaine and mepivacaine (11). The patient, a middle-aged man with a history of ischemic cardiac disease, remained in asystole and non-perfusing idioventricular rhythms for more

than twenty minutes despite standard ACLS. The report describes a rapid return of normal rhythm and vital signs after injection of 100 mL of 20% lipid. Litz et al published a very similar case of cardiac arrest after injection of ropivacaine for brachial plexus block in an elderly lady with heart disease (12). Standard CPR was ineffective for fifteen minutes, but chest compressions were stopped shortly after infusion of lipid emulsion. Both patients recovered without evidence of cardiac damage and both were neurologically intact. Subsequently, there have been unpublished reports of several instances where CNS symptoms associated with regional anesthesia (obtundation, loss of consciousness) were rapidly reversed with lipid infusion (personal communications, Rainer Litz, Dresden; Andrew Spence, Bermuda; Harvey Woehlk, Wisconsin). Thus, lipid infusion appears to interrupt local anesthetic-induced toxicity for both cardiovascular and central nervous systems.

General Applicability of Lipid Rescue Resuscitation

The lipid sink mechanism suggests that lipid infusion could provide a general method for treating poisoning by any sufficiently lipophilic agent. Alternately, by assuming that the underlying mechanism is specific to local anesthetics, lipid infusion might work for overdose due to any of amphipathic sodium channel blocker. Together, these two classes encompass a wide array of potential toxins, including: tricyclic antidepressants, calcium channel blockers, cocaine, anti-convulsants, anti-depressants, organic solvents, and bio-weapons. In support of this prediction, lipid infusion has recently been shown by Harvey and colleagues to improve cardiac function in a rabbit model of chlomipramine overdose where all controls exhibited intractable pulseless electrical activity, while all rabbits in the treatment group maintained normal circulation (13).

Future Directions: Research and Practice

The future use of lipid emulsion therapy will be directed by the findings in basic laboratory research. The main goals of such efforts include identifying the underlying mechanisms of action of lipid rescue resuscitation, identifying optimized regimens of treatment, and determining the range of toxins it can be used to treat. The full scope and potential clinical application of this simple method has yet to be determined. Understanding the method will likely extend its use beyond the niche of treating a complication of regional anesthesia.

Recommendations

Lipid infusion is still in its infancy and since no data are available from human trials regarding its efficacy or safety, all guidelines are based on laboratory findings in animal models and upon a small number of reported clinical cases. While no official recommendations are published, the treatment has, nevertheless, proven life-saving in a number of cases of local anesthetic toxicity. Suggestions for its use are posted on an educational website: www.lipidrescue.org. This site is dedicated to disseminating information on the use of lipid infusion and providing a forum for physicians to exchange ideas and experiences related to this method. Typical suggestions include:

Stock. 500 mL of 20% lipid emulsion (e.g., Intralipid) at sites where large doses of local anesthetic are likely to be used.

Therapy. An initial intravenous dose of lipid (1.5 mL/kg) is given by bolus and followed by a continuous infusion of 0.25 mL/kg/min. CPR should continue throughout as the lipid will only work if it is circulated to the heart. The bolus can be repeated twice more at 3-5 minute intervals for persistent circulatory collapse. Once blood pressure is re-established, the infusion should be continued for 15 minutes and can be increased to 0.5 mL/kg for declining blood pressure.

This is a general guideline that will be amended as further clinical and laboratory studies indicate. Future changes in the regimen will lead to improved efficacy and safety.

POSITION STATEMENT AND PRACTICE GUIDELINES ON THE USE OF MULTI-DOSE ACTIVATED CHARCOAL IN THE TREATMENT OF ACUTE POISONING

Reprinted from *American Academy of Clinical Toxicology; European Association of Poisons Centres and Clinical Toxicologists*, 1999, 37(6):731-51, by courtesy of Marcel Dekker, Inc.

SUMMARY STATEMENT

Introduction

- The challenge for clinicians managing poisoned patients is to identify at an early stage those who are most at risk of developing serious complications and who might potentially benefit, therefore, from elimination techniques.
- Multiple-dose activated charcoal therapy involves the repeated administration (more than two doses) of oral activated charcoal to enhance the elimination of drugs already absorbed into the body.
- No evidence has yet been published to demonstrate convincingly that multiple-dose activated charcoal reduces morbidity and mortality in poisoned patients.
- Further studies are required to establish its role and the optimal dosage regimen of charcoal to be administered.

Rationale

- Drugs with a prolonged elimination half-life following overdose and small volume of distribution (< 1 L/kg body weight) are particularly likely to have their elimination enhanced to a clinically significant degree by multiple-dose activated charcoal.
- Multiple-dose activated charcoal is thought to produce its beneficial effect by interrupting the enteroenteric and, in some cases, the enterohepatic and the enterogastric circulation of drugs. In addition, any unabsorbed drug still present in the gut will be absorbed to activated charcoal, thereby reducing drug absorption.

Animal Studies

- In animal studies multiple-dose activated charcoal has been shown to reduce the elimination half-life and increase the total body clearance of acetaminophen (paracetamol),¹ digoxin,¹ phenobarbital,² phenytoin,³ and theophylline.¹ The elimination of salicylate⁴ and valproic acid¹ was not enhanced by this means.

Volunteer Studies

- Studies in volunteers have demonstrated that multiple-dose activated charcoal increases the elimination of carbamazepine,⁵ dapsone,⁶ dextropropoxyphene,⁷ digitoxin,^{8,9} digoxin,⁸⁻¹⁰ disopyramide,¹¹ nadolol,¹² phenobarbital,^{5,13-15} phenylbutazone,⁵ phenytoin,^{16,17} piroxicam,¹⁸ quinine,¹⁹ sotalol,²⁰ and theophylline.²¹⁻²⁶
- The elimination of salicylate was increased by multiple-dose activated charcoal in two studies,^{27,28} but not in two other studies.^{29,30} Although a statistically significant difference was shown, the treatment effect was small.
- Multiple-dose activated charcoal therapy did not increase the elimination of astemizole,³¹ chlorpropamide,³² sodium valproate,³³ tobramycin,^{34,35} and vancomycin.³⁶
- The elimination half-life of amitriptyline,³⁷ but not of doxepin³⁸ or imipramine,³⁹ was also reduced by multiple-dose activated charcoal in volunteer studies. Crome, et al,⁴⁰ showed a significant reduction in the area under the curve (AUC) of nortriptyline after multiple-dose activated charcoal. However, there are good pharmacokinetic reasons to suggest that in the case of tricyclic antidepressants, a clinically significant increase in body clearance is unlikely to result from the use of such treatment, even though the apparent half-life may be shortened.

Clinical Studies

- Clinical studies of multiple-dose activated charcoal consist only of case series and reports.
- Studies in poisoned patients have confirmed those studies in volunteers which demonstrate that the elimination of carbamazepine,^{41,42} dapsone,^{6,43} phenobarbital,⁴⁴⁻⁴⁷ quinine,⁴⁸ and theophylline^{23,26,49-55} is enhanced by multiple-dose activated charcoal.
- Clearance values achieved by multiple-dose activated charcoal in the case of carbamazepine,⁸⁹⁻⁹¹ dapsone,⁴³ and phenobarbital⁹⁶ are comparable to those produced by the more invasive techniques of hemodialysis and hemoperfusion.
- There is also some evidence to suggest that, contrary to the findings in one animal⁴ and two volunteer studies,^{29,30} multiple-dose activated charcoal may increase the elimination of salicylate^{56,57}; these results need to be confirmed in further studies before this therapy can be recommended.
- Although the elimination of digoxin was enhanced by the use of multiple-dose activated charcoal in four experimental studies,^{1,8,9,10} in three case reports,⁵⁸⁻⁶⁰ and in one case series,⁶¹ it is unlikely that the increase in body clearance of digoxin will be of clinical significance because of the large volume of distribution of digoxin. Moreover, severe digoxin poisoning may be treated effectively with digoxin-specific antibody fragments. There is also limited clinical evidence that multiple-dose activated charcoal may increase the clearance of digitoxin.⁶²
- The elimination of dapsone was increased by multiple-dose activated charcoal in volunteer and clinical studies.^{6,43}
- Although an experimental study³⁶ did not demonstrate enhanced clearance, two case reports^{63,64} suggest that multiple-dose activated charcoal may increase vancomycin clearance.
- Multiple-dose activated charcoal does not appear to increase the clearance of meprobamate,^{65,66} methotrexate,⁶⁷ phenytoin,⁶⁸⁻⁷² tricyclic antidepressants,^{73,74} and valproic acid⁷⁵ in patients who have ingested or been administered these drugs.

Indications

- The use of multiple-dose activated charcoal should be considered if the patient has ingested a life-threatening amount of carbamazepine, dapsone, phenobarbital, quinine, or theophylline, and may obviate the need for invasive extracorporeal techniques in these cases.
- The ultimate decision to use multiple-dose activated charcoal therapy depends on:
 - the physician's clinical judgment regarding the expected outcome in a patient poisoned with carbamazepine, dapsone, phenobarbital, quinine, or theophylline;
 - the presence of a contraindication to the use of activated charcoal therapy;
 - the effectiveness of alternative methods of treatment.

Dosage Regimen

- The optimum dose of charcoal is unknown but it is recommended that after an initial dose of 50-100 g to an adult, activated charcoal should be administered at a rate of not less than 12.5 g/hour or equivalent. Lower doses (10-25 g) of activated charcoal may be employed in children less than 5 years of age as usually they have ingested smaller overdoses and their gut lumen capacity is smaller.
- Activated charcoal should be continued until the patient's condition and laboratory parameters, including plasma drug concentration, are improving.
- It may be difficult in clinical practice to administer substantial doses of activated charcoal because of drug-induced vomiting such as occurs with theophylline in overdose. Smaller doses (and therefore smaller volumes) of activated charcoal administered more frequently may reduce the likelihood of vomiting. However, it is often necessary to give an antiemetic intravenously to ensure satisfactory administration of charcoal, even by a nasogastric tube.

Coadministration of a Cathartic

- The need for concurrent administration of a cathartic, such as sorbitol, remains unproven and is not recommended. In particular, a cathartic should not be administered to young children because of the propensity to cause fluid and electrolyte imbalance.

Contraindications

Absolute

- An unprotected airway
- Presence of intestinal obstruction
- A gastrointestinal tract not anatomically intact

Relative

- Decreased peristalsis (decreased bowel sounds, abdominal distention, ileus) such as occurs following overdoses of drugs with opioid or anticholinergic properties.
- Multiple-dose charcoal should be administered cautiously in the presence of decreased peristalsis with careful monitoring for the development of obstruction and for the prevention of aspiration.

Complications of Use

- Treatment with multiple-dose activated charcoal is relatively free from serious side-effects, although transient constipation may occur if aqueous charcoal is administered in substantial dose, particularly in nonambulatory patients due to a depressed level of consciousness.
- Occasionally, bowel obstruction has been reported necessitating manual evacuation or surgical intervention.^{107,108,110,111}
- Regurgitation, with subsequent aspiration into the lungs of gastric contents containing charcoal, or direct instillation of charcoal into the lungs as a result of a misplaced nasogastric tube, has led rarely to severe pulmonary complications and death.^{112,117-119} Emesis of aqueous activated charcoal occurs infrequently. The incidence appears to be greater when activated charcoal is administered with sorbitol.

Supporting Documentation

Introduction

Charcoal is prepared from vegetable matter, usually peat, coal, wood, coconut shell, or petroleum. Charcoal is “activated” by heating it at high temperature in a stream of oxidizing gas (eg, steam, carbon dioxide, air) or with an activating agent such as phosphoric acid or zinc chloride, or by a combination of both. The process of activation creates a highly developed internal pore structure and thereby increases the surface area from 2-4 m²/g to an area in excess of 1500 m²/g. Medicinal activated charcoal must meet BP, USP, or similar standards and have a surface area of at least 900 m²/g.

Multiple-dose activated charcoal therapy is the repeated administration (more than two doses) of oral activated charcoal with the intent of enhancing drug elimination.

Multiple-dose activated charcoal is perceived as a simple, inexpensive, and safe therapy which may avoid the need for more invasive procedures such as hemodialysis and hemoperfusion. While studies in volunteers demonstrate that its administration both reduces the elimination half-life and increases drug clearance of some drugs, most of the clinical data supporting the use of multiple-dose activated charcoal are anecdotal case reports. Controlled clinical studies are necessary to establish the role of this therapy.

Methodology

In preparing this Position Statement all relevant scientific literature was identified by searching Medline, Toxline, and EMBASE using the terms “activated charcoal,” “multiple-dose activated charcoal,” and “repeat dose activated charcoal.” The original papers were obtained and reviewed critically by a group of clinical toxicologists chosen by the two sponsoring societies. A draft Position Statement was produced which went through multiple drafts before being approved by the boards of the two societies.

Rationale

Drugs with a prolonged elimination half-life following overdose are likely to have their elimination enhanced by multiple-dose activated charcoal.^{1,76} Other relevant pharmacokinetic factors include volume of distribution (< 1 L/kg body weight), pKa, and protein binding. If multiple-dose activated charcoal therapy is initiated

during a drug's distributive phase, particularly if it is long, it may have a considerable pharmacokinetic effect by interrupting drug distribution into tissues.¹ In addition, if a major route of elimination is no longer available due to the onset of organ failure, this treatment has the potential to make a contribution to total body clearance of the drug ingested which is clinically beneficial.

Mechanisms of Action

Multiple-dose activated charcoal is thought to produce its beneficial effects by:

1. Binding any drug which diffuses from the circulation into the gut lumen.⁷⁷ After absorption, a drug will reenter the gut by passive diffusion provided that the concentration there is lower than that in blood. The rate of passive diffusion depends on the concentration gradient and the intestinal surface area, permeability, and blood flow. Under these "sink" conditions, a concentration gradient is maintained and the drug passes continuously into the gut lumen where it is absorbed to charcoal. This process has been termed "gastrointestinal dialysis."⁷⁸ Animal studies have confirmed that activated charcoal significantly interrupts the enteroenteric circulation of phenobarbital.⁷⁹
2. Interrupting the enterohepatic and the enterogastric circulation of drugs.

Animal Studies

Acetaminophen (Paracetamol). Acetaminophen 30 mg/kg was administered intravenously over 12 minutes with three other drugs (aminophylline, digoxin, valproic acid) to seven pigs with an indwelling gastrostomy tube.¹ Activated charcoal 25 g with sorbitol (48 g) was administered as the initial intervention at time zero and an aqueous slurry of activated charcoal (25 g) was administered at 2, 4, 6, 12, 18, 24, and 30 hours via the gastrostomy tube. The mean acetaminophen half-life was reduced significantly ($p < 0.01$) from $1.7 \pm (\text{SD}) 0.2$ hours to 1.4 ± 0.3 hours and significantly increased ($p < 0.01$) the clearance from 4.57 ± 0.54 mL/minute/kg to 5.41 ± 0.63 mL/minute/kg.

Aspirin. In a crossover study, six fasted pigs received aspirin 300 mg/kg intravenously followed by no treatment or activated charcoal 1 g/kg every hour for six doses [the first dose contained sorbitol (70%) 4 mL/kg] via a gastrostomy tube.⁴ There were no statistical differences between the control and treatment arms. Mean peak serum salicylate concentrations were 474 ± 62 mg/L and 484 ± 3.9 mg/L, respectively ($p = 0.74$), and the AUC over 6 hours was $171,000 \pm 24,000$ mg times minutes/L in the control group and $188,000 \pm 18,000$ mg times minutes/L in the treatment group ($p = 0.22$).

Digoxin. Seven female pigs were administered digoxin 30 mcg/kg intravenously together with three other drugs (aminophylline, digoxin, valproic acid).¹ Activated charcoal (25 g) with sorbitol (48 g) was administered as the initial intervention at time zero and an aqueous slurry of activated charcoal (25 g) was administered at 2, 4, 6, 12, 18, 24, and 30 hours via an indwelling gastrostomy tube. The half-life was reduced significantly ($p < 0.001$) from a mean of $64.8 \pm (\text{SD}) 23.7$ hours to 17.2 ± 5.6 hours. Clearance was increased from 2.33 ± 0.85 mL/minute/kg to 7.05 ± 1.42 mL/minute/kg ($p < 0.001$).

Phenobarbital (Phenobarbitone). Arimori and Nakano² administered phenobarbital 10 mg/kg body weight intravenously to five fasted Wistar strain male rats. Activated charcoal 300 mg was given orally at time zero and then in a dose of 150 mg at 1, 2, 3, 4, and 6 hours after dosing. The mean phenobarbital elimination half-life was reduced significantly ($p < 0.05$) from $8.52 \pm (\text{SEM}) 0.62$ hours to 5.71 ± 0.35 hours and the mean total body clearance of phenobarbital was increased significantly ($p < 0.01$) from $50.2 \pm (\text{SEM}) 2.73$ mL/kg/hour to 77.0 ± 1.21 mL/kg/hour. There was a significant ($p < 0.01$) reduction in the mean AUC of 64% from 184.2 ± 9.56 mcg times hour/mL to 118.7 ± 188 mcg times hour/mL.

Phenytoin. A reduction in the elimination half-life of phenytoin by multiple-dose activated charcoal was reported by Arimori and Nakano.³ Five fasted Wistar strain rats were treated with activated charcoal 300 mg at time zero and 150 mg at 1, 2, 3, 4, and 6 hours after the administration of a single intravenous dose of phenytoin 10 mg/kg or 50 mg/kg body weight. There were no statistical differences between any parameters at 10 mg/kg. The mean elimination half-life at the 50 mg/kg dose fell significantly ($p < 0.05$) from $6.2 \pm (\text{SEM}) 0.73$ hours to 4.77 ± 0.43 hours and the total body clearance increased significantly ($p < 0.01$) from $0.16 \pm (\text{SEM}) 0.01$ L/kg/hour to 0.22 ± 0.01 L/kg/hour. The AUC was reduced significantly ($p < 0.01$) from 311.2 ± 19.3 mcg times hour/mL to 233.5 ± 12.4 mcg times hour/mL.

Theophylline. Arimori and Nakano² administered aminophylline 10 mg/kg body weight intravenously to five fasted Wistar strain rats. Activated charcoal 300 mg was given orally at time zero and then 150 mg was administered at 1, 2, 3, and 4 hours postdosing with aminophylline. The mean elimination half-life

was reduced significantly ($p < 0.05$) from $4.63 \pm (\text{SEM}) 0.49$ hours to 2.84 ± 0.20 hours and the mean total body clearance of theophylline was increased significantly ($p < 0.05$) from $66.7 \pm (\text{SEM}) 9.03$ mL/kg/hour to 101.2 ± 9.77 mL/kg/hour. There was a significant ($p < 0.02$) reduction in the mean AUC from 138.1 ± 17.5 mcg times hour/mL to 88.0 ± 8.39 mcg times hour/mL.

Aminophylline was administered intravenously to five dogs in doses of 50-100 mg/kg followed by duodenal administration of activated charcoal 45-50 g every hour for 7 hours (eight doses).⁸⁰ Although mean AUC values were reduced in the charcoal-treated group, no statistical analysis was undertaken and the results are therefore uninterpretable.

Chyka, et al,¹ administered theophylline (as aminophylline) 8.9 mg/kg intravenously over 12 minutes to seven pigs that were also coadministered digoxin, acetaminophen, and valproic acid. Activated charcoal (25 g) with sorbitol (48 g) was administered as the initial intervention at time zero and an aqueous slurry of activated charcoal (25 g) was administered at 2, 4, 6, 12, 18, 24, and 30 hours via a gastrostomy tube after the initiation of the aminophylline infusion. The mean (\pm SD) theophylline half-life was reduced from 9.4 ± 2.0 to 3.5 ± 2.3 ($p < 0.01$) hours and the AUC from 168.9 ± 34.3 mg/hour/L to 43.6 ± 9.8 mg/hour/L ($p < 0.001$).

Valproic acid. Valproic acid was administered intravenously over 12 minutes with three other drugs (acetaminophen, aminophylline, digoxin) to seven pigs with an indwelling gastrostomy tube.¹ Activated charcoal (25 g) with sorbitol (48 g) was administered as the initial intervention at time zero and an aqueous slurry of activated charcoal (25 g) was administered at 2, 4, 6, 12, 18, 24, and 30 hours via the gastrostomy tube, but did not reduce significantly the half-life and AUC or increase the clearance of valproic acid.

Volunteer Studies

Aspirin. Barone et al²⁷ gave activated charcoal 50 g to ten fasted volunteers at 1, 5, and 9 hours after the administration of aspirin 1944 mg. There was a statistically significant reduction ($p < 0.01$) in the mean percent recovery of total salicylate from the urine ($49.2\% \pm 12.48\%$) compared to controls [$91.0 \pm (\text{SD}) 6.12\%$]; serum salicylate concentrations were not measured.

Kirshenbaum et al²⁸ investigated the effect of multiple dose charcoal therapy in ten volunteers who were given aspirin 2880 mg (29-59 mg/kg body weight) orally, which produced a mean peak serum salicylate concentration of $192 \pm (\text{SD}) 27.6$ mg/L. During the treatment phase, between 4 and 10 hours postingestion, each received activated charcoal 25 g every 2 hours (total dose 100 g). A significant reduction ($p < 0.05$) in the AUC of 9% was observed in the treatment phase, with an 18% reduction ($p < 0.01$) in total urinary excretion of salicylate. While concluding that the “modest” effect of multiple dose charcoal on salicylate clearance suggested it was “of questionable value” in the treatment of acute salicylate poisoning, the authors acknowledged that the observed benefit would be potentially greater in severely intoxicated patients in whom the plasma concentrations would be significantly higher and the salicylate half-life substantially longer than in this study.

The administration of activated charcoal 25 g 4 hours after aspirin dosing (1300 mg orally) to six fasted adult volunteers, followed by three further doses of charcoal 10 g every 2 hours, did not result in a significant reduction in half-life or AUC.²⁹ Peak serum salicylate concentrations ranged from 55-136 mg/L.

Mayer et al³⁰ administered aspirin 2800 mg (33-44 mg/kg body weight) to nine volunteers and 4 hours later activated charcoal 25 g was given and repeated every 2 hours for four doses. Following charcoal treatment, no significant difference was observed in the mean peak serum salicylate concentrations: $160 \pm (\text{SD}) 17$ mg/L in the control group and 150 ± 24 mg/L in the charcoal group. No significant differences in the AUCs were observed.

Astemizole. Laine et al³¹ demonstrated that activated charcoal (12 g) administered twice daily (from 6 hours onwards) to seven volunteers for 8 days did not alter the rate of elimination or AUC (0-192 hours) of astemizole (30 mg).

Carbamazepine. In a randomized crossover study in five fasted volunteers given carbamazepine 400 mg orally, Neuvonen and Elonen⁵ found the mean elimination half-life was reduced significantly ($p < 0.05$) from $32 \pm (\text{SEM}) 3.4$ hours to 17.6 ± 2.4 hours following multiple-dose charcoal therapy (50 g at 10 hours postdosing; 17 g at 14, 24, 36, and 48 hours postdosing). The mean total body clearance was also increased significantly ($p < 0.05$) from $22.0 \pm (\text{SEM}) 1.9$ mL/minute to 40.0 ± 2.7 mL/minute.

Chlorpropamide. Neuvonen and Kärkkäinen³² demonstrated that the half-life of chlorpropamide was not reduced significantly by the use of multiple-dose activated charcoal (50 g at 6 hours followed by 12.5 g every 6 hours for 8 hours) following the administration of chlorpropamide 250 mg orally to six volunteers.

Dapsone. Neuvonen et al⁶ administered dapsone 500 mg to five volunteers over 4 days (100 mg daily for 3 days and 100 mg twice daily on day 4) in a randomized crossover study. Ten hours after the last dose, subjects were given charcoal 50 g, then 17 g every 12 hours for an additional four doses. The dapsone elimination half-life was reduced significantly ($p < 0.01$) from $20.5 \pm (\text{SEM}) 2.0$ hours during the control period to 10.8 ± 0.4 hours after charcoal. The half-life of the metabolic monoacetyldapsone was also reduced significantly ($p < 0.001$) during treatment.

Dextropropoxyphene. Kärkkäinen and Neuvonen⁷ found that the elimination half-lives of dextropropoxyphene and its metabolite, norpropoxyphene, were reduced in six volunteers given activated charcoal 50 g 6 hours after the oral administration of dextropropoxyphene 130 mg; further doses of charcoal (12.5 g) were administered every 6 hours for eight doses. It should be noted that in the control phase, volunteers received activated charcoal 50 g 5 minutes after dextropropoxyphene dosing. The mean elimination half-life of dextropropoxyphene was reduced significantly ($p < 0.05$) from $31.1 \pm (\text{SEM}) 4.2$ hours to 21.2 ± 3.1 hours and the mean elimination half-life of norpropoxyphene was reduced significantly ($p < 0.001$) from $34.4 \pm (\text{SEM}) 2.5$ hours to 19.8 ± 3.4 hours.

Digitoxin and digoxin. Park et al⁸ gave six adult volunteers intravenous infusions of digoxin (0.75 mg/70 kg body weight) or digitoxin (1 mg/70 kg body weight) followed either by water alone or activated charcoal (20 g immediately, then 20 g every 4 hours for 36 hours; a further 20 g dose was administered 48 hours postinfusion). The serum digoxin half-life was decreased significantly ($p < 0.05$) from $23.1 \pm (\text{SEM}) 1.7$ hours to 17.0 ± 1.5 hours, but the increase in digoxin clearance was not statistically significant ($p > 0.1$). The half-life of digitoxin was decreased significantly ($p < 0.01$) from 110.6 ± 11.0 hours to 51.1 ± 4.5 hours and digitoxin clearance was increased significantly ($p < 0.001$) from 0.24 ± 0.01 to 0.47 ± 0.04 L/hour. The authors also reported a reduction in the digoxin elimination half-life from 93.3 to 29.3 hours in a volunteer with chronic renal failure; the total body clearance of digoxin increased from 3.6 L/hour to 10.1 L/hour.

Reissel and Manninen⁹ found that during maintenance therapy with digoxin or digitoxin in six individuals aged 60-74 years, the administration of activated charcoal 6 g a day significantly decreased ($p < 0.001$) the mean plasma digoxin concentration by 31.2% and reduced significantly ($p < 0.05$) the mean serum digitoxin concentration by 18.3%.

Activated charcoal (225 g over 40 hours) was given to ten healthy volunteers after the intravenous administration of digoxin 10 mcg/kg. Charcoal increased significantly ($p < 0.005$) the total body clearance of digoxin from $12.2 \pm (\text{SD}) 2.0$ L/hour to 18.0 ± 2.9 L/hour and the terminal half-life was reduced significantly ($p < 0.005$) from $36.5 \pm (\text{SD}) 11.8$ hours to 21.5 ± 6.5 hours.¹⁰

Disopyramide. Arimori et al¹¹ administered activated charcoal (40 g at 4 hours and 20 g at 6, 8, and 12 hours) to six volunteers after they had been given disopyramide 200 mg orally. The mean elimination half-life was decreased significantly ($p < 0.05$) from $6.09 \pm (\text{SEM}) 0.48$ hours to 4.11 ± 0.45 hours and the total body clearance increased significantly ($p < 0.01$) from $0.113 \pm (\text{SEM}) 0.017$ L/hour/kg to 0.138 ± 0.019 L/hour/kg.

Naldolol. The elimination half-life of oral naldolol 80 mg in eight adult volunteers was reduced significantly ($p < 0.05$) from $17.3 \pm (\text{SEM}) 1.7$ hours to 11.8 ± 1.6 hours by small doses (500 mg at 3 and 4 hours after dosing and then 250 mg hourly for a further 8 hours) of activated charcoal tablets.¹²

Phenobarbital (Phenobarbitone). Neuvonen and Elonen⁵ gave five fasted volunteers activated charcoal 50 g at 10 hours and 17 g at 24, 36, and 48 hours after the oral administration of phenobarbital 200 mg and found that the mean phenobarbital elimination half-life was reduced significantly ($p < 0.05$) $110 \pm (\text{SEM}) 23$ hours to 19.8 ± 1.0 hours. The total phenobarbital clearance was increased significantly ($p < 0.05$) from $4.6 \pm (\text{SEM}) 0.9$ mL/min to 23.0 ± 3.0 mL/min.

Six volunteers were given activated charcoal 40 g at time zero and 20 g at 6, 12, 18, 24, 30, 42, and 66 hours following the intravenous administration of the phenobarbital 200 mg.¹³ The mean phenobarbital half-life was reduced significantly ($p < 0.01$) from $110 \pm (\text{SEM}) 8$ hours to 45 ± 6 hours, the mean total body clearance of phenobarbital was increased significantly ($p < 0.01$) from 4.4 ± 0.2 to 12.0 ± 1.6 mL/kg/hour, and the nonrenal clearance of phenobarbital was increased from 52% to 80% of the total body clearance.

In another study¹⁴ the effects of charcoal alone and a charcoal-sorbitol mixture on phenobarbital elimination were investigated in six men. Following the intravenous administration of phenobarbital 200 mg/70 kg over 1 hour, either activated charcoal 105 g or activated charcoal 105 g with sorbitol was given over a 36-hour

period (30 g at end of dosing; 15 g at 6, 12, 18, 24, and 36 hours after dosing). The mean phenobarbital elimination half-life ($T_{1/2}$ 3-60 hours) fell significantly ($p < 0.05$) from $72 \pm (\text{SD}) 7$ hours (control) to 36 ± 4 hours (charcoal alone), and 30 ± 4 hours (charcoal-sorbitol). However, there was no significant difference in the terminal elimination half-life in each group: 102 ± 19 hours (control), 119 ± 22 hours (charcoal alone), and 116 ± 25 hours (charcoal-sorbitol). The apparent mean systemic clearance of phenobarbital increased significantly (but no p value was included) from 0.0895 ± 0.019 mL/minute (control) to 0.141 ± 0.029 mL/minute/kg (charcoal alone) and 0.146 ± 0.36 mL/minute/kg (charcoal-sorbitol).

Frenia et al.¹⁵ administered phenobarbital 5 mg/kg to ten volunteers. Each volunteer received six doses of activated charcoal: 50 g with sorbitol (50 g of 70%) 30 minutes after phenobarbital and five 25 g doses at 4.5, 8.5, 12.5, 16.5 and 20.5 hours; and a dose of sorbitol (25 g of 70%) was administered at 12.5 and 24.5 hours. The mean (\pm SD) phenobarbital half-life was reduced significantly ($p = 0.005$) from 148.1 ± 332.1 hours to 18.87 ± 14.70 hours and the mean (\pm SD) phenobarbital clearance was increased significantly ($p < 0.0005$) from 2.79 ± 9.69 mL/kg/hour (control group) to 19.95 ± 11.5 mL/kg/hour (charcoal group).

Phenylbutazone. Multiple-dose activated charcoal (50 g 10 hours postdosing; 17 g at 14, 24, 36, and 48 hours postdosing) reduced significantly ($p < 0.05$) the mean elimination half-life of phenylbutazone from $51.5 \pm (\text{SEM}) 7.6$ hours to 36.7 ± 4.1 hours after the oral administration of phenylbutazone 200 mg.⁵ The total phenylbutazone clearance was also increased significantly ($p < 0.05$) from $1.5 \pm (\text{SEM}) 0.16$ mL/minute to 2.1 ± 0.23 mL/minute.

Phenytoin. The effect of multiple-dose activated charcoal on the elimination of intravenously administered phenytoin was studied in seven fasting volunteers by Mauro et al.¹⁶ Each participant received phenytoin 15 mg/kg intravenously over 60 minutes which produced a mean C_{max} of approximately 22 mg/L. At the end of the phenytoin infusion, activated charcoal 60 g with sorbitol was given followed by 30 g (with random sorbitol administration) at 2, 4, 8, 12, 24, 30, 36, and 48 hours (total dose 300 g over 48 hours). Charcoal significantly reduced ($p < 0.001$) the mean phenytoin elimination half-life from $44.5 \pm (\text{SD}) 14.0$ hours to 22.3 ± 6.9 hours.

In another study,¹⁷ eight fasted volunteers received phenytoin 15 mg/kg intravenously over 1 hour followed by charcoal 140 g over 10 hours (40 g at end of the infusion; 20 g at 2, 4, 6, 8, and 10 hours after the infusion). Half of the subjects received sorbitol in their loading dose and with every other dose of activated charcoal. Administration of activated charcoal led to a significant increase ($p = 0.008$) in mean phenytoin clearance from 15.3 ± 3.8 mL/minute/1.73 m² to 20.9 ± 5.2 mL/minute/1.73 m². There was a nonsignificant decrease in half-life from 25.5 ± 9.8 hours to 23.6 ± 15.9 hours after charcoal. The addition of sorbitol to the treatment regimen did not change clearance values.

Piroxicam. In a study with a randomized crossover design and six volunteers, Laufen and Leitold¹⁸ studied the use of multiple-dose activated charcoal following the administration of piroxicam 20 mg by either the oral or rectal route. In the oral drug administration phase, activated charcoal 50 g was administered at 10 hours postingestion followed by doses of 20-30 g for a total of 70 g every 24 hours up to 58 hours after piroxicam ingestion. The elimination half-life was reduced significantly ($p < 0.05$) from a mean (\pm SD) of 40.2 ± 10.0 hours (control group) to 19.6 ± 5.9 hours (charcoal group). The mean apparent total clearance increased significantly ($p < 0.05$) from 3.46 ± 1.33 mL/minute to 5.66 ± 1.41 mL/minute. In the rectal administration phase, activated charcoal 30 g was administered at 2 hours after drug delivery and 20-30 g was given at varying intervals for a total of 70 g every 24 hours. The elimination half-life was reduced significantly from a mean (\pm SD) of 40.7 ± 12.6 hours in the control group to 21.6 ± 6.4 hours in the charcoal group. There was also a significant ($p < 0.05$) increase in the mean (\pm SD) apparent total clearance from 3.65 ± 1.19 mL/minute to 6.86 ± 2.23 mL/minute.

Quinine. The effect of multiple-dose activated charcoal on quinine elimination was studied following a therapeutic (600 mg) dose of quinine bisulphate to seven adult fasted volunteers.¹⁹ Activated charcoal 50 g was administered 4 hours after quinine dosing and three further doses were given over the next 12 hours. Activated charcoal significantly lowered ($p < 0.001$) the quinine elimination half-life from $8.23 \pm (\text{SD}) 0.57$ to 4.55 ± 0.15 hours and the clearance was significantly increased ($p < 0.001$) from $11.8 \pm (\text{SD}) 1.23$ L/hour to 18.4 ± 2.8 L/hour.

Sotalol. The mean elimination half-life of sotalol was decreased significantly ($p < 0.01$) from $9.4 \pm (\text{SEM}) 0.4$ hours to 7.6 ± 0.3 hours by the administration of activated charcoal (50 g at 6 hours, then 12.5 g every 6 hours for eight doses) to seven fasted adult volunteers who had received sotalol 160 mg orally.²⁰

Theophylline. The effect of activated charcoal on theophylline kinetics when a sustained-release preparation was administered orally to 20 children in a dose of 10 mg/kg was studied by Lim et al.⁸¹ Five children given

activated charcoal 1 g/kg body weight (maximum 60 g) at 6, 9, and 12 hours postdosing had a 20.65% nonsignificant reduction in the AUC compared to controls.

Minton and Henry⁸² administered three sustained-release theophylline 200 mg tablets to ten fasted volunteers. Activated charcoal 50 g was given at 6 hours, with two further 25 g doses at 10 hours and 14 hours. The AUC of theophylline in the control group was $152.8 \pm$ (SD) 1.44 mg/L/hour and in the charcoal group was 65.3 ± 1.33 mg/L/hour. No statistical calculations were undertaken.

Goldberg et al⁸³ demonstrated that the addition of sorbitol to charcoal significantly reduced ($p < 0.01$) the AUC ($85.5 \pm$ [SEM] 10.0 mg/hour/L) when compared to multiple-dose charcoal alone (113 ± 5.7 mg/hour/L) and controls (304.6 ± 18.8 mg/hour/L). In this study, charcoal, with or without sorbitol, was administered at 6, 7, 8, 10, and 12 hours after administration of slow release theophylline 1200 mg/70 kg to nine subjects.

The effect of multiple-dose charcoal on the kinetics of an intravenous dose of aminophylline (6 mg/kg body weight) administered to five volunteers was investigated by Berlinger et al.²¹ Activated charcoal 40 g was given at time zero and 20 g at 2, 4, 6, 9, and 12 hours after completion of the theophylline infusion. Treatment with activated charcoal significantly decreased ($p < 0.05$) the mean elimination half-life from $6.4 \pm$ (SEM) 1.2 hours to 3.3 ± 0.4 hours. The AUC in the charcoal group was 42 ± 4 mg times hour/L compared to 78 ± 14 mg times hour/L in controls ($p < 0.05$).

Mahutte et al²³ administered an infusion of aminophylline 8 mg/kg to seven volunteers. Each then received activated charcoal 30 g at time zero and at 2, 4, and 6 hours. A significant reduction ($p < 0.001$) in the mean theophylline elimination half-life from $10.2 \pm$ (SD) 2.1 hours to 4.6 ± 1.3 hours was observed. The total body clearance of theophylline was also increased significantly ($p < 0.001$) by charcoal administration from $35.6 \pm$ (SD) 7.3 mL/kg/hour to 72.6 ± 17.0 mL/kg/hour.

The effect of different regimens of multiple-dose activated charcoal on the elimination of aminophylline 6 mg/kg given by infusion over 1 hour in six volunteers was investigated by Park et al.²⁴ A significant reduction ($p < 0.01$) in the mean theophylline elimination half-life from $9.1 \pm$ (SEM) 0.7 hours was achieved either with charcoal 20 g every 2 hours for six doses (4.3 ± 0.4 hours) or 10 g every hour for six doses (4.3 ± 0.2 hours). Park et al²⁵ also gave eight volunteers aminophylline 5-6 mg/kg intravenously over 60 minutes. Immediately on discontinuing the aminophylline infusions, the volunteers received activated charcoal either 5 g or 20 g every 2 hours for six doses. The 20 g regimen produced a significant reduction ($p < 0.01$) in the half-life ($4.9 \pm$ [SEM] 0.2 hours) compared to the 5 g regimen (6.3 ± 0.5 hours). The AUC was also reduced significantly ($p < 0.01$) from 88.9 ± 8.4 (5 g regimen) mg/L/hour to 67.7 ± 3.6 mg/L/hour (20 g regimen).

In another study,²⁶ six subjects with cirrhosis were given multiple-dose activated charcoal (40 g at time zero and 20 g at 2, 4, 6, 9, and 12 hours) following an infusion of aminophylline 6 mg/kg over 1 hour. The mean theophylline half-life during treatment was reduced significantly ($p < 0.05$) from $12.7 \pm$ (SEM) 4.0 hours to 4.0 ± 0.7 hours.

Five fasted volunteers received an infusion of aminophylline 8 mg/kg over 1 hour followed by various activated charcoal regimens: 12.5 g every hour for 8 hours; 25 g every 2 hours for 8 hours; 50 g every 4 hours for 8 hours.²² Each dosage regimen was preceded by activated charcoal 50 g and each subject received a total of 150 g. The mean theophylline elimination half-life was reduced significantly ($p < 0.05$) for each charcoal regimen compared to controls, but there was no significant difference between the treatment groups. Similarly, the mean AUC for each charcoal regimen was significantly lower ($p < 0.05$) than controls, although there was no significant difference between the charcoal regimens.

Tobramycin. Davis et al³⁴ administered tobramycin 2.5 mg/kg intravenously over 30 minutes to six volunteers. Activated charcoal 50 g was given prior to tobramycin administration and subsequent doses of 15 g were administered at 2, 4, and 6 hours. There was no difference in the mean values for total body clearance of tobramycin compared to control.

Multiple-dose activated charcoal (10 g 2 hours prior to dosing, 10 g at zero time, and 10 g at 2, 6, and 8 hours after dosing) had no effect on the elimination of tobramycin 1.5 mg/kg administered intravenously in five volunteers.³⁵

Tricyclic antidepressants. Kärkkäinen and Neuvonen³⁷ studied the impact of activated charcoal on the elimination of amitriptyline 75 mg administered orally to six fasted volunteers. Activated charcoal 50 g was given 6 hours after amitriptyline dosing and further doses (12.5 g) of charcoal were administered at 12, 18, 24, 30, 36, 42, 48, and 54 hours. Charcoal shortened significantly ($p < 0.05$) the elimination half-life of amitriptyline from $27.4 \pm$ (SEM) 4.8 hours (control) to 21.1 ± 3.3 hours (charcoal group). The AUC (0-72 hours) was also reduced significantly ($p < 0.05$) in the charcoal group.

In a further study, eight volunteers were given doxepin 50 mg orally and then received activated charcoal 15 g 3 hours later, followed by charcoal 10 g at 6, 9, 12, and 24 hours after dosing.³⁸ The half-life in the activated charcoal group $16.2 \pm \text{SEM } 2.3$ hours was not significantly different from the control group (17.9 ± 4.3 hours) and the clearance of doxepin in the activated charcoal group $1.23 \pm \text{SEM } 0.31$ L/hour/kg was not significantly different from the control group (0.93 ± 0.03 L/hour/kg).

The effect of multiple-dose activated charcoal on the elimination of imipramine was studied in a randomized crossover trial.³⁹ Four fasted volunteers received imipramine 12.5 mg/70 kg intravenously over 1 hour followed by either water or 180 g activated charcoal over 24 hours (20 g at 0, 2, 4, 6, 9, 12, 16, 20, and 24 hours after dosing). There was no significant difference ($p > 0.05$) in imipramine half-life in controls [$9.0 \pm \text{SEM } 0.8$ hours] compared to the charcoal treated group (10.9 ± 1.6 hours) or in the clearance values in the control group (992.2 ± 138.3 mL/minute/70 kg) and in the charcoal treated group (930.3 ± 101.9 mL/minute/70 kg).

Chrome et al⁴⁰ administered four separate doses of activated charcoal 5 g to six volunteers 30, 120, 240, and 360 minutes after they had been given nortriptyline 75 mg orally. There was a mean 72% (range 62% to 78%) reduction ($p < 0.01$) in peak nortriptyline concentrations and a significant reduction (mean 70%; range 58% to 76%; $p < 0.01$) in $\text{AUC}_{0-48 \text{ hours}}$ compared to control after multiple doses of charcoal. When only a single dose of activated charcoal 5 g was administered 30 minutes after nortriptyline, there was a mean 58% (range 30% to 81%) reduction in peak plasma nortriptyline concentrations and a mean 55% (range 32% to 67%) reduction in the $\text{AUC}_{0-48 \text{ hours}}$. The difference in peak nortriptyline concentrations and $\text{AUC}_{0-48 \text{ hours}}$ after single- and multiple-dose charcoal therapy was also significant ($p < 0.05$).

Valproic acid. Following the oral administration of sodium valproate 300 mg to seven volunteers, multiple-dose activated charcoal 20 g was administered at 4 hours; 10 g was given at 8, 12, 24, and 32 hours.³³ Activated charcoal did not significantly change the half-life of sodium valproate which was $20.0 \pm (\text{SD}) 6.8$ hours in the control group and 22 ± 9.2 hours in the charcoal group. The $\text{AUC}_{0-48 \text{ hours}}$ after activated charcoal was $408.0 \pm (\text{SD}) 114.5$ mg/L/hour which was not significantly different from control (398.1 ± 108.6 mg/L/hour).

Vancomycin. Davis et al³⁶ investigated the role of multiple-dose activated charcoal after the administration of vancomycin 1 g intravenously to six volunteers. Activated charcoal 50 g was administered before the infusion followed by 15 g doses at 2, 4, 6, and 8 hours after the start of the vancomycin infusion. Multiple-dose activated charcoal therapy did not enhance vancomycin clearance.

Clinical Studies

Clinical studies of multiple-dose activated charcoal consist only of case series and case reports.

Aspirin. Hillman and Prescott⁵⁶ described five patients with salicylate poisoning whose peak plasma salicylate concentrations were 425-655 mg/L. In two cases where the salicylate concentration exceeded 500 mg/L, alkaline diuresis was employed initially. All patients received multiple-dose activated charcoal (75 g, then 50 g every 4 hours) until their symptoms resolved. However, the charcoal preparation administered (Medicoal) contains substantial amounts of sodium bicarbonate and all patients developed an alkaline urine (personal communication) which may have further increased salicylate elimination. In a control group (selection criteria were not stated) of six patients with mild salicylate poisoning who were treated with oral fluids alone, the mean elimination half-life was 27 hours, whereas the mean half-life in the treatment group was less than 3.2 hours.

In seven patients, all of whom had salicylate concentrations greater than 500 mg/L and who received no other therapy, Vale⁵⁷ found the elimination half-life to be $9.7 \pm (\text{SD}) 3.0$ hours after each received at least 12.5 g/hour activated charcoal. However, no control data were included in this case series.

Conclusion. One animal study and two of four volunteer studies did not demonstrate increased salicylate clearance with multiple-dose charcoal therapy. Data in poisoned patients are insufficient to recommend the use of charcoal therapy.

Carbamazepine. After multiple-dose activated charcoal (mean total dose 203 ± 58 g), the mean elimination half-life in fifteen patients poisoned with carbamazepine was $8.6 \pm (\text{SD}) 2.4$ hours and the mean total body clearance was $113 \pm (\text{SD}) 44$ mL/minute,⁴¹ whereas in two other series of patients treated only with supportive measures,^{84,85} the mean elimination half-life was approximately 19 hours [$19.0 \pm (\text{SD}) 6.9$ hours⁸⁴ and $18.9 \pm (\text{SD}) 9.8$ hours⁸⁵].

Montoya-Cabrera et al⁴² administered multiple-dose activated charcoal (1 g/kg every 4 hours) to eight patients (mean total dose 386 ± 72 g). The mean (\pm SD) carbamazepine half-life was 9.5 ± 1.9 hours and the mean (\pm SD) total body clearance was 105.13 ± 20.4 mL/minute/kg.

The role of multiple-dose charcoal in carbamazepine poisoning was questioned by Watson et al,⁸⁶ who reported on its use in two children with acute, and two (one with two episodes of poisoning) with acute-on-chronic, carbamazepine intoxication. The peak carbamazepine concentrations in this study were between 22.4 and 60.0 mg/L. The mean elimination half-life of carbamazepine was 23.3 hours (one case) without charcoal, 10.17 hours ($p < 0.05$) when activated charcoal 30-50 g was given (two episodes of poisoning), and 7.21 hours ($p < 0.05$) when more than 50 g of charcoal was used (three episodes of poisoning). The authors reported no benefit from multiple-dose charcoal in terms of time to complete recovery despite the effect on the plasma half-life of the drug. However, this conclusion has been criticized by Vale and Heath,⁸⁷ who stated that the study was too small to test reliably the hypothesis that there exists a relationship between the dose of activated charcoal and time to recovery.

Conclusion. There is good evidence from animal and volunteer studies and from poisoned patients that the total body clearance of carbamazepine is enhanced significantly by multiple-dose activated charcoal therapy. In terms of total body clearance, multiple-dose charcoal is comparable to charcoal hemoperfusion (Table 1). However, a reduction in morbidity has not yet been demonstrated by its use.

Elimination	Half-life (hours)	Clearance (mL/minute)
Hemoperfusion	8.6-10.7 ⁹⁰	80-129 ⁸⁹⁻⁹¹
Multiple-dose charcoal	8.6 ± 2.4 ⁴¹	113 ± 44 ⁴¹
Multiple-dose charcoal	9.5 ± 1.9 ⁴¹	105.13 ± 20.4 ⁴¹

Dapsone. Neuvonen et al⁶ described two patients with dapsone poisoning. One received activated charcoal 20 g every 6 hours on days 5 and 6 postingestion, with a reduction in the elimination half-life from 88 to 13.5 hours. The second patient received charcoal 20 g every 6 hours only on the third day postoverdose. A reduction in the dapsone elimination half-life from 33 to 11 hours approximately was observed. Workers from the same unit⁴³ reported a further three patients with dapsone poisoning. The initial dapsone concentrations measured between 16-17 hours after ingestion were 28.0, 23.6, and 17.5 mg/L, respectively. Oral activated charcoal 20 g every 6 hours was administered for 1-2 days beginning 2-4 days postingestion. The mean dapsone elimination half-life was reduced from $77 \pm$ (SEM) 23 hours to 12.7 ± 0.7 hours.

Conclusion. Volunteer studies demonstrate that multiple-dose activated charcoal increases dapsone elimination. Clinical data support this conclusion and the elimination half-life achieved by charcoal is comparable to that (10.4 ± 1.7 hours) during hemodialysis.⁴³ However, it has not been demonstrated that methemoglobinemia and hemolytic anemia are less likely to result after the use of charcoal therapy.

Digitoxin. Pond et al⁶² advocated the use of multiple-dose charcoal in digitoxin poisoning, based on their experience of a patient with a peak plasma digitoxin concentration of 264 mcg/L who received activated charcoal 50 g initially, then 60 g (with magnesium citrate 250 mL) every 8 hours for 72 hours. Following charcoal, the digitoxin half-life was 18 hours compared to a half-life of 162 hours after discontinuation of charcoal.

Conclusion. Volunteer studies and one case report suggest that the clearance of digitoxin may be increased by multiple-dose activated charcoal, though clinical benefit has yet to be demonstrated. However, in severe cases of poisoning, digoxin-specific antibody fragments should be considered.

Digoxin. Boldy et al⁵⁸ described a 69-year-old man who had ingested a digoxin overdose and had a plasma digoxin concentration of 8.3 mcg/L, 14.5 hours postingestion. He received activated charcoal 100 g over 1 hour, then 50 g every 4 hours for a further seven doses. The plasma digoxin concentration fell to 1.0 mcg/L over the ensuing 48 hours with a terminal elimination half-life of 14 hours.

Lake et al⁵⁹ reported a 71-year-old woman with chronic renal failure and digoxin toxicity (peak plasma concentration 9 mcg/L) who was treated with activated charcoal 50 g followed by 25 g every 6 hours for 8 doses. The digoxin elimination half-lives calculated before, during, and after charcoal therapy were 7.3, 1.4, and 6.3 days, respectively.

Critchley and Critchley⁶⁰ described a 66-year-old male with an 8-year history of chronic renal failure who was suffering from digoxin toxicity (severe bradycardia and hypotension). The patient's serum digoxin concentration failed to decrease over 4 days despite the use of daily hemodialysis. On day 4, multiple-dose activated charcoal therapy was instituted (50 g every 6 hours for 48 hours). The serum digoxin concentration decreased from 2.1 mcg/L to 0.8 mcg/L within 48 hours. A second course of activated charcoal (50 g every 6 hours for 72 hours) was instituted from admission day 9 to 12, resulting in a decrease in the digoxin concentration from 0.8 mcg/L to 0.4 mcg/L. During each course of activated charcoal therapy, there was a precipitous reduction in the serum half-life of digoxin, but precise half-lives were not calculated.

Multiple-dose activated charcoal (dose not stated) increased the mean digoxin clearance in 23 patients to $98 \pm$ (SD) 34 mL/minute (mean clearance in sixteen nontreated patients 55 ± 17 mL/minute) and decreased the digoxin elimination half-life from $68 \pm$ (SD) 19 hours to 36 ± 14 hours (control group); all patients had plasma digoxin concentrations >2.5 mcg/L.⁶¹

Conclusion. The elimination half-life of digoxin was decreased by the use of multiple-dose activated charcoal in animal and volunteer studies, in two case reports and one case series. However, in severe cases of poisoning, digoxin-specific antibody fragments should be considered.

Meprobamate. Hassan⁶⁵ described a further two patients with meprobamate poisoning whose peak plasma concentrations were 320 mg/L and 240 mg/L. Each received oral activated charcoal 50 g every 4-6 hours for five doses after an initial loading dose (75 g in one patient). The elimination half-lives for meprobamate were 4.4 hours and 4.5 hours, respectively.

Three patients with meprobamate poisoning were treated with multiple-dose activated charcoal.⁶⁶ Peak meprobamate concentrations were 221 mg/L, 91 mg/L, and 80.5 mg/L, respectively, and all patients initially required mechanical ventilation. With charcoal therapy, the elimination half-lives for meprobamate were 4.0, 4.5, and 5.0 hours, respectively.

Conclusion. Reports of meprobamate poisoning managed without multiple-dose charcoal suggest an elimination half-life of about 13 hours⁹² and thus charcoal therapy may be effective in increasing drug elimination though there are no volunteer studies to confirm this.

Methotrexate. Serum methotrexate concentrations were estimated after a 6-hour infusion of 1 g/m² methotrexate had been administered to seven patients.⁶⁷ Each received activated charcoal 25 g at 12, 18, 24, 36, and 48 hours after the infusion. The elimination half-life in the charcoal treated group was reduced, but not significantly, from $8.46 \pm$ (SEM) 0.47 hours (controls) to 7.6 ± 0.44 hours (charcoal group).

Conclusion. This single study does not support the clinical use of multiple-dose activated charcoal after high-dose methotrexate therapy.

Phenobarbital (phenobarbitone). Goldberg and Berlinger⁴⁴ gave multiple-dose activated charcoal to two patients poisoned with phenobarbital. The first patient (serum phenobarbital concentration 141 mg/L) received activated charcoal 40 g (with sodium sulfate 20 g) on admission and activated charcoal 40 g (with magnesium citrate 60 mL) every 4 hours for five additional doses. The second patient (serum concentration 107 mg/L) was given activated charcoal 30 g (and sodium sulfate 30 g) 6 hours after admission and this dose was continued every 6 hours for a total of six doses. The phenobarbital elimination half-lives in these two patients were approximately 24 hours.

A randomized study of ten comatose patients who required endotracheal intubation and mechanical ventilation was reported by Pond et al.⁴⁵ The control group ($n = 5$) who received only a single dose of activated charcoal (mean plasma phenobarbital concentration 121 ± 31 mg/L) and the treatment group ($n = 5$) who received multiple doses of activated charcoal (mean plasma phenobarbital concentration 132 ± 36 mg/L) both received activated charcoal 50 g with magnesium citrate 250 mL on presentation and, in addition, patients in the treatment group were given activated charcoal 17 g together with sorbitol 70 mL (70%) every 4 hours until they had recovered sufficiently to be extubated. Although the mean elimination half-life of phenobarbital was shortened ($36 \pm$ (SD) 13 hours) significantly ($p < 0.01$) in the multiple-dose charcoal group when compared to the single-dose charcoal group (93 ± 52 hours), the length of time that the patients in each group required mechanical ventilation did not differ significantly, nor did the time spent in the hospital. This trial has been criticized as being too small and having unevenly matched groups.^{93,94}

In another series,⁴⁶ charcoal, in larger doses and given without cathartic, not only greatly enhanced the elimination of phenobarbital, but also decreased the time to recovery. Six patients with moderate to severe phenobarbital intoxication (mean peak plasma phenobarbital concentration 139.2 ± 76.8 mg/L) were treated with repeated oral doses of activated charcoal 50 g (in 3 cases the charcoal employed contained

sodium bicarbonate) following an initial dose of 50-150 g (total dose 225-500 g). During and for up to 12 hours after treatment with activated charcoal, the mean phenobarbital half-life was 11.7 ± 3.5 hours. The mean total body clearance of the drug during and up to 12 hours after administration of charcoal was 84 ± 34 mL/minute. It is possible that in the three patients receiving sodium bicarbonate, renal clearance of phenobarbital may have been enhanced. It should be noted that only one-third of the patients in this series were receiving long-term anticonvulsant therapy, in contrast to 100% of patients in the study reported by Pond et al.⁴⁵

The administration of six doses of activated charcoal (0.7 g/kg) to a severely brain-damaged neonate (weight 2.6 kg), treated with intravenous phenobarbital (50 mg/kg), decreased the serum phenobarbital half-life from a calculated 250 hours to 22 hours, enabling earlier initiation of brain-stem testing.⁴⁷

Conclusion. There is good evidence from animal and volunteer studies and from poisoned patients that the total body clearance of phenobarbital is enhanced significantly by multiple-dose activated charcoal therapy. In terms of total body clearance, multiple-dose charcoal is comparable to other elimination techniques such as hemodialysis and hemoperfusion (Table 2).

Elimination	Clearance (mL/minute)
Intrinsic clearance	4 ⁹⁵
Alkaline diuresis	7 ⁹⁶
Hemodialysis	49 ⁹⁷
Hemoperfusion	77 ^{96,98}
Multiple-dose charcoal	84 ^{46*}
*Estimated	

Phenytoin. A 21-year-old woman presented 9 hours after allegedly ingesting phenytoin 20 g and was treated with three doses (amount not stated) of activated charcoal every 2 hours (time after overdose not stated). The phenytoin concentration fell from 41 mg/L on admission to 11 mg/L on day 5 postoverdose.⁶⁸

Howard et al⁶⁹ reported the clinical course of a 36-year-old, hepatitis B-positive, chronic alcohol abuser receiving both phenobarbital and phenytoin long-term for epilepsy. Twenty-four hours before admission his plasma phenytoin concentration was 34 mg/L and on admission 47 mg/L, at which time features of phenytoin toxicity were present. He received activated charcoal 50 g with sorbitol 96 g every 6 hours for 4 doses. The phenytoin concentration decreased to 20 mg/L approximately 44 hours after admission. Since it is likely that this patient had taken an acute overdose of phenytoin and had induced hepatic enzymes, the benefit of multiple-dose activated charcoal is difficult to determine.

Ros and Black⁷⁰ described a 17-year-old epileptic whose serum phenytoin concentration at admission was 56 mg/L, rising to 69 mg/L after 24 hours. He was then treated with nine doses of activated charcoal 30 g every 4 hours. Thirty-eight hours after the first dose of charcoal, the serum phenytoin concentration had fallen to 22 mg/L. When charcoal was discontinued, the serum phenytoin concentration increased to 33 mg/L, then slowly declined.

Weichbrodt and Elliott⁷¹ reported a 38-year-old woman on long-term phenytoin therapy who was treated with multiple-dose activated charcoal after an overdose of phenytoin 10-15 g. She received an initial dose of activated charcoal 30 g at 7 hours postoverdose, followed by 30 g every 6 hours for 4.5 days commencing some 30 hours after overdose (magnesium citrate 180 mL was coadministered with each dose). Her peak serum phenytoin concentration (52 mg/L) was reached within 42.5 hours and the phenytoin concentration fell to within the therapeutic range 6 days postoverdose.

A further case of chronic phenytoin intoxication in a patient with severe liver disease was reported by Weidle et al.⁷² Seven days after commencing phenytoin 300 mg twice daily, the patient became agitated and incoherent and the serum phenytoin concentration was found to be 44.4 mg/L. Phenytoin was discontinued and 2 days later (phenytoin concentration 45.2 mg/L) she was commenced on a multiple-dose charcoal regimen of 30 g every 4 hours. After ten doses of charcoal, the serum phenytoin concentration was 11.4 mg/L. The authors estimated that the clearance had been increased by approximately 1.65 L/hour/1.78 m².

Conclusion. Although there is some evidence from animal and volunteer studies that multiple-dose activated charcoal may enhance phenytoin elimination, the five anecdotal case reports published to date do not confirm that this therapeutic approach is of clinical benefit.

Quinine. In five symptomatic patients with acute quinine poisoning, the mean elimination half-life was $8.1 \pm (\text{SD}) 1.1$ hours after each had been administered activated charcoal 50 g every 4 hours.⁴⁸ This should be compared to a half-life of approximately 26 hours in poisoned patients treated supportively.⁹⁹

Conclusion. A volunteer study has demonstrated that quinine elimination is enhanced significantly by multiple-dose activated charcoal and a single clinical study has confirmed this observation, even though the relatively large volume of distribution ($> 1\text{-}2.7$ L/kg) and high protein binding (70% to 90%) do not favor the use of charcoal therapy. Further studies are required to demonstrate that the serious sequelae encountered in quinine poisoning are reduced or even abolished by charcoal therapy.

Theophylline poisoning. Mahutte et al²³ reported a 72-year-old man with theophylline poisoning (admission concentration 31 mg/L) in whom four doses of activated charcoal 30 g every 2 hours reduced the pre-treatment half-life from 34.4 to 5.7 hours. Workers from the same unit subsequently described four further patients [mean \pm (SD) pretreatment theophylline concentrations were 37.1 ± 11.25 mg/L] in whom multiple-dose charcoal reduced the mean serum theophylline half-life from $23.30 \pm (\text{SD}) 7.95$ hours to 8.0 ± 3.95 hours.³⁵

Five patients with moderate theophylline poisoning who were treated with multiple-dose charcoal were reported by Radomski et al.²⁶ The mean serum theophylline half-life (SEM) was 4.9 ± 0.8 hours with peak serum theophylline concentrations ranging from 32-59 mg/L.

Amitai et al⁴⁹ reported two patients (a 34-year-old woman and a 5-month-old infant) with theophylline poisoning (peak plasma concentrations 100 mg/L and 97 mg/L, respectively). With activated charcoal 15 g hourly for nine doses commencing 14 hours after overdose, the adult patient's theophylline elimination half-life fell to 3.7 hours. The infant received three doses of activated charcoal: 10 g at 4.5 hours, 5 g at 8 hours, and 2.5 g at 11 hours postoverdose. The initial elimination half-life of 19 hours decreased to 2.4 hours after charcoal.

Following a medical error,⁵⁰ a patient with a peak theophylline concentration of 42.5 mg/L was treated with multiple-dose activated charcoal 15 g every 2 hours for four doses and the elimination half-life was reduced from 7.5 to 2.2 hours.

A 23-year-old woman attempted suicide by ingesting theophylline and terbutaline tablets.⁵¹ The peak (on admission) serum theophylline concentration was 111.4 mg/L. Treatment with multiple-dose activated charcoal 50 g every 6 hours led to a reduction in the theophylline half-life from 17.2 to 5.9 hours.

Two adolescents with serum theophylline concentrations > 100 mg/L were treated with a continuous nasogastric infusion of activated charcoal at a maximum rate of 50 g/hour.⁵² During the first 20 hours of charcoal therapy, the elimination half-life of theophylline was estimated as 7.7 and 13.5 hours, respectively, decreasing subsequently to 2.6 and 3.2 hours.

Sesler et al⁵³ reported fourteen cases of theophylline poisoning, ten of whom were treated with activated charcoal. Although several patients vomited charcoal, the mean theophylline half-life during charcoal therapy was $5.7 \pm (\text{SD}) 2.5$ hours.

A further five cases, including one reported previously by Amitai et al,⁴⁹ of theophylline poisoning due to medical error in infants under 7 months old, were reported by Shannon et al.⁵⁴ Multiple-dose activated charcoal resulted in an elimination half-life of $8.3 \pm (\text{SD}) 4.7$ hours ($n = 4$).

Conclusion. Patients poisoned severely with theophylline are invariably vomiting repeatedly, which makes administration of charcoal problematic, even via a nasogastric tube. In these circumstances, the use of an antiemetic intravenously should be considered. Studies in animals and volunteers confirm that the elimination of theophylline is enhanced by multiple-dose activated charcoal. Case reports also suggest that theophylline elimination is increased by this means although further studies are required to demonstrate that morbidity is reduced by multiple-dose charcoal therapy.

Tricyclic antidepressants. Swartz and Sherman⁷³ administered activated charcoal to three patients poisoned with amitriptyline. The first patient received two doses (50 g at 2 hours and 25 g at 10 hours postoverdose) of activated charcoal, the second patient received three doses (50 g at 2 hours, 25 g at 6 hours, and 25 g at 23 hours postoverdose), and the third patient received four doses (40 g at 1 hour, 20 g

at 4 hours, 20 g at 9 hours, and 20 g at 21 hours postoverdose) of activated charcoal. Although the authors concluded that charcoal "greatly accelerated tricyclic elimination," this cannot be supported from the data.

Three patients poisoned with dothiepin received activated charcoal 100-200 g following overdose.⁷⁴ The mean elimination half-life was $12.1 \pm$ (SD) 1.3 hours, which is not substantially different from cases treated supportively in the same series.

Conclusion. A variable effect on the elimination half-life of amitriptyline, doxepin, and imipramine has been reported in volunteer studies. However, it would not be expected from the very large volume of distribution of tricyclic antidepressants that their elimination would be enhanced by activated charcoal.

Valproic acid. A 26-month-old infant ingested a minimum of 4.5 g enteric-coated valproic acid. On arrival at hospital, activated charcoal 20 g was administered (no detectable valproic acid in the serum) and following a marked clinical deterioration (serum valproic acid 315 mg/L), gastric infusion of 3 g/hour activated charcoal was given from 9 hours to 25 hours postoverdose.⁷⁵ The elimination half-life was 4.8 hours, which is shorter than the 23 hours reported by Dupuis et al.¹⁰⁰

Conclusion. The elimination of sodium valproate was not enhanced in animal and volunteer studies by the use of multiple-dose charcoal therapy. It is possible that at higher plasma drug concentrations, when more free drug is likely to be present, such therapy could have greater benefit. Further studies are needed to confirm this.

Vancomycin. A 17-day-old neonate was administered vancomycin 500 mg intravenously. Multiple-dose activated charcoal 1 g/kg was administered 5 hours later and continued every 4 hours for 12 doses.⁶⁴ The half-life of vancomycin was calculated to be 9.4 hours.

A 47-day-old premature neonate received an overdose of vancomycin as a result of medical error. Exchange transfusion did not change the measured serum vancomycin concentration. Multiple doses of activated charcoal 1 g/kg were administered through a nasogastric tube every 4 hours (nine doses in all) beginning 5 hours after exchange transfusion. The calculated half-life prior to and after charcoal therapy was 35 hours and 12 hours, respectively. During therapy the serum vancomycin concentration fell from 230 mg/L to 42 mg/L.⁶³

Conclusion. The elimination of vancomycin was not increased by multiple-dose activated charcoal in a volunteer study. The apparent greater benefit of this treatment in two case reports is suggestive of benefit but further studies are required to confirm efficacy.

Dosage Regimen

If multiple-dose activated charcoal is considered appropriate, it is essential that the staff undertaking the procedure are experienced in its use both to reassure the conscious patient and to reduce the risk of complications in the obtunded patient.

A patient should be told that large and repeated doses of activated charcoal need to be given and that its administration may lead to a faster recovery. If appropriate, the patient should be informed that the treatment is to be given via a nasogastric tube. Such an approach is mandatory if the patient is unconscious but may also be necessary if the individual is nauseated or vomiting.

If the patient has ingested a drug in overdose which induces nausea and vomiting, the administration of activated charcoal, particularly if it contains sorbitol, may produce emesis. In these circumstances it is appropriate to administer an antiemetic intravenously to ensure compliance. Alternatively, smaller more frequent doses of charcoal may be used but are not always retained.

The dose of administered charcoal is probably of greater importance than the surface area of the charcoal.¹⁰¹ In a study involving six volunteers, activated charcoal 20 g, given every 2 hours, produced a significantly greater reduction in the half-life of theophylline than 5 g every 2 hours.²⁴ In addition, administering the same total dose of activated charcoal (120 g over 12 hours) in hourly doses rather than less frequently, resulted in a further reduction in half-life. Ilkhanipour et al²² have also confirmed that activated charcoal 12.5 g every hour (total dose 150 g over 12 hours) produced the greatest reduction in theophylline elimination half-life. Moreover, the more frequent administration of smaller doses of activated charcoal tends to prevent regurgitation which commonly occurs when large doses are given. There is some evidence that a continuous gastric infusion of charcoal, at least after a large initial dose (50-100 g), may offer advantages.⁵²

Clinical experience suggests that, after an initial dose of 50-100 g given to an adult, charcoal may be administered hourly, every 2 hours, or every 4 hours at a dose equivalent to 1.25 g/hour. In children, lower

doses (10-25 g) of charcoal may be employed because smaller overdoses have usually been ingested and the capacity of the gut lumen is smaller.

Coadministration of a Cathartic

The role of cathartics such as sorbitol, mannitol and sodium, and magnesium sulfate remains controversial. They are often given at the same time as activated charcoal in order to increase palatability. Sorbitol sweetens the mixture but palatability is not relevant if administration is via a nasogastric tube. Some studies (but not others) suggest that the coadministration of a cathartic may not only reduce drug absorption to charcoal but, paradoxically, increase absorption by increasing the volume of intestinal fluid.¹⁰² Furthermore, mannitol and sorbitol delay gastric emptying in man,¹⁰³ thereby reducing the amount of charcoal available to adsorb the drug in the small bowel. More recent evidence, however, indicates that in man the coadministration of a cathartic to charcoal may further hasten the elimination of phenobarbital¹⁴ and of a slow-release theophylline preparation,⁸³ although the combined use of sorbitol and charcoal was not without adverse effects. Two of the nine volunteers in the latter study developed liquid stools, severe abdominal cramps, nausea, sweating, and hypotension. However, Al-Shareef et al¹⁰⁴ did not demonstrate an additional benefit from the use of a sorbitol-charcoal formulation in the management of theophylline poisoning. Cathartics theoretically decrease the risk of constipation and hence small bowel obstruction if very large doses of activated charcoal are administered.

The need for a cathartic as part of a multiple-dose activated charcoal regimen remains unproven and many clinical toxicologists have not found it necessary to employ cathartics in clinical practice. While the use of sorbitol produces a more rapid onset of catharsis without the development of hypermagnesemia associated with the use of magnesium-containing cathartics, it too has well-recognized complications. It is probable that the increased morbidity from its use will outweigh any potential benefit (see Position Statement on Cathartics¹⁰⁵) and therefore the concurrent administration of a cathartic is not recommended. In particular, cathartics should not be administered to young children because of the propensity of laxatives to cause fluid and electrolyte imbalance.

Complications of Use

The administration of multiple-dose activated charcoal rarely produces clinically important side effects. Black stools and mild transient constipation are well recognized, but constipation is not usually severe enough to require treatment, even if a cathartic has not been coadministered.

Gastrointestinal Complications

An adult patient treated for carbamazepine poisoning with activated charcoal 240 g and magnesium citrate 600 mL developed an ileus which resolved with the administration of additional doses of magnesium citrate.¹⁰⁶ A further case of small bowel obstruction has been reported in a patient poisoned with amitriptyline who required a laparotomy 5 days after admission to remove a charcoal bezoar in the distal ileum; activated charcoal 30-60 g had been given every 4-6 hours for 5 days.¹⁰⁷

Atkinson et al¹⁰⁸ have described a 24-year-old patient intoxicated with barbiturates and benzodiazepines, who required a limited right hemicolectomy after he developed small bowel obstruction due to a large bolus of inspissated charcoal in the cecum. A total of 125 g of activated charcoal was administered over 18 hours.

A rectal ulcer with massive hemorrhage followed the administration of activated charcoal 50 g, with magnesium sulfate 50 g in a 1000 mL slurry every 4-6 hours for 50 hours, to a patient with organophosphorous insecticide poisoning.¹⁰⁹ Bloody stools did not occur until 10 days after she had ingested fenitrothion and passed hard charcoal masses.

Goulbourne and Cisek¹¹⁰ have reported the development of gastrointestinal obstruction 5 days after a patient poisoned with theophylline was given activated charcoal 350 g. The patient underwent laparotomy with lysis of low-grade adhesions at the ileocecal region, for which an ileotransverse colostomy was performed. On opening the bowel, several charcoal clumps were removed measuring 4.5 × 5 × 3 cm.

An obstructing charcoal mass (120 g) was found at the site of an intestinal perforation in a 39-year-old female who was receiving maintenance methadone and who had ingested a modest overdose of amitriptyline.¹¹¹ Apart from lethargy, she was asymptomatic but was prescribed activated charcoal 50 g every 4 hours; she declined more than 100 g. Four days later after two enemas, perforation occurred.

Respiratory Complications

In some reports it is unclear whether the respiratory complications described were due to the well-recognized consequences of aspiration of gastric contents into the lung or the aspiration of activated charcoal specifically. In one instance the presence of povidone in the charcoal formulation was thought to be the major factor.¹¹²

Severe airway obstruction has been reported in one infant given charcoal after vomiting was induced by syrup of ipecac.¹¹³ Accidental administration of activated charcoal into the lung produced an adult respiratory distress syndrome, but the patient recovered and was discharged home 14 days later.¹¹⁴ Even if recovery results, cerebral anoxic damage may have occurred.¹¹⁵ Bronchiolitis obliterans has followed aspiration of activated charcoal with fatal consequences.¹¹⁶

Six cases of fatal pulmonary aspiration of charcoal have been reported,^{112,117-119} but in one case¹¹² this was probably due to the povidone in the formulation rather than to activated charcoal itself.

Fluid, Electrolyte, and Acid-Base Abnormalities

The coadministration of cathartics may produce hypernatremia,¹²⁰⁻¹²² hypokalemia, hypermagnesemia,¹²³⁻¹²⁴ and metabolic acidosis, particularly in infants.

SUBSTANCE-RELATED DISORDERS

Adapted from Fuller MA and Sajatovic M, *Drug Information for Mental Health*, Hudson, OH: Lexi-Comp, Inc, 2001.

Substance-related disorders are conditions in which an individual uses/abuses a substance, leading to maladaptive behaviors and symptoms. In DSM-IV, substance-related disorders are further grouped into substance dependence and substance abuse. Substance abuse refers to a maladaptive pattern of substance use leading to clinically significant impairment or distress, manifested by at least one symptom that interferes with life functioning within a 12-month period. Diagnostic criteria for substance dependence requires at least three of the following within a 12-month period: development of tolerance to the substance, withdrawal symptoms, persistent desire/unsuccessful attempts to stop the substance, ingestion of larger amounts of substance than was intended, diminished life functioning, and persistent substance use in the phase of physical or psychological problems. Substance abuse and substance dependence are enormous societal problems. In the United States, the lifetime prevalence of substance abuse or dependence in adults is over 15%. Substance abuse prevalence is greatest among individuals 18-25 years of age. Substance abuse is also more common in men compared to women, and in urban residents compared to rural residents.

Over 50% of individuals with substance-related disorders have comorbid psychiatric disorders. Individuals with mental illness are about twice as likely to smoke as compared to the general population and to consume about 44% of cigarettes smoked nationally. The term "dual diagnosis" usually refers to individuals with concomitant substance abuse and psychiatric diagnosis. Comorbid psychiatric diagnoses, common in individuals who abuse substances, include major depression, personality disorder, particularly antisocial personality, anxiety disorders, and dysthymia. Genetic studies involving twins, adoptees, and siblings raised separately have suggested good evidence for familial patterns in alcohol abuse. Genetic patterns with other substances of abuse have not been well demonstrated.

General Treatment Recommendations

Individuals with substance abuse are often both physically and psychologically impaired. Management and treatment of substance abuse can be divided in the main areas of:

- treatment of acute intoxication/overdose
- treatment of withdrawal
- general treatments for psychological addiction/rehabilitation

Additionally, individuals who abuse substances frequently have comorbid psychiatric disorders which affect final outcome. Proper diagnosis and treatment of comorbid psychiatric disorders improve outcome in nearly all cases.

Psychosocial treatments include inpatient care (now increasingly rare in today's managed care settings), outpatient therapies which may be in individual or group settings, and self-help residential treatment programs (therapeutic communities).

Numerous studies have demonstrated that psychotherapy added to pharmacologic management promotes abstinence better than pharmacologic management alone.

Alcohol

Intoxication/Overdose (see Ethyl Alcohol)

Alcohol intoxication may be severe with extreme usage, potentially leading to respiratory depression, coma, and death. These individuals require close monitoring in an intensive care setting. An idiosyncratic reaction of severe behavioral symptoms occurring after relatively low level alcohol ingestion has been reported. Symptomatic support with environmental protection, and possibly the addition of low-dose antipsychotic medication, may be beneficial in these individuals (eg, haloperidol 1-2 mg orally or I.M.).

Withdrawal

Symptoms can begin within 6-48 hours postcessation and persist up to 5 days. About 5% of these patients will develop full-blown delirium tremens. The mortality rate for delirium tremens is 1% to 5%. Benzodiazepines are the most effective treatment for alcohol withdrawal. For tremor and mild agitation, an oral benzodiazepine such as lorazepam 1-2 mg every 4-6 hours is generally effective. Individuals with more severe agitation or hallucinations may require I.M. or I.V. medication. Chlordiazepoxide (25-100 mg orally) can be administered

as an alternative to lorazepam. Phenobarbital (5 mg/kg I.V. or 15 mg of phenobarbital for each 30 mL “1 ounce” of 80-100 proof) may be used for resistant cases. Phenytoin is not useful in treating ethanol withdrawal seizures. Trazodone (50-150 mg orally at night) can be used as a sleep aid. Beta-adrenergic blockers should be utilized to treat hyperadrenergic symptoms, especially in the elderly. Individuals with delirium tremens (or DTs) should be in closely observed medical settings (hospitalized) and must receive maintenance benzodiazepine treatment (eg, diazepam 0.15 mg/kg at 2.5 mg/minute) until behavior and autonomic symptoms (tachycardia, hypertension) stabilize. Dosage should then be titrated as clinically indicated. In very resistant cases, a propofol infusion (40 mg I.V. followed by an infusion of 50 mcg/kg/minute) can be considered with ventilatory support. Sodium pentobarbital (with appropriate airway management) is also a reasonable alternative. The initial dose is 3-5 mg/kg I.V., followed by a 100 mg/hour infusion for sedation. Oral baclofen (30 mg/day in divided doses for 10 days) has also been utilized to treat withdrawal. Most cases of DTs may be avoided if treated with oral or I.M. benzodiazepines when the patient is in the early alcohol withdrawal phase. Vital signs should be closely monitored as an index of severity of withdrawal. Intravenous fluid hydration with D₅ 0.9% NS at 300-1000 mL/hour should be instituted if dehydration is present. Other adjunctive agents to consider include clonidine, valproic acid (500 mg orally 3 times/day for 7 days), baclofen (10 mg every 8 hours), and carbamazepine. A supportive, nonthreatening and therapeutic environment is helpful as patients with alcohol withdrawal are often frightened and severely anxious. Treatment with benzodiazepines may be decreased in both dosage and frequency over the next several days as withdrawal symptoms resolve. The Clinical Institute Withdrawal Assessment for Alcohol Scale (CIWA) should be utilized to monitor withdrawal.

Acute alcoholic encephalopathy (Wernicke’s syndrome) should be managed with thiamine 50 mg/day I.M. or 100 mg/day orally for 1-2 weeks. Serum glucose, phosphate, and magnesium should be monitored. The chronic amnesic syndrome associated with long-term alcohol abuse (Korsakoff’s syndrome) may improve with thiamine 100 mg/day continued for 6-12 months, although most patients have limited cognitive recovery. Antipsychotics are generally best avoided in alcohol withdrawal as they may lower seizure threshold. However, in cases of failure of benzodiazepines to control paranoid behavioral symptoms or hallucinations, judicious use of antipsychotic medication may be helpful.

General Treatment

Most clinicians agree that complete abstinence from alcohol is the cornerstone of successful alcohol abuse treatment. Psychotherapy which focuses on drinking behavior and alternative behaviors is generally the most effective intervention. This includes individual, group, marital, and family therapies. Self-help groups such as Alcoholics Anonymous (AA) may be extremely helpful.

Specific biologic interventions that may be adjunctive in promoting alcohol abstinence are disulfiram, naltrexone, and some psychotropic drugs. Disulfiram competitively inhibits the enzyme aldehyde dehydrogenase, so that subsequent alcohol ingestion leads to serum acetaldehyde accumulation and resultant symptoms of flushing, feeling overheated, nausea, and general malaise. Dizziness, palpitations, and hypotension may occur. Symptoms generally persist for 30-60 minutes and may be useful in motivated, healthy patients in assisting with abstinence. Disulfiram must be taken daily, generally in the morning, and is usually prescribed at a dosage of 125-250 mg/day. Although some individuals benefit from the addition of disulfiram to an alcohol treatment regimen, its use must be weighed against the medical risks (severe hypotension, hypocalcemia, respiratory depression) if the individual continues to drink while on disulfiram.

Naltrexone, a narcotic antagonist, may also be a useful adjunct as part of an alcohol treatment regimen. Naltrexone at doses of 50 mg/day may reduce drinking in recovering alcoholics. Adverse effects may include hypertension, GI disturbance, and sedation. Rarely, liver functioning may become impaired, and hepatic screening and monitoring should be done concurrently.

Additional psychotropic medications that have been reported to be useful in alcohol treatment include antidepressants such as serotonin reuptake inhibitors and dopamine agonists. Additionally, treatment of existing comorbid psychiatric disorders such as major depression, bipolar disorder, or post-traumatic stress disorder (PTSD) will usually substantially improve outcome.

Cocaine

Intoxication/Overdose (see Cocaine)

The symptoms of cocaine intoxication are similar to alcohol. In cases of high-dose use or when intravenous route has been used, symptoms may be severe, including extreme anxiety, paranoia, and hallucinations. Severe hypertension, hyperthermia, and arrhythmias may occur. Management of autonomic hyperarousal

may benefit from benzodiazepines. Phentolamine may be beneficial in hypertensive crisis. Other supportive measures include close monitoring of vital signs, maintenance of fluid status, and ambient cooling for hyperthermia.

Withdrawal

Cocaine withdrawal is characterized by three phases: 1) an initial “cocaine crash” phase (fatigue, insomnia, depression) lasting for 1-2 days; 2) withdrawal phase (dysphoria, anxiety); followed by 3) an extinction phase. An intense craving for cocaine can occur at any time. Cocaine withdrawal symptoms generally are managed supportively with no specific identified pharmacologic treatments. Intense cocaine cravings may lead individuals to self-medicate with cocaine or other illicit substances.

General Treatment

As with alcohol and other drugs of abuse, abstinence from cocaine is essential in maintaining successful treatment. Psychotherapy has been proven to be helpful while some pharmacotherapies (desipramine, amantadine) have suggested efficacy in some individuals with reduced cocaine craving, dysphoria, and drug use. Comorbid psychiatric illness should be treated as needed to optimize outcome.

Opioids

Intoxication/Overdose

Most individuals with self-induced opioid intoxication (as with other types of illicit substance intoxication) do not present for treatment unless distressing physical or behavioral symptoms occur. Overdosage situations, however, are relatively common among chronic opioid drug abusers. Anoxia, coma, and death may occur unless intervention treatment is initiated. Initial measures include airway protection, vital sign monitoring, and administration of naloxone, an opiate antagonist. Naloxone may be given at an adult dose of 0.4-2 mg I.V. and should reverse overdose symptoms within 2 minutes. Dosage may be repeated twice more at 5-minute intervals, if necessary. Alternatively, nalmefene at doses of 0.5-1 mg in up to ten boluses can reverse opioid toxicity rapidly. Treating clinicians should also be alert to the possibility of concomitant substance overdose (eg, barbiturates) or medical conditions that may contribute to respiratory depression (eg, traumatic head injury). Patients with good response to naloxone may require repeated dosing over the next several hours as duration of action of naloxone generally does not exceed 4 hours. Care should be taken when using naloxone to guard against precipitating a withdrawal reaction in opioid-dependent patients.

Withdrawal

Withdrawal symptoms occur within 6-12 hours after ingestion of last drug dose in opioid-dependent persons. Treatment of opioid dependence involves management of primarily acute physical symptoms in the acute phase. For acute phase withdrawal (detoxification), the synthetic opioid methadone has been used successfully by many clinicians who treat substance abuse disorders. In patients who begin to exhibit signs and symptoms of opioid withdrawal (hypertension, tachycardia, sweating, lacrimation, rhinorrhea), methadone 1 mg orally is given as needed over the next 24 hours for a maximum of 10-40 mg over the first day of detoxification treatment. Once maintenance dosage requirements are determined (total methadone dose required to contain symptoms over the first 24 hours of detoxification), this dose can be given for an additional 2 days, then a slow daily taper initiated until the individual is to be maintained off opioid drugs. Other minor tranquilizers such as chlordiazepoxide (25-50 mg orally twice daily) or clorazepate (3.75-7.5 mg orally twice daily) can be used to treat opiate withdrawal during the first 72 hours. Ultra-rapid opioid detoxification has been used since the 1980s with varying success. Using principles of general anesthesia in combination with an opiate antagonist, followed by naltrexone maintenance therapy, 1-month abstinence rates vary from 53% to 93%.

Some clinicians use the nonopioid antihypertensive clonidine to treat symptoms of acute opioid withdrawal. Clonidine may be used alone or concurrently with methadone. For acute detoxification, clonidine 0.4-2 mg/day may be used. Due to its antihypertensive properties, pulse and blood pressure must be closely monitored. Some patients experience excessive sedation with clonidine, which may be moderated by dosage adjustments. Gastrointestinal cramps can be treated with dicyclomine (20 mg orally every 4-6 hours as needed), while nausea can be safely treated with prochlorperazine (10 mg orally or I.M. every 6 hours as needed). Loose stools may respond to loperamide (2 mg orally as needed, to a maximum daily dose of 6 mg). Trazodone (50-150 mg orally at night) can be given as a sleep aid.

An alternative compound, buprenorphine, a partial opioid antagonist, may be useful in acute detoxification situations (dose is about 3 mg/day sublingual up to 8 mg/day with a gradual taper 10-36 days). Like

methadone, dosage should be customized to the individual and tapered and eventually discontinued as tolerated.

General Treatment

Treatment of chronic opioid dependence involves both treatment of physical withdrawal symptoms and psychological dependence on the drug. Psychosocial and psychotherapeutic treatments are essential in promoting the lifestyle changes needed to prevent relapse.

Methadone maintenance has proven efficacy in some groups of opioid abusers. As with acute phase treatment, chronic methadone treatment dosage/format must be tailored to the individual. Usual daily oral dosage ranges from 40-120 mg/day. Generally, patients must come to the clinic daily (usually morning) to receive methadone. Other interventions involved in clinic treatment may include counseling, urine drug testing, vocational rehabilitation, etc. When used successfully, methadone maintenance reduces illegal drug use, and reduces the medical, legal, and societal ramifications associated with the illicit drug culture.

L- α -acetyl methadol (LAMM) is a long-acting opioid that has been successfully used to treat chronic opioid dependence. LAMM can be dosed at 30-80 mg 3 times/week and may eliminate the need for daily clinic visits, as is required for most methadone programs.

An alternative strategy in managing long-term opioid abuse treatment is the use of opioid antagonists. Naltrexone, a long-acting (72 hours) antagonist, blocks the euphoric effects of opioids, and may be taken 3 times/week at dosages of 100-150 mg. Theoretically, the use of naltrexone discourages persons from opioid use as it eliminates the subsequent CNS effects. Naltrexone works best with highly motivated individuals with good psychosocial support as there are no physical incentives (withdrawal symptoms) to continue taking opioid antagonist on a long-term basis.

Sedative/Hypnotic

Intoxication/Overdose

Severity of symptoms of sedative-hypnotic intoxication depends on drugs used, route administered, and tolerance of the individual to the drug. Sequelae of overdose are greatly worsened when alcohol or multiple sedative/hypnotics are combined. Respiratory depression is the major danger and successful management includes respiratory and cardiac support. Margin of safety in benzodiazepine overdose is much greater compared to barbiturate overdose where unintentional lethal dosing is not uncommon. In addition to standard supportive measures (vital sign monitoring, gastric lavage, hospitalization, etc), patients with overdose should be closely assessed for suicide risk and intent.

Withdrawal

As with toxicity, severity of withdrawal symptoms is dependent on a variety of clinical factors, including duration of drug use (usually maintenance of 1 month or longer for dependence to develop) and tolerance of the individual. Withdrawal of sedative-hypnotic is generally managed by either 1) gradual reduction of sedative substance or 2) substitution with a long-acting benzodiazepine or phenobarbital with subsequent taper and eventual discontinuation.

Gradual discontinuation from sedative-hypnotic is best accomplished with motivated patients in settings with good psychosocial supports. The rate of drug taper should be tailored to the individual, with slower titrations generally being most successful.

For benzodiazepine-dependent patients, substitution of an equivalent dose of long-acting benzodiazepine (eg, clonazepam) with gradual downward titration will promote reduction of withdrawal effects over time. As with other addiction treatments, concurrent psychosocial treatments will optimize clinical outcome.

For barbiturate-dependent individuals, the clinician should attempt to determine the patient's daily dose of barbiturates and stabilize withdrawal symptoms with the barbiturate. As many individuals who abuse sedative-hypnotics may be unreliable in providing accurate daily use information, the clinician may elect to assess barbiturate tolerance with a challenge dose of the short-acting barbiturate pentobarbital. This should be done in hospital settings. The patient undergoing sedative withdrawal is given 200 mg of pentobarbital and observed for resolution of withdrawal symptoms and mild intoxication. Patients in whom this occurs may then be maintained on pentobarbital 100-200 mg every 6 hours. Patients who are not intoxicated on the initial challenge dose of 200 mg are given an additional 100 mg pentobarbital every 2 hours (for a maximum of 500 mg) until mild toxicity develops. Maintenance pentobarbital dose is then determined based on total

amount of barbiturate needed to cause mild intoxication. Once stabilization is achieved, the clinician can then taper the dose by 10% daily. Alternatively, phenobarbital, a long-acting barbiturate, may be substituted for pentobarbital. Phenobarbital has the advantages of less frequent dosing, fewer fluctuations in blood level, and anticonvulsant activity. The equivalent dosing of 30 mg phenobarbital as a barbiturate is 100 mg pentobarbital, 100 mg secobarbital, 100 mg amobarbital, or 60 mg butabarbital. Other sedative-hypnotic agents equivalent to 30 mg phenobarbital in the withdrawal state include: chloral hydrate 500 mg; ethchlorvynol 350 mg; glutethimide 250 mg; meprobamate 400 mg; methaqualone 300 mg; methyprylon 100 mg.

General Treatment

Psychotherapeutic interventions appear to be the most effective long-term treatments in sedation/hypnotic abuse.

Benzodiazepine

Intoxication

Central nervous system depression with hypotension due to vasodilation and concomitant respiratory depression are the predominant sequelae. The mainstay of therapy is supportive with particular attention to ventilatory and circulatory support. Flumazenil (Children: 0.005-0.2 mg/kg; Adults: 0.5-5 mg) infused over 3-5 minutes is effective in reversing CNS and respiratory depression.

Withdrawal

Tolerance can develop rapidly in benzodiazepine therapy and from 15% to 44% of chronic users experience withdrawal symptoms when their benzodiazepine dose is decreased. Patients who take benzodiazepines for greater than 3 months are at risk for withdrawal. The onset of symptoms may be as short as 1 day for the longer acting benzodiazepines (ie, diazepam). Symptoms may last for 6 weeks. Symptoms are due to neuronal excitation and may include anxiety, insomnia, fever, tremor, nausea, tinnitus, myalgias, seizures, vomiting, and diaphoresis. Treatment consists of reinstatement of a long acting benzodiazepine with a gradual taper (over a period of 6-8 weeks). In cases of severe symptomatology, an intravenous infusion of diazepam (at 20 mg/hour or more) in a monitored setting may be initially required. Barbiturates are reasonable alternatives to benzodiazepines in treating benzodiazepine withdrawal. Phenobarbital 30 mg equivalency for benzodiazepines includes: alprazolam 0.5 mg; clorazepate 7.5 mg; chlordiazepoxide 25 mg; diazepam 5 mg; flurazepam 30 mg; lorazepam 1 mg; oxazepam 15 mg; temazepam 60 mg; triazolam 0.5 mg; clonazepam 0.25 mg. One-fourth of this calculated dose is administered and the dose is increased as necessary. The phenobarbital dose can be tapered after the patient is stabilized for 48 hours at a rate of 10% of the dose daily. Propranolol (20 mg 3-4 times/day) can be instituted on day 5 and continued for 2 weeks as an adjunctive agent.

Gamma Hydroxybutyrate (GHB)/Gamma Butyrolactone (GBL)

Intoxication

Central nervous system predominates and the mainstay of management is respiratory support. Hypothermia, hypotension, and seizures may also occur. Atropine can be used to treat bradycardia. Sudden arousal is usually noted 5-8 hours postingestion.

Withdrawal

Withdrawal symptoms may occur with constant use for a period of over 2 months, especially if there is a recent dose escalation. Central nervous system hyperactivity such as insomnia, tremor, delirium, psychosis, and auditory/visual hallucinations occurs within 12 hours of cessation of doses. Duration of symptoms ranges from 5-15 days. Treatment is supportive with lorazepam and/or haloperidol (5 mg) effective for treatment of delirium or psychosis. Often large doses of benzodiazepines are required. Pentobarbital (initial dose 2.5-5 mg/kg I.V.) can also be given to treat resistant symptoms. Other agents utilized include propofol (initial dose: 1-2 mg/kg; maintenance: 2-10 mg/kg/hour) and droperidol (2.5 mg). Avoid flumazenil, physostigmine, and naloxone.

Stimulants**Intoxication/Overdose**

Intoxication/overdose management involves reducing autonomic hyperactivity (tachycardia, hypertension) and managing CNS symptoms (agitation, psychosis/delirium, or seizures). Supportive measures such as appropriate hydration, vital sign monitoring, and cooling for hyperthermia are indicated. Anxiolytics or antipsychotics may be useful on a short-term basis, and a supportive, low-stimulation environment will reduce CNS irritability.

Withdrawal

Amphetamine withdrawal is generally treated supportively. The judicious use of antipsychotic medication may be of benefit to patients with post-amphetamine psychosis.

General Treatment

Psychotherapeutic interventions appear to be the most effective long-term treatment.

Caffeine**Intoxication**

Treatment for caffeine intoxication is outlined in the caffeine monograph (see Caffeine).

Withdrawal

Physical dependency to caffeine does exist with withdrawal symptoms usually occurring within 12-24 hours following cessation and peaks at 20-51 hours and may last for one week. A daily dose over 235 mg (about 2.5 cups of coffee/day) can increase the risk for likelihood of withdrawal. While lethargy and weakness may occur, facial flushing and severe headaches predominate this syndrome and may last as long as 9 days. Symptoms correlate with the amount ingested prior to cessation. Treatment focuses on a gradual reduction of caffeine intake over several days. Caffeine tablets may be useful in headache treatment.

Hallucinogens**Intoxication**

Individuals who experience toxic delirium, panic reactions, or psychosis associated with hallucinogens require a supportive environment (low stimulation with supervision) and may benefit from judicious dosing of anxiolytics (eg, diazepam 5-10 mg orally).

Withdrawal

Physical dependence and withdrawal symptoms have not been reported.

General Treatment

Psychotherapeutic interventions appear to be the most effective in long-term treatment.

Baclofen**Intoxication**

Treatment of baclofen intoxication is outlined in the baclofen monograph (see Baclofen).

Withdrawal

Baclofen withdrawal syndrome usually occurs within 12-72 hours following dose cessation. The syndrome is similar to the sedative-hypnotic withdrawal syndrome with agitation, delusions, spasticity, rhabdomyolysis, paranoia, psychosis, pruritus, hallucinations, hypertonia, fever, and seizures. Benzodiazepines (diazepam 5-10 mg orally every 6-12 hours) are the mainstay of baclofen withdrawal therapy. For acute intrathecal baclofen withdrawal, baclofen (10-20 mg orally every 6 hours) and cyproheptadine (4-8 mg orally every 6-8 hours) can also be utilized with the latter agent particularly effective in treating pruritus.

Inhalants

Intoxication

CNS effects of intoxication usually resolve within minutes to hours of inhalant use. Toxic effects depend on the solvent used and may require emergency treatment for arrhythmias or CNS hyperactivity (seizures). Some agents (such as toluene) produce renal damage and renal functioning should be monitored. Intoxication treatment is generally supportive.

Withdrawal

Withdrawal reactions occur rarely as most inhalant use is relatively short-lived. Symptoms that may occur are generally treated supportively with concurrent psychosocial interventions.

General Treatment

Psychotherapeutic interventions are generally most effective. Due to the young age of most patients, family therapy is often also indicated.

Selective Serotonin Reuptake Inhibitors (SSRIs)

Intoxication/Overdose

See individual monographs.

Withdrawal

Withdrawal occurs most frequently upon abrupt cessation with paroxetine, sertraline, fluoxetine, and venlafaxine. Paroxetine appears to be the SSRI with the highest incidence of withdrawal reactions. Symptoms usually begin within 1-2 days and involve dizziness, ataxia, anorexia, diarrhea, flu-like symptoms, diaphoresis, paresthesias, tremor, and sleep disturbances. Symptoms may last as long as 2-3 weeks. Temporary reinstatement of an SSRI with gradual tapering over several weeks is suggested. Ginger root, 1100 mg 3 times/day, for 1-2 weeks has been noted to be efficacious for sertraline withdrawal.

Synthesized Compounds

Intoxication/Overdose

PCP toxicity is best managed in a low-stimulation, secure environment. Benzodiazepines and careful use of antipsychotic medication may be helpful for the severe agitation/aggression sometimes seen in PCP intoxication. Some clinicians advocate promoting rapid drug excretion with ammonium chloride or ascorbic acid. Most PCP toxic reactions resolve within 1-3 days, but behavioral symptoms may persist for 2 weeks or more.

In acute intoxication situations, MDMA has been associated with cardiac arrhythmias suggesting a need for close intensive medical monitoring. Additionally, some designer drugs may contain contaminants which have been associated with chronic neurologic damage.

Withdrawal

Physical dependence on PCP generally does not occur, although psychological dependence may be associated with drug craving and relapse.

General Treatment

Psychotherapeutic interventions are generally most effective in the long term. Little is known about long-term treatment of designer drug abuse.

Marijuana

Intoxication

The incidence of acute adverse reactions to marijuana is quite low. In rare cases, individuals may experience acute panic, toxic delirium, or flashbacks. These generally remit spontaneously within 12-48 hours. Management may include anxiolytics or antipsychotics if behavioral symptoms are severe. Treatment is outlined in the marijuana monograph (see Marijuana (Cannabis)).

Withdrawal

Tolerance generally does not develop to marijuana, although heavy daily users may experience withdrawal symptoms of insomnia, diaphoresis, dysphoria, irritability, tremor, and nausea. Symptoms peak at 48 hours of abstinence and persist for 96 hours. There is no recognized withdrawal regimen.

General Treatment

As with other substance abuse disorders, individuals should receive psychosocial rehabilitation and there should be assessment and treatment of any coexisting psychiatric disorders.

Nicotine**Intoxication/Overdose**

Nicotine intoxication from tobacco use is rare. Excess nicotine from nicotine replacement therapies used in smoking cessation (ie, nicotine gum) may occasionally cause adverse effects such as nausea, headaches, or cardiac abnormalities. Treatment is outlined in the nicotine monograph (see Nicotine).

Withdrawal

Withdrawal symptoms begin within 6-12 hours and generally peak 24-72 hours after smoking cessation. Most symptoms last for approximately 1 month, although craving can persist for 6 weeks or longer. Smoking cessation is associated with slowing on EEG, and decline in metabolic rate, including mean heart rate decline of 8 beats/minute. Blood levels of some antidepressants (eg, clomipramine, desipramine, doxepin, imipramine, and nortriptyline) may increase as may some antipsychotic medications (eg, clozapine, fluphenazine, haloperidol) and some anxiolytics (eg, oxazepam, desmethyldiazepam).

The most successful treatment of nicotine withdrawal frequently includes both psychosocial and pharmacological interventions. Patients must generally be committed to quitting, and most clinicians advocate abrupt cessation of tobacco rather than gradual reduction. Approximately 33% of adults who smoke make an attempt to stop smoking each year. Relapse is common, particularly among those who attempt to quit smoking on their own without formal treatment. Approximately 50% of smokers eventually quit, although individuals with histories of anxiety or mood disorders or of schizophrenia are less likely to stop smoking. Most smokers require 5-7 attempts at smoking cessation before they eventually quit for good. Psychosocial treatments include behavior therapies (relapse prevention, relaxation, stimulus control among other techniques), education (group or individual), and hypnosis. Pharmacotherapies include nicotine replacement therapy, nicotine antagonists, agents that mimic nicotine effects, aversive therapies, and symptomatic management. Nicotine replacement therapy and antidepressants for symptomatic management are among the most commonly utilized pharmacologic measures.

Nicotine replacement provides the nicotine-dependent patient with nicotine in a form that is not associated with the carcinogenic elements in tobacco. Nicotine gum, transdermal nicotine patches, nicotine nasal spray, and nicotine inhalers are available for smoking cessation. Nicotine gum, now available over-the-counter, consists of 2-4 mg of nicotine in a polacrilex resin designed to be slowly chewed for 20-30 minutes. Nicotine absorption peaks 30 minutes after initiation of gum use. Most common adverse effects are GI complaints (nausea, anorexia) and headache. Although nicotine replacement has been used for relief of withdrawal symptoms, some patients utilize these therapies long-term.

Nicotine patches consist of nicotine impregnated into an adhesive patch for transdermal application. Patches are applied daily each morning upon quitting smoking with starting dosages of 21-22 mg/24-hour patch and 15 mg/16-hour patch. Patients should not smoke cigarettes while on patches as nicotine toxicity may occur. Typical treatment duration is 6-8 weeks. The nicotine inhaler contains a replaceable component that delivers nicotine in inhaled air. Unlike cigarettes which deliver nicotine directly into the arterial blood in the lungs, the inhaler delivers nicotine into the buccal mucosa.

In addition to nicotine replacement, some antidepressants (bupropion, doxepin, and desipramine) have been shown to improve the chances of nicotine abstinence. Sustained-release bupropion hydrochloride has been approved by the FDA for smoking cessation (150 mg every morning for 3 days, then 150 mg twice daily beginning 1-2 weeks prequit) for a minimum of 7-12 weeks. In addition to reducing nicotine withdrawal symptoms, bupropion S-R may diminish weight gain. Some clinicians utilize both bupropion and nicotine replacement concurrently.

Other pharmacologic therapies that have been reported to be potentially useful in the management of tobacco cessation include nicotine antagonists (eg, mecamylamine) and aversive treatments such as silver acetate gum, although efficacy of these agents are not proven. Some clinicians utilize clonidine at dosages of 0.1-0.4 mg/day for nicotine withdrawal in individuals who fail or are unable to tolerate other symptomatic treatment or nicotine replacement.

General Treatment

A widely used intervention for practitioners in general medical settings for smoking cessation is the “4 As” strategy of the National Cancer Institute. This consists of the following:

1. **Ask** and record smoking status. In several surveys, only about 50% of physicians asked patients about their tobacco use.
2. **Advise** to stop. Direct recommendation from a physician produces quit rates of 7% to 10%.
3. **Assist** the patient in addressing cessation. Identifying a quit date may assist in obtaining commitment to quit. Patients who are unable or unwilling to commit to quitting may benefit from educational materials at this time.
4. **Arrange** follow-up. This should occur within 3 days as the first several days after quitting are a critical period in relapse risk.

Most pharmacotherapies are primarily utilized during the initial period of quitting tobacco use. Psychological treatments/lifestyle changes, while also utilized during nicotine withdrawal, must also become long-term interventions. Although biologic treatments do not require concurrent psychological therapies, best outcome is usually associated with combined treatment.

Psychiatric Emergencies - Violence

Violent and agitated behavior creates an emergency situation due to potential risk to patients, bystanders, and healthcare staff. Patients with both nonpsychiatric and psychiatric disorders presenting to emergency rooms may exhibit violent or agitated behavior. It has been reported that up to 80% of teaching hospital emergency rooms experience patient assault of staff members. The initial task in managing a potentially violent individual is to assess for signs of impending violence such as verbal or physical threats, presence of objects that may be used as weapons, signs of substance intoxication, and level of agitation or psychiatric symptoms such as psychosis. Serum glucose should be determined as hypoglycemia may lead to aggressive behavior. Serum cholesterol levels have also been associated with aggressive behavior. Patients who are a potential risk of harm to self or others should be placed in a protective environment with an attempt to de-escalate the situation. Police or security assistance is often essential, and a calm show of overwhelming force may commonly lead to abandonment of threatening behavior by the patient. The use of physical restraints may be necessary for continued agitated or violent behavior if other less restrictive measures are ineffective, and prompt pharmacotherapy of underlying psychiatric or medical disorders should be initiated. A reassuring, safe, and low-stimulation environment is optimum. In some acutely agitated individuals, rapid tranquilization and the use of antipsychotics and benzodiazepines to control severely disruptive behavior is indicated. Beta-blockers may also be useful to treat this entity. If violent, agitated patients are unable to take oral medications (such as risperidone 1-2 mg), many clinicians use a high potency I.M. antipsychotic such as haloperidol 5-10 mg P.O., I.V., or I.M., repeated every 10-30 minutes until desired effects are achieved (start elderly dosing at 2 mg P.O. or I.M.), and/or an injectable benzodiazepine such as lorazepam 0.5-2 mg I.M. or I.V. to quickly sedate the patient and stabilize disruptive behavior. Droperidol 2.5-10 mg I.M. (or 0.05 mg/kg), risperidone 2 mg/day (up to 6 mg/day) P.O., ziprasidone 5-20 mg I.M. every 4-6 hours, or olanzapine 5-10 mg I.M. (I.M. route not available in the U.S.) may also be useful in treating psychotic patients. (**Note:** On December 5, 2001 Akorn, Inc. announced the addition of a **Black Box Warning** and Updated Warnings/Precautions in the Inapsine[®] (droperidol) product labeling. Droperidol is contraindicated in patients with known or suspected QT prolongation. It should be used with caution in patients with risk factors (CHF, bradycardia, diuretic use, cardiac hypertrophy, hypokalemia, hypomagnesemia, concomitant use of medications known to prolong the QT interval, age older than 65 years, ethanol abuse, benzodiazepine use, volatile anesthetics, and I.V. opiates. In patients where droperidol treatment is appropriate, dosage should be started low and titrated upward. EKG monitoring should be done prior to treatment and continued for 2-3 hours after treatment to monitor for arrhythmias.) Patients at risk for acute extrapyramidal symptoms may receive a concomitant anticholinergic agent such as benztropine 2 mg I.M. or diphenhydramine 25-50 mg I.M. The antipsychotic plus benzodiazepine combination may be repeated every 30-60 minutes, if needed, with antipsychotic haloperidol dosage generally not exceeding 20 mg/day, or the benzodiazepine may be given alternating with the antipsychotic. Avoid antipsychotic agents in anticholinergic-induced delirium. Rapid

tranquilization should not be confused with rapid neuroleptization, a procedure that was used in the past where patients were treated with “mega” doses of neuroleptic, and were placed at risk of severe neurological side effects. If patients are able to take oral medications, antipsychotic options are increased to include atypical antipsychotics such as risperidone, olanzapine, or quetiapine. Benzodiazepines may also be given orally (eg, diazepam 5-10 mg). For nonpsychotic patients, some clinicians utilize benzodiazepine monotherapy (eg, lorazepam 1-2 mg orally every 1-4 hours).

For the long-term management of individuals with chronic or intermittent aggression, there are a variety of interventions including psychotherapy, treatment of underlying psychiatric illness if present, and pharmacotherapies that target aggressive behaviors. Drugs that may diminish aggressive behavior include mood stabilizers such as lithium (target serum lithium level: 0.7-1 mM/L), valproate, cyproterone acetate [investigational] (doses up to 300 mg/day), pipamperone [investigational] (80-240 mg/day), and carbamazepine (300-800 mg/day). Antidepressants such as the SSRIs and trazodone may be useful as well as buspirone, and atypical antipsychotics such as clozapine.

Neuroleptic Malignant Syndrome

Neuroleptic malignant syndrome (NMS) is a condition characterized by progressive worsening (over 24-72 hours) of muscle rigidity, changes in consciousness, and autonomic instability. Symptoms of autonomic instability include sweating, fever, flushing, tachycardia, and labile blood pressure. Additionally, the white blood count (WBC) (in the range of 10,000-40,000 cells/mm³) and creatine phosphokinase (CPK) (up to 60,000 IU/L) may be elevated. Severe CPK elevation may be associated with renal failure. True NMS is a medical emergency. Fortunately, NMS is relatively rare, occurring in <1% of patients on conventional antipsychotics. NMS appears to be extremely rare with atypical antipsychotics. Over 60% of cases of NMS occur during the first 2 weeks of antipsychotic therapy, with strongest risk factors being male gender and previous history of NMS. Mortality ranges from 4% to 22% and is usually due to renal failure due to rhabdomyolysis or respiratory pneumonia. Management consists of early diagnosis, immediate discontinuation of antipsychotic drugs, symptomatic treatment, including I.V. hydration, antipyretics, and cooling blankets. Close monitoring of clinical status/vital signs is essential. Bromocriptine at dosages of 5 mg 3-4 times/day (up to 40 mg/day) or dantrolene at dosages of 3-5 mg/kg I.V. 4 times/day may be beneficial in acute NMS. Alternative therapies include carbidopa/levodopa (25/100), amantadine, carbamazepine, and electroconvulsive therapy.

Catatonia

Catatonia is a syndrome associated with a variety of medical disorders such as encephalopathy and ketoacidosis, and a variety of psychiatric disorders such as schizophrenia and serious mood disorders. Catatonia produces cataplexy and waxy flexibility, mutism, intermittent agitation, and resistance to movement and/or instructions. There exists a lethal form of catatonia in which patients experience hyperthermia, rigidity, rhabdomyolysis, and autonomic instability. As its name implies, lethal catatonia has high mortality if untreated.

Patients with suspected catatonia should have a thorough medical evaluation to identify and make appropriate interventions for treatable medical disorders. Clinical entities such as aspiration pneumonia and neuroleptic malignant syndrome can exhibit catatonic behavior with a fever. In cases where no medical etiology can be identified, patients are generally treated in inpatient psychiatric settings. I.V. amobarbital sodium (50 mg/minute for a total dose up to 300 mg) may be used to assist in obtaining history from psychiatric patients with catatonia. However, amobarbital is not effective in treating catatonia as its effects are short-lived and there may be risk of respiratory depression. More recently, it has been demonstrated that parenteral or oral lorazepam is helpful in catatonia and may more safely facilitate the patient's ability to give a history. Lethal catatonia may improve with antipsychotics or dantrolene although most rapid treatment of catatonia generally occurs with ECT. Other therapies used successfully in treating catatonia include risperidone (4 mg twice daily), intravenous biperiden (5 mg every 30 minutes, not to exceed 3 doses), clonazepam (1-7 mg I.M. or I.V.), clozapine (350 mg orally), amantadine (200 mg every 6-7 hours for 3 doses), lithium carbonate (1.2-1.5 g/day orally), and diazepam (up to 40 mg/day orally). Lorazepam (2 mg I.M.) can be used to treat psychogenic catatonia.

Agents Known to Elicit Aggressive or Catatonic Behavior	
Aggression	Catatonia
Alprazolam	Allopurinol
Acetylcarnitine	Amantadine (withdrawal)
Amantadine	Baclofen
Amineptine	Bulbocapnine
Amitriptyline	Bupropion
Amphetamine	Chlorpromazine
Androstenedione	Cocaine
Clobazam	Cycloserine
Clomipramine	Cyclosporine
Cocaine	Diphenhydramine
Cyproheptadine	Disulfiram
Dapsone	Doxylamine
Dehydroepiandrosterone	Ecstasy (hallucinogenic amphetamine)
Donepezil	Fluphenazine
Ethyl alcohol	<i>Kyllinga brevifolia</i> Rottb. (extract)
Felbamate	Lead
Fluoxetine	Loxapine
Gabapentin	Lysergic acid diethylamide
Heroin	Marijuana (cannabis)
Imipramine	Morphine sulfate
Medazepam	Phencyclidine
Melarsoprol	Piperazine
Ketamine	Pipothiazine (injection)
Lamotrigine	Primidone
Lead	Prochlorperazine
Lorazepam	Risperidone
Midazolam	Sulthiamine
Morphine sulfate	Trifluoperazine
Nandrolone	
Omeprazole	
Oxandrolone	
Oxymetholone	
Peginterferon alfa 2b	
Phencyclidine	
Rivastigmine	
Sodium oxybate	
Stanozolol	
Temazepam	
Testosterone	
Valproic acid	
Vigabatrin	
Zopiclone	

Acute Extrapyramidal Syndromes (Eps)

Acute Dystonias

Acute dystonias are uncomfortable, involuntary muscle spasms of the face, neck, trunk, or extremities associated with antipsychotic treatment. Dystonias occur in 10% to 15% of patients on conventional antipsychotic medications, usually in the first several weeks of treatment. Acute dystonias are much rarer with atypical antipsychotic medications. Manifestations of acute dystonia include facial grimacing, tongue twisting, dysarthria and/or dysphagia, eye deviation, neck twisting (torticollis), and back spasm (opisthotonos). Acute laryngospasm may be life-threatening. Most prominent risk factors for acute dystonia include male gender, history of acute extrapyramidal symptoms, and adolescence. When dystonia occurs, intramuscular anticholinergic medication (eg, diphenhydramine 50 mg I.M. or benztropine 2 mg I.M.) usually brings rapid symptom reduction. Subsequently, the patient should receive maintenance anticholinergic/antiparkinsonian medication (eg, benztropine 1-2 mg twice daily). Laryngospasm requires immediate I.V. treatment (eg, diphenhydramine 25-50 mg I.V.) or benztropine 2 mg I.V.

When initiating conventional antipsychotic agents in those patients with strong risk factors for developing acute dystonias, it is reasonable to begin prophylactic anticholinergic treatment. For elderly patients, due to increased risk of anticholinergic toxicity and potential adverse effects on cognitive status, it is usually best to avoid prophylactic anticholinergic medication.

Geriatric patients generally require lower doses of anticholinergic drug. Adverse effects associated with anticholinergic medication include constipation, urinary retention, tachycardia, and blurred vision. Intraocular pressure may be increased, posing some danger for patients with narrow-angle glaucoma. In addition, some individuals, particularly elderly patients, may develop a delirium-like presentation associated with anticholinergics that is characterized by disorientation, hallucinations, behavioral lability, and cognitive impairment. Occasionally, patients may abuse anticholinergics.

Patients on anticholinergic medication should be reassessed on a regular basis to determine continued need for medication. A significant number of patients on antipsychotic medication exhibit spontaneous reduction or resolution of EPS during continued antipsychotic medication therapy, particularly during the first 3 months of treatment. Therefore, after this time period, one should consider tapering anticholinergic agent. Tolerance often develops to dystonic effects over the first month of treatment, and need for maintenance anticholinergic medication should be reassessed at that point.

Akathisia

Akathisia is a subjective feeling of restlessness seen in 20% to 40% of patients on typical antipsychotic medications. Patients may appear agitated, with frequent pacing and inability to keep their legs still. As with all acute extrapyramidal adverse effects, akathisia is significantly less common with atypical antipsychotic agents. Primary management is to lower antipsychotic dosage, or switch antipsychotic agents to either an atypical antipsychotic or to a typical agent with lower dopamine-blocking potency. Medication management of symptoms of akathisia include benzodiazepines such as clonazepam 1 mg twice daily, or alternatively benztropine 1-2 mg/day. Beta-blocking drugs (eg, propranolol, atenolol, pindolol) may be useful in EPS. Beta-blockers appear to be most effective in treating akathisia. Use of beta blockers (propranolol or nadolol at doses up to 80 mg/day) with a benzodiazepine may be quite efficacious. Patients on beta-blockers may experience hypotension or bradycardia, thus, blood pressure and pulse should be monitored during initial drug titration. Clonidine is another agent that may be effective in akathisia. Usual dosage for akathisia is 0.2-0.8 mg/day. As with beta-blockers, hypotension may occur, and blood pressure should be monitored during initial titration. Clonidine should generally be tried after failure of beta-blockers to control akathisia. Recognition and management of akathisia is important as the condition can be extremely stressful to patients, and there is a danger of misdiagnosis if the agitation of akathisia is mistakenly attributed to worsening of psychotic symptoms.

Drug-Induced Parkinsonism

Antipsychotic medication-associated parkinsonism is characterized by rigidity, bradykinesia, masked facies, drooling, and tremor. While not strictly an emergency, the disabling symptoms occur subacutely within the first month of therapy on 10% to 15% of patients on typical antipsychotics. Drug-induced parkinsonism is significantly less common with atypical antipsychotics. Strongest risk factors for parkinsonism are female gender and older age. Treatment is with antiparkinsonian agents such as trihexyphenidyl 2 mg twice daily or benztropine 1-2 mg twice daily. Some tolerance may develop to parkinsonian effects. Alternatively, reduction

or resolution of parkinsonian symptoms may be achieved by decreasing antipsychotic medication dosage, switching to a lower potency typical agent, or switching to an atypical agent.

Dopaminergic agents, such as amantadine and levodopa, have also been reported to be useful in management of EPS. Amantadine has been reported to be beneficial in acute dystonia, akathisia, and drug-induced parkinsonism. As with anticholinergics, amantadine is believed to work by normalizing dopamine-acetylcholine balance in the striatum. Dosing of 100-400 mg/day in a once or twice daily pattern is usually used. Adverse effects with amantadine include orthostasis, peripheral edema, and a skin reaction called livedo reticularis (venous marbleization of the skin, usually lower extremities). Also, worsening of psychosis or delirium have been reported. Generally, amantadine should only be utilized after failure of anticholinergic agents. Levodopa is far less commonly used due to concern regarding worsening of psychotic illness.

Acarbose

Pronunciation (AY car bose)

CAS Number 56180-94-0

U.S. Brand Names Precose®

Use

Monotherapy, as indicated as an adjunct to diet to lower blood glucose in patients with type 2 diabetes mellitus (noninsulin dependent, NIDDM) whose hyperglycemia cannot be managed on diet alone

Combination with a sulfonylurea, metformin, or insulin in patients with type 2 diabetes mellitus (noninsulin dependent, NIDDM) when diet plus acarbose do not result in adequate glycemic control. The effect of acarbose to enhance glycemic control is additive to that of other hypoglycemic agents when used in combination.

Mechanism of Action Competitive inhibitor of pancreatic α -amylase and intestinal brush border α -glucosidases, resulting in delayed hydrolysis of ingested complex carbohydrates and disaccharides and absorption of glucose; dose-dependent reduction in postprandial serum insulin and glucose peaks; inhibits the metabolism of sucrose to glucose and fructose. Competitive inhibitor of pancreatic α -amylase and intestinal brush border α -glucosidases, resulting in delayed hydrolysis of ingested complex carbohydrates and disaccharides and absorption of glucose; dose-dependent reduction in postprandial serum insulin and glucose peaks; inhibits the metabolism of sucrose to glucose and fructose

Adverse Reactions

Central nervous system: Sleepiness, headache, vertigo

Dermatologic: Erythema, urticaria

Gastrointestinal: Abdominal pain and diarrhea tend to return to pretreatment levels over time, and the frequency and intensity of flatulence tend to abate with time; severe GI distress

Hepatic: Elevated liver transaminases

Neuromuscular & skeletal: Weakness

Signs and Symptoms of Overdose Overdose may result in transient increased flatulence, diarrhea, and abdominal discomfort which will subside shortly. Overdose will not result in hypoglycemia. However, acarbose may complicate the treatment of hypoglycemia from other causes, since it will inhibit the absorption of oral disaccharides (sucrose).

Pharmacodynamics/Kinetics

Absorption: <2% as active drug

Metabolism: Exclusively via GI tract, principally by intestinal bacteria and digestive enzymes; 13 metabolites identified

Bioavailability: Low systemic bioavailability of parent compound; acts locally in GI tract

Excretion: Urine (~34%)

Dosage

Oral:

Adults: Dosage must be individualized on the basis of effectiveness and tolerance while not exceeding the maximum recommended dose

Initial dose: 25 mg 3 times/day with the first bite of each main meal

Maintenance dose: Should be adjusted at 4- to 8-week intervals based on 1-hour postprandial glucose levels and tolerance. Dosage may be increased from 25 mg 3 times/day to 50 mg 3 times/day. Some patients may benefit from increasing the dose to 100 mg 3 times/day.

Maintenance dose ranges: 50-100 mg 3 times/day.

Maximum dose:

≤ 60 kg: 50 mg 3 times/day

> 60 kg: 100 mg 3 times/day

Patients receiving sulfonylureas: Acarbose given in combination with a sulfonylurea will cause a further lowering of blood glucose and may increase the hypoglycemic potential of the sulfonylurea. If hypoglycemia occurs, appropriate adjustments in the dosage of these agents should be made.

Dosing adjustment in renal impairment: $Cl_{cr} < 25$ mL/minute: Peak plasma concentrations were 5 times higher and AUCs were 6 times larger than in volunteers with normal renal function; however, long term clinical trials in diabetic patients with significant renal dysfunction have not been conducted and treatment of these patients with acarbose is not recommended

Stability Store at <25°C (77°F) and protect from moisture

Monitoring Parameters Postprandial glucose, glycosylated hemoglobin levels, serum transaminase levels should be checked every 3 months during the first year of treatment and periodically thereafter

Administration

Should be administered with the first bite of each main meal

Contraindications Hypersensitivity to acarbose or any component of the formulation; patients with diabetic ketoacidosis or cirrhosis; patients with inflammatory bowel disease, colonic ulceration, partial intestinal obstruction, or in patients predisposed to intestinal obstruction; patients who have chronic intestinal diseases associated with marked disorders of digestion or absorption, and in patients who have conditions that may deteriorate as a result of increased gas formation in the intestine

Warnings

Acarbose may increase the hypoglycemic potential of sulfonylureas. Oral glucose (dextrose) should be used in the treatment of mild-to-moderate hypoglycemia. Severe hypoglycemia may require the use of either intravenous glucose infusion or glucagon injection.

Treatment-emergent elevations of serum transaminases (AST and/or ALT) occurred in 15% of acarbose-treated patients in long-term studies. These serum transaminase elevations appear to be dose related. At doses > 100 mg 3 times/day, the incidence of serum transaminase elevations greater than 3 times the upper limit of normal was 2-3 times higher in the acarbose group than in the placebo group. These elevations were asymptomatic, reversible, more common in females, and, in general, were not associated with other evidence of liver dysfunction.

When diabetic patients are exposed to stress such as fever, trauma, infection, or surgery, a temporary loss of control of blood glucose may occur. At such times, temporary insulin therapy may be necessary.

Dosage Forms Tablet: 25 mg, 50 mg, 100 mg

Overdosage/Treatment

Decontamination: Activated charcoal/gastric lavage. Treatment is otherwise supportive.

Oral glucose (dextrose) should be used in mild to moderate hypoglycemia; severe hypoglycemia should be treated with I.V. glucose.

Drug Interactions

Calcium channel blocking agents: May decrease the efficacy of acarbose due to hyperglycemic effects.

Corticosteroids: May decrease the efficacy of acarbose due to hyperglycemic effects.

Digoxin: Acarbose decreases the bioavailability of digoxin, resulting in lower serum concentrations.

Diuretics (including thiazides): May decrease the efficacy of acarbose due to hyperglycemic effects.

Enzyme replacement (pancrelipase, amylase): May decrease the efficacy of acarbose due to effects on carbohydrate metabolism.

Estrogens: May decrease the efficacy of acarbose due to hyperglycemic effects.

Insulin: Acarbose may increase the hypoglycemic potential of insulin. Oral glucose (dextrose) should be used in the treatment of mild-to-moderate hypoglycemia; severe hypoglycemia may require the use of either intravenous glucose infusion or glucagon injection.

Isoniazid: May decrease the efficacy of acarbose due to hyperglycemic effects.

Nicotinic acid: May decrease the efficacy of acarbose due to hyperglycemic effects.

Oral contraceptives: May decrease the efficacy of acarbose due to hyperglycemic effects.

Phenothiazines: May decrease the efficacy of acarbose due to hyperglycemic effects.

Sulfonylureas: Acarbose may increase the hypoglycemic potential of sulfonylureas. Oral glucose (dextrose) should be used in the treatment of mild-to-moderate hypoglycemia; severe hypoglycemia may require the use of either intravenous glucose infusion or glucagon injection.

Thyroid hormones: May decrease the efficacy of acarbose due to hyperglycemic effects.

Pregnancy Risk Factor B

Pregnancy Implications Abnormal blood glucose levels are associated with a higher incidence of congenital abnormalities. Insulin is the drug of choice for the control of diabetes mellitus during pregnancy. It is not known whether acarbose is excreted in human milk

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Administer acarbose 3 times/day at the start (with the first bite) of each main meal. It is important to continue to adhere to dietary instructions, a regular exercise program, and regular testing of urine and/or blood glucose. The risk of hypoglycemia, its symptoms and treatment, and conditions that predispose to its development should be well understood by patients and responsible family members. A source of glucose (dextrose) should be readily available to treat symptoms of low blood glucose when taking acarbose in combination with a sulfonylurea or insulin. If side effects occur, they usually develop during the first few weeks of therapy and are mild to moderate GI effects, such as flatulence, diarrhea, or abdominal discomfort and generally diminish in frequency and intensity with time.

Acebutolol

Pronunciation (a se BYOO toe lole)

Related Information

- Selected Properties of Beta-Adrenergic Blocking Drugs

CAS Number 34381-68-5; 37517-30-9

U.S. Brand Names Sectral®

Synonyms Acebutolol Hydrochloride

Impairment Potential Yes

ACETAMINOPHEN

Use Treatment of hypertension; ventricular arrhythmias; angina

Mechanism of Action Competitively blocks beta₁-adrenergic receptors with little or no effect on beta₂-receptors except at high doses. Exhibits membrane stabilizing and intrinsic sympathomimetic activity ("quinidine-like effect"); low lipid solubility, therefore, little crosses blood-brain barrier.

Adverse Reactions

Cardiovascular: Persistent bradycardia, hypotension, chest pain, edema, heart failure, exacerbation of Raynaud's phenomenon, sinus bradycardia, myocardial depression, palpitations, QT prolongation

Central nervous system: CNS depression, confusion, dizziness, **fatigue**, drowsiness, night terrors, insomnia, headache, electroencephalogram abnormalities

Dermatologic: Exanthema, erythema multiforme, alopecia, toxic epidermal necrolysis, xerosis, urticaria, onycholysis, pruritus, psoriasis, licheniform eruptions, cutaneous vasculitis

Gastrointestinal: Constipation, abdominal pain, diarrhea, nausea, vomiting
Genitourinary: Impotence

Hepatic: Elevated liver enzymes

Respiratory: Hypersensitivity pneumonitis, pleurisy, pulmonary granulomas, rhinitis

Miscellaneous: Hyperhidrosis, cold extremities, lupus syndrome

Signs and Symptoms of Overdose Asystole, ataxia, bradycardia, cardiovascular collapse, cough, depression, dyspepsia, dyspnea, electromechanical dissociation, first degree AV block, flatulence, heart failure, hyperglycemia, hypoglycemia, hypotension, impotence, insomnia, myalgia, myasthenia gravis (exacerbation or precipitation), nocturia, QRS prolongation, wheezing

Pharmacodynamics/Kinetics

Onset of action: 1-2 hours

Duration: 12-24 hours

Absorption: Oral: 40%

Protein binding: 5% to 15%

Metabolism: Extensive first-pass effect

Half-life elimination: 6-7 hours

Time to peak: 2-4 hours

Excretion: Feces (~55%); urine (35%)

Dosage

Oral:

Adults:

Hypertension: 400-800 mg/day (larger doses may be divided); maximum: 1200 mg/day; usual dose range (JNC 7): 200-800 mg/day in 2 divided doses

Ventricular arrhythmias: Initial: 400 mg/day; maintenance: 600-1200 mg/day in divided doses

Elderly: Initial: 200-400 mg/day; dose reduction due to age related decrease in Cl_{cr} will be necessary; do not exceed 800 mg/day

Dosing adjustment in renal impairment:

Cl_{cr} 25-49 mL/minute/1.73 m²: Reduce dose by 50%.

Cl_{cr} <25 mL/minute/1.73 m²: Reduce dose by 75%.

Dosing adjustment in hepatic impairment: Use with caution.

Monitoring Parameters Blood pressure, orthostatic hypotension, heart rate, CNS effects, ECG

Administration

To discontinue therapy, taper dose gradually. May be administered without regard to meals.

Contraindications Hypersensitivity to beta-blocking agents; uncompensated congestive heart failure; cardiogenic shock; bradycardia or second- and third-degree heart block (except in patients with a functioning artificial pacemaker); sinus node dysfunction; pregnancy (2nd and 3rd trimesters)

Warnings Abrupt withdrawal of drug **should be avoided**. May result in an exaggerated cardiac responsiveness such as tachycardia, hypertension, ischemia, angina, myocardial infarction, and sudden death. It is recommended that patients be gradually tapered off beta-blockers (over a 2-week period) rather than via abrupt discontinuation. Although acebutolol primarily blocks beta₁-receptors, high doses can result in beta₂-receptor blockage. Use with caution in diabetic patients. Beta-blockers may impair glucose tolerance, potentiate hypoglycemia, and/or mask symptoms of hypoglycemia in a diabetic patient. Use with caution in bronchospastic lung disease and renal dysfunction (especially the elderly). Beta-blockers with intrinsic sympathomimetic activity do not appear to be of benefit in CHF and should be avoided. See Dosage - Renal/Hepatic Impairment.

Dosage Forms Capsule, as hydrochloride: 200 mg, 400 mg

Reference Range Acebutolol serum levels >13 mg/L associated with fatality

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Initiate support with fluids; epinephrine or dopamine may be useful; glucagon may be particularly effective for reversing cardiac manifestations; sympathomimetics (eg, epinephrine, dopamine, or amrinone), atropine, isoproterenol, glucagon, or a pacemaker may be used to treat the toxic bradycardia, asystole, and/or hypotension; acebutolol-induced ventricular tachycardia may respond to I.V. sodium bicarbonate (1-2 mEq/kg). The glucagon dose is 50-150 mcg/kg I.V. (~5-10 mg in adults) over 1 minute followed by continuous infusion of 1-5 mg/hour.

Enhancement of elimination: Multiple-dose activated charcoal may be effective; hemodialysis (4 hours) and extracorporeal oxygenation (12 hours) has been used successfully in one case

Test Interactions ↑ triglycerides, potassium, uric acid, cholesterol (S), glucose; ↓ HDL

Drug Interactions

Inhibits CYP2D6 (weak)

Alpha-blockers (prazosin, terazosin): Concurrent use of beta-blockers may increase risk of orthostasis.

Clonidine: Hypertensive crisis after or during withdrawal of either agent.

Drugs which slow AV conduction (digoxin): Effects may be additive with beta-blockers.

Glucagon: Acebutolol may blunt the hyperglycemic action of glucagon. Insulin and oral hypoglycemics: Acebutolol masks the tachycardia from hypoglycemia.

NSAIDs (ibuprofen, indomethacin, naproxen, piroxicam) may reduce the antihypertensive effects of beta-blockers.

Salicylates may reduce the antihypertensive effects of beta-blockers.

Sulfonamides: Beta-blockers may alter response to hypoglycemic agents. Verapamil or diltiazem may have synergistic or additive pharmacological effects when taken concurrently with beta-blockers.

Pregnancy Risk Factor B (manufacturer); D (2nd and 3rd trimesters - expert analysis)

Pregnancy Implications Acebutolol crosses the placenta. Beta-blockers have been associated with persistent bradycardia, hypotension, and IUGR; IUGR is probably related to maternal hypertension. Available evidence suggests beta-blockers are generally safe during pregnancy (JNC-7). Cases of neonatal hypoglycemia have been reported following maternal use of beta-blockers at parturition or during breast-feeding.

Lactation Enters breast milk/use caution

Additional Information Since bioavailability has been shown to increase about twofold in the elderly, they may require lower maintenance doses; therefore, as serum and tissue concentrations increase, beta₁ selectivity diminishes.

Acetaminophen

Pronunciation (a seet a MIN oh fen)

Related Information

• Donor Victims of Poisoning in Whom Transplantation of Organs Occurred

CAS Number 103-90-2

U.S. Brand Names Acephen® [OTC]; Aspirin Free Anacin® Maximum Strength [OTC]; Cetafen Extra® [OTC]; Cetafen® [OTC]; Comtrex® Sore Throat Maximum Strength [OTC]; ElixSure™ Fever/Pain [OTC]; Fernal® [OTC]; Genapap® Children [OTC]; Genapap® Extra Strength [OTC]; Genapap® Infant [OTC]; Genapap® [OTC]; Genebs® Extra Strength [OTC]; Genebs® [OTC]; Mapap® Arthritis [OTC]; Mapap® Children's [OTC]; Mapap® Extra Strength [OTC]; Mapap® Infants [OTC]; Mapap® [OTC]; Redutemp® [OTC]; Silapap® Children's [OTC]; Silapap® Infants [OTC]; Tylenol® 8 Hour [OTC]; Tylenol® Arthritis Pain [OTC]; Tylenol® Children's [OTC]; Tylenol® Extra Strength [OTC]; Tylenol® Infants [OTC]; Tylenol® Junior Strength [OTC]; Tylenol® Sore Throat [OTC]; Tylenol® [OTC]; Valorin Extra [OTC]; Valorin [OTC]

Synonyms APAP; N-Acetyl-P-Aminophenol; Paracetamol

Use

Treatment of mild to moderate pain and fever (antipyretic/analgesic);

does not have antirheumatic or anti-inflammatory effects

First used clinically in the United States in 1950

Mechanism of Action

Inhibits the synthesis of prostaglandin E₂ in the central nervous system and peripherally blocks pain impulse generation; produces antipyresis from inhibition of hypothalamic heat-regulating center

Exhibits Mild anti inflammatory effects via inhibition of peripheral COX-2

Adverse Reactions

Cardiovascular: Rare cardiomyopathy, bradycardia, cardiomegaly, pericardial effusion/pericarditis, Reye's-like syndrome, vasculitis, leukocytoclastic vasculitis

Central nervous system: Hypothermia

Dermatologic: Rash, toxic epidermal necrolysis, exanthema, pityriasis rosea-like reaction, erythema multiforme, acute generalized exanthematous pustulosis, alopecia, angioedema, urticaria, purpura, Stevens-Johnson syndrome, pruritus, erythema nodosum, exanthem, cutaneous vasculitis

Endocrine & metabolic: Elevated serum transaminases, hyponatremia, hypophosphatemia

Gastrointestinal: Vomiting, nausea, diarrhea, pancreatitis

Hematologic: Leukemoid reaction, thrombocytopenia

Hepatic: Hepatic encephalopathy, hepatitis (fulminant) with centrilobular necrosis (zone 3), jaundice, cirrhosis, liver transaminase rise may occur within 24 hours of ingestion, centrilobular hepatic necrosis, primary biliary cirrhosis, hepatic vasculitis
Ocular: Mydriasis, nystagmus, vision color changes (yellow tinge)
Renal: Renal injury with chronic use, acute tubular necrosis; renal failure (acute) is uncommon in overdose
Respiratory: Eosinophilic pneumonia, pulmonary vasculitis
Miscellaneous: Hypersensitivity reactions (rare), fixed drug eruption

Signs and Symptoms of Overdose The acute symptomatic presentation of acetaminophen toxicity can be divided into 4 phases:

Phase I (up to 1 day): Gastrointestinal irritability predominates with nausea, vomiting, and sweating. Large ingestions (> 75 g in adults; > 10 g in pediatric patients) can result in metabolic acidosis within 4 hours of ingestion. Cardiac effects (arrhythmias, bradycardia) may develop.
Phase II (1-3 days): Hepatic toxicity develops with elevation of hepatic enzymes, prothrombin time, and bilirubin. Amylase elevation may peak at 2 days. The patient may otherwise be asymptomatic. Oliguric renal failure may develop and may coincide with hepatic encephalopathy.
Phase III (3-5 days): Hepatic necrosis continues with disseminated intravascular coagulation, hepatic encephalopathy, portal hypertension, and icterus. The patient is at risk for hypoglycemia. Renal insufficiency may also be present.
Phase IV (5-14 days): Recovery with resolution of elevated hepatic enzymes usually occurs.

Admission Criteria/Prognosis Admit any patient with a 4 hour plasma acetaminophen level >150 mg/L or abnormal liver function tests, acidosis, or adult or adolescent ingestions >125 mg/kg

Pharmacodynamics/Kinetics

Onset of action: < 1 hour
Duration: 4-6 hours
Absorption: Incomplete; varies by dosage form
Protein binding: 8% to 43% at toxic doses
Metabolism: At normal therapeutic dosages, hepatic to sulfate and glucuronide metabolites, while a small amount is metabolized by CYP to a highly reactive intermediate (acetylimidoquinone) which is conjugated with glutathione and inactivated; at toxic doses (as little as 4 g daily) glutathione conjugation becomes insufficient to meet the metabolic demand causing an increase in acetylimidoquinone concentration, which may cause hepatic cell necrosis
Half-life elimination: Prolonged following toxic doses
Neonates: 2-5 hours
Adults: 1-3 hours (may be increased in elderly; however, this should not affect dosing)
Time to peak, serum: Oral: 10-60 minutes; may be delayed in acute overdoses
Excretion: Urine (2% to 5% unchanged; 55% as glucuronide metabolites; 30% as sulphate metabolites)

Dosage

Oral, rectal:
 Children < 12 years: 10-15 mg/kg/dose every 4-6 hours as needed; do not exceed 5 doses (2.6 g) in 24 hours; alternatively, the following doses may be used. See table.

Acetaminophen Dosing			
Age	Dosage (mg)	Age	Dosage (mg)
0-3 mo	40	4-5 y	240
4-11 mo	80	6-8 y	320
1-2 y	120	9-10 y	400
2-3 y	160	11 y	480

Note: Higher rectal doses have been studied for use in preoperative pain control in children. However, specific guidelines are not available and dosing may be product dependent. The safety and efficacy of alternating acetaminophen and ibuprofen dosing has not been established.
Adults: 325-650 mg every 4-6 hours or 1000 mg 3-4 times/day; do not exceed 4 g/day
Toxic dosage for hepatitis: 200 mg/kg
Dosing interval in renal impairment:
 Cl_{cr} 10-50 mL/minute: Administer every 6 hours
 Cl_{cr} < 10 mL/minute: Administer every 8 hours (metabolites accumulate)
Dosing adjustment/comments in hepatic impairment: Appears to be well tolerated in cirrhosis; serum levels may need monitoring with long-term use

Nomogram: Plasma or Serum Acetaminophen Concentration vs Time Post Acetaminophen Ingestion

Estimating potential for hepatotoxicity:
 The following nomogram has been developed to estimate the probability that plasma levels in relation to intervals post-ingestion will result in hepatotoxicity.

From Rumack BH and Matthew H, "Acetaminophen Poisoning and Toxicity," *Pediatrics*, June 1975, 55:871-6 with permission.

If the acetaminophen level determined at least 4 hours following an overdose falls above the broken line, administer the entire course of acetylcysteine treatment.

If the acetaminophen level, determined at least 4 hours following an overdose, falls below the broken line, acetylcysteine treatment is not necessary or if already initiated may be discontinued. Serum levels drawn before 4 hours may not represent peak levels.

Cautions for Use of this Chart:

- The time coordinates refer to time post-ingestion.
- The graph relates only to plasma levels following a single acute overdose ingestion.
- The broken line, which represents a 25% allowance below the solid line, is included to allow for possible errors in acetaminophen plasma assays and estimated time from ingestion of an overdose.

Monitoring Parameters Relief of pain or fever

Administration Suppositories: Do not freeze.

Suspension, oral: Shake well before pouring a dose.

Contraindications Hypersensitivity to acetaminophen or any component of the formulation

Warnings

Limit dose to < 4 g/day. May cause severe hepatic toxicity on acute overdose; in addition, chronic daily dosing in adults has resulted in liver damage in some patients. Use with caution in patients with alcoholic liver disease; consuming ≥ 3 alcoholic drinks/day may increase the risk of liver damage. Use caution in patients with known G6PD deficiency. OTC labeling: When used for self-medication, patients should be instructed to contact healthcare provider if used for fever lasting > 3 days or for pain lasting > 10 days in adults or > 5 days in children.

Dosage Forms

[DSC] = Discontinued product

Caplet: 500 mg

Cetafen Extra® Strength, Genapap™ Extra Strength, Genebs Extra Strength, Mapap Extra Strength, Tycolene Maximum Strength, Tylenol® Extra Strength: 500 mg

Caplet, extended release:

Tylenol® 8 Hour, Tylenol® Arthritis Pain: 650 mg

Capsule: 500 mg

Elixir: 160 mg/5 mL (120 mL, 480 mL, 3780 mL)

Apra Children's: 160 mg/5 mL (120 mL, 480 mL, 3780 mL) [alcohol free; contains benzoic acid; cherry and grape flavors]

Mapap Children's: 160 mg/5 mL (120 mL) [alcohol free; contains benzoic acid and sodium benzoate; cherry flavor]

Gelcap:

Mapap Extra Strength, Tylenol® Extra Strength: 500 mg

Geltab:

Tylenol® Extra Strength: 500 mg

Geltab, extended release:

Tylenol® 8 Hour: 650 mg

Liquid, oral: 500 mg/15 mL (240 mL)

Comtrex® Sore Throat Maximum Strength: 500 mg/15 mL (240 mL) [contains sodium benzoate; honey lemon flavor]

Genapap™ Children: 160 mg/5 mL (120 mL) [contains sodium benzoate; cherry and grape flavors]

Silapap®: 160 mg/5 mL (120 mL, 240 mL, 480 mL) [sugar free; contains sodium benzoate; cherry flavor]

Tylenol® Extra Strength: 500 mg/15 mL (240 mL) [contains sodium benzoate; cherry flavor]

Solution, oral: 160 mg/5 mL (120 mL, 480 mL)

Solution, oral drops: 80 mg/0.8 mL (15 mL) [droppers are marked at 0.4 mL (40 mg) and at 0.8 mL (80 mg)]

- Genapap™ Infant: 80 mg/0.8 mL (15 mL) [fruit flavor]
- Infantaire: 80 mg/0.8mL (15 mL, 30 mL)
- Silapap® Infant's: 80 mg/0.8 mL (15 mL, 30 mL) [contains sodium benzoate; cherry flavor]
- Suppository, rectal: 120 mg, 325 mg, 650 mg
- Acephen™: 120 mg, 325 mg, 650 mg
- FeverALL®: 80 mg, 120 mg, 325 mg, 650 mg
- Mapap: 125 mg, 650 mg
- Suspension, oral:
 - Mapap Children's: 160 mg/5 mL (120 mL) [contains sodium benzoate; cherry flavor]
 - Nortemp Children's: 160 mg/5 mL (120 mL) [alcohol free; contains sodium benzoate; cotton candy flavor]
 - Tylenol® Children's: 160 mg/5 mL (120 mL, 240 mL) [contains sodium benzoate; bubble gum yum, cherry blast, dye free cherry, grape splash, and very berry strawberry flavors]
 - Tylenol® Children's with Flavor Creator: 160 mg/5 mL (120 mL) [contains sodium 2 mg/5 mL and sodium benzoate; cherry blast flavor; packaged with apple (4), bubblegum (8), chocolate (4), & strawberry (4) sugar free flavor packets]
- Suspension, oral drops:
 - Mapap Infants: 80 mg/0.8 mL (15 mL, 30 mL) [contains sodium benzoate; cherry flavor]
 - Tylenol® Infants: 80 mg/0.8 mL (15 mL, 30 mL) [contains sodium benzoate; cherry, dye free cherry, and grape flavors]
- Syrup, oral:
 - ElixSure™ Fever/Pain: 160 mg/5 mL (120 mL) [bubble gum, cherry, and grape flavors] [DSC]
- Tablet: 325 mg, 500 mg
 - Aspirin Free Anacin® Extra Strength, Genapap™ Extra Strength, Genebs Extra Strength, Mapap Extra Strength, Pain Eze, Tylenol® Extra Strength, Valorin Extra: 500 mg
 - Cetafen®, Genapap™, Genebs, Mapap, Tycolene, Tylenol®, Valorin: 325 mg
- Tablet, chewable: 80 mg
 - Genapap™ Children: 80 mg [contains phenylalanine 6 mg/tablet; fruit and grape flavors]
 - Mapap Children's: 80 mg [contains phenylalanine 3 mg/tablet; bubble gum, fruit, and grape flavors]
 - Mapap Junior Strength: 160 mg [contains phenylalanine 12 mg/tablet; grape flavor]
 - Tylenol® Children's: 80 mg [fruit and grape flavors contain phenylalanine 3 mg/tablet; bubble gum flavor contains phenylalanine 6 mg/tablet] [DSC]
 - Tylenol® Junior: 160 mg [contains phenylalanine 6 mg/tablet; fruit and grape flavors] [DSC]
- Tablet, orally disintegrating: 80 mg, 160 mg
 - Tylenol® Children's Meltaways: 80 mg [bubble gum, grape, and watermelon flavors]
 - Tylenol® Junior Meltaways: 160 mg [bubble gum and grape flavors]

Reference Range Patients with concentrations > 150 mg/L before 4 hours can be empirically treated with acetylcysteine until repeat concentration after 4 hours has been obtained and interpreted; analgesic/antipyretic reference range: 10-30 mg/L (66-199 µmol/L); the antigenic biomarker (3-[cystein-s-yl]-APAP protein adducts [3-cys-A]) appearance in serum may be useful to confirm the diagnosis of acetaminophen-induced hepatic injury

Overdosage/Treatment

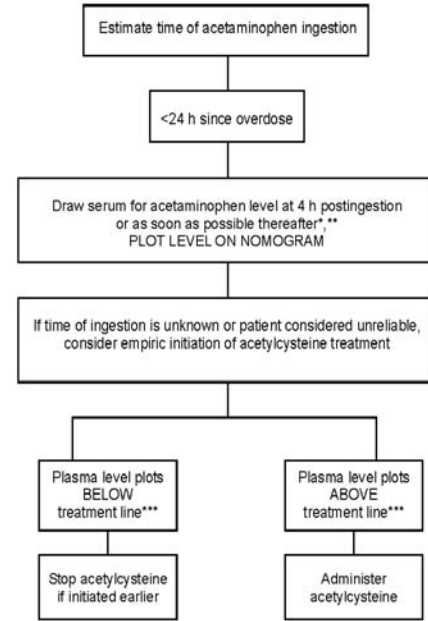

Decontamination: Lavage within 1 hour of overdose, activated charcoal if <2 hours following ingestion. While activated charcoal can decrease acetaminophen bioavailability by 30% when given within 1 hour postingestion, it does not appear useful if given at longer than 2 hours postingestion. Gastrointestinal decontamination may be more effective if more than 10 extended release tablets are ingested at 8 hours postingestion.

Supportive therapy: Acetylcysteine (antidote) indicated for:

- Any patient with a serum concentration above probable risk line on Rumack-Matthew nomogram
- Any patient presenting ≥24 hours following an ingestion with evidence of hepatic toxicity
- Empirically for any ingestion of ≥200 mg/kg where availability of serum concentration results exceeds 8 hours following ingestion; N-acetylcysteine is given orally 140 mg/kg followed by 70 mg/kg every 4 hours for 17 doses; although shorter 20-48 intravenous courses can be used also

See Acetylcysteine [ANTIDOTE]. See flow chart.

Acetadote® Treatment Flowchart

* Acetaminophen levels drawn <4 hours postingestion may be misleading.
 ** With the extended-release preparation, an acetaminophen level drawn <8 hours postingestion may be misleading. Draw a second level at 4-6 hours.
 *** Acetylcysteine may be withheld until acetaminophen assay results are available as long as initiation of treatment is not delayed beyond 8 hours postingestion. If more than 8 hours postingestion, start acetylcysteine treatment immediately.

For persistent vomiting, metoclopramide (10 mg to 1 mg/kg I.V. or I.M. 30 minutes before N-acetylcysteine dose) can be used. Prochlorperazine (10 mg I.V.) can also be added to metoclopramide. Other agents which can be used include droperidol (1.25-2.5 mg I.V. in adult) or ondansetron (up to 0.15 mg/kg I.V.). If vomiting persists, a nasogastric tube or duodenal tube may need to be inserted and thus N-acetylcysteine can be infused over 30-60 minutes.

Combination antiemetic therapy, which is very effective, may include metoclopramide (10 mg I.V.) followed by ondansetron (0.15 mg/kg); granisetron (10 mcg/kg I.V.) given over 5 minutes may also be used; patients with INR >2 should receive prophylactic antibiotics and sucralfate; consider liver transplantation if serum pH is <7.3 (despite adequate fluid replacement), or PT is > 50 seconds in U.S. (> 100 seconds in Europe) and grade III/IV hepatic encephalopathy and creatinine >300 µmol/L (3.3 mg/dL). APACHE score > 15 or serum phosphorous over 3.75 mg/dL are poor prognostic indicators.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective, but is usually not required if N-acetylcysteine therapy is given; forced diuresis is of no benefit; hemodialysis removes significant amounts of acetaminophen especially in patients with severe hepatic and renal dysfunction; usually not required if acetylcysteine is given; moderately dialyzable (20% to 50%). Exchange transfusion has been used successfully.

Extracorporeal removal (by charcoal hemoperfusion and/or high-flux dialysis) can be considered if the patient has (1) not received N-acetylcysteine within first 15 hours postingestion and (2) is at high risk for severe liver damage according to the nomogram or has peak AST or ALT >5000 units/L

Antidote(s)

- Acetylcysteine [ANTIDOTE]

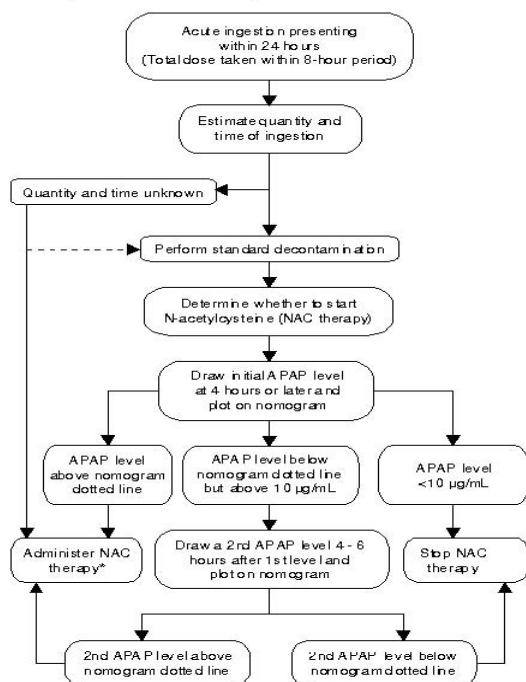

Diagnostic Procedures

- Acetaminophen, Serum

Test Interactions Can cause false elevation of urinary catecholamine and may interfere with blood glucose assays leading to false elevation

of glucose; false-positive acetaminophen levels with hyperbilirubinemia > 10 mg/L

Tylenol® Acetaminophen Extended Release

* See text for full discussion of NAC therapy, use of baseline LFTs, and other supportive care

Drug Interactions

Substrate (minor) of CYP1A2, 2A6, 2C9, 2D6, 2E1, 3A4; **Inhibits** CYP3A4 (weak)

Decreased effect: Barbiturates, carbamazepine, hydantoin, rifampin, sulfipyrazone may decrease the analgesic effect of acetaminophen. Cholestyramine may decrease acetaminophen absorption (separate dosing by at least 1 hour).

Increased toxicity: Barbiturates, carbamazepine, hydantoin, isoniazid, rifampin, sulfipyrazone may increase the hepatotoxic potential of acetaminophen. Chronic ethanol abuse increases risk for acetaminophen toxicity; effect of warfarin may be enhanced.

Pregnancy Risk Factor B

Pregnancy Implications Fetal liver toxicity can occur in overdose situations

Lactation Enters breast milk/compatible

Additional Information Toxic dosage for hepatitis: See Usual Dosage.

Cimetidine is not effective for hepatoprotection in acetaminophen overdose.

The 4-hour serum concentration can be approximated by $0.59 \times$ the amount ingested as mg/kg in patients taking only acetaminophen; acetylcysteine is not useful for treatment of renal disease induced by acetaminophen. For extended relief product ingestions, draw an acetaminophen level at least 4 hours post-ingestion; a second and third acetaminophen level should be drawn every 4-6 hours after the initial level. These levels should be plotted on the Rumack-Matthew nomogram at the times each were drawn; if any of the plasma levels are above the hepatotoxic line on the Rumack-Matthew nomogram, the entire course of acetylcysteine treatment should be administered; or, if initiated, completed. There is increased risk of liver toxicity in individuals who ingest 3 or more ethanol-containing beverages daily. See Overdose/Treatment flow chart (Tylenol® Acetaminophen Extended Release). When sustained release acetaminophen and drugs that slow GI motility are co-ingested, prolonged monitoring of levels is justified. In an *in vitro* model, with ingestion of > 10 tablets of extended release tablets there was an increase in the number of tablets that did not disintegrate at 8 hours.

A peak prothrombin time of 25 seconds at 2 days post-ingestion, or 40 seconds at 3 days, will usually be associated with hepatic encephalopathy (grade III) in acetaminophen overdose. Note that N-acetylcysteine can prolong clotting time. A normal initial prothrombin time correlates with a good outcome in acetaminophen overdose.

Predictors for fatal outcome include arterial pH < 7.3, prothrombin time > 50 seconds in the U.S. (> 100 seconds in Europe), creatinine (least discriminating) > 3.4 mg/dL (> 300 µmol/L). The combination of prothrombin time > 50 seconds (> 100 seconds in Europe) and serum creatinine > 3.4 mg/dL (> 300 µmol/L), with grade III to IV hepatic encephalopathy, is the best predictor of death (predictive accuracy of

0.83). Other predictors of mortality include a plasma factor V concentration $\leq 10\%$ of normal (especially in conjunction with a significant rise in factor VIII, leading to a factor VIII to factor V ratio > 30, or severe hepatic coma within 72 hours of overdose). The above criteria may be useful in the selection for liver transplantation.

High-dose (> 1 g) acetaminophen may cause bronchospasm in aspirin-sensitive asthmatic patients.

Watercress (*Nasturtium officinale*) can cause a decrease in oxidative metabolites of acetaminophen.

An increase of serum alpha-fetoprotein levels higher than 3.9 mcg/L on the day after the peak level of alanine aminotransferase may predict survival from severe acetaminophen-induced hepatotoxicity.

AcetaZOLAMIDE

Pronunciation (a set a ZOLE a mide)

Related Information

- Dichlorphenamide

CAS Number 59-66-5

U.S. Brand Names Diamox® Sequels®

Use Treatment of glaucoma (chronic simple open-angle, secondary glaucoma, preoperatively in acute angle-closure); drug-induced edema or edema due to congestive heart failure (adjunctive therapy); centrencephalic epilepsies (immediate release dosage form); prevention or amelioration of symptoms associated with acute mountain sickness

Unlabeled/Investigational Use Urine alkalinization; respiratory stimulant in COPD; metabolic alkalosis

Mechanism of Action Reversible inhibition of the enzyme carbonic anhydrase resulting in reduction of hydrogen ion secretion at the renal tubule and an increased renal excretion of sodium, potassium, bicarbonate, and water to decrease production of aqueous humor; also inhibits carbonic anhydrase in the central nervous system to retard abnormal and excessive discharge from CNS neurons

Adverse Reactions

Frequency not defined.

Cardiovascular: Flushing

Central nervous system: Ataxia, confusion, convulsions, depression, dizziness, drowsiness, excitement, fatigue, headache, malaise

Dermatologic: Allergic skin reaction, photosensitivity, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

Endocrine & metabolic: Electrolyte imbalance, growth retardation (children), hyperglycemia, hypoglycemia, hypokalemia, hyponatremia, metabolic acidosis,

Gastrointestinal: Appetite decreased, diarrhea, melena, nausea, taste alternation, vomiting

Genitourinary: Crystalluria, glycosuria, hematuria, polyuria, renal failure

Hematologic: Agranulocytosis, aplastic anemia, leukopenia, thrombocytopenia, thrombocytopenic purpura

Hepatic: Cholestatic jaundice, fulminant hepatic necrosis, hepatic insufficiency, liver function tests abnormal

Neuromuscular & skeletal: Flaccid paralysis, paresthesia

Ocular: Myopia

Otic: Hearing disturbance, tinnitus

Miscellaneous: Anaphylaxis

Pharmacodynamics/Kinetics

Onset of action: Capsule, extended release: 2 hours; I.V.: 2 minutes

Peak effect: Capsule, extended release: 8-12 hours; I.V.: 15 minutes; Tablet: 2-4 hours

Duration: Inhibition of aqueous humor secretion: Capsule, extended release: 18-24 hours; I.V.: 4-5 hours; Tablet: 8-12 hours

Distribution: Erythrocytes, kidneys; blood-brain barrier and placenta; distributes into milk (~30% of plasma concentrations)

Excretion: Urine (70% to 100% as unchanged drug)

Dosage

Note: I.M. administration is not recommended because of pain secondary to the alkaline pH

Children:**Glaucoma:**

Oral: 8-30 mg/kg/day or 300-900 mg/m²/day divided every 8 hours
I.V.: 20-40 mg/kg/24 hours divided every 6 hours, not to exceed 1 g/day

Edema: Oral, I.V.: 5 mg/kg or 150 mg/m² once every day

Epilepsy: Oral: 8-30 mg/kg/day in 1-4 divided doses, not to exceed 1 g/day; sustained release capsule is not recommended for treatment of epilepsy

Adults:**Glaucoma:**

Chronic simple (open-angle): Oral: 250 mg 1-4 times/day or 500 mg sustained release capsule twice daily
Secondary, acute (closed-angle): I.V.: 250-500 mg, may repeat in 2-4 hours to a maximum of 1 g/day

Edema: Oral, I.V.: 250-375 mg once daily

Epilepsy: Oral: 8-30 mg/kg/day in 1-4 divided doses; **sustained release capsule is not recommended for treatment of epilepsy**

Mountain sickness: Oral: 250 mg every 8-12 hours (or 500 mg extended release capsules every 12-24 hours)

Therapy should begin 24-48 hours before and continue during ascent and for at least 48 hours after arrival at the high altitude

Urine alkalization (unlabeled use): Oral: 5 mg/kg/dose repeated 2-3 times over 24 hours

Respiratory stimulant in COPD (unlabeled use): Oral, I.V.: 250 mg twice daily

Elderly: Oral: Initial: 250 mg twice daily; use lowest effective dose

Dosing adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer every 12 hours

Cl_{cr} <10 mL/minute: Avoid use (ineffective)

Hemodialysis: Moderately dialyzable (20% to 50%)

Peritoneal dialysis: Supplemental dose is not necessary

Monitoring Parameters Intraocular pressure, potassium, serum bicarbonate; serum electrolytes, periodic CBC with differential

Administration

Oral: May cause an alteration in taste, especially carbonated beverages; short-acting tablets may be crushed and suspended in cherry or chocolate syrup to disguise the bitter taste of the drug, do not use fruit juices, alternatively submerge tablet in 10 mL of hot water and add 10 mL honey or syrup

Contraindications Hypersensitivity to acetazolamide, sulfonamides, or any component of the formulation; hepatic disease or insufficiency; decreased sodium and/or potassium levels; adrenocortical insufficiency, cirrhosis; hyperchloremic acidosis, severe renal disease or dysfunction; severe pulmonary obstruction; long-term use in noncongestive angle-closure glaucoma

Warnings

Use in impaired hepatic function may result in coma. Use with caution in patients with respiratory acidosis and diabetes mellitus. Impairment of mental alertness and/or physical coordination may occur. Chemical similarities are present among sulfonamides, sulfonyleureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonamide allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe. Discontinue if signs of hypersensitivity are noted.

I.M. administration is painful because of the alkaline pH of the drug; use by this route is not recommended.

Drug may cause substantial increase in blood glucose in some diabetic patients; malaise and complaints of tiredness and myalgia are signs of excessive dosing and acidosis in the elderly.

Dosage Forms Capsule, extended release:

Diamox® Sequels®: 500 mg

Injection, powder for reconstitution: 500 mg

Tablet: 125 mg, 250 mg

Reference Range

Therapeutic range: 5-20 mg/L

Peak plasma level: 16 mcg/mL after 250 mg of acetazolamide

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Hemodialysis may remove as much as 30% of dose if performed prior to significant distribution

Test Interactions May cause false-positive results for urinary protein with Albustix®, Labstix®, Albutest®, Bumintest®; interferes with HPLC theophylline assay

Drug Interactions

Inhibits CYP3A4 (weak)

Amphetamines: Urinary excretion of amphetamine may be decreased; magnitude and duration of effects may be enhanced.

Carbamazepine: May increase serum concentrations of carbamazepine.

Cyclosporine trough concentrations may be increased resulting in possible nephrotoxicity and neurotoxicity.

Flecainide: May decrease excretion of flecainide.

Lithium: Serum concentrations may be decreased by acetazolamide; monitor.

Memantine: May decrease excretion of memantine.

Methenamine: Urinary antiseptic effect may be prevented by acetazolamide.

Phenytoin: Serum concentrations of phenytoin may be increased; incidence of osteomalacia may be enhanced or increased in patients on chronic phenytoin therapy.

Primidone serum concentrations may be decreased; carbonic anhydrase inhibitors may enhance the adverse/toxic effects of primidone.

Quinidine: Urinary excretion of quinidine may be decreased and effects may be enhanced.

Salicylate use (high dose) may result in carbonic anhydrase inhibitor accumulation and toxicity including CNS depression and metabolic acidosis. Salicylate toxicity might also be enhanced.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic in animal studies, however, there are no adequate and well-controlled studies in pregnant women.

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Nursing Implications Tablet may be crushed and suspended in cherry or chocolate syrup to disguise the bitter taste of the drug

Additional Information Sodium content of 500 mg injection: 47.2 mg (2.05 mEq)

AcetoHEXAMIDE

CAS Number 968-81-0

Use Adjunct to diet for the management of mild to moderately severe, stable, noninsulin-dependent (type II) diabetes mellitus

Mechanism of Action Causes hypoglycemia by stimulating pancreatic islet cells to release insulin; stimulates insulin release from the pancreatic beta cells; reduces glucose output from the liver; insulin sensitivity is increased at peripheral target sites; produces a mild diuretic effect and increases the urinary excretion of uric acid

Adverse Reactions

Cardiovascular: Sinus tachycardia

Central nervous system: **Headache**, ataxia, **dizziness**

Dermatologic: Skin rash, hives, photosensitivity

Endocrine & metabolic: Severe hypoglycemia, hyponatremia, syndrome of inappropriate antidiuretic hormone, hyperinsulinemia

Gastrointestinal: Nausea, vomiting, **epigastric fullness**, abdominal pain, **heartburn**, **diarrhea**, **anorexia**, **constipation**

Hematologic: Aplastic anemia, hemolysis, bone marrow suppression, thrombocytopenia, leukopenia, neutropenia, agranulocytosis, granulocytopenia

Hepatic: Cholestatic jaundice, cirrhosis

Neuromuscular & skeletal: Fasciculations

Ocular: Diplopia, photophobia

Toxicodynamics/Kinetics

Onset of effect: 1 hour

Peak hypoglycemic effects: 8-10 hours

Duration: 12-24 hours, prolonged with renal impairment

Distribution: Into breast milk

Protein binding: 85% to 88%

Metabolism: In the liver to hydroxyhexamide (active metabolite)

Half-life: Parent compound: 0.8-2.4 hours; Metabolite: 5-6 hours

Elimination: Urinary excretion of <40% as unchanged drug; ~80% to 95% of dose excreted in urine within 24 hours; ~15% excreted in bile

Dosage

Adults: Oral (elderly patients may be more sensitive and should be started at a lower dosage initially): 250 mg to 1.5 g/day in 1-2 divided doses; doses > 1.5 g/day are not recommended; if dose is ≤ 1 g, administer as a single daily dose

Dosing adjustment in renal impairment: Cl_{cr} <50 mL/minute: Avoid use; prolonged hypoglycemia occurs in azotemic patients

Dosing adjustment in hepatic impairment: Initiate therapy at lower than recommended doses

Monitoring Parameters Blood (preferred) and urine glucose concentrations should be monitored when therapy is started; normally takes 7 days to determine therapeutic response

Reference Range Glucose fasting: Adults: 80-140 mg/dL; Elderly: 100-180 mg/dL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Glucose (25 g I.V.) is mainstay of therapy. Glucagon (1-5 mg I.V., I.M., or SubQ) (0.03-0.1 mg/kg in pediatrics) will have limited benefit; diazoxide is a third-line agent (3-8 mg/kg/24 hours); octreotide (50 mcg every 12 hours SubQ) will suppress plasma insulin
Enhancement of elimination: Multiple dosing of activated charcoal may be effective. Peritoneal dialysis has been used with some success. Urine alkalization is also useful.

Antidote(s)

- Dextrose [ANTIDOTE]
- Glucagon [ANTIDOTE]
- Octreotide [ANTIDOTE]

Test Interactions May cause a false elevation of serum creatinine due to interference with tubular secretion of creatinine

Pregnancy Risk Factor D

Pregnancy Implications Abnormal blood glucose levels are associated with a higher incidence of congenital abnormalities. Insulin is the drug of choice for the control of diabetes mellitus during pregnancy.

Nursing Implications Advise patient to avoid alcohol or products containing alcohol; blood and urine glucose concentrations should be monitored when therapy is started; normally takes 7 days to determine therapeutic response

Acrivastine and Pseudoephedrine

Pronunciation (AK ri vas teen & soo doe e FED rin)

CAS Number 87848-99-5

U.S. Brand Names Semprex®-D

Synonyms Pseudoephedrine Hydrochloride and Acrivastine

Impairment Potential Yes. Acrivastine may mildly affect driving performance at therapeutic doses

Use Allergic rhinitis, rash, atopic eczema, demographism

Mechanism of Action Analog of triprolidine, a potent antihistamine with sedative but no anticholinergic effects; histamine H₁-receptor antagonist

Adverse Reactions

Cardiovascular: Sinus tachycardia

Central nervous system: Lethargy, lightheadedness, **headache, drowsiness**, insomnia

Gastrointestinal: Xerostomia, nausea, diarrhea, dyspepsia

Pharmacodynamics/Kinetics

Pseudoephedrine: See Pseudoephedrine.

Acrivastine:

Metabolism: Minimally hepatic

Time to peak: ~1.1 hours

Excretion: Urine (84%); feces (13%)

Dosage Oral: 8 mg every 4-6 hours

Contraindications Hypersensitivity to pseudoephedrine, acrivastine (or other alkylamine antihistamines), or any component of the formulation; MAO inhibitor therapy within 14 days of initiating therapy; severe hypertension, severe coronary artery disease; renal impairment (Cl_{cr} ≤ 48 mL/minute)

Warnings Use with caution in patients >60 years of age. Use with caution in patients with high blood pressure, ischemic heart disease, diabetes, increased intraocular pressure, GI or GU obstruction, asthma, thyroid disease, or prostatic hyperplasia. Not recommended for use in children.

Dosage Forms Capsule: Acrivastine 8 mg and pseudoephedrine hydrochloride 60 mg

Reference Range After a 12 mg oral dose, peak serum level is ~179 ng/mL within 1 hour of ingestion

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: There is no specific treatment for an antihistamine overdose, however, most of its clinical toxicity is due to anticholinergic effects. For anticholinergic overdose with severe life-threatening symptoms, physostigmine 1-2 mg (0.5 or 0.02 mg/kg for children) I.V., slowly may be given to reverse these effects in life-threatening situations.

Drug Interactions Decreased effect of guanethidine, reserpine, methyl-dopa, and beta-blockers

Increased toxicity with MAO inhibitors (hypertensive crisis), sympathomimetics, CNS depressants, ethanol (sedation)

Pregnancy Risk Factor B

Lactation Enters breast milk/contraindicated

signs and symptoms of rheumatoid arthritis and inhibits progression of structural damage.

Adverse Reactions

Cardiovascular: Hypertension, arrhythmias, atrial fibrillation, chest pain, congestive heart failure, coronary artery disorder, heart arrest, hypertensive encephalopathy, myocardial infarct, palpitations, pericardial effusion, pericarditis, peripheral edema, syncope, tachycardia, thrombosis (leg), vascular disorder

Central nervous system: **Headache**, confusion, fever, multiple sclerosis, pain in extremity, paresthesia, subdural hematoma, tremor

Dermatologic: **Rash**, cellulitis

Endocrine & metabolic: Hyperlipidemia, hypercholesterolemia, dehydration, menstrual disorder, parathyroid disorder

Gastrointestinal: Nausea, abdominal pain, esophagitis, gastroenteritis, gastrointestinal hemorrhage, vomiting

Genitourinary: Urinary tract infection, cystitis, pelvic pain

Hematologic: Agranulocytosis, granulocytopenia, leukopenia, pancytopenia, polycythemia

Hepatic: Cholecystitis, cholelithiasis, hepatic necrosis

Local: Injection site reaction

Neuromuscular & skeletal: Back pain, arthritis, bone fracture, bone necrosis, joint disorder, muscle cramps, myasthenia, pyogenic arthritis, synovitis, tendon disorder

Ocular: Cataract

Renal: Hematuria, kidney calculus, paraproteinemia, pyelonephritis

Respiratory: **Upper respiratory tract infection, sinusitis**, asthma, bronchospasm, dyspnea, lung function decreased, pleural effusion, pneumonia

Miscellaneous: **Accidental injury**, flu-like syndrome, adenoma, carcinoma (including breast, gastrointestinal, skin, urogenital), erysipelas, healing abnormality, herpes zoster, ketosis, lupus erythematosus syndrome, lymphoma, melanoma, sepsis, tuberculosis (reactivation of latent infection)

Pharmacodynamics/Kinetics

Distribution: V_d: 4.7-6 L; Synovial fluid concentrations: 31% to 96% of serum

Bioavailability: Absolute: 64%

Half-life elimination: Terminal: ~2 weeks (range 10-20 days)

Time to peak, serum: SubQ: 131 ± 56 hours

Excretion: Clearance increased in the presence of antiadalimumab antibodies; decreased in patients 40 years and older

Dosage SubQ: Adults: Rheumatoid arthritis: 40 mg every other week; may be administered with other DMARDs; patients not taking methotrexate may increase dose to 40 mg/weekly

Monitoring Parameters Improvement of symptoms; signs of infection; place and read PPD before initiation

Administration

For SubQ injection; rotate injection sites. Do not use if solution is discolored. Do not administer to skin which is red, tender, bruised, or hard.

Contraindications Hypersensitivity to adalimumab or any component of the formulation

Warnings

[U.S. Boxed Warnings]: Patients should be evaluated for latent tuberculosis infection with a tuberculin skin test prior to therapy. Treatment of latent tuberculosis should be initiated before adalimumab is used. Tuberculosis (disseminated or extrapulmonary) has been reactivated while on adalimumab. Most cases have been reported within the first 8 months of treatment. **[U.S. Boxed Warning]: Patients with initial negative tuberculin skin tests should receive continued monitoring for tuberculosis throughout treatment; active tuberculosis has developed in this population during treatment.** Rare reactivation of hepatitis B has occurred in chronic virus carriers; evaluate prior to initiation and during treatment. Adalimumab may affect defenses against infections and malignancies.

[U.S. Boxed Warning]: Serious and potential fatal infections (including invasive fungal and other opportunistic infections) have been reported in patients receiving TNF-blocking agents, including adalimumab. Use caution with chronic infection, history of recurrent infection, or predisposition to infection. Do not give to patients with an active chronic or localized infection. Many of the serious infections have occurred in patients on concomitant immunosuppressive therapy. Other opportunistic infections included *Histoplasma*, *Aspergillus*, and *Nocardia*. Use caution in patients who have resided in regions where histoplasmosis is endemic. Patients who develop a new infection while undergoing treatment with adalimumab should be monitored closely. If a patient develops a serious infection or sepsis, adalimumab should be discontinued. Rare cases of lymphoma have also been reported in association with adalimumab. Impact on the development and course of malignancies is not fully defined.

May exacerbate pre-existing or recent-onset demyelinating CNS disorders. Worsening and new-onset CHF has been reported; use caution in patients with decreased left ventricular function. Use caution in patients with CHF. Patients should be brought up to date with all immunizations

Adalimumab

Pronunciation (a da LIM yoo mab)

U.S. Brand Names Humira™

Synonyms Antitumor Necrosis Factor Apha (Human); D2E7; Human Antitumor Necrosis Factor Alpha

Use Treatment of active rheumatoid arthritis (moderate to severe) in patients with inadequate response to one or more disease-modifying antirheumatic drugs (DMARDs)

Mechanism of Action Adalimumab is a recombinant monoclonal antibody that binds to human tumor necrosis factor alpha (TNF-alpha) receptor sites, thereby interfering with endogenous TNF-alpha activity. Elevated TNF levels in the synovial fluid are involved in the pathologic pain and joint destruction in rheumatoid arthritis. Adalimumab decreases

before initiating therapy. No data are available concerning the effects of adalimumab on vaccination. Live vaccines should not be given concurrently. No data are available concerning secondary transmission of live vaccines in patients receiving adalimumab. Rare cases of pancytopenia (including aplastic anemia) have been reported with TNF-blocking agents; with significant hematologic abnormalities, consider discontinuing therapy. Positive antinuclear antibody titers have been detected in patients (with negative baselines) treated with adalimumab. Rare cases of autoimmune disorder, including lupus-like syndrome, have been reported; monitor and discontinue adalimumab if symptoms develop. May cause hypersensitivity reactions, including anaphylaxis; monitor. Safety and efficacy have not been established in pediatric patients.

Dosage Forms

Injection, solution [preservative free]:

Humira®: 40 mg/0.8 mL (1 mL) [prefilled glass syringe or Humira® pen; packaged with alcohol preps; needle cover contains latex]

Overdosage/Treatment Doses of up to 10 mg/kg have been tolerated in clinical trials. In case of overdose, treatment should be symptomatic and supportive.

Drug Interactions

Abatacept: Concurrent use may increase the risk of infection; avoid concurrent use.

Abciximab: Allergic reactions may be increased in patients who have received diagnostic or therapeutic monoclonal antibodies due to the presence of HACA; may also cause thrombocytopenia or decreased therapeutic effect.

Anakinra: Concomitant use may increase risk of infections; not recommended.

Vaccines (killed organism or component): Adalimumab may decrease the effect of vaccines; monitor.

Vaccines (live organism): Adalimumab may increase the risk of vaccinal infection; avoid concurrent use.

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic effects were not observed in animal studies; however, there are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if clearly needed.

Lactation Excretion in breast milk unknown/not recommended

single dose of 0.3 mg/kg or 12 mg. Follow each dose with normal saline flush.

≥ 50 kg: Refer to Adults dosing

Pediatric advanced life support (PALS): Treatment of SVT: I.V., I.O.: 0.1 mg/kg; if not effective, administer 0.2 mg/kg of PSVT; medium dose required: 0.15 mg/kg; maximum single dose: 12 mg. Follow each dose with normal saline flush.

Adults: 6 mg; if not effective within 1-2 minutes, 12 mg may be given; may repeat 12 mg bolus if needed

Maximum single dose: 12 mg

Follow each I.V. bolus of adenosine with normal saline flush

Note: Preliminary results in adults suggest adenosine may be administered via a central line at lower doses (ie, initial adult dose: 3 mg).

Adenoscan®: Continuous I.V. infusion via peripheral line: 140 mcg/kg/minute for 6 minutes using syringe or colometric infusion pump; total dose: 0.84 mg/kg. Thallium-201 is injected at midpoint (3 minutes) of infusion.

Hemodialysis: Significant drug removal is unlikely based on physicochemical characteristics.

Peritoneal dialysis: Significant drug removal is unlikely based on physicochemical characteristics.

Note: Higher doses may be needed for administration via peripheral versus central vein.

Monitoring Parameters ECG monitoring, heart rate, blood pressure

Administration

For rapid bolus I.V. use only; administer I.V. push over 1-2 seconds at a peripheral I.V. site as proximal as possible to trunk (not in lower arm, hand, lower leg, or foot); follow each bolus with normal saline flush. **Note:** Preliminary results in adults suggest adenosine may be administered via central line at lower doses (eg, adults initial dose: 3 mg)

Contraindications Hypersensitivity to adenosine or any component of the formulation; second- or third-degree AV block or sick sinus syndrome (except in patients with a functioning artificial pacemaker), atrial flutter, atrial fibrillation, and ventricular tachycardia (this drug is not effective in converting these arrhythmias to sinus rhythm). The manufacturer states that Adenoscan® should be avoided in patients with known or suspected bronchoconstrictive or bronchospastic lung disease.

Warnings

Adenosine decreases conduction through the AV node and may produce first-, second-, or third-degree heart block. Patients with pre-existing S-A nodal dysfunction may experience prolonged sinus pauses after adenosine; use caution in patients with first-degree AV block or bundle branch block; avoid use of adenosine for pharmacologic stress testing in patients with high-grade AV block or sinus node dysfunction (unless a functional pacemaker is in place). There have been reports of atrial fibrillation/flutter in patients with PSVT associated with accessory conduction pathways after adenosine. Rare, prolonged episodes of asystole have been reported, with fatal outcomes in some cases. Use caution in patients receiving other drugs which slow AV conduction (eg, digoxin, verapamil). Drugs which affect adenosine (theophylline, caffeine) should be withheld for five half-lives prior to adenosine use. Avoid dietary caffeine for 12-24 hours prior to pharmacologic stress testing.

Adenosine may also produce profound vasodilation with subsequent hypotension. When used as a bolus dose (PSVT), effects are generally self-limiting (due to the short half-life of adenosine). However, when used as a continuous infusion (pharmacologic stress testing), effects may be more pronounced and persistent, corresponding to continued exposure. Adenosine infusions should be used with caution in patients with autonomic dysfunction, stenotic valvular heart disease, pericarditis, pleural effusion, carotid stenosis (with cerebrovascular insufficiency), or uncorrected hypovolemia. Use caution in elderly patients; may be at increased risk of hemodynamic effects, bradycardia, and/or AV block.

A limited number of patients with asthma have received adenosine and have not experienced exacerbation of their asthma. Adenosine may cause bronchoconstriction in patients with asthma, and should be used cautiously in patients with obstructive lung disease not associated with bronchoconstriction (eg, emphysema, bronchitis).

Adenocard®: Transient AV block is expected. When used in PSVT, at the time of conversion to normal sinus rhythm, a variety of new rhythms may appear on the ECG. Administer as a rapid bolus, either directly into a vein or (if administered into an I.V. line), as close to the patient as possible (followed by saline flush).

Dosage Forms

Injection, solution [preservative free]: 3 mg/mL (2 mL, 4 mL)

Adenocard®: 3 mg/mL (2 mL, 4 mL)

Adenoscan®: 3 mg/mL (20 mL, 30 mL)

Reference Range 0.1-1.0 µmol/L

Overdosage/Treatment Supportive therapy: I.V. fluids for hypotensive effect; aminophylline may antagonize effects. External pacing may be required.

Drug Interactions

Carbamazepine may increase heart block.

Dipyridamole potentiates effects of adenosine; reduce dose of adenosine.

Adenosine

Pronunciation (a DEN oh seen)

CAS Number 56-56-5; 58-61-7

U.S. Brand Names Adenocard®; Adenoscan®

Synonyms 9-Beta-D-Ribofuranosyladenine

Use Adenocard®: Treatment of paroxysmal supraventricular tachycardia (PSVT) including that associated with accessory bypass tracts (Wolff-Parkinson-White syndrome); when clinically advisable, appropriate vagal maneuvers should be attempted prior to adenosine administration; **not effective in atrial flutter, atrial fibrillation, or ventricular tachycardia**
Adenoscan®: Pharmacologic stress agent used in myocardial perfusion thallium-201 scintigraphy

Unlabeled/Investigational Use Adenoscan®: Acute vasodilator testing in pulmonary artery hypertension

Mechanism of Action Endogenous nucleoside; produces transient atrioventricular block and coronary vasodilatation; slows conduction time through the AV node, interrupting the re-entry pathways through the AV node, restoring normal sinus rhythm. No direct ventricular effect.

Adverse Reactions

Cardiovascular: **Facial flushing, palpitations, chest pain, hypotension**, fibrillation (atrial) may last for up to 5 hours, flutter (atrial), sinus bradycardia, angina, arrhythmias (ventricular), vasodilation, AV block
Central nervous system: Lightheadedness, dizziness, tingling in arms, numbness, fear, burning sensation, **headache**, heaviness in arms, neck and back, pain

Gastrointestinal: Nausea, metallic taste, tightness in throat, pressure in groin

Ocular: Blurred vision

Respiratory: **Dyspnea**, bronchospasm, chest pressure, hypoventilation

Miscellaneous: **Diaphoresis**

Signs and Symptoms of Overdose Arrhythmias, bradycardia, hypotension, lightheadedness, numbness, urine discoloration (milky), wheezing

Pharmacodynamics/Kinetics

Onset of action: Rapid

Duration: Very brief

Metabolism: Blood and tissue to inosine then to adenosine monophosphate (AMP) and hypoxanthine

Half-life elimination: < 10 seconds

Dosage

Adenocard®: **Rapid I.V. push (over 1-2 seconds) via peripheral line:**
Infants and Children:

Manufacturer's recommendation:

< 50 kg: 0.05 to 0.1 mg/kg. If conversion of PSVT does not occur within 1-2 minutes, may increase dose by 0.05 to 0.1 mg/kg.
May repeat until sinus rhythm is established or to a maximum

ALBENDAZOLE

Theophylline and caffeine (methylxanthines) antagonize adenosine's effects; may require increased dose of adenosine.

Pregnancy Risk Factor C

Pregnancy Implications Reports of administration during pregnancy have indicated no adverse effects on fetus or newborn attributable to adenosine.

Lactation Excretion in breast milk unknown

Additional Information No negative inotropic effect; may be effective against theophylline-induced seizures

Specific References

Albendazole

Pronunciation (al BEN da zole)

CAS Number 54965-21-8

U.S. Brand Names Albenza®

Use Treatment of parenchymal neurocysticercosis caused by *Taenia solium* and cystic hydatid disease of the liver, lung, and peritoneum caused by *Echinococcus granulosus*

Unlabeled/Investigational Use Albendazole has activity against *Ascaris lumbricoides* (roundworm); *Ancylostoma caninum*; *Ancylostoma duodenale* and *Necator americanus* (hookworms); cutaneous larva migrans; *Enterobius vermicularis* (pinworm); *Gnathostoma spinigerum*; *Gongylo-nema* sp; *Hymenolepis nana* sp (tapeworms); *Mansonella perstans* (filariasis); *Opisthorchis sinensis* and *Opisthorchis viverrini* (liver flukes); *Strongyloides stercoralis* and *Trichuris trichiura* (whipworm); visceral larva migrans (toxocariasis); activity has also been shown against the liver fluke *Clonorchis sinensis*, *Giardia lamblia*, *Cysticercus cellulosae*, and *Echinococcus multilocularis*. Albendazole has also been used for the treatment of intestinal microsporidiosis (*Encephalitozoon intestinalis*), disseminated microsporidiosis (*E. hellem*, *E. cuniculi*, *E. intestinalis*, *Pleistophora* sp, *Trachipleistophora* sp, *Brachiola vesicularum*), and ocular microsporidiosis (*E. hellem*, *E. cuniculi*, *Vittaforma corneae*).

Mechanism of Action Active metabolite, albendazole, causes selective degeneration of cytoplasmic microtubules in intestinal and tegmental cells of intestinal helminths and larvae; glycogen is depleted, glucose uptake and cholinesterase secretion are impaired, and desecratory substances accumulate intracellularly. ATP production decreases causing energy depletion, immobilization, and worm death; albendazole has activity against *Ascaris lumbricoides* (roundworm), *Ancylostoma duodenale* and *Necator americanus* (hookworms), *Enterobius vermicularis* (pinworm), *Hymenolepis nana* and *Taenia* sp (tapeworms), *Opisthorchis sinensis* and *Opisthorchis viverrini* (liver flukes), *Strongyloides stercoralis* and *Trichuris trichiura* (whipworm); activity has also been shown against the liver fluke *Clonorchis sinensis*, *Giardia lamblia*, *Cysticercus cellulosae*, *Echinococcus granulosus* and *multilocularis*, and *Toxocara* sp.

Adverse Reactions

N = Neurocysticercosis; H = Hydatid disease

> 10%:

Central nervous system: Headache (11% - N; 1% - H)

Hepatic: LFTs Increased (~15% - H; <1% - N)

1% to 10%:

Central nervous system: Dizziness, vertigo, fever ($\leq 1\%$); intracranial pressure increased (1% - N), meningeal signs (1% - N)

Dermatologic: Alopecia (2% - H; <1% - N)

Gastrointestinal: Abdominal pain (6% - H; 0% - N); nausea/vomiting (3% to 6%)

Hematologic: Leukopenia (reversible) (<1%)

Miscellaneous: Allergic reactions (<1%)

<1%: Acute renal failure, agranulocytopenia, allergic reactions, granulocytopenia, pancytopenia, rash, thrombocytopenia, urticaria

Pharmacodynamics/Kinetics

Absorption: <5%; may increase up to 4-5 times when administered with a fatty meal

Distribution: Well inside hydatid cysts and CSF

Protein binding: 70%

Metabolism: Hepatic; extensive first-pass effect; pathways include rapid sulfoxidation (major), hydrolysis, and oxidation

Half-life elimination: 8-12 hours

Time to peak, serum: 2-2.4 hours

Excretion: Urine (<1% as active metabolite); feces

Dosage

Oral:

Children:

Cysticercus cellulosae (unlabeled use): 15 mg/kg/day (maximum: 800 mg/day) in 2 divided doses for 8-30 days; may be repeated as necessary

Echinococcus granulosus (tapeworm) (unlabeled use): 15 mg/kg/day (maximum: 800 mg) divided twice daily for 1-6 months

Children and Adults:

Neurocysticercosis:

<60 kg: 15 mg/kg/day in 2 divided doses (maximum: 800 mg/day) for 8-30 days

≥ 60 kg: 400 mg twice daily for 8-30 days

Note: Give concurrent anticonvulsant and steroid therapy during first week.

Hydatid:

<60 kg: 15 mg/kg/day in 2 divided doses (maximum: 800 mg/day) ≥ 60 kg: 400 mg twice daily

Note: Administer dose for three 28-day cycles with a 14-day drug-free interval in between.

Ancylostoma caninum, *Ascaris lumbricoides* (roundworm), *Ancylostoma duodenale*, and *Necator americanus* (hookworms) (unlabeled use): 400 mg as a single dose

Clonorchis sinensis (Chinese liver fluke) (unlabeled use): 10 mg/kg for 7 days

Cutaneous larva migrans (unlabeled use): 400 mg once daily for 3 days

Enterobius vermicularis (pinworm) (unlabeled use): 400 mg as a single dose; may repeat in 2 weeks

Gnathostoma spinigerum (unlabeled use): 400 mg twice daily for 21 days

Gongylo-nemiasis (unlabeled use): 10 mg/kg/day for 3 days

Mansonella perstans (unlabeled use): 400 mg twice daily for 10 days

Visceral larva migrans (toxocariasis) (unlabeled use): 400 mg twice daily for 5 days

Adults:

Cysticercus cellulosae (unlabeled use): 400 mg twice daily for 8-30 days; may be repeated as necessary

Disseminated microsporidiosis (unlabeled use): 400 mg twice daily

Echinococcus granulosus (tapeworm) (unlabeled use): 400 mg twice daily for 1-6 months

Intestinal microsporidiosis (unlabeled use): 400 mg twice daily for 21 days

Ocular microsporidiosis (unlabeled use): 400 mg twice daily, in combination with fumagillin

Monitoring Parameters Monitor fecal specimens for ova and parasites for 3 weeks after treatment; if positive, retreat; monitor LFTs, and clinical signs of hepatotoxicity; CBC at start of each 28-day cycle and every 2 weeks during therapy

Administration

Administer with meals. Administer anticonvulsant and steroid therapy during first week of neurocysticercosis therapy.

Contraindications Hypersensitivity to albendazole or any component of the formulation

Warnings

Discontinue therapy if LFT elevations are significant; may restart treatment when decreased to pretreatment values. Becoming pregnant within 1 month following therapy is not advised.

Neurocysticercosis: Corticosteroids should be administered 1-2 days before albendazole therapy to minimize inflammatory reactions. Steroid and anticonvulsant therapy should be used concurrently during the first week of therapy to prevent cerebral hypertension. If retinal lesions exist, weigh risk of further retinal damage due to albendazole-induced changes to the retinal lesion vs benefit of disease treatment.

Dosage Forms Tablet: 200 mg

Reference Range Peak plasma albendazole sulphoxide level following an oral dose of 400 mg ranges from 0.04-0.14 mcg/mL

Overdosage/Treatment

Decontamination: Emesis within 30 minutes/lavage within 1 hour; activated charcoal

Enhanced elimination: Hemodialysis is not useful

Drug Interactions **Substrate** (minor) of CYP1A2, 3A4; **Inhibits** CYP1A2 (weak)

Pregnancy Risk Factor C

Pregnancy Implications Albendazole has been shown to be teratogenic in laboratory animals and should not be used during pregnancy, if at all possible. Women should be advised to avoid pregnancy for at least 1 month following therapy. Discontinue if pregnancy occurs during treatment.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Should be taken with a high fat meal

Albuterol

Pronunciation (al BYOO ter ole)

Related Information

● Clenbuterol

CAS Number 18559-94-9

U.S. Brand Names AccuNeb™, Proventil® HFA; Proventil® Repetabs®; Proventil®; Ventolin® HFA; Ventolin® [DSC]; Volmax®; VoSpire ER™

Synonyms Albuterol Sulfate; Salbutamol

Use Bronchodilator in reversible airway obstruction due to asthma or COPD; prevention of exercise-induced bronchospasm

Mechanism of Action Relaxes bronchial smooth muscle by action on β_2 -receptors with little effect on heart rate

Adverse Reactions

Cardiovascular: **Tachycardia** (slight), **palpitations**, hypertension, flushing, shortened P-R segment, lengthened QT segment, cardiac arrhythmias, fibrillation (atrial), flutter (atrial), chest pain, tachycardia (supraventricular), torsade de pointes, sinus tachycardia, **pounding heartbeat**

Central nervous system: Dizziness, psychosis, headache, **nervousness**, CNS stimulation, hyperactivity, insomnia, mania

Dermatologic: Maculopapular rash, pruritus

Endocrine & metabolic: Hypokalemia, hyperglycemia

Gastrointestinal: **GI upset, nausea, xerostomia**

Neuromuscular & skeletal: **Tremor**

Miscellaneous: Systemic lupus erythematosus

Signs and Symptoms of Overdose Agitation, angina, diplopia, hyperglycemia, hypertension, hypokalemia, hypomagnesemia, increased intraocular pressure, seizures, thrombocytopenia, tachycardia, tremor. Cardiac arrest and death may be associated with abuse of beta-agonist bronchodilators.

Pharmacodynamics/Kinetics

Onset of action: Peak effect:

Nebulization/oral inhalation: 0.5-2 hours

CFC-propelled albuterol: 10 minutes

Ventolin[®] HFA: 25 minutes

Oral: 2-3 hours

Duration: Nebulization/oral inhalation: 3-4 hours; Oral: 4-6 hours

Metabolism: Hepatic to an inactive sulfate

Half-life elimination: Inhalation: 3.8 hours; Oral: 3.7-5 hours

Excretion: Urine (30% as unchanged drug)

Dosage

Oral:

Children: Bronchospasm (treatment):

2-6 years: 0.1-0.2 mg/kg/dose 3 times/day; maximum dose not to exceed 12 mg/day (divided doses)

6-12 years: 2 mg/dose 3-4 times/day; maximum dose not to exceed 24 mg/day (divided doses)

Extended release: 4 mg every 12 hours; maximum dose not to exceed 24 mg/day (divided doses)

Children > 12 years and Adults: Bronchospasm (treatment): 2-4 mg/dose 3-4 times/day; maximum dose not to exceed 32 mg/day (divided doses)

Extended release: 8 mg every 12 hours; maximum dose not to exceed 32 mg/day (divided doses). A 4 mg dose every 12 hours may be sufficient in some patients, such as adults of low body weight.

Elderly: Bronchospasm (treatment): 2 mg 3-4 times/day; maximum: 8 mg 4 times/day

Inhalation: MDI 90 mcg/puff:

Children \leq 12 years:

Bronchospasm (acute): 4-8 puffs every 20 minutes for 3 doses, then every 1-4 hours; spacer/holding-chamber device should be used

Exercise-induced bronchospasm (prophylaxis): 1-2 puffs 5 minutes prior to exercise

Children > 12 years and Adults:

Bronchospasm (acute): 4-8 puffs every 20 minutes for up to 4 hours, then every 1-4 hours as needed

Exercise-induced bronchospasm (prophylaxis): 2 puffs 5-30 minutes prior to exercise

Children \geq 4 years and Adults: Bronchospasm (chronic treatment): 1-2 inhalations every 4-6 hours; maximum: 12 inhalations/day

NIH guidelines: 2 puffs 3-4 times a day as needed; may double dose for mild exacerbations

Nebulization:

Children \leq 12 years:

Bronchospasm (treatment): 0.05 mg/kg every 4-6 hours; minimum dose: 1.25 mg, maximum dose: 2.5 mg

2-12 years: AccuNeb[™]: 0.63 mg or 1.25 mg 3-4 times/day, as needed, delivered over 5-15 minutes

Children > 40 kg, patients with more severe asthma, or children 11-12 years: May respond better with a 1.25 mg dose

Bronchospasm (acute): Solution 0.5%: 0.15 mg/kg (minimum dose: 2.5 mg) every 20 minutes for 3 doses, then 0.15-0.3 mg/kg (up to 10 mg) every 1-4 hours as needed; may also use 0.5 mg/kg/hour by continuous infusion. Continuous nebulized albuterol at 0.3 mg/kg/hour has been used safely in the treatment of severe status asthmaticus in children; continuous nebulized doses of 3 mg/kg/hour \pm 2.2 mg/kg/hour in children whose mean age was 20.7 months resulted in no cardiac toxicity; the optimal dosage for continuous nebulization remains to be determined.

Note: Use of the 0.5% solution should be used for bronchospasm (acute or treatment) in children < 15 kg. AccuNeb[™] has not been studied for the treatment of acute bronchospasm; use of the 0.5% concentrated solution may be more appropriate.

Children > 12 years and Adults:

Bronchospasm (treatment): 2.5 mg, diluted to a total of 3 mL, 3-4 times/day over 5-15 minutes

NIH guidelines: 1.25-5 mg every 4-8 hours

Bronchospasm (acute) in intensive care patients: 2.5-5 mg every 20 minutes for 3 doses, then 2.5-10 mg every 1-4 hours as needed, or 10-15 mg/hour continuously

Hemodialysis: Not removed

Peritoneal dialysis: Significant drug removal is unlikely based on physicochemical characteristics

Monitoring Parameters FEV₁, peak flow, and/or other pulmonary function tests; blood pressure, heart rate; CNS stimulation; serum glucose, serum potassium; asthma symptoms; arterial or capillary blood gases (if patients condition warrants)

Administration

Inhalation: MDI: Shake well before use; prime prior to first use, and whenever inhaler has not been used for > 2 weeks or when it has been dropped, by releasing 4 test sprays into the air (away from face)

Oral: Do not crush or chew extended release tablets.

Contraindications Hypersensitivity to albuterol, adrenergic amines, or any component of the formulation

Warnings

Optimize anti-inflammatory treatment before initiating maintenance treatment with albuterol. Do not use as a component of chronic therapy without an anti-inflammatory agent. Only the mildest forms of asthma (Step 1 and/or exercise-induced) would not require concurrent use based upon asthma guidelines. Patient must be instructed to seek medical attention in cases where acute symptoms are not relieved or a previous level of response is diminished. The need to increase frequency of use may indicate deterioration of asthma, and treatment must not be delayed.

Use caution in patients with cardiovascular disease (arrhythmia or hypertension or CHF), convulsive disorders, diabetes, glaucoma, hyperthyroidism, or hypokalemia. Beta agonists may cause elevation in blood pressure, heart rate, and result in CNS stimulation/excitation. β_2 agonists may increase risk of arrhythmia, increase serum glucose, or decrease serum potassium.

Do not exceed recommended dose; serious adverse events, including fatalities, have been associated with excessive use of inhaled sympathomimetics. Rarely, paradoxical bronchospasm may occur with use of inhaled bronchodilating agents; this should be distinguished from inadequate response. All patients should utilize a spacer device when using a metered-dose inhaler; in addition, face masks should be used in children < 4 years of age.

Because of its minimal effect on β_1 -receptors and its relatively long duration of action, albuterol is a rational choice in the elderly when an inhaled beta agonist is indicated. Oral use should be avoided in the elderly due to adverse effects. Patient response may vary between inhalers that contain chlorofluorocarbons and those which are chlorofluorocarbon-free.

Dosage Forms

Aerosol, for oral inhalation: 90 mcg/metered inhalation (17 g) [200 metered inhalations; contains chlorofluorocarbons]

Proventil[®]: 90 mcg/metered inhalation (17 g) [200 metered inhalations; contains chlorofluorocarbons]

Aerosol, for oral inhalation:

ProAir[™] HFA: 90 mcg/metered inhalation (8.5 g) [200 metered inhalations; chlorofluorocarbon free]

Proventil[®] HFA: 90 mcg/metered inhalation (6.7 g) [200 metered inhalations; chlorofluorocarbon free]

Ventolin[®] HFA: 90 mcg/metered inhalation (18 g) [200 metered inhalations; chlorofluorocarbon free]

Solution for nebulization: 0.042% (3 mL); 0.083% (3 mL); 0.5% (0.5 mL, 20 mL)

AccuNeb[®] [preservative free]: 0.63 mg/3 mL (3 mL) [0.021%]; 1.25 mg/3 mL (3 mL) [0.042%]

Proventil[®]: 0.083% (3 mL) [preservative free]; 0.5% (20 mL) [contains benzalkonium chloride]

Syrup, as sulfate: 2 mg/5 mL (480 mL)

Tablet: 2 mg, 4 mg

Tablet, extended release:

VoSpire ER[®]: 4 mg, 8 mg

Reference Range Serum albuterol levels > 25 ng/mL associated with increased cardiac toxicity; a level of 160 ng/mL was fatal

Overdosage/Treatment In cases of overdose, symptomatic and supportive therapies should be instituted, and prudent use of a cardioselective beta-adrenergic blocker (eg, atenolol or metoprolol) should be considered, keeping in mind the potential for induction of bronchoconstriction in an asthmatic individual. Adenosine may be effective in the management of tachycardia (ventricular); dialysis has not been shown to be of value in the treatment of an overdose with this agent.

Diagnostic Procedures

- Electrolytes, Blood

Drug Interactions**Substrate of CYP3A4 (major)**

Beta-adrenergic blockers (eg, propranolol) antagonize albuterol's effects; avoid concurrent use.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of albuterol. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

Halothane may increase risk of malignant arrhythmias; avoid concurrent use.

Inhaled ipratropium may increase duration of bronchodilation.

MAO inhibitors may increase side effects; monitor heart rate and blood pressure.

TCAs may increase side effects; monitor heart rate and blood pressure.

Sympathomimetics may increase side effects; monitor heart rate and blood pressure.

Pregnancy Risk Factor C

Pregnancy Implications Albuterol crosses the placenta; tocolytic effects, fetal tachycardia, fetal hypoglycemia secondary to maternal hyperglycemia with oral or intravenous routes reported. Available evidence suggests safe use during pregnancy.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Before using, the inhaler must be shaken well; assess lung sounds, pulse, and blood pressure before administration and during peak of medication; observe patient for wheezing after administration, if this occurs, call physician

Aldesleukin

Pronunciation (al des LOO kin)

U.S. Brand Names Proleukin®

Synonyms Epidermal Thymocyte Activating Factor; ETAF; IL-2; Interleukin-2; Lymphocyte Mitogenic Factor; NSC-373364; T-Cell Growth Factor; TCGF; Thymocyte Stimulating Factor

Use Primarily investigated in tumors known to have a response to immunotherapy, such as melanoma and metastatic renal cell carcinoma; has been used in conjunction with LAK cells, TIL cells, IL-1, and interferon

Unlabeled/Investigational Use Investigational: Multiple myeloma, HIV infection, and AIDS; may be used in conjunction with lymphokine-activated killer (LAK) cells, tumor-infiltrating lymphocyte (TIL) cells, interleukin-1, and interferons; colorectal cancer; non-Hodgkin's lymphoma; atopic eczema; chronic active Epstein-Barr infection

Mechanism of Action Aldesleukin promotes proliferation, differentiation, and recruitment of T and B cells, natural killer (NK) cells, and thymocytes; aldesleukin also causes cytolytic activity in a subset of lymphocytes and subsequent interactions between the immune system and malignant cells; aldesleukin can stimulate lymphokine-activated killer (LAK) cells and tumor-infiltrating lymphocytes (TIL) cells. LAK cells (which are derived from lymphocytes from a patient and incubated in aldesleukin) have the ability to lyse cells which are resistant to NK cells; TIL cells (which are derived from cancerous tissue from a patient and incubated in aldesleukin) have been shown to be 50% more effective than LAK cells in experimental studies.

Adverse Reactions

Cardiovascular: **Hypotension (85%), dose-limiting, possibly fatal; sinus tachycardia (70%); arrhythmias (22%); edema (47%); angina;** capillary-leak syndrome, including peripheral edema, ascites, pulmonary infiltration, and pleural effusion, may be dose-limiting and potentially fatal; myocardial infarction, congestive heart failure

Central nervous system: **Mental status changes (transient memory loss, confusion, drowsiness) (73%); dizziness (17%); cognitive**

changes, fatigue, malaise, somnolence and disorientation (25%); headaches, insomnia, paranoid delusion, seizures, coma

Dermatologic: **Macular erythematous rash (100% of patients on high-dose therapy); pruritus (48%); erythema (41%); rash (26%); exfoliative dermatitis (14%); dry skin (15%), alopecia**

Endocrine & metabolic: **Fever and chills (89%); low electrolyte levels (magnesium, calcium, phosphate, potassium, sodium) (1% to 15%); hypo- and hyperglycemia, increased electrolyte levels (magnesium, calcium, phosphate, potassium, sodium), hypothyroidism**

Gastrointestinal: **Nausea and vomiting (87%); diarrhea (76%); stomatitis (32%); GI bleeding (13%); weight gain (23%), anorexia (27%), pancreatitis**

Hematologic: **Anemia (77%); thrombocytopenia (64%); leukopenia (34%) - may be dose-limiting; coagulation disorders (10%)**

Hepatic: **Transient elevations of bilirubin (64%) and enzymes (56%); jaundice, ascites**

Local: Injection site reactions (SubQ doses)

Neuromuscular & skeletal: **Weakness; rigors** - respond to acetaminophen, diphenhydramine, an NSAID, or meperidine; arthralgia, myalgia

Renal: **Oliguria/anuria (63%, severe in 5% to 6%), proteinuria; renal failure** (dose-limiting toxicity) manifested as oliguria noted within 24-48 hours of initiation of therapy; marked **fluid retention, azotemia, and increased serum creatinine** seen, which may return to baseline within 7 days of discontinuation of therapy; **hypophosphatemia, hematuria, increased creatinine**

Respiratory: **Congestion (54%), dyspnea (27% to 52%), edema, pleural effusions**

Miscellaneous: **Pain (54%), infection (including sepsis and endocarditis) due to neutrophil impairment (23%), allergic reactions**

Pharmacodynamics/Kinetics

Distribution: V_d : 4-7 L; primarily in plasma and then in the lymphocytes

Bioavailability: I.M.: 37%

Half-life elimination: Initial: 6-13 minutes; Terminal: 80-120 minutes

Toxicodynamics/Kinetics

Absorption: Oral: Not absorbed; I.M., subcutaneous: 2% absorbed

Metabolism: Renal tubular catabolism

Dosage

Refer to individual protocols.

I.V.:

Renal cell carcinoma: 600,000 int. units/kg every 8 hours for a maximum of 14 doses; repeat after 9 days of rest for a total of 28 doses per course. Re-evaluate at 4 weeks. Retreat if needed 7 weeks after hospital discharge from previous course.

Melanoma:

Single-agent use: 600,000 int. units/kg every 8 hours for a maximum of 14 doses; repeat after 9 days of rest for a total of 28 doses per course. Re-evaluate at 4 weeks. Retreat if needed 7 weeks after hospital discharge from previous course.

In combination with cytotoxic agents: 24 million int. units/m² days 12-16 and 19-23

SubQ:

Single-agent doses: 3-18 million int. units/day for 5 days weekly and repeated weekly up to 6 weeks

In combination with interferon:

5 million int. units/m² 3 times/week

1.8 million int. units/m² twice daily 5 days/week for 6 weeks

Investigational regimen: SubQ: 11 million int. units (flat dose) daily × 4 days per week for 4 consecutive weeks; repeat every 6 weeks

Stability

Store vials of lyophilized injection in a refrigerator at 2°C to 8°C (36°F to 46°F). Reconstitute vials with 1.2 mL SWFI. Gently swirl; do not shake. Further dilute with 50 mL of D₅W. Smaller volumes of D₅W should be used for doses <1.5 mg; avoid concentrations <30 mcg/mL and >70 mcg/mL (an increased variability in drug delivery has been seen). Reconstituted vials and solutions diluted for infusion are stable for 48 hours at room temperature or refrigerated, per the manufacturer. Solution diluted with D₅W to a concentration of 220 mg/mL and repackaged into tuberculin syringes was reported to be stable for 14 days refrigerated.

Note: Filtration will result in significant loss of bioactivity

Recommendations for aldesleukin dilution:

Final dilution concentration <30 mcg/mL (<0.49 10⁶ int. units/mL):

Albumin must be added to bag prior to addition of aldesleukin at a final concentration of 0.1% (1 mg/mL) albumin; stable at room temperature or at ≥32°C (89°F) for 6 days. Continuous infusion via ambulatory infusion device raises aldesleukin to this temperature. These solutions do not contain a preservative; use for more than 24 hours may not be advisable.

Final dilution concentration ≥30 mcg/mL and ≤70 mcg/mL (≥0.49 and ≤1.1 10⁶ int. units/mL): Stable at room temperature for 6 days without albumin added or at ≥32°C (89°F) for 6 days only if albumin (0.1%) is added. (Continuous infusion via ambulatory infusion device raises aldesleukin to this temperature.) These solutions do not contain a preservative; use for more than 24 hours may not be advisable.

Final dilution concentration 70-100 mcg/mL (1.2-1.6 10⁶ int. units/mL): Unstable; avoid use.

Final dilution concentration > 100-500 mcg/mL (1.7-8.2 10⁶ int. units/mL): Stable at room temperature and at $\geq 32^{\circ}\text{C}$ ($\geq 89^{\circ}\text{F}$) for 6 days. Continuous infusion via ambulatory infusion pump or similar infusion device raises aldesleukin to this temperature. These solutions do not contain a preservative; use for more than 24 hours may not be advisable.

Monitoring Parameters: The following clinical evaluations are recommended for all patients prior to beginning treatment and then frequently during drug administration:

Standard hematologic tests including CBC, differential, and platelet counts; blood chemistries including electrolytes, renal and hepatic function tests

Chest x-rays

Monitoring during therapy should include vital signs (temperature, pulse, blood pressure, and respiration rate) and weight; in a patient with a decreased blood pressure, especially <90 mm Hg, cardiac monitoring for rhythm should be conducted. If an abnormal complex or rhythm is seen, an ECG should be performed; vital signs in these hypotension patients should be taken hourly and central venous pressure (CVP) checked.

During treatment, pulmonary function should be monitored on a regular basis.

Administration

Administer as I.V. infusion over 15 minutes; may be administered by SubQ injection

Management of symptoms related to vascular leak syndrome:

If actual body weight increases >10% above baseline, or rales or rhonchi are audible:

Administer furosemide at dosage determined by patient response

Administer dopamine hydrochloride 2-4 mcg/kg/minute to maintain renal blood flow and urine output

If patient has dyspnea at rest: Administer supplemental oxygen by face mask

If patient has severe respiratory distress: Intubate patient and provide mechanical ventilation; administer ranitidine (as the hydrochloride salt), 50 mg I.V. every 8-12 hours as prophylaxis against stress ulcers

Contraindications Hypersensitivity to aldesleukin or any component of the formulation; patients with abnormal thallium stress or pulmonary function tests; patients who have had an organ allograft; retreatment in patients who have experienced sustained ventricular tachycardia (≥ 5 beats), refractory cardiac rhythm disturbances, recurrent chest pain with ECG changes consistent with angina or myocardial infarction, intubation ≥ 72 hours, pericardial tamponade, renal dialysis for ≥ 72 hours, coma or toxic psychosis lasting ≥ 48 hours, repetitive or refractory seizures, bowel ischemia/perforation, GI bleeding requiring surgery

Warnings

Hazardous agent - use appropriate precautions for handling and disposal.

[U.S. Boxed Warning]: High-dose aldesleukin therapy has been associated with capillary leak syndrome (CLS) resulting in hypotension and reduced organ perfusion which may be severe and can result in death. Therapy should be restricted to patients with normal cardiac and pulmonary functions as defined by thallium stress and formal pulmonary function testing. Extreme caution should be used in patients with a history of prior cardiac or pulmonary disease. Patients must have a serum creatinine ≤ 1.5 mg/dL prior to treatment.

[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician in a facility with cardiopulmonary or intensive specialists and intensive care facilities available. Adverse effects are frequent and sometimes fatal. May exacerbate pre-existing or initial presentation of autoimmune diseases and inflammatory disorders. Patients should be evaluated and treated for CNS metastases and have a negative scan prior to treatment. Mental status changes (irritability, confusion, depression) can occur and may indicate bacteremia, hypoperfusion, CNS malignancy, or CNS toxicity.

[U.S. Boxed Warning]: Impaired neutrophil function is associated with treatment; patients are at risk for sepsis, bacterial endocarditis, and central line-related gram-positive infections. Antibiotic prophylaxis which has been associated with a reduced incidence of staphylococcal infections in aldesleukin studies includes the use of oxacillin, nafcillin, ciprofloxacin, or vancomycin.

[U.S. Boxed Warning]: Withhold treatment for patients developing moderate-to-severe lethargy or somnolence; continued treatment may result in coma. Standard prophylactic supportive care during high-dose aldesleukin treatment includes acetaminophen to relieve constitutional symptoms and an H₂ antagonist to reduce the risk of GI ulceration and/or bleeding.

Dosage Forms Injection, powder for reconstitution: 22 \times 10⁶ int. units [18 million int. units/mL = 1.1 mg/mL when reconstituted]

Overdosage/Treatment Supportive therapy: Hypotension should be treated with I.V. crystalloid infusion; vasopressor therapy should be

used for refractory hypotension; atropine can be used to treat symptomatic bradycardia; rigors can be treated with acetaminophen or ibuprofen and meperidine; droperidol can be used to control nausea and vomiting, while diphenoxylate/atropine can be used to treat diarrhea; pruritus can be treated with diphenhydramine and hydroxyzine; peptic ulcers can be treated with ranitidine

Drug Interactions

Beta-blockers and other antihypertensives may potentiate the hypotension seen with aldesleukin.

Corticosteroids: Have been shown to decrease toxicity of aldesleukin, but may decrease the efficacy of the lymphokine.

Increased toxicity: Concomitant administration of drugs possessing nephrotoxic (eg, aminoglycosides, indomethacin), myelotoxic (eg, cytotoxic chemotherapy), cardiotoxic (eg, doxorubicin), or hepatotoxic effects with aldesleukin may increase toxicity in these organ systems.

Iodinated contrast media: Acute reactions including fever, chills, nausea, vomiting, pruritus, rash, diarrhea, hypotension, edema, and oliguria have occurred within hours of contrast infusion; this reaction may occur within 4 weeks or up to several months after aldesleukin administration.

Psychotropic agents: Aldesleukin may affect central nervous function; therefore, interactions could occur following concomitant administration of psychotropic drugs (eg, narcotics, analgesics, antiemetics, sedatives, tranquilizers).

Pregnancy Risk Factor C

Pregnancy Implications There are no adequate and well-controlled studies in pregnant women; use during pregnancy only if benefits to the mother outweigh potential risk to the fetus. Contraception is recommended for fertile males or females using this medication.

Lactation Enters breast milk/contraindicated

Additional Information 1 Cetus unit = 6 int. units

1.1 mg = 18 \times 10⁶ int. units (or 3 \times 10⁶ Cetus units)

1 Roche unit (Teceleukin) = 3 int. units

Alendronate

Related Information

• Etidronate Disodium

CAS Number 121268-17-5; 66376-36-1

U.S. Brand Names Fosamax®

Synonyms Alendronate Sodium

Use Treatment and prevention of osteoporosis in postmenopausal females; treatment of osteoporosis in males; Paget's disease of the bone in patients who are symptomatic, at risk for future complications, or with alkaline phosphatase ≥ 2 times the upper limit of normal; treatment of glucocorticoid-induced osteoporosis in males and females with low bone mineral density who are receiving a daily dosage ≥ 7.5 mg of prednisone (or equivalent)

Mechanism of Action Aminobiphosphonate which inhibits osteoclastic bone resorption by binding to hydroxyapatite

Adverse Reactions

Note: Incidence of adverse effects increases significantly in patients treated for Paget's disease at 40 mg/day, mostly GI adverse effects.

Central nervous system: Headache

Dermatologic: Angioedema, photosensitivity (rare), pruritus, rash, urticaria, Stevens-Johnson syndrome, toxic epidermal necrolysis

Endocrine & metabolic: **Hypocalcemia** (transient, mild, 18%); **hypophosphatemia** (transient, mild, 10%), hypocalcemia (symptomatic)

Gastrointestinal: Abdominal pain, acid reflux, dyspepsia, nausea, flatulence, diarrhea, constipation, esophageal ulcer, gastroesophageal reflux disease, abdominal distension, gastritis, vomiting, dysphagia, gastric ulcer, melena, duodenal ulcer, esophageal erosions, esophageal perforation, esophageal stricture, esophagitis, taste perversion

Neuromuscular & skeletal: Musculoskeletal pain, muscle cramps

Ocular: Scleritis (rare), uveitis (rare)

Respiratory: Oropharyngeal ulceration

Miscellaneous: Hypersensitivity reactions

Pharmacodynamics/Kinetics

Distribution: 28 L (exclusive of bone)

Protein binding: $\sim 78\%$

Metabolism: None

Bioavailability: Fasting: 0.6%; reduced 60% with food or drink

Half-life elimination: Exceeds 10 years

Excretion: Urine; feces (as unabsorbed drug)

Toxicodynamics/Kinetics

Absorption: Oral: $\sim 1\%$ (reduced in presence of calcium and food)

Elimination: Renal: 50%

Dosage Oral: Adults: **Note:** Patients treated with glucocorticoids and those with Paget's disease should receive adequate amounts of calcium and vitamin D.

Osteoporosis in postmenopausal females:

Prophylaxis: 5 mg once daily or 35 mg once weekly

Treatment: 10 mg once daily or 70 mg once weekly

Osteoporosis in males: 10 mg once daily or 70 mg once weekly

Osteoporosis secondary to glucocorticoids in males and females:

Treatment: 5 mg once daily; a dose of 10 mg once daily should be used in postmenopausal females who are not receiving estrogen.

Paget's disease of bone in males and females: 40 mg once daily for 6 months

Retreatment: Relapses during the 12 months following therapy occurred in 9% of patients who responded to treatment. Specific retreatment data are not available. Retreatment with alendronate may be considered, following a 6-month post-treatment evaluation period, in patients who have relapsed based on increases in serum alkaline phosphatase, which should be measured periodically. Retreatment may also be considered in those who failed to normalize their serum alkaline phosphatase.

Elderly: No dosage adjustment is necessary

Dosage adjustment in renal impairment:

Cl_{cr} 35-60 mL/minute: None necessary

Cl_{cr} < 35 mL/minute: Alendronate is not recommended due to lack of experience

Dosage adjustment in hepatic impairment: None necessary

Monitoring Parameters Alkaline phosphatase should be periodically measured; serum calcium and phosphorus; monitor pain and fracture rate; hormonal status (male and female) prior to therapy; bone mineral density (should be done prior to initiation of therapy and after 6-12 months of combined glucocorticoid and alendronate treatment)

Administration

Alendronate must be taken with plain water (tablets 6-8 oz; oral solution 2 oz) first thing in the morning and ≥ 30 minutes before the first food, beverage, or other medication of the day. Patients should be instructed to stay upright (not to lie down) for at least 30 minutes **and** until after first food of the day (to reduce esophageal irritation). Patients should receive supplemental calcium and vitamin D if dietary intake is inadequate.

Contraindications Hypersensitivity to alendronate, other bisphosphonates, or any component of the formulation; hypocalcemia; abnormalities of the esophagus which delay esophageal emptying such as stricture or achalasia; inability to stand or sit upright for at least 30 minutes; oral solution should not be used in patients at risk of aspiration

Warnings

Use caution in patients with renal impairment (not recommended for use in patients with Cl_{cr} < 35 mL/minute); hypocalcemia must be corrected before therapy initiation; ensure adequate calcium and vitamin D intake. May cause irritation to upper gastrointestinal mucosa. Esophagitis, esophageal ulcers, esophageal erosions, and esophageal stricture (rare) have been reported; risk increases in patients unable to comply with dosing instructions. Use with caution in patients with dysphagia, esophageal disease, gastritis, duodenitis, or ulcers (may worsen underlying condition).

Bisphosphonate therapy has been associated with osteonecrosis, primarily of the jaw; this has been observed mostly in cancer patients, but also in patients with postmenopausal osteoporosis and other diagnoses. Risk factors include a diagnosis of cancer, with concomitant chemotherapy, radiotherapy, or corticosteroids; anemia, coagulopathy, infection, or pre-existing dental disease. Symptoms included nonhealing extraction socket or an exposed jawbone. There are no data addressing whether discontinuation of therapy reduces the risk of developing osteonecrosis; however, as a precautionary measure, dental exams and preventative dentistry should be performed prior to placing patients with risk factors on chronic bisphosphonate therapy. Invasive dental procedures should be avoided during treatment.

Infrequently, severe (and occasionally debilitating) bone, joint, and/or muscle pain have been reported during bisphosphonate treatment. The onset of pain ranged from a single day to several months. Symptoms usually resolve upon discontinuation. Some patients experienced recurrence when rechallenged with same drug or another bisphosphonate; avoid use in patients with a history of these symptoms in association with bisphosphonate therapy.

Safety and efficacy in children have not been established.

Dosage Forms

Note: Strength expressed as free acid

Solution, oral, as monosodium trihydrate:

FosamaxTM: 70 mg/75 mL [contains parabens; raspberry flavor]

Tablet, as sodium:

FosamaxTM: 5 mg, 10 mg, 35 mg, 40 mg, 70 mg

Reference Range After a 10 mg I.V. dose, peak serum level of alendronic acid is ~ 309 ng/mL

Overdosage/Treatment Supportive therapy: I.V. hydration; monitor urine flow and calcium and phosphorus level; for esophageal ulceration, discontinue the drug and give ranitidine 150 mg twice daily

Drug Interactions

Aminoglycosides: May lower serum calcium levels with prolonged administration. Concomitant use may have an additive hypocalcemic effect.

Antacids: May decrease the absorption of bisphosphonate derivatives; should be administered at a different time of the day. Antacids containing aluminum, calcium, or magnesium are of specific concern.

Calcium salts: May decrease the absorption of bisphosphonate derivatives. Separate oral dosing in order to minimize risk of interaction.

Iron salts: May decrease the absorption of bisphosphonate derivatives. Only oral iron salts and oral bisphosphonates are of concern.

Magnesium salts: May decrease the absorption of bisphosphonate derivatives. Only oral magnesium salts and oral bisphosphonates are of concern.

Nonsteroidal anti-inflammatory drugs (NSAIDs): May enhance the gastrointestinal adverse/toxic effects (increased incidence of GI ulcers) of bisphosphonate derivatives.

Phosphate supplements: Bisphosphonate derivatives may enhance the hypocalcemic effect of phosphate supplements.

Pregnancy Risk Factor C

Pregnancy Implications Safety and efficacy have not been established in pregnant women. Animal studies have shown delays in delivery and fetal/neonatal death (secondary to hypocalcemia). Bisphosphonates are incorporated into the bone matrix and gradually released over time. Theoretically, there may be a risk of fetal harm when pregnancy follows the completion of therapy. Based on limited case reports with pamidronate, serum calcium levels in the newborn may be altered if administered during pregnancy.

Lactation Excretion in breast milk unknown/use caution

Additional Information Better suited than etidronate for chronic therapy due to the fact that alendronic acid does not impair bone mineralization and thus does not increase the risk for osteomalacia. Rapid injection can lead to renal failure due to calcium bisphosphonate formation in renal tubules. Alendronate is 200-1000 times more potent than etidronate. Should be taken with a full glass of water; should not lie down for 30 minutes after taking this drug

Alfentanil

Pronunciation (al FEN ta nil)

CAS Number 64049-06-5; 70879-28-6; 71195-58-9

U.S. Brand Names Alfenta[®]

Synonyms Alfentanil Hydrochloride

Impairment Potential Yes

Use Analgesia; adjunct to anesthesia

Mechanism of Action Binds with stereospecific receptors at many sites within the CNS, increases pain threshold, alters pain perception, inhibits ascending pain pathways; is an ultra short-acting narcotic

Adverse Reactions

Cardiovascular: **Bradycardia, hypotension**, cardiac arrhythmias, hypotension (orthostatic), circulatory depression, sinus bradycardia, sinus tachycardia, **peripheral vasodilation**

Central nervous system: **Drowsiness**, confusion, CNS depression, seizures, agitation, paradoxical CNS excitation or delirium, dizziness, **sedation, increased intracranial pressure**, extrapyramidal symptoms

Dermatologic: Skin rash, hives, itching

Endocrine & metabolic: **Syndrome of inappropriate antidiuretic hormone release**

Gastrointestinal: **Nausea, vomiting**, biliary spasm, **constipation**

Genitourinary: Priapism

Neuromuscular & skeletal: Dysesthesia

Ocular: Blurred vision, **miosis**

Respiratory: Apnea, **respiratory depression** (at doses > 1000 mcg), bronchospasm, sinus arrest, apnea, laryngospasm

Miscellaneous: Cold, clammy skin, physical and psychological dependence with prolonged use

Signs and Symptoms of Overdose Clammy skin, CNS depression, dysphagia, hiccups, miosis, respiratory depression, seizures, wheezing

Pharmacodynamics/Kinetics

Onset of action: Rapid

Duration (dose dependent): 30-60 minutes

Distribution: V_d : Newborns, premature: 1 L/kg; Children: 0.163-0.48 L/kg;

Adults: 0.46 L/kg

Half-life elimination: Newborns, premature: 5.33-8.75 hours; Children: 40-60 minutes; Adults: 83-97 minutes

Toxicodynamics/Kinetics

Protein binding: 92%

Metabolism: Hepatic to noralfentanil

Dosage

Doses should be titrated to appropriate effects; wide range of doses is dependent upon desired degree of analgesia/anesthesia

Children < 12 years: Dose not established

Adults: Dose should be based on ideal body weight. See table.

Alfentanil					
Indication	Approx Duration of Anesthesia (min)	Induction Period (Initial Dose) (mcg/kg)	Maintenance Period (Increment-s/ Infusion)	Total Dose (mcg/kg)	Effects
Incremental injection	≤ 30	8-20	3-5 mcg/kg or 0.5-1 mcg/kg/min	8-40	Spontaneously breathing or assisted ventilation when required.
	30-60	20-50	5-15 mcg/kg	Up to 75	Assisted or controlled ventilation required. Attenuation of response to laryngoscopy and intubation.
Continuous infusion	> 45	50-75	0.5-3 mcg/kg/min average infusion rate 1-1.5 mcg/kg/min	Dependent on duration of procedure	Assisted or controlled ventilation required. Some attenuation of response to intubation and incision, with intraoperative stability.
Anesthetic induction	> 45	130-245	0.5-1.5 mcg/kg/min or general anesthetic	Dependent on duration of procedure	Assisted or controlled ventilation required. Administer slowly (over 3 minutes). Concentration of inhalation agents reduced by 30% to 50% for initial hour.

Stability Dilute in D₅W, normal saline, or LR

Monitoring Parameters Respiratory rate, blood pressure, heart rate

Administration

Administer I.V. slowly over 3-5 minutes or by I.V. continuous infusion

Contraindications Hypersensitivity to alfentanil hydrochloride, to narcotics, or any component of the formulation; increased intracranial pressure, severe respiratory depression

Warnings Use with caution in patients with drug dependence, head injury, acute asthma and respiratory conditions; hypotension has occurred in neonates with respiratory distress syndrome; use caution when administering to patients with bradyarrhythmias; rapid I.V. infusion may result in skeletal muscle and chest wall rigidity, impaired ventilation, or respiratory distress/arrest; inject slowly over 3-5 minutes; nondepolarizing skeletal muscle relaxant may be required. Alfentanil may produce more hypotension compared to fentanyl, therefore, be sure to administer slowly and ensure patient has adequate hydration.

Dosage Forms

Injection, solution [preservative free]: 500 mcg/mL (2 mL, 5 mL, 10 mL)

Alfenta[®]: 500 mcg/mL (2 mL, 5 mL, 10 mL, 20 mL)

Reference Range 100-340 ng/mL (depending upon procedure); 310-340 ng/mL adequate anesthesia for intra-abdominal surgery; 190 ng/mL adequate for skin closure; 100-200 ng/mL adequate for superficial surgery

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal for oral ingestion

Supportive therapy: Naloxone in large doses and/or a continuous infusion may be necessary

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Drug Interactions

Substrate of CYP3A4 (major)

Dextroamphetamine: May enhance the analgesic effect of morphine and other opiate agonists.

Increased toxicity with CNS depressants (eg, benzodiazepines, barbiturates, tricyclic antidepressants), erythromycin, reserpine, beta-blockers. CYP3A4 inhibitors: May increase the levels/effects of alfentanil. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Pregnancy Risk Factor C

Pregnancy Implications Neonatal respiratory depression can occur

Additional Information Alfentanil may produce more hypotension compared to fentanyl; therefore, administer slowly and ensure adequate hydration. Half-life is increased in burn patients. Since the drug does not release histamine, it can be used safely in patients with pheochromocytoma.

Alglucerase

Pronunciation (al GLOO ser ase)

CAS Number 143003-46-7

U.S. Brand Names Ceredase[®]

Synonyms Glucocerebrosidase

Use Replacement therapy for Gaucher's disease (type 1)

Mechanism of Action Glucocerebrosidase is an enzyme prepared from human placental tissue. Gaucher's disease is an inherited metabolic disorder caused by the defective activity of beta-glucosidase and the resultant accumulation of glucosyl ceramide laden macrophages in the liver, bone, and spleen. The disease affects an estimated 10,000-15,000 people in the United States, primarily of Eastern European Jewish descent, with up to 5,000 being symptomatic and requiring treatment; Ceredase[®] acts by replacing the missing enzyme associated with Gaucher's disease.

Adverse Reactions

Frequency not defined.

Cardiovascular: Peripheral edema

Central nervous system: Chills, fatigue, fever, headache, lightheadedness

Endocrine & metabolic: Hot flashes, menstrual abnormalities

Gastrointestinal: Abdominal discomfort, diarrhea, nausea, oral ulcerations, vomiting

Local: Injection site: Abscess, burning, discomfort, pruritus, swelling

Neuromuscular & skeletal: Backache, weakness

Miscellaneous: Dysosmia; hypersensitivity reactions (abdominal cramping, angioedema, chest discomfort, flushing, hypotension, nausea, pruritus, respiratory symptoms, urticaria); IgG antibody formation (~13%)

Signs and Symptoms of Overdose No obvious toxicity detected following single doses of up to 234 units/kg

Pharmacodynamics/Kinetics Half-life elimination: ~3-11 minutes

Dosage I.V.: Children and Adults: Dosing is individualized based on disease severity; average dose: 60 units/kg every 2 weeks. Range: 2.5 units/kg 3 times/week to 60 units/kg 1-4 times/week. Once patient response is well established, dose may be reduced every 3-6 months to determine maintenance therapy.

Monitoring Parameters CBC, platelets, liver function tests, IgG antibody formation, acid phosphatase (AP)

Administration

I.V.: Infuse I.V. over 1-2 hours; use of an in-line filter is recommended; do not shake solution as it denatures the enzyme

Contraindications Hypersensitivity to any component of the formulation

Warnings

Prepared from pooled human placental tissue that may contain the causative agents of some viral diseases. Patients who develop IgG antibodies may be at a higher risk for developing hypersensitivity. Use caution with androgen-sensitive malignancies or prior allergies to hCG. May cause early virilization in males <10 years of age. Safety and efficacy have not been established in children <2 years of age.

Dosage Forms

[DSC] = Discontinued product

Injection, solution [preservative free]: 10 units/mL (5 mL) [DSC]; 80 units/mL (5 mL) [contains human albumin 1%]

Overdosage/Treatment Supportive therapy: Acetaminophen for fever therapy

Test Interactions False positive pregnancy tests

Pregnancy Risk Factor C

Pregnancy Implications Animal studies have not been conducted.

Lactation Excretion in breast milk unknown/use caution

Allopurinol

Pronunciation (al oh PURE i nole)

CAS Number 315-30-0

U.S. Brand Names Aloprim™; Zyloprim®

Synonyms Allopurinol Sodium

Use

Oral: Prevention of attack of gouty arthritis and nephropathy; treatment of secondary hyperuricemia which may occur during treatment of tumors or leukemia; prevention of recurrent calcium oxalate calculi

I.V.: Treatment of elevated serum and urinary uric acid levels when oral therapy is not tolerated in patients with leukemia, lymphoma, and solid tumor malignancies who are receiving cancer chemotherapy

Mechanism of Action Decreases the production of uric acid by inhibiting the action of xanthine oxidase, an enzyme that converts hypoxanthine to xanthine and xanthine to uric acid

Adverse Reactions

Cardiovascular: Cerebral vasculitis, leukocytoclastic vasculitis, vasculitis
Central nervous system: Drowsiness, neuritis, fever, hyperthermia, aseptic meningitis

Dermatologic: **Pruritic maculopapular rash, exfoliative dermatitis, erythema multiforme, toxic pustuloderma, pustulosis, generalized granuloma annulare, Stevens-Johnson syndrome, exanthema, angioedema, urticaria, onycholysis, licheniform eruptions, cutaneous vasculitis**

Gastrointestinal: GI irritation, stomatitis

Hematologic: Leukocytosis, leukopenia, thrombocytopenia, eosinophilia, bone marrow suppression

Hepatic: Hepatitis, centrilobular hepatic necrosis, granulomatous hepatitis, cholestasis

Ocular: Cataracts, diplopia

Renal: Renal impairment, proteinuria, acute tubular necrosis, renal vasculitis

Miscellaneous: Systemic lupus erythematosus, fixed drug eruption, elevated antineutrophilic cytoplasmic antibodies (ANCA)

Signs and Symptoms of Overdose Most symptoms are from chronic use. Agranulocytosis, alopecia, cerebral edema, dysosmia, centrilobular hepatic necrosis, granulocytopenia, hematuria, hepatitis, hypersensitivity, hyperthermia, leukopenia, metallic taste, myoglobinuria, nausea, nephritis, neutropenia, paresthesia, pseudotumor cerebri, seizures, toxic epidermal necrolysis, vomiting, wheezing

Admission Criteria/Prognosis Admit ingestions > 6 g.

Pharmacodynamics/Kinetics

Onset of action: Peak effect: 1-2 weeks

Absorption: Oral: ~80%; Rectal: Poor and erratic

Distribution: V_d : ~1.6 L/kg; V_{ss} : 0.84-0.87 L/kg; enters breast milk

Protein binding: <1%

Metabolism: ~75% to active metabolites, chiefly oxypurinol

Bioavailability: 49% to 53%

Half-life elimination:

Normal renal function: Parent drug: 1-3 hours; Oxypurinol: 18-30 hours

End-stage renal disease: Prolonged

Time to peak, plasma: Oral: 30-120 minutes

Excretion: Urine (76% as oxypurinol, 12% as unchanged drug)

Allopurinol and oxypurinol are dialyzable

Dosage

Oral: Doses > 300 mg should be given in divided doses.

Children ≤ 10 years: Secondary hyperuricemia associated with chemotherapy: 10 mg/kg/day in 2-3 divided doses or 200-300 mg/m²/day in 2-4 divided doses, maximum: 800 mg/24 hours

Alternative (manufacturer labeling): <6 years: 150 mg/day in 3 divided doses; 6-10 years: 300 mg/day in 2-3 divided doses

Children > 10 years and Adults:

Secondary hyperuricemia associated with chemotherapy: 600-800 mg/day in 2-3 divided doses for prevention of acute uric acid nephropathy for 2-3 days starting 1-2 days before chemotherapy

Gout: Mild: 200-300 mg/day; Severe: 400-600 mg/day; to reduce the possibility of acute gouty attacks, initiate dose at 100 mg/day and increase weekly to recommended dosage.

Recurrent calcium oxalate stones: 200-300 mg/day in single or divided doses

Elderly: Initial: 100 mg/day, increase until desired uric acid level is obtained

I.V.: Hyperuricemia secondary to chemotherapy: Intravenous daily dose can be given as a single infusion or in equally divided doses at 6-, 8-, or 12-hour intervals. A fluid intake sufficient to yield a daily urinary output of at least 2 L in adults and the maintenance of a neutral or, preferably, slightly alkaline urine are desirable.

Children ≤ 10 years: Starting dose: 200 mg/m²/day

Children > 10 years and Adults: 200-400 mg/m²/day (max: 600 mg/day)

Dosing adjustment in renal impairment: Must be adjusted due to accumulation of allopurinol and metabolites:

Oral: Removed by hemodialysis; adult maintenance doses of allopurinol (mg) based on creatinine clearance (mL/minute): See table.

Adult Maintenance Doses of Allopurinol*

Creatinine Clearance (mL/min)	Maintenance Dose of Allopurinol (mg)
140	400 qd
120	350 qd
100	300 qd
80	250 qd
60	200 qd
40	150 qd
20	100 qd
10	100 q2d
0	100 q3d

*This table is based on a standard maintenance dose of 300 mg of allopurinol per day for a patient with a creatinine clearance of 100 mL/min.

Hemodialysis: Administer dose posthemodialysis or administer 50% supplemental dose

I.V.:

Cl_{cr} 10-20 mL/minute: 200 mg/day

Cl_{cr} 3-10 mL/minute: 100 mg/day

Cl_{cr} < 3 mL/minute: 100 mg/day at extended intervals

Monitoring Parameters CBC, serum uric acid levels, I & O, hepatic and renal function, especially at start of therapy

Administration

Oral: Should administer oral forms after meals with plenty of fluid.

I.V.: The rate of infusion depends on the volume of the infusion.

Whenever possible, therapy should be initiated at 24-48 hours before the start of chemotherapy known to cause tumor lysis (including adrenocorticosteroids). I.V. daily dose can be administered as a single infusion or in equally divided doses at 6-, 8-, or 12-hour interval.

Contraindications Hypersensitivity to allopurinol or any component of the formulation

Warnings

Do not use to treat asymptomatic hyperuricemia. Discontinue at first signs of rash. Caution in renal impairment, dosage adjustments needed. Use with caution in patients taking diuretics concurrently. Risk of skin rash may be increased in patients receiving amoxicillin or ampicillin. The risk of hypersensitivity may be increased in patients receiving thiazides, and possibly ACE inhibitors. Use caution with mercaptopurine or azathioprine.

Dosage Forms

Injection, powder for reconstitution, as sodium (Aloprim™): 500 mg

Tablet (Zyloprim®): 100 mg, 300 mg

Reference Range

Allopurinol: Therapeutic: 3-9 mcg/mL

Oxypurinol: Therapeutic: 4-8 mcg/mL

Blood allopurinol level of 231 mcg/mL has been associated with fatal centrilobular hepatic necrosis in an overdose setting

Serum uric acid: Adults: Male: 3.4-7.0 mg/dL (SI: 202-416 μmol/L) or slightly more; Female: 2.4-6.0 mg/dL (SI: 143-357 μmol/L) or slightly more

An increase occurs during childhood. Values > 7.0 mg/dL (SI: 416 μmol/L) are sometimes arbitrarily regarded as hyperuricemia, but there is no sharp line between normals on the one hand, and the serum uric acid of those with clinical gout. Normal ranges cannot be adjusted for purine ingestion, but high purine diet increases uric acid. Uric acid may be increased with body size, exercise, and stress. One fatal case was reported with levels of 230 mcg/mL; death is rare.

Overdosage/Treatment

Decontamination: Emesis within 30 minutes in ingestions; lavage within 1 hour if indicated in ingestions > 6 g; activated charcoal should be given
Supportive therapy: If significant amounts of allopurinol are thought to have been absorbed, it is a theoretical possibility that oxypurinol stones could be formed but no record of such occurrence in overdose exists. Alkalinization of the urine and forced diuresis can help prevent potential xanthine stone formation. Steroids and antihistamines are useful for hypersensitivity.

Enhancement of elimination: Removed by hemodialysis, but this modality is of unknown value in overdose

Test Interactions ↑ alkaline phosphatase, AST, ALT, bilirubin, eosinophils, BUN, creatinine; ↓ uric acid (S), cholesterol (S)

Drug Interactions

Ampicillin, amoxicillin: Incidence of rash may be increased.

Anticoagulants: Allopurinol may prolong the half-life of anticoagulants, effect seen with dicumarol; monitor.

ACE inhibitors: Captopril may increase risk of hypersensitivity.

Azathioprine: Metabolism inhibited by allopurinol; reduce azathioprine dose by 1/3 or 1/4.

Chlorpropamide: Half-life of chlorpropamide may be increased.
 Cyclosporine: Allopurinol may increase cyclosporine serum levels.
 Mercaptopurine: Metabolism inhibited by allopurinol; reduce mercaptopurine dose by $\frac{1}{3}$ or $\frac{1}{4}$.
 Thiazide diuretics: Toxicity and risk of hypersensitivity may be increased.
 Theophylline: Half-life of theophylline may be increased.
 Vidarabine: Neurotoxicity may be enhanced.

Pregnancy Risk Factor C

Pregnancy Implications There are few reports describing the use of allopurinol during pregnancy; no adverse fetal outcomes attributable to allopurinol have been reported in humans; use only if potential benefit outweighs the potential risk to the fetus.

Lactation Enters breast milk/use caution (AAP rates "compatible")

Additional Information Skin rash occurs most often in patients taking diuretics concurrently; may predispose patient to ampicillin-induced rash; alcohol decreases effectiveness

Indications for desensitization in patients with allopurinol-induced maculopapular eruptions:

- Patients with gout and renal insufficiency rendering uricosurics ineffective
- Patients with gout and allergy or intolerance of uricosuric drugs
- Patients with gout, "overproduction" hyperuricemia, uricosuria, and uric acid nephrolithiasis
- Patients with malignancy-associated hyperuricemia caused by cytolytic therapy for myelo- or lymphoproliferative disorder

For standard allopurinol desensitization protocol: See table.

Chao SC, Yang CC, and Lee JY, "Hypersensitivity Syndrome and Pure Red Cell Aplasia Following Allopurinol Therapy in a Patient with Chronic Kidney Disease," *Ann Pharmacother*, 2005, 39(9):1552-6.

Gomez-Cabrera MC, Pallardo FV, Sastre J, et al, "Allopurinol and Markers of Muscle Damage Among Participants in the Tour de France," *JAMA*, 2003, 289(19):2503-4.

Raebel MA, McClure DL, Simon SR, et al, "Frequency of Serum Creatinine Monitoring During Allopurinol Therapy in Ambulatory Patients," *Ann Pharmacother*, 2006, 40(3):386-91.

Elderly: 16.3 hours (range: 9-26.9 hours)
 Alcoholic liver disease: 19.7 hours (range: 5.8-65.3 hours)
 Obesity: 21.8 hours (range: 9.9-40.4 hours)

Time to peak, serum: 1-2 hours

Excretion: Urine (as unchanged drug and metabolites)

Dosage

Oral: **Note:** Treatment > 4 months should be re-evaluated to determine the patient's continued need for the drug

Children: Anxiety (unlabeled use): Immediate release: Initial: 0.005 mg/kg/dose or 0.125 mg/dose 3 times/day; increase in increments of 0.125-0.25 mg, up to a maximum of 0.02 mg/kg/dose or 0.06 mg/kg/day (0.375-3 mg/day)

Adults:

Anxiety: Immediate release: Effective doses are 0.5-4 mg/day in divided doses; the manufacturer recommends starting at 0.25-0.5 mg 3 times/day; titrate dose upward; maximum: 4 mg/day

Anxiety associated with depression: Immediate release: Average dose required: 2.5-3 mg/day in divided doses

Ethanol withdrawal (unlabeled use): Immediate release: Usual dose: 2-2.5 mg/day in divided doses

Panic disorder:

Immediate release: Initial: 0.5 mg 3 times/day; dose may be increased every 3-4 days in increments ≤ 1 mg/day; many patients obtain relief at 2 mg/day, as much as 10 mg/day may be required

Extended release: 0.5-1 mg once daily; may increase dose every 3-4 days in increments ≤ 1 mg/day (range: 3-6 mg/day)

Switching from immediate release to extended release: Patients may be switched to extended release tablets by taking the total daily dose of the immediate release tablets and giving it once daily using the extended release preparation.

Dose reduction: Abrupt discontinuation should be avoided. Daily dose may be decreased by 0.5 mg every 3 days, however, some patients may require a slower reduction. If withdrawal symptoms occur, resume previous dose and discontinue on a less rapid schedule.

Elderly: Elderly patients may be more sensitive to the effects of alprazolam including ataxia and oversedation. The elderly may also have impaired renal function leading to decreased clearance. The smallest effective dose should be used. Titrate gradually, if needed.

Immediate release: Initial 0.25 mg 2-3 times/day

Extended release: Initial: 0.5 mg once daily

Dosing adjustment in hepatic impairment: Reduce dose by 50% to 60% or avoid in cirrhosis

Monitoring Parameters Respiratory and cardiovascular status

Administration Immediate release preparations: Can be administered sublingually with comparable onset and completeness of absorption.

Extended release tablet: Should be taken once daily in the morning; do not crush, break or chew.

Contraindications Hypersensitivity to alprazolam or any component of the formulation (cross-sensitivity with other benzodiazepines may exist); narrow-angle glaucoma; concurrent use with ketoconazole or itraconazole; pregnancy

Warnings

Rebound or withdrawal symptoms, including seizures, may occur 18 hours to 3 days following abrupt discontinuation or large decreases in dose (more common in patients receiving >4 mg/day or prolonged treatment). Dose reductions or tapering must be approached with extreme caution. Breakthrough anxiety may occur at the end of dosing interval. Use with caution in patients receiving concurrent CYP3A4 inhibitors, particularly when these agents are added to therapy. Has weak uricosuric properties, use with caution in renal impairment or predisposition to urate nephropathy. Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics), renal impairment, or obese patients.

Causes CNS depression (dose related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury and should be used with extreme caution in patients who are at risk of these events (especially the elderly). Use with caution in patients with respiratory disease or impaired gag reflex.

Use caution in patients with depression, particularly if suicidal risk may be present. Episodes of mania or hypomania have occurred in depressed patients treated with alprazolam. May cause physical or psychological dependence - use with caution in patients with a history of drug dependence. Acute withdrawal, including seizures, may be precipitated in patients after administration of flumazenil to patients receiving long-term benzodiazepine therapy.

Benzodiazepines have been associated with anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior, have been reported with benzodiazepines, particularly in adolescent/

Alprazolam

Pronunciation (al PRAY zoe lam)

CAS Number 28981-97-7

U.S. Brand Names Alprazolam Intenso[®]; Xanax XR[®]; Xanax[®]

Impairment Potential Yes. Cognitive and psychomotor deficits occur in the elderly at doses of 0.25 mg and 0.5 mg. At the lower dose, the effect appears to last for 2.5 hours. (Pomara N, Tun H, DaSilva D, et al, "Benzodiazepine Use and Crash Risk in Older Patients," *JAMA*, 1998, 279(2):113-4.)

Use Treatment of anxiety disorder (GAD); panic disorder, with or without agoraphobia; anxiety associated with depression

Unlabeled/Investigational Use Anxiety in children

Mechanism of Action Binds at stereospecific receptors at several sites within the central nervous system, including the limbic system and reticular formation; effects may be mediated through GABA. Alprazolam is a triazolobenzodiazepine with some antidepressant activity.

Adverse Reactions

Cardiovascular: Hypotension

Central nervous system: **Drowsiness, fatigue, ataxia, lightheadedness, memory impairment, dysarthria, irritability, sedation, depression,** confusion, derealization, dizziness, disinhibition, akathisia, nightmares

Dermatologic: Dermatitis, rash

Endocrine & metabolic: **Libido decreased,** libido increased, **menstrual disorders**

Gastrointestinal: **Xerostomia, salivation decreased, appetite increased/decreased, weight gain/loss,** salivation increased, dyspepsia

Genitourinary: **Micturition difficulties,** sexual dysfunction, incontinence

Neuromuscular & skeletal: Rigidity, tremor, muscle cramps, ataxia, arthralgia

Otic: Tinnitus

Respiratory: Nasal congestion, dyspnea

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Coma, combativeness, confusion, delirium, depression, dermatitis, diminished reflexes, hypotension, hypothermia, insomnia, lightheadedness, leukocytosis, mania, photosensitivity, respiratory depression, somnolence

Pharmacodynamics/Kinetics

Distribution: V_d : 0.9-1.2 L/kg; enters breast milk

Protein binding: 80%

Metabolism: Hepatic via CYP3A4; forms two active metabolites (4-hydroxyalprazolam and α -hydroxyalprazolam)

Bioavailability: 90%

Half-life elimination:

Adults: 11.2 hours (range: 6.3-26.9)

pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Benzodiazepines have the potential to cause harm to the fetus, particularly when administered during the first trimester. In addition, withdrawal symptoms may occur in the neonate following *in utero* exposure. Use of alprazolam during pregnancy should be avoided. In addition, symptoms of withdrawal, lethargy, and loss of body weight have been reported in infants exposed to alprazolam and/or benzodiazepines while nursing; use during breast-feeding is not recommended.

Dosage Forms

Solution, oral [concentrate]:

Alprazolam Intensol®: 1 mg/mL (30 mL)

Tablet: 0.25 mg, 0.5 mg, 1 mg, 2 mg

Xanax®: 0.25 mg, 0.5 mg, 1 mg, 2 mg

Tablet, extended release: 0.5 mg, 1 mg, 2 mg, 3 mg

Xanax XR®: 0.5 mg, 1 mg, 2 mg, 3 mg

Tablet, orally disintegrating [scored]:

Niravam™: 0.25 mg, 0.5 mg, 1 mg, 2 mg [orange flavor]

Reference Range Therapeutic plasma level 20-30 ng/mL; postmortem levels average ~230 ng/mL in suicides; in the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur; postmortem levels in overdoses range from 122-390 mcg/L

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive: Treatment for benzodiazepine overdose is supportive. Rarely is mechanical ventilation required. Flumazenil has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression. Carbamazepine may be effective for withdrawal.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Antidote(s)

● Flumazenil [ANTIDOTE]

Test Interactions ↑ alkaline phosphatase; Visine®, Drano®, bleach may cause false-negative urine tests; oxazepam may interfere giving falsely elevated glucose results

Drug Interactions

Substrate of CYP3A4 (major)

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants. Includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of alprazolam. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of alprazolam. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil. Contraindicated with itraconazole and ketoconazole.

Fluoxetine: May increase plasma concentrations/effects of alprazolam.

Oral contraceptives: May increase serum levels/effects of alprazolam.

Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation.

Tricyclic antidepressants: Plasma concentrations of imipramine and desipramine have been reported to be increased 31% and 20%, respectively, by concomitant administration; monitor.

Pregnancy Risk Factor D

Pregnancy Implications Benzodiazepines have the potential to cause harm to the fetus, particularly when administered during the first trimester. In addition, withdrawal symptoms may occur in the neonate following *in utero* exposure. Use during pregnancy should be avoided.

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Nursing Implications Assist with ambulation during beginning therapy, raise bed rails and keep room partially illuminated at night; monitor for CNS respiratory depression

Additional Information Not intended for management of anxiety and minor distress associated with everyday life; treatment longer than 4 months should be re-evaluated to determine need for the drug; 1 mg of alprazolam is approximately equivalent in anxiolytic activity to 10 mg of diazepam

Alteplase

Pronunciation (AL te plase)

Related Information

● Reteplase

CAS Number 105857-23-6

U.S. Brand Names Activase®; Cathflo™ Activase®

Synonyms Alteplase, Recombinant; Alteplase, Tissue Plasminogen Activator, Recombinant; tPA

Use

Management of acute myocardial infarction for the lysis of thrombi in coronary arteries; management of acute massive pulmonary embolism (PE) in adults; acute ischemic stroke (within 3 hours after onset of symptoms and after exclusion of intracranial hemorrhage by a cranial computerized tomography scan or other diagnostic imaging modalities)

Acute myocardial infarction (AMI): Chest pain ≥20 minutes, ≤12-24 hours; S-T elevation ≥0.1 mV in at least two ECG leads

Acute pulmonary embolism (APE): Age ≤75 years: As soon as possible within 5 days of thrombotic event. Documented massive pulmonary embolism by pulmonary angiography or echocardiography or high probability lung scan with clinical shock.

Cathflo™ Activase®: Restoration of central venous catheter function

Unlabeled/Investigational Use Acute peripheral arterial occlusive disease

Mechanism of Action Initiates local fibrinolysis by binding to fibrin in a thrombus (clot) and converts entrapped plasminogen to plasmin; does not initiate systemic fibrinolysis in absence of a thrombus

Adverse Reactions

Cardiovascular: Hypotension, reperfusion arrhythmia (bradycardia, premature ventricular contraction), pericardial effusion/pericarditis, chest pain, sinus bradycardia, angina, arrhythmias (ventricular)

Central nervous system: Fever, seizures, intracranial hemorrhage

Dermatologic: Ecchymosis, angioneurotic edema (1 case)

Gastrointestinal: Gastrointestinal hemorrhage, nausea, vomiting, gingival hemorrhage

Genitourinary: GU hemorrhage

Local: Extravasation injury

Respiratory: Epistaxis, alveolar hemorrhage, pulmonary hemorrhage

Miscellaneous: Retroperitoneal hemorrhage, allergic reactions (rare), acute traumatic compartment syndrome

Signs and Symptoms of Overdose Coagulopathy, GI bleeding, increased incidence of intracranial bleeding or peripheral bleeding, headache, hematuria, hemoptysis, ocular hemorrhage

Pharmacodynamics/Kinetics

Duration: >50% present in plasma cleared ~5 minutes after infusion terminated, ~80% cleared within 10 minutes

Excretion: Clearance: Rapidly from circulating plasma (550-650 mL/minute), primarily hepatic; >50% present in plasma is cleared within 5 minutes after the infusion is terminated, ~80% cleared within 10 minutes

Dosage

I.V.:

Coronary artery thrombi: Front loading dose (weight-based):

Patients >67 kg: Total dose: 100 mg over 1.5 hours; infuse 15 mg over 1-2 minutes. Infuse 50 mg over 30 minutes. See "Note."

Patients ≤67 kg: Total dose: 1.25 mg/kg; infuse 15 mg I.V. bolus over 1-2 minutes, then infuse 0.75 mg/kg (not to exceed 50 mg) over next 30 minutes, followed by 0.5 mg/kg over next 60 minutes (not to exceed 35 mg). See "Note."

Note: Concurrently, begin heparin 60 units/kg bolus (maximum: 4000 units) followed by continuous infusion of 12 units/kg/hour (maximum: 1000 units/hour) and adjust to aPTT target of 1.5-2 times the upper limit of control. Infuse remaining 35 mg of alteplase over the next hour.

Acute pulmonary embolism: 100 mg over 2 hours.

Acute ischemic stroke: Doses should be given within the first 3 hours of the onset of symptoms; recommended total dose: 0.9 mg/kg (maximum dose should not exceed 90 mg) infused over 60 minutes.

Load with 0.09 mg/kg (10% of the 0.9 mg/kg dose) as an I.V. bolus over 1 minute, followed by 0.81 mg/kg (90% of the 0.9 mg/kg dose) as a continuous infusion over 60 minutes. Heparin should not be started for 24 hours or more after starting alteplase for stroke.

Intracatheter: Central venous catheter clearance: Cathflo™ Activase®:

Patients ≥10 to <30 kg: 110% of the internal lumen volume of the catheter (≤2 mg [1 mg/mL]); retain in catheter for ≤2 hours; may instill a second dose if catheter remains occluded

Patients ≥30 kg: 2 mg (1 mg/mL); retain in catheter for ≤2 hours; may instill a second dose if catheter remains occluded

Intra-arterial: Acute peripheral arterial occlusive disease (unlabeled use): 0.02-0.1 mg/kg/hour for up to 36 hours

Advisory Panel to the Society for Cardiovascular and Interventional Radiology on Thrombolytic Therapy recommendation: ≤ 2 mg/hour and subtherapeutic heparin (aPTT < 1.5 times baseline)

Stability

Activase®: The lyophilized product may be stored at room temperature (not to exceed 30°C/86°F), or under refrigeration; once reconstituted it must be used within 8 hours. Reconstitution:

50 mg vial: Use accompanying diluent (50 mL sterile water for injection); do not shake; final concentration: 1 mg/mL

100 mg vial: Use transfer set with accompanying diluent (100 mL vial of sterile water for injection); no vacuum is present in 100 mg vial; final concentration: 1 mg/mL Alteplase is **incompatible** with dobutamine, dopamine, heparin, and nitroglycerin infusions; physically **compatible** with lidocaine, metoprolol, and propranolol when administered via Y-site; **compatible** with either D₅W or NS. Standard dose: 100 mg/100 mL 0.9% NaCl (total volume: 200 mL)

Cathflo™ Activase®: Store lyophilized product under refrigeration; protect from excessive exposure to light when stored for extended periods of time. Reconstitution: Add 2.2 mL SWFI to vial; do not shake. Final concentration: 1 mg/mL. Once reconstituted, store at 2°C to 30°C (36°F to 86°F). Do not mix other medications into infusion solution.

Monitoring Parameters

When using for central venous catheter clearance: Assess catheter function by attempting to aspirate blood.

When using for management of acute myocardial infarction: Assess for evidence of cardiac reperfusion through resolution of chest pain, resolution of baseline ECG changes, preserved left ventricular function, cardiac enzyme washout phenomenon, and/or the appearance of reperfusion arrhythmias; assess for bleeding potential through clinical evidence of GI bleeding, hematuria, gingival bleeding, fibrinogen levels, fibrinogen degradation products, prothrombin times, and partial thromboplastin times.

Administration Activase®:

Bolus dose may be prepared by one of three methods:

- 1) removal of 15 mL reconstituted (1 mg/mL) solution from vial
- 2) removal of 15 mL from a port on the infusion line after priming
- 3) programming an infusion pump to deliver a 15 mL bolus at the initiation of infusion

Remaining dose may be administered as follows:

- 50 mg vial: Either PVC bag or glass vial and infusion set
- 100 mg vial: Insert spike end of the infusion set through the same puncture site created by transfer device and infuse from vial

If further dilution is desired, may be diluted in equal volume of 0.9% sodium chloride or D₅W to yield a final concentration of 0.5 mg/mL AD

Cathflo™ Activase®: Intracatheter: Instill dose into occluded catheter. Do not force solution into catheter. After a 30-minute dwell time, assess catheter function by attempting to aspirate blood. If catheter is functional, aspirate 4-5 mL of blood to remove Cathflo™ Activase® and residual clots. Gently irrigate the catheter with NS. If catheter remains nonfunctional, let Cathflo™ Activase® dwell for another 90 minutes (total dwell time: 120 minutes) and reassess function. If catheter function is not restored, a second dose may be instilled.

Contraindications

Hypersensitivity to alteplase or any component of the formulation

Treatment of acute MI or PE: Active internal bleeding; history of CVA; recent intracranial or intraspinal surgery or trauma; intracranial neoplasm; arteriovenous malformation or aneurysm; known bleeding diathesis; severe uncontrolled hypertension

Treatment of acute ischemic stroke: Evidence of intracranial hemorrhage or suspicion of subarachnoid hemorrhage on pretreatment evaluation; recent (within 3 months) intracranial or intraspinal surgery; prolonged external cardiac massage; suspected aortic dissection; serious head trauma or previous stroke; history of intracranial hemorrhage; uncontrolled hypertension at time of treatment (eg, > 185 mm Hg systolic or > 110 mm Hg diastolic); seizure at the onset of stroke; active internal bleeding; intracranial neoplasm; arteriovenous malformation or aneurysm; known bleeding diathesis including but not limited to: current use of anticoagulants or an INR > 1.7 , administration of heparin within 48 hours preceding the onset of stroke and an elevated aPTT at presentation, platelet count $< 100,000/\text{mm}^3$.

Other exclusion criteria (NINDS recombinant tPA study): Stroke or serious head injury within 3 months, major surgery or serious trauma within 2 weeks, GI or urinary tract hemorrhage within 3 weeks, aggressive treatment required to lower blood pressure, glucose level < 50 mg/dL or > 400 mg/dL, arterial puncture at a noncompressible site or lumbar puncture within 1 week, clinical presentation suggesting post-MI pericarditis, pregnancy, breast-feeding.

Warnings Concurrent heparin anticoagulation may contribute to bleeding. Monitor all potential bleeding sites. Doses > 150 mg are associated with increased risk of intracranial hemorrhage. Intramuscular injections and nonessential handling of the patient should be avoided. Venipunctures should be performed carefully and only when necessary. If arterial puncture is necessary, use an upper extremity vessel that can be

manually compressed. If serious bleeding occurs, the infusion of alteplase and heparin should be stopped.

For the following conditions, the risk of bleeding is higher with use of thrombolytics and should be weighed against the benefits of therapy: Recent major surgery (eg, CABG, obstetrical delivery, organ biopsy, previous puncture of noncompressible vessels), cerebrovascular disease, recent gastrointestinal or genitourinary bleeding, recent trauma, hypertension (systolic BP > 175 mm Hg and/or diastolic BP > 110 mm Hg), high likelihood of left heart thrombus (eg, mitral stenosis with atrial fibrillation), acute pericarditis, subacute bacterial endocarditis, hemostatic defects including ones caused by severe renal or hepatic dysfunction, significant hepatic dysfunction, pregnancy, diabetic hemorrhagic retinopathy or other hemorrhagic ophthalmic conditions, septic thrombophlebitis or occluded AV cannula at seriously infected site, advanced age (eg, > 75 years), patients receiving oral anticoagulants, any other condition in which bleeding constitutes a significant hazard or would be particularly difficult to manage because of location.

Coronary thrombolysis may result in reperfusion arrhythmias. Treatment of patients with acute ischemic stroke more than 3 hours after symptom onset is not recommended. Treatment of patients with minor neurological deficit or with rapidly improving symptoms is not recommended.

Cathflo® Activase®: When used to restore catheter function, use Cathflo® cautiously in those patients with known or suspected catheter infections. Evaluate catheter for other causes of dysfunction before use. Avoid excessive pressure when instilling into catheter.

Dosage Forms

Injection, powder for reconstitution, recombinant:

Activase®: 50 mg [29 million int. units; contains polysorbate 80; packaged with diluent]; 100 mg [58 million int. units; contains polysorbate 80; packaged with diluent and transfer device]

Cathflo® Activase®: 2 mg [contains polysorbate 80]

Reference Range Not routinely measured; literature supports therapeutic levels of 0.52-1.80 mcg/mL

Overdosage/Treatment Supportive therapy: Treat bleeding complications with transfusions of red blood cells, fresh frozen plasma, and cryoprecipitate; do not administer dextran; although human overdose data is lacking, administration of aminocaproic acid (Amicar®) at a dose of 3-5 g I.V. followed by an infusion rate of 1-1.25 g/hour may be useful

Test Interactions Decreases fibrinogen levels 16% to 36%

Drug Interactions

Aminocaproic acid (antifibrinolytic agent) may decrease effectiveness.

Drugs which affect platelet function (eg, NSAIDs, dipyridamole, ticlopidine, clopidogrel, IIb/IIIa antagonists) may potentiate the risk of hemorrhage; use with caution.

Heparin and aspirin: Use with aspirin and heparin may increase the risk of bleeding. However, aspirin and heparin were used concomitantly with alteplase in many patients in myocardial infarction or pulmonary embolism trials. This combination was prohibited in the NINDS tPA stroke trial.

Nitroglycerin may increase the hepatic clearance of alteplase, potentially reducing lytic activity (limited clinical information).

Warfarin or oral anticoagulants: Risk of bleeding may be increased during concurrent therapy.

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Assess for hemorrhage during first hour of treatment

Additional Information

Allergic reactions are unlikely

Investigational for angina, deep vein thrombosis, catheter thrombosis, peripheral artery thrombosis, and thrombotic stroke; has been used to treat acute myocardial infarction in a heart transplant recipient

For acute ischemic stroke, patients treated with alteplase were at least 30% more likely to have minimal or no disability at 3 months when compared to placebo. Increased incidence of symptomatic intracerebral hemorrhage noted within 36 hours of onset of stroke in e-PA treated group (6.4% in t-AP treated group versus 0.6% in placebo)

Altretramine

CAS Number 645-05-6

U.S. Brand Names Hexalen®

Synonyms Hexamethylmelamine; HEXM; HMM; HXM; NSC-13875

Use Palliative treatment of persistent or recurrent ovarian cancer

Mechanism of Action Although altretamine clinical antitumor spectrum resembles that of alkylating agents, the drug has demonstrated activity in alkylator-resistant patients. The drug selectively inhibits the incorporation of radioactive thymidine and uridine into DNA and RNA, inhibiting DNA and RNA synthesis; reactive intermediates covalently bind to microsomal proteins and DNA; can spontaneously degrade to demethylated melamines and formaldehyde which are also cytotoxic.

Adverse Reactions

Central nervous system: **Peripheral sensory neuropathy, neurotoxicity** (21%; may be progressive and dose-limiting), seizures, depression, dizziness

Dermatologic: Alopecia, rash

Gastrointestinal: **Nausea/vomiting** (50% to 70%), **anorexia** (48%), **diarrhea** (48%), stomach cramps

Hematologic: **Anemia, thrombocytopenia** (31%), **leukopenia** (62%), **neutropenia**

Hepatic: Alkaline phosphatase increased, hepatotoxicity

Neuromuscular & skeletal: Tremor

Pharmacodynamics/Kinetics

Absorption: Well absorbed (75% to 89%)

Distribution: Highly concentrated hepatically and renally; low in other organs

Protein binding: 50% to 94%

Metabolism: Hepatic; rapid and extensive demethylation to active metabolites (pentamethylmelamine and tetramethylmelamine)

Half-life elimination: 13 hours

Time to peak, plasma: 0.5-3 hours

Excretion: Urine (90%, <1% as unchanged drug)

Dosage

Refer to individual protocols. Oral:

Adults: 4-12 mg/kg/day in 3-4 divided doses for 21-90 days

Alternatively: 240-320 mg/m²/day in 3-4 divided doses for 21 days, repeated every 6 weeks

Alternatively: 260 mg/m²/day for 14-21 days of a 28-day cycle in 4 divided doses

Alternatively: 150 mg/m²/day in 3-4 divided doses for 14 days of a 28-day cycle

Monitoring Parameters CBC with differential, liver function tests; neurologic examination

Administration

Administer total daily dose as 3-4 divided doses after meals and at bedtime.

Contraindications Hypersensitivity to altretamine or any component of the formulation; pre-existing severe bone marrow suppression or severe neurologic toxicity; pregnancy

Warnings Hazardous agent - use appropriate precautions for handling and disposal. **[U.S. Boxed Warning]: Peripheral blood counts and neurologic examinations should be done routinely before and after drug therapy.** Myelosuppression and neurotoxicity are common; use with caution in patients previously treated with other myelosuppressive drugs or with pre-existing neurotoxicity. Use with caution in patients with renal or hepatic dysfunction. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.** Safety and efficacy in children have not been established.

Dosage Forms

Gelcap:

Hexalen®: 50 mg

Reference Range Peak plasma levels after a 200-300 mg/m² dose range from 0.3-20.8 mg/L

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Pyridoxine can be used to treat neuropathy (peripheral), although this mode of therapy is unproven

Antidote(s)

- Pyridoxine [ANTIDOTE]

Drug Interactions

MAO inhibitors: Altretamine may enhance the orthostatic effect of MAO inhibitors.

Pyridoxine: May diminish the therapeutic effect of altretamine; concurrent use not recommended.

Tricyclic antidepressants: Altretamine may enhance the orthostatic effect of tricyclic antidepressants.

Pregnancy Risk Factor D

Pregnancy Implications Teratogenic effects were noted in animal studies. There are no adequate and well-controlled studies in pregnant women. Women of childbearing potential should avoid becoming pregnant while on therapy.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Mucosal and dermal irritant

Aluminum Hydroxide

Pronunciation (a LOO mi num hye DROKS ide)

CAS Number 7429-90-5

UN Number 1309; 1396; 9260

U.S. Brand Names ALternaGel® [OTC]; Alu-Cap® [OTC]

Use Antacid; coloring agent in foods; antiperspirant; also found in sucralfate (207 mg aluminum per g dose)

Mechanism of Action Neutralizes hydrochloride in stomach to form Al (Cl)₃ salt + H₂O

Adverse Reactions

Frequency not defined.

Gastrointestinal: Constipation, stomach cramps, fecal impaction, nausea, vomiting, discoloration of feces (white speckles)

Endocrine & metabolic: Hypophosphatemia, hypomagnesemia

Signs and Symptoms of Overdose Toxicity is usually seen in the setting of water contamination used in hemodialysis, aluminum hydroxide toxicity in renal failure patients, and contamination of total parenteral nutrition. Aluminum antacids may cause constipation, phosphate depletion, bezoars or fecalith formation, and feces discoloration (black; white/speckling). In patients with renal failure, aluminum may accumulate to toxic levels; jaundice may also occur.

Toxicodynamics/Kinetics

Absorption: 12% gastric, <1% oral

Protein binding: 50%

Half-life: 276 minutes

Elimination: Renal clearance: 0.12 L/hour

Dosage

Oral:

Hyperphosphatemia:

Children: 50-150 mg/kg/24 hours in divided doses every 4-6 hours, titrate dosage to maintain serum phosphorus within normal range

Adults: Initial: 300-600 mg 3 times/day with meals

Antacid: Adults: 600-1200 mg between meals and at bedtime

Topical: Apply to affected area as needed; reapply at least every 12 hours

Monitoring Parameters Monitor phosphorous levels periodically when patient is on chronic therapy

Administration

Oral: Dose should be followed with water.

Contraindications Hypersensitivity to aluminum salts or any component of the formulation

Warnings

Oral: Hypophosphatemia may occur with prolonged administration or large doses; aluminum intoxication and osteomalacia may occur in patients with uremia. Use with caution in patients with CHF, renal failure, edema, cirrhosis, and low sodium diets, and patients who have recently suffered gastrointestinal hemorrhage; uremic patients not receiving dialysis may develop osteomalacia and osteoporosis due to phosphate depletion.

Elderly may be predisposed to constipation and fecal impaction. Careful evaluation of possible drug interactions must be done. When used as an antacid in ulcer treatment, consider buffer capacity (mEq/mL) to calculate dose.

Topical: Not for application over deep wounds, puncture wounds, infected areas, or lacerations. When used for self medication (OTC use), consult with healthcare provider if needed for >7 days or for use in children <6 months of age.

Dosage Forms

Oriment:

Dermagran®: 0.275% (120 g)

Suspension, oral: 320 mg/5 mL (473 mL)

ALternaGel®: 600 mg/5 mL (360 mL)

Reference Range Normal plasma aluminum levels are <10 mcg/L; levels >100 mcg/L are associated with toxicity; normal urinary aluminum level: 0.05-1 mg/L

Overdosage/Treatment

Supportive therapy: Diazepam can be used for seizure control. Consider deferoxamine for aluminum serum levels >60 mcg/L

Deferoxamine (15-20 mg/kg once weekly I.V.), traditionally used as an iron chelator, has been shown to increase urinary aluminum output

For dialysis patients: I.V.: 40-80 mg/kg once weekly prior to dialysis with reduction of dose to 20-60 mg/kg if a positive response occurs. Deferoxamine chelation of aluminum has resulted in improvements of clinical symptoms and bone histology. However, deferoxamine remains an experimental treatment for aluminum poisoning and has a significant potential for adverse effects.

Deferoxamine infused 1-2 hours at the end of dialysis; monitor iron levels carefully along with platelet counts

Enhancement of elimination: Hemodialysis or charcoal hemoperfusion will also remove aluminum; aluminum-desferrioxamine complex can be efficiently removed with high flux dialysate membranes

Drug Interactions

Decreased effect: Aluminum hydroxide may decrease the absorption of allopurinol, antibiotics (tetracyclines, quinolones, some cephalosporins), bisphosphonate derivatives, corticosteroids, cyclosporine, delavirdine, iron salts, imidazole antifungals, isoniazid, mycophenolate, penicillamine, phosphate supplements, phenytoin, phenothiazines, trientine.

Absorption of aluminum hydroxide may be decreased by citric acid derivatives.

Pregnancy Risk Factor C

Pregnancy Implications No data available on clinical effects on the fetus; available evidence suggests safe use during pregnancy and breast-feeding.

Lactation Excretion in breast milk unknown

Additional Information

Insoluble in water and alcohol; iron deficiency may increase aluminum absorption, possible association with dialysis, dementia, and renal osteodystrophy; aluminum comprises 8% of the earth's crust; bauxite is the main source of environmental aluminum

Aluminum only has one oxidation state (+3); background atmospheric aluminum levels range from 0.005-0.2 mg/m³; baseline drinking water aluminum levels range from 0.003-1.6 mg/L; soil aluminum levels range from 700 mg/kg to over 100,000 mg/kg

Foods containing highest aluminum levels are ground coffee beans (52 mg/kg), salt (31-37 mg/kg), natural peanut butter (26-94 mg/kg), pumpernickel bread (13.2 mg/kg), chocolate cookie, Orea® (12.7 mg/kg), spinach (8.7 mg/kg), and lettuce (7.2 mg/kg). Calcium gluconate contains 38.8 mcg aluminum per 8 mL volume; potassium acid phosphate contains 2.8 mcg aluminum per 1.3 mL total volume.

Aluminum is not bioconcentrated in plants or terrestrial food chain; antacids/buffered aspirin can contain from 4-562 mg/kg of aluminum. Daily intake of aluminum is ~2-14 mg by food ingestion, 0.2 mg through drinking water, and 0.2 mg by inhalation; total body burden of aluminum is ~30-50 mg (50% in bone, 25% in lungs).

Amantadine

Pronunciation (a MAN ta deen)

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 665-66-7

U.S. Brand Names Symmetrel®

Synonyms Adamantanamine Hydrochloride; Amantadine Hydrochloride
Use Prophylaxis and treatment of influenza A viral infection; treatment of parkinsonism; treatment of drug-induced extrapyramidal symptoms
Creutzfeldt-Jakob disease

Mechanism of Action As an antiviral, blocks the uncoating of influenza A virus preventing penetration of virus into host; antiparkinsonian activity may be due to blocking the reuptake of dopamine into presynaptic neurons and causing direct stimulation of postsynaptic receptors

Adverse Reactions

Cardiovascular: Edema, hypotension (orthostatic), QT prolongation, sinus bradycardia, myocardial depression, sinus tachycardia, peripheral edema

Central nervous system: Dizziness, ataxia, confusion, insomnia, difficulty concentrating, anxiety, restlessness, irritability, visual hallucinations, auditory hallucinations, headache, akathisia, panic attacks, extrapyramidal symptoms, amnesia

Gastrointestinal: Nausea, anorexia, constipation, xerostomia

Genitourinary: Urinary retention

Neuromuscular & skeletal: Rhabdomyolysis, peripheral neuropathy

Signs and Symptoms of Overdose Anticholinergic symptoms, blurred vision, bradycardia, cardiac arrhythmias (including torsades de pointes), chorea (extrapyramidal), CNS depression followed by stimulation, coma, congestive heart failure, depression, drowsiness, dystonic reactions, fever, hyperthermia, insomnia, mania, memory loss, metabolic acidosis, myasthenia gravis (exacerbation or precipitation), nausea, neuroleptic malignant syndrome, neutropenia, night terrors, photosensitivity, psychosis, pulmonary edema, seizures, slurred speech, tachycardia, vomiting

Admission Criteria/Prognosis Admit any ingestion > 1 g

Pharmacodynamics/Kinetics

Onset of action: Antidyskinetic: Within 48 hours

Absorption: Well absorbed

Distribution: V_d: Normal: 1.5-6.1 L/kg; Renal failure: 5.1 ± 0.2 L/kg; in saliva, tear film, and nasal secretions; in animals, tissue (especially lung) concentrations higher than serum concentrations; crosses blood-brain barrier

Protein binding: Normal renal function: ~67%; Hemodialysis: ~59%

Metabolism: Not appreciable; small amounts of an acetyl metabolite identified

Bioavailability: 86% to 90%

Half-life elimination: Normal renal function: 16 ± 6 hours (9-31 hours);

End-stage renal disease: 7-10 days

Excretion: Urine (80% to 90% unchanged) by glomerular filtration and tubular secretion

Total clearance: 2.5-10.5 L/hour

Dosage

Oral:

Children:

Influenza A treatment:

1-9 years: 5 mg/kg/day in 2 divided doses (manufacturers range: 4.4-8.8 mg/kg/day); maximum dose: 150 mg/day

≥ 10 years and < 40 kg: 5 mg/kg/day; maximum dose: 150 mg/day

10-12 years and ≥ 40 kg: 100 mg twice daily.

≥ 13 years: Refer to Adults dosing

Note: Initiate within 24-48 hours after onset of symptoms; discontinue as soon as possible based on clinical response (generally within 3-5 days or within 24-48 hours after symptoms disappear)

Influenza A prophylaxis: Refer to "Influenza A treatment" dosing

Note: Continue treatment throughout the peak influenza activity in the community or throughout the entire influenza season in patients who cannot be vaccinated. Development of immunity following vaccination takes ~2 weeks; amantadine therapy should be considered for high-risk patients from the time of vaccination until immunity has developed. For children < 9 years receiving influenza vaccine for the first time, amantadine prophylaxis should continue for 6 weeks (4 weeks after the first dose and 2 weeks after the second dose)

Adults:

Drug-induced extrapyramidal symptoms: 100 mg twice daily; may increase to 300-400 mg/day, if needed

Parkinson's disease or Creutzfeldt-Jakob disease (unlabeled use): 100 mg twice daily as sole therapy; may increase to 400 mg/day if needed with close monitoring; initial dose: 100 mg/day if with other serious illness or with high doses of other anti-Parkinson drugs

Influenza A viral infection: 100 mg twice daily; initiate within 24-48 hours after onset of symptoms; discontinue as soon as possible based on clinical response (generally within 3-5 days or within 24-48 hours after symptoms disappear)

Influenza A prophylaxis: 100 mg twice daily

Note: Continue treatment throughout the peak influenza activity in the community or throughout the entire influenza season in patients who cannot be vaccinated. Development of immunity following vaccination takes ~2 weeks; amantadine therapy should be considered for high-risk patients from the time of vaccination until immunity has developed

Elderly:

Influenza A treatment: ≤ 100 mg/day; initiate within 24-48 hours after onset of symptoms; discontinue as soon as possible based on clinical response (generally within 3-5 days or within 24-48 hours after symptoms disappear)

Influenza A prophylaxis: ≤ 100 mg/day

Note: Continue treatment throughout the peak influenza activity in the community or throughout the entire influenza season in patients who cannot be vaccinated. Development of immunity following vaccination takes ~2 weeks; amantadine therapy should be considered for high-risk patients from the time of vaccination until immunity has developed.

Dosing interval in renal impairment:

Cl_{cr} 30-50 mL/minute: Administer 200 mg on day 1, then 100 mg/day

Cl_{cr} 15-29 mL/minute: Administer 200 mg on day 1, then 100 mg on alternate days

Cl_{cr} < 15 mL/minute: Administer 200 mg every 7 days

Hemodialysis: Administer 200 mg every 7 days

Peritoneal dialysis: No supplemental dose is needed

Continuous arterio-venous or venous-venous hemofiltration: No supplemental dose is needed

Monitoring Parameters Renal function, Parkinson's symptoms, mental status, influenza symptoms, blood pressure

Contraindications Hypersensitivity to amantadine, rimantadine, or any component of the formulation

Warnings Use with caution in patients with liver disease, history of recurrent and eczematoid dermatitis, uncontrolled psychosis or severe psychoneurosis, seizures, and in those receiving CNS stimulant drugs; reduce dose in renal disease. When treating Parkinson's disease, do not discontinue abruptly. In many patients, the therapeutic benefits of

AMILORIDE

amantadine are limited to a few months. Elderly patients may be more susceptible to CNS effects (using 2 divided daily doses may minimize this effect). Has been associated with neuroleptic malignant syndrome (associated with dose reduction or abrupt discontinuation). Has not been shown to prevent bacterial infection or complications when used as prophylaxis or treatment of influenza A. Use with caution in patients with CHF, peripheral edema, or orthostatic hypotension. Avoid in angle closure glaucoma. Due to increased resistance, in June 2006, the CDC recommended that amantadine no longer be used for the treatment or prophylaxis of influenza A in the United States until susceptibility has been re-established.

Dosage Forms

Capsule, as hydrochloride: 100 mg
Syrup, as hydrochloride: 50 mg/5 mL (480 mL)
Tablet, as hydrochloride: 100 mg
Symmetrel®: 100 mg

Reference Range

Therapeutic range: 0.7-1 mcg/mL; toxic and potentially fatal: 4-23 mcg/mL; highest survival reported level in overdose: 27 mcg/mL

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur

Overdosage/Treatment

Decontamination: Emesis not recommended due to potential for seizures; lavage (within 1 hour) recommended in early ingestions after seizure control; activated charcoal of value; multiple-dose activated charcoal not studied

Supportive therapy: If symptomatic, observe for 24-48 hours since cardiac symptoms are delayed. Treatment should be directed at reducing CNS stimulation and maintaining cardiovascular function. Seizures can be treated with diazepam or lorazepam 5-10 mg I.V. every 15 minutes as needed, up to a total of 30 mg in adults (0.25-0.4 mg/kg/dose I.V. every 15 minutes as needed up to a total of 10 mg for children). Lidocaine is the drug of choice for ventricular arrhythmias, followed by procainamide, propranolol (if arrhythmias are due to beta-adrenergic excess); MgSO₄ for torsade de pointes. Avoid class IA (other than procainamide), isoproterenol, and class II agents. Pulmonary edema may respond to corticosteroids. Norepinephrine may be effective for hypotension. Physostigmine has been used and is recommended only in severe, life-threatening anticholinergic symptoms. Ice baths, bromocriptine, and/or dantrolene may be effective for malignant hyperthermia, but clinical experience in this setting is limited. Since bicarbonate prevents renal elimination, this modality should be avoided if possible.

Enhancement of elimination: Hemodialysis is of minimal value, as is peritoneal dialysis; slightly dialyzable (5% to 20%)

Drug Interactions

Anticholinergics may potentiate CNS side effects of amantadine; monitor for altered response. Includes benzotropine and trihexyphenidyl, as well as agents with anticholinergic activity such as quinidine, tricyclics, and antihistamines.

Thiazide diuretics: Hydrochlorothiazide has been reported to increase the potential for toxicity with amantadine (limited documentation); monitor response.

Triamterene: Has been reported to increase the potential for toxicity with amantadine (limited documentation); monitor response.

Trimethoprim: Has been reported to increase the potential for toxicity with amantadine (limited documentation); monitor for acute confusion.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic effects were observed in animal studies; limited data in humans. Impaired fertility has also been reported during animal studies and during human *in vitro* fertilization.

Lactation Enters breast milk/not recommended

Nursing Implications If insomnia occurs, the last daily dose should be taken several hours before retiring; assess parkinsonian symptoms prior to and throughout course of therapy

Additional Information Cardiac conduction disturbances may occur as long as 52 hours postingestion

Michalski LS, Hantsch CE, and Hou SH, "Amantadine Toxicity in a Renal Transplant Patient," *J Toxicol Clin Toxicol*, 2003, 41(5):679.

hepatic cirrhosis, and hypoaldosteronism; usually used in conjunction with more potent diuretics such as thiazides or loop diuretics

Unlabeled/Investigational Use Investigational: Cystic fibrosis; reduction of lithium-induced polyuria

Mechanism of Action Interferes with potassium/sodium exchange in the distal renal tubule

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), vasculitis

Central nervous system: Headache, dizziness

Dermatologic: Pruritus, photosensitivity, exanthema, alopecia, urticaria, purpura

Endocrine & metabolic: Hyperkalemia, hyponatremia

Gastrointestinal: Nausea, vomiting, abdominal pain, diarrhea, loss of taste perception, salt hypogeusia

Neuromuscular & skeletal: Leg ischemia, muscle cramps, paresthesia

Respiratory: Cough, dyspnea

Miscellaneous: Thirst

Signs and Symptoms of Overdose Constipation, cough, encephalopathy, hyperuricemia, hyponatremia, hypotension, impotence, numbness, photosensitivity

Pharmacodynamics/Kinetics

Onset of action: 2 hours

Duration: 24 hours

Absorption: ~15% to 25%

Distribution: V_d: 350-380 L

Protein binding: 23%

Metabolism: No active metabolites

Half-life elimination: Normal renal function: 6-9 hours; End-stage renal disease: 8-144 hours

Time to peak, serum: 6-10 hours

Excretion: Urine and feces (equal amounts as unchanged drug)

Dosage

Oral:

Children: Although safety and efficacy in children have not been established by the FDA, a dosage of 0.625 mg/kg/day has been used in children weighing 6-20 kg.

Adults: 5-10 mg/day (up to 20 mg)

Hypertension (JNC 7): 5-10 mg/day in 1-2 divided doses

Elderly: Initial: 5 mg once daily or every other day

Dosing adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer at 50% of normal dose.

Cl_{cr} <10 mL/minute: Avoid use.

Monitoring Parameters I & O, daily weights, blood pressure, serum electrolytes, renal function

Administration

Administer with food or meals to avoid GI upset.

Contraindications Hypersensitivity to amiloride or any component of the formulation; presence of elevated serum potassium levels (>5.5 mEq/L); if patient is receiving other potassium-conserving agents (eg, spironolactone, triamterene) or potassium supplementation (medicine, potassium-containing salt substitutes, potassium-rich diet); anuria; acute or chronic renal insufficiency; evidence of diabetic nephropathy. Patients with evidence of renal impairment or diabetes mellitus should not receive this medicine without close, frequent monitoring of serum electrolytes and renal function.

Warnings May cause hyperkalemia (patients with renal impairment or diabetes and the elderly are at greatest risk). Should be stopped at least 3 days before glucose tolerance testing. Use caution in severely ill patients in whom respiratory or metabolic acidosis may occur.

Dosage Forms Tablet, as hydrochloride: 5 mg

Reference Range Peak serum amiloride level: 30-50 ng/mL after a 20 mg dose

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hyperkalemia can be treated with glucose/insulin and sodium bicarbonate (1 mEq/kg); sodium polystyrene sulfonate can also be given; I.V. fluid administration of 0.45% sodium chloride with furosemide (1 mg/kg, up to 40 mg) can be used to promote urine flow

Test Interactions ↑ potassium (S)

Drug Interactions

Amoxicillin's absorption may be reduced; avoid concurrent use or observe for clinical response.

ACE inhibitors or angiotensin receptor antagonists can cause hyperkalemia, especially in patients with renal impairment, potassium-rich diets, or on other drugs causing hyperkalemia; avoid concurrent use or monitor closely.

Cyclosporine or tacrolimus: Risk of hyperkalemia may be increased by concurrent therapy.

NSAIDs: May decrease the effect of diuretics.

Potassium supplements may further increase potassium retention and cause hyperkalemia; avoid concurrent use.

Quinidine and amiloride together may increase risk of malignant arrhythmias; avoid concurrent use.

Amiloride

Pronunciation (a MIL oh ride)

CAS Number 17440-83-4; 2016-88-8; 2609-46-3

U.S. Brand Names Midamor® [DSC]

Synonyms Amiloride Hydrochloride

Use Counteracts potassium loss induced by other diuretics in the treatment of hypertension or edematous conditions including CHF,

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown/contraindicated

Additional Information Amiloride is considered an alternative to triamterene or spironolactone. Unlike triamterene, renal stone formation does not occur; diminishes the potassium excretion effects of thiazide diuretics. Medication should be discontinued if potassium level exceeds 6.5 mEq/L.

Specific References

Chobanian AV, Bakris GL, Black HR, et al, "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, 289(19):2560-71.

Aminophylline

Pronunciation (am in OFF i lin)

Related Information

- Theophylline

CAS Number 317-34-0

Synonyms Theophylline Ethylenediamine

Use Bronchodilator in reversible airway obstruction due to asthma or COPD; increase diaphragmatic contractility

Mechanism of Action Causes bronchodilatation, diuresis, CNS and cardiac stimulation, and gastric acid secretion by blocking phosphodiesterase which increases tissue concentrations of cyclic adenine monophosphate (cAMP) which in turn promotes catecholamine stimulation of lipolysis, glycogenolysis, and gluconeogenesis and induces release of epinephrine from adrenal medulla cells

Adverse Reactions

Uncommon at serum theophylline concentrations ≤ 15 mcg/mL

Cardiovascular: Tachycardia

Central nervous system: Nervousness, restlessness, insomnia, irritability, seizures

Dermatologic: Skin rash

Gastrointestinal: Nausea, vomiting, gastric irritation

Neuromuscular & skeletal: Tremor

Miscellaneous: Allergic reactions

Signs and Symptoms of Overdose Delirium, diuresis, feces discoloration (black), hypercalcemia, hyperglycemia, hypokalemia, hypotension, insomnia, irritability, lactic acidosis, nausea, seizures, tachycardia, vomiting. Repetitive vomiting is an indication to hold theophylline therapy and rule out toxicity by serum concentrations.

Pharmacodynamics/Kinetics**Theophylline:**

Absorption: Oral: Dosage form dependent

Distribution: 0.45 L/kg based on ideal body weight

Protein binding: 40%, primarily to albumin

Metabolism: Children >1 year and Adults: Hepatic; involves CYP1A2, 2E1, and 3A4; forms active metabolites (caffeine and 3-methylxanthine)

Half-life elimination: Highly variable and dependent upon age, liver function, cardiac function, lung disease, and smoking history

Time to peak, serum:

Oral: Immediate release: 1-2 hours

I.V.: Within 30 minutes

Excretion: Children >3 months and Adults: Urine (10% as unchanged drug)

Dosage

Treatment of acute bronchospasm: I.V.:

Loading dose (in patients not currently receiving aminophylline or theophylline): 6 mg/kg (based on aminophylline) administered I.V. over 20-30 minutes; administration rate should not exceed 25 mg/minute (aminophylline)

Approximate I.V. maintenance dosages are based upon **continuous infusions**; bolus dosing (often used in children <6 months of age) may be determined by multiplying the hourly infusion rate by 24 hours and dividing by the desired number of doses/day

6 weeks to 6 months: 0.5 mg/kg/hour

6 months to 1 year: 0.6-0.7 mg/kg/hour

1-9 years: 1 mg/kg/hour

9-16 years and smokers: 0.8 mg/kg/hour

Adults, nonsmoking: 0.5 mg/kg/hour

Older patients and patients with cor pulmonale: 0.3 mg/kg/hour

Patients with congestive heart failure: 0.1-0.2 mg/kg/hour

Dosage should be adjusted according to serum level measurements during the first 12- to 24-hour period. See table.

Bronchodilator: Oral: Children ≥ 45 kg and Adults: Initial: 380 mg/day (equivalent to theophylline 300 mg/day) in divided doses every 6-8 hours; may increase dose after 3 days; maximum dose: 928 mg/day (equivalent to theophylline 800 mg/day)

Stability Store injection at room temperature, do not refrigerate; protect from heat and from freezing; use only clear solutions; stability of parenteral admixture at room temperature (25°C): 30 days

Administration

Dilute with I.V. fluid to a concentration of 1 mg/mL and infuse over 20-30 minutes; maximum concentration: 25 mg/mL; maximum rate of infusion: 0.36 mg/kg/minute, and no greater than 25 mg/minute. I.M. administration is not recommended. Oral and I.V. should be administered around-the-clock rather than 4 times/day, 3 times/day, etc (ie, 12-6-12-6, not 9-1-5-9) to promote less variation in peak and trough serum levels.

Contraindications Hypersensitivity to theophylline, ethylenediamine, or any component of the formulation

Warnings If a patient develops signs and symptoms of theophylline toxicity, a serum level should be measured and subsequent doses held. Due to potential saturation of theophylline clearance at serum levels within (or in some patients less than) the therapeutic range, dosage adjustment should be made in small increments (maximum: 25% reduction). Due to wide interpatient variability, theophylline serum level measurements must be used to optimize therapy and prevent serious toxicity. Use caution with peptic ulcer, hyperthyroidism, seizure disorder, hypertension, or tachyarrhythmias.

Dosage Forms

Injection, solution, as dihydrate: 25 mg/mL (10 mL, 20 mL)

Tablet, as dihydrate: 100 mg, 200 mg

Reference Range

Therapeutic (theophylline):

Neonatal apnea: 6-13 mcg/mL

Sample size: 0.5-1 mL serum (red top tube)

Toxic: >20 mcg/mL

Timing of serum samples: If toxicity is suspected, draw a level at any time; if lack of therapeutic effect, draw a trough immediately before the next oral dose

Overdosage/Treatment

Decontamination: **Do not** use ipecac; lavage should be performed if <1 hour after ingestion and if >50 mg/kg was ingested; activated charcoal should be given; whole bowel irrigation should be considered for significant sustained release preparation ingestion

Supportive therapy: Metoclopramide, ranitidine, or ondansetron can be used for vomiting; hypotension should be treated with I.V. normal saline hydration. Phenylephrine or levarterenol are preferred vasopressors that can be utilized for hypotension, although an I.V. beta-adrenergic blocker (propranolol or esmolol) can be utilized in patients with no history of bronchospastic disease. Seizures may require diazepam/lorazepam along with phenobarbital; phenytoin is contraindicated. Lidocaine can be used for ventricular arrhythmias; must monitor for hypoglycemia.

Enhancement of elimination: Multiple doses of activated charcoal can halve the half-life of aminophylline/theophylline; do not use if an ileus is present. Charcoal hemoperfusion can increase the clearance of aminophylline/theophylline by approximately twofold to threefold over that of hemodialysis and is thus the extracorporeal modality of choice. Guidelines for charcoal hemoperfusion include a theophylline level >100 mcg/mL in an acute overdose setting (or 50 mcg/mL in a chronic setting), or the following signs if the level is >35 mcg/mL: ventricular arrhythmias, metabolic acidosis, hypotension, refractory to vasopressors or fluid therapy, seizures, ileus. If a sustained-release preparation is ingested or if the patient is >60 years of age, the threshold for using charcoal hemoperfusion should be lower. If the patient is experiencing fluid overload due to congestive heart failure, hemodialysis can be performed to remove both theophylline/aminophylline and fluid. Drug clearance rates for hemodialysis and hemoperfusion are 185 mL/kg/hour and 295 mL/kg/hour, respectively.

Test Interactions In selected procedures, caffeine in high concentrations cross reacts as theophylline.

Drug Interactions

Substrate of CYP1A2 (major), 2E1 (minor), 3A4 (minor)

CYP1A2 inducers: May decrease the levels/effects of aminophylline. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of aminophylline. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

Pregnancy Risk Factor C

Pregnancy Implications Theophylline crosses the placenta; adverse effects may be seen in the newborn. Theophylline metabolism may change during pregnancy; monitor serum levels.

Lactation Enters breast milk/compatible (AAP rates "compatible")

Nursing Implications Encourage patient to drink adequate fluids (2 L/day) to decrease mucous viscosity in airways; monitor vital signs, I & O, serum concentrations, and CNS effects (insomnia, irritability)

Guidelines for Drawing Theophylline Serum Levels

Dosage Form	Time to Draw Level
P.O. liquid, fast-release tab	Peak: 1 h post 4th dose; Trough: just before 4th dose
P.O. slow-release product	Peak: 4 h post 3rd dose; Trough: just before 3rd dose

AMIODARONE

Additional Information Elderly, acutely ill, and patients with severe respiratory problems, pulmonary edema, or liver dysfunction are at greater risk of toxicity because of reduced drug clearance. Saliva levels are approximately equal to 60% of plasma levels. Charcoal-broiled foods may increase elimination, reducing half-life by 50%. Cigarette smoking may require a dosage increase of 50% to 100%. Aminophylline, 100 mg, is equivalent to theophylline, 79 mg. Aminophylline (2.5 mg/kg) has been used to treat methotrexate-induced neurotoxicity in children.

Specific References

Abu-Laban RB, McIntyre CM, Christenson JM, et al, "Aminophylline in Bradyasystolic Cardiac Arrest: A Randomized Placebo-Controlled Trial," *Acad Emerg Med*, 2004, 11(5):435.

Amiodarone

Pronunciation (a MEE oh da rone)

CAS Number 1951-25-3; 19774-82-4

U.S. Brand Names Cordarone®; Pacerone®

Synonyms Amiodarone Hydrochloride
Use

Oral: Management of life-threatening recurrent ventricular fibrillation (VF) or hemodynamically unstable ventricular tachycardia (VT)

I.V.: Initiation of treatment and prophylaxis of frequency recurring VF and unstable VT in patients refractory to other therapy. Also, used for patients when oral amiodarone is indicated, but who are unable to take oral medication.

Unlabeled/Investigational Use Conversion of atrial fibrillation to normal sinus rhythm; maintenance of normal sinus rhythm

Prevention of postoperative atrial fibrillation during cardiothoracic surgery
Paroxysmal supraventricular tachycardia (SVT)

Control of rapid ventricular rate due to accessory pathway conduction in pre-excited atrial arrhythmias [ACLS guidelines]

Cardiac arrest with persistent ventricular tachycardia (VT) or ventricular fibrillation (VF) if defibrillation, CPR, and vasopressor administration have failed [ACLS/PALS guidelines]

Control of hemodynamically-stable VT, polymorphic VT with a normal QT interval, or wide-complex tachycardia of uncertain origin [ACLS/PALS guidelines]

Mechanism of Action Class III antiarrhythmic agent which inhibits adrenergic stimulation (alpha- and beta-blocking properties), affects sodium, potassium, and calcium channels, prolongs the action potential and refractory period in myocardial tissue; decreases AV conduction and sinus node function

Adverse Reactions

Cardiovascular: Atropine-resistant bradycardia, heart block, sinus arrest, myocardial depression, chest pain, congestive heart failure, paroxysmal tachycardia (ventricular), proarrhythmia, **hypotension** (I.V. 16%, refractory in rare cases), torsade de pointes with QT interval prolongation, angina, myocardial depression, pericardial effusion/pericarditis, sinus tachycardia, tachycardia (supraventricular), arrhythmias (ventricular), vasodilation, leukocytoclastic vasculitis, atrial fibrillation, acute intracranial hypertension (I.V.), vasculitis, nodal arrhythmia, sinus bradycardia, ventricular fibrillation

Central nervous system: (20% to 40% incidence): **Fatigue, malaise, psychosis, dizziness, encephalopathy, insomnia, night terrors, extrapyramidal reaction, fever, headache, restlessness, abulia, ataxia, parkinsonism, nightmares,** CNS depression, depression, proximal muscle asthenia, myelinopathy, pseudotumor cerebri, brainstem dysfunction, delirium

Dermatologic: Skin discoloration (slate blue), rash, alopecia, **photosensitization,** cutaneous vasculitis, angioedema, toxic epidermal necrolysis, Stevens-Johnson syndrome, erythema multiforme

Endocrine & metabolic: Hypothyroidism (or less commonly hyperthyroidism), hyperglycemia, increased triglycerides, gynecomastia, Hashimoto's disease, Graves' disease, autoimmune thyroid disease, thyroiditis, SIADH

Gastrointestinal: **Nausea, vomiting, anorexia, constipation,** metallic taste, pancreatitis, lingua villosa nigra, diarrhea

Genitourinary: Scrotal pain, epididymal pain and edema, impotence, noninfectious epididymitis, loss of libido

Hematologic: Coagulation abnormalities, thrombocytopenia, aplastic anemia, bone marrow granuloma, hemolytic anemia, pancytopenia

Hepatic: Elevated liver enzymes, severe hepatic toxicity (potentially fatal), elevated bilirubin, increased serum ammonia, hepatic steatosis, cholestatic hepatitis, cirrhosis, increased ALT/AST, neutropenia

Local: Injection site reactions

Neuromuscular & skeletal: **Tremors, paresthesia, weakness,** abnormal gait, myopathy, dyskinesias, myoclonic jerks

Ocular: Visual disturbances, corneal microdeposits (occur in a majority of patients, but lead to visual disturbance in ~10%), diplopia; photophobia, optic neuropathy, cataract, optic neuritis

Renal: Abnormal renal function

Respiratory: Potentially fatal: **Interstitial pneumonitis,** hypersensitivity pneumonitis, **pulmonary fibrosis;** may present with cough, dyspnea,

bronchiolitis obliterans, pleural effusion, organizing pneumonia, hemoptysis, pleuritis, pulmonary edema; **alveolitis,** bronchospasm, hypoxia, wheezing; ARDS has been reported in up to 2% of patients receiving I.V. amiodarone, and post-operatively in patients receiving oral amiodarone.

Miscellaneous: Diaphoresis, anaphylactic shock

Signs and Symptoms of Overdose Patients should be monitored for several days following ingestion. AV block, chest pain, cirrhosis, delirium, extension of pharmacologic effect, heart block, hemoptysis, hyperthyroidism, hypotension, hypothyroidism, insomnia, myopathy, night terrors, pseudotumor cerebri, photosensitivity, sinus bradycardia, sweating, syncope, thrombocytopenia, toxic epidermal necrolysis, QT prolongation

Admission Criteria/Prognosis Admit any patient with ECG abnormalities or any adult ingestion >3 g

Pharmacodynamics/Kinetics

Onset of action: Oral: 2 days to 3 weeks; I.V.: May be more rapid

Peak effect: 1 week to 5 months

Duration after discontinuing therapy: 7-50 days

Note: Mean onset of effect and duration after discontinuation may be shorter in children than adults

Distribution: V_d : 66 L/kg (range: 18-148 L/kg); crosses placenta; enters breast milk in concentrations higher than maternal plasma concentrations
Protein binding: 96%

Metabolism: Hepatic via CYP2C8 and 3A4 to active N-desethylamiodarone metabolite; possible enterohepatic recirculation

Bioavailability: Oral: ~50%

Half-life elimination: Terminal: 40-55 days (range: 26-107 days); shorter in children than adults

Excretion: Feces; urine (<1% as unchanged drug)

Dosage

Note: Lower loading and maintenance doses are preferable in women and all patients with low body weight.

Oral:

Children: Arrhythmias (unlabeled use):

Loading dose: 10-20 mg/kg/day in 1-2 doses for 4-14 days or until adequate control of arrhythmia or prominent adverse effects occur; alternative loading dose in children <1 year: 600-800 mg/1.73 m²/day in 1-2 divided doses/day

Maintenance dose: Dose may be reduced to 5 mg/kg/day for several weeks (or 200-400 mg/1.73 m²/day given once daily); if no recurrence of arrhythmia, dose may be further reduced to 2.5 mg/kg/day; maintenance doses may be given 5-7 days/week

Adults:

Ventricular arrhythmias: 800-1600 mg/day in 1-2 doses for 1-3 weeks, then when adequate arrhythmia control is achieved, decrease to 600-800 mg/day in 1-2 doses for 1 month; maintenance: 400 mg/day. Lower doses are recommended for supraventricular arrhythmias.

Prophylaxis of atrial fibrillation following open heart surgery (unlabeled use): 400 mg twice daily (starting in postop recovery) for up to 7 days. An alternative regimen of amiodarone 600 mg/day for 7 days prior to surgery, followed by 200 mg/day until hospital discharge, has also been shown to decrease the risk of post-operative atrial fibrillation. **Note:** A variety of regimens have been used in clinical trials.

Recurrent atrial fibrillation (unlabeled use): No standard regimen defined; examples of regimens include: Initial: 10 mg/kg/day for 14 days; followed by 300 mg/day for 4 weeks, followed by maintenance dosage of 100-200 mg/day (Roy D, 2000). Other regimens have been described and are used clinically (ie, 400 mg 3 times/day for 5-7 days, then 400 mg/day for 1 month, then 200 mg/day).

I.V.:

Children:

Arrhythmias (unlabeled use, dosing based on limited data): Loading dose: 5 mg/kg over 30 minutes; may repeat up to 3 times if no response. Maintenance dose: 2-20 mg/kg/day (5-15 mcg/kg/minute) by continuous infusion

Note: I.V. administration at low flow rates (potentially associated with use in pediatrics) may result in leaching of plasticizers (DEHP) from intravenous tubing. DEHP may adversely affect male reproductive tract development. Alternative means of dosing and administration (1 mg/kg aliquots) may need to be considered.

Pulseless VF or VT (PALS dosing): 5 mg/kg rapid I.V. bolus or I.O.; repeat up to a maximum dose of 15 mg/kg (300 mg)

Perfusing tachycardias (PALS dosing): Loading dose: 5 mg/kg I.V. over 20-60 minutes or I.O.; may repeat up to maximum dose of 15 mg/kg/day

Adults:

Breakthrough VF or VT: 150 mg supplemental doses in 100 mL D₅W over 10 minutes

Pulseless VF or VT: I.V. push: Initial: 300 mg in 20-30 mL NS or D₅W; if VF or VT recurs, supplemental dose of 150 mg followed by

infusion of 1 mg/minute for 6 hours, then 0.5 mg/minute (maximum daily dose: 2.1 g)

Prophylaxis of atrial fibrillation following open heart surgery (unlabeled use): 1000 mg infused over 24 hours (starting at postop recovery) for 2 days has been shown to reduce the risk of postoperative atrial fibrillation. **Note:** A variety of regimens have been used in clinical trials.

Stable VT or SVT (unlabeled use): First 24 hours: 1050 mg according to following regimen

Step 1: 150 mg (100 mL) over first 10 minutes (mix 3 mL in 100 mL D₅W)

Step 2: 360 mg (200 mL) over next 6 hours (mix 18 mL in 500 mL D₅W); 1 mg/minute

Step 3: 540 mg (300 mL) over next 18 hours: 0.5 mg/minute

Note: After the first 24 hours: 0.5 mg/minute utilizing concentration of 1-6 mg/mL

Note: When switching from I.V. to oral therapy, use the following as a guide:

- < 1-week I.V. infusion: 800-1600 mg/day
- 1- to 3-week I.V. infusion: 600-800 mg/day
- > 3-week I.V. infusion: 400 mg/day

Recommendations for conversion to intravenous amiodarone after oral administration: During long-term amiodarone therapy (ie, ≥ 4 months), the mean plasma-elimination half-life of the active metabolite of amiodarone is 61 days. Replacement therapy may not be necessary in such patients if oral therapy is discontinued for a period <2 weeks, since any changes in serum amiodarone concentrations during this period may **not** be clinically significant.

Elderly: No specific guidelines available. Dose selection should be cautious, at low end of dosage range, and titration should be slower to evaluate response.

Hemodialysis: Not dialyzable (0% to 5%); supplemental dose is not necessary.

Peritoneal dialysis effects: Not dialyzable (0% to 5%); supplemental dose is not necessary.

Dosing adjustment in hepatic impairment: Probably necessary in substantial hepatic impairment. No specific guidelines available.

Stability May precipitate in 0.9% saline solution, or when combined with flucloxacillin sodium, furosemide, quinidine, heparin sodium, aminophylline, cefamandole nafate, cefazolin sodium or mezlocillin sodium

Monitoring Parameters Blood pressure, heart rate (ECG) and rhythm throughout therapy; assess patient for signs of lethargy, edema of the hands or feet, weight loss, and pulmonary toxicity (baseline pulmonary function tests); liver function tests; monitor serum electrolytes, especially potassium and magnesium. Assess for thyroid dysfunction (thyroid function tests): Amiodarone partially inhibits the peripheral conversion of thyroxine (T₄) to triiodothyronine (T₃); serum T₄ and reverse triiodothyronine (rT₃) concentrations may be increased and serum T₃ may be decreased; most patients remain clinically euthyroid, however, clinical hypothyroidism or hyperthyroidism may occur.

Administration Oral: Administer consistently with regard to meals. Take in divided doses with meals if high daily dose or if GI upset occurs. If GI intolerance occurs with single-dose therapy, use twice daily dosing.

I.V.: Give I.V. therapy using an infusion pump through a central line or a peripheral line at a concentration of <2 mg/mL. Slow the infusion rate if hypotension develops. **Note:** I.V. administration at low flow rates (potentially associated with use in pediatrics) may result in leaching of plasticizers (DEHP) from intravenous tubing. DEHP may adversely affect male reproductive tract development. Alternative means of dosing and administration (1 mg/kg aliquots) may need to be considered.

Contraindications Hypersensitivity to amiodarone, iodine, or any component of the formulation; severe sinus-node dysfunction; second- and third-degree heart block (except in patients with a functioning artificial pacemaker); bradycardia causing syncope (except in patients with a functioning artificial pacemaker); pregnancy

Warnings

[U.S. Boxed Warning]: Only indicated for patients with life-threatening arrhythmias because of risk of toxicity. Monitor for pulmonary toxicity (hypersensitivity or interstitial/alveolar pneumonitis). Lung damage (abnormal diffusion capacity) may occur without symptoms. Pre-existing pulmonary disease does not increase risk of developing pulmonary toxicity, but if pulmonary toxicity develops then the prognosis is worse. Liver toxicity is common, but usually mild with evidence of increased liver enzymes. Severe liver toxicity can occur and has been fatal in a few cases.

Amiodarone can exacerbate the arrhythmia (including torsade de pointes), making it more difficult to tolerate or reverse. Other types of arrhythmias have occurred (eg, significant heart block, sinus bradycardia). Proarrhythmic effects may be prolonged. Use very cautiously and with close monitoring in patients with thyroid or liver disease. May cause hyper- or hypothyroidism. Hyperthyroidism may aggravate or cause breakthrough arrhythmias. May cause optic neuropathy and/or optic neuritis, usually resulting in visual impairment. Corneal microdeposits occur in a majority of patients, and may cause visual disturbances in

some patients (blurred vision, halos); these are not generally considered a reason to discontinue treatment.

[U.S. Boxed Warning]: Alternative therapies should be tried first before using amiodarone. Patients should be hospitalized when amiodarone is initiated. Due to complex pharmacokinetics, it is difficult to predict when an arrhythmia or interaction with a subsequent treatment will occur following discontinuation of amiodarone.

Amiodarone is a potent inhibitor of CYP enzymes and transport proteins (including p-glycoprotein), which may lead to increased serum concentrations/toxicity of a number of medications. Particular caution must be used when a drug with QT_c-prolonging potential relies on metabolism via these enzymes, since the effect of elevated concentrations may be additive with the effect of amiodarone. Carefully assess risk/benefit of coadministration of other drugs which may prolong QT_c interval. Correct electrolyte disturbances, especially hypokalemia or hypomagnesemia, prior to use and throughout therapy.

May cause hypotension and bradycardia (infusion-rate related). Caution in surgical patients; may enhance hemodynamic effect of anesthetics; associated with increased risk of adult respiratory distress syndrome (ARDS) postoperatively. Injection contains benzyl alcohol, which has been associated with "gasping syndrome" in neonates. Safety and efficacy of amiodarone in children has not been fully established.

Dosage Forms

[DSC] = Discontinued product

Injection, solution, as hydrochloride: 50 mg/mL (3 mL, 9 mL, 18 mL) [contains benzyl alcohol and polysorbate (Tween®) 80]

Cordarone®: 50 mg/mL (3 mL) [contains benzyl alcohol and polysorbate (Tween®) 80]

Tablet, as hydrochloride [scored]: 200 mg, 400 mg

Cordarone®: 200 mg

Pacerone®: 100 mg [not scored], 200 mg, 300 mg [DSC], 400 mg

Reference Range

Therapeutic: 1.5-2.5 mg/L (SI: 1-4 µmol/L) (parent); desethyl metabolite is active and is present in equal concentration to parent drug

Toxic effects can be observed at levels >2.5 mg/L for parent compound or 1.5 mcg/mL for desethylamiodarone

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; cholestyramine can also decrease absorption

Supportive therapy: Intoxication with amiodarone necessitates ECG monitoring. When bradycardia occurs atropine may be given, however, atropine resistant bradycardia has been reported. In cases of difficult to treat amiodarone-induced bradycardia, injectable isoproterenol or a temporary pacemaker may be required. Corticosteroids may be useful to treat amiodarone pulmonary toxicity; corticosteroid therapy can be used to treat amiodarone-induced pleural disease. Propylthiouracil (with lithium) has been used to treat amiodarone-induced thyrotoxicosis with normalization of T₄ levels within 5 weeks. Angiotensin amide may be useful in treating hypotension (refractory to other modalities) due to amiodarone toxicity. Amiodarone-induced ataxia can be successfully treated with acetazolamide (125-250 mg twice daily).

Enhancement of elimination: Multiple dose of activated charcoal may be useful. Cholestyramine (4 g/hour for 4 hours) may be useful to decrease half-life. Dialysis is not useful.

Test Interactions Thyroid function tests: Amiodarone partially inhibits the peripheral conversion of thyroxine (T₄) to triiodothyronine (T₃); serum T₄ and reverse triiodothyronine (rT₃) concentrations may be increased and serum T₃ may be decreased; most patients remain clinically euthyroid, however, clinical hypothyroidism or hyperthyroidism may occur; hyperglycemia. Causes a falsely increased free thyroxine level.

Drug Interactions

Substrate of CYP1A2 (minor), 2C8 (major at low concentrations), 2C19 (minor), 2D6 (minor), 3A4 (major); **Inhibits** CYP1A2 (weak), 2A6 (moderate), 2B6 (weak), 2C9 (moderate), 2C19 (weak), 2D6 (moderate), 3A4 (moderate)

Anesthetics (halogenated, inhaled): Amiodarone enhances the myocardial depressant and conduction effects of inhalation anesthetics; monitor.

Azole antifungals: May prolong QT_c, potentially leading to malignant arrhythmias; use caution.

Beta-blockers may cause excessive AV block; monitor response.

Calcium channel blockers (diltiazem, verapamil): May cause excessive AV block; monitor.

Cimetidine: May increase amiodarone blood levels.

Cholestyramine: May decrease amiodarone blood levels.

Cisapride: May prolong QT_c interval potentially leading to malignant arrhythmias.

Clonazepam effects may be increased by amiodarone.

Cyclosporine: Serum levels may be increased by amiodarone; monitor.

CYP2A6 substrates: Amiodarone may increase the levels/effects of CYP2A6 substrates. Example substrates include dexmedetomidine and ifosfamide.

CYP2C8 inducers: May decrease the levels/effects of amiodarone. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C8 inhibitors: May increase the levels/effects of amiodarone. Example inhibitors include atazanavir, gemfibrozil, and ritonavir.

CYP2C9 substrates: Amiodarone may increase the levels/effects of CYP2C9 substrates. Example substrates include bosentan, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, warfarin, and zafirlukast.

CYP2D6 substrates: Amiodarone may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Amiodarone may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of amiodarone. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of amiodarone. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

CYP3A4 substrates: Amiodarone may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, ergot derivatives, mirtazapine, nateglinide, nefazodone, tacrolimus, and venlafaxine.

Digoxin levels may be increased by amiodarone; consider reducing digoxin dose by 50% and monitor digoxin blood levels closely.

Fentanyl: Concurrent use may lead to bradycardia, sinus arrest, and hypotension.

Flecainide blood levels may be increased; consider reducing flecainide dose by 25% to 33% with concurrent use.

Fluoroquinolones (sparfloxacin, gatifloxacin, moxifloxacin): May result in additional prolongation of the QT interval; concurrent use of sparfloxacin is contraindicated.

HMG-CoA reductase inhibitors (lovastatin, simvastatin, and others dependent on CYP3A4 metabolism): Amiodarone inhibits metabolism of lovastatin and/or simvastatin and may increase the risk of myopathy and rhabdomyolysis. Concurrent use of lovastatin or simvastatin is not recommended, but if unavoidable, dose of lovastatin should not exceed 40 mg/day. The dose of simvastatin should not exceed 20 mg/day; consider alternative HMG-CoA reductase inhibitor.

Lidocaine: Amiodarone may increase serum levels/toxicity of lidocaine. Sinus bradycardia may occur with concurrent use.

Macrolide antibiotics: May prolong QT_c, potentially leading to malignant arrhythmias. Use caution and evaluate risk:benefit.

Metoprolol blood levels may be increased; monitor response.

Phenytoin blood levels may be increased by amiodarone; amiodarone blood levels may be decreased by phenytoin.

Procainamide and NAPA plasma levels may be increased; consider reducing procainamide dosage by 25% with concurrent use.

Propranolol blood levels may be increased.

Protease inhibitors (amprenavir, indinavir, ritonavir): May increase amiodarone blood levels and toxicity; concurrent use is contraindicated.

QT_c interval prolonging agents (including but not limited to amitriptyline, bepridil, disopyramide, erythromycin, haloperidol, imipramine, quinidine, pimozone, procainamide, sotalol, and thioridazine): Effect/toxicity increased; use with caution.

Quinidine blood levels may be increased; monitor quinidine trough concentration.

Rifampin may decrease amiodarone blood levels.

Theophylline blood levels may be increased.

Thyroid supplements: Amiodarone may alter thyroid function; monitor closely.

Warfarin: Hypoprothrombinemic response increased. Monitor INR closely when amiodarone is initiated or discontinued. Reduce warfarin's dose by $\frac{1}{3}$ to $\frac{1}{2}$ when amiodarone is started.

Pregnancy Risk Factor D

Pregnancy Implications May cause fetal harm when administered to a pregnant woman, leading to congenital goiter and hypo- or hyperthyroidism.

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Nursing Implications Assess patient for signs of thyroid dysfunction, drowsiness, edema of the hands and feet, weight loss, and pulmonary toxicity

Additional Information

CNS symptoms normally develop within 7 days; muscle asthenia may present a significant hazard for ambulation; elevated erythrocyte sedimentation rate is found in >60% of patients with amiodarone-induced pulmonary disease. Grapefruit juice increases bioavailability of oral amiodarone by 50%; use should be avoided during therapy. Amiodarone contains iodine 37.3% by weight.

Rate of amiodarone-induced pulmonary disease is 5% to 10% with daily dosage >400 mg. Risk factors include pre-existing disease, radiographic abnormalities, history of lung resection, or history of pulmonary angiography.

Amisulpride

CAS Number 71675-85-9

Use Schizophrenia; acute psychosis, tic disorders, infantile autism

Mechanism of Action A substituted benzamide with selective blockade of central dopamine (D₂) receptors; has antiemetic neuroleptic properties (not FDA approved in U.S.)

Adverse Reactions

Cardiovascular: Hypotension
 Central nervous system: Lethargy, extrapyramidal reaction
 Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, hyperprolactinemia
 Genitourinary: Impotence

Signs and Symptoms of Overdose Coma, confusion, hyperthermia, mydriasis, seizures, tachycardia, QT prolongation on ECG

Toxicodynamics/Kinetics

Distribution: V_d: 13-16 L/kg
 Protein binding: 17%
 Metabolism: Hepatic to inactive metabolites
 Half-life: 14.5-17.3 hours
 Elimination: Renal (70% of drug is unchanged)

Dosage Oral: 50 mg to 1.2 g daily

Reference Range Peak plasma level after single oral dose of 200 mg: ~350 ng/mL; blood amisulpride level after 3 g ingestion (50 mg/kg) associated with seizures and light coma was 9.63 mcg/mL; a postmortem level of 41.7 mcg/mL was associated with suicide due to amisulpride overdose

Overdosage/Treatment

Decontamination: Lavage within 3 hours; activated charcoal
 Supportive therapy: Benzodiazepines may be useful for seizure control

Amitriptyline

Pronunciation (a mee TRIP ti leen)

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antidepressant Agents
- Butriptyline
- Dibenzipin
- Therapeutic Drugs Associated with Hallucinations

CAS Number 549-18-8

U.S. Brand Names Elavil® [DSC]

Synonyms Amitriptyline Hydrochloride; Elavil

Impairment Potential Yes. Doses of 50 mg can cause impairment; a greater than 5-times increased risk of injurious auto crash involvement following ingestion ≥ 125 mg amitriptyline in elderly drivers

Use Relief of symptoms of depression

Unlabeled/Investigational Use Analgesic for certain chronic and neuropathic pain; prophylaxis against migraine headaches; treatment of depressive disorders in children

Mechanism of Action Increases synaptic concentration of serotonin and/or norepinephrine in the central nervous system by inhibition of their reuptake by the presynaptic neuronal membrane

Adverse Reactions

Anticholinergic effects may be pronounced; moderate to marked sedation can occur (tolerance to these effects usually occurs).

Frequency not defined.

Cardiovascular: Orthostatic hypotension, tachycardia, nonspecific ECG changes, changes in AV conduction, cardiomyopathy (rare), MI, stroke, heart block, arrhythmias, syncope, hypertension, palpitations

Central nervous system: Restlessness, dizziness, insomnia, sedation, fatigue, anxiety, impaired cognitive function, seizures, extrapyramidal symptoms, coma, hallucinations, confusion, disorientation, impaired coordination, ataxia, headache, nightmares, hyperpyrexia

Dermatologic: Allergic rash, urticaria, photosensitivity, alopecia

Endocrine & metabolic: Syndrome of inappropriate ADH secretion

Gastrointestinal: Weight gain, xerostomia, constipation, paralytic ileus, nausea, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, black tongue

Genitourinary: Urinary retention

Hematologic: Bone marrow depression, purpura, eosinophilia

Ocular: Blurred vision, mydriasis, ocular pressure increased

Otic: Tinnitus

Neuromuscular & skeletal: Numbness, paresthesia, peripheral neuropathy, tremor, weakness

Miscellaneous: Diaphoresis; withdrawal reactions (nausea, headache, malaise)

Postmarketing and/or case reports: Neuroleptic malignant syndrome (rare), serotonin syndrome (rare)

Signs and Symptoms of Overdose Agitation, bowel ischemia, confusion, decreased GI motility, delirium, dementia, dental erosion, ejaculatory disturbances, extrapyramidal reaction, fever, hallucinations, hyperacusis, hyperthermia, hyponatremia, hypotension, hypothermia, increased intraocular pressure, insomnia, lactation, memory loss, mania, myoglobinuria, neuroleptic malignant syndrome, nystagmus, paresthesia, periarteritis nodosa, photosensitivity, purpura, QRS prolongation, respiratory depression, seizures, tachycardia, urinary retention, urine discoloration (blue-green)

Admission Criteria/Prognosis Admit any patient who has any symptoms (including sinus tachycardia) 6 hours postingestion; admit any pediatric ingestion > 5 mg/kg

Pharmacodynamics/Kinetics

Onset of action: Migraine prophylaxis: 6 weeks, higher dosage may be required in heavy smokers because of increased metabolism; Depression: 4-6 weeks, reduce dosage to lowest effective level

Distribution: Crosses placenta; enters breast milk

Metabolism: Hepatic to nortriptyline (active), hydroxy and conjugated derivatives; may be impaired in the elderly

Half-life elimination: Adults: 9-27 hours (average: 15 hours)

Time to peak, serum: ~4 hours

Excretion: Urine (18% as unchanged drug); feces (small amounts)

Dosage

Children:

Chronic pain management (unlabeled use): Oral: Initial: 0.1 mg/kg at bedtime, may advance as tolerated over 2-3 weeks to 0.5-2 mg/kg at bedtime

Depressive disorders (unlabeled use): Oral: Initial doses of 1 mg/kg/day given in 3 divided doses with increases to 1.5 mg/kg/day have been reported in a small number of children (n=9) 9-12 years of age; clinically, doses up to 3 mg/kg/day (5 mg/kg/day if monitored closely) have been proposed

Migraine prophylaxis (unlabeled use): Oral: Initial: 0.25 mg/kg/day, given at bedtime; increase dose by 0.25 mg/kg/day to maximum 1 mg/kg/day. Reported dosing ranges: 0.1-2 mg/kg/day; maximum suggested dose: 10 mg

Adolescents: Depressive disorders: Oral: Initial: 25-50 mg/day; may administer in divided doses; increase gradually to 100 mg/day in divided doses

Adults:

Depression:

Oral: 50-150 mg/day single dose at bedtime or in divided doses; dose may be gradually increased up to 300 mg/day

I.M.: 20-30 mg 4 times/day

Migraine prophylaxis (unlabeled use): Oral: Initial: 10-25 mg at bedtime; usual dose: 150 mg; reported dosing ranges: 10-400 mg/day

Pain management (unlabeled use): Oral: Initial: 25 mg at bedtime; may increase as tolerated to 100 mg/day

Elderly: Depression: Oral: Initial: 10-25 mg at bedtime; dose should be increased in 10-25 mg increments every week if tolerated; dose range: 25-150 mg/day

Dosing interval in hepatic impairment: Use with caution and monitor plasma levels and patient response

Hemodialysis: Nondialyzable

Stability Keep oral solution in refrigerator; remains stable for 7 days after preparation; protect injection and Elavil® 10 mg tablets from light

Monitoring Parameters Monitor blood pressure and pulse rate prior to and during initial therapy; evaluate mental status; monitor weight; ECG in older adults and patients with cardiac disease

Contraindications Hypersensitivity to amitriptyline or any component of the formulation (cross-sensitivity with other tricyclics may occur); use of MAO inhibitors within past 14 days; acute recovery phase following myocardial infarction; concurrent use of cisapride

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. **Amitriptyline is not FDA-approved for use in children < 12 years of age.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Amitriptyline is not FDA approved for the treatment of bipolar depression.**

Often causes drowsiness/sedation, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Sedative effects may be additive with other CNS depressants and/or ethanol. The degree of sedation is very high relative to other antidepressants. May cause hyponatremia/SIADH. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Therapy should not be abruptly discontinued in patients receiving high doses for prolonged periods.

May cause orthostatic hypotension; the risk of this problem is very high relative to other antidepressants. Use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). The degree of anticholinergic blockade produced by this agent is very high relative to other cyclic antidepressants; use with caution in patients with urinary retention, benign prostatic hyperplasia, narrow-angle glaucoma, xerostomia, visual problems, constipation, or a history of bowel obstruction. May alter glucose control - use with caution in patients with diabetes.

Use with caution in patients with a history of cardiovascular disease (including previous MI, stroke, tachycardia, or conduction abnormalities). The risk of conduction abnormalities with this agent is high relative to other antidepressants. May lower seizure threshold - use caution in patients with a previous seizure disorder or condition predisposing to seizures such as brain damage, alcoholism, or

concurrent therapy with other drugs which lower the seizure threshold. Use with caution in hyperthyroid patients or those receiving thyroid supplementation. Use with caution in patients with hepatic or renal dysfunction and in elderly patients.

Dosage Forms Tablet, as hydrochloride: 10 mg, 25 mg, 50 mg, 75 mg, 100 mg, 150 mg

Reference Range

Therapeutic:

Amitriptyline and nortriptyline: 100-250 ng/mL (SI: 360-900 nmol/L)

Nortriptyline: 50-150 ng/mL (SI: 190-570 nmol/L)

Toxic: >500 ng/mL; seizures can occur at levels >1000 ng/mL (SI: >3605 nmol/L)

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur

Overdosage/Treatment

Decontamination: Lavage within 2-3 hours/activated charcoal; **do not** induce emesis; multiple dosing of activated charcoal is more effective

Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated. Ventricular arrhythmias and ventricular conduction defects often respond to concurrent systemic alkalinization (sodium bicarbonate 0.5-2 mEq/kg I.V.). Titrate to a serum pH of 7.45-7.55. Arrhythmias unresponsive to this therapy may respond to lidocaine 1 mg/kg I.V. followed by a titrated infusion. Phenytoin is also useful in treating ventricular dysrhythmias (15 mg/kg up to 1 g I.V.). Physostigmine (1-2 mg I.V. slowly for adults or 0.5 mg I.V. slowly for children) may be indicated for seizures or movement disorders but only as **a last resort**. Propranolol may also be utilized for supraventricular arrhythmias (rate: >160) at 1 mg/minute to a maximum of 5 mg in adults; pediatric dosage of 0.1 mg/kg/dose to 1 mg I.V.. Seizures usually respond to lorazepam or diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required. Patients must be monitored for at least 24 hours if any signs or symptoms are exhibited. Dobutamine is preferred over dopamine for hypotension, although there is conflicting animal data. Norepinephrine appears effective in treating hypotension; glucagon (10 mg I.V.) can be given to treat hypotension. Vasopressin (initial dose: 0.04 units/minute) may be an effective vasopressor in treating hypotension. Flumazenil is contraindicated; magnesium has potentiated adverse cardiac effects (ie, asystole, decreased left ventricular pressure) in an animal model, although it was used successfully in treating refractory ventricular fibrillation at a dose of 20 nmol I.V. (a total of 2 doses). For treatment of lingua villosa nigra, discontinue causative agent. Clean the tongue with a toothbrush and rinse mouth with a half-strength solution of hydrogen peroxide or 10% carbamide peroxide. Oral symptoms should subside in a few days.

TCA ovine antibody fragments (TCA Fab, Protherics Inc) have been developed and used investigational at a dose of 1-2 g over 30 minutes I.V.; if QRS was >100 msec or terminal deflection of QRS in lead aVR was >3 mm, a second dose (2 g over 30 min or 4 g over 1 hour) was given. If no response, a third infusion (4 g over 60 minutes or 8 g over 2 hours) was given.

Enhanced elimination: Multiple dosing of activated charcoal may be effective

Antidote(s)

● Sodium Bicarbonate [ANTIDOTE]

Test Interactions ↑ glucose, CPK, LDH, plasma catecholamine levels; cross reacts with phenothiazine levels

Drug Interactions

Substrate of CYP1A2 (minor), 2B6 (minor), 2C9 (minor), 2C19 (minor), 2D6 (major), 3A4 (minor); **Inhibits** CYP1A2 (weak), 2C9 (weak), 2C19 (weak), 2D6 (weak), 2E1 (weak)

Altretamine: Concurrent use may cause orthostatic hypertension.

Amphetamines: TCAs may enhance the effect of amphetamines; monitor for adverse CV effects.

Anticholinergics: Combined use with TCAs may produce additive anticholinergic effects.

Antihypertensives: Amitriptyline inhibits the antihypertensive response to bethanidine, clonidine, debrisoquin, guanadrel, guanethidine, guanabenz, guanfacine; monitor BP; consider alternate antihypertensive agent.

Beta-agonists: When combined with TCAs may predispose patients to cardiac arrhythmias.

Bupropion: May increase the levels of tricyclic antidepressants; based on limited information, monitor response.

Carbamazepine: Tricyclic antidepressants may increase carbamazepine levels; monitor.

Cholestyramine and colestipol: May bind TCAs and reduce their absorption; monitor for altered response.

Cisapride: May increase the risk of QT_c prolongation and/or arrhythmia; concurrent use is contraindicated.

Clonidine: Abrupt discontinuation of clonidine may cause hypertensive crisis; amitriptyline may enhance the response (also see note on antihypertensives).

CNS depressants: Sedative effects may be additive with TCAs; monitor for increased effect; includes benzodiazepines, barbiturates, antipsychotics, ethanol, and other sedative medications.

CYP2D6 inhibitors: May increase the levels/effects of amitriptyline; example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Epinephrine (and other direct alpha-agonists): Pressor response to I.V. epinephrine, norepinephrine, and phenylephrine may be enhanced in patients receiving TCAs. (**Note:** Effect is unlikely with epinephrine or levonordefrin dosages typically administered as infiltration in combination with local anesthetics.)

Fenfluramine: May increase tricyclic antidepressant levels/effects.

Hypoglycemic agents (including insulin): TCAs may enhance the hypoglycemic effects of tolazamide, chlorpropamide, or insulin; monitor for changes in blood glucose levels; reported with chlorpropamide, tolazamide, and insulin.

Levodopa: Tricyclic antidepressants may decrease the absorption (bioavailability) of levodopa; rare hypertensive episodes have also been attributed to this combination.

Linezolid: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** with agents which inhibit MAO (serotonin syndrome); this combination should be avoided.

Lithium: Concurrent use with a TCA may increase the risk for neurotoxicity.

MAO inhibitors: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** (serotonin syndrome); this combination should be avoided.

Methylphenidate: Metabolism of amitriptyline may be decreased.

Phenothiazines: Serum concentrations of some TCAs may be increased; in addition, TCAs may increase concentration of phenothiazines; monitor for altered clinical response.

QT_c prolonging agents: Concurrent use of tricyclic agents with other drugs which may prolong QT_c interval may increase the risk of potentially fatal arrhythmias; includes type Ia and type III antiarrhythmics agents, selected quinolones (sparfloxacin, gatifloxacin, moxifloxacin, grepafloxacin), cisapride, and other agents.

Ritonavir: Combined use of high-dose tricyclic antidepressants with ritonavir may cause serotonin syndrome in HIV-positive patients; monitor.

Sucralfate: Absorption of tricyclic antidepressants may be reduced with coadministration.

Sympathomimetics, indirect-acting: Tricyclic antidepressants may result in a decreased sensitivity to indirect-acting sympathomimetics; includes dopamine and ephedrine; also see interaction with epinephrine (and direct-acting sympathomimetics).

Tramadol: Tramadol's risk of seizures may be increased with TCAs.

Valproic acid: May increase serum concentrations/adverse effects of some tricyclic antidepressants.

Warfarin (and other oral anticoagulants): Amitriptyline may increase the anticoagulant effect in patients stabilized on warfarin; monitor INR.

Pregnancy Risk Factor D

Pregnancy Implications Teratogenic effects have been observed in animal studies. Amitriptyline crosses the human placenta; CNS effects, limb deformities and developmental delay have been noted in case reports.

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Additional Information Plasma levels do not always correlate with clinical effectiveness. The desired therapeutic effect (for depression) may take as long as 3-4 weeks, at that point the dosage should be reduced to the lowest effective level. When used for migraine headache prophylaxis, the therapeutic effect may take as long as 6 weeks. Because of increased metabolism, a higher dosage may be required in heavy smokers.

Admission Criteria/Prognosis Admit any symptomatic (cardiovascular) patient or ingestions > 1 mg/kg

Pharmacodynamics/Kinetics

Onset of action: Antihypertensive: 30-50 minutes
 Duration of antihypertensive effect: 24 hours
 Absorption: Oral: Well absorbed
 Distribution: V_d: 21 L/kg
 Protein binding: 93% to 98%
 Metabolism: Hepatic (> 90%) to inactive metabolite
 Bioavailability: 64% to 90%
 Half-life elimination: 30-50 hours; increased with hepatic dysfunction
 Time to peak, plasma: 6-12 hours
 Excretion: Urine (10% as parent, 60% as metabolite)

Dosage

Oral:
 Children 6-17 years: Hypertension: 2.5-5 mg once daily
 Adults:
 Hypertension: Initial dose: 5 mg once daily; maximum dose: 10 mg once daily. In general, titrate in 2.5 mg increments over 7-14 days. Usual dosage range (JNC-7): 2.5-10 mg once daily.
 Angina: Usual dose: 5-10 mg
 Elderly: Dosing should start at the lower end of dosing range due to possible increased incidence of hepatic, renal, or cardiac impairment. Elderly patients also show decreased clearance of amlodipine.
 Hypertension: 2.5 mg once daily
 Angina: 5 mg once daily
 Dialysis: Hemodialysis and peritoneal dialysis does not enhance elimination. Supplemental dose is not necessary.
Dosage adjustment in hepatic impairment:
 Angina: Administer 5 mg once daily.
 Hypertension: Administer 2.5 mg once daily.

Administration

May be administered without regard to meals.

Contraindications Hypersensitivity to amlodipine or any component of the formulation

Warnings Increased angina and/or MI has occurred with initiation or dosage titration of calcium channel blockers. Use caution in severe aortic stenosis. Use caution in patients with severe hepatic impairment. Dosage titration should occur after 7-14 days on a given dose.

Dosage Forms

Tablet:
 Norvasc®: 2.5 mg, 5 mg, 10 mg

Reference Range Peak plasma amlodipine level after a 10 mg oral dose: ~5.9 mcg/L; postmortem peripheral blood amlodipine level after a 140 mg overdose was 2.7 mg/L; therapeutic range: 3-11 ng/mL. Serum level of amlodipine of 140 ng/mL associated with an 800 mg ingestion and hypotension. Postmortem heart blood amlodipine level > 1 mg/L associated with fatal overdoses.

Overdosage/Treatment

Decontamination: Ipecac-induced emesis can hypothetically worsen calcium antagonist toxicity, since it can produce vagal stimulation. The potential for seizures precipitously following acute ingestion of large doses of a calcium antagonist may also contraindicate the use of ipecac. Lavage (within 1 hour)/activated charcoal is useful. Whole bowel irrigation for sustained release preparations.
 Supportive therapy: I.V. fluids and Trendelenburg positioning should be initiated as intoxication may cause hypotension. Calcium (calcium chloride I.V. 1-3 g in adults or 10-30 mg/kg in children over 5-10 minutes with repeats as needed) has been used as treatment for acute intoxications and is considered as second line therapy for shock after traditional use of vasopressors. Hyperinsulinemic therapy with 0.5-1.0 unit I.V. insulin bolus with an infusion of 0.2-1 unit/kg/hour plus a glucose bolus of 25 g I.V. and dextrose infusion to maintain a serum glucose > 100 mg/dL may reverse cardiogenic shock due to calcium blockers. Heart block may respond to isoproterenol, glucagon, atropine and/or calcium, although a temporary pacemaker may be required. Inamrinone or dopamine may be required for hypotension. Glucagon may increase myocardial contractility. High dose vasopressin (up to 4.8 units/hour) may be effective in treating hypotension.
 Vasopressin (20 IU bolus I.V. titrated by blood pressure to 4 to 5 IU/hour infusion) can increase systemic vascular resistance and cardiac output. Enhancement of elimination: Multiple dosing of activated charcoal is useful

Drug Interactions

Substrate of CYP3A4 (major); **Inhibits** CYP1A2 (moderate), 2A6 (weak), 2B6 (weak), 2C8 (weak), 2C9 (weak), 2D6 (weak), 3A4 (weak) Azole antifungals may inhibit calcium channel blocker metabolism; avoid this combination. Try an antifungal like terbinafine (if appropriate) or monitor closely for altered effect of the calcium channel blocker. Calcium may reduce the calcium channel blocker's effects, particularly hypotension.
 CYP1A2 substrates: Amlodipine may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, fluvoxamine, mexiletine, mirtazapine, ropinirole, theophylline, and trifluoperazine.

Amlodipine

Pronunciation (am LOE di peen)

Related Information

- Calcium Channel Blockers

CAS Number 111470-99-6; 88150-42-9; 88150-47-4

U.S. Brand Names Norvasc®

Synonyms Amlodipine Besylate

Use Treatment of hypertension and angina

Mechanism of Action A 1,4 dihydropyridine calcium channel blocking agent; a potent vasodilator

Adverse Reactions

Cardiovascular: Dose dependent **peripheral edema** (2% to 15%), flushing, palpitations, exacerbation of intracranial hypertension
 Central nervous system: Headache, fatigue, dizziness, somnolence, intracranial hemorrhage
 Dermatologic: Erythematous rash, pruritus, exanthema, erythema multiforme, alopecia, urticaria, purpura
 Gastrointestinal: Nausea, gingival hyperplasia, xerostomia, weight gain/loss
 Hematologic: Thrombocytopenia
 Hepatic: Jaundice
 Neuromuscular & skeletal: Arthralgias, myalgias

Signs and Symptoms of Overdose Bradycardia, conductive defects, hypotension, reflex tachycardia

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of amlodipine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.
 CYP3A4 inhibitors: May increase the levels/effects of amlodipine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.
 Grapefruit juice: May modestly increase amlodipine levels.
 Rifampin increases the metabolism of calcium channel blockers; adjust the dose of calcium channel blocker to maintain efficacy.
 Sildenafil, tadalafil, vardenafil: Blood pressure-lowering effects are additive; use caution.

Pregnancy Risk Factor C

Pregnancy Implications Embryotoxic effects have been demonstrated in small animals. No well-controlled studies have been conducted in pregnant women. Use in pregnancy only when clearly needed and when the benefits outweigh the potential hazard to the fetus.

Lactation Excretion in breast milk unknown/not recommended

Neuromuscular & skeletal: Rhabdomyolysis, paresthesia
 Ocular: Oculogyric crisis (extrapyramidal)

Signs and Symptoms of Overdose Acidosis, cognitive dysfunction, coma, dementia, depression, ejaculatory disturbances, extrapyramidal reaction, grand mal seizures, hematuria, hyperprolactinemia, impotence, incomplete right bundle-branch block, insomnia, mania, myoglobinuria, photosensitivity, neuroleptic malignant syndrome, nystagmus, supraventricular arrhythmias, renal failure (acute). Neurotoxic effects may be permanent.

Admission Criteria/Prognosis Admit any patient who is symptomatic (including sinus tachycardia) 6 hours postingestion; admit any pediatric ingestion > 5 mg/kg

Pharmacodynamics/Kinetics

Onset of antidepressant effect: Usually occurs after 1-2 weeks, but may require 4-6 weeks
 Absorption: Rapid and well absorbed
 Distribution: V_d : 0.9-1.2 L/kg; enters breast milk
 Protein binding: 80%
 Metabolism: Primarily hepatic
 Half-life elimination: Parent drug: 11-16 hours; Active metabolite (8-hydroxy): Adults: 30 hours
 Time to peak, serum: 1-2 hours
 Excretion: Urine (as unchanged drug and metabolites)

Dosage

Once symptoms are controlled, decrease gradually to lowest effective dose. Maintenance dose is usually given at bedtime to reduce daytime sedation. Oral:
 Children < 16 years: Not established
 Adolescents: Initial: 25-50 mg/day; increase gradually to 100 mg/day; may give as divided doses or as a single dose at bedtime
 Adults: Initial: 25 mg 2-3 times/day, if tolerated, dosage may be increased to 100 mg 2-3 times/day; may be given in a single bedtime dose when dosage < 300 mg/day
 Maximum daily dose:
 Inpatient: 600 mg
 Outpatient: 400 mg

Monitoring Parameters Monitor blood pressure and pulse rate prior to and during initial therapy evaluate mental status; monitor weight; ECG in older adults

Administration

May be administered with food to decrease GI distress.

Contraindications Hypersensitivity to amoxapine or any component of the formulation; use of MAO inhibitors within past 14 days; acute recovery phase following myocardial infarction

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. **Amoxapine is not FDA approved for use in patients < 16 years of age.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Amoxapine is not FDA approved for the treatment of bipolar depression.**

May cause sedation, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Sedative effects may be

Amoxapine

Pronunciation (a MOKS a peen)

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antidepressant Agents
- Therapeutic Drugs Associated with Hallucinations

CAS Number 14028-44-5

Synonyms Asendin [DSC]

Use Treatment of neurotic and endogenous depression and mixed symptoms of anxiety and depression

Mechanism of Action Reduces the reuptake of serotonin and norepinephrine and blocks the response of dopamine receptors to dopamine; low effect on serotonin reuptake. Amoxapine is a metabolite of the antipsychotic agent loxapine.

Adverse Reactions

Anticholinergic: Extrapyramidal effects, tardive dyskinesia, blurred vision
 Cardiovascular: Hypotension, sinus tachycardia, relatively low cardiac toxicity as compared to other tricyclic antidepressants, AV block, sinus tachycardia, tachycardia (supraventricular), arrhythmias (ventricular), vasculitis
 Central nervous system: **Drowsiness**, restlessness, **dizziness**, nervousness, insomnia, seizures, Parkinson's-like symptoms, chorea (extrapyramidal), tardive dyskinesia, fever, visual hallucinations, neuroleptic malignant syndrome, electroencephalogram abnormalities, hyperthermia
 Dermatologic: Rash, toxic epidermal necrolysis, exanthema, acne, acute generalized exanthematous pustulosis, alopecia, xerosis, purpura, pruritus, lingua villosa nigra
 Endocrine & metabolic: Amenorrhea, galactorrhea, syndrome of inappropriate antidiuretic hormone
 Gastrointestinal: **Constipation**, **xerostomia**, **nausea**, **unpleasant taste**, **weight gain**, pancreatitis, stomatitis
 Hematologic: Leukopenia/neutropenia (agranulocytosis, granulocytopenia)

additive with other CNS depressants and/or ethanol. The degree of sedation is moderate relative to other antidepressants. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Therapy should not be abruptly discontinued in patients receiving high doses for prolonged periods.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is low). May be associated with neuroleptic malignant syndrome.

May cause orthostatic hypotension (risk is moderate relative to other antidepressants) - use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). The degree of anticholinergic blockade produced by this agent is moderate relative to other cyclic antidepressants - use caution in patients with urinary retention, benign prostatic hyperplasia, narrow-angle glaucoma, xerostomia, visual problems, constipation, or history of bowel obstruction.

Use with caution in patients with a history of cardiovascular disease (including previous MI, stroke, tachycardia, or conduction abnormalities). The risk conduction abnormalities with this agent is moderate relative to other antidepressants. May lower seizure threshold - use caution in patients with a previous seizure disorder or condition predisposing to seizures such as brain damage, alcoholism, or concurrent therapy with other drugs which lower the seizure threshold. Use with caution in hyperthyroid patients or those receiving thyroid supplementation. Use with caution in patients with hepatic or renal dysfunction and in elderly patients.

Dosage Forms Tablet: 25 mg, 50 mg, 100 mg, 150 mg

Reference Range

Therapeutic:

Amoxapine 20-100 ng/mL (SI: 64-319 nmol/L)
8-OH-amoxapine: 150-400 ng/mL (SI: 478-1275 nmol/L)
Both: 200-500 ng/mL (SI: 637-1594 nmol/L)

Fatal: 261 ng/mL

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur

Overdosage/Treatment

Decontamination: Lavage (up to 8 hours postingestion)/activated charcoal; multiple dosing of activated charcoal may be effective; **do not** induce emesis

Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated. Propofol (2.5 mg/kg bolus I.V. followed by infusion of 0.2 mg/kg/minute) has been effective in terminating amoxapine-induced seizures in a case report; ventricular arrhythmias often respond to phenytoin 15-20 mg/kg (adults) with concurrent systemic alkalization (sodium bicarbonate 0.5-2 mEq/kg I.V.). Arrhythmias unresponsive to this therapy may respond to lidocaine 1 mg/kg I.V. followed by a titrated infusion. Seizures usually respond to diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required. Use physostigmine only as **a last resort**. For treatment of lingua villosa nigra, discontinue causative agent. Clean the tongue with a toothbrush and rinse mouth with a half-strength solution of hydrogen peroxide or 10% carbamide peroxide. Symptoms should subside in a few days.

Antidote(s)

- Sodium Bicarbonate [ANTIDOTE]

Test Interactions ↑ glucose; may ↑ prolactin level

Drug Interactions

Substrate of CYP2D6 (major)

Anticholinergics: Combined use with TCAs may produce additive anticholinergic effects.

Altretamine: Concurrent use may cause orthostatic hypertension.

Amphetamines: TCAs may enhance the effect of amphetamines; monitor for adverse CV effects.

Antihypertensives: Amitriptyline inhibits the antihypertensive response to bethanidine, clonidine, debrisoquin, guanadrel, guanethidine, guanabenz, guanfacine; monitor BP; consider alternate antihypertensive agent.

Beta-agonists: When combined with TCAs, may predispose patients to cardiac arrhythmias.

Bupropion: May increase the levels of tricyclic antidepressants; based on limited information; monitor response.

Carbamazepine: Tricyclic antidepressants may increase carbamazepine levels; monitor.

Cholestyramine and colestipol: May bind TCAs and reduce their absorption; monitor for altered response.

Clonidine: Abrupt discontinuation of clonidine may cause hypertensive crisis; amitriptyline may enhance the response.

CNS depressants: Sedative effects may be additive with TCAs; monitor for increased effect; includes benzodiazepines, barbiturates, antipsychotics, ethanol, and other sedative medications.

CYP2D6 inhibitors: May increase the levels/effects of amoxapine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Epinephrine (and other direct alpha-agonists): Pressor response to I.V. epinephrine, norepinephrine, and phenylephrine may be enhanced in patients receiving TCAs. (**Note:** Effect is unlikely with epinephrine or levonordefrin dosages typically administered as infiltration in combination with local anesthetics).

Fenfluramine: May increase tricyclic antidepressant levels/effects.

Hypoglycemic agents (including insulin): TCAs may enhance the hypoglycemic effects of tolazamide, chlorpropamide, or insulin; monitor for changes in blood glucose levels; reported with chlorpropamide, tolazamide, and insulin.

Levodopa: Tricyclic antidepressants may decrease the absorption (bioavailability) of levodopa; rare hypertensive episodes have also been attributed to this combination.

Linezolid: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** with agents which inhibit MAO (serotonin syndrome); this combination should be avoided.

Lithium: Concurrent use with a TCA may increase the risk for neurotoxicity.

MAO inhibitors: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** (serotonin syndrome); this combination should be avoided.

Methylphenidate: Metabolism of amitriptyline may be decreased.

Phenothiazines: Serum concentrations of some TCAs may be increased; in addition, TCAs may increase concentration of phenothiazines; monitor for altered clinical response.

QT_c-prolonging agents: Concurrent use of tricyclic agents with other drugs which may prolong QT_c interval may increase the risk of potentially fatal arrhythmias; includes type Ia and type III antiarrhythmics agents, selected quinolones (sparfloxacin, gatifloxacin, moxifloxacin, grepafloxacin), cisapride, and other agents.

Ritonavir: Combined use of high-dose tricyclic antidepressants with ritonavir may cause serotonin syndrome in HIV-positive patients; monitor.

Sucralate: Absorption of tricyclic antidepressants may be reduced with coadministration.

Sympathomimetics, indirect-acting: Tricyclic antidepressants may result in a decreased sensitivity to indirect-acting sympathomimetics; includes dopamine and ephedrine; also see interaction with epinephrine (and direct-acting sympathomimetics).

Tramadol: Tramadol's risk of seizures may be increased with TCAs.

Valproic acid: May increase serum concentrations/adverse effects of some tricyclic antidepressants.

Warfarin (and other oral anticoagulants): Amitriptyline may increase the anticoagulant effect in patients stabilized on warfarin; monitor INR.

Pregnancy Risk Factor C

Lactation Enters breast milk/contraindicated (AAP rates "of concern")

Nursing Implications May increase appetite and possibly a craving for sweets; recognize signs of neuroleptic malignant syndrome and tardive dyskinesia

Additional Information May take up to 2 weeks for full therapeutic effects to be apparent; maintenance dose is usually given at bedtime to reduce daytime sedation; tolerance develops in 1-3 months in some patients, close medical follow-up is essential

Amoxicillin

Pronunciation (a moks i SIL in)

CAS Number 26787-78-0; 34642-77-8; 61336-70-7

U.S. Brand Names Amoxil®; DisperMox™; Moxilin®; Trimox®

Synonyms *p*-Hydroxyampicillin; Amoxicillin Trihydrate; Amoxycillin

Use Treatment of otitis media, sinusitis, and infections caused by susceptible organisms involving the respiratory tract, skin, and urinary tract; prophylaxis of bacterial endocarditis in patients undergoing surgical or dental procedures; as part of a multidrug regimen for *H. pylori* eradication

Unlabeled/Investigational Use Postexposure prophylaxis for anthrax exposure with documented susceptible organisms

Mechanism of Action Interferes with bacterial cell wall synthesis during active multiplication, causing cell wall death and resultant bactericidal activity against susceptible bacteria

Adverse Reactions

Frequency not defined.

Central nervous system: Hyperactivity, agitation, anxiety, insomnia, confusion, convulsions, behavioral changes, dizziness

Dermatologic: Acute exanthematous pustulosis, erythematous maculopapular rash, erythema multiforme, Stevens-Johnson syndrome, exfoliative dermatitis, toxic epidermal necrolysis, hypersensitivity vasculitis, urticaria

Gastrointestinal: Nausea, vomiting, diarrhea, hemorrhagic colitis, pseudomembranous colitis, tooth discoloration (brown, yellow, or gray; rare)

AMPHOTERICIN B

Hematologic: Anemia, hemolytic anemia, thrombocytopenia, thrombocytopenia purpura, eosinophilia, leukopenia, agranulocytosis

Hepatic: Elevated AST (SGOT) and ALT (SGPT), cholestatic jaundice, hepatic cholestasis, acute cytolytic hepatitis

Signs and Symptoms of Overdose Many beta-lactam antibiotics have the potential to cause neuromuscular hyperirritability or convulsive seizures. Acute renal failure, hematuria, neuromuscular sensitivity, pemphigus

Pharmacodynamics/Kinetics

Absorption: Oral: Rapid and nearly complete; food does not interfere

Distribution: Widely to most body fluids and bone; poor penetration into cells, eyes, and across normal meninges

Pleural fluids, lungs, and peritoneal fluid; high urine concentrations are attained; also into synovial fluid, liver, prostate, muscle, and gallbladder; penetrates into middle ear effusions, maxillary sinus secretions, tonsils, sputum, and bronchial secretions; crosses placenta; low concentrations enter breast milk

CSF:blood level ratio: Normal meninges: <1%; Inflamed meninges: 8% to 90%

Protein binding: 17% to 20%

Metabolism: Partially hepatic

Half-life elimination:

Neonates, full-term: 3.7 hours

Infants and Children: 1-2 hours

Adults: Normal renal function: 0.7-1.4 hours

Cl_{cr} < 10 mL/minute: 7-21 hours

Time to peak: Capsule: 2 hours; Suspension: 1 hour

Excretion: Urine (80% as unchanged drug); lower in neonates

Dosage

Oral:

Children ≤3 months: 20-30 mg/kg/day divided every 12 hours

Children: >3 months and <40 kg: Dosing range: 20-50 mg/kg/day in divided doses every 8-12 hours

Ear, nose, throat, genitourinary tract, or skin/skin structure infections:
Mild to moderate: 25 mg/kg/day in divided doses every 12 hours or 20 mg/kg/day in divided doses every 8 hours
Severe: 45 mg/kg/day in divided doses every 12 hours or 40 mg/kg/day in divided doses every 8 hours

Acute otitis media due to highly-resistant strains of *S. pneumoniae*: Doses as high as 80-90 mg/kg/day divided every 12 hours have been used

Lower respiratory tract infections: 45 mg/kg/day in divided doses every 12 hours or 40 mg/kg/day in divided doses every 8 hours

Subacute bacterial endocarditis prophylaxis: 50 mg/kg 1 hour before procedure

Anthrax exposure (unlabeled use): **Note:** Postexposure prophylaxis only with documented susceptible organisms:

<40 kg: 15 mg/kg every 8 hours

≥40 kg: 500 mg every 8 hours

Adults: Dosing range: 250-500 mg every 8 hours or 500-875 mg twice daily; maximum dose: 2-3 g/day

Ear, nose, throat, genitourinary tract or skin/skin structure infections:
Mild to moderate: 500 mg every 12 hours or 250 mg every 8 hours
Severe: 875 mg every 12 hours or 500 mg every 8 hours

Lower respiratory tract infections: 875 mg every 12 hours or 500 mg every 8 hours

Endocarditis prophylaxis: 2 g 1 hour before procedure

Helicobacter pylori eradication: 1000 mg twice daily; requires combination therapy with at least one other antibiotic and an acid-suppressing agent (proton pump inhibitor or H₂ blocker)

Anthrax exposure (unlabeled use): **Note:** Postexposure prophylaxis only with documented susceptible organisms: 500 mg every 8 hours

Dosing interval in renal impairment: The 875 mg tablet should not be used in patients with Cl_{cr} <30 mL/minute.

Cl_{cr} 10-30 mL/minute: 250-500 mg every 12 hours

Cl_{cr} < 10 mL/minute: 250-500 mg every 24 hours

Dialysis: Moderately dialyzable (20% to 50%) by hemo- or peritoneal dialysis; approximately 50 mg of amoxicillin per liter of filtrate is removed by continuous arteriovenous or venovenous hemofiltration; dose as per Cl_{cr} < 10 mL/minute guidelines

Monitoring Parameters With prolonged therapy, monitor renal, hepatic, and hematologic function periodically; assess patient at beginning and throughout therapy for infection; monitor for signs of anaphylaxis during first dose

Administration Administer around-the-clock to promote less variation in peak and trough serum levels. The appropriate amount of suspension may be mixed with formula, milk, fruit juice, water, ginger ale or cold drinks; administer dose immediately after mixing.

DisperMox™: Dissolve 1 tablet in ~10 mL of water immediately before administration. Rinse container with additional water and drink entire contents to ensure that complete dose is taken. Do not chew or swallow tablet whole.

Contraindications Hypersensitivity to amoxicillin, penicillin, or any component of the formulation

Warnings In patients with renal impairment, doses and/or frequency of administration should be modified in response to the degree of renal impairment. A high percentage of patients with infectious mononucleosis have developed rash during therapy with amoxicillin. A low incidence of cross-allergy with other beta-lactams and cephalosporins exists.

Dosage Forms

[DSC] = Discontinued product

Capsule, as trihydrate: 250 mg, 500 mg

Amoxicil®: 500 mg

Trimox®: 250 mg, 500 mg [DSC]

Powder for oral suspension, as trihydrate: 125 mg/5 mL (80 mL, 100 mL, 150 mL); 200 mg/5 mL (50 mL, 75 mL, 100 mL); 250 mg/5 mL (80 mL, 100 mL, 150 mL); 400 mg/5 mL (50 mL, 75 mL, 100 mL)

Amoxil®: 200 mg/5 mL (5 mL, 50 mL, 75 mL, 100 mL) [contains sodium benzoate; bubble gum flavor]; 250 mg/5 mL (100 mL, 150 mL) [contains sodium benzoate; bubble gum flavor]; 400 mg/5 mL (5 mL, 50 mL, 75 mL, 100 mL) [contains sodium benzoate; bubble gum flavor]

Trimox®: 125 mg/5 mL (80 mL, 100 mL, 150 mL); 250 mg/5 mL (80 mL, 100 mL, 150 mL) [contains sodium benzoate; raspberry-strawberry flavor] [DSC]

Powder for oral suspension, as trihydrate [drops]:

Amoxil®: 50 mg/mL (30 mL) [contains sodium benzoate; bubble gum flavor]

Tablet, as trihydrate: 500 mg, 875 mg

Amoxil®: 500 mg, 875 mg

Tablet, chewable, as trihydrate: 125 mg, 200 mg, 250 mg, 400 mg

Amoxil®: 200 mg [contains phenylalanine 1.82 mg/tablet; cherry banana peppermint flavor]; 400 mg [contains phenylalanine 3.64 mg/tablet; cherry banana peppermint flavor]

Tablet, for oral suspension, as trihydrate:

DisperMox™: 200 mg [contains phenylalanine 5.6 mg; strawberry flavor]; 400 mg [contains phenylalanine 5.6 mg; strawberry flavor]; 600 mg [contains phenylalanine 11.23 mg; strawberry flavor] [DSC]

Reference Range After a 250 mg oral dose, peak plasma level of 5 mcg/mL and urine level >300 mcg/mL have been noted

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage within 1 hour (rarely necessary)/activated charcoal can be used

Supportive therapy: Allergic reactions can be treated with epinephrine, diphenhydramine, and corticosteroids. For treatment of lingua villosa nigra, discontinue causative agent. Clean the tongue with a toothbrush and rinse mouth with a half-strength solution of hydrogen peroxide or 10% carbamide peroxide. Symptoms should subside in a few days.

Enhancement of elimination: Hemodialysis or charcoal hemoperfusion can be useful in removing penicillin

Test Interactions Increases AST, ALT, protein

Drug Interactions

Allopurinol: Theoretically has an additive potential for amoxicillin rash.

Aminoglycosides: May be synergistic against selected organisms.

Methotrexate: Penicillins may increase the exposure to methotrexate during concurrent therapy; monitor.

Oral contraceptives: Anecdotal reports suggesting decreased contraceptive efficacy with penicillins have been refuted by more rigorous scientific and clinical data.

Probenecid, disulfiram: May increase levels of penicillins (amoxicillin).

Warfarin: Effects of warfarin may be increased.

Pregnancy Risk Factor B

Lactation Enters breast milk/compatible

Nursing Implications Assess patient at beginning and throughout therapy for infection; give around-the-clock rather than 3 times/day to promote less variation in peak and trough serum levels.

Additional Information

Food does not interfere with absorption; rash appearing after a few days of therapy may indicate hypersensitivity

Amoxil® chewable contains phenylalanine 1.82 mg per 200 mg tablet, phenylalanine 3.64 mg per 400 mg tablet. DisperMox™ contains phenylalanine 5.6 mg in each 200 mg and 400 mg tablet.

Amphotericin B

Pronunciation (am foe TER i sin bee con VEN sha nal)

CAS Number 1397-89-3

U.S. Brand Names Amphocin®; Fungizone®

Synonyms Amphotericin B Desoxycholate

Use Treatment of severe systemic infections and meningitis caused by susceptible fungi; fungal peritonitis; irrigant for bladder fungal infections; topically for cutaneous and mucocutaneous candidal infections

Unlabeled/Investigational Use Visceral leishmaniasis

Mechanism of Action Binds to ergosterol altering cell membrane permeability in susceptible fungi and causing leakage of cell components with subsequent cell death

Adverse Reactions

Cardiovascular: Hypotension, hypertension, cardiac arrest, tachycardia, dilated cardiomyopathy, flushing, myocarditis (hypersensitivity), fibrillation (atrial), flutter (atrial), sinus bradycardia, cardiomegaly, myocardial depression, myocarditis, sinus tachycardia

Central nervous system: **Fever, generalized pain, chills, headache, malaise**, delirium, seizures, psychosis, dysphoria, dizziness, parkinsonian symptoms, hyperthermia, hemiparesis, arachnoiditis, gustatory hallucinations, hypothermia, leukoencephalopathy

Dermatologic: Maculopapular rash, exanthema, exfoliative dermatitis, urticaria, purpura, pruritus

Endocrine & metabolic: **Hypokalemia, hypomagnesemia**, nephrogenic diabetes insipidus

Gastrointestinal: **Anorexia**, nausea, vomiting

Genitourinary: Urinary retention

Hematologic: **Anemia**, leukocytosis, coagulation defects, thrombocytopenia, agranulocytosis, leukopenia, bone marrow suppression

Hepatic: Acute liver failure

Local: Thrombophlebitis

Neuromuscular & skeletal: Myalgia, paresthesia, clonus, myoclonus, pain along lumbar nerves, rhabdomyolysis

Ocular: Vision changes, diplopia

Otic: Hearing loss

Renal: Acidosis (renal tubular), renal failure, **nephrotoxicity** (cortical ischemia), anuria, renal tubular acidosis type I

Respiratory: Dyspnea

Miscellaneous: Anaphylaxis

Signs and Symptoms of Overdose Anemia, anorexia, coagulopathy, congestive heart failure, encephalopathy, deafness, delirium, dysphoria, feces discoloration (black), fever, granulocytopenia, hematuria, hyperthyroidism, hypokalemia, hypomagnesemia, meningitis, myalgia, myoclonus, nausea, renal dysfunction, thrombocytopenia, tubular necrosis, vomiting

Pharmacodynamics/Kinetics

Distribution: Minimal amounts enter the aqueous humor, bile, CSF (inflamed or noninflamed meninges), amniotic fluid, pericardial fluid, pleural fluid, and synovial fluid

Protein binding, plasma: 90%

Half-life elimination: Biphasic: Initial: 15-48 hours; Terminal: 15 days

Time to peak: Within 1 hour following a 4- to 6-hour dose

Excretion: Urine (2% to 5% as biologically active form); ~40% eliminated over a 7-day period and may be detected in urine for at least 7 weeks after discontinued use

Dosage

The minimum dilution for amphotericin B infusions is 0.1 mg/mL for peripheral lines and 1 mg/mL for central lines

Infants and Children:

Test dose: I.V.: 0.1 mg/kg/dose to a maximum of 1 mg; infuse over 30-60 minutes. If the test dose is tolerated, the initial therapeutic dose is 0.25 mg/kg. The daily dose can then be gradually increased, usually in 0.25 mg/kg increments on each subsequent day until the desired daily dose is reached.

Maintenance dose: 0.25-1 mg/kg/day given once daily; infuse over 2-6 hours. Once therapy has been established, amphotericin B can be administered on an every other day basis at 1-1.5 mg/kg/dose.

I.T.: 25-100 mcg every 48-72 hours; increase to 500 mcg as tolerated

Adults: I.V.:

Test dose: 1 mg infused over 20-30 minutes. Institute therapy with 0.25 mg/kg administered over 2-6 hours; the daily dose can be gradually increased on subsequent days to the desired level

Maintenance dose: 0.25-1 mg/kg/day or 1.5 mg/kg every other day; do not exceed 1.5 mg/kg/day. If the test dose is tolerated, the initial therapeutic dose is 0.25 mg/kg. The daily dose can then be gradually increased, usually in 0.25 mg/kg increments on each subsequent day until the desired daily dose is reached.

Duration of therapy varies with nature of infection: Histoplasmosis, *Cryptococcus*, or blastomycosis may be treated with total dose of 2-4 g

I.T.: 25-300 mcg every 48-72 hours; increase to 500 mcg to 1 mg as tolerated

Children and Adults (doses up to 8 mg/kg in infants did not experience any permanent sequelae)

Bladder irrigation: 50 mg/day in 1 L of sterile water irrigation solution instilled over 24 hours for 2-7 days or until cultures are clear

Dialysate: 1-2 mg/L of peritoneal dialysis fluid either with or without low-dose I.V. amphotericin B (a total dose of 2-10 mg/kg given over 7-14 days)

Topical: Apply to affected areas 2-4 times/day for 1-4 weeks of therapy depending on nature and severity of infection

Visceral leishmaniasis unresponsive to antimony (investigational): 5-15 mg/kg/day for 5 days (in lipid complex)

Dosing adjustment in renal impairment: If renal dysfunction is due to the drug, the daily total can be decreased by 50% or the dose can be given every other day; I.V. therapy may take several months

Monitoring Parameters Renal function (monitor frequently during therapy), electrolytes (especially potassium and magnesium), liver function tests, temperature, PT/PTT, CBC; monitor input and output; monitor for signs of hypokalemia (muscle weakness, cramping, drowsiness, ECG changes, etc)

Administration

Amphotericin is administered by I.V. infusion over 2-6 hours at a final concentration not to exceed 0.1 mg/mL. In patients unable to tolerate a large fluid volume, amphotericin B 0.25 mg/mL in D₅W given through a central venous catheter is the highest concentration reported to have been administered.

Contraindications Hypersensitivity to amphotericin or any component of the formulation

Warnings Anaphylaxis has been reported with other amphotericin B-containing drugs. During the initial dosing, the drug should be administered under close clinical observation. Avoid use with other nephrotoxic drugs; drug-induced renal toxicity usually improves with interrupting therapy, decreasing dosage, or increasing dosing interval. Infusion reactions are most common 1-3 hours after starting the infusion and diminish with continued therapy. Use amphotericin B with caution in patients with decreased renal function. Pulmonary reactions may occur in neutropenic patients receiving leukocyte transfusions; separation of the infusions as much as possible is advised.

Dosage Forms Injection, powder for reconstitution, as desoxycholate: 50 mg

Reference Range Therapeutic: 1.0-2.0 mcg/mL (SI: 1.0-2.2 μmol/L)

Overdose/Treatment

Supportive therapy: Premedication with hydrocortisone, diphenhydramine, or nonsteroidal anti-inflammatory agents can decrease chills; phosphate buffer or heparin can be added to amphotericin B infusions to decrease thrombophlebitis; simultaneous use of mannitol (1 g/kg) or sodium supplements may decrease renal failure incidence; meperidine (50-75 mg) may be used to prevent or treat chills; coadministration of amiloride (5 mg twice daily) can decrease incidence of hypokalemia

Enhancement of elimination: Exchange transfusion has been used with limited success in infants; no significant effect on amphotericin B plasma levels on double exchange transfusion and thus this modality is not recommended; poorly dialyzed

Test Interactions ↑ BUN (S); ↓ magnesium, potassium (S), erythropoietin levels

Drug Interactions Increased nephrotoxicity: Aminoglycosides, cyclosporine, other nephrotoxic drugs.

Potential of hypokalemia: Corticosteroids, corticotropin.

Increased digitalis and neuromuscular-blocking agent toxicity due to hypokalemia.

Decreased effect: Pharmacologic antagonism may occur with azole antifungal agents (eg, miconazole, ketoconazole).

Pulmonary toxicity has occurred with concomitant administration of amphotericin B and leukocyte transfusions.

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications May premedicate patients with acetaminophen and diphenhydramine 30 minutes prior to the amphotericin infusion; meperidine (Demerol®) may help to reduce rigors

Additional Information Premedication with diphenhydramine and acetaminophen may reduce the severity of acute infusion-related reactions. Meperidine reduces the duration of amphotericin B-induced rigors and chilling. Hydrocortisone may be used in patients with severe or refractory infusion-related reactions. Bolus infusion of normal saline immediately preceding, or immediately preceding and following amphotericin B may reduce drug-induced nephrotoxicity. Risk of nephrotoxicity increases with amphotericin B doses >1 mg/kg/day. Infusion of admixtures more concentrated than 0.25 mg/mL should be limited to patients absolutely requiring volume restriction. Amphotericin B does not have a bacteriostatic constituent, subsequently admixture expiration is determined by sterility more than chemical stability.

Ampicillin

Pronunciation (am pi SIL in)

CAS Number 69-53-4

U.S. Brand Names Principen®

Synonyms Aminobenzylpenicillin; Ampicillin Sodium; Ampicillin Trihydrate

Use Treatment of susceptible bacterial infections (nonbeta-lactamase-producing organisms); susceptible bacterial infections caused by streptococci, pneumococci, nonpenicillinase-producing staphylococci, *Listeria*, meningococci; some strains of *H. influenzae*, *Salmonella*, *Shigella*, *E. coli*, *Enterobacter*, and *Klebsiella*

Mechanism of Action Interferes with bacterial cell wall synthesis during active multiplication, causing cell wall death and resultant bactericidal activity against susceptible bacteria

Adverse Reactions

Frequency not defined.
 Central nervous system: Fever, penicillin encephalopathy, seizures
 Dermatologic: Erythema multiforme, exfoliative dermatitis, rash, urticaria
Note: Appearance of a rash should be carefully evaluated to differentiate (if possible) nonallergic ampicillin rash from hypersensitivity reaction. Incidence is higher in patients with viral infections, *Salmonella* infections, lymphocytic leukemia, or patients that have hyperuricemia.
 Gastrointestinal: Black hairy tongue, diarrhea, enterocolitis, glossitis, nausea, pseudomembranous colitis, sore mouth or tongue, stomatitis, vomiting
 Hematologic: Agranulocytosis, anemia, hemolytic anemia, eosinophilia, leukopenia, thrombocytopenia purpura
 Hepatic: AST increased
 Renal: Interstitial nephritis (rare)
 Respiratory: Laryngeal stridor
 Miscellaneous: Anaphylaxis, serum sickness-like reaction

Signs and Symptoms of Overdose Cholestatic jaundice, colitis, deafness, erythema multiforme, hypokalemia hypoprothrombinemia, myalgia, myocarditis, toxic epidermal necrolysis

Pharmacodynamics/Kinetics

Absorption: Oral: 50%
 Distribution: Bile, blister, and tissue fluids; penetration into CSF occurs with inflamed meninges only, good only with inflammation (exceeds usual MICs)
 Normal meninges: Nil; Inflamed meninges: 5% to 10%
 Protein binding: 15% to 25%
 Half-life elimination:
 Children and Adults: 1-1.8 hours
 Anuria/end-stage renal disease: 7-20 hours
 Time to peak: Oral: Within 1-2 hours
 Excretion: Urine (~90% as unchanged drug) within 24 hours

Dosage

Infants and Children:
 Mild-to-moderate infections:
 I.M., I.V.: 100-150 mg/kg/day in divided doses every 6 hours (maximum: 2-4 g/day)
 Oral: 50-100 mg/kg/day in doses divided every 6 hours (maximum: 2-4 g/day)
 Severe infections/meningitis: I.M., I.V.: 200-400 mg/kg/day in divided doses every 6 hours (maximum: 6-12 g/day)
 Endocarditis prophylaxis: I.M., I.V.:
 Dental, oral, respiratory tract, or esophageal procedures: 50 mg/kg within 30 minutes prior to procedure in patients unable to take oral amoxicillin
 Genitourinary and gastrointestinal tract (except esophageal) procedures:
 High-risk patients: 50 mg/kg (maximum: 2 g) within 30 minutes prior to procedure, followed by ampicillin 25 mg/kg (or amoxicillin 25 mg/kg orally) 6 hours later; must be used in combination with gentamicin.
 Moderate-risk patients: 50 mg/kg within 30 minutes prior to procedure

Adults:

Susceptible infections:
 Oral: 250-500 mg every 6 hours
 I.M., I.V.: 250-500 mg every 6 hours
 Sepsis/meningitis: I.M., I.V.: 150-250 mg/kg/24 hours divided every 3-4 hours (range: 6-12 g/day)
 Endocarditis prophylaxis: I.M., I.V.:
 Dental, oral, respiratory tract, or esophageal procedures: 2 g within 30 minutes prior to procedure in patients unable to take oral amoxicillin
 Genitourinary and gastrointestinal tract (except esophageal) procedures:
 High-risk patients: 2 g within 30 minutes prior to procedure, followed by ampicillin 1 g (or amoxicillin 1 g orally) 6 hours later; must be used in combination with gentamicin
 Moderate-risk patients: 2 g within 30 minutes prior to procedure

Dosing interval in renal impairment:

$Cl_{cr} > 50$ mL/minute: Administer every 6 hours
 Cl_{cr} 10-50 mL/minute: Administer every 6-12 hours
 $Cl_{cr} < 10$ mL/minute: Administer every 12-24 hours
 Hemodialysis: Moderately dialyzable (20% to 50%); administer dose after dialysis
 Peritoneal dialysis: Moderately dialyzable (20% to 50%)
 Administer 250 mg every 12 hours
 Continuous arteriovenous or venovenous hemofiltration effects: Dose as for Cl_{cr} 10-50 mL/minute; ~50 mg of ampicillin per liter of filtrate is removed

Monitoring Parameters With prolonged therapy monitor renal, hepatic, and hematologic function periodically; observe signs and symptoms of anaphylaxis during first dose

Administration

Ampicillin can be administered IVP over 3-5 minutes at a rate not to exceed 100 mg/minute or I.V. intermittent infusion over 15-30 minutes; final concentration for I.V. administration should not exceed 100 mg/mL (IVP) or 30 mg/mL (I.V. intermittent infusion)

Contraindications Hypersensitivity to ampicillin, any component of the formulation, or other penicillins

Warnings Dosage adjustment may be necessary in patients with renal impairment. A low incidence of cross-allergy with other beta-lactams exists. High percentage of patients with infectious mononucleosis have developed rash during therapy with ampicillin. Appearance of a rash should be carefully evaluated to differentiate a nonallergic ampicillin rash from a hypersensitivity reaction. Ampicillin rash occurs in 5% to 10% of children receiving ampicillin and is a generalized dull red, maculopapular rash, generally appearing 3-14 days after the start of the therapy. It normally begins on the trunk and spreads over most of the body. It may be most intense at pressure areas, elbows, and knees.

Dosage Forms Capsule: 250 mg, 500 mg

Injection, powder for reconstitution, as sodium: 125 mg, 250 mg, 500 mg, 1 g, 2 g, 10 g

Powder for oral suspension: 125 mg/5 mL (100 mL, 200 mL); 250 mg/5 mL (100 mL, 200 mL)

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage within 1 hour (rarely necessary)/activated charcoal can be used; whole bowel irrigation is effective in decreasing bioavailability by 67%
 Supportive therapy: Allergic reactions can be treated with epinephrine, diphenhydramine, and corticosteroids
 Enhancement of elimination: Hemodialysis or charcoal hemoperfusion can be useful in removing penicillin; moderately dialyzable (20% to 50%)

Test Interactions Increases protein, urinary glucose (Benedict's solution, Clinistest®); positive Coombs' [direct]

Drug Interactions Allopurinol: Theoretically has an additive potential for ampicillin/amoxicillin rash.

Aminoglycosides: May be synergistic against selected organisms.

Methotrexate: Penicillins may increase the exposure to methotrexate during concurrent therapy; monitor.

Oral contraceptives: Anecdotal reports suggesting decreased contraceptive efficacy with penicillins have been refuted by more rigorous scientific and clinical data.

Probenecid, disulfiram: May increase levels of penicillins (ampicillin).

Warfarin: Effects of warfarin may be increased.

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic effects were not observed in animal studies. Ampicillin crosses the human placenta.

Lactation Enters breast milk/use caution

Nursing Implications Ampicillin and gentamicin should not be mixed in the same I.V. tubing or administered concurrently; give orally on an empty stomach (ie, 1 hour prior to, or 2 hours after meals) to increase total absorption. Give around-the-clock rather than 4 times/day to promote less variation in peak and trough serum levels.

Additional Information Sodium content of 5 mL suspension (250 mg/5 mL): 10 mg (0.4 mEq); sodium content of 1 g: 66.7 mg (3 mEq)

Amsacrine

Pronunciation (AM sah kreen)

Synonyms 4-(9-Acridinylamino)Methanesulfon-m-Anisidide; Acridinyl Anisidide; AMSA; m-AMSA; NSC-249992

Unlabeled/Investigational Use Investigational: Refractory acute lymphocytic and nonlymphocytic leukemias, Hodgkin's disease, and non-Hodgkin's lymphomas; head and neck tumors

Mechanism of Action Amsacrine has been shown to inhibit DNA synthesis by binding to, and intercalating with, DNA and inhibition of topoisomerase II activity.

Adverse Reactions

Cardiovascular: **ECG changes** (T-wave flattening, S-T wave alterations) consistent with anterolateral ischemia, ventricular fibrillation, ventricular extrasystoles, atrial tachycardia and fibrillation, congestive heart failure, cardiac arrest. Patients with hypokalemia, who have received >400 mg/m² of doxorubicin or daunorubicin (or the equivalent), >200 mg/m² of amsacrine within 48 hours, or a total dose of anthracycline + amsacrine >900 mg/m² have an increased risk of cardiac toxicity.

Central nervous system: Headache, dizziness, confusion, convulsions

Dermatologic: **Alopecia**

Endocrine & metabolic: Sperm production decreased

Gastrointestinal: **Nausea and vomiting (30%), diarrhea (30%), dose-limiting stomatitis (32%), oral ulceration**

Genitourinary: **Orange-red discoloration of the urine**

Hematologic: **Leukopenia** (nadir at 10 days); **thrombocytopenia** (nadir at 12-14 days), with recovery at 21-25 days, anemia

Hepatic: **Hyperbilirubinemia (30%), increased liver enzymes**

Local: **Phlebitis**

Neuromuscular & skeletal: Paresthesias

Ocular: Blurred vision

Miscellaneous: Allergic reactions

Pharmacodynamics/Kinetics

Distribution: V_d : 1.67 L/kg; minimal CNS penetration

Protein binding: 96% to 98%

Metabolism: Hepatic, to inactive metabolites (major metabolite is 5' glutathione conjugate)

Half-life elimination: 1.4-5 hours; Terminal: 5.6-7.8 hours

Excretion: Bile; urine (2% to 10% as unchanged drug)

Dosage

Refer to individual protocols. I.V.:

Children: 125-150 mg/m²/day for 5 days

Adults: 60-160 mg/m²/day every 3-4 weeks; 5- to 7-day I.V. infusions of 40-120 mg/m²/day every 3-4 weeks have also been reported.

Dosage adjustment in renal impairment: BUN >20 or S_{cr} >1.5: Administer 25% of normal dose.

Dosage adjustment in hepatic impairment: Bilirubin >2 mg/dL: Administer 75% of normal dose.

Stability

Intact vials are stored at controlled room temperature 15°C to 30°C (59°F to 86°F). Reconstitute 1.5 mL of solution by adding 13.5 mL of lactic acid diluent (provided with the drug) to form a 5 mg/mL solution. Solutions diluted for administration are stable for up to 48 hours at room temperature. The addition of 1 mEq/L of sodium bicarbonate increases the stability to 96 hours. Reconstituted vials may be stored at room temperature for up to 48 hours.

Note: Use of glass syringes and avoidance of plastic filters to draw up undiluted amsacrine solutions is recommended since the N,N-dimethylacetamide solvent has been reported to dissolve plastic syringes and filters.

Administration

I.V.: Administer as a 30- to 90-minute infusion or a 24-hour continuous infusion. Use of glass syringes and avoidance of plastic filters to draw up undiluted amsacrine solutions is recommended since the N,N-dimethylacetamide solvent has been reported to dissolve plastic syringes and filters. The solution can be placed in plastic bags when diluted for I.V. infusion.

Contraindications Hypersensitivity to amsacrine or any component of the formulation; hypokalemia

Warnings Procedures for proper handling and disposal of antineoplastic agents should be considered. The drug should be used cautiously in patients who have underlying cardiac disease, severe renal or hepatic dysfunction, or who have received high cumulative doses of anthracyclines. **Do not administer amsacrine if serum potassium <4 mEq/L.**

Dosage Forms Injection, solution [preservative free]: 50 mg/1.5 mL (supplied with L-lactic acid 0.0353 M 13.5 mL)

Androstenedione

Related Information

- Testosterone

Synonyms

 Andro

Use Often used for performance enhancement in sports; also has been used for libido enhancement (neither use FDA approved)

Mechanism of Action Androstenedione is a weak androgenic steroid hormone. It is a product of natural gonadal and adrenal synthesis. As a precursor to testosterone; converted in the body to testosterone. Testosterone regulates the development and function of the reproductive organs, enhances development of muscle and bone mass, and increases muscular strength. Androstenedione is believed to facilitate faster recovery from exercise and to promote muscle development in response to training.

Mechanism of Toxic Action A precursor to testosterone (and estrone); elevates serum testosterone from 15% to 300%

Adverse Reactions

Central nervous system: Euphoria, cerebrovascular accident, psychosis, aggressive behavior

Dermatologic: **Edema, acne**, pruritus, exacerbation of psoriasis, hirsutism (increase in pubic hair growth)

Endocrine & metabolic: Gynecomastia, **amenorrhea**, hypercalcemia, increased libido, **virilism, breast soreness**, hypoprolactinemia

Gastrointestinal: GI irritation, nausea, vomiting

Genitourinary: Impotence, testicular atrophy, clitoral enlargement, **priapism**, azoospermia, prostatic hypertrophy, prostatic carcinoma, **epididymitis, bladder irritability**

Hematologic: Polycythemia, leukopenia

Hepatic: Hepatic dysfunction, hepatic necrosis (especially with water-based oral preparations), cholestatic hepatitis, hepatocellular carcinoma, aminotransferase level elevation (asymptomatic)

Neuromuscular & skeletal: Piloerection

Miscellaneous: Hypersensitivity reactions

Signs and Symptoms of Overdose Cholestatic jaundice, depression, gynecomastia, hirsutism, hypercalcemia, hypertension, hypertrichosis, impotence, jaundice, leukopenia or neutropenia (agranulocytosis, granulocytopenia), oligospermia

Toxicodynamics/Kinetics Duration of action: 1-2 hours

Dosage Forms Androstenedione (androstene, adriol), 4-androstenediol (4-AD, androdiol), 5-androstenediol (5-AD, 5-androdiol), norandrostenediol (norandrostene), 19-norandrostenedione (19-nordione), 19-norandrostenediol (19-nordioli)

Reference Range

Male: 65-270 ng/dL; female, postmenopausal: <180 ng/dL; children, prepubertal: <60 ng/dL

While doses of 100 mg daily did not change serum testosterone or estradiol concentrations, doses of 300 mg daily did cause a significant increase in the above hormones

Overdosage/Treatment Decontamination: Oral: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Additional Information First synthesized in 1935. Has both androgenic and anabolic properties. Available as tablet: 50 mg, 100 mg.

Specific References

Aprotinin

Pronunciation (a proe TYE nin)

CAS Number 9087-70-1

U.S. Brand Names Trasylol®

Use Treatment of life-threatening hemorrhage caused by increased plasmin concentration; prophylactic use to reduce perioperative blood loss in patients undergoing cardiopulmonary bypass in repeat coronary artery bypass graft surgery; may be effective against streptokinase-induced bleeding

Mechanism of Action Serine protease inhibitor; inhibits plasmin, kallikrein, and platelet activation; a weak inhibitor of plasma pseudocholinesterase

Adverse Reactions Increase in postoperative renal dysfunction compared to placebo; anaphylactic reactions have been reported in of cases; such reactions are more likely to occur with repeated administration; bronchospasm and acute respiratory distress syndrome can result

Signs and Symptoms of Overdose Possible liver/tubular necrosis (acute) at a dose of 15 million KIU

Pharmacodynamics/Kinetics

Distribution: Extracellular space; renal phagolysomes

Metabolism: Aprotinin is slowly degraded by lysosomal enzymes.

Half-life elimination: 2.5 hours (plasma); terminal: 10 hours

Excretion: Urine (25% to 40%; <10% as unchanged drug)

Dosage

Test dose: **All** patients should receive a 1 mL I.V. test dose at least 10 minutes prior to the loading dose to assess the potential for allergic reactions

Regimen A:

2 million units (280 mg) loading dose I.V. over 20-30 minutes

2 million units (280 mg) into pump prime volume

500,000 units/hour (70 mg/hour) I.V. during operation

Regimen B:

1 million units (140 mg) loading dose I.V. over 20-30 minutes

1 million units (140 mg) into pump prime volume

250,000 units/hour (35 mg/hour) I.V. during operation

Stability Incompatible with corticosteroids, heparin, tetracyclines

Monitoring Parameters Bleeding times, prothrombin time, activated clotting time, platelet count, red blood cell counts, hematocrit, hemoglobin and fibrinogen degradation products; for toxicity also include renal function tests and blood pressure

Administration

Administer through a central line. Infuse loading dose over 20-30 minutes, then continuous infusion at 50 mL/hour (regimen A) or 25 mL/hour (regimen B). Rapid infusion (<20 minutes) can cause transient blood pressure decrease; to avoid incompatibility with heparin, add while recirculating the prime fluid of the cardiac bypass circuit.

Contraindications Hypersensitivity to aprotinin or any component of the formulation

ARGININE

Warnings [U.S. Boxed Warning]: Anaphylactic reactions are possible. Hypersensitivity reactions are more common with repeated use, especially when re-exposure is within 6 months. All patients should receive a test dose at least 10 minutes before loading dose. Patients with a history of allergic reactions to drugs or other agents may be more likely to develop a reaction. Epinephrine, steroids, and facilities for cardiopulmonary resuscitation should be available in case such a reaction occurs. Patients with a previous exposure to aprotinin (particularly when re-exposure is within 6 months) are at an increased risk for hypersensitivity reactions including anaphylactic or anaphylactoid reactions; pretreatment with an antihistamine and H₂ blocker before administration of the loading dose is recommended in these patients; delay the addition of aprotinin into the pump prime solution until the loading dose has been safely administered. Safety and efficacy in children have not been established.

Dosage Forms Injection, solution: 1.4 mg/mL [10,000 KIU/mL] (100 mL, 200 mL) [bovine derived]

Reference Range Plasma concentration of 250 KIU/mL in patients after receiving 2 million KIU I.V. loading dose

Overdosage/Treatment Supportive therapy: Bronchospasm can be treated with beta agonist therapy; anaphylaxis can be treated with epinephrine, antihistamines, and corticosteroids

Drug Interactions Captopril (and other ACE inhibitors): Antihypertensive effects may be blocked; monitor.

Fibrinolytic drugs may have poorer activity. Aprotinin blocks this fibrinolytic activity; monitor.

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic effects were not observed in animal studies. There are no adequate and well-controlled studies in pregnant women.

Lactation Excretion in breast milk unknown

Dosage Forms Injection, solution, as hydrochloride: 10% [100 mg/mL = 950 mOsm/L] (300 mL) [contains chloride 0.475 mEq/mL]

Reference Range Normal serum arginine level: 40-150 nmol/mL; fatal arginine (plasma) level: 1314 nmol/mL following a 3.9 g/kg infusion

Overdosage/Treatment Supportive therapy: Epinephrine and antihistamines can be used for allergic reactions. Monitor and treat electrolyte disturbances.

Test Interactions May ↑ increase BUN and serum creatinine

Drug Interactions Increased toxicity: Estrogen-progesterone combinations (increase growth hormone response and decrease glucagon and insulin effects); spironolactone (potentially fatal hyperkalemia has been reported)

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic effects were not observed in animal studies; however, the manufacturer does not recommend use of arginine during pregnancy.

Lactation Enters breast milk/use caution

Additional Information Chloride content of arginine is 47.5 mEq/100 mL (950 mOsmol/L); fatal I.V. dose: 3.9 g/kg

Aripiprazole

Pronunciation (ay ri PIP ray zole)

U.S. Brand Names Abilify®

Synonyms BMS 337039; OPC-14597

Use Treatment of schizophrenia; stabilization and maintenance therapy of bipolar disorder (with acute manic or mixed episodes)

Unlabeled/Investigational Use Depression with psychotic features

Mechanism of Action Aripiprazole is a quinolinone antipsychotic which exhibits high affinity for D₂, D₃, 5-HT_{1A}, and 5-HT_{2A} receptors; moderate affinity for D₄, 5-HT_{2C}, 5-HT₇, alpha, and H₁ receptors. It also possesses moderate affinity for the serotonin reuptake transporter; has no affinity for muscarinic receptors. Aripiprazole functions as a partial agonist at the D₂ and 5-HT_{1A} receptors, and as an antagonist at the 5-HT_{2A} receptor.

Adverse Reactions

>10%:

Central nervous system: Headache (31%), agitation (25%), anxiety (20%), insomnia (20%), somnolence (12%), akathisia (15%), lightheadedness (11%)

Endocrine & metabolic: Weight gain (8% to 30%; highest frequency in patients with BMI <23), pancreatitis

Gastrointestinal: Nausea (16%), dyspepsia (15%), constipation (13%), vomiting (11%)

1% to 10%:

Cardiovascular: Edema (peripheral 2%), hypertension (2%), tachycardia, hypotension, bradycardia, chest pain

Central nervous system: Extrapyramidal symptoms (6%), fever, depression, nervousness, mania, confusion, hallucination, hostility, paranoid reaction, suicidal thought, delusion, abnormal dream

Dermatologic: Rash (6%), dry skin, skin ulcer

Endocrine & metabolic: Dehydration, hypothyroidism

Gastrointestinal: Salivation increased (3%), anorexia

Genitourinary: Urinary incontinence, pelvic pain

Hematologic: Anemia, bruising

Neuromuscular & skeletal: Weakness (8%), myalgia (4%), tremor (4%), neck pain, neck rigidity, muscle cramp, CPK increased, abnormal gait

Ocular: Blurred vision (3%), conjunctivitis

Respiratory: Rhinitis (4%), pharyngitis (4%), asthma, cough (3%), dyspnea, pneumonia, sinusitis

Miscellaneous: Accidental injury (6%), flu-like syndrome

<1% (Limited to important or life-threatening): Albuminuria, alkaline phosphatase increased, ALT increased, angina, apnea, arthralgia, arthrosis, aspiration pneumonia, AST increased, ataxia, atrial fibrillation, atrial flutter, AV block, bilirubinemia, bone pain, bradykinesia, BUN increased, bundle branch block, cardiomegaly, cardiopulmonary failure, cataract, cerebral ischemia, cerebrovascular accident, CHF, chest tightness, cholecystitis, cholelithiasis, colitis, cyanosis, cystitis, deafness, deep vein thrombosis, delirium, diabetes mellitus, duodenal ulcer, eosinophilia, extrasystoles, fecal impaction, hematemesis, hematuria, hemoptysis, hemorrhage, hepatitis, hepatomegaly, hypercholesterolemia, hyper-/hypoglycemia, hyper-/hypokalemia, hyper-/hyponatremia, hyperthyroidism, hyperuricemia, hypoesthesia, hypokinesia, hypotonia, hypoxia, intestinal obstruction, intestinal perforation, LDH increased, leukocytosis, leukopenia, maculopapular rash, Mendelson's syndrome, MI, migraine, moniliasis, myoclonus, myopathy, neuroleptic malignant syndrome, melena, neuropathy, oculogyric crisis, palpitation, pancreatitis, panic attack, peptic ulcer, phlebitis, pulmonary edema, pulmonary embolism, QT prolongation, renal calculus, renal failure, respiratory failure, rhabdomyolysis, seborrhea, serum creatinine increased, stroke, suicide attempt, tardive dyskinesia, throat tightness, thrombocytopenia, thrombocytopenia, tongue edema, vesiculobullous rash

Postmarketing and/or case reports: Anaphylactic reaction, angioedema, laryngospasm

Arginine

Pronunciation (AR ji neen)

CAS Number 1119-34-2; 74-79-3

U.S. Brand Names R-Gene®

Synonyms Arginine Hydrochloride

Use Pituitary function test (growth hormone). Also used in treating ammonia intoxication in patients with cirrhosis.

Unlabeled/Investigational Use Management of severe, uncompensated, metabolic alkalosis (pH ≥7.55) after optimizing therapy with sodium and potassium supplements

Mechanism of Action Causes release of growth hormone, insulin, glucagon, and prolactin. Also has acidifying properties.

Adverse Reactions

Cardiovascular: Rapid I.V. infusion may produce flushing

Central nervous system: Headache

Endocrine & metabolic: Hyperkalemia

Gastrointestinal: Nausea, vomiting

Local: Venous irritation

Neuromuscular & skeletal: Numbness

Miscellaneous: Allergic reactions

Signs and Symptoms of Overdose Hyponatremia, hypotension due to vasodilation, hyperkalemia, increased intracranial pressure, metabolic acidosis, nausea, vomiting

Admission Criteria/Prognosis Admit ingestions over 30 g

Pharmacodynamics/Kinetics

Absorption: Oral: Well absorbed

Time to peak, serum: Oral: ~2 hours; I.V.: 20-30 minutes

Toxicodynamics/Kinetics

Duration of action: ~1 hour

Metabolism: Hepatic hydrolytic cleavage to urea and ornithine

Elimination: Renal

Dosage

I.V.: Pituitary function test:

Children: 500 mg/kg/dose administered over 30 minutes

Adults: 30 g (300 mL of a 10% solution) administered over 30 minutes

Ammonia intoxication in cirrhotics: 37.5-100 g (4 doses in 10 days) followed by 50 g/day for 5 days

Metabolic alkalosis: Dose in grams = desired decrease in serum bicarbonate level (mEq/L) times patient weight (kg), divided by 9.6.

Acidifying agent: 10 g infused over 30 minutes

Oral: Oligospermia: 2-4 g/day

Monitoring Parameters Monitor acid-base status (arterial or capillary blood gases), serum electrolytes (sodium, potassium, chloride, HCO₃⁻), BUN, glucose

Administration

May be infused without further dilution; maximum rate of I.V. infusion: 1 g/kg/hour (maximum: 60 g/hour).

Contraindications Hypersensitivity to arginine or any component of the formulation

Warnings Use caution with hepatic or renal impairment; use may lead to life-threatening hyperkalemia. Use caution with electrolyte imbalances or pediatric patients.

Signs and Symptoms of Overdose Lethargy, vomiting, salivation, hypotonia, coma (at ingestion of 17.1 mg/kg), ataxia, tremor

Admission Criteria/Prognosis Six-hour observation time is appropriate; asymptomatic patients can then be discharged

Pharmacodynamics/Kinetics

Onset: Initial: 1-3 weeks

Absorption: Well absorbed

Distribution: V_d : 4.9 L/kg

Protein binding: 99%, primarily to albumin

Metabolism: Hepatic, via CYP2D6, CYP3A4 (dehydro-aripiprazole metabolite has affinity for D2 receptors similar to the parent drug and represents 40% of the parent drug exposure in plasma)

Bioavailability: 87%

Half-life: Aripiprazole: 75 hours; CYP2D6 poor metabolizers: 146 hours; dehydro-aripiprazole: 94 hours

Time to peak, plasma: 3-5 hours

Delayed with high-fat meal: Aripiprazole: 3 hours; dehydro-aripiprazole: 12 hours

Excretion: Feces (55%), urine (25%); primarily as metabolites

Dosage

Oral: **Note:** Oral solution may be substituted for the oral tablet on a mg-per-mg basis, up to 25 mg. Patients receiving 30 mg tablets should be given 25 mg oral solution.

Adults:

Schizophrenia: 10-15 mg once daily; may be increased to a maximum of 30 mg once daily (efficacy at dosages above 10-15 mg has not been shown to be increased). Dosage titration should not be more frequent than every 2 weeks.

Bipolar disorder (acute manic or mixed episodes):

Stabilization: 30 mg once daily; may require a decrease to 15 mg based on tolerability (15% of patients had dose decreased); safety of doses > 30 mg/day has not been evaluated

Maintenance: Continue stabilization dose for up to 6 weeks; efficacy of continued treatment > 6 weeks has not been established

Dosage adjustment with concurrent CYP3A4 inducer therapy: with the addition of CYP3A4 inducers (eg, carbamazepine), aripiprazole dose should be doubled. If CYP3A4 inducers are withdrawn from therapy with aripiprazole, aripiprazole dose should be decreased by one-half.

Elderly: Refer to Adults dosing

Dosage adjustment in renal/hepatic impairment: No dosage adjustment required

Stability

Capsule: Store under refrigeration of 2°C to 8°C (36°F to 46°F); use within 6 months after opening

Tablet: Store at 25°C (77°F); excursions permitted to 15°C to 30°C (59°F to 86°F)

Monitoring Parameters Vital signs; fasting lipid profile and fasting blood glucose/Hgb A_{1c} (prior to treatment, at 3 months, then annually); BMI, personal/family history of diabetes, waist circumference; blood pressure; mental status, abnormal involuntary movement scale (AIMS), extrapyramidal symptoms (EPS). Weight should be assessed prior to treatment, at 4 weeks, 8 weeks, 12 weeks, and then at quarterly intervals. Consider titrating to a different antipsychotic agent for a weight gain ≥5% of the initial weight.

Administration

May be administered with or without food. Tablet and oral solution may be interchanged on a mg-per-mg basis, up to 25 mg. Doses using 30 mg tablets should be exchanged for 25 mg oral solution.

Contraindications Hypersensitivity to aripiprazole or any component of the formulation

Warnings

[U.S. Boxed Warning]: Patients with dementia-related behavioral disorders treated with atypical antipsychotics are at an increased risk of death compared to placebo. Aripiprazole is not approved for this indication.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is very low relative to typical/conventional antipsychotics, frequencies reported are similar to placebo). May be associated with neuroleptic malignant syndrome (NMS).

May be sedating, use with caution in disorders where CNS depression is a feature. May cause orthostatic hypotension (although reported rates are similar to placebo); use caution in patients at risk of this effect or those who would not tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications which may predispose). Clinical data have demonstrated an increased incidence of serious, including fatal, cerebrovascular events in elderly patients.

Use caution in patients with Parkinson's disease; hemodynamic instability; bone marrow suppression; predisposition to seizures; subcortical brain damage; and severe cardiac, hepatic, renal, or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use; use caution in patients at risk of pneumonia (ie, Alzheimer's disease). May alter temperature regulation or mask toxicity

of other drugs due to antiemetic effects. Use caution in patients with a history of drug abuse.

Atypical antipsychotics have been associated with development of hyperglycemia; in some cases, may be extreme and associated with ketoacidosis, hyperosmolar coma, or death. Reports of hyperglycemia with aripiprazole therapy have been few and specific risk associated with this agent is not known. Use caution in patients with diabetes or other disorders of glucose regulation; monitor for worsening of glucose control.

The possibility of a suicide attempt is inherent in psychotic illness or bipolar disorder; use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. Safety and efficacy in pediatric patients have not been established.

Dosage Forms

Solution, oral: 1 mg/mL (150 mL) [contains sucrose 400 mg/mL and fructose 200 mg/mL; orange cream flavor]

Tablet: 2 mg, 5 mg, 10 mg, 15 mg, 20 mg, 30 mg

Reference Range

Following ingestion of 17.1 mg/kg, serum levels of aripiprazole and dehydroaripiprazole was 1420 ng/mL and 453 ng/mL, respectively

Mean peak plasma concentrations range from 74-452 ng/mL for 5-30 mg doses, respectively.

Overdosage/Treatment

Decontamination: Activated charcoal and/or lavage

Supportive therapy: Mainstay of treatment

Drug Interactions

Substrate (major) of CYP2D6, 3A4

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Carbamazepine: Carbamazepine may decrease aripiprazole levels. Manufacturer recommends a doubling of the aripiprazole dose when carbamazepine is added.

CYP2D6 inhibitors: May increase the levels/effects of aripiprazole. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinorele.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of aripiprazole. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of aripiprazole. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Ketoconazole: Ketoconazole may increase aripiprazole levels. Manufacturer recommends a 50% reduction in dose during concurrent ketoconazole therapy.

Pregnancy Risk Factor C

Pregnancy Implications Aripiprazole demonstrated developmental toxicity in animal models. There are no adequate and well-controlled trials in pregnant women. Should be used in pregnancy only when potential benefit to mother outweighs possible risk to the fetus.

Lactation Excretion in breast milk unknown/not recommended

Ascorbic Acid

CAS Number 50-81-7

U.S. Brand Names C-500-GR™ [OTC]; C-Gram [OTC]; Cecon® [OTC]; Cevi-Bid® [OTC]; Dull-C® [OTC]; Vita-C® [OTC]

Synonyms Vitamin C

Use Prevention and treatment of scurvy; urinary acidification; dietary supplementation; chromium nephrotoxicity/dermal burns due to chromium

Unlabeled/Investigational Use Investigational: In large doses, to decrease the severity of "colds"; dietary supplementation; a 20-year study was recently completed involving 730 individuals which indicates a

ATENOLOL

possible decreased risk of death by stroke when ascorbic acid at doses ≥ 45 mg/day was administered

Mechanism of Action Necessary for collagen formation and tissue repair in the body; involved in some oxidation-reduction reactions, as well as many other metabolisms

Adverse Reactions

Cardiovascular: Flushing, chest pain, angina
Central nervous system: Faintness, dizziness, headache, fatigue
Dermatologic: Systemic contact dermatitis
Gastrointestinal: Nausea, vomiting, heartburn, diarrhea, esophageal ulceration, esophagitis
Renal: Hyperoxaluria

Signs and Symptoms of Overdose Dental erosion, esophageal ulceration, hematuria, intestinal bezoar or concretion, renal insufficiency, nephropathy, nephrotoxicity

Pharmacodynamics/Kinetics

Absorption: Oral: Readily absorbed; an active process thought to be dose dependent
Distribution: Large
Metabolism: Hepatic via oxidation and sulfation
Excretion: Urine (with high blood levels)

Dosage

Oral, I.M., I.V., SubQ:
Children:
Scurvy: 100-300 mg/day in divided doses for at least 2 weeks
Urinary acidification: 500 mg every 6-8 hours
Dietary supplement: 35-45 mg

Adults:

Scurvy: 100-250 mg 1-2 times/day
Urinary acidification: 4-12 g/day in 3-4 divided doses
Dietary supplement: 50-60 mg/day
Prevention and treatment of cold: 1-3 g/day
Recommended daily allowance: 60 mg

Antioxidant: I.V.: 0.5-1 g

Severe chromium poisoning: I.V.: 1 g every 10-20 minutes, up to 3 g
Chromium dermal burns: 10% topical ascorbic acid along with 10 g of oral ascorbic acid

Stability Injectable form should be stored under refrigeration (2°C to 8°C); protect oral dosage forms from light; is rapidly oxidized when in solution in air and alkaline media

Monitoring Parameters Monitor pH of urine when using as an acidifying agent

Administration

Avoid rapid I.V. injection.

Warnings Patients with diabetes and patients prone to recurrent renal calculi (eg, dialysis patients) should not take excessive doses for extended periods of time.

Dosage Forms

Capsule: 500 mg, 1000 mg
C-500-GR™: 500 mg
Capsule, timed release: 500 mg
Crystal (Vita-C®): 4 g/teaspoonful (100 g)
Injection, solution: 250 mg/mL (2 mL, 30 mL); 500 mg/mL (50 mL)
Cenolate®: 500 mg/mL (1 mL, 2 mL) [contains sodium hydrosulfite]
Powder, solution (Dull-C®): 4 g/teaspoonful (100 g, 500 g)
Solution, oral (Cecon®): 90 mg/mL (50 mL)
Tablet: 100 mg, 250 mg, 500 mg, 1000 mg
C-Gram: 1000 mg
Tablet, chewable: 100 mg, 250 mg, 500 mg [some products may contain aspartame]
Tablet, timed release: 500 mg, 1000 mg, 1500 mg
Cevi-Bid®: 500 mg

Reference Range Normal serum level: 10 mcg/mL

Overdosage/Treatment Decontamination: Lavage (within 1 hour)/activated charcoal; dilution with milk or water may minimize chances of esophageal injury

Test Interactions False-positive urinary glucose with cupric sulfate reagent, false-negative urinary glucose with glucose oxidase method; false-negative stool occult blood 48-72 hours after ascorbic acid ingestion; Hemocult® and Gastrocult® tests can be unreliable in detecting GI bleeding in iron overdoses treated with whole bowel irrigation (ferrous sulfate/ferrous gluconate: false-positive; ascorbic acid: false-negative); may cause a false elevation of serum creatinine through interference with laboratory determination

Drug Interactions

Decreased effect:
Aspirin (decreases ascorbate levels, increases aspirin)
Fluphenazine (decreases fluphenazine levels)
Warfarin (decreased effect)
Increased effect:
Iron (absorption enhanced)
Oral contraceptives (increased contraceptive effect)

Pregnancy Risk Factor A/C (dose exceeding RDA recommendation)

Lactation Enters breast milk/compatible

Nursing Implications Avoid rapid I.V. injection

Additional Information Sodium content of 1 g: ~5 mEq; >715 mg/day may result in slower progression of HIV illness (RR=0.55). Single doses of 40 g I.V. or chronic ingestions >2 g daily can result in renal toxicity.

Atenolol

Pronunciation (a TEN oh lole)

Related Information

• Selected Properties of Beta-Adrenergic Blocking Drugs

CAS Number 29122-68-7; 60966-51-0

U.S. Brand Names Tenormin®

Use Treatment of hypertension, alone or in combination with other agents; management of angina pectoris, postmyocardial infarction patients

Unlabeled/Investigational Use Acute ethanol withdrawal, supraventricular and ventricular arrhythmias, and migraine headache prophylaxis

Mechanism of Action Competitively blocks response to beta-adrenergic stimulation; more hydrophilic than propranolol; not lipid soluble

Adverse Reactions

Cardiovascular: Persistent bradycardia, hypotension, chest pain, edema, heart failure, AV block, exacerbation of Raynaud's phenomenon, sinus bradycardia, myocardial depression, QRS prolongation, vasculitis
Central nervous system: Dizziness, fatigue, insomnia, drowsiness, confusion, psychosis, CNS depression, headache, night terrors, memory impairment, paranoia
Dermatologic: Exacerbation of vitiligo, erythema multiforme, alopecia, toxic epidermal necrolysis, xerosis, urticaria, purpura, onycholysis, photosensitivity, pruritus; exanthema, licheniform eruptions, cutaneous vasculitis

Endocrine & metabolic: Sexual dysfunction, hyperprolactinemia

Gastrointestinal: Constipation, abdominal pain, diarrhea, nausea,

Genitourinary: Impotence, retroperitoneal fibrosis

Hepatic: Cholestasis

Respiratory: Dyspnea has occurred when daily dosage exceeds 100 mg/day, wheezing

Miscellaneous: Cold extremities, systemic lupus erythematosus

Signs and Symptoms of Overdose Ataxia, AV block, bradycardia, congestive heart failure, depression, dermatitis, dry eyes, dry mouth, hypoglycemia, hypotension, hypothermia, impotence, insomnia, night terrors, wheezing

Pharmacodynamics/Kinetics

Onset of action: Peak effect: Oral: 2-4 hours

Duration: Normal renal function: 12-24 hours

Absorption: Incomplete

Distribution: Low lipophilicity; does not cross blood-brain barrier

Protein binding: 3% to 15%

Metabolism: Limited hepatic

Half-life elimination: Beta:

Neonates: ≤ 35 hours; Mean: 16 hours

Children: 4.6 hours; children >10 years may have longer half-life (>5 hours) compared to children 5-10 years (<5 hours)

Adults: Normal renal function: 6-9 hours, prolonged with renal impairment; End-stage renal disease: 15-35 hours

Excretion: Feces (50%); urine (40% as unchanged drug)

Dosage

Oral:

Children: 1-2 mg/kg/dose given daily

Adults:

Hypertension: 25-50 mg once daily, may increase to 100 mg/day; doses >100 mg are unlikely to produce any further benefit

Angina pectoris: 50 mg once daily, may increase to 100 mg/day; some patients may require 200 mg/day

Postmyocardial infarction: Follow I.V. dose with 100 mg/day or 50 mg twice daily for 6-9 days postmyocardial infarction

I.V.: Postmyocardial infarction: Early treatment: 5 mg slow I.V. over 5 minutes; may repeat in 10 minutes; if both doses are tolerated, may start oral atenolol 50 mg every 12 hours or 100 mg/day for 6-9 days postmyocardial infarction

Dosing interval for oral atenolol in renal impairment:

Cl_{cr} 15-35 mL/minute: Administer 50 mg/day maximum

Cl_{cr} <15 mL/minute: Administer 50 mg every other day maximum

Hemodialysis: Moderately dialyzable (20% to 50%) via hemodialysis; administer dose postdialysis or administer 25-50 mg supplemental dose

Peritoneal dialysis: Elimination is not enhanced; supplemental dose is not necessary

Monitoring Parameters Acute cardiac treatment: Monitor ECG and blood pressure with I.V. administration; heart rate and blood pressure with oral administration

Administration

When administered acutely for cardiac treatment, monitor ECG and blood pressure. The injection can be administered undiluted or diluted with a compatible I.V. solution. May administer by rapid infusion (I.V. push) at a rate of 1 mg/minute or by slow infusion over ~30 minutes. Necessary monitoring for surgical patients who are unable to take oral beta-blockers (prolonged ileus) has not been defined. Some institutions require monitoring of baseline and postinfusion heart rate and blood pressure when a patient's response to beta-blockade has not been characterized (ie, the patient's initial dose or following a change in dose). Consult individual institutional policies and procedures.

Contraindications Hypersensitivity to atenolol or any component of the formulation; sinus bradycardia; sinus node dysfunction; heart block greater than first-degree (except in patients with a functioning artificial pacemaker); cardiogenic shock; uncompensated cardiac failure; pulmonary edema; pregnancy

Warnings Safety and efficacy in children have not been established. Administer cautiously in compensated heart failure and monitor for a worsening of the condition (efficacy of atenolol in heart failure has not been established). **[U.S. Boxed Warning]: Beta-blocker therapy should not be withdrawn abruptly (particularly in patients with CAD), but gradually tapered to avoid acute tachycardia, hypertension, and/or ischemia.** Use caution with concurrent use of beta-blockers and either verapamil or diltiazem; bradycardia or heart block can occur. Avoid concurrent I.V. use of both agents. Beta-blockers should be avoided in patients with bronchospastic disease (asthma). Atenolol, with B1 selectivity, has been used cautiously in bronchospastic disease with close monitoring. Use cautiously in peripheral arterial disease, especially if severe disease is present. Use cautiously in patients with diabetes - may mask hypoglycemic symptoms. May mask signs of thyrotoxicosis. May cause fetal harm when administered in pregnancy. Use cautiously in the renally impaired (dosage adjustment required). Use care with anesthetic agents which decrease myocardial function. Caution in myasthenia gravis.

Dosage Forms Injection, solution: 0.5 mg/mL (10 mL)

Tablet: 25 mg, 50 mg, 100 mg

Reference Range Peak plasma level of 1-2 mcg/mL 2-4 hours after 200 mg dose. Highest survivable atenolol (serum) level: 35 mcg/mL

Overdosage/Treatment

Decontamination: **Do not** use ipecac; lavage (within 1 hour)/activated charcoal is useful

Supportive therapy: Sympathomimetics (eg, epinephrine or dopamine), glucagon, atropine, or a pacemaker can be used to treat the toxic bradycardia, asystole, and/or hypotension. Initially, fluids may be the best treatment for toxic hypotension, with norepinephrine being used for refractory hypotension. Calcium chloride can be used to treat electro-mechanical dissociation caused by atenolol overdose.

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; hemodialysis may be of some benefit (moderately dialyzable 20% to 50%); hemodialysis clearance: ~29-39 mL/minute (45% of drug can be fractionally removed during 4 hours of hemodialysis)

Test Interactions ↑ triglycerides, potassium, uric acid, cholesterol (S), glucose; ↓ HDL

Drug Interactions

Alpha-blockers (prazosin, terazosin): Concurrent use of beta-blockers may increase risk of orthostasis.

Ampicillin, in single doses of 1 gram, decreases atenolol's pharmacologic actions.

Antacids (magnesium-aluminum, calcium antacids or salts) may reduce the bioavailability of atenolol.

Clonidine: Hypertensive crisis after or during withdrawal of either agent.

Drugs which slow AV conduction (digoxin): Effects may be additive with beta-blockers.

Glucagon: Atenolol may blunt the hyperglycemic action of glucagon.

Insulin and oral hypoglycemics: Atenolol masks the tachycardia that usually accompanies hypoglycemia.

NSAIDs (ibuprofen, indomethacin, naproxen, piroxicam) may reduce the antihypertensive effects of beta-blockers.

Salicylates may reduce the antihypertensive effects of beta-blockers.

Sulfonylureas: Beta-blockers may alter response to hypoglycemic agents.

Verapamil or diltiazem may have synergistic or additive pharmacological effects when taken concurrently with beta-blockers.

Pregnancy Risk Factor D

Pregnancy Implications Atenolol crosses the placenta; beta-blockers have been associated with persistent bradycardia, hypotension, and IUGR; IUGR is probably related to maternal hypertension. Available evidence suggests beta-blockers are generally safe during pregnancy (JNC-7). Cases of neonatal hypoglycemia have been reported following maternal use of beta-blockers at parturition or during breast-feeding.

Lactation Enters breast milk/use caution

Nursing Implications Patient's therapeutic response may be evaluated by looking at blood pressure, apical and radial pulses, fluid I & O, daily weight, respirations, and circulation in extremities before and during therapy; modify dosage in patients with renal insufficiency

Additional Information Most effective for treating hypertension in older, white patients

Atomoxetine

Pronunciation (AT oh mox e teen)

CAS Number 82248-59-7; 83015-26-3

U.S. Brand Names Strattera™

Synonyms Atomoxetine Hydrochloride; LY139603; Methylphenoxy-Benzene Propanamine; Tomoxetine

Use Treatment of attention deficit/hyperactivity disorder (ADHD)

Unlabeled/Investigational Use Treatment of depression

Mechanism of Action Selectively inhibits the reuptake of norepinephrine (Ki 4.5nM) with little to no activity at the other neuronal reuptake pumps or receptor sites. No anticholinergic effects.

Adverse Reactions

Percentages as reported in children and adults; some adverse reactions may be increased in "poor metabolizers" (CYP2D6).

Cardiovascular: Palpitations, tachycardia, systolic blood pressure increased, orthostatic hypotension

Central nervous system: **Headache**, fatigue/lethargy, irritability, somnolence, dizziness, mood swings, abnormal dreams, paresthesia, sleep disturbance, pyrexia, rigors, crying

Dermatologic: Dermatitis, rash, urticaria, angioedema

Endocrine & metabolic: Dysmenorrhea, libido decreased, menstruation disturbance, orgasm abnormal, weight loss

Gastrointestinal: **Xerostomia (4% to 21%), abdominal pain, insomnia, vomiting, anorexia, nausea**, dyspepsia, diarrhea, flatulence, constipation

Genitourinary: Erectile disturbance, ejaculatory disturbance, prostatitis, impotence

Neuromuscular & skeletal: Paresthesia, myalgia

Renal: Urinary retention/hesitation

Respiratory: **Cough**, rhinorrhea, sinus headache

Miscellaneous: Diaphoresis increased, sinusitis, ear infection, influenza, allergy

Hepatic: Hepatitis

Signs and Symptoms of Overdose Anorexia, dyspepsia, abdominal pain, rhabdomyolysis, tachycardia, agitation, hypertension, lethargy

Pharmacodynamics/Kinetics

Absorption: Rapid

Distribution: V_d: I.V.: 0.85 L/kg

Protein binding: 98%, primarily albumin

Metabolism: Hepatic, via CYP2D6 and CYP2C19; forms metabolites (4-hydroxyatomoxetine, active, equipotent to atomoxetine; N-desmethylatomoxetine in poor metabolizers, limited activity)

Bioavailability: 63% in extensive metabolizers; 94% in poor metabolizers

Half-life elimination: Atomoxetine: 5 hours (up to 24 hours in poor metabolizers); Active metabolites: 4-hydroxyatomoxetine: 6-8 hours;

N-desmethylatomoxetine: 6-8 hours (34-40 hours in poor metabolizers)

Time to peak, plasma: 1-2 hours

Excretion: Urine (80%, as conjugated 4-hydroxy metabolite); feces (17%)

Dosage

Oral:

Children and Adolescents ≤70 kg: ADHD: Initial: 0.5 mg/kg/day, increase after minimum of 3 days to ~1.2 mg/kg/day; may administer as either a single daily dose or two evenly divided doses in morning and late afternoon/early evening. Maximum daily dose: 1.4 mg/kg or 100 mg, whichever is less. In patients receiving effective CYP2D6 inhibitors (eg, paroxetine, fluoxetine, quinidine), do not exceed 1.2 mg/kg.

Children and Adolescents >70 kg: Refer to Adults dosing

Adults:

ADHD: Initial: 40 mg/day, increased after minimum of 3 days to ~80 mg/day; may administer as either a single daily dose or two evenly

divided doses in morning and late afternoon/early evening. May increase to 100 mg in 2-4 additional weeks to achieve optimal response. In patients receiving effective CYP2D6 inhibitors (eg, paroxetine, fluoxetine, quinidine), do not exceed 80 mg/day.

Depression (unlabeled use): 40-65 mg/day

Elderly: Use has not been evaluated in the elderly

Dosage adjustment in renal impairment: No adjustment needed

Dosage adjustment in hepatic impairment:

Moderate hepatic insufficiency (Child-Pugh class B): All doses should be reduced to 50% of normal

Severe hepatic insufficiency (Child-Pugh class C): All doses should be reduced to 25% of normal

Monitoring Parameters

Patient growth (weight/height gain in children); attention, hyperactivity, anxiety, worsening of aggressive behavior or hostility; blood pressure, pulse

Family members and caregivers need to monitor patient daily for emergence of irritability, agitation, unusual changes in behavior, and suicidal ideation. Pediatric patients should be monitored closely for suicidality, clinical worsening, or unusual changes in behavior, especially during the initial for months of therapy or at times of dose changes. Appearance of symptoms needs to be immediately reported to healthcare provider. Weekly office visits from patient or caregiver are necessary for the first 4 weeks, then every other week for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact may be required between office visits.

Administration

May be administered with or without food.

Contraindications Hypersensitivity to atomoxetine or any component of the formulation; use with or within 14 days of MAO inhibitors; narrow-angle glaucoma

Warnings

[U.S. Boxed Warning]: Use caution in pediatric patients; may be an increased risk of suicidal ideation. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Patients should be observed for, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. Atomoxetine is not approved for major depressive disorder. Patients presenting with depressive symptoms should be screened for bipolar disorder. A medication guide should be dispensed with each prescription. Use caution with hepatic (dosage adjustments necessary in hepatic impairment). Use may be associated with rare but severe hepatotoxicity; discontinue and do not restart if signs or symptoms of hepatotoxic reaction (eg, jaundice, pruritus, flu-like symptoms) are noted. Use caution in patients who are poor metabolizers of CYP2D6 metabolized drugs ("poor metabolizers"), bioavailability increases.

May cause increased heart rate or blood pressure; use caution with hypertension or other cardiovascular disease. Use caution with renal impairment. May cause urinary retention/hesitancy; use caution in patients with history of urinary retention or bladder outlet obstruction. Allergic reactions (including angioneurotic edema, urticaria, and rash) may occur.

Growth should be monitored during treatment. Height and weight gain may be reduced during the first 9-12 months of treatment, but should recover by 3 years of therapy. Safety and efficacy have not been evaluated in pediatric patients <6 years of age.

Dosage Forms

Capsule:

Strattera®: 10 mg, 18 mg, 25 mg, 40 mg, 60 mg, 80 mg, 100 mg

Reference Range Peak plasma atomoxetine level ranging from 315-1231 ng/mL noted following single 90 mg oral dose

Overdosage/Treatment

Effects of overdose unknown

Decontamination: Lavage and/or activated charcoal with ingestions exceeding 2 mg/kg

Drug Interactions

Substrate of CYP2C19 (minor), 2D6 (major)

β₂ agonists (albuterol): Atomoxetine may potentiate cardiovascular effects of albuterol.

CNS depressants: May enhance the adverse/toxic effect of atomoxetine.

CYP2D6 inhibitors: May increase the levels/effects of atomoxetine.

Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole. Dose adjustment may be needed when coadministered with CYP2D6 inhibitors in patients who are extensive metabolizers of CYP2D6.

Fluoxetine: CYP2D6 inhibitors (strong) may decrease the metabolism of CYP2D6 substrates such as atomoxetine. Manufacturer recommends dosage adjustment.

MAO inhibitors: Therapy with or within 2 weeks of atomoxetine may cause serious toxicity (eg, hyperthermia, rigidity, myoclonus, mental

status changes, autonomic instability, NMS). Combined use is contraindicated.

Paroxetine: May decrease the metabolism, via CYP isoenzymes, of atomoxetine. Manufacturer recommends dosage adjustment.

Quinidine: CYP2D6 inhibitors (strong) may decrease the metabolism of CYP2D6 substrates such as atomoxetine. Manufacturer recommends dosage adjustment.

Sympathomimetics (including epinephrine): Atomoxetine may increase heart rate or blood pressure. Use caution with pressor agents.

Pregnancy Risk Factor C

Pregnancy Implications No adequate and well-controlled studies in pregnant women; use only if potential benefit to the mother outweighs possible risk to fetus.

Lactation Excretion in breast milk unknown/use caution

Atorvastatin

Pronunciation (a TORE va sta tin)

CAS Number 134523-00-5; 134523-03-8

U.S. Brand Names Lipitor®

Use

Treatment of dyslipidemias or primary prevention of cardiovascular disease (atherosclerotic) as detailed below:

Primary prevention of cardiovascular disease (high-risk for CVD): To reduce the risk of MI or stroke in patients without evidence of heart disease who have multiple CVD risk factors or type 2 diabetes. Treatment reduces the risk for angina or revascularization procedures in patients with multiple risk factors.

Treatment of dyslipidemias: To reduce elevations in total cholesterol, LDL-C, apolipoprotein B, and triglycerides in patients with elevations of one or more components, and/or to increase HDL-C as present in Fredrickson type IIa, IIb, III, and IV hyperlipidemias; treatment of primary dysbetalipoproteinemia, homozygous familial hypercholesterolemia

Treatment of heterozygous familial hypercholesterolemia (HeFH) in adolescent patients (10-17 years of age, females >1 year postmenarche) having LDL-C ≥190 mg/dL or LDL ≥160 mg/dL with positive family history of premature cardiovascular disease (CVD) or with two or more CVD risk factors.

Mechanism of Action Inhibitor of 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase, the rate limiting enzyme in cholesterol synthesis (reduces the production of mevalonic acid from HMG-CoA); this then results in a compensatory increase in the expression of LDL receptors on hepatocyte membranes and a stimulation of LDL catabolism

Adverse Reactions

Cardiovascular: Chest pain, peripheral edema, facial edema, edema, palpitations, vasodilation, postural hypotension, arrhythmia, angina, hypertension, syncope

Central nervous system: Headache, insomnia, dizziness, fever, malaise, somnolence, abnormal dreams, emotional lability, incoordination, depression, migraine

Dermatologic: Rash, photosensitivity, cheilitis, pruritus, alopecia, dry skin, urticaria, acne, eczema, seborrhea, skin ulcer, ecchymosis, Stevens-Johnson syndrome, erythema multiforme, petechiae, angioneurotic edema, bullous rashes, toxic epidermal necrolysis

Endocrine & metabolic: Hyperglycemia, gout, hypoglycemia

Gastrointestinal: Abdominal pain, constipation, diarrhea, dyspepsia, flatulence, nausea, gastroenteritis, colitis, vomiting, gastritis, xerostomia, rectal hemorrhage, esophagitis, eructation, glossitis, stomatitis, anorexia, increased appetite, duodenal ulcer, dysphagia, enteritis, melena, gingival hemorrhage, tenesmus, pancreatitis, taste loss, taste perversion, weight gain

Genitourinary: Urinary tract infection, decreased libido, cystitis, impotence, epididymitis, vaginal hemorrhage, dysuria, nocturia, abnormal urination

Hematologic: Anemia, immune thrombocytopenia

Hepatic: Elevated transaminases, hepatitis, cholestatic jaundice, biliary pain

Neuromuscular & skeletal: Arthralgia, myalgia, back pain, arthritis, paresthesia, peripheral neuropathy, torticollis, facial paralysis, hyperkinesia, hypesthesia, hypertonica, leg cramps, bursitis, myasthenia, myositis, tendinous contracture, rhabdomyolysis, myopathy, weakness

Ocular: Amblyopia, glaucoma

Otic: Tinnitus, deafness

Renal: Hematuria, nephritis

Respiratory: Sinusitis, bronchitis, dyspnea, epistaxis, pharyngitis, rhinitis

Miscellaneous: Infection, flu-like syndrome, allergic reaction, phlebitis, anaphylaxis, fibrocystic breast disease, lymphadenopathy

Additional class-related events or case reports (not necessarily reported with atorvastatin therapy): Myopathy, increased CPK ($>10 \times$ normal), rhabdomyolysis, renal failure (secondary to rhabdomyolysis), alteration in taste, impaired extraocular muscle movement, facial paresis, tremor, memory loss, vertigo, paresthesia, peripheral neuropathy, peripheral nerve palsy, anxiety, depression, psychic disturbance, hypersensitivity reaction, angioedema, anaphylaxis, systemic lupus erythematosus-like syndrome, polymyalgia rheumatica, dermatomyositis, vasculitis, purpura, thrombocytopenia, leukopenia, hemolytic anemia, positive ANA, increased ESR, eosinophilia, arthritis, urticaria, photosensitivity, fever, chills, flushing, malaise, dyspnea, rash, toxic epidermal necrolysis, erythema multiforme, Stevens-Johnson syndrome, pancreatitis, hepatitis, cholestatic jaundice, fatty liver, cirrhosis, fulminant hepatic necrosis, hepatoma, anorexia, vomiting, alopecia, nodules, skin discoloration, dryness of skin/mucous membranes, nail changes, gynecomastia, decreased libido, erectile dysfunction, impotence, cataracts, ophthalmoplegia, elevated transaminases, increased alkaline phosphatase, increased GGT, hyperbilirubinemia, thyroid dysfunction

Pharmacodynamics/Kinetics

Onset of action: Initial changes: 3-5 days; Maximal reduction in plasma cholesterol and triglycerides: 2 weeks

Absorption: Rapid

Distribution: V_d : 318 L

Protein binding: $\geq 98\%$

Metabolism: Hepatic; forms active ortho- and parahydroxylated derivatives and an inactive beta-oxidation product

Half-life elimination: Parent drug: 14 hours

Time to peak, serum: 1-2 hours

Excretion: Bile; urine (2% as unchanged drug)

Dosage

Oral: **Note:** Doses should be individualized according to the baseline LDL-cholesterol levels, the recommended goal of therapy, and patient response; adjustments should be made at intervals of 2-4 weeks

Children 10-17 years (females >1 year postmenarche): HeFH: 10 mg once daily (maximum: 20 mg/day)

Adults: Hyperlipidemias: Initial: 10-20 mg once daily; patients requiring $>45\%$ reduction in LDL-C may be started at 40 mg once daily; range: 10-80 mg once daily

Primary prevention of CVD: 10 mg once daily

Dosing adjustment in renal impairment: No dosage adjustment is necessary.

Dosing adjustment in hepatic impairment: Do not use in active liver disease.

Monitoring Parameters Lipid levels after 2-4 weeks; LFTs, CPK

It is recommended that liver function tests (LFTs) be performed prior to and at 12 weeks following both the initiation of therapy and any elevation in dose, and periodically (eg, semiannually) thereafter

Administration

May be administered with food if desired; may take without regard to time of day.

Contraindications Hypersensitivity to atorvastatin or any component of the formulation; active liver disease; unexplained persistent elevations of serum transaminases; pregnancy

Warnings Secondary causes of hyperlipidemia should be ruled out prior to therapy. May cause hepatic dysfunction. Use with caution in patients who consume large amounts of ethanol or have a history of liver disease. Monitoring is recommended. Rhabdomyolysis with acute renal failure has occurred. Risk is dose related and is increased with concurrent use of lipid-lowering agents which may cause rhabdomyolysis (gemfibrozil, fibric acid derivatives, or niacin at doses ≥ 1 g/day) or during concurrent use with potent CYP3A4 inhibitors (including amiodarone, clarithromycin, cyclosporine, erythromycin, itraconazole, ketoconazole, nefazodone, grapefruit juice in large quantities, verapamil, or protease inhibitors such as indinavir, nelfinavir, or ritonavir). Weigh the risk versus benefit when combining any of these drugs with atorvastatin. Discontinue in any patient experiencing an acute or serious condition predisposing to renal failure secondary to rhabdomyolysis. Safety and efficacy have not been established in patients <10 years of age or in premenarcheal girls.

Dosage Forms Tablet: 10 mg, 20 mg, 40 mg, 80 mg

Overdosage/Treatment

Decontamination: Consider gastric decontamination for acute ingestions >200 mg; activated charcoal or cholestyramine may be useful

Supportive therapy: Monitor for rhabdomyolysis; adequate hydration with 0.9% NS is appropriate

Drug Interactions

Substrate of CYP3A4 (major); Inhibits CYP3A4 (weak)

Antacids: Plasma concentrations may be decreased when given with magnesium-aluminum hydroxide containing antacids (reported with atorvastatin and pravastatin). Clinical efficacy is not altered, no dosage adjustment is necessary.

Bile acid sequestrants (cholestyramine and colestipol): Reduce absorption of several HMG-CoA reductase inhibitors; separate administration times by at least 4 hours. Cholesterol-lowering effects are additive.

Cyclosporine: May increase serum concentrations of atorvastatin, increasing the risk of myopathy; monitor.

CYP3A4 inhibitors: May increase the levels/effects of atorvastatin. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Digoxin: Plasma concentrations of digoxin may be increased by $\sim 20\%$; monitor.

Fibric acid derivatives (clofibrate and fenofibrate): May increase the risk of myopathy and rhabdomyolysis.

Grapefruit juice: May inhibit metabolism of atorvastatin via CYP3A4; more likely to occur with lovastatin or simvastatin; avoid high dietary intake of grapefruit juice.

Niacin: May increase the risk of myopathy and rhabdomyolysis.

Pregnancy Risk Factor X

Pregnancy Implications A case of bone deformity, tracheoesophageal fistula, and anal atresia has been noted in a fetus after first trimester use of lovastatin and dextroamphetamine.

Lactation Enters breast milk/contraindicated

Additional Information Atorvastatin serum concentrations may be increased by grapefruit juice; avoid concurrent intake of large quantities (>1 quart/day). St John's wort may decrease atorvastatin levels.

Specific References

Sipe BE, Jones RJ, and Bokhart GH, "Rhabdomyolysis Causing AV Blockade Due to Possible Atorvastatin, Esomeprazole, and Clarithromycin Interaction," *Ann Pharmacother*, 2003, 37(6):808-11.

Azathioprine

Pronunciation (ay za THYE oh preen)

Related Information

- Mercaptopurine

CAS Number 446-86-6

U.S. Brand Names Azasan[®]; Imuran[®]

Synonyms Azathioprine Sodium

Use Adjunct with other agents in prevention of rejection of kidney transplants; also used in severe active rheumatoid arthritis unresponsive to other agents; other autoimmune diseases (ITP, SLE, MS, Crohn's disease)

Unlabeled/Investigational Use Adjunct in prevention of rejection of solid organ (nonrenal) transplants; steroid-sparing agent for corticosteroid-dependent Crohn's disease (CD) and ulcerative colitis (UC); maintenance of remission in CD; fistulizing Crohn's disease

Mechanism of Action Antagonizes purine metabolism and may inhibit synthesis of DNA, RNA, and proteins; may also interfere with cellular metabolism and inhibit mitosis

Adverse Reactions

Central nervous system: Fever, chills

Dermatologic: Alopecia, erythematous or maculopapular rash

Gastrointestinal: Nausea, vomiting, anorexia, diarrhea, aphthous stomatitis, pancreatitis

AZITHROMYCIN

Hematologic: Leukopenia, thrombocytopenia, anemia, pancytopenia (bone marrow suppression may be determined, in part, by genetic factors, ie, patients with TPMT deficiency are at higher risk)

Hepatic: Hepatotoxicity, jaundice, hepatic veno-occlusive disease

Neuromuscular & skeletal: Arthralgias

Ocular: Retinopathy

Miscellaneous: Rare hypersensitivity reactions (including myalgias, rigors, dyspnea, hypotension, serum sickness, rash); secondary infections may occur secondary to immunosuppression

Signs and Symptoms of Overdose Diarrhea, leukopenia (in 2-3 days), vomiting

Pharmacodynamics/Kinetics

Distribution: Crosses placenta

Protein binding: ~30%

Metabolism: Hepatic, to 6-mercaptopurine (6-MP), possibly by glutathione S-transferase (GST). Further metabolism of 6-MP (in the liver and GI tract), via three major pathways: Hypoxanthine guanine phosphoribosyltransferase (to 6-thioguanine-nucleotides, or 6-TGN), xanthine oxidase (to 6-thiouric acid), and thiopurine methyltransferase (TPMT), which forms 6-methylmercaptopurine (6-MMP).

Half-life elimination: Parent drug: 12 minutes; mercaptopurine: 0.7-3 hours; End-stage renal disease: Slightly prolonged

Time to peak, plasma: 1-2 hours (including metabolites)

Excretion: Urine (primarily as metabolites)

Dosage I.V. dose is equivalent to oral dose

Children and Adults: Renal transplantation: Oral, I.V.: 2-5 mg/kg/day to start, then 1-3 mg/kg/day maintenance

Adults: Rheumatoid arthritis: Oral: 1 mg/kg/day for 6-8 weeks; increase by 0.5 mg/kg every 4 weeks until response or up to 2.5 mg/kg/day

Dosing adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer 75% of normal dose

Cl_{cr} < 10 mL/minute: Administer 50% of normal dose

Administer dose posthemodialysis

CAPD effects: Unknown

CAVH effects: Unknown

Stability Stability of parenteral admixture at room temperature (25°C): 24 hours

Stability of parenteral admixture at refrigeration temperature (4°C): 16 days

Stable in neutral or acid solutions, but is hydrolyzed to mercaptopurine in alkaline solutions

Monitoring Parameters CBC, platelet counts, total bilirubin, alkaline phosphatase

Administration

Can be administered IVP over 5 minutes at a concentration not to exceed 10 mg/mL or azathioprine can be further diluted with normal saline or D₅W and administered by intermittent infusion over 15-60 minutes

Contraindications Hypersensitivity to azathioprine or any component of the formulation; pregnancy

Warnings [U.S. Boxed Warning]: Chronic immunosuppression increases the risk of neoplasia and serious infections. Azathioprine has mutagenic potential to both men and women and with possible hematologic toxicities; hematologic toxicities are dose related and may be more severe with renal transplants undergoing rejection. Gastrointestinal toxicity may occur within the first several weeks of therapy and is reversible. Symptoms may include severe nausea, vomiting, diarrhea, rash, fever, malaise, myalgia, hypotension, and liver enzyme abnormalities. Use with caution in patients with liver disease, renal impairment; monitor hematologic function closely. Patients with genetic deficiency of thiopurine methyltransferase (TPMT) or concurrent therapy with drugs which may inhibit TPMT may be sensitive to myelosuppressive effects. Azathioprine is metabolized to mercaptopurine; concomitant use may result in profound myelosuppression and should be avoided.

Dosage Forms

Injection, powder for reconstitution: 100 mg

Tablet [scored]: 50 mg

Azasan®: 75 mg, 100 mg

Imuran®: 50 mg

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage within 1 hour; give activated charcoal

Enhanced elimination: Hemodialysis (43% removed during 8 hours) can enhance azathioprine and its metabolites removal

Drug Interactions

ACE inhibitors: Concomitant therapy may induce anemia and severe leukopenia.

Allopurinol: May increase serum levels of azathioprine's active metabolite (mercaptopurine). Decrease azathioprine dose to 1/3 to 1/4 of normal dose.

Aminosalicylates (olsalazine, mesalamine, sulfasalazine): May inhibit TPMT, increasing toxicity/myelosuppression of azathioprine. Use caution.

Mercaptopurine: Azathioprine is metabolized to mercaptopurine; concomitant use may result in profound myelosuppression and should be avoided.

Warfarin: Effect may be decreased by azathioprine.

Pregnancy Risk Factor D

Pregnancy Implications Azathioprine was found to be teratogenic in animal studies; temporary depression in spermatogenesis and reduction in sperm viability and sperm count were also reported in mice. Azathioprine crosses the placenta in humans; congenital anomalies, immunosuppression, and intrauterine growth retardation have been reported. There are no adequate and well-controlled studies in pregnant women. Azathioprine should not be used to treat arthritis during pregnancy. The potential benefit to the mother versus possible risk to the fetus should be considered when treating other disease states.

Lactation Enters breast milk/not recommended

Additional Information Will not cause dermal toxicity if extravasation occurs

Azithromycin

Pronunciation (az ith roe MYE sin)

CAS Number 83905-01-5

U.S. Brand Names Zithromax®

Synonyms Azithromycin Dihydrate; Zithromax® TRI-PAK™; Zithromax® Z-PAK®

Use Treatment of acute otitis media due to *H. influenzae*, *M. catarrhalis*, or *S. pneumoniae*; pharyngitis/tonsillitis due to *S. pyogenes*; treatment of mild to moderate upper and lower respiratory tract infections, infections of the skin and skin structure, community-acquired pneumonia, pelvic inflammatory disease (PID), sexually-transmitted diseases (urethritis/cervicitis), pharyngitis/tonsillitis (alternative to first-line therapy), and genital ulcer disease (chancroid) due to susceptible strains of *C. trachomatis*, *M. catarrhalis*, *H. influenzae*, *S. aureus*, *S. pneumoniae*, *Mycoplasma pneumoniae*, and *C. psittaci*; acute bacterial exacerbations of chronic obstructive pulmonary disease (COPD) due to *H. influenzae*, *M. catarrhalis*, or *S. pneumoniae*; acute bacterial sinusitis

Unlabeled/Investigational Use Prevention of (or to delay onset of) or treatment of MAC in patients with advanced HIV infection; prophylaxis of bacterial endocarditis in patients who are allergic to penicillin and undergoing surgical or dental procedures; pertussis

Mechanism of Action Inhibits RNA-dependent protein synthesis at the chain elongation step; binds to the 50S ribosomal subunit resulting in blockage of transpeptidation

Adverse Reactions

Cardiovascular: Arrhythmias (ventricular)

Central nervous system: Headache, dizziness, fever, hypothermia

Dermatologic: Rash, angioedema, urticaria, photosensitivity, exanthema, cutaneous vasculitis

Endocrine & Metabolic: Inappropriate antidiuretic hormone secretion

Gastrointestinal: Diarrhea, nausea, abdominal pain, vomiting, cramping, hypertrophic pyloric stenosis, feces discoloration (greenish gray, white/speckling)

Hematologic: Eosinophilia

Hepatic: Elevation in hepatic enzymes, cholestatic jaundice

Local: Thrombophlebitis

Neuromuscular & skeletal: Myasthenia gravis, myalgia

Otic: Ototoxicity, tinnitus

Renal: Nephritis

Miscellaneous: Allergic reactions

Pharmacodynamics/Kinetics

Absorption: Rapid

Distribution: Extensive tissue; distributes well into skin, lungs, sputum, tonsils, and cervix; penetration into CSF is poor; I.V.: 33.3 L/kg; Oral: 31.1 L/kg

Protein binding (concentration dependent): 7% to 51%

Metabolism: Hepatic

Bioavailability: 38%, decreased by 17% with extended release suspension; variable effect with food (increased with immediate or delayed release oral suspension, unchanged with tablet)

Half-life elimination: Terminal: Immediate release: 68-72 hours; Extended release: 59 hours

Time to peak, serum: Immediate release: 2-3 hours; Extended release: 5 hours

Excretion: Biliary (major route); urine (6%)

Dosage

Note: Extended release suspension (Zmax™) is not interchangeable with immediate release formulations. Use should be limited to approved indications. All doses are expressed as immediate release azithromycin unless otherwise specified.

Oral:

Children <6 months: Pertussis (CDC guidelines): 10 mg/kg/day for 5 days

Children ≥6 months:

Community-acquired pneumonia, pertussis (CDC guidelines): 10 mg/kg on day 1 (maximum: 500 mg/day) followed by 5 mg/kg/day once daily on days 2-5 (maximum: 250 mg/day)

Bacterial sinusitis: 10 mg/kg once daily for 3 days (maximum: 500 mg/day)

Otitis media:

1-day regimen: 30 mg/kg as a single dose (maximum dose: 1500 mg)

3-day regimen: 10 mg/kg once daily for 3 days (maximum: 500 mg/day)

5-day regimen: 10 mg/kg on day 1 (maximum: 500 mg/day) followed by 5 mg/kg/day once daily on days 2-5 (maximum: 250 mg/day)

Children ≥2 years: Pharyngitis, tonsillitis: 12 mg/kg/day once daily for 5 days (maximum: 500 mg/day)

Children:

M. avium-infected patients with acquired immunodeficiency syndrome (unlabeled use): 5 mg/kg/day once daily (maximum dose: 250 mg/day) or 20 mg/kg (maximum dose: 1200 mg) once weekly given alone or in combination with rifabutin

Treatment and secondary prevention of disseminated MAC (unlabeled use): 5 mg/kg/day once daily (maximum dose: 250 mg/day) in combination with ethambutol, with or without rifabutin

Prophylaxis for bacterial endocarditis (unlabeled use): 15 mg/kg 1 hour before procedure

Uncomplicated chlamydia urethritis or cervicitis (unlabeled use): Children ≥45 kg: 1 g as a single dose

Adolescents ≥16 years and Adults:

Community-acquired pneumonia: Extended release suspension (Zmax™): 2 g as a single dose

Respiratory tract, skin and soft tissue infections, pertussis (CDC guidelines): 500 mg on day 1 followed by 250 mg/day on days 2-5 (maximum: 500 mg/day)

Alternative regimen: Bacterial exacerbation of COPD: 500 mg/day for a total of 3 days

Bacterial sinusitis: 500 mg/day for a total of 3 days

Extended release suspension (Zmax™): 2 g as a single dose

Urethritis/cervicitis:

Due to *C. trachomatis*: 1 g as a single dose

Due to *N. gonorrhoeae*: 2 g as a single dose

Chancroid due to *H. ducreyi*: 1 g as a single dose

Prophylaxis of disseminated *M. avium* complex disease in patient with advanced HIV infection (unlabeled use): 1200 mg once weekly (may be combined with rifabutin)

Treatment of disseminated *M. avium* complex disease in patient with advanced HIV infection (unlabeled use): 600 mg daily (in combination with ethambutol 15 mg/kg)

Prophylaxis for bacterial endocarditis (unlabeled use): 500 mg 1 hour prior to the procedure

I.V.: Adults:

Community-acquired pneumonia: 500 mg as a single dose for at least 2 days, follow I.V. therapy by the oral route with a single daily dose of 500 mg to complete a 7-10 day course of therapy

Pelvic inflammatory disease (PID): 500 mg as a single dose for 1-2 days, follow I.V. therapy by the oral route with a single daily dose of 250 mg to complete a 7-day course of therapy

Dosage adjustment in renal impairment: Use caution in patients with $Cl_{cr} < 10$ mL/minute

Dosage adjustment in hepatic impairment: Use with caution due to potential for hepatotoxicity (rare). Specific guidelines for dosing in hepatic impairment have not been established.

Stability

Injection: Store intact vials of injection at room temperature. Reconstitute the 500 mg vial with 4.8 mL of sterile water for injection and shake until all of the drug is dissolved. Each mL contains 100 mg azithromycin. Reconstituted solution is stable for 24 hours when stored below 30°C/86°F.

The initial solution should be further diluted to a concentration of 1 mg/mL (500 mL) to 2 mg/mL (250 mL) in 0.9% sodium chloride, 5% dextrose in water, or lactated Ringer's. The diluted solution is stable for 24 hours at or below room temperature (30°C or 86°F) and for 7 days if stored under refrigeration (5°C or 41°F).

Other medications should not be infused simultaneously through the same I.V. line.

Suspension: Store dry powder below 30°C (86°F); following reconstitution, store suspension at 5°C to 30°C (41°F to 86°F).

Tablets: Store between 15°C to 30°C (59°F to 86°F).

Monitoring Parameters Liver function tests, CBC with differential

Administration I.V.: Infusate concentration and rate of infusion for azithromycin for injection should be either 1 mg/mL over 3 hours or 2 mg/mL over 1 hour. Other medications should not be infused simultaneously through the same I.V. line.

Oral: Immediate release suspension and tablet may be taken without regard to food; extended release suspension should be taken on an empty stomach (at least 1 hour before or 2 hours following a meal), within 12 hours of reconstitution.

Contraindications Hypersensitivity to azithromycin, other macrolide antibiotics, or any component of the formulation

Warnings Use with caution in patients with hepatic dysfunction; hepatic impairment with or without jaundice has occurred chiefly in older children and adults. It may be accompanied by malaise, nausea, vomiting, abdominal colic, and fever; discontinue use if these occur. May mask or delay symptoms of incubating gonorrhea or syphilis, so appropriate culture and susceptibility tests should be performed prior to initiating azithromycin. Pseudomembranous colitis has been reported with use of macrolide antibiotics; use caution with renal dysfunction. Prolongation of the QT_c interval has been reported with macrolide antibiotics; use caution in patients at risk of prolonged cardiac repolarization. Safety and efficacy have not been established in children <6 months of age with acute otitis media, acute bacterial sinusitis, or community-acquired pneumonia, or in children <2 years of age with pharyngitis/tonsillitis. Suspensions (immediate release and extended release) are not interchangeable.

Dosage Forms

Note: Strength expressed as base

Injection, powder for reconstitution, as dihydrate: 500 mg

Zithromax®: 500 mg [contains sodium 114 mg (4.96 mEq) per vial]

Microspheres for oral suspension, extended release, as dihydrate:

Zmax™: 2 g [single-dose bottle; contains sodium 148 mg per bottle; cherry and banana flavor]

Powder for oral suspension, immediate release, as dihydrate:

Zithromax®: 100 mg/5 mL (15 mL) [contains sodium 3.7 mg/ 5 mL; cherry creme de vanilla and banana flavor]; 200 mg/5 mL (15 mL, 22.5 mL, 30 mL) [contains sodium 7.4 mg/5 mL; cherry creme de vanilla and banana flavor]; 1 g [single-dose packet; contains sodium 37 mg per packet; cherry creme de vanilla and banana flavor]

Tablet, as dihydrate:

Zithromax®: 250 mg [contains sodium 0.9 mg per tablet]; 500 mg [contains sodium 1.8 mg per tablet]; 600 mg [contains sodium 2.1 mg per tablet]

Zithromax® TRI-PAK™ [unit-dose pack]: 500 mg (3s)

Zithromax® Z-PAK® [unit-dose pack]: 250 mg (6s)

Tablet, as monohydrate: 250 mg, 500 mg, 600 mg

Reference Range Peak serum levels: 0.4-0.6 mg/L following a 500 mg dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Drug Interactions

Substrate of CYP3A4 (minor); **Inhibits** CYP3A4 (weak)

Cardiac glycosides: Macrolides may increase the serum concentrations of cardiac glycosides; monitor.

Colchicine: Macrolides may increase the adverse/toxic effects of colchicine.

Nelfinavir: May increase azithromycin serum levels; monitor for adverse effects.

Warfarin: Azithromycin and other macrolides may decrease metabolism, via CYP isoenzymes, of warfarin. Monitor for increased effects.

Pregnancy Risk Factor B

Pregnancy Implications Azithromycin has been shown to cross the placenta. It has been used as an alternative treatment of *Chlamydia* in late-term pregnancy. There are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if clearly needed.

Lactation Enters breast milk/use caution

Additional Information Suggestion of improvement of cyclosporine-associated gingival hyperplasia with treatment of azithromycin

Bacitracin

CAS Number 1405-87-4; 1405-89-6

U.S. Brand Names AK-Tracin® [DSC]; Baciguent® [OTC]; BaciM®

Use Treatment of susceptible bacterial infections (staphylococcal pneumonia and empyema); due to toxicity risks, systemic and irrigant uses of bacitracin should be limited to situations where less toxic alternatives would not be effective

Unlabeled/Investigational Use Oral administration: Successful in antibiotic-associated colitis; has been used for enteric eradication of vancomycin-resistant enterococci (VRE)

Mechanism of Action Inhibits bacterial cell wall synthesis by preventing transfer of mucopeptides into the growing cell wall

Adverse Reactions

Cardiovascular: Hypotension, tightness of chest, edema of lips and face
Central nervous system: Pain

Dermatologic: Rash, itching, contact dermatitis, urticaria, systemic contact dermatitis, immunologic contact urticaria

Gastrointestinal: Anorexia, nausea, vomiting, diarrhea, rectal itching and burning

Hematologic: Blood dyscrasias

Ocular: Diplopia

Otic: Ototoxicity

Renal: Nephrotoxic when given parenterally (tubular or glomerular necrosis); hematuria, albuminuria (reversible)

Miscellaneous: Anaphylactic shock, anaphylaxis following topical administration, diaphoresis

Signs and Symptoms of Overdose Hypokalemia, myasthenia gravis (exacerbation or precipitation), tubular necrosis (acute)

Pharmacodynamics/Kinetics

Duration: 6-8 hours

Absorption: Poor from mucous membranes and intact or denuded skin; rapidly following I.M. administration; not absorbed by bladder irrigation, but absorption can occur from peritoneal or mediastinal lavage

Distribution: CSF: Nil even with inflammation

Protein binding, plasma: Minimal

Time to peak, serum: I.M.: 1-2 hours

Excretion: Urine (10% to 40%) within 24 hours

Dosage

Do not administer I.V.:

Infants: I.M.:

≤ 2.5 kg: 900 units/kg/day in 2-3 divided doses

> 2.5 kg: 1000 units/kg/day in 2-3 divided doses

Children: I.M.: 800-1200 units/kg/day divided every 8 hours

Adults: Oral:

Antibiotic-associated colitis: 25,000 units 4 times/day for 7-10 days

VRE eradication (unlabeled use): 25,000 units 4 times/day for 7-10 days

Children and Adults:

Topical: Apply 1-5 times/day

Ophthalmic, ointment: Instill 1/4" to 1/2" ribbon every 3-4 hours into conjunctival sac for acute infections, or 2-3 times/day for mild to moderate infections for 7-10 days

Irrigation, solution: 50-100 units/mL in normal saline, lactated Ringer's, or sterile water for irrigation; soak sponges in solution for topical compresses 1-5 times/day or as needed during surgical procedures

Stability Sterile powder should be stored in the refrigerator; once reconstituted, bacitracin is stable for 1 week under refrigeration (2°C to 8°C); bacitracin sterile powder should be dissolved in 0.9% sodium chloride injection containing 2% procaine hydrochloride for I.M. use; do not use diluents containing parabens; bacitracin zinc is more stable than bacitracin

Monitoring Parameters I.M.: Urinalysis, renal function tests

Administration

For I.M. administration only, **do not administer I.V.** Confirm any orders for parenteral use. pH of urine should be kept >6 by using sodium bicarbonate. Bacitracin sterile powder should be dissolved in 0.9% sodium chloride injection containing 2% procaine hydrochloride. Do not use diluents containing parabens.

Contraindications Hypersensitivity to bacitracin or any component of the formulation; I.M. use is contraindicated in patients with renal impairment
Warnings [U.S. Boxed Warning]: I.M. use may cause renal failure due to tubular and glomerular necrosis; monitor renal function daily. Prolonged use may result in overgrowth of nonsusceptible organisms. Do not administer intravenously because severe thrombophlebitis occurs.

Dosage Forms

[DSC] = Discontinued product

Injection, powder for reconstitution (BaciM®): 50,000 units

Ointment, ophthalmic (AK-Tracin® [DSC]): 500 units/g (3.5 g)

Ointment, topical: 500 units/g (0.9 g, 15 g, 30 g, 120 g, 454 g)

Baciguent®: 500 units/g (15 g, 30 g)

Reference Range Doses of 200-300 units/kg every 6 hours (I.M.) produce plasma levels of 2 units/mL

Overdosage/Treatment Decontamination: Lavage (within 1 hour)/activated charcoal with oral ingestion; irrigate dermal exposure with soap and water

Drug Interactions Increased toxicity: Nephrotoxic drugs, neuromuscular blocking agents, and anesthetics (increases neuromuscular blockade).

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/use caution

Nursing Implications For I.M. injection only, do **not** administer I.V.; confirm any orders for parenteral use; pH of urine should be kept >6 by using sodium bicarbonate

Additional Information 1 unit is equivalent to 0.026 mg

Baclofen

Related Information

● Substance-Related Disorders

● Therapeutic Drugs Associated with Hallucinations

CAS Number 1134-47-0

U.S. Brand Names Lioresal®

Impairment Potential Yes

Use Treatment of reversible spasticity associated with multiple sclerosis or spinal cord lesions; intractable hiccups

Treatment of intractable spasticity caused by spinal cord injury, multiple sclerosis, and other spinal disease (spinal ischemia or tumor, transverse myelitis, cervical spondylosis, degenerative myelopathy); alcohol withdrawal

Mechanism of Action Inhibits transmission of both monosynaptic and polysynaptic reflexes at the spinal cord level, possibly by hyperpolarization of primary afferent fiber terminals, with resultant relief of muscle spasticity; a gamma aminobutyric acid (GABA_B) agonist

Adverse Reactions

Withdrawal reactions have occurred with abrupt discontinuation (particularly severe with intrathecal use).

Cardiovascular: Hypotension, palpitations, chest pain, syncope

Central nervous system: **Drowsiness, vertigo, psychiatric disturbances, insomnia, slurred speech, ataxia, hypotonia**, confusion, euphoria, excitement, depression, fatigue, headache, hallucinations, psychosis

Dermatologic: Rash

Endocrine & metabolic: Impotence, inability to ejaculate

Gastrointestinal: Xerostomia, anorexia, abnormal taste, abdominal pain, nausea, vomiting, diarrhea

Genitourinary: Enuresis, dysuria, nocturia, hematuria, polyuria

Neuromuscular & skeletal: **Weakness**, paresthesia

Respiratory: Dyspnea

Signs and Symptoms of Overdose Angina, bradycardia or tachycardia (ventricular) [flutter (atrial)], coma, dementia, depression, diarrhea, drowsiness, dyspnea, encephalopathy, euphoria, hypertension or hypotension, hypothermia, insomnia, impotence, mania, muscle hypotonia, nystagmus, respiratory depression, salivation, seizures, vomiting, wheezing

Pharmacodynamics/Kinetics

Onset of action: 3-4 days

Peak effect: 5-10 days

Absorption (dose dependent): Oral: Rapid

Protein binding: 30%

Metabolism: Hepatic (15% of dose)

Half-life elimination: 3.5 hours

Time to peak, serum: Oral: Within 2-3 hours

Excretion: Urine and feces (85% as unchanged drug)

Dosage

Oral (avoid abrupt withdrawal of drug):

Children:

2-7 years: Initial: 10-15 mg/24 hours divided every 8 hours; titrate dose every 3 days in increments of 5-15 mg/day to a maximum of 40 mg/day

≥ 8 years: Maximum: 60 mg/day in 3 divided doses

Adults: 5 mg 3 times/day, may increase 5 mg/dose every 3 days to a maximum of 80 mg/day

Hiccups: Adults: Usual effective dose: 10-20 mg 2-3 times/day

Intrathecal:

Test dose: 50-100 mcg, doses >50 mcg should be given in 25 mcg increments, separated by 24 hours. A screening dose of 25 mcg may be considered in very small patients. Patients not responding to screening dose of 100 mcg should not be considered for chronic infusion/implanted pump.

Maintenance: After positive response to test dose, a maintenance intrathecal infusion can be administered via an implanted intrathecal pump. Initial dose via pump: Infusion at a 24-hour rate dosed at twice the test dose. Avoid abrupt discontinuation.

Alcohol withdrawal (investigational): Oral: 30 mg/day for 10 consecutive days

Elderly: Oral (the lowest effective dose is recommended): Initial: 5 mg 2-3 times/day, increasing gradually as needed; if benefits are not seen withdraw the drug slowly.

Dosing adjustment in renal impairment: It is necessary to reduce dosage in renal impairment but there are no specific guidelines available

Hemodialysis: Poor water solubility allows for accumulation during chronic hemodialysis. Low-dose therapy is recommended. There have been several case reports of accumulation of baclofen resulting in toxicity symptoms (organic brain syndrome, myoclonia, deceleration and steep potentials in EEG) in patients with renal failure who have received normal doses of baclofen.

Administration

Intrathecal: For screening dosages, dilute with preservative-free sodium chloride to a final concentration of 50 mcg/mL for bolus injection into the subarachnoid space. For maintenance infusions, concentrations of 500-2000 mcg/mL may be used.

Contraindications Hypersensitivity to baclofen or any component of the formulation

Warnings Use with caution in patients with seizure disorder or impaired renal function. **[U.S. Boxed Warning]: Avoid abrupt withdrawal of the drug; abrupt withdrawal of intrathecal baclofen has resulted in severe sequelae (hyperpyrexia, obtundation, rebound/exaggerated spasticity, muscle rigidity, and rhabdomyolysis), leading to organ failure and some fatalities.** Risk may be higher in patients with injuries at T-6 or above, history of baclofen withdrawal, or limited ability to communicate. Elderly are more sensitive to the effects of baclofen and are more likely to experience adverse CNS effects at higher doses.

Dosage Forms Injection, solution, intrathecal [preservative free] (Lioresal®): 50 mcg/mL (1 mL); 500 mcg/mL (20 mL); 2000 mcg/mL (5 mL)

Tablet: 10 mg, 20 mg

Reference Range Toxicity can occur at baclofen blood levels > 1 mg/L; fatality associated with blood and urine baclofen levels of 17 mg/L and 760 mg/L, respectively

Overdosage/Treatment

Decontamination: Lavage within 1 hour for ingestions over 5 mg/kg; activated charcoal should also be used

Supportive therapy: Following initiation of essential overdose management, symptomatic and supportive treatment should be instituted; physostigmine can alleviate drowsiness when intrathecal baclofen toxicity is present; atropine can be utilized for bradycardia; diazepam or lorazepam can be used for seizure management; dantrolene (10 mg/kg) has been used to treat hyperthermia due to baclofen withdrawal; for intrathecal overdose, remove 30-50 mL of CSF fluid and treat supportively; flumazenil may be useful in reversing oral (but not intrathecal) baclofen-induced coma; flumazenil has been used to treat coma and respiratory depression with uneven results; caution should be used with flumazenil administration due to baclofen's inherent seizure properties. In a single case report, 10 mg I.V. of ondansetron reversed coma in a baclofen overdose.

Cyproheptadine (4-8 mg every 6-8 hours) can assist with benzodiazepine and baclofen in treating intrathecal baclofen withdrawal.

Antidote(s)

- Atropine [ANTIDOTE]
- Physostigmine [ANTIDOTE]

Test Interactions ↑ alkaline phosphatase, AST, glucose, ammonia (B); ↓ bilirubin (S)

Drug Interactions

Increased effect: Opiate analgesics, benzodiazepines, hypertensive agents
Increased toxicity: CNS depressants and ethanol (sedation), tricyclic antidepressants (short-term memory loss), clindamycin (neuromuscular blockade), guanabenz (sedation), MAO inhibitors (decrease blood pressure, CNS, and respiratory effects)

Pregnancy Risk Factor C

Pregnancy Implications Crosses placenta

Lactation Enters breast milk (small amounts)/compatible

Nursing Implications Epileptic patients should be closely monitored; supervise ambulation; avoid abrupt withdrawal of the drug

Additional Information

Baclofen withdrawal syndrome usually occurs within 12-72 hours following dose cessation. The syndrome is similar to the sedative-hypnotic withdrawal syndrome with agitation, delusions, spasticity, rhabdomyolysis, paranoia, psychosis, pruritus, hallucinations, hypertonia, fever, and seizures. Benzodiazepines (diazepam 5-10 mg orally every 6-12 hours) are the mainstay of baclofen withdrawal therapy. For acute intrathecal baclofen withdrawal, baclofen (10-20 mg orally every 6 hours) and cyproheptadine (4-8 mg orally every 6-8 hours) can also be utilized with the latter agent particularly effective in treating pruritus.

Elderly are sensitive to this drug

Belladonna

Pronunciation (bel a DON a)

Use Decrease gastrointestinal activity in functional bowel disorders and to delay gastric emptying as well as decrease gastric secretion

Mechanism of Action Belladonna is a mixture of the anticholinergic alkaloids atropine, hyoscyamine, and scopolamine (hyoscine). The belladonna alkaloids act primarily by competitive inhibition of the muscarinic actions of acetylcholine on structures innervated by post-ganglionic cholinergic neurons and on smooth muscle. The resulting effects include antisecretory activity on exocrine glands and intestinal mucosa and smooth muscle relaxation. The anticholinergic properties of scopolamine and atropine differ in that scopolamine has a more potent activity on the iris, ciliary body, and certain secretory glands; has more potent activity on the heart, intestine, and bronchial muscle, and a more prolonged duration of action; in contrast, hyoscyamine has actions similar to those of atropine, but is more potent in both its central and peripheral effects

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), fibrillation (ventricular), tachycardia, palpitations, sinus tachycardia, tachycardia (supraventricular), arrhythmias (ventricular)

Central nervous system: Confusion, anxiety, lightheadedness, headache, loss of memory, hallucinations, drowsiness, tiredness, ataxia, paranoia, fever

Dermatologic: Skin rash, **dry skin**

Endocrine & metabolic: Breast milk (decreased flow)

Gastrointestinal: **Constipation, xerostomia and dry throat**, nausea, vomiting, bloated feeling, dysphagia

Genitourinary: Dysuria

Neuromuscular & skeletal: Weakness

Ocular: Blurred vision, photophobia, vision color changes (red tinge), intraocular pain (increased), increased intraocular pressure, sensitivity to light (increased)

Respiratory: **Dry nose**

Miscellaneous: Enuresis, **diaphoresis (decreased)**

Signs and Symptoms of Overdose Anticholinergic toxicity may be caused by strong binding of a belladonna alkaloid to cholinergic receptors. Anticholinesterase inhibitors reduce acetylcholinesterase, the enzyme that breaks down acetylcholine and thereby allows acetylcholine to accumulate and compete for receptor binding with the offending anticholinergic.

Dosage

Tincture: Oral:

Children: 0.03 mL/kg 3 times/day

Adults: 0.6-1 mL 3-4 times/day

BENAZEPRIL

Stability Store in tight, light-resistant container at 15°C to 30°C

Monitoring Parameters CNS depression

Contraindications Hypersensitivity to belladonna or any component of the formulation; glaucoma, elevated intraocular pressure; significant hepatic or renal disease; pulmonary insufficiency

Dosage Forms Tincture: Belladonna alkaloids (principally hyoscyamine and atropine) 0.3 mg/mL with alcohol 65% to 70% (120 mL, 480 mL, 3780 mL)

Overdosage/Treatment Decontamination: With life-threatening symptoms, physostigmine 1-2 mg (0.5 or 0.02 mg/kg for children) SubQ or I.V. slowly may be given to reverse these effects

Drug Interactions Phenothiazines, amantadine, antiparkinsonian drugs, glutethimide, meperidine, tricyclic antidepressants, antiarrhythmic agents, some antihistamines

Pregnancy Risk Factor C

Nursing Implications Assist patient with ambulation

Benazepril

Related Information

- Angiotensin Agents

CAS Number 86541-75-5

U.S. Brand Names Lotensin®

Synonyms Benazepril Hydrochloride

Use Treatment of hypertension, either alone or in combination with other antihypertensive agents

Mechanism of Action Competitive inhibition of angiotensin I being converted to angiotensin II, a potent vasoconstrictor, through the angiotensin I-converting enzyme (ACE) activity, with resultant lower levels of angiotensin II which causes an increase in plasma renin activity and a reduction in aldosterone secretion

Adverse Reactions

Cardiovascular: Hypotension, tachycardia, palpitations, sinus tachycardia, vasodilation

Central nervous system: Fatigue, headache, dizziness

Dermatologic: Rash, photosensitivity, angioedema, urticaria, pruritus, exanthema

Endocrine & metabolic: Hyperkalemia, hypoglycemia

Gastrointestinal: Nausea, pancreatitis

Hematologic: Leukopenia, eosinophilia

Neuromuscular & skeletal: Hypertonia, paresthesia

Renal: Proteinuria

Respiratory: Transient cough during early therapy, rhinitis

Miscellaneous: Hypersensitivity reaction

Signs and Symptoms of Overdose Agranulocytosis, dermatitis, drowsiness, granulocytopenia, hypertonia, impotence, leukopenia, myalgia, neutropenia, renal insufficiency, severe hypotension

Pharmacodynamics/Kinetics

Reduction in plasma angiotensin-converting enzyme (ACE) activity:

Onset of action: Peak effect: 1-2 hours after 2-20 mg dose

Duration: >90% inhibition for 24 hours after 5-20 mg dose

Reduction in blood pressure:

Peak effect: Single dose: 2-4 hours; Continuous therapy: 2 weeks

Absorption: Rapid (37%); food does not alter significantly; metabolite (benazeprilat) itself unsuitable for oral administration due to poor absorption

Distribution: V_d : ~8.7 L

Metabolism: Rapidly and extensively hepatic to its active metabolite, benazeprilat, via enzymatic hydrolysis; extensive first-pass effect

Half-life elimination: Benazeprilat: Effective: 10-11 hours; Terminal:

Children: 5 hours, Adults: 22 hours

Time to peak: Parent drug: 0.5-1 hour

Excretion: Clearance: Nonrenal clearance (ie, biliary, metabolic) appears to contribute to the elimination of benazeprilat (11% to 12%), particularly patients with severe renal impairment; hepatic clearance is the main elimination route of unchanged benazepril

Dialysis: ~6% of metabolite removed within 4 hours of dialysis following 10 mg of benazepril administered 2 hours prior to procedure; parent compound not found in dialysate

Dosage

Oral: Hypertension:

Children ≥6 years: Initial: 0.2 mg/kg/day as monotherapy; dosing range: 0.1-0.6 mg/kg/day (maximum dose: 40 mg/day)

Adults: Initial: 10 mg/day in patients not receiving a diuretic; 20-40 mg/day as a single dose or 2 divided doses; the need for twice-daily dosing should be assessed by monitoring peak (2-6 hours after dosing) and trough responses.

Note: Patients taking diuretics should have them discontinued 2-3 days prior to starting benazepril. If they cannot be discontinued, then initial dose should be 5 mg; restart after blood pressure is stabilized if needed.

Elderly: Oral: Initial: 5-10 mg/day in single or divided doses; usual range: 20-40 mg/day; adjust for renal function; also see "Note" in Adults dosing.

Dosing interval in renal impairment: Cl_{cr} <30 mL/minute:

Children: Use is not recommended.

Adults: Administer 5 mg/day initially; maximum daily dose: 40 mg.

Hemodialysis: Moderately dialyzable (20% to 50%); administer dose postdialysis or administer 25% to 35% supplemental dose.

Peritoneal dialysis: Supplemental dose is not necessary.

Monitoring Parameters CBC, renal function tests, electrolytes

Contraindications Hypersensitivity to benazepril or any component of the formulation; angioedema or serious hypersensitivity related to previous treatment with an ACE inhibitor; bilateral renal artery stenosis; patients with idiopathic or hereditary angioedema; pregnancy (2nd and 3rd trimesters)

Warnings Anaphylactic reactions can occur. Angioedema can occur at any time during treatment (especially following first dose). Angioedema can occur at any time during treatment (especially following first dose). It may involve head and neck (potentially affecting the airway) or the intestine (presenting with abdominal pain). Prolonged monitoring may be required especially if tongue, glottis, or larynx are involved as they are associated with airway obstruction. Those with a history of airway surgery in this situation have a higher risk. Careful blood pressure monitoring with first dose (hypotension can occur especially in volume-depleted patients).

[U.S. Boxed Warning]: Based on human data, ACEIs can cause injury and death to the developing fetus when used in the second and third trimesters. ACEIs should be discontinued as soon as possible once pregnancy is detected. Dosage adjustment needed in renal impairment. Use with caution in hypovolemia; collagen vascular diseases; valvular stenosis (particularly aortic stenosis); hyperkalemia; or before, during, or immediately after anesthesia. Avoid rapid dosage escalation which may lead to renal insufficiency. Rare toxicities associated with ACE inhibitors include cholestatic jaundice (which may progress to hepatic necrosis) and neutropenia/agranulocytosis with myeloid hyperplasia. Hypersensitivity reactions may be seen during hemodialysis with high-flux dialysis membranes (eg, AN69). Deterioration in renal function can occur with initiation. Use with caution in unilateral renal artery stenosis and pre-existing renal insufficiency.

Dosage Forms Tablet, as hydrochloride: 5 mg, 10 mg, 20 mg, 40 mg Lotensin®: 5 mg, 10 mg, 20 mg, 40 mg

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam or diazepam (I.V. 5-10 mg bolus in adults every 15 minutes if needed up to a total of 30 mg; I.V. 0.25-0.4 mg/kg/dose up to a total of 10 mg in children) or to phenytoin or phenobarbital. For refractory hypotension, angiotensin amide infusion may be attempted.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; moderately dialyzable (20% to 50%); ~6% of metabolite was removed by 4 hours of dialysis following 10 mg of benazepril administered 2 hours prior to procedure; the parent compound was not found in the dialysate

Drug Interactions

α_1 blockers: Hypotensive effect increased.

Aspirin: The effects of ACE inhibitors may be blunted by aspirin administration, particularly at higher dosages, and/or increase adverse renal effects.

Diuretics: Hypovolemia due to diuretics may precipitate acute hypotensive events or acute renal failure.

Insulin: Risk of hypoglycemia may be increased.

Lithium: Risk of lithium toxicity may be increased; monitor lithium levels.

NSAIDs: May attenuate hypertensive efficacy; effect has been seen with captopril and may occur with other ACE inhibitors; monitor blood pressure. May increase adverse renal effects.

Potassium-sparing diuretics or potassium supplements (amilofide, potassium, spironolactone, triamterene): Increased risk of hyperkalemia. Trimethoprim (high dose) may increase the risk of hyperkalemia.

Pregnancy Risk Factor C (1st trimester)/D (2nd and 3rd trimesters)

Pregnancy Implications Decreased placental blood flow, low birth weight, fetal hypotension, preterm delivery, and fetal death have been noted with the use of some ACE inhibitors (ACEIs) in animal studies. Neonatal hypotension, skull hypoplasia, anuria, renal failure, oligohydramnios (associated with fetal limb contractures, craniofacial deformities, hypoplastic lung development), prematurity, intrauterine growth retardation, and patent ductus arteriosus have been reported with the use of ACEIs, primarily in the 2nd and 3rd trimesters. The risk of neonatal toxicity has been considered less when ACEIs have been used in the 1st trimester; however, major congenital malformations have been reported. The cardiovascular and/or central nervous systems are most commonly affected. Unless alternative agents are not appropriate, ACEIs should be discontinued as soon as possible once pregnancy is detected.

Lactation Enters breast milk/compatible

Nursing Implications Watch for hypotensive effect within 1-3 hours of first dose or new higher dose; many patients complain of transient cough during early therapy

Benzalkonium Chloride

Pronunciation (benz al KOE nee um KLOR ide)

CAS Number 8001-54-5

U.S. Brand Names 3M™ Cavilon™ Skin Cleanser [OTC]; Benza® [OTC]; HandClens® [OTC]; Ony-Clear [OTC] [DSC]; Zephiran® [OTC]

Synonyms BAC

Use Surface antiseptic and germicidal preservative

Mechanism of Action Quaternary ammonium disinfectant (cationic)

Adverse Reactions

- Cardiovascular: Hypotension
- Central nervous system: Lethargy, seizures, pain
- Dermatologic: Bullous or pustular reactions, contact dermatitis
- Endocrine & metabolic: Inhibits sperm motility
- Gastrointestinal (ingestion): Vomiting (hememetesis), burning mouth/throat, salivation, esophageal burns
- Ocular: Corneal damage
- Otic: May be ototoxic

Miscellaneous: Hypersensitivity, **corrosive burn at concentrations**

Signs and Symptoms of Overdose Confusion, elevated liver function test results, hypotension, metabolic acidosis, muscle paralysis, myoclonus, profuse diarrhea, seizures

Dosage Thoroughly rinse anionic detergents and soaps from the skin or other areas prior to use of solutions because they reduce the antibacterial activity of BAC. To protect metal instruments stored in BAC solution, add crushed antitrust tablets, 4 tablets/quart, to antiseptic solution, change solution at least once weekly. Not to be used for storage of aluminum or zinc instruments, instruments with lenses fastened by cement, lacquered catheters, or some synthetic rubber goods.

Stability Foams when shaken; **incompatible** with iodine, soaps, anionic detergent, iodides, citrates, salicylates, silver nitrate, fluorescein, nitrates, peroxide, lanolin, potassium permanganate, aluminum, caramel, kaolin, pine oil, zinc sulfate, zinc oxide, and yellow mercuric oxide

Contraindications Hypersensitivity to benzalkonium or any component of the formulation

Dosage Forms [DSC] = Discontinued product

Solution, topical:

Benza®: 1:750 (60 mL, 240 mL, 480 mL, 3840 mL)

HandClens®: 0.13% (120 mL, 480 mL, 800 mL)

Ony-Clear [DSC]: 1% (30 mL)

Zephiran®: 1:750 (240 mL, 3840 mL) [aqueous]

Solution, topical spray (3M™ Cavilon™ Skin Cleanser): 0.11% (240 mL)

Overdosage/Treatment

Decontamination: Oral: Activated charcoal may be useful, dilute with milk or water; **do not** induce emesis

Supportive therapy: Treat hypotension with isotonic saline; endoscopy may be required to evaluate gastrointestinal burns

Enhancement of elimination: Hemodialysis or forced diuresis is not useful

Pregnancy Risk Factor C

Benzbromarone

CAS Number 3562-84-3

Use Uricosuric agent which lowers uric acid concentrations; used for hyperuricemia, gout, and Lesch-Nyhan syndrome

Mechanism of Action Blocks proximal tubular reabsorption of uric acid; also increases gastrointestinal elimination of uric acid

Adverse Reactions

- Dermatologic: Petechiae
- Endocrine & metabolic: Gouty attacks
- Gastrointestinal: Diarrhea, nausea
- Genitourinary: Impotence
- Hematologic: Porphyrinogenic
- Hepatic: Elevated liver enzymes
- Ocular: Allergic conjunctivitis
- Renal: Elevated serum creatinine

Toxicodynamics/Kinetics

Onset of action: 3 hours

Peak effect: 8-12 hours

Duration: 15-21 hours

Absorption: Oral: 50%

Distribution: V_d: <0.3 L/kg

Protein binding: 99%

Metabolism: To benzarone and bromobenzarone

Half-life: 2.7 hours

Elimination: Feces (50%), renal

Dosage 50-200 mg/day

Reference Range Peak serum level of 1.84 mcg/mL after oral dose of 100 mg of benzbromarone

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosage activated charcoal may be effective

Additional Information Investigational (phase II trials) in the U.S.

Benzocaine

CAS Number 94-09-7

U.S. Brand Names Americaine® Anesthetic Lubricant; Americaine® [OTC]; Anbesol® Baby [OTC]; Anbesol® Maximum Strength [OTC]; Anbesol® [OTC]; Babee® Teething® [OTC]; Benzodent® [OTC]; Chiggerex® [OTC]; Chiggertox® [OTC]; Cylex® [OTC]; Detane® [OTC]; Foille® Medicated First Aid [OTC]; Foille® Plus [OTC]; Foille® [OTC]; HDA® Toothache [OTC]; Hurracaine®; Lanacane® [OTC]; Mycinettes® [OTC]; Orabase®-B [OTC]; Orajel® Baby Nighttime [OTC]; Orajel® Baby [OTC]; Orajel® Maximum Strength [OTC]; Orajel® [OTC]; Orasol® [OTC]; Solarcaine® [OTC]; Trocaine® [OTC]; Zilactin® Baby [OTC]; Zilactin®-B [OTC]

Synonyms Ethyl Aminobenzoate

Use Local anesthetic

Mechanism of Action Blocks both the initiation and conduction of nerve impulses by decreasing the neuronal membrane's permeability to sodium ions, which results in inhibition of depolarization with resultant blockade of conduction; a group I (ester) anesthetic; low water solubility

Adverse Reactions

Cardiovascular: Sinus tachycardia

Dermatologic: Eczema, urticaria, nonimmunologic contact urticaria, systemic contact dermatitis, immunologic contact urticaria, photoallergic reaction

Gastrointestinal: GI irritation, gagging, increased sour sensitivity taste

Hematologic: Methemoglobinemia in infants

Local: Burning, stinging, tenderness, rash, contact dermatitis, edema

Signs and Symptoms of Overdose Cyanosis, drowsiness, eczema, methemoglobinemia (within 1 hour), photosensitivity, tachycardia, tachypnea

Admission Criteria/Prognosis Admit ingestions > 100 mg/kg, symptomatic methemoglobinemia or methemoglobin levels > 30%; any patient with change in mental status or cardiopulmonary complaints should be admitted; asymptomatic patients with methemoglobin levels < 30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to < 15%

Pharmacodynamics/Kinetics

Absorption: Topical: Poor to intact skin; well absorbed from mucous membranes and traumatized skin

Metabolism: Hepatic (to a lesser extent) and plasma via hydrolysis by cholinesterase

Excretion: Urine (as metabolites)

Dosage Mucous membranes: Dosage varies depending on area to be anesthetized and vascularity of tissues

Topical: Apply to affected area as needed

Administration

Avoid application to large areas of broken skin, especially in children. When possible, apply to clean, dry area.

Contraindications Hypersensitivity to benzocaine, other ester-type local anesthetics, or any component of the formulation; secondary bacterial infection of area; ophthalmic use; otic preparations are also contraindicated in the presence of perforated tympanic membrane

Warnings

Methemoglobinemia has been reported following topical use (rare). When applied as a spray to the mouth or throat, multiple sprays (or sprays of longer than indicated duration) are not recommended. Use caution with breathing problems (asthma, bronchitis, emphysema, in smokers), heart disease, children < 6 months of age, and hemoglobin or enzyme abnormalities (glucose-6-phosphodiesterase deficiency, hemoglobin-M disease, NADH-methemoglobin reductase deficiency, pyruvate-kinase deficiency).

When used for self-medication (OTC), notify healthcare provider if condition worsens or does not improve within 7 days, or if swelling, rash, or fever develops. Do not use on open wounds. Avoid contact with the eyes.

Dosage Forms

Aerosol, oral spray (Hurracaine®): 20% (60 mL) [dye free; cherry flavor]

Aerosol, topical spray:

Americaine®: 20% (60 mL)

BENZONATATE

Dermoplast® Antibacterial: 20% (83 mL) [contains aloe vera, benzethonium chloride, menthol]
Dermoplast® Pain Relieving: 20% (60 mL, 83 mL) [contains menthol]
Foille®: 5% (92 g) [contains chloroxylenol 0.63% and corn oil]
Ivy-Rid®: 2% (83 mL)
Lanacane® Maximum Strength: 20% (120 mL) [contains alcohol]
Solarcaine®: 20% (120 mL) [contains triclosan 0.13%, alcohol 35%]
Combination package (Orajel® Baby Daytime and Nighttime):
Gel, oral [Daytime Regular Formula]: 7.5% (5.3 g)
Gel, oral [Nighttime Formula]: 10% (5.3 g)
Cream, oral:
Benzodent®: 20% (7.5 g, 30 g)
Orajel PM®: 20% (5.3 g, 7 g)
Cream, topical:
Lanacane®: 6% (30 g, 60 g)
Lanacane® Maximum Strength: 20% (30 g)
Gel, oral:
Anbesol®: 10% (7.5 g) [contains benzyl alcohol; cool mint flavor]
Anbesol® Baby: 7.5% (7.5 g) [contains benzoic acid; grape flavor]
Anbesol® Jr.: 10% (7 g) [contains benzyl alcohol; bubble gum flavor]
Anbesol® Maximum Strength: 20% (7.5 g, 10 g) [contains benzyl alcohol]
Dentapaine: 20% (11 g) [contains clove oil]
HDA® Toothache: 6.5% (15 mL) [contains benzyl alcohol]
Hurricane®: 20% (5 g) [dye free; wild cherry flavor]; (30 g) [dye free; mint, pina colada, watermelon, and wild cherry flavors]
Kanka® Soft Brush™: 20% (2 mL) [packaged in applicator with brush tip]
Orabase® with Benzocaine®: 20% (7 g) [contains ethyl alcohol 48%; mild mint flavor]
Orajel®: 10% (5.3 g, 7 g, 9.4 g)
Orajel® Baby Teething: 7.5% (9.4 g, 11.9 g) [cherry flavor]
Orajel® Baby Teething Nighttime: 10% (5.3 g)
Orajel® Denture Plus: 15% (9 g) [contains menthol 2%, ethyl alcohol 66.7%]
Orajel® Maximum Strength: 20% (5.3 g, 7 g, 9.4 g, 11.9 g)
Orajel® Mouth Sore: 20% (5.3 g, 9.4 g, 11.9 g) [contains benzalkonium chloride 0.02%, zinc chloride 0.1%]
Orajel® Multi-Action Cold Sore: 20% (9.4 g) [contains allantoin 0.5%, camphor 3%, dimethicone 2%]
Orajel® Ultra Mouth Sore: 15% (9.4 g) [contains ethyl alcohol 66.7%, menthol 2%]
Zilactin®-B: 10% (7.5 g)
Gel, topical (Detane®): 7.5% (15 g)
Liquid, oral:
Anbesol®: 10% (9 mL) [cool mint flavor]
Anbesol® Maximum Strength: 20% (9 mL) [contains benzyl alcohol]
Hurricane®: 20% (30 mL) [pina colada and wild cherry flavors]
Orajel® Baby Teething: 7.5% (13 mL) [very berry flavor]
Orajel® Maximum Strength: 20% (13 mL) [contains ethyl alcohol 44%, tartrazine]
Liquid, oral drop:
Dent's Maxi-Strength Toothache: 20% (3.7 mL) [contains alcohol 74%]
Rid-A-Pain Dental Drops: 6.3% (30 mL) [contains alcohol 70%]
Liquid, topical:
Chiggerex®: 2% (30 mL)
Outgro®: 20% (9 mL)
Skeeter Stik: 5% (14 mL) [contains menthol]
Tanac®: 10% (13 mL) [contains benzalkonium chloride]
Lozenge: 6 mg (18s) [contains menthol]; 15 mg (10s)
Cepacol® Sore Throat: 10 mg (18s) [contains cetylpyridinium, menthol; cherry, citrus, honey lemon, and menthol flavors]
Cepacol® Sore Throat: 10 mg (16s) [sugar free; contains cetylpyridinium, menthol; cherry and menthol flavors]
Cylex®: 15 mg [sugar free; contains cetylpyridinium chloride 5 mg; cherry flavor]
Mycinettes®: 15 mg (12s) [sugar free; contains sodium 9 mg; cherry or regular flavor]
Thorets: 18 mg (500s) [sugar free]
Trocaine®: 10 mg (40s, 400s)
Ointment, oral:
Anbesol® Cold Sore Therapy: 20% (7.1 g) [contains benzyl alcohol, allantoin, aloe, camphor, menthol, vitamin E]
Red Cross™ Canker Sore: 20% (7.5 g) [contains coconut oil]
Ointment, rectal (Americaine® Hemorrhoidal): 20% (30 g)
Ointment, topical:
Chiggerex®: 2% (50 g) [contains aloe vera]
Foille®: 5% (3.5 g, 14 g, 28 g) [contains chloroxylenol 0.1%, benzyl alcohol; corn oil base]
Pads, topical (Sting-Kill): 20% (8s) [contains menthol and tartrazine]
Paste, oral (Orabase® with Benzocaine): 20% (6 g)
Solution, otic drops (Oticaine, Otocaine™): 20% (15 mL)
Swabs, oral:
Hurricane®: 20% (6s, 100s) [dye free; wild cherry flavor]

Orajel® Baby Teething: 7.5% (12s) [berry flavor]
Orajel® Medicated Mouth Sore, Orajel® Medicated Toothache: 20% (8s, 12s) [contains tartrazine]
Zilactin® Toothache and Gum Pain: 20% (8s) [grape flavor]
Swabs, topical (Sting-Kill): 20% (5s) [contains menthol and tartrazine]
Wax, oral (Dent's Extra Strength Toothache Gum): 20% (1 g)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; gastric decontamination should be considered for ingestions > 100 mg/kg
Supportive therapy: Methemoglobinemia has been reported with benzocaine in oral overdose. Treatment is primarily symptomatic and supportive; termination of anesthesia by pneumatic tourniquet inflation should be attempted when the agent is administered by infiltration or regional injection. Methemoglobinemia may be treated with methylene blue, 1-2 mg/kg I.V. infused over several minutes. Seizures commonly respond to diazepam, while hypotension responds to I.V. fluids and Trendelenburg positioning. Bradyarrhythmias (when the heart rate is < 60) can be treated with I.V., I.M., or SubQ atropine 15 mcg/kg. With the development of metabolic acidosis, I.V. sodium bicarbonate 0.5-2 mEq/kg and ventilatory assistance should be instituted.

Enhancement of elimination: Hyperbaric oxygen or exchange transfusion should be considered if the patient does not respond to methylene blue; exchange transfusion should be considered if methemoglobin levels > 70%

Diagnostic Procedures

- Methemoglobin, Blood

● **Drug Interactions** May antagonize actions of sulfonamides

Pregnancy Risk Factor C

Pregnancy Implications Reproduction studies have not been conducted.

Lactation Excretion in breast milk unknown/use caution

Benzonatate

CAS Number 104-31-4

U.S. Brand Names Tessalon®

Use Symptomatic relief of nonproductive cough

Mechanism of Action Tetracaine congener with antitussive properties; suppresses cough by topical anesthetic action on the respiratory stretch receptors

Adverse Reactions

- Cardiovascular: Chest numbness
Central nervous system: Sedation, headache, dizziness
Dermatologic: Rash
Gastrointestinal: GI upset
Neuromuscular & skeletal: Numbness in chest
Ocular: Burning sensation in eyes
Respiratory: Nasal congestion

Signs and Symptoms of Overdose Coma, CNS stimulation, disorientation, seizure, restlessness, tremor, ventricular tachycardia

Admission Criteria/Prognosis Admit any symptomatic patient or any pediatric ingestion.

Pharmacodynamics/Kinetics

- Onset of action: Therapeutic: 15-20 minutes
Duration: 3-8 hours

Dosage Children > 10 years and Adults: Oral: 100 mg 3 times/day or every 4 hours up to 600 mg/day

Monitoring Parameters Monitor patient's chest sounds and respiratory pattern

Administration

Swallow capsule whole (do not break or chew).

Contraindications Hypersensitivity to benzonatate, related compounds (such as tetracaine), or any component of the formulation

Dosage Forms

- Capsule: 100 mg
Tessalon®: 100 mg, 200 mg

Reference Range Plasma benzonatate level of 2.5 mcg/mL associated with a 3.6 g ingestion and seizure development. Fatalities are associated with plasma levels > 4 mcg/mL.

Overdosage/Treatment

Decontamination: Lavage within 1 hour/activated charcoal
Supportive therapy: Ventricular tachycardia may respond to direct current cardioversion (100 joules).

Drug Interactions No data reported

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Change patient position every 2 hours to prevent pooling of secretions in lung; capsules are not to be crushed

Benztropine

Related Information

- Anticholinergic Effects of Common Psychotropics
- Therapeutic Drugs Associated with Hallucinations

CAS Number 86-13-5

U.S. Brand Names Cogentin®

Synonyms Benztropine Mesylate

Use Adjunctive treatment of all forms of parkinsonism; also used in treatment of drug-induced extrapyramidal effects (except tardive dyskinesia) and acute dystonic reactions

Mechanism of Action Thought to partially block striatal cholinergic receptors to help balance cholinergic and dopaminergic activity

Adverse Reactions

- Cardiovascular: Tachycardia, sinus bradycardia, sinus tachycardia, tachycardia (supraventricular)
 Central nervous system: Drowsiness, nervousness, visual hallucinations, restlessness, anxiety, extrapyramidal reaction, hyperthermia, coma, memory disturbance, mania, paranoia
 Dermatologic: **Dry skin**, urticaria, pruritus, exanthema
 Gastrointestinal: **Xerostomia, dry throat, constipation**, nausea, vomiting, ileus, esophageal atony
 Genitourinary: Urinary retention
 Neuromuscular & skeletal: Rhabdomyolysis, paresthesia
 Ocular: Blurred vision, mydriasis
 Respiratory: **Dry nose**
 Miscellaneous: **Diaphoresis (decreased)**

Signs and Symptoms of Overdose Blurred vision, CNS depression, chorea (extrapyramidal), confusion, dementia, dizziness, fever, hallucinations, hyperthermia, impotence, nausea, nervousness, memory loss, seizures, vomiting

Pharmacodynamics/Kinetics

- Onset of action: Oral: Within 1 hour; Parenteral: Within 15 minutes
 Duration: 6-48 hours
 Metabolism: Hepatic (N-oxidation, N-dealkylation, and ring hydroxylation)
 Bioavailability: 29%

Dosage Use in children <3 years of age should be reserved for life-threatening emergencies

- Drug-induced extrapyramidal reaction: Oral, I.M., I.V.:
 Children >3 years: 0.02-0.05 mg/kg/dose 1-2 times/day
 Adults: 1-4 mg/dose 1-2 times/day
 Acute dystonia: Adults: I.M., I.V.: 1-2 mg

Parkinsonism: Oral:

- Adults: 0.5-6 mg/day in 1-2 divided doses; if one dose is greater, administer at bedtime; titrate dose in 0.5 mg increments at 5- to 6-day intervals
 Elderly: Initial: 0.5 mg once or twice daily; increase by 0.5 mg as needed at 5-6 days; maximum: 6 mg/day

Monitoring Parameters Symptoms of EPS or Parkinson's, pulse, anticholinergic effects

Contraindications Hypersensitivity to benztropine or any component of the formulation; pyloric or duodenal obstruction, stenosing peptic ulcers; bladder neck obstructions; achalasia; myasthenia gravis; children <3 years of age

Warnings Use with caution in older children (dose has not been established). Use with caution in hot weather or during exercise. May cause anhidrosis and hyperthermia, which may be severe. The risk is increased in hot environments, particularly in the elderly, alcoholics, patients with CNS disease, and those with prolonged outdoor exposure. Elderly patients frequently develop increased sensitivity and require strict dosage regulation - side effects may be more severe in elderly patients with atherosclerotic changes. Use with caution in patients with tachycardia, cardiac arrhythmias, hypertension, hypotension, prostatic hyperplasia (especially in the elderly), any tendency toward urinary retention, liver or kidney disorders, and obstructive disease of the GI or GU tract. When given in large doses or to susceptible patients, may cause weakness and inability to move particular muscle groups. May be associated with confusion or hallucinations (generally at higher dosages). Intensification of symptoms or toxic psychosis may occur in patients with mental disorders. Benztropine does not relieve symptoms of tardive dyskinesia.

Dosage Forms Injection, solution, as mesylate (Cogentin®): 1 mg/mL (2 mL)

Tablet, as mesylate: 0.5 mg, 1 mg, 2 mg

Reference Range Toxic serum levels: >25 ng/mL

Overdosage/Treatment Supportive therapy: Anticholinergic toxicity is caused by strong binding of the drug to cholinergic receptors. Anticholinesterase inhibitors reduce acetylcholinesterase, the enzyme that breaks down acetylcholine and thereby allows acetylcholine to accumulate and compete for receptor binding with the offending anticholinergic. For anticholinergic overdose with severe life-threatening symptoms, physostigmine 1-2 mg (0.5 or 0.02 mg/kg for children) SubQ or I.V., slowly may be given to reverse these effects.

Drug Interactions

Substrate of CYP2D6 (minor)

Amantadine, rimantadine: Central and/or peripheral anticholinergic syndrome can occur when administered with amantadine or rimantadine.

Anticholinergic agents: Central and/or peripheral anticholinergic syndrome can occur when administered with narcotic analgesics, phenothiazines and other antipsychotics (especially with high anticholinergic activity), tricyclic antidepressants, quinidine and some other antiarrhythmics, and antihistamines.

Atenolol: Anticholinergics may increase the bioavailability of atenolol (and possibly other beta-blockers); monitor for increased effect.

Cholinergic agents: Anticholinergics may antagonize the therapeutic effect of cholinergic agents; includes tacrine and donepezil.

Digoxin: Anticholinergics may decrease gastric degradation and increase the amount of digoxin absorbed by delaying gastric emptying.

Levodopa: Anticholinergics may increase gastric degradation and decrease the amount of levodopa absorbed by delaying gastric emptying.

Neuroleptics: Anticholinergics may antagonize the therapeutic effects of neuroleptics.

Pregnancy Risk Factor C

Pregnancy Implications May cross the placenta

Lactation Excretion in breast milk unknown/use caution

Nursing Implications No significant difference in onset of I.M. or I.V. injection, therefore, there is usually no need to use the I.V. route. Improvement is sometimes noticeable a few minutes after injection.

Titrate dose in 0.5 mg increments at 5- or 6-day intervals.

Bepridil

CAS Number 49571-04-2; 64616-81-5; 64706-54-3; 74764-40-2

U.S. Brand Names Vasco® [DSC]

Use Treatment of chronic stable angina; only approved indication is hypertension, but may be used for congestive heart failure; doses should not be adjusted for at least 10 days after beginning therapy

Mechanism of Action Bepridil, a type 4 calcium antagonist, that possesses characteristics of the traditional calcium antagonist (nifedipine) but also possesses additional pharmacological properties. Similar to other calcium antagonists, bepridil relaxes vascular muscle, decreases pacemaker activity, and reduces cardiac muscle contractile force; however, a direct bradycardia effect of bepridil has been postulated, differing from calcium channel blockers. It is suggested that bradycardia effects arise out of direct action of bepridil on the S-A node; highly lipid soluble.

Adverse Reactions

Cardiovascular: Ventricular premature contractions, prolonged QT intervals, torsade de pointes, flattening or notched T waves, AV block, sinus bradycardia, QRS prolongation, sinus tachycardia, arrhythmias (ventricular), vasodilation

Central nervous system: **Headache, dizziness**

Dermatologic: Dermatitis, rash

Gastrointestinal: **Dyspepsia, nausea, abdominal pain, GI distress**, anorexia, GI upset, diarrhea, constipation, taste change

Genitourinary: Sexual difficulties

Hematologic: Agranulocytosis

Neuromuscular & skeletal: **Weakness**, tremors

Respiratory: Cough, nasal congestion, pharyngitis

Miscellaneous: Diaphoresis, flu-like syndrome

Signs and Symptoms of Overdose Bradycardia, asthenia, confusion, decreased cardiac output, drowsiness, gingival hyperplasia, hypotension, ileus, nausea, prolongation of QT interval, second or third degree AV block, torsade de pointes, tachycardia (ventricular)

Toxicodynamics/Kinetics

Distribution: V_d : 8.0 L/kg

Protein binding: 99%

Metabolism: Significant first-pass effect, metabolized to 4-hydroxyphenyl bepridil

Bioavailability: 59%

Half-life: Multiple doses: 42 hours; Single dose: 33 hours

Elimination: Renal: 66%; fecal: 22%

Dosage Adults: Oral: Initial: 200 mg/day, then adjust dose at 10-day intervals until optimal response is achieved; maximum daily dose: 400 mg

BETAMETHASONE

Monitoring Parameters ECG and serum electrolytes, blood pressure, signs and symptoms of congestive heart failure; elderly may need very close monitoring due to underlying cardiac and organ system defects

Reference Range Peak serum bepridil levels after a 400 mg dose: ~1631 ng/mL

Overdose/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Fluids and vasopressors (dopamine, norepinephrine, or amrinone) are successful in treating hypotension and negative inotropic effects, calcium is often required to reverse chronotropic effects, ventricular arrhythmias should be treated with lidocaine or magnesium for torsade de pointes. Hyperinsulinemic therapy with 0.5-1.0 unit I.V. insulin bolus with an infusion of 0.2-1 unit/kg/hour plus a glucose bolus of 25 g I.V. and dextrose infusion to maintain a serum glucose > 100 mg/dL may reverse cardiogenic shock due to calcium blockers.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Antidote(s)

- Calcium Gluconate [ANTIDOTE]

Test Interactions ↑ aminotransferases, CPK, LDH

Pregnancy Risk Factor C

≤ 12 years: Use is not recommended.

≥ 13 years: Use minimal amount for shortest period of time to avoid HPA axis suppression

Gel, augmented formulation: Apply once or twice daily; rub in gently. **Note:** Do not exceed 2 weeks of treatment or 50 g/week.

Lotion: Apply a few drops twice daily

Augmented formulation: Apply a few drops once or twice daily; rub in gently.

Note: Do not exceed 2 weeks of treatment or 50 mL/week.

Cream/ointment: Apply once or twice daily.

Augmented formulation: Apply once or twice daily.

Note: Do not exceed 2 weeks of treatment or 45 g/week.

Adolescents and Adults:

Oral: 2.4-4.8 mg/day in 2-4 doses; range: 0.6-7.2 mg/day

I.M.: Betamethasone sodium phosphate and betamethasone acetate: 0.6-9 mg/day (generally, $\frac{1}{3}$ to $\frac{1}{2}$ of oral dose) divided every 12-24 hours

Adults:

Intrabursal, intra-articular, intradermal: 0.25-2 mL

Intralesional: Rheumatoid arthritis/osteoarthritis:

Very large joints: 1-2 mL

Large joints: 1 mL

Medium joints: 0.5-1 mL

Small joints: 0.25-0.5 mL

Topical:

Foam: Apply to the scalp twice daily, once in the morning and once at night

Gel, augmented formulation: Apply once or twice daily; rub in gently.

Note: Do not exceed 2 weeks of treatment or 50 g/week.

Lotion: Apply a few drops twice daily

Augmented formulation: Apply a few drops once or twice daily; rub in gently.

Note: Do not exceed 2 weeks of treatment or 50 mL/week.

Cream/ointment: Apply once or twice daily

Augmented formulation: Apply once or twice daily.

Note: Do not exceed 2 weeks of treatment or 45 g/week.

Dosing adjustment in hepatic impairment: Adjustments may be necessary in patients with liver failure because betamethasone is extensively metabolized in the liver

Administration Oral: Not for alternate day therapy; once daily doses should be given in the morning.

I.M.: Do **not** give injectable sodium phosphate/acetate suspension I.V.

Topical: Apply topical sparingly to areas. Not for use on broken skin or in areas of infection. Do not apply to wet skin unless directed; do not cover with occlusive dressing. Do not apply very high potency agents to face, groin, axillae, or diaper area.

Foam: Invert can and dispense a small amount onto a saucer or other cool surface. Do not dispense directly into hands. Pick up small amounts of foam and gently massage into affected areas until foam disappears. Repeat until entire affected scalp area is treated.

Contraindications Hypersensitivity to betamethasone, other corticosteroids, or any component of the formulation; systemic fungal infections

Warnings

Topical use in patients ≤ 12 years of age is not recommended. May cause suppression of hypothalamic-pituitary-adrenal (HPA) axis, particularly in younger children or in patients receiving high doses for prolonged periods.

Very high potency topical products are not for treatment of rosacea, perioral dermatitis; not for use on face, groin, or axillae; not for use in a diapered area. Avoid concurrent use of other corticosteroids.

May suppress the immune system; patients may be more susceptible to infection. Use with caution in patients with systemic infections or ocular herpes simplex. Avoid exposure to chickenpox and measles.

Use with caution in patients with hypothyroidism, cirrhosis, ulcerative colitis; do not use occlusive dressings on weeping or exudative lesions and general caution with occlusive dressings should be observed; adverse effects may be increased. Discontinue if skin irritation or contact dermatitis should occur; do not use in patients with decreased skin circulation.

Dosage Forms

Note: Potency expressed as betamethasone base.

Cream, topical, as dipropionate: 0.05% (15 g, 45 g)

Maxivate®: 0.05% (45 g)

Cream, topical, as dipropionate augmented (Diprolene® AF): 0.05% (15 g, 50 g)

Cream, topical, as valerate (Beta-Val®): 0.1% (15 g, 45 g)

Foam, topical, as valerate (Luxiq®): 0.12% (50 g, 100 g, 150 g) [contains alcohol 60.4%]

Gel, topical, as dipropionate augmented: 0.05% (15 g, 50 g)

Injection, suspension (Celestone® Soluspan®): Betamethasone sodium phosphate 3 mg/mL and betamethasone acetate 3 mg/mL [6 mg/mL] (5 mL)

Lotion, topical, as dipropionate (Maxivate®): 0.05% (60 mL)

Betamethasone

Pronunciation (bay ta METH a sone)

Related Information

- Corticosteroids

U.S. Brand Names Beta-Val®; Celestone® Soluspan®; Celestone®; Diprolene® AF; Diprolene®; Luxiq®; Maxivate®

Synonyms Betamethasone Dipropionate, Augmented; Betamethasone Dipropionate; Betamethasone Sodium Phosphate; Betamethasone Valerate; Flubenisolone

Use Inflammatory dermatoses such as seborrheic or atopic dermatitis, neurodermatitis, anogenital pruritus, psoriasis, inflammatory phase of xerosis

Mechanism of Action Controls the rate of protein synthesis; depresses the migration of polymorphonuclear leukocytes, fibroblasts; reverses capillary permeability and lysosomal stabilization at the cellular level to prevent or control inflammation

Adverse Reactions

Systemic:

Cardiovascular: Congestive heart failure, edema, hyper-/hypotension

Central nervous system: Dizziness, headache, insomnia, intracranial pressure increased, lightheadedness, nervousness, pseudotumor cerebri, seizure, vertigo

Dermatologic: Ecchymoses, facial erythema, fragile skin, hirsutism, hyper-/hypopigmentation, perioral dermatitis (oral), petechiae, striae, wound healing impaired

Endocrine & metabolic: Amenorrhea, Cushing's syndrome, diabetes mellitus, growth suppression, hyperglycemia, hypokalemia, menstrual irregularities, pituitary-adrenal axis suppression, protein catabolism, sodium retention, water retention

Gastrointestinal: Abdominal distention, appetite increased, hiccups, indigestion, peptic ulcer, pancreatitis, ulcerative esophagitis

Local: Injection site reactions (intra-articular use), sterile abscess
Neuromuscular & skeletal: Arthralgia, muscle atrophy, fractures, muscle weakness, myopathy, osteoporosis, necrosis (femoral and humeral heads)

Ocular: Cataracts, glaucoma, intraocular pressure increased

Miscellaneous: Anaphylactoid reaction, diaphoresis, hypersensitivity, secondary infection

Topical:

Dermatologic: Acneiform eruptions, allergic dermatitis, burning, dry skin, erythema, folliculitis, hypertrichosis, irritation, miliaria, pruritus, skin atrophy, striae, vesiculation

Endocrine and metabolic effects have occasionally been reported with topical use.

Pharmacodynamics/Kinetics

Protein binding: 64%

Metabolism: Hepatic

Half-life elimination: 6.5 hours

Time to peak, serum: I.V.: 10-36 minutes

Excretion: Urine (<5% as unchanged drug)

Dosage

Base dosage on severity of disease and patient response

Children: Use lowest dose listed as initial dose for adrenocortical insufficiency (physiologic replacement)

I.M.: 0.0175-0.125 mg base/kg/day divided every 6-12 hours **or**

0.5-7.5 mg base/m²/day divided every 6-12 hours

Oral: 0.0175-0.25 mg/kg/day divided every 6-8 hours **or** 0.5-7.5 mg/m²/

day divided every 6-8 hours

Topical:

Lotion, topical, as dipropionate augmented (Diprolene®): 0.05% (30 mL, 60 mL)

Lotion, topical, as valerate (Beta-Val®): 0.1% (60 mL)

Ointment, topical, as dipropionate: 0.05% (15 g, 45 g)

Maxivate®: 0.05% (45 g)

Ointment, topical, as dipropionate augmented (Diprolene®): 0.05% (15 g, 50 g)

Ointment, topical, as valerate: 0.1% (15 g, 45 g)

Syrup, as base (Celestone®): 0.6 mg/5 mL (118 mL)

Drug Interactions

Inhibits CYP3A4 (weak)

Phenytoin, phenobarbital, rifampin increase clearance of betamethasone. Potassium-depleting diuretics increase potassium loss.

Skin test antigens, immunizations: Betamethasone may decrease response and increase potential infections.

Insulin or oral hypoglycemics: Betamethasone may increase blood glucose.

Pregnancy Risk Factor C

There are no reports linking the use of betamethasone with congenital defects in the literature. Betamethasone is often used in patients with premature labor [26-34 weeks gestation] to stimulate fetal lung maturation.

Pregnancy Implications Teratogenic effects were noted in animal studies. There are no reports linking the use of betamethasone with congenital defects in the literature. Betamethasone is often used in patients with premature labor [26-34 weeks gestation] to stimulate fetal lung maturation.

Lactation Excretion in breast milk unknown/use caution

Additional Information

Very high potency: Augmented betamethasone dipropionate ointment, lotion
High potency: Augmented betamethasone dipropionate cream, betamethasone dipropionate cream and ointment

Intermediate potency: Betamethasone dipropionate lotion, betamethasone valerate cream

Betaxolol

Related Information

- Selected Properties of Beta-Adrenergic Blocking Drugs

CAS Number 63659-18-7; 63659-19-8

U.S. Brand Names Betoptic® S; Kerlone®

Synonyms Betaxolol Hydrochloride

Use Treatment of chronic open-angle glaucoma, ocular hypertension; management of hypertension

Mechanism of Action Competitively blocks beta₁-receptors, with little or no effect on beta₂-receptors; lipophilic; no membrane stabilizing effect

Adverse Reactions

Cardiovascular: Bradycardia, palpitations, edema, congestive heart failure, sinus bradycardia, myocardial depression, QRS prolongation, Raynaud's phenomenon, pericarditis

Central nervous system: Dizziness, psychosis, fatigue, drowsiness, headache, depression

Dermatologic: Exfoliative dermatitis, acne, alopecia, angioedema, toxic epidermal necrolysis, xerosis, urticaria, purpura, photosensitivity, psoriasis, exanthema

Gastrointestinal: Xerostomia

Local: Mild ocular stinging and discomfort, tearing, erythema, itching

Neuromuscular & skeletal: Paresthesia

Ocular: Photophobia, decreased corneal sensitivity, keratitis

Respiratory: Rhinitis

Miscellaneous: Cold extremities, systemic lupus erythematosus, lupus

Signs and Symptoms of Overdose Abdominal pain, ataxia, bradycardia, depression, hypotension, night terrors, photophobia

Pharmacodynamics/Kinetics

Onset of action: Ophthalmic: 30 minutes; Oral: 1-1.5 hours

Duration: Ophthalmic: ≥ 12 hours

Absorption: Ophthalmic: Multiple systemic; Oral: ~100%

Metabolism: Hepatic to multiple metabolites

Protein binding: Oral: 50%

Bioavailability: Oral: 89%

Half-life elimination: Oral: 12-22 hours

Time to peak: Ophthalmic: ~2 hours; Oral: 1.5-6 hours

Excretion: Urine

Dosage

Adults:

Ophthalmic: Instill 1 drop twice daily.

Oral: 5-10 mg/day; may increase dose to 20 mg/day after 7-14 days if desired response is not achieved. Initial dose in elderly: 5 mg/day.

Dosage adjustment in renal impairment: Administer 5 mg/day. Can increase every 2 weeks up to a maximum of 20 mg/day.

$Cl_{cr} < 10$ mL/minute: Administer 50% of usual dose.

Stability Avoid freezing ophthalmic forms

Monitoring Parameters Ophthalmic: Intraocular pressure. Systemic: Blood pressure, pulse

Administration

Ophthalmic: Shake suspension well before using. Tilt head back and instill in eye. Keep eye open and do not blink for 30 seconds. Apply gentle pressure to lacrimal sac for 1 minute. Wipe away excess from skin. Do not touch applicator to eye and do not contaminate tip of applicator.

Contraindications Hypersensitivity to betaxolol or any component of the formulation; sinus bradycardia; heart block greater than first-degree (except in patients with a functioning artificial pacemaker); cardiogenic shock; uncompensated cardiac failure; pulmonary edema; pregnancy (2nd and 3rd trimester)

Warnings Administer cautiously in compensated heart failure and monitor for a worsening of the condition. Beta-blocker therapy should not be withdrawn abruptly (particularly in patients with CAD), but gradually tapered to avoid acute tachycardia, hypertension, and/or ischemia. Use caution with concurrent use of beta-blockers and either verapamil or diltiazem; bradycardia or heart block can occur. Use caution in patients with PVD (can aggravate arterial insufficiency). In general, beta-blockers should be avoided in patients with bronchospastic disease. Betaxolol, with beta₁ selectivity, should be used cautiously in bronchospastic disease with close monitoring. Use cautiously in diabetics because it can mask prominent hypoglycemic symptoms. Can mask signs of thyrotoxicosis. Dosage adjustment required in severe renal impairment and in patients on dialysis. Use care with anesthetic agents which decrease myocardial function. Safety and efficacy in pediatric patients have not been established.

Dosage Forms

Solution, ophthalmic, as hydrochloride: 0.5% (5 mL, 10 mL, 15 mL) [contains benzalkonium chloride]

Suspension, ophthalmic, as hydrochloride (Betoptic® S): 0.25% (2.5 mL, 5 mL, 10 mL, 15 mL) [contains benzalkonium chloride]

Tablet, as hydrochloride (Kerlone®): 10 mg, 20 mg

Reference Range Oral dose of 20 mg produces a level of 42.6 ng/mL 4-6 hours after ingestion; postmortem blood level of 36,000 mcg/mL reported in a betaxolol-poisoned fatality

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal for oral ingestion

Supportive therapy: Sympathomimetics (eg, epinephrine or dopamine), atropine, glucagon, or a pacemaker can be used to treat the toxic bradycardia, asystole, and/or hypotension; initially, fluids may be the best treatment for toxic hypotension

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Drug Interactions

Substrate (major) of CYP1A2, 2D6; **Inhibits** CYP2D6 (weak)

Acetylcholinesterase inhibitors: May enhance the bradycardic effect of beta-blockers.

Alpha/beta-agonists (direct-acting): Beta-blockers may enhance the vasopressor effect of alpha/beta-agonists (direct-acting).

α₁-blockers: Beta-blockers may enhance the orthostatic effect of alpha₁-blockers. The risk associated with ophthalmic products is probably less than systemic products.

α₂-agonists: Beta-blockers may enhance the rebound hypertensive effect of α₂-agonists. This effect can occur when the alpha₂-agonist is abruptly withdrawn.

Aminoquinolines (antimalarial): May decrease the metabolism, via CYP isoenzymes, of beta-blockers.

Amiodarone: May enhance the bradycardic effect of beta-blockers.

Antipsychotic agents (phenothiazines): May enhance the hypotensive effect of beta-blockers. Either group may decrease the metabolism of the other.

Barbiturates: May increase the metabolism, via CYP isoenzymes, of beta-blockers.

β₂-agonists: May diminish the bradycardic effect of beta-blockers (β₁ selective).

Calcium channel blockers (nondihydropyridine): May enhance the hypotensive effect of beta-blockers; may also decrease the metabolism of beta-blockers.

Cardiac glycosides: Beta-blockers may enhance the bradycardic effect of cardiac glycosides.

CYP1A2 inducers: May decrease the levels/effects of betaxolol. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of betaxolol. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

CYP2D6 inhibitors: May increase the levels/effects of betaxolol. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Dipyridamole: May enhance the bradycardic effect of beta-blockers.

Disopyramide: May enhance the bradycardic effect of beta-blockers.

Insulin: Beta-blockers may mask the hypoglycemic effect of insulin.

Lidocaine: Beta-blockers may decrease the metabolism of lidocaine.

Nonsteroidal anti-inflammatory agents (NSAIDs): May diminish the antihypertensive effect of beta-blockers.

BETHANECHOL

- Propafenone: May decrease the metabolism, via CYP isoenzymes, of beta-blockers. Propafenone possesses some independent beta-blocking activity.
- Propoxyphene: May decrease the metabolism, via CYP isoenzymes, of beta-blockers.
- Quinidine: May decrease the metabolism, via CYP isoenzymes, of beta-blockers.
- Rifamycin derivatives: May increase the metabolism, via CYP isoenzymes, of beta-blockers.
- Selective serotonin reuptake inhibitors (SSRIs): May enhance the bradycardic effect of beta-blockers.
- Sulfonylureas: Beta-blockers may enhance the hypoglycemic effect of sulfonylureas; beta-blockers appear to mask tachycardia as an initial symptom of hypoglycemia. Ophthalmic beta-blockers are probably associated with lower risk than systemic agents.
- Theophylline derivatives: Beta-blockers (beta₁ selective) may diminish the bronchodilatory effect of theophylline derivatives. This is true at higher beta-blockers doses where cardioselectivity is lost.
- Pregnancy Risk Factor** C (manufacturer); D (2nd and 3rd trimesters - expert analysis)
- Pregnancy Implications** Teratogenic effects were not observed in animal studies; however, there was drug-related postimplantation loss in rats and rabbits.
- Lactation** Oral: Enters breast milk/use caution
- Additional Information** Because of betaxolol's low lipid solubility, it is less likely to enter the CNS, decreasing the likelihood of CNS side effects.
- Specific References**

Bethanechol

CAS Number 590-63-6; 674-38-4

U.S. Brand Names Urecholine®

Synonyms Bethanechol Chloride

Use Nonobstructive urinary retention and retention due to neurogenic bladder

Unlabeled/Investigational Use Treatment and prevention of bladder dysfunction caused by phenothiazines; diagnosis of flaccid or atonic neurogenic bladder; gastroesophageal reflux

Mechanism of Action Stimulates cholinergic receptors in the smooth muscle of the urinary bladder and GI tract resulting in increased peristalsis, increased gastrointestinal and pancreatic secretions, bladder muscle contraction, and increased ureteral peristaltic waves

Adverse Reactions

Cardiovascular: Flushed skin, hypotension, tachycardia

Central nervous system: Headache, malaise

Gastrointestinal: Abdominal cramps, diarrhea, eructation, nausea, salivation, vomiting

Genitourinary: Urinary urgency

Ocular: Lacrimation, miosis

Respiratory: Asthmatic attacks, bronchial constriction

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Abdominal pain, AV block, defecation, diarrhea, drowsiness, flushing, headache, heart block, hypothermia, lacrimation, miosis, salivation, vomiting

Pharmacodynamics/Kinetics

Onset of action: 30-90 minutes

Duration: Up to 6 hours

Absorption: Variable

Dosage

Oral:

Children:

Urinary retention (unlabeled use): 0.6 mg/kg/day divided 3-4 times/day

Gastroesophageal reflux (unlabeled use): 0.1-0.2 mg/kg/dose given 30 minutes to 1 hour before each meal to a maximum of 4 times/day

Adults:

Urinary retention, neurogenic bladder, and/or bladder atony:

Oral: Initial: 10-50 mg 2-4 times/day (some patients may require dosages of 50-100 mg 4 times/day). To determine effective dose, may initiate at a dose of 5-10 mg, with additional doses of 5-10 mg hourly until an effective cumulative dose is reached. Cholinergic effects at higher oral dosages may be cumulative.

SubQ: Initial: 2.575 mg, may repeat in 15-30 minutes (maximum cumulative initial dose: 10.3 mg); subsequent doses may be given 3-4 times daily as needed (some patients may require more frequent dosing at 2.5- to 3-hour intervals). Chronic neurogenic atony may require doses of 7.5-10 every 4 hours.

Gastroesophageal reflux (unlabeled): Oral: 25 mg 4 times/day

Elderly: Use the lowest effective dose

Stability Store at room temperature of 15°C to 30°C (59°F to 86°F).

Monitoring Parameters Observe closely for side effects

Contraindications Hypersensitivity to bethanechol or any component of the formulation; mechanical obstruction of the GI or GU tract or when the strength or integrity of the GI or bladder wall is in question; hyperthyroidism, peptic ulcer disease, epilepsy, obstructive pulmonary disease, bradycardia, vasomotor instability, atrioventricular conduction defects, hypotension, or parkinsonism

Warnings Potential for reflux infection if the sphincter fails to relax as bethanechol contracts the bladder. Safety and efficacy in children have not been established.

Dosage Forms Tablet, as chloride: 5 mg, 10 mg, 25 mg, 50 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Atropine (2-4 mg in adults or 0.04-0.08 mg/kg in children) should be given to control muscarinic symptoms; diazepam or lorazepam can be given for seizure control

Antidote(s)

- Atropine [ANTIDOTE]

Test Interactions ↑ lipase, amylase (S), bilirubin, aminotransferases (ALT, AST) (S)

Drug Interactions

Decreased effect: Procainamide, quinidine.

Increased toxicity: Bethanechol and ganglionic blockers may cause a critical fall in blood pressure. Cholinergic drugs or anticholinesterase agents may have additive effects.

Pregnancy Risk Factor

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Contraindicated for I.M. or I.V. use due to a likely severe cholinergic reaction; for SubQ injection only - should never be give I.M. or I.V.; observe closely for side effects; have bedpan readily available if administered for urinary retention

Additional Information Cardiac effects are less likely with bethanechol than acetylcholine chloride (Covocho[®], Miochol[®]).

Biperiden

Related Information

- Dicyclomine

CAS Number 1235-82-1; 514-65-8

U.S. Brand Names Akineton®

Synonyms Biperiden Hydrochloride; Biperiden Lactate

Use Treatment of all forms of parkinsonism including drug-induced type (extrapyramidal symptoms)

Mechanism of Action Biperiden is a weak anticholinergic agent. The beneficial effects in Parkinson's disease and neuroleptic-induced extrapyramidal reactions are believed to be due to the inhibition of striatal cholinergic receptors.

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), fibrillation (ventricular), tachycardia, palpitations

Central nervous system: Confusion, drowsiness, headache, loss of memory, ataxia, tiredness, euphoria, agitation, paranoia, delusions, visual hallucinations, cognitive dysfunction, hypothermia, extrapyramidal reaction

Dermatologic: **Dry skin**, skin rash, urticaria

Endocrine & metabolic: Decreased flow of breast milk

Gastrointestinal: **Constipation, xerostomia or dry throat**, dysphagia, bloated feeling, nausea, vomiting

Genitourinary: Dysuria

Neuromuscular & skeletal: Weakness, paresthesia

Ocular: Intraocular pain (increased), blurred vision, sensitivity to light (increased)

Respiratory: **Dry nose**

Miscellaneous: **Diaphoresis (decreased)**

Signs and Symptoms of Overdose Dry mouth, hyperthermia, hypertension, ileus, mydriasis, tachycardia, urinary retention

Admission Criteria/Prognosis Admit any patient with symptoms of anticholinergic toxicity

Pharmacodynamics/Kinetics

Bioavailability: 29%

Half-life elimination, serum: 18.4-24.3 hours

Time to peak, serum: 1-1.5 hours

Dosage

Children:

Extrapyramidal reaction:

I.M.: 0.04 mg/kg/dose

I.V.: 1-2 mg

Adults:

Parkinsonism: Oral: 2 mg 3-4 times/day

Extrapyramidal:

Oral: 2 mg 1-3 times/day

I.M., I.V.: 2 mg every 30 minutes up to 4 doses or 8 mg/day

Monitoring Parameters Symptoms of EPS or Parkinson's, pulse, anticholinergic effects (ie, CNS, bowel, and bladder function)

Administration

I.V. must be given slowly

Contraindications Hypersensitivity to biperiden or any component of the formulation; narrow-angle glaucoma; bowel obstruction, megacolon; myasthenia gravis

Warnings Use with caution in patients with narrow-angle glaucoma, peptic ulcer, urinary tract obstruction, and hyperthyroidism.

Dosage Forms Tablet, as hydrochloride: 2 mg

Reference Range After a 4 mg oral dose, peak plasma levels range from 3.9-6.3 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: Physostigmine should be reserved for life-threatening anticholinergic effects; tachyarrhythmias can respond to physostigmine or I.V. beta-adrenergic blockers; agitation can be treated with benzodiazepines

Antidote(s)

- Physostigmine [ANTIDOTE]

Drug Interactions

Inhibits CYP2D6 (weak)

Amantadine, rimantadine: Central and/or peripheral anticholinergic syndrome can occur when administered with amantadine or rimantadine.

Anticholinergic agents: Central and/or peripheral anticholinergic syndrome can occur when administered with narcotic analgesics, phenothiazines and other antipsychotics (especially with high anticholinergic activity), tricyclic antidepressants, quinidine and some other antiarrhythmics, and antihistamines.

Atenolol: Anticholinergics may increase the bioavailability of atenolol (and possibly other beta-blockers); monitor for increased effect.

Cholinergic agents: Anticholinergics may antagonize the therapeutic effect of cholinergic agents; includes tacrine and donepezil.

Digoxin: Anticholinergics may decrease gastric degradation and increase the amount of digoxin absorbed by delaying gastric emptying.

Levodopa: Anticholinergics may increase gastric degradation and decrease the amount of levodopa absorbed by delaying gastric emptying.

Neuroleptics: Anticholinergics may antagonize the therapeutic effects of neuroleptics.

Pregnancy Risk Factor C

Nursing Implications No significant difference in onset of I.M. or I.V. injection, therefore, there is usually no need to use the I.V. route. Improvement is sometimes noticeable a few minutes after injection. Do not discontinue drug abruptly.

Bisacodyl

CAS Number 1336-29-4; 603-50-9

U.S. Brand Names Alophen® [OTC]; Bisac-Evac™ [OTC]; Bisacodyl Uniserts® [OTC]; Correctol® Tablets [OTC]; Doxidan® (reformulation) [OTC]; Dulcolax® [OTC]; Femilax™ [OTC]; Fleet® Bisacodyl Enema [OTC]; Fleet® Stimulant Laxative [OTC]; Gentlax® [OTC]; Modane Tablets® [OTC]; Veracolate [OTC]

Use Treatment of constipation; colonic evacuation prior to procedures or examination

Mechanism of Action Stimulates peristalsis by directly irritating the smooth muscle of the intestine, possibly the colonic intramural plexus; alters water and electrolyte secretion producing net intestinal fluid accumulation and laxation

Adverse Reactions

Endocrine & metabolic: Electrolyte and fluid imbalance (metabolic acidosis or alkalosis, hypocalcemia)

Gastrointestinal: Abdominal cramps, abdominal pain, nausea, vomiting, rectal burning

Signs and Symptoms of Overdose Abdominal pain, diarrhea, colonic atony, hypocalcemia, proctitis

Pharmacodynamics/Kinetics

Onset of action: Oral: 6-10 hours; Rectal: 0.25-1 hour

Absorption: Oral, rectal: Systemic, <5%

Dosage

Children:

Oral: >6 years: 5-10 mg (0.3 mg/kg) at bedtime or before breakfast

Rectal suppository:

<2 years: 5 mg as a single dose

>2 years: 10 mg

Adults:

Oral: 5-15 mg as single dose (up to 30 mg when complete evacuation of bowel is required)

Rectal suppository: 10 mg as single dose

Tannex:

Enema: 2.5 g in 1000 mL warm water

Barium enema: 2.5-5 g in 1000 mL barium suspension

Do not administer > 10 g within 72-hour period

Administration

Administer with a glass of water on an empty stomach for rapid effect. Do not administer within 1 hour of milk, any dairy products, or taking an antacid, to protect the coating.

Contraindications Hypersensitivity to bisacodyl or any component of the formulation; abdominal pain or obstruction, nausea, or vomiting

Dosage Forms

[DSC] = Discontinued product

Enema (Fleet® Bisacodyl Enema): 10 mg/30 mL (37 mL)

Suppository, rectal (Bisac-Evac™, Bisacodyl Uniserts®, Dulcolax®): 10 mg

Tablet, enteric coated (Alophen®, Bisac-Evac™, Correctol®, Dulcolax®, Femilax™, Fleet® Stimulant Laxative, Gentlax® [DSC], Modane®, Veracolate): 5 mg

Tablet, delayed release (Doxidan®): 5 mg

Reference Range Urinary bisacodyl diphenol level after a 10 mg oral dose ranges from 1-5 mcg/mL.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal (no cathartic)
Supportive therapy: I.V. crystalloid hydration with potassium replacement

Drug Interactions Decreased effect: Milk, antacids; decreased effect of warfarin

Pregnancy Risk Factor C

Nursing Implications Administer tablets 2 hours prior to, or 4 hours after antacids; increased pH may dissolve the enteric coating leading to GI distress; do not crush enteric coated drug product

Bismuth Subgallate

CAS Number 7440-69-9

Use Symptomatic treatment of mild, nonspecific diarrhea; skin protectant; antacid; in industry, used in boiler plugs, electrical fuses, solders, and dental techniques

Mechanism of Action Binds with thiol-containing enzyme in cerebrum; antimicrobial action against *Helicobacter pylori*

Adverse Reactions

Central nervous system: Headache, drowsiness, malaise, memory disturbance, seizures, ataxia, encephalopathy

Dermatologic: Oral lesions, bluish gum line, erythema, alopecia

Gastrointestinal: **Feces discoloration (black), discoloration of the tongue (darkening)**, stomatitis, nausea, vomiting, fecal impaction, anorexia, bezoars, metallic taste

Hematologic: Methemoglobinemia

Neuromuscular & skeletal: Osteoporosis, tremors

Renal: Acute tubular necrosis

Signs and Symptoms of Overdose Confusion, dementia, fever, hyperactivity, hyperthermia, jaundice, memory loss, methemoglobinemia, proteinuria, seizures, stomatitis, sweating, tongue discoloration, tubular necrosis

Pharmacodynamics/Kinetics

Absorption: Bismuth is minimally absorbed across the GI tract while the salt (eg, salicylate) may be readily absorbed

Metabolism: Undergoes chemical dissociation to various bismuth salts after oral administration

Dosage Oral: 1-2 tablets 3 times/day with meals

Dosing adjustment in renal impairment: Should probably be avoided in patients with renal failure

Dosage Forms Tablet, chewable: 200 mg

Reference Range Plasma levels <5 mcg/dL are not toxic

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: D-penicillamine (15-40 mg/kg/day up to 250-500 mg 4 times/day in adults; 20-30 mg/kg/day orally in children before meals) has been tested in animal models; no human use experience.

Alternatively, unithiol 250 mg I.V. every 4 hours within 6 hours of dialysis using a membrane with large pores. Continue dialysis until renal function is normal. Continue unithiol therapy with 500 mg/day in two divided doses for 2 weeks.

Antidote(s)

- Penicillamine [ANTIDOTE]

- Unithiol [ANTIDOTE]

Drug Interactions Decreased effect of tetracyclines

Increased toxicity of aspirin

Pregnancy Risk Factor C (D in 3rd trimester)

Nursing Implications Seek causes for diarrhea

Additional Information Bismuth subsalicylate (Pepto-Bismol®) contains 58% bismuth and 42% salicylate; do not exceed 4.2 g/day dosage; bismuth is radiopaque

Specific References

Dargan PI, Bailey CA, Greene SL, et al, "A Case of Severe Iatrogenic Bismuth Poisoning," *J Toxicol Clin Toxicol*, 2003, 41(5):738.

Bisoprolol

Related Information

- Atropine [ANTIDOTE]
- Glucagon [ANTIDOTE]
- Selected Properties of Beta-Adrenergic Blocking Drugs

CAS Number 104344-23-2; 66722-44-9; 66722-45-0

U.S. Brand Names Zebeta®

Synonyms Bisoprolol Fumarate

Use Treatment of hypertension, alone or in combination with other agents
Unlabeled/Investigational Use Angina pectoris, supraventricular arrhythmias, PVCs, CHF

Mechanism of Action Selective inhibitor of beta₁-adrenergic receptors; competitively blocks beta₁-receptors, with little or no effect on beta₂-receptors at doses < 10 mg

Adverse Reactions

Cardiovascular: Bradycardia, palpitations, edema, CHF, reduced peripheral circulation, arrhythmias, chest pain, orthostatic hypotension, syncope, vasculitis

Central nervous system: **Drowsiness, insomnia,** mental depression, confusion (especially in the elderly), hallucinations, headache, nervousness

Dermatologic: Angioedema, exfoliative dermatitis, itching, psoriasiform eruption

Endocrine & metabolic: **Decreased sexual ability**

Gastrointestinal: Diarrhea or constipation, nausea, vomiting, stomach discomfort

Genitourinary: Peyronie's disease

Hematologic: Leukopenia, thrombocytopenia

Ocular: Mild ocular stinging and discomfort, tearing, photophobia, decreased corneal sensitivity, keratitis

Respiratory: Bronchospasm, dyspnea

Miscellaneous: Cold extremities

Signs and Symptoms of Overdose Ataxia, bradycardia, cold extremities, cough, hypoglycemia, hypotension, impotence, insomnia, night terrors, wheezing

Pharmacodynamics/Kinetics

Onset of action: 1-2 hours

Absorption: Rapid and almost complete

Distribution: Widely; highest concentrations in heart, liver, lungs, and saliva; crosses blood-brain barrier; enters breast milk

Protein binding: 26% to 33%

Metabolism: Extensively hepatic; significant first-pass effect

Half-life elimination: 9-12 hours

Time to peak: 1.7-3 hours

Excretion: Urine (3% to 10% as unchanged drug); feces (<2%)

Dosage

Oral:

Adults: 2.5-5 mg once daily, may be increased to 10 mg, and then up to 20 mg once daily, if necessary

Hypertension (JNC 7): 2.5-10 mg once daily

Elderly: Initial dose: 2.5 mg/day; may be increased by 2.5-5 mg/day; maximum recommended dose: 20 mg/day

Dosing adjustment in renal/hepatic impairment: Cl_{cr} < 40 mL/minute: Initial: 2.5 mg/day; increase cautiously.

Hemodialysis: Not dialyzable

Monitoring Parameters Blood pressure, ECG, neurologic status

Contraindications Hypersensitivity to bisoprolol or any component of the formulation; sinus bradycardia; heart block greater than first-degree (except in patients with a functioning artificial pacemaker); cardiogenic shock; uncompensated cardiac failure; pulmonary edema; pregnancy (2nd and 3rd trimesters)

Warnings Administer cautiously in compensated heart failure and monitor for a worsening of the condition. Beta-blocker therapy should not be withdrawn abruptly (particularly in patients with CAD), but gradually tapered to avoid acute tachycardia, hypertension, and/or ischemia. Use caution in patients with PVD (can aggravate arterial insufficiency). Use caution with concurrent use of beta-blockers and either verapamil or diltiazem; bradycardia or heart block can occur. In general, beta-blockers should be avoided in patients with bronchospastic disease. Bisoprolol, with B1 selectivity, should be used cautiously in bronchospastic disease with close monitoring. Use cautiously in diabetics because it can mask prominent hypoglycemic symptoms. Can mask signs of thyrotoxicosis. Can cause fetal harm when administered in pregnancy. Dosage adjustment is required in patients with significant hepatic or renal dysfunction. Use care with anesthetic agents which decrease myocardial function.

Dosage Forms Tablet, as fumarate: 5 mg, 10 mg

Reference Range Peak plasma level of 56 ng/mL after 10 mg dose and 445 ng/mL after 100 mg dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** use ipecac

Supportive therapy: Glucagon (50-150 mcg/kg followed by continuous drip of 1-5 mg/hour) for positive chronotropic effect; atropine/isoproterenol can be utilized to increase heart rate; calcium chloride may also be effective; **do not** use epinephrine

Enhancement of elimination: Multiple dosing of activated charcoal is not likely to be of benefit; dialysis is not useful

Antidote(s)

- Atropine [ANTIDOTE]
- Glucagon [ANTIDOTE]

Test Interactions ↑ thyroxine (S), glucose; no effect on lipid profile

Drug Interactions

Substrate of CYP2D6 (minor), 3A4 (major)

Alpha-blockers (prazosin, terazosin): Concurrent use of beta-blockers may increase risk of orthostasis.

AV conduction-slowing agents (digoxin): Effects may be additive with beta-blockers.

Clonidine: Hypertensive crisis after or during withdrawal of either agent.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of bisoprolol. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of bisoprolol. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Glucagon: Bisoprolol may blunt the hyperglycemic action of glucagon.

Insulin: Bisoprolol may mask tachycardia from hypoglycemia.

NSAIDs (ibuprofen, indomethacin, naproxen, piroxicam) may reduce the antihypertensive effects of beta-blockers.

Salicylates may reduce the antihypertensive effects of beta-blockers.

Sulfonyleureas: Beta-blockers may alter response to hypoglycemic agents.

Pregnancy Risk Factor C (manufacturer); D (2nd and 3rd trimesters - expert analysis)

Pregnancy Implications No data available on whether bisoprolol crosses the placenta. Beta-blockers have been associated with persistent bradycardia, hypotension, and IUGR; IUGR is probably related to maternal hypertension. Available evidence suggests beta-blockers are generally safe during pregnancy (JNC-7). Cases of neonatal hypoglycemia have been reported following maternal use of beta-blockers at parturition or during breast-feeding.

Lactation Enters breast milk/use caution

Specific References

Chobanian AV, Bakris GL, Black HR, et al, "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, (19)289:2560-71.

Blasticidin S

CAS Number 2079-00-7

Synonyms BLA-s; Blaes-M

Use A contact fungicide used for control of rice blast (*Picicularia oryzae*) in Taiwan, Japan, Korea, Central and South America

Mechanism of Toxic Action A benzylamino benzene-sulfonate derived from fermentation of *Streptomyces griseochromogenes*, blasticidin S inhibits protein synthesis (spore protein polymerization). Can cause severe mucous membrane irritation.

Adverse Reactions

Cardiovascular: Hypotension, cyanosis, acrocyanosis

Central nervous system: Fever, headache

Dermatologic: Erythema

Endocrine & metabolic: Hyponatremia

Gastrointestinal: Vomiting (immediate and protracted), profuse watery diarrhea, abdominal pain, nausea

Ocular: Conjunctivitis, corneal ulcers, keratitis, blepharitis

Respiratory: Pharyngitis, dyspnea, cough, pulmonary edema, aspiration pneumonia, bronchospasm, stridor

Admission Criteria/Prognosis Admit any symptomatic patient (other than with local irritation) or any ingestion > 0.1 g

Monitoring Parameters ECG, electrolytes

Overdosage/Treatment

Decontamination: **Oral:** Dilute with water (4-8 ounces). **Do not** induce emesis. Lavage (within 1 hour)/activated charcoal or sodium polystyrene sulfonate (15 g of resin in adults or 1 g/kg in children every 6 hours).

Dermal: Wash the exposed area with soap and water. **Inhalation:** Administer humidified oxygen. **Ocular:** Copiously irrigate with saline or water. The addition of calcium salts within 30 minutes of exposure may decrease eye irritation.

Supportive therapy: Treat hypotension with I.V. crystalloid replacement. Vasopressors can be used for refractory cases. Corticosteroids may be helpful in treating respiratory adverse effects.

Additional Information Lethal oral dose (LD₅₀): ~20 mg/kg. Conjunctivitis can be caused by as little as 1 mcg of ocular exposure while 20 mcg can cause keratitis. Conjunctivitis usually develops within 5 hours and may take 10 days to resolve.

Bleomycin

CAS Number 11056-06-7; 9041-93-4

U.S. Brand Names Blenoxane®

Synonyms Bleo; Bleomycin Sulfate; BLM; NSC-125066

Use Treatment of squamous cell carcinomas, melanomas, sarcomas, testicular carcinoma, Hodgkin's lymphoma, and non-Hodgkin's lymphoma

Orphan drug: Sclerosing agent for malignant pleural effusion

Mechanism of Action Inhibits synthesis of DNA; binds to DNA leading to single- and double-strand breaks

Adverse Reactions

Cardiovascular: **Raynaud's phenomenon**

Central nervous system: **Chills**, hypersomnia, personality changes, memory impairment, thermal dysfunction, **mild febrile reaction**, **fever**

Dermatologic: Alopecia, hyperpigmentation, nailbed changes, vesiculation, radiation recall dermatitis, scleroderma, **pruritic erythema**

Gastrointestinal: **Stomatitis**, **anorexia**, **nausea**, **vomiting**, weight loss, loss of taste perception, **mucocutaneous toxicity**

Local: **Pain at tumor site**, **phlebitis**, extravasation injury

Respiratory: Dose related when total dose is >400 units or with single doses >30 units; pathogenesis is poorly understood, but may be related to damage of pulmonary, vascular, or connective tissue. Manifested as an acute or chronic interstitial pneumonitis with interstitial fibrosis, hypoxia, and death. Symptoms include cough, dyspnea, and bilateral pulmonary infiltrates noted on chest x-ray. It is controversial whether steroids improve symptoms of bleomycin pulmonary toxicity. Risk factors for development of pulmonary toxicity include cumulative dose >450 mg/m², age >70 years, pre-existing pulmonary disease, high oxygen therapy, concomitant chemotherapy, or thoracic irradiation. Bilateral lung opacities.

Miscellaneous: Patients may become febrile after intracavitary administration

Signs and Symptoms of Overdose Acrodynia, chills, cystitis (hemorrhagic), deafness, erythema, fever, hyperpigmentation, hyperthermia, hypocalcemia, pulmonary fibrosis, seizures, thrombocytopenia

Pharmacodynamics/Kinetics

Absorption: I.M. and intrapleural administration: 30% to 50% of I.V. serum concentrations; intraperitoneal and SubQ routes produce serum concentrations equal to those of I.V.

Distribution: V_d: 22 L/m²; highest concentrations in skin, kidney, lung, heart tissues; lowest in testes and GI tract; does not cross blood-brain barrier

Protein binding: 1%

Metabolism: Via several tissues including hepatic, GI tract, skin, pulmonary, renal, and serum

Half-life elimination: Biphasic (renal function dependent):

Normal renal function: Initial: 1.3 hours; Terminal: 9 hours

End-stage renal disease: Initial: 2 hours; Terminal: 30 hours

Time to peak, serum: I.M.: Within 30 minutes

Excretion: Urine (50% to 70% as active drug)

Dosage

Refer to individual protocols; 1 unit = 1 mg

May be administered I.M., I.V., SubQ, or intracavitary

Children and Adults:

Test dose for lymphoma patients: I.M., I.V., SubQ: Because of the possibility of an anaphylactoid reaction, ≤2 units of bleomycin for the first 2 doses; monitor vital signs every 15 minutes; wait a minimum of 1 hour before administering remainder of dose; if no acute reaction occurs, then the regular dosage schedule may be followed

Single-agent therapy:

I.M./I.V./SubQ: Squamous cell carcinoma, lymphoma, testicular carcinoma: 0.25-0.5 units/kg (10-20 units/m²) 1-2 times/week

CIV: 15 units/m² over 24 hours daily for 4 days

Combination-agent therapy:

I.M./I.V.: 3-4 units/m²

I.V.: ABVD: 10 units/m² on days 1 and 15

Maximum cumulative lifetime dose: 400 units

Pleural sclerosing: 60-240 units as a single infusion. Dose may be repeated at intervals of several days if fluid continues to accumulate (mix in 50-100 mL of D₅W, NS, or SWFI); may add lidocaine 100-200 mg to reduce local discomfort.

Dosing adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer 75% of normal dose

Cl_{cr} <10 mL/minute: Administer 50% of normal dose

Monitoring Parameters Pulmonary function tests (total lung volume, forced vital capacity, carbon monoxide diffusion), renal function, chest x-ray, temperature initially

Administration

Administer I.V. slowly over at least 10 minutes (no greater than 1 unit/minute) at a concentration not to exceed 3 units/mL; bleomycin for I.V. continuous infusion can be further diluted in normal saline (preferred) or D₅W

Contraindications Hypersensitivity to bleomycin or any component of the formulation; severe pulmonary disease; pregnancy

Warnings Hazardous agent - use appropriate precautions for handling and disposal. **[U.S. Boxed Warnings]: Occurrence of pulmonary fibrosis (commonly presenting as pneumonitis) is higher in elderly patients, patients receiving >400 units total lifetime dose or single doses >30 units, smokers, and patients with prior radiation therapy or receiving concurrent oxygen. A severe idiosyncratic reaction consisting of hypotension, mental confusion, fever, chills, and wheezing (similar to anaphylaxis) has been reported in 1% of lymphoma patients treated with bleomycin.** Since these reactions usually occur after the first or second dose, careful monitoring is essential after these doses. Follow manufacturer recommendations for administering O₂ during surgery to patients who have received bleomycin. Use caution with renal impairment, may require dose adjustment. May cause renal or hepatic toxicity. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.** Safety and efficacy in children have not been established.

Dosage Forms Injection, powder for reconstitution, as sulfate: 15 units, 30 units

Reference Range Steady-state levels for a dose of 20 units/day is from 50-200 milliunits/L

Overdosage/Treatment Supportive therapy: Use minimal amounts of oxygen; steroids are of uncertain benefit in preventing pulmonary fibrosis; use of 21-aminosteroids (U-74389 G; 10 mg/kg I.V.) to reduce pulmonary fibrosis is experimental

Test Interactions ↑ potassium (S)

Drug Interactions

Cisplatin: May decrease bleomycin elimination.

Digitalis glycosides: Bleomycin may decrease plasma levels of digoxin.

Phenytoin: Results in decreased phenytoin levels.

Pregnancy Risk Factor D

Pregnancy Implications Animal studies have demonstrated teratogenic and abortifacient effects. There are no adequate and well-controlled studies in pregnant women. Women of childbearing potential should avoid becoming pregnant during treatment.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Myelosuppressive effects: **WBC:** Rare. **Platelets:** Rare. Onset (days): 7; Nadir (days): 14; Recovery (days): 21

Specific References

Burdick MD, Murray LA, Keane MP, et al. "CXCL11 Attenuates Bleomycin-Induced Pulmonary Fibrosis via Inhibition of Vascular Remodeling," *Am J Respir Crit Care Med*, 2005, 171(3):261-8.

Botulinum Toxin Type A

Related Information

● Clostridium botulinum Food Poisoning

U.S. Brand Names Botox® Cosmetic; Botox®

Synonyms BTX-A

Use Treatment of strabismus and blepharospasm associated with dystonia (including benign essential blepharospasm or VII nerve disorders in patients ≥12 years of age); cervical dystonia (spasmodic torticollis) in patients ≥16 years of age; temporary improvement in the appearance of lines/wrinkles of the face (moderate to severe glabellar lines associated with corrugator and/or procerus muscle activity) in adult patients ≤65 years of age

Orphan drug: Treatment of dynamic muscle contracture in pediatric cerebral palsy patients

Unlabeled/Investigational Use Treatment of oromandibular dystonia, spasmodic dysphonia (laryngeal dystonia) and other dystonias (ie, writer's cramp, focal task-specific dystonias); migraine treatment and prophylaxis

Mechanism of Action Botulinum A toxin is a neurotoxin produced by *Clostridium botulinum*, spore-forming anaerobic bacillus. Six distinct antigenic types of neurotoxins are generated by *Clostridium botulinum*, named from A to F, however, only the A toxin has been used clinically. Botulinum A toxin is a double-chain protein with a molecular weight of ~900,000; active portion of the molecule is the light chain and the heavy chain is inactive. The toxin appears to affect only one structure in humans, the presynaptic membrane of the neuromuscular junction, where it prevents calcium-dependent release of acetylcholine and produces a state of denervation. Following injection of the toxin into a muscle, the degree of resultant skeletal muscle asthenia or paralysis is dependent upon the dose administered. Muscle inactivation persists until new fibrils grow from the nerve and form junction plates on new areas of the muscle-cell walls. The antagonist muscle shortens simultaneously ("contracture"), taking up the slack created by agonist paralysis; following several weeks of paralysis, alignment of the eye is measurably changed, despite return of innervation to the injected muscle. In patients with sixth nerve palsy, the objective is to prevent contracture of the ipsilateral medial rectus muscle while the patient awaits recovery of the palsied lateral rectus muscle.

Adverse Reactions

Adverse effects usually occur in 1 week and may last up to several months.

Cardiovascular: Arrhythmia, myocardial infarction, syncope (blepharospasm)

Central nervous system: **Headache** (cervical dystonia, reduction of glabellar lines; can occur with other uses), dizziness (cervical dystonia, reduction of glabellar lines); speech disorder (cervical dystonia), fever (cervical dystonia), drowsiness (cervical dystonia), vertigo with nystagmus (reduction of glabellar lines)

Dermatologic: Ecchymoses (blepharospasm), erythema multiforme, pruritus, psoriasisiform eruption, skin rash, urticaria

Gastrointestinal: **Dysphagia** (cervical dystonia), xerostomia (cervical dystonia), nausea (cervical dystonia, reduction of glabellar lines)

Local: Injection site reaction

Neuromuscular & skeletal: **Neck pain** (cervical dystonia), back pain (cervical dystonia); hypertonia (cervical dystonia); weakness (cervical dystonia, reduction of glabellar lines); facial pain (reduction of glabellar lines), stiffness (cervical dystonia, blepharospasm), numbness (cervical dystonia), facial weakness (blepharospasm), brachial plexopathy (cervical dystonia), focal facial paralysis (blepharospasm), exacerbation of myasthenia gravis (blepharospasm, reduction of glabellar lines)

Ocular: **Ptosis** (blepharospasm, strabismus, reduction of glabellar lines); vertical deviation (strabismus), dry eyes (blepharospasm), superficial punctate keratitis (blepharospasm), ectropion (blepharospasm), lagophthalmos (blepharospasm), eyelid edema (blepharospasm), tearing (blepharospasm), photophobia (blepharospasm); reduced blinking leading to corneal ulceration (blepharospasm), corneal perforation (blepharospasm); acute angle-closure glaucoma (blepharospasm), vitreous hemorrhage (blepharospasm), retrobulbar hemorrhage (strabismus), ciliary ganglion damage (strabismus), anterior segment eye ischemia (strabismus), retinal vein occlusion (reduction of glabellar lines), glaucoma (reduction of glabellar lines)

Otic: Abnormal hearing/hearing loss (reduction of glabellar lines)

Respiratory: **Upper respiratory infection** (cervical dystonia), cough (cervical dystonia), rhinitis (cervical dystonia), infection (reduction of glabellar lines), dyspnea (cervical dystonia), aspiration (cervical dystonia)

Miscellaneous: Flu syndrome (cervical dystonia, reduction of glabellar lines), allergic reactions

Signs and Symptoms of Overdose Blurred vision, conjunctivitis, corneal irritation, cranial nerve palsies, dermatitis, dry eyes, dry mouth, dysphagia, lacrimation, mydriasis, neuromuscular paralysis, photophobia

Pharmacodynamics/Kinetics

Onset of action (improvement):
 Blepharospasm: ~3 days
 Cervical dystonia: ~2 weeks
 Strabismus: ~1-2 days
 Reduction of glabellar lines (Botox® Cosmetic): 1-2 days, increasing in intensity during first week

Duration:
 Blepharospasm: ~3 months
 Cervical dystonia: <3 months
 Strabismus: ~2-6 weeks
 Primary axillary hyperhidrosis: 201 days (mean)
 Reduction of glabellar lines (Botox® Cosmetic): Up to 3 months

Absorption: Not expected to be present in peripheral blood at recommended doses

Time to peak:
 Blepharospasm: 1-2 weeks
 Cervical dystonia: ~6 weeks
 Strabismus: Within first week

Dosage

I.M.:

Children ≥ 16 years and Adults:
 Achalasia: 80 units (20 units in each quadrant) injected directly into inferior esophageal sphincter through upper endoscopy
 Cervical dystonia: For dosing guidance, the mean dose is 236 units (25th to 75th percentile range 198-300 units) divided among the affected muscles in patients previously treated with botulinum toxin. Initial dose in previously untreated patients should be lower. Sequential dosing should be based on the patient's head and neck position, localization of pain, muscle hypertrophy, patient response, and previous adverse reactions. The total dose injected into the sternocleidomastoid muscles should be ≤ 100 units to decrease the occurrence of dysphagia.
 Axillary hyperhidrosis: 200 units injected into the axilla
 Chronic anal fissure: 20 units through a 27 gauge needle near the fissure; after 2 months, can give second dose of 25 units of botulinum A

Children ≥ 12 years and Adults:
 Blepharospasm: Initial dose: 1.25-2.5 units injected into the medial and lateral pretarsal orbicularis oculi of the upper and lower lid; dose may be increased up to twice the previous dose if the response from the initial dose lasted ≤ 2 months; maximum dose per site: 5 units; cumulative dose in a 30-day period: ≤ 200 units. Tolerance may occur if treatments are given more often than every 3 months, but the effect is not usually permanent.
 Strabismus:

Initial dose:

Vertical muscles and for horizontal strabismus <20 prism diopters: 1.25-2.5 units in any one muscle
 Horizontal strabismus of 20-50 prism diopters: 2.5-5 units in any one muscle
 Persistent VI nerve palsy >1 month: 1.5-2.5 units in the medial rectus muscle

Re-examine patients 7-14 days after each injection to assess the effect of that dose. Subsequent doses for patients experiencing incomplete paralysis of the target may be increased up to twice the previous administered dose. The maximum recommended dose as a single injection for any one muscle is 25 units. Do not administer subsequent injections until the effects of the previous dose are gone.

Adults ≤ 65 years: Reduction of glabellar lines: An effective dose is determined by gross observation of the patient's ability to activate the superficial muscles injected. The location, size and use of muscles may vary markedly among individuals. Inject 0.1 mL dose into each of five sites, two in each corrugator muscle and one in the procerus muscle (total dose 0.5 mL).

Elderly: No specific adjustment recommended

Dosage adjustment in renal impairment: No specific adjustment recommended

Dosage adjustment in hepatic impairment: No specific adjustment recommended

Administration

Cervical dystonia: Use 25-, 27-, or 30-gauge needle for superficial muscles and a longer 22-gauge needle for deeper musculature; electromyography may help localize the involved muscles

Blepharospasm: Use a 27- or 30-gauge needle without electromyography guidance. Avoid injecting near the levator palpebrae superioris (may decrease ptosis); avoid medial lower lid injections (may decrease diplopia). Apply pressure at the injection site to prevent ecchymosis in the soft eyelid tissues.

Strabismus injections: Must use surgical exposure or electromyographic guidance; use the electrical activity recorded from the tip of the injections needle as a guide to placement within the target muscle. Local anesthetic and ocular decongestant should be given before injection. The volume of injection should be 0.05-0.15 mL per muscle. Many patients will require additional doses because of inadequate response to initial dose.

Reduction of glabellar lines (Botox® Cosmetic): Use a 30-gauge needle. Ensure injected volume/dose is accurate and where feasible keep to a minimum. Avoid injection near the levator palpebrae superioris. Medial corrugator injections should be at least 1 cm above the bony supraorbital ridge. Do not inject toxin closer than 1 cm above the central eyebrow.

Contraindications Hypersensitivity to albumin, botulinum toxin, or any component of the formulation; infection at the proposed injection site(s); pregnancy. Relative contraindications include diseases of neuromuscular transmission; coagulopathy including therapeutic anticoagulation; uncooperative patient.

Warnings

Higher doses or more frequent administration may result in neutralizing antibody formation and loss of efficacy. Product contains albumin and may carry a remote risk of virus transmission. Use caution if there is inflammation, excessive weakness, or atrophy at the proposed injection site(s). Have appropriate support in case of anaphylactic reaction. Use with caution in patients with neuromuscular diseases (such as myasthenia gravis), neuropathic disorders (such as amyotrophic lateral sclerosis), or patients taking aminoglycosides or other drugs that interfere with neuromuscular transmission. Ensure adequate contraction in women of childbearing years. Long-term effects of chronic therapy unknown.

Cervical dystonia: Dysphagia is common. It may be severe requiring alternative feeding methods. Risk factors include smaller neck muscle mass, bilateral injections into the sternocleidomastoid muscle, or injections into the levator scapulae. Dysphasia may be associated with increased risk of upper respiratory infection.

Blepharospasm: Reduced blinking from injection of the orbicularis muscle can lead to corneal exposure and ulceration.

Strabismus: Retrobulbar hemorrhages may occur from needle penetration into orbit. Spatial disorientation, double vision, or past pointing may occur if one or more extraocular muscles are paralyzed. Covering the affected eye may help. Careful testing of corneal sensation, avoidance of lower lid injections, and treatment of epithelial defects are necessary.

Primary axillary hyperhidrosis: Evaluate for secondary causes prior to treatment (eg, hyperthyroidism). Safety and efficacy for treatment of hyperhidrosis in other areas of the body have not been established.

Temporary reduction in glabellar lines: Do not use more frequently than every 3 months. Patients with marked facial asymmetry, ptosis, excessive dermatochalasis, deep dermal scarring, thick sebaceous skin, or the inability to substantially lessen glabellar lines by physically spreading them apart were excluded from clinical trials. Reduced

blinking from injection of the orbicularis muscle can lead to corneal exposure and ulceration. Spatial disorientation, double vision, or past pointing may occur if one or more extraocular muscles are paralyzed.

Dosage Forms Injection, powder for reconstitution [preservative free]: *Clostridium botulinum* toxin type A 100 units [contains human albumin]

Overdose/Treatment Supportive therapy: Treatment is entirely supportive; artificial ventilation may be required; antitoxins to botulism are of no benefit; neostigmine (intranasal: 3 puffs in each nostril prior to meals) has been used to treat dysphagia

Drug Interactions

Aminoglycosides: May increase neuromuscular blockade.

Neuromuscular-blocking agents: May increase neuromuscular blockade.

Other agents which may have neuromuscular-blocking activity: Calcium channel blockers, catecholamines, chloroquine, clindamycin, colistin, corticosteroids, digitalis glycosides, diuretics, inhalation anesthetics, lidocaine, lincomycin, magnesium salts, opioids, phenytoin, phenelzine, polymyxin B, procainamide, propranolol, quinidine, and tetracyclines.

Pregnancy Risk Factor C (manufacturer)

Pregnancy Implications Decreased fetal body weight, delayed ossification, maternal toxicity, abortions, and fetal malformations were observed in animal studies. Human reproduction studies have not been conducted. Avoid use in pregnancy.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications To alleviate spatial disorientation or double vision in strabismic patients, cover the affected eye; inject using a 27- to 30-gauge needle

Hematologic: Hemoglobin decreased, hematocrit decreased, WBCs increased/decreased

Hepatic: Transaminases increased, alkaline phosphatase increased, bilirubin increased

Neuromuscular & skeletal: Weakness, muscle spasm

Ocular: Blurred vision, depth perception decreased

Signs and Symptoms of Overdose Alkaline phosphatase increased, anterograde amnesia, ataxia, bilirubin increased, confusion, blurred vision, depression, depth perception decreased, dizziness, drowsiness, dystonia, euphoria, headache, hematocrit decreased, hemoglobin decreased, hyperglycemia, hypoglycemia, hypotension (rare), incontinence, lethargy, libido decreased, muscle spasm, nausea, palpitations, pruritus, rash, seizures, slurred speech, stupor, tachycardia, transaminases increased, vomiting, WBCs increased/decreased, weakness, xerostomia

Pharmacodynamics/Kinetics

Protein binding: 70%

Metabolism: Hepatic

Bioavailability: 60%

Half-life elimination: 20 hours

Excretion: Urine (69%), as metabolites

Dosage

Oral:

Adults: Initial: 6-18 mg/day in equally divided doses; initial course of treatment should not last longer than 1 week; optimal dosage range: 6-30 mg/day

Elderly/debilitated: Initial dose: Should not exceed 3 mg/day in divided doses

Stability Store at 20°C to 25°C (68°F to 77°F).

Administration

May be administered with or without food.

Contraindications Hypersensitivity to bromazepam or any component of the formulation (cross-sensitivity with other benzodiazepines may exist); myasthenia gravis; narrow-angle glaucoma; severe hepatic or respiratory disease; sleep apnea; pregnancy

Warnings

Rebound or withdrawal symptoms may occur following abrupt discontinuation or large decreases in dose. Dose reductions or tapering must be approached with caution. Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics), renal impairment, or obesity.

Causes CNS depression (dose related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury and should be used with caution in patients who are at risk of these events (especially the elderly).

Use with caution in patients with respiratory disease or impaired gag reflex. Use caution in patients with depression, especially if suicidal risk may be present. May cause physical or psychological dependence - use with caution in patients with a history of drug dependence. Acute withdrawal, including seizures, may be precipitated in patients after administration of flumazenil to patients receiving long-term benzodiazepine therapy.

Benzodiazepines have been associated with anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior, have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties. Safety and efficacy have not been established in patients < 18 years of age.

Dosage Forms

[CAN] = Canadian brand name

Tablet: 1.5 mg, 3 mg, 6 mg [not available in the U.S.]

Reference Range Therapeutic serum range for anxiety: ~0.08-0.2 mcg/mL; serum levels >0.3 mcg/mL and >1 mcg/mL are associated with toxicity and coma, respectively

Overdosage/Treatment

Decontamination: Lavage/activated charcoal for ingestion > 1 mg/kg

Supportive therapy: Rarely is mechanical ventilation required; flumazenil has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression and respiratory depression

Enhancement of elimination: Multiple dose activated charcoal may be effective

Drug Interactions

Substrate of CYP3A4 (major); **Inhibits CYP2E1** (weak)

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants (includes ethanol, barbiturates, narcotic analgesics, and other sedative agent); monitor for increased effect.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of bromazepam. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

Bromazepam

Pronunciation (broe MA ze pam)

CAS Number 1812-30-2

Impairment Potential Yes (with acute or chronic usage) at dosages > 3 mg

Use Short-term, symptomatic treatment of anxiety

Mechanism of Action Binds to stereospecific benzodiazepine receptors on the postsynaptic GABA neuron at several sites within the central nervous system, including the limbic system, reticular formation. Enhancement of the inhibitory effect of GABA on neuronal excitability results by increased neuronal membrane permeability to chloride ions. This shift in chloride ions results in hyperpolarization (a less excitable state) and stabilization.

Adverse Reactions

Frequency not defined.

Cardiovascular: Hypotension (rare), palpitations, tachycardia

Central nervous system: Drowsiness, ataxia, dizziness, confusion, depression, euphoria, lethargy, slurred speech, stupor, headache, seizures, anterograde amnesia, dystonia. In addition, paradoxical reactions (including excitation, agitation, hallucinations, and psychosis) are known to occur with benzodiazepines.

Dermatologic: Rash, pruritus

Endocrine & metabolic: Hyperglycemia, hypoglycemia

Gastrointestinal: Xerostomia, nausea, vomiting

Genitourinary: Incontinence, libido decreased

BUFLOMEDIL

CYP3A4 inhibitors: May increase the levels/effects of bromazepam. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Levodopa: Therapeutic effects may be diminished in some patients following the addition of a benzodiazepine; limited/inconsistent data.

Oral contraceptives: May decrease the clearance of some benzodiazepines (those which undergo oxidative metabolism); monitor for increased benzodiazepine effect.

Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation.

Pregnancy Risk Factor D (based on other benzodiazepines)

Pregnancy Implications Crosses the placenta. Oral clefts reported, however, more recent data does not support an association between drug and oral clefts; inguinal hernia, cardiac defects, spina bifida, urinary system abnormalities, dysmorphic facial features, skeletal defects, multiple other malformations reported; hypotonia and withdrawal symptoms reported following use near time of delivery

Lactation Enters breast milk/contraindicated (AAP rates other benzodiazepines "of concern")

Additional Information Not available in U.S.

Specific References

Mokhlesi B, Leikin JB, Murray P, et al, "Adult Toxicology in Critical Care: Part II: Specific Poisonings," *Chest*, 2003, 123(3):897-922.

BufloMEDIL

CAS Number 35543-24-9; 55837-25-7

Synonyms BufloMEDIL Hydrochloride; BufloMEDILum

Use Dementia; diabetic nephropathy or retinopathy; claudication; Raynaud's phenomenon

Mechanism of Action A peripheral vasodilator (arterioles greater than veins)

Adverse Reactions

Cardiovascular: Hypotension, syncope, AV block, sinus tachycardia, arrhythmias (ventricular), vasodilation
Central nervous system: Dizziness
Dermatologic: Skin rash, pruritus, exanthema
Gastrointestinal: Nausea, diarrhea
Miscellaneous: Anaphylaxis

Signs and Symptoms of Overdose Asystole, coma, flattened T wave on ECG, hypokalemia, hypotension, mydriasis, myoclonus, pulmonary edema, QT and QRS interval prolongation, respiratory depression, seizures, tachycardia, ventricular fibrillation

Admission Criteria/Prognosis Admit any symptomatic ingestion to a cardiac monitored bed or admit any ingestion > 500 mg

Pharmacodynamics/Kinetics

Distribution: V_d : 1.3-1.4 L/kg
Protein binding: 60% to 80%
Metabolism: Hepatic to para-desmethyl bufloMEDIL
Bioavailability: 50% to 80%
Half-life: 1.5-4.3 hours
Elimination: Renal (primarily); fecal (6%); total body clearance: 15-40 L/hour

Dosage Oral: 300-600 mg in divided doses

I.V.: Up to 400 mg

I.M.: 50 mg 3 times/day up to 2 weeks

Monitoring Parameters EKG, electrolytes

Contraindications Hypersensitivity to bufloMEDIL; immediate postpartum use; severe arterial bleeding; pregnancy; lactation; pediatric patients; following vascular surgery

Dosage Forms

Tablet, as hydrochloride: 150 mg, 300 mg, 600 mg

Drops, as hydrochloride: 150 mg/mL

Injection, as hydrochloride: 50 mg (ampul)

Reference Range Serum and urine bufloMEDIL levels 3 hours after a 3 g overdose: 24.8 mg/L and 324.4 mg/L, respectively; plasma bufloMEDIL levels > 5 mg/L are toxic; seizures occur with plasma levels > 10 mg/L

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage within 1 hour any ingestion > 1 g in adults/activated charcoal

Supportive therapy: In order to treat hypotension, a fluid challenge of isotonic saline (10-20 mL/kg) and placement in Trendelenburg position should first be performed; dopamine or norepinephrine can be given for refractory hypotension; ventricular arrhythmias may respond to serum alkalization (pH 7.45-7.55) with sodium bicarbonate (1-3 mEq/kg); avoid quinidine, disopyramide and procainamide; lidocaine, phenytoin, or bretylium can be used for refractory cases; lorazepam or diazepam can be used for seizure control

Antidote(s)

● Sodium Bicarbonate [ANTIDOTE]

Test Interactions Can cause a positive tricyclic antidepressant urinary immunoassay.

Drug Interactions Enhanced hypotensive effect can occur with ethanol or calcium channel blockers

Additional Information Minimum lethal dose: 2.2 g; Toxic oral dose: 600 mg; Seizuregenic dose: 900 mg

Bumetanide

CAS Number 28395-03-1

U.S. Brand Names Bumex®

Use Management of edema secondary to congestive heart failure or hepatic or renal disease including nephrotic syndrome; may also be used alone or in combination with antihypertensives in the treatment of hypertension; can be used in furosemide-allergic patients (1 mg is equivalent to 40 mg furosemide)

Mechanism of Action Inhibits reabsorption of sodium and chloride in the ascending loop of Henle and distal renal tubule, interfering with the chloride-binding cotransport system, thus causing increased excretion of water, sodium, chloride, magnesium, and calcium

Adverse Reactions

Cardiovascular: Hypotension, angina
Central nervous system: Dizziness, headache, encephalopathy
Dermatologic: Stevens-Johnson syndrome, bullous pemphigoid
Endocrine & metabolic: **Hypokalemia, hyperuricemia, hypochloremia, hypoglycemia,**
Gastrointestinal: Cramps, nausea, vomiting
Hepatic: Altered liver function test results
Neuromuscular & skeletal: Weakness
Otic: Ototoxicity
Renal: Elevated serum creatinine, **azotemia**, decreased uric acid excretion

Signs and Symptoms of Overdose Agranulocytosis, asterixis, chest pain, dermatitis, diarrhea, electrolyte depletion, granulocytopenia, hyperglycemia, hyperuricemia, hypokalemia, hypomagnesemia, hyponatremia, leukopenia, nausea, neutropenia, volume depletion, vomiting, xerostomia

Pharmacodynamics/Kinetics

Onset of action: Oral, I.M.: 0.5-1 hour; I.V.: 2-3 minutes
Duration: 4-6 hours
Distribution: V_d : 13-25 L/kg
Protein binding: 95%
Metabolism: Partially hepatic
Half-life elimination: Neonates: ~6 hours; Infants (1 month): ~2.4 hours; Adults: 1-1.5 hours
Excretion: Primarily urine (as unchanged drug and metabolites)

Dosage

Oral, I.M., I.V.:
Neonates (see Warnings/Precautions): 0.01-0.05 mg/kg/dose every 24-48 hours
Infants and Children: 0.015-0.1 mg/kg/dose every 6-24 hours (maximum dose: 10 mg/day)

Adults:

Edema:
Oral: 0.5-2 mg/dose (maximum dose: 10 mg/day) 1-2 times/day
I.M., I.V.: 0.5-1 mg/dose; may repeat in 2-3 hours for up to 2 doses if needed (maximum dose: 10 mg/day)
Continuous I.V. infusion: 0.9-1 mg/hour
Hypertension: Oral: 0.5 mg daily (maximum dose: 5 mg/day); usual dosage range (JNC 7): 0.5-2 mg/day in 2 divided doses

Monitoring Parameters Blood pressure, serum electrolytes, renal function

Administration

Give I.V. slowly, over 1-2 minutes

Contraindications Hypersensitivity to bumetanide, any component of the formulation, or sulfonyleureas; anuria; patients with hepatic coma or in states of severe electrolyte depletion until the condition improves or is corrected; pregnancy (based on expert analysis)

Warnings

Adjust dose to avoid dehydration. In cirrhosis, avoid electrolyte and acid/base imbalances that might lead to hepatic encephalopathy. Ototoxicity is associated with I.V. rapid administration, renal impairment, excessive doses, and concurrent use of other ototoxins. Hypersensitivity reactions can rarely occur. Monitor fluid status and renal function in an attempt to prevent oliguria, azotemia, and reversible increases in BUN and creatinine. Close medical supervision of aggressive diuresis required. Watch for and correct electrolyte disturbances. Coadministration of antihypertensives may increase the risk of hypotension.

Chemical similarities are present among sulfonamides, sulfonyleureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonyleurea allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

[U.S. Boxed Warning]: Loop diuretics are potent diuretics; excess amounts can lead to profound diuresis with fluid and electrolyte loss; close medical supervision and dose evaluation are required.

ed. *In vitro* studies using pooled sera from critically-ill neonates have shown bumetanide to be a potent displacer of bilirubin; avoid use in neonates at risk for kernicterus.

Dosage Forms

Injection, solution: 0.25 mg/mL (2 mL, 4 mL, 10 mL) [contains benzyl alcohol]

Tablet (Bumex®): 0.5 mg, 1 mg, 2 mg

Reference Range Effective plasma level: 40-80 ng/mL

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Hydration with 0.9% saline

Test Interactions ↑ BUN, creatinine, ammonia (B), amylase (S), glucose, uric acid (S); ↓ sodium, calcium, chloride, potassium

Drug Interactions

ACE inhibitors: Hypotensive effects and/or renal effects are potentiated by hypovolemia.

Antidiabetic agents: Glucose tolerance may be decreased.

Antihypertensive agents: Hypotensive effects may be enhanced.

Cholestyramine or colestipol may reduce bioavailability of bumetanide.

Digoxin: Bumetanide-induced hypokalemia may predispose to digoxin toxicity; monitor potassium.

Indomethacin (and other NSAIDs) may reduce natriuretic and hypotensive effects of diuretics.

Lithium: Renal clearance may be reduced. Isolated reports of lithium toxicity have occurred; monitor lithium levels.

NSAIDs: Risk of renal impairment may increase when used in conjunction with diuretics.

Ototoxic drugs (aminoglycosides, cis-platinum): Concomitant use of bumetanide may increase risk of ototoxicity, especially in patients with renal dysfunction.

Peripheral adrenergic-blocking drugs or ganglionic blockers: Effects may be increased.

Salicylates (high dose) with diuretics may predispose patients to salicylate toxicity due to reduced renal excretion or alter renal function.

Thiazides: Synergistic diuretic effects occur.

Pregnancy Risk Factor C (manufacturer); D (expert analysis)

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Be alert to complaints about hearing difficulty

Additional Information Patients with impaired hepatic function must be monitored carefully, often requiring reduced doses; larger doses may be necessary in patients with impaired renal function to obtain the same therapeutic response; can cause elevation of parathyroid hormone; patients allergic to sulfonamides may show allergy to bumetanide

Specific References

Chobanian AV, Bakris GL, Black HR, et al, "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, 289(19):2560-71.

Bunazosin

CAS Number 80755-51-7

Use Antihypertensive agent

Unlabeled/Investigational Use Investigational in the United States

Mechanism of Action Selective alpha₁-receptor blocking agent

Adverse Reactions

Cardiovascular: Syncope (first dose), postural hypotension, tachycardia, palpitations, chest pain, vasodilation

Central nervous system: Headache, fatigue, dizziness, confusion, depression

Dermatologic: Urticaria

Gastrointestinal: Nausea, xerostomia, constipation

Ocular: Miosis, ptosis

Otic: Tinnitus

Signs and Symptoms of Overdose Hypotension, miosis, oliguria, tachycardia

Toxicodynamics/Kinetics

Protein binding: 97%

Metabolism: Hepatic

Bioavailability: Oral: 45%

Half-life: 12 hours

Elimination: Fecal: 60%; Renal: 40%

Dosage

Renal insufficiency: Initial: 3 mg

Sustained release: 6 mg once daily; maximum dose: 12 mg/day

Reference Range Maximum plasma bunazosin level after 6 mg dose: ~6 ng/mL

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral vasoconstrictor may be required (eg, norepinephrine

0.1-0.2 mcg/kg/minute titrated to response). Treatment is primarily supportive and symptomatic.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Pregnancy Implications No teratogenic effects noted

Bupivacaine

CAS Number 14252-80-3; 18010-40-7; 2180-92-9

U.S. Brand Names Marcaine® Spinal; Marcaine®; Sensorcaine®-MPF; Sensorcaine®

Synonyms Bupivacaine Hydrochloride

Use Local anesthetic (injectable) for peripheral nerve block, infiltration, sympathetic block, caudal or epidural block, retrobulbar block

Mechanism of Action Blocks both the initiation and conduction of nerve impulses by decreasing the neuronal membrane's permeability to sodium ions, which results in inhibition of depolarization with resultant blockade of conduction; a group II (amide) anesthetic

Adverse Reactions

Cardiovascular: Cardiac arrest, hypotension, bradycardia, palpitations, sinus bradycardia, arrhythmias (ventricular)

Central nervous system: Convulsions, restlessness, anxiety, dizziness, seizures

Gastrointestinal: Nausea, vomiting, metallic taste

Neuromuscular & skeletal: Weakness

Ocular: Blurred vision, diplopia, conjunctivitis

Otic: Ototoxicity, tinnitus

Respiratory: Apnea, rhinitis

Signs and Symptoms of Overdose Cardiac arrest, cardiac depression, coma, cyanosis, depression, disorientation, hypoglycemia, light-headedness, myopathy, nystagmus, ototoxicity, ptosis, seizures, tinnitus

Pharmacodynamics/Kinetics

Onset of action: Anesthesia (route and dose dependent): 1-17 minutes

Duration (route and dose dependent): 2-9 hours

Protein binding: ~95%

Metabolism: Hepatic; forms metabolite (PPX)

Half-life elimination (age dependent): Neonates: 8.1 hours; Adults: 1.5-5.5 hours

Excretion: Urine (~6% unchanged)

Dosage

Dose varies with procedure, depth of anesthesia, vascularity of tissues, duration of anesthesia and condition of patient. Metabisulfites (in epinephrine-containing injection); do not use solutions containing preservatives for caudal or epidural block.

Local anesthesia: Maximum dose: 2 mg/kg

Local anesthesia with epinephrine: Maximum dose: 3 mg/kg

Caudal block (with or without epinephrine):

Children: 1-3.7 mg/kg

Adults: 15-30 mL of 0.25% or 0.5%

Epidural block (other than caudal block):

Children: 1.25 mg/kg/dose

Adults: 10-20 mL of 0.25% or 0.5%

Peripheral nerve block: 5 mL dose of 0.25% or 0.5% (12.5-25 mg); maximum: 2.5 mg/kg (plain); 3 mg/kg (with epinephrine); up to a maximum of 400 mg/day

Sympathetic nerve block: 20-50 mL of 0.25% (no epinephrine) solution

Stability Solutions with epinephrine should be protected from light

Monitoring Parameters Monitor fetal heart rate during paracervical anesthesia

Administration

Solutions containing preservatives should not be used for epidural or caudal blocks.

Contraindications Hypersensitivity to bupivacaine hydrochloride, amide-type local anesthetics, or any component of the formulation; obstetrical paracervical block anesthesia

Warnings Use with caution in patients with hepatic impairment. Not recommended for use in children < 12 years of age. The solution for spinal anesthesia should not be used in children < 18 years of age. **Do not use solutions containing preservatives for caudal or epidural block.** Local anesthetics have been associated with rare occurrences of sudden respiratory arrest; convulsions due to systemic toxicity leading to cardiac arrest have also been reported, presumably following unintentional intravascular injection. **[U.S. Boxed Warning]: The 0.75% is not recommended for obstetrical anesthesia.** A test dose is recommended prior to epidural administration (prior to initial dose) and all reinforcing doses with continuous catheter technique. Use caution with cardiovascular dysfunction. Use caution in debilitated, elderly, or acutely ill patients; dose reduction may be required.

Dosage Forms

Injection, solution, as hydrochloride [preservative free]: 0.25% [2.5 mg/mL] (10 mL, 20 mL, 30 mL, 50 mL); 0.5% [5 mg/mL] (10 mL, 20 mL, 30 mL); 0.75% [7.5 mg/mL] (10 mL, 20 mL, 30 mL)

Marcaine®: 0.25% [2.5 mg/mL] (10 mL, 30 mL); 0.5% [5 mg/mL] (10 mL, 30 mL); 0.75% [7.5 mg/mL] (10 mL, 30 mL)

BUPRENORPHINE

Marcaïne® Spinal: 0.75% [7.5 mg/mL] (2 mL) [in dextrose 8.25%]
Sensorcaïne®-MPF: 0.25% [2.5 mg/mL] (10 mL, 30 mL); 0.5% [5 mg/mL]
(10 mL, 30 mL); 0.75% [7.5 mg/mL] (10 mL, 30 mL)
Injection, solution, as hydrochloride (Marcaïne®, Sensorcaïne®): 0.25%
[2.5 mg/mL] (50 mL); 0.5% [5 mg/mL] (50 mL) [contains methylparaben]
Reference Range Therapeutic plasma levels: <3 mcg/mL

Overdosage/Treatment

Supportive therapy: Treatment is primarily symptomatic and supportive.
Termination of anesthesia by pneumatic tourniquet inflation should be attempted when the agent is administered by infiltration or regional injection. Seizures commonly respond to diazepam or lorazepam, while hypotension responds to I.V. fluids and Trendelenburg positioning. Bradyarrhythmias (when the heart rate is less than 60) can be treated with I.V., or SubQ atropine 15 mcg/kg. With the development of metabolic acidosis, I.V. sodium bicarbonate 0.5-2 mEq/kg and ventilatory assistance should be instituted.

Intravenous lipid infusions (100 mL of a 20% lipid infusion bolus) with one mg of atropine and one mg of epinephrine IV followed by a 0.5 mL/kg/min infusion over 2 hours has been used to resuscitate a patient successfully from a cardiac arrest. Propofol (100 mg I.V.) can be used as a secondary agent to treat seizures.

Drug Interactions **Substrate** (minor) of CYP1A2, 2C19, 2D6, 3A4

Pregnancy Risk Factor C

Pregnancy Implications Can result in fetal bradycardia and fetal death

Lactation Enters breast milk/not recommended

Additional Information Metabisulfites (in epinephrine-containing injection); do not use solutions containing preservatives for caudal or epidural block

Buprenorphine

CAS Number 52485-79-7; 53152-21-9

U.S. Brand Names Buprenex®; Subutex®

Synonyms Buprenorphine Hydrochloride

Impairment Potential Yes

Use

Injection: Management of moderate to severe pain

Tablet: Treatment of opioid dependence

Unlabeled/Investigational Use Injection: Heroin and opioid withdrawal

Mechanism of Action Opiate agonist/antagonist that produces analgesia by binding to kappa and mu opiate receptors in the CNS

Adverse Reactions

Injection:

- Cardiovascular: Bradycardia, cyanosis, flushing, hypertension, hypotension, pallor, tachycardia, Wenckebach block
Central nervous system: **Sedation**, agitation, coma, confusion, convulsion, depersonalization, depression, dizziness, dysphoria, euphoria, fatigue, hallucinations, headache, malaise, nervousness, psychosis, respiratory depression, slurred speech, vertigo
Dermatologic: Pruritus, rash, urticaria
Gastrointestinal: Appetite increased, constipation, flatulence, nausea, vomiting, xerostomia
Genitourinary: Urinary retention
Local: Injection site reaction
Neuromuscular & skeletal: Paresthesia, tremor, weakness
Ocular: Blurred vision, diplopia, miosis
Otic: Tinnitus
Respiratory: Apnea
Miscellaneous: Diaphoresis, allergic reaction

Tablet:

- Central nervous system: **Anxiety**, chills, **depression** dizziness, fever, **headache**, **insomnia**, nervousness, **pain**, somnolence
Gastrointestinal: **Abdominal pain**, **constipation**, diarrhea, dyspepsia, **nausea**, vomiting
Neuromuscular & skeletal: **Back pain**, **weakness**, rhabdomyolysis
Ocular: Lacrimation
Respiratory: Cough, pharyngitis, **rhinitis**
Miscellaneous: **Diaphoresis**, flu-like syndrome, **infection**, **withdrawal syndrome**

Signs and Symptoms of Overdose Bradycardia, CNS depression, depression, dysphoria, hypotension, pinpoint pupils

Pharmacodynamics/Kinetics

Onset of action: Analgesic: 10-30 minutes

Duration: 6-8 hours

Absorption: I.M., SubQ: 30% to 40%

Distribution: V_d : 97-187 L/kg

Protein binding: High

Metabolism: Primarily hepatic; extensive first-pass effect

Half-life elimination: 2.2-3 hours

Excretion: Feces (70%); urine (20% as unchanged drug)

Dosage Long-term use is not recommended

Note: These are guidelines and do not represent the maximum doses that may be required in all patients. Doses should be titrated to pain relief/prevention. In high-risk patients (eg, elderly, debilitated, presence of respiratory disease) and/or concurrent CNS depressant use, reduce dose by one-half. Buprenorphine has an analgesic ceiling.

Acute pain (moderate to severe):

Children 2-12 years: I.M., slow I.V.: 2-6 mcg/kg every 4-6 hours

Children \geq 13 years and Adults:

I.M.: Initial: Opiate-naïve: 0.3 mg every 6-8 hours as needed; initial dose (up to 0.3 mg) may be repeated once in 30-60 minutes after the initial dose if needed; usual dosage range: 0.15-0.6 mg every 4-8 hours as needed

Slow I.V.: Initial: Opiate-naïve: 0.3 mg every 6-8 hours as needed; initial dose (up to 0.3 mg) may be repeated once in 30-60 minutes after the initial dose if needed

Elderly: 0.15 mg every 6 hours; elderly patients are more likely to suffer from confusion and drowsiness compared to younger patients

Heroin or opiate withdrawal (unlabeled use): Children \geq 13 years and Adults: I.M., slow I.V.: Variable; 0.1-0.4 mg every 6 hours

Sublingual: Children \geq 16 years and Adults: Opioid dependence:

Induction: Range: 12-16 mg/day (doses during an induction study used 8 mg on day 1, followed by 16 mg on day 2; induction continued over 3-4 days). Treatment should begin at least 4 hours after last use of heroin or short-acting opioid, preferably when first signs of withdrawal appear. Titrating dose to clinical effectiveness should be done as rapidly as possible to prevent undue withdrawal symptoms and patient drop-out during the induction period.

Maintenance: Target dose: 16 mg/day; range: 4-24 mg/day; patients should be switched to the buprenorphine/naloxone combination product for maintenance and unsupervised therapy

Stability Tablet: Store at room temperature of 25°C (77°F).

Injection: Protect from excessive heat of >40°C (>104°F) and light.

Monitoring Parameters Pain relief, respiratory and mental status, CNS depression, blood pressure

Administration

I.V.: Administer slowly, over at least 2 minutes.

Sublingual: Tablet should be placed under the tongue until dissolved; should not be swallowed. If 2 or more tablets are needed per dose, all may be placed under the tongue at once, or 2 at a time; to ensure consistent bioavailability, subsequent doses should always be taken the same way.

Contraindications Hypersensitivity to buprenorphine or any component of the formulation

Warnings

An opioid-containing analgesic regimen should be tailored to each patient's needs and based upon the type of pain being treated (acute versus chronic), the route of administration, degree of tolerance for opioids (naïve versus chronic user), age, weight, and medical condition. The optimal analgesic dose varies widely among patients. Doses should be titrated to pain relief/prevention.

May cause respiratory depression - use caution in patients with respiratory disease or pre-existing respiratory depression. Potential for drug dependency exists, abrupt cessation may precipitate withdrawal. Use caution in elderly, debilitated, or pediatric patients. Use with caution in patients with depression or suicidal tendencies, or in patients with a history of drug abuse. Tolerance, psychological and physical dependence may occur with prolonged use. Use with caution in patients with hepatic, pulmonary, or renal function impairment. May cause CNS depression, which may impair physical or mental abilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Effects with other sedative drugs or ethanol may be potentiated. Elderly may be more sensitive to CNS depressant and constipating effects. Use with caution in patients with head injury or increased ICP, biliary tract dysfunction, pancreatitis, patients with history of ileus or bowel obstruction, glaucoma, hyperthyroidism, adrenal insufficiency, prostatic hyperplasia, urinary stricture, CNS depression, toxic psychosis, alcoholism, delirium tremens, or kyphoscoliosis. Partial antagonist activity may precipitate acute narcotic withdrawal in opioid-dependent individuals. Tablets, which are used for induction treatment of opioid dependence, should not be started until effects of withdrawal are evident.

Dosage Forms

Injection, solution (Buprenex®): 0.3 mg/mL (1 mL)

Tablet, sublingual (Subutex®): 2 mg, 8 mg

Additional dosage strength available in Canada: 0.4 mg

Reference Range

I.V. dose of 0.3 mg results in a plasma buprenorphine level of 0.5 mcg/L

Postmortem blood buprenorphine and norbuprenorphine levels in buprenorphine-related fatalities among opiate addicts ranged from 1.1-29 ng/mL (mean 8.4 ng/mL) and 0.2-12.6 ng/mL (mean 2.6 ng/mL), respectively.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal for oral ingestion

Supportive therapy: Naloxone in large doses (5-10 mg) and/or a continuous infusion may be necessary to reverse respiratory depression. As much as 10 mg of naloxone may be required to reverse sedation.

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Test Interactions

↑ amylase, lipase

Drug Interactions

Substrate of CYP3A4 (major); **Inhibits** CYP1A2 (weak), 2A6 (weak), 2C19 (weak), 2D6 (weak)

Cimetidine: May increase sedation from narcotic analgesics; however, histamine blockers may attenuate the cardiovascular response from histamine release associated with narcotic analgesics.

CNS depressants: May produce additive respiratory and CNS depression; includes benzodiazepines, barbiturates, ethanol, and other sedatives. Respiratory and CV collapse was reported in a patient who received diazepam and buprenorphine.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of buprenorphine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of buprenorphine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quiniidine, and verapamil.

Naltrexone: May antagonize the effect of narcotic analgesics; concurrent use or use within 7-10 days of injection for pain relief is contraindicated.

Pregnancy Risk Factor C

Pregnancy Implications Withdrawal has been reported in infants of women receiving buprenorphine during pregnancy. Onset of symptoms ranged from day 1 to day 8 of life, most occurring on day 1.

Lactation Enters breast milk/not recommended

Nursing Implications Gradual withdrawal of drug is necessary to avoid withdrawal symptoms

Additional Information

Buprenorphine injection: 0.4 mg = 10 mg morphine or 75 mg meperidine, has longer duration of action than either agent

Subutex® (buprenorphine) should be limited to supervised use whenever possible; patients should be switched to Suboxone® (buprenorphine/naloxone) for maintenance and unsupervised therapy

BuPROPion

Related Information

- Antidepressant Agents
- Drugs Used in Addiction Treatment
- Therapeutic Drugs Associated with Hallucinations

CAS Number 31677-93-7; 34911-55-2

U.S. Brand Names Wellbutrin SR®; Wellbutrin XL™; Wellbutrin®; Zyban®

Use Treatment of depression; adjunct in smoking cessation

Unlabeled/Investigational Use Attention-deficit/hyperactivity disorder (ADHD); depression associated with bipolar disorder

Mechanism of Action Bupropion is an antidepressant structurally different from all other previously marketed antidepressants; like other antidepressants the mechanism of bupropion's activity is not fully understood; the drug is a weak blocker of serotonin and norepinephrine re-uptake, inhibits neuronal dopamine re-uptake and is not a monoamine oxidase A or B inhibitor

Adverse Reactions

Cardiovascular: Arrhythmias, atrioventricular block, chest pain, extrasystoles, facial edema, flushing, hypertension (may be severe), hypotension, myocardial infarction, pallor, palpitations, peripheral edema, postural hypotension, syncope, tachycardia, vasodilation

Central nervous system: **Dizziness, headache, insomnia,** akinesia, agitation, alopecia, amnesia, anxiety, aphasia, ataxia, coma, confusion, coordination abnormal, delirium, depersonalization, depression, derealization, dysphoria, dystonia, EEG abnormality, emotional lability, euphoria, extrapyramidal syndrome, fever with rash (and other symptoms suggestive of delayed hypersensitivity resembling serum sickness), hallucinations, hostility, hypesthesia, hypokinesia, hypomania, irritability, malaise, manic reaction, memory decreased, migraine, nervousness, paranoid reaction, seizure, sleep disturbance, somnolence, stroke, suicidal ideation, tardive dyskinesia, vertigo

Dermatologic: Angioedema, dry skin, ecchymosis, exfoliative dermatitis, hirsutism, maculopapular rash, photosensitivity, pruritus, rash, urticaria

Endocrine & metabolic: Gynecomastia, hot flashes, hyperglycemia, hypoglycemia, impotence, libido decreased, libido increased, menstrual complaints, SIADH

Gastrointestinal: **Nausea, xerostomia,** abdominal pain, anorexia, appetite increased, colitis, constipation, diarrhea, dyspepsia, dysphagia, esophagitis, gastric reflux, gastrointestinal hemorrhage, gingivitis, glossitis, gum hemorrhage, intestinal perforation, mouth ulcers, pancreatitis, salivation increased, stomach ulcer, stomatitis, taste perversion, tongue edema, vomiting

Genitourinary: Cystitis, dyspareunia, dysuria, ejaculation abnormality, enuresis, nocturia, painful erection, testicular swelling, urinary frequency, urinary incontinence, urinary retention, vaginal irritation, vaginitis

Hematologic: Anemia, leukocytosis, leukopenia, pancytopenia, thrombocytopenia

Hepatic: Hepatic damage, hepatitis, jaundice

Local: Phlebitis

Neuromuscular & skeletal: Arthralgia, arthritis, ballismus, dysarthria, dyskinesia, hyperkinesia, hypertonia, leg cramps, muscle rigidity, muscle weakness, myalgia, musculoskeletal chest pain, myoclonus, neck pain, neuralgia, neuropathy, paresthesia, rhabdomyolysis, tremor, twitching

Ocular: Accommodation abnormality, amblyopia, blurred vision, diplopia, dry eye, mydriasis

Otic: Auditory disturbance, deafness, tinnitus

Renal: Glycosuria, polyuria
 Respiratory: **Pharyngitis**, bronchospasm, chills, cough increased, dyspnea, epistaxis, pulmonary embolism, sinusitis
 Miscellaneous: Allergic reaction (including anaphylaxis, pruritus, urticaria), bruxism, frigidity, increased diaphoresis, infection, lymphadenopathy, salpingitis, sciatica, thirst

Note: Data for the immediate-release formulation of bupropion revealed a seizure incidence of 0.4% in patients treated at doses in the 300-450 mg/day range. The estimated seizure incidence increases almost tenfold between 450 mg and 600 mg per day. Data for the sustained release dosage form revealed a seizure incidence of 0.1% in patients treated at a dosage range of 100-300 mg/day, and increases to ~0.4% at the maximum recommended dose of 400 mg/day.

Signs and Symptoms of Overdose Arched back, ataxia, confusion, delirium, fever, hypokalemia, hypophosphatemia, impotence, insomnia, labored breathing, leukopenia, mania, muscle rigidity, Parkinson's-like symptoms, salivation, seizures (21%), sinus tachycardia, slurred speech, vomiting

Admission Criteria/Prognosis Asymptomatic pediatric ingestions <200 mg may be discharged.

Pharmacodynamics/Kinetics

Absorption: Rapid
 Distribution: V_d : 19-21 L/kg
 Protein binding: 82% to 88%
 Metabolism: Extensively hepatic via CYP2B6 to hydroxybupropion; non-CYP-mediated metabolism to erythrohydrobupropion and threohydrobupropion. Metabolite activity ranges from 20% to 50% potency of bupropion.
 Bioavailability: 5% to 20% in animals
 Half-life:
 Distribution: 3-4 hours
 Elimination: 21 ± 9 hours; Metabolites: Hydroxybupropion: 20 ± 5 hours; Erythrohydrobupropion: 33 ± 10 hours; Threohydrobupropion: 37 ± 13 hours
 Time to peak, serum: Bupropion: ~3 hours; bupropion extended release: ~5 hours
 Metabolites: Hydroxybupropion, erythrohydrobupropion, threohydrobupropion: 6 hours
 Excretion: Urine (87%); feces (10%)

Dosage

Oral:
 Children and Adolescents: ADHD (unlabeled use): 1.4-6 mg/kg/day
 Adults:
 Depression:
 Immediate release: 100 mg 3 times/day; begin at 100 mg twice daily; may increase to a maximum dose of 450 mg/day
 Sustained release: Initial: 150 mg/day in the morning; may increase to 150 mg twice daily by day 4 if tolerated; target dose: 300 mg/day given as 150 mg twice daily; maximum dose: 400 mg/day given as 200 mg twice daily
 Extended release: Initial: 150 mg/day in the morning; may increase as early as day 4 of dosing to 300 mg/day; maximum dose: 450 mg/day
 Smoking cessation (Zyban®): Initiate with 150 mg once daily for 3 days; increase to 150 mg twice daily; treatment should continue for 7-12 weeks

Elderly: Depression: 50-100 mg/day, increase by 50-100 mg every 3-4 days as tolerated; there is evidence that the elderly respond at 150 mg/day in divided doses, but some may require a higher dose

Dosing adjustment/comments in renal impairment: Effect of renal disease on bupropion's pharmacokinetics has not been studied; elimination of the major metabolites of bupropion may be affected by reduced renal function. Patients with renal failure should receive a reduced dosage initially and be closely monitored.

Dosing adjustment in hepatic impairment:

Note: The mean AUC increased by ~1.5-fold for hydroxybupropion and ~2.5-fold for erythro/threohydrobupropion; median T_{max} was observed 19 hours later for hydroxybupropion, 31 hours later for erythro/threohydrobupropion; mean half-life for hydroxybupropion increased fivefold, and increased twofold for erythro/threohydrobupropion in patients with severe hepatic cirrhosis compared to healthy volunteers.

Mild to moderate hepatic impairment: Use with caution and/or reduced dose/frequency

Severe hepatic cirrhosis: Use with extreme caution; maximum dose:
 Wellbutrin®: 75 mg/day
 Wellbutrin SR®: 100 mg/day or 150 mg every other day
 Wellbutrin XL™: 150 mg every other day
 Zyban®: 150 mg every other day

Stability Store at controlled temperature of 20°C to 25°C (68°F to 77°F).

Monitoring Parameters Body weight; mental status for depression, suicidal ideation (especially at the beginning of therapy or when doses are increased or decreased), anxiety, social functioning, mania, panic attacks

Administration

May be taken without regard to meals. Sustained and extended release tablets should be swallowed whole; do not crush, chew, or divide. The insoluble shell of the extended-release tablet may remain intact during GI transit and is eliminated in the feces.

Contraindications Hypersensitivity to bupropion or any component of the formulation; seizure disorder; anorexia/bulimia; use of MAO inhibitors within 14 days; patients undergoing abrupt discontinuation of ethanol or sedatives (including benzodiazepines); patients receiving other dosage forms of bupropion

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. **Bupropion is not FDA approved for use in children.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Bupropion is not FDA approved for bipolar depression.**

The risk of seizures is dose-dependent and increased in patients with a history of seizures, anorexia/bulimia, head trauma, CNS tumor, severe hepatic cirrhosis, abrupt discontinuation of sedative-hypnotics or ethanol, medications which lower seizure threshold (antipsychotics, antidepressants, theophyllines, systemic steroids), stimulants, or hypoglycemic agents. Discontinue and do not restart in patients experiencing a seizure. May cause CNS stimulation (restlessness, anxiety, insomnia) or anorexia. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. May cause weight loss; use caution in patients where weight loss is not desirable. The incidence of sexual dysfunction with bupropion is generally lower than with SSRIs.

Use caution in patients with cardiovascular disease, history of hypertension, or coronary artery disease; treatment-emergent hypertension (including some severe cases) has been reported, both with bupropion alone and in combination with nicotine transdermal systems. Use with caution in patients with hepatic or renal dysfunction and in elderly patients; reduced dose recommended. Elderly patients may be at greater risk of accumulation during chronic dosing. May cause motor or cognitive impairment in some patients; use with caution if tasks requiring alertness such as operating machinery or driving are undertaken. Arthralgia, myalgia, and fever with rash and other symptoms suggestive of delayed hypersensitivity resembling serum sickness reported.

Extended release tablet: Insoluble tablet shell may remain intact and be visible in the stool.

Dosage Forms

Tablet, as hydrochloride (Wellbutrin®): 75 mg, 100 mg
 Tablet, extended release, as hydrochloride:
 Budeprion™ SR: 100 mg [contains tartrazine; equivalent to Wellbutrin® SR], 150 mg [equivalent to Wellbutrin® SR]
 Buproban™: 150 mg [equivalent to Zyban®]
 Wellbutrin XL™: 150 mg, 300 mg
 Tablet, sustained release, as hydrochloride: 100 mg, 150 mg [equivalent to Wellbutrin® SR], 150 mg [equivalent to Zyban®]
 Wellbutrin® SR: 100 mg, 150 mg, 200 mg
 Zyban®: 150 mg

Reference Range Blood levels > 170 ng/mL associated with seizures and therapeutic level is 50-100 ng/mL; level of 446 ng/mL associated with a fatality

Overdosage/Treatment

Decontamination: Lavage (within 12 hours)/activated charcoal
Supportive therapy: I.V. diazepam or lorazepam is useful in treating seizures

Enhancement of elimination: Multiple dose of activated charcoal may be useful

Test Interactions May lower serum potassium; fluoxetine can interfere with bupropion quantitation by HPLC analysis in plasma or serum

Drug Interactions

Substrate of CYP1A2 (minor), 2A6 (minor), 2B6 (major), 2C9 (minor), 2D6 (minor), 2E1 (minor), 3A4 (minor); **Inhibits** CYP2D6 (weak)

Note: Seizure threshold-lowering agents: Use with caution in individuals receiving other agents that may lower seizure threshold (antipsychotics, antidepressants, fluoroquinolones, theophylline, abrupt discontinuation of benzodiazepines, systemic steroids)

Amantadine: Concurrent use appears to result in a higher incidence of adverse effects; use caution.

CNS depressants: Concomitant use may increase adverse effects/toxicity.

CYP2B6 inducers: May decrease the levels/effects of bupropion. Example inducers include carbamazepine, nevirapine, phenobarbital, phenytoin, and rifampin.

CYP2B6 inhibitors: May increase the levels/effects of bupropion. Example inhibitors include desipramine, paroxetine, and sertraline.

Levodopa: Toxicity of bupropion is enhanced by levodopa.

MAO inhibitors: Toxicity of bupropion is enhanced by MAO inhibitors (phenelzine); concurrent use is contraindicated.

Nicotine: Treatment-emergent hypertension may occur; monitor BP in patients treated with bupropion and nicotine patch.

Selegiline: When used in low doses (<10 mg/day), risk of interaction is theoretically lower than with nonselective MAO inhibitors.

Tricyclic antidepressants: Serum levels may be increased by bupropion; in addition, these agents lower seizure threshold (see Note).

Pregnancy Risk Factor B

Pregnancy Implications A slight increase in malformations was observed in some animal studies. The manufacturer provides results from a retrospective database study conducted in women taking bupropion during pregnancy. The study showed no greater risk of congenital malformations following bupropion exposure in comparison to other antidepressant agents. There are no adequate and well-controlled studies in pregnant women. Bupropion should be used during pregnancy only if the potential benefit outweighs the possible risks. A registry has been established for women exposed to bupropion during pregnancy (800-336-2176).

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Nursing Implications Be aware that drug may cause seizures

BusPIRone

CAS Number 33386-08-2; 36505-84-7

U.S. Brand Names BuSpar®

Synonyms Buspirone Hydrochloride

Use Management of generalized anxiety disorder (GAD); treat bruxism induced by serotonin reuptake inhibitors

Unlabeled/Investigational Use Management of aggression in mental retardation and secondary mental disorders; major depression; potential augmenting agent for antidepressants; premenstrual syndrome

Mechanism of Action Selectively antagonizes CNS serotonin 5-HT_{1A} receptors without affecting benzodiazepine-GABA receptors; an azaspirodecanedione derivative with lower potential for addition or sedation than other anxiolytics

Adverse Reactions

Cardiovascular: Bradycardia, sinus bradycardia, palpitations, sinus tachycardia

Central nervous system: Sedation, disorientation, excitation, **dizziness**, dysphoria (at doses > 40 mg), extrapyramidal signs, **lightheadedness**, panic attacks, mania, fever, **headache**, ataxia, psychosis

Dermatologic: Rash, acne, alopecia, bullous skin disease, xerosis, urticaria, seborrheic dermatitis, pruritus, exanthema

Gastrointestinal: **Nausea**, vomiting, diarrhea, flatulence

Genitourinary: Urinary frequency

Hematologic: Leukopenia, eosinophilia

Hepatic: Elevated liver function test results

Neuromuscular & skeletal: Paresthesia, clonus, myoclonus

Ocular: Miosis

Respiratory: Nasal congestion

Signs and Symptoms of Overdose Agranulocytosis, bradycardia, depression, dizziness, drowsiness, dysphoria, dry mouth, extrapyramidal reaction, granulocytopenia, hyperprolactinemia, leukopenia, lightheadedness, memory loss, nausea, neutropenia, pinpoint pupils, seizures, vomiting

Pharmacodynamics/Kinetics

Absorption: Oral: ~100%

Distribution: V_d: 5.3 L/kg

Protein binding: 95%

Metabolism: Hepatic via oxidation; extensive first-pass effect

Bioavailability: ~4%

Half-life elimination: Mean: 2.4 hours (range: 2-11 hours)

Time to peak, serum: Within 0.7-1.5 hours

Excretion: Urine: 65%; feces: 35%; ~1% dose excreted unchanged

Dosage

Oral:

Generalized anxiety disorder:

Children and Adolescents: Initial: 5 mg daily; increase in increments of 5 mg/day at weekly intervals as needed, to a maximum dose of 60 mg/day divided into 2-3 doses

Adults: 15 mg/day (7.5 mg twice daily); may increase in increments of 5 mg/day every 2-4 days to a maximum of 60 mg/day; target dose for most people is 30 mg/day (15 mg twice daily)

Bruxism: 5 mg every night at bedtime

Dosing adjustment in renal or hepatic impairment: Buspirone is metabolized by the liver and excreted by the kidneys. Patients with impaired hepatic or renal function demonstrated increased plasma levels and a prolonged half-life of buspirone. Therefore, use in patients with severe hepatic or renal impairment cannot be recommended.

Monitoring Parameters Mental status, symptoms of anxiety

Contraindications Hypersensitivity to buspirone or any component of the formulation

Warnings Use in hepatic or renal impairment is not recommended; does not prevent or treat withdrawal from benzodiazepines. Low potential for

BUSULFAN

cognitive or motor impairment. Use with MAO inhibitors may result in hypertensive reactions.

Dosage Forms

Tablet, as hydrochloride: 5 mg, 7.5 mg, 10 mg, 15 mg, 30 mg
BuSpar®: 5 mg, 10 mg, 15 mg, 30 mg

Reference Range Peak plasma levels ≤ 6 ng/mL noted up to 90 minutes after a 20 mg dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: There is no known antidote for buspirone and most therapies are supportive and symptomatic in nature; diazepam or lorazepam may be used for seizures
Enhancement of elimination: Multiple dosing of activated charcoal would not be expected to be useful

Test Interactions \uparrow AST, ALT

Drug Interactions

Substrate of CYP2D6 (minor), 3A4 (major)

Calcium channel blockers: Diltiazem and verapamil may increase serum concentrations of buspirone; consider a dihydropyridine calcium channel blocker.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of buspirone. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of buspirone. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

MAO inhibitors: Buspirone should not be used concurrently with an MAO inhibitor due to reports of increased blood pressure; includes classic MAO inhibitors and linezolid (due to ability to inhibit MAO).

Nefazodone: Concurrent use may increase risk of CNS adverse events. Limit buspirone initial dose (eg, 2.5 mg/day).

Selegiline: Theoretically, risk of interaction with selective MAO type B inhibitor would be less than with nonselective inhibitors; however, this combination is generally best avoided.

SSRIs: Concurrent use of buspirone with SSRIs may cause serotonin syndrome. Some SSRIs may increase buspirone serum concentrations (see CYP3A4 inhibitors). Buspirone may increase the efficacy of fluoxetine in some patients; however, the anxiolytic activity of buspirone may be lost when combined with SSRIs (fluoxetine).

Trazodone: Concurrent use of buspirone with trazodone may cause serotonin syndrome.

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Monitor patient's mental status and for benzodiazepine withdrawal; food may increase the bioavailability of the drug

Additional Information Has shown little potential for abuse; related to ipsapirone; unpleasant taste; buspirone (15-60 mg/day) may be useful in treatment of sexual dysfunction during treatment with a selective serotonin reuptake inhibitor

Busulfan

CAS Number 55-98-1

U.S. Brand Names Busulfex®; Myleran®

Use

Oral: Chronic myelogenous leukemia and bone marrow disorders, such as polycythemia vera and myeloid metaplasia, conditioning regimens for bone marrow transplantation

I.V.: Combination therapy with cyclophosphamide as a conditioning regimen prior to allogeneic hematopoietic progenitor cell transplantation for chronic myelogenous leukemia

Unlabeled/Investigational Use Oral: Bone marrow disorders, such as polycythemia vera and myeloid metaplasia; thrombocytosis

Mechanism of Action Reacts with N-7 position of guanosine and interferes with DNA replication and transcription of RNA (an alkylating agent). Busulfan has a more marked effect on myeloid cells (and is, therefore, useful in the treatment of CML) than on lymphoid cells. The drug is also very toxic to hematopoietic stem cells (thus its usefulness in high doses in BMT preparative regimens). Busulfan exhibits little immunosuppressive activity. Interferes with the normal function of DNA by alkylation and cross-linking the strands of DNA.

Adverse Reactions

Cardiovascular: Pericardial fibrosis, pericardial effusion/pericarditis, endocardial fibrosis

Central nervous system: Dizziness, seizures, **generalized or myoclonic seizures and loss of consciousness have been associated with high-dose busulfan (4 mg/kg/day)**

Dermatologic: **Hyperpigmentation, alopecia**, dermal irritant, rash, **urticaria, erythema**

Endocrine & metabolic: Addison-like syndrome, hyperuricemia, **amenorrhea, ovarian suppression, malignant tumors have been reported in patients on busulfan therapy, sterility, ovarian failure**

Gastrointestinal: **Nausea, vomiting, diarrhea**, mucositis

Genitourinary: Hemorrhagic cystitis, **azoospermia, testicular atrophy**

Hematologic: Porphyria; **myelosuppression with nadirs of 14-21 days for leukopenia and thrombocytopenia; anemia, severe pancytopenia, bone marrow suppression**; since this is a delayed effect (busulfan affects the stem cells), the drug should be discontinued temporarily at the first sign of a large or rapid fall in any blood element. Some patients may develop bone marrow fibrosis or chronic aplasia which is probably due to the busulfan toxicity. In large doses, busulfan is myeloablative and is used for this reason in BMT.

Hepatic: Hepatic dysfunction, hepatic veno-occlusive disease, elevated liver function test results

Ocular: Blurred vision, **cataract formation**

Respiratory: After long-term or high-dose therapy, a syndrome known as busulfan lung may occur; this syndrome is manifested by a diffuse interstitial pulmonary fibrosis and persistent cough, fever, rales, and dyspnea; may be relieved by corticosteroids

Miscellaneous: Kaposi's sarcoma

Signs and Symptoms of Overdose Agranulocytosis, cataract, cholestatic jaundice, CNS depression, erythema multiforme, granulocytopenia, hematuria, hyperuricemia, leukopenia, myoclonus, neutropenia, periarthritis nodosa, seizures, sexual dysfunction

Pharmacodynamics/Kinetics

Duration: 28 days

Absorption: Rapid and complete

Distribution: V_d : ~ 1 L/kg; into CSF and saliva with levels similar to plasma

Protein binding: $\sim 14\%$

Metabolism: Extensively hepatic (may increase with multiple doses)

Half-life elimination: After first dose: 3.4 hours; After last dose: 2.3 hours

Time to peak, serum: Oral: Within 4 hours; I.V.: Within 5 minutes

Excretion: Urine (10% to 50% as metabolites) within 24 hours ($< 2\%$ as unchanged drug)

Dosage

Busulfan should be based on adjusted ideal body weight because actual body weight, ideal body weight, or other factors can produce significant differences in busulfan clearance among lean, normal, and obese patients; refer to individual protocols

Children:

For remission induction of CML: Oral: 0.06-0.12 mg/kg/day **OR** 1.8-4.6 mg/m²/day; titrate dosage to maintain leukocyte count above 40,000/mm³; reduce dosage by 50% if the leukocyte count reaches 30,000-40,000/mm³; discontinue drug if counts fall to $\leq 20,000/mm^3$

BMT marrow-ablative conditioning regimen:

Oral: 1 mg/kg/dose (ideal body weight) every 6 hours for 16 doses I.V.:

≤ 12 kg: 1.1 mg/kg/dose (ideal body weight) every 6 hours for 16 doses

> 12 kg: 0.8 mg/kg/dose (ideal body weight) every 6 hours for 16 doses
Adjust dose to desired AUC [1125 $\mu\text{mol}(\text{min})$] using the following formula:
Adjusted dose (mg) = Actual dose (mg) \times [target AUC $\mu\text{mol}(\text{min})$ / actual AUC $\mu\text{mol}(\text{min})$]

Adults:

For remission induction of CML: Oral: 4-8 mg/day (may be as high as 12 mg/day); Maintenance doses: Controversial, range from 1-4 mg/day to 2 mg/week; treatment is continued until WBC reaches 10,000-20,000 cells/mm³ at which time drug is discontinued; when WBC reaches 50,000/mm³, maintenance dose is resumed

BMT marrow-ablative conditioning regimen:

Oral: 1 mg/kg/dose (ideal body weight) every 6 hours for 16 doses I.V.: 0.8 mg/kg (ideal body weight or actual body weight, whichever is lower) every 6 hours for 4 days (a total of 16 doses)

I.V. dosing in morbidly obese patients: Dosing should be based on adjusted ideal body weight (AIBW) which should be calculated as ideal body weight (IBW) + 0.25 times (actual weight minus ideal body weight)

AIBW = IBW + 0.25 \times (AW - IBW)

Cyclophosphamide, in combination with busulfan, is given on each of two days as a 1-hour infusion at a dose of 160 mg/m² beginning on BMT day -3, 6 hours following the 16th dose of busulfan

Unapproved use:

Polycythemia vera: 2-6 mg/day

Thrombocytosis: 4-6 mg/day

Monitoring Parameters CBC with differential and platelet count, hemoglobin, liver function tests

Administration

Intravenous busulfan should be administered as a 2-hour infusion, every 6 hours for 4 consecutive days for a total of 16 doses.

BMT only: To facilitate ingestion of high oral doses, insert multiple tablets into gelatin capsules.

Contraindications Hypersensitivity to busulfan or any component of the formulation; failure to respond to previous courses; pregnancy

Warnings Hazardous agent - use appropriate precautions for handling and disposal. **[U.S. Boxed Warning]: May induce severe bone marrow hypoplasia.** Use caution in patients predisposed to seizures. Discontinue if lung toxicity develops. Busulfan has been causally related to the development of secondary malignancies (tumors and acute leukemias). Busulfan has been associated with ovarian failure (including failure to achieve puberty) in females. High busulfan area under the concentration versus time curve (AUC) values (> 1500 µM/minute) are associated with increased risk of hepatic veno-occlusive disease during conditioning for allogeneic BMT.

Dosage Forms

Injection, solution (Busulfex®): 6 mg/mL (10 mL)
Tablet (Myleran®): 2 mg

Reference Range Mean peak serum level of a busulfan dose of 1 mg/kg is ~1080 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Enhancement of elimination: Multiple dosing of charcoal may be effective

Antidote(s)

- Thrombopoietin [ANTIDOTE]

Drug Interactions Substrate of CYP3A4 (major)

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of busulfan. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of busulfan. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Itraconazole: May decrease busulfan clearance and increase risk of pulmonary toxicity; monitor.

Metronidazole: May increase busulfan plasma levels.

Other cytotoxic agents: Pulmonary toxicity may be additive.

Pregnancy Risk Factor D

Lactation Contraindicated

Nursing Implications Avoid I.M. injection if platelet count falls < 100,000/mm³

Additional Information Moderately radiopaque; alopecia is dose related

Specific References

Hoffer E, Akria L, Tabak A, et al, "A Simple Approximation for Busulfan Dose Adjustment in Adult Patients Undergoing Bone Marrow Transplantation," *Ther Drug Monit*, 2004, 26(3):331-5.

Duration: I.M., I.V.: 3-4 hours; Nasal: 4-5 hours

Absorption: Rapid and well absorbed

Protein binding: 80%

Metabolism: Hepatic

Bioavailability: Nasal: 60% to 70%

Half-life elimination: 2.5-4 hours

Excretion: Primarily urine

Dosage

Note: These are guidelines and do not represent the maximum doses that may be required in all patients. Doses should be titrated to pain relief/prevention. Butorphanol has an analgesic ceiling.

Adults:

Parenteral:

Acute pain (moderate to severe):

I.M.: Initial: 2 mg, may repeat every 3-4 hours as needed; usual range: 1-4 mg every 3-4 hours as needed

I.V.: Initial: 1 mg, may repeat every 3-4 hours as needed; usual range: 0.5-2 mg every 3-4 hours as needed

Preoperative medication: I.M.: 2 mg 60-90 minutes before surgery

Supplement to balanced anesthesia: I.V.: 2 mg shortly before induction and/or an incremental dose of 0.5-1 mg (up to 0.06 mg/kg), depending on previously administered sedative, analgesic, and hypnotic medications

Pain during labor (fetus >37 weeks gestation and no signs of fetal distress):

I.M., I.V.: 1-2 mg; may repeat in 4 hours

Note: Alternative analgesia should be used for pain associated with delivery or if delivery is anticipated within 4 hours

Nasal spray:

Moderate to severe pain (including migraine headache pain): Initial: 1 spray (~1 mg per spray) in 1 nostril; if adequate pain relief is not achieved within 60-90 minutes, an additional 1 spray in 1 nostril may be given; may repeat initial dose sequence in 3-4 hours after the last dose as needed

Alternatively, an initial dose of 2 mg (1 spray in each nostril) may be used in patients who will be able to remain recumbent (in the event drowsiness or dizziness occurs); additional 2 mg doses should not be given for 3-4 hours

Note: In some clinical trials, an initial dose of 2 mg (as 2 doses 1 hour apart or 2 mg initially - 1 spray in each nostril) has been used, followed by 1 mg in 1 hour; side effects were greater at these dosages

Dosage adjustment in renal impairment:

I.M., I.V.: Initial dosage should generally be 1/2 of the recommended dose; repeated dosing must be based on initial response rather than fixed intervals, but generally should be at least 6 hours apart

Nasal spray: Initial dose should not exceed 1 mg; a second dose may be given after 90-120 minutes

Dosage adjustment in hepatic impairment:

I.M., I.V.: Initial dosage should generally be 1/2 of the recommended dose; repeated dosing must be based on initial response rather than fixed intervals, but generally should be at least 6 hours apart

Nasal spray: Initial dose should not exceed 1 mg; a second dose may be given after 90-120 minutes

Elderly:

I.M., I.V.: Initial dosage should generally be 1/2 of the recommended dose; repeated dosing must be based on initial response rather than fixed intervals, but generally should be at least 6 hours apart

Nasal Spray: Initial dose should not exceed 1 mg; a second dose may be given after 90-120 minutes

Stability Store at room temperature, protect from freezing; **incompatible** when mixed in the same syringe with diazepam, dimenhydrinate, methohexital, pentobarbital, secobarbital, thiopental

Monitoring Parameters Pain relief, respiratory and mental status, blood pressure

Administration

Intranasal: Consider avoiding simultaneous intranasal migraine sprays; may want to separate by at least 30 minutes

Contraindications Hypersensitivity to butorphanol or any component of the formulation; avoid use in opiate-dependent patients who have not been detoxified, may precipitate opiate withdrawal; pregnancy (prolonged use or high doses at term)

Warnings An opioid-containing analgesic regimen should be tailored to each patient's needs and based upon the type of pain being treated (acute versus chronic), the route of administration, degree of tolerance for opioids (naive versus chronic user), age, weight, and medical condition. The optimal analgesic dose varies widely among patients. Doses should be titrated to pain relief/prevention. May cause CNS depression, which may impair physical or mental abilities. Effects with other sedative drugs or ethanol may be potentiated. Use with caution in patients with hepatic/renal dysfunction. Tolerance or drug dependence may result from extended use. Concurrent use of sumatriptan nasal spray and butorphanol nasal spray may increase risk of transient high blood pressure.

Butorphanol

CAS Number 42408-82-2; 58786-99-5

U.S. Brand Names Stadol® NS; Stadol®

Synonyms Butorphanol Tartrate

Impairment Potential Yes

Use

Parenteral: Management of moderate to severe pain; preoperative medication; supplement to balanced anesthesia; management of pain during labor

Nasal spray: Management of moderate to severe pain, including migraine headache pain

Mechanism of Action Mixed narcotic agonist-antagonist with central analgesic actions; binds to opiate receptors in the CNS (limbic system), causing inhibition of ascending pain pathways, altering the perception of and response to pain; produces generalized CNS depression

Adverse Reactions

Cardiovascular: Hypotension, flushing of the face, hypertension, bradycardia or tachycardia, sinus tachycardia

Central nervous system: CNS depression, anxiety, **drowsiness**, dizziness, lightheadedness, headache, agitation, malaise, restlessness, night terrors, confusion, hallucinations, false sense of well being, paradoxical CNS stimulation, acute psychosis

Dermatologic: Skin rash, pruritus

Gastrointestinal: Anorexia, nausea, vomiting, stomach cramps, constipation, xerostomia

Genitourinary: Decreased urination, painful urination

Neuromuscular & skeletal: Weakness

Ocular: Blurred vision

Otic: Ototoxicity, tinnitus

Respiratory: Apnea, respiratory depression, dyspnea

Miscellaneous: Dependence with prolonged use, diaphoresis (increased)

Signs and Symptoms of Overdose Biliary tract spasm, confusion, coma, diplopia, euphoria, disorientation, lightheadedness, night terrors, pulmonary hypertension

Pharmacodynamics/Kinetics

Onset of action: I.M.: 5-10 minutes; I.V.: < 10 minutes; Nasal: Within 15 minutes

Peak effect: I.M.: 0.5-1 hour; I.V.: 4-5 minutes

BUTRIPTYLINE

Dosage Forms

Injection, solution, as tartrate [preservative free] (Stadol®): 1 mg/mL (1 mL); 2 mg/mL (1 mL, 2 mL)

Injection, solution, as tartrate [with preservative] (Stadol®): 2 mg/mL (10 mL)

Solution, intranasal, as tartrate [spray]: 10 mg/mL (2.5 mL) [14-15 doses]

Reference Range

0.7-1.5 ng/mL

Overdose/Treatment

Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at $\frac{2}{3}$ the response dose/hour) may be required; naloxone (2 mg I.M.) has reversed intranasal butorphanol-induced apraxia

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Drug Interactions

Increased toxicity: CNS depressants, phenothiazines, barbiturates, skeletal muscle relaxants, alfentanil, guanabenz, and MAO inhibitors.

Pregnancy Risk Factor

C/D (prolonged use or high doses at term)

Pregnancy Implications

Crosses the placenta; sinusoidal fetal heart rate pattern described in two cases

Lactation

Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications

Raise bed rails; aid with ambulation

usually respond to lorazepam or diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required. Phenytoin is effective to decrease QRS complex interval. Do not use bretylium in hypotensive patients. Norepinephrine is effective for hypotension. Avoid procainamide or other type IA antiarrhythmics.

Additional Information

Less sedation than amitriptyline

Caffeine

Related Information

- Substance-Related Disorders

CAS Number 5743-12-4; 58-08-2; 69-22-7

U.S. Brand Names Cafcit®; Caffeine® [OTC]; Enerjets [OTC]; Lucidex [OTC]; No Doz® Maximum Strength [OTC]; Vivarin® [OTC]

Synonyms Caffeine and Sodium Benzoate; Caffeine Citrate; Sodium Benzoate and Caffeine

Use Central nervous system stimulant; treatment of idiopathic apnea of prematurity; has several advantages over theophylline in the treatment of neonatal apnea, half-life is ~3 times as long, allowing once daily dosing, drug levels do not need to be drawn at peak and trough; has a wider therapeutic window, allowing more room between an effective concentration and toxicity

Unlabeled/Investigational Use Caffeine and sodium benzoate: Treatment of spinal puncture headache; CNS stimulant; diuretic

Mechanism of Action Increases levels of 3-5-AMP by inhibiting phosphodiesterase; methyl xanthine, CNS stimulant which increases medullary respiratory center sensitivity to carbon dioxide, stimulates central inspiratory drive, and improves skeletal muscle contraction (diaphragmatic contractility)

Adverse Reactions

Cardiovascular: Flushing, chest pain, angina, palpitations, sinus tachycardia, tachycardia (supraventricular), arrhythmias (ventricular), vasodilation

Central nervous system: Headache, agitation, dizziness, delirium, hallucinations, insomnia, psychosis

Dermatologic: Urticaria

Gastrointestinal: Gastritis, decreased esophageal sphincter tone

Neuromuscular & skeletal: Fasciculations

Ocular: Miosis, increased intraocular pressure (> 180 mg caffeine)

Renal: Diuresis (<250 mg/day)

Signs and Symptoms of Overdose Delirium, diarrhea, hallucinations, hypercholesterolemia, hyperglycemia, hyperthermia, hypokalemia, hyponatremia, leukocytosis, insomnia, muscle twitching, myoglobinuria, nausea, premature ventricular contractions, rhabdomyolysis, seizures, tachycardia, tachycardia (ventricular), tinnitus, tremors, vomiting

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or ingestions >2 g should be admitted

Pharmacodynamics/Kinetics

Distribution: V_d :

Neonates: 0.8-0.9 L/kg

Children >9 months to Adults: 0.6 L/kg

Protein binding: 17% (children) to 36% (adults)

Metabolism: Hepatic, via demethylation by CYP1A2. **Note:** In neonates, interconversion between caffeine and theophylline has been reported (caffeine levels are ~25% of measured theophylline after theophylline administration and ~3% to 8% of caffeine would be expected to be converted to theophylline)

Half-life elimination:

Neonates: 72-96 hours (range: 40-230 hours)

Children >9 months and Adults: 5 hours

Time to peak, serum: Oral: Within 30 minutes to 2 hours

Excretion:

Neonates ≤1 month: 86% excreted unchanged in urine

Infants >1 month and Adults: In urine, as metabolites

Dosage

Apnea of prematurity: Oral:

Loading dose: 10-20 mg/kg as caffeine citrate (5-10 mg/kg as caffeine base). If theophylline has been administered to the patient within the previous 5 days, a full or modified loading dose (50% to 75% of a loading dose) may be given at the discretion of the physician.

Maintenance dose: 5-10 mg/kg/day as caffeine citrate (2.5-5 mg/kg/day as caffeine base) once daily starting 24 hours after the loading dose. Maintenance dose is adjusted based on patient's response, (efficacy and adverse effects), and serum caffeine concentrations.

Administration Oral: May be administered without regard to feedings or meals. May administer injectable formulation (caffeine citrate) orally.

Parenteral:

Caffeine citrate: Infuse loading dose over at least 30 minutes; maintenance dose may be infused over at least 10 minutes. May administer without dilution or diluted with D₅W to 10 mg caffeine citrate/mL.

Butriptyline

CAS Number 35941-65-2; 5585-73-9

Synonyms Butriptyline Hydrochloride

Use Depression

Mechanism of Action Increases synaptic concentration of serotonin and/or norepinephrine in the central nervous system by inhibition of their reuptake by the presynaptic neuronal membrane

Adverse Reactions

Cardiovascular: Postural hypotension, cardiomyopathy, cardiac arrhythmias, tachycardia, sudden death, QT prolongation

Central nervous system: Sedation, fatigue, anxiety, confusion, insomnia, psychosis, impaired cognitive function, seizures, extrapyramidal reactions are possible, restlessness, moderate to marked sedation can occur (tolerance to these effects usually occur), neuroleptic malignant syndrome, acute polyradiculopathy, visual hallucinations, encephalopathy

Dermatologic: Photosensitivity, cutaneous pseudolymphomas

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone (rarely)

Gastrointestinal: Xerostomia, increased appetite, constipation, adynamic ileus, lower esophageal sphincter tone may cause GE reflux, weight gain

Genitourinary: Urinary retention

Hematologic: Leukopenia (rarely), neutropenia, agranulocytosis, granulocytopenia, eosinophilia

Hepatic: Elevated liver enzymes, cholestatic jaundice

Neuromuscular & skeletal: Tremors, clonus, myoclonus, weakness

Ocular: Blurred vision, photophobia, diplopia, increased intraocular pressure, mydriasis

Respiratory: Hyperventilation, adult respiratory distress syndrome

Miscellaneous: Allergic reactions

Signs and Symptoms of Overdose Agitation, bowel ischemia, confusion, decreased gastrointestinal motility, delirium, dementia, dental erosion, ejaculatory disturbances, extrapyramidal reaction, fever, hallucinations, hyperacusis, hyperthermia, hyponatremia, hypotension, hypothermia, insomnia, increased intraocular pressure, lactation, mania, memory loss, myoglobinuria, neuroleptic malignant syndrome, nystagmus, paresthesia, periarthritis nodosa, photosensitivity, purpura, QRS prolongation, respiratory depression, seizures, tachycardia, urinary retention, urine discoloration (blue-green)

Pharmacodynamics/Kinetics

Absorption: 3 hours

Metabolism: Hepatic to n-desmethylbutriptyline

Dosage Oral: Initial: 25 mg 3 times/day (lower dose in elderly); maximum daily dose: 150 mg

Dosage Forms Tablet, as hydrochloride: 10 mg, 25 mg, 50 mg

Reference Range Peak plasma level after a single 75 mg oral dose: 0.024-0.11 mcg/mL; postmortem blood and urine butriptyline levels after an overdose estimated to be 3,425 g was 14.9 mg/L and 2.96 mg/L, respectively

Overdose/Treatment

Decontamination: Lavage (within 2-3 hours)/activated charcoal; **do not** induce emesis; multiple dosing of activated charcoal is more effective

Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated. Ventricular arrhythmias often respond to phenytoin 15-20 mg/kg (adults) with concurrent systemic alkalinization (sodium bicarbonate 0.5-2 mEq/kg I.V.). Arrhythmias unresponsive to this therapy may respond to lidocaine 1mg/kg I.V. followed by a titrated infusion. Physostigmine (1-2 mg I.V. slowly for adults or 0.5 mg I.V. slowly for children) may be indicated in seizures or movement disorders but should only be used as a last resort. Seizures

Caffeine and sodium benzoate: I.V. as slow direct injection. For spinal headaches, dilute in 1000 mL NS and infuse over 1 hour. Follow with 1000 mL NS; infuse over 1 hour. May administer I.M. undiluted.

Contraindications Hypersensitivity to caffeine or any component of the formulation; sodium benzoate is not for use in neonates

Warnings

Use with caution in patients with a history of peptic ulcer, gastroesophageal reflux, impaired renal or hepatic function, seizure disorders, or cardiovascular disease. Avoid use in patients with symptomatic cardiac arrhythmias, agitation, anxiety, or tremor. Over-the-counter [OTC] products contain an amount of caffeine similar to one cup of coffee; limit the use of other caffeine-containing beverages or foods.

Caffeine citrate should not be interchanged with caffeine and sodium benzoate. Avoid use of products containing sodium benzoate in neonates; has been associated with a potentially fatal toxicity ("gasping syndrome") in neonates, including metabolic acidosis, respiratory distress, gasping respirations, seizures, intracranial hemorrhage, hypotension, and cardiovascular collapse. *In vitro* and animal studies have shown that benzoate also displaces bilirubin from protein-binding sites. Neonates receiving caffeine citrate should be closely monitored for the development of necrotizing enterocolitis. Caffeine serum levels should be closely monitored to optimize therapy and prevent serious toxicity.

Dosage Forms

Caplet (Caffedrine[®], Vivarin[®]): 200 mg [OTC]

Injection, solution, as citrate [preservative free] (Cafcit[®]): 20 mg/mL (3 mL) [equivalent to 10 mg/mL caffeine base]

Injection, solution [with sodium benzoate]: Caffeine 125 mg/mL and sodium benzoate 125 mg/mL (2 mL); caffeine 121 mg/mL and sodium benzoate 129 mg/mL (2 mL)

Lozenge (Enerjets): 75 mg [OTC; Hazelnut coffee or mochamint flavor]
Solution, oral, as citrate (Cafcit[®]): 20 mg/mL (3 mL) [equivalent to 10 mg/mL caffeine base]

Tablet:

Lucidex: 100 mg [OTC]

NoDoz[®] Maximum Strength, Vivarin[®]: 200 mg [OTC]

Reference Range

Therapeutic: 8-14 mcg/mL for neonatal apnea

Toxic: >30 mcg/mL

Fatal: >80 mcg/mL

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** induce emesis

Supportive therapy: Vasopressin infusion can assist in raising blood pressure. Ventricular dysrhythmias and tachycardia (ventricular) with aberrancy have been successfully treated with procainamide in an adult (400 mg I.V. bolus followed by a 2 mg/minute infusion); esmolol or adenosine can be used to treat tachycardia

Seizures: If anticipated serum caffeine level is >20 mcg/mL or >2 g are ingested, pretreatment with phenobarbital (6-10 mg/kg I.V.) can be considered; midazolam or other benzodiazepine can be used to treat seizures

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; exchange transfusion (in the neonate) hemodialysis or charcoal hemoperfusion for 4-5 hours can be useful

Test Interactions ↑ uric acid (S); slight increase in urine VMA, catecholamines; can cause false elevation of serum theophylline

Drug Interactions

Substrate of CYP1A2 (major), 2C9 (minor), 2D6 (minor), 2E1 (minor), 3A4 (minor); **Inhibits** CYP1A2 (weak), 3A4 (moderate)

Benzodiazepines: Caffeine may diminish the sedative or anxiolytic effects of benzodiazepines.

CYP1A2 inducers: May decrease the levels/effects of caffeine. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of caffeine. Example inhibitors include fluvoxamine, ketoconazole, and rofecoxib.

Quinolone antibiotics (specifically ciprofloxacin, norfloxacin, ofloxacin): May increase the levels/effects of caffeine.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic effects in animal studies at caffeine doses >40 mg/day; association with increased rate of spontaneous abortion, low birthweight, and premature delivery; data is conflicting and no definitive association shown

Lactation Enters breast milk/use caution (AAP rates "compatible")

Additional Information

Lethal dose: Oral: 150-200 mg/kg; symptoms usually occur at a total caffeine dose of 500 mg

Coffee beans contain 1% to 2% caffeine; 40% of the bronchodilatory activity of theophylline; lithium blood levels increase during caffeine

withdrawal; analgesia from transcutaneous electrical nerve stimulation may be lessened with concomitant caffeine use; one 12 ounce glass of cola in a 40 pound child is equivalent to 4 glasses of coffee in a 160 pound adult; the average American adult ingests ~200 mg of caffeine/day

Caffeine content: Stimulants: 75-200 mg; Cold preparations: 30-75 mg
Coffee (5 oz): 100-150 mg/cup (brewed); 70 mg/cup (instant);
Decaffeinated coffee: 4 mg/cup; Tea: 30-50 mg/cup
Cola drinks (12 oz): 35-55 mg (Maximal allowable content of caffeine in 12 oz of soft drink is 72 mg [0.02%].); Dr. Pepper[®]: 40 mg; MelloYellow[®]: 52 mg; Mountain Dew[®] (12 oz): 54 mg; Coca-Cola[®] (12 oz): 46 mg; Jolt[®] (12 oz): 71 mg; Pepsi-Cola[®]: 38 mg; Tab[®]: 46 mg; Water Joe[®] (16 oz): 70 mg
Dark chocolate bar (29 g): 20-25 mg/bar; Milk chocolate bar (29 g): 6 mg/bar; Guarana (800 mg): 24-40 mg; Cocoa (5 oz): 2-20 mg; Hot cocoa (6 oz): 2-20 mg; Chocolate milk (8 oz): 2-7 mg

Calcitonin

CAS Number 12321-44-7; 47931-85-1; 60731-46-6; 9007-12-9

U.S. Brand Names Miacalcin[®]

Synonyms Calcitonin (Salmon)

Use Calcitonin (salmon): Treatment of Paget's disease of bone and as adjunctive therapy for hypercalcemia; also used in postmenopausal osteoporosis, cholecalciferol (vitamin D₃) induced hypercalcemia

Calcitonin (human): Treatment of Paget's disease of bone
Nasal spray (salmon calcitonin) has been used to treat postmenopausal osteoporosis in women >5 years postmenopause with a low bone mass.

Mechanism of Action Structurally similar to human calcitonin; regulates serum calcium concentration along with vitamin D and parathyroid hormone; acts on bone as well as kidneys and GI tract; directly inhibits osteoclastic bone resorption; promotes the renal excretion of calcium, phosphate, sodium, magnesium, and potassium by decreasing tubular reabsorption; increases the jejunal secretion of water, sodium, potassium, and chloride

Adverse Reactions

Cardiovascular: **Flushing of the face**, edema

Central nervous system: Dizziness, headache, chills

Dermatologic: Rash

Endocrine & metabolic: Hypocalcemia, hypophosphatemia, hyperprolactinemia

Gastrointestinal: **Nausea, anorexia, diarrhea**, metallic taste, salty taste, vomiting

Local: **Edema at injection site**

Neuromuscular & skeletal: Weakness, tingling of palms and soles

Renal: Diuresis, hypercalciuria

Respiratory: Dyspnea, nasal congestion

Miscellaneous: Shivering

Pharmacodynamics/Kinetics

Hypercalcemia: I.M. or SubQ:

Onset of action: ~2 hours

Duration: 6-8 hours

Absorption: Nasal: ~3% of I.M. level (range: 0.3% to 31%)

Distribution: Does not cross placenta

Half-life elimination: SubQ: 1.2 hours; Nasal: 43 minutes

Time to peak: Nasal: ~30-40 minutes

Excretion: Urine (as inactive metabolites)

Dosage

Dosage for calcitonin salmon is expressed in international units (int. units); dosage of calcitonin human is expressed in mg; dosage for children not established

Hepatic osteodystrophy:

Infants: 5-7 mcg/kg/day

Children and Adults: 20-100 mcg/kg/day or every other day, titrate to obtain normal serum calcium/phosphate levels

Calcitonin salmon:

Skin test: 1 unit/0.1 mL intracutaneously on the inner aspect of the forearm

The skin test is 0.1 mL of 10 int. units dilution of calcitonin (must be prepared) injected intradermally; observe injection site for 15 minutes for wheal or significant erythema

Paget's disease: SubQ: 100 units/day

Postmenopause osteoporosis:

I.M., SubQ: 100 units/day (concomitant therapy with supplemental calcium and vitamin D is recommended)

Nasal spray: 200 int. units/day (one actuation in one nostril); alternate nostrils daily

Hypercalcemia: I.M., SubQ: 4 units/kg every 12 hours, may increase to maximum of 8 units/kg every 6 hours

Calcitonin human: I.M., SubQ: Paget's disease: 0.5 mg/day initially; some patients require as little as 0.25 mg or 0.5 mg 2-3 times/week; some patients require up to 0.5 mg twice daily

Stability Refrigeration is recommended for calcitonin salmon, is stable for up to 2 weeks at room temperature; NS has been recommended for the dilution to prepare a skin test; protect from light; calcitonin human may be stored at room temperature

Monitoring Parameters Serum electrolytes and calcium; alkaline phosphatase and 24-hour urine collection for hydroxyproline excretion (Paget's disease); serum calcium

Administration Injection solution: Administer I.M. or SubQ; intramuscular route is recommended over the subcutaneous route when the volume of calcitonin to be injected exceeds 2 mL.

Nasal spray: Before first use, allow bottle to reach room temperature, then prime pump by releasing at least 5 sprays until full spray is produced. To administer, place nozzle into nostril with head in upright position. Alternate nostrils daily. Do not prime pump before each daily use. Discard after 30 doses.

Contraindications Hypersensitivity to calcitonin salmon or any component of the formulation

Warnings A skin test should be performed prior to initiating therapy of calcitonin salmon in patients with suspected sensitivity; have epinephrine immediately available for a possible hypersensitivity reaction. A detailed skin testing protocol is available from the manufacturers. Temporarily withdraw use of nasal spray if ulceration of nasal mucosa occurs. Safety and efficacy have not been established in pediatric patients.

Dosage Forms

Injection, solution, calcitonin-salmon: (Miacalcin®): 200 int. units/mL (2 mL)

Solution, nasal spray, calcitonin-salmon:

Fortical®: 200 int. units/0.09 mL (3.7 mL) [rDNA origin; contains benzyl alcohol; delivers 30 doses, 200 units/actuation]

Miacalcin®: 200 int. units/0.09 mL (3.7 mL) [contains benzalkonium chloride; delivers 30 doses, 200 units/actuation]

Reference Range Therapeutic: < 19 pg/mL (SI: 19 ng/L) basal, depending on the assay

Overdosage/Treatment Supportive therapy: I.V. hydration; monitor urine flow and calcium and phosphorus level; oral pizotyline (0.5 mg 3 times/day) may prevent adverse GI effects (nausea, vomiting, anorexia) of calcitonin therapy

Test Interactions ↓ calcium (S)

Pregnancy Risk Factor C

Pregnancy Implications Decreased birth weight was observed in animal studies. Calcitonin does not cross the placental barrier. There are no adequate and well-controlled studies in pregnant women.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications I.M. route is preferred; skin test should be performed prior to administration of salmon calcitonin; refrigerate when volume exceeds 2 mL

Calfactant

U.S. Brand Names Infasurf®

Use

Prevention of respiratory distress syndrome (RDS) in premature infants at high risk for RDS and for the treatment ("rescue") of premature infants who develop RDS

Prophylaxis: Therapy at birth with calfactant is indicated for premature infants <29 weeks of gestational age at significant risk for RDS. Should be administered as soon as possible, preferably within 30 minutes after birth.

Treatment: For infants ≤72 hours of age with RDS (confirmed by clinical and radiologic findings) and requiring endotracheal intubation.

Mechanism of Action Endogenous lung surfactant is essential for effective ventilation because it modifies alveolar surface tension, thereby stabilizing the alveoli. Lung surfactant deficiency is the cause of respiratory distress syndrome (RDS) in premature infants and lung surfactant restores surface activity to the lungs of these infants.

Adverse Reactions

Cardiovascular: Bradycardia, cyanosis

Respiratory: Airway obstruction, reflux, requirement for manual ventilation, reintubation

Signs and Symptoms of Overdose There have been no known reports of overdosage. While there are no known adverse effects of excess lung surfactant, overdoses would result in overloading the lungs with an isotonic solution. Ventilation should be supported until clearance of the liquid is accomplished.

Pharmacodynamics/Kinetics No human studies of absorption, bio-transformation, or excretion have been performed

Dosage Intratracheal administration **only:** Each dose is 3 mL/kg body weight at birth; should be administered every 12 hours for a total of up to 3 doses

Stability Gentle swirling or agitation of the vial of suspension is often necessary for redispersion. **Do not shake.** Visible flecks of the suspension and foaming at the surface are normal. Calfactant should be stored at refrigeration (2°C to 8°C/36°F to 46°F). Warming before administration is not necessary. Unopened and unused vials of calfactant that have been warmed to room temperature can be returned to refrigeration storage within 24 hours for future use. Repeated warming to room temperature should be avoided. Each single-use vial should be entered only once; the vial with any unused material should be discarded after the initial entry.

Monitoring Parameters Following administration, patients should be carefully monitored so that oxygen therapy and ventilatory support can be modified in response to changes in respiratory status

Administration

Should be administered intratracheally through an endotracheal tube. Dose is drawn into a syringe from the single-use vial using a 20-gauge or larger needle with care taken to avoid excessive foaming. Should be administered in 2 aliquots of 1.5 mL/kg each. After each aliquot is instilled, the infant should be positioned with either the right or the left side dependent. Administration is made while ventilation is continued over 20-30 breaths for each aliquot, with small bursts timed only during the inspiratory cycles. A pause, followed by evaluation of respiratory status and repositioning, should separate the two aliquots.

Warnings For intratracheal administration only; the administration of exogenous surfactants often rapidly improves oxygenation and lung compliance. Transient episodes of cyanosis, bradycardia, reflux of surfactant into the endotracheal tube, and airway obstruction were observed more frequently among infants treated with calfactant in clinical trials.

Dosage Forms Suspension, intratracheal [preservative free]: 35 mg/mL (6 mL)

Overdosage/Treatment Supportive therapy: Mechanical ventilation and reintubation may be required. Monitor for upper airway obstruction.

Candesartan

U.S. Brand Names Atacand®

Synonyms Candesartan Cilexetil

Use Alone or in combination with other antihypertensive agents in treating essential hypertension; treatment of heart failure (NYHA class II-IV)

Mechanism of Action Candesartan is an angiotensin receptor antagonist. Angiotensin II acts as a vasoconstrictor. In addition to causing direct vasoconstriction, angiotensin II also stimulates the release of aldosterone. Once aldosterone is released, sodium as well as water are reabsorbed. The end result is an elevation in blood pressure. Candesartan binds to the AT1 angiotensin II receptor. This binding prevents angiotensin II from binding to the receptor thereby blocking the vasoconstriction and the aldosterone secreting effects of angiotensin II.

Adverse Reactions

Cardiovascular: Flushing, chest pain, peripheral edema, tachycardia, palpitations, angina, myocardial infarction

Central nervous system: Dizziness, lightheadedness, drowsiness, fatigue, headache, vertigo, anxiety, depression, somnolence, fever

Dermatologic: Rash, angioedema
 Endocrine & metabolic: Hyperglycemia, hypertriglyceridemia, hyperuricemia
 Gastrointestinal: Nausea, diarrhea, vomiting, dyspepsia, gastroenteritis
 Neuromuscular & skeletal: Back pain, arthralgia, paresthesias, increased CPK, myalgia, weakness
 Renal: Hematuria
 Respiratory: Upper respiratory tract infection, pharyngitis, rhinitis, bronchitis, cough, sinusitis, epistaxis, dyspnea
 Miscellaneous: Diaphoresis (increased)

Signs and Symptoms of Overdose Hypotension and tachycardia

Pharmacodynamics/Kinetics

Onset of action: 2-3 hours
 Peak effect: 6-8 hours
 Duration: > 24 hours
 Distribution: V_d : 0.13 L/kg
 Protein binding: 99%
 Metabolism: To candesartan by the intestinal wall cells
 Bioavailability: 15%
 Half-life elimination (dose dependent): 5-9 hours
 Time to peak: 3-4 hours
 Excretion: Urine (26%)
 Clearance: Total body: 0.37 mL/kg/minute; Renal: 0.19 mL/kg/minute

Dosage

Adults: Oral:

Hypertension: Usual dose is 4-32 mg once daily; dosage must be individualized. Blood pressure response is dose-related over the range of 2-32 mg. The usual recommended starting dose of 16 mg once daily when it is used as monotherapy in patients who are not volume depleted. It can be administered once or twice daily with total daily doses ranging from 8-32 mg. Larger doses do not appear to have a greater effect and there is relatively little experience with such doses.

Congestive heart failure: Initial: 4 mg once daily; double the dose at 2-week intervals, as tolerated; target dose: 32 mg

Elderly: No initial dosage adjustment is necessary for elderly patients (although higher concentrations (C_{max}) and AUC were observed in these populations), for patients with mildly impaired renal function, or for patients with mildly impaired hepatic function.

Dosage adjustment in hepatic impairment: No initial dosage adjustment required in mild hepatic impairment. Consider initiation at lower dosages in moderate hepatic impairment (AUC increased by 145%). No data available concerning dosing in severe hepatic impairment.

Monitoring Parameters Supine blood pressure, electrolytes, serum creatinine, BUN, urinalysis, symptomatic hypotension, and tachycardia

Contraindications Hypersensitivity to candesartan or any component of the formulation; hypersensitivity to other A-II receptor antagonists; bilateral renal artery stenosis; pregnancy (2nd and 3rd trimesters)

Warnings [U.S. Boxed Warning]: Based on human data, drugs that act on the angiotensin system can cause injury and death to the developing fetus when used in the second and third trimesters. Angiotensin receptor blockers should be discontinued as soon as possible once pregnancy is detected. Avoid use or use a smaller dose in patients who are volume depleted; correct depletion first. May be associated with deterioration of renal function and/or increases in serum creatinine, particularly in patients dependent on renin-angiotensin-aldosterone system; deterioration may result in oliguria, acute renal failure, and progressive azotemia. Small increases in serum creatinine may occur following initiation; consider discontinuation only in patients with progressive and/or significant deterioration in renal function. Use with caution in unilateral renal artery stenosis, hepatic dysfunction, pre-existing renal insufficiency, or significant aortic/mitral stenosis. Use caution when initiating in heart failure; may need to adjust dose, and/or concurrent diuretic therapy, because of candesartan-induced hypotension. Although some properties may be shared between these agents, concurrent therapy with ACE inhibitor may be rational in selected patients.

Dosage Forms

Tablet, as cilexetil:

Atacand®: 4 mg, 8 mg, 16 mg, 32 mg

Reference Range Therapeutic blood concentration: 34-183 ng/mL

Overdosage/Treatment

Decontamination: Lavage/activated charcoal

Supportive therapy: I.V. crystalloid fluids should be utilized for hypotension; norepinephrine or dopamine are vasopressors that can be used

Drug Interactions

Substrate of CYP2C9 (minor); **Inhibits** CYP2C8 (weak), 2C9 (weak)

Lithium: Risk of toxicity may be increased by candesartan; monitor lithium levels.

NSAIDs: May decrease angiotensin II antagonist efficacy; effect has been seen with losartan, but may occur with other medications in this class; monitor blood pressure.

Potassium-sparing diuretics (amiloride, spironolactone, triamterene): May increase risk of hyperkalemia.

Potassium supplements: May increase the risk of hyperkalemia.
 Trimethoprim (high dose): May increase the risk of hyperkalemia.

Pregnancy Risk Factor C/D (2nd and 3rd trimesters)

Pregnancy Implications Candesartan should be discontinued as soon as possible when pregnancy is detected. Drugs which act directly on renin-angiotensin can cause fetal and neonatal morbidity and death. Fetal and neonatal toxicity have been reported in infants born to women treated with candesartan during pregnancy.

Lactation Enters breast milk/contraindicated

Specific References

Morton A, Muir J, and Lim D, "Rash and Acute Nephritic Syndrome Due to Candesartan," *BMJ*, 2004, 328(7430):25.

Cantharidin

Pronunciation (kan THAR e din)

CAS Number 56-25-7

U.S. Brand Names Verr-Canth™

Use Derived from the blister beetle (*Cantharis vesicatoria*), it has been used topically as a wart remover (at concentrations of 0.7% to 1%)

Unlabeled/Investigational Use Primary use is found today as an aphrodisiac

Mechanism of Action Cantharidin (an anhydride of cantharidic acid) is a dermal and mucosal vesicant; lipid soluble and thus systemic absorption can occur from dermal contact; a potent inhibitor of protein phosphatases types 1 and 2A

Adverse Reactions

Cardiovascular: Syncope

Central nervous system: Delirium, ataxia

Dermatologic: Dermal irritation, dermal burns, acantholysis

Gastrointestinal: GI hemorrhage, rectal bleeding, dysphagia

Genitourinary: Priapism

Hepatic: Fatty degeneration

Neuromuscular & skeletal: Hyperreflexia

Ocular: Conjunctivitis, iritis, keratitis

Renal: Proteinuria, hematuria

Respiratory: Burning of oropharynx

Signs and Symptoms of Overdose Abdominal pain, asystole, ataxia, coagulopathy, diarrhea, ECG abnormalities (S-T elevation), hyperreflexia, hypotension, renal failure (acute tubular necrosis), seizures (may last 36 hours), tachycardia, tachypnea, tenesmus, ventricular ectopy, ventricular tachycardia

Admission Criteria/Prognosis Admit any symptomatic patient to a cardiac monitored bed for at least 24 hours; any asymptomatic ingestion > 10 mg (or 4 dried blister beetles) should be admitted

Toxicodynamics/Kinetics Absorption: Absorbed by oral and dermal routes

Contraindications Hypersensitivity to cantharidin or any component of the formulation

Overdosage/Treatment

Decontamination:

Oral: **Do not** induce emesis; dilution with milk or water may be helpful; if no oral pathology is noted, cautious gastric lavage (if performed within 1 hour) with a soft nasogastric tube can be performed; although no studies as to its efficacy exist, activated charcoal can be administered

Dermal: Irrigate with soap and water

Ocular: Irrigate with copious amounts of saline

Supportive therapy: To treat hypotension, an isotonic crystalloid fluid challenge (10-20 mL/kg) can be performed with placement of patient in Trendelenburg position; refractory hypotension can be treated with dopamine or norepinephrine seizures can be treated with benzodiazepine; refractory seizures can be treated with phenobarbital or phenytoin; a urine flow rate of >4 L/day should be maintained with fluids and mannitol

Pregnancy Risk Factor C

Additional Information Minimal fatal dose: Oral: ~30 mg

Capreomycin

CAS Number 11003-38-6; 1405-37-4

U.S. Brand Names Capastat® Sulfate

Synonyms Capreomycin Sulfate

Use Treatment of tuberculosis in conjunction with at least one other antituberculosis agent

Mechanism of Action Polypeptide antibiotic; bacteriostatic

Adverse Reactions

Central nervous system: Vertigo

Endocrine & metabolic: Hypokalemia

Hematologic: Eosinophilia (dose-related, mild), leukocytosis, thrombocytopenia (rare)

Local: Pain, induration, and bleeding at injection site

CAPTOPRIL

Otic: **Ototoxicity** [subclinical hearing loss (11%), clinical loss (3%), tinnitus]

Renal: **Nephrotoxicity** (36%, increased BUN), acute tubular necrosis, Bartter's syndrome

Miscellaneous: Hypersensitivity (urticaria, rash, fever)

Pharmacodynamics/Kinetics

Half-life elimination: Normal renal function: 4-6 hours

Time to peak, serum: I.M.: ~1 hour

Excretion: Urine (as unchanged drug)

Dosage

I.M., I.V.:

Infants and Children: 15-30 mg/kg/day, up to 1 g/day maximum

Adults: 1 g/day (not to exceed 20 mg/kg/day) for 60-120 days, followed by 1 g 2-3 times/week

Elderly: Refer to Adults dosing; use with caution due to the increased potential for pre-existing renal dysfunction or impaired hearing

Dosing interval in renal impairment: Adults:

Cl_{cr} > 100 mL/minute: Administer 13-15 mg/kg every 24 hours

Cl_{cr} 80-100 mL/minute: Administer 10-13 mg/kg every 24 hours

Cl_{cr} 60-80 mL/minute: Administer 7-10 mg/kg every 24 hours

Cl_{cr} 40-60 mL/minute: Administer 11-14 mg/kg every 48 hours

Cl_{cr} 20-40 mL/minute: Administer 10-14 mg/kg every 72 hours

Cl_{cr} < 20 mL/minute: Administer 4-7 mg/kg every 72 hours

Monitoring Parameters Audiometric measurements and vestibular function at baseline and during therapy; renal function at baseline and weekly during therapy; serum potassium; liver function tests

Administration

I.M.: Administer by deep I.M. injection into a large muscle mass.

I.V.: Administer over 60 minutes.

Contraindications Hypersensitivity to capreomycin sulfate or any component of the formulation

Warnings [U.S. Boxed Warning]: Use in patients with renal insufficiency or pre-existing auditory impairment must be undertaken with great caution, and the risk of additional eighth nerve impairment or renal injury should be weighed against the benefits to be derived from therapy. Since other parenteral antituberculous agents (eg, streptomycin) also have similar and sometimes irreversible toxic effects, particularly on eighth cranial nerve and renal function, simultaneous administration of these agents with capreomycin is not recommended. Use with nonantituberculous drugs (ie, aminoglycoside antibiotics) having ototoxic or nephrotoxic potential should be undertaken only with great caution. Use caution with renal dysfunction and in the elderly. **[U.S. Boxed Warning]: Safety in pregnant women or pediatric patients not established.**

Dosage Forms Injection, powder for reconstitution, as sulfate: 1 g

Reference Range 1 g administered I.M. gives a peak serum concentration of 30 mcg/mL; desired serum steady-state level is 10 mcg/mL

Overdosage/Treatment

Decontamination: Lavage for ingestions > 1 g/activated charcoal

Enhancement of elimination: Hemodialysis if renal failure develops

Test Interactions ↑ BUN, WBCs; ↓ platelets, potassium

Drug Interactions Increased effect/duration of nondepolarizing neuromuscular blocking agents

Additive toxicity (nephrotoxicity and ototoxicity, respiratory paralysis): Aminoglycosides (eg, streptomycin)

Pregnancy Risk Factor C

Pregnancy Implications Capreomycin has been shown to be teratogenic in animal studies. There are no adequate and well-controlled studies in pregnant women; use during pregnancy only if the potential benefit to the mother outweighs the possible risk to the fetus.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Solution for injection may acquire a pale straw color and darken with time; this is not associated with a loss of potency or development of toxicity

Captopril

Related Information

- Angiotensin Agents

CAS Number 62571-86-2

U.S. Brand Names Capoten®

Synonyms ACE

Use Management of hypertension and treatment of congestive heart failure; increase circulation in Raynaud's phenomenon; idiopathic edema

Unlabeled/Investigational Use Treatment of hypertensive crisis, rheumatoid arthritis; diagnosis of anatomic renal artery stenosis, hypertension secondary to scleroderma renal crisis; diagnosis of aldosteronism, idiopathic edema, Bartter's syndrome, postmyocardial infarction for prevention of ventricular failure; increase circulation in Raynaud's phenomenon, hypertension secondary to Takayasu's disease; acute pulmonary edema

Mechanism of Action Competitive inhibitor of angiotensin-converting enzyme (ACE); prevents conversion of angiotensin I to angiotensin II, a potent vasoconstrictor; results in lower levels of angiotensin II which

causes an increase in plasma renin activity and a reduction in aldosterone secretion

Adverse Reactions

Cardiovascular: Hypotension, chest pain, tachycardia, pericardial effusion/pericarditis, angina, sinus tachycardia, vasodilation

Central nervous system: Psychosis, gustatory hallucinations

Dermatologic: Rash, pruritus, exfoliative dermatitis, hyperpigmentation in children, pemphigus, lichenoid eruptions, angioedema, hyperhidrosis, Stevens-Johnson syndrome, toxic epidermal necrolysis, xerosis, urticaria, purpura, exanthema, cutaneous vasculitis

Endocrine & metabolic: Hyperkalemia, hyponatremia, hypoglycemia

Gastrointestinal: Tongue irritation, altered taste, loss of taste perception, salty taste, esophagitis, aphthous stomatitis, xerostomia, scalded mouth syndrome, gastrointestinal vasculitis

Hematologic: Leukopenia/neutropenia (agranulocytosis, granulocytopenia), thrombocytopenia

Hepatic: Hepatitis, cholestatic hepatitis

Neuromuscular & skeletal: Paresthesia

Ocular: Phototoxic

Renal: Proteinuria, elevated BUN/serum creatinine, reversible renal failure, renal vasculitis

Respiratory: **Transient cough**, wheezing

Miscellaneous: Systemic lupus erythematosus, zinc depletion

Signs and Symptoms of Overdose Alopecia, atrial ectopy, bone marrow depression, bullous skin disease/pemphigoid, coagulopathy, cholestatic jaundice, diarrhea, drowsiness, dysosmia, eosinophilia, fever, hematuria, hyperkalemia, hyperthermia, hypoglycemia, hyponatremia, lichenoid eruptions, nephrotic syndrome, night terrors, oliguria, ototoxicity, Parkinson's-like symptoms, pemphigus, pericarditis, photosensitivity, renal insufficiency, seizures, severe hypotension, sweating, tinnitus, tubular necrosis, wheezing

Pharmacodynamics/Kinetics

Onset of action: Peak effect: Blood pressure reduction: 1-1.5 hours after dose

Duration: Dose related, may require several weeks of therapy before full hypotensive effect

Absorption: 60% to 75%; reduced 30% to 40% by food

Protein binding: 25% to 30%

Metabolism: 50%

Half-life elimination (renal and cardiac function dependent):

Adults, healthy volunteers: 1.9 hours; Congestive heart failure: 2.06 hours; Anuria: 20-40 hours

Excretion: Urine (95%) within 24 hours

Dosage

Note: Dosage must be titrated according to patient's response; use lowest effective dose. Oral:

Infants: Initial: 0.15-0.3 mg/kg/dose; titrate dose upward to maximum of 6 mg/kg/day in 1-4 divided doses; usual required dose: 2.5-6 mg/kg/day

Children: Initial: 0.5 mg/kg/dose; titrate upward to maximum of 6 mg/kg/day in 2-4 divided doses

Older Children: Initial: 6.25-12.5 mg/dose every 12-24 hours; titrate upward to maximum of 6 mg/kg/day

Adolescents: Initial: 12.5-25 mg/dose given every 8-12 hours; increase by 25 mg/dose to maximum of 450 mg/day

Adults:

Acute hypertension (urgency/emergency): 12.5-25 mg, may repeat as needed (may be given sublingually, but no therapeutic advantage demonstrated)

Hypertension:

Initial dose: 12.5-25 mg 2-3 times/day; may increase by 12.5-25 mg/dose at 1- to 2-week intervals up to 50 mg 3 times/day; maximum dose: 150 mg 3 times/day; add diuretic before further dosage increases

Usual dose range (JNC 7): 25-100 mg/day in 2 divided doses

Congestive heart failure:

Initial dose: 6.25-12.5 mg 3 times/day in conjunction with cardiac glycoside and diuretic therapy; initial dose depends upon patient's fluid/electrolyte status

Target dose: 50 mg 3 times/day

Maximum dose: 150 mg 3 times/day

LVD after MI: Initial dose: 6.25 mg followed by 12.5 mg 3 times/day; then increase to 25 mg 3 times/day during next several days and then over next several weeks to target dose of 50 mg 3 times/day

Diabetic nephropathy: 25 mg 3 times/day; other antihypertensives often given concurrently

Dosing adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer at 75% of normal dose.

Cl_{cr} < 10 mL/minute: Administer at 50% of normal dose.

Note: Smaller dosages given every 8-12 hours are indicated in patients with renal dysfunction; renal function and leukocyte count should be carefully monitored during therapy.

Hemodialysis: Moderately dialyzable (20% to 50%); administer dose postdialysis or administer 25% to 35% supplemental dose.

Peritoneal dialysis: Supplemental dose is not necessary.

Stability Unstable in aqueous solutions; to prepare solution for oral administration, mix prior to administration and use within 10 minutes

Monitoring Parameters BUN, serum creatinine, urine dipstick for protein, complete leukocyte count, and blood pressure

Administration

Unstable in aqueous solutions; to prepare solution for oral administration, mix prior to administration and use within 10 minutes.

Contraindications Hypersensitivity to captopril or any component of the formulation; angioedema related to previous treatment with an ACE inhibitor; idiopathic or hereditary angioedema; bilateral renal artery stenosis; pregnancy (2nd or 3rd trimester)

Warnings Anaphylactic reactions can occur. Angioedema can occur at any time during treatment (especially following first dose). It may involve head and neck (potentially affecting the airway) or the intestine (presenting with abdominal pain). Prolonged monitoring may be required especially if tongue, glottis, or larynx are involved as they are associated with airway obstruction. Those with a history of airway surgery in this situation have a higher risk. Careful blood pressure monitoring with first dose (hypotension can occur especially in volume-depleted patients).

[U.S. Boxed Warning]: Based on human data, ACEIs can cause injury and death to the developing fetus when used in the second and third trimesters. ACEIs should be discontinued as soon as possible once pregnancy is detected. Dosage adjustment needed in renal impairment. Use with caution in hypovolemia; collagen vascular diseases; valvular stenosis (particularly aortic stenosis); hyperkalemia; or before, during, or immediately after anesthesia. Avoid rapid dosage escalation which may lead to renal insufficiency. Rare toxicities associated with ACE inhibitors include cholestatic jaundice (which may progress to hepatic necrosis) and neutropenia/agranulocytosis with myeloid hyperplasia. If patient has renal impairment, then a baseline WBC with differential and serum creatinine should be evaluated and monitored closely during the first 3 months of therapy. Hypersensitivity reactions may be seen during hemodialysis with high-flux dialysis membranes (eg, AN69). Deterioration in renal function can occur with initiation. Use with caution in unilateral renal artery stenosis and pre-existing renal insufficiency.

Dosage Forms Tablet: 12.5 mg, 25 mg, 50 mg, 100 mg

Reference Range Plasma level of 6 mcg/mL associated with hypotension while a level of 60 mcg/mL associated with fatality

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam or diazepam (I.V. 5-10 mg bolus in adults every 15 minutes if needed up to a total of 30 mg; I.V. 0.25-0.4 mg/kg/dose up to a total of 10 mg in children) or to phenytoin or phenobarbital. Naloxone (2 mg) may reverse hypotension. Sulindac may be useful for captopril-induced cough. Inhaled sodium cromoglycate (total dose: 40 mg/day) can decrease ACE-inhibitor cough by 50%. For refractory hypotension, angiotensin amide infusion may be attempted.

Enhancement of elimination: Multiple dosing of activated charcoal or hemodialysis may be quite useful; moderately dialyzable (20% to 50%)

Antidote(s)

- Naloxone [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Urea Nitrogen, Blood

Test Interactions ↑ BUN, creatinine, potassium; positive Coombs' [direct]; ↓ cholesterol (S); may cause false-positive urine acetone determinations using sodium nitroprusside reagent

Drug Interactions

Substrate of CYP2D6 (major)

Allopurinol: Case reports (rare) indicate a possible increased risk of Stevens-Johnson syndrome when combined with captopril.

Alpha₁ blockers: Hypotensive effect increased.

Aspirin: The effects of ACE inhibitors may be blunted by aspirin administration, particularly at higher dosages and/or increase adverse renal effects.

CYP2D6 inhibitors: May increase the levels/effects of captopril. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Diuretics: Hypovolemia due to diuretics may precipitate acute hypotensive events or acute renal failure.

Insulin: Risk of hypoglycemia may be increased.

Lithium: Risk of lithium toxicity may be increased; monitor lithium levels, especially the first 4 weeks of therapy.

Mercaptopurine: Risk of neutropenia may be increased.

NSAIDs: May attenuate hypertensive efficacy; effect has been seen with captopril and may occur with other ACE inhibitors; monitor blood pressure. May increase adverse renal effects.

Potassium-sparing diuretics (amiloride, potassium, spironolactone, triamterene): Increased risk of hyperkalemia.

Potassium supplements may increase the risk of hyperkalemia.

Trimethoprim (high dose) may increase the risk of hyperkalemia.

Pregnancy Risk Factor C (1st trimester)/D (2nd and 3rd trimesters)

Pregnancy Implications Decreased placental blood flow, low birth weight, fetal hypotension, preterm delivery, and fetal death have been noted with the use of some ACE inhibitors (ACEIs) in animal studies. Neonatal hypotension, skull hypoplasia, anuria, renal failure, oligohydramnios (associated with fetal limb contractures, craniofacial deformities, hypoplastic lung development), prematurity, intrauterine growth retardation, and patent ductus arteriosus have been reported with the use of ACEIs, primarily in the 2nd and 3rd trimesters. The risk of neonatal toxicity has been considered less when ACEIs have been used in the 1st trimester; however, major congenital malformations have been reported. The cardiovascular and/or central nervous systems are most commonly affected. Unless alternative agents are not appropriate, ACEIs should be discontinued as soon as possible once pregnancy is detected.

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Nursing Implications Watch for hypotensive effect within 1-3 hours of first dose or new higher dose; many patients complain of transient cough during early therapy

Additional Information Most effective for treating hypertension in young, white patients; conversion factor from captopril to lisinopril is 5:1.

Carbamazepine

Related Information

- Carbamazepine-10,11-Epoxyde
- Therapeutic Drugs Associated with Hallucinations

CAS Number 298-46-4

U.S. Brand Names Carbatrol®, Epitol®, Tegretol®-XR; Tegretol®

Synonyms CBZ; SPD417

Use Partial seizures with complex symptomatology (psychomotor, temporal lobe), generalized tonic-clonic seizures (grand mal), mixed seizure patterns; pain relief of trigeminal or glossopharyngeal neuralgia

Unlabeled/Investigational Use Treatment of bipolar disorders and other affective disorders, resistant schizophrenia, ethanol withdrawal, restless leg syndrome, psychotic behavior associated with dementia, post-traumatic stress disorders

Mechanism of Action May depress activity in the nucleus ventralis of the thalamus or decrease synaptic transmission or to decrease summation of temporal stimulation leading to neural discharge by limiting influx of sodium ions across cell membrane or other unknown mechanisms; stimulates the release of ADH and potentiates its action in promoting reabsorption of water; chemically related to tricyclic antidepressants; in addition to anticonvulsant effects, carbamazepine has anticholinergic, antineuralgic, antidiuretic, muscle relaxant, and antiarrhythmic properties. May also decrease the turnover of γ -aminobutyric acid (GABA).

Adverse Reactions

Cardiovascular: Edema, congestive heart failure, syncope, bradycardia, hypertension or hypotension, AV block, arrhythmias, thrombophlebitis, thromboembolism

Central nervous system: Sedation, dizziness, fatigue, ataxia, confusion, headache, slurred speech, aseptic meningitis (case report)

Dermatologic: Rash, urticaria, toxic epidermal necrolysis, Stevens-Johnson syndrome, photosensitivity reaction, alterations in skin pigmentation, exfoliative dermatitis, erythema multiforme, purpura, alopecia, cutaneous vasculitis

Endocrine & metabolic: Hyponatremia, SIADH, fever, chills, hyperglycemia

Gastrointestinal: Nausea, vomiting, gastric distress, abdominal pain, diarrhea, constipation, anorexia, pancreatitis

CARBAMAZEPINE

Genitourinary: Urinary retention, urinary frequency, azotemia, renal failure, impotence

Hematologic: Aplastic anemia, agranulocytosis, eosinophilia, leukopenia, pancytopenia, thrombocytopenia, bone marrow suppression, acute intermittent porphyria, leukocytosis

Hepatic: Hepatitis, abnormal liver function tests, jaundice, hepatic failure, hepatic vasculitis

Neuromuscular & skeletal: Peripheral neuritis

Ocular: Blurred vision, nystagmus, lens opacities, conjunctivitis

Otic: Tinnitus, hyperacusis

Renal: Renal vasculitis

Respiratory: Eosinophilic pneumonia

Miscellaneous: Cutaneous T-cell lymphoma, hypersensitivity (including multiorgan reactions, may include vasculitis, disorders mimicking lymphoma, eosinophilia, hepatosplenomegaly), diaphoresis, lymphadenopathy

Signs and Symptoms of Overdose Agranulocytosis, agitation, alopecia, apnea, arrhythmias, ataxia, AV block, bone marrow depression, bradycardia, cholestatic jaundice, chorea (extrapyramidal), cognitive dysfunction, coma, cough, decreased GI motility, delirium, dizziness, drowsiness, dysosmia, encephalopathy, erythema multiforme, exfoliative dermatitis, extrapyramidal reaction, fever, flushing, gingival hyperplasia, granulocytopenia, hyperreflexia, hyperthermia, hypotension, hypothermia, hypothyroidism, hyponatremia, ileus, jaundice, leukocytosis, leukemoid reaction, leukopenia, lichenoid eruptions, lymphoma, mania, myoclonus, mydriasis, nausea, neuroleptic malignant syndrome, neutropenia, nystagmus, oliguria, photosensitivity, P-R prolongation, QRS prolongation, QT prolongation, seizures, toxic epidermal necrolysis, tremors, urinary retention, vomiting

Pharmacodynamics/Kinetics

Absorption: Slow

Distribution: V_d : Neonates: 1.5 L/kg; Children: 1.9 L/kg; Adults: 0.59-2 L/kg

Protein binding: Carbamazepine: 75% to 90%, may be decreased in newborns; Epoxide metabolite: 50%

Metabolism: Hepatic via CYP3A4 to active epoxide metabolite; induces hepatic enzymes to increase metabolism

Bioavailability: 85%

Half-life elimination:

Carbamazepine: Initial: 18-55 hours; Multiple doses: Children: 8-14 hours; Adults: 12-17 hours

Epoxide metabolite: Initial: 25-43 hours

Time to peak, serum: Unpredictable:

Immediate release: Suspension: 1.5 hour; tablet: 4-5 hours

Extended release: Carbatrol[®], Equetro[™]: 12-26 hours (single dose), 4-8 hours (multiple doses); Tegretol[®]-XR: 3-12 hours

Excretion: Urine 72% (1% to 3% as unchanged drug); feces (28%)

Dosage

Oral (dosage must be adjusted according to patient's response and serum concentrations):

Children:

<6 years: Initial: 5 mg/kg/day; dosage may be increased every 5-7 days to 10 mg/kg/day; then up to 20 mg/kg/day if necessary; administer in 2-4 divided doses

6-12 years: Initial: 100 mg twice daily or 10 mg/kg/day in 2 divided doses; increase by 100 mg/day at weekly intervals depending upon response; usual maintenance: 20-30 mg/kg/day in 2-4 divided doses (maximum dose: 1000 mg/day)

Children >12 years and Adults: 200 mg twice daily to start, increase by 200 mg/day at weekly intervals until therapeutic levels achieved; usual dose: 400-1200 mg/day in 2-4 divided doses; maximum dose: 12-15 years: 1000 mg/day, >15 years: 1200 mg/day; some patients have required up to 1.6-2.4 g/day

Trigeminal or glossopharyngeal neuralgia: Initial: 100 mg twice daily with food, gradually increasing in increments of 100 mg twice daily as needed; usual maintenance: 400-800 mg daily in 2 divided doses; maximum dose: 1200 mg/day

Elderly: 100 mg 1-2 times daily, increase in increments of 100 mg/day at weekly intervals until therapeutic level is achieved; usual dose: 400-1000 mg/day

Dosing adjustment in renal impairment: Cl_{cr} <10 mL/minute: Administer 75% of dose

Monitoring Parameters CBC with platelet count, reticulocytes, serum iron, liver function tests, urinalysis, BUN, serum carbamazepine levels, thyroid function tests, serum sodium; observe patient for excessive sedation, especially when instituting or increasing therapy

Administration

Suspension dosage form must be given on a 3-4 times/day schedule versus tablets which can be given 2-4 times/day. When carbamazepine suspension has been combined with chlorpromazine or thioridazine solutions a precipitate forms which may result in loss of effect. Therefore, it is recommended that the carbamazepine suspension dosage form not be administered at the same time with other liquid medicinal agents or

diluents. Damaged extended release tablets (without release portal) should not be administered.

Contraindications Hypersensitivity to carbamazepine, tricyclic antidepressants, or any component of the formulation; bone marrow depression; with or within 14 days of MAO inhibitor use; pregnancy

Warnings

Administer carbamazepine with caution to patients with history of cardiac damage, hepatic or renal disease. **[U.S. Boxed Warning]: Potentially fatal blood cell abnormalities have been reported following treatment.** Patients with a previous history of adverse hematologic reaction to any drug may be at increased risk. Early detection of hematologic change is important; advise patients of early signs and symptoms including fever, sore throat, mouth ulcers, infections, easy bruising, petechial or purpuric hemorrhage. Prescriptions should be written for the smallest quantity consistent with good patient care. The smallest effective dose is suggested for use in bipolar disorder to reduce the risk for overdose; high-risk patients should be monitored. Actuation of latent psychosis is possible.

Carbamazepine is not effective in absence, myoclonic, or akinetic seizures; exacerbation of certain seizure types have been seen after initiation of carbamazepine therapy in children with mixed seizure disorders. Abrupt discontinuation is not recommended in patients being treated for seizures. Dizziness or drowsiness may occur; caution should be used when performing tasks which require alertness (operating machinery or driving) until the effects are known. Coadministration of carbamazepine and delavirdine may lead to loss of virologic response and possible resistance. Elderly may have increased risk of SIADH-like syndrome. Carbamazepine has mild anticholinergic activity; use with caution in patients with increased intraocular pressure (monitor closely), or sensitivity to anticholinergic effects (urinary retention, constipation). Severe dermatologic reactions, including Lyell and Stevens-Johnson syndromes, although rarely reported, have resulted in fatalities. Drug should be discontinued if there are any signs of hypersensitivity.

Dosage Forms

Capsule, extended release (Carbatrol[®], Equetro[™]): 100 mg, 200 mg, 300 mg

Suspension, oral: 100 mg/5 mL (10 mL, 450 mL)

Tegretol[®]: 100 mg/5 mL (450 mL) [citrus vanilla flavor]

Tablet (Eptol[®], Tegretol[®]): 200 mg

Tablet, chewable (Tegretol[®]): 100 mg

Tablet, extended release (Tegretol[®]-XR): 100 mg, 200 mg, 400 mg

Reference Range

Therapeutic: 4-12 mcg/mL (SI: 17-51 μ mol/L). Patients who require higher levels (8-12 mcg/mL) (SI: 34-51 μ mol/L) should be watched closely. Side effects including CNS effects occur commonly at higher dosage levels. If other anticonvulsants are given, therapeutic range is 4-8 mcg/mL (SI: 17-34 μ mol/L).

Ataxia and nystagmus is noted at levels >10 mcg/mL (SI: >42 μ mol/L); levels >30 mcg/mL (SI: >127 μ mol/L) associated with coma and respiratory depression

Fatal: Levels of 54 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal is effective at binding certain chemicals and drugs, and this is especially true for carbamazepine

Supportive therapy: Other treatment is supportive/symptomatic; flumazenil has been reported to reverse coma although its use is contraindicated in patients with seizure disorder; flumazenil has been utilized to reverse carbamazepine induced coma (serum level 27.8 mg/L), but it should not be utilized in patients with an underlying seizure disorder. Furthermore, since carbamazepine may in itself be seizurogenic, it should probably not be used routinely in overdoses due to this agent. Lithium, diltiazem, miconazole, and metoclopramide use with carbamazepine has been associated with neurotoxicity. Do not use physostigmine.

Enhancement of elimination: Multiple dose of activated charcoal is effective; forced diuresis is not effective; clearance by hemoperfusion ranges from 80-129 mL/minute with 36% of the drug being removed during 4 hours; ~17% of the drug is normally excreted in 4 hours in a healthy person; charcoal hemoperfusion may be effective (hemoperfusion clearance is ~10 mL/hour/kg or ~5 times higher than intrinsic clearance)

Diagnostic Procedures

● Carbamazepine, Blood

Test Interactions ↑ BUN, AST, ALT, ammonia, bilirubin, alkaline phosphatase (S); ↓ calcium, T₃, T₄, sodium (S); may cause false-positive urine immunoassay for tricyclic antidepressants; produces sustained reduction of both free thyroxine and free triiodothyronine, at therapeutic levels

Drug Interactions

Substrate of CYP2C8 (minor), 3A4 (major); **Induces** CYP1A2 (strong), 2B6 (strong), 2C8 (strong), 2C9 (strong), 2C19 (strong), 3A4 (strong)
Acetaminophen: Carbamazepine may enhance hepatotoxic potential of acetaminophen; risk is greater in acetaminophen overdose.

Antimalarial drugs (chloroquine, mefloquine): Concomitant use with carbamazepine may reduce seizure control by lowering plasma levels; monitor.

Antipsychotics: Carbamazepine may enhance the metabolism (decrease the efficacy) of antipsychotics; monitor for altered response; dose adjustment may be needed.

Barbiturates: May reduce serum concentrations of carbamazepine; monitor.

Benzodiazepines: Serum concentrations and effect of benzodiazepines may be reduced by carbamazepine; monitor for decreased effect.

Calcium channel blockers: Diltiazem and verapamil may increase carbamazepine levels, due to enzyme inhibition (see below); other calcium channel blockers (felodipine) may be decreased by carbamazepine due to enzyme induction.

Chlorpromazine: **Note:** Carbamazepine suspension is incompatible with chlorpromazine solution. Schedule carbamazepine suspension at least 1-2 hours apart from other liquid medicinals.

Corticosteroids: Metabolism may be increased by carbamazepine.

Cyclosporine (and other immunosuppressants): Carbamazepine may enhance the metabolism of immunosuppressants, decreasing its clinical effect; includes both cyclosporine and tacrolimus.

CYP1A2 substrates: Carbamazepine may decrease the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, estrogens, fluvoxamine, mirtazapine, ropinirole, and theophylline.

CYP2B6 substrates: Carbamazepine may decrease the levels/effects of CYP2B6 substrates. Example substrates include bupropion, efavirenz, promethazine, selegiline, and sertraline.

CYP2C8 Substrates: Carbamazepine may decrease the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.

CYP2C9 Substrates: Carbamazepine may decrease the levels/effects of CYP2C9 substrates. Example substrates include bosentan, celecoxib, dapsone, fluoxetine, glimepiride, glipizide, losartan, montelukast, nateglinide, paclitaxel, phenytoin, sulfonamides, trimethoprim, warfarin, and zafirlukast.

CYP2C19 substrates: Carbamazepine may decrease the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, proton pump inhibitors, sertraline, and voriconazole.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of carbamazepine. Example inducers include aminoglutethimide, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins. Carbamazepine may induce its own metabolism.

CYP3A4 inhibitors: May increase the levels/effects of carbamazepine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nocardipine, propofol, protease inhibitors, quinine, telithromycin, and verapamil.

CYP3A4 substrates: Carbamazepine may decrease the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, clarithromycin, cyclosporine, erythromycin, estrogens, mirtazapine, nateglinide, nefazodone, nevirapine, protease inhibitors, tacrolimus, and venlafaxine.

Danazol: May increase serum concentrations of carbamazepine; monitor.

Delavirdine: May lead to loss of virologic response and possible resistance.

Doxycycline: Carbamazepine may enhance the metabolism of doxycycline, decreasing its clinical effect.

Ethosuximide: Serum levels may be reduced by carbamazepine.

Felbamate: May increase carbamazepine levels and toxicity (increased epoxide metabolite concentrations); carbamazepine may decrease felbamate levels due to enzyme induction.

Immunosuppressants: Carbamazepine may enhance the metabolism of immunosuppressants, decreasing its clinical effect; includes both cyclosporine and tacrolimus.

Isoniazid: May increase the serum concentrations and toxicity of carbamazepine; in addition, carbamazepine may increase the hepatic toxicity of isoniazid (INH).

Isotretinoin: May decrease the effect of carbamazepine.

Lamotrigine: Increases the epoxide metabolite of carbamazepine resulting in toxicity; carbamazepine increases the metabolism of lamotrigine.

Lithium: Neurotoxicity may result in patients receiving concurrent carbamazepine.

Loxapine: May increase concentrations of epoxide metabolite and toxicity of carbamazepine.

Methadone: Carbamazepine may enhance the metabolism of methadone resulting in methadone withdrawal.

Methylphenidate: concurrent use of carbamazepine may reduce the therapeutic effect of methylphenidate; limited documentation; monitor for decreased effect.

Neuromuscular blocking agents, nondepolarizing: Effects may be of shorter duration when administered to patients receiving carbamazepine.

Oral contraceptives: Metabolism may be increased by carbamazepine, resulting in a loss of efficacy.

Phenytoin: Carbamazepine levels may be decreased by phenytoin. Metabolism of phenytoin may be altered by carbamazepine; phenytoin levels may be increased or decreased.

SSRIs: Metabolism may be increased by carbamazepine (due to enzyme induction).

Theophylline: Serum levels may be reduced by carbamazepine.

Thioridazine: **Note:** Carbamazepine suspension is incompatible with thioridazine liquid. Schedule carbamazepine suspension at least 1-2 hours apart from other liquid medicinals.

Thyroid: Serum levels may be reduced by carbamazepine.

Tramadol: Tramadol's risk of seizures may be increased with TCAs (carbamazepine may be associated with similar risk due to chemical similarity to TCAs).

Tricyclic antidepressants: May increase serum concentrations of carbamazepine; carbamazepine may decrease concentrations of tricyclics due to enzyme induction.

Valproic acid: Serum levels may be reduced by carbamazepine; carbamazepine levels may also be altered by valproic acid.

Warfarin: Carbamazepine may inhibit the hypoprothrombinemic effects of oral anticoagulants via increased metabolism; this combination should generally be avoided.

Pregnancy Risk Factor D

Pregnancy Implications Crosses the placenta. Dysmorphic facial features, cranial defects, cardiac defects, spina bifida, IUGR, and multiple other malformations reported. Epilepsy itself, number of medications, genetic factors, or a combination of these probably influence the teratogenicity of anticonvulsant therapy. Benefit:risk ratio usually favors continued use during pregnancy and breast-feeding.

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Nursing Implications Observe patient for excessive sedation

Additional Information Suspension dosage form must be given on a 3-4 times/day schedule versus tablets which can be given 2-4 times/day; ECG changes do **not** correlate with serum carbamazepine levels; it is hypothesized that hematological toxicity and immune system toxicity is due to 9-acridine carboxyaldehyde metabolite. Carbamazepine (400-800 mg/day) has been used to treat cocaine dependence.

Carboplatin

CAS Number 41575-94-4

U.S. Brand Names Paraplatin®

Synonyms CBDCA; NSC-241240

Use Treatment of ovarian cancer

Unlabeled/Investigational Use Lung cancer, head and neck cancer, endometrial cancer, esophageal cancer, bladder cancer, breast cancer, cervical cancer, CNS tumors, germ cell tumors, osteogenic sarcoma, and high-dose therapy with stem cell/bone marrow support

Mechanism of Action Carboplatin is an alkylating agent which covalently binds to DNA; possible cross-linking and interference with the function of DNA

Adverse Reactions

Cardiovascular: Hypertension

Central nervous system: Neurotoxicity, malaise

Dermatologic: **Alopecia** (includes other agents in combination with carboplatin), urticaria, rash

Endocrine & metabolic: **Hypomagnesemia, hypokalemia, hyponatremia, hypocalcemia**; less severe than those seen after cisplatin (usually asymptomatic)

Gastrointestinal: **Nausea, vomiting, stomatitis**, diarrhea, anorexia

CARFENTANIL CITRATE

Hematologic: Myelosuppression is dose-related and is the dose-limiting toxicity; **thrombocytopenia** is the predominant manifestation, with a reported incidence of 37% in patients receiving 400 mg/m² as a single agent and 80% in patients receiving 520 mg/m²; **leukopenia** has been reported in 27% to 38% of patients receiving carboplatin as a single agent; hemorrhagic complications

Nadir: ~21 days following a single dose

Hepatic: **Alkaline phosphatase increased, AST increased** (usually mild and reversible)

Local: Pain at injection site

Neuromuscular & skeletal: Peripheral neuropathy (4% to 6%; up to 10% in older and/or previously-treated patients)

Otic: Ototoxicity; **hearing loss at high tones** (above speech ranges, up to 19%); clinically-important ototoxicity is not usually seen

Renal: Nephrotoxicity, **increases in creatinine and BUN** have been reported; most of them are mild and they are commonly reversible; considerably less nephrotoxic than cisplatin

Miscellaneous: Secondary malignancies, anaphylaxis

Pharmacodynamics/Kinetics

Distribution: V_d: 16 L/kg; into liver, kidney, skin, and tumor tissue

Protein binding: 0%; platinum is 30% irreversibly bound

Metabolism: Minimally hepatic to aquated and hydroxylated compounds

Half-life elimination: Terminal: 22-40 hours; Cl_{cr} > 60 mL/minute: 2.5-5.9 hours

Excretion: Urine (~60% to 90%) within 24 hours

Dosage

Refer to individual protocols: **Note:** Doses are usually determined by the AUC using the Calvert formula

IVPB, I.V. infusion, intraperitoneal:

Children:

Solid tumor: 300-600 mg/m² once every 4 weeks

Brain tumor: 175 mg/m² weekly for 4 weeks every 6 weeks, with a 2-week recovery period between courses

Adults:

Ovarian cancer: 300-360 mg/m² I.V. every 3-4 weeks

Autologous BMT: I.V.: 1600 mg/m² (total dose) divided over 4 days

Dosing adjustment in renal impairment: No guidelines are available.

Dosing adjustment in hepatic impairment: No guidelines are available. Intraperitoneal: 200-650 mg/m² in 2 L of dialysis fluid have been administered into the peritoneum of ovarian cancer patients

Stability Store intact vials at room temperature of 15°C to 30°C (59°F to 86°F); protect from light. Reconstitute powder to yield a final concentration of 10 mg/mL which is stable for 5 days at room temperature (25°C). Aluminum needles should not be used for administration due to binding with the platinum ion. Further dilution to a concentration as low as 0.5 mg/mL is stable at room temperature (25°C) or under refrigeration for 8 days in D₅W.

Monitoring Parameters CBC (with differential and platelet count), serum electrolytes, creatinine clearance, liver function tests

Administration

Do not use needles or I.V. administration sets containing aluminum parts that may come in contact with carboplatin (aluminum can react causing precipitate formation and loss of potency)

Administer as IVPB over 15 minutes up to a continuous intravenous infusion over 24 hours; may also be administered intraperitoneally

Contraindications History of severe allergic reaction to cisplatin, carboplatin, other platinum-containing formulations, or any component of the formulation; pregnancy; breast-feeding

Warnings

Hazardous agent - use appropriate precautions for handling and disposal. High doses have resulted in severe abnormalities of liver function tests.

[U.S. Boxed Warning]: Bone marrow suppression, which may be severe, and vomiting are dose related; reduce dosage in patients with bone marrow suppression and impaired renal function. Clinically significant hearing loss has been reported to occur in pediatric patients when carboplatin was administered at higher than recommended doses in combination with other ototoxic agents.

[U.S. Boxed Warning]: Increased risk of allergic reactions in patients previously exposed to platinum therapy. When administered as sequential infusions, taxane derivatives (docetaxel, paclitaxel) should be administered before the platinum derivatives (carboplatin, cisplatin) to limit myelosuppression and to enhance efficacy. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.** Safety and efficacy in children have not been established.

Dosage Forms

Injection, powder for reconstitution: 50 mg, 150 mg, 450 mg

Injection, solution: 10 mg/mL (5 mL, 15 mL, 45 mL, 60 mL)

Reference Range Therapeutic plasma carboplatin levels: 10-25 mcg/mL

Overdosage/Treatment

Supportive therapy: Nausea and vomiting can be treated with standard antiemetic therapies; patients should be vigorously hydrated 3 hours

before and after carboplatin treatment to prevent nephrotoxicity (I.V. normal saline at ~250 mL/hour)

Enhanced elimination: Hemodialysis can remove carboplatin at ~25% of the rate of intact kidney

Drug Interactions

Aminoglycosides may enhance the nephrotoxic and/or ototoxic effects of carboplatin, especially with higher doses of carboplatin.

Docetaxel, paclitaxel (taxane derivatives): When administered as sequential infusions, taxane derivatives should be administered before platinum derivatives to limit myelosuppression and to enhance efficacy.

Pregnancy Risk Factor D

Lactation Excretion in breast milk unknown/contraindicated

Carfentanil Citrate

Related Information

- Fentanyl

CAS Number 59708-52-0; 61380-27-6

Use Highly potent opioid analgesic usually used in veterinary medicine to immobilize large animals; used to study opiate receptors in brain imaging

Mechanism of Action Binds with stereospecific receptors at many sites within the CNS, increases pain threshold, alters pain reception, inhibits ascending pain pathways; a very specific mu-opioid agonist

Signs and Symptoms of Overdose Apnea, chest pain, coma, confusion, depression, dyspnea, exfoliative dermatitis, flatulence, hiccups, hypertension, hypertonia, hypotension, laryngospasm, pseudotumor cerebri, respiratory depression (especially with doses > 200 mcg), seizures

Toxicodynamics/Kinetics Duration of action: 2-24 hours

Dosage Incapacitation of large animals: Oral, I.M.: 6.8-18.8 mcg/kg.

Stability 59°F to 86°F; protect from prolonged excessive heat

Administration

Inject deep into large muscle mass of shoulder, back, or hindquarter of animal (deer, elk, moose)

Additional Information 8000-10,000 times more potent than morphine and 100 times as potent as fentanyl; may be a chemical submissive agent when inhaled

Carisoprodol

Related Information

- Meprobamate

CAS Number 78-44-4

U.S. Brand Names Soma®

Synonyms Carisoprodol; Isobamate

Impairment Potential Yes. Driving impairment can occur if combined serum levels of carisoprodol and meprobamate exceed 10 mg/L

Use Skeletal muscle relaxant

Mechanism of Action Precise mechanism is not yet clear, but many effects have been ascribed to its central depressant actions

Adverse Reactions

Cardiovascular: Hypotension, tachycardia, tightness in chest, flushing of face, sinus tachycardia

Central nervous system: Sedation, **drowsiness**, dizziness, fatigue, fainting, CNS depression, lightheadedness, headache, clumsiness, insomnia, ataxia

Dermatologic: Skin rash, hives, erythema multiforme

Gastrointestinal: Nausea, vomiting, stomach cramps

Hematologic: Aplastic anemia, eosinophilia, porphyrinogenic

Neuromuscular & skeletal: Trembling

Ocular: Diplopia, blurred vision, burning eyes, nystagmus

Respiratory: Dyspnea

Miscellaneous: Hiccups

Signs and Symptoms of Overdose Coma, CNS depression, depression, dizziness, erythema multiforme, insomnia, lightheadedness, nystagmus, respiratory depression, shock, stupor, hypotonia, agitation

Pharmacodynamics/Kinetics

Onset of action: ~30 minutes

Duration: 4-6 hours

Distribution: Crosses placenta; high concentrations enter breast milk

Metabolism: Hepatic, via CYP2C19 to active metabolite (meprobamate)

Half-life elimination: 2.4 hours; Meprobamate: 10 hours

Excretion: Urine, as metabolite

Dosage Adults: Oral: 350 mg 3-4 times/day; take last dose at bedtime; compound: 1-2 tablets 4 times/day

Monitoring Parameters Look for relief of pain and/or muscle spasm and avoid excessive drowsiness

Administration

Give with food to decrease GI upset.

Contraindications Hypersensitivity to carisoprodol, meprobamate, or any component of the formulation; acute intermittent porphyria

Warnings May cause CNS depression, which may impair physical or mental abilities. Effects with other sedative drugs or ethanol may be potentiated. Use with caution in patients with hepatic/renal dysfunction. Tolerance or drug dependence may result from extended use. Limit to 2-3 weeks; use caution in patients who may be prone to addiction. Idiosyncratic reactions and/or severe allergic reactions may occur. Idiosyncratic reactions occur following the initial dose and may include severe weakness, transient quadriplegia, euphoria, or vision loss (temporary). Has been associated (rarely) with seizures in patients with and without seizure history. Safety and efficacy in children <12 years of age have not been established.

Dosage Forms

Tablet: 350 mg
Soma®: 350 mg

Reference Range 600 mg oral dose can produce peak carisoprodol plasma level between 9-20 mg/L; plasma levels >30 mg/L associated with stupor, coma, or death

Overdosage/Treatment

Decontamination: Lavage (within 2 hours of ingestion)/activated charcoal
Supportive therapy: Benzodiazepines for seizure control; flumazenil at doses of 0.2 mg I.V. can reverse CNS depression due to carisoprodol. Hypotension should be treated with I.V. fluids and/or Trendelenburg positioning.

Enhancement of elimination: Forced diuresis is not helpful; multiple dosing of activated charcoal may be helpful.

Drug Interactions

Substrate of CYP2C19 (major)

CNS depressants (includes CNS depressants, benzodiazepines, and phenothiazines): Sedation may be increased; avoid concurrent use.

CYP2C19 inhibitors: May increase the levels/effects of carisoprodol. Example inhibitors include delavirdine, fluconazole, flvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

Pregnancy Risk Factor C

Pregnancy Implications Reproduction studies have not been conducted.

Lactation Enters breast milk (high concentrations)/not recommended

Nursing Implications Raise bed rails; institute safety measures; assist with ambulation

Additional Information Minimal lethal dose: Children: 3.5 g

Siddiqi M and Jennings CA, "A Near-Fatal Overdose of Carisoprodol (SOMA): Case Report," *J Toxicol Clin Toxicol*, 2004, 42(2):239-40.

Central nervous system: **Dizziness, ataxia**, headache, circumoral paresthesia, leukoencephalopathy

Dermatologic: **Hyperpigmentation of skin**, alopecia, dermatitis

Endocrine & metabolic: Gynecomastia, hyperprolactinemia

Gastrointestinal: **Nausea and vomiting occur within 2-4 hours after drug injection, dose-related**; stomatitis, diarrhea, anorexia, metallic taste

Genitourinary: Hemorrhagic cystitis

Emetic potential:

<200 mg: Moderately high (60% to 90%)
≥200 mg: High (>90%)

Hematologic: Anemia

Myelosuppressive: Delayed, occurs 4-6 weeks after administration and is dose-related; usually persists for 1-2 weeks; thrombocytopenia is usually more severe than leukopenia. Myelofibrosis and preleukemic syndromes have been reported.

WBC: Moderate; Platelets: Severe; Onset (days): 14; Nadir (days): 21-35; Recovery (days): 42-50

Hepatic: Reversible toxicity, **elevated liver function tests** in 20%, **hepatotoxicity** (26%), **hepatic necrosis (centrilobular)**

Local: **Burning at injection site; Irritant chemotherapy:** pain at injection site, extravasation injury

Ocular: **Ocular toxicity, retinal hemorrhages**, neuroretinopathy blindness

Renal: Azotemia, decrease in kidney size

Respiratory: Fibrosis occurs mostly in patients treated with prolonged total doses >1400 mg/m² or with bone marrow transplantation doses.

Risk factors include a history of lung disease, concomitant bleomycin, or radiation therapy. PFTs should be conducted prior to therapy and monitored. Patients with predicted FVC or DLCO <70% are at a higher risk. Idiopathic pneumonia can occur when dose exceeds 475 mg/m².

Pharmacodynamics/Kinetics

Distribution: Readily crosses blood-brain barrier producing CSF levels equal to 15% to 70% of blood plasma levels; enters breast milk; highly lipid soluble

Metabolism: Rapidly hepatic

Half-life elimination: Biphasic: Initial: 1.4 minutes; Secondary: 20 minutes (active metabolites: plasma half-life of 67 hours)

Excretion: Urine (~60% to 70%) within 96 hours; lungs (6% to 10% as CO₂)

Dosage

I.V. (refer to individual protocols):

Children: 200-250 mg/m² every 4-6 weeks as a single dose

Adults: Usual dosage (per manufacturer labeling): 150-200 mg/m² every 6-8 weeks as a single dose or divided into daily injections on 2 successive days

Alternative regimens:

75-120 mg/m² days 1 and 2 every 6-8 weeks **or**

50-80 mg/m² days 1,2,3 every 6-8 weeks

Primary brain cancer:

150-200 mg/m² every 6-8 weeks as a single dose **or**

75-120 mg/m² days 1 and 2 every 6-8 weeks **or**

20-65 mg/m² every 4-6 weeks **or**

0.5-1 mg/kg every 4-6 weeks **or**

40-80 mg/m²/day for 3 days every 6-8 weeks

Autologous BMT: ALL OF THE FOLLOWING DOSES ARE FATAL WITHOUT BMT

Combination therapy: Up to 300-900 mg/m²

Single-agent therapy: Up to 1200 mg/m² (fatal necrosis is associated with doses >2 g/m²)

Implantation (wafer): Adults: Recurrent glioblastoma multiforme, malignant glioma: Up to 8 wafers may be placed in the resection cavity (total dose 62.6 mg); should the size and shape not accommodate 8 wafers, the maximum number of wafers allowed should be placed

Hemodialysis: Supplemental dosing is not required

Dosing adjustment in hepatic impairment: Dosage adjustment may be necessary; however, no specific guidelines are available

Stability Injection: Store intact vials under refrigeration; vials are stable for 36 days at room temperature. Initially, dilute with 3 mL of absolute alcohol. Further dilute with SWFI to a concentration of 3.3 mg/mL. Solutions are stable for 8 hours at room temperature (25°C) and 24 hours under refrigeration (2°C to 8°C) and protected from light. Further dilution in D₅W or NS is stable for 8 hours at room temperature (25°C) and 48 hours under refrigeration (4°C) in glass or Excel® protected from light. Wafer: Store at or below -20°C (-4°F); may be kept at room temperature for up to 6 hours

Monitoring Parameters

CBC with differential and platelet count, pulmonary function, liver function, and renal function tests; monitor blood pressure during administration

Wafer: Complications of craniotomy (seizures, intracranial infection, brain edema)

Administration Injection: Significant absorption to PVC containers - should be administered in either glass or Excel® container. I.V. infusion

Carmustine

CAS Number 154-93-8

U.S. Brand Names BiCNU®, Gliadel®

Synonyms BCNU; bis-chloronitrosourea; Carmustinum; NSC-409962; WR-139021

Use

Injection: Treatment of brain tumors (glioblastoma, brainstem glioma, medulloblastoma, astrocytoma, ependymoma, and metastatic brain tumors), multiple myeloma, Hodgkin's disease, non-Hodgkin's lymphomas, melanoma, lung cancer, colon cancer

Wafer (implant): Adjunct to surgery in patients with recurrent glioblastoma multiforme; adjunct to surgery and radiation in patients with high-grade malignant glioma

Mechanism of Action Interferes with the normal function of DNA by alkylation and cross-linking the strands of DNA, and by possible protein modification

Adverse Reactions

Cardiovascular: **Hypotension is associated with HIGH-DOSE administration secondary to the high alcohol content of the diluent**, facial flushing is probably due to the ethanol used in reconstitution

over 1-2 hours is recommended; infusion through a free-flowing saline or dextrose infusion, or administration through a central catheter can alleviate venous pain/irritation

High-dose carmustine: Maximum rate of infusion of ≤ 3 mg/m²/minute to avoid excessive flushing, agitation, and hypotension; infusions should run over at least 2 hours; some investigational protocols dictate shorter infusions.

Fatal doses if not followed by bone marrow or peripheral stem cell infusions.

Extravasation management: Elevate extremity. Inject long-acting dexamethasone (Decadron® LA) or by hyaluronidase (Wydase®) throughout tissue with a 25- to 37-gauge needle. Apply warm, moist compresses.

Contraindications Hypersensitivity to carmustine or any component of the formulation; myelosuppression; pregnancy

Warnings

Hazardous agent - use appropriate precautions for handling and disposal.

[U.S. Boxed Warning]: Bone marrow suppression (thrombocytopenia, leukopenia) is the major toxicity and may be delayed; monitor blood counts weekly for at least 6 weeks after administration. Myelosuppression is cumulative; consider nadir blood counts from prior dose for dosage adjustment. May cause bleeding (due to thrombocytopenia) or infections (due to neutropenia); monitor closely. Administer with caution to patients with depressed platelet, leukocyte, or erythrocyte counts; renal or hepatic impairment. Diluent contains significant amounts of ethanol; use caution with aldehyde dehydrogenase-2 deficiency or history of "alcohol flushing syndrome."

[U.S. Boxed Warning]: Dose-related pulmonary toxicity may occur; patients receiving cumulative doses > 1400 mg/m² are at higher risk. Baseline pulmonary function tests are recommended. **[U.S. Boxed Warning]: Delayed onset of pulmonary fibrosis has occurred up to 17 years after treatment** in children (1-16 years) who received carmustine in cumulative doses ranging from 770-1800 mg/m² combined with cranial radiotherapy for intracranial tumors. May be associated with the development of secondary malignancies. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.** Safety and efficacy in children have not been established.

Dosage Forms

Injection, powder for reconstitution (BiCNU®): 100 mg [packaged with 3 mL of absolute alcohol as diluent]

Wafer (Gliadel®): 7.7 mg (8s)

Overdosage/Treatment Supportive therapy: Corticosteroids can be used to treat pulmonary toxicity; although its use is controversial, infiltration of 5 mL of 8.4% sodium bicarbonate (1 mM/mL solution) has been advocated for extravasation injuries

Antidote(s)

- Thrombopoietin [ANTIDOTE]

Drug Interactions

Cimetidine: Reported to cause bone marrow suppression.

Ethanol: Diluent for infusion contains alcohol; avoid concurrent use of medications that inhibit aldehyde dehydrogenase-2 or cause disulfiram-like reactions.

Etoposide: Reported to cause severe hepatic dysfunction with hyperbilirubinemia, ascites, and thrombocytopenia.

Pregnancy Risk Factor D

Pregnancy Implications Carmustine can cause fetal harm if administered to a pregnant woman.

Lactation Excretion in breast milk unknown/contraindicated

Additional Information Delayed onset pulmonary fibrosis occurring up to 17 years after treatment has been reported in patients who received cumulative > 1400 mg/m². Avoid ethanol.

Carteolol

Related Information

- Selected Properties of Beta-Adrenergic Blocking Drugs

CAS Number 51781-06-7; 51781-21-6

U.S. Brand Names Cartrol®; Ocupress® [DSC]

Synonyms Carteolol Hydrochloride

Use Management of hypertension; treatment of chronic open-angle glaucoma and intraocular hypertension

Mechanism of Action Blocks both beta₁- and beta₂-receptors and has mild intrinsic sympathomimetic activity; has negative inotropic and chronotropic effects and can significantly slow AV nodal conduction

Adverse Reactions

Cardiovascular: Mesenteric arterial thrombosis, AV block, persistent bradycardia, hypotension, chest pain, edema, heart failure, exacerbation of Raynaud's phenomenon, myocardial depression, QRS prolongation

Central nervous system: Fatigue, dizziness, headache, insomnia, drowsiness, night terrors, CNS depression, confusion

Dermatologic: Purpura, exfoliative dermatitis, acne, alopecia, angioedema, xerosis, photosensitivity, pruritus, psoriasis

Gastrointestinal: Ischemic colitis, abdominal pain, constipation, nausea, diarrhea, xerostomia, exanthem

Genitourinary: Impotence

Hematologic: Thrombocytopenia

Neuromuscular & skeletal: Paresthesia

Ocular: Corneal irritation, blurred vision with eye drop use

Respiratory: Wheezing, rhinitis

Miscellaneous: Cold extremities, diaphoresis (excessive), systemic lupus erythematosus

Signs and Symptoms of Overdose Arrhythmias, ataxia, cardiovascular collapse, colitis, congestive heart failure, cough, heart/respiratory failure and wheezing, insomnia, impotence, mesenteric ischemia, night terrors, pulmonary edema, purpura, severe hypotension, sinus bradycardia

Pharmacodynamics/Kinetics

Onset of action: Oral: 1-1.5 hours

Peak effect: 2 hours

Duration: 12 hours

Absorption: Oral: 80%

Protein binding: 23% to 30%

Metabolism: 30% to 50%

Half-life elimination: 6 hours

Excretion: Urine (as metabolites)

Dosage

Adults:

Oral: 2.5 mg as a single daily dose, with a maintenance dose normally 2.5-5 mg once daily

Ophthalmic: Instill 1 drop in eye(s) twice daily

Monitoring Parameters Ophthalmic: Intraocular pressure; Systemic: Blood pressure, pulse, CNS status

Administration

Oral: Administer with meals.

Ophthalmic: Intended for twice daily dosing. Keep eye open and do not blink for 30 seconds after instillation. Wear sunglasses to avoid photophobic discomfort. Apply gentle pressure to lacrimal sac during and immediately following instillation (1 minute).

Contraindications Hypersensitivity to carteolol or any component of the formulation; sinus bradycardia; heart block greater than first-degree (except in patients with a functioning artificial pacemaker); cardiogenic shock; bronchial asthma, bronchospasm, or COPD; uncompensated cardiac failure; pulmonary edema; pregnancy (2nd and 3rd trimesters)

Warnings Avoid abrupt discontinuation in patients with a history of CAD; slowly wean while monitoring for signs and symptoms of ischemia. Use caution in patients with PVD (can aggravate arterial insufficiency). Use caution with concurrent use of beta-blockers and either verapamil or diltiazem; bradycardia or heart block can occur. Patients with bronchospastic disease should not receive beta-blockers. Use cautiously in diabetics because it can mask prominent hypoglycemic symptoms. Can mask signs of thyrotoxicosis. Can cause fetal harm when administered in pregnancy. Dosage adjustment is required in patients with renal dysfunction. Use care with anesthetic agents that decrease myocardial function. Beta-blockers with intrinsic sympathomimetic activity have not been demonstrated to be of value in CHF.

Dosage Forms

[DSC] = Discontinued product

Solution, ophthalmic, as hydrochloride: 1% (5 mL, 10 mL, 15 mL) [contains benzalkonium chloride]

Ocupress® [DSC]: 1% (5 mL, 10 mL, 15 mL) [contains benzalkonium chloride]

Tablet, as hydrochloride (Cartrol®): 2.5 mg, 5 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not use** ipecac

Supportive therapy: Glucagon (50-150 mcg/kg followed by continuous drip of 1-5 mg/hour) for positive chronotropic effect; atropine/isoproterenol can be utilized to increase heart rate; calcium chloride may also be effective; **do not use** epinephrine

Enhancement of elimination: Multiple dosing of activated charcoal is not likely to be of benefit; dialysis is not useful

Drug Interactions

Substrate of CYP2D6 (minor)

Albuterol (and other beta₂ agonists): Effects may be blunted by nonspecific beta-blockers.

Alpha-blockers (prazosin, terazosin): Concurrent use of beta-blockers may increase risk of orthostasis.

Carteolol causes hypertension when used with local anesthetics (tetracaine, lidocaine, or bupivacaine) containing epinephrine.

Clonidine: Hypertensive crisis after or during withdrawal of either agent.

Drugs which slow AV conduction (digoxin): Effects may be additive with beta-blockers.

Glucagon: Carteolol may blunt the hyperglycemic action of glucagon.

Insulin: Carteolol may mask tachycardia from hypoglycemia.

NSAIDs (ibuprofen, indomethacin, naproxen, piroxicam) may reduce the antihypertensive effects of beta-blockers.

Salicylates may reduce the antihypertensive effects of beta-blockers.

Sulfonylureas: Beta-blockers may alter response to hypoglycemic agents.

Verapamil or diltiazem may have synergistic or additive pharmacological effects when taken concurrently with beta-blockers.

Pregnancy Risk Factor C (manufacturer); D (2nd and 3rd trimesters - expert analysis)

Lactation Excretion in breast milk unknown/use caution

Carvedilol

CAS Number 72956-09-3

U.S. Brand Names Coreg®

Use Mild to severe heart failure of ischemic or cardiomyopathic origin (usually in addition to standardized therapy); left ventricular dysfunction following myocardial infarction (MI); management of hypertension

Unlabeled/Investigational Use Angina pectoris

Mechanism of Action Noncardioselective beta-blocking agent with calcium channel blocking activity at higher dose (~30 times the normal dose); similar to labetalol in that there is some alpha₁-adrenergic antagonist effect, thus acting as a vasodilator; less alpha₁ effect than labetalol or prazosin

Adverse Reactions

Note: Frequency ranges include data from hypertension and heart failure trials. Higher rates of adverse reactions have generally been noted in patients with CHF. However, the frequency of adverse effects associated with placebo is also increased in this population. Events occurring at a frequency > placebo in clinical trials.

Cardiovascular: **Hypotension** (9% to 14%), **bradycardia** (2% to 10%), hypertension, AV block, angina, postural hypotension, syncope, dependent edema, palpitations, peripheral edema, generalized edema, cerebrovascular disorder, bundle branch block, myocardial ischemia, peripheral ischemia, tachycardia

Central nervous system: **Dizziness** (6% to 32%), **fatigue** (4% to 24%), headache, fever, paresthesia, somnolence, insomnia, malaise, hypesthesia, vertigo, abnormal thinking, aggravated depression, amnesia, convulsions, emotional lability, impaired concentration, migraine, nervousness, paranoia, paresis, sleep disorders

Dermatologic: Alopecia, erythematous rash, exfoliative dermatitis, maculopapular rash, photosensitivity, pruritus, psoriaform rash

Endocrine & metabolic: **Hyperglycemia** (5% to 12%), **weight gain** (10% to 12%), gout, hypercholesterolemia, dehydration, hyperkalemia, hypervolemia, hypertriglyceridemia, hyperuricemia, hypoglycemia, hyponatremia, diabetes mellitus, HDL-cholesterol decreased, hypokalemia, libido decreased (male)

Gastrointestinal: **Diarrhea** (2% to 12%), nausea, vomiting, melena, periodontitis, GI hemorrhage, xerostomia

Genitourinary: Hematuria, impotence, micturition (increased)

Hematologic: Thrombocytopenia, decreased prothrombin, purpura, anemia, atypical lymphocytes, leukopenia, pancytopenia

Hepatic: Increased transaminases, increased alkaline phosphatase, bilirubinemia

Neuromuscular & skeletal: **Weakness**, back pain, arthralgia, myalgia, muscle cramps, hypokinesia, neuralgia

Ocular: Blurred vision

Otic: Hearing decreased, tinnitus

Renal: Increased BUN, abnormal renal function, albuminuria, glycosuria, increased creatinine, kidney failure

Respiratory: Rhinitis, increased cough, asthma, bronchospasm, pulmonary edema, respiratory alkalosis

Miscellaneous: Injury, increased diaphoresis, allergy, sudden death, anaphylactoid reactions

Postmarketing and/or case reports: Aplastic anemia (rare): All events occurred in patients receiving other medications capable of causing this effect; Stevens-Johnson syndrome; cholestatic jaundice

Pharmacodynamics/Kinetics

Onset of action: 1-2 hours

Peak antihypertensive effect: ~1-2 hours

Absorption: Rapid; food decreases rate but not extent of absorption; administration with food minimizes risks of orthostatic hypotension

Distribution: V_d: 115 L

Protein binding: >98%, primarily to albumin

Metabolism: Extensively hepatic, via **CYP2C9**, **2D6**, **3A4**, and **2C19** (2% excreted unchanged); three active metabolites (4-hydroxyphenyl metabolite is 13 times more potent than parent drug for beta-blockade); first-pass effect; plasma concentrations in the elderly and those with cirrhotic liver disease are 50% and 4-7 times higher, respectively

Bioavailability: 25% to 35%

Half-life elimination: 7-10 hours

Excretion: Primarily feces

Dosage

Oral: Adults: Reduce dosage if heart rate drops to <55 beats/minute.

Hypertension: 6.25 mg twice daily; if tolerated, dose should be maintained for 1-2 weeks, then increased to 12.5 mg twice daily. Dosage may be increased to a maximum of 25 mg twice daily after 1-2 weeks. Maximum dose: 50 mg/day

Congestive heart failure: 3.125 mg twice daily for 2 weeks; if this dose is tolerated, may increase to 6.25 mg twice daily. Double the dose every 2 weeks to the highest dose tolerated by patient. (Prior to initiating therapy, other heart failure medications should be stabilized and fluid retention minimized.)

Maximum recommended dose:

Mild to moderate heart failure:

<85 kg: 25 mg twice daily

>85 kg: 50 mg twice daily

Severe heart failure: 25 mg twice daily

Left ventricular dysfunction following MI: Initial 3.125-6.25 mg twice daily; increase dosage incrementally (ie, from 6.25 to 12.5 mg twice daily) at intervals of 3-10 days, based on tolerance, to a target dose of 25 mg twice daily. **Note:** Should be initiated only after patient is hemodynamically stable and fluid retention has been minimized.

Angina pectoris (unlabeled use): 25-50 mg twice daily

Dosing adjustment in renal impairment: None necessary

Dosing adjustment in hepatic impairment: Use is contraindicated in severe liver dysfunction.

Monitoring Parameters Heart rate, blood pressure (base need for dosage increase on trough blood pressure measurements and for tolerance on standing systolic pressure 1 hour after dosing); renal studies, BUN, liver function

Administration

Administer with food.

Contraindications Hypersensitivity to carvedilol or any component of the formulation; patients with decompensated cardiac failure requiring intravenous inotropic therapy; bronchial asthma or related bronchospastic conditions; second- or third-degree AV block, sick sinus syndrome, and severe bradycardia (except in patients with a functioning artificial pacemaker); cardiogenic shock; severe hepatic impairment; pregnancy (2nd and 3rd trimesters)

Warnings

Initiate cautiously and monitor for possible deterioration in patient status (including symptoms of CHF). Adjustment of other medications (ACE inhibitors and/or diuretics) may be required. In severe chronic heart failure, trial patients were excluded if they had cardiac-related rales, ascites, or a serum creatinine >2.8 mg/dL. Congestive heart failure patients may experience a worsening of renal function; risks include ischemic disease, diffuse vascular disease, underlying renal dysfunction; systolic BP <100 mm Hg. Patients should be advised to avoid driving or other hazardous tasks during initiation of therapy due to the risk of syncope. Avoid abrupt discontinuation (may exacerbate underlying condition), particularly in patients with coronary artery disease; dose should be tapered over 1-2 weeks with close monitoring.

Manufacturer recommends discontinuation of therapy if liver injury occurs (confirmed by laboratory testing). Use caution in patients with PVD (can aggravate arterial insufficiency). Use caution with concurrent use of verapamil or diltiazem; bradycardia or heart block can occur. Use caution in patients with bronchospastic disease. Use cautiously in diabetics because it can mask prominent hypoglycemic symptoms. May mask signs of thyrotoxicosis. Use care with anesthetic agents that decrease myocardial function. Safety and efficacy in children <18 years of age have not been established.

Dosage Forms Tablet: 3.125 mg, 6.25 mg, 12.5 mg, 25 mg

Reference Range Peak serum levels of ~122 mcg/L achieved after oral 50 mg dose

Overdosage/Treatment

Decontamination: Gastric lavage (within 1 hour)/activated charcoal; **do not use ipecac**

Supportive therapy: Sympathomimetics (eg, epinephrine or dopamine), atropine, glucagon or a pacemaker can be used to treat the toxic bradycardia, asystole, and/or hypotension; inamrinone may also be effective for labetalol-induced hypotension; initially fluids may be the best treatment for toxic hypotension with norepinephrine being used for second-line therapy

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; not dialyzable

Drug Interactions

Substrate of CYP1A2 (minor), **2C9** (major), **2D6** (major), **2E1** (minor), **3A4** (minor)

Alpha-blockers (prazosin, terazosin): Concurrent use of beta-blockers may increase risk of orthostasis.

Beta-agonists: Beta-blockers may counteract desired effects of beta-agonists.

Calcium channel blockers (nondihydropyridine): May enhance hypotensive effects of beta-blockers.

Cimetidine: May increase carvedilol serum levels.

CASTOR OIL

CYP2C9 inducers: May decrease the levels/effects of carvedilol. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C9 Inhibitors may increase the levels/effects of carvedilol. Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nicardipine, NSAIDs, sulfonamides and tolbutamide.

CYP2D6 inhibitors: May increase the levels/effects of carvedilol. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Digoxin: Carvedilol may increase the serum levels of digoxin.

Disopyramide: May exacerbate heart failure or enhance bradycardic effect of beta-blockers.

Drugs which slow AV conduction (digoxin): Effects may be additive with beta-blockers.

Insulin and oral hypoglycemics: Carvedilol may mask symptoms of hypoglycemia.

NSAIDs (ibuprofen, indomethacin, naproxen, piroxicam) may reduce the antihypertensive effects of beta-blockers.

Rifampin: May increase the metabolism of carvedilol.

Salicylates: May reduce the antihypertensive effects of beta-blockers.

SSRIs: May decrease the metabolism of carvedilol.

Sulfonylureas: Beta-blockers may alter response to hypoglycemic agents.

Verapamil, diltiazem: May have synergistic or additive pharmacological effects when taken concurrently with beta-blockers.

Pregnancy Risk Factor C (manufacturer); D (2nd and 3rd trimesters - expert analysis)

Pregnancy Implications No data available on whether carvedilol crosses the placenta; beta-blockers have been associated with persistent bradycardia, hypotension, and IUGR; IUGR probably related to maternal hypertension. Cases of neonatal hypoglycemia have been reported following maternal use of beta-blockers at parturition or during breastfeeding. Use during pregnancy only if the potential benefit justifies the risk.

Lactation Excretion in breast milk unknown/contraindicated

Additional Information High concentrations of carvedilol (> 1 µmol/L) can cause calcium channel blocking effect; not useful for pheochromocytoma; should be taken with food

Specific References

Horani MH, Haas MJ, and Mooradian AD, "Suppression of Hyperglycemia-Induced Superoxide Formation and Endothelin-1 Gene Expression by Carvedilol," *Am J Ther*, 2006, 13(1):2-7.

Pregnancy Risk Factor X

Pregnancy Implications Can cause uterine contractures

Nursing Implications Do not administer at bedtime because of rapid onset of action

Additional Information Yellow liquid

Ceftriaxone

CAS Number 104376-79-6; 73384-59-5; 74578-69-1

U.S. Brand Names Rocephin®

Synonyms Ceftriaxone Sodium

Use Treatment of lower respiratory tract infections, acute bacterial otitis media, skin and skin structure infections, bone and joint infections, intra-abdominal and urinary tract infections, sepsis and meningitis due to susceptible organisms; documented or suspected infection due to susceptible organisms in home care patients and patients without I.V. line access; treatment of documented or suspected gonococcal infection or chancroid; emergency room management of patients at high risk for bacteremia, periorbital or buccal cellulitis, salmonellosis or shigellosis, and pneumonia of unestablished etiology (< 5 years of age); treatment of Lyme disease, depends on the stage of the disease (used in Stage II and Stage III, but not stage I; doxycycline is the drug of choice for Stage I)

Unlabeled/Investigational Use Treatment of chancroid, epididymitis, complicated gonococcal infections; sexually-transmitted diseases (STD); periorbital or buccal cellulitis; salmonellosis or shigellosis; atypical community-acquired pneumonia; Lyme disease; used in chemoprophylaxis for high-risk contacts and persons with invasive meningococcal disease; sexual assault

Mechanism of Action Inhibits bacterial cell wall synthesis by binding to one or more of the penicillin-binding proteins (PBPs) which in turn inhibits the final transpeptidation step of peptidoglycan synthesis in bacterial cell walls, thus inhibiting cell wall biosynthesis. Bacteria eventually lyse due to ongoing activity of cell wall autolytic enzymes (autolysins and murein hydrolases) while cell wall assembly is arrested.

Adverse Reactions

Cardiovascular: Flushing

Central nervous system: Chills, dizziness, seizures

Dermatologic: Rash, pruritus

Gastrointestinal: Diarrhea, dysgeusia, gallstones, nausea, vomiting, colitis, pseudomembranous colitis

Genitourinary: Vaginitis

Hematologic: Eosinophilia, thrombocytosis, leukopenia, agranulocytosis, anemia, basophilia, hemolytic anemia, leukocytosis, lymphocytosis, lymphopenia, monocytosis, neutropenia, thrombocytopenia

Hepatic: Elevated transaminases, jaundice, prolonged or decreased PT; increased alkaline phosphatase, increased bilirubin

Local: Pain, induration at injection site (I.V.); warmth, tightness, induration following I.M. injection, phlebitis

Renal: Increased BUN, glycosuria, hematuria, renal stones, urinary casts, nephrolithiasis, renal precipitations

Renal: Elevated creatinine

Respiratory: Bronchospasm, allergic pneumonitis

Miscellaneous: Anaphylaxis, candidiasis, serum sickness

Other reactions with cephalosporins include angioedema, aplastic anemia, asterixis, cholestasis, encephalopathy, erythema multiforme, hemorrhage, interstitial nephritis, neuromuscular excitability, pancytopenia, paresthesia, renal dysfunction, Stevens-Johnson syndrome, superinfection, toxic epidermal necrolysis, toxic nephropathy

Signs and Symptoms of Overdose Hypersensitivity and convulsions; many beta-lactam containing antibiotics have the potential to cause neuromuscular hyperirritability or convulsive seizures

Pharmacodynamics/Kinetics

Absorption: I.M.: Well absorbed

Distribution: Widely throughout the body including gallbladder, lungs, bone, bile, CSF (higher concentrations achieved when meninges are inflamed); crosses placenta; enters amniotic fluid and breast milk

Protein binding: 85% to 95%

Half-life elimination: Normal renal and hepatic function: 5-9 hours

Time to peak, serum: I.M.: 1-2 hours

Excretion: Urine (33% to 65% as unchanged drug); feces

Dosage

I.M., I.V.:

Neonates:

Postnatal age ≤ 7 days: 50 mg/kg/day given every 24 hours

Postnatal age > 7 days:

≤ 2000 g: 50 mg/kg/day given every 24 hours

> 2000 g: 50-75 mg/kg/day given every 24 hours

Gonococcal prophylaxis: 25-50 mg/kg as a single dose (dose not to exceed 125 mg)

Gonococcal infection: 25-50 mg/kg/day (maximum dose: 125 mg) given every 24 hours for 10-14 days

Infants and Children: 50-75 mg/kg/day in 1-2 divided doses every 12-24 hours; maximum: 2 g/24 hours

Castor Oil

CAS Number 8001-79-4

U.S. Brand Names Emulsoil® [OTC] [DSC]; Purge® [OTC]

Synonyms Oleum Ricini

Use Preparation for rectal or bowel examination or surgery; rarely used to relieve constipation; also applied to skin as emollient and protectant

Mechanism of Action Acts primarily in the small intestine; hydrolyzed to ricinoleic acid which reduces net absorption of fluid and electrolytes and stimulates peristalsis; oil is expressed from the seeds of *Ricinus communis*

Adverse Reactions

Frequency not defined.

Cardiovascular: Hypotension

Central nervous system: Dizziness

Endocrine & metabolic: Electrolyte disturbance

Gastrointestinal: Abdominal cramps, nausea, diarrhea

Genitourinary: Pelvic congestion

Pharmacodynamics/Kinetics Onset of action: 2-6 hours

Dosage

Oral:

Oil:

Children 2-11 years: 5-15 mL as a single dose

Children ≥ 12 years and Adults: 15-60 mL as a single dose

Emulsified (36.4%):

Children < 2 years: 5-15 mL/dose

Children 2-11 years: 7.5-30 mL/dose

Children ≥ 12 years and Adults: 30-60 mL/dose

Stability Protect from heat (castor oil emulsion should be protected from freezing)

Administration

Do not administer at bedtime because of rapid onset of action.

Dosage Forms

[DSC] = Discontinued product

Emulsion, oral (Emulsoil® [DSC]): 95% (60 mL)

Oil, oral: 100% (60 mL, 120 mL, 480 mL, 3840 mL)

Purge®: 95% (30 mL, 60 mL) [lemon flavor]

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal without a cathartic

Supportive therapy: I.V. fluid and electrolyte replacement; restrict solid food

Drug Interactions No data reported

Meningitis: 100 mg/kg/day divided every 12-24 hours, up to a maximum of 4 g/24 hours; loading dose of 75 mg/kg/dose may be given at start of therapy
 Acute otitis media: I.M., I.V.: 50 mg/kg in a single dose (maximum dose: 1 g)
 Persistent or relapsing acute otitis media: I.M., I.V.: 50 mg/kg once daily for 3 days (maximum dose: 1 g/day)
 Uncomplicated gonococcal infections, sexual assault, and STD prophylaxis: I.M.: 125 mg as a single dose plus doxycycline
 Complicated gonococcal infections:
 Infants: I.M., I.V.: 25-50 mg/kg/day in a single dose (maximum: 125 mg/dose); treat for 7 days for disseminated infection and 7-14 days for documented meningitis
 < 45 kg: 50 mg/kg/day once daily; maximum: 1 g/day; for ophthalmia, peritonitis, arthritis, or bacteremia: 50-100 mg/kg/day divided every 12-24 hours; maximum: 2 g/day for meningitis or endocarditis
 > 45 kg: 1 g/day once daily for disseminated gonococcal infections; 1-2 g dose every 12 hours for meningitis or endocarditis
 Acute epididymitis: I.M.: 250 mg in a single dose
 Adults: 1-2 g every 12-24 hours (depending on the type and severity of infection); maximum dose: 2 g every 12 hours for treatment of meningitis
 Uncomplicated gonorrhea: I.M.: 250 mg as a single dose
 Surgical prophylaxis: 1 g 30 minutes to 2 hours before surgery

Dosing adjustment in renal or hepatic impairment: No change necessary

Hemodialysis: Not dialyzable (0% to 5%); administer dose postdialysis
 Peritoneal dialysis: Administer 750 mg every 12 hours
 Continuous arteriovenous or venovenous hemofiltration: Removes 10 mg of ceftriaxone per liter of filtrate per day

Stability Reconstituted solution (100 mg/mL) is stable for 3 days at room temperature and 3 days when refrigerated; for I.V. infusion in NS or D₅W solution is stable for 3 days at room temperature, 10 days when refrigerated, or 26 weeks when frozen; after freezing, thawed solution is stable for 3 days at room temperature or 10 days when refrigerated. Incompatible with vancomycin or pentamidine

Monitoring Parameters Observe for signs and symptoms of anaphylaxis

Administration

Do not admix with aminoglycosides in same bottle/bag.
 I.M.: Inject deep I.M. into large muscle mass; a concentration of 250 mg/mL or 350 mg/mL is recommended for all vial sizes except the 250 mg size (250 mg/mL is suggested); can be diluted with 1:1 water and 1% lidocaine for I.M. administration.
 I.V.: Infuse intermittent infusion over 30 minutes.

Contraindications Hypersensitivity to ceftriaxone sodium, any component of the formulation, or other cephalosporins; **do not use in hyperbilirubinemic neonates**, particularly those who are premature since ceftriaxone is reported to displace bilirubin from albumin binding sites

Warnings Modify dosage in patients with severe renal impairment. Prolonged use may result in superinfection. Use with caution in patients with a history of penicillin allergy, especially IgE-mediated reactions (eg, anaphylaxis, urticaria). May cause antibiotic-associated colitis or colitis secondary to *C. difficile*. Discontinue in patients with signs and symptoms of gallbladder disease.

Dosage Forms

Note: Contains sodium 83 mg (3.6 mEq) per ceftriaxone 1 g
 Infusion [premixed in dextrose]: 1 g (50 mL); 2 g (50 mL)
 Injection, powder for reconstitution: 250 mg, 500 mg, 1 g, 2 g, 10 g

Reference Range Peak plasma ceftriaxone levels of 40 mcg/mL and 80 mcg/mL have been reported after I.M. administration of 0.5 g and 1 g, respectively.

Overdosage/Treatment Supportive therapy: Hemodialysis may be helpful to aid in removal of the drug from blood; otherwise, treatment is supportive or symptom directed. Anaphylaxis can be treated with standard therapy.

Test Interactions Positive direct Coombs', false-positive urinary glucose test using cupric sulfate (Benedict's solution, Clinitest®, Fehling's solution), false-positive serum or urine creatinine with Jaffé reaction

Drug Interactions

Coumarin derivative (eg, dicumarol, warfarin): Cephalosporins may increase the anticoagulant effect of coumarin derivatives.
 Uricosuric agents (eg, probenecid, sulfapyrazone): Uricosuric agents may decrease the excretion of cephalosporin; monitor for toxic effects.

Pregnancy Risk Factor B

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications For I.M. injection, the maximum concentration is 250 mg/mL; ceftriaxone can be diluted with 1:1 water and 1% lidocaine for I.M. administration. Do not admix with aminoglycosides in same bottle/bag.

Additional Information Sodium content of 1 g: 60 mg (2.6 mEq)

Cefuroxime

CAS Number 64544-07-6

U.S. Brand Names Ceftin®, Zinacef®

Synonyms Cefuroxime Axetil; Cefuroxime Sodium

Use Treatment of infections caused by staphylococci, group B streptococci, *H. influenzae* (type A and B), *E. coli*, *Enterobacter*, *Salmonella*, and *Klebsiella*; treatment of susceptible infections of the lower respiratory tract, otitis media, urinary tract, skin and soft tissue, bone and joint, sepsis and gonorrhea

Mechanism of Action Inhibits bacterial cell wall synthesis by binding to one or more of the penicillin-binding proteins (PBPs) which in turn inhibits the final transpeptidation step of peptidoglycan synthesis in bacterial cell walls, thus inhibiting cell wall biosynthesis. Bacteria eventually lyse due to ongoing activity of cell wall autolytic enzymes (autolysins and murein hydrolases) while cell wall assembly is arrested.

Adverse Reactions

Central nervous system: Dizziness, fever, headache, seizures
 Dermatologic: Cutaneous vasculitis, angioedema, erythema multiforme, rash, toxic epidermal necrolysis
 Gastrointestinal: Colitis, diarrhea, GI bleeding, nausea, stomach cramps, vomiting, pseudomembranous colitis
 Genitourinary: Vaginitis
 Hematologic: Eosinophilia, **decreased hemoglobin and hematocrit**, leukopenia, neutropenia, hemolytic anemia, pancytopenia, prolonged PT/INR, thrombocytopenia
 Hepatic: Increased transaminases, increased alkaline phosphatase, cholestasis
 Local: Thrombophlebitis, pain at injection site
 Renal: Increased BUN, increased creatinine, interstitial nephritis
 Miscellaneous: Anaphylaxis

Reactions reported with other cephalosporins include agranulocytosis, aplastic anemia, asterixis, encephalopathy, hemorrhage, neuromuscular excitability, serum-sickness reactions, superinfection, toxic nephropathy

Signs and Symptoms of Overdose Symptoms of overdose include neuromuscular hypersensitivity and convulsions. Many beta-lactam containing antibiotics have the potential to cause neuromuscular hyperirritability or convulsive seizures.

Pharmacodynamics/Kinetics

Absorption: Oral (cefuroxime axetil): Increases with food
 Distribution: Widely to body tissues and fluids; crosses blood-brain barrier; therapeutic concentrations achieved in CSF even when meninges are not inflamed; crosses placenta; enters breast milk
 Protein binding: 33% to 50%
 Bioavailability: Tablet: Fasting: 37%; Following food: 52%
 Half-life elimination: Adults: 1-2 hours; prolonged with renal impairment
 Time to peak, serum: I.M.: ~15-60 minutes; I.V.: 2-3 minutes
 Excretion: Urine (66% to 100% as unchanged drug)

Dosage

Note: Cefuroxime axetil film-coated tablets and oral suspension are not bioequivalent and are not substitutable on a mg/mg basis
 Children ≥ 3 months to 12 years:

Pharyngitis, tonsillitis: Oral:
 Suspension: 20 mg/kg/day (maximum: 500 mg/day) in 2 divided doses for 10 days
 Tablet: 125 mg every 12 hours for 10 days

Acute otitis media, impetigo: Oral:
 Suspension: 30 mg/kg/day (maximum: 1 g/day) in 2 divided doses for 10 days
 Tablet: 250 mg twice daily for 10 days

I.M., I.V.: 75-150 mg/kg/day divided every 8 hours; maximum dose: 6 g/day

Meningitis: Not recommended (doses of 200-240 mg/kg/day divided every 6-8 hours have been used); maximum dose: 9 g/day

Acute bacterial maxillary sinusitis:
 Suspension: 30 mg/kg/day in 2 divided doses for 10 days; maximum dose: 1 g/day
 Tablet: 250 mg twice daily for 10 days

Children ≥ 13 years and Adults:
 Oral: 250-500 mg twice daily for 10 days (5 days in selected patients with acute bronchitis)

Uncomplicated urinary tract infection: 125-250 mg every 12 hours for 7-10 days

Uncomplicated gonorrhea: 1 g as a single dose
 Early Lyme disease: 500 mg twice daily for 20 days

CELECOXIB

I.M., I.V.: 750 mg to 1.5 g/dose every 8 hours or 100-150 mg/kg/day in divided doses every 6-8 hours; maximum: 6 g/24 hours

Dosing adjustment in renal impairment:

Cl_{cr} 10-20 mL/minute: Administer every 12 hours

Cl_{cr} < 10 mL/minute: Administer every 24 hours

Hemodialysis: Dialyzable (25%)

Continuous arteriovenous or venovenous hemodiafiltration effects: Dose as for Cl_{cr} 10-20 mL/minute

Stability Reconstituted solution is stable for 24 hours at room temperature and 48 hours when refrigerated; I.V. infusion in NS or D₅W solution is stable for 24 hours at room temperature, 7 days when refrigerated, or 26 weeks when frozen; after freezing, thawed solution is stable for 24 hours at room temperature or 21 days when refrigerated

Monitoring Parameters Observe for signs and symptoms of anaphylaxis during first dose; with prolonged therapy, monitor renal, hepatic, and hematologic function periodically; monitor prothrombin time in patients at risk of prolongation during cephalosporin therapy (nutritionally-deficient, prolonged treatment, renal or hepatic disease)

Administration Oral: Administer around-the-clock to promote less variation in peak and trough serum levels.

Oral suspension: Administer with food. Shake well before use.

I.M.: Inject deep I.M. into large muscle mass.

I.V.: Inject direct I.V. over 3-5 minutes. Infuse intermittent infusion over 15-30 minutes.

Contraindications Hypersensitivity to cefuroxime, any component of the formulation, or other cephalosporins

Warnings Modify dosage in patients with severe renal impairment. Prolonged use may result in superinfection. Use with caution in patients with a history of penicillin allergy, especially IgE-mediated reactions (eg, anaphylaxis, urticaria). May cause antibiotic-associated colitis or colitis secondary to *C. difficile*. May be associated with increased INR, especially in nutritionally-deficient patients, prolonged treatment, hepatic or renal disease. Tablets and oral suspension are not bioequivalent (do not substitute on a mg-per-mg basis).

Dosage Forms

Infusion, as sodium [premixed] (Zinacef®): 750 mg (50 mL); 1.5 g (50 mL) [contains sodium 4.8 mEq (111 mg) per 750 mg]

Injection, powder for reconstitution, as sodium (Zinacef®): 750 mg, 1.5 g, 7.5 g [contains sodium 4.8 mEq (111 mg) per 750 mg]

Powder for oral suspension, as axetil (Ceftin®): 125 mg/5 mL (100 mL) [contains phenylalanine 11.8 mg/5 mL; tutti-frutti flavor]; 250 mg/5 mL (50 mL, 100 mL) [contains phenylalanine 25.2 mg/5 mL; tutti-frutti flavor]

Tablet, as axetil (Ceftin®): 250 mg, 500 mg

Reference Range Peak plasma level: 27 mcg/mL achieved 45 minutes after 750 mg I.M. dose

Overdosage/Treatment Supportive therapy: Hemodialysis may be helpful to aid in removal of the drug from blood. Most treatment is supportive or symptom directed following GI decontamination.

Test Interactions Positive direct Coombs', false-positive urinary glucose test using cupric sulfate (Benedict's solution, Clinites®), Fehling's solution), false-positive serum or urine creatinine with Jaffé reaction

Drug Interactions

Increased effect: High-dose probenecid decreases clearance.

Increased toxicity: Aminoglycosides increase nephrotoxic potential.

Pregnancy Risk Factor B

Lactation Enters breast milk/use caution

Nursing Implications Do not admix with aminoglycosides in same bottle/bag; obtain specimens for culture and sensitivity prior to the first dose

Additional Information Sodium content of 1 g: 54.2 mg (2.4 mEq)

Celecoxib

Related Information

- Nonsteroidal Anti-inflammatory Drugs

CAS Number 169590-42-5

U.S. Brand Names Celebrex®

Use Relief of the signs and symptoms of osteoarthritis; relief of the signs and symptoms of rheumatoid arthritis in adults; decreasing intestinal polyps in familial adenomatous polyposis (FAP); management of acute pain; treatment of primary dysmenorrhea

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase-2 (COX-2), which results in decreased formation of prostaglandin precursors.

Adverse Reactions

Cardiovascular: Peripheral edema, hypertension (aggravated), chest pain, myocardial infarction, palpitations, tachycardia, facial edema, vasculitis, torsade de pointes

Central nervous system: **Headache**, insomnia, dizziness, hallucinations (auditory)

Dermatologic: Skin rash, toxic epidermal necrolysis

Gastrointestinal: Dyspepsia, diarrhea, abdominal pain, nausea, flatulence

Neuromuscular & skeletal: Back pain

Renal: Increased BUN, increased creatinine, albuminuria, hematuria, renal calculi

Respiratory: Upper respiratory tract infection, sinusitis, pharyngitis, rhinitis

Miscellaneous: Accidental injury

Signs and Symptoms of Overdose Epigastric pain, drowsiness, lethargy, nausea, and vomiting; GI bleeding may occur. Rare manifestations include coma, hypertension, respiratory depression, and acute renal failure.

Pharmacodynamics/Kinetics

Distribution: V_d (apparent): 400 L

Protein binding: 97% to albumin

Metabolism: Hepatic via CYP2C9; forms inactive metabolites

Bioavailability: Absolute: Unknown

Half-life elimination: 11 hours (fasted)

Time to peak: 3 hours

Excretion: Urine (27% as metabolites, <3% as unchanged drug); feces (57%)

Dosage

Adults: Oral:

Acute pain or primary dysmenorrhea: Initial dose: 400 mg, followed by an additional 200 mg if needed on day 1; maintenance dose: 200 mg twice daily as needed

Familial adenomatous polyposis (FAP): 400 mg twice daily

Osteoarthritis: 200 mg/day as a single dose or in divided dose twice daily

Rheumatoid arthritis: 100-200 mg twice daily

Elderly: No specific adjustment is recommended. However, the AUC in elderly patients may be increased by 50% as compared to younger subjects. Use the lowest recommended dose in patients weighing <50 kg.

Dosing adjustment in renal impairment: No specific dosage adjustment is recommended; not recommended in patients with advanced renal disease

Dosing adjustment in hepatic impairment: Reduced dosage is recommended (AUC may be increased by 40% to 180%); decrease dose by 50% in patients with moderate hepatic impairment (Child-Pugh Class II)

Monitoring Parameters Periodic LFTs; in patients treated for FAP, continue routine endoscopic exams

Contraindications Hypersensitivity to celecoxib, sulfonamides, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy (3rd trimester)

Warnings

[U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, and new onset or worsening of pre-existing hypertension. Risk may be increased with duration of use or pre-existing cardiovascular risk factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF, cerebrovascular disease, ischemic heart disease, or hypertension.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients. Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS), and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with dehydration, decreased renal or hepatic function. Use of NSAIDs can compromise existing renal function, especially when Cl_{cr} < 30 mL/minute. Not recommended for use in severe renal or hepatic impairment.

Anaphylactoid reactions may occur, even with no prior exposure to celecoxib. Use caution in patients with known or suspected deficiency of cytochrome P450 isoenzyme 2C9. Safety and efficacy have not been established in patients <18 years of age. **[U.S. Boxed Warning]: Celecoxib is contraindicated for treatment of perioperative pain in the setting of coronary artery bypass surgery (CABG).**

Dosage Forms Capsule: 100 mg, 200 mg, 400 mg

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Symptomatic and supportive treatment. Forced diuresis, hemodialysis and/or urinary alkalinization may not be useful.

Drug Interactions

Substrate of CYP2C9 (major), 3A4 (minor); **Inhibits** CYP2C8 (moderate), 2D6 (weak)

ACE inhibitors: Antihypertensive effect may be diminished by celecoxib.

Aminoglycosides: Celecoxib may decrease excretion; monitor levels.
 Aspirin: Low-dose aspirin may be used with celecoxib, however, monitor for GI complications.
 Beta-blockers: Antihypertensive effect may be diminished by celecoxib.
 Bile acid sequestrants: May decrease absorption of NSAIDs.
 CYP2C8 Substrates: Celecoxib may increase the levels/effects of CYP2C8 substrates. Example substrates include amiodarone, paclitaxel, pioglitazone, repaglinide, and rosiglitazone.
 Cyclosporine: NSAIDs may increase levels/nephrotoxicity of cyclosporine.
 Fluconazole: Fluconazole increases celecoxib concentrations twofold. Lowest dose of celecoxib should be used.
 Hydralazine: Antihypertensive effect may be diminished by celecoxib.
 Lithium: Plasma levels of lithium are increased by ~17% when used with celecoxib. Monitor lithium levels closely when treatment with celecoxib is started or withdrawn.
 Loop diuretics (bumetanide, furosemide, torsemide): Natriuretic effect of furosemide and other loop diuretics may be decreased by celecoxib.
 Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Selective COX-2 inhibitors appear to have a lower risk of this toxicity, however, caution is warranted.
 Thiazide diuretics: Natriuretic effects of thiazide diuretics may be decreased by celecoxib.
 Vancomycin: Celecoxib may decrease excretion; monitor levels.
 Warfarin: Bleeding events (including rare intracranial hemorrhage in association with increased prothrombin time) have been reported with concomitant use. Monitor closely, especially in the elderly.

Pregnancy Risk Factor C/D (3rd trimester)

Pregnancy Implications In late pregnancy, this drug may cause premature closure of the ductus arteriosus.

Lactation Enters breast milk/not recommended (contraindicated in Canadian labeling)

Additional Information Cross-reactivity, including bronchospasm, between aspirin and other NSAIDs has been reported in aspirin-sensitive patients. The manufacturer suggests that celecoxib should not be administered to patients with this type of aspirin sensitivity and should be used with caution in patients with pre-existing asthma.

Celiprolol

CAS Number 56980-93-9; 57470-78-7

Synonyms Celiprolol Hydrochloride

Unlabeled/Investigational Use Hypertension, angina

Mechanism of Action Selective beta₁-adrenergic blocking agent with weak alpha₂ receptor blocking activity; no negative inotropic effect; may also stimulate beta₂ receptors resulting in vasodilatation

Adverse Reactions

Cardiovascular: Bradycardia, AV block, Raynaud's syndrome, congestive heart failure, sinus bradycardia, myocardial depression
 Central nervous system: Insomnia, dizziness, headache, depression
 Gastrointestinal: Nausea, diarrhea, xerostomia
 Neuromuscular & skeletal: Tremors

Signs and Symptoms of Overdose AV block, hypoglycemia, insomnia, wheezing

Pharmacodynamics/Kinetics

Absorption: 30% to 74%; reduced by food

Protein binding: 25%

Half-life elimination: 4-10 hours

Time to peak, plasma: 2-4 hours

Excretion: Urine (50%)

Dosage Oral: 200-600 mg once daily; no dosage alteration needed in elderly

Monitoring Parameters Monitor blood pressure, apical and radial pulses, I & O, daily weight, respirations, and circulation in extremities before and during therapy

Contraindications Hypersensitivity to celiprolol, any component of the formulation, or other beta-blocking agents; sinus bradycardia; heart block greater than first-degree (except in patients with a functioning artificial pacemaker); cardiogenic shock; uncompensated cardiac failure

Warnings Administer cautiously in compensated heart failure and monitor for a worsening of the condition. Avoid abrupt discontinuation in patients with a history of CAD; slowly wean while monitoring for signs and symptoms of ischemia. Use caution with concurrent use of beta-blockers and either verapamil or diltiazem; bradycardia or heart block can occur. In general, beta-blockers should be avoided in patients with bronchospastic disease. Use cautiously in PVD (can exacerbate arterial insufficiency). Can mask signs of thyrotoxicosis. Dosage adjustment is required in patients with renal dysfunction. Use care with anesthetic agents that decrease myocardial function.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** use ipecac

Supportive therapy: Glucagon (50-150 mcg/kg followed by continuous drip of 1-5 mg/hour) for positive chronotropic effect, inamrinone may need to be added; atropine/isoproterenol can be utilized to increase heart rate; calcium chloride may also be effective but this approach has not thoroughly been investigated; **do not** use epinephrine in that unopposed alpha effects may occur; pacemaker or intra-aortic balloon counter pulsation may be required

Enhancement of elimination: Multiple dosing of activated charcoal is not likely to be of benefit; dialysis is not useful; not dialyzable (0% to 5%)

Antidote(s)

- Glucagon [ANTIDOTE]

Drug Interactions

Expected interactions:

Alpha-blockers (prazosin, terazosin): Concurrent use of beta-blockers may increase risk of orthostasis.

Ampicillin, in single doses of 1 gram, decrease celiprolol's pharmacologic actions.

Antacids (magnesium-aluminum, calcium antacids or salts) may reduce the bioavailability of celiprolol.

Clonidine: Hypertensive crisis after or during withdrawal of either agent. Drugs which slow AV conduction (digoxin): Effects may be additive with beta-blockers.

Glucagon: Celiprolol may blunt the hyperglycemic action of glucagon.

Insulin and oral hypoglycemics: Celiprolol masks the tachycardia that usually accompanies hypoglycemia.

NSAIDs (ibuprofen, indomethacin, naproxen, piroxicam) may reduce the antihypertensive effects of beta-blockers.

Salicylates may reduce the antihypertensive effects of beta-blockers.

Sulfonylureas: Beta-blockers may alter response to hypoglycemic agents. Verapamil or diltiazem may have synergistic or additive pharmacological effects when taken concurrently with beta-blockers.

Additional Information Can cause decrease in serum cholesterol; HDL increases noted; can cause increase in thyroid function tests; reduction in fibrinogen levels have been described

Cephalexin

CAS Number 15686-71-2; 23325-78-2

U.S. Brand Names Biocef[®]; Keflex[®]

Synonyms Cephalexin Monohydrate

Use Treatment of susceptible bacterial infections, including those caused by group A beta-hemolytic *Streptococcus*, *Staphylococcus*, *Klebsiella pneumoniae*, *E. coli*, *Proteus mirabilis*, and *Shigella*; predominantly used for lower respiratory tract, urinary tract, skin and soft tissue, and bone and joint

Mechanism of Action Inhibits bacterial cell wall synthesis by binding to one or more of the penicillin-binding proteins (PBPs) which in turn inhibits the final transpeptidation step of peptidoglycan synthesis in bacterial cell walls, thus inhibiting cell wall biosynthesis. Bacteria eventually lyse due to ongoing activity of cell wall autolytic enzymes (autolysins and murein hydrolases) while cell wall assembly is arrested.

Adverse Reactions

Central nervous system: Dizziness, fatigue, headache
 Dermatologic: Rash, toxic epidermal necrolysis, urticaria, pemphigus vulgaris, erythema multiforme, angioedema, purpura, Stevens-Johnson syndrome, pruritus, exanthem

CEPHRADINE

Gastrointestinal: Nausea, diarrhea, vomiting, pseudomembranous colitis
Hematologic: Transient neutropenia, anemia, eosinophilia, hemolytic anemia
Hepatic: Transient elevation in liver enzymes
Ocular: Diplopia
Otic: Tinnitus
Miscellaneous: Fixed drug eruption

Signs and Symptoms of Overdose Crystalluria, seizures, toxic psychosis

Pharmacodynamics/Kinetics

Absorption: Delayed in young children
Distribution: Widely into most body tissues and fluids, including gallbladder, liver, kidneys, bone, sputum, bile, and pleural and synovial fluids; CSF penetration is poor; crosses placenta; enters breast milk
Protein binding: 6% to 15%
Half-life elimination: Adults: 0.5-1.2 hours; prolonged with renal impairment
Time to peak, serum: ~1 hour
Excretion: Urine (80% to 100% as unchanged drug) within 8 hours

Dosage

Oral:
Children: 25-50 mg/kg/day every 6 hours; severe infections: 50-100 mg/kg/day in divided doses every 6 hours; maximum: 3 g/24 hours
Adults: 250-1000 mg every 6 hours; maximum: 4 g/day
Dosing interval in renal impairment: $Cl_{cr} < 10$ mL/minute: Administer every 8-12 hours

Stability Refrigerate suspension after reconstitution; discard after 14 days

Monitoring Parameters With prolonged therapy monitor renal, hepatic, and hematologic function periodically; monitor for signs of anaphylaxis during first dose

Administration

Take without regard to food. If GI distress, take with food. Give around-the-clock to promote less variation in peak and trough serum levels.

Contraindications Hypersensitivity to cephalexin, any component of the formulation, or other cephalosporins

Warnings Modify dosage in patients with severe renal impairment; prolonged use may result in superinfection. Use with caution in patients with a history of penicillin allergy, especially IgE-mediated reactions (eg, anaphylaxis, urticaria). May cause antibiotic-associated colitis or colitis secondary to *C. difficile*.

Dosage Forms

[DSC] = Discontinued product
Capsule: 250 mg, 500 mg
Biocef®: 500 mg
Keflex®: 250 mg, 333 mg, 500 mg, 750 mg
Powder for oral suspension: 125 mg/5 mL (100 mL, 200 mL); 250 mg/5 mL (100 mL, 200 mL)
Biocef®: 125 mg/5 mL (100 mL); 250 mg/5 mL (100 mL)
Keflex®: 125 mg/5 mL (100 mL, 200 mL); 250 mg/5 mL (100 mL, 200 mL)
Tablet, for oral suspension (Panixine DisperDose™): 125 mg [contains phenylalanine 2.8 mg; peppermint flavor], 250 mg [contains phenylalanine 5.6 mg; peppermint flavor] [DSC]

Reference Range Peak serum cephalexin levels after a 1 g oral dose: ~32 mg/mL; therapeutic range: 12-30 mg/mL; level >120 mg/mL associated with seizures

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage within 1 hour for ingestions >500 mg/kg; activated charcoal or cholestyramine can be used to decrease absorption
Supportive therapy: Seizures can be treated with benzodiazepines; phenobarbital or phenytoin can be used for refractory seizures
Enhanced elimination: Moderately dialyzable (20% to 50%); 58% of dose can be removed in a 6-hour dialysis

Test Interactions False-positive Coombs' test, may falsely elevate creatinine values when Jaffé reaction is used, may cause false-positive results in urine glucose tests using cupric sulfate (Benedict's solution, Clinitest®), false-positive urinary proteins and steroids; can result in false elevation of theophylline by HPLC method. The presence of this drug can result in a decrease of reactivity of urinary leukocyte esterase

Drug Interactions Aminoglycosides: Increase nephrotoxic potential.
Probenecid: High-dose probenecid decreases clearance of cephalexin.
Typhoid vaccine: Antibiotics may diminish the efficacy of the live, attenuated Ty21a strain vaccine.

Pregnancy Risk Factor B

Pregnancy Implications Animal studies have not demonstrated fetal effects. There are no adequate and well-controlled studies in pregnant women. Use in pregnancy only if clearly needed.

Lactation Enters breast milk (small amounts)/use caution

Nursing Implications Obtain specimens for culture and sensitivity prior to the first dose

Cephadrine

CAS Number 31828-50-9; 38821-53-3; 58456-86-3

U.S. Brand Names Velosef®

Use Treatment of infections when caused by susceptible strains in respiratory, genitourinary, gastrointestinal, skin and soft tissue, bone and joint infections; treatment of susceptible gram-positive bacilli and cocci (never enterococcus); some gram-negative bacilli including *E. coli*, *Proteus*, and *Klebsiella* may be susceptible

Mechanism of Action Bactericidal antibiotic with a mechanism similar to that of penicillins; after penetrating the bacterial cell wall, it stops cell synthesis and thereby kills the organism

Adverse Reactions

Frequency not defined.
Central nervous system: Dizziness
Dermatologic: Rash, pruritus
Gastrointestinal: Diarrhea, nausea, vomiting, pseudomembranous colitis
Hematologic: Leukopenia, neutropenia, eosinophilia
Neuromuscular & skeletal: Joint pain
Renal: BUN increased, creatinine increased

Pharmacodynamics/Kinetics

Absorption: Well absorbed
Distribution: Widely into most body tissues and fluids including gallbladder, liver, kidneys, bone, sputum, bile, and pleural and synovial fluids; CSF penetration is poor; crosses placenta; enters breast milk
Protein binding: 18% to 20%
Half-life elimination: 1-2 hours; prolonged with renal impairment
Time to peak, serum: 1-2 hours
Excretion: Urine (~80% to 90% as unchanged drug) within 6 hours

Dosage

Oral:
Children ≥9 months: Usual dose: 25-50 mg/kg/day in divided doses every 6 hours
Otitis media: 75-100 mg/kg/day in divided doses every 6 or 12 hours (maximum: 4 g/day)
Adults: 250-500 mg every 6-12 hours
Dosing adjustment in renal impairment: Adults:
 Cl_{cr} 10-50 mL/minute: 250 mg every 6 hours
 $Cl_{cr} < 10$ mL/minute: 125 mg every 6 hours

Monitoring Parameters Observe for signs and symptoms of anaphylaxis during first dose

Administration

Administer around-the-clock to promote less variation in peak and trough serum levels. Shake oral suspension well.

Contraindications Hypersensitivity to cephradine, any component of the formulation, or cephalosporins

Warnings Use caution with renal impairment; dose adjustment required. Prolonged use may result in superinfection; use with caution in patients with a history of penicillin allergy, especially IgE-mediated reactions (eg, anaphylaxis, urticaria). May cause antibiotic-associated colitis or colitis secondary to *C. difficile*.

Dosage Forms

[DSC] = Discontinued product
Capsule: 250 mg, 500 mg [DSC]
Powder for oral suspension: 250 mg/5 mL (100 mL) [fruit flavor]

Reference Range Oral doses of 1 g result in a peak plasma level of 24 mcg/mL; intramuscular dose of 1 g results in a peak plasma level of 14 mcg/mL

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal
Supportive therapy: Anaphylaxis can be treated with epinephrine, antihistamines, and corticosteroids
Enhancement of elimination: Multiple dosing of activated charcoal may be effective; hemodialysis or hemoperfusion can help enhance elimination

Test Interactions False-positive Coombs' test, may falsely elevate creatinine values when Jaffé reaction is used, may cause false-positive results in urine glucose tests using cupric sulfate (Benedict's solution, Clinitest®), false-positive urinary proteins and steroids

Drug Interactions

Increased effect: High-dose probenecid decreases clearance.
Increased toxicity: Aminoglycosides may increase nephrotoxic potential.

Pregnancy Risk Factor B

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk/use caution

Additional Information Sodium concentration: 6 mEq/g

Cetirizine

CAS Number 83881-51-0; 83881-52-1

U.S. Brand Names Zyrtec®

Synonyms Cetirizine Hydrochloride; P-071; UCB-P071

Impairment Potential Yes. Minimal mental performance changes may occur at doses of 20 mg (none at lower doses); may mildly affect driving performance at therapeutic doses

Use Perennial and seasonal allergic rhinitis and other allergic symptoms including urticaria; chronic idiopathic urticaria

Mechanism of Action Potent antihistamine (H₁ receptor antagonist) with little antimuscarinic effects. It is a carboxylated metabolite of hydroxyzine. Also inhibits inflammatory cell migration, and exhibits a mild bronchodilatory effect

Adverse Reactions

Cardiovascular: Cardiac failure, chest pain, edema, face edema, hypertension, hypotension, palpitations, syncope, tachycardia

Central nervous system: Abnormal thinking, aggressiveness, amnesia, anxiety, ataxia, dizziness (adults 2%), fatigue (adults 6%), **headache** (children 11% to 14%, placebo 12%), insomnia, malaise (4%), **somnolence** (adults 14%, children 2% to 4%), confusion, convulsions, coordination abnormal, depersonalization, depression, dysphonia, emotional lability, euphoria, fever, flushing, fussiness, hallucinations, hyperesthesia, hypertonia, hypoesthesia, impaired concentration, irritability, migraine, nervousness, pain, paroniria, rigors, sleep disorder, suicidal ideation, suicide, tremor, vertigo

Dermatologic: Acne, alopecia, angioedema, bullous eruption, dermatitis, dry skin, eczema, erythematous rash, furunculosis, hyperkeratosis, hypertrichosis, maculopapular rash, pallor, photosensitivity, pruritus, purpura, rash, seborrhea, skin nodule, urticaria

Endocrine & metabolic: Breast pain (female), dehydration, diabetes mellitus, dysmenorrhea, hot flashes, intermenstrual bleeding, libido decreased, menorrhagia

Gastrointestinal: Abdomen enlarged, abdominal pain (children 4% to 6%), anorexia, appetite increased, diarrhea (children 2% to 3%), dry mouth (adults 5%), nausea (children 2% to 3%, placebo 2%), vomiting (children 2% to 3%) constipation, dyspepsia, eructation, flatulence, gastritis, hemorrhoids, melena, rectal hemorrhage, salivation increased, sputum increased, stomatitis, taste loss, taste perversion, tongue discoloration, tongue edema, ulcerative stomatitis, weight gain

Genitourinary: Cystitis, dysuria, leukorrhea, micturition frequency, urinary incontinence, urinary retention, urinary tract infection, vaginitis

Hepatic: Cholestasis, hepatitis, increased bilirubin, liver enzymes elevated (transient), abnormal liver function

Hematologic: Hemolytic anemia, thrombocytopenia

Neuromuscular & skeletal: Arthralgia, arthritis, arthrosis, back pain, hyperkinesia, leg cramps, leg edema, muscle weakness, myalgia, myelitis, orofacial dyskinesia, paralysis, paresthesia, twitching, weakness

Ocular: Accommodation loss, blindness, conjunctivitis, eye pain, glaucoma, ocular hemorrhage, periorbital edema, ptosis, visual field defect, xerophthalmia

Otic: Deafness, earache, ototoxicity, tinnitus

Renal: Glomerulonephritis, hematuria, polyuria

Respiratory: Bronchitis, bronchospasm (children 2% to 3%, placebo 2%) epistaxis (children 2% to 4%, placebo 3%), pharyngitis (children 3% to 6%, placebo 3%), dyspnea, hyperventilation, nasal polyp, pneumonia, rhinitis, sinusitis, upper respiratory tract infection

Miscellaneous: Anaphylaxis, lymphadenopathy, sweating, thirst, parosmia

Pharmacodynamics/Kinetics

Onset of action: 15-30 minutes

Absorption: Rapid

Protein binding, plasma: Mean: 93%

Metabolism: Limited hepatic

Half-life elimination: 8 hours

Time to peak, serum: 1 hour

Excretion: Urine (70%); feces (10%)

Dosage

Oral:

Children:

6-12 months: Chronic urticaria, perennial allergic rhinitis: 2.5 mg once daily

12 months to <2 years: Chronic urticaria, perennial allergic rhinitis: 2.5 mg once daily; may increase to 2.5 mg every 12 hours if needed

2-5 years: Chronic urticaria, perennial or seasonal allergic rhinitis: Initial: 2.5 mg once daily; may be increased to 2.5 mg every 12 hours or 5 mg once daily

Children ≥6 years and Adults: Chronic urticaria, perennial or seasonal allergic rhinitis: 5-10 mg once daily, depending upon symptom severity

Elderly (≥77 years): Initial: 5 mg once daily; adjust for renal impairment

Dosage adjustment in renal/hepatic impairment:

Children <6 years: Cetirizine use not recommended

Children 6-11 years: <2.5 mg once daily

Children ≥12 and Adults:

Cl_{cr} 11-31 mL/minute, hemodialysis, or hepatic impairment: Administer 5 mg once daily

Cl_{cr} <11 mL/minute, not on dialysis: Cetirizine use not recommended

Monitoring Parameters Relief of symptoms, sedation and anticholinergic effects

Administration

May be administered with or without food.

Contraindications Hypersensitivity to cetirizine, hydroxyzine, or any component of the formulation

Warnings Cetirizine should be used cautiously in patients with hepatic or renal dysfunction and the elderly. Use in breast-feeding women is not recommended. May cause drowsiness; use caution performing tasks which require alertness (eg, operating machinery or driving). Safety and efficacy in pediatric patients <6 months of age have not been established.

Dosage Forms

Syrup, as hydrochloride: 5 mg/5 mL (120 mL, 480 mL) [banana-grape flavor]

Tablet, as hydrochloride: 5 mg, 10 mg

Tablet, chewable, as hydrochloride: 5 mg, 10 mg [grape flavor]

Reference Range Peak levels after a 10 mg oral dose: ~341 ng/mL and 978 ng/mL in adults and pediatric patients, respectively

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Monitor respiratory status; physostigmine is probably not useful

Enhanced elimination: Hemodialysis removes <10% of the drug and is therefore not useful

Drug Interactions

Substrate of CYP3A4 (minor)

Increased toxicity: CNS depressants, anticholinergics

Pregnancy Risk Factor B

Pregnancy Implications Cetirizine was not shown to be teratogenic in animal studies, however, adequate studies have not been conducted in pregnant women. Use during pregnancy only if clearly needed.

Lactation Enters breast milk/not recommended

Chloral Hydrate

CAS Number 302-17-0; 480-30-8

U.S. Brand Names Aquachloral[®] Suppnettes[®]; Somnote[™]

Synonyms Chloral; Hydrated Chloral; Trichloroacetaldehyde Monohydrate

Impairment Potential Yes

Use Short-term sedative and hypnotic (<2 weeks), sedative/hypnotic for dental and diagnostic procedures; sedative prior to EEG evaluations

Mechanism of Action Central nervous system depressant effects are due to its active metabolite trichloroethanol, mechanism unknown; highly lipid soluble

Adverse Reactions

Cardiovascular: Bigeminy, tachycardia (ventricular), hypotension, QT prolongation, sinus bradycardia, congestive heart failure, sinus tachycardia, arrhythmias (ventricular)

Central nervous system: Disorientation, sedation, excitation (paradoxical), dizziness, fever, headache, ataxia, tachycardia (ventricular, bidirectional)

Gastrointestinal: GI irritation, nausea, vomiting, diarrhea, flatulence, gastric perforation

Hematologic: Leukopenia, eosinophilia

Hepatic: Hepatotoxicity

Local: Corrosive to skin

Ocular: Miosis

Respiratory: Laryngeal edema, aspiration

Miscellaneous: Physical and psychological dependence may occur with prolonged use of large doses; pear-like odor; aneuploidy induction

Signs and Symptoms of Overdose Acetone breath, acne, agranulocytosis, alopecia, cardiac arrhythmias, coma, cough, eczema, granulocytopenia, hyporeflexia, hypotension, hypothermia, ileus, jaundice, laryngospasm, leukopenia, myocardial depression, myoglobinuria, neutropenia, nystagmus, ptosis, rhabdomyolysis, respiratory depression, tachycardia (ventricular), tachycardia (ventricular, bidirectional), thirst, torsade de pointes, ventricular ectopy

Admission Criteria/Prognosis Admit any patient with respiratory depression, cardiac abnormalities, or ingestion >3 g.

Pharmacodynamics/Kinetics

Onset of action: Peak effect: 0.5-1 hour

Duration: 4-8 hours

Absorption: Oral, rectal: Well absorbed

Distribution: Crosses placenta; negligible amounts enter breast milk

CHLORAMBUCIL

Metabolism: Rapidly hepatic to trichloroethanol (active metabolite); variable amounts hepatically and renally to trichloroacetic acid (inactive)
Half-life elimination: Active metabolite: 8-11 hours
Excretion: Urine (as metabolites); feces (small amounts)

Dosage

Neonates: Oral, rectal: 25 mg/kg/dose for sedation prior to a procedure or 50 mg/kg as hypnotic

Children:

Sedation or anxiety: Oral, rectal: 5-15 mg/kg/dose every 8 hours (maximum: 500 mg/dose)

Prior to EEG: Oral, rectal: 20-25 mg/kg/dose, 30-60 minutes prior to EEG; may repeat in 30 minutes to maximum of 100 mg/kg or 2 g total

Hypnotic: Oral, rectal: 20-40 mg/kg/dose up to a maximum of 50 mg/kg/24 hours or 1 g/dose or 2 g/24 hours

Conscious sedation: Oral: 50-75 mg/kg/dose 30-60 minutes prior to procedure; may repeat 30 minutes after initial dose if needed, to a total maximum dose of 120 mg/kg or 1 g total

Adults: Oral, rectal:

Sedation, anxiety: 250 mg 3 times/day

Hypnotic: 500-1000 mg at bedtime or 30 minutes prior to procedure, not to exceed 2 g/24 hours

Dosing adjustment/comments in renal impairment: $Cl_{cr} < 50$ mL/minute: Avoid use

Hemodialysis: Dialyzable (50% to 100%); supplemental dose is not necessary

Dosing adjustment/comments in hepatic impairment: Avoid use in patients with severe hepatic impairment

Stability Sensitive to light; exposure to air causes volatilization; store in light-resistant, airtight container; **incompatible** with alkali, soluble barbiturates

Monitoring Parameters Vital signs, O_2 saturation and blood pressure with doses used for conscious sedation

Administration

Chilling the syrup may help to mask unpleasant taste. Do not crush capsule (contains drug in liquid form). Gastric irritation may be minimized by diluting dose in water or other oral liquid.

Contraindications Hypersensitivity to chloral hydrate or any component of the formulation; hepatic or renal impairment; gastritis or ulcers; severe cardiac disease

Warnings Use with caution in patients with porphyria. Use with caution in neonates. Drug may accumulate with repeated use; prolonged use in neonates associated with hyperbilirubinemia. Tolerance to hypnotic effect develops, therefore, not recommended for use >2 weeks. Taper dosage to avoid withdrawal with prolonged use. Trichloroethanol (TCE), a metabolite of chloral hydrate, is a carcinogen in mice; there is no data in humans. Chloral hydrate is considered a second line hypnotic agent in the elderly. Recent interpretive guidelines from the Centers for Medicare and Medicaid Services (CMS) discourage the use of chloral hydrate in residents of long-term care facilities.

Dosage Forms

Capsule (Somnote™): 500 mg

Suppository, rectal (Aquachloral® Supporettes®): 325 mg [contains tartrazine], 650 mg

Syrup: 500 mg/5 mL (480 mL) [contains sodium benzoate]

Reference Range Therapeutic: 2-12 mcg/mL of trichloroethanol; toxic serum trichloroethanol level: >100 mcg/mL, although 25 mcg/mL trichloroethanol has been correlated with fatalities

Overdosage/Treatment

Decontamination: Carefully lavage adult ingestions >2.4 g within 1 hour of ingestion, due to risk of perforation; activated charcoal should be utilized
Supportive therapy: Treatment is supportive and symptomatic; isoproterenol or atropine may be required for torsade de pointes; flumazenil has been used successfully in treating chloral hydrate overdose; ventricular arrhythmias may also respond to propranolol (2 mg I.V.) or metoprolol (5 mg I.V.) to titrate to a heart rate of 80-100 bpm.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; hemodialysis and/or charcoal hemoperfusion is effective; exchange transfusion also may be useful for neonatal intoxication; dialyzable (50% to 100%); clearance of trichloroethanol by hemodialysis is ~162 mL/minute with removal of 34% body stores over a 4-hour period; clearance by hemoperfusion is ~157-238 mL/minute with removal of 37% body stores during a 4-hour period

Test Interactions False-positive urine glucose using Clinitest® method; may interfere with fluorometric urine catecholamine and urinary 17-hydroxycorticosteroid tests; increases urine protein; well visualized on plain film x-ray; may interfere with BUN test

Drug Interactions

CNS depressants: Sedative effects and/or respiratory depression with chloral hydrate may be additive with other CNS depressants; monitor for increased effect; includes ethanol, sedatives, antidepressants, narcotic analgesics, and benzodiazepines.

Furosemide: Diaphoresis, flushing, and hypertension have occurred in patients who received I.V. furosemide within 24 hours after administration of chloral hydrate; consider using a benzodiazepine.

Phenytoin: Half-life may be decreased by chloral hydrate; limited documentation (small, single-dose study); monitor.

Warfarin: Effect of oral anticoagulants may be increased by chloral hydrate; monitor INR; warfarin dosage may require adjustment. Chloral hydrate's metabolite may displace warfarin from its protein binding sites resulting in an increase in the hypoprothrombinemic response to warfarin.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk/compatible

Nursing Implications Gastric irritation may be minimized by diluting dose in water or other oral liquid

Additional Information Tolerance to hypnotic effect develops, therefore, not recommended for use >2 weeks; taper dosage to avoid withdrawal with prolonged use; radiopaque; genotoxic; question of carcinogenesis is unanswered

Chlorambucil

CAS Number 305-03-3

U.S. Brand Names Leukeran®

Synonyms CB-1348; Chlorambucilum; Chloraminophene; Chlorbutinum; NSC-3088; WR-139013

Use Management of chronic lymphocytic leukemia, Hodgkin's and non-Hodgkin's lymphoma; breast and ovarian carcinoma; Waldenström's macroglobulinemia, testicular carcinoma, thrombocytopenia, choriocarcinoma

Mechanism of Action Interferes with DNA replication and RNA transcription by alkylation and cross-linking the strands of DNA; derived from mustine (a nitrogen mustard)

Adverse Reactions

Central nervous system: **Confusion, agitation, rarely generalized or focal seizures**, drowsiness, psychosis, **hallucinations, ataxia**, drug fever

Dermatologic: Skin rashes, dermal irritant, toxic epidermal necrolysis, **Skin hypersensitivity**

Endocrine & metabolic: Hyperuricemia, ovotoxic, can produce amenorrhea in females

Gastrointestinal: **Diarrhea, oral ulcerations are infrequent**

Genitourinary: Has caused chromosomal damage in man, oligospermia, both reversible and permanent sterility have occurred in both sexes; cystitis, azoospermia

Hematologic: Possible porphyria; **use with caution when receiving radiation; bone marrow suppression frequently occurs and occasionally bone marrow failure has occurred; blood counts should be monitored closely while undergoing treatment; leukopenia** (at doses in excess of 6.5 mg/kg), lymphocytopenia, **thrombocytopenia, anemia**

Hepatic: **Hepatotoxicity**, hepatic necrosis, liver failure

Neuromuscular & skeletal: **Tremors**, muscular myoclonus, paresthesia, weakness

Ocular: Transient blindness (at 1.5 mg/kg/day), **keratitis**

Respiratory: **Pulmonary fibrosis** at doses of 40 mg/kg

Miscellaneous: Cardiotoxic

Signs and Symptoms of Overdose Azoospermia, agranulocytosis, ataxia, coma (at 5 mg/kg), convulsions, granulocytopenia, hyperuricemia, leukopenia, neutropenia, oligospermia, toxic epidermal necrolysis

Pharmacodynamics/Kinetics

Absorption: Rapid and complete

Distribution: V_d : 0.14-0.24 L/kg

Protein binding: ~99%

Metabolism: Hepatic; active metabolite, phenylacetic acid mustard

Bioavailability: Reduced 10% to 20% with food

Half-life elimination: ~1.5 hours; Phenylacetic acid mustard: 2.5 hours
Time to peak, plasma: Within 1 hour; Phenylacetic acid mustard: 1.2-2.6 hours

Excretion: Urine (15% to 60% primarily as metabolites, <1% as unchanged drug or phenylacetic acid mustard: 2.5 hours)

Dosage

Oral (refer to individual protocols):

Children:

General short courses: 0.1-0.2 mg/kg/day **OR** 4.5 mg/m²/day for 3-6 weeks for remission induction (usual: 4-10 mg/day); maintenance therapy: 0.03-0.1 mg/kg/day (usual: 2-4 mg/day)

Nephrotic syndrome: 0.1-0.2 mg/kg/day every day for 5-15 weeks with low-dose prednisone

Chronic lymphocytic leukemia (CLL):

Biweekly regimen: Initial: 0.4 mg/kg/dose every 2 weeks; increase dose by 0.1 mg/kg every 2 weeks until a response occurs and/or myelosuppression occurs

Monthly regimen: Initial: 0.4 mg/kg, increase dose by 0.2 mg/kg every 4 weeks until a response occurs and/or myelosuppression occurs

Malignant lymphomas:

Non-Hodgkin's lymphoma: 0.1 mg/kg/day

Hodgkin's lymphoma: 0.2 mg/kg/day

Adults: 0.1-0.2 mg/kg/day or

3-6 mg/m²/day for 3-6 weeks, then adjust dose on basis of blood counts or

0.4 mg/kg and increased by 0.1 mg/kg biweekly or monthly or

14 mg/m²/day for 5 days, repeated every 21-28 days

Hemodialysis: Supplemental dosing is not necessary

Peritoneal dialysis: Supplemental dosing is not necessary

Stability Protect from light

Monitoring Parameters Liver function tests, CBC, platelets, serum uric acid

Administration

Usually administered as a single dose; preferably on an empty stomach.

Contraindications Hypersensitivity to chlorambucil or any component of the formulation; hypersensitivity to other alkylating agents (may have cross-hypersensitivity); pregnancy

Warnings

Hazardous agent - use appropriate precautions for handling and disposal. Convulsions have been observed; use with caution in patients with seizure disorder; history of nephrotic syndrome and high pulse doses are at higher risk of seizures. **[U.S. Boxed Warning]: May cause bone marrow suppression;** reduce initial dosage if patient has received myelosuppressive or radiation therapy, or has a depressed baseline leukocyte or platelet count within the previous 4 weeks. Lymphopenia may occur. Avoid administration of live vaccines to immunocompromised patients. Rare instances of severe skin reactions (eg, erythema multiforme, Stevens-Johnson syndrome) have been reported; discontinue if a reaction occurs.

[U.S. Boxed Warning]: Affects human fertility; carcinogenic in humans and probably mutagenic and teratogenic as well; chromosomal damage has been documented. Secondary malignancies and acute myelocytic leukemia may be associated with chronic therapy. Safety and efficacy in pediatric patients have not been established.

Dosage Forms Tablet: 2 mg

Reference Range Peak plasma level after a dose of 0.6-1.2 mg/kg: 1 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Replace blood products/diazepam or lorazepam for seizures

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; probably not dialyzable

Drug Interactions Patients may experience impaired immune response to vaccines; possible infection after administration of live vaccines in patients receiving immunosuppressants

Pregnancy Risk Factor D

Pregnancy Implications Urogenital malformation seen in rodent studies

Lactation Excretion in breast milk unknown

Additional Information Myelosuppressive effects: **WBC:** Moderate. **Platelets:** Moderate. Onset (days): 7. Nadir (days): 14-21

Chloramphenicol

CAS Number 530-43-8; 56-75-7; 982-57-0

U.S. Brand Names Chloromycetin[®] Sodium Succinate

Use Treatment of serious infections due to organisms resistant to other less toxic antibiotics or when its penetrability into the site of infection is clinically superior to other antibiotics to which the organism is sensitive; useful in infections caused by *Bacteroides*, *H. influenzae*, *Neisseria meningitidis*, *Salmonella*, and *Rickettsia*; active against many vancomycin-resistant enterococci

Mechanism of Action Reversibly binds to 50S ribosomal subunits of susceptible organisms preventing amino acids from being transferred to growing peptide chains thus inhibiting protein synthesis

Adverse Reactions

Three (3) major toxicities associated with chloramphenicol include: Aplastic anemia, an idiosyncratic reaction which can occur with any route of administration; usually occurs 3 weeks to 12 months after initial exposure to chloramphenicol

Bone marrow suppression is thought to be dose-related with serum concentrations >25 mcg/mL and reversible once chloramphenicol is discontinued; anemia and neutropenia may occur during the first week of therapy

Gray syndrome is characterized by circulatory collapse, cyanosis, acidosis, abdominal distention, myocardial depression, coma, and death; reaction appears to be associated with serum levels ≥50 mcg/mL; may

result from drug accumulation in patients with impaired hepatic or renal function

Additional adverse reactions, frequency not defined:

Central nervous system: Confusion, delirium, depression, fever, headache

Dermatologic: Angioedema, rash, urticaria

Gastrointestinal: Diarrhea, enterocolitis, glossitis, nausea, stomatitis, vomiting

Hematologic: Granulocytopenia, hypoplastic anemia, pancytopenia, thrombocytopenia

Ocular: Optic neuritis

Miscellaneous: Anaphylaxis, hypersensitivity reactions

Pharmacodynamics/Kinetics

Distribution: To most tissues and body fluids; readily crosses placenta; enters breast milk

CSF:blood level ratio: Normal meninges: 66%; Inflamed meninges: >66%

Protein binding: 60%

Metabolism: Extensively hepatic (90%) to inactive metabolites, principally by glucuronidation; chloramphenicol sodium succinate is hydrolyzed by esterases to active base

Half-life elimination:

Normal renal function: 1.6-3.3 hours

End-stage renal disease: 3-7 hours

Cirrhosis: 10-12 hours

Excretion: Urine (5% to 15%)

Dosage

Meningitis: I.V.: Infants >30 days and Children: 50-100 mg/kg/day divided every 6 hours

Other infections: I.V.:

Infants >30 days and Children: 50-75 mg/kg/day divided every 6 hours; maximum daily dose: 4 g/day

Adults: 50-100 mg/kg/day in divided doses every 6 hours; maximum daily dose: 4 g/day

Ophthalmic: Children and Adults: Instill 1-2 drops 4-6 times/day; increase interval between applications after 72 hours to 2-3 times/day; treatment should continue for ~7 days

Dosing adjustment/comments in hepatic impairment: Avoid use in severe liver impairment as increased toxicity may occur

Hemodialysis: Slightly dialyzable (5% to 20%) via hemo- and peritoneal dialysis; no supplemental doses needed in dialysis or continuous arteriovenous or veno-venous hemofiltration

Stability Injection: Store at room temperature prior to reconstitution; reconstituted solutions remain stable for 30 days; use only clear solutions; frozen solutions remain stable for 6 months

Ophthalmic: Refrigerate

Monitoring Parameters CBC with reticulocyte and platelet counts, periodic liver and renal function tests, serum drug concentration

Administration

Can be administered IVP over 5 minutes at a maximum concentration of 100 mg/mL, or I.V. intermittent infusion over 15-30 minutes at a final concentration for administration of ≤20 mg/mL

Contraindications Hypersensitivity to chloramphenicol or any component of the formulation

Warnings [U.S. Boxed Warning]: Serious and fatal blood dyscrasias have occurred after both short-term and prolonged therapy. Should not be used when less potentially toxic agents are effective. Prolonged use may result in superinfection. Use with caution in patients with impaired renal or hepatic function and in neonates. Reduce dose with impaired liver function. Use with care in patients with glucose 6-phosphate dehydrogenase deficiency.

Dosage Forms Injection, powder for reconstitution: 1 g [contains sodium ~52 mg/g (2.25 mEq/g)]

Reference Range

Timing of serum samples: Draw levels 1.5 hours and 3 hours after completion of I.V. or oral dose; trough levels may be preferred; should be drawn ≤1 hour prior to dose

Therapeutic: 10-25 mcg/mL; **Toxic:** >25 mcg/mL

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage within 1 hour (for doses >50 mg/kg)/activated charcoal

Supportive therapy: For optic neuropathy or paresthesia, give pyridoxine (vitamin B₆ 500 mg twice daily) and vitamin B₁₂ (0.5 mg/day) orally

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; hemodialysis may be effective and can reduce half-life to under 1 hour; hemoperfusion may also be effective; exchange transfusion may be helpful in neonates; slightly dialyzable (5% to 20%)

Antidote(s)

● Pyridoxine [ANTIDOTE]

Diagnostic Procedures

● Iron and Total Iron Binding Capacity/Transferrin

Test Interactions ↑ iron (B), prothrombin time; ↓ urea nitrogen (B), total iron binding capacity (S)

Drug Interactions Inhibits CYP2C9 (weak), 3A4 (weak)

CHLORDIAZEPOXIDE

Decreased effect: Phenobarbital and rifampin may decrease concentration of chloramphenicol.

Increased toxicity: Chloramphenicol inhibits the metabolism of chlorpromamide, phenytoin, oral anticoagulants.

Pregnancy Risk Factor C

Pregnancy Implications Crosses placenta

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Nursing Implications Give around-the-clock rather than 4 times/day to promote less variation in peak and trough serum levels

Additional Information Sodium content of 1 g (injection): 51.8 mg (2.25 mEq). Gray baby syndrome occurs when neonates are given large doses of chloramphenicol and cardiovascular collapse occurs; it is associated with plasma levels of 50-100 mcg/mL. Blood dyscrasias can occur with ocular use; no evidence of aplastic anemia with chloramphenicol eye drops

Chlordiazepoxide

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 438-41-5; 58-25-3

U.S. Brand Names Librium®

Synonyms Methaminodiazepoxide Hydrochloride

Impairment Potential Yes. Brief or extended period (up to 1 year) of use is consistent with driving impairment in the elderly; impairment is greatest in the first 7 days of use

Use Management of anxiety disorder or for the short-term relief of symptoms of anxiety; withdrawal symptoms of acute alcoholism; preoperative apprehension and anxiety

Mechanism of Action Benzodiazepine anxiolytic sedative that produces CNS depression at the subcortical level, except at high doses, whereby it works at the cortical level

Adverse Reactions

Cardiovascular: Tachycardia, vasculitis

Central nervous system: **Drowsiness, ataxia, lightheadedness, dizziness, slurred speech**, euphoria, headache, mental depression, hallucinations, insomnia, convulsions, paranoid symptoms, confusion, dystonic reactions

Dermatologic: Erythema multiforme, alopecia, angioedema, urticaria, purpura, pruritus, erythema nodosum, exanthem

Endocrine & metabolic: Changes in libido, gynecomastia

Gastrointestinal: Nausea, xerostomia, vomiting, diarrhea, constipation, abdominal cramps

Hematologic: Thrombocytopenia, anemia, leukopenia, neutropenia, agranulocytosis

Hepatic: Liver dysfunction

Local: Phlebitis

Neuromuscular & skeletal: Paresthesia, muscle spasm, trembling

Ocular: Blurred vision, photophobia

Miscellaneous: Allergic reaction, drug dependence, diaphoresis (excessive), systemic lupus erythematosus, fixed drug eruption

Signs and Symptoms of Overdose Agranulocytosis, cardiac arrhythmias, coma, ejaculatory disturbances, galactorrhea, granulocytopenia, hiccups, hyperglycemia, hypotension, hypothermia, jaundice, lactation, leukopenia, myoglobinuria, neutropenia, photosensitivity, respiratory depression, rhabdomyolysis

Pharmacodynamics/Kinetics

Distribution: V_d : 3.3 L/kg; crosses placenta; enters breast milk

Protein binding: 90% to 98%

Metabolism: Extensively hepatic to desmethyldiazepam (active and long-acting)

Half-life elimination: 6.6-25 hours; End-stage renal disease: 5-30 hours; Cirrhosis: 30-63 hours

Time to peak, serum: Oral: Within 2 hours; I.M.: Results in lower peak plasma levels than oral

Excretion: Urine (minimal as unchanged drug)

Dosage

Children:

< 6 years: Not recommended

> 6 years: Anxiety: Oral, I.M.: 0.5 mg/kg/24 hours divided every 6-8 hours

Adults:

Anxiety:

Oral: 15-100 mg divided 3-4 times/day

I.M., I.V.: Initial: 50-100 mg followed by 25-50 mg 3-4 times/day as needed

Preoperative anxiety: I.M.: 50-100 mg prior to surgery

Ethanol withdrawal symptoms: Oral, I.V.: 50-100 mg to start, dose may be repeated in 2-4 hours as necessary to a maximum of 300 mg/24 hours

Note: Up to 300 mg may be given I.M. or I.V. during a 6-hour period, but not more than this in any 24-hour period.

Dosing adjustment in renal impairment: $Cl_{cr} < 10$ mL/minute: Administer 50% of dose

Hemodialysis: Not dialyzable (0% to 5%)

Dosing adjustment/comments in hepatic impairment: Avoid use

Monitoring Parameters Respiratory and cardiovascular status, mental status, check for orthostasis

Administration I.M.: Administer by deep I.M. injection slowly into the upper outer quadrant of the gluteus muscle; use only the diluent provided for I.M. use; solutions made with SWFI or NS cause pain with I.M. administration

I.V.: Administer slowly over at least 1 minute; do not use the diluent provided for I.M. use; air bubbles form during reconstitution

Contraindications Hypersensitivity to chlordiazepoxide or any component of the formulation (cross-sensitivity with other benzodiazepines may also exist); narrow-angle glaucoma; pregnancy

Warnings

Active metabolites with extended half-lives may lead to delayed accumulation and adverse effects. Use with caution in elderly or debilitated patients, pediatric patients, patients with hepatic disease (including alcoholics) or renal impairment. Use with caution in patients with respiratory disease or impaired gag reflex. Use with caution in patients with porphyria.

Parenteral administration should be avoided in comatose patients or shock. Adequate resuscitative equipment/personnel should be available, and appropriate monitoring should be conducted at the time of injection and for several hours following administration. The parenteral formulation should be diluted for I.M. administration with the supplied diluent only. This diluent should not be used when preparing the drug for intravenous administration.

Causes CNS depression (dose related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents (lithium, phenothiazines). Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury and should be used with extreme caution in patients who are at risk of these events (especially the elderly).

Use caution in patients with depression, particularly if suicidal risk may be present. Use with caution in patients with a history of drug dependence. Benzodiazepines have been associated with dependence and acute withdrawal symptoms on discontinuation or reduction in dose. Acute withdrawal, including seizures, may be precipitated in patients after administration of flumazenil to patients receiving long-term benzodiazepine therapy.

Benzodiazepines have been associated with anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Dosage Forms

Capsule, as hydrochloride: 5 mg, 10 mg, 25 mg

Injection, powder for reconstitution, as hydrochloride: 100 mg [diluent contains benzyl alcohol, polysorbate 80, and propylene glycol]

Reference Range

Therapeutic: 0.1-3 mcg/mL (SI: 0-10 μ mol/L)

Toxic: > 20 mcg/mL (SI: > 77 μ mol/L); toxicity may be related to demoxepam levels > 10 mcg/mL

Urine drug screens can remain positive for 30 days

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Treatment for benzodiazepine overdose is supportive. Rarely is mechanical ventilation required. Flumazenil has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression; do not use stimulants.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; not dialyzable (0% to 5%)

Antidote(s)

- Flumazenil [ANTIDOTE]

Test Interactions Visine®, Drano®, hand soap, or bleach can result in false-negative tests for benzodiazepines

Drug Interactions

Substrate of CYP3A4 (major)

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of chlordiazepoxide. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of chlorthalidone.
 Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.
 Levodopa: Therapeutic effects may be diminished in some patients following the addition of a benzodiazepine; limited/inconsistent data.
 Oral contraceptives: May decrease the clearance of some benzodiazepines (those which undergo oxidative metabolism); monitor for increased benzodiazepine effect.
 Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation.

Pregnancy Risk Factor D

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk/not recommended

Nursing Implications Up to 300 mg may be given I.M. or I.V. during a 6-hour period, but not more than this in any 24-hour period; do not use diluent provided with parenteral form for I.V. administration; dissolve with normal saline instead

Additional Information Often formulated with amitriptyline hydrochloride

Chlorhexidine Gluconate

Pronunciation (klor HEKS i deen GLOO koe nate)

CAS Number 18472-51-0; 55-56-1

U.S. Brand Names Avagard™ [OTC]; BactoShield® CHG [OTC]; Betasept® [OTC]; ChlorPrep® [OTC]; Chlorostat® [OTC]; Dyna-Hex® [OTC]; Hibiclens® [OTC]; Hibistat® [OTC]; Operand® Chlorhexidine Gluconate [OTC]; Peridex®; PerioChip®; PerioGard®

Synonyms 3M™ Avagard™ [OTC]; CHG

Use Skin cleanser for surgical scrub, cleanser for skin wounds, preoperative skin preparation, germicidal hand rinse, and as antibacterial dental rinse. Chlorhexidine is active against gram-positive and gram-negative organisms, facultative anaerobes, aerobes, and yeast.

Orphan drug: Peridex®: Oral mucositis with cytoreductive therapy when used for patients undergoing bone marrow transplant

Mechanism of Action Chlorhexidine, a cationic polybiguanide, is an antiseptic and antimicrobial drug with bactericidal activity. At physiologic pH, chlorhexidine salts dissociate releasing a positively charged component. The bactericidal effect of chlorhexidine is a result of the binding of this cationic molecule to negatively charged bacterial cell walls and extramicrobial complexes. At low concentrations, this causes an alteration of bacterial cell osmotic equilibrium and leakage of potassium and phosphorous resulting in a bacteriostatic effect; at high concentrations of chlorhexidine, the cytoplasmic contents of the bacterial cell precipitate and result in cell death.

Adverse Reactions

- Cardiovascular: Sinus bradycardia, facial edema
- Dermatologic: Dermal hypersensitivity, urticaria, contact dermatitis (8%), immunologic contact urticaria, desquamation
- Endocrine & metabolic: Parotid gland edema with mouthwash
- Gastrointestinal: **Staining of oral surfaces (mucosa, teeth, dorsum of tongue), increased tartar on teeth, altered taste**, tongue irritation, oral irritation, salt hypogeusia
- Hematologic: Methemoglobinemia caused by conversion to parachloroaniline
- Ocular: Corneal irritation
- Respiratory: Dyspnea, nasal congestion

Signs and Symptoms of Overdose Bradycardia, deafness, esophageal ulceration, fatty degeneration of liver, gastritis, hemolysis with systemic absorption, methemoglobinemia on inhalation, pulmonary edema, tongue discoloration

Admission Criteria/Prognosis Any patient with change in mental status, GI symptoms, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Pharmacodynamics/Kinetics

- Topical hand sanitizer (Avagard™): Duration of antimicrobial protection: 6 hours
- Oral rinse (Peridex®, PerioGard®):
 Absorption: ~30% retained in the oral cavity following rinsing and slowly released into oral fluids; poorly absorbed
 Time to peak, plasma: Oral rinse: Detectable levels not present after 12 hours
 Excretion: Feces (~90%); urine (<1%)

Dosage

Adults:
 Oral rinse (Peridex®, PerioGard®):
 Precede use of solution by flossing and brushing teeth; completely rinse toothpaste from mouth. Swish 15 mL undiluted oral rinse around

in mouth for 30 seconds, then expectorate. Caution patient not to swallow the medicine. Avoid eating for 2-3 hours after treatment. (The cap on bottle of oral rinse is a measure for 15 mL.)

When used as a treatment of gingivitis, the regimen begins with oral prophylaxis. Patient treats mouth with 15 mL chlorhexidine, swishes for 30 seconds, then expectorates. This is repeated twice daily (morning and evening). Patient should have a re-evaluation followed by a dental prophylaxis every 6 months.

Cleanser:

Surgical scrub: Scrub 3 minutes and rinse thoroughly, wash for an additional 3 minutes

Hand sanitizer (Avagard™): Dispense 1 pumpful in palm of one hand; dip fingertips of opposite hand into solution and work it under nails. Spread remainder evenly over hand and just above elbow, covering all surfaces. Repeat on other hand. Dispense another pumpful in each hand and reapply to each hand up to the wrist. Allow to dry before gloving.

Hand wash: Wash for 15 seconds and rinse

Hand rinse: Rub 15 seconds and rinse

Periodontal chip: One chip is inserted into a periodontal pocket with a probing pocket depth ≥ 5 mm. Up to 8 chips may be inserted in a single visit. Treatment is recommended every 3 months in pockets with a remaining depth ≥ 5 mm. If dislodgment occurs 7 days or more after placement, the subject is considered to have had the full course of treatment. If dislodgment occurs within 48 hours, a new chip should be inserted.

Stability

Store at room temperature

Avagard™: Avoid excessive heat. Ethanol-containing products are flammable; keep away from flames or fire. Hand lotions and gel hand sanitizers are incompatible. The thickeners used in these products (eg, carbomer) react to form an insoluble salt and cause loss of antibacterial action.

Administration Hand sanitizer (Avagard™): To facilitate drying, continue rubbing hand prep into hands until dry.

Periodontal chip insertion: Pocket should be isolated and surrounding area dried prior to chip insertion. The chip should be grasped using forceps with the rounded edges away from the forceps. The chip should be inserted into the periodontal pocket to its maximum depth. It may be maneuvered into position using the tips of the forceps or a flat instrument. The chip biodegrades completely and does not need to be removed. Patients should avoid dental floss at the site of PerioChip® insertion for 10 days after placement because flossing might dislodge the chip.

Topical: Keep out of eyes, ears, and mouth. Do not routinely apply to wounds which involve more than superficial layers of skin.

Contraindications Hypersensitivity to chlorhexidine gluconate or any component of the formulation

Warnings

Oral: Staining of oral surfaces (mucosa, teeth, tooth restorations, dorsum of tongue) may occur; may be visible as soon as 1 week after therapy begins and is more pronounced when there is a heavy accumulation of unremoved plaque and when teeth fillings have rough surfaces. Stain does not have a clinically adverse effect, but because removal may not be possible, patient with frontal restoration should be advised of the potential permanency of the stain.

Topical: For topical use only. Keep out of eyes and ears. May stain fabric. There have been case reports of anaphylaxis following chlorhexidine disinfection. Not for preoperative preparation of face or head; avoid contact with meninges.

Dosage Forms

- Chip, for periodontal pocket insertion (PerioChip®): 2.5 mg
- Liquid, topical [surgical scrub]:
 Avagard™: 1% (500 mL) [contains ethyl alcohol and moisturizers]
 BactoShield® CHG: 2% (120 mL, 480 mL, 750 mL, 1000 mL, 3800 mL); 4% (120 mL, 480 mL, 750 mL, 1000 mL, 3800 mL) [contains isopropyl alcohol]
 Betasept®: 4% (120 mL, 240 mL, 480 mL, 960 mL, 3840 mL) [contains isopropyl alcohol]
 ChlorPrep®: 2% (0.67 mL, 1.5 mL, 3 mL, 10.5 mL) [contains isopropyl alcohol 70%; prefilled applicator]
 Dyna-Hex®: 2% (120 mL, 960 mL, 3840 mL); 4% (120 mL, 960 mL, 3840 mL)
 Hibiclens®: 4% (15 mL, 120 mL, 240 mL, 480 mL, 960 mL, 3840 mL) [contains isopropyl alcohol]
 Operand® Chlorhexidine Gluconate: 2% (120 mL); 4% (120 mL, 240 mL, 480 mL, 960 mL, 3840 mL) [contains isopropyl alcohol]
 Liquid, oral rinse: 0.12% (480 mL)
 Peridex®: 0.12% (480 mL) [contains alcohol 11.6%]
 PerioGard®: 0.12% (480 mL) [contains alcohol 11.6%; mint flavor]
 Pad [prep pad] (Hibistat®): 0.5% (50s) [contains isopropyl alcohol]
 Sponge/Brush (BactoShield® CHG): 4% per sponge/brush [contains isopropyl alcohol]

CHLORMEZANONE

Reference Range Topical use (vaginal or dermal) as an antiseptic agent results in serum chlorhexidine levels ranging from 0.01-0.128 mcg/mL. Following inadvertent administration of 10 mL of a 20% chlorhexidine gluconate solution I.V., a patient developed cardiac arrest within 20 minutes; postmortem blood chlorhexidine level was 39.5 mcg/mL. Serum chlorhexidine level of 24.6 mcg/mL has been associated with an oral overdose, ARDS, and fatality.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/dilution with milk or water (4-8 oz or 15 mL/kg); activated charcoal is not useful; irrigate skin/eyes
Supportive therapy: Methylene blue for methemoglobin toxicity

Test Interactions ↑ LFTs

Drug Interactions No data reported

Pregnancy Risk Factor B

Pregnancy Implications No teratogenic effects reported

Nursing Implications Inform patient that reduced taste perception during treatment is reversible with discontinuation of chlorhexidine

Chlormezanone

CAS Number 80-77-3

Use Anxiety; insomnia; muscle spasm

Mechanism of Action Precise mechanism is not yet clear, but many effects have been ascribed to its central depressant actions; an indirect GABA-A agonist

Adverse Reactions

Cardiovascular: Flushing, toxic epidermal necrosis
Central nervous system: Drowsiness, confusion, headache
Gastrointestinal: Nausea, xerostomia
Hematologic: Porphyrinogenic
Hepatic: Reversible jaundice, hepatitis
Neuromuscular & skeletal: Tremor, muscle weakness
Respiratory: Hyposmia

Signs and Symptoms of Overdose Ataxia, coma, hot dry skin, hypotension, hyporeflexia, mydriasis, tachycardia

Admission Criteria/Prognosis Admit any symptomatic patient or any adult ingestion > 5 g

Toxicodynamics/Kinetics

Peak plasma level: 2 hours
Duration of action: > 6 hours
Protein binding: ~50%
Metabolism: Hydrolysis in the stomach and then metabolized in the liver (4-chlorohippuric acid is the major metabolite)
Half-life: 19-53 hours
Elimination: Renal

Dosage

Oral:
Children > 5 years: 50-100 mg 3-4 times/day
Adults:

Anxiety: 100-200 mg 3-4 times/day
Insomnia: 400 mg at bedtime (200 mg in elderly patients)
Muscle spasm: 200-400 mg 3-4 times/day

Reference Range Therapeutic range (in a steady state of 600 mg/day for 5 days): ~ 10-14 mcg/mL. Levels > 18 mcg/mL are associated with mild toxicity (weakness, ataxia, tachycardia) while a postmortem blood and urine chlormezanone level in a fatality was 53 mcg/mL and 31 mcg/mL, respectively.

Overdosage/Treatment

Decontamination: Lavage (within 2 hours of ingestion)/activated charcoal
Supportive therapy: Benzodiazepines for seizure control
Enhancement of elimination: Forced diuresis is not helpful; multiple dosing of activated charcoal may be helpful. Following attempts to enhance drug elimination, hypotension should be treated with I.V. fluids and/or Trendelenburg positioning.

Chlorprocaine

CAS Number 133-16-4; 3858-89-7

U.S. Brand Names Nesacaine®-MPF; Nesacaine®

Synonyms Chlorprocaine Hydrochloride

Use Infiltration anesthesia and peripheral and epidural anesthesia

Mechanism of Action Ester local anesthetic similar to procaine produces conduction block at nerve cell membrane

Adverse Reactions

Cardiovascular: Myocardial depression, hypotension, bradycardia, cardiovascular collapse, edema, sinus bradycardia, congestive heart failure, sinus tachycardia
Central nervous system: Anxiety, restlessness, disorientation, confusion, psychosis, seizures, drowsiness, unconsciousness, chills
Dermatologic: Urticaria
Gastrointestinal: Nausea, vomiting
Local: Transient stinging or burning at injection site
Neuromuscular & skeletal: Tremors
Ocular: Blurred vision, diplopia, nystagmus

Otic: Ototoxicity, tinnitus

Respiratory: Respiratory arrest

Miscellaneous: Anaphylactoid reactions, shivering

Signs and Symptoms of Overdose Cardiac arrhythmias, coma, hypertension, mydriasis, seizures, tachycardia, tachypnea progressing to apnea

Pharmacodynamics/Kinetics

Onset of action: 6-12 minutes

Duration: 30-60 minutes

Distribution: V_d : Depends upon route of administration; high concentrations found in highly perfused organs such as liver, lungs, heart, and brain

Metabolism: Plasma cholinesterases

Excretion: Urine

Dosage

Dosage varies with anesthetic procedure, the area to be anesthetized, the vascularity of the tissues, depth of anesthesia required, degree of muscle relaxation required, and duration of anesthesia

Infiltration and peripheral nerve block: 1% to 2%

Infiltration, peripheral and central nerve block, including caudal and epidural block: 2% to 3%, without preservatives

Stability May contain sodium bisulfite

Monitoring Parameters Cardiovascular and respiratory status; mental status

Administration

Before injecting, withdraw syringe plunger to ensure injection is not into vein or artery.

Contraindications Hypersensitivity to chlorprocaine, other ester type anesthetics, or any component of the formulation; myasthenia gravis; do not use for subarachnoid administration

Warnings Use with caution in patients with hepatic impairment. **Do not use solutions containing preservatives for caudal or epidural block.** Local anesthetics have been associated with rare occurrences of sudden respiratory arrest; seizures due to systemic toxicity leading to cardiac arrest have also been reported, presumably following unintentional intravascular injection. A test dose is recommended prior to epidural administration (prior to initial dose) and all reinforcing doses with continuous catheter technique.

Dosage Forms

Injection, solution, as hydrochloride (Nesacaine®): 1% (30 mL); 2% (30 mL) [contains disodium EDTA and methylparaben]

Injection, solution, as hydrochloride [preservative free] (Nesacaine®-MPF): 2% (20 mL); 3% (20 mL)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal for oral ingestions

Supportive therapy: Treatment is primarily symptomatic and supportive. Termination of anesthesia by pneumatic tourniquet inflation should be attempted when the agent is administered by infiltration or regional injection. Seizures commonly respond to diazepam or lorazepam, while hypotension responds to I.V. fluids and Trendelenburg positioning. Bradyarrhythmias (when the heart rate is less than 60) can be treated with I.V., I.M. or SubQ atropine 15 mcg/kg. With the development of metabolic acidosis, I.V. sodium bicarbonate 0.5-2 mEq/kg and ventilatory assistance should be instituted. Chlorpromazine may be used to treat acute psychosis.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective for oral ingestions

Drug Interactions PABA (from ester-type anesthetics) may inhibit sulfonamides.

Pregnancy Risk Factor C

Pregnancy Implications Animal reproduction studies have not been conducted. Local anesthetics rapidly cross the placenta and may cause varying degrees of maternal, fetal, and neonatal toxicity. Close maternal and fetal monitoring (heart rate and electronic fetal monitoring advised) are required during obstetrical use. Maternal hypotension has resulted from regional anesthesia. Positioning the patient on her left side and elevating the legs may help. Epidural, paracervical, or pudendal anesthesia may alter the forces of parturition through changes in uterine contractility or maternal expulsive efforts. The use of some local anesthetic drugs during labor and delivery may diminish muscle strength and tone for the first day or two of life. Administration as a paracervical block is not recommended with toxemia of pregnancy, fetal distress, or prematurity. Administration of a paracervical block early in pregnancy has resulted in maternal seizures and cardiovascular collapse. Fetal bradycardia and acidosis also have been reported. Fetal depression has occurred following unintended fetal intracranial injection while administering a paracervical and/or pudendal block.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Before injecting, withdraw syringe plunger to ensure injection is not into vein or artery

Chloroquine

CAS Number 50-63-5

U.S. Brand Names Aralen®

Synonyms Chloroquine Phosphate

Use Suppression or chemoprophylaxis of malaria; treatment of uncomplicated or mild to moderate malaria; extraintestinal amebiasis
Rheumatoid arthritis; discoid lupus erythematosus

Mechanism of Action Binds to and inhibits DNA and RNA polymerase; interferes with metabolism and hemoglobin utilization by parasites; inhibits prostaglandin effects; additionally has quinidine-like cardiac effects

Adverse Reactions

Frequency not defined.

Cardiovascular: Hypotension (rare), ECG changes (rare; including T-wave inversion), cardiomyopathy

Central nervous system: Fatigue, personality changes, headache, psychosis, seizures, delirium, depression

Dermatologic: Pruritus, hair bleaching, pleomorphic skin eruptions, alopecia, lichen planus eruptions, alopecia, mucosal pigmentary changes (blue-black), photosensitivity

Gastrointestinal: Nausea, diarrhea, vomiting, anorexia, stomatitis, abdominal cramps

Hematologic: Aplastic anemia, agranulocytosis (reversible), neutropenia, thrombocytopenia

Neuromuscular & skeletal: Rare cases of myopathy, neuromyopathy, proximal muscle atrophy, and depression of deep tendon reflexes have been reported

Ocular: Retinopathy (including irreversible changes in some patients long-term or high-dose therapy), blurred vision

Otic: Nerve deafness, tinnitus, reduced hearing (risk increased in patients with pre-existing auditory damage)

Signs and Symptoms of Overdose Doses of 20 mg/kg are considered toxic. Arrhythmias, AV block, cardiovascular collapse, disseminated intravascular coagulation, headache, hypotension in very rapid progression, hypoglycemia, hypokalemia, hypopigmented hair, methemoglobinemia, myasthenia gravis (exacerbation or precipitation), myopathy, nystagmus, ptosis, seizures, urine discoloration (brown; yellow-brown; milky; rust); visual changes including blindness, corneal microdeposits, and vision color changes (blue tinge; green tinge; yellow tinge)

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or >3 g ingestion should be admitted; asymptomatic patients should be observed on an ECG monitor for 8 hours; predictors for fatality include QRS duration >0.12 seconds, ingested dose >6 g or chloroquine blood level >0.6 mg/L

Pharmacodynamics/Kinetics

Duration: Small amounts may be present in urine months following discontinuation of therapy

Absorption: Oral: Rapid (~89%)

Distribution: Widely in body tissues (eg, eyes, heart, kidneys, liver, lungs) where retention prolonged; crosses placenta; enters breast milk

Metabolism: Partially hepatic

Half-life elimination: 3-5 days

Time to peak, serum: 1-2 hours

Excretion: Urine (~70% as unchanged drug); acidification of urine increases elimination

Dosage

Suppression or prophylaxis of malaria: Oral:

Children: Administer 5 mg base/kg/week on the same day each week (not to exceed 300 mg base/dose); begin 1-2 weeks prior to exposure; continue for 4-6 weeks after leaving endemic area; if suppressive therapy is not begun prior to exposure, double the initial loading dose to 10 mg base/kg and administer in 2 divided doses 6 hours apart, followed by the usual dosage regimen

Adults: 500 mg/week (300 mg base) on the same day each week; begin 1-2 weeks prior to exposure; continue for 4-6 weeks after leaving endemic area; if suppressive therapy is not begun prior to exposure, double the initial loading dose to 1 g (600 mg base) and administer in 2 divided doses 6 hours apart, followed by the usual dosage regimen

Acute attack: Oral:

Children: 10 mg/kg (base) on day 1, followed by 5 mg/kg (base) 6 hours later and 5 mg/kg (base) on days 2 and 3

Adults: 1 g (600 mg base) on day 1, followed by 500 mg (300 mg base) 6 hours later, followed by 500 mg (300 mg base) on days 2 and 3

Extraintestinal amebiasis:

Children: Oral: 10 mg/kg (base) once daily for 2-3 weeks (up to 300 mg base/day)

Adults: Oral: 1 g/day (600 mg base) for 2 days followed by 500 mg/day (300 mg base) for at least 2-3 weeks

Rheumatoid arthritis, lupus erythematosus (unlabeled uses): Adults: 250 mg (150 mg base) once daily; reduce dosage following maximal response (taper to discontinue after response in lupus); generally requires 3-6 weeks

Note: Not considered first-line agent.

Dosing adjustment in renal impairment:

$Cl_{cr} < 10$ mL/minute: Administer 50% of dose

Hemodialysis: Minimally removed by hemodialysis

Monitoring Parameters Periodic CBC, examination for muscular weakness, and ophthalmologic examination in patients receiving prolonged therapy

Administration

Chloroquine phosphate tablets have also been mixed with chocolate syrup or enclosed in gelatin capsules to mask the bitter taste.

Contraindications Hypersensitivity to chloroquine or any component of the formulation; retinal or visual field changes

Warnings

Use with caution in patients with liver disease, G6PD deficiency, alcoholism or in conjunction with hepatotoxic drugs. May exacerbate psoriasis or porphyria. Retinopathy (irreversible) has occurred with long or high-dose therapy; discontinue drug if any abnormality in the visual field or if muscular weakness develops during treatment. Use caution in patients with pre-existing auditory damage; discontinue immediately if hearing defects are noted. Use caution in patients with seizure disorders.

Dosage Forms

Tablet, as phosphate: 250 mg [equivalent to 150 mg base]; 500 mg [equivalent to 300 mg base]

Aralen®: 500 mg [equivalent to 300 mg base]

Reference Range

Average plasma concentration: up to 0.4 mg/L

Toxic plasma concentration: >0.6 mg/L

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur by a tenfold increase as compared to the antemortem state.

Overdosage/Treatment

Decontamination: Activated charcoal within 30 minutes, if available, for prehospital use clearly indicated; lavage within 1 hour if the patient is obtunded

Supportive therapy: Early administration of diazepam or lorazepam and epinephrine appears beneficial; avoid class I antiarrhythmics; 2 mg (I.V.) of clonazepam has terminated chloroquine-induced nonconvulsive status epilepticus; aqueous epinephrine and diazepam (bolus of 1 mg/kg in children followed by an infusion of 0.4 mg/kg/hour) should be given following return of circulation following cardiopulmonary arrest due to chloroquine; inamrinone can be used to treat refractory hypotension

Enhancement of elimination: Minimally removed by hemodialysis; hemoperfusion useful early in course of ingestion, but toxicities often prevent use; multiple doses of activated charcoal may be effective

Antidote(s)

- Epinephrine [ANTIDOTE]

Diagnostic Procedures

- Electrolytes, Blood
- Urinalysis

Test Interactions A high concentration of chloroquine in urine gives a positive result with amphetamine CEDIA reagent.

Drug Interactions

Substrate (major) of CYP2D6, 3A4; **Inhibits** CYP2D6 (moderate)

Ampicillin: Chloroquine may reduce the absorption of ampicillin; separate administration by 2 hours.

Antacids and kaolin: Chloroquine and other 4-aminoquinolones may be decreased due to GI binding with kaolin or magnesium trisilicate.

Cimetidine: Cimetidine increases levels of chloroquine and probably other 4-aminoquinolones.

Cyclosporine: Chloroquine may increase cyclosporine concentrations; monitor.

CYP2D6 inhibitors: May increase the levels/effects of chloroquine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP2D6 substrates: Chloroquine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Chloroquine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of chloroquine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of chloroquine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Praziquantel: Chloroquine may decrease praziquantel concentrations.

Pregnancy Risk Factor C

CHLORPHENIRAMINE

Pregnancy Implications There are no adequate and well-controlled studies using chloroquine during pregnancy. However, based on clinical experience and because malaria infection in pregnant women may be more severe than in nonpregnant women, chloroquine prophylaxis may be considered in areas of chloroquine-sensitive *P. falciparum* malaria. Pregnant women should be advised not to travel to areas of *P. falciparum* resistance to chloroquine.

Lactation Enters breast milk/not recommended (AAP considers "compatible")

Additional Information Toxic dose: 5 mg/kg

Chlorpheniramine

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 113-92-8

U.S. Brand Names Aller-Chlor® [OTC]; Chlor-Trimeton® [OTC]; Chlorphen [OTC]; Diabetic Tussin® Allergy Relief [OTC]

Synonyms Chlorpheniramine Maleate; CTM

Impairment Potential Yes

Use Perennial and seasonal allergic rhinitis and other allergic symptoms including rash

Mechanism of Action Competes with histamine for H₁-receptor sites on effector cells in the GI tract, blood vessels, and respiratory tract

Adverse Reactions

Central nervous system: **Slight to moderate drowsiness**, headache, excitability, fatigue, nervousness, dizziness

Gastrointestinal: Nausea, xerostomia, diarrhea, abdominal pain, appetite increase, weight gain

Genitourinary: Urinary retention

Neuromuscular & skeletal: Arthralgia, weakness

Ocular: Diplopia, blepharospasm

Renal: Polyuria

Respiratory: **Thickening of bronchial secretions**, pharyngitis

Signs and Symptoms of Overdose Agranulocytosis, CNS depression, dry mouth, extrapyramidal reaction, flushing, granulocytopenia, leukopenia, mydriasis, neutropenia

Pharmacodynamics/Kinetics

Onset of action: 20-60 minutes

Duration: 8-12 hours

Absorption: Well from the GI tract; food in stomach delays absorption but does not affect bioavailability

Distribution: V_d: Children: 7 L/kg; Adults: 3.2 L/kg

Protein binding: 69% to 72%

Metabolism: In the liver

Half-life: Children: 13 hours; Adults: 20-24 hours; Renal failure: 280-330 hours

Time to peak serum concentration: 2-6 hours

Elimination: Metabolites and parent drug (3% to 4%) excreted in urine; 35% of total within 48 hours

Dosage

Children: Oral: 0.35 mg/kg/day in divided doses every 4-6 hours

2-6 years: 1 mg every 4-6 hours, not to exceed 6 mg in 24 hours

6-12 years: 2 mg every 4-6 hours, not to exceed 12 mg/day or sustained release 8 mg at bedtime

Children > 12 years and Adults: Oral: 4 mg every 4-6 hours, not to exceed 24 mg/day or sustained release 8-12 mg every 8-12 hours, not to exceed 24 mg/day

Elderly: Oral: 4 mg once or twice daily. **Note:** Duration of action may be 36 hours or more when serum concentrations are low.

Hemodialysis: Supplemental dose is not necessary

Administration

Timed release oral forms are to be swallowed whole, not crushed or chewed.

Contraindications Hypersensitivity to chlorpheniramine maleate or any component of the formulation; narrow-angle glaucoma; bladder neck obstruction; symptomatic prostate hypertrophy; during acute asthmatic attacks; stenosing peptic ulcer; pyloroduodenal obstruction. Avoid use in premature and term newborns due to possible association with SIDS.

Warnings Causes sedation, caution must be used in performing tasks which require alertness (eg, operating machinery or driving). Sedative effects of CNS depressants or ethanol are potentiated. Use with caution in patients with angle-closure glaucoma, pyloroduodenal obstruction

(including stenotic peptic ulcer), urinary tract obstruction (including bladder neck obstruction and symptomatic prostatic hyperplasia), hyperthyroidism, increased intraocular pressure, and cardiovascular disease (including hypertension and tachycardia). High sedative and anticholinergic properties, therefore may not be considered the antihistamine of choice for prolonged use in the elderly. May cause paradoxical excitation in pediatric patients, and can result in hallucinations, coma, and death in overdose.

Dosage Forms

Capsule, variable release:

QDALL® AR: Chlorpheniramine maleate 12 mg [immediate release and sustained release]

Syrup, as maleate:

Aller-Chlor®: 2 mg/5 mL (120 mL) [contains alcohol 5%]

Diabetic Tussin® Allergy Relief: 2 mg/5 mL (120 mL) [alcohol free, dye free, sugar free]

Tablet, as maleate: 4 mg

Aller-Chlor®, Chlor-Trimeton®, Chlorphen, Teldrin® HBP: 4 mg

Tablet, extended release, as maleate:

Chlor-Trimeton®: 12 mg

Reference Range In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment There is no specific treatment for an antihistamine overdose, however, most of its clinical toxicity is due to anticholinergic effects. Anticholinesterase inhibitors may be useful by reducing acetylcholinesterase. Anticholinesterase inhibitors include physostigmine, neostigmine, pyridostigmine, and edrophonium. For anticholinergic overdose with severe life-threatening symptoms, physostigmine 1-2 mg (0.5 or 0.02 mg/kg for children) I.V., slowly may be given to reverse these effects.

Drug Interactions

Substrate of CYP2D6 (minor), 3A4 (major); **Inhibits** CYP2D6 (weak)

Increased toxicity (CNS depression): CNS depressants, MAO inhibitors, tricyclic antidepressants, phenothiazines

CYP3A4 inhibitors: May increase the levels/effects of chlorpheniramine.

Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Pregnancy Risk Factor B

Additional Information Not effective for nasal stuffiness

ChlorproMAZINE

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antipsychotic Agents
- Therapeutic Drugs Associated with Hallucinations
- Zuclophenixol

CAS Number 50-53-3; 69-09-0

U.S. Brand Names Thorazine® [DSC]

Synonyms Chlorpromazine Hydrochloride; CPZ

Impairment Potential Yes

Use Control of mania; treatment of schizophrenia; control of nausea and vomiting; relief of restlessness and apprehension before surgery; acute intermittent porphyria; adjunct in the treatment of tetanus; intractable hiccups; combativeness and/or explosive hyperexcitable behavior in children 1-12 years of age and in short-term treatment of hyperactive children; Tourette's syndrome; tension and vascular headaches; LSD flashback control

Unlabeled/Investigational Use Management of psychotic disorders

Mechanism of Action Avoid rectal administration in immunocompromised patients. Blocks postsynaptic mesolimbic dopaminergic receptors in the brain; exhibits a strong alpha-adrenergic blocking effect and depresses the release of hypothalamic and hypophyseal hormones; strongly anticholinergic

Adverse Reactions

Cardiovascular: **Hypotension** (especially with I.V. use), **hypotension (orthostatic)**, **tachycardia**, **cardiac arrhythmias**, sinus tachycardia, vasodilation, torsade de pointes (5 cases)

Central nervous system: Sedation, drowsiness, restlessness, anxiety, extrapyramidal reactions, **pseudoparkinsonian** signs and symptoms, **akathisia**, **dystonias**, **dizziness**, **tardive dyskinesia**, neuroleptic malignant syndrome, seizures, altered central temperature regulation, fever, auditory and visual hallucinations, somnambulism

Dermatologic: Hyperpigmentation, pruritus, rash, photosensitivity, toxic epidermal necrolysis, pustulosis, immunologic contact urticaria, cutaneous vasculitis

Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, syndrome of inappropriate antidiuretic hormone

Gastrointestinal: GI upset, xerostomia, **constipation**, Ogilvie's syndrome, weight gain

Genitourinary: Urinary retention, impotence, priapism

Hematologic: Leukopenia/neutropenia (agranulocytosis, granulocytopenia) usually in patients with large doses for prolonged periods; thrombocytopenia, hemolysis, eosinophilia

Hepatic: Cholestatic jaundice (rare), cholestatic hepatitis, primary biliary cirrhosis

Neuromuscular & skeletal: Rhabdomyolysis, Meige syndrome

Ocular: **Retinal pigmentation** (>600 g total dosage), blurred vision, mydriasis, photophobia, nystagmus, diplopia, pigmentary deposits in the lens and cornea, epithelial keratopathy

Respiratory: **Nasal congestion**, eosinophilic pneumonia

Miscellaneous: Anaphylactoid reactions, systemic lupus erythematosus, **diaphoresis (decreased)**, antiphospholipid syndrome

Signs and Symptoms of Overdose Abnormal involuntary muscle movements, appetite (increased), coma, corneal microdeposits, deep sleep, delirium, ejaculatory disturbances, extrapyramidal reaction, hirsutism, hyperprolactinemia, hyperthermia, hypoglycemia, hypotension or hypertension, hypothermia, impotence, jaundice, myasthenia gravis (exacerbation or precipitation), neuroleptic malignant syndrome, night terrors, Parkinson's-like symptoms, photosensitivity, toxic epidermal necrolysis, QT prolongation, urine discoloration (pink; red; red-brown), vision color changes (brown tinge; yellow tinge)

Pharmacodynamics/Kinetics

Onset of action: I.M.: 15 minutes; Oral: 30-60 minutes

Absorption: Rapid

Distribution: V_d : 20 L/kg; crosses the placenta; enters breast milk

Protein binding: 92% to 97%

Metabolism: Extensively hepatic to active and inactive metabolites

Bioavailability: 20%

Half-life, biphasic: Initial: 2 hours; Terminal: 30 hours

Excretion: Urine (<1% as unchanged drug) within 24 hours

Dosage

Children \geq 6 months:

Schizophrenia/psychoses:

Oral: 0.5-1 mg/kg/dose every 4-6 hours; older children may require 200 mg/day or higher

I.M., I.V.: 0.5-1 mg/kg/dose every 6-8 hours

< 5 years (22.7 kg): Maximum: 40 mg/day

5-12 years (22.7-45.5 kg): Maximum: 75 mg/day

Nausea and vomiting:

Oral: 0.5-1 mg/kg/dose every 4-6 hours as needed

I.M., I.V.: 0.5-1 mg/kg/dose every 6-8 hours

< 5 years (22.7 kg): Maximum: 40 mg/day

5-12 years (22.7-45.5 kg): Maximum: 75 mg/day

Rectal: 1 mg/kg/dose every 6-8 hours as needed

Adults:

Schizophrenia/psychoses:

Oral: Range: 30-2000 mg/day in 1-4 divided doses, initiate at lower doses and titrate as needed; usual dose: 400-600 mg/day; some patients may require 1-2 g/day

I.M., I.V.: Initial: 25 mg, may repeat (25-50 mg) in 1-4 hours, gradually increase to a maximum of 400 mg/dose every 4-6 hours until patient is controlled; usual dose: 300-800 mg/day

Intractable hiccups: Oral, I.M.: 25-50 mg 3-4 times/day

LSD flashback control: Oral, I.M.: 50-100 mg every 3-4 hours until a response is seen

Nausea and vomiting:

Tetanus adjunct (usually with a barbiturate): I.M.: 25-50 mg 3-4 times/day or continuous I.V. infusion: 1 mg/minute

Oral: 10-25 mg every 4-6 hours

I.M., I.V.: 25-50 mg every 4-6 hours

Rectal: 50-100 mg every 6-8 hours

Elderly: Behavioral symptoms associated with dementia: Initial: 10-25 mg 1-2 times/day; increase at 4- to 7-day intervals by 10-25 mg/day. Increase dose intervals (bid, tid, etc) as necessary to control behavior response or side effects; maximum daily dose: 800 mg; gradual increases (titration) may prevent some side effects or decrease their severity.

Dosing adjustment/comments in hepatic impairment: Avoid use in severe hepatic dysfunction

Stability Protect oral dosage forms from light; a slightly yellowed solution does not indicate potency loss, but a markedly discolored solution should be discarded; diluted injection (1 mg/mL) with NS and stored in 5 mL vials remain stable for 30 days; not soluble with alkali, aminophylline, ampicillin, chlorothiazide, methohexitone, phenobarbital, amphotericin, sulfadimidine

Monitoring Parameters Vital signs; lipid profile, fasting blood glucose/Hgb A_{1c}; BMI; mental status; abnormal involuntary movement scale (AIMS); extrapyramidal symptoms (EPS)

Administration Note: Avoid skin contact with oral solution or injection solution; may cause contact dermatitis.

Oral: Dilute oral concentrate solution in juice before administration. Chlorpromazine concentrate is not compatible with carbamazepine suspension; schedule dosing at least 1-2 hours apart from each other.

I.V.: Direct of intermittent infusion: Infuse 1 mg or portion thereof over 1 minute.

Contraindications Hypersensitivity to chlorpromazine or any component of the formulation (cross-reactivity between phenothiazines may occur); severe CNS depression; coma

Warnings

Highly sedating, use with caution in disorders where CNS depression is a feature. Use with caution in Parkinson's disease. Caution in patients with hemodynamic instability; bone marrow suppression; predisposition to seizures, subcortical brain damage, severe cardiac, hepatic, renal, or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use - use with caution in patients at risk of aspiration pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May alter cardiac conduction - life-threatening arrhythmias have occurred with therapeutic doses of neuroleptics. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications which may predispose). Significant hypotension may occur, particularly with parenteral administration. Injection contains sulfites.

Phenothiazines may cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention). Therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other neuroleptics, chlorpromazine has a moderate potency of cholinergic blockade.

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is low-moderate relative to other neuroleptics). May be associated with neuroleptic malignant syndrome (NMS) or pigmentary retinopathy.

Dosage Forms

Injection, solution, as hydrochloride: 25 mg/mL (1 mL, 2 mL)

Tablet, as hydrochloride: 10 mg, 25 mg, 50 mg, 100 mg, 200 mg

Reference Range

Therapeutic: 50-300 ng/mL (SI: 157-942 nmol/L)

Toxic: > 750 ng/mL (SI: > 2355 nmol/L)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam or diazepam (I.V. 5-10 mg bolus in adults every 15 minutes if needed up to a total of 30 mg; I.V. 0.25-0.4 mg/kg/dose up to a total of 10 mg in children) or to phenytoin or phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 g), while other antiarrhythmics can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50 mg I.V. slow push followed by a maintenance dose for 48-72 hours. When these reactions are unresponsive to diphenhydramine, benztrapine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes.

Enhancement of elimination: Not dialyzable (0% to 5%); multiple dosing of activated charcoal would not be expected to be useful

Test Interactions False-positive for phenylketonuria, amylase, uroporphyrins, urobilinogen; possible false-negative pregnancy urinary test; may cause positive direct Coombs', may interfere with BUN and vitamin B₁₂ test determinations

Drug Interactions

Substrate of CYP1A2 (minor), 2D6 (major), 3A4 (minor); **Inhibits** CYP2D6 (strong), 2E1 (weak)

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Aluminum salts: May decrease the absorption of phenothiazines; monitor
Amphetamines: Efficacy may be diminished by antipsychotics; in addition, amphetamines may increase psychotic symptoms; avoid concurrent use

Anticholinergics: May inhibit the therapeutic response to phenothiazines and excess anticholinergic effects may occur; includes benztrapine, trihexyphenidyl, biperiden, and drugs with significant anticholinergic activity (TCAs, antihistamines, disopyramide)

Antihypertensives: Concurrent use of phenothiazines with an antihypertensive may produce additive hypotensive effects (particularly orthostasis)

Bromocriptine: Phenothiazines inhibit the ability of bromocriptine to lower serum prolactin concentrations

CHLORPROPAMIDE

CNS depressants: Sedative effects may be additive with phenothiazines; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol and other sedative agents

CYP2D6 inhibitors: May increase the levels/effects of chlorpromazine. Example inhibitors include delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP2D6 substrates: Chlorpromazine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Chlorpromazine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

Epinephrine: Chlorpromazine (and possibly other low potency antipsychotics) may diminish the pressor effects of epinephrine

Guanethidine and guanadrel: Antihypertensive effects may be inhibited by chlorpromazine

Levodopa: Chlorpromazine may inhibit the antiparkinsonian effect of levodopa; avoid this combination

Lithium: Chlorpromazine may produce neurotoxicity with lithium; this is a rare effect

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk.

Phenytoin: May reduce serum levels of phenothiazines; phenothiazines may increase phenytoin serum levels

Propranolol: Serum concentrations of phenothiazines may be increased; propranolol also increases phenothiazine concentrations

Polypeptide antibiotics: Rare cases of respiratory paralysis have been reported with concurrent use of phenothiazines

QT_c-prolonging agents: Effects on QT_c interval may be additive with phenothiazines, increasing the risk of malignant arrhythmias; includes type Ia antiarrhythmics, TCAs, and some quinolone antibiotics (sparfloxacin, moxifloxacin and gatifloxacin)

Sulfadoxine-pyrimethamine: May increase phenothiazine concentrations

Tricyclic antidepressants: Concurrent use may produce increased toxicity or altered therapeutic response

Trazodone: Phenothiazines and trazodone may produce additive hypotensive effects

Valproic acid: Serum levels may be increased by phenothiazines

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta; may cause damage to fetal retina

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Nursing Implications Dilute oral concentrate solution in juice before administration; avoid contact of oral solution or injection with skin (contact dermatitis); watch for hypotension when administering I.M. or I.V.

Additional Information Use decreased doses in elderly or debilitated patients. Extrapyramidal reaction may be more common in patients with hypocalcemia and in pediatric patients, especially those with dehydration or acute illnesses (viral or CNS infections). Avoid rectal administration in immunocompromised patients. May be useful in treating headaches due to meningitis.

ChlorpropAMIDE

CAS Number 99-20-2

U.S. Brand Names Diabinese®

Use Management of blood sugar in type 2 diabetes mellitus (noninsulin dependent, NIDDM)

Unlabeled/Investigational Use Neurogenic diabetes insipidus

Mechanism of Action Stimulates insulin release from the pancreatic beta cells; reduces glucose output from the liver; insulin sensitivity is increased at peripheral target sites

Adverse Reactions

Cardiovascular: Edema

Central nervous system: **Headache, dizziness**

Dermatologic: Skin rash, urticaria, photosensitivity, erythema multiforme, exfoliative dermatitis

Endocrine & metabolic: Disulfiram reaction, hypoglycemia, hyponatremia, SIADH

Gastrointestinal: **Anorexia, constipation, heartburn, epigastric fullness, nausea, vomiting, diarrhea**, proctocolitis

Hematologic: Agranulocytosis, aplastic anemia, bone marrow suppression, eosinophilia, hemolytic anemia, leukopenia, porphyria cutanea tarda, thrombocytopenia

Hepatic: Cholestatic jaundice

Signs and Symptoms of Overdose Agranulocytosis, ataxia, colitis, erythema multiforme, feces discoloration (black), granulocytopenia, hypoglycemia (may be prolonged), hyponatremia, jaundice, leukopenia, lichenoid eruptions, neutropenia, photosensitivity

Admission Criteria/Prognosis Admit all intentional adult overdoses. Pediatric patients should be observed in a medical setting through an overnight sleep cycle (and for a minimum of 8 hours). No intravenous glucose or dextrose should be given prophylactically. Asymptomatic

pediatric patients should have a blood glucose determination at 3-6 hours postingestion or immediately when symptoms (hunger, irritability, lethargy, tremulousness, tachycardia, diaphoresis, or seizures) develop. Any borderline blood glucose reading (about 70 mg/dL) are repeated in one hour. Consider regular 2- to 3-hour interval blood glucose measurements during sleep. If no hypoglycemic events occur and prebreakfast blood glucose levels are normal, pediatric patients can be monitored by parental observation at home.

Pharmacodynamics/Kinetics

Onset of action: Peak effect: ~6-8 hours

Distribution: V_d: 0.13-0.23 L/kg; enters breast milk

Protein binding: 60% to 90%

Metabolism: Extensively hepatic (~80%)

Half-life elimination: 30-42 hours; prolonged in elderly or with renal impairment

End-stage renal disease: 50-200 hours

Time to peak, serum: 3-4 hours

Excretion: Urine (10% to 30% as unchanged drug)

Dosage

Oral: The dosage of chlorpropamide is variable and should be individualized based upon the patient's response

Initial dose:

Adults: 250 mg/day in mild to moderate diabetes in middle-aged, stable diabetic

Elderly: 100-125 mg/day in older patients

Subsequent dosages may be increased or decreased by 50-125 mg/day at 3- to 5-day intervals

Maintenance dose: 100-250 mg/day; severe diabetics may require 500 mg/day; avoid doses >750 mg/day

Dosing adjustment/comments in renal impairment: Cl_{cr} <50 mL/minute: Avoid use

Hemodialysis: Removed with hemoperfusion

Peritoneal dialysis: Supplemental dose is not necessary

Dosing adjustment in hepatic impairment: Dosage reduction is recommended. Conservative initial and maintenance doses are recommended in patients with liver impairment because chlorpropamide undergoes extensive hepatic metabolism.

Monitoring Parameters Fasting blood glucose, normal Hgb A_{1c} or fructosamine levels; monitor for signs and symptoms of hypoglycemia (fatigue, sweating, numbness of extremities); monitor urine for glucose and ketones

Contraindications Hypersensitivity to sulfonyleureas, sulfonamides, or any component of the formulation; do not use with type 1 diabetes mellitus (insulin dependent, IDDM) or with severe renal, hepatic, thyroid, or other endocrine disease

Warnings

Patients should be properly instructed in the early detection and treatment of hypoglycemia; long half-life may complicate recovery from excess effects. Because of chlorpropamide's long half-life, duration of action, and the increased risk for hypoglycemia, it is not considered a hypoglycemic agent of choice in the elderly.

Chemical similarities are present among sulfonamides, sulfonyleureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with sulfonyleurea or sulfonamide allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

Product labeling states oral hypoglycemic drugs may be associated with an increased cardiovascular mortality as compared to treatment with diet alone or diet plus insulin. Data to support this association are limited, and several studies, including a large prospective trial (UKPDS) have not supported an association.

Dosage Forms Tablet: 100 mg, 250 mg

Reference Range

Glucose: Adults: 60-115 mg/dL

Elderly fasting glucose: 100-180 mg/dL

Chlorpropamide lethal level: >400 mcg/mL in nondiabetic patients

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Glucose (25 g I.V.) is mainstay of therapy. Glucagon (1-5 mg I.V., I.M., or SubQ) will have limited benefit (0.03-0.1 mg/kg in pediatrics); diazoxide is a third-line agent; octreotide (50 mcg SubQ every 12 hours) may be helpful in sulfonyleurea overdose.

For pediatric patients with profound sulfonyleurea-induced hypoglycemia: Give 0.5 g of dextrose per kg of body weight (5 mL/kg of 10% dextrose concentration of intravenous fluid, 2 mL/kg of D₂₅ or 1 mL/kg of D₅₀).

Enhancement of elimination: Multiple dosing of activated charcoal is not useful; alkalinization of urine is useful; charcoal hemoperfusion may remove as much as 80% of the body burden of chlorpropamide

Antidote(s)

● Dextrose [ANTIDOTE]

● Octreotide [ANTIDOTE]

Drug Interactions**Substrate** of CYP2C8/9 (minor)

Thiazides may decrease effectiveness of chlorpropamide

Possible interaction between chlorpropamide and fluoroquinolone antibiotics has been reported resulting in a potentiation of hypoglycemic action of chlorpropamide

Since this agent is highly protein bound, the toxic potential is increased when given concomitantly with other highly protein bound drugs (ie, phenylbutazone, oral anticoagulants, hydantoin, salicylates, NSAIDs, beta-blockers, sulfonamides) - increase hypoglycemic effect.

Ethanol increases disulfiram reactions.

Phenylbutazone can increase hypoglycemic effects.

Certain drugs tend to produce hyperglycemia and may lead to loss of control (ie, thiazides and other diuretics, corticosteroids, phenothiazines, thyroid products, estrogens, oral contraceptives, phenytoin, nicotinic acid, sympathomimetics, calcium channel blocking drugs, and isoniazid).

Possible interactions between chlorpropamide and coumarin derivatives have been reported that may either potentiate or weaken the effects of coumarin derivatives.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta; hypoglycemia, ear defects reported; other malformations reported but may have been secondary to poor maternal glucose control/diabetes. Insulin is the drug of choice for the control of diabetes mellitus during pregnancy. Prolonged hypoglycemia has been reported in neonates born to mothers who were receiving sulfonamides (particularly long-acting drugs).

Lactation Enters breast milk/contraindicated

Nursing Implications

Patients who are anorexic or NPO may need to hold the dose to avoid hypoglycemia

Monitor fasting blood glucose, normal Hgb A_{1c}, or fructosamine levels; monitor for signs and symptoms of hypoglycemia (fatigue, sweating, numbness of extremities); monitor urine for glucose and ketones

Chlorprothixene**CAS Number** 113-59-7

Use Management of psychotic disorders, emotional disturbances

Mechanism of Action Low anticholinergic activity with similar properties as chlorpromazine

Adverse Reactions

Cardiovascular: **Hypotension** (especially with I.V. use), **hypotension (orthostatic)**, tachycardia, cardiac arrhythmias, QT prolongation, sinus bradycardia, sinus tachycardia

Central nervous system: **Tardive dyskinesia, pseudoparkinsonian signs and symptoms, dizziness, akathisia, dystonias**, sedation, drowsiness, restlessness, anxiety, extrapyramidal reactions, neuroleptic malignant syndrome, seizures, altered central temperature regulation, fever, hyperthermia

Dermatologic: Hyperpigmentation, pruritus, rash, photosensitivity

Endocrine & metabolic: Amenorrhea, galactorrhea, gynecomastia, hyperprolactinemia

Gastrointestinal: GI upset, xerostomia, **constipation**, weight gain

Genitourinary: Urinary retention, impotence

Hematologic: Leukopenia/neutropenia (agranulocytosis, granulocytopenia) usually in patients with large doses for prolonged periods; thrombocytopenia, hemolysis, eosinophilia

Hepatic: Cholestatic jaundice

Ocular: **Retinal pigmentation**, diplopia, blurred vision, mydriasis

Miscellaneous: **Diaphoresis (decreased)**, anaphylactoid reactions, systemic lupus erythematosus

Signs and Symptoms of Overdose Abnormal involuntary muscle movements, coma, deep sleep, dry eyes, ejaculatory disturbances, extrapyramidal reaction, hyperactivity, hypotension, impotence, jaundice, neuroleptic malignant syndrome, neutropenia, oliguria with azotemia, Parkinson's-like symptoms, photosensitivity

Pharmacodynamics/Kinetics

Absorption: Oral absorption results in peak concentrations between 2-4 hours. Absorption may be affected by the inherent anticholinergic action on the gastrointestinal tissue causing variable absorption. Absorption from tablets is erratic with less variation seen with solutions.

Distribution: Widely distributed in tissues with CNS concentrations exceeding that of plasma due to their lipophilic characteristics.

Protein binding: Antipsychotic agents are bound 90% to 99% to plasma proteins; highly bound to brain and lung tissue and other tissues with a high blood perfusion.

Elimination: Elimination occurs through hepatic metabolism (oxidation) where numerous active metabolites are produced; active metabolites excreted in urine; elimination half-lives of antipsychotics ranges from 20-40 hours which may be extended in elderly due to decline in oxidative hepatic reactions (phase I) with age. The biologic effect of a single dose persists for 24 hours. When the patient has accommodated to initial side effects (sedation), once daily dosing is possible due to the long half-life of antipsychotics.

Steady-state plasma levels are achieved in 4-7 days; therefore, if possible, do not make dose adjustments more than once in a 7-day period. Due to the long half-lives of antipsychotics, as needed (PRN) use is ineffective since repeated doses are necessary to achieve therapeutic tissue concentrations in the CNS.

Dosage

Children > 6 years: Oral: 10-25 mg 3-4 times/day

Adults:

Oral: 25-50 mg 3-4 times/day, to be increased as needed; doses exceeding 600 mg/day are rarely required

I.M.: 25-50 mg up to 3-4 times/day

Monitoring Parameters Monitor for reduction of psychotic symptoms; hyperthermia, acute EPS, autonomic changes (irregular pulse/blood pressure, diaphoresis)

Administration

I.M. dose is 4-10 times the activity of oral dose

Contraindications Circulatory collapse, hypersensitivity to chlorprothixene or any component, comatose states due to central depressant drugs

Warnings Safety in children < 6 months of age has not been established; use with caution in patients with cardiovascular disease or seizures; bone marrow depression, severe liver or cardiac disease; significant hypotension may occur, especially when the drug is administered parenterally; extended release capsules and injection contain benzyl alcohol; injection also contains sulfites which may cause allergic reaction

Dosage Forms

Injection, as hydrochloride: 12.5 mg/mL (2 mL)

Solution, oral concentrate, as lactate and hydrochloride: 100 mg/5 mL (480 mL) [fruit flavor]

Tablet: 10 mg, 25 mg, 50 mg, 100 mg

Reference Range

Therapeutic: 0.04-0.30 mcg/mL

Fatal: 1.00-2.00 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required. Seizures commonly respond to lorazepam or diazepam (I.V. 5-10 mg bolus in adults every 15 minutes if needed up to a total of 30 mg; I.V. 0.25-0.4 mg/kg/dose up to a total of 10 mg in children) or to phenytoin or phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 g), while other antiarrhythmics can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with benzotropine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes.

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; combined hemodialysis/hemoperfusion over 4 hours may be beneficial; not dialyzable (0% to 5%)

Test Interactions ↑ cholesterol (S), glucose; ↓ uric acid (S)

Drug Interactions Decreased effect of guanethidine

Increased effect/toxicity: Ethanol, CNS depressants

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk.

Pregnancy Risk Factor C

Nursing Implications Observe for tremor and abnormal movement or posturing (extrapyramidal symptoms)

Additional Information Slight amine-like odor

Chlorthalidone**CAS Number** 77-36-1

U.S. Brand Names Thalitone®

Synonyms Hygroton

Use Management of mild to moderate hypertension, used alone or in combination with other agents; treatment of edema associated with congestive heart failure, nephrotic syndrome, or pregnancy

Mechanism of Action Sulfonamide-derived diuretic that inhibits sodium and chloride reabsorption in the cortical-diluting segment of the ascending loop of Henle

Adverse Reactions

Cardiovascular: Hypotension, myocarditis (hypersensitivity), myocarditis

Dermatologic: Psoriasiform eruption, photosensitivity

CHLORZOXAZONE

Endocrine & metabolic: Hypokalemia, hypercalcemia, hypercholesterolemia, fluid and electrolyte imbalances (hypocalcemia, hypomagnesemia, hyponatremia), hyperuricemia, hyperglycemia
Gastrointestinal: Pancreatitis
Genitourinary: Impotence
Hematologic: Rarely blood dyscrasias (ie, neutropenia, thrombocytopenia), agranulocytosis
Neuromuscular & skeletal: Rhabdomyolysis
Renal: Prerenal azotemia
Miscellaneous: Periarteritis nodosa

Signs and Symptoms of Overdose Confusion, diuresis, hypermotility, hyperglycemia, hyperuricemia, hypocalcemia, hypokalemia, hypomagnesemia, hyponatremia, impotence, LDL (increased), lethargy, muscle weakness, myasthenia gravis (exacerbation or precipitation), myopia, nocturia, periarteritis nodosa, photosensitivity, vision color changes (yellow tinge)

Pharmacodynamics/Kinetics

Onset of action: Peak effect: 2-6 hours
Duration: 24-72 hours
Absorption: 65%
Distribution: Crosses placenta; enters breast milk
Metabolism: Hepatic
Half-life elimination: 35-55 hours; may be prolonged with renal impairment; Anuria: 81 hours
Excretion: Urine (~50% to 65% as unchanged drug)

Dosage

Oral:
Children (nonapproved): 2 mg/kg/dose 3 times/week or 1-2 mg/kg/day
Adults: 25-100 mg/day or 100 mg 3 times/week; usual dosage range (JNC 7): 12.5-25 mg/day
Elderly: Initial: 12.5-25 mg/day or every other day; there is little advantage to using doses > 25 mg/day

Dosage adjustment in renal impairment: $Cl_{cr} < 10$ mL/minute: Administer every 48 hours

Monitoring Parameters Assess weight, I & O records daily to determine fluid loss; blood pressure, serum electrolytes, renal function

Contraindications Hypersensitivity to chlorthalidone or any component of the formulation; cross-sensitivity with other thiazides or sulfonamides; anuria; renal decompensation; pregnancy

Warnings Use with caution in patients with hypokalemia, renal disease, hepatic disease, gout, lupus erythematosus, or diabetes mellitus. Use with caution in severe renal diseases. Correct hypokalemia before initiating therapy. Chemical similarities are present among sulfonamides, sulfonyleureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics (except ethacrynic acid). Use in patients with thiazide or sulfonamide allergy is specifically contraindicated in product labeling, however, a risk of cross-reaction exists in patients with allergy to any of these compounds; avoid use when previous reaction has been severe.

Dosage Forms

Tablet: 25 mg, 50 mg, 100 mg
Thalitone®: 15 mg

Reference Range Peak serum chlorthalidone level of 6.3 mg/L after a single 200 mg dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: I.V. fluid and electrolyte replacement

Test Interactions ↑ creatine phosphokinase (CPK) (S), ammonia (B), amylase (S), calcium (S), cholesterol (S), glucose, increases acidity (S); ↓ chloride (S), magnesium, potassium (S), sodium (S)

Drug Interactions

ACE inhibitors: Increased hypotension if aggressively diuresed with a thiazide diuretic.

Beta-blockers increase hyperglycemic effects of thiazides in type 2 diabetes mellitus (noninsulin dependent, NIDDM)

Cyclosporine and thiazides can increase the risk of gout or renal toxicity; avoid concurrent use.

Digoxin toxicity can be exacerbated if a thiazide induces hypokalemia or hypomagnesemia.

Lithium toxicity can occur by reducing renal excretion of lithium; monitor lithium concentration and adjust as needed.

Neuromuscular blocking agents can prolong blockade; monitor serum potassium and neuromuscular status.

NSAIDs can decrease the efficacy of thiazides reducing the diuretic and antihypertensive effects.

Pregnancy Risk Factor B (manufacturer); D (expert analysis)

Pregnancy Implications Decreased birth weight, neonatal hypoglycemia, or neonatal thrombocytopenia can occur

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications Assess weight, I & O reports daily to determine fluid loss; take blood pressure with patient lying down and standing

Additional Information Recent studies have found chlorthalidone effective in the treatment of isolated systolic hypertension in the elderly

Specific References

Chobanian AV, Bakris GL, Black HR, et al, "The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure: The JNC 7 Report," *JAMA*, 2003, (19)289:2560-71.

Chlorzoxazone

CAS Number 95-25-0

U.S. Brand Names Parafon Forte® DSC

Impairment Potential Yes

Use Musculoskeletal pain, muscle spasm

Mechanism of Action Precise mechanism is not yet clear, but many effects have been ascribed to its central depressant actions

Adverse Reactions

Central nervous system: **Drowsiness**, opisthotonos, amnesia, dizziness

Dermatologic: Petechiae

Genitourinary: Orange colored urine

Hematologic: Porphyrinogenic

Hepatic: Hepatotoxicity (including fatal hepatic necrosis) is idiosyncratic and unpredictable, centrilobular necrosis

Neuromuscular & skeletal: Torticollis

Admission Criteria/Prognosis Admit any symptomatic patient or any adult ingestion > 5 g

Pharmacodynamics/Kinetics

Onset of action: ~1 hour

Duration: 6-12 hours

Absorption: Readily absorbed

Metabolism: Extensively hepatic via glucuronidation

Excretion: Urine (as conjugates)

Dosage

Children: 125-500 mg 3-4 times/day

Adult: 250-750 mg 3-4 times/day; maximum tolerated dose: 5 g

Monitoring Parameters Periodic liver functions tests

Contraindications Hypersensitivity to chlorzoxazone or any component of the formulation; impaired liver function

Dosage Forms

Caplet (Parafon Forte® DSC): 500 mg

Tablet: 250 mg, 500 mg

Reference Range Peak plasma levels following an oral 750 mg dose: ~36 mg/L at 38 minutes

Overdosage/Treatment

Decontamination: Lavage (within 2 hours of ingestion)/activated charcoal
Supportive therapy: Benzodiazepines for seizure control; for torticollis, 1-2 mg of benzotropine can be given; flumazenil can reverse coma due to chlorzoxazone (the dose of flumazenil used was 0.1 mg initially followed by 0.25 mg); hypotension should be treated with I.V. fluids and/or Trendelenburg positioning.

Enhancement of elimination: Forced diuresis is not helpful; multiple dosing of activated charcoal may be helpful.

Test Interactions False-positive serum test for aprobarbital may be noted with Toxi-Lab Screen™

Drug Interactions

Substrate of CYP1A2 (minor), 2A6 (minor), 2D6 (minor), 2E1 (major), 3A4 (minor); **Inhibits** CYP2E1 (weak), 3A4 (weak)

CNS depressants: Effects may be increased by chlorzoxazone.

CYP2E1 inhibitors: May increase the levels/effects of chlorzoxazone. Example inhibitors include disulfiram, isoniazid, and miconazole.

Disulfiram: May increase chlorzoxazone concentration; monitor.

Isoniazid: May increase chlorzoxazone concentration; monitor.

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/not recommended

Cholecalciferol

U.S. Brand Names Delta-D®; Quintox®; Rampage®

Synonyms: Oleovitamin D₃; Vitamin D₃

Use Rodenticide in grain bait

Mechanism of Toxic Action A vitamin D₃ compound (equipotent to vitamin D₂) which increases absorption of calcium and phosphorus from the gastrointestinal tract; usually found in concentrations of 0.075% (750 ppm)

Adverse Reactions

Cardiovascular: Hypertension

Central nervous system: Drowsiness, headache, confusion, dysosmia

Endocrine & metabolic: Hypercalcemia, hypomagnesemia, hyperphosphatemia, ectopic calcification

Gastrointestinal: Anorexia, nausea, vomiting, pancreatitis

Hematologic: Anemia

Neuromuscular & skeletal: Weakness

Ocular: Conjunctivitis, nystagmus

Renal: Azotemia, albuminuria, renal failure

Pharmacodynamics/Kinetics

Distribution: Primarily hepatic
 Protein binding: Extensively to vitamin D-binding protein
 Metabolism: Primary liver and kidney hydroxylation; glucuronidation (minimal)
 Half-life elimination: 14 hours
 Time to peak, plasma: 11 hours
 Excretion: As metabolites, urine (2.4%) and feces (4.9%)

Monitoring Parameters Calcium, renal function tests

Contraindications Hypercalcemia; hypersensitivity to cholecalciferol or any component of the formulation; malabsorption syndrome; evidence of vitamin D toxicity

Dosage Forms

Tablet: 1000 int. units
 Delta-D®: 400 int. units

Overdosage/Treatment

Decontamination: **Oral:** Lavage (within 1 hour); cholestyramine may be particularly effective (8 g twice daily) **Ocular:** Irrigate with saline.
 Supportive therapy: Hypercalcemia can be treated with saline, diuresis, furosemide (20-40 mg I.V.), and hydrocortisone (100 mg I.V. every 6 hours). Calcitonin (4-8 int. units/kg I.M. every 6-12 hours) can be used for persistent or severe hypercalcemia. Hemodialysis can also be used for severe hypercalcemia.
 Enhanced elimination: Forced saline diuresis (urine flow of 3 mL/kg/hour) - furosemide may be added as needed to maintain urine flow. Hemodialysis (against a calcium free dialysate) can be considered.

Drug Interactions Inhibits CYP2C9 (weak), 2C19 (weak), 2D6 (weak)

Thiazide diuretics, cholestyramine, colestipol, corticosteroids, mineral oil, orlistat, phenytoin, barbiturates, digitalis glycosides, antacids (magnesium)

Pregnancy Risk Factor A

Nursing Implications Do not administer more than the recommended amount. While taking this medication, your physician may want you to follow a special diet or take a calcium supplement. Follow this diet closely. Avoid taking magnesium supplements or magnesium containing antacids. Early symptoms of hypercalcemia include weakness, fatigue, somnolence, headache, anorexia, dry mouth, metallic taste, nausea, vomiting, cramps, diarrhea, muscle pain, bone pain, and irritability.

Additional Information 1 mg of cholecalciferol is equivalent to 40,000 int. units of vitamin D

Adults: 500 mg to 1.5 g 2-3 times/day or 3 g at bedtime; usual maintenance dose: 1-4.5 g/day

Elderly: 750 mg 3 times/day

Dosing adjustment/comments in renal impairment: Avoid use in severe renal impairment

Monitoring Parameters Serum magnesium with high dose therapy or in patients with impaired renal function; serum salicylate levels, renal function, hearing changes or tinnitus, abnormal bruising, weight gain and response (ie, pain)

Administration

Liquid may be mixed with fruit juice just before drinking. Do not administer with antacids. Take with a full glass of water and remain in an upright position for 15-30 minutes after administration.

Contraindications Hypersensitivity to salicylates, other nonacetylated salicylates, other NSAIDs, or any component of the formulation; bleeding disorders; pregnancy (3rd trimester)

Warnings

Salicylate salts may not inhibit platelet aggregation and, therefore, should not be substituted for aspirin in the prophylaxis of thrombosis. Use with caution in patients with impaired renal function, dehydration, erosive gastritis, asthma, or peptic ulcer. Discontinue use 1 week prior to surgical procedures. Children and teenagers who have or are recovering from chickenpox or flu-like symptoms should not use this product. Changes in behavior (along with nausea and vomiting) may be an early sign of Reye's syndrome; patients should be instructed to contact their healthcare provider if these occur.

Elderly are a high-risk population for adverse effects from NSAIDs. As many as 60% of elderly can develop peptic ulceration and/or hemorrhage asymptotically. Use lowest effective dose for shortest period possible. Tinnitus or impaired hearing may indicate toxicity. Tinnitus may be a difficult and unreliable indication of toxicity due to age-related hearing loss or eighth cranial nerve damage. CNS adverse effects may be observed in the elderly at lower doses than younger adults.

Dosage Forms

Liquid: 500 mg/5 mL (240 mL) [choline salicylate 293 mg and magnesium salicylate 362 mg per 5 mL; cherry cordial flavor]
 Tablet: 500 mg [choline salicylate 293 mg and magnesium salicylate 362 mg]; 750 mg [choline salicylate 440 mg and magnesium salicylate 544 mg]; 1000 mg [choline salicylate 587 mg and magnesium salicylate 725 mg]

Reference Range

Salicylate blood levels for anti-inflammatory effect: 10-30 mg/dL
 Analgesia and antipyretic effect: Up to 10 mg/dL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal may be most efficacious
 Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with bicarbonates, seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage
 Enhancement of elimination: Dialysis is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be effective

Test Interactions False-negative results for Clinistix® urine test; false-positive results with Clinitest®

Drug Interactions

ACE inhibitors: Effects of ACE inhibitors may be decreased by concurrent therapy with NSAIDs.
 Antacids: Concomitant use may lead to decreased salicylate concentration.
 Warfarin: Concomitant use may increase the hypoprothrombinemic effect of warfarin.

Pregnancy Risk Factor C/D (3rd trimester)

Pregnancy Implications Animal reproduction studies have not been conducted. Due to the known effects of other salicylates (closure of ductus arteriosus), use during late pregnancy should be avoided.

Lactation Enters breast milk/use caution

Nursing Implications Liquid may be mixed with fruit juice just before drinking

Choline Magnesium Trisalicylate

CAS Number 64425-90-7

U.S. Brand Names Trilisate® [DSC]

Synonyms Tricosal

Use Management of osteoarthritis, rheumatoid arthritis, and other arthritis; acute painful shoulder

Mechanism of Action Inhibits prostaglandin synthesis; acts on the hypothalamus heat-regulating center to reduce fever; blocks the generation of pain impulses

Adverse Reactions

Cardiovascular: Edema
 Central nervous system: Headache, lightheadedness, dizziness, drowsiness, lethargy, confusion, hallucinations
 Dermatologic: Rash, pruritus, bruising, erythema multiforme
 Gastrointestinal: Nausea, vomiting, diarrhea, heartburn, dyspepsia, epigastric pain, constipation, gastric ulceration, anorexia, weight gain, dysgeusia, duodenal ulceration, esophagitis
 Hematologic: Occult bleeding
 Hepatic: Hepatic enzymes increased
 Otic: Tinnitus, hearing impairment, hearing loss (irreversible)
 Renal: Increased BUN and creatinine
 Respiratory: Epistaxis, asthma

Signs and Symptoms of Overdose Bezoars, cognitive dysfunction, drowsiness, GI bleeding, GI upset, hypoglycemia, hyponatremia, nausea, nephrotic syndrome, nystagmus, ototoxicity, tinnitus, vomiting, wheezing
 Severe poisoning can manifest with coma, feces discoloration (black; pink; red; tarry), hyperglycemia, hyperthermia, hypotension, irritability, metabolic acidosis, renal failure and/or hepatic failure, respiratory depression, seizures, urine discoloration (pink)

Pharmacodynamics/Kinetics

Onset of action: Peak effect: ~2 hours
 Absorption: Stomach and small intestines
 Distribution: Readily into most body fluids and tissues; crosses placenta; enters breast milk
 Half-life elimination (dose dependent): Low dose: 2-3 hours; High dose: 30 hours
 Time to peak, serum: ~2 hours

Dosage

Oral (based on total salicylate content):
 Children <37 kg: 50 mg/kg/day given in 2 divided doses; 2250 mg/day for heavier children

Cidofovir

U.S. Brand Names Vistide®

Use Treatment of cytomegalovirus (CMV) retinitis in patients with acquired immunodeficiency syndrome (AIDS); currently under Phase I and II trials for systemic treatment of AIDS. **Note:** Should be administered with probenecid and intravenous saline in order to reduce nephrotoxicity.

Mechanism of Action As a nucleotide analog, cidofovir suppresses CMV replication by selective prevention of viral DNA synthesis through inhibition of CMV DNA polymerase; the active form is the intracellular metabolite, cidofovir diphosphate; cross-resistance to ganciclovir but not foscarnet has been demonstrated *in vitro*

Adverse Reactions

Cardiovascular: Hypotension, pallor, syncope, tachycardia
 Central nervous system: **Infection, chills, fever, headache, amnesia, anxiety, confusion, seizures, insomnia**, dizziness, hallucinations, depression, somnolence, malaise
 Dermatologic: **Alopecia, rash, acne, skin discoloration**, pruritus, urticaria
 Endocrine & metabolic: Hyperglycemia, hyperlipidemia, hypocalcemia, hypokalemia, dehydration, nephrogenic diabetes insipidus
 Gastrointestinal: **Nausea, vomiting, diarrhea, anorexia, abdominal pain, constipation, dyspepsia, gastritis**, abnormal taste, stomatitis
 Genitourinary: Glycosuria, urinary incontinence, urinary tract infections
 Hematologic: **Thrombocytopenia, neutropenia (not dose related), anemia**
 Neuromuscular & skeletal: **Weakness, paresthesia**, skeletal pain
 Ocular: **Amblyopia, conjunctivitis, ocular hypotony**, retinal detachment, iritis, uveitis, abnormal vision
 Renal: **Tubular damage, proteinuria, Cr elevations**, hematuria
 Respiratory: **Asthma, bronchitis, coughing, dyspnea, pharyngitis**, pneumonia, rhinitis, sinusitis
 Miscellaneous: Diaphoresis, allergic reactions

Pharmacodynamics/Kinetics

The following pharmacokinetic data is based on a combination of cidofovir administered with probenecid:
 Distribution: V_d : 0.54 L/kg; does not cross significantly into CSF
 Protein binding: <6%
 Metabolism: Minimal; phosphorylation occurs intracellularly
 Half-life elimination, plasma: ~2.6 hours
 Excretion: Urine

Dosage

Induction: 5 mg/kg I.V. over 1 hour once weekly for 2 consecutive weeks
 Maintenance: 5 mg/kg over 1 hour once every other week
 Administer with probenecid - 2 g orally 3 hours prior to the cidofovir dose and 1 g at 2 and 8 hours after completion of the infusion (total: 4 g)
 Hydrate with 1 L of 0.9% normal saline I.V. prior to cidofovir infusion; a second liter may be administered over a 1- to 3-hour period immediately following infusion, if tolerated

Dosing adjustment in renal impairment:

Cl_{cr} 41-55 mL/minute: 2 mg/kg
 Cl_{cr} 30-40 mL/minute: 1.5 mg/kg
 Cl_{cr} 20-29 mL/minute: 1 mg/kg
 Cl_{cr} < 19 mL/minute: 0.5 mg/kg
 If the Cr increases by 0.3-0.4 mg/dL, reduce the cidofovir dose to 3 mg/kg; DC therapy for increases \geq 0.5 mg/dL or development of \geq 3+ proteinuria

Stability Store admixtures under refrigeration for \leq 24 hours; prepare admixtures in a class two laminar flow hood, wearing protective gear; dispose of cidofovir as directed; wash and flush skin thoroughly with water if contact with skin

Monitoring Parameters Renal function (Cr, BUN, UAs), LFTs, WBCs, intraocular pressure and visual acuity

Administration

For I.V. infusion only. Infuse over 1 hour. Hydrate with 1 L of 0.9% NS I.V. prior to cidofovir infusion. A second liter may be administered over a 1- to 3-hour period immediately following infusion, if tolerated.

Contraindications Hypersensitivity to cidofovir; history of clinically-severe hypersensitivity to probenecid or other sulfa-containing medications; serum creatinine > 1.5 mg/dL; Cl_{cr} < 55 mL/minute; urine protein \geq 100 mg/dL (\geq 2+ proteinuria); use with or within 7 days of nephrotoxic agents; direct intraocular injection

Warnings [U.S. Boxed Warning]: Dose-dependent nephrotoxicity requires dose adjustment or discontinuation if changes in renal function occur during therapy (eg, proteinuria, glycosuria, decreased serum phosphate, uric acid or bicarbonate, and elevated creatinine). Neutropenia has been reported; monitor counts during therapy. Cases of ocular hypotony have also occurred; monitor intraocular pressure. Monitor for signs of metabolic acidosis. Safety and efficacy have not been established in children or the elderly. Administration must be accompanied by oral probenecid and intravenous saline prehydration. Prepare admixtures in a class two laminar flow hood, wearing protective gear; dispose of cidofovir as directed. [U.S. Boxed Warning]: Indicated only for CMV retinitis treatment in HIV patients; possibly carcinogenic based on animal data.

Dosage Forms Injection, solution [preservative free]: 75 mg/mL (5 mL)

Reference Range Peak serum cidofovir levels after I.V. dose of 5 mg/kg: ~12 mcg/mL; coadministration of probenecid may double peak serum cidofovir level

Overdose/Treatment Decontamination: Ipecac within 30 minutes; lavage within 1 hour/activated charcoal

Drug Interactions

Nephrotoxic agents: Drugs with nephrotoxic potential (eg, amphotericin B, aminoglycosides, foscarnet, and I.V. pentamidine) should not be used with or within 7 days of cidofovir therapy.

Zidovudine: Due to concomitant probenecid administration, temporarily discontinue or decrease zidovudine dose by 50% on the day of cidofovir administration only.

Pregnancy Risk Factor C

Pregnancy Implications Although studies are inconclusive, adenocarcinomas have occurred in animal studies with cidofovir; use during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Zidovudine (AZT) doses should be decreased or discontinued during cidofovir therapy since probenecid decreases its elimination; administration of probenecid with a meal may decrease associated nausea; acetaminophen and antihistamines may ameliorate hypersensitivity reactions; dilute in 100 mL 0.9% saline; administer probenecid and I.V. saline before each infusion; allow the admixture to come to room temperature before administration

Cimetidine**Related Information**

- Therapeutic Drugs Associated with Hallucinations

CAS Number 51481-61-9

U.S. Brand Names Tagamet® HB 200 [OTC]; Tagamet®

Use Short-term treatment of active duodenal ulcers and benign gastric ulcers; long-term prophylaxis of duodenal ulcer; gastric hypersecretory states; gastroesophageal reflux; prevention of upper GI bleeding in critically-ill patients; labeled for OTC use for prevention or relief of heartburn, acid indigestion, or sour stomach

Unlabeled/Investigational Use Part of a multidrug regimen for *H. pylori* eradication to reduce the risk of duodenal ulcer recurrence

Mechanism of Action Competitive inhibition of histamine at H_2 -receptors of the gastric parietal cells resulting in reduced gastric acid secretion

Adverse Reactions

Cardiovascular: Bradycardia, hypotension, AV block, sinus bradycardia
 Central nervous system: Dizziness, mental confusion, agitation, drowsiness, psychosis, delirium, fatigue, auditory and visual hallucination, fever, headache, gustatory hallucinations
 Dermatologic: Rash, pruritus, alopecia, erythema annulare centrifugum, Stevens-Johnson syndrome, exfoliative dermatitis, rash, cutaneous vasculitis, angioedema, toxic epidermal necrolysis, xerosis, urticaria, purpura, exanthem
 Endocrine & metabolic: Gynecomastia, reduces parathyroid hormone, nephrogenic diabetes insipidus, parotitis, decreased libido
 Gastrointestinal: Mild diarrhea, pancreatitis, lymphocytic colitis
 Genitourinary: Impotence
 Hematologic: Neutropenia, thrombocytopenia, granulocytopenia, aplastic anemia
 Hepatic: Elevation of AST and ALT
 Neuromuscular & skeletal: Myalgia
 Ocular: Mydriasis, photophobia
 Renal: Interstitial nephritis, elevated creatinine
 Respiratory: Asthma, bronchospasm
 Miscellaneous: Cutaneous lupus erythematosus, systemic lupus erythematosus, fixed drug eruption

Signs and Symptoms of Overdose Agranulocytosis, ataxia, AV block, bradycardia, cholestatic jaundice, coma, delirium, dementia, depression, disorientation, dry mouth, eosinophilia, erythema multiforme, extrapyramidal reaction, galactorrhea, granulocytopenia, hyperthermia, hyperprolactinemia, ileus, impotence, leukocytosis, leukopenia, mania, myalgia, mydriasis, myopathy, neutropenia, parotid pain, respiratory failure, slurred speech, sweating

Admission Criteria/Prognosis Admit any patient central nervous system or cardiovascular toxicity or any adult ingestion > 3 g

Pharmacodynamics/Kinetics

Onset of action: 1 hour
 Duration: 4-8 hours
 Absorption: Rapid
 Distribution: Crosses placenta; enters breast milk
 Protein binding: 20%
 Metabolism: Partially hepatic
 Bioavailability: 60% to 70%
 Half-life elimination: Neonates: 3.6 hours; Children: 1.4 hours; Adults: Normal renal function: 2 hours
 Time to peak, serum: Oral: 1-2 hours
 Excretion: Primarily urine (48% as unchanged drug); feces (some)

Dosage

Children: Oral, I.M., I.V.: 20-40 mg/kg/day in divided doses every 6 hours
 Children \geq 12 years and Adults: Oral: Heartburn, acid indigestion, sour stomach (OTC labeling): 200 mg up to twice daily; may take 30 minutes prior to eating foods or beverages expected to cause heartburn or indigestion

Adults:

Short-term treatment of active ulcers:

Oral: 300 mg 4 times/day or 800 mg at bedtime or 400 mg twice daily for up to 8 weeks

I.M., I.V.: 300 mg every 6 hours or 37.5 mg/hour by continuous infusion; I.V. dosage should be adjusted to maintain an intragastric pH \geq 5

Patients with an active bleed: Administer cimetidine as a continuous infusion (see above)

Duodenal ulcer prophylaxis: Oral: 400-800 mg at bedtime

Gastric hypersecretory conditions: Oral, I.M., I.V.: 300-600 mg every 6 hours; dosage not to exceed 2.4 g/day

Helicobacter pylori eradication (unlabeled use): 400 mg twice daily; requires combination therapy with antibiotics

Dosing adjustment/interval in renal impairment: Children and Adults:

Cl_{cr} 20-40 mL/minute: Administer every 8 hours or 75% of normal dose

Cl_{cr} 0-20 mL/minute: Administer every 12 hours or 50% of normal dose

Hemodialysis: Slightly dialyzable (5% to 20%)

Dosing adjustment/comments in hepatic impairment: Usual dose is safe in mild liver disease but use with caution and in reduced dosage in severe liver disease; increased risk of CNS toxicity in cirrhosis suggested by enhanced penetration of CNS

Monitoring Parameters CBC, gastric pH, occult blood with GI bleeding; monitor renal function to correct dose.

Administration Oral: Administer with meals so that the drug's peak effect occurs at the proper time (peak inhibition of gastric acid secretion occurs at 1 and 3 hours after dosing in fasting subjects and approximately 2 hours in nonfasting subjects; this correlates well with the time food is no longer in the stomach offering a buffering effect)

Injection: May be administered as a slow I.V. push or preferably as an I.V. intermittent or I.V. continuous infusion. Administer each 300 mg (or fraction thereof) over a minimum of 5 minutes when giving I.V. push. Give intermittent infusion over 15-30 minutes for each 300 mg dose. Intermittent infusions are administered over 15-30 minutes at a final concentration not to exceed 6 mg/mL; for patients with an active bleed, preferred method of administration is continuous infusion.

Contraindications Hypersensitivity to cimetidine, any component of the formulation, or other H₂ antagonists

Warnings

Reversible confusional states, usually clearing within 3-4 days after discontinuation, have been linked to use. Increased age (> 50 years) and renal or hepatic impairment are thought to be associated. Dosage should be adjusted in renal/hepatic impairment or in patients receiving drugs metabolized through the P450 system.

Over the counter (OTC) cimetidine should not be taken by individuals experiencing painful swallowing, vomiting with blood, or bloody or black stools; medical attention should be sought. A physician should be consulted prior to use when pain in the stomach, shoulder, arms or neck is present; if heartburn has occurred for > 3 months; or if unexplained weight loss, or nausea and vomiting occur. Frequent wheezing, shortness of breath, lightheadedness, or sweating, especially with chest pain or heartburn, should also be reported. Consultation of a healthcare provider should occur by patients if also taking theophylline, phenytoin, or warfarin; if heartburn or stomach pain continues or worsens; or if use is required for > 14 days. Pregnant or breast-feeding women should speak to a healthcare provider before use. OTC cimetidine is not approved for use in patients < 12 years of age.

Dosage Forms

[DSC] = Discontinued product

Infusion, as hydrochloride [premixed in NS]: 300 mg (50 mL)

Injection, solution, as hydrochloride: 150 mg/mL (2 mL, 8 mL) [8 mL size contains benzyl alcohol]

Liquid, oral, as hydrochloride: 300 mg/5 mL (240 mL, 480 mL) [contains alcohol 2.8%; mint-peach flavor]

Tablet: 200 mg [OTC], 300 mg, 400 mg, 800 mg

Tagamet®: 300 mg; 400 mg [DSC]

Tagamet® HB 200: 200 mg

Reference Range Therapeutic: 0.25-1 mcg/mL (SI: 1-4 μ mol/L); confusional occurs in levels > 2 mcg/mL (SI: > 8 μ mol/L)

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage within 1 hour; activated charcoal

Supportive therapy: Treatment is primarily symptomatic and supportive; routine use of physostigmine is not advised, although it can be used for life-threatening anticholinergic; benzodiazepines can be used to treat seizures

Enhancement of elimination: Multiple dosing of activated charcoal may be beneficial; hemodialysis may be useful in reducing half-life; should be considered in patients experiencing severe toxicity or renal failure; slightly dialyzable (5% to 20%)

Test Interactions \uparrow AST, ALT, creatinine (S); may cause a false elevation of serum creatinine due to interference with tubular secretion of creatinine

Drug Interactions

Inhibits CYP1A2 (moderate), 2C9 (weak), 2C19 (moderate), 2D6 (moderate), 2E1 (weak), 3A4 (moderate)

Note: There are many potential interactions. Listed are the most significant ones.

Alfentanil: Increased serum concentration; monitor for toxicity.

Amiodarone: Serum concentration of amiodarone is increased; avoid concurrent use.

Atazanavir: Absorption may be decreased by cimetidine; separate doses by 12 hours.

Benzodiazepines (except lorazepam, oxazepam, temazepam): Serum concentration of the benzodiazepine is increased; consider alternative H₂ antagonist or monitor for benzodiazepine toxicity.

Beta-blockers (except atenolol, betaxolol, bisoprolol, nadolol, penbutolol): Effects of the beta-blocker may be increased; use a renally-eliminated beta-blocker or alternative H₂ antagonist.

Calcium channel blockers (except amlodipine and nicardipine): Serum concentration of the CCB is increased; monitor for toxicity.

Carbamazepine: Plasma concentration of carbamazepine may increase transiently (1 week). Monitor for carbamazepine toxicity or use an alternative H₂ antagonist.

Carmustine: Myelotoxicity of carmustine is increased; avoid concurrent use.

Cefpodoxime, cefuroxime: Oral absorption of these agents may be reduced by increased pH; consider alternative antibiotic or separate dosing by at least 2 hours.

Cisapride: Bioavailability of cisapride is increased; avoid concurrent use.

Citalopram: Serum concentration of citalopram is increased; use an alternative H₂ antagonist or adjust citalopram dose.

Clozapine: Cimetidine may increase levels/effects; consider alternative H₂ antagonist

Cyclosporine: Serum concentration of cyclosporine may increase; monitor cyclosporine levels.

CYP1A2 substrates: Cimetidine may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, fluvoxamine, mexiletine, mirtazapine, ropinirole, theophylline, and trifluoperazine.

CYP2C19 substrates: Cimetidine may increase the levels/effects of CYP2C19 substrates. Example substrates include citalopram, diazepam, methsuximide, phenytoin, propranolol, and sertraline.

CYP2D6 substrates: Cimetidine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Cimetidine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 substrates: Cimetidine may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Delavirdine: Absorption of delavirdine is decreased; avoid concurrent use with H₂ antagonists.

Dofetilide: Cimetidine may increase the levels/effects of dofetilide; avoid concurrent use

Flecainide: Serum concentration of flecainide is increased, especially in patients with renal failure.

Ketoconazole, fluconazole, itraconazole (especially capsule): Decreased serum concentration; avoid concurrent use with H₂ antagonists.

Lidocaine: Serum concentration of lidocaine is increased; use alternative H₂ antagonist.

Metformin: Serum levels/effects may be increased by cimetidine; monitor for hypoglycemia.

Moricizine: Serum concentration of moricizine is increased; monitor for toxicity.

Phenytoin: Serum levels/effects may be increased by cimetidine; avoid concurrent use.

Procainamide: Cimetidine may increase levels/effects; monitor.

Propafenone: Serum concentration of propafenone is increased; monitor for toxicity.

Quinolones: Renal elimination of quinolone antibiotics may be decreased. Selective serotonin reuptake inhibitors (eg, paroxetine, citalopram): Serum concentrations may be increased by cimetidine; monitor.

Sulfonylureas: Cimetidine may increase levels/effects; monitor for hypoglycemia

Tacrine: Plasma concentration of tacrine is increased; consider alternative H₂ antagonist.

TCAs: Serum concentration is increased; consider alternative H₂ antagonist or monitor for TCAs toxicity.

Theophylline: Serum concentration of theophylline is increased; consider alternative H₂ antagonist.

Thioridazine: Serum levels/effects may be increased by cimetidine; concurrent use contraindicated by manufacturer.

CIPROFLOXACIN

Warfarin: INR is increased; cimetidine's effect is dose related. Use an alternative H₂ antagonist if possible or monitor INR closely and adjust warfarin dose as needed.

Pregnancy Risk Factor B

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk/not recommended

Additional Information Cimetidine is not effective for hepatoprotection in acetaminophen overdose; may inhibit absorption of cobalamin; may increase HDL cholesterol concentrations; may cause phytoestrogen formation. At doses >1 g/day of cimetidine, the risk of developing gynecomastia is 40 times that of nonusers.

Ciprofloxacin

Related Information

- Levofloxacin

CAS Number 85721-33-1 (base); 86483-48-9 (hydrochloride)

U.S. Brand Names Ciloxan[®]; Cipro[®] XR; Cipro[®]; Proquin[®] XR

Synonyms Ciprofloxacin Hydrochloride

Use Treatment of documented or suspected infections of the lower respiratory tract, sinuses, skin and skin structure, bone/joints, and urinary tract (including prostatitis) due to susceptible bacterial strains; especially indicated for pseudomonas infections and those due to multidrug-resistant gram-negative organisms, chronic bacterial prostatitis, infectious diarrhea, complicated gram-negative and anaerobic intra-abdominal infections (with metronidazole) due to *E. coli* (enteropathic strains), *B. fragilis*, *P. mirabilis*, *K. pneumoniae*, *P. aeruginosa*, *Campylobacter jejuni* or *Shigella*; approved for acute sinusitis caused by *H. influenzae* or *M. catarrhalis*; also used in treatment of typhoid fever due to *Salmonella typhi* (although eradication of the chronic typhoid carrier state has not been proven), osteomyelitis when parenteral therapy is not feasible, acute uncomplicated cystitis in females, to reduce incidence or progression of disease following exposure to aerolized *Bacillus anthracis*, febrile neutropenia (with piperacillin), and sexually transmitted diseases such as uncomplicated cervical and urethral gonorrhea due to *Neisseria gonorrhoeae*; used ophthalmologically for superficial ocular infections (corneal ulcers, conjunctivitis) due to susceptible strains

Acute pulmonary exacerbations in cystic fibrosis (children); cutaneous/gastrointestinal/oropharyngeal anthrax (treatment, children and adults); disseminated gonococcal infection (adults); chancroid (adults); prophylaxis to *Neisseria meningitidis* following close contact with an infected person

Mechanism of Action Inhibits DNA-gyrase in susceptible organisms; inhibits relaxation of supercoiled DNA and promotes breakage of double-stranded DNA

Adverse Reactions

Cardiovascular: Fibrillation (atrial), flutter (atrial), hypertension, palpitations, syncope, tachycardia (infants), vasculitis

Central nervous system: Agitation, aseptic meningitis, CNS depression, confusion, delusions, delirium, dizziness, fever, headache, insomnia, malaise, mania, night terrors, psychosis, paranoia, restlessness, seizures

Dermatologic: Acne, angioedema, bullous skin disease, cutaneous vasculitis, epidermal necrolysis, erythema nodosum, exanthem, Henoch-Schönlein purpura, photosensitivity, somnambulism, Stevens-Johnson syndrome, exfoliative dermatitis, phototoxicity, pruritus, rash, toxic pustulosis, urticaria

Gastrointestinal: Dysphagia, gastritis; gastrointestinal vasculitis, fecal discoloration (greenish gray, white/speckling), nausea, pancreatitis, stomatitis, tooth discoloration, vomiting, xerostomia, diarrhea, abdominal pain

Genitourinary: Urinary retention

Hematologic: Anemia, eosinophilia, hemolytic anemia, methemoglobinemia, thrombocytopenia, hemolytic uremic syndrome

Hepatic: Aminotransferase level elevation (asymptomatic), cholestasis, cholestatic jaundice, elevated liver enzymes, jaundice, hepatic necrosis

Neuromuscular & skeletal: Arthralgia, dyskinesia, exacerbation of myasthenia gravis, hemiplegia, myalgia, tendon rupture, tremors, paresthesia, peripheral neuropathy

Ocular: Diplopia, photophobia, keratitis, keratopathy, visual disturbance

Otic: Tinnitus

Renal: Hematuria, interstitial nephritis, proteinuria, renal failure, renal vasculitis, serum creatinine increased

Respiratory: Hyposmia, pulmonary vasculitis, rhinitis (children 3%)

Miscellaneous: Anaphylactoid reaction (rate of 1.2/100,000 prescriptions), elevated antineutrophilic cytoplasmic antibodies (ANCA) fixed drug eruption, serum sickness, toxic shock syndrome

Signs and Symptoms of Overdose Acute renal failure; seizures

Admission Criteria/Prognosis Admit any patient with CNS or renal abnormalities, or any adult ingestion >8 g

Pharmacodynamics/Kinetics

Absorption: Oral: Immediate release tablet: Rapid (~50% to 85%)

Distribution: V_d: 2.1-2.7 L/kg; tissue concentrations often exceed serum concentrations especially in kidneys, gallbladder, liver, lungs, gynecological tissue, and prostatic tissue; CSF concentrations: 10% of serum

concentrations (noninflamed meninges), 14% to 37% (inflamed meninges); crosses placenta; enters breast milk

Protein binding: 20% to 40%

Metabolism: Partially hepatic; forms 4 metabolites (limited activity)

Half-life elimination: Children: 2.5 hours; Adults: Normal renal function: 3-5 hours

Time to peak: Oral:

Immediate release tablet: 0.5-2 hours

Extended release tablet: Cipro[®] XR: 1-2.5 hours, Proquin[®] XR: 3.5-8.7 hours

Excretion: Urine (30% to 50% as unchanged drug); feces (15% to 43%)

Dosage Note: Extended release tablets and immediate release formulations are not interchangeable:

Children (see Warnings):

Oral: Immediate release formulation: 20-30 mg/kg/day in 2 divided doses; maximum: 1.5 g/day

Cystic fibrosis (unlabeled use): Children 5-17 years: 40 mg/kg/day divided every 12 hours administered following 1 week of I.V. therapy has been reported in a clinical trial; total duration of therapy: 10-21 days

Anthrax:

Inhalational (postexposure prophylaxis): 15 mg/kg/dose every 12 hours for 60 days; maximum: 500 mg/dose

Cutaneous (treatment, CDC guidelines): 10-15 mg/kg every 12 hours for 60 days (maximum: 1 g/day); amoxicillin 80 mg/kg/day divided every 8 hours is an option for completion of treatment after clinical improvement. **Note:** In the presence of systemic involvement, extensive edema, lesions on head/neck, refer to I.V. dosing for treatment of inhalational/gastrointestinal/oropharyngeal anthrax

I.V.:

Complicated urinary tract infection or pyelonephritis: Children 1-17 years: 6-10 mg/kg every 8 hours for 10-21 days (maximum: 400 mg/dose)

Cystic fibrosis (unlabeled use): Children 5-17 years: 30 mg/kg/day divided every 8 hours for 10-21 days (maximum: 400 mg/dose)

Anthrax:

Inhalational (postexposure prophylaxis): 10 mg/kg/dose every 12 hours for 60 days; do **not** exceed 400 mg/dose (800 mg/day)

Inhalational/gastrointestinal/oropharyngeal (treatment, CDC guidelines): Initial: 10-15 mg/kg every 12 hours for 60 days (maximum: 500 mg/dose); switch to oral therapy when clinically appropriate; refer to Adults dosing for notes on combined therapy and duration

Adults: Oral:

Urinary tract infection:

Acute uncomplicated: Immediate release formulation: 250 mg every 12 hours for 3 days

Acute uncomplicated pyelonephritis: Extended release formulation (Cipro[®] XR): 1000 mg every 24 hours for 7-14 days

Uncomplicated/acute cystitis: Extended release formulation (Cipro[®] XR, Proquin[®] XR): 500 mg every 24 hours for 3 days

Mild/moderate: Immediate release formulation: 250 mg every 12 hours for 7-14 days

Severe/complicated:

Immediate release formulation: 500 mg every 12 hours for 7-14 days

Extended release formulation (Cipro[®] XR): 1000 mg every 24 hours for 7-14 days

Lower respiratory tract, skin/skin structure infections: 500-750 mg twice daily for 7-14 days depending on severity and susceptibility

Bone/joint infections: 500-750 mg twice daily for 4-6 weeks, depending on severity and susceptibility

Infectious diarrhea: 500 mg every 12 hours for 5-7 days

Intra-abdominal (in combination with metronidazole): 500 mg every 12 hours for 7-14 days

Typhoid fever: 500 mg every 12 hours for 10 days

Urethral/cervical gonococcal infections: 250-500 mg as a single dose (CDC recommends concomitant doxycycline or azithromycin due to developing resistance; avoid use in Asian or Western Pacific travelers)

Disseminated gonococcal infection: 500 mg twice daily to complete 7 days of therapy (initial treatment with ceftriaxone 1 g I.M./I.V. daily for 24-48 hours after improvement begins)

Chancroid: 500 mg twice daily for 3 days

Sinusitis (acute): 500 mg every 12 hours for 10 days

Chronic bacterial prostatitis: 500 mg every 12 hours for 28 days

Anthrax:

Inhalational (postexposure prophylaxis): 500 mg every 12 hours for 60 days

Cutaneous (treatment, CDC guidelines): Immediate release formulation: 500 mg every 12 hours for 60 days. **Note:** In the presence of systemic involvement, extensive edema, lesions on head/neck,

refer to I.V. dosing for treatment of inhalational/gastrointestinal/oropharyngeal anthrax

Adults: I.V.:

Bone/joint infections:

Mild to moderate: 400 mg every 12 hours for 4-6 weeks
Severe or complicated: 400 mg every 8 hours for 4-6 weeks

Lower respiratory tract, skin/skin structure infections:

Mild to moderate: 400 mg every 12 hours for 7-14 days
Severe or complicated: 400 mg every 8 hours for 7-14 days

Nosocomial pneumonia (mild to moderate to severe): 400 mg every 8 hours for 10-14 days

Prostatitis (chronic, bacterial): 400 mg every 12 hours for 28 days

Sinusitis (acute): 400 mg every 12 hours for 10 days

Urinary tract infection:

Mild to moderate: 200 mg every 12 hours for 7-14 days
Severe or complicated: 400 mg every 12 hours for 7-14 days

Febrile neutropenia (with piperacillin): 400 mg every 8 hours for 7-14 days

Intra-abdominal infection (with metronidazole): 400 mg every 12 hours for 7-14 days

Anthrax:

Inhalational (postexposure prophylaxis): 400 mg every 12 hours for 60 days

Inhalational/gastrointestinal/oropharyngeal (treatment): 400 mg every 12 hours. **Note:** Initial treatment should include two or more agents predicted to be effective (per CDC recommendations). Agents suggested for use in conjunction with ciprofloxacin or doxycycline include rifampin, vancomycin, imipenem, penicillin, ampicillin, chloramphenicol, clindamycin, and clarithromycin. May switch to oral antimicrobial therapy when clinically appropriate. Continue combined therapy for 60 days.

Elderly: No adjustment needed in patients with normal renal function

Ophthalmic:

Solution: Children > 1 year and Adults: Instill 1-2 drops in eye(s) every 2 hours while awake for 2 days and 1-2 drops every 4 hours while awake for the next 5 days

Ointment: Children > 2 years and Adults: Apply a 1/2" ribbon into the conjunctival sac 3 times/day for the first 2 days, followed by a 1/2" ribbon applied twice daily for the next 5 days

Dosing adjustment in renal impairment:

Cl_{cr} 30-50 mL/minute: Oral: 250-500 mg every 12 hours

Cl_{cr} < 30 mL/minute: Acute uncomplicated pyelonephritis or complicated UTI: Oral: Extended release formulation: 500 mg every 24 hours

Cl_{cr} 5-29 mL/minute:

Oral: 250-500 mg every 18 hours

I.V.: 200-400 mg every 18-24 hours

Dialysis: Only small amounts of ciprofloxacin are removed by hemo- or peritoneal dialysis (<10%); usual dose: Oral: 250-500 mg every 24 hours following dialysis

Continuous arteriovenous or venovenous hemodiafiltration effects: Administer 200-400 mg I.V. every 12 hours

Stability

Refrigeration and room temperature:

Prepared bags: 14 days

Premixed bags: Manufacturer expiration dating

Out of overwrap stability: 14 days

Monitoring Parameters Patients receiving concurrent ciprofloxacin, theophylline, or cyclosporine should have serum levels monitored

Administration

Oral: May administer with food to minimize GI upset; avoid antacid use; maintain proper hydration and urine output. Administer immediate release ciprofloxacin and Cipro[®] XR at least 2 hours before or 6 hours after, and Proquin[®] XR at least 4 hours before or 6 hours after antacids or other products containing calcium, iron, or zinc (including dairy products or calcium-fortified juices). Separate oral administration from drugs which may impair absorption (see Drug Interactions).

Oral suspension: Should not be administered through feeding tubes (suspension is oil-based and adheres to the feeding tube). Patients should avoid chewing on the microcapsules.

Nasogastric/orogastric tube: Crush immediate-release tablet and mix with water. Flush feeding tube before and after administration. Hold tube feedings at least 1 hour before and 2 hours after administration.

Tablet, extended release: Do not crush, split, or chew. May be administered with meals containing dairy products (calcium content < 800 mg), but not with dairy products alone. Proquin[®] XR should be administered with a main meal of the day; evening meal is preferred.

Parenteral: Administer by slow I.V. infusion over 60 minutes to reduce the risk of venous irritation (burning, pain, erythema, and swelling); final concentration for administration should not exceed 2 mg/mL.

Contraindications Hypersensitivity to ciprofloxacin, any component of the formulation, or other quinolones; concurrent administration of tizanidine

Warnings

CNS stimulation may occur (tremor, restlessness, confusion, and very rarely hallucinations or seizures). Use with caution in patients with known or suspected CNS disorder. Potential for seizures, although very rare, may be increased with concomitant NSAID therapy. Use with caution in individuals at risk of seizures. Prolonged use may result in superinfection. Tendon inflammation and/or rupture have been reported with ciprofloxacin and other quinolone antibiotics. Risk may be increased with concurrent corticosteroids, particularly in the elderly. Discontinue at first sign of tendon inflammation or pain. Adverse effects, including those related to joints and/or surrounding tissues, are increased in pediatric patients and therefore, ciprofloxacin should not be considered as drug of choice in children (exception is anthrax treatment). Rare cases of peripheral neuropathy may occur.

Severe hypersensitivity reactions, including anaphylaxis, have occurred with quinolone therapy. Quinolones may exacerbate myasthenia gravis, use with caution (rare, potentially life-threatening weakness of respiratory muscles may occur). Use caution in renal impairment. Avoid excessive sunlight; may cause moderate-to-severe phototoxicity reactions.

Ciprofloxacin is a potent inhibitor of CYP1A2. Coadministration of drugs which depend on this pathway may lead to substantial increases in serum concentrations and adverse effects.

Dosage Forms

[DSC] = Discontinued product

Infusion [premixed in D₅W] (Cipro[®]): 200 mg (100 mL); 400 mg (200 mL) [latex free]

Injection, solution (Cipro[®]): 10 mg/mL (20 mL, 40 mL, 120 mL [DSC])

Microcapsules for oral suspension (Cipro[®]): 250 mg/5 mL (100 mL); 500 mg/5 mL (100 mL) [strawberry flavor]

Ointment, ophthalmic, as hydrochloride (Ciloxan[®]): 3.33 mg/g [0.3% base] (3.5 g)

Solution, ophthalmic, as hydrochloride (Ciloxan[®]): 3.5 mg/mL [0.3% base] (2.5 mL, 5 mL, 10 mL) [contains benzalkonium chloride]

Tablet: 250 mg, 500 mg, 750 mg

Cipro[®]: 100 mg, 250 mg, 500 mg, 750 mg

Tablet, extended release:

Cipro[®] XR: 500 mg [equivalent to ciprofloxacin hydrochloride 287.5 mg and ciprofloxacin base 212.6 mg]; 1000 mg [equivalent to ciprofloxacin hydrochloride 574.9 mg and ciprofloxacin base 425.2 mg]

Proquin[®] XR: 500 mg

Tablet, extended release [dose pack]:

Proquin[®] XR: 500 mg (3s)

Reference Range

Peak plasma concentrations after a 750 mg oral dose: 3.0 mcg/mL (9 µmol/g)

Therapeutic: 2.6-3.0 mcg/mL

Toxic: > 5.0 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Treatment should include adequate hydration and renal function monitoring. Magnesium or calcium-containing antacids may be given to decrease absorption of oral ciprofloxacin. Do **not** use flumazenil. Diazepam, phenobarbital, or phenytoin can be used for seizures.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; only small amounts of ciprofloxacin are removed by dialysis (<10%)

Test Interactions High urine concentrations of ciprofloxacin can invalidate EMIT urine drug screening procedures

Drug Interactions

Inhibits CYP1A2 (strong), 3A4 (weak)

Caffeine: Ciprofloxacin may decrease the metabolism of caffeine.

Corticosteroids: Concurrent use may increase the risk of tendon rupture, particularly in elderly patients (overall incidence rare).

CYP1A2 substrates: Ciprofloxacin may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, flvoxamine, mexiletine, mirtazapine, ropinirole, tizanidine, and trifluoperazine.

Foscarnet: Concomitant use with ciprofloxacin has been associated with an increased risk of seizures.

Glyburide: Quinolones may increase the effect of glyburide; monitor.

Metal cations (aluminum, calcium, iron, magnesium, and zinc) bind quinolones in the gastrointestinal tract and inhibit absorption. Concurrent administration of most antacids, oral electrolyte supplements, quinapril, sucralfate, some didanosine formulations (chewable/buffered tablets and pediatric powder for oral suspension), and other highly-buffered oral drugs, should be avoided. Ciprofloxacin should be administered 2 hours before or 6 hours after these agents.

Methotrexate: Ciprofloxacin may decrease renal secretion of methotrexate; monitor.

Pentoxifylline: Monitor for headache during concomitant therapy.

Phenytoin: Ciprofloxacin may decrease phenytoin levels; monitor.

Probenecid: May decrease renal secretion of quinolones.

Ropivacaine: Ciprofloxacin may decrease the metabolism of ropivacaine.

Sevelamer: May decrease absorption of oral ciprofloxacin.

Theophylline: Serum levels may be increased by ciprofloxacin; in addition, CNS stimulation/seizures may occur at lower theophylline serum levels due to additive CNS effects.

Tizanidine: Ciprofloxacin may increase serum levels of tizanidine. Concurrent administration is contraindicated.

Warfarin: The hypoprothrombinemic effect of warfarin may be enhanced by ciprofloxacin; monitor INR.

Pregnancy Risk Factor C

Pregnancy Implications Reports of arthropathy (observed in immature animals and reported rarely in humans) has limited the use of fluoroquinolones in pregnancy. According to the FDA, the Teratogen Information System concluded that therapeutic doses during pregnancy are unlikely to produce substantial teratogenic risk, but data are insufficient to say that there is no risk. In general, reports of exposure have been limited to short durations of therapy in the first trimester. When considering treatment for life-threatening infection and/or prolonged duration of therapy (such as in anthrax), the potential risk to the fetus must be balanced against the severity of the potential illness.

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Nursing Implications Hold antacids for 3-4 hours after giving

Additional Information

Tablets can be crushed and mixed with apple or fruit juice for pediatric administration.

A 12 g ingestion resulted in mild symptoms in an adult, but a 14 g ingestion resulted in acute renal failure

Not effective in eliminating typhoid carrier state; has been used unsuccessfully to treat infectious diarrhea due to *Pseudomonas aeruginosa* (500 mg twice daily for 10 days)

Food decreases the rate, but not the extent, of absorption. Ciprofloxacin serum levels may be decreased if taken with dairy products or calcium-fortified juices. Ciprofloxacin may increase serum caffeine levels if taken with caffeine. Avoid dong quai, St John's wort (may also cause photosensitization). Peak plasma ciprofloxacin levels are decreased when given concurrently with *Garcinia kola* seed extract.

Admission Criteria/Prognosis Admit any ingestion >1 mg/kg or any symptomatic patient

Pharmacodynamics/Kinetics

Onset of action: 0.5-1 hour

Protein binding: 97.5% to 98%

Metabolism: Extensively hepatic to norcisapride

Bioavailability: 35% to 40%

Half-life elimination: 6-12 hours

Excretion: Urine and feces (<10%)

Dosage

Oral:

Children: Not recommended

Adults: Initial: 10 mg 4 times/day at least 15 minutes before meals and at bedtime; in some patients the dosage will need to be increased to 20 mg to obtain a satisfactory result; reduce dosage in half in patients with liver failure

Chronic idiopathic constipation: 5 mg 3 times/day to 20 mg twice daily for 8-12 weeks

Liquid suspension: 10 mL 4 times/day at least 15 minutes before meals and at bedtime; can increase dose to 20 mL as needed

Contraindications

Hypersensitivity to cisapride or any component of the formulations; GI hemorrhage, mechanical obstruction, GI perforation, or other situations when GI motility stimulation is dangerous

Serious cardiac arrhythmias including ventricular tachycardia, ventricular fibrillation, torsade de pointes, and QT prolongation have been reported in patients taking cisapride with other drugs that inhibit CYP3A4. Some of these events have been fatal. Concomitant oral or intravenous administration of the following drugs with cisapride may lead to elevated cisapride blood levels and is contraindicated:

Antibiotics: Oral or I.V. erythromycin, clarithromycin, troleandomycin

Antidepressants: Nefazodone

Antifungals: Oral or I.V. fluconazole, itraconazole, miconazole, oral ketoconazole

Protease inhibitors: Indinavir, ritonavir, amprenavir, atazanavir

Cisapride is also contraindicated for patients with a prolonged electrocardiographic QT intervals (QT_c >450 msec), a history of QT_c prolongation, or known family history of congenital long QT syndrome; clinically significant bradycardia, renal failure, history of ventricular arrhythmias, ischemic heart disease, and congestive heart failure; uncorrected electrolyte disorders (hypokalemia, hypomagnesemia); respiratory failure; and concomitant medications known to prolong the QT interval and increase the risk of arrhythmia, such as certain antiarrhythmics, certain antipsychotics, certain antidepressants, bepridil, sparfloxacin, and terodiline. The preceding lists of drugs are not comprehensive. Cisapride should not be used in patients with uncorrected hypokalemia or hypomagnesemia or who might experience rapid reduction of plasma potassium such as those administered potassium-wasting diuretics and/or insulin in acute settings.

Warnings

On March 24, 2000, the FDA announced that the manufacturer of cisapride would voluntarily withdraw its product from the U.S. market on July 14, 2000. This decision was based on 341 reports of heart rhythm abnormalities including 80 reports of deaths. The company will continue to make the drug available to patients who meet specific clinical eligibility criteria for a limited-access protocol (contact 1-800-JANSSEN).

[U.S. Boxed Warning]: Serious cardiac arrhythmias including ventricular tachycardia, ventricular fibrillation, torsade de pointes, and QT prolongation have been reported in patients taking this drug. Many of these patients also took drugs expected to increase cisapride blood levels by inhibiting the cytochrome P450 3A4 enzymes that metabolize cisapride. These drugs include clarithromycin, erythromycin, troleandomycin, nefazodone, fluconazole, itraconazole, ketoconazole, indinavir and ritonavir. Some of these events have been fatal. Cisapride is contraindicated in patients taking any of these drugs. **QT prolongation, torsade de pointes (sometimes with syncope), cardiac arrest and sudden death have been reported in patients taking cisapride without the above-mentioned contraindicated drugs.** Most patients had disorders that may have predisposed them to arrhythmias with cisapride. Cisapride is contraindicated for those patients with: history of prolonged electrocardiographic QT intervals; renal failure; history of ventricular arrhythmias, ischemic heart disease, and CHF; uncorrected electrolyte disorders (hypokalemia, hypomagnesemia); respiratory failure; and concomitant medications known to prolong the QT interval and increase the risk of arrhythmia, such as certain antiarrhythmics, including those of Class 1A (such as quinidine and procainamide) and Class III (such as sotalol); tricyclic antidepressants (such as amitriptyline); certain tetracyclic antidepressants (such as maprotiline); certain antipsychotic medications (such as certain phenothiazines and sertindole), protease inhibitors, bepridil, sparfloxacin and terodiline. (The preceding lists of drugs are not comprehensive.) Recommended doses of cisapride should not be exceeded.

Patients should have a baseline ECG and an electrolyte panel (magnesium, calcium, potassium) prior to initiating cisapride (see Contra-

Cisapride

CAS Number 81098-60-4

U.S. Brand Names Propulsid®

Use

Investigational Limited Access Program:

Three treatment protocols:

- Adults: Gastroesophageal reflux disease (GERD), gastroparesis, pseudo-obstruction, and severe chronic constipation
- Pediatrics: Refractory GERD (associated with failure to thrive, asthma, bradycardia, apnea, or other serous conditions) or pseudo-obstruction
- Neonates: Feeding intolerance

For enrolling patients in the limited access program, physicians should call Janssen Pharmaceuticals at (800) 795-4247.

Cisapride should be handled as an investigational drug, with completion of FDA form 1572 and informed consent.

Mechanism of Action Enhances the release of acetylcholine at the myenteric plexus. *In vitro* studies have shown cisapride to have serotonin-4 receptor agonistic properties (similar to metoclopramide) without dopamine-blocking activity.

Adverse Reactions

Cardiovascular: Prolonged QT interval, chest pain, shock, angina

Central nervous system: Headache, insomnia, anxiety, nervousness, fever, dystonic reaction, extrapyramidal effects, motor akathisia, pain

Dermatological: Rash, pruritus, urticaria, exanthem

Gastrointestinal: Diarrhea, abdominal pain, nausea, constipation, flatulence, dyspepsia, vomiting, xerostomia

Ocular: Lacrimation

Respiratory: Rhinitis, sinusitis, coughing, upper respiratory tract infection

Miscellaneous: Increased incidence of viral infection

Signs and Symptoms of Overdose Abdominal cramping, diarrhea, insomnia, seizures

indications). Potential benefits should be weighed against risks prior administration of cisapride to patients who have or may develop prolongation of cardiac conduction intervals, particularly QT_c. These include patients with conditions that could predispose them to the development of serious arrhythmias, such as multiple organ failure, COPD, apnea and advanced cancer. Cisapride should not be used in patients with uncorrected hypokalemia or hypomagnesemia, such as those with severe dehydration, vomiting or malnutrition, or those taking potassium-wasting diuretics. Cisapride should not be used in patients who might experience rapid reduction of plasma potassium, such as those administered potassium-wasting diuretics and/or insulin in acute settings. Safety and effectiveness in children have not been established.

Reference Range Single oral dose of 10 mg results in plasma level of 41-65 mg/L; therapeutic range (serum): 32-75 mcg/mL; 900 mg ingestion associated with a serum cisapride level of 143 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Sinus tachydysrhythmias should be treated with esmolol (titrate to desired effect). Torsade de pointes can be treated with magnesium sulfate (Children: 25-50 mg/kg; Adults: 2 g), isoproterenol, or atrial overdrive pacing (at 130-150 beats/minute). Avoid class Ia and class III antiarrhythmic agents.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; hemodialysis is not useful

Drug Interactions

Substrate of CYP1A2 (minor), 2A6 (minor), 2B6 (minor), 2C9 (minor), 2C19 (minor), 3A4 (major); **Inhibits** CYP2D6 (weak), 3A4 (weak)

Azole antifungals (fluconazole, itraconazole, ketoconazole, miconazole) increase cisapride's concentration. Pre-existing cardiovascular disease or electrolyte imbalances increase the risk of malignant arrhythmias; concurrent use is contraindicated.

Bepridil increases the risk of malignant arrhythmias; concurrent use is contraindicated

Cimetidine increases the bioavailability of cisapride; use an alternative H₂ antagonist

Class Ia (quinidine, procainamide) and Class III (amiodarone, sotalol) antiarrhythmics increase the risk of malignant arrhythmias; concurrent use is contraindicated

CYP3A4 inhibitors: May increase the levels/effects of cisapride. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil. Concurrent use of azole antifungals, clarithromycin, erythromycin, nefazodone, and protease inhibitors is contraindicated.

Grapefruit juice may increase the bioavailability of cisapride; concomitant use should be avoided.

Macrolides (clarithromycin, erythromycin, troleandomycin) increase serum concentrations of cisapride. Risk of arrhythmias; concurrent use is contraindicated.

Nefazodone and maprotiline may increase the risk of malignant arrhythmias; concurrent use is contraindicated

Phenothiazines (prochlorperazine, promethazine) may increase the risk of malignant arrhythmias; concurrent use is contraindicated

Pimozide may prolong the QT interval; concurrent use is contraindicated. Protease inhibitors (amprenavir, atazanavir, indinavir, nelfinavir, ritonavir) increase cisapride's concentration. Increased risk of malignant arrhythmias; concurrent use is contraindicated.

Quinolone antibiotics: Sparfloxacin, gatifloxacin, moxifloxacin increase the risk of malignant arrhythmias; concurrent use is contraindicated

Sertindole may increase the risk of malignant arrhythmias; concurrent use is contraindicated

TCAs increase the risk of malignant arrhythmias; concurrent use is contraindicated

Warfarin: Isolated cases of increased INR; monitor closely

Pregnancy Risk Factor C

Pregnancy Implications Not associated with a major increase in risk of malformations or spontaneous abortions

Lactation Enters breast milk/use caution (AAP rates "compatible")

Additional Information In U.S., available via limited-access protocol only. Rate of torsade de pointes associated with cisapride: 1:120,000 patients

Cisplatin

Related Information

- Carboplatin

CAS Number 15663-27-1

U.S. Brand Names Platinol®-AQ

Synonyms CDDP

Use Treatment of bladder, testicular, and ovarian cancer

Unlabeled/Investigational Use Treatment of head and neck, breast, gastric, lung, esophageal, cervical, prostate and small cell lung cancer; Hodgkin's and non-Hodgkin's lymphoma; neuroblastoma; sarcomas, myeloma, melanoma, mesothelioma, and osteosarcoma

Mechanism of Action Inhibits DNA synthesis by the formation of DNA cross-links; denatures the double helix; covalently binds to DNA bases and disrupts DNA function; may also bind to proteins; the *cis*-isomer is 14 times more cytotoxic than the *trans*-isomer; both forms cross-link DNA but *cis*-platinum is less easily recognized by cell enzymes and, therefore, not repaired. Cisplatin can also bind two adjacent guanines on the same strand of DNA producing intrastrand cross-linking and breakage.

Adverse Reactions

Cardiovascular: Bradycardia, arrhythmias, tachycardia, sinus bradycardia, myocardial depression, sinus tachycardia

Central nervous system: **Neurotoxicity**, convulsions, fever, headache, visual hallucinations, Frey's syndrome, leukoencephalopathy

Dermatologic: Alopecia (mild), urticaria, scleroderma, acral erythema

Endocrine & metabolic: Hypomagnesemia, hypocalcemia, hyponatremia, hypokalemia, hypophosphatemia, **hyperuricemia**

Gastrointestinal: **Nausea, vomiting**, diarrhea, loss of taste perception, mouth sores

Hematologic: **Myelosuppression**, leukopenia, thrombocytopenia, **anemia**, neutropenia, hemolytic/uremic syndrome

Hepatic: Elevated liver enzymes (dose related)

Local: Phlebitis, extravasation injury

Neuromuscular & skeletal: Paresthesia, **neuropathy (peripheral)**, paralysis

Ocular: Papilledema, optic neuropathy, blurred vision, altered color vision, cortical blindness, visual field defects or loss

Otic: **Ototoxicity**, tinnitus (especially pronounced in children and the elderly)

Renal: **Nephrotoxicity** (dose-related proximal tubular defect usually seen in first month of treatment); **acute renal failure, azotemia, chronic renal dysfunction**; Fanconi syndrome

Miscellaneous: **Anaphylactoid reactions**, thirst

Signs and Symptoms of Overdose Bone marrow depression, congestive heart failure, cortical blindness, deafness, dermatitis, encephalopathy, Fanconi syndrome, hyperpigmented hair, hypertension, hyperthermia, hyperuricemia, hypocalcemia, hypokalemia, hypomagnesemia, hyponatremia, hypophosphatemia, hypopigmented hair, leukopenia or neutropenia (agranulocytosis, granulocytopenia), migraine headache (exacerbation), thirst, tubular necrosis

Pharmacodynamics/Kinetics

Distribution: I.V.: Rapidly into tissue; high concentrations in kidneys, liver, ovaries, uterus, and lungs

Protein binding: >90%

Metabolism: Nonenzymatic; inactivated (in both cell and bloodstream) by sulfhydryl groups; covalently binds to glutathione and thiosulfate

Half-life elimination: Initial: 20-30 minutes; Beta: 60 minutes; Terminal: ~24 hours; Secondary half-life: 44-73 hours

Excretion: Urine (>90%); feces (10%)

Dosage

Refer to individual protocols. **VERIFY ANY CISPLATIN DOSE EXCEEDING 100 mg/m² PER COURSE.**

Children (unlabeled uses):

Intermittent dosing schedule: 37-75 mg/m² once every 2-3 weeks or 50-100 mg/m² over 4-6 hours, once every 21-28 days

Daily dosing schedule: 15-20 mg/m²/day for 5 days every 3-4 weeks

Osteogenic sarcoma or neuroblastoma: 60-100 mg/m² on day 1 every 3-4 weeks

Recurrent brain tumors: 60 mg/m² once daily for 2 consecutive days every 3-4 weeks

Bone marrow/blood cell transfusion: Continuous Infusion: High dose: 55 mg/m²/day for 72 hours; total dose = 165 mg/m²

Adults:

Advanced bladder cancer: 50-70 mg/m² every 3-4 weeks

Head and neck cancer (unlabeled use): 100-120 mg/m² every 3-4 weeks

Malignant pleural mesothelioma in combination with pemetrexed (unlabeled use): 75 mg/m² on day 1 of each 21-day cycle; see Pemetrexed monograph for additional details

Metastatic ovarian cancer: 75-100 mg/m² every 3-4 weeks

Intraperitoneal: Cisplatin has been administered intraperitoneal with systemic sodium thiosulfate for ovarian cancer; doses up to 90-270 mg/m² have been administered and retained for 4 hours before draining

Testicular cancer: 10-20 mg/m²/day for 5 days repeated every 3-4 weeks

Dosing adjustment in renal impairment: The manufacturer(s) recommend that repeat courses of cisplatin should not be given until serum creatinine is < 1.5 mg/100 mL and/or BUN is < 25 mg/100 mL. There is no FDA-approved renal dosing adjustment guideline; the following guidelines have been used by some clinicians:

Kintzel, 1995:

Cl_{cr} 46-60 mL/minute: Reduce dose by 25%

Cl_{cr} 31-45 mL/minute: Reduce dose by 50%

Cl_{cr} < 30 mL/minute: Consider use of alternative drug

Aronoff, 1999:

Cl_{cr} 10-50 mL/minute: Administer 75% of dose

$Cl_{cr} < 10$ mL/minute: Administer 50% of dose
 Hemodialysis: Partially cleared by hemodialysis; administer dose post-hemodialysis
 CAPD effects: Unknown
 CAVH effects: Unknown

Stability Incompatible with sodium bicarbonate; do not infuse in solutions containing $< 0.2\%$ sodium chloride; do not refrigerate reconstituted solutions since precipitation may occur; protect from light; aluminum needles should not be used to administer the drug due to binding with the platinum

Monitoring Parameters Renal function (serum creatinine, BUN, Cl_{cr}); electrolytes (particularly magnesium, calcium, potassium) before and within 48 hours after cisplatin therapy; hearing test, neurologic exam (with high dose); liver function tests periodically, CBC with differential and platelet count; urine output, urinalysis

Administration Needles, syringes, catheters, or I.V. administration sets that contain aluminum parts should not be used for administration of drug. Pretreatment hydration with 1-2 L of fluid is recommended prior to cisplatin administration; adequate hydration and urinary output (> 100 mL/hour) should be maintained for 24 hours after administration.

I.V.: Rate of administration has varied from a 15- to 120-minute infusion, 1 mg/minute infusion, 6- to 8-hour infusion, 24-hour infusion, or per protocol; maximum rate of infusion of 1 mg/minute in patients with CHF

Extravasation management: Large extravasations (> 20 mL) of concentrated solutions (> 0.5 mg/mL) produce tissue necrosis. **Treatment is not recommended unless a large amount of highly concentrated solution is extravasated.** Mix 4 mL of 10% sodium thiosulfate with 6 mL sterile water for injection: Inject 1-4 mL through existing I.V. line cannula. Administer 1 mL for each mL extravasated; inject SubQ if needle is removed.

Recommendations for minimizing nephrotoxicity include:

- Prepare cisplatin in saline-containing vehicles
- Infuse dose over 24 hours
- Vigorous hydration (125-150 mL/hour) before, during, and after cisplatin administration
- Simultaneous administration of either mannitol or furosemide
- Pretreatment with amifostine
- Avoid other nephrotoxic agents (aminoglycosides, amphotericin, etc)

Contraindications Hypersensitivity to cisplatin, other platinum-containing compounds, or any component of the formulation (anaphylactic-like reactions have been reported); pre-existing renal insufficiency; myelosuppression; hearing impairment; pregnancy

Warnings Hazardous agent - use appropriate precautions for handling and disposal. **[U.S. Boxed Warning]: Doses > 100 mg/m² once every 3-4 weeks are rarely used and should be verified with the prescriber.** All patients should receive adequate hydration, with or without diuretics, prior to and for 24 hours after cisplatin administration. Reduce dosage in renal impairment. **[U.S. Boxed Warning]: Cumulative renal toxicity may be severe.** Elderly patients may be more susceptible to nephrotoxicity; select dose cautiously and monitor closely. **[U.S. Boxed Warnings]: Dose-related toxicities include myelosuppression, nausea, and vomiting. Ototoxicity, especially pronounced in children, is manifested by tinnitus or loss of high frequency hearing and occasionally, deafness.** Serum magnesium, as well as other electrolytes, should be monitored both before and within 48 hours after cisplatin therapy. When administered as sequential infusions, taxane derivatives (docetaxel, paclitaxel) should be administered before platinum derivatives (carboplatin, cisplatin). **[U.S. Boxed Warnings]: Anaphylactic-like reactions have been reported; may be managed with epinephrine, corticosteroids, and/or antihistamines. Should be administered under the supervision of an experienced cancer chemotherapy physician.**

Dosage Forms [DSC] = Discontinued product
 Injection, solution: 1 mg/mL (50 mL, 100 mL, 200 mL)
 Platinol®-AQ: 1 mg/mL (50 mL, 100 mL) [contains sodium 9 mg/mL] [DSC]

Reference Range

Plasma levels for cytotoxicity: 50 mg/L at 1 hour or 5 mg/L at 8 hours
 Heart and peripheral blood concentrations of platinum overdosage of 750 mg were 1515 and 1253 μ g/L, respectively. Concentrations in urine and bile were 1038 and 501 μ g/L, respectively.

Overdosage/Treatment

Supportive therapy: Erythropoietin can be given to prevent anemia; ondansetron, droperidol, metoclopramide, or corticosteroids can be given for emesis; sodium thiosulfate (7.5 g/m² I.V. followed by 2.13 g/m²/hour over 12 hours) or mannitol (12.5 g) and/or furosemide can decrease nephrotoxicity. Tachycardia can be treated with I.V. verapamil; allopurinol (600-800 mg/day in divided doses) may be useful in managing hyperuricemia. Amifostine (910 mg/m²) pretreatment may be protective of drug-induced neutropenia, renal toxicity, or ototoxicity.

Enhancement of elimination: Hemodialysis is not effective

Antidote(s)

- Amifostine [ANTIDOTE]
- Mannitol [ANTIDOTE]
- Sodium Thiosulfate [ANTIDOTE]

Diagnostic Procedures

- Electrolytes, Blood

Drug Interactions

Amifostine: Theoretically inactivates drug systemically; has been used clinically to reduce nephrotoxicity and neutropenia associated with administration of cisplatin.

Bleomycin: Delayed bleomycin elimination with decreased glomerular filtration rate.

Ethacrynic acid: Has resulted in severe ototoxicity in animals.

Sodium thiosulfate: Theoretically inactivates drug systemically; has been used clinically to reduce systemic toxicity with intraperitoneal administration of cisplatin.

Taxane derivatives (docetaxel, paclitaxel): When administered as sequential infusions, taxane derivatives should be administered before platinum derivatives to limit myelosuppression and to enhance efficacy.

Pregnancy Risk Factor D

Pregnancy Implications May be toxic to fetal urogenital tract

Lactation Enters breast milk/contraindicated

Nursing Implications Needles, syringes, catheters, or I.V. administration sets that contain aluminum parts should not be used for administration of drug; perform pretreatment hydration with 1-2 liters of fluid infused for 8-12 hours prior to dose; monitor for possible anaphylactoid reaction

Additional Information

Sodium content: 9 mg/mL (equivalent to 0.9% sodium chloride solution)

Osmolality of Platinol®-AQ = 285-286 mOsm

Citalopram

Related Information

- Antidepressant Agents

CAS Number 59729-32-7; 59729-33-8

U.S. Brand Names Celexa™

Synonyms Citalopram Hydrobromide; Nitalapram

Use Treatment of depression

Unlabeled/Investigational Use Treatment of dementia, smoking cessation, ethanol abuse, obsessive-compulsive disorder (OCD) in children, diabetic neuropathy

Mechanism of Action A bicyclic phthalane derivative, citalopram selectively inhibits serotonin reuptake in the presynaptic neurons

Adverse Reactions

Cardiovascular: Chest pain, QT prolonged, thrombosis, ventricular arrhythmia, torsade de pointes

Central nervous system: **Somnolence, insomnia**, anxiety, anorexia, agitation, yawning, akathisia, delirium, neuroleptic malignant syndrome, grand mal seizures

Dermatologic: Rash, pruritus, angioedema, bruising, epidermal necrolysis, erythema multiforme

Endocrine & metabolic: Sexual dysfunction, serotonin syndrome, SIADH, prolactinemia, spontaneous abortion

Gastrointestinal: **Nausea, xerostomia**, diarrhea, dyspepsia, vomiting, abdominal pain, weight gain, hemorrhage, pancreatitis

Genitourinary: Priapism

Hematologic: Hemolytic anemia, thrombocytopenia, prothrombin decreased

Neuromuscular & skeletal: Tremor, arthralgia, myalgia, choreoathetosis, dyskinesia, myoclonus, rhabdomyolysis

Ocular: Nystagmus

Renal: Acute renal failure

Respiratory: Cough, rhinitis, sinusitis

Miscellaneous: **Diaphoresis**, withdrawal syndrome, allergic reaction, anaphylaxis

Signs and Symptoms of Overdose Widened QRS complex at ingestions > 600 mg. Coma, CNS depression, prolonged QT interval, rhabdomyolysis, seizures (within a few hours of ingestion), tachycardia

Admission Criteria/Prognosis Admit any ingestion > 600 mg to a cardiac-monitored bed

Pharmacodynamics/Kinetics

Distribution: V_d : 12 L/kg

Protein binding, plasma: $\sim 80\%$

Metabolism: Extensively hepatic, including CYP, to N-demethylated, N-oxide, and deaminated metabolites

Bioavailability: 80%

Half-life elimination: 24-48 hours; average 35 hours (doubled with hepatic impairment)

Time to peak, serum: 1-6 hours, average within 4 hours

Excretion: Urine (10% as unchanged drug)

Note: Clearance was decreased, while AUC and half-life were significantly increased in elderly patients and in patients with hepatic impairment. Mild-to-moderate renal impairment may reduce clearance (17%) and prolong half-life of citalopram. No pharmacokinetic information is available concerning patients with severe renal impairment.

Dosage

Oral:

Children and Adolescents: OCD (unlabeled use): 10-40 mg/day

Adults: Depression: Initial: 20 mg/day, generally with an increase to 40 mg/day; doses of more than 40 mg are not usually necessary. Should a dose increase be necessary, it should occur in 20 mg increments at intervals of no less than 1 week. Maximum dose: 60 mg/day; reduce dosage in elderly or those with hepatic impairment.

Monitoring Parameters Monitor patient periodically for symptom resolution; mental status for depression, suicidal ideation (especially at the beginning of therapy or when doses are increased or decreased), anxiety, social functioning, mania, panic attacks; akathisia

Contraindications Hypersensitivity to citalopram or any component of the formulation; hypersensitivity or other adverse sequelae during therapy with other SSRIs; concomitant use with MAO inhibitors or within 2 weeks of discontinuing MAO inhibitors

Warnings *Major psychiatric warnings:*

- **[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders;** consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. A medication guide concerning the use of antidepressants in children and teenagers should be dispensed with each prescription. **Citalopram is not FDA approved for use in children.**

- The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Patients treated with antidepressants should be observed for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy.

- Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression or psychosis occur.

- May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Citalopram is not FDA approved for the treatment of bipolar depression.**

Key adverse effects:

- Anticholinergic effects: Relatively devoid of these side effects.
- CNS depression: Has a low potential to impair cognitive or motor performance; caution operating hazardous machinery or driving.
- SIADH and hyponatremia: Has been associated with the development of SIADH; hyponatremia has been reported rarely, predominately in the elderly.

Concurrent disease:

- Hepatic impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.
- Platelet aggregation: May impair platelet aggregation, resulting in bleeding.
- Renal impairment: Use caution; clearance is decreased and plasma concentrations are increased; a lower dosage may be needed.
- Sexual dysfunction: May cause or exacerbate sexual dysfunction.

Concurrent drug therapy:

- Anticoagulants/Antiplatelets: Use caution with concomitant use of NSAIDs, ASA, or other drugs that affect coagulation; the risk of bleeding is potentiated.
- CNS depressants: Use caution with concomitant therapy.
- MAO inhibitors: Potential for severe reaction when used with MAO inhibitors; autonomic instability, coma, death, delirium, diaphoresis, hyperthermia, mental status changes/agitation, muscular rigidity, myoclonus, neuroleptic malignant syndrome features, and seizures may occur.

Special populations:

- Elderly: Use caution in elderly patients.
- Pregnancy: Use caution in pregnant patients; high doses of citalopram have been associated with teratogenicity in animals.

Special notes:

- Electroconvulsive therapy: May increase the risks associated with electroconvulsive therapy; consider discontinuing, when possible, prior to ECT treatment.

- Withdrawal syndrome: May cause dysphoric mood, irritability, agitation, dizziness, sensory disturbances, anxiety, confusion, headache, lethargy, emotional lability, insomnia, hypomania, tinnitus, and seizures. Upon discontinuation of citalopram therapy, gradually taper dose. If intolerable symptoms occur following a decrease in dosage or upon discontinuation of therapy, then resuming the previous dose with a more gradual taper should be considered.

Dosage Forms Solution, oral: 10 mg/5 mL (240 mL) [alcohol free, sugar free; peppermint flavor]

Tablet: 10 mg, 20 mg, 40 mg

Reference Range Following a 50 mg oral dose, peak serum citalopram levels range from 120-160 nmol/L

Overdosage/Treatment

Decontamination: Lavage within 2 hours/activated charcoal

Supportive therapy: Administer I.V. hypertonic sodium chloride (~440 mM in 2 hours) or sodium bicarbonate (1-3 mEq/kg) to normalize QRS duration on ECG; benzodiazepines can be used to treat seizures

Enhanced elimination: Due to possibility of enterohepatic recirculation, multiple dosing of activated charcoal may be effective

Drug Interactions

Substrate of CYP2C19 (major), 2D6 (minor), 3A4 (major); **Inhibits** CYP1A2 (weak), 2B6 (weak), 2C19 (weak), 2D6 (weak)

Aspirin: Concomitant use of citalopram and NSAIDs, aspirin, or other drugs affecting coagulation has been associated with an increased risk of bleeding; monitor.

Beta-blockers: Citalopram may increase levels of some beta-blockers (see Carvedilol and Metoprolol); monitor carefully.

Buspiron: Concurrent use of citalopram with bupirone may cause serotonin syndrome; avoid concurrent use.

Carbamazepine: May enhance the metabolism of citalopram.

Carvedilol: Serum concentrations may be increased; monitor carefully for increased carvedilol effect (hypotension and bradycardia).

Cimetidine: May inhibit the metabolism of citalopram.

CYP2C19 inducers: May decrease the levels/effects of citalopram. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of citalopram. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of citalopram. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of citalopram. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Linezolid: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** with agents which inhibit MAO (serotonin syndrome); this combination should be avoided.

MAO inhibitors: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** with MAO inhibitors (serotonin syndrome); this combination should be avoided.

Meperidine: Combined use theoretically may increase the risk of serotonin syndrome.

Metoprolol: Citalopram may increase plasma levels of metoprolol; monitor for increased effect.

Moclobemide: Concurrent use of citalopram with moclobemide may cause serotonin syndrome; avoid concurrent use.

Nefazodone: Concurrent use of citalopram with nefazodone may cause serotonin syndrome.

NSAIDs: Concomitant use of citalopram and NSAIDs, aspirin, or other drugs affecting coagulation has been associated with an increased risk of bleeding; monitor.

Ritonavir: Combined use of citalopram with ritonavir may cause serotonin syndrome in HIV-positive patients; monitor.

Selegiline: Concurrent use with citalopram has been reported to cause serotonin syndrome; as an MAO type B inhibitor, the risk of serotonin syndrome may be less than with nonselective MAO inhibitors, and reports indicate that this combination has been well tolerated in Parkinson's patients.

Serotonin reuptake inhibitors: Concurrent use with other reuptake inhibitors may increase the risk of serotonin syndrome.

Sibutramine: May increase the risk of serotonin syndrome with SSRIs.

Sumatriptan (and other serotonin agonists): Concurrent use may result in toxicity; weakness, hyper-reflexia, and incoordination have been observed with sumatriptan and SSRIs. In addition, concurrent use may theoretically increase the risk of serotonin syndrome; includes sumatriptan, naratriptan, rizatriptan, and zolmitriptan.

Tramadol: Concurrent use of citalopram with tramadol may cause serotonin syndrome; avoid concurrent use.

Trazodone: Concurrent use of citalopram with trazodone may cause serotonin syndrome.

Venlafaxine: Combined use with citalopram may increase the risk of serotonin syndrome.

Pregnancy Risk Factor C

Pregnancy Implications Should be used in pregnancy only if potential benefit justifies potential risk

Lactation Enters breast milk/contraindicated

Adverse Reactions

Allergic: **Fever (70%), chills (18%); skin reactions (erythema, itching) at the catheter site (18%)**

Cardiovascular: Edema, tachycardia

Central nervous system: **Fatigue (17%), headache**, dizziness, pains, chills, malaise; severe infections, possibly related to thrombocytopenia

Dermatologic: **Rash**, pruritus, erythema

Gastrointestinal: Nausea (mild to moderate) usually not seen at doses <0.3 mg/kg/day, constipation, abdominal pain

Hematologic: **Myelosuppression** (common, dose-limiting), **leukopenia (70%), anemia (37%), thrombocytopenia**

Nadir: 5-10 days

Recovery: 4-8 weeks

Neuromuscular & skeletal: Myalgia, arthralgia, weakness, paraparesis, quadriplegia (reported at high doses)

Renal: Renal failure at high doses (>0.3 mg/kg/day)

Miscellaneous: Diaphoresis, delayed herpes zoster infections, tumor lysis syndrome, increased risk of opportunistic infection

Signs and Symptoms of Overdose Agranulocytosis, bone marrow suppression, granulocytopenia, insomnia, leukopenia, myalgia, neutropenia, quadriparesis, serum creatinine (increased)

Pharmacodynamics/Kinetics

Absorption: Oral: 55%; SubQ: 100%; Rectal: 20%

Distribution: V_d : 4.52 ± 2.82 L/kg

Protein binding: 20%

Metabolism: Hepatic; 5'-triphosphate moiety-active

Half-life elimination: Biphasic: Alpha: 25 minutes; Beta: 6.7 hours;

Terminal, mean: Normal renal function: 5.4 hours

Excretion: Urine (18% to 44%)

Clearance: Estimated systemic: 640 mL/hour/kg

Dosage I.V.: Refer to individual protocols.

Pediatrics: Acute leukemias: 6.2-7.5 mg/m²/day continuous infusion for days 1-5; maximum tolerated dose was 8.9 mg/m²/day.

Adults:

Hairy cell leukemia: Continuous infusion:

0.09-0.1 mg/kg/day days 1-7; may be repeated every 28-35 days or 3.4 mg/m²/day SubQ days 1-7

Chronic lymphocytic leukemia: Continuous infusion:

0.1 mg/kg/day days 1-7 or

0.028-0.14 mg/kg/day as a 2-hour infusion days 1-5

Chronic myelogenous leukemia: 15 mg/m²/day as a 1-hour infusion days 1-5; if no response increase dose to 20 mg/m²/day in the second course.

Stability Store intact vials under refrigeration 2°C to 8°C (36°F to 46°F).

Dilutions in 500 mL NS are stable for 72 hours. Stable in PVC containers for 24 hours at room temperature of 15°C to 30°C (59°F to 86°F) and 7 days in Pharmacia Deltec[®] cassettes. Solutions for 7-day infusion should be prepared in bacteriostatic NS.

Monitoring Parameters Monitor periodic assessment of peripheral blood counts, particularly during the first 4-8 weeks post-treatment, is recommended to detect the development of anemia, neutropenia, and thrombocytopenia and for early detection of any potential sequelae (ie, infection or bleeding)

Administration

I.V.: Administer as a 1- to 2-hour infusion or by continuous infusion

Contraindications Hypersensitivity to cladribine or any component of the formulation

Warnings Hazardous agent - use appropriate precautions for handling and disposal. **[U.S. Boxed Warnings]: Dose-dependent, reversible myelosuppression will occur; use with caution in patients with pre-existing hematologic or immunologic abnormalities. Neurologic toxicity has been reported, usually with higher doses, but may occur at normal doses. Acute renal toxicity has been reported with high doses; use caution when administering with other nephrotoxic agents.** Use caution with renal or hepatic impairment. Fever may occur, with or without neutropenia. Use caution in patients with high tumor burden; tumor lysis syndrome may occur. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.** Safety and efficacy in children have not been established.

Dosage Forms Injection, solution [preservative free]: 1 mg/mL (10 mL)

Reference Range Infusion of 8.9 mg/m²/day for 5 days results in a plasma concentration range of 20-54 nmol/L

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Cladribine extravasation can be treated with subcutaneous administration of chondroitin sulfate or hyaluronidase

Pregnancy Risk Factor D

Pregnancy Implications Teratogenic effects and fetal mortality were observed in animal studies. There are no adequate and well-controlled studies in pregnant women. Women of childbearing potential should avoid becoming pregnant.

Lactation Excretion in breast milk unknown/not recommended

Cladribine

CAS Number 4291-63-8

U.S. Brand Names Leustatin[®]

Synonyms 2-CdA; 2-Chlorodeoxyadenosine; NSC-105014

Use Treatment of hairy cell leukemia, chronic lymphocytic leukemia (CLL), chronic myelogenous leukemia (CML)

Unlabeled/Investigational Use Treatment of chronic lymphocytic leukemia (CLL), chronic myelogenous leukemia (CML), non-Hodgkin's lymphomas, progressive multiple sclerosis

Mechanism of Action A purine nucleoside analogue; prodrug which is activated via phosphorylation by deoxycytidine kinase to a 5'-triphosphate derivative. This active form incorporates into DNA to result in the breakage of DNA strand and shutdown of DNA synthesis. This also results in a depletion of nicotinamide adenine dinucleotide and adenosine triphosphate (ATP). Cladribine is cell-cycle nonspecific.

Clarithromycin

CAS Number 81103-11-9

U.S. Brand Names Biaxin® XL; Biaxin®

Use Treatment against most respiratory pathogens (eg, *S. pyogenes*, *S. pneumoniae*, *S. agalactiae*, *S. viridans*, *M. catarrhalis*, *C. trachomatis*, *Legionella* spp., *Mycoplasma pneumoniae*, *S. aureus*). Clarithromycin is highly active (MICs ≤ 0.25 mcg/mL) against *H. influenzae*, the combination of clarithromycin and its metabolite demonstrate an additive effect. Additionally, clarithromycin has shown activity against *C. pneumoniae* (including strain TWAR) and *M. avium* infection. Approved for pediatric use to treat *Mycobacterium avium* complex or otitis media. Clarithromycin may have some activity against *Cryptosporidium* and *Toxoplasma* encephalitis. Also used for disseminated *Mycobacterium avium* complex in advanced AIDs patients.

Unlabeled/Investigational Use Pertussis

Mechanism of Action Exerts its antibacterial action by binding to 50S ribosomal subunit resulting in inhibition of protein synthesis. The 14-OH metabolite of clarithromycin is twice as active as the parent compound against certain organisms.

Adverse Reactions

Cardiovascular: Tachycardia (ventricular), torsade de pointes, sinus tachycardia, arrhythmias (ventricular), vasculitis, leukocytoclastic vasculitis

Central nervous system: Headache, delirium, visual hallucinations, fever, psychosis

Dermatologic: Urticaria, pruritus, psoriasis, exanthem, cutaneous vasculitis

Gastrointestinal: Diarrhea, nausea, abnormal taste, dyspepsia, abdominal pain, pseudomembranous colitis, tooth discoloration, gastrointestinal vasculitis

Hematologic: Decreased white blood count, elevated prothrombin time, eosinophilia, thrombocytopenia, thrombocytopenic purpura

Hepatic: Elevation of AST, alkaline phosphatase, and bilirubin

Renal: Proteinuria, hematuria, elevated BUN/serum creatinine, interstitial nephritis

Respiratory: Respiratory tract infection

Miscellaneous: Loss of smell

Signs and Symptoms of Overdose Diarrhea, deafness with or without tinnitus or vertigo, eosinophilia, hematuria, jaundice, nausea, prostration, purpura, reversible pancreatitis, tachycardia (ventricular), vomiting

Pharmacodynamics/Kinetics

Absorption: Highly stable in presence of gastric acid (unlike erythromycin); food delays but does not affect extent of absorption

Distribution: Widely into most body tissues except CNS

Metabolism: Partially hepatic via CYP3A4; converted to 14-OH clarithromycin (active metabolite)

Bioavailability: 50%

Half-life elimination: Clarithromycin: 3-7 hours; 14-OH-clarithromycin: 5-9 hours

Time to peak: 2-4 hours

Excretion: Primarily urine

Clearance: Approximates normal GFR

Dosage

Oral:

Children ≥ 1 months: Pertussis (CDC guidelines): 15 mg/kg/day divided every 12 hours for 7 days; maximum: 1 g/day

Children ≥ 6 months:

Community-acquired pneumonia, sinusitis, bronchitis, skin infections: 15 mg/kg/day divided every 12 hours for 10 days

Mycobacterial infection (prevention and treatment): 7.5 mg/kg twice daily, up to 500 mg twice daily. **Note:** Safety of clarithromycin for MAC not studied in children < 20 months.

Prophylaxis of bacterial endocarditis: 15 mg/kg 1 hour before procedure (maximum dose: 500 mg)

Adults:

Usual dose: 250-500 mg every 12 hours **or** 1000 mg (two 500 mg extended release tablets) once daily for 7-14 days

Upper respiratory tract: 250-500 mg every 12 hours for 10-14 days

Pharyngitis/tonsillitis: 250 mg every 12 hours for 10 days

Acute maxillary sinusitis: 500 mg every 12 hours **or** 1000 mg (two 500 mg extended release tablets) once daily for 14 days

Lower respiratory tract: 250-500 mg every 12 hours for 7-14 days

Acute exacerbation of chronic bronchitis due to:

M. catarrhalis and *S. pneumoniae*: 250 mg every 12 hours for 7-14 days **or** 1000 mg (two 500 mg extended release tablets) once daily for 7 days

H. influenzae: 250 mg every 12 hours for 7-14 days **or** 1000 mg (two 500 mg extended release tablets) for 7 days

H. parainfluenzae: 500 mg every 12 hours for 7 days **or** 1000 mg (two 500 mg extended release tablets) for 7 days

Pneumonia due to:

C. pneumoniae, *M. pneumoniae*, and *S. pneumoniae*: 250 mg every 12 hours for 7-14 days **or** 1000 mg (two 500 mg extended release tablets) once daily for 7 days

H. influenzae: 250 mg every 12 hours for 7 days **or** 1000 mg (two 500 mg extended release tablets) once daily for 7 days

Mycobacterial infection (prevention and treatment): 500 mg twice daily (use with other antimycobacterial drugs, eg, ethambutol, clofazimine, or rifampin)

Pertussis (CDC guidelines): 500 mg twice daily for 7 days

Prophylaxis of bacterial endocarditis: 500 mg 1 hour prior to procedure

Uncomplicated skin and skin structure: 250 mg every 12 hours for 7-14 days

Helicobacter pylori: Dual or triple combination regimen with bismuth subsalicylate, tetracycline, clarithromycin, and an H_2 -receptor; or combination of omeprazole and clarithromycin; 500 mg every 8-12 hours for 10-14 days

Elderly: Pharmacokinetics are similar to those in younger adults; may have age-related reductions in renal function; monitor and adjust dose if necessary

Dosing adjustment in renal impairment:

$Cl_{cr} < 30$ mL/minute: Half the normal dose or double the dosing interval

In combination with ritonavir:

Cl_{cr} 30-60 mL/minute: Decrease clarithromycin dose by 50%

$Cl_{cr} < 30$ mL/minute: Decrease clarithromycin dose by 75%

Dosing adjustment in hepatic impairment: No dosing adjustment is needed as long as renal function is normal

Administration

Clarithromycin may be given with or without meals. Give every 12 hours rather than twice daily to avoid peak and trough variation.

Biaxin® XL: Should be given with food. Do not crush or chew extended release tablet.

Contraindications Hypersensitivity to clarithromycin, erythromycin, or any macrolide antibiotic; use with ergot derivatives, pimozide, cisapride; combination with ranitidine bismuth citrate should not be used in patients with history of acute porphyria or $Cl_{cr} < 25$ mL/minute

Warnings Dosage adjustment required with severe renal impairment, decreased dosage or prolonged dosing interval may be appropriate; antibiotic-associated colitis has been reported with use of clarithromycin. Macrolides (including clarithromycin) have been associated with rare QT prolongation and ventricular arrhythmias, including torsade de pointes. The extended release formulation consists of drug within a nondeformable matrix; following drug release/absorption, the matrix/shell is expelled in the stool. The use of nondeformable products in patients with known stricture/narrowing of the GI tract has been associated with symptoms of obstruction. Safety and efficacy in children < 6 months of age have not been established.

Dosage Forms

Granules for oral suspension (Biaxin®): 125 mg/5 mL (50 mL, 100 mL); 250 mg/5 mL (50 mL, 100 mL) [fruit punch flavor]

Tablet (Biaxin®): 250 mg, 500 mg

Tablet, extended release (Biaxin® XL): 500 mg

Reference Range Steady-state levels of 250 mg/dose of clarithromycin: ~ 1 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Acute gastrointestinal irritation can be treated with milk or bismuth subsalicylate, lidocaine can be used for ventricular arrhythmias

Drug Interactions

Substrate of CYP3A4 (major); **Inhibits** CYP1A2 (weak), 3A4 (strong) Alfentanil (and possibly other narcotic analgesics): Serum levels may be increased by clarithromycin; monitor for increased effect.

Benzodiazepines (those metabolized by CYP3A4, including alprazolam, midazolam, triazolam): Serum levels may be increased by clarithromycin; somnolence and confusion have been reported.

Bromocriptine: Serum levels may be increased by clarithromycin; monitor for increased effect.

Bupirone: Serum levels may be increased by clarithromycin; monitor.

Calcium channel blockers (felodipine, verapamil, and potentially others metabolized by CYP3A4): Serum levels may be increased by clarithromycin; monitor.

Carbamazepine: Serum levels may be increased by clarithromycin; monitor.

Cilostazol: Serum levels may be increased by clarithromycin; monitor.

Cisapride: Serum levels may be increased by clarithromycin; serious arrhythmias have occurred; concurrent use contraindicated.

Clopidogrel: Therapeutic effect may be decreased by clarithromycin; monitor.

Clozapine: Serum levels may be increased by clarithromycin; monitor.

Colchicine: Serum levels/toxicity may be increased by clarithromycin; monitor. Avoid use, if possible.

Cyclosporine: Serum levels may be increased by clarithromycin; monitor serum levels.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of clarithromycin. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of clarithromycin. Example inhibitors include azole antifungals, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

CYP3A4 substrates: Clarithromycin may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Delavirdine: Serum levels may be increased by clarithromycin; monitor.

Digoxin: Serum levels may be increased by clarithromycin; digoxin toxicity and potentially fatal arrhythmias have been reported; monitor digoxin levels.

Disopyramide: Serum levels may be increased by clarithromycin; in addition, QT_c prolongation and risk of malignant arrhythmia may be increased; avoid combination.

Ergot alkaloids: Concurrent use may lead to acute ergot toxicity (severe peripheral vasospasm and dysesthesia).

Fluconazole: Increases clarithromycin levels and AUC by ~25%

HMG-CoA reductase inhibitors (atorvastatin, lovastatin, and simvastatin): Clarithromycin may increase serum levels of "statins" metabolized by CYP3A4, increasing the risk of myopathy/rhabdomyolysis (does not include fluvastatin and pravastatin). Switch to pravastatin/fluvastatin or suspend treatment during course of clarithromycin therapy.

Methylprednisolone: Serum levels may be increased by clarithromycin; monitor.

Phenytoin: Serum levels may be increased by clarithromycin; other evidence suggested phenytoin levels may be decreased in some patients; monitor.

Pimozide: Serum levels may be increased, leading to malignant arrhythmias; concomitant use is contraindicated.

Protease inhibitors (amprenavir, nelfinavir, and ritonavir): May increase serum levels of clarithromycin.

QT_c-prolonging agents: Concomitant use may increase the risk of malignant arrhythmias.

Quinidine: Serum levels may be increased by clarithromycin; in addition, the risk of QT_c prolongation and malignant arrhythmias may be increased during concurrent use.

Quinolone antibiotics (sparfloxacin, gatifloxacin, or moxifloxacin): Concurrent use may increase the risk of malignant arrhythmias.

Rifabutin: Serum levels may be increased by clarithromycin; monitor.

Sildenafil, tadalafil, vardenafil: Serum levels may be increased by clarithromycin. Do not exceed single sildenafil doses of 25 mg in 48 hours, a single tadalafil dose of 10 mg in 72 hours, or a single vardenafil dose of 2.5 mg in 24 hours.

Tacrolimus: Serum levels may be increased by clarithromycin; monitor serum concentration.

Theophylline: Serum levels may be increased by clarithromycin; monitor.

Thioridazine: Risk of QT_c prolongation and malignant arrhythmias may be increased.

Valproic acid (and derivatives): Serum levels may be increased by clarithromycin; monitor.

Vinblastine (and vincristine): Serum levels may be increased by clarithromycin.

Warfarin: Effects may be potentiated; monitor INR closely and adjust warfarin dose as needed or choose another antibiotic

Zidovudine: Peak levels (but not AUC) of zidovudine may be increased; other studies suggest levels may be decreased.

Zopiclone: Serum levels may be increased by clarithromycin; monitor.

Pregnancy Risk Factor C

Pregnancy Implications There are no adequate and well-controlled studies in pregnant women. Due to adverse fetal effects reported in animal studies, the manufacturer recommends that clarithromycin not be used in a pregnant woman unless there are no alternatives to therapy.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Give every 12 hours rather than twice daily to avoid peak and trough variation

Additional Information In comparative trials, clarithromycin has been shown to be as effective treatment as penicillin for streptococcal pharyngitis, amoxicillin for acute maxillary sinusitis, ampicillin or erythromycin for acute bacterial exacerbations of chronic bronchitis, erythromycin for community acquired pneumonia, and erythromycin or cefadroxil for skin infections. In small studies, clarithromycin has also demonstrated efficacy in the treatment of *M. pneumoniae*, *C. pneumoniae*, and *Legionella pneumophila* respiratory tract infections. Additionally, the data from a short-term trial involving only small numbers of patients suggest that clarithromycin has clear activity against *M. avium* and may benefit patients with AIDS and disseminated *M. avium* infection.

Clemastine

CAS Number 14976-57-9; 15686-51-8

U.S. Brand Names Dayhist® Allergy [OTC]; Tavist® Allergy [OTC]

Synonyms Clemastine Fumarate

Use Perennial and seasonal allergic rhinitis and other allergic symptoms including rash

Mechanism of Action Competes with histamine for H₁-receptor sites on effector cells in the GI tract, blood vessels, and respiratory tract

Adverse Reactions

Frequency not defined.

Cardiovascular: Palpitations, hypotension, tachycardia

Central nervous system: Dyscoordination, sedation, slight to moderate somnolence, sleepiness, confusion, restlessness, nervousness, insomnia, irritability, fatigue, headache, increased dizziness

Dermatologic: Rash, photosensitivity

Gastrointestinal: Diarrhea, nausea, xerostomia, epigastric distress, vomiting, constipation

Genitourinary: Urinary frequency, difficult urination, urinary retention

Hematologic: Hemolytic anemia, thrombocytopenia, agranulocytosis

Ocular: Blurred vision

Otic: Tinnitus

Respiratory: Thickening of bronchial secretions

Miscellaneous: Anaphylaxis

Pharmacodynamics/Kinetics

Onset of action: Peak effect: Therapeutic: 5-7 hours

Duration: 8-16 hours

Absorption: Almost complete

Metabolism: Hepatic

Excretion: Urine

Dosage

Oral:

Infants and Children <6 years: 0.05 mg/kg/day as clemastine base or 0.335-0.67 mg/day clemastine fumarate (0.25-0.5 mg base/day) divided into 2 or 3 doses; maximum daily dosage: 1.34 mg (1 mg base)

Children 6-12 years: 0.67-1.34 mg clemastine fumarate (0.5-1 mg base) twice daily; do not exceed 4.02 mg/day (3 mg/day base)

Children ≥ 12 years and Adults:

1.34 mg clemastine fumarate (1 mg base) twice daily to 2.68 mg (2 mg base) 3 times/day; do not exceed 8.04 mg/day (6 mg base)

OTC labeling: 1.34 mg clemastine fumarate (1 mg base) twice daily; do not exceed 2 mg base/24 hours

Elderly: Lower doses should be considered in patients > 60 years

Monitoring Parameters Look for a reduction of rhinitis, urticaria, eczema, pruritus, or other allergic symptoms

Contraindications Hypersensitivity to clemastine or any component of the formulation; narrow-angle glaucoma

Warnings Safety and efficacy have not been established in children <6 years of age. Use caution with bladder neck obstruction, symptomatic prostate hypertrophy, asthmatic attacks, stenosing peptic ulcer, increased intraocular pressure, hyperthyroidism, cardiovascular disease, hypertension, and in the elderly. May cause drowsiness; use caution in performing tasks which require alertness.

Dosage Forms

Syrup, as fumarate [prescription formulation]: 0.67 mg/5 mL (120 mL) [0.5 mg base/5 mL; contains alcohol 5.5%; citrus flavor]

Tablet, as fumarate: 1.34 mg [1 mg base; OTC], 2.68 mg [2 mg base; prescription formulation]

Dayhist® Allergy, Tavist® Allergy: 1.34 mg [1 mg base]

Overdosage/Treatment Supportive therapy: There is no specific treatment for an antihistamine overdose, however, most of its clinical toxicity is due to anticholinergic effects. For anticholinergic overdose with severe life-threatening symptoms, physostigmine 1-2 mg (0.5 or 0.02 mg/kg for children) I.V., slowly may be given to reverse these effects.

Test Interactions May suppress wheal and flare response to antigen skin testing

Drug Interactions

Inhibits CYP2D6 (weak), 3A4 (weak)
 Increased toxicity (CNS depression): CNS depressants, MAO inhibitors, tricyclic antidepressants, phenothiazines

Pregnancy Risk Factor B

Lactation Enters breast milk/not recommended

Nursing Implications Raise bed rails, institute safety measures, assist with ambulation

Additional Information Clemastine fumarate 1.34 mg = clemastine base 1 mg; offers no significant benefit over other antihistamines except that it may be dosed twice daily (in adults) as compared to other antihistamines with more frequent dosing

Clenbuterol

Related Information

- Albuterol

CAS Number 21898-19-1; 3714-27-9

Use Asthma/exercise-induced asthma; also has been utilized as an ergogenic acid (unapproved use); used illicitly in animal feed to enhance animal weight gain

Mechanism of Action A long-acting sympathomimetic agent with direct β -2 adrenergic properties and enhanced lipolytic effect

Adverse Reactions

Cardiovascular: Tachycardia, palpitations (25%)
 Central nervous system: Dizziness, headache, tremors (11%), dyskinesia
 Dermal: Contact dermatitis
 Gastrointestinal: Nausea, dry mouth
 Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Hyperglycemia, hypokalemia, tachycardia (usually without elevated blood pressure), tremor; symptoms may last for 6 days

Admission Criteria/Prognosis Admit any ingestion >3 mcg/kg, or any patient with tachycardia or electrolyte deficiencies

Toxicodynamics/Kinetics

Onset of action: Initial: 15 minutes
 Duration of action: 4-12 hours
 Metabolism: Liver (slight)
 Bioavailability (oral): 70% to 80%
 Half-life: 25-39 hours
 Elimination: Renal (clearance 38-60 mL/minute)

Dosage

Oral: Adults: 20-40 mcg twice daily; ergogenic dose: up to 600 mcg/day
 Inhalation: 20 mcg 3 times/day

Reference Range Steady-state clenbuterol serum level is ~293 pg/mL in doses of 20 mcg twice daily

Overdosage/Treatment

Decontamination: Oral: Activated charcoal (without cathartic)
 Supportive therapy: Monitor and replace potassium as needed. Monitor cardiac status. Tachycardia can be treated with esmolol or metoprolol.

Pregnancy Implications A uterine relaxant

Additional Information May increase protein deposition in striated muscle by 20%, resulting in muscle hypertrophy (type II fibers).

Clobazam

CAS Number 22316-47-8

Impairment Potential Yes

Use Adjunctive treatment of epilepsy

Unlabeled/Investigational Use Monotherapy for epilepsy or intermittent seizures, antianxiety, anticonvulsant, and sedative agent

Mechanism of Action Facilitates gamma-aminobutyric acid neurotransmission; a 1,5 benzodiazepine derivative; weak hypnotic agent

Adverse Reactions

May induce systemic lupus erythematosus
 Cardiovascular: Hypotension (orthostatic), syncope
 Central nervous system: Sedation, dizziness, lightheadedness, headache, ataxia, CNS depression, depression, aggressive behavior
 Dermatologic: Toxic epidermal necrolysis
 Gastrointestinal: Xerostomia, weight gain

Signs and Symptoms of Overdose Confusion, dizziness

Pharmacodynamics/Kinetics

Absorption: Rapid
 Protein binding: 85% to 91%
 Metabolism: Hepatic via N-dealkylation (likely via CYP) to active metabolite (N-desmethyl), and glucuronidation
 Bioavailability: 87%
 Half-life elimination: 18 hours; N-desmethyl (active): 42 hours
 Time to peak: 15 minutes to 4 hours
 Excretion: Urine (90%), as metabolites

Dosage

Adults: 20-30 mg/day in divided doses or at night; maximum daily dose: 60 mg
 Elderly: 10-20 mg/day

Administration

May be administered with food.

Contraindications Hypersensitivity to clobazam or any component of the formulation (cross sensitivity with other benzodiazepines may exist); myasthenia gravis; narrow-angle glaucoma; severe hepatic or respiratory disease; sleep apnea; history of substance abuse; use in pregnancy (particularly 1st trimester); breast-feeding is contraindicated per manufacturer

Warnings

Rebound or withdrawal symptoms may occur following abrupt discontinuation or large decreases in dose (more common with prolonged treatment). Cautiously taper dose if drug discontinuation is required. Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics), renal impairment, or obese patients.

Causes CNS depression (dose related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury and should be used with caution in patients who are at risk of these events (especially the elderly). Use with caution in patients with respiratory disease or impaired gag reflex.

Tolerance and loss of seizure control have been reported with chronic administration. Not recommended in patients with psychosis or depression (particularly if suicidal risk may be present). May cause physical or psychological dependence - avoid in patients with a history of drug dependence. Acute withdrawal, including seizures, may be precipitated in patients after administration of flumazenil to patients receiving long-term benzodiazepine therapy.

Benzodiazepines have been associated with anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior, have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Dosage Forms

[CAN] = Canadian brand name

Tablet: 10 mg

Alti-Clobazam [CAN], Apo-Clobazam® [CAN], Clobazam-10 [CAN], Dom-Clobazam [CAN], Frisium® [CAN], Novo-Clobazam [CAN], PMS-Clobazam [CAN], ration-Clobazam [CAN]: 10 mg [not available in the U.S.]

Reference Range After a 40 mg oral dose, peak plasma levels are ~730 mcg/L

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Rarely is mechanical ventilation required; flumazenil has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression and respiratory depression

Enhancement of elimination: Multiple dose of activated charcoal is effective

Antidote(s)

- Flumazenil [ANTIDOTE]

Drug Interactions

Substrate (major) of CYP2C19 and 3A4

Anticonvulsants (carbamazepine, phenytoin, valproate, phenobarbital): Clinically-significant interactions are rare, but reports of clobazam increasing levels of carbamazepine, phenytoin, valproate, and phenobarbital exist. Enzyme-inducing agents may decrease clobazam concentrations.

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants. Includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect.

CYP2C19 inhibitors: May increase the levels/effects of clobazam. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of clobazam. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of clobazam. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Levodopa: Therapeutic effects may be diminished in some patients following the addition of a benzodiazepine; limited/inconsistent data.

Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation.

Pregnancy Risk Factor Not assigned; similar agents rated D. Contraindicated in 1st trimester (per manufacturer).

Pregnancy Implications Clobazam crosses the placenta. Oral clefts reported with benzodiazepines, however, more recent data does not support an association between drug and oral clefts. Inguinal hernia,

CLOFIBRATE

cardiac defects, spina bifida, dysmorphic facial features, skeletal defects, multiple other malformations also reported. Hypotonia and withdrawal symptoms reported following use during 3rd trimester or near time of delivery.

Lactation Enters breast milk/contraindicated (AAP rates other benzodiazepines "of concern"); clinical effects on infant include sedation

Additional Information Used to relieve phantom limb pain; similar efficacy as with buspirone in treatment of anxiety/panic disorders; oral ingestion of 300 mg has produced mental status changes; reduce dosage in elderly and cirrhosis

Clofibrate

CAS Number 637-07-0; 882-09-7

U.S. Brand Names Atromid-S® [DSC]

Use Adjunct to dietary therapy in the management of type III hyperlipidemias associated with high triglyceride levels

Mechanism of Action Mechanism is unclear but thought to reduce cholesterol synthesis and triglyceride hepatic-vascular transference (a fibric acid derivative)

Adverse Reactions

Cardiovascular: Angina, cardiac arrhythmias, cardiomyopathy, chest pain
Central nervous system: Headache, dizziness, fatigue

Dermatologic: Skin rash, pruritus, dry brittle hair, alopecia, Stevens-Johnson syndrome, desquamation (scaling), toxic epidermal necrolysis, exfoliative dermatitis, xerosis, urticaria, purpura, photosensitivity, exanthem

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone, gynecomastia

Gastrointestinal: **Nausea** which usually decreases with continued therapy or reduction in dosage; diarrhea, vomiting, dyspepsia, flatulence, abdominal distress, gallstones, stomatitis

Genitourinary: Impotence

Hematologic: Anemia, eosinophilia, eosinophilic pneumonitis, leukopenia, neutropenia, agranulocytosis, granulocytopenia

Hepatic: Increased liver function tests, increased incidence of cholecystitis

Neuromuscular & skeletal: Myalgia, aching, muscle cramping, myopathy (associated with hypoalbuminemia), rhabdomyolysis, weakness

Ocular: Photophobia

Renal: Rhabdomyolysis-induced renal failure, renal insufficiency, renal toxicity

Miscellaneous: Systemic lupus erythematosus

Signs and Symptoms of Overdose Cardiomegaly, cholelithiasis, desquamation, dysuria, erythema multiforme, fever, hematuria, hyperthermia, hyponatremia, impotence, lethargy, myalgia, myoglobinuria, photophobia

Toxicodynamics/Kinetics

Absorption: Occurs completely; intestinal transformation is required to activate the drug

Distribution: V_d : 5.5 L/kg

Protein binding: 95% (75% in patients with nephrotic syndrome)

Metabolism: In the liver to an inactive glucuronide ester and an active metabolite (clofibrilic acid)

Half-life: 6-24 hours, increases significantly with reduced renal function; with anuria: 110 hours

Time to peak serum concentration: Within 3-6 hours

Elimination: 40% to 70% excreted in urine; clearance: 1.5-2.0 mL/minute

Dosage

Adults: Oral: 500 mg 4 times/day; some patients may respond to lower doses

Dosing interval in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer every 12-18 hours

Cl_{cr} < 10 mL/minute: Avoid use

Monitoring Parameters Serum lipids, cholesterol and triglycerides, LFTs, CBC

Reference Range Therapeutic plasma level of parachlorophenoxyisobutyric acid: 80-150 mcg/mL

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Test Interactions ↑ creatine phosphokinase (CPK), aldolase, serum AST (S); ↓ alkaline phosphatase (S), cholesterol (S), glucose, uric acid (S), fibrinogen, plasma thyroxine

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Additional Information Atromid-S® discontinued in January 2001; not available in the U.S.

ClomiPHENE

CAS Number 15690-55-8; 15690-57-0; 50-41-9; 7599-79-3; 7619-53-6; 911-45-5

U.S. Brand Names Clomid®; Serophene®

Synonyms Clomiphene Citrate

Use Treatment of ovulatory failure in patients desiring pregnancy

Unlabeled/Investigational Use Male infertility

Mechanism of Action Induces ovulation by stimulating the release of pituitary gonadotropins; triphenylethylene which binds to estrogen receptors; acts as an antagonist at low doses but is an estrogen agonist at doses > 100 mg

Adverse Reactions

Central nervous system: Dizziness, psychosis, dementia, headache, ataxia, coma

Dermatologic: Alopecia (reversible), rash, neutrophilic dermatosis (Sweet's syndrome)

Endocrine & metabolic: **Ovarian enlargement**, ectopic pregnancy, gynecomastia, **hot flashes**, breast tenderness, diabetes insipidus, hypertriglyceridemia

Gastrointestinal: Gastric distention, bloating, nausea, vomiting, stomatitis, abdominal/pelvic pain, weight gain, pancreatitis

Ocular: **Blurring of vision**, photophobia, diplopia, cataract formation, palinopsia, color vision abnormalities

Renal: Polyuria

Miscellaneous: Anterior pituitary hemorrhage

Pharmacodynamics/Kinetics

Metabolism: Undergoes enterohepatic recirculation

Half-life elimination: 5-7 days

Excretion: Primarily feces; urine (small amounts)

Dosage Adults: Female: Oral: 50 mg/day for 5 days (first course); start the regimen on or about the fifth day of cycle; if ovulation occurs, do not increase dosage; if ovulation does not occur, increase next course to 100 mg/day for 5 days. Three courses of therapy are an adequate therapeutic trial. Further treatment is not recommended in patients who do not exhibit ovulation.

Contraindications Hypersensitivity to clomiphene citrate or any of its components; liver disease; abnormal uterine bleeding; enlargement or development of ovarian cyst; uncontrolled thyroid or adrenal dysfunction in the presence of an organic intracranial lesion such as pituitary tumor; pregnancy

Warnings Use with caution in patients unusually sensitive to pituitary gonadotropins (eg, polycystic ovary disease). Multiple pregnancies, blurring or other visual symptoms, ovarian hyperstimulation syndrome, and abdominal pain can occur.

Dosage Forms Tablet, as citrate: 50 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Due to its enterohepatic recirculation, multiple dosing of activated charcoal may be effective

Test Interactions FSH/LH levels increase by ~150%

Drug Interactions Decreased response when used with danazol; decreased estradiol response when used with clomiphene

Pregnancy Risk Factor X

Pregnancy Implications Multiple births occur in ~10% of pregnancies with induced ovulation; increased frequency of delayed follicular rupture and ectopic pregnancy also noted

Lactation Excretion in breast milk unknown/contraindicated

Additional Information Has been associated with testicular cancer, ectopic pregnancy, ovarian cancer

ClomiPRAMINE

CAS Number 17321-77-6; 303-49-1

U.S. Brand Names Anafranil®

Synonyms Clomipramine Hydrochloride

Use Treatment of obsessive-compulsive disorder (OCD)

Unlabeled/Investigational Use Depression, panic attacks, chronic pain

Mechanism of Action Clomipramine appears to affect serotonin uptake while its active metabolite, desmethylclomipramine, affects norepinephrine uptake; a tricyclic tertiary amine antidepressant

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), tachycardia, flushing, QRS prolongation, sinus tachycardia, tachycardia (supraventricular), vasculitis, cardiomyopathy, exacerbation of Brugada syndrome

Central nervous system: **Drowsiness, dizziness, headache**, neuroleptic malignant syndrome, convulsions, psychosis, serotonin syndrome (confusion, restlessness, diarrhea), aggressive behavior

Dermatologic: Photosensitivity, hypertrichosis, acne, alopecia, xerosis, urticaria, purpura, pruritus, psoriasis, exanthem

Endocrine & metabolic: Hyponatremia, syndrome of inappropriate antidiuretic hormone, spontaneous orgasm (when yawning) may occur, gynecomastia

Gastrointestinal: **Xerostomia, constipation, increased appetite, nausea, unpleasant taste, weight gain**, stomatitis, lingua villosa nigra

Hepatic: Acute hepatitis

Neuromuscular & skeletal: Hyperreflexia, clonus, myoclonus, paresthesia

Ocular: Amaurosis fugax, visual hallucinations

Respiratory: Eosinophilic pneumonia

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Agitation, agranulocytosis, apnea, confusion, hallucinations, hyperprolactinemia, hyperthermia, hypotension, lactation, leukopenia, mania, memory loss, myoclonus, neuroleptic malignant syndrome, nystagmus, photosensitivity, seizures, tachycardia, thrombocytopenia, urinary retention

Admission Criteria/Prognosis Admit any patient who displays symptoms (including sinus tachycardia) 6 hours postingestion

Pharmacodynamics/Kinetics

Absorption: Rapid

Metabolism: Hepatic to desmethylclomipramine (active); extensive first-pass effect

Half-life elimination: 20-30 hours

Dosage

Oral: Initial:

Children: 25 mg/day and gradually increase, as tolerated, to a maximum of 3 mg/kg/day or 200 mg/day, whichever is smaller

Adults: 25 mg/day and gradually increase, as tolerated, to 100 mg/day the first 2 weeks, may then be increased to a total of 250 mg/day maximum

Monitoring Parameters Pulse rate and blood pressure prior to and during therapy; ECG/cardiac status in older adults and patients with cardiac disease

Contraindications Hypersensitivity to clomipramine, other tricyclic agents, or any component of the formulation; use of MAO inhibitors within 14 days; use in a patient during the acute recovery phase of MI

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. **Clomipramine is FDA approved for the treatment of OCD in children ≥ 10 years of age.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Clomipramine is not FDA approved for the treatment of bipolar depression.**

May cause seizures (relationship to dose and/or duration of therapy) - do not exceed maximum doses. Use caution in patients with a previous seizure disorder or condition predisposing to seizures such as brain damage, alcoholism, or concurrent therapy with other drugs which lower the seizure threshold. Has been associated with a high incidence of sexual dysfunction. Weight gain may occur. May cause sedation, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Sedative effects may be additive with other CNS depressants and/or ethanol. The degree of sedation is very high relative to other antidepressants. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Therapy should not be abruptly discontinued in patients receiving high doses for prolonged periods.

May cause orthostatic hypotension (risk is moderate to high relative to other antidepressants) - use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). The degree of anticholinergic blockade produced by this agent is very high relative to other cyclic antidepressants - use caution in patients with urinary retention, benign prostatic hyperplasia, narrow-angle glaucoma, xerostomia, visual problems, constipation, or history of bowel obstruction.

Use with caution in patients with a history of cardiovascular disease (including previous MI, stroke, tachycardia, or conduction abnormalities). The risk conduction abnormalities with this agent is high relative to other antidepressants. Use with caution in hyperthyroid patients or those receiving thyroid supplementation. Use with caution in patients with hepatic or renal dysfunction and in elderly patient.

Dosage Forms Capsule, as hydrochloride: 25 mg, 50 mg, 75 mg

Reference Range Level of 6560 ng/mL associated with fatality; serum levels may not peak until the fourth day; plasma levels >1 mg/L associated with serious toxicity

Overdosage/Treatment

Decontamination: Lavage (within 3 hours)/activated charcoal; multiple dosing of activated charcoal may be effective

Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated. Ventricular arrhythmias often respond to phenytoin 15-20 mg/kg (adults) with concurrent systemic alkalization (sodium bicarbonate 0.5-2 mEq/kg I.V.). Arrhythmias unresponsive to this therapy may respond to lidocaine 1 mg/kg I.V. followed by a titrated infusion. Physostigmine (1-2 mg I.V. slowly for adults or 0.5 mg I.V. slowly for children) may be indicated in reversing seizures or movement disorders, but **only as a last resort**. Seizures usually respond to lorazepam or diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required. For treatment of lingua villosa nigra, discontinue causative agent. Clean the tongue with a toothbrush and rinse mouth with a half-strength solution of hydrogen peroxide or 10% carbamide peroxide. Symptoms should subside in a few days.

Test Interactions \uparrow glucose, plasma catecholamine

Drug Interactions

Substrate of CYP1A2 (major), 2C19 (major), 2D6 (major), 3A4 (minor); Inhibits CYP2D6 (moderate)

Altretamine: Concurrent use may cause orthostatic hypertension.

Amphetamines: TCAs may enhance the effect of amphetamines; monitor for adverse CV effects.

Anticholinergics: Combined use with TCAs may produce additive anticholinergic effects.

Antihypertensives: TCAs inhibit the antihypertensive response to beta-nidine, clonidine, debrisoquin, guanadrel, guanethidine, guanabenz, guanfacine; monitor BP; consider alternate antihypertensive agent.

Beta-agonists: When combined with TCAs may predispose patients to cardiac arrhythmias.

Bupropion: May increase the levels of tricyclic antidepressants; based on limited information; monitor response.

Carbamazepine: Tricyclic antidepressants may increase carbamazepine levels; monitor.

Cholestyramine and colestipol: May bind TCAs and reduce their absorption; monitor for altered response.

Clonidine: Abrupt discontinuation of clonidine may cause hypertensive crisis, amitriptyline may enhance the response.

CNS depressants: Sedative effects may be additive with TCAs; monitor for increased effect; includes benzodiazepines, barbiturates, antipsychotics, ethanol, and other sedative medications.

CYP1A2 inducers: May decrease the levels/effects of clomipramine. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of clomipramine. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

CYP2C19 inducers: May decrease the levels/effects of clomipramine. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of clomipramine. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

CYP2D6 inhibitors: May increase the levels/effects of clomipramine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP2D6 substrates: Clomipramine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Clomipramine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

Epinephrine (and other direct alpha-agonists): Pressor response to I.V. epinephrine, norepinephrine, and phenylephrine may be enhanced in patients receiving TCAs. (**Note:** Effect is unlikely with epinephrine or levonordefrin dosages typically administered as infiltration in combination with local anesthetics.)

Fenfluramine: May increase tricyclic antidepressant levels/effects.

Hypoglycemic agents (including insulin): TCAs may enhance the hypoglycemic effects of tolazamide, chlorpropamide, or insulin; monitor for changes in blood glucose levels; reported with chlorpropamide, tolazamide, and insulin.

Levodopa: Tricyclic antidepressants may decrease the absorption (bioavailability) of levodopa; rare hypertensive episodes have also been attributed to this combination.

Linezolid: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** with agents which inhibit MAO (serotonin syndrome); this combination should be avoided.

Lithium: Concurrent use with a TCA may increase the risk for neurotoxicity.

MAO inhibitors: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** (serotonin syndrome); this combination should be avoided.

Methylphenidate: Metabolism of some TCAs may be decreased.

Olanzapine: When used in combination, clomipramine and olanzapine have been reported to be associated with the development of seizures; limited documentation (case report).

Phenothiazines: Serum concentrations of some TCAs may be increased; in addition, TCAs may increase concentration of phenothiazines; monitor for altered clinical response.

QT_c-prolonging agents: Concurrent use of tricyclic agents with other drugs which may prolong QT_c interval may increase the risk of potentially fatal arrhythmias; includes type Ia and type III antiarrhythmic agents, selected quinolones (sparfloxacin, gatifloxacin, moxifloxacin, grepafloxacin), cisapride, and other agents.

Ritonavir: Combined use of high-dose tricyclic antidepressants with ritonavir may cause serotonin syndrome in HIV-positive patients; monitor.

Sucralfate: Absorption of tricyclic antidepressants may be reduced with coadministration.

Sympathomimetics, indirect-acting: Tricyclic antidepressants may result in a decreased sensitivity to indirect-acting sympathomimetics; includes dopamine and ephedrine; also see interaction with epinephrine (and direct-acting sympathomimetics).

Tramadol: Tramadol's risk of seizures may be increased with TCAs.

Valproic acid: May increase serum concentrations/adverse effects of some tricyclic antidepressants.

Warfarin (and other oral anticoagulants): TCAs may increase the anticoagulant effect in patients stabilized on warfarin; monitor INR.

Pregnancy Risk Factor C

Pregnancy Implications There are no adequate studies in pregnant women. Withdrawal symptoms (including dizziness, nausea, vomiting, headache, malaise, sleep disturbance, hyperthermia, and/or irritability) have been observed in neonates whose mothers took clomipramine up to delivery. Use in pregnancy only if the benefits to the mother outweigh the potential risks to the fetus.

Lactation Enters breast milk/contraindicated (AAP rates "of concern")

Nursing Implications Monitor pulse rate and blood pressure prior to and during therapy, evaluate mental status

Additional Information May also relieve depression, panic attacks, and chronic pain; may be unsafe to use in patients with porphyria; not effective for sleep apnea; radiopaque

Harvey M, and Cave G, "Intralipid Outperforms Sodium Bicarbonate in a Rabbit Model on Clomipramine Toxicity," *Ann Emerg Med*, 2007, 49:178-185.

Use Alone or as an adjunct in the treatment of petit mal variant (Lennox-Gastaut), akinetic, and myoclonic seizures; petit mal (absence) seizures unresponsive to succinimides; panic disorder with or without agoraphobia

Unlabeled/Investigational Use Restless legs syndrome; neuralgia; multifocal tic disorder; parkinsonian dysarthria; bipolar disorder; adjunct therapy for schizophrenia

Mechanism of Action Suppresses the spike-and-wave discharge in absence seizures by depressing nerve transmission in the motor cortex

Adverse Reactions

Reactions reported in patients with seizure and/or panic disorder. Frequency not defined.

Cardiovascular: Edema (ankle or facial), palpitations

Central nervous system: Amnesia, ataxia (seizure disorder ~30%; panic disorder 5%), behavior problems (seizure disorder ~25%), coma, confusion, depression, dizziness, drowsiness (seizure disorder ~50%), emotional lability, fatigue, fever, hallucinations, headache, hypotonia, hysteria, insomnia, intellectual ability reduced, memory disturbance, nervousness; paradoxical reactions (including aggressive behavior, agitation, anxiety, excitability, hostility, irritability, nervousness, nightmares, sleep disturbance, vivid dreams); psychosis, slurred speech, somnolence (panic disorder 37%), suicidal attempts, vertigo

Dermatologic: Hair loss, hirsutism, skin rash

Endocrine & metabolic: Dysmenorrhea, libido increased/decreased

Gastrointestinal: Abdominal pain, anorexia, appetite increased/decreased, coated tongue, constipation, dehydration, diarrhea, gastritis, gum soreness, nausea, weight changes (loss/gain), xerostomia

Genitourinary: Dysuria, ejaculation delayed, enuresis, impotence, micturition frequency, nocturia, urinary retention, urinary tract infection, colpitis

Hematologic: Anemia, eosinophilia, leukopenia, thrombocytopenia

Hepatic: Alkaline phosphatase increased (transient), hepatomegaly, serum transaminases increased (transient)

Neuromuscular & skeletal: Choreiform movements, coordination abnormal, dysarthria, muscle pain, muscle weakness, myalgia, tremor

Ocular: Blurred vision, eye movements abnormal, diplopia, nystagmus

Respiratory: Chest congestion, cough, bronchitis, hypersecretions, pharyngitis, respiratory depression, respiratory tract infection, rhinitis, rhinorrhea, shortness of breath, sinusitis

Miscellaneous: Allergic reactions, aphonia, dysidiadochokinesis, encopresis, "glassy-eyed" appearance, hemiparesis, lymphadenopathy

Signs and Symptoms of Overdose May produce ataxia, coma, confusion, cyanosis, depression, diminished reflexes, diplopia, dysarthria, hirsutism, hyperactivity, hypotension, neuroleptic malignant syndrome, purpura, somnolence; agranulocytosis, granulocytopenia, leukopenia, neutropenia

Pharmacodynamics/Kinetics

Onset of action: 20-60 minutes

Duration: Infants and young children: 6-8 hours; Adults: ≤ 12 hours

Absorption: Well absorbed

Distribution: Adults: V_d: 1.5-4.4 L/kg

Protein binding: 85%

Metabolism: Extensively hepatic via glucuronide and sulfate conjugation

Half-life elimination: Children: 22-33 hours; Adults: 19-50 hours

Time to peak, serum: 1-3 hours; Steady-state: 5-7 days

Excretion: Urine (<2% as unchanged drug); metabolites excreted as glucuronide or sulfate conjugates

Dosage

Oral:

Children < 10 years or 30 kg: Seizure disorders:

Initial daily dose: 0.01-0.03 mg/kg/day (maximum: 0.05 mg/kg/day) given in 2-3 divided doses; increase by no more than 0.5 mg every third day until seizures are controlled or adverse effects seen

Usual maintenance dose: 0.1-0.2 mg/kg/day divided 3 times/day, not to exceed 0.2 mg/kg/day

Adults:

Seizure disorders:

Initial daily dose not to exceed 1.5 mg given in 3 divided doses; may increase by 0.5-1 mg every third day until seizures are controlled or adverse effects seen (maximum: 20 mg/day)

Usual maintenance dose: 0.05-0.2 mg/kg; do not exceed 20 mg/day

Panic disorder: 0.25 mg twice daily; increase in increments of 0.125-0.25 mg twice daily every 3 days; target dose: 1 mg/day (maximum: 4 mg/day)

Discontinuation of treatment: To discontinue, treatment should be withdrawn gradually. Decrease dose by 0.125 mg twice daily every 3 days until medication is completely withdrawn.

Elderly: Initiate with low doses and observe closely

Hemodialysis: Supplemental dose is not necessary

Monitoring Parameters CBC, liver function tests

Administration

Orally-disintegrating tablet: Open pouch and peel back foil on the blister; do not push tablet through foil. Use dry hands to remove tablet and place in mouth. May be swallowed with or without water. Use immediately after removing from package.

Clonazepam

Related Information

- Flunitrazepam
- Nitrazepam
- Therapeutic Drugs Associated with Hallucinations

CAS Number 1622-61-3

U.S. Brand Names Klonopin®

Impairment Potential Yes. Plasma clonazepam levels >0.1 mg/L are consistent with impairment. Brief or extended period (up to 1 year) of use is consistent with driving impairment in the elderly; impairment is greatest in the first 7 days of use. (Baselt RC and Cravey RH, *Disposition of Toxic Drugs and Chemicals in Man*, 4th ed, Foster City, CA: Chemical Toxicology Institute, 1995.)

Contraindications Hypersensitivity to clonazepam or any component of the formulation (cross-sensitivity with other benzodiazepines may exist); significant liver disease; narrow-angle glaucoma; pregnancy

Warnings

Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics), or renal impairment. Use with caution in patients with respiratory disease or impaired gag reflex or ability to protect the airway from secretions (salivation may be increased). Worsening of seizures may occur when added to patients with multiple seizure types. Concurrent use with valproic acid may result in absence status. Monitoring of CBC and liver function tests has been recommended during prolonged therapy.

Causes CNS depression (dose related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury and should be used with extreme caution in patients who are at risk of these events (especially the elderly).

Use caution in patients with depression, particularly if suicidal risk may be present. Use with caution in patients with a history of drug dependence. Benzodiazepines have been associated with dependence and acute withdrawal symptoms, including seizures, on discontinuation or reduction in dose. Acute withdrawal, including seizures, may be precipitated in patients after administration of flumazenil to patients receiving long-term benzodiazepine therapy.

Benzodiazepines have been associated with anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior, have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Dosage Forms

Tablet: 0.5 mg, 1 mg, 2 mg

Tablet, orally disintegrating [wafer]: 0.125 mg, 0.25 mg, 0.5 mg, 1 mg, 2 mg

Reference Range

Sample size: 2 mL serum or plasma

Therapeutic: 10-50 ng/mL

Toxic: > 100 ng/mL

Timing of serum samples: Peak serum levels occur 1-3 hours after oral ingestion

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Treatment for benzodiazepine overdose is supportive. Rarely is mechanical ventilation required. Flumazenil has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression.

Enhancement of elimination: Multiple dose of activated charcoal may be effective

Antidote(s)

- Flumazenil [ANTIDOTE]

Drug Interactions

Substrate of CYP3A4 (major)

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of clonazepam. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of clonazepam. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Disulfiram: Disulfiram may inhibit the metabolism of clonazepam; monitor for increased benzodiazepine effect.

Levodopa: Therapeutic effects may be diminished in some patients following the addition of a benzodiazepine; limited/inconsistent data.

Oral contraceptives: May decrease the clearance of some benzodiazepines (those which undergo oxidative metabolism); monitor for increased benzodiazepine effect.

Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation.

Valproic acid: The combined use of clonazepam and valproic acid has been associated with absence seizures.

Pregnancy Risk Factor D

Pregnancy Implications Clonazepam was shown to be teratogenic in some animal studies. Clonazepam crosses the placenta. Benzodiazepine use during pregnancy is associated with increased risk of congenital malformations. Nonteratogenic effects (including neonatal flaccidity, respiratory and feeding problems, and withdrawal symptoms) during the postnatal period have also been reported with benzodiazepine use.

Epilepsy itself, number of medications, genetic factors, or a combination of these probably influence the teratogenicity of anticonvulsant therapy.

Lactation Enters breast milk/not recommended

Nursing Implications Observe patient for excess sedation, respiratory depression

Additional Information Ethosuximide or valproic acid may be preferred for treatment of absence (petit mal) seizures; clonazepam-induced behavioral disturbances may be more frequent in mentally handicapped patients; may be effective therapy for tinnitus will not usually give a positive urinary drug screen for benzodiazepines

Clonidine

Related Information

- Drugs Used in Addiction Treatment
- Therapeutic Drugs Associated with Hallucinations

CAS Number 4205-90-7; 4205-91-8

U.S. Brand Names Catapres-TTS®; Catapres®; Duraclon™

Synonyms Clonidine Hydrochloride

Impairment Potential Yes. Doses > 0.3 mg are associated with sedation in first-time users. (Baselt RC and Cravey RH, *Disposition of Toxic Drugs and Chemicals in Man*, 4th ed, Foster City, CA: Chemical Toxicology Institute, 1995, 178.)

Use Management of mild to moderate hypertension; either used alone or in combination with other antihypertensives

Orphan drug: Duraclon™. For continuous epidural administration as adjunctive therapy with intraspinal opiates for treatment of cancer pain in patients tolerant to or unresponsive to intraspinal opiates

Unlabeled/Investigational Use Heroin or nicotine withdrawal; severe pain; dysmenorrhea; vasomotor symptoms associated with menopause; ethanol dependence; prophylaxis of migraines; glaucoma; diabetes-associated diarrhea; impulse control disorder, attention-deficit/hyperactivity disorder (ADHD), clozapine-induced sialorrhea, neonatal opiate withdrawal

Mechanism of Action Stimulates α_2 -adrenoreceptors in the brain stem, thus activating an inhibitory neuron, resulting in reduced sympathetic outflow, producing a decrease in vasomotor tone and heart rate

Adverse Reactions

Cardiovascular: Exacerbation of Raynaud's phenomenon, hypotension, **bradycardia**, palpitations, tachycardia, congestive heart failure, AV block, transient paradoxical hypertension (at doses > 7 mg/day), hypertension (at doses > 7 mg/day), **hypertension (rebound)**, **hypotension (orthostatic)**, sinus bradycardia, myocardial depression, sinus tachycardia

Central nervous system: **Drowsiness, dizziness**, fatigue, insomnia, **anxiety**, auditory and visual hallucinations, headache, depression, psychosis, **confusion**

Dermatologic: Rash, pruritus, skin pigmentation after transdermal application, alopecia, angioedema, urticaria, exanthem

Endocrine & metabolic: Sodium and water retention, parotitis, parotid pain, hypoprolactinemia

Gastrointestinal: **Constipation**, anorexia, **xerostomia, nausea**, vomiting, Ogilvie's syndrome

Genitourinary: Impotence, **urinary tract infection**

Hepatic: Hepatitis

Local: Skin reactions with patch

Ocular: Miosis, diplopia

Miscellaneous: Anogenital cicatricial pemphigoid, systemic lupus erythematosus, pseudolymphoma

Signs and Symptoms of Overdose Apnea, ataxia, AV block, bradycardia (17% incidence in children), coma, CNS depression, delirium, dementia, diarrhea, dry eyes, heart block, hyperglycemia, hypoglycemia, hyponatremia, hyporeflexia, hypotension (15% incidence in children), hypothermia (usually resolves in 8 hours), hypotonia, impotence, insomnia, irritability, lethargy (80% incidence in children), miosis, nocturia, paralytic ileus, personality changes, respiratory depression (5% incidence in children), seizures, syncope

CLONIDINE

Admission Criteria/Prognosis Admit any symptomatic patient after a four hour observation or any pediatric ingestion over 0.2 mg

Pharmacodynamics/Kinetics

Onset of action: Oral: 0.5-1 hour; Transdermal: Initial application: 2-3 days
Duration: 6-10 hours
Distribution: V_d : Adults: 2.1 L/kg; highly lipid soluble; distributes readily into extravascular sites
Protein binding: 20% to 40%
Metabolism: Extensively hepatic to inactive metabolites; undergoes enterohepatic recirculation
Bioavailability: 75% to 95%
Half-life elimination: Adults: Normal renal function: 6-20 hours; Renal impairment: 18-41 hours
Time to peak: 2-4 hours
Excretion: Urine (65%, 32% as unchanged drug); feces (22%)

Dosage

Children:

Oral:

Hypertension: Initial: 5-10 mcg/kg/day in divided doses every 8-12 hours; increase gradually at 5- to 7-day intervals to 25 mcg/kg/day in divided doses every 6 hours; maximum: 0.9 mg/day

Clonidine tolerance test (test of growth hormone release from pituitary): 0.15 mg/m² or 4 mcg/kg as single dose

ADHD (unlabeled use): Initial: 0.05 mg/day; increase every 3-7 days by 0.05 mg/day to 3-5 mcg/kg/day given in divided doses 3-4 times/day (maximum dose: 0.3-0.4 mg/day)

Epidural infusion: Pain management: Reserved for patients with severe intractable pain, unresponsive to other analgesics or epidural or spinal opiates: Initial: 0.5 mcg/kg/hour; adjust with caution, based on clinical effect

Adults:

Oral:

Acute hypertension (urgency): Initial 0.1-0.2 mg; may be followed by additional doses of 0.1 mg every hour, if necessary, to a maximum total dose of 0.6 mg

Hypertension: Initial dose: 0.1 mg twice daily (maximum recommended dose: 2.4 mg/day); usual dose range (JNC 7): 0.1-0.8 mg/day in 2 divided doses

Nicotine withdrawal symptoms: 0.1 mg twice daily to maximum of 0.4 mg/day for 3-4 weeks

Transdermal: Hypertension: Apply once every 7 days; for initial therapy start with 0.1 mg and increase by 0.1 mg at 1- to 2-week intervals (dosages > 0.6 mg do not improve efficacy); usual dose range (JNC 7): 0.1-0.3 mg once weekly

Neonatal opiate withdrawal: 0.5-1 mcg/kg (oral)

Epidural infusion: Pain management: Starting dose: 30 mcg/hour; titrate as required for relief of pain or presence of side effects; minimal experience with doses > 40 mcg/hour; should be considered an adjunct to intraspinal opiate therapy

Elderly: Initial: 0.1 mg once daily at bedtime, increase gradually as needed

Dosing adjustment in renal impairment: $Cl_{cr} < 10$ mL/minute: Administer 50% to 75% of normal dose initially

Dialysis: Not dialyzable (0% to 5%) via hemo- or peritoneal dialysis; supplemental dose not necessary

Monitoring Parameters Blood pressure, standing and sitting/supine, mental status, heart rate

Administration Oral: Do not discontinue clonidine abruptly. If needed, gradually reduce dose over 2-4 days to avoid rebound hypertension

Transdermal patch: Patches should be applied weekly at bedtime to a clean, hairless area of the upper outer arm or chest. Rotate patch sites weekly. Redness under patch may be reduced if a topical corticosteroid spray is applied to the area before placement of the patch.

Contraindications Hypersensitivity to clonidine hydrochloride or any component of the formulation

Warnings

Gradual withdrawal is needed (over 1 week for oral, 2-4 days with epidural) if drug needs to be stopped. Patients should be instructed about abrupt discontinuation (causes rapid increase in BP and symptoms of sympathetic overactivity). In patients on both a beta-blocker and clonidine where withdrawal of clonidine is necessary, withdraw the beta-blocker first and several days before clonidine. Then slowly decrease clonidine.

Use with caution in patients with severe coronary insufficiency; conduction disturbances; recent MI, CVA, or chronic renal insufficiency. Caution in sinus node dysfunction. Discontinue within 4 hours of surgery then restart as soon as possible after. Clonidine injection should be administered via a continuous epidural infusion device. **[U.S. Boxed Warning]: Epidural clonidine is not recommended for perioperative, obstetrical, or postpartum pain.** It is not recommended for use in patients with severe cardiovascular disease or hemodynamic instability. In all cases, the epidural may lead to cardiovascular instability (hypotension, bradycardia). Transdermal patch may contain conducting metal (eg, aluminum); remove patch

prior to MRI. Due to the potential for altered electrical conductivity, remove transdermal patch before cardioversion or defibrillation. Clonidine cause significant CNS depression and xerostomia. Caution in patients with pre-existing CNS disease or depression. Elderly may be at greater risk for CNS depressive effects, favoring other agents in this population.

Dosage Forms

Injection, epidural solution, as hydrochloride [preservative free] (Dura-clon™): 100 mcg/mL (10 mL); 500 mcg/mL (10 mL)

Patch, transdermal [once-weekly patch]:

Catapres-TTS®-1: 0.1 mg/24 hours (4s)

Catapres-TTS®-2: 0.2 mg/24 hours (4s)

Catapres-TTS®-3: 0.3 mg/24 hours (4s)

Tablet, as hydrochloride (Catapres®): 0.1 mg, 0.2 mg, 0.3 mg

Reference Range

Therapeutic: 1-2 ng/mL (SI: 4.4-8.7 nmol/L); ingestion of a clonidine patch in a 14-month old girl resulted in a clonidine serum level of 4 ng/mL with major toxicity noted; ingestion of 2.9 mg/kg of clonidine resulted in a serum clonidine level of 64 ng/mL and severe toxicity in a 5-year-old
Peak clonidine plasma and cerebrospinal fluid levels following a 700 mcg bolus of epidural clonidine are ~4.4 and 418 ng/mL, respectively

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; whole bowel irrigation (200 mL/hour of GoLYTELY® increased up to a rate of 500 mL/hour) has been used successfully in decontamination of ingested clonidine patch in a girl who was 14 months of age who had been symptomatic

Supportive therapy: Treatment is primarily supportive and symptomatic. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral vasoconstrictor may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Naloxone may be utilized in treating the hypotension, CNS depression and/or apnea and should be given I.V. 0.01 mg/kg to 0.1 mg/kg, with repeats as needed. There is ~31% positive response rate to naloxone for clonidine toxicity and rebound hypertension does **not** occur. Atropine 15 mcg/kg I.V. may be needed for symptomatic bradycardia. Tolazoline may be utilized to treat hypotension and bradycardia refractory to above therapy (initial dose of tolazoline is 10 mg I.V.). Yohimbine (oral: 0.1 mg/kg) has been used successfully to reverse neurologic and cardiac effects.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; not dialyzable (0% to 5%); hemoperfusion may be helpful in removing clonidine

Antidote(s)

● Naloxone [ANTIDOTE]

Test Interactions ↑ sodium (S); ↓ catecholamines (U)

Drug Interactions

Antipsychotics: Concurrent use with antipsychotics (especially low potency) or nitroprusside may produce additive hypotensive effects.

Beta-blockers: May potentiate bradycardia in patients receiving clonidine and may increase the rebound hypertension of withdrawal; discontinue beta-blocker several days before clonidine is tapered.

CNS depressants: Sedative effects may be additive; monitor for increased effect; includes barbiturates, benzodiazepines, narcotic analgesics, ethanol, and other sedative agents.

Cyclosporine: Clonidine may increase cyclosporine (and perhaps tacrolimus) serum concentrations; cyclosporine dosage adjustment may be needed.

Hypoglycemic agents: Clonidine may decrease the symptoms of hypoglycemia; monitor patients receiving antidiabetic agents.

Levodopa: Effects may be reduced by clonidine in some patients with Parkinson's disease (limited documentation); monitor.

Local anesthetics: Epidural clonidine may prolong the sensory and motor blockade of local anesthetics.

Mirtazapine: Antihypertensive effects of clonidine may be antagonized by mirtazapine (hypertensive urgency has been reported following addition of mirtazapine to clonidine). In addition, mirtazapine may potentially enhance the hypertensive response associated with abrupt clonidine withdrawal. Avoid this combination; consider an alternative agent.

Narcotic analgesics: May potentiate hypotensive effects of clonidine.

Tricyclic antidepressants: Antihypertensive effects of clonidine may be antagonized by tricyclic antidepressants. In addition, tricyclic antidepressants may enhance the hypertensive response associated with abrupt clonidine withdrawal; avoid this combination; consider an alternative agent.

Verapamil: Concurrent administration may be associated with hypotension and AV block in some patients (limited documentation); monitor.

Pregnancy Risk Factor C

Pregnancy Implications Clonidine crosses the placenta. Caution should be used with this drug due to the potential of rebound hypertension with abrupt discontinuation.

Lactation Enters breast milk/not recommended

Nursing Implications Patches should be applied weekly at bedtime to a clean, hairless area of the upper outer arm or chest; rotate patch sites weekly

Additional Information Unsafe in patients with porphyria; rebound hypertension upon abrupt withdrawal usually occurs with doses > 1.2 mg/day; appears to be the preferred "Mickey Finn" drug used by criminals in Moscow/Russia; addition of clonidine (75-150 mcg) increased duration of analgesia produced by epidural morphine (2 mg) for cesarean delivery

Clorazepate

CAS Number 20432-69-3; 57109-90-7; 5991-71-9

U.S. Brand Names T-Tab®; Tranxene® SD™-Half Strength; Tranxene® SD™; Tranxene®

Synonyms Clorazepate Dipotassium; Tranxene T-Tab®

Impairment Potential Yes. Brief or extended period (up to 1 year) of use is consistent with driving impairment in the elderly; impairment is greatest in the first 7 days of use.

Use Treatment of generalized anxiety and panic disorders; management of alcohol withdrawal; adjunct anticonvulsant in management of partial seizures

Mechanism of Action Facilitates gamma aminobutyric acid (GABA)-mediated transmission inhibitory neurotransmitter action, depresses subcortical levels of CNS

Adverse Reactions

- Cardiovascular: Decreased systolic blood pressure, vasculitis
 Central nervous system: **Drowsiness**, headache, dizziness, mental confusion, nervousness
 Dermatologic: Urticaria, purpura, pruritus, exanthem
 Gastrointestinal: Xerostomia
 Hematologic: Decreased hematocrit
 Hepatic: Abnormal liver function test results
 Neuromuscular & skeletal: Paresthesia
 Ocular: Blurred vision
 Renal: Abnormal kidney function tests

Signs and Symptoms of Overdose Ataxia, coma, confusion, diminished reflexes, somnolence

Pharmacodynamics/Kinetics

- Onset of action: 1-2 hours
 Duration: Variable, 8-24 hours
 Distribution: Crosses placenta; appears in urine
 Metabolism: Rapidly decarboxylated to desmethyldiazepam (active) in acidic stomach prior to absorption; hepatically to oxazepam (active)
 Half-life elimination: Adults: Desmethyldiazepam: 48-96 hours; Oxazepam: 6-8 hours
 Time to peak, serum: ~1 hour
 Excretion: Primarily urine

Dosage

- Oral:
 Children 9-12 years: Anticonvulsant: Initial: 3.75-7.5 mg/dose twice daily; increase dose by 3.75 mg at weekly intervals, not to exceed 60 mg/day in 2-3 divided doses
 Children > 12 years and Adults: Anticonvulsant: Initial: Up to 7.5 mg/dose 2-3 times/day; increase dose by 7.5 mg at weekly intervals; not to exceed 90 mg/day
 Adults:

Anxiety: 7.5-15 mg 2-4 times/day, or given as single dose of 11.25 or 22.5 mg at bedtime

Alcohol withdrawal: Initial: 30 mg, then 15 mg 2-4 times/day on first day; maximum daily dose: 90 mg; gradually decrease dose over subsequent days

Stability Unstable in water

Monitoring Parameters Respiratory and cardiovascular status, excess CNS depression

Contraindications Hypersensitivity to clorazepate or any component of the formulation (cross-sensitivity with other benzodiazepines may exist); narrow-angle glaucoma; pregnancy

Warnings

Not recommended for use in patients <9 years of age or patients with depressive or psychotic disorders. Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics), or renal impairment. Active metabolites with extended half-lives may lead to delayed accumulation and adverse effects. Use with caution in patients with respiratory disease or impaired gag reflex. Avoid use in patients with sleep apnea.

Causes CNS depression (dose related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. Benzodiazepines have been associated with falls and traumatic injury and should be used with extreme caution in patients who are at risk of these events (especially the elderly).

Use caution in patients with depression, particularly if suicidal risk may be present. Use with caution in patients with a history of drug dependence. Benzodiazepines have been associated with dependence and acute withdrawal symptoms on discontinuation or reduction in dose. Acute withdrawal, including seizures, may be precipitated in patients after administration of flumazenil to patients receiving long-term benzodiazepine therapy.

Benzodiazepines have been associated with anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior, have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Dosage Forms

- Tablet, as dipotassium: 3.75 mg, 7.5 mg, 15 mg
 Tranxene® SD™: 22.5 mg [once daily]
 Tranxene® SD™-Half Strength: 11.25 mg [once daily]
 Tranxene® T-Tab®: 3.75 mg, 7.5 mg, 15 mg

Reference Range Therapeutic: 0.12-2.00 mcg/mL (SI: 0.36-6.02 µmol/L)

Overdose/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Treatment for benzodiazepine overdose is supportive; rarely is mechanical ventilation required. Flumazenil (Romazicon™) has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression.

Antidote(s)

- Flumazenil [ANTIDOTE]

Drug Interactions

Substrate of CYP3A4 (major)

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of clorazepate. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of clorazepate. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Levodopa: Therapeutic effects may be diminished in some patients following the addition of a benzodiazepine; limited/inconsistent data.

Oral contraceptives: May decrease the clearance of some benzodiazepines (those which undergo oxidative metabolism); monitor for increased benzodiazepine effect.

Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation.

Pregnancy Risk Factor D

Pregnancy Implications Fetal malformations described with first trimester use; crosses the placenta

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Observe patient for excess sedation, apnea; raise bed rails, initiate safety measures, assist with ambulation

Additional Information Clorazepate offers no advantage over the other benzodiazepines; can cause fetal malformations

Clotrimazole

CAS Number 23593-75-1

U.S. Brand Names Cruex[®] Cream [OTC]; Gyne-Lotrimin[®] 3 [OTC]; Lotrimin[®] AF Athlete's Foot Cream [OTC]; Lotrimin[®] AF Athlete's Foot Solution [OTC]; Lotrimin[®] AF Jock Itch Cream [OTC]; Mycelex[®] Twin Pack [OTC]; Mycelex[®]-7 [OTC]; Mycelex[®]

Use Treatment of susceptible fungal infections, including oropharyngeal candidiasis, dermatophytoses, superficial mycoses, and cutaneous candidiasis, as well as vulvovaginal candidiasis; limited data suggest that clotrimazole troches may be effective for prophylaxis against oropharyngeal candidiasis in neutropenic patients

Mechanism of Action An imidazole agent which binds to phospholipids in the fungal cell membrane altering cell wall permeability resulting in loss of essential intracellular elements

Adverse Reactions

Central nervous system: Drowsiness, confusion, CNS depression, depression

Dermatologic: Contact dermatitis

Gastrointestinal: Nausea, vomiting, anorexia

Hepatic: **Abnormal liver function tests**

Local: Mild burning, irritation, stinging to skin or vaginal area

Pharmacodynamics/Kinetics

Absorption: Topical: Negligible through intact skin

Time to peak, serum:

Oral topical (troche): Salivary levels occur within 3 hours following 30 minutes of dissolution time

Vaginal cream: High vaginal levels: 8-24 hours

Vaginal tablet: High vaginal levels: 1-2 days

Excretion: Feces (as metabolites)

Dosage

Children >3 years and Adults:

Oral:

Prophylaxis: 10 mg troche dissolved 3 times/day for the duration of chemotherapy or until steroids are reduced to maintenance levels

Treatment: 10 mg troche dissolved slowly 5 times/day for 14 consecutive days

Topical (cream, solution): Apply twice daily; if no improvement occurs after 4 weeks of therapy, re-evaluate diagnosis

Children >12 years and Adults:

Vaginal:

Cream:

1%: Insert 1 applicatorful vaginal cream daily (preferably at bedtime) for 7 consecutive days

2%: Insert 1 applicatorful vaginal cream daily (preferably at bedtime) for 3 consecutive days

Tablet: Insert 100 mg/day for 7 days or 500 mg single dose

Topical (cream, solution): Apply to affected area twice daily (morning and evening) for 7 consecutive days

Monitoring Parameters Periodic liver function tests during oral therapy with clotrimazole lozenges

Administration Oral: Allow to dissolve slowly over 15-30 minutes.

Topical: Avoid contact with eyes. For external use only. Apply sparingly. Protect hands with latex gloves. Do not use occlusive dressings.

Contraindications Hypersensitivity to clotrimazole or any component of the formulation

Warnings Clotrimazole should not be used for treatment of systemic fungal infection. Safety and effectiveness of clotrimazole lozenges (troches) in children <3 years of age have not been established. When using topical formulation, avoid contact with eyes.

Dosage Forms

Combination pack (Mycelex[®]-7): Vaginal tablet 100 mg (7s) and vaginal cream 1% (7 g)

Cream, topical: 1% (15 g, 30 g, 45 g)

Cruex[®]: 1% (15 g)

Lotrimin[®] AF Athlete's Foot: 1% (12 g, 24 g)

Lotrimin[®] AF Jock Itch: 1% (12 g)

Cream, vaginal: 2% (21 g)

Mycelex[®]-7: 1% (45 g)

Solution, topical: 1% (10 mL, 30 mL)

Lotrimin[®] AF Athlete's Foot: 1% (10 mL)

Tablet, vaginal (Gyne-Lotrimin[®] 3): 200 mg (3s)

Troche (Mycelex[®]): 10 mg

Reference Range Peak serum levels after dermal cream application: <0.001 mcg/mL; after vaginal tablet application, serum levels range from 0.02-0.05 mcg/mL; peak serum levels after a 1.5 g oral dose ranges from 1-5 mcg/mL

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or gastric lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Drug Interactions

Inhibits CYP1A2 (weak), 2A6 (weak), 2B6 (weak), 2C8 (weak), 2C9 (weak), 2C19 (weak), 2D6 (weak), 2E1 (weak), 3A4 (moderate)

CYP3A4 substrates: Clotrimazole may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Pregnancy Risk Factor B (topical); C (troches)

Lactation Excretion in breast milk unknown

Additional Information Periodic assessment of hepatic function is advisable in patients with pre-existing hepatic impairment; re-evaluate topical therapy after one month

Clozapine

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antipsychotic Agents
- Olanzapine

CAS Number 5786-21-0

U.S. Brand Names Clozaril[®]; Fazaclio[™]

Use Treatment of refractory schizophrenia; reduce risk of recurrent suicidal behavior in schizophrenia or schizoaffective disorder

Unlabeled/Investigational Use Schizoaffective disorder, bipolar disorder, childhood psychosis, severe obsessive-compulsive disorder

Mechanism of Action Tricyclic dibenzodiazepine structure; blocks dopamine receptors

Adverse Reactions

Cardiovascular: **Tachycardia**, angina, ECG changes, hypertension, hypotension, syncope, arrhythmias, cardiomyopathy (usually dilated), CHF, MI, myocarditis, pericardial effusion, pericarditis, thromboembolism

Central nervous system: **Drowsiness, dizziness**, akathisia, seizures, headache, nightmares, akinesia, confusion, insomnia, fatigue, myoclonic jerks, restlessness, agitation, lethargy, ataxia, slurred speech, depression, anxiety, neuroleptic malignant syndrome, tardive dyskinesia, stroke, status epilepticus

Dermatologic: Rash, photosensitivity

Endocrine & metabolic: Diabetes mellitus, hyperglycemia

Gastrointestinal: **Constipation, weight gain, sialorrhea**, abdominal discomfort, anorexia, diarrhea, heartburn, xerostomia, nausea, vomiting, fecal impaction, intestinal obstruction, paralytic ileus, salivary gland swelling

Genitourinary: **Urinary incontinence**, difficult urination, impotence

Hematologic: Eosinophilia, leukopenia, leukocytosis, agranulocytosis, granulocytopenia, thrombocytopenia

Hepatic: Liver function tests abnormal, cholestasis, hepatitis, jaundice

Neuromuscular & skeletal: Tremor, rigidity, hyperkinesia, weakness,

Ocular: Visual disturbances, blurred vision, narrow-angle glaucoma

Respiratory: Rhinorrhea, pulmonary embolism, aspiration

Miscellaneous: Diaphoresis (increased), fever, ESR increased, systemic lupus erythematosus

See table.

Clozapine-Induced Side Effects		
INCIDENCE AND MANAGEMENT		
Effect	Incidence	Management
Sedation & fatigue	35%	Initiate split dosing with long-term goal to administer twice daily with larger portion at bedtime (appears to be dose-dependent). For chronic sedation, consider an empiric trial of methylphenidate 5-20 mg/day.
Sialorrhea	25%	Clozapine may affect the swallowing mechanism; behavioral approach may be best. Consider lowering the dose. Pharmacological management consists of clonidine 0.1-0.9 mg/day (monitor blood pressure) or benzotropine 0.5-2 mg/day (monitor for increased anticholinergic side effects).
Weight gain	35%	Diet and exercise best. No pharmacological agent shown to be consistently useful; one study showed the addition of quetiapine to clozapine minimized weight gain; consider lowering dose.

INCIDENCE AND MANAGEMENT		
Effect	Incidence	Management
Urinary incontinence	25%	If patient receiving co-pharmacy with typical antipsychotic, consider discontinuing; pharmacological management consists of ephedrine 25-150 mg/d, oxybutynin 5 mg tid, or desmopressin.
Tachycardia	25%	Dose dependent. Beta-blocker; atenolol 50 mg/d or propranolol 10 mg tid (adjust for rate)
Constipation	20%	Discontinue other medications with anticholinergic activity, if possible. May need chronic psyllium and/or docusate.
Seizures	4%	Dose dependent. Valproic acid/valproate; initiate at 250 mg tid or 500 mg bid and titrate to serum level of at least 50 mcg/mL
Agranulocytosis	1%	Stop drug. Do not rechallenge. Consider filgrastim (G-CSF) or sargramostim (GM-CSF) during acute recovery phase.

Signs and Symptoms of Overdose Agitation, ataxia, coma, cognitive dysfunction, delirium, disorientation, enuresis, eosinophilia, extrapyramidal reaction, fasciculations, hypertension, hypoglycemia, hypotension, hypotonicity, impotence, inability to urinate, myoclonus, nausea, neuroleptic malignant syndrome, nystagmus, Parkinson's-like symptoms, salivation, seizures, torticollis, vomiting

Admission Criteria/Prognosis Admit any patient exhibiting acidosis or neurologic sequelae

Pharmacodynamics/Kinetics

Protein binding: 97% to serum proteins

Metabolism: Extensively hepatic; forms metabolites with limited or no activity

Bioavailability: 12% to 81% (not affected by food)

Half-life elimination: Steady state: 12 hours (range: 4-66 hours)

Time to peak: 2.5 hours (range: 1-6 hours)

Excretion: Urine (~50%) and feces (30%) with trace amounts of unchanged drug

Dosage

Oral: If dosing is interrupted for >48 hours, therapy must be reinitiated at 12.5-25 mg/day; may be increased more rapidly than with initial titration.

Children and Adolescents: Childhood psychosis (unlabeled use): Initial: 25 mg/day; increase to a target dose of 25-400 mg/day

Adults: Schizophrenia or to reduce risk of suicidal behavior: Initial: 12.5 mg once or twice daily; increased, as tolerated, in increments of 25-50 mg/day to a target dose of 300-450 mg/day after 2-4 weeks, may require doses as high as 600-900 mg/day for the treatment of schizophrenia; median dose to reduce risk of suicidal behavior is ~300 mg/day (range 12.5-900 mg)

Elderly: Schizophrenia: Dose selection and titration should be cautious

Note: In the event of planned termination of clozapine, gradual reduction in dose over a 1- to 2-week period is recommended. If conditions warrant abrupt discontinuation (leukopenia), monitor patient for psychosis and cholinergic rebound (headache, nausea, vomiting, diarrhea).

Monitoring Parameters

Mental status, ECG, WBC (see below), vital signs, fasting lipid profile and fasting blood glucose/Hgb A_{1c} (prior to treatment, at 3 months, then annually; BMI, personal/family history of obesity; waist circumference (weight should be assessed prior to treatment, at 4 weeks, 8 weeks, 12 weeks, and then at quarterly intervals. Consider titrating to a different antipsychotic agent for a weight gain ≥5% of the initial weight); blood pressure; abnormal involuntary movement scale (AIMS).

WBC and ANC should be obtained at baseline and at least weekly for the first 6 months of continuous treatment. If counts remain acceptable (WBC ≥3500/mm³, ANC ≥2000/mm³) during this time period, then they may be monitored every other week for the next 6 months. If WBC/ANC continue to remain within these acceptable limits after the second 6 months of therapy, monitoring can be decreased to every 4 weeks. (**Note:** The decrease in monitoring to every 4 weeks is applicable in the United States. Blood monitoring requirements related to the use of clozapine have not changed in Canada). If clozapine is discontinued, a weekly WBC should be conducted for an additional 4 weeks or until WBC is ≥3500/mm³ and ANC is ≥2000/mm³. If clozapine therapy is interrupted due to moderate leukopenia, weekly WBC/ANC monitoring is required for 12 months in patients restarted on clozapine treatment. If therapy is interrupted for reasons other than leukopenia/granulocytopenia, the 6-month time period for initiation of biweekly WBCs may need to be reset. This determination depends upon the treatment duration, the length of the break in therapy, and whether or not an abnormal blood event occurred.

Consult full prescribing information for determination of appropriate WBC/ANC monitoring interval (<http://www.clozaril.com/index.jsp>).

Administration

Orally-disintegrating tablet: Should be removed from foil blister by peeling apart (do not push tablet through the foil). Remove immediately prior to use. Place tablet in mouth and allow to dissolve; swallow with saliva. If dosing requires splitting tablet, throw unused portion away. May be taken without regard to food. Fazaclo™ contains phenylalanine 1.75 mg per 25 mg tablet and phenylalanine 6.96 mg per 100 mg tablet.

Contraindications Hypersensitivity to clozapine or any component of the formulation; history of agranulocytosis or granulocytopenia with clozapine; uncontrolled epilepsy, severe central nervous system depression or comatose state; paralytic ileus; myeloproliferative disorders or use with other agents which have a well-known risk of agranulocytosis or bone marrow suppression

Warnings

[U.S. Boxed Warning]: Patients with dementia-related behavioral disorders treated with atypical antipsychotics are at an increased risk of death compared to placebo. Clozapine is not approved for this indication.

[U.S. Boxed Warning]: Significant risk of agranulocytosis, potentially life-threatening. Therapy should not be initiated in patients with WBC <3500 cells/mm³ or ANC <2000 cells/mm³ or history of myeloproliferative disorder. WBC testing should occur periodically on an on-going basis (see prescribing information for monitoring details) to ensure that acceptable WBC/ANC counts are maintained. Initial episodes of moderate leukopenia or granulopoietic suppression confer up to a 12-fold increased risk for subsequent episodes of agranulocytosis. WBCs must be monitored weekly for at least 4 weeks after therapy discontinuation or until WBC is ≥3500/mm³ and ANC is ≥2000/mm³. Use with caution in patients receiving other marrow suppressive agents. Eosinophilia has been reported to occur with clozapine and may require temporary or permanent interruption of therapy. Due to the significant risk of agranulocytosis, it is strongly recommended that a patient must fail at least two trials of other primary medications for the treatment of schizophrenia (of adequate dose and duration) before initiating therapy with clozapine.

Cognitive and/or motor impairment (sedation) is common with clozapine, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving); use caution in patients receiving general anesthesia. **[U.S. Boxed Warning]: Seizures have been associated with clozapine use in a dose-dependent manner;** use with caution in patients at risk of seizures, including those with a history of seizures, head trauma, brain damage, alcoholism, or concurrent therapy with medications which may lower seizure threshold. Has been associated with benign, self-limiting fever (<100.4°F, usually within first 3 weeks). However, clozapine may also be associated with severe febrile reactions, including neuroleptic malignant syndrome (NMS). Clozapine's potential for extrapyramidal symptoms (including tardive dyskinesia) appears to be extremely low.

Deep vein thrombosis, myocarditis, pericarditis, pericardial effusion, cardiomyopathy, and CHF have also been associated with clozapine. **[U.S. Boxed Warning]: Fatalities due to myocarditis have been reported; highest risk in the first month of therapy, however, later cases also reported.** Myocarditis or cardiomyopathy should be considered in patients who present with signs/symptoms of heart failure (dyspnea, fatigue, orthopnea, paroxysmal nocturnal dyspnea, peripheral edema), chest pain, palpitations, new electrocardiographic abnormalities (arrhythmias, ST-T wave abnormalities), or unexplained fever. Patients with tachycardia during the first month of therapy should be closely monitored for other signs of myocarditis. Discontinue clozapine if myocarditis is suspected; do not rechallenge in patients with clozapine-related myocarditis. The reported rate of myocarditis in clozapine-treated patients appears to be 17-322 times greater than in the general population. Clozapine should be discontinued in patients with confirmed cardiomyopathy unless benefit clearly outweighs risk. Rare cases of thromboembolism, including pulmonary embolism and stroke resulting in fatalities, have been associated with clozapine.

May cause anticholinergic effects; use with caution in patients with urinary retention, benign prostatic hyperplasia, narrow-angle glaucoma, xerostomia, visual problems, constipation, or history of bowel obstruction. May cause hyperglycemia; in some cases may be extreme and associated with ketoacidosis, hyperosmolar coma, or death. Use with caution in patients with diabetes or other disorders of glucose regulation; monitor for worsening of glucose control. Use with caution in patients with hepatic disease or impairment; hepatitis has been reported as a consequence of therapy.

Use caution with cardiovascular, renal, or pulmonary disease. **[U.S. Boxed Warning]: May cause orthostatic hypotension (with or without syncope)** and tachycardia; use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). Concurrent use with benzodiazepines may increase the risk of severe cardiopulmonary reactions.

The possibility of a suicide attempt is inherent in psychotic illness or bipolar disorder; use caution in high-risk patients during initiation of

therapy. Prescriptions should be written for the smallest quantity consistent with good patient care.

Medication should not be stopped abruptly; taper off over 1-2 weeks. If conditions warrant abrupt discontinuation (leukopenia, myocarditis, cardiomyopathy), monitor patient for psychosis and cholinergic rebound (headache, nausea, vomiting, diarrhea). Consider titrating to a different antipsychotic agent for a weight gain $\geq 5\%$ of the initial weight). Elderly patients are more susceptible to adverse effects (including agranulocytosis, cardiovascular, anticholinergic, and tardive dyskinesia).

Dosage Forms

Tablet: 12.5 mg, 25 mg, 100 mg

Clozaril®: 25 mg, 100 mg

Tablet, orally disintegrating (FazaClo®): 25 mg [contains phenylalanine 1.75 mg; mint flavor], 100 mg [contains phenylalanine 6.96 mg; mint flavor]

Reference Range Therapeutic: 200-400 ng/mL; levels >500 ng/mL associated with change in mental status in children; levels >2000 ng/mL associated with CNS changes in adults; highest survivable clozapine serum level of 5200 ng/mL followed a 3 g clozapine ingestion and deep coma.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: I.V. fluids for hypotension; lorazepam, diazepam, phenobarbital, or phenytoin for seizures; granulocyte colony-stimulating factor may be useful for agranulocytosis; clozapine-induced hypotension (orthostatic) can be treated with fludrocortisone 0.1 mg/day, with increasing doses to 0.3 mg/day over 2 weeks; desmopressin (intranasal: 10 mcg at bedtime) can be used to treat clozapine-induced enuresis; lithium (600-900 mg/day) can be given to treat clozapine-induced neutropenia; pirenzepine (25-100 mg/day) can be used to treat clozapine-induced hypersalivation; benztropine at a dose of 2 mg/day can be used to treat sialorrhea; diphenhydramine can be used to treat extrapyramidal symptoms; clozapine-induced incontinence may respond to ephedrine (up to 150 mg/day); intranasal ipratropium bromide may be useful in the treatment of clozapine-induced sialorrhea

Enhancement of elimination: Multiple dose of activated charcoal may be useful

Antidote(s)

- Filgrastim [ANTIDOTE]

Test Interactions Nitrazepam can cause false elevation (~15%) of serum clozapine

Drug Interactions

Substrate of CYP1A2 (major), 2A6 (minor), 2C9 (minor), 2C19 (minor), 2D6 (minor), 3A4 (minor); **Inhibits** CYP1A2 (weak), 2C9 (weak), 2C19 (weak), 2D6 (moderate), 2E1 (weak), 3A4 (weak)

Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Anticholinergics: Clozapine has potent anticholinergic effects. May potentiate the effects of anticholinergic agents.

Antihypertensives: Clozapine may potentiate the hypotensive effects of antihypertensive agents.

Benzodiazepines: In combination with clozapine, may produce respiratory depression and hypotension, especially during the first few weeks of therapy; monitor for altered response.

Carbamazepine: A case of neuroleptic malignant syndrome has been reported in combination with clozapine; in addition, carbamazepine may alter clozapine levels (see enzyme inducers); monitor.

Citalopram: May increase the levels/effects of clozapine; monitor.

CNS depressants: Sedative effects may be additive with other CNS depressants; includes ethanol, barbiturates, benzodiazepines, narcotic analgesics, and other sedatives.

CYP1A2 inducers: May decrease the levels/effects of clozapine. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of clozapine. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

CYP2D6 substrates: Clozapine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Clozapine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

Epinephrine: Clozapine may reverse the pressor effect of epinephrine; use should be avoided in the treatment of drug-induced hypotension.

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk.

Omeprazole: May alter the concentrations/effects of clozapine; monitor.

Risperidone: Effects and/or toxicity may be increased when combined with clozapine; monitor.

Valproic acid: May cause reductions in clozapine concentrations; monitor for altered response.

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic effects were not seen in animal studies; however, there are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if clearly needed.

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Additional Information May be useful in the treatment of neuroleptic-induced vomiting (in doses up to 500 mg/day); ECG effects include T-wave inverse, S-T depression and S-T segment elevation

Cocaine

Related Information

- Donor Victims of Poisoning in Whom Transplantation of Organs Occurred

- Substance-Related Disorders

CAS Number 50-36-2; 53-21-4

Synonyms Cocaine Hydrochloride

Impairment Potential Yes. Positive qualitative urinary test for cocaethylene or the parent compound of cocaine is consistent with recent usage

Use Topical anesthesia for mucous membranes

Mechanism of Action Blocks both the initiation and conduction of nerve impulses by decreasing the neuronal membrane's permeability to sodium ions, which results in inhibition of depolarization with resultant blockade of conduction; interferes with the uptake of norepinephrine by adrenergic nerve terminals producing vasoconstriction; a type I antiarrhythmic

Adverse Reactions

Cardiovascular: Decreased heart rate with low doses, tachycardia with moderate doses, hypertension, cardiomyopathy, cardiac arrhythmias, myocarditis, QRS prolongation, Raynaud's phenomenon, cerebral vasculitis, thrombosis, fibrillation (atrial), flutter (atrial), sinus bradycardia, congestive heart failure, pulmonary hypertension, sinus tachycardia, tachycardia (supraventricular), arrhythmias (ventricular), vasoconstriction

Central nervous system: **CNS stimulation**, fever, nervousness, restlessness, euphoria, excitation, headache, psychosis, hallucinations, agitation, seizures, slurred speech, hyperthermia, dystonic reactions, cerebrovascular accident, vasculitis, clonic-tonic reactions, paranoia, sympathetic storm, aggressive behavior, leukoencephalopathy

Dermatologic: Skin infarction, pruritus, madarosis, bullous skin disease
Gastrointestinal: **Loss of taste perception**, nausea, anorexia, colonic ischemia

Genitourinary: Priapism, uterine rupture

Hematologic: Thrombocytopenia

Neuromuscular & skeletal: Chorea (extrapyramidal), paresthesia, tremors, fasciculations

Ocular: Mydriasis (peak effect at 45 minutes; may last up to 12 hours), sloughing of the corneal epithelium, ulceration of the cornea, iritis, mydriasis, chemosis

Renal: Myoglobinuria, necrotizing vasculitis

Respiratory: **Rhinitis, nasal congestion**, tachypnea, nasal mucosa damage (when snorting), hyposmia, bronchiolitis obliterans organizing pneumonia, acute respiratory distress syndrome, alveolar hemorrhage, pneumothorax, pneumomediastinum, eosinophilic pneumonia

Miscellaneous: **Loss of smell**, spontaneous bowel perforation, "washed-out" syndrome, asthma, Pott puffy tumor (PPT), acute atraumatic compartment syndrome

Signs and Symptoms of Overdose Abdominal pain, angina, apnea, ataxia, blurred vision, cardiomegaly, chest pain, CNS hemorrhage, colitis, coma, corneal irritation, delirium, dental erosion, depression, disorientation, dry mouth, dyspnea, epistaxis, euphoria, extrapyramidal reaction, hallucinations, hyperreflexia, hypertension, hyperthermia, impotence, insomnia, intracranial hemorrhage, lacrimation, mania, migraine headache (exacerbation), muscular spasm, myalgia, mydriasis, myocardial depression, myoglobinuria, nasal congestion, nystagmus, paroxysmal tachycardia (ventricular), photophobia, ptosis, rhabdomyolysis, respiratory alkalosis, respiratory depression, restlessness, seizures, sensory aberrations, sweating, tachycardia (ventricular), vomiting

Admission Criteria/Prognosis Patients with moderate to severe acute symptomatology (including chest pain, severe hyperadrenergic signs, hyperthermia, rhabdomyolysis, coagulopathy, mental status changes) should be admitted to an intensive care unit; patients with mild hyperadrenergic signs can be monitored for 6 hours and if resolving, can then be discharged; all body packers/body stuffers should be admitted even if asymptomatic (most complications occur within 4 hours).

Pharmacodynamics/Kinetics

Onset of action: Topical: Within 5 minutes following administration to mucosa; Inhalation: 3-5 seconds; I.V.: 10-60 seconds

Peak action: Inhalation: 1-3 minutes; I.V.: 3-5 minutes; Intranasal: 15-20 minutes

Duration: Inhalation: 5-15 minutes; I.V.: 20-60 minutes; Intranasal: 60-90 minutes

Absorption: Well absorbed through mucous membranes, limited by drug-induced vasoconstriction, and enhanced by inflammation

Distribution: V_d : 1.96-2.7 L/kg

Protein binding: ~90%

Metabolism: In the liver to benzoylecgonine, ecgonine methylester and norcocaine (active)

Bioavailability: Cocaine Smoked in glass pipes: 70%; Cocaine Smoked in corn cob pipes: 60%; Intranasal route: Dose dependent: 25% to 94%; Oral: 30%

Half-life: (Benzoylecgonine from all 3 routes: 3.55-5.79 hours); During first week of life: Cocaine: 11.6 hours; Benzoylecgonine: 11.2 hours; Intravenous: 37-41 minutes; Smoked: 58-89 minutes; Intranasal: 73-207 minutes

Elimination: Excreted primarily in urine as metabolites (benzoylecgonine and ecgonine methylester) unchanged drug (< 10%)

Dosage Topical application (ear, nose, throat, bronchoscopy): Dosage depends on the area to be anesthetized, tissue vascularity, technique of anesthesia, and individual patient tolerance; the lowest dose necessary to produce adequate anesthesia should be used; concentrations of 1% to 10% are used (not to exceed 1 mg/kg). Use reduced dosages for children, elderly, or debilitated patients.

Stability Store in well closed, light-resistant containers

Monitoring Parameters Vital signs

Administration

Topical: Use only on mucous membranes of the oral, laryngeal, and nasal cavities. Do not use on extensive areas of broken skin.

Contraindications Hypersensitivity to cocaine or any component of the topical solution; ophthalmologic anesthesia (causing sloughing of the corneal epithelium); pregnancy (nonmedicinal use)

Warnings For topical use only. Limit to office and surgical procedures only. Resuscitative equipment and drugs should be immediately available when any local anesthetic is used. Debilitated, elderly patients, acutely ill patients, and children should be given reduced doses consistent with their age and physical status. Use caution in patients with severely traumatized mucosa and sepsis in the region of the proposed application. Use with caution in patients with cardiovascular disease or a history of cocaine abuse. In patients being treated for cardiovascular complication of cocaine abuse, avoid beta-blockers for treatment.

Dosage Forms

Powder, as hydrochloride: 1 g, 5 g, 25 g

Solution, topical, as hydrochloride: 4% [40 mg/mL] (4 mL, 10 mL); 10% [100 mg/mL] (4 mL, 10 mL)

Reference Range

Therapeutic: 100-500 ng/mL (SI: 330 nmol/L)

Toxic: >1000 ng/mL (SI: >3300 nmol/L)

Blood cocaine levels in "bodypackers" may exceed 50,000 ng/mL

Average blood levels after smoking a standard dose of crack cocaine: 600-700 ng/mL

Average postmortem blood cocaine levels from deceased cocaine abusers: 2500 ng/mL

Highest postmortem cocaine level from bodypacker: 104,000 ng/mL

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Topical ophthalmic cocaine (10%) will cause a positive urine cocaine screen of ~48 hours when applied therapeutically in the eye.

Overdosage/Treatment

Decontamination: Activated charcoal is useful for oral ingestion; whole bowel irrigation should be considered for body packers or body stuffers of cocaine packets; oral bicarbonate decreased gastrointestinal cocaine absorption for body packers/stuffers in an *in vitro* model

Supportive therapy: Since no specific antidote for cocaine exists, serious toxic effects are treated symptomatically. Seizures are treated with lorazepam or diazepam. Benzodiazepines may also be useful for life-threatening arrhythmias, agitation, and/or hypertension. Sodium bicarbonate may decrease QRS prolongation. Phentolamine can be used for cocaine-induced vasoconstriction therapy. Hypertension can be treated with nitroprusside (0.5-10 mcg/kg/minute), nitroglycerin (10 mcg/minute), phentolamine (5-10 mg I.V.), or enalaprilat (0.625-1.25 mg). Although lidocaine may promote cocaine-induced seizures, it is probably safe to use if used over 3 hours after cocaine use. Lidocaine and sodium bicarbonate are first-line agents for hemodynamically stable ventricular tachycardia or refractory ventricular fibrillation. The combination of esmolol and lorazepam has been advocated to treat hyperadrenergic crisis, but this combination has not been well studied. Labetalol or beta adrenergic blockers are not recommended to treat cocaine-associated myocardial ischemia. Nicardipine (50 mg/hour I.V.) has been used to control hypertension due to crack cocaine overdose. Active cooling measures should take place if core temperature exceeds 40°C. Thrombolytic agents (preferably by intracoronary administration) can be used to treat acute coronary syndrome if uncontrolled hypertension does not exist.

Enhancement of elimination: Butyrylcholinesterase is strictly investigational; bisacodyl, psyllium, hydrophilic mucilloid, saline, or emollient laxative can be used to enhance fecal excretion of body packages.

Antidote(s)

- Phentolamine [ANTIDOTE]

Drug Interactions

Substrate of CYP3A4 (major); **Inhibits** CYP2D6 (strong), 3A4 (weak) Beta-blockers potentiate cocaine-induced coronary vasoconstriction (potentiate alpha-adrenergic effect of cocaine); avoid concurrent use.

CYP2D6 substrates: Cocaine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Cocaine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 inhibitors: May increase the levels/effects of cocaine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Sympathomimetic amines may cause malignant arrhythmias; avoid concurrent use.

Pregnancy Risk Factor C/X (nonmedicinal use)

Pregnancy Implications Sustained arrhythmias may occur in the neonatal period; genitourinary abnormalities may occur; prenatal cocaine exposure can impair fetal growth in a dose-dependent manner; uterine rupture can occur during late gestation

Lactation Enters breast milk/contraindicated

Additional Information

May cause corneas to become clouded or pitted, therefore, normal saline should be used to irrigate and protect corneas during surgery; not for injection; converted to cocaine sulfate as a drug of abuse; may precipitate porphyria. Increased incidence of anticardiolipin antibody has been reported in cocaine abusers (especially with I.V. use); positive rheumatoid factor also has been noted in cocaine abusers. Incidence of acute myocardial infarction in patients with cocaine-associated chest pain is ~6%; initial ECG is only sensitive for 36% of acute myocardial infarction; ethanol plus cocaine use produces cocaethylene which has a longer half-life (~2 hours) than cocaine. While cocaethylene can produce tachycardia, myocardial depression, and is a competitive muscarinic antagonist, no direct effect on blood pressure is usually seen. Age, cardiac risk factors, inferior infarction, and bradydysrhythmias can predict underlying coronary artery disease in cocaine-induced myocardial infarctions.

In a rodent model, cocaethylene may continue to form after death, but hepatic postmortem cocaethylene production ceases 1 hour after death. Cocaine is present on 79% of U.S. Currency analyzed in amounts >0.1 mcg and in 54% in amounts >1 mcg (highest amount recorded was 1327 mcg). Anticonvulsants (phenytoin, carbamazepine) have been used to treat cocaine dependence.

According to the Drug Abuse Warning Network, in 2004:

- Cocaine was involved in an estimated 383,350 Emergency Department (ED) visits.
- Cocaine and alcohol accounted for an estimated 83,816 ED visits.
- 46% of Cocaine ED visits involved Seeking detox.
- 13,940 cocaine ED visits involved a suicide attempt.

U.S. retail price per gram: 1981: \$500; 2000: \$150. Production in certain countries in 2000: Columbia: 266 tons; Peru: 54 tons; Bolivia: 13 tons.

- U.S. spending on illicit cocaine: 1988: 76 billion dollars; 2000: 36 billion dollars. Recovery rate from addiction is about 90%; about 21% of all U.S. drug users are dependent on cocaine (1999 data).

Ocular: Miosis
Respiratory: Apnea, respiratory depression, aspiration
Miscellaneous: Physical and psychological dependence, histamine release, fixed drug eruption

Signs and Symptoms of Overdose Ataxia, constipation, erythema multiforme, hallucinations, hypocalcemia, miosis, myasthenia gravis (exacerbation or precipitation), myoglobinuria, respiratory failure, rhabdomyolysis, somnolence, syncope, syndrome of inappropriate antidiuretic hormone (SIADH), urine discoloration (milky), vomiting

Pharmacodynamics/Kinetics

Onset of action: Oral: 0.5-1 hour; I.M.: 10-30 minutes

Peak effect: Oral: 1-1.5 hours; I.M.: 0.5-1 hour

Duration: 4-6 hours

Absorption: Oral: Adequate

Distribution: Crosses placenta; enters breast milk

Protein binding: 7%

Metabolism: Hepatic to morphine (active)

Half-life elimination: 2.5-3.5 hours

Excretion: Urine (3% to 16% as unchanged drug, norcodeine, and free and conjugated morphine)

Dosage

Note: These are guidelines and do not represent the maximum doses that may be required in all patients. Doses should be titrated to pain relief/prevention. Doses > 1.5 mg/kg body weight are not recommended.

Analgesic:

Children: Oral, I.M., SubQ: 0.5-1 mg/kg/dose every 4-6 hours as needed; maximum: 60 mg/dose

Adults:

Oral: 30 mg every 4-6 hours as needed; patients with prior opiate exposure may require higher initial doses. Usual range: 15-120 mg every 4-6 hours as needed

Oral, controlled release formulation (Codeine Contin[®], not available in U.S.): 50-300 mg every 12 hours. **Note:** A patient's codeine requirement should be established using prompt release formulations; conversion to long acting products may be considered when chronic, continuous treatment is required. Higher dosages should be reserved for use only in opioid-tolerant patients.

I.M., SubQ: 30 mg every 4-6 hours as needed; patients with prior opiate exposure may require higher initial doses. Usual range: 15-120 mg every 4-6 hours as needed; more frequent dosing may be needed

Antitussive: Oral (for nonproductive cough):

Children: 1-1.5 mg/kg/day in divided doses every 4-6 hours as needed; Alternative dose according to age:

2-6 years: 2.5-5 mg every 4-6 hours as needed; maximum: 30 mg/day

6-12 years: 5-10 mg every 4-6 hours as needed; maximum: 60 mg/day

Adults: 10-20 mg/dose every 4-6 hours as needed; maximum: 120 mg/day

Dosing adjustment in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer 75% of dose

Cl_{cr} < 10 mL/minute: Administer 50% of dose

Dosing adjustment in hepatic impairment: Probably necessary in hepatic insufficiency

Stability Store injection between 15°C to 30°C, avoid freezing; do not use if injection is discolored or contains a precipitate; protect injection from light

Monitoring Parameters Pain relief, respiratory and mental status, blood pressure, heart rate

Administration

Not approved for I.V. administration (although this route has been used clinically). If given intravenously, must be given slowly and the patient should be lying down. Rapid intravenous administration of narcotics may increase the incidence of serious adverse effects, in part due to limited opportunity to assess response prior to administration of the full dose. Access to respiratory support should be immediately available.

Contraindications Hypersensitivity to codeine or any component of the formulation; pregnancy (prolonged use or high doses at term)

Warnings

An opioid-containing analgesic regimen should be tailored to each patient's needs and based upon the type of pain being treated (acute versus chronic), the route of administration, degree of tolerance for opioids (naive versus chronic user), age, weight, and medical condition. The optimal analgesic dose varies widely among patients. Doses should be titrated to pain relief/prevention.

Use with caution in patients with hypersensitivity reactions to other phenanthrene derivative opioid agonists (morphine, hydrocodone, hydromorphone, levorphanol, oxycodone, oxymorphone); respiratory diseases including asthma, emphysema, COPD, or severe liver or renal insufficiency; some preparations contain sulfites which may cause allergic reactions; tolerance or drug dependence may result from extended use

Codeine

CAS Number 1420-53-7; 1422-07-7; 41444-62-6; 52-28-8; 5913-76-8; 6854-40-6; 76-57-3

Synonyms Codeine Phosphate; Codeine Sulfate; MethyImorphine

Impairment Potential Yes. Serum codeine level > 2.6 mg/L is consistent with driving impairment

Use Treatment of mild to moderate pain; antitussive in lower doses; dextromethorphan has equivalent antitussive activity but has much lower toxicity in accidental overdose

Mechanism of Action Binds to opiate receptors in the CNS, causing inhibition of ascending pain pathways, altering the perception of and response to pain; causes cough suppression by direct central action in the medulla; produces generalized CNS depression; also has a dose-related histamine-releasing effect

Adverse Reactions

Cardiovascular: Palpitations, hypotension, bradycardia, peripheral vasodilation, sinus bradycardia

Central nervous system: CNS depression, psychosis, increased intracranial pressure, agitation, dizziness, **drowsiness**, sedation

Dermatologic: Pruritus, systemic contact dermatitis, exfoliative dermatitis, pityriasis rosea-like reaction, acute generalized exanthematous pustulosis, angioedema, bullous skin disease, toxic epidermal necrolysis, erythema nodosum, exanthem

Endocrine & metabolic: Antidiuretic hormone release

Gastrointestinal: Nausea, vomiting, **constipation**, adynamic ileus, biliary tract spasm, xerostomia, pancreatitis

Genitourinary: Urinary tract spasm, urinary incontinence

Neuromuscular & skeletal: Paresthesia

COLCHICINE

Not recommended for use for cough control in patients with a productive cough; not recommended as an antitussive for children <2 years of age; the elderly may be particularly susceptible to the CNS depressant and confusion as well as constipating effects of narcotics

Not approved for I.V. administration (although this route has been used clinically). If given intravenously, must be given slowly and the patient should be lying down. Rapid intravenous administration of narcotics may increase the incidence of serious adverse effects, in part due to limited opportunity to assess response prior to administration of the full dose. Access to respiratory support should be immediately available

Dosage Forms

[CAN] = Canadian brand name

Injection, as phosphate: 15 mg/mL (2 mL); 30 mg/mL (2 mL) [contains sodium metabisulfite]

Tablet, as phosphate: 30 mg, 60 mg

Tablet, as sulfate: 15 mg, 30 mg, 60 mg

Tablet, controlled release (Codeine Contin®) [CAN]: 50 mg, 100 mg, 150 mg, 200 mg [not available in U.S.]

Reference Range

Therapeutic: 13-33 ng/mL

Toxic: Serum: >1.0 mcg/mL. In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Lethal: >1000 ng/mL

Methodology: Radioimmunoassay (RIA), gas chromatography (GC), high performance liquid chromatography (HPLC)

Peak codeine:morphine serum ratio: ~33:1

Overdosage/Treatment

Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at $\frac{2}{3}$ the response dose/hour) may be required

Enhancement of elimination: Multiple dosing of activated charcoal may be useful

Antidote(s)

- Nalmefene [ANTIDOTE]
- Naloxone [ANTIDOTE]

Test Interactions

↑ aminotransferases (ALT, AST) (S)

Drug Interactions

Substrate of CYP2D6 (major), 3A4 (minor); **Inhibits** CYP2D6 (weak) CYP2D6 inhibitors: May decrease the effects of codeine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Decreased effect with cigarette smoking

Increased toxicity: CNS depressants, phenothiazines, TCAs, other narcotic analgesics, guanabenz, MAO inhibitors, neuromuscular blockers

Pregnancy Risk Factor

C/D (prolonged use or high doses at term)

Pregnancy Implications

Crosses the placenta

Lactation

Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications

Observe patient for excessive sedation, respiratory depression, implement safety measures, assist with ambulation

decreases phagocytosis in joints, and lactic acid production, thereby reducing the deposition of urate crystals that perpetuates the inflammatory response; not an analgesic; antimotile, may be responsible for toxicity

Adverse Reactions

Cardiovascular: Hypotension, sinus bradycardia, vasculitis

Central nervous system: Confusion, delirium, seizures

Dermatologic: Rash, alopecia (in 2 to 3 weeks) bullous skin disease, toxic epidermal necrolysis, urticaria, pruritus, axonopathy, licheniform eruptions, exanthem

Endocrine & metabolic: Dehydration

Gastrointestinal: **Nausea, vomiting, diarrhea, abdominal pain**, steatorrhea, fecal discoloration (gray), pancreatitis

Genitourinary: Azoospermia

Hematologic: Leukopenia (in 4-6 days) neutropenia, agranulocytosis (0.8 mg/kg), thrombocytopenia, granulocytopenia, aplastic anemia, methemoglobinemia, megaloblastic anemia

Hepatic: Hepatotoxicity

Neuromuscular & skeletal: Myopathy, peripheral neuritis, paralysis, rhabdomyolysis

Ocular: Diplopia

Renal: Hematuria, acute tubular necrosis

Respiratory: Apnea, respiratory depression, respiratory collapse

Miscellaneous: Aneuploidy induction, fixed drug eruption

Signs and Symptoms of Overdose Apnea, bradycardia, diabetes insipidus, diarrhea, dysosmia, feces discoloration (gray), fever, hematuria, hypernatremia, hyperthermia, hypocalcemia, hypothermia, leukocytosis, myasthenia gravis (exacerbation or precipitation), myoglobinuria, nausea, nephritis, oligospermia (doses over 0.5mg/kg) polyuria, positis, purpura, rhabdomyolysis, sexual dysfunction, vomiting (doses over 0.5 mg/kg)

Admission Criteria/Prognosis Admit any symptomatic patient or ingestion over 0.5 mg/kg.

Pharmacodynamics/Kinetics

Onset of action: Oral: Pain relief: ~12 hours if adequately dosed

Distribution: Concentrates in leukocytes, kidney, spleen, and liver; does not distribute in heart, skeletal muscle, and brain

Protein binding: 10% to 31%

Metabolism: Partially hepatic via deacetylation

Half-life elimination: 12-30 minutes; End-stage renal disease: 45 minutes

Time to peak, serum: Oral: 0.5-2 hours, declining for the next 2 hours before increasing again due to enterohepatic recycling

Excretion: Primarily feces; urine (10% to 20%)

Dosage

Familial Mediterranean fever (unlabeled use): Prophylaxis: Oral:

Children:

≤5 years: 0.5 mg/day

>5 years: 1-1.5 mg/day in 2-3 divided doses

Adults: 1-2 mg daily in divided doses (occasionally reduced to 0.6 mg/day in patients with GI intolerance)

Gouty arthritis: Adults:

Prophylaxis of acute attacks: Oral: 0.6 mg twice daily; initial and/or subsequent dosage may be decreased (ie, 0.6 mg once daily) in patients at risk of toxicity or in those who are intolerant (including weakness, loose stools, or diarrhea); range: 0.6 mg every other day to 0.6 mg 3 times/day

Acute attacks:

Oral: Initial: 0.6-1.2 mg, followed by 0.6 every 1-2 hours; some clinicians recommend a maximum of 3 doses; more aggressive approaches have recommended a maximum dose of up to 6 mg. Wait at least 3 days before initiating another course of therapy

I.V.: Initial: 1-2 mg, then 0.5 mg every 6 hours until response, not to exceed total dose of 4 mg. If pain recurs, it may be necessary to administer additional daily doses. The amount of colchicine administered intravenously in an acute treatment period (generally ~1 week) should not exceed a total dose of 4 mg. Do not administer more colchicine by any route for at least 7 days after a full course of I.V. therapy.

Note: Many experts would avoid use because of potential for serious, life-threatening complications. Should not be administered to patients with renal insufficiency, hepatobiliary obstruction, patients >70 years of age, or recent oral colchicine use. Should be reserved for hospitalized patients who are under the care of a physician experienced in the use of intravenous colchicine.

Recurrent pericarditis (with aspirin): 1-2 mg the first day and then 0.5-1 mg/day for 6 months

Surgery: Gouty arthritis, prophylaxis of recurrent attacks: Adults: Oral: 0.6 mg/day or every other day; patients who are to undergo surgical procedures may receive 0.6 mg 3 times/day for 3 days before and 3 days after surgery

Primary biliary cirrhosis (unlabeled use): Adults: Oral: 0.6 mg twice daily

Elderly: Reduce maintenance/prophylactic dose by 50% in individuals >70 years

Dosing adjustment in renal impairment: Gouty arthritis, acute attacks:

Colchicine

Related Information

- Autumn Crocus

CAS Number

64-86-8

Use

Treatment of acute gouty arthritis attacks and prevention of recurrences of such attacks

Primary biliary cirrhosis; management of familial Mediterranean fever; pericarditis

Mechanism of Action

Alkaloids from meadow saffron; mechanism of action is not completely understood; decreases leukocyte motility,

Oral: Specific dosing recommendations not available from the manufacturer:

Prophylaxis:

Cl_{cr} 35-49 mL/minute: 0.6 mg once daily

Cl_{cr} 10-34 mL/minute: 0.6 mg every 2-3 days

Cl_{cr} < 10 mL/minute: Avoid chronic use of colchicine. Use in serious renal impairment is contraindicated by the manufacturer.

Treatment: Cl_{cr} < 10 mL/minute: Use in serious renal impairment is contraindicated by the manufacturer. If a decision is made to use colchicine, decrease dose by 75%.

Peritoneal dialysis: Supplemental dose is not necessary

Dosage adjustment in hepatic impairment: Avoid in hepatobiliary dysfunction and in patients with hepatic disease.

Monitoring Parameters CBC and renal function test

Administration

I.V.: Injection should be made over 2-5 minutes into tubing of free-flowing I.V. With compatible fluid. Do not administer I.M. or SubQ; severe local irritation can occur following SubQ or I.M. administration. Extravasation can cause tissue irritation.

Tablet: Administer orally with water and maintain adequate fluid intake.

Contraindications Hypersensitivity to colchicine or any component of the formulation; severe renal, gastrointestinal, hepatic, or cardiac disorders; blood dyscrasias; pregnancy (parenteral)

Warnings

Use with caution in debilitated patients or elderly patients; use caution in patients with mild-to-moderate cardiac, GI, renal, or liver disease. Severe local irritation can occur following SubQ or I.M. administration. Dosage reduction is recommended in patients who develop weakness or gastrointestinal symptoms (anorexia, diarrhea, nausea, vomiting) related to drug therapy.

Intravenous: Use only with extreme caution; potential for serious, life-threatening complications. Should not be administered to patients with renal insufficiency, hepatobiliary obstruction, patients > 70 years of age, or recent oral colchicine use. Should be reserved for hospitalized patients who are under the care of a physician experienced in the use of intravenous colchicine.

Dosage Forms

Injection, solution: 0.5 mg/mL (2 mL)

Tablet: 0.6 mg

Reference Range Plasma colchicine level of 12 ng/mL achieved after a 0.96 mg/kg overdose ingestion; patient was severely symptomatic; postmortem femoral blood colchicine level of 62 ng/mL associated with a suicidal overdose; peak plasma colchicine level of 2.2 ng/mL achieved after 1 mg oral dose

Overdosage/Treatment

Decontamination: Emesis not recommended due to potential for seizures; lavage (within 1 hour) indicated if early in ingestion (control seizures with benzodiazepines prior to lavage); activated charcoal with sorbitol (first dose only) 1-2 g/kg at 1/2 first dose every 2-6 hours until toxic symptoms abate and patient is stable

Supportive therapy: Granulocyte colony-stimulating factor (300 mcg/day SubQ) has been used to treat neutropenia; observe 2-12 hours due to latency of symptoms of toxicity; treat manifestations of toxicity accordingly; no specific antidote; supportive care is mainstay of treatment. Serum troponin I (Tnl) elevation with echocardiographic abnormalities may be useful in predicting impending cardiovascular collapse.

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; dialysis is not effective; not dialyzable (0% to 5%); colchicine specific antibodies are investigational

Antidote(s)

- Filgrastim [ANTIDOTE]

Test Interactions May cause false-positive urine tests for erythrocytes or hemoglobin; interferes with urine tests for hydrocorticoids

Drug Interactions Substrate of CYP3A4 (major); **Induces** CYP2C8 (weak), 2C9 (weak), 2E1 (weak), 3A4 (weak)

Cyclosporine: Concurrent use with colchicine may increase toxicity of colchicine.

CYP3A4 inhibitors: May increase the levels/effects of colchicine. Example inhibitors include azole antifungals, diclofenac, doxycycline, imatinib, isoniazid, nefazodone, nifedipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Macrolide antibiotics (clarithromycin, erythromycin, troleandomycin): May decrease the metabolism of colchicine resulting in severe colchicine toxicity. Avoid, if possible.

Telithromycin: May decrease the metabolism of colchicine resulting in colchicine toxicity. Avoid, if possible.

Verapamil: May increase colchicine toxicity (especially nephrotoxicity).

Pregnancy Risk Factor C (oral); D (parenteral)

Lactation Enters breast milk/use caution (AAP rates "compatible")

Additional Information Colchicine-specific Fab fragments are prepared from goat antiserum with an affinity constant of $2 \times 10^{10} \text{ M}^{-1}$; total plasma colchicine level may rise six- to tenfold after infusion of antibody fragment; this treatment may not prevent bone marrow depression, but can improve

hemodynamic status; colchicine may be useful in the treatment of Palmer fibromatosis.

Colchicine

Additional info: Probability of death due to ingestion of colchicine equals

$$\frac{e^{(0.964 \times 10^4 \times \text{dose (mg/kg)} + 0.282 (\text{PT}) + 0.265 \times 10^4 (\text{WBC}) + 0.611)}}{1 + e^{(0.964 \times 10^4 \times \text{dose (mg/kg)} + 0.282 (\text{PT}) + 0.265 \times 10^4 (\text{WBC}) + 0.611)}}$$

dose = ingested amount in mg/kg
PT = lowest prothrombin time in % control
WBC = highest white blood cell count in cells per L

Fatal dose: About 0.8 mg/kg

Cortisone

Related Information

- Corticosteroids

CAS Number 50-04-4; 53-06-5

Synonyms Compound E; Cortisone Acetate

Use Management of adrenocortical insufficiency

Mechanism of Action Decreases inflammation by suppression of migration of polymorphonuclear leukocytes and reversal of increased capillary permeability

Adverse Reactions

Cardiovascular: Edema, hypertension, QT prolongation, cardiomegaly, cardiomyopathy

Central nervous system: **Insomnia, nervousness**, mood swings, vertigo, seizures, headache, psychosis, pseudotumor cerebri, delirium, hallucinations, euphoria, depression, mania

Dermatologic: Hirsutism, acne, skin atrophy, hyperpigmentation, bruising, telangiectasia, striae

Endocrine & metabolic: Diabetes mellitus, Cushing's syndrome, pituitary-adrenal axis suppression, growth suppression, glucose intolerance, hypokalemia, alkalosis, amenorrhea, sodium and water retention, hyperglycemia

Gastrointestinal: **Increased appetite, indigestion**, peptic ulcer, nausea, vomiting, black stools, abdominal distention, esophagitis ulceration, pancreatitis

Neuromuscular & skeletal: Muscle weakness, osteoporosis, fractures, arthralgia, muscle wasting, rhabdomyolysis

Ocular: Cataracts, glaucoma

Respiratory: Epistaxis

Miscellaneous: Hypersensitivity reactions

Signs and Symptoms of Overdose When consumed in excessive quantities for prolonged periods, systemic hypercorticism and adrenal suppression may occur. In those cases, discontinuation and withdrawal of the corticosteroid should be done judiciously. Cushingoid changes from continued administration of large doses results in acne, central obesity, diabetes, ecchymoses, electrolyte and fluid imbalance, hirsutism, hyperlipidemia, hypertension, increased susceptibility to infection, moon face, myopathy, osteoporosis, peptic ulcer, sexual dysfunction, and striae.

Pharmacodynamics/Kinetics

Onset of action: Peak effect: Oral: ~2 hours; I.M.: 20-48 hours

Duration: 30-36 hours

Absorption: Slow

Distribution: Muscles, liver, skin, intestines, and kidneys; crosses placenta; enters breast milk

Metabolism: Hepatic to inactive metabolites

Half-life elimination: 0.5-2 hours; End-stage renal disease: 3.5 hours

Excretion: Urine and feces

Toxicodynamics/Kinetics

Peak effect: Oral: Within 2 hours; I.M.: Within 20-48 hours
 Duration of action: 30-36 hours
 Absorption: Slow rate of absorption
 Distribution: Crosses the placenta; appears in breast milk; distributes to muscles, liver, skin, intestines, and kidneys
 Plasma binding: 90%
 Metabolism: In the liver to inactive metabolites
 Half-life: 30 minutes to 2 hours; End stage renal disease: 3.5 hours
 Elimination: In bile and urine
Note: Insoluble in water; supplemental doses may be warranted during times of stress in the course of withdrawing therapy

Dosage

If possible, administer glucocorticoids before 9 AM to minimize adrenocortical suppression; dosing depends upon the condition being treated and the response of the patient; supplemental doses may be warranted during times of stress in the course of withdrawing therapy

Children:

Anti-inflammatory or immunosuppressive:

Oral: 2.5-10 mg/kg/day or 20-300 mg/m²/day in divided doses every 6-8 hours
 I.M.: 1-5 mg/kg/day or 14-375 mg/m²/day in divided doses every 12-24 hours

Physiologic replacement:

Oral: 0.5-0.75 mg/kg/day or 20-25 mg/m²/day in divided doses every 8 hours
 I.M.: 0.25-0.35 mg/kg/day once daily or 12.5 mg/m²/day

Stress coverage for surgery: I.M.: 1 and 2 days before preanesthesia, and 1-3 days after surgery: 50-62.5 mg/m²/day; 4 days after surgery: 31-50 mg/m²/day; 5 days after surgery, resume presurgical corticosteroid dose.

Adults: Oral, I.M.: 25-300 mg/day in divided doses every 12-24 hours

Hemodialysis effects: Supplemental dose is not necessary

Administration

Administer I.M. daily dose before 9 AM to minimize adrenocortical suppression

Contraindications Hypersensitivity to cortisone acetate or any component of the formulation; serious infections, except septic shock or tuberculous meningitis; administration of live virus vaccines; pregnancy

Warnings Use with caution in patients with hypothyroidism, cirrhosis, hypertension, CHF, ulcerative colitis, thromboembolic disorders, osteoporosis, convulsive disorders, peptic ulcer, diabetes mellitus, myasthenia gravis; prolonged therapy (>5 days) of pharmacologic doses of corticosteroids may lead to hypothalamic-pituitary-adrenal suppression, the degree of adrenal suppression varies with the degree and duration of glucocorticoid therapy; this must be taken into consideration when taking patients off steroids

Dosage Forms Tablet, as acetate: 25 mg

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal; acute overdose does not require tapering of dose
 Enhanced elimination: Its metabolite (prednisolone) is slightly dialyzable (5% to 20%)

Test Interactions May cause false elevation of digoxin by Abbott TDx method

Drug Interactions

Decreased effect:
 Barbiturates, phenytoin, rifampin may decrease cortisone effects
 Live virus vaccines
 Anticholinesterase agents may decrease effect
 Cortisone may decrease warfarin effects
 Cortisone may decrease effects of salicylates
 Increased effect: Estrogens (increase cortisone effects)
 Increased toxicity:
 Cortisone + NSAIDs may increase ulcerogenic potential
 Cortisone may increase potassium depletion due to diuretics

Pregnancy Risk Factor D

Lactation Enters breast milk/use caution

Nursing Implications I.M. use only; shake vial before measuring out dose; withdraw gradually following long-term therapy

Additional Information Insoluble in water

Ophthalmic: Treatment of vernal keratoconjunctivitis, vernal conjunctivitis, and vernal keratitis

Unlabeled/Investigational Use Oral: Food allergy, treatment of inflammatory bowel disease

Mechanism of Action Prevents the mast cell release of histamine, leukotrienes and slow-reacting substance of anaphylaxis by inhibiting degranulation after contact with antigens

Adverse Reactions

Cardiovascular: Pericardial effusion, pericarditis with pericardial tamponade
 Central nervous system: Dizziness, headache
 Dermatologic: Rash, eczema, angioedema, cutaneous vasculitis
 Endocrine & metabolic: Parotitis
 Gastrointestinal: **Unpleasant taste (inhalation aerosol)**, xerostomia, nausea, vomiting, diarrhea, throat irritation
 Genitourinary: Dysuria
 Hepatic: Hepatic vasculitis
 Neuromuscular & skeletal: Arthralgia, myositis
 Ocular: Ocular stinging, lacrimation, chemosis
 Respiratory: **Coughing, hoarseness**, sneezing, stuffy nose, wheezing, eosinophilic pneumonia
 Miscellaneous: Eosinophilic pneumonia, anaphylactic reaction, nasal burning, pulmonary infiltrates

Signs and Symptoms of Overdose Bronchospasm, dyspnea, dysuria, lacrimation, laryngeal edema, pericarditis, wheezing

Pharmacodynamics/Kinetics

Onset: Response to treatment:

Nasal spray: May occur at 1-2 weeks

Ophthalmic: May be seen within a few days; treatment for up to 6 weeks is often required

Oral: May occur within 2-6 weeks

Absorption:

Inhalation: ~8% reaches lungs upon inhalation; well absorbed

Oral: < 1% of dose absorbed

Half-life elimination: 80-90 minutes

Time to peak, serum: Inhalation: ~15 minutes

Excretion: Urine and feces (equal amounts as unchanged drug); exhaled gases (small amounts)

Dosage

Oral:

Systemic mastocytosis:

Neonates and preterm Infants: Not recommended

Infants and Children <2 years: 20 mg/kg/day in 4 divided doses; may increase in patients 6 months to 2 years of age if benefits not seen after 2-3 weeks; do not exceed 30 mg/kg/day

Children 2-12 years: 100 mg 4 times/day; not to exceed 40 mg/kg/day

Children > 12 years and Adults: 200 mg 4 times/day

Food allergy and inflammatory bowel disease:

Children <2 years: Not recommended

Children 2-12 years: Initial dose: 100 mg 4 times/day; may double the dose if effect is not satisfactory within 2-3 weeks; not to exceed 40 mg/kg/day

Children > 12 years and Adults: Initial dose: 200 mg 4 times/day; may double the dose if effect is not satisfactory within 2-3 weeks; up to 400 mg 4 times/day

Once desired effect is achieved, dose may be tapered to lowest effective dose

Inhalation:

For chronic control of asthma, taper frequency to the lowest effective dose (ie, 4 times/day to 3 times/day to twice daily):

Nebulization solution: Children >2 years and Adults: Initial: 20 mg 4 times/day; usual dose: 20 mg 3-4 times/day

Metered spray:

Children 5-12 years: Initial: 2 inhalations 4 times/day; usual dose: 1-2 inhalations 3-4 times/day

Children ≥ 12 years and Adults: Initial: 2 inhalations 4 times/day; usual dose: 2-4 inhalations 3-4 times/day

Prevention of allergen- or exercise-induced bronchospasm: Administer 10-15 minutes prior to exercise or allergen exposure but no longer than 1 hour before:

Nebulization solution: Children >2 years and Adults: Single dose of 20 mg

Metered spray: Children >5 years and Adults: Single dose of 2 inhalations

Ophthalmic: Children >4 years and Adults: 1-2 drops in each eye 4-6 times/day

Nasal: Allergic rhinitis (treatment and prophylaxis): Children ≥ 2 years and Adults: 1 spray into each nostril 3-4 times/day; may be increased to 6 times/day (symptomatic relief may require 2-4 weeks)

Dosage in renal/hepatic impairment: Specific guidelines not available; consider lower dose of oral product.

Cromolyn

CAS Number 15826-37-6; 16110-51-3

U.S. Brand Names Crolom[®]; Gastrocrom[®]; Intal[®]; Nasalcrom[®] [OTC]; Opticrom[®]

Synonyms Cromoglycic Acid; Cromolyn Sodium; Disodium Cromoglycate; DSCG

Use

Inhalation: May be used as an adjunct in the prophylaxis of allergic disorders, including rhinitis, asthma; prevention of exercise-induced bronchospasm

Oral: Systemic mastocytosis

Stability

Store at room temperature of 15°C to 30°C (59°F to 86°F); protect from light.

Nebulizer solution is **compatible** with metaproterenol sulfate, isoproterenol hydrochloride, 0.25% isoetharine hydrochloride, epinephrine hydrochloride, terbutaline sulfate, and 20% acetylcysteine solution for at least 1 hour after their admixture

Oral concentrate: Do not use if solution becomes discolored or forms a precipitate.

Monitoring Parameters Periodic pulmonary function tests

Administration

For oral use, cromolyn powder is dissolved in hot water and taken at least 30 minutes before meals

Contraindications Hypersensitivity to cromolyn or any component of the formulation; acute asthma attacks

Warnings Severe anaphylactic reactions may occur rarely; cromolyn is a prophylactic drug with no benefit for acute situations; caution should be used when withdrawing the drug or tapering the dose as symptoms may reoccur; use with caution in patients with a history of cardiac arrhythmias. Transient burning or stinging may occur with ophthalmic use. Dosage of oral product should be decreased with hepatic or renal dysfunction.

Dosage Forms

Aerosol, for oral inhalation, as sodium (Intal®): 800 mcg/inhalation (8.1 g) [112 metered inhalations; 56 doses], (14.2 g) [200 metered inhalations; 100 doses]

Solution for nebulization, as sodium (Intal®): 20 mg/2 mL (60s, 120s)

Solution, intranasal, as sodium [spray] (NasalCrom®): 40 mg/mL (13 mL, 26 mL) [5.2 mg/inhalation; contains benzalkonium chloride]

Solution, ophthalmic, as sodium (Crolom®, Opticrom®): 4% (10 mL) [contains benzalkonium chloride]

Solution, oral, as sodium (Gastrocrom®): 100 mg/5 mL (96s)

Reference Range Plasma levels not relatable to effect; peak plasma level after inhalation: ~15 ng/mL

Overdosage/Treatment

Decontamination: Oral: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Treat inhalation exposure with 100% humidified oxygen; treat anaphylaxis with epinephrine and corticosteroids; albuterol can be given for bronchospasm

Drug Interactions Corticosteroids: Ophthalmic preparation may be used with ophthalmic corticosteroids

Pregnancy Risk Factor B

Pregnancy Implications No known teratogenic effect

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Advise patient to clear as much mucus as possible before inhalation treatments

Additional Information Reserve systemic use in children <2 years of age for severe disease; avoid systemic use in premature infants

Cyanocobalamin

CAS Number 68-19-9

U.S. Brand Names Nascobal®

Synonyms Vitamin B₁₂

Use Treatment of pernicious anemia; vitamin B₁₂ deficiency; increased B₁₂ requirements due to pregnancy, thyrotoxicosis, hemorrhage, malignancy, liver or kidney disease; water-soluble vitamin with a wide margin of safety

Mechanism of Action Coenzyme for various metabolic functions, including fat and carbohydrate metabolism and protein synthesis, used in cell replication and hematopoiesis

Adverse Reactions

Cardiovascular: Peripheral vascular thrombosis

Dermatologic: Itching, rash

Endocrine & metabolic: Hypokalemia, hyperuricemia

Gastrointestinal: Diarrhea, bezoar formation

Miscellaneous: Allergic reactions, exacerbation of multiple myeloma

Signs and Symptoms of Overdose Hypokalemia

Pharmacodynamics/Kinetics

Absorption: Oral: Variable from the terminal ileum; requires the presence of calcium and gastric "intrinsic factor" to transfer the compound across the intestinal mucosa

Distribution: Principally stored in the liver and bone marrow, also stored in the kidneys and adrenals

Protein binding: To transcobalamin II

Metabolism: Converted in tissues to active coenzymes, methylcobalamin and deoxyadenosylcobalamin

Bioavailability: Intranasal:

Gel: 8.9% (relative to I.M.)

Solution: 6.1% (relative to I.M.)

Dosage

Recommended daily allowance (RDA):

Children 1-4 years: 3 mcg/day

Adults: 6 mcg/day

Nutritional deficiency: 25-250 mcg/day

Children:

Congenital pernicious anemia (if evidence of neurologic involvement):

I.M.: 1000 mcg/day for at least 2 weeks; maintenance: 50 mcg/month

Vitamin B₁₂ deficiency: I.M., SubQ: 1-5 mg given in single or SubQ doses of 100 mcg/day over 2 or more weeks

Adults:

Pernicious anemia: I.M., SubQ: 100 mcg/day for 6-7 days

Vitamin B₁₂ deficiency:

Oral: Usually not recommended, maximum absorbed from a single oral dose is 2-3 mcg

I.M., SubQ: 30 mcg/day for 5-10 days, followed by 100-200 mcg/month

Stability Clear pink to red solutions are stable at room temperature; protect from light; **incompatible** with chlorpromazine, phytonadione, prochlorperazine, warfarin, ascorbic acid, dextrose, heavy metals, oxidizing or reducing agents

Monitoring Parameters Serum potassium, erythrocyte and reticulocyte count, hemoglobin, hematocrit

Administration

I.M./SubQ: I.M. or deep SubQ are preferred routes of administration

Intranasal: Nasal spray: Prior to initial dose, activate (prime) spray nozzle by pumping unit quickly and firmly until first appearance of spray, then prime twice more. The unit must be reprimed once immediately before each use.

I.V.: Not recommended due to rapid elimination

Oral: Not recommended due to variable absorption; however, oral therapy of 1000-2000 mcg/day has been effective for anemia if I.M./SubQ routes refused or not tolerated.

Contraindications Hypersensitivity to cyanocobalamin or any component of the formulation, cobalt; hereditary optic nerve atrophy (Leber's disease)

Warnings I.M. route used to treat pernicious anemia; vitamin B₁₂ deficiency for >3 months results in irreversible degenerative CNS lesions; treatment of vitamin B₁₂ megaloblastic anemia may result in severe hypokalemia, sometimes fatal, due to intracellular potassium shift upon anemia resolution. B₁₂ deficiency masks signs of polycythemia vera; vegetarian diets may result in B₁₂ deficiency; pernicious anemia occurs more often in gastric carcinoma than in general population. Patients with Leber's disease may suffer rapid optic atrophy when treated with vitamin B₁₂; an intradermal test dose of parenteral B₁₂ is recommended prior to administration of intranasal product in patients suspected of cyanocobalamin sensitivity; do not use folic acid as substitute for vitamin B₁₂ in preventing anemia, as progression of spinal cord degeneration may occur; some parenteral products contain aluminum: use caution in neonates and patients with renal impairment.

Dosage Forms

[DSC] = Discontinued product

Gel, intranasal (Nascobal®): 500 mcg/0.1 mL (2.3 mL) [contains benzalkonium chloride; delivers 8 doses] [DSC]

Injection, solution: 1000 mcg/mL (1 mL, 10 mL, 30 mL) [may contain benzyl alcohol and/or aluminum]

Lozenge [OTC]: 100 mcg, 250 mcg, 500 mcg

Solution, intranasal spray (Nascobal®): 500 mcg/0.1 mL actuation (2.3 mL) [contains benzalkonium chloride; delivers 8 doses]

Tablet [OTC]: 50 mcg, 100 mcg, 250 mcg, 500 mcg, 1000 mcg, 5000 mcg

Twelve Resin-K: 1000 mcg [may be used as oral, sublingual, or buccal]

Tablet, extended release [OTC]: 1500 mcg

Tablet, sublingual [OTC]: 2500 mcg

Reference Range The lower limit of normal (critical to the diagnosis of B₁₂ deficiency/pernicious anemia) has not been firmly established; it is likely in the range of 100-250 pg/mL (SI: 74-185 pmol/L)

Overdosage/Treatment Supportive therapy: Allergic reactions can be treated with epinephrine, diphenhydramine, and corticosteroids

Test Interactions Methotrexate, pyrimethamine, and most antibiotics invalidate folic acid and vitamin B₁₂ diagnostic microbiological blood assays

Drug Interactions Neomycin, colchicine, anticonvulsants, and metformin may decrease oral absorption of B₁₂; chloramphenicol may decrease B₁₂ effects

Pregnancy Risk Factor A/C (dose exceeding RDA recommendation); C (nasal gel)

Lactation Enters breast milk/compatible

Nursing Implications I.M. or deep SubQ are preferred routes of administration; oral therapy is markedly inferior to parenteral therapy; monitor potassium concentrations during early therapy

Additional Information Radiopaque

Cyclizine

Pronunciation (SYE kli zeen)

CAS Number 303-25-3 (hydrochloride); 5897-19-8 (lactate); 82-92-8 (base)

U.S. Brand Names Marezine® [OTC]

Synonyms Cyclizine Hydrochloride; Cyclizine Lactate

CYCLOBENZAPRINE

Impairment Potential Yes

Use Prevention and treatment of nausea, vomiting, and dizziness associated with motion sickness; control of postoperative nausea and vomiting

Mechanism of Action Cyclizine is a piperazine derivative with properties of histamines. The precise mechanism of action in inhibiting the symptoms of motion sickness is not known. It may have effects directly on the labyrinthine apparatus and central actions on the labyrinthine apparatus and on the chemoreceptor trigger zone. Cyclizine exerts a central anticholinergic action.

Adverse Reactions

Cardiovascular: Palpitations, sinus tachycardia
Central nervous system: **Drowsiness**, dizziness, headache, euphoria, ataxia, paranoia
Dermatologic: Dermatitis
Gastrointestinal: Nausea, **xerostomia**
Genitourinary: Urinary retention
Hematologic: Blood dyscrasias, agranulocytosis
Hepatic: Hepatitis, cholestasis
Neuromuscular & skeletal: Weakness
Ocular: Diplopia
Renal: Polyuria

Signs and Symptoms of Overdose Cholestatic jaundice, CNS depression, diarrhea, dry mouth, dry nose, euphoria, extrapyramidal reaction, flushing, insomnia, mydriasis

Toxicodynamics/Kinetics Duration of action: 4-6 hours

Dosage

Children 6-12 years:

Oral: 25 mg up to 3 times/day

I.M.: Not recommended

Adults:

Oral: 50 mg taken 30 minutes before departure, may repeat in 4-6 hours if needed, up to 200 mg/day

I.M.: 50 mg every 4-6 hours as needed

Contraindications Hypersensitivity to cyclizine or any component of the formulation

Dosage Forms Tablet, as hydrochloride: 50 mg

Reference Range Peak serum concentrations of 69 ng/mL after a 50 mg oral dose

Overdosage/Treatment Decontamination: Lavage (within 1 hour)/activated charcoal

Drug Interactions Increased effect/toxicity with CNS depressants, ethanol

Pregnancy Risk Factor B

Nursing Implications Raise bed rails, institute safety measures, assist with ambulation

Additional Information Commonly abused with opiates for euphoric effects

Pharmacodynamics/Kinetics

Onset of action: ~1 hour

Duration: 12-24 hours

Absorption: Complete

Metabolism: Hepatic via CYP3A4, 1A2, and 2D6; may undergo enterohepatic recirculation

Bioavailability: 33% to 55%

Half-life elimination: 18 hours (range: 8-37 hours)

Time to peak, serum: 3-8 hours

Excretion: Urine (as inactive metabolites); feces (as unchanged drug)

Dosage

Oral: **Note:** Do not use longer than 2-3 weeks

Adults: Initial: 5 mg 3 times/day; may increase to 10 mg 3 times/day if needed

Elderly: 5 mg 3 times/day; plasma concentration and incidence of adverse effects are increased in the elderly; dose should be titrated slowly

Toxic symptoms occur with ingestions > 100 mg

Dosage adjustment in hepatic impairment:

Mild: 5 mg 3 times/day; use with caution and titrate slowly

Moderate to severe: Use not recommended

Contraindications Hypersensitivity to cyclobenzaprine or any component of the formulation; do not use concomitantly or within 14 days of MAO inhibitors; hyperthyroidism; congestive heart failure; arrhythmias; acute recovery phase of MI

Warnings Cyclobenzaprine shares the toxic potentials of the tricyclic antidepressants and the usual precautions of tricyclic antidepressant therapy should be observed; use with caution in patients with urinary hesitancy, angle-closure glaucoma, hepatic impairment, or in the elderly. Do not use concomitantly or within 14 days after MAO inhibitors; combination may cause hypertensive crisis, severe convulsions. Safety and efficacy have not been established in patients < 15 years of age.

Dosage Forms

Tablet, as hydrochloride: 5 mg, 10 mg

Flexeril®: 5 mg, 10 mg

Reference Range Therapeutic serum levels following a 40 mg dose: 10-40 ng/mL; a serum level of 260 ng/mL was associated with lethality; cyclobenzaprine blood concentration of ≥ 0.8 mg/L may be associated with a fatal outcome

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Physostigmine can be utilized for severe life-threatening anticholinergic effects; hyperthermic states may require dantrolene and/or bromocriptine similar to the treatment of neuroleptic malignant syndrome

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; dialysis is not useful

Antidote(s)

• Physostigmine [ANTIDOTE]

Test Interactions Cyclobenzaprine can falsely elevate serum amitriptyline; 5-fluorouracil can falsely elevate serum creatinine

Drug Interactions

Substrate of CYP1A2 (major), 2D6 (minor), 3A4 (minor)

Anticholinergics: Because of cyclobenzaprine's anticholinergic action, use with caution in patients receiving these agents.

CNS depressants: Effects may be enhanced by cyclobenzaprine.

CYP1A2 inhibitors: May increase the levels/effects of cyclobenzaprine. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

Guanethidine: Antihypertensive effect of guanethidine may be decreased; effect seen with tricyclic antidepressants.

MAO inhibitors: Do not use concomitantly or within 14 days after MAO inhibitors.

Tramadol: May increase risk of seizure; effect seen with tricyclic antidepressants and tramadol.

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Raise bed rails, institute safety measures, assist with ambulation

Additional Information Has tricyclic antidepressant effect (similar to amitriptyline) at doses of 75-250 mg/day; some antidepressant effects include anticholinergic effects, sedation, reserpine antagonism and norepinephrine potentiation

Cyclobenzaprine

CAS Number 303-53-7; 6202-23-9

U.S. Brand Names Flexeril®

Synonyms Cyclobenzaprine Hydrochloride

Impairment Potential Yes

Use Treatment of muscle spasm associated with acute painful musculoskeletal conditions

Mechanism of Action Reduces tonic somatic motor activity influencing both alpha and gamma motor neurons; structurally related to amitriptyline

Adverse Reactions

Cardiovascular: Arrhythmia, facial edema, hypotension, palpitation, tachycardia

Central nervous system: **Drowsiness** (29% to 39%), **dizziness**, fatigue, confusion, headache, irritability, mental acuity decreased, nervousness, agitation, hallucinations, insomnia, malaise, psychosis, seizures, abnormal thinking, vertigo

Dermatologic: Angioedema, pruritus, rash, urticaria

Gastrointestinal: Abdominal pain, constipation, ageusia, diarrhea, dyspepsia, nausea, **xerostomia** (21% to 32%), anorexia, gastritis, tongue edema, vomiting

Genitourinary: Urinary frequency, urinary retention

Hepatic: Cholestasis, hepatitis (rare), jaundice, liver function tests abnormal

Neuromuscular & skeletal: Muscle weakness, hypertonia, paresthesia, tremors

Ocular: Blurred vision, diplopia

Otic: Tinnitus

Respiratory: Pharyngitis

Miscellaneous: Anaphylaxis

Signs and Symptoms of Overdose Mean time to onset of symptoms: 1.4 hours (all patients should be symptomatic within 4 hours). Ataxia, combativeness (13%), delirium, diaphoresis, fever, hallucinations, lethargy (54%), mania, muscular rigidity, myalgia, mydriasis, rhabdomyolysis, tachycardia (33%)

Admission Criteria/Prognosis Admit any pediatric ingestion over 100 mg or any patient symptomatic 4 hours postingestion

Spiller HA and Cutino L, "Death: Two Case Reports," *J Forensic Sci*, 2003, 48(4):883-4.

Van Hoey NM, "Effect of Cyclobenzaprine on Tricyclic Antidepressant Assays," *Ann Pharmacother*, 2005, 39(7):1314-7.

Cyclophosphamide

CAS Number 50-18-0; 6055-19-2

U.S. Brand Names Cytoxan®

Synonyms GPM; CTX; CYT; NSC-26271

Use

Oncologic: Treatment of Hodgkin's and non-Hodgkin's lymphoma, Burkitt's lymphoma, chronic lymphocytic leukemia (CLL), chronic myelocytic leukemia (CML), acute myelocytic leukemia (AML), acute lymphocytic leukemia (ALL), mycosis fungoides, multiple myeloma, neuroblastoma, retinoblastoma, rhabdomyosarcoma, Ewing's sarcoma; breast, testicular, endometrial, ovarian, and lung cancers, and in conditioning regimens for bone marrow transplantation

Nononcologic: Prophylaxis of rejection for kidney, heart, liver, and bone marrow transplants, severe rheumatoid disorders, nephrotic syndrome, Wegener's granulomatosis, idiopathic pulmonary hemosiderosis, myasthenia gravis, multiple sclerosis, systemic lupus erythematosus, lupus nephritis, autoimmune hemolytic anemia, idiopathic thrombocytopenic purpura (ITP), macroglobulinemia, and antibody-induced pure red cell aplasia

Mechanism of Action Interferes with the normal function of DNA by alkylation and cross-linking the strands of DNA, and by possible protein modification; cyclophosphamide also possesses potent immunosuppressive activity; note that cyclophosphamide must be metabolized to its active form in the liver (an alkylating agent)

Adverse Reactions

Cardiovascular: High-dose therapy may cause cardiac dysfunction manifested as congestive heart failure; cardiac necrosis or hemorrhagic myocarditis has occurred rarely, but is fatal; cyclophosphamide may also potentiate the cardiac toxicity of anthracyclines, tachycardia, facial flushing, cardiomegaly, cardiomyopathy, myocardial depression, sinus tachycardia

Central nervous system: Headache, dizziness, fatigue, psychosis

Dermatologic: Skin rash, skin hyperpigmentation (hyperpigmentation of palms and soles), transverse ridging of nails, hepatic toxicity, and dermatitis; allergic skin reactions, radiation recall dermatitis, cutaneous vasculitis

Alopecia: Frequent (occurs in 40% to 60% of patients), hair will regrow although it may be of a different color or texture; hair loss usually occurs 3 weeks after therapy

Endocrine & metabolic: Hypokalemia, ovotoxic, syndrome of inappropriate antidiuretic hormone has occurred with I.V. doses > 50 mg/kg, hyperuricemia, nephrogenic diabetes insipidus

Fertility: May cause sterility; interferes with oogenesis and spermatogenesis; may be irreversible in some patients; gonadal suppression (amenorrhea)

Gastrointestinal: Nausea and vomiting occur more frequently with larger doses, usually beginning 6-10 hours after administration; also seen are anorexia, diarrhea, stomatitis, mucositis, pancreatitis, hemorrhagic colitis, feces discoloration (black)

Genitourinary: Severe, potentially fatal acute hemorrhagic cystitis or urinary fibrosis, believed to be a result of chemical irritation of the bladder by acrolein, a cyclophosphamide metabolite, occurs in 7% to 12% of patients and has been reported in up to 40% of patients in some series. Patients should be encouraged to drink plenty of fluids during therapy (most adults will require at least 2 L/day), void frequently, and avoid taking the drug at night. With large I.V. doses, I.V. hydration is usually recommended. The use of mesna and/or continuous bladder irrigation is rarely needed for doses < 2 g/m².

Hematologic: Thrombocytopenia and anemia are less common than leukopenia

Onset: 7 days

Nadir: 10-14 days

Recovery: 21 days

Hepatic: Jaundice, acute liver failure, cholestasis

Local: Extravasation injury

Neuromuscular & skeletal: Rhabdomyolysis

Renal: Tubular necrosis (acute) has occurred, but usually resolves after the discontinuation of therapy; Fanconi syndrome, renal tubular acidosis type II

Respiratory: Interstitial pulmonary fibrosis with prolonged high dosage has occurred, rhinorrhea, sinus congestion, nasal stuffiness occurs when given in large I.V. doses, sneezing during or immediately after the infusion

Miscellaneous: Patients experience runny eyes, distortion; diaphoresis, anaphylaxis, aneuploidy induction

Signs and Symptoms of Overdose Agranulocytosis, azoospermia, AV block, colitis, erythema multiforme, granulocytopenia, hematuria, hemorrhagic cystitis, hyperglycemia, hyperpigmented hair, hypertension, hy-

peruricemia, hyponatremia, hypokalemia, leukopenia, Mees' lines, neutropenia, oligospermia, tachycardia

Pharmacodynamics/Kinetics

Absorption: Oral: Well absorbed

Distribution: V_d: 0.48-0.71 L/kg; crosses placenta; crosses into CSF (not in high enough concentrations to treat meningeal leukemia)

Protein binding: 10% to 56%

Metabolism: Hepatic to active metabolites acrolein, 4-aldophosphamide, 4-hydroperoxycyclophosphamide, and nor-nitrogen mustard

Bioavailability: > 75%

Half-life elimination: 4-8 hours

Time to peak, serum: Oral: ~1 hour

Excretion: Urine (<30% as unchanged drug, 85% to 90% as metabolites)

Dosage

Refer to individual protocols

Patients who are heavily pretreated with cytotoxic radiation or chemotherapy, or who have compromised bone marrow function may require a 33% to 50% reduction in initial dose.

Children:

SLE: I.V.: 500-750 mg/m² every month; maximum dose: 1 g/m²

JRA/vasculitis: I.V.: 10 mg/kg every 2 weeks

Children and Adults:

Oral: 50-100 mg/m²/day as continuous therapy or 400-1000 mg/m² in divided doses over 4-5 days as intermittent therapy

I.V.:

Single doses: 400-1800 mg/m² (30-50 mg/kg) per treatment course (1-5 days) which can be repeated at 2-4 week intervals

Continuous daily doses: 60-120 mg/m² (1-2.5 mg/kg) per day

Autologous BMT: IVPB: 50 mg/kg/dose × 4 days or 60 mg/kg/dose for 2 days; total dose is usually divided over 2-4 days

Nephrotic syndrome: Oral: 2-3 mg/kg/day every day for up to 12 weeks when corticosteroids are unsuccessful

Dosing adjustment in renal impairment: A large fraction of cyclophosphamide is eliminated by hepatic metabolism

Some authors recommend no dose adjustment unless severe renal insufficiency (Cl_{cr} < 20 mL/minute)

Cl_{cr} > 10 mL/minute: Administer 100% of normal dose

Cl_{cr} < 10 mL/minute: Administer 75% of normal dose

Hemodialysis: Moderately dialyzable (20% to 50%); administer dose posthemodialysis

CAPD effects: Unknown

CAVH effects: Unknown

Dosing adjustment in hepatic impairment: Some authors recommend dosage reductions (of up to 30%); however, the pharmacokinetics of cyclophosphamide are not significantly altered in the presence of hepatic insufficiency.

Stability Store intact vials of powder at room temperature of 15°C to 30°C (59°F to 86°F). Reconstitute vials with sterile water, normal saline, or 5% dextrose to a concentration of 20 mg/mL. Reconstituted solutions are stable for 24 hours at room temperature and 6 days under refrigeration at 2°C to 8°C (36°F to 46°F). Further dilutions in D₅W or NS are stable for 24 hours at room temperature and 6 days at refrigeration.

Monitoring Parameters CBC with differential and platelet count, BUN, UA, serum electrolytes, serum creatinine

Administration May be administered I.P., intrapleurally, IVPB, or continuous I.V. infusion; may also be administered slow IVP in doses ≤ 1 g. I.V. infusions may be administered over 1-24 hours

Doses > 500 mg to approximately 2 g may be administered over 20-30 minutes

To minimize bladder toxicity, increase normal fluid intake during and for 1-2 days after cyclophosphamide dose. Most adult patients will require a fluid intake of at least 2 L/day. High-dose regimens should be accompanied by vigorous hydration with or without mesna therapy.

Tablets are not scored and should not be cut or crushed; should be administered during or after meals.

Contraindications Hypersensitivity to cyclophosphamide or any component of the formulation; pregnancy

Warnings Hazardous agent - use appropriate precautions for handling and disposal. Dosage adjustment needed for renal or hepatic failure.

Dosage Forms

Injection, powder for reconstitution (Cytoxan®): 500 mg, 1 g, 2 g [contains mannitol 75 mg per cyclophosphamide 100 mg]

Tablet (Cytoxan®): 25 mg, 50 mg

Overdose/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hyperuricemia can be treated with alkalization of urine along with allopurinol; cystitis (hemorrhagic) can be controlled with bladder irrigation of 5% to 10% formalin glutathione, 2-mercaptoethane sulfonate (30 mg/kg/day for 4 doses) may be uroprotective; additionally, bladder irrigation with prostaglandin F₂-alpha (carboprost tromethamine) has been used; bladder spasm can be controlled with oxybutynin chloride 2.5-5 mg orally 3 times/day. For extravasation, hyaluronidase or chondroitin sulfatase injected SubQ can be utilized; do not use warm

CYCLOSERINE

packs. To prevent cyclophosphamide-induced antidiuresis, continuous infusion of furosemide (mean dose of 0.128 mg/kg/hour) may be useful. Amifostine (910 mg/m²) pretreatment may be protective of drug-induced neutropenia, renal toxicity, or ototoxicity. Testosterone (100 mg I.M. every 15 days beginning 1 month before therapy) can prevent cyclophosphamide-induced azoospermia.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; hemodialysis may remove 36% of prodrug; moderately dialyzable (20% to 50%)

Antidote(s)

- Amifostine [ANTIDOTE]
- Thrombopoietin [ANTIDOTE]

Test Interactions Hyponatremia may develop due to syndrome of inappropriate antidiuretic hormone; ↑ uric acid (S)

Drug Interactions

Substrate of CYP2A6 (minor), 2B6 (major), 2C9 (minor), 2C19 (minor), 3A4 (major); **Inhibits** CYP3A4 (weak); **Induces** CYP2B6 (weak), 2C8 (weak), 2C9 (weak)

Allopurinol may cause increase in bone marrow depression and may result in significant elevations of cyclophosphamide cytotoxic metabolites.

Anesthetic agents: Cyclophosphamide reduces serum pseudocholinesterase concentrations and may prolong the neuromuscular blocking activity of succinylcholine; use with caution with halothane, nitrous oxide, and succinylcholine.

Chloramphenicol results in prolonged cyclophosphamide half-life to increase toxicity.

CYP2B6 inducers: May increase the levels/effects of acrolein (the active metabolite of cyclophosphamide). Example inducers include carbamazepine, nevirapine, phenobarbital, phenytoin, and rifampin.

CYP2B6 inhibitors: May decrease the levels/effects of acrolein (the active metabolite of cyclophosphamide). Example inhibitors include desipramine, paroxetine, and sertraline.

CYP3A4 inducers: CYP3A4 inducers may increase the levels/effects of acrolein (the active metabolite of cyclophosphamide). Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May decrease the levels/effects of acrolein (the active metabolite of cyclophosphamide). Example inhibitors include azole antifungals, ciprofloxacin, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, and verapamil.

Digoxin: Cyclophosphamide may decrease digoxin serum levels.

Doxorubicin: Cyclophosphamide may enhance cardiac toxicity of anthracyclines.

Tetrahydrocannabinol results in enhanced immunosuppression in animal studies.

Thiazide diuretics: Leukopenia may be prolonged.

Pregnancy Risk Factor D

Pregnancy Implications Multiple anomalies (cleft palate, absent thumbs, dysmorphic facies, skeletal and CNS abnormalities noted); crosses the placenta

Lactation Enters breast milk/contraindicated

Nursing Implications Encourage adequate hydration and frequent voiding to help prevent cystitis (hemorrhagic)

Additional Information May be used in combination with mesna to prevent hemorrhagic cystitis. Rarely required for doses <1.5-2 g/m².

Cardiac toxicity can occur at doses >2.4 g/m²

CycloSERINE

CAS Number 68-41-7

U.S. Brand Names Seromycin®

Use Adjunctive treatment in pulmonary or extrapulmonary tuberculosis; treatment of acute urinary tract infections caused by *E. coli* or *Enterobacter* sp when less toxic conventional therapy has failed or is contraindicated

Unlabeled/Investigational Use Treatment of Gaucher's disease

Mechanism of Action Inhibits bacterial cell wall synthesis by competing with amino acid (D-alanine) for incorporation into the bacterial cell wall; bacteriostatic or bactericidal

Adverse Reactions

Cardiovascular: Cardiac arrhythmias, congestive heart failure at doses >1 g/day

Central nervous system: Dizziness, seizures, confusion, paranoia, psychosis, paresis, coma, drowsiness, headache, delirium, absence seizures, catatonia

Dermatologic: Rash, Stevens-Johnson syndrome

Endocrine & metabolic: Vitamin B₁₂ deficiency

Hematologic: Folate deficiency

Hepatic: Elevated liver enzymes

Neuromuscular & skeletal: Tremor, dysarthria, hyperreflexia

Miscellaneous: Pellagra

Admission Criteria/Prognosis Admit adult ingestions >2 g

Pharmacodynamics/Kinetics

Absorption: ~70% to 90%

Distribution: Widely to most body fluids and tissues including CSF, breast milk, bile, sputum, lymph tissue, lungs, and ascitic, pleural, and synovial fluids; crosses placenta

Half-life elimination: Normal renal function: 10 hours

Metabolism: Hepatic

Time to peak, serum: 3-4 hours

Excretion: Urine (60% to 70% as unchanged drug) within 72 hours; feces (small amounts); remainder metabolized

Dosage

Some of the neurotoxic effects may be relieved or prevented by the concomitant administration of pyridoxine

Tuberculosis: Oral:

Children: 10-20 mg/kg/day in 2 divided doses up to 1000 mg/day for 18-24 months

Adults: Initial: 250 mg every 12 hours for 14 days, then give 500 mg to 1 g/day in 2 divided doses for 18-24 months (maximum daily dose: 1 g)

Dosing interval in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer every 12-24 hours

Cl_{cr} <10 mL/minute: Administer every 24 hours

Monitoring Parameters Periodic renal, hepatic, hematological tests, and plasma cycloserine concentrations

Contraindications Hypersensitivity to cycloserine or any component of the formulation

Warnings Epilepsy, depression, severe anxiety, psychosis, severe renal insufficiency, chronic alcoholism

Dosage Forms Capsule: 250 mg

Reference Range Toxicity is greatly increased at serum levels >30 mcg/mL; therapeutic cycloserine serum levels for *Mycobacterium tuberculosis*: 5-20 mcg/mL

Overdosage/Treatment

Supportive therapy: Neurotoxic effects can be prevented with use of pyridoxine (150-300 mg/day)

Enhanced elimination: Removed by dialysis

Test Interactions Possible assay interference with cyclosporine by HPLC

Drug Interactions Increased toxicity: Alcohol, isoniazid, ethionamide increase toxicity of cycloserine; cycloserine inhibits the hepatic metabolism of phenytoin

Pregnancy Risk Factor C

Lactation Enters breast milk/compatible

CycloSPORINE

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 59865-13-3

U.S. Brand Names Gengraf™; Neoral®; Restasis™; Sandimmune®

Synonyms CsA; CyA; Cyclosporin A

Use

Prophylaxis of organ rejection in kidney, liver, and heart transplants, has been used with azathioprine and/or corticosteroids; severe, active rheumatoid arthritis (RA) not responsive to methotrexate alone; severe, recalcitrant plaque psoriasis in nonimmunocompromised adults unresponsive to or unable to tolerate other systemic therapy

Ophthalmic emulsion (Restasis™): Increase tear production when suppressed tear production is presumed to be due to keratoconjunctivitis sicca-associated ocular inflammation (in patients not already using topical anti-inflammatory drugs or punctal plugs)

Unlabeled/Investigational Use Short-term, high-dose cyclosporine as a modulator of multidrug resistance in cancer treatment; allogeneic bone marrow transplants for prevention and treatment of graft-versus-host disease; also used in some cases of severe autoimmune disease (eg, SLE, myasthenia gravis) that are resistant to corticosteroids and other therapy; focal segmental glomerulosclerosis

Mechanism of Action Inhibition of production and release of interleukin II and inhibits interleukin II-induced activation of resting T lymphocytes

Adverse Reactions

Note: Adverse reactions reported with kidney, liver, and heart transplantation, unless otherwise noted. Although percentage is reported for specific condition, reaction may occur in anyone taking cyclosporine. [Reactions reported for rheumatoid arthritis (RA) are based on cyclosporine (modified) 2.5 mg/kg/day versus placebo.]

>10%:

Cardiovascular: Hypertension (13% to 53%; psoriasis 25% to 27%)

Central nervous system: Headache (2% to 15%; RA 17%, psoriasis 14% to 16%)

Dermatologic: Hirsutism (21% to 45%), hypertrichosis (RA 19%)

Endocrine & metabolic: Increased triglycerides (psoriasis 15%), female reproductive disorder (psoriasis 8% to 11%)

Gastrointestinal: Nausea (RA 23%), diarrhea (RA 12%), gum hyperplasia (4% to 16%), abdominal discomfort (RA 15%), dyspepsia (RA 12%)

Neuromuscular & skeletal: Tremor (12% to 55%)

Renal: Renal dysfunction/nephropathy (25% to 38%; RA 10%, psoriasis 21%), creatinine elevation $\geq 50\%$ (RA 24%), increased creatinine (psoriasis 16% to 20%)

Respiratory: Upper respiratory infection (psoriasis 8% to 11%)

Miscellaneous: Infection (psoriasis 24% to 25%)

Kidney, liver, and heart transplant only ($\leq 2\%$ unless otherwise noted):

Cardiovascular: Flushes ($< 1\%$ to 4%), myocardial infarction

Central nervous system: Convulsions (1% to 5%), anxiety, confusion, fever, lethargy

Dermatologic: Acne (1% to 6%), brittle fingernails, hair breaking, pruritus

Endocrine & metabolic: Gynecomastia ($< 1\%$ to 4%), hyperglycemia

Gastrointestinal: Nausea ($< 1\%$ to 10%), vomiting (2% to 10%), diarrhea (3% to 8%), abdominal discomfort ($< 1\%$ to 7%), cramps (0% to 4%), anorexia, constipation, gastritis, mouth sores, pancreatitis, swallowing difficulty, upper GI bleed, weight loss

Hematologic: Leukopenia ($< 1\%$ to 6%), anemia, thrombocytopenia

Hepatic: Hepatotoxicity ($< 1\%$ to 7%)

Neuromuscular & skeletal: Paresthesia (1% to 3%), joint pain, muscle pain, tingling, weakness

Ocular: Conjunctivitis, visual disturbance

Otic: Hearing loss, tinnitus

Renal: Hematuria

Respiratory: Sinusitis ($< 1\%$ to 7%)

Miscellaneous: Lymphoma ($< 1\%$ to 6%), allergic reactions, hiccups, night sweats

Rheumatoid arthritis only (1% to $< 3\%$ unless otherwise noted):

Cardiovascular: Hypertension (8%), edema (5%), chest pain (4%), arrhythmia (2%), abnormal heart sounds, cardiac failure, myocardial infarction, peripheral ischemia

Central nervous system: Dizziness (8%), pain (6%), insomnia (4%), depression (3%), migraine (2%), anxiety, hypoesthesia, emotional lability, impaired concentration, malaise, nervousness, paranoia, somnolence, vertigo

Dermatologic: Purpura (3%), abnormal pigmentation, angioedema, cellulitis, dermatitis, dry skin, eczema, folliculitis, nail disorder, pruritus, skin disorder, urticaria

Endocrine & metabolic: Menstrual disorder (3%), breast fibroadenosis, breast pain, diabetes mellitus, goiter, hot flashes, hyperkalemia, hyperuricemia, hypoglycemia, libido increased/decreased

Gastrointestinal: Vomiting (9%), flatulence (5%), gingivitis (4%), gum hyperplasia (2%), constipation, dry mouth, dysphagia, enanthema, eructation, esophagitis, gastric ulcer, gastritis, gastroenteritis, gingival bleeding, glossitis, peptic ulcer, salivary gland enlargement, taste perversion, tongue disorder, tooth disorder, weight loss/gain

Genitourinary: Leukorrhea (1%), abnormal urine, micturition urgency, nocturia, polyuria, pyelonephritis, urinary incontinence, uterine hemorrhage

Hematologic: Anemia, leukopenia

Hepatic: Bilirubinemia

Neuromuscular & skeletal: Paresthesia (8%), tremor (8%), leg cramps/muscle contractions (2%), arthralgia, bone fracture, joint dislocation, myalgia, neuropathy, stiffness, synovial cyst, tendon disorder, weakness

Ocular: Abnormal vision, cataract, conjunctivitis, eye pain

Otic: Tinnitus, deafness, vestibular disorder

Renal: Increased BUN, hematuria, renal abscess

Respiratory: Cough (5%), dyspnea (5%), sinusitis (4%), abnormal chest sounds, bronchospasm, epistaxis

Miscellaneous: Infection (9%), abscess, allergy, bacterial infection, carcinoma, fungal infection, herpes simplex, herpes zoster, lymphadenopathy, moniliasis, diaphoresis increased, tonsillitis, viral infection

Psoriasis only (1% to $< 3\%$ unless otherwise noted):

Cardiovascular: Chest pain, flushes

Central nervous system: Psychiatric events (4% to 5%), pain (3% to 4%), dizziness, fever, insomnia, nervousness, vertigo

Dermatologic: Hypertrichosis (5% to 7%), acne, dry skin, folliculitis, keratosis, pruritus, rash, skin malignancies

Endocrine & metabolic: Hot flashes

Gastrointestinal: Nausea (5% to 6%), diarrhea (5% to 6%), gum hyperplasia (4% to 6%), abdominal discomfort (3% to 6%),

dyspepsia (2% to 3%), abdominal distention, appetite increased, constipation, gingival bleeding

Genitourinary: Micturition increased

Hematologic: Bleeding disorder, clotting disorder, platelet disorder, red blood cell disorder

Hepatic: Hyperbilirubinemia

Neuromuscular & skeletal: Paresthesia (5% to 7%), arthralgia (1% to 6%)

Ocular: Abnormal vision

Respiratory: Bronchospasm (5%), cough (5%), dyspnea (5%), rhinitis (5%), respiratory infection

Miscellaneous: Flu-like symptoms (8% to 10%)

Postmarketing and/or case reports (any indication): Death (due to renal deterioration), mild hypomagnesemia, hyperkalemia, increased uric acid, gout, hyperbilirubinemia, increased cholesterol, encephalopathy, impaired consciousness, neurotoxicity

Ophthalmic emulsion (Restasis™): $> 10\%$: Ocular: Burning (17%)

1% to 10%: Ocular: Hyperemia (conjunctival 5%), eye pain, pruritus, stinging

Signs and Symptoms of Overdose Abdominal pain, cholestatic jaundice, colitis, coma, cortical blindness, deafness, delirium, dementia, diarrhea, dysgeusia, dysphoria, eclampsia, encephalopathy, facial flushing, fibrillation (atrial), gingival hyperplasia, gout, headache, hypercalcemia, hyperglycemia, hyperuricemia, hypertriglyceridemia, hypertrichosis, hypomagnesemia, hypertension, jaundice, leukopenia, lymphoma, malaise, mania, metabolic acidosis, myasthenia gravis (exacerbation or precipitation), myoclonus, renal dysfunction, seizures, sweating, thrombocytopenia, tubular necrosis, vomiting

Admission Criteria/Prognosis Admit any ingestion > 150 mg/kg

Pharmacodynamics/Kinetics

Absorption:

Ophthalmic emulsion: Serum concentrations not detectable.

Oral:

Cyclosporine (non-modified): Erratic and incomplete; dependent on presence of food, bile acids, and GI motility; larger oral doses are needed in pediatrics due to shorter bowel length and limited intestinal absorption

Cyclosporine (modified): Erratic and incomplete; increased absorption, up to 30% when compared to cyclosporine (non-modified); less dependent on food, bile acids, or GI motility when compared to cyclosporine (non-modified)

Distribution: Widely in tissues and body fluids including the liver, pancreas, and lungs; crosses placenta; enters breast milk

V_{dss} : 4-6 L/kg in renal, liver, and marrow transplant recipients (slightly lower values in cardiac transplant patients; children < 10 years have higher values)

Protein binding: 90% to 98% to lipoproteins

Metabolism: Extensively hepatic via CYP3A4; forms at least 25 metabolites; extensive first-pass effect following oral administration

Bioavailability: Oral:

Cyclosporine (non-modified): Dependent on patient population and transplant type ($< 10\%$ in adult liver transplant patients and as high as 89% in renal transplant patients); bioavailability of Sandimmune® capsules and oral solution are equivalent; bioavailability of oral solution is $\sim 30\%$ of the I.V. solution

Children: 28% (range: 17% to 42%); gut dysfunction common in BMT patients and oral bioavailability is further reduced

Cyclosporine (modified): Bioavailability of Neoral® capsules and oral solution are equivalent:

Children: 43% (range: 30% to 68%)

Adults: 23% greater than with cyclosporine (non-modified) in renal transplant patients; 50% greater in liver transplant patients

Half-life elimination: Oral: May be prolonged in patients with hepatic impairment and shorter in pediatric patients due to the higher metabolism rate

Cyclosporine (non-modified): Biphasic: Alpha: 1.4 hours; Terminal: 19 hours (range: 10-27 hours)

Cyclosporine (modified): Biphasic: Terminal: 8.4 hours (range: 5-18 hours)

Time to peak, serum: Oral:

Cyclosporine (non-modified): 2-6 hours; some patients have a second peak at 5-6 hours

Cyclosporine (modified): Renal transplant: 1.5-2 hours

Excretion: Primarily feces; urine (6%, 0.1% as unchanged drug and metabolites)

Dosage

Note: Neoral® and Sandimmune® are not bioequivalent and cannot be used interchangeably

Children: Transplant: Refer to adult dosing; children may require, and are able to tolerate, larger doses than adults.

Adults:

Newly-transplanted patients: Adjunct therapy with corticosteroids is recommended. Initial dose should be given 4-12 hours prior to

transplant or may be given postoperatively; adjust initial dose to achieve desired plasma concentration

Oral: Dose is dependent upon type of transplant and formulation:

Cyclosporine (modified):

Renal: 9 ± 3 mg/kg/day, divided twice daily

Liver: 8 ± 4 mg/kg/day, divided twice daily

Heart: 7 ± 3 mg/kg/day, divided twice daily

Cyclosporine (non-modified): Initial dose: 15 mg/kg/day as a single dose (range 14-18 mg/kg); lower doses of 10-14 mg/kg/day have been used for renal transplants. Continue initial dose daily for 1-2 weeks; taper by 5% per week to a maintenance dose of 5-10 mg/kg/day; some renal transplant patients may be dosed as low as 3 mg/kg/day

When using the non-modified formulation, cyclosporine levels may increase in liver transplant patients when the T-tube is closed; dose may need decreased

I.V.: Cyclosporine (non-modified): Initial dose: 5-6 mg/kg/day as a single dose ($\frac{1}{3}$ the oral dose), infused over 2-6 hours; use should be limited to patients unable to take capsules or oral solution; patients should be switched to an oral dosage form as soon as possible

Conversion to cyclosporine (modified) from cyclosporine (non-modified): Start with daily dose previously used and adjust to obtain preconversion cyclosporine trough concentration. Plasma concentrations should be monitored every 4-7 days and dose adjusted as necessary, until desired trough level is obtained. When transferring patients with previously poor absorption of cyclosporine (non-modified), monitor trough levels at least twice weekly (especially if initial dose exceeds 10 mg/kg/day); high plasma levels are likely to occur.

Rheumatoid arthritis: Oral: Cyclosporine (modified): Initial dose: 2.5 mg/kg/day, divided twice daily; salicylates, NSAIDs, and oral glucocorticoids may be continued (refer to Drug Interactions); dose may be increased by 0.5-0.75 mg/kg/day if insufficient response is seen after 8 weeks of treatment; additional dosage increases may be made again at 12 weeks (maximum dose: 4 mg/kg/day). Discontinue if no benefit is seen by 16 weeks of therapy.

Note: Increase the frequency of blood pressure monitoring after each alteration in dosage of cyclosporine. Cyclosporine dosage should be decreased by 25% to 50% in patients with no history of hypertension who develop sustained hypertension during therapy and, if hypertension persists, treatment with cyclosporine should be discontinued.

Psoriasis: Oral: Cyclosporine (modified): Initial dose: 2.5 mg/kg/day, divided twice daily; dose may be increased by 0.5 mg/kg/day if insufficient response is seen after 4 weeks of treatment. Additional dosage increases may be made every 2 weeks if needed (maximum dose: 4 mg/kg/day). Discontinue if no benefit is seen by 6 weeks of therapy. Once patients are adequately controlled, the dose should be decreased to the lowest effective dose. Doses lower than 2.5 mg/kg/day may be effective. Treatment longer than 1 year is not recommended.

Note: Increase the frequency of blood pressure monitoring after each alteration in dosage of cyclosporine. Cyclosporine dosage should be decreased by 25% to 50% in patients with no history of hypertension who develop sustained hypertension during therapy and, if hypertension persists, treatment with cyclosporine should be discontinued.

Focal segmental glomerulosclerosis: Initial: 3 mg/kg/day divided every 12 hours

Autoimmune diseases: 1-3 mg/kg/day

Keratoconjunctivitis sicca: Ophthalmic: Children ≥ 16 years and Adults: Instill 1 drop in each eye every 12 hours

Dosage adjustment in renal impairment: For severe psoriasis:

Serum creatinine levels $\geq 25\%$ above pretreatment levels: Take another sample within 2 weeks; if the level remains $\geq 25\%$ above pretreatment levels, decrease dosage of cyclosporine (modified) by 25% to 50%. If two dosage adjustments do not reverse the increase in serum creatinine levels, treatment should be discontinued.

Serum creatinine levels $\geq 50\%$ above pretreatment levels: Decrease cyclosporine dosage by 25% to 50%. If two dosage adjustments do not reverse the increase in serum creatinine levels, treatment should be discontinued.

Hemodialysis: Supplemental dose is not necessary.

Peritoneal dialysis: Supplemental dose is not necessary.

Dosage adjustment in hepatic impairment: Probably necessary; monitor levels closely

Stability Do not store oral solution in the refrigerator; use contents of oral solution within 2 months after opening; I.V. cyclosporine prepared in normal saline or D₅W is stable 6 hours in PVC or 24 hours in a glass container or PAB container or Excel[®] container; do not freeze

Monitoring Parameters

Monitor blood pressure and serum creatinine after any cyclosporine dosage changes or addition, modification, or deletion of other medications. Monitor plasma concentrations periodically.

Transplant patients: Cyclosporine trough levels, serum electrolytes, renal function, hepatic function, blood pressure, lipid profile

Psoriasis therapy: Baseline blood pressure, serum creatinine (2 levels each), BUN, CBC, serum magnesium, potassium, uric acid, lipid profile.

Biweekly monitoring of blood pressure, complete blood count, and levels of BUN, uric acid, potassium, lipids, and magnesium during the first 3 months of treatment for psoriasis. Monthly monitoring is recommended after this initial period. Also evaluate any atypical skin lesions prior to therapy. Increase the frequency of blood pressure monitoring after each alteration in dosage of cyclosporine. Cyclosporine dosage should be decreased by 25% to 50% in patients with no history of hypertension who develop sustained hypertension during therapy and, if hypertension persists, treatment with cyclosporine should be discontinued.

Rheumatoid arthritis: Baseline blood pressure, and serum creatinine (2 levels each); serum creatinine every 2 weeks for first 3 months, then monthly if patient is stable. Increase the frequency of blood pressure monitoring after each alteration in dosage of cyclosporine. Cyclosporine dosage should be decreased by 25% to 50% in patients with no history of hypertension who develop sustained hypertension during therapy and, if hypertension persists, treatment with cyclosporine should be discontinued.

Administration Oral solution: Do not administer liquid from plastic or styrofoam cup. May dilute Neoral[®] oral solution with orange juice or apple juice. May dilute Sandimmune[®] oral solution with milk, chocolate milk, or orange juice. Avoid changing diluents frequently. Mix thoroughly and drink at once. Use syringe provided to measure dose. Mix in a glass container and rinse container with more diluent to ensure total dose is taken. Do not rinse syringe before or after use (may cause dose variation).

I.V.: Following dilution, intravenous admixture should be administered over 2-6 hours. Discard solution after 24 hours. Anaphylaxis has been reported with I.V. use; reserve for patients who cannot take oral form. Patients should be under continuous observation for at least the first 30 minutes of the infusion, and should be monitored frequently thereafter. Maintain patent airway; other supportive measures and agents for treating anaphylaxis should be present when I.V. drug is given.

Ophthalmic emulsion: Prior to use, invert vial several times to obtain a uniform emulsion. Remove contact lenses prior to instillation of drops; may be reinserted 15 minutes after administration. May be used with artificial tears; allow 15 minute interval between products.

Contraindications Hypersensitivity to cyclosporine or any component of the formulation. Rheumatoid arthritis and psoriasis: Abnormal renal function, uncontrolled hypertension, malignancies. Concomitant treatment with PUVA or UVB therapy, methotrexate, other immunosuppressive agents, coal tar, or radiation therapy are also contraindications for use in patients with psoriasis. Ophthalmic emulsion is contraindicated in patients with active ocular infections.

Warnings

[U.S. Boxed Warning]: Use caution with other potentially nephrotoxic drugs (eg, acyclovir, aminoglycoside antibiotics, amphotericin B, ciprofloxacin). **[U.S. Boxed Warning]: Increased risk of lymphomas, other malignancies, infection.** **[U.S. Boxed Warning]: May cause hypertension.** Use caution when changing dosage forms; products are not equally interchangeable. Cyclosporine (modified) refers to the capsule dosage formulation of cyclosporine in an aqueous dispersion (previously referred to as "microemulsion"). **[U.S. Boxed Warning]: Cyclosporine (modified) has increased bioavailability as compared to cyclosporine (non-modified) and cannot be used interchangeably without close monitoring.** Monitor cyclosporine concentrations closely following the addition, modification, or deletion of other medications; live, attenuated vaccines may be less effective; use should be avoided.

Transplant patients: To be used initially with corticosteroids. May cause significant hyperkalemia and hyperuricemia. May cause seizures, particularly if used with high-dose corticosteroids. Encephalopathy has been reported, predisposing factors include hypertension, hypomagnesemia, hypocholesterolemia, high-dose corticosteroids, high cyclosporine serum concentration, and graft-versus-host disease; may be more common in patients with liver transplant. Make dose adjustments based on cyclosporine blood concentrations. **[U.S. Boxed Warning]: Adjustment of dose should only be made under the direct supervision of an experienced physician.** Anaphylaxis has been reported with I.V. use; reserve for patients who cannot take oral form.

Psoriasis: Patients should avoid excessive sun exposure; safety and efficacy in children < 18 years of age have not been established. **[U.S. Boxed Warning]: Risk of skin cancer may be increased with a history of PUVA and possibly methotrexate or other immunosuppressants, UVB, coal tar, or radiation.**

Rheumatoid arthritis: Safety and efficacy for use in juvenile rheumatoid arthritis have not been established. If receiving other immunosuppressive agents, radiation or UV therapy, concurrent use of cyclosporine is not recommended.

Ophthalmic emulsion: Safety and efficacy have not been established in patients < 16 years of age.

Products may contain corn oil, castor oil, ethanol, or propylene glycol; injection also contains Cremophor® EL (polyoxyethylated castor oil), which has been associated with rare anaphylactic reactions.

Dosage Forms

Capsule, soft gel, modified: 25 mg, 100 mg [contains castor oil, ethanol]
 Gengraf®: 25 mg, 100 mg [contains ethanol, castor oil, propylene glycol]
 Neoral®: 25 mg, 100 mg [contains dehydrated ethanol, corn oil, castor oil, propylene glycol]
 Capsule, soft gel, non-modified (Sandimmune®): 25 mg, 100 mg [contains dehydrated ethanol, corn oil]
 Emulsion, ophthalmic [preservative free, single-use vial] (Restasis®): 0.05% (0.4 mL) [contains glycerin, castor oil, polysorbate 80, carbomer 1342; 32 vials/box]
 Injection, solution, non-modified (Sandimmune®): 50 mg/mL (5 mL) [contains Cremophor® EL (polyoxyethylated castor oil), ethanol]
 Solution, oral, modified:
 Gengraf®: 100 mg/mL (50 mL) [contains castor oil, propylene glycol]
 Neoral®: 100 mg/mL (50 mL) [contains dehydrated ethanol, corn oil, castor oil, propylene glycol]
 Solution, oral, non-modified (Sandimmune®): 100 mg/mL (50 mL) [contains olive oil, ethanol]

Reference Range Reference ranges are method dependent and specimen dependent; use the same analytical method consistently

Method-dependent and specimen-dependent: Trough levels should be obtained:

Oral: 12-18 hours after dose (chronic usage)

I.V.: 12 hours after dose or immediately prior to next dose

Therapeutic range: Not absolutely defined, dependent on organ transplanted, time after transplant, organ function and CsA toxicity:

General range of 100-400 ng/mL

Toxic level: Not well defined, nephrotoxicity may occur at any level

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: Diazepam, lorazepam, phenytoin, or phenobarbital for seizure control; calcium channel blockers are preferred agent for treatment of hypertension (diltiazem or verapamil); azithromycin (500 mg/day for 1 day, then 250 mg/day for 4 days) or metronidazole (750 mg 3 times/day for 2 weeks) has been used to treat gingival hyperplasia; amlodipine (5 mg/day) in normotensive renal transplant recipients has resulted in decreased nephrotoxicity of cyclosporine. Cyclosporin-induced hypertension can be treated with labetalol or a dihydropyridine calcium antagonist.

Enhancement of elimination: Multiple dosing of activated charcoal can decrease half-life from 9 hours to under 3 hours (through enterohepatic recirculation of drug); hemodialysis is not useful (will remove ~3% of dose)

Diagnostic Procedures

- Cyclosporine, Blood

Test Interactions May falsely elevate specific whole blood, HPLC assay for cyclosporine if the sample is drawn from the same line through which the dose was administered (even with I.V. flush and/or the dose was administered hours before).

Drug Interactions

Substrate of CYP3A4 p-glycoprotein (major); **Inhibits** CYP2C9 p-glycoprotein (weak), 3A4 (moderate)

ACE inhibitors: May enhance nephrotoxic effects of cyclosporine.

Allopurinol: Increases cyclosporine concentrations by inhibiting cyclosporine metabolism.

Amiodarone: May increase cyclosporine concentrations by inhibiting cyclosporine metabolism.

Antibiotics: Concomitant use may potentiate renal dysfunction (seen with ciprofloxacin, gentamicin, tobramycin, vancomycin, trimethoprim and sulfamethoxazole); increased cyclosporine concentrations by inhibiting cyclosporine metabolism (seen with azithromycin, clarithromycin, erythromycin, and norfloxacin, quinupristin/dalfopristin); may decrease cyclosporine concentrations by inducing cyclosporine metabolism (seen with nafcillin, and rifampin); may decrease immunosuppressant effects (seen with ciprofloxacin); CNS disturbances, seizures (seen with ipipenem).

Anticonvulsants: May decrease cyclosporine concentrations by inducing cyclosporine metabolism (seen with carbamazepine, phenobarbital, and phenytoin)

Antineoplastics: Concomitant use may potentiate renal dysfunction (seen with melphalan)

Antifungals: Concomitant use may potentiate renal dysfunction (seen with amphotericin B, ketoconazole); increase cyclosporine concentrations by inhibiting cyclosporine metabolism (seen with fluconazole, itraconazole, and ketoconazole)

Bosentan: Cyclosporine may increase the serum concentration of bosentan. Bosentan may decrease the serum concentration of cyclosporine. Concurrent use is contraindicated.

Bromocriptine: Increases cyclosporine concentrations by inhibiting cyclosporine metabolism

Calcium channel blockers (diltiazem, nicardipine, verapamil): Increase cyclosporine concentrations by inhibiting cyclosporine metabolism. Nifedipine has been reported to increase the risk of gingival hyperplasia. Colchicine: May potentiate renal dysfunction; colchicine may increase cyclosporine concentrations by inhibiting metabolism. Cyclosporine may decrease the clearance of colchicine.

Corticosteroids: Systemic corticosteroids may increase the serum concentration of cyclosporine (reported with methylprednisolone). Cyclosporine may increase the serum concentration of systemic corticosteroids. Convulsions have been reported with high-dose methylprednisolone.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of cyclosporine. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of cyclosporine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

CYP3A4 substrates: Cyclosporine may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Danazol: Increases cyclosporine concentrations by inhibiting cyclosporine metabolism

Digoxin: Decreased clearance and decreased volume of distribution of digoxin; severe digitalis toxicity has been observed.

Fibric acid derivatives: May increase the risk of renal dysfunction and may alter cyclosporine concentrations; monitor.

H₂ blockers: Concomitant use may potentiate renal dysfunction (seen with cimetidine, ranitidine).

HMG-CoA reductase inhibitors: Cyclosporine may increase levels/effects of HMG-CoA reductase inhibitors, resulting in myalgias, rhabdomyolysis, acute renal failure; dosage adjustments of HMG-CoA reductase inhibitors are recommended.

Imatinib: May increase cyclosporine serum concentrations by inhibiting cyclosporine metabolism.

Immunosuppressives: Concomitant use may potentiate renal dysfunction (seen with tacrolimus, muromonab-CD3).

Metoclopramide: Increases cyclosporine concentrations by inhibiting cyclosporine metabolism.

Methotrexate: Cyclosporine increases plasma levels of methotrexate and decreases plasma levels of its metabolite; monitor closely for signs of toxicity.

Minoxidil: Concomitant use may lead to severe hypertrichosis.

NSAIDs: Concomitant use may potentiate renal dysfunction, especially in dehydrated patients (seen with diclofenac, naproxen, sulindac). In addition, diclofenac plasma levels are doubled when given with cyclosporine; the lowest possible dose of diclofenac should be used. Monitor serum creatinine.

Octreotide: May decrease cyclosporine concentrations by inducing cyclosporine metabolism.

Oral contraceptives (hormonal): May increase serum levels of cyclosporine; monitor for signs of toxicity.

Orlistat: May decrease absorption of cyclosporine; avoid concomitant use.

Protease inhibitors: Formal interaction studies have not been done; protease inhibitors are known to induce CYP3A4; use caution when using cyclosporine with indinavir, nelfinavir, ritonavir, or saquinavir.

Rifabutin: Formal interaction studies have not been done; rifabutin is known to increase the metabolism of medications via CYP3A4.

Sirolimus: Cyclosporine may increase serum levels/effects; monitor. Concurrent therapy may increase the risk of HUS/TTP/TMA. Administer sirolimus 4 hours after cyclosporine to minimize the increase in sirolimus blood levels.

Sulfipyrazone: May decrease cyclosporine levels by inducing cyclosporine metabolism; monitor.

Ticlopidine: May decrease cyclosporine concentrations by inducing cyclosporine metabolism.

Vaccines: Vaccination may be less effective; avoid use of live vaccines during therapy.

Voriconazole: Cyclosporine serum concentrations may be increased; monitor serum concentrations and renal function. Decrease cyclosporine dosage by 50% when initiating voriconazole.

Pregnancy Risk Factor C

Pregnancy Implications Cyclosporine crosses the placenta. Based on clinical use, premature births and low birth weight were consistently observed. Use only if the benefit to the mother outweighs the possible risks to the fetus.

Lactation Enters breast milk/not recommended

Nursing Implications Do not administer liquid from plastic or styrofoam cup; mixing with milk, chocolate milk, or orange juice preferably at room temperature, improves palatability; stir well and drink at once; do not allow to stand before drinking; rinse with more diluent to ensure that the total dose is taken; after use, dry outside of pipette; do not rinse with water or other cleaning agents; may cause inflamed gums

Additional Information

Cyclosporine (modified): Refers to the capsule dosage formulation of cyclosporine in an aqueous dispersion (previously referred to as "microemulsion"). Cyclosporine (modified) has increased bioavailability as compared to cyclosporine (non-modified) and cannot be used interchangeably without close monitoring.

Food interaction: Grapefruit juice increases absorption; unsupervised use should be avoided.

Herb/Nutraceutical interaction: Avoid St John's wort; as an enzyme inducer, it may increase the metabolism of and decrease plasma levels of cyclosporine; organ rejection and graft loss have been reported. Avoid cat's claw, echinacea (have immunostimulant properties).

Cyproheptadine

CAS Number 129-03-3; 41354-29-4; 969-33-5

U.S. Brand Names Periactin® [DSC]

Synonyms Cyproheptadine Hydrochloride; Periactin

Use Perennial and seasonal allergic rhinitis and other allergic symptoms including urticaria

Unlabeled/Investigational Use Appetite stimulation, blepharospasm, cluster headaches, migraine headaches, Nelson's syndrome, pruritus, schizophrenia, spinal cord damage associated spasticity, and tardive dyskinesia

Mechanism of Action Direct serotonin antagonist with anticholinergic and antihistamine effects

Adverse Reactions

Cardiovascular: Hypotension, palpitations, tachycardia, sinus tachycardia, vasculitis

Central nervous system: **Slight to moderate drowsiness**, dizziness, fatigue, ataxia, euphoria, seizures, lethargy, hyperthermia, cognitive dysfunction, aggressive behavior

Dermatologic: Angioedema, urticaria, purpura, licheniform eruptions, exanthem

Endocrine & metabolic: Hyperprolactinemia, hypoprolactinemia

Gastrointestinal: Nausea, vomiting, diarrhea, weight gain

Genitourinary: Urinary retention, dysuria

Hepatic: Jaundice

Neuromuscular & skeletal: Paresthesia

Ocular: Diplopia, increased intraocular pressure, photosensitivity, mydriasis

Otic: Tinnitus

Respiratory: **Thickening of bronchial secretions**, bronchoconstriction

Miscellaneous: Systemic lupus erythematosus

Signs and Symptoms of Overdose Agitation, confusion, hallucinations, mydriasis, seizures, tachycardia

Pharmacodynamics/Kinetics

Absorption: Completely

Metabolism: Almost completely hepatic

Excretion: Urine (>50% primarily as metabolites); feces (~25%)

Dosage

Oral:

Children:

Allergic conditions: 0.25 mg/kg/day or 8 mg/m²/day in 2-3 divided doses or

2-6 years: 2 mg every 8-12 hours (not to exceed 12 mg/day)

7-14 years: 4 mg every 8-12 hours (not to exceed 16 mg/day)

Migraine headaches: 4 mg 2-3 times/day

Children ≥ 12 years and Adults: Spasticity associated with spinal cord damage: 4 mg at bedtime; increase by a 4 mg dose every 3-4 days; average daily dose: 16 mg in divided doses; not to exceed 36 mg/day

Children > 13 years and Adults: Appetite stimulation (anorexia nervosa): 2 mg 4 times/day; may be increased gradually over a 3-week period to 8 mg 4 times/day

Adults:

Allergic conditions: 4-20 mg/day divided every 8 hours (not to exceed 0.5 mg/kg/day)

Cluster headaches: 4 mg 4 times/day

Migraine headaches: 4-8 mg 3 times/day

Dosage adjustment in hepatic impairment: Reduce dosage in patients with significant hepatic dysfunction

Contraindications Hypersensitivity to cyproheptadine or any component of the formulation; narrow-angle glaucoma; bladder neck obstruction; acute asthmatic attack; stenosing peptic ulcer; GI tract obstruction; concurrent use of MAO inhibitors; avoid use in premature and term newborns due to potential association with SIDS

Warnings Do not use in neonates, safety and efficacy have not been established in children <2 years of age; symptomatic prostate hypertrophy; antihistamines are more likely to cause dizziness, excessive sedation, syncope, toxic confusion states, and hypotension in the elderly. In case reports, cyproheptadine has promoted weight gain in anorexic adults, though it has not been specifically studied in the elderly. All cases of weight loss or decreased appetite should be adequately assessed.

Dosage Forms

Syrup, as hydrochloride: 2 mg/5 mL (473 mL) [contains alcohol 5%; mint flavor]

Tablet, as hydrochloride: 4 mg

Reference Range Postmortem peripheral blood and urine concentrations following fatal overdose: 0.62 mg/L and 0.75 mg/L

Overdosage/Treatment

Referral and treatment of ingestions >3 times usual dose suggested

Decontamination: Avoid ipecac (except prehospital), charcoal recommended; lavage indicated if obtunded or within 1 hour of ingestion or evidence of gastric hypomotility

Supportive therapy: There is no routine specific treatment; severe life-threatening symptoms may be treated with physostigmine; hypotension is best treated with norepinephrine or phenylephrine; seizures should be treated with benzodiazepines; in absence of secondary complications (cardiac ischemia), sinus tachycardia does not require specific therapy; renal failure due to rhabdomyolysis, hemodialysis may be employed; sodium bicarbonate may be of some value in wide complex tachycardias.

Test Interactions ↑ serum amylase; ↓ serum prolactin; reduces hypoglycemia-induced growth hormone secretion; can cause false-positive screen for serum tricyclic antidepressant

Drug Interactions

Cyproheptadine may potentiate the effect of CNS depressants.

MAO inhibitors may cause hallucinations when taken with cyproheptadine.

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown/contraindicated

Additional Information Lowers serum prolactin levels; also has been used to treat serotonin syndrome induced by the combination of sertraline and isocarboxazid at a dose of 4 mg; can cause dependence

Cytarabine

CAS Number 147-94-4; 69-74-9

U.S. Brand Names Cytosar-U®

Synonyms Ara-C; Arabinosylcytosine; Cytarabine Hydrochloride; Cytosine Arabinosine Hydrochloride; NSC-63878

Use Cytarabine is one of the most active agents in leukemia; also active against lymphoma, meningeal leukemia, and meningeal lymphoma; has little use in the treatment of solid tumors

Mechanism of Action This is a sustained-release formulation of the active ingredient cytarabine, which acts through inhibition of DNA synthesis; cell cycle-specific for the S phase of cell division; cytosine gains entry into cells by a carrier process, and then must be converted to its active compound; cytosine acts as an analog and is incorporated into DNA; however, the primary action is inhibition of DNA polymerase resulting in decreased DNA synthesis and repair; degree of its cytotoxicity correlates linearly with its incorporation into DNA; therefore, incorporation into the DNA is responsible for drug activity and toxicity

Adverse Reactions

High-dose therapy toxicities: Cerebellar toxicity, keratoconjunctivitis (make sure the patient is on steroid eye drops during therapy), corneal keratitis, hyperbilirubinemia, pulmonary edema, pericarditis, and tamponade

Cardiovascular: Cardiomegaly, pericarditis, chest pain, vasculitis

Central nervous system: **Fever (>80%)**, leukoencephalopathy, dizziness, headache, somnolence, confusion, malaise, extrapyramidal reactions; has produced seizures when given I.T.; cerebellar syndrome (or cerebellar toxicity) in 8% of patients (fatal or permanent in 1%); manifested as ataxia, dysarthria, and dysdiadochokinesia; has been

reported to be dose-related at cumulative doses >30 g/m². This may or may not be reversible.

Dermatologic: **Rash**, skin freckling, itching, alopecia, cellulitis at injection site, palmar-plantar erythrodysesthesia, acral erythema, cutaneous vasculitis

Endocrine & metabolic: Parotid disorder

Gastrointestinal: **Nausea, vomiting, diarrhea, and mucositis which subside quickly after discontinuing the drug; GI effects may be more pronounced with divided I.V. bolus doses than with continuous infusion; oral/anal ulceration;** acute pancreatitis

Emetic potential:

≤20 mg: Moderately low (10% to 30%)
250 mg to 1 g: Moderately high (60% to 90%)
>1 g: High (>90%)

Genitourinary: Urinary retention, hemorrhagic cystitis

Hematologic: **Myelosuppression; neutropenia and thrombocytopenia are severe, anemia may also occur**

Onset: 4-7 days

Nadir: 14-18 days

Recovery: 21-28 days

Hepatic: **Hepatic dysfunction, mild jaundice and acute increase in transaminases can be produced**

Local: **Thrombophlebitis**, extravasation injury

Neuromuscular & skeletal: Myalgia, bone pain, neuropathy (peripheral), neuritis

Ocular: Photophobia, blurred vision

Respiratory: Syndrome of sudden respiratory distress progressing to pulmonary edema, pneumonia, hyposmia

Miscellaneous: Sepsis

Pharmacodynamics/Kinetics

Distribution: V_d: Total body water; widely and rapidly since it enters the cells readily; crosses blood-brain barrier with CSF levels of 40% to 50% of plasma level

Metabolism: Primarily hepatic; metabolized by deoxycytidine kinase and other nucleotide kinases to aracytidine triphosphate (active); about 86% to 96% of dose is metabolized to inactive uracil arabinoside

Half-life elimination: Initial: 7-20 minutes; Terminal: 0.5-2.6 hours

Excretion: Urine (~80% as metabolites) within 24-36 hours

Dosage

I.V. bolus, IVPB, and CIV doses of cytarabine are very different. Bolus doses are relatively well tolerated since the drug is rapidly metabolized; but are associated with greater neurotoxicity. Continuous infusion uniformly results in myelosuppression. Refer to individual protocols. Children and Adults:

Remission induction:

I.V.: 100-200 mg/m²/day for 5-10 days; a second course, beginning 2-4 weeks after the initial therapy, may be required in some patients.

I.T.: 5-75 mg/m² every 2-7 days until CNS findings normalize; or age-based dosing:

<1 year: 20 mg

1-2 years: 30 mg

2-3 years: 50 mg

>3 years: 75 mg

Remission maintenance:

I.V.: 70-200 mg/m²/day for 2-5 days at monthly intervals

I.M., SubQ: 1-1.5 mg/kg single dose for maintenance at 1- to 4-week intervals

High-dose therapies:

Doses as high as 1-3 g/m² have been used for refractory or secondary leukemias or refractory non-Hodgkin's lymphoma.

Doses of 1-3 g/m² every 12 hours for up to 12 doses have been used

Bone marrow transplant: 1.5 g/m² continuous infusion over 48 hours

Hemodialysis: Supplemental dose is not necessary.

Peritoneal dialysis: Supplemental dose is not necessary.

Dosage adjustment in hepatic impairment: Dose may need to be adjusted since cytarabine is partially detoxified in the liver.

Stability Store intact vials of powder at room temperature 15°C to 30°C (59°F to 86°F). Reconstitute with SWI, D₅W or NS; reconstituted solutions are stable for up to 8 days at room temperature. Further dilution in D₅W or NS is stable for 8 days at room temperature (25°C).

Standard I.V. infusion dilution: Dose/250-1000 mL D₅W or NS.

Standard intrathecal dilutions: Dose/3-5 mL lactated Ringer's ± methotrexate (12 mg) ± hydrocortisone (15-50 mg); intrathecal solutions in 3-20 mL lactated Ringer's are stable for 7 days at room temperature (30°C); however, should be used within 24 hours due to sterility concerns

Note: Bacteriostatic diluent should not be used for the preparation of either high doses or intrathecal doses of cytarabine; may be used for I.M., SubQ, and low-dose (100-200 mg/m²) I.V. solution.

Monitoring Parameters Liver function tests, CBC with differential and platelet count, serum creatinine, BUN, serum uric acid

DALTEPARIN

Administration

Can be administered I.M., I.V. infusion, I.T., or SubQ at a concentration not to exceed 100 mg/mL

I.V. may be administered either as a bolus, IVPB (high doses of >500 mg/m²), or continuous intravenous infusion (doses of 100-200 mg/m²)

I.V. doses of ≥1.5 g/m² may produce conjunctivitis which can be ameliorated with prophylactic use of corticosteroid (0.1% dexamethasone) eye drops. Dexamethasone eye drops should be administered at 1-2 drops every 6 hours during and for 2-7 days after cytarabine is done.

Contraindications Hypersensitivity to cytarabine or any component of the formulation

Warnings Hazardous agent - use appropriate precautions for handling and disposal. **[U.S. Boxed Warning]: Potent myelosuppressive agent;** use with caution in patients with prior bone marrow suppression; monitor for signs of febrile neutropenia. High-dose regimens are associated with CNS, gastrointestinal, ocular (prophylaxis with ophthalmic corticosteroid drops is recommended), and pulmonary toxicities. Use with caution in patients with impaired renal (high dose cytarabine) and hepatic function; may be at higher risk for CNS toxicities; dosage adjustments may be required. Tumor lysis syndrome and subsequent hyperuricemia may occur with high dose cytarabine; monitor, consider allopurinol and hydrate accordingly. Cytarabine syndrome is characterized by fever, myalgia, bone pain, chest pain, maculopapular rash, conjunctivitis, and malaise, and may occur 6-12 hours following administration; may be managed with corticosteroids. **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.** Some products may contain benzyl alcohol; do not use products containing benzyl alcohol or products reconstituted with bacteriostatic diluent intrathecally or for high-dose cytarabine regimens.

Dosage Forms Injection, powder for reconstitution: 100 mg, 500 mg, 1 g, 2 g Injection, solution: 20 mg/mL (5 mL, 25 mL, 50 mL); 100 mg/mL (20 mL)

Reference Range Cytotoxic plasma cytarabine range: 50-100 mg/L (0.2-0.4 mM/L)

Overdosage/Treatment Supportive therapy: High-dose methylprednisolone therapy (10 mg/kg) may be useful to treat cytarabine-induced ARDS. Additionally, compartment syndrome due to isolated extremity perfusion can be relieved with I.V. methylprednisolone (1 g). Keratoconjunctivitis can be avoided with prophylactic use of corticosteroid eye drops (1-2 drops of 0.1% dexamethasone ophthalmic solution in each eye) every 4-6 hours while awake for 1 week following high-dose cytarabine therapy; metoclopramide (2 mg/kg) before, 2,4, and 6 hours post-therapy can reduce vomiting by 70%

Drug Interactions

Digoxin: Cytarabine may decrease the levels/effects of digoxin (oral tablet).

Flucytosine: Cytarabine may decrease the therapeutic effect of flucytosine.

Pregnancy Risk Factor D

Pregnancy Implications Congenital limb abnormalities have been noted

Lactation Excretion in breast milk unknown/not recommended

Additional Information Supplied with diluent containing benzyl alcohol, which should not be used when preparing either high-dose or I.T. doses; patients with creatinine clearances <60 mL/minute may be particularly at risk for neurotoxicity

Pharmacodynamics/Kinetics

Onset of action: 1-2 hours

Duration: > 12 hours

Half-life elimination (route dependent): 2-5 hours

Time to peak, serum: 4 hours

Dosage

Adults: SubQ:

Abdominal surgery:

Low-to-moderate DVT risk: 2500 int. units 1-2 hours prior to surgery, then once daily for 5-10 days postoperatively

High DVT risk: 5000 int. units 1-2 hours prior to surgery and then once daily for 5-10 days postoperatively

Patients undergoing total hip surgery: **Note:** Three treatment options are currently available. Dose is given for 5-10 days, although up to 14 days of treatment have been tolerated in clinical trials:

Postoperative start:

Initial: 2500 int. units 4-8 hours* after surgery

Maintenance: 5000 int. units once daily; start at least 6 hours after postsurgical dose

Preoperative (starting day of surgery):

Initial: 2500 int. units within 2 hours before surgery

Adjustment: 2500 int. units 4-8 hours* after surgery

Maintenance: 5000 int. units once daily; start at least 6 hours after postsurgical dose

Preoperative (starting evening prior to surgery):

Initial: 5000 int. units 10-14 hours before surgery

Adjustment: 5000 int. units 4-8 hours* after surgery

Maintenance: 5000 int. units once daily, allowing 24 hours between doses.

***Dose may be delayed if hemostasis is not yet achieved.**

Unstable angina or non-Q-wave myocardial infarction: 120 int. units/kg body weight (maximum dose: 10,000 int. units) every 12 hours for 5-8 days with concurrent aspirin therapy. Discontinue dalteparin once patient is clinically stable.

Immobility during acute illness: 5000 int. units once daily

Dosing adjustment in renal impairment: Half-life is increased in patients with chronic renal failure, use with caution, accumulation can be expected; specific dosage adjustments have not been recommended

Dosing adjustment in hepatic impairment: Use with caution in patients with hepatic insufficiency; specific dosage adjustments have not been recommended

Monitoring Parameters Periodic CBC including platelet count; stool occult blood tests; monitoring of PT and PTT is not necessary

Administration

For deep SubQ injection only. May be injected in a U-shape to the area surrounding the navel, the upper outer side of the thigh, or the upper outer quadrangle of the buttock. Apply pressure to injection site; do not massage. Use thumb and forefinger to lift a fold of skin when injecting dalteparin to the navel area or thigh. Insert needle at a 45- to 90-degree angle. The entire length of needle should be inserted. Do not expel air bubble from fixed-dose syringe prior to injection. Air bubble (and extra solution, if applicable) may be expelled from graduated syringes.

Administration once daily beginning prior to surgery and continuing 5-10 days after surgery prevents deep vein thrombosis in patients at risk for thromboembolic complications. For unstable angina or non-Q-wave myocardial infarction, dalteparin is administered every 12 hours until the patient is stable (5-8 days).

Contraindications Hypersensitivity to dalteparin or any component of the formulation; thrombocytopenia associated with a positive *in vitro* test for antiplatelet antibodies in the presence of dalteparin; hypersensitivity to heparin or pork products; patients with active major bleeding; patients with unstable angina or non-Q-wave MI undergoing regional anesthesia; not for I.M. or I.V. use

Warnings

[U.S. Boxed Warning]: Patients with recent or anticipated neuraxial anesthesia (epidural or spinal anesthesia) are at risk of spinal or epidural hematoma and subsequent paralysis. Consider risk versus benefit prior to neuraxial anesthesia. Risk is increased by concomitant agents which may alter hemostasis, as well as traumatic or repeated epidural or spinal puncture. Patient should be observed closely for bleeding if dalteparin is administered during or immediately following diagnostic lumbar puncture, epidural anesthesia, or spinal anesthesia.

Not to be used interchangeably (unit for unit) with heparin or any other low molecular weight heparins. Use with caution in patients with known hypersensitivity to methylparaben or propylparaben. Use with caution in patients with history of heparin-induced thrombocytopenia. Monitor platelet count closely. Rare thrombocytopenia may occur. Consider discontinuation of dalteparin in any patient developing significant thrombocytopenia. Monitor patient closely for signs or symptoms of bleeding. Certain patients are at increased risk of bleeding. Risk factors include bacterial endocarditis; congenital or acquired bleeding disorders; active ulcerative or angiodysplastic GI diseases; severe uncontrolled hypertension; hemorrhagic stroke; or use shortly after brain, spinal, or ophthalmology surgery; in patient treated concomitantly with platelet inhibitors; recent GI bleeding; thrombocytopenia or platelet

Dalteparin

U.S. Brand Names Fragmin®

Use Prevention of deep vein thrombosis which may lead to pulmonary embolism, in patients requiring abdominal surgery who are at risk for thromboembolic complications (eg, patients >40 years of age, obesity, patients with malignancy, history of deep vein thrombosis or pulmonary embolism, and surgical procedures requiring general anesthesia and lasting >30 minutes); prevention of DVT in patients undergoing hip-replacement surgery; patients immobile during an acute illness; acute treatment of unstable angina or non-Q-wave myocardial infarction; prevention of ischemic complications in patients on concurrent aspirin therapy

Active treatment of deep vein thrombosis

Mechanism of Action Low molecular weight heparin analog with a molecular weight of 4000-6000 daltons; the commercial product contains 3% to 15% heparin with a molecular weight <3000 daltons, 65% to 78% with a molecular weight of 3000-8000 daltons and 14% to 26% with a molecular weight >8000 daltons; while dalteparin has been shown to inhibit both factor Xa and factor IIa (thrombin), the antithrombotic effect of dalteparin is characterized by a higher ratio of antifactor Xa to antifactor IIa activity (ratio = 4)

Adverse Reactions

Cardiovascular: Edema

Central nervous system: Confusion, fever

Dermatologic: Ecchymosis, pruritus, alopecia

Hematologic: Hemorrhage, thrombocytopenia, erythema, hypochromic anemia, coagulopathy, hematoma

Gastrointestinal: Nausea

Local: Irritation, pain

defects; severe liver disease; hypertensive or diabetic retinopathy; or in patients undergoing invasive procedures.

Use with caution in patients with severe renal failure (has not been studied). Safety and efficacy in pediatric patients have not been established. Rare cases of thrombocytopenia with thrombosis have occurred. Multidose vials contain benzyl alcohol and should not be used in pregnant women. Heparin can cause hyperkalemia by affecting aldosterone. Similar reactions could occur with LMWHs. Monitor for hyperkalemia.

Dosage Forms

Injection, solution [multidose vial]: Antifactor Xa 10,000 int. units per 1 mL (9.5 mL) [contains benzyl alcohol]; antifactor Xa 25,000 units per 1 mL (3.8 mL) [contains benzyl alcohol]

Injection, solution [preservative free; prefilled syringe]: Antifactor Xa 2500 int. units per 0.2 mL (0.2 mL); antifactor Xa 5000 int. units per 0.2 mL (0.2 mL); antifactor Xa 7500 int. units per 0.3 mL (0.3 mL); antifactor Xa 10,000 int. units per 1 mL (1 mL)

Reference Range Therapeutic plasma anti-Xa levels (antifactor Xa): 0.1-0.6 units/mL (antithrombotic activity); activated partial thromboplastin time (APTT) is not considered useful for dalteparin monitoring

Overdosage/Treatment

Supportive therapy: Protamine can be used for severe bleeding upon withdrawal of heparin (1 mg of protamine for every 1 mg of dalteparin [100 units] by slow I.V. push up to 50 mg over 60 minutes). An additional 0.5 mg protamine per 100 int. units of dalteparin can be administered 2-4 hours after the initial dose if the PTT is still elevated. If serious bleeding occurs, give fresh frozen plasma in addition to protamine.

Enhancement of elimination: While hemodialysis is not beneficial, exchange transfusion has been used successfully in a neonate and plasma exchange has been used successfully in four older patients for thrombocytopenia

Antidote(s)

- Protamine Sulfate [ANTIDOTE]

Drug Interactions

Drugs which affect platelet function (eg, aspirin, NSAIDs, dipyridamole, ticlopidine, clopidogrel) may potentiate the risk of hemorrhage.

Thrombolytic agents increase the risk of hemorrhage.

Warfarin: Risk of bleeding may be increased during concurrent therapy. Dalteparin is commonly continued during the initiation of warfarin therapy to assure anticoagulation and to protect against possible transient hypercoagulability.

Pregnancy Risk Factor B

Pregnancy Implications Multiple-dose vials contain benzyl alcohol (avoid in pregnant women due to association with fetal syndrome in premature infants).

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Not intended for I.M. administration

Additional Information Molecular weight: 5000; sulfur content: 11%

Danaparoid

CAS Number 83513-48-8

U.S. Brand Names Orgaran® [DSC]

Synonyms Danaparoid Sodium

Use Prevention of postoperative deep vein thrombosis following elective hip replacement surgery

Unlabeled/Investigational Use Systemic anticoagulation for patients with heparin-induced thrombocytopenia: factor Xa inhibition is used to monitor degree of anticoagulation if necessary

Mechanism of Action A low molecular weight heparinoid with antifactor Xa activity and decreased platelet function effects (as compared with heparin)

Adverse Reactions

- Cardiovascular: Peripheral edema, generalized edema
- Central nervous system: Fever, insomnia, headache, dizziness
- Dermatologic: Rash, pruritus
- Gastrointestinal: Nausea, constipation, vomiting
- Genitourinary: Urinary tract infections, urinary retention
- Hematologic: Anemia, hemorrhage, hematoma, thrombocytopenia (7%)
- Hepatic: Transient elevation of liver enzymes
- Local: Injection site pain
- Neuromuscular & skeletal: Joint disorder, weakness

Pharmacodynamics/Kinetics

Onset of action: Peak effect: SubQ: Maximum antifactor Xa and antithrombin (antifactor IIa) activities occur in 2-5 hours
 Half-life elimination, plasma: Mean: Terminal: ~24 hours
 Excretion: Primarily urine

Dosage

SubQ:
 Children: Safety and effectiveness have not been established

Adults: 750 anti-Xa units (~55 mg) twice daily; beginning 1-4 hours before surgery and then not sooner than 2 hours after surgery and every 12 hours until the risk of DVT has diminished, the average duration of therapy is 7-10 days

Dosing adjustment in renal impairment: Adjustment may be necessary in elderly and patients with severe renal impairment; patients with serum creatinine levels ≥ 2.0 mg/dL should be carefully monitored

Monitoring Parameters Platelets, occult blood, and anti-Xa activity, if available; the monitoring of PT and/or PTT is not necessary

Administration

Administer by subcutaneous injection, **not** I.M. Have patient lie down and administer by deep SubQ injection using a fine needle (25- to 26-gauge). Rotate sites of injection.

Contraindications Hypersensitivity to danaparoid or thrombocytopenia associated with a positive *in vitro* test for antiplatelet antibodies in the presence of danaparoid; hypersensitivity to pork products or to sulfites (contains metabisulfite); patients with active major bleeding; severe hemorrhagic diathesis (hemophilia, idiopathic thrombocytopenic purpura); not for I.M. or I.V. use

Warnings

Patients with recent or anticipated neuraxial anesthesia (epidural or spinal anesthesia) are at risk of spinal or epidural hematoma and subsequent paralysis. Consider risk versus benefit prior to neuraxial anesthesia; risk is increased by concomitant agents which may alter hemostasis, as well as traumatic or repeated epidural or spinal puncture. Patient should be observed closely for bleeding if danaparoid is administered during or immediately following diagnostic lumbar puncture, epidural anesthesia, or spinal anesthesia.

Not to be used interchangeably (unit for unit) with heparin or any other low molecular weight heparins. Use with caution in patients with known hypersensitivity to methylparaben or propylparaben. Use with caution in patients with history of heparin-induced thrombocytopenia. Monitor patient closely for signs or symptoms of bleeding. Certain patients are at increased risk of bleeding. Risk factors include bacterial endocarditis; congenital or acquired bleeding disorders; active ulcerative or angiodysplastic GI diseases; severe uncontrolled hypertension; hemorrhagic stroke; use shortly after brain, spinal, or ophthalmology surgery; patient treated concomitantly with platelet inhibitors; recent GI bleeding; thrombocytopenia or platelet defects; severe liver disease; hypertensive or diabetic retinopathy; or patients undergoing invasive procedures. Use with caution in patients with severe renal failure (has not been studied). Safety and efficacy in pediatric patients have not been established. Heparin can cause hyperkalemia by affecting aldosterone. A similar reaction could occur with danaparoid. Monitor for hyperkalemia.

Dosage Forms

[CAN] = Canadian brand name

Injection, solution:

Orgaran® [CAN]: 750 anti-Xa units/0.6 mL (0.6 mL) [not available in the U.S.]

Reference Range After 3250 anti-Xa units given SubQ, peak plasma anti-Xa activity is ~0.4 anti-Xa unit/mL; anti-Xa activity >0.8 anti-Xa unit/mL may be associated with bleeding

Overdosage/Treatment Supportive therapy: Essentially the same treatment plan as with heparin; protamine sulfate is only partially effective in neutralizing danaparoid

Antidote(s)

- Protamine Sulfate [ANTIDOTE]

Drug Interactions Drugs which affect platelet function (eg, aspirin, NSAIDs, dipyridamole, ticlopidine, clopidogrel) may potentiate the risk of hemorrhage.

Thrombolytic agents increase the risk of hemorrhage.

Warfarin (and other oral anticoagulants) may increase the risk of bleeding with danaparoid.

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown/compatible

Danazol

CAS Number 17230-88-5

U.S. Brand Names Danocrine®

Use Treatment of endometriosis, fibrocystic breast disease, and hereditary angioedema; also used for refractory thrombocytopenic purpura in children

Unlabeled/Investigational Use Precocious puberty, gynecomastia, menorrhagia, idiopathic immune thrombocytopenia, lupus-associated thrombocytopenia, and autoimmune hemolytic anemia

Mechanism of Action Suppresses pituitary output of follicle-stimulating hormone and luteinizing hormone that causes regression and atrophy of normal and ectopic endometrial tissue; decreases rate of growth of abnormal breast tissue; reduces attacks associated with hereditary angioedema by increasing levels of C4 component of complement

Adverse Reactions

- Cardiovascular: Hypertension, tachycardia, edema, sinus tachycardia
- Central nervous system: Anxiety, depression, Guillain-Barré syndrome

DANTROLENE

Dermatologic: **Oily skin, acne, hirsutism**, photosensitivity, cystic acne, seborrheic dermatitis, alopecia, erythema multiforme, purpura, hypertrichosis, angioedema, urticaria, Stevens-Johnson syndrome, pruritus, exanthem

Endocrine & metabolic: **Amenorrhea, breakthrough bleeding, irregular menstrual periods, decreased breast size, fluid retention**, hyperglycemia, hot flashes, hypophosphatemia, hypoprolactinemia

Gastrointestinal: Pancreatitis, **weight gain**

Genitourinary: Monilial vaginitis, testicular atrophy, enlarged clitoris, cystitis

Hematologic: Thrombocytopenia, thrombocytosis, hypercalcemia, porphyrinogenic

Hepatic: Cholestatic jaundice, **hepatic impairment**, liver cancer

Neuromuscular & skeletal: Weakness, carpal tunnel syndrome, paresthesia

Otic: Hearing loss

Renal: Hematuria

Miscellaneous: **Voice deepening**, virilization, clitoral hypertrophy, hypoprogesteronism, bleeding gums, benign intracranial hypertension, hypogonadism, peliosis of spleen and liver, systemic lupus erythematosus

Pharmacodynamics/Kinetics

Onset of action: Therapeutic: ~4 weeks

Metabolism: Extensively hepatic, primarily to 2-hydroxymethylethisterone

Half-life elimination: 4.5 hours (variable)

Time to peak, serum: Within 2 hours

Excretion: Urine

Dosage

Adults: Oral:

Female: Endometriosis: Initial: 200-400 mg/day in 2 divided doses for mild disease; individualize dosage. Usual maintenance dose: 800 mg/day in 2 divided doses to achieve amenorrhea and rapid response to painful symptoms. Continue therapy uninterrupted for 3-6 months (up to 9 months).

Female: Fibrocystic breast disease: Range: 100-400 mg/day in 2 divided doses

Male/Female: Hereditary angioedema: Initial: 200 mg 2-3 times/day; after favorable response, decrease the dosage by 50% or less at intervals of 1-3 months or longer if the frequency of attacks dictates. If an attack occurs, increase the dosage by up to 200 mg/day.

Monitoring Parameters Signs and symptoms of intracranial hypertension (papilledema, headache, nausea, vomiting), lipoproteins, androgenic changes, hepatic function

Contraindications Hypersensitivity to danazol or any component of the formulation; undiagnosed genital bleeding; pregnancy; breast-feeding; porphyria; markedly impaired hepatic, renal, or cardiac function

Warnings Use with caution in patients with seizure disorders, migraine, or conditions influenced by edema. **[U.S. Boxed Warning]: Thromboembolism, thrombotic, and thrombophlebotic events have been reported (including life-threatening or fatal strokes).** **[U.S. Boxed Warning]: Peliosis hepatis and benign hepatic adenoma have been reported with long-term use** (may be complicated by acute intra-abdominal hemorrhage). **[U.S. Boxed Warning]: May cause benign intracranial hypertension (pseudotumor cerebri).** Breast cancer should be ruled out prior to treatment for fibrocystic breast disease. May increase risk of atherosclerosis and coronary artery disease due to decreased HDL and possible increase of LDL. May cause nonreversible androgenic effects. **[U.S. Boxed Warning]: Pregnancy must be ruled out prior to treatment.** Safety and efficacy in pediatric patients have not been established.

Dosage Forms

[DSC] = Discontinued product

Capsule: 50 mg, 100 mg, 200 mg

Danocrine®: 50 mg, 100 mg, 200 mg [DSC]

Reference Range Oral dose of 400 mg results in a peak plasma level of 0.08 ng/mL

Overdosage/Treatment Decontamination: Emesis with ipecac within 30 minutes or lavage within 1 hour; activated charcoal

Test Interactions ↑ serum glucagon; ↓ serum thyroxine levels, FSH, and LH

Drug Interactions

Inhibits CYP3A4 (weak)

Carbamazepine: Danazol may increase carbamazepine concentrations, requiring a decreased dosage of carbamazepine; monitor

Cyclosporine: Danazol may increase cyclosporine concentrations leading to increased toxicity; dosage of cyclosporine may need decreased; monitor

HMG-CoA reductase inhibitors: Concomitant use may lead to severe myopathy or rhabdomyolysis; effect seen with lovastatin

Hormonal contraceptives: Danazol also inhibits ovulation, possibly by acting at (and competing for) the same hormonal receptors; nonhormonal birth control methods are recommended during therapy.

Hypoglycemic agents: Danazol effects glucose metabolism, concurrent use may lead to hypoglycemia; monitor

Tacrolimus: Danazol may increase tacrolimus concentrations leading to increased toxicity; monitor

Warfarin: Increased anticoagulant effect; avoid concomitant use if possible

Pregnancy Risk Factor X

Pregnancy Implications Premature bone maturation, masculinization of urogenital sinus, clitoromegaly before 12th week of gestation in the female fetus; after the first trimester, clitoral hypertrophy would be primary effect in the female fetus

Lactation Enters breast milk/contraindicated

Nursing Implications Ensure patient is not pregnant before therapy

Dantrolene

Related Information

• Therapeutic Drugs Associated with Hallucinations

CAS Number 14663-23-1; 24868-20-0; 7261-97-4

U.S. Brand Names Dantrium®

Synonyms Dantrolene Sodium

Use Treatment of spasticity associated with spinal cord injury, stroke, cerebral palsy, or multiple sclerosis; treatment of malignant hyperthermia

Unlabeled/Investigational Use Neuroleptic malignant syndrome (NMS), considered possibly beneficial for fever and rigidity due to carbon monoxide, cocaine poisoning, alcohol withdrawal "ecstasy"

Mechanism of Action Acts directly on skeletal muscle by interfering with release of calcium ion from the sarcoplasmic reticulum; prevents or reduces the increase in myoplasmic calcium ion concentration that activates the acute catabolic processes associated with malignant hyperthermia

Adverse Reactions

Cardiovascular: Pleural effusion with pericarditis

Central nervous system: Convulsions, **drowsiness, dizziness, light-headedness**, confusion, headache, **fatigue**, speech disturbances, slurred speech, **tiredness**, chills, fever, insomnia, nervousness, CNS depression, auditory and visual hallucinations

Dermatologic: **Rash**, urticaria, pruritus, exanthem

Gastrointestinal: **Diarrhea, nausea, vomiting**, severe constipation, anorexia, stomach cramps

Genitourinary: Urinary retention, crystalluria

Hepatic: Hepatitis

Neuromuscular & skeletal: **Weakness**

Ocular: Visual disturbances, diplopia

Otic: Ototoxicity, tinnitus

Renal: Hematuria

Respiratory: Apnea, respiratory depression, eosinophilic pneumonia

Miscellaneous: Lymphocytic lymphoma

Signs and Symptoms of Overdose Crystalluria, disorientation, hematuria, hypotension, insomnia, jaundice, lethargy, lightheadedness, neutropenia, nocturia, pericarditis, respiratory depression, seizures

Pharmacodynamics/Kinetics

Absorption: Oral: Slow and incomplete

Metabolism: Hepatic

Half-life elimination: 8.7 hours

Excretion: Feces (45% to 50%); urine (25% as unchanged drug and metabolites)

Dosage

Spasticity: Oral:

Children: Initial: 0.5 mg/kg/dose twice daily, increase frequency to 3-4 times/day at 4- to 7-day intervals, then increase dose by 0.5 mg/kg to a maximum of 3 mg/kg/dose 2-4 times/day up to 400 mg/day

Adults: 25 mg/day to start, increase frequency to 2-4 times/day, then increase dose by 25 mg every 4-7 days to a maximum of 100 mg 2-4 times/day or 400 mg/day

Malignant hyperthermia: Children and Adults:

Oral: 4-8 mg/kg/day in 4 divided doses

Preoperative prophylaxis: Begin 1-2 days prior to surgery with last dose 3-4 hours prior to surgery

I.V.: 1 mg/kg; may repeat dose up to cumulative dose of 10 mg/kg (mean effective dose is 2.5 mg/kg), then switch to oral dosage

Preoperative: 2.5 mg/kg ~1¹/₄ hours prior to anesthesia and infused over 1 hour with additional doses as needed and individualized

Stability Reconstitute vial by adding 60 mL of sterile water for injection USP (**not bacteriostatic water for injection**); protect from light; use within 6 hours; avoid glass bottles for I.V. infusion

Monitoring Parameters Motor performance should be monitored for therapeutic outcomes; nausea, vomiting, and liver function tests should be monitored for potential hepatotoxicity; intravenous administration requires cardiac monitor and blood pressure monitor

Administration

I.V.: Therapeutic or emergency dose can be administered with rapid continuous I.V. push. Follow-up doses should be administered over 2-3 minutes.

Contraindications Active hepatic disease; should not be used where spasticity is used to maintain posture or balance

Warnings Use with caution in patients with impaired cardiac function or impaired pulmonary function. **[U.S. Boxed Warning]: Has potential for hepatotoxicity.** Overt hepatitis has been most frequently observed between the third and twelfth month of therapy. Hepatic injury appears to be greater in females and in patients >35 years of age.

Dosage Forms Capsule, as sodium: 25 mg, 50 mg, 100 mg

Dantrium®: 25 mg, 50 mg, 100 mg

Injection, powder for reconstitution, as sodium:

Dantrium®: 20 mg [contains mannitol 3 g]

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** use ipecac

Supportive therapy: Hypotension can be treated with isotonic I.V. fluids with the patient placed in the Trendelenburg position; dopamine or norepinephrine can be given if hypotension is refractory to above therapy

Antidote(s)

- DOPamine [ANTIDOTE]
- Norepinephrine [ANTIDOTE]

Test Interactions ↑ serum AST, ALT, alkaline phosphatase, LDH, BUN, and total bilirubin

Drug Interactions

Substrate of CYP3A4 (major)

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of dantrolene. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of dantrolene. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Increased toxicity: Estrogens (hepatotoxicity), CNS depressants (sedation), MAO inhibitors, phenothiazines, clindamycin (increased neuromuscular blockade), verapamil (hyperkalemia and cardiac depression), warfarin, clofibrate, and tolbutamide

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications 36 vials needed for adequate hyperthermia therapy; exercise caution at meals on the day of administration because difficulty swallowing and choking have been reported

Additional Information Routine I.V. prophylactic use of dantrolene for malignant hyperthermia is associated with multiple and frequent side effects and thus is **not** recommended

Specific References

Rusyniak DE and Sprague JE, "Toxin-Induced Hyperthermic Syndromes," *Med Clin North Am*, 2005, 89(6):1277-96 (review).

photosensitivity, sulfhemoglobinemia and aplastic anemia (rare), tachycardia, toxic epidermal necrolysis, tubular necrosis, vomiting

Signs and symptoms can appear in a few minutes to within 24 hours following ingestion, with methemoglobinemia and CNS stimulation the most common.

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Pharmacodynamics/Kinetics

Absorption:

Oral: Well absorbed

Topical: ~1% of the absorption of 100 mg tablet

Distribution: V_d: 1.5 L/kg; throughout total body water and present in all tissues, especially liver and kidney

Metabolism: Hepatic; forms metabolite

Half-life elimination: 30 hours (range: 10-50 hours)

Excretion: Urine (~85%)

Dosage

Oral:

Leprosy:

Children: 1-2 mg/kg/24 hours, up to a maximum of 100 mg/day

Adults: 50-100 mg/day for 3-10 years

Dermatitis herpetiformis: Adults: Start at 50 mg/day, increase to 300 mg/day, or higher to achieve full control, reduce dosage to minimum level as soon as possible

Pneumocystis carinii pneumonia (unlabeled use):

Prophylaxis:

Children > 1 month: 2 mg/kg/day once daily (maximum dose: 100 mg/day) or 4 mg/kg/dose once weekly (maximum dose: 200 mg)

Adults: 100 mg/day

Treatment: Adults: 100 mg/day in combination with trimethoprim (15-20 mg/kg/day) for 21 days

Brown recluse spider bites: 100 mg twice daily for 14 days

Dosing adjustment in renal impairment: Necessary, but no specific guidelines are available

Stability

Protect from light

Monitoring Parameters Monitor patient for signs of jaundice and hemolysis; CBC weekly for first month, monthly for 6 months, and semiannually thereafter

Administration Oral: May give with meals if GI upset occurs.

Topical: Apply to clean, dry skin; rub in completely. Wash hands after application.

Contraindications Hypersensitivity to dapsone or any component of the formulation

Warnings Use with caution in patients with severe anemia, G6PD, methemoglobin reductase or hemoglobin M deficiency; hypersensitivity to other sulfonamides; aplastic anemia, agranulocytosis and other severe blood dyscrasias have resulted in death; monitor carefully; treat severe anemia prior to therapy; serious dermatologic reactions (including toxic epidermal necrolysis) are rare but potential occurrences; sulfone reactions may also occur as potentially fatal hypersensitivity reactions; these, but not leprosy reactional states, require drug discontinuation; dapsone is carcinogenic in small animals. Safety and efficacy of topical dapsone has not been adequately evaluated in patient with G6PD deficiency or in patients <12 years of age.

Dosage Forms

Gel, topical (Aczone™): 5% (30 g)

Tablet: 25 mg, 100 mg

Reference Range Levels do not correlate with symptoms but may be used to confirm diagnosis; therapeutic concentrations: 0.5-5 mcg/mL; toxic effects can occur at levels >10 mcg/mL

Overdosage/Treatment

Decontamination: Emesis within 30 minutes, lavage (within 1 hour)/activated charcoal

Supportive therapy: Monitor methemoglobin, CBC, blood smear, platelets, urinalysis, liver function tests, and ABGs; hemolysis may require transfusion; methylene blue 1-2 mg/kg (up to 4 mg/kg) may be required for symptomatic patients or those with a methemoglobin >30%; methylene blue may precipitate hemolytic anemia in large doses, in patients with G6PD deficiency and in one case of dapsone overdose; cimetidine may decrease the rate of toxic metabolite although has not been tried in the overdose situation; cimetidine (400 mg 3 times/day) can lower methemoglobin levels by 25% in a nonoverdose setting

Enhanced elimination: Charcoal hemoperfusion may be useful (one case report) in patients who have clinical deterioration despite supportive care; hemodialysis has also been reported to decrease the half-life; plasma exchange has been utilized with varying degrees of success; multiple doses of activated charcoal enhance elimination and is considered treatment of choice and may be required for as long as 72 hours

Dapsone

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 80-08-0

U.S. Brand Names Aczone™

Synonyms Diaminodiphenylsulfone

Use Treatment of leprosy and dermatitis herpetiformis (infections caused by *Mycobacterium leprae*)

Prophylaxis of toxoplasmosis in severely immunocompromised patients; alternative agent for *Pneumocystis carinii* pneumonia prophylaxis (monotherapy) and treatment (in combination with trimethoprim); brown recluse spider bites

Mechanism of Action Dapsone is a sulfone antimicrobial; mechanism of action of the sulfones is similar to that of the sulfonamides. Sulfonamides are competitive antagonists of para-aminobenzoic acid (PABA) and prevent normal bacterial utilization of PABA for the synthesis of folic acid.

Adverse Reactions

Cardiovascular: Sinus tachycardia

Central nervous system: Insomnia, psychosis, dizziness, headache, visual hallucinations, axonopathy

Dermatologic: Exfoliative dermatitis, toxic epidermal necrolysis, erythema nodosum leprosum

Gastrointestinal: Nausea, vomiting

Hematologic: Hemolysis, methemoglobinemia, neutropenia, agranulocytosis, aplastic anemia, thrombocytosis, red blood cell aplasia, methemoglobinemia followed by hemolysis, pulmonary eosinophilia

Hepatic: Hepatitis, cholestatic jaundice

Neuromuscular & skeletal: Paresthesia, peripheral neuropathy

Ocular: Blurred vision

Otic: Ototoxicity, tinnitus

Miscellaneous: Mononucleosis-like syndrome

Signs and Symptoms of Overdose Aggressive behavior, coma (with large overdose), cyanosis, dyspnea, elevated bilirubin, elevated transaminases, erythema, erythema multiforme, hallucinations, hematuria, hemolysis with the appearance of Heinz bodies (common), hyperventilation, hypotension, insomnia, methemoglobinemia (common), nephrotic syndrome, oliguria, paresthesia (distal motor axonopathy),

DAUNORUBICIN HYDROCHLORIDE

Antidote(s)

- Methylene Blue [ANTIDOTE]

Drug Interactions Substrate of CYP2C8 (minor), 2C9 (major), 2C19 (minor), 2E1 (minor), 3A4 (major)

CYP2C9 Inducers may decrease the levels/effects of dapsone. Example inducers include carbamazepine, phenobarbital, phenytoin, rifampin, rifapentine, and secobarbital.

CYP2C9 Inhibitors may increase the levels/effects of dapsone. Example inhibitors include delavirdine, fluconazole, gemfibrozil, ketoconazole, nocardipine, NSAIDs, sulfonamides and tolbutamide.

CYP3A4 inducers: May decrease the levels/effects of dapsone. Example inducers include aminoglutethimide, carbamazepine, efavirenz, fosphenytoin, nafcillin, nevirapine, oxcarbazepine, phenobarbital, phenytoin, primidone, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of dapsone. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nocardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Didanosine: May decrease absorption of dapsone. Didanosine enteric coated capsules should not affect dapsone. Avoid other forms of didanosine.

Folic acid antagonists: May increase the risk of hematologic reactions of dapsone.

Probenecid: Decreases dapsone excretion.

Rifamycin derivatives: Increase metabolism of dapsone.

Trimethoprim: May increase toxic effects of both drugs.

Pregnancy Risk Factor C

Pregnancy Implications Does cross placenta but there have been cases with normal pregnancy outcomes with mothers taking dapsone; however, because it has the capacity to induce methemoglobinemia and hemolytic anemia, it has been suggested to limit its use in pregnancy; overdose in pregnancy has not been reported; secreted in milk with a few reports of neonatal hemolytic anemia

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Additional Information Dapsone accounts for about 42% of cases of acquired methemoglobinemia (with a mean peak methemoglobinemia of 7.6%)

Hepatic: Elevation of serum bilirubin, AST, and alkaline phosphatase

Local: Extravasation: Daunorubicin is a vesicant; infiltration can cause severe inflammation, tissue necrosis, and ulceration; if the drug is infiltrated, consult institutional policy, apply ice to the area, and elevate the limb

Miscellaneous: Fertility impairment

Pharmacodynamics/Kinetics

Distribution: Many body tissues, particularly the liver, kidneys, lung, spleen, and heart; not into CNS; crosses placenta; V_d : 40 L/kg

Metabolism: Primarily hepatic to daunorubicinol (active), then to inactive aglycones, conjugated sulfates, and glucuronides

Half-life elimination: Distribution: 2 minutes; Elimination: 14-20 hours;

Terminal: 18.5 hours; Daunorubicinol plasma half-life: 24-48 hours

Excretion: Feces (40%); urine (~25% as unchanged drug and metabolites)

Dosage

I.V. (refer to individual protocols):

Children:

ALL combination therapy: Remission induction: 25-45 mg/m² on day 1 every week for 4 cycles or 30-45 mg/m²/day for 3 days

AML combination therapy: Induction: I.V. continuous infusion: 30-60 mg/m²/day on days 1-3 of cycle

Note: In children <2 years or <0.5 m², daunorubicin should be based on weight - mg/kg: 1 mg/kg per protocol with frequency dependent on regimen employed

Cumulative dose should not exceed 300 mg/m² in children > 2 years; maximum cumulative doses for younger children are unknown.

Adults:

Range: 30-60 mg/m²/day for 3-5 days, repeat dose in 3-4 weeks

AML: Single agent induction: 60 mg/m²/day for 3 days; repeat every 3-4 weeks

AML: Combination therapy induction: 45 mg/m²/day for 3 days of the first course of induction therapy; subsequent courses: Every day for 2 days

ALL combination therapy: 45 mg/m²/day for 3 days

Cumulative dose should not exceed 400-600 mg/m²

Dosing adjustment in renal impairment:

Cl_{cr} <10 mL/minute: Administer 75% of normal dose

S_{cr} >3 mg/dL: Administer 50% of normal dose

Dosing adjustment in hepatic impairment:

Serum bilirubin 1.2-3 mg/dL or AST 60-180 int. units: Reduce dose to 75%

Serum bilirubin 3.1-5 mg/dL or AST >180 int. units: Reduce dose to 50%

Serum bilirubin >5 mg/dL: Omit use

Stability Store intact vials at room temperature and protect from light. Dilute vials with 4 mL SWFI for a final concentration of 5 mg/mL; reconstituted solution is stable for 4 days at 15°C to 25°C. Further dilution in D₅W, LR, or NS is stable at room temperature (25°C) for up to 4 weeks if protected from light.

Monitoring Parameters CBC with differential and platelet count, liver function test, ECG, ventricular ejection fraction, renal function test

Administration

Not for I.M. or SubQ administration. Administer IVP over 1-5 minutes into the tubing of a rapidly infusing I.V. solution of D₅W or NS; daunorubicin has also been diluted in 100 mL of D₅W or NS and infused over 15-30 minutes.

Extravasation management: Apply ice immediately for 30-60 minutes; then alternate off/on every 15 minutes for 1 day. Topical cooling may be achieved using ice packs or cooling pad with circulating ice water. Cooling of site for 24 hours as tolerated by the patient. Elevate and rest extremity 24-48 hours, then resume normal activity as tolerated. Application of cold inhibits vesicant's cytotoxicity. Application of heat or sodium bicarbonate can be harmful and is contraindicated. If pain, erythema, and/or swelling persist beyond 48 hours, refer patient immediately to plastic surgeon for consultation and possible debridement.

Contraindications Hypersensitivity to daunorubicin or any component of the formulation; congestive heart failure or arrhythmias; previous therapy with high cumulative doses of daunorubicin and/or doxorubicin; pre-existing bone marrow suppression; pregnancy

Warnings

Hazardous agent - use appropriate precautions for handling and disposal. Use with caution in patients who have received radiation therapy; reduce dosage in patients who are receiving radiation therapy simultaneously.

[U.S. Boxed Warnings]: Use caution with renal impairment or in the presence of hepatic dysfunction; dosage reduction is recommended. Potent vesicant; if extravasation occurs, severe tissue damage leading to ulceration and necrosis, and pain may occur. For I.V. use only. Severe bone marrow suppression may occur.

[U.S. Boxed Warning]: May cause cumulative, dose-related myocardial toxicity (concurrent or delayed). Total cumulative dose should take into account previous or concomitant treatment with cardiotoxic agents or irradiation of chest.

DAUNORUBICIN Hydrochloride

CAS Number 20830-81-3; 23541-50-6

U.S. Brand Names Cerubidine®

Synonyms Daunomycin; DNR; NSC-82151; Rubidomycin Hydrochloride

Use Treatment of ANLL and myeloblastic leukemia; questionable results in neuroblastoma; has been used for advanced HIV-associated Kaposi's sarcoma (orphan drug status)

Mechanism of Action Inhibition of DNA and RNA synthesis, by intercalating between DNA base pairs and by steric obstruction; is not cell cycle-specific for the S phase of cell division; daunomycin is preferred over doxorubicin for the treatment of ANLL because of its dose-limiting toxicity (myelosuppression) is not of concern in the therapy of this disease; has less mucositis associated with its use

Adverse Reactions

Vesicant chemotherapy

Cardiovascular: Congestive heart failure; maximum lifetime dose: Refer to Warnings; pericarditis/myocarditis

Central nervous system: Chills

Dermatologic: **Alopecia (versible)**, rash, pigmentation of nail beds, urticaria, hyperpigmentation, radiation recall dermatitis

Endocrine & metabolic: Hyperuricemia

Gastrointestinal: **Mild nausea or vomiting occurs in 50% of patients within the first 24 hours; stomatitis** may occur 3-7 days after administration, but is not as severe as that caused by doxorubicin; GI ulceration, diarrhea

Genitourinary: **Urine discoloration (red) for 1-2 days**

Hematologic:

Myelosuppressive: Dose-limiting toxicity, occurs in all patients; leukopenia is more significant than thrombocytopenia

WBC: Severe; Platelets: Severe; Onset (days): 7; Nadir (days): 14;

Recovery (days): 21-28

Irreversible myocardial toxicity may occur as total dosage approaches:

- 550 mg/m² in adults
- 400 mg/m² in patients receiving chest radiation
- 300 mg/m² in children >2 years of age

[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician].

Dosage Forms

Injection, powder for reconstitution: 20 mg, 50 mg

Cerubidine®: 20 mg

Injection, solution: 5 mg/mL (4 mL, 10 mL)

Overdosage/Treatment

Supportive therapy:

Extravasation management:

Apply ice immediately for 30-60 minutes; then alternate off/on every 15 minutes for one day

Topical cooling may be achieved using ice packs or cooling pad with circulating ice water; cooling of site for 24 hours as tolerated by the patient. Elevate and rest extremity 24-48 hours, then resume normal activity as tolerated. Application of cold inhibits vesicant's cytotoxicity.

Application of heat or sodium bicarbonate can be harmful and is contraindicated

If pain, erythema, and/or swelling persist beyond 48 hours, refer patient immediately to plastic surgeon for consultation and possible debridement

For extravasation, topical dimethyl sulfoxide (1.5 mL on site every 6-8 hours for 2 weeks) should be utilized; cardiomyopathy should be treated with salt restriction, diuretics and digitalis; allopurinol should be given to prevent urate nephropathy if massive cell lysis occurs

Test Interactions ↑ potassium (S), uric acid due to hyperuricemia secondary to cell lysis

Drug Interactions Patients may experience impaired immune response to vaccines; possible infection after administration of live vaccines in patients receiving immunosuppressants

Pregnancy Risk Factor D

Pregnancy Implications May cause fetal harm when administered to a pregnant woman. Animal studies have shown an increased incidence of fetal abnormalities.

Lactation Excretion in breast milk unknown/not recommended

Dehydroepiandrosterone

CAS Number 53-43-0

Use Not FDA approved: Has been used to boost the immune system, increase insulin sensitivity, improve symptoms in multiple sclerosis; as an antiobesity agent; for improvement of mood and memory in the elderly

Mechanism of Action An adrenal steroid and intermediate in testosterone and estradiol synthesis from cholesterol. It is secreted by the adrenal cortex primarily as a sulfate conjugate (DHEA-S).

Adverse Reactions

Dermatologic: Acne, hirsutism, alopecia

Hepatic: Transient hepatitis

Miscellaneous: Voice deepening (may be irreversible); may possibly increase development of breast, prostate, and ovarian cancer

Toxicodynamics/Kinetics Half-life: DHEA: 15-30 minutes; DHEA-S: 7-10 hours

Dosage

Oral:

Improvement of mood, energy, libido, and memory in the elderly: 30-90 mg/day for 4 weeks

Antiobesity: 1600 mg/day for 4 weeks

Increased insulin sensitivity in postmenopausal women: 50 mg daily for 3 weeks

Symptomatic improvement in systemic lupus erythematosus: 200 mg daily

Reference Range Average serum level of DHEA-S in men 25-34 years of age is $\sim 6.44 \pm 2.29$ $\mu\text{mol/L}$, falling to 1.15 ± 0.5 $\mu\text{mol/L}$ in men 75-84 years of age. Corresponding fall of DHEA levels is from 15.91 ± 6.05 nmol/L to 5.36 ± 1.69 nmol/L, respectively. The decline is relatively constant at $\sim 2\%$ per year. DHEA-S levels in young women are $\sim 10\%$ to 30% lower than in young men, but sex differences decline with age.

Overdosage/Treatment Decontamination: Oral: Emesis with syrup of ipecac within 30 minutes, or lavage within 1 hour; activated charcoal may be useful

Desipramine

Pronunciation (des IP ra meen)

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antidepressant Agents

CAS Number 50-47-5; 58-28-6

U.S. Brand Names Norpramin®

Synonyms Desipramine Hydrochloride; Desmethylinipramine Hydrochloride

Use Treatment of depression

Unlabeled/Investigational Use Analgesic adjunct in chronic pain; peripheral neuropathies; substance-related disorders (eg, cocaine withdrawal); attention-deficit/hyperactivity disorder (ADHD); depression in children ≤ 12 years of age

Mechanism of Action Traditionally believed to increase the synaptic concentration of norepinephrine (and to a lesser extent, serotonin) in the central nervous system by inhibition of its reuptake by the presynaptic neuronal membrane. However, additional receptor effects have been found including desensitization of adenylyl cyclase, down regulation of beta-adrenergic receptors, and down regulation of serotonin receptors.

Adverse Reactions

Cardiovascular: Cardiac arrhythmias, myocarditis, sinus tachycardia, tachycardia (supraventricular), torsade de pointes, exacerbation of Brugada syndrome

Central nervous system: **Drowsiness, dizziness, headache**, sedation, psychosis, confusion, excitation associated with falls, restlessness

Dermatologic: Photosensitivity, exfoliative dermatitis, acne, alopecia, angioedema, urticaria, purpura, pruritus, exanthem

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone, gynecomastia

Gastrointestinal: **Constipation, increased appetite, unpleasant taste, nausea, weight gain, xerostomia**, vomiting, craving sweets, bowel ischemia, lingua villosa nigra

Genitourinary: Urinary retention

Hematologic: Blood dyscrasias

Hepatic: Hepatitis

Neuromuscular & skeletal: **Weakness**, clonus, myoclonus, paresthesia

Ocular: Blurred vision, diplopia, photophobia, increased intraocular pressure, mydriasis

Otic: Ototoxicity, tinnitus

Respiratory: Pulmonary edema

Miscellaneous: Hypersensitivity reactions

Signs and Symptoms of Overdose Symptoms include severe hypotension, agitation, confusion, hypo-/hyperthermia, hypotension (severe), urinary retention, CNS depression, coma, cyanosis, dry mucous membranes, cardiac arrhythmias, seizures, changes in ECG (particularly in QRS axis and width), transient visual hallucinations, stupor, and muscle rigidity.

Admission Criteria/Prognosis Admit any patient who is symptomatic (including sinus tachycardia) 6 hours postingestion; admit any pediatric ingestion > 5 mg/kg

Pharmacodynamics/Kinetics

Onset of action: 1-3 weeks; Maximum antidepressant effect: > 2 weeks

Absorption: Well absorbed

Metabolism: Hepatic

Half-life elimination: Adults: 7-60 hours

Time to peak, plasma: 4-6 hours

Excretion: Urine (70%)

Dosage

Oral (not recommended for use in children < 12 years):

Adolescents: Initial: 25-50 mg/day; gradually increase to 100 mg/day in single or divided doses; maximum: 150 mg/day

Adults: Initial: 75 mg/day in divided doses; increase gradually to 150-200 mg/day in divided or single dose; maximum: 300 mg/day

Monitoring Parameters Monitor blood pressure and pulse rate prior to and during initial therapy evaluate mental status; monitor weight; ECG in older adults and those patients with cardiac disease; blood levels are useful for therapeutic monitoring

Contraindications Hypersensitivity to desipramine, drugs of similar chemical class, or any component of the formulation; use of MAO inhibitors within 14 days; use in a patient during the acute recovery phase of MI; concurrent use of thioridazine

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. Desipramine is FDA approved for the treatment of depression in adolescents.

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Desipramine is not FDA approved for the treatment of bipolar depression.**

May cause sedation, resulting in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Sedative effects may be additive with other CNS depressants and/or ethanol. The degree of sedation is low-moderate relative to other antidepressants. May cause hyponatremia/SIADH. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Therapy should not be abruptly discontinued in patients receiving high doses for prolonged periods.

May cause orthostatic hypotension (risk is moderate relative to other antidepressants) - use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly tolerated (cardiovascular disease or cerebrovascular disease). The degree of anticholinergic blockade produced by this agent is low relative to other cyclic antidepressants - however, caution should be used in patients with urinary retention, benign prostatic hyperplasia, narrow-angle glaucoma, xerostomia, visual problems, constipation, or a history of bowel obstruction.

Use with caution in patients with a history of cardiovascular disease (including previous MI, stroke, tachycardia, or conduction abnormalities). The risk conduction abnormalities with this agent is moderate relative to other antidepressants. Use caution in patients with a previous seizure disorder or condition predisposing to seizures such as brain damage, alcoholism, or concurrent therapy with other drugs which lower the seizure threshold. Use with caution in hyperthyroid patients or those receiving thyroid supplementation. Use with caution in patients with hepatic or renal dysfunction and in elderly patients.

Dosage Forms Tablet, as hydrochloride: 10 mg, 25 mg, 50 mg, 75 mg, 100 mg, 150 mg

Reference Range

Therapeutic: 150-300 ng/mL (SI: 560-1125 nmol/L)

Possible toxicity: >300 ng/mL (SI: >1070 nmol/L)

Toxic: >1000 ng/mL (SI: >3750 nmol/L)

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: Lavage (within 2-3 hours)/activated charcoal; multiple dosing of activated charcoal is more effective

Treatment is supportive and symptom-directed. Initiate gastric decontamination (emesis is contraindicated) and ECG monitoring immediately; monitor for a minimum of 6 hours. Sodium bicarbonate is indicated when the QRS interval is ≥ 0.10 seconds or the QT_c is >0.42 seconds. Ventricular arrhythmias and ECG changes (eg, QRS widening) often respond with concurrent systemic alkalization (sodium bicarbonate 0.5-2 mEq/kg I.V.). Arrhythmias unresponsive to phenytoin 15-20 mg/kg (adults) may respond to lidocaine 1 mg/kg I.V. followed by a titrated infusion. Physostigmine (1-2 mg slow I.V. for adults or 0.5 mg slow I.V. for children) may be indicated in reversing life-threatening cardiac arrhythmias. Seizures usually respond to diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required. Dialysis and diuresis have not been proven beneficial.

Antidote(s)

- Sodium Bicarbonate [ANTIDOTE]

Test Interactions

↑ glucose

Drug Interactions

Substrate of CYP1A2 (minor), 2D6 (major); **Inhibits** CYP2A6 (moderate), 2B6 (moderate), 2D6 (moderate), 2E1 (weak), 3A4 (moderate) α - and β -agonists: When combined with TCAs, may predispose patients to cardiac arrhythmias; may also enhance vasopressor effects; consider alternate therapy.

Altretamine: Concurrent use may cause orthostatic hypertension.

Amphetamines: TCAs may enhance the effect of amphetamines; monitor for adverse CV effects.

Anticholinergics: Combined use with TCAs may produce additive anticholinergic effects.

Barbiturates: May decrease the levels/effects of TCAs; monitor.

Bupropion: May increase the levels of tricyclic antidepressants; based on limited information; monitor response.

Carbamazepine: Tricyclic antidepressants may increase carbamazepine levels; monitor.

Cholestyramine and colestipol: May bind TCAs and reduce their absorption; monitor for altered response.

Clonidine: Abrupt discontinuation of clonidine may cause hypertensive crisis; amitriptyline may enhance the response.

CNS depressants: Sedative effects may be additive with TCAs; monitor for increased effect; includes benzodiazepines, barbiturates, antipsychotics, ethanol, and other sedative medications.

CYP2A6 substrates: Desipramine may increase the levels/effects of CYP2A6 substrates. Example substrates include dexmedetomidine and ifosfamide.

CYP2B6 substrates: Desipramine may increase the levels/effects of CYP2B6 substrates. Example substrates include bupropion, cyclophosphamide, irinotecan, ketamine, promethazine, propofol, and selegiline.

CYP2D6 inhibitors: May increase the levels/effects of desipramine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP2D6 substrates: Desipramine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine. Concurrent use with thioridazine is contraindicated.

CYP2D6 prodrug substrates: Desipramine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

CYP3A4 substrates: Desipramine may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Epinephrine (and other direct alpha-agonists): Pressor response to I.V. epinephrine, norepinephrine, and phenylephrine may be enhanced in patients receiving TCAs. (**Note:** Effect is unlikely with epinephrine or levonordefrin dosages typically administered as infiltration in combination with local anesthetics.)

False neurotransmitters (eg, guanadrel, methyl dopa): TCAs may diminish the antihypertensive effects of false neurotransmitters.

Fenfluramine: May increase tricyclic antidepressant levels/effects.

Hypoglycemic agents (including insulin): TCAs may enhance the hypoglycemic effects of tolazamide, chlorpropamide, or insulin; monitor for changes in blood glucose levels; reported with chlorpropamide, tolazamide, and insulin.

Levodopa: Tricyclic antidepressants may decrease the absorption (bioavailability) of levodopa; rare hypertensive episodes have also been attributed to this combination.

Linezolid: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** with agents which inhibit MAO (serotonin syndrome); this combination should be avoided.

Lithium: Concurrent use with a TCA may increase the risk for neurotoxicity.

MAO inhibitors: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** (serotonin syndrome); this combination should be avoided.

Methylphenidate: Metabolism of TCAs may be decreased.

Phenothiazines: Serum concentrations of some TCAs may be increased; in addition, TCAs may increase concentration of phenothiazines; monitor for altered clinical response.

Pramlintide: May increase the anticholinergic effects of TCAs.

QT_c -prolonging agents: Concurrent use of tricyclic agents with other drugs which may prolong QT_c interval may increase the risk of potentially fatal arrhythmias; includes type Ia and type III antiarrhythmics agents, selected quinolones (sparfloxacin, gatifloxacin, moxifloxacin, grepafloxacin), cisapride, and other agents.

Ritonavir: Combined use of high-dose tricyclic antidepressants with ritonavir may cause serotonin syndrome in HIV-positive patients; monitor. Serotonin modulators, SSRIs, sibutramine: Concomitant use may increase serotonergic effects; concurrent use with sibutramine is contraindicated.

Sympathomimetics, indirect-acting: Tricyclic antidepressants may result in a decreased sensitivity to indirect-acting sympathomimetics; includes dopamine and ephedrine; also see interaction with epinephrine (and direct-acting sympathomimetics).

Terbinafine: May increase the levels/effects of TCAs; monitor.

Tramadol: Tramadol's risk of seizures may be increased with TCAs.

Valproic acid: May increase serum concentrations/adverse effects of some tricyclic antidepressants.

Warfarin (and other oral anticoagulants): TCAs may increase the anticoagulant effect in patients stabilized on warfarin; monitor INR.

Pregnancy Risk Factor C

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Nursing Implications Monitor blood pressure and pulse rate prior to and during initial therapy; may increase appetite

Additional Information May unmask pheochromocytoma; nitroglycerin administration decreased survival time in a rodent model

Deslanoside

CAS Number 17598-65-1

Use Rapid digitalizing effect in emergency treatment of congestive heart failure, paroxysmal atrial tachycardia, fibrillation (atrial) and flutter

Adverse Reactions

Cardiovascular: Sinus bradycardia, AV block, S-A block, ectopic beats (atrial or nodal), arrhythmias (ventricular), bigeminy, trigeminy, atrial tachycardia with AV block, sinus tachycardia, tachycardia (supraventricular)

Central nervous system: Drowsiness, fatigue, neuralgia, dizziness, disorientation, chorea (extrapyramidal), visual hallucinations, paranoia, headache, extrapyramidal reactions

Endocrine & metabolic: Toxicity is enhanced by hypokalemia

Gastrointestinal: Vomiting, nausea, feeding intolerance, abdominal pain, diarrhea

Ocular: Blurred vision, halos, yellow or green vision, diplopia, photophobia, flashing lights

Signs and Symptoms of Overdose Arrhythmias, AV block, fibrillation (ventricular) or asystole, hyperkalemia, hypokalemia, hypotension, neuropathy (peripheral), tachycardia (ventricular), vision color changes (blue tinge; green tinge; red tinge; yellow tinge)

Toxicodynamics/Kinetics Half-life: 33 hours

Dosage I.M., I.V.:

Children:

Neonates, premature and full-term: 22 mcg divided into 2-3 doses every 3-4 hours

2 weeks to 3 years: 25 mcg/kg divided into 2-3 doses every 3-4 hours >3 years: 22.5 mcg/kg divided into 2-3 doses every 3-4 hours

Children and Adults: Highly individualized

Adults: Loading dose: 1.2-1.6 mg in 2 divided doses over 24 hours

Reference Range

Therapeutic: 0.5-2.0 ng/mL (SI: 0.6-2.6 nmol/L); Adults: <0.5 ng/mL (SI: <0.6 nmol/L) probably indicates underdigitalization unless there are special circumstances

Toxic: >2.0 ng/mL (SI: >2.6 nmol/L)

Fatal: >3.5 ng/mL (>4.8 nmol/L)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; whole bowel irrigation may be useful

Supportive therapy: Antidote: Life-threatening digoxin toxicity is treated with Digibind®; phenytoin, magnesium, and lidocaine are useful for arrhythmias; atropine is useful for bradycardia; avoid quinidine, bretylium, or cardioversion

Enhancement of elimination: Multiple dosing of activated charcoal may be useful; hemodialysis/hemoperfusion is ineffective

Diagnostic Procedures

- Digoxin, Blood

Test Interactions Digibind® increases total serum digoxin level ~50-fold; digoxin-like immunoreactive substance (DLIS), which is an endogenous natriuretic substance, may cause false elevation

Pregnancy Risk Factor C

neurologic sequelae in children with bacterial meningitis due to *Haemophilus influenzae* type b infections; no longer recommended for septic shock; used for thrombocytopenia in AIDS; may reduce peripheral edema due to docetaxel

Unlabeled/Investigational Use Dexamethasone suppression test: General indicator consistent with depression and/or suicide

Mechanism of Action Decreases inflammation by suppression of migration of polymorphonuclear leukocytes and reversal of increased capillary permeability; suppresses normal immune response. Dexamethasone's mechanism of antiemetic activity is unknown.

Adverse Reactions

Cardiovascular: Edema, hypertension, premature ventricular contraction, sinus bradycardia, arrhythmias (ventricular), QT prolongation, cardiomegaly, cardiomyopathy

Central nervous system: Headache, mania, dizziness, seizures, psychosis, pseudotumor cerebri, **insomnia**, CNS depression, depression, **neuropathic**

Dermatologic: Acne, dermatitis, skin atrophy, hypertrichosis, acute generalized exanthematous pustulosis

Endocrine & metabolic: Pituitary-adrenal axis suppression, growth suppression, hyperthyroidism, glucose intolerance, hypokalemia, alkalosis, Cushing's syndrome, hyperglycemia, hypoprolactinemia

Gastrointestinal: Peptic ulcer, nausea, vomiting, pancreatitis, fecal discoloration (dark brown), **increased appetite, indigestion**

Hematologic: Eosinopenia, leukocytosis, leukemoid reaction, thrombocytopenia, porphyria

Neuromuscular & skeletal: Myalgia, osteoporosis, fractures, rhabdomyolysis, weakness

Ocular: Cataracts, ptosis, photophobia, diplopia, increased intraocular pressure, glaucoma, blindness

Renal: Proteinuria

Miscellaneous: Hiccups

Pharmacodynamics/Kinetics

Onset of action: Acetate: Prompt

Duration of metabolic effect: 72 hours; acetate is a long-acting repository preparation

Metabolism: Hepatic

Half-life elimination: Normal renal function: 1.8-3.5 hours; Biological half-life: 36-54 hours

Time to peak, serum: Oral: 1-2 hours; I.M.: ~8 hours

Excretion: Urine and feces

Dosage

Children:

Antiemetic (prior to chemotherapy): I.V. (should be given as sodium phosphate): 5-20 mg given 15-30 minutes before treatment

Anti-inflammatory immunosuppressant: Oral, I.M., I.V. (injections should be given as sodium phosphate): 0.08-0.3 mg/kg/day or 2.5-10 mg/m²/day in divided doses every 6-12 hours

Extubation or airway edema: Oral, I.M., I.V. (injections should be given as sodium phosphate): 0.5-2 mg/kg/day in divided doses every 6 hours beginning 24 hours prior to extubation and continuing for 4-6 doses afterwards

Cerebral edema: I.V. (should be given as sodium phosphate): Loading dose: 1-2 mg/kg/dose as a single dose; maintenance: 1-1.5 mg/kg/day (maximum: 16 mg/day) in divided doses every 4-6 hours for 5 days then taper for 5 days, then discontinue

Bacterial meningitis in infants and children >2 months: I.V. (should be given as sodium phosphate): 0.6 mg/kg/day in 4 divided doses every 6 hours for the first 4 days of antibiotic treatment; start dexamethasone at the time of the first dose of antibiotic

Physiologic replacement: Oral, I.M., I.V.: 0.03-0.15 mg/kg/day or 0.6-0.75 mg/m²/day in divided doses every 6-12 hours

Adults:

Antiemetic:

Prophylaxis: Oral, I.V.: 10-20 mg 15-30 minutes before treatment on each treatment day

Continuous infusion regimen: Oral or I.V.: 10 mg every 12 hours on each treatment day

Mildly emetogenic therapy: Oral, I.M., I.V.: 4 mg every 4-6 hours

Delayed nausea/vomiting: Oral: 4-10 mg 1-2 times/day for 2-4 days or

8 mg every 12 hours for 2 days; then

4 mg every 12 hours for 2 days or

20 mg 1 hour before chemotherapy; then

10 mg 12 hours after chemotherapy; then

8 mg every 12 hours for 4 doses; then

4 mg every 12 hours for 4 doses

Anti-inflammatory:

Oral, I.M., I.V. (injections should be given as sodium phosphate): 0.75-9 mg/day in divided doses every 6-12 hours

I.M. (as acetate): 8-16 mg; may repeat in 1-3 weeks

Intralesional (as acetate): 0.8-1.6 mg

Intra-articular/soft tissue (as acetate): 4-16 mg; may repeat in 1-3 weeks

Dexamethasone

Related Information

- Corticosteroids

CAS Number 1177-87-3; 2265-64-7; 2392-39-4; 312-93-6; 3936-02-5; 50-02-2

U.S. Brand Names Decadron® Phosphate [DSC]; Decadron®; Dexamethasone Intensol®; DexPak® TaperPak®; Maxidex®

Synonyms Dexamethasone Sodium Phosphate

Use Systemically and locally for chronic inflammation, allergic, hematologic, neoplastic, and autoimmune diseases; may be used in management of cerebral edema, as a diagnostic agent, antiemetic; to prevent

Intra-articular, intralesional, or soft tissue (as sodium phosphate): 0.4-6 mg/day

Ophthalmic:

Ointment: Apply thin coating into conjunctival sac 3-4 times/day; gradually taper dose to discontinue

Suspension: Instill 2 drops into conjunctival sac every hour during the day and every other hour during the night; gradually reduce dose to every 3-4 hours, then to 3-4 times/day

Topical: Apply 1-4 times/day. Therapy should be discontinued when control is achieved; if no improvement is seen, reassessment of diagnosis may be necessary.

Chemotherapy: Oral, I.V.: 40 mg every day for 4 days, repeated every 4 weeks (VAD regimen)

Cerebral edema: I.V. 10 mg stat, 4 mg I.M./I.V. (should be given as sodium phosphate) every 6 hours until response is maximized, then switch to oral regimen, then taper off if appropriate; dosage may be reduced after 24 days and gradually discontinued over 5-7 days

Dexamethasone suppression test (depression indicator) or diagnosis for Cushing's syndrome (unlabeled uses): Oral: 1 mg at 11 PM, draw blood at 8 AM the following day for plasma cortisol determination

Physiological replacement: Oral, I.M., I.V. (should be given as sodium phosphate): 0.03-0.15 mg/kg/day or 0.6-0.75 mg/m²/day in divided doses every 6-12 hours

Treatment of shock:

Addisonian crisis/shock (ie, adrenal insufficiency/responsive to steroid therapy): I.V. (given as sodium phosphate): 4-10 mg as a single dose, which may be repeated if necessary

Unresponsive shock (ie, unresponsive to steroid therapy): I.V. (given as sodium phosphate): 1-6 mg/kg as a single I.V. dose or up to 40 mg initially followed by repeat doses every 2-6 hours while shock persists

Hemodialysis: Supplemental dose is not necessary

Peritoneal dialysis: Supplemental dose is not necessary

Stability Injection solution: Store at room temperature; protect from light and freezing.

Stability of injection of parenteral admixture at room temperature (25°C): 24 hours

Stability of injection of parenteral admixture at refrigeration temperature (4°C): 2 days; protect from light and freezing

Injection should be diluted in 50-100 mL NS or D₅W.

Monitoring Parameters Hemoglobin, occult blood loss, serum potassium, and glucose

Administration

Oral: Administer with meals to decrease GI upset.

I.M.: Acetate injection is **not** for I.V. use.

I.V.: Administer as a 5-10 minute bolus; rapid injection is associated with a high incidence of perianal discomfort.

Topical: For external use. Do not use on open wounds. Apply sparingly to occlusive dressings. Should not be used in the presence of open or weeping lesions.

Contraindications Hypersensitivity to dexamethasone or any component of the formulation; systemic fungal infections, cerebral malaria; ophthalmic use in viral (active ocular herpes simplex), fungal, or tuberculosis diseases of the eye

Warnings

Use with caution in patients with hypothyroidism, cirrhosis, hypertension, CHF, or thromboembolic disorders. Corticosteroids should be used with caution in patients with diabetes, glaucoma, cataracts, or tuberculosis; or patients at risk for osteoporosis. Use caution with GI diseases (diverticulitis, peptic ulcer, ulcerative colitis) due to perforation risk. Use caution following acute MI (corticosteroids have been associated with myocardial rupture). Use caution in renal and hepatic impairment. Because of the risk of adverse effects, systemic corticosteroids should be used cautiously in the elderly in the smallest possible effective dose for the shortest duration.

May cause suppression of hypothalamic-pituitary-adrenal (HPA) axis, particularly in younger children or in patients receiving high doses for prolonged periods. Symptoms of adrenocortical insufficiency in suppressed patients may result from rapid discontinuation/withdrawal; deficits in HPA response may persist for months following discontinuation and require supplementation during metabolic stress. Patients receiving ≥ 20 mg/day of prednisone (or equivalent) may be most susceptible. Particular care is required when patients are transferred from systemic corticosteroids to inhaled products due to possible adrenal insufficiency or exacerbation of underlying disease, including an increase in allergic symptoms. Fatalities have occurred due to adrenal insufficiency in asthmatic patients during and after transfer from systemic corticosteroids to aerosol steroids; aerosol steroids do **not** provide the systemic steroid needed to treat patients having trauma, surgery, or infections. Dexamethasone does not provide adequate mineralocorticoid activity in adrenal insufficiency (may be employed as a single dose while cortisol assays are performed). The lowest possible dose should be used during treatment; discontinuation and/or dose reductions should be gradual.

Controlled clinical studies have shown that orally-inhaled and intranasal corticosteroids may cause a reduction in growth velocity in pediatric

patients. (In studies of orally-inhaled corticosteroids, the mean reduction in growth velocity was ~ 1 cm per year [range 0.3-1.8 cm per year] and appears to be related to dose and duration of exposure). The growth of pediatric patients receiving inhaled corticosteroids, should be monitored routinely (eg, via stadiometry). To minimize the systemic effects of orally-inhaled and intranasal corticosteroids, each patient should be titrated to the lowest effective dose.

Acute myopathy has been reported with high dose corticosteroids, usually with use for neuromuscular transmission disorders; may involve ocular and/or respiratory muscles; monitor creatine kinase; recovery may be delayed. Corticosteroid use may cause psychiatric manifestations, including depression, euphoria, insomnia, mood swings, and personality changes. Pre-existing psychiatric conditions may be exacerbated by corticosteroid use.

May suppress the immune system; patients may be more susceptible to infection; use with caution in patients with systemic infections. Avoid exposure to chickenpox and measles.

Dosage Forms

[DSC] = Discontinued product

Elixir, as base: 0.5 mg/5 mL (240 mL)

Injection, solution, as sodium phosphate: 4 mg/mL (1 mL, 5 mL, 30 mL); 10 mg/mL (10 mL)

Injection, solution, as sodium phosphate [preservative free]: 10 mg/mL (1 mL)

Solution, ophthalmic, as sodium phosphate: 0.1% (5 mL)

Solution, oral: 0.5 mg/5 mL (500 mL)

Solution, oral concentrate:

Dexamethasone Intensol™: 1 mg/mL (30 mL) [contains alcohol 30%]

Suspension, ophthalmic:

Maxidex®: 0.1% (5 mL; 15 mL [DSC]) [contains benzalkonium chloride]

Tablet [scored]: 0.5 mg, 0.75 mg, 1 mg, 1.5 mg, 2 mg, 4 mg, 6 mg

DexPak® TaperPak®: 1.5 mg [51 tablets on taper dose card]

Reference Range Dexamethasone suppression test, overnight: 8 AM cortisol < 6 mcg/100 mL (dexamethasone 1 mg)

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal; acute overdose does not require tapering of dose
Supportive therapy: Hiccups can be treated with metoclopramide (10 mg every 6 hours)

Test Interactions May result in false elevation of digoxin level (by RIA); > 0.5 mg/day may interfere with TSH assay resulting in falsely low TSH levels

Drug Interactions

Substrate of CYP3A4 (minor); **Induces** CYP2A6 (weak), 2B6 (weak), 2C8 (weak), 2C9 (weak), 3A4 (weak)

Aminoglutethimide: May reduce the serum levels/effects of dexamethasone; likely via induction of microsomal isoenzymes.

Antacids: May increase the absorption of corticosteroids; separate administration by 2 hours.

Anticholinesterases: Concurrent use may lead to severe weakness in patients with myasthenia gravis.

Aprepitant: May increase the serum levels of corticosteroids; monitor.

Azole antifungals: May increase the serum levels of corticosteroids; monitor.

Barbiturates: May decrease the levels/effects of dexamethasone (systemic).

Bile acid sequestrants: May reduce the absorption of corticosteroids; separate administration by 2 hours.

Calcium channel blockers (nondihydropyridine): May increase the serum levels of corticosteroids; monitor.

Cyclosporine: Corticosteroids may increase the serum levels of cyclosporine. In addition, cyclosporine may increase levels of corticosteroids.

Estrogens: May increase the serum levels of corticosteroids; monitor.

Fluoroquinolones: Concurrent use may increase the risk of tendon rupture, particularly in elderly patients (overall incidence rare).

Isoniazid: Serum concentrations may be decreased by corticosteroids.

Macrolide antibiotics: May increase the levels/effects of dexamethasone (systemic).

Neuromuscular-blocking agents: Concurrent use with corticosteroids may increase the risk of myopathy.

Nonsteroidal anti-inflammatory drugs (NSAIDs): Concurrent use with corticosteroids may lead to an increased incidence of gastrointestinal adverse effects; use caution. NSAID (ophthalmic) may enhance the adverse/toxic effect of dexamethasone (ophthalmic).

Primidone: May decrease the levels/effects of dexamethasone (systemic); monitor.

Rifamycins: May decrease the levels/effects of dexamethasone (systemic); monitor.

Salicylates: Salicylates may increase the gastrointestinal adverse effects of corticosteroids.

Thalidomide: Concurrent use with corticosteroids may increase the risk of selected adverse effects (toxic epidermal necrolysis and DVT); use caution.

Vaccine (dead organism): Dexamethasone may decrease the effect of vaccines (dead organisms). In patients receiving high doses of systemic

corticosteroids for ≥ 14 days, wait at least 1 month between discontinuing steroid therapy and administering immunization.

Vaccine (live organism): Dexamethasone may increase the risk of vaccinal infection. The use of live vaccines is contraindicated in immunosuppressed patients.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic effects have been observed in animal studies. Dexamethasone has been used in patients with premature labor (26-34 weeks gestation) to stimulate fetal lung maturation. Crosses the placenta; transient leukocytosis reported. Available evidence suggests safe use during pregnancy.

Lactation Enters breast milk/use caution

Nursing Implications Give oral formulation with meals to decrease gastritis; topical formulation is for external use, do not use on open wounds; apply sparingly to occlusive dressings; should not be used in the presence of open or weeping lesions; **acetate injection is not for I.V. use**

Additional Information Not suitable for every-other-day dosing due to long duration of effect. Intravenous dexamethasone (2 mg I.V.) can impair ethyl alcohol's ability to stimulate sympathetic nerve discharge, and thus suppress alcohol-induced high blood pressure in the acute state. Nebulization of dexamethasone sodium phosphate (1.5 mg/kg up to 45 mg) may be as effective as oral prednisone in the emergency management of moderately severe asthma in children. Granisetron (3 mg I.V.) is effective when used with dexamethasone to prevent emesis due to chemotherapy.

Dexfenfluramine

CAS Number 3239-44-9; 3239-45-0

Synonyms Dexfenfluramine Hydrochloride; S5614

Use Management of obesity (initial body mass >30 kg/m³ or >27 kg/m³ with other risk factors such as hypertension, diabetes, or hyperlipidemia); given as an adjunct to dietary restriction; off the U.S. market as of September 15, 1997

Mechanism of Action Can cause elevation of serotonin in the brain which suppresses appetite for carbohydrates (but not protein-rich foods)

Adverse Reactions

Cardiovascular: Hypertension, primary pulmonary hypertension (18 cases per 1 million users per year), leukocytoclastic vasculitis

Central nervous system: Fatigue, **drowsiness**, **headache**, dizziness, **insomnia**, anxiety, depression (reactive), dysphoria, mania

Dermatologic: Urticaria, scleroderma

Endocrine & metabolic: Hyperprolactinemia

Gastrointestinal: **Abdominal discomfort**, **xerostomia**, nausea, vomiting, **diarrhea**

Hematologic: Porphyrinogenic

Neuromuscular & skeletal: **Weakness**

Renal: Polyuria

Pharmacodynamics/Kinetics

Peak serum levels: 2-4 hours

Metabolism: Hepatic to d-norfenfluramine (active metabolite)

Half-life:

18 hours (dexfenfluramine)

30 hours (d-norfenfluramine)

Dosage 15 mg 2 times/day with meals

Monitoring Parameters Monitor weight, eating habits, cardiopulmonary function including cardiac insufficiency, palpitations, exertional dyspnea, and/or chest pain; blood should also be monitored

Contraindications Hypersensitivity to dexfenfluramine or fenfluramine, glaucoma, pulmonary hypertension or use of monoamine oxidase inhibitors within 2 weeks of dexfenfluramine; children, pregnancy, or nursing women

Warnings Use with caution in patients with cardiac disease, renal or hepatic insufficiency, porphyria, drug abuse, psychiatric disorder, or organic causes for obesity

Dosage Forms Capsule, as hydrochloride: 15 mg

Reference Range After a 20 mg oral dose, peak serum level: ~ 16 mcg/L; peak serum metabolite d-norfenfluramine is 6 mcg/L

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage (within 4 hours)/activated charcoal

Supportive therapy: Treat hypotension with I.V. crystalloid solutions; vasopressors can be used for refractory cases; propranolol (1 mg/dose in adults or 0.01-0.1 mg/kg/dose in children over 10 minutes) or esmolol can be used to treat tachycardia; hyperpyrexia can be treated with external (passive) cooling

Test Interactions Can result in a positive urinary immunoassay for amphetamines, but will not confirm by gas chromatography/mass spectrometry

Drug Interactions Increased toxicity: Serotonin reuptake inhibitors and monoamine oxidase inhibitors may cause rigidity, hyperthermia, tremor, seizures, and delirium

Pregnancy Risk Factor C

Pregnancy Implications Spontaneous abortions in 1st trimester have been described

Additional Information On September 12, 1997, the FDA announced new summary information concerning abnormal echocardiogram findings in asymptomatic patients seen in five centers. These patients had been treated with fenfluramine or dexfenfluramine for up to 24 months, most often in combination with phentermine. Abnormal echocardiogram findings were reported in 92 of 291 subjects evaluated, including 80 reports of aortic regurgitation (mild or greater) and 23 reports of mitral regurgitation (moderate or greater). Those requiring further information can call 1-800-892-2718. Questions about returning products can be directed to 1-800-666-7248.

Dextroamphetamine

Related Information

- Diethylpropion
- Fenproporex
- Phenmetrazine
- Therapeutic Drugs Associated with Hallucinations

CAS Number 51-63-8; 51-64-9; 7528-00-9

U.S. Brand Names Dexedrine®; Dextrostat®

Synonyms Dextroamphetamine Sulfate

Impairment Potential Yes

Use Narcolepsy; attention-deficit/hyperactivity disorder (ADHD)

Unlabeled/Investigational Use Exogenous obesity; depression; abnormal behavioral syndrome in children (minimal brain dysfunction)

Mechanism of Action Blocks reuptake of dopamine and norepinephrine from the synapse, thus increases the amount of circulating dopamine and norepinephrine in cerebral cortex to reticular activating system; inhibits the action of monoamine oxidase and causes catecholamines to be released

Adverse Reactions

Cardiovascular: Hypertension, tachycardia (ventricular), tachycardia, palpitations, **cardiac arrhythmias**, vasculitis, sinus tachycardia, tachycardia (supraventricular), arrhythmias (ventricular)

Central nervous system: **Insomnia**, headache, **nervousness**, dizziness, seizures, mania, may precipitate Tourette's syndrome, CNS depression, dysphonia, irritability, agitation, euphoria, hallucination, extrapyramidal reaction, movement disorders, depression, paranoia, sympathetic storm, fever, hyperthermia, **restlessness**, **false feeling of well being**

Dermatologic: Urticaria

Endocrine & metabolic: Growth suppression, respiratory alkalosis, increased serum thyroxine (hyperthyroidism)

Gastrointestinal: Anorexia, nausea, vomiting, diarrhea, abdominal cramps, metallic taste, xerostomia, bitter dysgeusia

Genitourinary: Impotence

Hematologic: Porphyria, porphyrinogenic

Neuromuscular & skeletal: Tremors, choreoathetoid movements, fasciculations, rhabdomyolysis

Renal: Myoglobinuria

DEXTROMETHORPHAN

Respiratory: Tachypnea

Pharmacodynamics/Kinetics

Onset of action: 1-1.5 hours

Distribution: V_d : Adults: 3.5-4.6 L/kg; distributes into CNS; mean CSF concentrations are 80% of plasma; enters breast milk

Metabolism: Hepatic via CYP monooxygenase and glucuronidation

Half-life elimination: Adults: 10-13 hours

Time to peak, serum: T_{max} : Immediate release: 3 hours; sustained release: 8 hours

Excretion: Urine (as unchanged drug and inactive metabolites)

Dosage

Oral:

Children:

Narcolepsy: 6-12 years: Initial: 5 mg/day; may increase at 5 mg increments in weekly intervals until side effects appear (maximum dose: 60 mg/day)

Attention-deficit/hyperactivity disorder (ADHD):

3-5 years: Initial: 2.5 mg/day given every morning; increase by 2.5 mg/day in weekly intervals until optimal response is obtained; usual range: 0.1-0.5 mg/kg/dose every morning with maximum of 40 mg/day

≥ 6 years: 5 mg once or twice daily; increase in increments of 5 mg/day at weekly intervals until optimal response is obtained; usual range: 0.1-0.5 mg/kg/dose every morning (5-20 mg/day) with maximum of 40 mg/day

Children >12 years and Adults:

Narcolepsy: Initial: 10 mg/day, may increase at 10 mg increments in weekly intervals until side effects appear; maximum: 60 mg/day

Exogenous obesity (unlabeled use): 5-30 mg/day in divided doses of 5-10 mg 30-60 minutes before meals

Stability Protect from light

Monitoring Parameters Growth in children and CNS activity in all

Administration

Do not crush sustained release drug product. Administer as single dose in morning or as divided doses with breakfast and lunch. Should be administered 30 minutes before meals and at least 6 hours before bedtime.

Contraindications Hypersensitivity or idiosyncrasy to dextroamphetamine or other sympathomimetic amines. Patients with advanced arteriosclerosis, symptomatic cardiovascular disease, moderate to severe hypertension (stage II or III), hyperthyroidism, glaucoma, agitated states, patients with a history of drug abuse, and during or within 14 days following MAO inhibitor therapy.

Warnings

[U.S. Boxed Warning]: Dexamphetamine has been associated with serious cardiac cardiovascular events including sudden death in patients with pre-existing structural cardiac abnormalities or other serious heart problems. Using CNS stimulant treatment at usual doses in children and adolescents with serious heart problems and structural cardiac abnormalities has been associated with sudden death. In adults, stimulant use has been associated with sudden deaths, stroke, and myocardial infarction. Stimulant products should be avoided in the patients with known serious structural cardiac abnormalities, cardiomyopathy, serious heart rhythm abnormalities, or other serious cardiac problems that could increase the risk of sudden death that these conditions alone carry. Caution should be used in patients with hypertension and other cardiovascular conditions that might be exacerbated by increases in blood pressure or heart rate. Use of stimulants can cause an increase in blood pressure (average 2-4 mm Hg) and increases in heart rate (average 3-6 bpm), although some patients may have larger than average increases.

Use with caution in patients with bipolar disorder, cardiovascular disease, diabetes, seizure disorders, insomnia, porphyria, hypertension (stage I), or history of substance abuse. May exacerbate symptoms of behavior and thought disorder in psychotic patients. Stimulants may unmask tics in individuals with coexisting Tourette's syndrome. Potential for drug dependency exists - avoid abrupt discontinuation in patients who have received for prolonged periods. **[U.S. Boxed Warning]: Use in weight reduction programs only when alternative therapy has been ineffective; due to high potential for abuse and/or nontherapeutic use should be prescribed/dispensed sparingly.** Products may contain tartrazine - use with caution in potentially sensitive individuals. Stimulant use in children has been associated with growth suppression. May cause visual disturbances.

Dosage Forms Capsule, sustained release, as sulfate: 5 mg, 10 mg, 15 mg

Dexedrine® Spansule®: 5 mg, 10 mg, 15 mg

Tablet, as sulfate: 5 mg, 10 mg

Dexedrine®: 5 mg [contains tartrazine]

Dextrostat®: 5 mg, 10 mg [contains tartrazine]

Reference Range Urinary amphetamine concentrations at steady state (30 mg/day) range from 1100-17,800 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Seizures can be treated with lorazepam, diazepam, phenytoin, or phenobarbital; ventricular arrhythmias should be treated with lidocaine

Enhancement of elimination: Hemodialysis may be useful; do not acidify urine

Test Interactions False-positive amphetamine assays may result from coadministration with ranitidine, phenylpropanolamine, brompheniramine, chlorpromazine, fluspiriline, or pipothiazine

Drug Interactions Substrate of CYP2D6 (major)

Acidifiers: Very large doses of potassium acid phosphate or ammonium chloride may increase the renal elimination of amphetamines due to urinary acidification, resulting in lower blood level and efficacy of amphetamines.

Alkalinizers: Large doses of sodium bicarbonate or other alkalinizers may increase renal tubular reabsorption (decreased elimination) and enhance the effect of amphetamine; includes potassium or sodium citrate and acetate.

Antipsychotics: Efficacy of amphetamines may be decreased by antipsychotics; in addition, amphetamines may induce an increase in psychotic symptoms in some patients.

CYP2D6 inhibitors: May increase the levels/effects of dextroamphetamine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

Furazolidone: Amphetamines may induce hypertensive episodes in patients receiving furazolidone.

Guanethidine: Amphetamines inhibit the antihypertensive response to guanethidine; probably also may occur with guanadrel and other antihypertensives.

MAO inhibitors: Severe hypertensive episodes have occurred with amphetamine when used in patients receiving MAO inhibitors; concurrent use or use within 14 days is contraindicated.

Norepinephrine: Amphetamines enhance the pressor response to norepinephrine.

Sibutramine: Concurrent use of sibutramine and amphetamines may cause severe hypertension and tachycardia; use is contraindicated with SSRIs; amphetamines may increase the potential for serotonin syndrome when used concurrently with selective serotonin reuptake inhibitors (including fluoxetine, fluvoxamine, paroxetine, and sertraline).

Tricyclic antidepressants: Concurrent of amphetamines with TCAs may result in hypertension and CNS stimulation; avoid this combination.

Pregnancy Risk Factor C

Pregnancy Implications A case of bone deformity, tracheoesophageal fistula, and anal atresia has been noted in a fetus after first trimester use of lovastatin and dextroamphetamine.

Lactation Enters breast milk/contraindicated

Nursing Implications Last daily dose should be given 6 hours before retiring; do not crush sustained release drug product; dose should not be given in evening or at bedtime

Additional Information Illicit preparation may contain up to 24 g per spoon; 5 mg tablets contain tartrazine

Dextromethorphan

Related Information

• Therapeutic Drugs Associated with Hallucinations

CAS Number 125-69-9; 125-71-3; 6700-34-1

U.S. Brand Names Babee® Cof Syrup [OTC]; Benylin® Adult [OTC]; Benylin® Pediatric [OTC]; Creo-Terpin® [OTC]; Creomulsion® Cough [OTC]; Creomulsion® for Children [OTC]; Delsym® [OTC]; Dexalone® [OTC]; ElixSure™ Cough [OTC]; Hold® DM [OTC]; Pertussin® DM [OTC]; Robitussin® CoughGels™ [OTC]; Robitussin® Honey Cough; Robitussin® Maximum Strength Cough [OTC]; Robitussin® Pediatric Cough [OTC]; Scot-Tussin DM® Cough Chasers [OTC]; Silphen DM® [OTC]; Simply Cough™ [OTC]; Vicks® 44® Cough Relief [OTC]

Impairment Potential Yes

Use Symptomatic relief of coughs caused by minor viral upper respiratory tract infections or inhaled irritants; most effective for a chronic non-productive cough

Unlabeled/Investigational Use N-methyl-D-aspartate (NMDA) antagonist in cerebral injury

Mechanism of Action Chemical relative of morphine lacking narcotic properties; controls cough by depressing the medullary cough center; has

virtually no analgesic activity; acts through the sigma receptor with little dependence effect

Adverse Reactions

Cardiovascular: Sinus tachycardia
 Central nervous system: Drowsiness, dizziness, coma, auditory and visual hallucinations, insomnia, dystonia
 Gastrointestinal: Nausea
 Respiratory: Apnea, respiratory depression
 Miscellaneous: Fixed drug eruption

Signs and Symptoms of Overdose Ataxia, coma, dystonic reaction, excitation, fever, hyperactivity, hypertension, hyperthermia, insomnia, miosis, respiratory depression, tachycardia, tremors

Pharmacodynamics/Kinetics

Onset of action: Antitussive: 15-30 minutes
 Duration: ≤6 hours
 Metabolism: In the liver to an active metabolite (dextrophan)
 Half-life: 2-4 hours
 Time to peak: 2.5 hours
 Elimination: Principally in urine

Dosage

Oral:
 Children:
 2-5 years: 2.5-7.5 mg every 4-8 hours; extended release is 15 mg twice daily (maximum: 30 mg/24 hours)
 6-12 years: 5-10 mg every 4 hours or 15 mg every 6-8 hours; extended release is 30 mg twice daily (maximum: 60 mg/24 hours)
 Children > 12 years and Adults: 10-30 mg every 4-8 hours or 30 mg every 6-8 hours; extended release is 60 mg twice daily (maximum: 120 mg/24 hours)

Contraindications Hypersensitivity to dextromethorphan or any component of the formulation

Dosage Forms

[DSC] = Discontinued product
 Gelcap, as hydrobromide:
 Dexamone[®]: 30 mg
 Robitussin[®] CoughGels[™]: 15 mg [contains coconut oil]
 Liquid, as hydrobromide:
 Creo-Terpin[®]: 10 mg/15 mL (120 mL) [contains alcohol 25% and tartrazine]
 Simply Cough[®]: 5 mg/5 mL (120 mL) [contains sodium benzoate; cherry berry flavor]
 Vicks[®] 44[®] Cough Relief: 10 mg/5 mL (120 mL) [contains alcohol, sodium 10 mg/5 mL, sodium benzoate]
 Liquid, oral, as hydrobromide [freezer pops] (PediaCare[®] Children's Medicated Freezer Pops Long Acting Cough): 7.5 mg/25 mL (8s) [alcohol free; contains sodium benzoate, berry flavor also contains benzyl alcohol; glacier grape[™] and polar berry blue[™] flavors]
 Liquid, oral drops, as hydrobromide (PediaCare[®] Infants' Long-Acting Cough): 7.5 mg/0.8 mL (15 mL) [alcohol free, dye free; contains sodium benzoate; grape flavor]
 Lozenge, as hydrobromide:
 Hold[®] DM: 5 mg (10s) [cherry or original flavor]
 Scot-Tussin DM[®] Cough Chasers: 5 mg (20s)
 Strips, oral, as hydrobromide (Triaminic[®] Thin Strips[™] Long Acting Cough): 7.5 mg [equivalent to dextromethorphan 5 mg; cherry flavor]
 Suspension, extended release, as hydrobromide (Delsym[®]): 30 mg/5 mL (89 mL, 148 mL) [contains alcohol 0.26%, sodium 5 mg/5 mL; orange flavor]
 Syrup, as hydrobromide:
 Babee[®] Cof Syrup: 7.5 mg/5 mL (120 mL) [alcohol free, dye free; cherry flavor]
 Benylin[®] Adult: 15 mg/5 mL (120 mL) [alcohol free, sugar free; contains sodium benzoate; raspberry flavor] [DSC]
 Benylin[®] Pediatric: 7.5 mg/mL (120 mL) [alcohol free, sugar free; contains sodium benzoate; grape flavor] [DSC]
 Creomulsion[®] Cough: 20 mg/15 mL (120 mL) [alcohol free; contains sodium benzoate]
 Creomulsion[®] for Children: 5 mg/5 mL (120 mL) [alcohol free; contains sodium benzoate; cherry flavor]
 ElixSure[™] Cough: 7.5 mg/5 mL (120 mL) [cherry bubble gum flavor]
 Robitussin[®] Honey Cough: 10 mg/5 mL (120 mL) [alcohol free; contains sodium benzoate]
 Robitussin[®] Maximum Strength Cough: 15 mg/5 mL (120 mL, 240 mL) [contains alcohol, sodium benzoate]
 Robitussin[®] Pediatric Cough: 7.5 mg/5 mL (120 mL) [alcohol free; contains sodium benzoate; fruit punch flavor]
 Silphen DM[®]: 10 mg/5 mL (120 mL) [strawberry flavor]

Reference Range Serum level of 0.1 mcg/mL associated with coma

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) is recommended for ingestions > 10 mg/kg; activated charcoal is useful
 Supportive therapy: Naloxone hydrochloride (0.4-2 mg I.V., SubQ, or through an endotracheal tube); a continuous infusion (at $\frac{2}{3}$ the

response dose/hour) may be required; dystonic reactions can be treated with diphenhydramine (1 mg/kg up to 50 mg)

Antidote(s)

- Naloxone [ANTIDOTE]

Test Interactions Can result in a false-positive phencyclidine qualitative immunoassay screen

Drug Interactions Substrate of CYP2B6 (minor), 2C9 (minor), 2C19 (minor), 2D6 (major), 2E1 (minor), 3A4 (minor); **Inhibits** CYP2D6 (weak) CYP2D6 inhibitors: May increase the levels/effects of dextromethorphan. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole. MAO inhibitors: Dextromethorphan may increase effect/toxicity of MAO inhibitors.

Pregnancy Risk Factor C

Pregnancy Implications Dextromethorphan is teratogenic in chick embryos (neural crest/neural tube defects)

Nursing Implications Raise side rails, institute safety measures

Additional Information

Monitor for bromide poisoning.

According to the Drug Abuse Warning Network for 2004 (Dawn Report: Issue 32, 2006)

- An Estimated 12,584 Emergency Department visits involved pharmaceuticals containing dextromethorphan (DXM) which represented about 0.7% of all drug related ED visits.
- The rate of ED visits resulting from nonmedicinal use of DXM for those aged 12 to 20 years was 7.1 visits per 100,000 population compared with 2.6 visits or fewer per 100,000 for other age groups.
- ED patients aged 12 to 20 years accounted for nearly half (48%) of all the ED visits resulting from nonmedicinal use of DXM.
- Alcohol was implicated in over one third (36%) of ED visits involving nonmedicinal use of DXM for those aged 18 to 20 years and in 13% of visit for those age 12 to 17 years.

Diazepam

Related Information

- Seizures, Neonatal Guidelines
- Zopiclone

CAS Number 439-14-5

U.S. Brand Names Diastat[®] AcuDial[™]; Diastat[®]; Diazepam Intensol[®]; Valium[®]

Impairment Potential Yes. More than double-increased risk of involvement in injurious auto crash following ingestion of ≥20 mg diazepam in elderly drivers. Impairment can also occur at 10 mg doses in younger patients. Brief or extended period (up to 1 year) of use is consistent with driving impairment in the elderly; impairment is greatest in the first week of use. (Ray WA, Fought RL, and Decker MD, "Psychoactive Drugs and the Risk of Injurious Motor Vehicle Crashes in Elderly Drivers," *Am J Epidemiol*, 1992, 136(7):873-83.)

Use Management of anxiety disorders, ethanol withdrawal symptoms; skeletal muscle relaxant; treatment of convulsive disorders

Orphan drug: Viscous solution for rectal administration: Management of selected, refractory epilepsy patients on stable regimens of antiepileptic

DIAZEPAM

drugs (AEDs) requiring intermittent use of diazepam to control episodes of increased seizure activity

Unlabeled/Investigational Use Panic disorders; preoperative sedation, light anesthesia, amnesia

Mechanism of Action Depresses all levels of the CNS, including the limbic and reticular formation, probably through the increased action of gamma-aminobutyric acid (GABA), which is a major inhibitory neurotransmitter in the brain

Adverse Reactions

Cardiovascular: **Cardiac arrest, hypotension, bradycardia, cardiovascular collapse, tachycardia, chest pain**, syncope

Central nervous system: **Drowsiness, ataxia, amnesia, slurred speech, paradoxical excitement or rage, fatigue, lightheadedness, insomnia, memory impairment, headache, anxiety, depression**, confusion, nervousness, dizziness, akathisia, aggressive behavior

Dermatologic: **Rash**, dermatitis, exfoliative dermatitis, acne, angioedema, bullous eruptions, urticaria, purpura, pruritus, bullous skin disease/pemphigoid, exanthem, cutaneous vasculitis

Endocrine & metabolic: **Decreased libido**, menstrual irregularities, gynecomastia

Gastrointestinal: **Xerostomia, changes in salivation, constipation, nausea, vomiting, diarrhea, increased or decreased appetite**, weight gain or loss, xerostomia

Hematologic: Blood dyscrasias

Local: **Phlebitis, pain with injection**

Neuromuscular & skeletal: **Dysarthria**, rigidity, tremor, muscle cramps, reflex slowing, paresthesia

Ocular: **Blurred vision, diplopia**

Otic: Tinnitus

Respiratory: **Decrease in respiratory rate, apnea, laryngospasm**, nasal congestion, hyperventilation, pulmonary vasculitis

Miscellaneous: **Diaphoresis**, hiccups, physical and psychological dependence with prolonged use, fixed drug eruption, aneuploidy induction, acute traumatic compartment syndrome

Signs and Symptoms of Overdose Ataxia, cognitive dysfunction, coma, confusion, dysarthria, dyspnea, eosinophilia, extrapyramidal reaction, gynecomastia, hiccups, hypoaactive reflexes, hyporeflexia, hypotension, hypothermia, jaundice, memory loss, myoglobinuria, nystagmus, renal failure, respiratory depression, rhabdomyolysis, slurred speech, somnolence, thrombocytopenia

Pharmacodynamics/Kinetics

I.V.: Status epilepticus:

Onset of action: Almost immediate

Duration: 20-30 minutes

Absorption: Oral: 85% to 100%, more reliable than I.M.

Protein binding: 98%

Metabolism: Hepatic

Half-life elimination: Parent drug: Adults: 20-50 hours; increased half-life in neonates, elderly, and those with severe hepatic disorders; Active major metabolite (desmethyldiazepam): 50-100 hours; may be prolonged in neonates

Dosage

Oral absorption is more reliable than I.M.

Children:

Conscious sedation for procedures: Oral: 0.2-0.3 mg/kg (maximum: 10 mg) 45-60 minutes prior to procedure

Sedation/muscle relaxant/anxiety:

Oral: 0.12-0.8 mg/kg/day in divided doses every 6-8 hours

I.M., I.V.: 0.04-0.3 mg/kg/dose every 2-4 hours to a maximum of 0.6 mg/kg within an 8-hour period if needed

Status epilepticus:

Infants 30 days to 5 years: I.V.: 0.05-0.3 mg/kg/dose given over 2-3 minutes, every 15-30 minutes to a maximum total dose of 5 mg; repeat in 2-4 hours as needed **or** 0.2-0.5 mg/dose every 2-5 minutes to a maximum total dose of 5 mg

>5 years: I.V.: 0.05-0.3 mg/kg/dose given over 2-3 minutes every 15-30 minutes to a maximum total dose of 10 mg; repeat in 2-4 hours as needed **or** 1 mg/dose given over 2-3 minutes, every 2-5 minutes to a maximum total dose of 10 mg

Rectal: 0.5 mg/kg, then 0.25 mg/kg in 10 minutes if needed

Anticonvulsant (acute treatment): Rectal gel formulation:

Infants <6 months: Not recommended

Children <2 years: Safety and efficacy have not been studied

Children 2-5 years: 0.5 mg/kg

Children 6-11 years: 0.3 mg/kg

Children ≥ 12 years and Adults: 0.2 mg/kg

Note: Dosage should be rounded upward to the next available dose, 2.5, 5, 10, 15, and 20 mg/dose; dose may be repeated in 4-12 hours if needed; do not use more than 5 times per month or more than once every 5 days

Adolescents: Conscious sedation for procedures:

Oral: 10 mg

I.V.: 5 mg, may repeat with $\frac{1}{2}$ dose if needed

Adults:

Anxiety/sedation/skeletal muscle relaxant:

Oral: 2-10 mg 2-4 times/day

I.M., I.V.: 2-10 mg, may repeat in 3-4 hours if needed

Sedation in the ICU patient: I.V.: 0.03-0.1 mg/kg every 30 minutes to 6 hours

Status epilepticus: I.V.: 5-10 mg every 10-20 minutes, up to 30 mg in an 8-hour period; may repeat in 2-4 hours if necessary

Rapid tranquilization of agitated patient (administer every 30-60 minutes): Oral: 5-10 mg; average total dose for tranquilization: 20-60 mg

Elderly: Oral: Initial:

Anxiety: 1-2 mg 1-2 times/day; increase gradually as needed, rarely need to use >10 mg/day (watch for hypotension and excessive sedation)

Skeletal muscle relaxant: 2-5 mg 2-4 times/day

Hemodialysis: Not dialyzable (0% to 5%); supplemental dose is not necessary

Dosing adjustment in hepatic impairment: Reduce dose by 50% in cirrhosis and avoid in severe/acute liver disease

Monitoring Parameters Respiratory, cardiovascular, and mental status; check for orthostasis

Administration Intensol® should be diluted before use.

In children, do not exceed 1-2 mg/minute IVP; adults 5 mg/minute.

Rectal gel: Prior to administration, confirm that prescribed dose is visible and correct, and that the green "ready" band is visible. Patient should be positioned on side (facing person responsible for monitoring), with top leg bent forward. Insert rectal tip (lubricated) into rectum and push in plunger gently over 3 seconds. Remove tip of rectal syringe after 3 additional seconds. Buttocks should be held together for 3 seconds after removal. Dispose of syringe appropriately.

Contraindications Hypersensitivity to diazepam or any component of the formulation (cross-sensitivity with other benzodiazepines may exist); narrow-angle glaucoma; not for use in children <6 months of age (oral); pregnancy

Warnings

Diazepam has been associated with increasing the frequency of grand mal seizures. Withdrawal has also been associated with an increase in the seizure frequency. Use with caution with drugs which may decrease diazepam metabolism. Use with caution in elderly or debilitated patients, patients with hepatic disease (including alcoholics), or renal impairment. Active metabolites with extended half-lives may lead to delayed accumulation and adverse effects. Use with caution in patients with respiratory disease or impaired gag reflex.

Acute hypotension, muscle weakness, apnea, and cardiac arrest have occurred with parenteral administration. Acute effects may be more prevalent in patients receiving concurrent barbiturates, narcotics, or ethanol. Appropriate resuscitative equipment and qualified personnel should be available during administration and monitoring. Avoid use of the injection in patients with shock, coma, or acute ethanol intoxication. Intra-arterial injection or extravasation of the parenteral formulation should be avoided. Parenteral formulation contains propylene glycol, which has been associated with toxicity when administered in high dosages. Administration of rectal gel should only be performed by individuals trained to recognize characteristic seizure activity for which the product is indicated, and capable of monitoring response to determine need for additional medical intervention.

Causes CNS depression (dose-related) resulting in sedation, dizziness, confusion, or ataxia which may impair physical and mental capabilities. Patients must be cautioned about performing tasks which require mental alertness (eg, operating machinery or driving). Use with caution in patients receiving other CNS depressants or psychoactive agents. Effects with other sedative drugs or ethanol may be potentiated. The dosage of narcotics should be reduced by approximately 1/3 when diazepam is added. Benzodiazepines have been associated with falls and traumatic injury and should be used with extreme caution in patients who are at risk of these events (especially the elderly).

Use caution in patients with depression, particularly if suicidal risk may be present. Use with caution in patients with a history of drug dependence. Benzodiazepines have been associated with dependence and acute withdrawal symptoms on discontinuation or reduction in dose. Acute withdrawal, including seizures, may be precipitated in patients after administration of flumazenil to patients receiving long-term benzodiazepine therapy.

Diazepam has been associated with anterograde amnesia. Paradoxical reactions, including hyperactive or aggressive behavior, have been reported with benzodiazepines, particularly in adolescent/pediatric or psychiatric patients. Does not have analgesic, antidepressant, or antipsychotic properties.

Rectal gel: Safety and efficacy have not been established in children <2 years of age.

Oral: Safety and efficacy have not been established in children <6 months of age.

Injection: Safety and efficacy have not been established in children <30 days of age. Solution for injection may contain sodium benzoate, benzyl alcohol, or benzoic acid. Large amounts have been associated with "gaspings syndrome" in neonates.

Dosage Forms

Gel, rectal:

Diastat®: Pediatric rectal tip [4.4 cm]: 5 mg/mL (2.5 mg, 5 mg) [contains ethyl alcohol 10%, sodium benzoate, benzyl alcohol 1.5%; twin pack]

Diastat® AcuDial™ delivery system:

10 mg: Pediatric/adult rectal tip [4.4 cm]: 5 mg/mL (delivers set doses of 5 mg, 7.5 mg, and 10 mg) [contains ethyl alcohol 10%, sodium benzoate, benzyl alcohol 1.5%; twin pack]

20 mg: Adult rectal tip [6 cm]: 5 mg/mL (delivers set doses of 10 mg, 12.5 mg, 15 mg, 17.5 mg, and 20 mg) [contains ethyl alcohol 10%, sodium benzoate, benzyl alcohol 1.5%; twin pack]

Injection, solution: 5 mg/mL (2 mL, 10 mL) [may contain benzyl alcohol, sodium benzoate, benzoic acid]

Solution, oral: 5 mg/5 mL (5 mL, 500 mL) [wintergreen-spice flavor]

Solution, oral concentrate:

Diazepam Intenso®: 5 mg/mL (30 mL)

Tablet: 2 mg, 5 mg, 10 mg

Valium®: 2 mg, 5 mg, 10 mg

Reference Range

Therapeutic:

Diazepam: 0.2-1.5 mcg/mL (SI: 0.7-5.3 µmol/L)

N-desmethyldiazepam (nordiazepam): 0.1-0.5 mcg/mL (SI: 0.35-1.8 µmol/L)

Urine drug screens can remain positive for 30 days

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Rarely is mechanical ventilation required; flumazenil has been shown to selectively block the binding of benzodiazepines to CNS receptors, resulting in a reversal of benzodiazepine-induced CNS depression and respiratory depression

Enhancement of elimination: Multiple dose activated charcoal may be effective

Antidote(s)

- Flumazenil [ANTIDOTE]

Test Interactions False-negative urinary glucose determination when using Clinistix® or Diastix®; may inhibit thyroxine binding; may increase plasma testosterone

Drug Interactions

Substrate of CYP1A2 (minor), 2B6 (minor), 2C9 (minor), 2C19 (major), 3A4 (major); **Inhibits** CYP2C19 (weak), 3A4 (weak)

Calcium channel blockers, nondihydropyridine (diltiazem, verapamil): May decrease the metabolism, via CYP isoenzymes, of diazepam.

Clozapine: Benzodiazepines may enhance the adverse/toxic effect of clozapine.

CNS depressants: Sedative effects and/or respiratory depression may be additive with CNS depressants; includes ethanol, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect.

CYP2C19 inducers: May decrease the levels/effects of diazepam. Example inducers include aminoglutethimide, carbamazepine, phenytoin, and rifampin.

CYP2C19 inhibitors: May increase the levels/effects of diazepam. Example inhibitors include delavirdine, fluconazole, fluvoxamine, gemfibrozil, isoniazid, omeprazole, and ticlopidine.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of diazepam. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of diazepam. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nocardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Levodopa: Therapeutic effects may be diminished in some patients following the addition of a benzodiazepine; limited/inconsistent data.

Oral contraceptives: May decrease the clearance of some benzodiazepines (those which undergo oxidative metabolism); monitor for increased benzodiazepine effect.

Theophylline: May partially antagonize some of the effects of benzodiazepines; monitor for decreased response; may require higher doses for sedation.

Pregnancy Risk Factor D

Pregnancy Implications Crosses the placenta. Oral clefts reported, however, more recent data does not support an association between drug and oral clefts; inguinal hernia, cardiac defects, spina bifida, dysmorphic facial features, skeletal defects, multiple other malformations reported; hypotonia and withdrawal symptoms reported following use near time of delivery

Lactation Enters breast milk/contraindicated (AAP rates "of concern")

Nursing Implications In children, do not exceed 1-2 mg/minute IVP; adults 5 mg/minute; provide safety measures (ie, side rails, night light, and call button); remove smoking materials from area; supervise ambulation; do not exceed 5 mg/minute IVP; provide safety measures

(ie, side rails, night light, and call button); remove smoking materials from area; supervise ambulation

Additional Information Benzyl alcohol toxicity can develop after administration of high-dose intravenous diazepam (2.4 mg/kg/hour in 36 hours) in children; oral absorption more reliable than I.M.; intra-arterial injection may cause tissue necrosis

Diazoxide

CAS Number 364-98-7

U.S. Brand Names Hyperstat®; Proglycem®

Use Oral: Hypoglycemia related to islet cell adenoma, carcinoma, hyperplasia, or adenomatosis, nesidioblastosis, leucine sensitivity, or extrapancreatic malignancy

I.V.: Emergency lowering of blood pressure

Mechanism of Action Inhibits insulin release from the pancreas; produces direct smooth muscle relaxation of the peripheral arterioles which results in decrease in blood pressure and reflex increase in heart rate and cardiac output

Adverse Reactions

Cardiovascular: Hypotension, cardiomyopathy, tachycardia, flushing, heart block, cardiomegaly, chest pain, sinus bradycardia, angina, myocardial depression, sinus tachycardia, vasodilation

Central nervous system: Dizziness, seizures, headache, **extrapyramidal reaction** and development of abnormal facies with chronic oral use

Dermatologic: Rash, hirsutism (long-term treatment), edema, cellulitis upon extravasation

Endocrine & metabolic: Hyperglycemia, ketoacidosis, labor (inhibition), hyperuricemia, sodium and water retention

Gastrointestinal: Nausea, vomiting, anorexia, constipation, pancreatitis, loss of taste perception

Hematologic: Leukopenia, thrombocytopenia, hemolysis

Local: Pain, burning, phlebitis upon extravasation

Neuromuscular & skeletal: Weakness

Ocular: Lacrimation, diplopia

Signs and Symptoms of Overdose Agranulocytosis, AV block, bradycardia, chest pain, congestive heart failure, dermatitis, diplopia, dysosmia, fever, galactorrhea, granulocytopenia, hematuria, hemiplegia, hyperglycemia, hyperthermia, hypertrichosis, hyperuricemia, hypotension, ketoacidosis, lacrimation, leukopenia, lichenoid eruptions, nephrotic syndrome, neutropenia

Pharmacodynamics/Kinetics

Onset of action: Hyperglycemic: Oral: ~1 hour

Peak effect: Hypotensive: I.V.: ~5 minutes

Duration: Hyperglycemic: Oral: Normal renal function: 8 hours; Hypotensive: I.V.: Usually 3-12 hours

Protein binding: 90%

Half-life elimination: Children: 9-24 hours; Adults: 20-36 hours; End-stage renal disease: >30 hours

Excretion: Urine (50% as unchanged drug)

Dosage

Hyperinsulinemic hypoglycemia: Oral:

Newborns and Infants: 8-15 mg/kg/day in divided doses every 8-12 hours

Children and Adults: 3-8 mg/kg/day in divided doses every 8-12 hours

Hypertension: I.V.: Children and Adults: 1-3 mg/kg (maximum: 150 mg in a single injection); repeat dose in 5-15 minutes until blood pressure

DIBENZEPIN

adequately reduced; repeat administration every 4-24 hours monitoring blood pressure closely; do not use longer than 10 days

Stability Protect from light, heat, and freezing; avoid using darkened solutions; virtually insoluble in water

Monitoring Parameters Blood pressure, blood glucose, serum uric acid; intravenous administration requires cardiac monitor and blood pressure monitor

Administration

I.V. diazoxide is given undiluted by rapid I.V. injection over a period of 30 seconds or less, but may also be given by continuous infusion.

Contraindications Hypersensitivity to diazoxide, thiazides, or other sulfonamide derivatives; hypertension associated with aortic coarctation, arteriovenous shunts, pheochromocytoma, dissecting aortic aneurysm

Warnings Diabetes mellitus, renal or liver disease, coronary artery disease, or cerebral vascular insufficiency; patients may require a diuretic with repeated I.V. doses; use caution when reducing severely elevated blood pressure (use 150 mg minibolus only)

Dosage Forms

Capsule (Proglycem®): 50 mg [not available in the U.S.]

Injection, solution (Hyperstat®): 15 mg/mL (20 mL)

Suspension, oral (Proglycem®): 50 mg/mL (30 mL) [contains alcohol 7.25%; chocolate-mint flavor]

Reference Range Plasma level of 35 mg/L (152 µmol/L) produces a 25% reduction of mean arterial pressure

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: Insulin for hyperglycemia, fluid, and electrolyte restoration; place patient in Trendelenburg position if hypotensive; isotonic saline and/or dopamine or norepinephrine can be used

Enhancement of elimination: Low recovery with dialysis

Test Interactions ↑ glucose, sodium (S), uric acid (S); false-negative insulin response to glucagon

Drug Interactions

Decreased effect: Diazoxide may increase phenytoin metabolism or free fraction

Increased toxicity:

Diuretics and hypotensive agents may potentiate diazoxide adverse effects

Diazoxide may decrease warfarin protein binding

Pregnancy Risk Factor C

Pregnancy Implications Can cause infantile alopecia along with neonatal hyperglycemia

Lactation Excretion in breast milk unknown

Nursing Implications I.V. diazoxide is given undiluted by rapid I.V. injection over a period of 30 seconds or less; shake suspension well before using; extravasation can be treated with warm compresses

Additional Information Patients may require a diuretic with repeated I.V. doses.

Dibenzepin

Pronunciation (dye BENZ e pin)

Related Information

- Amitriptyline

CAS Number 315-80-0; 4498-32-2

Synonyms Dibenzepin Hydrochloride

Use Depression

Mechanism of Action A tricyclic antidepressant of the dibenzoepine group which selectively inhibits neuronal norepinephrine uptake

Adverse Reactions

Cardiovascular: Cardiac arrhythmias, cardiomyopathy, hypotension has been associated with falls, hypotension (orthostatic)

Central nervous system: **Drowsiness**, sedation, confusion, **dizziness**, psychosis, restlessness, fatigue, anxiety, nervousness, sleep disorders, seizures, delirium, hyperthermia, visual hallucinations

Dermatologic: Rash, photosensitivity

Endocrine & metabolic: Syndrome of inappropriate antidiuretic hormone

Gastrointestinal: **Nausea**, vomiting, **constipation**, **xerostomia**

Genitourinary: Urinary retention

Hematologic: Blood dyscrasias

Hepatic: Hepatitis, liver failure

Neuromuscular & skeletal: Clonus, myoclonus, weakness

Ocular: Blurred vision, photophobia, diplopia, increased intraocular pressure, mydriasis

Respiratory: Pulmonary edema may develop 45 hours postingestion

Miscellaneous: Hypersensitivity reactions, systemic lupus erythematosus

Signs and Symptoms of Overdose Agranulocytosis, alopecia, ataxia, cardiac arrhythmias, colitis, coma (mean duration: 6 hours), conduction defects, confusion, constipation, cyanosis, dementia, dental erosion, depression, disorientation, ejaculatory disturbances, eosinophilia, galactorrhea, granulocytopenia, hallucinations, hyperthyroidism, hypoglycemia, hyponatremia, hypotension, impotence, increased intraocular pressure, jaundice, lactation, leukopenia, mania, myasthenia gravis

(exacerbation or precipitation), myoclonus, neutropenia, nystagmus, ototoxicity, pulmonary edema (may develop 45 hours postingestion), QT prolongation, respiratory depression, seizure (usually within 3 hours of ingestion), QRS prolongation (with rightward terminal 40 millisecond frontal plane of QRS vector), tachycardia (sinus), tinnitus

Admission Criteria/Prognosis Admit any adult ingestion > 1 g

Pharmacodynamics/Kinetics

Metabolism: Hepatic demethylation to an active metabolite

Half-life: 5 hours

Dosage

Oral: 240-480 mg/day; maximum daily dose: 720 mg

I.M., I.V.: 360 mg/day

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage is effective if performed within 90 minutes/activated charcoal; multiple dosing of activated charcoal would be expected to be useful

Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated. Ventricular arrhythmias and ventricular conduction defects often respond to phenytoin 15-20 mg/kg (adults) with concurrent systemic alkalization (sodium bicarbonate 0.5-2 mEq/kg I.V.). Titrate to a serum pH of 7.45-7.55. Arrhythmias unresponsive to this therapy may respond to lidocaine 1 mg/kg I.V. followed by a titrated infusion. Physostigmine (1-2 mg I.V. slowly for adults or 0.5 mg I.V. slowly for children) may be indicated for seizures or movement disorders but only as a **last resort**. Propranolol may also be utilized for supraventricular arrhythmias (rate: > 160) at 1 mg/minute to a maximum of 5 mg in adults; pediatric dosage of 0.1 mg/kg/dose to 1 mg I.V.. Seizures usually respond to lorazepam or diazepam I.V. boluses (5-10 mg for adults up to 30 mg or 0.25-0.4 mg/kg/dose for children up to 10 mg/dose). If seizures are unresponsive or recur, phenytoin or phenobarbital may be required. Patients must be monitored for at least 24 hours if any signs or symptoms are exhibited. Dobutamine is preferred over dopamine for hypotension; glucagon (10 mg I.V.) can be given to treat hypotension. Flumazenil is contraindicated; magnesium has potentiated adverse cardiac effects (ie, asystole, decreased left ventricular pressure) in an animal model.

Additional Information Lethal dose: 35 mg/kg

Dibucaine

CAS Number 61-12-1; 85-79-0

U.S. Brand Names Nupercainal® [OTC]

Use Fast, temporary relief of pain and itching due to hemorrhoids, minor burns, other minor skin conditions

Mechanism of Action Blocks both initiation and conduction of nerve impulses by decreasing the neuronal membrane's permeability to sodium ions, which results in inhibition of depolarization with resultant blockade of conduction; it is an amide anesthetic, one of the most potent and long-acting and more vasodilatory properties; quinolone derivative

Adverse Reactions

Cardiovascular: Edema, fibrillation (atrial), AV block, sinus bradycardia

Dermatologic: Urticaria, cutaneous lesions

Gastrointestinal: Nausea, vomiting

Local: Burning, tenderness, irritation, inflammation, contact dermatitis, pruritus

Otic: Ototoxicity, tinnitus

Signs and Symptoms of Overdose Acidosis, ARDS, ataxia, bradycardia, coma, CNS depression, cough, cyanosis, flutter (atrial), hypotension, lethargy, ototoxicity, tinnitus, respiratory depression, seizures, ventricular arrhythmias, vomiting

Pharmacodynamics/Kinetics

Onset of action: ~15 minutes

Duration: 2-4 hours

Absorption: Poor through intact skin; well absorbed through mucous membranes and excoriated skin

Dosage

Children and Adults:

Rectal: Hemorrhoids: Insert ointment into rectum using a rectal applicator; administer each morning, evening, and after each bowel movement

Topical: Apply gently to the affected areas; no more than 30 g for adults or 7.5 g for children should be used in any 24-hour period

Stability Darkens on light exposure

Contraindications Hypersensitivity to amide-type anesthetics, ophthalmic use

Dosage Forms

Ointment: 1% (30 g, 454 g)

Nupercainal®: 1% (30 g, 60g) [contains sodium bisulfite]

Reference Range Plasma level of 71 ng/mL associated with seizures

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Treat seizures with lorazepam or diazepam; recurring seizures may require phenytoin or phenobarbital; sodium bicarbonate (1-2 mEq/kg) for treatment of acidosis; **do not** use lidocaine in order to treat ventricular arrhythmias; bretylium may be particularly effective;

although no cases exist for development of methemoglobin, amide anesthetics may cause this entity

Enhancement of elimination: Forced diuresis and hemodialysis may be beneficial

Drug Interactions No data reported

Pregnancy Risk Factor C

Nursing Implications Do not use near the eyes or over denuded surfaces or blistered areas

Additional Information Fatal oral dose: 0.8 mg/kg.

Formerly marketed as Percaine; not available in the U.S. as an injectable.

Child-resistant packaging was ordered by the U.S. Consumer Product Safety Commission for products containing more than 0.5 mg dibucaine. Dibucaine is 10 and 20 times more toxic than lidocaine and procaine, respectively.

Diclofenac

Related Information

● Nonsteroidal Anti-inflammatory Drugs

CAS Number 15307-79-6

U.S. Brand Names Cataflam®; Solaraze™; Voltaren Ophthalmic®; Voltaren®-XR; Voltaren®

Synonyms Diclofenac Potassium; Diclofenac Sodium

Use Acute and chronic treatment of rheumatoid arthritis, ankylosing spondylitis, and osteoarthritis; ophthalmic solution for postoperative inflammation after cataract extraction

Juvenile rheumatoid arthritis, gout, dysmenorrhea, biliary and renal colic, fever, and pain relief

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors. Mechanism of action for the treatment of AK has not been established.

Adverse Reactions

Cardiovascular: Circulatory collapse, vasculitis

Central nervous system: Headache, dizziness, aseptic meningitis, psychosis, cognitive dysfunction, coma, seizures

Dermatologic: **Rash**, pruritus, bullous lesions, exfoliative dermatitis, erythema multiforme, alopecia, angioedema, toxic epidermal necrolysis, urticaria, purpura, Stevens-Johnson syndrome, photosensitivity, psoriasis, exanthem, scalded skin syndrome

Endocrine & metabolic: Hyperkalemia, anion gap metabolic acidosis, fluid retention, erythema nodosum

Gastrointestinal: **Abdominal cramps, heartburn, indigestion, nausea**, vomiting, GI ulceration, constipation, diarrhea, dyspepsia, cecal diaphragm/intestinal stricture, diaphragm disease, aphthous stomatitis, xerostomia

Hematologic: Leukopenia, neutropenia, agranulocytosis, granulocytopenia; aplastic anemia (rare), platelet inhibition, thrombocytopenia, hemolytic anemia, immune hemolytic anemia

Hepatic: Elevated transaminases, hepatitis (fulminant), hepatic necrosis

Neuromuscular & skeletal: Clonus, myoclonus, paresthesia

Otic: Ototoxicity, tinnitus

Renal: Renal failure (acute), albuminuria, nephrotic syndrome, chronic renal failure

Respiratory: Wheezing, respiratory depression

Miscellaneous: Hypersensitivity, systemic lupus erythematosus (SLE)

Signs and Symptoms of Overdose Coagulopathy, cognitive dysfunction, drowsiness, GI bleeding, GI upset, lichenoid eruptions, nausea, nephrotic syndrome, ototoxicity, tinnitus, vomiting, wheezing. Severe poisoning can manifest with coma, hypotension, renal and/or hepatic failure, respiratory depression, and seizures.

Pharmacodynamics/Kinetics

Onset of action: Cataflam® is more rapid than sodium salt (Voltaren®) because it dissolves in the stomach instead of the duodenum

Absorption: Topical gel: 10%

Protein binding: 99% to albumin

Metabolism: Hepatic to several metabolites

Half-life elimination: 2 hours

Time to peak, serum: Cataflam®: ~1 hour; Voltaren®: ~2 hours

Excretion: Urine (65%); feces (35%)

Dosage

Adults:

Oral:

Analgesia (Cataflam®): Starting dose: 50 mg 3 times/day

Rheumatoid arthritis: 150-200 mg/day in 2-4 divided doses

Osteoarthritis: 100-150 mg/day in 2-3 divided doses

Ankylosing spondylitis: 100-125 mg/day in 4-5 divided doses

Ophthalmic: Instill 1 drop into affected eye 4 times/day beginning 24 hours after cataract surgery and continuing for 2 weeks

Monitoring Parameters Monitor CBC, liver enzymes; monitor urine output and BUN/serum creatinine; occult blood loss, hemoglobin, hematocrit

Administration

Oral: Do not crush tablets. Administer with food or milk to avoid gastric distress. Take with full glass of water to enhance absorption.

Ophthalmic: Wait at least 5 minutes before administering other types of eye drops.

Topical gel: Cover lesion with gel and smooth into skin gently. Do not cover lesion with occlusive dressings or apply sunscreens, cosmetics, or other medications to affected area.

Contraindications Hypersensitivity to diclofenac, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy (3rd trimester)

Warnings [U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension. Risk may be increased with duration of use or pre-existing cardiovascular risk factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF, or hypertension.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI, and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Not recommended for use in patients with advanced renal disease.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS), and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

The elderly are at increased risk for adverse effects (especially peptic ulceration, CNS effects, renal toxicity) from NSAIDs even at low doses.

Withhold for at least 4-6 half-lives prior to surgical or dental procedures.

Topical gel should not be applied to the eyes, open wounds, infected areas, or to exfoliative dermatitis. Monitor patients for 1 year following application of ophthalmic drops for corneal refractive procedures. Patients using ophthalmic drops should not wear soft contact lenses. Ophthalmic drops may slow/delay healing or prolong bleeding time following surgery.

Dosage Forms

[DSC] = Discontinued product

Gel, as sodium:

Solaraze®: 30 mg/g (50 g)

Solution, ophthalmic, as sodium:

Voltaren Ophthalmic®: 0.1% (2.5 mL, 5 mL)

Tablet, as potassium: 50 mg

Cataflam®: 50 mg

Tablet, delayed release, enteric coated, as sodium: 50 mg, 75 mg

Voltaren®: 25 mg [DSC], 50 mg [DSC], 75 mg

Tablet, extended release, as sodium: 100 mg

Voltaren®-XR: 100 mg

Reference Range Peak plasma diclofenac level after a 50 mg dose: ~735 ng/mL

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Hypotension/dehydration can be managed with I.V. fluid therapy; acidosis should be treated with I.V. sodium bicarbonate; seizures with benzodiazepines; antacids, blood products are indicated, as appropriate, for hemorrhage; famotidine (40 mg 2 times/day) can decrease incidence of gastric or duodenal ulcers in patients receiving long-term therapy of this drug

Enhancement of elimination: Dialysis or perfusion is indicated for secondary complications, acidosis, or renal failure and not toxin removal alone; multiple dosing of activated charcoal may be useful

Test Interactions ↑ bleeding time; causes falsely increased free thyroxine level

DICUMAROL

Drug Interactions **Substrate** (minor) of CYP1A2, 2B6, 2C8, 2C9, 2C19, 2D6, 3A4; **Inhibits** CYP1A2 (moderate), 2C9 (weak), 2E1 (weak), 3A4 (strong)

ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet drugs (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatide, tirofiban) can cause an increased risk of bleeding.

Beta-blockers: NSAIDs may decrease the antihypertensive effect of beta-blockers. Monitor.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids may increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

CYP1A2 substrates: Diclofenac may increase the levels/effects of CYP1A2 substrates. Example substrates include aminophylline, flvoxamine, mexiletine, mirtazapine, ropinirole, theophylline, and trifluoperazine.

CYP3A4 substrates: Diclofenac may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Gentamicin and amikacin serum concentrations are increased by indomethacin in premature infants. Results may apply to other aminoglycosides and NSAIDs.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use.

Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose. Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again.

Loop diuretics efficacy (diuretic and antihypertensive effect) is reduced. Indomethacin reduces this efficacy, however, it may be anticipated with any NSAID.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Thiazides antihypertensive effects are decreased; avoid concurrent use. Verapamil plasma concentration is decreased by diclofenac; avoid concurrent use.

Warfarin's INRs may be increased by piroxicam. Other NSAIDs may have the same effect depending on dose and duration. Monitor INR closely. Use the lowest dose of NSAIDs possible and for the briefest duration.

Pregnancy Risk Factor B (topical); C (oral)/D (3rd trimester)

Pregnancy Implications Closure of the ductus arteriosus in a fetus following *in utero* exposure

Lactation Excretion in breast milk unknown/not recommended

Additional Information Misoprostol (200 mcg) can prevent diclofenac-induced gastric ulcers (**not** duodenal ulcers)

Specific References

Schechner V, Hershcovici T, and Beigel Y, "Rhabdomyolysis Due to Combined Therapy with Cerivastatin and Diclofenac," *J Pharm Technol*, 2003(19):219-21.

Dicumarol

Pronunciation (dye KOO ma role)

Related Information

- Warfarin

CAS Number 66-76-2

Synonyms Bishydroxycoumarin

Use Prophylaxis and treatment of thromboembolic disorders

Mechanism of Action Depression of factors VII, IX, X, and II (sequential) - a hydroxycoumarin

Adverse Reactions

More likely to have gastrointestinal side effects than warfarin

Cardiovascular: Circulatory collapse, pericardial effusion/pericarditis

Central nervous system: Fever, intracranial hemorrhage

Dermatologic: Skin lesions, skin necrosis, alopecia, angioedema, bullous skin disease, urticaria, purpura, pruritus, exanthem

Gastrointestinal: Anorexia, nausea, vomiting, diarrhea, pancreatitis, hemorrhagic pancreatitis

Genitourinary: Priapism

Hematologic: Hemorrhage, ocular hemorrhage, bleeding gums, coagulopathy

Hepatic: Elevated prothrombin time

Renal: Renal tubular necrosis

Respiratory: Hemoptysis, alveolar hemorrhage, pulmonary hemorrhage

Miscellaneous: Feces discoloration (black), feces discoloration (light brown), feces discoloration (pink), feces discoloration (red)

Pharmacodynamics/Kinetics

Duration of action: 5-6 days

Absorption: Oral: Well (but unpredictably) absorbed - affected by food

Protein binding: 97%

Metabolism: In the liver

Half-life: Plasma: 1-2 days

Time to peak serum concentration: 1-9 hours

Elimination: In urine

Dosage Adults: Oral: 25-200 mg/day based on prothrombin time (PT) determinations

Stability Insoluble in water or alcohol

Contraindications Severe liver or kidney disease; open wounds; uncontrolled bleeding; hypersensitivity to dicumarol or any component

Warnings Concomitant use with vitamin K may decrease anticoagulant effect; monitor carefully; concomitant use with ethacrynic acid, indomethacin, mefenamic acid, phenylbutazone, or aspirin increases warfarin's anticoagulant effect and may cause severe GI bleeding; the plasma half-life of dicumarol is 1-2 days and its duration of action is 2-10 days; as this is considerably longer than warfarin, prescribers should be aware of this difference; peak levels should be expected 1-2 weeks after dose adjustment

Dosage Forms Tablet: 25 mg

Reference Range

Normal: 20-30 mcg/mL

Toxic: >70 mcg/mL

Overdosage/Treatment

Decontamination: Activated charcoal should be given; lavage can be performed within 1 hour of ingestion

Supportive therapy: Vitamin K₁ should be given in doses as outlined in phytonadione; monitor PT and INR till normalization

Enhancement of elimination: Multiple dosing of activated charcoal or cholestyramine may be useful

Antidote(s)

- Cholestyramine Resin [ANTIDOTE]

- Phytonadione [ANTIDOTE]

Diagnostic Procedures

- Bishydroxycoumarin, Blood

Drug Interactions May accentuate toxicities of oral hypoglycemics and anticonvulsants. The following will decrease prothrombin time - antacids, antihistamines, phenobarbital, carbamazepine, cholestyramine, meprobamate, glutethimide, ethchlorvynol, oral contraceptives, ranitidine, chloral hydrate, diuretics. Increased prothrombin time due to allopurinol, amiodarone, cimetidine, clofibrate, dextran, diazoxide, diflunisal, diuretics, disulfiram, fenoprofen, ibuprofen, indomethacin, influenza virus vaccine, methyl dopa, methylphenidate, MAO inhibitors, naproxen, nortriptyline, phenytoin, propylthiouracil, salicylates, quinidine, quinine, ranitidine, tolbutamide, thyroid drugs, sulindac, co-trimoxazole

Pregnancy Risk Factor D

Additional Information TLV-TWA: 0.1 mg/m³; IDLH: 200 mg/m³

Dicyclomine

Pronunciation (dye SYE kloe meen)

CAS Number 67-92-5; 77-19-0

U.S. Brand Names Bentyl®

Synonyms Dicyclomine Hydrochloride; Dicycloverine Hydrochloride

Use Treatment of functional disturbances of GI motility such as irritable bowel syndrome

Unlabeled/Investigational Use Urinary incontinence

Mechanism of Action Blocks the action of acetylcholine at parasympathetic sites in smooth muscle, secretory glands and the CNS

Adverse Reactions

Cardiovascular: Hypotension (orthostatic), tachycardia, palpitations, thrombosis with I.V. administration, cardiomegaly, cardiomyopathy

Central nervous system: Confusion, drowsiness, headache, lightheadedness, memory disturbance, loss of short-term memory, tiredness, seizures, coma, nervousness, excitement, insomnia, dizziness, delirium, psychosis

Dermatologic: **Dry skin**, rash, urticaria, pruritus

Endocrine & metabolic: Decreased flow of breast milk

Gastrointestinal: **Constipation, xerostomia and dry throat**, dysphagia, bloated feeling, nausea, vomiting, loss of taste perception

Genitourinary: Dysuria, urinary retention

Local: **Injection site reactions**

Neuromuscular & skeletal: Muscular hypotonia, weakness

Ocular: Blurred vision, intraocular pain (increased), sensitivity to light (increased)

Respiratory: **Dry nose**, asphyxia, respiratory distress, apnea (in neonates)

Miscellaneous: **Diaphoresis (decreased)**

Signs and Symptoms of Overdose Dry mouth, hypertension, hyperthermia, ileus, mydriasis, tachycardia, urinary retention

Pharmacodynamics/Kinetics

Onset of action: 1-2 hours

Duration: ≤4 hours

Absorption: Oral: Well absorbed

Metabolism: Extensive

Half-life elimination: Initial: 1.8 hours; Terminal: 9-10 hours

Excretion: Urine (small amounts as unchanged drug)

Dosage

Oral:

Infants >6 months: 5 mg/dose 3-4 times/day

Children: 10 mg/dose 3-4 times/day

Urinary incontinence: 8 mg/kg/day in 3 divided doses

Adults: Begin with 80 mg/day in 4 equally divided doses, then increase up to 160 mg/day

Urinary incontinence: 60-100 mg/day

I.M. (**should not be used I.V.**): Adults: 80 mg/day in 4 divided doses (20 mg/dose)

Monitoring Parameters Pulse, anticholinergic effect, urinary output, GI symptoms

Administration Do not administer I.V.

Contraindications Hypersensitivity to any anticholinergic drug; narrow-angle glaucoma; myasthenia gravis; should not be used in infants <6 months of age

Warnings Use with caution in patients with hepatic or renal disease, ulcerative colitis, hyperthyroidism, cardiovascular disease, hypertension, tachycardia, GI obstruction, obstruction of the urinary tract. The elderly are at increased risk for anticholinergic effects, confusion, and hallucinations.

Dosage Forms Capsule, as hydrochloride: 10 mg

Injection, solution, as hydrochloride: 10 mg/mL (2 mL)

Syrup, as hydrochloride: 10 mg/5 mL (480 mL)

Tablet, as hydrochloride: 20 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Physostigmine should be reserved for life-threatening anticholinergic effects; tachyarrhythmias can respond to physostigmine or I.V. beta-adrenergic blockers; agitation can be treated with benzodiazepines

Drug Interactions Decreased effect: Phenothiazines, anti-Parkinson's drugs, haloperidol, sustained release dosage forms; decreased effect with antacids

Increased toxicity: Anticholinergics, amantadine, narcotic analgesics, type I antiarrhythmics, antihistamines, phenothiazines, TCAs

Pregnancy Risk Factor B

Pregnancy Implications No increase in fetal abnormalities in mothers taking 40 mg/day during first trimester

Lactation Enters breast milk/contraindicated

Nursing Implications Raise bed rails, institute safety measures

Otic: Deafness

Respiratory: Cough, apnea, dyspnea, rhinitis

Signs and Symptoms of Overdose Fanconi syndrome, myalgia; peripheral neuropathy can occur at doses >20 mg/kg/day

Pharmacodynamics/Kinetics

Absorption: Subject to degradation by acidic pH of stomach; some formulations are buffered to resist acidic pH; ≤50% reduction in peak plasma concentration is observed in presence of food. Delayed release capsules contain enteric-coated beadlets which dissolve in the small intestine.

Distribution: V_d: Children: 35.6 L/m²; Adults: 1.08 L/kg

Protein binding: <5%

Metabolism: Has not been evaluated in humans; studies conducted in dogs show extensive metabolism with allantoin, hypoxanthine, xanthine, and uric acid being the major metabolites found in urine

Bioavailability: 42%

Half-life elimination:

Children and Adolescents: 0.8 hour

Adults: Normal renal function: 1.5 hours; active metabolite, ddATP, has an intracellular half-life >12 hours *in vitro*; Renal impairment: 2.5-5 hours

Time to peak: Buffered tablets: 0.67 hours; Delayed release capsules: 2 hours

Excretion: Urine (~55% as unchanged drug)

Clearance: Total body: Averages 800 mL/minute

Dosage Treatment of HIV infection: Oral (administer on an empty stomach):

Children:

2 weeks to 8 months: 100 mg/m² twice daily; 50 mg/m² may be considered in infants 2 weeks to 4 months

>8 months: 120 mg/m² twice daily; dosing range: 90-150 mg/m² twice daily; patients with CNS disease may require higher dose

Note: At least 2 tablets per dose should be administered for adequate buffering and absorption; tablets should be chewed or dispersed (in 1 ounce of water).

Adolescents and Adults: Dosing based on patient weight:

Note: Preferred dosing frequency is twice daily for didanosine tablets/oral solution

Chewable tablets, powder for oral solution:

<60 kg: 125 mg twice daily or 250 mg once daily

≥60 kg: 200 mg twice daily or 400 mg once daily

Note: Adults should receive 2-4 tablets per dose for adequate buffering and absorption; tablets should be chewed or dispersed

Delayed release capsule (Videx® EC):

<60 kg: 250 mg once daily

≥60 kg: 400 mg once daily

Dosing adjustment with tenofovir (didanosine tablets or delayed release capsules; based on tenofovir product labeling):

<60 kg: 200 mg once daily

≥60 kg: 250 mg once daily

Dosage adjustment in renal impairment: Dosing based on patient weight, creatinine clearance, and dosage form: See table.

Didanosine

CAS Number 69655-05-6

U.S. Brand Names Videx® EC; Videx®

Synonyms ddl; Dideoxyinosine

Use Treatment of HIV infection; always to be used in combination with at least two other antiretroviral agents

Mechanism of Action Didanosine, a purine nucleoside (adenosine) analog and the deamination product of dideoxyadenosine (ddA), inhibits HIV replication *in vitro* in both T cells and monocytes. Didanosine is converted within the cell to the mono-, di-, and triphosphates of ddA. These ddA triphosphates act as substrate and inhibitor of HIV reverse transcriptase substrate and inhibitor of HIV reverse transcriptase, thereby blocking viral DNA synthesis and suppressing HIV replication.

Adverse Reactions

Cardiovascular: Heart failure, cardiomyopathy, cardiomegaly, QT prolongation, vasodilation

Central nervous system: **Headache, anxiety, irritability, restlessness, insomnia**, malaise, CNS depression, cranial nerve palsies, fever, mania

Dermatologic: Rash, pruritus, erythema, eczema, alopecia, cutaneous vasculitis

Endocrine & metabolic: Hypokalemia, hyperuricemia (dose related), hypomagnesemia, hypocalcemia, hyperlactatemia (symptomatic)

Gastrointestinal: **Diarrhea, nausea, dyspepsia, vomiting, anorexia, stomatitis, pancreatitis, abdominal pain**

Hematologic: Thrombocytopenia

Hepatic: Elevated liver enzymes, hepatic failure, hepatitis (fulminant)

Neuromuscular & skeletal: **Paresthesia, peripheral neuropathy**, weakness

Ocular: Retinal depigmentation, photophobia, diplopia, amblyopia, blindness

Recommended Dose (mg) of Didanosine by Body Weight

Creatinine Clearance (mL/min)	≥ 60 kg		< 60 kg	
	Tablet ¹ (mg)	Delayed Release Capsule (mg)	Tablet ¹ (mg)	Delayed Release Capsule (mg)
≥ 60	400 qd or 200 bid	400 qd	250 qd or 125 bid	250 qd
30-59	200 qd or 100 bid	200 qd	150 qd or 75 bid	125 qd
10-29	150 qd	125 qd	100 qd	125 qd
< 10	100 qd	125 qd	75 qd	See footnote 2.

¹Chewable/dispersible buffered tablet; 2 tablets must be taken with each dose; different strengths of tablets may be combined to yield the recommended dose.

²Not suitable for use in patients <60 kg with Cl_{cr} <10 mL/minute; use alternate formulation.

Patients requiring hemodialysis or CAPD: Dose per Cl_{cr} <10 mL/minute
Hemodialysis: Removed by hemodialysis (40% to 60%)

Dosing adjustment in hepatic impairment: Should be considered; monitor for toxicity

Elderly patients have a higher frequency of pancreatitis (10% versus 5% in younger patients); monitor renal function and dose accordingly

Monitoring Parameters Serum potassium, uric acid, creatinine; hemoglobin, CBC with neutrophil and platelet count, CD4 cells; viral load; liver function tests, amylase; weight gain; perform dilated retinal exam every 6 months

Administration

Videx® EC: Take on an empty stomach; administer at least 1 hour before or 2 hours after eating.

Chewable/dispersible buffered tablets: The 200 mg tablet should only be used in once-daily dosing. At least 2 tablets, but no more than 4 tablets, should be taken together to allow adequate buffering. Tablets may be chewed or dispersed prior to consumption. To disperse, dissolve in 1 oz water, stir until uniform dispersion is formed, and drink immediately. May also add 1 oz of clear apple juice to initial dispersion if additional flavor is needed. The apple juice dilution is stable for 1 hour at room temperature. Do not mix with other juices.

Pediatric powder for oral solution: Prior to dispensing, the powder should be mixed with purified water USP to an initial concentration of 20 mg/mL and then further diluted with an appropriate antacid suspension to a final mixture of 10 mg/mL. Shake well prior to use.

Contraindications Hypersensitivity to didanosine or any component of the formulation

Warnings

[U.S. Boxed Warning]: Pancreatitis (sometimes fatal) has been reported; incidence is dose related. Risk factors for developing pancreatitis include a previous history of the condition, concurrent cytomegalovirus or *Mycobacterium avium-intracellulare* infection, and concomitant use of stavudine, pentamidine, or co-trimoxazole. Discontinue didanosine if clinical signs of pancreatitis occur. **[U.S. Boxed Warning]: Lactic acidosis, symptomatic hyperlactatemia, and severe hepatomegaly with steatosis (sometimes fatal) have occurred with antiretroviral nucleoside analogues, including didanosine.** Hepatotoxicity may occur even in the absence of marked transaminase elevations; suspend therapy in any patient developing clinical/laboratory findings which suggest hepatotoxicity. Pregnant women may be at increased risk of lactic acidosis and liver damage.

Peripheral neuropathy occurs in ~20% of patients receiving the drug. Retinal changes (including retinal depigmentation) and optic neuritis have been reported in adults and children using didanosine. Patients should undergo retinal examination every 6-12 months. Use with caution in patients with decreased renal or hepatic function, phenylketonuria, sodium-restricted diets, or with edema, CHF, or hyperuricemia. Twice-daily dosing is the preferred dosing frequency for didanosine tablets. Didanosine delayed release capsules are indicated for once-daily use.

Dosage Forms Capsule, delayed release: 200 mg, 250 mg, 400 mg
Videx® EC: 125 mg, 200 mg, 250 mg, 400 mg

Powder for oral solution, pediatric:

Videx®: 2 g, 4 g [makes 10 mg/mL solution after final mixing]

Tablet, buffered, chewable/dispersible:

Videx®: 25 mg, 50 mg, 100 mg, 150 mg, 200 mg [all strengths contain phenylalanine 36.5 mg/tablet; orange flavor] [DSC]

Reference Range Peak plasma level of 1-29 µmol/L following oral dose of 0.8-33 mg/kg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; hemodialysis may be effective in removing approximately 20% of dose

Test Interactions ↑ serum triglycerides, uric acid; ↓ serum calcium, potassium, magnesium

Drug Interactions Drugs whose absorption depends on the level of acidity in the stomach (such as ketoconazole, itraconazole, and dapsone) should be administered at least 2 hours prior to the buffered formulations of didanosine (not affected by delayed release capsules)

Decreased effect: Buffered formulations of didanosine (tablets, pediatric oral solution) may decrease absorption of quinolones or tetracyclines, separate dosing by 2 hours; didanosine should be held during PCP treatment with pentamidine; didanosine may decrease levels of indinavir.

Increased toxicity: Concomitant administration of other drugs (including hydroxyurea) which have the potential to cause peripheral neuropathy or pancreatitis may increase the risk of these toxicities.

Allopurinol: May increase didanosine concentration; avoid concurrent use.
Antacids: Concomitant use with buffered tablet or pediatric didanosine solution may potentiate adverse effects of aluminum- or magnesium-containing antacids.

Ganciclovir: May increase didanosine concentration; monitor.

Hydroxyurea: May precipitate didanosine-induced pancreatitis if added to therapy; concomitant use is not recommended.

Methadone: May decrease didanosine concentration; monitor.

Ribavirin: Coadministration may increase exposure to didanosine and/or its active metabolite, increasing the risk of hepatic decompensation or

other signs of mitochondrial toxicity, including pancreatitis, lactic acidosis, and peripheral neuropathy. Coadministration of ribavirin with didanosine should be undertaken with caution, and patients should be monitored closely for didanosine-related toxicities; suspend therapy if signs or symptoms of toxicity are noted.

Tenofovir: Coadministration may increase exposure to didanosine and/or its active metabolite increasing the risk or severity of didanosine toxicities, including pancreatitis, hyperglycemia, lactic acidosis, and peripheral neuropathy. Some patients have experienced reduced CD4 cell counts and/or decreased virologic response. Coadministration of tenofovir with didanosine should be undertaken with caution, and patients should be monitored closely for didanosine-related toxicities; specific dosing adjustment is recommended; suspend therapy if signs or symptoms of toxicity are noted.

Pregnancy Risk Factor B

Pregnancy Implications Cases of fatal and nonfatal lactic acidosis, with or without pancreatitis, have been reported in pregnant women. It is not known if pregnancy itself potentiates this known side effect; however, pregnant women may be at increased risk of lactic acidosis and liver damage. Hepatic enzymes and electrolytes should be monitored frequently during the 3rd trimester of pregnancy. Use during pregnancy only if the potential benefit to the mother outweighs the potential risk of this complication. Phase I/II studies have shown limited placental transfer. Health professionals are encouraged to contact the antiretroviral pregnancy registry to monitor outcomes of pregnant women exposed to antiretroviral medications (1-800-258-4263).

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications Administer liquified powder immediately after dissolving; avoid creating dust if powder spilled, use wet mop or damp sponge

Additional Information Each chewable tablet contains 36.5 mg phenylalanine and 8.6 mEq magnesium. Sodium content of buffered tablets: 264.5 mg (11.5 mEq).

Specific References

Diethylcarbamazine

CAS Number 1642-54-2; 90-89-1

Use An antihelmintic agent used to treat *Wuchereria bancrofti*, *Brugia malayi*, *Brugia timori*, or *Onchocerca volvulus*; has been used to treat dog heartworm

Mechanism of Action Antifilarial agent which kills parasite in adult stage (a piperazine derivative)

Adverse Reactions

Cardiovascular: Hypotension, tachycardia

Central nervous system: Dizziness, headache, fever

Dermatologic: Pruritus

Endocrine & metabolic: Abortifacient

Gastrointestinal: Vomiting, nausea

Neuromuscular & skeletal: Arthralgia

Ocular: Eye discomfort (optic neuritis)

Renal: Proteinuria

Miscellaneous: Hypersensitivity due to microfilariae death (Mazzotti reaction) which can occur within 2 hours; lymphadenopathy

Signs and Symptoms of Overdose Abdominal cramping, anorexia, dizziness, nausea, vomiting (> 1 g)

Admission Criteria/Prognosis Consider admitting hypersensitivity reactions (especially due onchocerciasis) or ingestions > 1 g

Toxicodynamics/Kinetics

Metabolism: N-oxide metabolites

Half-life: 9-13 hours; 15 hours in renal failure

Elimination: Renal

Dosage

Bancroftian filariasis: 6 mg/kg/day in 3 divided doses for 12 days

Brugian filariasis: 3-6 mg/kg/day in 3 divided doses for 6-12 days

In order to decrease severity of hypersensitivity reactions, initial dosage of 1 mg/kg/day can be increased to 6 mg/kg/day over 3 days; a corticosteroid agent can be added

Prophylaxis of Bancroftian/Malayan filariasis: 50 mg/month

Prophylaxis of loiasis: 4-5 mg/kg for 3 successive days each month

Onchocerciasis: 0.5-1 mg/kg for first 1-2 days, then 2 mg/kg twice daily for next 5-7 days

Reference Range Dose of 0.5 mg/kg can result in a peak plasma diethylcarbamazine citrate concentration of 100-150 ng/mL

Overdosage/Treatment

Decontamination: Oral: Lavage ingestions > 10 mg/kg/activated charcoal
Supportive therapy: Betamethasone can be used to treat hypersensitivity reactions during onchocerciasis treatment; antihistamines are of no value, although antipyretic or analgesic agents may be useful

Enhanced elimination: Avoid alkalization of urine if possible due to prolongation of serum half-life; multiple dosing of activated charcoal may be useful

Pregnancy Implications Uterine hypermotility (due to prostaglandin synthesis) may occur

Additional Information Encephalitis due to *Loa loa* infection may worsen during initial treatment with diethylcarbamazine citrate; use of corticosteroids may be useful for such treatment

Diethylpropion

CAS Number 134-80-5; 90-84-6

U.S. Brand Names Tenuate® Dospan®; Tenuate®

Synonyms Amfepramone; Diethylpropion Hydrochloride

Use Short-term adjunct in exogenous obesity

Unlabeled/Investigational Use Migraine

Mechanism of Action Diethylpropion is used as an anorexiatic agent possessing pharmacological and chemical properties similar to those of amphetamines. The mechanism of action of diethylpropion in reducing appetite appears to be secondary to CNS effects, specifically stimulation of the hypothalamus to release catecholamines into the central nervous system; anorexiatic effects are mediated via norepinephrine and dopamine metabolism. An increase in physical activity and metabolic effects (inhibition of lipogenesis and enhancement of lipolysis) may also contribute to weight loss.

Adverse Reactions

Cardiovascular: **Hypertension**, tachycardia, arrhythmias

Central nervous system: **Euphoria, nervousness, insomnia**, confusion, headache, psychosis, paranoid psychosis, auditory hallucinations, CNS depression, paranoia

Dermatologic: Alopecia, urticaria, ecchymosis

Endocrine & metabolic: Changes in libido, gynecomastia

Gastrointestinal: Nausea, vomiting, restlessness, constipation, diarrhea, abdominal cramps, metallic taste

Genitourinary: Dysuria, impotence

Hematologic: Blood dyscrasias, agranulocytosis, leukopenia

Neuromuscular & skeletal: Tremor, myalgia

Ocular: Blurred vision, mydriasis

Renal: Polyuria

Respiratory: Dyspnea

Miscellaneous: Diaphoresis (increased)

Pharmacodynamics/Kinetics

Onset of action: 1 hour

Duration: 12-24 hours

Dosage

Adults: Oral:

Tablet: 25 mg 3 times/day before meals or food

Tablet, controlled release: 75 mg at midmorning

Monitoring Parameters

Monitor CNS

Administration Do not crush 75 mg controlled release tablet. Dose should not be given in evening or at bedtime. Take tablets 1 hour before meals. Take controlled release tablet at midmorning.

Contraindications Hypersensitivity or idiosyncrasy to sympathomimetic amines. Patients with advanced arteriosclerosis, symptomatic cardiovascular disease, moderate to severe hypertension (stage II or III), hyperthyroidism, glaucoma, agitated states, patients with a history of drug abuse, and during or within 14 days following MAO inhibitor therapy. Concurrent use with other anorectic agents; stimulant medications are contraindicated for use in children with attention-deficit/hyperactivity disorders and concomitant Tourette's syndrome or tics.

Warnings

Use with caution in patients with bipolar disorder, diabetes mellitus, cardiovascular disease, seizure disorders, insomnia, porphyria, or mild hypertension (stage I). May exacerbate symptoms of behavior and thought disorder in psychotic patients. Stimulants may unmask tics in individuals with coexisting Tourette's syndrome. Potential for drug dependency exists - avoid abrupt discontinuation in patients who have received for prolonged periods. Stimulant use in children has been associated with growth suppression. Not recommended for use in patients <12 years of age.

Serious, potentially life-threatening toxicities may occur when thyroid hormones (at dosages above usual daily hormonal requirements) are used in combination with sympathomimetic amines to induce weight loss. Treatment of obesity is not an approved use for thyroid hormone.

Dosage Forms Tablet, as hydrochloride (Tenuate®): 25 mg

Tablet, controlled release, as hydrochloride (Tenuate® Dospan®): 75 mg

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage (within 4 hours)/activated charcoal

Supportive therapy: Treat hypotension with I.V. crystalloid solutions; vasopressors can be used for refractory cases; propranolol (1 mg/dose in adults or 0.01-0.1 mg/kg/dose in children over 10 minutes) or esmolol can be used to treat tachycardia; hyperpyrexia can be treated with external (passive) cooling

Drug Interactions Anorectic agents: Concurrent use with other anorectic agents may cause serious cardiac problems and is contraindicated. Furazolidone: May induce a hypertensive episode in patients receiving furazolidone.

Guanethidine: Diethylpropion may inhibit the antihypertensive response to guanethidine; probably also may occur with guanadrel.

MAO inhibitors: Severe hypertensive episodes have occurred with amphetamine when used in patients receiving MAO inhibitors; concurrent use or use within 14 days is contraindicated.

Norepinephrine: Diethylpropion may enhance the pressor response to norepinephrine.

Sibutramine: Concurrent use of sibutramine and diethylpropion may cause severe hypertension and tachycardia; use is contraindicated.

Tricyclic antidepressants: Concurrent use with tricyclic antidepressants may result in hypertension and CNS stimulation; avoid this combination.

Pregnancy Risk Factor B

Lactation Enters breast milk/not recommended

Nursing Implications Do not crush 75 mg controlled release tablets; dose should not be given in evening or at bedtime

Diethylstilbestrol

Pronunciation (dye eth il stil BES trole)

CAS Number 130-80-3; 56-53-1

Synonyms DES; Diethylstilbestrol Diphosphate Sodium; Stilbestrol

Use Palliative treatment of inoperable metastatic prostatic carcinoma and postmenopausal inoperable, progressing breast cancer

Mechanism of Action Competes with estrogenic and androgenic compounds for binding onto tumor cells and thereby inhibits their effects on tumor growth

Adverse Reactions

Cardiovascular: Hypertension, thromboembolism, myocardial infarction, **peripheral edema**, edema, angina

Central nervous system: Headache, CNS depression, dizziness, anxiety, stroke

Dermatologic: Rash, chloasma, melasma, bullous lesions, hypertrichosis, exfoliative dermatitis, angioedema, urticaria, purpura, pruritus, acanthosis nigricans, exanthem

Endocrine & metabolic: Gynecomastia, amenorrhea, **breast tenderness, enlargement of breasts (female & male)**, alterations in frequency and flow of menses, decreased glucose tolerance, decreased libido in males, increased libido in females

Gastrointestinal: **Nausea, anorexia, bloating**, vomiting, diarrhea, GI distress, pancreatitis

Hematologic: Thrombocytopenia, hemolytic anemia, pancytopenia, hypercalcemia, porphyrinogenic

Hepatic: Cholestatic jaundice, increased triglycerides and LDL

Ocular: Intolerance to contact lenses

Miscellaneous: Breast tumors, breast cancer, susceptibility to *Candida* infection (increased), risk of pre-eclampsia (increased), systemic lupus erythematosus

Signs and Symptoms of Overdose Chest pain, depression, dysuria, ectopic pregnancy, gynecomastia, hirsutism, hyperactivity, hyperprolactinemia, hypocalcemia, nausea

Pharmacodynamics/Kinetics

Metabolism: Hepatic

Excretion: Urine and feces

Dosage

Adults:

Male:

Prostate carcinoma: Oral: 1-3 mg/day

Diphosphate: Inoperable progressing prostate cancer:

Oral: 50 mg 3 times/day; increase up to 200 mg or more 3 times/day; maximum daily dose: 1 g

I.V.: Give 0.5 g, dissolved in 250 mL of saline or D₅W, administer

slowly the first 10-15 minutes then adjust rate so that the entire amount is given in 1 hour; repeat for ≥5 days depending on patient response, then repeat 0.25-0.5 g 1-2 times for 1 week or change to oral therapy

Female: Postmenopausal inoperable, progressing breast carcinoma:

Oral: 15 mg/day

Stability Intravenous solution should be stored at room temperature and away from direct light; solution is stable for 3 days as long as cloudiness or precipitation has not occurred

Monitoring Parameters Mammography should be performed in all women prior to starting estrogen therapy and then annually; blood pressure, Pap smear annually

Administration I.V. infusion: Dilute 0.5-1 g in 250-500 mL D₅W or NS; give 1-2 mL/minute for 10-15 minutes, then infuse remaining solution over 1 hour

Contraindications Undiagnosed vaginal bleeding; breast cancer except in select patients with metastatic disease; pregnancy

Warnings Use with caution in patients with a history of thromboembolism, stroke, myocardial infarction (especially >40 years of age who smoke), liver tumor, hypertension, cardiac, renal, or hepatic insufficiency; estro-

DIETHYLTOLUAMIDE

gens have been reported to increase the risk of endometrial carcinoma; do not use estrogens during pregnancy

Dosage Forms Injection, as diphosphate sodium (Stilphostrol®): 0.25 g (5 mL)

Tablet (Honvol®): 0.1 mg, 0.5 mg, 1 mg

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage within 1 hour; activated charcoal

Enhancement of elimination: Due to enterohepatic recirculation of drug, multiple dosing of activated charcoal may be effective

Test Interactions ↓ antithrombin III; ↓ serum folate concentration; ↑ prothrombin and factors VII, VIII, IX, X; ↑ platelet aggregability; ↑ thyroid binding globulin; ↑ total thyroid hormone (T₄); ↑ serum triglycerides/phospholipids; ↑ prolactin

Drug Interactions Decreased effect of oral anticoagulants

Increased effect of corticosteroids, succinylcholine, TCAs

Decreased DES levels: Barbiturates, phenytoin, rifampin

Pregnancy Risk Factor X

Nursing Implications Note potency difference between DES base and DES diphosphate

Additional Information Neoplasms associated with diethylstilbestrol use include renal, hepatic, angiosarcoma, breast, and clear-cell adenocarcinoma of the genital tract in women exposed to diethylstilbestrol *in utero*. The benefits of postmenopausal estrogen therapy may be substantial for some women. Diethylstilbestrol is not the drug of choice for vasomotor symptoms, to prevent bone loss, or to treat vaginal atrophy or urinary incontinence secondary to estrogen deficiency. Diethylstilbestrol does have a role in the treatment of inoperable, progressive prostatic carcinoma and inoperable, progressive breast cancer in select men and women. Risk of developing vaginal or cervical adenocarcinoma is 3 times greater with *in utero* exposure during first trimester as compared with fetal exposure after 13 weeks. *In utero* exposure to diethylstilbestrol does not appear to affect fertility or sexual function in males.

Diethyltoluamide

CAS Number 134-62-3

U.S. Brand Names OFF®

Synonyms 3-Methyl-N,N-Diethylbenzamide; Benzamide; DEET; Diethylamide; M-delphene; M-det; M-deta; M-Toluamide; M-Toluic Acid Diethylamide; Metadelphene; MGK Diethyltoluamide; N,N-Diethyl-3-Methyl-Diethyl-M-Toluamide; N,N-Diethyl-M-Toluamide; N,N-Diethyl-M-Toluic Acid

Commonly Found In Some formulations use as vehicles ethyl and isopropyl alcohols and freon, which may contribute significantly to toxicity

Use Insect repellent against mosquitoes, ticks, fleas, leeches, blackflies; used since 1957

Adverse Reactions

Cardiovascular: Hypotension, bradycardia, Reye's syndrome, sinus bradycardia

Central nervous system: Psychosis, seizures, coma, drowsiness, headache, mania, slurred speech, ataxia

Dermatologic: Urticaria, skin necrosis, bullous eruption

Gastrointestinal: Nausea, vomiting

Hepatic: Hepatic necrosis, steatosis

Neuromuscular & skeletal: Tremors, myoclonus, athetosis, hypertonicity

Miscellaneous: Anaphylactic shock

Signs and Symptoms of Overdose Coma and seizures may occur rapidly within 30-60 minutes after ingestion.

Abdominal pain, acute psychosis, anaphylactic shock, ataxia, bradycardia, bullous eruption/skin necrosis, burning sensation (eyes, lips, tongue, mouth), cerebral edema, clonic jerking, coma, confusion, contact rash, hypertonicity, hypotension, nausea, renal damage, seizures, skin irritation, toxic hepatitis, urticaria, vomiting

Toxicodynamics/Kinetics

Onset of action: Oral: Rapid

Absorption: Oral: Rapid. Topical: Within 6 hours

Distribution: Skin and fatty tissues retain DEET and its metabolites for 1-2 months after topical application and may act as reservoirs for DEET

Metabolism: Occurs in the liver by oxidative enzymes

Peak plasma concentration: 1 hour

Monitoring Parameters Monitor for renal and hepatic dysfunction with chronic oral and dermal exposures; consider CT and LP to rule out other causes for neurologic effects; sterile CSF pleocytosis, usually with lymphocytic predominance, has been associated with DEET

Significant and severe toxicity has occurred following both dermal and oral exposures to large amounts of DEET

Reference Range DEET serum level 8 hours after dermal application: 0.3 mg/dL (0.016 mM/L) in asymptomatic patient; serum concentration of DEET of 63 mg/L associated with hypotension, lethargy, and ECG changes (S-T abnormalities); serum DEET level of 168 mg/L to 239 mg/L associated with fatality

Overdosage/Treatment

Decontamination: **Oral:** Syrup of ipecac/emesis is contraindicated following oral ingestions due to rapid onset of coma and seizures; cautious gastric lavage (within 1 hour) followed by activated charcoal. **Dermal:** Topical corticosteroid or oral antihistamines can be used for dermal reaction.

Supportive therapy: Diazepam or lorazepam for seizures; phenobarbital for recurrent seizures. For dermal exposures, wash twice with copious amounts of soap and water, preferably using alcohol-detergent solutions such as "green soap". If irritation or pain persists after washing, consult physician to examine affected area. For eye exposure, irrigate with copious amounts of tepid water for at least 15 minutes. Patients should seek medical advice if irritation, pain, swelling, lacrimation, or photophobia persists.

Enhancement of elimination: Lipid based hemodialysis may be helpful, although there is no data on this modality.

Additional Information Severe toxicity occurred in a child 1 year of age following oral ingestion of 25 mL of 50% DEET. Severe toxicity and death occurred following oral ingestion of 50 mL of 100% DEET in adolescents or adults. Extensive daily dermal applications of 10% to 15% solutions for 2 days to 3 months have resulted in encephalopathy in children.

Diflunisal

Pronunciation (dye FLOO ni sal)

Related Information

● Nonsteroidal Anti-inflammatory Drugs

CAS Number 22494-42-4

U.S. Brand Names Dolobid®

Use Management of inflammatory disorders usually including rheumatoid arthritis and osteoarthritis; can be used as an analgesic for treatment of mild to moderate pain. Difluorophenyl derivative of salicylic acid.

Mechanism of Action Inhibits prostaglandin synthesis by decreasing the activity of the enzyme, cyclooxygenase, which results in decreased formation of prostaglandin precursors

Adverse Reactions

Cardiovascular: Tachycardia, palpitations, sinus tachycardia, vasculitis

Central nervous system: Dizziness, somnolence, insomnia, **headache**

Dermatologic: Rash, pruritus, Stevens-Johnson syndrome, toxic epidermal necrolysis, exfoliative dermatitis, alopecia, angioedema, bullous skin disease, urticaria, purpura, onycholysis, licheniform eruptions, exanthem

Endocrine & metabolic: **Fluid retention**

Gastrointestinal: Nausea, dyspepsia, GI pain, diarrhea, vomiting, constipation, flatulence, GI bleeding/perforation, aphthous stomatitis, xerostomia

Genitourinary: Dysuria

Hepatic: Intrahepatic cholestasis

Neuromuscular & skeletal: Paresthesia

Otic: Tinnitus (rare)

Renal: Interstitial nephritis, hematuria, albuminuria

Respiratory: Tachypnea, eosinophilic pneumonitis, pulmonary vasculitis

Miscellaneous: Hypersensitivity reactions, diaphoresis, fixed drug eruption

Signs and Symptoms of Overdose Chills, cholestatic jaundice, coagulopathy, coma, confusion, depression, dermatitis, drowsiness, eosinophilia, erythema multiforme, fever, gastritis, GI bleeding, hematuria, hyperthermia, hyperventilation, insomnia, lightheadedness, malaise, myalgia, nausea, nephritis, nephrotic syndrome, neutropenia, ototoxicity, photosensitivity, stomatitis, stupor, tachycardia, thrombocytopenia, tinnitus, toxic epidermal necrolysis, vomiting, wheezing

Pharmacodynamics/Kinetics

Onset of action: Analgesic: ~1 hour; maximal effect: 2-3 hours

Duration: 8-12 hours

Absorption: Well absorbed

Protein binding: >99%

Distribution: Enters breast milk

Metabolism: Extensively hepatic; metabolic pathways are saturable

Half-life elimination: 8-12 hours; prolonged with renal impairment

Time to peak, serum: 2-3 hours

Excretion: Urine (~3% as unchanged drug, 90% as glucuronide conjugates) within 72-96 hours

Dosage

Adults: Oral:

Pain: Initial: 500-1000 mg followed by 250-500 mg every 8-12 hours; maximum daily dose: 1.5 g

Inflammatory condition: 500-1000 mg/day in 2 divided doses; maximum daily dose: 1.5 g

Dosing adjustment in renal impairment: $Cl_{cr} < 50$ mL/minute: Administer 50% of normal dose

Administration

Tablet should be swallowed whole; do not crush or chew.

Contraindications Hypersensitivity to diflunisal, aspirin, other NSAIDs, or any component of the formulation; perioperative pain in the setting of coronary artery bypass surgery (CABG); pregnancy (3rd trimester)

Warnings [U.S. Boxed Warning]: NSAIDs are associated with an increased risk of adverse cardiovascular events, including MI, stroke, and new onset or worsening of pre-existing hypertension.

Risk may be increased with duration of use or pre-existing cardiovascular risk-factors or disease. Carefully evaluate individual cardiovascular risk profiles prior to prescribing. Use caution with fluid retention, CHF, or hypertension.

[U.S. Boxed Warning]: NSAIDs may increase risk of gastrointestinal irritation, ulceration, bleeding, and perforation. These events may occur at any time during therapy and without warning. Use caution with a history of GI disease (bleeding or ulcers), concurrent therapy with aspirin, anticoagulants and/or corticosteroids, smoking, use of alcohol, the elderly or debilitated patients.

Use of NSAIDs can compromise existing renal function. Renal toxicity can occur in patient with impaired renal function, dehydration, heart failure, liver dysfunction, those taking diuretics and ACEI and the elderly. Rehydrate patient before starting therapy. Monitor renal function closely. Diflunisal is not recommended for patients with advanced renal disease.

Use the lowest effective dose for the shortest duration of time, consistent with individual patient goals, to reduce risk of cardiovascular or GI adverse events. Alternate therapies should be considered for patients at high risk.

NSAIDs may cause serious skin adverse events including exfoliative dermatitis, Stevens-Johnson syndrome (SJS), and toxic epidermal necrolysis (TEN). Anaphylactoid reactions may occur, even without prior exposure; patients with "aspirin triad" (bronchial asthma, aspirin intolerance, rhinitis) may be at increased risk. Do not use in patients who experience bronchospasm, asthma, rhinitis, or urticaria with NSAID or aspirin therapy.

A hypersensitivity syndrome has been reported; monitor for constitutional symptoms and cutaneous findings; other organ dysfunction may be involved.

Use with caution in patients with decreased hepatic function. Closely monitor patients with any abnormal LFT. Severe hepatic reactions (eg, fulminant hepatitis, liver failure) have occurred with NSAID use, rarely; discontinue if signs or symptoms of liver disease develop, or if systemic manifestations occur.

Diflunisal is a derivative of acetylsalicylic acid and therefore may be associated with Reye's syndrome. Withhold for at least 4-6 half-lives prior to surgical or dental procedures. Safety and efficacy have not been established in children <12 years of age.

Dosage Forms

[DSC] = Discontinued product

Tablet: 500 mg

Dolobid®: 250 mg, 500 mg [DSC]

Overdosage/Treatment

Decontamination: Lavage/activated charcoal

Supportive therapy: Management of a nonsteroidal anti-inflammatory agent (NSAID) intoxication is primarily supportive and symptomatic. Fluid therapy is commonly effective in managing the hypotension that may occur following an acute NSAID overdose, except when this is due to an acute blood loss.

Enhancement of elimination: NSAID: Forced diuresis/hemodialysis are of no benefit

Test Interactions ↑ prothrombin time; ↓ uric acid (S); may cross-react with some salicylate assays

Drug Interactions

ACE inhibitors: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Aminoglycosides: NSAIDs may decrease the excretion of aminoglycosides.

Angiotensin II antagonists: Antihypertensive effects may be decreased by concurrent therapy with NSAIDs; monitor blood pressure.

Anticoagulants (warfarin, heparin, LMWHs) in combination with NSAIDs can cause increased risk of bleeding.

Antiplatelet agents (ticlopidine, clopidogrel, aspirin, abciximab, dipyridamole, eptifibatide, tirofiban) can cause an increased risk of bleeding.

Beta-blockers: NSAIDs may diminish the antihypertensive effects of beta blockers.

Bisphosphonates: NSAIDs may increase the risk of gastrointestinal ulceration.

Cholestyramine (and other bile acid sequestrants): May decrease the absorption of NSAIDs. Separate by at least 2 hours.

Corticosteroids may increase the risk of GI ulceration; avoid concurrent use.

Cyclosporine: NSAIDs may increase serum creatinine, potassium, blood pressure, and cyclosporine levels; monitor cyclosporine levels and renal function carefully.

Hydralazine's antihypertensive effect is decreased; avoid concurrent use. Lithium levels can be increased; avoid concurrent use if possible or monitor lithium levels and adjust dose.

Sulindac may have the least effect. When NSAID is stopped, lithium will need adjustment again.

Loop diuretics efficacy (diuretic and antihypertensive effect) is reduced. Indomethacin reduces this efficacy, however, it may be anticipated with any NSAID.

Methotrexate: Severe bone marrow suppression, aplastic anemia, and GI toxicity have been reported with concomitant NSAID therapy. Avoid use during moderate or high-dose methotrexate (increased and prolonged methotrexate levels). NSAID use during low-dose treatment of rheumatoid arthritis has not been fully evaluated; extreme caution is warranted.

Pemetrexed: NSAIDs may decrease the excretion of pemetrexed. Patients with Cl_{cr} 45-79 mL/minute should avoid long acting NSAIDs for 5 days before and 2 days after pemetrexed treatment.

Thiazides antihypertensive effects are decreased; avoid concurrent use.

Treprostinil: May enhance the risk of bleeding with concurrent use.

Vancomycin: NSAID's may decrease the excretion of vancomycin.

Pregnancy Risk Factor C (1st and 2nd trimesters); D (3rd trimester)

Pregnancy Implications C (first and second trimester); D (third trimester)

Lactation Enters breast milk/not recommended

Additional Information Fewer GI and antiplatelet effects as opposed to salicylate

Specific References

Proudfoot AT, Krenzelok EP, Vale JA, et al, "AACT/EAPCCT Position Paper on Urine Alkalinization," *J Toxicol Clin Toxicol*, 2004, 42(1):1-26.

Digitoxin**Related Information**

• Ouabain

CAS Number 71-63-6

Synonyms Crystodigin

Use Congestive heart failure, fibrillation (atrial), flutter (atrial), paroxysmal atrial tachycardia, and cardiogenic shock

Mechanism of Action Indirect effect through vagal stimulation. Most clinically important actions of digitalis on the S-A and AV nodes are mediated through the autonomic nervous system. Digitalis increases efferent vagal impulses, reflexly reduces sympathetic tone, and decreases the sinus rate. In a normal heart, the augmented vagal activity decreases the rate of generation of impulses in the S-A node. A decrease in sinus rate may not occur, but the maximum heart rate achieved during exercise is diminished. When the sinus rate is increased due to heart failure, digitalis has prominent negative chronotropic effects.

Adverse Reactions

Cardiovascular: Sinus bradycardia, AV block, S-A block, ectopic beats (atrial or nodal), arrhythmias (ventricular), bigeminy, trigeminy, tachycardia (atrial) with AV block, superior mesenteric artery thrombosis, QRS prolongation, sinus tachycardia, tachycardia (supraventricular), bidirectional ventricular tachycardia

Central nervous system: Drowsiness, fatigue, drowsiness, disorientation, dizziness, visual hallucinations, headache, psychosis

Dermatologic: Stevens-Johnson syndrome, exanthem

Endocrine & metabolic: Hyperkalemia with acute toxicity

Gastrointestinal: Vomiting, nausea, feeding intolerance, anorexia, abdominal pain, diarrhea, feces discoloration (black), colonic ischemia

Hematologic: Thrombocytopenia

Neuromuscular & skeletal: Neuralgia

Ocular: Blurred vision, halos, yellow or green vision, diplopia, photophobia, flashing lights, decreased visual acuity

Signs and Symptoms of Overdose Arrhythmias, asystole, AV block, bowel ischemia, delirium, depression, fibrillation (ventricular), gynecomastia, hyperkalemia, hypotension, neuropathy (peripheral), ototoxicity, photophobia, tachycardia (ventricular), tachycardia (ventricular, bidirectional), tinnitus, tremor, vision color changes (blue tinge; green tinge; orange tinge; red tinge; yellow tinge)

Pharmacodynamics/Kinetics

Absorption: 90% to 100%

Distribution: V_d : 7 L/kg

Protein binding: 90% to 97%

Metabolism: Hepatic (50% to 70%)

Half-life elimination: 7-8 days

Time to peak: 8-12 hours

Excretion: Urine and feces (30% to 50% as unchanged drug)

Dosage Oral:

Children: Doses are very individualized; **when recommended**, digitalizing dose is as follows:

- <1 year: 0.045 mg/kg
 - 1-2 years: 0.04 mg/kg
 - >2 years: 0.03 mg/kg which is equivalent to 0.75 mg/m²
- Maintenance: Approximately 1/10 of the digitalizing dose

Adults:

- Rapid loading dose: Initial: 0.6 mg followed by 0.4 mg and then 0.2 mg at intervals of 4-6 hours
- Slow loading dose: 0.2 mg twice daily for a period of 4 days followed by a maintenance dose
- Maintenance: 0.05-0.3 mg/day
- Most common dose: 0.15 mg/day

Dosing adjustment in renal impairment: $Cl_{Cr} < 10$ mL/minute: Administer 50% to 75% of normal dose.

Hemodialysis: Not dialyzable (0% to 5%)

Dosing adjustment in hepatic impairment: Dosage reduction is necessary in severe liver disease.

Stability Insoluble in water

Monitoring Parameters Monitor blood pressure and ECG closely

Contraindications Hypersensitivity to digitoxin or any component (rare); digitalis toxicity; beriberi heart disease; AV block; idiopathic hypertrophic subaortic stenosis; constrictive pericarditis; ventricular fibrillation; ventricular tachycardia

Warnings Use with caution in patients with hypoxia, hypothyroidism, or acute myocarditis. Do not use to treat obesity. Patients with incomplete AV block (Stokes-Adams attack) may progress to complete block with digitalis drug administration. Use with caution in patients with acute myocardial infarction, severe pulmonary disease, idiopathic hypertrophic subaortic stenosis, Wolff-Parkinson-White syndrome, sick sinus syndrome (bradyarrhythmias), amyloid heart disease, and constrictive cardiomyopathies. Adjust dose with renal or hepatic impairment and aged patients. Elderly may develop exaggerated serum/tissue concentrations due to decreased lean body mass, total body water, and age-related reduction in renal/hepatic function. Exercise will reduce serum concentrations of digoxin due to increased skeletal muscle uptake.

Dosage Forms Tablet: 0.1 mg, 0.2 mg

Reference Range

- Therapeutic: 18-22 ng/mL (23-28 nmol/L)
- Toxic: >25 ng/mL (>32 nmol/L)

Overdosage/Treatment

- Decontamination: Lavage (within 1 hour)/activated charcoal
- Supportive therapy: Antidote: Life-threatening digoxin toxicity is treated with Digibind®; ventricular pacing should be reserved for those patients not responding to Digibind®; torsade de pointes can be treated with magnesium sulfate and overdrive pacing (try to avoid isoproterenol)
- Enhancement of elimination: Since enterohepatic recirculation accounts for a low percentage of digitoxin metabolism (6.6%/day), cholestyramine or multiple dosing of activated charcoal would have virtually no effect on decreasing half-life; not dialyzable (0% to 5%); although hemodialysis is not useful, charcoal hemoperfusion (clearance ~30 mL/minute) can increase total body clearance of the drug 8-20 times (14% of drug removed during 4 hours)

Antidote(s)

- Cholestyramine Resin [ANTIDOTE]
- Digoxin Immune Fab [ANTIDOTE]

Diagnostic Procedures

- Digitoxin, Blood

Test Interactions Digibind® increases serum digitoxin level tenfold; digitoxin may interfere with a urinary 17-hydroxycorticosteroid assay; digoxin-like immunoreactive substance (DLIS), an endogenous natriuretic substance, may cause false elevation

Drug Interactions **Substrate** of CYP3A4 (major)

- Amiloride may reduce the inotropic response to digitoxin.
- Amiodarone reduces renal and nonrenal clearance of digitoxin and may have additive effects on heart rate.
- Beta-blocking agents (propranolol) may have additive effects on heart rate.
- Calcium preparations: Rare cases of acute digitalis glycoside toxicity have been associated with parental calcium (bolus) administration.
- Cholestyramine, colestipol, kaolin-pectin may reduce digitoxin absorption.
- CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of digitoxin. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.
- CYP3A4 inhibitors: May increase the levels/effects of digitoxin. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.
- Levothyroxine (and other thyroid supplements) may decrease digitoxin blood levels.
- Moricizine may increase the toxicity of digitalis glycosides (mechanism undefined).
- Propafenone increases digoxin blood levels. Effects may also occur with digitoxin. Monitor closely.

Propylthiouracil and methimazole may increase digitoxin blood levels by reducing thyroid hormone.

Quinidine increases digitoxin blood levels substantially; monitor blood levels/effect closely. Other related agents (hydroxychloroquine, quinine) should be used with caution.

Verapamil, diltiazem, bepridil, and nitrendipine increase digoxin concentrations, and may have similar effect on digitoxin. Other calcium channel blocking agents do not appear to share this effect.

Drugs which cause hypokalemia (thiazide and loop diuretics, amphotericin B): Hypokalemia may potentiate toxicity of digitalis glycosides.

These medications have been associated with reduced blood levels of digitalis glycosides which appear to be of limited clinical significance: Aminoglutethimide, antacids (magnesium- and aluminum-containing), sucralfate, sulfasalazine, ticlopidine.

These medications have been associated with increased digitalis glycoside blood levels which appear to be of limited clinical significance: Famciclovir, flecainide, ibuprofen, itraconazole, cimetidine, famotidine, fluoxetine, nefazodone, omeprazole, ranitidine, trimethoprim.

Pregnancy Risk Factor C

Nursing Implications Check apical pulse before administering

Additional Information Not available in U.S.

Digoxin

Related Information

- Ouabain
- Therapeutic Drugs Associated with Hallucinations

CAS Number 20830-75-5

U.S. Brand Names Digitek®, Lanoxicaps®, Lanoxin®

Use Treatment of congestive heart failure; slows the ventricular rate in tachyarrhythmias such as fibrillation (atrial), flutter (atrial), tachycardia (ventricular), paroxysmal atrial tachycardia, cardiogenic shock

Mechanism of Action Increases the influx of calcium ions, from extracellular to intracellular cytoplasm by inhibition of sodium and potassium ion movement across the myocardial membranes; this increase in calcium ions results in a potentiation of the activity of the contractile heart muscle fibers and an increase in the force of myocardial contraction (positive inotropic effect); inhibits adenosine triphosphatase (ATPase); decreases conduction through the S-A and AV nodes

Adverse Reactions

- Cardiovascular: Sinus bradycardia, AV block, S-A block, ectopic beats (atrial or nodal), tachycardia (ventricular), arrhythmias (ventricular), bigeminy, trigeminy, tachycardia (atrial) with AV block, superior mesenteric artery thrombosis, QRS prolongation, sinus tachycardia, tachycardia (supraventricular), vasculitis, tachycardia (ventricular, bidirectional)
- Central nervous system: Drowsiness, fatigue, disorientation, dizziness, auditory and visual hallucinations, paranoia, headache, psychosis, cerebral arteritis, extrapyramidal reaction
- Dermatologic: Stevens-Johnson syndrome, bullous skin disease, urticaria, purpura, pruritus, psoriasis, exanthem
- Endocrine & metabolic: Toxicity is enhanced by hypokalemia
- Gastrointestinal: Vomiting, nausea, feeding intolerance, anorexia, abdominal pain, diarrhea, fecal discoloration (black), colonic ischemia, esophagitis

Hematologic: Thrombocytopenia

Neuromuscular & skeletal: Neuralgia, chorea (extrapyramidal)

Ocular: Blurred vision, halos, yellow or green vision, diplopia, photophobia, flashing lights, decreased visual acuity, color vision abnormalities

Signs and Symptoms of Overdose AV block, arrhythmias, bowel ischemia, delirium, dementia, depression, dysphagia, fibrillation (ventricular) or asystole, gynecomastia, heart block, hyperkalemia, hypokalemia, hypotension, impotence, neuropathy (peripheral), night terrors, ototoxicity, photophobia, seizures, tachycardia (ventricular, bidirectional), tinnitus, tremors, vision color changes (blue tinge; green tinge; orange tinge; red tinge)

Pharmacodynamics/Kinetics

Onset of action: Oral: 1-2 hours; I.V.: 5-30 minutes

Peak effect: Oral: 2-8 hours; I.V.: 1-4 hours

Duration: Adults: 3-4 days both forms

Absorption: By passive nonsaturable diffusion in the upper small intestine; food may delay, but does not affect extent of absorption

Distribution:

Normal renal function: 6-7 L/kg

V_d: Extensive to peripheral tissues, with a distinct distribution phase which lasts 6-8 hours; concentrates in heart, liver, kidney, skeletal muscle, and intestines. Heart/serum concentration is 70:1. Pharmacologic effects are delayed and do not correlate well with serum concentrations during distribution phase.

Hyperthyroidism: Increased V_d

Hyperkalemia, hyponatremia: Decreased digoxin distribution to heart and muscle

Hypokalemia: Increased digoxin distribution to heart and muscles

Concomitant quinidine therapy: Decreased V_d

Chronic renal failure: 4-6 L/kg

Decreased sodium/potassium ATPase activity - decreased tissue binding

Neonates, full-term: 7.5-10 L/kg

Children: 16 L/kg

Adults: 7 L/kg, decreased with renal disease

Protein binding: 30%; in uremic patients, digoxin is displaced from plasma protein binding sites

Metabolism: Via sequential sugar hydrolysis in the stomach or by reduction of lactone ring by intestinal bacteria (in ~10% of population, gut bacteria may metabolize up to 40% of digoxin dose); metabolites may contribute to therapeutic and toxic effects of digoxin; metabolism is reduced with CHF

Bioavailability: Oral (formulation dependent): Elixir: 75% to 85%; Tablet: 70% to 80%

Half-life elimination (age, renal and cardiac function dependent):

Neonates: Premature: 61-170 hours; Full-term: 35-45 hours

Infants: 18-25 hours

Children: 35 hours

Adults: 38-48 hours

Adults, anephric: 4-6 days

Half-life elimination: Parent drug: 38 hours; Metabolites: Digoxigenin: 4 hours; Monodigitoxoside: 3-12 hours

Time to peak, serum: Oral: ~1 hour

Excretion: Urine (50% to 70% as unchanged drug)

Toxicodynamics/Kinetics

Onset of action: Oral: 1-2 hours; I.V.: 5-30 minutes;

Peak effect: Oral: 2-8 hours; I.V.: 1-4 hours

Duration: Adults: 3-4 days

Distribution: Minimal to body fat; high concentrations in myocardium, skeletal muscle, and kidney; crosses blood-brain barrier

V_d : Neonates, premature: 4.5 L/kg; Neonates, full-term: 7.5-10 L/kg;

Children: 16 L/kg; Adults: 7 L/kg; decreased V_d with renal disease

Protein binding: 23%

Metabolism: Small amount in the liver and gut by bacteria

Bioavailability: Dependent upon formulation, elixir: 70% to 85%, tablets: 60% to 80%, capsules: 90% to 100%

Half-life: Dependent upon age, renal and cardiac function: Premature: 61-170 hours; Neonates, full-term: 35-45 hours; Infants: 18-25 hours;

Children: 35 hours; Adults: 38-48 hours;

Anephric: >4.5 days

Elimination: 50% to 70% excreted unchanged in urine; ~7% of the drug is normally excreted in 4 hours in a healthy person

Dosage When changing from oral (tablets or liquid) or I.M. to I.V. therapy, dosage should be reduced by 20% to 25%. See table.

Dosage Recommendations for Digoxin*

Age	Total Digitalizing Dose† (mcg/kg)		Daily Maintenance Dose‡ (mcg/kg)	
	P.O.	I.V. or I.M.	P.O.	I.V. or I.M.
Preterm infant	20-30	15-25	5-7.5	4-6
Full term infant	25-35	20-30	6-10	5-8
1 mo-2 y	35-60	30-50	10-15	7.5-12
2-5 y	30-40	25-35	7.5-10	6-9
5-10 y	20-35	15-30	5-10	4-8
>10 y	10-15	8-12	2.5-5	2-3
Adult	0.75-1.5 mg	0.5-1 mg	0.125-0.5 mg	0.1-0.4 mg

*Based on lean body weight and normal renal function for age. Decrease dose in patients with decreased renal function.

†Give one-half of the total digitalizing dose (TDD) in the initial dose, then give one-quarter of the TDD in each of two subsequent doses at 8- to 12-hour intervals. Obtain EKG 6 hours after each dose to assess potential toxicity.

‡Divided every 12 hours in infants and children <10 years of age. Given once daily to children >10 years and adults.

Dosing adjustment/interval in renal impairment:

Cl_{cr} 10-50 mL/minute: Administer 25% to 75% of dose or every 36 hours

Cl_{cr} <10 mL/minute: Administer 10% to 25% of dose or every 48 hours

Reduce loading dose by 50% in ESRD

Stability Protect elixir and injection from light; solution compatibility: D_5W , $D_{10}W$, NS, sterile water for injection (when diluted fourfold or greater)

Monitoring Parameters When to draw serum digoxin concentrations: Digoxin serum concentrations are monitored because digoxin possesses a narrow therapeutic serum range; the therapeutic endpoint is difficult to quantify and digoxin toxicity may be life-threatening. Digoxin serum levels should be drawn at **least 4 hours after an intravenous dose and at least 6 hours after an oral dose (optimally 12-24 hours after a dose)**. Initiation of therapy:

If a loading dose is given: Digoxin serum concentration may be drawn within 12-24 hours after the initial loading dose administration. Levels drawn this early may confirm the relationship of digoxin plasma levels and response but are of little value in determining maintenance doses.

If a loading dose is not given: Digoxin serum concentration should be obtained after 3-5 days of therapy

Maintenance therapy:

Trough concentrations should be followed just prior to the next dose or at a minimum of 4 hours after an I.V. dose and at least 6 hours after an oral dose

Digoxin serum concentrations should be obtained within 5-7 days (approximate time to steady-state) after any dosage changes. Continue to obtain digoxin serum concentrations 7-14 days after any change in maintenance dose. **Note:** In patients with end-stage renal disease, it may take 15-20 days to reach steady-state.

Additionally, patients who are receiving potassium-depleting medications such as diuretics, should be monitored for potassium, magnesium, and calcium levels

Digoxin serum concentrations should be obtained whenever any of the following conditions occur:

Questionable patient compliance or to evaluate clinical deterioration following an initial good response

Changing renal function

Suspected digoxin toxicity

Initiation or discontinuation of therapy with drugs (amiodarone, quinidine, verapamil) which potentially interact with digoxin; if quinidine therapy is started; digoxin levels should be drawn within the first 24 hours after starting quinidine therapy, then 7-14 days later or empirically skip one day's digoxin dose and decrease the daily dose by 50%

Any disease changes (hypothyroidism)

Heart rate and rhythm should be monitored along with periodic ECGs to assess both desired effects and signs of toxicity

Follow closely (especially in patients receiving diuretics or amphotericin) for decreased serum potassium and magnesium or increased calcium, all of which predispose to digoxin toxicity

Assess renal function

Be aware of drug interactions

Administration

I.M.: Inject no more than 2 mL per injection site. May cause intense pain.

I.V.: May be administered undiluted or diluted fourfold in D_5W , NS, or SWFI for direct injection. Less than fourfold dilution may permit drug precipitation. Inject slowly 1-5 minutes for undiluted form.

Contraindications Hypersensitivity to digoxin or any component of the formulation; hypersensitivity to cardiac glycosides (another may be tried); history of toxicity; ventricular tachycardia or fibrillation; idiopathic hypertrophic subaortic stenosis; constrictive pericarditis; amyloid disease; second- or third-degree heart block (except in patients with a functioning artificial pacemaker); Wolff-Parkinson-White syndrome and atrial fibrillation concurrently

Warnings Withdrawal in CHF patients may lead to recurrence of CHF symptoms. Some arrhythmias that digoxin is used to treat may be exacerbated in digoxin toxicity. Sinus nodal disease may be worsened. Adjust doses in renal impairment and when verapamil, quinidine or amiodarone are added to a patient on digoxin. Correct hypokalemia and hypomagnesemia before initiating therapy. Calcium, especially when administered rapidly I.V., can produce serious arrhythmias. Atrial arrhythmias associated with hypermetabolic states are very difficult to treat. Rate control in atrial fibrillation may be better in a sedentary patient than an active one. Use with caution in acute MI (within 6 months). Serum concentration monitoring should be done before the next dose (patient can hold AM dose for blood test) for an accurate assessment. Reduce or hold dose 1-2 days before elective electrical cardioversion.

Dosage Forms

Capsule:

Lanoxicaps®: 100 mcg, 200 mcg [contains ethyl alcohol]

Injection, solution: 250 mcg/mL (1 mL, 2 mL)

Lanoxin®: 250 mcg/mL (2 mL) [contains alcohol 10% and propylene glycol 40%]

Injection, solution [pediatric]: 100 mcg/mL (1 mL)

Solution, oral: 50 mcg/mL (2.5 mL, 5 mL, 60 mL)

Tablet: 125 mcg, 250 mcg

Digitek®, Lanoxin®: 125 mcg, 250 mcg

Reference Range

Therapeutic: 0.5-2.0 ng/mL (SI: 0.6-2.6 nmol/L); Adults: <0.5 ng/mL (SI: <0.6 nmol/L) probably indicates underdigitalization unless there are special circumstances

Toxic: >2.0 ng/mL (SI: >2.6 nmol/L); fatalities associated with levels >3.5 ng/mL (>4.8 nmol/L)

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; whole bowel irrigation may be useful

Supportive therapy: Antidote: Life-threatening digoxin toxicity is treated with Digibind®; phenytoin, magnesium, and lidocaine are useful for cardiac arrhythmias; atropine is useful for bradycardia; avoid quinidine, bretylium, or cardioversion; ventricular pacing should be reserved for patients not responding to Digibind®; delirium can also respond to Digibind®; torsade de pointes can be treated with magnesium sulfate and overdrive pacing (try to avoid isoproterenol)

Enhancement of elimination: Multiple dosing of activated charcoal may be useful but is usually not required if Digibind® is used; exchange transfusion is of no benefit; hemodialysis/hemoperfusion is ineffective; not dialyzable (0% to 5%); multiple doses of cholestyramine (4 g every 4 hours for four doses) can help enhance elimination

Antidote(s)

- Cholestyramine Resin [ANTIDOTE]
- Digoxin Immune Fab [ANTIDOTE]

Diagnostic Procedures

- Digoxin, Blood

Test Interactions Digibind® increases total serum digoxin level ~50-fold; digoxin-like immunoreactive substance (DLIS), an endogenous natriuretic substance, may cause false elevation

Drug Interactions Substrate of CYP3A4 (minor)

Amiloride may reduce the inotropic response to digoxin.

Amiodarone reduces renal and nonrenal clearance of digoxin and may have additive effects on heart rate. Reduce digoxin dose by 50% with start of amiodarone.

Benzodiazepines (alprazolam, diazepam) have been associated with isolated reports of digoxin toxicity.

Beta-blocking agents (propranolol) may have additive effects on heart rate.

Calcium preparations: Rare cases of acute digoxin toxicity have been associated with parenteral calcium (bolus) administration.

Carvedilol may increase digoxin blood levels in addition to potentiating its effects on heart rate.

Cholestyramine, colestipol, kaolin-pectin may reduce digoxin absorption. Separate administration.

Cyclosporine may increase digoxin levels, possibly due to reduced renal clearance.

Erythromycin, clarithromycin, and tetracyclines may increase digoxin (not capsule form) blood levels in a subset of patients.

Indomethacin has been associated with isolated reports of increased digoxin blood levels/toxicity.

Itraconazole may increase digoxin blood levels in some patients; monitor.

Levothyroxine (and other thyroid supplements) may decrease digoxin blood levels.

Metoclopramide may reduce the absorption of digoxin tablets.

Moricizine may increase the toxicity of digoxin (mechanism undefined).

Penicillamine has been associated with reductions in digoxin blood levels

Propafenone increases digoxin blood levels. Effects are highly variable; monitor closely.

Propylthiouracil (and methimazole) may increase digoxin blood levels by reducing thyroid hormone.

Quinidine increases digoxin blood levels substantially. Effect is variable (33% to 50%). Monitor digoxin blood levels/effect closely. Reduce digoxin dose by 50% with start of quinidine. Other related agents (hydroxychloroquine, quinine) should be used with caution.

Spirolactone may interfere with some digoxin assays, but may also increase blood levels directly. However, spiro lactone may attenuate the inotropic effect of digoxin. Monitor effects of digoxin closely.

Succinylcholine administration to patients on digoxin has been associated with an increased risk of arrhythmias.

Verapamil diltiazem, bepridil, and nitrendipine increased serum digoxin concentrations. Other calcium channel blocking agents do not appear to share this effect. Reduce digoxin's dose with the start of verapamil.

Drugs which cause hypokalemia (thiazide and loop diuretics, amphotericin B): Hypokalemia may potentiate digoxin toxicity.

These medications have been associated with reduced digoxin blood levels which appear to be of limited clinical significance: Aminoglutethimide, aminosalicylic acid, aluminum-containing antacids, sucralfate, sulfasalazine, neomycin, ticlopidine.

These medications have been associated with increased digoxin blood levels which appear to be of limited clinical significance: Famciclovir, flecainide, ibuprofen, fluoxetine, nefazodone, cimetidine, famotidine, ranitidine, omeprazole, trimethoprim.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk (small amounts)/compatible

Nursing Implications Check apical pulse before administering

Additional Information Lethal dose: Children: 4 mg; Adults: 10 mg; Toxic dose: Oral: 2 mg

Death rate approaches 50% when serum digoxin levels are >6 ng/mL; digoxin-specific antibodies have reversed thrombocytopenia caused by digoxin;

Mean total hospital cost of digoxin toxicity is \$4,087.05 ± 2,659.76; mean length of stay: 3.3 ± 1.2 days

Diltiazem

Related Information

- Calcium Channel Blockers

CAS Number 33286-22-5; 42399-41-7

U.S. Brand Names Cardizem® CD; Cardizem® LA; Cardizem® SR; Cardizem®; Cartia XT™; Dilacor® XR; Diltia XT®; Taztia XT™; Tiazac®

Synonyms Diltiazem Hydrochloride

Use

Oral: Essential hypertension; chronic stable angina or angina from coronary artery spasm

Injection: Atrial fibrillation or atrial flutter; paroxysmal supraventricular tachycardia (PSVT)

Unlabeled/Investigational Use Investigational: Therapy of Duchenne muscular dystrophy

Mechanism of Action A benzothiazepine calcium channel blocker which inhibits calcium ion from entering the "slow channels" or select voltage-sensitive areas of vascular smooth muscle and myocardium during depolarization, producing a relaxation of coronary vascular smooth muscle and coronary vasodilation; increases myocardial oxygen delivery in patients with vasospastic angina

Adverse Reactions

Cardiovascular: Edema* (2% to 15%), AV block, pain, bradycardia, hypotension, vasodilation, extrasystoles, flushing, palpitations, angina, arrhythmia, bundle branch block, congestive heart failure, ECG abnormalities, ventricular extrasystoles, asystole

Central nervous system: Headache* (5% to 12%), dizziness, nervousness, amnesia, depression, abnormal dreams, hallucinations, insomnia, pain, personality change, extrapyramidal symptoms

Dermatologic: Rash, bruising, petechiae, photosensitivity, pruritus, alopecia, angioedema, erythema multiforme, exfoliative dermatitis, purpura, Stevens-Johnson syndrome, toxic epidermal necrolysis
 Endocrine & metabolic: Gout, gynecomastia, hyperglycemia, hyperuricemia
 Gastrointestinal: Dyspepsia, constipation, vomiting, diarrhea, anorexia, dry mouth, dysgeusia, nausea, weight gain, gingival hyperplasia
 Genitourinary: Crystalluria, impotence, nocturia
 Hematologic: Bleeding time increased, hemolytic anemia, leukopenia, thrombocytopenia
 Hepatic: Alkaline phosphatase increased, LDH increased, SGOT increased, SGPT increased
 Local: Injection site reactions: Burning, itching
 Neuromuscular & skeletal: Weakness, myalgia, CPK elevated, gait abnormality, muscle cramps, neck rigidity, paresthesia, tremor
 Ocular: Amblyopia, retinopathy
 Otic: Tinnitus
 Renal: Albuminuria, polyuria
 Respiratory: Rhinitis, pharyngitis, dyspnea, bronchitis, sinus congestion, epistaxis
 Miscellaneous: Allergic reaction
 *Represents range for various dosage forms

Signs and Symptoms of Overdose Asystole, AV block, bradycardia, congestive heart failure, constipation, erythema multiforme, gingival hyperplasia, gynecomastia, hyperglycemia, hypotension, hypothermia, mania, myopathy, purpura, toxic epidermal necrolysis

Pharmacodynamics/Kinetics

Onset of action: Oral: Immediate release tablet: 30-60 minutes
 Absorption: 70% to 80%
 Distribution: V_d : 3-13 L/kg; enters breast milk
 Protein binding: 70% to 80%
 Metabolism: Hepatic; extensive first-pass effect; following single I.V. injection, plasma concentrations of N-monodesmethyl-diltiazem and desacetyldiltiazem are typically undetectable; however, these metabolites accumulate to detectable concentrations following 24-hour constant rate infusion. N-monodesmethyl-diltiazem appears to have 20% of the potency of diltiazem; desacetyldiltiazem is about 25% to 50% as potent as the parent compound.
 Bioavailability: Oral: ~40%
 Half-life elimination: Immediate release tablet: 3-4.5 hours, may be prolonged with renal impairment
 Time to peak, serum: Immediate release tablet: 2-4 hours
 Excretion: Urine and feces (primarily as metabolites)

Dosage Adults:

Oral:
 Angina:
 Capsule, extended release (Cardizem[®] CD, Cartia XT[™], Dilacor XR[®], Diltia XT[™], Tiazac[®]): Initial: 120-180 mg once daily (maximum dose: 480 mg/day)
 Tablet, extended release (Cardizem[®] LA): 180 mg once daily; may increase at 7- to 14-day intervals (maximum recommended dose: 360 mg/day)
 Tablet, immediate release (Cardizem[®]): Usual starting dose: 30 mg 4 times/day; usual range: 180-360 mg/day

Hypertension:

Capsule, extended release (Cardizem[®] CD, Cartia XT[™], Dilacor XR[®], Diltia XT[™], Tiazac[®]): Initial: 180-240 mg once daily; dose adjustment may be made after 14 days; usual dose range (JNC 7): 180-420 mg/day; Tiazac[®]: usual dose range: 120-540 mg/day
 Capsule, sustained release (Cardizem[®] SR): Initial: 60-120 mg twice daily; dose adjustment may be made after 14 days; usual range: 240-360 mg/day
 Tablet, extended release (Cardizem[®] LA): Initial: 180-240 mg once daily; dose adjustment may be made after 14 days; usual dose range (JNC 7): 120-540 mg/day
Note: Elderly: Patients ≥ 60 years may respond to a lower initial dose (ie, 120 mg once daily using extended release capsule)

I.V.: Atrial fibrillation, atrial flutter, PSVT:

Initial bolus dose: 0.25 mg/kg actual body weight over 2 minutes (average adult dose: 20 mg)
 Repeat bolus dose (may be administered after 15 minutes if the response is inadequate.): 0.35 mg/kg actual body weight over 2 minutes (average adult dose: 25 mg)
 Continuous infusion (requires an infusion pump; infusions > 24 hours or infusion rates > 15 mg/hour are not recommended): Initial infusion rate of 10 mg/hour; rate may be increased in 5 mg/hour increments up to 15 mg/hour as needed; some patients may respond to an initial rate of 5 mg/hour.

If diltiazem injection is administered by continuous infusion for > 24 hours, the possibility of decreased diltiazem clearance, prolonged elimination half-life, and increased diltiazem and/or diltiazem metabolite plasma concentrations should be considered.

Conversion from I.V. diltiazem to oral diltiazem: Start oral approximately 3 hours after bolus dose.

Oral dose (mg/day) is approximately equal to [rate (mg/hour) $\times 3 + 3$] $\times 10$.

3 mg/hour = 120 mg/day
 5 mg/hour = 180 mg/day
 7 mg/hour = 240 mg/day
 11 mg/hour = 360 mg/day

Dosing comments in renal/hepatic impairment: Use with caution as extensively metabolized by the liver and excreted in the kidneys and bile.

Dialysis: Not removed by hemo- or peritoneal dialysis; supplemental dose is not necessary.

Monitoring Parameters Liver function tests, blood pressure, ECG

Administration

Oral: Do not crush long acting dosage forms.

Tiazac[®]: Capsules may be opened and sprinkled on a spoonful of applesauce. Applesauce should be swallowed without chewing, followed by drinking a glass of water.

I.V.: Bolus doses given over 2 minutes with continuous ECG and blood pressure monitoring. Continuous infusion should be via infusion pump.

Contraindications Hypersensitivity to diltiazem or any component of the formulation; sick sinus syndrome; second- or third-degree AV block (except in patients with a functioning artificial pacemaker); hypotension (systolic < 90 mm Hg); acute MI and pulmonary congestion

Warnings Concomitant use with beta-blockers or digoxin can result in conduction disturbances. Avoid concurrent I.V. use of diltiazem and a beta-blocker. Use caution in left ventricular dysfunction (can exacerbate condition). Symptomatic hypotension can occur. Use with caution in hepatic or renal dysfunction.

Dosage Forms [DSC] = Discontinued product

Capsule, extended release, as hydrochloride [once-daily dosing]: 120 mg, 180 mg, 240 mg, 300 mg
 Cardizem[®] CD: 120 mg, 180 mg, 240 mg, 300 mg, 360 mg
 Cartia XT[™]: 120 mg, 180 mg, 240 mg, 300 mg
 Dilacor[®] XR, Diltia XT[®]: 120 mg, 180 mg, 240 mg
 Taztia XT[™]: 120 mg, 180 mg, 240 mg, 300 mg, 360 mg
 Tiazac[®]: 120 mg, 180 mg, 240 mg, 300 mg, 360 mg, 420 mg
 Capsule, sustained release, as hydrochloride [twice-daily dosing] (Cardizem[®] SR [DSC]): 60 mg, 90 mg, 120 mg
 Injection, solution, as hydrochloride: 5 mg/mL (5 mL, 10 mL, 25 mL)
 Injection, powder for reconstitution, as hydrochloride (Cardizem[®]): 25 mg
 Tablet, as hydrochloride (Cardizem[®]): 30 mg, 60 mg, 90 mg, 120 mg
 Tablet, extended release, as hydrochloride (Cardizem[®] LA): 120 mg, 180 mg, 240 mg, 300 mg, 360 mg, 420 mg

Reference Range Zero order kinetics are noted with massive ingestion relating to plasma levels > 2000 ng/mL; therapeutic serum diltiazem levels: 50-200 ng/mL; peak plasma diltiazem and desacetyldiltiazem plasma levels following a 14.94 g (150 mg/kg) diltiazem overdose were 7044 ng/mL and 1837.55 ng/mL, respectively; this was associated with cardiogenic shock and asystole

Overdosage/Treatment

Multiple doses may be necessary with SR products. Whole bowel irrigation may be used; monitor bowel sounds and blood pressure.

Decontamination: Lavage (within 1 hour)/activated charcoal is useful; ipecac-induced emesis can hypothetically worsen calcium antagonist toxicity, since it can produce vagal stimulation. The potential for seizures precipitously following acute ingestion of large doses of a calcium antagonist may also contraindicate the use of ipecac.

Supportive therapy: Supportive and symptomatic treatment, including I.V. fluids and Trendelenburg positioning, should be initiated as intoxication may cause hypotension. Intra-aortic balloon pump may be useful. Calcium (calcium chloride I.V. 1-3 g in adults or 10-30 mg/kg in children over 5-10 minutes with repeats as needed) has been used as a treatment for acute intoxications, it should be reserved for those cases where definite signs of myocardial depression are evident and as a second line therapy for refractory hypotension following use of vasopressors. Hyperinsulinemic therapy with 0.5-1.0 unit I.V. insulin bolus with an infusion of 0.2-1 unit/kg/hour plus a glucose bolus of 25 g I.V. and dextrose infusion to maintain a serum glucose > 100 mg/dL may reverse cardiogenic shock due to calcium blockers. Diltiazem may be particularly unresponsive to calcium; heart block may respond to isoproterenol, glucagon, atropine and/or calcium, although a temporary pacemaker may be required. Hypotension can be treated with norepinephrine, dopamine, or amrinone; use diazepam or lorazepam for seizures. Glucagon may increase myocardial contractility.

Enhancement of elimination: Multiple dosing of activated charcoal may not be effective; charcoal hemoperfusion may not be effective; following 3 $\frac{1}{2}$ hours of charcoal hemoperfusion, diltiazem levels fell from 1100 ng/mL to 375 ng/mL in one case; thus, therapeutic effectiveness of this modality is questionable. Albumin dialysis using molecular adsorbents recirculating system (MARS[®]) may assist in improving hemodynamic status.

Vasopressin (20 IU bolus I.V. titrated by blood pressure to 4 to 5 IU/hour infusion) can increase systemic vascular resistance and cardiac output.

Antidote(s)

- Glucagon [ANTIDOTE]

Drug Interactions **Substrate** of CYP2C9 p-glycoprotein (minor), 2D6 (minor), 3A4 p-glycoprotein (major); **Inhibits** CYP2C9 p-glycoprotein (weak), 2D6 (weak), 3A4 p-glycoprotein (moderate)

Alfentanil's plasma concentration is increased. Fentanyl and sufentanil may be affected similarly.

Amiodarone use may lead to bradycardia, other conduction delays, and decreased cardiac output; monitor closely if using together.

Azole antifungals may inhibit the calcium channel blocker's metabolism; avoid this combination. Try an antifungal like terbinafine (if appropriate) or monitor closely for altered effect of the calcium channel blocker.

Benzodiazepines (midazolam, triazolam) plasma concentrations are increased by diltiazem; monitor for prolonged CNS depression.

Beta-blockers may have increased pharmacodynamic interactions with diltiazem (see Warnings/Precautions).

Buspirone: Diltiazem may increase serum levels of buspirone; monitor. Calcium may reduce the calcium channel blocker's effects, particularly hypotension.

Carbamazepine's serum concentration is increased and toxicity may result; avoid this combination.

Cimetidine reduced diltiazem's metabolism; consider an alternative H₂ antagonist.

Cyclosporine's serum concentrations are increased by diltiazem; avoid the combination. Use another calcium channel blocker or monitor cyclosporine trough levels and renal function closely.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of diltiazem. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of diltiazem. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

CYP3A4 substrates: Diltiazem may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, cyclosporine, mirtazapine, nateglinide, nefazodone, sildenafil (and other PDE-5 inhibitors), tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Digoxin's serum concentration can be increased in some patients; monitor for increased effects of digoxin.

HMG-CoA reductase inhibitors (atorvastatin, lovastatin, simvastatin): Serum concentration will likely be increased; consider pravastatin/fluvasastatin or a second generation dihydropyridine calcium channel blocker as an alternative.

Lithium neurotoxicity may result when diltiazem is added; monitor lithium levels.

Moricizine's serum concentration is increased; monitor clinical response closely.

Nafcillin decreases plasma concentration of diltiazem; avoid this combination.

Nitroprusside's dose required reduction in patients started on diltiazem; monitor blood pressure.

Protease inhibitor like amprenavir and ritonavir may increase diltiazem's serum concentration.

Quinidine: Diltiazem may increase serum levels of quinidine. Dosage adjustment may be required.

Rifampin increases the metabolism of calcium channel blockers; adjust the dose of the calcium channel blocker to maintain efficacy or consider an alternative to rifampin.

Sildenafil, tadalafil, vardenafil: Blood pressure-lowering effects may be additive; use caution.

Tacrolimus's serum concentrations are increased by diltiazem; avoid the combination. Use another calcium channel blocker or monitor tacrolimus trough levels and renal function closely.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic and embryotoxic effects have been demonstrated in small animals

Lactation Enters breast milk/not recommended (AAP considers "compatible")

Nursing Implications Do not crush sustained release capsules

Additional Information Toxic dose: Children: 6 mg/kg. Adults: 2 g
Response to atropine may not be observed until after I.V. calcium administration; erythema may precede elevation of liver function tests by 3-5 days; most effective for treating hypertension in African-Americans
Formula for I.V. to Oral diltiazem conversion: Daily diltiazem oral dose = [(mg/hour infusion rate) × 3 + 3] × 10. Discontinue the continuous infusion ~4 hours after the first dose of Cardizem® CD.

Dimenhydrinate**Related Information**

- Therapeutic Drugs Associated with Hallucinations

CAS Number 523-87-5

U.S. Brand Names Dramamine® [OTC]; Hydrate® [DSC]; TripTone® [OTC]

Impairment Potential Yes

Use Treatment and prevention of nausea, dizziness, and vomiting associated with motion sickness

Treatment of Meniere's disease

Mechanism of Action Competes with histamine for H₁-receptor sites on effector cells in the GI tract, blood vessels, and respiratory tract; blocks chemoreceptor trigger zone, diminishes vestibular stimulation and depresses labyrinthine function through its central anticholinergic activity

Adverse Reactions

Cardiovascular: Hypotension, sinus tachycardia

Central nervous system: **Drowsiness**, paradoxical CNS stimulation, dizziness, auditory and visual hallucinations, headache, ataxia

Gastrointestinal: Anorexia, dry mucous membranes

Genitourinary: Urinary frequency

Hematologic: Porphyria

Local: Pain at the injection site

Ocular: Blurred vision, affects color/night vision

Otic: Ototoxicity, tinnitus

Respiratory: **Thickening of bronchial secretions**

Signs and Symptoms of Overdose Toxicity may resemble atropine overdosage; CNS depression or CNS stimulation, mydriasis; dry mucous membranes

Pharmacodynamics/Kinetics

Onset of action: Oral: ~15-30 minutes

Duration: ~4-6 hours

Absorption: Oral: Well absorbed

Distribution: Wide throughout body

Metabolism: Extensive in the liver

Elimination: Renal

Dosage

Children:

Oral:

2-5 years: 12.5-25 mg every 6-8 hours, maximum: 75 mg/day

6-12 years: 25-50 mg every 6-8 hours, maximum: 150 mg/day

I.M.: 1.25 mg/kg or 37.5 mg/m² 4 times/day, not to exceed 300 mg/day

Adults: Oral, I.M., I.V.: 50-100 mg every 4-6 hours, not to exceed 400 mg/day

Contraindications Hypersensitivity to dimenhydrinate or any component

Warnings

Causes sedation, caution must be used in performing tasks which require alertness (eg, operating machinery or driving). Sedative effects of CNS depressants or ethanol are potentiated. Use with caution in patients with

angle-closure glaucoma, pyloroduodenal obstruction (including stenotic peptic ulcer), urinary tract obstruction (including bladder neck obstruction and symptomatic prostatic hyperplasia), hyperthyroidism, increased intraocular pressure, and cardiovascular disease (including hypertension and tachycardia). May cause paradoxical excitation in pediatric patients, and can result in hallucinations, coma, and death in overdose.

Note: Parenteral formulations (not available in the U.S.) intended for I.V. and I.M. use are distinct and should not be confused. The I.M. formulation can be used for I.V. administration only after dilution.

Dosage Forms

[CAN] = Canadian brand name

Caplet (TripTone®): 50 mg [DSC]

Capsule, softgel (Gravol®) [CAN]: 50 mg [not available in the U.S.]

Capsule, long-acting (Gravol® L/A) [CAN]: 75 mg, 100 mg [not available in the U.S.]

Injection, solution:

Gravol® I.M. [CAN]: 50 mg/mL (1 mL, 5 mL) [not available in the U.S.]

Gravol® I.V. [CAN]: 10 mg/mL (5 mL) [not available in the U.S.]

Solution, oral (Gravol® [CAN], Children's Motion Sickness [CAN]): 3 mg/mL (75 mL) [not available in the U.S.]

Suppository, rectal (Gravol® [CAN], Sab-Dimenhidrate [CAN]): 75 mg, 100 mg [not available in the U.S.]

Tablet:

Dinate® [CAN], Jamp® Travel Tablet [CAN], Nauseato® [CAN]: 50 mg

Dramamine®: 50 mg

Gravol® Filmkote Jr [CAN]: 25 mg [not available in the U.S.]

Gravol® Filmkote [CAN]: 50 mg [not available in the U.S.]

Tablet, chewable:

Dramamine®: 50 mg [contains phenylalanine 1.5 mg/tablet and tartrazine; orange flavor]

Gravol® Chewable for Children [CAN]: 25 mg [not available in the U.S.]

Gravol® Chewable for Adults [CAN]: 50 mg [not available in the U.S.]

Overdosage/Treatment Supportive therapy: There is no specific treatment for an antihistamine overdose; however, most of its clinical toxicity is due to anticholinergic effects. Anticholinesterase inhibitors may be useful by reducing acetylcholinesterase. Anticholinesterase inhibitors include physostigmine, neostigmine, pyridostigmine, and edrophonium. For anticholinergic overdose with severe life-threatening symptoms, physostigmine 1-2 mg (0.5 or 0.02 mg/kg for children) I.V., slowly may be given to reverse these effects.

Drug Interactions

Increased effect/toxicity with CNS depressants, anticholinergics, TCAs, MAO inhibitors

Increased toxicity of antibiotics, especially aminoglycosides (ototoxicity)

Pregnancy Risk Factor B

Pregnancy Implications Crosses placenta; possible oxytocic effect on the uterus at term

Nursing Implications I.V. injection must be diluted to 10 mL with NS and given at 25 mg/minute

Additional Information Dramamine® II contains meclizine

Dimethyl Sulfoxide

Pronunciation (dye meth il sul FOKS ide)

CAS Number 67-68-5

U.S. Brand Names Rimso®-50

Synonyms DMSO

Use Industrial solvent; only approved by FDA for treatment of interstitial cystitis; may be a vehicle for other agents; extravasation of chemotherapy agents

Unlabeled/Investigational Use I.V. use (dose 1 mg/kg) to reduce intracranial pressure in trauma patients; also being studied for its free radical scavenging properties, stress-induced gastric ulcers, and tissue protectant

Adverse Reactions

Cardiovascular: Sinus tachycardia

Gastrointestinal: **Garlic-like breath**

Signs and Symptoms of Overdose

Symptoms are rarely reported.

Agitation, altered taste, diarrhea, dizziness, dysosmia, facial flushing, garlic-onion odor of breath, headache, hemoglobinuria, hypernatremia, mild elevation of liver function tests, photophobia, possible hemolysis when given I.V., pruritus, vasodilation, tachycardia, urine discoloration (red), possible encephalopathy (rare), vomiting

Toxicodynamics/Kinetics

Absorption: Well absorbed from all routes

Distribution: Rapid

Metabolism: Oxidized to dimethylsulfone and reduced to dimethylsulfide

Half-life: Parent drug: 11-14 hours; dimethylsulfone: 60-70 hours

Time to peak: Dermal: 4-8 hours

Elimination: Most DMSO and metabolites excreted in urine

Dosage

Topical: 1.5 mL of a 90% solution every 6 hours for 2 weeks can be used to treat extravasation of anthracycline chemotherapeutic agents or mitomycin

One protocol that is effective for prevention of soft tissue injury due to extravasation of vesicant cytotoxic drugs (excluding vinca alkaloids):

Topical application of 4 drops/10 cm² of skin surface of 99% DMSO over an area twice affected and left to air dry without dressings. Repeat every 8 hours for 1 week. Apply local cooling every 8 hours for 3 days.

Monitoring Parameters May be analyzed but levels are not helpful

Administration Not for I.V. or I.M. use

Dosage Forms Solution, intravesical: 50% [500 mg/mL] (50 mL)

Reference Range Dermal dose of 1 g/kg resulted in peak serum dimethyl sulfoxide level of 504-506 mg/L and peak dimethyl sulfone serum level of 333-514 mg/L; oral dose of 1 g/kg resulted in peak serum dimethyl sulfoxide levels of 1029-3380 mg/L and peak dimethyl sulfone level of 263-596 mg/L

Overdosage/Treatment

Decontamination: Emesis within 30 minutes, lavage (within 1 hour)/activated charcoal with sorbitol

Supportive therapy: Evaluate and monitor liver function, renal function, hemoglobin, and platelet count. Prevention of soft tissue injury due to extravasation of vesicant cytotoxic drugs (excluding vinca alkaloids):

See protocol in Usual Dosage

Enhancement of elimination: No data; multiple dosing with activated charcoal may be effective; dialysis does not appear to be effective

Drug Interactions **Inhibits** CYP2C9 (weak), 2C19 (weak)

Increased toxicity with sulindac

Pregnancy Risk Factor C

Pregnancy Implications Unknown risk; appears to be teratogenic in animals

Lactation Excretion in breast milk unknown

Additional Information Symptoms from DMSO exposure may be due to other substances carried into the body; it may carry water soluble drugs and provide a dermal reservoir for sustained effect

Diphenhydramine

Related Information

- Anticholinergic Effects of Common Psychotropics
- Therapeutic Drugs Associated with Hallucinations

CAS Number 147-24-0

U.S. Brand Names Aler-Cap [OTC]; Aler-Dryl [OTC]; Aler-Tab [OTC]; AllerMax® [OTC]; Altaryl [OTC]; Banophen® Anti-Itch [OTC]; Banophen® [OTC]; Benadryl® Allergy [OTC]; Benadryl® Children's Allergy Fastmelt® [OTC]; Benadryl® Children's Allergy [OTC]; Benadryl® Dye-Free Allergy [OTC]; Benadryl® Injection; Benadryl® Itch Stopping Extra Strength [OTC]; Benadryl® Itch Stopping [OTC]; Compoz® Nighttime Sleep Aid [OTC]; Dermamycin® [OTC]; Dermarest® Plus [OTC]; Dermarest® Insect Bite [OTC]; Diphenhist [OTC]; Diphen® AF [OTC]; Diphen® [OTC]; Dytan™; Genahist® [OTC]; Hydramine® [OTC]; Nytol® Quick Caps [OTC]; Nytol® Quick Gels [OTC]; Q-Dryl [OTC]; Quenalin [OTC]; Siladryl® Allergy [OTC]; Siladryl® DAS [OTC]; Silphen® [OTC]; Simply Sleep® [OTC]; Sleep-ettes D [OTC]; Sleepinal® [OTC]; Sominex® Maximum Strength [OTC]; Sominex® [OTC]; Triaminic® Thin Strips™ Cough and Runny Nose [OTC]; Twilite® [OTC]; Unisom® Maximum Strength SleepGels® [OTC]

Synonyms Diphenhydramine Citrate; Diphenhydramine Hydrochloride; Diphenhydramine Tannate

Impairment Potential Yes. Doses >50 mg or serum levels >50 ng/mL are consistent with impairment (Gengo FM and Manning C, "A Review of the Effects of Antihistamines on Mental Processes Related to Automobile Driving," *J Allergy Clin Immunol*, 1990, 86(2): 1034-9.)

Use Reversal of toxin-induced extrapyramidal reactions or serum sickness secondary to antivenin; antitussive; antinotion sickness; sleep-aid; useful in anaphylaxis and allergy treatment

Mechanism of Action Competes with histamine for H₁-receptor sites on effector cells in the gastrointestinal tract, blood vessels, and respiratory tract; anticholinergic and sedative effects are also seen

Adverse Reactions

Cardiovascular: Hypotension, palpitations, prolonged QT interval, QRS prolongation, sinus tachycardia, vasculitis

Central nervous system: **Slight to moderate drowsiness**, sedation, disorientation, dizziness, paradoxical excitement, extrapyramidal symptoms, fatigue, insomnia, visual hallucinations, acute dystonia, fever, hyperthermia, seizures, ataxia

Dermatologic: Angioedema, toxic epidermal necrolysis, urticaria, purpura, pruritus, exanthem, photoallergic reaction, cutaneous vasculitis

Gastrointestinal: Nausea, vomiting, dry mucous membranes, xerostomia

Genitourinary: Urinary retention, impotence, urinary incontinence

DIPHENHYDRAMINE

- Hematologic: Porphyria
Neuromuscular & skeletal: Tremors, trismus
Ocular: Blurred vision, mydriasis, nystagmus (vertical/horizontal), color vision abnormalities
Respiratory: **Thickening of bronchial secretions**, bronchospasm
Miscellaneous: Dental erosion, fixed drug eruption
- Signs and Symptoms of Overdose** Overdose may result in death in infants and children. Catatonic stupor (15%), coma, CNS stimulation or depression, delirium, mydriasis, nystagmus, rhabdomyolysis, seizures, tachycardia, toxic psychosis
- Admission Criteria/Prognosis** Any symptomatic patient with ECG abnormalities or ingestions over 10 mg/kg should be considered for admission
- Pharmacodynamics/Kinetics**
Onset of action: Maximum sedative effect: 1-3 hours
Duration: 4-7 hours
Protein binding: 78%
Metabolism: Extensively hepatic; smaller degrees in pulmonary and renal systems; significant first-pass effect
Bioavailability: Oral: 40% to 60%
Half-life elimination: 2-8 hours; Elderly: 13.5 hours
Time to peak, serum: 2-4 hours
Excretion: Urine (as unchanged drug)
- Dosage** Children: Oral, I.M., I.V.: 5 mg/kg/day or 150 mg/m²/day in divided doses every 6-8 hours, not to exceed 300 mg/day
Adults:
Oral: 25-50 mg every 4-6 hours
I.M., I.V.: 10-50 mg in a single dose every 2-4 hours, not to exceed 400 mg/day
Fatal dose: 25 mg/kg
- Stability** Protect from light
- Monitoring Parameters** Relief of symptoms, mental alertness
- Contraindications** Hypersensitivity to diphenhydramine or any component of the formulation; acute asthma; not for use in neonates
- Warnings** Causes sedation, caution must be used in performing tasks which require alertness (eg, operating machinery or driving). Sedative effects of CNS depressants or ethanol are potentiated. Use with caution in patients with angle-closure glaucoma, pyloroduodenal obstruction (including stenotic peptic ulcer), urinary tract obstruction (including bladder neck obstruction and symptomatic prostatic hyperplasia), hyperthyroidism, increased intraocular pressure, and cardiovascular disease (including hypertension and tachycardia). Diphenhydramine has high sedative and anticholinergic properties, so it may not be considered the antihistamine of choice for prolonged use in the elderly. May cause paradoxical excitation in pediatric patients, and can result in hallucinations, coma, and death in overdose. Some preparations contain sodium bisulfite; syrup formulations may contain alcohol. Some preparations contain soy protein; patients with soy protein or peanut allergies should avoid.
- Dosage Forms** Caplet, as hydrochloride: 25 mg, 50 mg

Hydramine[®]: 12.5 mg/5 mL (120 mL, 480 mL) [alcohol free]
Q-Dryl: 12.5 mg/5 mL (120 mL) [alcohol free; cherry flavor]
Quenalin: 12.5 mg/5 mL (120 mL) [fruit flavor]
Siladryl[®] Allergy: 12.5 mg/5 mL (120 mL, 240 mL, 480 mL) [alcohol free, sugar free; black cherry flavor]
Siladryl[®] DAS: 12.5 mg/5 mL (120 mL) [alcohol free, dye free, sugar free; black cherry flavor]
Liquid, topical, as hydrochloride [stick] (Benadryl[®] Itch Stopping Extra Strength): 2% (14 mL) [contains zinc acetate 0.1% and alcohol]
Solution, oral, as hydrochloride:
Banophen[®]: 12.5 mg/5mL (480 mL) [sugar free]
Diphenhist: 12.5 mg/5 mL (120 mL, 480 mL) [alcohol free; contains sodium benzoate]
Solution, topical, as hydrochloride [spray]:
Benadryl[®] Itch Stopping Extra Strength: 2% (60 mL) [contains zinc acetate 0.1% and alcohol]
Dermamycin[®], Dermarest[®] Insect Bite: 2% (60 mL) [contains menthol 1%]
Strips, oral, as hydrochloride (Triaminic[®] Thin Strips™ Cough and Runny Nose): 12.5 mg (16s) [grape flavor]
Suspension, as tannate: 25 mg/5 mL (120 mL)
Dytan™: 25 mg/5 mL (120 mL) [strawberry flavor]
Syrup, as hydrochloride (Silphen[®] Cough): 12.5 mg/5 mL (120 mL, 240 mL, 480 mL) [contains alcohol; 5%; strawberry flavor]
Tablet, as hydrochloride: 25 mg, 50 mg
Aler-Tab, Benadryl[®] Allergy, Genahist[®], Sleepinal[®], Sominex[®]: 25 mg
Tablet, chewable, as hydrochloride (Benadryl[®] Children's Allergy): 12.5 mg [contains phenylalanine 4.2 mg/tablet; grape flavor]
Tablet, chewable, as tannate (Dytan™): 25 mg [contains phenylalanine; strawberry flavor]
Tablet, orally disintegrating, as citrate (Benadryl[®] Children's Allergy Fastmelt[®]): 19 mg [equivalent to diphenhydramine hydrochloride 12.5 mg; contains phenylalanine 4.5 mg/tablet and soy protein isolate; cherry flavor]
- Reference Range**
Therapeutic: Serum: Antihistamine 30-50 ng/mL (117.5-195.8 nmol/L); Sedative: 50-300 ng/mL (195.8-1174.9 nmol/L)
Toxic: Diphenhydramine level of 12.8 mg/L has been associated with fatality
In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.
- Overdosage/Treatment**
Decontamination: Lavage (within 1 hour) with ingestions over 5 mg/kg in pediatrics or over 150 mg in adults; activated charcoal can be most useful; **do not** use a cathartic if diarrhea is present
Supportive therapy: Propranolol or esmolol can be used for tachyarrhythmias (avoid quinidine or disopyramide in that conduction disturbances can occur); benzodiazepine can be utilized for seizures; if anticholinergic findings are present with the seizures (or if coma or delirium is present) a trial of physostigmine may be useful; wide complex QRS conduction defects may respond to I.V. sodium bicarbonate; seizures have responded to sodium bicarbonate in a rodent model. Initiate cooling technique if core body temperature is > 104 °F (40 °C).
Enhanced elimination: Dialysis/hemoperfusion is not useful; charcoal hemoperfusion with in-line hemodialysis and regional citrate oagulation may be beneficial in patients with cardiac abnormalities
- Antidote(s)**
● Physostigmine [ANTIDOTE]
- Test Interactions** May suppress wheal and flare reaction to skin test antigens; false-positive methadone or opiate enzyme immunoassay may result with diphenhydramine or doxylamine; may cause false-positive urinary assay for propoxyphene on EMIT II immunoassay. May cause false-positive phencyclidine on fluorescence polarization urinary immunoassay.
- Drug Interactions** Inhibits CYP2D6 (moderate)
Amantadine, rimantadine: Central and/or peripheral anticholinergic syndrome can occur when administered with amantadine or rimantadine
Anticholinergic agents: Central and/or peripheral anticholinergic syndrome can occur when administered with narcotic analgesics, phenothiazines and other antipsychotics (especially with high anticholinergic activity), tricyclic antidepressants, quinidine and some other antiarrhythmics, and antihistamines
Atenolol: Drugs with high anticholinergic activity may increase the bioavailability of atenolol (and possibly other beta-blockers); monitor for increased effect
Cholinergic agents: Drugs with high anticholinergic activity may antagonize the therapeutic effect of cholinergic agents; includes donepezil, rivastigmine, and tacrine

CNS depressants: Sedative effects may be additive with CNS depressants; includes ethanol, benzodiazepines, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect

CYP2D6 substrates: Diphenhydramine may increase the levels/effects of CYP2D6 substrates. Example substrates include amphetamines, selected beta-blockers, dextromethorphan, fluoxetine, lidocaine, mirtazapine, nefazodone, paroxetine, risperidone, ritonavir, thioridazine, tricyclic antidepressants, and venlafaxine.

CYP2D6 prodrug substrates: Diphenhydramine may decrease the levels/effects of CYP2D6 prodrug substrates. Example prodrug substrates include codeine, hydrocodone, oxycodone, and tramadol.

Digoxin: Drugs with high anticholinergic activity may decrease gastric degradation and increase the amount of digoxin absorbed by delaying gastric emptying

Ethanol: Syrup should not be given to patients taking drugs that can cause disulfiram reactions (ie, metronidazole, chlorpropamide) due to high alcohol content

Levodopa: Drugs with high anticholinergic activity may increase gastric degradation and decrease the amount of levodopa absorbed by delaying gastric emptying

Neuroleptics: Drugs with high anticholinergic activity may antagonize the therapeutic effects of neuroleptics

Pregnancy Risk Factor B

Pregnancy Implications Crosses placenta; use with temazepam can cause profound fetal CNS depression

Lactation Enters breast milk/contraindicated

Nursing Implications I.V. must be given slowly

Additional Information Has antiemetic and topical anesthetic properties; false-positive results with methadone or opiate enzyme immunoassay may occur with diphenhydramine or doxylamine; liquid preparations may also contain significant amounts of alcohol; topical administration on infants and small children has led to severe systemic toxicity, particularly in presence of varicella infection

Diphenoxylate and Atropine

CAS Number 3810-80-8; 915-30-0

U.S. Brand Names Lomocot®; Lomotil®; Lonox®

Synonyms Atropine and Diphenoxylate

Use Treatment of diarrhea with nonbacterial causes

Mechanism of Action Diphenoxylate inhibits excessive gastrointestinal motility and gastrointestinal propulsion (an analogue of meperidine); commercial preparations contain a subtherapeutic amount of atropine to discourage abuse

Adverse Reactions

Effects of atropine are noted first followed by diphenoxylate

Cardiovascular: Tachycardia, flushing, sinus tachycardia

Central nervous system: Sedation, dizziness, headache, hyperthermia, euphoria, drowsiness, irritability, seizures, coma, hallucination, hyperexcitability, ataxia

Dermatologic: Pruritus, rash

Gastrointestinal: Nausea, vomiting, abdominal pain, abdominal discomfort, paralytic ileus, pancreatitis, xerostomia, anorexia, constipation

Genitourinary: Urinary retention

Neuromuscular & skeletal: Weakness

Ocular: Blurred vision

Respiratory: Apnea, respiratory depression (young children may be at greater risk)

Miscellaneous: Physical and psychological dependence with prolonged use

Signs and Symptoms of Overdose Paralytic ileus

Admission Criteria/Prognosis Admit any significant pediatric ingestion due to delayed symptom progression of toxicity.

Pharmacodynamics/Kinetics

Atropine: See Atropine monograph.

Diphenoxylate:

Onset of action: Antidiarrheal: 45-60 minutes

Duration: Antidiarrheal: 3-4 hours

Absorption: Well absorbed

Metabolism: Extensively hepatic via ester hydrolysis to diphenoxylate acid (active)

Half-life elimination: Diphenoxylate: 2.5 hours; Diphenoxylate acid: 12-14 hours

Time to peak, serum: 2 hours

Excretion: Primarily feces (49% as unchanged drug and metabolites); urine (~14%, <1% as unchanged drug)

Dosage

Use with caution in young children due to variable responses; if there is no response within 48 hours, the drug is unlikely to be effective and should be discontinued.

Oral:

Children 2-12 years: 0.3-0.4 mg/kg/day of diphenoxylate in 2-4 divided doses

Adults: 15-20 mg/day of diphenoxylate in 3-4 divided doses

Monitoring Parameters Watch for signs of atropinism (dryness of skin and mucous membranes, tachycardia, thirst, flushing); monitor number and consistency of stools; observe for signs of toxicity, fluid and electrolyte loss, hypotension, and respiratory depression

Administration If there is no response within 48 hours of continuous therapy, this medication is unlikely to be effective and should be discontinued; if chronic diarrhea is not improved symptomatically within 10 days at maximum dosage, control is unlikely with further use. Use of the liquid preparation is recommended in children <13 years of age; use plastic dropper provided when measuring liquid.

Contraindications Hypersensitivity to diphenoxylate, atropine, or any component of the formulation; obstructive jaundice; diarrhea associated with pseudomembranous enterocolitis or enterotoxin-producing bacteria; not for use in children <2 years of age

Warnings

Use in conjunction with fluid and electrolyte therapy when appropriate. In case of severe dehydration or electrolyte imbalance, withhold diphenoxylate/atropine treatment until corrective therapy has been initiated. Inhibiting peristalsis may lead to fluid retention in the intestine aggravating dehydration and electrolyte imbalance. Reduction of intestinal motility may be deleterious in diarrhea resulting from *Shigella*, *Salmonella*, toxigenic strains of *E. coli*, and pseudomembranous enterocolitis associated with broad-spectrum antibiotics; use is not recommended.

Use with caution in children. Younger children may be predisposed to toxicity; signs of atropinism may occur even at recommended doses, especially in patients with Down syndrome. Overdose in children may result in severe respiratory depression, coma, and possibly permanent brain damage.

Use caution with acute ulcerative colitis, hepatic or renal dysfunction. If there is no response with 48 hours, this medication is unlikely to be effective and should be discontinued; if chronic diarrhea is not improved symptomatically within 10 days at maximum dosage, control is unlikely

DIPYRIDAMOLE

with further use. Physical and psychological dependence have been reported with higher than recommended dosing.

Dosage Forms

Solution, oral: Diphenoxylate hydrochloride 2.5 mg and atropine sulfate 0.025 mg per 5 mL (5 mL, 10 mL, 60 mL)

Lomotil[®]: Diphenoxylate hydrochloride 2.5 mg and atropine sulfate 0.025 mg per 5 mL (60 mL) [contains alcohol 15%; cherry flavor]

Tablet: Diphenoxylate hydrochloride 2.5 mg and atropine sulfate 0.025 mg

Lomotil[®], Lonox[®]: Diphenoxylate hydrochloride 2.5 mg and atropine sulfate 0.025 mg

Reference Range Peak plasma level after 5 mg of diphenoxylate: 0.01 mg/L of diphenoxylate and 0.04 mg/L of difenoxine

Overdosage/Treatment

Decontamination: Lavage (within 3 hours)/activated charcoal

Supportive therapy: Naloxone for respiratory/central nervous system depression

Enhanced elimination: Due to delayed drug absorption and enterohepatic recirculation, multiple dosing of activated charcoal may be useful

Antidote(s)

- Naloxone [ANTIDOTE]

Drug Interactions Pramlintide: Pramlintide may enhance the anticholinergic effect of anticholinergics; additive effects on reduced GI motility may occur.

Pregnancy Risk Factor C

Pregnancy Implications Neonatal respiratory depression/withdrawal can occur

Lactation Enters breast milk/use caution

Dipyridamole

CAS Number 58-32-2

U.S. Brand Names Persantine[®]

Use Maintain patency after surgical grafting procedures including coronary artery bypass; with warfarin to decrease thrombosis in patients after artificial heart valve replacement; for chronic management of angina pectoris; with aspirin to prevent coronary artery thrombosis; in combination with aspirin or warfarin to prevent other thromboembolic disorders

Mechanism of Action Inhibits the activity of adenosine deaminase and phosphodiesterase, which causes an accumulation of adenosine, adenine nucleotides, and cyclic AMP; these mediators then inhibit platelet aggregation and may cause vasodilation; may also stimulate release of prostacyclin or PGD₂

Adverse Reactions

Cardiovascular: **Exacerbation of angina pectoris**, vasodilation, flushing, angina, pericardial effusion/pericarditis, sinus bradycardia, vasodilation, syncope

Central nervous system: **Dizziness**, headache (dose related)

Dermatologic: Rash, pruritus, angioedema

Gastrointestinal: Abdominal distress, nausea, vomiting, hemorrhoids, salty taste

Neuromuscular & skeletal: Weakness

Respiratory: Asthma, pulmonary edema, hyposmia

Signs and Symptoms of Overdose Bradycardia, chest pain, cholelithiasis, coagulopathy, hypotension, myalgia, metallic taste, peripheral vasodilation, wheezing

Pharmacodynamics/Kinetics

Absorption: Readily, but variable

Distribution: Adults: V_d: 2-3 L/kg

Protein binding: 91% to 99%

Metabolism: Hepatic

Half-life elimination: Terminal: 10-12 hours

Time to peak, serum: 2-2.5 hours

Excretion: Feces (as glucuronide conjugates and unchanged drug)

Dosage

Oral:

Children: 4-10 mg/kg/day in 3 divided doses
Doses of 4-10 mg/kg/day have been used investigationally to treat albuminuria in pediatric renal disease

Adults: 75-400 mg/day in 3-4 divided doses

I.V.: 0.14 mg/kg/minute for 4 minutes; maximum dose: 60 mg

Stability

Insoluble in water

Monitoring Parameters

Blood pressure, heart rate

Administration

I.V.: Infuse diluted solution over 4 minutes; following dipyridamole infusion, inject thallium-201 within 5 minutes. **Note:** Aminophylline should be available for urgent/emergent use; dosing of 50-100 mg (range: 50-250 mg) IVP over 30-60 seconds.

Tablet: Administer with water 1 hour before meals.

Contraindications Hypersensitivity to dipyridamole or any component of the formulation

Warnings Use caution in patients with hypotension and severe cardiac disease. Use caution in patients on other antiplatelet agents or anticoagulation. Severe adverse reactions have occurred rarely with I.V. administration. Use the I.V. form with caution in patients with bronchospastic disease or unstable angina. Have aminophylline ready in case of urgency or emergency with I.V. use. Safety and efficacy in children < 12 years of age have not been established.

asthma, pulmonary edema, hyposmia

Dosage Forms Injection, solution: 5 mg/mL (2 mL, 10 mL)

Tablet: 25 mg, 50 mg, 75 mg

Persantine[®]: 25 mg, 50 mg, 75 mg

Reference Range 300 mg oral dose associated with a serum dipyridamole level of 2.9 mcg/mL

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Fluids and vasopressors may be helpful although hypotension is often transient; coronary vasodilation may be reversed by aminophylline

Enhancement of elimination: Multiple dose of activated charcoal may be useful; dialysis unlikely to help because highly protein bound

Test Interactions May result in falsely elevated lipoprotein

Drug Interactions Adenosine: Blood levels and pharmacologic effects of adenosine are increased; consider reduced doses of adenosine.

Cholinesterase inhibitors: May counteract effect of cholinesterase inhibitor and may aggravate myasthenia gravis.

Xanthine derivatives (eg, theophylline): May reduce the pharmacologic effects of dipyridamole; hold theophylline preparations for 36-48 hours before dipyridamole facilitated stress test.

Pregnancy Risk Factor B

Pregnancy Implications Small amounts cross placenta

Lactation Enters breast milk/use caution

Nursing Implications Dilute I.V. dipyridamole in at least a 1:2 ratio with D₅W

Additional Information Dipyridamole may also be given 2 days prior to open heart surgery to prevent platelet activation by extracorporeal bypass pump; doses of 4-10 mg/kg/day have been used investigationally to treat albuminuria in pediatric renal disease

Dirithromycin

CAS Number 62013-04-1

U.S. Brand Names Dynabac[®]

Use Not yet FDA-approved for community-acquired pneumonia, pharyngitis/tonsillitis, bronchitis, skin and skin structure infections

Mechanism of Action Macrolide antibiotic similar to erythromycin, dirithromycin; inhibits RNA-dependent protein synthesis by binding to 50-S subunit of ribosomes

Adverse Reactions

Central nervous system: Headache, dizziness

Dermatologic: Urticaria

Gastrointestinal: Abdominal pain, diarrhea, nausea, dyspepsia, flatulence

Neuromuscular & skeletal: Weakness

Respiratory: Rhinitis

Pharmacodynamics/Kinetics

Absorption: Rapid

Distribution: V_d: 800 L; rapidly and widely (higher levels in tissues than plasma)

Protein binding: 14% to 30%

Metabolism: Hydrolyzed to erythromycylamine

Bioavailability: 10%

Half-life elimination: 8 hours (range: 2-36 hours)

Time to peak: 4 hours

Excretion: Feces (81% to 97%)

Dosage 500 mg/day

Monitoring Parameters Temperature, CBC

Administration Administer with food or within an hour following a meal. Do not alter (chew or crush) enteric coated dosage form.

Contraindications Hypersensitivity to any macrolide or component of dirithromycin; use with pimozide

Warnings Pseudomembranous colitis has been reported and should be considered in patients presenting with diarrhea subsequent to therapy with dirithromycin.

Dosage Forms

[DSC] = Discontinued product

Tablet, enteric coated: 250 mg [DSC]

Reference Range After a 500 mg oral dose, peak plasma level was 0.5 mg/L

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Acute gastrointestinal irritation can be treated with milk or bismuth subsalicylate; lidocaine can be used for ventricular arrhythmias

Elimination: Hemodialysis is not effective

Drug Interactions Substrate of CYP3A4 (minor)

Increased effect: Absorption of dirithromycin is slightly enhanced with concomitant antacids and H₂ antagonists; dirithromycin may, like erythromycin, increase the effect of alfentanil, anticoagulants, bromo-

criptine, carbamazepine, cyclosporine, digoxin, disopyramide, ergots, methylprednisolone, cisapride.

Increased toxicity: Avoid use with pimozone (due to risk of significant cardiotoxicity) and triazolam.

Note: Interactions with nonsedating antihistamines (eg, astemizole), cisapride, and theophylline are not known to occur; however, caution is advised with coadministration.

Pregnancy Risk Factor C

Pregnancy Implications Animal studies indicate the use of dirithromycin during pregnancy should be avoided if possible.

Lactation Excretion in breast milk unknown/use caution

Additional Information Effective against gram-positive organisms (*Legionella*, *Helicobacter pylori*, and *Chlamydia trachomatis*)

Disopyramide

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 22059-60-5; 3737-09-5

U.S. Brand Names Norpace® CR; Norpace®

Synonyms Disopyramide Phosphate

Use Suppression and prevention of unifocal and multifocal premature, ventricular premature complexes, coupled tachycardia (ventricular); also effective in the conversion of fibrillation (atrial), flutter (atrial), and paroxysmal atrial tachycardia to normal sinus rhythm and prevention of the recurrence of these arrhythmias after conversion by other methods

Unlabeled/Investigational Use Hypertrophic obstructive cardiomyopathy (HOCM)

Mechanism of Action Class IA antiarrhythmic: Decreases myocardial excitability and conduction velocity; reduces disparity in refractory between normal and infarcted myocardium; possesses anticholinergic, peripheral vasoconstrictive, and negative inotropic effects

Adverse Reactions

Cardiovascular: Congestive heart failure, edema, chest pain, syncope and hypotension; conduction disturbances including AV block, QRS prolongation, QT prolongation, fibrillation (atrial), flutter (atrial), sinus bradycardia, angina, myocardial depression, tachycardia (supraventricular), arrhythmias (ventricular)

Central nervous system: Fatigue, malaise, nervousness, acute psychosis, CNS depression, dizziness, headache, auditory and visual hallucinations, psychosis

Dermatologic: Generalized rashes

Endocrine & metabolic: Hypoglycemia, may initiate contractions of pregnant uterus, hyperkalemia may enhance toxicities, hyperinsulinemia, elevation of cholesterol and triglycerides

Gastrointestinal: Constipation, nausea, vomiting, diarrhea, GI pain, gas, anorexia, xerostomia, decreased bowel sounds, weight gain, dry throat

Genitourinary: **Urinary retention/hesitancy**, impotence

Hematologic: Granulocytopenia

Hepatic: Hepatic cholestasis, liver enzymes (elevated)

Neuromuscular & skeletal: Paresthesia, weakness

Ocular: Blurred vision, photophobia, diplopia, mydriasis, acute angle-closure glaucoma, dry eyes

Respiratory: Dyspnea, dry nose

Miscellaneous: Anaphylactic shock

Signs and Symptoms of Overdose Agranulocytosis, anticholinergic effects, apnea, asystole, AV block, bradycardia, cardiac arrhythmias, cardiac conduction disturbances, coma, congestive heart failure, drowsiness, granulocytopenia, heart block, hypoglycemia, hypotension, impotence, increased intraocular pressure, jaundice, leukopenia, loss of consciousness, mydriasis, neutropenia, paroxysmal tachycardia (ventricular), photosensitivity, QRS prolongation, QT prolongation, respiratory arrest, seizures, slurred speech, torsade de pointes, urine discoloration (milky)

Pharmacodynamics/Kinetics

Onset of action: 0.5-3.5 hours

Duration: 1.5-8.5 hours

Absorption: 60% to 83%

Protein binding (concentration dependent): 20% to 60%

Metabolism: Hepatic to inactive metabolites

Half-life elimination: Adults: 4-10 hours; prolonged with hepatic or renal impairment

Excretion: Urine (40% to 60% as unchanged drug); feces (10% to 15%)

Dosage Oral:

Children:

< 1 year: 10-30 mg/kg/24 hours in 4 divided doses

1-4 years: 10-20 mg/kg/24 hours in 4 divided doses

4-12 years: 10-15 mg/kg/24 hours in 4 divided doses

12-18 years: 6-15 mg/kg/24 hours in 4 divided doses

Note: 600 mg ingestion in a child can be fatal

Adults:

< 50 kg: 100 mg every 6 hours or 200 mg every 12 hours (controlled release)

> 50 kg: 150 mg every 6 hours or 300 mg every 12 hours (controlled release); if no response, may increase to 200 mg every 6 hours; maximum dose required for patients with severe refractory tachycardia (ventricular) is 400 mg every 6 hours

Dosing adjustment in renal impairment: 100 mg (nonsustained release) given at the following intervals, based on creatinine clearance (mL/minute):

Cl_{cr} 30-40 mL/minute: Administer every 8 hours

Cl_{cr} 15-30 mL/minute: Administer every 12 hours

Cl_{cr} < 15 mL/minute: Administer every 24 hours or alter the dose as follows:

Cl_{cr} 30-<40 mL/minute: Reduce dose 50%

Cl_{cr} 15-30 mL/minute: Reduce dose 75%

Dosing interval in hepatic impairment: 100 mg every 6 hours or 200 mg every 12 hours (controlled release)

Monitoring Parameters ECG, blood pressure, urinary retention, CNS anticholinergic effects (confusion, agitation, hallucinations, etc)

Administration Do not break or chew controlled release capsules. Administer around-the-clock to Administer around-the-clock rather than 4 times/day (ie, 12-6-12-6, not 9-1-5-9) to promote less variation in peak and trough serum levels

Contraindications Hypersensitivity to disopyramide or any component of the formulation; cardiogenic shock; pre-existing second- or third-degree heart block (except in patients with a functioning artificial pacemaker); congenital QT syndrome; sick sinus syndrome

Warnings Monitor and adjust dose to prevent QT_c prolongation. Avoid concurrent use with other medications that prolong QT interval or decrease myocardial contractility. Correct hypokalemia before initiating therapy; may worsen toxicity. Watch for proarrhythmic effects. [U.S. Boxed Warning]: In the Cardiac Arrhythmia Suppression Trial (CAST), recent (> 6 days but < 2 years ago) myocardial infarction patients with asymptomatic, nonlife-threatening ventricular arrhythmias did not benefit and may have been harmed by attempts to suppress the arrhythmia with flecainide or encainide. An increased mortality or nonfatal cardiac arrest rate (7.7%) was seen in the active treatment group compared with patients in the placebo group (3%). The applicability of the CAST results to other populations is unknown. Antiarrhythmic agents should be reserved for patients with life-threatening ventricular arrhythmias. May precipitate or exacerbate CHF. Due to significant anticholinergic effects, do not use in patients with urinary retention, BPH, glaucoma, or myasthenia gravis. Reduce dosage in renal or hepatic impairment. The extended release form is not recommended for Cl_{cr} < 40 mL/minute. In patients with atrial fibrillation or flutter, block the AV node before initiating. Use caution in Wolff-Parkinson-White syndrome or bundle branch block. Monitor closely for hypotension during the initiation of therapy.

Boxed Warning: In the Cardiac Arrhythmia Suppression Trial (CAST), recent (> 6 days but < 2 years ago) myocardial infarction patients with asymptomatic, nonlife-threatening ventricular arrhythmias did not benefit and may have been harmed by attempts to suppress the arrhythmia with flecainide or encainide. An increased mortality or nonfatal cardiac arrest rate (7.7%) was seen in the active treatment group compared with patients in the placebo group (3%). The applicability of the CAST results to other populations is unknown. Antiarrhythmic agents should be reserved for patients with life-threatening ventricular arrhythmias. May precipitate or exacerbate CHF. Due to significant anticholinergic effects, do not use in patients with urinary retention, BPH, glaucoma, or myasthenia gravis. Reduce dosage in renal or hepatic impairment. The extended release form is not recommended for Cl_{cr} < 40 mL/minute. In patients with atrial fibrillation or flutter, block the AV node before initiating. Use caution in Wolff-Parkinson-White syndrome or bundle branch block. Monitor closely for hypotension during the initiation of therapy.

Dosage Forms Capsule (Norpace®): 100 mg, 150 mg

Capsule, controlled release (Norpace® CR): 100 mg, 150 mg

Reference Range

Therapeutic:

Atrial arrhythmias: 2.8-3.2 mcg/mL (SI: 8.3-9.4 µmol/L)

Ventricular arrhythmias: 3.3-7.5 mcg/mL (SI: 9.7-22.0 µmol/L)

Toxic: > 7.0 mcg/mL (SI: > 20.7 µmol/L)

Fatal: Levels > 16.0 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Phenytoin and lidocaine are useful for ventricular arrhythmia; isoproterenol is useful to reverse cardiac depressant effects. Resuscitative effort may need to be prolonged. Calcium chloride may be useful for electromechanical dissociation.

Enhancement of elimination: Forced diuresis, charcoal hemoperfusion is effective; multiple dosing of activated charcoal may be effective; since plasma protein decreases as disopyramide levels rise, hemodialysis may be useful in enhancing elimination (clearance of 123 mL/minute with 40% of drug removed during 4 hours of hemodialysis)

Test Interactions ↓ glucose; disopyramide can cross react with methadone urinary immunoassay tests

Drug Interactions Substrate of CYP3A4 (major)

Beta-blockers may cause additive/excessive negative inotropic activity. CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of disopyramide. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of disopyramide. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Erythromycin and clarithromycin increase disopyramide blood levels; may cause QRS widening and/or QT interval prolongation.

Procainamide, quinidine, propafenone, or flecainide can cause increased/excessive negative inotropic effects or prolonged conduction.

Drugs which may prolong the QT interval (amiodarone, amitriptyline, bepridil, cisapride, disopyramide, erythromycin, haloperidol, imipramine, pimozone, quinidine, sotalol, and thioridazine) may be additive with disopyramide; use with caution.

DISULFIRAM

Sparfloxacin, gatifloxacin, and moxifloxacin may result in additional prolongation of the QT interval; concurrent use is contraindicated.

Pregnancy Risk Factor C

Pregnancy Implications May cause uterine contractions

Lactation Enters breast milk/compatible

Disulfiram

Related Information

- Drugs Used in Addiction Treatment
- Therapeutic Drugs Associated with Hallucinations

CAS Number 97-77-8

U.S. Brand Names Antabuse®

Use Management of chronic alcoholics; also used to treat allergic nickel dermatitis and can enhance the elimination of nickel

Mechanism of Action Disulfiram is a thiamur derivative which interferes with aldehyde dehydrogenase. When taken concomitantly with alcohol, there is an increase in serum acetaldehyde levels. High acetaldehyde causes uncomfortable symptoms, including flushing, nausea, thirst, palpitations, chest pain, dizziness, and hypotension. This reaction is the basis for disulfiram use in postwithdrawal long-term care of alcoholism. May also boost the immune function in HIV patients.

Adverse Reactions

Alcohol-disulfiram reaction:

Cardiovascular: Flushing, cardiovascular collapse, myocardial infarction, chest pain, angina, vasodilation, Reye's-like syndrome

Central nervous system: **Drowsiness**, dizziness, seizures, death, auditory and visual hallucinations, psychosis, headache, paranoia, gustatory hallucinations, parkinsonism, catatonia, extrapyramidal reactions, axonopathy

Dermatologic: Systemic contact dermatitis, nickel dermatitis recall

Gastrointestinal: Nausea, vomiting, metallic taste

Hematologic: Methemoglobin (as high as 52.8% has been described in a disulfiram ethanol reaction)

Hepatic: Hepatitis

Ocular: Retrobulbar neuritis, blepharospasm

Respiratory: Dyspnea

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Symptoms develop within 12 hours; Ataxia, blindness, dementia, depression, dysphoria, eczema, facial flushing, garlic-like breath, impotence, mania, memory loss, metallic taste, nystagmus, paresthesia, ptosis, rotten egg breath, seizures, syncope, thrombocytopenia

Pharmacodynamics/Kinetics

Onset of action: Full effect: 12 hours

Duration: ~ 1-2 weeks after last dose

Absorption: Rapid

Metabolism: To diethylthiocarbamate

Protein binding: 96%

Excretion: Feces and exhaled gases (as metabolites)

Dosage Adults: Oral: Maximum daily dose: 500 mg/day in a single dose for 1-2 weeks; average maintenance dose: 250 mg/day; range: 125-500 mg; duration of therapy is to continue until the patient is fully recovered socially and a basis for permanent self control has been established; maintenance therapy may be required for months or even years

Monitoring Parameters Hypokalemia; liver function tests at baseline and after 10-14 days of treatment; CBC, serum chemistries, liver function tests should be monitored during therapy

Administration

Administration of any medications containing alcohol, including topicals, is contraindicated. Do not administer disulfiram if ethanol has been consumed within the prior 12 hours.

Contraindications Hypersensitivity to disulfiram and related compounds or any component of the formulation; patients receiving or using ethanol, metronidazole, paraldehyde, or ethanol-containing preparations like cough syrup or tonics; psychosis; severe myocardial disease and coronary occlusion

Warnings Use with caution in patients with diabetes, hypothyroidism, seizure disorders, nephritis (acute or chronic), hepatic cirrhosis or insufficiency. [**U.S. Boxed Warning**]: **Should never be administered to a patient when he/she is in a state of ethanol intoxication, or without his/her knowledge.** Patient must receive appropriate counseling, including information on "disguised" forms of ethanol (tonics, mouthwashes, etc) and the duration of the drug's activity (up to 14 days). Severe (sometimes fatal) hepatitis and/or hepatic failure have been associated with disulfiram. May occur in patients with or without prior history of abnormal hepatic function.

Dosage Forms Tablet: 250 mg

Reference Range Peak blood disulfiram level after a 500 mg dose: 0.38 mg/L; peak DDC level is ~ 1.2 mg/L; peak carbon disulfide level is 14 mg/L; concomitant ethanol levels > 0.12 g/dL associated with unconsciousness when ethanol is used with disulfiram

Overdosage/Treatment To prevent absorption, lavage (up to 10 hours postingestion) and activated charcoal should be given; management of

disulfiram reaction: Institute support measures to restore blood pressure (pressors and fluids); antihistamines are useful to treat flushing; monitor for hypokalemia; metoclopramide or prochlorperazine can be used for vomiting; dopamine is not useful to treat disulfiram-ethanol induced hypotension; norepinephrine is the preferred agent; use of 4-methylpyrazole (7-10 mg/kg) or ascorbic acid (1 g I.V.) is investigational and not well documented in treating disulfiram-ethanol reaction; multiple dosing of activated charcoal may be useful in disulfiram overdose

Antidote(s)

- Norepinephrine [ANTIDOTE]

Test Interactions ↑ cholesterol (S), acetone levels; ↓ catecholamines (U)

Drug Interactions

Substrate (minor) of CYP1A2, 2A6, 2B6, 2D6, 2E1, 3A4; **Inhibits** CYP1A2 (weak), 2A6 (weak), 2B6 (weak), 2C9 (weak), 2D6 (weak), 2E1 (strong), 3A4 (weak)

Benzodiazepines: Disulfiram may increase serum concentrations of benzodiazepines; includes only benzodiazepines which undergo oxidative metabolism (all but oxazepam, lorazepam, temazepam).

Cocaine: Disulfiram may increase serum concentrations of cocaine; avoid concurrent use.

Co-trimoxazole: Intravenous trimethoprim-sulfamethoxazole contains 10% ethanol as a solubilizing agent and may interact with disulfiram; monitor for disulfiram reaction.

CYP2E1 substrates: Disulfiram may increase the levels/effects of CYP2E1 substrates. Example substrates include inhalational anesthetics, theophylline, and trimethadione.

Diphenhydramine: Syrup contains ethanol, avoid use of syrup; monitor for disulfiram reaction.

Ethanol: Disulfiram results in severe ethanol intolerance (disulfiram reaction) secondary to disulfiram's ability to inhibit aldehyde dehydrogenase; this combination should be avoided. Pharmaceutical products should be evaluated for possible inclusion of ethanol (eg, elixirs).

Isoniazid: Concurrent use with disulfiram may result in adverse CNS effects; this combination should be avoided.

MAO inhibitors: Concurrent use with disulfiram may result in adverse CNS effects; this combination should be avoided.

Metronidazole: Concurrent use with disulfiram may result in adverse CNS effects; this combination should be avoided.

Omeprazole: May cause CNS adverse effects (limited documentation); monitor.

Phenytoin: Disulfiram may increase theophylline serum concentrations; toxicity may occur.

Theophylline: Disulfiram may increase theophylline serum concentrations; toxicity may occur.

Tricyclic antidepressants: Disulfiram may increase adverse CNS effects; monitor for acute changes in mental status.

Warfarin: Disulfiram inhibits the metabolism of warfarin resulting in an increased hypoprothrombinemic response; avoid when possible or monitor INR closely and adjust warfarin dosage.

Pregnancy Risk Factor C

Pregnancy Implications Increased incidence of clubfoot, limb reduction, vertebral fusion have been reported

Lactation Excretion in breast milk unknown

Nursing Implications Administration of any medications containing alcohol including topicals is contraindicated

Docetaxel

Related Information

- Paclitaxel

CAS Number 114977-28-5; 148408-66-6

U.S. Brand Names Taxotere®

Synonyms NSC-628503; RP-6976

Use Treatment of locally-advanced or metastatic breast cancer, after failure of prior chemotherapy; treatment of locally-advanced or metastatic nonsmall cell lung cancer (NSCLC) after failure of prior platinum-based chemotherapy; in combination with cisplatin in treatment of patients who have not previously received chemotherapy for unresected NSCLC

Unlabeled/Investigational Use: Treatment of pancreatic, head and neck, and ovarian cancers, soft tissue sarcoma, and melanoma

Mechanism of Action Semisynthetic agent prepared from a noncytotoxic precursor which is extracted from the needles of the European Yew *Taxus baccata*. Docetaxel differs structurally from the prototype taxoid, paclitaxel, by substitutions at the C-10 and C-5 positions. It is an antimicrotubule agent, but exhibits a unique mechanism of action. Unlike other antimicrotubule agents that induce microtubule disassembly (eg, vinca alkaloids and colchicine), docetaxel promotes the assembly of microtubules from tubulin dimers, and inhibits the depolymerization of tubulin which leads to bundles of microtubules in the cell.

Adverse Reactions

Note: Frequencies cited for nonsmall cell lung cancer and breast cancer treatment. Exact frequency may vary based on tumor type, prior treatment, premedication, and dosage of docetaxel.

Cardiovascular: **Fluid retention, including peripheral edema, pleural effusions, and ascites (33% to 47%)**; may be more common at cumulative doses ≥ 400 mg/m² (up to 64% in breast cancer patients with dexamethasone premedication); hypotension, arrhythmias, atrial fibrillation, MI

Central nervous system: Confusion, loss of consciousness (transient), seizures

Dermatologic: **Alopecia (56% to 76%)**; **nail disorder (11% to 31%, banding, onycholysis, hypo- or hyperpigmentation)**, rash, skin eruptions, erythema multiforme, radiation recall, Stevens-Johnson syndrome

Endocrine & metabolic: Dehydration

Gastrointestinal: **Mucositis/stomatitis (26% to 42%, severe in 6% to 7%)**, may be dose-limiting (premedication may reduce frequency and severity); **nausea and vomiting (40% to 80%, severe in 1% to 5%)**; **diarrhea (33% to 43%)**, taste perversion, gastrointestinal hemorrhage, gastrointestinal obstruction, gastrointestinal perforation, ileus, ischemic colitis, neutropenic enterocolitis

Hematologic: **Myelosuppression, neutropenia (75% to 85%), thrombocytopenia, anemia**

Onset: 4-7 days

Nadir: 5-9 days

Recovery: 21 days

Hepatic: **Transaminase levels increased**, bilirubin increased, hepatitis

Neuromuscular & skeletal: **Neurosensory changes (paresthesia, dysesthesia, pain) noted in 23% to 49% (severe in up to 6%). Motor neuropathy, including weakness**, noted in as many as 16% of lung cancer patients (severe in up to 5%); **myalgia (3% to 21%)**, arthralgia. Neuropathy may be more common at higher cumulative docetaxel dosages or with prior cisplatin therapy.

Ocular: Lacrimal duct obstruction, visual disturbances

Respiratory: Acute respiratory distress syndrome (ARDS), interstitial pneumonia, pulmonary edema, pulmonary embolism, pulmonary fibrosis

Miscellaneous: **Hypersensitivity reactions (6% to 13%; angioedema, rash, flushing, fever, hypotension)**; frequency substantially reduced by premedication with dexamethasone starting one day prior to docetaxel administration; infusion site reactions

Pharmacodynamics/Kinetics

Administered by I.V. infusion and exhibits linear pharmacokinetics at the recommended dosage range

Distribution: V_d: 12-16 L/kg. Exhibits a triphasic decline in plasma concentrations. Initial rapid decline represents distribution to the peripheral compartment and the terminal phase reflects a relatively slow efflux of docetaxel from the peripheral compartment. Mean steady state: 36.6-95.6 L/m², indicating extensive extravascular distribution and/or tissue binding. Mean steady state volume of distribution is 113 liters.

Protein binding: 94% mainly to alpha₁-acid glycoprotein, albumin, and lipoproteins

Metabolism: Oxidative metabolism by the liver; isoenzymes of cytochrome P450 (CYP3A) are involved in metabolism

Half-life: α , β , and γ phases: 4 minutes, 36 minutes, and 11.1 hours, respectively

Elimination: Following oxidative metabolism, docetaxel is eliminated in both urine (6%) and feces (75%) with approximately 80% eliminated in the first 48 hours

Mean values for total body clearance: 21 L/hour/m²

Dosage

Adults: I.V. infusion: Refer to individual protocols:

Breast cancer (locally-advanced or metastatic): 60-100 mg/m² over 1 hour every 3 weeks; patients initially started at 60 mg/m² who do not develop toxicity may tolerate higher doses

Nonsmall-cell lung cancer: I.V.: 75 mg/m² over 1 hour every 3 weeks

Dosing adjustment for toxicity:

Note: Toxicity includes febrile neutropenia, neutrophils ≤ 500 /mm³ for > 1 week, severe or cumulative cutaneous reactions; in nonsmall cell lung cancer, this may also include other grade 3/4 nonhematologic toxicities.

Breast cancer: Patients dosed initially at 100 mg/m²; reduce dose to 75 mg/m²; **Note:** If the patient continues to experience these adverse reactions, the dosage should be reduced to 55 mg/m² or therapy should be discontinued

Nonsmall cell lung cancer:

Monotherapy: Patients dosed initially at 75 mg/m² should have dose held until toxicity is resolved, then resume at 55 mg/m²; discontinue patients who develop \geq grade 3 peripheral neuropathy.

Combination therapy: Patients dosed initially at 75 mg/m², in combination with cisplatin, should have the docetaxel dosage reduced to 65 mg/m² in subsequent cycles; if further adjustment is required, dosage may be reduced to 50 mg/m²

Dosing adjustment in hepatic impairment: Total bilirubin \geq the upper limit of normal (ULN), or AST/ALT > 1.5 times the ULN concomitant with alkaline phosphatase > 2.5 times the ULN: Docetaxel **should not be administered.**

Stability

Store intact vials at 2°C to 25°C (36°F to 77°F) and protect from light. Intact vials of solution should be further diluted with 13% (w/w) ethanol/water to a final concentration of 10 mg/mL. Do not shake. Initial diluted solution is stable for 8 hours at room temperature or under refrigeration. Docetaxel dose should be further diluted with 0.9% sodium chloride or 5% dextrose in water to a final concentration of 0.3-0.9 mg/mL and must be prepared in a glass bottle, polypropylene, or polyolefin plastic bag to prevent leaching of plasticizers.

Non-PVC tubing **must** be used. Diluted solutions are stable for up to 4 weeks at room temperature 15°C to 25°C (59°F to 77°F) in polyolefin containers. (Thiesen J and Kramer I, *Pharm World Sci*, 1999, 21(3): 137-41.)

Although the stability of some antineoplastic agents may be long, it is probably considered good pharmaceutical practice to allow a maximum expiration dating of 24 hours due to possible sterility concerns. The manufacturer recommends use within 4 hours.

Monitoring Parameters Monitor for hypersensitivity reactions and fluid retention

Administration

Anaphylactoid-like reactions have been reported: Premedication with dexamethasone (4-8 mg orally twice daily for 3 or 5 days starting 1 day prior to administration of docetaxel).

Administer I.V. infusion over 1-hour through nonsorbing (nonpolyvinylchloride) tubing; in-line filter is not necessary. When administered as sequential infusions, taxane derivatives should be administered before platinum derivatives (cisplatin, carboplatin) to limit myelosuppression and to enhance efficacy.

Contraindications Hypersensitivity to docetaxel or any component of the formulation; prior hypersensitivity to medications containing polysorbate 80; pre-existing bone marrow suppression (neutrophils < 1500 cells/mm³); pregnancy

Warnings

Hazardous agent – use appropriate precautions for handling and disposal.

[U.S. Boxed Warnings]: Use caution in hepatic disease; avoid use in patients with bilirubin exceeding upper limit of normal (ULN) or AST and/or ALT > 1.5 times ULN in conjunction with alkaline phosphatase > 2.5 times ULN; patients with abnormal liver function are at increased risk of treatment-related adverse events. Severe hypersensitivity reactions characterized by hypotension, bronchospasms, anaphylaxis, or minor reactions characterized by generalized rash/erythema may occur. Fluid retention syndrome characterized by pleural effusions, ascites, edema, and weight gain (2-15 kg) has also been reported. The incidence and severity of the syndrome increase sharply at cumulative doses ≥ 400 mg/m². Patients should be premedicated with a corticosteroid to prevent hypersensitivity reactions and fluid retention; severity is reduced with dexamethasone premedication starting one day prior to docetaxel administration.

Neutropenia is the dose-limiting toxicity; however, this rarely results in treatment delays and prophylactic colony stimulating factors have not been routinely used. **[U.S. Boxed Warning]: Patients with abnormal liver function, those receiving higher doses and patients with nonsmall cell lung cancer and a history of prior treatment with platinum derivatives who receive docetaxel doses higher than 100 mg/m² are at higher risk for treatment-related mortality.** Patients with increased liver function tests experienced more episodes of neutropenia with a greater number of severe infections. **[U.S. Boxed Warning]: Patients with an absolute neutrophil count < 1500 cells/mm³ should not receive docetaxel.** When administered as sequential infusions, taxane derivatives (docetaxel, paclitaxel) should be administered before platinum derivatives (carboplatin, cisplatin) to limit myelosuppression and to enhance efficacy.

Cutaneous reactions including erythema and desquamation have been reported; may require dose reduction. Dosage adjustment is recommended with severe neurosensory symptoms (paresthesia, dysesthesia, pain). **[U.S. Boxed Warning]: Should be administered under the supervision of an experienced cancer chemotherapy physician.** Safety and efficacy in children < 16 years of age have not been established.

Dosage Forms Injection, solution [concentrate]:

Taxotere®: 20 mg/0.5 mL (0.5 mL, 2 mL) [contains Polysorbate 80®; diluent contains ethanol 13%]

Overdosage/Treatment Supportive therapy: Extravasation of docetaxel does not usually cause significant injury. Hypersensitivity reactions should be treated with standard therapy.

Drug Interactions **Substrate** of CYP3A4 (major); **Inhibits** CYP3A4 (weak)

Antifungal agents (imidazole): Imidazole antifungal agents may decrease the metabolism (via CYP isoenzymes) of docetaxel; avoid concurrent use. Carboplatin, cisplatin (platinum derivatives): When administered as sequential infusions, taxane derivatives should be administered before platinum derivatives to limit myelosuppression.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of docetaxel. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

DOCUSATE

CYP3A4 inhibitors: May increase the levels/effects of docetaxel. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Pregnancy Risk Factor D

Pregnancy Implications Animal studies have demonstrated embryotoxicity, fetal toxicity, and maternal toxicity. There are no adequate and well-controlled studies in pregnant women; however, fetal harm may occur. Women of childbearing potential should avoid becoming pregnant. A pregnancy registry is available for all cancers diagnosed during pregnancy at Cooper Health (856-757-7876).

Lactation Excretion in breast milk unknown/contraindicated

Additional Information St John's wort may decrease docetaxel levels.

Specific References

Behrens RJ, Gulley JL, and Dahut WL, "Pulmonary Toxicity During Prostate Cancer Treatment with Docetaxel and Thalidomide," *Am J Ther*, 2003, 10(3):228-32.

Docosate

CAS Number 128-49-4; 577-11-7; 7491-09-0

U.S. Brand Names Colace[®] [OTC]; D-S-S[®] [OTC]; Diacto[®] [OTC]; Docusoft-S[™] [OTC]; DOS[®] [OTC]; ex-lax[®] Stool Softener [OTC]; Fleet[®] Sof-Lax[®] [OTC]; Genasoft[®] [OTC]; Phillips[®] Stool Softener Laxative [OTC]; Surfak[®] [OTC]

Synonyms Dioctyl Calcium Sulfosuccinate; Dioctyl Sodium Sulfosuccinate; Docusate Calcium; Docusate Potassium; Docusate Sodium; DOSS; DSS

Use Stool softener in patients who should avoid straining during defecation and constipation associated with hard, dry stools

Unlabeled/Investigational Use Ceruminolytic

Mechanism of Action An emollient laxative which reduces surface tension of the oil-water interface of the stool resulting in enhanced incorporation of water and fat allowing for stool softening; also promotes intestinal secretion of potassium, water, sodium, and chloride

Adverse Reactions Gastrointestinal: Intestinal obstruction, diarrhea, abdominal cramping, throat irritation

Signs and Symptoms of Overdose Abdominal cramps, diarrhea, fluid loss, hypokalemia, hypomagnesemia, nausea, vomiting

Pharmacodynamics/Kinetics

Onset of action: 12-72 hours

Excretion: Feces

Dosage Docusate salts are interchangeable; the amount of sodium or calcium per dosage unit is clinically insignificant

Infants and Children <3 years: Oral: 10-40 mg/day in 1-4 divided doses

Children: Oral:

3-6 years: 20-60 mg/day in 1-4 divided doses

6-12 years: 40-150 mg/day in 1-4 divided doses

Adolescents and Adults: Oral: 50-500 mg/day in 1-4 divided doses

Older Children and Adults: Rectal: Add 50-100 mg of docusate liquid to enema fluid (saline or water); administer as retention or flushing enema
Ceruminolytic (unlabeled use): Intra-aural: Administer 1 mL of docusate sodium in 2 mL syringes; if no clearance in 15 minutes, irrigate with 50-100 mL normal saline (this method is 80% effective)

Stability

Store intact vials at 2°C to 25°C (36°F to 77°F) and protect from light. Intact vials of solution should be further diluted with 13% (w/w) ethanol/water to a final concentration of 10 mg/mL. Do not shake. Initial diluted solution is stable for 8 hours at room temperature or under refrigeration.

Docetaxel dose should be further diluted with 0.9% sodium chloride or 5% dextrose in water to a final concentration of 0.3-0.9 mg/mL and must be prepared in a glass bottle, polypropylene, or polyolefin plastic bag to prevent leaching of plasticizers.

Non-PVC tubing **must** be used. Diluted solutions are stable for up to 4 weeks at room temperature 15°C to 25°C (59°F to 77°F) in polyolefin containers. (Thiesen J and Kramer I, *Pharm World Sci*, 1999, 21(3):137-41.)

Although the stability of some antineoplastic agents may be long, it is probably considered good pharmaceutical practice to allow a maximum expiration dating of 24 hours due to possible sterility concerns. The manufacturer recommends using within 4 hours.

Administration Anaphylactoid-like reactions have been reported:

Premedication with dexamethasone (8 mg orally twice daily for 3 or 5 days starting 1 day prior to administration of docetaxel).

Administer I.V. infusion over 1-hour. When administered as sequential infusions, taxane derivatives should be administered before platinum derivatives (cisplatin, carboplatin) to limit myelosuppression and to enhance efficacy.

Contraindications Hypersensitivity to docusate or any component of the formulation; concomitant use of mineral oil; intestinal obstruction, acute abdominal pain, nausea, or vomiting

Warnings Prolonged, frequent or excessive use may result in dependence or electrolyte imbalance

Dosage Forms Capsule, as calcium (Surfak[®]): 240 mg

Capsule, as sodium: 100 mg, 250 mg

Colace[®]: 50 mg [contains sodium 3 mg], 100 mg [contains sodium 5 mg]

Docusoft-S[™]: 100 mg [contains sodium 5 mg]

DOK[™], Genasoft[®]: 100 mg

DOS[®], D-S-S[®]: 100 mg, 250 mg

Dulcolax[®] Stool Softener: 100 mg [contains sodium 5 mg]

Phillips[®] Stool Softener Laxative: 100 mg [contains sodium 5.2 mg]

Enema, rectal, as sodium (Enemeez[®]): 283 mg/5 mL 5 mL

Gelcap, as sodium (Fleet[®] Sof-Lax[®]): 100 mg

Liquid, as sodium: 150 mg/15 mL (480 mL)

Colace[®]: 150 mg/15 mL (30 mL) [contains sodium 1 mg/mL]

Diacto[®]: 150 mg/15 mL (480 mL) [vanilla flavor]

Silace: 150 mg/15 mL (480 mL) [lemon-vanilla flavor]

Syrup, as sodium: 60 mg/15 mL (480 mL)

Colace[®], Diacto[®]: 60 mg/15 mL (480 mL) [alcohol free, sugar free; contains sodium 36 mg/5 mL]

Silace: 20 mg/5 mL (480 mL) [peppermint flavor]

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal without a cathartic

Supportive therapy: I.V. fluid and electrolyte replacement; restrict solid food

Test Interactions ↑ transaminases; ↓ potassium (S), chloride (S)

Pregnancy Risk Factor C

Pregnancy Implications Can cause hypomagnesemia in the neonate; no evidence for congenital malformations

Lactation Excretion in breast milk unknown/compatible

Nursing Implications Docusate liquid should be given with milk, fruit juice, or infant formula to mask the bitter taste

Additional Information Docusate sodium 5-10 mg/mL liquid instilled in the ear as a ceruminolytic produces substantial ear wax disintegration within 15 minutes and complete disintegration after 24 hours. A safe agent to be used in elderly; some evidence that doses <200 mg are ineffective; stool softeners are unnecessary if stool is well hydrated or "mushy" and soft; shown to be ineffective used long-term.

Dofetilide

U.S. Brand Names Tikosyn[™]

Use Prevention and treatment of fibrillation (atrial), flutter (atrial), paroxysmal tachycardia (ventricular), tachycardia (ventricular), fibrillation (ventricular); used in conjunction of implantable defibrillator

Mechanism of Action Selective class III antiarrhythmic agent (investigational agent undergoing phase III trials in U.S.); more potent than sotalol, it causes selective blockade of potassium channels in the myocardium that prolongs ventricular refractoriness

Adverse Reactions Cardiovascular: Prolongs QT intervals on ECG (dose dependent), possible increase in incidence of torsade de pointes (4% to 8%), sinus bradycardia

Pharmacodynamics/Kinetics

Absorption: >90%

Distribution: V_d: 3 L/kg

Protein binding: 60% to 70%

Metabolism: Hepatic via CYP3A4, but low affinity for it; metabolites formed by N-dealkylation and N-oxidation

Bioavailability: >90%

Half-life elimination: 10 hours

Time to peak: Fasting: 2-3 hours

Excretion: Urine (80%, 80% as unchanged drug, 20% as inactive or minimally active metabolites); renal elimination consists of glomerular filtration and active tubular secretion via cationic transport system

Dosage Oral: 0.25-1 mg twice daily in patients with sustained tachycardia (ventricular) (lower dose in patients with renal insufficiency)

I.V.:

Supraventricular tachycardia: 1-10 mcg/kg over 15 minutes followed by 0.12-0.5 mcg/kg maintenance infusion

Ventricular arrhythmia: 1.5-15 mcg/kg

Monitoring Parameters ECG monitoring with attention to QT_c and occurrence of ventricular arrhythmias, baseline serum creatinine and changes in serum creatinine. Check serum potassium and magnesium levels if on medications where these electrolyte disturbances can occur, or if patient has a history of hypokalemia or hypomagnesemia. QT or QT_c must be monitored at specific times prior to the first dose and during the first 3 days of therapy. Thereafter, QT or QT_c and creatinine clearance must be evaluated at 3-month intervals.

Administration Do not open capsules.

Contraindications Hypersensitivity to dofetilide or any component of the formulation; patients with congenital or acquired long QT syndromes, do not use if a baseline QT interval or QT_c is >440 msec (500 msec in patients with ventricular conduction abnormalities); severe renal impairment (estimated Cl_{cr} <20 mL/minute); concurrent use with verapamil, cimetidine, hydrochlorothiazide (alone or in combinations), trimethoprim (alone or in combination with sulfamethoxazole), itraconazole, ketoconazole,

zole, prochlorperazine, or megestrol; baseline heart rate <50 beats/minute; other drugs that prolong QT intervals (phenothiazines, cisapride, bepridil, tricyclic antidepressants, sparfloxacin, gatifloxacin, moxifloxacin; hypokalemia or hypomagnesemia; concurrent amiodarone, clarithromycin, or erythromycin

Warnings

[U.S. Boxed Warning]: Must be initiated (or reinitiated) in a setting with continuous monitoring and staff familiar with the recognition and treatment of life-threatening arrhythmias. Patients must be monitored with continuous ECG for a minimum of 3 days, or for a minimum of 12 hours after electrical or pharmacological cardioversion to normal sinus rhythm, whichever is greater. Patients should be readmitted for continuous monitoring if dosage is later increased.

Reserve for patients who are highly symptomatic with atrial fibrillation/atrial flutter; torsade de pointes significantly increases with doses >500 mcg twice daily; hold class I or class III antiarrhythmics for at least three half-lives prior to starting dofetilide; use in patients on amiodarone therapy only if serum amiodarone level is <0.3 mg/L or if amiodarone was stopped for >3 months previously; correct hypokalemia or hypomagnesemia before initiating dofetilide and maintain within normal limits during treatment. Risk of hypokalemia and/or hypomagnesemia may be increased by potassium-depleting diuretics, increasing the risk of torsade de pointes. Concurrent use with other drugs known to prolong QT_c interval is not recommended.

Patients with sick sinus syndrome or with second or third-degree heart block should not receive dofetilide unless a functional pacemaker is in place. Defibrillation threshold is reduced in patients with ventricular tachycardia or ventricular fibrillation undergoing implantation of a cardioverter-defibrillator device. Safety and efficacy in children (<18 years old) have not been established. Use with caution in renal impairment; not recommended in patients receiving drugs which may compete for renal secretion via cationic transport. Use with caution in patients with severe hepatic impairment.

Dosage Forms Capsule: 125 mcg, 250 mcg, 500 mcg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal (for oral ingestion)

Supportive therapy: No human overdose experience since this agent inhibits intracellular potassium transport, agents such as glucose/insulin and hyperventilation may assist in creasing intracellular potassium concentrations; need to monitor for hypokalemia and torsade de pointes
Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Drug Interactions Substrate of CYP3A4 (minor)

If dofetilide needs to be discontinued to allow dosing of other potentially interacting drug(s) (see below), a washout period of at least 2 days is needed before starting the other drug(s).

Cimetidine, a cation transport system inhibitor, inhibits dofetilide's elimination and can cause a 58% increase in dofetilide's plasma levels; concomitant use is contraindicated.

Diuretics and other drugs (aminoglycosides) which deplete potassium and magnesium may increase dofetilide toxicity (torsade de pointes).

Concurrent use of hydrochlorothiazide is contraindicated.

Hydrochlorothiazide: May enhance the QT_c-prolonging effect of dofetilide. May increase serum concentration of dofetilide. Concurrent use is contraindicated.

Itraconazole: May decrease the metabolism of dofetilide. Concurrent use is contraindicated.

Ketoconazole increases dofetilide's C_{max} (53% males, 97% females) and the AUC (41% males, 69% females) when used concurrently; concomitant use is contraindicated.

QT_c-prolonging agents (including bepridil, cisapride, clarithromycin, erythromycin, tricyclic antidepressants, phenothiazines, sparfloxacin, gatifloxacin, moxifloxacin): Use is contraindicated.

Renal cationic transport inhibitors (including triamterene, metformin, amiloride, prochlorperazine, megestrol) may increase dofetilide levels; coadminister with caution.

Trimethoprim (alone or in combination with sulfamethoxazole) increases dofetilide's C_{max} (103%) and AUC (93%); concomitant use is contraindicated.

Verapamil causes an increase in dofetilide's peak plasma levels by 42%. In the supraventricular arrhythmia and a higher incidence of torsade de pointes was seen in patients on verapamil; concomitant use is contraindicated.

Pregnancy Risk Factor C

Pregnancy Implications Dofetilide has been shown to adversely affect *in utero* growth, organogenesis, and survival of rats and mice. There are no adequate and well-controlled studies in pregnant women. Dofetilide should be used with extreme caution in pregnant women and in women of childbearing age only when the benefit to the patient unequivocally justifies the potential risk to the fetus.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Increases myocardial refractoriness; peak onset of torsade de pointes is within 1 hour of I.V. use and within 2 hours of oral use

Donepezil

U.S. Brand Names Aricept®

Synonyms E2020

Use Treatment of mild to moderate dementia of the Alzheimer's type
Unlabeled/Investigational Use Attention-deficit/hyperactivity disorder (ADHD), behavioral syndromes in dementia

Mechanism of Action Alzheimer's disease is characterized by cholinergic deficiency in the cortex and basal forebrain, which contributes to cognitive deficits. Donepezil reversibly and noncompetitively inhibits centrally-active acetylcholinesterase, the enzyme responsible for hydrolysis of acetylcholine. This appears to result in increased concentrations of acetylcholine available for synaptic transmission in the central nervous system.

Adverse Reactions

Cardiovascular: Syncope, chest pain

Central nervous system: **Headache**, fatigue, insomnia, dizziness, depression, abnormal dreams, somnolence, seizures, paranoia

Dermatologic: Bruising

Gastrointestinal: **Nausea, diarrhea**, anorexia, vomiting, weight loss

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Muscle cramps, arthritis, body pain

Renal: Polyuria

Pharmacodynamics/Kinetics

Absorption: Well absorbed

Protein binding: 96%, primarily to albumin (75%) and α₁-acid glycoprotein (21%)

Metabolism: Extensively to four major metabolites (two are active) via CYP2D6 and 3A4; undergoes glucuronidation

Bioavailability: 100%

Half-life elimination: 70 hours; time to steady-state: 15 days

Time to peak, plasma: 3-4 hours

Excretion: Urine 57% (17% as unchanged drug); feces 15%

Dosage Oral:

Children: ADHD (unlabeled use): 5 mg/day

Adults: Dementia of Alzheimer's type: Initial: 5 mg/day at bedtime; may increase to 10 mg/day at bedtime after 4-6 weeks

Monitoring Parameters

Behavior, mood, bowel function

Administration

Aricept® ODT: Allow tablet to dissolve completely on tongue and follow with water.

Contraindications

Hypersensitivity to donepezil, piperidine derivatives, or any component of the formulation

Warnings Cholinesterase inhibitors may have vagotonic effects which may cause bradycardia and/or heart block with or without a history of cardiac disease; syncopal episodes have been associated with donepezil. Use with caution with sick sinus syndrome or other supraventricular cardiac conduction abnormalities, with seizures, COPD, or asthma. Use with caution in patients at risk of ulcer disease (ie, previous history or NSAID use), or in patients with bladder outlet obstruction. May cause diarrhea, nausea, and/or vomiting, which may be dose-related.

Dosage Forms Tablet, as hydrochloride (Aricept®): 5 mg, 10 mg
Tablet, orally disintegrating, as hydrochloride (Aricept® ODT): 5 mg, 10 mg

Reference Range Following a 5 mg oral dosing regimen, steady-state plasma donepezil concentration is ~30 ng/mL

Overdosage/Treatment

Decontamination: Lavage within 1 hour/activated charcoal

Supportive therapy: Atropine can be used to treat bradycardia

Drug Interactions Substrate (minor) of CYP2D6, 3A4

Anticholinergic agents: Effects of donepezil may be inhibited by anticholinergic agents (benztropine)

Antipsychotic agents: Acetylcholinesterase inhibitors (central) may increase the risk of antipsychotic-related extrapyramidal symptoms; monitor.

Cholinergic agents: A synergistic effect may be seen with concurrent administration of succinylcholine or cholinergic agonists (bethanechol); excessive cholinergic stimulation and toxicity may occur; use caution.

Cocaine may prolong or potentiate cocaine activity.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic effects were not observed in animal studies. There are no adequate and well-controlled studies in pregnant women.

Lactation Excretion in breast milk unknown/not recommended

Dornase Alfa

U.S. Brand Names Pulmozyme®

Synonyms DNase; Recombinant Human Deoxyribonuclease

Use Management of cystic fibrosis patients to reduce the frequency of respiratory infections that require parenteral antibiotics, and to improve pulmonary function

Unlabeled/Investigational Use Treatment of chronic bronchitis

Mechanism of Action The hallmark of cystic fibrosis lung disease is the presence of abundant, purulent airway secretions composed primarily of highly polymerized DNA. The principal source of this DNA is the nuclei of degenerating neutrophils, which is present in large concentrations in infected lung secretions. The presence of this DNA produces a viscous mucous that may contribute to the decreased mucociliary transport and persistent infections that are commonly seen in this population. Dornase alfa is a deoxyribonuclease (DNA) enzyme produced by recombinant gene technology. Dornase selectively cleaves DNA, thus reducing mucous viscosity and, as a result, airflow in the lung is improved and the risk of bacterial infection may be decreased. Pulmonary function improves after 3 days of use.

Adverse Reactions

Cardiovascular: **Chest pain**, angina

Dermatologic: **Rash**

Ocular: Conjunctivitis

Respiratory: Cough, dyspnea, **pharyngitis**, laryngitis, hoarse throat, wheezing, rhinitis, hemoptysis

Miscellaneous: **Voice alteration** (most noted in female patients)

Pharmacodynamics/Kinetics

Onset of action: Nebulization: Enzyme levels are measured in sputum in ~15 minutes

Duration: Rapidly declines

Dosage Children >5 years and Adults: Inhalation: 2.5 mg once daily through selected nebulizers in conjunction with a Pulmo-Aide® or a Pari-Proneb® compressor

Stability Must be stored in the refrigerator at 2°C to 8°C (36°F to 46°F) and protected from strong light; should not be exposed to room temperature for a total of 24 hours

Administration Nebulization: Should not be diluted or mixed with any other drugs in the nebulizer, this may inactivate the drug

Contraindications Hypersensitivity to dornase alfa, Chinese hamster ovary cell products (eg, epoetin alfa), or any component of the formulation

Warnings No clinical trials have been conducted to demonstrate safety and effectiveness of dornase in patients with pulmonary function <40% of normal or in patients for longer treatment periods >12 months; no data exists regarding safety during lactation

Dosage Forms Solution for nebulization: 1 mg/mL (2.5 mL)

Overdosage/Treatment Supportive therapy: 100% humidified oxygen; beta agonist bronchodilation for wheezing

Drug Interactions Dornase alfa can be effectively and safely used in conjunction with standard CF therapies including oral, inhaled, and parenteral antibiotics, bronchodilators, enzyme supplements, vitamins, oral and inhaled corticosteroids, and analgesics. No formal drug interaction studies have been performed.

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown

Nursing Implications Should not be diluted or mixed with any other drugs in the nebulizer, this may inactivate the drug

Doxazosin

CAS Number 74191-85-8; 77883-43-3

U.S. Brand Names Cardura®

Synonyms Doxazosin Mesylate

Use Alpha-blocking agent for treatment of hypertension; treatment of benign prostatic hyperplasia (BPH)

Mechanism of Action Doxazosin is a long-acting selective inhibitor of postjunctional α_1 -adrenoceptors as demonstrated in isolated animal tissues and anesthetized healthy animals. Doxazosin is a water soluble quinazoline analogue of prazosin, and on a weight-for-weight basis is approximately half as potent as prazosin in postsynaptic α_1 -adrenoceptor inhibition in animals and man. Inhibition of these α_1 -adrenergic receptors in the peripheral vasculature prevents vasoconstriction from adrenergic stimulation; therefore, allowing vasodilation and a reduction in blood pressure. Because of doxazosin's and similar α_1 -adrenergic blockers specificity, they preserve feedback control of transmitter norepinephrine release and, therefore, cause minimal reflex activation.

Adverse Reactions

Cardiovascular: Palpitations, arrhythmia, orthostatic hypotension (dose-related), hypotension, tachycardia, edema, chest pain, syncope, flushing, angina, bradycardia, myocardial infarction, pallor, peripheral ischemia

Central nervous system: **Dizziness**, **headache**, vertigo, nervousness, somnolence, anxiety, depression, ataxia, abnormal thinking, agitation, amnesia, confusion, depersonalization, emotional lability, fever, hyp-

oesthesia, impaired concentration, migraine, paranoia, paresis, stroke, fatigue, insomnia

Dermatologic: Alopecia, xerosis, urticaria, purpura, pruritus, licheniform eruptions, exanthem, rash, eczema,

Endocrine & metabolic: Decreased libido, sexual dysfunction, breast pain, gout, hot flashes, hypokalemia, gynecomastia, lymphadenopathy, impotence

Gastrointestinal: Nausea, vomiting, xerostomia, diarrhea, constipation, abdominal discomfort, flatulence, anorexia, fecal incontinence, gastroenteritis, taste perversion, weight gain, weight loss, dyspepsia

Genitourinary: Incontinence, polyuria, priapism, enuresis, micturition abnormality, nocturia, urinary tract infection

Hematologic: Leukopenia, thrombocytopenia

Hepatic: Cholestasis, hepatitis

Neuromuscular & skeletal: Back pain; paresthesia, movement disorder, hypertonia, weakness, myalgia, muscle cramps, rigors, twitching, cataplexy, arthritis

Ocular: Abnormal vision, conjunctivitis, abnormal lacrimation, photophobia

Otic: Tinnitus, earache, parosmia

Renal: Renal calculus, hematuria

Respiratory: Rhinitis, dyspnea, sinusitis, epistaxis, bronchospasm, coughing, pharyngitis

Miscellaneous: Systemic lupus erythematosus, flu-like syndrome, diaphoresis, infection, thirst, allergic reaction

Signs and Symptoms of Overdose Drowsiness, lightheadedness, severe hypotension, tachycardia

Pharmacodynamics/Kinetics

Not significantly affected by increased age

Duration: >24 hours

Protein binding: Extended release: 98%

Metabolism: Extensively hepatic to active metabolites; primarily via CYP3A4; secondary pathways involve CYP2D6 and 2C19

Bioavailability: Extended release relative to immediate release: 54% to 59%

Half-life elimination: 15-22 hours

Time to peak, serum: Immediate release: 2-3 hours; extended release: 8-9 hours

Excretion: Feces (63% primarily as metabolites); urine (9%)

Dosage Oral:

Adults: 1 mg once daily in morning or evening; may be increased to 2 mg once daily. Thereafter titrate upwards, if needed, over several weeks, balancing therapeutic benefit with doxazosin-induced postural hypotension

Hypertension: Maximum dose: 16 mg/day

BPH: Goal: 4-8 mg/day; maximum dose: 8 mg/day

Elderly: Initial: 0.5 mg once daily

Monitoring Parameters

Blood pressure, standing and sitting/supine

Administration Cardura® XL: Tablets should be swallowed whole; do not crush, chew, or divide.

Contraindications Hypersensitivity to quinazolines (prazosin, terazosin), doxazosin, or any component of the formulation

Warnings

Can cause significant orthostatic hypotension and syncope, especially with first dose; anticipate a similar effect if therapy is interrupted for a few days, if dosage is rapidly increased, or if another antihypertensive drug (particularly vasodilators) or a PDE5 inhibitor is introduced. Patients should be cautioned about performing hazardous tasks when starting new therapy or adjusting dosage upward. Prostate cancer should be ruled out before starting for BPH. Use with caution in mild to moderate hepatic impairment; not recommended in severe dysfunction. Intraoperative floppy iris syndrome has been observed in cataract surgery patients who were on or were previously treated with alpha1 blockers. Causality has not been established and there appears to be no benefit in discontinuing alpha blocker therapy prior to surgery. Safety and efficacy in children have not been established.

The extended release formulation consists of drug within a nondeformable matrix; following drug release/absorption, the matrix/shell is expelled in the stool. The use of nondeformable products in patients with known stricture/narrowing of the GI tract has been associated with symptoms of obstruction. Use caution in patients with increased GI retention (eg, chronic constipation) as doxazosin exposure may be increased. Extended release formulation is not approved for the treatment of hypertension.

Dosage Forms Tablet: 1 mg, 2 mg, 4 mg, 8 mg

Cardura®: 1 mg, 2 mg, 4 mg, 8 mg

Tablet, extended release:

Cardura® XL: 4 mg, 8 mg

Reference Range 8 mg dose is associated with a serum level of 60 ng/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Treatment is supportive with fluids; use only pure alpha-adrenergic pressors for hypotension (norepinephrine, phenylephrine); dobutamine may also be helpful

Enhancement of elimination: Multiple dose of activated charcoal may be effective; not removed by dialysis

Antidote(s)

- DOBUTamine [ANTIDOTE]

Drug Interactions ACE inhibitors: Hypotensive effect (particularly orthostasis) may be increased.

Beta-blockers: Hypotensive effect may be increased.

Calcium channel blockers: Hypotensive effect may be increased.

Phosphodiesterase-5 (PDE5) inhibitors (eg, sildenafil, tadalafil, vardenafil): Blood pressure-lowering effects are additive. Use with caution and monitor.

Pregnancy Risk Factor C

Pregnancy Implications Some studies demonstrated embryolethality resulting from doxazosin exposure during organogenesis. Delayed post-natal development was also noted. There are no adequate and well-controlled studies in pregnant women. Use only if benefit outweighs risk.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Syncope may occur (usually within 90 minutes of the initial dose)

Specific References

McConnell JD, Roehrborn CG, Bautista OM, et al, "The Long-Term Effect of Doxazosin, Finasteride, and Combination Therapy on the Clinical Progression of Benign Prostatic Hyperplasia: Medical Therapy of Prostatic Symptoms (MTOPS) Research Group," *N Engl J Med*, 2003, 349(25):2387-98.

Doxepin

Related Information

- Anticholinergic Effects of Common Psychotropics
- Antidepressant Agents
- Therapeutic Drugs Associated with Hallucinations

CAS Number 1229-29-4; 1668-19-5; 25127-31-5; 4698-39-9

U.S. Brand Names Prudoxin™; Sinequan®; Zonalon®

Synonyms Doxepin Hydrochloride

Impairment Potential Yes. Single oral dose of 25 mg can prolong choice reaction time. (Stromberg C, Seppala T, and Mattila MJ, "Acute Effects of Maprotiline, Doxepin, and Zimeldine with Alcohol in Healthy Volunteers," *Arch Int Pharmacodyn Ther*, 1988, 291:217-28.)

Use

Oral: Depression

Topical: Short-term (<8 days) management of moderate pruritus in adults with atopic dermatitis or lichen simplex chronicus

Unlabeled/Investigational Use Analgesic for certain chronic and neuropathic pain; anxiety

Mechanism of Action Increases the synaptic concentration of serotonin and/or norepinephrine in the central nervous system by inhibition of their reuptake by the presynaptic neuronal membrane; also an H₂-receptor antagonist

Adverse Reactions

Oral: Frequency not defined.

Cardiovascular: Hypotension, hypertension, tachycardia

Central nervous system: Drowsiness, dizziness, headache, disorientation, ataxia, confusion, seizure

Dermatologic: Alopecia, photosensitivity, rash, pruritus

Endocrine & metabolic: Breast enlargement, galactorrhea, SIADH, increase or decrease in blood sugar, increased or decreased libido

Gastrointestinal: Xerostomia, constipation, vomiting, indigestion, anorexia, aphthous stomatitis, nausea, unpleasant taste, weight gain, diarrhea, trouble with gums, decreased lower esophageal sphincter tone may cause GE reflux

Genitourinary: Urinary retention, testicular edema

Hematologic: Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, purpura

Neuromuscular & skeletal: Weakness, tremors, numbness, paresthesia, extrapyramidal symptoms, tardive dyskinesia

Ocular: Blurred vision

Otic: Tinnitus

Miscellaneous: Diaphoresis (excessive), allergic reactions

Topical:

Cardiovascular: Edema

Central nervous system: **Drowsiness (22%)**, anxiety, dizziness, emotional changes

Dermatologic: **Stinging/burning (23%)**, contact dermatitis

Gastrointestinal: **Xerostomia**, taste alteration, tongue numbness

Signs and Symptoms of Overdose Ataxia, confusion, cyanosis, dental erosion, ejaculatory disturbances, extrapyramidal reaction, galactorrhea, gynecomastia, hallucinations, hypoglycemia, myoglobinuria, hypotension, hypothermia, nystagmus, photosensitivity, priapism, QT prolongation, respiratory depression, rhabdomyolysis, seizures, tachycardia, urinary retention

Pharmacodynamics/Kinetics

Onset of action: Peak effect: Antidepressant: Usually >2 weeks;

Anxiolytic: may occur sooner

Absorption: Following topical application, plasma levels may be similar to those achieved with oral administration

Distribution: Crosses placenta; enters breast milk

Protein binding: 80% to 85%

Metabolism: Hepatic; metabolites include desmethyldoxepin (active)

Half-life elimination: Adults: 6-8 hours

Excretion: Urine

Dosage Oral (entire daily dose may be given at bedtime): Depression or anxiety (unlabeled use):

Children: 1-3 mg/kg/day in single or divided doses

Adolescents: Initial: 25-50 mg/day in single or divided doses; gradually increase to 100 mg/day

Adults: Initial: 30-150 mg/day at bedtime or in 2-3 divided doses; may gradually increase up to 300 mg/day; single dose should not exceed 150 mg; select patients may respond to 25-50 mg/day

Elderly: Use a lower dose and adjust gradually

Dosing adjustment in hepatic impairment: Use a lower dose and adjust gradually

Topical: Pruritus: Adults and Elderly: Apply a thin film 4 times/day with at least 3- to 4-hour interval between applications; not recommended for use >8 days. **Note:** Low-dose (25-50 mg) oral administration has also been used to treat pruritus, but systemic effects are increased.

Stability Protect from light

Monitoring Parameters Monitor blood pressure and pulse rate prior to and during initial therapy; monitor mental status, weight; ECG in older adults; adverse effects may be increased if topical formulation is applied to >10% of body surface area

Administration Oral: Do not mix oral concentrate with carbonated beverages (physically incompatible).

Topical: Apply thin film to affected area; use of occlusive dressings is not recommended.

Contraindications Hypersensitivity to doxepin, drugs from similar chemical class, or any component of the formulation; narrow-angle glaucoma; urinary retention; use of MAO inhibitors within 14 days; use in a patient during acute recovery phase of MI

Warnings

[U.S. Boxed Warning]: Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. Such observation would generally include at least weekly face-to-face contact with patients or their family members or caregivers during the first 4 weeks of treatment, then every other week visits for the next 4 weeks, then at 12 weeks, and as clinically indicated beyond 12 weeks. Additional contact by telephone may be appropriate between face-to-face visits. Adults treated with antidepressants should be observed similarly for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. A medication guide should be dispensed with each prescription. **Doxepin is approved for treatment of depression in adolescents.**

The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Monitor for worsening of depression or suicidality, especially during initiation of therapy or with dose increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy. Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression occur.

May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Doxepin is not FDA approved for the treatment of bipolar depression.**

Often causes sedation, which may result in impaired performance of tasks requiring alertness (eg, operating machinery or driving). Sedative effects may be additive with other CNS depressants and/or ethanol. The degree of sedation is very high relative to other antidepressants. May increase the risks associated with electroconvulsive therapy. Consider discontinuing, when possible, prior to elective surgery. Therapy should not be abruptly discontinued in patients receiving high doses for prolonged periods.

May cause orthostatic hypotension (risk is moderate relative to other antidepressants) - use with caution in patients at risk of hypotension or in patients where transient hypotensive episodes would be poorly

tolerated (cardiovascular disease or cerebrovascular disease). The degree of anticholinergic blockade produced by this agent is high relative to other cyclic antidepressants - use caution in patients with benign prostatic hyperplasia, xerostomia, visual problems, constipation, or history of bowel obstruction.

Use with caution in patients with a history of cardiovascular disease (including previous MI, stroke, tachycardia, or conduction abnormalities). The risk conduction abnormalities with this agent is moderate relative to other antidepressants. Use caution in patients with a previous seizure disorder or condition predisposing to seizures such as brain damage, alcoholism, or concurrent therapy with other drugs which lower the seizure threshold. Use with caution in hyperthyroid patients or those receiving thyroid supplementation. Use with caution in patients with hepatic or renal dysfunction and in elderly patients. Cream formulation is for external use only (not for ophthalmic, vaginal, or oral use). Do not use occlusive dressings. Use for >8 days may increase risk of contact sensitization. Doxepin is significantly absorbed following topical administration; plasma levels may be similar to those achieved with oral administration.

Dosage Forms [DSC] = Discontinued product

Capsule, as hydrochloride: 10 mg, 25 mg, 50 mg, 75 mg, 100 mg, 150 mg
Sinequan®: 10 mg, 25 mg, 50 mg, 75 mg, 100 mg, 150 mg [DSC]

Cream, as hydrochloride:

Prudoxin™: 5% (45 g) [contains benzyl alcohol]

Zonalon®: 5% (30 g, 45 g) [contains benzyl alcohol]

Solution, oral concentrate, as hydrochloride (Sinequan®): 10 mg/mL (120 mL)

Sinequan®: 10 mg/mL (120 mL) [DSC]

Reference Range

Therapeutic: 110-250 ng/mL

Toxic: >500 ng/mL

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; multiple dosing of activated charcoal may be effective

Supportive therapy: Following initiation of essential overdose management, toxic symptoms should be treated. Ventricular arrhythmias often respond to systemic alkalization (sodium bicarbonate 0.5-2 mEq/kg I.V.). Arrhythmias unresponsive to this therapy may respond to lidocaine 1 mg/kg I.V. followed by a titrated infusion. Seizures usually respond to diazepam or lorazepam I.V. boluses. If seizures are unresponsive or recur, phenobarbital may be required. Quinidine, disopyramide, and procainamide are contraindicated. Hemoperfusion or hemodialysis is generally not of benefit. Hypotension can respond to crystalloid infusion; norepinephrine or dopamine can be used as a second line agent.

Antidote(s)

- Sodium Bicarbonate [ANTIDOTE]

Test Interactions

↑ glucose, catecholamine

Drug Interactions

Substrate (major) of CYP1A2, 2D6, 3A4

Altrexamine: Concurrent use may cause orthostatic hypertension.

Amphetamines: TCAs may enhance the effect of amphetamines; monitor for adverse CV effects.

Anticholinergics: Combined use with TCAs may produce additive anticholinergic effects

Antihypertensives: TCAs may inhibit the antihypertensive response to bethanidine, clonidine, debrisoquin, guanadrel, guanethidine, guanabenz, guanfacine; monitor BP; consider alternate antihypertensive agent.

Beta-agonists (nonselective): When combined with TCAs may predispose patients to cardiac arrhythmias.

Bupropion: May increase the levels of tricyclic antidepressants; based on limited information; monitor response.

Carbamazepine: Tricyclic antidepressants may increase carbamazepine levels; monitor.

Cholestyramine and colestipol: May bind TCAs and reduce their absorption; monitor for altered response.

Clonidine: Abrupt discontinuation of clonidine may cause hypertensive crisis, amitriptyline may enhance the response.

CNS depressants: Sedative effects may be additive with TCAs; monitor for increased effect; includes benzodiazepines, barbiturates, antipsychotics, ethanol and other sedative medications.

CYP1A2 inducers: May decrease the levels/effects of doxepin. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of doxepin. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

CYP2D6 inhibitors: May increase the levels/effects of doxepin. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of doxepin. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 inhibitors: May increase the levels/effects of doxepin. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, izoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Epinephrine (and other direct alpha-agonists): Pressor response to I.V. epinephrine, norepinephrine, and phenylephrine may be enhanced in patients receiving TCAs. (**Note:** Effect is unlikely with epinephrine or levonordefrin dosages typically administered as infiltration in combination with local anesthetics.)

Fenfluramine: May increase tricyclic antidepressant levels/effects.

Hypoglycemic agents (including insulin): TCAs may enhance the hypoglycemic effects of tolazamide, chlorpropamide, or insulin; monitor for changes in blood glucose levels; reported with chlorpropamide, tolazamide, and insulin.

Levodopa: Tricyclic antidepressants may decrease the absorption (bioavailability) of levodopa; rare hypertensive episodes have also been attributed to this combination.

Linezolid: Hyperpyrexia, hypertension, tachycardia, confusion, and **deaths have been reported** with agents which inhibit MAO (serotonin syndrome); this combination should be avoided.

Lithium: Concurrent use with a TCA may increase the risk for neurotoxicity.

MAO inhibitors: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and **deaths have been reported** (serotonin syndrome); this combination is contraindicated.

Methylphenidate: Metabolism of TCAs may be decreased.

Phenothiazines: Serum concentrations of some TCAs may be increased; in addition, TCAs may increase concentration of phenothiazines; monitor for altered clinical response.

QT_c-prolonging agents: Concurrent use of tricyclic agents with other drugs which may prolong QT_c interval may increase the risk of potentially fatal arrhythmias; includes type Ia and type III antiarrhythmics agents, selected quinolones (sparfloxacin, gatifloxacin, moxifloxacin, grepafloxacin), cisapride, and other agents.

Ritonavir: Combined use of high-dose tricyclic antidepressants with ritonavir may cause serotonin syndrome in HIV-positive patients; monitor.

Sucralfate: Absorption of tricyclic antidepressants may be reduced with coadministration.

Sympathomimetics, indirect-acting: Tricyclic antidepressants may result in a decreased sensitivity to indirect-acting sympathomimetics; includes dopamine and ephedrine; also see interaction with epinephrine (and direct-acting sympathomimetics).

Tramadol: Tramadol's risk of seizures may be increased with TCAs.

Valproic acid: May increase serum concentrations/adverse effects of some tricyclic antidepressants.

Warfarin (and other oral anticoagulants): TCAs may increase the anticoagulant effect in patients stabilized on warfarin; monitor INR.

Pregnancy Risk Factor B (cream); C (all other forms)

Pregnancy Implications Teratogenic effects were not observed in animal studies; however, there are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if clearly needed.

Lactation Enters breast milk/not recommended (AAP rates "of concern")

Additional Information Entire daily dose may be given at bedtime; avoid unnecessary exposure to sunlight; found in a 5% concentration in Zonalon® topical cream for pruritus; toxic reactions can occur due to percutaneous absorption

DOXORubicin

Related Information

- DAUNORubicin Hydrochloride

CAS Number 23214-92-8; 25316-40-9

U.S. Brand Names Adriamycin PFS®; Adriamycin RDF®; Rubex®

Synonyms ADR (error-prone abbreviation); Adria; Doxorubicin Hydrochloride; Hydroxydaunomycin Hydrochloride; Hydroxyldaunorubicin Hydrochloride; NSC-123127

Use Leukemias, lymphomas, multiple myeloma, osseous and nonosseous sarcomas, mesotheliomas, germ cell tumors of the ovary or testis, and carcinomas of the head and neck, thyroid, lung, breast, stomach,

pancreas, liver, ovary, bladder, prostate, and uterus; neuroblastoma, osteosarcoma

Mechanism of Action Inhibition of DNA and RNA synthesis by intercalation between DNA base pairs by inhibition of topoisomerase II and by steric obstruction. Doxorubicin intercalates at points of local uncoiling of the double helix. Although the exact mechanism is unclear, it appears that direct binding to DNA (intercalation) and inhibition of DNA repair (topoisomerase II inhibition) result in blockade of DNA and RNA synthesis and fragmentation of DNA. Doxorubicin is also a powerful iron chelator; the iron-doxorubicin complex can bind DNA and cell membranes and produce free radicals that immediately cleave the DNA and cell membranes.

Adverse Reactions Cardiovascular: Myocarditis, myocardial infection, pericarditis, transient ECG abnormalities (supraventricular tachycardia, S-T wave changes, atrial or ventricular extrasystoles); generally asymptomatic and self-limiting. Congestive heart failure, dose-related, may be delayed for 7-8 years after treatment. Cumulative dose, mediastinal/pericardial radiation therapy, cardiovascular disease, age, and use of cyclophosphamide (or other cardiotoxic agents) all increase the risk.

Recommended maximum cumulative doses:

No risk factors: 550 mg/m²

Concurrent radiation: 450 mg/m²

Note: Regardless of cumulative dose, if the left ventricular ejection fraction is <30% to 40%, the drug is usually not given.

Dermatologic: **Alopecia, radiation recall**, skin "flare" at injection site; discoloration of saliva, sweat, or tears; skin rash, pigmentation of nail beds, nail banding, onycholysis, urticaria

Endocrine & metabolic: Hyperuricemia, infertility, sterility

Gastrointestinal: **Nausea, vomiting, stomatitis, GI ulceration, anorexia, diarrhea**

Genitourinary: **Discoloration of urine, mild dysuria, urinary frequency, hematuria, bladder spasms, cystitis following bladder instillation**

Hematologic: **Myelosuppression, primarily leukopenia (75%); thrombocytopenia and anemia** (onset: 7 days, nadir: 10-14 days, recovery: 21-28 days)

Hepatic: Hepatitis, elevations of bilirubin and transaminases

Miscellaneous: Systemic hypersensitivity (including urticaria, pruritus, angioedema, dysphagia, and dyspnea)

Signs and Symptoms of Overdose Dysuria, hematuria, hyperuricemia, lacrimation, leukopenia or neutropenia (agranulocytosis, granulocytopenia), Mees' lines, myocardial depression, onycholysis, tongue discoloration

Admission Criteria/Prognosis May discharge asymptomatic patients after 8 hours of observation

Pharmacodynamics/Kinetics

Absorption: Oral: Poor (<50%)

Distribution: V_d: 25 L/kg; to many body tissues, particularly liver, spleen, kidney, lung, heart; does not distribute into the CNS; crosses placenta

Protein binding, plasma: 70%

Metabolism: Primarily hepatic to doxorubicinol (active), then to inactive aglycones, conjugated sulfates, and glucuronides

Half-life elimination:

Distribution: 10 minutes

Elimination: Doxorubicin: 1-3 hours; Metabolites: 3-3.5 hours

Terminal: 17-30 hours

Male: 54 hours; Female: 35 hours

Excretion: Feces (~40% to 50% as unchanged drug); urine (~3% to 10% as metabolites, 1% doxorubicinol, <1% Adriamycin aglycones, and unchanged drug)

Clearance: Male: 113 L/hour; Female: 44 L/hour

Dosage Refer to individual protocols. I.V.:

Children:

35-75 mg/m² as a single dose, repeat every 21 days or

20-30 mg/m² once weekly or

60-90 mg/m² given as a continuous infusion over 96 hours every 3-4 weeks

Adults: Usual or typical dose: 60-75 mg/m² as a single dose, repeat every 21 days or other dosage regimens like 20-30 mg/m²/day for 2-3 days, repeat in 4 weeks or 20 mg/m² once weekly

The lower dose regimen should be given to patients with decreased bone marrow reserve, prior therapy or marrow infiltration with malignant cells

Dosing adjustment in renal impairment:

Mild to moderate renal failure: Adjustment is not required

C_{cr} < 10 mL/minute: Administer 75% of normal dose

Hemodialysis: Supplemental dose is not necessary

Dosing adjustment in hepatic impairment:

Bilirubin 1.2-3 mg/dL: Administer 50% of dose

Bilirubin 3.1-5 mg/dL: Administer 25% of dose

Bilirubin > 5 mg/dL: Do not administer drug

Stability Protect from light, must be dispensed in an amber bag; store powder vials at room temperature, refrigerate liquid vials; reconstituted powder vials stable for 24 hours at room temperature and 48 hours if

refrigerated; unstable in solutions with a pH <3 or >7. **Incompatible** with heparin, fluorouracil, aminophylline, cephalothin, methotrexate, dexamethasone, diazepam, hydrocortisone, furosemide. Y-site is **compatible** with doxorubicin, vincristine, cyclophosphamide, dacarbazine, bleomycin, vinblastine.

Monitoring Parameters CBC with differential and platelet count, cardiac and liver function tests

Administration

Administer I.V. push over 1-2 minutes or IVPB. Continuous infusions may be administered via central line. **Avoid extravasation**, associated with severe ulceration and soft tissue necrosis. Flush with 5-10 mL of I.V. solution before and after drug administration. Incompatible with heparin. Monitor for local erythematous streaking along vein and/or facial flushing (may indicate rapid infusion rate).

Extravasation management: Apply ice immediately for 30-60 minutes; then alternate off/on every 15 minutes for 1 day. Topical cooling may be achieved using ice packs or cooling pad with circulating ice water. Cooling of site for 24 hours as tolerated by the patient. Elevate and rest extremity 24-48 hours, then resume normal activity as tolerated. Application of cold inhibits vesicant's cytotoxicity. **Application of heat or sodium bicarbonate can be harmful and is contraindicated.** If pain, erythema, and/or swelling persist beyond 48 hours, refer patient immediately to plastic surgeon for consultation and possible debridement.

Contraindications Hypersensitivity to doxorubicin or any component of the formulation; congestive heart failure or arrhythmias; previous therapy with high cumulative doses of doxorubicin and/or daunorubicin; pre-existing bone marrow suppression; pregnancy

Warnings Hazardous agent - use appropriate precautions for handling and disposal. Use with caution in patients who have received radiation therapy or in the presence of hepatobiliary dysfunction; reduce dosage in patients who are receiving radiation therapy simultaneously. Administration of live vaccines to immunosuppressed patients may be hazardous.

Total dose should not exceed 550 mg/m² or 450 mg/m² in patients with previous or concomitant treatment with daunorubicin, cyclophosphamide, or irradiation of the cardiac region. **[U.S. Boxed Warning]: Irreversible myocardial toxicity may occur** as total dosage approaches 550 mg/m².

A baseline cardiac evaluation (ECG, LVEF, +/- ECHO) is recommended, especially in patients with risk factors for increased cardiac toxicity and in pediatric patients. Pediatric patients are at increased risk for delayed cardiotoxicity. **[U.S. Boxed Warnings]: Reduce dose in patients with impaired hepatic function; severe myelosuppression is also possible. Secondary acute myelogenous leukemia may occur following treatment.**

[U.S. Boxed Warnings]: I.V. use only. Doxorubicin is a potent vesicant; if extravasation occurs, severe tissue damage leading to ulceration and necrosis, and pain may occur. Should be administered under the supervision of an experienced cancer chemotherapy physician.

Dosage Forms

Injection, powder for reconstitution, as hydrochloride: 10 mg, 20 mg, 50 mg [contains lactose]

Adriamycin RDF®: 10 mg, 20 mg, 50 mg, 150 mg [contains lactose; rapid dissolution formula]

Rubex®: 50 mg, 100 mg [contains lactose]

Injection, solution, as hydrochloride [preservative free]: 2 mg/mL (5 mL, 10 mL, 25 mL, 100 mL)

Adriamycin PFS® [preservative free]: 2 mg/mL (5 mL, 10 mL, 25 mL, 37.5 mL, 100 mL)

Reference Range No relationship between serum level and cytotoxicity; mean plasma doxorubicin level following 10-15 mg/m²/day for 5 days of doxorubicin was 7.8-90 ng/mL

Overdosage/Treatment

Supportive therapy: Prophylactically, dexrazoxane (Zinecard®) (10 times the dose of doxorubicin 30 minutes prior to doxorubicin treatment) may reduce cardiotoxicity of doxorubicin; topical DMSO (1.5 mL of a 50% solution every 6 hours for 2 weeks) with cold compresses can be used to treat extravasation. Levocarnitine daily 2-3 days before and 2 days after (1 g 3 times with 1 g I.V. on day of therapy doxorubicin treatment) may decrease cardiotoxicity; topical dimethylsulfoxide or local hydrocortisone (100 mg/2 mL) injections with cold compresses can be used to treat extravasation injury

Enhancement of elimination: While hemodialysis is not useful, Amberlite hemoperfusion may be effective if initiated within 1 hour of administration

Antidote(s)

● Dexrazoxane [ANTIDOTE]

● Levocarnitine [ANTIDOTE]

Drug Interactions **Substrate** (major) of CYP2D6, 3A4; **Inhibits** CYP2B6 (moderate), 2D6 (weak), 3A4 (weak)

Allopurinol may enhance the antitumor activity of doxorubicin (animal data only).

Cyclophosphamide enhances the cardiac toxicity of doxorubicin by producing additional myocardial cell damage.

Cyclosporine may decrease clearance of parent and metabolite and may induce coma or seizures and enhance hematologic toxicity.

CYP2B6 substrates: Doxorubicin may increase the levels/effects of CYP2B6 substrates. Example substrates include bupropion, promethazine, propofol, selegiline, and sertraline.

CYP2D6 inhibitors: May increase the levels/effects of doxorubicin. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of doxorubicin. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifampin.

CYP3A4 inhibitors: May increase the levels/effects of doxorubicin. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nifedipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Digoxin: Doxorubicin may decrease plasma levels and effectiveness of digoxin.

Mercaptopurine increases toxicities.

Paclitaxel reduces doxorubicin clearance and increases toxicity if administered prior to doxorubicin.

Phenobarbital increases elimination (decreases effect) of doxorubicin.

Phenytoin: Doxorubicin may decrease plasma levels and effectiveness of phenytoin.

Progesterone: High doses of progesterone enhance toxicity (neutropenia and thrombocytopenia).

Streptozocin greatly enhances leukopenia and thrombocytopenia.

Verapamil alters the cellular distribution of doxorubicin and may result in increased cell toxicity by inhibition of the P-glycoprotein pump. Based on mouse studies, cardiotoxicity may be enhanced by verapamil.

Zidovudine: Doxorubicin may decrease the antiviral activity of zidovudine.

Pregnancy Risk Factor D

Pregnancy Implications Advise patients to avoid becoming pregnant (females) and to avoid causing pregnancy (males).

Lactation Enters breast milk/contraindicated

Nursing Implications Local erythematous streaking along the vein and/or facial flushing may indicate too rapid a rate of administration; avoid extravasation, drug is a vesicant; if extravasation occurs, apply ice

Additional Information Cutaneous squamous cell carcinoma (Marjolin's ulcer) has been associated at the site of doxorubicin extravasation 10 years after drug administration

Myelosuppressive effects: **WBC:** Moderate. **Platelets:** Moderate. Onset (days): 7. Nadir (days): 10-14. Recovery (days): 21-28

Doxycycline

CAS Number 10592-13-9; 17086-28-1; 24390-14-5; 564-25-0; 83038-87-3

U.S. Brand Names Adoxa™; Doryx®; Doxy-100®; Monodox®; Oracea™; Periostat®; Vibra-Tabs®; Vibramycin®

Synonyms Doxycycline Calcium; Doxycycline Hyclate; Doxycycline Monohydrate

Use Principally in the treatment of infections caused by susceptible *Rickettsia*, *Chlamydia*, and *Mycoplasma*; alternative to mefloquine for malaria prophylaxis; treatment for syphilis, uncomplicated *Neisseria gonorrhoeae*, *Listeria*, *Actinomyces israelii*, and *Clostridium* infections in penicillin-allergic patients; used for community-acquired pneumonia and other common infections due to susceptible organisms; anthrax due to *Bacillus anthracis*, including inhalational anthrax (postexposure); treatment of infections caused by uncommon susceptible gram-negative and gram-positive organisms including *Borrelia recurrentis*, *Ureaplasma urealyticum*, *Haemophilus ducreyi*, *Yersinia pestis*, *Francisella tularensis*, *Vibrio cholerae*, *Campylobacter fetus*, *Brucella* spp, *Bartonella bacilliformis*, and *Calymmatobacterium granulomatis*; treatment of inflammatory lesions associated with rosacea

Unlabeled/Investigational Use Sclerosing agent for pleural effusion injection; vancomycin-resistant enterococci (VRE)

Mechanism of Action Inhibits protein synthesis by binding with the 30S and possibly the 50S ribosomal subunit(s) of susceptible bacteria; may also cause alterations in the cytoplasmic membrane

Adverse Reactions

Cardiovascular: Vasculitis

Central nervous system: Increased intracranial pressure, bulging fontanelles in infants, headache

Dermatologic: Rash, photosensitivity, hyperpigmentation, toxic pustuloderma, Stevens-Johnson syndrome, exfoliative dermatitis, erythema multiforme, angioedema, toxic epidermal necrolysis, urticaria, purpura, psoriasis, yellow fingernail, exanthem

Endocrine & metabolic: Parotitis, black thyroid

Gastrointestinal: Nausea, diarrhea, esophagitis and esophageal ulceration with the hyclate salt formulation; vomiting

Hematologic: Neutropenia, eosinophilia, porphyria

Hepatic: Hepatotoxicity

Local: Phlebitis (I.V. administration)

Neuromuscular & skeletal: Paresthesia

Renal: Polyuria, Fanconi-like reaction (albuminuria, hypokalemia, acidosis) with outdated drug

Respiratory: Hyposmia

Miscellaneous: May cause **discoloration of teeth in children**, hiccups, systemic lupus erythematosus, fixed drug eruption

Signs and Symptoms of Overdose Leukopenia or neutropenia (agranulocytosis, granulocytopenia); photosensitivity, hypokalemia, flatulence

Pharmacodynamics/Kinetics

Absorption: Oral: Almost complete; reduced by food or milk by 20%

Distribution: Widely into body tissues and fluids including synovial, pleural, prostatic, seminal fluids, and bronchial secretions; saliva, aqueous humor, and CSF penetration is poor; readily crosses placenta; enters breast milk

Protein binding: 90%

Metabolism: Not hepatic; partially inactivated in GI tract by chelate formation

Half-life elimination: 12-15 hours (usually increases to 22-24 hours with multiple doses); End-stage renal disease: 18-25 hours

Time to peak, serum: 1.5-4 hours

Excretion: Feces (30%); urine (23%)

Dosage Children:

Anthrax: Doxycycline should be used in children if antibiotic susceptibility testing, exhaustion of drug supplies, or allergic reaction preclude use of penicillin or ciprofloxacin. For treatment, the consensus recommendation does not include a loading dose for doxycycline.

Inhalational (postexposure prophylaxis) (*MMWR*, 2001, 50:889-893): Oral, I.V. (use oral route when possible):

≤8 years: 2.2 mg/kg every 12 hours for 60 days

>8 years and ≤45 kg: 2.2 mg/kg every 12 hours for 60 days

>8 years and >45 kg: 100 mg every 12 hours for 60 days

Cutaneous (treatment): Oral: See dosing for "Inhalational (post-exposure prophylaxis)"

Note: In the presence of systemic involvement, extensive edema, and/or lesions on head/neck, doxycycline should initially be administered I.V.

Inhalational/gastrointestinal/oropharyngeal (treatment): I.V.: Refer to dosing for inhalational anthrax (postexposure prophylaxis); switch to oral therapy when clinically appropriate; refer to Adults dosing for "Note" on combined therapy and duration

Children ≥8 years (<45 kg): Susceptible infections: Oral, I.V.: 2-5 mg/kg/day in 1-2 divided doses, not to exceed 200 mg/day

Children >8 years (>45 kg) and Adults: Susceptible infections: Oral, I.V.: 100-200 mg/day in 1-2 divided doses

Acute gonococcal infection (PID) in combination with another antibiotic: 100 mg every 12 hours until improved, followed by 100 mg orally twice daily to complete 14 days

Community-acquired pneumonia: 100 mg twice daily

Lyme disease: Oral: 100 mg twice daily for 14-21 days

Early syphilis: 200 mg/day in divided doses for 14 days

Late syphilis: 200 mg/day in divided doses for 28 days

Uncomplicated chlamydial infections: 100 mg twice daily for ≥7 days

Endometritis, salpingitis, parametritis, or peritonitis: 100 mg I.V. twice daily with cefoxitin 2 g every 6 hours for 4 days and for ≥48 hours after patient improves; then continue with oral therapy 100 mg twice daily to complete a 10- to 14-day course of therapy

Sclerosing agent for pleural effusion injection (unlabeled use): 500 mg as a single dose in 30-50 mL of NS or SWI

Periodontitis: Oral (Periostat®): 20 mg twice daily as an adjunct following scaling and root planing; may be administered for up to 9 months. Safety beyond 12 months of treatment and efficacy beyond 9 months of treatment have not been established.

Adults:

Anthrax:

Inhalational (postexposure prophylaxis): Oral, I.V. (use oral route when possible): 100 mg every 12 hours for 60 days (*MMWR*, 2001, 50:889-93); **Note:** Preliminary recommendation, FDA review and update is anticipated.

Cutaneous (treatment): Oral: 100 mg every 12 hours for 60 days. **Note:** In the presence of systemic involvement, extensive edema, lesions on head/neck, refer to I.V. dosing for treatment of inhalational/gastrointestinal/oropharyngeal anthrax

Inhalational/gastrointestinal/oropharyngeal (treatment): I.V.: Initial: 100 mg every 12 hours; switch to oral therapy when clinically appropriate; some recommend initial loading dose of 200 mg, followed by 100 mg every 8-12 hours (*JAMA*, 1997, 278:399-411).

Note: Initial treatment should include two or more agents predicted to be effective (per CDC recommendations). Agents suggested for use in conjunction with doxycycline or ciprofloxacin include rifampin, vancomycin, imipenem, penicillin, ampicillin, chloramphenicol, clindamycin, and clarithromycin. May switch to oral antimicrobial therapy when clinically appropriate. Continue combined therapy for 60 days

Rosacea: (Oracea™): Oral: 40 mg once daily in the morning

Dosing adjustment in renal impairment: No adjustment necessary
Dialysis: Not dialyzable; 0% to 5% by hemo- and peritoneal methods or by continuous arteriovenous or venovenous hemofiltration: No supplemental dosage necessary

Stability Tetracyclines form toxic products when outdated or when exposed to light, heat, or humidity; reconstituted solution is stable for 72 hours (refrigerated); for I.V. infusion in NS or D₅W solution, complete infusion should be completed within 12 hours; discard remaining solution

Monitoring Parameters Periodic monitoring of renal, hepatic, and hematologic function tests

Administration Oral: Administer with adequate fluid to reduce risk of esophageal irritation and ulceration; may administer with meals to decrease GI upset

Doryx®: Capsules may be opened and contents sprinkled on applesauce. Applesauce should be swallowed immediately; do not chew. Follow with 8 ounces of water. Applesauce should not be hot and should be soft enough to swallow without chewing.

I.V.: Infuse I.V. doxycycline over 1-4 hours

Contraindications Hypersensitivity to doxycycline, tetracycline or any component of the formulation; children <8 years of age, except in treatment of anthrax (including inhalational anthrax postexposure prophylaxis); severe hepatic dysfunction; pregnancy

Warnings

Do not use during pregnancy - use of tetracyclines during tooth development may cause permanent discoloration of the teeth and enamel hypoplasia; prolonged use may result in superinfection, including oral or vaginal candidiasis; photosensitivity reaction may occur with this drug; avoid prolonged exposure to sunlight or tanning equipment. Anti-anabolic effects of tetracyclines can increase BUN leading to significant renal dysfunction and hepatotoxicity in patients with pre-existing renal impairment. Autoimmune syndromes have been reported; if symptomatic conduct LFT and discontinue drug. Tetracyclines have been associated with pseudotumor cerebri. Avoid in children ≤8 years of age.

Additional specific warnings: Periostat®: Effectiveness has not been established in patients with coexistent oral candidiasis; use with caution in patients with a history or predisposition to oral candidiasis. Oracea™: Should not be used for the treatment or prophylaxis of bacterial infections, since the lower dose of drug per capsule may be sub-therapeutic and promote resistance.

Dosage Forms [DSC] = Discontinued product

Capsule, as hyclate: 50 mg, 100 mg

Vibramycin®: 100 mg

Capsule, as monohydrate (Monodox®): 50 mg, 100 mg

Capsule, coated pellets, as hyclate (Doryx®): 75 mg, 100 mg [DSC]

Capsule, variable release (Oracea™): 40 mg [30 mg (immediate-release) and 10 mg (delayed-release)]

Injection, powder for reconstitution, as hyclate (Doxy-100®): 100 mg

Powder for oral suspension, as monohydrate (Vibramycin®): 25 mg/5 mL (60 mL) [raspberry flavor]

Syrup, as calcium (Vibramycin®): 50 mg/5 mL (480 mL) [contains sodium metabisulfite; raspberry-apple flavor]

Tablet, as hyclate: 100 mg

Periostat®: 20 mg

Vibra-Tabs®: 100 mg

Tablet, as monohydrate:

Adoxa™: 50 mg, 75 mg, 100 mg

Adoxa® Pak™ 1/75 [unit-dose pack]: 75 mg (31s)

Adoxa® Pak™ 1/100 [unit-dose pack]: 100 mg (31s)

Adoxa® Pak™ 1/150 [unit-dose pack]: 150 mg (30s)

Adoxa® Pak™ 2/100 [unit-dose pack]: 100 mg (60s)

Tablet, delayed-release coated pellets, as hyclate (Doryx®): 75 mg [contains sodium 4.5 mg (0.196 mEq)], 100 mg [contains sodium 6 mg (0.261 mEq)]

Reference Range Peak plasma level of 3 mg/L (6.5 μmol/L) following a 200 mg dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; dilute with milk or water to avoid corrosive gastrointestinal effects

Supportive therapy: Antacids effective for gastrointestinal irritation

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; can increase fecal elimination by binding to doxycycline after intestinal secretion; not dialyzable

Test Interactions False-negative urine glucose using Clinistix®, Tes-Tape®

Drug Interactions **Substrate** of CYP3A4 (major); **Inhibits** CYP3A4 (moderate)

Antacids (containing aluminum, calcium, or magnesium): Decreased absorption of tetracyclines

Anticoagulants: Tetracyclines may decrease plasma thrombin activity; monitor

Barbiturates: Decreased half-life of doxycycline

Carbamazepine: Decreased half-life of doxycycline

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of doxycycline. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

CYP3A4 substrates: Doxycycline may increase the levels/effects of CYP3A4 substrates. Example substrates include benzodiazepines, calcium channel blockers, mirtazapine, nateglinide, nefazodone, tacrolimus, and venlafaxine. Selected benzodiazepines (midazolam and triazolam), cisapride, ergot alkaloids, selected HMG-CoA reductase inhibitors (lovastatin and simvastatin), and pimozide are generally contraindicated with strong CYP3A4 inhibitors.

Iron-containing products: Decreased absorption of tetracyclines

Methoxyflurane: Concomitant use may cause fatal renal toxicity.

Oral contraceptives: Anecdotal reports suggesting decreased contraceptive efficacy with tetracyclines have been refuted by more rigorous scientific and clinical data.

Phenytoin: Decreased half-life of doxycycline

Pregnancy Risk Factor D

Pregnancy Implications Exposure during the last half or pregnancy causes permanent yellow-gray-brown discoloration of the teeth. Tetracyclines also form a complex in bone forming tissue, leading to a decreased fibula growth rate when given to premature infants. According to the FDA, the Teratogen Information System concluded that therapeutic doses during pregnancy are unlikely to produce substantial teratogenic risk, but data are insufficient to say that there is no risk. In general, reports of exposure have been limited to short durations of therapy in the first trimester. When considering treatment for life-threatening infection and/or prolonged duration of therapy (such as in anthrax), the potential risk to the fetus must be balanced against the severity of the potential illness.

Lactation Enters breast milk/not recommended

Nursing Implications Infuse I.V. doxycycline over 1 hour

Additional Information

Not as antianabolic as other tetracyclines.

If liquid doxycycline is unavailable for the treatment of anthrax, emergency doses may be prepared for children using the tablets.

Crush one 100 mg tablet and grind into a fine powder. Mix with 4 teaspoons of food or drink (lowfat milk, chocolate milk, chocolate pudding, or apple juice). Appropriate dose may be taken from this mixture. Mixture may be stored for up to 24 hours. Dairy mixtures should be refrigerated; apple juice may be stored at room temperature. U.S. Food and Drug Administration, Center for Drug Evaluation and Research, "How to Prepare Emergency Dosages of Doxycycline at Home for Infants and Children," April 25, 2003, viewable at http://www.fda.gov/cder/drug/infopage/penG_doxy/doxycyclinePeds.htm, last accessed May 8, 2003.

Doxylamine

CAS Number 562-10-7

U.S. Brand Names Good Sense Sleep Aid [OTC]; Unisom® SleepTabs® [OTC]

Synonyms Doxylamine Succinate

Use Sleep aid; antihistamine for hypersensitivity reactions and antiemetic

Mechanism of Action Competes with histamine at H₁-receptor sites on effector cells in blood vessels, central nervous system, GI tract, striated muscle, and respiratory tract

Adverse Reactions

Cardiovascular: Tachycardia

Central nervous system: Sedation, paradoxical stimulation in children, hyperthermia

Gastrointestinal: Dry mucous membranes, constipation, nausea, vomiting, pancreatitis

Genitourinary: Urinary retention

Neuromuscular & skeletal: Tremors

Ocular: Blurred vision, mydriasis

Signs and Symptoms of Overdose Overdose may result in death; cardiopulmonary arrest, catatonic psychosis, CNS depression or stimulation, elevated CPK, mydriasis, seizures, rhabdomyolysis, tachycardia

Admission Criteria/Prognosis Any symptomatic patient and/or elevated CPK

Pharmacodynamics/Kinetics

Onset of effect: 30 minutes

Duration: 4-6 hours

Absorption: Well absorbed

Distribution: V_d: 2.5 L/kg

Metabolism: Via multiple metabolic pathways including N-demethylation, oxidation, hydroxylation, N-acetylation to metabolites including nordoxylamine, dinordoxylamine

Half-life elimination: 10-12 hours

Excretion: Urine (primarily as metabolites)

Dosage Oral: Children > 12 years and adults: 25 mg at bedtime

Administration

Main dose should be taken at bedtime to provide relief in the early morning hours.

DROPERIDOL

Contraindications Hypersensitivity to doxylamine or any component of the formulation

Warnings May cause drowsiness; patient should avoid tasks requiring alertness (eg, driving, operating machinery) until effects are known. Sedative effects of CNS depressants or ethanol are potentiated. Use with caution in patients with angle-closure glaucoma, pyloroduodenal obstruction (including stenotic peptic ulcer), urinary tract obstruction (including bladder neck obstruction and symptomatic prostatic hyperplasia), hyperthyroidism, increased intraocular pressure, and cardiovascular disease (including hypertension and tachycardia). If sleeplessness persists for >2 weeks, medical evaluation should occur. Safety and efficacy not established in children <12 years of age.

Dosage Forms Tablet, a succinate:

Good Sense Sleep Aid, Unisom® SleepTabs®: 25 mg

Reference Range

Therapeutic: Not established; nonintoxicated postmortem blood concentrations range from 0.05-0.8 mg/L

Toxic: Fatalities reported with concentrations of 0.7, 12.0, and 17.0 mg/L in blood, postmortem blood, and urine, respectively

Retrospective review has found no correlation between concentrations and toxic effects in intoxicated patients.

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal can be most useful; **do not** use a cathartic if diarrhea is present

Supportive therapy: Propranolol or esmolol can be used for tachyarrhythmias (avoid quinidine or disopyramide in that conduction disturbances can occur); benzodiazepine can be utilized for seizures; if anticholinergic findings are present with the seizures (or if coma is present) a trial of physostigmine may be useful; wide complex QRS conduction defects may respond to sodium bicarbonate; seizures have responded to sodium bicarbonate in a rodent model

Enhanced elimination: Dialysis/hemoperfusion is not useful

Test Interactions May suppress wheal and flare reactions to skin test antigens; false-positive results with methadone or opiate enzyme immunoassay may occur with diphenhydramine or doxylamine

Drug Interactions

Anticholinergic agents: Central and/or peripheral anticholinergic syndrome can occur when administered with narcotic analgesics, phenothiazines and other antipsychotics (especially with high anticholinergic activity), tricyclic antidepressants, quinidine and some other antiarrhythmics, and antihistamines.

Cholinergic agents: Drugs with high anticholinergic activity may antagonize the therapeutic effect of cholinergic agents; includes donepezil, rivastigmine, and tacrine.

CNS depressants: Sedative effects may be additive with CNS depressants; includes ethanol, benzodiazepines, barbiturates, narcotic analgesics, and other sedative agents; monitor for increased effect.

Pregnancy Risk Factor B

Pregnancy Implications Doxylamine has been approved for used in pregnancy-associated nausea and vomiting.

Lactation Excretion in breast milk unknown

Additional Information Found in many OTC cough/cold preparations

Specific References

Khosla U, Ruel KS, and Hunt DP, "Antihistamine-Induced Rhabdomyolysis," *South Med J*, 2003, 96(10):1023-6.

Dermatologic: Alopecia, contact dermatitis, hyperpigmentation, photosensitivity (rare), pruritus, rash

Endocrine & metabolic: **Swelling of breasts**, amenorrhea, galactorrhea, gynecomastia, sexual dysfunction

Gastrointestinal: **Weight gain, constipation**, nausea, vomiting, adynamic ileus, xerostomia

Genitourinary: Dysuria, overflow incontinence, priapism, urinary retention

Hematologic: Agranulocytosis, leukopenia (usually with large doses for prolonged periods)

Hepatic: Cholestatic jaundice, obstructive jaundice

Ocular: Decreased visual acuity, blurred vision, retinal pigmentation

Respiratory: Laryngospasm, respiratory depression

Miscellaneous: Heat stroke

Signs and Symptoms of Overdose Cardiac conduction disturbances can occur if daily intravenous dose exceeds 50 mg. Chills, coma, extrapyramidal reaction, hallucinations, hypotension, myasthenia gravis (exacerbation or precipitation), neuroleptic malignant syndrome, Parkinson's-like symptoms, tachycardia, wheezing

Pharmacodynamics/Kinetics

Onset of action: Peak effect: Parenteral: ~30 minutes

Duration: Parenteral: 2-4 hours, may extend to 12 hours

Absorption: I.M.: Rapid

Distribution: Crosses blood-brain barrier and placenta

V_d: Children: ~0.25-0.9 L/kg; Adults: ~2 L/kg

Protein binding: Extensive

Metabolism: Hepatic, to *p*-fluorophenylacetic acid, benzimidazolone, *p*-hydroxypiperidine

Half-life elimination: Adults: 2.3 hours

Excretion: Urine (75%, <1% as unchanged drug); feces (22%, 11% to 50% as unchanged drug)

Dosage

Titrate carefully to desired effect

Children 2-12 years: Nausea and vomiting: I.M., I.V.: 0.05-0.06 mg/kg (maximum initial dose: 0.1 mg/kg); additional doses may be repeated to achieve effect; administer additional doses with caution

Adults: Nausea and vomiting: I.M., I.V.: Initial: 2.5 mg; additional doses of 1.25 mg may be administered to achieve desired effect; administer additional doses with caution

Stability Stability of parenteral admixture at room temperature (25°C): 24 hours

Monitoring Parameters To identify QT prolongation, a 12-lead ECG prior to use is recommended; continued ECG monitoring for 2-3 hours following administration is recommended. Vital signs; lipid profile, fasting blood glucose/Hgb A_{1c}, serum magnesium and potassium; BMI; mental status, abnormal involuntary movement scale (AIMS); observe for dystonias, extrapyramidal side effects, and temperature changes

Administration Administer I.M. or I.V.; I.V. should be administered slow IVP (over 2-5 minutes) or IVPB; ECG monitoring for 2-3 hours after administration is recommended

Contraindications Hypersensitivity to droperidol or any component of the formulation; known or suspected QT prolongation, including congenital long QT syndrome (prolonged QT_c is defined as >440 msec in males or >450 msec in females)

Warnings

May alter cardiac conduction. [**U.S. Boxed Warning**]: **Cases of QT prolongation and torsade de pointes, including some fatal cases, have been reported.** Use extreme caution in patients with bradycardia (<50 bpm), cardiac disease, concurrent MAOI therapy, Class I and Class III antiarrhythmics or other drugs known to prolong QT interval, and electrolyte disturbances (hypokalemia or hypomagnesemia), including concomitant drugs which may alter electrolytes (diuretics).

Use with caution in patients with seizures, bone marrow suppression, or severe liver disease. May be sedating, use with caution in disorders where CNS depression is a feature. Caution in patients with hemodynamic instability, predisposition to seizures, subcortical brain damage, renal or respiratory disease. Esophageal dysmotility and aspiration have been associated with antipsychotic use - use with caution in patients at risk of pneumonia (ie, Alzheimer's disease). Caution in breast cancer or other prolactin-dependent tumors (may elevate prolactin levels). May alter temperature regulation or mask toxicity of other drugs due to antiemetic effects. May cause orthostatic hypotension - use with caution in patients at risk of this effect or those who would tolerate transient hypotensive episodes (cerebrovascular disease, cardiovascular disease, or other medications which may predispose). Significant hypotension may occur; injection contains benzyl alcohol; injection also contains sulfites which may cause allergic reaction.

May cause anticholinergic effects (confusion, agitation, constipation, xerostomia, blurred vision, urinary retention). Therefore, they should be used with caution in patients with decreased gastrointestinal motility, urinary retention, BPH, xerostomia, or visual problems. Conditions which also may be exacerbated by cholinergic blockade include narrow-angle glaucoma (screening is recommended) and worsening of myasthenia gravis. Relative to other neuroleptics, droperidol has a low potency of cholinergic blockade.

Droperidol

CAS Number 548-72-3

U.S. Brand Names Inapsine®

Synonyms Dehydrobenzperidol

Impairment Potential Yes

Use Antiemetic in surgical and diagnostic procedures; preoperative medication in patients when other treatments are ineffective or inappropriate

Mechanism of Action Alters the action of dopamine in the CNS, at subcortical levels, to produce sedation; it is a butyrophenone with phenothiazine-like properties

Adverse Reactions

ECG changes and retinal pigmentation are more common than with chlorpromazine. Relative to other neuroleptics, droperidol has a low potency of cholinergic blockade.

Cardiovascular: QT_c prolongation (dose dependent), hypotension (especially orthostatic), tachycardia, abnormal T waves with prolonged ventricular repolarization, arrhythmia, torsade de pointes, ventricular tachycardia

Central nervous system: **Restlessness, anxiety, extrapyramidal symptoms, dystonic reactions, pseudoparkinsonian signs and symptoms, tardive dyskinesia, seizures, altered central temperature regulation, akathisia**, hallucinations, sedation, drowsiness, neuroleptic malignant syndrome, tardive dystonia

May cause extrapyramidal symptoms, including pseudoparkinsonism, acute dystonic reactions, akathisia, and tardive dyskinesia (risk of these reactions is high relative to other neuroleptics). May be associated with neuroleptic malignant syndrome (NMS) or pigmentary retinopathy. Safety in children <6 months of age has not been established.

Dosage Forms Injection, solution: 2.5 mg/mL (1 mL, 2 mL)

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. fluids or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam or diazepam (I.V. 5-10 mg bolus in adults every 15 minutes if needed up to a total of 30 mg; I.V. 0.25-0.4 mg/kg/dose up to a total of 10 mg in children) or to phenytoin or phenobarbital. Also critical cardiac arrhythmias often respond to I.V. phenytoin (15 mg/kg up to 1 g), while other antiarrhythmics can be used. Neuroleptics often cause extrapyramidal reaction (eg, dystonic reactions) requiring management with diphenhydramine 1-2 mg/kg (adults) up to a maximum of 50 mg I.M. or I.V. slow push followed by a maintenance dose for 48-72 hours. When these reactions are unresponsive to diphenhydramine, benztropine mesylate I.V. 1-2 mg (adults) may be effective. These agents are generally effective within 2-5 minutes.

Drug Interactions Acetylcholinesterase inhibitors (central): May increase the risk of antipsychotic-related extrapyramidal symptoms; monitor. CNS depressants: Sedative effects may be additive with other CNS depressants; monitor for increased effect; includes benzodiazepines, barbiturates, antipsychotics, ethanol, opiates, and other sedative medications

Cyclobenzaprine: Droperidol and cyclobenzaprine may have an additive effect on prolonging the QT interval; based on limited documentation; monitor

Inhalation anesthetics: Droperidol in combination with certain forms of induction anesthesia may produce peripheral vasodilation and hypotension

Metoclopramide: May increase extrapyramidal symptoms (EPS) or risk. Potassium- or magnesium-depleting agents: May increase the risk of serious arrhythmias with droperidol; includes many diuretics, aminoglycosides, cyclosporine, supraphysiologic doses of corticosteroids with mineralocorticoid effects, laxatives, and amphotericin B; monitor serum potassium and magnesium levels closely.

Propofol: An increased incidence of postoperative nausea and vomiting have been reported following coadministration

QT_c-prolonging agents: May result in additive effects on cardiac conduction, potentially resulting in malignant or lethal arrhythmias; concurrent use is contraindicated. Includes cisapride, Class I and Class III antiarrhythmics (amiodarone, dofetilide, procainamide, quinidine, sotalol), pimozide, some quinolone antibiotics (moxifloxacin, sparfloxacin, gatifloxacin), tricyclic antidepressants, and some phenothiazines (mesoridazine, thioridazine).

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Lactation Excretion in breast milk unknown

Additional Information

Butyrophenone derivative that produces tranquilization, sedation, and an antiemetic effect; does not possess analgesic effects; has little or no amnesic properties.

May cause hypotension and reflex tachycardia. This is more pronounced when the drug is given intravenously. Warnings concerning QT prolongation have altered recommendations concerning perioperative use and monitoring. Baseline 12-lead ECG screening is recommended, and continued ECG monitoring for 2-3 hours postadministration is advised. Use should be limited to patients in whom alternatives are unacceptable.

Duloxetine

Pronunciation (doo LOX e teen)

CAS Number 136434-34-9

U.S. Brand Names Cymbalta®

Synonyms (+)-(-)-N-Methyl-γ-(1-naphthylloxy)-2-thiophenepropylamine Hydrochloride; Duloxetine Hydrochloride; LY248686

Use Treatment of major depressive disorder; management of pain associated with diabetic neuropathy

Unlabeled/Investigational Use Treatment of stress incontinence; management of chronic pain syndromes; management of fibromyalgia

Mechanism of Action Duloxetine is a potent inhibitor of neuronal serotonin and norepinephrine reuptake and a weak inhibitor of dopamine reuptake. Duloxetine has no significant activity for muscarinic cholinergic, H₁-histaminergic, or α₂-adrenergic receptors. Duloxetine does not possess MAO-inhibitory activity.

Adverse Reactions

> 10%:

Central nervous system: Somnolence (7% to 15%), dizziness (6% to 14%), headache (13%), insomnia (8% to 11%)

Gastrointestinal: Nausea (14% to 22% - usually subsides within 1-2 weeks), xerostomia (5% to 15%), diarrhea (8% to 13%), constipation (5% to 11%)

1% to 10%:

Cardiovascular: Palpitations (1%)

Central nervous system: Fatigue (2% to 10%), anxiety (3%), fever (1% to 2%), hypoesthesia (1%), irritability (1%), lethargy (1%), nervousness (1%), nightmares (1%), restlessness (1%), sleep disorder (1%), vertigo (1%), yawning (1%)

Dermatologic: Hyperhidrosis (6%), pruritus (1%), rash (1%)

Endocrine & metabolic: Libido decreased (3% to 6%), orgasm abnormality (3% to 4%), hot flushes (2%), anorgasmia (1%), hypoglycemia (1%)

Gastrointestinal: Appetite decreased (3% to 8%), vomiting (5% to 6%), dyspepsia (4%), loose stools (2% to 3%), weight loss (1% to 2%), gastritis (1%)

Genitourinary: Erectile dysfunction (1% to 4%), ejaculation delayed (3%), ejaculatory dysfunction (3%), pollakiuria (1% to 3%), dysuria (1%), urinary symptoms (hesitancy, obstructive symptoms; 1%)

Hepatic: Transaminases increased transiently: Occasionally associated with hyperbilirubinemia and/or increased alkaline phosphatase (1%)

Neuromuscular & skeletal: Muscle cramp (4% to 5%), weakness (2% to 4%), myalgia (1% to 3%), tremor (1% to 3%), muscle tightness (1%), muscle twitching (1%), rigors (1%)

Ocular: Blurred vision (4%), mydriasis

Respiratory: Nasopharyngitis (7% to 9%), cough (3% to 6%), pharyngolaryngeal pain (1% to 3%)

Miscellaneous: Diaphoresis increased (6%), night sweats (1%)

< 1%: Abdominal pain, acne, agitation, alopecia, anemia, aphthous stomatitis, ataxia, atrial fibrillation, bloody stools, bruxism, bundle branch block, CHF, cholesterol increased, colitis, dehydration, diplopia, disorientation, diverticulitis, dysarthria, dyslipidemia, dysphagia, ecchymosis, eczema, edema (peripheral), eruption, erythema, esophageal stenosis, facial edema, flu-like syndrome, gastric emptying impaired, gastric irritation, gastric ulcer, gingivitis, glaucoma, hepatic steatosis, hypercholesterolemia, hyperlipidemia, hypertensive crisis, hypertriglyceridemia, irritable bowel syndrome, keroconjunctivitis sicca, leukopenia, lymphadenopathy, macular degeneration, maculopathy, malaise, mania, melena, MI, micturition urgency, mood swings, muscle weakness, nephropathy, nocturia, oropharyngeal edema, phlebitis, photopsia, photosensitivity, retinal detachment, seizure, stomatitis, suicide, tachycardia, thirst, thrombocytopenia, urinary retention, visual disturbance, weight increased; withdrawal syndrome (including headache, dizziness, nightmares, irritability, paresthesia, and/or vomiting)

Postmarketing and/or case reports: Anaphylactic reaction, angioneurotic edema, bilirubin increased, hepatitis, hyponatremia, jaundice, orthostatic hypotension, Stevens-Johnson syndrome, syncope, urticaria

Pharmacodynamics/Kinetics

Absorption: Well absorbed, 3-hour delay in absorption after ingestion

Distribution: 1640 L

Protein binding: >90%

Metabolism: Hepatic, via CYP1A2 and CYP2D6; forms multiple metabolites (inactive)

Half-life elimination: 12 hours (range 8-17 hours)

Time to peak: 6 hours

Excretion: As metabolites; urine (70%), feces (20%); total body clearance: 114 L/hour

Bioavailability: <70% (oral)

Dosage Oral:

Adults:

Treatment of major depressive disorder: Initial: 40-60 mg/day; dose may be divided (ie, 20 or 30 mg twice daily) or given as a single daily dose of 60 mg; maximum dose: 60 mg/day

Management of diabetic neuropathy: 60 mg once daily; lower initial doses may be considered in patients where tolerability is a concern and/or renal impairment is present

Management of chronic pain syndromes (unlabeled use): 60 mg once daily

Management of fibromyalgia (unlabeled use): 60 mg twice daily

Management of stress incontinence (unlabeled use): 40 mg twice daily

Elderly:

Treatment of major depressive disorder: Initial dose: 20 mg 1-2 times/day; increase to 40-60 mg/day as a single daily dose or in divided doses

Other indications: Refer to Adults dosing

Dosage adjustment in renal impairment: Not recommended for use in Cl_{cr} <30 mL/minute or ESRD; in mild-moderate impairment, lower initial doses may be considered with titration guided by response and tolerability

Dosage adjustment in hepatic impairment: Not recommended for use in hepatic impairment

Stability Store at 25°C (77°F), excursions permitted to 15°C to 30°C (59°F to 86°F)

Monitoring Parameters Blood pressure should be regularly monitored, especially in patients with a high baseline blood pressure; mental status for depression, suicidal ideation (especially at the beginning of therapy or when doses are increased or decreased), anxiety, social functioning, mania, panic attacks

Administration Capsule should be swallowed whole; do not break open or crush.

Contraindications Hypersensitivity to duloxetine or any component of the formulation; concomitant use or within 2 weeks of MAO inhibitors; uncontrolled narrow angle glaucoma

Warnings Major psychiatric warnings:

- Antidepressants increase the risk of suicidal thinking and behavior in children and adolescents with major depressive disorder (MDD) and other depressive disorders; consider risk prior to prescribing. Closely monitor for clinical worsening, suicidality, or unusual changes in behavior; the child's family or caregiver should be instructed to closely observe the patient and communicate condition with healthcare provider. A medication guide concerning the use of antidepressants in children and teenagers should be dispensed with each prescription. **Duloxetine is not FDA approved for use in children.**
- The possibility of a suicide attempt is inherent in major depression and may persist until remission occurs. Patients treated with antidepressants should be observed for clinical worsening and suicidality, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases. Worsening depression and severe abrupt suicidality that are not part of the presenting symptoms may require discontinuation or modification of drug therapy. Use caution in high-risk patients during initiation of therapy.
- Prescriptions should be written for the smallest quantity consistent with good patient care. The patient's family or caregiver should be alerted to monitor patients for the emergence of suicidality and associated behaviors such as anxiety, agitation, panic attacks, insomnia, irritability, hostility, impulsivity, akathisia, hypomania, and mania; patients should be instructed to notify their healthcare provider if any of these symptoms or worsening depression or psychosis occur.
- May worsen psychosis in some patients or precipitate a shift to mania or hypomania in patients with bipolar disorder. Monotherapy in patients with bipolar disorder should be avoided. Patients presenting with depressive symptoms should be screened for bipolar disorder. **Duloxetine is not FDA approved for the treatment of bipolar depression.**

Key adverse effects:

- CNS depression: Has a low potential to impair cognitive or motor performance; caution operating hazardous machinery or driving.
- SIADH and hyponatremia: Has been associated with the development of SIADH; hyponatremia has been reported rarely, predominately in the elderly
- Urinary hesitancy: May cause increased urinary resistance; advise patient to report symptoms of urinary hesitation/difficulty.

Concurrent disease:

- Hepatic impairment and/or ethanol use: May cause hepatotoxicity; avoid use in patients with substantial alcohol intake, evidence of chronic liver disease, or hepatic impairment.
- Narrow-angle glaucoma: Associated with an increased risk of mydriasis in patients with controlled narrow-angle glaucoma.
- Renal impairment: Use with caution; clearance is decreased and plasma concentrations are increased; not recommended for use when $Cl_{cr} < 30$ mL/minute or ESRD.
- Sexual dysfunction: May cause or exacerbate sexual dysfunction.
- Seizure disorders: Use caution with a previous seizure disorder or condition predisposing to seizures such as brain damage or alcoholism.

Concurrent drug therapy:

- Agents which lower seizure threshold: Concurrent therapy with other drugs which lower the seizure threshold.
- CNS depressants: Use caution with concomitant therapy.
- MAO inhibitors: Potential for severe reaction when used with MAO inhibitors; autonomic instability, coma, death, delirium, diaphoresis, hyperthermia, mental status changes/agitation, muscular rigidity, myoclonus, neuroleptic malignant syndrome features, and seizures may occur.

Can increase serum half-life and concentration of desipramine

Special notes:

- Electroconvulsive therapy: May increase the risks associated with electroconvulsive therapy; consider discontinuing, when possible, prior to ECT treatment.
- Withdrawal syndrome: May cause dysphoric mood, irritability, agitation, dizziness, sensory disturbances, anxiety, confusion, headache, lethargy, emotional lability, insomnia, hypomania, tinnitus, and seizures. Upon discontinuation of duloxetine therapy, gradually taper dose. If intolerable symptoms occur following a decrease in dosage or upon discontinuation of therapy, then resuming the previous dose with a more gradual taper should be considered.

Dosage Forms Capsule: 20 mg, 30 mg, 60 mg [contains enteric coated pellets]

Reference Range Peak plasma duloxetine and desmethyl metabolite level following a 20 mg oral dose is approximately 13 ng/mL and <2 ng/mL, respectively

Overdosage/Treatment

Decontamination: Lavage (within 3 hours) or administer oral activated charcoal for adult ingestions >1.5 g
Supportive: Monitor for serotonin syndrome; care is supportive

Drug Interactions Substrate (major) of CYP1A2, 2D6; **inhibits** CYP2D6 (moderate)

Bupirone: Concurrent use of duloxetine with bupirone may cause serotonin syndrome; avoid concurrent use.

CYP1A2 inducers: May decrease the levels/effects of duloxetine. Example inducers include aminoglutethimide, carbamazepine, phenobarbital, and rifampin.

CYP1A2 inhibitors: May increase the levels/effects of duloxetine. Example inhibitors include ciprofloxacin, fluvoxamine, ketoconazole, norfloxacin, ofloxacin, and rofecoxib.

CYP2D6 inhibitors: May increase the levels/effects of duloxetine. Example inhibitors include chlorpromazine, delavirdine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, ritonavir, and ropinirole. Desipramine: Duloxetine may increase desipramine levels.

Linezolid: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and deaths have been reported with agents which inhibit MAO (serotonin syndrome); this combination should be avoided.

MAO inhibitors: Hyperpyrexia, hypertension, tachycardia, confusion, seizures, and deaths have been reported with MAO inhibitors (serotonin syndrome); this combination is contraindicated. Wait 5 days after discontinuation of duloxetine before initiating therapy with a MAO inhibitor.

Meperidine: Combined use theoretically may increase the risk of serotonin syndrome.

Moclobemide: Concurrent use of duloxetine with moclobemide may cause serotonin syndrome; avoid concurrent use.

Nefazodone: Concurrent use of duloxetine with nefazodone may cause serotonin syndrome.

Selegiline: Concurrent use with SSRIs has been reported to cause serotonin syndrome; as an MAO type B inhibitor, the risk of serotonin syndrome may be less than with nonselective MAO inhibitors, and reports indicate that this combination has been well tolerated in Parkinson's patients.

SSRIs: Concurrent use with serotonin reuptake inhibitors may increase the risk of serotonin syndrome.

Sibutramine: May increase the risk of serotonin syndrome with SNRIs.

Sumatriptan (and other serotonin agonists): Concurrent use may result in toxicity; weakness, hyper-reflexia, and incoordination have been observed with sumatriptan and SSRIs (and/or SNRIs). In addition, concurrent use may theoretically increase the risk of serotonin syndrome; includes almotriptan, sumatriptan, naratriptan, rizatriptan, and zolmitriptan.

Thioridazine: Duloxetine may increase serum concentrations of thioridazine, which has been associated with the development of malignant ventricular arrhythmias; use caution

Tramadol: Concurrent use of duloxetine with tramadol may cause serotonin syndrome; avoid concurrent use.

Trazodone: Concurrent use of duloxetine with trazodone may cause serotonin syndrome.

Tricyclic antidepressants: Serum levels/effects may be increased by duloxetine; use caution

Venlafaxine: Combined use with duloxetine may increase the risk of serotonin syndrome.

Pregnancy Risk Factor C

Nonteratogenic effects including respiratory distress, cyanosis, apnea, seizures, temperature instability, feeding difficulty, vomiting, hypoglycemia, hypo- or hypertonia, hyper-reflexia, jitteriness, irritability, constant crying, and tremor have been reported in the neonate immediately following delivery after exposure late in the third trimester. Adverse effects may be due to toxic effects of SNRI or drug discontinuation. There are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if the potential benefit to the mother outweighs the possible risk to the fetus. If treatment during pregnancy is required, consider tapering therapy during the third trimester.

Pregnancy Implications Decreased fetal weight and behavioral effects have been reported in animal studies. Nonteratogenic effects including respiratory distress, cyanosis, apnea, seizures, temperature instability, feeding difficulty, vomiting, hypoglycemia, hypo- or hypertonia, hyper-reflexia, jitteriness, irritability, constant crying, and tremor have been reported in the neonate immediately following delivery after exposure late in the third trimester. Adverse effects may be due to toxic effects of SNRI or drug discontinuation. There are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if the potential benefit to the mother outweighs the possible risk to the fetus. If treatment during pregnancy is required, consider tapering therapy during the third trimester.

Lactation Enters breast milk/not recommended

Edrophonium

CAS Number 116-38-1; 312-42-1

U.S. Brand Names Enlon®; Reversol®

Synonyms Edrophonium Chloride

Use Diagnosis of myasthenia gravis; differentiation of cholinergic crises from myasthenia crises; reversal of nondepolarizing neuromuscular blockers; adjunct treatment of respiratory depression caused by curare overdose

Mechanism of Action Inhibits destruction of acetylcholine by acetylcholinesterase which facilitates transmission of impulses across myoneural junction

Adverse Reactions

Cardiovascular: Arrhythmias, hypotension, bradyarrhythmias, ventricular asystole (after a dose of 10 mg), chest pain, flutter (atrial), sinus bradycardia, angina

Central nervous system: Convulsions, seizures

Gastrointestinal: **Nausea, vomiting**, abdominal pain, **diarrhea, excessive salivation, stomach cramps**

Genitourinary: Urinary frequency

Neuromuscular & skeletal: Weakness, muscle cramps

Ocular: Diplopia, photophobia, miosis, blurred vision

Respiratory: Laryngospasm, wheezing, respiratory paralysis, tachypnea

Miscellaneous: **Diaphoresis**, increased secretions

Signs and Symptoms of Overdose Bronchospasm, fibrillation (atrial), hypotension, miosis, muscle weakness, nausea, respiratory paralysis, seizures, vomiting, wheezing

Pharmacodynamics/Kinetics

Onset of action: I.M.: 2-10 minutes; I.V.: 30-60 seconds

Duration: I.M.: 5-30 minutes; I.V.: 10 minutes

Distribution: V_d : Adults: 1.1 L/kg

Half-life elimination: Adults: 1.2-2.4 hours; Anephric patients: 2.4-4.4 hours

Excretion: Adults: Primarily urine (67%)

Dosage

Usually administered I.V., however, if not possible, I.M. or SubQ may be used:

Infants:

I.M.: 0.5-1 mg

I.V.: Initial: 0.1 mg, followed by 0.4 mg if no response; total dose = 0.5 mg

Children:

Diagnosis: Initial: 0.04 mg/kg over 1 minute followed by 0.16 mg/kg if no response, to a maximum total dose of 5 mg for children <34 kg, or 10 mg for children >34 kg **or**

Alternative dosing (manufacturer's recommendation):

≤34 kg: 1 mg; if no response after 45 seconds, repeat dosage in 1 mg increments every 30-45 seconds, up to a total of 5 mg

>34 kg: 2 mg; if no response after 45 seconds, repeat dosage in 1 mg increments every 30-45 seconds, up to a total of 10 mg

I.M.:

<34 kg: 1 mg

>34 kg: 5 mg

Titration of oral anticholinesterase therapy: 0.04 mg/kg once given 1 hour after oral intake of the drug being used in treatment; if strength improves, an increase in neostigmine or pyridostigmine dose is indicated

Adults:

Diagnosis:

I.V.: 2 mg test dose administered over 15-30 seconds; 8 mg given 45 seconds later if no response is seen; test dose may be repeated after 30 minutes

I.M.: Initial: 10 mg; if no cholinergic reaction occurs, administer 2 mg 30 minutes later to rule out false-negative reaction

Titration of oral anticholinesterase therapy: 1-2 mg given 1 hour after oral dose of anticholinesterase; if strength improves, an increase in neostigmine or pyridostigmine dose is indicated

Reversal of nondepolarizing neuromuscular blocking agents (neostigmine with atropine usually preferred): I.V.: 10 mg over 30-45 seconds; may repeat every 5-10 minutes up to 40 mg

Termination of paroxysmal atrial tachycardia: I.V. rapid injection: 5-10 mg

Differentiation of cholinergic from myasthenic crisis: I.V.: 1 mg; may repeat after 1 minute. **Note:** Intubation and controlled ventilation may be required if patient has cholinergic crisis

Dosing adjustment in renal impairment: Dose may need to be reduced in patients with chronic renal failure

Monitoring Parameters Pre- and postinjection strength (cranial musculature is most useful); heart rate, respiratory rate, blood pressure

Administration Edrophonium is administered by direct I.V. injection; see Dosage

Contraindications Hypersensitivity to edrophonium, sulfites, or any component of the formulation; GI or GU obstruction

Warnings Use with caution in patients with bronchial asthma and those receiving a cardiac glycoside; atropine sulfate should always be readily available as an antagonist. Overdosage can cause cholinergic crisis which may be fatal. I.V. atropine should be readily available for treatment of cholinergic reactions.

Dosage Forms Injection, solution, as chloride:

Enlon®: 10 mg/mL (15 mL) [contains sodium sulfite]

Reversol®: 10 mg/mL (10 mL) [contains sodium sulfite]

Reference Range Dose of 0.5 mcg/kg gives mean plasma concentration of 7.82 nmol/mL and will probably decrease cholinesterase levels by >80%

Overdose/Treatment Supportive therapy: For muscarinic symptoms, the antidote is atropine 0.4-0.5 mg I.V. repeated every 3-10 minutes (initial doses as high as 1.2 mg have been administered). Skeletal muscle effects of edrophonium are not alleviated by atropine. Pralidoxime (2-PAM) may be needed to reverse severe muscle asthenia or paralysis; although, since edrophonium is such a short-acting drug, 2-PAM use is usually not necessary.

Antidote(s)

• Atropine [ANTIDOTE]

• Pralidoxime [ANTIDOTE]

Test Interactions ↑ aminotransferases (ALT, AST) (S), amylase (S)

Drug Interactions Decreased effect: Atropine, nondepolarizing muscle relaxants, procainamide, quinidine

Increased effect: Succinylcholine, digoxin, I.V. acetazolamide, neostigmine, physostigmine

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Nursing Implications Atropine sulfate should be available at bedside

Additional Information Overdosage can cause cholinergic crisis which may be fatal. Atropine should be readily available for treatment of cholinergic reactions. Pralidoxime may reverse muscle asthenia.

Eflornithine

CAS Number 96020-91-6

U.S. Brand Names Vaniqa™

Synonyms DFMO; Eflornithine Hydrochloride

Use

Cream: Females ≥12 years: Reduce unwanted hair from face and adjacent areas under the chin

Orphan status: Injection: Treatment of meningoencephalitic stage of *Trypanosoma brucei gambiense* infection (sleeping sickness) *P. carinii* infection, cryptosporidiosis infections in HIV-infected patients

Mechanism of Action Eflornithine exerts antitumor and antiprotozoal effects through specific, irreversible ("suicide") inhibition of the enzyme ornithine decarboxylase (ODC). ODC is the rate-limiting enzyme in the biosynthesis of putrescine, spermine, and spermidine, the major polyamines in nucleated cells. Polyamines are necessary for the synthesis of DNA, RNA, and proteins and are, therefore, necessary for cell growth and differentiation. Although many microorganisms and higher plants are able to produce polyamines from alternate biochemical pathways, all mammalian cells depend on ornithine decarboxylase to produce polyamines. Eflornithine inhibits ODC and rapidly depletes animal cells of putrescine and spermidine; the concentration of spermine remains the same or may even increase. Rapidly dividing cells appear to be most susceptible to the effects of eflornithine.

Adverse Reactions

Central nervous system: Convulsions

Dermatologic: Alopecia

Gastrointestinal: Diarrhea, vomiting

Hematologic: **Anemia, leukopenia, thrombocytopenia**

Otic: Hearing impairment, deafness

Signs and Symptoms of Overdose In mice and rats CNS depression, seizures and death have occurred. Human overdose cases have not been published. Leukopenia, neutropenia, agranulocytosis, granulocytopenia

Pharmacodynamics/Kinetics

Absorption: Topical: <1%

Half-life elimination: I.V.: 3-3.5 hours; Topical: 8 hours

Excretion: Primarily urine (as unchanged drug)

Dosage

Children ≥12 years and Adults: Females: Topical: Apply thin layer of cream to affected areas of face and adjacent chin twice daily, at least 8 hours apart

Adults: I.V. infusion: 100 mg/kg/dose given every 6 hours (over at least 45 minutes) for 14 days

Dosing adjustment in renal impairment: Injection: Dose should be adjusted although no specific guidelines are available

Monitoring Parameters CBC with platelet counts

Administration

I.V.: Administered I.V. only; infuse over 45 minutes. Not for I.M. administration.

Cream: Apply thin layer of eflornithine cream to affected areas of face and adjacent chin area twice daily, at least 8 hours apart. Rub in thoroughly. Hair removal techniques must still be continued; wait at least 5 minutes after removing hair to apply cream. Do not wash affected area for at least 8 hours following application.

Contraindications Hypersensitivity to eflornithine or any component of the formulation

Warnings Injection: For I.V. use only; not for I.M. administration. Must be diluted before use; frequent monitoring for myelosuppression should be done; use with caution in patients with a history of seizures and in patients with renal impairment; serial audiograms should be obtained; due to the potential for relapse, patients should be followed up for at least 24 months

Cream: For topical use by females only; discontinue if hypersensitivity occurs; safety and efficacy in children < 12 years has not been studied

Dosage Forms

Cream, topical, as hydrochloride: 13.9% (30 g)
Injection, solution, as hydrochloride: 200 mg/mL (100 mL) [orphan drug status]

Overdosage/Treatment

Decontamination: Activated charcoal
Supportive therapy: General poison management; no known antidote

Test Interactions ↑ BUN; ↓ RBC, WBC, platelets

Drug Interactions Cream: Possible interactions with other topical products have not been studied.

Pregnancy Risk Factor C

Pregnancy Implications There are no adequate and well-controlled studies of topical eflornithine cream in pregnant women. The potential benefits to the mother versus the possible risks to the fetus should be considered prior to use.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Must be diluted before use and used within 24 hours of preparation

Enalapril

Related Information

- Angiotensin Agents
- CAS Number** 75847-73-3; 76095-16-4
- U.S. Brand Names** Vasotec®
- Synonyms** Enalapril Maleate; Enalaprilat

Use Management of mild to severe hypertension; treatment of congestive heart failure, left ventricular dysfunction after myocardial infarction

Unlabeled/Investigational Use Unlabeled: Hypertensive crisis, diabetic nephropathy, rheumatoid arthritis, diagnosis of anatomic renal artery stenosis, hypertension secondary to scleroderma renal crisis, diagnosis of aldosteronism, idiopathic edema, Bartter's syndrome, postmyocardial infarction for prevention of ventricular failure
Investigational: Severe congestive heart failure in infants, neonatal hypertension, acute pulmonary edema

Mechanism of Action Competitive inhibitor of angiotensin-converting enzyme (ACE); prevents conversion of angiotensin I to angiotensin II, a potent vasoconstrictor; results in lower levels of angiotensin II which causes an increase in plasma renin activity and a reduction in aldosterone secretion

Adverse Reactions

- Cardiovascular:** Hypotension, chest pain, syncope, bradycardia, sinus bradycardia, angina, vasodilation, vasculitis
- Central nervous system:** Fatigue, psychosis, insomnia, dizziness, headache
- Dermatologic:** Rash, pemphigus, angioedema (0.68%), toxic pustuloderma, toxic epidermal necrolysis, exfoliative dermatitis, erythema multiforme, alopecia, urticaria, purpura, Stevens-Johnson syndrome, photosensitivity, pruritus, licheniform eruptions, exanthem, scalded mouth syndrome, Henoch-Schönlein purpura, cutaneous vasculitis
- Endocrine & metabolic:** Hypoglycemia, gynecomastia, hyperkalemia, syndrome of inappropriate antidiuretic hormone secretion
- Gastrointestinal:** Nausea, dyspepsia, diarrhea, pancreatitis, loss of taste perception (less than with captopril), metallic taste, salty taste
- Genitourinary:** Impotence
- Hematologic:** Leukopenia/neutropenia (agranulocytosis, granulocytopenia), anemia, pancytopenia
- Neuromuscular & skeletal:** Muscle cramps
- Otic:** Decreased hearing acuity
- Renal:** Deterioration in renal function, proteinuria, diuresis, renal vasculitis
- Respiratory:** Cough, hyposmia
- Miscellaneous:** Systemic lupus erythematosus

Signs and Symptoms of Overdose Hypotension is usually not severe in overdose patients and manifests itself within 1 hour with a maximal effect at 4 hours. Azotemia, bradycardia, coagulopathy deafness,

depression, eosinophilia, hypoglycemia, insomnia, pemphigus, ototoxicity, thrombocytopenia, tinnitus

Pharmacodynamics/Kinetics

Onset of action: Oral: ~1 hour
Duration: Oral: 12-24 hours
Absorption: Oral: 55% to 75%
Protein binding: 50% to 60%
Metabolism: Prodrug, undergoes hepatic biotransformation to enalaprilat
Half-life elimination:

Enalapril: Adults: Healthy: 2 hours; Congestive heart failure: 3.4-5.8 hours

Enalaprilat: Infants 6 weeks to 8 months old: 6-10 hours; Adults: 35-38 hours

Time to peak, serum: Oral: Enalapril: 0.5-1.5 hours; Enalaprilat (active): 3-4.5 hours

Excretion: Urine (60% to 80%); some feces

Dosage

Use lower listed initial dose in patients with hyponatremia, hypovolemia, severe congestive heart failure, decreased renal function, or in those receiving diuretics.

Oral: **Enalapril:** Children 1 month to 16 years: Hypertension: Initial: 0.08 mg/kg (up to 5 mg) once daily; adjust dosage based on patient response; doses >0.58 mg/kg (40 mg) have not been evaluated in pediatric patients

Investigational: Congestive heart failure: Initial oral doses of **enalapril:** 0.1 mg/kg/day increasing as needed over 2 weeks to 0.5 mg/kg/day have been used in infants

Investigational: Neonatal hypertension: I.V. doses of **enalaprilat:** 5-10 mcg/kg/dose administered every 8-24 hours have been used; monitor patients carefully; select patients may require higher doses

Adults:

Oral: **Enalapril:**

Hypertension: 2.5-5 mg/day then increase as required; usual dose range (JNC 7): 2.5-40 mg/day in 1-2 divided doses. **Note:** Initiate with 2.5 mg if patient is taking a diuretic which cannot be discontinued. May add a diuretic if blood pressure cannot be controlled with enalapril alone.

Heart failure: As standard therapy alone or with diuretics, beta-blockers, and digoxin, initiate with 2.5 mg once or twice daily (usual range: 5-20 mg/day in 2 divided doses; target: 40 mg)

Asymptomatic left ventricular dysfunction: 2.5 mg twice daily, titrated as tolerated to 20 mg/day

I.V.: **Enalaprilat:**

Hypertension: 1.25 mg/dose, given over 5 minutes every 6 hours; doses as high as 5 mg/dose every 6 hours have been tolerated for up to 36 hours. **Note:** If patients are concomitantly receiving diuretic therapy, begin with 0.625 mg I.V. over 5 minutes; if the effect is not adequate after 1 hour, repeat the dose and administer 1.25 mg at 6-hour intervals thereafter; if adequate, administer 0.625 mg I.V. every 6 hours.

Heart failure: Avoid I.V. administration in patients with unstable heart failure or those suffering acute myocardial infarction.

Conversion from I.V. to oral therapy if not concurrently on diuretics: 5 mg once daily; subsequent titration as needed; if concurrently receiving diuretics and responding to 0.625 mg I.V. every 6 hours, initiate with 2.5 mg/day.

Dosing adjustment in renal impairment:

Oral: Enalapril:

Cl_{cr} 30-80 mL/minute: Administer 5 mg/day titrated upwards to maximum of 40 mg.

Cl_{cr} < 30 mL/minute: Administer 2.5 mg day; titrated upward until blood pressure is controlled.

For heart failure patients with sodium < 130 mEq/L or serum creatinine > 1.6 mg/dL, initiate dosage with 2.5 mg/day, increasing to twice daily as needed. Increase further in increments of 2.5 mg/dose at > 4-day intervals to a maximum daily dose of 40 mg.

I.V.: Enalaprilat:

Cl_{cr} > 30 mL/minute: Initiate with 1.25 mg every 6 hours and increase dose based on response.

Cl_{cr} < 30 mL/minute: Initiate with 0.625 mg every 6 hours and increase dose based on response.

Hemodialysis: Moderately dialyzable (20% to 50%); administer dose postdialysis (eg, 0.625 mg I.V. every 6 hours) or administer 20% to 25% supplemental dose following dialysis; Clearance: 62 mL/minute.

Peritoneal dialysis: Supplemental dose is not necessary, although some removal of drug occurs.

Dosing adjustment in hepatic impairment: Hydrolysis of enalapril to enalaprilat may be delayed and/or impaired in patients with severe hepatic impairment, but the pharmacodynamic effects of the drug do not appear to be significantly altered; no dosage adjustment.

Stability Solutions for I.V. infusion mixed in NS or D₅W, are stable for 24 hours at room temperature

Monitoring Parameters Blood pressure, renal function, WBC, serum potassium; blood pressure monitor required during intravenous administration

Administration Administer direct IVP over at least 5 minutes or dilute up to 50 mL and infuse; discontinue diuretic, if possible, for 2-3 days before beginning enalapril therapy

Contraindications Hypersensitivity to enalapril or enalaprilat; angioedema related to previous treatment with an ACE inhibitor; patients with idiopathic or hereditary angioedema; bilateral renal artery stenosis; pregnancy (2nd and 3rd trimesters)

Warnings

Anaphylactic reactions can occur. Angioedema can occur at any time during treatment (especially following first dose). It may involve head and neck (potentially affecting the airway) or the intestine (presenting with abdominal pain). Prolonged monitoring may be required especially if tongue, glottis, or larynx are involved as they are associated with airway obstruction. Those with a history of airway surgery in this situation have a higher risk. Careful blood pressure monitoring with first dose (hypotension can occur especially in volume-depleted patients).

[U.S. Boxed Warning]: Based on human data, ACEIs can cause injury and death to the developing fetus when used in the second and third trimesters. ACEIs should be discontinued as soon as possible once pregnancy is detected. Dosage adjustment needed in renal impairment. Use with caution in hypovolemia; collagen vascular diseases; valvular stenosis (particularly aortic stenosis); hyperkalemia; or before, during, or immediately after anesthesia. Avoid rapid dosage escalation which may lead to renal insufficiency.

Rare toxicities associated with ACE inhibitors include cholestatic jaundice (which may progress to hepatic necrosis) and neutropenia/agranulocytosis with myeloid hyperplasia. Hypersensitivity reactions may be seen during hemodialysis with high-flux dialysis membranes (eg, AN69). Hyperkalemia may rarely occur. If patient has renal impairment then a baseline WBC with differential and serum creatinine should be evaluated and monitored closely during the first 3 months of therapy. Use with caution in unilateral renal artery stenosis and pre-existing renal insufficiency.

Dosage Forms

Injection, solution, as enalaprilat: 1.25 mg/mL (1 mL, 2 mL) [contains benzyl alcohol]

Tablet, as maleate (Vasotec®): 2.5 mg, 5 mg, 10 mg, 20 mg

Reference Range Enalaprilat plasma level of 40 mcg/L (104 mM/L) can produce a mean blood pressure reduction of 12 mm Hg

Overdosage/Treatment

Decontamination: Ipecac (within 30 minutes)/lavage (within 1 hour)/activated charcoal

Supportive therapy: Following initiation of essential overdose management, toxic symptom treatment and supportive treatment should be initiated. Hypotension usually responds to I.V. normal saline or Trendelenburg positioning. If unresponsive to these measures, the use of a parenteral inotrope may be required (eg, norepinephrine 0.1-0.2 mcg/kg/minute titrated to response). Seizures commonly respond to lorazepam or diazepam (I.V. 5-10 mg bolus in adults every 15 minutes if needed up to a total of 30 mg; I.V. 0.25-0.4 mg/kg/dose up to a total of 10 mg in children) or to phenytoin or phenobarbital. Naloxone may antagonize hypotensive effects. Inhaled sodium cromoglycate (total dose: 40 mg/day) can decrease ACE-inhibitor cough by 50%. Picotamide (600 mg twice daily) can also decrease ACE-inhibitor cough. In Great Britain, I.V. use of angiotensin II at a dose of 22 ng/kg/minute has been shown to result in elevation of blood pressure and cardiac output in an enalapril overdose. For refractory hypotension, angiotensin amide infusion may be attempted.

Enhanced elimination: Multiple dosing of activated charcoal may be effective

Test Interactions ↑ BUN, creatinine, potassium; positive Coombs' [direct]; ↓ cholesterol (S); may cause false-positive urine acetone determinations using sodium nitroprusside reagent

Drug Interactions **Substrate** of CYP3A4 (major)

α₁ blockers: Hypotensive effect increased.

Aspirin: The effects of ACE inhibitors may be blunted by aspirin administration, particularly at higher dosages (see Cardiovascular Considerations) and/or increase adverse renal effects.

CYP3A4 inducers: CYP3A4 inducers may decrease the levels/effects of enalapril. Example inducers include aminoglutethimide, carbamazepine, nafcillin, nevirapine, phenobarbital, phenytoin, and rifamycins.

Diuretics: Hypovolemia due to diuretics may precipitate acute hypotensive events or acute renal failure.

Insulin: Risk of hypoglycemia may be increased.

Lithium: Risk of lithium toxicity may be increased; monitor lithium levels, especially in the first 4 weeks of therapy.

Mercaptopurine: Risk of neutropenia may be increased.

NSAIDs: May attenuate hypertensive efficacy; effect has been seen with captopril and may occur with other ACE inhibitors; monitor blood pressure. May increase risk of renal adverse effects.

Potassium-sparing diuretics (amiloride, spironolactone, triamterene): Increased risk of hyperkalemia.

Potassium supplements may increase the risk of hyperkalemia.

Trimethoprim (high dose) may increase the risk of hyperkalemia.

Pregnancy Risk Factor C (1st trimester)/D (2nd and 3rd trimesters)

Pregnancy Implications Decreased placental blood flow, low birth weight, fetal hypotension, preterm delivery, and fetal death have been noted with the use of some ACE inhibitors (ACEIs) in animal studies. Neonatal hypotension, skull hypoplasia, anuria, renal failure, oligohydramnios (associated with fetal limb contractures, craniofacial deformities, hypoplastic lung development), prematurity, intrauterine growth retardation, and patent ductus arteriosus have been reported with the use of ACEIs, primarily in the 2nd and 3rd trimesters. The risk of neonatal toxicity has been considered less when ACEIs have been used in the 1st trimester; however, major congenital malformations have been reported. The cardiovascular and/or central nervous systems are most commonly affected. Unless alternative agents are not appropriate, ACEIs should be discontinued as soon as possible once pregnancy is detected.

Lactation Enters breast milk/not recommended (AAP rates "compatible")

Nursing Implications May cause depression in some patients; discontinue if angioedema of the face, extremities, lips, tongue, or glottis occurs

Additional Information Severe hypotension may occur in patients who are sodium and/or volume depleted. Initiate lower doses and monitor closely when starting therapy in these patients. Reduces albuminuria in sickle cell anemia by up to 70%

Angioedema is more likely to occur in black patients, those older than 65 years, and those with a history of drug rash or seasonal allergies.

Enfuvirtide

U.S. Brand Names Fuzeon™

Synonyms T-20

Use Treatment of HIV-1 infection in combination with other antiretroviral agents in treatment-experienced patients with evidence of HIV-1 replication despite ongoing antiretroviral therapy

Mechanism of Action Binds to the first heptad-repeat (HR1) in the gp41 subunit of the viral envelope glycoprotein. Inhibits the fusion of HIV-1 virus with CD4 cells by blocking the conformational change in gp41 required for membrane fusion and entry into CD4 cells

Adverse Reactions

Central nervous system: **Insomnia**, depression, anxiety, Guillain-Barré syndrome

Dermatologic: Pruritus

Endocrine & metabolic: Weight loss, anorexia, hyperglycemia

Gastrointestinal: Triglycerides increased, appetite decreased, constipation, abdominal pain, pancreatitis, taste disturbance, serum amylase increased

Hematologic: Eosinophilia, anemia, thrombocytopenia, neutropenia

Hepatic: Serum transaminases increased

Local: **Injection site reactions (98%; may include pain, erythema, induration, pruritus, ecchymosis, nodule or cyst formation)**, injection site infection

Neuromuscular & skeletal: Neuropathy, weakness, myalgia

Ocular: Conjunctivitis

Renal: Renal insufficiency, renal failure

Respiratory: Cough, pneumonia (4.7 events per 100 patient years vs 0.61 events per 100 patient years in control group), sinusitis

Miscellaneous: Infections, flu-like symptoms, lymphadenopathy, hypersensitivity reactions (symptoms may include rash, fever, nausea, vomiting, hypotension, and hepatic transaminases increased), worsening of abacavir hypersensitivity, sixth nerve palsy

Pharmacodynamics/Kinetics

Distribution: V_d: 5.5 L

Protein binding: 92%

Metabolism: Proteolytic hydrolysis (CYP isoenzymes do not appear to contribute to metabolism); clearance: 24.8 mL/hour/kg

Half-life elimination: 3.8 hours

Time to peak: 8 hours

ENOXACIN

Dosage

SubQ:
Children ≥ 6 years: 2 mg/kg twice daily (maximum dose: 90 mg twice daily)

Adults: 90 mg twice daily

Dosage adjustment in renal impairment: No dosage adjustment required

Stability Store powder at 25°C (77°F); excursions permitted to 15°C to 30°C (59 to 86°F). Reconstitute with 1.1 mL SWFI; tap vial for 10 seconds and roll gently to ensure contact with diluent; then allow to stand until solution is completed; may require up to 45 minutes to form solution. Reconstituted solutions should be refrigerated and must be used within 24 hours.

Administration Inject subcutaneously into upper arm, abdomen, or anterior thigh. Do not inject into moles, scar tissue, bruises, or the navel. Rotate injection site, give injections at a site different from the preceding injection site; do not inject into any site where an injection site reaction is evident.

Contraindications Hypersensitivity to enoxivirtide or any component of the formulation

Warnings Monitor closely for signs/symptoms of pneumonia; associated with an increased incidence during clinical trials, particularly in patients with a low CD4 cell count, high initial viral load, I.V. drug use, smoking, or a history of lung disease. May cause hypersensitivity reactions (symptoms may include rash, fever, nausea, vomiting, hypotension, and elevated transaminases). In addition, local injection site reactions may occur. An inflammatory response to indolent or residual opportunistic infections (immune reconstitution syndrome) has occurred with antiretroviral therapy; further investigation is warranted. Safety and efficacy have not been established in children < 6 years of age.

Dosage Forms Injection, powder for reconstitution [preservative free]: Fuzeon®: 108 mg [90 mg/mL following reconstitution; available in convenience kit of 60 vials, SWFI, syringes, alcohol wipes, patient instructions]

Drug Interactions No interactions have been identified which would require alteration of other antiretroviral drugs.

Pregnancy Risk Factor B

Pregnancy Implications An antiretroviral registry has been established to monitor maternal and fetal outcomes in women receiving antiretroviral drugs. Physicians are encouraged to register patients at 1-800-258-4263.

Lactation Excretion in breast milk unknown/contraindicated

Enoxacin

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 74011-58-8

Use Complicated and uncomplicated urinary tract infections caused by susceptible gram-negative and gram-positive bacteria

Mechanism of Action Enoxacin exerts its antibacterial activity, as do other quinolone-azaquinolone antibiotics, by inhibition of bacterial DNA gyrase

Adverse Reactions

Central nervous system: Restlessness, dizziness, confusion, seizures, headache, CNS depression, visual hallucinations, depression

Dermatologic: Rash, photosensitivity, urticaria, exanthem, photoallergic reaction

Gastrointestinal: Nausea, diarrhea, vomiting, GI bleeding, feces discoloration (white/speckling)

Hematologic: Anemia

Hepatic: Elevated liver enzymes

Neuromuscular & skeletal: Tremors, arthralgia

Ocular: Phototoxic

Renal: Renal failure (acute), elevation of serum creatinine and BUN

Toxicodynamics/Kinetics

Absorption: 98%

Distribution: Penetrates well into tissues and body secretions

Bioavailability: Essentially the bioavailability as I.V. administration; administration with food does not affect bioavailability

Half-life: 3-6 hours (average)

Elimination: Primarily excreted in urine; however, significant drug concentrations are achieved in feces

Dosage Adults: Oral: 400 mg twice daily

Dosing adjustment in renal impairment: $Cl_{cr} < 50$ mL/minute: Administer 50% of dose

Reference Range Peak plasma level: 3 mg/L after a 750 mg oral dose

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Pregnancy Risk Factor C

Enoxaparin

CAS Number 74011-58-8

U.S. Brand Names Lovenox®

Synonyms Enoxaparin Sodium

Use

DVT Treatment (acute): Inpatient treatment (patients with and without pulmonary embolism) and outpatient treatment (patients without pulmonary embolism)

DVT prophylaxis: Following hip or knee replacement surgery, abdominal surgery, or in medical patients with severely-restricted mobility during acute illness in patients at risk of thromboembolic complications

Note: High-risk patients include those with one or more of the following risk factors: > 40 years of age, obesity, general anesthesia lasting > 30 minutes, malignancy, history of deep vein thrombosis or pulmonary embolism

Unstable angina and non-Q-wave myocardial infarction (to prevent ischemic complications)

Unlabeled/Investigational Use Prophylaxis and treatment of thromboembolism in children

Mechanism of Action Inhibits thrombin

Adverse Reactions

Cardiovascular: Edema

Central nervous system: Confusion, fever, intracranial bleed

Dermatologic: Ecchymosis, erythema, skin necrosis, eczematous plaques, itchy erythematous patches, pruritus, urticaria, vesicobullous rash, purpura, skin necrosis

Endocrine & metabolic: Hyperlipidemia, hypertriglyceridemia

Gastrointestinal: Nausea, diarrhea

Hematologic: Hemorrhage, thrombocytopenia, hypochromic anemia, coagulopathy, thrombocytosis, hematoma, spontaneous splenic rupture

Hepatic: Increased ALT/AST

Local: Local irritation, pain

Neuromuscular & skeletal: Erythromelalgia

Miscellaneous: Allergic reaction, anaphylactoid reaction, retroperitoneal bleed

Spinal or epidural hematomas can occur following neuraxial anesthesia or spinal puncture, resulting in paralysis. Risk is increased in patients with indwelling epidural catheters or concomitant use of other drugs affecting hemostasis. Prosthetic valve thrombosis, including fatal cases, has been reported in pregnant women receiving enoxaparin as thromboprophylaxis. Thrombocytopenia with thrombosis: Cases of heparin-induced thrombocytopenia (some complicated by organ infarction, limb ischemia, or death) have been reported.

Pharmacodynamics/Kinetics

Onset of action: Peak effect: SubQ: Antifactor Xa and antithrombin (antifactor IIa): 3-5 hours

Duration: 40 mg dose: Antifactor Xa activity: ~ 12 hours

Metabolism: Hepatic, to lower molecular weight fragments (little activity)

Protein binding: Does not bind to heparin binding proteins

Half-life elimination, plasma: 2-4 times longer than standard heparin, independent of dose; based on anti-Xa activity: 4.5-7 hours

Excretion: Urine (40% of dose; 10% as active fragments)

Dosage

SubQ:

Infants and Children (unlabeled use):

Infants < 2 months: Initial:

Prophylaxis: 0.75 mg/kg every 12 hours

Treatment: 1.5 mg/kg every 12 hours

Infants > 2 months and Children ≤ 18 years: Initial:

Prophylaxis: 0.5 mg/kg every 12 hours

Treatment: 1 mg/kg every 12 hours

Adults:

DVT prophylaxis:

Hip replacement surgery:

Twice-daily dosing: 30 mg twice daily, with initial dose within 12-24 hours after surgery, and every 12 hours until risk of DVT has diminished or the patient is adequately anticoagulated on warfarin.

Once-daily dosing: 40 mg once daily, with initial dose within 9-15 hours before surgery, and daily until risk of DVT has diminished or the patient is adequately anticoagulated on warfarin.

Knee replacement surgery: 30 mg twice daily, with initial dose within 12-24 hours after surgery, and every 12 hours until risk of DVT has diminished (usually 7-10 days).

Abdominal surgery: 40 mg once daily, with initial dose given 2 hours prior to surgery; continue until risk of DVT has diminished (usual 7-10 days).

Medical patients with severely-restricted mobility during acute illness: 40 mg once daily; continue until risk of DVT has diminished

DVT treatment (acute): **Note:** Start warfarin within 72 hours and continue enoxaparin until INR is between 2.0 and 3.0 (usually 7 days).

Inpatient treatment (with or without pulmonary embolism): 1 mg/kg/dose every 12 hours or 1.5 mg/kg once daily.

Outpatient treatment (without pulmonary embolism): 1 mg/kg/dose every 12 hours.

Unstable angina or non-Q-wave MI: 1 mg/kg twice daily in conjunction with oral aspirin therapy (100-325 mg once daily); continue until clinical stabilization (a minimum of at least 2 days)

Elderly: Increased incidence of bleeding with doses of 1.5 mg/kg/day or 1 mg/kg every 12 hours; injection-associated bleeding and serious adverse reactions are also increased in the elderly. Careful attention should be paid to elderly patients <45 kg.

Dosing adjustment in renal impairment: SubQ:

$Cl_{cr} \geq 30$ mL/minute: No specific adjustment recommended (per manufacturer); monitor closely for bleeding

$Cl_{cr} < 30$ mL/minute:

DVT prophylaxis in abdominal surgery, hip replacement, knee replacement, or in medical patients during acute illness: 30 mg once daily

DVT treatment (inpatient or outpatient treatment in conjunction with warfarin): 1 mg/kg once daily

Unstable angina, non-Q-wave MI (with ASA): 1 mg/kg once daily

Dialysis: Enoxaparin has not been FDA approved for use in dialysis patients. It's elimination is primarily via the renal route. Serious bleeding complications have been reported with use in patients who are dialysis dependent or have severe renal failure. LMWH administration at fixed doses without monitoring has greater unpredictable anticoagulant effects in patients with chronic kidney disease. If used, dosages should be reduced and anti-Xa activity frequently monitored, as accumulation may occur over days. Many clinicians would not use enoxaparin in this population especially without timely anti-Xa activity assay results.

Hemodialysis: Supplemental dose is not necessary.

Peritoneal dialysis: Significant drug removal is unlikely based on physicochemical characteristics.

Stability Incompatible with gentamicin

Monitoring Parameters Platelets, occult blood, and anti-Xa activity, if available; the monitoring of PT and/or PTT is not necessary

Administration Should be administered by deep SubQ injection to the left or right anterolateral and left or right posterolateral abdominal wall. To avoid loss of drug from the 30 mg and 40 mg syringes, do not expel the air bubble from the syringe prior to injection. In order to minimize bruising, do not rub injection site. An automatic injector (Lovenox EasyInjector™) is available with the 30 mg and 40 mg syringes to aid the patient with self-injections. **Note:** Enoxaparin is available in 100 mg/mL and 150 mg/mL concentrations.

Contraindications Hypersensitivity to enoxaparin, heparin, or any component of the formulation; thrombocytopenia associated with a positive *in vitro* test for antiplatelet antibodies in the presence of enoxaparin; hypersensitivity to pork products; active major bleeding; not for I.M. or I.V. use

Warnings

[U.S. Boxed Warning]: Patients with recent or anticipated neuraxial anesthesia (epidural or spinal anesthesia) are at risk of spinal or epidural hematoma and subsequent paralysis. Consider risk versus benefit prior to neuraxial anesthesia; risk is increased by concomitant agents which may alter hemostasis, as well as traumatic or repeated epidural or spinal puncture. Patient should be observed closely for bleeding if enoxaparin is administered during or immediately following diagnostic lumbar puncture, epidural anesthesia, or spinal anesthesia.

Do not administer intramuscularly. Not recommended for thromboprophylaxis in patients with prosthetic heart valves (especially pregnant women). Not to be used interchangeably (unit for unit) with heparin or any other low molecular weight heparins. Use caution in patients with history of heparin-induced thrombocytopenia. Monitor patient closely for signs or symptoms of bleeding. Certain patients are at increased risk of bleeding. Risk factors include bacterial endocarditis; congenital or acquired bleeding disorders; active ulcerative or angiodysplastic GI diseases; severe uncontrolled hypertension; hemorrhagic stroke; use shortly after brain, spinal, or ophthalmology surgery; patients treated concomitantly with platelet inhibitors; recent GI bleeding; thrombocytopenia or platelet defects; severe liver disease; hypertensive or diabetic retinopathy; or in patients undergoing invasive procedures. Monitor platelet count closely. Rare cases of thrombocytopenia have occurred. Manufacturer recommends discontinuation of therapy if platelets are <100,000/mm³. Risk of bleeding may be increased in women <45 kg and in men <57 kg. Use caution in patients with renal failure; dosage adjustment needed if $Cl_{cr} < 30$ mL/minute. Safety and efficacy in pediatric patients have not been established. Use with caution in the elderly (delayed elimination may occur). Heparin can cause hyperkalemia by affecting aldosterone. Similar reactions could occur with LMWHs. Monitor for hyperkalemia. Multiple-dose vials contain benzyl alcohol (use caution in pregnant women).

Dosage Forms

Injection, solution, as sodium [graduated prefilled syringe; preservative free]: 60 mg/0.6 mL (0.6 mL); 80 mg/0.8 mL (0.8 mL); 100 mg/mL (1 mL); 120 mg/0.8 mL (0.8 mL); 150 mg/mL (1 mL)

Injection, solution, as sodium [multidose vial]: 100 mg/mL (3 mL) [contains benzyl alcohol]

Injection, solution, as sodium [prefilled syringe; preservative free]: 30 mg/0.3 mL (0.3 mL); 40 mg/0.4 mL (0.4 mL)

Reference Range Risk of bleeding increases when antifactor Xa levels exceed 0.4 unit/mL

Overdosage/Treatment

Supportive therapy: In the event of a serious bleeding episode in a patient receiving enoxaparin therapy, protamine may be used. The recommended dose of protamine can be found in the following table. It is important to realize that protamine will neutralize a maximum of 60% to 70% of enoxaparin. If serious bleeding occurs, protamine should be used in conjunction with FFP. An additional 0.5 mg protamine per 1 mg enoxaparin can be administered 2-4 hours after the initial dose if PTT is still elevated at this time.

Enhancement of elimination: While hemodialysis is not beneficial, exchange transfusion has been used successfully in a neonate and plasma exchange has been used successfully in four older patients for thrombocytopenia. See table.

Recommended Protamine Dosing		
<8 Hours Since Last Dose	8-12 Hours Since Last Dose	>12 Hours Since Last Dose
1 mg protamine per 1 mg enoxaparin	0.5 mg protamine per 1 mg enoxaparin	No recommended dose: protamine probably not of value at this time

Antidote(s)

- Protamine Sulfate [ANTIDOTE]

Drug Interactions

Drugs which affect platelet function (eg, aspirin, NSAIDs, dipyridamole, ticlopidine, clopidogrel) may potentiate the risk of hemorrhage.

Thrombolytic agents increase the risk of hemorrhage.

Warfarin: Risk of bleeding may be increased during concurrent therapy.

Enoxaparin is commonly continued during the initiation of warfarin therapy to assure anticoagulation and to protect against possible transient hypercoagulability.

Pregnancy Risk Factor B

Pregnancy Implications There are no adequate and well-controlled studies using enoxaparin in pregnant women. Animal studies have not shown teratogenic or fetotoxic effects. Postmarketing reports include congenital abnormalities (cause and effect not established) and also fetal death when used in pregnant women. In addition, prosthetic valve thrombosis, including fatal cases, has been reported in pregnant women receiving enoxaparin as thromboprophylaxis. Multiple-dose vials contain benzyl alcohol; use caution in pregnant women.

Lactation Excretion in breast milk unknown/use caution

Additional Information ~1/2 the weight of heparin with 20% of the activity

Ephedrine

Related Information

- Ephedra
- Therapeutic Drugs Associated with Hallucinations

CAS Number 134-72-5; 299-42-3; 50906-05-3

U.S. Brand Names Pretz-D® [OTC]

Synonyms Ephedrine Sulfate

Impairment Potential Yes

Use Bronchial asthma; nasal congestion; acute wheezing; acute hypotensive states

Mechanism of Action Releases tissue stores of epinephrine and thereby produces an alpha- and beta-adrenergic stimulation

Adverse Reactions

Cardiovascular: Hypertension, cardiomyopathy, cardiomegaly, sinus tachycardia

Central nervous system: **CNS-stimulating effects, nervousness, anxiety, fear, psychosis, tension, agitation, excitation, restlessness, irritability, insomnia,** auditory and visual hallucinations, vasculitis, mania, paranoia, psychosis, sympathetic storm, **apprehension, hyperactivity**

Endocrine & metabolic: Hypokalemia
 Gastrointestinal: Nausea, anorexia
 Neuromuscular & skeletal: Tremors, weakness

Signs and Symptoms of Overdose CNS depression, depression, dry skin, dysrhythmias, insomnia, mydriasis, respiratory alkalosis, respiratory depression, seizures, vomiting

Pharmacodynamics/Kinetics

Onset of action: Oral: Bronchodilation: 0.25-1 hour
 Duration: Oral: 3-6 hours
 Distribution: Crosses placenta; enters breast milk
 Metabolism: Minimally hepatic
 Half-life elimination: 2.5-3.6 hours
 Excretion: Urine (60% to 77% as unchanged drug) within 24 hours

Dosage

Children:

Oral, SubQ: 3 mg/kg/day or 25-100 mg/m²/day in 4-6 divided doses every 4-6 hours
 I.M., slow I.V. push: 0.2-0.3 mg/kg/dose every 4-6 hours

Adults:

Oral: 25-50 mg every 3-4 hours as needed
 I.M., SubQ: 25-50 mg, parenteral adult dose should not exceed 150 mg in 24 hours
 I.V.: 5-25 mg/dose slow I.V. push repeated after 5-10 minutes as needed, then every 3-4 hours not to exceed 150 mg/24 hours

Nasal spray:

Children 6-12 years: 1-2 sprays into each nostril, not more frequently than every 4 hours
 Children ≥ 12 years and Adults: 2-3 sprays into each nostril, not more frequently than every 4 hours

Stability Protect all dosage forms from light

Monitoring Parameters Blood pressure, pulse, urinary output, mental status; cardiac monitor and blood pressure monitor required

Contraindications Hypersensitivity to ephedrine or any component of the formulation; cardiac arrhythmias; angle-closure glaucoma; concurrent use of other sympathomimetic agents

Warnings Blood volume depletion should be corrected before ephedrine therapy is instituted; use caution in patients with unstable vasomotor symptoms, diabetes, hyperthyroidism, prostatic hyperplasia, or a history of seizures; also use caution in the elderly and those patients with cardiovascular disorders such as coronary artery disease, arrhythmias, and hypertension. Ephedrine may cause hypertension resulting in intracranial hemorrhage. Long-term use may cause anxiety and symptoms of paranoid schizophrenia. Avoid as a bronchodilator; generally not used as a bronchodilator since new beta₂ agents are less toxic. Use with caution in the elderly, since it crosses the blood-brain barrier and may cause confusion.

Dosage Forms

Capsule, as sulfate: 25 mg
 Injection, solution, as sulfate: 50 mg/mL (1 mL, 10 mL)
 Solution, intranasal spray, as sulfate (Pretz-D[®]): 0.25% (50 mL)

Reference Range Postmortem blood level of 11 mg/L associated with a fatal ephedrine overdose; therapeutic serum level: 0.04-0.08 mcg/mL

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
 Supportive therapy: There is no specific antidote for ephedrine intoxication and the bulk of the treatment is supportive. Hyperactivity and agitation usually respond to reduced sensory input, however with extreme agitation haloperidol (2-5 mg I.M. for adults) may be required. Hyperthermia is best treated with external cooling measures, or when severe or unresponsive, muscle paralysis with pancuronium may be needed. Hypertension is usually transient and generally does not require treatment unless severe. For diastolic blood pressures >110 mm Hg, a nitroprusside infusion should be initiated. Seizures usually respond to diazepam or lorazepam I.V. and/or phenytoin maintenance regimens.

Drug Interactions

Alpha- and beta-adrenergic-blocking agents decrease ephedrine vasopressor effects.
 Cardiac glycosides or general anesthetics may increase cardiac stimulation.
 MAO inhibitors or atropine may increase blood pressure
 Sympathomimetic agents: Additive cardiostimulation with other sympathomimetic agents.
 Theophylline may lead to cardiostimulation.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta; fetal tachycardia can occur

Lactation Enters breast milk/not recommended

Nursing Implications Protect from light; do not administer unless solution is clear

Additional Information Ephedrine is a precursor in the illicit manufacture of methamphetamine; ephedrine is extracted by dissolving ephedrine tablets in water or alcohol (50,000 tablets can result in 1 kg of ephedrine); conversion to methamphetamine occurs at a rate of 50% to 70% of the

weight of ephedrine; ephedrine is synthesized by the reductive condensation of L-1-phenyl-1-acetylcarbinol with methylamine. See table.

Ephedrine products are marketed under a variety of packaging gimmicks and names. The following products are marketed as natural versions of illegal drugs:		
Cloud 9	Herbal Ecstasy	Ritual Spirit
Fat Burner	Herbal x GWM	Thermoslim
Herbal Bliss		
Truck stop ephedrine products include the following:		
357 Magnum	Heads Up	Mini-Thins
Efedrin	Max Alert	Thin-Edrine
GoPower	Maxephedrine	Turbo Tabs
Many products contain a form of ephedrine called ma huang, with ephedrine concentrations as much as 16 times higher than the naturally occurring levels.		
AM Trim and Firm	Herbal Fuel	Super Day Trim
Blasting Caps	Kickers Instant Energy Caplets	Summit Select
Chi Powder	Mega Ripped	Super Fat Burners
Cybergenics	New Zest	Smart Body
Dextrate	New Zest Plus	Thermo Diet
Diet Max	Now	Thermo Slim
Diet Max LiquidGels	Nura One	Thermogenics
Diet Now	Performance Energy	Thermojetics
Diet Pep	Power Trim	Thinline III
Ephedra 850	Pro Ripped	Trim Time Tea
Excell Energy	Ripped Fuel Tea	Ultra Diet Prep
Excell Ultra High Energy Performance	Quick Shot Energel	Up Your Gas

Epoetin Alfa

Related Information

- Therapeutic Drugs Associated with Hallucinations

CAS Number 113427-24-0; 122312-54-3

U.S. Brand Names Epogen[®]; Procrit[®]

Synonyms rHuEPO- α ; EPO; Erythropoietin; NSC-724223

Use

- Treatment of anemia related to zidovudine therapy in HIV-infected patients; in patients when the endogenous erythropoietin level is ≤ 500 mU/mL and the dose of zidovudine is ≤ 4200 mg/week
- Treatment of anemia associated with chronic renal failure (CRF) including dialysis (end-stage renal disease, ESRD) and nondialysis patients. Prior to therapy, serum ferritin should be >100 ng/dL and transferrin saturation (serum iron/iron binding capacity $\times 100$) of 20% to 30%; nondialysis patients should have a hematocrit $<30\%$
- Treatment of anemia in cancer patients on chemotherapy; in patients with nonmyeloid malignancies where anemia is caused by the effect of

the concomitantly administered chemotherapy; to decrease the need for transfusions in patients who will be receiving chemotherapy for a minimum of 2 months

Reduction of allogeneic blood transfusion in surgery patients (with hemoglobin >10 g/dL up to 13 g/dL) scheduled to undergo elective, noncardiac, nonvascular surgery

Unlabeled/Investigational Use Anemia associated with rheumatic disease; hypogenerative anemia of Rh hemolytic disease; sickle cell anemia; acute renal failure; Gaucher's disease; Castleman's disease; paroxysmal nocturnal hemoglobinuria; anemia of critical illness (limited documentation); anemia of prematurity

Mechanism of Action A glycosylated protein hormone which induces erythropoiesis by stimulating the division and differentiation of committed erythroid progenitor cells; induces the release of reticulocytes from the bone marrow into the bloodstream, where they mature to erythrocytes. There is a dose response relationship with this effect. This results in an increase in reticulocyte counts followed by a rise in hematocrit and hemoglobin levels. Studies in lab animals suggest that epoetin may have an effect on megakaryoblast development, and increased platelet counts have been noted in dialysis patients receiving epoetin.

Adverse Reactions

Cardiovascular: **Hypertension**, edema, chest pain, CVA/TIA, MI, thrombosis

Central nervous system: **Headache**, fever, fatigue, seizures

Dermatologic: Rash

Endocrine & metabolic: Hyperkalemia

Gastrointestinal: **Nausea**, vomiting, diarrhea

Neuromuscular & skeletal: **Arthralgia**, asthenia

Miscellaneous: Flu-like syndrome, hypersensitivity reactions

Signs and Symptoms of Overdose Coagulopathy, conjunctivitis, erythrocytosis, hallucinations, polycythemia

Pharmacodynamics/Kinetics

Onset of action: Several days

Peak effect: 2-3 weeks

Distribution: V_d : 9 L; rapid in the plasma compartment; concentrated in liver, kidneys, and bone marrow

Metabolism: Some degradation does occur

Bioavailability: SubQ: ~21% to 31%; intraperitoneal epoetin: 3% (a few patients)

Half-life elimination: Cancer: SubQ: 16-67 hours; Chronic renal failure: 4-13 hours

Time to peak, serum: Chronic renal failure: 5-13 hours

Excretion: Feces (majority); urine (small amounts, 10% unchanged in normal volunteers)

Dosage Chronic renal failure patients: I.V., SubQ:

Children: Initial dose: 50 units/kg 3 times/week

Adults: Initial dose: 50-100 units/kg 3 times/week

Reduce dose when

1) hematocrit approaches 36% **or**

2) when hematocrit increases >4 points in any 2-week period

Increase dose if hematocrit does not increase by 5-6 points after 8 weeks of therapy and hematocrit is below suggested target range

Suggested target hematocrit range: 30% to 36%

Maintenance dose: Individualize to target range

Dialysis patients: Median dose:

Children: 167 units/kg/week **or** 76 units/kg 2-3 times/week

Adults: 75 units/kg 3 times/week

Nondialysis patients:

Children: Dosing range: 50-250 units/kg 1-3 times/week

Adults: Median dose: 75-150 units/kg

Zidovudine-treated, HIV-infected patients (patients with erythropoietin levels >500 mU/mL are unlikely to respond): I.V., SubQ:

Children: Initial dose: Reported dosing range: 50-400 units/kg 2-3 times/week

Adults: 100 units/kg 3 times/week for 8 weeks

Increase dose by 50-100 units/kg 3 times/week if response is not satisfactory in terms of reducing transfusion requirements or increasing hematocrit after 8 weeks of therapy

Evaluate response every 4-8 weeks thereafter and adjust the dose accordingly by 50-100 units/kg increments 3 times/week

If patients have not responded satisfactorily to a 300 units/kg dose 3 times/week, it is unlikely that they will respond to higher doses

Stop dose if hematocrit exceeds 40% and resume treatment at a 25% dose reduction when hematocrit drops to 36%

Cancer patients on chemotherapy: Treatment of patients with erythropoietin levels >200 mU/mL is **not recommended**

Children: I.V.: 600 units/kg once weekly (maximum: 40,000 units)

Adults: SubQ: Initial dose: 150 units/kg 3 times/week or 40,000 units once weekly; commonly used doses range from 10,000 units 3 times/week to 40,000-60,000 units once weekly.

Dose adjustment: If response is not satisfactory in terms of reducing transfusion requirement or increasing hematocrit after 8 weeks of therapy, the dose may be increased up to 300 units/kg 3 times/week.

If patients do not respond, it is unlikely that they will respond to higher doses.

If hematocrit exceeds 40%, hold the dose until it falls to 36% and reduce the dose by 25% when treatment is resumed.

Surgery patients: Prior to initiating treatment, obtain a hemoglobin to establish that is >10 mg/dL or ≤13 mg/dL: Adults: SubQ: Initial dose: 300 units/kg/day for 10 days before surgery, on the day of surgery, and for 4 days after surgery

Alternative dose: 600 units/kg in once weekly doses (21, 14, and 7 days before surgery) plus a fourth dose on the day of surgery

Anemia of critical illness (unlabeled use): Adults: SubQ: 40,000 units once weekly

Anemia of prematurity (unlabeled use): Infants: I.V., SubQ: Dosing range: 500-1250 units/kg/week; commonly used dose: 250 units/kg 3 times/week; supplement with oral iron therapy 3-8 mg/kg/day

Dosage adjustment in renal impairment:

Dialysis patient: Usually administered as I.V. bolus 3 times/week. While administration is independent of the dialysis procedure, it may be administered into the venous line at the end of the dialysis procedure to obviate the need for additional venous access.

Chronic renal failure patients not on dialysis: May be given either as an I.V. or SubQ injection.

Hemodialysis: Supplemental dose is not necessary.

Peritoneal dialysis: Supplemental dose is not necessary.

Monitoring Parameters Blood pressure; hematocrit/hemoglobin, CBC with differential and platelets, transferrin saturation and ferritin. Suggested tests to be monitored and their frequency: See table.

Test	Initial Phase Frequency	Maintenance Phase Frequency
Hematocrit/hemoglobin	2 × /week	2-4 × /month
Blood pressure	3 × /week	3 × /week
Serum ferritin	Monthly	Quarterly
Transferrin saturation	Monthly	Quarterly
Serum chemistries including CBC with differential, creatinine, blood urea nitrogen, potassium, phosphorous	Regularly per routine	Regularly per routine

Hematocrit should be determined twice weekly until stabilization within the target range (30% to 36%), and twice weekly for at least 2-6 weeks after a dose increase.

Administration Patients with CRF on dialysis: May be administered I.V. bolus into the venous line after dialysis.

Patients with CRF not on dialysis: May be administered I.V. or SubQ

Contraindications Hypersensitivity to erythropoietin, albumin (human) or mammalian cell-derived products, or any component of the formulation; uncontrolled hypertension

Warnings

Use caution with history of seizures or hypertension; blood pressure should be controlled prior to start of therapy and monitored closely throughout treatment. Excessive rate of rise of hematocrit may be possibly associated with the exacerbation of hypertension or seizures; decrease the epoetin dose if the hemoglobin increase exceeds 1 g/dL in any 2-week period. Use caution in patients at risk for thrombosis or with history of cardiovascular disease. Increased mortality has been observed when aggressive dosing is used in CHF or anginal patients undergoing hemodialysis. Multidose vials contain benzyl alcohol; do not use in premature infants.

Pure red cell aplasia (PRCA) with neutralizing antibodies to erythropoietin has been reported in patients treated with recombinant products; may occur more in patients with CRF. Patients should be evaluated for any loss of effect to therapy and treatment discontinued with evidence of PRCA. Response to therapy may be limited by multiple factors; refer to Additional Information for details.

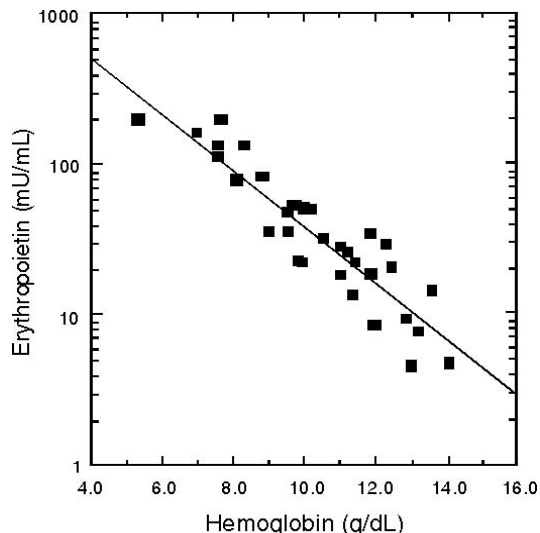

Prior to and during therapy, iron stores must be evaluated; iron supplementation should be given during therapy. Use caution with porphyria, exacerbation of porphyria has been reported in patients with chronic renal failure. Not recommended for acute correction of severe anemia or as a substitute for transfusion. Safety and efficacy in children <1 month of age have not been established.

Dosage Forms Injection, solution [preservative free]: 2000 units/mL (1 mL); 3000 units/mL (1 mL); 4000 units/mL (1 mL); 10,000 units/mL (1 mL); 40,000 units/mL (1 mL) [contains human albumin] Injection, solution [with preservative]: 10,000 units/mL (2 mL); 20,000 units/mL (1 mL) [contains human albumin and benzyl alcohol]

Reference Range

Guidelines should be based on the following figure or published literature. Guidelines for estimating appropriateness of endogenous EPO levels for varying levels of anemia via the EIA assay method: See figure. The reference range for erythropoietin in serum, for subjects with normal hemoglobin and hematocrit, is 4.1-22.2 mU/mL by the EIA method. Erythropoietin levels are typically inversely related to hemoglobin (and

hematocrit) levels in anemias not attributed to impaired erythropoietin production.

Zidovudine-treated HIV patients: Available evidence indicates patients with endogenous serum erythropoietin levels >500 mU/mL are unlikely to respond

Cancer chemotherapy patients: Treatment of patients with endogenous serum erythropoietin levels >200 mU/mL is not recommended

Overdosage/Treatment Supportive therapy: Adequate airway and other supportive measures and agents for treating anaphylaxis should be present when I.V. drug is given; venesection can successfully reduce blood pressure if hypertension does **not** respond to antihypertensive agents in the setting of erythropoietin overdosage

Pregnancy Risk Factor C

Pregnancy Implications Epoetin alfa has been shown to have adverse effects in animal studies. Studies suggest that rHuEPO- α does not cross the human placenta. Based on case reports, treatment with rHuEPO- α may be an option in pregnant women with ESRD on dialysis. Amenorrhic premenopausal women should be cautioned that menstruation may resume following treatment with rHuEPO- α and contraception should be considered if pregnancy is to be avoided.

Lactation Excretion in breast milk unknown/use caution

Additional Information

May require supplemental iron to keep ferritin levels >100 ng/dL; frequently used by athletes for "blood doping"; response to erythropoietin of metastatic renal cell carcinoma has been reported; high ratio of soluble transferrin to ferritin may be indicative of exogenous erythropoietin use

Due to the delayed onset of erythropoiesis (7-10 days to \uparrow reticulocyte count; 2-6 weeks to \uparrow hemoglobin), erythropoietin is of no value in the acute treatment of anemia. Emergency/stat orders for erythropoietin are inappropriate.

Eptifibatide

U.S. Brand Names Integrilin®

Synonyms Intrifiban

Use Treatment of patients with acute coronary syndrome (UA/NQMI), including patients who are to be managed medically and those undergoing percutaneous coronary intervention (PCI including PTCA; intracoronary stenting)

Mechanism of Action Eptifibatide is a synthetic cyclic heptapeptide which blocks the platelet glycoprotein IIb/IIIa receptor, the binding site for fibrinogen, von Willebrand factor, and other ligands. Inhibition of binding at this final common receptor reversibly blocks platelet aggregation and prevents thrombosis.

Adverse Reactions

Bleeding is the major drug-related adverse effect. Major bleeding was reported in 4.4% to 10.5%, minor bleeding was reported in 10.5% to 14.2%, requirement for transfusion was reported in 5.5% to 12.8%.

Cardiovascular: Hypotension

Central nervous system: Intracranial hemorrhage

Hematologic: Acute profound thrombocytopenia, fatal bleeding events

Local: Injection site reaction

Neuromuscular & skeletal: Back pain

Miscellaneous: Anaphylaxis

Pharmacodynamics/Kinetics

Onset of action: Within 1 hour

Duration: Platelet function restored ~4 hours following discontinuation

Protein binding: ~25%

Half-life elimination: 2.5 hours

Excretion: Primarily urine (as eptifibatide and metabolites); significant renal impairment may alter disposition of this compound

Clearance: Total body: 55-58 mL/kg/hour; Renal: ~50% of total in healthy subjects

Dosage

I.V.: Adults:

Acute coronary syndrome: Bolus of 180 mcg/kg (maximum: 22.6 mg) over 1-2 minutes, begun as soon as possible following diagnosis, followed by a continuous infusion of 2 mcg/kg/minute (maximum: 15 mg/hour) until hospital discharge or initiation of CABG surgery, up to 72 hours. Concurrent aspirin (160-325 mg initially and daily thereafter) and heparin therapy (target aPTT 50-70 seconds) are recommended.

Percutaneous coronary intervention (PCI) with or without stenting: Bolus of 180 mcg/kg (maximum: 22.6 mg) administered immediately before the initiation of PCI, followed by a continuous infusion of 2 mcg/kg/minute (maximum: 15 mg/hour). A second 180 mcg/kg bolus (maximum: 22.6 mg) should be administered 10 minutes after the first bolus. Infusion should be continued until hospital discharge or for up to 18-24 hours, whichever comes first; minimum of 12 hours of infusion is recommended. Concurrent aspirin (160-325 mg 1-24 hours before PCI and daily thereafter) and heparin therapy (ACT 200-300 seconds during PCI) are recommended. Heparin infusion after PCI is discouraged. In patients who undergo coronary artery bypass graft surgery, discontinue infusion prior to surgery.

Dosing adjustment in renal impairment: Dialysis is a contraindication to use.

Acute coronary syndrome: $Cl_{cr} < 50$ mL/minute or $S_{cr} > 2$ mg/dL: Use 180 mcg/kg bolus (maximum: 22.6 mg) and 1 mcg/kg/minute infusion (maximum: 7.5 mg/hour)

Percutaneous coronary intervention (PCI) with or without stenting: $Cl_{cr} < 50$ mL/minute or $S_{cr} > 2$ mg/dL: Use 180 mcg/kg bolus (maximum: 22.6 mg) administered immediately before the initiation of PCI and followed by a continuous infusion of 1 mcg/kg/minute (maximum: 7.5 mg/hour). A second 180 mcg/kg (maximum: 22.6 mg) bolus should be administered 10 minutes after the first bolus.

Stability Vials should be stored refrigerated at 2°C to 8°C (36°F to 46°F). Protect from light until administration. Do not use beyond the expiration date. Discard any unused portion left in the vial.

Monitoring Parameters Coagulation parameters, signs/symptoms of excessive bleeding. Laboratory tests at baseline and monitoring during therapy: hematocrit and hemoglobin, platelet count, serum creatinine, PT/

Factors Limiting Response to Epoetin Alfa	
Factor	Mechanism
Iron deficiency	Limits hemoglobin synthesis
Blood loss/hemolysis	Counteracts epoetin alfa-stimulated erythropoiesis
Infection/inflammation	Inhibits iron transfer from storage to bone marrow
	Suppresses erythropoiesis through activated macrophages
Aluminum overload	Inhibits iron incorporation into heme protein
Bone marrow replacement Hyperparathyroidism Metastatic, neoplastic	Limits bone marrow volume
Folic acid/vitamin B ₁₂ deficiency	Limits hemoglobin synthesis
Patient compliance	Self-administered epoetin alfa or iron therapy

aPTT (maintain aPTT between 50-70 seconds unless PCI is to be performed), and ACT with PCI (maintain ACT between 200-300 seconds during PCI).

Administration Visually inspect for discoloration or particulate matter prior to administration

The bolus dose should be withdrawn from the 10 mL vial into a syringe and administered by I.V. push over 1-2 minutes

Begin continuous infusion immediately following bolus administration, administered directly from the 100 mL vial

The 100 mL vial should be spiked with a vented infusion set

Contraindications Hypersensitivity to eptifibatide or any component of the product; active abnormal bleeding or a history of bleeding diathesis within the previous 30 days; history of CVA within 30 days or a history of hemorrhagic stroke; severe hypertension (systolic blood pressure >200 mm Hg or diastolic blood pressure >110 mm Hg) not adequately controlled on antihypertensive therapy; major surgery within the preceding 6 weeks; current or planned administration of another parenteral GP IIb/IIIa inhibitor; thrombocytopenia; dependency on renal dialysis

Warnings Bleeding is the most common complication. Most major bleeding occurs at the arterial access site where the cardiac catheterization was done. When bleeding can not be controlled with pressure, discontinue infusion and heparin. Use caution in patients with hemorrhagic retinopathy or with other drugs that affect hemostasis. Concurrent use with thrombolytics has not been established as safe. Minimize other procedures including arterial and venous punctures, I.M. injections, nasogastric tubes, etc. Sheath should not be removed unless the aPTT <45 sec or the ACT <150 sec. Use caution in renal dysfunction (estimated Cl_{cr} < 50 mL/minute); dosage adjustment required. Safety and efficacy in pediatric patients have not been determined.

Dosage Forms Injection, solution: 0.75 mg/mL (100 mL); 2 mg/mL (10 mL, 100 mL)

Overdosage/Treatment Supportive therapy: Essentially no overdose experience; anaphylaxis may be treated with standard treatment; discontinue heparin; use pressure techniques if bleeding develops; consider platelet transfusion for patients with serious, uncontrolled bleeding and if bleeding time is >10 minutes

Drug Interactions

Cephalosporins which contain the MTT side chain may theoretically increase the risk of hemorrhage.

Drotrecogin alfa: Antiplatelet agents (eg, eptifibatide) may enhance the adverse/toxic effect of drotrecogin alfa; bleeding may occur.

Drugs which affect platelet function (eg, aspirin, NSAIDs, dipyridamole, ticlopidine, clopidogrel) may potentiate the risk of hemorrhage; use with caution.

Heparin and aspirin: Use with aspirin and heparin may increase bleeding over aspirin and heparin alone. However, aspirin and heparin were used concurrently in the majority of patients in the major clinical studies of eptifibatide.

Thrombolytic agents theoretically may increase the risk of hemorrhage; use with caution.

Warfarin and oral anticoagulants: Risk of bleeding may be increased during concurrent therapy.

Other IIb/IIIa antagonists: Avoid concomitant use of other glycoprotein IIb/IIIa antagonists (see Contraindications).

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic effects were not observed in animal studies

Lactation Excretion in breast milk unknown/use caution

Nursing Implications

Do not shake the vial; maintain bleeding precautions, avoid unnecessary arterial and venous punctures, use saline or heparin lock for blood drawing, assess sheath insertion site and distal pulses of affected leg every 15 minutes for the first hour and then every 1 hour for the next 6 hours. Arterial access site care is important to prevent bleeding. Care should be taken when attempting vascular access that only the anterior wall of the femoral artery is punctured, avoiding a Seldinger (through and through) technique for obtaining sheath access. Femoral vein sheath placement should be avoided unless needed. While the vascular sheath is in place, patients should be maintained on complete bedrest with the head of the bed at a 30° angle and the affected limb restrained in a straight position.

Observe patient for mental status changes, hemorrhage, assess nose and mouth mucous membranes, puncture sites for oozing, ecchymosis and hematoma formation, and examine urine, stool and emesis for presence of occult or frank blood; gentle care should be provided when removing dressings.

Mechanism of Action Ergot alkaloid alpha-adrenergic blocker directly stimulates vascular smooth muscle to vasoconstrict peripheral and cerebral vessels; may also have antagonist effects on serotonin

Adverse Reactions

Cardiovascular: Absence of pulse, bradycardia, cardiac valvular fibrosis, cyanosis, edema, ECG changes, hypertension, ischemia, precordial distress and pain, tachycardia, vasospasm

Central nervous system: Vertigo

Dermatologic: Gangrene, itching

Gastrointestinal: Anal or rectal ulcer (with overuse of suppository), nausea, vomiting

Genitourinary: Retroperitoneal fibrosis

Neuromuscular & skeletal: Muscle pain, numbness, paresthesias, weakness

Respiratory: Pleuropulmonary fibrosis

Miscellaneous: Cold extremities

Signs and Symptoms of Overdose Asthenia, bradycardia, chest pain, colitis, drowsiness, hypertension, hypotension, impaired mental function, myalgia, nausea, nystagmus, seizures, shock and death, unconsciousness, vasospastic effects, vision color changes (red tinge), vomiting

Pharmacodynamics/Kinetics

Absorption: Oral: Erratic; enhanced by caffeine coadministration

Metabolism: Extensively hepatic

Time to peak, serum: 0.5-3 hours

Half-life elimination: 2 hours

Excretion: Feces (90% as metabolites)

Dosage

Oral (Cafergot®, Wigraine®): 2 tablets at onset of attack; then 1 tablet every 30 minutes as needed; maximum: 6 tablets per attack; do not exceed 10 tablets/week.

Sublingual (Ergomar®): 1 tablet under tongue at first sign, then 1 tablet every 30 minutes if needed; maximum dose: 3 tablets/24 hours, 5 tablets/week

Rectal (Cafergot®): 1 suppository rectally at first sign of an attack; follow with second dose after 1 hour, if needed; maximum: 2 per attack; do not exceed 5/week.

Administration

Do not crush sublingual tablets.

Contraindications Hypersensitivity to ergotamine or any component of the formulation; peripheral vascular disease; hepatic or renal disease; coronary artery disease; hypertension; sepsis; ergot alkaloids are contraindicated with strong inhibitors of CYP3A4 (includes protease inhibitors, azole antifungals, and some macrolide antibiotics); pregnancy

Warnings

Avoid prolonged administration or excessive dosage because of the danger of ergotism (intense vasoconstriction), gangrene, cardiac valvular fibrosis, retroperitoneal and/or pleuropulmonary fibrosis. Patients who take ergotamine for extended periods of time may experience withdrawal symptoms and rebound headache when ergotamine is discontinued. May be harmful due to reduction in cerebral blood flow; may precipitate angina, myocardial infarction, or aggravate intermittent claudication; therefore, not considered a drug of choice in the elderly.

[U.S. Boxed Warning]: Concomitant use with medications considered to be "strong" CYP3A4 inhibitors has been associated with acute ergot toxicity; use caution with inhibitors of CYP3A4 enzymes.

Dosage Forms Tablet, sublingual: Ergotamine tartrate 2 mg

Reference Range Serum levels >1.8 ng/mL are toxic

Overdosage/Treatment

Decontamination: Gastric lavage within 1 hour or induction of emesis within 30 minutes, activated charcoal; keep extremities warm; consider gastric decontamination for ingestions >1 mg/kg
