Signs and Symptoms of Overdose Aspiration, ataxia, blistering, coma (3000 ppm), cough, dementia, dizziness, lethargy, headache, hematuria, hoarseness, leukopenia, mydriasis, ototoxicity, paresthesia, seizures, tinnitus, tremors, tachycardia, erythema, vomiting (ingestion of 9 g)

Admission Criteria/Prognosis Symptomatic patients 12 hours post-inhalation exposure should be admitted; patients who have ingested a significant amount of benzene should be admitted

Toxicodynamics/Kinetics

Absorption: Inhalation: Rapid (70% to 80% within first 5 minutes). Oral: 90% to 97% of dose in rodent models. Dermal: < 1%; absorption rate: 0.4 mg/cm²/hour

Metabolism: Hepatic via cytochrome P450-dependent mixed function oxidase through two detoxification pathways: 1) via glutathione to mercapturic acid, and 2) through sulfate/glucuronide conjugation. Hematotoxic metabolites include hydroquinone, phenol, muconic di-aldehyde, and catechol.

Half-life: 8 hours

Elimination: Renal (< 1%) and by inhalation (16% to 42%). Through dermal absorption as much as 30% can be excreted through the kidneys as phenol. Oral ingestion (rabbit model): 43% was eliminated through the lungs (1.5% as carbon dioxide), with urinary excretion accounting for 33%.

Monitoring Parameters Obtain baseline complete blood count; if abnormal, peroxidase, leukocyte alkaline phosphatase, an iron level, and a reticulocyte count should be performed. Urinary levels of muconic and S-phenylmercapturic acid samples at the end of work shift are better exposure indicators for benzene than phenol. The BEI for S-phenylmercapturic acid muconic acid are 25 mcg/g creatinine and 500 mcg/g creatinine at the end of shift respectively.

Reference Range Normal urine phenol level < 10 mg/L, blood benzene level of 0.2 mg/L is consistent with exposure of 25 ppm as is a urinary phenol level of 200 mg/L

Overdosage/Treatment

Decontamination:

Oral: Basic poison management. Lavage within 2 hours of ingestion with respiratory protection. Activated charcoal may be useful. Diazepam and/or phenytoin may be helpful in controlling seizures. Indomethacin has been demonstrated to decrease myelotoxicity in rodent models, but human data are lacking. Due to the possibility of arrhythmias, avoid epinephrine.

Inhalation: Move patient to fresh air; give 100% humidified oxygen

Ocular: Irrigate with copious amounts of water or saline

Dermal: Remove contaminated clothing and wash area thoroughly with soap and water

Enhancement of elimination: Although there is no experience in its use, acetylcysteine has a theoretical role in increasing glutathione stores and enhancing elimination.

Drug Interaction

Ethyl alcohol can potentiate the severity of benzene-induced hematological abnormalities

Weak genotoxicity; can cross the placenta

Additional Information

Estimated oral lethal dose: 1 mL/kg and lethal (rapidly) air concentration over 20,000 ppm. Serious health effects can occur with one hour exposure at air concentrations > 150 ppm

Daily benzene intake of a smoker (32 cigarettes daily) is ~10 times (1.8 mg/day) that of a nonsmoker. Median benzene levels in homes with smokers is ~50% greater than that of nonsmokers (3.3 ppb vs 2.2 ppb).

BENZENE

Atmospheric half-life of benzene is ~5.6 days. In water, it is ~17 days, although the half-life of its hydroxyl radicals in water may be 8-9 months. Benzene was substantially reduced in automotive gasoline after 1995 (see Gasoline monograph). It has been estimated that benzene exposure to pumping gasoline at service stations is ~1 ppm. Ambient median benzene levels in urban areas is ~12.6 ppb, while California's median benzene levels are much lower (3.3 ppb) due to stricter gasoline requirements.

Biomarkers indicative for significant benzene (below 4000/mm³), low erythrocyte counts (below 4,000,000/m³), or elevated leukocyte alkaline phosphatase levels.

TLV-TWA: 0.5 ppm; IDLH: 500 ppm; STEL: 1 ppm

Gas density: 2.8

Specific gravity: 0.88

Slightly water soluble

Odor threshold: 1.5-5 ppm

Median level of benzene found in snow samples (near Denver, Colorado): 0.02 mcg/L

Blood testing: Use lavender top (EDTA) tube and refrigerate (minimum volume 7 mL)

In November 2005, FDA received private laboratory results reporting low levels of benzene in a small number of soft drinks that contained benzoate salts (an antimicrobial) and ascorbic acid (vitamin C). FDA has no regulatory limits for benzene in beverages other than bottles water, for which FDA uses the US Environmental Protection Agency (EPA) maximum contaminant level (MCL) of 5 ppb for drinking water, as a quality standard.

Benzene is found in the air from emissions from burning coal and oil, gasoline service stations, and motor vehicle exhaust. Benzene is a carcinogen and has caused cancer in workers exposed to high levels from workplace air. Benzene can form at the parts per billion (ppb) level in some beverages that contain both benzoate salts and ascorbic acid (vitamin C) or erythorbic acid (a closely related substance (isomer) also known as d-ascorbic acid). Elevated temperatures and light can stimulate benzene formation in the presence of benzoate salts and vitamin C, while sugar and EDTA salts inhibit benzene formation.

As follow-up to the November 2005 benzene findings, FDA's Center for Food Safety and Applied Nutrition (CFSAN) initiated a limited survey of beverages with a focus on soft drinks that contain both benzoate and ascorbic or erythorbic acid. The vast majority of beverages sampled to date (including those containing both benzoate preservative and ascorbic acid) contain either no detectable benzene or levels below the 5 ppb limit for drinking water.

The follow table lists benzene levels in particular beverages that are > 1 ppb only. For method 1, the estimated limit of detection (LOD) is 0.2 ppb when benzene is determined with cryogenic focusing using the m/z 78 ion in the scan mode. For method 2, the estimated LOD is 0.02 ppb when benzene is determined without cryogenic focusing using the m/z 78 ion in the Slim mode. Multiple results reported for the same lot of a soft drink were usually obtained from a resampling of the same bottle at a later time. Results indicate benzene levels measured on individual purchased beverages.

Benzidine

Related Information

- 4,4'-Methylenebis (2-Chloroaniline)

Applies to Fast Corinth Base B

CAS Number 92-87-5

UN Number 1885

Synonyms 4,4'-Diphenyldiamine; Benzidin

Use In the production of azo dyes for leathers, textiles, and paper; not produced in the U.S. for dye manufacture

Mechanism of Toxic Action Intermediate metabolites through hepatic degradation; may be carcinogenic

Adverse Reactions

Dermatologic: Allergic eczematous dermatitis

Miscellaneous: Cutaneous T-cell lymphoma

Toxicodynamics/Kinetics

Absorption: Through intact skin, lungs, intestine

Metabolism: Hepatic to N-acetylbenzidine; undergoes enterohepatic recirculation

Half-life: 5 hours

Elimination: Renal and bile

Reference Range

Urine levels in workers exposed to benzidine based dyes ranged from:

Benzidine: 0-363 mcg/L

Monoacetylbenzidine: 6-1117 mcg/L

Diacetylbenzidine: 4-160 mcg/L

Overdosage/Treatment

Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal. **Do not** use mineral oil as a cathartic in that oils may enhance intestinal absorption. **Dermal:** Irrigate with soap and water; remove contaminated clothing. **Ocular:** Irrigate with saline.

Supportive therapy: While no human treatment data exists, interruption of benzidine metabolism by such agents as aspirin or indomethacin (through inhibition of cyclooxygenase) may reduce peroxide formation. Similarly, a reducing agent such as ascorbic acid may decrease levels of toxic oxidized reactive metabolites which can be carcinogenic.

Enhancement of elimination: Due to enterohepatic recirculation, multiple dosing of activated charcoal may be effective.

Additional Information Occupationally exposed workers may have a higher incidence of bladder (transitional cell) carcinoma; may alter natural killer cell activity. Atmospheric half-life: 12 hours. Water half-life: 100 days

Beryllium

CAS Number 1304-56-9; 13327-32-7; 13510-48-0; 13510-49-1; 13597-99-4; 14215-00-0; 35089-00-0; 66104-24-3; 7440-41-7; 7787-47-5; 7787-49-7; 7787-56-6

UN Number 1566; 1567; 2464

Synonyms Beryl; Glucinium

Commonly Found In Ore processing, aircraft disc brakes, space vehicles, optics, microwave oven components, automotive electronics, fuel containers

Mechanism of Toxic Action Acute (rare) and chronic toxicities most commonly seen with inhalation exposure of soluble compounds in occupational setting; inhibits phosphatases, hexokinase, lactate dehydrogenase

Adverse Reactions

Cardiovascular: Chest pain, angina, cor pulmonale

Dermatologic: Skin ulceration

Gastrointestinal: Salty taste

Hematologic: Granulomas

Hepatic: Granulomatous hepatitis

Renal: Kidney stones, nephritis

Respiratory: Chronic "sarcoid-like" pulmonary disease; acute bronchitis after exposure to soluble to be at levels of 25 to 600 mg/m³; lung cancer

Signs and Symptoms of Overdose Conjunctivitis (acute), dermatotoxicity (dermal irritation, granuloma, skin ulcers), nausea, pneumonitis, pulmonary fibronodular disease, right-sided heart failure, seizures, vomiting

Admission Criteria/Prognosis Significant, acute exposure should be admitted for 3 days due to delayed onset of pneumonitis

Toxicodynamics/Kinetics

Absorption: Inhalation (primarily); oral and dermal (poorly absorbed)

Protein binding: 70%

Metabolism: Not biotransformed

Half-life: 2-8 weeks

Reference Range Urine concentrations: 0.4-1.0 mcg/L in controls

Overdosage/Treatment

Decontamination: Remove from exposure source; oxygen indicated for symptomatic inhalation exposure

Dermal: Beryllium foreign body residues need to be removed for skin ulceration to heal.

Supportive therapy: Chronic pulmonary symptoms may respond to corticosteroids. Oral exposure should be treated by diluting with milk or water. Chelation is not effective. A high calcium diet might displace beryllium from bones. Bronchodilators such as albuterol may be useful. Persons with chronic beryllium disease have had a variable response to corticosteroid treatment.

Additional Information

Beryllium is odorless; chronic beryllium poisoning requires at least four of these findings:

1. Exposure
2. Beryllium in lung/granulomas
3. Respiratory disease
4. Radiograph of fibronodular disease
5. Restrictive pulmonary function
6. Consistent lung/lymph pathology

Up to 16% of individuals are sensitized following exposure

Average concentration of beryllium: Atmospheric air: <0.1 ng/m³; fresh

water: 10-1000 ng/L; soil: 2.8-5 mg/kg; cigarette smoke: 2% to 10%

Idiosyncratically affects 5% of heavily exposed workers after 1- to 20-year latency

TLV: 0.002 mg/m³

Beryllium measurable in lung and granulomas of chronic beryllium disease patients; also useful in lymphoblast transformation test from bronchoalveolar lavage fluid

Insoluble in water

Air beryllium levels > 100 mcg/m³ can result in acute beryllium disease.

Appropriate rescuer personnel protective equipment include a dust mist respirator.

Biphenyl

CAS Number 92-52-4

Synonyms Difenilo; Diphenyl; E230; Phenylbenzene

Use Fungistatic agent for fruits; used in petroleum refineries as a heat transfer agent and used as an insulating oil

Mechanism of Toxic Action An irritant; also may be an inhibitor of the enzyme adenosine transaminase which accounts for fungistatic properties

Signs and Symptoms of Overdose Cirrhosis, cough, epistaxis, fatigue, headache, hepatic necrosis, insomnia, nausea, numbness, ocular/oral irritation, Parkinsonism symptoms, throat irritation, tremor, vomiting

Admission Criteria/Prognosis Admit any patient with symptomatic gastrointestinal signs or exposures >20 ppm; TLV-TWA is 0.2 ppm

Toxicodynamics/Kinetics

Absorption: Dermal absorption may occur

Metabolism: Hepatic

Elimination: Renal, biliary

Monitoring Parameters Renal function, liver function tests

Overdosage/Treatment Decontamination: **Dermal:** Wash area with soap and water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate with water or saline.

Pregnancy Implications No adverse effects documented

Additional Information GI symptoms can occur at concentrations >20 ppm; TLV-TWA: 0.2 ppm; IDLH: ~60 ppm

Colorless and solid at room temperature

Borates

CAS Number 10043-35-3; 10294-33-4; 1303-86-2; 1303-96-4; 7440-42-8; 7637-07-2

UN Number 1008; 1458; 2692

U.S. Brand Names Borax®; Dobill's Solution®

Synonyms Boric Anhydride; Boron Oxide; Boron Sesquioxide; Boron Trioxide; Magnesium Perborate; Sodium Biborate; Sodium Borate; Sodium Metaborate; Sodium Perborate; Sodium Pyroborate; Sodium Tetraborate

Use Various; used in herbicides; common ingredient of medicated powders, skin lotions, mouthwashes, toothpastes, powders, water softeners, topical astringents and antiseptics; also used in making glass fibers, enamels, glazes, fire-resistant materials, pigments, paints, catalysts, photographic agents, and insecticides; found in rodent and ant poisons

Adverse Reactions

Central nervous system: Fever, hyperthermia

Miscellaneous: Toxic shock-like syndrome

Signs and Symptoms of Overdose Toxicity may be delayed for hours.

Gastrointestinal upset, vomiting (has been described as blue-green), retching, CNS depression, restlessness, irritability, and seizures occur from chronic exposure. Death results from dehydration, shock, circulatory collapse and renal failure. Renal failure, oliguria, and anuria occur several days after exposure. Metabolic acidosis may occur. Erythematous rash (usually on buttocks and scrotum) with desquamation occurring where rash is persistent and on mucous membranes, perianal and anal surfaces. Alopecia totalis can occur with acute or chronic poisoning.

Admission Criteria/Prognosis Patients with acidosis, renal impairment, or ingestions >200 mg/kg in children or >6 g in adults, should be admitted.

Toxicodynamics/Kinetics

Absorption: Through gastrointestinal tract, mucous membranes, and abraded and denuded skin

Distribution: V_d : 0.17-0.5 L/kg; distributes to all tissues except brain in 30 minutes

Half-life: 5-27 hours

Peak CNS concentration: In 3 hours

Elimination: 50% excreted in urine within 12 hours and 80% to 100% over 5-7 days

Warnings/Precautions High affinity for brain, liver, and kidney; damage to tissues, especially renal tubular epithelium may be irreversible

Reference Range Normal: 0.0-0.72 mg/dL in children; 0.0-0.2 mg/dL in adults; levels do not seem to correlate well with severity of symptoms; levels >40 mg/dL associated with fatality in infants

Overdosage/Treatment

Decontamination: **Oral:** Ipecac within 30 minutes or lavage within 1 hour; activated charcoal will probably not be useful. Gastric decontamination should occur with ingestions >200 mg/kg in a child or >6 g in an adult.

Dermal: Wash skin with soap and water. **Ocular:** Irrigate with saline.

Supportive therapy: Monitor for hypotension, shock, seizures

Enhancement of elimination: Hemodialysis or exchange transfusion may enhance elimination. Saline diuresis may be of some benefit. Early institution of peritoneal dialysis, in asymptomatic patients ingesting a large dose, has been advocated.

Additional Information

Average daily boron intake in humans: 10-25 mg

Average amount of boron in surface water: ~0.1 mg/L

Mean boron level in soil in U.S.: 26 mg/kg

FDA tolerance limit for boron in citrus fruit: 8 ppm

Concentration of boron in sea water: ~4.5 mg/L

How supplied: Boric acid: White powder or crystalline solid. Sodium tetraborate anhydrous: Light gray and odorless. Sodium tetraborate decahydrate and pentahydrate: White, odorless, crystalline solids.

Boric Acid

CAS Number 10043-35-3

Use

Food preservatives, emulsifiers, neutralizers, antifungal water softeners, contact lens cleaner, antiseptics, pesticides (for cockroaches)

Ophthalmic: Mild antiseptic used for inflamed eyelids

Topical ointment: Temporary relief of chapped, chafed, or dry skin, diaper rash, abrasions, minor burns, sunburn, insect bites, and other skin irritations

Mechanism of Action Disinfectant, astringent

Adverse Reactions

Central nervous system: CNS stimulation followed by CNS depression, fever

Dermatologic: Erythematous skin eruptions, pruritus, alopecia, erythrodermic desquamation (2-3 days after exposure) (boiled lobster appearance)

Gastrointestinal: Gastrointestinal disturbance, vomiting, nausea, diarrhea, feces discoloration (black), feces discoloration (blue), feces discoloration (blue-green)

Hepatic: Elevated liver function test results

Renal: Acute tubular necrosis

Signs and Symptoms of Overdose Cardiovascular collapse, confusion, dermatitis, desquamation, elevated liver function test results, circulatory collapse, diarrhea, dry skin, hyperthermia, toxic epidermal necrolysis, seizures, urine discoloration (blue-green)

Pharmacodynamics/Kinetics

Absorption: Not well absorbed through intact skin; absorbed well through inflamed skin

Half-life: 12 hours

Elimination: Renal, within 96 hours of ingestion

Dosage Apply to lower eyelid 1-2 times/day

Contraindications Hypersensitivity to boric acid or any component

Warnings If irritation persists or increases, discontinue use

Dosage Forms Ointment, topical: 10% (30 g)

Reference Range Normal boric acid levels: Children: 0.0-0.7 mg/dL; Adults: 0.0-0.2 mg/dL; levels of 2.0-15.0 mg/dL are associated with survival; levels >40.0 mg/dL are associated with lethality

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage within 1 hour for ingestions >200 mg/kg or 12 g total ingestion/activated charcoal will not adsorb boric acid well; irrigate skin with soap and water for dermal exposure

Supportive therapy: Treat hypotension with isotonic saline, dopamine, or norepinephrine

Enhancement of elimination: Exchange transfusion or hemodialysis should be considered for serious toxic manifestations or if renal failure develops. Boric acid serum levels >200 $\mu\text{mol/mL}$ should be considered as indication for hemodialysis.

Drug Interactions Increases riboflavin excretion

Nursing Implications Application to abraded skin or open wounds has caused fatal poisonings in infants

Additional Information Not a corrosive substance

Bromates

Related Information

• Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 7758-01-2; 7789-38-0

UN Number 1450; 3213

Use Found in permanent wave hair neutralizers as potassium bromate (2%) or sodium bromate (10%), and bread preservatives

Mechanism of Toxic Action Mucosal irritant; oxidizing effect on renal tubule can cause renal failure; potassium bromate may be more toxic than sodium bromate

Signs and Symptoms of Overdose Albuminuria, deafness, diarrhea, dizziness, hemolysis, hiccups, hypotension, nausea, ototoxicity, renal failure, seizures, tachypnea, tinnitus (more common in adults than children), vomiting

Admission Criteria/Prognosis Admit any pediatric or adult ingestion > 30 mg/kg body weight.

Toxicodynamics/Kinetics Distribution: V_d : 0.24 L/kg

Overdosage/Treatment

Decontamination: Lavage within 1 hour with sodium bicarbonate (2% to 5%) to prevent formation of hydrobromic acid.

Supportive therapy: Give sodium thiosulfate (10-50 mL of a 10% solution over 30-60 minutes) to convert bromate to less toxic bromide; monitor with audiograms.

Enhancement of elimination: Hemodialysis can be used if renal failure ensues, but is not effective in reducing bromide levels.

Bromethalin

Applies to Assault (0.01%); Vengeance (0.01%)

CAS Number 63333-35-7

Synonyms EL-614

Use Rodenticide in concentrations of ~0.01%

Mechanism of Toxic Action A neurotoxin which acts by uncoupling oxidative phosphorylation particularly in the central nervous system

Adverse Reactions

Cardiovascular: Cerebral edema has occurred in animal studies

Central nervous system: Coma, seizures

Neuromuscular & skeletal: Myoclonus, tremors

Admission Criteria/Prognosis Admit any symptomatic patient; asymptomatic patients need to be observed for up to 24 hours; ingestions > 0.5 mg/kg may require observation

Toxicodynamics/Kinetics

Absorption: Oral: Absorbed well; not well absorbed dermally

Metabolism: Metabolized to desmethyl bromethalin which is as active as the parent compound in uncoupling oxidative phosphorylation

Half-life: 135 hours (animals)

Overdosage/Treatment

Decontamination: **Oral:** Do **not** induce emesis. Lavage within 1 hour ingestions > 1 bait package (0.5 mg/kg). Activated charcoal with sorbitol may be useful. **Ocular:** Irrigate with saline.

Supportive therapy: Monitor for cerebral edema. Supportive care includes phenytoin (or a benzodiazepine), mannitol, and dexamethasone with hyperventilation to decrease increased intracranial pressure.

Additional Information Bait pellets are green in color

Bromides

Related Information

- Bromisovalerylurea

Impairment Potential

Commonly Includes Sodium, potassium, and ammonium bromide; also in multiple medications as salt form of drug; dextromethorphan hydrobromide, homatropine hydrobromide, neostigmine, potassium, propantheline, pyridostigmine, quinine hydrobromide, scopolamine hydrobromide; although this source of bromism has been rare in the U.S. since 1974.

Mechanism of Action Central nervous system depressant

Adverse Reactions

Central nervous system: Headache, slurred speech, hallucinations, retrograde amnesia, memory disturbance, hyperesthesia, CNS depression, depression

Dermatologic: Papules (erythematous, pustular) usually on legs, acneiform eruptions

Endocrine & metabolic: Hypochloremia, hypothyroidism

Gastrointestinal: Nausea, vomiting, anorexia, feces discoloration (black)

Neuromuscular & skeletal: Hypo- or areflexia, tremors, clonus

Signs and Symptoms of Overdose Chronic toxicity often causes acne-like rash; amnesia, ataxia, decreased anion gap, dementia, erythema multiforme, gastric bezoar, hallucinations, hypothyroidism, mydriasis, nausea, nystagmus, papilledema, photophobia, pseudotumor cerebri, sedation, slurred speech, tremors, vomiting

Admission Criteria/Prognosis Symptomatic patients, patients with impairment of renal function, serum bromide levels > 150 mcg/mL (in chronic ingestions) or acute oral ingestions > 10 g should be admitted

Toxicodynamics/Kinetics

Absorption: ≥ 90%, can form bezoar

Distribution: V_d : 0.35-0.48 L/kg

Protein binding: 0%

Half-life: 9-15 days

Elimination: Via tubular secretion, renal clearance: 26 mL/kg/day

Reference Range Therapeutic serum bromide levels: 750-1500 mcg/mL; symptoms of toxicity from bromides usually occur at serum bromine levels > 1500 mcg/mL; coma > 2000 mcg/mL; fatal levels > 3000 mcg/mL; background blood bromide level averages ~5.3 mcg/mL (range: 2.5-11.7 mcg/mL); urine bromide levels > 0.25 mg/dL are associated with exposure

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal may be useful for organic bromide compounds (carbromal). Consider whole bowel irrigation

Supportive therapy: I.V. administration of sodium chloride or oral sodium chloride (2-3 g) 3-4 times daily with 4-10 liters of fluid

Enhancement of elimination: Forced saline diuresis to maintain a urine flow of 3-5 mL/kg/hour; hemodialysis can reduce half-life to 1-2 hours; indications for hemodialysis include depressed mental status, cardiac failure, renal failure, or bromide serum levels > 2000 mcg/mL; furosemide (1 mg/kg up to 40 mg) can be added to ensure adequate urine output of 3-6 mL/kg/hour; mannitol and ethacrynic acid can also be used

Diagnostic Procedures

- Anion Gap, Blood

Test Interactions Causes negative anion gap: Bromide can interfere with chloride determinations on virtually all standard laboratory tests (including sequential multiple analyzers). It can also interfere with bicarbonate determinations in some analyzers.

Pregnancy Implications Can cause fetal CNS depression; microcephaly, heart malformations, intrauterine growth retardation, club foot, hypotonia, polydactyly have been documented

Additional Information Transient rise in concentrations are often seen in initial days of treatment; radiopaque; daily dietary intake: 0.1-0.3 mg/kg body weight

Bromisovalerylurea

Related Information

- Bromides

CAS Number 496-67-3

Use A sedative-hypnotic agent primarily used in Japan for sleep disorders

Mechanism of Action CNS depressant similar to bromides

Signs and Symptoms of Overdose Amnesia, ataxia, confusion, delirium, dysarthria, gastric atony, hepatitis, pancreatitis, rhabdomyolysis, toxic epidermal necrolysis, vasculitis, vomiting

Toxicodynamics/Kinetics Elimination: Renal: 3-5 hours

Dosage Oral: 600-900 mg

Reference Range Total BVU serum levels > 10 mcg/mL associated with toxicity; if (+)-BVU/total BVU ratio is > 35%, a considerable amount of the drug remains in the GI tract, not yet absorbed

Overdosage/Treatment

Decontamination: Oral: Avoid gastric lavage due to the fact that dissolution and absorption of the remaining BVU can be accelerated by lavage. Suggested mode for gastric decontamination is oral use of activated charcoal.

Supportive therapy: Intravenous administration of sodium chloride

Enhanced elimination: Although no formal studies exist, charcoal hemoperfusion may remove a significant amount of drug.

Pregnancy Implications Bromism can occur in the fetus

Bromoform

Related Information

- Adipose Tissue Ranges of Toxins

- Dibromochloromethane

CAS Number 75-25-2

UN Number 2515

Synonyms Methylene Tribromide; Tribromomethane

Use Not produced in the U.S.; used as a fluid for mineral ore separation, a laboratory reagent and used in quality control in the electronics industry; formerly used medicinally as a sedative or antitussive agent

Mechanism of Toxic Action Central nervous depressant; can be generated during water chlorination when water reacts with organic acids; thus, exposure can occur through drinking water (levels usually ~5 mcg/L)

Adverse Reactions

Central nervous system: Depression

Miscellaneous: On inhalation, can be a mucosal irritant and lacrimator

Signs and Symptoms of Overdose May be hepatotoxic and nephrotoxic; coma, miosis, respiratory depression, stupor, tremor

Toxicodynamics/Kinetics

Absorption: Absorbed by inhalation and oral routes (60% to 90%)

Metabolism: Oxidation in liver

Elimination: Pulmonary hepatotoxic in animal models

Reference Range Background blood levels in individuals exposed to bromoform only through drinking water is ~0.6 ppb

BROMOPHOS

Overdosage/Treatment

Decontamination (oral overdose): Lavage (within 1 hour)/activated charcoal

Supportive therapy: Although human overdose experience has been virtually nonexistent over the past 90 years, respiratory support appears to be a crucial modality. Naloxone may be of some benefit; otherwise, treat as for bromides.

Drug Interaction Rate of metabolism may be increased with phenobarbital

Additional Information

Fatal oral dose: 250-500 mg/kg

Colorless liquid with a sweet odor; not flammable. Prepared by mixing acetone with sodium hypobromite or by treating chloroform with aluminum bromide. Anesthetic properties similar to chloroform. Upon heating, it decomposes to bromide ion fumes.

Odor threshold: Air: 13.45 mg/m³; Water: 0.5 mg/L. OSHA: PEL-TWA: 0.5 ppm; TLV-TWA: 0.5 ppm. Mean urban ambient air concentration of bromoform: 3.6 ppt

FDA: Bottled water regulation for total trihalomethanes: 0.1 mg/L

Atmospheric half-life: Possibly 1-2 months; estimated daily dose to an average adult: <1 mcg

Ocular: Irrigation with copious tepid sterile water or saline
Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses >100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.M. or I.V. initially, or ~1/2 the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of organophosphates.

Antidote(s)

- Atropine [ANTIDOTE]
- Glycopyrrolate [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information

Red blood cell cholinesterase and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected.

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Bromophos

CAS Number 2104-96-3

U.S. Brand Names Brofene®; Nexion®

Synonyms O,O-Dimethyl-O-(2,5-Dichloro-4-Bromophenyl) Phosphorothioate

Use Marketed as insecticide granules, dusting agent, or spray liquid with or without petroleum derivative as a solvent

Mechanism of Toxic Action Irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, QT prolongation, sinus bradycardia, sinus tachycardia

Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia

Genitourinary: Incontinence

Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure), intermediate syndrome

Signs and Symptoms of Overdose

Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, diaphragmatic paralysis, dysarthria, excessive sweating, generalized asthenia, headache, heart block, decreased hemoglobin, decreased red blood cell count, decreased platelet count, fecal incontinence, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, urinary incontinence, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure, and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia, and asthenia are infrequently observed weeks to months following acute exposure to certain organophosphates.

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure

Metabolism: Rapid to weakly active compounds through hepatic hydrolysis and other pathways

Elimination: Metabolites are excreted in urine

Warnings/Precautions Risk of aspiration pneumonitis exists following oral exposure to agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. **Do not** give a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach also may be used

Button Batteries (Discontinued)

Synonyms Disc Battery; Watch Battery

Mechanism of Toxic Action Leakage of mercury, potassium, lithium thionyl chloride, or sodium hydroxide at the site of the battery seal can cause gastrointestinal burns; electrical burns or pressure necrosis can occur in the gastrointestinal tract

Adverse Reactions

Gastrointestinal: Esophageal impaction for larger cells (>20 mm in diameter); can also occur in infants <1 year of age for cells >16 mm in diameter: dysphagia, odynophagia, intestinal obstruction

Respiratory: Tachypnea, tracheoesophageal fistula, nasal septal perforation

Signs and Symptoms of Overdose Abdominal pain, dysphagia, esophageal ulceration, fever, tachypnea

Admission Criteria/Prognosis Asymptomatic patients with batteries that have passed beyond the esophagus may be discharged on a regular diet

Monitoring Parameters Mercury levels (for mercury-based batteries) and radiographs

Overdosage/Treatment

Supportive therapy: Avoid emetics. Withhold nasal or otic drops for exposure to nose or ear. Remove promptly if located in airway or in esophagus. Obtain plain radiographs to localize and estimate size of battery. Mercury level for mercury-containing cells may be required. Endoscopic removal for esophageal impaction. If the battery is beyond the esophagus, it is likely (85%) to pass within 96 hours, with 99% of all ingested batteries passing within 7 days. Batteries >15 mm in diameter are less likely to pass through the gastrointestinal tract spontaneously, in children younger than 6 years of age. Cimetidine can be used to reduce corrosion.

Enhancement of elimination: Metoclopramide may be utilized when there are no signs for obstruction or peritonitis. Similarly, one dose of a saline cathartic or sorbitol can be utilized, although these modalities have not been proven to be of value. Polyethylene glycol use has not been well defined and can be considered for batteries located (in asymptomatic patients) distal to the esophagus. Symptomatic patients require surgery or endoscopy. Repeat radiograph in 4-7 days.

Additional Information Strain all stools. Button battery hotline: 202-625-3333

Butyl Alcohol

Applies to Lacquer; Paint; Pharmaceuticals (Extractant in Manufacture); Resin

CAS Number 71-36-3

UN Number 1120

Synonyms Butan-1-ol; Butanol; Butyl Hydroxide; Propylcarbinol; Propyl-methanol

Use In solvents in paints, lacquers, and resins; also used as extractants in the manufacture of pharmaceuticals; has been used as a sedative

Mechanism of Toxic Action Central nervous system depression

Adverse Reactions

Central nervous system: Depression

Gastrointestinal: Irritant to mucous membranes

Signs and Symptoms of Overdose Ataxia, coma, corneal abnormalities, cough, confusion, dermal erythema, diarrhea, dizziness, drowsiness, fatigue, eye irritation (at 50 ppm), feces discoloration (black), headache (slight), keratitis, porphyria, respiratory depression, vomiting

Toxicodynamics/Kinetics

Absorption: Rapid from the GI tract and dermally

Elimination: By the kidneys faster than ethanol

Overdosage/Treatment

Decontamination: Ipecac/activated charcoal may be useful

Enhancement of elimination: Use hemodialysis for persistent coma.

Diagnostic Procedures

• Electrolytes, Blood

• Glucose, Random

• Osmolality, Serum

Additional Information Minimum toxic dose: 3-7 oz. Fuel oil odor is irritating. In pregnancy, tert-butyl alcohol may be fetotoxic. Odor threshold: 50 ppm. TLV-TWA: 100 ppm

Cadmium

CAS Number 7440-43-9

UN Number 2570

Commonly Found In Solder, metal ores, amalgams, alkaline storage batteries (nickel cadmium batteries), polyvinyl chloride pigments, electroplating processes, cigarette smoke; production of phosphate fertilizers

Mechanism of Toxic Action Local irritation with system toxic effects, primarily proximal renal tubular dysfunction causing impaired regulation of calcium, uric acid and phosphorus, along with proteinuria and glucosuria.

Adverse Reactions

Cardiovascular: Hypertension, shock, cardiomegaly, cardiomyopathy, cor pulmonale

Central nervous system: Fever, seizures, chills

Dermatologic: Photosensitivity

Endocrine & metabolic: Sexual dysfunction, hypokalemia

Gastrointestinal: Diarrhea, vomiting, metallic taste, bad taste, salivation

Genitourinary: Urine discoloration (dark)

Hematologic: Anemia

Hepatic: Hepatic necrosis

Neuromuscular & skeletal: Osteomalacia, myoclonus

Ocular: Visual evoked potential abnormalities

Renal: Nephrotoxicity, renal tubular necrosis, renal failure, proteinuria, acidosis (renal tubular), Fanconi syndrome, glomerulonephritis, renal cell cancer - Nephrolithiasis

Respiratory: Emphysema, bronchitis, cough, bronchiolitis obliterans, hyposmia

Miscellaneous: Tooth discoloration, cutaneous T-cell lymphoma

Signs and Symptoms of Overdose Acute inhalational exposure resembles metal fume fever. Acute oral exposure causes albuminuria, diarrhea, glycosuria, hepatic necrosis, hypochromic anemia, hypokalemia, hypotension, metallic taste, myoclonus, nephritis, photosensitivity, respiratory arrest, seizures, and vomiting. Chemical pneumonitis can be progressive.

Admission Criteria/Prognosis Acutely symptomatic individuals or chronically exposed patients with blood cadmium levels >15 mcg/L or

urinary cadmium excretion >100 mcg/day should be admitted; survival after 4 days postexposure is usually associated with recovery

Toxicodynamics/Kinetics

Potential carcinogen

Absorption: 10% either pulmonary or gastrointestinal (increased G.I. absorption in iron-deficient patients)

Distribution: Concentrates in liver and kidney; does not cross placenta; low concentrations in breast milk

Protein binding: Bound primarily to metallothionein and albumin in the +2 valence

Half-life, elimination: 7 to 30 years

Reference Range

Suggested significant exposure with urinary levels >20 mcg/L (concentrations fourfold higher in smokers than nonsmokers) or blood levels >10 mcg/L.

Normal range of whole blood Cd levels:

Smokers: 1.4-4.5 mcg/L

Nonsmokers: 0.4-1 mcg/L

Normal Hair Cd levels:

Smokers: 1 mg/kg

Nonsmokers: 0.5 mg/kg

Normal Cd urinary level is <1 mcg/L

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage within 1 hour; whole bowel irrigation may be helpful; can dilute with milk or water. Activated charcoal does not appear to be effective.

Supportive therapy: No treatment for chronic intoxication. BAL and calcium disodium EDTA are contraindicated due to increased incidence of cadmium-induced renal disease. Dimercaptosuccinic acid (150 mg 3 times/day for 5 days, then twice daily for 14 days) has been shown to increase cadmium excretion by ~30%.

Enhancement of elimination: Hemoperfusion would not be expected to be effective.

Antidote(s)

• Succimer [ANTIDOTE]

Diagnostic Procedures

• Cadmium, Blood

• Cadmium, Hair

• Cadmium, Urine

Additional Information

Environmental exposure in Japan resulted in Itai-Itai disease. Increased beta₂-microglobulin excretion is a nonspecific marker for cadmium renal toxicity. Diabetic patients appear to be particularly prone to the adverse renal effects of cadmium.

Foods which contain the highest levels of cadmium include potatoes (0.04 ppm), leafy vegetables (0.03 ppm), grain and cereal products (0.02 ppm); total daily intake from food is ~30 mcg of cadmium.

Content of cadmium in cigarettes averages from 1-2 mcg per cigarette.

Mean body burden of cadmium: 1.65 mg in nonsmokers; 11.34 mg in smokers (0.03-0.04 mg of cadmium/pack-year).

Zinc deficiency may exacerbate cadmium-induced nephrotoxicity. High doses of deferoxamine may reduce cadmium induced liver and renal toxicity (in a rodent model).

Lethal oral amount of Cd salts - 5 grams

Calcium Hypochlorite

Related Information

• Sodium Hypochlorite

CAS Number 7778-54-3

UN Number 1748; 2208; 2880

Synonyms B-K Powder; Bleaching Powder; Calcium Hypochloride; Chlorinated Lime; Lo-Bax; Losantin Lime Chloride

Use Bleaching agent, algicide, oxidizing agent, fungicide, deodorant, disinfectant; used in sugar refining and preparation of surgical chlorinated soda solution (Dakin's solution)

Mechanism of Toxic Action Corrosive - oxidizing agent directly related to concentration of chlorine

Adverse Reactions

Cardiovascular: Chest pain, angina

Dermatologic: Dermatitis

Ocular: Eye irritation

Signs and Symptoms of Overdose Chest pain, erythema, dyspnea, local edema, pain, sore throat, vomiting

CALCIUM OXIDE

Overdosage/Treatment

Decontamination: **Oral:** Do not induce vomiting. Do not use gastric lavage. Dilute with milk or water. Endoscopy may be useful for oral ingestions. (Endoscopy is usually not required with a 3% to 6% solution ingestion.) Do not neutralize. **Dermal:** Irrigate skin with saline. **Ocular:** Irrigate copiously with water or saline.

Supportive therapy: Ocular: Topical mydriatic agents (ie, 1% atropine twice daily) and topical antibiotics with topical steroids (1% prednisolone tapered over 10 days) can be used.

Additional Information Whitish granular powder with strong odor of chlorine; usually found in concentrations >50%. Specific gravity 2.35. Decomposed by water and alcohol and may ignite when in contact with acids or organic materials

Calcium Oxide

CAS Number 1305-78-8

UN Number 1910

U.S. Brand Names Stomylex™

Synonyms Calcium Monoxide; Calx; Quick Lime

Commonly Found In Manufacture of steel, aluminum, glass; used in sewage treatments; found in dry cement (60% to 67%)

Mechanism of Toxic Action Strong alkaline irritant; can be formed when calcium reacts with water; calcium oxide reacts with water to form calcium hydroxide

Adverse Reactions

Cardiovascular: Tachycardia

Dermatologic: Dermal burns, erythema, skin edema

Gastrointestinal: Esophageal ulceration, dysphagia, vomiting, abdominal pain

Ocular: Ocular burns, glaucoma, conjunctivitis, corneal ulceration (may be delayed for 1 week), corneal opacification, lacrimation, blinking

Renal: Oliguria

Respiratory: Dyspnea, tachypnea, nasal ulceration, stridor, bronchospasm

Monitoring Parameters CBC, electrolytes, chest x-ray, ocular pH

Overdosage/Treatment

Decontamination:

Oral: Dilute with small amounts of milk or water (not >8 ounces in adults or 4 ounces in children). Do not give syrup of ipecac. Do not lavage. Do not give activated charcoal.

Dermal: Brush off particles of calcium oxide. Irrigate with saline or water under low pressure. Monitor pH of runoff.

Inhalation: Administer 100% oxygen.

Ocular: Irrigate with copious amounts of saline or water. Particles may need to be removed mechanically. Follow saline or water irrigation with irrigation of 0.01-0.05 M EDTA solution for 15 minutes. Cycloplegics (1% atropine twice daily) can be used to prevent ciliary spasm and topical antibiotics should be used.

Supportive therapy: For oral ingestion, perform endoscopy within 24 hours if a significant ingestion occurs, or when stridor, dysphagia, or drooling are present. Corticosteroids (0.1 mg/kg of dexamethasone daily or 1-2 mg/kg of prednisone daily for 3 weeks and then taper) may be useful for second or third degree gastrointestinal burns, although their usefulness has not been investigated in controlled human trials. Use of sucralfate or H₂-blockers is also unproven. Albuterol or other beta-adrenergic agonist agents can be used to treat bronchospasm.

Antidote(s)

- Edetate Disodium [ANTIDOTE]

Additional Information Exposure to 9 mg/m³ can cause lacrimation; found in various dermatological preparations in Europe. pH in a water solution of calcium oxide: ~12.5. Specific gravity: 3.3. IDLH: 25 mg/m³; TWA: 2 mg/m³

Calcium Polysulfide

Synonyms Lime Sulfur

Use Control tree fungus

Mechanism of Toxic Action Mucosal caustic agent; can cause metabolic acidosis

Adverse Reactions

Cardiovascular: Sinus tachycardia

Central nervous system: Coma

Dermatologic: Dermal irritation

Endocrine & metabolism: Metabolic acidosis

Gastrointestinal: Esophageal stricture, perioral cyanosis

Hepatic: Liver failure

Neuromuscular & skeletal: Rhabdomyolysis

Renal: Renal failure

Miscellaneous: Sulfur or rotten egg odor

Admission Criteria/Prognosis Admit any symptomatic patient or ingestion > 100 mL

Toxicodynamics/Kinetics Elimination: Renal

Reference Range Normal serum sulfate level: 0.5-1.5 mEq/L; levels >2.3 mEq/L may be associated with acidosis

Overdosage/Treatment

Decontamination: **Oral:** Do not induce emesis; lavage (within 1 hour)/activated charcoal. **Dermal:** Wash with soap and water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate with copious amounts of water.

Supportive therapy: Treatment similar to hydrogen sulfide: Treat acidosis with sodium bicarbonate (1-2 mEq/kg); sodium nitrite (300 mg in adults) may be useful.

Additional Information Releases hydrogen sulfide upon contact with water or acids; 400 mL can be fatal if taken orally

Camphor

CAS Number 21368-68-3; 464-48-2; 464-49-3; 76-22-2

UN Number 2717

Synonyms 2-Camphanone; Anemone Camphor; Formosa Camphor; Gum Camphor; Huile de Camphre; Kampfer; Laurel Camphor; Matricaria Camphor

Use Plasticizer, moth repellent, preservative in pharmaceuticals and cosmetics, in lacquers and varnishes, explosives, and pyrotechnics; used as an antipruritic, topical rubefacient, aphrodisiac, abortifacient, contraceptive, cold remedy, suppressor of lactation, and antiseptic; camphorated liniment or oil usually contains 20% camphor; camphor spirits usually 10%

Mechanism of Action Stimulant of cerebral cortex

Adverse Reactions

Cardiovascular: Tachycardia, Reye's syndrome, sinus tachycardia

Central nervous system: Headache, dizziness, delirium, seizures, coma

Dermatologic: Nonimmunologic contact urticaria, eczema

Gastrointestinal: Nausea, vomiting

Hepatic: Elevated liver function tests

Neuromuscular & skeletal: Myoclonus, fasciculations

Ocular: Mydriasis, strabismus

Renal: Albuminuria

Respiratory: Tachypnea

Signs and Symptoms of Overdose A distinctive oral odor may be apparent; tachycardia, CNS depression, renal failure. Convulsions may occur suddenly without warning or may be preceded by dementia, fasciculations, hyperventilation, irritability, mental confusion, neuromuscular hyperactivity, tremors, and jerky extremity movement. Seizures may be followed by coma and apnea. Vomiting may occur shortly after ingestion (a gastrointestinal irritant). Hepatic transaminases may be mildly and briefly elevated. Most symptoms occur within 30 minutes. Chronic ingestion may cause granulomatous hepatitis.

Admission Criteria/Prognosis Ingestions of > 1 g in adults (or 30 mg/kg in a child), or symptomatic patients, should be admitted, probably into an intensive care unit; if asymptomatic for 4 hours after a small ingestion, the patient can probably be safely discharged

Pharmacodynamics/Kinetics

Absorption: Readily through skin and mucous membranes

Distribution: V_d: 2-4 L/kg

Protein binding: 61%

Metabolism: Rapidly oxidized and conjugated in liver; metabolites may accumulate in fat stores

Half-life: 93-167 minutes

Peak effect: 90 minutes

Elimination: Odor of camphor may appear in urine; excreted primarily in urine; can also be excreted through the lungs

Dosage See Additional Information.

Monitoring Parameters Liver/renal function; monitor neurologic status

Contraindications Do not use in infants

Dosage Forms Translucent crystalline mass, blocks, or powder

Reference Range Levels > 14.5 ng/L associated with seizures

Overdosage/Treatment

Decontamination: Lavage (within 1 hour for ingestions > 30 mg/kg)

Eye: Irrigate with room temperature tap water for 15 minutes

Dermal: Wash affected area thoroughly with soap and water; systemic toxicity from dermal exposure is unlikely

Supportive therapy: Treat seizures with benzodiazepines; if seizures are refractory, phenobarbital or pentobarbital should be initiated; ventilatory support may be required; do not give alcohols, oils, or fats because this will increase absorption

Enhancement of elimination: Lipid hemoperfusion and resin hemoperfusion has been reported to decrease levels in patients with refractory seizures; hemodialysis is ineffective; charcoal hemoperfusion may be helpful, although not as clear a benefit as resin hemoperfusion; all of these techniques are somewhat controversial

Pregnancy Risk Factor C

Pregnancy Implications Crosses placenta and has been associated with one fetal death; three other cases report healthy outcomes

Additional Information Minimum lethal dose: 1 g (50 mg/kg). Odor is aromatic and pungent; aromatic taste produces sensation of cold; may mimic Reye's syndrome; TLV-TWA: 5 ppm; IDLH: 200 mg/m³

Specific References

Capecitabine

U.S. Brand Names Xeloda®

Synonyms NSC-712807

Use Treatment of metastatic colorectal cancer, metastatic breast cancer

Mechanism of Action Capecitabine is a prodrug of fluorouracil. It undergoes hydrolysis in the liver and tissues to form fluorouracil which is the active moiety. Fluorouracil is a fluorinated pyrimidine antimetabolite that inhibits thymidylate synthetase, blocking the methylation of deoxyuridylic acid to thymidylic acid, interfering with DNA, and to a lesser degree, RNA synthesis. Fluorouracil appears to be phase specific for the G₁ and S phases of the cell cycle.

Adverse Reactions

Cardiovascular: Angina, atrial fibrillation, bradycardia, cardiac arrest, cardiac failure, cardiomyopathy, cerebrovascular accident, chest pain, deep vein thrombosis, dysrhythmia, **edema**, electrocardiogram changes, hypertension, hypotension, myocardial infarction, myocardial ischemia, myocarditis, pericardial effusion, tachycardia, venous thrombosis, ventricular extrasystoles

Central nervous system: Ataxia, confusion, depression, dizziness, encephalopathy, **fatigue**, **fever**, headache, insomnia, irritability, loss of consciousness, mood alteration, **pain**, sedation, vertigo

Dermatologic: Alopecia, **dermatitis**, ecchymoses, nail disorders, **palmar-plantar erythrodysesthesia** (hand-and-foot syndrome) (may be dose limiting), photosensitivity reaction, pruritus, radiation recall syndrome, skin discoloration, skin ulceration

Endocrine & metabolic: Dehydration, hot flush, hypokalemia, hypomagnesemia, hypertriglyceridemia

Gastrointestinal: Abdominal distension, **anorexia**, **abdominal pain**, colitis, **constipation**, **decreased appetite**, **diarrhea (may be dose limiting)**, duodenitis, dyspepsia, dysphagia, esophagitis, gastric ulcer, gastritis, gastroenteritis, GI hemorrhage, hematemesis, hemorrhage, ileus, increased appetite, intestinal obstruction, **mild to moderate nausea**, motility disorder, necrotizing enterocolitis, oral candidiasis, oral discomfort, proctalgia, **stomatitis**, taste disturbance upper GI inflammatory disorders, toxic dilation of intestine, **vomiting**, weight gain

Genitourinary: Nocturia

Hematologic: **Anemia**, idiopathic thrombocytopenic purpura, **lymphopenia**, leukopenia, **neutropenia**, pancytopenia, **thrombocytopenia**

Hepatic: Ascites, **increased bilirubin**, cholestasis, hepatitis, hepatic failure, hepatic fibrosis

Local: Thrombophlebitis

Neuromuscular & skeletal: Arthralgia, arthritis, back pain, bone pain, dysarthria, joint stiffness, limb pain, myalgia, neuropathy, **paresthesia**, tremor

Ocular: Abnormal vision, conjunctivitis, **eye irritation**, keratoconjunctivitis

Renal: Renal impairment

Respiratory: Asthma, bronchitis, bronchopneumonia, bronchospasm, cough, **dyspnea**, epistaxis, hemoptysis, hoarseness, laryngitis, pneumonia, pulmonary embolism, respiratory distress, sore throat

Miscellaneous: Cachexia, diaphoresis increased, fibrosis, fungal infection, influenza-like illness, hypersensitivity, lymphedema, viral infection, sepsis, thirst

Signs and Symptoms of Overdose Alopecia, diarrhea, myelosuppression, nausea, vomiting

Pharmacodynamics/Kinetics

Absorption: Rapid and extensive

Protein binding: <60%; ~35% to albumin

Metabolism:

Hepatic: Inactive metabolites: 5'-deoxy-5-fluorocytidine, 5'-deoxy-5-fluorouridine

Tissue: Active metabolite: Fluorouracil

Half-life elimination: 0.5-1 hour

Time to peak: 1.5 hours; Fluorouracil: 2 hours

Excretion: Urine (96%, 57% as α -fluoro- β -alanine); feces (<3%)

Dosage Oral:

Adults: 2500 mg/m²/day in 2 divided doses (~12 hours apart) at the end of a meal for 2 weeks followed by a 1- or 2-week rest period

Elderly: The elderly may be pharmacodynamically more sensitive to the toxic effects of fluorouracil. Insufficient data are available to provide dosage modifications.

Dosing adjustment in renal impairment:

Cl_{cr} 50-80 mL/minute: No adjustment of initial dose

Cl_{cr} 30-50 mL/minute: Reduce dose by 25%

Cl_{cr} <30 mL/minute: Do not use

Dosing adjustment in hepatic impairment:

Mild to moderate impairment: No starting dose adjustment is necessary; however, carefully monitor patients

Severe hepatic impairment: Patients have not been studied

Dosage modification guidelines:

Recommended Dose Modifications		
Toxicity NCI Grades	During a Course of Therapy (Monotherapy)	Dose Adjustment for Next Cycle (% of starting dose)
Grade 1	Maintain dose level	Maintain dose level
Grade 2		
1st appearance	Interrupt until resolved to grade 0-1	100%
2nd appearance	Interrupt until resolved to grade 0-1	75%
3rd appearance	Interrupt until resolved to grade 0-1	50%
4th appearance	Discontinue treatment permanently	
Grade 3		
1st appearance	Interrupt until resolved to grade 0-1	75%
2nd appearance	Interrupt until resolved to grade 0-1	50%
3rd appearance	Discontinue treatment permanently	
Grade 4		
1st appearance	Discontinue permanently	50%
	or	
	If physician deems it to be in the patient's best interest to continue, interrupt until resolved to grade 0-1	

Stability Store tablets at room temperature of 25°C (77°F).

Monitoring Parameters Renal function should be estimated at baseline to determine initial dose; during therapy, CBC with differential, hepatic function, and renal function should be monitored

Administration Capecitabine is administered orally, usually in two divided doses taken 12 hours apart. Doses should be taken after meals with water.

Contraindications Hypersensitivity to capecitabine, fluorouracil, or any component of the formulation; known deficiency of dihydropyrimidine dehydrogenase (DPD); severe renal impairment (Cl_{cr} <30 mL/minute); pregnancy

Warnings

Hazardous agent - use appropriate precautions for handling and disposal.

Use with caution in patients with bone marrow suppression, poor nutritional status, ≥80 years of age, or renal or hepatic dysfunction. Patients with baseline moderate renal impairment require dose reduction. Patients with mild-to-moderate renal impairment require careful monitoring and subsequent dose reduction with any grade 2 or higher adverse event. Use with caution in patients who have received extensive pelvic radiation or alkylating therapy. Use cautiously with warfarin; altered coagulation parameters and bleeding have been reported. Rare and unexpected severe toxicity (stomatitis, diarrhea, neutropenia, neurotoxicity) may be attributed to dihydropyrimidine dehydrogenase (DPD) deficiency.

Capecitabine can cause severe diarrhea; median time to first occurrence is 34 days. Subsequent doses should be reduced after grade 3 or 4 diarrhea or recurrence of grade 2 diarrhea. Necrotizing enterocolitis (typhlitis) has been reported.

Hand-and-foot syndrome (palmar-plantar erythrodysesthesia or chemotherapy-induced acral erythema) is characterized by numbness, dysesthesia/paresthesia, tingling, painless or painful swelling, erythema, desquamation, blistering, and severe pain. If grade 2 or 3 hand-and-foot syndrome occurs, interrupt administration of capecitabine until the event resolves or decreases in intensity to grade 1. Following grade 3 hand-and-foot syndrome, decrease subsequent doses of capecitabine.

There has been cardiotoxicity associated with fluorinated pyrimidine therapy, including myocardial infarction, angina, dysrhythmias, cardiogenic shock, sudden death, ECG changes, and cardiomyopathy. These adverse events may be more common in patients with a history of coronary artery disease. **[U.S. Boxed Warning]: Capecitabine may increase the anticoagulant effects of warfarin; monitor closely.** Safety and efficacy in children <18 years of age have not been established.

CAPTAN

Dosage Forms Tablet: 150 mg, 500 mg

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal for oral ingestion

Supportive therapy: Monitor hematologically for at least 4 weeks. Allopurinol (300 mg 3 times/day) may be useful in decreasing toxicity; for treatment of acute encephalopathy, dexamethasone (10 mg every 6 hours I.V.) and thiamine may expedite neurologic recovery.

Enhancement of elimination: Forced diuresis or hemodialysis may enhance elimination

Drug Interactions Phenytoin: Concomitant use may increase the levels/effects of phenytoin; monitor.

Warfarin: Capecitabine may decrease the metabolism of warfarin; monitor closely.

Pregnancy Risk Factor D

Pregnancy Implications There are no adequate and well-controlled studies using capecitabine in pregnant women; however, fetal harm may occur. Women of childbearing potential should avoid pregnancy.

Lactation Excretion in breast milk unknown/not recommended

Additional Information Food reduced the rate and extent of absorption of capecitabine.

Captan

Applies to Foliage Protection

CAS Number 133-06-2

U.S. Brand Names Orthocide® 406; Orthocide®; Vancide® 89

Synonyms Captane; Captano

Use Foliage protection

Mechanism of Toxic Action A phthalimide (chloroalkyl thio) fungicide which is not phytotoxic is a dermal sensitizer which causes allergic dermatitis through a cell-mediated (type IV) immunologic reaction.

Signs and Symptoms of Overdose Conjunctivitis, dermatitis, desquamation, persistent erythema, photosensitivity

Toxicodynamics/Kinetics

Absorption: Poor through the GI tract (60%)

Metabolism: Hepatic

Elimination: Urine (52%), feces (16%), air (23%)

Overdosage/Treatment Decontamination: **Oral:** Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal. **Dermal:** Irrigate skin with soap and water. **Inhalation:** Administer 100% humidified oxygen

Specific References

Carbaryl

CAS Number 63-25-2

UN Number 2757

U.S. Brand Names Arilate®; Carbatox®; Crunch®; Hexavin®; Sevin®; Vioxan®

Synonyms 1-Naphthyl N-Methylcarbamate

Use Marketed as an insecticide dusting agent or spray liquid

Mechanism of Toxic Action Reversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, edema, sinus bradycardia, sinus tachycardia

Central nervous system: Toxicity is limited because carbamates do not significantly cross the blood-brain barrier; CNS changes occur with most severe intoxications, hyperactivity

Endocrine & metabolism: Hypoglycemia

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness, paralysis

Ocular: Diplopia

Respiratory: Cough, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose Delayed neurotoxicity manifesting as limb asthenia has been reported following a massive ingestion of carbaryl (~500 mg/kg). Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, cranial nerve palsies, confusion, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, flaccid paralysis, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, tachycardia, tachypnea, skeletal muscle fasciculation, vomiting

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital

staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. **Do not** use a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach may also be used
Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure. Diazepam is the agent of choice for seizure control and should be given as pretreatment in seriously ill patients.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses >100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or ~1/2 the dose of atropine).

2-PAM: Experimental data has indicated that carbaryl toxicity may be potentiated by oxime therapy. Do not use 2-PAM for a known or strongly suspected single ingestion of carbaryl.

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of organophosphates.

Antidote(s)

• Atropine [ANTIDOTE]

Diagnostic Procedures

• Creatinine, Serum

• Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine; administration of oxime antidotes (2-PAM and obidoxime) has been shown to increase carbaryl toxicity in animal models

Additional Information

Odorless and colorless, white, or gray solid

Red blood cell cholinesterase, and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure and are theoretically useful for differentiating between carbamate and organophosphate exposures.

RBC cholinesterase is typically not analyzed by in-house laboratories and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition, thus they may not be useful in ruling out carbamate exposure.

Decreased sperm counts and sperm motility have been noted in a rodent model.

Vapor pressure: 0.005 mm Hg at 20°C

ACGIH TLV: 5 mg/m³; PEL-TWA: 5 mg/m³; IDLH: 625 mg/m³

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Carbinoxamine

CAS Number 3505-38-2; 486-16-8

U.S. Brand Names CarbihistCarbinoxamine PD; Carboxine; Histex™ CT; Histex™ I/E; Histex™ PD; Palgic; Pediatix™

Synonyms Carbinoxamine Maleate; Carbinoxamine Tannate

Use Allergic rhinitis

Mechanism of Action An ethanolamine antihistamine which blocks acetylcholine at muscarinic receptors; also has serotonin antagonist effects

Adverse Reactions

Central nervous system: **Drowsiness**, dizziness

Dermatologic: Contact dermatitis

Gastrointestinal: Anorexia, diarrhea, nausea, xerostomia, vomiting

Genitourinary: Dysuria

Renal: Polyuria

Respiratory: **Thickening of bronchial secretions**

Signs and Symptoms of Overdose Usually occur within 2 hours of ingestion; ataxia, coma, diplopia, dry mouth, fever, mydriasis, seizures, tachycardia, tremor, visual hallucinations

Pharmacodynamics/Kinetics Half-life elimination: 10-20 hours

Dosage Children: 0.2-0.4 mg/kg/day
Adults: 4-8 mg given 3 or 4 times/day

Administration Shake suspension well before use.

Contraindications Hypersensitivity to carbinoxamine or any component of the formulation; use with or within 14 days of MAO inhibitor therapy

Warnings Use caution with asthma, increased intraocular pressure, hypothyroidism, cardiovascular disease, hypertension, pyloroduodenal obstruction, symptomatic prostatic hyperplasia, or bladder neck obstruction. Causes sedation; caution must be used in performing tasks which require mental alertness (eg, operating machinery or driving). May cause paradoxical excitation in pediatric patients. Safety and efficacy have not been established in children <9 months of age.

Dosage Forms

[DSC] = Discontinued product

Capsule, variable release:

Histex™ I/E: Carbinoxamine maleate 2 mg [immediate release] and carbinoxamine maleate 8 mg [extended release] [DSC]

Liquid, as maleate:

Carbihist: 4 mg/5 mL (120 mL) [cotton candy flavor] [DSC]

Carbinoxamine PD: 4 mg/5 mL (480 mL) [bubble gum flavor] [DSC]

Carboxine: 1.75 mg/5 mL (480 mL) [bubble gum flavor] [DSC]

Histex™ PD: 4 mg/5 mL (480 mL) [alcohol free, dye free, sugar free; bubble gum flavor]

Pediatex™: 1.75 mg/5 mL (480 mL) [alcohol free, dye free, sugar free; cotton candy flavor] [DSC]

Solution, as maleate:

Palgic: 4 mg/5 mL (480 mL) [bubble gum flavor]

Suspension, as tannate:

Pediatex™ 12: Carbinoxamine 3.6 mg per 5 mL (480 mL) [contains sodium benzoate; candy apple flavor] [DSC]

Suspension, variable release:

Histex™ PD-12: Carbinoxamine maleate 2 mg [immediate release] and carbinoxamine tannate 6 mg [extended release] per 5 mL (120 mL, 480 mL) [alcohol free, dye free, sugar free; contains sodium benzoate; bubble gum flavor]

Tablet, as maleate [scored]:

Palgic: 4 mg

Overdosage/Treatment

Decontamination: Oral: Do **not** induce emesis; lavage (within 2 hours)/activated charcoal

Supportive therapy: Physostigmine has been useful to successfully reverse visual hallucination; this agent should be reserved for life-threatening anticholinergic symptoms; benzodiazepines can be used for seizure control or for treatment of agitation

Enhanced elimination: Multiple dosing of activated charcoal may be effective

Drug Interactions

Barbiturates (and other CNS depressants): CNS depressant effects may be increased.

MAO inhibitors: Anticholinergic effects of the antihistamine may be increased and prolonged.

Tricyclic antidepressants: CNS depressant effects may be increased.

Pregnancy Risk Factor C

Pregnancy Implications Animal reproduction studies have not been conducted.

Lactation Excretion in breast milk unknown/use caution

Carbon Dioxide

CAS Number 124-38-9

UN Number 1013; 1845 (dry ice)

Synonyms Carbonic Acid Gas; Carbonic Anhydride; CO₂; Dry Ice

Use In urea synthesis; manufacture of soft drinks; used in fire extinguishers; dry ice; exposure can also occur from brewing, mining, and foundry work; dry ice has been used for cryotherapy (to treat warts/nevi)

Mechanism of Toxic Action

Inhalation: Simple asphyxiant (a colorless, odorless gas)

Solid form (as dry ice): Can cause freeze injury

Adverse Reactions

Cardiovascular: Tachycardia, hypotension, cyanosis, edema, chest pain, angina

Central nervous system: Insomnia, headache, dizziness, confusion, lightheadedness, memory loss, ataxia, coma, seizures, delirium, panic attacks, psychosis

Endocrine & metabolic: Metabolic acidosis (dry ice)

Gastrointestinal: Nausea, throat irritation

Ocular: Decreased vision, photophobia, eye irritation, color vision abnormalities, diplopia, ptosis, visual evoked potential abnormalities

Respiratory: Cough, respiratory acidosis, apnea, tachypnea, hyposmia

Monitoring Parameters Arterial blood gases

Overdosage/Treatment

Inhalation: Administer 100% humidified oxygen

Supportive: Seizures can be treated with benzodiazepine or phenobarbital. A freeze injury due to dermal exposure to dry ice should be managed with rapid rewarming (water bath 40°C to 42°C for 1/2 hour), with digit or extremity elevation. Management is otherwise similar to that of a thermal burn.

Additional Information

Signs of asphyxia can occur at oxygen concentrations <16%; oxygen levels <10% may be lethal; ambient carbon dioxide concentrations >35% can cause circulatory and respiratory depression; symptoms can occur at 1% concentration; TLV: 5000 ppm; IDLH: 50,000 ppm lethal carbon dioxide concentration in one minute inhalation: 100,000 ppm; specific gravity: 1.101

Carbon dioxide build-up due to inadequate ventilation is one of the major causes of "sick building syndrome" (~52% of cases of sick building syndrome). Recommended indoor ventilation rate for general office environment is 20 cfm (0.56 m³/min), which allows for indoor carbon dioxide to rise ~0.05 volume % above outdoor carbon dioxide levels

For seven occupants per 1000 square feet (93 m²) with 10 feet (3 m) of office ceiling, there should be 0.84 air changes per hour (8400 cubic foot/hour of outdoor air).

Dry ice is solid carbon dioxide maintained at -80°F (-26°C); can cause freeze injury if directly applied to skin and can cause asphyxiation if gas sublimates in an enclosed room; can combine with moisture to condense in thick, low lying fog

60% of carbon dioxide production remains in atmosphere (where upon it is used for plant photosynthesis). The green house effect occurs from increases in carbon dioxide (~1 ppm yearly) due to increased formation (combustion) and reduced decomposition (deforestation). Carbon dioxide does not support combustion soluble in water (1:1 ratio); with no caustic effect.

Inhalation of carbon dioxide (10% concentration) can raise intraocular pressure

Carbon Disulfide

Applies to Corrosion Inhibitors; Gold Plating; Matches (Manufacture); Nickel Plating; Photography (Instant Color); Rayon; Solvent (Gums, Resins)

CAS Number 75-15-0

UN Number 1131

U.S. Brand Names Caswell No 162; Weeviltox®

Synonyms Carbon Bisulfide; Carbon Sulfide; Dithiocarbonic Anhydride

Use Organic solvent used in gums and resins; used in manufacture of matches, instant color photography, corrosion inhibitors, gold and nickel plating, and rayon

Mechanism of Toxic Action Reacts with amino and thiols to inhibit cellular functions; damages the hepatic enzyme systems

Adverse Reactions

Cardiovascular: May be atherosclerogenic, angina, chest pain

Central nervous system: CNS depression, polyneuropathy, parkinsonism, hypothermia, seizures, memory disturbance, depression, mania, extrapyramidal reactions, axonopathy

Dermatologic: Burns on dermal contact

Hepatic: Fatty degeneration of liver

Neuromuscular & skeletal: Paresthesia, tremors

Ocular: Color vision abnormalities, visual evoked potential abnormalities

Respiratory: Dyspnea, hyposmia

Signs and Symptoms of Overdose Possibly diabetogenic; death can occur from respiratory paralysis. Burning of upper airway, cranial nerve palsies, diplopia, dizziness, dyspnea, headache, hypertension, nausea, neuritis, nystagmus, psychosis, rotten egg breath, seizures, tremor, vomiting, Decreased Spermatogenesis

Toxicodynamics/Kinetics

Absorption: Dermal absorption does occur; lipid soluble

Metabolism: Hepatic cytochrome P450 to carbonyl sulfide; also detoxified by glutathione pathway

Half-life: <1 hour

Elimination: Excreted by the lungs

CARBON MONOXIDE

Reference Range Monitor urine level of 2-thiothiazolidine-4-carboxylic acid; blood carbon disulfide levels ranging from 0.1-0.78 mg/L associated with air levels of ~80 ppm

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal

Supportive therapy: Avoid catecholamines due to probable monoamine oxidase inhibition; diazepam/lorazepam can be used for seizures. Pyridoxine use for neurologic toxicity is unproven. Although its use is unproven, there is a theoretical basis in which to use acetylcysteine to help detoxify carbon disulfide.

Additional Information

Fatal oral dose: 15 mL

Colorless liquid; may have aromatic, sweet odor; similar effect of disulfiram; parkinsonism has been described; may cause a reduction of urine homovanillic acid and vanillylmandelic acid concentrations

TLV-TWA: 10 ppm; IDLH: 5000 ppm; PEL-TWA: 4 ppm

Odor threshold: 0.1 ppm. Atmospheric half-life: 12 days. Water half-life: ~1 year

Ambient carbon disulfide levels average 65 ppt in urban areas and 41 ppt in rural areas

Specific References

Chang SJ, Shih TS, Chou TC, et al, "Electrocardiographic Abnormality for Workers Exposed to Carbon Disulfide at a Viscose Rayon Plant," *J Occup Environ Med*, 2006, 48(1):394-99.

bin levels > 25%, or if patient remains symptomatic after 4 hours on 100% oxygen, should be considered for admission; ~²/₃ of comatose patients will recover

Toxicodynamics/Kinetics

Absorption: Readily through the lungs; does not accumulate over time

Half-life: 5-6 hours in room air; 30-90 minutes in 100% oxygen;

30 minutes in hyperbaric oxygen; 100% oxygen in children: 44 minutes

Elimination: Through the lungs.

Effect of anemia and carboxyhemoglobin on oxyhemoglobin dissociation curve. Note that 60% carboxyhemoglobin has a greater affinity for oxygen than an equivalent physiological anemia which indicates that carbon monoxide shifts the oxygen dissociation curve leftward.

Monitoring Parameters

Arterial blood gases, carboxyhemoglobin
Reference Range Carboxyhemoglobin level by CO-Oximeter™: Endogenous level: ≤0.65; smokers may have from 3% to 8%. Severe symptoms may start at 10%; >35% is associated with fatalities from acute exposure; BEI is <8%; venous and arterial samples are equivalent

Overdosage/Treatment

Decontamination: 100% humidified oxygen by nonbreather face mask until asymptomatic if patient is not pregnant. If pregnant, the patient should be on 100% nonbreather face mask for 5 times the length of time needed for the carboxyhemoglobin level to be <5%. Continue therapy until carboxyhemoglobin level is <5%. Hyperbaric oxygen for patients with acute neurotoxicity, patients with angina, maternal carboxyhemoglobin of 15% in pregnant patients, or asymptomatic carboxyhemoglobin of 25%. **Do not** consider hypothermia or exchange transfusion. Hyperbaric oxygen should be administered at 2.8 ATA within 6 hours of exposure to carbon monoxide for maximum benefit.

Supportive therapy: Dopamine (17 mcg/kg/minute) has been shown in a case report to reverse carbon monoxide-induced blindness.

Antidote(s)

- Oxygen (Hyperbaric) [ANTIDOTE]

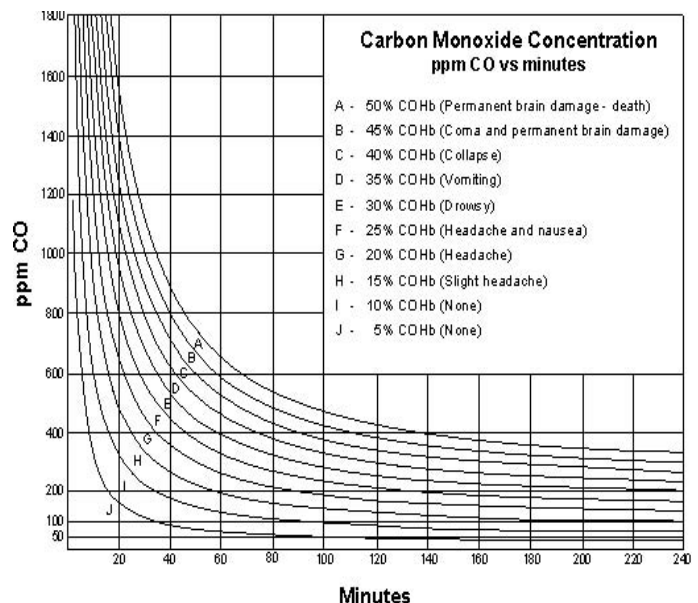

Diagnostic Procedures

- Carboxyhemoglobin, Blood
- Computed Transaxial Tomography, Head Studies
- Electrolytes, Blood
- Glucose, Random
- Urea Nitrogen, Blood

Additional Information

Colorless, odorless gas. Delayed neurotoxicity consisting of short-term memory deficit, ataxia, cognitive impairment may occur 2-3 weeks after an acute exposure. Parkinson syndrome may occur.

Carbon monoxide detectors are usually set to alarm at 85 decibels at indoor carbon monoxide air concentrations of 70 ppm (within 189 minutes), 150 ppm (within 50 minutes) or 400 ppm (within 15 minutes). Essentially, these concentrations, with corresponding time exposure, will result in a carboxyhemoglobin level of 10% during periods of heavy exertion. A carbon monoxide detector shall operate at or below the plotted limits for the 10% COHb curve as shown in the figure. If the detector employs a variable sensitivity setting, test measurements are to be made at maximum and minimum settings. For this test, three carbon monoxide concentrations (100, 200, 400 ppm) are to be used as specified in the figure.

According to estimates from the Bureau of Labor statistics, carbon monoxide accounted for 867 nonfatal work-related carbon monoxide exposures in private industry and 32 work-related deaths in 1992.

TLV-TWA: 50 ppm; IDLH: 1200 ppm; PEL-TWA: 35 ppm

Carbon Monoxide

Related Information

- Asphalt

CAS Number 630-08-0

UN Number 1016

Synonyms Carbon Oxide; Carbonic Oxide; CO; Exhaust Gas; Flue Gas

Commonly Found In Auto exhaust, byproduct of methylene chloride; produced in a closed space fire due to incomplete combustion of materials

Mechanism of Toxic Action Causes tissue hypoxia and inhibition of cellular respiration; binds to myoglobin, cytochrome a, a₃ and also increases xanthine oxidase and nitric oxide production resulting in oxidative stress; may cause cerebral glutamate elevation along with lipid peroxidation and cerebral edema

Adverse Reactions

Cardiovascular: Cardiac abnormalities most pronounced, syncope, sinus bradycardia, cardiomyopathy, cardiomegaly, chest pain, palpitations, sinus tachycardia

Central nervous system: CNS effects, acute neurological abnormalities including dementia, drowsiness, coma, seizures, headache, confabulation, Parkinson-like syndrome, memory disturbance, depression, psychosis, bilateral putaminal involvement, leukoencephalopathy

Delayed neurological sequelae observed within 40 days of significant carbon monoxide poisoning (12% to 43% incidence) including disorientation, bradykinesia, chorea (extrapyramidal), equilibrium disturbances, apathy, cogwheel rigidity, aphasia, incontinence, personality changes, short-term memory deficit, seizure disorders, and chronic headaches

Dermatologic: Bullous eruptions

Neuromuscular & skeletal: Chorea, apraxia, neuropathy (peripheral), rhabdomyolysis

Ocular: Cortical blindness, visual evoked potential abnormalities

Otic: Deafness

Signs and Symptoms of Overdose

Acute effects of carbon monoxide poisoning (adapted from Ernst A and Zibrak JD, "Carbon Monoxide Poisoning," *N Engl J Med*, 1998, 339(22):1603-8): Abdominal pain and muscle cramping (5%); chest pain (9%); concentration difficulties, confusion, or disorientation (43%); loss of consciousness (6%); nausea and vomiting (47%); shortness of breath (usually associated with hyperventilation) (40%); throbbing, bitemporal headache (91%); dizziness or vertigo (77%); visual changes (25%); weakness primarily in the legs (53%)

Other (<5%): Arrhythmias, AV block, bradycardia, cortical blindness in children, fever, hallucinations, hearing loss (sensorineural), hot flashes, hypotension, hypothermia, muscle necrosis, myoglobinuria, tinnitus,

Other effects commonly seen are lethargy, mydriasis, nystagmus, tachycardia

Carbon monoxide presentation in 140 children (from Mathieu D and Mathieu-Nolf M, *J Toxicol Clin Toxicol*, 2001, 39:266): Abnormal extensor plantar response (8%); cerebellar impairment (8%); flaccidity (17%); headache (37%); hyperreflexia (42%); lethargy/coma (19%); loss of consciousness (37%); seizures (5%); vomiting (22%)

Admission Criteria/Prognosis Acute neurologic symptoms, abnormal ECG, metabolic acidosis, chest pain, rhabdomyolysis, carboxyhemoglo-

Carbon monoxide intoxication may also result from methylene chloride exposure.

Half-life for carboxyhemoglobin elimination is ~27.5 minutes with use of an inflatable portable hyperbaric chamber (modified Ganow bag) at 1.58 ATA

Automobile exhaust may contain as high as 7% carbon monoxide.

Occupations particularly at risk from exposure to carbon monoxide: Blast furnace operators; bus drivers; carbide manufacturers; cooks/bakers; fire fighters; formaldehyde manufacturers; garage mechanics; iron/steel foundry (cupola); kraft paper pulp mills (Kraft recovery furnaces); lead molders; liners; operators of snow melting machines; petroleum-refining plants (catalytic cracking units); pulmonary function test practitioners; skating rinks (from Zamboni ice cleaners); tollway booth collectors; traffic policeman; warehouse storage and loading facilities (forklift operators); welders

Xenobiotics in which carbon monoxide is a metabolic byproduct:

- Methylene chloride (peak of 50% COHb described in humans)
- Dibromomethane (peak of 27% COHb in rodents)*
- Diiodomethane (peak of 14.2% COHb described postingestion in a girl, 20 months of age)
- Bromochloromethane (peak of 11% COHb in rodents)*
- 1,3-Benzodioxoles*
- Tetrahalomethane (?)*
- Dibromochloromethane*
(?) = Possible

*Noted in rodents only

Suggested indications for hyperbaric oxygen include: Coma or any period of loss of consciousness; COHb > 25% or > 15% if pregnant; signs of cardiac abnormality; history of ischemic heart disease and COHb > 20%; recurrent symptoms for up to 3 weeks; nonresolution of symptoms on oxygen after 6 hours; neurologic symptoms other than a transient headache; metabolic acidosis; abnormal and persistent psychometric testing; muscle necrosis, pulmonary edema, dysrhythmias, EKG changes, brain changes on neuroimaging

Risk of CO poisoning due to outdoor generators can be minimized by:

Placement of outdoor generator over 8 feet from building

Locate generators on the opposite side of building away from window air conditioners

Avoid connecting generator to a central electric panel

Celebrities in whom carbon monoxide was involved in their deaths: Ron Luciano (baseball umpire) 1995; Kevin Carter (photojournalist) 1994; Vitas Gerulaitis (tennis player) 1994; Jug McSpadden (golfer); Thelma Todd (actress) 1935; Dan White (murderer) 1985; Don Wilson (baseball pitcher) 1975; Emile Zola (novelist) 1902; Flora Disney (1938); Jimmy Campbell (bluegrass fiddle player) 2003; Rosey Nix Adams (daughter of June Carter Cash) 2003; Steve Neal (political writer, Chicago) 2004; Nick and Mary Yankovic (parents of "Weird Al" Yankovic) 2004; Zurab Zhvania (Prime Minister of Georgia) 2005; William Inge (playwright), 1973; Brad Delp (lead singer for the group Boston), 2007.

Carbon Tetrachloride

Applies to Fluorocarbons; Fumigation of Grain; Insecticide

CAS Number 56-23-5

UN Number 1846

U.S. Brand Names Benzinoform®; Fasciolin®; Flukoids®; Freon 10®; Halon 104®; Tetraform®

Synonyms Carbon Chloride; Perchlormethane; Tetrachloromethane; Tetrasol

Use In the production of fluorocarbons, fumigation of grain, and as an insecticide

Mechanism of Toxic Action Antihelminthic; cirrhosis of liver, renal insufficiency; free radicals bind to hepatocytes which lead to lipid peroxidation and cell death

Adverse Reactions

Cardiovascular: Tachycardia, sinus tachycardia
Central nervous system: Memory disturbance, leukoencephalopathy
Gastrointestinal: Feces discoloration (clay/putty)
Hepatic: Hepatotoxicity, centrilobular hepatic necrosis
Ocular: Eye irritation
Miscellaneous: Suspected human carcinogen (liver cancer and leukemia), cutaneous T-cell lymphoma

Signs and Symptoms of Overdose Aplastic anemia, anuria, ataxia, coma, confusion, delirium, dementia, hematuria, jaundice, nausea, seizures, skin erythema, tremor (intention), vomiting

Admission Criteria/Prognosis Any symptomatic patient, or any patient with radiopaque solvent on abdominal radiograph should be admitted

Toxicodynamics/Kinetics

Absorption: Readily from the skin, lungs, and the GI tract (85%; rapid, within 10 minutes); can produce renal or hepatic toxicity from any of these sites

Metabolism: In the liver, metabolites include hexachloroethane, carbon dioxide, and phosgene

Half-life: Oral: 40-85 hours. Inhalation: 1-40 hours

Elimination: Excreted through the lungs (50% to 80%) as carbon dioxide

Reference Range Toxic: 2.0-5.0 mg/dL

Overdosage/Treatment

Decontamination: **Inhalation:** Administer 100% humidified oxygen. **Dermal:** Remove contaminated clothing (especially leather), shoes, belts, hats, etc and place in a sealed plastic bag. Wash skin thoroughly with soap and water. **Oral:** Basic poison management; avoid ipecac. **Do not** use catecholamines due to enhancement of ventricular arrhythmia. Avoid enzyme-inducing agents such as phenobarbital.

Supportive therapy: Hyperbaric oxygen may be of benefit to prevent hepatitis. N-acetylcysteine (at 140 mg/kg oral loading dose, followed by 70 mg/kg every 4 hours for 17 doses) may be of benefit to prevent hepatitis if given within 16 hours postexposure. Due to the fact that these agents induce cytochrome P450, avoid the use of ethanol or phenobarbital.

Antidote(s)

- Acetylcysteine [ANTIDOTE]
- Oxygen (Hyperbaric) [ANTIDOTE]

Diagnostic Procedures

- Electrolytes, Blood
- Electrolytes, Urine

Additional Information

Lethal dose: 43 mg/kg

Colorless liquid with odor of chloroform; N-acetylcysteine may be of benefit (research studies); radiopaque

TLV-TWA: 5 ppm; IDLH: 300 ppm; PEL-TWA: 2 ppm

Atmospheric half-life: Over 30 years. Water half-life: ~6-12 months. Soil half-life: 6-12 months

Average urban ambient carbon tetrachloride levels: 0.1-0.3 ppb; average indoor carbon tetrachloride level: 0.2-0.4 ppb; median drinking water carbon tetrachloride level: 0.3-0.7 mcg/L; average daily exposure of carbon tetrachloride: ~0.11 mcg/kg

Cesium

CAS Number 7440-46-2

UN Number 1407

Synonyms Cs

Use In manufacture of photoelectric cells; as a gamma ray source (¹³⁷Cs) for wheat, potato, and flour sterilization

Mechanism of Toxic Action Radioactive cesium emits gamma radiation which can result in tissue damage; may enhance brain levels of norepinephrine and dopamine

Adverse Reactions

Cardiovascular: Torsade de pointes
Central nervous system: Euphoria
Dermatologic: Skin erythema
Endocrine: Reduced male fertility
Gastrointestinal: Vomiting, diarrhea, nausea
Ocular: Lacrimation, conjunctivitis

Toxicodynamics/Kinetics

Absorption: Oral: 78%; Dermal: 3% (¹³⁷Cs)

Half-life: ¹³⁴Cs: 2 years; ¹³⁷Cs: 30 years

Elimination: Urinary

Overdosage/Treatment Decontamination: Oral: Prussian blue (10 g or 125 mg/kg orally twice daily) may be efficacious

Additional Information Cesium acts similar to potassium. It is naturally occurring as a stable isotope (¹³³Cs) at an average of 1 ppm in granite rock and 4 ppm in sedimentary rock. Seawater concentration: 0.5 mcg/L. Concentration of ¹³⁴Cs in Poland, 1975: 1.1 pCi/m³. Concentration of ¹³⁴Cs above Chernobyl, May 8, 1986: 1,756 pCi/m³

Decay Properties of the Radioactive Isotopes of Cesium

Isotope	Half-life (years)	Decay mode	Intensity percent	Beta particle energy (MeV)
¹³⁴ Cs	2.062	β ₁ ⁻	27	0.02309
		β ₂ ⁻	2.5	0.1234
		β ₃ ⁻	70	0.2101
¹³⁷ Cs	30	β ₁ ⁻	94.6	0.1734
		β ₂ ⁻	5.4	0.4246

Chenopodium Oils

CAS Number 8006-99-3

Synonyms Oil of American Wormseed; Volatile Oil

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose Abdominal pain, dizziness, flushing, headache, nausea, salivation (start several hours after ingestion), tinnitus, vomiting; followed by ataxia, coma, deafness, drowsiness, and in some cases progresses to tachycardia, seizures, and death

Respiratory depression is seen with large ingestions and pulmonary edema is a common finding in fatal cases. Renal damage (hematuria and albuminuria) and hepatitis. Mucous membrane irritant, CNS depressant or CNS stimulant. CNS depression may be rapid (30 minutes) or delayed (up to 4 hours) and may continue for up to 3 days; chemical pneumonitis and pulmonary edema are possible

Camphor causes mydriasis while eucalyptus oil may cause miosis; seizures may occur with eucalyptus oil; tachycardia and bradycardia have been reported. Camphor causes sudden seizures, abdominal pain, diarrhea, sudden seizures, and vomiting; mild elevation of liver enzymes

Toxicodynamics/Kinetics

Absorption: Well absorbed through mucous membranes

Metabolism: By the liver

Elimination: Excreted primarily through kidney

Reference Range No toxic levels established

Overdosage/Treatment

Decontamination: Emesis is not recommended because as an essential oil, *Chenopodium* oil may be aspirated and there is potential for CNS depression and seizures. Gastric lavage within 1 hour is preferred. Activated charcoal is recommended. For products with a thick hydrocarbon base, gastric lavage may decrease systemic effects.

Supportive therapy: Liver function and renal function should be monitored. Cardiac and respiratory systems should be supported. CNS depression and electrolytes should be followed closely.

Enhancement of elimination: Eucalyptus oil has been successfully treated with mannitol and peritoneal and hemodialysis. Camphor has been reported to be extracted with amberlite resin hemoperfusion. Use of enhanced elimination techniques for these overdoses should be based on the amount ingested, the clinical picture, and/or symptoms that are failing to respond to supportive care.

Drug Interaction Enhances the penetration of fluorouracil on excised skin

Additional Information Volatile oils: Camphor, cedar leaf, cinnamon oil, eucalyptus, lavender, menthol, myristica, peppermint oil, sandalwood oil, saffras oil, thymol, turpentine oil; may explode when heated

Chloralose

CAS Number 15879-93-3

Use Rodent, mole, crow poison

Mechanism of Toxic Action A central nervous system depressant which acts as a stimulant on spinal reflexes (similar to strychnine).

Adverse Reactions

Cardiovascular: Tachycardia, facial flushing

Central nervous system: Ataxia, coma, hypothermia, hyperthermia, headache

Hematologic: Leukocytosis

Neuromuscular & skeletal: Rhabdomyolysis, myoclonus

Ocular: Miosis

Respiratory: Apnea, respiratory depression

Toxicodynamics/Kinetics

Metabolism: Hepatic to urochloral acid

Elimination: Renal (urochloral acid)

Reference Range Plasma chloralose >3.5 mg/L is associated with coma. Postmortem blood level of 151 mg/L has been associated with chloralose-induced fatality. Urine chloralose concentration of 15.2 mg/L is associated with seizures. May undergo postmortem redistribution.

Overdosage/Treatment

Decontamination: **Oral:** Do not induce emesis. Gastric lavage (within 1 hour)/activated charcoal should be considered. **Inhalation:** Administer 100% humidified oxygen.

Supportive therapy: Seizures should be managed with benzodiazepines. Barbiturates or phenytoin are second-line agents. Propofol has been used to treat myoclonus.

Additional Information Oral toxic dose: Infants: 20 mg/kg. Adults: 1 g.

Chlorate Salts

CAS Number 7775-09-0

UN Number 1461; 3210

Synonyms Asex; B-Herbttox; Chlorate of Soda; Chlorate Salt of Sodium; Chlorax; Chloric Acid-Sodium Salt; De-fol-ate; Desolat; Drexel Acetol; Evalu-Super; Grain Sorghum Harvest Aid; Granex O; Harvest-Aid; Klorex; Kusa-Tohru; Ortho C-1 Defoliant and Weed Killer; Rasikal; Shed-a-Leaf; Sodium Chlorate; Travex; Tumbleaf; Val-Drop

Use Historically used as antiseptics, it is primarily found in weed killers (sodium chlorate), and in the manufacture of matches and explosives.

Adverse Reactions Cardiovascular: Sinus tachycardia

Signs and Symptoms of Overdose Cyanosis resistant to oxygen therapy; nausea, vomiting, and abdominal cramping; diarrhea or colic usually precede pallor; methemoglobinemia and hemolysis may occur; drowsiness, coma, and seizures have been reported. Moderate elevations of LFTs with hepatomegaly and jaundice have been reported. Chlorates are nephrotoxic; acute renal insufficiency with oliguria or anuria is common. Severe exposure may cause subacute intravascular coagulation and leukocytosis lasting 40 days. Chronic exposure to chlorates of 5-10 days will also follow a similar pattern.

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15% or patients with hyperkalemia. These symptoms usually occur within 4 hours of exposure.

Toxicodynamics/Kinetics

Absorption: Good through respiratory and gastrointestinal tract; poor through skin

Elimination: Slow through the kidneys

Monitoring Parameters When 1 mL of a 1% (w/v) solution of diphenylamine in concentrated sulfuric acid is added to material containing chlorates, a blue color is produced; urine is probably the fluid of choice, but blood can also be measured through spectrophotometry for chlorate

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with sorbitol
Supportive therapy: Obtain baseline hemoglobin, hematocrit, and methemoglobin; monitor urinalysis, BUN, creatinine, CBC, and methemoglobin; transfuse if needed. Alkaline diuresis may be required if significant hemoglobinuria; methylene blue 1-2 mg/kg/dose of 1% slow I.V. for those patients who are symptomatic or with methemoglobin >30%; additional doses may be required. A DIC profile may be needed. Sodium thiosulfate should be considered (2-5 g oral or in 100 mL of 5% sodium hydrochloride) for symptomatic patients to attempt to inactivate the chlorate ion, although this modality is not proven to be effective. Methemoglobinemia produced by chlorates may be refractory to methylene blue.

Enhancement of elimination: Exchange transfusion combined with hemodialysis or peritoneal dialysis should be considered in severely intoxicated patients.

Antidote(s)

- Methylene Blue [ANTIDOTE]
- Sodium Thiosulfate [ANTIDOTE]

Additional Information How supplied: Potassium chlorate: Colorless or white crystals or powder. Sodium chlorate: Colorless to pale yellow crystals or powder

Chlordane

CAS Number 12789-03-6; 5103-71-9; 5103-74-2; 57-74-9

U.S. Brand Names Chlordane[®]; Niran[®]; Octachlor[®]; Ortho-Klor[®]; Velsicol[®] 1068

Use Organochlorine subterranean termiticide by which all commercial use was discontinued by the EPA in April, 1988

Mechanism of Toxic Action Neurotoxic mechanism unknown; may involve competitive inhibition of GABA or reduced levels of norepinephrine involved in neuronal transmission

Adverse Reactions

Cardiovascular: Tachycardia, Raynaud's phenomenon, sinus tachycardia, Reye's-like syndrome

Central nervous system: Headache, dizziness, irritability, seizures (usually within 3 hours of exposure), paresthesia

Dermatologic: Scleroderma

Gastrointestinal: Nausea, diarrhea, anorexia

Genitourinary: Oliguria

Hematologic: Aplastic anemia

Hepatic: Jaundice, elevated liver function test results

Neuromuscular & skeletal: Paresthesia

Ocular: Blurred vision, diplopia

Respiratory: Dyspnea

Toxicodynamics/Kinetics

Absorption: By inhalation (76%), oral, and dermal routes

Metabolism: Hepatic; active metabolites include heptachlor and oxychlordane

Half-life: 88 days

Elimination: Primarily fecal

Reference Range Ingestion of 215 g (3 g/kg) of chlordane resulted in a chlordane blood level of 5 mg/L (patient recovered); seizures can occur at chlordane serum levels of 2-4 mcg/L

Overdosage/Treatment

Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal or cholestyramine; **do not** use oil-based cathartics. **Dermal:** Repeated and copious scrubbing with soap and water

CHLORDECONE

Supportive therapy: Since barbiturates hasten the elimination of oxychlorthane, this may be the antiseizure drug of choice. Benzodiazepines can also be used.

Enhancement of elimination: Multiple doses of activated charcoal or cholestyramine may be useful.

Additional Information Lethal oral dose: 25 mg/kg. Can cause sclerodermatous changes of the hands. World Health Organization guideline limit for drinking water: 0.3 mcg/L TWA-TLV: 0.5 mg/m³

Specific References

Hardell L, Andersson SO, Carlberg M, et al, "Adipose Tissue Concentrations of Persistent Organic Pollutants and the Risk of Prostate Cancer," *J Occup Environ Med*, 2006, 48:700-7.

Chlordecone

CAS Number 143-50-0

U.S. Brand Names Compound 1189®; Kepone®; Merex®

Synonyms Decachloroketone

Use Insecticide (fire ant, slugs, grass mole cricket, tobacco fireworm) on tobacco, shrubs, and banana plants

Mechanism of Toxic Action Increases permeability of neuronal membrane; has estrogenic properties

Adverse Reactions

Cardiovascular: Pleuritic chest pain, edema, angina
Central nervous system: Auditory and visual hallucinations, headache, slurred speech, ataxia, increased intracranial pressure, axonopathy
Dermatologic: Rash, maculopapular rash
Gastrointestinal: Nausea
Genitourinary: Oligospermia
Hepatic: Elevated alkaline phosphatase
Neuromuscular & skeletal: Tremors, arthralgia, neuropathy (peripheral)
Ocular: Cataracts, nystagmus, papilledema

Toxicodynamics/Kinetics

Absorption: Inhalation, oral (90%), and dermal
Metabolism: Hepatic reduction to chlordecone alcohol
Half-life: 63-148 days
Elimination: Primarily fecal (biliary)

Monitoring Parameters Alkaline phosphatase

Reference Range Blood chlordecone levels >1 ppm associated with neurotoxicity; blood levels >2000 ng/mL associated with tremor

Overdosage/Treatment

Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal or cholestyramine. **Dermal:** Wash with soap and water. **Ocular:** Copious irrigation with saline

Supportive therapy: **Do not** use phenytoin for tremor since it may exacerbate tremor. Propranolol may be effective in alleviating tremor. Prednisolone has been used to alleviate headache due to increased intracerebral pressure.

Enhancement of elimination: Due to enterohepatic recirculation, multiple dosing with cholestyramine (4 g every 8 hours) has been shown to be effective.

Additional Information FDA action level for oysters, clams, mussels, and fin fish: 0.03 ppm; crabs: 0.4 ppm; high bioaccumulation potential in fish

Chlorfenvinphos

CAS Number 18708-86-6; 18708-87-7; 470-90-6

UN Number 2783

U.S. Brand Names Apachlor®; Birlane®; Dermaton®; Supone®; Unitox®

Synonyms O,O-Diethyl O-(2-Chloro-1(2',4'-Dichlorophenyl)Vinyl) Phosphate

Use Marketed as insecticide granules, dusting agent, or spray liquid with or without petroleum derivative as a solvent

Mechanism of Toxic Action Potent, irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, QT prolongation, sinus bradycardia, sinus tachycardia
Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia
Genitourinary: Urinary incontinence
Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia
Respiratory: Pulmonary edema, respiratory depression
Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose

Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension,

hypotension, lacrimation, miosis (unreactive to light), mydriasis (rarely), metabolic acidosis and hyperglycemia (severe intoxication), pallor, nausea, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure, and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia, and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure. Dermal rate: 0.06-1.43 cm²/hour

Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways

Half-life: 12-15 hours

Elimination: Metabolites are excreted in urine

Warnings/Precautions Environmentally persistent; chlorfenvinphos is a soil applied insecticide used for arable crops, and may translocate into plants, fruits, and vegetables grown in treated soil; risk of aspiration pneumonitis exists with agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Reference Range Serum concentration: Chlorfenvinphos level of 300 ng/mL associated with severe respiratory distress and bronchial hypersecretion; blood chlorfenvinphos level 3 hours after oral ingestion of 50 mL of 50% chlorfenvinphos is ~300 ng/mL

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Lavage within 1 hour with a 5% sodium bicarbonate or 2% potassium permanganate. Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. When using activated charcoal, **do not** use a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can also be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses >100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or ~1/2 the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed treatment and large volumes of distribution of organophosphates. Hemoperfusion clearance was used successfully in one case report (68 mL/minute), with the highest value of clearance observed during the fourth hour of hemoperfusion.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information

Toxic dose (dermal): 10 mg/kg

Red blood cell cholinesterase, and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management.

Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected.

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

An amber liquid with a mild odor

Specific gravity: 1.36

Half-life in soil: 9-210 days; Atmospheric half-life: 7-92 hours; Water half-life: 170 days (pH 6); 80 days (pH 8)

Cooking will partially reduce chlorfenvinphos residues

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Chlorine

Related Information

- Chlorine Dioxide
- Sodium Hypochlorite

Applies to Bleach; Disinfectant (Water); Pulp Mills; Swimming Pools

CAS Number 7782-50-5

UN Number 1017

U.S. Brand Names Clorox®

Synonyms Bertholite

Commonly Found In War gas used in World War I; can be produced by mixing bleach with acid

Use In pulp mills and for swimming pools; also used in bleaching; used as a water disinfectant

Mechanism of Toxic Action Converted to hydrogen chloride in lung parenchyma, strong irritant and corrosive agent; free radical generation may be present

Adverse Reactions

Cardiovascular: Cardiovascular collapse, chest pain, angina

Ocular: Lacrimation

Respiratory: Pulmonary edema, bronchoconstriction, reactive airways dysfunction syndrome, bronchiectasis

Miscellaneous: Increased risk for lymphoma

Signs and Symptoms of Overdose Airway irritation, chest pain, cough, dermal burns, dyspnea, eye irritation, headache, hyperchloremic metabolic acidosis, hypertension, hypotension, stomatitis, vomiting, wheezing

Admission Criteria/Prognosis Ongoing pulmonary symptoms 6 hours postexposure requires hospital admission

Toxicodynamics/Kinetics Absorption: Not well absorbed, low solubility

Reference Range Not measurable

Overdosage/Treatment

Supportive therapy: Administer 100% humidified oxygen. A 3.5% to 5% sodium bicarbonate solution by nebulization may be helpful for acute respiratory symptoms. Wheezing can be treated with beta-adrenergic agonists. Steroids are of no proven benefit. Avoid use of intravenous sodium bicarbonate.

Endoscopy is not necessary when the subject accidentally swallows a small quantity (<40 mL) of diluted bleach, the clinical examination is normal, the bleach contains <3% of available chlorine, and bleach pH is <12. Otherwise, endoscopy should be performed within 6-12 hours after ingestion. Inverse-ratio ventilation using lower tidal volume mechanical ventilation (6 mL/kg) and plateau pressures of 30 cm water may decrease mortality. While positive end expiratory pressures should be considered, oxygen toxicity should be monitored. Use of perfluorocarbon partial liquid ventilation and exogenous surfactant in chemical-induced ARDS is investigational.

Diagnostic Procedures

- Lung Scan, Ventilation

Additional Information

Green-yellow gas. Taste threshold: 5 ppm. Odor threshold: 3.5 ppm. TLV-TWA: 0.5 ppm; IDLH: 30 ppm; PEL-TWA: 0.5 ppm

Mixing hypochlorite (bleach) with an acid can release chlorine gas; mixing hypochlorite (bleach) with ammonia can release chloramine gas.

As a water disinfectant, chlorine is bactericidal at levels of 0.2 mg/L and cysticidal at 1.5-2 residual free chlorine (pH 7).

Environmental persistence: Low

Chlorine Dioxide

CAS Number 10049-04-4

UN Number 9191

Synonyms Alcide; Anthium Dioxide

Use An intermediate, from water treatment and disinfecting applications (eg, pulp bleaching) when generated from sodium chlorite utilization (usually with sulfuric acid)

Mechanism of Toxic Action Mucosal irritation; a strong oxidizer

Signs and Symptoms of Overdose Bronchospasm, conjunctivitis, cough, dyspnea, headache, leukocytosis, rhinitis, tachycardia

Toxicodynamics/Kinetics Elimination: Urinary

Overdosage/Treatment

Decontamination: **Inhalation:** Administer 100% humidified oxygen;

Ocular: Irrigate with copious amounts of saline or water

Supportive therapy: Treat bronchospasm with beta-adrenergic agonist agents; corticosteroids may be useful

Additional Information A yellow gas with pungent odor; decomposes rapidly in sunlight and carbon monoxide. Maximum residual disinfectant level for chlorine dioxide in water is 0.8 mg/L. Daily exposure to chlorine dioxide via drinking water: 1.6-2 mg/day. Minimal IDLH: 5 ppm. Lethal concentration in air: 19 ppm. TLV: 0.1 ppm. Air levels of 2-5 ppm are irritating.

Chloroacetophenone

Related Information

- Chlorobenzylidene Malononitrile

Applies to Tear Gas

CAS Number 532-27-4

UN Number 1697

Synonyms CAF; CN; MACE; Phenacyl Chloride

Use Active ingredient in tear gas; riot control

Mechanism of Toxic Action Lacrimator - irritation due to the active halogen group reacting transiently with sulfhydryl groups

Adverse Reactions

Dermal: Allergic contact dermatitis, burning sensation of the skin, dermal erythema, bullous dermatitis

Gastrointestinal: Metallic taste, vomiting

Ocular: Ocular burning, blepharospasms, lacrimation (eye symptoms may last for 30 minutes)

Respiratory: Bronchospasm (may be delayed for 36 hours), pulmonary edema (may be delayed for 24 hours), cough, sneezing

Signs and Symptoms of Overdose Agitation, bronchospasm, cough, erythema, eye pain, lacrimation, laryngospasm (may be delayed for 2 days), nausea, pharyngitis, rhinorrhea, skin irritation, sneezing, tearing, vomiting

Toxicodynamics/Kinetics

Onset of effect: Rapid

Duration: Usually resolves in 30 minutes, skin effects may last for 2-3 hours

Absorption: Not absorbed

Overdosage/Treatment

Decontamination: Move patient rapidly to fresh air and monitor for wheezing. Administer 100% humidified oxygen. Personnel should avoid contaminating themselves. Wash skin with soap and at least two liters of water.

Ocular: Avoid rubbing eyes as it may prolong effect. Copious irrigation with water or saline is needed.

Supportive therapy: Solution of antacid (magnesium hydroxide - aluminum hydroxide - simethicone) gently blotted topically over exposed facial areas (avoiding eyes) may help resolve symptoms. Bronchospasm can be treated with inhaled beta₂ agonists. Inverse-ratio ventilation using lower tidal volume mechanical ventilation (6 mL/kg) and plateau pressures of 30 cm water may decrease mortality. While positive end expiratory pressures should be considered, oxygen toxicity should be monitored. Use of perfluorocarbon partial liquid ventilation and exogenous surfactant in chemical-induced ARDS is investigational.

Additional Information

Colorless to white vapor with a fragrant odor of apple blossoms; insoluble in water. Can be detected using gas chromatography/mass spectrophotometry (GC/MS). TLV-TWA: 0.05 ppm; IDLH: 100 mg/m³; PEL-TWA: 0.05 ppm. Vapor density: 5.3 (with air). Atmospheric half-life: 9.2 days

Threshold for eye irritation: 0.3 mg/m³ (permanent eye injury may occur)

Incapacitating dose: 5-20 mg/m³

Median incapacitating dose: 80 mg/m³/minute

Median lethal dose: 7000 mg/m³/minute (dispersed from solvent); 14,000 mg/m³/minute (from thermal grenade)

CHLOROBENZENE

Decomposes to chlorine when heated; no bioconcentration
Environmental persistence: Short
Action on metal: Tarnishes steel, mild corrosion

Specific References

Blain PG, "Tear Gases and Irritant Incapacitants, 1-Chloroacetophenone, 2-Chlorobenzylidene Malononitrile and Dibenz[b,f]-1,4-Oxazepine," *Toxicol Rev*, 2003, 22(2):103-10 (review).

Chlorobenzene

Applies to Caswell No 183A; DDT (Production); Degreaser (Car Parts); Solvent

CAS Number 108-90-7

UN Number 1134

Synonyms Benzene Chloride; MCB; Monochlorobenzene

Use Solvent used in production of DDT, phenol compounds (replaced primarily by cumene), diisocyanate, nitrochlorobenzene, and degreasing car parts

Adverse Reactions

Cardiovascular: Cyanosis
Central nervous system: CNS depression, seizures, coma, hyperesthesia
Hematologic: Methemoglobinemia
Neuromuscular & skeletal: Muscle spasms, neuritis, myoclonus
Miscellaneous: Mucosal irritant (at levels >200 ppm)

Toxicodynamics/Kinetics

Absorption: Inhalation: 38% to 45%. Gastrointestinal: 31%
Metabolism: Hepatic transition to 4-chlorophenol and through glutathione conjugation to parachlorophenyl mercapturic acid

Reference Range Levels of residents living near a former toxic chemical dump ranged from 25-120 mcg/L of chlorobenzene in the urine and 0.05-17 ng/L of chlorobenzene in blood

Overdosage/Treatment

Decontamination: **Dermal:** Wash with soap and water. **Ocular:** Irrigate with normal saline.

Supportive therapy: Respiratory support with administration of 100% humidified oxygen

Additional Information This compound can decompose through heating to chlorine gas. Odor threshold: 0.21 ppm; IDLH: 2400 ppm; PEL-TWA: 75 ppm

Chlorobenzylidene Malononitrile

Applies to Deep Freeze; Paralyzer

CAS Number 2698-41-1

Synonyms CS; Ortho-Chlorobenzylidene Malonitrile

Use Active ingredient in tear gas

Mechanism of Toxic Action Lacrimator: May be metabolized to thiocyanate in peripheral tissues

Adverse Reactions

Dermatologic: Dermal burns
Ocular: Ocular burning, blepharospasms, cataract
Respiratory: Bronchospasm (may be delayed for 36 hours), pulmonary edema (may be delayed for 24 hours)

Signs and Symptoms of Overdose Agitation, bronchospasm, cough, erythema, eye pain, lacrimation, laryngospasm, nausea, pharyngitis, reactive airway disease, rhinorrhea, skin irritation, sneezing, tearing, vomiting

Toxicodynamics/Kinetics

Onset of action: Immediate
Metabolism: Hepatic hydrolysis to O-chlorobenzaldehyde and malononitrile; peripheral metabolism may produce thiocyanate

Overdosage/Treatment

Decontamination: Move patient to fresh air and monitor for wheezing. Personnel should avoid contaminating themselves. Wash skin with soap and water. Avoid rubbing of eyes as it may prolong effect. Copious irrigation is needed. Recovery usually will occur within 10-20 minutes.

Dermal: Skin can be washed with a mild alkaline solution (6% sodium bicarbonate, 3% sodium carbonate and 1% benzalkonium chloride) to hasten elimination.

Supportive therapy: Monitor for cyanide in cases of ingestion or extremely high exposure. Inverse-ratio ventilation using lower tidal volume mechanical ventilation (6 mL/kg) and plateau pressures of 30 cm water may decrease mortality. While positive end expiratory pressures should be considered, oxygen toxicity should be monitored. Use of perfluorocarbon partial liquid ventilation and exogenous surfactant in chemical-induced ARDS is investigational.

Additional Information LD-50 (respiratory concentration) is estimated to be 25,000-150,000 mg/m³/minute. Soft contact lenses may minimize exposure. A white crystalline solid (density: 1.3) with a pepper odor. IDLH: 2 mg/m³; PEL-TWA: 0.05 ppm

Specific References

Blain PG, "Tear Gases and Irritant Incapacitants, 1-Chloroacetophenone, 2-Chlorobenzylidene Malononitrile and Dibenz[b,f]-1,4-Oxazepine," *Toxicol Rev*, 2003, 22(2):103-10 (review).

Chloroform

Pronunciation (KLOR oh form)

Related Information

● Adipose Tissue Ranges of Toxins

CAS Number 67-66-3

UN Number 1888

Synonyms Formyl Trichloride; Freon 20; Methane Trichloride; TCM; Trichloroform; Trichloromethane

Synonyms Trichloromethane

Use Solvent, grain fumigant, found in emulsions, spirits, tinctures; has been used as an anesthetic agent, refrigerant, and aerosol propellant

Mechanism of Toxic Action A direct depressant on the respiratory center in the brain stem; interferes with gangliosides in neuronal membranes and phospholipids on surfactant layer in lungs; can cause lipid peroxidation

Adverse Reactions

Cardiovascular: Sinus bradycardia, sinus tachycardia, arrhythmias (ventricular), vasodilation

Central nervous system: Psychosis

Dermatologic: Nonimmunologic contact urticaria

Gastrointestinal: Nausea and vomiting can occur at doses of 22-237 ppm

Hepatic: Centrilobular hepatic necrosis, aminotransferase level elevation (asymptomatic)

Ocular: Blepharospasm

Miscellaneous: Aneuploidy induction, cutaneous T-cell lymphoma

Signs and Symptoms of Overdose

Bradycardia, CNS depression, dizziness, drowsiness, dry mouth, fibrillation, nausea, headache, hemolysis, hepatitis, hepatomegaly, hypotension, tachycardia (ventricular), vomiting

Burning, corneal injury, conjunctivitis, and urticaria may occur with eye exposure. Acetone breath, cardiac arrest, cardiac arrhythmias, mydriasis, and nystagmus have been reported. Chemical pneumonitis, pulmonary edema, and respiratory depression may occur. Chronic use may produce degenerative brain changes and psychotic behavior.

Admission Criteria/Prognosis Significant, acute exposures should be admitted; see Additional Information

Toxicodynamics/Kinetics

Absorption: Well through inhalation, oral, and dermal exposure
Distribution: V_d: 2.6 L/kg; throughout and soluble in adipose tissue
Metabolism: To chloromethanol, hydrochloric acid, phosgene, chloride, and CO₂

Half-life: Inhalation: 8 hours

Elimination: Primarily from lungs in the form of chloroform and carbon dioxide; <1% excreted in urine

Monitoring Parameters Gas chromatograph and flame ionization detector as well as HPLC have been used to determine levels in blood; blood levels in fatalities range from 1-12 mg/dL

Dosage Forms Liquid: 480 mL

Reference Range Blood chloroform levels with anesthesia: 0.07-0.165 mg/mL. Postmortem blood and urine chloroform level of 18.1 mg and 1.5 mg/L has been associated with fatality. Ranges of blood chloroform (postmortem) levels in fatalities are 10-194 mg/L.

Overdosage/Treatment

Decontamination: Emesis within 30 minutes, lavage (within 1 hour)/activated charcoal. Remove from area of exposure and remove clothing; wash thoroughly.

Supportive therapy: Treatment of cardiac and respiratory status. Lidocaine, propranolol, bretylium, phenytoin, disopyramide, or overdrive pacing has been used in treatment of PVCs. Atropine may be used if severe bradycardia is present. If oral ingestion, radiograph may show radiopacity. Monitor blood glucose, urinalysis, LFTs and renal function. Administration of N-acetylcysteine for treatment of hepatitis is still theoretical.

Antidote(s)

● Atropine [ANTIDOTE]

Drug Interaction Thiopentone can increase incidence of hypotension

Additional Information

Lethal dose: Oral: 0.5 g/kg (as little as 10 mL may cause death). Fatal dose: 40,000 ppm. Anesthetic dose: 8000-10,000 ppm.

Listed as a suspected carcinogen; radiopaque

Odor threshold: Air: 85 ppm; Water: 2.4 ppm; TLV-TWA: 10 ppm

Atmospheric half-life: 80 days. Water (pH 9) half-life: 25-37 years

Average atmospheric chloroform levels in urban areas: 0.00002-0.002 ppm. Average indoor chloroform levels: 0.0002-0.004 ppm. Average chloroform levels near indoor, heated swimming pools: 0.035-0.2 ppm.

Average daily intake of chloroform through drinking water: 4-88 mcg; from urban ambient atmosphere: 6-200 mcg

Foods containing chloroform include: Butter: 1100 mcg/kg; mixed cereal: 220 mcg/kg; infant food: 230 mcg/kg; cheddar cheese: 83 mcg/kg; grains: 1.4-3000 mcg/kg; dried legumes: 6.1-57 mcg/kg; dairy products: 7-1100 mcg/kg

Chloromethane

Applies to Butyl Rubber (Production); Freon 40; Herbicide; Methyl Cellulose (Production); Oil Extractant; Polystyrene Foam (Molding); Polyurethane Foam (Molding); Propellant; R40; Refrigerant; Silicone (Production)

CAS Number 74-87-3

UN Number 1063

U.S. Brand Names Artic®

Synonyms Methyl Chloride; Monochloromethane

Use Chlorinated hydrocarbon used in the production of silicones, butyl rubber, methyl cellulose; was also used as a refrigerant (although this use has declined over the past 30 years), as a propellant, and as a herbicide; also used in molding polystyrene and polyurethane foams and as an oil extractant

Mechanism of Toxic Action Hepatically and renally toxic through probably glutathione depletion and lipid peroxidation; also a neurotoxic agent

Adverse Reactions

Cardiovascular: Sinus tachycardia

Central nervous system: Fever

Respiratory: Primarily from inhalation with a latent period of up to 2 days postinhalation; respiratory depression, nephritis

Signs and Symptoms of Overdose Neurological effects will usually occur at air concentrations >30,000 ppm. Asthenia, albuminuria, anemia, ataxia, blurred vision, cirrhosis (long-term exposure), coma, confusion, depression, dermal erythema, diarrhea, diplopia, dizziness, drowsiness, elevated BUN, elevated creatinine, fatigue, headache, hematuria, hypotension, jaundice, mydriasis, nausea, oliguria, proteinuria, seizures, sleep disturbances, slurred speech, tachycardia, tremor, vertigo, vomiting, wheezing

Toxicodynamics/Kinetics

Absorption: Not absorbed through intact skin; can be absorbed through the lungs by a rate of between 1.4-3.7 mcg/kg/minute

Protein binding: 0%

Metabolism: Hepatic and erythrocyte conjugation with glutathione to S-methylcysteine

Half-life: 50-90 minutes (beta phase)

Elimination: Primarily pulmonary; less than 0.01% per minute is renally excreted

Monitoring Parameters CBC, liver enzymes, renal tests, urine analysis

Reference Range After exposure to 50 ppm, chloromethane breath levels range from 50-80 mcg/L; while chloromethane blood levels range from 35-100 mcg/L

Overdosage/Treatment

Decontamination: Inhalation: Move patient out of environment; administer 100% humidified oxygen

Supportive therapy: Benzodiazepines for seizure control; symptoms usually abate after 6 hours

Drug Interaction Lethargy may be more pronounced in patients also taking a benzodiazepine

Additional Information Lethal concentration: 20,000 ppm. Toxic symptoms: 200 ppm.

Colorless gas with a sweet odor. Odor threshold: 10 ppm. IDLH: 10,000 ppm; TLV-TWA: 50 ppm. Atmospheric half-life: ~1 year. Ground water half-life: ~2 years. Natural background air concentration: ~1 ppb.

U.S. chloromethane production in 1994 was ~451.3 million kg.

Chloropicrin

Applies to Fumigant (Stored Grain); Fungicide; Insecticide; Tear Gas (World War I)

CAS Number 76-06-2

UN Number 1580

Synonyms C.P.; Nitrochloroform; Pepper Gas; Trichloronitromethane; Vomiting Gas

Use Used as a tear gas in World War I; now used as a stored grain fumigant, insecticide, and fungicide; often used as a warning agent for fumigants

Mechanism of Toxic Action Lacrimator, mucous membrane irritant

Signs and Symptoms of Overdose Abdominal pain (10%), agitation, anxiety, cough, dizziness, dyspnea, dysuria (3%), headache (48%), eye

irritation, nausea (19%), pulmonary edema, pleuritic chest pain (19%), rhabdomyolysis, sore throat, vomiting

Admission Criteria/Prognosis Admit any patient with prolonged dyspnea or rhabdomyolysis

Overdosage/Treatment

Decontamination: Remove from exposure; administer 100% humidified oxygen. **Dermal:** Remove all clothing and wash skin with at least 2 L of cold water. **Ocular:** Irrigate with water or saline for at least 15 minutes. Supportive therapy: Nonsteroidal anti-inflammatory agents can be used to treat pleuritic chest pain.

Additional Information Can penetrate any standard gas mask. Lacrimation can occur at levels of 3-37 ppm within 30 seconds. Lethal concentration is 119 ppm at 30 minutes. Thermal decompensation products include phosgene, nitrosyl chloride, chlorine, carbon monoxide, and nitrogen oxides. Odor threshold: 1.1 ppm. Irritant effect threshold: 0.3 ppm. IDLH: 4 ppm; TLV-TWA: 0.1 ppm

CHLOROXYLENOL

Specific References

Centers for Disease Control and Prevention (CDC), "Exposure to Tear Gas from A Theft-Deterrent Device on a Safe," *MMWR Morb Mortal Wkly Rep*, 2004, 53(8):176-7.

Chloroxylenol

CAS Number 88-04-0

Synonyms PCMX

Commonly Includes Disinfectant agents (4.8% concentration in Dettol®)

Use Effective against gram-positive bacteria; a chlorinated phenol compound

Mechanism of Action Central nervous system and cardiac depression
Signs and Symptoms of Overdose Aspiration pneumonia, bronchospasm, coma, laryngeal edema, nodal tachycardia, pulmonary edema, respiratory failure

Pharmacodynamics/Kinetics Elimination: Renal

Monitoring Parameters Electrolytes, renal function, chest x-ray

Dosage Forms Solution: 4.8%

Reference Range Postmortem blood chloroxylenol level of 2.3 mg/100 mL associated with fatality

Overdosage/Treatment

Decontamination: **Oral:** Do not induce emesis; lavage may be considered if airway is protected; activated charcoal is of uncertain efficacy.

Ocular: Irrigate with saline.

Supportive therapy: Hypotension can be treated with I.V. crystalloid solutions and Trendelenburg placement; dopamine can be used for refractory cases; verapamil can be used for nodal tachycardia

Additional Information Not a caustic agent

hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. **Do not** give a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can also be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or ~¹/₂ the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed treatment and large volumes of distribution of organophosphates.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Additional Information

Toxic dose: 300 mg/kg
Red blood cell cholinesterase, and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected.

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Less likely than other organophosphates to induce organophosphate-induced delayed neuropathy

Emits a sulfur (garlic) odor at airborne concentrations > 1 ppb

Atmospheric half-life: 6.34 hours

EPA tolerance range for agriculture products: 0.05-15 ppm

Estimated daily dietary intake for a 14-16 year old male in the U.S.: ~3.4 ng/kg body weight

Tolerance in food: Citrus oil: 25 ppm; Corn oil: 3 ppm; Mint oil: 10 ppm;

Peanut oil: 1.5 ppm; Animal feeds: 0.5-15 ppm

TLV-TWA: 0.2 mg/m³

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Chlorpyrifos

CAS Number 2921-88-2

UN Number 2783

U.S. Brand Names Dursban TC®; Dursban®; Lorsban®; Pynrex®

Synonyms O,O-Diethyl-O-(3,5,6-Trichloro-2-Pyridyl) Phosphorothioate; Phosphorothioic Acid; Trichlorpyrifos (Discontinued)

Use Broad spectrum insecticide for control of mosquitoes, flies, cockroaches, fleas, and termites (TC formulation); has been used as an ascaricide and a veterinary ectoparasiticide

Adverse Reactions

Cardiovascular: QT prolongation, sinus bradycardia, sinus tachycardia
Central nervous system: Anxiety, restlessness, dizziness, dystonic reactions, cognitive dysfunction, hypothermia

Dermatologic: Mild skin irritant

Neuromuscular & skeletal: Choreoathetosis

Ocular: **Miosis** (82%), mydriasis can be present in severely affected individuals; conjunctivitis, photophobia, opsoclonus

Respiratory: Rhinorrhea

Miscellaneous: Diaphoresis, intermediate syndrome

Signs and Symptoms of Overdose

Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure, and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia, and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates. Cases of delayed neurotoxicity have been described.

Toxicodynamics/Kinetics

Absorption: Oral: 70%. Dermal: <3%

Metabolism: Hepatic to diethylphosphate, diethylthiophosphate, and 3,5,6-trichloro-2-pyridinol (TCP)

Half-life: 27 hours

Reference Range Oral dose of 5 mg/kg followed by dermal exposures between 0.5-5 mg/kg 2 weeks later produced blood chlorpyrifos levels <30 mcg/L (blood TCP levels were 0.9 mg/L 6 hours after oral ingestion and 0.06 mg/L 24 hours after dermal administration); a single oral dose of 0.5 mg/kg can depress plasma cholinesterase levels by 85%; urine 3,5,6-trichloro 2-pyridinol (TCP) level of 25 mcg/mg creatinine is associated with a 30% decrease of cholinesterase level

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to

Martinez MA, Ballesteros S, de la Torre CS, et al, "Attempted Suicide by Ingestion of Chlorpyrifos: Identificatin in Serum and Gastric Content by GC-FID/GC-MS," *J Anal Toxicol*, 2004, 28:609-15.

Chromium

Related Information

- Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 10025-73-7; 10060-12-5; 10101-53-8; 12018-01-8; 12314-42-0; 13530-65-9; 25013-82-5; 7440-47-3; 7775-11-3; 7778-50-9; 7789-02-8; 7789-09-5; 7789-12-0

UN Number 1439; 1463; 1758; 2720

U.S. Brand Names Chrometrace®

Synonyms Cr; Hexaqua chromium Chloride

Commonly Found In Chromium exposure may be found in battery manufacturers, painters, printers, welders, jewelers, steel workers, oil drillers, match manufacturers, leather workers, lithographers, tanners, cement workers

Mechanism of Action Chromium picolinate is the only active form of chromium. It appears that chromium, in its trivalent form, increases insulin sensitivity and improves glucose transport into cells. The mechanism by which this happens could include one or more of the following:

Increase the number of insulin receptors

Enhance insulin binding to target tissues

Promote activation of insulin-receptor tyrosine kinase activity

Enhance beta cell sensitivity in the pancreas

Mechanism of Toxic Action Dermatologic and pulmonary sensitizers; possibly carcinogenic with compounds of valence +6 (hexavalent)

Adverse Reactions

Dermatologic: Dermal sensitization, systemic contact dermatitis

Gastrointestinal: Gastroenteritis

Hematologic: Hemolysis, methemoglobinemia

Hepatic: Hepatic necrosis

Renal: Acute tubular necrosis

Respiratory: Asthma, bronchospasm, hyposmia

Miscellaneous: Anaphylactoid reactions, cutaneous T-cell lymphoma

Signs and Symptoms of Overdose Acute nausea, coma, dark red urine and stool, hypotension, skin burns, thrombocytopenia, vomiting

Toxicodynamics/Kinetics

Absorption, chromium III: Oral: 3%; also absorbed dermally and through inhalation; gut absorption: <2%

Half-life: Inhalation: 4-10 hours

Hexavalent: Urinary: 15-41 hours

Elimination: Inhalation and dermal: Renal. Oral: Primarily fecal

Reference Range

Serum: Normal population urine range: 0.24-1.80 mcg/L; Whole blood chromium concentrations >2mg/L are lethal

Some laboratories report much higher "normals" because the methods they use or the collection technique is not adequate to prevent substantial contamination. If a laboratory reports "<1 ng/mL" or some similar figure without a lower level for normal, the value can be relied upon to discover toxic states, perhaps, but not deficiency states. Serum levels of 10 ng/mL correspond to short-term atmospheric exposure limit of 0.1 mg/m³ of chromium trioxide. Serum levels even higher would be expected in acute systemic toxicity. Almost a twofold diurnal variation is noted in serum chromium levels, with the level highest in the morning and falling after each meal as insulin levels rise. Serum chromium levels are ~60% of normal in diabetic patients, which overlaps the normal range.

Normal urinary concentration is <10 mcg/L in healthy adults receiving 30-100 mcg chromium daily. Levels vary with the laboratory and have declined with improved methods of avoiding contamination. Levels two to threefold above this may reflect supplementation or excess losses. Levels elevated tenfold and higher have been seen in exposed asymptomatic tannery workers. Spot levels of chromium in urine of 30 ng/g creatinine correspond to the short-term atmospheric exposure limit of 0.1 mg/m³ of chromium trioxide in industrial exposure situations.

Median hair chromium content: 0.234 mg/kg; median nail chromium content: 0.52 mg/kg.

Mean Breast Milk Concentration: 0.3 mg/Liter

Overdosage/Treatment

Decontamination:

Oral: Lavage within 1 hour with 1% ascorbic acid solution (10 g ascorbic acid orally for every L of lavage fluid). **Do not** use antacids since antacids may increase absorption.

Dermal: Copious irrigation. Use 10% ascorbic acid topically to convert hexavalent chromium to a less toxic trivalent form.

Supportive therapy: Nephrotoxicity can be managed with ascorbic acid (1 g I.V. every 10-20 minutes up to 3 g), although this therapy has not been supported in clinical trials. Monitor serum/urine pH during treatment with ascorbic acid. Topical ascorbic acid may be effective in treating chromium dermatitis. 2,3-Dimercaptopropane sulphonate (DMPS or unithiol) is also useful to enhance this metal's elimination at a dose of 100 mg 3 times/day orally for 5 days, or 250 mg I.V. every 4 hours for 24 hours, then 250 mg every 6 hours.

Enhancement of elimination: Acetylcysteine may be an effective therapy in enhancing chromium elimination. Hemodialysis should also be employed, especially if renal insufficiency is present. Double volume exchange transfusion can lower plasma chromium concentration by 75% in infants. Due to accumulation of chromium in the liver, orthotopic cadaveric liver transplantation has been performed successfully in a comatose patient with hepatic necrosis, 5 days after ingesting potassium dichromate. Peritoneal dialysis is *not* effective.

Antidote(s)

- Unithiol [ANTIDOTE]

Diagnostic Procedures

- Chromium, Serum
- Chromium, Urine

Drug Interaction Chromium can cause a decrease in insulin requirements.

Drug Interactions Any medications that may also affect blood sugars; (eg, beta-blockers, thiazides, any medications prescribed to treat diabetes); discuss chromium use prior to initiating

Additional Information

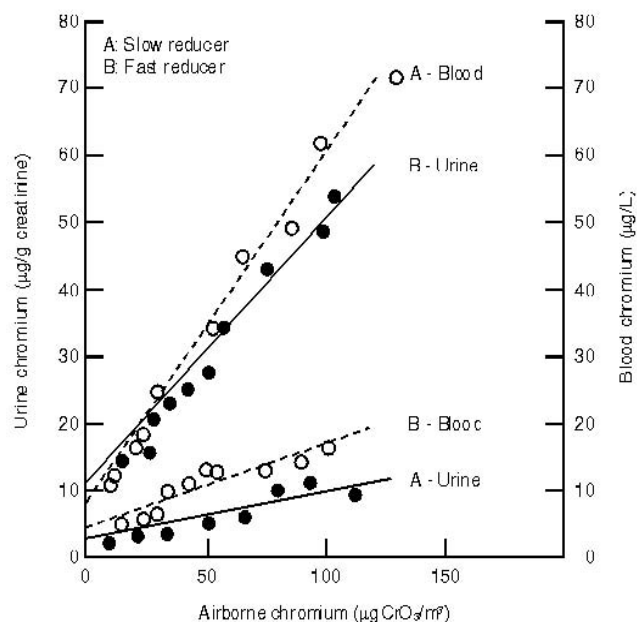

Minimum lethal dose: Potassium dichromate: 0.1 g; Lethal dose:

Hexavalent chromium: Oral: ~1 g.

Increased lung cancer mortality identified among workers with cumulative urinalysis measure >200 mcg/L - years chromium.

Determination of the amount of chromium in the serum or urine of normal persons is extremely difficult, due to the very low levels present. Levels observed are in the 0.1 ng/mL range, equivalent to one part in 10 billion. Extreme caution must be taken to avoid contamination by dust (from skin, leather, cloth) and contact with steel (which contains chromium). See figure.

Linear Relationship Between Water Soluble Chromium Concentrations in Workroom Air and the Chromium Concentrations in Blood and Urine at the End of a 5-Day Shift in Workers of a Dichromate Plant

From "Toxicological Profile for Chromium," U.S. Department of Health and Human Services, Agency for Toxic Substances and Disease Registry, August 1998.

Chromium is felt to be an essential element in the human, with chromium III purported to be an integral part of "glucose tolerance factor," a partially characterized complex that has been suggested to contain two

CHROMIUM

molecules of nicotinic acid and a small oligopeptide complexed to chromium III. This organic moiety is thought necessary for insulin action on the cell surface. Deficiency of chromium can cause an acquired insulin resistance or diabetes mellitus with associated hyperlipidemia in otherwise well-nourished patients. The classic cases, however, were reported prior to the availability of accurate serum levels of chromium, and reported levels then in "deficiency" were tenfold or more higher than we now know to be "normal". Chromium deficiency with associated glucose intolerance and fasting hypoglycemia has been most often observed during refeeding of malnourished individuals after famine starvation in relief programs. In infants, one or more oral doses of chromium, 250 mcg, have been curative. Chromium deficiency with associated glucose intolerance has also been observed in long-term parenteral nutrition when inadequate chromium was included. Neuropathy, encephalopathy, and abnormalities of amino acid profile (serum low in branched-chain amino acids and high in aromatic amino acids) have been noted in conjunction with this condition.

With regard to toxicity, pure metallic chromium is nontoxic. Chromium III is poorly absorbed and much less toxic than chromium VI. Industrial monitoring for toxicity in the past has relied on air samples largely for total and hexavalent chromium, the major species of concern. Workers are potentially exposed in tanneries, mines, and industries for metal plating, welding, photography, paint, dye, and explosives. Skin exposure may lead to dermatitis, and respiratory exposure to bronchitis, asthma, and lung cancer. Hair contains 1000-fold more chromium than serum or urine, and hair chromium content does correlate with industrial exposure; but more data are needed before hair chromium monitoring can replace industrial air monitoring and samples of blood and urine in cases of suspected toxicity or deficiency. Acute systemic chromate toxicity may cause acute tubular necrosis, acute hepatitis, seizures, and coma. Acute respiratory or gastrointestinal symptoms relate to the locus of absorption. Intermediate levels of long-term exposure may cause tubular albuminuria in industrial workers.

Chromium supplementation has been shown by some workers to improve glucose tolerance and improve insulin efficiency in glucose intolerant (but not in normal or overtly diabetic) patients on diets equivalent to the lower quartile of ordinary chromium intake in the United States. The implication is that many individuals in the U.S. population have a marginal chromium intake. We may, therefore, anticipate increased self-medication and supplementation in the future, and greater medical interest in this trace metal. The literature regarding chromium was for many years confused due to difficulties with analysis and contamination. Much old work needs to be repeated, and this field is still very much in flux.

The main excretory pathway for chromium III is renal. Estimated safe and adequate, oral intake recommended by the U.S. National Academy of Sciences range from 50-200 mcg/day, but in the U.S. 90% of people eat less, the mean intake being 25-33 mcg/day. Such intake recommendations likely derive from the 1980s when average estimated intake was determined to be 50-100 mcg/day. With increasingly accurate assays, new recommended ranges may be set lower. Absorption of chromium III is on the order of 0.5%, by radioisotope studies. One hospital pharmacy supplies 12 mcg of chromium from MTE5® trace mineral parenteral nutrition supplement per day. We are unaware of a large survey.

Cigarette tobacco contains 0.24-6.3 mg/kg of chromium. Atmospheric total chromium levels in the U.S. are 0.01-0.03 mcg/m³ in urban areas and <0.01 mcg/m³ in rural areas. River and lake chromium content is <30 mcg/L and 5 mcg/L, respectively.

Expected residence in air is <10 days; concentration in U.S. drinking water of chromium is 0.4-8 mcg/L; concentration in tobacco is 0.24-14.6 mg/kg.

Cobalt

Related Information

- Adipose Tissue Ranges of Toxins

CAS Number 10026-22-9; 10724-43-4; 1307-96-6; 1308-04-9; 1308-06-1; 513-79-1; 7440-48-4; 7646-79-9

UN Number 1318; 2001

Synonyms Cobalt Chloride; Cobalt Oxide; Cobalt Sulfate

Commonly Found In Superalloys as a paint drier, magnets, in pigment manufacture, glass decolorizer; industries with significant exposure to cobalt include tool sharpeners, miners, grinders; component in hard metal

Mechanism of Toxic Action Essential element in vitamin B₁₂ which acts as a coenzyme in hemopoiesis

Adverse Reactions

Cardiovascular: Cardiomyopathy

Dermatologic: Contact dermatitis, allergic dermatitis, eczema, nonimmunologic contact urticaria, systemic contact dermatitis, airborne contact dermatitis

Endocrine & metabolic: Metabolic acidosis, hypothyroidism, hyperlipidemia, goiter

Gastrointestinal: Nausea, vomiting, diarrhea

Hematologic: Anemia or polycythemia (not noted after inhalation exposure), methemoglobinemia, neutropenia

Ocular: Optic atrophy, conjunctivitis

Respiratory: Wheezing, interstitial fibrosis, and giant cell pneumonitis, pulmonary fibrosis, bronchospasm, asthma

Renal: Goodpasture's syndrome

Signs and Symptoms of Overdose Cardiomegaly, cyanosis, hypothyroid goiter, hypertension, polycythemia, pruritus

Toxicodynamics/Kinetics

Absorption: Variable gastrointestinal absorption (18% to 97%); absorbed through skin and also by inhalation

Half-life: 5-10 years

Elimination: Through lungs and renal feces

Reference Range Normal levels of urine: Up to 2.2 mcg/L; Plasma: Up to 1.2 mcg/L; Hair: 0.047 mg/kg; Nails: 0.06 mg/kg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal. In oral ingestion, iron can decrease cobalt absorption.

Supportive therapy: Sodium bicarbonate for metabolic acidosis. Restrictive pulmonary symptoms (hard metal disease) can be treated with prednisone (40-60 mg/day) and cyclophosphamide (25 mg twice daily).

Enhancement of elimination: Calcium disodium EDTA (50 mg/kg/day for 5 days) can increase cobalt excretion fourfold. BAL, acetylcysteine, or succimer has been shown experimentally to increase fecal excretion of cobalt. Hemodialysis may be of some value.

Antidote(s)

- Acetylcysteine [ANTIDOTE]
- Dimercaprol [ANTIDOTE]
- Edetate Calcium Disodium [ANTIDOTE]
- Succimer [ANTIDOTE]

Diagnostic Procedures

- Cobalt, Serum
- Cobalt, Urine

Drug Interaction Iron deficiency leads to increased oral absorption; oral iron can reduce amounts of cobalt absorbed

Additional Information

Cobalt, a metallic element, is a component of vitamin B₁₂ and is found in most foods. The daily requirement is unknown, as is deficiency in humans. Cobalt has the capacity to cause polycythemia, and for that reason, cobaltous chloride is used to successfully treat certain types of anemia. Accidental overdose of cobaltous chloride, especially in children, may lead to cyanosis, coma, and death. Cobalt dust inhaled in industrial settings may produce asthma and pulmonary symptoms. Long-term exposure may result in accumulation and cause polycythemia, goiter, cardiomyopathy, and nerve damage. Epidemic of lethal cardiomyopathy due to ingestion of 0.04-0.14 mg/kg/day of cobalt which was added as a foam stabilizer, occurred in the U.S. and Canada in the 1960s.

Total body content of cobalt: 1-1.5 mg

Normal amounts of cobalt ingested from food: 50-40 mcg/day

Daily intake > 6 mg can cause cardiomyopathy; air concentrations > 100 mcg/m³ can cause pulmonary fibrosis.

Mean urban air concentrations range from 1-2 ng/m³; concentration of in drinking water is < 5 mcg/L; average concentration in the earth's crust is 25 mg/kg.

Tobacco contains < 2.3 mg cobalt/kg dry weight.

IDLH: 20 mg/m³; PEL-TWA: 0.05 mg/m³; TLV-TWA: 0.05 mg/m³

CAS Number 10290-12-7; 12002-03-8; 12069-69-1; 12258-96-7; 1317-39-1; 1332-40-7; 142-71-2; 20427-59-2; 26506-47-8; 3251-23-8; 544-92-3; 7288-92-0; 7440-50-8; 7758-89-6; 7758-99-8; 866-82-0

UN Number 1479; 1578; 1585; 1586; 2630; 2721; 2775; 2776; 3009; 3010

Commonly Found In Elemental copper, and as the following hydrated or anhydrous salts: acetate, arsenate, chlorate, chloride, citrate, cyanide, dinitrate, fluoroborate, hydrate, hydroxide, malonate, oxide, oxychloride, selenate, silicate, sulfate, and copper in association with organochlorine (DDT), or carbamate insecticide; used in electrical industry, plumbing, industrial valves and fittings, pigments, furniture polish

Mechanism of Toxic Action Copper is a cofactor for ascorbic acid oxidase, catalase, peroxidase, lactase, and tyrosinase; copper may induce hemolysis through oxidation of hemoglobin sulfhydryl groups, thereby increasing permeability of the red blood cell. Copper also inhibits the sulfhydryl moieties of G6PD and glutathione, thereby reducing their free radical scavenging activities.

Adverse Reactions

Cardiovascular: Shock and cardiovascular collapse

Central nervous system: Lethargy, confusion, coma, drowsiness, hyperthermia, fever, extrapyramidal reactions, bilateral putaminal involvement

Dermatologic: Delayed allergic contact dermatitis, immunologic contact urticaria - Green hair shafts

Gastrointestinal: Oral thermal injury, GI ulceration, gastroenteritis (at ingestions > 15 mg of copper sulfate)

Hematologic: Hemolysis

Hepatic: Hepatitis, aminotransferase level elevation (asymptomatic), granulomatous liver disease (noncaseating)

Neuromuscular & skeletal: Rhabdomyolysis

Ocular: Corneal discoloration (chalcosis), eye irritation, conjunctivitis, corneal ulceration

Renal: Renal tubular necrosis, renal failure

Respiratory: Irritation, nasal ulceration, wheezing, rales

Miscellaneous: Metal fume fever

Signs and Symptoms of Overdose Acute tubular necrosis and renal failure, allergic contact dermatitis, blue-green vomitus, cardiovascular collapse, corneal discoloration and ulceration, diarrhea, feces discoloration (black), fibrosis, gastroenteritis, hair discoloration (green), hemolysis, hepatomegaly and hepatitis with centrilobular necrosis and biliary stasis, hypotension, jaundice, metallic taste, mucous membrane irritation, nasal ulceration, nausea, oral ulceration, pulmonary edema, shock, ulceration and burns, urticaria, vomiting. Methemoglobinemia is a rare finding, occurring only in severe cases (hemolysis and shock).

Admission Criteria/Prognosis Admit any adult ingestion > 1 g or pediatric ingestion > 25 mg or if hemolysis is present.

Toxicodynamics/Kinetics

Onset of reaction: Hemorrhagic gastritis, diarrhea, hemolytic anemia, and renal tubule necrosis may follow 36-48 hours after exposure

Absorption: Oral: ~ 30%

Distribution: V_d: 2 L/kg; found extensively in red blood cells, kidney, liver, and lungs

Protein binding: 95% to ceruloplasmin; 5% to albumin

Half-life: 26 days

Elimination: Urine: 4%; bile and feces: 80%

Reference Range Serum copper concentrations average 1 mg/L in normal patients, and 2 mg/L in pregnant patients (10.5-23 μmol/L); serum copper concentrations > 5 mg/mL are usually accompanied by signs of toxicity; whole blood copper concentrations correlate more closely with toxicity, but are usually not available; normal urinary copper excretion: 33 mcg/L (602 mcg/L in Wilson's disease); normal hair level: 17.7 ppm copper in first 3 cm of proximal end of scalp hair and ~ 11.9 ppm copper in pubic hair

Overdosage/Treatment

Decontamination: **Oral:** Lavage within 1 hour cautiously, but because of gastrointestinal ulceration and erosion, **do not** induce emesis. Activated charcoal does not bind copper. **Dermal:** Prompt thorough scrubbing of all affected areas with soap and water **Inhalation:** Remove from exposure, give supplemental oxygen, and treat wheezing. **Ocular:** Irrigation with copious tepid water or saline

Supportive therapy: Airway management, treatment of wheezing, humidified oxygen administration, and close monitoring for renal compromise. BAL (dimercaprol) (1 to 5 mg/kg/m) or penicillamine. Penicillamine dose is 1 to 2 grams daily (20 to 30 mg/kg) in 4 divided doses should be considered for massive ingestions, persistent symptomatology, or persistently elevated serum copper concentrations. BAL may be useful; penicillamine may be used in patients who will tolerate oral therapy. Trientine might be an effective copper chelator in an overdose setting, although it has not been studied for this use. Monitor for hemolysis.

Shock: Treat blood loss aggressively with I.V. fluids and vasopressors such as dopamine or norepinephrine. Consider endoscopy to rule out corrosive gastrointestinal injury and blood loss.

Enhancement of elimination: Dialysis or hemoperfusion has not been demonstrated to increase the elimination of copper. Adding albumin to

Copper

Additional Information

Metal fume fever has been reported at copper dust concentrations of 0.075-0.12 mg/m³. Copper salts were previously used as medicinal agents. Exposure may also follow the use of older vending machines, and brass or copper cooking or drinking vessels. Copper metal is radiopaque, but copper salts are not; elemental copper is poorly absorbed orally, but dusts or fumes may cause pneumonitis and metal fume fever. Copper salts may be irritating to the gastrointestinal tract, and may possess other toxicities due to salts such as arsenate or cyanide. Anhydrous compounds may produce thermal injury following contact with water or mucous membranes. Most U.S. coins contain 75% copper; diethyldithiocarbamate (intraocular use) is not useful to prevent ocular opacification due to copper nitrate.

How supplied: Elemental copper as solid metal (coin, etc); powdered copper; copper salt powder and granules; liquid for spraying (with or without petroleum distillate, organochlorine, or carbamate)

Diethyldithiocarbamate (intraocular use) is not useful to prevent ocular opacification due to copper nitrate.

Nut and nut products (especially unsalted pecans) contain the highest amount of copper (0.067-1.245 mg of copper per 100 g/nut). Most U.S. coins contain 75% copper.

Average daily intake of copper by inhalation: 600 mcg. Average daily intake of copper through drinking water: 0.15 mg. Average daily intake is ~1-2 mg. Mean copper content of cigarette tobacco: 24.7 ppm (only 0.2% of this copper passes through mainstream smoke)

Soil copper concentration: ~50 ppm; Atmospheric copper concentration: 5-200 ng/m³. Airborne copper concentration is 8-12 ng/m³ in indoor atmosphere (increased with use of kerosene-based space heaters). Water copper concentration: <100 mcg/L. Seawater contains <5 ppb of copper.

Taste threshold of copper in water: 1-5 mg/L. Discoloration (blue/green) in water: >5 mg/L.

ACGIH TLV: 1 mg/m³ (dusts/mists), 0.2 mg/m³ (fumes); PEL-TWA: 1 mg/m³ (dusts/mists), 0.1 mg/m³ (fumes)

See table.

Coumaphos

CAS Number 56-72-4

UN Number 2783

U.S. Brand Names Asuntol®; Baymix®; Co-Ral® Animal Insecticide; Co-Ral®; Meldane®; Muscatox®; Resitox®

Synonyms Bayer-21199; Coumafos

Use Used as a topical ectoparasiticide for livestock

Mechanism of Toxic Action Irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions Central nervous system: Cognitive dysfunction, hypothermia

Signs and Symptoms of Overdose Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypotension, hypertension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, QT prolongation, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure, and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia, and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Warnings/Precautions Risk of aspiration pneumonitis exists with agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. **Do not** give a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of organophosphates.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses >100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M., or ~1/2 the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Additional Information Very high mortality rate when ingested (17% to 31%).

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality. Heat stable; a colorless (or tan) combustible crystalline solid with a slight sulfur odor and insoluble in water.

Creosote

Related Information

- Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 8001-58-9 (coal tar); 8021-39-4 (wood)

U.S. Brand Names Sakresote[®] 100 (Coal Tar Creosote)

Synonyms Coal Tar Creosote (Creosote Oil, Brick Oil); Wood Creosote (Beechwood Creosote)

Use

Wood creosote: Disinfectant, carbonate, laxative, and expectorant (rarely used in U.S.)

Coal tar creosote: Carbonization of coal (bituminous) to produce natural gas (coking procedure); also used as a timber preservative

Mechanism of Toxic Action Mucosal irritant

Adverse Reactions

Cardiovascular: Increased diastolic pressure, hypertension, hyperemia

Dermatologic: Dermal burns/irritation, phototoxic, photosensitivity

Gastrointestinal: Oropharyngeal ulceration, esophageal corrosion

Hepatic: Hepatic degeneration

Ocular: Keratoconjunctivitis, photophobia

Renal: Albuminuria, renal failure

Signs and Symptoms of Overdose Anuria, dizziness, dyspnea, light-headedness, myoclonus, nasal irritation on inhalation

Toxicodynamics/Kinetics

Absorption: Dermal absorption may occur

Metabolism: Hepatic to 1-hydroxypyrene

Reference Range Workers of coal tar creosote excrete from 1-40 mcg of creosote/g creatinine in urine

Overdosage/Treatment

Decontamination: **Oral:** Do not induce emesis. Lavage (within 1 hour) with olive oils may be effective. Activated charcoal (not castor oil) should be given. **Ocular:** Copious irrigation with saline should be performed.

Supportive therapy: Inhalation: Give 100% humidified oxygen.

Enhancement of elimination: Charcoal hemoperfusion may be effective; hemodialysis is not effective.

Additional Information Fatal oral dose of coal tar creosote: Children: 1-2 g; Adults: 7 g

Coal tar creosote is possibly related to increased incidence of bladder cancer, squamous papilloma, and carcinomas. Phototoxicity of coal tar creosote may be enhanced with tetracycline.

Cresols

CAS Number 108-39-4 (meta); 1319-77-3; 95-48-7 (ortho)

UN Number 2022; 2076

Synonyms Cresylic Acid; Hydroxytoluene; Methylphenol; Tar Acids

Use Organic acid which occurs naturally in mammals and plants (Easter lily, jasmine, camphor, eucalyptus); also found as a byproduct of natural fires (volcano lightening), through the combustion of petroleum fuels, wood, or coal (fly-ash); ortho cresol has been used as an antiseptic; a metabolic breakdown product of toluene

Mechanism of Toxic Action Mucosal irritant and a central nervous system depressant

Adverse Reactions

Cardiovascular: Premature ventricular contractions, tachycardia, sinus tachycardia, cerebral edema

Dermatologic: Dermal burns

Gastrointestinal: Oropharyngeal burns, hemorrhagic pancreatitis

Hematologic: Methemoglobinemia, intravascular hemolysis, Heinz body anemia

Hepatic: Fatty degeneration

Ocular: Lacrimation, corneal burns, optic atrophy

Renal: Hematuria, eosinophilic necrosis, renal failure

Respiratory: Necrosis of bronchial epithelium, pulmonary edema

Signs and Symptoms of Overdose Abdominal pain, aspiration, coma, cough with bloody sputum, drowsiness, dyspnea, facial paralysis, hypoactivity, seizures, tremor, vomiting

Toxicodynamics/Kinetics

Absorption: Dermal: May be absorbed (fatalities can occur)

Elimination: Renal

Reference Range Para-cresol concentration in urine normally averages ~90 mg/L (range: 20-200 mg/L); serum cresol level >90 mg/L associated with lethality

Overdosage/Treatment

Decontamination: **Oral:** Dilute with water or milk; activated charcoal may be useful. **Do not** induce emesis. **Dermal:** Wash copiously with soap and water. **Ocular:** Irrigate copiously with saline.

Supportive therapy: Convulsions can be treated with a benzodiazepine or phenobarbital. Significant methemoglobinemia should be treated with methylene blue.

Antidote(s)

- Methylene Blue [ANTIDOTE]

Diagnostic Procedures

- Methemoglobin, Blood

Additional Information

Lethal oral dose: 2 g/kg. Lethal dermal dose: 2 g/kg

Individuals with glucose-6-phosphate deficiency may be at higher risk for methemoglobin formation. Toxicity may be enhanced when a patient is exposed concomitantly to oxidizing compounds (ie, hydroquinone). Cigarette smokers may inhale as much as 3 mcg/day of cresols. Not to be used for dermal disinfection

Cyanide

Related Information

- Donor Victims of Poisoning in Whom Transplantation of Organs Occurred

- Laetrile[®]

CAS Number 57-12-5

UN Number 1588

Synonyms Carbon Nitride Ion

Commonly Found In Gold and silver ore extraction, electroplating, fumigant, stainless steel manufacture, petroleum refining, rodenticide; plant sources include amygdalin glycodes (such as peach pits), cassava, linium, prunus, sorghum, and bamboo sprouts; also a byproduct of nitroprusside and succinonitrile along with laetrile

Mechanism of Toxic Action Forms a stable complex with ferric ion of cytochrome oxidase enzymes inhibiting cellular respiration (at cytochrome aa₃); then converted to thiocyanate (less toxic form) by rhodanase enzyme. Cyanide can also cause lipid peroxidation in the brain due to inhibition of antioxidant enzymes.

Adverse Reactions

Cardiovascular: Myocardial depression, hypotension, sinus bradycardia, angina, chest pain, congestive heart failure, sinus tachycardia, vasodilation

Central nervous system: CNS stimulation followed by CNS depression, extrapyramidal reactions, bilateral putaminal involvement

Endocrine & metabolic: Goiter, hypothyroidism

Gastrointestinal: Bitter almond, burning taste

Neuromuscular & skeletal: Rhabdomyolysis

Ocular: Blurred vision

Respiratory: Respiratory depression

Signs and Symptoms of Overdose Agitation, apnea, bitter almond breath, coma, cyanosis, dizziness, flushing, headache, hyperventilation, hypothermia, hypotension, metabolic acidosis, mydriasis, myoglobinuria, nausea, nystagmus, pruritus, pulmonary edema, ototoxicity, seizures, skin irritation, tachycardia followed by bradycardia, tachypnea, tinnitus, vomiting

Admission Criteria/Prognosis All symptomatic patients should probably be admitted to an intensive care unit for 1-2 days; asymptomatic patients should be observed for at least 2 hours and then can be discharged; survival after 4 hours (in an acute exposure) is usually associated with recovery

Toxicodynamics/Kinetics

Absorption: By inhalation (58% to 77%), oral (~50%), dermally, and ocular

Distribution: V_d: 0.4 L/kg

Metabolism: Hepatic by rhodanase or 3-mercaptopyruvate to thiocyanate; also combines with hydroxocobalamin to form cyanocobalamin (vitamin B₁₂)

Half-life: 0.7-2.1 hours

Elimination: Excreted through the lungs and the kidneys

Reference Range

Whole blood levels: Smoker: ≤0.5 mg/L

Flushing and tachycardia seen at 0.5-1.0 mg/L; obtundation at 1.0-2.5 mg/L

Coma and death occur at >2.5 mg/L

Plasma cyanide: Normal: 4-5 mcg/L; Asymptomatic (with metabolic acidosis): 80 mcg/L; Death: >260 mcg/L

Red blood cell cyanide: Normal: <26 mcg/L; Metabolic acidosis: 1040 mcg/L; Symptomatic: 5200 mcg/L; Fatal: >10,400 mcg/L

Note: A plasma lactate concentration >8 mM/L is 94% sensitive and 70% specific for a blood cyanide level >1 mg/L (40 μmol/L).

Mean urine cyanide level of 37 mg/L (range 0.4-230 mg/L) associated with fatal poisoning

Overdosage/Treatment

Decontamination: Basic poison management (lavage within 1 hour/activated charcoal). Emesis is contraindicated due to the rapid course of neurologic symptoms. Give 100% oxygen.

Supportive therapy: Give sodium bicarbonate for acidosis. Cyanide antidote kit (amyl nitrite, sodium nitrite followed by sodium thiosulfate) was the primary therapeutic modality. Hydroxocobalamin (5 grams IV., repeat as necessary in adults) is the current therapy. Methemoglobin

formation due to nitrites occurs with a target methemoglobin level of ~20%, although clinical responses do occur at levels of 5%.

Enhancement of elimination: Hemodialysis and charcoal hemoperfusion have been utilized. Hyperbaric oxygen may also be utilized, although its efficacy is uncertain.

Antidote(s)

- Amyl Nitrite [ANTIDOTE]
- Cyanide Antidote Kit [ANTIDOTE]
- Hydroxocobalamin [ANTIDOTE]
- Oxygen (Hyperbaric) [ANTIDOTE]
- Sodium Nitrite [ANTIDOTE]
- Sodium Thiosulfate [ANTIDOTE]

Diagnostic Procedures

- Anion Gap, Blood
- Cyanide, Blood
- Electrolytes, Blood
- Methemoglobin, Blood
- Thiocyanate, Blood or Urine

Additional Information

Fatal dose of cyanide: 200-300 mg (adult)

Fatal dose (hydrogen cyanide): **Dermal:** 100 mg/kg. **Inhalation** for < 1 hour: 110-135 ppm. **Oral:** 0.6-1.5 mg/kg

Toxic inhalation concentration of cyanide is 10 ppm.

Bitter almond odor, zinc cyanide is odorless. Up to 60% of the population may be unable to smell cyanide. Parkinsonism has been noted after ingestion of sodium or potassium cyanide. Hydroxocobalamin and dicobalt-EDTA are used for chelation in Europe.

The ratio of red blood cell to plasma cyanide concentrations is 60:1.

Residence time in atmosphere of hydrogen cyanide: 2 years. In natural rivers half-life of cyanide is 10-24 days.

Daily intake of hydrogen cyanide by inhalation: ~3.8 mcg; through drinking water: 0.4-0.7 mcg. Allowable daily intake: ~0.6 mg

Fruit juice typically contains from 1.9-5.3 mg/L of hydrogen cyanide while apricot pits contain 89-2,170 mg/kg (wet weight). Inhaled smoke from cigarettes contains from 10-400 mcg/cigarette, while sidestream smoke usually runs <27% of mainstream smoke concentrations. Average cyanide emission rate in automobiles varies from 11-14 mg/mile in cars; catalytic converters can reduce cyanide emissions by 90%.

Dermal exposure of 10% sodium cyanide to a large body surface area will cause symptoms within 20 minutes

A 5 g dose of hydroxocobalamin appears to bind all cyanide ions in patients with initial cyanide levels up to 40 µmol/L

Plasma lactate (half-life ~4 hours in treated cyanide poisoning) may be useful in determining treatment efficacy in cyanide poisoning
ACGIH-TLW-TWA: 5 mg/m³; IDLH: 50 mg/m³; PEL-TWA: 5 mg/m³

Cyclohexyl Nitrite

Related Information

- Nitrites

U.S. Brand Names D and E®

Use Principle abuse potential in male homosexuals used to facilitate anal intercourse

Mechanism of Toxic Action Vasodilation/smooth muscle relaxation

Signs and Symptoms of Overdose Toxicity in rodents noted primarily anemia and leukopenia at doses of 100 ppm; hypotonia and methemoglobinemia are possible.

Overdosage/Treatment

Decontamination: Basic poison management; methylene blue for symptomatic methemoglobinemia

Supportive therapy: Hyperbaric oxygen may be of use, though controlled human data are lacking.

Additional Information Estimated dose of inhalation by abuse: 2200 ± 200 ppm

DDD

Related Information

- DDT

- Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 72-54-8

U.S. Brand Names Dilene®; Rothane®

Synonyms 1,1-Bis(4-Chlorophenyl)-2; 2-Dichloroethane; TDE

Use Primarily as a pesticide; one form (ortho, para DDD) was used as a medicinal agent for the treatment of adrenal gland carcinoma

Mechanism of Toxic Action Organochlorine agent, interferes with sodium, potassium, and calcium ion movement along neuronal membranes; may be related to serotonin deficiency in the brain

Adverse Reactions Not well described in humans, but probably very similar to DDT; nervous system would appear to be target organ

Toxicodynamics/Kinetics

Absorption: Inhalation, oral, and dermal

Metabolism: Hepatic to 1,1-bis(parachlorophenyl) ethane (DDNU)

Elimination: Renal

Overdosage/Treatment

Decontamination: **Oral: Do not** induce emesis. Lavage within 1 hour (with water or mannitol)/activated charcoal is effective. **Do not** use an oil-based cathartic in that absorption may increase. **Dermal:** Wash with soap and water. **Ocular:** Irrigate copiously with saline.

Supportive therapy: Seizures may be treated with a benzodiazepine, phenobarbital, or phenytoin. Avoid catecholamines.

Enhancement of elimination: Multiple dosing of activated charcoal or cholestyramine (4 g every 8 hours) may be effective after recent oral exposure.

Additional Information Metabolite of DDT; degrades slowly by solar radiation in the atmosphere to carbon dioxide and hydrochloric acid

Cyanogenic Plants

Plant	Amount of Hydrogen Cyanide Released	Maximum Amygdalin Content (in the seeds or pits)
Apricot seeds	0.1-4.1 mg/g	8%
Peach seeds	0.4-2.6 mg/g	6%
Apple seeds	0.61 mg/g	
Bitter almond seeds	0.9-4.9 mg/g	5%
Cassava (whole root)	0.4 mg/g	
Cassava (dried root)	2.45 mg/g	
Sorghum whole plant (immature)	2.5 mg/g	
Amygdalin	59.1 mg/g	
Cotoneaster	15-185 ppm	
Plum		2.5%

DDT**Related Information**

- DDD

CAS Number 50-29-3

UN Number 2761

U.S. Brand Names Anofex®; Chlorophenothane®; Detoxan®; Dicophane®; Genitox® Pentachlorin®

Synonyms 4,4' DDT; Dichlorodiphenyltrichloroethane

Use Primarily as an insecticide on cotton, peanut, and soybean crops; not imported into the U.S. since 1972; contaminant of dicofol

Mechanism of Toxic Action Organochlorine agent, interferes with sodium, potassium, and calcium ion movement along neuronal membranes; may be related to serotonin deficiency in the brain; estrogenic action has been described

Adverse Reactions

Cardiovascular: Tachycardia, Raynaud's phenomenon, sinus tachycardia
Central nervous system: Headache, dizziness, seizures can occur at oral doses > 16 mg/kg, anxiety, delirium

Dermatologic: Sclerodermatous changes on hands have been described
Endocrine & metabolic: Hypomagnesemia

Gastrointestinal: Nausea noted at oral doses of 6 mg/kg; vomiting noted at a dose of 10 mg/kg; stomatitis

Hematologic: Aplastic anemia, thrombocytopenia

Hepatic: Liver enzymes (elevated) can occur, centrilobular hepatic necrosis

Neuromuscular & skeletal: Tremors, myoclonus

Ocular: Opsoclonus, optic neuropathy, neuritis (retrobulbar), visual evoked potential abnormalities

Miscellaneous: Diaphoresis, breast cancer

Toxicodynamics/Kinetics

Absorption: Through inhalation, oral, and dermal exposure

Distribution: Concentrated in fat

Metabolism: Hepatic to 2,2-bis(parachlorophenyl) acetic acid (DDA)

Elimination: Urine (feces at high doses)

Reference Range DDT blood levels in asymptomatic individuals not occupationally exposed to DDT was <15 mcg/L (0.04 µmol/L); in those individuals occupationally exposed, average blood DDT level was 57 mcg/L (0.16 µmol/L); average daily intake of 18 mg by occupational exposure results in DDA urine levels of ~1.27 mg/L (3.59 µmol/L)

Overdosage/Treatment

Decontamination: **Oral: Do not** induce emesis. Lavage within 1 hour (with water or mannitol)/activated charcoal is effective. **Do not** use an oil-based cathartic in that absorption may increase. **Dermal:** Wash with soap and water. **Ocular:** Irrigate copiously with saline.

Supportive therapy: Seizures may be treated with a benzodiazepine, phenobarbital, or phenytoin. Avoid catecholamines.

Enhancement of elimination: Multiple dosing of activated charcoal or cholestyramine (4 g every 8 hours) may be effective after recent oral exposure.

Additional Information Carcinogenic in animals (primarily liver)

Atmospheric half-life: 2 days (to carbon dioxide and hydrochloric acid).

Soil half-life: 2-15 years

Estimated dietary intake of DDT in the U.S. (per person): 1970: 240 mcg; 1974: 8 mcg; 1980: 2.4 mcg; 1981: 2.2 mcg

Acceptable daily DDT intake established by WHO: 20 mcg/kg; root and leafy vegetables have highest amount of DDT (0.4-0.6 ppb)

PEL-TWA (skin designation): 1 mg/m³, TLV-TWA: 1 mg/m³

Demeton-S-Methyl

Applies to Meta-Systox

CAS Number 919-86-8

UN Number 3018

Use Pesticide

Mechanism of Toxic Action Irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system. Delayed presentation of toxicity.

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or **hypodynamic** (~7% to 10%) states, tachycardia, hypertension, QT prolongation, sinus bradycardia, sinus tachycardia

Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia, opisthotonos

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Pancreatitis (after ingestion of 1.5 mg/kg), diarrhea

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness (delayed paralysis, delayed paresthesia), rhabdomyolysis

Ocular: Miosis

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure), diaphoresis

Signs and Symptoms of Overdose

Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, dementia, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, nystagmus, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Admission Criteria/Prognosis Any symptomatic patient or an asymptomatic patient following a severe exposure should be admitted probably into an intensive care unit; asymptomatic patients following a moderate exposure can be discharged after 8 hours of observation

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment. Gastric lavage with water, 5% sodium bicarbonate or 2% potassium permanganate can be considered within 1 hour of ingestion. **Do not** use a cathartic with activated charcoal.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.M. or I.V. initially, or ~¹/₂ the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Obidoxime: 4-6 mg/kg of obidoxime repeated every 4-6 hours may be given instead of 2-PAM

Diazepam is effective in reducing muscle fasciculations or treating seizure.

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of organophosphates.

Denatonium Benzoate

CAS Number 3734-33-6; 86398-53-0

U.S. Brand Names Bitrex®; Bitter Safe®

Use An alcohol denaturant (in toilet preparations) which is used as a bittering taste agent in household automotive or industrial compounds; used for nail-biting/thumb-sucking deterrent

DIAZINON

Mechanism of Toxic Action Recognition of bitter taste by oral taste cells may be due to intracellular calcium rise leading to neurotransmitter release

Adverse Reactions

Cardiovascular: Chest pain, angina

Dermatologic: Urticaria, dermal irritation can occur at concentrations >500 ppm

Gastrointestinal: Vomiting

Respiratory: Bronchospasm

Admission Criteria/Prognosis If not symptomatic following 4 hours observation (postexposure), the patient may be discharged

Overdosage/Treatment Decontamination: **Oral:** Essentially no therapy is required when used as a food or industrial additive. If > 1 g is ingested, emesis with ipecac within 30 minutes or lavage (within 1 hour) and activated charcoal can be administered. **Ocular:** Irrigate copiously with saline.

Additional Information Lethal dose: Animals: ~600 mg/kg. Taste threshold: 10 ppb. Bitter taste: 10 ppm (0.001%). Usually found in powder or granular form; in industrial solutions may be found with ethylene glycol (25%) or ethyl alcohol (21.45%)

Specific References

Mullins ME and Zane Horowitz B, "Was It Necessary to Add Bitrex (Denatonium Benzoate) to Automotive Products?" *Vet Hum Toxicol*, 2004, 46(3):150-2.

Diazinon

CAS Number 333-41-5

UN Number 2783

U.S. Brand Names Alfa-Tox®; Bazinon®; Diazol®; Gardentox®; Knox-Out®; Spectracide®

Synonyms O,O-Diethyl O-2-Isopropyl-4-Methyl-6-Pyrimidinyl Thiophosphate

Use Marketed as insecticide granules, dusting agent, or spray liquid with or without petroleum derivative as a solvent

Mechanism of Toxic Action Irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system. High lipid solubility which can result in delayed presentation of toxicity.

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, tachycardia, hypertension, QT prolongation, sinus bradycardia, sinus tachycardia

Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Pancreatitis (after ingestion of 1.5 mg/kg), diarrhea

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia, rhabdomyolysis

Ocular: Miosis

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure), diaphoresis, intermediate syndrome

Signs and Symptoms of Overdose Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, dementia, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, nystagmus, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Admission Criteria/Prognosis Any symptomatic patient or an asymptomatic patient following a severe exposure should be admitted probably into an intensive care unit; asymptomatic patients following a moderate exposure can be discharged after 8 hours of observation

Toxicodynamics/Kinetics

Absorption: Readily through gastrointestinal (~85%), dermal (3% to 4%), or inhalation

Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways

Half-life: 15 hours

Elimination: Metabolites are excreted in urine

Warnings/Precautions Significant dermal absorption may occur across intact skin; risk of aspiration pneumonitis exists following oral exposure to

agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Reference Range

Peak plasma diazinon levels in symptomatic patients (who survived) ranged from 0.1-1.7 mg/L

Mild poisoning: Serum cholinesterase: 20% to 50% of normal

Moderate poisoning: Serum cholinesterase: 10% to 20% of normal

Severe poisoning (respiratory distress and coma): Serum cholinesterase: < 10%

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment. Gastric lavage with water, 5% sodium bicarbonate or 2% potassium permanganate can be considered within 1 hour of ingestion; **do not** use cathartic with activated charcoal.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles.

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses >100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.M. or I.V. initially, or ~¹/₂ the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of organophosphates.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information Oral ingestion of 294 mg/kg of a 10% diazinon formulation associated with fatality; diazinon may prolong the effects of succinylcholine

Red blood cell cholinesterase and serum pseudocholesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected.

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Yellow to brown liquid; vapor pressure: 0.00014 mm Hg at 20°C; thermal breakdown products include nitrogen and sulfur oxides

Water solubility: 40 ppm. Water half-life: 3 days to 7.7 weeks (shorter in acidic conditions)

Mean atmospheric diazinon levels in urban areas: 2.1 ng/m³

ACGIH TLV: 0.1 mg/m³; PEL-TWA: 0.1 mg/m³

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Dibenzoyl Peroxide**CAS Number** 94-36-0**UN Number** 2085; 2086; 2087; 2088; 2089; 2090**Synonyms** Benzoyl Peroxide; Lucidol**Use** In concentrations of 5% to 10% topically for the treatment of acne, ulcers, bed sores, and pyoderma gangrenosum**Mechanism of Toxic Action** Allergen for skin sensitization, enhances platelet aggregation**Adverse Reactions**

- Cardiovascular: Sinus bradycardia
- Dermatologic: Dermal irritation, immunologic contact urticaria
- Gastrointestinal: Irritation of throat
- Hematologic: Can cause platelet aggregation (vitamin E may be of some use in preventing platelet aggregation)
- Ocular: Eye irritation
- Respiratory: Irritation of nose
- Miscellaneous: May be a tumor promoter

Signs and Symptoms of Overdose Conjunctivitis, erythema, skin edema**Toxicodynamics/Kinetics**

- Absorption: Not well absorbed
- Elimination: Metabolized to and excreted as benzoic acid (95%)

Overdosage/Treatment Decontamination: **Oral:** Dilution with 4-8 oz of milk or water. **Inhalation:** Give 100% humidified oxygen. **Dermal:** Irrigate with soap and water.**Additional Information** Odorless gas, flammable and explosive. TLV-TWA: 5 mg/m³; IDLH: 1000 mg/m³; PEL-TWA: 5 mg/m³**Diborane****CAS Number** 19287-45-7**UN Number** 1911**Synonyms** Boroethane; Boron Hydride**Use** Doping agent in semiconductors; strong reducing agent; used in rubber manufacture and rocket fuels**Mechanism of Toxic Action** Pulmonary irritant (upper airway); a colorless gas**Adverse Reactions**

- Cardiovascular: Chest tightness
- Central nervous system: Headache, chills, dizziness, fever
- Gastrointestinal: Nausea
- Neuromuscular & skeletal: Tremor, paresthesia
- Respiratory: Cough, bronchospasm, tachypnea, pneumonitis, pulmonary edema

Overdosage/Treatment Decontamination: **Inhalation:** Administer 100% humidified oxygen.**Additional Information** Hydrolyzes rapidly in water to hydrogen and boric acid; very flammable and may autoignite. Specific gravity: 0.21. Odor threshold (rotten egg): 2-4 ppm. IDLH: 40 ppm; TLV: 0.1 ppm**Dibromochloromethane****Related Information**

- Adipose Tissue Ranges of Toxins
- Bromoform

CAS Number 124-48-1**Synonyms** Chlorodibromomethane**Use** Inadvertently generated during water chlorination process (usually <5 mcg/L; median: 1.2 mcg/L)**Mechanism of Toxic Action** CNS depressant**Adverse Reactions** No human data; hepatitis; hepatotoxic (centrilobular necrosis) in animal models; a central nervous system depressant with little long lasting behavioral effect**Toxicodynamics/Kinetics**

Absorption: Absorbed by inhalation and oral routes

Metabolism: Hepatic oxidation

Elimination: Pulmonary

Overdosage/Treatment

Decontamination (oral overdose): Lavage (within 1 hour)/activated charcoal

Supportive therapy: Although human overdose experience is virtually nonexistent over the past 90 years, respiratory support appears to be a crucial modality. Naloxone may be of some benefit; otherwise, treat as for bromides.

Additional Information Not flammable; a colorless to pale yellow liquid. Mean ambient air chlorodibromomethane urban values: 3.8 ppt. Average daily dose: <1 mcg/kg. PEL-TWA: 0.5 ppm**Dichloronaphthoquinone****Applies to** Disinfectant (Vegetable Seeds); Fungicide (Foliage/Textile); Herbicide (Aquatic)**CAS Number** 117-80-6**U.S. Brand Names** Algistat®; Compound 605®; Phygon®**Synonyms** Dichlone; Quintar; Sanquinon**Use** Vegetable seed disinfectant; foliage/textile fungicide; aquatic herbicide**Adverse Reactions**

- Dermatologic: Dermal irritation
- Gastrointestinal: Nausea, vomiting
- Ocular: Conjunctivitis

Signs and Symptoms of Overdose Coma, vomiting**Toxicodynamics/Kinetics** Absorption: Poor from the GI tract**Overdosage/Treatment**

Decontamination: Lavage (within 1 hour)/charcoal. Irrigate skin with soap and water. Irrigate eyes with saline with a Morgan lens.

Supportive therapy: Endoscopy for oral ingestion to evaluate gastrointestinal mucosal injury

Additional Information Heating dichloronaphthoquinone can emit chlorine fumes.**Dichlorphenamide****Pronunciation** (dye klor FEN a mide)**CAS Number** 120-97-8**U.S. Brand Names** Daranide®**Synonyms** Diclofenamide**Use** Adjunct in treatment of open-angle glaucoma and perioperative treatment for angle-closure glaucoma; also has been used to treat muscle weakness in patients with hypokalemic periodic paralysis resistant to acetazolamide**Mechanism of Action** A nonbacteriostatic sulfonamide that inhibits carbonic anhydrase resulting in renal excretion of sodium potassium, bicarbonate, and water**Adverse Reactions**

- Central nervous system: **Tiredness, malaise**, CNS depression, disorientation, drowsiness, fever, **fatigue**, depression
- Dermatologic: Rash, urticaria, erythema multiforme, toxic epidermal necrolysis
- Endocrine & metabolic: Hyperchloremic metabolic acidosis, hypokalemia, elevated blood glucose
- Gastrointestinal: **Diarrhea, anorexia, metallic taste**, GI irritation, xerostomia, black stools
- Genitourinary: Dysuria, **increased urination**
- Hematologic: Blood dyscrasias, bone marrow suppression
- Neuromuscular & skeletal: Paresthesias
- Ocular: Myopia
- Renal: Renal calculi, polyuria

Toxicodynamics/Kinetics

- Onset of action: 0.1-5 hours
- Peak effect: 2-4 hours
- Duration: 6-12 hours
- Distribution: Wide volume of distribution

Dosage

Oral:

Adults: 100-200 mg to start followed by 100 mg every 12 hours until desired response is obtained; maintenance dose: 25-50 mg 1-3 times/day
Hypokalemic periodic paralysis: 50 mg 2 times daily for 1 week then 50 mg 3 times/day**Contraindications** Hypersensitivity to dichlorphenamide or any component of the formulation; severe pulmonary obstruction; severe renal impairment**Warnings** Chemical similarities are present among sulfonamides, sulfonureas, carbonic anhydrase inhibitors, thiazides, and loop diuretics

DICHLORVOS

(except ethacrynic acid). In patients with allergy to one of these compounds, a risk of cross-reaction exists; avoid use when previous reaction has been severe.

Dosage Forms Tablet: 50 mg

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal
Enhancement of elimination: Hemodialysis may remove as much as 30% of dose if performed prior to significant distribution

Test Interactions ↑ chloride (S); ↓ potassium; false-positive urinary protein

Drug Interactions Increased lithium excretion and altered excretion of other drugs by alkalization of the urine

Pregnancy Risk Factor C

Nursing Implications May cause drowsiness, institute safety measures

Additional Information More potent than acetazolamide

Dichlorvos

Applies to SD 1750

CAS Number 11095-17-3; 11096-21-2; 116788-91-1; 12772-40-6; 55819-32-4; 62-73-7; 62139-95-1; 95828-55-0

UN Number 2783

U.S. Brand Names Astrobot®; Atgard®; Canogard®; Duo-Kill®

Synonyms DDVP

Use Organophosphate insecticide (which is a breakdown product of trichlorfon); usually used to control insects in warehouses (tobacco, mushroom, animal shelters) and also is an active ingredient in flea collars for dogs and cats

Mechanism of Toxic Action Irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states; edema, QT prolongation

Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia, polyneuropathy, Horner's syndrome

Respiratory: Respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose

Abdominal pain, agitation, asthose, bronchorrhea, AV block, bradycardia, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24-96 hours postorganophosphate exposure, and is independent of the acute cholinergic crisis; late paresthesia characterized by stocking and glove paresthesia, anesthesia, and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates; symptoms may be delayed for 3 hours

Admission Criteria/Prognosis Any symptomatic patient or an asymptomatic patient following a severe exposure should be admitted probably into an intensive care unit; asymptomatic patients following a moderate exposure can be discharged after 8 hours of observation

Toxicodynamics/Kinetics

Absorption: Rapid

Half-life: 8-20 minutes

Elimination: 27% eliminated as CO₂ in lungs; 9% in urine

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment. Gastric lavage with water, 5% sodium bicarbonate or 2% potassium permanganate can be considered within 1 hour of ingestion. **Do not** use a cathartic with activated charcoal.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure. Asoxime chloride or HI-6 (an experimental oxime) has been used effectively in reactivating red blood cell cholinesterase (at a dose of 500 mg dissolved in 3 mL of distilled water, I.M. 4 times/day for 2-7 days) in 60 patients with dichlorvos poisoning. Therapeutic serum level of HI-6: ~4 mcg/mL; it may act synergistically when given with atropine; total dosage of HI-6 ranged from 4-14 g; no adverse symptoms were noted.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses >100 mg) may be necessary in massive exposures

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.M. or I.V. initially, or ~1/2 the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of organophosphates.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Additional Information

Toxic dose: 300 mg/kg. Lethal oral dose: 400 mg/kg

Red blood cell cholinesterase, and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected.

Threshold dose that would produce reduction of plasma cholinesterase (but not red blood cell cholinesterase) is ~0.03 mg/kg/day by inhalation (0.006 mg/kg/day in patients with liver disease) and 0.02 mg/kg/day by oral ingestion

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Emits a sulfur (garlic) odor at airborne concentrations >1 ppb.

The intermediate syndrome is not related to delayed neuropathy.

Colorless to amber liquid; does not bioaccumulate in the human body

Estimated atmospheric half-life: 2-320 days. Soil half-life: 10-17 days.

Specific gravity: 1.415

TLV-TWA: 0.9 mg/m³ (skin)

Malathion may potentiate the toxicity of dichlorvos.

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Dicrotophos

CAS Number 141-66-2

U.S. Brand Names Bidrin®; Ektofos®

Synonyms Dimethyl *cis*-2-Dimethylcarbamoyl-1-Methylvinyl Phosphate

Use Marketed as insecticide granules, dusting agent, or spray liquid with or without petroleum derivative as a solvent

Mechanism of Toxic Action Potent, irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, QT prolongation, sinus bradycardia, sinus tachycardia

Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, fecal and urinary incontinence, excessive sweating, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, respiratory depression, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure, and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia, and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure

Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways

Elimination: Metabolites are excreted in urine

Warnings/Precautions Significant absorption through intact skin may occur; risk of aspiration pneumonitis exists with agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. **Do not** give a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach may be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed treatment and large volumes of distribution of organophosphates.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses >100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.M. or I.V. initially, or $\sim 1/2$ the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information Brown liquid with mild ester odor; red blood cell cholinesterase, and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected.

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

ACGIH TLV: 0.25 mg/m³; PEL-TWA: 0.25 mg/m³

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Dieldrin

Related Information

- Adipose Tissue Ranges of Toxins
- Aldrin

CAS Number 60-57-1

U.S. Brand Names Alvit®; Dieldrix®; Octalox®; Quintox®; Red Shield®

Synonyms HEOD

Use Termiticide; banned by EPA in 1970s

Mechanism of Toxic Action Organochlorine agent which may be a competitive inhibitor of the inhibitory neurotransmitter GABA at the GABA A receptor

Adverse Reactions

Cardiovascular: Tachycardia, hypertension, sinus tachycardia

Central nervous system: Convulsions, headache, dizziness, seizures

Dermatologic: Contact dermatitis

Gastrointestinal: Nausea, vomiting, anorexia

Hematologic: Hemolysis

Hepatic: Elevated liver enzymes

Neuromuscular & skeletal: Muscle twitching

Ocular: Nystagmus, optic neuropathy, scotoma, visual evoked potential abnormalities

Miscellaneous: May increase serum cholesterol levels

Toxicodynamics/Kinetics

Absorption: Absorbed by oral and dermal routes

Distribution: V_d: 13-69 L/kg

Metabolism: By epoxide hydrolase to 6,7-trans-dihydroxydieldrin glucuronide; aldrin dicarboxylic acid; also metabolized to pentachloro-eketone (Klein's metabolite) and 9-hydroxydieldrin glucuronide

Half-life: 2-12 months

Elimination: Feces

Overdosage/Treatment

Decontamination: **Oral:** Activated charcoal. **Dermal:** Soap and water wash. **Ocular:** Irrigate with saline.

Supportive therapy: Beta-adrenergic blocking agents may be used for tachycardia or hypertension. Benzodiazepines, phenobarbital, or phenytoin can be used for seizures.

Enhancement of elimination: Multiple dosing of activated charcoal may be effective.

Additional Information Lethal dose: Oral: 71 mg/kg. Highest dietary intake is from garden fruits (0.0021 mcg/day), fish, poultry, and meat (0.0012 mcg/day). Odor threshold: 0.047 mg/kg. Estimated atmospheric lifetime: 1 day

Diethyl Phthalate

Related Information

- Adipose Tissue Ranges of Toxins

CAS Number 84-66-2

U.S. Brand Names Anozol®; Neantine®; Palatinol® A; Phthalol®; Placidol® E; Solvanol®

Synonyms DEP; Ethyl Phthalate

Use Plasticizer (photographic applications, toothbrushes, toys, tool handles) and in cosmetics (nail polish, hair spray, perfume, bath products)

Mechanism of Toxic Action Irritant

Adverse Reactions Dermatologic: Dermal irritant, allergic contact dermatitis

Toxicodynamics/Kinetics Absorption: Slightly through intact human skin

Overdosage/Treatment Decontamination: **Dermal:** Wash with soap and water. **Ocular:** Irrigate copiously with water.

Diethylene Glycol

CAS Number 111-46-6

Synonyms Diglycol; Ethylene Diglycol; Glycol Ether

Commonly Found In Industrial solvents and antifreeze; softening agent in cellophane; in silver sulfadiazine; A Plasticizer

Mechanism of Toxic Action Central nervous system depression and nephrotoxicity with intravascular hemolysis, mechanism unknown

Adverse Reactions

Hepatic: Hepatotoxicity

Renal: Renal tubular necrosis (acute); renal failure due to bilateral cortical necrosis (onset 2 to 6 days)

Signs and Symptoms of Overdose Coma and pulmonary edema can develop; metabolic acidosis is less common than with ethylene glycol; diarrhea, drowsiness, feces discoloration (black), hepatotoxicity, jaundice, leukocytosis, porphyria, tachypnea; Onset may be delayed for 1-2 days

Toxicodynamics/Kinetics

Absorption: Small amount may be absorbed dermally; not absorbed by inhalation

Metabolism: Oxidized by alcohol dehydrogenase and aldehyde dehydrogenase to 2-hydroxyethoxy-acetaldehyde and then to 2-hydroxy-ethoxyacetic acid (2-HEAA)

Half-life: 3 hours

Elimination: 70% excreted unchanged; major metabolite is (2-hydroxyethoxy) acetic acid

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage (within 2 hours/activated charcoal)

Supportive therapy: Ethanol therapy may be theoretically useful to block conversion to toxic metabolites, but there is no human experience. Treat acidosis with I.V. sodium bicarbonate (1-2 mEq/kg). 4-Methylpyrazole (10 mg/kg body weight, I.V.) over a 1-hour period and repeated in 2 hours has been helpful in one case.

Enhancement of elimination: Hemodialysis for severe metabolic disturbance or renal failure

Antidote(s)

- Sodium Bicarbonate [ANTIDOTE]

Diagnostic Procedures

- Osmolality, Serum

Additional Information Diethylene glycol is colorless and odorless but has a sweet taste; more toxic than ethylene glycol. A radiopaque compound with rapid absorption. Can cause centrilobular necrosis of the liver. Average amount of diethylene glycol in PEG: 4.3 mcg/mL; average amount consumed in a patient is ~11 mg.

Diethylene Glycol Monobutyl Ether

CAS Number 112-34-5

Synonyms Butoxyethoxy Ethanol; Butyl Carbitol; Butyl Digol; Butyl Diicinel

Use Low foaming cleaning agent; solvent for cellulose nitrate; oil, dye, rubber, soap, and printing industry

Mechanism of Toxic Action A monoalkyl ether of diethylene glycol can cause mild mucosal irritation with some nephrotoxic potential

Signs and Symptoms of Overdose Conjunctivitis, cyanosis, dermal erythema on contact, increased intraocular pressure, renal failure, tachypnea, uremia

Admission Criteria/Prognosis Admit any symptomatic patient or any ingestion >2 mL/kg

Toxicodynamics/Kinetics Absorption: Some dermal absorption can occur (0.035 mg/cm²/hour)

Monitoring Parameters Renal function: Arterial blood gas

Overdosage/Treatment

Decontamination: **Oral:** Emesis within 30 minutes or lavage with ingestions >2 mL/kg within 2 hours of ingestion; activated charcoal may be effective. **Dermal:** Wash with soap and water. **Inhalation:** Give 100% humidified oxygen. **Ocular:** Irrigate copiously with saline.

Supportive therapy: Ethanol treatment should **not** be utilized.

Additional Information Rise in intraocular pressure is usually transient in animal studies (lasting <1 hour). Ocular toxicity is probably dose related with the threshold for production of keratitis and conjunctivitis at 25% and 10% concentration, respectively. A colorless, odorless liquid with a specific gravity of 0.95; miscible in water and oils; flammable. IDLH: 700 ppm; OSHA: PEL: 1 ppm

Diisopropylmethylphosphonate

CAS Number 1445-75-6

Synonyms DIMP

Use A byproduct (2% to 3%) in the manufacture process of the nerve gas sarin (GB); used in the military as a stimulant in chemical warfare training

Mechanism of Toxic Action Essentially unknown; while this agent is an organophosphate compound, acetylcholinesterase inhibition is minimal; central nervous system toxicity is major effect in animal studies

Adverse Reactions

No human data available

Central nervous system: Ataxia noted in animal studies

Ocular: Eye irritation

Toxicodynamics/Kinetics

Absorption: Orally and somewhat dermally (7% in animal studies)

Metabolism: Hydrolysis to isopropyl methylphosphonic acid and methylphosphonic acid (does not accumulate in the body)

Elimination: Renal

Overdosage/Treatment

Decontamination: **Oral:** Lavage/activated charcoal. **Dermal:** Remove contaminated clothing, wash skin with soap and water. **Ocular:** Irrigate eyes with saline.

Supportive therapy: It is unclear whether treatment with atropine/pralidoxime would be helpful.

Enhanced elimination: Hemoperfusion with a grafted butyl-XAD-4 sorbent may be most efficacious.

Additional Information Colorless liquid with a boiling point of 174°C; density: 0.976 g/mL. Slightly soluble in water; negligible human exposure due to vaporization from surface water; degrades slowly in the environment. Was manufactured as a byproduct of sarin at the Rocky Mountain Arsenal (RMA) near Denver, Colorado from 1953-1957.

Dimethyl Phthalate

Related Information

- Di-n-Butyl Phthalate

CAS Number 131-11-3

Synonyms Avolin

Use Insect repellent

Mechanism of Toxic Action Mucosal irritant

Adverse Reactions

Ocular: Eye pain

Respiratory: Oropharyngeal burning

Overdosage/Treatment Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal. **Dermal:** Wash exposed area with soap and water. **Ocular:** Irrigate with water or saline. **Inhalation:** Administer 100% humidified oxygen.

Additional Information Oral LD₅₀ in rats: 2400 mg/kg. Dibutylphthalate is more resistant to laundering removal in fabrics than dimethyl phthalate.

Dimethylnitrosamine

CAS Number 62-75-9

Synonyms DMN; DMNA; NDMA; Nitrous Dimethylamine

Use Formerly used as a solvent in the production of rubbers, plastics, rocket fuels and lubricants, this agent may be found as an environmental pollutant and in nitrate-cured meats

Mechanism of Toxic Action As a potent methylating agent; this compound is hepatotoxic and liver or renal carcinogen (in animals)

Adverse Reactions

Cardiovascular: Cerebral edema

Central nervous system: Fever (oral exposure), seizures, headache, malaise

Gastrointestinal: Prolonged vomiting (for up to 2 days), GI hemorrhage

Hematologic: Coagulopathy, thrombocytopenia

Hepatic: Icterus, hepatomegaly, hepatic necrosis, centrilobular necrosis, ascites, hepatic fibrosis

Ocular: Photophobia, conjunctivitis, uveitis

Respiratory: Pulmonary edema, pulmonary hemorrhage

Admission Criteria/Prognosis Admit any ingestion > 10 mg/kg or any symptomatic patient

Toxicodynamics/Kinetics

Absorption: Oral, dermal and inhalation

Metabolism: Hepatic to metabolites which may be carcinogenic (methyl carbonium ion)

Monitoring Parameters PT, PTT, liver function tests, CBC, chest x-ray

Overdosage/Treatment

Decontamination: **Oral:Do not** induce emesis. Lavage (within 1 hour)/activated charcoal. **Dermal:** Remove clothing, wash skin with soap and water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate copiously with water or saline.

Supportive therapy: Benzodiazepines can be initially used for seizures. Phenytoin or phenobarbital can be used for refractory seizures.

Additional Information Potential lethal oral dose: Child: 30 mg/kg; Adult: 1.8 g. A yellow, oily liquid; pretreatment with ethanol may increase hepatotoxicity.

Di-n-Butyl Phthalate

Related Information

- Dimethyl Phthalate

Applies to Caswell No 292; Glow-in-the-Dark Products; Insect Repellent; Plasticizer; Solvent

CAS Number 84-74-2

UN Number 9095

U.S. Brand Names Staflex® DBP; Uniflex® DBP

Synonyms Butylphthalate; DBP; Dibutyl Ester; Dibutyl Phthalate

Use Plasticizer for polyvinyl chloride; insect repellent, also used as a solvent for perfume oils; concrete additive; in plastisol formulations for carpets; a solvent for nail polish; found in glow-in-the-dark wands and necklaces

Mechanism of Toxic Action Uncouples oxidative phosphorylation

Adverse Reactions

Cardiovascular: Hypertension

Central nervous system: Dizziness, coma, polyneuritis

Dermatologic: Allergic dermatitis

Gastrointestinal: Nausea

Ocular: Keratitis, photophobia, lacrimation

Renal: Nephritis

Signs and Symptoms of Overdose Asthenia, dizziness (after a 10 g ingestion), lacrimation, ocular irritation, photophobia, spasms

Admission Criteria/Prognosis Admit any symptomatic patient

Toxicodynamics/Kinetics

Absorption: Inhalation: Well absorbed. Dermal: Absorbed slowly through intact skin (0.07 mcg/cm²/hour)

Metabolism: Hepatic hydrolysis to phthalic acid and butanol

Overdosage/Treatment Decontamination: **Oral:** Dilute with water; lavage (within 1 hour)/activated charcoal. **Dermal:** Wash exposed area with soap and water. **Inhalation:** Administer 100% oxygen. **Ocular:** Irrigate with water or saline.

Additional Information Seasonal peak exposure for glow compound is July. Bitter taste. Specific gravity: 1.05. TLV-TWA: 5 mg/m³; IDLH: 9,300 mg/m³

Dinitroresol

CAS Number 497-56-3; 534-52-1; 609-93-8; 616-73-9

UN Number 1598

U.S. Brand Names Antinonin®; Detal®; Dinitrol®; Ditrosol®; Elgetol®; Selinon®; Sinox®; Victoria Orange®

Synonyms DNC; DNOC; DNPC

Use Contact herbicide (for broad leaf weeds); insecticide useful against locusts; fungicide; unapproved for weight reduction earlier this century

Mechanism of Toxic Action Uncouples oxidative phosphorylation

Adverse Reactions

Cardiovascular: Tachycardia, sinus tachycardia

Central nervous system: Lethargy, seizures, headaches, hyperthermia

Dermatologic: Yellow stains on skin, rash, mild dermal irritant, fingernail discoloration (yellow)

Gastrointestinal: Nausea

Neuromuscular & skeletal: Acrodynia

Ocular: Cataracts

Respiratory: Tachypnea, dyspnea

Miscellaneous: Diaphoresis

Toxicodynamics/Kinetics

Absorption: Inhalation, oral (40%), and by dermal routes

Metabolism: Hepatic

Half-life: 5-6 days

Reference Range Serum dinitroresol (ortho) level of 1000 mcg/mL associated with fatality; toxic blood levels if exposed to > 30 ppm

Overdosage/Treatment

Decontamination: **Oral:Do not** induce emesis; lavage (within 1 hour)/activated charcoal. Castor oil (nonpurgative dose) may reduce absorption by almost 50%. **Dermal:** Wash with soap and water. **Ocular:** Irrigate with copious amounts of saline.

Supportive therapy: Benzodiazepine for seizure control; chlorpromazine (high doses), salicylates, barbiturates, or anticholinergic agents can potentiate toxicity of dinitroresol. Reduce body temperature by means of sponge baths or lavage with cold solutions. Haloperidol use (in competing with binding sites) is experimental. Ten mL of a 2.5% solution (I.V.) of sodium methyl thiouracil has been claimed to reduce the metabolic rate induced by dinitroresol, although this is unproven. Enhancement of elimination: Dialysis or forced diuresis is not helpful.

Additional Information Toxic oral dose: > 0.75 mg/kg/day. After death, rigor mortis develops rapidly.

Dinitrophenols

CAS Number 25550-58-7; 329-71-5; 51-28-5; 573-56-8; 577-71-9; 586-11-8; 66-56-8

UN Number 1320; 1599

Use In synthesis of dyes and organic chemicals; pesticide, herbicide, fungicide, and acaricide; pH reagent; potassium and ammonium ion detection; wood preservative; World War I explosive agent; had been used against lice; also used in weight control (100 mg 3 times/day) in the 1930s

Mechanism of Toxic Action Uncouples oxidative phosphorylation

Adverse Reactions

Cardiovascular: Tachycardia, shock

Central nervous system: Lethargy, seizures, headache, fever, hyperthermia, coma, sedation

Dermatologic: Yellow stains on skin, rash, mild dermal irritant

Endocrine & metabolic: Acidosis

Gastrointestinal: Nausea, vomiting, feces discoloration (yellow), hypogeusia, salt hypogeusia

Hematologic: Neutropenia, hemolytic anemia, methemoglobinemia (by 2,4 dinitrophenol only), agranulocytosis, aplastic anemia

Hepatic: Hepatic injury, jaundice

Neuromuscular & skeletal: Peripheral neuritis, neuropathy (peripheral)

Ocular: Cataracts, increased intraocular pressure, nystagmus, blurred vision

Renal: Oliguria, renal failure

Respiratory: Tachypnea, dyspnea, hyperventilation

Miscellaneous: Diaphoresis

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels > 30% should be admitted; asymptomatic patients with methemoglobin levels < 30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to < 15% or oral dose over 3 mg/kg

Toxicodynamics/Kinetics

Absorption: Dermal and oral routes

Metabolism: Hepatic to aminonitrophenols

Half-life: 5-14 days

Elimination: Hepatic

Reference Range

Blood dinitrophenol level > 10 mcg/mL associated with toxicity; blood dinitrophenol levels > 28 mcg/mL associated with fatality

Postmortem Blood Dinitrophenol level of 48 mg/L associated with fatality.

Toxicity associated with serum and urine DNP levels of 11 and 37 mg/L, respectively

Overdosage/Treatment

Decontamination: **Oral:Do not** induce emesis; lavage (within 1 hour)/activated charcoal. Castor oil (nonpurgative dose) may reduce absorption by almost 50%. **Dermal:** Wash with soap and water. **Ocular:** Irrigate with copious amounts of saline.

Supportive therapy: Benzodiazepine for seizure control. Chlorpromazine (high doses), salicylates, barbiturates, or anticholinergic agents can potentiate the toxicity of dinitroresol. Reduce body temperature by means of sponge baths, ice packs, or lavage with cold solutions. Haloperidol use (in competing with binding sites) is experimental. Ten mL of a 2.5% solution (intravenous) of sodium methyl thiouracil has been claimed to reduce the metabolic rate induced by dinitroresol, although this is unproven. Methemoglobinemia can be treated with methylene blue. Dantrolene can be used to treat hyperthermia.

Enhancement of elimination: Dialysis or forced diuresis is not helpful.

Additional Information Toxic oral dose: 3-5 mg/kg. Atmospheric half-life: Probably exceeds 1 month; does not accumulate in the body; fatal dose: 1 g

DI-N-OCTYLPHTHALATE

Politi L, Vignali C and Poletini A, "LC-MS-MS Analysis of 2,4-Dinitrophenol and Its Phase I and II Metabolites in a Case of Fatal Poisoning," *J Anal Toxicol*, 2007, 31:55-61.

Di-n-Octylphthalate

CAS Number 117-84-0

U.S. Brand Names Cellulflux DOP®; Dinopol NOP®; Polycizer 162®; PX-138®; Vinicizer 85®

Synonyms DNOP; DOP; Phthalic Acid, Dioctyl Ester

Use Colorless, odorless chemical primarily used as a plasticizer in plastics and PVC resin production; active ingredient in pesticides and can be found in electrical capacitor fluid and plastisols for carpetback coating

Mechanism of Toxic Action Hepatotoxin which causes centrilobular necrosis and accumulation of fat; loss of glycogen has also been noted

Adverse Reactions No human health effects noted, while this agent is a skin and eye irritant, the liver appears to be the target organ of toxicity with centrilobular fat accumulation and glycogen loss; can also serve as a promoter that results in hepatic adenomas and carcinomas

Toxicodynamics/Kinetics

Absorption: Primarily oral; not significantly absorbed by dermal or inhalation route

Metabolism: Hepatic hydrolysis to mono-n-octylphthalate beta oxidation then occurs to form phthalate monoesters

Half-life: 20 minutes (I.V. administration)

Elimination: Renal

Monitoring Parameters Liver function tests, glucose

Overdosage/Treatment Decontamination: **Oral:** Dilute with milk or water; activated charcoal can be utilized. **Dermal:** Wash with soap and water. **Ocular:** Copious irrigation with saline

Additional Information Lethal oral dose: ~0.5-15 g/kg. Levels of di-n-octylphthalate in drinking water: <0.5 ppb. Atmospheric half-life: 4.5-4.8 hours. TLV-TWA: 5 mg/m³

Dioxathion

CAS Number 78-34-2

U.S. Brand Names Delnatex®; Delnav®; Deltic®

Use Marketed as insecticide granules, dusting agent, or spray liquid with or without petroleum derivative as a solvent

Mechanism of Toxic Action Irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, QT prolongation, sinus bradycardia, sinus tachycardia
Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhoea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure, and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia, and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure

Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways

Elimination: Metabolites are excreted in urine

Warnings/Precautions Risk of aspiration pneumonitis exists with agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles.

Do not give a cathartic

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline.

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure
Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed treatment and large volumes of distribution of organophosphates.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses >100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or ~1/2 the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information

Poorly volatile amber liquid; thermal degradation products include sulfur oxides; red blood cell cholinesterase, and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected. The intermediate syndrome is not related to delayed neuropathy. QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

ACGIH TLV: 0.2 mg/m³; PEL-TWA: 0.2 mg/m³

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Diquat Dibromide

Related Information

- Paraquat

Applies to

Herbicide

CAS Number 2764-72-9; 85-00-7

Commonly Found In Ethylene bipyridylum

Mechanism of Toxic Action Similar to paraquat, diquat is a potent redox cyclor, which through a hydroxyl radical, can cause oxidative stress (through depletion of NADPH) and lipid peroxidation; can result in brainstem (particularly pons) infarction

Adverse Reactions

Dermatologic: Fingernail dystrophy, fingernail discoloration (brown)

Gastrointestinal: Third spacing of gastrointestinal fluid; paralytic ileus

Neuromuscular & skeletal: Rhabdomyolysis

Ocular: Cataract

Renal: Renal failure, proximal tubular degeneration, proteinuria

Respiratory: Pulmonary fibrosis less likely to occur than with paraquat, epistaxis

Signs and Symptoms of Overdose

Coma, dermal burns, fingernail loss, drowsiness (72-96 hours postingestion), hypotension, Mees' lines, paralytic ileus, parkinsonism, seizures
Oliguria/Anuria usually begins within 2-3 days post ingestion with ingestions (oral) exceeding one gram. Renal function improves within 7 to 10 days.

Admission Criteria/Prognosis Patients with known or suspected exposures should be admitted

Overdosage/Treatment

Decontamination: **Oral:** Emesis (within 30 minutes)/lavage (within 1 hour) with activated charcoal: 15%; Fuller's earth; or 7% bentonite (Bentonite/Fuller's earth dosage: Children < 12 years of age: 2 g/kg; Adults: 100-150 g). Sodium polystyrene sulfonate may also be effective. **Dermal:** Flush skin with copious amounts of water.

Supportive therapy: Do not utilize oxygen in that it may promote pulmonary fibrosis, although this is not as likely to occur as in paraquat. Monitor for hypercalcemia if Fuller's earth is used. Morphine sulfate can be used for pain control.

Enhancement of elimination: Multiple dosing of activated charcoal, Fuller's earth (100-150 g in adults or 2 g/kg in children), or bentonite may be given every 2-4 hours. Charcoal hemoperfusion for prolonged periods of time (up to 10 hours) may be helpful if instituted within 4 hours. Forced diuresis is not helpful.

Additional Information

Minimal lethal dose: 20 mL of a 20% solution (6-12 g)

A 60 g diquat ingestion resulting in a diquat serum level of 64 mcg/mL was fatal with marked renal tubular damage on autopsy. Does not produce pulmonary fibrosis. Dithionate test: 1 part urine, 0.5 part sodium dithionate in NaOH: Deep blue color indicates presence of paraquat or diquat

Disulfoton

CAS Number 298-04-4

UN Number 2783

U.S. Brand Names Di-Syston®; Dimax®; Dithiosystox®; Solvirex®

Synonyms Ethylthiodemeton; Thiodemeton

Use Crop systemic organophosphate insecticide and acaricide; useful for mosquito abatement

Mechanism of Toxic Action Highly toxic organophosphate agent which causes irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, tachycardia, hypertension, QT prolongation, sinus bradycardia, sinus tachycardia

Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hyperthermia

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Pancreatitis (after ingestion of 1.5 mg/kg), diarrhea

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia

Ocular: Can cause myopia in children, miosis

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure), diaphoresis

Signs and Symptoms of Overdose Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Toxicodynamics/Kinetics

Absorption: Easily absorbed orally and possibly dermally

Metabolism: To phosphorothiolate sulfone (active metabolite)

Warnings/Precautions Risk of aspiration pneumonitis exists following oral exposure to agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Reference Range Blood disulfoton level of 1.45 nmol/g associated with fatality; peak plasma phosphorodithioate sulfone concentration of 1322 ng/mL 56 hours postingestion resulted in severe toxicity, but survival levels may rebound in first 2-3 days

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to

hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment. Gastric lavage with water, 5% sodium bicarbonate or 2% potassium permanganate can be considered within 1 hour of ingestion. **Do not** use a cathartic with activated charcoal.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. Prolonged or repetitive gastric lavage (with activated charcoal) may be beneficial to prevent rebound of plasma levels due to delayed absorption.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.M. or I.V. initially, or ~1/2 the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of organophosphates. Due to enterohepatic recirculation, multiple dosing of activated charcoal may be effective.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Additional Information Lethal adult dose: 500 mg

Not carcinogenic; cross tolerance with chlorpyrifos noted in rodents

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Diuron

CAS Number 330-54-1

Commonly Found In Dailon®; Diater®; Di-On®; Direx 4L®; Diurex®; Diurof®; Rout®

Mechanism of Toxic Action Inhibitor of plant photosynthesis, a urea substituted herbicide

Signs and Symptoms of Overdose Can cause methemoglobinemia

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Toxicodynamics/Kinetics

Metabolism: To 1-(3,4-dichlorophenyl)-3-methyl urea and to 1-(3,4-dichlorophenyl) urea

Elimination: Urine

Reference Range Maximum tolerated dose: 38 mg/kg

Overdosage/Treatment Supportive therapy: Methylene blue 1-2 mg/kg/dose if methemoglobinemia is noted

Antidote(s)

- Methylene Blue [ANTIDOTE]

Additional Information Available as a 80% powder/40% suspension in water; or can be combined with bramcil or sodium metaborate

Endosulfan

CAS Number 1031-07-8; 115-29-7; 33213-65-9

UN Number 2761

U.S. Brand Names Beosit®; Endocide®; Endosulphan®; Malix®; Thifor®; Thiodan®; Thionex®

Synonyms Hoe-2671

Use Crop pesticide usually applied before harvest on tobacco and fruit trees; used as a wood preservative

Mechanism of Toxic Action No mechanism proven although decrease of brain acetylcholinesterase, serotonin, norepinephrine has been hypothesized; also acts as a GABA antagonist; chlorinated hydrocarbon (sulfurous acid ester)

ENDOTHALL

Adverse Reactions

Cardiovascular: Tachycardia, cyanosis, edema, sinus tachycardia
Central nervous system: Seizures, dizziness, confusion, loss of consciousness, agitation, ataxia
Endocrine & metabolic: Metabolic acidosis, hyperglycemia
Gastrointestinal: Nausea, vomiting, diarrhea
Hematologic: Thrombocytopenia, leukocytosis
Neuromuscular & skeletal: Tremors
Ocular: Miosis
Renal: Tubular necrosis (acute)
Respiratory: Dyspnea, pulmonary edema

Signs and Symptoms of Overdose Rhabdomyolysis, seizures

Toxicodynamics/Kinetics

Absorption: By inhalation, oral (65%) and dermal (25%) routes
Distribution: V_d : Alpha-endosulfan: 43,740 L; beta-endosulfan: 260,600 L
Metabolism: Hepatic to endosulfan lactone, hydroxyether, and ether
Half-life: Alpha-endosulfan: 24 hours; beta-endosulfan: 60 hours
Elimination: Primarily fecal

Reference Range Blood and urine endosulfan sulfate levels following a 260 mg/kg ingestion, resulting in a fatality, were 874 mcg/L and 1 mcg/L, respectively.

Overdosage/Treatment

Decontamination: **Do not** induce emesis. Lavage (within 1 hour)/activated charcoal or cholestyramine; **do not** use an oil-based cathartic. Supportive therapy: Diazepam or phenobarbital for seizure control
Enhancement of elimination: Multiple dosing of activated charcoal or cholestyramine (4 g every 8 hours) may be useful in increasing clearance.

Additional Information Ethanol may enhance toxicity.

Supportive therapy: Diazepam or phenytoin may be used for seizure control. Try to avoid catecholamines as arrhythmias can be induced. Assisted ventilation with succinylcholine (0.5-1 mg/minute for 1 day) for seizure control may be necessary. Atropine can be used to control bronchial secretions.

Enhancement of elimination: Multiple dosing of activated charcoal or cholestyramine (4 g every 8 hours) may be useful in increasing clearance.

Additional Information Fatal oral dose: 12 g (100 mg/kg). Seizurgenic oral dose: 0.25 mg/kg

IDLH: 200 mg/m³

Endrin concentration in foods (contaminated flour) > 150 ppm can cause seizures upon ingestion.

Milk or ethanol can increase toxicity of endrin by enhancing its absorption; onset of seizures is usually within 4 hours postingestion; bioaccumulation does not occur

Epichlorohydrin

CAS Number 106-89-8

UN Number 2023

Synonyms 1-Chloro-2,3-Epoxypropane; Chloromethyloxirane; ECH; Oxirane

Use Used in Epoxy production; also used in insecticide, agricultural chemicals; elastomers and as a solvent in rubber, paper and paint industries. It is a curing agent.

Mechanism of Toxic Action Mucosal irritant at air concentrations > 10 ppm; also is a contact allergen

Adverse Reactions

Cardiovascular: Facial edema
Dermatologic: Dermal burns, blisters
Gastrointestinal: Nausea, vomiting, abdominal pain
Hepatic: Hepatomegaly
Ocular: Eye irritation (at concentrations > 20 ppm), blepharospasm, eyelid or corneal edema
Renal: Renal lesions (at concentrations > 100 ppm)
Respiratory: Rhinorrhea, cough, pneumonitis, possible incidence of lung cancer (increased)

Toxicodynamics/Kinetics Absorption: Inhalation, dermal, or GI routes

Overdosage/Treatment Decontamination: **Dermal:** Wash carefully with soap and water. Dermal reaction may be delayed for several hours. Epichlorohydrin can penetrate leather or rubber, therefore, these clothing items need to be discarded. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate copiously.

Additional Information Causes dose-dependent decrease in sperm motility and decrease male (but not female) fertility in animals; possibly mutagenic. TLV-TWA: 2 ppm; OSHA: PEL-TWA (transitional limit): 5 ppm. Odor threshold (chloroform like): 10 ppm; IDLH: 75 ppm.

Ether

Pronunciation (EE ther)

CAS Number 60-29-7

UN Number 1155

Synonyms Diethyl Ether; Ethyl Oxide

Use Anesthetic/industrial solvent in manufacture of synthetic dyes and plastics

Mechanism of Toxic Action Dermal/mucosal irritant

Signs and Symptoms of Overdose Anorexia, bradycardia, CNS depression, coma, conjunctivitis, cough, dermal ulcers, dizziness, euphoria, headache, hepatotoxicity, hyperglycemia (2.9 mg % per ounce of ether), hypothermia, laryngeal spasm, nephritis, proteinuria, respiratory depression, salivation, seizures, slurred speech, visual/auditory hallucinations, vomiting

Toxicodynamics/Kinetics

Absorption: Well absorbed by inhalation and oral routes; not well absorbed dermally

Metabolism: Primarily to carbon dioxide and acetaldehyde

Elimination: Primary pulmonary (87%)

Dosage Forms Liquid: 4 oz, 8 oz

Reference Range

Analgesic level: Arterial blood ether level of 100-500 mg/L

Anesthetic level: Arterial blood ether level between 500-1500 mg/L

Estimated blood level at 400 ppm: ~18 mg/L

Overdosage/Treatment

Decontamination: **Oral:** Dilute with 4-8 ounces of milk or water. **Dermal:** Wash with soap and water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate with copious amounts of normal saline.

Supportive therapy: Benzodiazepine can be used to treat seizures. Barbiturates or phenytoin/fosphenytoin can be used as a secondary agent.

Additional Information Lethal oral dose: 1 ounce

A colorless, liquid with an aromatic odor; highly flammable. Specific gravity: 0.7. Boiling point: 35°C. TLV-TWA: 400; IDLH: 19,000

Endothall

CAS Number 145-73-3

Commonly Found In Endothall; Aquathol; Hydout; Hydrothol 47; Tri-Endothall; Niagrathal; 3,6-Endoxohexahydrophthalic Acid

Mechanism of Toxic Action Water herbicide (organic acid)

Signs and Symptoms of Overdose Mucous membrane and skin irritation; can cause abdominal pain, acidosis, anuria, disseminated intravascular coagulation, diarrhea, hematemesis, hypotension

Toxicodynamics/Kinetics Absorption: Dermal: Slight

Reference Range Postmortem blood level of 1 mg/dL documented

Overdosage/Treatment

Decontamination: **Oral:** Activated charcoal; dilute with 4-8 oz of milk or water; lavage or emesis is contraindicated. **Dermal:** Flush skin with soap and water. **Ocular:** Flush eyes with water or saline.

Supportive therapy: Avoid adrenergic amines.

Additional Information Minimum lethal dose: 130 mg/kg; 7 g ingestion can be lethal. Emits acrid fumes when heated.

Endrin

Related Information

● Adipose Tissue Ranges of Toxins

CAS Number 53494-70-5; 72-20-8; 7421-93-4

UN Number 2811

U.S. Brand Names Delta-keto® 153; Hexadrin®; Medrin®

Use Chlorinated hydrocarbon pesticide, rodenticide, and avicide used on tobacco, apple trees, cotton, sugar cane, and grain; not used in U.S. since 1986

Mechanism of Toxic Action Interferes with normal flux of sodium and potassium ions over axonal membrane

Adverse Reactions

Cardiovascular: Hypotension, shock
Central nervous system: Seizures, dizziness, hyperthermia
Gastrointestinal: Nausea, vomiting, hypersalivation
Hematologic: Thrombocytopenia
Neuromuscular & skeletal: Tremors
Otic: Temporary deafness
Respiratory: Respiratory depression

Toxicodynamics/Kinetics

Absorption: By inhalation, oral, and dermal (1.5%) routes
Metabolism: Hepatic oxidation and hydroxylation occurs to 12-hydroxyendrin and 12-ketoendrin
Elimination: Urine

Reference Range Blood endrin level of 0.05 mg/L associated with seizures

Overdosage/Treatment

Decontamination: **Do not** induce emesis. Lavage (within 1 hour)/activated charcoal or cholestyramine; **do not** use an oil-based cathartic.

Effect/standards (ether concentration ppm): Range of odor detection: 0.8-1920. Mucosal irritation: 200. Dizziness: 2000. Surgical anesthesia induction: 100,000-150,000. Fatal: > 100,000

Ethion

Applies to Bladan; Ethanox; Nialate; Rodocide

CAS Number 563-12-2

Use An organothiophosphate pesticide used as an acaricide on fruit trees, fiber crops, nut trees, forage crops, and vegetables; also used as a topically applied pesticide agent on livestock

Mechanism of Toxic Action Irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (18% to 21%) or hypodynamic (~7% to 10%) states, tachycardia, hypertension, QT prolongation, sinus bradycardia, sinus tachycardia

Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Diarrhea

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia

Ocular: Can cause myopia in children, miosis

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure), diaphoresis

Signs and Symptoms of Overdose

Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Toxicodynamics/Kinetics

Absorption: Rapid by oral and dermal routes

Metabolism: Desulfurated by hepatic enzymes to active form (ethion monooxon)

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles.

Do not give a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed treatment and large volumes of distribution of organophosphates.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.M. or I.V. initially, or $\sim 1/2$ the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurrent symptoms.

Additional Information Lethal oral dose is ~ 15 mg/kg. Exposure limit (TWA) of skin: 0.4 mg/m³. A white or amber liquid with a sulfur odor. Atmospheric half-life: 40 minutes. Aerobic soil half-life: 69-102 days

Ethyl Acetate

CAS Number 141-78-6

UN Number 1173

Synonyms Acetic Acid; Ethyl Ester; Vinegar Naphtha

Use A solvent utilized in the lacquer industry and in artificial fruit essences

Mechanism of Toxic Action Mild mucosal irritant

Signs and Symptoms of Overdose Conjunctivitis, nose/throat irritation (at concentrations > 400 ppm), eczema

Toxicodynamics/Kinetics

Metabolism: Hydrolysis to acetic acid and ethanol

Half-life: 10 minutes

Overdosage/Treatment Decontamination: **Oral:** Lavage within 1 hour/activated charcoal **Dermal:** Wash skin with water. **Inhalation:** 100% humidified oxygen should be utilized. **Ocular:** Irrigate with copious amounts of water or saline for at least 15 minutes.

Additional Information IDLH: 10,000 ppm; TLV-TWA: 400 ppm; Odor threshold: 1 ppm (ether-like)

Ethyl Mercaptan

CAS Number 75-08-1

UN Number 2363

Synonyms Ethyl Sulfhydrate; Ethyl Thioalcohol

Use A product of vinous fermentation and petroleum products, it is used as an odorant for natural gas; also used in production of fungicides, plastics, and insecticides

Mechanism of Toxic Action Mucosal irritant which can cause CNS depression; may inhibit mitochondrial electron transport

Adverse Reactions

Central nervous system: Fatigue, lethargy, coma

Gastrointestinal: Oropharyngeal irritation, nausea

Respiratory: Nasal irritation, respiratory depression

Admission Criteria/Prognosis Admit any patient with neurologic symptomatology or known exposure > 500 ppm

Toxicodynamics/Kinetics

Absorption: Inhalation and oral routes

Metabolism: Hepatic oxidation

Elimination: Renal

Monitoring Parameters Chest x-ray, arterial blood gases, liver and renal function tests

Reference Range Blood ethyl mercaptan levels in rats of ~ 200 nanomoles/mL associated with reversible coma

Overdosage/Treatment Decontamination: **Oral:** Do not lavage or induce emesis. Activated charcoal may be used. **Dermal:** Wash area with soap and water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate with water or saline.

Additional Information Symptoms can occur at exposures > 4 ppm; a colorless to yellow liquid with a garlic- or leek-like odor. Odor threshold: 0.26-0.97 ppb. Specific gravity: 0.8

Ethyl Methacrylate

CAS Number 97-63-2

UN Number 2277

Use In manufacture of plastics, building and furniture, dental plates

Mechanism of Toxic Action Mucosal/irritant; TLV-5 ppm.

Adverse Reactions

Central nervous system: Dizziness, lethargy

Dermatologic: Allergic contact dermatitis

Gastrointestinal: Oropharyngeal irritation

Neuromuscular & skeletal: Tremors

Ocular: Eye irritant

Respiratory: Nasal irritation

Overdosage/Treatment Decontamination: **Oral:** Activated charcoal.

Dermal: Wash exposed area with soap and water. **Ocular:** Irrigate with saline or water.

Ethylbenzene

Related Information

- Adipose Tissue Ranges of Toxins

Applies to Degreaser; Paint Thinner; Solvent (Asphalt, Fuels, Naphtha)

CAS Number 100-41-4

UN Number 1175

Synonyms EB; Ethylbenzol; Phenylethane

Use Solvent which is found in asphalt, fuels, and naphtha; used in the products of styrene and other organic chemicals; used in paint thinners and as a degreaser

ETHYLENE DICHLORIDE

Mechanism of Toxic Action Aromatic hydrocarbon with mucosal irritant effects; central nervous system depression can occur at very high concentrations

Adverse Reactions

Central nervous system: Dizziness at levels >2000 ppm
Dermatologic: Dermal irritant at levels of 200 ppm
Hematologic: Anemia (long-term exposure)
Hepatic: Hepatotoxicity
Ocular: Eye irritation with lacrimation at levels >1000 ppm
Respiratory: Upper respiratory tract irritation at levels >2000 ppm

Toxicodynamics/Kinetics

Absorption: Rapid from inhalation (57%) and skin (rate of 20-33 mg/cm²/hour)
Metabolism: Hepatic to mandelic acid and phenylglyoxylated acid
Elimination: Renal

Reference Range Ethylbenzene blood levels of 61 mcg/L associated with anemia; at 100 ppm exposure of ethylbenzene, it has been estimated that urine phenylglyoxylic acid and mandelic acid concentrations would be 95 mg/L and 395 mg/L, respectively

Overdosage/Treatment

Decontamination: **Do not** induce emesis or lavage due to risk of aspiration pneumonia. Activated charcoal can adsorb benzene.
Supportive therapy: Benzodiazepines for seizure control; avoid use of catecholamines due to risk of ventricular arrhythmia

Additional Information Not associated with cancer; carbon monoxide and ethanol inhibit metabolism of ethylbenzene in rodents; does not bioaccumulate. Minimal uptake of fluorescein on ocular exposure; BEI (urinary mandelic acid) at the end of shift at the end of work week: 2 g/L or 1.5 g/g creatinine. Frequently found in ground water at hazardous waste sites (average concentration: 0.65 ppm). IDLH: 2000 ppm; TLV-PEL: 100 ppm

Ethylene Dichloride

Applies to Fumigant; Solvent

CAS Number 107-06-2

UN Number 1184

Synonyms 1,2-Dichloroethane; 1,2-Dichloroethane (1,2-DCE); Borer Sol; Brocide; DCE; Dutch Oil; EDC; Freon 150; Glycol Dichlorid

Use Fat solvent; soil fumigant

Mechanism of Toxic Action CNS depression; also can cause increased myocardial irritability and mucosal injury; glutathione depletion may occur

Adverse Reactions

Cardiovascular: Cardiovascular failure, fibrillation (ventricular), arrhythmias (ventricular)
Central nervous system: CNS depression, delirium, headache, dizziness
Endocrine & metabolic: Hypercalcemia (late finding)
Hepatic: Elevated liver enzymes, fatty degeneration
Renal: Tubular necrosis (acute)
Respiratory: Pulmonary edema, respiratory failure

Signs and Symptoms of Overdose Abdominal pain, asthenia, corneal lesions, diarrhea, dizziness, dyspnea, headache, throat burning, tremor, vomiting

Toxicodynamics/Kinetics

Absorption: Well absorbed dermally, through lung (90%) and GI tract (90%)

Metabolism: Hepatic (saturated at oral dose of 25 mg/kg orally or 50 ppm by inhalation)

Elimination: Through lungs

Reference Range Oral dose of 25 mg/kg or inhalation dose >150 ppm correspond to blood level of 5-10 mcg/mL

Overdosage/Treatment

Decontamination: **Oral:** Emesis is contraindicated; dilute with milk or water. **Dermal:** Wash exposed areas with soap and water. **Ocular:** Irrigate with saline.

Supportive therapy: Supplemental oxygen. Benzodiazepines can be used for seizure control. Phenytoin or barbiturates can be used for refractory seizures. Although not formally studied, administration of N-acetylcysteine may replenish glutathione and may decrease pulmonary injury.

Additional Information Fatalities have occurred at doses of 30-70 g. Pleasant odor. Odor threshold: 50-100 ppm. Specific gravity: 1.26. TLV-TWA: 10 ppm; IDLH: 1000 ppm; PEL-TWA: 50 ppm

Ethylene Glycol

Applies to Antifreeze; Coolant

CAS Number 107-21-1

Synonyms Ethylene Alcohol; Ethylene Dihydrate; Glycol Alcohol; Monoethylene Glycol

Use Automotive radiator antifreeze and coolants, solvent

Mechanism of Toxic Action Metabolized into glycolic acid and oxalate via the alcohol dehydrogenase pathway (ADH), thus producing profound metabolic acidosis

Adverse Reactions

Cardiovascular: Myocarditis, QT prolongation, sinus tachycardia
Central nervous system: Ataxia, anisocoria, coma, cranial nerve palsies, cranial nerve dysfunction (6th nerve), seizures, headache, slurred speech
Endocrine & metabolic: Hypocalcemia, metabolic acidosis, osmolal gap
Gastrointestinal: Feces discoloration (black)
Hematologic: Leukemoid reaction, porphyria
Neuromuscular & skeletal: Hyperreflexia, rhabdomyolysis
Ocular: Diplopia, mydriasis, nystagmus, optic neuropathy
Renal: Myoglobinuria, renal tubular damage progressing to renal insufficiency
Respiratory: Hyperventilation, respiratory irritation/cough on inhalation
Miscellaneous: Breast cancer

Signs and Symptoms of Overdose

Similar to methanol ingestion, ethylene glycol can initially result in inebriation. Ethylene glycol toxicity can be divided into three stages:

Stage I (30 minutes to 12 hours after ingestion): Inebriation, ataxia, and metabolic acidosis with resulting respiratory compensation (Kussmaul's breathing), seizures, hypocalcemia, cranial nerve palsies, calcium oxaluria (4-8 hours after ingestion), and myoclonus. Coma can occur, and death is usually due to cerebral edema during this stage.

Stage II (12-36 hours after ingestion): Respiratory status deteriorates with tachypnea, tachycardia, cyanosis, dyspnea, and pulmonary edema with developing cardiomegaly. Death is usually due to cardiovascular causes or bronchopneumonia during this stage.

Stage III (36-72 hours after ingestion): Renal failure dominates this phase, with acute tubular necrosis, hematuria, oliguria, albuminuria, or anuria occurring. Noncardiogenic pulmonary edema may occur in this stage.

Admission Criteria/Prognosis Any symptomatic patient, acidosis, any patient with suspected ingestion, or serum ethylene glycol levels >10 mg/dL 2 hours postexposure should be admitted

Toxicodynamics/Kinetics

Absorption: Oral: Rapid. Inhalation: Not well absorbed, unless aerosolized; inhalation of aerosolized ethylene glycol usually results in a blood ethylene glycol level <30 mg/dL; respiratory irritation can occur at air levels >50 ppm; dermal: negligible through intact skin

Distribution: V_d: 0.83 L/kg; glycolate: 0.55 L/kg

Metabolism: Liver with principle toxic metabolites including glycolic acid (96%) and oxalic acid (2.3%). See figure.

Metabolic Pathway for Oxidation of Ethylene Glycol*

Adapted from the U.S. Department of Health and Human Services, "Technical Report for Ethylene Glycol/Propylene Glycol," Agency for Toxic Substances and Disease Registry, May 1993.

Half-life: Elimination:

No ethanol therapy: 3 hours. During ethanol therapy: 17 hours.

During ethanol therapy and hemodialysis: 2¹/₂ hours.

During 4-MP therapy: 19.7 hours. During 4-MP therapy and hemodialysis: 3.5 hours. Glycolate: 10 hours (endogenous). 2¹/₂ hours (during hemodialysis)

Elimination: Renal clearance: 3.2 mL/kg/minute

Reference Range

Highest survivable serum ethylene glycol level: 2361 mg/dL (after ingestion of 3 L ethylene glycol in an adult)

Toxic: Plasma level: 20 mg/dL

Fatal: Levels > 85 mg/dL

Mean urine ethylene glycol concentration of 5700 mg/L (range 600-10,800 mg/L) associated with fatal poisoning

Overdosage/Treatment

Decontamination: **Oral:** Avoid emesis with ipecac. Activated charcoal is not effective at a 5:1 ratio (charcoal:toxin). Higher doses of activated charcoal may be needed, but this is of unproven benefit. **Dermal:** Wash with soap and water. **Ocular:** Irrigate copiously with saline.

Supportive therapy: Ethanol or 4-methylpyrazole therapy should be initiated at ethylene glycol level 20 mg/dL, severe acidosis or electrolyte abnormality present, or renal failure. Treat acidosis with I.V. sodium bicarbonate. Administer thiamine and pyridoxine, 100 mg once a day for 2 days for both drugs. Calcium chloride or calcium gluconate can be given for hypocalcemia. 4-MP is a specific antagonist of alcohol dehydrogenase and can be used instead of ethanol therapy.

Enhancement of elimination: Hemodialysis should be considered if ethylene glycol level is >20 mg/dL or if metabolic acidosis is present. Continuous arteriovenous or venovenous hemodiafiltration may be useful. The hemodialysis clearance of glycolate with a blood flow rate of 250-400 mL/minute is ~170 mL/minute.

Antidote(s)

- Alcohol, Ethyl [ANTIDOTE]
- Fomepizole [ANTIDOTE]
- Pyridoxine [ANTIDOTE]
- Sodium Bicarbonate [ANTIDOTE]

Diagnostic Procedures

- Anion Gap, Blood
- Crystals, Urine
- Electrolytes, Blood
- Osmolality, Serum
- Osmolality, Urine

Test Interactions Falsely increased whole blood lactate levels may occur with certain enzymatic analyzers due to interference with glycolate

Additional Information

Lethal dose: 100 mL (1.5 mL/kg). Lowest survival pH reported was 6.46 in an ethylene glycol toxic patient (no neurologic sequelae).

Specific gravity: 1.12 g/mL; odor threshold: 62.5 mg/m³

Sweet tasting liquid. Atmospheric half-life: 24-50 hours. Water half-life: 3-5 days

Contribution of a serum concentration level of 100 mg/dL to elevation of osmolar gap: 16

Existence of propionic acid through inborn errors of metabolism can give a false-positive ethylene glycol level

Ethylene Oxide

Applies to Brake Fluids; Cosmetics; Detergents; Ethylene Glycol (Production); Fumigant; Inks; Plasticizers

CAS Number 75-21-8

UN Number 1040

U.S. Brand Names Anprolene®; Oxyfume®

Synonyms Dihydrooxirene; Dimethylane Oxide; E+O; Merpol; Oxidoethane; Oxirane; T-Gas

Use Gas sterilization agent (can inactivate all organisms); used in the production of ethylene glycol, cosmetics, detergents, inks, brake fluids, plasticizers, fumigant

Mechanism of Toxic Action Alkylating agent; irritant

Adverse Reactions

Cardiovascular: Cardiovascular collapse, sinus bradycardia
Central nervous system: CNS depression, axonopathy (peripheral)
Gastrointestinal: Mucous membrane irritation
Hematologic: Methemoglobinemia
Neuromuscular & skeletal: Motor and sensory neuropathy, peripheral neuropathy

Respiratory: Asthma, bronchospasm, reactive airways disease syndrome
Miscellaneous: Cutaneous T-cell lymphoma

Signs and Symptoms of Overdose Bradycardia, coma, conjunctivitis, contact dermatitis, cough, dermal burns, dizziness, dyspnea, headache, myoclonus, nystagmus, polyneuropathy, possible increased risk for leukemia or gastric cancer, pulmonary edema, seizures, vomiting

Admission Criteria/Prognosis Any symptomatic patient 12 hours postexposure should be admitted; any patient with bronchospasm or pulmonary edema should be admitted

FENSULFOTHION

Toxicodynamics/Kinetics

Absorption: Orally and by inhalation

Metabolism: Hepatic; two pathways: hydrolysis to ethylene glycol and glutathione conjugation to mercapturic acid

Overdosage/Treatment Decontamination: Basic poison management; do not induce emesis. Irrigate skin with high pressure water.

Additional Information

A blister agent

It has been estimated that 270,000 U.S. workers are potentially exposed to ethylene oxide, most in the health care industry.

Air levels in a hospital sterilizing unit: 0.1-7.8 ppm

Ether-like odor. Odor threshold: 430 ppm (air); 140 mg/L (water).

Atmospheric half-life: 69-149 days. Water half-life: 9-14 days. TLV-TWA: 1 ppm; IDLH: 800 ppm; PEL-TWA: 1 ppm

Specific References

Finch CK and Lobo BL, "Acute Inhalant-Induced Neurotoxicity with Delayed Recovery," *Ann Pharmacother*, 2005, 39(1):169-72.

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or $\sim 1/2$ the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of organophosphates.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information

Red blood cell cholinesterase, and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected.

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Yellow/tan viscous/oily liquid with a garlic odor; noncombustible, with a vapor pressure of 0.00003 mm Hg at 20°C

ACGIH TLV: 0.2 mg/m³; PEL-TWA: 0.2 mg/m³

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Fensulfotion

CAS Number 115-90-2

U.S. Brand Names Dansit®

Use Marketed as insecticide granules, dusting agent, or spray liquid with or without petroleum derivative as a solvent

Mechanism of Toxic Action Potent, irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, QT prolongation, sinus bradycardia, sinus tachycardia

Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose

Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, QT prolongation, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure, and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia, and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Admission Criteria/Prognosis Any symptomatic patient or an asymptomatic patient following a severe exposure should be admitted probably into an intensive care unit; asymptomatic patients following a moderate exposure can be discharged after 8 hours of observation

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure

Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways

Elimination: Metabolites are excreted in urine

Warnings/Precautions Risk of aspiration pneumonia exists with agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. Do not induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. Do not give a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline

Fenthion

CAS Number 55-38-9

U.S. Brand Names Baytex®; Entex®; Lysoff®; Spotton®; Tiguvon®

Use Marketed as insecticide granules, dusting agent, or spray liquid with or without petroleum derivative as a solvent

Mechanism of Toxic Action Irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, QT prolongation, sinus bradycardia, sinus tachycardia

Central nervous system: Depression, seizures, hyperactivity, extrapyramidal symptoms (dystonia, resting tremor, choreoathetosis) can develop from 4-40 days postexposure, cognitive dysfunction, hypothermia

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure), intermediate syndrome

Signs and Symptoms of Overdose

Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely),

nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure, and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia, and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates. Symptomatology may be delayed over 12 hours due to high lipid solubility.

Admission Criteria/Prognosis Observe for 96 hours

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure

Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways

Elimination: Metabolites are excreted in urine

Warnings/Precautions Rapid dermal absorption may occur across intact skin; toxicity may be prolonged due to the high lipid solubility exhibited by fenthion; a risk of aspiration pneumonitis exists following oral exposure to agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Reference Range Postmortem blood fenthion level of 3.8 mcg/mL

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. **Do not** give a cathartic.

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure; pralidoxime may be required to be given for a longer period of time (4-6 days; 22 days in 1 report)

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed treatment and large volumes of distribution of organophosphates.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses >100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or $\sim 1/2$ the dose of atropine)

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudochoolinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information

Red blood cell cholinesterase and serum pseudochoolinesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudochoolinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected. While muscarinic signs may not be marked, neurologic paralysis can occur within 72 hours; respiratory paralysis can last for a mean time of 132 hours.

Fenthion is very lipid soluble with peak intensity of symptoms occurring in 30-96 hour postexposure.

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Yellow to tan viscous liquid with a mild garlic odor

Vapor pressure: 0.00003 mm Hg at 20°C

ACGIH TLV: 0.2 mg/m³; PEL-TWA: 0.2 mg/m³

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Specific References

Eddleston M, Eyer P, Worek F, et al, "Differences Between Organophosphorus Insecticides in Human Self-Poisoning: A Prospective Cohort Study," *Lancet*, 2005, 366(9495):1452-9.

Fipronil

CAS Number 120068-37-3

U.S. Brand Names Regent 50 SC®

Use Broad spectrum pesticide for use against crop infestation (rice, cotton); against locusts/grasshoppers, human head lice, cockroaches, ants, fleas/ticks on domestic animals; usually available as a 4.95 solution in propylene glycol; an ectoparasiticide (topical) in veterinary practice

Mechanism of Toxic Action An N-phenyl-pyrazole which blocks gamma-aminobutyric acid (GABA) induced rapid chloride currents in neurons. Affinity of fipronil for insects' receptors is about 1000 fold as compared to human receptors.

Signs and Symptoms of Overdose Ocular irritation, drowsiness, seizures are possible (28%); dermal irritation, dizziness, nausea, vomiting, diaphoresis, agitation; symptoms usually resolve in 12 hours

Toxicodynamics/Kinetics

Absorption (oral): Rapid

Metabolism: To active sulfone metabolites. Photoconversion to a desulfinyl compound can occur.

Reference Range Serum fipronil level of 1600 mcg/L associated with seizure

Overdosage/Treatment

Decontamination: Oral: Lavage within 1 hour / activated charcoal

Supportive therapy: Diazepam (10-15 mg I.V. in adults) is effective in termination of seizures; phenytoin is not likely to be beneficial

Additional Information Clear, slightly yellow liquid with almond or ester odor

Specific References

Fung HT, Chan KK, Ching WM, et al, "A Case of Accidental Ingestion of Ant Bait Containing Fipronil," *J Toxicol Clin Toxicol*, 2003, 41(3):245-8.

Formaldehyde

Applies to Adhesive; Disinfectant (Hemodialysis Machines); Electrical Insulation; Embalming; Fireproofing; Glue; Lacquer; Tannery Products

CAS Number 50-00-0

UN Number 1198 (solution); 2209 (formalin)

Synonyms Fannoform; Formic Aldehyde, Formalin; Fyde; Hoch; Methanol; Morbicid; Paraform; Trioaxane; Veracur

Use Embalming, fireproofing, glues/adhesives, lacquers, electrical insulation, tannery products; disinfectant use is limited to hemodialysis machines

Mechanism of Toxic Action Covalently binds to proteins and causes cell necrosis; mucous membrane irritant; synthesized by methanol oxidation.

Adverse Reactions

Cardiovascular: Cardiovascular collapse, hypotension

Central nervous system: CNS depression, panic attacks

Dermatologic: Contact dermatitis, dermal irritation, nonimmunologic contact urticaria, immunologic contact urticaria, airborne contact dermatitis

Endocrine & metabolic: Metabolic acidosis

Gastrointestinal: Coagulation necrosis on ingestion, vomiting, diarrhea, feces discoloration (black), throat irritation

Ocular: Visual evoked potential abnormalities

Renal: Nephritis, renal failure

Respiratory: Wheezing, tachypnea, bronchospasm, sinonasal cancer, asthma

Miscellaneous: Aneuploidy induction, cutaneous T-cell lymphoma

Signs and Symptoms of Overdose Ataxia, coma, cough, dizziness, drowsiness, dyspnea, tachypnea, gastritis, wheezing (at levels as low as 0.1 ppm), epistaxis, hyposmia, sore throat (over 5 ppm), anosmia, laryngospasm, ocular irritation (at 2 ppm), urticaria, pustovascular lesions, brownish skin and discoloration

FORMALDEHYDE

Admission Criteria/Prognosis Development of metabolic acidosis or bronchospasm within 6 hours postexposure should constitute admission; asymptomatic patients may be discharged after 6 hours of observation; any patient with cardiopulmonary symptoms developing 6-12 hours postexposure should probably be admitted into an intensive care unit; survival after 2 days postexposure usually results in recovery

Toxicodynamics/Kinetics

Absorption: Well absorbed from the GI tract and by inhalation; to a lesser extent, absorbed through the skin. Dermal absorption is ~5%. Absorption from nasal portion of respiratory tract is near 100%.

Metabolism: Rapidly (within 1.5 minutes) to formic acid which is then metabolized to carbon dioxide and water

Half-life: Formate: 1.5 hours; formaldehyde: 3.3 hours

Reference Range Blood formaldehyde levels of 4.8 mg/L and 11 mg/L associated with fatality due to ingestion

Overdosage/Treatment

Decontamination: Basic poison management. Lavage within 1 hour; **do not** induce emesis; dilute with water.

Oral: Activated charcoal may be useful.

Inhalation: Administer 100% humidified oxygen

Ocular: Irrigate with copious amounts of saline.

Supportive therapy: Correct acidosis with sodium bicarbonate (1-2 mEq/kg I.V.); endoscopy to evaluate mucosal injury. Bronchospasm can be treated with beta-agonist therapy.

Enhancement of elimination: Consider hemodialysis if acidosis develops or if methanol is elevated due to formalin exposure.

Antidote(s)

- Sodium Bicarbonate [ANTIDOTE]

Diagnostic Procedures

- Anion Gap, Blood
- Electrolytes, Blood

Additional Information Implicated in squamous cell carcinoma of the nasopharynx (probable human carcinogen)
Ingestion of 30 mL (of a 37% solution) may cause fatalities. See table.

Indoor Concentrations of Formaldehyde in U.S. Homes			
Building Type	Concentration (ppm)		
	Number	Range	Mean
With UFFI*	> 1200	0.01-3.4	0.05-0.12
Without UFFI*	131	0.01-0.17	0.025-0.07
Compliant

*UFFI = Urea formaldehyde foam insulation
Reference: U.S. Department of Health and Human Services, "Toxicological Profile for Formaldehyde," Agency for Toxic Substances and Disease Registry, September 1997.

Odor threshold in water: 50 ppm. Odor threshold in air: 0.5-1 ppm. Taste threshold: 50 ppm. TLV-TWA: 1 ppm; IDLH: 20 ppm; PEL-TWA: 3 ppm. Airborne concentrations > 2 ppm can cause mucosal irritation, while concentrations > 50 ppm will cause serious injury within 10 minutes. Formalin contains 37% formaldehyde and 12% to 15% methanol

Potential Human Exposure to Formaldehyde	
Source of Formaldehyde	(mg/day)
Air	
Outdoor air (10% of time)	0.02
Indoor air	
Home (65% of time)	
Conventional	0.5-2.0
Prefabricated (chipboard)	1-10

Table (Continued)	
Source of Formaldehyde	(mg/day)
Workplace (25% of time)	
Without occupational exposure	0.2-0.8
With 1 mg/m ³ occupational exposure	5
Food (formaldehyde not in free form)	1-10
Environmental tobacco smoke (10% to 25% of total indoor exposure)	0.1-1
Smoking (20 cigarettes/day)	1

Reference: ATSDR and Fishbein L, "Exposure from Occupational Versus Other Sources," *Scand J Work Environ Health*, 1992, 18(1):5-16.

Atmospheric half-life: 19 hours in clean air; 9-10 hours in polluted air
Ambient urban formaldehyde air levels range from 5.5-67.7 ppb
Pulmonary function tests are recommended in patients with reactive airways dysfunction following formaldehyde inhalation
Dermal exposures > 2% concentration can cause skin irritation
Dissolves easily in water

Metabolic Pathways of Formaldehyde Biotransformation

1. Metabolism to formate / CO₂

2. Binding to tetrahydrofolate (TH₄)

3. Nonenzymatic reactions with sulfhydryl groups and urea

4. DNA and protein cross-linking

FM = formaldehyde, TH₄ = tetra hydrofolate, DNA = deoxyribonucleic acid, GSH = glutathione, NAD⁺ = nicotinamide adenosine dinucleotide, SFGH = S-formyl glutathione hydrolase, FDH = formaldehyde dehydrogenase.

From "Toxicological Profile for Formaldehyde," U.S. Department of Health and Human Services, Agency for Toxic Substances and Disease Registry, September 1997.

Freon

Applies to Fire Extinguishers; Propellant; Refrigerant

Synonyms Dichlorodifluoromethane; Difluoroethane (Freon 152); Fluorinated Hydrocarbons; Halon

Use Refrigerant and in fire extinguishers/propellant

Mechanism of Toxic Action Can cause cold injury to surface on contact, sensitizer of myocardium to catecholamines

Adverse Reactions

Cardiovascular: Myocardial depression, arrhythmias, sinus bradycardia, congestive heart failure

Dermatologic: Contact dermatitis

Respiratory: Pulmonary edema, bronchoconstriction, asthma

Signs and Symptoms of Overdose Ataxia, bradycardia, coma, conjunctivitis, diarrhea, dizziness, drowsiness, dyspnea, hemoptysis, seizures, slurred speech, tremor

Toxicodynamics/Kinetics

Absorption: Immediate

Half-life: 75 minutes

Reference Range Postmortem blood levels of chlorodifluoromethane (Freon 22) and trichlorofluoromethane (Freon 11) of 71 mg/L and 63 mg/L, respectively, have been associated with fatality.

Overdosage/Treatment Decontamination: Basic poison management; avoid emesis; avoid catecholamines

Additional Information Odor of "fresh cut grass;" levels peak almost immediately after inhalation; heating may produce phosgene

Furfural

CAS Number 98-01-1

UN Number 1199

Synonyms Furof; Quakeral

Use A heterocyclic aldehyde commonly used as a solvent in butadiene/aromatic compound extractions, and in manufacture of ant poisons, food products, and fuels (found in cocoa, tea, coffee, beer, wine, bread, and milk)

Mechanism of Toxic Action A dermal and mucosal irritant which can cause CNS depression

Signs and Symptoms of Overdose Conjunctivitis, excessive lacrimation, headache, nasal irritation, and throat irritation can occur at air concentrations of 2-14 ppm. Dermal exposure can cause eczema, pain, and irritation. Inhalation exposure can cause cough, shortness of breath, and sore throat.

Toxicodynamics/Kinetics

Metabolism: Hepatic oxidation to furoic acid

Half-life: 2-2.5 hours

Elimination: Renal

Reference Range Normal amount of urinary furoic acid: 15 mmol/mol creatinine (15 mg/g creatinine). Biological exposure index (BEI): 200 mmol/mol creatinine (200 mg/g creatinine) at end of work shift.

Overdosage/Treatment Decontamination: **Dermal:** Wash with water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate with saline. **Oral:** Dilute with 4-8 ounces of milk and water. Activated charcoal may be useful.

Additional Information A colorless oily liquid. A 60 mg oral ingestion can cause headache. Atmospheric half-life is 0.44 days. No significant bioconcentration.

Specific References

Tan ZB, Tonks CE, O'Donnell GE, et al, "An Improved HPLC Analysis of the Metabolite Furoic Acid in the Urine of Workers Occupationally Exposed to Furfural," *J Anal Toxicol*, 2003, 27(1):43-6.

Gasoline

Related Information

- Benzene
- Lead
- Methyl Tert-Butyl Ether
- Toluene Diisocyanate

CAS Number 8006-61-9

UN Number 1203; 1257

Synonyms Mogas; Motor Fuel; Motor Spirit; Natural Gasoline; Petrol

Use Fuel for internal combustion engines

Mechanism of Toxic Action A volatile hydrocarbon with central nervous system depressant and arrhythmogenic effects

Adverse Reactions

Cardiovascular: Sinus bradycardia

Central nervous system: Panic attacks with inhalation

Neuromuscular & skeletal: Rhabdomyolysis

Renal: Alpha 2u-globulin nephropathy

Signs and Symptoms of Overdose

Death from ingestion is usually due to aspiration. Symptoms occur at 1000 ppm after 1 hour; ataxia, confusion, delirium dysarthria, euphoria, hallucinations (visual, auditory and tactile), headache, mania, tremor, vertigo

Inhalation: Arrhythmia, ataxia, dizziness, drowsiness, hallucinations, insomnia, intra-alveolar hemorrhage, muscle cramps, myoclonus, nausea, paresthesias, pulmonary edema, vomiting

Ingestion: Aspiration, belching, disseminated intravascular coagulation can occur, elevated hepatic enzymes, hematuria, hemolysis, hypotension, oliguria, pulmonary congestion

Admission Criteria/Prognosis Patients who develop tachypnea, cyanosis, dyspnea, CNS depression, tachycardia, or fever within 8 hours of exposure should be admitted; asymptomatic patients can be discharged after 8 hours observation

Toxicodynamics/Kinetics

Protein binding: None

Half-life: 17 hours

Elimination: Pulmonary/renal

Reference Range Urine phenol level (for benzene measurement) >40 mg/L is consistent with gasoline exposure in gasoline pump workers; blood 2 methylpentane level >50 mg/L has been associated with fatality Postmortem Gasoline concentration in heart blood and vitreous humor of 22.3 and 1 mg/L respectively, associated with fatal inhalation of motorcycle exhaust.

Overdosage/Treatment

Decontamination: **Do not** induce emesis or lavage due to risk of aspiration pneumonia. Activated charcoal can adsorb benzene.

Dermal: Wash with soap and water

Supportive therapy: Benzodiazepines for seizure control; avoid use of catecholamines due to risk of ventricular arrhythmia; treat burns with standard burn therapy; monitor for carbon monoxide

Aggressive airway management; intubation if pulmonary response is worrisome and/or loss of consciousness/CNS symptoms suggest potential loss of airway protection

For inhalation injuries, nebulized budesonide (0.5 mg every 12 hours for 4 days - pediatric dose) may be helpful

Diagnostic Procedures

- Lead, Urine

Additional Information

Boiling point : 104-401°F

Highly lipid soluble; gasoline contains a mixture of benzene (0.5%-2.5%), toluene, xylene, ethyl benzene, and possible lead (tetraethyl lead); other additives include ethylene dichloride and ethylene dibromide; lead poisoning is unusual from inhalation of gasoline containing tetraethyl lead

Odor threshold of gasoline: 0.25 ppm. Lethal inhalation concentration: 5000 ppm. Lethal ingestion concentration: 5 g/kg (12 oz)

Ambient level of gasoline at service stations is usually <100 ppm

OSHA - PEL-TWA: 300 ppm; TLV-TWA: 300 ppm

Lead in agriculture gasoline use should be phased out in 1995; goal of phase I toxic reduction is 15% and phase II toxic reduction is 20% to 22%; see table.

Aviation gasoline has a lead concentration of 1.28 grams per liter (as opposed to unleaded gasoline which has 0.03 grams per liter of lead). Aviation gasoline is 24% toluene and 75% aliphatic hydrocarbon.

Automotive Gasoline				
Fuel Parameter	Conventional Gasoline (prior to 1995)	Reformulated Gasoline		
		Phase I (1995-1999)	Phase II (2000-)	California
Reid vapor pressure (psi)	8.7/7.8	8.0/7.1	6.7	6.8
Sulfur (ppm)	339	305	140	30

Benzene (vol%)	1.5	0.95	0.95	0.8

*Increased oxygen percentage obtained by addition of ethanol or methanol.
†Of fuel evaporated at 200°F.
‡Of fuel evaporated at 300°F.

GLUFOSINATE

Specific gravity for gasoline is 0.75-0.8

A 1% solution of gasoline (inhaled) can produce symptoms within 5 minutes; 15-20 breaths of gasoline can result in intoxication for as long as 6 hours; Canada has replaced lead with methylcyclopentadienyl manganese tricarbonyl (MMT) which can produce manganese toxicity

Glufosinate

Applies to Herbicide

U.S. Brand Names Basta®

Synonyms GLA

Use Herbicide (plant inhibitor of glutamine synthetase); replaces paraquat in use

Mechanism of Toxic Action Related to glutamic acid; can excite amino acid in the central nervous system

Signs and Symptoms of Overdose May be delayed for up to 38 hours. Amnesia, ataxia, coma, dysarthria, edema, fever, hypotension, lethargy, leukocytosis, nystagmus, oral ulcers, seizures, tremor

Admission Criteria/Prognosis Admit any asymptomatic ingestion of Basta® > 1 mL/kg for at least 48 hours

Toxicodynamics/Kinetics

Absorption, oral: 30%

Distribution: V_d : ~2 L/kg

Elimination: Renal (clearance: 83 mL/minute)

Overdosage/Treatment

Decontamination: Do not use ipecac or induce vomiting. Lavage within 1 hour of ingestion; activated charcoal should be used.

Supportive therapy: Benzodiazepines should be used to treat seizures.

Enhancement of elimination: Hemodialysis may be useful (clearance by hemodialysis is ~50 mL/minute).

Additional Information Lethal dose: 3 mL/kg; Toxic oral dose: 1.6 mL/kg. Basta® is 18.5% glufosinate.

Glutaraldehyde

CAS Number 111-30-8

Synonyms 1,5,-Pentanedial; Glutaral; GTA

Use An aliphatic dialdehyde as a biocide/disinfectant; often used as a sterilizing agent in medical facilities and as a histological fixative; also used in embalming solutions; used topically in a 2% to 10% solution to treat warts, hyperhidrosis, and onychomycosis (#2 aldehyde used in the U.S.)

Mechanism of Toxic Action A contact irritant and sensitizer

Adverse Reactions

Cardiovascular: Chest pain, tachycardia

Central nervous system: Headache, dizziness, ataxia

Neuromuscular & skeletal: Muscle twitching

Ocular: Conjunctivitis, corneal opacity

Respiratory: Nasal irritation, bronchospasm, asthma

Overdosage/Treatment

Decontamination: **Dermal:** Irrigate with copious amounts of water.

Inhalation: Administer 100% humidified oxygen. **Ocular:** Irrigate with saline.

Supportive Care: Treat bronchospasm with standard therapy. (Beta-2 agonists)

Additional Information TLV: 0.05 ppm; odor threshold: 0.04 ppm; ocular/respiratory irritant at 0.3 ppm; rubber gloves are not protective; ocular injury (in animal studies) occurred at glutaraldehyde concentrations > 1%; dermal injury (in rabbits) occurred at 5% concentration
Oily liquid/not flammable

Glycol Ethers

Applies to Anti-icing Agents; Leather Treatment Products; Solvent (Industrial); Varnish Remover

Synonyms Alkylene Oxide Adducts; Cellosolves

Use In the production of photoresists of the microelectronic industry, industrial solvents, varnish removers, leather treatment products, anti-icing agents

Mechanism of Toxic Action Hemolysis, bone marrow depression by metabolites by interfering with RNA and DNA synthesis

Adverse Reactions

Cardiovascular: Sinus tachycardia, arrhythmias (ventricular)

Central nervous system: Encephalopathy, coma

Hematologic: Bone marrow suppression, hemolytic anemia

Hepatic: Fatty degeneration of the liver (methyl ether)

Renal: Tubular necrosis (acute), renal failure

Signs and Symptoms of Overdose Ataxia, coma, confusion, drowsiness, headache, hemorrhagic gastritis, hyperventilation, hypocalcemia, hypokalemia, hypotension, metabolic acidosis, tachycardia (ventricular), tremor; symptoms may be delayed up to 18 hours

Toxicodynamics/Kinetics

Absorption: Readily through the skin, lungs, and GI tract

Elimination: Oxidized by alcohol dehydrogenase and excreted in urine

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/ activated charcoal

Supportive therapy: Treat acidosis with sodium bicarbonate. Ethanol administration may be of some use.

Enhancement of elimination: Hemodialysis is useful for renal failure or acid abnormalities.

Antidote(s)

- Sodium Bicarbonate [ANTIDOTE]

Diagnostic Procedures

- Crystals, Urine

- Electrolytes, Blood

Additional Information Minimum lethal dose: 8 mL (methoxyethanol)

Mild etheral odor

Order of toxicity: Methoxyethanol > ethoxyethanol > butoxyethanol; may give a positive ethylene glycol level on laboratory testing

Diagnostic effects caused by glycol ethers include hypocalcemia (methyl ether), hypokalemia (methyl ether and butyl ether), pancytopenia, metabolic acidosis with high anion gap, and oxalate crystals may be seen in urine; does not affect osmolar gap

Glyphosate

Applies to Herbicide

CAS Number 1071-83-6

U.S. Brand Names Bronco®; Glifonox®; Glycel®; Glyphotox®; Kleen-up®; Network®; Rodeo®; Roundup®; Weedoff®

Synonyms N-(Phosphonomethyl) glycine; GlySH

Use Herbicide

Mechanism of Toxic Action The surfactant (polyoxyethyleneamine) may cause uncoupling of oxidative phosphorylation (although this mechanism is in question); additionally is a mucosal irritant and a myocardial depressant

Signs and Symptoms of Overdose Acute tubular necrosis (10%), anuria, bronchospasm, cough, diarrhea, drowsiness, dysphagia, dyspnea, vomiting, esophagitis, excessive hematemesis, gastritis, hematuria, hypotension, hyperkalemia, leukocytosis (average 14,300 cells/mm³), metabolic acidosis (78% of cases), noncardiogenic pulmonary edema (5% to 13%), nystagmus, oliguria, oral mucosal ulceration, piloerection, respiratory failure, salivation, hemolysis

Toxicodynamics/Kinetics

Absorption: May be absorbed dermally (<2%)

Half-life: 2-3 hours

Elimination: Renal

Monitoring Parameters CBC, arterial blood gases, electrolytes

Reference Range

Serum glyphosate levels > 1000 ppm associated with severe symptoms

Urine glyphosate concentration of 11,200 mg/L associated with fatal poisoning

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** induce emesis; may dilute with milk or water

Supportive therapy: Primarily supportive; do not give pralidoxime; sodium bicarbonate can be given for metabolic acidosis

Enhanced elimination: No evidence that forced diuresis is effective; early use of hemodialysis may be useful to treat acidosis or other metabolic abnormalities

Additional Information

Minimal lethal dose: 60 mL (in an 84-year-old man)

Patients > 40 years who ingest > 150 mL are at highest risk for death

Helium**CAS Number** 7440-59-7**UN Number** 1046**Synonyms** He

Use Often used as an inhalant of misuse; also may be a byproduct in welding; a balloon filler heating medium; used in neon signs and mixed-gas sea diving

Mechanism of Toxic Action Can cause arterial gas embolism

Signs and Symptoms of Overdose Blurriness, clonus, coma, nausea, dizziness, headache, limb weakness, neck pain, paresthesia, seizures (all symptoms of cerebral gas embolism); can cause dermal burns upon skin contact. Laryngeal changes can occur.

Admission Criteria/Prognosis Admit any patient with neurologic symptoms or signs of pneumothorax

Overdosage/Treatment

Decontamination: Inhalation: Humidified 100% oxygen

Supportive therapy: Hyperbaric oxygen may be useful if signs of arterial gas embolism develop.

Antidote(s)

- Oxygen (Hyperbaric) [ANTIDOTE]

Additional Information Liquid helium is a colorless, tasteless, odorless liquid which is easily vaporized. Atmospheric concentrations >20 mg/dL can cause symptoms. Heliox is 20% oxygen and 80% helium, used in patients with airway disease and decompression illness. Specific gravity: 0.15. Vapor density: 0.14

Heptachlor**Related Information**

- Adipose Tissue Ranges of Toxins
- Chlordane

CAS Number 1024-57-3; 76-44-8**U.S. Brand Names** Drinox®; Heptagran®; Heptamul®; Soleptax®; Termide®; Velsicol 104®

Use While it had been used as a dermal insecticide and for control of crop pests and termites, its use has been sharply curtailed in the U.S. by the EPA since 1988; primarily currently used as a termiticide for domestic use and in fire ant control in power transformers

Mechanism of Toxic Action In the cyclodiene class of organochlorine pesticides; interferes with axonal transmembrane flux of sodium and potassium; also inhibits oxidative phosphorylation

Adverse Reactions

- Cardiovascular: Raynaud's phenomenon
 Dermatologic: Scleroderma
 Gastrointestinal: Nausea, vomiting
 Hematologic: Thrombocytopenia
 Neuromuscular & skeletal: Tremors
 Ocular: Mydriasis

Toxicodynamics/Kinetics

Absorption: Oral

Metabolism: Hepatic epoxidation to heptachlor epoxide and oxychlordane

Reference Range Dairy farm workers exposed to heptachlor from raw milk (levels up to 89 ppm) had elevated blood heptachlor epoxide levels (0.84 ± 1.0 ppb) and oxychlordane levels (0.71 ± 0.8 ppb). U.S. sampling of adipose tissue averages ~0.1 ppm (FDA "action level").

Overdosage/Treatment

Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal or cholestyramine; **do not** administer milk or cream as it can enhance absorption. **Dermal:** Wash with soap and water; avoid oils as they can enhance absorption. **Inhalation:** Administer 100% humidified oxygen. Enhancement of elimination: Multiple dosing of activated charcoal or cholestyramine may be effective.

Additional Information Usually found in conjunction with chlordane exposure. Heptachlor can be formed as a chlordane metabolite. Some association with leukemia noted; can cause sclerodermatous changes of the hands. Leather clothing absorbs heptachlor. Odor threshold: 0.3 mg/m³. TLV-TWA: 0.5 mg/m³; IDLH: 100 mg/m³

Hexabromobiphenyl**Related Information**

- Polychlorinated Biphenyls

CAS Number 36355-01-8; 59536-65-1; 67774-32-7**Synonyms** Firemaster BP-6; Firemaster FF-1

Use Fire retardant in thermoplastics for use in motor housing, electrical products, and auto upholstery; not imported or produced in the U.S. since 1979

Mechanism of Toxic Action Binds to a cellular receptor (Ah receptor) which alters protein and enzyme synthesis

Adverse Reactions Similar to polychlorinated biphenyl agents; halogen acne, hypothyroidism, impairment of memory upon inhalation; elevated liver function test results and hepatomegaly have been noted after oral ingestion; hepatocellular carcinomas have been noted in animal models

Toxicodynamics/Kinetics

Absorption: By dermal contact, oral, or inhalation routes

Protein binding: 80%

Metabolism: Hepatic debromination and hydroxylation

Elimination: Fecal and urinary routes

Reference Range General population adipose tissue concentration: Ranges from 1.0-2.0 mcg/kg; baseline serum level of polybrominated biphenyls: ~0.2 mcg/L

Overdosage/Treatment Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal or cholestyramine. **Dermal:** Wash with soap and water. **Ocular:** Irrigate with saline.

Additional Information Exposure can occur via ingestion of contaminated food; one such episode occurred in Michigan involving contaminated feed from polybrominated biphenyls (PBB) in May 1973; dairy products were involved. While spray drying of milk reduced PBB levels in milk, there was no effect when pasteurization, aging of cheese, or freeze drying occurred; pressure cooking meat also reduces meat PBB content. Atmospheric half-life: 182 days

Hexachlorobenzene**Related Information**

- Cholestyramine Resin [ANTIDOTE]
- Edetate Calcium Disodium [ANTIDOTE]
- Pentachlorophenol

Applies to Seed Treatment**CAS Number** 118-74-1**UN Number** 2729**U.S. Brand Names** Amatin®; Anti-Carie®; Bent-Cure®; Bent-No-More®; No Bent®; Sanocide®**Synonyms** HCB; Perchlorobenzene; Phenyl Perchloryl

Use Waste product of perchlorethylene used for seed treatment

Mechanism of Toxic Action Induction of porphyria can occur by inhibition of the enzyme uroporphyrinogen decarboxylase and increased d-ALA-synthetase, thus increasing uroporphyrin III levels; lipid peroxidation and mitochondrial inhibition can also occur

Adverse Reactions

In children, diarrhea, fever, pink skin papules are noted; hypochromic anemia

Central nervous system: Hypothermia

Dermatologic: Skin blisters, epidermolysis, increased pigmentation, porphyria cutanea tarda syndrome ("pink sore disease") from estimated ingestion of 0.05-0.2 g/day; scleroderma

Endocrine & metabolic: Thyromegaly

Gastrointestinal: Anorexia

Genitourinary: Urine discoloration (port wine)

Hematologic: Porphyria

Hepatic: Hepatomegaly, centrilobular hepatic necrosis

Neuromuscular & skeletal: Hand atrophy, muscle weakness, paresthesia in children

Respiratory: Pulmonary irritant

Signs and Symptoms of Overdose Alopecia, ataxia, hirsutism, hyperthermia, porphyria

HEXACHLOROBUTADIENE

Toxicodynamics/Kinetics

Distribution: Very lipophilic; found in breast milk

Metabolism: Hepatic to pentachlorophenol, pentachlorobenzene, and tetrachlorobenzene

Half-life: 60 days

Reference Range Whole blood hexachlorobenzene levels of 0.41 ppb not associated with adverse health effects

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Avoid sunlight. Calcium disodium ethyl-enediamine-tetracetic acid (EDTA) at 1.5 g I.V. for 5 days or 500 mg to 1.5 g/day orally has been shown to be useful. Barbiturates should be used for seizure control.

Enhancement of elimination: Multiple dosing of activated charcoal or cholestyramine may be effective.

Additional Information Increased death rate in children with maternal hexachlorobenzene-induced porphyria during first 2 years of life, probably through contaminated breast milk. Little CNS toxicity. Insoluble in water. Atmospheric half-life: 90 days. Soil half-life: 3-6 years Pentachlorophenol can increase toxicity (porphyrogenicity) of hexachlorobenzene.

Hexachlorobutadiene

Related Information

- Adipose Tissue Ranges of Toxins

Applies to Fumigant; Solvent (Rubber, Lubricants, Chlorofluorocarbons)

CAS Number 87-68-3

UN Number 2279

Synonyms Dolen-Pur; Perchlorobutadiene

Use Solvent in the manufacture of rubber, lubricants, and chlorofluorocarbons; fumigant; fluid in gyroscopes

Mechanism of Toxic Action Cysteine metabolite causes uncoupling of oxidative phosphorylation and inhibition of cytochrome oxidase activity and electron transport in the mitochondria

Adverse Reactions Increased serum bile acids with chronic inhalation exposure (0.005-0.02 ppm)

Toxicodynamics/Kinetics

Absorption: After inhalation

Metabolism: Conjugation with glutathione (toxic metabolite)

Elimination: Biliary

Reference Range Range noted in human adipose tissue 0.8-8.0 mcg/kg wet weight

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal; **do not** use oil-based cathartic

Supportive therapy: In animal studies, probenecid decreased levels of mercapturic acid derivative and decreased renal toxicity.

Enhancement of elimination: Due to enterohepatic recirculation, multiple dosing of activated charcoal may be effective.

Additional Information Range of urban ambient air hexachlorobutadiene levels: 2-11 ppt. Drinking water contains <3 ppt; not found in sewage samples. PEL-TWA: 0.02 ppm; TLV-TWA: 0.02 ppm

Hexachlorocyclopentadiene

Applies to C-56; HRS1655

CAS Number 77-47-4

UN Number 2646

U.S. Brand Names Graphlox

Synonyms HCCPD; Perchlorocyclopentadiene

Use Key chemical intermediate in chlorinated pesticides (present up to 1% as a contaminant), in manufacture of flame retardants, nonflammable resins, and dyes

Mechanism of Toxic Action A mucosal irritant which is directly toxic at the cellular level

Signs and Symptoms of Overdose Abdominal cramps, dermal irritation, elevation of hepatic enzymes, headache (may last up to 6 weeks), lacrimation, nasal irritation (at levels >1 ppm), nausea, ocular irritation, proteinuria (usually resolves in 3 weeks); may increase risk of urogenital infection in females

Toxicodynamics/Kinetics Absorption: By lung, dermal, and GI routes

Overdosage/Treatment

Decontamination: **Oral:** Dilute with milk or water. **Dermal:** Wash with soap and water. **Inhalation:** Remove from environment and administer humidified oxygen.

Enhancement of elimination: Hemodialysis or hemoperfusion is unlikely to be of any benefit.

Additional Information Readily absorbed by soil and sediment. Atmospheric half-life: <1 day. Water half-life: <5 minutes. OSHA: PEL-TWA: 0.1 ppm; TLV-TWA: 0.01 ppm

Hexachloroethane

CAS Number 67-72-1

UN Number 9037

U.S. Brand Names Avlothane®; Distokal®; Distopan®; Egitol®; Phenohep®

Synonyms Carbon Hexachloride; HCE; Perchloroethane

Use Moth repellent; antihelmintic agent in sheep; used in the military in smoke screens and pyrotechnic devices

Mechanism of Toxic Action Mucosal irritant; this chlorinated hydrocarbon can cause a tubular nephropathy and hepatic toxicity through free radical-induced lipid peroxidation

Adverse Reactions No systemic adverse effects described in humans although there is one report of a liver tumor associated with a 6-year hexachloroethane exposure; liver and kidneys are target organs for pathology in animals; neurotoxicity (ataxia and tremor) has also been noted; not fetotoxic in rodent models; blepharospasm, lacrimation, and photophobia noted to fume exposure; alpha 2u-globulin nephropathy

Toxicodynamics/Kinetics

Absorption: Limited from inhalation or dermal routes. Oral absorption: 50% to 88%

Metabolism: Hepatic to tetrachloroethane and pentachloroethane

Overdosage/Treatment

Decontamination: **Oral:Do not** induce emesis. Lavage (within 1 hour)/activated charcoal; **do not** administer milk or cream in that it can increase absorption. **Dermal:** Remove contaminated clothing; wash with soap and water. **Ocular:** Irrigate copiously with saline.

Supportive therapy: Although there is no experience in this toxicity, N-acetylcysteine may have a theoretical role in reducing hepatotoxic effects.

Enhancement of elimination: Although there is no experience in this toxicity, hemodialysis may play a role in enhancing elimination of hexachloroethane in patients developing renal failure.

Additional Information Hexachloroethane is a metabolite of carbon tetrachloride. Odor threshold: Air: 0.015 ppm (camphoraceous); water: 0.01 mg/L. Background air level in northern hemisphere: 5-7 ppt. Water half-life: 1 year. TLV-TWA: 1 ppm

Hexamethylene Diisocyanate

CAS Number 822-06-0

UN Number 2281

U.S. Brand Names Desmodur H; Mondur HX

Synonyms HDI; HMDI

Use Production of plastics, synthetic rubber, varnishes, lacquers, paints (hardener in automobile and airline paint), wire insulation, polyurethane foam and glues

Mechanism of Toxic Action Respiratory tract irritant which can induce bronchospasm

Adverse Reactions

Cardiovascular: Chest tightness, cor pulmonale

Central nervous system: Fever, headache, fatigue

Hematologic: Leukocytosis

Respiratory: Bronchospasm, wheezing, cough, bronchitis, laryngitis, nasal irritation, dyspnea

Admission Criteria/Prognosis Admit any symptomatic patient; asymptomatic patients may be discharged after 6 hours of observation

Toxicodynamics/Kinetics

Absorption: By dermal, inhalation and oral routes

Metabolism: 1,6-hexamethylene diamine (HDA)

Half-life (HDA): 1.2 hours

Elimination: Renal

Monitoring Parameters Arterial blood gas, chest x-ray

Overdosage/Treatment

Decontamination: **Dermal:** Flush skin with soap and water. Isopropyl alcohol can also be used to help decontaminate intact skin. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate with saline.

Supportive therapy: For treatment of bronchoconstriction, administer inhaled beta-agonist agents.

Additional Information Concentrations >0.02 ppm can cause severe respiratory symptoms.

Pale yellow liquid with a pungent odor. Density: ~1.05 g/mL. Odor threshold in air: 0.001-0.02 ppm. Atmospheric half-life: 2 days. Rapidly hydrolyzed in water (water half-life: 10 minutes). TLV-TWA: 0.005 ppm

Hexane

CAS Number 110-54-3

UN Number 1208

Synonyms Dipropyl; Hexyl Hydride; Skellysolve B

Commonly Found In Production of glues, adhesives, paints, shoes, and furniture; component of crude oil

Mechanism of Toxic Action Metabolite 2,5-hexanedione is neurotoxic; 2-methyl pentone leads to hexone

Adverse Reactions

Cardiovascular: Tachycardia, sinus tachycardia
 Central nervous system: CNS depression, axonopathy
 Ocular: Visual evoked potential abnormalities
 Respiratory: Respiratory depression

Signs and Symptoms of Overdose Blurred vision, dyspnea, lacrimation, muscle cramps, ototoxicity, upper airway irritation, tinnitus, peripheral sensorimotor neuropathy; muscle wasting/atrophy (peripheral muscles are affected first). Exposure to 500 ppm of hexane over several months can lead to peripheral neuropathy.

Admission Criteria/Prognosis Symptomatic patients or patients with abnormal chest x-rays should be admitted

Toxicodynamics/Kinetics

Absorption: Through the skin (within 30 minutes), GI tract, and lungs
 Metabolism: To 2,5-hexanedione
 Half-life: 1.5-2 hours
 Elimination: Excreted renally

Reference Range Urine concentration of 2,5-hexanedione should be <5 mg/L; background blood hexane concentrations in unexposed adults range from 0.02-7.7 mcg/L (average: 0.6 mcg/L); it has been estimated that ~3 mg hexanedione per gram creatinine corresponds to inhalation daily exposure of 50 ppm of hexane

Overdosage/Treatment Decontamination: **Oral:** Lavage within 1 hour; dilute with 4-8 oz of milk or water. **Dermal:** Wash skin with soap and water. **Inhalation:** Administer 100% humidified oxygen.

Drug Interaction Acetone may potentiate neurotoxicity of hexane

Additional Information

Parkinsonism may occur with chronic exposure, along with a sensory polyneuropathy and memory deficits.

A colorless liquid with a faint odor; insoluble in water. Odor threshold: 0.0064 mg/L in water and 130 ppm in air. Estimated half-life in pond water: 2.7 hours to 6.8 days. TLV-TWA: 50 ppm

Ambient atmospheric hexane levels in urban areas: 1.6-5.5 ppb; hexane comprises ~2% of volatile organic compounds in urban air from combustible sources

HMX**Related Information**

- RDX

Applies to Plastic Explosives; Rocket Fuel Propellant

CAS Number 2691-41-0

UN Number 0226

Synonyms Cyclotetramethylenetetranitramine; High Melting Explosive; Octogen

Use Explosive polynitramine which is primarily used in nuclear devices to implode fissionable material; also used as a solid rocket fuel propellant and in plastic explosives; also used to implode fissionable materials in nuclear devices to achieve critical mass; primarily produced in the U.S. at the Holston Army Ammunition Plant in Kingsport, Tennessee

Mechanism of Toxic Action Essentially not known but may involve its toxic metabolites nitrite, hydrazines, and formaldehyde

Adverse Reactions No documented adverse effects to exposure in humans have been described; in animals, this toxin appears to act as a neurological stimulant at oral doses over 1500 mg/kg; methemoglobinemia, mild skin irritation

Signs and Symptoms of Overdose Seizures

Toxicodynamics/Kinetics

Absorption: Oral: Poor (<5% in animals); peak absorption: 6-10 hours
 Metabolism: To nitrites and then nitroreduction to hydrazines
 Elimination: Renal, expired air, fecal (primarily oral ingestion)

Reference Range Measured blood octogen level of 2.5 mg/L associated with seizure

Overdosage/Treatment

Decontamination: **Oral:** Emesis (within 30 minutes) or lavage (within 1 hour); activated charcoal may help reduce absorption. **Dermal:** Wash with soap and water. **Do not** use oils since they may increase absorption. **Ocular:** Irrigate with saline.

Supportive therapy: Methylene blue for symptomatic methemoglobinemia or methemoglobin levels >30%; benzodiazepines/phenobarbital for seizures

Additional Information

Colorless, odorless, solid crystals
 Explodes at high temperatures (over 279°C); not usually found in air; essentially insoluble in water (5 mL/L at 25°C). Photolytic half-life in water: 1-70 days
 EPA lifetime drinking water standard: 400 mcg/L

Specific References

Testud F, Descotes J, and LeMeur B, "Acute Occupational Poisoning by Octogen: First Case Report," *Clin Toxicol*, 2006, 44:189-90.

Hydrazine

Applies to Corrosion Inhibitor; Laboratory Reagent; Mirrors (Silvering); Pesticides; Pharmaceutical Agents (Production); Photography; Rocket Fuel; Scavenging Agent for Oxygen; Soldering Flux

CAS Number 302-01-2

UN Number 2029; 2030

U.S. Brand Names Levoxin®; Oxytreat 35®; Zerox®

Synonyms Anhydrous Hydrazine; Diamide; Diamine

Use Commonly used as a rocket fuel, laboratory reagent, soldering flux, photography, silvering of mirrors and inhibitor of corrosion; also used in preparation of pharmaceutical agents, pesticides, and as a scavenging agent for oxygen; had been used (unapproved) as medication for sickle cell disease and cancer

Mechanism of Toxic Action Hydrazines are direct cellular toxins which also produce a pyridoxine deficiency by binding to vitamin B₆ derivatives and thus inhibiting reactions that require vitamin B₆ as a cofactor

Adverse Reactions

Cardiovascular: Hypotension (due to myocardial depression), fibrillation (atrial), shock, flutter (atrial), congestive heart failure, facial edema

Central nervous system: Fever, coma, headache, ataxia, seizures

Dermatologic: Dermal irritant, eczema, photosensitivity. Burns (>2.5% concentration)

Gastrointestinal: Anorexia, vomiting, nausea, salivation

Genitourinary: Renal failure

Hematologic: Hemolysis, methemoglobinemia (monomethylhydrazine)

Hepatic: Hepatotoxicity (fatty degeneration), hepatic failure

Neuromuscular & skeletal: Arthralgia, tremor

Ocular: Eye irritation, nystagmus, mydriasis

Respiratory: Dyspnea, pulmonary edema, rhinitis, cough

Miscellaneous: Cutaneous T-cell lymphoma, periarteritis nodosa, systemic lupus erythematosus

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Toxicodynamics/Kinetics

Absorption: By oral, inhalation, and dermal routes

Half-life: 2 hours

Metabolism: Hepatic to acetyl hydrazine, diacetyl hydrazine, and pyruvate hydrazine (through binding with ketoacids)

Elimination: Renal

Overdosage/Treatment

Dermal: Irrigate with water

Decontamination: **Oral:** Do not induce emesis; lavage (within 1 hour)/activated charcoal. **Ocular:** Hydrazine hydrate is a strong corrosive alkali agent, need to irrigate copiously with saline

Supportive therapy: Pyridoxine hydrochloride (25 mg/kg I.V.) may be antidotal for coma or seizures. Methylene blue can be used for symptomatic methemoglobinemia due to monomethylhydrazine.

Enhancement of elimination: Force urine diuresis (with the addition of mannitol); may increase the clearance of hydrazine

Antidote(s)

- Methylene Blue [ANTIDOTE]
- Pyridoxine [ANTIDOTE]

Additional Information Symptoms may be delayed for 14 hours following skin exposure. Weak ammonia odor threshold: 3.7 ppm (ammonia gas odor). Water and atmospheric half-life: <2 hours. TLV-TWA: 0.1 ppm; IDLH: 80 ppm: Does not react to water.

Specific References

Keyes DC, Shepherd G, Borys D, et al, "Space Shuttle Columbia Disaster: Utilization of Poison Centers," *J Toxicol Clin Toxicol*, 2003, 41(5):688.

Hydrogen Chloride

Applies to Rubber; Vinyl Chloride

CAS Number 7647-01-0

UN Number 1050; 1789

Synonyms Chlorohydric Acid; Hydrochloride; Muriatic Acid; Spirits of Salt
Use In the manufacture of vinyl chloride and rubber; a combustible product of vinyl chloride (PVC); Metal/toilet bowl cleaner

Mechanism of Toxic Action Corrosive through strong acidity to the skin, eyes, nose, respiratory and GI tract; primarily local effects through denatured enzymes, minimal systemic effects; high water solubility leading to upper airway edema

Adverse Reactions

Inhalation:

Cardiovascular: Chest pain, angina, tachycardia

Central nervous system: Chills, hyperthermia, fever

Nasal: Irritation, ulceration, epistaxis

Ocular: Corneal injury, conjunctivitis

Respiratory: Laryngeal spasms, noncardiogenic pulmonary edema (may be delayed for 24-72 hours), reactive airways disease syndrome, cough

HYDROGEN FLUORIDE

Signs and Symptoms of Overdose By inhalation: tachycardia, laryngospasm, hyperchloremic metabolic acidosis, chest tightness, choking sensation, conjunctivitis, cough, dermal burns, dizziness, dyspnea, headache, hemoptysis, nasal ulcerations, nausea

Admission Criteria/Prognosis Patients with cardiopulmonary symptoms should be admitted

Toxicodynamics/Kinetics

Absorption: Not absorbed

Metabolism: Ionized to hydronium and chloride ions

Reference Range Postmortem results of fatality due to hydrogen chloride ingestion are very low blood pH (<5) within 24 hours after death, and elevated Cl⁻ concentration in heart blood (about 200 nmol/L) and gastric contents (about 700 mmol/L - normal value about 100 mmol/L)

Overdosage/Treatment

Decontamination: **Dermal:** Remove contaminated clothing. Wash area with copious amounts of soap and water. **Ocular:** Remove contact lenses; irrigate with saline or water for at least 20 minutes

Supportive therapy: Give 100% humidified oxygen. Treat wheezing with inhaled beta agonists. Corticosteroids may be helpful. I.V. fluids should be administered cautiously to avoid a net positive fluid balance. Dopamine or norepinephrine are vasopressors of choice. Partial liquid ventilation may be useful. Dermal burns can be treated with standard therapy. Inverse-ratio ventilation using lower tidal volume mechanical ventilation (6 mL/kg) and plateau pressures of 30 cm water may decrease mortality. While positive end expiratory pressures should be considered, oxygen toxicity should be monitored. Use of perfluorocarbon partial liquid ventilation and exogenous surfactant in chemical-induced ARDS is investigational.

Additional Information Pungent odor; clear, colorless. Odor threshold: 1-5 ppm. TLV-ceiling: 5 ppm; IDLH: 100 ppm

Throat irritation at 5 ppm. Amounts over 1000 ppm can be fatal within a few minutes. Plant toxicity at 100 ppm

Metal: Incompatible with zinc
pH of 1 N solution is 0.1

Hydrogen Fluoride

Related Information

- Ammonium Bifluoride

Applies to Computer Screen (Production); Etching (Glass/Porcelain); Fluorescent Bulbs (Production)

CAS Number 7664-39-3

UN Number 1052; 1786; 1790

Synonyms Fluohydric Acid; Hydrofluoric Acid

Commonly Found In Automotive cleaning products; production of integrated circuits

Use In etching and cleaning of glass and porcelain; produce computer screen, fluorescent bulbs; refine high octane gasoline

Mechanism of Toxic Action Corrosive, produces heat when exposed to water; binds calcium, potassium, and magnesium; dissociates in tissue to free H⁺ and F⁻ ions; fluoride anion inhibits Na⁺/K⁺ ATPase enzyme

Adverse Reactions

Cardiovascular: Fibrillation (ventricular)

Dermatologic: Dermal burns, onycholysis

Gastrointestinal: Vomiting (with ingestion)

Respiratory: Pneumonitis, hemorrhagic pulmonary edema, reactive airways disease syndrome

Signs and Symptoms of Overdose Bone pain, blistering, burns, diarrhea (22%), pain, pulmonary edema, nausea (22%), skin erythema, vomiting (with ingestion)

Admission Criteria/Prognosis Patients with >1% total body surface area burns, abnormal serum calcium levels, or who do not respond to treatment should probably be admitted; if pain occurs within 1 hour of exposure, patient should probably be admitted; survival after 4 days postexposure usually results in recovery. Note: QT interval may be prolonged for as long as 60 hours. Any ingestion should be admitted.

Toxicodynamics/Kinetics

Onset of action: Immediate corrosive effects although symptoms may be delayed 12-24 hours

Absorption: Inhalation and dermal routes

Half-life: 2-9 hours

Elimination: Renal

Reference Range Normal plasma fluoride levels are <0.1 mcg/L; highest survivable fluoride level after 10 g HF ingestion was 38.4 mg/L

Overdosage/Treatment

Decontamination:

Oral: Dilute with 250 mL of milk or water. Emesis is contraindicated. As first aid, affected extremity can be irrigated with water and bathed in

an iced solution of 25% magnesium sulfate. Give 300 mL of magnesium citrate orally for oral ingestion. Give 20 mL 10% calcium gluconate I.V. for oral ingestion. Magnesium sulfate may also be given I.V. (**do not** use calcium chloride for injection). The total I.V. calcium dose is ~1 g of calcium for each gram of fluoride ingested. Monitor serum calcium every 30 minutes until calcium normalizes. A 2.5% calcium gluconate gel can also be utilized.

Dermal: Remove all contaminated clothing; irrigate with copious amounts of water.

Inhalation: Give 100% oxygen. Nebulized calcium gluconate (4 mL of a 2.5% solution mixed in normal saline and delivered with 100% oxygen as a nebulized treatment) for inhalation exposures, or infiltrate with subcutaneous injection of 0.5 mL of 10% calcium gluconate, or 10% magnesium sulfate with a 30-gauge needle not greater than 0.5 mL/cm².

Ocular: Irrigate with normal saline. **Do not** give calcium gluconate subconjunctivally. Irrigation with 1% calcium gluconate may be also used, but does not appear to have any significant advantage over irrigation with normal saline. Treat for 2 days with topical antibiotics, cycloplegics and corticosteroids.

Supportive therapy: Arterial infusion of dilute calcium concentrations for distal extremity burns may be useful. Suggested dose is 10 mL of 10% calcium gluconate diluted in 50 mL of D₅W infused over a 4-hour period with a pump. Do not infuse magnesium through arterial cannula.

Enhancement of elimination: Hemodialysis may be used to remove fluoride anions.

Antidote(s)

- Amyl Nitrite [ANTIDOTE]
- Calcium Gluconate [ANTIDOTE]
- Magnesium Sulfate [ANTIDOTE]

Diagnostic Procedures

- Electrolytes, Blood

Additional Information

Fatal ingested dose: 1.5 g or 20 mg/kg.

Minimum lethal exposure: 1.5 g (20 mg/kg orally) or 2.5% to 22% total body surface area third degree burns

Concentrations >20% will result in burns becoming apparent within hours. It may take up to 1 day for burns to be apparent following topical exposure to concentrations <20%.

There were 33,795 hydrofluoric acid exposures called into U.S. Poison Centers with 26 deaths reported (1983-8).

Solution: Colorless. Odor threshold: 0.03 mg/m³. TLV-ceiling: 3 ppm; IDLH: 20 ppm; PEL-TWA: 3 ppm

Latex gloves are not protective; as little as 7 mL of anhydrous topical hydrogen fluoride can cause profound hypocalcemia; a 2.5% total body surface burn can be fatal due to electrolyte imbalance

To make calcium gel for dermal exposure to hydrogen fluoride, 3.5 g of calcium gluconate can be added to 5 oz tube of a surgical lubricant (water soluble such as K-Y[®] Jelly); alternatively can be ground into a fine powder and added to 20 mL of surgical lubricant (water soluble such as K-Y[®] Jelly), resulting in a 32.5% slurry. Calcium chloride should not be used for these purposes.

A commercial 2.5% calcium gluconate gel (as "H-F Antidote Gel") is available in 25 g tubes from Pharmascience, Inc. Montreal, Quebec, Canada (514-340-1114); in U.S. at 175 Rano St. Buffalo, NY, 14207 (1-800-207-4477).

Hydrogen Sulfide

Related Information

- Asphalt
- Calcium Polysulfide
- Sulfhemoglobin

Applies to Brewing; Farming; Glue; Lithography; Rayon (Manufacture); Tanning

CAS Number 7783-06-4

UN Number 1053

Synonyms Hepatic Gas; Hydrosulfuric Acid; Sewer Gas; Stink Damp; Sulfureted Hydrogen

Commonly Found In Volcanoes, manure

Use In farming, brewing, tanning, glue making, lithography, rayon manufacture

Mechanism of Toxic Action Inhibition of cytochrome oxidase; irritant

Adverse Reactions

- Cardiovascular: Sinus bradycardia
- Central nervous system: CNS depression, subacute encephalopathy, amnesia
- Dermatologic: Dermal irritation
- Neuromuscular & skeletal: Myoglobinuria
- Ocular: Color vision abnormalities
- Respiratory: Pulmonary edema, respiratory depression, hyperventilation

Signs and Symptoms of Overdose Conjunctivitis, cough, dementia, dyspnea, extrapyramidal symptoms, hypertension, hyposmia, hypothermia, lacrimation, myoglobinuria, nausea, vomiting. Higher concentrations may cause bradycardia, coma, confusion, dizziness, headache, hypotension, paresthesia, rotten egg breath, seizures.

Admission Criteria/Prognosis Symptomatic patients 4 hours postexposure should be admitted; survival after 4 hours is usually associated with recovery

Toxicodynamics/Kinetics

- Absorption: Readily as a systemic toxicant through the lungs and GI tract
- Metabolism: To thiosulfate
- Elimination: Oxidized by hemoglobin and liver and renally excreted

Monitoring Parameters Albuminuria and hematuria; methemoglobin if giving nitrite therapy; sulfhemoglobin levels are of no use

Reference Range Normal whole blood sulfide: <0.05 mg/L; >0.9 mg/L has been correlated with death; serum thiosulfate >1.3 mcg/mL associated with toxicity; serum thiosulfate level > 12 mcg/mL associated with immediate fatality; normal levels of thiosulfate: blood: not detectable; urine: <8 mcg/mL

Overdosage/Treatment

- Supportive therapy: 100% humidified oxygen; hyperbaric oxygen if symptoms do not improve with supplemental oxygen. Amyl nitrate and sodium nitrite (10 mg/kg up to 300 mg) can be given within 15 minutes of exposure (monitor for methemoglobinemia). Do not give sodium thiosulfate. **Dermal:** Wash surfaces with soap and water.
- Enhancement of elimination: For infants, consider exchange transfusion.

Antidote(s)

- Oxygen (Hyperbaric) [ANTIDOTE]
- Sodium Nitrite [ANTIDOTE]

Diagnostic Procedures

- Lactic Acid, Blood
- Methemoglobin, Blood
- Urinalysis

Additional Information

Air levels >800 ppm can be fatal; overall mortality: 2% to 6%. Neurologic sequelae of survivors include intention tremor, amnesia, ataxia

Measurement of sulfhemoglobin or sulfmethemoglobin levels are not clinically useful in hydrogen sulfide poisoning.

Produced by decaying organic matter; colorless; rotten egg odor at levels of 0.0047 ppm; note that olfactory fatigue occurs at 100-150 ppm

Occupations at risk for hydrogen sulfide poisoning: Agriculture (liquid manure systems); fishing; brewers; leather industry (tanning); glue making; rubber vulcanization; geologists; nuclear reactor technicians (heavy water production); natural gas/petroleum/oil (exploration, refining, or transport); felt/artificial silk production; abattoirs; chemist (purification and preparation of phosphorus barium sulfur/sesquisulfide carbonate; organic sulfur); sulfur dye production (brown, black, blue); beet sugar factory; lithography; fertilizer production; sausage production; industrial paper plants (Kraft process); mining (coal, lead, gypsum, sulfur); sewer construction; well/tunnel digging; septic tank cleaning, industrial waste disposal; caisson work; metal smelting; roofing asphalt; pesticide production; rayon production (viscose process). See table.

Hydrogen Sulfide Dose–Effect Relationship	
PPM	Response
0.05	Taste threshold
0.005 to 0.25	Odor threshold
5 to 10	Odor is obvious/muscle fatigability
50 to 150	Ocular irritation
80 to 100	Mild symptoms (nausea, vomiting, salivation, lacrimation)
100 to 150	Olfactory nerve paralysis/fatal to birds and guinea pigs
150 to 300	Blepharospasm, blurred vision
250 to 500	Pulmonary edema/bronchopneumonia
50 to 500	Respiratory irritant
500	Central nervous system depression within 30 minutes

Table (Continued)

PPM	Response
800 to 1000	Lethal level, coma or respiratory arrest within 30 minutes
Over 1000	One single breath can cause coma or respiratory arrest
Work Place Standards	
10	TLV-TWA
15	STEL
300	IDLH
Short-Term Inhalation Limits	
200	10 minutes
100	30 minutes
50	60 minutes

Imazapyr

Applies to Assault; Chopper; Contain; HerbicideArsenal; Pivot

Use An imidazolinone herbicide which blocks the biosynthesis of valine, leucine, and isoleucine through inhibition of the plant enzyme acetylhydroxy acid synthetase

Mechanism of Toxic Action Can cause GI irritation upon ingestion or pulmonary injury from aspiration; it is a weak acid

Signs and Symptoms of Overdose Abdominal pain, coma, elevated bilirubin, fever, hypotension, leukocytosis, liver dysfunction, metabolic acidosis, oral ulcers, renal dysfunction, respiratory distress, stool incontinence, urine incontinence, vomiting

Admission Criteria/Prognosis Admit any ingestion over a mouthful

Overdosage/Treatment Decontamination: **Oral:** Activated charcoal with cathartic for any ingestion over a mouthful. **Ocular:** Irrigate with copious amounts of saline. Supportive therapy: Metabolic acidosis should be treated with 1-2 mEq/kg of sodium bicarbonate I.V.

Additional Information Slight odor of acetic acid

Isofenphos

CAS Number 25311-71-1

U.S. Brand Names Amaze®; Oftanol®

Use Insecticide

Mechanism of Toxic Action Irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Signs and Symptoms of Overdose Bradycardia, bronchorrhea, bronchospasm, diaphoresis, mental confusion, miosis, and salivation usually start within 6 hours of symptoms and may persist for 2 weeks.

Toxicodynamics/Kinetics

- Distribution: V_d: 3.3 L/kg (central compartment); 6.3 L/kg (at steady state)
- Half-life: ~2-3 days
- Clearance: 0.86 L/kg/day

Reference Range Following an injected (I.M.) dose of 21.15 mg/kg, peak plasma isofenphos concentration: 2.25 mg/L and associated with severe muscarinic and nicotinic symptoms

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. **Do not** give a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline

ISOPROPYL ALCOHOL

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to the effectiveness of the prescribed treatment and large volumes of distribution of organophosphates.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.M. or I.V. initially, or ~1/2 the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Isopropyl Alcohol

Applies to Rubbing Alcohol

CAS Number 67-63-0

UN Number 1219

Synonyms Alcojel; Chromar; Dimethyl Carbinol; Isopropanol; Propol; "Blue Heaven"

Commonly Found In Rubbing alcohol (usually 70% concentration), secondary propyl alcohol, solvents in perfumes, paint thinners, cleaners, disinfectants, racing fuels

Mechanism of Toxic Action Metabolized by alcohol dehydrogenase to acetone which contributes to central nervous system depression

Adverse Reactions

Cardiovascular: Congestive heart failure, sinus tachycardia, Reye's-like syndrome

Central nervous system: Ataxia, depression, drowsiness, headache

Dermatologic: Immunologic contact urticaria

Hepatic: Impaired gluconeogenesis

Neuromuscular & skeletal: Areflexia

Miscellaneous: Acute traumatic compartment syndrome

Signs and Symptoms of Overdose Aplastic anemia, coma, feces discoloration (black), hemolytic anemia, hyperglycemia, hypoglycemia, hypotension due to myocardial depression, hypothermia, lethargy, myoglobinuria, porphyria, rhabdomyolysis, tachycardia, vomiting

Admission Criteria/Prognosis Ingestion of > 15 mL of 70% alcohol (3 swallows) in an infant (~1.5 mL/kg) is an indication for admission; any symptomatic patient (within 3 hours postexposure) or with a serum isopropyl alcohol level > 100 mg/dL or with ketosis should probably be admitted

Toxicodynamics/Kinetics

Absorption: Rapid from GI tract or by inhalation; little absorption through intact skin

Distribution: V_d : 0.5-0.7 L/kg

Metabolism: In the liver; 15% metabolized to acetone; acetone is present in serum within 1 hour and in urine within 3 hours of ingestion

Half-life: Isopropyl alcohol: 1-3 hours. Acetone: 17-24 hours

Peak plasma level: 1 hour postingestion

Elimination: Excreted renally, 25% to 50% unchanged

Reference Range

Toxic: > 50 mg/dL

Serum level > 128 mg/dL associated with profound lethargy; death can also occur at this level, but usually occurs at levels > 200 mg/dL if no medical supportive care is available

Overdosage/Treatment

Decontamination: Activated charcoal may be useful when used in a charcoal solvent ratio of 20:1. **Do not** induce emesis with ipecac.

Enhancement of elimination: Hemodialysis in those patients who do not respond to supportive therapy or whose levels exceed 400 mg/dL.

Hemodialysis can clear 137 mL/minute of isopropanol and 165 mL/minute of acetone. Peritoneal dialysis offers no clear benefit.

Diagnostic Procedures

- Glucose, Random
- Osmolality, Serum
- Osmolality, Urine

Test Interactions Acetone and acetoacetate may result in false elevation of serum creatinine at serum acetone levels > 40 mg/dL; serum creatinine rises 1 mg/dL for every 100 mg/dL of acetone

Additional Information Lethal dose: Adults: 240 mL. Serious illness may occur with ingestion of 10 mL; twice as lethal as ethanol. No long-

term sequelae; can cause skin burns when used topically on premature infants. Spirituous odor but a clean colorless liquid; bitter taste. Contribution of a serum concentration level of 100 mg/dL to elevation of osmolar gap: 17. Specific gravity: 0.79 g/mL; IDLH: 20,000 ppm; TLV-TWA: 400 ppm; Odor threshold: 90 mg/mm³

Jet Fuel-4

Related Information

- Stoddard Solvent

Applies to MIL-T-5624-L-Amd 1

CAS Number 50815-00-4

UN Number 1863

Synonyms Jet Fuel: JP-4; JP-4

Use Aviation turbine fuel used by the U.S. military (constitutes 85% of turbine fuel used by Department of Defense)

Mechanism of Toxic Action A mixture of alkanes (43%), cycloalkanes (11%), alkylbenzenes (12%), and naphthalenes (2%) which can cause CNS depression

Adverse Reactions

Central nervous system: Neurologic: headache, dizziness, polyneuropathy (on long-term exposure), ataxia, panic attacks

Dermatologic: Dermal irritant

Gastrointestinal: Nausea

Neuromuscular & skeletal: Weakness (at inhalation levels between 3000-7000 ppm)

Renal: Alpha₂I-globulin nephropathy

Admission Criteria/Prognosis Patients who develop tachypnea, cyanosis, dyspnea, CNS depression, tachycardia, or fever within 8 hours of exposure should be admitted; asymptomatic patients can be discharged after 8 hours observation

Overdosage/Treatment

Decontamination: **Oral:** **Do not** induce emesis or lavage due to risk of aspiration pneumonia. Activated charcoal can adsorb benzene. **Dermal:**

Wash with soap and water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Flush with saline or water for at least 15 minutes.

Supportive therapy: Benzodiazepines for seizure control; avoid use of catecholamines due to risk of ventricular arrhythmia

Additional Information Odor threshold: 1 ppm; PEL-TWA: 400 ppm

Specific References

Wright BR, "Hydrocarbon Fuels," *Forensic Examiner*, 2004, 13(2):16-9.

Jet Fuel-5/Jet Fuel-8

CAS Number 70892-10-3; 8008-20-6

UN Number 1223

Synonyms Aviation Kerosene; JP-5; JP-8; Nato F-34; NATO F-44

Use Aviation fuel with higher kerosene content than Jet Fuel-4. Jet Fuel-5 is used by the United States Navy for use aboard aircraft carriers and also used on surface ships. Jet Fuel-8 is used by the United States Air Force and NATO forces.

Mechanism of Toxic Action Kerosene-based organic solvent causing CNS depression and bronchoconstriction by acting on the vagus nerve and inhibiting acetylcholinesterase

Adverse Reactions

Cardiovascular: Palpitations, hypertension (mild), tachycardia, cardiomegaly

Central nervous system: Ataxia, concentration difficulties, headache, dizziness, fatigue, fever, coma

Dermatologic: Blisters, erythema, peeling skin, pruritus

Gastrointestinal: Nausea, anorexia, vomiting

Hematologic: Leukocytosis

Ocular: Eye irritation

Renal: Alpha 2u-globulin nephropathy

Respiratory: Aspiration pneumonia, bronchitis, cough, dyspnea, tachypnea, bronchoconstriction, pulmonary edema, pneumothorax, lipoidal pneumonia

Miscellaneous: Neurasthenia

Admission Criteria/Prognosis Admit any symptomatic patient; fever may be a prognostic sign for pulmonary involvement; any patient with fever, abnormal chest x-ray, dyspnea, history of spontaneous emesis, or mixed ingestion should be admitted; ingestions > 1 mL/kg and/or any symptomatic patient 6 hours postexposure should be considered for admission

Toxicodynamics/Kinetics Absorption: By inhalation, oral and dermal routes

Monitoring Parameters Arterial blood gases, chest x-ray (2 hours after ingestion), prothrombin time, liver function tests

Overdosage/Treatment

Decontamination:

Oral: Do not consider gastric emptying if the amount ingested is < 100 mL. While some studies suggest ipecac-induced emesis in the alert patient, gastric lavage with airway protection may also be used. Activated charcoal may be useful (although human data is lacking). Saline-based cathartics may be used.

Dermal: Flush skin with soap and water; if blisters develop, use sterile water.

Inhalation: Administer 100% humidified oxygen.

Ocular: Irrigate with saline.

Supportive therapy: Selective beta₂ agonists (inhaled) can be used to treat bronchospasm. Antibiotics or corticosteroids are not useful (prophylactically) in treating pneumonitis. Extracorporeal membrane oxygenation can be considered if respiratory failure occurs.

Drug Interaction Asbestos may increase toxicity of kerosene based fuels

Additional Information Both jet fuels are clear liquids with kerosene-like odor. Benzene content: <0.02%. Odor threshold: 0.08 ppm. Density: ~0.8 kg/L. Aromatic content of JP-8: 14.5% to 18.8%.

Specific References

Kerosene

Related Information

- Jet Fuel-5/Jet Fuel-8

Applies to Mobil Oil Cooling System Cleaner

CAS Number 70892-10-3; 8008-20-6

UN Number 1223

U.S. Brand Names Deobase®

Synonyms Coal Oil; Fuel Oil Number 1; Kerosine; Range Oil; Straight Run Kerosene

Use Originally produced for jet fuel engine; domestic heating; illuminating fuel; a vehicle in pesticides and lighter fluid; solvent in paints

Mechanism of Toxic Action A product of straight-run distillation of crude petroleum, kerosene is a hydrocarbon with low viscosity and low volatility which can produce a pneumonitis upon aspiration

Adverse Reactions

Cardiovascular: Tachycardia, cardiomegaly, cyanosis, chest pain

Central nervous system: Fatigue, sleep disturbances, dizziness, headache, coma, fever, irritability, ataxia, cognitive dysfunction

Dermatologic: Erythema, bullae, pruritus, blisters, acne, eczema

Gastrointestinal: Vomiting, hematemesis, abdominal pain

Hematologic: **Leukocytosis** (37% to 80%)

Hepatic: Hepatotoxicity, cirrhosis

Respiratory: Pneumonitis, aspiration pneumonia, pleural effusion, lipoidal pneumonia, pneumothorax, emphysema, cough, dyspnea

Admission Criteria/Prognosis Any patient with fever, abnormal chest x-ray, dyspnea, history of spontaneous emesis, or mixed ingestion should be admitted; ingestions > 1 mL/kg and/or any symptomatic patient 6 hours postexposure should be considered for admission

Toxicodynamics/Kinetics Absorption: Dermal, oral and inhalation absorption can occur

Monitoring Parameters Arterial blood gases, chest x-ray (2 hours after ingestion), prothrombin time, liver function tests

Overdosage/Treatment

Decontamination:

Oral: Very controversial; certainly it is generally agreed that in ingestions of small amounts (< 30 mL in children), no gastrointestinal decontamination should occur.

Due to the relative lack of CNS toxicity of kerosene, it is probably not efficacious to perform gastric evacuation for a pure kerosene ingestion. If a toxic additive (ie, benzene, insecticide, heavy metal, etc) is ingested, emesis with syrup of ipecac within 30 minutes (in an alert individual who has not vomited), or gastric lavage within 1 hour, may be performed. Activated charcoal is probably of some use. Avoid use of mineral oil cathartics.

Dermal: Wash liberally with soap and water.

Ocular: Irrigate eyes copiously with saline or water.

Supportive therapy: Prophylactic administration of antibiotics and/or corticosteroids does **not** appear to be useful. Avoid catecholamine use due to the risk of precipitating cardiac arrhythmia.

Respiratory failure: Extracorporeal membrane oxygenation can be considered.

Drug Interaction May increase sedative properties of hexobarbital

Additional Information

Minimum lethal oral dose: 1890 mg/kg

Toxic inhalation dosage: 0.1-0.2 mL. Maximum tolerated oral exposure: 1700 mg/kg.

Oral ingestion of 10-30 mL can result in pulmonary complications in 2% to 3% of individuals.

Hypoprothrombinemia may be the earliest laboratory indicator for liver dysfunction.

Note that use of kerosene space heaters can result in increased emission rates of carbon monoxide (average of 7.4 ppm).

Specific gravity: 0.8. Odor threshold: 0.08-1 ppm

Kratom

Scientific Name *Mitragyna speciosa*

Use As an opium substitute; the tree is native to Thailand and Malaysia. Used as a tea, or the leaves can be chewed or smoked. Typical tea dose is 10-15 g.

Mechanism of Toxic Action Contains mitragynine, an indole alkaloid that is similar to psilocybin and is a μ - and Δ -subtype receptor agonist (about 10% of the action of morphine)

Signs and Symptoms of Overdose Coma, vertigo, lethargy, tremors, nausea, vomiting, can be a stimulant (at doses of mitragynine > 50 mg), miosis, constipation, doses > 25 g of kratom leaves can be toxic.

Overdosage/Treatment Supportive care: Supportive care is mainstay of therapy. Mild withdrawal syndrome with chronic use may occur.

Pregnancy Implications Effects not known

Additional Information Alkaloids resemble yohimbine; illegal in Australia, Cambodia, Malaysia, Myanmar, and Thailand. Exhibits psychoactive properties; typical effects last for 2-6 hours

Specific References

Matsumoto K, Horie S, Ishikawa H, et al, "Antinociceptive Effect of 7-Hydroxymitragynine in Mice: Discovery of an Orally Active Opioid Analgesic from the Thai Medicinal Herb *Mitragyna speciosa*," *Life Sci*, 2004, 74:2143-55.

Lead

CAS Number 10031-22-8; 10101-63-0; 13424-46-9; 13814-96-5; 301-04-2; 7439-92-1; 7758-95-4; 7758-97-6

UN Number 1616; 2291; 2811

Use Lead is available in 19 inorganic and 2 organic compounds; common sources (especially for children) are air, water, soil, and leaded paint chips. Use of tap water (as "first-drawn" or with excessive boiling or stored in lead-based kettles) in reconstituting infant formulas for infants; additional sources/uses include leaded foreign bodies such as bullet fragments, numerous imported Asian products, herbal/folk remedies, Mexican remedies for "empacho" and home abortifacients; recreational sources include lead-based cosmetics, contamination of illicitly distilled alcohols or illicit intravenous drug products, leaded gasoline "sniffing", and even chewing colored plastic wires.

Mechanism of Toxic Action

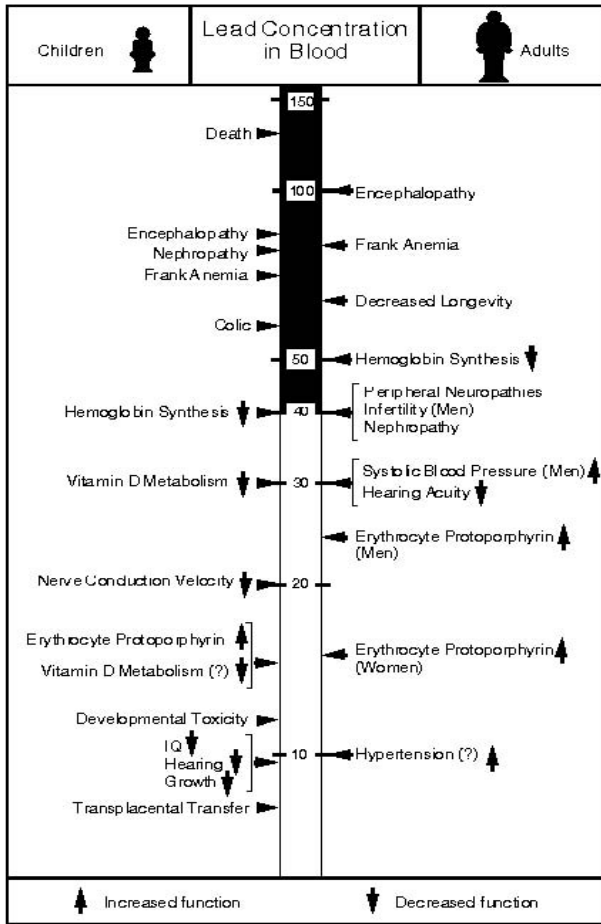

Lead's effects are mediated by its ability to complex sulfhydryl groups and other ligands, in enzyme systems throughout the body

Alkyl lead is moderately irritating. Hemoglobin biosynthesis is affected by inhibition of Delta aminolevulinic acid synthetase and dehydrase, Coproporphyrinogen decarboxylase and Ferrochelatase thus leading to increase, in protoporphyrine. Red Blood cell survival time is shortened. Renal lesions in proximal tubule and loop of Henle occur leading to renal insufficiency. Degenerative changes in motoneurons (axons) and encephalopathic changes in nervous system are target sites

Adverse Reactions

Lead toxicity occurs in the acute, acute-on-chronic, or chronic settings secondary to environmental, occupational, intentional, or recreational activities. Acute exposures are commonly associated with symptoms of malaise, nausea, vomiting, myoclonus, metallic taste, fasciculations, abdominal pain; severe exposures can result in encephalopathy, and death; chronic exposures manifest with neuropsychiatric symptoms, anemia, renal dysfunction/chronic failure, hypertension, arthralgias, teratogenesis, and impotence. See chart.

**Effects of Inorganic Lead on Children and Adults--
Lowest Observable Adverse Effect Levels**

Note that blood levels are usually > 40 µg/dL when anemia is recognized (ie, an apparently normal CBC does not rule out plumbism).
Adapted from U.S. Department of Health and Human Services, Royce SE and Needleman HL, eds, "Case Studies in Environmental Medicine: Lead Toxicity," Agency for Toxic Substances and Disease Registry, June 1990.

Distribution: Three compartment model predominantly stored in bones (90%), lead is also found in brain, kidney, and liver tissue; blood lead (< 1% body stores) is 95% intracellular
Half-life: blood: 28-36 days; soft Tissues: 30-40 days
Elimination: Elimination rates between the three compartments vary from ~40 days for blood and soft tissues to 20-30 years for bone stores; blood contains about 4% of total body burden of lead

Monitoring Parameters Lead concentrations, erythrocyte protoporphyrin, KUB, potassium x-ray fluorescence, CBC, creatinine, electrolytes, CNS effects

Warnings/Precautions After chelation, especially in chronic toxicity, redistribution of lead into blood and soft tissues leads to a "rebound" in lead concentrations; also failure to remove the patient from the source(s) of lead will prevent adequate response to chelation therapy

Reference Range

Asymptomatic and whole blood lead concentrations of > 10-25 mcg/dL is an indication for the initiation of community prevention programs, 25-50 mcg/dL with positive LMT is an indication for EDTA, > 45 mcg/dL is an indication for succimer, and > 50 mcg/dL is an indication for BAL and EDTA; lead mobilization test (LMT); this test is performed by administering 500 mg/m² of CaNa₂-ethylenediaminetetraacetic acid (EDTA) and then collecting urine for 8 hours; a positive result is defined as determining a ratio of urinary lead/dose EDTA > 0.6 or a total urinary excretion of > 200 mcg of lead

Inhibition of hemoglobin Synthesis is reflected by an Erythrocyte protoporphyrin blood level over 35 ug/dl, and may lag in respect to lead exposure by up to six weeks

See chart for the CDC's action level for blood lead in children.

Centers for Disease Control's Action Level for Lead Over Past 35 Years

Adapted from Health and Human Services, "Case Studies in Environmental Medicine: Lead Toxicity," Agency for Toxic Substances and Disease Registry, June 1990.

Cardiovascular: Sinus bradycardia, cardiomyopathy, cardiomegaly, vasoconstriction, Reye's-like syndrome

Central nervous system: Ataxia, encephalopathy, headache, learning disabilities, drowsiness, dementia, mood and/or mental status changes, seizures, memory disturbance, catatonia, CNS depression, depression, psychosis, fever, hyperthermia, aggressive behavior

Endocrine & metabolic: Growth suppression, syndrome of inappropriate antidiuretic hormone, hypermineralization

Gastrointestinal: Abdominal pain, colic, constipation, nausea, vomiting, sweet taste

Hematologic: Anemia (at lead levels > 40 mcg/dL), hemolysis

Hepatic: Hepatitis

Neuromuscular & skeletal: Arthralgia, paresthesia, rhabdomyolysis

Ocular: Blurred vision, diplopia, optic neuropathy, color vision abnormalities, visual evoked potential abnormalities

Renal: Proteinuria, hematuria, chronic renal failure due to interstitial nephritis, acute tubular necrosis, renal cell cancer

Signs and Symptoms of Overdose

Mild toxicity: Drowsiness, irritability, mild fatigue, myalgia or paresthesia, occasional abdominal discomfort

Moderate toxicity: Arthralgia, constipation, deafness, difficulty concentrating, diffuse abdominal pain, general fatigue, headache, muscular exhaustibility, tremor, vomiting, weight loss

Severe toxicity: Blindness, colic (intermittent, severe abdominal cramps), cranial nerve palsies, encephalopathy (may abruptly lead to seizures, changes in consciousness, coma, and death), lead line (blue-black) on gingival tissue, paresis or paralysis

Admission Criteria/Prognosis Any symptomatic patient, or blood lead level > 60 mcg/dL, or free erythrocyte porphyrin level > 7 times normal (> 35 mcg/dL), or radiopacities in gastrointestinal tract on KUB, should be admitted; mortality in patients with lead encephalopathy approaches 25% with 50% of survivors exhibiting permanent neurological deficits

Toxicodynamics/Kinetics

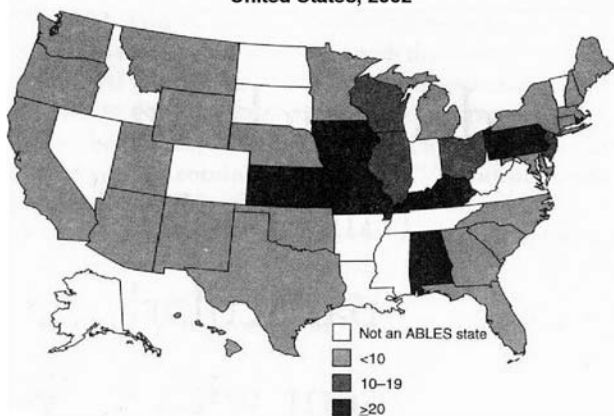

Absorption: Pulmonary absorption is 30% to 85%; gastric absorption is 5% to 15% in adults and up to 40% in children; gastric absorption can increase to 50% in the presence of calcium, iron, and zinc deficiencies and is also increased in pregnancy

Number of Workers with Elevated Blood Levels (BLLs) by Industry Adult Blood Lead Epidemiology and Surveillance (ABLES) Program*, 2002

Industry (Standard Industrial Classification [SIC])	≥ 25 mcg/dL	≥ 40 mcg/dL
Manufacture of storage batteries (SIC 3691)	1494	141
Painting, paperhanging, and decorating (SIC 1721)	863	236
Mining of lead and zinc ores (SIC 1031)	522	70
Secondary smelting (SIC 3341)	384	63
Wholesale distribution of electrical apparatus and equipment, wiring supplies, and construction materials (SIC 5063)	351	55
Manufacture of primary batteries (SIC 3692)	209	15
Bridge tunnel and elevated highway construction (SIC 1622)	149	16
Special trade contractors (eg, lead abatement workers) (SIC 1799)	144	33
Primary smelting (SIC 3339)	121	17
Auto repair shops (eg, radiator repair) (SIC 7539)	106	24

*A total of 27 of 35 ABLES states reported; eight states (Alabama, Arizona, Georgia, Kentucky, North Carolina, Pennsylvania, Rhode Island, and Wyoming) did not track BLLs by SIC code.

Rate* of Adult Blood Lead Levels ≥ 25 mcg/dL, By State - Adult Blood Lead Epidemiology and Surveillance Program†, United States, 2002

* Per 100,000 employed persons aged ≥ 16 years, according to the Bureau of Labor Statistics' Current Population Survey.

† Alabama, Arizona, California, Connecticut, Florida, Georgia, Hawaii, Illinois, Iowa, Kansas, Kentucky, Maine, Maryland, Massachusetts, Michigan, Minnesota, Missouri, Montana, Nebraska, New Hampshire, New Jersey, New Mexico, New York, North Carolina, Ohio, Oklahoma, Oregon, Pennsylvania, Rhode Island, South Carolina, Texas, Utah, Washington, Wisconsin, and Wyoming.

Average State Rate* of Adult Blood Lead Levels (BLLs), By Year - Adult Blood Lead Epidemiology and Surveillance Program†, United States, 1994-2002

* Per 100,000 employed persons aged ≥ 16 years, according to the Bureau of Labor Statistics' Current Population Survey. The average is determined by first calculating individual state rates for each year, and then calculating the average.

† Alabama, Arizona, California, Connecticut, Florida, Georgia, Hawaii, Illinois, Iowa, Kansas, Kentucky, Maine, Maryland, Massachusetts, Michigan, Minnesota, Missouri, Montana, Nebraska, New Hampshire, New Jersey, New Mexico, New York, North Carolina, Ohio, Oklahoma, Oregon, Pennsylvania, Rhode Island, South Carolina, Texas, Utah, Washington, Wisconsin, and Wyoming.

Overdosage/Treatment

Decontamination: Prehospital ipecac within 30 minutes, otherwise gastric lavage within 1 hour or whole bowel irrigation (especially if abdominal radiograph is positive for lead ingestion)

Antidotes:

BAL indicated for: Any encephalopathic patient for at least one 5-day treatment course; any other symptomatic patient for at least one 3-day treatment course; any asymptomatic patient with a lead concentration of 70 mcg/dL

EDTA indicated for: Any patient receiving BAL at least 4 hours after the initial BAL dose; as single agent, for any asymptomatic patient with a lead concentration of > 45 mcg/dL; any patient with lead concentrations between 25-55 mcg/dL with the lead mobilization test

Succimer indicated for: Asymptomatic patients with blood lead concentrations > 45 mcg/dL; encephalopathic patients with contraindications to BAL therapy

Penicillamine indicated for: Any patient unable to receive or tolerate BAL, EDTA, and succimer

Supportive: Seizures should be treated with diazepam: Children: 0.1-0.3 mg/kg slowly; Adults: Up to 10 mg I.V. may repeat if necessary. For cerebral edema, controlled ventilation (keeping CO₂ arterial pressure between 25-30 mm Hg) along with an osmotic diuretic (ie, mannitol) may be helpful. Urine output should be maintained at 1-2 mL/kg/hour, but forced diuresis should not be utilized.

Enhancement of elimination: Succimer: Lead complex is hemodialyzable, there is no other effective use for elimination enhancement

procedures in lead poisoning. When hemodialysis is combined with chelation with EDTA, the plasma half-life of lead decreases from 9-6 hours to 9 hours, as compared with EDTA chelation alone. Exchange transfusion may be helpful in patients with acute elevation of lead levels (> 100 mcg/dL).

Antidote(s)

- Dimercaprol [ANTIDOTE]
- Edetate Calcium Disodium [ANTIDOTE]
- Penicillamine [ANTIDOTE]
- Succimer [ANTIDOTE]
- Unithiol [ANTIDOTE]

Diagnostic Procedures

- Heavy Metal Screen, Blood
- Lead, Blood
- Lead, Urine

Pregnancy Implications The adverse effect on fetal neuro-development due to fetal lead exposure is most pronounced during the first trimester.

Additional Information

Long-term lead exposure can lead to renal impairment and hypertension in middle-aged men. Suggestion of an association between gliomas and occupational lead exposure (blood lead levels > 1.4 μ mol/L) has recently been noted. Lead appears to decrease erythropoietin production.

Three hallmarks of lead-induced immunotoxicity

1. Suppression of the Th1-dependent delayed-type hypersensitivity response as well as production of Th1 cytokines
2. Elevate production of IgE antibodies
3. Macrophage modulation into increased production of proinflammatory cytokines

Tibial x-ray fluorescence (XRF) provides an estimate of cumulative lead exposure.

Urinary N-acetyl-3-D-glucosamidase activity may be a sensitive but nonspecific marker for lead-induced renal tubular damage. Equation for calculating blood lead levels from a single route of exposure is:

Lead concentration (mcg/dL = daily exposure of lead (mcg) \times fractional absorption divided by 3.3)

Between 1976 and 1999, mean blood lead levels in pediatric patients (younger than 6 years of age) have decreased from 13 mcg/dL (0.66 μ mol/L) to 2.0 mcg/dL (0.15 μ mol/L). Prevalence of blood lead levels > 10 mcg/dL (0.48 μ mol/L) in non-Hispanic Blacks is estimated to be 21.9% for those living in housing built before 1946 and 13.7% for those residing in housing built between 1946-73.

1 mcg/dL = 0.0483 μ mol/L

In 1991, 9% of children in the U.S. had blood lead levels ≥ 10 mcg/dL. Lead intoxication has been observed in children but rarely in adults in a residential setting. The following table shows the average daily intake of lead over a 10-year span in children and adults. See table.

Daily Average Intake of Lead* (mcg lead/day)						
Age	Year					
	1980	1982	1984	1986	1988	1990
6-11 mo	~ 34	20	16.7	10	5	3.8
2 y

*Adapted from U.S. Department of Health and Human Services, *Toxicological Profile for Lead, TP 92/12*, Agency for Toxic Substances and Diseases Registry, April, 1993.

The following table shows the average daily intakes of lead for adults, based on an analysis of 27 market basket samples taken nationwide for a 1980-82 Total Diet Study.

Food Group	Average Adult Intake (mcg/d)
Dairy products	4.54
Meat, fish, and poultry	4.09
Grain and cereal products	9.84
Potatoes	1.39

LEAD

Table (Continued)	
Food Group	Average Adult Intake (mcg/d)
Leafy vegetables	0.94
Legume vegetables	9.18
Root vegetables	1.39
Garden fruits	4.44
Fruits	10
Oils and fats	1.23
Sugar and adjuncts	2.34
Beverages	6.86
Total lead intake per day	56.5

Lead has been detected in a variety of foods; typical concentrations of lead in various foods are listed in the table.

Food Group	Concentration (mcg/g)
Dairy products	0.003-0.083
Meat, fish, and poultry	0.002-0.159
Grain and cereal products	0.002-0.136
Vegetables	0.005-0.649
Fruit and fruit juices	0.005-0.223
Oils, fats, and shortenings	0.002-0.028
Sugar and adjuncts	0.006-0.073
Beverages	0.002-0.041 (mcg/L)

PEL-TWA: 0.05 mg/m³

Action level in drinking water: 0.015 mg/L

Action level for home water lead amounts are 15 ppb for first draw water and 5 ppb for purged-line water (water that has run for at least 1 minute) In Illinois, 2231 cases of adult lead poisoning were reported in 1994 (up 43% from 1993). Overall in the United States, an estimated 900,000 workers are exposed to lead on the job.

Sources of lead exposure:

Occupational: Auto repairers, battery manufacturers, bridge reconstruction workers, construction workers, gas station attendants, glass manufacturers, lead miners, lead smelters and refiners, plastic manufacturers, plumbers, pipe fitters, policemen, printers, rubber product manufacturers, shipbuilders, steel welders or cutters

Environmental: Ceramicware, lead containing paint, leaded gasoline, plumbing leachate, soil/dust near lead industries, roadways, lead painted homes

Hobbies & related activities: Car or boat repair, glazed pottery making, home remodeling, lead soldering (eg, electronics), painting, preparing lead shot, fishing sinkers, stained glass making, target shooting at firing ranges; pool cue chalk may contain more than 500 ppm of lead

Substance use: Cosmetics, folk remedies, gasoline "huffing", health foods, moonshine whiskey

OSHA requires removal of any adult employee with blood lead levels ≥ 50 mcg/dL

OSHA Interim Final Standard for Lead in Construction (permissible lead exposure limit) is 50 mcg/m³

Current CDC recommendations for allowable lead concentration: Surface paint: $\leq .06\%$ lead; Household soil and dust: < 1000 ppm lead; Tap water: < 15 ppm lead; Household floor dust: 200 mcg/sq ft; Household window sill dust: 500 mcg/sq ft; Household window well dust: 800 mcg/sq ft

Some types of imported plastic miniblinds contain as much as 2,874 mcg/sq ft (Federal Housing and Urban Development Child-Safety limit is 500 mcg/sq ft of window sill); other sources for lead include imported (from China) crayons, bulk water tanks, wrappers from certain brands of Mexican candy, pool cue chalk and folk-remedy powders (ie, azarcon, greta)

Lead dust can be removed by scrubbing with water plus a phosphate detergent or powdered dishwasher detergent. Vacuuming lead dust should be performed with a high efficiency particle arresting (HEPA) vacuum cleaner. Since lead is more soluble in acidic solutions, vinegar can cause leaching of lead from leaded containers or bottles.

The Environmental Protection Agency lowered the amount of lead used in gasoline from 1.1 g of lead/gallon to 0.1 g of lead/gallon in 1985. In 1996, a total ban of lead in gasoline went into effect.

Adulterants, including lead, have been noted in Asian traditional or folk medicines. Folk remedies and cosmetics from East Indian, Pakistani, Chinese, and Latin American cultures that have contained lead include alarcon, alkohl, azarcon, bali goli, coral, gliasard, greta, kohl, "Koo Sar Pills", liga, pay-loo-ah, rueda, and surma. Other sources of lead ingestion have included contaminated ground paprika, ayurvedic metal-mineral tonics, Deshi Dewa (a fertility drug), hai gen fen (clam-shell powder) added to tea, and pigment used in plastic wire insulation.

Observational data suggests a 2-3 point IQ decrease with a serum lead increase from 10 to 20 mcg/dL in children; however, there appears to be no cognitive, behavioral, or neuropsychological improvement after 3 years of succimer therapy in chronic lead exposure with serum lead < 45 mcg/dL.

Mean time for blood lead to decline has been linearly related to the peak in blood lead. The linear relationship was described by the following equation: time (# of months required to achieve a blood lead < 10 mcg/dL) = 0.845 times peak lead.

Estimated Prevalence¹ of Children Aged 1-5 Years with Blood Lead Levels (BLLs) ≥ 10 mcg/dL² - United States, 1976-1980, 1988-1991, 1991-1994, and 1999-2000

Survey	Prevalence of BLLs ≥ 10 mcg/dL		Children with BLLs ≥ 10 mcg/dL	
	(%)	(95% CI ³)	No.	(95% CI)
1976-1980	88.2	(83.8-92.6)	13,500,000	(12,800,000-14,100,000)
1988-1991	8.6 ⁴	(4.8-12.4)	1,700,000	(960,000-2,477,000)
1991-1994	4.4	(2.9-6.6)	890,000	(590,000-1,330,000)
1999-2000	2.2 ⁵	(1.0-4.3)	434,000 ⁵	(189,000-846,000)

Source: National Health and Nutrition Examination Surveys (NHANES).

Note: In 1991, NHANES III Phase 1 was completed and Phase 2 was begun.

¹Estimated number of children 1-5 years of age with BLLs ≥ 10 mcg/dL divided by estimated population of children 1-5 years of age.

²CDC has determined BLL ≥ 10 mcg/dL is a level of concern.

³Confidence interval.

⁴Estimate differs slightly from that published previously because of updates in coding and weighting of survey data.

⁵Data for 1999-2000 are highly variable (relative standard error $> 30\%$).

Blood Lead Levels ≥ 10 μ g/dL Among Children 1-5 Years - United States, 1976-1980, 1988-1991, 1991-1994, and 1999-2000¹

¹Data for 1999-2000 are highly variable (relative standard error $> 30\%$).

Source: National Health and Nutrition Examination Surveys (NHANES).

Lewisite

Related Information

- Arsenic

CAS Number 541-25-3

Synonyms Chlorovinyl Arsine Dichloride

Use First synthesized in U.S. in 1918 for vesicant warfare. It is ten times more volatile than mustard gas and is often mixed with sulfur mustard (U.S. stockpiles are scheduled to be destroyed by April, 2007).

Mechanism of Toxic Action Dermal exposure results in increased capillary permeability and localized edema, thus enhancing absorption. Combines with thiol groups to cause local toxicity.

Signs and Symptoms of Overdose Hypotension, tachycardia, hypothermia, ocular burns, conjunctivitis, miosis, lacrimation, noncardiogenic pulmonary edema (usually associated with plural effusion), cough, dyspnea, tachypnea, weakness, nausea, vomiting, salivation, hypovolemia, hemolytic anemia (no bone marrow depression), dermal burns, blisters, erythema (within 30 minutes), skin edema

Overdosage/Treatment

Decontamination: **Inhalation:** Administer 100% humidified oxygen; remove from source. **Ocular:** Remove contact lenses, irrigate with tepid water or saline for at least 20 minutes. A 5% ophthalmologic compounded ointment or solution may be helpful if given within minutes of exposure. **Dermal:** Decontaminate immediately with 5% solution of sodium hypochlorite; use soap and water if bleach is not available. A 5% topical dimercaprol ointment or solution may prevent vesicant effects.

Supportive therapy: Monitor serum/24-hour urine arsenic levels. Indications for chelation include: cough with dyspnea or signs of pulmonary edema, > 1% total body surface area of dermal burn, or ≥5% of body surface in which there is skin damage or erythema noted within 30 minutes of exposure. Chelation should be continued until 24-hour urinary arsenic excretion falls under 50 mcg/L. Chelators include 2,3-dimercapto-1-propanesulfonic acid, succimer, or dimercaprol.

Antidote(s)

- Dimercaprol [ANTIDOTE]
- Succimer [ANTIDOTE]
- Unithiol [ANTIDOTE]

Additional Information An oily liquid with a geranium odor

150 mg/m³/minute causes 1% mortality

Dermal absorption: As little as 0.5 mL can cause systemic effects (2 mL can be lethal). Vesication can occur with 14 mcg exposure.

All plants die at levels over 50 mg/L. Atmospheric half-life: 1.2 days; water half-life: 5-10 days

Environmental persistence: Shorter in hot climates

Specific References

Lindsay CD, Hambrook JL, Brown RF, et al, "Examination of Changes in Connective Tissue Macromolecular Components of Large White Pig Skin Following Application of Lewisite Vapour," *J Appl Toxicol*, 2004, 24(1):37-46.

Limonene

CAS Number 138-86-3

UN Number 2052

Synonyms Cinene; Dipentene

Use Manufacture of resins, solvent, flavoring agent; in perfumes, stabilizer for aerosols; used medicinally in Japan to dissolve gallstones; found in citrus dill and pine oils

Mechanism of Toxic Action Dermal irritant/sensitizing agent

Signs and Symptoms of Overdose Aspiration may lead to lipid pneumonia; contact dermatitis, dermal irritation, oliguria, proteinuria, pruritus

Toxicodynamics/Kinetics

Absorption: Oral/dermal routes

Elimination: Renal (~90%). Fecal (~10%)

Monitoring Parameters Urine analysis/chest x-ray

Overdosage/Treatment

Decontamination: **Oral: Do not** induce emesis. Lavage can be performed within 1 hour, with activated charcoal. Dilute oral ingestions with 4-8 ounces of milk or water (in children up to 15 mL/kg). **Dermal:** Wash with soap and water. **Inhalation:** Treat with 100% humidified oxygen.

Supportive therapy: Topical corticosteroids with systemic antihistamines can be used to treat dermal irritation.

Additional Information Lethal dose: Oral: 0.5-5 g/kg. Colorless liquid with lemon-like odor. Odor threshold: 10 ppb. Specific gravity: 0.84.

Lysergic Acid Diethylamide

Related Information

- Highlights of Recent Reports (2006) on Substance Abuse and Mental Health

CAS Number 50-37-3

Synonyms LSD

Impairment Potential Yes. Blood LSD level >0.002 mg/L has been associated with cognitive dysfunction. (Baselt RC and Cravey RH, *Disposition of Toxic Drugs and Chemicals in Man*, 4th ed, Foster City, CA: Chemical Toxicology Institute, 1995, 436.)

Mechanism of Action Agonist at 5-hydroxytryptamine presynaptic receptor in midbrain

Mechanism of Toxic Action Agonist at 5-hydroxytryptamine presynaptic receptor in the midbrain

Adverse Reactions

Cardiovascular: Sinus tachycardia

Central nervous system: Palinopsia, dysphoria, memory disturbance, psychosis

Ocular: Color vision abnormalities

Signs and Symptoms of Overdose Ataxia, coma, delirium, diarrhea, euphoria, fear, fever, flushing, hallucinations (auditory and visual), hyperglycemia, hyperreflexia, hyperthermia, hypertonia, lacrimation, leukocytosis, mydriasis, nausea, neuroleptic malignant syndrome, psychosis, respiratory arrest, rhabdomyolysis, seizures, sweating, tachycardia, tachypnea, tremors, vision color changes (increased color perception), vomiting

Admission Criteria/Prognosis Persistent psychotic/confused behavior

Pharmacodynamics/Kinetics

Onset of action: 20-90 minutes (10 minutes I.V.)

Duration: 6-8 hours

Distribution: V_d : 0.28 L/kg

Protein binding: 90%

Metabolism: To 2-oxylysergic acid diethylamide

Half-life: 3-5 hours

Toxicodynamics/Kinetics

Onset of action: 20-90 minutes (10 minutes I.V.)

Duration: 6-8 hours

Distribution: V_d : 0.28 L/kg

Protein binding: 90%

Metabolism: To 2-oxylysergic acid diethylamide

Half-life: 3-5 hours

Reference Range Dose of 500 mcg orally resulted in peak plasma levels of 4.2 ng/mL

Overdosage/Treatment

Decontamination: Activated charcoal with oral ingestion

Supportive therapy: Dantralone (25 mg 3 times/day) should be given for neuroleptic malignant syndrome. Diazepam or lorazepam can be used for agitation. Haloperidol can be given for hallucinations. L-5-hydroxytryptophan with carbidopa (25 mg 4 times/day) may improve LSD-induced psychosis.

Diagnostic Procedures

- Lysergic Acid Diethylamine Level

Drug Interaction When combined with lithium and fluoxetine, can cause seizures; sertraline or paroxetine can incite occurrence of LSD flashback episodes (primarily visual); LSD, like panic attacks and visual disorders, can be exacerbated by risperidone; reserpine enhances LSD effect; chronic monoamine oxidase inhibitor use; allopurinol and fluoxetine inhibits LSD effect

Drug Interactions When combined with lithium and fluoxetine, can cause seizures; sertraline or paroxetine can incite occurrence of LSD flashback episodes (primarily visual); LSD, like panic attacks and visual disorders, can be exacerbated by risperidone; reserpine enhances LSD effect; chronic monoamine oxidase inhibitor use; allopurinol and fluoxetine inhibits LSD effect

Pregnancy Implications Can cause uterine contractions; effects on fetus is unknown, although increased incidence of limb defects and ocular abnormalities

Additional Information

Lethal dose: 0.2-1 mg/kg. Hallucinogenic dose: Oral: 100-750 mcg; I.V.: 50-500 mcg.

May be given as sugar cube, on filter or blotting paper, as a tablet or capsule; flashbacks may be induced by alcohol or selective serotonin reuptake inhibitory (SSRI) drugs; urine may be positive for up to 120 hours by radioimmunoassay; odorless, colorless, tasteless

Oregon has the highest rate of LSD users: 4.9% in high school and 2.5% of eighth graders report current use. LSD is the second most commonly used drug (second to marijuana) by United States military personnel with 0.6% and 1.5% reporting its use within the past month and year respectively in 1995.

Mid-Year 2000 Emergency Department Drug Abuse Warning Network (DAWN) data: **Note:** LSD is sometimes used in combination with other drugs; therefore, one Emergency Department (ED) episode can include mentions of one or more drugs.

* During the first half of 2000, there were 2096 ED mentions of LSD, which is not significantly different than the 2427 mentions for the first half of 1999.

Malathion

Related Information

- Donor Victims of Poisoning in Whom Transplantation of Organs Occurred

CAS Number 121-75-5

UN Number 2783

U.S. Brand Names Carbofos®; Compound 4049®; Cythion®; Fosfothion®; Mercaptothion®; Ovide®

Synonyms O,O-Dimethyldithiophosphate Diethylmercaptosuccinate

Use Marketed as insecticide granules, powder or dusting agent, or spray liquid concentrate with or without petroleum derivative as a solvent

Mechanism of Toxic Action Irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** or **hypodynamic** states, QT prolongation, Raynaud's phenomenon, sinus bradycardia, sinus tachycardia, torsade de pointes

Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia, extrapyramidal reactions

Dermatologic: Scleroderma

Endocrine & metabolic: Diabetes insipidus, hypernatremia

Gastrointestinal: Pancreatitis

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness (delayed), paralysis, sclerodermatous changes accompanied by Raynaud's phenomena, delayed paresthesia

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure), intermediate syndrome

Signs and Symptoms of Overdose

Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, dementia, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, garlic-like breath, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure, and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia, and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Admission Criteria/Prognosis Any symptomatic patient or an asymptomatic patient following a severe exposure should be admitted probably into an intensive care unit; asymptomatic patients following a moderate exposure can be discharged after 8 hours of observation

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure

Metabolism: Rapid to weakly active compounds through hepatic hydrolysis and other pathways

Half-life: 2.9 hours

Elimination: Metabolites excreted in urine

Administration

Refer to Dosing.

Contraindications Hypersensitivity to malathion or any component of the formulation; use in neonates and/or infants

Warnings

For topical use only; avoid contact with eyes. Lotion is flammable; do not expose to open flames; patients should avoid electric heat sources (eg, hair dryers, curling irons). Safety and efficacy in children <6 years of age have not been established.

Significant dermal absorption may occur across intact skin; risk of aspiration pneumonitis exists following oral exposure to agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Dosing Forms Lotion: 0.5% (59 mL)

Dosage Forms Lotion: 0.5% (59 mL) [contains isopropyl alcohol 78%]

Reference Range

A 1.8 g ingestion with undetectable pseudocholinesterase resulted in a serum malathion level of 0.35 mg/L 2 hours postingestion.

Mild poisoning: Serum cholinesterase is 20% to 50% of normal;

Moderate poisoning: Serum cholinesterase is 10% to 20% of normal

Severe poisoning (respiratory distress and coma): Serum cholinesterase is <10%

Fatal malathion blood levels range from 0.3-1880 mg/L

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. **Do not** give a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed treatment and large volumes of distribution of organophosphates.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.M. or I.V. initially, or ~1/2 the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Pregnancy Risk Factor B

Pregnancy Implications No evidence of teratogenicity in animal models. There are no adequate and well-controlled studies in pregnant women. Use (or handle) during pregnancy only if clearly needed.

Additional Information

Red blood cell cholinesterase and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure. RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

The intermediate syndrome is not related to delayed neuropathy.

Colorless to brown liquid with foul, skunk-like odor; thermal degradation products include sulfur and phosphorus oxides

Water solubility: 143 ppm. **Vapor pressure:** 0.00004 mm Hg at 20°C.

ACGIH TLV: 10 mg/m³; **PEL-TWA:** 10 mg/m³ (total dust); 5 mg/m³ (respirable fraction of dust); **IDLH:** 5000 mg/m³

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378

Manganese**Related Information**

- Adipose Tissue Ranges of Toxins

CAS Number 1313-13-1; 1317-34-6; 14024-58-9; 6156-78-1; 7439-96-5; 7773-01-5; 7785-87-7

UN Number 1490

U.S. Brand Names Mangimin [OTC]

Synonyms Manganese Chloride; Manganese Sulfate

Commonly Found In Elemental manganese metal, and as the following salts: acetate, chloride, dioxide, and sulfate; found in fertilizer, welding rods, ceramics, electrical coils, matches, animal food additives

Mechanism of Action Cofactor in many enzyme systems, stimulates synthesis of cholesterol and fatty acids in liver, and influences mucopolysaccharide synthesis

Mechanism of Toxic Action Catalyses dopamine depletion and free radical production within the central nervous system; results in diffuse cortical and cerebellar degeneration

Adverse Reactions

Central nervous system: Parkinson-like syndrome, nervousness, dementia, ataxia, irritability, "manganese psychosis", memory disturbance, metal fume fever, CNS depression, depression, psychosis, extrapyramidal reactions

Genitourinary: Impotence

Hematologic: Methemoglobinemia

Neuromuscular & skeletal: Bradykinesia, gait instability, chorea (extrapyramidal)

Ocular: Visual evoked potential abnormalities

Otic: Ototoxicity

Respiratory: Pleuritis, pneumonia

Signs and Symptoms of Overdose Symptoms correlate with duration of exposure, either acute or chronic. Acute exposure primarily results in respiratory symptoms such as cough, pleuritis, pneumonia, and in GI irritation and pancreatitis. Chronic exposure primarily results in CNS symptoms such as nervousness, irritability, Parkinson-like symptoms, nystagmus, tremor, fasciculations, slurred speech, feces discoloration (dark brown); diminished libido, "manganese psychosis" (*Locura manganical*), limb asthenia, and insomnia may persist for several months.

Pharmacodynamics/Kinetics

Absorption: Oral: Poor (3% to 4%)

Distribution: Concentrated in mitochondria of pituitary gland, pancreas, liver, kidney, and bone

Excretion: Bile (primarily); urine (negligible)

Monitoring Parameters Periodic manganese plasma level

Administration

Solution for injection: Do not administer I.M. or by direct I.V. injection; acidic pH of the solution may cause tissue irritations and it is hypotonic

Contraindications High manganese levels; severe liver dysfunction or cholestasis (conjugated bilirubin >2 mg/dL) due to reduced biliary excretion

Warnings Manganese chloride solution for injection contains aluminum; use caution with impaired renal function and in premature infants. Use caution with hepatic impairment.

Dosage Forms

Injection, solution, as chloride [preservative free]: 0.1 mg/mL (10 mL) [contains aluminum ≤100 mcg/mL]

Injection, solution, as sulfate: 0.1 mg/mL (10 mL)

Tablet, as aspartate: 93 mg [equivalent to elemental manganese 25 mg]

Tablet, as gluconate: 5.7 mg [as elemental manganese]; 550 mg [equivalent to elemental manganese 30 mg]; 600 mg [equivalent to elemental manganese 50 mg]

Tablet, chelated: 50 mg [as elemental manganese]

Mangimin: 10 mg [as elemental manganese]

Reference Range Typical normal ranges in adults: CSF: 0.4-1.2 mcg/100 mL. Serum: 0.9-2.9 mcg/L. Whole blood: 4-15 mcg/L. Urine: <10 mcg/L.

Overdosage/Treatment**Decontamination:**

Oral: Since most symptomatic exposures are chronic, emesis with ipecac within 30 minutes or gastric lavage within 1 hour may be used to eliminate large acute ingestions. Chronically exposed patients may become obtunded or may develop acute respiratory symptoms, and should not receive lavage or ipecac. Single dose activated charcoal will not adsorb manganese but is useful for coingestants.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water

Ocular: Irrigation with copious tepid water or saline

Inhalation: Remove patient from source of exposure

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration; and close monitoring for renal compromise, respiratory decompensation, or further convulsive activity

Chelation: EDTA therapy instituted early in manganese intoxication is most promising. BAL and succimer have not demonstrated utility in chronic toxicity.

Intention tremor: Trihexyphenidil 1-5 mg/day orally in divided doses

Anti-Parkinson's therapy: Improvement in neurologic toxicity may result with using anti-Parkinson's therapy of levodopa 3.5-12 g/day orally, or levodopa/carbidopa (Sinemet®) 100 mg/25 mg 2-3 times/day orally, up to 6 tablets/day for 8 weeks.

Antidote(s)

- Charcoal [ANTIDOTE]
- Edetate Calcium Disodium [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Electrolytes, Blood
- Glucose, Random
- Magnetic Resonance Scan, Brain
- Urea Nitrogen, Blood

Pregnancy Risk Factor C

Pregnancy Implications Mn crosses the placenta but does not accumulate in the fetus.

Lactation Enters breast milk/compatible

Additional Information

Urine or plasma concentrations of manganese do not correlate with severity of symptoms. Toxicity following ingestion of inorganic salts is unlikely because of poor gastrointestinal absorption; neurologic manifestations may be permanently established after 1-2 years of chronic exposure. Magnetic resonance imaging may be useful for manganese encephalopathy (T₁ weighted imaging).

Foods with the highest amount of manganese concentrations are nuts and nut products (18-47 ppm); average amount of ingestion of manganese from food: 3.8 mg/day; average cup of tea may contain from 0.4-1.3 mg of manganese; legumes may contain from 2-7 ppm of manganese

Manganese toxic patients have a tendency to fall backwards, to not have a prominent tremor, and do not respond well to dopaminomimetic medication as opposed to idiopathic parkinsonism patients.

Safe infant daily dose: 0.7-1 mg

Mean level in drinking water: 4-32 mcg/L

Average ambient atmospheric manganese levels: Urban: 33 ng/m³; Nonurban: 5 ng/m³

Concentration in soil: 40-900 mg/kg. Atmospheric half-life (in sunlight): 15 seconds

TLV-TWA: Dust: 5 mg/m³; Fumes: 1 mg/m³; IDLH: 10,000 mg/m³; PEL-TWA: 1 mg/m³ (fumes)

Mercury

Related Information

- Dimercaprol [ANTIDOTE]
- Mercury Levels in Commercial Fish and Shellfish
- Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 7439-97-6

UN Number 1629; 2024; 2025; 2809

Commonly Found In

Inorganic mercury salts; organic mercury; elemental mercury; found in thimerosal, fireworks, button batteries

Used by amalgam makers, jewelers, paint manufacturers, laboratorians, taxidermists, embalmers, dye makers, fur processors, photographers, electroplaters

Mechanism of Toxic Action Causes cell membrane damage; elemental and organic mercury are CNS toxins; inorganic is a corrosive; organic mercury causes teratogenicity; high-binding affinity of divalent cation form of mercury to thiol or sulfhydryl protein groups occur

Adverse Reactions

Cardiovascular: Hypertension, tachycardia, hypotension, cranial nerve palsies, cardiomyopathy, cardiomegaly, palpitations, QT prolongation, sinus tachycardia, arrhythmias (ventricular), vasoconstriction

Central nervous system: Dementia, hyperthermia, encephalopathy, ataxia, Jarisch-Herxheimer reaction, CNS depression

Dermatologic: Dermal granuloma, skin granuloma, systemic contact dermatitis, exanthem

Gastrointestinal: Salivation, metallic taste

Hematologic: Thrombocytopenia, eosinophilia

Neuromuscular & skeletal: Tremor, myoclonus, neuritis, rhabdomyolysis

Ocular: Nystagmus, diplopia, photophobia, visual evoked potential abnormalities

Otic: Deafness

Renal: Glomerulonephritis

Respiratory: Hyposmia

Miscellaneous: Toxic shock-like syndrome

Signs and Symptoms of Overdose Elemental mercury is poorly absorbed orally, with minimal adverse effects. Inhalation acutely can cause chemical pneumonitis, gingivostomatitis, and noncardiogenic pulmonary edema. Chronic exposure to mercury vapor causes acrodynia, alopecia, fasciculations, fatigue, hematuria, insomnia, leukocytosis, memory loss, proteinuria, tremor

Inorganic mercury: After oral administration: Abdominal pain, ATN, GI bleeding, GI irritation, possible CNS toxicity, renal failure, shock

Organic mercury: CNS toxicity including ataxia, dysarthria, hearing and visual loss, paresthesias; gastrointestinal distress

Admission Criteria/Prognosis Significant exposure to mercury vapor, inorganic mercury, or organic mercury compounds usually requires admission; ingestion of small amounts of elemental mercury usually does not require admission; alkyl mercury inhalation exposure (chronic) may result in residual central nervous system impairments

Toxicodynamics/Kinetics

Absorption: Elemental mercury is poorly absorbed orally and well absorbed by inhalation while inorganic and organic mercury are well absorbed orally; metallic mercury is minimally absorbed dermally (0.024 ng of mercury absorbed per cm² of skin)

Distribution: Elemental to CNS, kidney, liver, and heart; inorganic mercury concentrates in the kidney; organic mercury (alkyl mercury groups) distributes throughout the body while methylmercury concentrates in blood and CNS

Metabolism: Metallic/inorganic mercury: Oxidized to an inorganic divalent form in the red blood cells (note that ethanol can inhibit this step)

Half-life:

Elemental and inorganic: 40-60 days. Organic: 70 days; organic converted to divalent cation form in tissues

Elimination: Metallic: Urine, feces, and lung. Inorganic: Urine, feces. Organic: Primarily feces

Reference Range

Urinary and whole blood levels can be obtained; urinary values are normally <10 mcg/L and whole blood <20 mcg/L; geometric mean blood mercury levels are 0.3 mcg/L for children 1-5 years of age and 1.2 mcg/L for women 16-49 years of age. Whole blood levels >50 mcg/L are usually associated with gastroenteritis and acute tubular necrosis. Urinary levels for organic mercury are not useful since 90% is eliminated through bile in the feces. Urinary mercury levels >56 mcg/L can result in neurotoxic effects (due to elemental mercury), although neurologic signs are not usually manifested until urinary mercury levels exceed 100 mcg/L.

Note that hair mercury analysis measures organic (not organic or elemental mercury) methyl mercury exposures only. Reference range for unexposed individuals is <1 mcg/g.

Overdosage/Treatment

Decontamination:

Oral: Lavage if ingested within 1 hour. Charcoal has been shown to decrease inorganic mercury absorption in rats and should be

used. Milk or egg white may also be useful to bind mercury, as is 5% sodium formaldehyde or a 2% to 5% sodium bicarbonate solution. Whole bowel irrigation with GoLYTELY® may be beneficial if abdominal x-ray shows evidence of mercury. **Do not** induce emesis for inorganic mercury ingestions as this agent has corrosive properties.

Inhalation: Patients should be monitored for pulmonary edema and pneumonitis; give oxygen if necessary.

Dermal: Wash with tincture of green soap and water.

Ocular: Copious irrigation with saline

Supportive therapy: D-penicillamine can be administered orally in 4 divided doses totaling 20-30 mg/kg (250 mg 4 times/day in adults) if prolonged therapy is required, especially for short-chain alkyl organic mercury compounds. Another less toxic form of penicillamine, N-acetylpenicillamine (from Aldrich Chemical Co, Milwaukee, WI), is a specific chelator for mercury. Both are also effective for long-chain alkyl, aryl mercurials, or for treatment of acrodynia. 2,3-Dimercaptopropane sulphate (DMPS or unithiol) is also useful to enhance mercury elimination.

Elemental mercury: Oral DMSA (succimer) 10 mg/kg every 8 hours for 5 days, then 10 mg/kg every 12 hours for 2 or more weeks, will enhance urinary mercury excretion.

Inorganic mercury: BAL 5 mg/kg deep I.M. initially, then 2.5 mg/kg every 12 hours for 10 days. If given within the first 2 hours, BAL may prevent renal toxicity. **Do not give BAL I.V..**

Organic mercury: Oral DMSA (succimer) with dosing as above for methyl mercury exposure. BAL is contraindicated.

BAL is not recommended for elemental and organic mercury poisoning since BAL may cause redistribution of mercury to the brain, which is the primary target organ in these poisonings.

Enhancement of elimination: Generally ineffective. BAL, mercury complex is dialyzable and is useful in patients with renal failure; it does not enhance elimination in those with good renal function. Some clinical improvement with increased clearance has been noted after exchange transfusion.

Organic mercury: Oral neostigmine may improve motor strength in chronic methyl mercury exposure.

Antidote(s)

- Succimer [ANTIDOTE]
- Unithiol [ANTIDOTE]

Diagnostic Procedures

- Mercury, Blood
- Mercury, Urine
- Urinalysis

Drug Interaction BAL forms toxic metabolites with cadmium, iron, selenium, and uranium; BAL may cause interference with iodine accumulation in the thyroid

Additional Information BAL should be administered deep I.M.; **do not give I.V..** See table.

Estimated Average Daily Intake and Retention of Total Mercury and Mercury Compounds in the General Population

Source of Exposure	Elemental Mercury Vapor	Inorganic Mercury Compounds	Methylmercury
Air	0.030 (0.024)	0.002 (0.001)	0.008 (0.0064)
Food			
Fish	0	0.600 (0.042)	2.4 (2.3)
Non-fish	0	3.6 (0.25)	0
Drinking water	0	0.050 (0.0035)	0
Dental amalgams	3.8-21 (3-17)	0	0
Total	3.9-21 (3-17)	4.3 (0.3)	2.41 (2.31)

Note: Values given are the estimated average daily intake (in mcg/day) for adults in the general population who are not occupationally exposed to mercury; the figures in parentheses represent the estimated amount retained in the body of an adult.

Estimated Number of Workers Potentially Exposed to Mercury and Various Mercury Compounds in the Workplace

Mercury Compounds	Number of Workers	Number of Female Workers
Mercury (metallic)	71,933	23,826
Mercury chloride	45,492	18,717
Mercury acetate	6063	2770
Mercuric sulfide	98	—
Phenylmercuric acetate	28,347	5150
Methylmercuric chloride	14	5

Source: RTECS 1998.

Reference: "Toxicological Profile for Mercury," U.S. Department of Health and Human Services, Agency for Toxic Substances and Disease Registry, March 1999.

EPA maximum mercury exposure limit: 0.1 mcg/kg/day
 Ambient atmospheric mercury levels range from 10-20 ng/m³. Surface water levels: <5 ng/L. Soil levels: 20-625 ng/g
 IDLH: Mercury vapor: 28 mg/m³
 Alkyl mercury compounds: 10 mg/m³
 WHO guideline for drinking water: 1 mcg/L; EPA standard mercury limit for drinking water: 2 mcg/L; FDA standard limit for bottled water: 2 mcg/L
 Resident air mercury level limit (ATSDR): 0.05 mcg/m³
 Permissible tolerable weekly intake: 5 mcg/kg
 Mean mercury levels in fish: ~0.4 mcg/g. See Mercury Concentrations in the Top 10 Types of Fish Consumed by the U.S. Population and Fish and Shellfish with Much Lower Mercury Levels
 Other foods: ~0.004 mcg/g
 Cigarette smoke: ~0.004 mcg/cigarette
 Estimated daily intake of mercury from air: 0.2 mcg; from drinking water: 0.1 mcg
 Residence atmospheric time of elemental mercury: 6-24 months
 Average methyl mercury content in tuna: 0.17 ppm
 Chinese herbal balls may contain from 7.8-621.3 mg of mercury and from 0.1-36.6 mg of arsenic
 Latex gloves are of no protection with mercury. Suggested hand protection is use of a flexible, plastic laminate glove worn under a heavy duty neoprene outer glove.

Accidental soft tissue deposition of liquid mercury from a thermometer results in little to no toxicity and usually does not require chelation

What to do if elemental (metallic) mercury spills in your home:

Mercury spills should be considered a hazardous material incident. If any amount greater than that from a small thermometer is spilled (or if mercury from a fever thermometer is spilled on a porous surface), call your local environmental health department, local board of health, poison control center, or your physician, even if no one has symptoms. Do not attempt to clean the spills by yourself or with a vacuum cleaner, or to remove mercury from carpeting or a porous (eg, furniture or unfinished wood) surface. Discard contaminated carpeting and rugs. Open windows to ventilate and evacuate the area until professionally assessed and cleaned. If a small amount (eg, from a fever thermometer) is spilled on a nonporous (eg, tile or wood) surface follow the instructions below:

- Remove all gold jewelry.
- Using an index card or stiff paper, gather the droplets together into a glass jar with a tight lid or a "Ziplock" plastic bag. Masking, cellophane, or duct tape may be helpful in removing mercury.
- Avoid skin contact.
- Contact your local health department as to proper disposal.
- Provide additional ventilation for the affected area for 2 days.
- Ordinary gloves are of no protection in handling mercury and thereby preventing poisoning. Flexible laminated gloves worn under heavy duty neoprene outer gloves afford adequate hand protection. Elemental Mercury can volatilize at temperatures over 88° F. Density of elemental mercury is 13.5 g/ml, in water and 6.93 (vapor density) in air. Air Elemental mercury concentrations are usually less than 0.001 mg/m³ in relation to broken mercury based thermometers or thermostats.

Metal Fume Fever

Related Information

- Zinc Oxide

Synonyms Brass Chills; Braz's Disease; Copper Fever; Fume Fever; Metal Shakes; Monday Morning Fever; Welding Fume Fever; Zinc Shakes

Commonly Found In Produced when inhaling metal oxides such as zinc oxide, copper, brass, cadmium, tin, iron, nickel, manganese, aluminum, antimony, arsenic, lead, silver, selenium, chromium, cobalt, magnesium; encountered with welding or torch cutting

Mechanism of Toxic Action May have a direct respiratory tract effect resulting in chemotaxis of leukocytes with pyrogen and chemotactic factor release. May be a form of hypersensitivity pneumonitis.

Adverse Reactions

Respiratory and gastrointestinal symptoms ~5 hours postexposure

Respiratory: Asthma (zinc/cobalt exposure)

Hematology: Leukocytosis

Signs and Symptoms of Overdose Usually occur 3-12 hours after exposure. Sudden onset of abdominal pain, blurred vision, dyspnea, flushing, headache, metallic taste, mild fever (<104°F or 40°C), myalgia, nausea, nonproductive cough, pleuritic chest pain, sore throat, tachypnea, sweating, thirst, vomiting; usually does not last for over 48 hours. Chest radiographs are usually normal.

Admission Criteria/Prognosis Abnormal chest x-ray, cardiopulmonary symptomatic patients not resolving 8 hours postexposure should be admitted

Toxicodynamics/Kinetics Absorption: Primary route is inhalation

Reference Range Zinc levels >2 mg/L are above normal

Overdosage/Treatment Supportive therapy: Humidified oxygen; chelation is not effective. The course is usually benign; symptoms usually resolve in 1-2 days. Antacids can be used to treat GI symptoms. Chest x-rays are unlikely to be abnormal (except with exposure to zinc oxide fumes). Leukocytosis of 12,000-16,000 cells/mm³ is common. Glucocorticoid administration is of uncertain benefit and can be considered in patients with pulmonary infiltrates.

Diagnostic Procedures

- Heavy Metal Screen, Blood

Metaldehyde

CAS Number 108-62-3; 9002-91-9

UN Number 1332

U.S. Brand Names Halizan®; Meta-Fuel®; Metason®; Slug Death®; Slugit® Pellets

Use A molluscicide (in pellet form); snail/slug bait, heating fuel, ingredient in fire lighters

Mechanism of Toxic Action Acyclic tetramer of acetaldehyde with direct effects on neurotransmitters (ie, decreases gamma-aminobutyric acid, noradrenaline, 5-hydroxytryptamine); mucosal irritant

Adverse Reactions

Cardiovascular: Hypotension, flushing

Central nervous system: Lethargy, seizures, ataxia, coma, fever, confusion, opisthotonos, hyperthermia

Dermatologic: Pruritus

Endocrine & metabolic: Metabolic acids

Gastrointestinal: Salivation, nausea, diarrhea, abdominal pain, vomiting

Ocular: Mydriasis

Neuromuscular & skeletal: Tremors, hypertension

Respiratory: Bronchial secretions, cough

Signs and Symptoms of Overdose Hyperthermia, mydriasis, conjunctivitis, hypotension, drowsiness, seizures, nausea, vomiting, abdominal pain, diarrhea, coma, headache, epistaxis, metabolic acidosis, thrombocytopenia, rhabdomyolysis, dermatitis, tachycardia

Toxicodynamics/Kinetics

Onset of action: Usually within 3 hours

Metabolism: Hydrolyzed in the stomach (by gastric acid) to acetaldehyde

Half-life: 27 hours

Reference Range Serum acetaldehyde level of 1 mg/dL (and urine metaldehyde level of 3 mg/dL) associated with seizures and acidosis

Overdosage/Treatment

Decontamination: Lavage (within 2 hours)/activated charcoal

Supportive therapy: Seizures should be treated with benzodiazepine, phenobarbital, or phenytoin; sodium bicarbonate for acidosis. Movement disorders can be treated with diphenhydramine (1 mg/kg up to 50 mg).

Enhancement of elimination: Diuresis or hemodialysis is not expected to be useful.

Drug Interaction May have synergistic toxic effects with ethanol

Additional Information

Tasteless white crystalline substrate; minimal lethal dose: Children: 4 g; fatal dose (oral): ~100 mg/g

Adverse reactions often related to dose ingested:

<50 mg/kg: Spasms, tachycardia, nausea

50-100 mg/kg: Ataxia, hypertonia

100-200 mg/kg: Seizures, tremor

>400 mg/kg: Coma, death

Memory loss may occur and last for several months.

Usual concentration in U.S. is <4%; but in Europe, metaldehyde concentration in molluscicides may approach 50%

Very flammable

Specific References

Shih CC, Chang SS, Chan YL, et al, "Acute Methaldehyde Poisoning in Taiwan," *Vet Hum Toxicol*, 2004, 46(3):140-3.

Methacrylates

CAS Number 80-62-6

Synonyms Methacrylate Monomer; Methyl Ester of Methacrylic Acid; Methyl Methacrylate Monomer; MMA; Monocite Methacrylate Monomer; Pegalan

Use In bone cements; artificial fingernail extender

Mechanism of Toxic Action Not well known

Adverse Reactions Moderate irritant and sensitizer, once polymerized becomes inert and nontoxic; vasodilation and transient hypotension have been reported following use as a bone cement; direct cardiotoxicity has been noted; oral ingestion can produce vomiting, GI ulceration

Signs and Symptoms of Overdose Allergic dermatitis, headache and irritability, hepatic metabolism disturbances. Occupational asthma has been associated with various methyl methacrylates.

Toxicodynamics/Kinetics Metabolism: Possible in liver and hydroxylated to an alcohol, then oxidized to aldehyde and deformulated to pyruvic acid where it enters Krebs cycle

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Parenteral nutrition for severe gastrointestinal burns

Additional Information

How supplied: Bone cement, medicinal spray adhesives, or nonirritant bandage, solvent, dental ceramic filler or cement, surgical implants; to coat contact lenses, the polymer is a constituent of plexiglass, lucite and Perspex

Monomer has an acrid odor until polymerizes; the colorless liquid form has a fruity smell; may polymerize and cause an exothermic reaction

Methane

CAS Number 74-82-8

UN Number 1971

Synonyms Fire Damp; Marsh Gas; Methyl Hydride; Natural Gas (85% Methane)

Commonly Found In Sludge digestion; produced through natural breakdown of sewage; raw material for hydrogen, ammonia, or acetylene production; found in mining industry

Mechanism of Toxic Action Asphyxiant - Displaces oxygen from the atmosphere

Adverse Reactions

Cardiovascular: Sinus tachycardia

Respiratory: Hypoxia, hyperventilation; no direct lung damage

Signs and Symptoms of Overdose Blurred or decreased vision, CNS depression, cough, tachycardia, tachypnea, unconsciousness

Overdosage/Treatment Supportive therapy: 100% humidified oxygen

Additional Information Death can occur at 75% concentration. Colorless, odorless. TLV-TWA: No limits as long as sufficient atmospheric oxygen is available. Usually when asphyxiant is 33% of atmosphere, symptoms will develop. Methane is flammable at concentrations of 5%.

Methanol

Related Information

- Donor Victims of Poisoning in Whom Transplantation of Organs Occurred

Applies to Antifreeze (Gas Line); Antifreeze (Windshield Washer); Gasoline Additive; Paint Remover

CAS Number 67-56-1

UN Number 1230

Synonyms Carbinol; Methyl Alcohol; Wood Alcohol; Wood Naphtha

METHANOL

Commonly Found In Industrial and household solvent

Use Fuel, paint remover; also an additive to gasoline; used in gas line antifreeze, windshield washer antifreeze

Mechanism of Toxic Action Slowly metabolized to formaldehyde and then converted rapidly to formic acid which accounts for the acidosis and ocular toxicity

Adverse Reactions

Cardiovascular: Sinus bradycardia

Central nervous system: Bilateral putaminal involvement

Endocrine & metabolic: Anion gap metabolic acidosis (lactic acidosis)

Neuromuscular & skeletal: Rhabdomyolysis

Ocular: Visual abnormalities, blindness with edematous optic disk, photophobia, optic neuropathy

Renal: Hematuria, osmolal gap

Signs and Symptoms of Overdose Symptoms may not occur for 6-30 hours. Blurred vision or diplopia progressing to blindness in ~33% of patients; bilateral basal ganglia lesions, bradycardia, coma, dementia, dyspnea, extrapyramidal symptoms, feces discoloration (black), headache, hemorrhage, hyperventilation, hypomagnesemia, hypophosphatemia, hypotension, porphyria, metabolic acidosis, myoglobinuria, nystagmus, ototoxicity, parkinsonism, paresthesia, renal failure, tinnitus, seizures, visual changes

Admission Criteria/Prognosis Any symptomatic patient, acidosis, any patient with suspected ingestion, ingestion of >4 mL of 100% methanol or peak serum methanol levels >20 mg/dL should be admitted

Toxicodynamics/Kinetics

Specific gravity: 0.79 g/mL

Absorption: Dermally (enhanced with gasoline mixtures), by inhalation (58%), and through the GI tract (~100%)

Distribution: V_d : 0.6 L/kg

Protein binding: 0%

Metabolism: Slowly in the liver by alcohol dehydrogenase to formaldehyde and then to formic acid. See figure.

Methanol Metabolism to Toxic Intermediate — Formaldehyde and Formic Acid (Formate)

Discovery of methanol's metabolic pathway has led to several practical treatments; among them are the therapeutic administration of ethanol and folic acid. Alcohol dehydrogenase, the enzyme responsible for the first step of methanol metabolism, has an approximately nine fold greater affinity for ethanol than for methanol. Administration of ethanol blocks the oxidation of methanol, preventing the lethal synthesis of formaldehyde and formic acid and increasing the amount of methanol that is eliminated unchanged (now approximately equal amounts in urine and exhaled breath). Administration of folic acid and its analogues, which affect Step 3, enhances the conversion of toxic formic acid to carbon dioxide and water.

Adapted from Shusterman D and Osterloh JD, "Methanol Toxicity," *Case Studies in Environmental Medicine*, U.S. Department of Health and Human Services, Agency for Toxic Substances and Disease Registry, July 1992.

Peak serum concentration: Within 1 hour; found in higher concentrations in ocular and cerebrospinal fluids

Half-life, elimination: 8-28 hours (8 mg/dL/hour); with hemodialysis: 2 hours; 50 hours in the presence of ethanol

During 4-MP therapy: 54.4 hours. During 4-MP therapy and hemodialysis: 2.8 hours

Elimination: ~3% excreted unchanged renally and 12% by the lungs; ~22% of the drug is normally excreted in 4 hours

Reference Range

Blood methanol level >50 mg/dL is associated with severe toxicity; minimal lethal level without treatment: 80 mg/dL; baseline methanol level from endogenous and dietary sources: <0.15 mg/dL

Central nervous system toxicity usually appears at blood methanol level of 20 mg/dL; ocular symptoms occur at 100 mg/dL; fatality can occur at blood methanol level >150 mg/dL; serum formate level >20 mg/dL is consistent with ocular symptoms and metabolic acidosis

Endogenous serum formate concentrations: 0.6-1.6 mg/L; inhalation of methanol at concentrations of 200 ppm for 4 hours (or roughly 4 mg/kg) can result in peak serum and urine methanol levels of 6.5 mg/L and 0.9 mg every 4 hours, respectively

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic in a 5:1 ratio (charcoal:methanol); higher doses of activated charcoal may be needed, but this is of unproven benefit. **Do not** induce emesis by ipecac if initiated longer than 30 minutes after ingestion.

Dermal: Wash with soap and water.

Ocular: Irrigate copiously with saline.

Supportive therapy: Treat acidosis with sodium bicarbonate (I.V.). Leucovorin calcium, 1 mg/kg up to 50 mg, followed by folic acid, 1 mg/kg up to 50 mg (every 4 hours), should be given in symptomatic patients. Folic acid, at the same dose, may be given alone in asymptomatic patients. Treat acidosis aggressively with I.V. sodium bicarbonate. Ethanol therapy should be initiated if the methanol level is >20 mg/dL, the patient has anion-gap acidosis, or other symptoms develop. 4-MP is a specific antagonist of alcohol dehydrogenase and can be used instead of ethanol therapy.

Enhancement of elimination: Hemodialysis (with ethanol) should be utilized for methanol levels >20 mg/dL or if metabolic acidosis is present, if any visual impairment is present, or if adult consumption exceeds 40 mL. Clearance of methanol by hemodialysis is estimated to be 98-176 mL/minute.

The following protocol has been used in India to treat vision loss due to methanol

- 1 gram intravenous methylprednisolone in 500 ml of ringers lactate infused slowly over 2 hours daily for 3 days followed by oral prednisolone (40 mg) daily for 14 days. Oral steroids were tapered over 4 to 6 weeks
- Oral cyclandelate (400 mg) once daily for six weeks
- Intramuscular hydroxycobalamine (1.5 ml) once daily for one week
- Oral pentoxifylline (400 mg) once daily for six weeks

Antidote(s)

- Alcohol, Ethyl [ANTIDOTE]
- Folic Acid [ANTIDOTE]
- Fomepizole [ANTIDOTE]
- Leucovorin [ANTIDOTE]
- Sodium Bicarbonate [ANTIDOTE]

Diagnostic Procedures

- Anion Gap, Blood
- Electrolytes, Blood
- Magnetic Resonance Scan, Brain
- Osmolality, Serum
- Osmolality, Urine

Drug Interaction Methanol poisoning and heparin can increase risk for cerebral hemorrhage

Additional Information Minimum oral lethal exposure: ~50 mL with blindness occurring at 10 mL

Methanol has one-third the intoxicating effect of ethanol; discontinue ethanol therapy if methanol level is <10 mg/dL, or acidosis or central nervous system abnormalities have resolved.

Parkinson syndrome has been described. Headaches can occur at air methanol levels in the range of 200-375 ppm.

Bilateral basal ganglion lesions along with symmetrical putamen necrosis may be noted on CT scan or MRI

Reduction of serum pH and development of acidosis may take 6-8 hours. Contribution of a serum concentration level of 100 mg/dL to elevation of osmolar gap: 31

Dose of methanol that will saturate the folate pathway is ~210 mg/kg. Methanol content in fruits, vegetables, and fruit juices can approach 140 mg/L; in fermented beverages it can be up to 1.5 g/L; since ~10% of ingested aspartame is converted to methanol in the intestine, a 12-ounce can of carbonated soda (containing 200 mg of aspartame) can produce ~20 mg of methanol; estimated daily methanol ingestion from noncarbonated drinks: 0.3-1.1 mg/kg
Odor threshold: 100-250 ppm. TLV-TWA: 200 ppm

Methidathion

CAS Number 950-37-8

U.S. Brand Names Sumonil®; Supracide®; Ultracide®

Use Marketed as insecticide granules, dusting agent, or spray liquid with or without petroleum derivative as a solvent

Mechanism of Toxic Action Potent, irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, QT prolongation, sinus bradycardia, sinus tachycardia
Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting
An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure, and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia, and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure

Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways

Elimination: Metabolites are excreted in urine

Warnings/Precautions Risk of aspiration pneumonitis exists with agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles.

Do not give a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of organophosphates.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or ~1/2 the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information

Red blood cell cholinesterase, and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected.

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Methiocarb

CAS Number 2032-65-7

U.S. Brand Names Draza®; Mesuro®

Synonyms 3,5-Dimethyl-4-Methylthiophenyl N-Methylcarbamate

Use Marketed as an insecticide dusting powder or a colorless spray liquid

Mechanism of Toxic Action Reversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, QT prolongation, edema, sinus bradycardia, sinus tachycardia

Central nervous system: Toxicity is limited because carbamates do not significantly cross the blood-brain barrier; CNS changes occur with most severe intoxications, hyperactivity, cognitive dysfunction, hypothermia

Endocrine & metabolism: Hypoglycemia

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness, paralysis

Ocular: Diplopia

Respiratory: Cough, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure

Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways

Elimination: Metabolites are excreted in urine

Warnings/Precautions Risk of aspiration pneumonia exists following oral exposure to agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. **Do not** give a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach may be effective

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should

be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or ~1/2 the dose of atropine).

2-PAM: Although not specifically indicated, 2-PAM may be considered in the following situations:

Life-threatening symptoms such as respiratory paralysis

Continued excessive atropine requirements

Concomitant organophosphate and carbamate exposure

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of carbamates

Antidote(s)

● Atropine [ANTIDOTE]

Diagnostic Procedures

● Creatinine, Serum

● Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information

Red blood cell cholinesterase, and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure and are theoretically useful for differentiating between carbamate and organophosphate exposures; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition, thus they may not be useful in ruling out carbamate exposure.

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Methomyl

CAS Number 16752-77-5

U.S. Brand Names Lannate®; Lanox®; Nudrin®

Use Marketed as an insecticide dusting agent

Mechanism of Toxic Action Potent, reversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, QT prolongation, sinus bradycardia, sinus tachycardia

Central nervous system: Toxicity is limited because carbamates do not significantly cross the blood-brain barrier; CNS changes occur with most severe intoxications, paresthesia, hyperactivity, cognitive dysfunction, hypothermia

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness, paralysis

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Possesses a slight sulfur odor

Thermal breakdown products include nitrogen oxides and sulfur oxides.

ACGIH TLV: 2.5 mg/m³; PEL-TWA: 2.5 mg/m³

Vapor pressure: 0.00005 mm Hg at 20°C

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Specific References

Methoxychlor

CAS Number 72-43-5

UN Number 2761

U.S. Brand Names Marlate®; Methoxicide®; Metox®; Metron®; Prentox®

Synonyms DMDT; Methoxy-DDT

Use Essentially has replaced DDT (dichlorodiphenyltrichloroethane); methoxychlor is an effective insecticide used on crops, stored grain, livestock, pets, garbage containers, and sewage areas; also used in aerial operations regarding mosquito abatement

Mechanism of Toxic Action Metabolites of methoxychlor essentially act as estrogen analogues; also may deactivate the sodium channel after neuronal activation thus leading to neuronal hyperexcitability

Adverse Reactions While no systemic adverse effects have been attributed solely to methoxychlor to date, the central nervous system and reproductive system (as an estrogen analogue) have been target organs in animal studies

Toxicodynamics/Kinetics

Metabolism: Hepatic demethylation to metabolites conjugated to glucuronic acid

Elimination: Primarily fecal

Reference Range Serum methoxychlor level of 0.67 mcg/mL associated with hypotension in a suicide attempt.

Overdosage/Treatment

Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal; **do not** use oil-based cathartics in that increased absorption of methoxychlor may result. **Dermal:** Remove contaminated clothing; wash with soap and water. **Ocular:** Copious irrigation with saline

Supportive therapy: Benzodiazepines or phenobarbital can be used for seizure control.

Enhancement of elimination: Due to its high lipid solubility and low rate of enterohepatic recirculation (5% to 10%), multiple dosing of activated charcoal is not expected to be effective.

Additional Information

Lethal oral dose of methoxychlor is ~6400 mg/kg

No adverse effects noted in human volunteers ingesting 2 mg/kg/day for 8 weeks

Average daily intake is estimated to be from 0.15 mcg in infants to 0.28 mcg in adults.

TLV-TWA: 10 mg/m². Odor threshold in water: 4.7 ppm (fruity).

Half-life: Atmospheric: 1-11 hours. Water: 1 year. Soil: 30-100 days.

Methyl Bromide

Applies to Fire Extinguishers; Fumigant (Insects)

CAS Number 74-83-9

UN Number 1062

U.S. Brand Names Embafume®; Terabol®

Synonyms Bercema; Bromomethane; Monobromomethane

Use Degreasing wool, extracting oils, insect fumigant, fire extinguishers

Mechanism of Toxic Action Intense vesicant; alkylating agent/sulphydryl enzyme inhibitors

Adverse Reactions

Cardiovascular: Myocardial irritability, Reye's-like syndrome, hypotension

Central nervous system: CNS depression, extrapyramidal signs, cerebellar ataxia, headache, confusion, seizures, psychosis, amnesia

Dermatologic: Skin necrosis, blister

Hepatic: Liver injury, hepatomegaly, centrilobular necrosis

Neuromuscular & skeletal: tremors, axonopathy, myoclonus

Ocular: Blurred vision, diplopia, mydriasis

Renal: Nephritis, oliguria, albuminuria

Respiratory: Pulmonary edema, pulmonary hemorrhage

Miscellaneous: Potentially carcinogenic

Signs and Symptoms of Overdose Acetone breath, anorexia, coma, dermal burns, distal neuritis, dizziness, drowsiness, dyspnea, focusing difficulty, headache, hyperthermia, hyposmia, loss of ankle reflexes, myoclonus, nausea, nystagmus, seizures, vomiting

Admission Criteria/Prognosis Symptomatic patients 12 hours post-exposure should be admitted; while survival after 3 days is usually associated with recovery, central nervous system abnormalities may persist for months

Toxicodynamics/Kinetics

Absorption: By inhalation or through the skin

Metabolism: Hepatic, metabolites to methanol and bromide ion

Half-life: Probably <1 hour

Reference Range Serum bromide levels >5 mg/100 mL require worker removal from the contaminated environment; levels >15 mg/100 mL are associated with toxicity. Serum bromide level of 27 mg/dL and urine bromide level of 6.2 mg/dL were related to fatality.

Overdosage/Treatment

Decontamination: Basic poison management; **do not** induce vomiting; dilute with 4-8 oz of milk or water. For inhalation, give 100% humidified oxygen.

Supportive therapy: Benzodiazepines or phenobarbital can be used for seizure control, if seizures are unresponsive to these agents, thiopental anesthesia should be considered. Use of N-acetylcysteine for dermal exposure to "chelate" unbound methyl bromide is experimental and may worsen clinical effects. Fosphenytoin can be used to treat seizures, vasopressors such as dopamine and phenylephrine can also be used.

Enhanced elimination: Hemodialysis can increase clearance of bromide.

Antidote(s)

- Dimercaprol [ANTIDOTE]

Additional Information Permanent neurological sequelae include depression, paralysis, ataxia, myoclonus. Colorless, odorless gas; burning

METHYL ETHYL KETONE

taste. Readily penetrates leather. Average daily inhalation dose in U.S. urban areas: 4.5-24.5 mcg/adult. TLV-TWA: 5 ppm; IDLH: 250 ppm; PEL-TWA: 5 ppm

Methyl Ethyl Ketone

Applies to Aluminum Foil (Manufacture); Drugs of Abuse (Production); Solvent; Synthetic Leather (Manufacture)

CAS Number 78-93-3

UN Number 1193; 1232

U.S. Brand Names Meetco®

Synonyms 2-Butanone; 2-Oxobutane; Ethyl Methyl Ketone; MEK; Methyl Acetone

Use In production of drugs of abuse; used as a solvent for coatings, adhesives, magnetic tapes, printing inks, paint remover, vinyl films, polystyrene, polyurethane; also used in manufacture of aluminum foil and synthetic leather

Mechanism of Toxic Action Mucosal irritant and central nervous system depressant

Adverse Reactions

Cardiovascular: Hypotension, tachycardia

Central nervous system: Headache at 300 ppm; coma, dizziness, fatigue, panic attacks

Dermatologic: Urticaria, immunologic contact urticaria

Endocrine & metabolic: Metabolic acidosis, hyperglycemia

Hematologic: Methemoglobinemia

Gastrointestinal: Nausea

Neuromuscular & skeletal: Paresthesia

Ocular: Eye irritant at 200 ppm; can cause conjunctival irritation, mydriasis

Respiratory: Irritant at 100 ppm; hyperventilation

Toxicodynamics/Kinetics

Absorption: Inhalation: 41% to 56%

Protein binding: 0%

Metabolism: Hepatic to 3-hydroxy-2-butanone and 2,3-butanediol

Half-life: 49-96 minutes

Elimination: Lungs

Reference Range Plasma 2-butanone level of 95 mg/100 mL consistent with coma in an oral ingestion

Overdosage/Treatment

Decontamination: **Do not** use ipecac. Lavage (preferably with a cuffed endotracheal tube in place to prevent aspiration) for large ingestions within 2 hours; activated charcoal may be useful.

Supportive therapy: Sodium bicarbonate for acidosis

Additional Information Colorless liquid with acetone odor. Odor threshold: < 10 ppm. OSHA-PEL: 200 ppm. OSHA-STEL: 300 ppm. BEI: 2 mg MEK/L.

Methyl Ethyl Ketone Peroxide

Applies to Curing Agent for Plastics and Fiberglass Resins; Hardener for Plastics and Fiberglass Resins

CAS Number 1338-23-4

UN Number 2550

Synonyms 2-Butanone Peroxide; MEK Peroxide; MEKP

Use As a hardener and curing agent for plastics and fiberglass resins

Mechanism of Toxic Action Free radical formation with lipid peroxidation; caustic agent which can also cause glutathione depletion; a strong oxidizer

Adverse Reactions

Cardiovascular: Myocarditis

Central nervous system: Coma

Dermatologic: Eczema

Gastrointestinal: Vomiting

Hematologic: Coagulopathy, leukocytosis

Ocular: Irritation (at concentrations > 3%)

Respiratory: Pneumonitis, stridor

Admission Criteria/Prognosis Admit any ingestion > 10 mL

Overdosage/Treatment

Decontamination: **Oral:** Avoid emesis or lavage. **Dermal:** Irrigate with soap and water. **Ocular:** Irrigate with copious amounts of saline

Supportive therapy: Early upper gastrointestinal endoscopy is suggested but not studied

Acetylcysteine at I.V. doses of 140 mg/kg loading followed by 70 mg/kg every 4 hours for 12 doses may be hepatoprotective

Additional Information Ingestion of > 50 mL is toxic. A colorless liquid with an acetone-like odor, often available in a 40% to 60% solution with dimethyl phthalate; often stored in refrigerators

Specific References

Maloney GE, Pallasch EM, Ahkter S, et al, "Methyl Ethyl Ketone Peroxide Ingestion in a Toddler Treated with N-Acetylcysteine," *Clin Toxicol (Phila)*, 2005, 43:658.

Methyl Isocyanate

Related Information

- Methylene Diisocyanate
- Toluene Diisocyanate

CAS Number 624-83-9

UN Number 2480

Synonyms Isocyanate; Isocyanatomethane; MIC

Use Intermediate agent in the production of carbaryl (Sevin®), a carbamate pesticide and herbicides. Etiologic agent of inadvertent release in 1984 in Bhopal, India.

Mechanism of Toxic Action Mucosal irritant; reacts with water to form exothermic reaction; hydrolyzes to form methylamine and CO₂. MIC is a more potent irritant than other forms of isocyanates. May also result in an allergic response.

Adverse Reactions

Cardiovascular: Chest pain, angina

Central nervous system: Fatigue, vertigo, ataxia, anxiety

Dermal: Erythema, edema

Gastrointestinal: Vomiting, throat irritation

Ocular: Burning eyes, lacrimation, blepharospasm, photophobia, corneal ulceration, punctate keratopathy, lid edema, corneal irritation may persist for one year postexposure

Neuromuscular & skeletal: Muscle weakness, tremor

Renal: Acidosis (renal tubular)

Respiratory: Cough, dyspnea, bronchospasm (persists for 3-7 days), wheezing, interstitial edema, bronchiolitis

Toxicodynamics/Kinetics Absorption: By inhalation and dermal routes

Reference Range Leukocytosis, lymphocytosis and elevated erythrocyte sedimentation rate noted; blood carboxyhemoglobin, methemoglobin, and thiocyanate levels may be high, but this may be due to contaminants

Overdosage/Treatment

Decontamination:

Inhalation: Give 100% humidified oxygen.

Ocular: Remove contact lenses; irrigation with copious amount of water or saline

Supportive therapy: Beta agonist agents with theophylline may be helpful; steroids (prednisone or high-dose inhaled beclomethasone) may be useful. Thiosulfate does not appear to be helpful and cyanide antidotal therapy should not be utilized. Inverse-ratio ventilation using lower tidal volume mechanical ventilation (6 mL/kg) and plateau pressures of 30 cm water may decrease mortality. While positive end expiratory pressures should be considered, oxygen toxicity should be monitored. Use of perfluorocarbon partial liquid ventilation and exogenous surfactant in chemical-induced ARDS is investigational.

Experience after Bhopal, India 1984 exposure of 865 pregnancies revealed that 43% did not result in a live birth and an infant death rate of 14%. MIC can cross placental barrier; skeletal malformations noted in rodent studies.

Additional Information

Mucous membrane irritant threshold: 0.2 ppm. Unbearable exposure: 21 ppm; respiratory response is likely at an air concentration of > 0.5 ppm Very flammable. TLV-TWA: 0.02 ppm. Odor threshold: 2 ppm

Toxic agent responsible for 3,828 deaths in December 1984 in Bhopal, India

Pyrolysis decomposition products include hydrogen cyanide and carbon dioxide; MDI is more toxic when heated

Involved in the recall of > 8 billion cigarettes by the Philip Morris Co in May 1995 due to contaminated plasticizer compound in the cigarette filter

Specific References

Ranjan N, Sarangi S, Padmanabhan VT, et al, "Methyl Isocyanate Exposure and Growth Patterns of Adolescents in Bhopal," *JAMA*, 2003, 290(14):1856-7.

Methyl Mercaptan

Applies to Jet Fuel; Odorless Hazardous Gases (Agent to Add Odor); Pesticides; Plastics

CAS Number 74-93-1

UN Number 1064

Synonyms Methanethiol; Thiomethanol; Thiomethyl Alcohol

Use Production of jet fuel, pesticides, and plastics; used as an agent to add odor to odorless hazardous gases (not natural gas)

Mechanism of Toxic Action Can cause oxidative stress to red blood cell membranes (especially in patients with glucose-6-phosphate dehydrogenase deficiency) thus resulting in hemolysis

Adverse Reactions

Cardiovascular: Tachycardia, hypertension, sinus tachycardia

Central nervous system: Seizures, coma, headache, dizziness

Hematologic: Hemolytic anemia, methemoglobinemia, anemia

Ocular: Eye irritation

Renal: Diuresis

Miscellaneous: Mucosal irritation

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Toxicodynamics/Kinetics

Absorption: By inhalation
Metabolism: To dimethyl sulfide
Elimination: Primarily by lungs

Overdosage/Treatment

Decontamination: **Dermal:** Wash with soap and water. **Inhalation:** Give 100% humidified oxygen. **Ocular:** Irrigate copiously with saline.

Supportive therapy: Treat symptomatic methemoglobinemia with methylene blue (monitor closely in G6PD-deficient patients). Promote an alkaline diuresis to avoid adverse renal effects of hemolysis. Diazepam or lorazepam can be initially used to treat seizures. Refractory seizures can be treated with phenytoin or phenobarbital. Hypertensive emergencies can be treated with nitroprusside (0.1-5 mcg/kg/minute up to 10 mcg/kg/minute). Labetalol or hydralazine can be used for hypertensive urgencies.

Antidote(s)

- Methylene Blue [ANTIDOTE]

Diagnostic Procedures

- Methemoglobin, Blood

Additional Information Flammable gas which can be explosive; a reduced sulfur gas from pulp air emissions. Gas specific gravity: 1.66. Very soluble in water. Odor threshold: 1.6 ppb (rotten cabbage). TLV-TWA: 0.5 ppm; IDLH: 400 ppm. Atmospheric half-life: 0.2-30 hours

Methyl Tert-Butyl Ether

Related Information

- Gasoline

CAS Number 1634-04-4

UN Number 2398

Synonyms MBE; MTBE; Tert-Butyl Methyl Ether

Use Reformulated gasoline; pharmaceutical agent to dissolve gallstones through an intraductal route via a thistle catheter; to increase octane (up to 15%) and reduce levels of carbon monoxide emissions; oxygenate agent in motor gasoline

Investigational: Cholesterol gallstones

Mechanism of Toxic Action Lipophilic, volatile solvent which acts as a central nervous system depressant (through changes in neuronal membrane fluidity)

Adverse Reactions

Central nervous system: Headache, dizziness, sedation, ataxia, coma
Gastrointestinal: Nausea, vomiting
Hematologic: Hemolysis
Ocular: Eye irritation, lacrimation
Respiratory: Coughing, nasal irritation

Admission Criteria/Prognosis Patients who develop tachypnea, cyanosis, dyspnea, CNS depression, tachycardia, or fever within 8 hours of exposure should be admitted; asymptomatic patients can be discharged after 8 hours observation

Toxicodynamics/Kinetics

Absorption: Inhalation (2.4%), orally, and dermally
Metabolism: Hepatic to tert-butanol, formaldehyde, methanol, and carbon dioxide
Half-life (rodents): 1-2 hours
Elimination: Lungs, feces, and urine

Monitoring Parameters Liver function tests, chest x-ray

Reference Range

Median blood levels of MTBE: Commuters: 0.1 mcg/L; Car repairers: 2.0 mcg/L (tert-butanol: 15 mcg/L); Gas station attendants: 15.0 mcg/L (tert-butanol: 75 mcg/L)

Healthy volunteers exposed for 1 hour at 1.7 ppm: 17.0 mcg/L
After intracystic administration, mean tert-butanol blood levels were 0.04 mg/mL and 0.02-0.03 mg/mL in urine

Overdosage/Treatment

Decontamination: **Oral:Do not** induce emesis. Activated charcoal is not recommended since it is poorly absorbed to activated charcoal; dilute with milk or water. **Dermal:** Wash with soap and water. **Ocular:** Copious irrigation with saline. **Inhalation:** 100% humidified oxygen
Not genotoxic; no specific toxicity to reproduction and development

Additional Information

Intraductal dose of MTBE for treatment of gallstones: 1-15 mL (up to 140 mL) instilled 3-6 times/minute and then reaspirated.

Methanol is only detected in trace amounts and is not considered to be a major problem.

Odor threshold in water: 680 ppb. Atmospheric lifetime: 4 days. Ambient water level of MTBE: 15-81 mcg/L. Median level of MTBE in snow samples (near Denver): 0.05 mcg/L. Workplace environmental exposure level (8-hour weighted average): 100 ppm

Maximum permissible concentration of MTBE in Europe: 15%

MTBE → TBA → TBA-Glucuronide

2-methyl-1,2-propanediol → 2-hydroxy-isobutyrate

Acetone

McGregor D, "Methyl Tertiary-Butyl Ether: Studies for Potential Human Health Hazards," *Crit Rev Toxicol*, 2006, 36:319-58.

Methylene Chloride

CAS Number 75-09-2

UN Number 1593

Synonyms Dichloromethane; Freon 30; Methane Dichloride

Commonly Found In Paint and varnish removers, fire extinguishers, and fumigants

Mechanism of Toxic Action Solvent-induced depression/carbon monoxide effects

Adverse Reactions

Central nervous system: Anesthesia, headache (5000 ppm), decreased hearing (300 ppm), syncope, memory disturbance, chest pain, lightheadedness (500 ppm), hyperthermia, erythema (mild burns), dry scaling, dyspnea, lethargy, seizures, fatigue, corneal vorns, nausea, vomiting

Renal: Tubular necrosis (acute)

Signs and Symptoms of Overdose Dermal burns, dizziness, dyspnea, encephalopathy, eye irritation, lightheadedness, skin irritation, tremor

Admission Criteria/Prognosis Oral ingestions >0.5 mL/kg, carboxyhemoglobin level >5% in nonsmokers, or symptomatic patients should be admitted

Toxicodynamics/Kinetics

Absorption: Inhalation (70% to 75%), oral (98% within 20 minutes), and dermal

Metabolism: Converted hepatically to carbon monoxide (30%) and carbon dioxide (70%)

Half-life: 40 minutes

Elimination: Primarily pulmonary (carbon monoxide/carbon dioxide)

Monitoring Parameters Laboratory data for surveillance would include complete blood count, liver function tests, post-shift carboxyhemoglobin, pulmonary function testing, and electrocardiogram

Reference Range

Blood levels of 2 mg/L correlate with exposure of 200 ppm; carboxyhemoglobin levels in nonsmokers are usually in the range of 8% to 20% postexposure

Fatal methylene chloride urine levels range from 2-160 mg/L

Overdosage/Treatment

Decontamination: Basic poison management. Dermal/ocular: Irrigate with copious amounts of saline or water

Supportive therapy: 100% humidified oxygen; hyperbaric oxygen has been advocated for patients with neurological abnormalities; monitor carboxyhemoglobin levels

Diagnostic Procedures

- Carboxyhemoglobin, Blood

Additional Information Minimum lethal oral dose: 0.5-5.0 mL/kg; acute oral lethal dose: 375 mg/kg; acute air concentration exposure for lethality: 50,000 ppm

Colorless fluid, pleasant odor; not flammable or explosive

Adverse health effects on newborns may occur at methylene chloride levels of >565 mg/L in drinking water.

Mean concentrations in drinking water: Usually <1 mcg/L. Odor threshold (sweet): Water: 9.1 ppm; air: 160-620 ppm. Atmospheric half-life: 100-500 days. TLV-TWA: 50 ppm; IDLH: 5000 ppm; PEL-TWA: 500 ppm

Ambient atmospheric concentrations of methylene chloride in U.S. urban areas range from 0.8-6.7 ppt; in rural/suburban areas, the range is from 0.18-2.1 ppt. Hair spray can cause levels as high as 50 ppm (TWA: 0.17 ppm) of methylene chloride.

Upon heating of methylene chloride to decomposition, phosgene gas may be liberated.

Hoffer E, Tabak A, Scherb I, et al, "Monitoring of Occupational Exposure to Methylene Chloride: Sampling Protocol and Stability of Urine Samples," *J Anal Toxicol*, 2005, 29(8):794-8.

Methylene Dianiline

Applies to Corrosive Inhibitor; Hardening Agent (Epoxy Resin); Polyurethane (Curing Agent); Polyurethane Foam (Production)

CAS Number 101-77-9

UN Number 2651

U.S. Brand Names Ancamine TL; Epicure DDM; Tonox

Synonyms 4,4-Methylene Dianiline; DDM; MDA

Use Curing agent for polyurethane; corrosive inhibitor; used in preparation of A₃₀ dyes; production of 4-4'-methenedianiline diisocyanate and other polymeric isocyanates which are used in polyurethane foam, isocyanate resins and elastomer; also used in production of epoxy-resin hardening agents

Mechanism of Toxic Action Contact allergen, hepatotoxin; possibly carcinogenic in humans (urinary tract)

Adverse Reactions

Central nervous system: Psychosis
 Dermatologic: Erythema multiforme
 Hematologic: Eosinophilia
 Hepatic: Toxic hepatitis ("Epping jaundice"), cholestasis
 Ocular: Optic neuritis
 Respiratory: Bronchoconstriction

Signs and Symptoms of Overdose Dyspnea, epigastric pain, hepatomegaly, jaundice, myalgia, nausea, ocular irritation, visual dysfunction; yellow discoloration of skin, fingernails, and hair

Toxicodynamics/Kinetics

Absorption: Dermal (13%), inhalation and oral
 Metabolism: Hepatic oxidation to N-hydroxymethylenedianiline
 Half-life: 9-19 hours
 Elimination: Renal (primarily) and feces

Reference Range Can be measured in urine to a detection level of 2 mcg/L

Overdosage/Treatment

Decontamination: **Oral:** Ipecac or lavage within 1 hour; activated charcoal. **Dermal:** Flush with soap and water. **Ocular:** Irrigate with saline.
 Supportive therapy: Beta agonists (nebulized) can be utilized for bronchoconstriction.

Additional Information Faint amine-like odor; irritating at levels of 1 ppm. Specific gravity: 1.1; not volatile in water. Atmospheric half-life: 1.6 hours. TLV-TWA: 0.1 ppm. Causative agent in "Epping jaundice" due to flour contamination in Epping, England in 1965.

Specific References

Stout PR, Horn CK, and Klette KL, "Rapid Simultaneous Determination of Amphetamine (AMP); Methamphetamine; 3,4-Methylenedioxyamphetamine (MDA); 3,4-Methylenedioxyamphetamine (MDMA); and 3,4-Methylenedioxyethylamphetamine (MDEA) in Urine by Solid-Phase Extraction and GC-MS: A Method Optimized for High-Volume Laboratories," *J Anal Toxicol*, 2003, 27:190.

Methylene Diisocyanate

Related Information

- Methyl Isocyanate
- Toluene Diisocyanate

CAS Number 101-68-8

UN Number 2487; 2489

Synonyms MDI; Methylene Bisphenyl Isocyanate

Use Production of rigid polyurethane foams and plastics

Mechanism of Toxic Action A respiratory irritant and pulmonary sensitizer

Adverse Reactions Respiratory: Asthma, reactive airways dysfunction syndrome

Signs and Symptoms of Overdose Abdominal pain, bronchospasm, chest pain, conjunctivitis, cough, dyspnea, eye irritation, headache, vomiting

Overdosage/Treatment

Decontamination: **Oral:** Do not induce emesis; dilute with milk or water. **Dermal:** Wash with soap and water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate with copious amounts of saline.
 Supportive therapy: Bronchodilators can be used for bronchospasm.

Additional Information Light yellow to white crystals. Specific gravity: 1.19. TLV-TWA: 0.005 ppm; IDLH: 10 ppm. Magna Dry Incorporated, Henison, MI 42428 (616) 457-6664 can be contacted regarding emergency information of MDI.

Methylparathion

CAS Number 298-00-0

UN Number 3017

U.S. Brand Names A-Gro®; Azofos®; Bladan-M®; Dalf®; E601®, ME-Parathion®; Metapon®; Nitrox®; Penncap-M®; Wofatox®

Synonyms Cotton Poison

Use Insecticide which is applied to crops, cotton, soybeans, and fruit trees; approved for outdoor use only. See tables.

Incidents of Illegal Domestic Indoor Use of Methyl Parathion

Year	Location	Number of Residences Involved	Estimated Cost of Cleanup
1984	Tunica, Mississippi	1*	—
1994	Lorain County, Ohio	232	\$20 million
1995	Detroit, Michigan	4	\$1 million
1996	Jackson County, Mississippi	2600	\$50 million
1997	Cook County, Illinois	680	\$20 million
1997	Texas City, Texas	7	—

* Two deaths (children)

Action Level for Residential Relocation

Age (years)	Urinary Methylparathion Level (parts per billion)
0-1 (and pregnant women)	> 50
1-16	> 300
> 16	> 600

All urine levels are creatinine adjusted.
 Relocation rate in previous episodes ranges from 4% to 12%.
 From Environmental Protection Agency, 1997.

Mechanism of Toxic Action Potent, irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system; this is in the class of a phosphorothioate organophosphate; high lipid solubility which can result in delayed toxicity

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, QT prolongation, AV block
 Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia
 Endocrine & metabolic: Hypoglycemia
 Genitourinary: Urinary incontinence
 Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia, rhabdomyolysis
 Ocular: Ptosis
 Respiratory: Pulmonary edema, respiratory depression
 Miscellaneous: Flu-like symptoms (especially with chronic exposure), intermediate syndrome

Admission Criteria/Prognosis Any symptomatic patient or an asymptomatic patient following a severe exposure should be admitted probably into an intensive care unit; asymptomatic patients following a moderate exposure can be discharged after 8 hours of observation

Toxicodynamics/Kinetics

Absorption: Inhalation, oral, and dermal routes
 Metabolism: Enzymatic hydrolysis to dimethylphosphoric acid and 4-nitrophenol
 Elimination: Renal

Reference Range

Mild poisoning: Serum cholinesterase is 20% to 50% of normal
 Moderate poisoning: Serum cholinesterase is 10% to 20% of normal
 Severe poisoning (respiratory distress and coma): Serum cholinesterase is < 10%

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can also be used
Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of organophosphates.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses >100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M.)

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Additional Information

Estimated lethal dose: Oral: Adults: 5-50 mg/kg (7 drops to 1 teaspoon)

No neurologic effect at oral daily doses of up to 19 mg

Depression of cholinesterase can occur with daily dosage >0.43 mg/kg. The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Toxicity is lower than that of parathion

Estimated daily intake in adults: **Inhalation:** In agricultural areas: 0.1-2.6 mcg. **Ingestion:** Food: 0.01-2 mcg; Drinking water: 0.4 mcg

Soil half-life (degrades faster in nonsterile soil): Aerobic: 64 days; Anaerobic: 7 days. Odor threshold: 0.012 ppm (rotten egg). Water half-life: pH <8: 72-89 days (40°C); pH >8: 4 days (40°C)

Can leave a yellow stain following spraying

As of mid-July 1997, approximately 4500 premises have been reported sprayed with methylparathion; 18,000 people have been affected, including 10,000 children and 2300 people have been relocated until their homes can be cleaned up. The U.S. Environmental Protection Agency (EPA) estimates that the cost of this problem as of July 1997 is \$200 million. Incidents of indoor methylparathion use continue to be reported, the most recent in Texas City, Texas, in May 1997. For more information, or to obtain the "ATSDR Methyl Parathion Expert Panel Report," contact Leslie Campbell, MS at ATSDR, DHEP, 1600 Clifton Road, NE, MS E33, Atlanta, GA 30333; telephone: (404)639-6205; fax: (404)639-6208; e-mail: lca2@cdc.gov

Metobromuron

Applies to Herbicide

U.S. Brand Names Galex®; Patoran®

Synonyms 3-(Para-Bromophenyl)-L-Methoxyl-L-Methylurea

Use Herbicide used in control of grasses and broadleaf weeds

Mechanism of Toxic Action A substituted phenylurea herbicide which can cause methemoglobinemia due to its aniline derivative.

Adverse Reactions

Cardiovascular: Cyanosis, hemolysis

Central nervous system: Dizziness

Endocrine & metabolic: Metabolic acidosis

Gastrointestinal: Vomiting

Hematologic: Methemoglobinemia (may be late onset)

Admission Criteria/Prognosis Monitor for methemoglobinemia in any ingestion, for 24 hours

Toxicodynamics/Kinetics

Metabolism: Hydrolysis pathway yielding toxic aniline metabolites (4-bromoaniline, bromoacetanilide, bromophenylurea)

Elimination: Renal

Reference Range Peak serum and urine levels following an adult ingestion of 250 mL (50% metobromuron) were 4.9 mg/L and 0.6 mg/L respectively, 17 hours postingestion.

Overdosage/Treatment

Decontamination: Lavage within 2 hours any ingestion; activated charcoal can be given

Supportive therapy: I.V. methylene blue (1% concentration: 1.5-2 mg/L) should be given for symptomatic patients or methemoglobin levels >30%. Administer 100% oxygen therapy.

Antidote(s)

- Methylene Blue [ANTIDOTE]

Mineral-Based Crankcase Oil

CAS Number 8002-05-9

UN Number 1267; 1270

Synonyms API 79-7; Automotive Motor Oil; Base Engine Oil; Marine Diesel Oil; Petroleum

Use Supplemental fuel in engines, steam boilers, and domestic oil burners; incorporated into asphalt and as a dust suppressant on rural roads

Mechanism of Toxic Action Mixture of low and high molecular weight hydrocarbons (aliphatic, aromatic, naphthenic, and paraffinic); sulfur, oxygen, nitrogen compounds, and metals (lead, zinc, cadmium, nickel) may be present

Adverse Reactions

Central nervous system: Headache

Dermatologic: Rash

Gastrointestinal: Stomatitis

Neuromuscular & skeletal: Tremors

Ocular: Eye irritation at levels of 18.9 mg/m³

Admission Criteria/Prognosis Patients who develop tachypnea, cyanosis, dyspnea, CNS depression, tachycardia, or fever within 8 hours of exposure should be admitted; asymptomatic patients can be discharged after 8 hours observation

Toxicodynamics/Kinetics

Absorption: Some dermally

Elimination: Primarily fecal

Overdosage/Treatment Decontamination: **Oral:** Dilute with water. **Dermal:** Wash skin with water and mild green (lipophilic) soap. **Ocular:** Copious irrigation with normal saline

Additional Information Monitor for toxicity of lead or molybdenum in used oil.

Oil from engines emitted directly with auto exhaust at concentrations of 0.1-0.3 L/1000 km

Lead levels on road surfaces treated with this compound are over 5 times higher than background lead levels (209 mg/kg vs 39 mg/kg respectively).

Hydrocarbon levels at the surface of treated roads range from 5880-13,441 mg/kg.

Background concentration of hydrocarbons in road soil near industrial area is ~856 mcg/g; near highways it is 265 mcg/g

Mirex**Related Information**

- Adipose Tissue Ranges of Toxins

CAS Number 2385-85-5

U.S. Brand Names Dechlorane® 4070; Ferriamicide®

Synonyms Fire Ant Bait

Use Primarily an insecticide to control fire ants and Western harvester ants; control leaf cutters, mealy bugs, and yellow jackets; historical use (until 1972) as a fire retardant

Mechanism of Toxic Action In animal models, mirex induces liver growth possibly mediated by corticosterone

Adverse Reactions None described in humans; target organ in animal models for toxicity is liver and thyroid

Toxicodynamics/Kinetics

Metabolism: Not metabolized

Half-life: > 1 year

Elimination: Primarily fecal and through breast milk

Reference Range Mirex blood levels in asymptomatic unexposed individuals should be <0.04 ng/g whole blood

Overdosage/Treatment

Decontamination: **Oral:** Lavage within 1 hour/activated charcoal or cholestyramine. **Dermal:** Flush skin with soap and water.

Supportive therapy: Propranolol may be effective in treatment of tremors. Phenobarbital can be used for seizure control.

Enhancement of elimination: Although data are lacking, cholestyramine resin (4 g every 8 hours) may be effective.

Additional Information Water half-life: 48 hours; virtually insoluble in water. Soil half-life: 10 years. FDA action level for fish: 0.1 ppm.

Molybdenum

CAS Number 7439-98-7

Synonyms Mo

Use A byproduct of uranium mining, molybdenum is used in metallurgy; molybdenum trioxide is a corrosive inhibitor as is zinc molybdate; molybdenite is used as a lubricant

Mechanism of Toxic Action An essential component of several enzymes (aldehyde oxidase, xanthine oxidase, and sulfite oxidase) which catalyze oxidation-reduction reactions. It is an upper respiratory tract irritant and in animals the formation of trithiomolybdate may disturb copper metabolism.

MONOSODIUM METHANARSENATE

Signs and Symptoms of Overdose Anorexia, arthralgias, diarrhea, fatigue, gout (hyperuricemia), headache, and low copper levels have occurred with chronic exposure. Pneumoconiosis can occur.

Toxicodynamics/Kinetics

Absorption: Oral: 50% to 93%

Elimination: Renal (high copper and sulfates appear to enhance renal elimination)

Monitoring Parameters Uric acid, copper, renal/liver function tests

Reference Range Normal population range: Whole blood: <5 ng/mL; urine: 10-124 mcg/L

Overdosage/Treatment Decontamination: **Oral:** Emesis or lavage within 2 hours for ingestions > 100 mg. Activated charcoal is of unknown utility. **Dermal:** Wash skin with soap and water. **Inhalation:** Administer 100% humidified oxygen.

Additional Information Average dietary intake: 0.1-0.5 mg/day

Ambient air concentrations: Urban: 0.01-0.03 mcg/m³. Rural: 0.001-0.0032 mcg/m³. From coal fly ash: 7-160 mg/kg

Soil average concentration: 1-2 mg/kg. Sewage sludge: 1-40 mg/kg. Water: <3 mcg/L

Monosodium Methanarsenate

Applies to Arsenic

CAS Number 2163-80-6

Synonyms Arsonate Liquid; MSMA

Use Pesticide / herbicide

Signs and Symptoms of Overdose Agranulocytosis, alopecia, blindness, cough, encephalopathy, fasciculations, fever, garlic-like breath, hematuria, hemolytic anemia, hypotension, lacrimation, leukopenia, Mees' lines (on nail beds; forms at 4-6 weeks postexposure), myoglobinuria, neuritis, nystagmus, pancytopenia, paresthesia, radiopacity, seizures, stocking-glove sensory neuropathy, sweating, tachycardia, torsade de pointes, tremor

Reference Range

Urine concentrations in nonexposed individuals ≤50 mcg/L; hair concentrations detectable 30 hours postingestion; urine ≥100 mcg/L is suggestive for chronic exposure; blood not usually helpful, although blood arsenic levels > 1000 mcg/L are usually associated with fatality; background blood arsenic level is usually <1 mcg/L

Mean urine concentration of arsenic 0.2 mg/L associated with fatal poisoning

Overdosage/Treatment

Decontamination:

Oral: Lavage (within 1 hour)/activated charcoal. Aluminum hydroxide may prevent absorption of pentavalent arsenic compounds (due to its phosphate-binding abilities), although this has not been investigated in humans. Whole bowel irrigation is effective.

Dermal: Remove contaminated clothing; wash with soap and water.

Ocular: Copious irrigation with saline

Supportive therapy: Succimer (at standard doses to treat lead poisoning) is probably the treatment of choice. 2,3-Dimercaptopropane sulphonate (DMPS or unithiol) is also useful to enhance this metal's elimination at a dose of 100 mg 3 times/day orally for 5 days. 2,3-Dimercaptopropane-sulphonate (DMPS), a water soluble derivative of dimercaprol, has been recently demonstrated to prevent polyneuropathy when started within 48 hours of exposure at a dose of 5 mg/kg I.V. every 4 hours for 24 hours, and then 400 mg orally every 4 hours for 5-7 days. BAL should be utilized for severe acute exposures except for arsine gas. Penicillamine provides long-term therapy or alternatives to BAL.

Enhanced elimination: Hemodialysis clearance of arsenic ranges from 76-87 mL/minute; the clinical utility of this modality is unknown. No studies have been performed regarding hemodialysis with metal-chelate compound. Clearance of arsenic through hemodialysis is estimated to range from 76-87 mL/minute. Due to tissue binding of arsenic, this is not felt to be a useful modality for removal of arsenic. No current studies exist on the use of chelation with extracorporeal removal methods.

Additional Information Probably more hepatotoxic and ototoxic than inorganic arsenic

Monitor audiometry

Lethal dose is probably about 1700 mg/kg

Specific References

DeCapitani EM, Vieira RJ, Madureira PR, et al, "Auditory Neurotoxicity and Hepatotoxicity After MSMA (Monosodium Methanarsenate) High Dose Oral Intake," *J Tox Clin Tox*, 2005, 43:287-9.

Morpholine

CAS Number 110-91-8; 147-90-0

UN Number 1760; 2054

U.S. Brand Names Deposal®; Retarcyl®

Synonyms Diethylene Imidoxide; Diethylene Oxide

Use

A corrosion inhibitor and solvent for resins, waxing and dyes; used also as an emulsifier, plasticizer, antioxidant, and insecticide

Morpholine salicylate: Therapeutically for musculoskeletal disorders

Mechanism of Toxic Action Mucosal irritants; an alkaline caustic agent (pH ~11)

Signs and Symptoms of Overdose Conjunctivitis, corneal edema, cough and nasal irritation (after 1.5 minute exposure at 1200 ppm), dermal irritation at concentrations >25%, foggy blue-grey vision with halos surrounding lights after vapor exposure (glaucompsia), pharyngitis

Admission Criteria/Prognosis Patients with persistent pulmonary symptoms 6-8 hours after exposure or known exposures at concentrations > 1000 ppm should be considered for hospital admission

Toxicodynamics/Kinetics

Absorption: Via dermal/oral routes

Protein binding: None

Half-life: 2-5 hours in animal studies

Elimination: Renal

Monitoring Parameters Chest x-ray, liver/renal function test

Overdosage/Treatment Decontamination: **Oral:** Dilute with water within 1 hour postexposure. **Dermal:** Wash with soap and water. **Inhalation:** Administer 100% oxygen. **Ocular:** Irrigate copiously with saline for at least 30 minutes.

Additional Information Colorless liquid (with an amine-like odor). Specific gravity 1.002, with a vapor density at 38°C of 1.1. Odor threshold (in air): 0.01 ppm. Odor threshold (in water): 0.2 mg/L. Taste threshold (in water): 0.2 mg/L. TLV: 20 ppm, PEL-STEL 30 ppm; IDLH: 8000 ppm

Mustard Gas

CAS Number 505-60-2

Synonyms Bis(2-Chloroethyl) Sulfide; Distilled Mustard; HD; MG; S-Mustard; Yperite

Use Primarily of historical use during World War I as a vesicant chemical warfare agent; most recently used for this purpose during the Iran-Iraq War in the 1980s; derivative of this chemical has been used as an antineoplastic agent (an alkylating agent - nitrogen mustard)

Mechanism of Toxic Action Dermal, ocular, and respiratory corrosive agent; this agent combines with DNA thus preventing cell replication

Adverse Reactions

Children may have a shorter time for symptom onset with more severe skin lesions.

Central nervous system: Fever

Dermatologic: Erythema and pruritus; may be delayed for up to 8 hours, then ulceration, dermal burns, and blisters can result

Gastrointestinal: Vomiting, nausea, diarrhea, anorexia

Hematologic: Bone marrow suppression, pancytopenia; leukopenia usually occurs 7-10 days postexposure; eosinophilia can be seen in children

Ocular: Lacrimation, photophobia, blepharospasm, ocular irritation, opacification, blindness

Respiratory: Dyspnea, cough (usual onset is 1-12 hours postexposure)

Toxicodynamics/Kinetics

Absorption: Lungs or skin (at a rate of 1-4 mcg/cm²/minute); 20% absorption rate dermally

Metabolism: Hepatic through hydrolysis and glutathione pathways

Elimination: Renal accounts for ~21% of excretion

Reference Range Urine thiodiglycol levels >30 ng/mL 12 days post-exposure associated with severe ocular and skin lesions

Overdosage/Treatment

Decontamination: **Note:** Penetrates wood, leather, rubber, and paints; decontamination must occur within 2 minutes.

Oral: Activated charcoal or 150 mL of 2% sodium thiosulfate orally

Dermal: Remove all contaminated clothing. Towels soaked in 0.2% chloramine-T in water (Dakin solution) placed over wounds for the first 2 hours may be helpful. Wash with soap and water (not hot). Can wash with dilute (0.5%) hypochlorite, then neutralize with 2.5% sodium thiosulfate. If no water is available, dry decontamination with Fuller's earth can be utilized. Treat wounds as burns with use of 1% silver sulfadiazine (twice daily). Leave small blisters (<1 cm) intact; unroof larger blisters and irrigate.

Ocular: Copious irrigation with saline (neutralize with 2.5% solution of sodium thiosulfate); remove contact lenses

Respiratory: Administer 100% oxygen. A nebulized mist of 2.5% sodium thiosulfate may be helpful as a neutralizing agent if given within 15 minutes of exposure.

Supportive therapy: N-acetylcysteine 4 times/day (up to 150 mg/kg), along with ascorbic acid (3 g), thienamycin (2 g twice daily), L-carnitine (3 g), and sodium thiosulfate (3-12.5 g/day), has been used to ameliorate effects, but it is unproven in its efficacy. For ocular exposure, topical antibiotics, mydriatics, and possibly corticosteroids can be utilized. Vaseline® placed on eyelid edges may prevent lids from adhering. For dermal burns, topical antibiotics with systemic analgesics are the mainstay of therapy. Do not overhydrate the patient. Do not fluid resuscitate as in thermal burns. Colony stimulating factor may be helpful in treating leukopenia. Prednisone (60-125 mg/day) orally can be helpful in treating pulmonary toxicity. Bronchospasm should be treated with beta₂ adrenergic agonist agents.

Additional Information Toxic dermal dose: 0.1% solution
Fair skinned individuals are more at risk for adverse dermal effects than dark skinned individuals.
Total white blood cell count <200 is a harbinger for fatality. No mustard can be isolated in blister fluid.
Higher wind speeds, higher temperature and humidity increase the atmospheric vaporization rate; may persist in soil for weeks
Combat zones atmospheric concentration of mustard gas during WWI was estimated to be from 3-5 ppm; case fatality rate: 2% to 4%.
Since mustard gas binds rapidly and avidly to tissue proteins, decontamination must begin immediately, and increasing elimination of absorbed chemical is difficult.

N,N-Dimethyl-P-Toluidine

CAS Number 99-97-8

Use Found in solutions used in production of artificial fingernails solution

Mechanism of Toxic Action Methemoglobin producer through active metabolite

Signs and Symptoms of Overdose Acetone breath, cyanosis, drooling, Heinz body formation (formation of methemoglobinemia takes 2-3 hours), methemoglobinemia

Toxicodynamics/Kinetics Metabolism: Probably to paramethylphenyl hydroxylamine (active producer of methemoglobin)

Monitoring Parameters Methemoglobin

Reference Range Ingestion of 6 mg/kg resulted in methemoglobinemia of 43%

Overdose/Treatment

Decontamination: Emesis within 30 minutes, lavage (within 1 hour)/activated charcoal. Remove patient from inhalation and administer 100% humidified air. Exposed skin and eyes should be irrigated with water.

Supportive therapy: Methemoglobinemia: Treat symptomatic patients or if level is >20%, administer 100% oxygen. If required, methylene blue: 1-2 mg/kg/dose I.V. over a few minutes; may repeat in 4 hours if needed. Doses > 15 mg/kg may cause hemolysis. High doses of methylene blue may precipitate Heinz body formation and hemolysis. Transfusion of PRBCs may be needed. Treatment for myoglobinuria may require urine alkalization and maintenance of adequate urinary output to prevent renal damage.

Antidote(s)

- Methylene Blue [ANTIDOTE]

Naphthalene

Related Information

- Adipose Tissue Ranges of Toxins

CAS Number 91-20-3

UN Number 1334; 2304

Synonyms Camphor Tar; Moth Balls; Moth Flakes; Naphthalin; Naphthene; White Tar

Use Moth repellents, toilet bowl deodorizers, in scintillation counters, in the manufacture of phallic anhydride, naphthol, hydrogenated naphthalenes, and halogenated naphthalenes; formerly used as an antihelmintic

Mechanism of Toxic Action Hemolysis caused by oxidation products of naphthalene; in patients with G6PD deficiency, metabolites cause instability of erythrocyte glutathione

Adverse Reactions

Cardiovascular: Sinus tachycardia

Hematologic: Glucose-6-phosphate dehydrogenase deficiency-induced hemolytic anemia

Signs and Symptoms of Overdose Anemia, coma, drowsiness, fever, headache, hematuria, hemolysis, hyperkalemia, methemoglobinemia, restlessness, seizures, urine discoloration (black) and vomiting may develop in severe intoxications. Tachycardia or hypotension may also occur. Hepatocellular injury is rare, but may occur in 3-5 days after exposure.

Admission Criteria/Prognosis Consider admission if ingestion of more than one mothball has occurred and patient is symptomatic, if CBC or urinalysis is abnormal, or if the patient has a previous hematological condition (ie, G6PD deficiency); any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Toxicodynamics/Kinetics

Absorption: Dermal: Also enhanced by oil. Inhalation: Rapid. Oral: Erratic; soluble in oil so coadministration will enhance absorption

Metabolism: Through liver; oxidation to naphthol and naphthoquinone; glutathione conjugated to thioethers are also noted

Elimination: Excreted in kidney as a 1,4-naphthoquinone metabolite over a 2-week period; fecal excretion accounts for <10%

Reference Range Adipose tissue levels up to 63 mcg/kg have been detected in asymptomatic individuals

Overdose/Treatment

Decontamination: **Oral:** Emesis or lavage within 2 hours; activated charcoal. Avoid milk for 2-3 hours in that absorption may increase.

Dermal: Wash with soap and water; avoid oil-based compounds.

Ocular: Copious irrigation with saline

Supportive therapy: Alkaline diuresis may be needed if hemolysis occurs (use Ringer's lactate or I.V. sodium bicarbonate to keep urine pH >7.5). Mannitol or furosemide may be required to promote urine flow. Methylene blue: 1-2 mg/kg of 1% if the patient is symptomatic or has a methemoglobin level >30%. Transfusion for severe anemia. Dialysis has been used for supportive care. Exchange transfusion has been used for supportive care, but is not routinely recommended.

For inhalation injuries, nebulized budesonide (0.5 mg every 12 hours for 4 days - pediatric dose) was found to be helpful

Antidote(s)

- Methylene Blue [ANTIDOTE]

Additional Information Detection and quantitation of naphthalene and metabolites through TLC, HPLC, gas chromatography with mass spectrometry, and high resolution proton magnetic resonance. CBC with smear

N-BUTYL CHLORIDE

to detect for schistocytes and cell fragments, BUN, creatinine, electrolytes, methemoglobin, urinalysis (check for hemoglobinuria), G6PD, LFTs; urine may be sent for 1-naphthol.

See table.

Distinguishing Characteristics of Mothballs			
	PDB	Naphtha	Camphor
Physical	Wet and oily	Dry	
Water	Sink	Sink	Float
4 oz water + 3 heaping tsp salt	Sink	Float	Float
Drop of turpentine	Soluble	Moderately soluble	
Heating	Green color	No color	

PDB = paradichlorobenzene.
Naphtha = naphthalene.

Odor threshold: Water: 0.021 mg/L. Air: 0.44 mg/m³
Water half-life (photolysis): 71 hours (surface water); 550 days (deep water > 5 meters)
Ambient atmospheric concentration in U.S.: ~1 ppm
PEL-TWA: 10 ppm (50 mg/m³); TLV-TWA: 10 ppm (52 mg/m³); IDLH: 500 ppm
In drinking water, concentrations as high as 1.5 mcg/L have been noted. Average daily intake of naphthalene is ~19 mcg by inhalation and 0.002-4 mcg from drinking water.

N-Butyl Chloride

Applies to Butylchloride; Sergeants Capsules

CAS Number 109-69-3

UN Number 1127

Synonyms 1-Chlorobutane

Use Veterinary antinematodal agent (for ascarids and hookworms)

Mechanism of Toxic Action Dermal irritant; weak central nervous system depressant

Signs and Symptoms of Overdose Skin irritation (human data lacking)

Overdosage/Treatment Decontamination: **Dermal:** Irrigate with soap and water. **Gastric:** Do not induce emesis; dilute with milk or water.

Ocular: Irrigate with normal saline. **Respiratory:** Administer 100% humidified oxygen.

Additional Information LD₅₀ in rats: 2.67 g/kg by oral ingestion and ~8000 ppm by inhalation

No evidence for carcinogenicity

Colorless liquid with a pungent odor; usually found in capsule form.

Moderately explosive; when heated, can decompose to hydrochloric acid and phosgene

Density: 0.88. Vapor density: 3.2. Boiling point: 78°C

Nerve Agents

Related Information

- Diisopropylmethylphosphonate

CAS Number 107-44-8 (sarin); 50782-69-9 (VX); 77-81-6 (tabun); 96-64-0 (soman)

Synonyms Sarin (GB or Isopropyl Methylphosphonofluoridate); Soman (GD or Pinacolyl Methylphosphonofluoridate); Tabun (Ethyl N-Dimethylphosphoramidocyanidate or GA); VX (Methylphosphonoithioic Acid S-(2-bis(1-Methyl-Ethyl)Amino)Ethyl) o-Ethyl Ester or V)

Use Chemical warfare weapon

Mechanism of Toxic Action Similar to organophosphate agent; inhibits the enzyme acetylcholinesterase thus resulting in acetylcholine excess at the neuronal synapse; may penetrate blood brain barrier and thus affect GABA transmission

Adverse Reactions

Cardiovascular: Sinus bradycardia

Central nervous system: Insomnia, fatigue, memory loss, seizures (soman), ataxia, coma, headache

Gastrointestinal: Diarrhea, nausea

Ocular: Lacrimation, miosis (may take 40-50 days for pupillary response to normalize)

Respiratory: Rhinorrhea; death is usually due to respiratory failure, cough

Miscellaneous: Excess muscarinic activity (bronchial secretion, salivation, diaphoresis, miosis, bronchospasm, bradycardia) and nicotinic activity (muscle twitching, weakness, paralysis)

Admission Criteria/Prognosis Patients who are asymptomatic 18 hours postexposure can be discharged; there are no delayed effects

Toxicodynamics/Kinetics

Onset of action: Inhalation (except for VX): Within 5 minutes. Dermal: 1 hour

Half-time: Aging of sarin-acetylcholine complex: 5 hours. Aging of soman-acetylcholine complex: 2 minutes. Aging of VX-acetylcholine complex: 1-2 days

Metabolism of VX: VX hydrolysis → EMP + DAET; DAET + S-adenosyl-L-methione (through thiol-s-methyl transferase) → DAEMS + S-adenosyl-L-homocysteine

Reference Range

Cholinesterase activity <10% of normal is consistent with severe poisoning

Serum DAEMS and EMPA levels 1 hour following a fatal VX dermal exposure was 143 ng/mL and 1.25 mcg/mL, respectively.

Overdosage/Treatment

Decontamination: **Dermal:** Remove all contaminated clothing. Wash with 1% to 5% hypochlorite solution (household bleach) followed by copious water irrigation. If bleach is not available, a gentle blotting with an alkaline soap can be used. Dilute ammonia may be helpful for VX exposure. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate with saline.

Supportive therapy: Atropine is the mainstay of treatment with doses from 10-20 mg cumulatively over the first 2-3 hours usually required. This should be titrated to bronchial secretions and not to ocular signs. Pralidoxime should be administered (1-2 g I.V. over 10 minutes, repeat in 1 hour if weakness occurs, then every 4-12 hours as needed). Pralidoxime should be used within 3 hours post-sarin exposure; may not be useful for soman or tabun. Obidoxime may be effective for tabun, sarin, or GF at an initial I.M. or slow I.V. infusion of 250 mg; may be repeated every 2 hours up to 750 mg total dose. Homatropine can be utilized to treat miosis which may last for weeks postexposure. Diazepam or midazolam has been an effective anticonvulsant in primate models. Since aging is longer for tabun or VX, pralidoxime may be particularly useful; administer oxygen. Seizures often respond to atropine or pralidoxime. For refractory seizures, diazepam can be used. In fact, 5-10 mg of diazepam is often given as pretreatment in severely affected patients. Hemodialysis/hemoperfusion has been noted to increase cholinesterase levels and improve clinical symptomatology in one patient. Asoxime chloride may be useful when used with atropine for treatment of sarin, soman, and GF exposure.

Antidote(s)

- Asoxime Chloride [ANTIDOTE]
- Atropine [ANTIDOTE]
- Obidoxime Chloride [ANTIDOTE]
- Pralidoxime [ANTIDOTE]
- Pyridostigmine [ANTIDOTE]

Additional Information

Lethal dermal dose (70 kg adult): Sarin: 1.7 g. Tabun: 1 g. Soman: 100 mg; VX: 6 mg

Acute sarin exposure may cause a delayed effect on the vestibulocerebellar system with females being more sensitive than males.

G agents are volatile and are both an inhalation and dermal threat. VX exhibits low volatility (like motor oil) and is primarily a dermal threat while also an inhalation threat.

Sarin has been implicated in the Tokyo subway terrorist incident occurring in March, 1995. It has been estimated that 800 kg of sarin will cause heavy casualties over 1 square mile area. Sarin is 4000 times more potent than parathion. Lethal inhaled dose of tabun, sarin, and soman is ~1 mg; VX has highest lethality in dermal applications (as an oily liquid) rather than through inhalation; while sarin and tabun may cause a delayed neuropathy, VX is not known to cause a delayed neuropathy. Emergency medical ambulances in New York City now stock up to 52 mg of atropine; this is up from 4 mg which was a typical ambulance stock of atropine before the March, 1995 Tokyo subway sarin attack.

In the sarin subway attack in Tokyo (March 20, 1995), of the 5510 cases there were 12 deaths and 17 patients requiring ventilatory support.

Rescuers should wear protective masks (ie, charcoal filter of self-contained breathing apparatus) with heavy rubber gloves.

Pretreatment with pyridostigmine bromide (30 mg orally every 8 hours) may be effective (especially for soman).

For maximum control limits: See table.

Maximum Agent Control Limits		
	Workplace (8 h in mg/m ³)	General Population (72 h TWA mg/m ³)
Sarin and tabun	1 × 10 ⁻⁵	3 × 10 ⁻³
VX	1 × 10 ⁻⁴	3 × 10 ⁻⁶

Contaminated equipment can be washed with 10% hypochlorite solution. These agents are 4-6 times denser than air and thus remain close to the ground; they are soluble in water, but hydrolyze in alkaline solutions (see Treatment). Contaminated vegetation with VX can cause toxic effects upon ingestion.

Butyrylcholinesterase can sequester tabun, soman, VX, and sarin within 5 seconds in a rodent model. Human data is lacking.

Nickel

Related Information

- Nickel Carbonyl
- CAS Number** 7440-02-0
- UN Number** 2881;1325

Synonyms Carbonyl Nickel Powder; Nickel Sponge; Raney Alloy; Raney Nickel

Mechanism of Toxic Action In nickel refiners, nickel is a respiratory tract carcinogen

Adverse Reactions

Nickel carbonyl is much more toxic than nickel metal or alloys; dermal reactions to nickel carbonyl are rare

Cardiovascular: Cardiomyopathy

Central nervous system: Dizziness, headache

Dermatologic: Eczema

Gastrointestinal: Diarrhea, metallic taste, nausea, vomiting

Hematologic: Leukocytosis

Hepatic: Elevated bilirubin, elevated transaminases (SGPT)

Neuromuscular & skeletal: Weakness

Respiratory: Asthma, cough, dyspnea, hoarseness, nasal carcinomas, pulmonary edema

Miscellaneous: Cutaneous T-cell lymphoma

Signs and Symptoms of Overdose CNS stimulation followed by cold clammy skin, contact dermatitis (nickel itch), coma, cough, diarrhea, dyspnea, ECG changes, erythrocytosis, giddiness, hematuria, hypoxemia, hypothermia, impaired thermoregulation, leukocytosis, metallic taste, nasal carcinoma, nausea, seizures, sleeplessness, sore throat, transient increase in ALT and bilirubin, urticaria, vomiting

Admission Criteria/Prognosis Admit any symptomatic patient or ingestion > 500 mg

Toxicodynamics/Kinetics

Absorption: Inhalation: 35%. Oral: 1% to 27% (reduced by food). Dermal: Nickel sulfate: 55% to 77%

Distribution: Nickel carbonyl crosses the alveolar membrane and dissociates to nickel and carbon monoxide; wide volume of distribution

Protein binding: 59%

Half-life: 11-60 hours

Elimination: Excreted primarily in urine; oral ingestion results in a large amount excreted through gastrointestinal tract

Warnings/Precautions Do not use DDC for divalent nickel poisoning.

Reference Range Normal blood levels: 1.1-4.6 mcg/L; serum nickel concentrations >8 mcg/L are associated with excessive exposure; normal urine level is ~50 mcg/L; an 8-hour urine level of <100 mcg/L associated with mild exposure, 100-500 mcg/L associated with moderate exposure, and > 500 mcg/L associated with severe exposure

Overdosage/Treatment

Decontamination: **Oral:** Dilute with milk. **Dermal:** Wash with soap and water. **Inhalation:** Give 100% humidified oxygen. **Ocular:** Copious irrigation with saline.

Supportive therapy: To treat moderate to severe nickel exposures (urine nickel concentrations over 100 mcg per L): Oral diethyldithiocarbamate

(DDC) 50 mg/kg is administered during first 24 hours. On succeeding days, oral DDC is administered every 8 hours until the patient is asymptomatic (and the urine nickel is under 50 mcg/L). DDC may be given intravenously by adding ten ml of a sterile phosphate buffer solution (500 mg/dl) to one gram of powdered DDC contained in a sterile ampule. DDC I.V. is then administered at a dose of 25 to 100 mg/kg over the first 24 hours, and as outlined above on succeeding days.

Enhancement of elimination: Forced saline diuresis can decrease half-life of nickel sulfate and nickel chloride by >50%

Antidote(s)

- Diethyldithiocarbamate Trihydrate [ANTIDOTE]

Diagnostic Procedures

- Nickel, Urine

Additional Information

Fatal dose of elemental nickel: ~2 g. 30 minute exposure of 30 ppm airborne concentration is potentially fatal.

Oral ingestion of 73 mg of elemental nickel can produce toxic symptoms. Skin application of 1:10,000 dose of nickel salts can elicit a sensitivity reaction.

Cigarette smoking accounts for 2-12 mcg of nickel inhaled per cigarette pack.

Baking powder (13.4 ppm), orange pekoe tea (7.6 ppm), buckwheat (6.5 ppm), and cocoa (5 ppm) contain the highest amount of nickel.

Most U.S. coins contain ~25% nickel.

Range of atmospheric nickel concentration in urban U.S. areas: 1-328 ng/m³.

In rural areas, the range is 0.6-78 ng/m³.

Average daily intake of nickel from food: ~168 mcg; from drinking water: ~2 mcg; from inhalation: 0.1-1 mcg

Range of nickel in drinking water: 3-7 mcg/L. Range of nickel in soil: 5-500 ppm

TWA-TLV: 15 mcg/m³

Specific References

Nickel Carbonyl

Related Information

- Nickel
- Nickel Carbonyl

CAS Number 13463-39-3

UN Number 1259

Synonyms Nickel Tetracarbonyl

Use Catalyst in petroleum and rubber industries; used in electroplating; formed as an intermediate (by a reaction with carbon monoxide) in nickel ore purification

Mechanism of Toxic Action Inhibits ribonucleic acid synthesis; mucosal irritant

Adverse Reactions

Symptoms may be delayed 12-24 hours

Cardiovascular: Tachycardia, bradycardia, QT prolongation, chest pain, myocarditis, cyanosis (may be a delayed effect), sinus bradycardia, angina, sinus tachycardia

Central nervous system: Headache, dizziness, delirium, hyperthermia, chills, seizures, low grade fever, neurasthenic syndrome

Dermatologic: Dermal burns

Gastrointestinal: Nausea, vomiting, diarrhea (2-3 days postexposure), stomach pains, sore throat

Hematologic: Leukocytosis

Hepatic: Elevated liver enzymes

Neuromuscular & skeletal: Weakness

Renal: Proteinuria

Respiratory: Pulmonary edema, dyspnea, interstitial pneumonitis may be delayed from 12 hours to 5 days postexposure and may last for 1 month, tachypnea, asthma, cough, bronchospasm, interstitial fibrosis

Miscellaneous: Diaphoresis

Admission Criteria/Prognosis Any symptomatic patients; any patient with a urinary nickel level >100 mcg/L; or inhalation of >2 ppm (essentially if one can detect the odor of this agent for 30 minutes, the patient should be admitted)

Toxicodynamics/Kinetics

Absorption: By inhalation

Metabolism: Metabolized to carbon monoxide and nickel

Elimination: Urine

Monitoring Parameters Carboxyhemoglobin levels, urinary nickel levels, chest x-ray, arterial blood gases

Reference Range Normal blood levels: 1.1-4.6 mcg/L; an 8-hour urine level of <100 mcg/L associated with mild exposure, 100-500 mcg/L associated with moderate exposure, and >500 mcg/L associated with severe exposure

Overdosage/Treatment

Decontamination: **Dermal:** Wash with soap and water. **Inhalation:** Give 100% humidified oxygen. **Ocular:** Copious irrigation with saline

NITRATES

Supportive therapy: Diethyldithiocarbamate (DDC) is the preferred chelating agent.

Indication for treatment of sodium DDC is 8-hour postexposure urine nickel concentration > 100 mcg Ni/L. Benzodiazepines can be used to treat seizures. Disulfiram can enhance the elimination of nickel and has been used to treat nickel dermatitis. Disulfiram (250-750 mg every 8 hours or half the DDC dose) is second-choice therapy to diethyldithiocarbamate. Oxygen, bronchodilators, and steroids (for adrenocortical insufficiency) may be required. The dose of DDC is 35-45 mg DDC/kg orally over the first day, followed by 400 mg every 8 hours until the patient is symptom free. I.V. dose is 12.5 mg DDC/kg.

Enhancement of elimination: Forced saline diuresis can decrease half-life.

Antidote(s)

- Diethyldithiocarbamate Trihydrate [ANTIDOTE]

Diagnostic Procedures

- Nickel, Urine

Additional Information

Lethal air concentration: 3-30 ppm at 30 minutes. Symptoms can occur at 2 ppm.

Potentially carcinogenic (nasal and lung cancer)

Nickel carbonyl is the most toxic of nickel compounds. nickel carbonyl is formed when nickel is in contact with carbon monoxide. Toxicity from nickel carbonyl results from inhalation, whereas toxicity from Ni²⁺ results from oral/parenteral exposure. In nickel carbonyl poisoning, after the acute symptoms subside, delayed pulmonary, cardiac, and neurologic symptoms occur after 1-5 days.

Cigarette smoke contains ~3.5 ppm of nickel carbonyl

Colorless gas with a "sooty" or musty odor with an odor threshold of 1 ppm; heavier than air (vapor density is almost 6); highly explosive

Nitrates

Related Information

- Propylene Glycol Dinitrate

Applies to Cold Packs

UN Number 1477; 3218

Commonly Found In Munition and explosives (dynamite is 60% nitrates); may be found in well water; certain plants (datura, solanum, sorghum species)

Use Ammonium nitrates are in cold packs

Mechanism of Toxic Action Accelerates atherosclerosis

Adverse Reactions

Cardiovascular: Hypotension, tachycardia, fibrillation (atrial), bigeminy; nitrate withdrawal syndrome includes vasodilatory effects (flushing, headaches), flutter (atrial), angina, chest pain, sinus tachycardia, arrhythmias (ventricular)

Gastrointestinal: Gastritis, feces discoloration (black)

Hematologic: Methemoglobinemia

Miscellaneous: Can produce sulfhemoglobin

Signs and Symptoms of Overdose Fatigue, headaches, hematuria, nausea, vomiting, dyspnea within 2 hours; coma, cyanosis, and pallor may develop later

Toxicodynamics/Kinetics

Absorption: Oral: Well absorbed; not absorbed through intact skin

Metabolism: By gastrointestinal bacteria to nitrites

Elimination: Renal

Reference Range Mean urine nitrate level: 41-56 mcg/mL; normal plasma nitrate level: ~37 µmol/L; normal saliva nitrate level: 5-10 mg/L

Overdosage/Treatment

Decontamination: **Do not** induce emesis for ammonium nitrate ingestion; methylene blue (1-2 mg/kg per dose) for elevated methemoglobin as needed every 4 hours

Oral: Dilute with 4-8 ounces of milk or water; activated charcoal may be useful for oral decontamination

Ocular: Irrigate eyes with normal saline.

Enhanced elimination: Although formal studies are lacking, hyperbaric oxygen may be useful in severe exposures. Exchange transfusion may be useful.

Antidote(s)

- Methylene Blue [ANTIDOTE]

Diagnostic Procedures

- Methemoglobin, Blood
- Sulfhemoglobin

Test Interactions May result in a low measured oxygen saturation, resulting in an oxygen saturation gap

Additional Information Toxic dose: 5 mg/kg/day (chronically)

Can penetrate gloves

It appears that age and serum creatinine levels are inversely associated with development of vascular headache due to nitrates. Risk for headache decreases by ~40% for a 10 year increase in age and is 5 times less likely in patients with serum creatinine levels > 133 µmol/L as opposed to levels < 97 µmol/L.

EPA standard for nitrate in drinking water: 10 mg/L, 9% of household wells nationally exceed this value.

Nitrites

Applies to Corrosive Inhibition; Cyanide Antidote Kits; Dyes; Fabrics; Linen; Photography

UN Number 2627

Synonyms Poppers; Snappers; Thrust

Commonly Found In Inhalation abuse of volatile nitrates

Use In cyanide antidote kits; used in the manufacture of dyes, fabrics, and linen; photography; corrosive inhibition

Mechanism of Toxic Action Peripheral vasodilation; produces methemoglobin; is an oxidizing agent

Adverse Reactions

Cardiovascular: Paradoxical bradycardia, hypotension, sinus bradycardia, vasodilation

Hematologic: Methemoglobinemia followed by hemolysis

Ocular: Visual disturbances

Respiratory: Tachypnea

Miscellaneous: Infants, pregnant women, and patients with malignancy may be especially sensitive

Signs and Symptoms of Overdose Abdominal pain, blurred vision, cyanosis, diarrhea, dyspnea, flushing, headache, lightheadedness (postural), nausea, seizures, skin irritation, vomiting

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels > 30% should be admitted; asymptomatic patients with methemoglobin levels < 30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to < 15%

Toxicodynamics/Kinetics

Absorption: May be by inhalation, ingestion or dermal routes

Metabolism: 60% metabolized - most to ammonia

Elimination: Excreted renally (40% unchanged)

Monitoring Parameters Obtain methemoglobin levels - cyanosis may occur at levels > 20%

Reference Range Fatal nitrite serum range: 0.5-350 mg/L

Overdosage/Treatment

Decontamination: Basic poison management; methylene blue for symptomatic methemoglobinemia

Supportive therapy: Hyperbaric oxygen may be of use, though controlled human data are lacking.

Antidote(s)

- Methylene Blue [ANTIDOTE]

Diagnostic Procedures

- Methemoglobin, Blood

Additional Information Ingestion of 10 mL of isobutyl or amyl nitrate may be toxic. Oral ingestion produces more rapid methemoglobin than inhalation. May be toxic at > 0.4 mg/kg

Specific References

Ringling S, Boo T, and Botte E, "Methemoglobinemia from Nitrite-Contaminated Punch," *J Toxicol Clin Toxicol*, 2003, 41(5):730-1.

Nitrobenzene

Applies to Caswell No 66

CAS Number 98-95-3

UN Number 1662

Synonyms Nitrobenzol Oil of Mirbane

Use Production of aniline, cellulose ethers, and acetaminophen; perfume agent in soaps; solvent in shoe dyes (preservative) and floor polishes

Mechanism of Toxic Action Binds to hemoglobin which results in methemoglobin formation; resembles aniline in its action

Adverse Reactions

Cardiovascular: Tachycardia, hypotension, shock, sinus tachycardia, cyanosis

Central nervous system: Headache, coma, seizures, dizziness

Dermatologic: Skin discoloration (blue-black)

Gastrointestinal: Nausea

Genitourinary: Urine discoloration (dark)

Hematologic: Methemoglobin formation (postexposure from 30 minutes to 12 hours), hemolytic anemia

Hepatic: Hepatomegaly, elevated liver function test results

Neuromuscular & skeletal: Paresthesia

Ocular: Retrobulbar neuritis, optic neuropathy

Respiratory: Respiratory failure, bitter almond breath, apnea

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels > 30% should be admitted; asymptomatic patients with methemoglobin levels < 30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to < 15%

Toxicodynamics/Kinetics

Absorption: Inhalation: 80% to 87%. Oral, dermal: ~50%

Half-life: 84 hours (of metabolites)

Metabolism: Primarily intestinal reduction to nitrosobenzene, phenylhydroxylamine, and aniline

Elimination: Primarily renal (within first 2 hours) in the forms of para-aminophenol and para-nitrophenol (most toxic metabolite)

Overdosage/Treatment

Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal.

Dermal: Wash with soap and water. **Ocular:** Irrigate copiously with saline.

Supportive therapy: Treat symptomatic methemoglobinemia with methylene blue. Seizures can be treated with benzodiazepines or phenobarbital.

Enhancement of elimination: Exchange transfusion has been utilized in an adult for 6 hours, to reduce severe methemoglobinemia from 65% to 25% levels.

Additional Information

Fatal oral dose: 1 g

Higher airborne concentrations of nitrobenzene (up to 0.1 ppb) are noted in summer than in winter. Methemoglobinemia can develop after exposure of 3-6 ppm for several hours.

Odor threshold (almond-like): Water: 0.11 mg/L. Air: 0.092 mg/m³. PEL-TWA: 1 ppm; TLV-TWA: 1 ppm; IDLH: 200 ppm. Atmospheric half-life: 6 months to 6 years

Specific References

Chang AS, Morgan BW, Birkholz DA, et al, "A Case Report and Laboratory Analysis of Fatal Methemoglobinemia After Ingestion of Nitrobenzene," *Clin Toxicol (Phila)*, 2005, 43:746.

Nitroethane

CAS Number 79-24-3

UN Number 2842

Use Industrial solvent found in artificial nail removers

Mechanism of Toxic Action A mucosal irritant which can produce methemoglobinemia in 6-12 hours postexposure; a potent oxidizing agent

Signs and Symptoms of Overdose Cyanosis, dyspnea, methemoglobinemia

Admission Criteria/Prognosis Observe any ingestion for 24 hours

Toxicodynamics/Kinetics

Half-life: 6 hours

Metabolism: To nitrite by the liver and GI tract

Overdosage/Treatment

Decontamination: **Oral:** Do not induce emesis. **Inhalation:** Administer 100% humidified oxygen.

Supportive therapy: Methylene blue (1-2 mg/kg/dose I.V.) for symptomatic methemoglobinemia

Antidote(s)

- Methylene Blue [ANTIDOTE]

Diagnostic Procedures

- Methemoglobin, Blood

Additional Information A colorless liquid with a fruity odor. IDLH: 1000 ppm

Nitrofen

CAS Number 1836-75-7

U.S. Brand Names Mezotox®; Niclofen®; Nip®; Nitrochlor®; Tokkorn® Trixilin®; Tok®

Synonyms Nitrofen

Mechanism of Toxic Action A diphenyl ether which can cause photobleaching and has phytotoxic effects by interfering with ATP synthesis

Signs and Symptoms of Overdose Diarrhea, dizziness, headache, nausea, vomiting; eye, skin, and lung irritation

Overdosage/Treatment Decontamination: Remove contaminated clothing (especially leather); wash thoroughly with soap and water. Irrigate eyes with normal saline for ocular exposure.

Nitrogen Dioxide

CAS Number 10102-44-0

UN Number 1067

Synonyms Nitrogen Peroxide

Commonly Found In Exhaust from metal cleaning, electric arc welding

Use Found in grain storage silos (levels as high as 2000 ppm), encountered in welding, production of fuels

Mechanism of Toxic Action Pulmonary lipid auto-oxidation and free radical reactions with proliferation of pulmonary Type II cells

Adverse Reactions

Cardiovascular: Weak, rapid pulse; cardiovascular collapse

Central nervous system: Hyperthermia

Dermatologic: Hair discoloration

Gastrointestinal: Acid taste

Respiratory: Pulmonary edema, asphyxia, asthma, bronchospasm

Signs and Symptoms of Overdose Bronchiolitis obliterans (may develop 2-6 weeks postexposure), bronchospasm, cough, dyspnea, fever, leukocytosis, methemoglobin (possible), ocular irritation, pulmonary edema (may be delayed for 30 hours)

Admission Criteria/Prognosis Admit all patients with pulmonary symptomatology

Toxicodynamics/Kinetics

Absorption: Through the lungs

Metabolism: Reacts in pulmonary tract to form nitric acid

Monitoring Parameters Arterial blood gas, methemoglobin, chest x-ray

Overdosage/Treatment

Decontamination: Inhalation: Administer 100% humidified oxygen.

Supportive therapy: Directed at the pulmonary system. Although it has been advocated to give corticosteroids early on (ie, 1 g of methylprednisolone), no data from controlled trials are available. Hyperbaric oxygen was detrimental in one animal model. Ascorbic acid (1 g orally) or deferoxamine has been proposed for respiratory protection, although these modalities have not been studied in humans. Symptomatic methemoglobinemia should be treated with methylene blue.

Antidote(s)

- Methylene Blue [ANTIDOTE]

Diagnostic Procedures

- Methemoglobin, Blood

Additional Information

Death: 100 ppm.

Mucous membrane irritation: 13 ppm. Pulmonary irritation: 25 ppm (at 1 hour). Pulmonary edema: 50-100 ppm (at 1 hour)

A reddish-brown gas which is formed by nitrates in corn, hay, or alfalfa by anaerobic fermentation; concentrations in silos: 200-2000 ppm of nitrogen dioxide

Poorly water soluble. Specific gravity: 1.45 (liquid); 1.58 (gas). Odor threshold: 1-5 ppm. IDLH: 50 ppm; TLV-TWA: 3 ppm.

Specific References

Nitromethane

CAS Number 75-52-5

UN Number 1261

Use Constituent found in fuels for model aircraft engines and dragsters; solvent also used for rocket fuel; component in fuel-based fires

Mechanism of Toxic Action A lipid soluble solvent with relatively low toxicity; animal studies reveal sciatic nerve degeneration; a mild irritant

Signs and Symptoms of Overdose Bronchospasm, cough, local eye or dermal irritation, Parkinson-like motor dysfunction (chronic exposure)

Overdosage/Treatment

Decontamination: **Dermal:** Wash skin with soap and water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate eyes with water.

Supportive therapy: Inhaled sympathomimetic bronchodilators should be used to treat bronchospasm.

Test Interactions Will produce false elevation of serum creatinine by the Jaffé-based assay; a nitromethane serum concentration of 5 µmol/L (which will result in minimal symptoms) can result in a serum creatinine of ~18 mg/dL.

Additional Information A colorless oily liquid with a fruity odor. Solution pH: 6.1. IDLH: 1000 ppm; PEL-TWA: 100 ppm. Odor threshold: <200 ppm

Specific References

Nitrophenol

Applies to Dye Stuffs and Pigments (Production); Fungicide; Laboratory Reagent

CAS Number 100-02-7 (4-Nitrophenol); 88-75-5 (2-Nitrophenol)

UN Number 1663

U.S. Brand Names Atonik®

Use Primarily as a laboratory reagent, fungicide, and in production of dye stuffs and pigments; 4-nitrophenol is a metabolite of nitrobenzene

Mechanism of Toxic Action Formation of methemoglobinemia

Adverse Reactions No experience in humans; animals develop methemoglobinemia; stomatitis is also noted; skin discoloration (blue-black) hyperthermia may occur

NITROPHENOLUREA

Toxicodynamics/Kinetics

Absorption: Probably by inhalation, oral, or dermal exposure
Metabolism: Hepatic to glucuronide or sulfate conjugates
Elimination: Renal within 48 hours

Reference Range Urinary 4-nitrophenol levels in general population is <10 mcg/L; may also be noted in nitrobenzene, methyl-, or ethyl parathione exposures

Overdosage/Treatment

Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal
Dermal: Wash with soap and water. **Ocular:** Irrigate with saline.
Supportive therapy: Methylene blue for symptomatic methemoglobinemia. Treat hyperthermia with sponge baths, ice pack and cool oral fluids. Avoid salicylates and atropine.

Additional Information 4-nitrophenol is more toxic than 2-nitrophenol. Vehicular exhaust contains 3.1 ppb of 2-nitrophenol. Atmospheric half-life: 18 days. Water half-life (photolysis): 1-13 days (longer with high pH)

Nitrophenolurea

Synonyms PNU; Pyriminil; Vacor

Mechanism of Toxic Action Interferes with nicotinamide metabolism resulting in pancreatic beta-cell destruction

Adverse Reactions

Cardiovascular: Chest pain, shock
Central nervous system: Neuropathic, chills
Endocrine & metabolic: Diabetes mellitus, hyperinsulinemia
Neuromuscular & skeletal: Peripheral neuropathy

Signs and Symptoms of Overdose GI irritation, hyperglycemia with or without ketoacidosis, hypotension

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage within 1 hour, followed by oral activated charcoal
Supportive therapy: Nicotinamide (also known as niacinamide) (I.M., I.V.): 500 mg loading dose followed by doses of 100-200 mg I.M. or I.V. every 4 hours for 48 hours. Orally, patient may take 100 mg nicotinamide 3-5 times/day for 2 weeks; children can be given half the adult dose. Insulin may be needed for hyperglycemia.
Supportive therapy: Diabetes: Insulin and fluids

Diagnostic Procedures

● Anion Gap, Blood

Additional Information Withdrawn in U.S. as general use pesticide in 1979; smells like peanuts; yellow color appears like cornmeal

Nitrous Oxide

Applies to Anesthetic; Foaming Agent; Rocket Fuel

CAS Number 10024-97-2

UN Number 1020

Synonyms Factitious Air; Laughing Gas; Nitrogen Monoxide; Whipplet

Use As an anesthetic, foaming agent, and rocket fuel

Mechanism of Action General CNS depressant action; may act similarly as inhalant general anesthetics by stabilizing axonal membranes to partially inhibit action potentials leading to sedation; may partially act on opiate receptor systems to cause mild analgesia; central sympathetic stimulating action supports blood pressure, systemic vascular resistance, and cardiac output; it does not depress carbon dioxide drive to breath. Nitrous oxide increases cerebral blood flow and intracranial pressure while decreasing hepatic and renal blood flow; has analgesic action similar to morphine.

Mechanism of Toxic Action Asphyxiant; oxidizes cobalt in vitamin B₁₂; partial agonist of opioid receptors

Adverse Reactions

Cardiovascular: Hypotension, arrhythmias, AV dissociation, cerebral edema
Central nervous system: CNS depression, ataxia
Hematologic: Bone marrow suppression, methemoglobin formation, aplastic anemia (chronic use)
Neuromuscular & skeletal: Neuropathy (peripheral), myeloneuropathies
Miscellaneous: Potential carcinogen

Signs and Symptoms of Overdose Agranulocytosis, dizziness, dyspnea, euphoria, headache, leukopenia, mood disorder, neuritis, nausea and vomiting (rarely); possible pneumothorax by barotrauma

Pharmacodynamics/Kinetics

Onset of action: Inhalation: 2-5 minutes
Absorption: Rapid via lungs; blood/gas partition coefficient is 0.47
Metabolism: Body: <0.004%
Excretion: Primarily exhaled gases; skin (minimal amounts)

Contraindications Hypersensitivity to nitrous oxide or any component of the formulation; nitrous oxide should not be administered without oxygen; should not be given to patients after a full meal

Warnings Nausea and vomiting occurs postoperatively in ~15% of patients. Prolonged use may produce bone marrow suppression and/or neurologic dysfunction. Oxygen should be briefly administered during emergence from prolonged anesthesia with nitrous oxide to prevent diffusion hypoxia. Patients with vitamin B₁₂ deficiency (pernicious anemia) and those with other nutritional deficiencies (alcoholics) are at increased risk of developing neurologic disease and bone marrow suppression with exposure to nitrous oxide. May be addictive.

Dosing Forms Supplied in blue cylinders

Dosage Forms Supplied in blue cylinders

Reference Range Arterial blood nitrous oxide concentrations associated with surgical anesthesia range from 170-220 mL/L

Overdosage/Treatment Supportive therapy: Give 100% humidified oxygen. Hyperventilation and 20% mannitol for cerebral edema; dexamethasone may be useful. Naloxone may reverse analgesic action; avoid epinephrine. Treat symptomatic methemoglobinemia with methylene blue. Replace vitamin B₁₂ as needed for chronic exposures. Do not administer hyperbaric oxygen. Pretreatment with methylcobalamin (5 mg I.V.) 2 hours postanesthesia induction and folic acid (15 mg I.V.) at end of anesthesia has been hematoprotective.

Antidote(s)

- Methylene Blue [ANTIDOTE]
- Naloxone [ANTIDOTE]

Drug Interactions No data reported

Pregnancy Risk Factor No data reported

Additional Information Minimal toxic dose by inhalation: 24 mg/kg over 2 hours. Chronic inhalation may result in pancytopenia. Colorless, sweet odor. TLV-TWA: 50 ppm. Nitrous oxide cylinders are painted blue.

N-Methyl-2-Pyrrolidone

CAS Number 872-50-4

Synonyms M-Pyrol; Methylpyrrolidone; NMP

Use A dipolar solvent used in microelectronics (cleaning of silicon chips, deflashing); in petroleum industry (natural gas, acetylene and toluene recovery); paint strippers (replacing methylene chloride); and in wire coating operations

Mechanism of Toxic Action A cyclic amide with mucosal irritant properties; can cause encephalopathy; also is a weak acetylcholinesterase inhibitor

Adverse Reactions

Headaches and eye irritation at air levels as low as 0.7 ppm for 30-minute exposure
Dermatologic: Contact dermatitis, pruritus, vesicular dermal eruptions

Toxicodynamics/Kinetics

Absorption: Dermal and inhalation routes
Metabolism: Hepatic hydrolysis
Elimination: Renal

Overdosage/Treatment Decontamination: **Dermal:** Flush with soap and water. **Ocular:** Irrigate copiously with saline.

Additional Information Colorless liquid with a mild odor; can penetrate latex gloves. Density: 1.027. Vapor density: 3.4

N-Nitrosodiphenylamine

Applies to TJB

CAS Number 86-30-6

U.S. Brand Names Curetard A[®]; Delac J[®]; Naugard TJB[®]; Redax[®]; Retarder J[®]; Vulcatard A[®]

Synonyms Diphenylnitrosamine; NDPA; NDPHA

Use Retardant (to prevent premature vulcanization of rubber) in rubber processing industry

Mechanism of Toxic Action DNA adduct formation in bladder may be the mechanism for urinary bladder cancer

Adverse Reactions No human toxic effects described; toxic effects in animals appear to be carcinogenesis (bladder) and skin ulcerations on dermal contact (0.1 mL of 0.1% solution for 20 weeks); nephrotoxicity has also been noted; does not bioaccumulate

Toxicodynamics/Kinetics

Absorption: Oral and dermal
Metabolism: Hepatic denitrosation to diphenylamine and nitric oxide
Elimination: Primarily renal within 2 days

Overdosage/Treatment Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal. **Dermal:** Wash with soap and water. **Ocular:** Irrigate with saline.

Additional Information Soluble in water (40 mg/L). Atmospheric half-life: ~7 hours.

Adding wheat straw in soil to increase microbial activity reduces soil residence time from 30 days to 10 days. Tire chemical factories may have workplace air levels as high as 6 ppm (47 mcg/m³).

Osmium

CAS Number 20816-12-0

UN Number 2471

Synonyms Osmic Acid; Osmium Tetroxide; Parosmic Acid

Mechanism of Toxic Action Direct irritant to mucous membranes, skin, eyes

Adverse Reactions Eyes, nose, throat, neurologic, gastrointestinal, dermatologic

Signs and Symptoms of Overdose Angina, chest pain, conjunctivitis, cough, dermatitis, headache, pulmonary edema, respiratory tract irritation, rhinitis, visual changes, wheezing

Toxicodynamics/Kinetics No human ingestions reported

Overdosage/Treatment

Decontamination: Remove patient from toxic environment, administer 100% humidified oxygen. Provide ventilatory assistance if needed. Decontaminate skin and eyes with water.

Supportive therapy: Treat wheezing with bronchodilators. The role of steroids is equivocal in the prevention of pulmonary edema.

Additional Information Concentration of 0.1 mg/m³ associated with ocular irritation. Direct contact may cause green-black discoloration of skin. No harmful effects at 0.001 mg/m³ for 6 hours (ACGIH 1986). TCLO (human): 133 mcg/m³ lacrimation; 1 ppm = 10 mg/m³. TLV-TWA: 0.002 ppm; TLV-STEL: 0.0006 ppm; OSHA PEL-TWA: 0.002 mg/m³

Palladium

CAS Number 7440-05-3

Mechanism of Toxic Action Colloidal palladium hydroxides cause RBC hemolysis; chronic intoxication results in malignant lung tumor and decreased growth

Adverse Reactions

Dermatologic: Dermal irritant, dermatitis

Respiratory: Inhalation: Wheezing, asthma

Signs and Symptoms of Overdose Classic signs/symptoms of allergic reaction; cough, eczema, eosinophilia, dyspnea, lymphocytosis, rash, rhinorrhea, urticaria, wheezing

Toxicodynamics/Kinetics Absorption: Poor from gastrointestinal tract

Reference Range No TLV recommended

Overdosage/Treatment

Decontamination: Irrigation

Supportive therapy: Beta agonists can be used for wheezing.

Additional Information Causes black discoloration at site of injection; water soluble

Para-Dichlorobenzene

Applies to Fumigant (Mold/Mildew); Moth Repellent; Pesticide; Toilet Deodorant

CAS Number 106-46-7

UN Number 1592

U.S. Brand Names Paracide®; Paradow; Paramoth; Santochlor

Synonyms 1,4-Dichlorobenzene; Dichloride; PDB

Use Toilet/refuse deodorant; mold and mildew fumigant; moth repellent; diaper pail repellent; pesticide (for tree boring insects and ants); control blue mold in tobacco seed beds

Mechanism of Toxic Action Mucosal irritant due to necrosis of tissue proteins by epoxide intermediates which are nephrotoxic and hepatotoxic by promoting cellular degeneration and vacuolation

Adverse Reactions

Central nervous system: Cerebellar ataxia

Dermatologic: Allergic purpura, dermal burns, skin edema, hyperpigmentation

Hematological: Hemolysis/methemoglobin formation (especially in children), granuloma development

Hepatic: Hepatitis and hepatic necrosis with cirrhosis

Ocular: Eye irritation (at 80-160 ppm)

Renal: Glomerulonephritis, alpha 2u-globulin nephropathy

Signs and Symptoms of Overdose Acute hemolytic anemia, ataxia, cirrhosis, diarrhea, dyspnea, headache, hepatic necrosis, jaundice, methemoglobinemia, nausea, oral burning, petechiae, pulmonary granulomas (upon inhalation), purpura, slurred speech, vomiting

Toxicodynamics/Kinetics

Absorption: By dermal routes, and: Inhalation: 20%. Oral: 100%

Metabolism: Hepatic: Oxidation to 2,5-dichlorophenol and 2,3-dichloroquinol

Elimination: Renal and biliary

Monitoring Parameters Methemoglobin level, CBC, liver function test

Reference Range Urine 2,5-dichlorophenol level range of 90-100 mg/L associated with air para-dichlorobenzene levels of 33 ppm; mean urinary 2,5-dichlorophenol in nonoccupationally exposed subjects is 2 mg/L; whole blood paradichlorobenzene levels averaging 10 mcg/L associated with Tokyo residents; mean blood level of 1,4-dichlorobenzene is 3.2 ng/L in nonsmokers and 2.2 ng/L in smokers.

Overdosage/Treatment

Decontamination: **Oral:** Emesis within 30 minutes (>5 g ingestion) or lavage (within 1 hour) in conjunction with activated charcoal may be utilized. **Do not** dilute with milk. **Dermal:** Wash with soap and water; remove contaminated clothing. **Ocular:** Irrigate with saline.

Supportive therapy: Treat symptomatic methemoglobinemia (or methemoglobinemia >30%) with methylene blue.

Antidote(s)

- Methylene Blue [ANTIDOTE]

Diagnostic Procedures

- Methemoglobin, Blood

Additional Information

A nasal irritant at air levels >50 ppm.

Strongly radiopaque aromatic odor with an odor threshold of 0.2 ppm in air and 0.01 mg/L in water.

Average adult exposure: 35 mcg/day by inhalation and 0.2 mcg/day through drinking water

For drinking water, median dichlorobenzene levels are ~0.03 ppb; mean soil level is ~0.4 ppb.

Milk or fatty foods promote oral absorption.

Soft drink and milk samples contained 0.1 mcg/kg (ppb), while butter, margarine, peanut butter, flour, and pastry mix contained concentrations of 1.3-2.7 mcg/kg, 12.2-14.5 mcg/kg, 7.3 mcg/kg, and 22 mcg/kg (ppb), respectively.

PEL-TWA: 77 ppm; IDLH: 1000 ppm

Mean indoor air dichlorobenzene concentration is ~4 ppb.

Levels of 1,4-dichlorobenzene Detected in Workplace Air

Occupation	Concentration (ppm)	
	Maximum	Range
Monochlorobenzene manufacturing plant	8.3	5.48-8.63
Abrasive-wheel plant	16.43	7.97-16.43
Mothball manufacturing plant	24.90	8.96-24.90
Chlorobenzene manufacturing plant	33.86	23.90-33.86
1,4-Dichlorobenzene manufacturing plant	548	11.95-548
Monochlorobenzene and dichlorobenzene manufacturing plant	722	—

Source: IARC 1982

Reference: U.S. Department of Health and Human Services, *Toxicological Profile for 1,4-Dichlorobenzene*, Agency for Toxic Substances and Disease Registry, December, 1998.

Paramethoxyamphetamine

Synonyms 4-Methoxyamphetamine; PMA

Impairment Potential Blood PMA levels >0.09 mg/L are associated with driving impairment

Use A recreational hallucinogen found primarily in Australia and Western Europe

Mechanism of Toxic Action A methoxylated phenethylamine with sympathomimetic actions

Admission Criteria/Prognosis Admit any patient with elevated temperature or ingestion > 100 mg.

Toxicodynamics/Kinetics

Metabolism: Hepatic demethylation to 4-hydroxyamphetamine

Elimination: Urine

Dosing Forms

Capsule: 80 mg, 90 mg

Tablet: 50 mg, 60 mg, 90 mg

Reference Range

Hallucinogenic effects seen with PMA blood levels: 0.4 mg/L

Toxic effects seen with PMA levels: >0.5 mg/L

Fatality associated with levels > 1 mg/L

Overdosage/Treatment

Decontamination: Gastric decontamination should be considered for any ingestion > 100 mg; lavage within 1 hour; activated charcoal should be given.

Supportive therapy: Severe hyponatremia (serum sodium <120 mM/L) can be treated with either continuous infusion of 0.9% normal saline or 3% normal saline at 50 mL/hour, with furosemide 40 mg twice daily. Seizures should be treated with a benzodiazepine or barbiturate. Hyperthermia should be aggressively treated with cooling blankets, ice packs, and cooling fans. The role of chlorpromazine, cyproheptadine, dantrolene, or beta-adrenergic blockers is uncertain in treating hyperthermia. Ventricular arrhythmias may respond to lidocaine. Benzodiazepines can be given for agitation. Nitroprusside or phenolamine can be given for hypertensive emergency. Hypotension should be treated with crystalloid fluids. Hypertension can be treated with an alpha-

PARAPHENYLENEDIAMINE

blocker (phentolamine) and beta-adrenergic blocker. Esmolol may be useful in treating tachyarrhythmias.

Additional Information Hallucinogenic dose: 50 mg

Paraphenylenediamine

CAS Number 106-50-3; 624-18-0

UN Number 1673

Synonyms Paradiaminobenzene; PPD; "Blackstones"

Use Black dye used on fur or as a hair dye, photographic developer, and as a chemical intermediate in the production of polyparaphenyleneterephthalamide

Mechanism of Toxic Action Aniline derivative; can cause muscle necrosis through free radical production; ~4% of individuals can develop allergic reactions

Adverse Reactions

- Cardiovascular: Hypotension, shock, facial edema, myocarditis
- Central nervous system: Vertigo
- Dermatologic: Erythema multiforme, skin necrosis, hyperkeratosis
- Gastrointestinal: Vomiting, abdominal pain
- Hematologic: Methemoglobinemia
- Hepatic: Hepatic necrosis
- Neuromuscular & skeletal: Tremor, rhabdomyolysis
- Ocular: Lacrimation, exophthalmos, proptosis, iritis, optic neuritis, cataract, conjunctival erythema
- Renal: Acute tubular necrosis, oliguria, proximal tubular degeneration
- Respiratory: Dyspnea, bronchospasm, wheezing
- Miscellaneous: Laryngeal edema, anaphylaxis

Toxicodynamics/Kinetics Absorption: Orally; <1% absorbed by dermal route

Monitoring Parameters Urinalysis, CPK, renal function tests

Overdosage/Treatment

- Decontamination: **Oral: Do not** administer ipecac for oral ingestion; activated charcoal can be administered. **Dermal:** Wash with soap and water. **Ocular:** Irrigate copiously with saline.
- Supportive therapy: Intravenous fluid hydration and diuretics should be given for treatment of myoglobinuria. Standard antianaphylaxis therapy can be administered.

Additional Information

- Ingestion of 1.8 g associated with acute renal failure in an adult
- White to light purple crystals. IDLH: 25 mg/m³; TLV-TWA: 0.1 mg/m³
- Cosmetic use is common in Sudan, India, Israel, Pakistan, and Morocco, but is not permitted in the U.S.

Paraquat

Related Information

- Diquat Dibromide
- Toxins Which Should Be Lavaged with Solutions Other Than Water

Applies to

CAS Number 1910-42-5; 2074-50-2; 4685-14-7

Synonyms 1,1'-Dimethyl-4,4'-Dipyridilium Ion; Dimethyl Viologen; Gamoxone; PP-148; PP-190

Commonly Found In Crisquat; Dextrone; Dexuron; Esgran; Goldquat 276; Gramoxone; Hebaxon; Osaquat Super; Sweep

Mechanism of Toxic Action

Usually in a 20% solution; a quaternary nitrogen compound which can produce photobleaching by destroying plant cellular membrane; can also inhibit photosynthesis; pulmonary toxicity involves xanthine oxidase

Adverse Reactions

- Cardiovascular: Vasodilatation
- Central nervous system: No acute neurological signs, hyperthermia
- Dermatologic: Dermal irritation, fingernail atrophy, fingernail loss, Mees' lines, fingernail discoloration (brown), fingernail dystrophy, burns, blisters
- Gastrointestinal: Nausea, vomiting, GI ulceration, pancreatitis, dysphagia
- Hematologic: Hemolytic anemia
- Hepatic: Centrilobular hepatic necrosis
- Neuromuscular & skeletal: Rhabdomyolysis
- Ocular: Corneal edema (by ocular contact)
- Renal: Myoglobinuria
- Respiratory: Cough, pulmonary fibrosis, nasal bleeding with inhalation, acute respiratory distress syndrome

Signs and Symptoms of Overdose

- Group I, mild poisoning (<20 mg/kg): Diarrhea, nausea, vomiting
- Group II, moderate poisoning (20-40 mg/kg): Diarrhea, pulmonary fibrosis, immediate vomiting, renal/hepatic failure - death in 2 weeks
- Group III, severe poisoning (>40 mg/kg): Diarrhea, immediate vomiting, oropharyngeal ulceration with cardiac, respiratory, hepatic, and renal failure - death usually within 1-4 days

Admission Criteria/Prognosis Patients with known or suspected exposures should be admitted

Toxicodynamics/Kinetics

- Absorption: Dermal absorption can occur through skin that is not intact.
- Oral absorption: 30%
- Distribution: V_d: 1.2-1.6 L/kg
- Half-life: 12-120 hours
- Elimination: Renal

Reference Range Severity index of paraquat poisoning (SIPP) is determined by multiplying the elapsed time (hours) from ingestion to arrival, by the serum paraquat level (in mg/L). A value > 10 is indicative of a fatality. Plasma level of 3 mg/L associated with death

Overdosage/Treatment

- Decontamination: Emesis (within 30 minutes)/lavage (within 1 hour) with activated charcoal, Fuller's earth (15%), or 7% bentonite (dose of Fuller's Earth or Bentonite: Children <12 years: 2 g/kg; Adults: 100-150 g). Sodium polystyrene sulfonate may also be effective.
- Ocular: Irrigate with saline or water for at least 15 minutes
- Dermal: Remove contaminated clothing and wash skin with copious amounts of soap and water. Skin damage may be delayed for 1-3 days. Systemic toxicity is rare from dermal exposure.

Supportive therapy:

Vomiting can be controlled with ondansetron 8 mg (5 mg/m³ in children) by slow I.V. injection or I.V. infusion over 15 minutes

Do not utilize oxygen in that it may promote pulmonary fibrosis. Monitor for hypercalcemia if Fuller's earth is used. Inhaled nitric oxide (at 25 ppm) has been used to treat ARDS. Nitric oxide inhalation (10-20 ppm) via BiPAP has been used successfully in case reports. Vitamin C (4000 mg/day) and vitamin E (250 mg/day), dexamethasone, cyclophosphamide, and acetylcysteine have been used to treat lung toxicity, but are of unproven benefit. As antioxidants, deferoxamine (100 mg/kg over 24 hours) and acetylcysteine (loading dose: 150 mg/kg then 300 mg/kg/day for 3 weeks) with hemodialysis (6 hours) have been utilized successfully in a massive paraquat ingestion (maximum serum paraquat level of 28 mcg/mL). High-dose cyclophosphamide (15 mg/kg I.V. the first day followed by 10 mg/kg on day two, 7 mg/kg on days 3-5 and 5 mg/kg daily until total dose is 4 g or leukocyte count is <3000/mm³), along with dexamethasone (1.5 mg/kg daily for first 4 days followed by 1 mg/kg on days 5-7 and 24 mg/day thereafter), has been used to increase survival in mild to severe paraquat poisoning, when used in conjunction with basic poison management. Morphine sulphate can be used for pain control. S-carboxymethylcysteine (20 mg/kg orally four times per day for 2-3 weeks) has been used, in conjunction with general supportive measures, successfully as an antioxidant.

Enhancement of elimination: Multiple dosing of activated charcoal, Fuller's earth (100-150 g in adults or 2 g/kg in children), or bentonite may be given every 2-4 hours. Charcoal hemoperfusion for prolonged periods of time (up to 10 hours) may be helpful if instituted within 10 hours. Forced diuresis is not helpful. Hemoperfusion clearance is estimated to be 57-156 mL/minute. Continuous arteriovenous hemodialysis/hemoperfusion (CAVHD-HP) can also result in nondetectable serum paraquat levels (without rebound) within 2-3 days after treatment. Paraquat clearance with CAVHD ranges from 730-2,145 mL/minute.

Diagnostic Procedures

- Paraquat, Blood

Additional Information Faint ammonia-like odor. Not well absorbed through intact skin but prolonged contact can cause systemic toxicity. Restrictive pulmonary dysfunction is a long-term sequelae following acute paraquat exposure. Dithionate test: 1 part urine, 0.5 part sodium dithionate in IN NaOH: deep blue color indicates presence of paraquat or diquat. For additional information contact Syngenta: (800) 327-8633.

Parathion

CAS Number 56-38-2

UN Number 2783; 2784

U.S. Brand Names Bay E-605®; Bladan F®; Orthophos®

Synonyms EthylParathion; O,O-DiethylO-p-NitrophenylPhosphorothioate

Mechanism of Toxic Action Potent, irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

- Cardiovascular:** **Hyperdynamic** (~18% to 21%) or **hypodynamic** (~7% to 10%) states, edema, QT prolongation, Raynaud's phenomenon, sinus bradycardia, sinus tachycardia, torsade de pointes
- Central nervous system:** Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia, extrapyramidal reactions
- Dermatologic:** Scleroderma
- Endocrine & metabolic:** Parotitis
- Gastrointestinal:** Pancreatitis
- Genitourinary:** Urinary incontinence
- Neuromuscular & skeletal:** Weakness (delayed), paralysis, delayed paresthesia, rhabdomyolysis, peripheral neuropathy
- Ocular:** Visual evoked potential abnormalities
- Miscellaneous:** Flu-like symptoms (especially with chronic exposure); intermediate syndrome

Signs and Symptoms of Overdose

Abdominal pain, agitation, AV block, asystole, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, dementia, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, garlic-like breath, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, nystagmus, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure, and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia, and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Admission Criteria/Prognosis Any symptomatic patient or an asymptomatic patient following a severe exposure should be admitted probably into an intensive care unit; asymptomatic patients following a moderate exposure can be discharged after 8 hours of observation

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure

Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways

Elimination: Metabolites are excreted in urine as p-nitrophenol

Warnings/Precautions Risk of aspiration pneumonia exists with agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Reference Range

Serum parathion levels in asymptomatic occupationally exposed worker range from 0.004-0.2 mg/L; urine p-nitrophenol levels in these indivi-

duals ranged from 0.4-13.2 mg/L; no correlation in cholinesterase (plasma or red blood cell) noted

Mild poisoning: Serum cholinesterase is 20% to 50% of normal;

Moderate poisoning: Serum cholinesterase is 10% to 20% of normal

Severe poisoning (respiratory distress and coma): Serum cholinesterase is <10%

Fatal parathion blood levels range from 0.5-34 mcg/mL; postmortem fat tissue parathion level: 6.5 mg/kg

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment

Oral: Activated charcoal (without cathartic) can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure; asoxime chloride may be useful when used with atropine

Enhancement of elimination: Exchange transfusion in adults: 500-2000 mL may be useful in severe poisonings. While hemodialysis has **not** been shown to be useful, charcoal hemoperfusion has produced a clearance of 59% of the blood flow. While parathion in itself is not dialyzable, its toxic metabolite paroxon can be removed by hemodialysis. Parathion and paroxon are also removable by hemoperfusion, although the clinical utility of these methods requires further investigation.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or ~1/2 the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Obidoxime: Adults: 250 mg I.V. bolus (slow) followed by continuous I.V. infusion at 750 mg/24 hours.

Antidote(s)

- Asoxime Chloride [ANTIDOTE]
- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pesticide Screen, Chlorinated
- Pesticide Screen, Organophosphate
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information

Lethal oral dose: Adults: 25 g;

Yellow to brown liquid with a garlic odor; thermal degradation products include sulfur, nitrogen, and phosphorus oxides; red blood cell cholinesterase, and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected.

The intermediate syndrome is not related to delayed neuropathy.

Reactive when combined with endrin.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Water solubility: 12 ppm. **Odor threshold:** 0.04 ppm. **Vapor pressure:** 0.0004 mm Hg at 20°C

PENTABORANE

ACGIH TLV: 0.1 mg/m³; PEL-TWA: 0.1 mg/m³ IDLH: 20 mg/m³
Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Pentaborane

CAS Number 19624-22-7

UN Number 1380

Synonyms Dihydropentaborane

Use Rocket propellant; reducing agents; gasoline additive

Mechanism of Toxic Action May deplete monoamine neurotransmitters in the central nervous system (inhibition of norepinephrine, dopamine and serotonin metabolism)

Adverse Reactions

Cardiovascular: Hypotension, tachycardia, fibrillation (atrial), flutter (atrial), sinus tachycardia, cerebral edema

Central nervous system: Hyperthermia, seizures, coma, increased intracranial pressure, opisthotonos, headache, hallucinations, dizziness, memory deficits, confusion, impaired concentration

Endocrine & metabolic: Increased serum transaminase levels, metabolic acidosis

Gastrointestinal: Garlic-like breath

Hepatic: Liver necrosis, fatty liver degeneration

Ocular: Cortical blindness

Neuromuscular & skeletal: Quadriplegia, tremor, muscle spasm

Renal: Myoglobinuria

Miscellaneous: Hiccups

Toxicodynamics/Kinetics Absorption: Oral, inhalation or dermal

Overdosage/Treatment

Decontamination: **Oral:** Do not induce emesis; lavage (within 1 hour)/activated charcoal may be useful. **Dermal:** Use cool water. An exothermic reaction may develop, therefore, monitor for dermal burns. A 3% aqueous ammonia solution can also be used to complex the borane. **Inhalation:** Administer 100% oxygen. **Ocular:** Irrigate with saline or water.

Supportive therapy: Benzodiazepines can be used to treat seizures. Phenobarbital or phenytoin can be used to treat refractory seizures. Sodium bicarbonate (1-2 mEq/kg) can be used to treat acidosis.

Additional Information Colorless liquid with garlic-like odor. Can ignite spontaneously in air. Specific gravity: 0.61. Odor threshold: 0.8 ppm. TLV: 0.005 ppm; IDLH: 3 ppm

Pentachlorophenol

Applies to Disinfectant; Fungicide; Herbicide; Termiticide; Wood Preservative

CAS Number 87-86-5

UN Number 3155

U.S. Brand Names Chlon®; Dowicide® 7; Dura Tree® II; Fungifen®; Lauxtol®; Penta Ready®; Permasan®; Santophen® 20; Woodtreat®

Synonyms PCP; Penchlorol

Use Termiticide, fungicide, herbicide, and disinfectant; primarily used as a wood preservative, 0.1% concentration; restricted use pesticide

Mechanism of Toxic Action Uncouples oxidative phosphorylation; hexachlorobenzene, pentachlorobenzene, and hexachlorocyclohexene all metabolize to pentachlorophenol

Adverse Reactions

Cardiovascular: Tachycardia, sinus tachycardia

Central nervous system: Seizures, hyperthermia

Dermatologic: Alopecia, urticaria

Endocrine & metabolic: Acidosis, polydipsia

Gastrointestinal: Nausea, vomiting

Hematologic: Hemolysis, aplastic anemia

Hepatic: Hepatotoxicity with elevated liver function test results

Neuromuscular & skeletal: Tremors, muscle spasms

Ocular: Mydriasis, retrobulbar neuritis

Renal: Nephrotoxicity (reduced glomerular filtration rate and tubular function)

Respiratory: Hyperventilation, pulmonary irritation

Miscellaneous: Dermal and ocular irritant (at levels in air >0.1 ppm), intense thirst, diaphoresis

Admission Criteria/Prognosis Symptomatic patients, urine pentachlorophenol levels > 36 ppm, acidosis, hyperthermia, or electrolyte abnormalities should be admitted

Toxicodynamics/Kinetics

Absorption: Dermal: 62% in oil-based solution and 16% in aqueous based. Inhalation: 76% to 88%. Oral: Within 1.3 hours

Distribution: V_d: 0.35 L/kg

Protein binding: 99% in animal models

Metabolism: Hepatic conjugation to form a glucuronide and oxidative dechlorination to form tetrachloro-para-hydroquinone (TCHQ)

Half-life: 13-19 days (ethanol solution); 30 hours (sodium salt)

Elimination: Renal (~78% as pentachlorophenol and 12% as pentachlorophenol glucuronide)

Reference Range

Mean blood pentachlorophenol level in patients with neurological symptoms: 22 mcg/L (range: 4-60 mcg/L); people living in log homes can have 10 times the blood levels than general population (420 ppb vs 40 ppb, respectively); adipose tissue levels in general population: 26.3 mcg/kg; baseline urine pentachlorophenol level in general population: 3.4 ppb; for residents of log homes: 69 ppb; mean urinary daily excretion of pentachlorophenol: ~4.3 nmol

Mean pentachlorophenol urine level of 153 mg/L (range 28-520 mg/L) associated with fatal poisoning

Overdosage/Treatment

Decontamination: **Oral:** Lavage within 1 hour of exposure. Cholestyramine can be effective in adsorbing this agent. **Dermal:** Remove all contaminated clothing; wash with soap and water. **Ocular:** Copious irrigation with saline

Supportive: Cool with external methods. Avoid use of aspirin or atropine. Diazepam can be used for muscle spasm.

Enhancement of elimination: Exchange transfusion may be effective in infants. Due to enterohepatic recirculation, multiple dosing of cholestyramine (4 g every 8 hours) may be effective. Dialysis, forced diuresis, or hemoperfusion is not useful. Plasmapheresis may be useful.

Additional Information

Lethal oral dose: 1 g (~17 mg/kg); profound rigor mortis can be observed immediately after death

Concentrations >10% can cause dermal irritation

Usually contaminated with chlorinated dibenzo-para-dioxins.

WHO guideline for drinking water is 10 mcg/L.

Dairy products, grains, and cereals have highest levels of this agent

Daily dietary intake: ~1.5 mg. Daily drinking water intake: 0.02-24 mcg
Inhalation exposure of general U.S. population: 12-136 mcg/day; residents of log homes: 140-157 mcg/day due primarily to treated logs (although this agent is no longer used for this purpose); sealers decrease this concentration significantly

Soil samples within one foot of treated utility poles: 3-654 ppm

PEL-TWA (skin): 0.5 mg/m³; IDLH: 150 mg/m³. Half-life in soil: 2-4 weeks
Year-End 1999 Emergency Department Drug Abuse Warning Network (DAWN) data: Emergency Department mentions for PCP/PCP combinations remained relatively stable between 1998 (4033 mentions) and 1999 (4969 mentions). Mentions of PCP/PCP combinations in 1999 were 6% lower than in 1992 (5282 mentions).

Specific References

Proudfoot AT, "Pentachlorophenol Poisoning," *Toxicol Rev*, 2003, 22(1): 3-11.

Pepper Spray

CAS Number 404-86-4 (capsaicin)

Use Riot control; active ingredient in tear gas

Mechanism of Toxic Action Lacrimator - irritation due to the active halogen group reacting with sulfhydryl groups; contains the mucosal irritant oleoresin of capsicum (which stimulates pain fibers) in a 1% to 10% concentration.

Adverse Reactions

Dermatologic: Vesiculation of skin (rare)

Ocular: **Ocular burning (56%)**, blepharospasms, cataract, **conjunctival irritation (44%)**, **lacrimation (16%)**, corneal abrasion

Respiratory: Bronchospasm (may be delayed for 36 hours), pulmonary edema (may be delayed for 24 hours)

Overdosage/Treatment

Decontamination: Move patient to fresh air and monitor for wheezing. Personnel should avoid contaminating themselves. Wash skin with soap and water. Avoid rubbing of eyes as it may prolong effect. Copious irrigation is needed.

Supportive therapy: Solution of antacid (magnesium hydroxide - aluminum hydroxide - simethicone) gently blotted topically over exposed facial areas (avoiding eyes) may help resolve symptoms.

Additional Information Exists as a white solid

Specific References

Swami RH, Judge BS, and Furbee RB, "Accidental Ingestion of Cayenne Pepper Sauce Requiring Prolonged Ventilatory Support," *J Toxicol Clin Toxicol*, 2003, 41(5):653.

Petroleum Distillates - Naphtha

CAS Number 8030-30-6

UN Number 2553

Synonyms Benzin; Painters' Naphtha; Petroleum Spirit; White Spirit

Commonly Found In Coal tar, solvent for oils, lacquers, paints, rubber cement

Mechanism of Toxic Action Aspiration pneumonia related to low viscosity agents

Adverse Reactions

Central nervous system: CNS depression

Gastrointestinal: Irritant of mucous membranes

Hematologic: Methemoglobinemia

Respiratory: Aspiration pneumonitis

Miscellaneous: Intravenous administration produces fever and local tissue damage

Signs and Symptoms of Overdose Unlikely to produce systemic signs. Cough (persistent), dermatitis, dizziness, dyspnea, erythema, fever, headache, hematuria, hemoptysis, nausea

Admission Criteria/Prognosis Patients who develop tachypnea, cyanosis, dyspnea, CNS depression, tachycardia, or fever within 8 hours of exposure should be admitted; asymptomatic patients can be discharged after 8 hours observation

Toxicodynamics/Kinetics Absorption: Not well absorbed in the GI tract
Overdose/Treatment

Supportive therapy: Pulsed corticosteroid therapy (1000 mg/day of I.V. hydrocortisone for 3 days with a 7-week gradual taper) may lead to improvement of naphtha-induced adult respiratory distress syndrome

Decontamination: **Do not** induce emesis or lavage; basic poison management; avoid positive net fluid balance; avoid catecholamines due to sensitivity of myocardium

Additional Information IDLH: 10,000 ppm; PEL-TWA: 500 ppm

Phencyclidine

CAS Number 77-10-1; 956-90-1

Synonyms PCP

Impairment Potential Yes. Blood phencyclidine levels >0.007 mg/L are associated with driving impairment (Baselt RC and Cravey RH, *Disposition of Toxic Drugs and Chemicals in Man*, 4th ed, Foster City, CA: Chemical Toxicology Institute, 1995, 602.)

Mechanism of Action Related to ketamine, PCP is an arylcyclohexylamine which stimulates alpha-adrenergic receptors

Adverse Reactions

Cardiovascular: Tachycardia, pericardial effusion/pericarditis, sinus tachycardia

Central nervous system: Violent behavior, aggressive behavior; psychosis, paranoia, hallucinations, ataxia, synesthesia, dysphoria, sympathetic storm

Endocrine & metabolic: Hypoglycemia

Gastrointestinal: Vomiting

Hepatic: Aminotransferase level elevation (asymptomatic)

Ocular: Nystagmus, lacrimation, mydriasis (miosis in children)

Signs and Symptoms of Overdose Coma, delirium, depression, encephalopathy, fasciculations, fear, fever, headache, hyperacusis, hypertension, hyperthermia, hyperuricemia, hypoglycemia, hypothermia, impotence, insomnia, lacrimation, mania, myoclonus, myoglobinuria, myopathy, ptosis, respiratory depression, rhabdomyolysis, seizures, sweating, tachycardia

Admission Criteria/Prognosis Patients with blood phencyclidine level >30 ng/mL; transient apnea, catatonia, severe psychosis, rhabdomyolysis; sustained adrenergic signs may require admission

Pharmacodynamics/Kinetics

Distribution: V_d : 6.2 L/kg

Protein binding: 60% to 70%

Metabolism: Hepatic via oxidative hydroxylation

Half-life elimination: 1 hour; Overdose: 17.6 hours

Excretion: Urine (33 mL/minute)

Dosage Joints are 100-400 mg PCP by weight; tablets are ~5 mg

Reference Range

Serum levels: Catatonia and excitation: 20-30 ng/mL; myoclonus and coma: 30-100 ng/mL; hypotension, seizures, fatalities: >100 ng/mL

Urinary levels do not correlate with clinical symptoms

In the postmortem state, anatomical site concentration differences (ie, postmortem redistribution) may occur.

Overdose/Treatment

Decontamination: Activated charcoal for oral ingestions

Supportive therapy: Benzodiazepine for agitation; haloperidol (5 mg I.M.) improves psychotic symptoms; rhabdomyolysis can be treated with I.V. hydration, alkalization, and mannitol; lorazepam or diazepam can be used to calm and sedate the patient

Enhanced elimination: Continuous gastric suction (due to gastric secretion of PCP) may increase elimination and should be considered in the comatose patient; multiple dosing of activated charcoal may be effective

Test Interactions Adulteration with bleach can cause false-negative urine immunoassays; doxylamine may result in a false-positive urine gas chromatographic test; dextromethorphan, diphenhydramine, or high doses of thioridazine may result in a false-positive immunoassay screen;

ketamine is not expected to result in a positive immunoassay on most systems

Drug Interactions

Substrate of CYP3A4 (major); **Inhibits** CYP3A4 (weak)

CYP3A4 inhibitors: May increase the levels/effects of phencyclidine.

Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Pregnancy Implications Neonatal irritability, hypertonia, tremors

Additional Information Mid-Year 2000 Emergency Department Drug Abuse Warning Network (DAWN) data: **Note:** Phencyclidine is sometimes used in combination with other drugs; therefore, one Emergency Department (ED) episode can include mentions of one or more drugs.

- In the first half of 2000, there were 3153 ED mentions of PCP/PCP combinations, which was 49% greater than in the first half of 1999. The number of PCP/PCP combination mentions, which began to decline in 1996, has since leveled off.

Phenibut

CAS Number 35568-37-7

Synonyms Beta-phenyl-gamma-aminobutyric Acid HCl; Fenibut; Phenyl-gam

Use Neuropsychotropic drug developed in Russia in the 1960s; has anxiolytic effects; usually ingested as a powder

Mechanism of Action A beta-phenyl derivative of the inhibitory central nervous system neuromediator GABA with GABA(A) and GABA(B) agonist effects. Also stimulates dopamine receptors.

Adverse Reactions Sedation, lethargy

Dosage About 250 mg 3 times/day

Overdose/Treatment

Decontamination: Oral activated charcoal may be useful within 1 hour of ingestion

Supportive care: Naloxone is not effective; flumazenil has unknown effectiveness; respiratory depression and cardiac effects are minimal

Specific References

Lapin I, "Phenibut (Beta-phenyl-GABA): A Tranquilizer and Nootropic Drug," *CNS Drug Rev*, 2001, 7(4):471-81.

Phenmedipham

Applies to Weed Control (Sugar Beets)

CAS Number 13684-63-4

U.S. Brand Names Betanal[®]; EP-452; Fenmedifam[®]; Kemifan[®]; Spin-Aid[®]

Synonyms Methyl-3-Metatolycarbamoloxyphenyl Carbamate

Use Control weeds of sugar beet crops

Mechanism of Toxic Action Inhibitor of photosynthesis

Signs and Symptoms of Overdose Bullous dermatitis, photosensitivity reaction

Overdose/Treatment Decontamination: Remove contaminated clothing (especially leather); wash thoroughly with soap and water. Irrigate eyes with normal saline for ocular exposure.

Additional Information Does not affect cholinesterase; leather absorbs phenmedipham

Phosdrin

CAS Number 7786-34-7

UN Number 2783

U.S. Brand Names Mevinphos[®]; Phosdrin[®]

Use Insecticide

Mechanism of Toxic Action Highly toxic organophosphate agent which causes irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, tachycardia, hypertension, edema

Central nervous system: Depression, seizures, hyperactivity

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Pancreatitis, diarrhea

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness, paralysis, paresthesia (delayed)

Ocular: Can cause myopia in children, miosis, vertical nystagmus

PHOSGENE

Miscellaneous: Flu-like symptoms (especially with chronic exposure), diaphoresis

Signs and Symptoms of Overdose

Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hyperamylasemia, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Admission Criteria/Prognosis Patients will usually be symptomatic within 2 hours of ingestion; admit any adult ingestion >5 mg or any symptomatic patient

Toxicodynamics/Kinetics

Onset: Within 2 hours

Absorption: GI: Dermal-toxic, dermal: 14 mg/kg

Elimination: Renal (as dimethylphosphate)

Reference Range Postmortem blood and urine levels after a successful suicide attempt (dose unknown): 360 ppm and 8 ppm, respectively; urine dimethylphosphate levels in a mildly symptomatic patient: 2 ppm

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment. Gastric lavage with water, 5% sodium bicarbonate or 2% potassium permanganate can be considered within 1 hour of ingestion. **Do not** use a cathartic with activated charcoal.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. Prolonged or repetitive gastric lavage (with activated charcoal) may be beneficial to prevent rebound of plasma levels due to delayed absorption. **Do not** give a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can also be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses >100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or $\sim 1/2$ the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of organophosphates. Due to enterohepatic recirculation, multiple dosing of activated charcoal may be effective.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Additional Information Toxic daily dose (which can result in reduced red cell cholinesterase): ~ 1.5 mg. A pale yellow to orange liquid with little odor. Specific gravity: 1.25. TLV: 0.1 mg/m³. Associated solvent: Hexyleneglycol

Use In the manufacture of isocyanates, aniline dyes, plastics, and insecticides. Initially prepared in 1812, but used extensively in World War I gas warfare (approximately 1.3 million victims and 90,000 fatalities); product of combustion of volatile chlorine compounds

Mechanism of Toxic Action Direct cytotoxicity through diamide formation which crosslink cell components. Reacts readily with hydroxyl, sulfhydryl, and ammonia groups found in albumin, amino acids, and vitamins; pulmonary irritant with low water solubility thus primarily affecting lung parenchyma on inhalation (delayed alveolar injury)

Adverse Reactions

Cardiovascular: Hypotension, bradycardia, sinus bradycardia, angina, Raynaud's phenomenon, leukocytosis

Endocrine & metabolic: Hypovolemia

Hematologic: Methemoglobinemia, leukocytosis (atypical lymphocytosis), hemolysis (>200 ppm)

Ocular: Conjunctivitis, corneal opacification

Respiratory: Respiratory distress, pulmonary edema ("pink foam"), acute respiratory distress syndrome, tachypnea, dyspnea

Signs and Symptoms of Overdose Asthenia, chest pain, cough, dermal burns, dyspnea, headache, hemoptysis, nausea, ocular irritation, throat burning, vomiting; pulmonary edema within 1-2 hours (high dose), 4-6 hours (moderate dose), 8-24 hours (low dose)

Admission Criteria/Prognosis Patients with known or suspected phosgene exposure >25 ppm/minute, should be observed for at least 12 hours. Patients with development of bronchospasm or pulmonary edema should probably be admitted into an intensive care unit. Survival after 48 hours is usually associated with recovery.

Toxicodynamics/Kinetics Metabolism: Hydrolyzes slowly to produce carbon dioxide and hydrochloric acids

Overdosage/Treatment

Decontamination: **Oral:** Lavage within 1 hour. Irrigate exposed areas.

Steroids may be helpful. **Do not** use diuretics. **Dermal:** Remove contaminated clothing. Irrigate copiously with saline or water (especially with diphosgene exposure). **Respiratory:** Administer 100% humidified oxygen. **Ocular:** Irrigate with saline

Supportive therapy: Bedrest; monitor and treat for pulmonary edema. Support of pulmonary function is the mainstay of therapy with mechanical ventilation and positive end-expiratory pressure. The use of nebulized sodium bicarbonate, leukotriene-receptor antagonists, ibuprofen, methylprednisolone, cyclophosphamide, colchicine, and N-acetylcysteine (I.V. or nebulized) has met with some success in experimental models, but is of uncertain clinical benefit. Even so, if exposure to over 50 ppm of phosgene is considered, suggested regimen for pulmonary edema prophylaxis include: ibuprofen 800 mg P.O., methylprednisolone 1 g I.V. or dexamethasone phosphate 10 mg by aerosol, aminophylline 5 mg/kg I.V. or P.O. followed by 1 mg/kg every 8-12 hours to achieve serum aminophylline level of 10-20 mcg/mL, terbutaline 0.25 mg SubQ, N-acetylcysteine 10-20 mL of a 20% solution by aerosolization, oxygen as needed. Use of parenteral prednisolone (1 g I.V.), aerosolized dexamethasone, and theophylline may be useful, but has not been studied in humans. Prophylactic administration of prednisolone (250 mg I.V.), ibuprofen, or N-acetylcysteine (20 mL of a 20% solution) has also not been clinically demonstrated to prevent pulmonary edema. Inverse-ratio ventilation using lower tidal volume mechanical ventilation (6 mL/kg) and plateau pressures of 30 cm water may decrease mortality. While positive end expiratory pressures should be considered, oxygen toxicity should be monitored. Use of perfluorocarbon partial liquid ventilation and exogenous surfactant in chemical-induced ARDS is investigational.

Diagnostic Procedures

- Electrolytes, Blood
- Pulse Oximetry

Additional Information

Vapor contact of >3 ppm phosgene with wet skin may lead to erythema.

Phosgene levels >330 ppm/minute can be fatal. Prolonged exposure at 3 ppm for 3 hours can be fatal. Levels >4 ppm can cause ocular irritation and 5 ppm can cause cough. Liquid phosgene is a frostbite hazard.

Pulmonary edema developing within 4 hours is a bad prognosis; usually it will develop within 4-8 hours postexposure. Olfactory paralysis may occur after a short time of initial exposure. Blindness may occur. On chest x-ray, blurred enlargement of hilar area may be the earliest finding. Rescuer contamination possibility from affected patients is low.

Colorless gas; latent period may last 3 days. Estimated worldwide production is >5 billion pounds. Odor threshold: 0.5 ppm. At low doses, it has a freshly mowed grass odor; higher doses give a pungent odor.

Vapor density: >4. TLV-TWA: 0.1 ppm; IDLH: 2 ppm; PEL-TWA: 0.1 ppm Soluble in water; rapidly hydrolyzed in water to hydrochloric acid and carbon dioxide. Does not bioconcentrate.

Environmental half-life of phosgene in soil and water: 3 minutes to 1 hour Clinically resembles: Chlorine

Environmental persistence: Low; air concentrations are reduced by rain or fog

Kales SN and Christiani DC, "Acute Chemical Emergencies," *N Engl J Med*, 2004, 350(8):800-8.

Phosgene

Applies to Dyes, Aniline (Manufacture); Insecticides (Manufacture); Plastics (Manufacture)

CAS Number 75-44-5

UN Number 1076

Synonyms Agent CG; Carbon Oxychloride; Carbonic Dichloride; Carbonyl Chloride; Chloroformyl Chloride; Diphosgene; Phosgen

Phosphine

Related Information

- Aluminum Phosphide
- Zinc Phosphide

Applies to Grain Fumigation; Rat Poison

CAS Number 7803-51-2

UN Number 2199

Synonyms Delicia; Detia Gas EX-B; Hydrogen Phosphide; PH₃; Phosphoret Hydrogen; Phosphorus Trihydride

Use Silicon crystal treatment in semiconductor industry, contaminant in acetylene, grain fumigation, and rat poisons. Produced by reaction of hydrogen with metal phosphides.

Mechanism of Toxic Action Protoplasmic toxicity inhibits cytochrome C oxidase pathway primarily in myocardium

Adverse Reactions

Cardiovascular: Tachycardia, cardiovascular collapse, hypotension, flutter (atrial), angina, sinus tachycardia, arrhythmias (ventricular), chest tightness

Central nervous system: Panic attacks, coma, seizures, dizziness

Hepatic: Hepatic toxicity (late)

Neuromuscular & skeletal: Rhabdomyolysis, intention tremor

Renal: Oliguria, renal failure

Respiratory: Pulmonary edema, shortness of breath, dyspnea

Signs and Symptoms of Overdose Abdominal pain, ataxia, cardiac arrhythmia, chest pain, cough, diplopia, dizziness, drowsiness, dyspnea, fibrillation (atrial), garlic-like breath, irritability, jaundice, seizures, tachycardia (ventricular), tremor, vomiting, diarrhea

Admission Criteria/Prognosis

Mild exposure: Asymptomatic individuals can be discharged after 6 hours of observation

Serious exposure: Patients should be observed for pulmonary edema or liver damage for 72 hours; survival after 4 days is usually associated with recovery

Toxicodynamics/Kinetics Onset of action: Rapid, within 3 hours of exposure

Reference Range Blood and urine phosphorus levels are not reliable

Overdosage/Treatment

Decontamination: Inhalation: Oxygenation; if ingested, lavage within 1 hour with 1:10,000 dilution of potassium permanganate to reduce availability of phosphine; activated charcoal may be useful

Supportive therapy: Calcium gluconate and magnesium sulfate may be useful for cardiac arrhythmia. Magnesium sulphate may be particularly useful at a dose of 3 g (continuous I.V. infusion) over 3 hours followed by 6 g/day for the next 3-5 days; may be unresponsive to vasopressin. Inverse-ratio ventilation using lower tidal volume mechanical ventilation (6 mL/kg) and plateau pressures of 30 cm water may decrease mortality. While positive end expiratory pressures should be considered, oxygen toxicity should be monitored. Use of perfluorocarbon partial liquid ventilation and exogenous surfactant in chemical-induced ARDS is investigational.

Enhancement of elimination: Hemodialysis may be useful in cases of renal damage.

Antidote(s)

- Calcium Gluconate [ANTIDOTE]
- Magnesium Sulfate [ANTIDOTE]

Additional Information Adult deaths have been described with ingestion of 4 g of zinc phosphide or 500 mg aluminum phosphide. Colorless gas; flammable; garlic odor. Odor (garlic) threshold: 2 ppm. IDLH: 50 ppm

Specific References

Lauterbach M, Solak E, Kaes J, et al, "Epidemiology of Hydrogen Phosphide Exposures in Humans Reported to the Poison Center in Mainz, Germany, 1983-2003," *Clin Toxicol*, 2005, 43:575-81.

Pine Oil

Related Information

- Turpentine Oil

CAS Number 8002-09-3

UN Number 1272

Synonyms Unipine; Yurmor Pine Oil

Use Disinfectant/cleaning agent

Mechanism of Toxic Action CNS depression and mucosal irritation

Adverse Reactions

Cardiovascular: Bradycardia, hypotension, syncope

Central nervous system: Fever, ataxia, coma, headache

Dermatologic: Nonimmunologic contact urticaria

Gastrointestinal: Nausea, vomiting, diarrhea

Renal: Anuria, renal failure, myoglobinuria

Respiratory: Tachypnea, coughing, aspiration pneumonitis, dyspnea

Admission Criteria/Prognosis Admit ingestions of >20% solution or any symptomatic individual 6 hours postingestion

Toxicodynamics/Kinetics

Absorption: Gastrointestinal

Elimination: Pulmonary (violet-like odor)

Monitoring Parameters Arterial blood gas, renal function, chest x-ray, urine analysis

Reference Range Postmortem levels of 1- α -terpineol following an ingestion of ~100 mL of Pine-Sol[®] were: Blood: 11.2 mg/L; urine: 5.76 mg/L; gastric: 15.3 g/L. Postmortem acetone concentrations were: Blood: 25 mg/dL; vitreous humor: 31 mg/dL; urine: 33 mg/dL; and gastric: 28 mg/dL. Postmortem concentrations of isopropanol were <10 mg/dL in the blood, vitreous humor, urine, and gastric contents.

Overdosage/Treatment

Decontamination: Oral: May be considered if the patient presentation is within 1 hour of ingestion. Emesis in the alert patient may be the preferred method for gastric decontamination, in that, pulmonary complications appear to be less frequent as compared to gastric lavage. Activated charcoal can be used although there is no data on its effectiveness. **Dermal:** Wash with soap and water. **Ocular:** Irrigate copiously with saline.

Supportive therapy: Hypotension: Crystalloid fluid bolus (10-20 mL/kg) with placement in Trendelenburg position should be utilized. Dopamine or norepinephrine can be used as vasopressors.

Enhanced elimination: Exchange transfusion (over a 3 hour period) helped improve the CNS respiratory depression in one pediatric patient.

Additional Information

Fatal dose: 0.5 ounces (14 g) of pure pine oil (or 75 mL of a 20% solution) in a child, 8 ounces in an adult

Ingestions of pine oil solutions <20% result in minimal symptomatology.

Monitor for coingestants (ie, isopropyl alcohol).

Respiratory odor is that of violets. Specific gravity: 9

Pine oil is a mixture of terpene alcohols; Pine-Sol[®] may contain from 15% to 35% pine oil.

Platinum

CAS Number 7440-06-4

Synonyms Liquid Bright Platinum; Platin; Platinum Black; Platinum Sponge

Adverse Reactions

Eyes, nose, respiratory, dermatologic, immunologic contact urticaria

Central nervous system: Axonopathy

Respiratory: Asthma

Signs and Symptoms of Overdose Classic signs/symptoms of allergic reaction; cough, dyspnea, eczema, eosinophilia, lymphocytosis, neuritis, rash, rhinorrhea, urticaria, wheezing

Toxicodynamics/Kinetics

Absorption: Oral: Poor. Inhalation: Readily absorbed

Distribution: To soft tissue

Protein binding: 90% to 95%

Half-life: 59-73 hours

Overdosage/Treatment

Decontamination: Irrigation

Supportive therapy: Beta agonists can be used for wheezing

Diagnostic Procedures

- Platinum, Blood
- Platinum, Urine

Additional Information Platinum metal is biologically inert. Parenteral administration of platinum salts in an animal model produces seizures, coma, and death. Simple platinum salts are toxic to the gastrointestinal tract. Complex platinum salts are toxic to the nervous system. An allergic response to complex platinum salts is known as platinosis. TLV-TWA metallic platinum dust: 1 mg/m³; for soluble platinum salts: 0.002 mg/m³

Plutonium

Applies to Nuclear Weapons

CAS Number 7440-07-5

UN Number 2918

Synonyms Plutonium Metal; Plutonium-236 Isotope; Plutonium-237 Isotope; Plutonium-238 Isotope; Plutonium-239 Isotope; Plutonium-240 Isotope; Plutonium-241 Isotope; Plutonium-242 Isotope; Plutonium-243 Isotope; Pu

Use Primarily in the production of nuclear weapons (plutonium-239 isotope); also used as a heat source for thermoelectric power devices (plutonium-238 isotope) (especially the breeder type of reactor)

Adverse Reactions

Dermatologic: Dermal burns

Local: Causes tissue necrosis on contact

Toxicodynamics/Kinetics

Absorption: By inhalation (especially more soluble forms of plutonium such as plutonium citrate or plutonium nitrate); very limited absorption by oral or dermal routes (0.0002% per hour of plutonium nitrate)

Distribution: Highest concentration after inhalation in tracheobronchial lymph nodes and liver

Half-life: 180-200 years

Elimination: By feces and urine

Overdosage/Treatment

Decontamination: Remove contaminated clothing; isolate all run-off.

Dermal: Irrigate with water; scrub gently with soft sponge or brush (avoid abrading skin). A 50% powdered detergent solution followed by a 5% sodium hypochlorite solution can be used for persistent contamination.

Ocular: Wash copiously with saline.

Supportive therapy: DTPA (diethylenetriamine pentacetic acid) which is available from the Radiation Emergency Assistance Center (865-576-1004) is an effective chelator. The calcium salt should be used as follows: 1 g of Ca^{++} DTPA diluted in 250 mL of 5% dextrose in water should be infused over a 1- to 1¹/₂-hour time period daily for 5 days. CaNa_2 EDTA (calcium Versenate[®]) can also be used, but is less effective. DTPA should be used for dermal exposure with open wounds as well as inhalation or oral ingestion.

Antidote(s)

- Diethylene Triamine Penta-Acetic Acid [ANTIDOTE]

Additional Information Carcinogenic in animals (squamous cell).

Decontamination should be monitored by use of a Geiger-Mueller counter.

Cigarettes can accentuate plutonium toxicity.

Odorless and tasteless. Physical half-life: 24,900 years

Background radiation to an individual in U.S. is estimated to be 360 mrem (2.6 mSv).

Specific References

Additional Information

Toxic oral dose: 500 mg

Low water solubility inducer of hepatic microsomal enzymes

Usually mixed with chlorine; high food concentration is in fish (almost 1 ppm)

Average daily intake of PCB by inhalation: ~100 ng; by drinking water: <200 ng

Tropospheric water half-life: 3.5-83.2 days. Water half-life: 27-82 days

Urban atmospheric concentrations of PCB in the U.S. range from 0.5-30 ng/m³ (mean: 5-10 ng/m³).

Lake Michigan average PCB level: 1.8 ng/L; Lake Huron: 0.5 ng/L

Polychlorinated Dibenzofurans**Related Information**

- Polychlorinated Biphenyls

CAS Number 39001-02-0; 51207-31-9; 55673-89-7; 57117-31-4; 57117-35-8; 57117-37-0; 57117-41-6; 57117-44-9; 60851-34-5; 67517-48-0; 67562-39-4; 69698-58-4; 70648-25-8; 70648-26-9; 72918-21-9; 75627-02-0

Synonyms Chlorodibenzofurans; Dibenzo-p-Dioxins; PCDF

Use No commercial use; primarily produced as byproducts during the production of polychlorinated biphenyl agents (PCBs) (ie, Agent Orange), polychlorinated phenols, herbicides, and chlorine bleaching at paper and pulp mills; formed from the photolysis of PCBs and from PCB transformer fires or incineration

Mechanism of Toxic Action Binds to a cellular receptor (Ah receptor) which alters protein and enzyme synthesis

Adverse Reactions

Central nervous system: Headache

Dermatologic: Dermal changes include comedo formatting, hyperpigmentation, hyperkeratosis, acneiform eruptions on face, head, and trunk

Endocrine & metabolic: Elevated serum triglycerides

Gastrointestinal: **Vomiting** (25% on oral exposure), **diarrhea** (18%)

Genitourinary: Increased urinary excretion of uroporphyrin

Hematologic: Normocytic anemia, leukocytosis

Neuromuscular & skeletal: Limb neuralgia, neuropathy (peripheral), paresthesia

Toxicodynamics/Kinetics

Absorption: Through ingestion, inhalation, or dermal routes

Metabolism: Hepatic hydroxylation followed by glucuronidation

Half-life: >7 years of 2,3,7,8-tetrachlorodibenzoparadioxin

Elimination: Feces

Reference Range Whole blood level of total PCDFs in occupationally exposed individuals is over double that of nonexposed subjects (103 ppt vs 47 ppt, respectively)

Overdosage/Treatment

Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal.

Dermal: Remove contaminated clothing; wash with soap and water.

Ocular: Irrigate copiously with saline.

Enhancement of elimination: Multiple dosing of cholestyramine (4 g 3 times/day) has been inconclusive.

Additional Information Carcinogenic in mice models at doses of 0.5-2 mcg/kg/week.

Possible increased risk of soft tissue sarcoma

These chemicals are solid at room temperature.

2,3,7,8-substituted PCDFs seem to be the most hepatotoxic agent of CDF; tetra-CDF, penta-CDF, and hexa-CDF have skin tumor promoter activity

Tropospheric lifetime of PCDFs: 1.9-39 days (higher chlorinated congeners have longer lifetimes)

Foods (especially meat and shellfish) account for the highest amount of CDF ingested daily.

Inhalation accounts for only 3% of total daily CDF intake.

Specific References

Gupta A, Schechter A, Aragaki CC, et al, "Dioxin Exposure and Benign Prostatic Hyperplasia," *J Occup Environ Med*, 2006, 48:708-14.

Polychlorinated Biphenyls**Related Information**

- Adipose Tissue Ranges of Toxins
- Polychlorinated Dibenzofurans

CAS Number 11096-82-5; 11097-69-1; 11100-14-4; 11104-28-2; 11141-16-5; 12672-29-6; 12674-11-2; 12737-87-0; 1336-36-3; 37317-41-2; 37324-23-5; 53469-21-9

UN Number 2315

Synonyms Aroclor; Chlorbipheny; Clophen; Fenclor; Kanechlor; PCB; Phenochlor

Use Was used (up until 1979) as a coolant in capacitors and transformers; also had been used as a lubricant for gas turbine engines

Mechanism of Toxic Action Binds to a cellular receptor (Ah receptor) which alters protein and enzyme synthesis

Adverse Reactions

Central nervous system: Headache, fatigue

Dermatologic: Hyperpigmentation, chloracne, orbital swelling, pruritus, fingernail dystrophy, acne

Endocrine & metabolic: Elevated serum triglycerides, Hashimoto's disease, Graves' disease, autoimmune thyroid disease, thyroiditis

Gastrointestinal: Nausea, vomiting, diarrhea

Hepatic: Hepatitis

Neuromuscular & skeletal: Peripheral neuropathy

Miscellaneous: Hyperthyroxinemia (with normal TSH levels) have been noted; clearly carcinogenic in animals (hepatocellular), not well described in humans

Toxicodynamics/Kinetics

Absorption: By inhalation (80%), oral, and dermal (15% to 56%)

Distribution: Accumulates in fat

Metabolism: Hepatic hydroxylation and conjugation with glucuronic acid; as rate of chlorination of biphenyl rings increases, metabolic rate decreases

Half-life: 4 months to 2 years

Elimination: Primarily fecal

Reference Range

Blood level of general unexposed population: ~20 ppb; in adipose tissue: 1-2 ppm

Geometric means of serum PCB levels found among the general population (serum PCBs in humans):

- Occupational exposure to PCBs (workers): 12.0-119.0 ppb
- Nonoccupational exposure and eating PCB-contaminated fish: 2.1-56.0 ppb
- Nonoccupational exposure and not eating PCB-contaminated fish: 0.9-15.0 ppb

Note: PCB production is banned or sharply curtailed throughout the world; therefore, the above levels are steadily decreasing

Overdosage/Treatment Decontamination: Oral: Lavage (within 1 hour)/activated charcoal. Dermal: Remove contaminated clothing; wash with soap and water. Acetone can also be used for dermal washing.

Inhalation: Administer 100% humidified oxygen.

Polycyclic Aromatic Hydrocarbons

CAS Number 120-12-7; 129-00-0; 191-24-2; 192-97-2; 193-39-5; 205-82-3; 205-99-2; 206-44-0; 207-08-9; 208-96-8; 218-01-9; 50-32-8; 53-70-3; 56-55-3; 83-32-9; 85-01-8; 86-73-7

Synonyms Acenaphthylene; Anthracene; Benzo[a]pyrene (BaP); Benzo[b]fluoranthene; Benzo[e]pyrene; Benzo[ghi]perylene; Benzo[j]fluoranthene; Benzo[k]fluoranthene; Benz[a]anthracene; Chrysene; Dibenz[a,h]anthracene; Dihydroacenaphthylene; Fluoranthene; Fluorene; PAH; Phenanthrene; Polycyclic Organic Matter; POM; Pyrene

Commonly Found In Tobacco smoke, tar oil, automobile exhaust, flue gases, smoked foods, coke production

Use In rubber industry as a plasticizer; anthracene is used in dye production

Mechanism of Toxic Action Fused benzene ring compounds (usually 3 rings) which bind to DNA (especially diol-epoxide metabolites) leading to tumor initiation; can also cause decrease in brain dopamine and norepinephrine in the corpus striatum and hypothalamus

Adverse Reactions

Gastrointestinal: Anthracene laxatives can cause melanosis of colon and rectum

Miscellaneous: Lung (upon inhalation) and skin cancers can occur

Dermatologic: Warts can occur upon dermal exposure as can pemphigus vulgaris

Endocrine & metabolic: Ovotoxic

Benzo(a)anthracene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, chrysene, and indeno(1,2,3-c,d)pyrene are considered a probable human carcinogen (EPA classification B₂)

Respiratory: Upper airway irritation, Decreased pulmonary function

Admission Criteria/Prognosis Patients who develop tachypnea, cyanosis, dyspnea, CNS depression, tachycardia, or fever within 8 hours of exposure should be admitted; asymptomatic patients can be discharged after 8 hours observation

Toxicodynamics/Kinetics

Absorption: Orally, by inhalation, and dermal exposure

Metabolism: Hepatic, epoxidation and epoxide conversion to Arene oxides, phenols, and quinones

Elimination: Renal

Overdosage/Treatment Decontamination: Oral: Do not induce emesis; activated charcoal may be useful. Dermal: Wash with soap and water.

Ocular: Copious irrigation with saline

Additional Information

Soluble in organic solvents; relatively insoluble in water

Skin carcinogen in animals

Retinoids, dietary plant phenols (ie, tannic acid) and N-acetylcysteine (NAC) may be effective in animal models in antagonizing the tumorigenic effect of benzo(a)pyrene.

Formed after incomplete pyrolysis of fossil fuel; furnaces, coal refuse fires, and coke production account for a large amount of emissions; formed when tars and mineral oils are heated.

Smoking three packs of cigarettes daily can increase exposure of PAH to 6-15 mcg/day.

Spinach, tea, meat, and fish have the highest amount of PAH levels.

Daily intake of carcinogenic PAHs by an adults is estimated to be 1-5 mcg (6-9 mcg for individuals ingesting a large amount of meat).

Inhalation daily dose is estimated to be 0.2 mcg/day.

Drinking water is estimated to contribute 0.006 mcg/day of PAHs.

Surface water concentrations of BaP range from 0.6-114 ng/L.

Atmospheric half-life: Usually ~1 month. Soil half-life: 2 days to 2 months

Polyethylene Glycol - Low Molecular Weight

Related Information

● Polyethylene Glycol - High Molecular Weight [ANTIDOTE]

CAS Number 19005-08-7; 25322-68-3

Synonyms Aklapol; PEG-200, PEG-400, PEG-600

Use A liquid found as vehicles in cosmetics, topical medications and hair products; also found in Lava Lamps® (PEG-200)

Mechanism of Toxic Action Proximal renal tubular necrosis can develop; hypercalcemia may be relatable to increased parathyroid hormone secretion

Signs and Symptoms of Overdose Azotemia, coma, contact dermatitis, hypercalcemia, hyperosmolarity, metabolic acidosis (anion gap), oliguria, renal failure. Topical use can cause systemic effects, especially in burn patients.

Monitoring Parameters Osmolarity, pH, calcium, creatinine

Overdosage/Treatment

Decontamination: Dermal: Wash with soap and water.

Supportive therapy: Treat acidosis with sodium bicarbonate (1-2 mEq/kg). Enhanced elimination: Six hours of dialysis were useful in one case of accidental intoxication. It is unclear whether dialysis enhanced elimination or was used to support deteriorating renal status.

Additional Information When heated, fumes can be irritating.

Potassium Permanganate

Related Information

● Manganese

CAS Number 7722-64-7

UN Number 1490

U.S. Brand Names Permatasico; Permitabs

Synonyms Chameleon Mineral; Condy's Crystals; KMnO₄

Use Bleaching agent, dyeing wood, chemistry reagent, photography, purifying water; also used in illegal fireworks production. Used as a topical bactericidal agent at concentrations of 0.01% (1:10,000 solution).

Mechanism of Toxic Action Solutions >1:5000 concentration are irritating; an oxidizing agent with alkaline caustic effects; systemic injury is due to oxidative injury by free radicals

Signs and Symptoms of Overdose Brownish discoloration of mucous membranes, cough, esophageal stricture, GI hemorrhage, hemorrhagic pancreatitis, ocular irritation, stridor, vomiting

Admission Criteria/Prognosis Admit any patient with gastrointestinal symptoms

Toxicodynamics/Kinetics Absorption: Poor

Dosage Forms Solution, topical: 0.1% [1 mg/mL = 1:1000]; 0.02% [0.2 mg/mL = 1:5000]; 0.01% [0.1 mg/mL = 1:10,000]

Overdosage/Treatment

Decontamination: Oral: Activated charcoal may be useful. Dilute with milk or water. **Ocular:** Irrigate with saline or 5% to 10% ascorbic acid solution to dissolve manganese oxide deposits. (Dissolve 550 mg tablet of ascorbic acid in 25 mL of 0.9% NaCl and irrigate the eyes.)

Supportive therapy: Consider esophagogastrosocopy within 1 day for esophageal injury.

Additional Information Fatal oral dose is 10 g

For phosphides and yellow or white phosphorous ingestion, a 1:5000 solution is given orally to convert phosphorous to nontoxic oxides followed by activated charcoal and mineral oil cathartic.

On contact with water, it forms potassium hydroxide, oxygen, and manganese dioxide.

Profenofos

CAS Number 41198-08-7

U.S. Brand Names Curacron®; Polycron®; Seleccion®

Synonyms O-(4-Bromo-2-Chlorophenyl)-O-Ethyl-S-Propylphosphorothioate

Use Marketed as insecticide granules, dusting agent, or spray liquid with or without petroleum derivative as a solvent

Mechanism of Toxic Action Irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, QT prolongation, sinus bradycardia, sinus tachycardia

Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhoea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure, and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia, and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

PROPANE

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure
Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways
Elimination: Metabolites are excreted in urine

Warnings/Precautions Risk of aspiration pneumonia exists with agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Reference Range Postmortem whole blood and urine profenofos concentration following suicide ingestion: 1200 ng/mL and 350 ng/mL, respectively

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal (without cathartic) can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed treatment and large volumes of distribution of organophosphates.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or $\sim 1/2$ the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information Red blood cell cholinesterase, and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected.

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Mechanism of Toxic Action Displaces oxygen resulting in hypoxia

Adverse Reactions

Cardiovascular: Tachycardia, myocardial ischemia, angina, sinus tachycardia

Central nervous system: Coma

Neuromuscular & skeletal: Rhabdomyolysis

Ocular: Decreased visual acuity

Respiratory: Tachypnea

Signs and Symptoms of Overdose Chest pain, cyanosis, dizziness, dyspnea, headache, seizures

Reference Range Postmortem blood propane level of 2.8 mg/L associated with fatality from inhalant abuse

Overdosage/Treatment Supportive therapy: Oxygen therapy - 100% humidified oxygen

Additional Information Colorless gas; petroleum-like odor; heavier than air; may form a vapor cloud as a result from refrigeration effect of liquified propane. IDLH: 20,000 ppm

Propoxur

CAS Number 114-26-1

U.S. Brand Names Baygon®; Isocarb®

Synonyms N-Methyl-2-Isopropoxyphenylcarbamate

Use Marketed as insecticide granules, dusting agent, or spray liquid with or without petroleum derivative as a solvent

Mechanism of Toxic Action Reversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, QT prolongation, edema, sinus bradycardia, sinus tachycardia, arrhythmias (ventricular)

Central nervous system: Toxicity is limited because carbamates do not significantly cross the blood-brain barrier; CNS changes occur with most severe intoxications; hyperactivity

Endocrine & metabolism: Hypoglycemia

Genitourinary: Urinary incontinence

Neuromuscular & skeletal: Weakness, paralysis

Ocular: Diplopia

Respiratory: Cough, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting. Disseminated intravascular coagulation has been reported following massive exposure.

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure

Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways, and may undergo enterohepatic recirculation

Elimination: Metabolites are excreted in urine

Warnings/Precautions Risk of aspiration pneumonia exists following oral exposure to agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. **Do not** give a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should

Propane

Applies to Ethylene (Manufacture)

CAS Number 74-98-6

UN Number 1978

Synonyms Dimethylmethane; Propyl Hydride

Commonly Found In Component in fuels, solvent

Use In the manufacture of ethylene

be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or $\sim 1/2$ the dose of atropine).

2-PAM: Although not specifically indicated, 2-PAM may be considered in the following situations:

Life-threatening symptoms such as respiratory paralysis

Continued excessive atropine requirements

Concomitant organophosphate and carbamate exposure

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of carbamates.

Antidote(s)

- Atropine [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information

Red blood cell cholinesterase, and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure and are theoretically useful for differentiating between carbamate and organophosphate exposures; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition, thus they may not be useful in ruling out carbamate exposure.

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Propylene Glycol

Pronunciation (PROE pi leen GLYE kole)

Applies to Antifreeze; Cosmetics; De-icer; Silver Sulfadiazine Cream, Topical; Solvent (Pharmaceuticals)

CAS Number 57-55-6

Synonyms Methyl Glycol; PG 12; Propane-1,2-Diol; Trimethyl Glycol

Use In cosmetics and as a solvent in pharmaceuticals; also used as a de-icer; automobile radiator antifreeze; found in intravenous preparations of Ativan[®], Apresoline[®], Bactrim[™], Dilantin[®], Brevibloc[®], Lanoxin[®], Librium[®], MVI-12[®], phenobarbital, Tridil[®], and Valium[®]. Also found in topical silver sulfadiazine cream.

Mechanism of Toxic Action Metabolized to lactic acid, pyruvic acid, acetic acid, and propionaldehyde

Adverse Reactions

Cardiovascular: Bradycardia, arrhythmias (ventricular), arrhythmias, shock, sinus bradycardia

Endocrine & metabolic: Hypoglycemia, lactic acidosis, hyperosmolality, acidosis

Hematologic: Hemolysis, anemia

Renal: Renal failure

Signs and Symptoms of Overdose CNS depression, feces discoloration (black), hypotension, lacrimation, porphyria, seizures, stupor

Toxicodynamics/Kinetics

Distribution: V_d : 0.55 L/kg

Metabolism: To lactic acid and pyruvic acid

Half-life: Adults: 2-5 hours

Peak serum concentration: 1 hour postingestion

Elimination: 12% to 45% excreted unchanged renally; total body elimination: 0.1 L/kg/hour

Dosage Forms Liquid: 10%, 100%

Reference Range Propylene glycol level (mg/dL): $84.6 + (7.8 \times \text{osmolar gap in mOsm/kg})$; serum level of 6-1000 mg/L has been noted following intravenous administration; serum propylene glycol level > 177 mg/L can result in anion gap lactic acidosis

Overdosage/Treatment

Decontamination: **Do not** use ipecac.

Supportive therapy: Sodium bicarbonate (I.V.) for metabolic acidosis; ethanol therapy is not useful

Enhancement of elimination: Hemodialysis may be effective.

Antidote(s)

- Sodium Bicarbonate [ANTIDOTE]

Diagnostic Procedures

- Glucose, Random
- Lactic Acid, Blood
- Osmolality, Serum

Drug Interaction May cause a transient neutralization of heparin.

Additional Information

60 mL of propylene glycol can cause stupor in infants

Patients with burns over 35% of total body surface area are at risk for propylene glycol toxicity if silver sulfadiazine is used.

Clear, colorless, and odorless; $\sim 1/3$ as intoxicating as ethanol

Added to foods at concentrations up to 15% in food seasoning

Density: 1.036 g/mL. Atmospheric half-life: 20-32 hours. Water half-life 1.3-2.3 years

How supplied: Liquid: 10%, 100% Emergency information can be obtained from Dow Chemical Company (Midland, Michigan) (517) 636-4400 or 800-258-2436.

Propylene Glycol Dinitrate

CAS Number 106602-80-6 (Otto Fuel II); 6423-43-4

Synonyms Isopropylene Dinitrate; Methyl Nitroglycol; PGDN

Use Nitrated ester primarily used as a propellant in Otto Fuel II (a liquid monopropellant used by the U.S. Navy in torpedoes and other weapons); has been used in explosives

Adverse Reactions

Central nervous system: Ataxia at air levels of 1.5 ppm; headaches; dizziness at levels of 0.5 ppm

Gastrointestinal: Nausea at levels of 0.5 ppm

Hematologic: Methemoglobin levels as high as 24% noted in rodents exposed to 200 ppm for 4 hours

Toxicodynamics/Kinetics

Absorption: Inhalation and dermal

Metabolism: Broken down in erythrocytes to nitrate

Elimination: Urinary

Monitoring Parameters Methemoglobin

Reference Range Blood propylene glycol dinitrate level of 5 ppb noted after 3.2 hours exposure to 1.5 ppm air concentration

Overdosage/Treatment

Decontamination: **Oral:** Dilute with milk or water. Activated charcoal may be given. **Dermal:** Wash with soap and water. **Inhalation:** Administer 100% oxygen. **Ocular:** Irrigate with saline.

Supportive therapy: Methylene blue for symptomatic methemoglobinemia

Antidote(s)

- Methylene Blue [ANTIDOTE]

Additional Information Highly explosive agent. Slightly soluble in water (1.3 g/L) and does not persist in water for more than a few days; near U.S. torpedo facilities, air levels of propylene glycol dinitrate range from 0-2.2 ppm. PEL-TWA: 0.05 ppm. TLV-TWA (skin designation): 0.05 ppm

Pyrethrins

CAS Number 121-20-0; 121-21-1; 121-29-9; 25402-06-6; 52645-53-1; 8003-34-7

U.S. Brand Names A-200[™] Pyrinatate [OTC]; Alfadex[®]; RID[®] [OTC]; Tisit[®] [OTC]

Synonyms *Chrysanthemum cinerariaefolium*; Ambush; Buhach; BW-21-Z; Cinerin; Cyclopropanecarboxylic Acid; Dalmation-Insect Flowers; Dalmation-Insect Powder; Ectiban; Firmotox; FMX 33297; Insect Powder; Jasmolin; Permethrin; Permetrina (Portuguese); Persian-Insect Powder; Pounce; Pyrethrum Esters; Trieste Flowers

Commonly Found In Pyrethrins include pyrethrum extract and the pyrethrum esters: cinerin I and II, jasmolin I and II, and pyrethrin I and II; semisynthetic derivatives (pyrethroids) include allethrin, barthrin, bioallethrin, bioresmethrin, cyclethrin, cypermethrin, decamethrin, dime-thrin, fenvalerate, flucythrinate, permethrin, phenothrin, and resmethrin; preparations often contain a synergist which increases stability and insecticidal activity, such as N-isobutyldecylenamidepiperonyl butoxide, piperonyl cyclonene, n-octyl sulfoxide of isosafrole, n-propylisome, and sesamex; sprays often formulated in petroleum solvent bases, such as

PYRIDINE

kerosene and naphtha, which are generally more hazardous than the pyrethrins

Use Treatment of *Pediculus humanus* infestations; primarily used for indoor insect control

Mechanism of Toxic Action Delay closure of sodium channel by holding activation gate in the open position, producing a prolonged sodium current during the end of depolarization; sodium tail currents are more prolonged with pyrethroids with an alpha-cyano group (eg, cypermethrin, fenvalerate, flucythrinate) than with other pyrethroids. Derived from flowers that belong to the chrysanthemum family. The mechanism of action on the neuronal membranes of lice is similar to that of DDT. Piperonyl butoxide is usually added to pyrethrin to enhance the product's activity by decreasing the metabolism of pyrethrins in arthropods.

Adverse Reactions

Cardiovascular: Chest pain, angina

Central nervous system: Axonopathy

Dermatologic: Pruritus, erythema

Local: Burning, stinging

Respiratory: Oropharyngeal irritation, wheezing, sneezing, rhinitis, hyper-sensitivity pneumonitis, bronchospasm, asthma

Signs and Symptoms of Overdose Generally of very low order of toxicity in man due to low bioavailability and high first-pass metabolism. Pyrethrins are potent sensitizers, therefore, the most common complications are hypersensitivity reactions including anaphylactic shock, asthma; erythematous, vesicular, papular bullous contact dermatitis (occurs in 50% of those sensitive to ragweed, sometimes with eosinophilia); and wheezing. Asthenia, dizziness, headache, nausea, and vomiting are commonly seen with oral ingestions. Other symptoms that may occur include chest pain, cough, pneumonitis, pulmonary edema, and seizures. Ingestion of massive quantities or concentrated formulations may cause ataxia, cardiopulmonary arrest, CNS stimulation, and tremor. Hypersensitivity reactions (dyspnea, sneezing, wheezing), nasal congestion, rhinorrhea, and scratchy throat may be seen with inhalational exposure. Corneal abrasions may occur with eye exposure. Paresthesia and erythema are common following dermal exposure. In general, pyrethroids or synthetic derivatives are neither cutaneous sensitizers nor irritants and are less toxic than natural pyrethrins; however, they may cause paresthesias following dermal exposure. Synergists appear to be of even lower toxicity, based on experiments with laboratory mammals, despite their ability to enhance insecticidal activity. However, it has been postulated that they might have the potential to inhibit the microsomal enzyme metabolism of pyrethrins and perhaps increase their toxicity in man.

Admission Criteria/Prognosis Symptomatic patients 6 hours postexposure

Toxicodynamics/Kinetics

Onset of action: ~30 minutes

Absorption: Rapid; pyrethrins and pyrethroids are believed to be poorly absorbed through intact skin

Distribution: Through body tissues and brain

Metabolism: Rapid, however pathways of metabolism are somewhat controversial; pyrethrins I and II are metabolized rapidly by hydrolysis to chrysanthemumic acid and an alcohol, which is oxidized to the aldehyde and acid or conjugated with glucuronide; more recent evidence in rats indicates that the principal metabolites are oxidation products; pyrethroids are primarily metabolized by ester hydrolysis

Elimination: Slowly excreted in bile and urine and may remain detectable in body tissues for up to 3 weeks after ingestion

Monitoring Parameters Seizures, respiratory distress, and hypersensitivity reactions

Dosing Forms

All in combination with piperonyl butoxide

Gel, topical: 0.3% (30 g)

Liquid, topical: 0.2% (60 mL, 120 mL); 0.3% (60 mL, 118 mL, 120 mL, 177 mL, 237 mL, 240 mL)

Shampoo, topical: 0.3% (59 mL, 60 mL, 118 mL, 120 mL, 240 mL); 0.33% (120 mL)

Reference Range Pyrethrin plasma levels are not clinically useful; peak permethrin blood concentration of 868 ng/mL following ingestion of 600 mL of 20% permethrin emulsion resulted in GI irritation and little neurotoxicity

Overdosage/Treatment

Decontamination: Usually sufficient for most causal exposures. For oral ingestions, gastric emptying should be performed with lavage (within 1 hour), avoiding syrup of ipecac/emesis due to risk of seizures. Follow with administration of activated charcoal. The principal concern with most solutions and sprays is the hydrocarbon solvent. For preparations containing a hydrocarbon, refer to the appropriate monograph. Avoid administration of fats and oils, which increase intestinal absorption of pyrethrins. Diazepam or lorazepam for seizures; atropine may be effective for diarrhea. Irrigate eye exposures promptly with copious amounts of water. Wash contaminated skin promptly with copious amounts of soap and water.

Supportive therapy: Topical oil of vitamin E, (every 4 hours lightly applied), may relieve paresthesias; symptomatic and supportive treatment for allergic reactions; epinephrine or diphenhydramine for allergic reactions; nebulized bronchodilators for wheezing

Additional Information

For external use only

Avoid touching eyes, mouth, or other mucous membranes; contact physician if irritation occurs or if condition does not improve in 2-3 days; patients with allergy to ragweed may develop cross-allergy to pyrethrins; avoid if known hypersensitivity to pyrethrins

IDLH: 5000 mg/m³; TLV-TWA: 5 mg/m³; PEC-TWA: 5 mg/m³

How supplied: **Gel, topical:** 0.3% (30 g, 480 g); **Liquid, topical:** 0.18% (60 mL); 0.2% (60 mL, 120 mL); 0.3% (60 mL, 120 mL, 240 mL);

Shampoo: 0.3% (60 mL, 118 mL); 0.33% (60 mL, 120 mL)

Pyridine

CAS Number 110-86-1

UN Number 1282

Synonyms Azabenzene; Azine

Use Primarily in production of pesticides, herbicides, antihistamines, steroids, sulfa antibiotics, water repellents, dyes, paint, and rubber; flavoring agent and as an agent to denature alcohol

Mechanism of Toxic Action Lipid peroxidation of the brain can occur

Adverse Reactions

Cardiovascular: Tachycardia, sinus tachycardia

Central nervous system: Lethargy, headaches, slurred speech, insomnia, fatigue

Dermatologic: Dermatitis

Gastrointestinal: Nausea, vomiting

Hematologic: Methemoglobinemia

Hepatic: Cirrhosis

Ocular: Visual evoked potential abnormalities

Respiratory: Tachypnea

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Toxicodynamics/Kinetics

Absorption: with oral ingestion

Metabolism: Hepatic to N-methylpyridinium

Elimination: Renal

Overdosage/Treatment Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal; **do not** induce emesis. **Dermal:** Wash with soap and water. **Ocular:** Irrigate with saline.

Additional Information Lethal dose: 125 mL

Central nervous symptoms can occur with exposures of 6-12 ppm; inhibits metabolism of benzene; not usually detected in ambient air

Yearly total pyridine intake: ~500 mg

Odor threshold: Air: 0.17 ppm; water: 0.95 mg/L. Atmospheric half-life: 23-46 days. Water half-life: 1.2 years. Soil half-life: 3 days. PEL-TWA: 5 ppm; TLV-TWA: 5 ppm; IDLH: 3600 ppm

Pyrimidifen

Synonyms 5-chloro-N-(2-[4-(2-ethoxyethyl)-2,3-dimethylphenoxy]ethyl)-6-ethylpyrimidin-4-amine

Use An acaricide and insecticide first synthesized in Japan; used against fruit/vegetable mites

Mechanism of Toxic Action Similar structure to organochlorine agents with central nervous system effects (primarily depression)

Signs and Symptoms of Overdose Mydriasis, coma, apnea, hypotension, hypothermia, metabolic acidosis, hyperkalemia, hepatitis, acute renal failure

Overdosage/Treatment

Decontamination: Oral: Lavage within 1 hour/activated charcoal

Supportive therapy: Metabolic acidosis can be treated with 1-2 mEq/kg. Hypotension can be treated with crystalloid fluids; dopamine or norepinephrine are vasopressors of choice

Additional Information 40 mL of a 10% solution ingested orally is fatal

Specific References

Radium**Related Information**

- Radon

CAS Number 7440-14-4

Synonyms Radium-223; Radium-224; Radium-226; Radium-228

Use Radiation source in treating neoplasms

Adverse Reactions

Hematologic: Leukopenia
Hepatic: Cirrhosis
Ocular: Cataracts
Miscellaneous: Sarcoma

Toxicodynamics/Kinetics

Absorption: Inhalation and oral (~20%)
Elimination: Primarily fecal

Overdosage/Treatment Decontamination: **Dermal:** Wash with soap and water. Monitor with a Geiger-Mueller counter. **Ocular:** Irrigate with saline.

Additional Information

Lethal dose: Oral: 56 uCi/kg (2.074 kBq/kg)

Bone sarcomas, breast cancer, and liver cancer have been associated with radium exposure; chronic myeloid leukemia also noted

Malignancy can occur at a dose of 1.03 uCi/kg (38 kBq/kg)

Residence atmosphere time: 1-10 days

Radium-223: Decay mode: Alpha; Soil half-life: 11 days

Radium-224: Decay mode: Alpha; Soil half-life: 4 days

Radium-226: Decay mode: Alpha; Soil half-life: 1620 years

Radium-228: Decay mode: Beta; Soil half-life: 6 years

Specific References

Koenig KL, Goans RE, Hatchett RJ, et al, "Medical Treatment of Radiological Casualties: Current Concepts," *Ann Emerg Med*, 2005, 45(6):643-52.

Lloyd RD, Taylor GN, and Miller SC, "Does Low Dose Internal Radiation Increase Lifespan?" *Health Phys*, 2004, 86(6):629-32.

Mechanism of Toxic Action Attaches to bronchial epithelium which can lead to malignant transformation

Adverse Reactions

Dermal: Radiation recall dermatitis

Ocular: Cataracts

Renal: Nephritis

Respiratory: Emphysema, pulmonary fibrosis at high doses

Miscellaneous: Lung cancer (additive effect with smoking)

Toxicodynamics/Kinetics

Absorption: Inhalation: 30% to 40%. Oral: 90%. Dermal: 5%

Half-life: Air: 4 days. Lungs: 6-60 hours. Fat: 21-130 minutes. Oral ingestion: 18-180 minutes

Metabolism: Radium daughters include polonium 218, lead 214, bismuth 214, and polonium 214; does not undergo biological metabolism

Elimination: Exhalation primarily

Overdosage/Treatment

Decontamination: Affected homes may require subslab depressurization.

Open windows can reduce indoor radon levels by 50% to 70%. See figure.

Subslab Depressurization

Supportive therapy: Cataracts and lung carcinoma are treated with standard therapies. Affected individuals should stop smoking.

Additional Information Radon is odorless, inert, and colorless. For radioactive properties: See table.

Radon**Related Information**

- Radium

CAS Number 10043-92-2; 14859-67-7

Synonyms Radon 222; Rn

Use Product of natural decay of uranium which is then converted to radium 222 and finally as a sixth decay product as uranium 238; miners can be exposed in uranium or phosphate mines; also used as a gas tracer in detecting leaks and in the study of atmospheric transport; building materials made of vanadium or concrete produced from phosphate slag may have elevated radon content. See figure.

Sources of Radon and Common Entry Points

**Radioactive Properties of ²²²Radon and Its Daughter Products**

Radionuclide	Half-life	Radiation Energies (MeV)		
		α	β	γ
²²² Radon	3.8 days	5.49	—	—
²¹⁸ Polonium	3.1 min	6.00	—	—
²¹⁴ Lead	26.8 min	—	0.67 0.73	0.30 0.35

²¹⁰ Lead	22.3 yr	—	0.016 0.06	0.05
²¹⁰ Bismuth	5 d	—	1.16	—
²¹⁰ Polonium	138 d	5.31	—	—
²⁰⁶ Lead	No half-life; stable element			

Adapted from: Shlein B, *The Health Physics and Radiological Health Handbook*, Scinta; Silver Spring, MD, 1992

Ambient, outdoor air concentration: 0.2-0.7 pCi/L. EPA action level: 4 pCi/L (0.02 working level of radon); levels exceeding the EPA action level may be present in ~25% of homes in the U.S. Average radon 222 concentration in groundwater: 200-600 pCi/L (7-22 Bq/L). For risk assessment: See tables.

Radon Risk if You Smoke			
Radon Level	If 1000 people who smoked were exposed to this level over a life-time...	The risk of cancer from radon exposure compares to...	What to Do: Stop smoking and...
20 pCi/L	About 135 people could get lung cancer	100 times the risk of drowning	Fix your home
10 pCi/L	About 71 people could get lung cancer	100 times the risk of dying in a home fire	Fix your home
8 pCi/L	About 57 people could get lung cancer		Fix your home
4 pCi/L	About 29 people could get lung cancer	100 times the risk of dying in an airplane crash	Fix your home
2 pCi/L	About 15 people could get lung cancer	2 times the risk of dying in a car crash	Consider fixing between 2 and 4 pCi/L
1.3 pCi/L	About 9 people could get lung cancer	(Average indoor radon level)	(Reducing radon levels below 2 pCi/L is difficult)
0.4 pCi/L	About 3 people could get lung cancer	(Average outdoor radon level)	

U.S. Department of Health and Human Services, "Radon Toxicity," *Case Studies in Environmental Medicine*, Agency for Toxic Substances and Disease Registry, September, 1992.
Note: If you are a former smoker, your risk may be lower.

Radon Risk if You Have Never Smoked			
Radon Level	If 1000 people who never smoked were exposed to this level over a life-time...	The risk of cancer from radon exposure compares to...	What to Do:
20 pCi/L	About 8 people could get lung cancer	The risk of being killed in a violent crime	Fix your home
10 pCi/L	About 4 people could get lung cancer		Fix your home
8 pCi/L	About 3 people could get lung cancer	10 times the risk of dying in an airplane crash	Fix your home
4 pCi/L	About 2 people could get lung cancer	The risk of drowning	Fix your home
2 pCi/L	About 1 person could get lung cancer	The risk of dying in a home fire	Consider fixing between 2 and 4 pCi/L
1.3 pCi/L	<1 person could get lung cancer	(Average indoor radon level)	(Reducing radon levels below 2 pCi/L is difficult)
0.4 pCi/L	<1 person could get lung cancer	(Average outdoor radon level)	

U.S. Department of Health and Human Services, "Radon Toxicity," *Case Studies in Environmental Medicine*, Agency for Toxic Substances and Disease Registry, September, 1992.
Note: If you are a former smoker, your risk may be higher.

RDX

Applies to Composition C-4

CAS Number 121-82-4

Synonyms Cyclonite; Hexogen; Hexolite; PBX

Use Class A explosive; nitrate compound used in plastic explosives, fireworks, and as a detonator; rodenticide

Mechanism of Toxic Action Causes fatty degeneration of liver; seizure mechanism of action is unknown

Adverse Reactions

Cardiovascular: Tachycardia, sinus tachycardia

Central nervous system: Seizures, irritability, amnesia, confusion, hyperthermia

Dermatologic: Dermal irritant

Gastrointestinal: Nausea, vomiting

Hematologic: Anemia

Hepatic: Hepatic steatosis

Neuromuscular & skeletal: Muscle twitching, myoclonus

Renal: Hematuria

Miscellaneous: Liver tumors (adenomas and carcinomas) produced in rodent models

Toxicodynamics/Kinetics

Absorption: Oral (slowly) and inhalation; not readily absorbed by dermal route

Distribution: V_d : 2.2 L/kg

Half-life: 15 hours

Elimination: Feces (primarily) and urine

Reference Range Serum RDX level of 10.7 mg/L associated with seizures

Overdosage/Treatment

Decontamination: **Oral:** Activated charcoal may be used; gastric lavage within 5 hours. **Dermal:** Wash hands with soap and water. **Inhalation:** Humidified 100% oxygen. **Ocular:** Irrigate with saline.

Supportive therapy: Seizures can be treated with benzodiazepines or phenobarbital. Clonazepam is also an effective anticonvulsant.

Additional Information

Toxic oral dose: 15 mL

Oral dose of 85 mg/kg has caused seizures in a child; symptoms can occur with ingested daily dose of 0.1 mg/kg; can produce a "high" similar to ethanol

Atmospheric half-life: 1.5 hours. Water half-life: 9-13 hours (by photolysis). PEL-TWA: 1.5 mg/m³ (skin designation). TLV-TWA: 1.5 mg/m³ (skin designation)

Rhodium

CAS Number 7440-16-6

Mechanism of Toxic Action Some reaction with rhodium and DNA/RNA is apparent; it is not known what the clinical implication of this is

Adverse Reactions Likely that soluble rhodium is toxic, but there is no human literature to support this; mice have shown both respiratory and CNS depression; immunologic contact urticaria

Signs and Symptoms of Overdose Mild ocular irritation, urticaria

Toxicodynamics/Kinetics Absorption: Elemental rhodium is poorly soluble and minimally absorbed; organic rhodium and rhodium trichloride are more readily absorbed

Reference Range No established toxic levels; TWA (metal): 1 mg/m³; TWA (insoluble compound): 1 mg/m³; TWA (soluble compound): 0.01 mg/m³

Overdosage/Treatment Decontamination: Irrigate eyes with normal saline using a Morgan's lens.

Ruthenium

CAS Number 7440-18-8

Signs and Symptoms of Overdose Fumes may be injurious to eyes and lungs.

Reference Range No TLV recommended

Overdosage/Treatment

Decontamination: Irrigate eyes with normal saline using a Morgan's lens.

Supportive therapy: Humidified oxygen for fume exposure

Selenious Acid

CAS Number 7783-00-8

Synonyms Selenous Acid, Monohydrated Selenium Dioxide

Commonly Found In Component of compound for gun blueing agent, reagent for alkaloids

Mechanism of Toxic Action Inhibition of sulfhydryl-containing enzymes

Adverse Reactions

Cardiovascular: Hypertension, tachycardia, cardiomyopathy, sinus tachycardia

Central nervous system: Convulsions

Dermatologic: Alopecia

Gastrointestinal: Pharyngeal edema, intestinal distention, hypersalivation, garlic odor, vomiting, watery diarrhea, burns to the esophagus, pharyngeal, and gastrointestinal tract

Neuromuscular & skeletal: Myopathy

Signs and Symptoms of Overdose Dermal irritation, diarrhea, garlic breath odor, hypersalivation, muscle spasms, seizures, vomiting

Toxicodynamics/Kinetics

Absorption: Inhalation: 97%. Ingestion: 87%. Dermal: 9% to 27% in rodent studies

Half-life: 1.2 days

Elimination: 50% excreted renally

Monitoring Parameters Thrombocytopenia, leukocytosis, metabolic acidosis, hyperglycemia, transient elevation of hepatic enzymes

Reference Range

Normal range: Urine: 7.0-160.0 mcg/L; Blood: 100.0-340.0 mcg/L; Serum: 86.0-125.0 mcg/L

Toxic range: Urine: >400.0 mcg/L; Postmortem serum level of 18.4 mg/L and urine level of 2.11 mg/L described in one case report

Overdosage/Treatment

Decontamination: Emesis is contraindicated; basic poison management with lavage (within 1 hour)/activated charcoal

Supportive therapy: British Anti-Lewisite (BAL), calcium sodium EDTA, D-penicillamine are contraindicated since they can increase renal injury

Diagnostic Procedures

• Glucose, Random

Additional Information Ingestion of 15 mL of 2% solution has been fatal in a 2 year old; 30-60 mL fatal in adults. Garlic odor; vapors are pink; bitter taste. Odor threshold: 0.002 mg/m³. TLV-TWA: 0.2 mg/m³ IDLH: 100 mg/m³; PEL-TWA: 0.2 mg/m³

Selenium

CAS Number 7782-49-2

UN Number 2658

U.S. Brand Names Selenicaps [OTC]; Selenimin [OTC]; Selepen®

Synonyms Selenate

Use Blasting caps, rectifiers, photoelectric cells, nutritional food additive for poultry and livestock

Mechanism of Action Part of glutathione peroxidase which protects cell components from oxidative damage due to peroxidases produced in cellular metabolism

Adverse Reactions Eyes, nose, throat, cardiovascular, respiratory, neurologic, gastrointestinal, hepatic, genitourinary, dermatologic, alopecia, blind staggers

Signs and Symptoms of Overdose CNS depression → coma, eye redness, fatty degeneration of liver, fingernail loss, garlic-like breath, hair discoloration (red), hyposmia, increased LFTs, metal fume fever, metallic taste, myoglobinuria, nasal irritation, nausea, paresthesia, photocontact dermatitis, prolonged QT, pruritus, pulmonary edema, salivation, sore throat, thrombocytopenia, tremor, T-wave flattening → inversion, tubular degeneration, vomiting

Admission Criteria/Prognosis Admit any patient exhibiting gastrointestinal or pulmonary effects, or with a serum selenium level >1000 ng/mL

Pharmacodynamics/Kinetics

Absorption: Orally (80%) and by inhalation

Distribution: To all soft tissue, especially liver and kidney

Protein binding: 95%

Half-life: 12-41 hours

Excretion: Urine, feces, lungs, skin

Contraindications Hypersensitivity to selenium or any component of the formulation

Dosage Forms

Capsule (Selenicaps): 200 mcg [sugar, starch, wheat, yeast, gluten free]

Injection, solution: 40 mcg/mL (10 mL)

Selepen®: 40 mcg/mL (10 mL, 30 mL) [30 mL size contains benzyl alcohol]

Tablet: 50 mcg, 100 mcg, 200 mcg

Selenimin: 50 mcg, 125 mcg, 200 mcg

Tablet, timed release: 200 mcg

Reference Range

Normal range:

Serum: 95-165 ng/mL; serum levels >1000 ng/mL are associated with gastrointestinal toxicity, while serum selenium levels >2000 ng/mL may be lethal

Urine: 15-150 mcg/L

Overdosage/Treatment

Decontamination: **Oral:** Emesis is contraindicated; basic poison management with lavage (within 1 hour)/activated charcoal. **Dermal:** Remove contaminated clothing; wash with soap and water. **Ocular:** Irrigate with saline.

Supportive therapy: British Anti-Lewisite (BAL), calcium sodium EDTA, D-penicillamine are contraindicated since they can increase renal injury;

humidified oxygen for fume exposure; ascorbic acid can increase toxic effects and should be avoided

Diagnostic Procedures

• Selenium, Serum

• Selenium, Urine

Drug Interactions No data reported

Pregnancy Risk Factor C

Additional Information

Fatal dose: Children: 15 mL (2% selenious acid); Adults: 30 mL

Serum selenium levels are significantly lower (24 ng/mL versus 39 ng/mL in control patients) in chronic alcohol abuse patients

Soluble selenites, selenates, and organic selenium compounds are more toxic than the insoluble (ie, selenium sulfide)

24-hour urine level: <30 mcg/L

Average hair levels in U.S.: 0-0.5 ppm Average air concentrations: 0.1-10 ng/m³. Average seawater selenium: 0.04-0.12 mcg/L

Average concentration in earth's crust: 0.05-0.09 mg/kg; highest concentrations are found in volcanic rocks in Western and Midwest U.S. and may be as high as 120 mg/kg; coal contains 2 mg/kg, while crude petroleum contains as high as 950 mg/kg

Daily intake: ~0.07-0.15 mg

Raw beef kidney (average 1.7 mg selenium/kg weight), swordfish (2.8 mg/kg), and Brazilian nuts (14.7 mg/kg) are foods containing highest amount of selenium. Selenium content in milk: <2 ppm. Selenium content in marlin: <4.3 ppm

TLV-TWA: 0.2 mg/m³

Specific References

Selenium Dioxide

CAS Number 7746-08-4

UN Number 2811

Synonyms Selenium Oxide

Commonly Found In Gun-blueing solution

Use Catalyst in production of organic compounds

Mechanism of Toxic Action Inhibition of sulfhydryl-containing enzymes; selenium is a component of glutathione peroxidase enzyme

Adverse Reactions

Central nervous system: Coma

Neuromuscular & skeletal: Rhabdomyolysis

Respiratory: Wheezing

Miscellaneous: Fingernails, teeth, and hair may stain red

Signs and Symptoms of Overdose Cough, dermal burns, dizziness, dyspnea, fever, gagging, headache, sternal pain, tachypnea, throat irritation, transient loss of consciousness

Toxicodynamics/Kinetics Absorption: Inhalation: Well absorbed

Reference Range Normal range: Serum: 95-165 ng/mL; Urine: 15-150 mcg/L

Overdosage/Treatment

Decontamination: Oxygenation; 10% ointment of sodium thiosulfate may be useful. British Anti-Lewisite (BAL) is contraindicated.

Dermal: Remove contaminated clothing; wash with soap and water.

Ocular: Irrigate with saline.

Supportive therapy: British Anti-Lewisite (BAL), calcium sodium EDTA, D-penicillamine are contraindicated since they can increase renal injury. Ascorbic acid can increase toxic effects and should be avoided.

Silver

CAS Number 7440-22-4

Synonyms Argentum; Shell Silver; Silber

Use Primarily in photography and electronic products (ie, batteries); coinage use was discontinued in 1970

Mechanism of Toxic Action Silver has a strong affinity for sulfhydryl groups and proteins; systemic toxicity is rare due to rapid binding to proteins; argyria is a blue-gray discoloration of skin, mucous membrane, and eye which results from silver deposition

Adverse Reactions HEENT, respiratory, photocontact dermatitis, sinus bradycardia

Signs and Symptoms of Overdose Blue-gray discoloration of conjunctiva, cornea, and lens; abdominal pain, bradycardia, bronchitis, cough, feces discoloration (black), hypertension, hyposmia, nail bed pigmentation, proteinuria, skin burns, throat irritation, wheezing

Admission Criteria/Prognosis Adult ingestions >3 g (or 1 g of elemental silver by injection) should be considered for admission

Toxicodynamics/Kinetics

Absorption: Oral (10% to 20%); absorption from the respiratory tract and gastrointestinal tract occurs with soluble silver salts; complex salts are dermally absorbed; burn patients absorb silver from silver sulfadiazine

SODIUM AZIDE

Distribution: Widely distributed
Half-life, biological: Human lung: ~1 day
Elimination: Primarily excreted through bile

Reference Range

Normal blood levels: Undetectable
Mean blood silver levels: 0.11 mcg/mL documented in workers of a photographic materials manufacturer exposed to 0.001-0.1 mg/m³ of silver

Overdosage/Treatment

Decontamination: **Do not** induce emesis. Activated charcoal may be utilized.

Supportive therapy: Wheezing can be treated with nebulized beta-agonist agents.

Diagnostic Procedures

- Silver, Serum
- Silver, Urine

Additional Information

Lethal dose: Silver nitrate: Oral: 10 g; Colloidal metal solution: I.V.: 50 g;
Toxic dose: Silver nitrate: Oral: 2 g

Argyria is the development of a slate gray or blue gray irreversible pigmentation of skin due to deposition of silver sulfide in the dermis; argyria generally occurs after injection of 1 g of elemental silver or ingestion of 3.8 g;

Average dietary intake of silver: 70-88 mcg with drinking water providing ~20 mcg of silver

Permissible amount of silver in bottled water: 0.05 mg/L

Background water silver levels: ~0.2 mcg/L in freshwater and 0.25 mcg/L in salt water

Background atmospheric silver levels: <1 ng/m³

Average silver concentration in earth's crust: 0.1 ppm

Shellfish (particularly oysters) may contain as much as 5.5 mg/kg of silver

Cigarettes contain from 0.2 mg/kg (nonfilter) to 0.3 mg/kg (filter) of silver
OSHA TWA: 0.01 mg/m³. PEL-TWA: 0.01 mg/m³

Specific References

Vukmir RB, "Abdominal Pain in a Child Associated with Dental Amalgam Ingestion," *Am J Emerg Med*, 2005, 23(3):391-3.

Enhancement of elimination: Extracorporeal removal is of no benefit.
Exchange transfusion does not appear to be beneficial.

Additional Information

Fatal oral dose: 13 mg/kg

Oral dose of 0.5 mcg/kg can result in reduction of blood pressure; positive ferric chloride (10% to 20%) test of gastric aspirate can occur (red precipitate)

Rescuer can become mildly toxic (headache, nausea) from expired air or gastric aspirate of sodium azide toxic patients (due to hydrazoic acid)

Odorless, colorless, highly explosive. Specific gravity: 1.846. TLV-ceiling: 0.11 ppm

Byproducts of sodium azide detonation include sodium hydroxide and nitrogen.

Other chemical constituents in automobile air bags include 2,4-dinitrotoluene, boron, potassium nitrate, nitrocellulose and cupric oxide

Sodium Hypochlorite

Related Information

- Calcium Hypochlorite
- Chlorine

Applies to Bleach

CAS Number 8007-59-8

UN Number 1791

Synonyms Carrel-Dakin Solution; Clorox; Hypochlorous Acid; Sodium Salt

Commonly Found In Bleach, disinfectants, deodorizers, water purifiers

Mechanism of Toxic Action Corrosive - oxidizing agent directly related to concentration of chlorine; the pH of household bleach: 10.8-11.4

Adverse Reactions

Cardiovascular: Hypotension, bradycardia, cardiac arrest, chest pain, shock, sinus bradycardia, angina

Dermatologic: Dermal burns, blistering, onycholysis

Gastrointestinal: Esophageal perforation

Hematologic: Hemolysis, anemia

Ocular: Photophobia, blepharospasm, conjunctival edema and pain

Respiratory: Aspiration

Signs and Symptoms of Overdose Chest pain, dyspnea, erythema, hypernatremia, local edema, pain, sore throat, vomiting

Admission Criteria/Prognosis Admit any patient with change in mental status.

Toxicodynamics/Kinetics Metabolism: In the stomach, acid solution forms hypochlorous acid and HCl

Monitoring Parameters Produces high osmolal gap (I.V. use). May cause hypernatremia and hyperchloremia.

Overdosage/Treatment

Decontamination: **Do not** induce vomiting. **Do not** use gastric lavage; dilute with milk or water. Irrigate eyes and skin with saline. Early endoscopy may be useful for oral ingestions; **do not** neutralize.

Oral: Endoscopy is usually not required with a 3% to 6% solution ingestion. **Dermal:** Rinse with water. **Ocular:** Irrigate copiously with water, or saline.

Supportive therapy: Ocular: Topical mydriatic agents (ie, 1% atropine twice daily) and topical antibiotics with topical steroids (1% prednisolone tapered over 10 days) can be used.

Dexamethasone (1 mg/kg/day) should be considered for management of airway edema.

Diagnostic Procedures

- Electrolytes, Blood
- Osmolality, Serum

Additional Information Odor of liquid bleach. Chloramine gas is liberated when ammonia and bleach are mixed. Chlorine gas is emitted when sodium hypochlorite decomposes in a fire.

Sodium Monofluoroacetate

Related Information

● Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 62-74-8

UN Number 2629

U.S. Brand Names Compound 1080®

Synonyms Fluoroacetic Acid (Sodium Salt); SMFA; Sodium Fluoroacetate

Use Rodenticide (banned in U.S. in 1972); used for coyote control in Mexico; possible agroterrorism agent

Sodium Azide

CAS Number 12136-89-9; 26628-22-8

UN Number 1687

Synonyms Azium; Azomide

Use Shell detonators in explosive industry; found as principle agent (350-600 g) for providing nitrogen for the rapid expansion (in 0.05 seconds) of automobile air bags; preservative for laboratory reagents (concentration ~1 mg/mL); nematocide; herbicide

Mechanism of Toxic Action Mucosal irritant; may inhibit oxidative phosphorylation; can cause vasodilatation

Adverse Reactions

Cardiovascular: Asystole, hypotension, initial bradycardia followed by tachycardia, chest pain, arrhythmias (atrial/ventricular), myocardial depression, congestive heart failure, vasodilation, cardiopathy

Central nervous system: Hypothermia, hyperthermia, headache, agitation, seizures, coma

Dermatologic: Dermal burns

Endocrine & metabolic: Polydipsia, metabolic acidosis

Gastrointestinal: Diarrhea, nausea, vomiting, abdominal cramps

Hematologic: Leukocytosis

Neuromuscular & skeletal: Weakness, hyporeflexia, paresthesia

Ocular: Photophobia, lacrimation, keratitis, corneal burn, mydriasis

Respiratory: Hyperventilation, tachypnea, dyspnea, pulmonary edema

Miscellaneous: Diaphoresis

Admission Criteria/Prognosis Admit any ingestion > 40 mg in adults or any symptomatic patient 2 hours postexposure; any patient with metabolic acidosis should be admitted

Toxicodynamics/Kinetics

Absorption: Inhalation, dermal or ingestion

Metabolism: Converted to nitric oxide

Monitoring Parameters Arterial blood gas, ECG, creatine phosphokinase, electrolytes, chest x-ray

Reference Range Postmortem blood levels (following ingestion of sodium azide): 8-262 mg/L

Overdosage/Treatment

Decontamination: **Oral:** Activated charcoal. **Dermal:** Flush with water.

Inhalation: Administer 100% humidified oxygen. **Ocular:** Copious irrigation with saline or water

Supportive therapy: I.V. sodium bicarbonate (1-3 mEq/kg) for acidosis; phenobarbital is probably the most effective agent to treat seizures.

Hypotension can be treated with crystalloid solution (10-20 mL/kg) and placement in Trendelenburg position. Vasopressors (dopamine or norepinephrine) can be used for resistant cases. The use of sodium nitrite or hyperbaric oxygen is of theoretical benefit, with human data lacking in efficacy.

Mechanism of Toxic Action Metabolized to fluorocitrate which then blocks Krebs cycle metabolism by inhibiting the mitochondrial enzyme aconitase

Adverse Reactions

Cardiovascular: Prolonged QT intervals on ECG, fibrillation (ventricular), hypotension, arrhythmias (ventricular)
 Central nervous system: Auditory hallucinations, seizures, tetany, coma, ataxia
 Endocrine & metabolic: Hypocalcemia
 Gastrointestinal: Vomiting, salivation
 Hepatic: Hepatic necrosis
 Neuromuscular & skeletal: Paresthesia, hypertonicity, carpopedal spasms
 Ocular: Nystagmus
 Renal: Renal failure (acute)
 Respiratory: Hemorrhagic pulmonary edema, hyperventilation

Signs and Symptoms of Overdose Typically begin 30-90 minutes after exposure; coma, hallucinations, hypotension, muscle spasms, mydriasis, myoglobinuria, paresthesia, seizures, sinus tachycardia, stupor. Late findings include renal and/or hepatic necrosis.

Admission Criteria/Prognosis Any symptomatic patient, any electrolyte abnormalities, acidosis, or suspected ingestions > 2 mg/kg should be considered for admission into an intensive care unit; poor prognostic signs include hypotension, metabolic acidosis, increased serum creatinine and ventricular tachycardia development

Toxicodynamics/Kinetics Absorption: Through gastrointestinal tract and lungs; dermal absorption does not appear to occur if skin is intact

Reference Range

Autopsy urinary levels of 368 mg/L associated with lethality 17 hours after exposure to 465 mg of sodium fluoroacetate
 Mean urinary sodium monofluoroacetate level of 368 mg/L associated with fatal poisoning

Overdosage/Treatment

Decontamination: Lavage within 1 hour with magnesium sulfate or activated charcoal. Dermal: Remove contaminated clothing and irrigate skin with soap and water.

Supportive therapy: Treat seizures with phenobarbital or diazepam, intravenous calcium (10-20 mL of 10% calcium chloride in adults or 10-20 mL/kg in children); or 0.1-0.2 mL/kg of 10% calcium gluconate up to 20 mL should be given for evidence of hypocalcemia (prolonged QT interval, tetany). Mephentermine may be more effective than levarterenol in treating hypotension. Digitalis can be utilized in pulmonary edema. Procainamide may be useful for ventricular arrhythmias. Glycerol monoacetate effective in animals; clinical use not as promising. Acetamide (500 mL of 10% solution in D₅W infused over 30 minutes every 4 hours) or ethanol use is also controversial (to inhibit the conversion of fluoroacetate to fluorocitrate). Acetamide or ethanol therapy has been used in experimental models, but this modality has not been substantiated in humans.

Enhancement of elimination: Multiple dose of activated charcoal may be effective

Diagnostic Procedures

- Glucose, Random

Additional Information

Approximately 2-10 mg/kg is fatal.
 A white, odorless powder usually associated with a blue dye; initially developed for chemical warfare
 Vinegar taste only when in solution; water soluble. When heated, toxic sodium oxide and fluoride fumes are emitted.
 Ethanol treatment may aggravate hypokalemia.
 Fluoroacetamide is less toxic; trifluoroacetic acid used in high performance liquid chromatography is an irritant and can be dermally absorbed, but is not as toxic
 IDLH: 2.5 mg/m³
 STEL: 0.15 mg/β

Höjer J, Hung HT, Du NT, et al, "An Outbreak of Severe Rodenticide Poisoning in North Vietnam Caused by Illegal Fluoroacetate," *J Toxicol Clin Toxicol*, 2003, 41(5):646.

Sodium Oleate

Applies to Oleate

CAS Number 143-19-1

Synonyms Olate Flakes

Use Insecticide; also used topically in hemorrhoidal therapy

Mechanism of Toxic Action An anionic surfactant which can result in localized injury. Lung exposure can result in activation of coagulation and thus creation of microemboli.

Signs and Symptoms of Overdose Oral ingestion: Hypoxia, leukocytosis, pneumonitis, tachypnea

Admission Criteria/Prognosis Admit any symptomatic patient

Overdosage/Treatment

Decontamination: No gastric decontamination required

Supportive therapy: High-dose glucocorticosteroids may be helpful to prevent lung injury. High-frequency jet ventilation and PEEP may be required.

Stoddard Solvent

CAS Number 8030-30-6; 8052-41-3

UN Number 1255; 1256; 1271; 2553

U.S. Brand Names Teksolve S®; Varsol 1®

Synonyms Dry Cleaning Safety Solvent (used in 15% of plants); Spotting Naphtha; White Spirits

Use Petroleum solvent which is used as a paint thinner, printing ink, adhesive, in liquid photocopier toners, degreaser used in dry cleaning plants

Mechanism of Toxic Action Mixture of hydrocarbons (alkanes, cycloalkanes, and aromatics), this solvent can cause central nervous system depression and cerebral atrophy and axonal prenodal swellings

Adverse Reactions

Central nervous system: Dizziness, headache, ataxia, memory disturbance

Gastrointestinal: Nausea

Hematologic: Methemoglobinemia

Hepatic: Elevated liver function test results

Ocular: Eye irritation

Renal: Glomerulonephritis, nephritis

Admission Criteria/Prognosis Patients who develop tachypnea, cyanosis, dyspnea, CNS depression, tachycardia, or fever within 8 hours of exposure should be admitted; asymptomatic patients can be discharged after 8 hours observation

Toxicodynamics/Kinetics

Absorption: From lungs, orally, and dermally

Distribution: V_d: 10-11 L/kg

Metabolism: Hepatic to dimethylbenzoic acid

Elimination: Urine/feces (clearance: 263 mL/minute)

Reference Range Mean blood level after an exposure (airborne) of 600 mg/m³ for 5 days (6 hours/day): ~2-2.5 mg/L

Overdosage/Treatment Decontamination: **Oral:** Dilute with water. **Dermal:** Wash with soap and water. **Ocular:** Irrigate with saline.

Additional Information Odor threshold: 0.9 ppm. Insoluble in water. TLV-TWA: 100 ppm; PEL-TWA: 100 ppm

Strychnine

Related Information

- Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 509-42-2; 57-24-9; 60-41-3; 60491-10-3; 66-32-1

UN Number 1692

U.S. Brand Names Certox®; Dolco Mouse Ceral®; Kwik-kill®; Mouse-Rid®; Mouse-Tox®; Pied Piper Mouse Seed®; Ro-Dex®

Synonyms *Strychnos ignatii*; *Strychnos nux-vomica*; *Strychnos tiente*

Use Rodenticide; also used as an adulterant in production of illicit cocaine, heroin, and amphetamine; an antiquated antidote historically used in analeptic treatment for barbiturate overdose; unapproved use for non-ketotic hyperglycinemia and sleep apnea (100 mcg/kg)

Mechanism of Toxic Action Strychnine competitively antagonizes the inhibitory action of glycine at the postsynaptic receptors in the spinal cord; this loss of postsynaptic inhibition results in excessive motor neuron activity; binding within the CNS may also be responsible for exaggerated responses to visual, auditory, and tactile stimulation

Adverse Reactions

Cardiovascular: Sinus tachycardia

Central nervous system: Anxiety and seizures without loss of consciousness, dysesthesia

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Dysphagia, bitter taste

Neuromuscular & skeletal: Rigidity, muscle cramps, hypertonicity, trismus

Ocular: Nystagmus

Respiratory: Tachypnea, apnea, respiratory paralysis

Miscellaneous: Hypersensitivity to external stimuli

Signs and Symptoms of Overdose Acidosis, agitation and anxiety (followed by excessive muscular activity and hypertonicity), apnea and cyanosis, death (from respiratory and cardiac arrest), fasciculations; hypertension, hypomagnesemia, tachypnea, and hyperthermia accompanying muscular activity; hypertonicity, leukocytosis, limb rigidity, metabolic acidosis, neck and back stiffness, opisthotonos, prodromal syndrome of muscular cramps and pain, respiratory paralysis, rhabdomyolysis and myoglobinuria, risus sardonicus (sardonic grinning), seizures (during which patients remain awake and lucid), tachycardia, trismus

Admission Criteria/Prognosis Any symptomatic patient should probably be admitted into an intensive care unit; asymptomatic patients 6-8 hours after a suspected exposure can be discharged; asymptomatic patients 4- to 6-hours postingestion may be discharged

Toxicodynamics/Kinetics

Onset of symptoms: Oral: 15-30 minutes. Intranasal, parenteral: <5 minutes

Absorption: Complete and rapid absorption following oral or parenteral exposure; readily absorbed through intact skin and mucosal surfaces

Distribution: V_d : 13 L/kg; rapid tissue distribution

Metabolism: Hepatic microsomal oxidation through P450 pathways; evidence of saturable metabolism at higher concentrations with V_{max} = 3.7 mg/kg/hour and K_m = 1.46 mg/L

Half-life: 10 hours; half-life in overdose: 10-16 hours

Elimination: ~10% to 20% excreted unchanged in liver within 24 hours

Warnings/Precautions Any external visual, auditory, or tactile stimuli may precipitate muscle hyperactivity and seizures; minimize any external stimuli

Reference Range Postmortem levels following a fatal exposure of strychnine were: Concentrations in subclavian blood: 1.82 mg/mL; inferior vena cava blood: 3.32 mg/mL; urine: 3.35 mg/mL; bile: 11.4 mg/mL; liver: 98.6 mg/kg; lung: 12.3 mg/kg; spleen: 11.8 mg/kg; brain: 2.42 mg/kg; skeletal muscle: 2.32 mg/kg. Dermal exposure (~1 cupfull) results in plasma and urine strychnine levels of 196 ng/mL and 6850 ng/mL, respectively.

Overdosage/Treatment

Decontamination:

Oral: **Do not** induce emesis because of danger of sudden respiratory compromise or aspiration following seizures or muscle spasms. Gastric lavage should be approached cautiously and only after aggressive control of muscular dysphoria. Activated charcoal should be administered as soon as possible. The efficacy of repeated-dose activated charcoal has not been documented.

Dermal exposure: Prompt thorough scrubbing of all affected areas with soap and water

Ocular exposure: Irrigation with copious tepid water or saline

Supportive therapy: Airway management, ventilatory assistance, and humidified oxygen administration

Hyperthermia: Treat with cooling blankets, cool water sponging, and cold water lavage. Antipyretics are not effective.

Rhabdomyolysis: Vigorously hydrate to a urine output of 100-200 mL/hour

Metabolic acidosis: Treat with sodium bicarbonate.

Hyperkalemia: Consider insulin and sodium polystyrene sulfonate for significant hyperkalemia. Also consider urinary alkalinization or parenteral mannitol administration of 0.5-1 g/kg I.V. every 4-6 hours to enhance elimination.

Convulsions: Minimize external stimuli and treat with benzodiazepines or barbiturates. Consider neuromuscular blockade with pancuronium and barbiturate coma with status epilepticus. Diazepam is the anticonvulsant of choice.

Enhancement of elimination: Rapid metabolism and early onset and resolution of symptoms reduce the utility of dialysis or hemoperfusion.

Antidote(s)

- Charcoal [ANTIDOTE]
- Mannitol [ANTIDOTE]
- Sodium Bicarbonate [ANTIDOTE]

Additional Information

Lethal dose: Children: 15 mg; Adults: 50 mg

Has a bitter taste

Any exposure to strychnine should be considered potentially life-threatening.

Intensive care unit admission criteria include seizures, acidosis, and hypoxia. Observation care unit admission criteria include evidence of hyperreflexia or neuromuscular irritability, hypertension or tachycardia, that persists longer than 4 hours for onset.

Patients who remain asymptomatic for at least 6 hours, or who become asymptomatic and remain so for at least 6 hours, may be considered for medical clearance.

How supplied: Powder/tablets (veterinary)

Styrene**Related Information**

- Adipose Tissue Ranges of Toxins

CAS Number 100-42-5

UN Number 2055

Synonyms Cinnamene; Ethenylbenzene; Phenylethylene; Vinylbenzene

Use Production of polystyrene plastics for use in insulation or fiberglass materials

Mechanism of Toxic Action Essentially unknown; may cause increase in brain serotonin and noradrenaline levels; can cause central nervous system depression

Adverse Reactions

Central nervous system: Air styrene levels >30 ppm can cause changes in EEG and psychomotor changes, cognitive dysfunction

Gastrointestinal: Nausea (at 376 ppm after 1 hour), metallic taste, stomatitis, sore throat

Neuromuscular & skeletal: Neuropathy (peripheral)

Ocular: Eye irritation (at 376 ppm after 1 hour exposure), rotatory nystagmus, neuritis (retrobulbar), optic neuropathy, visual evoked potential abnormalities

Otic: Ototoxicity (decreased hearing at middle/high frequencies)

Respiratory: Rhinorrhea, bronchospasm, cough, aspiration, asthma

Toxicodynamics/Kinetics

Absorption: Inhalation: 63%. Oral/dermal: Limited with absorption rate being 1 mcg/cm²/minute or ~0.1% to 2% of inhalation absorption amount

Distribution: V_d : 1.2-1.7 L/kg Adipose tissue

Metabolism: Hepatic to hippuric acid, mandelic acid (MA) and phenylglyoxylic acid (PGA)

Elimination: Urine as MA (57%), PGA (33%), and hippuric acid (8%)

Half-life: 2-4 days

Reference Range

Workers exposed to TWA levels of inhalation of styrene (biological exposure indices or BEI): Before shift: 0.02 mg/L; End shift: 1 mg/L

Urine levels of MA (1 g/L) and PGA (250 mcg/L); urine level of AA of 0.8 g/L has been associated with some central nervous system depression

An exposure of 80 ppm of styrene has been associated with a blood styrene level of ~1 mcg/mL; general population blood styrene level: 0.4 mcg/L; fat levels range from 8-350 ng/g

Central nervous system effects can occur at blood styrene levels >2.4 mg/L.

Overdosage/Treatment

Decontamination: **Oral:** Dilute with water; **do not** induce emesis.

Activated charcoal may be effective. **Dermal:** Remove contaminated clothing; wash with soap and water. **Ocular:** Irrigate with saline.

Supportive therapy: Inhaled beta agonist agents may be used for bronchospasm.

Additional Information

Dissolves rubber and corrodes copper

Increased cholinesterase activity noted

Relationship between workplace styrene air levels and urine MA concentration is expressed as: $\ln(\text{styrene air concentration in PPM}) = 3.4915 + 1.0568 \times \ln(\text{urinary MA level in mg/L})$

Indoor air exposure daily of styrene: 14-151 mcg. Exposure from drinking water: 0-0.5 mcg/day. Exposure from food: ~30 mcg/day. Urban ambient air styrene levels: 0.6-21 mcg/m³

Half-life in groundwater: 6 weeks to 7.5 months. Atmospheric half-life: 0.5-17 hours. Atmospheric half-life by photolysis: 50 years

Styrene is found in cigarette smoke at the level of 18 mcg/cigarette

PEL-TWA: 50 ppm; TLV-TWA: 50 ppm; IDLH: 700 ppm

Sulfur Dioxide

Applies to Bleach (Production); Solvent (Petroleum Manufacture); "Acid Rain" (Component)

CAS Number 7446-09-5

UN Number 1079

Synonyms Sulfur Oxide; Sulfurous Anhydride

Commonly Found In Disinfectant, fumigant, food preservative, Portland cement manufacture, antioxidant; air pollutant near smelters; associated with kerosene space heaters

Use In the manufacture of sulfites, thiosulfates, and sulfonation of oils. Also used in production of sulfuric acid; used in bleach production and as a solvent in petroleum manufacture. A component of "acid rain".

Mechanism of Toxic Action Irritation to mucous membranes, highly soluble. Upon inhalation can cause increased airway resistance due to bronchoconstriction; impairs mucociliary clearance in the lungs.

Adverse Reactions

Cardiovascular: Angina, tachycardia
 Dermatologic: Immunologic contact urticaria
 Ocular: Eye irritation with corneal injury (at 10 ppm)
 Gastrointestinal: Nausea and vomiting (at 40 ppm)
 Respiratory: Upper respiratory tract edema and obstruction, pulmonary edema, bronchoconstriction, reactive airways disease syndrome, hyposmia, cough, bronchiolitis obliterans

Signs and Symptoms of Overdose Caustic dermal burns, chest pain, choking sensation, cough, cyanosis, dyspnea, lacrimation, rhinorrhea

Toxicodynamics/Kinetics

Metabolism: with ambient air, it is oxidized to sulfur trioxide then hydrated to sulfuric acid by sulfite oxidase

Elimination: Excreted in urine as inorganic sulfate

Reference Range Sulfhemoglobin formation has been associated with exposure; levels of 6% to 12% associated with death

Overdosage/Treatment

Decontamination: Oxygenation/respiratory support: 100% humidified oxygen. Irrigate eyes with saline water.

Supportive therapy: Aerosolized sodium bicarbonate (5%) may alleviate respiratory mucous membrane irritation (although this is not proven); beta-adrenergic agents for wheezing. Zafirlukast (20 mg orally) inhibits sulfur dioxide-induced bronchoconstriction (at sulfur dioxide concentrations of ~3 ppm) in patients with asthma. Cromolyn sodium may be useful.

Diagnostic Procedures

- Sulfhemoglobin

Additional Information Bronchoconstriction may progress to reactive airway disease. Colorless; sulfur odor. Odor threshold: 1 ppm. TLV-TWA: 2 ppm. IDLH: 100 ppm. For ambient air concentrations and levels found in foods and vegetables: See tables.

Ambient Air Concentrations of Sulfur Dioxide in Different Parts of the World *

Location	Sulfur Dioxide Concentrations (mcg/m ³)	Year
Rural New York	3.38-7.44 (0.0013-0.0028 ppm)	1984-6
Pennsylvania	26-31 (0.01-0.012 ppm)	1983
Rural Pennsylvania	3-131 (0.0011-0.05 ppm)	1984
Bermuda	0-1.67 (0-0.0006 ppm)	1982-3
Coastal Delaware	13.4 (0.005 ppm)	1985
Bermuda (mid-ocean)	0.7 (0.00027 ppm)	1985
Northwest Territories, Canada	0.33-0.69 (0.00013-0.00026 ppm)	1981 (Nov-Dec)
Northwest Territories, Canada	2.3-4.3 (0.00088-0.0016 ppm)	1982 (Feb)
Ontario, Canada	8.4-16.2 (0.0032-0.0062 ppm)	1982
Ontario, Canada	0.1-62.8 (0.024 ppm)	1984
Near H ₂ SO ₄ producer, United Kingdom	0.5-120 (0.002-0.046 ppm)	1981

Sulfur Trioxide

Related Information

- Sulfuric Acid

Applies to Sulfan

CAS Number 7446-11-9

UN Number 1829

Synonyms Sulfur Oxide

Use Intermediate in production of sulfuric acid and explosives; an oxidizing agent

Mechanism of Toxic Action Mucosal irritation

Signs and Symptoms of Overdose Bronchospasm, cough, dizziness, nasal irritation, pleuritic chest pain, wheezing

Toxicodynamics/Kinetics Metabolism: Forms with water in the respiratory tract to form sulfuric acid and heat

Reference Range Normal sulfate concentration range in blood is 0.8-1.2 mg/dL

Overdosage/Treatment

Decontamination: Inhalation: Administer 100% humidified oxygen.

Supportive therapy: Nebulized beta-agonists should be used to treat bronchospasm.

Additional Information A clear, colorless acidic liquid which is not flammable

Sulfuric Acid

Applies to Dyes (Manufacture); Explosives (Manufacture); Fertilizer Production (Phosphate); Metal Cleaning; Ore Processing; Paper Pulp; Petroleum (Manufacture); Toilet Bowl Cleaners

CAS Number 7664-93-9; 8014-95-7 (oleum)

UN Number 1830; 1831; 1832

Synonyms Battery Acid; Dihydrogen Sulfate; Oil of Vitriol; Oleum (Fuming Sulfuric Acid); Sulfur Acid; Sulphine Acid; Vitriol Brown Oil

Commonly Found In Automotive batteries; used in fur and leather industries; component in smog; major component in acid rain; formed from sulfur trioxide and water

Use In the manufacture of acetic acid, hydrochloric acid, hydrolysis of cellulose; used for metal cleaning; primarily used in phosphate fertilizer production; it is also used in the manufacture of dyes, explosives, petroleum, paper pulp, ore processing. Toilet bowl cleaners (which contain sodium bisulfite) produce sulfuric acid upon contact with water.

Mechanism of Toxic Action Acid oxidizer; corrosive to the skin, eyes, mucous membranes, gastrointestinal and respiratory tracts; chars tissue by removing water

Adverse Reactions

Cardiovascular: Shock, vascular collapse, chest pain, angina

Central nervous system: Headache

Gastrointestinal: Gastritis, throat irritation

Ocular: Lacrimation, iritis, cataracts, glaucoma

Renal: Renal failure

Respiratory: Tachypnea, bronchoconstriction, ARDS, laryngeal edema, cough, dyspnea

Signs and Symptoms of Overdose Choking, corneal burns, cough, discoloration of teeth, dyspnea, hemoptysis/hematemesis. Esophageal/gastric burns are rare, but ingestion of 15-50 mL (of a 26.4 to 35.4 normal solution) can cause severe gastroesophageal burns and gastric perforation. Dermal contact with > 10% concentration is caustic. Dermal contact at > 50% total body surface area can be fatal as dermal burns with coagulative necrosis develop. Corneal exposure at concentrations > 1.25% can result in severe ocular damage.

Admission Criteria/Prognosis Admit any symptomatic patient, or dermal contact > 30% total body surface area over extremities or trunk

Toxicodynamics/Kinetics

Absorption: Can be absorbed

Metabolism: Dissociates into hydronium and sulfate

Elimination: Renal (as sulfate)

Reference Range Normal blood sulfate concentration range: 0.8-1.2 mg/dL

Overdosage/Treatment

Decontamination: **Do not** induce emesis. Treat inhalation injuries with supplemental oxygen. Activated charcoal is not effective. Dilute with cold milk, cornstarch, or large amounts of cold water; endoscopy for severe mouth burns

Ocular: Irrigate copiously with saline (preferred over water due to less heat production). Irrigation may need to last for 3 hours. Continue to irrigate until runoff exhibits a neutral pH. Topical mydratics and antibiotics may be useful.

Dermal: Irrigate affected area with copious amounts of water. Remove jewelry and clothing

Enhancement of elimination: Hemodialysis if renal failure develops

Additional Information

Lethal dose: 135 mg/kg

Clear, colorless gas; odorless except when heating (choking odor)

Reacts violently with water or alcohol; will corrode or dissolve metals

SULFURYL FLUORIDE

Miscible in water
pH of a 1N solution: 0.3; 0.1N: 1.2; 0.01N: 2.1
Vapor density: 3.4
TLV-TWA: 1 mg/m³
TLV-STEL: 3 mg/m³
IDLH: 80 mg/m³
PEL-TWA: 1 mg/m³
Background sulfate levels in North American lakes are 20-40 ueq/L, although eastern North American lakes can have concentrations as high as 100 ueq/L.

Sulfuryl Fluoride

CAS Number 2699-79-8

UN Number 2191

U.S. Brand Names Vikane®

Synonyms Sulfonyl Fluoride; Sulfur Difluoride; Sulfuric Oxyfluoride

Use Fumigant insecticide against drywood termites; also used in organic synthesis and produced by heating barium difluosulfate

Mechanism of Toxic Action Mucosal irritant; direct content in its liquified form can cause a frostbite injury; systemic fluorosis can occur

Adverse Reactions

Cardiovascular: Tachycardia (supraventricular), hypotension
Central nervous system: Seizures, cognitive dysfunction, irritability
Dermatologic: Pruritus, dermatitis congelations
Gastrointestinal: Vomiting, nausea, anorexia, abdominal cramps
Neuromuscular & skeletal: Weakness, paresthesia, carpopedal spasm
Ocular: Eye irritation
Renal: Proteinuria, azotemia
Respiratory: Pharyngeal irritation, dyspnea, cough, pulmonary edema, bronchospasm, nasal irritation
Miscellaneous: Frostbite

Admission Criteria/Prognosis Admit any patient who is symptomatic 6 hours postexposure

Toxicodynamics/Kinetics Absorption: Inhalation

Monitoring Parameters Chest x-ray, fluoride level, calcium level, ECG

Reference Range Serum fluoride level of 0.5 mg/L associated with fatality; serum fluoride level > 0.1 mg/L is consistent with exposure

Overdosage/Treatment

Decontamination: **Inhalation:** Give 100% humidified oxygen. **Ocular:** Irrigate copiously with saline. **Dermal:** Wash the area with soap and water.

Supportive therapy: Frostbite can be treated with standard therapy. Hypocalcemia can be treated with calcium (0.5-1 g). Hypotension can be treated with isotonic fluids and placement in Trendelenburg position. Dopamine or norepinephrine can be used for refractory hypotension. Benzodiazepines or barbiturates can be used for seizure control.

Additional Information Odorless, colorless, nonflammable gas which is heavier than air (density: 3.72 g/L). TLV-TWA: 5 ppm; TLV-STEL: 10 ppm; IDLH: 1000 ppm

Terbufos

CAS Number 13071-79-9

U.S. Brand Names Counter®

Synonyms Phosphorodithiotic Acid S-((Tert-Butylthio)methyl) O,O-Diethyl Ester

Use Commonly marketed as insecticide granules, or spray liquid with or without petroleum derivative as a solvent

Mechanism of Toxic Action Potent, irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or **hypodynamic** (~7% to 10%) states, QT prolongation, sinus bradycardia, sinus tachycardia
Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia
Genitourinary: Urinary incontinence
Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia
Respiratory: Pulmonary edema, respiratory depression
Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose

Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure
Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways

Elimination: Metabolites are excreted in urine

Warnings/Precautions Risk of aspiration pneumonitis exists with agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material including the use of protective clothing, masks, goggles, and respiratory equipment.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Oral: Activated charcoal (without cathartic) can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles.

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of organophosphates.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or ~1/2 the dose of atropine)

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms.

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information

Red blood cell cholinesterase and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected.

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Water solubility: 6 ppm

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

Tetrachloroethane

CAS Number 79-34-5

UN Number 1702

U.S. Brand Names Bonoform®; Cellon®; Westron®

Synonyms 1,1,2,2-Tetrachloroethane; Acetylene Tetrachloride

Use Primarily as a solvent in metal cleaning procedures, paint removers, varnishes, photographic films, and oil or fat extractant; production of trichloroethylene, tetrachloroethylene, and 1,2-dichloroethylene

Mechanism of Toxic Action Central nervous system depression; direct effect on neuronal membrane and hepatotoxic effects can occur through lipid peroxidation

Adverse Reactions

Cardiovascular: Hypotension
 Central nervous system: Confusion, delirium, coma
 Gastrointestinal: Nausea, vomiting, anorexia (gastrointestinal effects seen with exposure levels of 116 ppm for 10-30 minutes), diarrhea
 Hematologic: Leukocytosis
 Hepatic: Fatty degeneration of liver, centrilobular hepatic necrosis
 Ocular: Lacrimation, eye irritation
 Miscellaneous: Cutaneous T-cell lymphoma

Admission Criteria/Prognosis Patients who develop tachypnea, cyanosis, dyspnea, CNS depression, tachycardia, or fever within 8 hours of exposure should be admitted; asymptomatic patients can be discharged after 8 hours observation

Toxicodynamics/Kinetics

Absorption: Through inhalation (97%), oral, and dermal routes
 Metabolism: Hepatic to glyoxylic acid and oxalic acid, tetrachloroethylene is also a metabolite
 Elimination: Through lungs, feces, and urine

Reference Range Toxic effects are predicted to occur at blood tetrachloroethane levels > 1.1 ng/mL (1.1 ppt)

Overdosage/Treatment Decontamination: **Oral:** Dilute with milk. **Dermal:** Remove contaminated clothing; wash with soap and water. **Ocular:** Irrigate with saline or water.

Additional Information

Minimal lethal dose: Oral: 357 mg/kg; Toxic dose (causing coma): Oral: 100 mg/kg
 Nonflammable. Odor threshold: Air: 3-5 ppm (chloroform-like); water: 0.5 ppm. PEL-TWA: 1 ppm; TLV-TWA (skin): 1 ppm; IDLH: 150 ppm. Atmospheric half-life: > 800 days. Atmospheric concentrations in U.S. (urban/suburban): Mean level: 5.4 ppt; drinking water: < 0.5 ppb

Specific References

Clewell HJ, Gentry PR, Kester JE, et al, "Evaluation of Physiologically Based Pharmacokinetic Models in Risk Assessment: An Example with Perchloroethylene," *Crit Rev Toxicol*, 2005, 35(5):413-33.

Estimated daily intake: Inhalation: 41-204 mcg; Drinking water: 0.6-6 mcg
 Ambient atmospheric urban concentrations: ~0.8 ppb
 Drinking water tetrachloroethylene: 0.3-3 ppb
 Dairy products contain 0.3-13 mcg/kg; beverages average 2-3 mcg/kg
 Water half-life at pH 7 (25°C): ~9 months (by hydrolysis). Atmospheric half-life: 96-251 days
 Air tetrachloroethylene levels: Cars: Up to 300 ppm. Homes: 3-480 ppm.
 Dry cleaning operations: 0-1200 ppm. Retained on clothes after dry cleaning: 1-3.7 kg
 For duration and effect of inhaling vapors: See table.

Dose-Response Relationship for Humans Inhaling Tetrachloroethylene Vapors

Levels in Air	Duration of Exposure	Effect on Nervous System
50 ppm		Odor threshold
100 ppm	7 h	Headache, drowsiness
200 ppm	2 h	Dizziness, uncoordination
600 ppm	10 min	Dizziness, loss of inhibitions
1000 ppm	1-2 min	Marked dizziness, intolerable eye and respiratory tract irritation
1500 ppm	30 min	Coma

U.S. Department of Health and Human Services, "Hospital Emergency Departments: A Planning Guide for the Management of Contaminated Patients," *Managing Hazardous Materials Incidents*, Agency for Toxic Substances and Diseases Registry, 1995, 2:796.

Specific References

Lomax RB, Ridgway P, and Meldrum M, "Does Occupational Exposure to Organic Solvents Affect Colour Discrimination?" *Toxicol Rev*, 2004, 23(2):91-121 (review).

Tetraethyl Pyrophosphate

CAS Number 107-49-3

UN Number 3018

U.S. Brand Names Fosvex®; Griso®; Hexamite®; Tetron®

Synonyms TEPP

Use Marketed as insecticide spray liquid with or without petroleum derivative as a solvent

Mechanism of Toxic Action Potent, irreversible inhibition of acetylcholinesterase and plasma cholinesterase, resulting in excess accumulation of acetylcholine at muscarinic and nicotinic receptors, and in the central nervous system

Adverse Reactions

Cardiovascular: **Hyperdynamic** (~18% to 21%) or hypodynamic (~7% to 10%) states, QT prolongation, sinus bradycardia, sinus tachycardia
 Central nervous system: Depression, seizures, hyperactivity, cognitive dysfunction, hypothermia
 Genitourinary: Urinary incontinence
 Neuromuscular & skeletal: Weakness (delayed), paralysis, delayed paresthesia
 Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Flu-like symptoms (especially with chronic exposure)

Signs and Symptoms of Overdose Abdominal pain, agitation, asystole, AV block, bradycardia, bronchorrhoea, coma, confusion, cranial nerve palsies, decreased hemoglobin, decreased platelet count, decreased red blood cell count, diaphragmatic paralysis, dysarthria, excessive sweating, fecal and urinary incontinence, generalized asthenia, headache, heart block, hypertension, hypotension, lacrimation, metabolic acidosis and hyperglycemia (severe intoxication), miosis (unreactive to light), mydriasis (rarely), nausea, pallor, pulmonary edema, QT prolongation, respiratory depression, salivation, seizures, skeletal muscle fasciculation and flaccid paralysis, tachycardia, tachypnea, vomiting

An "intermediate syndrome" of limb asthenia and respiratory paralysis has been reported to occur between 24 and 96 hours postorganophosphate exposure and is independent of the acute cholinergic crisis. Late paresthesia characterized by stocking and glove paresthesia, anesthesia and asthenia is infrequently observed weeks to months following acute exposure to certain organophosphates.

Toxicodynamics/Kinetics

Absorption: Readily through oral, dermal, or respiratory exposure
 Metabolism: Rapidly metabolized to weakly active compounds through hepatic hydrolysis and other pathways
 Elimination: Metabolites are excreted in urine

Warnings/Precautions Risk of aspiration pneumonitis exists with agents having a hydrocarbon vehicle; severe laryngeal irritation and violent coughing may result from exposure to dusting powders; exposure to dusting powders and insecticide granules may cause contact dermatitis

Tetrachloroethylene

Applies to Degreaser; Dry Cleaning (Fabrics); Freon (Manufacture)

CAS Number 127-18-4

UN Number 1897

Synonyms 1,1,2,2-Tetrachloroethylene; PCE®; Perchlor; Perclene; Tetra

Use In textile industry for dry cleaning fabric; degreasing; used in the manufacture of freons, anthelmintic for animals

Mechanism of Toxic Action CNS depressant, irritant; probable human carcinogen

Adverse Reactions

Central nervous system: CNS depression
 Ocular: Eye irritation at air levels > 1000 ppm, visual evoked potential abnormalities
 Respiratory: Irritation, respiratory depression

Signs and Symptoms of Overdose Ataxia, conjunctival injection, cough, dermatitis, epistaxis, euphoria, headache, hepatomegaly, irritability, nausea, short-term memory deficiency, sweating

Toxicodynamics/Kinetics

Absorption: Well absorbed in the lungs and GI tract; not well absorbed dermally; highly lipid soluble
 Distribution: V_d : 8.2 L/kg
 Half-life: Oral: 144 hours. Inhalation: 33-72 hours. In adipose tissues: 72 hours

Metabolism: In the liver to trichloroacetic acid and trichloroethanol
 Elimination: 80% excreted through the lungs, metabolites excreted renally

Reference Range Tetrachloroethylene serum level of 100 mcg/dL and trichloroacetic acid levels in urine of 7 mg/L correlate with weekly exposure of 50 ppm; BEI of 1 mg/L; an oral ingestion of 12-16g in a 6-year-old boy resulted in a blood tetrachloroethylene level of 21 mcg/dL 1-hour postingestion; mean blood concentration of tetrachloroethylene following 50 ppm exposure 8 hours daily, 5 days weekly: Estimated to range from 1.6-2.3 mg/L; urine levels would be ~19 mg/L

Overdosage/Treatment

Decontamination: **Dermal:** Remove contaminated clothing; wash with soap and water. **Inhalation:** Give 100% humidified oxygen. **Ocular:** Irrigate with saline.
 Supportive therapy: Controlled hyperventilation (volume 10 L/minute) may be useful. Epinephrine may predispose the patient to cardiac arrhythmia.

Additional Information

Clear, colorless; fruity odor of chloroform; radiopaque. Odor threshold: 5-50 ppm. TLV-TWA: 50 ppm. Symptoms occur at 75 ppm.

TETRAHYDROFURAN

Overdosage/Treatment

Decontamination: Isolation, bagging, and disposal of all contaminated clothing and other articles. All emergency medical workers and hospital staff should follow appropriate precautions regarding exposure to hazardous material, including the use of protective clothing, masks, goggles, and respiratory equipment.

Oral: Activated charcoal can be administered either orally or via a nasogastric tube. **Do not** induce emesis because of danger of sudden respiratory compromise, alterations in mental status, seizures, coma, and possible aspiration of hydrocarbon vehicles. **Do not** give a cathartic.

Dermal: Prompt thorough scrubbing of all affected areas with soap and water, including hair and nails; 5% bleach can be used

Ocular: Irrigation with copious tepid sterile water or saline

Supportive therapy: Airway management, ventilatory assistance, humidified oxygen administration, and close monitoring for sudden respiratory failure

Enhancement of elimination: Dialysis and hemoperfusion are not indicated due to effectiveness of the prescribed antidotal treatment and large volumes of distribution of organophosphates.

Antidote:

Atropine: Administration should be guided by respiratory status, starting at 2-5 mg I.V. every 5-10 minutes as needed, and should be titrated to the resolution of excess pulmonary secretions. Frequent administration of large doses (cumulative doses > 100 mg) may be necessary in massive exposures.

Glycopyrrolate: May be administered if atropine is unavailable (200-400 mcg I.V. or I.M. initially, or $\sim 1/2$ the dose of atropine).

2-PAM: For more significant exposures (ie, exposures requiring large doses of atropine, or with recurring symptoms, or exposures to more lipid soluble agents), administration should follow: 1-2 g I.V. over 10-30 minutes, repeated in 1 hour if asthenia recurs, then every 4-12 hours for recurring symptoms

Antidote(s)

- Atropine [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Diagnostic Procedures

- Creatinine, Serum
- Pseudocholinesterase, Serum

Drug Interaction Paralysis is potentiated by neuromuscular blockade (ie, pancuronium, vecuronium, succinylcholine, atracurium, doxacurium, mivacurium); inhibition of serum esterase prolongs the half-life of succinylcholine, cocaine, and other ester anesthetics; cholinergic toxicity is potentiated by cholinesterase inhibitors such as physostigmine

Additional Information Red blood cell cholinesterase and serum pseudocholinesterase may be depressed following acute or chronic organophosphate exposure; RBC cholinesterase is typically not analyzed by in-house laboratories, and is usually not available for consideration during acute management. Pseudocholinesterase levels may be rapidly available from some in-house laboratories, but are not as reliable a marker of organophosphate exposure because of variability secondary to variant genotypes, hepatic disease, oral estrogen use, or malnutrition. Because of this variability, true indication of suppression of either of these enzymes can only be estimated through comparison to pre-exposure values; these enzymes may be useful in measuring a patient's recovery postexposure, especially if the recovery is not progressing as expected.

The intermediate syndrome is not related to delayed neuropathy.

QT_c prolongation on ECG in the setting of organophosphate poisoning is associated with a high incidence of respiratory failure and mortality.

Colorless/light amber liquid with faint fruity odor; noncombustible; slowly hydrolyses in water and is therefore environmentally persistent; thermal breakdown products include phosphoric acid;

ACGIH TLV: 0.0004 ppm; IDLH: 10 mg/m³

Other information concerning pesticide exposures is available through the EPA-funded National Pesticide Telecommunications Network: 1-800-858-7378 (weekdays, 8 AM to 6 PM, Central Standard time)

ness, elevated hepatic enzymes, headache, hypotension, mydriasis, nausea, tinnitus

Reference Range Following an oral ingestion with resultant deep coma, serum and urine tetrahydrofuran were reported as 813 mg/L (11.3 mM/L) and 850 mg/L (11.8 mM/L), respectively. Serum and urine gamma hydroxybutyric acid levels in this patient were 239 mg/L (2.3 mM/L) and 2977 mg/L (28.6 mM/L), respectively.

Overdosage/Treatment

Decontamination: **Dermal:** Wash with soap and water. **Oral:** Dilute with milk or water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate with copious amounts of saline.

Supportive therapy: Care is supportive; ventilatory support may be required. Hypotension can be treated initially with isotonic saline (I.V.) at 10-20 mL/kg with Trendelenburg positioning. Dopamine or norepinephrine can be utilized for refractory hypotension.

Additional Information TLV-TWA: 220 ppm; IDLH: 20,000 ppm; odor threshold (ether-like odor): 20-50 ppm; coma producing at 25,000 ppm

Tetramethylammonium Hydroxide

CAS Number 75-59-2

Synonyms TMA

Commonly Found In Snails (*Neptunea* species) - found in salivary glands

Mechanism of Toxic Action A ganglionic blocker; direct action on nicotinic/muscarinic receptors on postganglionic nerves in smooth muscle, cardiac muscle, and exocrine glands through an increase of intracellular sodium ions which causes increase in neuronal membrane potential and reduced ganglionic excitability. Similar mode of action as nicotine.

Signs and Symptoms of Overdose Temporary blindness, diplopia, photophobia, lacrimation, blurred vision, hypotension, dizziness, headache, seizures, apnea, nausea, vomiting, paralytic ileus, dry mouth, urticaria

Toxicodynamics/Kinetics

Oral absorption: Rapid

Protein binding: Low

Half-life: One hour

Elimination: Renal (95%)

Overdosage/Treatment

Decontamination: Oral: Activated charcoal

Supportive therapy: Seizures can be treated with benzodiazepines or phenobarbital. Hypotension can be treated with crystalloid infusion (10-20 mL/kg) intravenously and Trendelenburg placement. Dopamine or norepinephrine can be given if hypotension is refractory. Symptoms usually short-lived.

Additional Information Lethal dose is ~ 3 -4 mg/kg

Tetramethylenedisulfotetramine

CAS Number 80-12-6

Synonyms Tetramine; TETS

Use Rodenticide (found in China)

Mechanism of Toxic Action Noncompetitive gamma-aminobutyric acid (GABA) antagonist through neuronal chloride channel blockade

Signs and Symptoms of Overdose Tachycardia, seizures (generalized), coma, mydriasis. Onset of symptoms may be 30 minutes to 13 hours

Overdosage/Treatment

Decontamination: Activated charcoal; lavage within 1 hour

Supportive therapy: Lorazepam/phenobarbital needed for seizure control. Succinylcholine (1 mg/kg) may be required. Pyridoxine (70 mg/kg) has been used with uncertain benefit.

Additional Information Oral human LD₅₀: 100 mcg/kg; white powder 100 times more toxic than potassium cyanide

Specific References

Barrueto F Jr, Furdyna PM, Hoffman RS, et al, "Status Epilepticus from an Illegally Imported Chinese Rodenticide: Tetramine," *J Toxicol Clin Toxicol*, 2003, 41(7):991-4.

Tetryl

CAS Number 479-45-8

UN Number 0208

Synonyms CE; N-Methyl-N,2,4,6-Tetranitroaniline; Nitramine; Tetralite; Tetryl

Use Primarily as a military explosive (detonator and primer)

Mechanism of Toxic Action Essentially unknown; can cause an allergic reaction

Adverse Reactions

Central nervous system: Fatigue, headache, irritability

Dermatologic: Yellow staining of skin, rash, urticaria, skin discoloration (brown-yellow) upon exposure to sunlight

Gastrointestinal: Nausea, vomiting, abdominal pain, anorexia, stomatitis

Hematologic: Leukocytosis

Tetrahydrofuran

Applies to Audio and Video Tapes; Glue; Ink; Paint; Solvent to Dissolve Plastic (Polyvinyl Chloride, Polyurethane, Epoxy); Varnish

CAS Number 109-99-9

UN Number 2056

Synonyms Butylene Oxide; THF

Use Solvent used to dissolve several types of plastic (polyvinyl chloride, polyurethanes, epoxy); also used in processing of glue, paint, varnish, ink; used in production of audio and video tapes

Mechanism of Toxic Action A mild respiratory irritant with general anesthetic-like effects; a possible precursor to gamma hydroxybutyric acid (GHB); has been described in one bacterium (*Rhodococcus ruber*) and case report (see Reference Range and Specific References)

Signs and Symptoms of Overdose Blurred vision, chest pain, coma, conjunctivitis, cough, dermatitis (at liquid concentrations >20%), dizzi-

Hepatic: Liver failure, jaundice
 Ocular: Conjunctivitis
 Respiratory: Bronchospasm, cough, epistaxis, sneezing

Toxicodynamics/Kinetics

Absorption: By inhalation, dermal, and oral routes
 Metabolism: Hepatic to picramic acid
 Elimination: Probably renal

Overdosage/Treatment

Decontamination: **Dermal:** Wash with soap and water. Calamine lotion or zinc oxide may be used to treat dermatitis. **Ocular:** Irrigate with saline. Supportive therapy: Epistaxis can be treated with local therapy.

Additional Information Odorless but highly explosive; colorless but becomes yellow when exposed to light. Atmospheric half-life: 11 days. Water half-life: 302 days (lower at higher pH). Soil half-life: 1.2 weeks. PEL-TWA (skin designation): 1.5 mg/m³

Thallium Sulfate**Related Information**

- Toxins Which Should Be Lavaged with Solutions Other Than Water
CAS Number 7440-28-0

Use Primarily in semiconductor industry in manufacture of switches and closures; radiopharmaceutical agent banned by the EPA as a pesticide in 1972

Mechanism of Toxic Action Thallium distributes intracellularly like potassium; it is a cellular toxin; inhibits mitochondrial oxidative phosphorylation, disrupts protein synthesis, alters heme metabolism

Adverse Reactions Neurologic, dysphagia, cardiac, hepatic, renal, dermatologic, gastrointestinal, pulmonary, salivation, chorea (extrapyramidal), xerostomia, sinus bradycardia, QRS prolongation, sinus tachycardia

Signs and Symptoms of Overdose Alopecia, ataxia, bradycardia, cardiac arrhythmias, cerebral edema, coma, degeneration of central and peripheral nervous systems, tremor, delirium, dementia, disorientation, drowsiness, fatty infiltration, feces discoloration (black), fever (poor prognostic sign), garlic-like breath, gastroenteritis, hyperesthesia of palm and sole, lacrimation, liver necrosis, Mees' lines, metallic taste, motor/sensory neuropathy, mydriasis, nausea, nephritis, optic neuropathy, paresthesia, pulmonary edema, seizures, tachycardia, vomiting. GI symptoms occur within 1 day. Neurological symptoms occur 4-6 days postingestion.

Admission Criteria/Prognosis Any symptomatic patient or development of hypocalcemia should be admitted; suspected ingestions should also be admitted

Toxicodynamics/Kinetics

Absorption: Through skin and gastrointestinal tract
 Distribution: V_d: 1-5 L/kg; following intoxication, highest concentration found in kidney and urine with lesser amounts in intestine, thyroid, testes, pancreas, skin, bone, spleen
 Half-life: 2-4 days
 Elimination: Large amount excreted in urine within first 24 hours after which fecal elimination predominates

Reference Range Blood levels >30 mcg/L are indicative of thallium exposure; toxicity associated urine levels >20 mcg/L. Serum thallium and cerebrospinal fluid levels of 8700 mcg/L and 1200 mcg/L, respectively, have been associated with fatality. Unexposed individuals will have Blood and urine thallium levels less than 2 ug/L (9.78 nmole/c) and 5 ug/L (24.5 nmole/L), respectively.

Overdosage/Treatment

Decontamination:
 Oral: Lavage (with 1% sodium iodine to convert thallium sulfate to thallium iodine) is preferable over ipecac. Activated charcoal or polystyrene sulfonate may be effective. Prussian blue (not commercially available for therapeutic use and not FDA approved) exchanges thallium for potassium and is fecally excreted; dosage: 250 mg/kg orally in 4 divided doses; continue therapy until thallium urinary level falls to <0.5 mcg/24 hours. Acetylcysteine treatment is investigational.
 Dermal: Remove contaminated clothing; wash with soap and water.
 Ocular: Irrigate with saline.
 Enhancement of elimination: Multiple dosing of activated charcoal may be effective. Potassium chloride has been recommended in the past to increase elimination (when given after 48-72 hours), but may result in increased CNS toxicity. Forced saline diuresis (500 mL/hour of urine output) is recommended. Hemodialysis or hemoperfusion may theoretically be effective, but has not been demonstrated to be beneficial in humans. Furosemide can enhance urinary thallium excretion in animal models.

Additional Information

Estimated lethal dose: Humans: 10-12 mg/kg
 Odorless, tasteless, radiopaque
 Chelating agents are not effective. Dithiocarb worsens symptoms by causing central redistribution of thallium. Monitor for hypocalcemia in the acute phase. Assay blood by flame atomic absorption.
 The water soluble salts of thallium (sulfate, acetate, malonate, and carbonate) are more toxic than the sulfide and iodide (less water soluble).
 Estimated daily thallium intake in a 70 kg adult: Drinking water: 2 mcg;
 Food: 5 mcg; Inhalation: 3.4 ng

Thallium is present in concentrations of 0.024 mcg/g of cigarettes and 0.06-0.17 mcg/g in cigar stubs

Thallium contaminated heroin has been documented in France. Average ambient urban air concentration of thallium: 0.04 ng/m³; thallium is present in earth's crust at concentrations of 0.3-0.7 ppm
 PEL-TWA: 0.1 mg/m³; TLV-TWA: 0.1 mg/m³; IDLH: 20 mg/m³

Thiram

Applies to Foliage Disinfectant; Latex; Rubber Accelerator; Seed Disinfectant

CAS Number 137-26-8

U.S. Brand Names Arasan®; Pomarso®; Puralin®; Rezifilm®; Sporete®; Tersan-75®; Thiurad®; Tuads®; Tulisan®

Synonyms Tetramethyl Thiuram Disulfide; Thiram; Thiuram

Use Foliage disinfectant for fruits, mushrooms; rubber accelerator (volcanizing agent); seed disinfectant; a component of latex

Mechanism of Toxic Action Antioxidant and bisdithiocarbamate; inhibits the enzyme acetaldehyde dehydrogenase

Adverse Reactions

Dermatologic: Dermal irritation, eczema
 Endocrine & metabolic: Disulfiram-like reaction with ethanol may occur
 Ocular: Conjunctivitis
 Respiratory: Sneezing, rhinitis, cough

Signs and Symptoms of Overdose Cholinergic symptoms do not occur. Ataxia, confusion, diarrhea, dizziness, drowsiness, nausea, paralysis, vomiting

Toxicodynamics/Kinetics Metabolism: To carbon disulfide

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal for ingestion; irrigate for skin exposure
 Supportive therapy: Oxygen for antabuse-like reaction; crystalloid solution for hypotension

Drug Interaction Disulfiram-like reaction with ethanol may occur

Additional Information No effect on cholinesterase; acceptable daily intake: 5 mcg/kg affects acetaldehyde dehydrogenase for 10-14 days; ~10 times as potent as disulfiram

Thorium

CAS Number 7440-29-1

UN Number 2975

Synonyms Pyrophoric; Thorium 232

Use Refractory applications, welding electrodes, lamp mantles, and in nuclear weapon production, portable gas lighters

Mechanism of Toxic Action Most toxic effects are through alpha-radiation effects

Adverse Reactions

Hematologic: Aplastic anemia, leukopenia, anemia
 Hepatic: Elevated liver function test results
 Miscellaneous: Increased incidence of pancreatic cancers and hematopoietic tissue malignancies

Toxicodynamics/Kinetics

Absorption: By inhalation (5%); limited absorption by oral route (0.02% to 1%)
 Distribution: Bone and soft tissue
 Half-life: 2.6 years
 Elimination: Feces

Reference Range

General population blood level in the United Kingdom: 2.4 mcg/L
 Background urine level: <0.001 mcg/L

Overdosage/Treatment

Decontamination: Remove contaminated clothing; isolate all run-off.
 Dermal: Irrigate with water; scrub gently with a soft sponge or brush (avoid abrading skin). A 50% powdered detergent solution followed by a

5% sodium hypochlorite solution can be used for persistent contamination.

Ocular: Wash copiously with saline.

Supportive therapy: DTPA (diethylenetriamine pentacetic acid), which is available from the Radiation Emergency Assistance Center (615-576-1004), is an effective chelator. The calcium salt should be used as follows: 1 g of calcium DTPA diluted in 250 mL of 5% dextrose in water should be infused over a 1- to 1.5-hour time period daily for 5 days. CaNa_2 EDTA (calcium Versenate®) can also be used, but is less effective. DTPA should be used for dermal exposure with open wounds as well as inhalation or oral ingestion.

Additional Information

Thorotrast is a colloid consisting of thorium-232 dioxide (25%) and dextran used as an I.V. contrast agent up to 1955. Granulomas, blood disorders, and hemangiosarcoma of the liver have been associated with its use (after a delay of 20 years).

Estimated daily intake in U.S.: < 0.02 pCi Sesame seeds are foods with highest thorium concentration (0.01 pCi/g wet weight). Thorium 232 rarely exceeds 0.1 pCi/L in natural waters. In soil the average soil concentration is 6 mcg/g.

Tin

Related Information

- Adipose Tissue Ranges of Toxins

CAS Number 18282-10-5 (Stannic Oxide); 683-18-1 (Dibutyltin Chloride); 7440-31-5; 7772-99-8 (Stannous Chloride)

UN Number 1759 (Stannous Chloride)

Synonyms Mat Powder; Sn; Tin Flake

Use Primarily in the manufacture of containers (particularly aerosol cans); used to coat copper wire and as a soldering agent. Tributyltin salts are used as fungicides on ships.

Mechanism of Toxic Action Possible toxic mechanism may involve uncoupling of oxidative phosphorylation; mucosal irritant

Adverse Reactions

Inorganic tin:

- Dermatologic: Dermal irritation
- Gastrointestinal: Nausea, vomiting, diarrhea
- Respiratory: Pneumoconiosis
- Miscellaneous: Mucosal irritation

Organic tin:

- Central nervous system: Headache, disorientation, dizziness, seizures, polyneuropathy, dementia, vascular encephalopathy, photophobia
- Dermatologic: Dermal burns on contact with phenyltin
- Gastrointestinal: Stomatitis
- Hepatic: Fatty degeneration of liver
- Ocular: Photophobia, nystagmus, diplopia, visual evoked potential abnormalities
- Otic: Tinnitus, ototoxicity
- Neuromuscular & skeletal: Hyporeflexia
- Renal: Renal tubule injury
- Respiratory: Respiratory depression

Toxicodynamics/Kinetics

Absorption: Inorganic tin is not readily absorbed by any route; organic tin is readily absorbed by inhalation, dermal, and oral routes

Half-life: 4-400 days

Elimination: Feces and urine

Reference Range General population adipose tissue level: 8.7-15 mcg/g; normal mean urine tin concentration: 17 mcg/mL; average blood tin level: ~ 0.14 mg/L

Overdosage/Treatment

Decontamination: **Oral:** Dilute with water. **Dermal:** Wash with soap and water. **Ocular:** Irrigate with saline.

Supportive therapy: Chelation therapy is not effective.

Additional Information

Toxic oral dose: Triethyltin: 70 mg (> 8 days)

Radiopaque; a cause of metal fume fever

Half-life in water: > 89 days (photolysis)

Ambient air concentrations of tin in U.S. cities: < 0.8 mcg/m³

Mean soil background tin levels in U.S.: 0.89 mg tin/kg soil. Inorganic metal tin: 2 mg/m³. Organic tin (skin exposure): 0.1 mg/m³

TLV-TWA:

Canned food may contain from 1.8-500 mg/kg with all-lacquered cans having lower tin concentrations.

Estimated daily intake of tin in U.S. by an adult: 4 mg from food and 0.003 mg by inhalation (virtually none from drinking water)

Specific References

Dopp E, Hartmann LM, Florea AM, et al, "Environmental Distribution, Analysis, and Toxicity of Organometal(loid) Compounds," *Crit Rev Toxicol*, 2004, 34(3):301-33 (review).

Titanium

CAS Number 7550-45-0

UN Number 1838

Synonyms Titanic Chloride; Titanium Tetrachloride; Titanocene; "Tickle"

Use Production of iridescent glass and artificial pearls; production of inorganic titanium compounds; has been used by the military as a smoke-producing screen

Mechanism of Toxic Action Respiratory irritant

Adverse Reactions Respiratory, eye, nose, throat, gastrointestinal, temperature regulation, dermatologic (including dermal burns), fever

Signs and Symptoms of Overdose Irritation of mouth, nose, and throat; chemical pneumonitis; pulmonary edema; edema of pharynx and vocal cord; stenosis of larynx, trachea, upper bronchia; vomiting. Eye exposure may result in cataract, suppurative conjunctivitis, and keratitis. Burns of the GI tract may lead to strictures and fever.

Toxicodynamics/Kinetics

Absorption: Oral: $\sim 3\%$

Elimination: In urine

Reference Range Normal urine concentration: 10 mcg/L

Overdosage/Treatment

Decontamination:

Oral: **Do not** evacuate gastric contents. Following oral exposure, dilute with water or milk. **Do not** use a neutralizing solution because of exothermic reaction.

Dermal: **Do not** immediately wash with water. First dry wipe (with towels or gauze, before irrigating with water to prevent hydrochloric acid burns), whereupon a yellow or white granular deposit will be noted. At this point, wash the deposit off with cool water. Dermal burns can be treated by traditional methods.

Ocular: Wipe eyelids preliminarily with a dry cloth or gauze, then irrigate copiously with water (3-4 L over 20 minutes). **Do not** use neutralizing solutions.

Supportive therapy: The utility of corticosteroids is unclear in the prevention and treatment of noncardiogenic pulmonary edema.

Additional Information Colorless, fuming liquid; soluble in cold water; has a penetrating acid odor. Titanium tetrachloride in the presence of moisture decomposes to hydrochloric acid and titanium dioxide; heat is liberated. Titanium forms four oxides: titanium monoxide, titanium trioxide, titanium dioxide, and titanium trioxide. ACGIH TLV: 10 mg/m³; OSHA TWA: 15 mg/m³ dust

Specific References

Fryzek JP, Chadda B, Marano D, et al, "A Cohort Mortality Study Among Titanium Dioxide Manufacturing Workers in the United States," *J Occup Environ Med*, 2003, 45(4):400-9.

Toluene

Related Information

- Adipose Tissue Ranges of Toxins
- Methyl Isocyanate
- Methylene Diisocyanate

CAS Number 108-88-3

UN Number 1294

Synonyms Methyl Benzene; Tolu-Sol

Impairment Potential Exposure to > 500 ppm toluene or blood toluene level > 1 mg/L can result in impairment

Commonly Found In Glues, paint removers, pesticides, degreasers

Mechanism of Toxic Action Three mechanisms proposed: Alters lipid structure of cell membranes; Alters membrane-bound enzyme or receptor-site specificity; Toxic metabolite modifies function of cell micro-somal proteins and RNA

Adverse Reactions

Cardiovascular: Angina, cardiomyopathy, cardiomegaly, bradycardia, syncope

Central nervous system: CNS depression following early CNS stimulation, panic attacks, memory disturbance, dizziness, leukoencephalopathy

Endocrine & metabolic: Adrenal insufficiency due to bilateral adrenal hemorrhage

Hepatic: Transient liver injury, aminotransferase level elevation (asymptomatic)

Neuromuscular & skeletal: Rhabdomyolysis, muscle weakness (usually spares central and respiratory muscles), quadriplegia

Ocular: Visual evoked potential abnormalities

Renal: Renal tubular acidosis type IV, renal tubular acidosis type I

Respiratory: Bronchitis, wheezing, pulmonary edema

Signs and Symptoms of Overdose Asthenia, bradycardia, burns, chorea (extrapyramidal), dementia, euphoria, eye irritation, fatigue, hypokalemia, irritability, memory loss, metabolic acidosis, mydriasis, myoglobinuria, nonoliguric renal failure, ototoxicity, skin irritation, tachycardia, tinnitus, vomiting

Admission Criteria/Prognosis Symptomatic patients (or patients who ingested toluene) should be admitted; asymptomatic patients can be

discharged after 6-12 hours of observation; survival after 3 days postacute exposure is usually associated with recovery; any patient with cardiopulmonary complaints should be admitted; asymptomatic patients 8 hours postexposure can be discharged; survival after 1 day postexposure is usually associated with recovery. Patients exposed to known air concentration of toluene levels >500 ppm should be admitted.

Toxicodynamics/Kinetics

Absorption: Readily by inhalation (within 30 minutes) or ingestion (within 2 hours); slowly by dermal route (14-23 mg/cm²/hour); accumulates in adipose tissue

Metabolism: Hepatic to hippuric acid (60% to 70%), benzoyl glucuronide (10% to 20%), and ortho or para cresol (<1%)

Half-life: 3 days

Elimination: Hippuric acid excreted in urine, 20% excreted through the lungs, unchanged

Monitoring Parameters Monitor for benzene contamination

Reference Range Determined by measurement of urine hippuric acid.

Average urine hippuric acid level in nonexposed individuals is ~0.8 g/L; for individuals exposed to 200 ppm toluene, average urinary hippuric acid level is ~6 g/L. Blood toluene levels of 1.0-2.5 mg/L are associated with intoxication. Coma and death occur at levels of 2.5-10.0 mg/L. Blood toluene BEI is 1.0 mg/L. S-benzyl-N-acetyl-L-cysteine can be measured by HPLC and GC/MS at a lower urinary detection limit of 0.01 mg/L. Median S-p-toluymercapturic acid urinary level following exposure is 63 ppm toluene is 20 mcg/L.

Overdosage/Treatment

Decontamination: **Oral:** Emesis is contraindicated. Lavage is not to be used unless there is a large ingestion. **Dermal:** Wash with soap and water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate with saline.

Supportive therapy: Avoid epinephrine because of myocardial sensitization. Avoid haloperidol which can further deplete dopamine concentration of the brain. Avoid aspirin due to increased ototoxicity and decreased toluene clearance. Prednisone or aerosolized beclomethasone may prevent bronchospasm in TDI-sensitized patients, while atropine or cromolyn do not appear to exhibit a protective effect. Theophylline may have only a partial effect. Amantadine hydrochloride (100 mg daily, increased after 2 weeks to 100 mg twice daily) has been used successfully in treating cerebellar and visual dysfunction.

Diagnostic Procedures

- Electrolytes, Blood

Additional Information

Lethal oral dose: 625 mg/kg

Colorless liquid, sweet odor. Odor threshold: 0.4-2 ppm. Specific gravity: 1.22. Urinary BEI of o-cresol: 1 mg/g creatinine. Atmospheric half-life: 10-104 hours. Soil half-life: 1-7 days. TLV-TWA: 100 ppm; PEL-TWA: 200 ppm

The largest source of airborne emissions is through combustion of gasoline (5% to 7% toluene by weight).

Levels in drinking water are usually <3 mcg/L. Drinking water contributes 0.3-0.5 mcg/day of toluene exposure.

Estimated daily dose by inhalation: 300 mcg. Cigarette smoking can cause a daily increase in toluene inhalation of 1000 mcg.

Mean toluene level in ambient air: 2.8 ppb in urban areas; 0.4 ppb in rural areas

Median level of toluene found in snow samples (near Denver, Colorado): 0.05 mcg/L. See table.

Median Toulene Levels in Ambient Air			
Sampling Location	Number of Samples	Daily mean (ppb)	Concentration (mcg/m ³)
Remote	225	0.049	0.18
Rural	248	0.35	1.3
Suburban	958	0.195	0.731
Urban	2519	2.883	10.81
Source dominated	104	6.314	23.67
Indoor	101	8.4	31.5
Workplace	80	0.865	3.24

Toluene Diisocyanate

Related Information

- Hexamethylene Diisocyanate

Applies to Elastomers (Manufacture); Polyurethane Foams (Manufacture)

CAS Number 584-84-9

UN Number 2078

Synonyms Meta-Toluene Diisocyanate; TDI

Use In the manufacture of polyurethane foams, elastomers

Mechanism of Toxic Action Irritation to mucous membranes/sensitizer as an allergen

Adverse Reactions

- Cardiovascular: Chest pain, angina, cor pulmonale
- Central nervous system: Panic attacks, headache, insomnia, euphoria, ataxia, memory loss
- Respiratory: Respiratory irritation and sensitization, wheezing, hemorrhagic alveolitis, reactive airways disease syndrome, pulmonary hemorrhage, asthma

TOXAPHENE

Signs and Symptoms of Overdose Ataxia, burning of nose and throat, chest pain, choking, cough, decreased libido, dyspnea, euphoria, eye irritation, hemoptysis, impotence, nausea, nystagmus, retrosternal chest pain, vomiting

Toxicodynamics/Kinetics

Metabolism: May be metabolized to 2,4-toluene diamine (a carcinogen)
Elimination: Renal

Reference Range Air level exposure of ~0.005 ppm can result in a 6-8 hour urine level of 8.6 mcg/L

Overdosage/Treatment Decontamination: Emesis is contraindicated.

Oral: Dilute with milk or water; basic poison management. **Inhalation:** Give supplemental oxygen, bronchodilators

Additional Information

Asthma and chronic bronchitis are long-term sequelae. Acute pulmonary pathology will be evident within 8 hours. While solid tumor formation has been associated with TDI exposure in rodents, NIOSH considers TDI to be a potential human carcinogen.

There is a potential for secondary contamination after liquid exposure; no risk for secondary (ie, from victims) contamination exposure.

Fruity, pungent odor; TDI reacts with water to form carbon dioxide and polyureas; it is essentially insoluble in water. Odor threshold: 2 ppm. TLV-TWA: 0.005 ppm; IDLH: 10 ppm

Admission Criteria/Prognosis Admit any patient with systemic symptomatology or ingestion > 100 mL

Monitoring Parameters Cholinesterase levels

Overdosage/Treatment

Decontamination: **Oral:** For amounts > 100 mL, emesis with ipecac can be considered if performed within 30 minutes of ingestion. Activated charcoal may be useful. **Inhalation:** Administer 100% humidified oxygen.

Supportive therapy: If muscarinic symptoms develop, use of atropine may be helpful. Nicotinic signs should be treated with pralidoxime or obidoxime.

Antidote(s)

- Atropine [ANTIDOTE]
- Obidoxime Chloride [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Additional Information Symptoms of respiratory irritation can occur for 6-hour exposures > 123 ppm. Specific gravity: 0.976. IDLH: 1300 mg/m³

Trichloroethane

CAS Number 71-55-6

UN Number 2831

Synonyms CF 2; Methyl Chloroform; Strobane; TCA; TCE

Impairment Potential Exposure to air trichloroethane levels > 1000 ppm can result in impairment.

Commonly Found In Cleaning solvent, lubricant, ink, typewriter correction fluid; also is frequently used in an abused setting ("bagging")

Mechanism of Toxic Action CNS depression, rapid anesthetic action

Adverse Reactions

Cardiovascular: Hypotension, cardiovascular collapse, fibrillation (ventricular), shock, arrhythmias (ventricular)

Central nervous system: Anesthesia, axonopathy (peripheral)

Hematologic: Methemoglobinemia

Neuromuscular & skeletal: Neuropathy (peripheral), paresthesias

Ocular: Eye irritation

Respiratory: Pulmonary edema, respiratory depression, eosinophilic pneumonia

Signs and Symptoms of Overdose Acetone breath, agitation, ataxia, coma, diarrhea, diplopia, dizziness, drowsiness, erythema, hallucinations, nausea, seizures, vomiting

Toxicodynamics/Kinetics

Absorption: Rapid dermally, through inhalation, or through ingestion

Metabolism: Hepatic (< 10%) to trichloroacetic acid

Half-life: 53 hours

Elimination: Primarily by the lungs (91%)

Reference Range Fatal serum levels range from 1.7-42.0 mg/L of trichloroethane concentration. Blood level of 1.4 mg/L consistent with exposure of 250 ppm for 1/2 hour.

Overdosage/Treatment

Decontamination: **Oral:** Emesis is contraindicated; dilute with milk. **Dermal:** Wash with soap and water; isopropyl alcohol can be used.

Inhalation: Administer 100% humidified oxygen. **Ocular:** Irrigate with saline.

Supportive therapy: Propranolol may be beneficial for tachycardia. Avoid catecholamines as they can sensitize the myocardium. Calcium gluconate or phenylephrine has been useful to treat hypotension in the dog model.

Drug Interaction Alcohol-Disulfiram like reaction (Degreaser's Flush): Initiated within 30 minutes of alcohol ingestion; Peaks in one hour and then resolves in one hour. Flushing starts on the nose and cheeks.

Additional Information

Levels of 1000 ppm will cause ataxia.

BEI of urinary trichloroacetic acid is 10 mcg/L

Estimated daily intake: 50-1000 mg by all routes of exposure

Door spray lubricants, VCR cleaners, typewriter correction fluid, and nonacid drain cleaners have the highest amount of 1,1,1-trichloroethane.

Foods with the highest levels include allspice (16,000 ppb), celery seed (909 ppb), and pickling spice (549 ppb).

Pleasant odor. Odor threshold: 120-500 ppm. Atmospheric half-life: 2.7-6 years. Soil half-life (aerobic degradation): ~1 week. Urban atmospheric concentration in U.S.: 0.1-1 ppb. TLV-TWA: 350 ppm; PEL-TWA: 350 ppm

Specific References

DiCarlo MA, "Household Products: A Review," *Vet Hum Toxicol*, 2003, 45(5):256-61.

Trichloroethylene

Applies to Adhesives; degreaser (Industrial); fire retardant; lacquer; solvents (house cleaning); typewriter correction fluid

CAS Number 79-01-6

UN Number 1710

Synonyms Acetylene Trichloride; TRI; trichloren; trilene

Toxaphene

CAS Number 8001-35-2

UN Number 2761

U.S. Brand Names Agricide Maggot Killer®; Alltox®; Camphofene®; Geniphene®; Huilex®; Motox®; Penphene®; Phenatox®; Phenicide®; Tox-Sol®; Toxakil®

Synonyms Camphoclor; Chlorinated Camphene

Use Chlorinated hydrocarbon insecticide used on livestock to control lice, flies, ticks, mange, and mites; used in treating flowering plants; not used on agricultural commodities as of 1993

Mechanism of Toxic Action Blocks GABA-regulated chloride ionophore of the neuronal synapse

Adverse Reactions

Gastrointestinal: Salivation

Neuromuscular & skeletal: Rhabdomyolysis

Signs and Symptoms of Overdose Ataxia, elevated liver function tests, hyperthermia, nausea, respiratory failure, seizures, tremor

Toxicodynamics/Kinetics

Absorption: Oral and dermal

Metabolism: Hepatic dechlorination, oxidation, and dehydrodechlorination

Elimination: Urine and feces

Overdosage/Treatment

Decontamination: **Oral:** Do not induce emesis; lavage (within 1 hour)/activated charcoal. **Dermal:** Remove contaminated clothing (especially leather); wash with soap and water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate copiously with saline.

Supportive therapy: Benzodiazepines, phenobarbital, or phenytoin may be used for seizure control. Avoid catecholamine in that it may increase myocardial irritability and result in ventricular arrhythmias.

Enhancement of elimination: Multiple dosing of activated charcoal or cholestyramine may be effective. Hemodialysis or hemoperfusion is not likely to be beneficial.

Drug Interaction May decrease effect of warfarin

Additional Information

Minimum lethal dose: Oral: 2-7 g. Seizuregenic dose: Oral: 10 mg/kg. Toxic dose: Dermal: 660 mg/kg

Adrenal-based corticosteroid synthesis may be decreased; contains 67% to 69% chlorine

Average dietary intake for an adult: <0.01 mcg/kg/day, Average

inhalation exposure: ~0.0004-0.0033 mcg/day

Atmospheric residence time: 46-70 days. Water half-life: > 10 years

PEL-TWA: 0.5 mg/m³; TLV-TWA: 0.5 mg/m³

Tributyl Phosphate

Related Information

- Adipose Tissue Ranges of Toxins

CAS Number 126-73-8

Synonyms TBP

Use Antifoaming agent; hydraulic fluid; plasticizer; solvent for uranium extraction

Mechanism of Toxic Action Vapors (especially hot) are irritants; weak cholinesterase inhibition

Adverse Reactions

Central nervous system: Headache

Dermatologic: Dermatitis

Gastrointestinal: Nausea

Ocular: Eye irritation

Respiratory: Cough

Use Industrial degreaser, fire retardant, lacquer/adhesive, house cleaning solvent, typewriter correction fluid

Mechanism of Toxic Action CNS depressant; may induce peroxisome proliferation

Adverse Reactions

Cardiovascular: Fibrillation (ventricular), bradycardia, Raynaud's phenomenon, sinus bradycardia, arrhythmias (ventricular)

Central nervous system: CNS depression

Hepatic: Hepatitis, centrilobular hepatic necrosis, aminotransferase level elevation (asymptomatic)

Ocular: Diplopia, blurred vision progressing to blindness, optic neuropathy

Renal: Tubular necrosis (acute)

Respiratory: Pulmonary edema, respiratory depression

Miscellaneous: Aneuploidy induction, trigeminal neuro-pathy

Signs and Symptoms of Overdose Ataxia, bradycardia, cranial nerve palsies, cyanosis, dementia, dizziness, dyspnea, fatigue, headache, impotence, loss of taste, mydriasis, nystagmus, resting tremor, salivation, seizures, slurred speech, vomiting

Admission Criteria/Prognosis Patients (regardless of radiological signs) should be admitted if they are symptomatic 6 hours postexposure; survival after 6 hours usually associated with recovery

Toxicodynamics/Kinetics

Absorption: Rapid by ingestion and inhalation; minimal dermal exposure

Metabolism: In the liver; fat soluble

Half-life: 30-38 hours

Elimination: Excreted in urine, feces, and lung (16%)

Reference Range Blood concentrations of 5.0-10.0 mg/dL related to anesthetic action; levels of 0.3-11.0 mg/dL are associated with fatalities; blood level of 0.1 mg/dL is consistent with exposure of 100 ppm

Overdosage/Treatment

Decontamination: Dermal: Wash with soap and water. Ocular: Irrigate with saline. Oral: Do not induce emesis; activated charcoal may be used.

Supportive therapy: Avoid catecholamines in that they may sensitize the myocardium. Propranolol may be useful for treatment.

Drug Interaction Alcohol - Disulfiram like reaction (Degreaser's Flush): Initiated within 30 minutes of alcohol ingestion; peaks in one hour and then resolves in one hour. Flushing starts on the nose and cheeks.

Additional Information

Toxic ingestion: 0.5 mL/kg

Degreaser's flush occurs in workers who ingest ethanol following exposure to trichloroethylene.

Chloroform odor. Odor threshold: 20 ppm. TLV-TWA: 50 ppm; PEL-TWA: 100 ppm

BEI of urinary trichloroacetic acid: 100 mg/g creatinine

Atmospheric half-life: 6.8 days. Ambient atmospheric levels in urban areas: 0.46 ppb.

Average air intake: 11-33 mcg/day. Average intake through drinking water: 2-20 mcg/day

Trichloroethylene Subregistry: Je Anne Burg PhD, Agency for Toxic Substances and Disease Registry, 1600 Clifton Road, NE, Mailstop E 31, Atlanta, GA 30333: (404) 639-6202

Triethylene Glycol

Applies to Brake Fluid

CAS Number 112-27-6

Synonyms Glycdonitrile; TEG

Use Found in brake fluid

Mechanism of Toxic Action A short chain polyethylene glycol which can break down into organic acids through an alcohol dehydrogenase pathway. It is unclear whether ethylene glycol or its metabolites are produced by this pathway.

Signs and Symptoms of Overdose Coma, metabolic acidosis

Antidotes

Sodium bicarbonate fomepizole

Admission Criteria/Prognosis Admit any ingestion

Overdosage/Treatment

Decontamination: Oral: Activated charcoal should be administered.

Dermal: Irrigate with soap and water

Supportive therapy: Intravenous sodium bicarbonate should be used to treat acidosis. Ethanol administration or fomepizole should be given as

an inhibitor of alcohol dehydrogenase. Thiamine, pyridoxine, and folinic acid can also be administered.

Enhancement of elimination: Although no formal studies exist, the low molecular weight and high water solubility of TEG makes this a candidate for hemodialysis removal.

Trimellitic Anhydride

CAS Number 552-30-7

Synonyms Anhidrotrimellitic Acid; TMA; TMAN

Use Curing agent for epoxy; used in manufacture of plastics and paints; used as anticorrosive surface

Mechanism of Toxic Action Causes four clinical respiratory illnesses, three of which are immunologically mediated upon inhalation (1) IgE-mediated allergic rhinitis with bronchospasm; (2) a late respiratory systemic syndrome with cough, dyspnea, fever, and arthralgias occurring 4-12 hours postexposure; (3) hemoptysis, dyspnea and cough leading to restrictive lung disease and respiratory failure often termed "pulmonary disease-anemia syndrome"; and (4) respiratory irritation from high-dose exposure

Adverse Reactions

Central nervous system: Fever

Dermatologic: Contact dermatitis

Hematologic: Hemolytic anemia

Neuromuscular & skeletal: Myalgia, arthralgia

Respiratory: Pulmonary hemorrhage, hemorrhagic alveolitis, allergic rhinitis, cough, bronchospasm, dyspnea, pneumonitis, pulmonary edema, asthma

Admission Criteria/Prognosis Symptomatic patients should be admitted; asymptomatic exposures may be discharged after 12-hour observation postexposure

Monitoring Parameters Arterial blood gas, chest x-ray

Overdosage/Treatment Supportive therapy: Administer 100% humidified oxygen. Bronchodilators and beta agonist agents can be useful. Corticosteroids are of uncertain benefit.

Additional Information Levels of IgE antibody activity to trimellitic human serum albumin may be elevated. Usually found as crystals with a melting point of 162°C. OSHA 8-hour TWA: 0.005 ppm. Soluble in ether and acetone.

Tungsten

CAS Number 7440-33-7

Use Found in light filaments, heating elements, welding electrodes, electron tubes, ceramics, cutting tools. Mostly used in the form of tungsten carbide. Also used in heat shields, arc lamps, electrodes, and gyroscopes

Mechanism of Toxic Action Irritant - may generate hydroxyl radicals in lungs contributing to pulmonary fibrosis

Signs and Symptoms of Overdose Pulmonary fibrosis, ocular/nasal irritation, cough, dyspnea, memory deficits, seizures, headache, coma, renal insufficiency, acute tubular necrosis, skin irritation; nausea, metabolic acidosis, hyperkalemia (oral ingestion)

Toxicodynamics/Kinetics Elimination: Renal

Reference Range General population: Blood tungsten level: 1-6 mcg/L; urine tungsten level: <0.085 mcg/L; hair tungsten level: 16 ppb

Overdosage/Treatment

Decontamination:

Inhalation: Administer 100% humidified oxygen

Ocular: Copiously irrigate with saline or water

Oral: Lavage within 1 hour of oral ingestion

Supportive therapy: Seizures can be treated with benzodiazepines

Drug Interaction May enhance pulmonary toxicity of cobalt

Additional Information

Most common valence is +6; highest melting point of all metals (3,410°C)

Concentration of tungsten:

Ambient air: <10 ng/m³

Surface soil: 0.68-2.7 mg/kg dry weight

Sea water: 0.1 mcg/L

Usual dietary intake: ~49 mcg/day

Occupational exposure: See table.

Occupations with Potential Tungsten Exposure	
Alloy makers	Melting, pouring, casting workers
Carbonyl workers	Metal sprayers
Ceramic workers	Ore-refining and foundry workers
Cemented tungsten carbide workers	Paint and pigment makers
Cement makers	Papermakers
Dyemakers	Penpoint makers

TURPENTINE OIL

Dyers	Petroleum refinery workers
Flameproofers	Photographic developers
High-speed tool steelworkers	Spark-plug makers
Incandescent-lamp makers	Textile dryers
Industrial chemical synthesizers	Tool grinders
Inkmakers	Tungsten and molybdenum miners
Lamp-filament makers	Waterproofing makers
Lubricant makers	Welders

"Occupational Exposure to Tungsten and Cemented Carbide," *NIOSH*, 1977, 21-171.

Specific References

U.S. Department of Health and Human Services, *Toxicological Profile for Tungsten*, Syracuse Research Corp, 2003.

Turpentine Oil

Related Information

- Limonene
- Pine Oil

CAS Number 8006-64-2; 9005-90-7

UN Number 1299

U.S. Brand Names Ozothine®

Synonyms Gum Spirits; Spirits of Turpentine

Commonly Found In Oleoresin solvent, paint vehicle, deodorizer fragrance, rubefacient

Mechanism of Toxic Action CNS depressant, irritant to mucous membranes; high volatility with low viscosity

Adverse Reactions

Cardiovascular: Tachycardia, sinus tachycardia

Central nervous system: Ataxia, coma, fever, insomnia, dizziness, seizures (can occur after ingestions >200 mL), headache (inhalation >750 ppm for several hours)

Dermatologic: Contact dermatitis, erythema, blister, urticaria, nonimmunologic contact urticaria, airborne contact dermatitis

Gastrointestinal: Hemorrhagic gastritis, diarrhea

Genitourinary: Hemorrhagic cystitis, dysuria

Ocular: Conjunctivitis, blepharospasm, mydriasis, eye irritation is perceptible at 175 ppm

Renal: Glomerulonephritis, hematuria, albuminuria

Respiratory: Pulmonary edema, aspiration pneumonitis, wheezing, coughing, dyspnea

Miscellaneous: Hypersensitivity reactions in 2.6% of population

Signs and Symptoms of Overdose Aspiration, chills, cough, dyspnea, eye pain, fever, seizures, vomiting

Admission Criteria/Prognosis Patients who develop tachypnea, cyanosis, dyspnea, CNS depression, tachycardia, or fever within 8 hours of exposure should be admitted; asymptomatic patients can be discharged after 8 hours observation; admit if the patient is symptomatic 6 hours postingestion or if pediatric ingestion is >5 mL

Toxicodynamics/Kinetics

Absorption: Well absorbed through the GI tract, by inhalation, and dermally; high fat solubility

Metabolism: In the liver

Elimination: Renally and through the lungs

Reference Range Blood and urine turpentine level after a severe adult overdose was 28 mcg/mL and 15 mcg/mL, respectively

Overdosage/Treatment

Decontamination: Emesis is indicated only for large ingestions and within 30 minutes of ingestion. Lavage only after the patient is intubated.

Activated charcoal is useful. Steroids are not beneficial. Seizures can be treated with a benzodiazepine. Phenobarbital or phenytoin can be used for refractory seizures. **Ocular:** Irrigate copiously with saline.

Enhanced elimination: Hemoperfusion may be useful if utilized very early in the hospital course.

Additional Information

Minimum lethal dose: Children: 15 mL; Adults: 140 mL

Pungent odor, although an odor of violets may be noted in overdose settings; urinary odor is that of violets. Combustible. TLV-TWA: 100 ppm; IDLH: 1900 ppm; PEL-TWA: 100 ppm

Density: 0.9, constituents; terpenes and camphenes, and 3-carene

Usual amount of turpentine oil used in food or beverage flavoring: ~20 ppm

Mechanism of Toxic Action Uranyl ion complexes with bicarbonate and produces acute renal proximal tubular damage/failure

Adverse Reactions

Renal: Renal tubular damage with a dose >0.1 mg/kg, acute tubular necrosis

Miscellaneous: Possible increase in skin cancer rate

Signs and Symptoms of Overdose Albuminuria, elevated BUN, pulmonary edema, weight loss, wheezing

Toxicodynamics/Kinetics

Absorption: Uranyl ion is rapidly absorbed from gastrointestinal tract

Distribution: Lung retains insoluble salts following inhalation

Half-life: 1500 days

Elimination: 66% renal excretion within 24 hours

Reference Range Average uranium concentration in N.Y. human blood donors: 0.14 mcg uranium/kg wet weight of both whole blood and red blood cells; a urinary uranium concentration of >100 mcg/L is indicative of recent uranium exposure

Overdosage/Treatment

Decontamination: Irrigate with soap and water. Waste should be kept in separate receptacles. Use a Geiger-Mueller meter to survey the extent of contamination.

Supportive therapy: Give 1-3 mEq/kg of I.V. sodium bicarbonate to cause a forced alkaline diuresis which can be nephroprotective. Chelating agents such as sodium 4,5-dihydroxybenzene-1,3-disulphonate (Tiron®) or diethylamine-tetramine pentaacetic acid (DTPA) are of uncertain efficacy.

Additional Information

Soluble uranium compound is known as uranyl ion. Radon decays and forms radon daughters (isotopes of lead, bismuth, and polonium). The radon daughters attach to dust particles and are inhaled by uranium miners. Uranium tetrafluoride and uranyl fluoride are hydrolyzed to HF. Can call U.S. Department of Energy Regional Coordinating Office at 615-576-1004.

Average daily intake from food and water: 1 mcg

Estimated intake due to drinking water: 0.6-2 pCi/day (0.02-0.07 Bq/day)

Rock levels of uranium range from 0.5-4.7 mcg/g

Soil levels average ~1.8 mcg/g in the U.S.

Atmospheric half-life of uranyl fluoride: 35 minutes

Root crops (potatoes, parsnips, turnips) have the highest uranium levels, and thus dietary daily uranium intake may range from 3.3-4.2 mcg

Essentially insoluble in water

Average Uranium Concentrations in Drinking Water for States Where Concentration Exceeds 1pCi/L

Concentration >1 pCi/L

Concentration ≤1 pCi/L

Source: NCRP 198 4b

Uranium

CAS Number 7440-61-1

UN Number 2979

Use Primarily in nuclear power plants, radiation shielding material, x-ray targets, gyro compasses, and in large incandescent lamps; mordant in silk and wood industry

Vanadium

Related Information

● Adipose Tissue Ranges of Toxins

CAS Number 7440-62-2

UN Number 3285

Use Primarily as an alloying agent in steel; jet engine manufacture; pesticide production, inks, dyes and pigments

Mechanism of Toxic Action Vanadium reduces alveolar macrophage viability; this may account for vanadium's respiratory irritant effect; vanadium also causes redistribution of iron, chromium, copper, manganese, and zinc; it also has positive inotropic effects on the heart

Adverse Reactions

HEENT, cardiovascular, respiratory, neurologic, gastrointestinal, dermatologic, salivation
Respiratory: Asthma

Signs and Symptoms of Overdose Abdominal pain, black stools, CNS depression, dermatitis, diarrhea, dry mouth, epistaxis, green tongue, headache, metallic taste, occupational asthma, ocular irritation, peripheral vasoconstriction (of lungs, spleen, kidney, intestine) pulmonary edema, rhinitis, tracheitis

Toxicodynamics/Kinetics

Absorption: Primarily through inhalation; oral and dermal absorption is poor

Distribution: Although vanadium is found throughout tissues, majority is found in fat

Elimination: Excreted in both urine and feces

Reference Range Normal urine levels: <8 mcg/24 hours; total body burden considered to be safe in U.S.: 0.5 mg/L; normal serum vanadium levels: 1-2 mcg/L

Overdosage/Treatment

Decontamination: **Oral:** Lavage within 1 hour, followed by dilution with milk or water; give a cathartic. **Dermal:** Wash with soap and water. **Ocular:** Irrigate with saline.

Enhancement of elimination: BAL is not useful. Deferoxamine mesylate or ethylene diamine tetracetate has had some success in animal models.

Additional Information Toxic dose of ammonium metavanadate is 10 g.

VINYL ACETATE

Pentavalent vanadium is more toxic than other forms; the parenteral form is most toxic, followed by inhalation and oral; U.S. coal can contain as much as 10 g/kg of vanadium
Drinking water concentrations: Average 4.3 mcg/L
Daily adult intake by inhalation: ~ 1 mcg
Atmospheric residence time: 1 day
Mean vanadium content in urban areas is ~ 11 ng/m³
Vanadium concentration in earth's crust: 150 mg/kg; Average content in U.S. soil: 200 mg/kg
Food items with highest levels include ground parsley (1800 ng/g), freeze-dried spinach (533-840 ng/g), wild mushrooms (50-2000 ng/g), and oysters (450 ng/g)
ACGIH TLV: 0.05 mg/m³ respirable dust or fumes; OSHA TWA: 0.5 mg/m³ dust, 0.1 mg/m³ fumes
Air content of Bahrain (during burning of oil fields of Kuwait in 1991): 11-42 ng/m³

Vinyl Acetate

CAS Number 108-05-4

UN Number 1301

U.S. Brand Names VAC[®]; VYAC[®]; Zeset T[®]

Synonyms 1-Acetoxy-Ethylene; Acetic Acid; Ethanoic Acid; Ethenyl Ester; Vinyl Ethanoate

Use Production of polyvinyl acetate (adhesives, wood gluing, paints) and polyvinyl alcohol (adhesives, textiles, automobile glass)

Mechanism of Toxic Action Primarily a respiratory irritant

Adverse Reactions

Cardiovascular: Chest pain, angina
Central nervous system: Insomnia, dizziness
Dermatologic: Dermatitis, blisters
Gastrointestinal: Throat irritation, mucous membrane irritation
Hepatic: Elevated liver function test results
Neuromuscular & skeletal: Neuropathy (peripheral)
Ocular: Eye irritation
Respiratory: Cough, hoarseness, bronchospasm
Miscellaneous: Polyneuritis

Toxicodynamics/Kinetics

Absorption: Probably through inhalation, oral, and dermal routes
Metabolism: Plasma and liver esterases hydrolyze vinyl acetate to acetaldehyde and acetic acid along with carbon dioxide

Overdosage/Treatment Decontamination: **Oral:** Dilute with milk or water. **Dermal:** Wash with soap and water. **Inhalation:** Administer 100% humidified oxygen. **Ocular:** Irrigate with saline.

Additional Information Irritation can occur at air concentrations > 20 ppm. Odor threshold: 0.12 ppm. Half-life in water: 7.3 days. Atmospheric half-life: 4-6.5 hours. Amount of vinyl acetate in a cigarette: 400 ng. TLV-TWA: 10 ppm.

Vinyl Chloride

Applies to Methylchloroform (Production); Polyvinyl Chloride (Production); Refrigerant

CAS Number 75-01-4

UN Number 1086

Synonyms Chloroethylene; Ethylene Monochloride

Commonly Found In Adhesives, propellants

Use As a refrigerant, used in production of methylchloroform and in manufacture of polyvinyl chloride (PVC)

Mechanism of Toxic Action Dermal exposure to escaping pressurized gas may cause injury or frostbite due to rapid evaporation; narcotic properties; metabolite (chloroethylene epoxide) is toxic; human carcinogen - angiosarcoma of the liver

Adverse Reactions

Cardiovascular: Fibrillation (ventricular), Raynaud's phenomenon, arrhythmias (ventricular)
Central nervous system: CNS depression
Neuromuscular & skeletal: Peripheral neuropathy
Respiratory: Respiratory irritation, respiratory depression

Signs and Symptoms of Overdose Arthralgia, ataxia, dyspnea, epigastric pain, euphoria, fatigue, fingernail clubbing, headache, hepatomegaly, loss of libido, ocular irritation, seizures. Inhalation of high concentrations may result in narcotic-like CNS and apnea. Chronic exposure may result in hepatic angiosarcoma. Cancers of the brain, liver, and lung have also been documented. In addition, chronic exposure may result in "vinyl chloride disease" which consists of a scleroderma-like condition of the connective tissue of the fingers and thickening of the dermis, acro-osteolysis, and Raynaud's-type phenomenon. Thrombocytopenia may also occur.

Admission Criteria/Prognosis Any patient with central nervous system or respiratory abnormalities should be admitted

Toxicodynamics/Kinetics

Absorption: Inhalation or dermal exposure; 42% retained in the lungs; concentrated in the liver and kidneys

Metabolism: In the liver, thiodiglycolic acid is the major metabolite

Elimination: Excreted renally

Reference Range Urine thiodiglycolic acid level of 0.3-4.0 mg/L may indicate recent exposure

Overdosage/Treatment

Decontamination: **Oral:** Do not induce emesis; lavage/activated charcoal

Dermal: Remove and discard all contaminated clothing as hazardous waste. Wash exposed areas twice with soap and water and rinse well. Wash water should be contained and appropriately discarded. **Ocular:** Irrigate with saline.

Supportive therapy: Symptomatic and supportive care are the mainstay of treatment. Administer 100% humidified oxygen as needed. Frostbite should be treated with rapid rewarming in a 42°C water bath.

Additional Information

Liver and renal function tests should be performed and repeated annually. Rescue and treatment personnel should take care not to become exposed; this may include self-contained breathing apparatus, chemical protective gloves and goggles, and fluorocarbon rubber protective clothing.

Colorless, pleasant sweet ether odor. Odor threshold: 260 ppm. TLV-TWA: 5 ppm. Atmospheric half-life: 1.2-1.8 days. Cigarette smoke contains 5.6-27 ng/cigarette. Daily intake by an average U.S. adult by inhalation, ingestion, or dermal route is essentially zero

White Phosphorus

CAS Number 12185-10-3; 7723-14-0

UN Number 1381 (dry or in water); 2447 (molten)

Synonyms Phosphorus Tetramen; Red Phosphorus; Yellow Phosphorus
Commonly Found In Phosphorus sesquisulfide, phosphine gas

Use Fertilizers, roach poisons, rodenticides, water treatment; used in military as ammunition in motor/artillery shells

Mechanism of Toxic Action Damages endoplasmic reticulum; inhibits fatty acid oxidation

Adverse Reactions

Cardiovascular: Hypotension, tachycardia, fibrillation (atrial), flutter (atrial), sinus tachycardia

Central nervous system: Lethargy, irritability, coma, hyperthermia

Dermatologic: Dermal burns

Endocrine & metabolic: Hypoglycemia can occur on chronic exposure

Gastrointestinal: GI Irritant, vomiting, abdominal cramps

Hematologic: Anemia, leukopenia, hemolysis

Hepatic: Degeneration and hepatic necrosis

Neuromuscular & skeletal: Degeneration and osteoporosis, fasciculations, asterixis, hemiplegia

Renal: Tubular necrosis (acute) and cortical necrosis

Respiratory: Cough on inhalation, tachypnea, dyspnea

Miscellaneous: "Phoshy jaw" (degeneration and necrosis of soft tissue and teeth in oral cavity resulting in life-threatening infections); fatty deposition of muscles and liver, decreases in serum calcium, potassium, and sodium; liver/renal toxicity along with cerebral edema may occur after 5-10 days

Signs and Symptoms of Overdose Breath odor, coma, dermal burns, flatulence, GI irritation, hypocalcemia, luminescent stool, seizures; vomiting followed by asymptomatic phase of < 12 hours to 3 days with subsequent signs/symptoms of hepatic or renal failure. Chronic exposure (5+ years) results in osteoporosis and bone degeneration, commonly of jaw ("phoshy jaw"), and feces discoloration (black).

Admission Criteria/Prognosis Any patient with ingestion of white or yellow phosphorus should probably be admitted

Toxicodynamics/Kinetics

Absorption: By oral routes; yellow phosphorus well absorbed dermally and orally; phosphine gas absorbable in lungs; red phosphorus nonabsorbable

Metabolism: Oxidation and hydrolysis to hypophosphites

Elimination: Urine and feces

Reference Range Normal serum phosphate concentrations: 3.0-4.5 mg/100 mL

Overdosage/Treatment

Decontamination:

Oral: Do not induce emesis. Lavage within 2-3 hours with 1:5000 to 1:10,000 potassium permanganate or water. Activated charcoal may be used.

Dermal: Remove contaminated clothing; brush off phosphorus from skin and then continuously irrigate skin with water. Apply saline soaked dressings to the affected area. Avoid any lipid-based ointments. Phosphorus will fluoresce under a Wood's lamp. Remove visualized phosphorus particles with metal forceps or a WaterPik® appliance. A 1% copper sulfate solution or silver nitrate has been advocated to aid in decontamination of dermal burns, although its use is controversial. Burns may give off odor or smoke.

Inhalation: Administer 100% humidified oxygen

Ocular: Irrigate with saline for at least 15 minutes. Following saline irrigation, several drops of 3% copper sulfate solution (applied within 15 minutes) can be given to help prevent ocular burns and then remove particles mechanically.

Supportive therapy: Treat dermal burns in traditional method. Watch for secondary infections. Monitor calcium and glucose levels. Steroids are of no benefit in preventing liver injury. Morphine sulfate can be used to treat pain. Monitor fluids as third spacing and fluid loss can occur with GI or dermal injury. N-acetylcysteine may reduce hepatic toxicity when given early postexposure:

Dose regimen: 150 mg/kg in 200 mL D₅W over 15 minutes, then 50 mg/kg in 500 mL D₅W for 4 hours, then 100 mg/kg in 1000 mL D₅W for 16 hours has been utilized. Monitor for hypocalcemia.

Enhancement of elimination: Mineral oil (100 mL in adults or 1.5 mL/kg in children <12 years of age) can be used as a cathartic. Exchange transfusion may be helpful.

Additional Information Lethal oral dose: 1 mg/kg (yellow phosphorus) Garlic breath odor and luminescent vomitus, flatus, or stool is pathognomonic although not frequent.

Vomiting can occur after oral ingestion of 2-23 mg/kg.

Note that phosphine gas may emanate from emesis, lavage fluid, and feces from affected patients. Thus, the patient's room should be well ventilated.

Red phosphorus is not soluble and essentially not absorbed through the gastrointestinal tract and is, therefore, considered nontoxic.

Phosphine gas has a garlic odor.

Gas release occurs in industrial use or with moisture contamination of aluminum or zinc phosphide rodenticides.

Match phosphorus content is essentially nontoxic. Match toxicities are secondary to potassium chlorate content.

Atmospheric half-life: 5 minutes

PEL-TWA: 0.1 mg/m³; TLV-TWA: 0.1 mg/m³

Xylene

Related Information

- Amitraz

Applies to Glue; Paint; Polymers

CAS Number 106-42-3; 108-38-3; 1330-20-7; 95-47-6

UN Number 1307

Synonyms Dimethyl Benzene; Methyltoluene; Violet 3; Xylol

Impairment Potential Acute exposures > 300 ppm or blood xylene levels > 3 mg/L are consistent with impairment.

Use In histology laboratories (M-xylene), manufacture of polymers, glues, paints, and as a vehicle for pesticides

Mechanism of Toxic Action Anesthetic at high doses (> 5000 ppm)

Adverse Reactions

Central nervous system: CNS depression

Dermatologic: Scleroderma

Endocrine & metabolic: Sexual dysfunction

Hepatic: Liver necrosis

Renal: Hematuria

Respiratory: Irritation to upper airway

Signs and Symptoms of Overdose CNS depression, cough, dementia, dizziness, fatigue, headache, nausea, nystagmus, ocular irritation, skin irritation, syncope, throat burning

Admission Criteria/Prognosis Symptomatic patients should be admitted; asymptomatic patients can be discharged after 6-12 hours observation

Toxicodynamics/Kinetics

Absorption: By inhalation, dermally, or through the GI tract

Protein binding: 90%

Metabolism: In the liver

Half-life: 20-30 hours

Elimination: 2,4-Xylenol and methyl hippuric acid are excreted renally; xylene is protein bound

Reference Range BEI of methyl hippuric acid (urine) is 1.5 g/g creatinine; blood level of 1 mg/L is consistent with exposure of 100 ppm

Overdosage/Treatment

Decontamination: Oral: Do not induce emesis; dilute with milk or water.

Dermal: Wash with soap and water. **Ocular:** Irrigate with saline.

Supportive therapy: Avoid use of catecholamines since they may exacerbate myocardial irritability.

Diagnostic Procedures

- Electrolytes, Blood

Additional Information Lethal oral dose: 15 mL

Patients may be more sensitive to ethanol.

Aspirin or ethanol can produce a false-positive urine test result for hippuric acid.

Air xylene concentrations > 10,000 ppm can result in unconsciousness and death.

Xylene may be present in the gas phase delivery in cigarettes at a concentration of up to 20 mcg/cigarette.

Sweet odor. Odor threshold: 0.05 ppm

Average daily intake by inhalation: ~353 mcg. Average daily intake through drinking water: ~39.4 mcg/kg/day. Average amount in drinking water: ~2 mcg/L.

Soil half-life: 1-2 days (photo-oxidation). Water half-life (by biodegradation) 10.3 days; by volatilization: 5.6 hours. TLV-TWA: 100 ppm; PEL-TWA: 100 ppm. Median urban atmospheric level: 7.2 ppb. Atmospheric half-life: 0.5-1 day.

Zinc Phosphide

Related Information

- Phosphine
- White Phosphorus

CAS Number 1314-84-7; 39342-49-9

UN Number 1714

Synonyms Blue-Ox®; Kil-Rat®; Mous-Con®; Ratol; Rumetan®; Stutox; Zinc Tox

Use Rodenticide

Mechanism of Toxic Action Liberates phosphine gas when ingested; phosphine (which is a cytochrome C oxidase inhibitor) acts rapidly to cause gastrointestinal and pulmonary irritation

Adverse Reactions

Central nervous system: Headache, fatigue, ataxia

Endocrine & metabolic: Metabolic acidosis, hypocalcemia

Gastrointestinal: Nausea, vomiting

Hepatic: Centrilobular necrosis (hepatic), jaundice

Neuromuscular & skeletal: Paresthesias, intention tremor

Ocular: Diplopia

Respiratory: Pulmonary edema, cough, dyspnea

Admission Criteria/Prognosis Admit any exposure for 48-72 hours to monitor respiratory status; ingestions > 1 g should be admitted

Reference Range 180 g of the rodenticide ingestion resulted in a zinc serum level of ~6 ppm

Overdosage/Treatment

Decontamination:

Oral: Very controversial; if the patient has not vomited, emesis can be induced with syrup of ipecac within 30 minutes of ingestion. Although several cases which recovered involved gastric lavage, it should be noted that water can assist in liberating phosphine gas. A 5% sodium bicarbonate solution has been advocated to limit acid hydrolysis of zinc phosphide, but this modality has not been studied in humans.

Dermal: Brush/scrape off the flakes from the skin and then wash skin copiously

Inhalation: Use 100% humidified oxygen.

Supportive therapy: Intravenous crystalloid fluid hydration with sodium bicarbonate (1-2 mEq/kg) to treat acidosis; pulmonary edema should be aggressively treated; mechanical ventilation may be necessary. Monitor and treat for hypocalcemia. Morphine sulfate can be used to treat pain.

Enhancement of elimination: Mineral oil (Adults: 100 mL; Children <12 years: 1.5 mL/kg) may be of some benefit in treating ingested zinc phosphide.

Additional Information Lethal dose may be as little as 4 g, although survival of ingestions up to 100 g has occurred. Symptoms may occur at 10 ppm. Monitor for phosphine gas from GI fluids of affected patients; keep patient's room well ventilated. Rotten fish odor at 1-3 ppm. Less corrosive than white phosphorus

SECTION III
BIOLOGICAL AGENTS

GENERAL CONSIDERATIONS REGARDING EXPOSURES TO BIOLOGICAL AGENTS

Anthony M. Burda, RPh, CSPI, DABAT and Carol Ann DesLauriers, PharmD, CSPI

Some of the most interesting and challenging poisonings for the toxicologist or specialist in poison information are exposures to biological agents. Included in this category are a myriad of naturally occurring chemical toxins, alkaloids, venoms, and microbial contaminants. Representative sources for these biologicals are plants, fungi (mushrooms), spoiled or tainted food (food contamination), venomous fish (fish stings), insect/spider bites and stings, and reptile/snake envenomations.

The incidence and significance of biological intoxications can be illustrated through data extracted from the 2004 annual report of the American Associations of Poison Control Centers Toxic Exposure Surveillance System (TESS). See following table. Data reported to TESS in 2004 were compiled from 62 poison control centers.

Frequency and Outcomes of Human Exposures to Biologicals						
Biological	2004 Exposures	No Effect	Minor Effect	Moderate Effect	Major Effect	Death
Fish stings	2,814	84	739	252	7	0
Food contamination	69,915	5,672	12,537	2,517	82	1
Insect/spider bites/stings	79,020	1,133	18,101	4,577	138	2
Mammal bites	6,653	296	1,613	312	6	0
Mushroom ingestion	8,601	3,769	1,094	848	59	5
Plant exposures	74,811	14,982	6,278	1,442	80	5
Snake and other reptile bites	8,313	293	3,011	1,793	187	3
Other/unknown bite or envenomation	463	5	145	43	2	0
Total	250,590	26,234	43,518	11,784	561	16

Adapted from Watson WA, Litovitz TL, Rodgers GC Jr, et al, "2004 Annual Report of the American Association of Poison Control Centers Toxic Exposure Surveillance System," *Am J Emerg Med*, 2005, 23(5):589-666.

Out of 2,438,644 human exposure cases in 2004, 250,590 involved poisonings with biological agents. Therefore, it is significant to note that 10.3 percent of all poisoning episodes handled by clinicians involved a substance in this group. Accordingly, it is incumbent upon physicians and poison control center specialists to be familiar with toxicity and treatment approaches.

Although the incidence of these poisonings is high, morbidity and mortality are low. Only 5 percent of the outcomes reported had a moderate or major outcome. Fatalities were rare with only 16 reported deaths. This figure accounts for only 1.35 percent of the 1,183 fatal cases reported to TESS in 2004.

It should also be pointed out that TESS data is largely comprised of ingestions of small quantities of both toxic and nontoxic specimens by pediatric patients. For instance, a large number of pediatric "tastes" of nontoxic houseplants (eg, spider plant, jade, etc.) far outnumber the more serious poisonings such as the adult foraging for mushrooms for food.

There are at least five important considerations for the clinician managing an exposure involving a biological substance: identification of the poison, quantification of the dose, lack of specific laboratory analysis, lack of specific antidotes, and use of nonmedical consultants. Although these potential problems may add to the complexities of patient management, they are by no means insurmountable. Patient management may be enhanced when available resources are combined with consultations with the nearest regional poison control center and skilled toxicologist. The designated regional poison control center can be reached via the toll-free national hot line, 1-800-222-1222.

Identification of the Poison

In many cases of unintentional poisoning or intentional overdose, the identification of the offending medication or chemical can be determined with little difficulty. An accurate patient or family history, over-the-counter and

prescription bottles retrieved from the scene, ingredient listings on containers, or a material safety data sheet (MSDS) on file at the work site can provide immediate identification of the substance(s) involved.

When triaging exposures involving biological agents, however, the above methods of identification may be of little or no value. Plants, mushrooms, spiders and snakes are not conveniently tagged with their unique botanical, mycological, or zoological nomenclature. Accurate identification may hinge on a combination of piecing together a fragmented exposure history, recognizing a constellation of signs and symptoms as a particular toxidrome, and/or utilizing the expertise of a nonhealthcare professional such as a botanist or mycologist.

Consider the problem of substance identification inherent in each of the following scenarios:

- A small child arrives home to admit he/she “ate a small handful of those little red berries on a bush out in the prairie.”
- A mother calls to state that her toddler ingested a few bites of a household plant she can best describe as “green and has leaves.”
- The weekend trail hiker clad in shorts and sandals who arrives in the ED after being bitten by a snake but was too stunned to recall any pertinent identifying characteristics.
- The amateur mushroom picker who experiences cramping, vomiting, and diarrhea one hour after consuming his gatherings with no intact specimens which would allow you to compare the mushrooms to ones pictured in reference manuals or online.
- An adult who presents with a necrotic lesion on the leg several days after being bitten or stung by an unknown insect while sleeping in a basement apartment.
- An otherwise healthy adult complains of gastritis and malaise after dining out at a restaurant buffet. Suspected causes may include, but not be limited to, *Salmonella* in poultry, a seafood toxin, *Staphylococcus* in a creamed dressing, a food additive, or preservative, *Clostridium perfringens* in a gravy, or a drug-alcohol interaction.

Quantification of a Dose

In most cases of exposure to biological agents, the exact dose of the offending agent may never be known. Marked variation exists inter- and intra-species, between geographic or structural location, and even seasonally. Under these circumstances, the severity of the event is best judged by the nature and extent of the signs, symptoms, or laboratory abnormalities.

The following are a few examples:

- It may be well documented that a small child ingested exactly six unripe Black Nightshade (*Solanum nigrum*) berries. It is unknown how many milligrams of solanine alkaloid comprised the actual ingested dose.
- In some instances of exposure, the dose involved may be zero. For instance, a person may show fang marks as proof of a rattlesnake bite yet show no local or systemic toxicity, since approximately 20 percent of all snake bites are described as “dry bites.”
- With regard to food-borne microbial toxins, quantification may be performed in some laboratories (ie, public health departments). This process is slow, not routinely ordered, and is of little clinical value in treating individual cases of food poisoning.
- Individual susceptibility may play a major role in determining a response to a given dose of biological agent. For example, several people may be exposed to dusts and pollens of the common chrysanthemum flowers (*Chrysanthemum morifolium*). However, only one may require ED treatment to correct bronchospasm and wheezing secondary to hypersensitivity to the naturally occurring pyrethrum in the plant.

Nonspecificity of Laboratory Analysis

When a patient exposed to a biological agent presents to a healthcare facility, rapid laboratory analysis to identify and quantify the agent is not readily available. In these cases, treatment plans will be influenced by exposure history, clinical presentation, and other laboratory indices. These considerations taken together will give a much clearer picture of the severity of the exposure and development of a reasonable patient plan.

Examples where nonspecific laboratory tests are valuable in the monitoring and management of patients exposed to biological agents are:

- Serial serum potassium measurements and continuous EKG monitoring in ingestions of Oleander (*Nerium oleander*), a cardiac glycoside-containing plant
- Frequent coagulation profiles and CBCs following Crotalinae snake envenomation
- Frequent liver and kidney function tests following ingestion of death cap (*Amanita phalloides*), a cyclopeptide-containing mushroom
- A stat CBC, electrolytes, and urinalysis in evaluating a debilitated food poison patient
- Platelet count, PT, PTT, BUN, and creatinine in suspected bites of the brown recluse (*Loxosceles reclusa*) spider

Few Specific Antidotes

Few specific antidotes exist to treat exposures to biological agents. In a vast majority of these cases, close observation and conservative symptomatic and supportive care are the mainstays of therapy.

A majority of exposures to biologicals, especially those originating from the home environment, can be safely handled with calm reassurance and simple over-the-counter remedies such as:

- The BRATT diet with glucose/electrolyte solutions for mild food poisoning cases
- Application of ice and antipruritics (eg, diphenhydramine, hydrocortisone, or benzocaine) for non-venomous insect bites and stings
- Antiseptics and wound care for nonpoisonous snake bites
- Home observation and telephone follow-up for ingestion of mouthful amounts of lawn mushrooms
- Antihistamines (eg, diphenhydramine) may ameliorate mild histamine reactions (flushing, pruritus, headache, and palpitations) associated with scombroid fish poisoning

A few notable antidotes for biologic toxins do exist. Their use is generally reserved for serious and life-threatening poisoning incidents. Examples of these antidotes are:

- Rattlesnake or pit viper (polyvalent Crotalidae; polyvalent immune fab, Crofab[®]) antivenin
- Eastern coral snake (*Micrurus fulvius*) antivenin (Note: No antivenin for Arizona coral snake [*Micruoides euryxantus*])
- Black widow spider (*Latrodectus mactans*) antivenin
- Botulism (trivalent types A, B, and E) for botulism (*Clostridium botulinum*)
- Physostigmine for severe anticholinergic complications from Jimson Weed (*Datura stramonium*) or Deadly Nightshade (*Atropa belladonna*)
- Pyridoxine for neurologic symptoms due to ingestion of monomethyl hydrazine mushrooms like the false morel (*Gyromitra esculenta*)
- Atropine to reverse cholinergic symptoms due to ingestion of muscarine-containing mushrooms like the Inocybe
- Digoxin-specific Fab fragments to reverse toxicity associated with Oleander (*Nerium oleander*) and Foxglove (*Digitalis purpurea*) plant poisoning
- Although more of an infectious disease issue, various antimicrobial agents may be indicated for specific illnesses attributed to food-borne pathogens (eg, sulfamethoxazole/trimethoprim in cases of shigellosis and ampicillin with gentamicin for severe cases of listeriosis).

Hospital pharmacies affiliated with regional poison control centers may serve as antidote depots. Rarely used antidotes such as antivenin along with guidelines for their usage are available on a 24-hour basis. If a particular pharmaceutical is not stored in the center, referrals for emergency access from other sources such as pharmaceutical companies, zoos or aquariums can be quickly made.

Need for Nonmedical Consultants

In providing optimal care to the patient poisoned by more commonly encountered medications and chemicals, the clinician may call upon the services of a number of other medical consultants. Biological intoxications are unique in that identification of the toxic specimen may require consultation with nonmedical professionals. Accordingly, these professionals and scientists are located in diverse nonhealthcare facility settings such as museums, zoos, aquariums, arboretums, botanical gardens, greenhouses, florist shops, universities, cooperative extension services, and mycological societies.

Consider the indispensable value of the expertise rendered by a nonmedical consultant in the following scenarios:

- a herpetologist to identify an unknown snake
- a mycologist to identify an unknown mushroom
- an entomologist for insect identification
- a botanist to identify an unknown wild plant specimen
- a florist or horticulturist to identify an unknown household plant

Regional poison control centers often maintain updated consultant files and are an excellent source for these referrals. To expedite the identification of specimens, consultants may rely on the Internet through digital imaging and e-mail.

Until such time as the biological specimen is identified precisely, the poison control center can formulate a management strategy. The treatment regimen can then be modified once the accurate identification of the substance is made.

MANAGEMENT OF PLANT EXPOSURES

Edward P. Krenzelok, PharmD, FAACT, DABAT and Terry D. Jacobsen, PhD, FLS

The toxicity of some plants has been recognized and feared for millennia. Historically, plant toxins have played important roles in ancient medicine and politics. As testimony, the Ebers Papyrus, which has origins to 1600 BC, contains hundreds of prescriptions and concoctions, many containing toxic plants as the primary ingredients. The infamous death of Socrates in 399 BC is attributed to ingestion of a beverage laced with poison hemlock.¹ Ancient Romans allegedly assassinated political adversaries through the use of poisonous plants. History has painted a nefarious picture of various plants, and when considered with the gross distortions about the toxicity of some botanicals, plant exposures are often regarded as being indiscriminately associated with significant morbidity and mortality. However, plant exposures are associated only rarely with a fatal outcome - only 19 fatalities in nearly one million reported plant exposures!²

Plant exposures, as reported to poison information centers, are common, accounting for 4.4% of all exposures. Following are the 15 most common human exposures.³

The 15 Most Common Human Exposures

1. Analgesics
2. Cleaning substances
3. Cosmetics and personal care products
4. Sedatives/hypnotics/antipsychotics
5. Foreign bodies
6. Topicals
7. Cough and cold preparations
8. Antidepressants
9. Pesticides
10. Bites/envenomations
11. Plants
12. Alcohols
13. Cardiovascular drugs
14. Antihistamines
15. Food products, food poisoning

Plants are ubiquitous, being found both indoors and outdoors. Their presence in every aspect of society influences the large number of exposures reported to poison information centers. Furthermore, their beautiful foliage, enticing berries, and mystical qualities attract both young children and adults. Young children sample their environment due to curiosity and excessive hand-to-mouth activity, resulting in the ingestion of a plant. Adults are intrigued by the use of plants, especially herbs, as alternatives to traditional medicine. (See Herbal Agents section.) Additionally, adults may boldly sample the roots or other parts of unidentified plants as food sources. The majority of exposures involve children younger than 6 years of age.

The following list identifies the most common plant exposures.⁴ The presence of a plant on this list does not suggest that it is associated with significant toxicity. However, to paraphrase Paracelsus, "everything is poisonous, only the amount differentiates a poison from a remedy," and this idiom should be considered in the evaluation of each plant exposure. It is most important not to become complacent with plant exposures, since a limited number of plants are associated with significant morbidity and rare, but sobering mortality. A discussion of outcomes and toxicity following exposure to common plants is included, as well as a discussion of plants that are likely to produce adverse outcomes.

The 20 Most Common Plant Exposures in the U.S.³

1. Peace lily (*Spathiphyllum* spp)
2. Holly (*Ilex* spp)
3. Philodendron (*Philodendron* spp)
4. Poinsettia (*Euphorbia pulcherrima*)
5. Pokeweed, inkberry (*Phytolacca americana*)

6. Poison ivy (*Toxicodendron radicans*)
7. Rubber tree, weeping fig (*Ficus* spp)
8. Nightshade, Jerusalem cherry (*Solanum* spp)
9. Apple, crabapple (plant parts) (*Malus* spp)
10. Christmas cactus (*Schlumbergera bridgesii*)
11. Jade plant (*Crassula* spp)
12. Oleander (*Nerium oleander*)
13. Pothos, devil's ivy (*Epipremnum aureum*)
14. Chrysanthemum (*Chrysanthemum*) spp
15. Caladium (*Caladium* spp)
16. Dumbcane (*Dieffenbachia* spp)
17. English ivy (*Hedera helix*)
18. Cactus (*Cactus* spp)
19. Dandelion (*Taraxacum officinale*)
20. Lilyturf (*Liriope muscari*)

Most plant exposures that involve the ingestion route are not associated with the development of any symptoms. A review of 768,284 plant ingestions revealed that only 6.9% of patients became symptomatic.⁵ The most common symptom group categories were:

Gastrointestinal	63.7%	Respiratory	3.9%
Dermatological	16.9%	Cardiovascular	2.0%
Neurological	5.0%	Other	4.5%
Ophthalmological	4.0%		

Pitfalls

There are numerous pitfalls that challenge the clinician who is concerned about potential plant toxicity or is treating acute toxicity from exposure to plants.

Many of the frightening stories about the precipitous demise of individuals who consumed water from a vase that contained lily of the valley, roasted wieners on oleander sticks, consumed apple seeds, swallowed a poinsettia leaf, etc, are unsubstantiated. However, these myths have been perpetuated in "authoritative" textbooks, leading to undue concern, aggressive therapy, and inappropriate hospitalization.

Proper identification of a plant is the key to prognosis, therapy, and preventing unnecessary treatment. However, identification of the botanical is often difficult. The patient who attempts to describe a plant over the telephone is rarely successful, unless the clinician has exceptional knowledge about the flora of a particular region. Even having an actual sample of the plant (often dried and traumatized) in the office or emergency department presents a significant identification challenge. There are several ways to resolve the issue if a sample is available. Place the plant sample in water (if possible) to restore its natural appearance. The local floral shop or nursery may be able to assist in the identification. Consider sending a fax or pdf of the plant leaves to a poison information center. County agricultural agents are an excellent resource, especially for the identification of outdoor plants. Those fortunate enough to have botanists available at a local university may have an arrangement to assist in the identification of plants. However, if a patient is asymptomatic and there is no implication that the plant may be very toxic, such as water or poison hemlock, ultimate identification is unnecessary and only expends resources unnecessarily.

Ideally, each cultivated plant should be labeled with its botanical name. For example, *Euphorbia pulcherrima* is the botanical name for poinsettia, which is also known as the Christmas flower and Christmas star. Knowing the botanical name will direct the poison center specialist or the botanist to the correct toxicology information. Common names are often regional and a single common name may be associated with several different botanical species, leading to the other dissemination of incorrect information. To further confound the identification process, hundreds of imported exotic plants are available commercially. The botanical name may not be known and the same plant may have numerous common names.

Treatment

The majority of plant exposures can be managed with the proverbial “glass of milk for the child and a tincture of reassurance for the parent.” Few exposures will require gastrointestinal decontamination or the use of a pharmacological antagonist such as digoxin immune Fab or physostigmine. Therefore, the general management of plant exposures will be addressed in this section since it is applicable to most plant exposures and specific antidotal therapy will be discussed only as necessary.

Most plant exposures are ingestions and terminating further exposure to the plant will limit the potential for toxicity. Careful removal of clothing that may be contaminated with poison ivy or other plant residue can prevent the development of problems. Removing any visible plant debris from the victim’s (usually a child) mouth is adequate intervention in most patients. While there is no evidence to support the use of oral irrigation or dilution with a beverage, they are customary therapies. Dilution with cool fluids may relieve the irritating sensation or disagreeable taste associated with some plants. The placebo effect of dilution should not be overlooked. Similarly, perioral and other dermal exposures may respond to gentle cleansing with soap and water. Rashes and dermatitis may develop and the use of nonprescription hydrocortisone-containing lotion, ointment, or cream may have palliative effects.

The majority of plant ingestions are accidental, involving exposure to small amounts. This makes the use of gastrointestinal decontamination unnecessary. Additionally, several other factors make the use of gastrointestinal decontamination of limited value. Of primary importance is the fact that gastrointestinal decontamination procedures have not been proven to have any impact on morbidity and mortality of the poisoned patient (“AACT/EAPCCT Position Statements on Gastrointestinal Decontamination,” *J Toxicol Clin Toxicol*, 1997, 35:695-762). Secondly, the intentional ingestion of plants for abuse purposes or self-harm are the incidents that have the highest morbidity. Like most intentional poisonings, there is a significant delay in the time from the ingestion to when treatment is sought. Delays decrease the efficacy of gastrointestinal decontamination. Activated charcoal must come in contact with the toxin to be absorbed. It is unlikely that toxins distal to the stomach can be “caught” by activated charcoal. Therefore, most therapy is supportive care to manage the occasional adverse sequelae that may develop.

Ipecac-Induced Emesis

Ipecac Syrup. Induced emesis has no role to play in the management of toxic plant ingestions. There are no available data that demonstrate a reduction in poisoning morbidity or mortality from the induction of emesis.^{6,7} If morbidity or mortality are anticipated, immediate referral to an emergency department is advised.

Gastric Lavage

Gastric lavage has no demonstrated utility in the management of plant exposures. The delay from ingestion to decontamination therapy may result in gastric emptying, moving the toxic plant from the stomach to the small intestine, and making it nonretrievable. Plant debris may consist of large fragments which are too large for removal via the gastric lavage tube. This is especially true in the pediatric population, where small bore lavage tubes are used. However, there are no data which demonstrate the effectiveness of gastric lavage in the management of plant poisonings.⁸

Activated Charcoal

Many alkaloids and derivatives are known to be adsorbed by activated charcoal. If a plant toxin is adsorbed by activated charcoal, its absorption will be reduced and subsequent toxicity limited or eliminated. However, activated charcoal efficacy is limited by the delay in the institution of therapy. Activated charcoal must come in contact with the toxin to be effective. It does not have the ability to “catch” the toxic plant unless the toxic components of the plant are subject to enterohepatic circulation or enteroenteric secretion. These characteristics have not been elucidated for most plants; therefore, multiple dose activated charcoal therapy is of hypothetical use only. If activated charcoal is used to manage a patient with actual or potential plant poisoning, 25-50 g may be administered as aqueous activated charcoal to children and 50-100 g to adults. Be cognizant that commercial activated charcoal products are slurries and not suspensions. Therefore, the products must be agitated vigorously for at least 30 seconds prior to administration. The container should be rinsed repetitively with small amounts of water to ensure that the entire contents of the container have been administered. Only aqueous activated charcoal should be used. Products that contain a fixed dose of sorbitol are especially hazardous to very young children and should not be used in children or adults.^{9,10}

Cathartics

Cathartics used alone or in combination with activated charcoal have no role in the management of plant poisoning exposures or in any type of poisoning case.¹¹

Whole Bowel Irrigation

There may be some limited value of whole bowel irrigation in the management of patients who have ingested large quantities of plant material, especially seeds which may not have rapid bioavailability. Beyond such special circumstances, whole bowel irrigation has little utility in the treatment of plant ingestion patients.¹²

Common Plant Exposures

- Philodendron* species** (heartleaf philodendron, parlor ivy) and ***Dieffenbachia* species** (Dumbcane, mother-in-law's tongue)

Philodendron and *Dieffenbachia* species account for approximately 10% of the reported plant exposures and are members of the family Araceae.¹³ As such, they share common toxins and accordingly, common manifestations of toxicity.¹⁴

The sap and morphological parts (stems, leaves, etc) of the plant contain calcium oxalate crystals, aromatic amines, alkaloids, and proteolytic enzymes.¹⁵ When a portion of the plant is chewed by a curious child, toxicity may be induced both mechanically and chemically. Raphides of calcium oxalate may be fired into oral mucosa when idioblasts are physically disrupted via chewing.^{15,16} The mechanical injury of tissues allows the secondary entry of irritants such as proteolytic enzymes. The net effect is irritation and inflammation.¹⁵⁻¹⁸ Hence, the common name "Dumbcane" for *Dieffenbachia* reflects the acute oral inflammation (inability to speak = dumb) which may occur after biting into the "cane" or stalk of the *Dieffenbachia*.

There is documented support of a cause:effect relationship between exposure to *Philodendron*/*Dieffenbachia* species and toxicity.¹⁴⁻²⁰ However, the villainous reputation of these plants is greatly exaggerated and not justified. A review of nearly 97,000 exposures to *Philodendron*/*Dieffenbachia* species demonstrated clearly that moderate and major toxicity were rare.¹³ Overall, *Philodendron* exposures are associated with a lower incidence of adverse effects.⁴ This may be secondary to the presence of less calcium oxalate or there may be differences which are related to chemical constituents and proteolytic enzymes. Minor irritation may occur in up to 10.5% of *Philodendron* exposure patients and 24.5% of those exposed to *Dieffenbachia* species, but it is rare for the irritation to justify referral to an emergency department.⁴ *Epipremnum aureum* (pothos, devil's ivy, golden pothos) is also a member of the family Araceae and often confused with the *Philodendron*. It should be considered to have the same toxic principles.

There is no merit to using gastrointestinal decontamination procedures unless an inordinate amount of plant material has been ingested as in an intentional event. Most importantly, any visible plant debris should be removed from the oral pharynx. Dilution with a cold beverage is used customarily and may soothe irritation in symptomatic patients. Symptomatic patients may also respond to sucking on ice or a popsicle.
- Euphorbia pulcherrima*** (Poinsettia, Christmas flower, Christmas star)

A 1920 publication by JF Rock in a Hawaiian journal catapulted *Euphorbia pulcherrima*, most commonly referred to as the poinsettia, into the limelight as being one of the most poisonous plants in the world.²¹ Allegedly, a 2-year-old child had a fatal outcome after ingesting a portion of a poinsettia plant. Botanical and medical texts used this unconfirmed incident to perpetuate the poinsettia as a sinister plant. The lay press and even the Food and Drug Administration sensationalized the poinsettia as a botanical villain with statements like "one poinsettia leaf can kill a child."²² However, neither animal studies nor human case reports have substantiated the claims of significant morbidity and mortality – exonerating the poinsettia from being labeled as a truly poisonous plant in the category with water and poison hemlock. Research conducted in animals where poinsettia doses of up to 50 g/kg were ingested failed to reveal significant toxicity.²³⁻²⁵ This is supported by the analysis of 22,793 human exposures where there were no fatalities and only 3% of patients developed minor toxicity.²² The latex sap which exudes from damaged leaves may produce dermal irritation.²⁶ Dermal exposures to poinsettia may produce a slightly higher incidence of irritation than that experienced by individuals who have oral exposures or ingestions.²²

The ingestion of poinsettia does not require gastrointestinal decontamination and removal of plant debris from the mouth is adequate intervention. Skin irritation, although uncommon and usually minor, may be prevented by washing the exposed area(s) with soap and water.

- ***Capsicum annuum*** (pepper, chili pepper, hot pepper, Christmas pepper, cayenne, jalapeño)
 There are very few plants which produce acute toxicity. *Capsicum annuum* is one of the exceptions and is associated with very common manifestations – extreme irritation to the skin, mucous membranes, and even the gastrointestinal tract due to peristaltic effects. The generic name is aptly attributed to and is derived from a Greek word meaning “I bite.”²⁷ While peppers of the *Capsicum* genus are used primarily in Southwestern and Mexican-style cooking, they must not be confused with the table pepper which is a spice derived from the berry of *Piper nigrum* and not related phylogenetically.²⁷
 The peppers in genus *Capsicum* contain capsaicin which is extremely irritating. As testimony to its irritant properties, the oleoresin extracted from *Capsicum* is the major ingredient in “pepper gas,” which is used for personal protection and by law enforcement officials as a way to immobilize temporarily an assailant by spraying the pepper gas into the eyes. Handling peppers can produce discomforting irritation which is often spread to the face, eyes, and mouth via the hands. Children are especially vulnerable since they may develop dermal irritation resulting in crying, which leads to ocular irritation as the child wipes tears from her eyes. While the dermal irritation may be intense, the development of blisters is rare.
 There are many suggested panaceas to remedy the intense irritation – most of which are of little or no value. Multiple washing of the skin with soap and warm water is probably the best intervention. Immersion of the affected skin in cold water may provide short-term relief, but does not remove the source of the problem.²⁸ The use of a vinegar/water solution has been proposed, but not supported enthusiastically.²⁹ Soaking the affected skin in vegetable oil is thought to provide relief of longer duration than the sole use of cold water.²⁸ Severe dermal pain may necessitate the use of topical anesthetics to ameliorate the discomfort.³⁰ Prolonged ocular irrigation may provide some relief in patients with eye exposures.
- ***Ilex species*** (holly, English holly, European holly, Christmas holly, American holly, emetic holly)
 American holly (*Ilex opaca*) and English holly (*Ilex aquifolium*) are outdoor plants that have green rigid leaves and bright red berries. These colorful plants are common components of Christmas holiday centerpieces and other decorations. The bright red berries are enticing to small children and result in a high incidence of holiday exposures.
 Holly was once thought to be highly toxic, rivaling some of the most poisonous plants. Ilicin and saponins may produce gastrointestinal irritation, but the profound toxicity which included central nervous system depression and life-threatening hematemesis appears to be without foundation.³¹ In one series assessing the toxicity of 21,675 *Ilex* species exposures, only 4.4% of the patients developed minor symptoms and 0.11% had moderate effects.³² There were neither major sequelae nor fatalities. The ingestion of multiple berries does not usually produce toxic manifestations unless the berries are chewed, resulting in nausea, vomiting, cramping, and diarrhea.³¹ Since the leaf tips are spine-like, mechanical irritation may develop. One member of the genus, *Ilex vomitoria*, as its botanical name suggests, has potent emetic properties. It is differentiated easily from American and English hollies since it has a different leaf structure and the berries are usually yellow. Exposures to this species are uncommon.
 Most exposures require no intervention. However, patients, especially children, who ingest a large quantity of berries may benefit from the use of activated charcoal. While unlikely to occur, excessive emesis or diarrhea may necessitate fluid and electrolyte replacement.
- ***Crassula argentea*** (jade plant, dwarf rubber plant, rubber plant, cauliflower ears)
 This is a very popular houseplant and there is no documented evidence that it is associated with toxicity. However, the size and semirigid nature of the leaves make the ingestion of this plant a possible esophageal or airway obstruction hazard in small children.
- ***Ficus species*** (fig, weeping fig)
 Several *Ficus* species are common houseplants. In general, they should be considered to be relatively nontoxic. Some species of the genus may exude a sap that is capable of causing dermatitis. However, this is a rare manifestation. Washing affected areas with soap and water should provide adequate intervention for dermal exposures.

- ***Toxicodendron* species** (poison ivy, poison oak, poison sumac)
Poison ivy is probably the most well-known of all poisonous plants. Its notoriety is well-attested to by the tens of thousands who experience its classic toxic effect – dermatitis. Although the toxicity of poison ivy is appreciated universally, most people are unable to identify the plant, which is characterized by a three leaf cluster. Further complicating the identification process is the ability of poison ivy to grow as a climbing, woody, opportunistic vine or as a shrub of varying proportions. Like *Capsicum annuum*, poison ivy and the other *Toxicodendron* species are associated with a high incidence of toxicity following exposure. Unlike *Capsicum* species, the toxicity is delayed for periods of hours up to 2 weeks and not everyone develops a sensitivity reaction after exposure. Examination of nearly 19,000 exposures to *Toxicodendron* species revealed that at least 70% of individuals who reported their exposure to a poison center became symptomatic.⁴ The pruritic, erythematous, and vesicular rash which develops is caused by a phenolic oily resin. The resin persists even in dead foliage and vines. Burning dead plant material, which contains a *Toxicodendron* species, volatilizes the resin and makes it bioavailable for inhalation and extensive dermal exposure. Most individuals are not aware of the exposure until they become symptomatic. Therefore, dermal decontamination is of little or no value unless the exposure is repetitive by wearing clothing that has been contaminated with the sensitizing resin. The resin fixes rapidly to the skin and washing with soap and water may be of value only if instituted within the first 5-10 minutes after exposure. Barrier creams are thought to be of little or no value. The use of cool compresses and topical steroids may relieve the symptoms. Patients with extensive dermatitis or systemic involvement may have a dramatic response to oral or parenteral corticosteroids. The use of oral antihistamines may relieve the pruritus. Barrier creams are available commercially and may help to prevent an exposure and the resultant dermatitis.
- ***Phytolacca* species** (poke, pokeweed, pokeberry, scoke, inkberry, pigeonberry, poke salet)
This genus contains the well-known species *Phytolacca americana*, commonly referred to as poke. The toxic principles are triterpene saponins and a variety of mitogens.³³ This plant is considered to be a delicacy. The young leaves and stems are soaked in salt water and then undergo successive cookings, each time in fresh water.³³ Allegedly, this eliminates the toxins, which is a matter of some contention. Contrary to popular opinion, most patients do not become symptomatic after a modest exposure to poke. Analysis of 17,773 reported poke exposures yielded minor toxic effects in 5.8% and moderate toxicity in 0.4%.⁴ No major toxic effects were reported and there were no fatalities. The primary manifestations of ingestion are gastrointestinal effects, which may include abdominal cramping, nausea, vomiting, and diarrhea. Fluid and electrolyte imbalance may occur if vomiting and diarrhea are severe. Headache may develop and the symptom complex can persist for 48 hours. There is not concurrence as to what constitutes a toxic exposure to poke. The ingestion of small amounts is unlikely to be associated with toxic effects. Soap and water decontamination should be considered for dermal exposures.
- ***Brassaia actinophylla*** (schefflera, umbrella plant, umbrella tree, Australian ivy palm, queens umbrella tree)
This plant is known commonly as the schefflera or umbrella tree. The exact nomenclature status of schefflera is in flux and it may appear in the literature or on plant labels as either *Schefflera actinophylla* or *Brassaia actinophylla*. It is native to Australia, but it thrives as a houseplant. Along with *Euphorbia pulcherrima*, *Crassula argentea*, and *Ficus* species, this plant should be considered to be relatively nontoxic. *Brassaia actinophylla* contains a small amount of calcium oxalate in its leaves.³⁴ However, this should not be regarded as being a clinically significant amount. Although rare, contact dermatitis has been reported.³⁵ The ingestion of a small amount of this plant should be regarded as a nontoxic exposure. Dermatitis is a rare event, but simple decontamination with soap and water may eliminate that possibility.

Selected Plants with Known Morbidity and Mortality

As illustrated by the most common plant exposures, most plant exposures are not associated with significant toxicity. However, there are a notable few that have the potential to produce significant toxicity, even death. Most patients who suffer severe toxicity or who have a fatal outcome are those who ingested large amounts of plant material intentionally for substance abuse or with suicidal intent. The ingestion of a small amount by a child is not usually associated with any morbidity.

- ***Datura species*** (jimson weed, Jamestown weed, angel's trumpet, moon flower, thornapple, stinkweed, La Reina del la Noche)
Datura stramonium and *Datura meteloides* are commonly referred to as jimson weed. All parts of jimson weed contain the belladonna tropine alkaloids, such as atropine, hyoscyamine, and scopolamine. Jimson weed, especially the seeds, is abused for the psychoactive effects of the belladonna alkaloids. Hallucinogenic effects are sought, but the anticholinergic toxidrome (tachycardia, fever, dry mouth, confusion, etc) also develops when hallucinogenic amounts are used. The majority of abusers are 17-18 years of age and most recover with conservative therapy.^{2,36,37} Gastrointestinal decontamination is of little value since the patient rarely presents for therapy until becoming symptomatic, suggesting that substantial absorption has occurred. Patients with severe anticholinergic poisoning may require the administration of the cholinesterase inhibitor physostigmine.³⁶ However, physostigmine should not be used prophylactically or injudiciously since it is not without its own toxic effects. A retrospective study of 17 individuals who were self-poisoned by jimson weed revealed that neither the administration of physostigmine nor the use of gastric lavage decreased the need for intensive care or the duration of hospitalization.^{37,38}
- **Lethal hemlocks** (water hemlock, poison hemlock)
Conium maculatum (poison hemlock) and *Cicuta maculata* (water hemlock) were responsible for 7 of the 19 plant-related fatalities that occurred from 1985-1994.² This is a relatively high fatality rate since the total number of reported exposures was only 582.² Most of the fatalities are the result of improper identification of these plants. The roots are mistaken as being wild carrots or parsnips and when consumed in sufficient quantity, grave toxicity develops.
Conium maculatum contains coniine which is a peripheral neurotoxin that produces curare-like effects on neuromuscular junctions and nicotinic effects on autonomic ganglia.³⁹⁻⁴² The toxidrome consists of ascending skeletal muscle hypotonia or flaccidity that can progress to paralysis of the respiratory musculature. Initial effects may include sialorrhea, nausea, vomiting, abdominal cramps, and diarrhea followed by gastrointestinal hypotonia and dry mouth.⁴¹
The toxicity from *Cicuta maculata* ingestion is attributed to cicutoxin. The toxic effects of cicutoxin are more morbidly impressive and violent than those from coniine.⁴²⁻⁴⁶ Early muscarinic effects are localized to the gastrointestinal tract.^{44,46} Systemic muscarinic effects (bronchial secretions) leading to respiratory distress may occur. However, pathognomonic of severe cicutoxin poisoning are violent multiple major motor seizures.⁴²⁻⁴⁶ The symptoms may begin within 30 minutes after ingestion.⁴⁶
Gastrointestinal decontamination with activated charcoal may be beneficial in patients with recent ingestions. Otherwise, the cornerstone of therapy is aggressive supportive care.
- ***Nerium oleander*** (oleander, rosebay, rose laurel)
Nerium oleander is the subject of considerable folklore concerning fatal poisoning in children who ingested hot dogs cooked on an oleander branch. This report surfaces frequently and results in profound anxiety among those who treat oleander exposures. While that anecdote has not been confirmed, there are numerous reports that describe oleander poisoning in humans.⁴⁷⁻⁵¹ *Nerium oleander* contains cardiac glycosides, similar in pharmacological activity to digitalis glycosides. However, nearly all of the serious cases involved the intentional ingestion of *Nerium oleander* as an herbal tea for medicinal use or for self-harm.⁴⁷⁻⁴⁹ Symptoms typical of digitalis poisoning that may develop include gastrointestinal, cardiac arrhythmias, and hyperkalemia. The unintentional ingestion of a small amount by a child does not mandate gastrointestinal decontamination. Large ingestions, usually intentional, may necessitate the use of aggressive gastrointestinal decontamination. Serious oleander poisoning may respond to the use of digoxin immune Fab, since the oleander and digitalis glycosides are similar structurally.^{50,51} *Nerium oleander* should not be confused with *Thevetia peruviana*, commonly referred to as yellow oleander. *Thevetia peruviana* has been associated with serious cardiovascular toxicity and numerous fatalities. While it is cultivated in North America, it is not a common North American oleander.

Ackee Fruit Food Poisoning

Scientific Name *Blighia sapida*

Commonly Found In

Unripe ackee fruit in Jamaica (introduced in 1778), West Africa, Central America, South Florida, southern California, and Hawaii

Mechanism of Toxic Action Contains hypoglycin A and B which are CNS depressants and inhibit fatty acid oxidation; incubation period: 6-48 hours (can be as short as 2 hours)

Signs and Symptoms of Overdose Symptoms may be delayed 6-48 hours (can be as short as 2 hours); overdose can lead to seizures(31%) and coma; hypokalemia may occur; hypothermia, hypoglycemia (19%), vomiting (97%), loss of consciousness (43%)

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission. Asymptomatic patients may be discharged after 6 hours of observation.

Overdosage/Treatment

Decontamination: Do not utilize ipecac; activated charcoal may be useful
Supportive therapy: Intravenous fluids/electrolyte replacement including glucose

Treat seizures with benzodiazepines.

In a single report, methylene blue (to stimulate hepatic gluconeogenesis) along with riboflavin have been used to treat encephalopathy.

Antidote(s)

- Dextrose [ANTIDOTE]

Diagnostic Procedures

- Electrolytes, Blood
- Glucose, Random

Additional Information

Also known as "Jamaican vomiting sickness"; incidence in the Caribbean is estimated at 1:1000 persons/year; ingestion usually occurs at breakfast or lunch

Hypoglycin is water soluble. A pear-shaped fruit with a leathery, straw-colored to brightly red capsule with a bright yellow inner coating; emanates from a 40 foot tree. It is the unripe fruit and seeds that are most toxic. The unripe fruit is toxic even if cooked. The fruit first appears in the trees in winter (December to March).

Specific References

Joskow R, Belson M, Vesper H, et al, "Ackee Fruit Poisoning: An Outbreak Investigation in Haiti 2000-2001, and Review of the Literature," *Clin Toxicol*, 2006, 44:267-73.

Acorns

Scientific Name *Quercus* species

Mechanism of Toxic Action Contains tannic acid, an astringent that precipitates proteins; at least partially metabolized to gallic acid

Signs and Symptoms of Overdose Abdominal pain, bloody diarrhea, constipation, hemorrhagic colitis, possible kidney and liver damage, nausea, vomiting

Toxicodynamics/Kinetics Absorption: Peak absorption of tannic acid solutions has been reported as 2-3 hours

Overdosage/Treatment

Decontamination: Induction of vomiting is controversial, vomiting may be appropriate for large ingestions; activated charcoal and cathartics may also be of value

Supportive therapy: As needed

Additional Information Toxic dose in humans has not been established

Aloe

Pronunciation (AL oh)

Scientific Name *Aloe vera*

Synonyms Aloe Vera

Uses For topical use only; irritant dermatitis, minor burns, roentgen dermatitis

Mechanism of Toxic Action

Contains barbaloin (a glycoside of anthraquinone origin); also contains tannins, emodin, and volatile oils, as well as bradykinase (a protease inhibitor)

Adverse Reactions

Central nervous system: Catharsis

Dermatologic: Contact dermatitis (allergic)

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Diarrhea, abdominal cramps

Renal: Albuminuria, proteinuria, hematuria (may cause red discoloration of urine)

Contraindications Known hypersensitivity to aloe

Warnings Do not use in eyes

Dosage Forms Gel; 4 oz

Overdosage/Treatment Supportive care: Replace gastrointestinal fluid with I.V. or oral fluids

Pregnancy Risk Factor C

Specific References

Lee A, Chui PT, Aun CS, et al, "Possible Interaction Between Sevoflurane and Aloe Vera," *Ann Pharmacother*, 2004, 38(10):1651-4.

Amaryllis

Related Information

- Star-of-Bethlehem (*Hippobroma longiflora*)
- Star-of-Bethlehem (*Ornithogalum pyrenaicum*)

Mechanism of Toxic Action Contains lycorine (an *Amaryllidaceae* alkaloid), a centrally acting emetic

Adverse Reactions Dermatologic: May cause dermatitis

Signs and Symptoms of Overdose Symptoms develop soon after oral ingestion (within 30 minutes) and resolve within 3 hours (according to one report); abdominal pain, diarrhea, nausea, salivation, vomiting

Overdosage/Treatment Decontamination: Ipecac relatively contraindicated, may be useful, if given soon after ingestion; vomiting has not occurred with ingestion of more than one bulb; activated charcoal with cathartic/lavage (within 1 hour) may be beneficial depending on amount ingested and time elapsed since ingestion

Additional Information All parts contain alkaloid. Toxic part: Bulb is most toxic

Angel's Trumpet

Scientific Name *Brugmansia saulevelii*; *Datura saulevelii*

Uses As a hallucinogen; often brewed as tea

Mechanism of Toxic Action Contains as much as 0.65 mg scopolamine and 0.2 mg atropine in each blossom, thus producing central anticholinergic activity; also contains hycosamine. All parts of the plant are toxic.

Adverse Reactions

Cardiovascular: Tachycardia

Central nervous system: Hyperthermia, agitation, coma, delirium, hallucination (auditory and visual)

Gastrointestinal: Xerostomia

Genitourinary: Urinary retention

Neuromuscular & skeletal: Hyperreflexia, seizures, clonus

Ocular: Mydriasis

Signs and Symptoms of Overdose Paralysis or seizures noted after ingestion of >6 flowers (a lethal dose). Symptoms usually develop within 10 minutes after tea ingestion and 3 hours after leaf ingestion. Tea from ~5 flowers can produce symptoms within 1 hour. Hallucinations may last for 4 days. Mydriasis may last for several days. Usual recovery time: 48-72 hours.

Overdosage/Treatment

Decontamination: Oral: Lavage within 2 hours if >3 flowers are ingested. Activated charcoal may be useful.

Supportive therapy: Physostigmine (1-4 mg I.V.) has been used in life-threatening cases.

Additional Information Indigenous to South America, Australia, and Florida. A perennial shrub or small tree up to 15 feet tall, with white, pendulous, trumpet-shaped flowers up to 1 foot long. Found as an ornamental bush in low elevations in the tropics.

Specific References

Centers for Disease Control and Prevention (CDC), "Suspected Moonflower Intoxication - Ohio, 2002," *MMWR Morb Mortal Wkly Rep*, 2003, 52(33):788-91.

Anthrax

Scientific Name *Bacillus anthracis*

Commonly Found In A disease of herbivores (sheep, goats, cattle, pigs); primarily found in Africa and Asia; also may be a biological warfare agent

Mechanism of Toxic Action A gram-positive sporulating rod which contains a lethal toxin (a metalloprotease) and an edema toxin (which inhibits phagocytosis). The lethal toxin also causes lysis of macrophages and induces release of tumor necrosis factor and interleukin 1.

Signs and Symptoms of Overdose Three forms:

Cutaneous anthrax: Spores gain entry through broken skin. Disease develops 2-5 days postexposure. Starts as a nonpainful papule which over 1-2 days becomes vesicular with localized surrounding edema. The vesicle generally ruptures in 1 week, thereby creating an ulcer which progresses to a black eschar. The eschar falls off in ~2-3 weeks. Fever, headache, and painful lymphadenopathy may also occur.

Fatality rate for cutaneous anthrax is 5% to 20% in untreated patients and 1% in treated patients. Systemic manifestation may occur in 5% to 20% of patients.

Gastrointestinal anthrax: Spore-contaminated meat is ingested and invasion in the terminal ileum or cecum can occur. Disease manifests itself in 2-5 days with severe abdominal pain, bloody vomitus and stools (melena), massive ascites, and copious, watery diarrhea. Oropharynx ulcers and lymphadenopathy (cervical) may develop.

Inhalation: Inhaled spores are taken up by macrophages and transported to hilar and mediastinal lymph nodes where germination occurs. Incubation is 1-6 days. Low-grade fever, nonproductive cough, diaphoresis, and myalgias initially occur followed abruptly by respiratory distress, bacteremia, sepsis, shock, and death. Chest x-ray typically reveals widened mediastinum and pleural effusions. Meningitis with subarachnoid hemorrhage may also occur in up to 50% of patients.

Admission Criteria/Prognosis Any inhalation or gastrointestinal exposure or symptomatic patient.

Overdosage/Treatment

Decontamination:

Dermal: Thoroughly wash exposed skin and clothing with soap and water.

Gastrointestinal or inhalation exposure: High-dose intravenous penicillin G (4 million units every 4 hours) is the drug of choice. Alternative agents include ciprofloxacin (400 mg I.V. every 12 hours) or doxycycline (100 mg every 12 hours). Antibiotics should be given for 60 days; pediatric dosage is 20-30 mg/kg of ciprofloxacin I.V. divided into two daily doses not to exceed 1 g/day. For children <45 kg, 2.2 mg/kg doxycycline I.V. every 12 hours can also be used. For children younger than 12 years of age, penicillin G 50,000 units/kg I.V. every 6 hours is optimal therapy if strain is susceptible. Early mechanical ventilation, vasopressors, and correcting electrolyte imbalances can help improve survival.

Cutaneous anthrax can be treated with oral antibiotics (fluoroquinolones, tetracycline, or amoxicillin) for 2 months. Short courses of prophylactic antibiotics delay but do not prevent disease.

Contained Casualty Setting Inhalational Anthrax - Recommended Therapy:

Children:

Initial I.V. therapy¹:

Ciprofloxacin 10-15 mg/kg every 12 hours. **Note:** Oral ciprofloxacin may be acceptable, if I.V. ciprofloxacin is not available, because it is rapidly and well-absorbed from the GI tract without substantial first-pass metabolism loss. After oral dosing, maximum serum concentration is attained in 1-2 hours, except in the presence of vomiting or ileus. Maximum dose should not exceed 1 g/day.

or

Doxycycline: **Note:** Doxycycline may be less optimal in suspected meningitis due to poor CNS penetration. Serious infections (eg, Rocky Mountain spotted fever) in young children should be treated with tetracyclines (American Academy of Pediatrics recommendation).

- >8 years (>45 kg): 100 mg every 12 hours
- >8 years (≤45 kg): 2.2 mg/kg every 12 hours
- ≤8 years: 2.2 mg/kg every 12 hours

and

1-2 additional microbials:²

Duration: Initial: I.V..³

Ciprofloxacin 10-15 mg/kg every 12 hours (dosage should not exceed 1 g/day),

or

Doxycycline:

- >8 years (>45 kg): 100 mg twice daily
- >8 years (≤45 kg): 2.2 mg/kg twice daily
- ≤8 years: 2.2 mg/kg twice daily

Continue oral and I.V. treatment for 60 days due to potentially persistent spores following aerosol exposure.

Adults:

Initial I.V. therapy¹: Ciprofloxacin 400 mg every 12 hours, or, doxycycline, 100 mg every 12 hours (doxycycline may be less optimal with suspected meningitis, due to poor CNS penetration), and, 1-2 additional antimicrobials.²

Duration: Initial: I.V..³: Ciprofloxacin 500 mg twice daily or doxycycline 100 mg twice daily. Continue oral and I.V. treatment for 60 days due to potentially persistent spores following aerosol exposure.

Pregnant women⁴: Same for nonpregnant Adults

Initial I.V. therapy: Same as Adults.

Duration: I.V. treatment initially before switching to oral antimicrobial therapy when clinically appropriate (ciprofloxacin and doxycycline should be considered essential first-line therapy). Oral regimens are the same as Adults.³

Immunocompromised individuals: Same as Children and Adults.

¹ For patients with severe edema and for meningitis (based on experience with bacterial meningitis of other etiologies) steroids may be considered as adjunct therapy.

² Other agents with *in vitro* activity include rifampin, vancomycin, penicillin, ampicillin, chloramphenicol, imipenem, clindamycin, and clarithromycin. Penicillin and ampicillin should not be used alone due to possible constitutive and inducible β-lactamases in *Bacillus anthracis*. Infectious disease consult is advised.

³ Initial I.V. therapy may be adjusted based upon the clinical course, prior to switching to oral antimicrobial therapy when appropriate (1-2 antimicrobial agents may be adequate with clinical improvement).

⁴ Tetracyclines may be indicated for life-threatening illness (even in pregnant women). Adverse effects on developing teeth and bones are dose-related; thus, doxycycline may be used briefly (7-14 days) before 6 months of gestation. A high death rate from infection outweighs the risk associated with the antimicrobial agent.

Mass Casualty Setting or Postexposure Prophylaxis Inhalational Anthrax - Recommended Therapy: (Some of the following recommendations are not FDA approved, but are based on *in vitro* and animal studies.)

Oral:

Children:

Initial¹: Ciprofloxacin 20-30 mg/kg/day in 2 daily doses; do not exceed 1 g/day.

Alternative (if proven susceptible strain):

Weight ≥20 kg: Amoxicillin 500 mg every 8 hours³

Weight <20 kg: Amoxicillin 40 mg/kg in 3 doses every 8 hours³

Adults:

Initial¹: Ciprofloxacin 500 mg every 12 hours

Alternative (if proven susceptible strain):

Doxycycline 100 mg every 12 hours. Based on *in vitro* studies, tetracycline 500 mg every 6 hours could be substituted; the fluoroquinolones gatifloxacin and moxifloxacin have mechanisms of action consistent with ciprofloxacin and could be substituted.

Amoxicillin 500 mg every 8 hours³

Duration: 60 days after exposure

Pregnant women:

Initial¹: Ciprofloxacin 500 mg every 12 hours

Alternative (if proven susceptible strain): Amoxicillin 500 mg every 8 hours³

Duration: 60 days after exposure

Immunosuppressed individuals: Same as for Children and Adults

¹ Ofloxacin 400 mg orally every 12 hours or levofloxacin 500 mg orally every 24 hours could be substituted for ciprofloxacin (based on *in vitro* studies).

² If use of ciprofloxacin is precluded (eg, adverse reactions, antibiotic susceptibility testing, or exhausted drug supply), doxycycline adult dosage (for weight >45 kg) can be used. For children weighing <45 kg, doxycycline 2.5 mg/kg orally every 12 hours can be used.

³ Amoxicillin is suitable for postexposure prophylaxis only after 10-14 days of fluoroquinolone or doxycycline treatment and only if these two classes of medications are contraindicated (eg, pregnancy, lactation, intolerance to other antibiotics, age <18 years) per CDC recommendations.

Cutaneous Anthrax Associated with Bioterrorism - Recommended Therapy¹:

Oral:

Children: **Note:** Young children should be treated with tetracyclines for serious infections (eg, Rocky Mountain spotted fever), according to the American Academy of Pediatrics.

Initial²:

Ciprofloxacin 10-15 mg/kg every 12 hours; do not exceed 1 g/day

or

Doxycycline:

- >8 years (>45 kg): 100 mg every 12 hours
- >8 years (≤45 kg): 2.2 mg/kg every 12 hours
- ≤8 years: 2.2 mg/kg every 12 hours

Duration: 60 days³

Adults:

Initial²: Ciprofloxacin 500 mg twice daily or doxycycline 100 mg twice daily

Duration: 60 days³

Pregnant women:

Initial^{2,4}: Ciprofloxacin 500 mg twice daily or doxycycline 100 mg twice daily.

Duration: 60 days³

Immunocompromised individuals: Same as Children and Adults.

¹ Signs of systemic involvement, extensive edema, or head/neck lesions require I.V. therapy and a multidrug approach. See Contained Casualty Setting - Recommended Therapy.

² First-line therapy should be ciprofloxacin or doxycycline. If fluoroquinolone or tetracycline class drugs cannot be taken, amoxicillin can be substituted: Children: Amoxicillin 80 mg/kg orally divided into 3 doses at 8-hour increments can be used for completion of therapy following clinical improvement. Adults: Amoxicillin 500 mg orally 3 times a day. The need to achieve appropriate minimum inhibitory drug concentration is the basis for oral amoxicillin dosage.

³ Sixty days is recommended for bioterrorism-related attacks due to the likelihood of aerosolized *Bacillus anthracis* exposure (previous guidelines suggest 7-10 days of treatment for cutaneous anthrax).

⁴ Tetracyclines or ciprofloxacin may be indicated for life-threatening illness, though they are not recommended during pregnancy. Adverse effects on developing teeth and bones are dose-related; thus, doxycycline could be used briefly (7-14 days) before 6 months of gestation.

Additional Information

Can be cleared to work in research laboratory 3 weeks after 3rd anthrax vaccine dose (0.5 mL SubQ) with annual booster dose after 18 months

Toxic dose: Inhalation: 4000-80,000 spores
 Industrial processing of animal hair accounted for 153 (65%) of 236 anthrax cases reported to the CDC from 1955-1999. While most of these cases were cutaneous anthrax, 10% were inhalation anthrax.

- Methods to prevent inhalation anthrax from animal hide/hair exposure:
- Work with hides that are tanned or treated (air drying does not destroy *B anthracis* spores)
 - Regular hand washing with soap and warm water
 - Wearing durable protective gloves
 - Working in a well-ventilated workplace
 - Spores can be inactivated by heating hides to an internal temperature of 158°F (70°C) or placement in boiling water for over 30 minutes
 - Remove clothing before leaving workplace and launder
 - Clean workplace with high-efficiency particulate air vacuum
 - Avoid vigorous shaking or beating hides

Diagnosis of Inhalational Anthrax:

Sudden appearance of several cases of severe acute febrile illness with fulminant course and death; or acute febrile illness in those identified as at-risk following a specific attack.

Widened mediastinum, infiltrates, and pleural effusion on chest radiograph. Hyperdense hilar and mediastinal nodes, mediastinal edema, infiltrates, and pleural effusion on chest CT scan. Hemorrhagic pleural effusions on thoracentesis.

Gram-positive bacilli on peripheral blood smear. Growth of large Gram-positive bacilli with preliminary identification of *Bacillus* species on blood culture.

Pathology findings of hemorrhagic mediastinitis, hemorrhagic thoracic lymphadenitis, and hemorrhagic meningitis. DFA stain of infected tissues.

Anthrax vaccine adsorbed (AVA) product (obtained from Michigan Department of Public Health) is given at 0, 2, and 4 weeks and 6, 12, and 18 months with yearly boosters (at a dose of 0.5 mL subcutaneously). Two doses may be protective against inhalation exposure. Overall efficacy for cutaneous anthrax is 92.5%. Protective masks should be capable of filtering 1-5 µm particles (U.S. military current M17 and M40 gas masks). Standard blood cultures can grow out organisms in 6-24 hours.

Patients who progress to the fulminant phase have a mortality rate of 97% (regardless of the treatment they receive).

Interim Guidelines for Evacuation and Personal Decontamination of Workers After a Positive Autonomous Detection System (ADS) Signal Indicates Presence of a Biologic Agent	
Worker Category	Evacuation / Decontamination Procedures
Group 1. Workers who did not enter the production area containing the ADS device during the sampling and testing period (eg, 1.5 hours) before the positive ADS signal and who were not in an area that shares a heating, ventilating, and air conditioning (HVAC) system with the production area experiencing the positive signal	Evacuate; no special decontamination steps are needed
Group 2. All workers who were present in the production area containing the ADS device during the sampling and testing period before the positive ADS signal or who were in an area that shares an HVAC system with the production area experiencing the positive signal.	<ul style="list-style-type: none"> ● Evacuate immediately ● Remove potentially contaminated outer garments at the site ● Wash all areas of skin (eg, face, arms, hands, and legs) exposed at the time of the positive ADS signal with mild soap and copious amounts of warm water ● Use replacement outer garments and shoes
Group 3. Workers identified in advance as particularly at risk of exposure to a higher concentration of deposited spores as a result of direct physical contact with aerosol-generating equipment	<ul style="list-style-type: none"> ● Evacuate immediately ● Remove potentially contaminated garments at the site ● Take a shower at the site to wash all areas of exposed and unexposed skin with mild soap and warm water ● Use replacement outer garments, underwear, and shoes

Adapted from Meehan PJ, Rosenstein NE, Gillen M, et al, "Responding to Detection of Aerosolized *Bacillus anthracis* by Autonomous Detection Systems in the Workplace," *MMWR*, 2004, 53(RR07):1-12.

Apple

Scientific Name *Malus sylvestris*
Mechanism of Toxic Action Fruit contains up to 17% pectin and pectic acids; seeds contain amygdalin which is a cyanogenic glycoside
Adverse Reactions Dermatologic: Immunologic contact urticaria
Signs and Symptoms of Overdose Apple seed ingestion: Acidosis, anorexia, ataxia, coma, cyanosis, dizziness, hypotension, tachypnea, vomiting (may be the initial symptom), weakness
Admission Criteria/Prognosis Admit any ingestion > 50 seeds

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic; **do not** induce emesis; a 25% solution of sodium thiosulfate (300 mL in adults) can be instilled in the stomach following lavage

Supportive therapy: Administer high flow oxygen; cyanide antidote kit should be administered for symptomatic or acidotic patients; sodium bicarbonate (1-2 mEq/kg) should be administered to treat acidosis

Antidote(s)

- Cyanide Antidote Kit [ANTIDOTE]

Additional Information A deciduous tree with white or pink flowers; apple seeds contain ~0.61 mg of hydrogen cyanide per gram of seed (Average lethal dose of cyanide: Oral: Adult: ~50 mg).

Apricot

Scientific Name *Prunus armeniaca*

Mechanism of Toxic Action Amygdalin (a cyanogenic glycoside) is hydrolyzed in the gut to release hydrocyanic acid, cellular hypoxia occurs after absorption and complexation with cytochrome oxidase

Adverse Reactions

Cardiovascular: Cyanosis
Central nervous system: Lethargy, drowsiness, headache, coma, seizures
Gastrointestinal: Abdominal pain, vomiting
Neuromuscular & skeletal: Paralysis
Respiratory: Dyspnea
Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Symptoms delayed 30 minutes to 2 hours or longer due to hydrolysis preferentially occurring in alkaline duodenum, plus intestinal flora hydrolyzing amygdalin

Admission Criteria/Prognosis All symptomatic patients should probably be admitted to an intensive care unit for 1-2 days; asymptomatic patients should be observed for at least 2 hours and then can be discharged; survival after 4 hours (in an acute exposure) is usually associated with recovery

Overdosage/Treatment

Decontamination: Basic poison management; vomiting is contraindicated due to rapid course of the neurologic symptoms; give 100% oxygen
Supportive therapy: Give sodium bicarbonate for acidosis; cyanide antidote kit should be used for patients symptomatic from cyanide toxicity
Enhancement of elimination: Hemodialysis and charcoal hemoperfusion have been utilized; hyperbaric oxygen may also be utilized; hydroxocobalamin and dicobalt-EDTA used for chelation in Europe

Antidote(s)

- Cyanide Antidote Kit [ANTIDOTE]

Diagnostic Procedures

- Anion Gap, Blood
- Cyanide, Blood
- Electrolytes, Blood
- Methemoglobin, Blood

Additional Information Toxic dose: 1-2 pits likely nontoxic; toxicity unusual with accidental ingestion. Amygdalin is also found in leaves, flowers, bark, seeds; young leaves have highest concentration; intact pit does not release chemical; apricot most toxic within species. Cyanide content in apricot kernels ranges from 0.122-4.09 mg/g.

Aristolochic Acid

CAS Number 313-67-7; 61117-05-3

Commonly Found In Herbal preparations (*Aristolochia Fang Chi*) and in plants in the family *Aristolochia*, a perennial herb which grows in forests. The dried rhizome and roots are the active parts. The herbal products have been used in Europe for weight reduction.

Mechanism of Toxic Action The alkaloids aristolochic acid I and aristolochic acid II can produce acute tubular necrosis and are carcinogenic/mutagenic through metabolite binding [7-(deoxyadenosine-N⁶Oyl)-aristolactam I DNA adduct] in the renal system.

Signs and Symptoms of Overdose Mean period of usage for development of renal toxicity is 13.3 months. Hypertension, interstitial renal (cortical) fibrosis (also called Chinese herb nephropathy and possibly Balkan nephropathy), metabolic acidosis (with renal failure), reversible hepatitis, tachycardia, urothelial carcinoma

Admission Criteria/Prognosis Admit any patient with renal or electrolyte abnormalities.

Overdosage/Treatment Supportive therapy: Treat acidosis with intravenous sodium bicarbonate (1-2 mEq/kg). Prednisolone 1 mg/kg for 1 month tapering off 0.1 mg/kg every 2 weeks may slow progression of renal disease. Avoid alkalinizing the urine, since renal toxicity may increase.

Additional Information Fatal acute I.V. dose: 2 mg/kg

Arizona Bark Scorpion

Scientific Name *Centruroides sculpturatus*

Mechanism of Toxic Action Neurotoxin which is heat stable; neurotoxin increases sodium transfer

Adverse Reactions

Cardiovascular: **Sinus tachycardia** (92%), arrhythmias (ventricular); sudden death (7%)

Respiratory: Bronchospasm, laryngospasm, pulmonary edema (especially in children)

Signs and Symptoms of Overdose Abnormal ocular movements (33% to 58%), agitation (5% to 59%), ataxia, AV block, blurred vision, dysphagia (4% to 33%), fasciculations, hyperglycemia, hypersalivation (21% to 35%), hyperreflexia, hypertension (33%), hyperthermia, myoclonus, pain, pain at site of bite (19% to 70%), paresthesia (8% to 53%), restlessness, salivation, seizures, slurred speech, stridor, sweating, tachycardia, tachypnea, vomiting

Grading for *Centruroides sculpturatus* envenomation:

Grade I: Local pain and/or paresthesia

Grade II: Pain and/or paresthesias remote from envenomation site with local signs present

Grade III: Either cranial nerve or somatic skeletal neuromuscular dysfunction

Grade IV: Both cranial nerve and somatic skeletal neuromuscular dysfunction

Admission Criteria/Prognosis Admit symptomatic patients; rapid progression within 4 hours indicates poor prognosis; survival after 2 days usually associated with recovery

Toxicodynamics/Kinetics Onset of symptoms: Within 1 hour

Overdosage/Treatment

Decontamination: Pressure tourniquet (50-70 mm Hg) to slow systemic absorption on affected limb; apply cold packs to bite area

Supportive therapy: Antivenom from goat serum (I.V.); propranolol or phentolamine can be used for hypertension; bradycardia can respond to atropine. Steroids are probably not useful. Prazosin (0.125 mg in children and 0.5 mg in adults) may also be useful in treating hypertension. Seizures can initially be treated with benzodiazepines; phenobarbital can be utilized for refractory seizures. Hyperthermia can be treated with tepid water sponge bathing and acetaminophen. For grade III or IV envenomations, a midazolam bolus of 0.3 mg/kg (maximum 2 mg in children) followed by, if necessary, a continuous I.V. infusion of 0.1 to 0.3 mg/kg/hour, can be used for treatment. Atropine can be used to treat excessive oral secretions. Prazosin (1 mg every 6 hours) can assist in resolution of significant sympathetic symptoms (ie, hypertension).

Antivenin is available from the Good Samaritan Poison Center in Phoenix, Arizona (602-253-3334); available in Arizona only.

Antidote(s)

- *Centruroides* Scorpion Venom Antisera [ANTIDOTE]

Drug Interaction Avoid phenothiazines in that they can lower the seizure threshold

Additional Information Antivenom dose is one vial; give second vial at 1 hour if symptoms not improved; allergic effects can occur. An arthropod with two body segments and eight legs. The long, segmented abdomen terminates into a curved tail (the stinging apparatus). Claw-like pincers anteriorly are characteristic features.

Asparagus (Berries and Young Shoots)

Scientific Name *Asparagus officinalis*

Adverse Reactions

Dermatologic: Pruritus, vesiculation
Gastrointestinal: GI irritation, GI upset

Signs and Symptoms of Overdose Allergic dermatitis after repeated exposure; berries may cause GI irritation

Overdosage/Treatment

Decontamination: Wash thoroughly
Supportive therapy: Treat symptoms

Atlantic Mussel Food Poisoning

Commonly Found In Shellfish, mussels

Mechanism of Toxic Action Toxin involves domoic acid structurally similar to glutamate which can cause neuronal necrosis in the amygdaloid nucleus and hippocampus; incubation period: 5 hours

Adverse Reactions Central nervous system: Memory disturbances

Signs and Symptoms of Overdose Bronchorrhea, diarrhea, facial grimacing, nausea, short-term memory loss. Long-term anterograde memory loss (10%), GI cramping, vomiting. Onset of GI signs ranges from 15 minutes to 38 hours; onset of neurological signs occurs within 2 days. Can cause headache, hypotension, myoclonus, piloerection, and seizures

AZALEA

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment

Decontamination: Avoid ipecac; activated charcoal with cathartic may be used; lavage (with isotonic bicarbonate solution) within 1 hour may be useful

Supportive therapy: Diazepam or phenobarbital is useful for seizures, fluids for hypotension

Test Interactions Can result in elevated serum creatinine

Additional Information Toxic Dose: Probably >60 mg orally. Heat stable toxin which is not destroyed by cooking; neurologic symptoms may be more pronounced in the elderly; domoic acid activates glutamate receptors thus causing seizures; mortality rate: 2%. Found in North Atlantic, Pacific coast, and Gulf of Mexico; Canadian standards for domoic acid in mussels is 20 mcg/100 g of tissue

Azalea

Related Information

- Rhododendron

Scientific Name *Rhododendron nudiflorum*

Mechanism of Toxic Action Contains grayanotoxin which binds to a subset of sodium channels causing structural modifications which cause slow opening of these channels which leads to cell depolarization

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose Asthenia, bradycardia, dermatitis, hypotension, nausea, oral numbness or burning, paresthesia, sweating, seizures, transient blindness, visual changes, vomiting

Overdosage/Treatment

Decontamination: Avoid ipecac, vagal stimulation increases toxicity; lavage (within 1 hour)/activated charcoal with cathartic

Supportive therapy: Atropine for bradycardia, I.V. fluids should be sufficient for hypotension

Antidote(s)

- Atropine [ANTIDOTE]

Additional Information Three whole leaves or flowers likely nontoxic; consider decontamination if more. Toxicity is unpredictable, variable among rhododendron types. Toxic part: Whole plant is toxic, especially foliage; contaminated honey may cause systemic symptoms

Bacillus cereus Food Poisoning (Type I and II)

Commonly Found In Fried rice (Type I), cereals (Type II), vegetables (Type II), milk (Type II), meat (Type II), turkey (Type II)

Mechanism of Toxic Action

Type I: Heat and pH stable toxin; incubation period: 1-6 hours (emetic form)

Type II: Heat labile enterotoxin; incubation period: 10-12 hours (diarrheal form)

Signs and Symptoms of Overdose Fever is uncommon

Type I: Vomiting is prominent, abdominal cramps and diarrhea can occur

Type II: Watery diarrhea, abdominal cramps; can cause more volume depletion than Type I

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment *Bacillus cereus* food poisoning does not respond to antimicrobial therapy. Attention should instead be focused on supportive measures such as hydration and electrolyte balance. Clinically significant infections with this organism should be treated with vancomycin intravenously. Unlike other *Bacillus* species (eg, *Bacillus alvei*, *B. subtilis*, *B. circulans*, etc), *Bacillus cereus* is often resistant to beta-lactam antibiotics such as the penicillins and cephalosporins. Vancomycin should be used until the antimicrobial susceptibility pattern is finalized; limited data suggests the addition of an aminoglycoside to vancomycin may have some minor benefit in serious infections. Due to high biliary levels of the emetic toxin, multiple dosing of activated charcoal may be effective.

Diagnostic Procedures

- Electrolytes, Blood
- Stool Culture

Additional Information

Microbiology: *Bacillus cereus* is an aerobic, gram-positive bacillus associated with a variety of disease states including food poisoning, ocular infections, bacteremia, and septicemia. *Bacillus cereus* is a spore-forming aerobic which stains gram-positive or gram-variable. It grows readily on standard laboratory media and does not need special culturing techniques.

Epidemiology: *Bacillus cereus* is ubiquitous in the environment, growing readily in such diverse areas as soil, water, vegetables, decaying matter, and dust. In certain individuals, it can be part of the normal

human flora, explaining in part its tendency to colonize surgical wounds and serious burn injuries. The needles and syringes of heroin addicts in the United States have also been found to be contaminated with this bacterium. *Bacillus cereus* food poisoning, caused by ingestion of a toxin elaborated by this organism, has been reported from several countries around the world, including the United States and Canada.

Clinical Syndromes:

● **The "emetic form" of *Bacillus cereus* food poisoning:** This results from the ingestion of a preformed toxin produced by this organism. Nausea, vomiting, and abdominal cramping usually occur soon (1-6 hours) following the ingestion of contaminated foods. In particular, this emetic toxin has been associated with fried rice served in Chinese food restaurants. The spores of *B. cereus* can survive the process of boiling rice followed by quick frying. Fulminant liver failure has been described.

● **The "diarrheal form" of *Bacillus cereus* food poisoning:** This results from ingestion of a different, heat-labile enterotoxin. The incubation period is longer than for the emetic form, usually more than 9 hours. Profuse watery diarrhea is the predominant symptom, along with abdominal cramping.

Diagnosis: *Bacillus cereus* is readily identified in the laboratory from cultures of blood and other sterile body fluids. In cases of suspected *Bacillus* food poisoning, the implicated foods should be cultured for this organism. There is little benefit in culturing the patient's stool since GI tract colonization is not uncommon. As mentioned previously, isolation of *Bacillus cereus* from the blood need not be treated in every case, and clinical judgment is required.

Baneberries

Scientific Name *Actaea alba*; *Actaea arguta*; *Actaea pachypoda*; *Actaea rubra*

Mechanism of Toxic Action GI is unclear; dermatitis is contact type; protoanemonin reacts with SH groups and inactivates enzymes

Adverse Reactions

Cardiovascular: Sinus tachycardia

Dermatologic: Dermatitis and vesiculation may occur

Ocular: Conjunctivitis

Signs and Symptoms of Overdose Bloody diarrhea, circulatory failure, confusion, dizziness, dysuria, gastroenteritis, headache, hematuria, oral irritation, seizures, tachycardia, visual hallucinations

Admission Criteria/Prognosis Patients who are persistently symptomatic three hours postexposure should be admitted

Toxicodynamics/Kinetics

Onset of effect: Oral: Within 30 minutes

Duration: Dermal: May take several weeks to resolve. Oral: Within 3 hours

Overdosage/Treatment

Decontamination: Ipecac relatively contraindicated due to rapid onset of symptoms, lavage within 1 hour recommended in large ingestion; activated charcoal with cathartic may be beneficial; **do not** give cathartic if diarrhea has developed

Supportive therapy: Maintain hydration and electrolyte balance; hydration also decreases protoanemonin concentration in urine; for dermal, wash thoroughly; antihistamine and corticosteroid therapy as indicated; monitor fluid and electrolyte status

Additional Information Oral symptoms of pain and burning usually limit potential for systemic toxicity. Toxic part: Root, berries, and sap

Bird of Paradise

Mechanism of Toxic Action Seeds contain tannins, leaves may contain hydrocyanic acid

Signs and Symptoms of Overdose Diarrhea, dizziness, drowsiness, GI irritation, vomiting

Toxicodynamics/Kinetics

Onset of effect: Within 30 minutes

Duration: Within 24 hours

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage within 1 hour recommended if asymptomatic and more than small amount ingested

Supportive therapy: Fluid and electrolyte replacement as needed

Additional Information Toxic dose: Ingestion of 5 seed pods has caused poisoning. Not a cyanide risk. Toxic part: Seeds, pods, leaves, and roots

Black Locust

Scientific Name *Robinia pseudoacacia*

Mechanism of Toxic Action Ricin, a toxalbumin inhibits protein synthesis

Adverse Reactions In addition to vomiting and diarrhea, late phase toxicity due to cytotoxic effects on liver, CNS, kidney, and adrenal system

Signs and Symptoms of Overdose Acutely causes irritation to oropharynx, esophagus, and GI tract; may cause hemorrhage and tissue sloughing

Toxicodynamics/Kinetics Acute effects occur within 8 hours; late phase complications delayed by 2-5 days possibly with asymptomatic phase in between

Overdosage/Treatment

Decontamination: Activated charcoal may be useful; consider using osmotic cathartic despite hyperactive bowel as decreased exposure to mucosa may be beneficial, follow fluid and electrolyte status closely if symptomatic; if symptomatic, maintain high urine flow; consider alkalization to prevent hemoglobin crystallization in severe poisonings; guaiac emesis, stool, follow fluid and electrolyte status; check hematologic parameters in severe poisoning, hepatic enzymes

Additional Information Toxicity may occur with as little as one bean. Toxicity is variable; related to variations within plants and GI absorption, seed has hard coat; rupture makes toxin available; symptomatic patients should be hospitalized; asymptomatic patients that have received early thorough decontamination may be observed at home. Honey locust is nontoxic. Toxic part: Bark, seeds, and leaves are toxic

Black Mustard

Related Information

- Black Pepper

Scientific Name *Brassica nigra*

Uses Often used as a spice or seasoning agent; it is currently illegally sold in the U.S. as a mustard oil. Also used as a folk remedy for upset stomach.

Mechanism of Toxic Action Contains ~1% sinigrin (a thioglycoside) which is converted upon contact with water to isothiocyanate, a volatile compound which is a severe irritant.

Signs and Symptoms of Overdose Adult respiratory distress syndrome, airway edema, aspiration, cough, dyspnea, hypoxemia, irritant contact dermatitis, pneumonitis

Overdosage/Treatment

Dermal: Irrigate with soap and water.

Supportive: Pulmonary support may be necessary (supplemental oxygen, intubation, ventilator, inhaled beta₂-agonists).

Black Nightshade

Related Information

- Deadly Nightshade

Scientific Name *Solanum americanum*; *Solanum nigrum*

Mechanism of Toxic Action Contains toxic alkaloids; some plants may also contain alpha-cholinergic alkaloids

Adverse Reactions Central nervous system: Psychosis

Signs and Symptoms of Overdose Anticholinergic effects may or may not be present to varying degrees; asthenia, diarrhea, drowsiness, fever, headache, hallucinations, nausea, sweating, visual changes, vomiting

Toxicodynamics/Kinetics Toxicity occurs within 2-24 hours, diarrhea may last 3-6 days, anticholinergic effects may delay GI emptying and produce delayed effects

Overdosage/Treatment

Decontamination: Ipecac if vomiting has not already occurred, lavage (within 1 hour) and/or charcoal may be beneficial if the patient presents symptomatic

Supportive therapy: Maintain fluid and electrolyte balance as necessary, support vital signs; physostigmine will reverse anticholinergic toxicity that may be associated with exposure; intravenous physostigmine can be useful in treating anticholinergic toxicity

Antidote(s)

- Physostigmine [ANTIDOTE]

Drug Interaction Solanine poorly absorbed, delayed decontamination may be effective

Additional Information Toxic dose: 2-3 green berries or 6 red or black berries should not cause significant toxicity (fatal dose reported as: 200 berries). Toxicity may be mistaken for food poisoning; plants may also contain varying amounts of anticholinergic alkaloids. Toxic part: Green or yellow berries more toxic than red or black

Black Pepper

Related Information

- Black Mustard

Scientific Name *Piper nigrum*

Uses Spice/seasoning agent

Mechanism of Toxic Action Dried, unripe fruit contains 5% to 9% piperine (a volatile oil) which is a potent irritant.

Signs and Symptoms of Overdose Adult respiratory distress syndrome, airway edema, aspiration, cough, diaphoresis, dyspnea, hypoxemia, pneumonitis

Overdosage/Treatment

Decontamination: **Inhalation:** Administer 100% humidified oxygen.

Ocular: Irrigate with saline

Additional Information A vine native to southern India and Sri Lanka.

Black Widow Spider

Scientific Name *Latrodectus mactans*

Mechanism of Toxic Action Contains a highly neurotoxic venom which destroys cholinergic and adrenergic nerve terminals; also increases calcium permeability of the nerve terminal, thus resulting in acetylcholine release

Adverse Reactions

Cardiovascular: Hypertension, myocarditis

Dermatologic: Target lesions, erythema, edema, toxic epidermal necrolysis, urticarial rash

Genitourinary: Priapism, urinary retention

Hematologic: Leukocytosis

Neuromuscular & skeletal: Fasciculations, muscle weakness, paresthesia, peripheral neuropathy

Ocular: Ptosis

Renal: Pyuria, proteinuria, microscopic hematuria

Respiratory: Respiratory arrest

Miscellaneous: Lymphadenopathy, diaphoresis

Signs and Symptoms of Overdose

The initial bite may be sharply painful or unrecognized; possible papule or punctum on exam, with surrounding skin slightly erythematous and indurated. Within 30-60 minutes of the bite, however, involuntary spasm and rigidity affect the large muscle groups of the abdomen and limbs. Abdominal pain (15% to 50%), dyspnea, fever (10% to 15%), headaches (5% to 25%), hyperreflexia, hypersalivation, nausea, ptosis, tachypnea, tachycardia, vomiting

Abdominal rigidity without specific tenderness is characteristic of envenomation. Mortality rate is ~5% (patients in the extremes of age groups or individuals with pre-existing hypertension are especially susceptible). Death is usually due to cardiovascular collapse.

Admission Criteria/Prognosis Admit any patient in respiratory distress; with cardiovascular symptoms (including hypertension); protracted pain; pediatric or elderly patients, pregnancy or cardiac history. Hospitalization is usually required for known black widow spider bite. Recovery usually occurs within 1 week; fatalities are exceedingly rare.

Overdosage/Treatment

Decontamination: Wound care including tetanus prophylaxis; pain and muscle spasm may be managed initially with calcium gluconate 10% solution at 10 mL/dose; may start calcium infusion; mean calcium dose is 1.4 g

Antivenin is available and should be reserved for cases involving respiratory arrest, seizures, uncontrolled hypertension, or pregnancy; usual therapeutic dose: I.V. infusion: 1-2 vials. Monitor for anaphylactoid reactions due to horse serum protein in the antivenom. Pretreatment with SubQ epinephrine 1:1000 (0.01 mL/kg or 0.01 mg/kg; maximum: 0.3 mL) is suggested.

Treatment dose of antivenom: I.V.: 2.5 mL (1 vial) in 50-100 mL of D₅W or normal saline infused over ~20-30 minutes

Administration of a second vial is considered for individuals who weigh > 40 kg or for patients who do not respond to the first dose within 1 hour.

Supportive therapy: Alternative muscle relaxants including methocarbamol or benzodiazepines do not appear to be as effective as calcium for pain control

Antidote(s)

- Antivenin (*Latrodectus mactans*) [ANTIDOTE]
- Calcium Gluconate [ANTIDOTE]

Additional Information The *Latrodectus* species is found in the entire North American continent although it prefers warmer climates. It avoids human dwellings and is most often located in corners of buildings, gardens, ground cover, trash piles, stables, outdoor toilets and woodpiles. The female (10-18 mm in size and 4 times larger than the male) is responsible for all envenomations. The venom gland contains ~0.2 mg of venom. The spider exhibits a shiny black color with a red hour glass appearance on the abdomen of the female. Its bite usually occurs on the extremities, with leg bites usually resulting in abdominal pain.

BLEEDING HEART

Rogers JJ, Stanford C, and Dart RC, "The Use of Visual Analog Pain Scales in Black Widow Spider Envenomation," *J Anal Toxicol*, 2006, 2(1):46-7.

Bleeding Heart

Scientific Name *Dicentra spectabilis*

Mechanism of Toxic Action Isoquinoline-type alkaloids may cause dermatitis

Signs and Symptoms of Overdose Burning sensation, erythema, pruritus

Overdosage/Treatment

Decontamination: Dermal: Wash thoroughly

Supportive therapy: Antihistamines and corticosteroids as needed

Additional Information Do not confuse with nontoxic hemorrhage heart vine; systemic toxicity not seen in humans. Toxic part: All parts are toxic; foliage and roots are most toxic

Blue-Ringed Octopus

Mechanism of Toxic Action Bite - envenomation; autonomic ganglia blockade; maculotoxin (tetrodotoxin)

Adverse Reactions

Central nervous system: Ataxia, perioral and intra-oral anesthesia
Neuromuscular & skeletal: Flaccid muscular paralysis, paresthesia

Respiratory: Respiratory depression

Signs and Symptoms of Overdose Aphonia, blurred vision, burning sensation, coma, local ischemia, numbness, pain, paresthesia, respiratory collapse, slurred speech

Admission Criteria/Prognosis All patients should be observed at least 12-24 hours

Overdosage/Treatment

Decontamination: No antivenin

Supportive therapy: Symptomatic and supportive; for serious envenomations, be prepared to provide artificial ventilation, wound care

Additional Information Range: Waters off the coast of Australia

Boston Ivy

Scientific Name *Parthenocissus tricuspidata*

Mechanism of Toxic Action Leaves are toxic and contain soluble and insoluble oxalates

Signs and Symptoms of Overdose

Dermal: Irritation, pain, swelling; may also cause dermatitis

Ocular: Sap may cause corneal abrasion, lacrimation, pain, photophobia

Oral: Diarrhea, dysphonia, edema, salivation, vomiting

Miscellaneous: Hypocalcemia, renal injury due to calcium oxalate precipitation

Overdosage/Treatment

Decontamination: Oral: Dilute; ipecac/lavage/activated charcoal not likely necessary; milk/water to dilute

Supportive therapy: For treatment of soluble oxalates, which may cause systemic oxalate toxicity, keep well hydrated, monitor renal function, fluid/electrolytes; hypocalcemia may occur which can be treated with calcium gluconate, monitor urine for crystals; treat other symptoms supportively

Box Jellyfish

Related Information

- Jellyfish
- Sea Wasp

Scientific Name *Carybdea rastonii* (Jimble); *Chironex fleckeri*; *Chiropsalmus marsupialis*; *Chiropsalmus quadrigatus*; *Chiropsalmus quadrumanus*; *Scyphozoa* Class

Mechanism of Toxic Action Sting, venom; lethal fraction and lethal hemolytic-dermatonecrotic fraction. The neurotoxin may cause an influx of calcium ion into the cell.

Adverse Reactions

Cardiovascular: Hypotension, cardiovascular collapse, vasoconstriction
Dermatologic: Vesicular dermal eruption; pruritus; edema. Red-brown to purple flare pattern. Skin blisters can develop within 6 hours. Skin necrosis can develop in 12-18 hours.

Central nervous system: CNS depression, coma

Local: Wheal

Musculoskeletal: Muscle spasm, cramps

Ocular: Conjunctivitis, corneal ulcer, iritis, chemosis

Respiratory: Wheezing, pulmonary edema, respiratory depression/collapse

Signs and Symptoms of Overdose Symptoms usually do not develop for 6-12 hours; atrioventricular block, cardiovascular collapse, coma, erythema, hypotension, laryngeal edema, nausea, pain, respiratory depression, vomiting. An annular or ladder-like pattern of small papular or wheal-like eruptions may suggest a box jellyfish sting.

Overdosage/Treatment

Decontamination: Rapidly assess airway; support with artificial ventilation, if necessary; immediately rinse with seawater, should then prevent further envenomation by applying acetic acid 5% (vinegar) to any tentacles still adhering to tissue; if acetic acid is not available, use isopropyl alcohol 40% to 70% or finally may use aluminum sulfate; following dermal decontamination, shave the area with a scalpel, then repeat local decontamination therapy. Ocular exposures are to be decontaminated by water irrigation only. **Do not** rub affected area. Wear gloves during decontamination. Meat tenderizers have been used, however, they are not preferred decontamination measures and should not have prolonged contact times (> 10 minutes). Do not use fresh water, in that, nematocyst firing may occur. Nematocysts can be removed by using sticky tape. Cold packs can be applied to the affected area.

Supportive therapy: Give intravenous fluids (isotonic saline) to treat hypotension

Antivenin should be administered I.V. diluted 1:5 with isotonic crystalloid; dose equals 1 ampul or 20,000 units over 5 minutes; if administered I.M., use 3 ampuls or 60,000 units

Antivenin available in Australia through Commonwealth Serum Laboratories, Melbourne.

Additional Information Most venomous of all sea creatures; appears as a gelatinous umbrella with multiple long tentacles. The stinging apparatus is located at the outer surface of the tentacles or near its tubular mouth. Stings from tentacles >5 meters result in severe symptoms; use of verapamil is still controversial. Range: Found chiefly in the waters off Northern Queensland, Australia; may be found in the open ocean

Specific Reference

Currie BJ, "Marine Antivenoms," *J Toxicol Clin Toxicol*, 2003, 41(3):301-8.

Box Thorn

Scientific Name *Lycium halimifolium*

Mechanism of Toxic Action The whole plant may contain atropine and other anticholinergic compounds

Adverse Reactions Cardiovascular: Sinus tachycardia

Signs and Symptoms of Overdose Constipation, delirium, dry mouth, mydriasis, tachycardia

Overdosage/Treatment

Decontamination: Ipecac (within 30 minutes)/lavage (within 1 hour), activated charcoal, cathartic may be considered in large ingestions

Supportive therapy: Propranolol may be used for tachyarrhythmias

Antidote(s)

- Physostigmine [ANTIDOTE]

Breynia officinalis

Mechanism of Toxic Action Can cause direct liver toxicity and is a mucosal irritant

Adverse Reactions

Ingestion:

Cardiovascular: Hypertension

Central nervous system: Vertigo, headache, numbness, fatigue

Gastrointestinal: Vomiting, diarrhea, bloody diarrhea, gastritis

Hepatic: Hepatomegaly, hepatitis

Renal: Hematuria

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Monitor liver function tests; administer H₂ blocking agents to treat gastritis

Additional Information Often marketed as a herbal drug under the proprietary name "Chi R Yun," which has been used to treat venereal diseases, growth retardation, and heart failure. Hepatotoxicity usually occurs within 1 day of ingestion and lasts for 2-4 weeks.

Brown Recluse Spider

Scientific Name *Loxosceles reclusa*

Mechanism of Toxic Action Toxin has sphingomyelinase activity which has lytic action on red blood cells

Signs and Symptoms of Overdose Mild erythema and pruritus can progress to severe skin ulceration. Systemic findings occur at 1-3 days and can include: Anemia, dark urine, fever, hemolysis, hemolytic anemia, hypotension, myalgias, myopathy, nausea, severe vomiting, thrombocytopenia. The bite site may have a "halo" appearance with a small pustule surrounded by pallor. The wound can become necrotic in 3 days. Death may be related to disseminated intravascular coagulation or renal failure.

Admission Criteria/Prognosis Hospitalization usually not required acutely; necrotic lesions may require hospitalization 2-3 days postexposure; patients with rapidly expanding lesions or evidence of hemolysis should be admitted

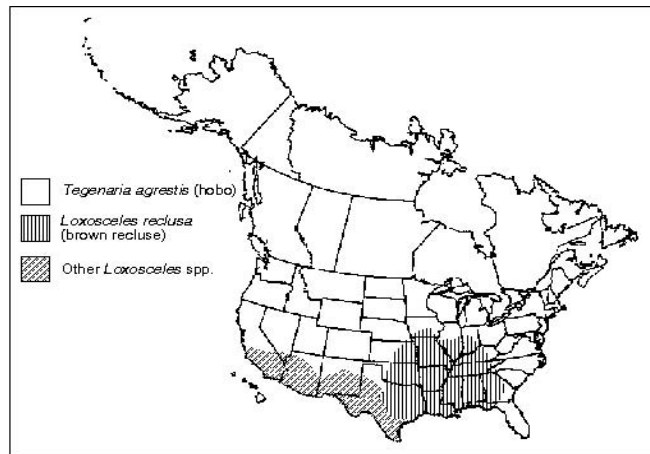

Overdosage/Treatment Supportive therapy: Elevate affected limb; antihistamine may be given for pruritus; dexamethasone (4 mg I.M. 4 times/day)

can be helpful if given early in the course; dapsone (50-200 mg orally divided into twice daily dosing) or colchicine (1.2 mg orally, then 0.6 mg every 2 hours for 2 days, then 0.6 mg every 4 hours for 2 days) may be helpful to avoid cutaneous necrosis; ice packs may relieve pain/heat may exacerbate pain; hyperbaric oxygen has been used (2-6 days postbite) in order to improve necrotic lesions. Hyperbaric oxygen if used within 48 hours may reduce skin necrosis. A recent rabbit study did not reveal any benefit of hyperbaric oxygen, dapsone, or cyproheptadine in the treatment of brown recluse spider envenomation. Nitro-patches applied over the bite site for 12 hours may be helpful in reducing pain and skin necrosis, although it must be noted that this method is unproven and has not been formally studied.

Antidote(s)

- Oxygen (Hyperbaric) [ANTIDOTE]

Additional Information Bites usually occur at night; dorsal cephalothorax has characteristic fiddle-shaped marking. Range: South/Southwestern U.S., Illinois, Iowa, Ohio, not found in Pacific northwest; necrotic arachnidism is likely due to *Tegenaria agrestis* bites

From "Necrotic Arachnidism," *MMWR Morb Mortal Wkly Rep*, 1996, 45(21):435.

Buckeye

Scientific Name *Aesculus californica*; *Aesculus glabra*; *Aesculus parviflora*

Mechanism of Toxic Action Contains aesculin which is a mixture of saponins and is cytotoxic

Signs and Symptoms of Overdose Diarrhea, oral irritation, vomiting. Repeat exposure or large amounts in small children may also produce ataxia, CNS depression, muscle asthenia, myoclonus, and paralysis.

Overdosage/Treatment

Decontamination: 1-2 berries: Activated charcoal alone may be more beneficial than vomiting since effects of ipecac are similar to toxicity; more than 1-2 berries may cause more severe GI effects and systemic effects, therefore, use of ipecac may be worthwhile to prevent more serious effects; cathartics should be avoided

Supportive therapy: Maintain proper electrolyte and fluid balance, support cardiac and respiratory function if necessary; monitor fluid and electrolytes

Additional Information Toxic dose: 1-2 seeds may cause gastroenteritis only; repeat exposures allow saponin absorption through irritated mucous membranes. Aesculin content in seeds varies with growth and peaks in mid-July to mid-August. Toxic part: Young leaves, flowers, and bark are most toxic

Buffalo Pea

Scientific Name *Thermopsis montana*; *Thermopsis rhombifolia*

Mechanism of Toxic Action Flowers and seeds contain quinololizidine alkaloids

Signs and Symptoms of Overdose Abdominal cramping, dizziness, headache, nausea, oral irritation, tachycardia, tremors, vomiting

Admission Criteria/Prognosis Patients who are asymptomatic 10 hours postingestion can be discharged home

Overdosage/Treatment

Decontamination: Lavage within 1 hour; activated charcoal can be given

Supportive therapy: Rehydration with I.V. crystalloid solution

Additional Information Found in Western Canada; seed ingestions may exhibit a longer delay of symptoms; flower ingestions become symptomatic within 3 hours

Bufotenine

CAS Number 487-93-4

Commonly Found In Skin glands (parotid glands) of toads (*Bufo alvarius*, Colorado river toad) and *Bufo marinus* (cane toad); in the seeds and leaves of *Piptadenia peregrina* and *Piptadenia macrocarpa*; found in the Chinese preparation Yixin Wan, Kyushin, and Lu-Shen Wan; also found in the mushrooms *Amanita citrina*, *Amanita porphyria*, and *Amanita tomentella*

Mechanism of Toxic Action Indole alkaloid with serotonergic activity; also inhibits sodium, potassium, and muscle ATPase activity in muscle similar to digoxin

Signs and Symptoms of Overdose Cardiac arrhythmias similar to digitalis toxicity, dyspnea, hypokalemia, salivation, seizures

Admission Criteria/Prognosis Asymptomatic patients with normal electrocardiogram and electrolytes can be discharged after a 12-hour observation; any symptomatic patient should be admitted to a cardiac monitor bed

Reference Range Serum digoxin levels as high as 3.9 ng/mL have been described

Overdosage/Treatment

Decontamination: Activated charcoal with cathartic may be effective in ingestions; mucous membranes should be flushed with water

Supportive therapy: Diazepam or lorazepam may be utilized for agitation or seizures; phenobarbital is also effective for seizures; although it is unproven in a clinical setting, digoxin specific Fab antibodies can be considered if a toxic arrhythmia develops (5-10 vials); atropine can be utilized for bradyarrhythmias while phenytoin can be used for ventricular arrhythmias

Enhancement of elimination: Multiple dosing of activated charcoal may be effective

Antidote(s)

- Digoxin Immune Fab [ANTIDOTE]

Test Interactions Cross reacts to give a positive digoxin reading in immunoreactive assays; cardioactive steroids of the bufadienolide class may cross react with polyclonal digoxin immunoassays

Additional Information Hyperkalemia can be a prognostic sign in overdose situations. Usual mechanism of abuse is through licking the skin of the toad, although "toad smoking" and ingestions have occurred; the Colorado river toad is found in the Sonoran desert of Northern Mexico along with southern California and Arizona; while the toads primarily live underground, they do emerge during the rainy season in midsummer; not centrally active at oral doses of 50 mg or I.V. doses of 20 mg or I.M. doses of 40 mg; 100 kg of *Amanita citrina* contains only 7 g of bufotenine. Adverse reactions to bufotenin should be reported to FDA's Med Watch Program: (800)332-1088.

Bushmaster

Scientific Name *Lachesis mutus*

Signs and Symptoms of Overdose Coagulopathy

Overdosage/Treatment

Decontamination: Rapid transport to medical facility; immobilize area; if negative pressure suction device is available, this may be used; **do not** incise the wound; constriction band may be applied, not a tourniquet; ABC assessment, physical exam; mark extent of local edema with skin-marking pen

Supportive therapy: Repeat lab testing every 3-4 hours for first 12 hours; I.V. fluids, tetanus prophylaxis and analgesics may need to be given; antibiotics may be indicated for infected wound sites; antivenin indicated for moderate to severe envenomation

Antidote: Wyeth crotalid polyvalent antivenin: Treat moderate to severe envenomations with increments of 5-10 vials at a time; skin test per manufacturer's instructions; if positive, may prophylax with H₁- and H₂-histamine receptor blockers; give until local injury has stopped and coagulopathy is reversed; complications include allergic reaction, anaphylaxis, and delayed serum sickness

Antidote(s)

- Antivenin (Crotalidae) Polyvalent [ANTIDOTE]

BUTTERCUP

Additional Information Largest American poisonous snake (length to 12 feet); unlike other pit vipers, lays eggs from which young are hatched

Buttercup

Scientific Name *Ranunculus aquatilis*

Mechanism of Toxic Action Contains protoanemonin, which reacts with SH groups to produce irritation and vesication, excreted unchanged in urine

Signs and Symptoms of Overdose Abdominal cramps, blistering, bloody diarrhea, contact dermatitis, pain and swelling, potential for renal irritation or damage if a large enough amount is ingested, salivation, vomiting, ulceration

Toxicodynamics/Kinetics Significant dermal symptoms may take several weeks to resolve

Overdosage/Treatment

Decontamination: Avoid use of ipecac or cathartics, consider lavage (within 1 hour) and/or activated charcoal with large ingestion to prevent systemic absorption and possibility of subsequent renal irritation
Supportive therapy: Maintain fluid and electrolytes, maintain adequate urine flow in large overdose; monitor symptomatic patients for fluid or electrolyte deficiencies

Additional Information Toxic dose: Not established, but overdose producing systemic effects is unlikely due to painful skin contact. Plant is most toxic during flowering stage. Toxic part: Sap

Caterpillars

Commonly Found In Larvae of *Lepidoptera* (moths and butterflies)

Mechanism of Toxic Action Caterpillar spines and spicules can cause an urticarial dermatitis; stings by *Lonomia obliqua* and *Lonomia achelous* may cause a hemorrhagic syndrome (melena, hematuria, ecchymosis); coagulopathy may last 1 month

Adverse Reactions

Central nervous system: Fever, malaise, headache, seizures (*Megalopyge opercularis* exposures)

Dermatologic: Erythema, urticaria, pruritus, vesiculation (*Megalopyge lanata*), erythema multiforme (*Euproctis chrysorrhoea*), nonimmunologic contact urticaria, vesicular dermal eruptions

Gastrointestinal: Vomiting (after oral ingestion)

Hematologic: Eosinophilia

Neuromuscular & skeletal: Pain (Puss caterpillar can cause severe pain)

Ocular: Eye irritation, photophobia, uveitis, keratoconjunctivitis, lacrimation

Respiratory: Rhinorrhea, bronchitis, dyspnea, bronchospasm

Overdosage/Treatment

Decontamination: **Oral:** Dilute with milk or water. **Dermal:** Apply and strip (with adhesive tape or facial peel) at sting site promptly; spicules can be washed out with running water or can be removed manually with a forceps; intermittent ice application may reduce pain. **Ocular:** Irrigate with water
Supportive therapy: Local symptoms can be treated with a potent topical steroid to a small area over a 2- to 3-day period (ie, Temovate[®] cream 0.05%, Ultravate[™] cream 0.05% or Diprolene[®] ointment 0.05%); severe cases can be treated with an antihistamine (terfenadine 60 mg 3 times/day) or anti-inflammatory agents (tolmetin sodium 400 mg 3 times/day); codeine, meperidine or oxymorphone can be used to treat severe pain; calcium gluconate (10 mL of a 10% solution, I.V.) has been useful to treat pain in a small series of patients

Additional Information Hand and feet are primarily envenomation sites; 61% of patients will experience symptoms for over 24 hours; peak incidence of *Megalopyge opercularis* stings is in the autumn

Caladium

Mechanism of Toxic Action Contains insoluble calcium oxalate crystals which cause mechanical injury

Signs and Symptoms of Overdose Ocular: Contact with sap may produce corneal abrasion, lacrimation, pain, photophobia, and deposition of calcium oxalate crystals on corneal epithelium
Oral: Dysphonia, irritation, pain, swelling, vomiting

Toxicodynamics/Kinetics Irritation is immediate

Overdosage/Treatment

Decontamination: **Oral:** Dilute; ipecac/lavage/activated charcoal/cathartic not likely necessary; milk/water to rinse crystals. **Dermal:** Wash thoroughly. **Ocular:** Irrigate with tepid water for 15 minutes

Supportive therapy: Cool compresses may minimize pain and swelling

Additional Information Contact with sap or mouthful ingestions may produce symptoms. Ice or popsicles may help oral irritation, especially in children. Toxic part: Whole plant including sap

Calla

Scientific Name *Zantedeschia aethiopia*

Mechanism of Toxic Action Contains insoluble calcium oxalate crystals which cause mechanical irritation

Signs and Symptoms of Overdose

Oral: Diarrhea, dysphonia, edema, salivation, vomiting

Dermal: Irritation, pain, swelling

Ocular: Sap may cause corneal abrasion, lacrimation, pain, and photophobia; oxalate crystals may be deposited on cornea; may also cause dermatitis

Toxicodynamics/Kinetics Rapid onset of local symptoms

Overdosage/Treatment

Decontamination: **Dermal:** Wash thoroughly. **Ocular:** Irrigate. **Oral:** Dilute; ipecac/lavage/activated charcoal with cathartic not likely necessary; milk/water to rinse crystals

Supportive therapy: Cool compresses may minimize pain and swelling

Additional Information Symptoms dependent on liberation of oxalate crystals or contact with sap, dried plant will not liberate crystals; wide variation in potential for toxicity between plants; treat symptoms. Toxic part: Whole plant

Campylobacter jejuni Food Poisoning

Commonly Found In Poultry, meat, dairy products

Mechanism of Toxic Action Heat labile enterotoxin; incubation period: 1-7 days

Adverse Reactions Central nervous system: Guillain-Barré syndrome (within 3 months of infection - median 9 days)

Signs and Symptoms of Overdose Abdominal pain, bloody diarrhea, cramping, diarrhea, feces discoloration (red), fever, malaise, vomiting

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment The organism is sensitive *in vitro* to many common antimicrobial agents including erythromycin, ciprofloxacin, tetracyclines, aminoglycosides, and others. Ampicillin or penicillin should usually be avoided, and the susceptibility to co-trimoxazole is variable. Most patients with *Campylobacter* enteritis do not require antibiotics; they recover quickly without sequelae. Antimicrobial therapy should be targeted towards the more acutely ill patient. Limited clinical trials suggest that the following groups may benefit from the prompt use of antibiotics: children with severe dysentery, adults with severe bloody diarrhea and fever, individuals with worsening symptoms when seeking medical attention, and prolonged diarrhea (> 1 week). Treatment with antibiotics does not prolong the fecal carriage of *C. jejuni* (as opposed to *Salmonella*). The drug of choice is erythromycin. For the toxic patient, combination therapy may be useful, but consultation should be made with an Infectious Disease specialist.

Diagnostic Procedures

- Stool Culture

Additional Information

Febrile seizures may occur in children; meningitis or endocarditis may occur as may Guillain-Barré syndrome

Microbiology:

Campylobacter jejuni is a curved, gram-negative bacillus which is the most common cause of bacterial diarrhea in the United States; on Gram's stain, *Campylobacter jejuni* appears as a curved, comma-shaped, gram-negative rod which often has a distinctive "seagull wing" appearance

Campylobacter jejuni is a microaerophilic organism and fails to grow under routine aerobic and anaerobic conditions. The laboratory should be informed that *C. jejuni* is suspected clinically and a special request made for *Campylobacter* culture. A 5% to 10% oxygen, 5% to 10% carbon dioxide, and 80% to 90% nitrogen atmosphere is generally used to facilitate growth.

Epidemiology: Infection with this agent occurs worldwide. With >2 million cases per year in the U.S., *Campylobacter*-induced enteritis is more common than *Salmonella* and *Shigella* combined. The organism is found in the gastrointestinal flora of a number of wild and domestic animals, most notably in chickens. Transmission to humans generally occurs by consumption of the meat or milk of an infected animal, consumption of water contaminated with the feces of infected animals (eg, mountain streams), or fecal-oral transmission from an infected human or household pet. Undercooked chicken is notorious for transmission of *C. jejuni*, accounting for >50% of the cases of campylobacteriosis. Outbreaks have been linked to unpasteurized goat's cheese, clams, and untreated stream water in Wyoming. Infection occurs year-round but is most common in the summer months.

Clinical Syndromes:

- **Acute enteritis:** The organism can cause destructive, ulcerative changes in the mucosal surfaces of the small intestine (especially jejunum and distal ileum) and colon. Invasion of the organism causes inflammation of the lamina propria, bowel wall edema, and crypt abscesses. Patients initially present with nonspecific symptoms such as fever, headache, and myalgias. One to 2 days later, there is crampy abdominal pain and diarrhea. The quality and severity of the diarrhea is variable (although usually mild), and stools may be frequent and watery

or visibly bloody. Most cases resolve spontaneously without antimicrobial therapy within 1 week. Less commonly, a fulminant acute colitis may occur. Again, a nonspecific prodrome of fever and malaise precedes any gastrointestinal complaints. However, the diarrhea which follows is voluminous and bloody with large amounts of mucus. Tenesmus is common and further suggests involvement of the colon. Fevers can reach 40°C and occasionally the patient can appear in extremis. This syndrome may be confused with bacillary dysentery from *Shigella* species, severe salmonellosis, or even the initial presentation of inflammatory bowel disease (particularly if it is in a young adult). Toxic megacolon may complicate the hospital course.

● **Appendicitis-like syndrome:** Occasionally, *C. jejuni* can cause right lower quadrant pain mimicking appendicitis, without diarrhea. This "pseudoappendicitis" has been seen in association with other enteric pathogens including *Yersinia enterocolitica*.

● **Bacteremia:** This is an unusual finding in *C. jejuni* infection (even when the patient is febrile), unlike *Campylobacter fetus* which is commonly recovered from the blood. Blood cultures may turn positive several days after a mild diarrheal illness has already resolved; in such cases, antibiotic therapy is usually unnecessary. In other cases, bacteremia may be sustained, particularly in immunocompromised hosts, and this may suggest a deep focus of infection. Infectious disease consultation is appropriate in such cases since prolonged antimicrobial therapy may be necessary.

● **Septic abortion:** *C. jejuni* infection in the pregnant female may lead to this complication. However, *Campylobacter* bacteremia during pregnancy does not automatically justify a therapeutic abortion since the outcome is not uniformly poor.

Diagnosis: *Campylobacter jejuni* should be suspected in any case of acute gastroenteritis or fulminant colitis. The findings of fecal leukocytes and occult blood in the stool are suggestive of campylobacteriosis and other gastrointestinal infections such as those caused by *Salmonella* sp, *Shigella* sp, enteroinvasive *E. coli*, enterohemorrhagic *E. coli* (O157:H7), Crohn's disease or ulcerative colitis, and others. The diagnosis is confirmed by a positive stool culture for *C. jejuni* or positive blood cultures for the organism.

Cashew

Scientific Name *Anacardium occidentale*

Mechanism of Toxic Action Shell contains anacardic acid, cardol, anacardol, irritants that can precipitate type IV cell-mediated allergic reaction (allergic contact dermatitis)

Signs and Symptoms of Overdose Dermatitis, nausea, vomiting

Toxicodynamics/Kinetics

Onset of effect: Variable, but effects usually seen within 24-48 hours

Peak dermal effect: After 3-5 days

Overdosage/Treatment

Decontamination: Soap and water washing likely ineffective unless done within 5-15 minutes after exposure

Supportive therapy: Cool compresses or showers, Burow's solution, topical/oral steroids

Additional Information Raw nut should not be eaten; may cause dermatitis in persons sensitized to toxicodendron species. Toxic part: Shell contains toxin

Castor Bean

Scientific Name *Ricinus communis*

Mechanism of Toxic Action Contains ricin: A toxalbumin which inhibits protein metabolism and DNA synthesis; can cause agglutination of defibrinated blood *in vitro*

Signs and Symptoms of Overdose Latent symptom period may be as long as 8 hours; abdominal burning, anaphylaxis, bronchospasm, contact dermatitis, diarrhea, elevation of hepatic enzymes and serum creatinine can occur, fever, hematuria, hypotension, GI hemorrhage, GI irritation, general weakness may manifest, miosis and urticaria may manifest, nausea, oropharyngeal burning, seizures, shivering, tachycardia, thirst, vomiting

Admission Criteria/Prognosis Any symptomatic patient should be admitted. Asymptomatic patients may be discharged after an 8- to 10-hour observation.

Toxicodynamics/Kinetics

Absorption: Poorly absorbed orally; can be absorbed by inhalation

Half-life: 48 hours

Elimination: Renal

Monitoring Parameters CBC, liver and renal function, blood sugar

Reference Range Following adult ingestion of 30 beans, plasma and urine ricin levels were 1.5 mcg/L and 0.3 mcg/L, respectively

Overdosage/Treatment

Decontamination: **Oral:** Emesis or lavage within 1 hour with ingestions of 1 castor bean/10 kg body weight. Activated charcoal can be used without a cathartic. **Dermal:** Wash with soap and water. **Inhalation:** Give 100% humidified oxygen. **Ocular:** Copious irrigation with saline for at least 20 minutes

Supportive: Replace fluid/electrolyte loss; suggest alkalization of urine to prevent hemoglobin agglutination in kidney

Enhanced elimination: Hemodialysis is not useful

Additional Information

By injection, ricin can be quite toxic with: Estimated lethal dose: Humans: 1 mg/kg; Animals: 0.0001 mg/kg. Lethal dose: Oral: ~5-8 seeds.

Chewing the seeds increases the toxic potential with lethality occurring after a 1- or 2-seed ingestion. Ricin is not dialyzable, but is water soluble and heat labile. Seeds and foliage are toxic parts of the plant. Due to ricin's insolubility in oil, castor oil is not toxic and can be used as a laxative or a lubricant in industry. The plant is found in southern United States, Guam, and Hawaii. The bean's hard coat must be ruptured for toxicity to occur. Hepatic/adrenal/renal toxicity may occur after 2-5 days postexposure. As of 1996, 15 deaths in 839 case reports have been documented (most occurring before 1945).

Cathinone

Related Information

● Methcathinone

CAS Number 71031-15-7

Mechanism of Toxic Action Derived from the leaves of the *Catha edulis* (Khat) plant (an evergreen bush which grows up to 5 meters in Eastern Africa at high altitudes); this stimulant possesses local anesthetic, anorectic, and neuromuscular junction blocking activities; may have some monoamine oxidase inhibition properties; similar in action to cocaine or amphetamines

Adverse Reactions

Cardiovascular: Tachycardia, hypertension, palpitations, flushing
Central nervous system: Fever, insomnia, headache, mania, visual/auditory hallucinations, euphoria, psychosis, paranoia, hyperthermia
Gastrointestinal: Xerostomia, anorexia, constipation
Genitourinary: Urinary retention, impotence
Neuromuscular & skeletal: Tremors, rhabdomyolysis
Ocular: Mydriasis
Respiratory: Tachypnea, dyspnea
Miscellaneous: Diaphoresis

Toxicodynamics/Kinetics

Onset of action: 20 minutes

Duration of action: 2 hours

Metabolism: To norephedrine and norpseudoephedrine

Elimination: Renal

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic
Supportive therapy: Agitation can be treated with chlorpromazine, benzodiazepines, or haloperidol; ventricular arrhythmias can be treated with lidocaine, procaine, or bretylium; hyperthermia can be treated with standard cooling techniques (avoid salicylates)

Enhancement of elimination: Multiple dosing of activated charcoal may be effective; although acid diuresis may enhance its elimination, this modality is not recommended due to its danger in exacerbating renal failure due to rhabdomyolysis

Test Interactions May result in false-positive urinary amphetamine or phenylpropanolamine radioimmunoassay test

Additional Information

Toxic dose: Khat (0.1% to 0.3% cathinone): 100-200 g Anorexiant: 15-60 mg.

Khat is usually utilized by chewing the leaves and swallowing its juice; red khat has a higher cathinone content than white khat; khat addiction can be treated with bromocriptine mesylate (1.25 mg every 6 hours as an initial dose); for medicinal purposes (as an anorexiant): 15-60 mg

Century Plant

Scientific Name *Agave americana*

Mechanism of Toxic Action Contains insoluble calcium oxalate crystals which cause mechanical irritation; may also cause dermatitis

Signs and Symptoms of Overdose

Oral: Dysphonia, diarrhea, edema, salivation, vomiting

Dermal: Irritation, pain, swelling

Ocular: Sap may cause corneal abrasion, lacrimation, pain, and photophobia; oxalate crystals may be deposited on cornea; may also cause dermatitis

Toxicodynamics/Kinetics Onset of action: Rapid onset of local symptoms due to oxalate; dermatitis reaction may develop within a few hours

Overdosage/Treatment

Decontamination: **Oral:** Dilute; ipecac/lavage/activated charcoal with cathartic not likely necessary. **Dermal:** Wash thoroughly; antihistamines/steroids may be useful. **Ocular:** Irrigate

Supportive therapy: Cool compresses may minimize pain and swelling

Additional Information Toxic part: Sap, although other parts may be also (especially thorns)

Cherry

Scientific Name *Prunus serotina*

Mechanism of Toxic Action Contains amygdalin, a cyanogenic glycoside hydrolyzed to hydrocyanic acid in the gut, complexes with cytochrome oxidase to produce cellular hypoxia after absorption

Signs and Symptoms of Overdose Abdominal pain, coma, cyanosis, drowsiness, dyspnea, headache, lethargy, paralysis, seizures, sweating, vomiting

Overdosage/Treatment

Decontamination: Basic poison management; vomiting is contraindicated due to rapid course of the neurologic symptoms; give 100% oxygen
Supportive therapy: Give sodium bicarbonate for acidosis; cyanide antidote kit should be used for patients symptomatic from cyanide toxicity
Enhancement of elimination: Hemodialysis and charcoal hemoperfusion have been utilized; hyperbaric oxygen may also be utilized; hydroxocobalamin and dicobalt-EDTA used for chelation in Europe

Additional Information Toxic dose: 1-2 pits likely nontoxic, toxicity uncommon after accidental ingestion. Intact pit does not release CN

Chicken Soup

Scientific Name *Gallus domesticus* (in a broth)

Uses Food product; has been advocated to treat emaciation, upper respiratory tract infections, leprosy, asthma, and for aircraft-fuel (sodium chloride)

Mechanism of Toxic Action High sodium content

Adverse Reactions Gastrointestinal: Salty taste

Signs and Symptoms of Overdose Coma, dehydration, delirium, hyperchlorhydria, hypernatremia, hyperosmolarity, tachycardia

Overdosage/Treatment

Decontamination: Gastric: Activated charcoal probably is not useful;
Ocular: Irrigate copiously with water

Supportive therapy: For hypernatremia, give 30-50 mEq/L of sodium (half chloride, half bicarbonate) by slow I.V. infusion; prepare solution by adding 15-25 mEq/L sodium chloride (2.5 mEq/mL) and 15-25 mEq sodium bicarbonate (1 mEq/mL) to 1 liter D₅W; administer at a rate of 2/3 maintenance with a goal of achieving normal serum sodium at 24-36 hours after initiating treatment; seizures may occur if serum sodium is lowered too quickly; seizures can be treated with lorazepam or diazepam 0.1-0.25 mg/kg; hypernatremia is resolved through the use of diuretics and free water replacement

Enhancement of elimination: Peritoneal dialysis should be considered in infants who are salt poisoned; hemodialysis should be considered in patients who are refractory to other therapies on in patients with renal impairment

Additional Information Should not be given in large amounts to infants or the elderly. Contains sodium cytarabine hexa-methyl-acetyl lutitric tetrazolamine (schmaltz). Some broths may contain from 200-250 mEq/L sodium. A therapeutic effect has been documented for the common cold by one study (Saketkhuo, et al) which demonstrated an increased nasal mucous velocity following hot chicken soup ingestion. The Campbell's® Low Sodium Chicken Noodle soup contains ~1.5 mg of sodium per serving ounce of soup (2.17 mEq/L) and ~1 mEq of potassium per ounce. Patients with significant renal impairment should reduce their portion or further dilute low-sodium formulations of chicken soup. Monitoring parameters: Sodium serum osmolality

Christmas Cherry

Scientific Name *Solanum pseudocapsicum*

Mechanism of Toxic Action Contains solanocapsine, an alkaloid related to salanine that is structurally similar to a cardiac glycoside and has irritant effect similar to saponins

Adverse Reactions

Cardiovascular: Sinus bradycardia

Central nervous system: Psychosis

Signs and Symptoms of Overdose Bradycardia, diarrhea, drowsiness, headache, hypotension, nausea, vomiting

Toxicodynamics/Kinetics Effects expected within 2-24 hours

Overdosage/Treatment

Decontamination: If necessary due to large ingestion, use ipecac (within 30 minutes) if soon after ingestion; otherwise, consider activated charcoal with cathartic or lavage within 1 hour

Supportive therapy: Maintain proper fluid and electrolyte balance

Additional Information Toxic dose: Unclear, but large amount likely necessary for toxicity. Potential for solanine toxicity but no cases on record

Christmas Rose

Mechanism of Toxic Action Primary toxicity relates to proteoanemonin which reacts with SH groups to produce vesicant action; also contains saponins that act as irritants

Signs and Symptoms of Overdose Abdominal pain, bloody diarrhea, oral numbness, seizures, vomiting

Toxicodynamics/Kinetics Significant dermal symptoms may take several weeks to resolve

Overdosage/Treatment

Decontamination: Avoid use of ipecac or cathartics, consider lavage within 1 hour and/or activated charcoal with large ingestion to prevent systemic absorption and possibility of subsequent renal irritation
Supportive therapy: Maintain fluid and electrolytes, maintain adequate urine flow in large overdose; monitor symptomatic patients for fluid or electrolyte deficiencies

Additional Information Small amounts likely to produce symptoms; Family: Buttercup; Toxic part: Entire plant; digitalis toxicity; varies within the species and is not seen in *Helleborus niger*

Chrysanthemum

Scientific Name *Chrysanthemum*

Adverse Reactions Dermatologic: Photoallergy

Signs and Symptoms of Overdose Allergic dermatitis, pruritus, erythema, hives, localized edema

Overdosage/Treatment

Decontamination: Wash skin with soap and water

Supportive therapy: Oral or topical corticosteroids or diphenhydramine may be beneficial

Additional Information Ingestion of large amounts of flowers may cause pyrethrin-type toxicity

Ciguatera Food Poisoning

Related Information

- Neurotoxic Shellfish Poisoning

Commonly Found In Amberjack, barracuda, dolphin, eel, emperor fish, red snapper, sea bass, surgeon fish in Caribbean or South Pacific oceans

Mechanism of Toxic Action Due to ingestion of dinoflagellates, ciguatoxin accumulates in larger fish; affects membranes and ionic flux of nervous tissue. Ciguatoxin is a lipid soluble toxin which modulates sodium ion entry in neuronal tissue, thus producing sustained depolarization. Other toxins include maitotoxin (a hemolysin) and palytoxin (which inhibits sodium-potassium ATPase, thus resulting in muscle contractions and rhabdomyolysis).

Adverse Reactions

Dermatologic: Pruritus

Gastrointestinal: Nausea, vomiting, diarrhea, abdominal cramping

Genitourinary: Balanitis, dyspareunia

Neuromuscular & skeletal: Peripheral neuropathy, cold allodynia

Signs and Symptoms of Overdose Three phases:

Phase I (1-6 hours postingestion): Abdominal pain, gastrointestinal symptoms, headache, nausea, vomiting, watery diarrhea

Phase II (6-12 hours postingestion): Neurologic symptoms: Adynamic ileus, extremity paresthesias, heat-cold reversal. Blurred vision, metallic taste, myalgia, pruritus, and sinus bradycardia are also common.

Phase III (> 12 hours postingestion): Ataxia, dysesthesia, hypotension, hypothermia, weakness; respiratory complications are rare

Admission Criteria/Prognosis Admit if there is significant volume loss; neurologic symptoms (within 24 hours postingestion), or bradycardia occurs; patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment

Decontamination: Activated charcoal (a cathartic is usually not required); avoid magnesium containing cathartics

Supportive therapy: Atropine is useful for bradycardia (sinus); amitriptyline (25 mg twice daily), nifedipine, or mannitol (1 g/kg over 30-45 minutes) has been used for paresthesias with some effect; fluid/electrolyte replacement; atropine can be utilized for treatment of symptomatic hypotension; crystalloid fluids are initial therapy for hypotension; dopamine is a vasopressor of choice if necessary; gabapentin (400 mg 3 times/day, orally) may be helpful in treating pruritus and dysesthesia

Antidote(s)

- Mannitol [ANTIDOTE]

Diagnostic Procedures

- Electrolytes, Blood

Additional Information Ciguatoxin is odorless and tasteless. Minimum pathogenic dose of ciguatoxin: 0.6 ng/kg; stable in heat and gastric acid. Can be transmitted through sexual intercourse. May occur in farm-raised salmon. Mortality rate: 0.1%. Duration of acute GI symptoms: 8.5 hours.

Claviceps purpurea

Commonly Found In A contaminant fungus (ascomycete) which is found in rye, wheat, barley, oats, and bluegrasses; etiologic agent for "St Anthony's Fire." See Mycotoxins

Mechanism of Toxic Action Contains an ergot/alkaloid; additional substances this fungus can produce include histamine, tyramine, isoamylamine, acetylcholine, acetaldehyde, and tryptophan

Adverse Reactions Central nervous system: Psychosis

Signs and Symptoms of Overdose Dysphoria, gangrene, hallucinations, headache, paresthesias, seizures, vasospasm

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Seizures can be treated with benzodiazepines initially; phenobarbital or phenytoin can be used for refractory seizures; treatment is symptomatic with captopril, nifedipine, prazosin, vasodilators (nitroprusside) or nitroglycerin for hypertension; phentolamine can also be used; diazepam can be utilized for seizures; heparin, dextran, or corticosteroids can be used for hypercoagulable state; hyperbaric oxygen can be used as an adjunct to treat localized tissue hypoxia. Hyperbaric oxygen can be used to treat peripheral ischemia. Cyproheptadine (orally 4 mg 3 times/day) can be used to reverse ergot-induced vasoconstriction.

Additional Information This mold can invade rye ovaries producing a dark, purplish mass called a sclerotium. Found during warm, rainy weather in the summer and ingested in bread. LSD can be synthesized from one of its ergot alkaloids (ergometrine). Current standards require that <0.3% of grain be contaminated.

Clostridium botulinum Food Poisoning

Related Information

- Antitoxin Botulinum Types A, B, and E [ANTIDOTE]
- Botulinum Toxin Type A
- Botulism, Diagnostic Procedure
- Heroin
- Stool Culture

Commonly Found In Food poisoning: Poorly preserved meat, sausage, fruit, or vegetables (type A or B), marine products (type E), liver pate, venison jerky (type F); black tar heroin-intravenous drug abusers (wound botulism)

Mechanism of Toxic Action An anaerobic, spore-forming, gram-positive bacteria; ingestion of the toxin or wound contamination are likely routes of exposure; a heat labile neurotoxin which causes irreversible neuromuscular blockade and prevents acetylcholine release; the spores are heat-resistant

Signs and Symptoms of Overdose Symptoms may be delayed 12-36 hours. GI symptoms are usually absent in wound botulism. Adynamic ileus, aspiration, blurred vision, constipation followed by descending paralysis and respiratory failure, cranial nerve palsies, dry mouth, dry skin, dysphagia, fasciculations, hyporeflexia, mydriasis, ptosis, slurred speech

Admission Criteria/Prognosis Any suspected exposure or symptomatic patient should be admitted; patients with neurologic toxicity or respiratory failure should be admitted into intensive care unit

Overdosage/Treatment

Decontamination: **Do not** induce vomiting, lavage (within 1 hour) with activated charcoal (sorbitol as a cathartic) may be useful to remove spores if there is a known ingestion; activated charcoal avidly bind to *C. botulinum*, type A neurotoxin. Avoid magnesium-based cathartics since magnesium may enhance neurotoxicity.

Supportive therapy: Primarily respiratory: Mechanical ventilation may be necessary; "tensilon test" up to 10 mg of edrophonium I.V. over 5 minutes; may show improvement in muscle strength in botulism; guanidine (15-50 mg/kg/day orally) may be given (although its use is not proven). Trivalent (A, B, E) (Liosiero) antitoxin should precede administration; give 2 mL of antitoxin diluted in 100 mL of 0.9% saline over 30 minutes; 10 mL of antitoxin may be given in another 2-4 hours, then at 12- to 24-hour intervals as necessary. Sensitivity skin testing should proceed antitoxin administration. Give 20 mL of antitoxin diluted in 100 mL of 0.9% saline over 30 minutes intravenously. 10 mL of antitoxin may be given in another 2-4 hours, then at 12- to 24-hour intervals as necessary. 4-Aminopyridine (0.5 mg/kg I.V. bolus; 0.25 mg/kg/hour continuous infusion I.V.) may improve peripheral strength but not respiratory parameters. Avoid magnesium since it may enhance the action of the toxin. Trivalent (ABE) antitoxin is usually most effective if administered within 24 hours. Usually, only one vial dose is necessary.

Antidote(s)

- Antitoxin Botulinum Types A, B, and E [ANTIDOTE]

Diagnostic Procedures

- Botulism, Diagnostic Procedure

Additional Information

Lethal dose: Humans: 1 pg/kg

Stools or gastric contents may be contagious; infantile botulism has been related to honey ingestion; symptoms may be delayed for 1 week.

Antitoxin can be obtained from the CDC (404-639-3753 [days], 404-639-2888 [nights]).

Electromyogram shows decreased evoked action potential at 2 Hz/sec and an increased evoked action potential at 50 Hz/sec; up to 15% of affected individuals will have normal electromyograms

Thirty-four cases of foodborne botulism have been reported to the CDC in 1994. Boiling food for 10 minutes (> 100°C) destroys the toxin; cooked foods should not be kept at room temperature (4°C to 60°C) for longer than 4 hours; recent cases have been associated with commercial pot pies, home-canned foods, asparagus, green beans, peppers, and onions sauteed in margarine.

Twenty-five cases of wound botulism reported in 1995 (23 of them in California, almost all due to intravenous drug injection).

Injection of "black tar" heroin (which has been the predominant form of heroin in the western United States during the 1990's either intramuscularly or subcutaneously) is the primary risk factor for development of wound botulism (46 cases in California from 1988 to 1995).

Type A toxin has the highest case fatality rate; overall fatality rate for foodborne botulism is 5% to 10%; for wound botulism it is 15%

Epidemiology, diagnosis, treatment, prevention, and reporting of infant (intestinal) botulism (MMWR, 2003, 52(2):23)

Epidemiology

- Intestinal botulism is the most common form of human botulism reported in the United States; approximately 100 cases are reported annually.
- The majority of cases occur among infants aged ≤6 months; intestinal botulism is seen rarely in adults.
- The majority of cases are caused by botulinum toxin types A and B.
- The case-fatality rate of hospitalized patients is <1%
- Although ingesting honey is a known risk factor, the source of spores for the majority of cases is unknown.
- Ingestion of *Clostridium botulinum* spores, which exist worldwide in the soil and dust, is believed to be the principal route of exposure.

Clinical findings

- Reporting symptoms range from constipation and mild lethargy to hypotonia and respiratory insufficiency.
- Symptoms in infants aged ≤12 months include constipation, lethargy, poor feeding, weak cry, bulbar palsies (eg, ptosis, expressionless face, and difficulty swallowing), and failure to thrive.
- Presenting symptoms might be followed by progressive weakness, impaired respiration, and sometimes death.
- Differential diagnosis includes sepsis, dehydration, Werdnig-Hoffman disease, Guillain-Barré syndrome, myasthenia gravis, drug or toxin ingestions, metabolic disorders, and meningoencephalitis or myelitis.

Laboratory testing

- Laboratory confirmation requires detection of 1) botulinum toxin in stool or serum by using mouse neutralization assay or 2) isolation of toxigenic *C. botulinum* (or related clostridia) in the feces by using stool enrichment culture techniques.
- To avoid delay, treatment should be administered without awaiting laboratory confirmation.

Prevention and reporting

- Avoid feeding honey to infants aged ≤12 months.
- Report all cases to local and state health departments.

Epidemiology, diagnosis, treatment, and prevention of foodborne botulism (MMWR, 2003, 52(2):25)

Epidemiology

- Caused by eating foods contaminated with preformed toxins of *Clostridium botulinum*
- Home-canned foods and raw or fermented Alaska Native dishes commonly associated with illness
- During 1973-1998, a total of 814 cases and an annual median of 24 cases (range: 14-94 cases) of foodborne botulism reported in the United States; 236 (29%) in Alaska.
- Humans affected by toxin types A, B, E, and rarely F; type E intoxication associated exclusively with eating marine animals
- Classified as a category A terrorism agent

Clinical findings

- Cranial nerve palsies
- Symmetrically descending flaccid voluntary muscle weakness possibly progressing to respiratory compromise
- Normal body temperature
- Normal sensory nerve examination findings
- Intact mental status despite groggy appearance
- Differential diagnosis includes Guillain-Barré syndrome, myasthenia gravis, stroke, drug overdose, and other entities

Laboratory findings

- Normal cerebrospinal fluid values
- Specific electromyography (EMG) findings including:
 - normal motor conduction velocities
 - normal sensory nerve amplitudes and latencies
 - decreased evoked muscle action potential
 - facilitation following rapid repetitive nerve stimulation

- Standard mouse bioassay positive for toxin from clinical specimens and/or suspect food; requires up to 4 days for final results

Recommended treatment

- Prompt administration of polyvalent equine-source antitoxin:
 - can decrease the progression of paralysis and severity of illness
 - will not reverse existing paralysis
 - available in the United States only through the public health system
- Place suspect cases in an intensive care setting
- Monitor for respiratory function deterioration every 4 hours using forced vital capacity testing.
- Provide mechanical ventilation if necessary

Prevention and control

- Boil raw or fermented Alaska Native dishes and home-canned foods ≥ 10 minutes before eating.
- Follow recommended home-canning procedures.
- Notify state health department immediately of suspected cases.

Environmental conditions that facilitate spore growth and germination include pH < 4.6 anaerobic conditions, low salt or sugar content, and temperatures over 4°C (39.2°F)

Fermented tofu (soybean curd) may be a media for Botulism Type A. Between 1958 to 1989 home-fermented bean products accounted for 63% of the 2000 cases of food borne botulism in China.

Clostridium perfringens Poisoning

Related Information

- Botulism, Diagnostic Procedure
- Electrolytes, Blood
- Stool Culture

Commonly Found In Meat, poultry, dairy products, fruits, vegetables, meat-based gravies (food poisoning)

Mechanism of Toxic Action Anaerobic, gram-positive, spore-forming organism; 12 toxins have been associated with toxin A and C causing disease in humans. Enterotoxin causes fluid secretion; incubation period: 12-24 hours; rarely lasts more than 1 day.

Signs and Symptoms of Overdose Abdominal cramps, diarrhea, myocarditis, myopathy; vomiting and fever are rare

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment In general, the treatment of clostridial infection is high-dose penicillin G, to which the organism has remained susceptible. For skin and soft tissue infections, the extent of infection determines the need for surgical debridement. When wounds are simply colonized with clostridia, neither antibiotics nor surgery are indicated. Localized soft tissue infections can often be managed by surgical debridement alone, without antibiotics. When systemic symptoms are present and there is extension of infection into deeper tissues, antibiotics and surgical intervention are required. In fulminant cases of gas gangrene with myonecrosis, immediate surgical intervention (debridement, amputation) is the primary treatment of choice, and antibiotics have little effect. Hyperbaric oxygen with surgery and antibiotic therapy may reduce mortality.

Diagnostic Procedures

- Botulism, Diagnostic Procedure

Additional Information

Heat labile; destroyed by cooking at 100°C

Microbiology: *Clostridium perfringens* is an anaerobic gram-positive rod; occasionally it can appear gram-negative or gram-variable. It is a spore-forming organism, but the spores are not usually seen on Gram's stain. It has been termed "aerotolerant" because of its ability to survive when exposed to oxygen for limited periods of time.

The organism produces 12 toxins active in tissues and several enterotoxins which cause severe diarrhea; four toxins can be lethal. The toxins separate the species into five types, A-E.

- Alpha toxin: A lecithinase which damages cell membranes. It is produced by *C. perfringens* type A. It is the major factor causing tissue damage in *C. perfringens*-induced gas gangrene (myonecrosis). The toxin is a phospholipase which hydrolyzes phosphatidylcholine and sphingomyelin and leads to increased vascular permeability, myocardial depression, hypotension, bradycardia, and shock.

- Enterotoxin: Produced mainly by *C. perfringens* type A but also by types C and D. This toxin is responsible for the diarrheal syndromes classically ascribed to this organism. The enterotoxin binds to intestinal epithelial cells after the human ingests food contaminated with *C. perfringens*. The small bowel (ileum) is primarily involved. The toxin inhibits glucose transport and causes protein loss.

- Beta toxin: Produced by *C. perfringens* type B and C. This toxin causes enteritis necroticans or pigbel. This disease is seen in New Guinea where some natives ingest massive amounts of pork at feasts after first gorging on sweet potatoes. The sweet potatoes have protease inhibitors which prevent the person from degrading the beta toxin which is ingested in the contaminated pork.

Epidemiology: *C. perfringens* is ubiquitous in the environment, being found in soil and decaying vegetation. The organism has been isolated from nearly every soil sample ever examined except in the sand of the

Sahara desert. In the human, *C. perfringens* is common in the human GI tract. In one study, it was found in 28 of 40 adults. It can also be commonly recovered from many mammals including cats, dogs, whales, and others. About 1000 cases of gas gangrene occur yearly in the United States.

Clinical Syndromes:

The organism can be pathogenic, commensal, or symbiotic. Important diseases caused by *C. perfringens* include the following:

- **Food poisoning:** *C. perfringens* is one of the most common causes of food poisoning in the United States. Foods commonly contaminated with *C. perfringens* are meat, poultry, and meat products such as gravies, hash, and stew. Human disease is caused by ingestion of heat-labile toxin; the highest risk comes from meats which are partially cooked, cooled, then reheated. Spores present in the food germinate during the reheating process. Symptoms include watery diarrhea and abdominal cramps, which occur about 12 hours after the meal; fever is generally not part of this illness. Vomiting is unusual. Duration of symptoms is about 24 hours; the diagnosis is made by culturing the stools and, for epidemiological purposes, the food.
- **Pigbel:** See description under Microbiology above. This follows massive ingestion of contaminated pork and sweet potatoes. Incubation period is 24 hours. There is intense abdominal pain, bloody diarrhea, vomiting, shock, and intestinal perforation in some cases; a vaccine is available for travelers.
- **Gas gangrene:** Usually seen near wounds, swelling, crepitus, bullae, can advance at a rate of 2 cm/hour. Nontraumatic gas gangrene has a strong association with underlying malignancy (most often colorectal)

Diagnosis:

The diagnosis of infection by *C. perfringens* begins with a high index of suspicion when a patient presents with one of the clinical syndromes described above. One important caveat is that the laboratory isolation of *C. perfringens* from a necrotic wound does not necessarily imply disease from this organism; many wounds can be colonized. In the right clinical setting, however, a positive *C. perfringens* culture and a compatible clinical presentation are highly suggestive of disease caused by this agent. Gram's stain preparations of wound material, uterine tissue, cervical discharge, muscle tissues, and other relevant materials should be made; a predominance of gram-positive rods should bring anaerobic infection, including *C. perfringens*, to mind.

In patients with clostridial septicemia, accompanying abnormalities may be a clue to clostridial disease before culture confirmation is made. Patients may have disseminated intravascular coagulation with a brisk hemolysis, hemoglobinuria, and proteinuria. X-rays of diseased areas may reveal the presence of gas in muscle or soft tissue; this is suggestive of clostridial infection, although other anaerobes (and aerobes) can cause gas formation. If clostridial myonecrosis is suspected, a muscle biopsy usually performed at the time of tissue debridement, can be diagnostic.

The classic presentation of infant botulism is hypotonia (floppy baby syndrome), constipation, difficulty in feeding, and a weak cry. Some cases of sudden death syndrome have been traced to ingesting honey containing *C. botulinum*. Both *C. botulinum* and *C. butyricum* have been identified as species capable of toxin production. Auto-intoxication may occur from toxin production during organism growth in tissue, the intestinal tract in both adults and infants, and in wounds.

Cobras

Scientific Name *Boulengerina annulata* (Banded Water Cobra); *Den-draspis* species; *Naja kaouthia* (Asiatic Cobra); *Naja naja arabicus* (Arabian Cobra); *Naja naja naja* (Indian Cobra, Asian Cobra); *Naja nigricollis* (African Spitting Cobra); *Naja nivea* (Cape Cobra)

Mechanism of Toxic Action Venom: Antitoxins that are neuromuscular depolarizing agents; also may contain phospholipases and cardiotoxins

Adverse Reactions

Cardiovascular: Hypotension, cardiovascular collapse, local edema
Central nervous system: Coma, seizures, hyperthermia
Local: Tissue necrosis
Neuromuscular & skeletal: Paresthesias, paralysis
Ocular: Eye pain, conjunctivitis, blindness, corneal injury (with spitting cobra spit), ptosis, ophthalmoplegia

Signs and Symptoms of Overdose Coagulopathy

Admission Criteria/Prognosis All patients should be admitted (probably into an intensive care unit); admit all leg bites; asymptomatic arm/hand bites may be observed for 6 hours and then discharged

Overdosage/Treatment

Decontamination: Rapid transport to medical facility; immobilize area; if negative pressure suction device is available, this may be used; **do not** incise the wound; constriction band may be applied, not a tourniquet; ABC assessment, physical exam; mark extent of local edema with skin-marking pen

Supportive therapy: Repeat lab testing every 3-4 hours for first 12 hours; I.V. fluids, tetanus prophylaxis and analgesics may need to be given; antibiotics may be indicated for infected wound sites; antivenin indicated for moderate to severe envenomation; neurologic findings may respond to intravenous edrophonium (10 mg for adults following pretreatment with 0.6 mg of atropine to block the muscarinic acetylcholine effects). The patient may then be treated with a longer-acting anticholinesterase agent such as neostigmine methyl sulfate (0.5 mg I.V. or SQ in adults) every 20 minutes. Alternatively, neostigmine methyl sulfate (0.5 mg I.V. or SQ every 20 minutes) has been used to reverse neurotoxicity due to an Asiatic Cobra bite. Thai Red Cross Asiatic Cobra antivenin (up to 600 mL) may be needed to treat neurotoxicity due to Asiatic Cobra bites. For antidote, in U.S., contact nearest regional poison center for availability. France, India, and South Africa are international sources for antivenin.

Additional Information Family: Elapidae; neck flares to form characteristic hood

Colubrids

Scientific Name *Dispholidus typhus*; *Thelotornis kirtlandi*

Signs and Symptoms of Overdose Venoms may cause fatality; venom of *Dispholidus typhus* may contain a prothrombin-activating enzyme that can cause a prolonged coagulation defect; coagulopathy

Overdosage/Treatment Supportive therapy: Monitor blood counts and replace with blood products as necessary; monitor for occult hemorrhage

Additional Information Family: Colubridae; *Opisthoglypha* (grooved fangs under eyes). Range: (Boomslang): African rain forest, southern African rain forest; *Thelotornis kirtlandi* (Bird Snake): central and southern African rain forest. Adults average 4-6 feet in length

Cone Shells

Scientific Name *Conus aulicus*; *Conus geographus*; *Conus gloriamaris*; *Conus omaria*; *Conus strictus*; *Conus textile*; *Conus tulipa*

Mechanism of Toxic Action Venom; neurotoxin (may have a curare effect)

Adverse Reactions

Cardiovascular: Cardiac failure, cerebral edema
Central nervous system: Coma
Hematologic: Disseminated intravascular coagulation
Respiratory: Respiratory arrest

Signs and Symptoms of Overdose Aphonia, blurred vision, burning sensation, coma, local ischemia, pain, numbness, paresthesia, respiratory collapse, slurred speech

Overdosage/Treatment

Decontamination: Place involved area in hot water (110°F to 115°F) to relieve pain; tetanus toxoid and immune globulin should be administered if not current; no antivenin available

Additional Information Range: Shallow Indo-Pacific waters

Copperhead Snake

Scientific Name *Agkistrodon contortrix*

Mechanism of Toxic Action Venom; quality and potency vary among species; composition: 90% water with 5-15 enzymes, 3-12 nonenzymatic proteins, as well as other unidentified substances

Signs and Symptoms of Overdose

Local signs: Bullae, edema, erythema, ecchymosis, hemorrhage, lymphangitis, tenderness, and (rarely) compartment syndrome.
Systemic signs: Asthenia, chills, CNS depression, coagulopathy, fasci-culations, hypotension, nausea, paresthesia, sweating, vomiting
Coagulopathies can occur including hypofibrinogenemia, increased PT and PTT, and thrombocytopenia. Hematuria, hemoconcentration, hypoproteinemia, hypotension, lactic acidosis, proteinuria, and shock are also potential complications.

Admission Criteria/Prognosis Patients with evidence of snakebite should be observed for 6-12 hours; if there are no systemic abnormalities (such as coagulopathy) or rapidly expanding edema, patient can be discharged

Overdosage/Treatment

Decontamination: Immobilize the area, rapid transport to medical facility. Use negative pressure device to remove venom if available, **do not** incise the wound; constriction band may be applied, **not** a tourniquet
Wyeth crotalid polyvalent antivenin; treat moderate to severe envenomations with increments of 5-10 vials at a time; skin test per manufacturer's instructions; if positive skin test develops, may prophylax with H₁- and H₂-receptor blockers; give until local injury has stopped and coagulopathy is reversed; complications include allergic reactions, anaphylaxis, and delayed serum sickness
Supportive therapy: ABC assessment, physical exam; mark the extent of local edema with skin marking pen; repeat CBC, platelets, PT, PTT, fibrinogen, CPK, UA every 3-4 hours for at least first 12 hours; I.V. fluids, tetanus prophylaxis, and analgesics may be given as needed;

CORN LILY (VERATRUM)

treat infected wounds with antibiotics. Snakes' mouths contain primarily gram-negative and anaerobic organisms.

Antidote(s)

- Antivenin (Crotalidae) Polyvalent [ANTIDOTE]

Additional Information Family: Crotalidae (Pit Viper). Range: Eastern U.S. to southern Texas. Distinguishing characteristics: Facial pits, vertical elliptical pupils, triangular head, single row of subcaudal scales. Case fatality rate: 0.01%; usually there is a relative benign course and antivenin is not required.

Specific References

Corn Lily (Veratrum)

Scientific Name *Veratrum californicum*

Mechanism of Toxic Action Contains veratrum alkaloids which act on nerve cells lowering the stimulus threshold, thus resulting in repetitive nerve firing after a single stimulus

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose Abdominal pain, blurred vision, bradycardia, confusion, hypertension (uncommon), hypotension, mydriasis, nausea, sweating, oral burning, vomiting, vertigo. These alkaloids produce different effects in various nerve groups depending on their baseline stimulus threshold (afferent vagal fibers of coronary sinus and left ventricle are most affected).

Toxicodynamics/Kinetics

Onset: Within 30 minutes to 4 hours

Duration: 12-15 hours

Overdosage/Treatment

Decontamination: Avoid ipecac due to vagal stimulation, potentiating rapid onset of symptoms; activated charcoal with cathartic may be useful, but might not be tolerated if the patient is vomiting

Supportive therapy: Atropine for bradycardia, hypotension may require I.V. fluids or vasopressors

Additional Information Toxic dose: Unclear; likely 1-2 bulbs in a child. Grows to 4 feet. Range: Western U.S. Toxic part: All. Monitoring parameters: Monitor fluid and electrolyte status in symptomatic patients; ECG monitoring in severely symptomatic patients.

Crotalidae

Related Information

- Rattlesnakes

Scientific Name *Agkistrodon contortrix* (Copperhead); *Agkistrodon piscivorus* (Cottonmouth); *Sistrurus catenatus* (Pygmy Rattlesnake, Massasauga)

Mechanism of Toxic Action Venom, quality and potency vary among species; composition is 90% water with 5-15 enzymes, 3-12 non-enzymatic proteins, as well as other unidentified substances

Adverse Reactions

Gastrointestinal: Metallic taste

Neuromuscular & skeletal: Rhabdomyolysis

Signs and Symptoms of Overdose Systemic: Asthenia, chills, CNS depression, fasciculations, hypotension, orolingual edema, paresthesia, nausea, sweating, vomiting. Coagulopathy can occur including hypofibrinogenemia, increased PT and PTT, and thrombocytopenia. Hematuria, hemoconcentration, hypoproteinemia, lactic acidosis, myopathy, proteinuria, and shock are also potential complications

Local: Bullae, ecchymosis (ascending), edema, erythema, hemorrhage, lymphangitis, tenderness, and (rarely) compartment syndrome

Admission Criteria/Prognosis Admit all leg bites. Patients with evidence of snakebite should be observed for 12 hours; if there are no systemic abnormalities (such as coagulopathy) or edema, patient can be discharged

Overdosage/Treatment

Decontamination: Rapid transport to medical facility; wash the site with soap and water; immobilize and keep it lower than the heart; if negative pressure suction device is available, this may be used; **do not** incise the wound; do not apply tourniquet or ice. ABC assessment, physical exam; mark extent of local edema with skin-marking pen

Supportive therapy: Repeat lab testing every 3-4 hours for first 12 hours; I.V. fluids, tetanus prophylaxis and analgesics may need to be given; antibiotics may be indicated for infected wound sites; antivenin indicated for moderate to severe envenomation. Fasciotomy should be considered if the compartment pressure remains elevated after

infusion of at least 20 vials of antivenin and before the patient has signs or symptoms of compartment syndrome (pressures >30 mm Hg despite limb elevation) for 12 hours.

Antidote:

Wyeth crotalid polyvalent antivenin: Treat moderate to severe envenomations with increments of 5-10 vials at a time; skin test per manufacturer's instructions; prophylax with H₁- and H₂-histamine receptor blockers; give until local injury has stopped or coagulopathy is reversed; complications include allergic reaction, anaphylaxis, and delayed serum sickness

Newer affinity-purified, mixed monospecific crotalid antivenom ovine Fab antivenom is being developed by Protherics, Inc. (Nashville, TN); each vial contains 750 mg Fab and 90 mg NaCl and is reconstituted in 10 mL of normal saline; initial dose: 4 vials diluted in normal saline (250 mL) administered over 60 minutes I.V. See Antivenin (Crotalidae) Polyvalent [ANTIDOTE] for further dosing details.

Antidote(s)

- Antivenin (Crotalidae) Polyvalent [ANTIDOTE]
- Antivenin, Polyvalent Crotalid (Ovine) Fab [ANTIDOTE]

Additional Information Distinguishing characteristics: Facial pits, vertical elliptical pupils, triangular head, single row of subcaudal scales; 6-12 foot brown/tan snake with dark rhomboid markings. Range: Indigenous to Central and South America. Case fatality rate is as high as 14% in some case series. Copperhead exposure is unlikely to require antivenin therapy.

Crown of Thorns

Related Information

- Milkbush

Scientific Name *Euphorbia millii*; *Euphorbia*

Mechanism of Toxic Action Contact dermatitis

Signs and Symptoms of Overdose Blistering, erythema, irritation, potentially severe ocular pain, swelling, temporary blindness ulceration, vesication

Toxicodynamics/Kinetics Symptoms are delayed 2-8 hours with peak effects at 8-24 hours; blisters heal in several days; ocular symptoms may take a month to resolve

Overdosage/Treatment

Decontamination: **Oral:** Dilute with milk or water. **Dermal:** Wash thoroughly with soap and water. **Ocular:** Irrigate with copious tepid water or saline

Supportive therapy: Antibiotics if infected, oral corticosteroids may be useful for severe reactions; no antidote; antihistamines are not likely to be beneficial

Additional Information Toxicity varies within species; blisters should heal without scarring

Cycad Nut

Scientific Name *Cycas circinalis*

Mechanism of Toxic Action Contains cyasin (methylazoxymethanol), an aglycone which is a hepatocarcinogen and colonic tumorigen through means of methylation

Adverse Reactions

Neuromuscular & skeletal: Amyotrophic lateral sclerosis
Hepatic: Hepatitis, hepatic necrosis

Toxicodynamics/Kinetics Metabolism: Gut hydrolysis to methylazoxymethanol (MAM), a potent hepatocarcinogen and colonic tumorigen

Overdosage/Treatment Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal with cathartic

Additional Information Cycads had been used for food; detoxification occurs by cutting stems and seeds into small pieces, soaking in water for several days, drying and grinding into flour

Cyclospora cayetanensis Food Poisoning

Commonly Found In Reptiles, myriapods, insectivores, raspberries, strawberries, contaminated water, raw vegetables, cow manure

Mechanism of Toxic Action A coccidian parasitic agent which can cause protracted watery diarrhea of uncertain mechanism

Adverse Reactions

Central nervous system: Low grade fever, headache, fatigue
Gastrointestinal: One day prodrome of anorexia, malaise, explosive watery diarrhea, nausea, severe abdominal cramping and vomiting; while diarrhea may remit and relapse over a 4-day cycle, the duration of illness lasts a mean time of 43 days

Overdosage/Treatment Supportive therapy: Fluid replacement is the mainstay of therapy; antibiotic treatment consists of a 7-day course of oral trimethoprim (TMP)-sulfamethoxazole (SMX); 160 mg TMP plus 800 mg SMX twice daily for adults and 5 mg/kg TMP plus 25 mg/kg SMX twice daily for children

Additional Information Seasonal peak is from April to June; cyanobacteria (blue-green algae) with variable acid-fast staining properties; previously called cyanobacterium-like body; under light microscopy, these organisms appear as a cluster of nonrefractile 8-10 μm spheres with a thick cell wall and an absence of a nucleus but presence of dark granules in cytoplasm; under ultraviolet light, these organisms autofluoresce; incubation period is one week; transmission is by fecal-oral route; suspected cases should be reported to the CDC's Division of Parasitic Diseases (770) 488-7760; may be found in developing countries (Nepal, Haiti), Mexico and in AIDS patients; midwestern outbreak in summer of 1996 relatable to contaminated raspberries and strawberries

Daffodil

Scientific Name *Narcissus pseudo-narcissus*

Mechanism of Toxic Action Contains lycorine alkaloid

Signs and Symptoms of Overdose Humans: Abdominal pain, allergic and contact dermatitis, nausea, vomiting

Toxicodynamics/Kinetics All parts of plant are toxic, especially the bulb; contains crinine, narcissine, lycorine, and other

Overdosage/Treatment

Decontamination: Ipecac relatively contraindicated; may be useful, if given soon after ingestion; vomiting has not occurred with ingestion of more than one bulb; activated charcoal with cathartic/lavage (within 1 hour) may be beneficial depending on amount ingested and time elapsed since ingestion

Supportive therapy: Wash skin extremely thoroughly with soap and water

Additional Information Toxic dose: Not established. Bulbs have been mistaken for onions. Toxic part: All parts contain alkaloid, bulb is most toxic

Daphne

Scientific Name *Daphne mezereum*

Mechanism of Toxic Action Contains mezerein (in the bark) and daphne toxin which are extremely irritating; seeds contain acrid resin; drying does not decrease toxicity

Adverse Reactions

Cardiovascular: Shock, facial edema
Central nervous system: Fever, headache, delirium, seizures, lethargy
Dermatologic: Blisters
Gastrointestinal: Nausea, vomiting, abdominal pain, watery diarrhea, dysphagia

Hematologic: Hematuria, proteinuria
Neuromuscular & skeletal: Muscle twitching
Miscellaneous: Thirst

Signs and Symptoms of Overdose Diarrhea, inflammation, mild to severe dermal irritation (which may include pruritus, edema, erythema, vesiculation), nausea, ocular irritation, possible severe gastroenteritis, possible temporary blindness, vomiting

Toxicodynamics/Kinetics Few reports of exposure available, unclear; dermal symptoms may be immediate or delayed by several hours and resolve within 4-7 days

Absorption: Orally and through intact skin

Overdosage/Treatment

Decontamination: **Oral:** Ipecac relatively contraindicated, may be useful if given soon after ingestion if the patient is asymptomatic, activated charcoal with cathartic may be of benefit, lavage within 1 hour may be beneficial in large overdose or in asymptomatic patients presenting later. **Dermal:** Wash thoroughly even if asymptomatic. **Ocular:** Irrigate copiously with saline.

Supportive therapy: Monitor fluid and electrolyte balance in patients with vomiting and diarrhea; seizures can be treated with benzodiazepines, phenobarbital, or phenytoin

Oral: Maintain proper fluid and electrolyte balance in symptomatic patients

Dermal: Antihistamines and steroids have not clearly been beneficial

Ocular: Supportive care

Additional Information Toxic dose: A single berry or leaf may produce symptoms; 2-3 may be fatal in a child; 12 may cause significant toxicity in an adult. Family: Thymelaeaceae. Range: Common hedge of United States, Eastern Canada, and Europe. Toxic part: Whole plant is poisonous. About 4-5 feet in height; leaves are elliptic and vivid green; flowers are lilac purple or white and about 1 cm in length; fruits are scarlet or yellow.

Deadly Nightshade

Related Information

- Black Nightshade
- Woody Nightshade

Scientific Name *Solanum dulcamara*

Mechanism of Toxic Action Contains toxic alkaloids, solanine most significant structurally similar to cardioglycoside, causes hemolytic and hemorrhagic damage to GI tract similar to saponins; some plants may also contain alpha-cholinergic alkaloids

Adverse Reactions Central nervous system: Psychosis

Signs and Symptoms of Overdose Anticholinergic effects (may or may not be present to varying degrees), asthenia, diarrhea, drowsiness, fever, hallucinations, headache, nausea, seizures, sweating, vomiting, visual changes

Toxicodynamics/Kinetics Toxicity occurs within 2-24 hours, diarrhea may last 3-6 days, anticholinergic effects may delay GI emptying and produce delayed effects

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes if vomiting has not already occurred, lavage (within 1 hour) and/or charcoal may be beneficial if the patient presents symptomatic

Supportive therapy: Maintain fluid and electrolyte balance as necessary, support vital signs; physostigmine will reverse anticholinergic toxicity that may be associated with exposure

Antidote(s)

- Physostigmine [ANTIDOTE]

Additional Information Toxic dose: 2-3 green berries or 6 red or black berries should not cause significant toxicity (fatal dose: 200 berries).

Toxic part: All parts of plant contain solanine and are regarded as toxic. Peak plasma and urine atropine levels 10 hours after ingestion of 6 raw berries and 200 g of cooked berries (and associated with coma) were 217 mcg/L and 3092 mcg/L respectively

Death Camas

Scientific Name *Zigadenus nuttallii*; *Zigadenus paniculatus*; *Zigadenus venenosus*

Mechanism of Toxic Action Contains an alkaloid (zygacine) of the veratrum group which increases muscle and nerve excitability; younger plants are more toxic

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose Ataxia, bradycardia, diarrhea, hyperactive deep tendon reflexes, coma, hypotension, muscle fasciculation, muscle spasticity, respiratory depression, vomiting, nausea, abdominal pain, dizziness, flushing, headache, hematemesis

Overdosage/Treatment

Decontamination: Gastric lavage within 2 hours; activated charcoal
Supportive therapy: While bradycardia may respond to atropine, hypotension will not; give isotonic saline I.V. and supplement with vasopressors (dopamine or norepinephrine) as needed; recovery usually noted within 2 days

DELPHINIUM

Additional Information A common plant of the lily family often confused with sego lilies or wild onion; leaves are V-shaped; yellow flowers appear in summer; 1-2 bulbs (10-15 g) can produce symptoms. Range: Found in the dry soil of the Western U.S.

Specific References

Peterson MC and Rasmussen GJ, "Intoxication with Foothill Camas (*Zigadenus paniculatus*)," *J Toxicol Clin Toxicol*, 2003, 41(1):63-5.

Delphinium

Adverse Reactions Cardiovascular: Sinus bradycardia, sinus tachycardia, arrhythmias (ventricular)

Signs and Symptoms of Overdose No reports of human toxicity. May contain alkaloids with effects similar to monkshood; tingling and burning of fingers, lips, toes and tongue are seen first; then sweats, hypothermia, chills, paresthesia, numbness, dry mouth; later: arrhythmias (supraventricular), bradycardia, diarrhea, hypotension, pain, paralysis, seizures, ventricular fibrillation

Overdosage/Treatment

Decontamination: Ipecac is questionable due to inducing rapid onset of symptoms; lavage within 1 hour may be beneficial, activated charcoal with cathartic

Supportive therapy: Fluid and electrolyte replacement; arrhythmias are relatively refractory to drug therapy

Additional Information Range: Found in central U.S.

Devil's Ivy

Scientific Name *Epipremnum aureum*

Mechanism of Toxic Action Contains insoluble calcium oxalate crystals which cause mechanical irritation; also may cause irritant dermatitis

Signs and Symptoms of Overdose Sap may cause ocular pain, lacrimation, photophobia, corneal abrasion; oxalate crystals may be deposited on cornea; dermal pain, irritation, and swelling; edema, diarrhea, dysphonia, salivation, vomiting

Toxicodynamics/Kinetics Rapid onset of local symptoms

Overdosage/Treatment

Decontamination: **Oral:** Dilute; ipecac/lavage/activated charcoal not likely necessary. **Dermal:** Wash thoroughly. **Ocular:** Irrigate

Supportive therapy: **Oral:** Ice cream may provide some relief. **Dermal/ocular:** Cool compresses may minimize pain.

Additional Information Symptoms dependent on liberation of oxalate crystals or contact with sap; dried plant will not liberate crystals; insoluble calcium oxalates will not cause systemic symptoms. Toxic part: Whole plant

Dieffenbachia

Mechanism of Toxic Action Contains insoluble calcium oxalate crystals which cause mechanical irritation; may also cause irritation through an unclear enzymatic process.

Signs and Symptoms of Overdose Dermal pain, diarrhea, dysphonia, edema, irritation, salivation, swelling, vomiting; oxalate crystals may be deposited on cornea; sap may cause corneal abrasion, lacrimation, ocular pain, photophobia; may cause dermatitis

Admission Criteria/Prognosis Admit any ingestion > 3 g (of the leaf) or evidence of upper airway obstruction

Toxicodynamics/Kinetics Rapid onset of local symptoms

Overdosage/Treatment

Decontamination: **Dermal:** Wash thoroughly; **Ocular:** Irrigate; **Oral:** Dilute; ipecac/lavage/activated charcoal not likely necessary; oral irritation can be treated with ice or a popsicle

Supportive therapy: Cool compresses may minimize pain and swelling; dexamethasone ophthalmic ointment can be used for eye exposure

Additional Information

Lethal dose: Oral: 3 g.

Symptoms are dependent on liberation of oxalate crystals or contact with sap; dried plant will not liberate crystals; wide variation in potential for toxicity between plants. Treat symptoms. Insoluble calcium oxalate will not cause systemic symptoms; ingestion of stems or stalk may cause upper airway obstruction. Toxic part: Whole plant

Elapids

Scientific Name *Micrurus euryxanthus*; *Micrurus fulvius*

Mechanism of Toxic Action Neurotoxin - average amount of dry venom injected: 2-6 mg; significant envenomations occur in 60% of cases

Signs and Symptoms of Overdose Western coral snake: Local injury Eastern coral snake: Asthenia (within 1-2 hours), coagulopathy, diplopia, fasciculations, nausea, paresthesias, vomiting; complete paralysis within 36 hours may occur

Admission Criteria/Prognosis All patients should be admitted (probably into an intensive care unit)

Overdosage/Treatment

Decontamination: Incision and suction can be performed within 30 minutes (1 hour if a tourniquet is in place); wide excision and suction should be reserved for severe envenomations on the trunk

Supportive therapy: Antivenin should be administered as soon as possible for Eastern coral snake envenomation (usual dose: 4-6 vials); horse-derived antivenin is available (Wyeth)

Antidote(s)

- Antivenin (*Micrurus fulvius*) [ANTIDOTE]

Additional Information Family: Elapidae. Range: Western coral snake is found in Arizona and New Mexico, while Eastern coral snake is found in North Carolina, Florida, and the gulf states; average length is 16-28 inches

Antivenin has been given on affected extremity distal to a blood pressure cuff (inflated to block arterial flow) while massaging the extremity to the blood pressure cuff (similar to the Bier-block anesthetic technique)

Elderberry

Scientific Name *Sambucus*

Mechanism of Toxic Action Laxative effect unclear; also contains cyanogenic glycoside

Signs and Symptoms of Overdose Diarrhea, nausea; effects of cyanogenic glycoside include abdominal pain, coma, cyanosis, drowsiness, dyspnea, headache, seizures, sweating, vomiting

Overdosage/Treatment

Decontamination: Ipecac (within 30 minutes) recommended in ingestions of leaves, roots, bark, unripe fruit; activated charcoal with cathartic may be useful; **do not** give cathartic if diarrhea has developed

Supportive therapy: Maintain fluid and electrolyte balance

Additional Information Toxic dose: Unclear; variable. Ripe fruit is edible when cooked; raw fruit may cause nausea or diarrhea if eaten in large amounts; leaves, roots, bark, unripe fruit may cause more severe diarrhea, although roots, stems, and leaves contain cyanogenic glycosides; there are no documented reports of cyanide toxicity. Range: Native to Western U.S. and Canada

English Ivy

Scientific Name *Hedera helix*

Mechanism of Toxic Action Falcarinol which is an irritant and sensitizer, is a potent alkylating agent; polyacetylenes cause direct contact irritation

Signs and Symptoms of Overdose Irritant contact dermatitis is the most common finding. Linear and streaked vesicles may be seen. Ingestion may cause ataxia, burning sensation in the throat, coma, diarrhea, difficulty breathing, mydriasis, nausea, rash, and vomiting.

Overdosage/Treatment

Decontamination: **Oral:** Corticosteroids are used to treat the irritant dermatitis, but the reaction may not subside for 3-4 weeks

Supportive therapy: Systemic symptoms require symptomatic and supportive treatment

Additional Information Low concentrations of falcarinol have been found to be irritating; specific amounts of plant material required to produce systemic symptoms are unknown, but poisonings are rare. Range: Native to Europe; commonly found throughout the U.S. and southern Canada. Toxic part: All of the plant, especially leaves and berries

Escherichia coli Food Poisoning

Commonly Found In Contaminated water

Mechanism of Toxic Action Can produce heat labile and heat stable enterotoxins. Enteropathogenic *E. coli* and enterohemorrhagic *E. coli* (serogroup O157) produce Shiga toxin; incubation period: 1-3 days. Enterohemorrhagic *E. coli* produces hemorrhagic colitis and hemolytic uremia syndrome.

Adverse Reactions Hematologic: Hemolytic/uremic syndrome

Signs and Symptoms of Overdose Watery diarrhea (enterotoxin); fever and vomiting are unlikely

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment Supportive therapy: While fluoroquinolones are effective for empiric treatment in adults with severe acute diarrhea, antibiotics should be avoided if initial infection with enterohemorrhagic *E. coli* is suspected, especially in children. Thus, the stool culture should be used to guide therapy. Fluid/electrolyte replacement is the mainstay of therapy. Antimotility agents should **not** be used.

Diagnostic Procedures

- Stool Culture

Additional Information

Can cause necrotizing enterocolitis in the newborn or weanling diarrhea (in poor sanitation areas)

Escherichia coli, enterohemorrhagic:

Microbiology: Enterohemorrhagic *E. coli* causes a distinct form of hemorrhagic colitis in humans. Like other *E. coli* strains, enterohemorrhagic *E. coli* is a facultative, gram-negative bacillus. The most common serotype is O157:H7; essentially all published information regarding enterohemorrhagic *E. coli* refers only to this serotype.

Epidemiology:

In 1982, the first large-scale outbreak of *E. coli* O157:H7 colitis was described. Multiple cases of severe bloody diarrhea were found to be epidemiologically linked to ingestion of contaminated hamburger meat. Since then, the organism has been recognized as an important cause of bloody diarrhea and the hemolytic uremic syndrome. Over 12 major outbreaks have been reported, along with numerous sporadic cases. The majority of cases have been traced to contaminated ground beef, although other potential sources have been cited, including unpasteurized milk, apple cider, municipal water, and roast beef. The organism inhabits the GI tract of some healthy cattle and is thought to contaminate meat during slaughter and the processing of ground beef ("internal contamination"). If the ground beef is undercooked, the organism remains viable; undercooking of hamburger patties has proven important in several outbreaks.

In 1993, a well-publicized multistate outbreak of *E. coli* O157:H7 took place in the Western United States (Washington, California, Idaho, and Nevada). Over 500 infections and four deaths were documented. The vast majority of cases were ultimately linked to contaminated hamburger meat from a particular restaurant chain. Further investigation by the Centers for Disease Control identified several slaughter plants in the United States and one in Canada as the probable source. Thousands of contaminated patties not yet consumed were discovered. In March, 1994, the USDA Food Safety and Inspection Service recommended that all raw meat should be cooked thoroughly, with an increase in the internal temperature for cooked hamburgers to 155°F.

A 2-year nationwide surveillance study by the Centers for Disease Control has found *E. coli* O157:H7 to be the most commonly identified pathogen associated with bloody diarrhea. In many parts of the U.S., *E. coli* O157:H7 is the second most common cause of bacterial diarrhea.

Acquisition of disease is usually by ingestion of contaminated food, but person-to-person transmission has been documented, especially in day care centers. Children and elderly individuals are at highest risk for severe infections. Simple and careful hand washing essentially eliminates the probability of person-to-person transmission.

Case fatality rates in elderly patients range from 3% to 36%. Incidence of *E. coli* O157:H7 in all cases of diarrhea range from 0.6% to 2.4% (highest in children <5 years of age; lower for persons 50-59 years of age). Progression to hemorrhagic colitis with *E. coli* O157:H7 is 38% to 61%.

Clinical Syndromes:

- **Hemorrhagic colitis:** *E. coli* O157:H7 causes a bloody diarrhea associated with abdominal cramps. Pathologically, there is no invasion or inflammation of the intestinal mucosa, and thus fever is often absent. The diarrhea is caused by Shiga-like toxins. In most cases, the illness resolves within 7 days, but death can occur in the elderly.

- **Hemolytic uremic syndrome:** ~5% to 10% of patients with *E. coli* O157:H7 diarrhea develop a syndrome characterized by acute renal failure, thrombocytopenia, and evidence of hemolysis on a peripheral blood smear. Children are at high risk for this syndrome, with ~15% of children developing hemolytic-uremic syndrome soon after diarrhea. Ten percent of children with this syndrome present with a generalized seizure. The patient may be toxic-appearing, and the presentation may be confused with a variety of diseases including sepsis with disseminated intravascular coagulation, vasculitis, thrombotic thrombocytopenia purpura, and others. The estimated mortality is 3% to 5%.

Diagnosis:

Enterohemorrhagic *E. coli* should be strongly considered in any patient presenting with bloody diarrhea, whether or not hemolytic uremic syndrome is present. It is likely that many sporadic cases of *E. coli* O157:H7 diarrhea occur in the community and go unrecognized for two reasons: many clinicians do not order stool cultures for stable patients with diarrhea; many microbiology laboratories do not routinely culture stools for *E. coli* O157:H7 unless there is a specific order from the physician.

Diagnosis is confirmed by isolation of *E. coli* O157:H7 from stool specimens and subsequent serological confirmation. This requires special media in the microbiology laboratory (sorbitol-MacConkey medium). Other methods for the rapid detection of this organism are currently under study.

Escherichia coli, nonenterohemorrhagic:

Microbiology: *Escherichia coli* is a lactose-positive, gram-negative, facultative bacillus with variable motility. A member of the Enterobacteriaceae family, *E. coli* is probably the most widely studied free-living organism. Most *E. coli* are nonpigmented, produce lysine decarboxylase, utilize acetate as a carbon source, and hydrolyze tryptophan to indole. Serologic typing is based on three surface antigens (O, H, K). The lipopolysaccharide of the cell wall is known as endotoxin and is a factor in sepsis and septic shock in infected individuals.

Epidemiology: *E. coli*, as well as other Enterobacteriaceae, are normal colonizers of the human and animal gastrointestinal tract. It is often considered an opportunistic pathogen in hospitalized or debilitated patients but is the most common cause of urinary tract infections among "normal" hosts.

Diagnosis: *E. coli* infection diagnosis can be made by identification through Gram's stain and culture in patients with relevant clinical syndromes. No special media or conditions are necessary to grow this organism. *E. coli* should always be one of several suspected organisms in patients with peritonitis.

Escherichia coli O157:H7 causes an estimated 20,000 cases of diarrhea in the U.S. of which 6% result in the hemolytic-uremic syndrome. As of March, 1995, 33 states have enacted legislation designating *E. coli* O157:H7 infection as a reportable disease.

From January 1, 1993 through September 14, 1995, there were a total of 63 outbreaks of *E. coli* O157:H7 in 32 states; 40% of these outbreaks were related to ground beef

USDA Meat and Poultry Hotline for *E. coli* O157:H7 and O111:H2 exposures: (800) 535-4555.

Specific Reference

Bruce MG, Curtis MB, Payne MM, et al, "Lake-Associated Outbreak of *Escherichia coli* O157:H7 in Clark County, Washington, August 1999," *Arch Pediatr Adolesc Med*, 2003, 157(10):1016-21.

Eucalyptus Oil

Scientific Name *Eucalyptus globulus*

U.S. Brand Names Bosisto's® Eucalyptus Spray; Eucalyptamint®; Gelodurat®

Uses A volatile oil often used as a liniment; taken orally for treatment of cough or catarrh

Mechanism of Toxic Action Contains as much as 70% of the substance citronellal which is an irritant. Obtained from the leaves and terminal branches of the Eucalyptus (Myrtaceae) dives or Eucalyptus radiata.

Adverse Reactions

Central nervous system: Fever, dizziness, ataxia
Dermatologic: Contact dermatitis (allergic and irritant)
Gastrointestinal: Nausea, vomiting, diarrhea

Respiratory: Bronchospasm, cough, tachypnea, lipoid pneumonia

Signs and Symptoms of Overdose Apnea, coma, cyanosis, hypoflexia, miosis, pulmonary edema, respiratory depression, seizures, slurred speech, tachycardia

Toxicodynamics/Kinetics Elimination: Lungs/GI tract

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) if any amount is ingested; **do not** induce emesis; activated charcoal with cathartic can be used
Supportive therapy: Benzodiazepines are initial choice for seizure control; phenytoin or phenobarbital can be used for refractory seizures

FIR CLUB MOSS

Enhanced elimination: Hemodialysis (with peritoneal dialysis and with mannitol) has been used successfully in one case

Additional Information

Toxic dosage:

Fatal dose: ~3.5 mL

Liniments: Concentrations as high as 25% eucalyptus oil

Therapeutic: Oral: ~0.5 mL/dose

Specific gravity: 0.9;

Camphor-like odor; after ingestion, the patient's breath may continue to elicit this odor for as long as 2 weeks; oil solution can cause a lipid pneumonia

Fir Club Moss

Scientific Name *Lycopodium selego*

Mechanism of Toxic Action Contains huperzine A, an alkaloid agent with significant inhibition of acetylcholinesterase; contains 3.6 μmol of huperzine A per gram of dried plant

Signs and Symptoms of Overdose Vomiting and diarrhea usually develop within 1.5 hours. Dizziness, extremity cramps, hypertension, and slurred speech can occur. Five grams of the dried substance can cause the above symptoms. Symptoms usually abate in 2-3 days; mild hypokalemia may develop.

Reference Range Ingestion of 4 μmol of huperzine A will yield a peak plasma concentration of 35 mM/L at 80 minutes. A plasma level of 78 mM/L results in approximately a 56% inhibition of acetylcholinesterase.

Overdosage/Treatment

Decontamination: Activated charcoal within 1 hour of ingestion may be useful.

Supportive therapy: Monitor electrolytes. Atropine may be useful in treating cholinergic symptoms.

Additional Information A small (<30 cm) creeping evergreen found in temperate climates; these plants resemble pine with needle-like leaves.

Fire Ants

Scientific Name *Solenopsis invicta*; *Solenopsis richteri*

Mechanism of Toxic Action Venom (average amount injection: 0.04-0.11 μL), piperidine alkaloids causing histamine release and necrosis in human skin; similar toxin to the brown recluse spider; also contains phospholipase and hyaluronidase

Adverse Reactions

Cardiovascular: Sinus tachycardia

Miscellaneous: Allergic reaction symptoms; anaphylaxis in 0.6% to 1% of stings

Signs and Symptoms of Overdose Characteristic signs include edema, erythema, pain, and wheal formation at the sting site. Dyspnea, fever (for 1-2 days), hypertension, nausea, tachycardia, and seizures may occur. Classic allergic reaction symptoms may be seen. A 2-3 mm sterile pustule may be noted (occasionally this may be hemorrhagic). Pustules may last 3-8 days.

Overdosage/Treatment Supportive therapy: Urticaria can be treated with epinephrine and antihistamines (H₁- and H₂-blocking agents); oral corticosteroids can be given; local pain can be treated with local injections of lidocaine

Antidote(s)

● Epinephrine [ANTIDOTE]

Additional Information Family: Formicidae. Range: southern U.S.; native to South America; attracted to electric current. Infestations found as far north as Virginia Beach, Virginia. In Eastern Tennessee, 7% of the ant population survived during the winter of 1993-4. There are ~3000 bites reported annually in the U.S.; ~2% of fire ant bites result in severe consequences.

Fire-Bellied Toad

Scientific Name *Bombina bombina*

Uses Found in aquariums as pets

Mechanism of Toxic Action Contains bombesin (a cardiovascular toxin which can cause increased blood pressure and smooth muscle stimulation) and bombinin (which can cause hemolysis) which can be secreted from venom glands on the skin

Adverse Reactions

Central nervous system: Lethargy

Dermatologic: Hives, dermal irritation

Gastrointestinal: Oral irritation

Ocular: Irritation, eyelid edema, miosis

Admission Criteria/Prognosis Admit any patient with systemic toxicity

Overdosage/Treatment

Decontamination: **Oral:** Emesis within 30 minutes of ingestion, or lavage within 1 hour of ingestion; activated charcoal with cathartic. **Dermal:** Wash with soap and water. **Ocular:** Irrigate with saline.

Supportive therapy: Systemic allergic symptoms can be treated with diphenhydramine.

Additional Information Native to Eastern Europe and Western Asia; ocular symptoms usually resolve within 1 day; dorsal side of toad is green with black splotches; ventral is black with red splotches

Fire Coral

Scientific Name *Hydrozoa millepor*

Mechanism of Toxic Action Nematocysts bear tentacles which cause intense local reaction

Signs and Symptoms of Overdose Burning and pain; rash and erythema may also occur. Abdominal pain, chills, and fever occur less commonly. Severe abrasions can result from sharp exoskeletons. Full thickness skin burns may result. Rubbing the affected area worsens the envenomation. Blisters can be seen within 6 hours. Symptom resolution occurs within 1 week.

Overdosage/Treatment

Decontamination: Soak affected area in hot water (110°F to 115°F); sea water rather than freshwater is preferred. Coral cuts should be cleansed (with acetic acid 5% or isopropyl alcohol 40% to 70%) and debrided. **Do not rub affected area.**

Supportive therapy: Treat rash with epinephrine and antihistamines; dermatitis can be treated with a topical steroid cream

Additional Information Family: Milleporidae; *Millepora alcicornis*: Found in Caribbean; *Millepora dichotoma*: Found in Red Sea, Pacific

Flowering Maple

Scientific Name Abutilon Hybridum

Adverse Reactions

Dermatologic: May cause dermatitis

Miscellaneous: Allergic skin reactions have been reported

Overdosage/Treatment

Decontamination: Wash skin with soap and water

Supportive: Mild cases can be treated with antihistamines (with or without epinephrine)

Four-O'Clock

Scientific Name *Mirabilis jalapa*

Signs and Symptoms of Overdose Handling the roots or seeds may result in dermatitis. Ingestion may cause abdominal pain, diarrhea, nausea, and vomiting. Smoking or eating the seeds is rumored to result in hallucinogenic effects.

Overdosage/Treatment Decontamination: Charcoal may be of value, one dose of cathartic may be considered if symptoms have not begun

Additional Information Toxic dose: Not established; Toxin: Trigonelline; Range: Native to Mexico and Central and South America, cultivated throughout the U.S.; Toxic part: Roots and seeds

Foxglove

CAS Number 17575-20-1

Scientific Name *Digitalis purpurea*

Mechanism of Toxic Action Leaves and seeds contain digitalis glycosides which inhibit the sodium - potassium ATPase pump, causing decreased intracellular potassium and increased intracytoplasmic calcium

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose GI effects (nausea and vomiting) usually precede cardiovascular effects by several hours. Asystole, AV block, bradycardia, decreased QT interval and prolonged P-R interval, fibrillation (atrial), flutter (atrial), heart block (first, second, and third degree), hypotension, ventricular arrhythmias. Contact dermatitis, delirium, dizziness, confusion, fatigue, headache, hyperkalemia and seeing yellow halos have also been reported.

Admission Criteria/Prognosis Asymptomatic patients with normal electrocardiogram and electrolytes can be discharged after a 12-hour observation; any symptomatic patient should be admitted to a cardiac monitor bed; unintentional ingestions rarely require admission

Toxicodynamics/Kinetics Upper limit of peak toxicity: 12 hours; all symptomatic patients should be observed for a minimum of 24 hours

Reference Range Serum concentration of digitalis glycosides following a nonfatal adult overdose was: gitoxin 13.1 ng/mL; digitoxin 112.6 ng/mL, digitoxigenin 3.3 ng/mL, and digitoxigenin mono-digitoxoside 8.9 ng/mL. Peak urinary levels were reached at 30 hours postingestion.

Overdosage/Treatment

Decontamination: Lavage within 1 hour and multidose activated charcoal with cathartic enhance total body clearance of digitalis; whole bowel irrigation is also beneficial in removing plant debris from the GI tract and is recommended for ingestions of large amounts of plant material

Supportive therapy: Monitor cardiac status and serum potassium levels; bradycardia will frequently respond to atropine; phenytoin is the recommended treatment for ventricular arrhythmias because it will also improve conduction through the AV node; lidocaine can also be used to treat ventricular arrhythmias, but will not have an effect on AV

conduction; other antiarrhythmics which have been used in arrhythmias resistant to the above therapy include magnesium, amiodarone, and bretylium; a pacemaker should be considered for bradycardia and AV nodal blocks resistant to medical management

Antidote: Digoxin immune Fab has been shown to interact with several different plant cardiac glycosides and may be beneficial in cases resistant to conventional treatment; indications for its use include ventricular arrhythmias resistant to conventional treatment, severe bradycardia and/or second or third degree heart block resistant to atropine and phenytoin

Antidote(s)

- Digoxin Immune Fab [ANTIDOTE]

Diagnostic Procedures

- Digitoxin, Blood

Additional Information

One cup of foxglove tea produced junctional rhythm with a heart rate the 40s with frequent PVCs, in an adult.

In accidental ingestion in children, ipecac and home observation are recommended for ingestion of one leaf or less. If more than one leaf is ingested, decontamination and observation in the emergency room are recommended.

Persons taking digoxin, beta-blockers, and calcium channel blockers are more susceptible to the toxin. Digitoxin assay has been shown to cross-react with the digitalis glycoside and thus may be beneficial in documenting ingestion; however, serum levels and toxicity do not necessarily correlate.

Family: Schrophulariaceae; Range: Native to Europe, but commonly found in the U.S. Toxin: Digitalis, digitoxin, cardiac glycosides

Specific References

Ciancaglioni PP, Vence T, Benitez JG, et al, "Foxglove Salad Ingestion," *Clin Toxicol (Phila)*, 2005, 43:761.

Francisella tularensis

Mechanism of Toxic Action A nonmotile, aerobic gram-negative coccobacillus which can cause infections via dermal, gastrointestinal, and pulmonary routes. As little as 10 organisms can result in infection. Causes focal suppurative necrosis of tissue, resulting in granulomatous reactions. Target organs include lungs, lymph nodes, spleen, liver, and kidney. Two strains exist: Type A (highly virulent in humans) and Type B.

Adverse Reactions Miscellaneous: Mononucleosis-like syndrome

Signs and Symptoms of Overdose

Abrupt onset with high fever, headache, low backache, rigors, and sore throat. Other associated symptoms include dry cough, dyspnea, hemoptysis, pleuritic chest pain, and tachypnea. Radiological studies reveal peribronchial infiltrates leading to hilar adenopathy, multilobar pneumonia, and pleural effusion. Extrapulmonary symptoms include anorexia, diarrhea, diaphoresis, nausea, vomiting, and weakness. Type A infection fatality rate may be as high as 60% in untreated pneumonia, although in the U.S., the fatality rate is <2%. Type B strains are rarely fatal. Incubation is ~3-5 days.

Ulceroglandular tularemia results from handling a contaminated carcass, or after an arthropod bite. A local cutaneous papule forms which then ulcerates within 2-3 days. Regional adenopathy then develops.

Oropharyngeal tularemia results from drinking contaminated water or eating contaminated food. Stomatitis develops with exudative pharyngitis and pronounced cervical or retropharyngeal adenopathy. See tables.

Working Group Consensus Recommendations for Treatment of Patients with Tularemia in a Contained Casualty Setting*	
Contained Casualty Recommended Therapy	
Adults	
Preferred choices	Streptomycin, 1 g I.M. twice daily
	Gentamicin, 5 mg/kg I.M. or I.V. once daily†
Alternative choices	
	Doxycycline, 100 mg I.V. twice daily
	Chloramphenicol, 15 mg/kg I.V. 4 times/day†
	Ciprofloxacin, 400 mg I.V. twice daily†
Children	
Preferred choices	
	Streptomycin, 15 mg/kg I.M. twice daily (should not exceed 2 g/day)
	Gentamicin, 2.5 mg/kg I.M. or I.V. 3 times/day†

Table (Continued)	
Contained Casualty Recommended Therapy	
Alternative choices	
	Doxycycline; if weight ≥45 kg, 100 mg I.V. twice daily; if weight <45 kg, 2.2 mg/kg I.V. twice daily
	Chloramphenicol, 15 mg/kg I.V. 4 times/day†
	Ciprofloxacin, 15 mg/kg I.V. twice daily†‡
Pregnant Women	
Preferred choices	
	Gentamicin, 5 mg/kg I.M. or I.V. once daily†
	Streptomycin, 1 g I.M. twice daily
Alternative choices	
	Doxycycline, 100 mg I.V. twice daily
	Ciprofloxacin, 400 mg I.V. twice daily†

*Treatment with streptomycin, gentamicin, or ciprofloxacin should be continued for 10 days; treatment with doxycycline or chloramphenicol should be continued for 14-21 days. Persons beginning treatment with intramuscular (I.M.) or intravenous (I.V.) doxycycline, ciprofloxacin, or chloramphenicol can switch to oral antibiotic administration when clinically indicated.

†Not a U.S. Food and Drug Administration-approved use.

‡Ciprofloxacin dosage should not exceed 1 g/day in children

Adapted from Dennis DT, Inglesby TV, Henderson DA, et al, "Tularemia as a Biological Weapon: Medical and Public Health Management," *JAMA*, 2001, 285(21):2763-73.

Working Group Consensus Recommendations for Treatment of Patients with Tularemia in a Mass Casualty Setting and for Postexposure Prophylaxis*	
Mass Casualty Recommended Therapy	
Adults	
Preferred choices	
	Doxycycline, 100 mg orally twice daily
	Ciprofloxacin, 500 mg orally twice daily†
Children	
Preferred choices	
	Doxycycline; if ≥45 kg, give 100 mg orally twice daily; if <45 kg, give 2.2 mg/kg orally twice daily
	Ciprofloxacin, 15 mg/kg orally twice daily†‡
Pregnant Women	
Preferred choices	
	Ciprofloxacin, 500 mg orally twice daily†
	Doxycycline, 100 mg orally twice daily

*One antibiotic appropriate for patient age, should be chosen from among alternatives. The duration of all recommended therapies in this table is 14 days.

†Not a U.S. Food and Drug Administration-approved use.

‡Ciprofloxacin dosage should not exceed 1 g/day in children

Adapted from Dennis DT, Inglesby TV, Henderson DA, et al, "Tularemia as a Biological Weapon: Medical and Public Health Management," *JAMA*, 2001, 285(21):2763-73.

Additional Information

A potential biological weapon. Natural reservoirs for infection include small mammals (eg, mice, water rats, squirrels, rabbits) which are infected through tick, fly, or mosquito bites. Tularemia is found in the U.S. and Eurasia. Most cases in the U.S. are located in rural areas of south central and western states. Adults involved in hunting, trapping, butchering, and farming are at particular risk. Most cases occur between June and September. Information on diagnostic testing of specimens can be obtained from state public health laboratories and the

FUNNEL WEB SPIDER

Division of Vector-Borne Infectious Diseases: CDC, Fort Collins, Colorado [(970) 221-6400; e-mail: dvbid@cdc.gov].

Human-to-human transmission is lacking. In the event of a laboratory spill, decontaminate by spraying the suspected contaminate with a 10% bleach solution (one part bleach to nine parts water). After 10 minutes, clean the area with a 70% solution of isopropyl alcohol. Soapy water can be used to irrigate the remaining solution. Standard levels of chlorine in water usually protect against waterborne infection.

Correlates of protective immunity appear ~2 weeks following natural infection or vaccination. Given the short incubation period of tularemia and incomplete protection of current vaccination against inhalational tularemia, vaccination is not recommended for postexposure prophylaxis. The Working Group recommends use of the live vaccine strain only for laboratory personnel routinely working with *F. tularensis*.

Can be cleared to work in research lab after any positive skin reaction at site following live vaccine administration with seroconversion.

Funnel Web Spider

Related Information

- Tarantulas

Scientific Name *Atrax robustus* (Southern Australia); *Hadronyche formidabilis* (New South Wales); *Trechona venosa* (South America)

Mechanism of Toxic Action Venom contains a potent neurotoxin (atratotoxin) which causes neurotransmitter release (acetylcholine, norepinephrine and epinephrine) at the motor end plate through the autonomic nervous system; hypertension is caused by vasoconstriction; robustoxin can cause dyspnea and muscle fasciculations

Signs and Symptoms of Overdose Two phases:

Phase I (minutes following envenomation): Localized piloerection with widespread muscle fasciculations (first noted in facial, lingual and intercostal regions). Over the next 20 minutes muscle fasciculations may become generalized. From 5-30 minutes severe hypertension, tachycardia, hyperthermia, and coma with increased intracranial pressure develop. Diaphoresis, diarrhea, elevated creatine phosphokinase levels, lacrimation, metabolic acidosis, muscle writhing, salivation, and trismus also are noted. Death within 30 minutes may be due to laryngeal spasm, apnea, or pulmonary edema.

Phase II (1-2 hours after envenomation): Cholinergic crisis abates (and patient may regain consciousness). In severe cases, hypotension may ensue with pulmonary edema and apnea.

Admission Criteria/Prognosis Admit any symptomatic patient; asymptomatic patients 4 hours postbite may be discharged

Overdosage/Treatment

Decontamination: Since the venom travels primarily through lymphatics, the affected limb should be immobilized with crepe bandage tourniqueting; proximal pneumatic tourniquets may also be useful as is a Sawyer negative pressure suction device

Supportive therapy: Atropine should be used to control bronchorrhoea and salivation; esmolol or propranolol can be used for hypertension or tachycardia; a purified IgG antivenom of rabbit origin is the mainstay of treatment and should be considered in any patient with muscle fasciculations, salivation, lacrimation, piloerection, hypertension, dyspnea, or mental status changes; developed by Commonwealth Serum Laboratories in Australia in 1980, it is given intravenously 2 ampules (100 mg) every 15 minutes until symptoms improve; pretreatment should occur with an antihistamine and 100 mg of hydrocortisone sodium succinate; no skin testing is needed

Antidote(s)

- Atropine [ANTIDOTE]

Additional Information These large spiders (up to 5 cm) prefer cool moist regions and can inhabit burrows under rocks or logs (*Atrax*), be tree dwelling (*Hadronyche*) or be sedentary living in holes or plants (*Trechona*)

Giant Elephants Ear

Scientific Name *Alocasia macrorrhiza*

Mechanism of Toxic Action Calcium oxalate (which is distributed throughout the entire plant and can cause local mucosal swelling) and a saphotoxin (which can result in gastroenteritis or neurotoxicity).

Signs and Symptoms of Overdose Develop almost immediately: Abdominal pain, dysarthria, dysphagia, dysphonia, excess salivation, hypocalcemia, lip swelling, ocular irritation, oral cavity numbness, oral

cavity ulcers, sore throat. All symptoms (except for oral cavity numbness) resolve within one week.

Admission Criteria/Prognosis Admit any patient with abdominal pain or airway compromise. Monitor for renal failure and hypocalcemia. Admit any patient ingesting more than three mouthfuls.

Overdosage/Treatment Supportive therapy: Ingestions should be treated with the patient drinking 120-240 mL of ice water. Oral gargling with Xylocaine® can reduce oral pain. Monitor for hypocalcemia and renal failure.

Additional Information A plant native to Southwest Asia and Northern Australia, found along coastal wetlands and valleys. Has been used to treat snake and insect bites by either topical application or drinking the plant's juice with vinegar and ginger juice.

Gila Monster

Related Information

- Mexican Beaded Lizard

Scientific Name *Heloderma cinctum*; *Heloderma suspectum*

Mechanism of Toxic Action Venom contains hyaluronidase, gelatinase, helothermine, phospholipase A, kallikrein, and serotonin; venom is proteolytic with minimal tissue breakdown seen

Adverse Reactions

Cardiovascular: Sinus tachycardia

Hematologic: Coagulopathy

Miscellaneous: Anaphylaxis

Signs and Symptoms of Overdose Exophthalmus, tachypnea, thrombocytopenia, tinnitus. Generalized asthenia, hypotension, localized erythema and edema, leukocytosis, nausea, regional lymphadenopathy, sweating, tachycardia, and vomiting may occur. Localized pain may be severe.

Admission Criteria/Prognosis Admit if symptomatic for systemic reaction after 6 hours postexposure; mortality: ~5% (children), ~1% (adults)

Overdosage/Treatment

Decontamination: Avoid breaking off teeth when removing lizard; flame, cold water immersion, and handheld cast spreaders can assist in disengaging lizard

Supportive therapy: Local wound care with broad spectrum antibiotics should be administered; monitor tetanus immunization status; patient should be observed for at least 6 hours for systemic reactions; antivenom therapy (through the Poisonous Animal Research Laboratory at Arizona State University or the Venom Poisoning Center at the University of Southern California) is experimental

Additional Information Lethal dose: 5-8 mg. Endemic in the southwestern United States, these lizards are 30-50 cm long; usually docile but will bite and hang on tenaciously when provoked; teeth may break and be left in the wound (teeth are not radiopaque); venom glands are located in lower anterior jaw; 30% of bites have no venom injected; *Heloderma horridum* (the beaded lizard) found in Mexico has a similar type of venom; submerging the animal in cold water may subdue the lizard thus allowing for disengagement; a handheld cast spreader can also be used to disengage the reptile's mandible

Specific Reference

Morgan BW, Lee C, Damiano L, et al, "Reptile Envenomation 20-Year Mortality as Reported by US Medical Examiners," *South Med J*, 2004, 97(7):642-4.

Golden Chain Tree

Mechanism of Toxic Action Contains cytisine which has effects similar to nicotine

Adverse Reactions

Cardiovascular: Sinus tachycardia

Gastrointestinal: Constipation

Genitourinary: Urinary retention

Signs and Symptoms of Overdose Asthenia, ataxia, drowsiness, headache, hypotension, mydriasis, nausea, pallor, paralysis, seizures, tachycardia, vomiting

Admission Criteria/Prognosis Symptomatic patients 4-6 hours post-exposure should be admitted

Toxicodynamics/Kinetics Onset of symptoms: Within 15 minutes to 4 hours

Overdosage/Treatment

Decontamination: Ipecac relatively contraindicated because of risk of seizures occurring rapidly with large ingestion; lavage (within 1 hour)/activated charcoal with cathartic if large amounts ingested

Supportive care: Maintain respiration and blood pressure in symptomatic patient; urinary retention may respond to bethanechol

Additional Information Small tree (grows to 30 feet high). Range: Found in southern U.S. Toxic part: All parts toxic, no reports of toxic exposure to this plant exist in the U.S.; however, British literature reports poisonings

Grass Spider

Scientific Name *Agelenopsis aperta*

Mechanism of Toxic Action Unknown; can cause local tissue necrosis.

Signs and Symptoms of Overdose Ataxia, disorientation, headache, lethargy, myalgia, pallor. Local lesions are ~1.5 cm in diameter and are black-blue in color with a white center, appearing within 30 minutes. Local lesions may last for ~1 week.

Overdosage/Treatment Supportive therapy: Oral antibiotics should be considered such as dicloxacillin (250 mg 4 times/day). Analgesics (ibuprofen or acetaminophen) can be used for pain control.

Additional Information The spider is native to the western United States. It is 13-18 mm long with eight eyes and two brown longitudinal stripes on its tan cephalothorax. Its abdomen is long with an undulating pattern of brown and tannish coloring on the dorsal aspect. It also contains two long spinnerets posterior to the abdomen.

Green Lynx Spider

Mechanism of Toxic Action Venom is "squirted" from the oral cavity (at a range of 40 cm); envenomation can also occur through bites; venom is thought to be proteolytic

Signs and Symptoms of Overdose Sharp pain at bite site, erythema, pruritus. Symptoms usually resolve within 48 hours. Conjunctivitis can occur with ocular envenomation. Wound necrosis usually does not occur.

Overdosage/Treatment Supportive therapy: Local wound care (with tetanus prophylaxis) is all that is usually required; antibiotics are usually not necessary. If ocular envenomation occurs, copious irrigation of the affected eye with saline or water is suggested.

Additional Information A bright green spider with long, spiny-haired legs, usually found in grass or on plants in the southern U.S. and central Mexico. Most envenomations occur in the fall.

Hawaiian Baby Woodrose

Scientific Name *Argyrea nervosa*

Impairment Potential Can occur if >3 seeds are ingested

Mechanism of Toxic Action Related to LSD; contains ergoline alkaloids (ergine/isoergine) in the seeds, which exhibit indole alkaloid effects similar to LSD

Adverse Reactions

Cardiovascular: Tachycardia

Central nervous system: Paranoia, agitation, psychosis (which can start ~5 hours postingestion)

Gastrointestinal: Nausea, vomiting

Hematologic: Leukocytosis

Ocular: Visual hallucinations

Overdosage/Treatment

Decontamination: Oral: If >3 seeds are ingested, activated charcoal can be given; lavage (within 1 hour) may be useful

Supportive therapy: Benzodiazepine can be given to treat agitation

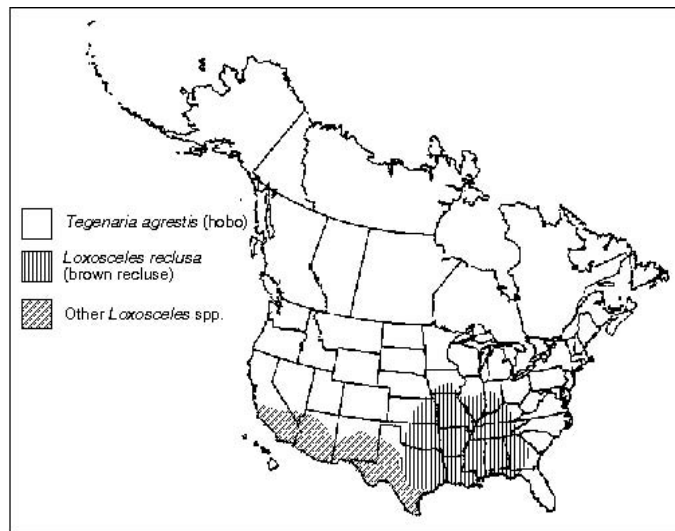

Additional Information A tropical woody vine with rose-colored flowers and thick black seeds; found in Hawaii, Florida, southern California, and India

Hobo Spider

Scientific Name *Tegenaria agrestis*

Mechanism of Toxic Action Arachnotoxins have hemolytic properties

Signs and Symptoms of Overdose While the bite of the hobo spider may initially be painless, induration (with surrounding erythema) may occur within 30 minutes. Blisters can develop in 15-35 hours. Following blister rupture (with exudative fluid), eschar with underlying necrosis and eventual sloughing can occur. Lesions become fully necrotic in ~50% of cases and can take 45 days to fully heal (with scar formation). Deeper bites may take up to 3 years to heal. Systemic symptoms can occur as early as 30 minutes postbite. Severe headache, anorexia, nausea, dizziness, lethargy, dry mouth, and generalized weakness initially occur and can be followed by fever, visual disturbances, memory loss, hallucinations and vomiting. Severe systemic reactions such as aplastic anemia, thrombocytopenia, pancytopenia, and profuse secretory diarrhea are rare but can be fatal.

From "Necrotic Arachnidism," *MMWR Morb Mortal Wkly Rep*, 1996, 45(21):435.

Overdosage/Treatment Supportive therapy: Oral diphenhydramine with alternating local applications of heat and ice can be utilized; severe hematologic abnormalities (other than leukocytosis) may respond to systemic corticosteroids; while surgical repair may be necessary, it should not be initiated until primary necrotizing process is completed; in severe cases with rapidly progressive necrosis, dapsone (50-200 mg/day in twice daily dosing) or colchicine (1.2 mg orally followed by 0.6 mg every 2 hours for 2 days then 0.6 mg every 4 hours for 2 days) may be useful; hyperbaric oxygen can be considered for necrotic lesions progressing to skin sloughing

Additional Information A large (7-14 mm body length; 27-45 mm leg span) brown spider with gray markings which can move quickly (1 meter/second); it is found in dark moist areas on ground or basement levels (ie, wood piles, crawl spaces) and are abundant from midsummer to fall; found in central Utah, Alaskan panhandle, southwest Canada, Washington, Oregon and Idaho; bites may be confused with brown recluse spiders

Specific Reference

Vetter RS and Isbister GK, "Do Hobo Spider Bites Cause Dermonecrotic Injuries?" *Ann Emerg Med*, 2004, 44(6):605-7.

Holly

Scientific Name *Ilex aquifolium*; *Ilex opaca*; *Ilex vomitoria*

Uses Native Americans used the plant as an emetic and cardiac stimulant

Mechanism of Toxic Action Irritation of the gastrointestinal tract

Signs and Symptoms of Overdose Diarrhea, nausea, and vomiting

Overdosage/Treatment

Decontamination: Charcoal may be of value; one dose of cathartic may be given if symptoms have not begun; gastric decontamination emesis with ipecac within 30 minutes or lavage within 1 hour for ingestions over six berries (especially if the berries are chewed)

Supportive therapy: Replace fluids and electrolytes as needed to prevent dehydration

Additional Information Toxic dose: Not well established; apparently berries must be eaten in quantity to produce toxic symptoms. Range: Found throughout the eastern and southern U.S. Toxin: Ilexanthin, ilex acid, tannic acid, ilicin. Toxic part: Berries are toxic in quantity

Hyacinth

Scientific Name *Hyacinthus orientalis*

Signs and Symptoms of Overdose Predominantly include diarrhea, GI irritation, nausea, stomach cramps, and vomiting. Contact dermatitis has been reported. May cause rhinitis or trigger an asthma attack in sensitive individuals.

Overdosage/Treatment Supportive therapy: Maintain fluid and electrolyte balance as needed

Additional Information Toxic dose: Not well quantified; symptoms have been reported after small ingestions. Range: Common garden plant throughout U.S.. Toxin: Thought to be narcissine-like alkaloids. Toxic part: Bulb

Hydrangea

Scientific Name *Hydrangea arborescens*; *Hydrangea paniculata*

Mechanism of Toxic Action Amygdalin (a cyanogenic glycoside) is hydrolyzed in the gut to release hydrocyanic acid; cellular hypoxia occurs after absorption and complexation with cytochrome oxidase

HYDROIDS (CORAL)

Signs and Symptoms of Overdose Reported poisonings have shown hydrangea to cause nausea and gastroenteritis; may also cause contact dermatitis

Admission Criteria/Prognosis All symptomatic patients should probably be admitted to an intensive care unit for 1-2 days; asymptomatic patients should be observed for at least 2 hours and then can be discharged; survival after 4 hours (in an acute exposure) is usually associated with recovery

Overdosage/Treatment

Decontamination: Activated charcoal with cathartic may be beneficial; lavage within 1 hour would be indicated if the patient exhibited cyanogenic effects

Supportive therapy: Maintain fluid and electrolyte balance; give sodium bicarbonate for acidosis; treat as cyanide exposure if acidosis is present.

Antidote(s)

- Cyanide Antidote Kit [ANTIDOTE]

Diagnostic Procedures

- Anion Gap, Blood
- Electrolytes, Blood
- Methemoglobin, Blood

Additional Information No cases of cyanogenic toxicity on record. Toxic part: Buds, flowers, and leaves

Hydroids (Coral)

Mechanism of Toxic Action Nematocysts cause intense local reaction
Signs and Symptoms of Overdose Stings produce a painful stinging sensation. Abdominal pain, fever, diarrhea have occurred rarely. Rash and erythema are likely for free-floating Portuguese Man-of-War, orange-striped jellyfish, and the stinging Medusa. May cause generalized symptoms including arthralgia, coagulopathy, intense local pain (electric shock-like), myalgias, and lymphadenopathy with asthenia, fever, and headache.

Overdosage/Treatment Supportive therapy: Epinephrine or antihistamines can be used for rash; muscle spasms can be treated with calcium gluconate I.V.; coral cuts should be cleansed and debrided; dermatitis can be treated with a topical corticosteroid cream. Meat tenderizer solution neutralizes protein toxin and thus can be sprinkled over wound of Portuguese Man-of-War; irrigate with sea water (not fresh water); apply 5% acetic acid or 40% to 70% isopropyl alcohol to inactivate nematocysts; diluted ammonia hydroxide may also be used; remove remaining nematocysts by shaving the area.

Additional Information Exoskeleton of calcium carbonate; an encrustation. Family: Hydrozoa; *Millepora* (Florida Keys and Caribbean). Phylum: Coelenterata Range: Found attached to rocks in shallow water in temperate zones

Hymenoptera

Related Information

- Fire Ants

Scientific Name *Apoidea* (Honey Bee); *Formicidae* (Fire Ant); *Myrmecia* (Jumper Ant, primarily located in Australia); *Politinae* (Wasp); *Vespoidea* (Yellow Jacket, Hornet)

Mechanism of Toxic Action The venom contains multiple allergens (phospholipase, hyaluronidase, acid phosphatase, etc) which can result in an IgE mediated anaphylactic reaction. Mast cell degranulating peptides are also found and can cause histamine release from mast cells.

Signs and Symptoms of Overdose

Multiple stings can result in systemic reactions. Anaphylactic reactions can occur immediately and are characterized by chest tightness, chills, dyspnea, hypotension, laryngeal edema, tachycardia, stridor, and urticaria. Hepatic necrosis, hemolysis, proteinuria, renal failure and thrombocytopenia have been noted following multiple bee or hornet stings. Local dermal effects have included angioedema, erythema, localized pain, pruritus, and swelling (> 10 cm). Serum sickness (with arthralgia) may occur along with rhabdomyolysis.

Admission Criteria/Prognosis Admit any patient with systemic symptomatology or with more than 50 stings.

Overdosage/Treatment

Decontamination: Remove the stinger and venom apparatus as soon as possible. Irrigate the area as soon as possible with soap and water. Supportive therapy: Anaphylaxis should be treated with standard measures (ie, epinephrine, antihistamines, vasopressors, and corticosteroids). Methylprednisolone 1-2 mg/kg I.V. every 6 hours should be considered. Serum sickness can be treated with corticosteroids; urticaria often improves with SubQ administration of epinephrine (1:1000) or an antihistamine. Monitor for rhabdomyolysis in severe and multiple stings.

Antidote(s)

- Epinephrine [ANTIDOTE]

Drug Interaction Use of calcium channel blockers, beta adrenergic blockers, or nonsteroidal anti-inflammatory drugs may increase the severity of Hymenoptera stings.

Additional Information The African honey bees (*Apis mellifera scutellata*) have been migrating north from Latin America since 1956. As opposed to the European honey bees (*Apis mellifera*), African honey bees (also known as "killer bees") exhibit more aggressive behavior with multiplicity of stings and a larger reaction distance (1091 yards for the African honey bee as compared to <30 yards for the European bee). Thus, a healthy adult can usually outrun these bees since they do not usually pursue farther than the above distances. The individual should run with mouth and nose covered. Spraying the bees with soapy water can help immobilize the insect. Anaphylactic emergency treatment kits containing epinephrine should be readily available to individuals with a history of anaphylaxis. Venom immunotherapy can be considered for individuals with a history of anaphylaxis or life-threatening systemic reaction. Patients with a history of dermal reactions are usually not candidates for venom immunotherapy.

Indian Tobacco

Related Information

- Star-of-Bethlehem (*Ornithogalum pyrenaicum*)
- Star-of-Bethlehem (*Ornithogalum umbellatum*)

Scientific Name

Lobelia inflata

Uses Variety of purposes over the years; the extract has been used as an emetic; lobeline sulfate has been used as an aid to stop smoking

Mechanism of Toxic Action Contains lobeline alkaloids which have nicotinic-like action and other piperidine alkaloids

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose Abdominal pain, bradycardia, coma, diarrhea, euphoria, hypertension, nausea, paralysis, vomiting, seizures, tremor; dermatitis has also been reported

Overdosage/Treatment Decontamination: Emesis within 30 minutes or lavage within 1 hour may be useful in large, recent ingestions if the patient has not started vomiting; activated charcoal with cathartic should be administered; seizures should be managed by benzodiazepines

Additional Information

Lobeline content may vary; specific toxic amounts of plant material is unknown; most poisonings have been from herbal preparations

Other related toxic species are *Lobelia cardinalis*, *Lobelia siphilitica*, and *Lobelia berlandieri*; *Eriogonum umbellatum* is also known as Indian tobacco and is considered nontoxic

Family: Campanulaceae; Range: Grows extensively throughout the U.S.; Toxic part: All parts, especially roots and seeds; Toxic dose: 50 mg of dried herb; poisoning is more transient than that of nicotine

Iris

Scientific Name

Iris germanica

Mechanism of Toxic Action Resinous substance irisin which acts as an irritant

Signs and Symptoms of Overdose Abdominal pain, burning sensation in mouth and throat, diarrhea, nausea, vomiting. Dermal contact may result in burning sensation and dermatitis.

Overdosage/Treatment Decontamination: Gastrointestinal decontamination may be of value in large recent ingestions

Supportive therapy: Replace fluids and electrolytes as necessary

Additional Information Toxic dose: Specific quantities have not been determined. There are many species of iris with similar toxicities. Family: Iridaceae. Range: Common garden flower cultivated throughout the U.S. Toxic part: Mainly the bulb, but possibly all parts

Jack-in-the-Pulpit

Scientific Name

Arisaema triphyllum

Mechanism of Toxic Action Entire plant contains calcium oxalate crystals which cause oral irritation, swelling, pain, and slurred speech; large ingestions necessary for systemic toxicity are unlikely to occur due to oral irritation seen with ingestion

Signs and Symptoms of Overdose

Dermal: Irritation, pain, swelling

Ocular: Sap may cause corneal abrasion, lacrimation, pain, photophobia; may also cause dermatitis; oxalate crystals may be deposited on cornea
 Oral: Diarrhea, dysphonia, edema, salivation, vomiting

Overdosage/Treatment

Decontamination: **Oral:** Dilute; ipecac/lavage/activated charcoal not likely necessary; milk/water to rinse crystals. **Dermal:** Wash thoroughly.
Ocular: Irrigate with tepid water for 15 minutes.

Supportive therapy: Cool compresses may minimize pain and swelling

Additional Information Toxin: Calcium oxalate crystals

Jatropha Multifida

Synonyms Coral Plan; Physic Nut

Use Oil used in West Africa to treat parasitic conditions and rheumatism.

Mechanism of Toxic Action Plant contains curcin (a toxalbumin - a proteolytic enzyme that inhibits the 60S ribosomal subunit) and a purgative oil that resembles ricinoleic acid in castor oil. Toxins found in seeds/fruit/sap.

Adverse Reactions Miosis, leukocytosis, vomiting (protracted), lethargy. As few as one seed can cause intoxication in children.

Overdosage/Treatment

Decontamination: **Oral:** Activated charcoal; **Dermal:** Wash with soap and water

Supportive care: Intravenous rehydration with crystalloid solutions

Additional Information Native to tropical Americas, West Africa, and Australia. A decorative garden plant with sweet flavored fruit.

Specific References

Koltin D, Uziel Y, Schneidermann D, et al, "A Case of Jatropha Multifida Poisoning Resembling Organophosphate Intoxication," *Clin Toxicol*, 2006, 44:337-8.

Jellyfish

Related Information

- Box Jellyfish

Scientific Name *Aurelia aurita*; *Carybdea alata*

Mechanism of Toxic Action Stings; venoms from nematocysts contain antigenic polypeptides and enzymes (DNAase, histamine); prostaglandin-induced vasodilation can occur

Adverse Reactions

Severe stings may include hematuria, syncope, paralysis, renal insufficiency, hypotension, cardiorespiratory failure

Central nervous system: Fever, chills

Dermatologic: Nonimmunologic contact urticaria

Neuromuscular & skeletal: Muscle spasms

Signs and Symptoms of Overdose Anaphylactic shock (rare), ataxia, burning, diaphoresis, headache, nausea, pain, rash (usually a linear flagellate pattern of small, papular erythematous eruptions), regional lymph node involvement, skin ulceration, urticaria

Overdosage/Treatment

Decontamination: Wear gloves during decontamination. **Do not** rub affected area. Hot fresh water (40°C to 41°C) immersion of the affected area within 30 minutes may be effective in decreasing pain due to Hawaiian box jellyfish (*Carybdea alata*) stings. Immediately rinse with seawater. Prevent further envenomation by applying acetic acid 5% (vinegar) to any tentacles still adhering to tissue. If acetic acid is not available, use isopropyl alcohol 40% to 70%; or finally, may use aluminum sulfate. Remove tentacles with a gloved hand or forceps. Meat tenderizers have been used; however, they are not preferred for decontamination and should not have prolonged contact time (> 10 minutes). Shave envenomated area after initial treatment, then repeat local decontamination therapy. Ocular exposures are to be decontaminated by water irrigation only.

Supportive therapy: Local symptoms persisting after the initial treatment may be treated with antihistamines, local anesthetics, or steroid lotion; tetanus prophylaxis should be given according to patient's immunization status. Refractory hyperpigmentation can be treated with topical hydroquinone bleaches. Anaphylaxis should be treated with standard therapy.

Additional Information Largest jellyfish in the Arctic Lion's Mane whose tentacles can reach > 100 feet in length. Dead jellyfish can release toxins. Class: Scyphozoa. Range: All oceans

Jequirity Bean

Scientific Name *Abrus precatorius*

Mechanism of Toxic Action Abrin, a toxalbumin, inhibits protein synthesis

Signs and Symptoms of Overdose Acutely causes irritation to esophagus, GI tract, and oropharynx; may cause hemorrhage and tissue sloughing. Acute demyelination encephalitis.

Toxicodynamics/Kinetics Acute effects occur within 8 hours; late phase complications delayed by 2-5 days possibly with asymptomatic phase in between

Overdosage/Treatment Decontamination: Activated charcoal may be useful; consider using osmotic cathartic despite hyperactive bowel as decreased exposure to mucosa may be beneficial, follow fluid and electrolyte status closely if symptomatic; if symptomatic, maintain urine flow; consider alkalinization to prevent hemoglobin crystallization in severe poisonings; guaiac vomiting, stool, follow fluid and electrolyte status; check hematologic parameters in severe poisoning, hepatic enzymes

Additional Information Toxicity may occur with as little as one bean. Scarlet bean-shaped seed with a black spot where attached inside pod; used in necklaces and as good luck charms; toxicity will not occur unless seed coat is broken; toxicity is variable; related to variations within plants and GI absorption, seed has hard coat; rupture makes toxin available; symptomatic patients should be hospitalized; asymptomatic patients that have received early thorough decontamination may be observed at home; has been used as an abortifacient; Toxic part: Bark, seeds, and leaves

Jimson Weed

Scientific Name *Datura stramonium*

Impairment Potential Yes

Mechanism of Toxic Action The whole plant, especially the foliage and seeds, contains anticholinergic compounds like atropine, hyoscyamine, and scopolamine; seeds contain highest amount of atropine (0.1 mg atropine per seed); ~50-100 seeds may cause severe intoxication and hallucinations. **Note:** Seeds are often ingested for their deliriant effect.

Adverse Reactions

Cardiovascular: Sinus tachycardia

Central nervous system: Memory disturbances, psychosis, fever, hyperthermia

Signs and Symptoms of Overdose Usually occur within 1 hour and may last for 2 days: Auditory hallucinations, decreased bowel sounds, delirium, disorientation, dizziness, hypertension, mydriasis, nausea, pruritus, seizures, tachycardia, urinary retention, visual hallucinations, vomiting. Hallucinations usually resolve within 18 hours. Mydriasis can persist for several days.

Toxicodynamics/Kinetics May decrease GI motility and, therefore, slow absorption

Overdosage/Treatment

Decontamination: Due to decreased GI motility, lavage may be useful unless the patient is symptomatic with anticholinergic toxidrome

Supportive therapy: Physostigmine may be useful to treat life-threatening anticholinergic symptoms; physostigmine should not be used in this ingestion if tricyclic antidepressants are a suspected coingestant due to the potential for seizures; propranolol can be used to help in treating cardiovascular complications; benzodiazepines should be used for treatment of agitation

Additional Information Toxin: Anticholinergic compounds; ²/₃ of exposures occur from August through November; manifestations of anticholinergic poisoning usually resolve within 3 days; not sold as an herbal dietary supplement in U.S. The 50-100 brown-black seeds in the fruit pods each contain ~0.05-0.1 mg of atropine.

Jonquil

Scientific Name *Narcissus jonquilla*

Mechanism of Toxic Action Contains lycorine (an *Amaryllidaceae* alkaloid) a centrally acting emetic

JUNIPER TAR

Signs and Symptoms of Overdose Usually abdominal pain, diarrhea, nausea, salivation, and vomiting. Symptoms develop soon after oral ingestion (within 30 minutes) and resolve within 3 hours (according to one report).

Overdosage/Treatment Decontamination: Ipecac relatively contraindicated; activated charcoal with cathartic/lavage within 1 hour may be beneficial depending on amount ingested and time elapsed since ingestion

Additional Information Toxic dose: Not established. Colchicine-like effects seen at ingestions >5 mg/kg. Toxic part: All parts contain alkaloid; bulb is most toxic

Juniper Tar

Scientific Name *Juniperus oxycedrus*

Uses Sebhorrea, eczema, psoriasis (topical use)

Mechanism of Toxic Action Has keratolytic, antipruritic, and antimicrobial effects *in vitro* due to the extracts (methanol, dichloromethane) which can inhibit histamine, serotonin, acetylcholine, and anti-inflammatory response; contains etheric oils, triepene, and phenols

Adverse Reactions Ocular: Conjunctivitis (on contact)

Signs and Symptoms of Overdose Oral: Fever, headache, myalgias, nausea, vomiting, cough, hypotension, gingival erosions, leukocytosis, polyuria, renal insufficiency, hematuria, proteinuria, thrombocytopenia, tachycardia

Dosage

Ointments are in the 1% to 5R range

Shampoos are in the 4% to 20% range

Overdosage/Treatment

Decontamination: Lavage/activated charcoal within 2 hours of ingestion
Supportive therapy: Crystalloid intravenous fluids for hypotension; dopamine (10 mcg/kg/minute) can be vasopressor of choice

Additional Information Evergreen tree which grows in Europe, Asia (specifically Turkey), and North America. Destructive distillation of wood of the plant is used to prepare the oil. The oil is dark with a tar-like odor and bitter taste.

Specific References

Koruk St, Ozyilkam E, Kaya P, et al, "Juniper Tar Poisoning," *Clin Tox*, 2005, 1:47-9.

King Cobra

Scientific Name *Ophiophagus hannah*

Mechanism of Toxic Action Venom contains polypeptides which cause a postsynaptic neuromuscular block along with possessing hemorrhagic activity.

Signs and Symptoms of Overdose Usually occur within 6 hours: Abdominal pain, cranial nerve palsies, dysarthria, dysphagia with increased secretions, facial muscle weakness, headache, hypotension (in ~5% to 10% of cases), leukocytosis, nausea, ptosis, tachycardia, vomiting. Neurological symptoms may progress to coagulopathy (increased prothrombin time), coma, confusion, flaccid paralysis, hyporeflexia, and lethargy. Local tissue necrosis from the bite may be delayed 2-4 days.

Admission Criteria/Prognosis Transport any bite to the hospital. Asymptomatic individuals may be discharged at 6 hours postbite with close follow-up.

Overdosage/Treatment Supportive therapy: Monitor respiratory status. Cholinesterase inhibitors are ineffective. Specific antivenin is available: Thai Red Cross king cobra antivenin (Bangkok, Thailand) may be found at zoological parks. Skin testing may be required. After a negative skin test, infuse intravenously 15 vials (150 mL) of reconstituted antivenin diluted in 850 mL of 0.9% normal saline over a 2-hour period. Australian tiger snake antivenin is a second choice if king cobra antivenin is not available. Mechanical ventilation may be required.

Diagnostic Procedures

- Prothrombin Time

Additional Information Largest poisonous snake (~7-13 feet long), found in Southeast Asia and India. Ninety-four percent of bites result in envenomation. When biting, these snakes hold tightly to the victim and chew the tissue while envenomation occurs. It has a large occipital shield with a narrow hood. Adults are brown or greenish-yellow with a darker tail.

Lantana

Scientific Name *Lantana camara*

Adverse Reactions Central nervous system: Delirium

Signs and Symptoms of Overdose Ataxia, coma, cyanosis, death, diarrhea, drowsiness, dyspnea, mydriasis, photophobia, vomiting

Overdosage/Treatment Decontamination: If the patient is not already vomiting, then vomiting or lavage (within 1 hour) should be initiated following ingestion of green berries, not ripe berries or leaves, followed by activated charcoal with cathartic

Drug Interaction Thujone-containing and gamolenic-acid containing herbs can lower the seizure threshold leading to increased anticonvulsant dosage requirements.

Additional Information Toxic dose: Specific quantities are unknown, any amount of unripe (green) berries should be considered potentially hazardous; animal toxicity from grazing on leaves is well known. Family: Verbenaceae; Toxin: Leaves contain triterpenes, lantadene A or B; toxic component of berry is unknown. Range: Tropical plant found in Florida and Texas. Toxic part: Unripe berries, toxicity of other parts is unknown

Leeches

Scientific Name *Hirudo medicinalis*

U.S. Brand Names Exhirud[®]

Uses Blood evacuation; used in skin graft repair, breast reconstruction, periorbital hematomas, digital reimplantations, ring avulsion injuries; useful in areas where there is good arterial flow but no venous outflow

Mechanism of Toxic Action Contains several anticoagulants in its salivary glands including hirudin, hementin, hyaluronidase, lodellins, eglins, cathepsin G, subtilisin, and fibrinases

Adverse Reactions

Dermatologic: Ecchymosis

Hematologic: Hemorrhage, anemia

Local: Wound infection, scarring at wound site

Toxicodynamics/Kinetics Elimination: Hirudin: Renal

Overdosage/Treatment

Decontamination: **Pharyngeal:** Gargle with salt water or vinegar. **Dermal:** Do not pull leech off since its jaws may break off resulting in an ulcer or wound infection; salt, salt water, or vinegar can aid in topical leech removal

Supportive therapy: Wound infection rate is ~20%; wound infections can be treated with amoxicillin (with or without clavulanic acid) or cefuroxime; tetanus prophylaxis should be performed; localized hemorrhage can be controlled with firm pressure

Additional Information

A black freshwater annelid, 25-40 mm in length.

A leech can ingest ~5-15 mL of blood; leeches should never be reused; therapy is usually 3-7 days. Localized wound hemorrhage may continue for up to one day. Contraindications include hemorrhagic diathesis, croup, and erysipelas.

Leeches may be vectors for *Aeromonas hydrophila* and *Trypanosoma cruzi*. Erysipelas and puerperal fevers have been known to be transmitted by leeches.

Disposal: Place leeches in a container of 70% isopropyl alcohol for 5 minutes, then dispose per infectious waste protocol.

Medicinal leeches may be obtained from: Leeches USA, 300 Shames Dr,

Westbury, NY 11590: (516) 333-2570 or (800) 645-3569

Emergency delivery: (800) 488-4400, ext 2475

Lepidoptera

Scientific Name *Megalopyge opercularis*

Mechanism of Toxic Action Toxin found on spines that break off into skin - "passive stinging"; irritant; may also contain histamine

Signs and Symptoms of Overdose Blindness, coughing can occur on inhalation, dyspnea, fever, headache, lymphadenopathy (lepidopterism), muscle cramps, pain at injury site, paralysis, pruritus, rash, seizures, vomiting

Overdosage/Treatment

Decontamination: Wash skin with warm water, hairs or broken spines can be removed by applying and then peeling Scotch[®] tape on the surface of the skin

Supportive therapy: Antihistamines/analgesics

Lice

Scientific Name *Pediculus humanus*; *Phthirus pubis*

Mechanism of Toxic Action Requires human blood to survive; an ectoparasite

Signs and Symptoms of Overdose Erythema, pruritus. Secondary impetiginization can occur. Small macules may be seen in *Phthirus pubis* (maculae ceruleae).

Overdosage/Treatment

General principles of treating pediculosis include discarding or carefully laundering clothing, discarding infested combs or hats, and laundering bedsheets. In general, clothes and bedsheets can be effectively decontaminated by dry cleaning or by machine washing and drying in a hot cycle. Secondary bacterial infections of the skin are common and generally respond to antibiotics effective against *Staphylococcus aureus* (dicloxacillin, erythromycin, and others). Pruritus is typically quite severe and may be alleviated by hydroxyzine (Atarax[®]), diphenhydramine (Benadryl[®]), and/or topical steroid creams.

Treatment guidelines:

- **Pediculosis corporis:** Since the louse resides mainly in the creases of clothes and not on the host, the infection can often be eradicated by delousing contaminated items and maintaining careful hygiene.
- **Pediculosis capitis:** Several agents are effective: 1% lindane (Kwell®) shampoo to the scalp, pyrethrin liquid (RID), or permethrin creme rinse (Nix™). These insecticides are probably equal in efficacy. Only lindane requires a prescription. **Caution:** Lindane has been associated with seizures and other nervous system toxicities. However, the risk of serious adverse effects during treatment for pediculosis is small due to its minimal systemic absorption. Nevertheless, lindane should be avoided in pregnancy and in lactating women.
- **Pediculosis pubis:** The treatment recommendations are the same as for *P. capitis*. In addition, sexual partners should be identified and treated in the same manner. Pediculosis involving the eyelashes should **not** be treated with insecticides. Instead, occlusive ophthalmic ointment should be applied to the eyelashes twice daily for at least 8 days in an attempt to smother the parasites.

Patients should be seen in follow-up if symptoms persist 1 week after treatment. A second application may be necessary. Some clinicians routinely instruct patients to reapply the insecticide at the 1 week point.

Diagnostic Procedures

- **Arthropod Identification**

Additional Information Transmitted through body contact. Family: Anoplura; *Pediculus humanus corporis* (head louse, body louse); *Phthirus pubis* (crab louse)

Microbiology: Human lice are ectoparasites and thus tend to live on or in the skin of the host. They belong to the insect class *Hexapoda*. There are three species important in human infection. *Pediculus humanus* var. *corporis* is the human body louse, *Pediculus humanus* var. *capitis* is the human head louse, and *Phthirus pubis* is the crab louse. The body and head louse have similar appearances and are ~4 mm long. The pubic louse is much wider and has a crab-like appearance from which its name is derived; the eggs adhere to human hair and to clothing, and are termed nits.

Epidemiology: Humans are the reservoir for lice. Infestations have been described worldwide especially in areas of overcrowding. The incubation period is ~1-4 weeks following exposure. Individuals are communicable until all the lice and eggs have been treated and destroyed. Pediculosis capitis is a particular problem with school-aged children, where the practice of sharing combs or brushes facilitates epidemic transmission. All socioeconomic backgrounds are at risk for head lice. In contrast, pediculosis corporis is seen mainly in areas of poor sanitation. The body louse resides almost exclusively in soiled clothing, rather than the skin, and only leaves the clothing for a blood meal from the host. Pediculosis corporis also transmits the rickettsial infection epidemic typhus, as well as several others. *Phthirus pubis* is usually sexually transmitted, although spreading via infested bedding or clothing can occur.

Clinical Syndromes:

- **Pediculosis corporis:** Typically, the patient complains of severe pruritus, and small, erythematous papules are found on the body. Often extensive self-induced excoriations across the trunk are noted. If left untreated for long periods, hyperpigmentation and scarring may occur, called "vagabond's disease."
- **Pediculosis capitis:** The most common presentation is intractable scalp pruritus. On examination there may be evidence of secondary bacterial infection of the scalp from excoriations. At times, an "id reaction" occurs, characterized by a dramatic skin eruption over the arms and trunk, felt to be a hypersensitivity reaction.
- **Phthirus pubis:** Most patients present with pruritus in the region of the pubic hairs, but other areas may be involved including the eyelashes and hairs in the axilla; secondary bacterial infections are less common.

Diagnosis: The diagnosis of pediculosis is often suspected when an individual presents with severe pruritus. On some occasions, the patient may have identified lice themselves or have had a recent contact history. The diagnosis is confirmed by finding lice (1-4 mm long, depending on species) and/or the "nits" (usually 1 mm or less, attached to hairs).

hypotension, ventricular arrhythmias; seeing yellow halos and hyperkalemia have also been reported

Admission Criteria/Prognosis Asymptomatic patients with normal electrocardiogram and electrolytes can be discharged after a 12-hour observation; any symptomatic patient should be admitted to a cardiac monitor bed

Overdosage/Treatment

Decontamination: Lavage within 1 hour and multidose activated charcoal enhance total body clearance of digitalis; whole bowel irrigation is also beneficial in removing plant debris from the GI tract and is recommended for ingestions of large amounts of plant material

Supportive therapy: Monitor cardiac status and serum potassium levels; bradycardia will frequently respond to atropine; phenytoin is the recommended treatment for ventricular arrhythmias because it will also improve conduction through the AV node; lidocaine can also be used to treat ventricular arrhythmias, but will not have an effect on AV conduction; other antiarrhythmics which have been used in arrhythmias resistant to the above therapy include magnesium, amiodarone, and bretylium; a pacemaker should be considered for bradycardia and AV nodal blocks resistant to medical management

Digoxin immune Fab has been shown to interact with several different plant cardiac glycosides and may be beneficial in cases resistant to conventional treatment; indications for its use include ventricular arrhythmias resistant to conventional treatment, severe bradycardia, and/or second or third degree heart block resistant to atropine and phenytoin

Antidote(s)

- Digoxin Immune Fab [ANTIDOTE]

Additional Information Toxin: Cardiac glycosides

Lionfish

Scientific Name *Pterosis volitans*

Adverse Reactions Cardiovascular: Sinus bradycardia, sinus tachycardia

Signs and Symptoms of Overdose Burning, pain, swelling in wound; erythema, nausea, numbness, paresthesia, or vomiting which lasts 8-12 hours. Systemic symptoms are rare and include abdominal cramps, bradycardia, dyspnea, headache, hypotension, tachycardia, sweating, syncope

Overdosage/Treatment

Decontamination: Soak affected limb in hot water for 30-90 minutes (110°F to 115°F); provides relief in 94% of patients; antivenin is rarely needed (may be available in seaquariums)

Supportive therapy: Digital nerve block with 0.25% bupivacaine can help reduce pain from digital bites

Additional Information Venom has vasodilatory effect. Range: Found in Pacific/Indian Oceans; bottom-dwelling fish

Listeria monocytogenes Food Poisoning

Commonly Found In Unpasteurized milk, feta cheese, undercooked chicken

Mechanism of Toxic Action

Listeria monocytogenes is a gram-positive bacillus which causes sporadic cases of meningoencephalitis, neonatal infection, septicemia, and several less common syndromes; it is a leading cause of meningitis in immunocompromised individuals, especially renal transplant patients.

The organism is an aerobic, gram-positive rod which does not produce spores. At times it may assume a more coccoid appearance on Gram's stain of clinical samples (eg, cerebrospinal fluid) and may thus be mistaken for gram-positive cocci such as *Streptococcus pneumoniae*.

Listeria can also be confused morphologically with the more commonly seen *Corynebacterium* species, which are also gram-positive bacilli (but are often contaminants). *Listeria* is primarily an intracellular pathogen, and tends to reside within mononuclear phagocytes of the host. This feature is thought to contribute to its pathogenicity, since the organism can spread from cell to cell in a somewhat protected fashion.

When *Listeria monocytogenes* meningitis is suspected, the clinician should try to submit at least 10 mL of cerebrospinal fluid for bacterial culture, since only a few *Listeria* organisms may be present. The organism generally grows well on most routine media used in the laboratory, and special requests for selective or enrichment cultures for *Listeria* are usually not necessary. It is important that the clinician does not automatically dismiss a report of a "gram-positive rod" isolated from multiple blood or a sterile body site as a contaminant, particularly in an immunocompromised host in whom *Listeria* infection is possible.

Adverse Reactions Cardiovascular: Pericardial effusion/pericarditis

Signs and Symptoms of Overdose Foodborne listeriosis: A prodromal illness of fever with nausea, vomiting, headache, or backache may precede the clinical syndrome (refer to Additional Information) by as long as one week.

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in

Lily-of-the-Valley

Scientific Name *Convallaria majalis*

Mechanism of Toxic Action Whole plant contains cardiac glycosides convallamatin and convallarin

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose GI effects (nausea and vomiting) usually precede cardiovascular effects by several hours. Asystole, AV block, bradycardia, confusion, contact dermatitis, dizziness, fatigue, fibrillation (atrial), flutter (atrial), decreased QT interval and prolonged P-R interval, heart block (first, second, and third degree), headache,

electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment Supportive therapy: No randomized comparison trials have been performed to determine the drug(s) of choice for listeriosis. *In vitro* data show the organism is susceptible to many antibiotics. The most clinical experience has been limited to penicillin and ampicillin, and they are probably equivalent. Occasionally, penicillin-resistant strains of *Listeria* have been reported, and thus results of susceptibility testing should be followed up on. There is some *in vitro* evidence to suggest the combination of penicillin (or ampicillin) with an aminoglycoside may be synergistic against *Listeria*, and this combination has been used in serious, life-threatening infections; trimethoprim-sulfamethoxazole may also be effective. Cephalosporins do not reliably cover this organism and should not be used for cases of *Listeria* meningitis. Consultation with an infectious disease specialist is appropriate in complicated cases or in the patient with a penicillin allergy.

Additional Information

Incidence of listeriosis has decreased by 44% in the U.S. from 1989 to 1993.

Epidemiology: The epidemiology of listeriosis can be important in certain cases, since clinical presentations may be nonspecific. The precise prevalence of human infection is unclear, but the attack rate appears to be increasing (perhaps due to better reporting or laboratory recognition). Asymptomatic carriage of *Listeria* in stools is relatively frequent; some studies suggest a fecal excretion rate of 1% or more in healthy humans. Humans may be exposed to *Listeria* by one of several routes: consumption of contaminated food, direct exposure to infected animals, or exposure to environmental reservoirs (soil, water, etc).

Cases of listeriosis tend to be sporadic and difficult to predict. Most infections occur in the summer months and are more common in urban than rural settings, despite its reputation as a zoonotic infection. Often, the source of the *Listeria* remains unknown. Increasing attention has been given to foodborne transmission, particularly in the setting of a traceable outbreak. Mexican-style cheese, coleslaw, undercooked chicken, hot dogs, dairy products, and other foods have caused outbreaks. The ability of the organism to survive (and even multiply) during refrigeration probably contributes to food-related transmission.

Infection with *Listeria* usually occurs in definable groups in the community. Cell mediated immunity is critically important in defense against *Listeria*, whereas neutropenia is not clearly a risk factor. Those at highest risk include patients with solid organ transplants, malignancies (particularly lymphoma), and patients receiving corticosteroids. Pregnant females, neonates, and alcoholics are additional groups at risk for infection. Interestingly, listeriosis does not appear to be a common pathogen in patients with AIDS, despite the deficiencies in T-cell function. Although uncommon, serious infections with *Listeria* have been described in otherwise healthy individuals.

Diagnosis: Except for granulomatosis infantiseptica, the clinical presentations of listeriosis are not unique and microbiological confirmation is necessary. Depending on the clinical site of infection, specimens of blood and body fluids should be sent, as described above. Agglutination studies for antibodies directed against *L. monocytogenes* have little value. Stool culture or serologic testing is not useful.

Clinical Syndromes:

- **Adult meningoenzephalitis:** *Listeria* is the most common cause of community-acquired meningitis in immunosuppressed individuals. *Listeria* meningitis can be quite variable in its presentation and can range from a subacute course to a rapid and fulminant one. In some cases the diagnosis may be quite difficult when high fevers and nuchal rigidity are absent. There are no pathognomonic features of *Listeria* meningitis which allow diagnosis on clinical grounds alone. CSF chemical analysis is variable and frequently nondiagnostic. The degree of CSF pleocytosis can range from several cells to $> 12,000$ cells/mm³. Differential cell counts vary from nearly 100% polymorphonuclear cells to 100% mononuclear cells. Often a modest elevation of CSF protein is seen, along with a minor decrease in CSF glucose. The differential diagnosis of a subacute meningitis in an immunosuppressed host must also include *Cryptococcus neoformans*. The finding of focal brain lesions by CT scan or MRI broadens the differential to include toxoplasmosis, *Nocardia asteroides*, bacterial brain abscess, fungal meningitis, and others. Meningoenzephalitis has also been sporadically reported in otherwise healthy individuals and should be considered in the differential diagnosis of any community-acquired meningitis.

- **Meningoenzephalitis of the neonate:** This is a "late-onset" neonatal disease, occurring several days to weeks postpartum. As with adult cases, isolated neonatal meningitis from *Listeria* can be variable in its presentation. Fever may be low grade or absent, and irritability and failure to thrive may be the only clues. CSF findings in the neonate are similar to those in the adult. It is important to review the Gram's stain of CSF carefully to avoid confusing *Listeria* with Group B streptococci, a common cause of neonatal meningitis.

- **Cerebritis:** This form of nonmeningeal central nervous system infection is gaining increased recognition. Patients may complain of fever, cephalgia, and hemiparesis. This form of listeriosis may be

mistaken for a stroke, vasculitis, brain tumor, or abscess. CT and MRI scans suggest focal inflammation without a discrete abscess or ring enhancement. Cerebrospinal fluid is usually normal and CSF cultures are negative for *Listeria*. The diagnosis is usually made when *Listeria* is isolated from blood cultures.

- **Listeriosis in pregnancy:** Unfortunately, this is often difficult to diagnose, since the woman may be asymptomatic or complain of only a mild fever and malaise. Other symptoms variably present include diarrhea and flank pain. The differential diagnosis is usually broad and listeriosis may be mistaken for pyelonephritis, lower urinary tract infection, and viral syndromes (eg, influenza). Blood cultures may be positive and should be performed. Complications include premature delivery, septic abortion, and *in utero* fetal infection.

- **Granulomatosis infantiseptica:** This unique, transplacentally acquired infection is severe and often lethal. It is an "early onset" neonatal infection apparent within hours of birth. Typically, the infants are seriously ill. There are widespread abscesses involving visceral organs such as the liver, spleen, lungs, intestinal tract, and brain. The lesions are usually abscesses with polymorphonuclear leukocytes, but granulomas have also been seen (referred to as "miliary granulomatosis"). Dark papular skin lesions may be present on the trunk and lower extremities, suggesting the diagnosis. Gram's stain and culture of meconium, amniotic fluid, conjunctival exudates, CSF, throat, blood, or skin lesions frequently are positive for *L. monocytogenes*. Antibiotic therapy should be started immediately if this diagnosis is suspected, since death may occur if treatment is withheld until cultures are finalized.

- **Septicemia:** *Listeria* can be isolated from the blood in adults and neonates who present from the community with nonspecific fever and chills. Bacteremias are more likely in profoundly immunosuppressed hosts but have been seen in alcoholics, diabetics, pregnancy, and normal healthy individuals. The clinical presentation can be indistinguishable from gram-negative sepsis, with high fevers and hypotension (so-called "typhoidal listeremia"). On rare occasion, the diagnosis is suggested by the finding of a monocytosis on the peripheral blood smear, but blood cultures remain the highest yield.

- **Miscellaneous:** Endocarditis, ocular infections, lymphadenitis, osteomyelitis, brain abscess, peritonitis, and other focal infections have been rarely reported.

Lupine

Scientific Name *Lupinus species*

Mechanism of Toxic Action All parts of the plants, especially the ripe seeds, contain quinolizidine alkaloids, lupanine, and some piperidine compounds; different species have varying concentrations of these alkaloids, and therefore, produce various effects; not all species are toxic; toxin is inactivated if the plant is dried

Adverse Reactions Cardiovascular: Sinus tachycardia

Signs and Symptoms of Overdose Asthenia, coma, difficulty breathing, frothing of the mouth, jaundice, loss of motor control, mydriasis, myoclonus, nervousness, PVCs, seizures, tachycardia. Amyotrophy and spasticity have been reported from chronic ingestions. Death generally occurs from respiratory paralysis.

Toxicodynamics/Kinetics Onset of symptoms: Within 1 hour, but can be delayed up to one day

Overdosage/Treatment

Decontamination: Ipecac is probably not necessary in accidental ingestions and relatively contraindicated in large ingestions; lavage within 1 hour and activated charcoal with cathartic are probably beneficial for large ingestions

Supportive therapy: Required with particular attention to respiratory status

Additional Information Accidental ingestion of one plant leaf or a few seeds should be considered basically nontoxic; ingestion of 3 g of seeds per month for 8 years was associated with amyotrophy and spasticity; ingestion of 500 mL of water used to "de-bitter" lupine seeds resulted in mydriasis, tachycardia, PVCs, and urinary retention which resolved in 48 hours. Toxin: Lupinine

Mango

Scientific Name *Mangifera indica*

Mechanism of Toxic Action Shell contains anacardic acid, cardol, anacardol, irritants that can precipitate type IV cell-mediated allergic reaction (allergic contact dermatitis)

Signs and Symptoms of Overdose Dermatitis, nausea, orange skin discoloration, vomiting

Toxicodynamics/Kinetics Onset of effect: Variable, but effects usually seen within 24-48 hours

Peak effect: After 3-5 days

Overdosage/Treatment

Decontamination: Soap and water washing likely ineffective unless done within 5-15 minutes after exposure

Supportive therapy: Cool compresses or showers, Burow's solution, topical/oral steroids

Additional Information An evergreen found in India and most of the tropics (cultivated for its fruit); remove skin before eating; fruit weighs 4-5 lbs; indigenous on Indian subcontinent. May cause dermatitis in persons previously exposed to *Toxicoderon* (genus) plants. Toxic part: Fruit skin, sap, and shell

Marijuana (Cannabis)

Related Information

- Highlights of Recent Reports (2006) on Substance Abuse and Mental Health

CAS Number 8063-14-7

Scientific Name *Cannabis sativa*

Impairment Potential Yes; Mean detection time for marijuana metabolites using a 100 ng/mL urinary cutoff by immunoassay is about 24 hours. Delta-9-THC plasma levels as low as 2 ng/mL (or whole blood levels of 1.1 ng/mL) is consistent with recent usage and probably impairment. Studies have demonstrated that 94% of drivers with plasma delta-9-THC levels over 25 ng/mL have failed standard roadside sobriety testing. Pilots exposed to marijuana demonstrated impaired flying skills as long as 24 hours postexposure.

Mechanism of Toxic Action Antiemetic for therapeutic uses/hallucinogenic; derived from the hemp plant, *Cannabis sativa* (which contains 2% to 6% tetrahydrocannabinol and which is psychotropically active in the (-) enantiomeric form); affects serotonin release along with increasing catecholaminergic effect while inhibiting parasympathetic effects

Adverse Reactions

Cardiovascular: Dose-related tachycardia, sinus tachycardia, postural hypotension (may last for 2 hours), ventricular tachycardia

Central nervous system: Irritability, disorientation, euphoria, short-term memory disturbance, distortion of time and space, dysphoria, hyperthermia, synesthesia, hypothermia, psychosis

Dermatologic: Urticaria, pruritus, exanthem

Gastrointestinal: Constipation

Genitourinary: Urinary retention, impotence

Neuromuscular & skeletal: Trismus, fine tremor

Ocular: Lateral gaze nystagmus, mydriasis, injected conjunctival vessels

Respiratory: Bronchial irritation

Miscellaneous: Thirst

Signs and Symptoms of Overdose

I.V. administration can cause diarrhea, nausea, vomiting, fevers and can progress in 12 hours to cyanosis, hypotension, renal failure, thrombocytopenia, rhabdomyolysis.

Mild cannabis intoxication (10 g/month): Fatigue, impaired recall, perceptual alterations, relaxation, sense of well being

Moderate intoxication (30 g/month): Depersonalization, memory deficits, mood swings

Excessive intoxication (60 g/month): Delusions, hallucinations, impaired coordination, paranoia, slurred speech

Admission Criteria/Prognosis Any patient who has injected a cannabinoid (need to monitor for azotemia, thrombocytopenia, and rhabdomyolysis), will require admission; severe psychotic episodes or hyperthermia will require admission

Toxicodynamics/Kinetics

Onset of action: Inhalation: 6-12 minutes; Oral: 30-120 minutes

Duration of acute effect: 0.5-3 hours

Absorption: Smoking: 18% to 50%; Ingestion: 5% to 20%

Distribution: V_d : 10 L/kg; increases with chronic use

Metabolism: Major metabolite is 11-hydroxy-tetrahydrocannabinol

Protein binding: 97% to 99%

Half-life: 28 hours (first-time users); 56 hours (chronic users)

Elimination: Feces (30% to 35%); renal (15% to 20%)

Reference Range

Following single use of marijuana (by an infrequent user): Serum concentration of Δ^9 -tetrahydrocannabinol (THC) peaks in 10 minutes and falls below 5 ng/mL (or 2.75 ng/mL of whole blood) within 3 hours and to below 1 ng/mL (or 0.55 ng/mL of whole blood) within 6 hours.

The carboxylic acid metabolite, 11-nor-9-carboxy- Δ^9 -tetrahydrocannabinol (THCA) peaks in about 2.5 hours after a single use and can persist above 2 ng/mL (plasma) for more than 3 days.

One puff of marijuana cigarette yields a plasma THC concentration of 7.0 ng/mL (1.75% THC cigarette) to 18.1 ng/mL (3.55% THC cigarette); mean peak salivary levels correspond to 864 ng/mL (1.75% THC) to 4167 ng/mL (3.55% THC); bleach may cause a 14% to 45% decrease in THC concentration in urine immunoassay results; THC plasma levels of 7-29 ng/mL can result in production of 50% of maximal subjective high effect

Overdosage/Treatment

Decontamination: Ingestion: Lavage oral ingestion (within 1 hour)/activated charcoal with cathartic

Supportive therapy: Benzodiazepines for agitation; hypotension can be treated with Trendelenburg/crystalloid infusion; tachycardia can be treated with beta-blockers

Test Interactions Alkaline/acidic urine (or dilute urine) may cause false-negative urinary immunoassay tests; Visine® adulteration may also cause false-negative tests; bleach may cause a 14% to 45% decrease in THC concentration in urine immunoassays; urine drug screen is positive for 6 days with one-time use; may be positive for weeks with chronic use. When Pyridium® chlorochromate ("Urine Luck") adulterant is added to urine (at pH of 5-7), ~58% to 100% of THC-acid is lost, resulting in a possible false-negative assay. There have been reports of false-positive urine immunoassay screening tests for tetrahydrocannabinol (THC) in patients receiving pantoprazole.

Drug Interaction Attenuation of drowsiness can occur with concomitant administration of CNS depressants; pretreatment with indomethacin may cause attenuation of the euphoria with decreased cardiac effects; cocaine, atropine along with tricyclic antidepressants may cause additive increase in heart rate; disulfiram may produce hypomanic state; may cause additive increase in blood pressure when given with amphetamines

Additional Information

Lethal dose: 30 mg/kg.

One "joint" weighs 0.5-1 g with an average THC content of 1% to 2% (5-20 mg); hash oil contains 30% to 50% THC; hashish is 3% to 6% THC; toxic dose is 15 mg/kg THC;

Decreases intraocular pressure; can cause bronchodilatation; therapeutic uses include prevention of nausea (oral THC dose of 5-15 mg/m²), and appetite suppression; higher THC levels are associated with higher puff amount and higher potency; levels are not associated with how long puffs are held. THC levels can range from 33 ng/mL (with a 30 mL puff, 1.75% THC) to 167 ng/mL (90 mL puff, 3.55% THC concentration). Potential for medicinal uses of cannabinoids include to alleviate chemotherapy-induced nausea and vomiting, lowering intraocular pressure, antiseizure medication, muscle relaxation in spastic disorders, appetite stimulation, relief of phantom limb pain, menstrual cramps, and migraine therapy.

First-time use of cannabis can precipitate an acute psychotic episode persisting for several months, with no previous psychiatric history. Decreases intraocular pressure; can cause bronchodilatation; therapeutic uses include prevention of nausea (oral THC dose of 5-15 mg/m²), and appetite suppression; higher THC levels are associated with higher puff amount and higher potency; levels are not associated with how long puffs are held. THC levels can range from 33 ng/mL (with a 30 mL puff, 1.75% THC) to 167 ng/mL (90 mL puff, 3.55% THC concentration). Potential for medicinal uses of cannabinoids include to alleviate chemotherapy-induced nausea and vomiting, lowering intraocular pressure, antiseizure medication, muscle relaxation in spastic disorders, appetite stimulation, relief of phantom limb pain, menstrual cramps, and migraine therapy.

According to the Drug Abuse Warning Network (DAWN)

- Marijuana was estimated to be involved in 215, 665 emergency department visits in 2004.
- Marijuana was found in 8% of visits related to suicide attempts and 15% seeking detox visits.
- Marijuana was also involved in 15% of ED visits involving malicious poisoning.
- Marijuana rates of ED use was highest for patients aged 18 to 24 years old.
- Marijuana and alcohol combination use accounted for 33, 954 ED visits.

Marsh Marigold

Scientific Name *Caltha palustris*

Mechanism of Toxic Action Contains protoanemonin, which reacts with SH groups to produce irritation and vesication; chemical is excreted unchanged in urine

Signs and Symptoms of Overdose Abdominal cramps, blistering, bloody diarrhea, contact dermatitis, hematemesis, pain and swelling, salivation, and ulceration. Potential for renal irritation or damage if a sufficient amount is ingested.

Toxicodynamics/Kinetics Significant dermal symptoms may take several weeks to resolve

Overdosage/Treatment

Decontamination: Avoid use of ipecac or cathartics, consider lavage (within 1 hour) and/or activated charcoal with large ingestion to prevent systemic absorption and possibility of subsequent renal irritation

Supportive therapy: Maintain fluid and electrolytes, maintain adequate urine flow in large overdose; monitor symptomatic patients for fluid or electrolyte deficiencies

Additional Information Toxic dose: Not established, but overdose producing systemic effects is unlikely due to painful skin contact. Toxic part: All parts are toxic, young plants prior to flowering probably not toxic

Mayapple

Scientific Name *Podophyllum peltatum*

Uses Podophyllum has been used for treatment of venereal warts; podophyllotoxin appears to have anticancer activity

Mechanism of Toxic Action Podophyllum and podophyllotoxin block cell division in the metaphase; they have a direct effect on mitochondria and are spindle poisons

Adverse Reactions

Cardiovascular: Sinus tachycardia
Endocrine & metabolic: Abortifacient

Signs and Symptoms of Overdose Severe diarrhea, nausea, and vomiting are typical early toxic manifestations. Dyspnea, hypotension, tachypnea, and tachycardia are frequently seen. Ataxia, coma, dizziness, drowsiness, paralysis, paresthesia, and stupor have been reported. Agranulocytopenia, death, granulocytopenia, leukopenia, liver injury, neutropenia, oliguria, renal failure, and thrombocytopenia have all been reported. Hypokalemia and metabolic alkalosis have been reported from chronically using podophyllum as a purgative. Conjunctivitis, keratitis, and ulcerative skin lesions have been reported in workers handling the powdered rhizome.

Toxicodynamics/Kinetics Absorption: Well absorbed both orally and dermally

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) may be useful in patients with large ingestions that have not developed vomiting yet; activated charcoal with cathartic should be administered

Elimination: Hemodialysis is ineffective in removing podophyllum but may be required in patients experiencing renal failure

Additional Information Toxic dose: Not well established, 350 mg of podophyllum has been reported to cause death. European Mandrake (*Mandragora officinarum*) is unrelated to Mayapple or American Mandrake. Family: Podophyllaceae (formerly *Berberidaceae*). Toxin: Podophyllin resin, podophyllotoxin. Range: Florida to Texas, north to western Quebec, southern Ontario, and Minnesota. Toxic part: Leaves, roots, and unripe fruit; ripe fruit is edible

Mescaline

Related Information

- Peyote

CAS Number 54-04-6

Scientific Name *Lophophora williamsii*

Mechanism of Toxic Action Hallucinogenic methoxylated amphetamine stimulating both serotonin and dopamine receptors in the central nervous system

Adverse Reactions

Cardiovascular: Sinus bradycardia, angina
Endocrine & metabolic: Hyperprolactinemia

Signs and Symptoms of Overdose Ataxia, bradycardia, chest pain, coma, dizziness, fever, flashbacks, flushing, hallucinations, headache, hyperreflexia, hypertension, mydriasis, myoglobinuria, psychosis, rhabdomyolysis, sweating, tachypnea, tremor, vomiting

Admission Criteria/Prognosis Patients who are asymptomatic after 4 hours postexposure may be discharged

Toxicodynamics/Kinetics

Duration of effect: Psychic effects last 6-12 hours

Protein binding: No binding

Metabolism: Hepatic to inactive metabolites

Half-life: 6 hours

Elimination: Renal (55% to 60% unchanged)

Reference Range Hallucinogenic effects occur at blood levels of mescaline of 1.5-14.8 mcg/mL; peak blood level after an oral 500 mg dose: 3.8 mg/mL at 2 hours postingestion and 1.5 mg/L at 7 hours postingestion; after a 5 mg/kg intravenous dose, peak blood mescaline level was 14.8 mcg/mL 15 minutes postdose.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic
Supportive therapy: Benzodiazepines are useful for agitation; haloperidol or chlorpromazine can be used if psychiatric symptoms are not responsive to benzodiazepines; do not use phenothiazines for treatment of flashback

Drug Interaction Flashbacks may be exacerbated by phenothiazines

Additional Information Hallucinogenic dose: Oral: 5 mg/kg. Active ingredient in the peyote cactus (*Lophophora williamsii*). Available as whole dried cactus tops ("buttons"); peyote contains 1% to 6% mescaline; each "button" contains ~45 mg of mescaline. Range: Found in the Southwestern U.S. and Mexico

Specific References

Henry JL, Epley J, and Rohrig TP, "The Analysis and Distribution of Mescaline in Postmortem Tissues," *J Anal Toxicol*, 2003, 27(6): 381-2.

Methcathinone

Related Information

- Cathinone

CAS Number 71031-15-7

Mechanism of Toxic Action Related to cathinone (khat) found naturally in *Catha edulis*; found primarily in production of clandestine labs in Washington, Illinois, Missouri, and upper Michigan peninsula; derived from ephedrine with amphetamine-like actions; causes release of dopamine from caudate nucleus

Adverse Reactions Cardiovascular: Sinus tachycardia

Signs and Symptoms of Overdose Abdominal pain, agitation, anorexia, auditory hallucinations, back pain, constipation, fever, headache, hypertension (dose related), leukocytosis, myoglobinuria, paranoia, rhabdomyolysis, slurred speech, sweating, tachycardia (dose-related), tremor, visual hallucinations

Toxicodynamics/Kinetics Metabolism: To ephedrine and phenylpropanolamine (norephedrine)

Reference Range Reference levels of methcathinone in symptomatic individuals were measured at 56 ng/mL and 78 ng/mL

Overdosage/Treatment

Decontamination: GI lavage (within 1 hour)/activated charcoal with cathartic or phenothiazines

Supportive therapy: Benzodiazepines for agitation

Test Interactions Does not result in positive amphetamine on urine immunoassays

Additional Information Toxic Dose: Estimated to be 80-250 mg by intranasal use (can be used I.V.); typical daily dose: 500-1000 mg. Ephedrine, pseudoephedrine, and phenylpropanone may turn up positive in drug testing in that these chemicals are used in the production of methcathinone

Mexican Beaded Lizard

Related Information

- Gila Monster

Mechanism of Toxic Action Venom is secreted from glands which are located at the posterior edge of the lower jaw and then released into the wound upon mastication. The venom contains hyaluronidase, phospholipase A2, proteolytic enzymes, serotonin, N-benzoyl-L-arginine ethyl ester hydrolase, exendin-4, helothermine, and gilatoxin. Helothermine may have calcium channel blocking properties; gilatoxin is a presynaptic neurotoxin without any hemotoxic effects. Effective envenomation rate in bites is approximately 70%.

Signs and Symptoms of Overdose Anaphylaxis, severe pain, local wound edema, erythema, nausea, vomiting, anxiety, hypotension, tachycardia, diaphoresis, leukocytosis, dizziness, lymphangitis, angioedema

Overdosage/Treatment

Decontamination: Methods to disengage the lizard include pulling the lizard by its tail, prying the jaws open with sticks or metallic objects, or pouring noxious substances down its mouth. Irrigate wound with copious amounts of water.

Supportive therapy: Anaphylaxis can be treated with standard therapy; pain can be treated with opioids. Symptoms usually resolve within one day.

Additional Information The Mexican beaded lizard is native to arid, rocky regions of southwestern Mexico and Guatemala. The lizards are slow moving, nocturnal creatures growing to lengths of 1 meter and weighing 2 kg. The tough dorsal skin is comprised of large, blackish bead-like scales with yellow spots. Normally docile, these lizards are tenacious biters when provoked. The more prolonged the attachment time, the more severe envenomation. Anaphylaxis can occur upon repeated envenomation.

Specific Reference

Cantrell FL, "Envenomation by the Mexican Beaded Lizard: A Case Report," *J Toxicol Clin Toxicol*, 2003, 41(3):241-4.

Milkbush

Related Information

- Crown of Thorns

Scientific Name *Euphorbia*

Signs and Symptoms of Overdose Entire plant can cause an irritant dermatitis; gastroenteritis (nausea, vomiting, diarrhea) can develop upon ingestion. Keratoconjunctivitis and iritis can also develop upon ocular contact.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with sorbitol
Dermal: Wash with soap and water

Supportive therapy: Replace fluid loss with saline and electrolytes as needed antihistamines and/or corticosteroids can be utilized for severe dermal reactions

Mistletoe

Scientific Name *Phoradendron flavescens*; *Phoradendron macrophyllum*; *Phoradendron rubrum*; *Phoradendron serotinum*; *Phoradendron tomentosum*; *Viscum album*

Adverse Reactions

Cardiovascular: Sinus bradycardia, myocardial depression, congestive heart failure, angina, orthostatic hypotension
Central nervous system: Chills, fever, headache

Signs and Symptoms of Overdose Abdominal pain, diarrhea, nausea, and vomiting may be seen. Ataxia, bradycardia, cardiovascular collapse, hypotension, and seizures have all been reported.

Admission Criteria/Prognosis Any patient asymptomatic 6 hours postingestion can be discharged home; admit any ingestion >20 berries or 5 leaves

Overdosage/Treatment

Decontamination: Ipecac (within 30 minutes) or lavage (within 1 hour) may be of value in recent, large ingestions (over 3 berries or 2 leaves) where vomiting has not yet occurred; activated charcoal should be administered; because of the probable diarrhea from substantial mistletoe ingestion, activated charcoal should be given as a water slurry
Supportive therapy: Replace fluids and electrolytes as needed; benzodiazepine can be given for seizure control

Additional Information

Toxic dose: Specific quantities are unknown; it is generally thought that ingestion of more than 2-3 berries is required for poisoning; most serious poisonings are from ingestion of teas or extracts of mistletoe

Family: Loranthaceae; Toxin: Phoratoxin and viscotoxin; Range: All mistletoes are parasitic plants and typically grow on deciduous trees such as oak; *P. rubrum* grows only on mahogany trees; in the U.S., *Viscum album* is found only in California. Toxic part: All parts are considered toxic except for the berries of *Viscum album*

Mites

Scientific Name *Arachnida*; *Demodex folliculorum*; *Sarcoptes scabiei*; *Trombicula irritans*

Signs and Symptoms of Overdose Pruritic erythematous papules, eczematous eruption, erythema multiforme, fever

Overdosage/Treatment Supportive therapy: For scabies: All infested cohabitants should be treated simultaneously to avoid reinfection. Bed linens and clothing worn within 2 days should be washed and dried on hot settings or stored in tightly sealed plastic bags for one week. Permethrin (5% cream) should be applied topically and left on for 8-12 hours. Retreatment can occur in one week. Lindane (1% lotion) is an alternative treatment; it can be applied and left topically for 8 hours and then washed off. Retreatment can occur in one week. Lindane should not be used on nonintact skin or immediately after bathing or in patients with neurological or hepatic diseases. Additionally, neither permethrin should be used in young infants, pregnant or nursing mothers. For infants, pregnant or nursing mothers, precipitated sulfur (6%) in petrolatum can be applied for 3 consecutive nights. A recently described alternative therapy for patients older than 5 years of age: ivermectin: 200 mcg/kg as a single dose in healthy patients or 200 mcg/kg one time dose (repeating as necessary in two weeks) in HIV-infected patients. Pruritus or eczema can be treated with topical steroids. Oral antihistamines and topical steroid cream (ie, flucocinonide cream) for relief of pruritus

Additional Information

May transmit rickettsial pox, murine typhus, Q fever, tularemia, plague; the follicle mite (*Demodex folliculorum*) may be implicated in Kawasaki syndrome; Family: Acarina

Microbiology: *Sarcoptes scabiei*, or the human mite, is the causative agent of scabies, a common parasitic infestation of the skin *Sarcoptes scabiei* is an ectoparasite of humans belonging to the class *Arachnida*. It tends to form skin "burrows" several millimeters wide within the stratum corneum of the epidermis. The fertilized female deposits its eggs in these skin burrows, and the larvae exit after several days to become adults weeks later. The adult is ~0.3 mm long.

Epidemiology: Scabies is distributed world wide. The incidence in the U.S. has been increasing since the 1970s. The reservoir resides in humans, although animal mites can sometimes cause brief human disease. Transmission is person to person by direct contact. Occasionally, transmission may occur when there is contact with heavily contaminated clothing or bedsheets. The incubation period varies from several days to weeks. Infected individuals remain communicable until all the ova and mites are eradicated from the skin.

Clinical Syndromes:

• **Human scabies:** Patients present with intense itching, usually in the interdigital web spaces, along the "belt line," the genital region, the periumbilical area, and also on the wrists, elbows, knees, and feet. Additional areas are common in children, including the hands and face. On physical examination, the characteristic burrows may be seen, appearing linear and several millimeters wide, often in the interdigital spaces. Atypical presentations of scabies may occur, including vesicles

and bullae in infants, eczema, and rash. A variant known as "nodular scabies" has been described in which there are small, brown, intensely pruritic nodules usually on the penis and scrotum. An unusual manifestation of severe scabies called "Norwegian scabies" has been seen in immunocompromised individuals and patients with Down syndrome. The skin is diffusely scaling and thickened as a result of infestation of thousands of mites. Secondary bacterial infections of the skin may occur in all forms of scabies.

• **Animal scabies:** This is due to *Sarcoptes scabiei* var. *Canis*, carried on some dogs; the clinical presentation is similar to human scabies although burrows are not present

Diagnosis: Infestation with scabies is often suspected when an individual presents with pruritic papules, or an otherwise compatible clinical history. Some patients may present because of a recent history of contact. It should be noted that scabies often imitates other skin lesions, and thus a broad differential diagnosis should be entertained if the linear burrows are not demonstrated. Other diagnostic considerations include impetigo, insect bites, drug eruptions, varicella, eczema, and others.

The linear burrows of the mite can be further demonstrated by applying blue ink over a possible burrow. The ink is drawn into the defect and when excess ink is wiped off with an alcohol pad, the ink within the burrow remains. This and other suspicious areas should be covered with oil, the area should be scraped with a sterile blade, the scrapings should be placed into oil on a microscope slide, and the preparation should be examined with a microscope.

To decrease mite allergen measurements below sensitization level, the following interventions may be helpful:

- Remove carpeting from floors
- Replace upholstered furniture with leather or vinyl covered furniture
- Reduce indoor humidity level
- Hot dry steam cleaning followed by vacuuming carpeting or upholstered furniture if present

Monkshood

Scientific Name *Aconitum napellus*; *Aconitum uncinatum*

Mechanism of Toxic Action Aconite has a vagal action on the heart and also a more direct action on the heart muscle; death usually occurs; 2 hours to respiratory failure or heart failure usually 1-6 hours but can be from minutes to 4 days

Adverse Reactions

Cardiovascular: Torsade de pointes, sinus bradycardia, sinus tachycardia, tachycardia (supraventricular), arrhythmias (ventricular)
Central nervous system: Lack of CNS depression

Miscellaneous: Poor prognosis

Signs and Symptoms of Overdose Symptoms occur in 10-20 minutes. Tingling and burning of fingers, lips, toes, and tongue are seen first. Then chills, dry mouth, hypothermia, numbness, paresthesia, and sweating occur. Arrhythmias (supraventricular), bradycardia, diarrhea, hypotension, pain, paralysis, seizures, and ventricular fibrillation occur later. Vaguely mediated bradycardia (which may be associated with AV block) is found in 10% to 20% of fatal poisonings.

Overdosage/Treatment

Decontamination: Ipecac use is contraindicated due to inducing rapid onset of symptoms; lavage within 1 hour may be beneficial, activated charcoal with cathartic

Supportive therapy: Fluid and electrolyte replacement; arrhythmias are relatively refractory to drug therapy; I.V. magnesium sulfate can be used to treat ventricular dysrhythmia; bradycardia can be treated with atropine

Enhancement of elimination: Charcoal hemoperfusion can help reverse ventricular arrhythmias.

Additional Information Fatal dose: 2 g. Fatalities have occurred with ingestion of 2-4 g of root. Estimated lethal dose of plant: 1 g. Toxin: Aconitine. Toxic part: All parts, especially seeds and roots. Monitoring parameters: Cardiac rhythm

Monosodium Glutamate Food Poisoning

CAS Number 142-47-2

Commonly Found In Chinese food, sausage, canned soup, Accent®

Signs and Symptoms of Overdose Angina, angioedema, burning sensation, chest pain, flushing, headache, hypokalemia, paresthesia, syncope, tremor, and wheezing occur within 30 minutes postingestion and may last for 1-3 hours. GI symptoms are minimal.

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment Supportive therapy: Diphenhydramine may be useful, usually self-limited

Diagnostic Procedures

- Electrolytes, Blood

Additional Information Salty or sweet to taste; soluble in water; used as a flavor enhancer. Intravenous doses can cause hypokalemia or alkalosis; absorption is most rapid in a fasting state. Patients with severe, poorly controlled asthma are predisposed to an adverse reaction. The symptom complex can occur in healthy individuals within 20 minutes after ingestion of 3 g of monosodium glutamate on an empty stomach. Symptoms usually last < 1 hour. A typical serving of glutamate-treated food contains <0.5 mg of monosodium glutamate.

Mooneed

Scientific Name *Menispermum canadense*

Signs and Symptoms of Overdose Reportedly a stimulant action similar to water hemlock; seizures are the major concern

Overdosage/Treatment Decontamination: Activated charcoal with cathartic may be of value in recent ingestions; manage seizures with diazepam or lorazepam

Additional Information Family: Menispermaceae. A woody, smooth vine which can grow up to 12 feet. Toxin: Dauricine and other isoquinoline alkaloids. Range: Found in the eastern U.S. Toxic part: Probably the whole plant, but especially the fruit

Morning Glory

CAS Number 2390-99-0; 2889-26-1; 478-94-4; 548-43-6; 602-85-7

Scientific Name *Ipomoea purpurea*; *Rivea corymbosa*

Mechanism of Toxic Action Source of lysergic acid amide which is ~ 10% as potent as lysergic acid diethylamide (LSD)

Adverse Reactions

Cardiovascular: Shock, sinus tachycardia

Central nervous system: CNS depression, memory loss, psychosis, delirium, dysphoria, memory disturbance

Ocular: Vision color changes (increased color perception)

Miscellaneous: Synesthesia

Signs and Symptoms of Overdose Anxiety, depersonalization, depression, diarrhea, drowsiness, flushing, hypotension, mydriasis, tachycardia

Overdosage/Treatment

Decontamination: Activated charcoal with cathartic with oral ingestion

Supportive therapy: Dantrolene (25 mg 2-4 times/day) should be given for neuroleptic malignant syndrome; diazepam or lorazepam can be used for agitation; haloperidol can be given for hallucinations

Additional Information Toxic dose: 300 seeds contain the equivalent of 200-300 mcg of LSD. Often a contaminant in soy bean crops.

Mosquitoes

Scientific Name *Anopheles freeborni*; *Anopheles quadrimaculatus*

Signs and Symptoms of Overdose Anaphylactic reaction, urticarial reaction (rash)

Overdosage/Treatment Supportive therapy: Local application of calamine lotion or aluminum acetate (Burow's solution); allergic reactions can be treated with standard therapy; parenteral corticosteroids can also be given for severe systemic symptoms; cetirizine (5-10 mg orally) can reduce wheal/flare response by 50%

Additional Information Order: Diptera. Family: Culicidae. Vectors for filariasis. Anopheline (*A. quadrimaculatus* and *A. freeborni*) are the vectors for malaria (*Plasmodium*); N,N-diethyl-m-toluamides or DEET is an effective repellent.

Mountain Laurel

Scientific Name *Kalmia latifolia*; *Kalmia*

Mechanism of Toxic Action Contains grayanotoxin which binds to a subset of sodium channels causing structural modifications, thereby causing slow opening of these channels which leads to cell depolarization

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose Asthenia, bradycardia, dermatitis, hypotension, nausea, oral numbness or burning, paresthesia, seizures, sweating, transient blindness, visual changes, vomiting

Overdosage/Treatment

Decontamination: Avoid ipecac, vagal stimulation increases toxicity; lavage (within 1 hour)/activated charcoal with cathartic

Supportive therapy: Atropine for bradycardia, I.V. fluids should be sufficient for hypotension

Additional Information Three whole leaves or flowers likely nontoxic; consider decontamination if more; toxicity is unpredictable, variable among azalea types. Toxic part: Leaves and honey

Mushrooms, Toxic (Group 1) Cyclopeptides

CAS Number 17466-45-4; 21150-22-1; 21150-23-2; 23109-05-9; 28227-92-1; 39412-56-1

Scientific Name *Amanita bisporigera*; *Amanita ocreata*; *Amanita phalloides*; *Amanita subballiacea*; *Amanita tenuifolia*; *Amanita verna*; *Amanita virosa*; *Conocybe filaris*; *Galerina autumnalis*; *Galerina marginatus*; *Galerina speciosissimus*; *Lepiota clypeolarioides*; *Lepiota helveola*; *Lepiota rufescens*

Mechanism of Toxic Action

Contains the cyclopeptides phallotoxins, amatoxins, and virotoxins. Only amatoxins are considered important in human poisoning and cause liver necrosis through inhibition of RNA polymerase II.

Adverse Reactions

Three phases: I: Gastroenteritis: up to 24 hours postingestion (incubation is 8-12 hours); II: Remission: up to 72 hours postingestion; III: Hepatic/renal effects: 3-6 days postingestion

Cardiovascular: Hypotension, cardiomyopathy

Central nervous system: Encephalopathy, coma, seizures

Gastrointestinal: Nausea, vomiting, colicky abdominal pain, hepatitis, pancreatitis

Hematologic: Coagulopathy

Hepatic: Hepatic failure (fulminant), chronic active hepatitis may be long-term sequelae

Renal: Renal failure, acute tubular necrosis

Admission Criteria/Prognosis All suspected ingestions should be admitted; probably in an intensive care unit

Toxicodynamics/Kinetics

Absorption: Phallotoxin not well absorbed though the gastrointestinal tract

Distribution: V_d : 160-290 mL/kg

Protein binding: Not protein bound

Elimination: Excreted in urine, feces, and bile; enterohepatic recirculation may occur

Reference Range There is no correlation of symptoms or outcome to concentration of amatoxin in serum

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic

Supportive Therapy: I.V. fluids, lactulose, neomycin for hepatic failure; vitamin K and fresh frozen plasma may be needed to treat coagulopathy

Proposed antidotes: High dose Penicillin G (300,000-1,000,000 units/kg/day), silymarin, cimetidine 300 mg I.V. every 8 hours, thioctic acid and N-acetylcysteine (efficacy of each has been questioned). Silymarin and thioctic acid are not commercially available in the United States. Dose of silymarin (Silibinin): I.V.: 5 mg/kg I.V. infusion over 1 hour followed by 20 mg/kg/day by continuous infusion for 6 days. N-acetylcysteine therapy or silybin dihemisuccinate appear to be the most effective therapy

Extracorporeal liver assistance methods utilizing an albumin dialysate (molecular absorbent recycling system or MARS) has been utilized to remove protein-bound and water soluble substances in patients with liver failure and grade III or IV hepatic encephalopathy in Europe. Successful results with avoidance of orthotopic hepatic transplantation have been noted with patients exposed to *Amanita phalloides*. It has been safely utilized in children as young as seven years old. Complications include decreases in platelet counts (by 15%) and prolongation of activated prothrombin time (by 21%). Blood pressure, hemoglobin, white blood cell count, electrolytes, transaminases, and albumin levels do not appear to be significantly affected. Refer to Specific References.

Other proposed treatments: Charcoal hemoperfusion within 24 hours of ingestion (efficacy is controversial). **Orthotopic liver transplant has been successful and may be necessary in the most severe cases.** Multiple dosing of activated charcoal may be useful.

Antidote(s)

- Silymarin [ANTIDOTE]

Test Interactions

Monitor for hypochloronemia and hypokalemia during gastroenteritis phase. Insulin, calcitonin, and parathyroid hormone levels are increased. Serum thyroxine levels are decreased. Hypoglycemia may also develop.

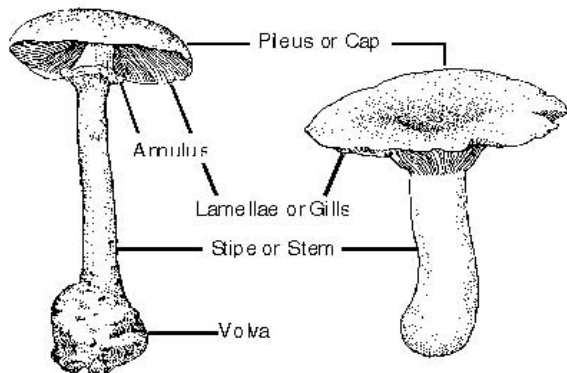

Additional Information

Estimated lethal dose: 0.1 mg/kg; one *Amanita* cap may be lethal in an adult

Amanita species are diagnosed by having a white spore print, gills that do not reach the stem, the presence of a volva (see figure), and often, but not always, an annulus (see figure). *Lepiota* species display these same features, but they always lack a volva. *Galerina* and *Conocybe* species have brown to rusty brown spore prints. The species listed above have an annulus but no volva. Differentiation and correct identification for small brown fungi are based on microscopic examination of spores and other features. Amatoxins are extremely stable

MUSHROOMS, TOXIC (GROUP 2) MONOMETHYLHYDRAZINES

compounds, resistant to heat, drying, freezing, and not degraded enzymatically. The Meixner/Weiland test can be used to detect the presence of amatoxins. Squeeze one drop of juice from a fresh mushroom cap onto newsprint or filter paper (circle spot with a pencil to locate). Let dry at room temperature and out of sunlight. Apply one drop of concentrated hydrochloric acid. A change to a blue color will indicate the presence of amatoxins; compare to a control spot (without mushroom juice). *Amanita phalloides* ingestion may account for up to 90% of mushroom-related deaths worldwide with a fatality rate of 20% to 30%. Fatality is associated with large dose, short latency period before onset of symptoms, severe coagulopathy, and age younger than 10 years. See figure.

Mushrooms, Toxic (Group 2) Monomethylhydrazines

CAS Number 16568-02-8; 60-34-4; 69349-96-8

Scientific Name *Gyromitra ambigua*; *Gyromitra brunnea*; *Gyromitra caroliniana*; *Gyromitra esculenta*; *Gyromitra fastigiata*; *Gyromitra gigas*; *Gyromitra infula*; *Helvella* species, *Sarcosphaera crasa*; *Peziza* species

Uses Monomethylhydrazine is used as rocket fuel; it is a strong reducing agent in industry (DOT/UN: 1244) and a corrosive inhibitor

Mechanism of Toxic Action Gyromitrin present in the mushroom is hydrolyzed upon digestion to N-methyl-N-formylhydrazine (MFH) and monomethylhydrazine (MMH); MMH is an inhibitor of coenzyme pyridoxyl

phosphate and gamma-aminobutyric acid in the CNS; MFH is believed to deplete hepatic cytochrome P450

Adverse Reactions

Central nervous system: Seizures, coma, dizziness, delirium, fever

Gastrointestinal: Nausea, vomiting, abdominal pain, cramps, watery diarrhea

Hematologic: Hemolytic anemia

Hepatic: Hepatitis, jaundice

Renal: Nephritis may develop in 1-2 days

Admission Criteria/Prognosis All suspected ingestions should be admitted

Toxicodynamics/Kinetics

Absorption: May also occur via inhalation of fumes while cooking, MMH can be absorbed through intact skin

Metabolism: 25% metabolized to monomethylhydrazine

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic

Supportive therapy: I.V. fluids

Antidotal therapy: Pyridoxine 25 mg/kg I.V. for seizures

Antidote(s)

- Methylene Blue [ANTIDOTE]
- Pyridoxine [ANTIDOTE]

Diagnostic Procedures

- Glucose, Random

Drug Interaction Phenobarbital may have an enhanced effect due to interference of hepatic metabolism

Additional Information

Lethal dose: Children: 10-30 mg/kg; Adults: 20-50 mg/kg

These species are not typical mushroom shaped; *Gyromitra* and *Helvella* species are stalked with a brain-shaped or saddle-shaped swollen "cap" on top, respectively; species of *Peziza* are typical cup fungi; *Sarcoscypha crasa* starts out spherical and then splits open to form a star-shaped cup; all of these species are usually found on the ground and are most commonly encountered in the spring; there is wide variation in individual susceptibility to poisoning by gyromitrins, estimated tolerance up to 35 mcg/kg of gyromitrin; toxins are heat labile, however, parboiling does not guarantee edibility and toxicity may occur from inhaling vapors

Mushrooms, Toxic (Group 3) Cholinergic

CAS Number 2552-55-8 (ibotenic acid); 2763-96-4 (muscimol)

Scientific Name *Clitocybe dealbata*; *Clitocybe dilatata*; *Clitocybe morbi-fera*; *Clitocybe rivulosa*; *Inocybe fastigiata*; *Inocybe geophylla*; *Inocybe lacera*; *Inocybe mapipes*; *Inocybe mixtilis*; *Inocybe pantouillardi*; *Inocybe pudica*; *Inocybe sororia*; *Inocybe subdstricta*; *Mycena pura*

Mechanism of Toxic Action Contains the compound muscarine which is structurally similar to acetylcholine and produces symptoms of cholinergic excess; muscarine is not degraded by acetylcholinesterase enzyme

Adverse Reactions

Cardiovascular: Bradycardia, hypotension, hypertension, arrhythmias

Central nervous system: Delirium, dizziness, ataxia, somnolence, seizures, psychosis, euphoria, residual headaches, fever, coma, visual hallucinations, hyperthermia

Gastrointestinal: Vomiting, watery diarrhea, salivation

Neuromuscular & skeletal: Myoclonus

Ocular: Miosis, lacrimation, teichopsia

Miscellaneous: Diaphoresis

Admission Criteria/Prognosis Can observe for 6-8 hours; if symptomatic, admission is suggested; ingestions >20 mushrooms will probably require admission

Toxicodynamics/Kinetics

Onset of action: Within 30 minutes

Duration: Variable, dose-related

Overdosage/Treatment Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic; I.V. hydration with isotonic saline; atropine 1-2 mg I.V. in adults or 0.05 mg/kg in children, only if significant signs of cholinergic crisis are present; benzodiazepines are indicated for treating seizures

Diagnostic Procedures

- Electrolytes, Blood

Additional Information

Estimated lethal dose: Muscarine: 40-180 mg; Toxic dose: Fresh mushrooms: ~100 g or less

These species of *Clitocybe* usually grow in grassy areas or along roadways. They are whitish in color, have white spores, and have gills that often run part way down the stem. The common name for *Inocybe* is fiber head because of the distinctive fibers that radiate from the center of the cap and run to the margin. Species of *Inocybe* have a clay brown spore print and often have a spermatoid odor.

Specific References

- Saviuc P, Dematteis M, Mezin P, et al. "Toxicity of the *Clitocybe amoenolens* Mushroom in the Rat," *Vet Hum Toxicol*, 2003, 45(4):180-2.

Mushrooms, Toxic (Group 4) [Antabuse®]**Scientific Name** *Coprinus atramentarius***Mechanism of Toxic Action** The metabolite of coprine, 1-aminocyclopropanol, inhibits aldehyde dehydrogenase and thus produces an antabuse-like reaction when consumed with alcohol**Adverse Reactions**

Cardiovascular: Flushing, cardiovascular collapse, myocardial infarction, chest pain

Central nervous system: Dizziness, headache, seizures

Gastrointestinal: Nausea, vomiting, metallic taste

Hepatic: Hepatitis

Neuromuscular & skeletal: Paresthesia

Ocular: Retrobulbar neuritis, nystagmus

Respiratory: Dyspnea

Miscellaneous: Diaphoresis

Admission Criteria/Prognosis Admit if there are ECG changes or persistent symptoms**Toxicodynamics/Kinetics**

Onset of action: 0.5-2 hours

Duration of action: 4-6 hours

Duration of effects: 3-6 hours

Sensitivity to alcohol may last up to 72 hours

Overdosage/Treatment Decontamination: Lavage (within 1 hour)/activated charcoal; management of disulfiram reaction: Institute support measures to restore blood pressure (pressors and fluids); monitor for hypokalemia; metoclopramide or prochlorperazine can be used for vomiting; dopamine is **not** useful to treat disulfiram-ethanol induced hypotension; norepinephrine is the preferred agent; use of 4-methylpyrazole is investigational**Antidote(s)**

- Norepinephrine [ANTIDOTE]

Drug Interaction INH, metronidazole, phenytoin, alcohol, warfarin, diazepam, chlorthalidone, diazepam; can cause elevation of theophylline**Additional Information** Toxic dose: Hallucinogenic: 10-20 mg of psilocin. *Coprinus atramentarius* is one of the inky-caps which are characterized by having fruit bodies that undergo autodigestion; it usually grows in clusters in grassy areas; it gives a black spore print; approximately less than 1100th the potency of LSD**Mushrooms, Toxic (Group 5) Anticholinergic****CAS Number** 2552-55-8 (ibotenic acid); 2763-96-4 (muscimol)**Scientific Name** *Amanita cothurnata*; *Amanita crenulata*; *Amanita frostiana*; *Amanita gemmata*; *Amanita muscaria*; *Amanita pantherina***Mechanism of Toxic Action** Inebriation syndrome is due primarily to the toxin ibotenic acid and its decarboxylation product, muscimol; ibotenic acid is structurally related to the excitatory neurotransmitter glutamic acid while muscimol is related to the inhibitory neurotransmitter GABA; combined action of both toxins may explain the initial excitation and inebriation followed by the prolonged coma-like sleep seen with poisoning by Group V mushrooms**Adverse Reactions**

Cardiovascular: Tachycardia, hypotension

Central nervous system: Delirium, dizziness, ataxia, somnolence, seizures, psychosis, euphoria, residual headaches, fever, coma, hyperthermia, visual hallucinations

Gastrointestinal: Vomiting (rare), xerostomia

Neuromuscular & skeletal: Myoclonus, fasciculations

Ocular: Mydriasis

Renal: Renal failure (within 1 week of ingestion)

Admission Criteria/Prognosis Can observe for 6-8 hours; if symptomatic, admission is suggested; ingestion of more than two mushrooms will probably require admission**Toxicodynamics/Kinetics**

Onset of action: 1 hour

Duration of action: 24 hours

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Diazepam can be utilized for delirium and for seizures; physostigmine should only be used for life-threatening anticholinergic crisis (0.5-2 mg I.V. over a 5 minute period); hemodialysis if renal failure develops

Antidote(s)

- Physostigmine [ANTIDOTE]

Additional Information

Toxic dose: Ibotenic acid: 30-60 mg; Muscimol: 6 mg. Sensory derangement can be produced at a dose of 2-4 mushrooms; maximum survivable ingestion: 20 mushrooms

Amanita muscaria contains only trace amounts of muscarine and is not considered part of Group III; *Amanita* species are diagnosed by having a white spore print, gills that do not reach the stem, the presence of a volva, and often, but not always, an annulus. See figure in Mushrooms,Toxic (Group I) Cyclopeptides; do not confuse any of these with the *Amanita* species containing Group I toxins.**Mushrooms, Toxic (Group 6) Psychedelic****CAS Number** 520-52-5; 520-53-6**Scientific Name** *Conocybe cyanopus*; *Conocybe smithii*; *Gymnopilus aeruginosa*; *Gymnopilus luteus*; *Gymnopilus spectabilis*; *Gymnopilus validipes*; *Panaeolus campanatus*; *Panaeolus foeniculii*; *Panaeolus sphinctrinus*; *Panaeolus subbalteatus*; *Pluteus salicinus*; *Psilocybe baecystis*; *Psilocybe caerulescens*; *Psilocybe caerulipes*; *Psilocybe cubensis*; *Psilocybe cyanescens*; *Psilocybe pelliculosa*; *Psilocybe semilanceolata*; *Psilocybe strictipes*; *Psilocybe stuntzii*; *Stropharia semiglobata***Mechanism of Toxic Action** Contains psilocybin and psilocin which are indole alkaloids similar to LSD, possible serotonin antagonists**Adverse Reactions**

Cardiovascular: Tachycardia, flushing, hypertension, sinus tachycardia, Wolff-Parkinson-White syndrome

Central nervous system: Ataxia, chills, headache, dizziness, fever, seizures, visual hallucinogens (colored patterns, impaired distance perception), psychosis, leukoencephalopathy

Gastrointestinal: Vomiting

Genitourinary: Urinary incontinence

Hematologic: Methemoglobinemia

Neuromuscular & skeletal: Myalgias, paresthesias, hyperkinesia, rigors, weakness

Ocular: Mydriasis

Admission Criteria/Prognosis Admit if fever/seizures occur; any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%**Toxicodynamics/Kinetics**

Onset of action: Within 20 minutes

Duration: 6-15 hours

Absorption: Oral: 50%

Metabolism: Hepatic

Elimination: Renal

Overdosage/Treatment Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic

Supportive therapy: Diazepam for panic attacks; chlorpromazine may be useful for treatment of hallucinations; flashback may occur 4 months later

Additional Information

Roughly 5-6 dried mushroom caps may produce hallucinations, perceptual changes at 6-12 mg psilocybin, true hallucinations at >12 mg psilocybin

The base of the stem of most of these species turns blue to blue-green when handled; many of these species are small and brown to dark colored and as such are easy to confuse with other species including the deadly toxic Group I species *Conocybe filaris* (Deadly *Conocybe*); most species in these genera are not hallucinogenic.**Specific References**Grieshaber AF, Moore KA, and Levine B, "The Detection of Psilocin in Human Urine," *J Forensic Sci*, 2001, 46(3):627-30.Gross ST, "Psychotropic Drugs in Developmental Mushrooms: A Case Study Review," *J Forensic Sci*, 2002, 47(6):1298-302.Kunz MW, Rauber-Lüthy CH, Meier PJ, et al, "Acute Poisoning with Hallucinogenic Psilocybe Mushrooms in Switzerland," *J Toxicol Clin Toxicol*, 2000, 38(2):233-4.Tiscione NB and Miller MI, "Psilocin Identified in a DUID Investigation," *J Anal Toxicol*, 2006, 30:342-3..**Mushrooms, Toxic (Group 7) Gastrointestinal Irritants****Scientific Name** *Agaricus arvensis*; *Agaricus hondensis*; *Agaricus placomyces*; *Agaricus silvicola*; *Agaricus xanthodermus*; *Amanita brunescens*; *Amanita chlorinosma*; *Amanita flavoconia*; *Amanita flavorubescens*; *Amanita frostiana*; *Amanita parvicolvata*; *Boletus luridus*; *Boletus pulcherrimus*; *Boletus satanus*; *Boletus sensibilis*; *Chlorophyllum molybdites*; *Entoloma* species; *Gomphus floccosa*; *Gomphus kauffmanii*; *Hebeloma crustuliniforme*; *Hebeloma fastibile*; *Hebeloma mesophaeum*; *Hebeloma sinapizans*; *Helvella* species; *Hypholoma fasciculare*; *Lactarius chrysorheus*; *Lactarius glaucescens*; *Lactarius helvus*; *Lactarius repraesentaneus*; *Lactarius rufus*; *Lactarius scrobiculatus*; *Lactarius torminosus*; *Lactarius uvidus*; *Lepiota clypeolaria*; *Lepiota cristata*; *Lepiota lutea*; *Lepiota naucina*; *Omphalotus olearius*; *Paxillus involutus*; *Ramaria formosa*; *Ramaria gelatinosa*; *Russula emetica*; *Scleroderma citrinum*; *Tricholoma* species; *Tylopilus felleus*; *Verpa bohemica***Mechanism of Toxic Action** Gastrointestinal irritants, diverse toxins, most mechanisms have not been identified**Adverse Reactions**

Cardiovascular: Pallor

MUSHROOMS, TOXIC (GROUP 8) RENAL TOXIC

Central nervous system: Fatigue, drowsiness, headache (*Entoloma lividum*), chills

Gastrointestinal (within 3 hours): Nausea, vomiting, watery diarrhea progressing to bloody diarrhea, abdominal pain

Neuromuscular & skeletal: Myalgias

Overdosage/Treatment

Decontamination: Activated charcoal

Supportive therapy: Isotonic fluids for rehydration; symptoms usually resolve within 24 hours

Additional Information Species listed as having Group VII toxins are numerous and diverse ranging from mushrooms to coral fungi to puffballs; the Jack O'Lantern (*Omphalotus olearius*) is commonly ingested due to a superficial similarity to the choice edible chanterelle; *Chlorophyllum molybdites* (Green-spored *Lepiota*) is another commonly ingested toxic mushroom; it is large, white, and grows commonly in lawns throughout the United States; it can be identified by the green tinted gills and green spore print.

Mushrooms, Toxic (Group 8) Renal Toxic

CAS Number 37338-80-0

Scientific Name *Cortinarius atrovirens*; *Cortinarius gentilis*; *Cortinarius orellanoides*; *Cortinarius orellanus*; *Cortinarius rainierensis*; *Cortinarius splendens*; *Cortinarius vitellinus*

Mechanism of Toxic Action Contains orelline and orellanine which can cause interstitial nephritis, renal tubular damage

Adverse Reactions

Central nervous system: Chills, headaches

Dermatologic: **Skin rash** (12%)

Gastrointestinal: Nausea, vomiting, **diarrhea** (20%), anorexia, constipation

Neuromuscular & skeletal: Myalgias, **paresthesias** (15%)

Otic: Ototoxicity, tinnitus

Renal: Oliguria, **renal failure** (30% to 46%) can be delayed in onset up to weeks after exposure, **polyuria** (30%)

Miscellaneous: Coldness, cold feeling, intense thirst

Toxicodynamics/Kinetics Onset of action: Delay of symptoms may occur as long as 17 days later but usually occur 24-36 hours postingestion

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal

Supportive therapy: Isotonic fluids for rehydration; renal transplant may be required for renal failure; forced diuresis is not effective; furosemide may increase renal dysfunction

Enhanced elimination: Hemodialysis or charcoal hemoperfusion should be started as soon as possible to prevent renal failure

Drug Interaction Increased toxicity may occur with phenobarbital or furosemide

Additional Information Lethal dose: Fresh mushrooms or 3-10 caps: 100-200 g/kg

Cortinarius gentilis (Deadly Cort) and *Cortinarius rainierensis* have been found in the western United States but, to our knowledge, poisonings due to these fungi are unknown in the United States. May be present (orellanine) in renal biopsy materials.

Mushrooms, Toxic (Group 9) Renal Toxic

Scientific Name *Amanita smithiana*

Mechanism of Toxic Action

Contains the nephrotoxic compounds allenic norleucine and chlorocrotylglycine

Adverse Reactions Gastrointestinal side effects (nausea, vomiting, and diarrhea), along with dizziness and diaphoresis, usually occur within 1/2-12 hours. Oliguric renal failure associated with renal tubular necrosis usually occurs within 2-5 days postingestion. Other side effects include blurred vision, elevated liver function tests, pruritus, and metabolic acidosis associated with the renal failure.

Overdosage/Treatment

Decontamination: Although no formal studies exist, activated charcoal (1 g/kg) could be given to prevent absorption within 1 hour of ingestion

Supportive therapy: Treatment is entirely supportive; monitor electrolytes; renal failure may require hemodialysis for several weeks before resolution.

Additional Information *Amanita smithiana* is a large white mushroom with a 5-12.5 cm wide cap, a 10-20 cm stem, and a 1-3 cm thick bulb. It is found primarily in the Pacific Northwest and resembles the matsutake mushroom (*Tricholoma magnivalere*). Unlike the matsutake mushroom, *Amanita smithiana* is odorless.

Mushrooms, Toxic (Group 10)

Scientific Name *Amanita smithiana*

Synonyms Smith's amarita

Mechanism of Toxic Action Can cause renal toxicity through the chemicals amino-hexadienoic acid and chlorocrotylglycine which can result in renal tubular acidosis and necrosis

Adverse Reactions

Onset of nausea and vomiting may be delayed for as long as 12 hours.

Ocular: Blurred vision

Central nervous system: Anxiety, dizziness

Gastrointestinal: Nausea, vomiting, diarrhea, abdominal pain

Hepatic: Elevated transaminase level

Renal: Acute renal failure, oliguria, anuria can occur 4 to 6 days post ingestion. Renal Tubular acidosis.

Dermal: Diaphoresis, Pruritis.

Overdosage/Treatment

Decontamination: Although no formal studies exist, activated charcoal

(1 g/kg) could be given to prevent absorption within 1 hour of ingestion

Supportive therapy: Treatment is entirely supportive; monitor electrolytes; renal failure may require hemodialysis for several weeks before resolution.

Additional Information Commonly found in the Pacific Northwest, it usually appears in the fall. *Amanita smithiana* has an ivory colored, convex cap up to 1.8 cm in diameter with felt-like brownish patches.

Mustard Tree

Scientific Name *Nicotiana glauca*

Mechanism of Toxic Action All parts of the plant contain nicotine and are considered toxic

Adverse Reactions Cardiovascular: Sinus bradycardia, sinus tachycardia

Signs and Symptoms of Overdose Low doses can cause asthenia, headache, nausea, oral irritation, sweating, thirst, and vomiting. Higher doses can cause CNS stimulation followed by depression, confusion, hallucinations, hypertension, hyperthermia, seizures, and tachycardia followed by bradycardia, hypotension, and an irregular pulse.

Admission Criteria/Prognosis Symptomatic patients or patients with tachycardia or hypertension 4 hours postexposure should be admitted; survival after 4 hours is usually associated with complete recovery

Overdosage/Treatment

Decontamination: **Oral:** Emesis not recommended due to potential for seizures. Lavage within 1 hour with 1:10,000 potassium permanganate (100 mg/L) is recommended in ingestions after control of seizures;

activated charcoal with cathartic use in acute ingestions not well established. **Dermal:** Wash area well with cool water and dry; soap (especially alkaline soaps) may increase absorption; remove any remaining transdermal systems; nicotine will continue to be absorbed several hours after removal due to depot in skin

Supportive therapy: Control seizures with benzodiazepines; if continuous, use phenytoin or phenobarbital; atropine can be utilized for cholinergic toxicity while phentolamine can be used for hypertension

Enhancement of elimination: Hemodialysis/hemoperfusion of unknown value; multiple doses of activated charcoal may be effective; while acidifying the urine may enhance elimination, this modality is not recommended due to inherent dangers; would proceed with forced diuresis

Additional Information Range: Arizona, Texas, Mexico, California, Hawaii

Needlefish

Scientific Name *Tylosurus crocodilus*

Mechanism of Toxic Action Penetrating bite injury not involving envenomation.

Adverse Reactions

Local: Wound edema, erythema; vascular injury with compartment syndrome may occur. Secondary infections (myositis or cellulitis) may be caused by *Vibrio* species.

Miscellaneous: Radiopaque

Admission Criteria/Prognosis Admit any nonextremity bite or bite with suspected vascular injury.

Overdosage/Treatment Supportive therapy: Apply direct pressure over wound if vascular injury is suspected. Obtain x-ray of affected area (the beak of the needlefish is radiopaque). Wound exploration may be necessary to remove fragments. If a joint is involved, arthroscopy should be considered. Vigorously irrigate all wounds. Tetanus prophylaxis (if not up to date) should be given. Appropriate intravenous antibiotics include ciprofloxacin, imipenem-cilastatin, cefoperazone, cefotaxime, ceftazidime, gentamicin, or trimethoprim-sulfamethoxazole. Oral antibiotics which are appropriate include trimethoprim-sulfamethoxazole, ciprofloxacin, or doxycycline.

Additional Information A blue-green surface fish found in all oceans of the subtropical or tropical regions; this fish may grow to ~5 feet long with its beak accounting for ~25% of its length. May leap out of the water at high speeds in the direction of light.

Nephtytis

Scientific Name *Syngonium podophyllum*; *Syngonium*

Mechanism of Toxic Action Contains insoluble calcium oxalate crystals which cause mechanical irritation; may also cause irritation through an unclear enzymatic process

Signs and Symptoms of Overdose

Dermal: Dermatitis, irritation, pain, swelling

Ocular: Sap may cause corneal abrasion, lacrimation, pain, photophobia; oxalate crystals may be deposited on cornea; may also cause dermatitis

Oral: Diarrhea, dysphonia, edema, salivation, vomiting

Toxicodynamics/Kinetics Rapid onset of local symptoms**Overdosage/Treatment**

Decontamination: **Oral:** Dilute; ipecac/lavage/activated charcoal not likely necessary. **Dermal:** Wash thoroughly. **Ocular:** Irrigate

Supportive therapy: Cool compresses may minimize pain and swelling

Additional Information Toxic part: Whole plant contains calcium oxalate crystals

Neurotoxic Shellfish Poisoning**Related Information**

- Ciguatera Food Poisoning
- Paralytic Shellfish Poisoning

Commonly Found In Mussels, shellfish (bivalves)

Mechanism of Toxic Action Shellfish ingestion of the toxic dinoflagellate *Ptychodiscus brevis*, produces the neurotoxin brevetoxin; additionally, the dinoflagellate *Ptychodiscus veneficum* can cause this illness. Brevetoxins are a muscarinic agonist.

Signs and Symptoms of Overdose Abdominal pain, ataxia, bradycardia (lasting up to 12 hours), coma, confusion, diarrhea, dizziness, dysphagia, headache, hyporeflexia, lacrimation, myalgia, mydriasis, paresthesia, pruritus, reversal of hot/cold temperature, rhinorrhea, seizures, sneezing, tremor. Bronchospasm and cough can occur from aerosolized *P. brevis* particles.

Admission Criteria/Prognosis All symptomatic patients should be admitted

Overdosage/Treatment

Decontamination: Dermal: Wash with soap and water; lavage (within 1 hour)/activated charcoal (avoid magnesium cathartics)

Supportive therapy: Although no human studies exist, atropine has been useful in treating bronchospasm, rhinorrhea, lacrimation, and salivation in animal studies. Thus ipratropium bromide may be efficacious in treating bronchospasm. Seizures can be treated with benzodiazepines; refractory seizures can be treated with barbiturates or phenytoin. Hypotension can be treated with intravenous fluids or vasopressors.

Additional Information Incubation period: ~3 hours (range: 15 minutes to 18 hours). Duration of illness: ~17 hours (range: 1-72 hours). Heat stable, lipid soluble toxin; may be a cause of red tides. Usually found off of Florida in the Gulf of Mexico.

Oak

Scientific Name *Quercus*

Signs and Symptoms of Overdose Abdominal pain, bloody diarrhea, constipation, nausea, possible kidney and liver damage, vomiting

Overdosage/Treatment

Decontamination: Induction of vomiting is controversial, vomiting may be appropriate for large ingestions; activated charcoal and cathartics may also be of value

Supportive therapy: As needed

Octopus

Scientific Name *Octopus bairdi*

Mechanism of Toxic Action Bite - envenomation

Adverse Reactions Local: Erythema

Signs and Symptoms of Overdose Aponia, blurred vision, burning sensation, cardiovascular collapse, coma, local ischemia, numbness, pain, paresthesia, slurred speech

Admission Criteria/Prognosis All patients should be observed at least 12-24 hours

Overdosage/Treatment Symptomatic/supportive/wound care; no antidote available; Hypotension should be treated with standard therapy; if unresponsive to standard therapy, norepinephrine or phenylephrine infusion may be required.

Additional Information Octopus bites are rare, but can result in severe envenomations if due to blue-ringed octopus. Range: Warm/shallow waters including rock pools in the intertidal zones

Oleander

Scientific Name *Nerium odorum*; *Nerium oleander*

Mechanism of Toxic Action Entire plant contains cardiac glycosides oleandrin, oleandroside, and nerin

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose GI effects (nausea and vomiting) usually precede cardiovascular effects by several hours. Asystole, AV block, bradycardia, confusion, contact dermatitis, decreased QT interval and prolonged P-R interval, delirium, dizziness, fatigue, fibrillation (atrial),

flutter (atrial), headache, heart block (first, second, and third degree), hyperkalemia, hypotension, seeing yellow halos, ventricular arrhythmias

Admission Criteria/Prognosis Asymptomatic patients with normal electrocardiogram and electrolytes can be discharged after a 12-hour observation; any symptomatic patient should be admitted to a cardiac monitor bed

Reference Range Postmortem concentrations following suicide by water extraction of oleander: Heart blood: 9.8 ng/ml; Cerebrospinal fluid: 10.1 ng/mL

Overdosage/Treatment

Decontamination: Lavage within 1 hour and multidose activated charcoal enhance total body clearance of digitalis; whole bowel irrigation is also beneficial in removing plant debris from the GI tract and is recommended for ingestions of large amounts of plant material

Supportive therapy: Monitor cardiac status and serum potassium levels; bradycardia will frequently respond to atropine; phenytoin is the recommended treatment for ventricular arrhythmias because it will also improve conduction through the AV node; lidocaine can also be used to treat ventricular arrhythmias, but will not have an effect on AV conduction; other antiarrhythmics which have been used in arrhythmias resistant to the above therapy include magnesium, amiodarone, and bretylium; a pacemaker should be considered for bradycardia and AV nodal blocks resistant to medical management

Enhancement of elimination: Multiple-dose activated charcoal is effective in reducing deaths and life-threatening arrhythmias after yellow oleander poisoning.

Antidote: Digoxin immune Fab has been shown to interact with several different plant cardiac glycosides and may be beneficial in cases resistant to conventional treatment; indications for its use include ventricular arrhythmias resistant to conventional treatment, severe bradycardia and/or second or third degree heart block resistant to atropine and phenytoin

Antidote(s)

- Digoxin Immune Fab [ANTIDOTE]

Additional Information Variable toxicity of leaves depending on growing conditions and time of year; seven leaves have produced bradycardia, nausea, vomiting, and abdominal cramps. Toxin: Cardiac glycosides. Oleander poisoning can occur from smoke inhalation from burning oleander leaves.

Oriental Hornet

Scientific Name *Vespa orientalis* (Hymenoptera sp.)

Mechanism of Toxic Action Venom contains acetylcholine, histamine, serotonin, catecholamines, kinins, and phospholipases

Signs and Symptoms of Overdose Acute tubular necrosis, anaphylaxis, anuria, coagulopathy, dyspnea, fever, hemolysis, hepatotoxicity, hypoglycemia, hyporeflexia, hypotension, rhabdomyolysis, seizures, thrombocytopenia

Overdosage/Treatment Supportive therapy: Treat anaphylaxis with epinephrine, antihistamines, and corticosteroids; hypotension can be treated with I.V. crystalloid fluid and vasopressor agents

Additional Information Lethal dose: Mice: 2.5 mg/kg. Hemolysis is due to orientotoxin and phospholipase A₂ and is usually manifested within 12 hours of envenomations

Ostrich Fern

Scientific Name *Matteuccia struthiopteris*; *Onoclea struthiopteris*; *Pteritis struthiopteris*

Mechanism of Toxic Action Essentially unknown; may contain a heat-labile toxin that can cause gastroenteritis

Signs and Symptoms of Overdose Usually begin within 12 hours of ingestion (incubation mean: 6 hours); abdominal pain, diarrhea, headache, nausea, vomiting. Symptoms usually last ~1 day.

Overdosage/Treatment Supportive therapy: Primarily symptomatic; replace fluid loss either orally or with intravenous hydration

Additional Information Spring vegetable; large fern with oblong shaped leaves found along rivers, streams, and coastal waters; usually nontoxic, but a gastroenteritis syndrome has recently been described; recommendation is to boil the plant for 15 minutes or steam for 10-12 minutes before eating. Range: Eastern North America

Pansy

Scientific Name *Viola* species

Mechanism of Toxic Action Myosin and glucosides produce a cathartic effect, but large ingestions are required

Signs and Symptoms of Overdose Diarrhea, nausea, vomiting

Overdosage/Treatment Supportive therapy: Fluid replacement is seldom required; treat symptomatically

Additional Information Toxin: Seeds contain myosin and glucosides

Paralytic Shellfish Poisoning

Related Information

- Neurotoxic Shellfish Poisoning

Commonly Found In Alaskan butterclam, sea scallop, Californian sea mussel, Australian xanthid crab, butterclams, oysters, rock scallop, Washington clam

Mechanism of Toxic Action Consumption of toxic dinoflagellate (protists) by the shellfish (bivalve mollusks) can then concentrate the neurotoxin (saxitoxin, neosaxitoxin, gonyautoxin); these neurotoxins can block neuromuscular transmission by blocking ionic permeability of neurons to sodium. Additional vasodilatation can occur.

Adverse Reactions Cardiovascular: Sinus tachycardia

Signs and Symptoms of Overdose Aphonia, ataxia, blindness (temporary), diarrhea, dizziness, dysphagia, dyspnea, headache, hypotension, incoherent speech, nystagmus, ophthalmoplegia, paralysis, paresthesias, respiratory failure, salivation, tachycardia, tongue/lip numbness, trismus. Death is usually due to respiratory paralysis within 12 hours. Sensation of loose teeth can occur, as can diaphoresis.

Admission Criteria/Prognosis All symptomatic patients should be admitted; asymptomatic patients can be discharged following 8 hours observation postexposure

Toxicodynamics/Kinetics

Absorption: Oral: Well absorbed

Elimination: Renal

Overdosage/Treatment

Decontamination: Oral: Lavage with water or 2% sodium bicarbonate within 2 hours of exposure; activated charcoal can be utilized with cathartics (but avoid magnesium-based cathartics)

Supportive therapy: Hypotension can be treated with intravenous fluids and vasopressors

Enhanced elimination: Hemodialysis has been utilized with uneven results; cannot be recommended for routine use

Test Interactions Elevation of creatine kinase (MB) not related to severity of poisoning

Drug Interaction Ethyl alcohol may increase toxicity of this agent

Additional Information

Lethal dose: ~0.5 mg (or ~80 mcg of pure toxin/100 g of tissue); Toxic oral dose: ~0.2 mg

Presence of blooms indicates that >20,000 organisms exist in 1 mL of water, and it is possible that blooms may reach 40 million/mL. Typically, time of onset is from May to November.

The toxin is acid and heat stable and stored in the liver, gills, and siphons of the shellfish. Onset can occur in ~30 minutes. Children may be more sensitive to neurotoxin than adults

Saxitoxin from the dinoflagellate *Pyrodinium bahamense* have been found in the Southern (*Spherooides nephelus*), checkered (*Spherooides testudineus*) and bandtail (*spherooides spengleri*) puffer fish in the Western Atlantic. Saxitoxins were detected in skin, muscle and viscera at concentrations up to 22, 104 micrograms of saxitoxin equivalents per 100 grams tissue in the ovaries (action level is 80 micrograms of saxitoxin equivalents per 100 grams of tissue).

Specific Reference

Landsber JH, Hall, S, Johannessen JN et al, "Saxitoxin Puffer Fish Poisoning in the United States with the First Report of *Pyrodinium bahamense* as the Potative Toxin Source," *Environ Health Perspect*, 2006, 114:1502-7.

Pasteurella multocida

Signs and Symptoms of Overdose

Animal bite-wound infections: Patients who have *Pasteurella* inoculated via a bite wound develop rapid onset of local pain, erythema, and

edema. This may occur within hours of the bite or may be delayed by several days. Common sites include the upper extremities (in particular, hands), legs, and the head and neck region. An important complication is the development of regional lymphadenopathy. Occasionally, *Pasteurella* infection may be the cause of lymph node enlargement of unknown etiology; such patients should be questioned about seemingly minor animal scratches as well. Bite-wound infections are often limited to soft tissue cellulitis or focal abscesses. At times, the course may be complicated by tenosynovitis and osteomyelitis, which can be particularly difficult to treat when involving the hand. Note that the specific entity known as "cat scratch disease" is not caused by *Pasteurella multocida*. The exact cause of this lymphadenopathy syndrome is still being debated.

Upper and lower respiratory infections: This unusual presentation of *Pasteurella* infection may be seen in patients who have had a significant exposure to animals but lack a history of an animal bite. *Pasteurella* has been implicated as a rare cause of bronchitis, sinusitis, and pneumonia in both healthy individuals and in those with underlying chronic bronchitis.

Infection in the immunocompromised host: Serious and life-threatening *Pasteurella* infections have been reported in patients with underlying malignancies, organ transplantations, and HIV infection.

Miscellaneous infections: Meningitis, arthritis, peritonitis (particularly patients undergoing peritoneal dialysis), corneal ulcers, ophthalmitis, and urinary tract infections are rarely reported.

Overdosage/Treatment Supportive therapy: Drug of choice for pasteurellosis is penicillin. If the infection is minor and limited to soft tissue, a trial of oral penicillin may be attempted (eg, penicillin V, 500 mg orally every 6 hours). If the infection is more serious, parenteral penicillin should be used. This includes deep wound infections of the extremities, osteomyelitis, septic arthritis, tenosynovitis, and pneumonia. Consultation with an infectious disease specialist may be useful in complicated cases, where therapy may be prolonged and surgical debridement necessary. Other antimicrobial agents are probably effective, but the clinical experience is more limited: tetracycline, ampicillin, possibly ciprofloxacin, and the cephalosporins. Infectious disease consultation may be helpful for therapy with alternative agents.

Additional Information

Microbiology: *Pasteurella multocida* is a gram-negative rod which is primarily a pathogen in wild and domestic animals, but is also capable of causing sporadic human diseases such as animal bite infection, osteomyelitis, pneumonia, and sepsis. *P. multocida* is an aerobic, gram-negative coccobacillus which does not form spores. It belongs to the family Pasteurellaceae and is thus related to *Haemophilus* species. There are six distinct species of *Pasteurella*, but the most common to cause human disease is *Pasteurella multocida*. Special requests for identification for this organism are helpful for the microbiology laboratory but are usually not necessary; the organism grows readily on several standard culture media such as blood agar or chocolate agar.

Epidemiology:

P. multocida is a normal commensal of the oropharynx and the GI tract of several kinds of animals. However, it is only rarely recovered from the respiratory tract of humans, and has been found to be part of the normal oral flora only in individuals with significant animal contact (eg, veterinarians). The frequency of recovery of this organism from a healthy animal depends on the particular animal species, as follows: cats, 50% to 75%; dogs, 10% to 60%; pigs, 50%; and rats, 15%.

Pasteurella has been reported in all age groups. Human infection usually occurs following an animal bite or scratch. One study found that up to 17% of patients being treated in an emergency room for an animal bite ultimately developed a *Pasteurella* infection. Cat scratches or bites cause the majority of *Pasteurella* infections (~65% of cases). Dog bites are responsible for ~35% of cases. A smaller number of cases of *Pasteurella* infections is due to animal exposures without a clear history of an animal bite or scratch; the patient tends to be frequently exposed to animals (such as a veterinarian, livestock handler, pet shop worker), and the infections are generally in the respiratory tract, although cases of intra-abdominal infection have also been described. A small percentage of patients are infected with *P. multocida* without any significant animal exposure.

Diagnosis: *P. multocida* infection should be included in the differential diagnosis of any wound infection following an animal bite or deep scratch. The diagnosis strongly suggests if the onset of local inflammation is within 3-24 hours of the bite, and if the animal involved was a cat. Longer periods of incubation are more suggestive of streptococcal or staphylococcal infection, although certainly cases of pasteurellosis may have a delayed onset. The diagnosis is more difficult for nonbite *Pasteurella* infections; the clinician must carefully inquire about unusual or prolonged animal exposures in the workplace and at home.

Peach

Scientific Name *Prunus persica* species

Mechanism of Toxic Action Amygdalin (a cyanogenic glycoside) is hydrolyzed in the gut to release hydrocyanic acid; cellular hypoxia occurs after absorption and complexation with cytochrome oxidase

Signs and Symptoms of Overdose Symptoms may be delayed 30 minutes to 2 hours or longer due to hydrolysis preferentially occurring in alkaline duodenum, plus intestinal flora hydrolyzing amygdalin

Admission Criteria/Prognosis All symptomatic patients should probably be admitted to an intensive care unit for 1-2 days; asymptomatic patients should be observed for at least 2 hours and then can be discharged; survival after 4 hours (in an acute exposure) is usually associated with recovery

Overdosage/Treatment

Decontamination: Basic poison management; vomiting is contraindicated due to rapid course of the neurologic symptoms. Give 100% oxygen.

Supportive therapy: Give sodium bicarbonate for acidosis

Enhancement of elimination: Hemodialysis and charcoal hemoperfusion have been utilized; hyperbaric oxygen may also be utilized; hydroxocobalamin and dicobalt-EDTA used for chelation in Europe

Antidote(s)

- Cyanide Antidote Kit [ANTIDOTE]

Diagnostic Procedures

- Anion Gap, Blood
- Electrolytes, Blood
- Methemoglobin, Blood

Additional Information Toxic dose: 1-2 pits likely nontoxic; toxicity unusual with accidental ingestion. Intact pit does not release chemical; apricot most toxic within the genus; peach leaves (in Australia) may have a cyanide content as high as 66 mg per 100 g of leaves. Toxic part: Amygdalin is found in leaves, flowers, bark, seeds; young leaves have highest concentration.

Peony (Common)

Scientific Name *Paeonia* species

Mechanism of Toxic Action Toxin is located in plant's roots and the site of action is unknown

Signs and Symptoms of Overdose Contact dermatitis with dermal exposure. Oral exposure based on rat data: Low dose (62.5 mg/kg) produces a diuretic effect; medium dose (125-500 mg/kg) produces anti-inflammatory activity and decreased GI secretions; high dose (> 500 mg/kg) causes CNS depression

Toxicodynamics/Kinetics

Absorption: Rapid

Half-life: 30 minutes

Overdosage/Treatment

Topical steroids are probably beneficial for contact dermatitis

Decontamination: Ipecac is of questionable benefit due to the rapid absorption and onset of action; activated charcoal with sorbitol will aid in clearance of the toxin

Supportive therapy: Respiratory support is most critical intervention; maintain fluid and electrolyte replacement during diuretic phase, however, electrolyte depletion is not as severe as with hydrochlorothiazide

Additional Information Minimal clinical symptoms are expected with accidental plant ingestion; clinically significant doses may be seen in ingestions of many Oriental medicines which contain this ingredient; paeonol 250 mg/kg is about as effective of a diuretic as hydrochlorothiazide 10 mg/kg; LD₅₀ (based on rat data): 3430 mg/kg. Toxin: Paeonol. Monitor electrolytes during the diuretic phase.

Peyote

Related Information

- Mescaline

Scientific Name *Lophophora williamsii*

Mechanism of Toxic Action Mescaline - structurally similar to amphetamines producing CNS and sympathetic stimulation and hallucinations

Signs and Symptoms of Overdose Anxiety, asthenia, ataxia, blurred vision, dizziness, drowsiness, fever, flashbacks, flushing, hallucinations (visual, auditory), headache, hunger, hypertension, increased pulse, increased respiratory rate, mydriasis, nausea and vomiting preceding hallucinations, paranoia, polyuria, salivation, suicide, tremor

Admission Criteria/Prognosis Patients who are asymptomatic after 4 hours postexposure may be discharged

Toxicodynamics/Kinetics

Urine, blood levels not correlated with clinical effects

Duration of action: >6 hours

Overdosage/Treatment

Decontamination: Ipecac may cause increased agitation especially in paranoid individuals and is unlikely to be of benefit once clinical symptoms present; activated charcoal with cathartic preferred

Supportive therapy: Symptoms may need to be treated with benzodiazepines and/or haloperidol/chlorpromazine; flashbacks may be worsened by phenothiazines; no deaths reported from overdosage of mescaline/peyote

Additional Information Toxic dose: Typically, 300-500 mg or 6-12 peyote "buttons". May be contaminated; consider coingestants; "microdots" may also contain LSD; ~ 1/2000 the potency of LSD and ~ 1/20 the potency of psilocybin

Pfiesteria piscicida

Mechanism of Toxic Action

A dinoflagellate found in sediment of primary freshwater (salinity < 15,000 ppm) with an unidentifiable toxin (lipid/water soluble) that appears to affect frontal and inferior temporal cortical brain areas.

Portal of entry: Dermal or pulmonary

Signs and Symptoms of Overdose Conjunctivitis, burning sensation, cough, bronchospasm, and sore throat are the immediate symptoms noted on contact. Within 3 hours, myalgia, generalized headache, pruritus, and memory impairment (decreased concentration ability) along with peripheral neuropathy can occur. Nausea, vomiting, secretory diarrhea, vesicular/papular rash, and abdominal cramps can occur within 24 hours. Persistent effects include rash (up to 2 months), memory loss (up to 6 months), bronchospasm, and diarrhea.

Overdosage/Treatment Supportive therapy: Symptomatic care. Diphenhydramine (up to 1 mg/kg every 4-6 hours I.V. or P.O.) can assist in pruritus and headache treatment. Cholestyramine (4 grams 3 times/day for 3 days) may decrease loose stools.

Additional Information

Person-to-person or fish-to-person transmission does not occur. Associated with fish kills and ulcers on fish. Found in coastal areas near the mouth of a river.

Pfiesteria hotlines:

Maryland: 888-584-3100

Virginia: 888-238-6154

North Carolina: 888-823-6915

Phone: 410-957-1550

Philodendron

Scientific Name *Philodendron*

Mechanism of Toxic Action Entire plant contains calcium oxalate crystals which cause oral irritation, swelling, pain, and slurred speech; large ingestions necessary for systemic toxicity are unlikely to occur due to oral irritation seen with ingestion

Signs and Symptoms of Overdose Oral irritation, pain, slurred speech, swelling, vomiting

Overdosage/Treatment

Decontamination: Emesis within 30 minutes or lavage (within 1 hour)/activated charcoal not usually necessary unless massive ingestion is suspected; dilution may be beneficial; milk/water to rinse crystals; oral irritation can be treated with ice or a popsicle

Supportive therapy: I.V. hydration may be needed

Additional Information Fatal dose due to oxalates is estimated to be 700 g of leaves (5 g of oxalate). Toxin: Calcium oxalate crystals concentration is < 1%.

Pit Vipers

Commonly Found In Genera *Crotalus* (rattlesnake), *Agkistrodon* (copperhead, cottonmouth), *Sistrurus* (pygmy rattler, massasauga)

Mechanism of Toxic Action Venom; quality and potency vary among species; composition: 90% water with 5-15 enzymes, 3-12 nonenzymatic proteins, as well as other unidentified substances

Signs and Symptoms of Overdose

Local: Bullae, ecchymosis, edema, erythema, hemorrhage, lymphangitis, tenderness, compartment syndrome (rarely)

Systemic: Asthenia, chills, CNS depression, fasciculations, hypotension, nausea, paresthesia, sweating, vomiting

Coagulopathy including hypofibrinogenemia, increased PT and PTT, and thrombocytopenia can occur. Hematuria, hemoconcentration, hypoproteinemia, hypotension, lactic acidosis, proteinuria, and shock are potential complications.

Overdosage/Treatment

Decontamination: Rapid transport to medical facility; immobilize area; if negative pressure suction device is available, this may be used; **do not** incise the wound; constriction band may be applied, **not** a tourniquet

POINSETTIA

- Wyeth crotalid polyvalent antivenin; treat moderate to severe envenomations with increments of 5-10 vials at a time; skin test per manufacturer's instructions; if positive skin test develops, may prophylax with H₁- and H₂-receptor blockers; give until local injury has stopped and coagulopathy is reversed; complications include allergic reactions, anaphylaxis, and delayed serum sickness

Supportive therapy: ABC assessment, physical exam; mark the extent of local edema with skin marking pen; repeat CBC, platelets, PT, PTT, fibrinogen, CPK, urinalysis every 3-4 hours for at least first 12 hours; I.V. fluids, tetanus prophylaxis, and analgesics may be given as needed; treat infected wounds with antibiotics. Snakes' oral cavity contain primarily gram-negative and anaerobic organisms.

Antidote(s)

- Antivenin (Crotalidae) Polyvalent [ANTIDOTE]

Additional Information

Family: Viperidae; subfamily: Crotalidae

Distinguishing characteristics: Facial pits, vertical elliptical pupils, triangular head, single row of subcaudal scales. All poisonous serpents except coral snakes belong to this group; copperheads, cottonmouths, and rattlesnakes are members

Antivenin has been given on affected extremity distal to a blood pressure cuff (inflated to block arterial flow) while massaging the extremity to the blood pressure cuff (similar to the Bier-block anesthetic technique). Monitor coagulation parameters for at least 2 days

Poinsettia

Related Information

- Star-of-Bethlehem (*Ornithogalum pyrenaicum*)
- Star-of-Bethlehem (*Ornithogalum umbellatum*)

Scientific Name *Euphorbia pulcherrima*

Signs and Symptoms of Overdose Frequently believed to be a toxic (even lethal) plant, the poinsettia has little toxicity. Nausea, vomiting, and skin irritation are rarely reported to Poison Control Centers. Gastrointestinal symptoms are mild, self-limited, and seldom require fluid replacement. Estimates, based on animal data, have indicated that a 50-pound child would have to ingest 500-600 leaves to cause symptoms.

Overdosage/Treatment Wash off patient if irritation is experienced; dilute with water, milk, or juice for ingestions

Additional Information Family: Euphorbiaceae. Toxin: Acrid principle, not fully defined chemically. Range: Tropical plant widely distributed as a Christmas decoration

Poison Hemlock

Scientific Name *Conium maculatum*

Mechanism of Toxic Action Coniine toxicity resembles that of nicotine; there is initial stimulation of autonomic ganglia, followed by depression

Adverse Reactions Cardiovascular: Sinus bradycardia, sinus tachycardia

Signs and Symptoms of Overdose Apnea, ataxia, burning sensation in the throat, coma, disconjugate gaze, miosis, myoglobinuria, nausea, paralysis of skeletal muscles, renal failure, respiratory paralysis, rhabdomyolysis, seizures, slurred speech, tachycardia followed by bradycardia, vomiting

Overdosage/Treatment

Decontamination: Lavage within 1 hour may be performed; administer activated charcoal with cathartic

Supportive therapy: Be prepared to support respirations; provide symptomatic and supportive treatment; manage seizures with diazepam or lorazepam

Additional Information Reportedly used by the Greeks to execute Socrates; human toxicity has been reported from eating birds that feed on poison hemlock. Family: Umbelliferae. Range: Found in the Eastern U.S., the West coast, and the Rocky Mountains. Toxin: Coniine. Toxic part: Whole plant

Specific References

Labay L, McMullin M, Diamond F, et al, "Analysis of Coniine in Blood and Gastric in a Poison Hemlock Death," *J Anal Toxicol*, 2006, 30:134.

Poison Ivy

Scientific Name *Rhus radicans*; *Toxicodendron radicans*

Mechanism of Toxic Action Contains urushiol; shell contains anacardic acid, cardol, anacardol, irritants that can precipitate type IV cell-mediated allergic reaction (allergic contact dermatitis)

Signs and Symptoms of Overdose Dermatitis, proteinuria

Admission Criteria/Prognosis Patient with disabling symptoms (who are immunocompromised) should be admitted. Ingestion of over 2-3 berries should have gastric decontamination and admission

Toxicodynamics/Kinetics

Onset of effect: Variable, but effects usually seen within 24-48 hours
Peak effect: After 3-5 days

Overdosage/Treatment

Decontamination: **Dermal:** Soap and water washing likely ineffective unless done within 5-15 minutes after exposure; wash clothes thoroughly; clean fingernails **Ocular:** Irrigate copiously for 15-20 minutes with saline/topical use of steroids may be useful

Supportive therapy: Cool compresses or showers, Burow's solution, topical/oral steroids; oral prednisone should be used (and tapered) over a 2-3 week course. Frequent soapless showers several times daily with warm but not hot water may be useful. Oral antihistamines can be useful. Steroid creams which may be useful include hydrocortisone creams (>0.5%), desoximetasone cream (0.25% - do not use on face or intertriginous areas), fluocinonide (0.05%), or triamcinolone cream (0.025% or 0.1%); all applied 3 times daily. Only use a thin film in children due to possible adrenal reaction.

Additional Information

Exudate in blisters is sterile.

Toxic part: Sap of entire plant is toxic

Bentoquatam (5%), when applied topically 15 minutes prior to potential exposure, may prevent development of rash due to poison ivy, poison oak, or poison sumac; do not use if rash has developed.

Topical agents used for relief of pruritus with varying efficacy include baking soda paste; Calamine[®] lotion; ice; jewelweed (*Impatiens capensis*), crushed leaf or liquid extracts; gumweed (*Grindelia squarrosa* or *Grindelia robusta*) - alcohol-based tincture; oak and willow bark (*Quercus*; *Salix*) - added to bath; plantain (*Plantago*); chickweed (*Stellaria media*); witch hazel lotion; green clay powder

Specific References

Poison Lily

Scientific Name *Veratrum viride*

Mechanism of Toxic Action Contains alkaloids which modulate the sodium channel of cardiac tissue, thus increasing sodium conductivity

Signs and Symptoms of Overdose Symptoms usually occur within 1 hour and consist of a bitter/sharp taste followed by nausea, vomiting, diaphoresis, and confusion. Cardiovascular signs include bradycardia, hypotension, bundle branch block, and myocardial ischemia. Numbness and decreased bowel sounds with miosis can develop. Peaked T waves may be seen on ECG.

Overdosage/Treatment

Decontamination: Activated charcoal without a cathartic within 1 hour postingestion

Supportive therapy: Monitor for hypotension; crystalloid fluids and vasopressor support may be required for treatment. Atropine is useful in treating bradycardia. Resolution of symptoms usually occurs within 48 hours.

Additional Information Commonly mistaken for leeks or skunk cabbage

Poison Oak

Scientific Name *Rhus quercifolium*; *Toxicodendron quercifolium*

Mechanism of Toxic Action Contains urushiol; shell contains anacardic acid, cardol, anacardol, irritants that can precipitate type IV cell-mediated allergic reaction (allergic contact dermatitis)

Signs and Symptoms of Overdose Dermatitis

Admission Criteria/Prognosis Patient with disabling symptoms (who are immunocompromised) should be admitted. Ingestion of over 2-3 berries should have gastric decontamination and admission

Pokeweed

Scientific Name *Phytolacca americana*

Uses In folk medicine for rheumatism, arthritis, ringworm, and purgative, etc

Adverse Reactions

Cardiovascular: Mobitz type 1 heart block

Miscellaneous: Increased plasma cells

Signs and Symptoms of Overdose Symptoms usually occur within 6 hours. Abdominal pain, AV block, death, diarrhea, dyspnea, lymphocytosis, nausea, seizures, vomiting

Overdosage/Treatment

Decontamination: **Oral:** Administer activated charcoal (in aqueous slurry) for recent ingestions. **Dermal:** Wash with soap and water

Supportive therapy: Replace fluids and electrolytes as needed. Symptoms usually resolve within 1 day.

Additional Information Young leaves may be rendered nontoxic if boiled, rinsed, and boiled again; berries also appear to be edible if cooked. Grows up to 10 feet. Family: Phytolaccaceae. Toxin: Triterpene saponins, pokeweed mitogen. Range: Eastern half of the U.S., California, and Hawaii. Toxic part: Whole plant, especially the root

Portuguese Man-of-War

Scientific Name *Physalia pelagica*; *Physalia utriculus*

Commonly Found In Atlantic Portuguese Man-of-War (*Physalia physalis*); Pacific Portuguese Man-of-War (*Physalia utriculus*)

Signs and Symptoms of Overdose Maculopapular rash with intense pain; may progress to hyperpigmented vesicles and pustules. Systemic reaction includes asthenia, muscle spasms, nausea, pain, paresthesia, and vomiting. In rare cases, respiratory and cardiovascular depression may occur. Systemic effects are more common with the Atlantic Portuguese Man-of-War. Symptoms may last for up to 48 hours.

Overdosage/Treatment

Decontamination: Immobilize area to avoid further discharge of nematocysts; inactivate nematocysts with alcohol or vinegar (5% acetic acid); remove remaining tentacles by applying flour or shave cream and scraping with a sharp instrument

Supportive therapy: Pain control, oral antihistamine, local anesthetics, steroid cream, and tetanus prophylaxis as indicated; systemic effects may require respiratory and circulatory support

Additional Information Invertebrate, contains a nitrogen and carbon monoxide flotation device which functions as a sail similar to a Portuguese admiral's hat; venom consists of a protein neurotoxin

Potato (Leaves, Stems, Tubercles)

Scientific Name *Solanum tuberosum*

Mechanism of Toxic Action Contains toxic alkaloids, solanine most significant structurally similar to cardioglycoside, causes hemolytic and hemorrhagic damage to GI tract similar to saponins; some plants may also contain alpha-cholinergic alkaloids

Adverse Reactions Central nervous system: Psychosis

Signs and Symptoms of Overdose Asthenia, diarrhea, drowsiness, fever, hallucinations, headache, nausea, sweating, vomiting, visual changes. Anticholinergic effects may or may not be present to varying degrees.

Toxicodynamics/Kinetics Unclear

Overdosage/Treatment

Decontamination: Ipecac (within 30 minutes) if vomiting has not already occurred, lavage (within 1 hour) and/or charcoal may be beneficial if the patient presents symptomatic

Supportive therapy: Maintain fluid and electrolyte balance as necessary, support vital signs; physostigmine will reverse anticholinergic toxicity that may be associated with exposure

Antidote(s)

- Physostigmine [ANTIDOTE]

Additional Information Toxic dose: Variable. Mature, properly stored tuber is edible; green foliage, immature tuber, improperly stored tuber (exposed to light) may be toxic

Privet (Berries and Leaves)

Scientific Name *Ligustrum vulgare*

Signs and Symptoms of Overdose Symptoms develop shortly after ingestion and include abdominal tenderness, diarrhea, GI irritation, nausea, vomiting

Overdosage/Treatment

Decontamination: Emesis/lavage usually not necessary due to vomiting which commonly occurs when the plant is ingested

Supportive therapy: Replace fluid/electrolyte losses

Additional Information Toxin: Ligon glycosides, saponins, and seco-iridoid bitter agents; gastroenteritis may last for 2-3 days; a small deciduous shrub with lanceolated leaves found in eastern U.S.

Puss Caterpillar

Scientific Name *Megalopyge opercularis* (in Texas, North Carolina); *Lagoa crispata* (Oklahoma)

Commonly Found In Southern U.S.

Mechanism of Toxic Action Spines/hairs can penetrate the skin and inject toxins that can exhibit proteolytic activity

Signs and Symptoms of Overdose Immediate, intense local pain on contact followed by, within one hour, erythema and vesicles. Blister development may occur within 48 hours. Pruritis may also occur.

Overdosage/Treatment

Decontamination: Dermal - Immediate application of adhesive tape to site may be effective in removing spines. Avoid scratching or rubbing area.

Supportive therapy: Topical corticosteroid preparations may be effective. Opioid agents typically not effective for pain control

Rabies Virus

Related Information

- Animal and Human Bites Guidelines

Mechanism of Toxic Action

Rabies virus is a bullet-shaped single-stranded RNA virus which belongs to the family Rhabdoviridae. A number of important viral proteins have been identified such as viral polymerase, nucleocapsid protein, glycoprotein, and others. Some of these proteins have been used to develop specific diagnostic monoclonal antibodies. Rabies virus can be isolated under the proper conditions in tissue culture. During active rabies infection, the virus can be cultured from a variety of human (and animal) tissues including saliva, brain tissue, respiratory secretions, and urine; the virus is most easily recovered from brain tissue.

The virus is highly neurotropic. When a human is inoculated with rabies virus, the viral glycoprotein attaches to the plasma membrane of cells, possibly the nicotinic acetylcholine receptor. The virus then replicates in skeletal muscle, and when the titer is high enough, it invades nearby sensory and motor nerves and enters the nervous system. It travels along the axon at speeds up to 20 mm/day and eventually reaches the spinal cord. From there, dissemination through the central nervous

system occurs rapidly and encephalitis ensues. Other peripheral nerves become involved; the organism can be recovered from the saliva due to infection of nerves in the salivary glands.

Adverse Reactions Central nervous system: Cranial nerve palsies, aerophobia, hydrophobia

Signs and Symptoms of Overdose **Clinical rabies:** There is a variable period of incubation before the onset of symptoms (4 days to 19 years), but most cases occur within 1 year of exposure (usually 1-3 months). The initial prodrome of rabies is nonspecific with malaise, fatigue, and fever. In many patients, there may be pain at the initial exposure site. After ~10 days, the patient enters an acute neurologic phase, characterized by bizarre behavior, hyperactivity, and confusion. Photophobia, anisocoria, areflexia, and paresthesia may be noted. A small stimulus can elicit short periods of thrashing, biting, and other behaviors. Many patients will display hydrophobia (fear of water); there is often severe laryngospasm and choking when trying to drink water. This will progress to paralysis, which dominates the clinical picture for some days. Patients typically lapse into coma and develop respiratory failure or arrhythmias, leading to death in most cases, despite full support in intensive care units. Occasional cases of recovery from rabies have been reported.

Overdosage/Treatment

Supportive therapy: Wound treatment and the administration of both RIG and vaccine (for previously unvaccinated persons) are essential components of rabies postexposure prophylaxis. Postexposure prophylaxis should begin immediately for persons bitten by animals suspected or proven to be rabid. A greater than 1-year incubation period has been reported in humans. Therefore, if the clinical signs of rabies are not present, postexposure prophylaxis is indicated regardless of the length of delay when a documented or likely exposure has occurred.

Clinical management consists of supportive care and neuroprotective measures, including a drug-induced coma and ventilator support. Intravenous ribavirin has been used under an investigational protocol.

Coma induction with ketamine (2 mg/kg/hour) with midazolam (1-3.5 mg/kg/hour) to suppress background EEG has shown to be helpful. Ribavirin (33 mg/kg load followed by 16 mg/kg every 6 hours); amantadine (200 mg/day) has also been used.

Based on studies done in Germany and Iran, the World Health Organization, in 1997, recommended a regimen of RIG and six doses of HDCV over a 90-day period. Used this way, the vaccine was found to be safe and effective in protecting persons bitten by animals proven to be rabid, and produced excellent antibody response in all recipients. U.S. studies by the CDC documented that a regimen of one dose of RIG and five doses of HDCV over a 28-day period was safe and produced an excellent antibody response in all recipients. RVA and PCEC clinical trials have demonstrated immunogenicity equivalent to that of HDCV.

Important measures for preventing rabies include immediate and thorough washing of all bite wounds and scratches with soap and water and a virucidal agent (eg, povidone-iodine solution) irrigation. In animal studies, the likelihood of rabies has been shown to be markedly reduced with thorough wound cleansing alone, without other postexposure prophylaxis.

There is currently no treatment for rabies once it has become clinically established. Mortality approaches 100%. Thus, the main treatment issues involve rabies prevention, particularly postexposure prophylaxis. The physician deciding whether or not to initiate rabies treatment (rabies vaccine, rabies immunoglobulin) must answer the following questions: Has a significant exposure occurred, and what is the risk that an animal is rabid?

A significant exposure includes the following.

- An animal bite, defined as penetration of the person's skin by teeth with contamination of the wound with saliva
- Contamination of the mucous membranes with saliva or other potentially infectious tissue from an infected animal
- Certain nonbite exposures, including contamination of scratches, scrapes, wounds, or mucous membranes with saliva or other infectious tissues. The risk of rabies after nonbite exposures is extremely rare, although scattered cases have been reported.

Petting a rabid animal or contacting its blood or body fluids is not an exposure. If it appears that a significant exposure has taken place, the physician must determine whether or not the animal was rabid. As outlined by Fishbein and Robinson, this depends on the percentage of animals found to be rabid in the species in the particular geographical area.

Group 1: Rabies is endemic in animal species involved in exposure. This includes:

- bats - anywhere in the United States (3% to 20% positive for rabies); almost 50% of the rabies cases in the U.S. since 1980 were associated with bat vectors
- terrestrial animals - skunks, raccoons, foxes in areas of United States where rabies is endemic
- dogs in developing countries
- dogs in the United States along the Mexican border.
- For Group 1 exposure, treatment should be initiated for both bite and nonbite exposures.

Group 2: Rabies is not endemic in species involved, but is endemic in other wild animals in the area. The risk of rabies is ~10 times lower in these animals compared with the predominant species. These animals include:

- wild carnivores such as wolves, bobcats, bears, and groundhogs. Up to 20% may have rabies. Bite exposures from these should be treated. Nonbite exposures should either be treated or the local health department consulted.
- rodents (squirrels, hamsters, guinea pigs, gerbils, rats, mice) have a low incidence of rabies, 0.01%. Bite exposures should not be treated (or in exceptional cases, the local health department could be consulted). Nonbite exposures should not be treated.
- dogs and cats - in the United States, the risk of rabies in dogs is less than 1% (except along the Mexican border) in areas where rabies is common in other land animals. In addition, dogs almost always show signs of clinical rabies shortly after the virus is present in saliva. Bite exposure should not be treated if a healthy dog (or cat) is captured; the animal should be observed for 10 days. If the animal develops signs of rabies, treatment in the human should be commenced immediately. If the animal is a stray, it should be sacrificed immediately and the head removed and shipped to an appropriate laboratory. Treatment is delayed pending laboratory testing. The same approach is recommended for nonbite exposures.

Group 3: Rabies is not endemic in the animal species involved in the exposure and is uncommon in other wild animals in the region. This includes most domestic cats and dogs and wild land animals in Idaho, Washington, Utah, Nevada, and Colorado, where the proportion of rabid animals is very low. For bite or nonbite exposures from Group 3 animals, either consult the local health department or do not treat.

Postexposure treatment consists of:

- Vigorous wound cleaning - this has been shown to decrease the risk of rabies.
- Administration of rabies vaccine, either human diploid-cell rabies vaccine or rabies vaccine adsorbed. For persons not previously vaccinated, rabies vaccine should be given 1 mL I.M. on days 0, 3, 7, 14, and 28. Abbreviated regimens have been described. For persons previously vaccinated, the rabies vaccine should be given 1 mL I.M. on days 0 and 3.
- Administration of rabies immunoglobulin. For persons not previously vaccinated, this should be given at 20 int. units/kg of body weight. If possible, one-half the dose should be injected locally near the original wound and the rest given I.M. (using a new needle). For persons previously vaccinated, rabies immunoglobulin is not recommended.

Diagnostic Procedures

- Rabies Identification

Additional Information

Bats remain an important reservoir of rabies and cause sporadic cases.

Risk of rabies after a bite by a rabid animal is ~50 times that of the risk after scratches.

During 1980-2000, a total of 26 (74%) of rabies-virus variants obtained from patients in the United States were associated with insectivorous bats, most commonly silver-haired and Eastern pipistrelle bats, including a variant from a fatal case of rabies reported in Wisconsin in 2000.

Human rabies is distinctly unusual in the U.S. although it is still problematic in some areas worldwide; in large part, this is due to the control of canine rabies in this country. Of the rabies cases reported since 1960, the great majority involved males <16 years of age or >50 years of age. Most cases in the U.S. are now reported from the following groups:

- U.S. travelers to foreign countries who sustain a dog bite in a rabies-endemic region
- persons bitten by wild animals in the U.S.
- persons with unknown exposure history

A few cases of "nonbite rabies" have been reported and include:

- laboratory exposure to rabies virus (aerosolized virus)
- rabies contracted from corneal transplant from an infected donor (6 cases)
- inhalation of aerosolized virus in caves with high concentrations of bat secretions (rare)
- contact of virus on mucous membranes, scratches, or eyes (rare)

Diagnosis: Currently, there are no tests available to detect rabies prior to the development of symptoms. The virus is felt to be immunologically "protected" in the muscle cells or nerve cells near the inoculation site, and antibody production occurs late in infection. Rabies encephalitis may be difficult to distinguish from other forms of viral encephalitis. Laboratory tests available include:

- rabies neutralizing antibody
- rabies viral culture of saliva, cerebrospinal fluid, urine, respiratory secretions
- brain biopsy - specimens may be submitted for rabies viral culture; immunofluorescent rabies antibody staining of brain cells; and pathologic examination for Negri bodies, which are cytoplasmic inclusions characteristic of rabies encephalitis seen in 20% to 30% of cases

Caribbean islands in which there is a risk of rabies infections (particularly in rural areas) include Cuba, Dominican Republic, Grenada, Haiti, Puerto Rico, Trinidad, and Tobago

Mean duration between initial presentation and death: ~16 days

Rabies is transmitted in the saliva of infected mammals. The virus enters the host's central nervous system causing encephalomyelitis that is almost always fatal. Due to a marked decrease of rabies cases among domestic animals in the U.S. in the 1940s and 1950s, indigenously acquired rabies among humans substantially decreased. From 1980-1997, 95-247 cases were reported each year among dogs, and only two human cases were reported each year on average, in which rabies was attributable to variants of the virus associated with indigenous dogs. Therefore, in the U.S. the likelihood of human exposure to a rabid domestic animal has greatly decreased. But during the same period, 12 human rabies cases were attributed to rabies virus variants, associated with dogs from outside the U.S. Thus, in areas where canine rabies is still endemic, international travelers have an increased risk of exposure to rabies.

Rabies among wildlife (eg, raccoons, skunks, bats) has become more prevalent since the 1950s, accounting for >85% of all reported cases of animal rabies since 1976. Rabies occurs throughout the continental U.S. among wildlife with only Hawaii remaining consistently rabies-free. The most important potential source of infection for humans and domestic animals in the U.S. is wildlife. Twenty-one (58%) of the 36 human cases of rabies diagnosed in the U.S. since 1980 have been associated with bat variants. In most other countries including most of Asia, Africa, and Latin America, dogs are still the major species with rabies, and the most common source of rabies among humans. From 1980 through 1997, of the 36 human rabies deaths reported to the Centers for Disease Control and Prevention (CDC), 12 (33%) appear to have been related to rabid animals outside the U.S.

Every year approximately 16,000-39,000 persons receive postexposure prophylaxis, even though rabies among humans is rare in the U.S. The risk of infection must be accurately assessed in order to appropriately manage potential human exposure to rabies. Administering postexposure rabies prophylaxis is medically urgent, and though not a medical emergency, decisions must not be delayed.

Safety, immunogenicity, and efficacy data of active and passive rabies comes from both human and animal studies. Extensive field experience from many areas of the world indicates that postexposure prophylaxis combining wound treatment, passive immunization, and vaccination is uniformly effective when appropriately applied; though controlled human trials have not been performed. Rabies has occasionally developed among humans, however, when key elements of rabies postexposure prophylaxis were omitted or incorrectly administered. See tables.

Rabies Biologics – United States, 1999

Human Rabies Vaccine	Product Name	Manufacturer
Human diploid cell vaccine (HDCV)		Pasteur-Merieux Serum et Vaccins, Connaught Laboratories, Inc Phone: (800) VACCINE or 822-2463
● Intramuscular	Imovax® Rabies	
● Intradermal	Imovax® Rabies I.D.

Rabies Pre-exposure Prophylaxis Guide – United States, 1999

Risk Category	Nature of Risk	Typical Populations	Pre-exposure Recommendations
Continuous	Virus present continuously, often in high concentrations. Specific exposures likely to go unrecognized. Bite, nonbite, or aerosol exposure.	Rabies research laboratory workers;* rabies biologics production workers.	Primary course. Serologic testing every 6 months; booster vaccination if antibody titer is below acceptable level.†
Frequent	Exposure usually episodic, with source recognized, but exposure also might be unrecognized. Bite, nonbite, or aerosol exposure.	Rabies diagnostic lab workers,* spelunkers, veterinarians and staff, and animal-control and wildlife workers in rabies-enzootic areas.	Primary course. Serologic testing every 2 years; booster vaccination if antibody titer is below acceptable level.†
Infrequent (greater than population at large)	Exposure nearly always episodic with source recognized. Bite or nonbite exposure.	Veterinarians and animal-control and wildlife workers in areas with low rabies rates. Veterinary students. Travelers visiting areas where rabies is enzootic and immediate access to appropriate medical care including biologics is limited.	Primary course. No serologic testing or booster vaccination.
Rare (population at large)	Exposure always episodic with source recognized. Bite or nonbite exposure.	U.S. population at large, including persons in rabies-enzootic areas.	No vaccination necessary.

*Judgment of relative risk and extra monitoring of vaccination status of laboratory workers is the responsibility of the laboratory supervisor.

†Minimum acceptable antibody level is complete virus neutralization at a 1:5 serum dilution by the rapid fluorescent focus inhibition test. A booster dose should be administered if the titer falls below this level.

Adapted from "Human Rabies Prevention – United States, 1999. Recommendations of the Advisory Committee on Immunization Practices (ACIP)," *MMWR Morb Mort Wkly Rep*, 1999, 48(RR-1):1-21.

Rabies Postexposure Prophylaxis Guide – United States, 1999

Animal Type	Evaluation and Disposition of Animal	Postexposure Prophylaxis Recommendations
Dogs, cats, and ferrets	Healthy and available for 10 days observation	Persons should not begin prophylaxis unless animal develops clinical signs of rabies.*
	Rabid or suspected rabid	Immediately vaccinate.
	Unknown (eg, escaped)	Consult public health officials.
Skunks, raccoons, foxes, and most other carnivores; bats	Regarded as rabid unless animal proven negative by laboratory tests†	Consider immediate vaccination.

RABIES VIRUS

Table (Continued)		
Animal Type	Evaluation and Disposition of Animal	Postexposure Prophylaxis Recommendations
Livestock, small rodents, lagomorphs (rabbits and hares), large rodents (woodchucks and beavers), and other mammals	Consider individually.	Consult public health officials. Bites of squirrels, hamsters, guinea pigs, gerbils, chipmunks, rats, mice, other small rodents, rabbits, and hares almost never require antirabies postexposure prophylaxis.

*During the 10-day observation period, begin postexposure prophylaxis at the first sign of rabies in a dog, cat, or ferret that has bitten someone. If the animal exhibits clinical signs of rabies, it should be euthanized immediately and tested.
 †The animal should be euthanized and tested as soon as possible. Holding for observation is not recommended. Discontinue vaccine if immunofluorescence test results of the animal are negative.
 Adapted from "Human Rabies Prevention – United States, 1999. Recommendations of the Advisory Committee on Immunization Practices (ACIP)," *MMWR Morb Mort Wkly Rep*, 1999, 48(RR-1):1-21.

Rabies Pre-exposure Prophylaxis Schedule – United States, 1999		
Type of Vaccination	Route	Regimen
Primary	Intramuscular	HDCV, PCEC, or RVA; 1 mL (deltoid area), one each on days 0,* 7, and 21 or 28
	Intradermal	HDCV; 0.1 mL, one each on days 0,* 7, and 21 or 28
Booster	Intramuscular	HDCV, PCEC, or RVA; 1 mL (deltoid area), day 0* only
	Intradermal	HDCV; 0.1 mL, day 0* only

HDCV = human diploid cell vaccine; PCEC = purified chick embryo cell vaccine; RVA = rabies vaccine adsorbed.
 * Day 0 is the day the first dose of vaccine is administered.
 Adapted from "Human Rabies Prevention – United States, 1999. Recommendations of the Advisory Committee on Immunization Practices (ACIP)," *MMWR Morb Mort Wkly Rep*, 1999, 48(RR-1):1-21.

Rabies Postexposure Prophylaxis Schedule – United States, 1999		
Vaccination Status	Treatment	Regimen*
Not previously vaccinated	Wound cleansing	All postexposure treatment should begin with immediate thorough cleansing of all wounds with soap and water. If available, a virucidal agent such as a povidone-iodine solution should be used to irrigate the wounds.
	RIG	Administer 20 int. units/kg body weight. If anatomically feasible, the full dose should be infiltrated around the wound(s) and any remaining volume should be administered I.M. at an anatomical site distant from vaccine administration. Also, RIG should not be administered in the same syringe as vaccine. Because RIG might partially suppress active production of antibody, no more than the recommended dose should be given.

Table (Continued)		
Vaccination Status	Treatment	Regimen*
	Vaccine	HDCV, RVA, or PCEC 1 mL, I.M. (deltoid area†), one each on days 0‡, 3, 7, 14, and 28.
Previously vaccinated§	Wound cleansing	All postexposure treatment should begin with immediate thorough cleansing of all wounds with soap and water. If available, a virucidal agent such as a povidone-iodine solution should be used to irrigate the wounds.
	RIG	RIG should not be administered.
	Vaccine	HDCV, RVA, or PCEC 1 mL, I.M. (deltoid area†), one each on days 0‡ and 3.

HDCV = human diploid cell vaccine; PCEC = purified chick embryo cell vaccine; RVA = rabies vaccine adsorbed. I.M. = intramuscular.
 *These regimens are applicable for all age groups, including children.
 †The deltoid area is the only acceptable site of vaccination for adults and older children. For younger children, the outer aspect of the thigh may be used. Vaccine should never be administered in the gluteal area.
 ‡Day 0 is the day the first dose of vaccine is administered.
 §Any person with a history of pre-exposure vaccination with HDCV, RVA or PCEC; prior postexposure prophylaxis with HDCV, RVA, or PCEC; or previous vaccination with any other type of rabies vaccine and a documented history of antibody response to the prior vaccination. Adapted from "Human Rabies Prevention – United States, 1999. Recommendations of the Advisory Committee on Immunization Practices (ACIP)," *MMWR Morb Mort Wkly Rep*, 1999, 48(RR-1):1-21.

Cell Culture Rabies Vaccines Widely Available Outside the United States	
Purified chick embryo cell vaccine (PCEC)	Rabipur®
Purified vero cell rabies vaccine (PVRV)	Verorab™ Imovax® Rabies Vero TRC Verorab™
Human diploid cell vaccine (HDCV)	Rabivac™
Purified duck embryo vaccine (PDEV)	Lyssavac N™

Adapted from "Human Rabies Prevention – United States, 1999. Recommendations of the Advisory Committee on Immunization Practices (ACIP)," *MMWR Morb Mort Wkly Rep*, 1999, 48(RR-1):1-21.

When chloroquine phosphate was routinely used for malaria prophylaxis, it was discovered that the drug decreased the antibody response to concomitantly administered HDCV rabies vaccine. Therefore, HDCV should not be administered intradermally to a person who is traveling to malaria-endemic countries while the person is receiving one of the chloroquine-related antimalarials. In this situation, I.M. administration of three doses of 0.1 mL of rabies vaccine for pre-exposure prophylaxis provides a sufficient margin of safety.

Animal rabies epidemiology and evaluation of involved species:

Bats: Bats are increasingly implicated as important wildlife reservoirs for variants of rabies virus transmitted to humans. Rabid bats have been documented in 49 continental states. Recent epidemiologic data suggest that transmission of rabies virus can occur from minor, seemingly unimportant, or unrecognized bat bites. Inaccurate recall of exposure history and the limited injury inflicted by a bat bite (in contrast to lesions caused by terrestrial carnivores) could limit the ability of healthcare providers to determine the risk for rabies resulting from a bat encounter. Human and domestic animal contact with bats should be minimized, bats should not be kept as pets, and untrained and unvaccinated persons should never handle bats.

In all potential exposures of humans to bats, the bat should be safely collected (if possible) and submitted for rabies diagnosis. Human postexposure rabies prophylaxis is recommended with bite, scratch, or mucous membrane exposure to a bat, unless the bat is available for testing and is negative for evidence of rabies. When there is reasonable probability that a bite, scratch, or mucous membrane exposure has occurred, even if not apparent, postexposure prophylaxis might be appropriate.

On the basis of available, but sometimes conflicting information from the 21 reported bat-associated cases of human rabies since 1980, in 1-2 cases a bite was reported and in 10-12 cases no bite was detected, though apparent contact occurred. In 7-10 cases no bat exposure was reported, but an undetected or unreported bat bite remains the most plausible hypothesis. Clustering of bat-associated human cases within the same household has never been reported. Consequently, when direct contact between a human and bat has occurred, postexposure prophylaxis should be considered unless the exposed person can be certain a bite, scratch, or mucous membrane exposure did not occur.

When a bat is found indoors and there is no history of contact with a human, postexposure prophylaxis must be balanced between its likely effectiveness and the apparent low risk such exposures present. In this case, for persons who were in the same room as the bat and who might be unaware that direct contact occurred (eg, a mentally disabled or intoxicated person, a sleeping person who awakens and finds a bat in the room, or an adult who witnesses a bat in the room of a previously unattended child) and rabies cannot be ruled out by testing the bat, postexposure prophylaxis can be considered. However, postexposure prophylaxis for other household members would not be warranted.

Wild terrestrial carnivores: Terrestrial animals most often infected with rabies are raccoons, skunks, foxes, and coyotes. Possible exposure must be considered for all bites by such wildlife. After patients are exposed to wildlife, postexposure prophylaxis should be initiated as soon as possible, unless the animal has already been tested and shown not to be rabid. Postexposure prophylaxis can be stopped if already initiated, when subsequent immunofluorescence testing shows the exposing animal was not rabid. Since signs of rabies cannot be reliably interpreted among wildlife, any such animal that exposes a person should be immediately euthanized (avoiding unnecessary damage to the head) and the brain submitted for rabies testing. If testing results are negative by immunofluorescence, the saliva can be assumed to be virus-free, and postexposure prophylaxis is not required for the person bitten.

Other wild animals: Small rodents (eg, squirrels, hamsters, guinea pigs, gerbils, chipmunks, rats, mice) and lagomorphs (including rabbits and hares) are almost never found to be infected with rabies and have not been known to transmit rabies to humans. In areas of the country where raccoon rabies was enzootic, woodchucks accounted for 93% of the 371 cases reported to the CDC from 1990-1996. Consultation with the state or local health department should be made before deciding to initiate antirabies postexposure prophylaxis. Wild animal hybrids, the offspring of wild animals crossbred to domestic dogs and cats, are considered wild animals by the National Association of State and Public Health Veterinarians (NASPHV) and the Council of State and Territorial Epidemiologists (CSTE). These animals should be euthanized and tested rather than confined and observed when they bite humans, because the period of rabies virus shedding is unknown. Neither wild animals nor wild animal hybrids should be kept as pets. Animals kept in the U.S. Department of Agriculture-licensed research facilities or accredited zoological parks should be evaluated on a case-by-case basis.

Domestic dogs, cats, and ferrets: Because the likelihood of rabies in domestic animals varies by region, the need for postexposure prophylaxis also varies. Rabies among dogs (in the continental U.S.) is reported most commonly along the United States/Mexico border and sporadically in areas with enzootic wildlife rabies in the U.S. More rabid cats than dogs were reported in the U.S. during most of the 1990s. Of these cases, the majority were associated with the epizootic of rabies among raccoons in the eastern U.S. Fewer cat vaccination laws, fewer leash laws, and the roaming habits of cats may contribute to the large number of rabies-infected cats. Dogs are the major vectors of rabies in developing countries and exposures to dogs in such countries represent an increased risk of rabies transmission. Ferrets are now considered in the category with dogs and cats, rather than in the category of wild terrestrial carnivores due to new information about rabies pathogenesis and viral shedding patterns in ferrets. Healthy domestic cats, dogs, or ferrets that bite a person can be confined and observed for 10 days. Any illness in the animal during confinement or before release should be evaluated by a veterinarian and immediately reported to the public health department. If signs suggestive of rabies develop, the animal should be euthanized and its refrigerated head sent for examination to a qualified laboratory. If the animal is a stray or unwanted, it should be observed for 10 days or euthanized immediately and submitted for rabies examination.

Rapeseed Oil

Uses Liniment (in place of olive oil), edible oil (in place of soybean oil), soaps

Mechanism of Toxic Action A vegetable oil expressed from the seeds of *Brassica napus* (*Brassica campestris*), contains isothiocyanates (3-butenyl isothiocyanate and erucic acid); can contain several irritant oils; 5-vinyloxazolidinethione can stimulate growth of the thyroid gland

Adverse Reactions

Cardiovascular: Pulmonary hypertension
Hepatic: Hepatic necrosis, cholestatic jaundice
Respiratory: Pneumonitis

Signs and Symptoms of Overdose Goitrogenic (can stimulate growth of the thyroid gland). Toxic oil syndrome (which is very similar to eosinophilia-myalgia syndrome) has been related to an aniline-like contaminant (3-phenylaminoalanine) in rapeseed oil used for cooking in Spain (in 1981). Symptoms (lasting 5-20 days) consisted of non-necrotizing vasculitis, pneumonitis, pruritic maculopapular exanthema, cutaneous leukocytoclastic vasculitis, or erythema multiforme. Eosinophilia, liver function abnormalities, and ANA levels may remain elevated for 4 months. Ten percent of patients developed cutaneous brown or yellow papules in 5 or 6 months. Other manifestations include pneumonitis, pulmonary hypertension, scleroderma-like features, or esophageal motility abnormalities. More than 19,000 people were affected (with at least 340 deaths) in Spain in 1981. Hepatic necrosis and cholestatic jaundice can also develop, with a mortality rate of this veno-occlusive injury approaching 20%.

Overdosage/Treatment Decontamination: Gastric: No need to decontaminate after ingestions of rapeseed oil with low (ie, under 2%) content of erucic acid; otherwise treatment is entirely supportive

Additional Information Level of erucic acid below 2% used in edible foods or oils (except infant formula), and as stabilizer in peanut butter, or emulsifier in shortenings of cake mixes. At this amount of erucic acid, ingestion essentially is not toxic. Monitoring parameters: Thyroid function test, liver function test, eosinophil count

Rattlesnakes

Related Information

- Crotalidae

Scientific Name *Crotalus adamanteus*; *Crotalus atrox*; *Crotalus horridus*; *Crotalus lepidus*; *Crotalus molossus*; *Crotalus scutulatus*; *Crotalus viridis*; *Sistrurus catenatus*; *Sistrurus miliarius*

Mechanism of Toxic Action Venom; quality and potency vary among species; composition: 90% water with 5-15 enzymes, 3-12 nonenzymatic proteins, as well as other unidentified substances

Signs and Symptoms of Overdose Local signs include bullae, compartment syndrome (rarely), ecchymosis, edema, erythema, hemorrhage, lymphangitis, and tenderness. Systemic signs and symptoms include asthenia, chills, CNS depression, fasciculations, hyperthermia, hypotension, nausea, paresthesia, sweating, and vomiting. Coagulopathy can occur including hypofibrinogenemia, increased PT and PTT, and thrombocytopenia. Hematuria, hemoconcentration, hypotension, hypoproteinemia, lactic acidosis, proteinuria, and shock are also potential complications. Neurotoxic effects of Mojave rattlesnake venom may be delayed in onset.

Admission Criteria/Prognosis Patients with evidence of snakebite should be observed for 6-12 hours; if there are no systemic abnormalities (such as coagulopathy) or rapidly expanding edema, patient can be discharged; patients with bites due to Mojave rattlesnake (*Crotalus lepidus lepidus*) should be admitted to monitor respiratory and neurologic status

Overdosage/Treatment

Decontamination: Rapid transport to medical facility; immobilize area; if negative pressure suction device is available, this may be used; **do not** incise the wound; constriction band may be applied, **not** a tourniquet

RED-BACK SPIDER

- Wyeth crotalid polyvalent antivenin: treat moderate to severe envenomations with increments of 5-10 vials at a time; skin test per manufacturer's instructions; if positive skin test develops, may prophylax with H₁- and H₂-receptor blockers; give until local injury has stopped and coagulopathy is reversed; complications include allergic reactions, anaphylaxis, and delayed serum sickness
- Newer affinity-purified, mixed monospecific crotalid antivenom ovine Fab antivenom is being developed by Therapeutics Antibodies, Inc. (Nashville, TN); each vial contains 750 mg Fab and 90 mg NaCl and is reconstituted in 10 mL of normal saline; initial dose: 4 vials diluted in normal saline (250 mL) administered over 60 minutes I.V.; a second dose of 4 vials can be given if clinical signs or laboratory parameters worsen

Supportive therapy: ABC assessment, physical exam; mark the extent of local edema with skin marking pen; repeat CBC, platelets, PT, PTT, fibrinogen, CPK, UA every 3-4 hours for at least first 12 hours; I.V. fluids, tetanus prophylaxis, and analgesics may be given as needed; treat infected wounds with antibiotics. Snakes' mouths contain primarily gram-negative and anaerobic organisms. Ocular exposure from rattlesnake "spitting" can be treated with ocular irrigation of normal saline.

Antidote(s)

- Antivenin (Crotalidae) Polyvalent [ANTIDOTE]
- Antivenin, Polyvalent Crotalid (Ovine) Fab [ANTIDOTE]

Additional Information

Family: Crotalidae (Pit Viper): Banded Rock Rattlesnake: *Crotalus lepidus klauberi*; Black-Tailed Rattlesnake: *Crotalus molossus molossus*; Canebrake Rattlesnake: *Crotalus horridus atricaudatus*; Carolina Pygmy Rattlesnake: *Sistrurus miliarius miliarius*; Dusky Pygmy Rattlesnake: *Sistrurus miliarius barbouri*; Eastern Diamondback Rattlesnake: *Crotalus adamanteus*; Eastern Massasauga: *Sistrurus catenatus catenatus*; Mojave Rattlesnake: *Crotalus scutulatus scutulatus*; Mottled Rock Rattlesnake: *Crotalus lepidus lepidus*; Prairie Rattlesnake: *Crotalus viridis viridis*; Timber Rattlesnake: *Crotalus horridus horridus*; Western Diamondback Rattlesnake: *Crotalus atrox*; Western Massasauga: *Sistrurus catenatus tergestinus*; Western Pygmy Rattlesnake: *Sistrurus miliarius streckeri*

Red-back Spider

Applies to Black Widow Spider

Scientific Name *Latrodectus hasseltii*

Mechanism of Toxic Action Venom contains alpha-latrotoxin, a polypeptide which acts on the neuromuscular junction to cause release of norepinephrine and acetylcholic with resultant neuromediation blockade. Red-back spiders found in Australia often result in more severe envenomations than black widow spider bites.

Signs and Symptoms of Overdose Median duration of effect: 2 hours; local pain (20%), erythema, localized diaphoresis, irritability, hypertension, paresthesias (6% to 10% occurring within 2 hours and peaking in 24 hours); local muscular pain, edema, nausea, vomiting; muscle pain begins within 2 hours of envenomation; fasciculations, tachycardia (50%), fever (15%), hyperreflexia (15% to 30%), salivation, leukocytosis

Overdosage/Treatment

Decontamination: Skin: Wash with soap and water

Supportive therapy: Morphine (Adults: 2-10 mg in adults I.V. or Children: 0.1 mg/kg I.V.) is effective for pain control; diazepam or methocarbamol

can be given as a muscle relaxant. For severe systemic signs, high-risk patients or pain resistant to opiates, antivenom can be given. *Latrodectus hasseltii* antivenom is effective in 94% of cases; dose is 1-2 vials I.M. or slow I.V. (diluted in 40-100 mL of normal saline). Monitor for allergic reaction or serum sickness. *Latrodectus mactans* antivenom can be given in place of *Latrodectus hasseltii* antivenom at a dose of 1 vial (2.5 mL) of antivenom in 50-100 mL of D₅W or normal saline given I.V. over 20-30 minutes. The antivenom may also be given I.M. in the anterolateral thigh. No specific therapy for paresthesias.

Additional Information Adult female is 10-15 mm with leg span of 30 mm; black body with characteristic red or orange stripe on upper abdomen and red hourglass shape on underside. Found in open country area, rubbish, wood heaps, and under bark of dead trees in Australia/New Zealand.

Reduviids

Scientific Name *Triatoma sanguisuga*

Signs and Symptoms of Overdose Multiple, essentially painless bites. Dermal lesions may be papular, vesicular, or a rash. Lymphangitis, nausea, and vomiting may also occur. Laryngeal and oropharyngeal edema may occur in sensitive individuals.

Overdosage/Treatment Supportive therapy: Ice to area decreases edema and pain; antihistamine may be useful for rash, lesions

Additional Information Family: Reduviidae. Characteristics: Almost 1 inch in length, *Triatoma sanguisuga* is dark brown with orange markings along the posterior two-thirds of its body. Range: Located on the Pacific coast; habits are nocturnal; generally found in South America. *Triatoma* species are the vectors (through insect waste material) of Chagas' disease by transmission of *Trypanosoma cruzi*

Rhododendron

Related Information

- Azalea

Scientific Name *Rhododendron*

Mechanism of Toxic Action Contains grayanotoxin which binds to a subset of sodium channels causing structural modifications which cause slow opening of these channels which leads to cell depolarization

Adverse Reactions

Cardiovascular: Sinus bradycardia

Gastrointestinal: Abdominal cramps, nausea

Signs and Symptoms of Overdose Asthenia, ataxia, AV block, bradycardia, dermatitis, hypotension, nausea, oral numbness or burning, paresthesia, seizures, sweating, transient blindness and visual changes, vomiting

Overdosage/Treatment

Decontamination: Avoid ipecac, vagal stimulation increases toxicity; lavage (within 1 hour)/activated charcoal with cathartic

Supportive therapy: Atropine for bradycardia, I.V. fluids should be sufficient for hypotension

Antidote(s)

- Atropine [ANTIDOTE]

Additional Information Three whole leaves or flowers likely nontoxic; consider decontamination if more; toxicity is unpredictable, variable among rhododendron types. Toxic part: Whole plant, especially foliage. Contaminated honey may cause systemic symptoms

Rubber Vine

Scientific Name *Cryptostegia grandiflora*

Mechanism of Toxic Action All parts of the plant contain potentially cardioactive substances

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose Gastrointestinal irritation likely only; potential to cause digitalis-like toxicity including arrhythmias, bradycardia, dizziness, gastrointestinal upset, hypotension, vomiting

Admission Criteria/Prognosis Asymptomatic patients with normal electrocardiogram and electrolytes can be discharged after a 12-hour observation; any symptomatic patient should be admitted to a cardiac monitor bed

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) and multidose activated charcoal enhance total body clearance of digitalis; whole bowel irrigation is also beneficial in removing plant debris from the GI tract and is recommended for ingestions of large amounts of plant material

Supportive therapy: Monitor cardiac status and serum potassium levels; bradycardia will frequently respond to atropine; phenytoin is the

recommended treatment for ventricular arrhythmias because it will also improve conduction through the AV node; lidocaine can also be used to treat ventricular arrhythmias, but will not have an effect on AV conduction; other antiarrhythmics which have been used in arrhythmias resistant to the above therapy include magnesium, amiodarone, and bretylium; a pacemaker should be considered for bradycardia and AV nodal blocks resistant to medical management

Antidote: Digoxin immune Fab has been shown to interact with several different plant cardiac glycosides and may be beneficial in cases resistant to conventional treatment; indications for its use include ventricular arrhythmias resistant to conventional treatment, severe bradycardia and/or second or third degree heart block resistant to atropine and phenytoin

Antidote(s)

- Digoxin Immune Fab [ANTIDOTE]

Additional Information Cases of death from these plants have been reported in India; GI irritant. Toxin: Cardiac glycoside

Salmonella Food Poisoning

Commonly Found In Unpasteurized milk, raw eggs, meat (poultry), pet turtles, pet chicks

Mechanism of Toxic Action Gram-negative rod which is invasive to the intestines (endotoxin); incubation period: ~8 hours postingestion

Adverse Reactions

Cardiovascular: Pericardial effusion/pericarditis, QT prolongation, sinus tachycardia

Endocrine & metabolic: Hypokalemia

Signs and Symptoms of Overdose May last 3-5 days. Asthenia, bloody diarrhea, fever, GI cramping, headache, green loose stools, photophobia, myocarditis, vomiting

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment

Note: *Salmonella* species resistant to multiple antimicrobials are increasing in frequency. *In vitro* susceptibility studies should be performed, particularly in severe cases. Treatment guidelines vary with the type of syndrome, as follows:

- **Enterocolitis:** The majority of cases are self-resolving and do not need antibiotics. Clinical trials have demonstrated that a variety of antibiotics fail to influence the course of mild infections and may prolong excretion of the organisms. For severe cases, or in the immunosuppressed host, a number of antibiotics are usually effective including ampicillin, chloramphenicol, co-trimoxazole, and third-generation cephalosporins.

- **Typhoid fever:** Cases should be treated promptly. Chloramphenicol and ampicillin are effective and have been the most extensively studied. Recent studies show that ciprofloxacin is highly active. Third-generation cephalosporins and co-trimoxazole are useful in organisms that are resistant to standard agents.

- **Bacteremia:** Ampicillin, chloramphenicol, co-trimoxazole, and third-generation cephalosporins are all effective. However, chloramphenicol should be avoided in endocarditis or mycotic aneurysms. Ciprofloxacin is effective in treating recurrent *Salmonella* bacteremia in AIDS.

- **Chronic carriage:** Ampicillin or amoxicillin for 6 weeks, although relapses are common; if there is underlying gallbladder disease, cholecystectomy may be an option with repeated relapses; ciprofloxacin may also be effective

Diagnostic Procedures

- Electrolytes, Blood
- Stool Culture

Additional Information

Outbreaks occur most commonly in summer months; *Salmonella enteritidis* is the most common in the U.S.; killed by heat (72°C); can cause carrier state, septic arthritis

Microbiology: *Salmonella* species are gram-negative bacilli which are important causes of bacterial gastroenteritis, septicemia, and a non-specific febrile illness called typhoid fever. Unfortunately, the classification system for the different *Salmonella* species is complex and confusing to most clinicians. Over 2000 separate serotypes have been identified; and, in the past and currently, each is named as if it was a species. Most experts agree that there are 7 distinct subgroups of *Salmonella* (1, 2, 3a, 3b, 4, 5, and 6), each of which contain many serotypes ("species"). The main pathogens in humans are serotypes, *S. choleraesuis*, *S. typhi*, and *S. paratyphi*, (all in subgroup 1).

Salmonella is an aerobic gram-negative bacillus in the family Enterobacteriaceae. It is almost always associated with disease when isolated from humans, and is not considered part of the normal human flora. As with other members of this family, *Salmonella* carries the endotoxin lipopolysaccharide on its outer membrane, which is released upon cell lysis.

Epidemiology: It is estimated that ~3 million new cases of salmonellosis occur each year. *Salmonella* species are found worldwide. Many are

easily recovered from animals such as chickens, birds, livestock, rodents, and reptiles (turtles). Some serotypes cause disease almost exclusively in man (*S. typhi*) while others are primarily seen in animals but can cause severe disease when infecting humans (*S. choleraesuis*). Transmission is via ingestion of contaminated materials, particularly raw fruits and vegetables, oysters and other shellfish, and contaminated water. Eggs, poultry, and other dairy products are important sources. Outbreaks have been described in the summer months where children consume contaminated egg salad. Other outbreaks have been associated with pet turtles, other pets, marijuana, and rarely food handlers. The incubation period is ~1-3 weeks. The period of communicability lasts until all *Salmonella* have been eradicated from the stool or urine. Reptile-associated salmonellosis (lizards, snakes, turtles, and especially Iguanas), can be quite hazardous to pregnant women, children <5 years of age, or immunocompromised patients. The Centers for Disease Control have recommended that reptiles should not be kept in child care centers and may not be appropriate pets in the above patient categories. Individuals should always wash hands after handling reptiles or reptile cages and reptiles should be kept out of food preparation areas.

Clinical infection is favored when there is a high inoculum of bacteria in the ingested food, since experimental models suggest that 10⁶ bacteria are needed for clinical disease. Contaminated food improperly refrigerated will allow such multiplication. Host factors are important; and disease is more likely in immunocompromised individuals, sickle cell disease, or achlorhydria (gastric acid decreases the viable bacterial inoculum). Although salmonellosis can occur at any age, children are most commonly infected.

Clinical Syndromes: The following are the major syndromes associated with salmonellosis; it should be emphasized that these syndromes are often overlapping

- **Gastroenteritis:** The most common manifestation of *Salmonella* infection. After ingestion of contaminated food, the bacteria are absorbed in the terminal portion of the small intestine. The organisms then penetrate into the lamina propria of the ileocecal area. Following this, there is reticuloendothelial hypertrophy with usually a brisk host immune response. As the organisms multiply in the lymphoid follicles, polymorphonuclear leukocytes attempt to limit the infection. There is release of prostaglandins and other mediators which stimulate cyclic AMP. This results in intestinal fluid secretion which is nonbloody. Clinically, the patient complains of nausea, vomiting, and diarrhea from several hours to several days after consumption of contaminated food. Other symptoms include fever, malaise, muscle aches, and abdominal pain. Symptoms usually resolve from several days to 1 week, even without antibiotics.

- **Typhoid fever:** Also known as enteric fever, this febrile illness is caused classically by *S. typhi*. Following ingestion of the bacteria, the organisms pass into the ileocecal area where intraluminal multiplication occurs. There is a mononuclear host cell response, but the organisms remain viable within the macrophages. The bacteria are carried to the organs of the reticuloendothelial system (spleen, liver, bone marrow) by the macrophages; and clinical signs of infection become apparent. Patients complain of insidious onset of fever, myalgias, headache, malaise, and constipation, corresponding to this phase of bacteremia. A pulse-temperature dissociation may be present. A characteristic rash may be seen in ~50% of patients, called "rose spots", which are 2-4 mm pink maculopapular lesions that blanch with pressure, usually on the trunk. Symptoms last for 1 or more weeks. During this time, bacteria multiply in the mesenteric lymphoid tissue; and these areas eventually exhibit necrosis and hemorrhage. There are microperforations of the abdominal wall. *Salmonella* spreads from the liver through the gallbladder and eventually back into the intestines. This phase of intestinal reinfection is characterized by prominent GI symptoms including diarrhea. Overall, fatality with treatment is <2%. A similar, but milder syndrome, can occur with *S. paratyphi*, called paratyphoid fever.

- **Chronic carrier state:** Following infection with *S. typhi*, up to 5% of patients will excrete the bacteria for over 1 year. Such patients are termed chronic carriers and are asymptomatic. Millions of viable bacteria are present in the biliary tree and are shed into the bile and into the feces. Urinary carriage can also occur, particularly in patients who are co-infected with *Schistosoma haematobium*. The chronic carrier state is less important for other *Salmonella* species, where the carriage rate is <1%.

Diagnosis: Laboratory confirmation is generally required, since the major syndromes are seldom distinctive enough to be diagnosed solely on clinical criteria. *Salmonella* grows readily on most media under standard aerobic conditions. Cultures from blood, joint aspirations, and cerebrospinal fluid can be plated on routine media. Specimens which are likely to contain other organisms, such as stool or sputum, require selective media; and the laboratory should be appropriately notified. Recovery of *Salmonella* from the stool is the most common means of establishing the diagnosis, and enrichment media are available to maximize the yield. Other laboratory findings may suggest salmonellosis, including a profound leukopenia often seen with typhoid fever.

Recent antimicrobial therapy may render blood and stool cultures negative. In such cases, proctoscopy with biopsy and culture of ulcerations may establish the diagnosis in the enterocolitis syndrome. Serologic tests are not particularly useful in this instance. When typhoid fever is suspected but the patient has already received antimicrobial agents, bone marrow biopsies as well as skin biopsies of any rose spots may yield *Salmonella typhi* in culture. Serologic studies are more helpful in diagnosing typhoid fever, but >50% of patients will fail to show the expected rise in agglutinins against the typhoid O antigen.

Prevalence of *Salmonella* in raw beef carcasses is 1% and in ground beef is 5% to 7%. From 1976 through 1994, rates of isolation of *Salmonella* serotype enteritidis in the United States increased from 0.5-3.9/ thousand population. During and through 1985, there were 582 *Salmonella* enteritidis outbreaks involving 24,058 cases, 2290 hospitalizations and 70 deaths. 12% of all outbreaks (but 90% of all deaths) in the United States from 1985-91 occurred in hospitals or nursing homes.

Recommendations for preventing *Salmonella* serotype enteritidis (SE) infections associated with eggs (MMWR Morb Mortal Wkly Rep, 2003):

For egg producers:

- Flock-based SE-control programs that include routine microbiological testing should be adopted and implemented by industry nationwide.

For retail and food service establishments and institutional settings:

- In retail and food service establishments, pasteurized egg products or pasteurized in-shell eggs are recommended in place of pooled eggs or raw or undercooked shell eggs. If used, raw shell eggs should be fully cooked. If shell eggs are served undercooked, a consumer advisory should be posted in accordance with the Food Code.
- In hospitals, nursing homes, adult or childcare facilities, and senior centers, pasteurized egg products or pasteurized in-shell eggs should be used in place of pooled eggs or raw or undercooked eggs.
- Eggs should be purchased or received from a distributor refrigerated, and stored refrigerated at ≤45°F (≤7°C) at all times.

For egg consumers:

- Consumption of raw or undercooked eggs should be avoided, especially by young children, elderly persons, and persons with weakened immune systems or debilitating illness.
- Eggs should be cooked until both the white and the yolk are firm and eaten promptly after cooking.
- Hands, cooking utensils, and food-preparation surfaces should be washed with soap and water after contact with raw eggs.
- Eggs should be purchased or received from a retail store or distributor refrigerated, and stored refrigerated at ≤45°F (≤7°C) at all times.

Isolation Rate* of *Salmonella* Serotype Enteritidis (SE), by Year United States, 1990-2001

*Per 100,000 population

Sand Brier

Scientific Name *Solanum carolinense*
Mechanism of Toxic Action Whole plant contains solanine, a gastrointestinal irritant; spines or prickles can cause local ocular damage
Adverse Reactions Central nervous system: Psychosis
Signs and Symptoms of Overdose Ingestion: Diaphoresis, diarrhea (within 2-24 hours, lasting up to 6 days), fever, nausea, vomiting; headache and salivation may also occur
Overdosage/Treatment
Decontamination: Lavage (within 1 hour)/activated charcoal
Supportive therapy: Monitor and replace electrolytes
Additional Information A perennial weed which can grow to 3 feet having creeping rhizomes, loose clusters of white or bluish, five-lobed flowers, and yellow berries; found in sandy soil, gardens and fields from New England to Nebraska and southern U.S.

Schefflera

Scientific Name *Brassaia actinophylla*
Adverse Reactions Dermatologic: Minimal risk of contact dermatitis
Overdosage/Treatment Oral prednisone can help relieve vesiculobulbous eruptions; minimally toxic
Additional Information Does not include umbrella tree of *Musanga* genus. Toxin: Falcarinol. An evergreen native to Australia, can grow to 40 feet high.

Scombroid Food Poisoning

Commonly Found In Skipjack, mackerel, bluefish, mahi-mahi, salmon, Japanese saury, kingfish, tuna (usually poorly refrigerated). See table.

Fish Implicated in Scombroid Fish Poisoning		
Scientific Name		Common Name
Family	Genus and Species	
Scombridae	<i>Thunnus thunnus</i>	Northern bluefin tuna
	<i>Euthynnus peiambia</i>	Skipjack tuna
	<i>E. affinis</i>	Kawakawa
	<i>Auxis thazard</i>	Frigate tuna
	<i>Sarda sarda</i>	Atlantic bonito
	<i>Scomber scombrus</i>	Atlantic mackerel
	<i>Scomber japonicus</i>	Chub of Pacific mackerel
	<i>Rastrelliger kanagurta</i>	Long-jawed mackerel, Indian mackerel
	<i>Grammatorcymus bicarinatus</i>	Double-lined mackerel, scaly kingfish
	<i>Scomberomous cavalla</i>	King mackerel
Scomberesocidae	<i>Scomberesox</i>	Atlantic saury
	<i>Cololabis saira</i>	Pacific saury
Xiphiidae	<i>Xiphias gladius</i>	Swordfish
	<i>Tetrapurus audax</i>	Striped marlin fish
Istiophoridae	<i>Istiophorus lathyterus</i>	Indo-Pacific sailfish
	<i>Makaira mazara</i>	Indo-Pacific blue marlin
Pomatomidae	<i>Scombrops boops</i>	Japanese bluefish
	<i>Pomatomus saltatrix</i>	Bluefish
Coryphaenidae	<i>Coryphaena hippurus</i>	Dolphin fish, mahi-mahi
Cerangidae	<i>Trachurus japonicus</i>	Horse mackerel
	<i>Seriola colburni</i>	Pacific amberjack
	<i>Decapierus muroadsi</i>	Amberstripe
Cluiperidae	<i>Clupea pallasii</i>	Pacific herring
	<i>Herklotsichthys zunasi</i>	Japanese scaled sardine
	<i>Sardinops melanotisticus</i>	Japanese pilchard
	<i>Sardina pilchardus</i>	European pilchard
	<i>Sardinella aurita</i> or <i>S. lemura</i>	Round sardinella
	<i>Amblygaster sirm</i>	Spotted sardinella

Table (Continued)		
Scientific Name		Common Name
Family	Genus and Species	
Dorosomatinae	<i>Clupanodon thrissa</i>	
Engraulidae	<i>Engraulis encrasicolus</i>	European anchovy
	<i>Centengraulis mysticentus</i>	Anchoveta
Arripidae	<i>Arripia</i>	Australian salmon, Kahawai
Salmonidae	<i>Oncorhynchus</i>	Salmon, trout
Syndoatidae	<i>Harpadon neherens</i>	Bombay duck

From Wu M-L, Yang C-C, Yang G-Y, et al, "Scombroid Fish Poisoning: An Overlooked Marine Food Poisoning," *Vet Hum Toxicol*, 1997, 39(4):237, with permission.

Mechanism of Toxic Action Histidine found in fish musculature causes clinical syndrome; onset develops within 1 hour (often with 10 minutes); resolves within 36 hours

Signs and Symptoms of Overdose Erythematous flushing, facial edema, headache, nausea, palpitations, pruritus, slurred speech, vomiting, watery diarrhea (explosive), wheezing. See table.

Symptoms and Signs of 48 Cases of Scombroid Fish Poisoning		
Symptoms or Signs	Number of Cases (%)	Onset time (minutes, range, and median)
Dizziness	28 (58.3)	15-240 (100)
Diarrhea	23 (47.9)	5-480 (180)
Hot flush	22 (45.8)	5-210 (60)
Headache	19 (39.6)	5-290 (80)
Weakness	18 (37.5)	15-180 (75)
Abdominal cramps	14 (29.2)	5-200 (75)
Nausea	15 (31.3)	5-60 (37)
Pruritis	12 (25.0)	30-205 (75)
Palpitation	10 (20.8)	15-210 (85)
Chest tightness	9 (18.8)	25-210 (90)
Conjunctiva hyperemia	10 (20.8)	5-120 (75)
Swelling of lips and face	6 (12.5)	25-85 (50)
Skin rash	8 (16.7)	45-85 (50)
Numbness of mouth, tongue	6 (12.5)	5-50 (5)
Blurred vision	6 (12.5)	15-75 (45)
Dyspnea	5 (10.4)	25-120 (25)
Vomiting	3 (6.3)	120 (120)
Anxiety	3 (6.3)	25 (25)
Chill	3 (6.3)	75-120 (85)
Burning throat	2 (4.2)	55 (55)
Rhinorrhea	1 (2.1)	

From Wu M-L, Yang C-C, Yang G-Y, et al, "Scombroid Fish Poisoning: An Overlooked Marine Food Poisoning," *Vet Hum Toxicol*, 1997, 39(4):238.

Admission Criteria/Prognosis Admit if symptoms persist after 6 hours of observation, if bronchospasm, hypotension, or urticaria occur, or if neurologic symptoms occur; symptoms usually resolve in 36 hours; patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of 6:14R age group should be considered for admission

Overdosage/Treatment Supportive therapy: Fluids for dehydration; diphenhydramine (25-50 mg) with cimetidine (300 mg) or ranitidine (50 mg) can cause resolution of symptoms; angioedema/bronchospasm can be treated with beta agonists (under 15°C)

Additional Information Heat stable; refrigeration prevents scombroid poisoning; fish may have a peppery taste; can cause elevated blood and urine histamine levels; cultures are not useful; isoniazid may exacerbate symptoms

Specific References

Thundiyil JF, Murphy NG, Tan JH, et al, "Scombroid-Induced Myocardial Ischemia," *J Toxicol Clin Toxicol*, 2004, 42(5):727.

Scorpion Fish

Scientific Name *Synanceja horrida*

Mechanism of Toxic Action Fish contains spines covered with integumentary sheaths from which venom is released through grooves on the spine as it travels from glands located at the base; venom is composed of high-molecular weight, heat labile, nondialyzable proteins; potency between the scorpion fish and other species is similar; the difference in clinical presentation may lie in the amount and way in which the venom is delivered; venom is a muscle toxin affecting cardiac, involuntary, and skeletal muscles

Adverse Reactions Cardiovascular: Sinus bradycardia, sinus tachycardia, arrhythmias (ventricular)

Signs and Symptoms of Overdose

Severity depends on the number of stings, species, amount of venom, patient age and health. Severe pain peaks in 60-90 minutes and lasts 6-12 hours, up to 24 hours. The wound may become cyanotic and ischemic and with edema, erythema, warmth, and vesicle formation.

Systemic signs and symptoms include abdominal pain, anxiety, arthritis, AV block, bradycardia, CHF, delirium, diarrhea, dyspnea, fasciculations, fever, headache, hypertension, hypotension, lymphangitis, nausea, pallor, paralysis, paresthesia, pericardial effusion, pericarditis, rash, respiratory distress, seizures, sweating, syncope, tachycardia, tremor, ventricular fibrillation, and vomiting. Death usually occurs within the first 6-8 hours from respiratory paralysis.

Admission Criteria/Prognosis Asymptomatic patients should be observed for 8-12 hours and if the patient remains asymptomatic, may be safely discharged

Overdosage/Treatment

Decontamination: Immerse wound in hot water (110 to 115°F) to tolerance to inactivate heat labile components of the venom for 30-90 minutes as needed for pain relief, repeat if pain reoccurs; remove pieces of spine from wound; surgical removal of the spines may be necessary

Supportive therapy: Local pain may be treated with tissue infiltration with lidocaine; systemic symptoms should be treated with supportive care (fluids for hypotension). Drain and unroof blisters.

Antidote: Antivenin for stonefish envenomations does exist (Commonwealth Serum Laboratories, Melbourne, Australia); bites from other members of the Scorpaenidae family usually do not require this antivenin

Additional Information Family: Scorpaenidae; three groups separated by different genera based on the venom apparatus; *Pterois* (zebrafish, turkeyfish, lionfish, butterfly cod); *Scorpaena* (scorpion fish, sculpin); *Synanceja* (stonefish). Range: Bottom dwellers found in shallow water, bays, and among coral reef and rocky coastlines; camouflaged by their shape and color; found in tropical and sometimes temperate oceans

Scotch Broom

Scientific Name *Cytisus*; *Genista scoparia*; *Sarothamnus scoparius*; *Spartium scoparium*

Mechanism of Toxic Action Contains cytisine which has effects similar to nicotine

Adverse Reactions Cardiovascular: Sinus tachycardia

Signs and Symptoms of Overdose Asthenia, ataxia, drowsiness, headache, hypotension, mydriasis, nausea, pallor, paralysis, possible dermatitis, seizures, tachycardia, vomiting

Toxicodynamics/Kinetics Onset of symptoms: Within 15 minutes to 4 hours

Overdosage/Treatment

Decontamination: Ipecac relatively contraindicated because of risk of seizures occurring rapidly with large ingestion; lavage (within 1 hour)/activated charcoal with cathartic if large amounts ingested

Supportive care: Maintain respiration and blood pressure in symptomatic patient

Sea Anemones

Scientific Name *Actinia* species; *Actinodendron* species; *Adamsia* species; *Anemonia* species; *Anthea* species; *Anthoptreura* species; *Chondylactis* species; *Physobranchia* species; *Rhodactis howesii*; *Sagartia* species; *Stichactis* species; *Triactis* species

Mechanism of Toxic Action Hemolysis through phospholipase A activity; thalassin, congestin, hypotoxin; toxic proteins: equinatoxin, possible potassium channel blockers, sodium channel blockers, cytolysin activity

SEA CUCUMBER

Signs and Symptoms of Overdose

Dermal sting: Abdominal pain, burning, chills, fever, headache, malaise, myalgias, necrosis, thirst, ulceration, vomiting. Hepatic failure may occur from the sting of the genus *Chondylactis*.

Ingestion of *R. howesi*: Agitated hemolysis can also be seen with coelenterate venoms

Overdosage/Treatment

Decontamination: If ingested, gastric decontamination including charcoal/lavage within 1 hour; irrigate if eye exposure; hot water generally recommended, though heat will denature

Supportive therapy: Pain control, wound care, antihistamines (oral and topical), topical steroids

Toxin neutralization:

- Dilute ammonium hydroxide, sodium bicarbonate, olive oil, sugar, ethyl alcohol with varying success

- Irrigate with sea water and then topical acetic acid 5% (vinegar) recommended; shave area

Antidote: No specific antidote; antihistamines (oral and topical), topical steroids

Additional Information Phylum: Coelenterata; Class: Anthozoa: *Rhodactis howesi* (brown or green anemone)

Sea Cucumber

Scientific Name *Actinopyga agassizi*; *Neothyrone gibbosa*

Mechanism of Toxic Action Contains a potent triterpenoid tetraglycoside called holothurin in its body walls which has hemolytic and cytolytic properties

Adverse Reactions

Cardiovascular: Edema

Dermatologic: Contact dermatitis, pruritus, erythema, dermal granuloma

Ocular: Blindness (can cause severe eye irritation with blindness if there is eye contact)

Overdosage/Treatment

Decontamination: **Dermal:** Immerse wound in hot water (110°F to 115°F) for 30-90 minutes; decontaminate with 5% acetic acid (vinegar) or 40% to 70% isopropyl alcohol **Ocular:** Anesthetize with proparacaine (0.5%) and irrigate with 100-250 mL of normal saline

Supportive: Ocular: Cycloplegics and corticosteroid ophthalmic solutions can be used

Additional Information Found in Gulf of California, Bahamian sea; this sausage-shaped bottom feeder with a white/purple body can be found in shallow or deep waters

Specific References

Robinson R, Nahata M, Mahan J, et al, "Potential Heavy Metal Exposure from Tiger Tail Cucumber (*Holothuria thomas*) Envenomation," *Vet Hum Toxicol*, 2004, 46(4):225 (letter).

Sea Urchins

Scientific Name *Arbacia punctulata*

Mechanism of Toxic Action The venom apparatus (pedicellaria) is located in the spines and is attached to the stalks; venom contains steroid glycosides, hemolysins, proteases, serotonin and cholinergic substances; some Pacific urchins (*Tripeustes*) contain neurotoxic substances; detached venom apparatus can remain active for several hours

Adverse Reactions

Central nervous system: Guillain-Barré syndrome

Hematologic: Dermal granuloma

Neuromuscular & skeletal: Bulbar palsy

Miscellaneous: Delayed hypersensitivity (local edema) may occur at 2-4 weeks postexposure.

Signs and Symptoms of Overdose Burning, hypersensitivity hepatitis, myalgias, pain, redness, stinging, swelling. Guillain-Barré syndrome with hyporeflexia, meningoencephalitis, and bulbar polyneuritis has been reported. Dermal granulomas and paralysis have also been reported.

Overdosage/Treatment

Decontamination: Remove spines if possible. Use hot water soaks (<113°F for 30-90 minutes). Surgical removal may be necessary, especially if located in or near a joint.

Supportive therapy: 2-hour infections, tetanus; all pedicellaria must be removed; the venom apparatus is opaque on soft tissue radiographs; removal may require microsurgical techniques; antibiotics and tetanus should be considered; intralesional injection of triamcinolone hexacetonide (5 mg/mL) can be used to treat granulomas; spines are quite brittle and will usually be extruded within 3 days. Prednisone (20 mg/day orally for 5 days) can be given for delayed hypersensitivity reactions.

Antidote: No specific antidote

Additional Information Egg-shaped or globular echinoderm found on rocky or sandy bottoms; slow moving and nocturnal in habits

Specific References

Morocco A, "Sea Urchin Envenomation," *Clin Toxicol (Phila)*, 2005, 43(2):119-20.

Sea Wasp

Related Information

- Box Jellyfish

Scientific Name *Chironex fleckeri*

Commonly Found In Australia *Chiropsalmus quadrigatus* - Philippines

Signs and Symptoms of Overdose Edema, erythema, pain, necrosis, vesiculation. Systemic effects include myocardial and respiratory depression, nausea, and vomiting. Fatality can occur within 1 minute of exposure.

Overdosage/Treatment

Decontamination: Sheep antivenins, fluids, vasopressors, antiarrhythmics as needed; immobilize affected area, inactivate nematocysts with alcohol or vinegar; immediately rinse with seawater, should then prevent further envenomation by applying acetic acid 5% (vinegar) to any tentacles still adhering to tissue; if acetic acid is not available, use isopropyl alcohol 40% to 70% or finally may use aluminum sulfate; shave envenomated area after initial treatment, then repeat local decontamination therapy. Ocular exposures are to be decontaminated by water irrigation only. **Do not** rub affected area. Wear gloves during decontamination. Meat tenderizers have been used, however they are not preferred decontamination measures and should not have prolonged contact times (> 10 minutes).

Sheep antivenin (Commonwealth Serum Laboratories, Melbourne, Australia): Dose: I.V.: 20,000 units (1 vial) over 5 minutes after skin testing

Additional Information Invertebrate, most venomous sea creature

Sedum

Signs and Symptoms of Overdose There is no evidence that the plant is toxic when taken internally. Some species have produced contact dermatitis.

Overdosage/Treatment

Decontamination: Wash, irrigate

Supportive therapy: Corticosteroids or antihistamines may be used

Shamrock

Scientific Name *Oxalis hedysaroides*

Mechanism of Toxic Action Contains soluble and insoluble oxalates; soluble oxalates may cause damage to the kidney, brain, liver, or heart

Signs and Symptoms of Overdose Dermatitis, hypocalcemia, hypocalcemic arrhythmia, metabolic acidosis, renal damage, tetany

Toxicodynamics/Kinetics Onset: Within 2-12 hours

Overdosage/Treatment

Decontamination: Dilute; ipecac/lavage/activated charcoal not likely necessary; milk/water to dilute crystals

Supportive therapy: For treatment of soluble oxalates, which may cause systemic oxalate toxicity, keep well hydrated, monitor renal function, fluid/electrolytes; hypocalcemia may occur which can be treated with calcium gluconate, monitor urine for crystals; treat other symptoms supportively

Additional Information Toxic dose: Unclear, but unlikely due to large amount necessary. Family: Oxalidaceae

Shellfish Food Poisoning

Commonly Found In Shellfish, blue mussel

Mechanism of Toxic Action May contain either clinophysistoxin (okadaic acid), pectenotoxin, or yessotoxin which can cause fluid secretion in the intestines; incubation period: 4-12 hours postingestion

Signs and Symptoms of Overdose Abdominal cramping, chills, diarrhea, fasciculations, nausea, slurred speech, vomiting

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment

Decontamination: **Do not** use ipecac or laxatives; activated charcoal is of little use; lavage with isotonic bicarbonate solution may make shellfish toxin less potent

Supportive therapy: Fluid and electrolyte replacement therapy

Diagnostic Procedures

- Electrolytes, Blood

Additional Information Heat stable toxin

Shigella Food Poisoning

Scientific Name *Shigella sonnei*

Commonly Found In Potatoes, milk products, tossed salad, meat salad, stewed apples, raw oysters

Mechanism of Toxic Action Can produce an enterotoxin along with a Shiga toxin (*S. dysenteriae*) which stimulates fluid secretion from the intestines; intestinally invasive gram-negative bacteria; incubation period: 1-3 days postingestion

Adverse Reactions Hematologic: Hemolytic/uremic syndrome

Signs and Symptoms of Overdose Feces discoloration (yellow/green); watery, mucoid, bloody diarrhea. Possible cough, dementia, high fever, nausea, and vomiting, seizures in children

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment Most cases of *Shigella* dysentery are self-resolving. Some have suggested that antibiotics be reserved for severe cases, but this does not eliminate the reservoir for infection in the community. Antibiotics have been shown to shorten the period of excretion of the organism in the feces as well as decreasing morbidity. The antibiotic of choice is co-trimoxazole for both children and adults. Ciprofloxacin (500 mg twice daily for 5 days) or azithromycin (500 mg orally on day 1 then, 250 mg once daily for 4 days) is also effective. However, some strains are resistant to trimethoprim, particularly in Africa and Southeast Asia, and *in vitro* susceptibility testing should be performed on all isolates. The quinolones have been effective for shigellosis in clinical trials and are useful alternatives. Antimotility agents such as opiates, paregoric, and diphenoxylate (Lomotil®) should be avoided, because of the potential for worsening the dysentery and for predisposing to toxic megacolon.

Diagnostic Procedures

- Electrolytes, Blood
- Stool Culture

Test Interactions WBCs have a marked shift to the left (bandemia)

Additional Information

Outbreaks occur most commonly in the summer; large amount of fecal leukocytes (polymorphonuclear) are noted; monitor electrolytes

Microbiology: *Shigella* species are gram-negative rods which cause a severe diarrheal syndrome, called shigellosis or bacillary dysentery. *Shigella* species belong to the family Enterobacteriaceae, and are, for all practical purposes, biochemically and genetically identical to *E. coli*. Four species of *Shigella* have been identified: *S. dysenteriae*, *S. flexneri*, *S. boydii*, and *S. sonnei*; there are approximately 40 serotypes.

- *Shigella sonnei* is most common in the industrial world and accounts for ~64% of the cases in the United States. *S. flexneri* is seen primarily in underdeveloped countries. Shigellosis can be seen following ingestion of as few as 200 organisms.

Epidemiology: Infection with *Shigella* sp is primarily a problem in the pediatric population, with most infections in the 1- to 4-year age group. Outbreaks of epidemic proportions have been described in day care centers and nurseries. The reservoir for the bacteria is in humans. Transmission is by direct or indirect fecal-oral transmission from patient or carrier; hand transmission is important. Less commonly, transmission occurs by consumption of contaminated water, milk, and food. The organism is able to produce outbreaks in areas of poor sanitation, in part due to the low number of organisms required to produce disease. Shigellosis is the most communicable of the bacterial diarrheas.

Clinical Syndromes: *Shigella* species invade the intestinal mucosa wherein they multiply and cause local tissue damage. The organisms rarely penetrate beyond the mucosa and thus the isolation in blood cultures is unusual, even with the toxic patient. Mucosal ulcerations are common. Some strains are known to elaborate a toxin (the Shiga-toxin), which contributes to mucosal destruction and probably causes the watery diarrhea seen initially.

- **Dysentery:** Initially, the patient complains of acute onset of fever, abdominal cramping, and large volumes of very watery diarrhea. This phase is enterotoxin mediated and reflects small bowel involvement. Within 24-48 hours, the fever resolves but the diarrhea turns frankly bloody, with mucus and pus in the stools as well. Fecal urgency and tenesmus are common. This phase reflects direct colonic invasion. This two-phased "descending infection" is suggestive of dysentery. Diarrhea and abdominal pain are almost universally present, but the other symptoms may be absent. Physical examination is variable and patients may be comfortable or frankly toxic. Rectal examination is often painful due to friable and inflamed rectal mucosa. The course may be complicated from dehydration from diarrhea and vomiting, particularly in the elderly and in infants. Normally, the infection is self limited and resolves within ~1 week even without antibiotics. Complications are unusual and include febrile seizures (particularly in infants), septicemia, and the hemolytic uremic syndrome (usually from the Shiga-toxin from *S. dysenteriae* 1).

- **Reactive arthritis:** Following dysentery from *Shigella*, a postinfectious arthropathy resembling Reiter's syndrome has been described, particularly in patients who are HLA-B27 positive

Diagnosis: Dysentery from *Shigella* should be suspected in any patient presenting with fever and bloody diarrhea. A history of a "descending infection" as described above is further suggestive. However, the differential diagnosis of fever with bloody diarrhea is broad and includes

salmonellosis, *Campylobacter* enteritis, infection with *E. coli* O157:H7, and inflammatory bowel disease. The WBC count may show either a leukocytosis, leukopenia, or be normal.

There are two important laboratory tests indicated in suspected cases.

- Stool exam for fecal leukocytes: Numerous white blood cells will be present during the colonic phase of the infection. Note that this is not diagnostic for *Shigella* infections; it indicates that the colonic mucosa is inflamed, from whatever cause. The finding of sheets of fecal leukocytes on smear narrows the differential diagnosis of infectious diarrheas considerably.
- Stool culture for *Shigella*: Recovery of the organism from stool is more easily performed early in the illness when the concentration in the stool is highest. Samples should be brought to the laboratory as soon as possible to maximize viability, and specific culture for *Shigella* sp should be requested.

Squill

Scientific Name *Scilla maritima*; *Urginea maritima*

Mechanism of Toxic Action Contains scillaren-A, scillaren-B, glucosyllaren A, scillaridin A, and scilliroside which are cardiac glycosides

Adverse Reactions

Cardiovascular: Arrhythmias (ventricular), bradycardia, sinus bradycardia, vasodilation

Central nervous system: Seizures

Endocrine & metabolic: Hyperkalemia, hypothyroidism

Gastrointestinal: Nausea, vomiting, diarrhea

Admission Criteria/Prognosis Asymptomatic patients with normal electrocardiogram and electrolytes can be discharged after a 12-hour observation; any symptomatic patient should be admitted to a cardiac monitor bed

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) and multidose activated charcoal enhance total body clearance of digitalis; whole bowel irrigation is also beneficial in removing plant debris from the GI tract and is recommended for ingestions of large amounts of plant material

Supportive therapy: Monitor cardiac status and serum potassium levels; bradycardia will frequently respond to atropine; phenytoin is the recommended treatment for ventricular arrhythmias because it will also improve conduction through the AV node; lidocaine can also be used to treat ventricular arrhythmias, but will not have an effect on AV conduction; other antiarrhythmics which have been used in arrhythmias resistant to the above therapy include magnesium, amiodarone, and bretylium; a pacemaker should be considered for bradycardia and AV nodal blocks resistant to medical management

Antidote: Digoxin immune Fab has been shown to interact with several different plant cardiac glycosides and may be beneficial in cases resistant to conventional treatment; indications for its use include ventricular arrhythmias resistant to conventional treatment, severe bradycardia and/or second or third degree heart block resistant to atropine and phenytoin

Antidote(s)

- Digoxin Immune Fab [ANTIDOTE]

Test Interactions Serum digoxin level can be detectable by enzyme immunoassay method

Additional Information Bulbs (which resemble onions) can weigh as much as 2 mg and often are used as a folk remedy. Range: Eastern Mediterranean and South Africa

Squirting Cucumber

Scientific Name *Ecballium elaterium*

Mechanism of Toxic Action Irritant; contains alkaloid resins and glycosides; also a purgative and has anti-inflammatory effects

Adverse Reactions Cardiovascular: Sinus tachycardia

Signs and Symptoms of Overdose Diarrhea, dyspnea, facial edema, laryngeal edema, mucosal irritation, neurotoxicity, renal failure, tachycardia, vomiting

Overdosage/Treatment Supportive therapy: Corticosteroids can be used for edema; hemodialysis can be utilized for renal failure; epinephrine (0.3 mg I.V.) can be used to treat uvular angioedema

Additional Information Region: Endemic to the Mediterranean region; has been used medicinally in Crete and Greece for constipation, rheumatic diseases, and sinusitis, although a death has recently been reported by its use for sinusitis through aspiration; similar toxins also found in colocynth (bitter apple). Toxic part: All parts of the plant are toxic, especially the ovoid green fruit.

Staphylococcus Food Poisoning

Scientific Name *Staphylococcus aureus*

Commonly Found In Ham, pork, poultry, potato salad, egg salad, and foods stored at room temperature

Mechanism of Toxic Action Heat stable enterotoxin; incubation period: 1-6 hours

Adverse Reactions

Cardiovascular: Myocarditis

Miscellaneous: Toxic shock-like syndrome

Signs and Symptoms of Overdose Abdominal pain, diarrhea (associated with upper GI signs), low-grade fever, nausea, vomiting

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment Supportive therapy: Fluid/electrolyte replacement; usual duration of illness is 20 hours.

Diagnostic Procedures

- Electrolytes, Blood
- Stool Culture

Additional Information

Microbiology: *Staphylococcus* derives its name from the Greek word staphyle meaning "bunch of grapes". On Gram's stain, staphylococci are gram-positive cocci, 0.7-1.2 µm, nonspore forming, occurring singly, in pairs, in short 4-5 cocci chains or clusters. Staphylococci grow rapidly both as an aerobic and anaerobe on blood agar. The colonies are sharply defined, smooth, and 1-4 mm in diameter. Staphylococci are catalase-positive and differ from micrococci by the following: anaerobic acid production from glucose, sensitivity <200 mg/mL lysostaphin, and production of acid from glycerol in the presence of 0.4 mg/mL erythromycin.

- *Staphylococcus aureus* may have a golden pigmentation secondary to carotenoid and produce β-hemolysis on horse, sheep, or human blood agar after an incubation of 24-48 hours. *Staphylococcus epidermidis* and coagulase-negative staph (CNS) are often used interchangeably but recognize that there are over 30 species of CNS of which *S. epidermidis* is the most common. It is important to distinguish three clinically relevant species: *S. aureus*, *S. epidermidis*, and *S. saprophyticus*.

Clinical Syndromes:

Food poisoning: Usually caused by ingestion of heat stable enterotoxin B; second most common cause of acute food poisoning. May occur by person-to-person transmission. Incubation 2-6 hours after ingestion of toxin contained in custard-filled bakery goods, canned foods, processed meats, potato salads, and ice cream. Patients present with acute salivation, nausea, vomiting progressing to abdominal cramps, and watery, nonbloody diarrhea (risk of dehydration).

Diagnosis: Diagnosis is made by Gram's stain and culture with sensitivities of appropriate site. Semiquantitation roll technique by Dennis Maki in which catheter is rolled over surface of blood agar plate is useful in suggesting a true intravascular catheter sepsis when both blood culture grows MSSE and count > 15 colonies on blood agar plate.

Star-of-Bethlehem (*Hippobroma longiflora*)

CAS Number 134-63-4; 90-69-7

Scientific Name *Hippobroma longiflora*; *Isotoma longiflora*; *Laurentia longiflora*

Mechanism of Toxic Action All parts of the plant, especially seed capsules and roots, contain the toxin diphenyl lobelidol; this toxin produces primary stimulation and secondary depression of autonomic ganglia; also acts as a central stimulant, affecting medullary centers for respiration and vomiting; high concentrations have a curare-like effect

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose Low doses cause abdominal pain, dermatitis, diarrhea, hypothermia, increased salivation, metallic taste, nausea, sweating, tachypnea, and vomiting. High doses cause bradycardia, coma, hypertension, paralysis, and seizures.

Admission Criteria/Prognosis Asymptomatic patients with normal electrocardiogram and electrolytes can be discharged after a 12-hour observation; any symptomatic patient should be admitted to a cardiac monitor bed

Toxicodynamics/Kinetics

Onset of symptoms: Following SubQ injection, within minutes

Absorption: Well absorbed orally, cutaneously, and by inhalation

Overdosage/Treatment

Decontamination: Ipecac is generally not necessary for houseplant ingestions; ipecac is controversial for other preparations which contain lobeline, but probably not advisable secondary to the rapid onset of symptoms and the possibility of seizures; lavage (within 1 hour) and activated charcoal with cathartic are the treatment of choice for symptomatic patients

Supportive therapy: Respiratory status and seizures

Additional Information

Toxic dose: In cats: 0.4-4 mg/kg: Nausea, vomiting; 60 mg/kg: Convulsions and death; 80 mg/kg: Respiratory paralysis; toxicity is very unlikely with the houseplants which are available; dried material has little activity; lobeline is used in many homeopathic medicines (anti-asthmatic, spasmolytics, and emetics); toxicity is possible from these preparations due to the narrow therapeutic margin

Family: Lobeliaceae. Range: Native to the tropics, but found throughout the West Indies, Hawaii, and Guam. Toxin: Lobeline

Star-of-Bethlehem (*Ornithogalum pyrenaicum*)

Related Information

- Amaryllis
- Indian Tobacco
- Poinsettia

Scientific Name *Ornithogalum pyrenaicum*

Mechanism of Toxic Action All parts of the plant, especially the bulb, contain the digitalis-like glycosides convallatoxin and convallioside

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose GI effects (nausea and vomiting) usually precede cardiovascular effects by several hours. Asystole, AV block, bradycardia, heart block (first, second, and third degree), decreased QT interval and prolonged P-R interval, fibrillation (atrial), flutter (atrial), hypotension, ventricular arrhythmias. Confusion, contact dermatitis, dizziness, fatigue, headache, hyperkalemia, and seeing yellow halos have also been reported.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) and multidose activated charcoal enhance total body clearance of digitalis; whole bowel irrigation is also beneficial in removing plant debris from the GI tract and is recommended for ingestions of large amounts of plant material

Supportive therapy: Monitor cardiac status and serum potassium levels; bradycardia will frequently respond to atropine; phenytoin is the recommended treatment for ventricular arrhythmias because it will also improve conduction through the AV node; lidocaine can also be used to treat ventricular arrhythmias, but will not have an effect on AV conduction; other antiarrhythmics which have been used in arrhythmias resistant to the above therapy include magnesium, amiodarone, and bretylium; a pacemaker should be considered for bradycardia and AV nodal blocks resistant to medical management

Antidote: Digoxin immune Fab has been shown to interact with several different plant cardiac glycosides and may be beneficial in cases resistant to conventional treatment; indications for its use include ventricular arrhythmias resistant to conventional treatment, severe bradycardia and/or second or third degree heart block resistant to atropine and phenytoin

Antidote(s)

- Digoxin Immune Fab [ANTIDOTE]

Additional Information Toxin: Cardiac glycoside

Star-of-Bethlehem (*Ornithogalum umbellatum*)

Related Information

- Amaryllis
- Indian Tobacco
- Poinsettia

Scientific Name *Ornithogalum umbellatum*

Mechanism of Toxic Action All parts of the plant, especially the bulb, contain digitalis-like glycosides similar to those seen in Lily-of-the-Valley

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose GI effects (nausea and vomiting) usually precede cardiovascular effects by several hours. Asystole, AV block, bradycardia, confusion, contact dermatitis, decreased QT interval and prolonged P-R interval, dizziness, fatigue, fibrillation (atrial), flutter (atrial), headache, heart block (first, second, and third degree) hyperkalemia, hypotension, ventricular arrhythmias, and seeing yellow halos have also been reported.

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) and multidose activated charcoal enhance total body clearance of digitalis; whole bowel irrigation is also beneficial in removing plant debris from the GI tract and is recommended for ingestions of large amounts of plant material

Supportive therapy: Monitor cardiac status and serum potassium levels; bradycardia will frequently respond to atropine; phenytoin is the recommended treatment for ventricular arrhythmias because it will also improve conduction through the AV node; lidocaine can also be used to treat ventricular arrhythmias, but will not have an effect on AV conduction; other antiarrhythmics which have been used in arrhythmias resistant to the above therapy include magnesium, amiodarone, and bretylium; a pacemaker should be considered for bradycardia and AV nodal blocks resistant to medical management

Antidote: Digoxin immune Fab has been shown to interact with several different plant cardiac glycosides and may be beneficial in cases

resistant to conventional treatment; indications for its use include ventricular arrhythmias resistant to conventional treatment, severe bradycardia and/or second or third degree heart block resistant to atropine and phenytoin

Antidote(s)

- Digoxin Immune Fab [ANTIDOTE]

Additional Information Toxin: Cardiac glycosides

Starfish

Scientific Name *Acanthaster planci*

Mechanism of Toxic Action *Acanthaster planci* is the only venomous starfish; it contains toxic saponins and histamine-like substances in its spine surfaces; other venom components include phospholipase A₂; some starfish contain tetrodotoxin

Adverse Reactions

Cardiovascular: Edema

Central nervous system: Dizziness

Dermatologic: Wounds can be quite painful and pruritic with copious bleeding; dermal symptoms usually resolve within 3 hours; retained spinal fragments can result in dermal granuloma

Gastrointestinal: Vomiting (~ 1-hour postinjury), nausea

Hematologic: Dermal granuloma

Neuromuscular & skeletal: Paresthesia

Overdosage/Treatment

Decontamination: **Dermal:** Immerse wound in hot water (110°F to 115°F) for 30-90 minutes; **do not** scald the wound; cold water, vinegar soak, or aluminum acetate soaks can be used for local pain relief; irrigate site of puncture wound; obtain soft tissue radiograph if there is a possibility of retained spine. **Ocular:** Irrigate copiously with saline

Supportive therapy: Steroid creams, antihistamines or topical solutions such as calamine with 0.5% menthol can be used to treat dermatitis

Additional Information Crown-of-Thorns Starfish is found in Gulf of California, Pacific and Indian oceans, and Red Sea; a stellate echinoderm with thorny spines held erect by muscle tissue, the starfish are usually bottom dwellers and attain sizes up to 70 cm in diameter; the spines may grow up to 6 cm

Starfruit Food Poisoning

Scientific Name *Averrhoa carambola*

Commonly Found In Southern China, Taiwan, India, Pacific Islands, Australia, Central America, Caribbean Islands, Brazil, Phillipines, tropical West Africa, and southern Florida

Mechanism of Toxic Action Unknown, possibly a metabolite

Signs and Symptoms of Overdose Intractable hiccups, nausea, vomiting, asthenia, insomnia, confusion, agitation, numbness, paresthesias, seizures, coma, death when ingested by chronic renal failure dialysis-dependent patients. Symptoms typically occur 2-4 hours after consumption. Oxalic acid nephropathy reported in patients without underlying renal disease.

Admission Criteria/Prognosis All dialysis-dependent patients with suspected starfruit intoxication should be admitted and referred for urgent hemodialysis. Deaths reported in patients treated by either intermittent peritoneal or hemodialysis, especially after altered consciousness has occurred.

Overdosage/Treatment

Decontamination: Activated charcoal may be useful

Supportive therapy: Treat accordingly, however, patients have generally been responsive to daily hemodialysis therapy only. Hiccups have not responded to phenothiazines or metoclopramide; seizures have persisted and worsened despite phenytoin and barbiturates. Treat seizures with benzodiazepines. Continuous renal replacement therapies also appear effective.

Additional Information As many as 80% of dialysis-dependent patients consuming starfruit may develop hiccups. One case series had 7 deaths in 32 dialysis-dependent patients. Symptoms have rebounded/reoccurred within a few hours after individual dialysis sessions.

Specific References

Neto MM, da Costa JAC, Cairasco NG, et al, "Intoxication by Starfruit (*Averrhoa carambola*) in 32 Uremic Patients: Treatment and Outcome," *Nephrol Dial Transplant*, 2003, 18:120-5.

Stinging Catfish

Scientific Name *Heteropneustes fossilis*

Synonyms Celu Neenu; Pla Sheet

Mechanism of Toxic Action A venomous freshwater catfish found in Asia and India and a popular aquarium fish in Eastern Europe. Venom causes inflammatory reactions and venom glands are located near the pectoral and dorsal fins of the male.

Signs and Symptoms of Overdose Dermal erythema, edema, local wound necrosis, tachycardia, weakness, hypotension, nausea, vomiting,

paresthesias, dizziness, local pain, numbness. Symptoms are virtually immediate.

Overdosage/Treatment Supportive: Major focus is on symptomatic care. Wound can be immersed in hot water (45°C or 113°F) for about 45 minutes to inactivate the toxin - irrigate with fresh water and remove foreign material. Consider delayed surgical closure (if possible). Hypotension can be treated with isotonic saline (10-20 mL/kg) and Trendelenberg position. Dopamine or norepinephrine can be used as vasopressors. There is no antivenom.

Additional Information Fish can reach up to 70 cm in length

Specific References

Satora L, Pach J, Targosz D, et al, "Stinging Catfish Poisoning," *Clin Tox (Phila)*, 2005, 43:893-4.

Stonefish

Scientific Name *Synanceja horrida*

Mechanism of Toxic Action Fish contains spines covered with integumentary sheaths from which venom is released through grooves on the spine as it travels from glands located at the base; venom is composed of high-molecular weight, heat labile, nondialyzable proteins; potency between the scorpion fish and other species are similar, the difference in clinical presentation may lie in the amount and way in which the venom is delivered; venom is a muscle toxin affecting cardiac, involuntary, and skeletal muscles

Adverse Reactions Cardiovascular: Sinus bradycardia, sinus tachycardia, arrhythmias (ventricular)

Signs and Symptoms of Overdose

Severity depends on the number of stings, species, amount of venom, and patient age and health. Severe pain peaks in 60-90 minutes and lasts 6-12 hours, up to 24 hours. The wound may become cyanotic and ischemic with edema, erythema, warmth, and vesicle formation.

Systemic signs and symptoms include abdominal pain, anxiety, arthritis, AV block, bradycardia, CHF, delirium, diarrhea, fever, headache, hypertension, hypotension, lymphangitis, nausea, pallor, paralysis, pericardial effusion/pericarditis, peripheral neuropathies, rash, respiratory distress, seizures, sweating, syncope, tachycardia, tremor, ventricular fibrillation, and vomiting. Death usually occurs within the first 6-8 hours from respiratory paralysis.

Overdosage/Treatment

Decontamination: Immerse wound in hot water to tolerance to inactivate heat labile components of the venom for 30-90 minutes as needed for pain relief, repeat if pain reoccurs; remove pieces of spine from wound; surgical removal of the spines may be necessary

Supportive therapy: Local pain may be treated with tissue infiltration with lidocaine; systemic symptoms should be treated with supportive care (fluids for hypotension)

Antidote: Antivenin for stonefish envenomations does exist (Commonwealth Serum Laboratories, Melbourne, Australia); bites from other members of the Scorpaenidae family usually do not require this antivenin

Antivenin is available in 2 mL vials; made of hyperimmune horse serum; 10 mg of dried antivenin neutralized by 1 mL; dilute in 50-100 mL normal saline and give slow I.V.; skin test before administration; adverse reactions include anaphylaxis and serum sickness; available from Sea World, San Diego (619-222-6363, ext 2201); Sea World, Aurora, OH (216-562-8101); and Steinhart Aquarium, San Francisco, CA (415-770-7171).

Additional Information Family: Scorpaenidae; three groups separated by different genera based on the venom apparatus: *Pterois* (zebrafish, turkfish, lionfish, butterfly cod); *Scorpaena* (scorpion fish, sculpin); *Synanceja* (stonefish). Range: Found in shallow waters, very motionless, near rocks, coral, or buried in sand

Specific References

Currie BJ, "Marine Antivenoms," *J Toxicol Clin Toxicol*, 2003, 41(3):301-8.

Streptococcus Food Poisoning

Commonly Found In Eggs/dairy products, steamed lobster, meat, sausage

Mechanism of Toxic Action Groups A, D, or G *Streptococcus* onset: 1-4 days postingestion

Adverse Reactions

Cardiovascular: Pericardial effusion/pericarditis

Miscellaneous: Toxic shock-like syndrome

Signs and Symptoms of Overdose Asthenia, diarrhea, enlarged cervical adenopathy, fever, headache, myalgia, pyoderma, sore throat, vomiting

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment Supportive therapy: Fluid/electrolyte therapy; penicillin may prevent secondary attacks

STRIPED BLISTER BEETLES

Diagnostic Procedures

- Electrolytes, Blood

Additional Information Heat sensitive

Striped Blister Beetles

CAS Number 56-25-7

Scientific Name *Epicauta* species (*Meloidae*)

Mechanism of Toxic Action Cantharidin causing a dermatitis manifesting several hours postexposure; average concentration: 2.6% to 4.3%

Adverse Reactions

Dermatologic: Blisters, vesiculobullae

Ocular: Conjunctivitis

Renal: Nephritis, renal failure

Signs and Symptoms of Overdose Blisters, vesiculobullae (usually painless when broken or rubbed)

Overdosage/Treatment

Decontamination: Wash skin with soap and water

Supportive therapy: Steroid cream may be helpful to decrease inflammation

Additional Information Range: Eastern U.S., Nova Scotia, Saskatchewan

Sulfite Food Poisoning

CAS Number 10196-04-0; 10257-55-3; 4429-42-9; 7446-09-5; 7631-90-5; 7757-74-6; 7757-83-7; 7790-56-9

Commonly Found In Sausages, fruits, vegetables, wine, beer, soft drinks, bronchodilator aerosols, injectable preparation of metoclopramide, epinephrine, aminophylline, photography, metal lubricants, lidocaine, dexamethasone, phenylephrine, isoproterenol, dopamine

Mechanism of Toxic Action Preservative in food as an antioxidant; can cause type I hypersensitivity reaction due to a cholinergic reflex mechanism. Onset of symptoms: Within 1 hour

Adverse Reactions Cardiovascular: Sinus tachycardia

Signs and Symptoms of Overdose Abdominal cramps, flushing, hand eczema, hypotension, nausea, rash, seizures, sweating, tachycardia, vomiting, watery diarrhea, wheezing

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment

Decontamination: Avoid ipecac; dilute with 4-8 oz of milk or water

Supportive therapy: Fluid/electrolyte replacement; epinephrine or diphenhydramine for allergic manifestations

Antidote(s)

- Epinephrine [ANTIDOTE]

Diagnostic Procedures

- Electrolytes, Blood

Additional Information Primary route of exposure is by ingestion, inhalation, or intravenous; minimum dose for CNS toxicity is 6 mg/kg

Sweet Pea

Scientific Name *Lathyrus odoratus*

Adverse Reactions Cardiovascular: Sinus bradycardia

Signs and Symptoms of Overdose Bradycardia, paralysis, respiratory depression, seizures

Overdosage/Treatment

Large quantities must be ingested chronically to result in toxicity

Exclude *Lathyrus* peas from the diet

Symptomatic and supportive treatment

Additional Information Toxin: Beta-aminopropionitrile. Range: Found throughout the U.S. Toxic part: All parts, particularly the seeds

Tabernanthe iboga Baillon

Mechanism of Toxic Action African shrub which contains ibogaine (or igobine) which is an indole alkaloid that acts as an interruption of psychostimulant or opiate addiction; decreases extracellular dopamine levels

Adverse Reactions Central nervous system: Chewing roots can cause excitement, confusion, hallucinations

Toxicodynamics/Kinetics

Distribution (in primate model): 7 L/kg;

Metabolism: To noribogaine in liver by demethylation

Bioavailability (in primate model): 8%

Overdosage/Treatment Decontamination: Oral: Activated charcoal

Additional Information Can potentiate analgesic effect of morphine; after a 25 mg/kg dose, peak serum ibogaine concentration is almost 200 ng/mL (peak noribogaine level: 600 ng/mL); brand name of ibogaine: Endabuse® (NIH - 10567)

Tarantulas

Related Information

- Funnel Web Spider

Scientific Name *Aphonopelma* species; *Bothriocyrtum* species; *Dugesia henzi*; *Pamphobeteus* species; *Theraphosa blondi*; *Ummidia* species

Mechanism of Toxic Action Venom contains hyaluronidase, nucleotides and polyamines (spermine); local histamine release can occur at site of bites or contact with the spider's hair

Signs and Symptoms of Overdose Local dermal reaction consists of erythema and edema. Wound necrosis usually does not occur. Urticaria is usually caused by penetration of barbed hairs into the skin. Pruritus can last for weeks. Lymphangitis and paresthesias can occur.

Overdosage/Treatment

Decontamination: Barbed hairs can be removed by adhesive or cellophane tape followed by irrigation of skin with normal saline

Supportive therapy: Topical or systemic corticosteroids with oral antihistamines can be used to treat pruritus

Additional Information A large (up to 10 cm), slow jumping spider found in tropical (Western desert U.S.) areas; bites are rarely encountered; hairs often used in "itching powder" in novelty stores

Specific Reference

Seifert SA, "Sunburst Tarantula (*Pterinochilus murinus*) Envenomation," *J Toxicol Clin Toxicol*, 2003, 41(5):700.

Tartrazine Food Poisoning

CAS Number 1934-21-0

Mechanism of Toxic Action Coloring agent in foods can cause hypersensitivity reactions (not IgE-related); incubation period: 30 minutes

Signs and Symptoms of Overdose Can last several hours; anaphylaxis, angioedema, rash, wheezing

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment Supportive therapy: Epinephrine/diphenhydramine for allergic manifestations; intravenous crystalloid with electrolyte replacement for dehydration

Antidote(s)

- Epinephrine [ANTIDOTE]

Additional Information 8% to 15% of affected individuals are intolerant of salicylates

Tetrodotoxin Food Poisoning

Commonly Found In Pufferfish, blow fish, botefe, tambores, swell fish, *Taricha* newt, blue-ringed octopus, *Atelopus* frogs, xanthid crab, starfish, and fugu, ocean sunfishes, porcupine fishes

Mechanism of Toxic Action A neurotoxin on the motor axons and skeletal muscle tissue (inhibits sodium conductance of nerve cells); incubation time: 10 minutes to 3 hours postingestion

Adverse Reactions

Cardiovascular: **Hypertension** (24%), hypotension, sinus bradycardia

Neuromuscular & skeletal: Peripheral neuropathy

Ocular: Miosis (4%) may last for 24 hours followed by mydriasis

Signs and Symptoms of Overdose Asthenia, ataxia, blurred vision, dysarthria, dysphagia, dyspnea, fasciculation, headache, hypothermia, hypotension following apnea, lacrimation, mydriasis, paralysis, salivation, seizures, slurred speech, sweating, tingling of the lips, vomiting, watery diarrhea. Respiratory depression can occur within 2 hours as can paralysis. Fatality rate is 60%. Death is usually due to respiratory paralysis and can occur within 6-24 hours.

Admission Criteria/Prognosis All patients should be observed at least 12-24 hours

Toxicodynamics/Kinetics

Half-life: ~3 hours

Elimination: Urine

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) with 2% bicarbonate solution/activated charcoal with laxative; avoid ipecac

Supportive therapy: Fluids, norepinephrine (8-12 mcg/minute in adults, 0.1-0.2 mcg/kg/minute in children) for hypotension; atropine is useful for bradycardia; mechanical ventilation may be required for respiratory support; early intubation is of vital importance in severe tetrodotoxin toxicity

Additional Information Fatal dose: 10 mcg/kg (200,000 mouse units of tetrodotoxin). Can produce total paralysis with fixed mydriasis; when pronouncing patients dead, caution is advised; not heat labile; heat stable, water soluble toxin; mean time to onset of symptoms: 2 hours; duration of symptoms: 22 hours to 5 days.

Specific References

Hayashida M, Hayakawa H, Wada K, et al, "Sensitive Determination of Tetrodotoxin Using Column-Switching Liquid Chromatography-Mass

Spectrometry with Electrospray Ionization in Mouse Serum," *J Anal Toxicol*, 2004, 28(1):46-9.

How CK, Chern CH, Huang YC, et al, "Tetrodotoxin Poisoning," *Am J Emerg Med*, 2003, 21(1):51-4.

Tobacco

Scientific Name *Nicotiana tabacum*

Mechanism of Toxic Action All parts of the plant contain the toxin nicotine which stimulates motor endplates, ganglionic sites, and smooth muscles by a direct acetylcholine-like action

Adverse Reactions

Cardiovascular: Sinus bradycardia, sinus tachycardia

Respiratory: Eosinophilic pneumonia

Signs and Symptoms of Overdose Low doses can cause asthenia, headache, nausea, oral irritation, sweating, thirst, and vomiting. Higher doses can cause confusion, hallucinations, CNS stimulation followed by CNS depression, hypertension, hyperthermia, seizures; and tachycardia followed by hypotension, bradycardia, and an irregular pulse.

Admission Criteria/Prognosis Symptomatic patients or patients with tachycardia or hypertension 4 hours postexposure should be admitted; survival after 4 hours is usually associated with complete recovery

Toxicodynamics/Kinetics

Onset of action: 15-60 minutes

Duration: 3-12 hours

Absorption: Well absorbed by all routes

Half-life: 0.8-2.2 hours

Overdosage/Treatment

Decontamination: Ipecac is contraindicated due to the risk of seizures; lavage (within 1 hour) and multidosed activated charcoal may enhance total body clearance of nicotine

Supportive therapy: Seizures usually respond to diazepam or lorazepam; hypotension generally resolves with I.V. fluids

Additional Information Human fatalities have been seen at 0.8 mg/kg of nicotine, but depend largely on the extent of spontaneous vomiting. Toxin: Nicotine

Tomato (Leaves and Stems)

Scientific Name *Lycopersicon lycopersicum*; *Lycopersicon*; *Solanum*

Mechanism of Toxic Action Contains toxic alkaloids, solanine most significant structurally similar to cardioglycoside, causes hemolytic and hemorrhagic damage to GI tract similar to saponins; some plants may also contain alpha-cholinergic alkaloids

Signs and Symptoms of Overdose Asthenia, diarrhea, drowsiness, fever, hallucinations, headache, nausea, sweating, visual changes, vomiting. Anticholinergic effects may or may not be present to varying degrees.

Toxicodynamics/Kinetics Toxicity occurs within 2-24 hours, diarrhea may last 3-6 days, anticholinergic effects may delay GI emptying and produce delayed effects

Overdosage/Treatment

Decontamination: Ipecac (within 30 minutes) if vomiting has not already occurred, lavage (within 1 hour) and/or charcoal may be beneficial if the patient presents symptomatic

Supportive therapy: Maintain fluid and electrolyte balance as necessary, support vital signs; physostigmine will reverse anticholinergic toxicity that may be associated with exposure

Antidote(s)

- Physostigmine [ANTIDOTE]

Additional Information Toxic dose: Unclear, toxicity reported in livestock. Toxic part: Green fruit and entire plant excluding ripe fruit potentially toxic

Trichinella spiralis Food Poisoning

Commonly Found In Dogs, swine, cats, rats, bear meat, pork

Mechanism of Toxic Action Ingestion of *Trichinella* cysts which will eventually produce mucosal invasive larvae; incubation period: ~1 week

Signs and Symptoms of Overdose Abdominal cramps, cranial nerve palsies, fever, headache, malaise, myalgia, periorbital edema, rash

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment

Decontamination: Majority of symptomatic patients need supportive care only as infection is self-limited. Benzimidazole carbonates may be given. Mebendazole 200-400 mg 3 times/day for 3 days followed by 400-500 mg 3 times/day for 10 days is active against both invasive and encystment stages. Mebendazole does not cross the blood-brain barrier. Thiabendazole 25 mg/kg twice daily for 7 days is indicated to eliminate gut-dwelling adult worms. It is not effective against larval stages in tissue. Not well tolerated secondary to increased GI side

effects. Albendazole is still under investigation. Steroids (prednisone 40-60 mg/day) may reduce inflammation and are recommended in serious infections.

Overall prognosis is related to severity and intensity of initial infection as well as effectiveness of antiparasitic agents, anti-inflammatory agents, patient's immune status, and whether any end-organ damage was rendered. Mortality related to pulmonary, cardiac, and CNS involvement.

All patients traveling outside the United States should receive pre-travel counseling. Smoking, microwaving, and freezing are not reliable means of eliminating trichinosis.

Diagnostic Procedures

- Electrolytes, Blood

Additional Information

Dissemination to striated muscles can occur in the second week; can cause myocarditis or meningitis. Prevalent on both coasts in the U.S., Australia, and the Pacific islands.

Microbiology: *Trichinella spiralis*, a nematode, is the infectious agent of human trichinosis. The adult male worm measures 1.5 mm in length and the adult female measures 2-4 mm; the average lifespan is 4 months. Identification is made by demonstration of the characteristic encapsulated larvae in biopsy specimens of infected muscles. The cyst wall is derived from the host cell muscle; the larva may incite an inflammatory reaction characterized by surrounding lymphocytes and eosinophils and eventual larval calcification.

Epidemiology: *Trichinella* is found worldwide except Australia and several Pacific islands. Trichinosis results from consumption of undercooked pork, unsanitary cooking practices and contaminated meats; its reservoirs include pigs, horses, bears, and arctic mammals. The three subspecies reflect three sylvatic cycles - arctic, temperate, and tropical. The incidence in the U.S. continues to decline probably because of increased public awareness, commercial freezing, and legislature prohibiting feeding of raw garbage to swine. From 1982-1986, approximately 57 cases per year were reported with three associated deaths. From 1987-1990, 206 cases were reported to the CDC. Most of the cases reported in the U.S. are associated with improperly cooked game animals and travel to Mexico, Asia, and other endemic areas.

Trichinosis results from ingestion of encysted larvae in the contaminated meat. The acid-pepsin environment in the stomach digest the cyst wall, releasing the infectious larvae which burrow and attach to the mucosa at the base of the villi. Over a 6- to 10-day period, the larvae molt four times to become sexually mature adult worms which attach to the duodenal and jejunal mucosa producing between 200-1500 larvae over the next 2 weeks. The newborn or first-stage larvae penetrate the gut mucosa into the lamina propria. An immunologic reaction partially mediated by IgE-mast cell system results in release of vasoactive substances that promote intestinal motility and secretion (diarrhea). The larvae then migrate into the draining lymphatics and blood vessels and have a high predilection to invade muscles of increased use and blood flow (ie, diaphragm, extraocular muscles, masseters, tongue, deltoids, and gastrocnemius). Once penetrated into the skeletal muscle, the larvae elicit a host inflammatory response which surrounds the larvae and creates granulomas and calcifications; only larvae that encyst mature. Larvae may remain viable and infective for many years even in calcified cysts.

The severity of the symptoms is directly related to the larvae load. Patients usually remain asymptomatic with 1-10 larvae per gram muscle, and systemic illness occurs with 50-100 larvae per gram.

Clinical Syndromes:

- **Asymptomatic:** 90% to 95% infections are asymptomatic
- **Self-limited:** 1-2 weeks after ingestion, patients experience enteric phase associated with nonbloody diarrhea and abdominal cramps. Approximately 2-4 weeks later, patients experience fever, intense myalgia especially extraocular and masseters, periorbital edema, conjunctivitis, headache, and/or subconjunctival and subungual petechia. 90% will have peripheral eosinophilia which peaks at 3-4 weeks. Absence of eosinophilia is a poor prognostic sign; ~50% will have elevated CK and LDH enzymes.
- **Arctic trichinosis:** Described in Northern Canada and Alaska in which patients have eaten contaminated walrus or seals. Associated with diarrhea lasting up to 14 weeks, mild and transitory myalgia without fever, peripheral eosinophilia, and no pathogens isolated in stools to explain etiology.
- **Myocarditis:** Incidence of ~5% of symptomatic patients. Typically occurs 3 weeks after larvae migration and presents with tachycardia and chest pain mimicking infarction. Patients have myocardium invasion without encystment; ECG reveals benign, reversible nonspecific ECG changes. May develop nonspecific inflammatory myocarditis predominantly eosinophilic and sometimes associated with pericarditis. Fewer than 0.1% patients die from cardiac complications (ie, congestive heart failure).
- **Pulmonary:** Up to 6% symptomatic patients may develop cough and dyspnea on exertion presumed secondary to larvae migration associated with infiltrates, hemorrhage, and allergic granulomatous reactions

- **CNS:** Prevalence of 10% to 24% in symptomatic patients. In the first 2 weeks when larvae migration is maximal, can result in CNS invasion which appears as meningoencephalitis with delirium and confusion. Larvae encystment may result in focal neurological deficits, anal/urinary sphincter dysfunction, cranial nerve palsies especially VI and VII, seizures, dizziness, anisocoria, tinnitus, diminished auditory acuity, or ataxia. Papilledema, hemianopia, aphasia, and paresis have been reported. CNS and peripheral nerve deficits generally resolve in 4-6 months but may persist up to 10 years. May also cause eosinophilic meningitis. CT scan is usually normal but may see multiple nodular or ring enhancing lesions 3-8 mm and calcification. EEG reveals nonspecific abnormalities consistent with diffuse encephalopathy.

Diagnosis: CDC case definition must fit one of two criteria:

- Positive muscle biopsy or positive serology titer in a patient with clinical symptoms compatible with trichinosis including eosinophilia, fever, myalgias, or periorbital edema
 - In an outbreak (at least one person must fit above criteria), must have either a positive serology titer or clinical symptoms compatible with trichinosis in a person who shared the implicated meat source
- IgM and IgE serology tests are helpful in distinguishing active from previous infection

Tulip

Scientific Name *Tulipa*

Mechanism of Toxic Action Allergic dermatitis

Signs and Symptoms of Overdose Blistering, brittle nails, crusting, fissuring, hyperkeratosis, rash (possibly with associated erythema). Tingling sensation of fingers may be an early indication of symptoms. Symptoms are not necessarily restricted to the area of direct exposure. Dust may produce symptoms.

Toxicodynamics/Kinetics Dermal reaction may be delayed 12 hours

Overdosage/Treatment

Decontamination: Dermal: Wash thoroughly

Supportive therapy: Corticosteroids or antihistamines may be useful for allergic reactions

Tung Nut

Scientific Name *Aleurites fordii*

Commonly Found In Southeastern U.S., Cuba, Taiwan, China, Japan, India, Central Asia

Mechanism of Toxic Action A deciduous tree (15-40 feet tall) in which all parts of the plant (especially the hard seeds) are toxic; contains several constituents (pentosan, phorbol, triolein) which are mucosal irritants; the seeds can be confused for chestnuts or walnuts and may have a peanut-like odor; tung oil is extracted from the seeds

Signs and Symptoms of Overdose Abdominal pain, anorexia, chills, diarrhea, dizziness, dyspnea, elevated liver function tests, fever, headache, hyperglycemia, hyperthermia, leukocytosis, muscle weakness, seizures, sore throat, tachypnea, tremor, urinary retention, vomiting. Tung oil poisonings are more likely to produce systemic effects (fever, dyspnea, seizures), while tung nut toxicity is more likely to produce acute gastrointestinal complaints.

Admission Criteria/Prognosis Admit any seed ingestion or any patient symptomatic 4 hours postingestion.

Overdosage/Treatment

Decontamination: Oral: Activated charcoal

Supportive therapy: Monitor fluid/electrolyte status; replace as needed

Additional Information Ingestion of 1 seed may be toxic. Not sold as dietary supplement; upon heating, tung oil vapors can result in an allergic contact dermatitis; tung oil has been prescribed (in herbal medicine) for erysipelas, scabies, and to treat constipation; onset of symptoms is usually within 4 hours; commonly found in U.S., Cuba, Taiwan, China, Japan, India, Central Asia

Turkey Fish

Mechanism of Toxic Action Fish contains spines covered with integumentary sheaths from which venom is released through grooves on the spine as it travels from glands located at the base; venom is composed of high-molecular weight, heat labile, nondialyzable proteins; potency between the scorpion fish and other species are similar, the difference in clinical presentation may lie in the amount and way in which the venom is delivered; venom is a muscle toxin affecting cardiac, involuntary, and skeletal muscles

Adverse Reactions Cardiovascular: Sinus bradycardia, sinus tachycardia, arrhythmias (ventricular)

Signs and Symptoms of Overdose

Severity depends on the number of stings, species, amount of venom, and the patient's age and health. Severe pain peaks in 60-90 minutes and lasts 6-12 hours, up to 24 hours. The wound may become ischemic and cyanotic with edema, erythema, vesicle formation, and warmth.

Systemic signs and symptoms may include abdominal pain, anxiety, arthritis, AV block, bradycardia, CHF, delirium, diarrhea, fever, headache, hypertension, hypotension, lymphangitis, nausea, pallor, paralysis, paresthesia, pericardial effusion/pericarditis, rash, respiratory distress, seizures, sweating, syncope, tachycardia, tremor, ventricular fibrillation, vomiting. Death usually occurs within the first 6-8 hours from respiratory paralysis.

Overdosage/Treatment

Decontamination: Immerse wound in hot water to tolerance to inactivate heat labile components of the venom for 30-40 minutes; remove pieces of spine from wound; surgical removal of the spines may be necessary

Supportive therapy: Local pain may be treated with tissue infiltration with lidocaine; systemic symptoms should be treated with supportive care (fluids for hypotension)

Antidote: Antivenin for stonefish envenomations does exist (Commonwealth Serum Laboratories, Melbourne, Australia); bites from other members of the Scorpaenidae family usually do not require this antivenin

Additional Information Family: Scorpaenidae; three groups separated by different genera based on the venom apparatus: *Pterois* (zebrafish, turkeyfish, lionfish, butterfly cod); *Scorpaena* (scorpion fish, sculpin); *Synanceja* (stonefish). Range: Very beautiful coral reef fish found in Asia; usually single or paired in shallow water; contains vertical dark stripes with lengths up to 35 inches

Tyramine Hydrochloride Food Poisoning

CAS Number 51-67-2; 60-19-5

Commonly Found In Cheeses (especially aged cheeses), yeast extracts, spoiled (decaying) meats, pickled herring, smoked fish, alcohol-containing beverages, broad bean pods (fava beans)

Mechanism of Toxic Action Can precipitate the release of norepinephrine

Adverse Reactions Hepatic: G6PD deficiency-induced hemolytic anemia

Signs and Symptoms of Overdose Headache, hypertension, hypotension, mydriasis, palpitations, possible intracerebral hemorrhage, sweating, vertigo

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment Supportive therapy: Phentolamine mesylate to treat hypertensive crises (I.V.: 2.5-5 mg; titrate as necessary)

Additional Information Should not consume tyramine-containing foods within 14 days of MAO ingestion; can cause hypertensive crisis when given with MAO inhibitors or amphetamines; when given in combination with chlorpromazine, hypotension can result. Tyramine hydrochloride is not noted in cottage cheese or cream cheese. Milk and cream are also safe; cooking does not inactivate tyramine.

Upas Tree

Scientific Name *Antiaris toxicaria*

Uses In poison darts (from blowpipe), spears, and arrows

Mechanism of Toxic Action Contains cardiac glycoside and dihydrochalcone (antiarrone) derivatives; also is a mucosal irritant

Signs and Symptoms of Overdose Arrhythmias, coma, dermal burns, elevated creatine kinase, esophageal ulceration, mouth ulceration, myoglobinuria, oliguric renal failure, rhabdomyolysis

Overdosage/Treatment

Decontamination: Oral: Lavage (within 1 hour)/activated charcoal with cathartic

Supportive therapy: Although data are lacking, since this agent has digoxin-like effects, an approach similar to digoxin overdose management (including digoxin-specific Fab fragments) may be helpful

Additional Information Found in tropical Asia and Africa, a tall tree which grows up to 250 feet with oblong leaves and pear shaped purple or red fruit; the latex of this plant may be mixed with other plant extracts, arsenic or snake venom in order to increase toxicity; although there are case reports of death due to ingestion, usually this route of entry is not toxic to a healthy adult. Similar toxicity to *Antiaris africana*. Monitor electrolytes, ECG, and creatinine kinase.

Vibrio cholerae and *Vibrio parahaemolyticus* Food Poisoning

Commonly Found In Uncooked shellfish and raw seafood

Mechanism of Toxic Action *Vibrio parahaemolyticus* and *Vibrio cholerae* are motile, gram-negative rods; *V. parahaemolyticus* produces Shiga toxin; *V. cholerae* produces cholera toxin (an enterotoxin) which inhibits absorption and enhances intestinal secretion; incubation period: 12-14 hours

Adverse Reactions Endocrine & metabolic: Hypokalemia
Signs and Symptoms of Overdose Grayish, watery diarrhea [rice-water stools] (profuse); fluid losses may exceed 1 L/hour

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment

Vibrio cholerae: Early and rapid replacement of fluid and electrolytes can decrease the mortality to < 1%. Oral rehydration is usually successful, but in severe cases, intravenous replacement is required. When fluid and electrolyte imbalances are corrected, cholera is a short, self-limiting disease lasting a few days. According to the *MMWR*, doxycycline, tetracycline, co-trimoxazole, erythromycin, and furazolidone have all demonstrated effectiveness in decreasing the diarrhea and bacterial shedding in this disease. The usual recommendation is doxycycline 300 mg as a single dose for adults, and co-trimoxazole 5 mg/kg as trimethoprim, twice daily for 3 days. Single dose azithromycin (20 mg/kg P.O.; maximum dose: 1 g) is also effective.

Vibrio parahaemolyticus: Tetracycline: 500 mg 4 times/day for 5 days
 Supportive therapy: Cholera: Azithromycin at a single oral 1 g dose can shorten the duration of diarrhea.

Diagnostic Procedures

- Electrolytes, Blood
- Stool Culture

Additional Information

Immunity with cholera vaccines is relatively short-lived; can cause hypokalemia; toxin is heat labile; in 1993-94, a total of 69 cholera cases were reported to the CDC with 65 cases (94%) being associated with foreign travel

Microbiology:

Vibrio cholerae is an oxidase-positive, fermentative, gram-negative rod that can have a comma-shaped appearance on initial isolation. *V. cholerae* can be subdivided by the production of endotoxin and agglutination in 0-1 antisera with the nomenclature of *V. cholerae* 0-1, atypical or nontoxigenic 0-1, or non-0-1. The serogroup 0-1 can further be subdivided into the El Tor and classic cholera biotypes which can be further subdivided into a variety of serotypes. The major virulence factor of *V. cholerae* is the extracellular enterotoxin produced by the 0-1 strain, although nontoxin-producing organisms have been implicated in some outbreaks.

V. cholerae is a facultative anaerobe which grows best at a pH of 7.0 and at a wide temperature range (18°C to 37°C). *Vibrio* species can be differentiated from other gram-negative bacilli by their sensitivity to 0129 and may be speciated by a variety of biochemical tests.

Epidemiology:

Cholera is usually spread and transmitted by contamination of water and food by infected feces. Person-to-person transmission is less common due to the large organism load necessary for infection. Asymptomatic carriers play a minor role in cholera outbreaks. Outbreaks may be seasonally dependent based on either temperature or rainfall. Transmission by food can be eliminated by thorough cooking; adequate sanitation is the best means of cholera prevention. There have been several pandemics of cholera reported since 1817, originating in Bengal and subsequently spreading to a variety of geographic locations, responsible for hundreds of thousands of deaths. The latest pandemic originated in Indonesia in 1961 and moved to the Western hemisphere. In 1991, a cholera outbreak in Peru and 20 other countries in the Western hemisphere accounted for > 600,000 cases with 5000 deaths caused by El Tor 0-1.

Clinical Syndromes: After a 2- to 5-day incubation period, classic cholera is characterized by an abrupt onset of vomiting and profuse watery diarrhea with flecks of mucus (rice water stool). Fluid losses can be significant (up to 20 L/day). Hypovolemic shock and metabolic acidosis can cause death within a few hours of onset, especially in children. Mortality, in untreated cases, is as high as 60%. Milder forms of the disease also occur, especially with the non-0-1 cholera.

Diagnosis: Organisms can be identified by darkfield microscopy showing large numbers of comma-shaped organisms with significant motility. However, this test is relatively insensitive and is nonspecific. Thiosulfate-citrate-bile salt-sucrose agar (TCBS) or alkaline peptone broth are used to facilitate growth and identification. Positive identification depends on serologic and biochemical testing.

Vibrio vulnificus

Commonly Found In Ingestion of raw oysters and clams; stingray exposure; handling of raw shellfish. Found in highest concentrations between April and October in warm salt water.

Mechanism of Toxic Action A gram-negative bacteria that possesses a hemolytic and cytotoxic toxin. Also produces protease, collagenase, and phospholipases.

Signs and Symptoms of Overdose

Three distinct syndromes occur:

Primary septicemia: Following ingestion, fever (103°F to 104°F) and chills occur first followed by nausea, vomiting, anorexia, and diarrhea (in less than one-half of affected patients). Dramatic skin eruptions can occur beginning as hemorrhagic bullae on the trunk and extremities, progressing to necrotic ulcers. Necrotic fasciitis, myositis, and gangrene can also occur. Hypotension develops with 12 hours of ingestion and is associated with a 90% mortality. Median incubation time is 28 hours.

Gastroenteritis following ingestion is usually self-limited and associated with vomiting, abdominal cramps, and watery diarrhea.

By handling affected salt water shellfish, wound infections can occur with associated skin lacerations, puncture wounds, or abrasions. Penetrating stingray or crab-bite injuries may also cause wound infections. Initially, swelling and erythema with intense pain occur at the site of infection, followed by fluid-filled bullae with surrounding erythema and edema. Septicemia or gas gangrene may develop.

Admission Criteria/Prognosis Admit any symptomatic patient.

Overdosage/Treatment Supportive therapy: Intravenous fluids should be used to treat hypotension. Septicemia or wound infection can be treated with tetracycline (or intravenous doxycycline) with ceftazidime. Aminoglycosides may also be effective as is chloramphenicol. Surgical debridement or even limb amputation may be required for wound infection.

Additional Information Between 1989 and 1996, 149 serious illnesses resulting in 75 deaths from *Vibrio vulnificus* have been documented by the CDC. Individuals at high risk for septicemia include those patients with liver disease, alcoholism, hemochromatosis, or compromised immune status. Preventive measures include boiling live oysters in water for 3-5 minutes after the shells open or steaming live oysters for 4-9 minutes. Shucked oysters or clams should be boiled for at least 3 minutes (or until edges curl), or fried in oil for at least 3 minutes at 375°F for 10 minutes, or broiled 3 inches from heat for 3 minutes, or baked at 450°F for 10 minutes.

Vietnamese Centipede

Scientific Name *Scolopendra subspinipes*

Mechanism of Toxic Action Venom may contain bioactive compounds which may contain proteases, immunoreactive agents, and cytolytic agents.

Signs and Symptoms of Overdose Local signs: Burning, edema, lymphadenitis, pain, transient bleeding, skin erythema. There are few systemic signs.

Overdosage/Treatment Local wound care is the mainstay of treatment. Diphenhydramine may reduce localized edema. Prophylactic antibiotics are not necessary.

Additional Information Large centipede (23 cm in length), often acquired as pets.

Water Hemlock

Scientific Name *Cicuta bulbifera*; *Cicuta douglasii*; *Cicuta maculata*

Mechanism of Toxic Action Contains the toxin cicutoxin which is located throughout the plant but especially in its root. Cicutoxin is seizurgenic possibly through stimulation of central nervous system cholinergic pathways.

Adverse Reactions

Cardiovascular: Sinus tachycardia

Central nervous system: Memory disturbance (of short-term memory) may last for 1 week, seizures within 1 hour

Gastrointestinal: GI symptoms occur within 30 minutes

Signs and Symptoms of Overdose Acidosis, death, diarrhea, hypotension, mydriasis, myoglobinuria, nausea, renal failure, rhabdomyolysis, seizures, tachycardia, vomiting

Overdosage/Treatment

Decontamination: Activated charcoal with cathartic for recent ingestions
 Supportive therapy: Provide symptomatic and supportive therapy; manage seizures with diazepam or lorazepam; recurring seizures may need

WHELK POISONING

barbiturate or phenytoin treatment, general anesthesia may be required for seizure control; sodium bicarbonate can be given for acidosis

Enhancement of elimination: Hemodialysis was useful in one case report

Additional Information Fatal dose: 1 square inch piece of root may be fatal upon ingestion. Family: Umbelliferae. Toxin: Cicutoxin. Toxic part: Whole plant, especially the root. Range: *Cicuta douglasii* is found in swamps in Western U.S. and Alaska; *Cicuta maculata* and *Cicuta bulbifera* are common in the Eastern U.S.; all are deadly.

Whelk Poisoning

Scientific Name *Neptunea antigua*; *Neptunea arthritica*; *Buccinum*; *Fusitriton*

Uses Commonly used as fish bait

Mechanism of Toxic Action Contains tetramine (an automatic ganglionic blocker which is a curare-like substance) in the salivary gland of the red whelk

Adverse Reactions

Symptoms usually resolve within 1 day

Central nervous system: Dizziness, headache, ataxia

Dermatologic: Urticaria

Gastrointestinal: Nausea, constipation, vomiting, xerostomia

Neuromuscular & skeletal: Muscle paralysis, muscle twitching, weakness

Ocular: Blurred vision, photophobia

Overdosage/Treatment

Decontamination: **Do not** induce emesis

Supportive therapy: Replace fluids; can treat urticaria with antihistamines

Additional Information No fatalities known; found in Britain and Japan.

Whelks are brightly colored mollusks found on rocks, sand or gravel. Intoxication can occur in the raw, cooked or canned state. Concentration of tetramine is highest during the summer.

White Chameleon

Scientific Name *Atractylis gummifera*

Mechanism of Toxic Action A thistle-like plant found in the dry areas of the Mediterranean (Tunisia, Morocco, Italy), it is often confused with wild artichoke. Major toxicity is from rhizome ingestion which are oxidative phosphorylation inhibitors (the glycosides atractyloside and carboxyatractyloside).

Signs and Symptoms of Overdose Tachypnea, hypothermia, hypotension, metabolic acidosis, hyperkalemia, tachycardia, headache, abdominal pain, vomiting, mydriasis, hematemesis, diarrhea, hyporeflexia, hepatic failure, hepatic necrosis (due to prolonged ischemia), renal failure, coagulopathy, leukocytosis (80%), hypoglycemia (93% of children)

Overdosage/Treatment

Decontamination: Oral: Activated charcoal/lavage within 2 hours. Dermal: Wash skin with soap and water

Supportive therapy: Treat hypotension with 10-20 mL/kg of isotonic I.V. fluids and place in Trendelenburg position; dopamine/norepinephrine are vasopressors of choice

Additional Information One root/root extract may be toxic

Specific References

Hamouda C, Hedhili A, Ben Salah N, et al, "A Review of Acute Poisoning from *Atractylis Gummifera* L.," *Vet Hum Toxicol*, 2004, 46(3):144-6.

Wild Cucumber

Scientific Name *Echinocystis oregana*; *Marah oreganus*

Mechanism of Toxic Action Contains cucurbitacin which is a cytotoxic substance

Signs and Symptoms of Overdose Abdominal pain, cyanosis, DIC, hypotension, leg cramps, mydriasis

Toxicodynamics/Kinetics Symptoms can occur within 9 hours

Overdosage/Treatment Supportive therapy: Treat hypotension with fluids, colloids, and pressor solutions

Additional Information Ovoid fruit found on a perennial vine; similar spiny pods as Jimson weed. Range: Usually located in Western North America

Wild Hops

Scientific Name *Bryonia*

Mechanism of Toxic Action Contains bryonin, bryonidin, bryonicine and bryoamarid glycosides in the berries and rootstock which are irritants

Adverse Reactions

Dermatologic: Contact dermatitis

Gastrointestinal: Vomiting, diarrhea, abdominal pain

Overdosage/Treatment Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic

Additional Information A perennial climbing plant with yellow-green flowers and scarlet pea-sized berries; berries are quite toxic with 40

berries and 15 berries being a fatal dose in an adult and child, respectively

Wild Mustard

Scientific Name *Brassica* species

Signs and Symptoms of Overdose Contact dermatitis, nausea, vomiting

Overdosage/Treatment

Decontamination: Dermal: Decontaminate area, remove any foreign bodies which remain, topical steroids may be of benefit

Supportive therapy:

Dermal: Observe for any signs of infection

Oral: Supportive care and fluid replacement is seldom required

Additional Information No specific cases of human toxicity have been reported. Family: Cruciferae. Range: Seen over much of the temperate zones of the U.S. Toxin: Hairs of the plant can cause mechanical injury, and seeds contain GI irritants.

Wisteria

Scientific Name *Wisteria*

Mechanism of Toxic Action Contains glycosides which cause GI upset

Signs and Symptoms of Overdose Abdominal pain, fluid loss, minimal diarrhea, oral burning, nausea, shock, vomiting

Toxicodynamics/Kinetics Unclear, but duration reported to be 24 hours

Overdosage/Treatment

Decontamination: Oral: Activated charcoal with cathartic may be beneficial

Supportive therapy: Maintain fluid and electrolyte balance

Additional Information Toxic dose: Two seeds or pods can be toxic.

Toxic part: All, pods and seeds mostly; symptoms resolve within 1-2 days

Woody Nightshade

Scientific Name *Solanum dulcamara*

Mechanism of Toxic Action Contains the toxic glycoalkaloid solanine (in all parts of the plant) which can inhibit cholinesterase activity, irritate gastrointestinal mucosal membranes and exhibits weak cardiac glycoside activity

Adverse Reactions

Cardiovascular: Bradycardia

Central nervous system: Fever, headache, CNS depression, delirium

Gastrointestinal: Nausea, vomiting

Hematologic: Increased white blood cell count

Ocular: Mydriasis

Neuromuscular & skeletal: Weakness, tremor

Respiratory: Apnea

Miscellaneous: Diaphoresis

Admission Criteria/Prognosis Admit ingestions > 10 berries

Toxicodynamics/Kinetics

Peak GI absorption: 12 hours

Half-life: 11 hours

Elimination: Renal

Overdosage/Treatment

Decontamination: Do **not** induce emesis; lavage within 6-8 hours/activated charcoal with cathartic

Supportive therapy: Physostigmine can be utilized for anticholinergic crisis; monitor fluids/electrolytes

Antidote(s)

● Physostigmine [ANTIDOTE]

Additional Information A weed that is found in northern and eastern United States and Canada; usually a shrub or slender vine with red berries, purple flowers and often heart-shaped leaves; bitter tasting

Yellow Sac Spider

Scientific Name *Chiracanthium* sp

Mechanism of Toxic Action Unknown; spider may hold on very tightly causing mechanical damage along with dermal irritation

Signs and Symptoms of Overdose Pruritic, erythematous wheal and dull pain occur at bite site within 30 minutes. Eschar formation can develop within 24 hours. Abdominal cramps, headache, lymphadenopathy, and nausea can develop.

Overdosage/Treatment Supportive therapy: Oral antihistamines can be utilized; cool compresses, limb elevation and immobilization with analgesics are suggested; monitor for secondary infections

Additional Information Body size: 7-16 mm with long slender hairy legs (total diameter 30 mm); dorsal abdomen can have a median longitudinal stripe; most bites occur in autumn; found in New England, Hawaii, eastern U.S. and Utah; very tenacious; often must be removed from bite area

Yersinia enterocolitica Food Poisoning

Commonly Found In Milk, tofu

Mechanism of Toxic Action *Yersinia enterocolitica* is a gram-negative bacillus which is invasive and produces a heat stable toxin; incubation period: 1 to 3 days

Adverse Reactions Gastrointestinal: Appendicitis

Signs and Symptoms of Overdose Abdominal pain (may resemble appendicitis), arthritis, diarrhea, erythema nodosum, fever, mesenteric lymphadenitis

Admission Criteria/Prognosis Patients with dehydration (who cannot take fluids orally), immunocompromised patients, severe disturbance in electrolytes or acid-base status, or patients at extreme in terms of age group should be considered for admission

Overdosage/Treatment Many cases of enterocolitis and mesenteric adenitis secondary to *Yersinia* are self-resolving, and the role of antibiotics is unclear. Patients with *Yersinia* septicemia, however, definitely require antibiotic therapy since the mortality approaches 50%. The organism is susceptible *in vitro* to a number of agents, including third-generation cephalosporins, ciprofloxacin, piperacillin, co-trimoxazole, and aminoglycosides. Most isolates are resistant to penicillin, ampicillin, and first-generation cephalosporins. The optimal drug regimen *in vivo* has not been defined in the literature. For serious infections it seems reasonable to treat initially with a combination (eg, third-generation cephalosporin and aminoglycoside) until the patient has stabilized.

Diagnostic Procedures

- Electrolytes, Blood

Additional Information

Infection rate is increased with prolonged (> 36 hours) deferoxamine use

Microbiology: *Yersinia enterocolitica* is a gram-negative bacillus named for the French bacteriologist Alexander Yersin, who discovered *Yersinia pestis* (the cause of plague) in 1894. *Y. enterocolitica* is an unusual cause of enterocolitis, terminal ileitis mimicking acute appendicitis, and septicemia. The organism is an aerobic gram-negative rod, nonlactose fermenting, which is motile at 25°C. It is unusual in that it grows better at somewhat cooler temperatures than do other pathogenic gram-negative rods (25°C to 32°C); it also is able to grow well at 4°C, which is the basis for CEM.

Epidemiology: *Yersinia enterocolitica* is endemic in many animals which serve as reservoirs (cattle, pigs, dogs, cats, and others). The usual route of human infection is via ingestion of contaminated food, milk, and water. There have been three major foodborne epidemics in the United States:

- June 1982, outbreak in several states linked to consumption of milk pasteurized at a plant in Memphis, Tennessee; 172 positive cultures from cases in Tennessee, Arkansas, and Mississippi, where patients presented with diarrhea, fever, and abdominal pain; it also included 24 cases of extraintestinal infections including throat, blood, urinary tract, central nervous system, and wounds
- 1976, contaminated chocolate milk in New York state
- 1982, contaminated tofu in Washington state

Clinical Syndromes:

● **Enterocolitis:** *Yersinia enterocolitica* is a rare cause of enterocolitis. The severity of symptoms can be quite variable and can range from mild fever, diarrhea and abdominal pain, to fulminant colitis with spiking fevers and rectal hemorrhage.

● **Mesenteric adenopathy with or without terminal ileitis:** This form of *Yersinia* infection is known to mimic acute appendicitis. Patients present with right lower quadrant pain, fever, and leukocytosis. Upon laparotomy, the appendix is normal; but enlarged mesenteric lymph nodes are palpable and when cultured will yield the organism. This has been described primarily in adolescents, although cases have been reported in adults.

● **Polyarthritis:** This has been described as the sole manifestation of *Yersinia enterocolitica* infection or as a secondary manifestation of gastrointestinal infection. Well documented cases have been described in Scandinavia, where up to 30% of cases develop erythema nodosum; and 10% to 30% develop polyarthritis (especially associated with HLA-B27 haplotype). *Yersinia* antigens have recently been found in synovial fluid cells from patients suffering from reactive arthritis following *Yersinia* infection.

● **Liver abscess:** *Yersinia* is a rare, but reported cause of liver abscess in the absence of typical enterocolitis symptoms

● **Ascending infection of an extremity:** Recently cases of infections of the hand and upper extremity due to *Yersinia enterocolitica* have been described. These infections occurred in adults preparing contaminated chitterlings (pig intestines) with local inoculation into the hand via small cuts.

● **Septicemia:** *Yersinia* is an unusual cause of community-acquired septicemia, but may occur following ingestion of heavily contaminated food. Risk factors for septicemia are cirrhosis, malignancy, diabetes mellitus, and patients with iron overload syndromes (such as hemochromatosis, frequent blood transfusions). Typically, there is fever, myalgias, confusion, and possibly hypotension. Symptoms of enterocolitis, such as diarrhea and abdominal pain, may be completely absent, adding to the diagnostic confusion; elevated liver enzymes and muscle enzymes may occur; blood cultures are often positive for the organism.

ocolitis, such as diarrhea and abdominal pain, may be completely absent, adding to the diagnostic confusion; elevated liver enzymes and muscle enzymes may occur; blood cultures are often positive for the organism.

● **Miscellaneous:** Other manifestations of *Yersinia* infection include osteomyelitis, meningitis, pharyngitis (without enterocolitis), intra-abdominal abscess

Diagnosis: In the absence of an outbreak, the diagnosis of enterocolitis due to *Yersinia* is difficult to make on clinical grounds alone. Thus, laboratory confirmation is important in most cases. Appropriate specimens for culture include stool, blood, lymph node, pharyngeal exudates, ascites fluid, and cerebrospinal fluid. Joint aspiration fluid may be sent for *Yersinia* culture in the appropriate clinical setting (ie, reactive polyarthritis following a diarrheal illness), but the yield is extremely low. The laboratory should be notified if a stool specimen is being examined for *Yersinia*; serologic tests for specific antibody production to *Yersinia enterocolitica* are available in some laboratories.

Yersinia pestis

Mechanism of Toxic Action An enzootic infection of rodents found in every continent (except Australia and Antarctica); most U.S. cases are found in the western U.S.; an anaerobic nonmotile, gram-negative coccobacillus usually transmitted by a flea bite (although it can be transmitted by domestic cats). The organism migrates through the lymphatic system resulting in lymph node destruction. Primary pneumonic plague occurs through inhalation of bacilli with symptoms occurring within 6 days of exposure. Symptoms of bubonic plague include fever, chills, tender lymphadenopathy, and buboes. The lesions are 1-10 cm in diameter, painful, warm, and are located in the groin, axilla, or neck region. Symptoms usually begin within 8 days after being infected. Septicemia, gangrene of acral regions, and disseminated intravascular coagulation can occur. A secondary pneumonic plague due to hematogenous spread of the bacilli can occur, with symptoms of dyspnea, cough, and hemoptysis.

Signs and Symptoms of Overdose Pneumonic and plague: Abdominal pain (17%), aminotransferase elevation, ARDS (50% mortality), azotemia, bronchopneumonia, chest pain, cough, cyanosis, delirium, diarrhea (28%), dyspnea, epistaxis, fever, headache, hemoptysis, hypotension, leukocytosis, lobar consolidation, lymphadenopathy, malaise, meningitis, myalgias, nausea (34%), purpura, seizures, shortness of breath, splenomegaly, tachycardia, tachypnea, vomiting (39%)

Overdosage/Treatment

Any person with a fever of 38.5 °C or higher, should begin prophylactic antibiotic therapy during a pneumonic plague epidemic; any infected patient should be isolated for the first 2 days of antibiotic therapy until clinical improvement occurs; respiratory droplet precautions should be utilized; exudates or discharge should be handled with rubber gloves; seizures can be treated with a benzodiazepine or phenobarbital
Supportive therapy: See table.

Recommendations for Treatment of Patients With Pneumonic Plague		
Patient Category	Recommended Therapy	
	Contained Casualty Setting*	
Adults	Preferred	Streptomycin 1 g I.M. twice daily Gentamicin, 5 mg/kg I.M. or I.V. once daily or 2 mg/kg loading dose followed by 1.7 mg/kg I.M. or I.V. 3 times/day [†]
	Alternative	Doxycycline, 100 mg I.V. twice daily or 200 mg I.V. once daily Ciprofloxacin, 400 mg I.V. twice daily [‡] Chloramphenicol, 25 mg/kg I.V. 4 times/day [§]
Children	Preferred	Streptomycin, 15 mg/kg I.M. twice daily (maximum daily dose, 2 g) Gentamicin, 2.5 mg/kg I.M. or I.V. 3 times/day [†]
	Alternative	Doxycycline: If ≥45 kg, give adult dosage; if <45 kg, give 2.2 mg/kg I.V. twice daily (maximum, 200 mg/day) Ciprofloxacin, 15 mg/kg I.V. twice daily [‡] Chloramphenicol, 25 mg/kg I.V. 4 times/day [§]

Table (Continued)		
Patient Category	Recommended Therapy	
	Contained Casualty Setting*	
Pregnant women	Preferred	Gentamicin, 5 mg/kg I.M. or I.V. once daily or 2 mg/kg loading dose followed by 1.7 mg/kg I.M. or I.V. 3 times/day [†]
	Alternative	Doxycycline, 100 mg I.V. twice daily or 200 mg I.V. once daily Ciprofloxacin, 400 mg I.V. twice daily [‡]
Patient Category	Mass Casualty Setting and Postexposure Prophylaxis*	
Adults	Preferred	Doxycycline, 100 mg orally twice daily** Ciprofloxacin, 500 mg orally twice daily [‡]
	Alternative	Chloramphenicol, 25 mg/kg orally 4 times/day [§]
Children¶	Preferred	Doxycycline**: If ≥45 kg, give adult dosage; if <45 kg, then give 2.2 mg/kg orally twice daily Ciprofloxacin, 20 mg/kg orally twice daily
	Alternative	Chloramphenicol, 25 mg/kg orally 4 times/day [§]
Pregnant women#	Preferred	Doxycycline, 100 mg orally twice daily** Ciprofloxacin, 500 mg orally twice daily
	Alternative	Chloramphenicol, 25 mg/kg orally 4 times/day [§]

*These are consensus recommendations of the Working Group on Civilian Biodefense and are not necessarily approved by the FDA. One antimicrobial agent should be selected; therapy should be continued for 10 days; oral therapy should be substituted when the patient's condition improves.

I.M. = intramuscular; I.V. = intravenous.

[†]Aminoglycosides must be adjusted according to renal function. Evidence suggests that gentamicin 5 mg/kg I.M. or I.V. once daily, would be efficacious in children, although this is not yet widely accepted in clinical practice. Neonates up to 1 week of age and premature infants should receive gentamicin, 2.5 mg/kg I.V. twice daily.

[‡]Other fluoroquinolones can be substituted at doses appropriate for age. Ciprofloxacin dosage should not exceed 1 g/day in children.

[§]Concentration should be maintained between 5 and 20 mcg/mL. Concentrations >25mcg/mL can cause reversible bone marrow suppression.

[¶]In children, ciprofloxacin dose should not exceed 1 g/day, chloramphenicol should not exceed 4 g/day. Children younger than 2 years of age should not receive chloramphenicol.

[#]In neonates, gentamicin loading dose of 4 mg/kg should be given initially.

•Duration of treatment of plague in mass casualty setting is 10 days. Duration of postexposure prophylaxis to prevent plague infection is 7 days.

[¶]Children younger than 2 years of age should not receive chloramphenicol. Oral formulation available only outside the U.S.

**Tetracycline could be substituted for doxycycline

Additional Information

An aerosol of plague bacillus could remain viable for up to 1 hour at a distance of 10 kilometers

Mortality: 50% to 60% for untreated bubonic plague; 100% for untreated septicemia, or 10% to 20% in treated cases of pneumonic plague

Largest number of reported cases in Tanzania, Viet Nam and Zaire

Additional information can be obtained from the Center for Disease Control's plague center in Fort Collins, Colorado: (970) 221-6450

Yew

Scientific Name *Taxus* species

Mechanism of Toxic Action All parts of the plant are toxic except the red fleshy aril; the toxin appears to inhibit sodium and calcium current in cardiac cells causing a block of the distal portion of the conduction tissue of the heart; the hard seed coat is resistant to digestive enzymes and is nontoxic unless chewed or broken

Adverse Reactions Cardiovascular: Sinus bradycardia, sinus tachycardia, arrhythmias (ventricular)

Signs and Symptoms of Overdose Abdominal pain, asthenia, AV block, cardiac arrhythmias (sinus bradycardia, ventricular tachycardia, ventricular fibrillation, heart block), coma, contact dermatitis, cyanotic lips, dizziness, headache, hypokalemia, hypotension, mydriasis, nausea, pale complexion, respiratory distress/arrest, seizures, tachycardia, vomiting. Death is usually secondary to arrhythmias, circulatory collapse, or respiratory failure.

Admission Criteria/Prognosis Asymptomatic patients with normal electrocardiogram and electrolytes can be discharged after a 12-hour observation; any symptomatic patient should be admitted to a cardiac monitor bed; patients who are symptomatic 3 hours postexposure should be admitted

Toxicodynamics/Kinetics Onset of symptoms: Generally within 1-3 hours; in large ingestions, cardiovascular collapse can occur within 30 minutes

Reference Range Postmortem 3,5-dimethoxyphenol blood and bile levels of 21 ng/mL and 104 ng/mL, respectively, were noted in a male who died of yew toxicity.

Overdosage/Treatment

Decontamination: Ipecac is contraindicated secondary to rapid onset of symptoms; lavage is of questionable benefit, due to the large size of the seeds, unless the seeds are chewed well; activated charcoal with sorbitol is recommended; **do not** consider gastric decontamination if fewer than 6 berries are ingested; whole bowel irrigation is beneficial for ingestions of large amounts of plant material

Supportive therapy: Hypotension can be resistant to dopamine and dobutamine, and may require norepinephrine; bradycardia and complete heart block has on occasion been resistant to atropine; external pacing and/or digoxin immune Fab may be of benefit; monitor electrolytes; anaphylactoid reactions should be treated with epinephrine, antihistamines and fluids. Dysrhythmias with widened QRS complex should be treated with I.V. sodium bicarbonate.

Antidote(s)

- Digoxin Immune Fab [ANTIDOTE]
- Norepinephrine [ANTIDOTE]

Additional Information

Literature suggests that <6 berries produce minimal symptoms, and ingestion of 150 leaves can produce death within 5 hours; LD₅₀ in mice and rats is ~20 mg/kg. Red aril is not toxic; ingestion of 150 yew leaves has been fatal; ingestion of intact berries may cause only mild GI symptoms.

Family: Taxaceae. Range: The Yew genus occurs in many areas of the world, however in the U.S., it is located deep in the woods of Western North Carolina to the North Central and Northeastern U.S. Toxin: Taxine

SECTION IV
HERBAL AGENTS

Achyranthes Aspera

Synonyms Abora; Mnyoli; Muyon; Nara

Uses Chinese folk medicine used as an antipyretic/anti-inflammatory agent and diuretic. Also used for treatment of constipation, malaria, bronchitis, and sprains.

Mechanism of Toxic Action Contains saponins which are cardiotoxic by inhibition of cyclic adenosine 3', 5' monophosphate (CAMP) phosphodiesterase; also exhibits muscarinic acetylcholine inhibition; contains achyranthine

Signs and Symptoms of Overdose Hypotension, coma, bradycardia, hypoactive bowel sounds

Admission Criteria/Prognosis Admit ingestion over 1000 mL of decoction or any symptomatic patient.

Overdosage/Treatment

Decontamination: Oral: Lavage within 1 hour/activated charcoal

Supportive therapy: Hypotension can be treated with intravenous crystalloid solutions. Dopamine (8-12 mcg/kg/minute) can be used as a vasopressor.

Additional Information A perennial herb 1.5-5 feet tall found in Africa. Single green to pink ovate flower with small (2.5-3 mm) fruit; lance-shaped leaves

Specific References

Han ST and Un CC, "Cardiac Toxicity Caused by Achyranthes Aspera," *Vet Hum Toxicol*, 2003, 45(4):212-3.

Ajuga Nipponensis Makino

Use Antitussive, expectorant, diuretic, anti-inflammatory, hepatoprotection

Mechanism of Action Contains cyasterone and ajugasterone which may exhibit inhibitory effects on TPA-induced tumor promotion; may be nephrotoxic

Signs and Symptoms of Overdose Vomiting, diarrhea, anorexia, renal failure, hyponatremia, oliguria, weakness

Dosage Possibly toxic dosage: 30 g of fresh plant mixed in 100 g of water

Overdosage/Treatment

Oral:

Decontamination: Activated charcoal is of unknown efficacy

Supportive care: Monitor electrolytes/renal status

Additional Information Usually found North and West of Taiwan; leaves are oval shaped (3-7 cm long) with white petal blossoms in summer and autumn; grows in sandy soil near the sea

Specific References

Liao SC, Chiu TF, Chen JC, et al, "Ajuga Nipponensis Makino Poisoning," *Clin Toxicol*, 2005, 43(6):583-5.

Arnica Flower

Scientific Name *Arnica chamissonis*; *Arnica latifolia*; *Arnica montana*

Synonyms Leopard's Bane; Mountain Snuff; Mountain Tobacco

Uses For external topical use in treatment of minor trauma (bruises, contusions, hematomas). Not to be taken for internal use.

Mechanism of Toxic Action Contains several flavonoid glycosides and sesquiterpene lactones along with coumarins (scopoletin and umbelliferone) and volatile oils. The sesquiterpene lactones exhibit a slight anti-inflammatory and analgesic effect.

Adverse Reactions Dermatologic: Contact dermatitis, eczema

Signs and Symptoms of Overdose A 1 oz ingestion can cause mucous membrane irritation which can result in abdominal pain, vomiting, and diarrhea. Dyspnea and cardiac arrest can occur.

Dosage Ointment: Apply topically, not more than 25% tincture or more than 15% "arnica oil". Do not use for prolonged therapy or on damaged skin. One suggested dose is use of 1 tablespoon of arnica tincture in 500 mL of cold water applied to the affected area several times daily. A patch test may be necessary to denote allergy to arnica.

Overdosage/Treatment **Oral:** If >1 oz is ingested, gastric lavage followed by activated charcoal should be given; otherwise, dilute with water. **Dermal, topical:** Irrigate with soap and water.

Additional Information A perennial bright daisy-like flower which grows up to 2 feet in Europe and Southern Russia.

Autumn Crocus

Related Information

- Colchicine

CAS Number 64-86-8

Scientific Name *Colchicum autumnale*

Synonyms Fall Crocus; Meadow Crocus; Meadow Saffron; Mysteria; Wonderbulb

Uses Colchicine has been used for centuries to treat gout and rheumatism

Mechanism of Toxic Action Inhibits cell division by blocking spindle formation and inhibiting mitosis; cells with high turnover rates are most affected

Adverse Reactions

Central nervous system: Hyperthermia, sedation

Dermatologic: Skin alterations and alopecia (with prolonged use)

Gastrointestinal: Diarrhea, nausea, vomiting, abdominal pain

Hematologic: Leukopenia, agranulocytosis and aplastic anemia (with prolonged use)

Neuromuscular & skeletal: Myopathy (with prolonged use)

Signs and Symptoms of Overdose

1st phase: 2-24 hours postexposure: Abdominal pain, electrolyte abnormalities, hypotension, nausea, vomiting and diarrhea resulting in hypovolemia; peripheral leukocytosis has been reported

2nd phase: 1-7 days postexposure: Bone marrow depression, coagulopathy, multisystem failure, mental status changes, oliguric renal failure, paresthesia, proteinuria, pulmonary edema, respiratory failure, sudden asystole

3rd phase: 7 or more days: Alopecia and rebound leukocytosis

Toxicodynamics/Kinetics

Absorption: Rapid with peak levels occurring in 30 minutes to 2 hours

Distribution: V_d : 2 L/kg; distributed within 30 minutes; deacetylated in the liver and both colchicine and its metabolites undergo enterohepatic recirculation

Protein binding: Weak, 10% to 30%

Dosage

As little as 7-8 mg of colchicine have resulted in fatalities; ingestion of 12 flowers of *Colchicum autumnale* has caused death; colchicine ingestions ≥ 0.5 mg/kg are associated with severe poisoning and death

Per Commission E: Therapeutic dosage for acute gout attack: Initial: Oral: 1 mg colchicine, followed by 0.5-1.5 mg every 1-2 hours until pain subsides; total daily dosage must not exceed 8 mg colchicine

Overdosage/Treatment

Decontamination: Lavage (within 1 hour) may be indicated if performed prior to the onset of symptoms; multiple dose activated charcoal should be of value; one dose of a cathartic may be used if administered prior to the onset of symptoms; due to the delay in the onset of toxicity, asymptomatic patients should be observed for at least 12 hours

Supportive therapy: Aggressive supportive therapy may be required in symptomatic patients; this includes fluid and electrolyte replacement and respiratory support. Hypotension unresponsive to fluids should be treated with dopamine or norepinephrine.

Enhancement of elimination: Hemodialysis and exchange transfusions have not been useful and are not recommended

Antidote(s)

- DOPamine [ANTIDOTE]
- Epinephrine [ANTIDOTE]

Test Interactions Colchicine decreases serum cholesterol levels; may interfere with some urine steroid tests

Drug Interaction None known with this plant (as per Commission E); colchicine therapy can increase cyclosporine levels

Pregnancy Risk Factor Contraindicated by Commission E

Additional Information Nasal insufflation can result in toxicity. Toxic parts: Entire plant. Colchicine concentrations range from 0.1% in the flowers to 0.8% in the seeds. Family: Liliaceae; Toxin: Colchicine and related alkaloids. Range: Native to Europe, widely cultivated in the U.S. Not sold in U.S. herb/dietary supplement market; use is pharmaceutical only for production of colchicine

Specific References

Gabrscek L, Lesnicar G, Krivec B, et al, "Accidental Poisoning with Autumn Crocus," *J Toxicol Clin Toxicol*, 2004, 42(1):85-8.

Ayahuasca

Scientific Name *Banisteriopsis* species

Synonyms Caapi; Daime; Hoasca; Lagé; Yajé

Use Religious purposes in South America (as a sacrament)

Mechanism of Action Derived from the woody vine *Banisteriopsis caapi*; this tea contains harmala alkaloids which reversibly inhibit monoamine oxidase type-A; contains N,N dimethyltryptamine (DMT) which acts as a psychotrope; the leaves of the plant *Psychotria viridia* may also be added to the tea

Adverse Reactions Central nervous system: Hallucinations

Toxicodynamics/Kinetics Peak plasma levels (DMT): Oral: 60 minutes: I.V.: 2 minutes

Dosage 2 mL/kg of the tea

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage within 60 minutes/activated charcoal with cathartic

Supportive therapy: Benzodiazepines may be useful for sedation

Drug Interactions Although this interaction has not been described, use of this tea with specific serotonin reuptake inhibitors may precipitate the serotonin syndrome

Additional Information Average levels of DMT and tetrahydroharmine following a dose of 2 mL/kg: ~15.8 ng/mL and 90.8 ng/mL respectively

BETEL NUT

Betel Nut

Scientific Name *Areca catechu*

U.S. Brand Names Sting (Tantric Corporation)

Synonyms Quids

Uses Often chewed with betel leaves and lime slake for mood elevation. Used in India, Pakistan, Bangladesh, China, New Guinea, Sri Lanka, Singapore, Thailand, and Taiwan. Also used for pain control, as a masticatory.

Mechanism of Toxic Action Contains six reduced pyridine alkaloids which may be carcinogenic. Also, the unroasted betel nut contains arecoline which is a cholinergic agent. Roasting the betel nut converts arecoline to arecaine which is far less toxic. CNS depression may occur by inhibiting uptake of gamma-aminobutyric acid.

Adverse Reactions

Cardiovascular: **Palpitations** (45% to 50%), tachycardia (within 6 minutes of use; lasts ~17 minutes), hypotension; supraventricular tachycardia has been described

Central nervous system: **Dizziness** (70%)

Gastrointestinal: Oral cancer, vomiting, leukoplakia (chronic use), dark brown staining of teeth

Ocular: Miosis, blurred vision

Renal: Milk alkali syndrome

Respiratory: Wheezing, bronchoconstriction, dyspnea; pulmonary edema with high dosage

Miscellaneous: Diaphoresis (on first use)

Dosage Less than three nuts are usually chewed in combination with slaked lime, tobacco, clove, or cinnamon.

Overdosage/Treatment

Decontamination: Lavage within 1 hour. Activated charcoal can be given. Supportive therapy: For bronchoconstriction, aerosolized beta-agonists with steroids and ipratropium should be given. Supraventricular tachycardia has been treated with verapamil (1-5 mg I.V.). Diazepam (5 mg I.V.) can be used for agitation.

Drug Interaction Use with alcohol may accentuate cardiac abnormalities.

Additional Information Betel nut is the ripe seed of the palm tree *Areca catechu*. An estimated 600 million people worldwide (15% of the world's population) use it daily. The *Areca* palm tree grows up to 100 feet tall with a thin (6 inch) trunk; native to Malaysia, the fruit of this tree is about the size and shape of a hen's egg.

Specific References

Kumar M, Kannan A, and Upreti RK, "Effect of Betel/Areca Nut (*Areca catechu*) Extracts on Intestinal Epithelial Cell Lining," *Vet Hum Toxicol*, 2000, 42(5):257-60.

Overdosage/Treatment Decontamination: Ipecac or lavage within 1 hour of any ingestion >200 mg of extract. Activated charcoal is of unknown utility.

Drug Interaction May augment antiproliferative effect of tamoxifen.

Additional Information Tall upright perennial herb (3-8 feet tall), native to eastern United States. Roots and leaves are most toxic parts. Fruit is ovoid with flat seeds.

Specific References

Hernández MG and Pluchino S, "*Cimicifuga racemosa* for the Treatment of Hot Flashes in Women Surviving Breast Cancer," *Maturitas*, 2003, 44(Suppl 1):S59-65.

Buckthorn Bark

Related Information

- Cascara Sagrada
- Senna

Scientific Name *Rhamnus alnifolia*; *Rhamnus cathartica*; *Rhamnus frangula*

APHA Botanical Safety Rating System Class 2b, 2c, 2d

Synonyms Alder Buckthorn; Arrow Wood; Berry Alder; Black Dogwood; Frangula; Hart's Horn; Maythorn; Persian Berry; Purging Buckthorn

Uses Laxative

Mechanism of Toxic Action Contains frangulin, an anthraquinone which stimulates the colon

Adverse Reactions

Per Commission E:

Endocrine & metabolic: Long-term use/abuse can cause electrolyte imbalance

Gastrointestinal: In single incidents, cramp-like discomforts of gastrointestinal tract requiring a reduction in dosage

Signs and Symptoms of Overdose Abortifacient; could potentially cause kidney damage with a large enough ingestion; abdominal pain, cramping, diarrhea, nausea, vomiting

Toxicodynamics/Kinetics Onset is likely soon after ingestion

Dosage 1 g; mild intoxication upon ingestion of berries by children; apparently ingestion of ~20 berries or chewing the fresh bark is necessary to induce pronounced symptoms;

Per Commission E: 20-30 mg hydroxyanthracene derivatives, calculated as glycofrangulin A

Warnings Use of two stimulating laxatives longer than recommended can cause intestinal sluggishness per Commission E

Overdosage/Treatment

Decontamination: Ipecac/cathartic not recommended, activated charcoal/lavage (within 1 hour) may be useful

Supportive therapy: Treat any fluid or electrolyte imbalance

Drug Interaction Per Commission E: Potentiation of cardiac glycosides (with long-term use) is possible due to loss in potassium; effect on anti-arrhythmics is possible; potassium deficiency can be increased by simultaneous application of thiazide diuretics, corticosteroids, and licorice root

Additional Information May color alkaline urine red; do not confuse with hematuria; bark should be aged 1 year in order to decrease harsh laxative action; berry (fruit) also used in Germany. Toxic parts: Fruit, leaves, and bark

Bilberry

Scientific Name *Vaccinium myrtillus*

U.S. Brand Names Alcodin®; Antocin®; Difrarel®; Largaritor®; Myrataven®; Myrticol®; Retinol®; Tegens®

Synonyms Bog Bilberries; Myrtillus; Whortleberries

Uses In herbal medicine, dried fruits are used as a diuretic and astringent; also used to treat diarrhea; antiulcer effect may also prevent cataracts or macular degeneration

Mechanism of Toxic Action Anthocyanidin pigment increases gastric mucosal release of prostaglandin E2

Signs and Symptoms of Overdose Hypotension (secondary to vasodilatation)

Dosage Oral: 240-480 mg extract standardized to 25% anthocyanosides in 2-3 doses

Overdosage/Treatment Decontamination: Oral: Dilute with milk or water; activated charcoal with cathartic may be used

Additional Information See Commission E; blue/blackberries are edible and have a sweet taste; a European plant whose leaves are utilized in teas

Black Cohosh

Scientific Name *Cimicifuga racemosa*

U.S. Brand Names Remifemin (an ethanolic extract of the rhizome)

Uses Alleviate perimenopausal and postmenopausal symptoms; also used for premenstrual discomfort and dysmenorrhea

Mechanism of Toxic Action Contains triterpene glycosides which exhibit estrogenic effects and suppression of luteinizing hormone with no effect on follicle-stimulating hormone or prolactin. Also contains isoflavone and formononetin, which may bind to estrogen receptors.

Adverse Reactions

Cardiovascular: Plants have been known to cause bradycardia and hypotension

Central nervous system: Dizziness, tremor

Endocrine & metabolic: Abortifacient

Gastrointestinal: GI discomfort (7%)

Dosage Each 20 mg of Remifemin contains 1 mg of triterpene 27-deoxyacetin. Current dosage is 20 mg Remifemin twice daily for menopausal symptoms.

Cascara Sagrada

Related Information

- Buckthorn Bark
- Senna

CAS Number 8015-89-2; 8047-27-6

Scientific Name *Rhamnus purshiana*

APHA Botanical Safety Rating System Class 2b, 2c, 2d

U.S. Brand Names Brevilax®; Colamin®; Legapas® 100; Péristaline®; Sagrada-Lax®

Uses Laxative

Mechanism of Toxic Action Contains anthraquinone glycosides (>8%) called cascariosides A, B, C and D which can increase colonic motility

Adverse Reactions

Central nervous system: Dizziness

Per Commission E:

Endocrine & metabolic: Long-term use/abuse can cause electrolyte imbalance

Gastrointestinal: In single incidents, cramp-like discomforts of GI tract requiring a reduction in dosage

Toxicodynamics/Kinetics

Onset of laxative effect: 6-8 hours

Metabolism: Hydrolyzed by colonic bacteria to active ingredients

Dosage Oral:

Bitter cascara, fluid extract: 1 mL

Aromatic cascara sagrada: 5 mL

Cascara sagrada extract (tablet): 325 mg at bedtime

Powdered bark (capsule): 1 g (1/2 teaspoon)

Per Commission E: 20-30 mg hydroxyanthracene derivatives, calculated as glycofrangulin A

Overdosage/Treatment Decontamination: **Do not** induce emesis; lavage (within 1 hour)/activated charcoal can be used

Drug Interaction Per Commission E: Potentiation of cardiac glycosides (with long-term use) is possible due to loss in potassium; effect on antiarrhythmics is possible; potassium deficiency can be increased by simultaneous application of thiazide diuretics, corticosteroids, and licorice root

Pregnancy Risk Factor C

Additional Information A deciduous tree (grows to 12 feet) native to Pacific Northwest with small green flowers (in clusters); like buckthorn, the bark should be aged 1 year to decrease the harsh laxative effects

Catnip

Scientific Name *Nepeta cataria*

Synonyms Cat's Play; Cataria; Catmint; Catnep; Catrup; Catswort; Field Balm; Nip

Uses Antidiarrheal, antipyretic, carminative, menstrual cramps, sedative. Used for colic in infants (as an enema). Also used to treat migraine. Tea has a diuretic effect.

Mechanism of Toxic Action Contains nepetalactone (80% to 95%) and tannin substances which may cause central nervous system stimulation and hallucinations.

Signs and Symptoms of Overdose Headache, malaise, vomiting. Symptoms usually last a few hours.

Dosage Tea: Two teaspoons of ground or dried forms mixed in 1 L of water to prepare tea; can drink 2-3 cups/day.

Tincture: 0.5-1 teaspoon up to 3 times/day

Overdosage/Treatment

Decontamination: Oral activated charcoal may be effective.

Supportive therapy: Symptomatic treatment: Diazepam (0.1-0.3 mg/kg in children or 10 mg in adults) may be used to treat hallucinations.

Additional Information Native in Europe. Active agents are found in the aerial parts of this 1 meter tall perennial plant with 2-8 cm leaves. Not recommended in Commission E. Dried leaves have also been smoked as a "joint" or in a pipe. Mint-like odor.

Chamomile

Scientific Name *Anthemis nobilis*; *Chamaemelum nobile*; *Chamomilla recutita*; *Matricaria chamomilla*; *Matricaria recutita* L.

APHA Botanical Safety Rating System Class 1

Synonyms *Matricaria chamomilla*; *Matricaria recutita*

Uses Topical anti-inflammatory agent; the tea (which may contain 10% to 15% of the volatile oil) has been used for indigestion and its hypnotic properties; used to flavor cigarette tobacco

Mechanism of Action

Pharmacologic activities include antispasmodic, anti-inflammatory, antilucer, and antibacterial effects; a sedative effect has also been documented. While the toxicity of its main chemical constituent (Bisabolol) is low, the tea is essentially prepared from various allergens (ie, pollen-laden flower heads) which can cause hypersensitivity reactions especially in atopic individuals; contains various flavonoids (apigenin, herniarin)

Adverse Reactions

Only 5-7 cases have been reported in California, 100 years of the medical literature, associated with those with severe ragweed allergies. Dermatologic: Contact dermatitis, immunologic contact urticaria. Gastrointestinal: Vomiting (from dried flowering heads). Miscellaneous: Anaphylaxis

Dosage

Tea: ±150 mL H₂O poured of heaping tablespoon (±3 g) of herb, covered and steeped 5-10 minutes; tea used 3-4 times/day for G.I. upset

Contraindications Known hypersensitivity to *Asteraceae/Compositae* family

Dosage Forms Ointment:

Reference Range Peak blood level of herniarin: ~35 ng/mL ~1 hour after an oral dose of 40 mL

Overdosage/Treatment Supportive therapy: Treat allergic reactions with standard therapy (ie, epinephrine, antihistamines, vasopressors if required)

Drug Interactions

May increase effect of coumarin-type anticoagulants at high dosages. Tannin-containing herbs can cause a decrease in iron absorption.

Pregnancy Implications Excessive use should be avoided due to potential teratogenicity

Additional Information See Commission E; cross sensitivity may occur in individuals allergic to ragweed pollens, asters or chrysanthemums

Chaparral

Scientific Name *Larrea tridentata*

APHA Botanical Safety Rating System

Class 2d; not to be used in large amounts by persons with pre-existing kidney disease and liver conditions (eg, hepatitis and cirrhosis)

Synonyms *Larrea tridentata*; Creosote bush; Greasewood; Hediollida

Use Herbal medicine to treat acne, bowel cramps, analgesic agent and to "retard aging" (not substantiated)

Mechanism of Action Contains a potent antioxidant (nordihydroguaiaretic acid or NDGA) which inhibits lipoxygenase and cyclo-oxygenase pathways

Adverse Reactions

Dermatologic: Contact dermatitis

Gastrointestinal: Anorexia

Hematologic: Coagulopathy

Hepatic: Lobular necrosis, jaundice, aminotransferase level elevation (asymptomatic)

Miscellaneous: Necrosis

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal with cathartic

Supportive therapy: Orthotopic liver transplantation may be required to treat liver failure

Additional Information A branched bush or shrub that is olive green and can grow to a height of 9 feet in the desert regions of Southwestern U.S. and Mexico. Approximately 200 tons of chaparral were sold in the U.S. for use as teas and herbal dietary supplements in the 20 years from 1973-1993, according to informal herb industry estimates. Few adverse reactions were reported during this period. A medical review by three physicians of patient records obtained from FDA regarding hepatitis associated with chaparral ingestion could not definitively conclude that chaparral was the causative agent. Idiosyncratic reactions were suggested.

Chaste Tree

Scientific Name *Vitex agnus-castus*

APHA Botanical Safety Rating System Class 2b; may counteract the effectiveness of birth control pills

Synonyms *Vitex agnus-castus*

Uses In herbal medicine, it is used in treatment of menstrual disorders, premenstrual syndrome and mastodynia

Mechanism of Action The fruit (actually a drupe) contains triterpenoids which may have dopaminergic properties, thus decreasing prolactin secretion

Adverse Reactions

Dermatologic: Pruritus, rash, hives, urticaria

Endocrine & metabolic: Decreased prolactin level

Dosage As a concentrated alcoholic extract: ~20 mg/day

Per Commission E: Average daily dose: 3 g herb or equivalent preparations

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic. Supportive therapy: Antihistamines can be used to treat pruritus although there is no data on this modality

Drug Interactions None known per Commission E but may counteract the effectiveness of birth control pills

Additional Information A small deciduous multitrunk tree which can grow up to 25 feet; native to Mediterranean region with flowers blooming in summer; the dried ripe fruit (which is brown/black with a pepperish flavor or aroma) contains the active chemical ingredients

Cleistanthus Collinus

Synonyms Oduvan

Uses Extract of crushed leaves used as a cattle/fish poison or abortifacient

Mechanism of Toxic Action Toxic constituents are dyphyllin and its glycosides (cleistanthin A and cleistanthin B) and collinusin which are irritants. Can induce DNA damage or apoptosis and may reduce or inhibit thiol/thiol-containing enzymes (specifically lactate dehydrogenase or cholinesterase). May cause glutathione depletion.

Signs and Symptoms of Overdose Leukocytosis, hypokalemia (72%), renal failure (30%), weakness, prolonged QT_c interval, inverted T waves, premature ventricular complexes, respiratory failure, elevated hepatic transaminases, hypotension, metabolic acidosis (high anion gap), hyperchloremia, coagulopathy, proteinuria, alkaline urinary pH, ptosis, mydriasis, hyporeflexia

Overdosage/Treatment

Decontamination: Lavage within 2 hours/activated charcoal

Supportive therapy: Hypotension can be treated with intravenous crystalloids. Vasopressor of choice is dopamine or norepinephrine. Monitor and replace potassium as needed. Sodium bicarbonate (1-2 mEq/kg) to treat acidosis. N-acetylcysteine may be of hepatoprotective benefit.

Additional Information A plant found in India, Malaysia, and Africa

Specific References

Eswarappa S, Chakraborty AR, Palatty BU, et al, "Cleistanthus Collinus Poisoning: Case Reports and Review of the Literature," *J Toxicol Clin Toxicol*, 2003, 41(4):369-72.

CLOVE

Clove

Scientific Name *Caryophyllus aromaticus*; *Eugenia caryophyllata*
Syzygium aromaticum

APHA Botanical Safety Rating System Class 1 (clove bud not oil)

Synonyms Caryoph; Eugenol; Oil of Cloves; Pentogen (clove oil); Tropical Myrtle

Use

Applied topically to alleviate toothache

Carminative; flavoring agent; clove oil contains 85% to 92% eugenol which is effective as a local anesthetic and anesthetic in dentistry; soap fragrance

Mechanism of Toxic Action Eugenol acts similarly to other phenol agents by inhibiting prostaglandin synthesis and causing depression of pain receptors; can also cause uncoupling of oxidative phosphorylation

Adverse Reactions

Dermatologic: Dermatitis, urticaria

Endocrine & metabolic: Hypoglycemia, metabolic acidosis

Gastrointestinal: Vomiting

Hematologic: Disseminated intravascular coagulation

Hepatic: Hepatotoxicity

Ocular: Lacrimation

Renal: Proteinuria

Respiratory: Pulmonary edema (when injected)

Miscellaneous: Anaphylaxis, anhidrosis

Clove cigarettes:

Gastrointestinal: Sore throat

Respiratory: Bronchospasm, hemoptysis, pulmonary edema, epistaxis, bronchiectasis, pleural effusion

Toxicodynamics/Kinetics Metabolism: Hepatic

Dosage

Clove oil:

Oral: Toxic dose: Infant: 15 mL (500 mg/kg of eugenol); oil is not used therapeutically in concentrations >0.06%

Therapeutic: 1-2 drops on tooth cavity not more than 4 times/day

Warnings Per Commission E: Oil:

Oral: Alcoholism, anticoagulants, hemophilia, kidney disease, paracetamol, prostatic cancer, SLE

Dermal: Hypersensitive, diseased or damaged skin, all children <2 years of age

Oil in concentrated form may irritate mucous membranes

Dosage Forms Liquid: 3.75 mL

Overdosage/Treatment

Decontamination:

Oral: Dilute with milk or water; activated charcoal with cathartic may be given; endoscopy may be required within 1 day of ingestion to assess local gastrointestinal mucosal injury

Ocular: Irrigate copiously with saline

Supportive therapy: Anaphylaxis should be treated with epinephrine, diphenhydramine and corticosteroids; beta-adrenergic agonist agents can be used for bronchospasm; while the use of N-acetylcysteine has been proposed (due to the common metabolic pathways of acetaminophen and eugenol), this modality has not been studied in humans; disseminated intravascular coagulopathy (DIC) can be treated with vitamin K, fresh frozen plasma, heparin and factor VII with protein C, and antithrombin III

Additional Information The clove tree grows to ~30 feet and is found in warm climates in the Molucca Islands. The stems, buds and leaves can yield clove oil. Acceptable daily oral intake of eugenol: 2.5 mg/kg. Level of clove in foods does not exceed 0.236%. Clove cigarettes ("Kreteks") contain 60% tobacco and 40% ground clove. The primary components of clove cigarette smoke include eugenol (13 mg), beta-caryophyllene (1.2 mg), eugenol acetate (0.7 mg), alpha-humulene (0.16 mg), and caryophyllene-epoxide (<0.1 mg).

Specific References

Coltsfoot

Scientific Name *Tussilago farfara*

Synonyms Cough Plant; Coughwort; Horse Foot; Horse Hoof

Uses Coughs/bronchial congestion/respiratory infections; antitussive agent banned in Canada

Mechanism of Toxic Action Contains pyrrolizidine alkaloid senkirkine (0.015%) which is a hepatic carcinogen. While young preblossoming flowers contain the highest amount of this agent, senkirkine is also found in its leaves. May also suppress platelet activating factor (or PAF).

Adverse Reactions While toxicity has not been described in humans, hepatic veno-occlusive disease and hemangioendothelial sarcoma of the liver has been described in laboratory rodents. Classified by the FDA as a herb of undefined safety.

Dosage Per Commission E: 4 g, 5 g, or 6 g of drug (dried herb) daily; not to exceed 10 mcg pyrrolizidine alkaloids with 1,2 unsaturated necine structure including their N-oxides. Not longer than 4-6 weeks per year.

Overdosage/Treatment Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal with cathartic; be aggressive in gastric decontamination in children

Additional Information A low, woolly perennial herb with solitary terminal yellow flowers and basal leaves which appear after flowering. Plant is native in Europe but found in northern U.S. and southern Canada. Flowers and leaves have been used for herbal medicine, particularly in Europe. Monitor liver function tests.

Comfrey

Scientific Name *Symphytum officinale*

APHA Botanical Safety Rating System

Class 2a: *Symphytum uplandicum* (Russian Comfrey): External use only, except under supervision of a qualified expert

Class 2a, 2b, 2c: *Symphytum officinale* (Common Comfrey)

U.S. Brand Names Traumaplant®

Synonyms Blackwort; Bruisewort; Bum Plant; Green Drink; Knitbone; Russian Comfrey; Slippery Root

Uses External use in herbal medicine for wound healing

Mechanism of Toxic Action Contains hepatotoxic pyrrolizidine alkaloids with the highest concentration occurring in the root

Adverse Reactions Hepatic: Hepatotoxicity, hepatic veno-occlusive disease, hepatic necrosis, ascites, jaundice

Dosage Per Commission E: External use should not exceed 100 mcg/day equivalent of pyrrolizidine alkaloid content with 1,2-unsaturated necine structure, including their N-oxides

Overdosage/Treatment Decontamination: Ipecac within 30 minutes or lavage within 1 hour; activated charcoal with cathartic

Additional Information A perennial with bell-shaped yellow or rose flowers (~1 cm long); plant grows to a height of 3 feet in moist grasslands; liver damage is dose dependent; causes liver and pancreatic tumors in animals. Unfortunately, the comfrey products (made from roots and/or leaves) sold in U.S. are not assayed for PA content, as they are in Germany. The American Herbal Products Association has voluntarily restricted its members from selling comfrey for internal use.

Cottonseed

Synonyms *Gossypium*; Gossypol; Mian Hua Gam

Uses Has been used as a male antifertility agent in China at doses from 75-100 mg twice monthly (~3 g/year). Spermatogenesis usually normalizes after 3 months postdiscontinuation, although the inhibition of spermatogenesis may be long-term in 20% of males.

Mechanism of Toxic Action Cottonseed (family: Malvaceae) contains from 0.1% to 6.6% gossypol (a yellowish binaphthol compound) which is a nonsteroidal agent that inhibits human sperm motility and production, by inhibition of the gonadal enzyme lactate dehydrogenase X. There are no hormonal abnormalities noted, with testicular mitochondria being the target organ.

Signs and Symptoms of Overdose Amenorrhea, anorexia; azoospermia, oligospermia; doses >2 g may cause diarrhea and heart failure; fatigue (13%) and decreased libido (7%) have been observed; hypokalemia can occur due to renal potassium loss

Admission Criteria/Prognosis Admit any ingestion >1 g

Toxicodynamics/Kinetics Half-life: 286 hours

Monitoring Parameters Serum potassium

Reference Range Peak plasma gossypol level 5 hours after a 20 mg oral dose: ~996 ng/mL

Overdosage/Treatment

Decontamination: Any ingestion >20 mg in adults: Ipecac or lavage within 1 hour

Supportive therapy: Monitor serum potassium; potassium supplementation may be necessary

Drug Interaction May enhance the androgenic effect of methyltestosterone; hypokalemia may be exacerbated when gossypol is given with diuretic agents

Creatine Monohydrate

Synonyms Methyl Guanidine-Acetic Acid

Uses Reportedly can increase performance in short-duration, high-intensity, repetitive (isokinetic) muscle actions (ie, weightlifting, rowing); not useful for endurance

Mechanism of Toxic Action

Reportably increases adenosine triphosphate levels by acting as a substrate for creatine kinase.

May also enhance actin/myosin production in muscles.

Adverse Reactions

Endocrine & metabolic: Water retention
 Gastrointestinal: Weight gain (up to 5 lb), abdominal cramps, diarrhea
 Neuromuscular & skeletal: Myalgia
 Renal: Renal dysfunction, proteinuria

Toxicodynamics/Kinetics Elimination: In urine as creatinine

Dosage Loading dose of 5 g 4 times/day (0.3 g/kg) for 5-9 days followed by a maintenance dose of 2-5 g/day for up to 8 weeks

Overdosage/Treatment Decontamination: No reports of acute adverse effects in overdosage situation. Suggest gastric decontamination (ipecac or lavage) for ingestions > 1 g/kg. Monitor BUN.

Test Interactions No effect on serum creatinine, although BUN increase may be seen; CPK may be elevated

Additional Information Total body creatine pool is 120 g (95% in skeletal muscle). Average daily dietary intake is 1 g/day. Red meat, tuna, cod, salmon, herring, beef, and pork have the highest amount of creatine. 1 kg of raw steak contains almost 4 g of creatine. Endogenous creatine (~2 g/day) is synthesized in the liver, kidneys, and pancreas from glycine, arginine, and methionine.

Echinacea

Scientific Name *Echinacea angustifolia*; *Echinacea pallida*; *Echinacea purpurea*

APHA Botanical Safety Rating System Class 1

U.S. Brand Names Echinaguard®; Echinase®; Super Echinacea®

Synonyms *Echinacea angustifolia*; American Coneflower; Black Sampson; Black Susans; Comb Flower; Coneflower; Indian Head; Purple Coneflower; Scurvy Root; Scurry Root; American Coneflower; Snakeroot

Use Prophylaxis and treatment of cold and flu; also used as an immunostimulant in herbal medicine; used to treat minor upper respiratory tract infections, urinary tract infections, wound/skin infections, arthritis, vaginal yeast infections

Mechanism of Action Contains a caffeic acid glycoside named echinacoside (0.1% concentration) which is bactericidal. Other caffeic acid glycosides and isolutylamides associated with the plant can cause immune stimulation by increasing leukocyte phagocytosis and promoting T-cell activation. Also has an antihyaluronidase and anti-inflammatory activity; constituents have been associated with antitumor, antispasmodic effects

Adverse Reactions

Central nervous system: Fever
 Gastrointestinal: Tingling sensation of tongue, nausea, vomiting
 Hematologic: Leukocytosis
 Miscellaneous: Allergic reactions (rarely)
 Per Commission E: None known for oral and external use

Dosage

Capsule/tablet or tea form: 500 mg to 2 g 3 times/day
 May be applied topically
 Continuous use should not exceed 8 weeks
 Per Commission E: Expressed juice (of fresh herb): 6-9 mL/day

Contraindications Autoimmune diseases, such as collagen vascular disease (Lupus, RA), multiple sclerosis; allergy to sunflowers, daisies, ragweed; tuberculosis, HIV, AIDS, pregnancy, breast-feeding; parenteral administration only contraindicated per Commission E; oral use of *Echinacea* not contraindicated during pregnancy by Commission E

Overdosage/Treatment Supportive therapy: Can treat allergic manifestations with an antihistamine

Drug Interactions

Theoretically may alter response to immunosuppressive therapy
 Avoid using with other hepatotoxic agents (anabolic steroids, amiodarone, methotrexate, or ketoconazole)

Additional Information Commission E only approves *E. purpurea* fresh juice from leaves and herb, and *E. pallida* root preparations; persons allergic to sunflowers may display cross-allergy potential with this herb; a perennial daisy-like flowering plant 2-5 feet high usually found in the midwest and southeastern United States; contraindications in tuberculosis, leukocytosis, collagen vascular disease, multiple sclerosis, tachyphylaxis can occur if used > 8 weeks

Ephedra

Related Information

- Ephedrine

Scientific Name Consists of dried young branches of *Ephedra sinica*, *Ephedra equisetina*, and *Ephedra Gerardiana*

APHA Botanical Safety Rating System Class 2b, 2c, 2d; contraindicated in anorexia, bulimia, glaucoma, and persons with thyroid imbalance; not recommended for long-term use

U.S. Brand Names Cloud 9; Ultimate Xphoria

Synonyms *Ephedra sinica*; Joint Fir; Ma-Huang; Mormon Tea; Poptillo; Sea Grape; Squaw Tea; Teamsters' Tea; Yellow Horse

Use Herbal medicinal uses include treatment for asthma, bronchitis, edema, arthritis, headache, fever, urticaria; also used for weight reduction and for euphoria

Mechanism of Action An alpha- and beta-adrenergic stimulant; most species contain ephedrine and/or pseudoephedrine although *E. nevadensis* may not contain any ephedrine; tannin contributes to its bitter taste

Adverse Reactions

Cardiovascular: Hypertension, cardiomyopathy, vasculitis, cardiomegaly, palpitations, vasoconstriction, tachycardia, myocarditis

Central nervous system: CNS-stimulating effects, **nervousness**, anxiety, fear, psychosis, tension, agitation, excitation, **restlessness**, irritability, **insomnia**, auditory and visual hallucinations, sympathetic storm, headache

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Nausea, anorexia

Hepatic: Aminotransferase level elevation (asymptomatic)

Neuromuscular & skeletal: Tremors, weakness

Signs and Symptoms of Overdose CNS depression, depression, dry skin, dysrhythmias, insomnia, mydriasis, respiratory alkalosis, respiratory depression, seizures, vomiting

Dosage

E. sinica extracts (with 10% alkaloid content): 125-250 mg 3 times/day
 As a tea: Steeping 1 heaping teaspoon in 240 mL of boiling water for 10 minutes (equivalent to 15-30 mg of ephedrine)

Per Commission E: Single dose: Herb preparation corresponds to 15-30 mg total alkaloid (calculation as ephedrine)

Contraindications Per Commission E: Anxiety, restlessness, hypertension, glaucoma, impaired cerebral circulation, prostate adenoma with residual urine accumulation, pheochromocytoma, thyrotoxicosis

Warnings AHPA warning as of March 1994 for ephedra product labels: "Seek advice from 2 healthcare professionals prior to use if you are pregnant or nursing, or if you have high blood pressure, heart or thyroid disease, diabetes, difficulty in urination due to prostate enlargement, or if taking 2 MAO inhibitors or any other prescription drug. Reduce or discontinue use if nervousness, tremor, sleeplessness, loss of appetite, or nausea occur. Not intended for use by persons < 18 years of age. Keep out of reach of children."

Reference Range Therapeutic serum level of ephedrine: 0.04-0.08 mcg/mL

Overdose/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic Supportive therapy: There is no specific antidote for ephedrine intoxication and the bulk of the treatment is supportive. Hyperactivity and agitation usually respond to reduced sensory input, however with extreme agitation haloperidol (2-5 mg I.M. for adults) may be required. Hyperthermia is best treated with external cooling measures, or when severe or unresponsive, muscle paralysis with pancuronium may be needed. Hypertension is usually transient and generally does not require treatment unless severe. For diastolic blood pressures > 110 mm Hg, a nitroprusside infusion should be initiated. Seizures usually respond to diazepam or lorazepam I.V. and/or phenytoin maintenance regimens.

Drug Interactions Per Commission E: May potentiate with MAO inhibitors in combination with cardiac glycosides or halothane; arrhythmias; with guanethidine: Enhancement of sympathomimetic effect; with MAO inhibitors: Potentiates sympathomimetic effect of ephedrine

Pregnancy Risk Factor Contraindicated

Additional Information Erect evergreen shrubs growing up to 6 feet in height with rounded flowers blooming in early spring; while the fruits are nearly alkaloid free, the green stems and twigs contain the highest amount of ephedrine and pseudoephedrine; Mormon tea (*Ephedra nevadensis*) contains large amount of tannin, no ephedrine (but possibly t-norpseudoephedrine, a CNS stimulant) and can produce a mild diuresis along with constipation; in fact North and Central American ephedra species lack sympathomimetic alkaloids

Mechanism of Action Active ingredient is parthenolide ($\approx 0.2\%$ concentration), a sesquiterpene which is a serotonin antagonist; also, the plant may be an inhibitor of prostaglandin synthesis and platelet aggregation; has spasmolytic effect on cerebral blood vessels; other anti-inflammatory effects, antimicrobial, antifungal

Adverse Reactions

Dermatologic: Contact dermatitis

Gastrointestinal: **Mouth ulcerations**, swelling of tongue

Signs and Symptoms of Overdose Abdominal pain, loss of taste, nausea, vomiting

Dosage

125 mg of a preparation standardized to 0.2% parthenolide (250 mcg)

Dried aerial parts: Oral: 50-200 mg

Tincture: (1:5, 25% ethanol): 5-20 drops

Contraindications Pregnancy, breast-feeding; children <2 years of age; allergies to feverfew and other members of the Asteraceae, daisy, ragweed, chamomile

Overdose/Treatment

Decontamination: **Oral: Do not** induce emesis; dilute with milk or water

Dermal: Wash skin with soap and water

Supportive therapy: Treat contact dermatitis with diphenhydramine and/or steroids

Drug Interactions Use with caution in patients taking aspirin or anticoagulants due to increased potential for bleeding; tannin-containing herbs can cause a decrease in iron absorption; nonsteroidal anti-inflammatory drugs may reduce the effectiveness of feverfew

Additional Information

Not reviewed by Commission E; a perennial bush which grows up to 3 feet tall with daisy-like yellow or white flowers; leaves are bitter tasting; contraindications in pregnancy and children <2 years of age

This herbal preparation should be discontinued for 2-3 weeks prior to surgery.

Garcinia cambogia

U.S. Brand Names Citrin®

Synonyms HCA

Uses Rheumatism; purgative; potential for weight loss and appetite control

Mechanism of Toxic Action Contains an organic acid known as (-) hydroxy citric acid (HCA) which inhibits lipogenesis and increases production of glycogen; also may be an appetite suppressant

Signs and Symptoms of Overdose None known

Dosage 250-800 mg of HCA/day

Overdose/Treatment Decontamination: Oral: Lavage within 1 hour; activated charcoal

Additional Information Fruit of the evergreen tree *G. cambogia* and *G. indica* found in southern Asia; usually associated with chromium; additional information can be obtained by calling America's Finest, Inc, 3481 Old Conejo Road (#101), Newbury Park, CA 91320 (1-800-350-3305)

Garlic

CAS Number 8008-99-9

Scientific Name *Allium sativum*

APHA Botanical Safety Rating System Class 2c; GI upset in sensitive persons

U.S. Brand Names Carisano®; Cirkulin®; Garlicin®; Garlimega®; Garlique®; Iija Rogoff®; Kwaj®; Kyolic®; PureGar®; Sapec®

Synonyms *Allium sativum*; Ajo; Chives; Comphor of the Poor; Nectar of the Gods; Poor Mans Treacle; Rustic Treacle; Shallots; Stinking Rose; Taisan

Use Herbal medicine used for lowering LDL cholesterol and triglycerides, and raising HDL cholesterol; protection against atherosclerosis, hypertension, antiseptic agent; may lower blood glucose and decrease thrombosis; potential anti-inflammatory and antitumor effects

Mechanism of Action Garlic bulbs contain alliin, a parent to the substance allicin (after the bulb is ground), which is odoriferous and may have some antioxidant activity; ajoene (a byproduct of allicin) has potent platelet inhibition effects; garlic can also decrease LDL cholesterol levels and increase fibrinolytic activity

Adverse Reactions

Cardiovascular: Prolonged prothrombin time

Dermatologic: Skin blistering, eczema, systemic contact dermatitis, immunologic contact urticaria

Gastrointestinal: Gastrointestinal upset and changes in intestinal flora (in rare cases) per Commission E

Ocular: Lacrimation

Respiratory: Asthma (upon inhalation of garlic dust)

Miscellaneous: Allergic reactions (in rare cases); change in odor of skin and breath per Commission E

Feverfew

Scientific Name *Chrysanthemum parthenium*; *Tanacetum parthenium*

APHA Botanical Safety Rating System Class 2b

U.S. Brand Names Feverfew Herb®; Partenelle®

Synonyms *Tanacetum parthenium*; Altamisa; Bachelor's Buttons; Chamomile Grande; Chrysanthemematrice; European Feverfew; Feather-Fully; Featherfew; Featherfoil; Febrifuge Plant; Feddygen Fenyw; Flirt-root; Grande Chamomile; Midsummer Daisy; Mutterkraut; Nosebleed; Santa Maria; Vetter-Voo; Wild Chamomile; Wild Quinine

Use Prophylaxis and treatment of migraine headaches; used to treat menstrual complaints and fever

Signs and Symptoms of Overdose Burning sensation of mouth, dizziness, hematoma, leukocytosis, lightheadedness, nausea, sweating. At doses > 50 g daily anorexia, diarrhea, vomiting, and menorrhagia may develop.

Toxicodynamics/Kinetics

Half-life: N-acetyl-S-allyl-L-cysteine: 6 hours

Elimination: Pulmonary and renal

Dosage Average daily dose for cardiovascular benefits: ~0.25-1 g/kg or 1-4 cloves daily in an 80 kg individual in divided doses

Toxic dose: >5 cloves or >25 mL of extract can cause gastrointestinal symptoms

Reference Range Urinary N-acetyl-S-allyl-L-cysteine following ingestion of 600 mg of fresh garlic totals ~0.4 mg

Overdosage/Treatment Decontamination: **Oral:** Ipecac within 30 minutes or lavage within 1 hour acute ingestions >25 mL of garlic extract; dilute with milk or water; activated charcoal may prevent absorption.

Ocular: Irrigate with saline

Drug Interactions Iodine uptake may be reduced with garlic ingestion; can exacerbate bleeding in patients taking aspirin or anticoagulant agents; may increase risk of hypoglycemia, may increase response to antihypertensives

Pregnancy Implications Avoid use in pregnancy/lactation

Additional Information See Commission E; ~1% as active as penicillin as an antibiotic; number one over-the-counter drug in Germany

Specific References

Germander

Scientific Name *Teucrium chamaedrys*

APHA Botanical Safety Rating System Class 3

Synonyms *Teucrium chamaedrys*; Wall Germander

Use In folk medicine to treat obesity

Mechanism of Action Hepatotoxic; possibly through cytochrome P-450 isozymes by reactive intermediates (epoxides) that are detoxified by glutathione; contains polyphenol derivatives, diterpenes, flavonoids, and tannins

Adverse Reactions Hepatic: Jaundice, elevated liver function test results, hepatic necrosis (centrilobular), aminotransferase level elevation (asymptomatic)

Dosage Daily dose: 600 mg to 1.62 g

Monitoring Parameters Liver function tests

Dosage Forms Capsules: 200-275 mg (no longer marketed)

Herbal teas: ~1 g/bag of germander (no longer marketed)

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal with cathartic

Supportive therapy: Although there are no human or animal data, due to the fact that glutathione depletion can result in increased hepatotoxicity in mice, there exists a rationale to use N-acetylcysteine

Additional Information Not reviewed by Commission E; not generally sold in the United States, mainly in Europe; plant is found in Eastern Europe and Mediterranean; dexamethasone or clotrimazole may increase hepatotoxicity; hepatotoxicity usually presents 3-18 hours after ingestion; blossoms are used in folk medicine in Europe, not in U.S.

Germanium

Synonyms Ge

Uses Health food supplement in Japan; thought to exhibit immunomodulating effects (organogermanium compounds)

Mechanism of Toxic Action Organic germanium compounds and germanium oxide can cause lactic acidosis and renal dysfunction (tubular epithelial cell injury with lipofuscin granule accumulation) usually after long-term use (> 5 g).

Signs and Symptoms of Overdose Anorexia, fatigue, hepatic failure, lactic acidosis, muscular pain, nephritis, neuropathy, paresthesia, pulmonary edema, vomiting, weight loss

Toxicodynamics/Kinetics

Absorption: Rapid, from the GI tract

Elimination: Renal

Reference Range Normal serum Ge level is ~0.005 mcg/mL. Normal urinary Ge level is <1 mcg/g creatinine.

Overdosage/Treatment

Decontamination: **Oral:** Emesis within 30 minutes or lavage within 1 hour any ingestion.

Supportive therapy: Monitor renal status; note that urinalysis is likely to be unremarkable. Prednisone is unlikely to be beneficial in treating muscle or renal dysfunction. Monitor BUN and creatinine.

Additional Information Usual daily ingestion is ~1 mg in foods rich in germanium (oat and barley)

Ginger

Scientific Name *Zingiber officinale*

APHA Botanical Safety Rating System Class 1

U.S. Brand Names Travel Sickness[®]; Travellers[®]; Zintona[®]

Synonyms *Zingiber officinale*

Use In herbal medicine as a digestive aid; for treatment of nausea (antiemetic) and motion sickness; also used as a menstruation promoter in Chinese herbal medicine; headaches, colds and flu; ginger oil is used as a flavoring agent in beverages and mouthwashes; may be useful in some forms of arthritis

Mechanism of Action Unknown; may increase GI motility and thus block nausea feedback from the GI tract; appears to decrease prostaglandin synthesis; may have cardiostimulant activity; may inhibit platelet aggregation

Adverse Reactions Gastrointestinal: Increased salivation

Signs and Symptoms of Overdose Possible CNS depression with large doses

Dosage

For preventing motion sickness or digestive aid: 1-4 g/day (250 mg of ginger root powder 4 times/day)

Per Commission E: 2-4 g/day or equivalent preparations

Contraindications Gallstones per Commission E

Overdosage/Treatment Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic

Drug Interactions May alter response to cardiostimulant, hypoglycemia, anticoagulant, antiplatelet agents; avoid concomitant use with warfarin.

Pregnancy Risk Factor No administration for morning sickness during pregnancy per Commission E; however, two-peer reviewed revision of the literature does not justify this caution; Commission E made its cautions based on animal studies and *in vitro* mutagenicity studies (2) on one compound, gingerol. Indian and Chinese women use large amounts of ginger routinely in their diet during pregnancy with no ill effects on pregnancy or fetus.

Pregnancy Implications No administration for morning sickness during pregnancy per Commission E; however, two-peer reviewed revision of the literature does not justify this caution; Commission E made its cautions based on animal studies and *in vitro* mutagenicity studies (2) on 1 compound, gingerol. Indian and Chinese women use large amounts of ginger routinely in their diet during pregnancy with no ill effects on pregnancy or fetus. High doses may be abortifacient.

Additional Information Density of ginger oil is ~0.9; ginger is a perennial plant with green-purple flowers similar to orchids which grows in India, the Orient, and Jamaica; 8 oz of ginger ale contains ~1 g of ginger; ginger tea (1 cup) contains ~250 mg of ginger

Ginkgo biloba

Scientific Name Ginkgoaceae (family)

APHA Botanical Safety Rating System Class 1

U.S. Brand Names Ginkoba[®]

Synonyms BN-52063; EGb; GBE; Ginkgold; Ginkgopower; Ginkgink; Kaveri; Kew Tree; Maidenhair Tree; Oriental Plum Tree; Rōkan; Silver Apricot; Superjinkgo; Tanakan; Tanakene; Tebonin; Tramisal; Valverde; Vasan; Vital

Use

Dilates blood vessels; plant/leaf extract has been used in Europe for intermittent claudication, arterial insufficiency, and cerebral vascular disease (dementia); tinnitus, visual disorders, traumatic brain injury, vertigo of vascular origin

Per Commission E: Demential syndromes including memory deficits, etc (tinnitus, headache); depressive emotional conditions, primary degenerative dementia, vascular dementia, or both

Investigational: Asthma, impotence (male)

Mechanism of Action Inhibits platelet aggregation; *Ginkgo biloba* leaf extract contains terpenoids and flavonoids which can allegedly inactivate oxygen-free radicals causing vasodilatation and antagonize effects of platelet activating factor (PAF); fruit pulp contains ginkolic acids which are allergens (seeds are not sensitizing)

Adverse Reactions

Cardiovascular: Palpitations, bilateral subdural hematomas

Central nervous system: Headache (very seldom per Commission E), dizziness, seizures (in children), restlessness, subarachnoid hemorrhage

Dermatologic: Urticaria, cheilitis

Gastrointestinal: Nausea, diarrhea, vomiting, stomatitis, proctitis; very seldom stomach or intestinal upsets (per Commission E)

Ocular: Hyphema

Miscellaneous: Allergic skin reactions (very seldom per Commission E)

Admission Criteria/Prognosis Admit any ingestion with neurologic abnormalities or ingestions >2 pieces of fruit

Toxicodynamics/Kinetics

Onset of CNS effects: 1 hour
Peak absorption: 2-3 hours
Duration of action: 7 hours
Bioavailability: 70% to 100%
Half-life: Ginkgolide A: 4 hours; Ginkgolide B: 10.6 hours; Bilobalide: 3.2 hours

Dosage Usual dosage: ~40 mg 3 times/day with meals; 60 mg twice daily depending on indication; maximum dose: 360 mg/day
Cerebral ischemia: 120 mg/day in 2-3 divided doses (24% flavonoid-glycoside extract, 6% terpene glycosides)

Contraindications Pregnancy, patients with clotting disorders; hypersensitivity to *Ginkgo biloba* preparations per Commission E

Reference Range Peak plasma concentration of flavonol-glycoside following a 300 mg oral dose: ~150 ng/mL. The serum concentration of 4-metoxypyridoxine was 360 ng/mL following ingestion of 60 roasted ginkgo seeds in a 2-year-old female with seizures.

Overdosage/Treatment

Decontamination: **Dermal:** Washing skin within 10 minutes may prevent dermal allergic contact dermatitis; remove all clothing. **Oral:** Lavage (within 1 hour)/activated charcoal (laxative not needed)

Supportive therapy: Although human data are lacking, since the central nervous system effects may be due to 4-*o*-methylpyridoxine (an antipyridoxine compound), pyridoxine may be useful after ingestion of ginkgo seeds or kernels in children; topical corticosteroids can be used for skin reactions

Drug Interactions Due to effects on PAF, use with caution in patients receiving anticoagulants or platelet inhibitors; may diminish the effectiveness of anticonvulsants

Additional Information Beneficial effects for cerebral ischemia in the elderly occur after one month of use

Grown on plantations, leaves are extracted with organic solvent (acetone) to a potency of 24% flavonoids and 6% terpenoids. Can increase alpha waves and decrease slow potentials in EEG. An Oriental deciduous tree with plum-like fruits (in autumn) and flowers in spring. May reach a height of 125' (20' girth) and is found in U.S., Europe, China, and Japan. Cross reactivity for contact dermatitis due to the fruit pulp exists with poison ivy and poison oak; the dermatological symptoms may last for 10 days. Inner bark is used as a whitish brown cloth dye. Leaf extract has been used in herbal medicine to treat dementia, chronic tinnitus, vertigo, cochlear deafness, and impotence.

Reference range: Maximum plasma level of ginkgolide A and ginkgolide B after an 80 mg oral dose: 15 mg/mL and 4 mg/mL, respectively; maximum plasma level of bilobalide after a 120 mg oral dose: ~18.8 mg/mL

Ginkgo biloba may reverse genital anesthesia and diminished sexual desire induced by fluoxetine.

This herbal preparation should be discontinued for 2-3 weeks prior to surgery.

Use A popular ingredient in herbal teas; has been advocated for its antistress and adaptogenic effects although these effects have not been scientifically confirmed, there's much "suggestive" scientific literature

Mechanism of Action The active agent (ginsenosides) may have CNS stimulant and estrogen-like effect, anti-inflammatory, antiplatelet; used as an adaptogen; may lower cholesterol; not effective as an aphrodisiac

Adverse Reactions

Cardiovascular: Tachycardia, hypertension, sinus tachycardia
Central nervous system: Nervousness, agitation, mania, cerebral arteritis
Dermatologic: Stevens-Johnson syndrome
Endocrine & metabolic: Hypoglycemia, metrorrhagia
Hematologic: Lymphocytosis

Signs and Symptoms of Overdose Ginseng abuse syndrome (noted in patients ingesting 3-15 g/day for up to 2 years) is characterized by morning edema, euphoria, diarrhea, insomnia, nervousness, and skin eruptions.

Dosage Herbal tea: Usually ~1.75 g; 0.5-2 g/day
Per Commission E: 1-2 g of dried root or equivalent preparations

Monitoring Parameters Blood sugar, blood pressure

Contraindications Estrogen-receptor positive breast cancer

Dosage Forms

Capsule: 100 mg
Liquid: 140 mg/15 mL

Overdosage/Treatment Decontamination: Usually decontamination is not required for ingestions under 3 g; lavage (within 1 hour)/activated charcoal can be utilized

Drug Interactions

May decrease effects of loop diuretics (furosemide); theoretically may increase effect of antiplatelet agents, anticoagulants, hypoglycemics, and hypotensive agents

May cause increase in INR when given with warfarin. Avoid aspirin or anticoagulant use due to the antiplatelet effect of *P. ginseng*. Mania can occur when given with phenelzine. Siberian ginseng has been reported to cause elevated digoxin levels when given with digoxin. Insomnia, headaches, irritability, and tremulousness have been reported after simultaneous administration of ginseng and phenelzine.

Pregnancy Implications Not recommended in pregnancy or breast-feeding

Additional Information In U.S., the root crop of ginseng is obtained from *Panax quinquefolius* L (American ginseng) or *Panax trifolius* L (Dwarf ginseng). The plants are found in woody areas and are ~3 feet tall with yellow-green flowers and red/yellow fruits (from June to July). Additional information can be obtained from: Ginseng Board of Wisconsin, 16-H Menard Plaza, Wausau, Wisconsin 54401; (715)845-7300

Capsules: 100-200 mg ginseng claimed per capsule (0.4-23.2 mg of ginsenoside noted per capsule). Most brands contain <8% concentration of ginsenoside/capsule. Contraindicated in diabetes and hypertension. Vaginal administration can cause serious vaginal hemorrhage.

Golden Seal

Scientific Name *Hydrastis canadensis*

APHA Botanical Safety Rating System Class 2b

Synonyms *Hydrastis canadensis*; Eye Balm; Eye Root; Indian Eye; Orange Root; Jaundice Root; Tumeric Root; Yellow Indian Paint; Yellow Root

Use Gastrointestinal and peripheral vascular activity; also used in sterile eye washes, as a mouthwash, laxative, hemorrhoids, and to stop postpartum hemorrhage. Efficacy not established in clinical studies; has been used to treat mucosal inflammation/gastritis

Mechanism of Action Contains the alkaloids hydrastine (4%) and berberine (6%), which at higher doses can cause vasoconstriction, hypertension, and mucosal irritation; berberine can produce hypotension

Signs and Symptoms of Overdose Brown discoloration of urine, diarrhea, hypotension, mydriasis, nausea, paresthesias, respiratory depression, seizures, uterine contractions, vomiting

Toxicodynamics/Kinetics

Absorption: Oral
Elimination: Renal

Dosage

Solid form: Usual dosage: 5-10 grains
Tea: Prepared from 6 g (10 mL) of the herb in 240 mL of water

Contraindications Pregnancy, breast-feeding

Ginseng

Scientific Name *Panax ginseng*

APHA Botanical Safety Rating System Class 2d; contraindicated in hypertension

U.S. Brand Names Bio-Star®; Ginsana®; Ginsun®; Neo Ginsana®

Synonyms *P. quinquefolium* L.; *P. trifolius* L.; Korean Ginseng; Ninjin; Panax; Pannag

Overdosage/Treatment

Decontamination: Activated charcoal with cathartic

Supportive therapy: Benzodiazepines can be utilized for seizure control

Test Interactions Can produce a false-negative for urinary cannabinoids by immunoassay

Drug Interactions May interfere with vitamin B absorption

Additional Information Not reviewed by Commission E; a perennial with green-white flowers and dark red berries (from April to May) that is found from Vermont to Arkansas

Specific References

Myles D, "Saving wild Ginseng, Goldenseal, and Other Native Plants from Mountain Top Removal" *Herbalgram*, 2007, 73: 50-55

Palanisamy A, Haller C, Olson KR, "Photosensitivity Reaction in a Woman Using an Herbal Supplement Containing Ginseng, Goldenseal, and Bee Pollen," *J Toxicol Clin Toxicol*, 2003, 41(6):865-7.

Hawthorn

Scientific Name *Crataegus laevigata*; *Crataegus monogyna*; *Crataegus oxyacantha*

APHA Botanical Safety Rating System Class 1

U.S. Brand Names Arterio-K[®]; Basticrat[®]; Born[®]; Cardiplant[®]; Cordapur[®]; Coronal[®]; Cratamed[®]; Naranocor[®]; Regulacor[®]

Synonyms *Crataegus laevigata*; *Crataegus monogyna*; *Crataegus oxyacantha*; *Crataegus pinnatifida*; Blackthorn; English Hawthorn; Haw; Maybush; Thorn Plum; Whitehorn

Use In herbal medicine to treat cardiovascular abnormalities (arrhythmia, angina), increased cardiac output, increased contractility of heart muscle; also used as a sedative

Mechanism of Action Contains flavonoids, catechin, and epicatechin which may be cardioprotective and have vasodilatory properties; shown to dilate coronary vessels

Signs and Symptoms of Overdose CNS depression, hypotension, syncope

Dosage

Tincture: 1 teaspoon twice daily for up to several weeks

Tea: 2 teaspoons of crushed leaves or fruit per cup of boiling water

Daily dose of total flavonoids: ~ 10 mg

Per Commission E: 160-900 mg native water-ethanol extract (ethanol 45% v/v or methanol 70% v/v, drug-extract ratio: 4-7:1, with defined flavonoid or procyanidin content), corresponding to 30-168.7 mg procyanidins, calculated as epicatechin, or 3.5-19.8 mg flavonoids, calculated as hyperoside in accordance with DAB 10 [German pharmacopoeia #10] in 2 or 3 individual doses; duration of administration: 6 weeks minimum

Contraindications Pregnancy and breast-feeding

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic

Supportive therapy: Treat hypotension with I.V. crystalloid infusion and placement in Trendelenburg position; vasopressor agents can be used in refractory cases

Drug Interactions Antihypertensives (effect enhanced), digoxin; effects with Viagra[®] unknown

Pregnancy Implications Do not use

Additional Information A small deciduous tree which can grow up to 25'; its white, strongly aromatic flowers bloom in mid to late spring; tincture has a bitter taste

Hops

Scientific Name *Humulus lupulus*

APHA Botanical Safety Rating System Class 2d; some writers advise against use in depression

Synonyms *Humulus lupulus*; Common Hops; European Hops; Lupulin

Use

In herbal medicine as a sleep aid (sometimes combined with valerian root)

Per Commission E: Mood disturbances such as restlessness and anxiety, sleep disturbances

Mechanism of Action Contains several bitter acids (lupulone, myrcene, humulone) which may have antimicrobial activity, inhibit smooth muscle activity, and exhibit CNS depression; probable dermal irritant

Adverse Reactions None known relating to herb (as per Commission E); Dermatologic: Contact dermatitis (upon exposure to extracts)

Dosage Per Commission E: Single dose: 0.5 g

Overdosage/Treatment Decontamination: **Oral:** Do not induce emesis; lavage (within 1 hour)/activated charcoal with cathartic. **Dermal:** Wash with soap and water

Additional Information A perennial, climbing vine with heights up to 25 feet found in Germany and Pacific Northwest; loses most of its activity (85%) after 9 months of storage; not to be confused with Wild Hops (*Bryonia*)

Horse Chestnuts

CAS Number 11072-93-8; 531-75-9; 6805-41-0

Scientific Name *Aesculus hippocastanum*

U.S. Brand Names Aescorin N; Aescuven; Feparil; Flogencyl; Plissamur; REXILUVEN S; Réparil; Tecura; Vasotonin; Venoplast; Venostasin

Uses In herbal medicine for treatment of chronic venous insufficiency (varicose veins); I.V. use in Europe to prevent postoperative edema

Mechanism of Toxic Action Contains aesculin, a saponin glycoside with diuretic effects and can reduce lysosomal enzyme activity; also increases venous tone

Adverse Reactions

Per Commission E:

Dermatologic: Pruritus

Gastrointestinal: Nausea, and gastric complaints may occur in isolated cases after oral intake

Signs and Symptoms of Overdose Abdominal pain, cramping, diarrhea, mydriasis, nausea, twitching, vomiting. Could potentially cause kidney damage with a large enough ingestion. Fever (in children), headache, and vomiting can occur after ingesting a single seed. Anaphylaxis and renal failure have been reported following I.V. administration.

Toxicodynamics/Kinetics

Onset: Soon after ingestion

Absorption: Oral: Poor

Protein binding: 50% (in frogs)

Dosage Mild intoxication upon ingestion of berries by children; apparently ingestion of ~ 20 berries or chewing the fresh bark is necessary to induce pronounced symptoms

Aescin:

Oral: Initial: 90-150 mg

Maintenance daily dose: 35-70 mg

Maximum I.V. dose: 20 mg

Per Commission E: Aescin (escin): 100 mg corresponds to 250-312.5 mg extract twice daily in delayed release form

Reference Range Peak plasma concentration of beta-aesculin after oral ingestion of 300 mg of extract: ~ 30 ng/mL

Overdosage/Treatment

Decontamination: Ipecac/cathartic not recommended, activated charcoal/lavage (within 1 hour) may be useful; dilute with milk or water; activated charcoal or lavage if 3 or more seeds are ingested

Supportive therapy: Treat any fluid or electrolyte imbalance

Additional Information May color alkaline urine red; do not confuse with hematuria; bitter taste; a large deciduous tree with fruit containing 1-6 seeds and predominantly white flowers found in U.S., Canada, and southeastern Europe

Toxic parts: Fruit, leaves, and bark are poisonous

Kava

CAS Number 495-85-2; 500-62-9; 500-64-1

Scientific Name *Piper methysticum*

APHA Botanical Safety Rating System Class 2d; caution required when driving or when operating other equipment; simultaneous consumption with alcohol or barbiturates may potentiate inebriation

U.S. Brand Names Herbal Ecstasy 2; Herbal Ecstasy; Kavosporal Forte

Synonyms *Piper methysticum*; Awa; Kev; Kew; Tonga

Impairment Potential Yes

Use Conditions of nervous anxiety, stress, and restlessness per Commission E; used for sleep induction and to reduce anxiety

Mechanism of Action Contains alpha-pyrones in root extracts; may possess central dopaminergic antagonistic properties

Adverse Reactions Central nervous system: Euphoria

Signs and Symptoms of Overdose Ataxia, deafness, extrapyramidal effects, sedation, yellow skin discoloration

Dosage Per Commission E: Herb and preparations equivalent to 60-120 mg kava pyrones

Contraindications Per Commission E: Pregnancy, breast-feeding, endogenous depression. "Extended continuous intake can cause a temporary yellow discoloration of skin, hair and nails. In this case, further application must be discontinued. In rare cases, allergic skin reactions occur. Also, accommodative disturbances (eg, enlargement of the pupils and disturbances of the oculomotor equilibrium) have been described."

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic

Supportive therapy: Can treat extrapyramidal reactions with benzotropine and/or diphenhydramine

Drug Interactions Coma can occur from concomitant administration of kava and alprazolam; may potentiate alcohol or CNS depressants, barbiturates, psychopharmacological agents

Pregnancy Risk Factor Contraindicated per Commission E

Pregnancy Implications Do not use

Additional Information Social and ceremonial drink in South Pacific islands; has medicinal use as a G.U. antiseptic, antipyretic, diuretic, local anesthetic, and muscle relaxant agent; shrubs can grow 8-20 feet tall with

green stems and rounded fruit; characteristic yellow discoloration rash resembles pellagra, but does not respond to nicotinamide

Kava lactones detected in urine by gas chromatography/mass spectrometry following ingestion of 450 g of commercial kava:

Dihydrokawain, kawain, desmethoxyyangonin, tetrahydroyangonin, dihydromethysticin, 11-methoxytetrahydroyangonin, yangonin, methysticin, dehydromethysticin

Kombucha

Synonyms Kargasok "Tea"; Kombucha Mushroom; Kombucha Tea; Kwassan; Manchurian Tea; Manchurian "Fungus"; T'Chai from the Sea; Teekwass; "Fungus" Japonicus

Uses Folk/herbal remedy used to relieve arthritis; treat insomnia, hypertension, ache; stimulate hair growth; used by AIDS patients to stimulate the immune (T-cell) system (all these actions are unproven); other claims include elimination of wrinkles and cleansing the gallbladder; has been used in alternative medicine for HIV therapy although its use has markedly decreased

Mechanism of Toxic Action Unknown bacterial products may affect gut's bacterial flora

Adverse Reactions

- Central nervous system: Coma
 Dermatologic: Erythematous rash
 Endocrine & metabolic: Severe metabolic acidosis
 Gastrointestinal: Anorexia
 Hepatic: Hepatotoxicity, hepatitis, hepatomegaly
 Hematologic: Thrombocytopenia, disseminated intravascular coagulopathy
 Respiratory: Cough (nonproductive)

Signs and Symptoms of Overdose Abdominal cramping, allergic symptoms, anorexia, chest pain, cough, elevated prothrombin time, erythematous rash, hepatomegaly, hepatotoxicity (usually resolves within a month), nausea, thrombocytopenia

Dosage 4-8 ounces/day

Overdosage/Treatment Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic

Supportive therapy: Symptoms are usually self limited

Additional Information

Due to acidic nature of the tea (pH is ~1.8), it should not be prepared or stored in ceramic or lead crystal containers. During fermentation process, ethanol (up to 1.5%), ethyl acetate, acetic acid, lactic acid, glucuronic acid, heparin, hyaluronic acid, chondroitin sulfate acid, mukoiitin sulfate, or lactic acid may be produced. Found as a gray, flat patty (3" in diameter) which is fermented in black tea and sugar. A 6" wide gray fungus that is often ingested in sugared tea after fermentation; production of 0.5% alcohol, glucuronic acid, hyaluronic acid, chondroitin sulfate acid, usnic acid, mukoiitin sulfate, heparin, lactic acid along with *Acetobacter ketogenum* and *Pichia fermentans* has been associated with the tea; not a fungus but a fungal symbiot that is a 6" patty which has been used in Asia and Europe as an unproven therapeutic agent for rheumatism, intestinal disorders, and premenstrual syndrome.

Usually referred to as a mushroom, several species of yeast and bacteria are held together by a thin membrane. Some species associated with the Kombucha colony include *S. ludwigii*, *S. pombe*, *Bacterium xylinum*, *Acetobacter ketogenum*, *S. gluconicum*, *B. xylinoides*, *B. katogenum*, *Pichia fermentans*, and *Torula* sp, *Saccharomyces cerevisiae*, and *Candida valida*. In addition, contamination with *Aspergillus* may be present.

Laetrile®

Related Information

- Amyl Nitrite [ANTIDOTE]
- Cyanide

CAS Number 1332-94-1; 29883-15-6

Synonyms Amygdalin; Vitamin B₁₂; Vitamin B₁₇

Uses While it has been used for cancer therapy, it is ineffective and no known medicinal or nutritional value exists.

Mechanism of Toxic Action Releases cyanide within the GI tract through enzymatic degradation by betaglucosidase or emulsion; intrave-

nous laetrile does not result in cyanide exposure; synthesized from Amygdalin (mandelonitrile beta-d-gentiobioside)

Signs and Symptoms of Overdose Coma, headache, hypotension, metabolic acidosis, seizures, tachycardia, tachypnea, vomiting

Reference Range 500 mg 3 times/day results in blood cyanide level of 2.1 mcg/mL

Overdosage/Treatment

Decontamination: Basic poison management (lavage within 1 hour/activated charcoal with cathartic); emesis is contraindicated due to rapid course of the neurologic symptoms; give 100% oxygen
 Supportive therapy: Give sodium bicarbonate for acidosis; cyanide antidote kit (amyl nitrate, sodium nitrate followed by sodium thiosulfate)
 Enhancement of elimination: Hemodialysis and charcoal hemoperfusion have been utilized; hyperbaric oxygen may also be utilized; hydroxocobalamin, dicobalt-EDTA, and 4-dimethylaminophenol used for chelation in Europe

Antidote(s)

- Cyanide Antidote Kit [ANTIDOTE]
- Hydroxocobalamin [ANTIDOTE]
- Oxygen (Hyperbaric) [ANTIDOTE]
- Sodium Nitrite [ANTIDOTE]
- Sodium Thiosulfate [ANTIDOTE]

Additional Information Usual commercial source is from the kernel of *Prunus armeniaca*. A 500 mg laetrile tablet may contain between 5-51 mg of hydrogen cyanide per gram.

Lemon Grass Oil

Scientific Name *Andropogon citratus*; *Cymbopogon citratus*

APHA Botanical Safety Rating System Class 2b (herb)

Synonyms Capim-Cidrao; Guatemala Lemongrass; Lemongrass; Madagascar Lemongrass

Use Perfumes; flavoring agent; used also as a hypotensive and carminative in folk medicine

Mechanism of Action Major active ingredient is citral which is an irritant and has sedative effect (by decreasing neuronal activity)

Signs and Symptoms of Overdose Allergic contact dermatitis, CNS depression at high doses, mucosal irritation, skin irritation with citral concentrations >8%

Admission Criteria/Prognosis Admit any ingestion >1 mL/kg

Toxicodynamics/Kinetics

- Absorption: Rapidly absorbed orally, can be absorbed dermally
 Metabolism: Hepatic
 Elimination: Renal

Dosage Acceptable daily intake for food: 500 mcg of citral

Overdosage/Treatment Decontamination: **Oral:** Dilute with milk or water. **Dermal:** Wash with cool water (warm water may increase severity of reactions). **Ocular:** Irrigate copiously with saline

Additional Information Not widely used in U.S. market as an herbal dietary supplement; plant is a perennial grass native to Ceylon and Southern India

Licorice

Scientific Name *Glycyrrhiza glabra*; *Glycyrrhiza lepidota*; *Glycyrrhiza uralensis*

APHA Botanical Safety Rating System Class 2b, 2c, 2d; not for prolonged use or in high doses except under supervision of 2 qualified health practitioners; contraindicated for diabetes and in hypertension, liver disorders, severe kidney insufficiency, and hypokalemia; may potentiate potassium depletion of thiazide diuretics and stimulant laxatives, and cardiac glycosides and cortisol

U.S. Brand Names DGL Licorice

Synonyms *G. pallidiflora*; *G. uralensis*; *Glycyrrhiza glabra*; Glycocomme; Lakriment Neu; Liquorice; Sweet Root; Ulgastriin Neo

Use

- Foodstuff in chewing gum, chewing tobacco, cough preparations
 Per Commission E: Catarrhs of the upper respiratory tract and gastric/duodenal ulcers

Mechanism of Action From the root of the plants *Glycyrrhiza glabra*, *Glycyrrhiza lepidota*, *Glycyrrhiza uralensis*; the toxic component is glycyrrhizic acid which inhibits enzymes in the degradation of mineralocorticoid hormones (aldosterone); also may act as a mineralocorticoid; inhibits steroid dehydrogenase and release enzymes

Adverse Reactions

- Cardiovascular: Hypertension, edema
 Central nervous system: Headache, seizures, tetany
 Endocrine & metabolic: Amenorrhea, hyponatremia, hypokalemia, hypomagnesemia
 Neuromuscular & skeletal: Myopathy, carpopedal spasms, rhabdomyolysis
 Ocular: Bilateral ptosis
 Renal: Myoglobinuria

Per Commission E: On prolonged use and with higher doses, mineral corticoid effects may occur in the form of sodium and water retention and potassium loss, accompanied by hypertension, edema, and hypokalemia, and in rare cases, myoglobinuria

Toxicodynamics/Kinetics

Metabolism: Glycyrrhizic acid is converted to glycyrrhetic acid

Half-life: Glycyrrhizic acid: 5 hours

Elimination: Fecal: 53% to 61%

Dosage 100 g (equivalent to 700 mg of glycyrrhizic acid) of licorice found in 2-4 licorice twists; toxic effect can be seen if ingested daily (2-3 twists) for 2-4 weeks

Per Commission E: 5-15 g root/day, equivalent to 200-600 mg glycyrrhizin; succus liquiritiae (juice): 0.5-1 g for catarrhs of upper respiratory tract; 1.5-3 g for gastric/duodenal ulcers; equivalent preparations

Contraindications Per Commission E: Cholestatic liver disorders, liver cirrhosis, hypertension, hypokalemia, severe kidney insufficiency, pregnancy

Reference Range Peak plasma concentration of glycyrrhetic acid after 100 mg oral dose: ~0.2 mcg/mL

Overdosage/Treatment Supportive therapy: Fluid/electrolyte (especially potassium) replacement; spironolactone (1 g/day in divided doses) also may be useful in reversing electrolyte abnormalities; tetany can be treated with magnesium sulfate

Drug Interactions

Attenuated effect of strychnine, tetrodotoxin, nicotine, cocaine, barbiturates, pilocarpine, urethane, epinephrine, and ephedrine through glucuronic-like conjugation action; traditional emmenagogue; increases progesterone and cortisol half-life; concomitant use of furosemide can exacerbate hypokalemia

Per Commission E: Potassium loss due to other drugs (eg, thiazide diuretics), can be increased; with potassium loss, sensitivity to digitalis glycosides increases

Pregnancy Risk Factor Contraindicated per Commission E

Additional Information Syndrome of pseudoprimary hyperaldosteronism is a complication of chronic licorice ingestion; serum potassium as low as 0.9 mM/L has been noted; licorice ingestion can result in serum testosterone decreases and an increase in serum 17-hydroxy-progesterone

Reference range: Ingestions of 2-4 licorice twists daily (100 g of licorice) for 2-4 weeks can result in a plasma glycyrrhetic acid level of up to 480 ng/mL; renin, antidiuretic hormone, aldosterone, potassium levels fall; elevated prolactin levels may occur. Daily use of 20-40 g can result in severe hypokalemia.

Specific References

Cinatl J, Morgenstern B, Bauer G, et al, "Glycyrrhizin, An Active Component of Licorice Roots, and Replication of SARS-Associated Coronavirus," *Lancet*, 2003, 361(9374):2045-6.

Delgoda R and Westlake AC, "Herbal Interactions Involving Cytochrome P450 Enzymes: A Mini Review," *Toxicol Rev*, 2004, 23(4):239-49.

Lobelia

Scientific Name *Lobelia inflata*

APHA Botanical Safety Rating System Class 2b, 2d; may cause nausea and vomiting; not to be taken in large doses; dose-dependent cardioactivity has been observed

U.S. Brand Names Bantron Smoking Deterrent Tablets; Lobatox; Lobidram Computabs; Nikoban; Refrane; Stop Smoke

Synonyms *Lobelia inflata*; Bladder-Pod; Emetic Herb; Eye-Bright; Indian Tobacco; Kinnikinnik; Lobelia Herb; Low Belia; Puke Weed; Wild Tobacco

Use In herbal medicine as an expectorant, relief of muscle spasms; also incorporated (in doses of 2-4 mg) in tablets/lozenges or chewing gum to aid in smoking cessation

Mechanism of Action Plant contains ≈0.48% of pyridine-derived alkaloids (lobeline, lobelanine, lobelanidine); Lobeline acts similarly to nicotine as a stimulant with ≈5% to 20% of its potency

Signs and Symptoms of Overdose Abdominal pain, coma, dermal irritation, diaphoresis, euphoria, hypertension, hypothermia, nausea, paralysis, respiratory depression, salivation, seizures, tachycardia, vomiting

Toxicodynamics/Kinetics Absorption: Orally, dermally, and through inhalation

Dosage Toxic dose:

Dried herb: 50 mg

Lobelia, tincture: 1 mL

Lobeline: 8 mg

Toxic daily dose: >20 mg

Therapeutic dose:

Lobeline hydrochloride:

SubQ: 10 mg (up to 20 mg/day)

I.V.: 3 mg (maximum daily dose: 20 mg)

Lobeline sulfate: 2-4 mg

Overdosage/Treatment

Decontamination:

Oral: **Do not** induce emesis; lavage (within 1 hour)/ingestions >8 mg of lobeline, 50 mg of dried herb or 1 mL of tincture of lobelia; activated charcoal with cathartic can then be used

Ocular: Irrigate with saline copiously

Dermal: Wash with soap and water

Supportive therapy: Seizures can be treated with benzodiazepines; phenobarbital or phenytoin can be used for refractory seizures; hypotension can be treated with intravenous fluid bolus (10-20 mL/kg) and placement in Trendelenburg position; dopamine or norepinephrine can be used for refractory cases

Additional Information Not reviewed by Commission E; found in eastern North America with small, pale blue flowers; acrid/bitter taste; can cause euphoria; an annual weed which grows by roadsides and in open woods; irritating odor

Margosa Oil

Synonyms Azadirachta

Use A folk remedy in India, Japan, and Southeast Asia; antihelminthic, insecticidal, or analgesic agent; an extract from the dried stem bark and tree leaves of *Azadirachta indica* (Neem tree)

Mechanism of Action Irritant: CNS stimulant; toxin (an unsaturated hydroxy-aldehyde) appears to be heat stable

Adverse Reactions

Cardiovascular: Reye's-like syndrome, cerebral edema

Central nervous system: Lethargy, seizures, coma

Endocrine & metabolic: Metabolic acidosis

Gastrointestinal: Vomiting (15 minutes to 4 hours)

Hematology: Leukocytosis

Hepatic: Steatosis of the liver

Neuromuscular & skeletal: Tremor

Respiratory: Tachypnea, dyspnea

Overdosage/Treatment

Decontamination: **Do not** induce emesis; lavage within 1 hour (if spontaneous emesis has not already occurred), activated charcoal with cathartic

Supportive therapy: Benzodiazepines have been used to treat seizures; paraldehyde has also been used to terminate seizures; mannitol and/or dexamethasone should be used to treat cerebral edema

Additional Information Not generally available in U.S. market; not listed with Commission E; some Neem extracts are used as ingredients in imported (from India) toothpastes and in natural cosmetics, but **not** as a dietary supplement for oral consumption

Maté

Scientific Name *Ilex paraguariensis*

APHA Botanical Safety Rating System Class 2d; not recommended for excessive or long-term use

Synonyms *Ilex paraguariensis*; Jesuit's Tea; Paraguay Tea; St Bartholomew's Tea

Use

Herbal medicine as a depurative, stimulant, and diuretic

Per Commission E: Physical fatigue

Mechanism of Action Plant contains caffeine; leaves contain rutin, alpha-amyrin, trigonelline, choline and ursolic acid; teas contain caffeine; may also contain belladonna alkaloids as a contamination

Adverse Reactions

Cardiovascular: Tachycardia

Central nervous system: Fever, disorientation

Dermatologic: Flushed skin

Gastrointestinal: Xerostomia

Genitourinary: Urinary retention

Ocular: Mydriasis

Miscellaneous: Incidence of esophageal cancer and bladder cancer increased when used with tobacco (in chronic users)

Dosage One cup of maté (6 ounces) is equivalent to 25-50 mg of caffeine
Per Commission E: Daily dose: 3 g of drug (dried herb); equivalent preparations

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic
Supportive therapy: Physostigmine (0.5 mg in children, up to 4 mg in adult as a total dose) has been used to treat severe anticholinergic toxicity due to ingestion of Paraguay tea contaminated with anticholinergic agents. This modality should not be used for treating effects of caffeine exposure.

Additional Information A climbing evergreen shrub which can grow to 20 feet; native to South American countries; greenish white flowers with small deep red berries; leaves contain as much as 2% caffeine along with theophylline (0.05%); teas should be used with caution in patients with elevated blood pressure, diabetes, or ulcer disease

Melaleuca Oil

CAS Number 8022-72-8

Scientific Name *Melaleuca alternifolia*

U.S. Brand Names Amber Gold; Dessert Essence

NETTLES

Synonyms Australian Tree Oil; Tea Tree Oil; Ti-Tree Oil

Use Marketed as having fungicidal, bactericidal properties; also used as a topical dermal agent for burns

Mechanism of Action Consists of plant terpenes, pinenes, and cineole, derived from the *Melaleuca alternifolia* tree, the colorless or pale yellow oil can cause CNS depression

Signs and Symptoms of Overdose Aspiration pneumonitis, ataxia, CNS depression, lethargy

Admission Criteria/Prognosis Admit any patient who is symptomatic 5 hours postexposure

Toxicodynamics/Kinetics Metabolism: Hepatic

Dosage Minimal toxic dose: Infant: < 10 mL

Monitoring Parameters Pulse oximetry

Overdosage/Treatment Decontamination: Activated charcoal with cathartic

Additional Information

Oral: Mildly toxic. Dermal: Very mild irritant; no dermal sensitization; no phototoxicity

Found in New South Wales (Australia) on the north coast in swampy lowlands, this paper-bark tree can grow up to 20 feet high; the tree may also be found in southern U.S. (Florida), Spain, or Portugal; nutmeg odor; has been used to treat acne vulgaris, athlete's foot, and vaginitis

Specific References

Morris MC, Donoghue A, Markowitz JA, et al, "Ingestion of Tea Tree Oil (Melaleuca Oil) by a 4-Year-Old Boy," *Pediatr Emerg Care*, 2003, 19(3):169-171.

Drug Interactions

Decreased effect of antihypertensives

Increased toxicity with disulfiram (possible seizures, delirium), fluoxetine (and other serotonin active agents), TCAs (cardiovascular instability), meperidine (cardiovascular instability), phenothiazine (hyperpyretic crisis), levodopa, sympathomimetics (hyperpyretic crisis), barbiturates, Rauwolfia alkaloids (eg, reserpine), dextroamphetamine (psychoses), foods containing tyramine (hypertension, headache, seizures); theophylline/caffeine (hyperthermia), cyclobenzaprine (fever/seizures)

Potentiation of hypoglycemia with oral hypoglycemic agents

Serotonin syndrome (shivering, muscle rigidity, salivation, agitation, and hyperthermia) can occur with concomitant administration of venlafaxine and tranylcypromine

Pregnancy Implications Nutmeg ingestion has been reported to increase fetal heart rate

Additional Information

Toxic dose: 1-3 nutmegs can cause toxic symptoms

Toxic parts: Volatile oil in seed and seed coat appears to be responsible for pharmacologic effects

Nutmeg is the seed of *Myristica fragrans*; the spice mace is from the seed coat of *Myristica fragrans*

Family: Myristicaceae

Toxin: Myristicin, elemicin, geraniol

Range: Grows in India, Ceylon, and Grenada

Nettles

Scientific Name *Urtica dioica*; *Urtica parviflora*; *Urtica urens*

APHA Botanical Safety Rating System Class 1 (leaf)

Synonyms Stinging Nettles

Uses Root extracts used in herbal medicine for treatment of urinary difficulties due to enlarged prostate (prostate adenoma stages 1 and 11); leaf extracts have been used topically for rheumatic disorders

Mechanism of Toxic Action Unknown; the hairs on stems and leaves contain dermal irritants (histamine, acetylcholine, and 5-hydroxytryptamine); also may have a diuretic action

Adverse Reactions

Dermatologic: Dermal irritation/stinging may last up to 12 hours; burning sensation, contact urticaria, nonimmunologic contact urticaria
Neuromuscular & skeletal: Paresthesias

Dosage Prostatic hypertrophy: 4-6 g/day or as a fluid extract from roots: 5 mL every 8 hours for 6 months
Leaf: 8-12 g/day

Overdosage/Treatment

Decontamination: **Dermal:** Wash with soap and water. **Oral:** Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal with cathartic
Supportive therapy: Topical steroids or systemic antihistamines may be useful to treat dermal irritation; brush and wash exposed clothing

Additional Information A perennial plant which has stems which can grow to 6 feet; the stems and leaves contain the toxic bristles or stinging hairs; fresh tender shoots do not cause stinging sensation; also boiling or drying can eliminate the stinging sensation; small, greenish flowers bloom from June through September; young roots are edible when cooked and contain significant amounts of carotene and vitamin C; contraindications in pregnancy

Nutmeg

Scientific Name *Myristica fragrans*

APHA Botanical Safety Rating System Class 2b; Class 3; **Note:** Classification and concerns are based on therapeutic use, not relevant to consumption as a spice

Use In folk medicine for delayed menses

Mechanism of Action One theory for nutmeg's pharmacologic properties is that myristicin and elemicin are metabolized to psychoactive amphetamine derivatives, MMDA (3-methoxy-4,5 dimethylenedioxyamphetamine) and TMA (3,4,5-trimethoxyamphetamine); geraniol is a potent emetic

Adverse Reactions

Cardiovascular: Sinus tachycardia

Endocrine & metabolic: Abortion

Signs and Symptoms of Overdose The most prominent effects of significant ingestions include hallucinations, nausea, and profound vomiting. Dry skin, feeling of impending doom, hypotension, hypothermia, miosis, mydriasis, and tachycardia may also be seen. Symptoms may be delayed up to 8 hours after ingestion.

Dosage It is estimated that 2 tablespoons of ground nutmeg will produce toxicity; however, amounts may vary depending on the content of volatile oil. See Additional Information

Overdosage/Treatment

Decontamination: Administer activated charcoal with cathartic for recent substantial ingestions
Supportive therapy: Symptomatic and supportive treatment as needed

Passion Flower

Scientific Name *Passiflora incarnata*

U.S. Brand Names Sedacalm®

Synonyms *Passiflora* spp; Apricot Vine; Maypop; Passion Vine

Use Mild insomnia, neuralgia, anxiety; sedative (Wolfman, 1994; Speroni, 1988)

Mechanism of Action

The constituents, maltol and ethylmaltol, have been shown to produce central nervous system sedation and a reduction in spontaneous motor activity (low doses) in laboratory animals. In humans, passion flower may be effective when used in combination with other sedative and anti-anxiety herbs such as valerian. These effects may be due to synergism, but also may be due to the potential binding of passion flower constituents to benzodiazepine receptors *in vivo*.

Contains flavonoids (vitexin, isovitexin, apigenin, schaftoside, isoschaftoside, and swertisin) and harmane alkaloids (concentration <0.01%) which may affect neurotransmitter metabolism and exhibit a motility inhibiting effect on smooth muscle in animal studies (as per Commission E).

Adverse Reactions

Cardiovascular: Bradycardia, ventricular bigeminy, ventricular tachycardia, prolonged QT interval, U waves on ECG

Central nervous system: Lethargy

Dermatologic: Urticaria

Gastrointestinal: Nausea, vomiting

Respiratory: IgE mediated occupational asthma, rhinitis

Admission Criteria/Prognosis Admit any ingestion >1 g/kg or any symptomatic patient.

Dosage Sedacalm®: 500 mg to 1 g, 3 times/day; up to 8 g daily of active drug has been recommended

Contraindications Based on pharmacological effects, may cause drowsiness; use caution when driving an automobile or operating heavy machinery. Use with caution in individuals taking anti-anxiety agents, antidepressants, hypnotics, or sedatives. Reported in animal studies to increase sleeping time induced by hexobarbital (Aoyagi, 1974).

Warnings Use all herbal supplements with extreme caution in children <2 years of age and in pregnancy or lactation. Some herbs are contraindicated in pregnancy or lactation; make sure to observe warnings. Use with caution in individuals on medication and with pre-existing medical conditions. Always review for potential herb-drug interactions (HDIs) and other warnings. Large and prolonged doses may increase the potential for adverse effects. Herbs may cause transient adverse effects such as nausea, vomiting, and GI distress due to a variety of chemical constituents. Caution should be used in individuals having known allergies to plants.

Overdosage/Treatment

Decontamination: Lavage within 1 hour/activated charcoal without cathartic

Supportive therapy: Antiemetics and crystalloid I.V. fluids can be utilized for dehydration

Drug Interactions Anxiolytics, antidepressants, barbiturates, sedatives
Additional Information A perennial climbing vine with large (5-9 cm) white, blue, purple, or pale red flowers and a yellow oval fruit. The woody stem may be as long as 10 meters in length. The plant is usually found in the Southeast U.S. and South America.

Specific References

Wolfman C, Viola H, Paladini A, et al, "Possible Anxiolytic Effects of Chrysin, A Central Benzodiazepine Receptor Ligand Isolated from *Passiflora coerulea*," *Pharmacol Biochem Behav*, 1994 47(1):1-4

Pennyroyal Oil

CAS Number 8007-44-1

APHA Botanical Safety Rating System

Class 2b

Synonyms *Mentha pulegium*; Pulegium Oil

Use Insect repellent; inducing delayed menses, rubefacient; is used primarily by natural health advocates (not FDA approved for stated use)

Mechanism of Action Derived from the herbs European pennyroyal (*Mentha pulegium*) and American pennyroyal (*Hedeoma pulegioides*); contain several monoterpenes, one of which (pulegone) is hepatotoxic by causing depletion of glutathione

Adverse Reactions

Cardiovascular: Hypotension

Central nervous system: Confusion, delirium, agitation, hallucinations (auditory and visual); seizures (within 3 hours)

Endocrine & metabolic: Abortifacient, menstrual bleeding

Gastrointestinal: Nausea, vomiting, abdominal pain

Hematologic: Hemolytic anemia, disseminated intravascular coagulation

Hepatic: Hepatic failure, centrilobular necrosis

Renal: Renal failure, hematuria, acute tubular necrosis

Respiratory: Epistaxis

Admission Criteria/Prognosis Patients can be discharged home if asymptomatic 4 hours postingestion; admit any adult ingestion > 5 mL

Toxicodynamics/Kinetics

Absorption: Oral: Good

Metabolism: Hepatic to menthofuran (toxic metabolite)

Half-life: 2.2 hours (animals)

Dosage Oil dose used for above purposes: 0.12-0.6 mL

Reference Range Menthofuran serum levels of 10 ng/mL and 41 ng/mL associated with multiple organ failure in infants

Overdosage/Treatment

Decontamination: Due to aspiration risk, **do not** induce emesis; lavage (within 1 hour) is recommended; activated charcoal (with cathartic) may be useful

Supportive therapy: N-acetylcysteine (loading dose: 140 mg/kg, then 70 mg/kg every 4 hours) should be administered within the first few hours postingestion for ingestions > 10 mL; benzodiazepines can be used for seizures

Additional Information Fatal dose: 15 mL. Not reviewed by Commission E; mint-like odor; pulegone may deplete glutathione stores in the liver; a yellow oil; hepatotoxicity has occurred after drinking teas from the herb; should not be taken internally; postmortem pulegone and menthofuran levels in a fatality were 18 ng/mL and 1 ng/mL respectively; a menthofuran level of 40 ng/mL obtained 10 hours postingestion associated with mild toxicity

Peppermint Oil

CAS Number 8006-90-4

Scientific Name *Mentha piperita*

APHA Botanical Safety Rating System Class 1 (leaf); oil not listed

U.S. Brand Names China Maze; Cholaktol; Citaethol; Colpermin;

Kiminto; Mentacur; Mintec

Uses

Fragrant/flavoring agent; this volatile oil is also used in herbal medicine as a spasmolytic (for upper GI tract/bile duct); for irritable bowel syndrome; antibacterial agent; treatment for nausea and dyspepsia; none of these uses are FDA approved

Per Commission E: External use: Myalgia and neuralgia

Mechanism of Toxic Action The oil contains menthol (29% to 48%), menthone (20% to 31%), and methyl acetate (3% to 10%) along with small quantities of eucalyptol and azulene; may have spasmolytic activity on smooth muscles

Adverse Reactions

Cardiovascular: Flushing

Central nervous system: Headache

Dermatologic: Contact dermatitis, urticaria, erythematous

Signs and Symptoms of Overdose Menthol is the major toxic constituent. Abdominal pain, ataxia, atrial fibrillation, bradycardia, coma, dizziness, lethargy, nausea, skin rash, tremor, vomiting, vertigo

Admission Criteria/Prognosis Admit adult ingestions > 1 g of peppermint oil

Toxicodynamics/Kinetics

Absorption: Rapid

Metabolism (menthol): To menthol glucuronide

Dosage

Peppermint oil: 0.2-0.4 mL 3 times/day

Peppermint spirit (10% peppermint oil and 15% peppermint leaf extract): 1 mL (20 drops) with water

Toxic dose: 0.3 g (12 drops of pure oil)

Per Commission E:

Daily internal dose: 6-12 drops

Irritable colon: Single dose: 0.2 mL

Enterically coated form, daily dose: 0.6 mL

Inhalation: 3-4 drops in hot H₂O

External: Semisolid preparations: 5% to 20%

Aqueous-alcohol preparations: 5% to 10%

Nasal ointments: 1% to 5% oil

Reference Range Peak urinary total menthol content following ingestion of 0.6 mL of peppermint oil: ~117 mg

Overdosage/Treatment

Decontamination:

Oral: Lavage (within 1 hour)/activated charcoal with cathartic; **do not** induce emesis

Ocular: Irrigate copiously with saline or water

Supportive therapy: Symptomatic bradycardia can be treated with atropine (although this has not been formally studied)

Additional Information Peppermint plant is a perennial with purple/lilac-colored flowers and yields up to 1% volatile oil; do not give to children; contraindications in pregnancy, cholecystitis, and hepatic damage

Polygonum multiflorum

Synonyms Chinese Combind; Fo-Ti; He Shou-Wu

Use Tuberous root (raw or processed) used for vertigo, insomnia, constipation

Mechanism of Action Contains 2 anthraquinones (emodin and physcin) which may cause catharsis and a toxic hepatitis

Adverse Reactions

Cardiovascular: Palpitations

Central nervous system: Dizziness, fever

Dermatologic: Erythema, rash, pruritus, photosensitivity

Gastrointestinal: Nausea, diarrhea

Hepatic: Hepatitis, jaundice

Ocular: Blurred vision

Respiratory: Tachypnea

Overdosage/Treatment Supportive therapy: Hepatitis can resolve within 3 weeks upon discontinuation of drug; antihistamines can be used for pruritus

Additional Information A climbing evergreen plant native in Japan

Propolis

Synonyms Bee Glue; Bee Propolis; Hive Dross

Uses Has been advocated as an anti-inflammatory agent, antibacterial agent (for treatment of tuberculosis), treatment for gastric or duodenal ulcers, superficial dermal infections

Mechanism of Toxic Action A natural resin obtained from the buds of conifers or poplar trees; collected and used by honey bees to seal their hives; most of the anti-inflammatory properties seem to be due to its flavonoid pigments; aqueous extract of propolis can inhibit the enzyme dihydrofolate reductase; a dermal sensitizing agent; has been known to cause hypersensitivity reactions; contains flavonoids, phenolic acids, hydrogen peroxide, and pollen (5%); a component of honey; a known free radical scavenger

Signs and Symptoms of Overdose No systemic toxicity seen; local dermatitis, erythema, and pruritus may occur; oral ulceration/mucositis can occur with lozenges

Overdosage/Treatment

Decontamination: Dermal: Wash with soap and water

Supportive therapy: Topical corticosteroids with diphenhydramine can be used to treat propolis-induced dermatitis

Specific References

Cohen HA, Varsano I, Kahan E, et al, "Effectiveness of an Herbal Preparation Containing Echinacea, Propolis, and Vitamin C in Preventing Respiratory Tract Infections in Children: A Randomized, Double-Blind, Placebo-Controlled, Multicenter Study," *Arch Pediatr Adolesc Med*, 2004, 158(3):217-21.

Psoralea Corylifolia

Synonyms Babchi; Boh-Gol-Zhee; Pa-Go-Zhee

Use Folk remedy prevalent in Far East Asia for management of osteoporosis, osteomalacia, bone fractures; also has been used to treat psoriasis and vitiligo. Usually dried mature seeds or leaves are used daily, often in tea-form.

PYGEUM AFRICANUM

Mechanism of Action Seeds contain psoralen, isosoralen, and psoralidin which are potent cell growth inhibitors; leaves contain genistein - a phytoestrogen

Signs and Symptoms of Overdose Photodermatitis (from seeds), cholestatic hepatitis, jaundice, elevated transaminase

Overdosage/Treatment

Oral:
Decontamination: Activated charcoal is of uncertain benefit
Supportive care: Monitor liver function tests

Additional Information Native to India; herbaceous plant of the leguminosae family with pea-like flowers

Specific References

Nam SW, Baek JT, Lee DS, et al, "A Case of Acute Cholestatic Hepatitis Associated with the Seeds of *Psoralea Corylifolia* (Boh-Gol-Zhee)," *Clin Toxicol*, 2005, 43(6):589-91.

Pygeum africanum

U.S. Brand Names Tadenan

Uses Treatment of mild to moderate benign prostatic hyperplasia

Mechanism of Toxic Action Contains beta-sitosterol (a phytosterol) which competes with androgens, thus decreasing intraprostatic prostaglandin levels. The pentacyclic triterpenes also reduce inflammation and edema through inhibition of glycosyl-transferase activity. Androgen synthesis in the prostate is also inhibited by ferulic acid esters of fatty alcohols.

Adverse Reactions Gastrointestinal: GI upset

Dosage Oral: 50 mg twice daily (tablets); maximum daily dose: 200 mg

Overdosage/Treatment Decontamination: Gastric decontamination should probably occur for ingestions >500 mg. Lavage within 1 hour and/or activated charcoal should be used.

Additional Information Found in the bark of the evergreen African prune tree. Commonly used as a second-line agent if *Serenoa repens* (saw palmetto) is unsuccessful. Not evaluated by Commission E.

Reishi Mushroom

Scientific Name *Ganoderma lucidum*

Uses Antineoplastic/immune stimulant agent in herbal medicine

Mechanism of Toxic Action Contains ganoderan B which can induce hepatic enzymes and increase plasma insulin levels

Adverse Reactions

Central nervous system: Dizziness
Dermatologic: Dermatitis, pruritus
Gastrointestinal: Diarrhea
Neuromuscular & skeletal: Bone pain

Overdosage/Treatment Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic
Supportive therapy: Oral antihistamines can be used to treat pruritus

Additional Information Contraindications with hemophilia (due to high adenosine content); an edible brown mushroom found on California hardwoods

Rhubarb

Scientific Name *Rheum officinale*; *Rheum palmatum*; *Rheum rhaponticum*

APHA Botanical Safety Rating System Class 2b, 2d; contraindicated in intestinal obstruction, abdominal pain of unknown origin, or any inflammatory condition of the intestines (appendicitis, colitis, Crohn's disease, irritable bowel, etc), and in children <12; not for long-term use in excess of 8-10 days; individuals with a history of kidney stones should use cautiously

Uses Stimulant laxative; constipation (per Commission E)

Mechanism of Toxic Action Leaves are toxic and contain soluble and insoluble oxalates; contains soluble and insoluble sodium and potassium oxalates

Adverse Reactions

Per Commission E:
Endocrine & metabolic: Disturbances of electrolyte balance, especially potassium deficiency in long-term use/abuse; potassium deficiency can lead to disorders of cardiac function especially with cardiac glycosides, diuretics, and corticoadrenal steroids
Gastrointestinal: Cramp-like discomforts of gastrointestinal tract in single incidents; pseudomelanosis coli in long-term use/abuse
Renal: Albuminuria, hematuria in long-term use/abuse

Signs and Symptoms of Overdose Dermal pain, dermatitis, diarrhea, dysphonia, edema, feces discoloration (yellow-green), hypocalcemia, irritation, oxalate crystals may be deposited on cornea, renal injury (due to calcium oxalate precipitation), salivation, seizures, swelling, vomiting. Sap may cause corneal abrasion, lacrimation, ocular pain, photophobia

Dosage Per Commission E: 20-30 mg hydroxyanthracene derivatives/day calculated as Rhein

Warnings Per Commission E: Use of stimulant laxatives for longer than recommended short-term application can cause an increase in intestinal sluggishness

Overdosage/Treatment

Decontamination: Oral: Dilute; ipecac/lavage/activated charcoal not likely necessary; milk/water to rinse crystals

Supportive therapy: For treatment of soluble oxalates, which may cause systemic oxalate toxicity, keep well hydrated, monitor renal function, fluid/electrolytes; hypocalcemia may occur which can be treated with calcium gluconate, monitor urine for crystals; treat other symptoms supportively

Drug Interaction Per Commission E: Long-term use/abuse, due to loss in potassium, an increase in effectiveness of cardiac glycosides and an effect on antiarrhythmics is possible. Potassium deficiency can be increased by simultaneous application of thiazide diuretics, corticoadrenal steroids or licorice root.

Rue

Scientific Name *Ruta graveolens*

APHA Botanical Safety Rating System Class 2b, 2d; contraindicated in poor kidney function; avoid prolonged exposure to sunlight

Synonyms Common Rue; Garden Rue; German Rue; Herb-of-Grace

Use Antispasmodic, abortifacient, emmenagogue, topical insect repellent

Mechanism of Action Contains the alkaloids, arborine, and arborinine; also contains rutamarin (a coumarin); antispasmodic effect on gastrointestinal smooth muscle; may inhibit implantation of fertilized cells in uterus; the furocoumarins found on fresh leaves can cause a photosensitivity reaction

Adverse Reactions

Per Commission E:

Dermatologic: Oil can cause contact dermatitis; phototoxic reactions causing dermatoses have been noted

Hepatic: Severe liver damage

Renal: Proteinuria, hematuria

Therapeutic dosages can have these effects:

Central nervous system: Melancholic moods, sleep disorders, tiredness, dizziness

Neuromuscular & skeletal: Spasms

Juice of fresh leaves can lead to:

Cardiovascular: Low pulse

Central nervous system: Fainting, sleepiness

Endocrine & metabolic: Abortion

Gastrointestinal: Painful irritations of stomach and intestines, swelling of the tongue

Miscellaneous: Clammy skin

Signs and Symptoms of Overdose Topical administration of fresh leaves can cause dermal erythema, blistering, and photosensitization.

Volatile oil may be an irritant and can cause hepatic and renal abnormalities. Nausea and vomiting upon ingestion

Overdosage/Treatment Decontamination: **Oral:** Lavage (within 1 hour)/activated charcoal with cathartic **Dermal:** Wash with soap and water; avoid sunlight

Pregnancy Risk Factor Contraindicated

Additional Information Fatal dose: ~100 mL of the oil or 4 ounces of fresh leaves.

See Commission E; rue oil is used as an abortifacient; it is a pale yellow oil (density: 0.8) which is not water soluble; the plant (which is native to Europe but found worldwide) is an evergreen shrub which can grow to 2-3 feet with yellow flowers blooming in summer

Sabah Vegetable

Scientific Name *Sauropus albicans*; *Sauropus androgynus*

U.S. Brand Names Defat® (in U.S.)

Synonyms Asin-Asin; Checker Manis; Weight Reduction Vegetable

Commonly Found In Malaysia, Thailand, India, Taiwan; shrub-like plant which can grow up to 1.5 m high

Use Has been used (at a daily dose of 150 g) for weight reduction and vision protection

Mechanism of Action Fresh leaves contain papaverine alkaloid (580 mg/100 g of leaves); papaverine inhibits cellular respiration, is a mild calcium antagonist and vasodilator

Adverse Reactions

Cardiovascular: Palpitations, prolonged QT interval, torsade de pointes, chest tightness

Central nervous system: Insomnia, anxiety, fatigue, dizziness

Dermatologic: Rashes

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Anorexia

Neuromuscular & skeletal: Tremor

Respiratory: Dyspnea, hypoxia, cough, tachypnea, obstructive lung disease, bronchiolitis obliterans (may all develop after 4 months of use), wheezing and rales may also occur

Overdosage/Treatment

Decontamination: Ipecac (within 30 minutes)/activated charcoal with cathartic is useful

Supportive therapy: Lorazepam or diazepam 10-20 mg (0.25-0.4 mg/kg for children) is helpful for seizures; I.V. fluids and alpha-adrenergic pressors should be used for hypotension; sodium bicarbonate (1 mEq/kg) is useful to treat acidosis

Enhanced elimination: Multiple dosing of activated charcoal may be useful

Additional Information Not sold in U.S. market; commonly found in Malaysia, Thailand, India, Taiwan; shrub-like plant which can grow up to 1.5 meters high

Sassafras Oil

CAS Number 8006-80-2

Scientific Name *Sassafras albidum*

APHA Botanical Safety Rating System Class 2d (leaf, root); not for long-term use; do not exceed recommended dosage

Synonyms *Sassafras albidum*; Oleum Sassafras

Use Banned by FDA in food since 1960; has been used as a mild counterirritant on the skin (ie, for lice or insect bites); should not be ingested

Mechanism of Action Contains safrole (up to 80%) which inhibits liver microsomal enzymes; its metabolite may cause hepatic tumors

Adverse Reactions

(Primarily related to sassafras oil and safrole)

Cardiovascular: Tachycardia, flushing, hypotension, sinus tachycardia

Central nervous system: Anxiety, hallucinations, vertigo, aphasia

Dermatologic: Contact dermatitis

Gastrointestinal: Vomiting

Hepatic: Fatty changes of the liver, hepatic necrosis

Ocular: Mydriasis

Miscellaneous: Diaphoresis

Little documentation of adverse effects due to ingestion of herbal tea

Toxicodynamics/Kinetics

Absorption: Safrole is absorbed orally

Metabolism: Hepatic to 1-hydroxysafrole (possible carcinogenic metabolite)

Elimination: Renal primarily

Dosage Sassafras tea can contain as much as 200 mg (3 mg/kg) of safrole

Overdosage/Treatment

Decontamination: Emesis (within 30 minutes) can be considered for ingestion > 5 mL if airway is protected; activated charcoal with cathartic can be used

Supportive therapy: Hypotension can be treated with intravenous crystalloid (10-20 mL/kg) and placement in Trendelenburg position; dopamine or norepinephrine can be used for refractory cases

Additional Information Lethal dose: ~5 mL; Toxic dose: Humans: 0.66 mg/kg based on rodent studies. A yellow liquid which may also contain eugenol, pinene, and d-camphor; specific gravity: 1.07; not reviewed by Commission E

Saw Palmetto

Scientific Name *Serenoa repens*

APHA Botanical Safety Rating System Class 1

U.S. Brand Names Prostatective

Synonyms *Sabal serrulata*; *Sabalis serrulatae*; *Serenoa repens*; American Dwarf Palm Tree; Cabbage Palm; Palmetto Scrub; Sabal Palmetto; Sabal

Use

In herbal medicine, plant extracts have been used to manage prostatic enlargement (benign prostate hyperplasia only)

Per Commission E: Urination problems in benign prostatic hyperplasia stages 1 & 2

Mechanism of Action Liposterolic extract of the berries may inhibit the enzymes 5 α -reductase, along with cyclo-oxygenase and 5-lipoxygenase, thus exhibiting antiandrogen and anti-inflammatory effects; does not reduce prostatic enlargement but may help increase urinary flow (not FDA approved)

Adverse Reactions

Central nervous system: Headache

Endocrine & metabolic: Gynecomastia

Gastrointestinal: Stomach problems (in rare cases) per Commission E

Signs and Symptoms of Overdose Diarrhea

Toxicodynamics/Kinetics Absorption: Oral: Low

Dosage

Daily dose: ~320 mg; tea products are not utilized

Per Commission E: 1-2 g fruits/berries daily or 320 mg standardized extract; lipophilic ingredients extracted with lipophilic solvents (hexane or ethanol 90% v/v)

Contraindications Pregnancy and breast-feeding

Warnings Per Commission E: Relieves only the difficulties associated with enlarged prostate without reducing the enlargement; consult a physician at regular intervals

Overdosage/Treatment

Decontamination: Ipecac within 30 minutes or lavage (within 1 hour)/activated charcoal with cathartic

Pregnancy Implications Do not use

Additional Information A fan palm plant growing up to 10' tall on the southern Atlantic coast; the red to brownish black berries, when ripe, are used in herbal medicine; this product has no effect on PSA or testosterone levels

Senna**Related Information**

- Buckthorn Bark
- Cascara Sagrada

CAS Number 128-57-4; 52730-36-6; 52730-37-7; 8013-11-4; 81-27-6

Scientific Name *Cassia acutifolia*; *Cassia angustifolia*; *Cassia senna*

U.S. Brand Names Senlax[®]; Sennakot[®]; Sennocol[®]; X-Prep[®]

Synonyms Alexandrine Senna; Tinnevelley Senna

Use Short-term treatment of constipation; evacuate the colon for bowel or rectal examinations

Mechanism of Toxic Action Contains up to 3% anthraquinone glycosides which can cause colonic stimulation

Adverse Reactions

Cardiovascular: Palpitations

Central nervous system: Tetany, dizziness

Dermatologic: Finger clubbing (reversible)

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Vomiting (with fresh plant leaves or pods), diarrhea, abdominal cramping, nausea, melanosis coli (reversible), cachexia

Genitourinary: Red discoloration in alkaline urine (yellow-brown in acidic urine)

Hepatic: Hepatitis, aminotransferase level elevation (asymptomatic)

Renal: Oliguria, proteinuria

Respiratory: Dyspnea

Per Commission E:

Endocrine & metabolic: Long-term use/abuse can cause electrolyte imbalance

Gastrointestinal: In single incidents, cramp-like discomforts of gastrointestinal tract requiring a reduction in dosage

Toxicodynamics/Kinetics

Onset of action: Oral: 6-8 hours; Suppository: 0.5-2 hours

Metabolism: Hydrolyzed by bacteria in the colon thus releasing active sennosides

Elimination: Urine and feces

Dosage Sennosides:

Children > 6 years: 20 mg at bedtime

Adults: 20-40 mg with water at bedtime

Senna granules: 2.5-5 mL (163-326 mg) at bedtime; maximum dose: 10 mL (652 mg)/day

Senna tablets:

Children > 60 pounds: 1 tablet (187 mg) at bedtime; maximum daily dose: 2 tablets

Adults: 1-2 tablets (187-374 mg) at bedtime; maximum daily dose: 4 tablets (Note: Extra strength senna tablets contain 374 mg each)

Senna syrup:

Children 1 month to 1 year: 1.25-2.5 mL (55-109 mg) at bedtime up to 5 mL/day

1-5 years: 2.5-5 mL (109-218 mg) at bedtime, up to 10 mL/day

5-15 years: 5-10 mL (218-436 mg) at bedtime, up to 20 mL/day

Adults: 10-15 mL (436-654 mg); maximum daily dose: 30 mL (1308 mg)

Senna suppositories:

Children > 60 pounds: 1/2 suppository (326 mg)

Adults: 1 suppository (652 mg) at bedtime; can repeat in 2 hours

Tea: 1/2 to 2 teaspoons of leaves (0.5-4 g of the herb)

Administration Oral: Once daily doses should be taken at bedtime. Granules may be eaten plain, sprinkled on food, or mixed in liquids

Contraindications Per Commission E: Intestinal obstruction, acute intestinal inflammation (eg, Crohn's disease), colitis ulcerosa, appendicitis, abdominal pain of unknown origin; pregnancy

Warnings Not recommended for over-the-counter (OTC) use in patients experiencing stomach pain, nausea, vomiting, or a sudden change in

ST JOHN'S WORT

bowel movements which lasts >2 weeks. Not recommended for OTC use in children <2 years of age.

Dosage Forms

[DSC] = Discontinued product

Granules (Senokot®): Sennosides 15 mg/teaspoon (60 g, 180 g, 360 g) [cocoa flavor] [DSC]

Liquid:

Senexon: Sennosides 8.8 mg/5 mL (240 mL)

X-Prep®: Sennosides 8.8 mg/5 mL (75 mL) [alcohol free; contains sugar 50 g/75 mL; available individually or in a kit] [DSC]

Liquid concentrate (Fletcher's® Castoria®): Senna concentrate 33.3 mg/mL (75 mL) [alcohol free; contains sodium benzoate; root beer flavor]

Syrup (Uni-Senna): Sennosides 8.8 mg/5 mL (240 mL) [contains alcohol; butterscotch flavor]

Tablet: Sennosides 8.6 mg, 15 mg, 25 mg

ex-lax®: Sennosides USP 15 mg

ex-lax® Maximum Strength: Sennosides USP 25 mg

Perdiem® Overnight Relief: Sennosides USP 15 mg

Sennatural™, Senokot®, Senexon®, Senna-Gen®, Uni-Senna: Sennosides 8.6 mg

Tablet, chewable:

ex-lax®: Sennosides USP 15 mg [chocolate flavor]

Evac-U-Gen: Sennosides 10 mg

Reference Range Total rhein plasma concentration does not exceed 160 ng/mL after therapeutic dosing

Overdosage/Treatment Decontamination: Do not induce emesis; lavage (within 1 hour)/activated charcoal can be used

Drug Interaction Per Commission E: Potentiation of cardiac glycosides (with long-term use) is possible due to loss in potassium; effect on anti-arrhythmics is possible; potassium deficiency can be increased by simultaneous application of thiazide diuretics, corticosteroids, and licorice root

Pregnancy Risk Factor C

Pregnancy Implications May discolor urine or feces; monitor I & O

Additional Information Both leaf and fruits ("pods") are used; avoid prolonged use; may increase potency and toxicity of digitalis; the plant is found in North Africa and India; a low branching shrub with large yellow leaves on the top of the plant are harvested; hypersensitivity to the ingredients; contraindications in fecal impaction, bowel obstruction, and abdominal pain

St John's Wort

CAS Number 548-04-9 (hypericin)

Scientific Name *Hypericum perforatum*

APHA Botanical Safety Rating System Class 2d; may potentiate pharmaceutical MAO inhibitors

U.S. Brand Names Esberic®; Hyperforat®; Lophakomp-Hypericum®; Millepertuis®; Neuroplant®; Psychotonin M®; VIMRxgn

Synonyms *Hypericum perforatum*; Amber Touch-and-Feel; Goatweed; Klamath Weed; Rosin Rose

Use

Mild to moderate depression; also used traditionally for treatment of stress, anxiety, insomnia; used topically for vitiligo; also a popular drug for AIDS patients due to possible antiretroviral activity; used topically for wound healing

Per Commission E: Psychovegetative disorders, depressive moods, anxiety and/or nervous unrest; oily preparations for dyspeptic complaints; oily preparations externally for treatment of post-therapy of acute and contused injuries, myalgia, first degree burns

Mechanism of Action Active ingredients are xanthenes flavonoids (hypericin) which can act as monoamine oxidase inhibitors, although *in vitro* activity is minimal; majority of activity appears to be related to GABA modulation; may be related to dopamine, serotonin norepinephrine modulation also

Adverse Reactions

Cardiovascular: Sinus tachycardia

Central nervous system: Hypomania

Dermatologic: Photosensitization is possible, especially in fair-skinned persons (per Commission E)

Gastrointestinal: Stomach pains, abdominal pain

Miscellaneous: Allergic reactions (0.5%)

Signs and Symptoms of Overdose Diarrhea, drowsiness, fever, hypertension, nausea, photosensitivity, pruritus, rash, tachycardia

Dosage

Tincture: 1/4 to 1 teaspoon up to 3 times/day

Topical: Crushed leaves and flowers are applied to affected area after cleansing with soap and water

Per Commission E: 2-4 g drug (dried herb) or 0.2-1 mg of total hypericin in other forms of drug application

Contraindications Endogenous depression, pregnancy, children <2 years of age (not confirmed in animal models, *in vitro* only).

Reference Range Hypericin serum level of 4 ng/mL obtained 8 hours after ingestion of 1 mg extract of hypericin

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic
Supportive therapy: Agitation, tachycardia, and hypertension can be treated with a benzodiazepine

Drug Interactions Avoid amphetamines or other stimulants; use with caution in patients taking MAO inhibitors, levodopa, and 5-hydroxytryptophan; avoid tyramine-containing foods due to presence of hypericin although human data of this potential drug interaction is lacking; tannin-containing herbs can cause a decrease in iron absorption; may enhance the side effects of narcotics and selective serotonin reuptake inhibitors; may increase side effects of ethanol and melatonin. Photosensitivity may be particularly aggravated with tetracycline or chlorpromazine use. St John's wort may induce hepatic enzymes, thus enhancing theophylline clearance. Concomitant administration with protease inhibitors may result in decreased plasma levels of the protease inhibitor; similar effects can be seen with cyclosporine and non-nucleoside reverse transcriptase inhibitors. Hypericum (St John's wort) extract reduces the bioavailability of digoxin by 25%. Concomitant administration of St John's Wort and paroxetine can result in serotonin syndrome. St John's wort (*Hypericum*) appears to induce CYP3A enzymes and has led to 57% reductions in indinavir AUCs and 81% reductions in trough serum concentrations, which may lead to treatment failures. St John's wort may decrease atorvastatin levels.

Pregnancy Implications Do not use

VIMRxgn is a synthetic hypericin for HIV treatment; leaves and tops of *Hypericum perforatum* plant used in herbal medicine. St John's wort is a perennial that reaches 2 feet tall with the aroma similar to turpentine; golden yellow flowers bloom in early summer. Young plant is almost as toxic as the mature plant. Hypericin inhibits both type A and type B monoamine oxidase; contraindications in endogenous depression, pregnancy, children <2 years of age (not confirmed in animal models, *in vitro* only). This herbal preparation should be discontinued for 2-3 weeks prior to surgery.

Hypericum extract ZE, 250 mg twice daily, appears to be as effective as imipramine, 75 mg twice daily, for treatment of mild to moderate depression for 6 weeks.

Ting Kung Teng

Scientific Name *Erycibe henryi prain*

Synonyms Bao Gong Teng

Use Stems/roots are used to treat arthritis/musculoskeletal symptoms; eye drops are used to treat glaucoma in China

Mechanism of Action A member of the morning glory family (convolvulaceae), this plant is a shrub which grows at low elevations in Taiwan, Southern China, and Southern Japan. Contains EhP which are tropane alkaloids (scopoletin and scopolin) which exhibit muscarinic, cholinergic, and sedative effects.

Signs and Symptoms of Overdose Onset is usually within 10 minutes; vomiting, diarrhea, dizziness, lacrimation, hypersalivation, diaphoresis, weakness, rhinorrhea, ventricular tachycardia, miosis, bradycardia, hypotension, hypothermia

Overdosage/Treatment

Decontamination: Activated charcoal may be useful

Supportive: Treatment is primarily supportive; atropine can be used to treat symptomatic bradycardia; lidocaine or amiodarone can be used to

treat ventricular arrhythmias - cardioversion (electrical) may be necessary

Additional Information Therapeutic dose for arthritis: 3-8 g; oral doses >27 g can produce severe symptoms

Specific References

Huang HH, Yen DH, Wu ML, et al, "Acute *Erycibe henryi* prain (Ting Kung Teng) Poisoning," *Clin Tox*, 2006, 44:71-5.

Valerian

CAS Number 8057-49-6

Scientific Name *Valeriana officinalis*

APHA Botanical Safety Rating System Class 1

U.S. Brand Names Nervex®; Neuro!®; Orasedon®; Sanox-N®; Ticalma®; Valerian Root; Valerianaheel®; Valmane®

Synonyms *Valeriana edulis*; *Valeriana wallichii*; Garden Heliotrope; Jacob's Ladder; Phu; Radix Valerianae; Radix; Red Valerian

Use

Herbal medicine use as a sleep-promoting agent and minor tranquilizer (similar to benzodiazepines); used in anxiety, panic attacks, intestinal cramps, headaches

Per Commission E: Restlessness, sleep disorders based on nervous conditions

Mechanism of Action Most pharmacologic activity located in fresh root or dried rhizome; the plant contains essential oils (valerenic acid and valenol, valepotriates, and alkaloids <0.2% concentration) which may affect neurotransmitter levels (serotonin, GABA, and norepinephrine); also has antispasmodic properties

Signs and Symptoms of Overdose Abdominal cramping, blurred vision, fatigue, fine tremor, headache, mydriasis. Intravenous exposure can cause hypocalcemia, hypokalemia, hypophosphatemia, hypotension, lethargy, and piloerection. Contact with the plant can cause contact dermatitis. Hepatotoxicity (probably due to an idiosyncratic hypersensitivity) has been noted.

Admission Criteria/Prognosis Admit any intravenous exposure or any adult oral ingestion >20 g

Dosage Up to 1 g at night

Per Commission E:

Tea: 2-3 g of drug per cup of H₂O for tea; once to several times/day

Tincture: 1/2 to 1 teaspoon (1-3 mL) once to several times/day

Extracts: Equal to 2-3 g of drug

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic Supportive therapy: Hypotension can be treated with I.V. crystalloid therapy

Drug Interactions Not synergistic with alcohol; potentiation of other CNS depressants is possible

Additional Information *Valeriana officinalis* is a perennial plant that can reach 5 feet in height with tiny white or pink flowers. It is found in Europe, Canada, and Northern U.S. Preparations may contain multiple components.

Specific References

Wiener SW, Hoffman RS, and Nelson LS, "Withdrawal Symptoms After Valerian Cessation," *J Toxicol Clin Toxicol*, 2003, 41(5):721.

Wormwood

CAS Number 471-15-8; 546-80-5

Scientific Name *Artemisia absinthium*

APHA Botanical Safety Rating System Class 2b, 2c, 2d; not for long-term use; do not exceed recommended dose

Synonyms *Artemisia absinthium*; Absinthium; Assenzio; Bitter Wormwood; Losna; Mugwort; Pelin; Qinghaosu Extract; Wormseed

Use

Homeopathic medicine, used as an anthelmintic, bitter tonic, hair tonic, sedative, flavoring agent (in vermouth)

Per Commission E: Loss of appetite, dyspepsia, biliary dyskinesia

Mechanism of Action Contains Thujone (a volatile oil of terpene structure), which binds to the same neuronal receptors as tetrahydrocannabinol; can inhibit porphyrin synthesis; also contains absinthin (bittering agent) and santonin (anthelmintic for roundworms)

Signs and Symptoms of Overdose "Absinthism": Anorexia, color vision disturbance, coma, contact dermatitis (from flowers), delirium, diaphoresis, diarrhea, dysphoria, euphoria, giddiness, headache, mania, memory impairment, paranoia, psychosis, respiratory depression, seizures (>15 g ingestion), thirst, tremors, vertigo, visual hallucinations, vomiting

Toxicodynamics/Kinetics Metabolism: (Thujone) Hepatic (oxidative metabolism)

Dosage Tea: 2-3 g/day

Overdosage/Treatment

Decontamination: Lavage (within 1 hour)/activated charcoal with cathartic Supportive therapy: Seizures can be managed with a benzodiazepine or barbiturate; psychiatric abnormalities can be managed with a benzodiazepine or neuroleptic agent

Drug Interaction Thujone-containing and gamolenic acid-containing herbs can lower the seizure threshold leading to increased anticonvulsant dosage requirements.

Pregnancy Implications Avoid

Additional Information

Not popular in the U.S.; taste threshold (Absinthin): 1 part in 70,000: A shrub with small green-yellow flowers from July through September. Grows naturally in Europe but found in Northeastern and North Central U.S. Wormwood extract has been used in absinth, an emerald green bitter liquor banned in Europe and U.S. Absinth has been thought to cause Vincent van Gogh's psychosis. The tea uses dried leaves and flowering tops.

Per Commission E: In toxic doses, thujone, the active component of the oil, acts as a convulsant poison. Thus, essential oil must not be used except in combinations.

SECTION V

ANTIDOTES AND DRUGS USED IN TOXICOLOGY

POISON ANTIDOTE PREPAREDNESS IN HOSPITALS

Anthony Burda, RPh, Illinois Poison Center

Michael Wahl, MD, Advocate Illinois Masonic Medical Center & Illinois Poison Center

Christina Hantsch, MD, Loyola University Medical Center & Illinois Poison Center

The quantities of medications listed in the IPC's (Illinois Poison Center's) antidote list are suggested guidelines; the amounts may be adjusted based on factors such as anticipated usage in the hospital's local area, the nearest alternate sources of antidotes, the distance to tertiary care institutions, etc. Keep in mind that some antidotes (eg, the cyanide antidote kit) must be immediately available on-site when a patient arrives at a hospital. Inadequate antidote preparedness may lead to increased morbidity or mortality.

All healthcare professionals should become familiar with regional poison control center poison prevention and treatment services. Staffed by pharmacists, nurses, physicians, and poison specialists, poison centers are available 24 hours a day, 7 days a week to all residents and health professionals of each state for consultation on the treatment of poisonings, medication interactions, occupational exposures, hazardous material incidents, envenomations, and other poison-related concerns.

The following statement can be attributed to Darryl S. Rich, PharmD, JCAHO Associate Director, Home Care Accreditation Services.

"The Joint Commission, in moving towards a functional and nondepartmental approach to its standard manuals, no longer has such a specific standard related to antidotes. However, there are two standards that would apply to the need for a pharmacy to maintain a supply of common antidotes in stock. Standard TX 3.1. The organization identified an appropriate selection of medications available for prescribing and ordering. This standard specifically required hospitals to develop criteria for the selection of products maintained in stock by the pharmacy. Those criteria must address patient need, given the diseases and conditions treated by the hospital and its emergency room.

The second relevant standard is TX 3.5.5. Emergency medications are consistently available, controlled, and secure in the pharmacy and patient care areas. Although this standard usually refers to the control and security of medications in emergency medication carts on the patient units, it can be used if appropriately selected antidotes (which the Joint Commission considers emergency medications) are not readily available.

Thus, from TX 3.1, it is incumbent upon the medical staff and the pharmacy, through its Pharmacy and Therapeutics Committee or other medical staff committee responsible for formulary selection, to select which antidotes the pharmacy should stock. Under standard TX 3.5.5, the pharmacy must then make sure the selected antidotes are readily available."

Illinois Poison Center Antidote List			
Uses and Suggested Minimum Stock Quantities for Various Poison Antidotes Used for Treatment of Poisonings Illinois Poison Center 24-Hour Hotline: 1-800-942-5969			
Antidote	Poison/Drug/Toxin	Suggested Minimum Stock Quantity	Rationale/Comments
N-Acetylcysteine (Mucomyst®)	Acetaminophen Carbon tetrachloride Other hepatotoxins	600 mL in 10 mL or 30 mL vials of 20% solution	Acetaminophen is the most common drug involved in intentional and unintentional poisonings. This amount (600 mL/120 g) provides enough antidote to treat an adult for an entire 3-day course of therapy, or enough to treat 3 adults for 24 hours. Several vials may be stocked in the ED to provide a loading dose and the remaining vials in the pharmacy for the q4h maintenance doses.

POISONING AND TOXICOLOGY

Illinois Poison Center Antidote List (Continued)			
Antidote	Poison/Drug/Toxin	Suggested Minimum Stock Quantity	Rationale/Comments
Amyl nitrite, sodium nitrite, and sodium thiosulfate (cyanide antidote kit)	Acetonitrile Acrylonitrile Bromates (thiosulfate only) Chlorates (thiosulfate only) Cyanide (eg, HCN, KCN and NaCN) Cyanogenic glycoside natural sources (eg, apricot pits and peach pits) Hydrogen sulfide (nitrites only) Laetrile Nitroprusside (thiosulfate only) Smoke inhalation (combustion of synthetic materials)	One to two kits	Stock one kit in the ED. Consider also stocking one kit in the pharmacy. Note: This has a short shelf-life of 18 months.
Antivenin, Crotalidae polyvalent	Pit viper envenomation (eg, rattlesnakes, cottonmouths, and copperheads)	Ten vials	Stock in pharmacy. Advised in geographic areas with endemic populations of copperhead, water moccasin, or eastern massasauga rattlesnakes. In low-risk areas, know nearest alternate source of antivenin. Note: 20-40 vials or more may be needed for moderate to severe envenomations. The antivenin must be administered in a critical care setting since it is an equine-derived product.
Antivenin, Crotalidae polyvalent Immune Fab - Ovine (CroFab®)	Pit viper envenomation (eg, rattlesnakes, cottonmouths, and copperheads)	Four to six vials	Stock in pharmacy. Recently FDA-approved product that is a possible alternate to equine product. May have lower risk of hypersensitivity reaction than equine product. Average dose in premarketing trials was 12 vials, but more may be needed. Note: Store in refrigerator. See equine antivenin also.
Antivenin, <i>Latrodectus mactans</i> (black widow spider)	Black widow spider envenomation	Zero to one vial	<i>Latrodectus</i> envenomations are very rare in Illinois. This product is only used for severe envenomations. Antivenin must be given in a critical care setting since it is an equine-derived product. Know the nearest source of antidote. Note: Product must be refrigerated at all times.
Atropine sulfate	α_2 -agonists (eg, clonidine, guanabenz, and guanfacine) Antimuscarinic agents (eg, pyridostigmine) Bradycardia-producing agents (eg, beta-blockers, calcium channel blockers, and digitalis glycosides) Cholinergic agonists (eg, bethanechol) Organophosphate and carbamate insecticides Muscarine-containing mushrooms (eg, Clitocybe and Inocybe) Nerve agents (eg, sarin, soman, tabun, and VX) Tacrine	Total 100-150 mg Available in various formulations: 0.4 mg/mL (1 mL, 0.4 mg ampuls) 0.4 mg/mL (20 mL, 8 mg vials) 0.1 mg/mL (10 mL, 1 mg ampuls)	The product should be immediately available in the ED. Some may also be stored in the pharmacy or other hospital sites, but should be easily mobilized if a severely poisoned patient needs treatment. Note: Product is necessary for adequate preparedness for a weapon of mass destruction (WMD) incident.
Calcium chloride and Calcium gluconate	Beta-blockers Black widow spider (<i>Latrodectus mactans</i>) envenomation Calcium channel blockers Fluoride salts (eg, NaF) Hydrofluoric acid (HF) Hyperkalemia (not digoxin-induced) Hypermagnesemia	10% calcium chloride: fifteen 10 mL vials 10% calcium gluconate: five 10 mL vials	Stock in ED. More may be stocked in pharmacy. Many ampuls of calcium chloride may be necessary in life-threatening calcium channel blocker or hydrofluoric acid poisoning.
Calcium disodium EDTA (Versenate®)	Lead Zinc salts (eg, zinc chloride)	One 5 mL amp (200 mg/mL)	Stock in pharmacy. One vial provides one day of therapy for a child. More may be needed in lead endemic areas.

Illinois Poison Center Antidote List (Continued)			
Antidote	Poison/Drug/Toxin	Suggested Minimum Stock Quantity	Rationale/Comments
Deferoxamine mesylate (Desferal®)	Iron	Twelve 500 mg vials	Stock in pharmacy. Note: Per package insert, the maximum daily dose is 6 g (12 vials). However, this dose may be exceeded in serious poisonings.
Digoxin immune fab (Digibind®)	Cardiac glycoside-containing plants (eg, foxglove and oleander) Digitoxin Digoxin	Ten vials	Stock in ED or pharmacy. This amount (10 vials) may be given to a digoxin-poisoned patient in whom the digoxin level is unknown. This amount would effectively neutralize a steady-state digoxin level of 14.2 ng/mL in a 70 kg patient. More may be necessary in severe intoxications. Know nearest source of additional supply.
Dimercaprol (BAL in Oil®)	Arsenic Copper Gold Lead Mercury	Two 3 mL ampuls (100 mg/mL)	Stock in pharmacy. This amount provides two doses of 3-5 mg/kg/dose given q4h to treat one seriously poisoned adult or provides enough to treat a 15 kg child for 24 hours.
Ethanol	Ethylene glycol Methanol	4 L of 10% ethanol in D ₅ W and 1 pint of 95% ethanol	Stock in pharmacy. This amount (4 L) provides enough to treat an adult (70 kg) with a loading dose followed by a maintenance infusion for 12 hours during dialysis. Note: Ethanol is unnecessary if fomepizole is stocked.
Flumazenil (Romazicon®)	Benzodiazepines Zolpidem	Total 1 mg: two 5 mL vials (0.1 mg/mL)	Suggested minimum is for ED stocking. Due to risk of seizures, use with extreme caution, if at all, in poisoned patients. More may be stocked in the pharmacy for use in reversal of conscious sedation.
Folic acid Folinic acid (leucovorin)	Methanol Methotrexate, trimetrexate Pyrimethamine Trimethoprim	Folic acid: three 50 mg vials Folinic acid: one 50 mg vial	Stock in pharmacy. For methanol-poisoned patients with an acidosis, give 50 mg folinic acid initially, then 50 mg of folic acid q4h for six doses.
Fomepizole (Antizol®)	Ethylene glycol Methanol	One 1.5 g vial Note: Available in a kit of four 1.5 g vials	Stock in pharmacy. Know where nearest alternate supply is located. One vial will provide at least one initial adult dose. Hospitals with critical care and hemodialysis capabilities may consider stocking one kit of four vials (enough to treat one patient for up to several days). Note: Product has a two-year shelf life; however, the manufacturer will replace expired product at no cost.
Glucagon	Beta-blockers Calcium channel blockers Hypoglycemia Hypoglycemic agents	Fifty 1 mg vials	Stock 20 mg in ED and remainder in pharmacy. This amount provides approximately 5-10 hours of high-dose therapy in life-threatening beta-blocker or calcium channel blocker poisoning.
Hyperbaric oxygen (HBO)	Carbon monoxide Carbon tetrachloride Cyanide Hydrogen sulfide Methemoglobinemia Brown recluse spider (<i>Loxosceles reclusus</i>) envenomation	Post the location and phone number of nearest HBO chamber.	Consult the regional poison control center to determine if HBO treatment is indicated.
Methylene blue	Methemoglobin-inducing agents including aniline, butyl nitrite, nitrates, nitrites, dapsone, dinitrophenol, local anesthetics (eg, benzocaine), metoclopramide, monomethylhydrazine-containing mushrooms (eg, <i>Gyromitra</i>), naphthalene, nitrobenzene, phenazopyridine	Three 10 mL ampuls 3 (10 mg/mL)	Stock in pharmacy. This amount provides 3 doses of 1-2 mg/kg (0.1-0.2 mL/kg).

POISONING AND TOXICOLOGY

Illinois Poison Center Antidote List (Continued)			
Antidote	Poison/Drug/Toxin	Suggested Minimum Stock Quantity	Rationale/Comments
Nalmefene (Revox®) Naloxone (Narcan®)	α ₂ agonists (eg, clonidine, guanabenz, and guanfacine) Angiotensin converting enzyme (ACE) inhibitors Coma of unknown cause Imidazoline decongestants (eg, oxymetazoline and tetrahydrozoline) Opioids (eg, codeine, dextromethorphan, diphenoxylate, fentanyl, heroin, meperidine, morphine, and propoxyphene) Tramadol Valproic acid	Nalmefene: None required Naloxone: Total 40 mg, any combination of 0.4 mg, 1 mg, and 2 mg ampuls	Stock 20 mg naloxone in the ED and 20 mg elsewhere in the institution. Note: Nalmefene has a longer duration of action but it offers no therapeutic advantage over a naloxone infusion.
D-Penicillamine (Cuprimine®)	Arsenic Copper Mercury	None required as an antidote. Available in bottles of 100 capsules (125 mg or 250 mg/capsule)	D-Penicillamine is no longer considered the drug of choice for heavy metal poisonings. It may be stocked in the pharmacy for other indications such as Wilson's disease or rheumatoid arthritis.
Physostigmine salicylate (Antilirium®)	Anticholinergic alkaloid-containing plants (eg, deadly nightshade and jimson weed) Antihistamines Atropine and other anticholinergic agents Intrathecal baclofen	Two 2 mL ampuls (1 mg/mL)	Stock in ED or pharmacy. Usual adult dose is 1-2 mg slow I.V. push. Note: Duration of effect is 30-60 minutes.
Phytonadione (vitamin K ₁) (AquaMEPHYTON®, Mephyton®)	Indanedione derivatives Long-acting anticoagulant rodenticides (eg, brodifacoum and bromadiolone) Warfarin	Two 0.5 mL ampuls (2 mg/mL) and two 5 mL ampuls (10 mg/mL)	Stock in pharmacy. Note: Menadione (vitamin K ₃ , Synkavite®) is ineffective and cannot be stocked as a substitute.
Pralidoxime chloride (2-PAM) (Protopam®)	Antimyasthenic agents (eg, pyridostigmine) Nerve agents (eg, sarin, soman, tabun and VX) Organophosphate insecticides Tacrine	Six 1 g vials	Stock in ED or pharmacy. Note: Serious intoxications may require 500 mg/h (12 g/day). Product is necessary for adequate preparedness for a weapon of mass destruction (WMD) incident.
Protamine sulfate	Enoxaparin Heparin	Variable, consider recommendation of hospital P&T Committee Available as 5 mL ampuls (10 mg/mL) and 25 mL vials (250 mg/25 mL)	Stock in pharmacy.
Pyridoxine hydrochloride (vitamin B ₆)	Acrylamide Ethylene glycol Hydrazine Isoniazid (INH) Monomethylhydrazine-containing mushrooms (eg, Gyromitra)	Four 30 mL vials (100 mg/mL 3 g/vial) or ten 10 mL vials (100 mg/mL, 1 g/vial)	Stock in ED or pharmacy. Usual dose is 1 g pyridoxine HCl for each g of INH ingested. If amount ingested is unknown, give 5 g of pyridoxine. Repeat dose if seizures are uncontrolled. Know nearest source of additional supply.
Sodium bicarbonate	Chlorine gas Hyperkalemia Serum alkalization: Agents producing a quinidine-like effect as noted by widened QRS complex on EKG (eg, amantadine, carbamazepine, chloroquine, cocaine, diphenhydramine, flecainide, propoxyphene, tricyclic antidepressants, quinidine, and related agents) Urine alkalization: Weakly acidic agents (eg, chlorophenoxy herbicides, chlorpropamide, phenobarbital, and salicylates)	Twenty 50 mEq vials	Stock 10 vials in the ED and 10 vials elsewhere in the hospital.
Succimer (Chemet®)	Arsenic Lead Mercury	One bottle of 100 capsules (100 mg/capsule)	Stock in pharmacy. FDA approved only for pediatric lead poisoning; however it has shown efficacy for other heavy metal poisonings.

Acetylcysteine

Pronunciation (a se teel SIS teen)

CAS Number 19542-74-6 (Acetylcysteine Sodium); 616-91-1

U.S. Brand Names Acetadote[®]; Mucomyst[®]

Synonyms N-Acetyl-L-cysteine; N-Acetylcysteine; Acetylcysteine Sodium; Mercapturic Acid; Mucomyst; NAC

Impairment Potential bypass

Use

Antidote for acute acetaminophen toxicity; for hepatic failure/encephalopathy following delayed presentation (>24 hours) of an acute acetaminophen overdose; has been used in alternative medicine to treat HIV infection; possibly beneficial as a free radical scavenger for any significant acute hepatotoxic exposures.

Acute acetaminophen ingestions:

>7.5 g ingested in an adult or >200 mg/kg in a child if no serum acetaminophen level is available

Serum acetaminophen 4-hour level >150 mcg/mL

Evidence of hepatotoxicity or measurable acetaminophen levels >24 hours postacute ingestion

Unknown quantity ingested and >24 hours has elapsed since time of ingestion or unable to obtain serum acetaminophen levels within 12 hours of ingestion

Repeated supratherapeutic dosing: Initial serum acetaminophen level >10 mcg/mL or with evidence of hepatotoxicity

Unlabeled/Investigational Use Prevention of radiocontrast-induced renal dysfunction (oral, I.V.); distal intestinal obstruction syndrome (DIOS, previously referred to as meconium ileus equivalent)

Mechanism of Action An antioxidant; exerts mucolytic action through its free sulfhydryl group which opens up the disulfide bonds in the mucoproteins thus lowering the viscosity. The exact mechanism of action in acetaminophen toxicity is unknown. It may act by maintaining or restoring glutathione levels or by acting as an alternative substrate for conjugation with the toxic metabolite.

Adverse Reactions

Inhalation: Frequency not defined.

Central nervous system: Drowsiness, chills, fever

Gastrointestinal: Vomiting, nausea, stomatitis

Local: Irritation, stickiness on face following nebulization

Respiratory: Bronchospasm, rhinorrhea, hemoptysis

Miscellaneous: Acquired sensitization (rare), clamminess, unpleasant odor during administration

Intravenous:

Cardiovascular: Angioedema, vasodilation, hypotension, tachycardia, syncope, chest tightness, flushing (15%)

Central nervous system: Dysphoria

Dermatologic: Urticaria (14%), rash, facial erythema, palmar erythema, pruritus (3%), pruritus with rash and vasodilation

Gastrointestinal: Vomiting (<1% to 10%), nausea (1% to 10%), dyspepsia

Neuromuscular & skeletal: Gait disturbance

Ocular: Eye pain

Otic: Ear pain

Respiratory: Bronchospasm (9%), cough, dyspnea pharyngitis, rhinorrhea, rhonchi, throat tightness,

Miscellaneous: Anaphylactoid reactions (2% to 10%; reported as severe in 1% or moderate in 10% of patients within 15 minutes of first infusion; mild to moderate in 6% to 7% of patients after 60 minutes); diaphoresis

Pharmacodynamics/Kinetics

Onset of action: Inhalation: 5-10 minutes

Duration: Inhalation: >1 hour

Distribution: 0.47 L/kg

Protein binding, plasma: 83%

Half-life elimination:

Reduced acetylcysteine: 2 hours

Total acetylcysteine: Adults: 5.5 hours; Newborns: 11 hours

Time to peak, plasma: Oral: 1-2 hours

Excretion: Urine

Dosage

Acetaminophen poisoning: Children and Adults:

Oral: 140 mg/kg; followed by 17 doses of 70 mg/kg every 4 hours; repeat dose if emesis occurs within 1 hour of administration; therapy should continue until all doses are administered even though the acetaminophen plasma level has dropped below the toxic range

I.V. (Acetadote[®]): Loading dose: 150 mg/kg over 60 minutes. Loading dose is followed by 2 additional infusions: Initial maintenance dose of 50 mg/kg infused over 4 hours, followed by a second maintenance dose of 100 mg/kg infused over 16 hours. To avoid fluid overload in patients <40 kg and those requiring fluid restriction, decrease volume of D₅W proportionally. Total dosage: 300 mg/kg administered over 21 hours.

Note: If commercial I.V. form is unavailable, the following dose has been reported for I.V. administration using solution for oral inhala-

tion (unlabeled): Loading dose: 140 mg/kg, followed by 70 mg/kg every 4 hours, for a total of 13 doses (loading dose and 48 hours of treatment); infuse each dose over 1 hour through a 0.2 micron Millipore filter (in-line).

Experts suggest that the duration of acetylcysteine administration may vary depending upon serial acetaminophen levels and liver function tests obtained during treatment. In general, patients without measurable acetaminophen levels and without significant LFT elevations (>3 times the ULN) can safely stop acetylcysteine after ≤24 hours of treatment. The patients who still have detectable levels of acetaminophen, and/or LFT elevations (>1000 units/L) continue to benefit from addition acetylcysteine administration

THREE-BAG Method Dosage Guide by Weight, Patients <40 kg

Body Weight		LOADING Dose		SECOND Dose		THIRD Dose	
(kg)	(lb)	Acetadote (mL)	5% Dextrose (mL)	Acetadote (mL)	5% Dextrose (mL)	Acetadote (mL)	5% Dextrose (mL)
30	66	22.5	100	7.5	250	15	500
25	55	18.75	100	6.25	250	12.5	500
20	44	15	60	5	140	10	280
15	33	11.25	45	3.75	105	7.5	210
10	22	7.5	30	2.5	70	5	140

Adjuvant therapy in respiratory conditions (such as phosgene): **Note:** Patients should receive an aerosolized bronchodilator 10-15 minutes prior to acetylcysteine.

Inhalation, nebulization (face mask, mouth piece, tracheostomy): Acetylcysteine 10% and 20% solution (Mucomyst[®]) (dilute 20% solution with sodium chloride or sterile water for inhalation); 10% solution may be used undiluted

Infants: 1-2 mL of 20% solution or 2-4 mL 10% solution until nebulized given 3-4 times/day

Children and Adults: 3-5 mL of 20% solution or 6-10 mL of 10% solution until nebulized given 3-4 times/day for about 20 minutes; dosing range: 1-10 mL of 20% solution or 2-20 mL of 10% solution every 2-6 hours

Inhalation, nebulization (tent, croupette): Children and Adults: Dose must be individualized; may require up to 300 mL solution/treatment

Direct instillation: Adults:

Into tracheostomy: 1-2 mL of 10% to 20% solution every 1-4 hours
Through percutaneous intrathecal catheter: 1-2 mL of 20% or 2-4 mL of 10% solution every 1-4 hours via syringe attached to catheter

Diagnostic bronchogram: Nebulization or intrathecal: Adults: 1-2 mL of 20% solution or 2-4 mL of 10% solution administered 2-3 times prior to procedure

Prevention of radiocontrast-induced renal dysfunction (unlabeled use):

Adults: Oral: 600 mg twice daily for 2 days (beginning the day before the procedure); may be given as powder in capsules, some centers use solution (diluted in cola beverage or juice). Hydrate patient with saline concurrently.

Treatment of phosgene inhalation (investigational): Children and Adults: 10-20 mL of a 20% solution by aerosolization

Stability

Solution for injection (Acetadote[®]): Store vials at room temperature, 20°C to 25°C (68°F to 77°F); following reconstitution with D₅W, solution is stable for 24 hours at room temperature

Acetadote[®]: Discard unused portion

Loading dose: Dilute 150 mg/kg in D₅W 200 mL

Initial maintenance dose: Dilute 50 mg/kg in D₅W 500 mL

Second maintenance dose: Dilute 100 mg/kg in D₅W 1000 mL

Solution for inhalation (Mucomyst[®]): Store unopened vials at room temperature; once opened, store under refrigeration and use within 96 hours. The 20% solution may be diluted with sodium chloride or sterile water; the 10% solution may be used undiluted. A color change may occur in opened vials (light purple) and does not affect the safety or efficacy.

Intravenous administration of solution for inhalation (unlabeled route):

Using D₅W, dilute acetylcysteine 20% oral solution to a 3% solution.

Acetadote[®] is compatible with 5% dextrose, 1/2 normal saline (0.45% sodium chloride injection), and water for injection.

Monitoring Parameters Acetylcysteine overdose: AST, ALT, bilirubin, PT, serum creatinine, BUN, serum glucose and electrolytes. Acetylcysteine levels at ~4 hours post-ingestion (~8 hours if extended release acetaminophen), and 4-6 hours later to assess for possible hepatotoxicity.

Administration

Inhalation: Acetylcysteine is incompatible with tetracyclines, erythromycin, amphotericin B, iodized oil, chymotrypsin, trypsin, and hydrogen peroxide. Administer separately. Intermittent aerosol treatments are commonly given when patient arises, before meals, and just before retiring at bedtime.

Oral: For treatment of acetaminophen overdose, administer orally as a 5% solution. Dilute the 20% solution 1:3 with a cola, orange juice, or other soft drink. Use within 1 hour of preparation. Unpleasant odor becomes less noticeable as treatment progresses. If patient vomits within 1 hour of dose, readminister.

I.V.: Intravenous formulation (Acetadote®): Administer loading dose of 150 mg/kg over 60 minutes, followed by two separate maintenance infusions: 50 mg/kg over 4 hours followed by 100 mg/kg over 16 hours. If not using commercially available I.V. formulation, use a 0.2-µ millipore filter (in-line).

Contraindications Hypersensitivity to acetylcysteine or any component of the formulation

Warnings

Inhalation: Since increased bronchial secretions may develop after inhalation, percussion, postural drainage, and suctioning should follow. If bronchospasm occurs, administer a bronchodilator; discontinue acetylcysteine if bronchospasm progresses.

Intravenous: Acute flushing and erythema have been reported; usually occurs within 30-60 minutes and may resolve spontaneously. Serious anaphylactoid reactions have also been reported. Acetylcysteine infusion may be interrupted until treatment of allergic symptoms is initiated; the infusion can then be carefully restarted. Treatment for anaphylactic reactions should be immediately available. Use caution with asthma or history of bronchospasm.

Acetaminophen overdose: The modified Rumack-Matthew nomogram allows for stratification of patients into risk categories based on the relationship between the serum acetaminophen level and time after ingestion. There are several situations where the nomogram is of limited use. Serum acetaminophen levels obtained prior to 4-hour postingestion are not interpretable; patients presenting late may have undetectable serum concentrations, but have received a lethal dose. The nomogram is less predictive in a chronic ingestion or in an overdose with an extended release product. Acetylcysteine should be administered for any signs of hepatotoxicity even if acetaminophen serum level is low or undetectable. The nomogram also does not take into account patients at higher risk of acetaminophen toxicity (eg, alcoholics, malnourished patients).

Dosage Forms

Injection, solution:

Acetadote®: 20% [200 mg/mL] (30 mL) [contains disodium edetate]
Solution, inhalation/oral: 10% [100 mg/mL] (4 mL, 10 mL, 30 mL); 20% [200 mg/mL] (4 mL, 10 mL, 30 mL)

Reference Range Determine acetaminophen level as soon as possible, ideally at least 4 hours after ingestion; toxic concentration with possible hepatotoxicity >150 mcg/mL (probably hepatotoxicity >200 mcg/mL) at 4 hours or 50 mcg/mL at 12 hours; serum N-acetylcysteine level is ~500 mg/L 15 minutes after a loading dose of 150 mg/kg. An I.V. dose of 150 mg/kg results in an approximate serum N-acetylcysteine level of 554 mg/L. Peak plasma N-acetylcysteine level in the I.V. protocol is approximately 6-35 times higher than in the oral protocol.

Test Interaction Intravenous N-Acetylcystein can decrease clotting factors within the first hour of administration thus increasing Prothrombin time; usually resolved in 16 hours

Drug Interactions Adsorbed orally by activated charcoal; clinical significance is minimal, though, once a pure acetaminophen ingestion requiring N-acetylcysteine is established; further charcoal dosing is unnecessary once the appropriate initial charcoal dose is achieved (5-10 g:g acetaminophen)

Pregnancy Risk Factor B

Pregnancy Implications Based on limited reports using acetylcysteine to treat acetaminophen overdose in pregnant women, acetylcysteine has been shown to cross the placenta in a limited manner and may provide protective levels in the fetus

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Assess patient for nausea, vomiting, and skin rash following oral administration for treatment of acetaminophen poisoning; intermittent aerosol treatments are commonly given when patient arises, before meals, and just before retiring at bedtime

Additional Information

Rate of adverse effects from intravenous N-acetylcysteine is 11% to 14% Acetadote® may turn from an essentially colorless liquid to a slight pink or purple color once the stopper is punctured. Acetadote® is a hyperosmolar solution.

Alcohol, Ethyl

Pronunciation (AL koe hol, ETH il)

Related Information

- Ethyl Alcohol

U.S. Brand Names Lavacol® [OTC]

Synonyms Alcohol, Absolute; Alcohol, Dehydrated; Ethanol; Ethyl Alcohol EtOH

Impairment Potential Yes. See Ethyl Alcohol

Commonly Includes Whiskey; Vodka

Use Antidotal therapy for methanol and ethylene glycol intoxication

Unlabeled/Investigational Use Antidote for ethylene glycol overdose; antidote for methanol overdose; treatment of fat occlusion of central venous catheters

Mechanism of Action Competitive antagonism with methanol and ethylene glycol as substrate alcohol dehydrogenase; the interaction thereby results in decreased formation of toxic metabolites and metabolic acidosis

Adverse Reactions

Cardiovascular: Postural hypotension, palpitations, hypotension (orthostatic), syncope

Central nervous system: Inebriation, sedation, coma, memory loss

Endocrine & metabolic: Hypoglycemia, osmolal gap, breast cancer, hyperprolactinemia

Gastrointestinal: Nausea, vomiting, gastritis

Neuromuscular & skeletal: Osteoporosis

Ocular: Ptosis

Respiratory: Respiratory sedation, apnea

Signs and Symptoms of Overdose See Ethyl Alcohol

Pharmacodynamics/Kinetics

Absorption: Oral: Rapid

Distribution: V_d : 0.6-0.7 L/kg; decreased in women

Metabolism: Hepatic (90% to 98%) to acetaldehyde or acetate

Half-life elimination: Rate: 15-20 mg/dL/hour (range: 10-34 mg/dL/hour); increased in alcoholics

Excretion: Kidneys and lungs (~2% unchanged)

Dosage

Oral: Loading dose: 1 g/kg (may be diluted in juice), then for maintenance: 0.1 g/kg/hour (in nondrinkers) or 0.2 g/kg/hour (in a chronic drinker); on dialysis, double the maintenance dose

I.V.: Administer 750 mg/kg as a loading dose, followed by 100-150 mg/hour; increase to 175-200 mg/kg in chronic alcoholics, or during hemodialysis; see table.

Ethyl Alcohol Dosage			
	5% I.V.	10% I.V.	50% P.O.
Loading	15 mL/kg	7.5 mL/kg	1.5 mL/kg
Maintenance	2-4 mL/kg	1-2 mL/kg	0.2-0.4 mL/kg/hr
Maintenance during hemodialysis	4-7 mL/kg	2-3.5 mL/kg	0.4-0.7 mL/kg/hr

Monitoring Parameters Respiration rate, blood pressure

Administration

Oral: Ethylene glycol or methanol poisoning: Dilute ethyl alcohol to 20% solution and administer hourly via NG tube. Oral treatment is not recommended outside of a hospital setting.

I.V.: Ethylene glycol or methanol poisoning: Administer as a 10% solution in D₅W. Initial dose should be administered over 1 hour.

Treatment of occluded central venous catheter: Instill a 70% solution with a volume equal to the internal volume of the catheter. Assess patency at 30-60 minutes (or per institutional protocol).

Intraneural: Separate needles should be used for each of multiple injections or sites to prevent residual alcohol deposition at sites not intended for tissue destruction. Inject slowly after determining proper placement of needle. Since dehydrated alcohol is hypobaric when compared with spinal fluid, proper positioning of the patient is essential to control localization of injections into the subarachnoid space.

Contraindications Hypersensitivity to ethyl alcohol or any component of the formulation; seizure disorder and diabetic coma; subarachnoid injection of dehydrated alcohol in patients receiving anticoagulants; pregnancy

Warnings

Ethyl alcohol is a flammable liquid and should be kept cool and away from any heat source. Proper positioning of the patient for neurolytic administration is essential to control localization of the injection of dehydrated alcohol (which is hypobaric) into the subarachnoid space; avoid extravasation. Not for SubQ administration. Do not administer simultaneously with blood due to the possibility of pseudoagglutination or hemolysis; may potentiate severe hypoprothrombic bleeding. Clinical evaluation and periodic lab determinations, including serum ethanol levels, are necessary to monitor effectiveness, changes in electrolyte concentrations, and acid-base balance (when used as an antidote).

Use with caution in patients with diabetes (ethyl alcohol decreases blood sugar), hepatic impairment, patients with gout, shock, following cranial surgery, and in anticipated postpartum hemorrhage. Monitor blood glucose closely, particularly in children as treatment of ingestions is associated with hypoglycemia. Avoid extravasation during I.V. administration. Water intoxication can occur with high infusion rates using I.V. products. Ethyl alcohol passes freely into breast milk at a level approximately equivalent to maternal serum level; minimize dermal

exposure of ethyl alcohol in infants as significant systemic absorption and toxicity can occur.

Dosage Forms

Foam, topical:

Epi-Clenz™: 62% (240 mL, 480 mL) [instant hand sanitizer; contains aloe vera and vitamin E]

Gel, topical:

Epi-Clenz™: 70% (45 mL, 120 mL, 480 mL) [instant hand sanitizer; contains aloe vera and vitamin E]

GelRite: 67% (120 mL, 480 mL, 800 mL) [instant hand sanitizer; contains vitamin E]

Gel-Stat™: 62% (120 mL, 480 mL) [instant hand sanitizer]

Isagel®: 60% (59 mL, 118 mL, 621 mL, 800 mL) [instant hand sanitizer]

Prevacare®: 60% (120 mL, 240 mL, 960 mL, 1200 mL, 1500 mL) [instant hand sanitizer]

Protection Plus®: 62% (800 mL) [instant hand sanitizer]

Purell®: 62% (15 mL, 30 mL, 59 mL, 120 mL, 236 mL, 250 mL, 360 mL, 500 mL, 800 mL, 1000 mL, 2000 mL) [instant hand sanitizer; contains moisturizers and vitamin E]

Purell® Moisture Therapy: 62% (75 mL) [instant hand sanitizer]

Purell® with Aloe: 62% (15 mL, 59 mL, 236 mL, 360 mL, 800 mL, 1000 mL, 2000 mL) [instant hand sanitizer; contains aloe and tartrazine]

Infusion [in D₅W, dehydrated]: Alcohol 5% (1000 mL)

Injection, solution [dehydrated]: 98% (1 mL, 5 mL)

Liquid, topical [denatured]: 70% (3840 mL)

Lavacol®: 70% (473 mL)

Lotion, topical:

Purell® 2 in 1: 62% (60 mL, 360 mL, 1000 mL) [instant hand sanitizer]

Towelettes, topical:

Isagel®: 60% (50s, 300s) [instant hand sanitizer]

Purell®: 62% (24s, 35s, 175s) [instant hand sanitizer]

Pregnancy Risk Factor D/X (prolonged use or high doses at term)

Pregnancy Implications Use only if the potential benefits outweigh the risks; ethanol crosses the placenta readily and enters fetal circulation

Lactation Enters breast milk/use caution (AAP rates "compatible")

Nursing Implications Patients receiving ethanol by infusion or mouth, may become obtunded and inebriated; they should be cared for in a carefully monitored environment

CAS Number 20537-88-6; 63717-27-1

U.S. Brand Names Ethyo[®]

Synonyms Ethiofos; Gammaphos; WR-2721; YM-08310

Use Reduce the incidence of moderate to severe xerostomia in patients undergoing postoperative radiation treatment for head and neck cancer, where the radiation port includes a substantial portion of the parotid glands. Reduce the cumulative renal toxicity associated with repeated administration of cisplatin in patients with advanced ovarian cancer or nonsmall cell lung cancer.

Mechanism of Action Organic thiophosphate compound which acts as a free radical scavenger agent; can be nephroprotective from alkylating agent effects; radioprotectant and can cause hypocalcemia through inhibition of bone resorption and parathyroid hormone secretion

Adverse Reactions

Cardiovascular: Hypotension (related to dose and infusion rates), flushing, cardiac arrest

Central nervous system: Drowsiness, sedation, fever, chills, dizziness, somnolence

Dermatologic: Exfoliative dermatitis, toxicoderma

Endocrine & metabolic: Hypocalcemia, hypomagnesemia

Gastrointestinal: Nausea, vomiting (may be severe)

Respiratory: Sneezing

Miscellaneous: Feeling of warmth/coldness, hiccups

Pharmacodynamics/Kinetics

Distribution: V_d: 3.5 L

Metabolism: Hepatic dephosphorylation to two metabolites (active-free thiol and disulfide)

Half-life elimination: 8-9 minutes

Excretion: Urine

Clearance, plasma: 2.17 L/minute

Dosage

Adults:

Cisplatin-induced renal toxicity, reduction: I.V.: 740-910 mg/m² once daily 30 minutes prior to cytotoxic therapy

Notes: Doses >740 mg/m² are associated with a higher incidence of hypotension and may require interruption of therapy or dose modification for subsequent cycles. For 910 mg/m² doses, the manufacturer suggests the following blood pressure-based adjustment schedule:

The infusion of amifostine should be interrupted if the systolic blood pressure decreases significantly from baseline, as defined below:

Decrease of 20 mm Hg if baseline systolic blood pressure < 100

Decrease of 25 mm Hg if baseline systolic blood pressure 100-119

Decrease of 30 mm Hg if baseline systolic blood pressure 120-139

Decrease of 40 mm Hg if baseline systolic blood pressure 140-179

Decrease of 50 mm Hg if baseline systolic blood pressure ≥ 180

If the blood pressure returns to normal within 5 minutes (assisted by fluid administration and postural management) and the patient is asymptomatic, the infusion may be restarted so that the full dose of amifostine may be administered. If the full dose of amifostine cannot be administered, the dose of amifostine for subsequent cycles should be 740 mg/m².

Xerostomia from head and neck cancer, reduction:

I.V.: 200mg/m²/day during radiation therapy or

SubQ: 500 mg/day during radiation therapy

Stability Store intact vials of lyophilized powder at room temperature (20°C to 25°C/68°F to 77°F). Reconstitute with 9.7 mL of sterile 0.9% sodium chloride. The reconstituted solution (500 mg/10 mL) is chemically stable for up to 5 hours at room temperature (25°C) or up to 24 hours under refrigeration (2°C to 8°C). Amifostine should be further diluted in 0.9% sodium chloride to a concentration of 5-40 mg/mL; diluted solutions (5-40 mg/mL) are stable for up to 5 hours at room temperature (25°C) or up to 24 hours under refrigeration (2°C to 8°C). For SubQ administration, reconstitute with 2.4 mL NS or SWFI.

Monitoring Parameters Blood pressure should be monitored every 5 minutes during the infusion

Administration I.V.: Administer over 3-15 minutes; administration as a longer infusion is associated with a higher incidence of side effects

Contraindications Hypersensitivity to amifostine, aminothiols compounds, or any component of the formulation

Warnings

Patients who are hypotensive or dehydrated should not receive amifostine. Interrupt antihypertensive therapy for 24 hours before amifostine. Patients who cannot safely stop their antihypertensives 24 hours before amifostine should not receive it. Patients should be adequately hydrated prior to amifostine infusion and kept in a supine position during the infusion. Blood pressure should be monitored every 5 minutes during the infusion. If hypotension requiring interruption of therapy occurs, patients should be placed in the Trendelenburg position and given an

infusion of normal saline using a separate I.V. line; subsequent infusions may require a dose reduction. Use caution in patients with cardiovascular and cerebrovascular disease and any other patients in whom the adverse effects of hypotension and nausea/vomiting may have serious adverse events.

It is recommended that antiemetic medication, including dexamethasone 20 mg I.V. and a serotonin 5-HT₃ receptor antagonist be administered prior to and in conjunction with amifostine. Rare hypersensitivity reactions, including anaphylaxis and severe cutaneous reaction, have been reported with a higher frequency in patients receiving amifostine as a radioprotectant. Discontinue if allergic reaction occurs; do not rechallenge.

Reports of clinically-relevant hypocalcemia are rare, but serum calcium levels should be monitored in patients at risk of hypocalcemia, such as those with nephrotic syndrome. Safety and efficacy in children have not been established.

Dosage Forms

Injection, powder for reconstitution:

Ethyo[®]: 500 mg

Reference Range Peak serum amifostine after an I.V. dose of 150 mg/m² ranges from 100-900 μmol/L

Overdosage/Treatment Supportive therapy: Keep patient well hydrated; monitor renal status, calcium, and magnesium

Antidote(s)

- Cisplatin
- Cyclophosphamide

Drug Interactions Antihypertensives: May potentiate the hypotensive effects of amifostine.

Pregnancy Risk Factor C

Pregnancy Implications Animal studies have demonstrated embryotoxicity. There are no adequate and well-controlled studies in pregnant women.

Lactation Excretion in breast milk unknown/not recommended

Amyl Nitrite

Pronunciation (AM il NYE trite)

Related Information

- Cyanide Antidote Kit [ANTIDOTE]

CAS Number 110-46-3; 463-04-7

Synonyms Isoamyl Nitrite

Impairment Potential Yes

Use Coronary vasodilator in angina pectoris; an adjunct in treatment of cyanide poisoning; also used to produce changes in the intensity of heart murmurs

Mechanism of Action Vasodilator (vascular smooth muscle relaxant)

Adverse Reactions

Cardiovascular: Postural hypotension, cutaneous flushing of head, neck, and clavicular area, palpitations, tachycardia, sinus tachycardia, vasodilation

Central nervous system: Headache, incoherent speech

Dermatologic: Contact dermatitis

Gastrointestinal: Nausea, colitis, vomiting

Genitourinary: Penile erection is enhanced, retarded ejaculation

Hematologic: Heinz body hemolysis/hemolytic anemia, methemoglobinemia followed by hemolysis

Ocular: Increased intraocular pressure, blurred vision, yellow vision

Respiratory: Tracheobronchitis

Signs and Symptoms of Overdose Ataxia, bradycardia, coma, cyanosis, dyspnea, methemoglobinemia (may be followed by hemolysis), stupor, tachycardia, hypotension due to vasodilation

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Pharmacodynamics/Kinetics

Onset of action: Angina: Within 30 seconds

Duration: 3-15 minutes

Dosage 1-6 inhalations from one capsule are usually sufficient to produce the desired effect

Stability Store in cool place, protect from light; insoluble in water; inflammable

Monitoring Parameters Monitor blood pressure during therapy

Administration Administer nasally. Patient should not be sitting. Crush ampul in woven covering between fingers and then hold under patient's nostrils.

Contraindications Hypersensitivity to nitrates; severe anemia; head injury; angle-closure glaucoma; postural hypotension; head trauma or cerebral hemorrhage; pregnancy

Warnings Use with caution in patients with increased intracranial pressure, low systolic blood pressure, and coronary artery disease.

Dosage Forms Vapor for inhalation [crushable covered glass capsules]: Amyl nitrite USP (0.3 mL)

Drug Interactions

Ethanol taken with amyl nitrite may have additive side effects.
Sildenafil: Avoid concurrent use of sildenafil; severe reactions may result.

Pregnancy Risk Factor X

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Administer by nasal inhalation; patient should be sitting; crush ampul in woven covering between fingers and then hold under patient's nostrils

Angiotensin Amide

CAS Number 11128-99-7; 53-73-6

Use Has been used to treat hypotension; may be antidotal for angiotensin-converting enzyme inhibitor overdose. May possibly be useful in treating hypotension due to amiodarone.

Mechanism of Action Related to the peptide angiotensin II, this pressor agent increases peripheral resistance of peripheral blood vessels (splanchnic, renal, cutaneous).

Adverse Reactions Cardiovascular: Hypertension, bradycardia (reflex)

Dosage Hypotension: Continuous intravenous infusion: 1-10 mg of drug in 1 liter of 0.9% sodium chloride or 5% glucose. Titrate to desired blood pressure. Doses up to 18 mcg/minute have been used, but most patients will respond to doses of 3-10 mcg/minute.

Antitoxin Botulinum Types A, B, and E

Use Prophylaxis or active treatment of individuals who have eaten food known or strongly suspected of being infected with *Clostridium botulinum*

Adverse Reactions

Cardiovascular: Tachycardia, cardiovascular collapse, flushing, cyanosis, sinus tachycardia

Dermatologic: Urticaria

Ocular: **Dry eyes, lagophthalmos, ptosis, photophobia, vertical deviation**

Respiratory: Wheezing, bronchospasm, apnea

Miscellaneous: Signs or symptoms of anaphylaxis (typically occur within 20-60 minutes); serum sickness may occur within 14 days of administration and is more likely to follow a repeat injection of equine serum; hypersensitivity

Stability Excessive agitation or shaking of the reconstituted vial may cause foaming, which may lead to denaturation of the antivenin

Monitoring Parameters Resolution of symptoms of botulism, or emergence of symptoms of sensitivity to the antitoxin

Administration Administer 1-2 vials slowly I.V. in a 1:10 dilution with 0.9% normal saline (may also give a dose of 1 vial I.M.), and then subsequent doses every 2-4 hours I.V. based on clinical findings. Avoid magnesium since it may enhance the action of the toxin. Trivalent (ABE) antitoxin is usually most effective if administered within 24 hours. Usually, only one vial dose is necessary.

Pregnancy Risk Factor C

Pregnancy Implications Use only if the potential benefits outweigh the risks; it is not known if botulinum antitoxin antibodies cross the placenta

Antivenin (Crotalidae) Polyvalent

Pronunciation (an tee VEN in (kroe TAL ih die) pol i VAY lent)

U.S. Brand Names Antivenin Polyvalent [Equine]; CroFab™ [Ovine]

Synonyms Crotalidae Antivenin; Crotaline Antivenin, Polyvalent; North and South American Antisnake-Bite Serum; Pit Viper Antivenin; Snake (Pit Vipers) Antivenin

Use Neutralization of venoms of North and South American crotalids: rattlesnake, massasauga, cantil, copperhead, cottonmouth, water moccasins, fer-de-lance, bushmaster

Mechanism of Action Enhances venom elimination but has no effect on local tissue injury

Adverse Reactions

Cardiovascular: Chest pain, hypotension

Central nervous system: Chills, nervousness

Dermatologic: Cellulitis, bruising, pruritus, rash, urticaria

Gastrointestinal: Anorexia, nausea

Hematologic: Coagulation disorder, thrombocytopenia

Neuromuscular & skeletal: Back pain, circumoral paresthesia, general paresthesia, myalgia

Respiratory: Asthma, cough, dyspnea, sputum increased, wheezing

Miscellaneous: Allergic reaction, serum sickness, subcutaneous nodule, wound infection

Pharmacodynamics/Kinetics

Half-life elimination: Antivenin polyvalent (ovine): 12-23 hours (based on limited data)

Time to peak: Antivenin polyvalent (equine): I.M.: ≥ 8 hours

Dosage

Children and Adults: Crotalid envenomation:

Antivenin polyvalent (equine): I.M., I.V.: Initial sensitivity test: 0.02-0.03 mL of a 1:10 dilution of normal horse serum or antivenin given

intracutaneously; also give a control test using normal saline in the opposite extremity. A positive reaction occurs within 5-30 minutes. A negative reaction does not rule out the possibility of an immediate or delayed reaction with treatment.

Minimal envenomation: 50-100 mL (5-10 vials)

Moderate envenomation: 100-200 mL (10-20 vials)

Severe envenomation: >200 mL (≥ 20 vials)

Note: The entire initial dose of antivenin should be administered as soon as possible to be most effective (within 6 hours after the bite). I.V. is the preferred route of administration. When administered I.V., infuse the initial 5-10 mL dilution over 3-5 minutes while carefully observing the patient for signs and symptoms of sensitivity reactions. If no reaction occurs, continue infusion at a safe I.V. fluid delivery rate. Additional doses of antivenin are based on clinical response to the initial dose. If swelling continues to progress, symptoms increase in severity, hypotension occurs, or decrease in hematocrit appears, an additional 10-50 mL (1-5 vials) should be administered.

Antivenin polyvalent (ovine): Skin testing is not indicated. If it is necessary to give I.M., administer in the buttocks; avoid if possible.

I.V.: Minimal or moderate envenomation:

Initial dose: 4-6 vials, dependent upon patient response. Treatment should begin within 6 hours of snakebite; monitor for 1 hour following infusion. Repeat with an additional 4-6 vials if control is not achieved with initial dose. Continue to treat with 4- to 6-vial doses until complete arrest of local manifestations, coagulation tests, and systemic signs are normal. Administer I.V. over 60 minutes at a rate of 25-50 mL/hour for the first 10 minutes. If no allergic reaction is observed, increase rate to 250 mL/hour. Monitor closely

Maintenance dose: Once control is achieved, administer 2 vials every 6 hours for up to 18 hours (3 doses); optimal dosing past 18 hours has not been established; however, treatment may be continued if deemed necessary based on the patient's condition.

Stability

Antivenin polyvalent (equine): Store in refrigerator, avoid temperatures $>37^{\circ}\text{C}$. For I.V. infusion; reconstitute each vial with 10 mL of bacteriostatic water for injection, provided with the antivenin; mix by gentle swirling; use within 48 hours. To prepare for I.V. use, further prepare a 1:1-1:10 dilution of reconstituted antivenin in normal saline or D₅W; use within 24 hours

Antivenin polyvalent (ovine): Store between 2°C to 8°C (36°F to 46°F); do not freeze. Reconstitute each vial with 10 mL sterile water and mix by gentle swirling. Further dilute total dose in 250 mL NS; use within 4 hours of reconstitution

Monitoring Parameters Vital signs; hematocrit, hemoglobin, platelet count (multiple times daily); prothrombin time, clot retraction, bleeding and coagulation times, BUN, electrolytes, bilirubin, size of bitten area (repeat every 15-30 minutes); intake and output, signs and symptoms of anaphylaxis/allergy

Administration

I.M.: Antivenin polyvalent (equine): May be used in cases of minimal envenomation; I.V. route is preferred. Administer into a large muscle mass, preferably the gluteal area. Avoid nerve trunks. Do not inject into finger or toe.

I.V.:

Antivenin polyvalent (equine): Infuse the initial 5-10 mL dilution over 3-5 minutes while carefully observing the patient for signs and symptoms of sensitivity reactions. If no reaction occurs, continue infusion at a safe I.V. fluid delivery rate. Total dose should be administered as soon as possible.

Antivenin polyvalent (ovine): Administer I.V. over 60 minutes at a rate of 25-50 mL/hour for the first 10 minutes. If no allergic reaction is observed, increase rate to 250 mL/hour. Monitor closely Epinephrine and diphenhydramine should be available during the infusion. Decreasing the rate of infusion may help control some adverse effects. Do not inject into finger or toe.

Contraindications Hypersensitivity to any component of the formulation, unless the benefits outweigh the risks and appropriate management for anaphylaxis is available

Warnings Should be used within 4-6 hours of snakebite to prevent clinical deterioration and development of coagulation abnormalities. Coagulation abnormalities are due directly to snake venom interference with the coagulation cascade. Recurrent coagulopathy occurs in approximately 50% of patients and may persist for 1-2 weeks or more. Patients should be monitored for at least 1 week and evaluated for other, pre-existing conditions associated with bleeding disorders. In severe rattlesnake bites, a decrease in platelets may occur, lasting hours to several days, and whole blood transfusions may not be effective treatment. Anaphylaxis and anaphylactoid reactions are possible due to animal proteins in the antivenin. Patients should also be monitored for delayed allergic reactions or serum sickness. Antivenin polyvalent (equine) contains phenol, thimerosal, and is made from horse serum. A skin test for horse-serum sensitivity should be done prior to treatment. Antivenin polyvalent (ovine) is processed with papain and may cause hypersensitivity reactions in patients allergic to papaya, other papaya extracts, papain, chymopapain,

ANTIVENIN (*LATRODECTUS MACTANS*)

or the pineapple enzyme bromelain. There may also be cross allergy with dust mite and latex allergens. Antivenin polyvalent (ovine) also contains thimerosal and is made from sheep plasma.

Dosage Forms

Injection, powder for reconstitution:

Antivenin (Crotalidae) polyvalent [equine]: Derived from *Crotalus adamanteus*, *C. atrox*, *C. durissus terrificus*, and *Bothrops atrox* snake venoms [equine origin; contains phenol and thimerosal; packaged with diluent and normal horse serum for sensitivity testing]

CroFab™ [ovine]: Derived from *Crotalus adamanteus*, *C. atrox*, *C. scutulatus*, and *Agkistrodon piscivorus* snake venoms [ovine origin; contains thimerosal; manufactured with papain]

Drug Interactions No drug interaction studies have been conducted

Pregnancy Risk Factor C

Pregnancy Implications Reproduction studies have not been conducted. Products contain thimerosal, which may be associated with neurological and renal toxicities in the fetus and very young children.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications

Administer at a slower rate initially; monitor for signs and symptoms of sensitivity reactions. Reactions to antivenin may occur anytime during treatment and for weeks after administration.

Antivenin polyvalent (equine): Antivenin may be administered I.M. for minimal envenomation. I.V. administration of antivenin is preferred for moderate to severe envenomation or in the presence of shock; do not inject into a finger or toe

should be readily available. After one test dose, give 1 vial I.V. diluted in normal saline (50-100 mL) infused over ~20-30 minutes; pretreatment with epinephrine or with an antihistamine may prevent allergic reactions; may repeat with a second dose if the patient weighs >40 kg or if there is no response

Warnings Carefully review allergies and history of exposure to products containing horse serum. History of atopic sensitivity to horses may increase risk of immediate sensitivity reactions. A skin or conjunctival test should be performed prior to use in all patients. A desensitization protocol is available if sensitivity tests are mildly or questionably positive to reduce risk of immediate severe hypersensitivity reaction. Desensitization should be performed only when antivenin administration would be lifesaving. In otherwise healthy adults (16-60 years), use of antivenin may be deferred and other treatments may be considered. Epinephrine 1:1000 should be readily available.

Dosage Forms Injection, powder for reconstitution: 6000 antivenin units [equine origin; contains thimerosal; packaged with diluent and normal horse serum for sensitivity testing]

Pregnancy Risk Factor C

Pregnancy Implications Use only if the potential benefits outweigh risks; it is not known if *L. mactans* antivenin antibodies cross the placenta

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Patient should be closely monitored for symptoms of hypersensitivity or anaphylaxis during skin or eye testing, desensitization, drug administration, and for 24 hours following administration

Antivenin (*Micrurus fulvius*)

Pronunciation (an tee VEN in mye KRU rus FUL vee us)

Synonyms North American Coral Snake Antivenin

Use Envenomation by the eastern coral snake (*Micrurus fulvius fulvius*) or the Texas coral snake (*M. fulvius tener*); antivenin therapy should be instituted as soon as the biting snake is identified as *M. fulvius fulvius* or *M. fulvius tener*, because systemic symptoms may be impossible to reverse at a later time

Mechanism of Action Refined, concentrated, and lyophilized preparation of serum globulins from horses immunized with eastern coral snake (*M. fulvius fulvius*) venom

Adverse Reactions

Cardiovascular: Shock, facial edema

Central nervous system: Apprehension

Dermatologic: Urticaria

Neuromuscular & skeletal: Peripheral neuritis, muscle weakness

Miscellaneous: Anaphylaxis, serum sickness

Dosage I.V.: Children and Adults: 3-5 vials by slow injection (dependent on severity of signs/symptoms; some patients may need more than 10 vials)

Stability Prior to reconstitution, store at 2° C to 8° C (36° F to 46° F); do not freeze. Dilute each vial with SWFI 10 mL. Vial contains a vacuum which will pull the diluent in, point diluent stream at the center of the lyophilized pellet. If diluent runs down side of vial, the pellet will float and adhere to vial stopper. Swirl gently, do not shake, for 1 minute then repeat every 5 minutes. Reconstitution takes ~30 minutes/vial. Color of final solution may vary from clear to slight yellow or green.

Excessive agitation or shaking of the reconstituted vial may cause foaming, which may lead to denaturation of the antivenin

Monitoring Parameters Resolution of symptoms of *M. fulvius* intoxication or emergence of symptoms of sensitivity to the antivenin; also monitor respiratory function and oxygenation, as well as the urine for hemoglobinuria

Administration Similar scheme as per antivenin for Crotalidae; usually less amount of vials need to be administered; average dose: 4-6 vials; rarely more than 10 vials are necessary; can treat allergic reactions with antihistamines and corticosteroids

Contraindications Concomitant use with opioid analgesics or other respiratory depressants; history of anaphylaxis to equine-derived serum is a relative contraindication

Warnings When administering this agent, have ready access to drugs and equipment for resuscitation. Use caution with asthma, hay fever, urticaria, equine allergy, prior injections with equine serum. Perform skin test prior to administration. The absence of a skin hypersensitivity reaction does not exclude anaphylaxis or hypersensitivity following antivenin administration. False-negative rate for skin testing is 10% with similar agents. Conversely, hypersensitivity is not an absolute contraindication in a significantly envenomated patient. Delayed serum sickness may occur even with a negative allergic history and absence of reaction to skin test.

Dosage Forms Injection, powder for reconstitution: Derived from *Micrurus fulvius* venom [equine origin; contains phenol and thimerosal; packaged with diluent] [DSC]

Drug Interactions

Beta-blockers: May increase severity of anaphylaxis.

Opioid analgesics: Use of morphine and other narcotics which depress respiration are contraindicated.

Sedatives: Use with extreme caution.

Pregnancy Risk Factor C

Antivenin (*Latrodectus mactans*)

Pronunciation (an tee VEN in lak tro DUK tus MAK tans)

Synonyms Black Widow Spider Species Antivenin (*Latrodectus mactans*)

Use Symptoms of envenomation by the black widow spider (*Latrodectus mactans*) including severe hypertension or pain refractory to analgesia, calcium, or sedation; and/or abdominal muscle spasm in pregnancy, threatened spontaneous abortion or early onset labor; also patients in respiratory distress; patients with cardiac disease; pediatric patients or the elderly

Mechanism of Action Refined, concentrated, and lyophilized preparation of serum globulins from horses immunized with black widow spider (*Latrodectus mactans*) venom

Adverse Reactions

Cardiovascular: Tachycardia, cardiovascular collapse, flushing, cyanosis, sinus tachycardia

Dermatologic: Urticaria

Respiratory: Wheezing, bronchospasm, apnea

Miscellaneous: Other signs or symptoms of anaphylaxis (typically occur within 20-60 minutes); serum sickness may occur within 14 days of administration, and is more likely to follow a repeat injection of equine serum

Signs and Symptoms of Overdose Localized diaphoresis at site of bite

Stability Excessive agitation or shaking of the reconstituted vial may cause foaming, which may lead to denaturation of the antivenin

Monitoring Parameters Resolution of symptoms of *L. mactans* intoxication or emergence of symptoms of sensitivity to the antivenin

Administration Administer a test dose: 0.01-0.02 mL of reconstituted antivenom diluted 1:10, administered SubQ. Resuscitation equipment

Pregnancy Implications Use only if the potential benefits outweigh risks; it is not known if *M. fulvius* antivenin antibodies cross out the placenta

Nursing Implications Patient should be closely monitored for symptoms of hypersensitivity or anaphylaxis during skin or eye testing, desensitization, drug administration, and for 24 hours following administration

Antivenin, Polyvalent Crotalidae (Ovine) Fab

U.S. Brand Name CroFab®

Use Neutralization of venoms of North American crotalid (minimal to moderate severity)

Mechanism of Action ~5.2 times as potent as Wyeth antivenin in neutralization of venom with reversal of venom-induced platelet aggregation; may reverse neurotoxicity

Adverse Reactions

Miscellaneous: Serum sickness (1 in 42 patients)

Dermal: Urticaria, rash

Pharmacodynamics/Kinetics

Half life: (Total Fab): 12 to 23 hours

Dosage Initial dose: 4 to 6 vials infused IV over 60 minutes. Infuse initial dose slowly over the first ten minutes at a 25 to 50 ml/hour rate. Repeat, if necessary, until initial control is achieved (complete arrest of local manifestations and normalization of coagulation test results and systemic signs). After initial control is achieved, give two vials I.V. every six hours for up to 18 hours. Follow up dose of two vials may be given as deemed necessary. In clinical trials, a medium dose of 12 vials was used. No skin testing is required.

Monitoring Parameters Prothrombin time, platelet count, fibrinogen concentration

Contraindications Hypersensitivity to papaya or papain (weigh benefits to risks)

Reference Range Total Fab following injection of 6 vials: 740 mg/L

Pregnancy Risk Factor C

Additional Information Distributed by Fougera (www.fougera.com): Phone 800-645-9833 Reconstitute with 250 ml of 0.9% sodium chloride (4 to 6 vials).

Asoxime Chloride

Related Information

- Obidoxime Chloride [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

CAS Number 34433-31-3

Unlabeled/Investigational Use

Investigational: Has been used in dichlorvos and dimethoate poisoning; rodent experiments indicate that it may be effective in tabun, sarin, VX soman or GF exposure with atropine used as a pretreatment

Mechanism of Action A cholinesterase reactivator; may be more effective for the diethoxy group of organophosphates than the dimethoxy type; may be effective in treating VX, sarin, soman, or GF-type nerve gas

Dosage Nerve gas or parathion exposure: 500 mg diluted in 3 mL of distilled water intramuscularly 4 times/day for 2-7 days; total dosage range: 4-14 g

Reference Range Therapeutic serum HI-6 level is ~4 mcg/mL

Antidote(s)

- Obidoxime Chloride [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

Atropine

Pronunciation (A troe peen)

CAS Number 51-55-8; 55-48-1; 5908-99-6

U.S. Brand Names AtroPen®; Atropine-Care®; Isopto® Atropine; Sal-Tropine™

Synonyms Atropine Sulfate

Use

Injection: Preoperative medication to inhibit salivation and secretions; treatment of symptomatic sinus bradycardia; AV block (nodal level); ventricular asystole; antidote for nerve agents, organophosphate pesticide poisoning; anticholinesterase, cholinergic medication poisoning, and muscarinic symptoms of mushroom poisoning (*Clitocybe*, *Inocybe*)
Ophthalmic: Produce mydriasis and cycloplegia for examination of the retina and optic disc and accurate measurement of refractive errors;uveitis

Oral: Inhibit salivation and secretions

Unlabeled/Investigational Use Pulseless electric activity, asystole, neuromuscular blockade reversal; treatment of nerve agent toxicity (chemical warfare) in combination with pralidoxime

Mechanism of Action Blocks the action of acetylcholine at parasympathetic sites in smooth muscle, secretory glands, and the central muscarinic receptors; increases cardiac output, dries secretions, antagonizes histamine and serotonin

Adverse Reactions

Severity and frequency of adverse reactions are dose related and vary greatly; listed reactions are limited to significant and/or life-threatening.
Cardiovascular: Arrhythmia, flushing, hypotension, palpitation, tachycardia
Central nervous system: Ataxia, coma, delirium, disorientation, dizziness, drowsiness, excitement, fever, hallucinations, headache, insomnia, nervousness, weakness

Dermatologic: Anhidrosis, urticaria, rash, scarlatiniform rash

Gastrointestinal: Bloating, constipation, delayed gastric emptying, loss of taste, nausea, paralytic ileus, vomiting, xerostomia

Genitourinary: Urinary hesitancy, urinary retention

Ocular: Angle-closure glaucoma, blurred vision, cycloplegia, dry eyes, mydriasis, ocular tension increased

Respiratory: Dyspnea, laryngospasm, pulmonary edema

Miscellaneous: Anaphylaxis

Signs and Symptoms of Overdose Ataxia, blurred vision, coma, dilated unreactive pupils, diminished or absent bowel sounds, dryness of mucous membranes, flushing, foul breath, hallucinations (lilliputian), hypertension, hyperthermia, ileus, increased respiratory rate, ototoxicity (deafness), seizures, swallowing difficulty, tachycardia, tinnitus, urinary retention

Pharmacodynamics/Kinetics

Onset of action: I.V.: Rapid

Absorption: Complete

Distribution: Widely throughout the body; crosses placenta; trace amounts enter breast milk; crosses blood-brain barrier

Metabolism: Hepatic

Half-life elimination: 2-3 hours

Excretion: Urine (30% to 50% as unchanged drug and metabolites)

Dosage

Neonates, Infants, and Children: Doses <0.1 mg have been associated with paradoxical bradycardia.

Inhibit salivation and secretions (preanesthesia): Oral, I.M., I.V., SubQ:

<5 kg: 0.02 mg/kg/dose 30-60 minutes preop then every 4-6 hours as needed. Use of a minimum dosage of 0.1 mg in neonates <5 kg will result in dosages >0.02 mg/kg. There is no documented minimum dosage in this age group.

>5 kg: 0.01-0.02 mg/kg/dose to a maximum 0.4 mg/dose 30-60 minutes preop; minimum dose: 0.1 mg

Alternate dosing:

3-7 kg (7-16 lb): 0.1 mg

8-11 kg (17-24 lb): 0.15 mg

11-18 kg (24-40 lb): 0.2 mg

18-29 kg (40-65 lb): 0.3 mg

>30 kg (>65 lb): 0.4 mg

Bradycardia: I.V., intratracheal: 0.02 mg/kg, minimum dose 0.1 mg, maximum single dose: 0.5 mg in children and 1 mg in adolescents; may repeat in 5-minute intervals to a maximum total dose of 1 mg in children or 2 mg in adolescents. (**Note:** For intratracheal administration, the dosage must be diluted with normal saline to a total volume of 1-5 mL). When treating bradycardia in neonates, reserve use for those patients unresponsive to improved oxygenation and epinephrine.

Children: Organophosphate or carbamate poisoning:

I.V.: 0.03-0.05 mg/kg every 10-20 minutes until atropine effect, then every 1-4 hours for at least 24 hours

I.M. (AtroPen®): Mild symptoms: Administer dose listed below as soon as exposure is known or suspected. If severe symptoms develop after first dose, 2 additional doses should be repeated in 10 minutes; do not administer more than 3 doses. Severe symptoms: Immediately administer 3 doses as follows:

<6.8 kg (15 lbs): Use of **AtroPen® formulation not recommended**; administer atropine 0.05 mg/kg

6.8-18 kg (15-40 lbs): 0.5 mg/dose

18-41 kg (40-90 lbs): 1 mg/dose

>41 kg (>90 lbs): 2 mg/dose

Adults (doses <0.5 mg have been associated with paradoxical bradycardia):

BROMOCRIPTINE

Asystole or pulseless electrical activity: I.V.: 1 mg; repeat in 3-5 minutes if asystole persists; total dose of 0.04 mg/kg; may give intratracheally in 10 mL NS (intratracheal dose should be 2-2.5 times the I.V. dose)

Inhibit salivation and secretions (preanesthesia):

I.M., I.V., SubQ: 0.4-0.6 mg 30-60 minutes preop and repeat every 4-6 hours as needed

Oral: 0.4 mg, may repeat every 4-6 hours

Bradycardia: I.V.: 0.5-1 mg every 5 minutes, not to exceed a total of 3 mg or 0.04 mg/kg; may give intratracheally in 10 mL NS (intratracheal dose should be 2-2.5 times the I.V. dose)

Neuromuscular blockade reversal: I.V.: 25-30 mcg/kg 60 seconds before neostigmine or 7-10 mcg/kg in combination with edrophonium

Organophosphate or carbamate poisoning:
I.V.: 2 mg, followed by 2 mg every 15 minutes until adequate atropinization has occurred; initial doses of up to 6 mg may be used in life-threatening cases. Total daily doses as high as 100 mg daily have been reported.

I.M. (AtroPen®): Mild symptoms: Administer 2 mg as soon as exposure is known or suspected. If severe symptoms develop after first dose, 2 additional doses should be repeated in 10 minutes; do not administer more than 3 doses. Severe symptoms: Immediately administer three 2 mg doses.

Mydriasis, cycloplegia (preprocedure): Ophthalmic (1% solution): Instill 1-2 drops 1 hour before procedure.

Uveitis: Ophthalmic:

1% solution: Instill 1-2 drops 4 times/day

Ointment: Apply a small amount in the conjunctival sac up to 3 times/day; compress the lacrimal sac by digital pressure for 1-3 minutes after instillation

Stability Store injection at controlled room temperature of 15°C to 30°C (59°F to 86°F); avoid freezing. In addition, AtroPen® should be protected from light.

Monitoring Parameters Heart rate, blood pressure, pulse, mental status; intravenous administration requires a cardiac monitor

Administration

I.M.: AtroPen®: Administer to outer thigh. May be given through clothing as long as pockets at the injection site are empty. Hold auto-injector in place for 10 seconds following injection; massage the injection site.

I.V.: Administer undiluted by rapid I.V. injection; slow injection may result in paradoxical bradycardia.

Contraindications Hypersensitivity to atropine or any component of the formulation; narrow-angle glaucoma; adhesions between the iris and lens; tachycardia; obstructive GI disease; paralytic ileus; intestinal atony of the elderly or debilitated patient; severe ulcerative colitis; toxic megacolon complicating ulcerative colitis; hepatic disease; obstructive uropathy; renal disease; myasthenia gravis (unless used to treat side effects of acetylcholinesterase inhibitor); asthma; thyrotoxicosis; Mobitz type II block

Warnings

Heat prostration can occur in the presence of a high environmental temperature. Psychosis can occur in sensitive individuals. The elderly may be sensitive to side effects. Use caution in patients with myocardial ischemia. Use caution in hyperthyroidism, autonomic neuropathy, BPH, CHF, tachyarrhythmias, hypertension, and hiatal hernia associated with reflux esophagitis. Use with caution in children with spastic paralysis.

AtroPen®: There are no absolute contraindications for the use of atropine in organophosphate poisonings, however, use caution in those patients where the use of atropine would be otherwise contraindicated. Formulation for use by trained personnel only.

Dosage Forms

Injection, solution, as sulfate: 0.05 mg/mL (5 mL); 0.1 mg/mL (5 mL, 10 mL); 0.4 mg/mL (0.5 mL, 1 mL, 20 mL); 0.5 mg/mL (1 mL); 1 mg/mL (1 mL)

AtroPen® [prefilled autoinjector]: 0.5 mg/0.7 mL (0.7 mL); 1 mg/0.7 mL (0.7 mL); 2 mg/0.7 mL (0.7 mL)

Ointment, ophthalmic, as sulfate: 1% (3.5 g)

Solution, ophthalmic, as sulfate: 1% (5 mL, 15 mL)

Atropine-Care®: 1% (2 mL)

Isopto® Atropine: 1% (5 mL, 15 mL)

Tablet, as sulfate (Sal-Tropine™): 0.4 mg

Reference Range Therapeutic range: 3-25 ng/mL. Peak serum atropine level after a 1 mg I.V. dose: ~0.003 mg/L (within 30 minutes of administration); blood level (postmortem) of 0.2 mg/L and urine level of 1.5 mg/L associated with fatality; peak plasma and urine atropine levels 10 hours after ingestion of 6 raw nightshade berries and 200 g of cooked berries (and associated with coma) were 217 mcg/L and 3092 mcg/L, respectively

Drug Interactions

Drugs with anticholinergic activity (including phenothiazines and TCAs) may increase anticholinergic effects when used concurrently.

Sympathomimetic amines may cause tachyarrhythmias; avoid concurrent use.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk (trace amounts)/use caution (AAP rates "compatible")

Nursing Implications Give by rapid I.V. injection since slow infusion may cause a paradoxical bradycardia; may give intratracheal in 1 mg/10 mL dilution only

Additional Information Expired atropine products have been shown to have significant potency and may be an option in mass casualty events.

Bromocriptine

Pronunciation (broe moe KRIP teen)

CAS Number 22260-51-1; 25614-03-3

U.S. Brand Names Parlodel®

Synonyms Bromocriptine Mesylate

Use

Amenorrhea with or without galactorrhea; infertility or hypogonadism; prolactin-secreting adenomas; acromegaly; Parkinson's disease

A previous indication for prevention of postpartum lactation was withdrawn voluntarily by Sandoz Pharmaceuticals Corporation

Has been used to decrease drug craving following discontinuation of cocaine abuse

Unlabeled/Investigational Use Neuroleptic malignant syndrome

Mechanism of Action Semisynthetic ergot alkaloid derivative with direct dopaminergic agonist activity at striatal receptors

Adverse Reactions

Cardiovascular: Hypertension then hypotension, syncope, hypertensive crisis, cerebral infarction, hypotension (orthostatic), acrocyanosis, Raynaud's phenomenon, shock, sinus bradycardia, arrhythmias (ventricular), vasoconstriction, vasculitis, pericarditis, postpartum intracranial hemorrhage

Central nervous system: Headache, dizziness, insomnia, auditory and visual hallucinations, seizures, extrapyramidal symptoms, cognitive dysfunction, hallucinations, lightheadedness, mania, meningitis, night terrors, paranoia, psychosis, gustatory hallucinations, hypothermia, paresthesia

Dermatologic: Alopecia, scleroderma, exanthema, urticaria, purpura

Endocrine & metabolic: Hyponatremia, hypoprolactinemia

Gastrointestinal: Nausea, vomiting, abdominal cramps, anorexia, xerostomia

Genitourinary: Retroperitoneal fibrosis, impotence, clitoral hypertrophy

Hematologic: Leukopenia, coagulopathy, thrombocytopenia

Neuromuscular & skeletal: Clonus, myoclonus, erythromelalgia, chorea (extrapyramidal), dyskinesias

Ocular: Myopia

Otic: Ototoxicity

Renal: Renal insufficiency

Respiratory: Pleuropulmonary fibrosis, pleural effusion, rhinorrhea, hyposmia

Pharmacodynamics/Kinetics

Bioavailability: 28%
 Protein binding: 90% to 96%
 Metabolism: Primarily hepatic
 Half-life elimination: Biphasic: Initial: 6-8 hours; Terminal: 50 hours
 Time to peak, serum: 1-2 hours
 Excretion: Feces; urine (2% to 6% as unchanged drug)

Dosage

Oral: Adults:
 Parkinsonism: 1.25 mg 2 times/day, increased by 2.5 mg/day in 2- to 4-week intervals (usual dose range is 30-90 mg/day in 3 divided doses), though elderly patients can usually be managed on lower doses
 Neuroleptic malignant syndrome: 2.5-5 mg 3 times/day
 Hyperprolactinemia: 2.5 mg 2-3 times/day
 Acromegaly: Initial: 1.25-2.5 mg increasing as necessary every 3-7 days; usual dose: 20-30 mg/day
 Prolactin-secreting adenomas: Initial: 1.25-2.5 mg/day; daily range 2.5-10 mg.

Dosing adjustment in hepatic impairment: No guidelines are available, however, may be necessary

Monitoring Parameters Monitor blood pressure closely as well as hepatic, hematopoietic, and cardiovascular function

Contraindications Hypersensitivity to bromocriptine, ergot alkaloids, or any component of the formulation; ergot alkaloids are contraindicated with potent inhibitors of CYP3A4 (includes protease inhibitors, azole antifungals, and some macrolide antibiotics); uncontrolled hypertension; severe ischemic heart disease or peripheral vascular disorders; pregnancy (risk to benefit evaluation must be performed in women who become pregnant during treatment for acromegaly, prolactinoma, or Parkinson's disease - hypertension during treatment should generally result in efforts to withdraw)

Warnings

Complete evaluation of pituitary function should be completed prior to initiation of treatment. Use caution in patients with impaired renal or hepatic function, a history of peptic ulcer disease, dementia, psychosis, or cardiovascular disease (myocardial infarction, arrhythmia). Symptomatic hypotension may occur in a significant number of patients. In addition, hypertension, seizures, MI, and stroke have been rarely associated with bromocriptine therapy. Severe headache or visual changes may precede events. The onset of reactions may be immediate or delayed (often may occur in the second week of therapy). Concurrent antihypertensives or drugs which may alter blood pressure should be used with caution. Concurrent use with levodopa has been associated with an increased risk of hallucinations. Consider dosage reduction and/or discontinuation in patients with hallucinations. Hallucinations may require weeks to months before resolution.

In the treatment of acromegaly, discontinuation is recommended if tumor expansion occurs during therapy. Digital vasospasm (cold sensitive) may occur in some patients with acromegaly; may require dosage reduction. Patients who receive bromocriptine during and immediately following pregnancy as a continuation of previous therapy (eg, acromegaly) should be closely monitored for cardiovascular effects. Should not be used post-partum in women with coronary artery disease or other cardiovascular disease. Use of bromocriptine to control or prevent lactation or in patients with uncontrolled hypertension is not recommended.

Monitoring and careful evaluation of visual changes during the treatment of hyperprolactinemia is recommended to differentiate between tumor shrinkage and traction on the optic chiasm; rapidly progressing visual field loss requires neurosurgical consultation. Discontinuation of bromocriptine in patients with macroadenomas has been associated with rapid regrowth of tumor and increased prolactin serum levels. Pleural and retroperitoneal fibrosis have been reported with prolonged daily use. Cardiac valvular fibrosis has also been associated with ergot alkaloids. Safety and effectiveness in patients <15 years of age (for pituitary adenoma) have not been established.

Dosage Forms

Capsule, as mesylate: 5 mg
 Parlodel®: 5 mg
 Tablet, as mesylate: 2.5 mg
 Parlodel®: 2.5 mg

Reference Range Peak plasma level of 24.6 ng/mL achieved after a dose of 100 mg

Test Interactions Bromocriptine may increase BUN, serum AST, serum ALT, serum CPK, alkaline phosphatase, and serum uric acid; may interfere with TSH assay resulting in falsely low TSH levels

Drug Interactions

Substrate of CYP3A4 (major); **Inhibits** CYP1A2 (weak), 3A4 (weak)
 Alpha agonists/sympathomimetics: May enhance the adverse/toxic effect of bromocriptine, including increased blood pressure, ventricular arrhythmias, and seizures. **Note:** The use of epinephrine in combination local anesthetics should pose no clinical concern.

Antihypertensives: Concurrent use with bromocriptine may increase the risk of hypotension and/or orthostasis. Use caution.

Antifungals, azole derivatives (itraconazole, ketoconazole) increase levels of ergot alkaloids by inhibiting CYP3A4 metabolism, resulting in toxicity; concomitant use is contraindicated.

Antipsychotics: May diminish the effects of bromocriptine (due to dopamine antagonism); these combinations should generally be avoided.

CYP3A4 inhibitors: May increase the levels/effects of bromocriptine. Example inhibitors include azole antifungals, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, telithromycin, and verapamil.

Levodopa: Concurrent use may increase the risk of hallucinations. Dosage reduction may be required.

Macrolide antibiotics: Erythromycin, clarithromycin, and troleandomycin may increase levels of ergot alkaloids by inhibiting CYP3A4 metabolism, resulting in toxicity (ischemia, vasospasm); concomitant use is contraindicated.

MAO inhibitors: The serotonergic effects of ergot derivatives may be increased by MAO inhibitors. Monitor for signs and symptoms of serotonin syndrome.

Metoclopramide: May diminish the effects of bromocriptine (due to dopamine antagonism); concurrent therapy should generally be avoided.

Protease inhibitors (ritonavir, amprenavir, indinavir, nelfinavir, and saquinavir) increase blood levels of ergot alkaloids by inhibiting CYP3A4 metabolism, acute ergot toxicity has been reported; concomitant use is contraindicated.

Serotonin agonists: Concurrent use with bromocriptine may increase the risk of serotonin syndrome (includes buspirone, SSRIs, TCAs, nefazodone, sumatriptan, and trazodone).

Sibutramine: May cause serotonin syndrome; concurrent use with ergot alkaloids is contraindicated.

Telithromycin: May increase levels of ergot alkaloids by inhibiting CYP3A4 metabolism, resulting in toxicity (ischemia, vasospasm); concomitant use is contraindicated.

Pregnancy Risk Factor B

Pregnancy Implications No evidence of teratogenicity or fetal toxicity in animal studies. Bromocriptine is used for ovulation induction in women with hyperprolactinemia. In general, therapy should be discontinued if pregnancy is confirmed unless needed for treatment of macroprolactinoma. Data collected from women taking bromocriptine during pregnancy suggest the incidence of birth defects is not increased with use. However, the majority of women discontinued use within 8 weeks of pregnancy. Women not seeking pregnancy should be advised to use appropriate contraception.

Lactation Enters breast milk/contraindicated

Nursing Implications Raise bed rails and institute safety measures; aid patient with ambulation; may cause postural hypotension and drowsiness

Budesonide

Pronunciation (byoo DES oh nide)

U.S. Brand Names Entocort™ EC; Pulmicort Respules®; Pulmicort Turbuhaler®; Rhinocort® Aqua®

Use

Intranasal: Children ≥6 years of age and Adults: Management of symptoms of seasonal or perennial rhinitis

Nebulization: Children 12 months to 8 years: Maintenance and prophylactic treatment of asthma; may be useful for hydrocarbon inhalation injuries

Oral capsule: Treatment of active Crohn's disease (mild to moderate) involving the ileum and/or ascending colon

Oral inhalation: Maintenance and prophylactic treatment of asthma; includes patients who require corticosteroids and those who may benefit from systemic dose reduction/elimination

Mechanism of Action Controls the rate of protein synthesis, depresses the migration of polymorphonuclear leukocytes, fibroblasts, reverses capillary permeability, and lysosomal stabilization at the cellular level to prevent or control inflammation

Adverse Reactions

Reaction severity varies by dose and duration; not all adverse reactions have been reported with each dosage form.

> 10%:

- Central nervous system: Oral capsule: Headache (up to 21%)
- Gastrointestinal: Oral capsule: Nausea (up to 11%)
- Respiratory: Respiratory infection, rhinitis, dysphonia
- Miscellaneous: Symptoms of HPA axis suppression and/or hypercorticism (acne, easy bruising, fat redistribution, striae, edema) may occur in > 10% of patients following administration of dosage forms which result in higher systemic exposure (ie, oral capsule), but may be less frequent than rates observed with comparator drugs (prednisolone). These symptoms may be rare (<1%)

following administration via methods which result in lower exposures (topical).

1% to 10%:

- Cardiovascular: Syncope, edema, hypertension
- Central nervous system: Chest pain, dysphonia, emotional lability, fatigue, fever, insomnia, migraine, nervousness, pain, dizziness, vertigo
- Dermatologic: Bruising, contact dermatitis, eczema, pruritus, pustular rash, rash
- Endocrine & metabolic: Hypokalemia, adrenal insufficiency
- Gastrointestinal: Abdominal pain, anorexia, diarrhea, dry mouth, dyspepsia, gastroenteritis, oral candidiasis, taste perversion, vomiting, weight gain, flatulence, oral candidiasis (4% to 13%)
- Hematologic: Cervical lymphadenopathy, purpura, leukocytosis
- Neuromuscular & skeletal: Arthralgia, fracture, hyperkinesia, hyper-tonia, myalgia, neck pain, weakness, paresthesia, back pain
- Ocular: Conjunctivitis, eye infection, cataracts
- Otic: Earache, ear infection, external ear infection
- Respiratory: Bronchitis, bronchospasm, cough, epistaxis, nasal irritation, pharyngitis, sinusitis, stridor
- Miscellaneous: Allergic reaction, flu-like syndrome, herpes simplex, infection, moniliasis, viral infection, voice alteration, weight gain, 22% elevation of HDL cholesterol

<1%: Aggressive reactions, alopecia, angioedema, avascular necrosis of the femoral head, depression, dyspnea, hoarseness, hypersensitivity reactions (immediate and delayed; include rash, contact dermatitis, angioedema, bronchospasm), intermenstrual bleeding, irritability, nasal septum perforation, osteoporosis, psychosis, somnolence

Postmarketing and/or case reports: Growth suppression, benign intracranial hypertension

Pharmacodynamics/Kinetics

Onset of action: Respules®: 2-8 days; Rhinocort® Aqua®: ~10 hours; Turbuhaler®: 24 hours
 Duration: Asthma: 12-24 hours
 Peak effect: Respules®: 4-6 weeks; Rhinocort® Aqua®: ~2 weeks; Turbuhaler®: 1-2 weeks

Absorption: Capsule: Rapid and complete
 Dermal absorption; 1% to 3%

Distribution: 2.2-3.9 L/kg

Protein binding: 85% to 90%

Metabolism: Hepatic via CYP3A4 to two metabolites: 16 alpha-hydroxyprednisolone and 6 beta-hydroxybudesonide; minor activity

Bioavailability: Limited by high first-pass effect; Capsule: 9% to 21%; Respules®: 6%; Turbuhaler®: 6% to 13%; Nasal: 34%

Half-life elimination: 2-3.6 hours

Time to peak: Capsule: 30-600 minutes (variable in Crohn's disease); Respules®: 10-30 minutes; Turbuhaler®: 1-2 hours; Nasal: 1 hour

Excretion: Urine (60%) and feces as metabolites

Total body clearance: 0.9-1.8 L/minute

Dosage

Nasal inhalation: (Rhinocort® Aqua®): Children ≥6 years and Adults: 64 mcg/day as a single 32 mcg spray in each nostril. Some patients who do not achieve adequate control may benefit from increased dosage. A reduced dosage may be effective after initial control is achieved.

Maximum dose: Children <12 years: 128 mcg/day; Adults: 256 mcg/day

Nebulization: Children 12 months to 8 years: Pulmicort Respules®: Titrate to lowest effective dose once patient is stable; start at 0.25 mg/day or use as follows:

- Hydrocarbon inhalation injuries: 0.5 mg every 12 hours for 4 days
- Previous therapy of bronchodilators alone: 0.5 mg/day administered as a single dose or divided twice daily (maximum daily dose: 0.5 mg)
- Previous therapy of inhaled corticosteroids: 0.5 mg/day administered as a single dose or divided twice daily (maximum daily dose: 1 mg)
- Previous therapy of oral corticosteroids: 1 mg/day administered as a single dose or divided twice daily (maximum daily dose: 1 mg)

Oral inhalation:

- Children ≥6 years:
 - Previous therapy of bronchodilators alone: 200 mcg twice initially which may be increased up to 400 mcg twice daily
 - Previous therapy of inhaled corticosteroids: 200 mcg twice initially which may be increased up to 400 mcg twice daily
 - Previous therapy of oral corticosteroids: The highest recommended dose in children is 400 mcg twice daily

- Adults:
 - Previous therapy of bronchodilators alone: 200-400 mcg twice initially which may be increased up to 400 mcg twice daily
 - Previous therapy of inhaled corticosteroids: 200-400 mcg twice initially which may be increased up to 800 mcg twice daily
 - Previous therapy of oral corticosteroids: 400-800 mcg twice daily which may be increased up to 800 mcg twice daily

NIH Guidelines (NIH, 1997) (give in divided doses twice daily):

Children:

“Low” dose: 100-200 mcg/day

“Medium” dose: 200-400 mcg/day (1-2 inhalations/day)

“High” dose: >400 mcg/day (>2 inhalation/day)

Adults:

“Low” dose: 200-400 mcg/day (1-2 inhalations/day)

“Medium” dose: 400-600 mcg/day (2-3 inhalations/day)

“High” dose: >600 mcg/day (>3 inhalation/day)

Oral: Adults: Crohn's disease: 9 mg once daily in the morning; safety and efficacy have not been established for therapy duration >8 weeks; recurring episodes may be treated with a repeat 8-week course of treatment

Note: Treatment may be tapered to 6 mg once daily for 2 weeks prior to complete cessation. Patients receiving CYP3A4 inhibitors should be monitored closely for signs and symptoms of hypercorticism; dosage reduction may be required.

Dosage adjustment in hepatic impairment: Monitor closely for signs and symptoms of hypercorticism; dosage reduction may be required.

Stability

Nebulizer: Store upright at 20°C to 25°C (68°F to 77°F) and protect from light. Do not refrigerate or freeze. Once aluminum package is opened, solution should be used within 2 weeks. Continue to protect from light.

Nasal inhaler: Store with valve up at 15°C to 30°C (59°F to 86°F). Use within 6 months after opening aluminum pouch. Protect from high humidity.

Nasal spray: Store with valve up at 20°C to 25°C (68°F to 77°F) and protect from light. Do not freeze.

Monitoring Parameters Monitor growth in pediatric patients.

Administration

Inhalation: Inhaler should be shaken well immediately prior to use; while activating inhaler, deep breathe for 3-5 seconds, hold breath for ~10 seconds and allow ≥1 minute between inhalations. Rinse mouth with water after use to reduce aftertaste and incidence of candidiasis.

Nebulization: Shake well before using. Use Pulmicort Respules® with jet nebulizer connected to an air compressor; administer with mouthpiece or facemask. Do not use ultrasonic nebulizer. Do not mix with other medications in nebulizer. Rinse mouth following treatments to decrease risk of oral candidiasis (wash face if using face mask).

Oral capsule: Capsule should be swallowed whole; do not crush or chew.

Contraindications

Hypersensitivity to budesonide or any component of the formulation
 Inhalation: Contraindicated in primary treatment of status asthmaticus, acute episodes of asthma; not for relief of acute bronchospasm

Warnings

May cause hypercorticism and/or suppression of hypothalamic-pituitary-adrenal (HPA) axis, particularly in younger children or in patients receiving high doses for prolonged periods. Particular care is required when patients are transferred from systemic corticosteroids to products with lower systemic bioavailability (ie, inhalation). May lead to possible adrenal insufficiency or withdrawal from steroids, including an increase in allergic symptoms. Patients receiving prolonged therapy ≥20 mg per day of prednisone (or equivalent) may be most susceptible. Aerosol steroids do **not** provide the systemic steroid needed to treat patients having trauma, surgery, or infections.

Controlled clinical studies have shown that orally-inhaled and intranasal corticosteroids may cause a reduction in growth velocity in pediatric patients. (In studies of orally-inhaled corticosteroids, the mean reduction in growth velocity was approximately 1 centimeter per year [range 0.3-1.8 cm per year] and appears to be related to dose and duration of exposure.) To minimize the systemic effects of orally-inhaled and intranasal corticosteroids, each patient should be titrated to the lowest effective dose. Growth should be routinely monitored in pediatric patients.

May suppress the immune system; patients may be more susceptible to infection. Use with caution in patients with systemic infections or ocular herpes simplex. Avoid exposure to chickenpox and measles. Corticosteroids should be used with caution in patients with diabetes, hypertension, osteoporosis, peptic ulcer, glaucoma, cataracts, or tuberculosis. Use caution in hepatic impairment. Enteric-coated capsules should not be crushed or chewed.

Dosage Forms

[CAN] = Canadian brand name

Capsule, enteric coated (Entocort® EC): 3 mg

Powder for oral inhalation:

Pulmicort Turbuhaler®: 200 mcg/inhalation (104 g) [delivers ~160 mcg/inhalation; 200 metered doses]

Pulmicort Turbuhaler® [CAN]: 100 mcg/inhalation [delivers 200 metered doses]; 200 mcg/inhalation [delivers 200 metered doses]; 400 mcg/inhalation [delivers 200 metered doses] [not available in the U.S.]

Suspension, intranasal [spray] (Rhinocort® Aqua®): 32 mcg/inhalation (8.6 g) [120 metered doses]

Suspension for nebulization (Pulmicort Respules®): 0.25 mg/2 mL (30s), 0.5 mg/2 mL (30s)

Reference Range Plasma budesonide level of 5 nmol/L obtained within 5 hours of a 9 mg oral dose

Overdosage/Treatment

Acute overdosage does not require any treatment.

Inhaled formulations: Symptoms of overdose include irritation and burning of the nasal mucosa, sneezing, intranasal and pharyngeal *Candida* infections, nasal ulceration, epistaxis, rhinorrhea, nasal stuffiness, headache.

When consumed in excessive quantities, over 3 weeks, systemic hypercorticism and adrenal suppression may occur, in those cases discontinuation and withdrawal of the corticosteroid should be done judiciously. Treatment should be symptomatic and supportive; monitor electrolytes

Drug Interactions

Substrate of CYP3A4 (major)

Cimetidine: Decreased clearance and increased bioavailability of budesonide.

CYP3A4 inhibitors: Serum level and/or toxicity of budesonide may be increased; this effect was shown with ketoconazole, but not erythromycin. Other potential inhibitors include amiodarone, cimetidine, clarithromycin, delavirdine, diltiazem, dirithromycin, disulfiram, fluoxetine, fluvoxamine, grapefruit juice, indinavir, itraconazole, ketoconazole, nefazodone, nevirapine, propoxyphene, quinupristin-dalfopristin, ritonavir, saquinavir, telithromycin, verapamil, zafirlukast, and zileuton.

Proton pump inhibitors (omeprazole, pantoprazole, rabeprazole): Theoretically, alteration of gastric pH may affect the rate of dissolution of enteric-coated capsules. Administration with omeprazole did not alter kinetics of budesonide capsules.

Salmeterol: The addition of salmeterol has been demonstrated to improve response to inhaled corticosteroids (as compared to increasing steroid dosage).

Pregnancy Risk Factor C/B (Pulmicort Respules[®] and Turbuhaler[®], Rhinocort[®] Aqua[®])

Pregnancy Implications Use only if potential benefit to the mother outweighs the possible risk to the fetus. Studies of pregnant women using inhaled budesonide have not demonstrated an increased risk of abnormalities. Hypoadrenalism has been reported in infants.

Lactation Enters breast milk/use caution

Specific References

Calcium Chloride

Pronunciation (KAL see um KLOR ide)

CAS Number 10035-04-8; 10043-52-4; 7774-34-7

Use Cardiac resuscitation when epinephrine fails to improve myocardial contractions, cardiac disturbances of hyperkalemia, hypocalcemia or calcium channel blocking agent toxicity; also used for fluoride, hydrogen fluoride, ethylene glycol, magnesium sulfate, oxalate, and possibly for black widow spider bites

Unlabeled/Investigational Use Calcium channel blocker overdose

Mechanism of Action Moderates nerve and muscle performance via action potential excitation threshold regulation

Mechanism of Toxic Action Moderates nerve and muscle performance via action potential excitation threshold regulation

Adverse Reactions

Cardiovascular: Vasodilation, hypotension, bradycardia, cardiac arrhythmias, fibrillation (ventricular), syncope, shock, sinus bradycardia, arrhythmias (ventricular),

Central nervous system: Lethargy, coma

Dermatologic: Erythema

Endocrine & metabolic: Hypomagnesemia, hypercalcemia

Gastrointestinal: Elevated serum amylase

Local: Tissue necrosis (more irritant than calcium gluconate), extravasation injury

Neuromuscular & skeletal: Muscle weakness

Renal: Hypercalciuria

Signs and Symptoms of Overdose Coma, lethargy, nausea, vomiting

Pharmacodynamics/Kinetics

Distribution: Crosses placenta; enters breast milk

Excretion: Primarily feces (as unabsorbed calcium); urine (20%)

Dosage

I.V. (calcium chloride is 3 times as potent as calcium gluconate):

Cardiac arrest in the presence of hyperkalemia or hypocalcemia, magnesium toxicity, or calcium antagonist toxicity:

Infants and Children: 10-30 mg/kg; may repeat in 5-10 minutes if necessary

Adults: 10 mL/dose every 10-20 minutes

Hypocalcemia:

Infants and Children: 10-20 mg/kg/dose, repeat every 4-6 hours if needed

Adults: 500 mg to 1 g at 1- to 3-day intervals

Hydrofluoric acid burns: Intra-arterial infusion: 10 mL of 10% calcium chloride in 40 mL of normal saline over 4 hours

Tetany:

Neonates: 2.4 mEq/kg/day

Infants and Children: 10 mg/kg over 5-10 minutes; may repeat after 6 hours or follow with an infusion with a maximum dose of 200 mg/kg/day

Adults: 1 g over 10-30 minutes; may repeat after 6 hours

Electrical-mechanical dissociation:

Due to propranolol: 1 g

Due to disopyramide: 1-3 g

Reversal of neuromuscular blockade due to polymixin antibiotics and anesthetic agents: I.V.: 1 g

Hypocalcemia secondary to citrated blood transfusion give 0.45 mEq elemental calcium for each 100 mL citrated blood infused

Stability Admixture incompatibilities: Carbonates, phosphates, sulfates, tartrates

Monitoring Parameters ECG

Administration Generally, I.V. infusion rates should not exceed 0.7-1.5 mEq/minute (0.5-1 mL/minute); stop the infusion if the patient complains of pain or discomfort; do not inject calcium chloride I.M. or administer SubQ since severe necrosis and sloughing may occur. Do not use scalp vein or small hand or foot veins for I.V. administration. Warm to body temperature; administer slowly, do not exceed 1 mL/minute (inject into ventricular cavity - not myocardium).

Contraindications In ventricular fibrillation during cardiac resuscitation, hypercalcemia, and in patients with risk of digitalis toxicity, renal or cardiac disease; not recommended in treatment of asystole and electro-mechanical dissociation; patients with suspected digoxin toxicity

Warnings Avoid too rapid I.V. administration (<1 mL/minute) and extravasation. Use with caution in digitalized patients, respiratory failure, or acidosis. Hypercalcemia may occur in patients with renal failure, and frequent determination of serum calcium is necessary. Avoid metabolic acidosis (ie, administer only 2-3 days then change to another calcium salt).

Dosage Forms Injection, solution [preservative free]: 10% [100 mg/mL] (10 mL) [equivalent to elemental calcium 27.2 mg/mL, calcium 1.36 mEq/mL]

Reference Range Serum 9-10.4 mg/dL; due to a poor correlation between the serum ionized calcium (free) and total serum calcium, particularly in states of low albumin or acid/base imbalances, direct measurement of ionized calcium is recommended. In low albumin states, the corrected total serum calcium may be estimated by this equation (assuming a normal albumin of 4 g/dL); corrected total calcium = total serum calcium + 0.8 (4- measured serum albumin).

Overdosage/Treatment

Supportive therapy: Can be used to treat electromechanical dissociation caused by atenolol overdose

Following withdrawal of the drug, treatment consists of bedrest, liberal intake of fluids, reduced calcium intake, and cathartic administration. Severe hypercalcemia requires I.V. hydration and forced diuresis. Urine output should be monitored and maintained at >3 mL/kg/hour. I.V. saline and natriuretic agents (eg, furosemide) can quickly and significantly increase excretion of calcium.

Test Interactions Increases calcium (S); decreases magnesium

Drug Interactions

Calcium channel blockers (eg, verapamil) effects may be diminished; monitor response.

Levothyroxine: Calcium carbonate (and possibly other calcium salts) may decrease T₄ absorption; separate dose from levothyroxine by at least 4 hours.

Thiazide diuretics can cause hypercalcemia; monitor response.

May potentiate digoxin toxicity. High doses of calcium with thiazide diuretics may result in milk-alkali syndrome and hypercalcemia.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Nursing Implications Monitor ECG if calcium is infused faster than 2.5 mEq/minute (occasionally necessary in treating hyperkalemia)

Extravasation: Give hyaluronidase (1:10 dilution of a 150 unit vial in saline equivalent to 15 units/mL) SubQ in multiple (usually about 5) injections of 0.2 mL each to help increase absorption

Calcium Gluconate

Pronunciation (KAL see um GLOO koe nate)

CAS Number 18016-24-5; 299-28-5

Use Treatment and prevention of hypocalcemia, treatment of tetany, cardiac disturbances of hyperkalemia, cardiac resuscitation when epinephrine fails to improve myocardial contractions, hypocalcemia, calcium channel blocker toxicity, black widow spider bites

Unlabeled/Investigational Use Hydrofluoric acid (HF) burns; calcium channel blocker overdose

Mechanism of Action Moderates nerve and muscle performance via action potential excitation threshold regulation

Adverse Reactions

Cardiovascular: Vasodilation, hypotension, bradycardia, cardiac arrhythmias, fibrillation (ventricular), syncope, sinus bradycardia, arrhythmias (ventricular)

Central nervous system: Lethargy, coma, mental confusion, mania

Dermatologic: Erythema

Endocrine & metabolic: Hypomagnesemia, hypercalcemia

Gastrointestinal: Elevated serum amylase

Local: Tissue necrosis, extravasation injury

Neuromuscular & skeletal: Muscle weakness

Ocular: Corneal calcification

Renal: Hypercalciuria

Signs and Symptoms of Overdose Coma, lethargy, nausea, vomiting

Pharmacodynamics/Kinetics

Absorption: Requires vitamin D; calcium is absorbed in soluble, ionized form; solubility of calcium is increased in an acid environment

Distribution: Primarily in bones and teeth; crosses placenta; enters breast milk

Protein binding: Primarily albumin

Excretion: Primarily feces (as unabsorbed calcium); urine (20%)

Dosage

Dosage is in terms of **elemental** calcium

Dietary Reference Intake:

0-6 months: 210 mg/day

7-12 months: 270 mg/day

1-3 years: 500 mg/day

4-8 years: 800 mg/day

Adults, Male/Female:

9-18 years: 1300 mg/day

19-50 years: 1000 mg/day

≥51 years: 1200 mg/day

Female: Pregnancy: Same as for Adults, Male/Female

Female: Lactating: Same as for Adults, Male/Female

Dosage expressed in terms of **calcium gluconate**

Hypocalcemia: I.V.:

Neonates: 200-800 mg/kg/day as a continuous infusion or in 4 divided doses

Infants and Children: 200-500 mg/kg/day as a continuous infusion or in 4 divided doses

Adults: 2-15 g/24 hours as a continuous infusion or in divided doses

Hypocalcemia: Oral:

Children: 200-500 mg/kg/day divided every 6 hours

Adults: 500 mg to 2 g 2-4 times/day

Osteoporosis/bone loss: Oral: 1000-1500 mg in divided doses/day

Hypocalcemia secondary to citrated blood infusion: I.V.: Give 0.45 mEq **elemental** calcium for each 100 mL citrated blood infused

Hypocalcemic tetany: I.V.:

Neonates: 100-200 mg/kg/dose, may follow with 500 mg/kg/day in 3-4 divided doses or as an infusion

Infants and Children: 100-200 mg/kg/dose (0.5-0.7 mEq/kg/dose) over 5-10 minutes; may repeat every 6-8 hours or follow with an infusion of 500 mg/kg/day

Adults: 1-3 g (4.5-16 mEq) may be administered until therapeutic response occurs

Calcium antagonist toxicity, magnesium intoxication, or cardiac arrest in the presence of hyperkalemia or hypocalcemia: Calcium chloride is recommended calcium salt: I.V.:

Infants and Children: 60-100 mg/kg/dose (maximum: 3 g/dose)

Adults: 500-800 mg; maximum: 3 g/dose

Maintenance electrolyte requirements for total parenteral nutrition: I.V.:

Daily requirements: Adults: 8-16 mEq/1000 kcal/24 hours

Dosing adjustment in renal impairment: $Cl_{cr} < 25$ mL/minute: Dosage adjustments may be necessary depending on the serum calcium levels

Stability

Do not refrigerate solutions; IVPB solutions/I.V. infusion solutions are stable for 24 hours at room temperature

Standard diluent: 1 g/100 mL D₅W or NS; 2 g/100 mL D₅W or NS

Maximum concentration in parenteral nutrition solutions is variable depending upon concentration and solubility (consult detailed reference).

Incompatible with sodium bicarbonate, carbonates, phosphates, sulfates, and tartrates

Stable in D₅LR, D₅NS, D₅W, D₁₀W, D₂₀W, LR, NS; **incompatible** in fat emulsion 10%

Y-site administration: **Incompatible** with amphotericin B cholesteryl sulfate complex, fluconazole, indomethacin

Compatibility in syringe: **Incompatible** with metoclopramide

Compatibility when admixed: **Incompatible** with amphotericin B, cefamandole, cefazolin, clindamycin, dobutamine, floxacillin, methylprednisolone sodium succinate

Monitoring Parameters Serum calcium

Administration I.M. injections should be administered in the gluteal region in adults, usually in volumes <5 mL; avoid I.M. injections in children and adults with muscle mass wasting; do not use scalp veins or

small hand or foot veins for I.V. administration; generally, I.V. infusion rates should not exceed 0.7-1.5 mEq/minute (1.5-3.3 mL/minute); stop the infusion if the patient complains of pain or discomfort. Warm to body temperature; administer slowly, usually no faster than 1.5-3.3 mL/minute, do not inject into the myocardium when using calcium during advanced cardiac life support. Topical therapy for hydrofluoric acid exposures with 2.5% gel applied to affected area every 4 hours as needed. 2.5% gel can be prepared by mixing 5 oz of KY Jelly or Surgilube® with 25 mL of 10% calcium gluconate.

Contraindications Ventricular fibrillation during cardiac resuscitation; digitalis toxicity or suspected digoxin toxicity; hypercalcemia

Warnings Injection solution is for I.V. use only; do not inject SubQ or I.M. Avoid too rapid I.V. administration and avoid extravasation. Use with caution in digitalized patients, severe hyperphosphatemia, respiratory failure, or acidosis. May produce cardiac arrest. Hypercalcemia may occur in patients with renal failure; frequent determination of serum calcium is necessary. Use caution with renal disease. Solutions may contain aluminum; toxic levels may occur following prolonged administration in premature neonates or patients with renal dysfunction.

Dosage Forms

Injection, solution [preservative free]: 10% [100 mg/mL] (10 mL, 50 mL, 100 mL, 200 mL) [equivalent to elemental calcium 9 mg/mL; calcium 0.46 mEq/mL]

Powder: 347 mg/tablespoonful (480 g)

Tablet: 500 mg [equivalent to elemental calcium 45 mg]; 650 mg [equivalent to elemental calcium 58.5 mg]; 975 mg [equivalent to elemental calcium 87.75 mg]

Reference Range Serum: 9.0-10.4 mg/dL; due to a poor correlation between the serum ionized calcium (free) and total serum calcium, particularly in states of low albumin or acid/base imbalances, direct measurement of ionized calcium is recommended. If ionized calcium is unavailable, in low albumin states, the corrected **total** serum calcium may be estimated by this equation (assuming a normal albumin of 4 g/dL); corrected total calcium = total serum calcium + 0.8(4 - measured serum albumin).

Overdosage/Treatment Acute single ingestions of calcium salts may produce mild gastrointestinal distress, but hypercalcemia or other toxic manifestations are extremely unlikely. Treatment is supportive.

Test Interactions ↑ calcium (S); ↓ magnesium

Drug Interactions

Bisphosphonate derivatives: Absorption may be decreased by calcium salts.

Calcium channel blockers (eg, verapamil) effects may be diminished; monitor response.

Digoxin: May potentiate digoxin toxicity.

Dobutamine: Calcium salts may diminish the therapeutic effect of dobutamine.

Levothyroxine: Calcium carbonate (and possibly other calcium salts) may decrease T₄ absorption; separate dose from levothyroxine by at least 4 hours.

Phosphate supplements: Calcium salts may decrease the absorption of phosphate supplements.

Quinolone antibiotics: Calcium salts may decrease the absorption of quinolone antibiotics with oral administration of both agents.

Thiazide diuretics: Thiazide diuretics may decrease the excretion of calcium salts. Continued concomitant use can also result in metabolic alkalosis.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk

Centruroides Scorpion Venom Antisera

Use Severe *Centruroides* scorpion envenomation (grade IV)

Mechanism of Action Made by lyophilizing micron-filtered hypersensitized goat serum

Adverse Reactions

Cardiovascular: Sinus tachycardia

Gastrointestinal: Pancreatitis

Miscellaneous: Delayed **allergic reactions** (58%) include rash, urticaria, serum sickness

Dosage One vial I.V.; give second vial I.V. in 1 hour if symptoms not improved; do not administer I.M.

Overdosage/Treatment Supportive therapy: Midazolam (by continuous I.V. infusion) can be given to treat agitation and involuntary motor activity.

Charcoal

Pronunciation (CHAR kole)

CAS Number 16291-96-6

U.S. Brand Names Actidose-Aqua® [OTC]; Actidose® with Sorbitol [OTC]; CharcoAid G® [OTC]; Charcoal Plus® DS [OTC]; Charcocaps® [OTC]; EZ-Char™ [OTC]; Kerr Insta-Char® [OTC]; Liqui-Char® [OTC] [DSC]

Synonyms Activated Carbon; Activated Charcoal; Adsorbent Charcoal; Liquid Antidote; Medicinal Carbon; Medicinal Charcoal

Use Emergency treatment in poisoning by drugs and chemicals; repetitive doses for gastrointestinal dialysis for drug overdose and in uremia to adsorb various waste products; hyperbilirubinemia; has been used as an aid in the diagnosis of colouterine fistula

Mechanism of Action Adsorbs toxic substances or irritants, thus inhibiting GI absorption and for selected drugs increasing clearance by interfering with enterohepatic recycling or dialysis across intestinal vascular membranes; adsorbs intestinal gas; the addition of sorbitol results in hyperosmotic laxative action causing catharsis

Adverse Reactions

Gastrointestinal: **Vomiting** 6%-15% with charcoal alone, 16%-56% with sorbitol; **diarrhea with sorbitol, constipation**, intestinal obstruction can occur (only with multiple dosing of activated charcoal), **stools will turn black**

Ocular: Corneal abrasions (2 cases)

Respiratory: Aspiration usually does not cause major problems in adults, but can cause tracheal obstruction in infants; very rarely, aspiration pneumonia (8 case reports; 3 fatalities) more likely with ingestions treated with multiple doses

Pharmacodynamics/Kinetics Excretion: Feces (as charcoal)

Dosage

Oral: Ideally, achieving a 10 g charcoal:1 g toxin dose is the desired outcome

Acute poisoning: Single dose: Charcoal with sorbitol (**Note:** Check product label for sorbitol content):

Children and Adults: At least 5-10 times the weight of the ingested poison and other coingestants on a g:g ratio; minimum dose is probably 15-30 g; in young children sorbitol dose should not exceed 1.5 g/kg/day

Adults: 30-100 g

Charcoal in water: Same as above, but sorbitol should be added in appropriate daily doses

Single dose:

Infants and Children 1-12 years: 15-30 g

Adults: 30-100 g

Multiple dose (use only one appropriate dose of cathartic daily):

Infants <1 year: 15-30 g every 4-6 hours

Children 1-12 years: 20-25 g every 2 hours until clinical observations and serum drug concentration have returned to a subtherapeutic range or the development of absent bowel sounds or ileus

Adults: 20-25 g every 2 hours

Stability Adsorbs gases from air, store in closed container

Administration Flavoring agents (eg, chocolate) and sorbitol can enhance charcoal's palatability. If treatment includes ipecac syrup, induce vomiting prior to administration of charcoal. Often given with a laxative or cathartic; check for presence of bowel sounds before administration.

Contraindications Intestinal obstruction; GI tract not anatomically intact; patients at risk of hemorrhage or GI perforation; if use would increase risk and severity of aspiration; not effective for cyanide, mineral acids, caustic alkalis, organic solvents, iron, ethanol, methanol poisoning, lithium; do not use charcoal with sorbitol in patients with fructose intolerance; charcoal with sorbitol not recommended in children <1 year of age

Warnings When using ipecac with charcoal, induce vomiting with ipecac before administering activated charcoal since charcoal adsorbs ipecac syrup. Charcoal may cause vomiting which is hazardous in petroleum distillate and caustic ingestions. If charcoal in sorbitol is administered, doses should be limited to prevent excessive fluid and electrolyte losses. Use caution with decreased peristalsis. Most effective when administered within 1 hour of ingestion for most ingestions. May absorb maintenance medications too.

Dosage Forms

[DSC] = Discontinued product

Capsule, activated (Char-Caps, Charcocaps®): 260 mg

Granules, activated (CharcoAid G®): 15 g (120 mL) [DSC]

Liquid, activated:

Actidose-Aqua®: 15 g (72 mL); 25 g (120 mL); 50 g (240 mL)

Kerr Insta-Char®: 25 g (120 mL) [cherry flavor]; 50 g (240 mL) [unflavored or cherry flavor]

Liquid, activated [with sorbitol]:

Actidose® with Sorbitol: 25 g (120 mL); 50 g (240 mL)

Kerr Insta-Char®: 25 g (120 mL); 50 g (240 mL) [cherry flavor]

Pellets, activated (EZ-Char™): 25 g

Powder for suspension, activated: 30 g, 240 g

Tablets, activated (Charcoal Plus® DS): 250 mg

Drug Interactions Do not administer concomitantly with syrup of ipecac.

Pregnancy Risk Factor C

Lactation Does not enter breast milk/compatible

Nursing Implications Instruct patient to drink slowly, rapid administration appears to increase frequency of vomiting; for persistent vomiting, activated charcoal can be administered as a continuous enteral infusion at doses of 10-25 g/hour; fluid volume and sorbitol dosing must be reviewed carefully; concentrated slurries may clog airway; stools will turn black; vigorous shaking of the product is suggested

Cholestyramine Resin

Pronunciation (koe LES tee a meen REZ in)

CAS Number 11041-12-6

U.S. Brand Names Prevalite®; Questran® Light; Questran®

Use Adjunct in the management of primary hypercholesterolemia; pruritus associated with elevated levels of bile acids; diarrhea associated with excess fecal bile acids, tropical diarrhea; binding toxicologic agents, such as digitoxin, possibly phenobarbital, warfarin, lindane, lithium lorazepam, methotrexate, chlordecone; pseudomembranous colitis (*Clostridium difficile*), oxaluria

Mechanism of Action Forms a nonabsorbable complex with bile acids in the intestine, releasing chloride ions in the process; inhibits enterohepatic reuptake of intestinal bile salts and thereby increases the fecal loss of bile salt-bound low density lipoprotein cholesterol; an anion-exchange resin (chloride form)

Adverse Reactions

Dermatologic: Rash, irritation of perianal area, skin
 Endocrine & metabolic: Hyperchloremic acidosis, hypoprothrombinemia, hypernatremia from free water loss due to diarrhea
 Gastrointestinal: Constipation, nausea, vomiting, abdominal distention and pain, malabsorption of fat-soluble vitamins, fecal impaction, steatorrhea, tongue irritation
 Genitourinary: Increased urinary calcium excretion
 Hepatic: Elevation of alkaline phosphatase and liver function test results

Signs and Symptoms of Overdose Gastrointestinal obstruction/concretion

Pharmacodynamics/Kinetics

Onset of action: Peak effect: 21 days
 Absorption: None
 Excretion: Feces (as insoluble complex with bile acids)

Dosage

Oral (dosages are expressed in terms of anhydrous resin):
 Children: 240 mg/kg/day in 3 divided doses; need to titrate dose depending on indication
 Adults: 4 g 1-2 times/day to a maximum of 24 g/day and 6 doses/day
 Dialysis: Not removed by hemo- or peritoneal dialysis; supplemental doses not necessary with dialysis or continuous arteriovenous or venovenous hemofiltration

Stability Store powder at controlled room temperature of 15°C to 30°C (59°F to 86°F). Mix contents of 1 packet or 1 level scoop of powder with 4-6 oz of beverage. Allow to stand 1-2 minutes prior to mixing. May also be mixed with highly-fluid soups, cereals, applesauce, etc. Suspension may be used for up to 48 hours after refrigeration.

Administration Administer with water or pulpy fruit

Contraindications Hypersensitivity to bile acid sequestering resins or any component of the formulation; complete biliary obstruction; bowel obstruction

Warnings Not to be taken simultaneously with many other medicines (decreased absorption). Treat any diseases contributing to hypercholesterolemia first. May interfere with fat-soluble vitamins (A, D, E, K) and folic acid. Chronic use may be associated with bleeding problems (especially in high doses). May produce or exacerbate constipation problems. Fecal impaction may occur. Hemorrhoids may be worsened.

Dosage Forms

Powder for oral suspension: 4 g of resin/5 g of powder (5 g packets, 210 g can) [contains phenylalanine 14 mg/5 g]; 4 g of resin/5.7 g of powder (5.7 g packets, 240 g can) [light formulation]; 4 g of resin/9 g of powder (9 g packets, 378 g can)
 Prevalite®: 4 g of resin/5.5 g of powder (5.5 g packets, 231 g can) [contains phenylalanine 14.1 mg/5.5 g; orange flavor]
 Questran®: 4 g of resin/9 g of powder (9 g packets, 378 g can)
 Questran® Light: 4 g of resin/6.4 g of powder (5 g packets, 268 g can) [contains phenylalanine 28.1 g/6.4 g]

Test Interactions ↑ prothrombin time (S); ↓ cholesterol (S), iron (B)

Drug Interactions

Cholestyramine can reduce the absorption of numerous medications when used concurrently. Give other medications 1 hour before or 4-6 hours after giving cholestyramine. Medications which may be affected include HMG-CoA reductase inhibitors, thiazide diuretics, propranolol (and potentially other beta-blockers), corticosteroids, thyroid hormones, digoxin, valproic acid, NSAIDs, loop diuretics, sulfonylureas, troglitazone (and potentially other agents in this class).

Warfarin and other oral anticoagulants: Hypoprothrombinemic effects may be reduced by cholestyramine. Separate administration times (as detailed above) and monitor INR closely when initiating or discontinuing.

Pregnancy Risk Factor C

Pregnancy Implications Cholestyramine is not absorbed systemically, but may interfere with vitamin absorption; therefore, regular prenatal supplementation may not be adequate. There are no studies in pregnant women; use with caution.

Lactation Does not enter breast milk/use caution

Nursing Implications Do not administer the powder in its dry form; just prior to administration, mix with fluid or with applesauce; administer warfarin at least 1-2 hours prior to, or 6 hours after cholestyramine because cholestyramine may bind warfarin and decrease its total absorption. (**Note:** Cholestyramine itself may cause hypoprothrombinemia in patients with impaired enterohepatic circulation.)

Synonyms Amyl Nitrite, Sodium Thiosulfate, and Sodium Nitrite; Cyanide Antidote Kit; Sodium Thiosulfate, Sodium Nitrite, and Amyl Nitrite

Use Treatment of cyanide poisoning

Dosage For cyanide poisoning, a 0.3 mL ampul of amyl nitrite is crushed every minute and vapor inhaled for 15-30 seconds until an I.V. sodium nitrite infusion is available. Following administration of 300 mg I.V. sodium nitrite, inject 12.5 g sodium thiosulfate I.V. (over ~ 10 minutes), if needed; injection of both may be repeated at 1/2 the original dose.

Administration Sodium nitrite should be administered at a rate of 2.5-5 mL/minute.

Contraindications Hypersensitivity to amyl nitrite, sodium nitrite, nitrates, sodium thiosulfate, or any component of the formulation; severe anemia, pregnancy (amyl nitrite)

Warnings When cyanide poisoning is related to smoke inhalation, if possible, the patient should be in a hyperbaric chamber before the kit is administered; the methemoglobin initially produced by sodium nitrite injection may otherwise exacerbate concomitant carbon monoxide poisoning that has already severely diminished oxygen-carrying capacity in red cells

Dosage Forms

Kit [each kit contains] (Cyanide Antidote Package):
 Injection, solution:
 Sodium nitrite 300 mg/10 mL (2)
 Sodium thiosulfate 12.5 g/50 mL (2)
 Inhalant: Amyl nitrite 0.3 mL (12)
 [kit also includes disposable syringes, stomach tube, tourniquet, and instructions]

Drug Interactions Sodium nitrite antagonizes acetylcholine, epinephrine, and histamine effects; sodium nitrite potentiates hypotensive effects and/or anticholinergic effects of tricyclic antidepressants, antihistamines, and meperidine and related CNS depressants; ethanol increases the toxicity of amyl nitrite

Pregnancy Risk Factor C (sodium thiosulfate and sodium nitrite); X (amyl nitrite)

Deferiprone

CAS Number 30652-11-0

Unlabeled/Investigational Use

Investigational: Prevention of chronic iron overload in patients with transfusion-dependent beta-thalassemia

Mechanism of Action Orally active iron chelator

Adverse Reactions

Cardiovascular: Vasculitis
 Hematologic: Bone marrow suppression, thrombocytopenia, leukopenia
 Neuromuscular & skeletal: Arthritis, arthralgia

Dosage Oral: 75-100 mg/kg/day in 3 divided doses

Reference Range Oral dose of 25 mg/kg produces a peak plasma level of 14-17 mcg/mL

Test Interactions ↓ serum ferritin; ↑ urinary excretion of iron

Deferoxamine

Pronunciation (de fer OKS a meen)

CAS Number 138-14-7; 1950-39-6; 70-51-9

U.S. Brand Names Desferal®

Synonyms Deferoxamine Mesylate

Use Acute iron intoxication when serum iron is > 450-500 mcg/dL or when clinical signs of significant iron toxicity exist; chronic iron overload secondary to multiple transfusions; iron overload secondary to congenital anemias; hemochromatosis

Unlabeled/Investigational Use Removal of corneal rust rings following surgical removal of foreign bodies; diagnosis or treatment of aluminum induced toxicity associated with chronic kidney disease (CKD)

Mechanism of Action Complexes with trivalent ions (ferric ions) to form ferrioxamine, which is removed by the kidneys

Adverse Reactions

Cardiovascular: Flushing, hypotension, tachycardia, shock, edema, sinus tachycardia
 Central nervous system: Fever, seizures
 Dermatologic: Erythema, urticaria, pruritus, rash, cutaneous wheal formation
 Endocrine & metabolic: Growth suppression
 Gastrointestinal: Abdominal discomfort, diarrhea, appendicitis
 Genitourinary: Dysuria, urine discoloration (pink)
 Local: Pain and induration at injection site
 Neuromuscular & skeletal: Leg cramps, exacerbation of myasthenia gravis
 Ocular: Blurred vision, cataract, visual field defects, night blindness, macular edema, retinopathy
 Otic: Hearing loss, tinnitus
 Renal: Renal insufficiency

Miscellaneous: Anaphylaxis, possible risk of fungal and *Y. enterocolitica* infections (increased); *Yersinia*, *Zygomycetes* and *Aeromonas hydrophila* infection have been associated with deferoxamine administration;

Cyanide Antidote Kit

Pronunciation (SOW dee um NYE trite, SOW dee um thye oh SUL fate, & AM il NYE trite)

U.S. Brand Names Cyanide Antidote Package

phycomycosis; thrombocytopenia, toxicity, fibrosis and edema at high doses (over 24 hours) - restrictive lung pathology has been noted

Signs and Symptoms of Overdose

Pharmacodynamics/Kinetics

Absorption: I.M.: Erratic

Metabolism: Hepatic; binds with iron to form ferrioxamine

Half-life elimination: Parent drug: 6.1 hours; Ferrioxamine: 5.8 hours

Excretion: Urine (as unchanged drug and ferrioxamine)

Dosage

Oral use is probably not effective; 100 mg DFO binds ~10 mg iron and 4.1 mg of aluminum

Children:

Acute iron intoxication:

I.M.: 90 mg/kg/dose every 8 hours

I.V.: 10-15 mg/kg/hour (up to 35 mg/kg/hour with caution in severe poisoning); in nonpoisoning settings, maximum dose

Chronic iron overload:

I.V.: 15 mg/kg/hour

SubQ: 20-40 mg/kg/day over 8-12 hours

Aluminum-induced bone disease (unlabeled use): 20-40 mg/kg every hemodialysis treatment, frequency dependent on clinical status of the patient

Dialysis patients for general aluminum toxicity (levels >60 mcg/dL): 40-80 mg/kg I.V. once weekly prior to dialysis with a dose reduction to 20-60 mg/kg with a positive response

Adults:

Acute iron intoxication:

I.M.: 1 g stat, then 0.5 g every 4 hours for two doses, then 0.5 g every 4-12 hours up to 6 g/day

I.V.: 15 mg/kg/hour, up to 6-8 g/day; maximum given 16 g/day without side effects

Chronic iron overload:

I.M.: 0.5-1 g every day

SubQ: 1-2 g every day over 8-24 hours

Stability Protect from light; reconstituted solutions (sterile water) may be stored at room temperature for 7 days

Monitoring Parameters Serum iron, total iron-binding capacity; ophthalmologic exam (funduscopy, slit-lamp exam) and audiometry with chronic therapy

Administration

I.V.: Urticaria, hypotension, and shock have occurred following rapid I.V. administration; limiting infusion rate to 15mg/kg/hour may help avoid infusion-related adverse effects.

Acute iron toxicity: The manufacturer states that the I.M. route is preferred; however, the I.V. route is generally preferred in patients with severe toxicity (ie, patients in shock). For the first 1000 mg, infuse at 15 mg/kg/hour (although rates up to 40-50 mg/kg/hour have been given in patients with massive iron intoxication). Subsequent doses may be given over 4-12 hours; maximum I.V. rate (per manufacturer): 15 mg/kg/hour.

Diagnosis or treatment of aluminum induced toxicity with CKD: Administer dose over 1 hour

SubQ: When administered for chronic iron overload, daily dose should be given over 8-24 hours using portable pump.

Contraindications Hypersensitivity to deferoxamine or any component of the formulation; patients with severe renal disease and anuria, primary hemochromatosis

Warnings Use with caution in patients with pyelonephritis; may increase susceptibility to *Yersinia enterocolitica*. Ocular and auditory disturbances and growth retardation (children only), have been reported following prolonged administration. Has been associated with adult respiratory distress syndrome (ARDS) following excessively high-dose treatment of acute intoxication. Caution must be used in performing tasks which require alertness (eg, operating machinery or driving). Patients should be informed that urine may have a reddish color.

Dosage Forms Injection, powder for reconstitution, as mesylate: 500 mg, 2 g

Test Interactions May interfere with colorimetric iron assays, along with total iron binding capacity

Drug Interactions

Prochlorperazine: Concurrent use may cause loss of consciousness or coma.

Vitamin C: Concomitant treatment with vitamin C (>500 mg/day) has been associated with cardiac impairment

Pregnancy Risk Factor C

Pregnancy Implications Do not withhold chelation treatment for iron overdose solely due to pregnancy; has caused fetal skeletal abnormalities in animal models but is probably safe to use in the gravid patient

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Iron chelate colors urine salmon pink, which is concentration and pH dependent; I.M. is preferred route; maximum I.V. rate is 35 mg/kg/hour; incompatible with heparin

Specific References

Prasannan L, Flynn JT, Levine JE, et al, "Acute Renal Failure Following Deferoxamine Overdose," *Pediatr Nephrol*, 2003, 18(3):283-5.

Dexrazoxane

Pronunciation (deks ray ZOKS ane)

CAS Number 24584-09-6

U.S. Brand Names Zinecard®

Synonyms ICRF-187

Use Reduction of the incidence and severity of cardiomyopathy associated with doxorubicin administration in women with metastatic breast cancer who have received a cumulative doxorubicin dose of 300 mg/m² and who would benefit from continuing therapy with doxorubicin. It is not recommended for use with the initiation of doxorubicin therapy.

Mechanism of Action Derivative of EDTA; potent intracellular chelating agent. The mechanism of cardioprotectant activity is not fully understood. Appears to be converted intracellularly to a ring-opened chelating agent that interferes with iron-mediated oxygen free radical generation thought to be responsible, in part, for anthracycline-induced cardiomyopathy.

Adverse Reactions

Dermatologic: Alopecia, urticaria, recall skin reaction, extravasation

Endocrine & metabolic: Serum amylase increased, serum calcium decreased, serum triglycerides increased

Gastrointestinal: Nausea, vomiting (mild)

Hematologic: Myelosuppression, **neutropenia**, thrombocytopenia

Hepatic: AST/ALT increased, bilirubin increased

Pharmacodynamics/Kinetics

Distribution: V_d: 22-22.4 L/m²

Protein binding: None

Half-life elimination: 2.1-2.5 hours

Excretion: Urine (42%)

Clearance, renal: 3.35 L/hour/m²; Plasma: 6.25-7.88 L/hour/m²

Dosage

Adults: I.V.: A 10:1 ratio of dexrazoxane:doxorubicin (500 mg/m² dexrazoxane: 50 mg/m² doxorubicin)

Dosage adjustment in hepatic impairment: Since doxorubicin dosage is reduced in hyperbilirubinemia, a proportional reduction in dexrazoxane dosage is recommended (maintain ratio of 10:1).

Stability

Store intact vials at controlled room temperature (15°C to 30°C/59°F to 86°F). Reconstituted and diluted solutions are stable for 6 hours at controlled room temperature or under refrigeration (2°C to 8°C/36°F to 46°F).

Must be reconstituted with 0.167 Molar (M/6) sodium lactate injection to a concentration of 10 mg dexrazoxane/mL sodium lactate. Reconstituted dexrazoxane solution may be diluted with either 0.9% sodium chloride injection or 5% dextrose injection to a concentration of 1.3-5 mg/mL in intravenous infusion bags.

Monitoring Parameters Since dexrazoxane will always be used with cytotoxic drugs, and since it may add to the myelosuppressive effects of cytotoxic drugs, frequent complete blood counts are recommended

Administration Administer by slow I.V. push or rapid (5-15 minutes) I.V. infusion from a bag. Administer doxorubicin within 30 minutes after beginning the infusion with dexrazoxane.

Contraindications Hypersensitivity to dexrazoxane or any component of the formulation; use with chemotherapy regimens that do not contain an anthracycline

Warnings Hazardous agent; use appropriate precautions for handling and disposal. Dexrazoxane may add to the myelosuppression caused by chemotherapeutic agents. Dexrazoxane does not eliminate the potential for anthracycline-induced cardiac toxicity. Carefully monitor cardiac function. Dosage adjustment required for moderate or severe renal insufficiency. Safety and efficacy in pediatric patients have not been established.

Dosage Forms Injection, powder for reconstitution: 250 mg, 500 mg [10 mg/mL when reconstituted]

Reference Range Peak plasma dexrazoxane level after a 500 mg/m² infusion: 36.5 mcg/mL

Test Interactions ↑ serum amylase (without evidence for pancreatitis); ↑ serum iron, ↓ serum zinc

Pregnancy Risk Factor C

Pregnancy Implications Avoid use in pregnant women unless the potential benefit justifies the potential risk to the fetus

Lactation Excretion in breast milk unknown/not recommended

Dextran 1

Pronunciation (DEKS tran won)

CAS Number 9004-54-0

U.S. Brand Names Promit®

Use Prophylaxis of serious anaphylactic reactions to I.V. infusion of dextran in a dose-dependent manner; can prevent clot formation due to ergotism

Mechanism of Action Binds to dextran-reactive immunoglobulin without bridge formation and no formation of large immune complexes

Mechanism of Toxic Action Produces plasma volume expansion by virtue of its highly colloidal starch structure, similar to albumin

DEXTROSE

Adverse Reactions

Cardiovascular: Mild hypotension, bradycardia, tightness of chest, chest pain, shock, sinus bradycardia, angina
Central nervous system: Fever
Dermatologic: Urticaria
Gastrointestinal: Nausea, vomiting
Hematologic: Coagulopathy
Neuromuscular & skeletal: Arthralgia
Renal: Renal failure
Respiratory: Wheezing, nasal congestion
Miscellaneous: Anaphylaxis

Signs and Symptoms of Overdose Bradycardia, hypotension

Dosage

I.V. (time between dextran 1 and dextran solution should not exceed 15 minutes):

Children: 0.3 mL/kg 1-2 minutes before I.V. infusion of dextran

Adults: 20 mL 1-2 minutes before I.V. infusion of dextran

Administration Infuse over 1 minute.

Contraindications Hypersensitivity to dextrans or any component of the formulation; **dextran** contraindicated

Warnings Severe hypotension and bradycardia can occur. If any reaction occurs, do not administer dextran. Mild dextran-induced anaphylactic reactions are not prevented.

Dosage Forms Injection, solution: 150 mg/mL (20 mL)

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Nursing Implications Do not dilute or admix with dextrans

Dextrose

CAS Number 50-99-7; 5996-10-1

Use Patients with altered mental status due to hypoglycemia

Mechanism of Action A carbohydrate substrate for aerobic metabolism

Adverse Reactions

Central nervous system: Confusion, has been associated with worsening of ischemic strokes

Endocrine & metabolic: Hypokalemia, hyperglycemia, hypomagnesemia, hypophosphatemia

Gastrointestinal: Sweet taste

Local: Vein irritation, thrombophlebitis, extravasation injury

Respiratory: Pulmonary edema

Miscellaneous: Hyperosmolar solution which can cause a Volkmann's contraction of an extremity if extravasation occurs

Dosage

Dextrose 50% solution (parenteral administration)

Children: Dilute to 10% to 25% and give 2-4 mL/kg body weight

"Rule of 50" for Providing 0.5 g of Dextrose Intravenously in Pediatric Patients with Sulfonyleurea-induced Hypoglycemia

Dextrose Concentration of I.V. Fluid	Volume to be Administered
10%	5 mL/kg
25%	2 mL/kg
50%	1 mL/kg

Adults: 50-100 mL

Use caution in elderly patients, starting at the low end of the dosing range, reflecting the greater frequency of decreased hepatic, renal, or cardiac function, and of concomitant disease or other drug therapy.

Monitoring Parameters Serum glucose

Test Interactions May cause false elevation of serum creatinine through interference with laboratory determination

Specific References

Calello DP, Kelly A, and Osterhoudt KC, "Case Files of the Medical Toxicology Fellowship Training Program at the Children's Hospital of Philadelphia: A Pediatric Exploratory Sulfonyleurea Ingestion," *J Med Toxicol*, 2006, 2(1):19-24.

McGee D, Chen A, and de Garavilla L, "Dextrose Is Absorbed by Rectum in Hypoglycemic Rats," *J Emerg Med*, 2003, 24(3):253-7.

Diethyldithiocarbamate Trihydrate

CAS Number 148-18-5

Synonyms DDC

Unlabeled/Investigational Use

Investigational: Chelating agent for nickel; a metabolite of disulfiram, it has also been used to treat thallium poisoning, but is not effective; shown to be active against HIV *in vitro*

Mechanism of Action Binds to nickel; the nickel-diethyldithiocarbamate complex is lipophilic thus enhancing its elimination

Adverse Reactions Gastrointestinal: Nausea

Dosage

Mild or doubtful nickel exposure (urine nickel < 100 mcg/L): Oral: 2 g in divided doses (every 4 hours)

Severe nickel exposure urine (levels 100-500 mcg/L): adult dose Oral: Initial: 2 g with 1 g sodium bicarbonate, then 1 g at 4 hours, 600 mg at 8 hours, 400 mg at 16 hours, and 400 mg every 8 hours thereafter until urine Ni is < 50 mcg/L

Alternatively, 35-45 mg/kg/day on day one, then 400 mg every 8 hours until symptoms are resolved or urine nickel levels are < 50 mcg/L;

Urine nickel levels > 500 mcg/L: Give 25-100 mg/kg/day (I:V)

DDC may be given intravenously by adding ten ml of a sterile phosphate buffer solution to one gram of powdered DDC contained in a sterile ampule I.V DDC 25-100 mg/kg is administered over the first 24 hours as described above.

How supplied: One gram sterile powder ampule.

Diethylene Triamine Penta-Acetic Acid

CAS Number 67-43-6

Use Chelating absorbed multivalent radioisotopes of the actinide series (plutonium, neptunium, americium) as well as cesium and actinide; may be useful for uranium, curium, californium, cerium, yttrium, lanthanum, scandium, promethium, niobium, manganese, thorium, lutetium, zirconium, and zinc; on IND status

Mechanism of Action Chelation for multivalent radioisotopes

Adverse Reactions

Central nervous system: Chills, fever

Dermal: Pruritus

Gastrointestinal: Transient nausea, vomiting, diarrhea

Neuromuscular & skeletal: Muscle cramps in first day of therapy

Renal: Nephrotoxicity

Miscellaneous: Ca-DTPA may cause zinc depletion leading to transient anosmia

Dosage 1 g of the calcium salt diluted in 250 mL of 5% dextrose in water infused over 60-90 minutes; may be repeated daily for 5 days; zinc salt can be used for pregnant patients; may be aerosolized through nebulization

Stability Store in cool environment and away from sunlight

Monitoring Parameters Urine analysis, radioassay, renal function and blood counts during therapy, pulse and blood pressure

Pregnancy Risk Factor C (Zn-DTPA); D (Ca-DTPA)

Digoxin Immune Fab

U.S. Brand Names Digibind®; DigiFab™

Synonyms Antidigoxin Fab Fragments, Ovine

Use Treatment of life-threatening or potentially life-threatening digoxin intoxication, including:

- Acute digoxin ingestion (ie, > 10 mg in adults or > 4 mg in children)
- Acute digoxin serum level > 15 ng/ml
- Empiric diagnosis for undiagnosed bradycardia, ventricular arrhythmics or bradyarrhythmia unresponsive to atropine
- Chronic ingestions leading to steady-state digoxin concentrations > 6 ng/mL in adults or > 4 ng/mL in children
- Manifestations of digoxin toxicity due to overdose (life-threatening ventricular arrhythmias, progressive bradycardia, second- or third-degree heart block not responsive to atropine, serum potassium > 5 mEq/L in adults or > 6 mEq/L in children)

Useful in treating delirium due to digitalis; also effective for oleander, Squill, Yellow oleander, Dogbane, Bufo toads, Lily of the Valley, Purple Foxglove, foxglove lanatoside C ingestions

Mechanism of Action Binds with molecules of digoxin or digitoxin and is then excreted by the kidneys and removed from the body; promotes egress of free intracellular digoxin into extracellular fluid whereupon it is rapidly bound; prevents reassociation to membrane receptors

Adverse Reactions Allergic reactions (very rare), hypokalemia, phlebitis, postural hypotension, serum sickness. Cardiovascular effects (due to withdrawal of digitalis) include exacerbation of low cardiac output states and congestive heart failure, rapid ventricular response in patients with atrial fibrillation.

Pharmacodynamics/Kinetics

Onset of action: I.V.: Improvement in 2-30 minutes for toxicity

Half-life elimination: 15-20 hours; prolonged with renal impairment

Excretion: Urine; undetectable amounts within 5-7 days

Dosage

See package insert. To determine the dose of digoxin immune Fab, first determine the total body load of digoxin (TBL) as follows (using either an approximation of the amount ingested or a postdistribution serum digoxin concentration):

TBL of digoxin (in mg) = C (in ng/mL) × 5.6 × body weight (in kg)/1000
or TBL = mg of digoxin ingested (as tablets or elixir) × 0.8;
C = postdistribution digoxin concentration (taken minimally 6 hours after ingestion)

Dose of digoxin immune Fab (in mg) I.V. = TBL × 66.7 or dose of digoxin immune Fab (in number of 38 mg vials) = [C of digoxin (in ng/mL) × body weight (in kg)]/100

If neither ingestion amount or serum level is known: Adult dosage is 20 vials (760 mg) I.V. infusion; see tables.

Approximate Digibind® Dose for Reversal of a Single Large Digoxin Overdose

5	2 mg*	4 mg	8 mg	15 mg	23 mg	30 mg	38 mg
10	4 mg	8 mg	15 mg	30 mg	46 mg	61 mg	76 mg
20	8 mg	15 mg	30 mg	61 mg	91 mg	122 mg	152 mg

*Dilution of reconstituted vial to 1 mg/mL may be desirable.

Stability Should be refrigerated (2°C to 8°C). Reconstitute by adding 4 mL sterile water, resulting in 10 mg/mL for I.V. infusion. The reconstituted solution may be further diluted with NS to a convenient volume (eg, 1 mg/mL). Reconstituted solutions should be used within 4 hours if refrigerated. For very small doses, vial can be reconstituted by adding an additional 36 mL of sterile isotonic saline, to achieve a final concentration of 1 mg/mL.

Monitoring Parameters

Serum potassium, serum digoxin concentration prior to first dose of digoxin immune Fab; **digoxin levels will greatly increase with digoxin immune Fab use and are not an accurate determination of body stores**; standard digoxin concentration measurements may be misleading until Fab fragments are eliminated from the body.

Patients with renal failure should be monitored for a prolonged period for re-intoxication with digoxin following the rerelease of bound digoxin into the blood.

Administration Continuous I.V. infusion over 15-30 minutes is preferred; digoxin immune Fab is reconstituted by adding 4 mL sterile water, resulting in 10 mg/mL for I.V. infusion, the reconstituted solution may be further diluted with NS to a convenient volume (eg, 1 mg/mL)

Contraindications Hypersensitivity to sheep products or any component of the formulation

Warnings Suicidal attempts often involve multiple drugs. Consider other drug toxicities as well. Hypersensitivity reactions can occur. Epinephrine should be immediately available. Serum potassium levels should be

monitored, especially during the first few hours after administration. Total serum digoxin concentrations will rise precipitously following administration of this drug (has no clinical meaning - avoid monitoring serum concentrations). If digoxin was being used to treat CHF then may see exacerbation of symptoms as digoxin level is reduced. Use with caution in renal failure (experience limited) - the complex will be removed from the body more slowly. Monitor for reoccurrence of digoxin toxicity. Has reversed thrombocytopenia induced by digoxin. Failure of response to adequate treatment may call diagnosis of digitalis toxicity into question. Digoxin immune Fab is processed with papain and may cause hypersensitivity reactions in patients allergic to papaya, other papaya extracts, papain, chymopapain, or the pineapple enzyme bromelain. There may also be cross allergy with dust mite and latex allergens.

Dosage Forms

Injection, powder for reconstitution:

Digibind®: 38 mg

DigiFab™: 40 mg

Reference Range Digoxin toxic concentration: >2.0 ng/mL

Test Interactions ↑ digoxin 50-fold; ↓ potassium; may ↓ glucose in patients with low glycogen stores

Drug Interactions Digoxin: Following administration of digoxin immune Fab, serum digoxin levels are markedly increased due to bound complexes (may be clinically misleading, since bound complex cannot interact with receptors).

Pregnancy Risk Factor C

Pregnancy Implications Animal reproduction studies have not been conducted. Safety and efficacy in pregnant women have not been established. Use during pregnancy only if clearly needed.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Continuous I.V. infusion over 15-30 minutes is preferred; digoxin immune Fab is reconstituted by adding 4 mL sterile water, resulting in 10 mg/mL for I.V. infusion, the reconstituted solution may be further diluted with normal saline to a convenient volume (eg, 1 mg/mL)

Dimercaprol

Pronunciation (dye mer KAP role)

Related Information

- Unithiol [ANTIDOTE]

CAS Number 59-52-9

U.S. Brand Names BAL in Oil®

Synonyms BAL; British Anti-Lewisite; Dithioglycerol

Use Antidote to gold, arsenic, mercury, methyl bromide, methyl iodide, or trivalent antimony poisoning; adjunct to edetate calcium disodium in lead poisoning; possibly effective for bismuth, polonium, chromium, copper, nickel, tungsten, or zinc

Mechanism of Action Sulfhydryl group combines with ions of various heavy metals to form relatively stable, nontoxic, soluble chelates which are excreted in bile and urine

Adverse Reactions

Cardiovascular: **Hypertension, tachycardia**, chest pain, angina, sinus tachycardia

Central nervous system: Nervousness, fever, headache, seizures, **convulsions**

Gastrointestinal: Vomiting, nausea, salivation

Hematologic: Transient neutropenia, glucose-6-phosphate dehydrogenase deficiency-induced hemolytic anemia

Local: Pain at injection site

Ocular: Blepharospasm

Renal: Nephrotoxicity

Respiratory: Rhinorrhea

Miscellaneous: Burning sensation of the lips, mouth, throat, eyes, diaphoresis

Pharmacodynamics/Kinetics

Distribution: To all tissues including the brain

Metabolism: Rapidly hepatic to inactive metabolites

Time to peak, serum: 0.5-1 hour

Excretion: Urine

DOBUTAMINE

Dosage

Children and Adults:

I.M.:

Mild arsenic and gold poisoning: 2.5 mg/kg/dose every 6 hours for 2 days, then every 12 hours on the third day, and once daily thereafter for 10 days

Severe arsenic and gold poisoning: 3 mg/kg/dose every 4 hours for 2 days then every 6 hours on the third day, then every 12 hours thereafter for 10 days

Mercury poisoning: Initial: 5 mg/kg followed by 2.5 mg/kg/dose 1-2 times/day for 10 days

Lead poisoning (use with edetate calcium disodium):

Mild: 3-5 mg/kg/dose every 4 hours for 2 days, then 2.5-3 mg/kg/dose every 6 hours for 2 days, then 2.5-3 mg/kg/dose every 12 hours for 1 week

Severe: 4 mg/kg/dose every 4 hours for 5-7 days

Acute encephalopathy: Initial: 4 mg/kg/dose, then every 4 hours

Topical dermal/ocular dose for Lewisite exposure: <20% solution

Administration Administer deep I.M. only; keep urine alkaline to protect renal function

Contraindications Hepatic insufficiency (unless due to arsenic poisoning); do not use on iron, cadmium, or selenium poisoning

Warnings Potentially a nephrotoxic drug, use with caution in patients with oliguria or glucose 6-phosphate dehydrogenase deficiency; keep urine alkaline to protect kidneys; administer all injections deep I.M. at different sites

Dosage Forms Injection, oil: 100 mg/mL (3 mL) [contains benzyl benzoate and peanut oil]

Test Interactions May ↓ Iodine I-131 thyroid uptake values

Drug Interactions Toxic complexes with iron, cadmium, selenium, or uranium

Pregnancy Risk Factor C

Pregnancy Implications C

Nursing Implications Administer deep I.M. only; urine should be kept alkaline

Dobutamine	
Creatinine Clearance (mL/min)	Dosage Interval
30-40	q8h
15-30	q12h
< 15	q24h

Maximum I.V. dose: 40 mcg/kg/minute

Maximum survivable dose on record: 130 mcg/kg/minute for 30 minutes. See table.

Infusion Rates of Various Dilutions of Dobutamine

Desired Delivery Rate (mcg/kg/min)	Infusion Rate (mL/kg/min)	
	500 mcg/mL*	1000 mcg/mL†
2.5	0.005	0.0025
5.0	0.01	0.005
7.5	0.015	0.0075
10.0	0.02	0.01
12.5	0.025	0.0125
15.0	0.03	0.015

*500 mg per liter or 250 mg per 500 mL of diluent.

†1000 mg per liter or 250 mg per 250 mL of diluent.

Stability Remix solution every 24 hours; incompatible with sodium bicarbonate solutions; store reconstituted solution under refrigeration for 48 hours or 6 hours at room temperature; pink discoloration of solution indicates slight oxidation but **no** significant loss of potency

Monitoring Parameters Blood pressure, ECG, heart rate, CVP, RAP, MAP, urine output; if pulmonary artery catheter is in place, monitor CI, PCWP, and SVR; also monitor serum potassium

Administration Use infusion device to control rate of flow; administer into large vein. Do not administer through same I.V. line as heparin, hydrocortisone sodium succinate, cefazolin, or penicillin.

To prepare for infusion:

$$\frac{6 \times \text{weight (Kg)} \times \text{desired dose (mcg/kg/min)}}{\text{I.V. infusion rate (mL/h)}} = \frac{\text{mg drug to be added to}}{10 \text{ mL of I.V. fluid}}$$

Contraindications Hypersensitivity to dobutamine or sulfites (some contain sodium metabisulfite), or any component of the formulation; idiopathic hypertrophic subaortic stenosis (IHSS)

Warnings May increase heart rate. Patients with atrial fibrillation may experience an increase in ventricular response. An increase in blood pressure is more common, but occasionally a patient may become hypotensive. May exacerbate ventricular ectopy. If needed, correct hypovolemia first to optimize hemodynamics. Ineffective in the presence of mechanical obstruction such as severe aortic stenosis. Use caution post-MI (can increase myocardial oxygen demand). Use cautiously in the elderly starting at lower end of the dosage range.

Dosage Forms

Infusion, as hydrochloride [premixed in dextrose]: 1 mg/mL (250 mL, 500 mL); 2 mg/mL (250 mL); 4 mg/mL (250 mL)

Injection, solution, as hydrochloride: 12.5 mg/mL (20 mL, 40 mL, 100 mL) [contains sodium bisulfite]

Test Interactions Dobutamine (and to a lesser extent dopamine) can cause profound negative interference with the enzymatic method for serum creatinine determination, producing a false depression of serum creatinine

Drug Interactions

Beta-blockers (nonselective ones) may increase hypertensive effect; avoid concurrent use.

Cocaine may cause malignant arrhythmias; avoid concurrent use.

Guanethidine can increase the pressor response; be aware of the patient's drug regimen.

MAO inhibitors potentiate hypertension and hypertensive crisis; avoid concurrent use.

Methyldopa can increase the pressor response; be aware of patient's drug regimen.

Reserpine increases the pressor response; be aware of patient's drug regimen.

TCAs increase the pressor response; be aware of patient's drug regimen.

Pregnancy Risk Factor B

Pregnancy Implications B

Lactation Excretion in breast milk unknown

Nursing Implications

Alkaline solutions (sodium bicarbonate); do not give through same I.V. line as heparin, hydrocortisone sodium succinate, cefazolin, or penicillin; administer into large vein; use infusion device to control rate of flow

DOBUTamine

CAS Number 49745-95-1

U.S. Brand Names Dobutrex®

Synonyms Dobutamine Hydrochloride

Use Short-term management of patients with cardiac decompensation; useful for hypotension induced by tricyclic antidepressants, beta-adrenergic blockers, doxazosin, calcium channel blockers, or sedative-hypnotic toxicity

Unlabeled/Investigational Use Positive inotropic agent for use in myocardial dysfunction of sepsis

Mechanism of Action Stimulates beta₁-adrenergic receptors, causing increased contractility and heart rate, with little effect on beta₂- or alpha-receptors

Adverse Reactions

Symptoms can occur for up to 2 hours

Cardiovascular: **Ectopic beats, chest pain, angina**, tachycardia, fibrillation (atrial), hypertension, **palpitations, elevated blood pressure**; in higher doses, **tachycardia (ventricular) or cardiac arrhythmias** may be seen; patients with fibrillation (atrial) or flutter (atrial) are at risk of developing a rapid ventricular response; syncope, sinus tachycardia, arrhythmias (ventricular)

Central nervous system: Headache, fever, hyperthermia

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Nausea, vomiting

Genitourinary: Urinary incontinence

Hematologic: Coagulopathy, platelet inhibition

Local: Extravasation injury

Neuromuscular & skeletal: Leg cramps (mild), neuropathy (peripheral), paresthesia, tingling sensation

Respiratory: Dyspnea, tachypnea

Signs and Symptoms of Overdose Fatigue, nervousness

Pharmacodynamics/Kinetics

Onset of action: I.V.: 1-10 minutes

Peak effect: 10-20 minutes

Metabolism: In tissues and hepatically to inactive metabolites

Half-life elimination: 2 minutes

Excretion: Urine (as metabolites)

Dosage

I.V. infusion:

Neonates and Children: 2.5-15 mcg/kg/minute, titrate to desired response

Adults: 2.5-15 mcg/kg/minute; maximum: 40 mcg/kg/minute, titrate to desired response. See table.

Extravasation: Use phentolamine as antidote; mix 5 mg with 9 mL of normal saline; inject a small amount of this dilution into extravasated area; blanching should reverse immediately. Monitor site; if blanching should recur, additional injections of phentolamine may be needed.

DOPamine

Pronunciation (DOE pa meen)

CAS Number 51-61-6; 62-31-7

Synonyms Dopamine Hydrochloride; Intropin

Use Adjunct in the treatment of shock which persists after adequate fluid volume replacement; dose-related inotropic and vasopressor effects; stimulates dopaminergic, beta- and alpha-receptors

Unlabeled/Investigational Use Symptomatic bradycardia or heart block unresponsive to atropine or pacing

Mechanism of Action Stimulates both adrenergic and dopaminergic receptors, lower doses are mainly dopaminergic stimulating and produces renal and mesenteric vasodilation, higher doses also are both dopaminergic and beta₁-adrenergic and produces cardiac stimulation and renal vasodilation, large doses stimulate alpha-adrenergic receptors. A metabolic precursor to norepinephrine.

Adverse Reactions

Cardiovascular: **Ectopic heartbeats, tachycardia, vasoconstriction, hypotension, cardiac conduction abnormalities, widened QRS complex**, bradycardia, hypertension, **arrhythmias (ventricular)**, gangrene of the extremities (with high doses for prolonged periods or even with low doses in patients with occlusive vascular disease), **palpitations**, facial flushing, fibrillation (atrial), flutter (atrial), sinus bradycardia, pulmonary hypertension, sinus tachycardia, tachycardia (supraventricular)

Central nervous system: Anxiety, **headache**, dizziness,

Endocrine & metabolic: Hypoprolactinemia

Gastrointestinal: **Nausea, vomiting**, decreased esophageal sphincter tone

Genitourinary: Decreased urine output

Local: Extravasation injury

Neuromuscular & skeletal: Piloerection

Ocular: Mydriasis

Renal: Azotemia

Respiratory: **Dyspnea**

Signs and Symptoms of Overdose Fixed and dilated pupils, tachycardia, severe hypertension

Pharmacodynamics/Kinetics

Children: Dopamine has exhibited nonlinear kinetics in children; with medication changes, may not achieve steady-state for ~1 hour rather than 20 minutes

Onset of action: Adults: 5 minutes

Duration: Adults: <10 minutes

Metabolism: Renal, hepatic, plasma; 75% to inactive metabolites by monoamine oxidase and 25% to norepinephrine

Half-life elimination: 2 minutes

Excretion: Urine (as metabolites)

Clearance: Neonates: Varies and appears to be age related; clearance is more prolonged with combined hepatic and renal dysfunction

Dosage

I.V. infusion:

Neonates: 1-20 mcg/kg/minute continuous infusion, titrate to desired response

Children: 1-20 mcg/kg/minute, maximum: 50 mcg/kg/minute continuous infusion, titrate to desired response

Adults: 1-5 mcg/kg/minute up to 50 mcg/kg/minute, titrate to desired response; infusion may be increased by 1-4 mcg/kg/minute at 10- to 30-minute intervals until optimal response is obtained

If dosages >20-30 mcg/kg/minute are needed, a more direct-acting pressor may be more beneficial (ie, epinephrine, norepinephrine)

The hemodynamic effects of dopamine are dose-dependent:

Low-dose: 1-5 mcg/kg/minute, increased renal blood flow and urine output

Intermediate-dose: 5-15 mcg/kg/minute, increased renal blood flow, heart rate, cardiac contractility, and cardiac output

High-dose: >15 mcg/kg/minute, alpha-adrenergic effects begin to predominate, vasoconstriction, increased blood pressure

Stability Protect from light; solutions that are darker than slightly yellow should not be used; incompatible with alkaline solutions or iron salts; compatible when coadministered with dobutamine, epinephrine, isoproterenol, and lidocaine

Monitoring Parameters Blood pressure, ECG, heart rate, CVP, RAP, MAP, urine output; if pulmonary artery catheter is in place, monitor CI, PCWP, SVR, and PVR

Administration

Administer into large vein to prevent the possibility of extravasation; use infusion device to control rate of flow; due to short half-life, withdrawal of the drug is often the only necessary treatment

Extravasation: Use phentolamine as antidote; mix 5 mg with 9 mL of normal saline; inject a small amount of this dilution into extravasated area; blanching should reverse immediately. Monitor site; if blanching should recur, additional injections of phentolamine may be needed.

Contraindications Hypersensitivity to sulfites (commercial preparation contains sodium bisulfite); pheochromocytoma; ventricular fibrillation

Warnings Use with caution in patients with cardiovascular disease or cardiac arrhythmias or patients with occlusive vascular disease. Correct hypovolemia and electrolytes when used in hemodynamic support. May cause increases in HR and arrhythmia. Avoid infiltration - may cause severe tissue necrosis. Use with caution in post-MI patients.

Dosage Forms

Infusion, as hydrochloride [premixed in D₅W]: 0.8 mg/mL (250 mL, 500 mL); 1.6 mg/mL (250 mL, 500 mL); 3.2 mg/mL (250 mL)

Injection, solution, as hydrochloride: 40 mg/mL (5 mL, 10 mL); 80 mg/mL (5 mL); 160 mg/mL (5 mL) [contains sodium metabisulfite]

Test Interactions Dobutamine (and to a lesser extent dopamine) can cause profound negative interference with the enzymatic method for serum creatinine determination, producing a false depression of serum creatinine; may interfere with TSH assay resulting in falsely low TSH levels

Drug Interactions

Beta-blockers (nonselective ones) may increase hypertensive effect; avoid concurrent use.

Cocaine may cause malignant arrhythmias; avoid concurrent use.

Guanethidine's hypotensive effects may only be partially reversed; may need to use a direct-acting sympathomimetic.

MAO inhibitors potentiate hypertension and hypertensive crisis; avoid concurrent use.

Methyldopa can increase the pressor response; be aware of patient's drug regimen.

Reserpine increases the pressor response; be aware of patient's drug regimen.

TCAs increase the pressor response; be aware of patient's drug regimen.

Pregnancy Risk Factor C

Pregnancy Implications Not known if it crosses the placenta

Lactation Excretion in breast milk unknown

Nursing Implications

Monitor continuously for free flow

Extravasation: Use phentolamine as antidote; mix 5 mg with 9 mL of normal saline; inject a small amount of this dilution into extravasated area; blanching should reverse immediately. Monitor site; if blanching should recur, additional injections of phentolamine may be needed. If phentolamine is not available, topical nitroglycerin paste or subcutaneous administration of terbutaline (at a 1:1 to 1:10 dilution) may be effective alternative treatment.

Edetate Calcium Disodium

Pronunciation (ED e tate KAL see um dye SOW dee um)

CAS Number 23411-34-9; 62-33-9

U.S. Brand Names Calcium Disodium Versenate®

Synonyms CaEDTA ; Calcium Disodium Edetate; Calcium EDTA; EDTA (Calcium Disodium)

Use Treatment of acute and chronic lead, manganese, scandium, lanthanum, plutonium, or zinc poisoning; may aid in the diagnosis of lead poisoning

Unlabeled/Investigational Use

Investigational: Cholelitholytic agent (through biliary duct infusion) for pigment bile duct stones

Mechanism of Action Calcium is displaced by divalent and trivalent heavy metals, forming a nonionizing soluble complex that is excreted in urine.

Adverse Reactions

Cardiovascular: Hypotension, arrhythmias, ECG changes

Central nervous system: Fever, headache, chills

Dermatologic: Skin lesions, cheilosis

Endocrine & metabolic: Hypercalcemia, zinc deficiency

Gastrointestinal: GI upset, anorexia, nausea, vomiting

Hematologic: Transient marrow suppression, anemia

Hepatic: Mild increase in liver function test results

Local: Pain at injection site following I.M. injection, thrombophlebitis following I.V. infusion (at concentration >5 mg/mL)

Neuromuscular & skeletal: Arthralgia, tremor, numbness, paresthesia

Ocular: Lacrimation

Renal: Renal tubular necrosis, proteinuria, microscopic hematuria

Respiratory: Sneezing, nasal congestion

Miscellaneous: Zinc depletion

Pharmacodynamics/Kinetics

Onset of action: Chelation of lead: I.V.: 1 hour
 Absorption: I.M., SubQ: Well absorbed
 Distribution: Into extracellular fluid; minimal CSF penetration
 Half-life elimination, plasma: I.M.: 1.5 hours; I.V.: 20 minutes
 Excretion: Urine (as metal chelates or unchanged drug); decreased GFR decreases elimination

Dosage

Several regimens have been recommended:
 Diagnosis of lead poisoning: Mobilization test (not recommended by AAP guidelines): I.M., I.V.:
 Children: 500 mg/m²/dose, (maximum dose: 1 g) as a single dose or divided into 2 doses
 Adults: 500 mg/m²/dose
 Treatment of lead poisoning: Children and Adults (each regimen is specific for route):
 Symptoms of lead encephalopathy and/or blood lead level >70 mcg/dL: Treat 5 days; give first dose after, then given in conjunction with dimercaprol; wait a minimum of 2 days with no treatment before considering a repeat course:
 I.M.: 250 mg/m²/dose every 4 hours
 I.V.: 50 mg/kg/day as 24-hour continuous I.V. infusion or 1-1.5 g/m² I.V. as either an 8- to 24-hour infusion or divided into 2 doses every 12 hours
 Symptomatic lead poisoning **without** encephalopathy or asymptomatic with blood lead level >70 mcg/dL: Treat 3-5 days; treatment with dimercaprol is recommended until the blood lead level concentration <50 mcg/dL:
 I.M.: 167 mg/m² every 4 hours
 I.V.: 1 g/m² as an 8- to 24-hour infusion or divided every 12 hours
 Asymptomatic **children** with blood lead level 45-69 mcg/dL: I.V.: 25 mg/kg/day for 5 days as an 8- to 24-hour infusion or divided into 2 doses every 12 hours
 Depending upon the blood lead level, additional courses may be necessary; repeat at least 2-4 days and preferably 2-4 weeks apart
 Adults with lead nephropathy: An alternative dosing regimen reflecting the reduction in renal clearance is based upon the serum creatinine. Refer to the following:
 Dose of Ca EDTA based on serum creatinine:
 S_{cr} ≤2 mg/dL: 1 g/m²/day for 5 days*
 S_{cr} 2-3 mg/dL: 500 mg/m²/day for 5 days*
 S_{cr} 3-4 mg/dL: 500 mg/m²/dose every 48 hours for 3 doses*
 S_{cr} >4 mg/dL: 500 mg/m²/week*

*Repeat these regimens monthly until lead excretion is reduced toward normal.

Stability Dilute with 0.9% sodium chloride or D₅W; physically **incompatible** with D₁₀W, lactated Ringer's, Ringer's

Monitoring Parameters BUN, creatinine, urinalysis, I & O, and ECG during therapy; intravenous administration requires a cardiac monitor, blood and urine lead concentrations

Administration For intermittent I.V. infusion, administer the dose I.V. over at least 1 hour in asymptomatic patients, 2 hours in symptomatic patients; for I.V. continuous infusion, dilute to 2-4 mg/mL in D₅W or normal saline and infuse over at least 8 hours, usually over 12-24 hours; for I.M. injection, 1 mL of 1% procaine hydrochloride may be added to each mL of EDTA calcium to minimize pain at injection site

Contraindications Severe renal disease, anuria

Warnings

[U.S. Boxed Warning]: **Use with extreme caution in patients with lead encephalopathy and cerebral edema.** In these patients, I.V. infusion has been associated with lethal increase in intracranial pressure; I.M. injection is preferred.

Edetate calcium disodium is potentially nephrotoxic; renal tubular acidosis and fatal nephrosis may occur, especially with high doses; ECG changes may occur during therapy; do not exceed recommended daily dose. If anuria, increasing proteinuria, or hematuria occurs during therapy, discontinue calcium EDTA. Minimize nephrotoxicity by adequate hydration, establishment of good urine output, avoidance of excessive doses, and limitation of continuous administration to ≤5 days.

Exercise caution in the ordering, dispensing, and administration of this EDTA product. Edetate calcium disodium (CaEDTA) may be confused with edetate disodium (Na₂EDTA). CDC recommends that edetate disodium should never be used for chelation therapy in children. Fatal hypocalcemia may result if edetate disodium is used for chelation therapy instead of edetate calcium disodium.

Dosage Forms Injection, solution: 200 mg/mL (5 mL)

Test Interactions If calcium EDTA is given as a continuous I.V. infusion, stop the infusion for at least 1 hour before blood is drawn for lead concentration, to avoid a falsely elevated value.

Drug Interactions Decreased effect: Do not use simultaneously with zinc insulin preparations; do not mix in the same syringe with dimercaprol

Pregnancy Risk Factor B

Edetate Disodium

Pronunciation (ED e tate dye SOW dee um)

CAS Number 139-33-3; 150-38-9; 6381-92-6

U.S. Brand Names Endrate®

Synonyms Edathamil Disodium; EDTA (Disodium); Na₂EDTA ; Sodium Edetate

Use Emergency treatment of hypercalcemia; also used as contact lens cleaner; also used as a 0.05 molar topical solution for alkali ocular exposure due to calcium hydroxide (lime) from motor or cement exposures; also chelates lead, copper, manganese, zinc, lanthanum, plutonium, scandium, or yttrium; useful in treating extravasation due to mithramycin

Mechanism of Action Chelates with divalent or trivalent metals to form a soluble complex that is then eliminated in urine

Adverse Reactions

Cardiovascular: Arrhythmias, transient hypotension, shock, vasculitis, pericardial effusion/pericarditis
 Central nervous system: Seizures, fever, headache, chills
 Dermatologic: Skin eruptions, exfoliative dermatitis, dermatitis, skin lesions
 Endocrine & metabolic: Hypocalcemic tetany, hypomagnesemia, hypokalemia
 Gastrointestinal: Nausea, vomiting, abdominal cramps, diarrhea
 Genitourinary: Urinary frequency
 Hematologic: Anemia
 Local: Pain at the site of injection, thrombophlebitis
 Neuromuscular & skeletal: Back pain, muscle cramps, paresthesia, myalgia, leg cramps
 Renal: Nephrotoxicity, acute tubular necrosis
 Respiratory: Death from respiratory arrest, respiratory failure, sneezing
 Miscellaneous: Yawning

Pharmacodynamics/Kinetics

Metabolism: None
 Half-life elimination: 20-60 minutes
 Time to peak: I.V.: 24-48 hours
 Excretion: Following chelation: Urine (95%); chelates within 24-48 hours

Dosage

Hypercalcemia: I.V.:
 Children: 40-70 mg/kg/day slow infusion over 3-4 hours or more to a maximum of 3 g/24 hours; administer for 5 days and allow 5 days between courses of therapy
 Adults: 50 mg/kg/day over 3 or more hours to a maximum of 3 g/24 hours; a suggested regimen of 5 days followed by 2 days without drug and repeated courses up to 15 total doses
 Mithramycin extravasation: 150 mg of sodium edetate either through offending I.V. catheter or through multiple SubQ injections; apply ice to affected area

Monitoring Parameters Cardiac function (ECG monitoring); blood pressure during infusion; renal function should be assessed before and during therapy; monitor calcium, magnesium, and potassium levels; cardiac monitor required

Administration Must be diluted before use in 500 mL D₅W or normal saline to <30 mg/mL

Contraindications Severe renal failure or anuria

Warnings

Use of this drug is recommended only when the severity of the clinical condition justifies the aggressive measures associated with this type of therapy. Use with caution in patients with renal dysfunction, intracranial lesions, seizure disorders, coronary or peripheral vascular disease.

Exercise caution in the ordering, dispensing, and administration of this EDTA product. Edetate disodium (Na₂EDTA) may be confused with edetate calcium disodium (CaEDTA). CDC recommends that edetate disodium should never be used for chelation therapy in children. Fatal hypocalcemia may result if edetate disodium is used for chelation therapy instead of edetate calcium disodium.

Dosage Forms Injection, solution: 150 mg/mL (20 mL)

Drug Interactions Increased effect of insulin (edetate disodium may decrease blood glucose concentrations and reduce insulin requirements in diabetic patients treated with insulin)

Pregnancy Risk Factor C

Nursing Implications Avoid extravasation; patient should remain supine for a short period after infusion

Epinephrine

Pronunciation (ep i NEF rin)

Related Information

● Insect Sting Kit [ANTIDOTE]

CAS Number 51-43-4

U.S. Brand Names Adrenalin®, Epifrin®, EpiPen® Jr, EpiPen®, Primatens® Mist [OTC]

Synonyms Adrenaline; Epinephrine Bitartrate; Epinephrine Hydrochloride; Racepinephrine

Use Bronchospasms, anaphylactic reactions, bradycardia, cardiac arrest, management of open-angle (chronic simple) glaucoma, hypotension, allergic reactions to antivenin, specifically improved mortality secondary to chloroquine overdose

Unlabeled/Investigational Use ACLS guidelines: Ventricular fibrillation (VF) or pulseless ventricular tachycardia (VT) unresponsive to initial defibrillatory shocks; pulseless electrical activity, asystole, hypotension unresponsive to volume resuscitation; symptomatic bradycardia or hypotension unresponsive to atropine or pacing; inotropic support

Mechanism of Action Stimulates alpha-adrenergic, β_1 - and β_2 -adrenergic receptors; small doses can cause vasodilation via β_2 vascular receptors; decreases production of aqueous humor and increases aqueous outflow; dilates the pupil by contracting the dilator muscle

Adverse Reactions

Cardiovascular: Pallor, **tachycardia**, hypertension, increased myocardial oxygen consumption, cardiac arrhythmias, sudden death, chest pain, superior mesenteric artery thrombosis, shock, ventricular arrhythmias, cardiomyopathy, cardiomegaly, angina, palpitations, sinus tachycardia, tachycardia (supraventricular), tachycardia (ventricular, bidirectional), vasoconstriction, **pounding heartbeat**

Central nervous system: Anxiety, headache, sympathetic storm, **nervousness, restlessness**

Dermatologic: Exfoliative dermatitis, alopecia, urticaria, exanthem

Endocrine & metabolic: Lactic acidosis, hyperglycemia, hypophosphatemia, hyperkalemia, hypokalemia

Gastrointestinal: Nausea, intestinal ischemia, xerostomia

Genitourinary: Acute urinary retention in patients with bladder outflow obstruction

Local: Tissue ischemia and necrosis with extravasation

Neuromuscular & skeletal: Weakness

Ocular: Precipitation of or exacerbation of narrow-angle glaucoma, vision color changes (green tinge)

Renal: Decreased renal and splanchnic blood flow

Miscellaneous: Allergic reactions, fixed drug eruption

Signs and Symptoms of Overdose Cardiac arrhythmias, hyperglycemia, hypertension (which may result in subarachnoid hemorrhage and hemiplegia), metabolic acidosis, pulmonary edema, renal failure, tachycardia (ventricular, bidirectional), unusually large pupils

Pharmacodynamics/Kinetics

Onset of action: Bronchodilation: SubQ: ~5-10 minutes; Inhalation: ~1 minute

Distribution: Crosses placenta

Metabolism: Taken up into the adrenergic neuron and metabolized by monoamine oxidase and catechol-o-methyltransferase; circulating drug hepatically metabolized

Excretion: Urine (as inactive metabolites, metanephrine, and sulfate and hydroxy derivatives of mandelic acid, small amounts as unchanged drug)

Dosage

Neonates: Cardiac arrest: I.V.: 0.01-0.03 mg/kg (0.1-0.3 mL/kg of **1:10,000** solution) every 3-5 minutes as needed. Although I.V. route is preferred, may consider administration of doses up to 0.1 mg/kg through the endotracheal tube until I.V. access established; dilute intratracheal doses to 1-2 mL with normal saline.

Infants and Children:

Asystole/pulseless arrest, bradycardia, VT/VF (after failed defibrillations):

I.V., I.O.: 0.01 mg/kg (0.1 mL/kg of **1:10,000** solution) every 3-5 minutes as needed (maximum: 1 mg)

Intratracheal: 0.1 mg/kg (0.1 mL/kg of **1:1000** solution) every 3-5 minutes (maximum: 10 mg)

Continuous I.V. infusion: 0.1-1 mcg/kg; doses <0.3 mcg/kg/minute generally produce β -adrenergic effects and higher doses generally produce α -adrenergic vasoconstriction; titrate dosage to desired effect

Bronchodilator: SubQ: 0.01 mg/kg (0.01 mL/kg of **1:1000**) (single doses not to exceed 0.5 mg) every 20 minutes for 3 doses

Nebulization: 1-3 inhalations up to every 3 hours using solution prepared with 10 drops of 1:100

Children <4 years: S2[®] (racepinephrine, OTC labeling): Croup: 0.05 mL/kg (max 0.5 mL/dose); dilute in NS 3 mL. Administer over ~15 minutes; do not administer more frequently than every 2 hours.

Inhalation: Children \geq 4 years: Primatene[®] Mist: Refer to Adults dosing.

Decongestant: Children \geq 6 years: Refer to Adults dosing

Hypersensitivity reaction:

SubQ, I.V.: 0.01 mg/kg every 20 minutes; larger doses or continuous infusion may be needed for some anaphylactic reactions

SubQ, I.M.:

15-30 kg: Twinject[™]: 0.15 mg (for self-administration following severe allergic reactions to insect stings, food, etc)

>30 kg: Refer to Adults dosing

I.M.:

<30 kg: Epipen[®] Jr: 0.15 mg (for self-administration following severe allergic reactions to insect stings, food, etc)

>30 kg: Refer to Adults dosing

Adults:

Asystole/pulseless arrest, bradycardia, VT/VF:

I.V., I.O.: 1 mg every 3-5 minutes; if this approach fails, higher doses of epinephrine (up to 0.2 mg/kg) may be indicated for treatment of specific problems (eg, beta-blocker or calcium channel blocker overdose)

Intratracheal: Administer 2-2.5 mg for VF or pulseless VT if I.V./I.O. access is delayed or cannot be established; dilute in 5-10 mL NS or distilled water. **Note:** Absorption is greater with distilled water, but causes more adverse effects on PaO₂.

Bradycardia (symptomatic) or hypotension (not responsive to atropine or pacing): I.V. infusion: 2-10 mcg/minute; titrate to desired effect

Bronchodilator:

SubQ: 0.3-0.5 mg (**1:1000**) every 20 minutes for 3 doses

Nebulization: 1-3 inhalations up to every 3 hours using solution prepared with 10 drops of the **1:100** product

S2[®] (racepinephrine, OTC labeling): 0.5 mL (~10 drops). Dose may be repeated not more frequently than every 3-4 hours if needed. Solution should be diluted if using jet nebulizer.

Inhalation: Primatene[®] Mist (OTC labeling): One inhalation, wait at least 1 minute; if relieved, may use once more. Do not use again for at least 3 hours.

Decongestant: Intranasal: Apply 1:1000 locally as drops or spray or with sterile swab

Hypersensitivity reaction:

I.M., SubQ: 0.3-0.5 mg (1:1000) every 15-20 minutes if condition requires (I.M. route is preferred)

>30 kg: Twinject[™]: 0.3 mg (for self-administration following severe allergic reactions to insect stings, food, etc)

I.M.: >30 kg: Epipen[®]: 0.3 mg (for self-administration following severe allergic reactions to insect stings, food, etc)

I.V.: 0.1 mg (1:10,000) over 5 minutes. May infuse at 1-4 mcg/minute to prevent the need to repeat injections frequently.

Stability Protect from light, oxidation turns drug pink, then a brown color; solutions should not be used if they are discolored or contain a precipitate; stability of injection of parenteral admixture at room temperature and refrigeration: 24 hours; unstable in alkaline solution; do not use D₅W as a diluent; D₅W is incompatible with epinephrine

Monitoring Parameters Pulmonary function, heart rate, blood pressure, site of infusion for blanching, extravasation; cardiac monitor and blood pressure monitor required

Administration Central line administration only; intravenous infusions require an infusion pump

Endotracheal: Doses (2-2.5 times the I.V. dose) should be diluted to 10 mL with NS or distilled water prior to administration

Epinephrine can be administered SubQ, I.M., I.V., or intracardiac injection

I.M. administration into the buttocks should be avoided

Preparation of adult I.V. infusion: Dilute 1 mg in 250 mL of D₅W or NS (4 mcg/mL); administer at an initial rate of 1 mcg/minute and increase to desired effects; at 20 mcg/minute pure alpha effects occur

1 mcg/minute: 15 mL/hour

2 mcg/minute: 30 mL/hour

3 mcg/minute: 45 mL/hour, etc

Extravasation management:

Initial care:

Treatment of digital epinephrine autoinjector injuries is primarily supportive.

Warm soaks and warm compresses are the mainstay of treatment.

If symptoms persist or worsen after 1-2 hours of conservative management, consider using an antidotal therapy.

Antidotal therapy:

Phentolamine: Mix 5 mg with 9 mL of NS. Inject a small amount of this dilution into extravasated area using a 24- to 27 gauge needle. Blanching should reverse immediately. Monitor site. If blanching should recur, additional injections of phentolamine may be needed (not to exceed a total volume of 10 mL).

Terbutaline: Create a 1 mg/mL solution of terbutaline to normal saline (1:1 dilution). Use a 24- to 27-gauge needle to inject the terbutaline subcutaneously in affected area; response is usually immediate; repeat as necessary.

Nitroglycerin paste: Apply paste to affected portion of the digit until clinical improvement is noted.

Disposition of extravasation:

Most patients who present with digital injections of an epinephrine autoinjector have a mild and self-limited clinical course. If an antidotal therapy is used, observation for ~1 hour is recommended. If the presentation has worsened or not improved during that time, consider repeating the initial therapy or trying an alternate treatment modality.

Contraindications Hypersensitivity to epinephrine or any component of the formulation; cardiac arrhythmias; angle-closure glaucoma

Warnings Use with caution in elderly patients, patients with diabetes mellitus, cardiovascular diseases (angina, tachycardia, myocardial infarction), thyroid disease, or cerebral arteriosclerosis, Parkinson's; some products contain sulfites as preservatives. Rapid I.V. infusion may cause death from cerebrovascular hemorrhage or cardiac arrhythmias. Oral inhalation of epinephrine is **not** the preferred route of administration. Avoid topical application where reduced perfusion could lead to ischemic tissue damage (eg, penis, ears, digits).

Dosage Forms

Aerosol for oral inhalation:
 Primatene[®] Mist: 0.22 mg/inhalation (15 mL, 22.5 mL) [contains CFCs]
Injection, solution [prefilled auto injector]:
 EpiPen[®]: 0.3 mg/0.3 mL [1:1000] (2 mL) [contains sodium metabisulfite; available as single unit or in double-unit pack with training unit]
 EpiPen[®] Jr: 0.15 mg/0.3 mL [1:2000] (2 mL) [contains sodium metabisulfite; available as single unit or in double-unit pack with training unit]
 Twinject[™]: 0.15 mg/0.15 mL [1:1000] (1.1 mL) [contains sodium bisulfite; two 0.15 mg doses per injector]; 0.3 mg/0.3 mL [1:1000] (1.1 mL) [contains sodium bisulfite; two 0.3 mg doses per injector]
Injection, solution, as hydrochloride: 0.1 mg/mL [1:10,000] (10 mL); 1 mg/mL [1:1000] (1 mL) [products may contain sodium metabisulfite]
 Adrenalin[®]: 1 mg/mL [1:1000] (1 mL, 30 mL) [contains sodium bisulfite]
Solution for oral inhalation, as hydrochloride:
 Adrenalin[®]: 1% [10 mg/mL, 1:100] (7.5 mL) [contains sodium bisulfite]
Solution for oral inhalation [racepinephrine]:
 S2[®]: 2.25% (0.5 mL, 15 mL) [as d-epinephrine 1.125% and l-epinephrine 1.125%; contains metabisulfites]
 Solution, topical [racepinephrine]:
 Raphon: 2.25% (15 mL) [as d-epinephrine 1.125% and l-epinephrine 1.125%; contains metabisulfites]

Reference Range Therapeutic: 31-95 pg/mL (SI: 170-520 pmol/L); norepinephrine level of 438 pg/mL associated with myocardial ischemia in children

Test Interactions ↑ bilirubin (S), catecholamines (U), glucose, uric acid (S)

Drug Interactions Increased toxicity: Increased cardiac irritability if administered concurrently with halogenated inhalational anesthetics, beta-blocking agents, alpha-blocking agents

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Lactation Excretion in breast milk unknown

Nursing Implications

Protect from light; oxidation turns dark pink, then brown - solutions should not be used if they are discolored or contain a precipitate. Epinephrine is unstable in alkaline solution.

Extravasation: Use phentolamine as antidote; mix 5 mg with 9 mL of normal saline; inject a small amount of this dilution into extravasated area; blanching should reverse immediately. Monitor site; if blanching should recur, additional injections of phentolamine may be needed. If phentolamine is not available, topical nitroglycerin paste or subcutaneous administration of terbutaline (at a 1:1 to 1:10 dilution) may be effective alternative treatment.

Filgrastim

U.S. Brand Names Neupogen[®]

Synonyms G-CSF; Granulocyte Colony Stimulating Factor

Use Stimulation of granulocyte production in patients with malignancies, including myeloid malignancies; receiving myelosuppressive therapy associated with a significant risk of neutropenia; severe chronic neutropenia (SCN); receiving bone marrow transplantation (BMT); undergoing peripheral blood progenitor cell (PBPC) collection useful for colchicine toxicity or radiation

Mechanism of Action Stimulates the production, maturation, and activation of neutrophils, G-CSF activates neutrophils to increase both their migration and cytotoxicity. See table.

Comparative Effects — G-CSF vs GM-CSF

Proliferation/Differentiation	G-CSF (Filgrastim)	GM-CSF (Sargramostim)
Neutrophils	Yes	Yes
Eosinophils	No	Yes
Macrophages	No	Yes
Neutrophil migration	Enhanced	Inhibited

Adverse Reactions

Cardiovascular: Chest pain, transient arrhythmia (supraventricular), pericardial effusion/pericarditis, ventricular arrhythmias, angina, tachycardia (supraventricular)
Central nervous system: **Fever**, headache, **neutropenic fever**
Dermatologic: **Alopecia**, skin rash, neutrophilic dermatosis (Sweet's syndrome), exacerbation of acne, psoriasis, angioneurotic edema, cutaneous vasculitis
Endocrine & metabolic: Fluid retention, hypothyroidism
Gastrointestinal: **Nausea, vomiting, diarrhea**, anorexia, stomatitis, constipation, **mucositis, splenomegaly**, sore throat
Hematologic: Leukocytosis, thrombocytopenia
Local: Pain at injection site, thrombophlebitis
Neuromuscular & skeletal: **Skeletal pain**, weakness
Ocular: Iritis, photophobia
Renal: Renal vasculitis
Respiratory: Dyspnea, cough, eosinophilic pneumonia
Miscellaneous: Anaphylactic reaction, lymphoma

Pharmacodynamics/Kinetics

Onset of action: ~24 hours; plateaus in 3-5 days
Duration: ANC decreases by 50% within 2 days after discontinuing filgrastim; white counts return to the normal range in 4-7 days; peak plasma levels can be maintained for up to 12 hours
Absorption: SubQ: 100%
Distribution: V_d: 150 mL/kg; no evidence of drug accumulation over a 11- to 20-day period
Metabolism: Systemically degraded
Half-life elimination: 1.8-3.5 hours
Time to peak, serum: SubQ: 2-6 hours

Dosage

Refer to individual protocols.

Dosing, even in morbidly obese patients, should be based on actual body weight. Rounding doses to the nearest vial size often enhances patient convenience and reduces costs without compromising clinical response.

Myelosuppressive therapy: 5 mcg/kg/day - doses may be increased by 5 mcg/kg according to the duration and severity of the neutropenia.

Bone marrow transplantation: 5-10 mcg/kg/day - doses may be increased by 5 mcg/kg according to the duration and severity of neutropenia; recommended steps based on neutrophil response:

When ANC > 1000/mm³ for 3 consecutive days: Reduce filgrastim dose to 5 mcg/kg/day

If ANC remains > 1000/mm³ for 3 more consecutive days: Discontinue filgrastim

If ANC decreases to < 1000/mm³: Resume at 5 mcg/kg/day

If ANC decreases < 1000/mm³ during the 5 mcg/kg/day dose, increase filgrastim to 10 mcg/kg/day and follow the above steps

Peripheral blood progenitor cell (PBPC) collection: 10 mcg/kg/day or 5-8 mcg/kg twice daily in donors. The optimal timing and duration of growth factor stimulation has not been determined.

Severe chronic neutropenia:

Congenital: 6 mcg/kg twice daily

Idiopathic/cyclic: 5 mcg/kg/day

Colchicine overdose: Daily doses of 300 mg SubQ for 5 days has been used in adults

Not removed by hemodialysis

Stability

Store at 2°C to 8°C (36°F to 46°F); do not expose to freezing or dry ice. Prior to administration, filgrastim may be allowed to be at room

temperature for a maximum of 24 hours. It may be diluted in dextrose 5% in water to a concentration ≥ 15 mcg/mL for I.V. infusion administration. Minimum concentration is 15 mcg/mL; concentrations < 15 mcg/mL require addition of albumin (1 mL of 5%) to the bag to prevent absorption. This diluted solution is stable for 7 days under refrigeration or at room temperature. **Filgrastim is incompatible with 0.9% sodium chloride (normal saline).**

Standard diluent: ≥ 375 mcg/25 mL D₅W

Monitoring Parameters CBC and platelet count should be obtained twice weekly. Leukocytosis (white blood cell counts $\geq 100,000/\text{mm}^3$) has been observed in $\sim 2\%$ of patients receiving G-CSF at doses > 5 mcg/kg/day. Monitor platelets and hematocrit regularly.

Administration

The UHC Colony-Stimulating Factors Expert Panel has made the following clinical and administrative recommendations:

Clinical:

Very few data are available to support the therapeutic interchangeability of G-CSF and GM-CSF. On the basis of the panel's clinical experience and in the absence of conclusive data, interchangeability is acceptable in limited situations, as indicated in the UHC CSF guidelines.

For most indications, an ANC of $< 500 \times 10^6$ cells/L can be recommended as a starting point for the initiation of therapy. Stopping CSF therapy is based on a biologic endpoint, and the panel felt that CSF therapy could be discontinued in most patients at an ANC $\geq 5000 \times 10^6$ cells/L, depending on the expected nadir of chemotherapy. Several panel members suggested an ANC endpoint to CSF therapy at 2000×10^6 cells/L.

Food and Drug Administration labeling recommends daily dosing of G-CSF at 5 mcg/kg, but panel members felt that doses as low as 2 mcg/kg might be effective for some indications. Daily doses of > 10 mcg/kg were considered not appropriate for any chemotherapy regimens. Overall, CSF dosing on the basis of patient weight has not been well studied.

In general, patients should not receive CSFs with their first cycle of cancer chemotherapy. Patients who have previously demonstrated febrile neutropenia following chemotherapy or have had a previous positive response to CSF therapy following chemotherapy would be appropriate for CSF therapy.

Certain chemotherapeutic regimens may warrant CSF use for every patient. These clinical situations should be determined at each UHC member institution. Some examples cited by the panel include patients in the following categories: adult acute lymphocytic leukemia, induction therapy; previously radiated Hodgkin's disease; previous pelvic radiation; adjuvant breast cancer chemotherapy (to avoid any treatment delays caused by neutropenia); and AIDS lymphoma treatment with myelosuppressive chemotherapy.

Administrative:

CSF guidelines developed by an institution for inpatient use should apply to the outpatient setting

Several examples of strategies for CSF cost-containment were offered by the panel, including requiring blood count results prior to dispensing CSF doses; strictly enforced inpatient and outpatient use guidelines; institutional reimbursement precertification for CSF patients; accessing pharmaceutical company reimbursement assistance/indigent programs; forming biotechnology review committees; and dosing based on vial size, rather than on a mcg/kg basis, using the smallest clinically acceptable vial size

Contraindications Hypersensitivity to filgrastim, *E. coli*-derived proteins, or any component of the formulation

Warnings

Do not use filgrastim in the period 24 hours before to 24 hours after administration of cytotoxic chemotherapy because of the potential sensitivity of rapidly dividing myeloid cells to cytotoxic chemotherapy. Precaution should be exercised in the usage of filgrastim in any malignancy with myeloid characteristics. Filgrastim can potentially act as a growth factor for any tumor type, particularly myeloid malignancies. Tumors of nonhematopoietic origin may have surface receptors for filgrastim. Safety and efficacy have not been established with patients receiving radiation therapy, or with chemotherapy associated with delayed myelosuppression (eg, nitrosoureas, mitomycin C).

Allergic-type reactions have occurred with first or later doses. Reactions tended to occur more frequently with intravenous administration and within 30 minutes of infusion. Rare cases of splenic rupture or adult respiratory distress syndrome have been reported in association with filgrastim; patients must be instructed to report left upper quadrant pain or shoulder tip pain or respiratory distress. Use caution in patients with sickle cell diseases; sickle cell crises have been reported following filgrastim therapy.

Dosage Forms

Injection, solution [preservative free]: 300 mcg/mL (1 mL, 1.6 mL) [vial; contains sodium 0.035 mg/mL and sorbitol]

Injection, solution [preservative free]: 600 mcg/mL (0.5 mL, 0.8 mL) [prefilled Singleject[®] syringe; contains sodium 0.035 mg/mL and sorbitol]

Reference Range Peak plasma level as high as 600 ng/mL achieved after I.V. doses of 3-60 mcg/kg

Test Interactions \uparrow uric acid, lactate dehydrogenase, alkaline phosphatase; may \downarrow cholesterol

Pregnancy Risk Factor C

Pregnancy Implications Animal studies have demonstrated adverse effects and fetal loss. Filgrastim has been shown to cross the placenta in humans. There are no adequate and well-controlled studies in pregnant women. Use only if potential benefit to mother justifies risk to the fetus.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Do not mix with sodium chloride solutions

Flumazenil

CAS Number 78755-81-4

U.S. Brand Names Romazicon[®]

Use Benzodiazepine antagonist - reverses sedative effects of benzodiazepines used in general anesthesia; for management of benzodiazepine or zolpidem overdose; flumazenil does **not** antagonize the CNS effects of other GABA agonists (such as ethanol, barbiturates, or general anesthetics), **does not** reverse narcotics; may be useful for baclofen, carbamazepine, chloral hydrate, and zopiclone overdoses; chlorzoxazone overdose; gabapentin-induced coma; may be used to reverse paradoxical reactions to benzodiazepines in children; possible antidotal effect by flumazenil in zaleplon-induced coma and bluish-green urine; has been reported to reverse antihistamine-induced coma

Mechanism of Action Antagonizes the effect of benzodiazepines on the GABA/benzodiazepine receptor complex, including synergistic effects with the other GABA agonists.

Adverse Reactions

Cardiovascular: Cardiac arrhythmias, bradycardia, tachycardia, chest pain, hypertension, extrasystoles (ventricular), altered blood pressure (increases and decreases), AV block, sinus bradycardia, angina, sinus tachycardia, arrhythmias (ventricular), junctional tachycardia, ventricular tachycardia

Central nervous system: Convulsions (more common in patients with tricyclic antidepressant overdoses), fatigue, **dizziness/vertigo**, amnesia, delirium, dysphoria, fear, headache, agitation, emotional lability, anxiety, nervousness, malaise, abnormal crying, euphoria, CNS depression, somnolence

Endocrine & metabolic: Hot flashes

Gastrointestinal: **Nausea, vomiting**, xerostomia

Local: Pain at injection site

Neuromuscular & skeletal: Tremors, weakness

Ocular: Blurred vision, vision disorders

Otic: Abnormal hearing

Respiratory: Dyspnea, hyperventilation

Miscellaneous: Withdrawal syndrome, hiccups, diaphoresis (increased), cold sensation, shivering

Pharmacodynamics/Kinetics

Onset of action: 1-3 minutes; 80% response within 3 minutes

Peak effect: 6-10 minutes

Duration: Resedation: ~ 1 hour; duration related to dose given and benzodiazepine plasma concentrations; reversal effects of flumazenil may wear off before effects of benzodiazepine

Distribution: Initial V_d : 0.5 L/kg; V_{dss} 0.77-1.6 L/kg

Protein binding: 40% to 50%

Metabolism: Hepatic; dependent upon hepatic blood flow

Half-life elimination: Adults: Alpha: 7-15 minutes; Terminal: 41-79 minutes

Excretion: Feces; urine (0.2% as unchanged drug)

Dosage

Children and Adults: I.V.: See table.

Flumazenil	
Pediatric Dosage (further studies needed)	
Pediatric dosage for reversal of conscious sedation and general anesthesia:	
Initial dose	0.01 mg/kg over 15 seconds (maximum: 0.2 mg)
Repeat doses (maximum: 4 doses)	0.005-0.01 mg/kg (maximum: 0.2 mg) repeated at 1-minute intervals
Maximum total cumulative dose	1 mg or 0.05 mg/kg (whichever is lower)
Adult Dosage	
Adult dosage for reversal of conscious sedation and general anesthesia:	
Initial dose	0.2 mg intravenously over 15 seconds

FOLIC ACID

Table (Continued)	
Adult Dosage	
Repeat doses	If desired level of consciousness is not obtained, 0.2 mg may be repeated at 1-minute intervals.
Maximum total cumulative dose	1 mg (usual dose: 0.6-1 mg) In the event of resedation: Repeat doses may be given at 20-minute intervals with maximum of 1 mg/dose and 3 mg/hour.
Adult dosage for suspected benzodiazepine overdose:	
Initial dose	0.2 mg intravenously over 30 seconds; if the desired level of consciousness is not obtained, 0.3 mg can be given over 30 seconds
Repeat doses	0.5 mg over 30 seconds repeated at 1-minute intervals
Maximum total cumulative dose	3 mg (usual dose 1-3 mg) Patients with a partial response at 3 mg may require additional titration up to a total dose of 5 mg. If a patient has not responded 5 minutes after cumulative dose of 5 mg, the major cause of sedation is not likely due to benzodiazepines. In the event of resedation: May repeat doses at 20-minute intervals with maximum of 1 mg/dose and 3 mg/hour.

Resedation: Repeated doses may be given at 20-minute intervals as needed; repeat treatment doses of 1 mg (at a rate of 0.5 mg/minute) should be given at any time and no more than 3 mg should be given in any hour. After intoxication with high doses of benzodiazepines, the duration of a single dose of flumazenil is not expected to exceed 1 hour; if desired, the period of wakefulness may be prolonged with repeated low intravenous doses of flumazenil, or by an infusion of 0.1-0.4 mg/hour. Most patients with benzodiazepine overdose will respond to a cumulative dose of 1-3 mg and doses >3 mg do not reliably produce additional effects. Rarely, patients with a partial response at 3 mg may require additional titration up to a total dose of 5 mg. **If a patient has not responded 5 minutes after receiving a cumulative dose of 5 mg, the major cause of sedation is not likely to be due to benzodiazepines.**

Elderly: No differences in safety or efficacy have been reported. However, increased sensitivity may occur in some elderly patients.

Dosing in renal impairment: Not significantly affected by renal failure ($Cl_{cr} < 10$ mL/minute) or hemodialysis beginning 1 hour after drug administration

Dosing in hepatic impairment: Initial dose of flumazenil used for initial reversal of benzodiazepine effects is not changed; however, subsequent doses in liver disease patients should be reduced in size or frequency

Stability Store at 15°C to 30°C (59°F to 86°F). For I.V. use only; compatible with D₅W, lactated Ringer's, or normal saline; once drawn up in the syringe or mixed with solution use within 24 hours; discard any unused solution after 24 hours

Monitoring Parameters Monitor patients for return of sedation or respiratory depression

Administration I.V.: Administer in freely-running I.V. into large vein. Inject over 15 seconds for conscious sedation and general anesthesia and over 30 seconds for overdose.

Contraindications Hypersensitivity to flumazenil, benzodiazepines, or any component of the formulation; patients given benzodiazepines for control of potentially life-threatening conditions (eg, control of intracranial pressure or status epilepticus); patients who are showing signs of serious cyclic-antidepressant overdose

Warnings [U.S. Boxed Warning]: Benzodiazepine reversal may result in seizures in some patients. Patients who may develop seizures include patients on benzodiazepines for long-term sedation, tricyclic antidepressant overdose patients, concurrent major sedative-hypnotic drug withdrawal, recent therapy with repeated doses of parenteral benzodiazepines, myoclonic jerking or seizure activity prior to flumazenil administration. Flumazenil does not reverse respiratory depression/hypoventilation or cardiac depression. Resedation occurs more frequently in patients where a large single dose or cumulative dose of a benzodiazepine is administered along with a neuromuscular blocking agent and multiple anesthetic agents. Flumazenil should be used with caution in the intensive care unit because of increased risk of unrecognized benzodiazepine dependence in such settings. Should not be used to diagnose benzodiazepine-induced sedation. Reverse neuromuscular blockade before considering use. Flumazenil does not antagonize the CNS effects of other GABA agonists (such as ethanol, barbiturates, or general anesthetics); nor does it reverse narcotics. Use with caution in

patients with a history of panic disorder; may provoke panic attacks. Use caution in drug and ethanol-dependent patients; these patients may also be dependent on benzodiazepines. Not recommended for treatment of benzodiazepine dependence. Use with caution in head injury patients. Use caution in patients with mixed drug overdoses; toxic effects of other drugs taken may emerge once benzodiazepine effects are reversed. Flumazenil does not consistently reverse amnesia; patient may not recall verbal instructions after procedure. Use caution in severe hepatic dysfunction and in patients relying on a benzodiazepine for seizure control. Safety and efficacy have not been established in children >1 year of age.

Dosage Forms Injection, solution: 0.1 mg/mL (5 mL, 10 mL) [contains edetate sodium]

Reference Range Plasma flumazenil levels between 10-20 mcg/L for 1-2 hours reverse benzodiazepine-induced CNS depression; average peak flumazenil blood level of 66 ng/mL achieved within 1 minute of administering 1 mg of flumazenil endotracheally

Drug Interactions Nonbenzodiazepine hypnotics (zaleplon, zolpidem, zopiclone): Flumazenil reverses the effects of these hypnotics.

Pregnancy Risk Factor C

Pregnancy Implications Teratogenic effects were not seen in animal studies. Embryocidal effects were seen at large doses. There are no adequate or well-controlled studies in pregnant women. Use only if clearly needed.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Parenteral: For I.V. use only; administer via freely running I.V. infusion into larger vein to decrease chance of pain, phlebitis

Folic Acid

Pronunciation (FOE lik AS id)

CAS Number 59-30-3; 6484-89-5

Synonyms Folicin; Folate; Pteroylglutamic Acid

Use Treatment of megaloblastic and macrocytic anemias due to folate deficiency; used in methanol toxicity, methotrexate toxicity, chronic alcoholism

Mechanism of Action Necessary for normal erythropoiesis

Adverse Reactions

Central nervous system: Irritability, difficulty sleeping, confusion, insomnia, hyperthermia, fever

Dermatologic: Pruritus

Gastrointestinal: GI upset, bitter taste, flatulence

Miscellaneous: Hypersensitivity reactions, anaphylactic shock, zinc depletion, anaphylaxis

Pharmacodynamics/Kinetics

Onset of effect: Peak effect: Oral: 0.5-1 hour

Absorption: Proximal part of small intestine

Dosage

Oral, I.M., I.V., SubQ:

Minimal daily requirement: 50 mcg; pregnant/critically ill: 100-200 mcg

Infants: 0.1 mg/day

Children: Initial: 1 mg/day

Deficiency: 0.5-1 mg/day

Maintenance dose:

< 4 years: Up to 0.3 mg/day

> 4 years: 0.4 mg/day

Adults: Initial: 1 mg/day

Deficiency: 1-3 mg/day

Maintenance dose: 0.5 mg/day

Pregnant and lactating women: 0.8 mg/day

Stability Incompatible with oxidizing and reducing agents and heavy metal ions

Monitoring Parameters Hemoglobin

Administration Oral, but may also be administered by deep I.M., SubQ, or I.V. injection; a diluted solution for oral or parenteral administration may be prepared by diluting 1 mL of folic acid injection (5 mg/mL), with 49 mL sterile water for injection; resulting solution is 0.1 mg folic acid/1 mL

Contraindications Hypersensitivity to folic acid or any component of the formulation

Warnings Not appropriate for monotherapy with pernicious, aplastic, or normocytic anemias when anemia is present with vitamin D deficiency. Doses >0.1 mg/day may obscure pernicious anemia with continuing irreversible nerve damage progression. Resistance to treatment may occur with depressed hematopoiesis, alcoholism, deficiencies of other vitamins. Injection contains benzyl alcohol (1.5%) as preservative (use care in administration to neonates).

Dosage Forms

Injection, solution, as sodium folate: 5 mg/mL (10 mL) [contains benzyl alcohol]

Tablet: 0.4 mg, 0.8 mg, 1 mg

Reference Range Therapeutic: 0.005-0.015 mcg/mL

Test Interactions Falsely low serum concentrations may occur with the *Lactobacillus casei* assay method in patients on anti-infective (ie, tetracycline) therapy

Drug Interactions

Phenytoin: Folic acid may decrease phenytoin concentrations

Raltitrexed: Folic acid may diminish the therapeutic effect of raltitrexed

Pregnancy Risk Factor A/C (dose exceeding RDA recommendation)

Pregnancy Implications 400 mcg/day needed to prevent neural tube defects (spina bifida)

Lactation Enters breast milk/compatible

Nursing Implications Oral, but may also be administered by deep I.M., SubQ, or I.V. injection; a diluted solution for oral or for parenteral administration may be prepared by diluting 1 mL of folic acid injection (5 mg/mL), with 49 mL sterile water for injection; resulting solution is 0.1 mg folic acid per 1 mL

Fomepizole

Pronunciation (foe ME pi zole)

CAS Number 7554-65-6

U.S. Brand Names Antizol®

Synonyms 4-Methylpyrazole; 4-MP

Use FDA approved for ethylene glycol and methanol toxicity

Unlabeled/Investigational Use Known or suspected propylene glycol toxicity

Mechanism of Action Complexes and inactivates alcohol dehydrogenase competitively, thus preventing formation of the toxic metabolites of the alcohols

Adverse Reactions

Central nervous system: **Headache**, dizziness

Dermatologic: Rash

Gastrointestinal: **Dose-related nausea**, metallic taste

Hematologic: Eosinophilia

Hepatic: Transient increases in liver transaminases (possibly due to underlying ingestion)

Ocular: Nystagmus, vertical nystagmus

Pharmacodynamics/Kinetics

Onset of effect: Peak effect: Maximum: 1.5-2 hours

Absorption: Oral: Readily absorbed

Distribution: V_d : 0.6-1.02 L/kg; rapidly into total body water

Protein binding: Negligible

Metabolism: Hepatic to 4-carboxypyrazole (80% to 85% of dose), 4-hydroxymethylpyrazole, and their N-glucuronide conjugates; following multiple doses, induces its own metabolism via CYP oxidases after 30-40 hours

Half-life elimination: Has not been calculated; varies with dose

Excretion: Urine (1% to 3.5% as unchanged drug and metabolites)

Dosage

Oral: 15 mg/kg followed by 5 mg/kg in 12 hours and then 10 mg/kg every 12 hours until levels of toxin are not present

One other protocol (from France) suggests an infusion of 10-20 mg/kg before dialysis and intravenous infusion of 1-1.5 mg/kg/hour during hemodialysis

Loading dose of 15 mg/kg I.V. followed by 10 mg/kg I.V. every 12 hours for 48 hours, then 15 mg/kg every 12 hours until methanol or ethylene glycol levels are <20 mg/dL; supplemental doses required during dialysis

Dosing in patients requiring hemodialysis:

Dose at the beginning of hemodialysis. If <6 hours since last dose, do not administer dose; if ≥6 hours since last dose, administer next scheduled dose.

Dosing during hemodialysis: every 4 hours

Dosing at the time hemodialysis is **completed**:

Time between last dose and the end of hemodialysis:

<1 hour: Do not administer dose at the end of hemodialysis

1-3 hours: Administer $\frac{1}{2}$ of next scheduled dose

>3 hours: Administer next scheduled dose

Maintenance dosing **off** hemodialysis: Give next scheduled dose 12 hours from last dose administered

Stability Store vials at room temperature. Antizol® diluted in 0.9% sodium chloride injection or 5% dextrose injection is stable for at least 48 hours when stored refrigerated or at room temperature. After dilution, do not use beyond 24 hours.

Monitoring Parameters Fomepizole plasma levels should be monitored; response to fomepizole; monitor plasma/urinary ethylene glycol or methanol levels, urinary oxalate (ethylene glycol), plasma/urinary osmolality, renal/hepatic function, serum electrolytes, arterial blood gases; anion and osmolar gaps, resolution of clinical signs and symptoms of ethylene glycol or methanol intoxication

Administration Antizol® solidifies at temperatures <25°C (<77°F). If the Antizol® solution has become solid in the vial, the solution should be liquefied by running the vial under warm water or by holding in the hand. Solidification does not affect the efficacy, safety, or stability of Antizol®. Using sterile technique, the appropriate dose of Antizol® should be drawn from the vial with a syringe and injected into at least 100 mL of sterile 0.9% sodium chloride injection or dextrose 5% injection. Mix well. The entire contents of the resulting solution should be infused over 30 minutes. Antizol®, like all parenteral products, should be inspected visually for particulate matter prior to administration, whenever solution and container permit.

Contraindications Documented serious hypersensitivity reaction to fomepizole or other pyrazoles; hypersensitivity to any component of the formulation

Warnings Should not be given undiluted or by bolus injection; fomepizole is metabolized in the liver and excreted in the urine, use caution with hepatic or renal impairment; hemodialysis should be used in patients with renal failure, significant or worsening metabolic acidosis, or ethylene glycol/methanol levels ≥50 mg/dL; monitor and manage adverse events of intoxication (respiratory distress syndrome, visual disturbances, hypocalcemia); safety and efficacy in pediatric patients have not been established

Dosage Forms Injection, solution [preservative free]: 1 g/mL (1.5 mL)

Reference Range Serum fomepizole concentrations >15 mg/L provide complete inhibition of alcohol dehydrogenase

Pregnancy Risk Factor C

Pregnancy Implications Reproduction studies have not been conducted; use in pregnant women only if the benefits clearly outweigh the risks.

Lactation Excretion in breast milk unknown/not recommended

Glucagon

Pronunciation (GLOO ka gon)

CAS Number 16941-32-5

U.S. Brand Names GlucaGen® Diagnostic Kit; GlucaGen®; Glucagon Diagnostic Kit; Glucagon Emergency Kit

Synonyms Glucagon Hydrochloride

Use

Hypoglycemia; diagnostic aid in the radiologic examination of GI tract when a hypotonic state is needed; useful in esophageal food impaction, cardiogenic shock

Investigational: Nebulized for asthma

Unlabeled/Investigational Use Used with some success as a cardiac stimulant in management of severe cases of beta-adrenergic or calcium channel blocking agent, calcium channel blocker, or oral hypoglycemia overdose; may be useful in treating hypotension due to imipramine

toxicity; noninsulin-dependent diabetes mellitus; also used in allergic reactions

Mechanism of Action Stimulates adenylate cyclase to produce increased cyclic AMP, which promotes hepatic glycogenolysis and gluconeogenesis, causing a raise in blood glucose levels

Adverse Reactions

Frequency not defined.

Cardiovascular: Hypotension (up to 2 hours after GI procedures), hypertension, tachycardia

Gastrointestinal: Nausea, vomiting (high incidence with rapid administration of high doses)

Miscellaneous: Hypersensitivity reactions, anaphylaxis

Signs and Symptoms of Overdose Allergic reactions, dizziness, hyperglycemia, hypertension, hypokalemia, hypotension, nausea, weakness, vomiting

Pharmacodynamics/Kinetics

Onset of action: Peak effect: Blood glucose levels: Parenteral:

I.V.: 5-20 minutes

I.M.: 30 minutes

SubQ: 30-45 minutes

Duration: Hyperglycemia: 60-90 minutes

Metabolism: Primarily hepatic; some inactivation occurring renally and in plasma

Half-life elimination, plasma: 3-10 minutes

Dosage

Allergic reactions: I.V.:

Children: 0.03-0.1 mg/kg/dose up to 1 mg; repeat every 5-20 minutes

Adults: 1 mg; repeat every 5 minutes; can give up to 5 mg/dose; for infusion, can titrate at a rate of 1-5 mg/hour

Hypoglycemia or insulin shock therapy: I.M., I.V., SubQ:

Neonates: 0.3 mg/kg/dose; maximum: 1 mg/dose

Children: 0.025-0.1 mg/kg/dose, not to exceed 1 mg/dose, repeated in 20 minutes as needed

Adults: 0.5-1 mg, may repeat in 20 minutes as needed

Cardiotoxic agent toxicity: I.V.: 0.05 mg/kg (up to 10 mg) over 1 minute, then continuous infusion of 2-5 mg/hour in 5% dextrose

Diagnostic aid: Adults: I.M., I.V.: 0.25-2 mg 10 minutes prior to procedure

Facilitate passage of foreign bodies from distal esophagus into stomach: I.V.: 0.5-1 mg over 30 seconds, may be repeated

Nebulized for asthma: 2 mg diluted in 3 mL of saline

Stability Prior to reconstitution, store at controlled room temperature of 20°C to 25° (69°F to 77°F); do not freeze. Reconstitute powder for injection by adding 1 mL of sterile diluent to a vial containing 1 unit of the drug, to provide solutions containing 1 mg of glucagon/mL. Gently roll vial to dissolve. If dose to be administered is <2 mg of the drug, then use only the diluent provided by the manufacturer. If >2 mg, use sterile water for injection. Use immediately after reconstitution. May be kept at 5°C for up to 48 hours if necessary.

Monitoring Parameters Blood pressure, blood glucose, heart rate

Administration I.V.: Bolus may be associated with nausea and vomiting.

Continuous infusions may be used in beta-blocker overdose/toxicity.

Contraindications Hypersensitivity to glucagon or any component of the formulation; insulinoma; pheochromocytoma

Warnings Use caution with prolonged fasting, starvation, adrenal insufficiency or chronic hypoglycemia; levels of glucose stores in liver may be decreased. Following response to therapy, oral carbohydrates should be administered to prevent hypoglycemia.

Dosage Forms

Injection, powder for reconstitution, as hydrochloride:

GlucaGen®: 1 mg [equivalent to 1 unit; contains lactose 107 mg]

GlucaGen® Diagnostic Kit: 1 mg [equivalent to 1 unit; contains lactose 107 mg; packaged with sterile water]

GlucaGen® HypoKit™: 1 mg [equivalent to 1 unit; contains lactose 107 mg; packaged with prefilled syringe containing sterile water]

Glucagon®: 1 mg [equivalent to 1 unit; contains lactose 49 mg]

Glucagon Diagnostic Kit, Glucagon Emergency Kit: 1 mg [equivalent to 1 unit; contains lactose 49 mg; packaged with diluent syringe containing glycerin 12 mg/mL and water for injection]

Reference Range Normal range: 50-60 pg/mL

Drug Interactions Oral anticoagulant: Hypoprothrombinemic effects may be increased possibly with bleeding; effect seen with glucagon doses of 50 mg administered over 1-2 days

Pregnancy Risk Factor B

Lactation Excretion in breast milk unknown/compatible

Glycopyrrolate

Pronunciation (glye koe PYE roe late)

U.S. Brand Names Robinul® Forte; Robinul®

Synonyms Glycopyrronium Bromide

Use Vagal-mediated bradycardia, gastric secretion reduction; also used as an adjunct to relieve GI tract spasms, as an antisialagogue agent, adjunct in anesthesia, to reverse effects of nondepolarizing muscle relaxants

Unlabeled/Investigational Use

Investigational: Asthma

May be helpful in treating organophosphate poisoning; gustatory sweating (Frey syndrome)

Mechanism of Action Quaternary ammonium anticholinergic agent 5 times as potent as atropine with fewer cardiovascular or CNS side effects

Adverse Reactions

Cardiovascular: Palpitations, tachycardia

Central nervous system: Headache, insomnia, dizziness, fever

Dermatologic: **Dry skin**

Gastrointestinal: **Xerostomia, dry throat, constipation**, loss of taste perception

Genitourinary: Impotence

Local: **Irritation at injection site**

Ocular: Mydriasis (after large doses)

Neuromuscular & skeletal: Weakness

Respiratory: **Dry nose**

Miscellaneous: **Diaphoresis (decreased)**

Pharmacodynamics/Kinetics

Onset of action: Oral: 50 minutes; I.M.: 15-30 minutes; I.V.: ~1 minute

Peak effect: Oral: ~1 hour; I.M.: 30-45 minutes

Duration: Vagal effect: 2-3 hours; Inhibition of salivation: Up to 7 hours;

Anticholinergic: Oral: 8-12 hours

Absorption: Oral: Poor and erratic

Distribution: V_d: 0.2-0.62 L/kg

Metabolism: Hepatic (minimal)

Bioavailability: ~10%

Half-life elimination: Infants: 22-130 minutes; Children 19-99 minutes;

Adults: ~30-75 minutes

Excretion: Urine (as unchanged drug, I.M.: 80%, I.V.: 85%); bile (as unchanged drug)

Dosage

Children:

Reduction of secretions (preanesthetic):

Oral: 40-100 mcg/kg/dose 3-4 times/day

I.M., I.V.: 4-10 mcg/kg/dose every 3-4 hours; maximum: 0.2 mg/dose or 0.8 mg/24 hours

Intraoperative: I.V.: 4 mcg/kg not to exceed 0.1 mg; repeat at 2- to 3-minute intervals as needed

Preoperative: I.M.:

<2 years: 4.4-8.8 mcg/kg 30-60 minutes before procedure

>2 years: 4.4 mcg/kg 30-60 minutes before procedure

Children and Adults: Reverse neuromuscular blockade: I.V.: 0.2 mg for each 1 mg of neostigmine or 5 mg of pyridostigmine administered or 5-15 mcg/kg glycopyrrolate with 25-70 mcg/kg of neostigmine or 0.1-0.3 mg/kg of pyridostigmine (agents usually administered simultaneously, but glycopyrrolate may be administered first if bradycardia is present)

Adults:

Reduction of secretions:

Intraoperative: I.V.: 0.1 mg repeated as needed at 2- to 3-minute intervals

Preoperative: I.M.: 4.4 mcg/kg 30-60 minutes before procedure

Peptic ulcer:

Oral: 1-2 mg 2-3 times/day

I.M., I.V.: 0.1-0.2 mg 3-4 times/day

Monitoring Parameters Heart rate; anticholinergic effects; bowel sounds

Administration For I.V. administration, glycopyrrolate may also be administered via the tubing of a running I.V. infusion of a compatible solution; may be administered in the same syringe with neostigmine or pyridostigmine.

Contraindications Hypersensitivity to glycopyrrolate or any component of the formulation; severe ulcerative colitis, toxic megacolon complicating ulcerative colitis, paralytic ileus, obstructive disease of GI tract, intestinal atony in the elderly or debilitated patient; unstable cardiovascular status in acute hemorrhage; narrow-angle glaucoma; acute hemorrhage; tachycardia; obstructive uropathy; myasthenia gravis

Warnings Use caution in elderly, patients with autonomic neuropathy, hepatic or renal disease, ulcerative colitis (may precipitate/aggravate toxic megacolon), hyperthyroidism, CAD, CHF, arrhythmias, tachycardia, BPH, or hiatal hernia with reflux. Use of anticholinergics in gastric ulcer treatment may cause a delay in gastric emptying due to antral stasis. Caution should be used in individuals demonstrating decreased pigmentation (skin and iris coloration, dark versus light) since there has been some evidence that these individuals have an enhanced sensitivity to the

anticholinergic response. May cause drowsiness, eye sensitivity to light, or blurred vision; caution should be used when performing tasks which require mental alertness, such as driving. The risk of heat stroke with this medication may be increased during exercise or hot weather. Infants, patients with Down syndrome, and children with spastic paralysis or brain damage may be hypersensitive to antimuscarine effects. Product packaging may contain latex. Injection contains benzyl alcohol (associated with gasping syndrome in neonates). Not recommended for use in children <12 years of age for the management of peptic ulcer or <16 years for preanesthetic use.

Dosage Forms

Injection, solution (Robinul®): 0.2 mg/mL (1 mL, 2 mL, 5 mL, 20 mL) [contains benzyl alcohol]

Tablet:

Robinul®: 1 mg

Robinul® Forte: 2 mg

Reference Range Peak plasma glycopyrrolate level was ~6.3 ng/mL 10 minutes after intramuscular injection of 6 mcg/kg

Drug Interactions

Anticholinergic agents: Effects of other anticholinergic agents or medications with anticholinergic activity may be increased by glycopyrrolate.

Potassium chloride: Severity of potassium chloride-induced gastrointestinal lesions (when potassium is given in a wax matrix formulation, eg, Klor-Con®) may be increased by glycopyrrolate.

Praminitide: May enhance the anticholinergic effects of anticholinergics. These effects are specific to the GI tract.

Pregnancy Risk Factor B

Pregnancy Implications No teratogenic effects; in normal doses (4 mcg/kg), does not appear to affect fetal heart rate

Lactation Excretion in breast milk unknown/use caution

Specific Reference

Hydroxocobalamin

Pronunciation (hye droks oh koe BAL a min)

U.S. Brand Names Cyanokit®

CAS Number 13422-52-1

Synonyms Vitamin B₁₂

Use Treatment of pernicious anemia, vitamin B₁₂ deficiency, increased B₁₂ requirements due to pregnancy, thyrotoxicosis, hemorrhage, malignancy, liver or kidney disease

Unlabeled/Investigational Use Neuropathies, multiple sclerosis

Mechanism of Action Coenzyme for various metabolic functions, including fat and carbohydrate metabolism and protein synthesis, used in cell replication and hematopoiesis. Also binds to cyanide ion preferentially than iron in cytochrome oxidase.

Adverse Reactions

Cardiovascular: Transient hypertension and tachycardia

Dermatologic: Itching, urticaria, erythema, pink discoloration to skin/mucous membranes (at doses >4 g, resolves in 1-2 days)

Endocrine & metabolic: Hypokalemia

Gastrointestinal: Diarrhea, feces discoloration (red), nausea

Genitourinary: Urine discoloration (pink/deep red)

Hematologic: Polycythemia

Local: Pain at injection site, erythema, rash

Respiratory: Pulmonary edema

Miscellaneous: Anaphylactoid reactions

Pharmacodynamics/Kinetics

Distribution: V_d: 0.2-0.3 L/kg

Half-life: 1.6-5.4 hours

Elimination: Renal (clearance: ~0.31 L/hour); Cyanide exposure: 37%; Normal subjects: 62%

Dosage

Vitamin B₁₂ deficiency: I.M.:

Children: 1-5 mg given in single doses of 100 mcg over 2 or more weeks, followed by 30-50 mcg/month

Adults: 30 mcg/day for 5-10 days, followed by 100-200 mcg/month

Cyanide toxicity starting dose is 5 grams in adults (two 2.5 gram vials) administered by intravenous infusion over 15 minutes. A second dose of five grams I.V. may be given depending on the response and clinical situation. The recommended diluent is 0.9% sodium chloride

Administration Administer I.M. only; may require coadministration of folic acid

Contraindications None

Warnings Some products contain benzoyl alcohol; avoid use in premature infants; an intradermal test dose should be performed for hypersensitivity; use only if oral supplementation not possible or when treating pernicious anemia. Hypersensitivity to cyanocobalamin or any component of the formulation, cobalt; patients with hereditary optic nerve atrophy

Dosage Forms Substantial increases in blood pressure may occur

Reference Range Normal vitamin B₁₂ plasma level: 200-800 pg/mL; peak serum level after a 5 g dose: ~300 µmol/L

Test Interaction May result in artificial increases in serum creatinine, bilirubin, triglycerides, cholesterol, total protein, glucose, albumin, alkaline phosphatase, hemoglobin, basophils and urine pH. May artificially decrease ALT and amylase.

Drug Interactions Incompatible with diazepam, dobutamine, dopamine, fentanyl, nitroglycerin, pentobarbital, propofol and thiopental.

Pregnancy Risk Factor How supplied: 2.5 grams vials pregnancy category C

Lactation Enters breast milk/compatible

Nursing Implications Administer I.M. only; may require coadministration of folic acid

Additional Information Suspected adverse effects can be reported to Dey L.P. (800-429-7751) or FDA at 1-800-FDA-1088.

Insect Sting Kit

Pronunciation (ep i NEF rin & klor fen IR a meen)

U.S. Brand Names Ana-Kit®

Synonyms Insect Sting Kit

Use Anaphylaxis; emergency treatment of insect bites or stings (ie, yellow jacket, honeybee, hornet, wasp, deerfly, kissing bug) by the sensitive patient when self-treatment may occur within minutes of insect sting or exposure to an allergenic substance

Dosage

Children and Adults:

Epinephrine:

<2 years: 0.05-0.1 mL

2-6 years: 0.15 mL

6-12 years: 0.2 mL

>12 years: 0.3 mL

Chlorpheniramine:

<6 years: 1 tablet

6-12 years: 2 tablets

>12 years: 4 tablets

Stability Protect from light, store at room temperature, prevent from freezing

Dosage Forms Kit: Epinephrine hydrochloride 1:1000 [prefilled syringe, delivers two 0.3 mL doses; contains sodium bisulfite] (1 mL), chlorpheniramine maleate chewable tablet 2 mg (4), sterile alcohol pads [isopropyl alcohol 70%] (2), tourniquet (1)

Antidote(s)

● Epinephrine [ANTIDOTE]

Drug Interactions

Chlorpheniramine: **Substrate** of CYP2D6 (minor), 3A4 (major); **Inhibits** CYP2D6 (weak)

Also see individual agents.

Pregnancy Implications Refer to Epinephrine monograph.

Nursing Implications Not intended for I.V. use (I.M. or SubQ only)

Ipecac Syrup

Pronunciation (IP e kak SIR up)

CAS Number 8012-96-2

Synonyms Syrup of Ipecac

Use Formerly used for the treatment of acute oral drug overdose and in certain poisonings; now largely abandoned for routine use; potential value in treating cellular poisons without antidotes or supportive care options

Mechanism of Action Irritates the gastric mucosa and stimulates the medullary chemoreceptor trigger zone to induce vomiting

Adverse Reactions

Cardiovascular: Cardiotoxicity, tachycardia, heart block, congestive heart failure, pericardial effusion/pericarditis, hypotension, prolongation of QT interval, shock, flutter (atrial), cardiomegaly, myocardial depression, myocarditis, sinus tachycardia

Central nervous system: Lethargy, hypotonia

Dermatologic: Stevens-Johnson syndrome

Gastrointestinal: Protracted vomiting, diarrhea, gastric rupture, Mallory-Weiss tear, hemorrhagic colitis

Hepatic: Hepatomegaly, elevated liver enzymes

Neuromuscular & skeletal: Myopathy, myalgia, tremor

Respiratory: Pneumomediastinum

ISOPROTERENOL

Signs and Symptoms of Overdose Cardiomyopathy, diarrhea, fibrillation (atrial), hypotension, persistent vomiting

Pharmacodynamics/Kinetics

Onset of action: 15-30 minutes

Duration: 20-25 minutes; 60 minutes in some cases

Absorption: Significant amounts, mainly when it does not produce emesis

Excretion: Urine; emetine (alkaloid component) may be detected in urine 60 days after excess dose or chronic use

Dosage

Oral:

Children:

6-12 months: 5-10 mL followed by 10-20 mL/kg of water; repeat dose one time if vomiting does not occur within 20 minutes

1-12 years: 15 mL followed by 10-20 mL/kg of water; repeat dose one time if vomiting does not occur within 20 minutes

Adults: 15-30 mL followed by 200-300 mL of water; repeat dose one time if vomiting does not occur within 20 minutes

Administration Do not administer to unconscious patients. Patients should be kept active and moving following administration of ipecac. If vomiting does not occur after second dose, gastric lavage may be considered to remove ingested substance.

Contraindications Hypersensitivity to ipecac or any component of the formulation; do not use in unconscious patients; patients with no gag reflex; following ingestion of strong bases, acids, or volatile oils; when seizures are likely

Warnings Do not confuse ipecac syrup with ipecac fluid extract, which is 14 times more potent; use with caution in patients with cardiovascular disease and bulimics; may not be effective in antiemetic overdose

Dosage Forms Syrup: 70 mg/mL (30 mL) [contains alcohol]

Reference Range Blood emetine level within hours of a 30 mL oral dose: 0-75 mcg/L

Drug Interactions

Decreased effect: Activated charcoal, milk, carbonated beverages

Increased toxicity: Phenothiazines (chlorpromazine has been associated with serious dystonic reactions)

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Do not administer to unconscious patients; if vomiting does not occur after second dose, gastric lavage may be considered to remove ingested substance

Specific References

Garrison J, Shepherd G, Huddleston WL, et al, "Evaluation of the Time Frame for Home Ipecac Syrup Use When Not Kept in the Home," *J Toxicol Clin Toxicol* 2003, 41(3):217-21.

Manoguerra AS, Cobaugh DJ, Guidelines for the Management of Poisoning Consensus Panel, "Guideline on the Use of Ipecac Syrup in the Out-of-Hospital Management of Ingested Poisons," *Clin Toxicol (Phila)*, 2005, 43(1):1-10 (review).

"Position Paper: Ipecac Syrup," *J Toxicol Clin Toxicol*, 2004, 42(2):133-43 (review).

Metabolism: Via conjugation in many tissues including hepatic and pulmonary

Half-life elimination: 2.5-5 minutes

Excretion: Urine (primarily as sulfate conjugates)

Dosage

I.V.: Cardiac arrhythmias:

Children: Initial: 0.1 mcg/kg/minute (usual effective dose 0.2-2 mcg/kg/minute)

Adults: Initial: 2 mcg/minute; titrate to patient response (2-10 mcg/minute)

Stability Do not use discolored solutions; limit exposure to heat, light or air; stability of parenteral admixture at room temperature (25°C) and at refrigeration temperature (4°C): 24 hours; **incompatible** when mixed with aminophylline, furosemide; **incompatible** with alkaline solutions

Monitoring Parameters ECG, heart rate, respiratory rate, arterial blood gas, arterial blood pressure, CVP; serum glucose, serum potassium, serum magnesium

Administration I.V. infusion administration requires the use of an infusion pump. To prepare infusion: See formula.

$6 \times \text{weight (kg)} \times \text{desired dose (mcg/kg/min)}$

I.V. infusion rate (mL/h) = mg of drug added to 100 mL I.V. fluid

Contraindications Hypersensitivity to sulfites or isoproterenol, any component of the formulation, or other sympathomimetic amines; angina, pre-existing cardiac arrhythmias (ventricular); tachycardia or AV block caused by cardiac glycoside intoxication

Warnings Use with extreme caution; not currently a treatment of choice; use with caution in elderly patients, diabetics, renal or cardiovascular disease, seizure disorder, or hyperthyroidism; excessive or prolonged use may result in decreased effectiveness.

Dosage Forms Injection, solution, as hydrochloride: 0.02 mg/mL (10 mL); 0.2 mg/mL (1:5000) (1 mL, 5 mL) [contains sodium metabisulfite]

Reference Range Peak plasma isoproterenol level of 0.0004 mg/L achieved after an I.V. injection of 0.063 mcg/kg postmortem level of 0.1 mg/L noted following a death in an asthmatic patient relatable to isoproterenol use

Overdosage/Treatment Treatment includes immediate discontinuation and symptomatic and supportive therapies. Cautious use of beta-adrenergic blocking agents may be considered in severe cases.

Drug Interactions Increased toxicity: Sympathomimetic agents may cause headaches and elevate blood pressure; general anesthetics may cause arrhythmias

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Nursing Implications Give around-the-clock to promote less variation in peak and trough serum levels

Leucovorin

CAS Number 1492-18-8; 41926-89-3; 58-05-9

Synonyms 5-Formyl Tetrahydrofolate; Calcium Leucovorin; Citrovorum Factor; Folinic Acid; Leucovorin Calcium

Use Antidote for folic acid antagonists (methotrexate, trimethoprim, pyrimethamine); treatment of megaloblastic anemias when folate is deficient as in infancy, sprue, pregnancy, and nutritional deficiency when oral folate therapy is not possible; in combination with fluorouracil in the treatment of colon cancer

Mechanism of Action Reduced form of folic acid, but does not require a reduction reaction by an enzyme for activation, allows for purine and thymidine synthesis, a necessity for normal erythropoiesis

Adverse Reactions

Frequency not defined.

Dermatologic: Rash, pruritus, erythema, urticaria

Hematologic: Thrombocytosis

Respiratory: Wheezing

Miscellaneous: Anaphylactoid reactions

Signs and Symptoms of Overdose ECG changes

Pharmacodynamics/Kinetics

Onset of action: Oral: ~30 minutes; I.V.: ~5 minutes

Absorption: Oral, I.M.: Rapid and well absorbed

Metabolism: Intestinal mucosa and hepatically to 5-methyl-tetrahydrofolate (5MTHF; active)

Bioavailability: 31% following 200 mg dose; 98% following doses \leq 25 mg

Half-life elimination: Leucovorin: 15 minutes; 5MTHF: 33-35 minutes

Excretion: Urine (80% to 90%); feces (5% to 8%)

Dosage

Children and Adults:

Adjunctive therapy with antimicrobial agents (pyrimethamine): Oral: 2-15 mg/day for 3 days or until blood counts are normal or 5 mg every 3 days; doses of 6 mg/day are needed for patients with platelet counts $< 100,000/\text{mm}^3$

Rescue dose: I.V.: 10 mg/m² to start, then 10 mg/m² every 6 hours orally for 72 hours; if serum creatinine 24 hours after methotrexate is elevated 50% or more or the serum MTX concentration is $> 5 \times 10^{-6}$ M,

Isoproterenol

Pronunciation (eye soe proe TER e nole)

CAS Number 299-95-6; 51-30-9; 6700-39-6; 7683-59-2

U.S. Brand Names Isuprel®

Synonyms Isoproterenol Hydrochloride

Use Ventricular arrhythmias due to AV nodal block; hemodynamically compromised bradyarrhythmias or atropine- and dopamine-resistant bradyarrhythmias (when transcutaneous/venous pacing is not available); temporary use in third-degree AV block until pacemaker insertion

Unlabeled/Investigational Use Pharmacologic overdrive pacing for torsade de pointes; diagnostic aid (vasovagal syncope)

Mechanism of Action Relaxes bronchial smooth muscle by action on β_2 -receptors; causes increased heart rate and contractility by action on β_1 -receptors

Adverse Reactions

Cardiovascular: Premature ventricular beats, bradycardia, hypertension, hypotension, chest pain, palpitations, tachycardia, ventricular arrhythmias, myocardial infarction size increased

Central nervous system: Headache, nervousness, restlessness

Endocrine & metabolic: Serum glucose increased, serum potassium decreased, hypokalemia

Gastrointestinal: Nausea, vomiting

Respiratory: Dyspnea

Signs and Symptoms of Overdose Tachycardia, tremor, hypertension, hypotension, angina, and seizures. Hypokalemia also may occur. Cardiac arrest and death may be associated with abuse of beta-agonist bronchodilators.

Pharmacodynamics/Kinetics

Onset of action: Bronchodilation: I.V.: Immediate

Duration: I.V.: 10-15 minutes

increase dose to 100 mg/m²/dose every 3 hours until serum methotrexate level is $< 1 \times 10^{-8}$ M. See graph.

Investigational: Post I.T. methotrexate: Oral, I.V.: 12 mg/m² as a single dose; post high-dose methotrexate: 100-1000 mg/m²/dose until the serum methotrexate level is $< 1 \times 10^{-7}$ M; with 5FU: Oral: 500 mg/m²/day divided into 4 doses for 5 days

Methanol poisoning: 1 mg/kg; may repeat in 4 hours; further therapy should be with folic acid (secondary to cost and availability)

Plasma MTX concentration as a therapeutic guide to high-dose MTX therapy with leucovorin factor rescue. Leucovorin is continued until the plasma MTX level is $< 1 \times 10^{-7}$ M. Each dose of leucovorin is increased if the plasma MTX concentration is excessively high, according to the guidelines. With 4- to 6-hour high-dose MTX infusions, plasma drug values $> 5 \times 10^{-5}$ and 10^{-6} M at 24 and 48 hours after starting the infusion, respectively, are often predictive of delayed MTX clearance. See graph.

The drug should be given parenterally instead of orally in patients with GI toxicity, nausea, vomiting, and when individual doses are > 25 mg.

Stability Store at room temperature; protect from light. Leucovorin should be reconstituted with SWFI, bacteriostatic NS, BWFI, NS, or D₅W. Reconstituted solution is chemically stable for 7 days; reconstitutions with bacteriostatic water for injection, U.S.P., must be used within 7 days. Parenteral admixture is stable for 24 hours stored at room temperature (25°C) and for 4 days when stored under refrigeration (4°C).

Monitoring Parameters

Plasma methotrexate concentration as a therapeutic guide to high-dose methotrexate therapy with leucovorin factor rescue. Leucovorin is continued until the plasma methotrexate level < 0.05 μmol/mL.

With 4- to 6-hour high-dose methotrexate infusions, plasma drug values in excess of 50 and 1 μmol at 24 and 48 hours after starting the infusion, respectively, are often predictive of delayed methotrexate clearance

Administration Refer to individual protocols. Leucovorin should not be administered concurrently with methotrexate. It is commonly initiated 24 hours after the start of methotrexate. Toxicity to normal tissues may be irreversible if leucovorin is not initiated by ~40 hours after the start of methotrexate. As a rescue after folate antagonists, leucovorin may be administered by I.V. bolus injection, I.M. injection, or orally. Doses > 25 mg should be administered parenterally. In combination with fluorouracil, leucovorin is given before or concurrent with fluorouracil. Leucovorin is usually administered by I.V. bolus injection or short (10-15 minutes) I.V. infusion. Other administration schedules have been used; refer to individual protocols.

Contraindications Hypersensitivity to leucovorin or any component of the formulation; pernicious anemia or vitamin B₁₂-deficient megaloblastic anemias

Dosage Forms

Injection, powder for reconstitution, as calcium: 50 mg, 100 mg, 200 mg, 350 mg, 500 mg

Injection, solution, as calcium: 10 mg/mL (50 mL)

Tablet, as calcium: 5 mg, 10 mg, 15 mg, 25 mg

Drug Interactions May decrease efficacy of co-trimoxazole against *Pneumocystis carinii* pneumonitis

Pregnancy Risk Factor C

Lactation Enters breast milk/compatible

Nursing Implications I.V. infusion should not exceed 160 mg of leucovorin per minute

Levocarnitine

CAS Number 541-15-1

U.S. Brand Names Carnitor®

Synonyms L-Carnitine

Use

Orphan drug:

Oral: Primary systemic carnitine deficiency; acute and chronic treatment of patients with an inborn error of metabolism which results in secondary carnitine deficiency

I.V.: Acute and chronic treatment of patients with an inborn error of metabolism which results in secondary carnitine deficiency; prevention and treatment of carnitine deficiency in patients with end-stage renal disease who are undergoing hemodialysis.

Also used to treat hepatotoxicity due to valproic acid overdose/toxicity See Overdosage/Treatment in Valproic Acid and Derivatives

Mechanism of Action Involved in fatty acid transport from the cytosol to mitochondria where upon lipid catabolism occurs

Adverse Reactions

Gastrointestinal: Nausea, vomiting, abdominal cramps, diarrhea (dose related)

Neuromuscular & skeletal: Myasthenia

Pharmacodynamics/Kinetics

Metabolism: Hepatic (limited with moderate renal impairment), to trimethylamine (TMA) and trimethylamine N-oxide (TMAO)

Bioavailability: Oral: ~10% to 20%

Half-life elimination: 17.4 hours

Time to peak: Oral: 3.3 hours

Excretion: Urine (76%, 4% to 9% as unchanged drug); feces ($< 1\%$)

Dosage

Oral:

Infants/Children: Initial: 50 mg/kg/day; titrate to 50-100 mg/kg/day in divided doses with a maximum dose of 3 g/day

Adults: 990 mg (oral tablets) 2-3 times/day or 1-3 g/day (oral solution)

I.V.:

Metabolic disorders: 50 mg/kg as a slow 2- to 3-minute I.V. bolus or by I.V. infusion

Severe metabolic crisis:

A loading dose of 50 mg/kg over 2-3 minutes followed by an equivalent dose over the following 24 hours administered as every 3 hours or every 4 hours (never less than every 6 hours either by infusion or by intravenous injection)

All subsequent daily doses are recommended to be in the range of 50 mg/kg or as therapy may require

The highest dose administered has been 300 mg/kg

It is recommended that a plasma carnitine concentration be obtained prior to beginning parenteral therapy accompanied by weekly and monthly monitoring

ESRD patients on hemodialysis:

Predialysis levocarnitine concentrations below normal (40-50 μmol/L): 10-20 mg/kg dry body weight as a slow 2- to 3-minute bolus after each dialysis session

Dosage adjustments should be guided by predialysis trough levocarnitine concentrations and downward dose adjustments (to 5 mg/kg after dialysis) may be made as early as every 3rd or 4th week of therapy

Note: Safety and efficacy of oral carnitine have not been established in ESRD. Chronic administration of high oral doses to patients with severely compromised renal function or ESRD patients on dialysis may result in accumulation of metabolites.

For treatment of valproic acid induced hyperammonemia: Clinically ill: 100 mg/kg IV (up to six grams) over 30 min then 15 mg/kg over 30 min 94 hours; clinically well: 100 mg/kg/day divided 96 hr up to 3 grams per day

Monitoring Parameters Plasma concentrations should be obtained prior to beginning parenteral therapy, and should be monitored weekly to monthly. In metabolic disorders: monitor blood chemistry, vital signs, and plasma carnitine levels (maintain between 35-60 μmol/L). In ESRD patients on dialysis: Plasma levels below the normal range should prompt initiation of therapy. Monitor predialysis (trough) plasma carnitine levels.

Administration

Oral: Solution may be dissolved in either drink or liquid food, and should be consumed slowly. Doses should be spaced every 3-4 hours throughout the day, preferably during or following meals.

I.V.:

Hemodialysis patients: Injection should be administered over 2-3 minutes into the venous return line after each dialysis session.

Carnitine deficiency: Administer as a bolus dose over 2-3 minutes or by infusion. Doses should be administered every 3-6 hours

Warnings Caution in patients with seizure disorders or in those at risk of seizures (CNS mass or medications which may lower seizure threshold). Both new-onset seizure activity as well as an increased frequency of seizures has been observed. Safety and efficacy of oral carnitine have not been established in ESRD. Chronic administration of high oral doses to

MAFENIDE

patients with severely compromised renal function or ESRD patients on dialysis may result in accumulation of potentially toxic metabolites.

Dosage Forms

Capsule: 250 mg

Injection, solution: 200 mg/mL (5 mL, 12.5 mL)

Carnitor®: 200 mg/mL (5 mL)

Solution, oral: 100 mg/mL (118 mL)

Carnitor®: 100 mg/mL (118 mL) [cherry flavor]

Tablet: 330 mg, 500 mg

Carnitor®: 330 mg

Reference Range Normal endogenous serum levocarnitine level is 57 µmol/L for obese men, 50 µmol/L for men who are not obese, 46 µmol/L for obese women and 39 µmol/L for women who are not obese. A plasma free carnitine level below 20 µmol/L represents a deficient state. Human breast milk contains levocarnitine concentrations of 50-100 nmol/L.

Pregnancy Risk Factor B

Pregnancy Implications No adequate or well controlled studies in pregnant women. However, carnitine is a naturally occurring substance in mammalian metabolism. In breast-feeding women, use must be weighed against the potential exposure of the infant to increased carnitine intake.

Lactation Excretion in breast milk unknown/use caution

Specific References

Caraccio TR and Mofenson HC, "Carnitine," *J Toxicol Clin Toxicol*, 2003, 41(6):897.

Mafenide

Pronunciation (MA fe nide)

CAS Number 13009-99-9; 138-39-6

U.S. Brand Names Sulfamylon®

Synonyms Mafenide Acetate

Use

Adjunct in the treatment of second- and third-degree burns to prevent septicemia caused by susceptible organisms such as *Pseudomonas aeruginosa*; vesicant exposure

Orphan drug: Prevention of graft loss of meshed autografts on excised burn wounds

Mechanism of Action Interferes with bacterial folic acid synthesis through competitive inhibition of para-aminobenzoic acid

Adverse Reactions

Frequency not defined.

Cardiovascular: Facial edema

Central nervous system: Pain

Dermatologic: Rash, erythema, pruritus

Endocrine & metabolic: Hyperchloremia, metabolic acidosis

Hematologic: Porphyria, bone marrow suppression, hemolytic anemia, bleeding, methemoglobinemia (in 2 pediatric patients)

Local: Burning sensation, excoriation

Respiratory: Hyperventilation, tachypnea, dyspnea

Miscellaneous: Hypersensitivity

Pharmacodynamics/Kinetics

Absorption: Diffuses through devascularized areas and is rapidly absorbed from burned surface

Metabolism: To para-carboxybenzene sulfonamide, a carbonic anhydrase inhibitor

Time to peak, serum: 2-4 hours

Excretion: Urine (as metabolites)

Dosage Children and Adults: Topical: Apply once or twice daily with a sterile gloved hand; apply to a thickness of approximately 16 mm; the burned area should be covered with cream at all times

Stability

Mafenide 5% topical solution preparation:

Dissolve the 50 g mafenide acetate (Sulfamylon®) packet in 200 mL of either sterile water for irrigation or sterile saline for irrigation (minimum solubility of 50 g of mafenide is in 200 mL of either solution)

Sterilize this solution by pushing through a 0.22 micron filter

Further dissolve this 200 mL of sterile Sulfamylon® solution in 800 mL of the initial diluent (either sterile water for irrigation or normal saline for irrigation)

This solution is stable and sterile for a total of 48 hours at room temperature

Note: Mafenide acetate topical solution **cannot** be mixed with nystatin due to reduced activity of mafenide

Note: Pilot *in vitro* studies: Silvadene® and Furacin® cream combined with nystatin cream were equally effective against the microorganisms as were the individual drugs. However, Sulfamylon® cream combined with nystatin lost its antimicrobial capability. [*J Burn Care Rehabil* 1989, 109:508-11.]

Monitoring Parameters Acid base balance

Contraindications Hypersensitivity to mafenide, sulfites, or any component of the formulation

Warnings Use with caution in patients with renal impairment and in patients with G6PD deficiency; prolonged use may result in superinfection

Dosage Forms

Cream, topical, as acetate: 85 mg/g (60 g, 120 g, 454 g) [contains sodium metabisulfite]

Powder, for topical solution: 5% (5s) [50 g/packet]

Reference Range After topical use, maximum serum mafenide levels range from 0.05 to 1.7 mmol/L after 2- to 4-hour exposure

Drug Interactions No data reported

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Nursing Implications For external use only; monitor acid base balance

Magnesium Citrate

Pronunciation (mag NEE zhuh SIT rate)

CAS Number 3344-18-1

Synonyms Citrate of Magnesia

Use Evacuates bowel prior to certain surgical and diagnostic procedures

Mechanism of Action A saline cathartic which promotes bowel evacuation by causing osmotic retention of fluid which distends the colon with increased peristaltic activity

Adverse Reactions

Cardiovascular: Hypotension, shock, QRS prolongation, vasodilation

Gastrointestinal: Abdominal cramps, diarrhea, gas formation; vomiting (frequency of 17% at doses >233 mg/kg)

Endocrine & metabolic: Hypermagnesemia

Renal: Renal failure

Respiratory: Respiratory depression

Signs and Symptoms of Overdose Diarrhea, nausea, vomiting.

Serious, potentially life-threatening electrolyte disturbances may occur with long-term use or overdosage. **Serum level > 12 mEq/L** may be fatal.

Serum level ~10 mEq/L may cause complete heart block.

Pharmacodynamics/Kinetics

Absorption: Oral: 15% to 30%

Excretion: Urine

Dosage

Cathartic: Oral:

Children:

< 6 years: 0.5 mL/kg up to a maximum of 200 mL repeated every 4-6 hours until stools are clear

6-12 years: 1/3 to 1/2 bottle

Adults ≥ 12 years: 1/2 to 1 full bottle as needed

Administration To increase palatability, chill the solution prior to administration.

Contraindications Renal failure, appendicitis, abdominal pain, intestinal impaction, obstruction or perforation, diabetes mellitus, complications in gastrointestinal tract, patients with colostomy or ileostomy, ulcerative colitis or diverticulitis

Warnings Use with caution in patients with impaired renal function, especially if $Cl_{cr} < 30$ mL/minute (accumulation of magnesium which may lead to magnesium intoxication). Use caution in patients receiving a cardiac glycoside; may increase the AV-blocking effects. Use with caution in patients with lithium administration; use with caution with neuromuscular-blocking agents, and CNS depressants.

Dosage Forms

Solution, oral: 290 mg/5 mL (300 mL) [cherry and lemon flavors]

Tablet: 100 mg [as elemental magnesium]

Reference Range Normal urine level: 1-6 mM/L. Serum magnesium:

Children: 1.5-1.9 mg/dL ~1.2-1.6 mEq/L; Adults: 2.2-2.8 mg/dL ~1.8-2.3 mEq/L

Test Interactions ↑ magnesium; ↓ protein, calcium (S), ↓ potassium (S)

Pregnancy Risk Factor B

Nursing Implications To increase palatability, manufacturer suggests chilling the solution prior to administration

Specific Reference

Dribben WH, Farber NB, and Olney JW, "High-Dose Magnesium Induces Apoptotic Neurodegeneration in the Developing Mouse Brain," *J Toxicol Clin Toxicol*, 2003, 41(5):749.

Magnesium Sulfate

Pronunciation (mag NEE zhuh SUL fate)

CAS Number 10034-99-8; 7487-88-9

Synonyms Epsom Salts; MgSO₄ (error-prone abbreviation)

Use Treatment and prevention of hypomagnesemia; seizure prevention in severe pre-eclampsia or eclampsia, pediatric acute nephritis; short-term treatment torsade de pointes; treatment of cardiac arrhythmias (VT/VF) caused by hypomagnesemia; short-term treatment of constipation or soaking aid; useful for digitalis toxicity, chronic alcoholism, injection for hydrofluoric acid burns

Mechanism of Action Essential in the synthesis of adenosine triphosphate (ATP) and other enzymes involved in muscle contractility and neuronal transmissions; promotes bowel evacuation by causing osmotic retention of fluid which distends the colon with increased peristaltic activity when taken orally; parenterally, decreases acetylcholine in motor nerve terminals and acts on myocardium by slowing rate of S-A node impulse formation and prolonging conduction time

Adverse Reactions

Adverse effects with parenteral MgSO₄ therapy are related to the magnesium serum level

Serum magnesium levels >3 mg/dL:

Central nervous system: CNS depression
Gastrointestinal: Diarrhea

Serum magnesium >5 mg/dL:

Cardiovascular: Flushing
Central nervous system: Somnolence
Gastrointestinal: Diarrhea

Neuromuscular & skeletal: Depressed deep tendon reflexes, myalgia, blocked peripheral neuromuscular transmission leading to anticonvulsant effects

Serum magnesium >12 mg/dL:

Cardiovascular: Complete heart block
Endocrine & metabolic: Hypercalcemia, hypernatremia
Gastrointestinal: Diarrhea
Respiratory: Respiratory paralysis

Signs and Symptoms of Overdose Coma, diuresis, ECG changes, fibrillation (atrial), flushing, flutter (atrial), heart block, hyporeflexia, hypotension, hypothermia, lethargy, muscle weakness, nausea, QRS prolongation, respiratory depression, vomiting

Pharmacodynamics/Kinetics

Onset of action: Oral: Cathartic: 1-2 hours; I.M.: 1 hour; I.V.: Immediate
Duration: I.M.: 3-4 hours; I.V.: 30 minutes

Absorption: Oral: Inversely proportional to amount ingested; 40% to 60% under controlled dietary conditions; 15% to 36% at higher doses

Distribution: Bone (50% to 60%); extracellular fluid (1% to 2%)

Protein binding: 30%, to albumin

Excretion: Urine (as magnesium)

Dosage

The recommended dietary allowance (RDA) of magnesium is 4.5 mg/kg which is a total daily allowance of 350-400 mg for adult men and 280-300 mg for adult women. During pregnancy the RDA is 300 mg and during lactation the RDA is 355 mg. Average daily intakes of dietary magnesium have declined in recent years due to processing of food. The latest estimate of the average American dietary intake was 349 mg/day. Dose represented as MgSO₄ unless stated otherwise.

Note: Serum magnesium is poor reflection of replelational status as the majority of magnesium is intracellular; serum levels may be transiently normal for a few hours after a dose is given, therefore, aim for consistently high normal serum levels in patients with normal renal function for most efficient repletion

Hypomagnesemia:

Neonates: I.V.: 25-50 mg/kg/dose (0.2-0.4 mEq/kg/dose) every 8-12 hours for 2-3 doses

Children: I.M., I.V.: 25-50 mg/kg/dose (0.2-0.4 mEq/kg/dose) every 4-6 hours for 3-4 doses, maximum single dose: 2000 mg (16 mEq), may repeat if hypomagnesemia persists (higher dosage up to 100 mg/kg/dose MgSO₄ I.V. has been used); maintenance: I.V.: 30-60 mg/kg/day (0.25-0.5 mEq/kg/day)

Adults:

Oral: 3 g every 6 hours for 4 doses as needed

I.M., I.V.: 1 g every 6 hours for 4 doses; for severe hypomagnesemia: 8-12 g MgSO₄/day in divided doses has been used

Management of seizures and hypertension: Children: I.M., I.V.: 20-100 mg/kg/dose every 4-6 hours as needed; in severe cases doses as high as 200 mg/kg/dose have been used

Eclampsia, pre-eclampsia: Adults:

I.M.: 1-4 g every 4 hours

I.V.: Initial: 4 g, then switch to I.M. or 1-4 g/hour by continuous infusion

Note: Maximum dose not to exceed 30-40 g/day; maximum rate of infusion: 1-2 g/hour

Life-threatening arrhythmia: I.V.: 1-2 g (8-16 mEq) in 100 mL D₅W, administered over 5-60 minutes followed by an infusion of 0.5-1 g/hour, or

1-6 g administered over several minutes, followed by (in some cases)

I.V. infusion of 3-20 mg/minute for 5-48 hours (depending on patient response and serum magnesium levels)

Maintenance electrolyte requirements:

Daily requirements: 0.2-0.5 mEq/kg/24 hours or 3-10 mEq/1000 kcal/24 hours

Maximum: 8-16 mEq/24 hours

Cathartic: Oral:

Children:

2-5 years: 2.5-5 g/kg/day in a single or divided doses

6-11 years: 5-10 g/day in a single or divided doses

Children ≥ 12 years and Adults: 10-30 g/day in a single or divided doses

Soaking aid: Topical: Adults: Dissolve 2 capfuls of powder per gallon of warm water

Dosing adjustment/comments in renal impairment: Cl_{cr}<25 mL/minute: Do not administer or monitor serum magnesium levels carefully. See guidelines below.

Magnesium Replacement Guidelines

Normal magnesium serum concentrations (MDACC):

Children: 1.5-1.5 mg/dL (1.2-1.6 mEq/L)

Adults: 1.5-2.5 mg/dL (1.2-2.0 mEq/L)

If serum magnesium is <1.5 mg/dL (<1.2 mEq/L), repletion should be considered.

Note: Serum magnesium is a poor reflection of replelational status as the majority of magnesium is intracellular; serum levels may be transiently normal for a few hours after a dose is given; therefore, aim for consistently high normal serum levels in patients with normal renal function for most efficient repletion.

Magnesium formulations:

Magnesium gluconate 500 mg tablet (2.5 mEq/tablet)

Magnesium hydroxide (MOM) (13.7 mEq/5 mL)

Magnesium chloride 535 mg tablet (5.2 mEq/tablet)

Magnesium oxide 420 mg (20.8 mEq/capsule)

Magnesium citrate liquid (3.85-4.71 mEq/5 mL)

Mylanta®-II (13.7 mEq/5 mL)

Maalox® Plus (6.9 mEq/5 mL)

Oral magnesium supplementation:

Oral magnesium is generally not adequate for repletion in patients with serum magnesium concentrations <1.5 mg/dL (<1.2 mEq/L).

Magnesium chloride 535 mg/tablet = 5.2 mEq/tablet given 2 tablets 3 times/day for 5-7 days.

May need **more** if renal function is good or absorptive capacity is poor.

May need **less** if renal function deteriorates. Reassess to determine maintenance dose, if necessary, at 0.35-0.45 mEq/kg/day.

Intravenous repletion (available as 50% solution, 2 mL vials = 1 g or 8 mEq)

Asymptomatic or serum concentration >1.2 mg/dL (>1.0 mEq/L)

<50 mg 16-32 mEq/day infused over 24 hours for 5-7 days

>50 mg 24-40 mEq/day infused over 24 hours for 5-7 days

Symptomatic or serum concentration <1.2 mg/dL (<1.0 mEq/L)

<50 mg 24-40 mEq/day infused over 24 hours for 5-7 days

>50 mg 32-48 mEq/day infused over 24 hours for 5-7 days

Maximal rate of infusion: 2 g/hour to avoid hypotension. Doses of 4 g/hour have been given in emergencies (eclampsia, seizures).

Optimally, should add magnesium to I.V. fluids, but bolus doses are also effective. Monitor renal function and for hypocalcemia. Patients exhibiting hypokalemia should receive concomitant potassium replacement therapy.

Follow-up monitoring:

Serum magnesium will equilibrate over 2-4 days with intracellular concentrations. Therefore, caution should be exercised in interpreting serum levels immediately after boluses.

Stability

Refrigeration of intact ampuls may result in precipitation or crystallization.

Parenteral admixture is stable at room temperature (25°C) for 60 days.

I.V. is **incompatible** when mixed with fat emulsion (flocculation), calcium gluceptate, clindamycin, dobutamine, hydrocortisone (same syringe), nafcillin, polymyxin B, procaine hydrochloride, tetracyclines, thiopental.

Monitoring Parameters

Monitor blood pressure when administering MgSO₄ I.V.; serum magnesium levels should be monitored to avoid overdose; monitor for diarrhea; monitor for arrhythmias, hypotension, respiratory and CNS depression during rapid I.V. administration

Administration

Oral: Dissolve powder in 1/2 glass of water; may add lemon juice to improve taste

Injection: May be administered I.M. or I.V.

I.M.: A 25% or 50% concentration may be used for adults and a 20% solution is recommended for children

I.V.: Magnesium may be administered IVP, IVPB or I.V.; when giving

I.V. push, must dilute first and should not be given any faster than 150 mg/minute. Hypotension and asystole may occur with rapid administration.

Maximal rate of infusion: 2 g/hour to avoid hypotension; doses of 4 g/hour have been given in emergencies (eclampsia, seizures); optimally, should add magnesium to I.V. fluids, but bolus doses are also effective

Topical: Dissolve 2 cups of powder per gallon of warm water to use as a soaking aid. To make a compress, dissolve 2 cups of powder per 2 cups of hot water and use a towel to apply as a wet dressing.

Contraindications Hypersensitivity to any component of the formulation; heart block; myocardial damage

Warnings

Use with caution in patients with impaired renal function, hepatitis, or Addison's disease (accumulation of magnesium may lead to magnesium intoxication). Monitor serum magnesium level, respiratory rate, deep tendon reflex, renal function when magnesium sulfate is

MANNITOL

administered parenterally. Use with extreme caution in patients with myasthenia gravis or other neuromuscular disease.

Constipation (self-medication, OTC use): For occasional use only; serious side effects may occur with prolonged use. For use only under the supervision of a healthcare provider in patients with kidney dysfunction, or with a sudden change in bowel habits which persist for >2 weeks. Do not use if abdominal pain, nausea, or vomiting are present.

Dosage Forms

Infusion [premixed in D₅W]: 10 mg/mL (100 mL); 20 mg/mL (500 mL, 1000 mL)

Infusion [premixed in water for injection]: 40 mg/mL (100 mL, 500 mL, 1000 mL); 80 mg/mL (50 mL)

Injection, solution: 125 mg/mL (8 mL); 500 mg/mL (2 mL, 5 mL, 10 mL, 20 mL, 50 mL)

Powder: Magnesium sulfate USP (480 g, 1810 g, 1920 g)

Reference Range

Serum magnesium:

Children: 1.5-1.9 mg/dL ~1.2-1.6 mEq/L

Adults: 2.2-2.8 mg/dL ~1.8-2.3 mEq/L

Cardiotoxic effects: >12 mg/dL

Muscle paralysis: >15 mg/dL

Test Interactions Analytical interference by calcium salts can result in false depression of magnesium levels.

Drug Interactions

Calcium channel blockers: Calcium channel blockers may enhance the adverse/toxic effect of magnesium salts. Magnesium salts may enhance the hypotensive effect of calcium channel blockers.

Neuromuscular-blocking agents: Magnesium salts may enhance the neuromuscular-blocking effect of neuromuscular-blocking agents. Only of concern in patients with increased serum magnesium concentrations.

Pregnancy Risk Factor B

Pregnancy Implications No harmful effects regarding breast-feeding; hypermagnesemia can lead to neonatal intrauterine growth retardation, CNS respiratory depression

Lactation Enters breast milk/compatible

Nursing Implications Monitor arrhythmias, hypotension, diarrhea, respiratory and CNS depression during rapid I.V. administration; monitor serum magnesium level to avoid overdoses

Endocrine & metabolic: Fluid and electrolyte imbalance, water intoxication, hypernatremia, dehydration and hypovolemia secondary to rapid diuresis, hyponatremia

Gastrointestinal: Xerostomia, diarrhea (oral ingestion), colonic perforation (oral ingestion), **nausea, vomiting**

Local: Tissue necrosis

Ocular: Blurred vision

Renal: Focal osmotic nephrosis of proximal convoluted tubules, **polyuria**

Respiratory: Pulmonary edema

Miscellaneous: Allergic reactions, osmolal gap

Signs and Symptoms of Overdose Cardiovascular collapse, chest pain, chills, headache, hypotension, ototoxicity (deafness), polyuria, renal failure, tinnitus. Pulmonary edema has occurred after a dose of 400 g over 2.5 hours; can cause diarrhea when taken orally.

Pharmacodynamics/Kinetics

Onset of action: Diuresis: Injection: 1-3 hours; Reduction in intracranial pressure: ~15-30 minutes

Duration: Reduction in intracranial pressure: 1.5-6 hours

Distribution: Remains confined to extracellular space (except in extreme concentrations); does not penetrate the blood-brain barrier (generally, penetration is low)

Metabolism: Minimally hepatic to glycogen

Half-life elimination: 1.1-1.6 hours

Excretion: Primarily urine (as unchanged drug)

Dosage

I.V.:

Children:

Test dose (to assess adequate renal function): 200 mg/kg over 3-5 minutes to produce a urine flow of at least 1 mL/kg/hour for 1-3 hours

Initial: 0.5-1 g/kg

Maintenance: 0.25-0.5 g/kg/hour given every 4-6 hours

Adults:

Test dose: 12.5 g (200 mg/kg) over 3-5 minutes to produce a urine flow of at least 30-50 mL of urine per hour over the next 2-3 hours

Initial: 0.5-1 g/kg

Maintenance: 0.25-0.5 g/kg every 4-6 hours; usual adult dose: 20-200 g/24 hours

Intracranial pressure: Cerebral edema: 1.5-2 g/kg/dose I.V. as a 15% to 20% solution over ≥30 minutes; maintain serum osmolality 310-320 mOsm/kg

Preoperative for neurosurgery: 1.5-2 g/kg administered 1-1.5 hours prior to surgery

Transurethral irrigation: Use urogenital solution as required for irrigation

Stability Should be stored at room temperature (15°C to 30°C) and protected from freezing; crystallization may occur at low temperatures; do not use solutions that contain crystals, heating in a hot water bath and vigorous shaking may be utilized for resolubilization; cool solutions to body temperature before using

Monitoring Parameters Renal function, daily fluid I & O, serum electrolytes, serum and urine osmolality; for treatment of elevated intracranial pressure, maintain serum osmolality 310-320 mOsm/kg

Administration Inspect for crystals prior to administration. If crystals present redissolve by warming solution. Use filter-type administration set; in-line 5-micron filter set should always be used for mannitol infusion with concentrations ≥20%; administer test dose (for oliguria) I.V. push over 3-5 minutes; avoid extravasation; for cerebral edema or elevated ICP, administer over 20-30 minutes; crenation and agglutination of red blood cells may occur if administered with whole blood.

Contraindications Hypersensitivity to mannitol or any component or the formulation; severe renal disease (anuria); severe dehydration; active intracranial bleeding except during craniotomy; progressive heart failure, pulmonary congestion, or renal dysfunction after mannitol administration; severe pulmonary edema or congestion

Warnings

Should not be administered until adequacy of renal function and urine flow is established; use 1-2 test doses to assess renal response. Diuretic effects may mask and intensify underlying dehydration; excessive loss of water and electrolytes may lead to imbalances and aggravate pre-existing hyponatremia. May cause renal dysfunction especially with high doses; use caution in patients taking other nephrotoxic agents, with sepsis or pre-existing renal disease. To minimize adverse renal effects, adjust to keep serum osmolality less than 320 mOsm/L. Discontinue if evidence of acute tubular necrosis.

In patients being treated for cerebral edema, mannitol may accumulate in the brain (causing rebound increases in intracranial pressure) if circulating for long periods of time as with continuous infusion; intermittent boluses preferred. Cardiovascular status should also be evaluated; do not administer electrolyte-free mannitol solutions with blood. If hypotension occurs monitor cerebral perfusion pressure to insure adequate.

Dosage Forms

Injection, solution: 5% [50 mg/mL] (1000 mL); 10% [100 mg/mL] (500 mL, 1000 mL); 15% [150 mg/mL] (500 mL); 20% [200 mg/mL] (150 mL, 250 mL, 500 mL); 25% [250 mg/mL] (50 mL)

Mannitol

Pronunciation (MAN i tole)

CAS Number 69-65-8

U.S. Brand Names Osmitrol®; Resectisol®

Synonyms D-Mannitol

Use Reduction of increased intracranial pressure associated with cerebral edema; promotion of diuresis in the prevention and/or treatment of oliguria or anuria due to acute renal failure; reduction of increased intraocular pressure; promoting urinary excretion of toxic substances (lithium); used for ciguatera poisoning

Mechanism of Action Increases the osmotic pressure of glomerular filtrate, which inhibits tubular reabsorption of water and electrolytes and increases urinary output

Adverse Reactions

Cardiovascular: Circulatory overload, diuresis, congestive heart failure, angina

Central nervous system: Convulsions/seizures, **headache**

Dermatologic: Urticaria

Osmitrol®: 5% [50 mg/mL] (1000 mL); 10% [100 mg/mL] (500 mL, 1000 mL); 15% [150 mg/mL] (500 mL); 20% [200 mg/mL] (250 mL, 500 mL)

Solution, urogenital (Resectisol®): 5% [50 mg/mL] (2000 mL, 4000 mL)

Test Interactions ↑ or ↓ inorganic phosphorus (B); lowers serum sodium; causes false-positive ethylene glycol

Drug Interactions Lithium toxicity (with diuretic-induced hyponatremia)

Pregnancy Risk Factor C

Pregnancy Implications Reproduction studies have not been conducted.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications In-line 5-micron filter set should always be used for mannitol infusion with concentrations of 20% or greater; avoid extravasation; crenation and agglutination of red blood cells may occur if administered with whole blood; appears to be compatible with furosemide

Mesna

Pronunciation (MES na)

CAS Number 19767-45-4

U.S. Brand Names Mesnex®

Synonyms Sodium 2-Mercaptoethane Sulfonate

Use Orphan drug: Prevention of hemorrhagic cystitis induced by ifosfamide

Unlabeled/Investigational Use Prevention of hemorrhagic cystitis induced by cyclophosphamide

Mechanism of Action In blood, mesna is oxidized to dimesna which in turn is reduced in the kidney back to mesna, supplying a free thiol group which binds to and inactivates acrolein, the urotoxic metabolite of ifosfamide and cyclophosphamide

Adverse Reactions

It is difficult to distinguish reactions from those caused by concomitant chemotherapy.

Cardiovascular: Tachycardia

Gastrointestinal: **Bad taste in mouth with oral administration (100%), vomiting** (secondary to the bad taste after oral administration, or with high I.V. doses)

Hematologic: Decreased platelet count

Local: Injection site reaction

Neuromuscular & skeletal: Limb pain, myalgia

Respiratory: Tachypnea

Miscellaneous: Anaphylaxis, hypersensitivity

Pharmacodynamics/Kinetics

Distribution: No tissue penetration

Protein binding: 69% to 75%

Metabolism: Rapidly oxidized intravascularly to mesna disulfide; mesna disulfide is reduced in renal tubules back to mesna following glomerular filtration.

Bioavailability: Oral: 45% to 79%

Half-life elimination: Parent drug: 24 minutes; Mesna disulfide: 72 minutes

Time to peak, plasma: 2-3 hours

Excretion: Urine; as unchanged drug (18% to 26%) and metabolites

Dosage

Children and Adults (refer to individual protocols):

I.V.: Recommended dose is 60% of the ifosfamide dose given in 3 divided doses (0, 4, and 8 hours after the start of ifosfamide)

Alternative I.V. regimens include 80% of the ifosfamide dose given in 4 divided doses (0, 3, 6, and 9 hours after the start of ifosfamide) and continuous infusions

I.V./Oral: Recommended dose is 100% of the ifosfamide dose, given as 20% of the ifosfamide dose I.V. at hour 0, followed by 40% of the ifosfamide dose given orally 2 and 6 hours after start of ifosfamide

Stability Store intact vials and tablets at controlled room temperature of 20°C to 25°C (68°F to 77°F). Opened multidose vials may be stored and used for up to 8 days after opening. Dilute injection in 50-1000 mL D₅W, NS, or lactated Ringer's for infusion. Solutions in D₅W or lactated Ringer's are stable for at least 48 hours at room temperature. Solutions in NS are stable for at least 24 hours at room temperature. Solutions in plastic syringes are stable for 9 days under refrigeration, or at room or body temperature. Stability in syringes decreases if air is in the filled syringe. Solutions of mesna and ifosfamide in lactated Ringer's are stable for 7 days in a PVC ambulatory infusion pump reservoir. Mesna injection is stable for at least 7 days when diluted 1:2 or 1:5 with grape- and orange-flavored syrups or 11:1 to 1:100 in carbonated beverages for oral administration.

Monitoring Parameters Urinalysis

Administration

Oral: Administer orally in tablet formulation or parenteral solution diluted in water, milk, juice, or carbonated beverages; patients who vomit within 2 hours of taking oral mesna should repeat the dose or receive I.V. mesna

I.V.: Administer by short (15-30 minutes) infusion or continuous (24 hour) infusion

Contraindications Hypersensitivity to mesna or other thiol compounds, or any component of the formulation

Warnings Examine morning urine specimen for hematuria prior to ifosfamide or cyclophosphamide treatment; if hematuria (> 50 RBC/HPF) develops, reduce the ifosfamide/cyclophosphamide dose or discontinue the drug; will not prevent or alleviate other toxicities associated with ifosfamide or cyclophosphamide and will not prevent hemorrhagic cystitis in all patients. Allergic reactions have been reported; patients with autoimmune disorders may be at increased risk. Symptoms ranged from mild hypersensitivity to systemic anaphylactic reactions. I.V. formulation contains benzyl alcohol; do not use in neonates or infants.

Dosage Forms

Injection, solution: 100 mg/mL (10 mL) [contains benzyl alcohol]

Tablet: 400 mg

Test Interactions False-positive urinary ketones with Multistix® or Labstix®

Drug Interactions Decreased effect: Warfarin: Questionable alterations in coagulation control

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic effects were not observed in animal studies. There are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if clearly needed.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications Used in conjunction with ifosfamide; examine morning urine specimen for hematuria prior to ifosfamide or cyclophosphamide treatment; if hematuria develops, reduce the ifosfamide/cyclophosphamide dose or discontinue the drug

Methylene Blue

Pronunciation (METH i leen bloo)

CAS Number 61-73-4; 7220-79-3

U.S. Brand Names Urolene Blue®

Use Antidote for drug-induced methemoglobinemia, indicator dye, chronic urolithiasis; bacteriostatic genitourinary antiseptic

Unlabeled/Investigational Use Has been used topically (0.1% solutions) in conjunction with polychromatic light to photoinactivate viruses such as herpes simplex; has been used alone or in combination with vitamin C for the management of chronic urolithiasis; also has been suggested to treat ackee fruit encephalopathy.

Mechanism of Action Weak germicide; in low concentrations, hastens the conversion of methemoglobin to hemoglobin; has opposite effect at high concentrations by converting ferrous iron of reduced hemoglobin to ferric iron to form methemoglobin; in cyanide toxicity, it combines with cyanide to form cyanmethemoglobin preventing the interference of cyanide with the cytochrome system; indicated for symptomatic methemoglobinemia (usually when methemoglobin levels are > 20%)

Adverse Reactions

Cardiovascular: Hypotension, cyanosis, large I.V. doses have been associated with precordial pain

Central nervous system: Dizziness/vertigo, mental confusion, headache, fever/pyrexia at doses of 7 mg/kg

Dermatologic: Stains skin a bluish color at doses > 80 mg/kg

Gastrointestinal: Nausea, vomiting, abdominal pain at doses of 7 mg/kg; **fecal discoloration (blue-green)**

Genitourinary: Bladder irritation, dysuria, **urine discoloration (blue or green)**

Hematologic: Formation of methemoglobin, hemolytic anemia in patients with glucose-6-phosphate dehydrogenase deficiency, hemolytic anemia

Local: Extravasation injury

Neuromuscular & skeletal: Hyperreflexia

Ocular: Vision color changes (blue tinge)

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Feces discoloration (black; blue), jaundice, urine discoloration (blue; blue-green; green; green-yellow; yellow-brown). Doses > 20 mg/kg can cause hemolysis and hypotension.

Pharmacodynamics/Kinetics

Absorption: Oral: 53% to 97%

Excretion: Urine and feces

Dosage

Children: NADPH-methemoglobin reductase deficiency: Oral: 1-1.5 mg/kg/day (maximum: 4 mg/kg/day) given with 5-8 mg/kg/day of ascorbic acid

Children and Adults: Methemoglobinemia: I.V.: 1-2 mg/kg or 25-50 mg/m² over several minutes; may be repeated in 1 hour if necessary; use the higher dose if methemoglobin levels exceed 60%

Adults:

Genitourinary antiseptic: Oral: 55-130 mg 3 times/day with a full glass of water (maximum: 300 mg/day)

NALMEFENE

Monitoring Parameters Hemoglobin, methemoglobin concentrations should drop within 1 hour

Administration Administer I.V. undiluted by direct I.V. injection over several minutes.

Contraindications Hypersensitivity to methylene blue or any component of the formulation; intraspinal injection; renal insufficiency; pregnancy (injected intra-amniotically)

Warnings Do not inject SubQ or intrathecally; use with caution in young patients and in patients with G6PD deficiency; continued use can cause profound anemia

Dosage Forms

Injection, solution: 10 mg/mL (1 mL, 10 mL)
Tablet (Urolene Blue®): 65 mg

Test Interactions Can reduce arterial lactate concentration in septic shock

Pregnancy Risk Factor C/D (injected intra-amniotically)

Nursing Implications Inject over several minutes to avoid high concentration; SubQ injection may cause necrotic abscess; may be diluted with normal saline

Nalmefene

Pronunciation (NAL me feen)

CAS Number 55096-26-9; 58895-64-0

U.S. Brand Names Revex®

Synonyms Nalmefene Hydrochloride

Use Reversal of adverse opiate effects

Unlabeled/Investigational Use May be useful for pruritus

Mechanism of Action Derivative of naltrexone with opioid antagonist effects; does not produce opiate agonist effects

Adverse Reactions

Cardiovascular: Hypotension, tachycardia, hypertension, shock, sinus bradycardia, sinus tachycardia

Central nervous system: Dizziness, fatigue, fever, headache, chills

Gastrointestinal: Nausea, vomiting

Neuromuscular & skeletal: Paresthesia

Respiratory: Pulmonary edema

Pharmacodynamics/Kinetics

Onset of action: I.M., SubQ: 5-15 minutes

Distribution: V_d: 8.6 L/kg; rapid

Protein binding: 45%

Metabolism: Hepatic via glucuronide conjugation to metabolites with little or no activity

Bioavailability: I.M., SubQ: 100%

Half-life elimination: 10.8 hours

Time to peak, serum: Serum: I.M.: 2.3 hours; I.V.: <2 minutes; SubQ: 1.5 hours

Excretion: Feces (17%); urine (<5% as unchanged drug)

Clearance: 0.8 L/hour/kg

Dosage

Reversal of postoperative opioid depression: Blue labeled product (100 mcg/mL): Titrate to reverse the undesired effects of opioids; initial dose for nonopioid dependent patients: 0.25 mcg/kg followed by 0.25 mcg/kg incremental doses at 2- to 5-minute intervals; after a total dose > 1 mcg/kg, further therapeutic response is unlikely

Management of known/suspected opioid overdose: Green labeled product (1000 mcg/mL): Initial dose: 0.5 mg/70 kg; may repeat with 1 mg/70 kg in 2-5 minutes; further increase beyond a total dose of 1.5 mg/70 kg will not likely result in improved response and may result in cardiovascular stress and precipitated withdrawal syndrome. (If opioid dependency is suspected, administer a challenge dose of 0.1 mg/70 kg; if no withdrawal symptoms are observed in 2 minutes, the recommended doses can be administered.)

Note: If recurrence of respiratory depression is noted, dose may again be titrated to clinical effect using incremental doses.

Note: If I.V. access is lost or not readily obtainable, a single SubQ or I.M. dose of 1 mg may be effective in 5-15 minutes.

Dosing adjustment in renal or hepatic impairment: Not necessary with single uses, however, slow administration (over 60 seconds) of incremental doses is recommended to minimize hypertension and dizziness

Monitoring Parameters Symptoms of withdrawal; signs/symptoms of respiratory depression; pain

Administration Check dosage strength carefully before use to avoid error. Slow administration (over 60 seconds) of incremental doses is

recommended to minimize hypertension and dizziness in renal patients. Dilute drug (1:1) with diluent and use smaller doses in patients known to be at increased cardiovascular risk. May be administered via I.M. or SubQ routes if I.V. access is not feasible. A single SubQ or I.M. dose of 1 mg may be effective in 5-15 minutes.

Contraindications Hypersensitivity to nalmefene, naltrexone, or any component of the formulation

Warnings May induce symptoms of acute withdrawal in opioid-dependent patients; recurrence of respiratory depression is possible if the opioid involved is long-acting; observe patients until there is no reasonable risk of recurrent respiratory depression. Safety and efficacy have not been established in children. Avoid abrupt reversal of opioid effects in patients of high cardiovascular risk or who have received potentially cardiotoxic drugs. Pulmonary edema and cardiovascular instability, including ventricular fibrillation, have been reported in association with abrupt reversal with other narcotic antagonists. Animal studies indicate nalmefene may not completely reverse buprenorphine-induced respiratory depression. Use caution with renal impairment.

Dosage Forms

Injection, solution:

Revex®: 100 mcg/mL (1 mL) [blue label]; 1 mg/mL (2 mL) [green label]

Reference Range Therapeutic plasma level: 0.5 ng/mL

Drug Interactions

Flumazenil: May increase the risk of toxicity with flumazenil. An increased risk of seizures has been associated with flumazenil and nalmefene coadministration

Narcotic analgesics: Decreased effect of narcotic analgesics; may precipitate acute withdrawal reaction in physically dependent patients

Pregnancy Risk Factor B

Pregnancy Implications Animal studies have not demonstrated fetal harm or fertility impairment. There are no adequate and well-controlled studies in pregnant women. Use only if clearly needed.

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Check dosage strength carefully before use to avoid error (labeling is color-coded; postoperative reversal - blue, overdose management - green); monitor patients for signs of withdrawal, especially those physically dependent who are in pain or at high cardiovascular risk

Specific Reference

Fang WB, Andrenyak DM, Moody DE, et al, "Determination of Nalmefene in Plasma by High-Performance Liquid Chromatography-Electrospray Ionization-Tandem Mass Spectrometry," *J Anal Toxicol*, 2004, 28:298-9.

Naloxone

CAS Number 357-08-4; 465-65-6; 51481-60-8

U.S. Brand Names Narcan®

Synonyms N-allylnoroxymorphone Hydrochloride; Naloxone Hydrochloride

Use Reverses CNS and respiratory depression in suspected narcotic/opiate overdose; neonatal opiate depression; coma of unknown etiology

Unlabeled/Investigational Use

Investigational: Shock, alcohol ingestion; pruritus due to cholestasis; also useful in clonidine, camylofin, valproic acid, and captopril overdose; may be useful in reversing cardiac depression due to dextropropoxyphene

Mechanism of Action Competes and displaces narcotics at narcotic/opiate receptor sites

Adverse Reactions

Cardiovascular: Hypertension (may be significant), hypotension, tachycardia, arrhythmias (ventricular), shock, sinus tachycardia

Central nervous system: Insomnia, irritability, anxiety, narcotic withdrawal, psychosis, dysphoria

Dermatologic: Rash

Gastrointestinal: Nausea, vomiting

Genitourinary: Urinary urgency

Hematologic: Coagulopathy

Ocular: Blurred vision

Respiratory: Pulmonary edema has been described

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Agitation, anxiety, anorexia, bradycardia, diaphoresis (at 2-4 mg/kg), focal seizures, hypotension, irritability, laryngospasm, nausea

Pharmacodynamics/Kinetics

Onset of action: Endotracheal, I.M., SubQ: 2-5 minutes; I.V.: ~2 minutes
Duration: 20-60 minutes; since shorter than that of most opioids, repeated doses are usually needed

Distribution: Crosses placenta

Metabolism: Primarily hepatic via glucuronidation

Half-life elimination: Neonates: 1.2-3 hours; Adults: 1-1.5 hours

Excretion: Urine (as metabolites)

Dosage

I.M., I.V. (preferred), intratracheal, SubQ:

Postanesthesia narcotic reversal: Infants and Children: 0.01 mg/kg; may repeat every 2-3 minutes, as needed based on response

Opiate intoxication:

Children:

Birth (including premature infants) to 5 years or <20 kg: 0.1 mg/kg; repeat every 2-3 minutes if needed; may need to repeat doses every 20-60 minutes
>5 years or ≥20 kg: 2 mg/dose; if no response, repeat every 2-3 minutes; may need to repeat doses every 20-60 minutes

Children and Adults: Continuous infusion: I.V.: If continuous infusion is required, calculate dosage/hour based on effective intermittent dose used and duration of adequate response seen, titrate dose 0.04-0.16 mg/kg/hour for 2-5 days in children, adult dose typically 0.25-6.25 mg/hour (short-term infusions as high as 2.4 mg/kg/hour have been tolerated in adults during treatment for septic shock); alternatively, continuous infusion utilizes $\frac{2}{3}$ of the initial naloxone bolus on an hourly basis; add 10 times this dose to each liter of D₅W and infuse at a rate of 100 mL/hour; $\frac{1}{2}$ of the initial bolus dose should be readministered 15 minutes after initiation of the continuous infusion to prevent a drop in naloxone levels; increase infusion rate as needed to assure adequate ventilation; 2 mg naloxone in 3 mL saline can be delivered via nebulization

Narcotic overdose: Adults: I.V.: 0.4-2 mg every 2-3 minutes as needed; may need to repeat doses every 20-60 minutes, if no response is observed after 10 mg, question the diagnosis. **Note:** Use 0.1-0.2 mg increments in patients who are opioid dependent and in postoperative patients to avoid large cardiovascular changes.

Stability Protect from light; stable in 0.9% sodium chloride and D₅W at 4 mcg/mL for 24 hours; do not mix with alkaline solutions

Monitoring Parameters Respiratory rate, heart rate, blood pressure

Administration

Intratracheal: Dilute to 1-2 mL with normal saline

I.V. push: Administer over 30 seconds as undiluted preparation

I.V. continuous infusion: Dilute to 4 mcg/mL in D₅W or normal saline

Contraindications Hypersensitivity to naloxone or any component of the formulation

Warnings Due to an association between naloxone and acute pulmonary edema, use with caution in patients with cardiovascular disease or in patients receiving medications with potential adverse cardiovascular effects (eg, hypotension, pulmonary edema or arrhythmias). Excessive dosages should be avoided after use of opiates in surgery. Abrupt postoperative reversal may result in nausea, vomiting, sweating, tachycardia, hypertension, seizures, and other cardiovascular events (including pulmonary edema and arrhythmias). May precipitate withdrawal symptoms in patients addicted to opiates, including pain, hypertension, sweating, agitation, irritability; in neonates: shrill cry, failure to feed. Recurrence of respiratory depression is possible if the opioid involved is long-acting; observe patients until there is no reasonable risk of recurrent respiratory depression.

Dosage Forms

[DSC] = Discontinued product

Injection, solution, as hydrochloride: 0.4 mg/mL (1 mL, 10 mL)

Narcan®: 0.4 mg/mL (1 mL) [DSC]

Reference Range Plasma naloxone levels at 2 and 5 minutes after a 0.4 mg I.V. dose: 0.01 mg/L and 0.004 mg/L, respectively

Test Interactions Will not give a false-positive enzymatic urine screen for opiates

Drug Interactions Narcotic analgesics: Decreased effect of narcotic analgesics; may precipitate acute withdrawal reaction in physically dependent patients

Pregnancy Risk Factor B

Pregnancy Implications Consider benefit to the mother and the risk to the fetus before administering to a pregnant woman who is known or suspected to be opioid dependent. May precipitate withdrawal in both the mother and fetus.

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications The use of neonatal naloxone is no longer recommended because unacceptable fluid volumes will result, especially to small neonates; the 0.4 mg/mL preparation is available and can be accurately dosed with appropriately sized syringes (1 mL)

Neostigmine

Pronunciation (nee oh STIG meen)

CAS Number 114-80-7; 51-60-5; 59-99-4

U.S. Brand Names Prostigmin®

Synonyms Neostigmine Bromide; Neostigmine Methylsulfate

Use Second-line agent for envenomation by Asian snakes or intoxication with tetradotoxin exposures if edrophonium supplies are depleted; reversal of the effects of nondepolarizing neuromuscular blocking agents after surgery

Mechanism of Action Inhibits destruction of acetylcholine by acetylcholinesterase which facilitates transmission of impulses across myoneural junction

Adverse Reactions

Cardiovascular: Bradycardia, hypotension, bradyarrhythmias, asystole (maximum effect: 90 minutes), chest pain, sinus bradycardia, angina

Central nervous system: Restlessness, agitation, seizures, slurred speech, headache, coma, ataxia

Gastrointestinal: **Hyperperistalsis, nausea, vomiting, salivation, stomach cramps, diarrhea, defecation**

Neuromuscular & skeletal: Tremors, fasciculations, weakness

Ocular: Miosis, lacrimation, nystagmus

Respiratory: Bronchoconstriction, increased bronchial secretion

Miscellaneous: **Diaphoresis, radiopaque**

Signs and Symptoms of Overdose Blurred vision, bradycardia, excessive sweating, muscle weakness, nausea, tachypnea, tearing and salivation, vomiting

Pharmacodynamics/Kinetics

Onset of action: I.M.: 20-30 minutes; I.V.: 1-20 minutes

Duration: I.M.: 2.5-4 hours; I.V.: 1-2 hours

Absorption: Oral: Poor, <2%

Metabolism: Hepatic

Half-life elimination: Normal renal function: 0.5-2.1 hours; End-stage renal disease: Prolonged

Excretion: Urine (50% as unchanged drug)

Dosage

Myasthenia gravis: Diagnosis: I.M.:

Children: 0.04 mg/kg as a single dose

Adults: 0.02 mg/kg as a single dose

Myasthenia gravis: Treatment:

Children:

Oral: 2 mg/kg/day divided every 3-4 hours

I.M., I.V., SubQ: 0.01-0.04 mg/kg every 2-4 hours

Adults:

Oral: 15 mg/dose every 3-4 hours

I.M., I.V., SubQ: 0.5-2.5 mg every 1-3 hours

Reversal of nondepolarizing neuromuscular blockade after surgery in conjunction with atropine or glycopyrrrolate: I.V.:

Infants: 0.025-0.1 mg/kg/dose

Children: 0.025-0.08 mg/kg/dose

Adults: 0.5-2.5 mg; total dose not to exceed 5 mg

Bladder atony: Adults: I.M., SubQ:

Prevention: 0.25 mg every 4-6 hours for 2-3 days

Treatment: 0.5-1 mg every 3 hours for 5 doses after bladder has emptied

Monitoring Parameters Respiratory status/muscle weakness

Administration May be administered undiluted by slow I.V. injection over several minutes

Contraindications Hypersensitivity to neostigmine, bromides, or any component of the formulation; GI or GU obstruction

Warnings Does **not** antagonize and may prolong the phase I block of depolarizing muscle relaxants (eg, succinylcholine); use with caution in patients with epilepsy, asthma, bradycardia, hyperthyroidism, cardiac arrhythmias, or peptic ulcer; adequate facilities should be available for cardiopulmonary resuscitation when testing and adjusting dose for myasthenia gravis; have atropine and epinephrine ready to treat hypersensitivity reactions; overdosage may result in cholinergic crisis, this must be distinguished from myasthenic crisis; anticholinesterase insensitivity can develop for brief or prolonged periods

Dosage Forms

Injection, solution, as methylsulfate: 0.5 mg/mL (1 mL, 10 mL); 1 mg/mL (10 mL)

Tablet, as bromide: 15 mg

Test Interactions ↑ aminotransferase [ALT (SGPT)/AST (SGOT)] (S), amylase (S)

Drug Interactions

Anticholinergics: Effects may be reduced with cholinesterase inhibitors; atropine antagonizes the muscarinic effects of cholinesterase inhibitors

Beta-blockers without ISA: Activity may increase risk of bradycardia

Calcium channel blockers (diltiazem or verapamil): May increase risk of bradycardia

Cholinergic agonists: Effects may be increased with cholinesterase inhibitors

NOREPINEPHRINE

Corticosteroids: May see increased muscle weakness and decreased response to anticholinesterases shortly after onset of corticosteroid therapy in the treatment of myasthenia gravis. Deterioration in muscle strength, including severe muscular depression, has been documented in patients with myasthenia gravis while receiving corticosteroids and anticholinesterases.

Digoxin: Increased risk of bradycardia with concurrent use

Neuromuscular blockers: Depolarizing neuromuscular blocking agents effects may be increased with cholinesterase inhibitors; nondepolarizing agents are antagonized by cholinesterase inhibitors

Pregnancy Risk Factor C

Pregnancy Implications Does not cross placental barrier except with large doses

Lactation Excretion in breast milk unknown/not recommended

Nursing Implications In the diagnosis of myasthenia gravis, all anticholinesterase medications should be discontinued for at least 8 hours before administering neostigmine

Norepinephrine

Pronunciation (nor ep i NEF rin)

CAS Number 51-40-1; 51-41-2; 6981-49-5

U.S. Brand Names Levophed®

Synonyms Levarterenol Bitartrate; Noradrenaline Acid Tartrate; Noradrenaline; Norepinephrine Bitartrate

Use Treatment of shock which persists after adequate fluid volume replacement; useful for hypotension induced by tricyclic antidepressants, disulfiram-ethanol interaction, phenothiazine antidysrhythmic agents

Mechanism of Action Stimulates beta₁-adrenergic receptors and alpha-adrenergic receptors causing increased contractility and heart rate as well as vasoconstriction, thereby increasing systemic blood pressure and coronary blood flow

Adverse Reactions

Cardiovascular: Cardiac arrhythmias, palpitations, bradycardia, tachycardia, hypertension, chest pain, superior mesenteric artery thrombosis, pallor, ischemic necrosis and sloughing of superficial tissue after extravasation, sinus bradycardia, cardiomyopathy, cardiomegaly, angina, sinus tachycardia, vasoconstriction

Central nervous system: Anxiety, fear, headache

Gastrointestinal: Vomiting

Genitourinary: Uterine contractions

Local: Organ ischemia (due to vasoconstriction of renal and mesenteric arteries)

Ocular: Photophobia, nystagmus

Respiratory: Respiratory distress

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Cerebral hemorrhage, hypotension, seizures, sweating

Pharmacodynamics/Kinetics

Onset of action: I.V.: Very rapid-acting

Duration: Limited

Metabolism: Via catechol-o-methyltransferase (COMT) and monoamine oxidase (MAO)

Excretion: Urine (84% to 96% as inactive metabolites)

Dosage

I.V. infusion (dose stated in terms of norepinephrine base):

Children: Initial: 0.05-0.1 mcg/kg/minute, titrate to desired effect

Rate (mL/hour) = dose (mcg/kg/minute) × weight (kg) × 60 minutes/hour divided by concentration (mcg/mL)

Adults: 8-12 mcg/minute as an infusion; initiate at 4 mcg/minute and titrate to desired response

Note: Dose stated in terms of norepinephrine base

Rate of infusion: 4 mg in 500 mL D₅W

2 mcg/minute = 15 mL/hour

4 mcg/minute = 30 mL/hour

6 mcg/minute = 45 mL/hour

8 mcg/minute = 60 mL/hour

10 mcg/minute = 75 mL/hour

12 mcg/minute = 90 mL/hour

14 mcg/minute = 105 mL/hour

16 mcg/minute = 120 mL/hour

18 mcg/minute = 135 mL/hour

20 mcg/minute = 150 mL/hour

Stability

Readily oxidized; protect from light. Do not use if brown coloration. Stable in D₅NS, D₅W, LR; may dilute with D₅W or D₅NS, but not recommended to dilute in normal saline; not stable in alkaline solutions. Stability of parenteral admixture at room temperature (25°C) is 24 hours.

Y-site administration: Incompatible with insulin (regular), thiopental

Compatibility when admixed: Incompatible with aminophylline, amobarbital, chlorothiazide, chlorpheniramine, pentobarbital, phenobarbital, phenytoin, sodium bicarbonate, streptomycin, thiopental

Monitoring Parameters Blood pressure, heart rate, urine output, peripheral perfusion

Administration Administer into large vein to avoid the potential for extravasation; potent drug, must be diluted prior to use. Rate (mL/hour) = dose (mcg/kg/minute) × weight (kg) × 60 minutes/hour divided by concentration (mcg/mL)

To prepare for infusion:

$$\frac{6 \times \text{weight (Kg)} \times \text{desired dose (mcg/kg/min)}}{\text{I.V. infusion rate (mL/h)}} = \frac{\text{mg drug to be added to}}{10 \text{ mL of I.V. fluid}}$$

Contraindications Hypersensitivity to norepinephrine, bisulfites (contains metabisulfite), or any component of the formulation; hypotension from hypovolemia except as an emergency measure to maintain coronary and cerebral perfusion until volume could be replaced; mesenteric or peripheral vascular thrombosis unless it is a lifesaving procedure; during anesthesia with cyclopropane or halothane anesthesia (risk of ventricular arrhythmias)

Warnings Assure adequate circulatory volume to minimize need for vasoconstrictors. Avoid hypertension; monitor blood pressure closely and adjust infusion rate. Avoid extravasation; infuse into a large vein if possible. Avoid infusion into leg veins. Watch I.V. site closely. **[U.S. Boxed Warning]:** If extravasation occurs, infiltrate the area with diluted phentolamine (5-10 mg in 10-15 mL of saline) with a fine hypodermic needle. Phentolamine should be administered as soon as possible after extravasation is noted.

Dosage Forms Injection, solution, as bitartrate: 1 mg/mL (4 mL) [contains sodium metabisulfite]

Reference Range 24-hour urine catecholamine level: <100 mcg; normal plasma basal norepinephrine level: 100-447 pg/mL

Drug Interactions

Beta-blockers (nonselective ones) may increase hypertensive effect; avoid concurrent use. Cocaine may cause malignant arrhythmias; avoid concurrent use.

Guanethidine can increase the pressor response; be aware of the patient's drug regimen.

MAO inhibitors potentiate hypertension and hypertensive crisis; avoid concurrent use.

Methyldopa can increase the pressor response; be aware of patient's drug regimen.

Reserpine increases the pressor response; be aware of patient's drug regimen.

TCAs increase the pressor response; be aware of patient's drug regimen.

Pregnancy Risk Factor C

Pregnancy Implications Crosses the placenta

Lactation Excretion in breast milk unknown

Nursing Implications

Central line administration required; do not administer NaHCO₃ through an I.V. line containing norepinephrine; administer into large vein to avoid the potential for extravasation; potent drug, must be diluted prior to use

Extravasation: Use phentolamine as antidote; mix 5 mg with 9 mL of NS; inject a small amount of this dilution into extravasated area; blanching should reverse immediately. Monitor site; if blanching should recur, additional injections of phentolamine may be needed.

Obidoxime Chloride

Related Information

- Asoxime Chloride [ANTIDOTE]
- Pralidoxime [ANTIDOTE]

CAS Number 114-90-9; 7683-36-5

Use A cholinesterase activator similar to pralidoxime; used primarily in Europe for organophosphate poisoning and sarin or tabun nerve gas toxicity

Mechanism of Action A quaternary oxime which reactivates cholinesterase; used in conjunction with atropine; less toxic than pralidoxime; has weak anticholinergic activity

Adverse Reactions

Cardiovascular: Hypertension, tachycardia at doses >5 mg/kg

Gastrointestinal: Nausea, vomiting, diarrhea, xerostomia

Hepatic: Transient rise in liver enzymes

Local: Pain at injection site

Neuromuscular & skeletal: Paresthesia

Ocular: Diplopia, blurred vision

Miscellaneous: Menthol-like aftertaste, "hot-feeling"

Dosage

Children: 4-8 mg/kg not to exceed 250 mg

Adults:

I.M. or slow I.V.: Initial: 250 mg, may be repeated once or twice at 2-hour intervals; maximum daily dose: 750 mg; a 5-day course can be considered for moderate to severe exposure

Continuous infusion: About 0.5 mg/kg/hour up to a maximum dose of 750 mg daily

Reference Range Therapeutic blood level: 4 mg/L

Octreotide

Pronunciation (ok TREE oh tide)

CAS Number 79517-01-4; 83150-76-9

U.S. Brand Names Sandostatin LAR[®]; Sandostatin[®]

Synonyms NSC-671663; Octreotide Acetate

Use Useful in treating hypoglycemia due to sulfonyleurea ingestion; variceal hemorrhage, acromegaly, carcinoid syndrome, vasoactive intestinal peptide tumors, pancreatic and enteric fistulas, secretory diarrhea; radiation-induced diarrhea; treatment of L-asparaginase induced pancreatitis

Unlabeled/Investigational Use AIDS-associated secretory diarrhea (including *Cryptosporidiosis*), control of bleeding of esophageal varices, breast cancer, cryptosporidiosis, Cushing's syndrome (ectopic), cystoid macular edema, insulinomas, small bowel fistulas, pancreatic tumors, gastrinoma, postgastrectomy dumping syndrome, chemotherapy-induced diarrhea, graft-versus-host disease (GVHD) induced diarrhea, Zollinger-Ellison syndrome, congenital hyperinsulinism

Mechanism of Action An octapeptide analogue of somatostatin which inhibits growth hormone secretion and insulin secretion

Adverse Reactions

Adverse reactions vary by route of administration. Frequency of cardiac, endocrine, and gastrointestinal adverse reactions were generally higher in acromegalics.

> 16%:

Cardiovascular: Sinus bradycardia (19% to 25%), chest pain (16% to 20%)

Central nervous system: Fatigue (1% to 20%), malaise (16% to 20%), dizziness (5% to 20%), headache (6% to 20%), fever (16% to 20%)

Endocrine & metabolic: Hyperglycemia (2% to 27%)

Gastrointestinal: Diarrhea (5% to 61%), abdominal discomfort (5% to 61%), flatulence (<10% to 38%), constipation (9% to 21%), nausea (5% to 61%), cholelithiasis (27%; length of therapy dependent), biliary duct dilatation (12%), biliary sludge (24%; length of therapy dependent), loose stools (5% to 61%), vomiting (4% to 21%)

Hematologic: Antibodies to octreotide (up to 25%; no efficacy change)

Local: Injection pain (2% to 50%; dose- and formulation-related)

Neuromuscular & skeletal: Backache (1% to 20%), arthropathy (16% to 20%)

Respiratory: Dyspnea (16% to 20%), upper respiratory infection (16% to 20%)

Miscellaneous: Flu symptoms (1% to 20%)

5% to 15%:

Cardiovascular: Conduction abnormalities (9% to 10%), arrhythmia (3% to 9%), hypertension, palpitations, peripheral edema

Central nervous system: Anxiety, confusion, depression, hypoesthesia, insomnia, vertigo

Dermatologic: Pruritus, rash

Endocrine & metabolic: Hypothyroidism (2% to 12%), goiter (2% to 8%)

Gastrointestinal: Abdominal pain, anorexia, cramping, dehydration, discomfort, hemorrhoids, tenesmus (4% to 6%), dyspepsia (4% to 6%), steatorrhea (4% to 6%), feces discoloration (4% to 6%), weight loss

Genitourinary: UTI

Hematologic: Anemia

Hepatic: Hepatitis

Neuromuscular & skeletal: Arthralgia, leg cramps, myalgia, paresthesia, rigors, weakness

Otic: ear ache, otitis media

Renal: renal calculus

Respiratory: coughing, pharyngitis, sinusitis, rhinitis

Miscellaneous: Allergy, diaphoresis

1% to 4%:

Cardiovascular: Angina, cardiac failure, cerebral vascular disorder, edema, flushing, hematoma, phlebitis, tachycardia

Central nervous system: Abnormal gait, amnesia, dysphonia, hallucinations, nervousness, neuralgia, neuropathy, somnolence, tremor, vertigo

Dermatologic: Acne, alopecia, bruising, cellulitis, urticaria

Endocrine & metabolic: Hypoglycemia (2% to 4%), hypokalemia, hypoproteinemia, gout, cachexia, menstrual irregularities, breast pain, impotence, hyperkalemia

Gastrointestinal: Colitis, diverticulitis, dysphagia, fat malabsorption, gastritis, gastroenteritis, gingivitis, glossitis, melena, rectal bleeding, stomatitis, taste perversion, xerostomia

Genitourinary: Incontinence

Hematologic: Epistaxis

Hepatic: Ascites, jaundice

Local: Injection hematoma

Neuromuscular & skeletal: Hyperkinesia, hypertonia, joint pain

Ocular: Blurred vision, visual disturbance

Otic: Tinnitus

Renal: Albuminuria, renal abscess

Respiratory: Bronchitis, pleural effusion, pneumonia, pulmonary embolism

Miscellaneous: Bacterial infection, cold symptoms, moniliasis

< 1%: Abdomen enlarged, anaphylactic shock, anaphylactoid reaction, aneurysm, aphasia, appendicitis, arthritis, atrial fibrillation, basal cell carcinoma, Bell's palsy, breast carcinoma, burning eyes, cardiac arrest, CHF, CK increased, creatinine increased, deafness, diabetes insipidus, diabetes mellitus, facial edema, fatty liver, galactorrhea, gallbladder polyp, gallstones, GI hemorrhage, glaucoma, gynecomastia, hematuria, hemiparesis, hepatitis, hyperesthesia, hypertensive reaction, hypoadrenalism, intestinal obstruction, intracranial hemorrhage, iron deficiency, ischemia, joint effusion, lactation, leg cramps, LFTs increased, libido decreased, malignant hyperpyrexia, MI, migraine, muscle cramping, nephrolithiasis, orthostatic hypotension, pancreatitis, paranoia, paresis, peptic ulcer, petechiae, pituitary apoplexy, pneumothorax, pulmonary hypertension, pulmonary nodule, Raynaud's syndrome, renal insufficiency, retinal vein thrombosis, rhinorrhea, scotoma, seizure, status asthmaticus, suicide attempt, throat discomfort, thrombocytopenia, thrombophlebitis, thrombosis, vaginitis, visual field defect, wheal/erythema

Pharmacodynamics/Kinetics

Duration: SubQ: 6-12 hours

Absorption: SubQ: Rapid

Distribution: V_d: 14 L (13-30 L in acromegaly)

Protein binding: 65%, mainly to lipoprotein (41% in acromegaly)

Metabolism: Extensively hepatic

Bioavailability: SubQ: 100%; I.M.: 60% to 63% of SubQ dose

Half-life elimination: 1.7-1.9 hours; up to 3.7 hours with cirrhosis

Time to peak, plasma: SubQ: 0.4 hours (0.7 hours acromegaly); I.M.: 1 hour

Excretion: Urine (32%)

Dosage

Infants and Children:

Secretory diarrhea (unlabeled use): I.V., SubQ: Doses of 1-10 mcg/kg every 12 hours have been used in children beginning at the low end of the range and increasing by 0.3 mcg/kg/dose at 3-day intervals.

Suppression of growth hormone (animal data) is of concern when used as long-term therapy.

Congenital hyperinsulinism (unlabeled use): SubQ: Doses of 3-40 mcg/kg/day have been used

Adults: SubQ, I.V.: Initial: 50 mcg 2 to 4 times/day and titrate dose based on patient tolerance, response, and indication

For sulfonyleurea overdose: Adults 50 to 100 mcg SQ every 6 hours; Children: 1 to 1.5 mcg per kg every 6 hours SQ.

Carcinoid: Initial 2 weeks: 100-600 mcg/day in 2-4 divided doses; usual range 50-1500 mcg/day

VIPomas: Initial 2 weeks: 200-300 mcg/day in 2-4 divided doses; usual range 150-750 mcg/day

Diarrhea (unlabeled use): Initial: I.V.: 50-100 mcg every 8 hours; increase by 100 mcg/dose at 48-hour intervals; maximum dose: 500 mcg every 8 hours

Esophageal varices bleeding (unlabeled use): I.V. bolus: 25-50 mcg followed by continuous I.V. infusion of 25-50 mcg/hour

Acromegaly: Initial: SubQ: 50 mcg 3 times/day; titrate to achieve growth hormone levels <5 ng/mL or IGF-I (somatomedin C) levels <1.9 U/mL in males and <2.2 U/mL in females; usual effective dose 100 mcg 3 times/day; range 300-1500 mcg/day

Note: Should be withdrawn yearly for a 4-week interval (8 weeks for depot injection) in patients who have received irradiation. Resume if levels increase and signs/symptoms recur.

Acromegaly, carcinoid tumors, and VIPomas (depot injection): Patients must be stabilized on subcutaneous octreotide for at least 2 weeks before switching to the long-acting depot: Upon switch: 20 mg I.M. intragluteally every 4 weeks for 2-3 months, then the dose may be modified based upon response. Patients receiving depot injection for carcinoid tumor or VIPoma should continue to receive their SubQ injections for the first 2 weeks at the same dose in order to maintain therapeutic levels.

Dosage adjustment for acromegaly: After 3 months of depot injections the dosage may be continued or modified as follows:

GH ≤2.5 ng/mL, IGF-1 is normal, symptoms controlled: Maintain octreotide LAR[®] at 20 mg I.M. every 4 weeks

OXYGEN (HYPERBARIC)

GH >2.5 ng/mL, IGF-1 is elevated, and/or symptoms uncontrolled: Increase octreotide LAR[®] to 30 mg I.M. every 4 weeks

GH ≤1 ng/mL, IGF-1 is normal, symptoms controlled: Reduce octreotide LAR[®] to 10 mg I.M. every 4 weeks

Note: Patients not adequately controlled may increase dose to 40 mg every 4 weeks. Dosages >40 mg are not recommended

Dosage adjustment for carcinoid tumors and VIPomas: After 2 months of depot injections the dosage may be continued or modified as follows:

Increase to 30 mg I.M. every 4 weeks if symptoms are inadequately controlled

Decrease to 10 mg I.M. every 4 weeks, for a trial period, if initially responsive to 20 mg dose

Dosage >30 mg is not recommended

Elderly: Elimination half-life is increased by 46% and clearance is decreased by 26%; dose adjustment may be required.

Dosage adjustment in renal impairment: Severe renal failure requiring dialysis: Clearance is reduced by ~50%; specific dosing guidelines not available

Monitoring Parameters

Acromegaly: Growth hormone, somatomedin C (IGF-1)

Carcinoid: 5-HIAA, plasma serotonin and plasma substance P

VIPomas: Vasoactive intestinal peptide

Chronic therapy: Thyroid function (baseline and periodic), vitamin B₁₂ level, blood glucose, cardiac function (heart rate, EKG)

Administration

Regular injection formulation (do not use if solution contains particles or is discolored): Administer SubQ or I.V.; I.V. administration may be IVP, IVPB, or continuous I.V. infusion:

IVP should be administered undiluted over 3 minutes

IVPB should be administered over 15-30 minutes

Continuous I.V. infusion rates have ranged from 25-50 mcg/hour for the treatment of esophageal variceal bleeding

Depot formulation: Administer I.M. intragluteal (avoid deltoid administration); alternate gluteal injection sites to avoid irritation. Do not administer Sandostatin LAR[®] intravenously or subcutaneously; must be administered immediately after mixing.

Contraindications Hypersensitivity to octreotide or any component of the formulation

Warnings May impair gall bladder function; monitor patients for cholelithiasis. Use with caution in patients with renal impairment. Somatostatin analogs may affect glucose regulation; in type I diabetes, severe hypoglycemia may occur; in type II diabetes or nondiabetic patients, hyperglycemia may occur. Insulin and other hypoglycemic medication requirements may change. Bradycardia, conduction abnormalities, and arrhythmia have been observed in acromegalic patients; use caution with CHF or concomitant medications that alter heart rate or rhythm. May alter absorption of dietary fats; monitor for pancreatitis. Chronic treatment has been associated with abnormal Schillings test; monitor vitamin B₁₂ levels. Tumors which secrete growth hormone may increase in size; monitor. Suppresses secretion of TSH; monitor for hypothyroidism.

Dosage Forms

Injection, microspheres for suspension, as acetate [depot formulation]:

Sandostatin LAR[®]: 10 mg, 20 mg, 30 mg [with diluent and syringe]

Injection, solution, as acetate: 0.2 mg/mL (5 mL); 1 mg/mL (5 mL)

Sandostatin[®]: 0.2 mg/mL (5 mL); 1 mg/mL (5 mL)

Injection, solution, as acetate [preservative free]: 0.05 mg/mL (1 mL); 0.1 mg/mL (1 mL); 0.5 mg/mL (1 mL)

Sandostatin[®]: 0.05 mg/mL (1 mL); 0.1 mg/mL (1 mL); 0.5 mg/mL (1 mL)

Reference Range Peak plasma octreotide after 200 mcg I.V. and SubQ doses: ~27.8 ng/mL and 10.6 ng/mL, respectively

Test Interactions May interfere with the TSH assay, resulting in falsely low TSH levels

Drug Interactions

Bromocriptine: Bioavailability of bromocriptine may be increased by octreotide.

Cyclosporine: Case reports of transplant rejection due to reduction of serum cyclosporine levels when cyclosporine was given orally in conjunction with a somatostatin analogue.

QT_c-prolonging agents: Octreotide may enhance the adverse/toxic effects of other QT_c-prolonging agents. Use with caution; monitor.

Pregnancy Risk Factor B

Pregnancy Implications Teratogenic effects were not reported in animal studies. Octreotide crosses the human placenta; data concerning use in pregnancy is limited.

Lactation Excretion in breast milk unknown/use caution

Oxygen (Hyperbaric)

Use Carbon monoxide, carbon tetrachloride, cyanide, hydrocarbon, hydrogen sulfide, methylene chloride, mushroom (*Amanita* toxin), brown recluse spider bite, chloroform; also decompression sickness, air emboli, and anaerobic infections

Unlabeled/Investigational Use May also be useful in methemoglobinemia; treatment of helium-induced embolism; to treat ergotamine-induced peripheral ischemia; useful for necrotic arachnidism caused by *Lampona cylindrata* (spider found in Australia); radiation-related bone and soft tissue complications (osteoradionecrosis); gas gangrene

Mechanism of Action Displaces carbon monoxide from binding sites and increases elimination rate; also alleviates cerebral edema and CO-induced peroxidation

Adverse Reactions

Ocular: Temporary visual deficits, vision color changes (increased color perception), retinal vessel narrowing

Otic: Otic discomfort, ruptured tympanic membranes

Miscellaneous: Barotrauma to CNS or lung and seizures are reported with prolonged durations (greater than those used for CO poisoning)

Dosage 2.5-3 atmospheres

Reference Range Concentrations of CO >30% in nonpregnant patients or >20% in pregnant patients are indications for treatment

Pregnancy Risk Factor No data reported

Pregnancy Implications Well tolerated in the treatment of carbon monoxide and indicated for the treatment of pregnant patients when symptomatic or with carboxyhemoglobin levels >20%

Penicillamine

Pronunciation (pen i SIL a meen)

CAS Number 2219-30-9; 52-67-5; 59-53-0

U.S. Brand Names Cuprimine[®]; Depen[®]

Synonyms D-3-Mercaptovaline; D-Penicillamine; β,β-Dimethylcysteine

Use Treatment of Wilson's disease, cystinuria, adjunct in the treatment of rheumatoid arthritis

Unlabeled/Investigational Use Lead, mercury, copper, arsenic, and possibly gold poisoning (**Note:** Oral succimer [DMSA] is preferable for lead or mercury poisoning)

Mechanism of Action Chelates with lead, copper, mercury, iron, and other heavy metals to form stable, soluble complexes that are excreted in urine; depresses circulating IgM rheumatoid factor, depresses T-cell but not B-cell activity; combines with cystine to form a compound which is more soluble, thus cystine calculi are prevented

Adverse Reactions

Cardiovascular: Edema of the feet, or lower legs; periarteritis nodosa, AV block, facial edema, vasculitis

Central nervous system: **Fever**, seizures, chills, tiredness, dysphoria, dysosmia, Guillain-Barré syndrome, sedation, extrapyramidal reactions, agitation, anxiety, dystonia, mental disorders

Dermatologic: **Rash**, pemphigus, increased friability of the skin, hirsutism, epidural necrosis, **hives**, **itching**, psoriasiform eruptions, fingernail discoloration (yellow), fingernail dystrophy, lichenoid eruptions, scleroderma, seborrheic dermatitis, skin discoloration (yellow), **urticaria**, vitiligo, bullous pemphigoid, exfoliative dermatitis, alopecia, toxic

epidermal necrolysis, xerosis, purpura, erythema nodosum, exanthem, cutaneous vasculitis

Endocrine & metabolic: Iron deficiency, gynecomastia, hyperglycemia, insulin antibody formation, Hashimoto's disease, Graves' disease, autoimmune thyroid disease, thyroiditis, thymoma, breast enlargement (3-18 months)

Gastrointestinal: Oral lesions, diarrhea, colitis, nausea, vomiting, **hypogeusia**, anorexia, weight gain, sore throat, metallic taste, altered taste, stomatitis, salt hypogeusia, aphthous stomatitis

Genitourinary: Bloody and cloudy urine

Hematologic: Leukopenia, thrombocytopenia (12% to 27% in patients with rheumatoid arthritis), eosinophilia, aplastic anemia, hemolytic anemia, lymphopenia, sideroblastic anemia, neutropenia, agranulocytosis

Hepatic: Hepatic dysfunction

Neuromuscular & skeletal: **Arthralgia**, myasthenia gravis, polymyositis (dermatomyositis), myositis, weakness, peripheral sensory and motor neuropathies, myasthenic syndrome, dysarthria, myalgia, tremor

Ocular: Optic neuritis, ptosis, diplopia, retinopathy, photophobia, ophthalmoplegia

Otic: Tinnitus

Renal: Nephrotic syndrome, renal vasculitis, hematuria, glomerulonephritis, Goodpasture-like syndrome, albuminuria

Respiratory: Obliterative bronchiolitis, pulmonary fibrosis, interstitial pneumonitis, coughing or wheezing, rhinitis, pleural effusion, alveolar hemorrhage, pulmonary hemorrhage, bronchiolitis obliterans organizing pneumonia, asthma, eosinophilic pneumonia, pulmonary vasculitis

Miscellaneous: Lymphadenopathy, allergic reactions, SLE-like syndrome, white spots on lips or mouth, elevated antineutrophilic cytoplasmic antibodies (ANCA)

Signs and Symptoms of Overdose Acrodynia, agitation, dysphagia, hemoptysis, hypertrichosis, nausea, seizures, vomiting

Pharmacodynamics/Kinetics

Onset of action: Rheumatoid arthritis: 2-3 months; Wilson's disease: 1-3 months

Absorption: 40% to 70%

Protein binding: 80% to albumin

Metabolism: Hepatic (small amounts)

Half-life elimination: 1.7-3.2 hours

Time to peak, serum: ~2 hours

Excretion: Urine (30% to 60% as unchanged drug)

Dosage

Oral:

Rheumatoid arthritis:

Children: Initial: 3 mg/kg/day (≤ 250 mg/day) for 3 months, then 6 mg/kg/day (≤ 500 mg/day) in divided doses twice daily for 3 months to a maximum of 10 mg/kg/day in 3-4 divided doses

Adults: 125-250 mg/day, may increase dose at 1- to 3-month intervals up to 1-1.5 g/day

Wilson's disease (doses titrated to maintain urinary copper excretion > 1 mg/day):

Infants < 6 months: 250 mg/dose once daily

Children < 12 years: 250 mg/dose 2-3 times/day

Adults: 250 mg 4 times/day

Cystinuria:

Children: 30 mg/kg/day in 4 divided doses

Adults: 1-4 g/day in divided doses every 6 hours

Lead poisoning (unlabeled use): In acute poisoning, continue until blood lead level is < 15 mcg/dL; may also be used in other heavy metal poisoning:

Children: 25-35 mg/kg/day, administered in 3-4 divided doses; initiating treatment at 25% of this dose and gradually increasing to the full dose over 2-3 weeks may minimize adverse reactions

Adults: 250-500 mg/dose every 8-12 hours

Primary biliary cirrhosis: 250 mg/day to start, increase by 250 mg every 2 weeks up to a maintenance dose of 1 g/day, usually given 250 mg 4 times/day

Arsenic poisoning: Children: 100 mg/kg/day in divided doses every 6 hours for 5 days; maximum: 1 g/day

Dosing adjustment/comments in renal impairment: $Cl_{cr} < 50$ mL/minute: Avoid use

Stability Store in tight, well-closed containers

Monitoring Parameters

Urinalysis, CBC with differential, platelet count (twice weekly); weekly measurements of urinary and blood concentration of the intoxicating metal is indicated (3 months has been tolerated). In Wilson's disease, liver function tests should be monitored every 3 months during the first year of treatment.

CBC: WBC $< 3500/mm^3$, neutrophils $< 2000/mm^3$ or monocytes $> 500/mm^3$ indicate need to stop therapy immediately; quantitative 24-hour urine protein at 1- to 2-week intervals initially (first 2-3 months); urinalysis, LFTs occasionally; platelet counts $< 100,000/mm^3$ indicate need to stop therapy until numbers of platelets increase

Administration

For patients who cannot swallow, contents of capsules may be administered in 15-30 mL of chilled puréed fruit or fruit juice. Give on an empty stomach (1 hour before meals and at bedtime).

Cystinuria: If administering 4 equal doses is not feasible, administer the larger dose at bedtime.

Rheumatoid arthritis: Doses ≤ 500 mg/day may be given as a single dose; > 500 mg administer in divided doses

Contraindications Hypersensitivity to penicillamine or any component of the formulation; renal insufficiency (in patients with rheumatoid arthritis); patients with previous penicillamine-related aplastic anemia or agranulocytosis; breast-feeding; pregnancy (in patients with rheumatoid arthritis)

Warnings Cross-sensitivity with penicillin is possible; therefore, should be used cautiously in patients with a history of penicillin allergy. Once instituted for Wilson's disease or cystinuria, continue treatment on a daily basis; interruptions of even a few days have been followed by hypersensitivity with reinstitution of therapy. Penicillamine has been associated with fatalities due to agranulocytosis, aplastic anemia, thrombocytopenia, Goodpasture's syndrome, and myasthenia gravis. **[U.S. Boxed Warning]: Patients should be warned to report promptly any symptoms suggesting toxicity (fever, sore throat, chills, bruising, or bleeding);** approximately 33% of patients will experience an allergic reaction; toxicity may be dose related, use caution in the elderly. Use caution with other hematopoietic-depressant drugs (eg, gold, immunosuppressants, antimalarials, phenylbutazone); hematologic and renal adverse reactions are similar. Proteinuria or hematuria may develop; monitor for membranous glomerulopathy which can lead to nephrotic syndrome. In rheumatoid arthritis patients, discontinue if gross hematuria or persistent microscopic hematuria develop. Monitor liver function tests periodically due to rare reports of intrahepatic cholestasis or toxic hepatitis. **[U.S. Boxed Warning]: Should be administered under the close supervision of a physician familiar with the toxicity and dosage considerations.**

Dosage Forms

[DSC] = Discontinued product

Capsule (Cuprimine[®]): 125 mg [DSC], 250 mg

Tablet (Depen[®]): 250 mg

Test Interactions Positive ANA

Drug Interactions

Antacids: May decrease the effects of penicillamine.

Digoxin: Penicillamine may decrease the levels of digoxin; monitor.

Iron salts: May decrease the effects of penicillamine.

Pregnancy Risk Factor D

Pregnancy Implications Correlated with cutis laxa in neonates

Lactation Excretion in breast milk unknown/contraindicated

Nursing Implications For patients who cannot swallow, contents of capsules may be administered in 15-30 mL of chilled puréed fruit or fruit juice; patients should be warned to report promptly any symptoms suggesting toxicity

Phentolamine

Pronunciation (fen TOLE a meen)

CAS Number 65-28-1

U.S. Brand Names Regitine[®]

Synonyms Phentolamine Mesylate; Regitine [DSC]

Use Diagnosis of pheochromocytoma and treatment of hypertension associated with pheochromocytoma or other forms of hypertension caused by excess sympathomimetic amines; as treatment of dermal necrosis after extravasation of drugs with alpha-adrenergic effects (norepinephrine, dopamine, epinephrine); may reverse cocaine-induced coronary artery vasoconstriction.

Unlabeled/Investigational Use Treatment of pralidoxime-induced hypertension

Mechanism of Action Competitively blocks alpha-adrenergic receptors to produce brief antagonism of circulating epinephrine and norepinephrine to reduce hypertension caused by these catecholamines; no inotropic activity

Adverse Reactions

Cardiovascular: **Reflex tachycardia, anginal pain**, myocardial infarction, **hypotension (orthostatic)**, tachycardia, chest pain, facial flushing, pulmonary hypertension, sinus tachycardia, vasodilation

Central nervous system: Fainting, severe headache

Endocrine & metabolic: Hypocalcemia, can precipitate disulfiram-like reaction with ethanol

Gastrointestinal: **Nausea, abdominal pain, diarrhea, vomiting, exacerbation of peptic ulcer**, decreased esophageal sphincter tone

Genitourinary: Priapism with injection into corpus cavernosum

Neuromuscular & skeletal: Weakness

Respiratory: **Nasal congestion**

Pharmacodynamics/Kinetics

Onset of action: I.M.: 15-20 minutes; I.V.: Immediate

Duration: I.M.: 30-45 minutes; I.V.: 15-30 minutes

Metabolism: Hepatic

PHYSOSTIGMINE

Half-life elimination: 19 minutes
Excretion: Urine (10% as unchanged drug)

Dosage

Treatment of alpha-adrenergic drug extravasation: SubQ:
Children: 0.1-0.2 mg/kg diluted in 10 mL 0.9% sodium chloride infiltrated into area of extravasation within 12 hours
Adults: Infiltrate area with small amount of solution made by diluting 5-10 mg in 10 mL 0.9% sodium chloride within 12 hours of extravasation; do not exceed 0.1-0.2 mg/kg or 5 mg total
If dose is effective, normal skin color should return to the blanched area within 1 hour

Diagnosis of pheochromocytoma: I.M., I.V.:

Children: 0.05-0.1 mg/kg/dose, maximum single dose: 5 mg
Adults: 5 mg

Surgery for pheochromocytoma: Hypertension: I.M., I.V.:

Children: 0.05-0.1 mg/kg/dose given 1-2 hours before procedure; repeat as needed every 2-4 hours until hypertension is controlled; maximum single dose: 5 mg
Adults: 5 mg given 1-2 hours before procedure and repeated as needed every 2-4 hours

Hypertensive crisis: Adults: 5-20 mg
Treatment of pralidoxime-induced hypertension (unlabeled use): I.V.:

Children: 1 mg
Adults and Elderly: 5 mg

Reverse cocaine-induced cardiac vasoconstriction: Titrate in 1 mg doses
Treatment of opioid-induced acute gastroparesis: 0.5 mg/kg I.V. over sixty minutes

Stability Reconstituted solution is stable for 48 hours at room temperature and 1 week when refrigerated

Monitoring Parameters Blood pressure, heart rate; area of infiltration

Administration Treatment of extravasation: Infiltrate area of extravasation with multiple small injections; use 27- or 30-gauge needles and change needle between each skin entry

Contraindications Hypersensitivity to phentolamine or any component of the formulation; renal impairment; coronary or cerebral arteriosclerosis; concurrent use with phosphodiesterase-5 (PDE-5) inhibitors including sildenafil (> 25 mg), tadalafil, or vardenafil

Warnings Myocardial infarction, cerebrovascular spasm and cerebrovascular occlusion have occurred following administration. Use with caution in patients with gastritis or peptic ulcer, tachycardia, or a history of cardiac arrhythmias.

Dosage Forms Injection, powder for reconstitution, as mesylate: 5 mg

Test Interactions ↑ LFTs, rarely

Drug Interactions

Epinephrine, ephedrine: Effects may be decreased.

Ethanol: Increased toxicity (disulfiram reaction).

Sildenafil, tadalafil, vardenafil: Blood pressure-lowering effects are additive. Use of tadalafil or vardenafil is contraindicated by the manufacturer. Use sildenafil with extreme caution (dose ≤ 25 mg).

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Nursing Implications Infiltrate the area of dopamine extravasation with multiple small injections using only 27- or 30-gauge needles and changing the needle between each skin entry; take care not to cause so much swelling of the extremity or digit that a compartment syndrome occurs; monitor patient for orthostasis; assist with ambulation

Physostigmine

Pronunciation (fye zoe STIG meen)

Related Information

- Toxins Which Should Be Lavaged with Solutions Other Than Water

CAS Number 57-47-6; 57-64-7; 64-47-1

U.S. Brand Names Antilirium®

Synonyms Eserine Salicylate; Physostigmine Salicylate; Physostigmine Sulfate

Use Second-line agent for envenomation of Asian snakes or intoxication with tetrodotoxin exposures if edrophonium supplies are depleted; reverse toxic CNS effects caused by anticholinergic drugs; controversial role for baclofen, and tricyclic antidepressant toxicity

Mechanism of Action Inhibits destruction of acetylcholine by acetylcholinesterase which facilitates transmission of impulses across myoneural junction

Adverse Reactions

Cardiovascular: Palpitations, bradycardia
Central nervous system: Restlessness, nervousness, hallucinations, seizures
Gastrointestinal: Nausea, salivation, diarrhea, stomach pains
Genitourinary: Frequent urge to urinate
Neuromuscular & skeletal: Muscle twitching

Ocular: Lacrimation, miosis

Respiratory: Dyspnea, bronchospasm, respiratory paralysis, pulmonary edema

Miscellaneous: Diaphoresis

Signs and Symptoms of Overdose Blurred vision, excessive sweating, fasciculations, hallucinations, hypertension, laryngospasm, muscle weakness, nausea, seizures, tearing and salivation, vomiting

Pharmacodynamics/Kinetics

Onset of action: ~5 minutes

Duration: 0.5-5 hours

Absorption: I.M., SubQ: Readily absorbed

Distribution: Crosses blood-brain barrier readily and reverses both central and peripheral anticholinergic effects

Metabolism: Hepatic and via hydrolysis by cholinesterases

Half-life elimination: 15-40 minutes

Dosage

Children: Anticholinergic drug overdose: Reserve for life-threatening situations only: I.V.: 0.01-0.03 mg/kg/dose (maximum: 0.5 mg/minute); may repeat after 5-10 minutes to a maximum total dose of 2 mg or until response occurs or adverse cholinergic effects occur
Adults: Anticholinergic drug overdose:

I.M., I.V., SubQ: 0.5-2 mg to start, repeat every 20 minutes until response occurs or adverse effect occurs

Repeat 1-4 mg every 30-60 minutes as life-threatening signs (arrhythmias, seizures, deep coma) recur; maximum I.V. rate: 1 mg/minute

Stability Do not use solution if cloudy or dark brown

Monitoring Parameters Heart rate, respiratory rate

Administration Injection: Infuse slowly I.V. at a maximum rate of 0.5 mg/minute in children or 1 mg/minute in adults. Too rapid administration (I.V. rate not to exceed 1 mg/minute) can cause bradycardia, hypersalivation leading to respiratory difficulties and seizures.

Contraindications Hypersensitivity to physostigmine or any component of the formulation; GI or GU obstruction; physostigmine therapy of drug intoxications should be used with extreme caution in patients with asthma, gangrene, severe cardiovascular disease, or mechanical obstruction of the GI tract or urogenital tract. In these patients, physostigmine should be used only to treat life-threatening conditions.

Warnings Use with caution in patients with epilepsy, asthma, diabetes, gangrene, cardiovascular disease, bradycardia. Discontinue if excessive salivation or emesis, frequent urination or diarrhea occur. Reduce dosage if excessive sweating or nausea occurs. Administer I.V. slowly or at a controlled rate not faster than 1 mg/minute. Due to the possibility of hypersensitivity or overdose/cholinergic crisis, atropine should be readily available; not intended as a first-line agent for anticholinergic toxicity or Parkinson's disease.

Dosage Forms Injection, solution, as salicylate: 1 mg/mL (2 mL [contains benzyl alcohol and sodium metabisulfite])

Reference Range Fifteen minutes after a 2 mg oral dose of physostigmine salicylate, plasma level was reported as 1.03 ng/mL

Test Interactions ↑ aminotransferase [ALT (SGPT)/AST (SGOT)] (S), amylase (S); ↑ serum cortisol, prolactin, and epinephrine levels

Drug Interactions Increased toxicity: Bethanechol, methacholine, succinylcholine may increase neuromuscular blockade with systemic administration

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Phytonadione

Pronunciation (fye toe na DYE one)

CAS Number 84-80-0

U.S. Brand Names AquaMEPHYTON® [DSC]; Mephyton®

Synonyms Methylphytyl Naphthoquinone; Phylloquinone; Phytomenadione; Vitamin K₁

Use Prevention and treatment of hypoprothrombinemia caused by drug-induced or anticoagulant-induced vitamin K deficiency, hemorrhagic disease of the newborn; phytonadione is more effective and is preferred to other vitamin K preparations in the presence of impending hemorrhage; oral absorption depends on the presence of bile salts

Mechanism of Action Promotes liver synthesis of clotting factors (II, VII, IX, X)

Adverse Reactions

Cardiovascular: Acrocyanosis
Dermatologic: Scleroderma, eczematous dermatitis (following subcutaneous administration)
Gastrointestinal: GI upset
Local: Pain, swelling, tenderness at injection site
Miscellaneous: Acrosclerosis

Signs and Symptoms of Overdose Hemiplegia

Pharmacodynamics/Kinetics

Onset of action: Increased coagulation factors: Oral: 6-10 hours; I.V.: 1-2 hours

Peak effect: INR values return to normal: Oral: 24-48 hours; I.V.: 12-14 hours. Half life is 2 hours

Absorption: Oral: From intestines in presence of bile; SubQ: Variable

Metabolism: Rapidly hepatic

Excretion: Urine and feces

Dosage

SubQ is the preferred (per manufacturer) parenteral route; I.V. route should be restricted for emergency use only

Minimum daily requirement: Not well established

Infants: 1-5 mcg/kg/day

Adults: 0.03 mcg/kg/day

Hemorrhagic disease of the newborn:

Prophylaxis: I.M.: 0.5-1 mg within 1 hour of birth

Treatment: I.M., SubQ: 1-2 mg/dose/day

Oral anticoagulant overdose:

Infants and Children:

No bleeding, rapid reversal needed, patient **will require** further oral anticoagulant therapy: SubQ, I.V.: 0.5-2 mg

No bleeding, rapid reversal needed, patient **will not require** further oral anticoagulant therapy: SubQ, I.V.: 2-5 mg

Significant bleeding, not life-threatening: SubQ, I.V.: 0.5-2 mg

Significant bleeding, life-threatening: I.V.: 5 mg over 10-20 minutes

Adults: Oral, I.V., SubQ: 1-10 mg/dose depending on degree of INR elevation

Serious bleeding or major overdose: 10 mg I.V. (slow infusion); may repeat every 12 hours (have required doses up to 25 mg)

Vitamin K deficiency: Due to drugs, malabsorption, or decreased synthesis of vitamin K

Infants and Children:

Oral: 2.5-5 mg/24 hours

I.M., I.V., SubQ: 1-2 mg/dose as a single dose

Adults:

Oral: 5-25 mg/24 hours

I.M., I.V., SubQ: 10 mg

For Rodenticide (long-acting anti-coagulants) (oral): 15 to 600 mg per day divided every 6 to 12 hours. If INR > 5, Begin with an oral dose of fifty mg and then titrate with 9 to 12 hours dosing. May require weeks to months of therapy.

Stability Protect injection from light at all times; may be autoclaved

Monitoring Parameters

Administration I.V. administration: Dilute in normal saline, D₅W or D₅NS and infuse slowly; rate of infusion should not exceed 1 mg/minute. **This route should be used only if administration by another route is not feasible.** The parenteral preparation has been administered orally to neonates. I.V. administration should not exceed 1 mg/minute; for I.V. infusion, dilute in PF (preservative free) D₅W or normal saline.

Contraindications Hypersensitivity to phytonadione or any component of the formulation

Warnings

Allergic reactions (injectable): [U.S. Boxed Warning]: Severe reactions resembling hypersensitivity (eg, anaphylaxis) reactions have occurred rarely during or immediately after I.V. administration (even with proper dilution and rate of administration). Allergic reactions have also occurred with I.M. and SubQ injections.

Route: Oral administration is the safest and requires the presence of bile salts for absorption. In obstructive jaundice or with biliary fistulas, concurrent administration of bile salts would be necessary for proper absorption. Manufacturers recommend the SubQ route over other parenteral routes, however, SubQ is less predictable when compared to the oral route, and efficacy may be delayed. The American College of Chest Physicians recommends the I.V. route in patients with serious or life-threatening bleeding secondary to use of vitamin K antagonists such as warfarin. The I.V. route should be restricted to emergency situations only where oral phytonadione cannot be used. Efficacy (eg, control of bleeding, decrease in INR) is delayed regardless of route of administration; patient management may require other treatments in the interim.

Reversing anticoagulant induced hypoprothrombinemia: Administer a dose that will quickly lower the INR into a safe range without causing resistance to warfarin. High phytonadione doses may lead to warfarin resistance for at least one week.

Newborns: Use caution in newborns, especially premature infants; hemolysis, jaundice, and hyperbilirubinemia have been reported with larger than recommended doses. Some dosage forms contain benzyl alcohol which has been associated with "gaspings syndrome" in premature infants.

Hypoprothrombinemia caused by liver disease: If initial doses do not reverse coagulopathy, then higher doses are unlikely to have any effect.

Note: Ineffective in hereditary hypoprothrombinemia.

Renal dysfunction: Use caution with renal dysfunction (including premature infants). Injectable products may contain aluminum; may result in toxic levels following prolonged administration.

Dosage Forms

Injection, aqueous colloidal: 2 mg/mL (0.5 mL); 10 mg/mL (1 mL) [contains benzyl alcohol]

Tablet: 5 mg

Reference Range Normal range: 0.09-2.12 mcg/L

Drug Interactions

Coumarin derivatives: Phytonadione may diminish the anticoagulant effect; monitor INR.

Orlistat: Phytonadione (oral) may not be properly absorbed when administered concurrently; separate doses by at least 2 hours.

Pregnancy Risk Factor

Lactation Enters breast milk/use caution (APP rates "compatible")

Nursing Implications I.V. administration: Dilute in normal saline, D₅W or D₅NS and infuse slowly; rate of infusion should not exceed 1 mg/minute.

This route should be used only if administration by another route is not feasible. The parenteral preparation has been administered orally to neonates. I.V. administration should not exceed 1 mg/minute; for I.V. infusion, dilute in PF (preservative free) D₅W or normal saline.

Additional Information Coagulation factors increase within 3 to 6 hours after I.V. administration and 6 to 12 hours after oral administration.

Polyethylene Glycol - High Molecular Weight

Pronunciation (pol i ETH i leen GLY kol ee LEK troe lite soe LOO shun)

CAS Number 25322-68-3

U.S. Brand Names Colyte®; GoLYTELY®; MiraLax™; NuLytely®; Tri-Lyte™

Synonyms Electrolyte Lavage Solution

Use Whole bowel irrigation in acute overdoses of iron, zinc sulfate, lead oxide, lithium, ampicillin, heavy metals, "body packers"; sustained release medications; also used in bowel cleansing procedures

Mechanism of Action Nonabsorbable agent which increases bowel osmotic pressure

Adverse Reactions

Cardiovascular: Ectopy (ventricular)

Central nervous system: Coma

Dermatologic: Nonimmunologic contact urticaria, systemic contact dermatitis, immunologic contact urticaria

Endocrine & metabolic: Metabolic acidosis, hypercalcemia

Gastrointestinal: **Nausea**, diarrhea, **abdominal fullness, bloating**, vomiting, taste disturbance

Pharmacodynamics/Kinetics Onset of effect: Oral: ~1-2 hours

Dosage

For gastrointestinal decontamination:

Oral: Children and Adults: 15-60 mL/kg/hour until clear rectal effluent appears; rate nearly universally requires a naso- or orogastric tube

Nasogastric tube: Administer through a #12 French nasogastric tube with head of bed elevated at least 45°

Children: 9 months to 6 years: 500 mL/hour

Children: 6-12 years: 1000 mL/hour

Adolescents and Adults: 1500-2000 mL/hour

If emesis occurs, decrease infusion rate by 50% for up to 1 hour and then return to the original rate. Metoclopramide can be utilized as an antiemetic and promotility agent (10 mg I.V. initial dose, with 10 mg I.V. in 8 hours with erythromycin 250 mg I.V.)

Monitoring Parameters Electrolytes, serum glucose, BUN, urine osmolality; children <2 years of age should be monitored for hypoglycemia, dehydration, hypokalemia

POTASSIUM IODIDE

Administration Oral: Rapid drinking of each portion is preferred to drinking small amounts continuously. Do not add flavorings as additional ingredients before use. Chilled solution often more palatable.

Contraindications Hypersensitivity to polyethylene glycol or any component of the formulation; gastrointestinal obstruction, gastric retention, bowel perforation, toxic colitis, megacolon

Warnings Do not add flavorings as additional ingredients before use; observe unconscious or semiconscious patients with impaired gag reflex or those who are otherwise prone to regurgitation or aspiration during administration; use with caution in ulcerative colitis, caution against the use of hot loop polypectomy. Evaluate patients with symptoms of bowel obstruction (nausea, vomiting, abdominal pain or distension) prior to use.

Dosage Forms

Powder, for oral solution: PEG 3350 240 g, sodium sulfate 22.72 g, sodium bicarbonate 6.72 g, sodium chloride 5.84 g, and potassium chloride 2.98 g (4000 mL)

Colyte®:

PEG 3350 240 g, sodium sulfate 22.72 g, sodium bicarbonate 6.72 g, sodium chloride 5.84 g, and potassium chloride 2.98 g (4000 mL) [available with citrus berry, lemon lime, cherry, and pineapple flavor packets]

PEG 3350 227.1 g, sodium sulfate 21.5 g, sodium bicarbonate 6.36 g, sodium chloride 5.53 g, and potassium chloride 2.82 g (4000 mL) [regular and pineapple flavor]

GoLyte®:

Disposable jug: PEG 3350 236 g, sodium sulfate 22.74 g, sodium bicarbonate 6.74 g, sodium chloride 5.86 g, and potassium chloride 2.97 g (4000 mL) [regular and pineapple flavor]

Packets: PEG 3350 227.1 g, sodium sulfate 21.5 g, sodium bicarbonate 6.36 g, sodium chloride 5.53 g, and potassium chloride 2.82 g (4000 mL) [regular flavor]

NuLyte®: PEG 3350 420 g, sodium bicarbonate 5.72 g, sodium chloride 11.2 g, and potassium chloride 1.48 (4000 mL) [cherry, lemon-lime, and orange flavors]

TriLyte™: PEG 3350 420 g, sodium bicarbonate 5.72 g, sodium chloride 11.2 g, and potassium chloride 1.48 (4000 mL) [supplied with flavor packets]

Drug Interactions Oral medications should not be administered within 1 hour of start of therapy

Pregnancy Risk Factor C

Pregnancy Implications Reproduction studies have not been conducted in animals or in humans.

Lactation Excretion in breast milk unknown/use caution

Adverse Reactions

Central nervous system: Fever, headache

Dermatologic: Urticaria, acne, angioedema, cutaneous hemorrhage

Endocrine & metabolic: Goiter with hypothyroidism, parotitis

Gastrointestinal: Metallic taste, GI upset, soreness of teeth and gums

Hematologic: Eosinophilia, hemorrhage (mucosal)

Neuromuscular & skeletal: Arthralgia

Respiratory: Rhinitis

Miscellaneous: Lymph node enlargement

Signs and Symptoms of Overdose Angioedema, laryngeal edema

Pharmacodynamics/Kinetics

Onset of action: Hyperthyroidism: 24-48 hours

Peak effect: 10-15 days after continuous therapy

Duration: Radioactive iodine exposure: ~24 hours

Dosage

Oral:

Adults: RDA: 150 mcg (iodide)

Expectorant:

Children (Pima®):

<3 years: 162 mg 3 times day

>3 years: 325 mg 3 times/day

Adults:

Pima®: 325-650 mg 3 times/day

SSKI®: 300-600 mg 3-4 times/day

Preoperative thyroidectomy: Children and Adults: 50-250 mg (1-5 drops

SSKI®) 3 times/day or 0.1-0.3 mL (3-5 drops) of strong iodine (Lugol's

solution) 3 times/day; administer for 10 days before surgery

Radiation protectant to radioactive isotopes of iodine (Pima®):

Children:

Infants up to 1 year: 65 mg once daily for 10 days; start 24 hours prior to exposure

>1 year: 130 mg once daily for 10 days; start 24 hours prior to exposure

Adults: 195 mg once daily for 10 days; start 24 hours prior to exposure

To reduce risk of thyroid cancer following nuclear accident (dosing should continue until risk of exposure has passed or other measures are implemented):

Children (see adult dose for children >68 kg):

Infants <1 month: 16 mg once daily

1 month to 3 years: 32 mg once daily

3-18 years: 65 mg once daily

Children >68 kg and Adults (including pregnant/lactating women): 130 mg once daily

Thyrotoxic crisis:

Infants <1 year: 150-250 mg (3-5 drops SSKI®) 3 times/day

Children and Adults: 300-500 mg (6-10 drops SSKI®) 3 times/day or

1 mL strong iodine (Lugol's solution) 3 times/day

Sporotrichosis (cutaneous, lymphocutaneous): Adults: Oral: Initial: 5

drops (SSKI®) 3 times/day; increase to 40-50 drops (SSKI®) 3 times/

day as tolerated for 3-6 months

Note: Ineffective for disseminated sporotrichosis.

Stability Store in tight, light-resistant containers at temperature <40°C; freezing should be avoided

Monitoring Parameters Thyroid function tests, signs/symptoms of hyperthyroidism

Administration

Pima®: When used as an expectorant, take each dose with at least 4-6 ounces of water

SSKI®: Dilute in a glassful of water, fruit juice or milk. Take with food to decrease gastric irritation

Contraindications Hypersensitivity to iodine or any component of the formulation; hyperkalemia; pulmonary edema; impaired renal function; hyperthyroidism; iodine-induced goiter; dermatitis herpetiformis; hypocomplementemic vasculitis

Warnings Prolonged use can lead to hypothyroidism; cystic fibrosis patients have an exaggerated response; can cause acne flare-ups, can cause dermatitis; use with caution in patients with a history of thyroid disease, Addison's disease, cardiac disease, myotonia congenita, tuberculosis, acute bronchitis

Dosage Forms

Solution, oral:

SSKI®: 1 g/mL (30 mL, 240 mL) [contains sodium thiosulfate]

ThyroShield™: 65 mg/mL (30 mL) [black raspberry flavor]

Syrup (Pima®): 325 mg/5 mL (473 mL) [equivalent to iodide 249 mg/5 mL; black raspberry flavor]

Tablet:

Iosat™: 130 mg

ThyroSafe™: 65 mg [equivalent to iodine 50 mg]

Test Interactions Thyroid function tests

Drug Interactions

ACE inhibitors: Concurrent use may lead to hyperkalemia, cardiac arrhythmias or cardiac arrest.

Diuretics, potassium-sparing: Concurrent use may lead to hyperkalemia, cardiac arrhythmias, or cardiac arrest.

Lithium: May cause additive hypothyroid effects.

Potassium Iodide

Pronunciation (poe TASS ee um EYE oh dide)

CAS Number 7681-11-0

U.S. Brand Names Iosat™ [OTC]; Pima®, SSKI®

Synonyms KI

Use Block thyroidal uptake of radioactive isotopes of iodine in a radiation emergency

Unlabeled/Investigational Use Lymphocutaneous and cutaneous sporotrichosis

Mechanism of Action Inhibits uptake of I-131 by thyroid

Potassium (and potassium-containing products): Concurrent use may lead to hyperkalemia, cardiac arrhythmias, or cardiac arrest.

Pregnancy Risk Factor D

Pregnancy Implications Crosses the placenta

Lactation Enters breast milk/use caution (AAP rates "compatible")

Pralidoxime

Pronunciation (pra li DOKS eem)

Related Information

- Obidoxime Chloride [ANTIDOTE]

CAS Number 51-15-0

U.S. Brand Names Protopam®

Synonyms 2-PAM; 2-Pyridine Aldoxime Methochloride; Pralidoxime Chloride

Use Reverse muscle paralysis caused by toxic exposure to organophosphate anticholinesterase pesticides and chemicals; control of overdose of anticholinesterase medications used to treat myasthenia gravis (ambenonium, neostigmine, pyridostigmine). Not usually useful for carbamate poisoning

Unlabeled/Investigational Use

May be effective for tacrine toxicity; treatment of nerve agent toxicity (chemical warfare) in combination with atropine

Not generally indicated for carbamate ingestions, although recent reports have shown a benefit in reversing nicotinic symptoms refractory to atropine; questionable efficacy for selected organophosphates (ciodrin, dimefox, dimethoate, methyl diazinon, phorate, schaadon, weesyn)

Mechanism of Action Reactivates cholinesterase that had been inactivated by phosphorylation due to exposure to organophosphate pesticides by displacing the enzyme from its nicotinic receptor sites; most effective if given within 24 hours of exposure; has greater impact on reversing nicotinic effects versus muscarinic

Adverse Reactions

Cardiovascular: Tachycardia, hypertension

Central nervous system: Dizziness, headache, drowsiness

Dermatologic: Rash

Gastrointestinal: Nausea

Hepatic: Transient increases in ALT, AST

Local: Pain at injection site after I.M. administration

Neuromuscular & skeletal: Muscle rigidity, weakness

Ocular: Accommodation impaired, blurred vision, diplopia

Renal: Renal function decreased

Respiratory: Hyperventilation, laryngospasm

Signs and Symptoms of Overdose Blurred vision, dizziness, nausea, tachycardia, vertigo

Pharmacodynamics/Kinetics

Protein binding: None

Metabolism: Hepatic

Half-life elimination: 74-77 minutes

Time to peak, serum: I.V.: 5-15 minutes

Excretion: Urine (80% to 90% as metabolites and unchanged drug)

Dosage

Organic phosphorus poisoning (use in conjunction with atropine; atropine effects should be established before pralidoxime is administered): I.V. (may be given I.M. or SubQ if I.V. is not feasible):

Children: 20-50 mg/kg/dose; repeat in 1-2 hours if muscle weakness has not been relieved, then at 8- to 12-hour intervals if cholinergic signs recur

Adults: 1-2 g; repeat in 1 hour if muscle weakness has not been relieved, then at 8- to 12-hour intervals if cholinergic signs recur. When the poison has been ingested, continued absorption from the lower bowel may require additional doses; patients should be titrated as long as signs of poisoning recur; dosing may need repeated every 3-8 hours.

Treatment of acetylcholinesterase inhibitor toxicity: Adults: I.V.: Initial: 1-2 g followed by increments of 250 mg every 5 minutes until response is observed

Elderly: Refer to Adults dosing; dosing should be cautious, considering possibility of decreased hepatic, renal, or cardiac function

Dosing adjustment in renal impairment: Dose should be reduced

Monitoring Parameters Heart rate, respiratory rate, blood pressure, continuous ECG; cardiac monitor and blood pressure monitor required for I.V. administration

Administration I.V.: Infuse over 15-30 minutes at a rate not to exceed 200 mg/minute; may administer I.M. or SubQ if I.V. is not accessible. If a more concentrated 5% solution is used, infuse over at least 5 minutes.

Contraindications Hypersensitivity to pralidoxime or any component of the formulation; poisonings due to phosphorus, inorganic phosphates, or organic phosphates without anticholinesterase activity; poisonings due to pesticides or carbamate class (may increase toxicity of carbaryl)

Warnings Use with caution in patients with myasthenia gravis; dosage modification required in patients with impaired renal function; use with caution in patients receiving theophylline, succinylcholine, phenothiazines, respiratory depressants (eg, narcotics, barbiturates).

Dosage Forms Injection, powder for reconstitution, as chloride: 1 g

Reference Range Pralidoxime concentration of 4 mcg/mL therapeutic *in vitro*; pralidoxime plasma level >14 mcg/mL is associated with side effects (ie, dizziness and blurred vision)

Drug Interactions

Decreased effect: Atropine, although often used concurrently with pralidoxime to offset muscarinic stimulation, these effects can occur earlier than anticipated

Increased effect: Barbiturates (potentiated)

Increased toxicity: Use with aminophylline, morphine, theophylline, and succinylcholine is contraindicated; use with reserpine and phenothiazines should be avoided in patients with organophosphate poisoning

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/not recommended

Additional Information Intramuscular pralidoxime can be drawn from autoinjectors and be used for intravenous therapy.

Protamine Sulfate

CAS Number 9009-65-8; 9012-00-4

Use Treatment of heparin, dalteparin, enoxaparin overdose; neutralize heparin during surgery or dialysis procedures

Unlabeled/Investigational Use Treatment of low molecular weight heparin (LMWH) overdose

Mechanism of Action Weak anticoagulant; combines with strongly acidic heparin to form a stable complex (salt) neutralizing the anticoagulant activity of both drugs: Derived from male salmon gonads.

Adverse Reactions

Cardiovascular: Hypotension, cyanosis, bradycardia, flushing, syncope, sinus bradycardia, vasodilation

Central nervous system: Lassitude

Dermatologic: Urticaria

Gastrointestinal: Nausea, vomiting

Hematologic: Thrombocytopenia, bleeding, coagulopathy, leukopenia

Neuromuscular & skeletal: Numbness

Respiratory: Wheezing, dyspnea, pulmonary edema, pulmonary hypertension

Miscellaneous: Hypersensitivity reactions (anaphylaxis and anaphylactic shock)

Signs and Symptoms of Overdose Hypertension; may cause hemorrhage

Pharmacodynamics/Kinetics Onset of action: I.V.: Heparin neutralization: ~5 minutes

Dosage

Heparin neutralization: I.V.: Protamine dosage is determined by the dosage of heparin; 1 mg of protamine neutralizes 90 USP units of heparin (lung) and 115 USP units of heparin (intestinal); maximum dose: 50 mg

Heparin overdose, following intravenous administration: I.V.: Since blood heparin concentrations decrease rapidly after administration, adjust the protamine dosage depending upon the duration of time since heparin administration as follows: See table.

Time Elapsed	Dose of Protamine (mg) to Neutralize 100 units of Heparin
Immediate	1-1.5
30-60 min	0.5-0.75
>2 h	0.25-0.375

Heparin overdosage, following SubQ injection: I.V.: 1-1.5 mg protamine per 100 units heparin; this may be done by a portion of the dose (eg, 25-50 mg) given slowly I.V. followed by the remaining portion as a

PYRIDOSTIGMINE

continuous infusion over 8-16 hours (the expected absorption time of the SubQ heparin dose)

LMWH overdose (unlabeled use): **Note:** Anti-factor Xa activity never completely neutralized (maximum: ~60% to 75%)

Enoxaparin: 1 mg protamine for each mg of enoxaparin; if PTT prolonged 2-4 hours after first dose, consider additional dose of 0.5 mg for each mg of enoxaparin.

Dalteparin or tinzaparin: 1 mg protamine for each 100 anti-Xa int. unit of dalteparin or tinzaparin; if PTT prolonged 2-4 hours after first dose, consider additional dose of 0.5 mg for each 100 anti-Xa int. unit of dalteparin or tinzaparin.

Note: Excessive protamine doses may worsen bleeding potential.

Stability Refrigerate, avoid freezing; remains stable for at least 2 weeks at room temperature; **incompatible** with cephalosporins and penicillins; preservative-free formulation does not require refrigeration. Reconstitute vial with 5 mL sterile water; if using protamine in neonates, reconstitute with preservative-free sterile water for injection; resulting solution equals 10 mg/mL.

Monitoring Parameters Coagulation test, aPTT or ACT, cardiac monitor and blood pressure monitor required during administration

Administration For I.V. use only; **incompatible** with cephalosporins and penicillins; administer slow IVP (50 mg over 10 minutes); rapid I.V. infusion causes hypotension; resulting solution equals 10 mg/mL; inject without further dilution over 1-3 minutes; maximum of 50 mg in any 10-minute period

Contraindications Hypersensitivity to protamine or any component of the formulation

Warnings May not be totally effective in some patients following cardiac surgery despite adequate doses; may cause hypersensitivity reaction in patients with a history of allergy to fish (have epinephrine 1:1000 available) and in patients sensitized to protamine (via protamine zinc insulin); too rapid administration can cause severe hypotensive and anaphylactoid-like reactions. Heparin rebound associated with anticoagulation and bleeding has been reported to occur occasionally; symptoms typically occur 8-9 hours after protamine administration, but may occur as long as 18 hours later.

Dosage Forms Injection, solution, as sulfate [preservative free]: 10 mg/mL (5 mL, 25 mL)

Reference Range Protamine plasma levels of 0.02-0.5 mg/mL are associated with prolonged activated partial thromboplastin time and prothrombin time

Pregnancy Risk Factor C - Generally safe

Lactation Excretion in breast milk unknown

Additional Information Lepirudin, Desirudin and Bivalirudin are not reversed by protamine

Distribution: 19 ± 12 L

Metabolism: Hepatic

Bioavailability: 10% to 20%

Half-life elimination: 1-2 hours; Renal failure: ≤ 6 hours

Excretion: Urine (80% to 90% as unchanged drug)

Dosage

Myasthenia gravis:

Oral:

Children: 7 mg/kg/24 hours divided into 5-6 doses

Adults: Highly individualized dosing ranges: 60-1500 mg/day, usually 600 mg/day divided into 5-6 doses, spaced to provide maximum relief

Sustained release formulation: Highly individualized dosing ranges: 180-540 mg once or twice daily (doses separated by at least 6 hours); **Note:** Most clinicians reserve sustained release dosage form for bedtime dose only.

I.M., slow I.V. push:

Children: 0.05-0.15 mg/kg/dose

Adults: To supplement oral dosage pre- and postoperatively during labor and postpartum, during myasthenic crisis, or when oral therapy is impractical: $\sim 1/30$ th of oral dose; observe patient closely for cholinergic reactions

or

I.V. infusion: Initial: 2 mg/hour with gradual titration in increments of 0.5-1 mg/hour, up to a maximum rate of 4 mg/hour

Pretreatment for Soman nerve gas exposure (military use): Oral: Adults: 30 mg every 8 hours beginning several hours prior to exposure; discontinue at first sign of nerve agent exposure, then begin atropine and pralidoxime

Reversal of nondepolarizing muscle relaxants:

Note: Atropine sulfate (0.6-1.2 mg) I.V. immediately prior to pyridostigmine to minimize side effects: I.V.:

Children: Dosing range: 0.1-0.25 mg/kg/dose*

Adults: 0.1-0.25 mg/kg/dose; 10-20 mg is usually sufficient*

*Full recovery usually occurs ≤ 15 minutes, but ≥ 30 minutes may be required

Dosage adjustment in renal dysfunction: Lower dosages may be required due to prolonged elimination; no specific recommendations have been published

Stability

Injection: Protect from light.

Tablet:

30 mg: Store under refrigeration at 2°C to 8°C (36°F to 46°F) and protect from light; stable at room temperature for up to 3 months

Mestinoin®: Store at 25°C (77°F); protect from moisture

Monitoring Parameters Observe for cholinergic reactions, particularly when administered I.V.

Administration Do not crush sustained release tablet.

Contraindications Hypersensitivity to pyridostigmine, bromides, or any component of the formulation; GI or GU obstruction

Warnings Use with caution in patients with epilepsy, asthma, bradycardia, hyperthyroidism, cardiac arrhythmias, or peptic ulcer; adequate facilities should be available for cardiopulmonary resuscitation when testing and adjusting dose for myasthenia gravis; have atropine and epinephrine ready to treat hypersensitivity reactions; overdosage may result in cholinergic crisis, this must be distinguished from myasthenic crisis; anticholinesterase insensitivity can develop for brief or prolonged periods. Safety and efficacy in pediatric patients have not been established.

Regonol® injection contains 1% benzyl alcohol as the preservative (not intended for use in newborns).

Dosage Forms

Injection, solution, as bromide:

Mestinoin®: 5 mg/mL (2 mL)

Regonol®: 5 mg/mL (2 mL) [contains benzyl alcohol]

Syrup, as bromide (Mestinoin®): 60 mg/5 mL (480 mL) [raspberry flavor; contains alcohol 5%, sodium benzoate]

Tablet, as bromide (Mestinoin®): 60 mg

Tablet, sustained release, as bromide (Mestinoin® Timespan®): 180 mg

Test Interactions ↑ aminotransferase [ALT (SGPT)/AST (SGOT)] (S), amylase (S)

Drug Interactions

Aminoglycosides (gentamicin, kanamycin, neomycin, streptomycin): Use of high parenteral doses may intensify/prolong neuromuscular blockade, or lead to resistance of neuromuscular blockade reversal, especially if used with other nondepolarizing neuromuscular-blocking drugs.

Antibiotics (bacitracin, colistin, polymyxin B, sodium colistimethate, tetracycline): Use of high parenteral doses may intensify/prolong neuromuscular blockade, or lead to resistance of neuromuscular blockade reversal, especially if used with other nondepolarizing neuromuscular-blocking drugs.

Beta blockers: Pyridostigmine and beta-blockers may both cause bradycardia and hypotension, effect may be additive; monitor.

Depolarizing neuromuscular-blocking agents (succinylcholine): Increased neuromuscular blocking effect with concomitant use.

Pyridostigmine

Pronunciation (peer id oh STIG meen)

CAS Number 101-26-8

U.S. Brand Names Mestinoin® Timespan®, Mestinoin®

Synonyms Pyridostigmine Bromide

Use Second-line agent for envenomation by Asian snakes or intoxication with tetrodotoxin exposures if edrophonium supplies are depleted; reversal of the effects of nondepolarizing neuromuscular blocking agents after surgery; pretreatment for chemical warfare agents (ie, Soman nerve gas), thus making the use of atropine and pralidoxime more effective; symptomatic treatment of myasthenia gravis

Mechanism of Action Inhibits destruction of acetylcholine by acetylcholinesterase which facilitates transmission of impulses across myoneural junction

Adverse Reactions

Cardiovascular: Arrhythmias (especially bradycardia), hypotension, tachycardia, AV block, nodal rhythm, nonspecific ECG changes, cardiac arrest, syncope, flushing

Central nervous system: Convulsions, dysarthria, dysphonia, dizziness, loss of consciousness, drowsiness, headache

Dermatologic: Skin rash, thrombophlebitis (I.V.), urticaria

Gastrointestinal: Hyperperistalsis, nausea, vomiting, salivation, diarrhea, stomach cramps, dysphagia, flatulence, abdominal pain

Genitourinary: Urinary urgency

Neuromuscular & skeletal: Weakness, fasciculations, muscle cramps, spasms, arthralgias, myalgia

Ocular: Small pupils, lacrimation, amblyopia

Respiratory: Increased bronchial secretions, laryngospasm, bronchiolar constriction, respiratory muscle paralysis, dyspnea, respiratory depression, respiratory arrest, bronchospasm

Miscellaneous: Diaphoresis (increased), anaphylaxis, allergic reactions

Signs and Symptoms of Overdose Blurred vision, excessive sweating, muscle weakness, nausea, salivation, tearing, vomiting

Pharmacodynamics/Kinetics

Onset of action: Oral, I.M.: 15-30 minutes; I.V. injection: 2-5 minutes

Duration: Oral: Up to 6-8 hours (due to slow absorption); I.V.: 2-3 hours

Absorption: Oral: Very poor

Edrophonium: Increased toxicity with concomitant use.
 Magnesium: Patients with elevated serum magnesium concentrations may experience enhanced neuromuscular blockage with blocking agents. The reversing effect of pyridostigmine may be compensated.
 Quinidine: Recurrent paralysis may occur when quinidine is administered with nondepolarizing neuromuscular-blocking drugs. This may complicate attempts to reverse blockade with pyridostigmine.
 Quinolone antibiotics (ciprofloxacin, norfloxacin): Case reports suggest these drugs may exhibit neuromuscular-blocking effects (especially in some patients with myasthenia gravis); monitor.

Pregnancy Risk Factor C

Pregnancy Implications Safety has not been established for use during pregnancy. The potential benefit to the mother should outweigh the potential risk to the fetus. When pyridostigmine is needed in myasthenic mothers, giving dose parenterally 1 hour before completion of the second stage of labor may facilitate delivery and protect the neonate during the immediate postnatal state.

Lactation Enters breast milk/compatible

Nursing Implications Observe for cholinergic reactions, particularly when administered I.V.

Pyridoxine

Pronunciation (peer i DOKS een)

CAS Number 58-56-0; 65-23-6

U.S. Brand Names Aminoxin® [OTC]

Synonyms Pyridoxine Hydrochloride; Vitamin B₆

Use Prevents and treats vitamin B₆ deficiency, pyridoxine-dependent seizures in infants, adjunct to treatment of acute toxicity from acrylamide, isoniazid, cycloserine, penicillamine, altretamine, or hydrazine overdose; optic neuritis due to isoniazid or chloramphenicol; hydrazine-containing mushrooms (*Gyromitra*)

Unlabeled/Investigational Use Useful for primary oxaluria; questionable and unproven use in carbon disulfide toxicity; has been used subcutaneously to treat mitomycin C extravasation; seizures due to ginkgo seed ingestion

Mechanism of Action Precursor to pyridoxal, which functions in the metabolism of proteins, carbohydrates, and fats; pyridoxal also aids in the release of liver and muscle stored glycogen, inhibits lactation

Adverse Reactions

Central nervous system: Sensory neuropathy (after chronic administration of large doses), seizures (following I.V. administration of very large doses), headache, hypotonia, memory disturbance

Dermatologic: Photosensitivity, bullous lesions, palmar-plantar erythrodysesthesia syndrome

Endocrine & metabolic: Decreased serum folic acid concentration

Gastrointestinal: Nausea

Hepatic: Elevated AST

Local: Burning or stinging at injection site

Neuromuscular & skeletal: Paresthesia

Respiratory: Respiratory distress

Miscellaneous: Allergic reactions have been reported; may suppress lactation at doses > 600 mg/day

Signs and Symptoms of Overdose Ataxia, lethargy, seizures, sensory neuropathy

Pharmacodynamics/Kinetics

Absorption: Enteral, parenteral: Well absorbed

Metabolism: Via 4-pyridoxic acid (active form) and other metabolites

Half-life elimination: 15-20 days

Excretion: Urine

Dosage

Neuropathy may occur at doses > 2 g/day.

Acute hydrazine toxicity (treatment): A pyridoxine dose of 25 mg/kg in divided doses I.M./I.V. has been used.

Acute isoniazid toxicity (treatment of seizures and/or coma): A dose of pyridoxine hydrochloride equal to the amount of INH ingested can be given I.M./I.V. in divided doses together with other anticonvulsants; can give as much as 1 g/kg in adults or 250 mg/kg in children

Dietary deficiency: Oral:

Children: 5-10 mg/24 hours for 3 weeks

Adults: 10-20 mg/day for 3 weeks

Drug-induced neuritis (eg, isoniazid, hydralazine, penicillamine, cycloserine): Oral:

Children: 10-50 mg/24 hours; prophylaxis: 1-2 mg/kg/24 hours

Adults: 100-200 mg/24 hours; prophylaxis: 10-100 mg/24 hours

Ginkgo seed ingestion (seizure treatment and prevention): I.V.: 2 mg/kg

Mitomycin C extravasation: SubQ: Inject (100 mg/mL- 75-300 mg total) around affected area - dilute one to threefold

Pyridoxine-dependent Infants:

Oral: 2-100 mg/day

I.M., I.V.: 10-100 mg

Nausea and vomiting during pregnancy: 25-30 mg daily

Stability Protect from light

Administration Burning may occur at the injection site after I.M. or SubQ administration; seizures have occurred following I.V. administration of very large doses

Contraindications Hypersensitivity to pyridoxine or any component of the formulation

Warnings Dependence and withdrawal may occur with doses >200 mg/day

Dosage Forms

Capsule, as hydrochloride: 250 mg

Injection, solution, as hydrochloride: 100 mg/mL (1 mL)

Tablet, as hydrochloride: 25 mg, 50 mg, 100 mg, 200 mg, 250 mg, 500 mg

Tablet, enteric coated, as hydrochloride (Aminoxin®): 20 mg

Reference Range

A broad normal range is ~25-80 ng/mL (SI: 122-389 nmol/L)

HPLC method for pyridoxal phosphate normal range: 3.5-18 ng/mL (SI: 17-88 nmol/L)

Peak serum level following 1 g: I.V. infusion: 9.97 ng/μL; I.V. bolus: 44.6 ng/μL; Oral: 15.75 ng/μL

Test Interactions Urobilinogen

Drug Interactions Decreased serum levels of levodopa, phenobarbital, and phenytoin

Pregnancy Risk Factor A/C (dose exceeding RDA recommendation)

Pregnancy Implications Seizures in an infant following *in utero* exposure

Lactation Enters breast milk/compatible

Nursing Implications Burning may occur at the injection site after I.M. or SubQ administration; seizures have occurred following I.V. administration of very large doses

Serpacwa [Antidote]

Use Topical agent serving as protectant (physical barrier) to urushiol and methyl nicotinate (surrogates for chemical warfare agents); currently indicated only for military personnel wearing mission-oriented protective posture (MOPP) gear; it should be applied only when chemical warfare is imminent and not for training purposes

Mechanism of Action Contains a 50:50 mixture of perfluoroalkylpolyether and polytetrafluoroethylene which acts as a physical barrier to agents

Adverse Reactions Miscellaneous: Flu-like syndrome

Dosage Apply to skin by hand until there is a barely noticeable white film layer. One-third of the packet should be applied evenly around wrists, neck, and boot tops (of the lower leg); remaining two-thirds of the packet should be applied evenly to axillae, groin, and waist. Prior to application, use a dry towel or cloth to remove perspiration, insect repellent, camouflage paint or dirt from skin.

Pregnancy Risk Factor C

Silver Sulfadiazine

Pronunciation (SIL ver sul fa DYE a zeen)

CAS Number 22199-08-2

U.S. Brand Names Silvadene®; SSD® AF; SSD®; Thermazene®

Use Prevention and treatment of infection in second and third degree burns; vesicant exposure

Mechanism of Action Acts upon the bacterial cell wall and cell membrane. Bactericidal for many gram-negative and gram-positive bacteria and is effective against yeast. Active against *Pseudomonas aeruginosa*, *Pseudomonas maltophilia*, *Enterobacter* species, *Klebsiella* species, *Serratia* species, *Escherichia coli*, *Proteus mirabilis*, *Morganella morganii*, *Providencia rettgeri*, *Proteus vulgaris*, *Providencia* species, *Citrobacter* species, *Acinetobacter calcoaceticus*, *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Enterococcus* species, *Candida albicans*, *Corynebacterium diphtheriae*, and *Clostridium perfringens*

Adverse Reactions

Frequency not defined.

Dermatologic: Itching, rash, erythema multiforme, discoloration of skin, photosensitivity

Hematologic: Hemolytic anemia, leukopenia (usually transient), agranulocytosis, aplastic anemia

Hepatic: Hepatitis

Renal: Interstitial nephritis, crystalluria

Miscellaneous: Allergic reactions may be related to sulfa component, hyperthermia

Pharmacodynamics/Kinetics

Absorption: Significant percutaneous absorption of silver sulfadiazine can occur especially when applied to extensive burns

Half-life elimination: 10 hours; prolonged with renal impairment

Time to peak, serum: 3-11 days of continuous therapy

Excretion: Urine (~50% as unchanged drug)

Dosage Children and Adults: Topical: Apply once or twice daily with a sterile-gloved hand; apply to a thickness of 1/16"; burned area should be covered with cream at all times

Stability Silvadene® cream will occasionally darken either in the jar or after application to the skin. This color change results from a light

SILYMARIN

catalyzed reaction which is a common characteristic of all silver salts. A similar analogy is the oxidation of silverware. The product of this color change reaction is silver oxide which ranges in color from gray to black. Silver oxide has rarely been associated with permanent skin discoloration. Additionally, the antimicrobial activity of the product is not substantially diminished because the color change reaction involves such a small amount of the active drug and is largely a surface phenomenon.

Monitoring Parameters Serum electrolytes, urinalysis, renal function tests, CBC in patients with extensive burns on long-term treatment

Administration Apply with a sterile-gloved hand. Apply to a thickness $\frac{1}{16}$ ". Burned area should be covered with cream at all times.

Contraindications Hypersensitivity to silver sulfadiazine or any component of the formulation; premature infants or neonates <2 months of age (sulfonamides may displace bilirubin and cause kernicterus); pregnancy (approaching or at term)

Warnings Use with caution in patients with G6PD deficiency, renal impairment, or history of allergy to other sulfonamides; sulfadiazine may accumulate in patients with impaired hepatic or renal function; fungal superinfection may occur; use of analgesic might be needed before application; systemic absorption is significant and adverse reactions may occur

Dosage Forms

Cream, topical: 1% (25 g, 50 mg, 85 g, 400 g)
Silvadene®, Thermozone®: 1% (20 g, 50 g, 85 g, 400 g, 1000 g)
SSD®: 1% (25 g, 50 g, 85 g, 400 g)
SSD® AF: 1% (50 g, 400 g)

Drug Interactions Decreased effect: Topical proteolytic enzymes are inactivated

Pregnancy Risk Factor B

Lactation For external use

Specific Reference

Ronen G, Cohen AD, Bogdanov-Berezovsky A, et al, "A Randomized Controlled Trial of Silver Sulfadiazine, Biafine, and Saline-Soaked Gauze in the Treatment of Superficial Partial-Thickness Burn Wounds in Pigs," *Acad Emerg Med*, 2004, 11:339-342.

hypernatremia, muscle cramps, nausea, pulmonary edema, seizures, tetany, weakness

Pharmacodynamics/Kinetics

Onset of action: Oral: Rapid; I.V.: 15 minutes

Duration: Oral: 8-10 minutes; I.V.: 1-2 hours

Absorption: Oral: Well absorbed

Excretion: Urine (<1%)

Dosage

Cardiac arrest: **Routine use of NaHCO₃ is not recommended and should be given only after adequate alveolar ventilation has been established and effective cardiac compressions are provided**

Infants and Children: I.V.: 0.5-1 mEq/kg/dose repeated every 10 minutes or as indicated by arterial blood gases; rate of infusion should not exceed 10 mEq/minute; neonates and children <2 years of age should receive 4.2% (0.5 mEq/mL) solution

Adults: I.V.: Initial: 1 mEq/kg/dose one time; maintenance: 0.5 mEq/kg/dose every 10 minutes or as indicated by arterial blood gases

Metabolic acidosis: Infants, Children, and Adults: Dosage should be based on the following formula if blood gases and pH measurements are available:

$\text{HCO}_3^- \text{ (mEq)} = 0.3 \times \text{weight (kg)} \times \text{base deficit (mEq/L)}$

Administer $\frac{1}{2}$ dose initially, then remaining $\frac{1}{2}$ dose over the next 24 hours; monitor pH, serum HCO₃⁻, and clinical status

Note: If acid-base status is not available: Dose for older Children and Adults: 2-5 mEq/kg I.V. infusion over 4-8 hours; subsequent doses should be based on patient's acid-base status

Chronic renal failure: Oral: Initiate when plasma HCO₃⁻ <15 mEq/L

Children: 1-3 mEq/kg/day

Adults: Start with 20-36 mEq/day in divided doses, titrate to bicarbonate level of 18-20 mEq/L

Hyperkalemia: Adults: I.V.: 1 mEq/kg over 5 minutes

Renal tubular acidosis: Oral:

Distal:

Children: 2-3 mEq/kg/day

Adults: 0.5-2 mEq/kg/day in 4-5 divided doses

Proximal: Children and Adults: Initial: 5-10 mEq/kg/day; maintenance: Increase as required to maintain serum bicarbonate in the normal range

Urine alkalization: Oral:

Children: 1-10 mEq (84-840 mg)/kg/day in divided doses every 4-6 hours; dose should be titrated to desired urinary pH

Adults: Initial: 48 mEq (4 g), then 12-24 mEq (1-2 g) every 4 hours; dose should be titrated to desired urinary pH; doses up to 16 g/day (200 mEq) in patients <60 years and 8 g (100 mEq) in patients >60 years

Antacid: Adults: Oral: 325 mg to 2 g 1-4 times/day

Stability Store injection at room temperature; protect from heat and from freezing; use only clear solutions; do not mix NaHCO₃ with calcium salts, catecholamines, atropine

Monitoring Parameters Serum electrolytes including calcium, urinary pH, arterial blood gases (if indicated)

Administration For I.V. administration to infants, use the 0.5 mEq/mL solution or dilute the 1 mEq/mL solution 1:1 with **sterile water**; for direct I.V. infusion in emergencies, administer slowly (maximum rate in infants: 10 mEq/minute); for infusion, dilute to a maximum concentration of 0.5 mEq/mL in dextrose solution and infuse over 2 hours (maximum rate of administration: 1 mEq/kg/hour)

Contraindications Alkalosis, hypernatremia, severe pulmonary edema, hypocalcemia, unknown abdominal pain

Warnings Rapid administration in neonates and children <2 years of age has led to hypernatremia, decreased CSF pressure and intracranial hemorrhage. **Use of I.V. NaHCO₃ should be reserved for documented metabolic acidosis and for hyperkalemia-induced cardiac arrest.** Routine use in cardiac arrest is not recommended. Avoid extravasation, tissue necrosis can occur due to the hypertonicity of NaHCO₃. May cause sodium retention especially if renal function is impaired; not to be used in treatment of peptic ulcer; use with caution in patients with CHF, edema, cirrhosis, or renal failure. Not the antacid of choice for the elderly because of sodium content and potential for systemic alkalosis.

Dosage Forms

Granules, effervescent (Brioschi®): 2.69 g/packet (6 g) [unit-dose packets; contains sodium 770 mg/packet; lemon flavor]; 2.69 g/capful (120 g, 240 g) [contains sodium 770 mg/capful; lemon flavor]

Infusion [premixed in sterile water]: 5% (500 mL)

Injection, solution:

4.2% [42 mg/mL = 5 mEq/10 mL] (10 mL)

7.5% [75 mg/mL = 8.92 mEq/10 mL] (50 mL)

8.4% [84 mg/mL = 10 mEq/10 mL] (10 mL, 50 mL)

Neut®: 4% [40 mg/mL = 2.4 mEq/5 mL] (5 mL)

Powder: Sodium bicarbonate USP (120 g, 480 g) [contains sodium 30 mEq per $\frac{1}{2}$ teaspoon]

Tablet: 325 mg [3.8 mEq]; 650 mg [7.6 mEq]

Reference Range Therapeutic (sodium): 135-145 mEq/L (SI: 135-145 mM/L)

Silymarin

CAS Number 22888-70-6; 65666-07-1

Unlabeled/Investigational Use Used in Europe for treatment of mushroom-induced hepatic disorders (not FDA approved in U.S.) caused by Group I mushrooms and organic solvents

Mechanism of Action Hepatotropic: May prevent amatoxin penetration into hepatocytes

Adverse Reactions

Dermatologic: Rashes

Gastrointestinal: Laxative effects, colicky abdominal pain, fluid diarrhea, vomiting

Neuromuscular & skeletal: Weakness

Miscellaneous: Allergic reactions, diaphoresis

Dosage

Oral: 140 mg 2-3 times/day

I.V.: 20-80 mg/kg/day in 4 divided doses (over a 2-hour period for each infusion)

Sodium Bicarbonate

Pronunciation (SOW dee um bye KAR bun ate)

CAS Number 144-55-8

U.S. Brand Names Brioschi® [OTC]; Neut®

Synonyms Baking Soda; NaHCO₃; Sodium Acid Carbonate; Sodium Hydrogen Carbonate

Use Management of metabolic acidosis; antacid; alkalize urine; severe diarrhea; can reverse QRS prolongation in antidepressant overdose, cocaine, and propoxyphene; cardiac conduction defects due to quinidine-like action of cardiotoxic drugs; increases protein binding of tricyclic antidepressants

Unlabeled/Investigational Use Nebulized sodium bicarbonate is useful to treat chlorine gas exposure; also used to prevent rhabdomyolysis-induced renal failure; useful in extravasation injury due to carmustine; metformin-induced lactic acidosis

Mechanism of Action Dissociates to provide bicarbonate ion which neutralizes hydrogen ion concentration and raises blood and urinary pH

Adverse Reactions

Cardiovascular: Edema, cerebral hemorrhage (especially with rapid injection of the hyperosmotic NaHCO₃ solution in infants)

Endocrine & metabolic: Metabolic alkalosis, hypernatremia, hypokalemia, hypocalcemia, intracranial acidosis, increased affinity of hemoglobin for oxygen-reduced pH in myocardia

Gastrointestinal: **Gastric distention, flatulence may occur with oral administration**, gastric rupture

Local: Tissue necrosis, ulceration after I.V. extravasation

Signs and Symptoms of Overdose Confusion, cyanosis, hypocalcemia, hypokalemia, hypokalemic/hypochloremic metabolic alkalosis,

Drug Interactions

Decreased effect/levels of lithium, chlorpropamide, methotrexate, tetracyclines, and salicylates due to urinary alkalization
Increased toxicity/levels of amphetamines, anorexiant, mecamlamine, ephedrine, pseudoephedrine, flecainide, quinidine, quinine due to urinary alkalization

Pregnancy Risk Factor C

Lactation Enters breast milk/compatible

Nursing Implications Advise patient of milk-alkali syndrome if use is long-term; observe for extravasation when giving I.V.; incompatible with acids, acidic salts, alkaloid salts, calcium salts, catecholamines, atropine

Sodium Nitrite

Pronunciation (SOW dee um NYE trite)

Related Information

- Cyanide Antidote Kit [ANTIDOTE]

CAS Number 7632-00-0

Use Cyanide toxicity in conjunction with amyl nitrite pearls and sodium thiosulfate

Unlabeled/Investigational Use May be of use in hydrogen sulfide poisoning

Mechanism of Action Vasodilation and methemoglobin producer

Adverse Reactions

Cardiovascular: Tachycardia, hypotension from vasodilation, syncope, cyanosis, flushing, sinus tachycardia
Central nervous system: Headache
Gastrointestinal: Nausea, vomiting
Miscellaneous: Forms methemoglobin

Signs and Symptoms of Overdose Cardiovascular collapse, coma, hemolysis/hemolytic anemia, seizures

Admission Criteria/Prognosis Any patient with change in mental status, cardiopulmonary complaints, or methemoglobin levels >30% should be admitted; asymptomatic patients with methemoglobin levels <30% may be considered for discharge after 6 hours of observation and if methemoglobin levels fall to <15%

Dosage

Cyanide toxicity:

Children (without anemia): 4.5-10 mg/kg (0.15-0.33 mL/kg of a 3% solution up to 10 mL)

Adults: 300 mg (10 mL of a 3% solution)

Acceptable daily intake: 0.4 mg/kg

Monitoring Parameters Methemoglobin levels

Warnings Sodium nitrite and amyl nitrite in excessive doses induce methemoglobinemia

Dosage Forms Injection: 300 mg/10 mL

Reference Range Sodium nitrite levels associated with fatalities range from 0.5-350 mg/L

Antidote(s)

- Cyanide Antidote Kit [ANTIDOTE]

Sodium Polystyrene Sulfonate

Pronunciation (SOW dee um pol ee STYE reen SUL fon ate)

Related Information

- Adipose Tissue Ranges of Toxins

CAS Number 25704-18-1; 9003-59-2

U.S. Brand Names Kayexalate[®]; Kionex[™]; SPS[®]

Use Treatment of hyperkalemia; gastric decontamination for lithium

Mechanism of Action Removes potassium by exchanging sodium ions for potassium ions in the intestine before the resin is passed from the body

Adverse Reactions

Frequency not defined.

Endocrine & metabolic: Hypermnatremia, hypokalemia, hypocalcemia, hypomagnesemia,

Gastrointestinal: Anorexia, colonic necrosis (rare), constipation, fecal impaction, intestinal obstruction (due to concretions in association with aluminum hydroxide), nausea, vomiting

Pharmacodynamics/Kinetics

Onset of action: 2-24 hours

Absorption: None

Excretion: Completely feces (primarily as potassium polystyrene sulfonate)

Dosage Hyperkalemia:

Children:

Oral: 1 g/kg/dose every 6 hours

Rectal: 1 g/kg/dose every 2-6 hours (In small children and infants, employ lower doses by using the practical exchange ratio of 1 mEq K⁺/g of resin as the basis for calculation)

Adults:

Oral: 15 g (60 mL) 1-4 times/day

Rectal: 30-50 g every 6 hours

Instructions for sodium polystyrene sulfonate enema:

Insert the tubing into the rectum ~20 cm. Administer a body-temperature tap water enema (250-500 mL) to remove any feces in the rectum and sigmoid colon.

Shake the sodium polystyrene sulfonate suspension well and mix 2:1 with tap water in the enema bucket prior to administration (ie, 60 mL sodium polystyrene sulfonate and 30 mL water).

Reinsert the enema tube into the rectum ~20 cm and administer the prescribed sodium polystyrene sulfonate dose (usual range, 15-60 g), then remove the tube.

Make sure the enema is retained for several hours, to allow exchange of sodium for potassium ions. If leakage occurs, elevate the patient's hips with pillows.

Reinsert the tube to 20 cm and administer cleansing enema(s) of body-temperature tap water (250-1000 mL) to flush any remaining sodium polystyrene sulfonate enema out of the colon to remove potassium ions and prevent adverse reactions.

For additional information, call your pharmacist or the drug information center.

Stability Store prepared suspensions at 15°C to 30°C (59°F to 86°F); store repackaged product in refrigerator and use within 14 days; freshly prepared suspensions should be used within 24 hours; do not heat resin suspension

Monitoring Parameters Exchange capacity is 1 mEq/g *in vivo*, and *in vitro* capacity is 3.1 mEq/g, therefore, a wide range of exchange capacity exists such that close monitoring of serum electrolytes (potassium, sodium, calcium, magnesium) is necessary; ECG

Administrations

Oral: Administer oral (or NG) as ~25% sorbitol solution; never mix in orange juice. Chilling the oral mixture will increase palatability.

Rectal: Enema route is less effective than oral administration. Administer cleansing enema first. Retain enema in colon for at least 30-60 minutes and for several hours, if possible. Enema should be followed by irrigation with normal saline to prevent necrosis.

Contraindications Hypersensitivity to sodium polystyrene sulfonate or any component of the formulation; hypernatremia, hypokalemia, obstructive bowel disease

Warnings Use with caution in patients with severe CHF, hypertension, edema, or renal failure; avoid using the commercially available liquid product in neonates due to the preservative content; large oral doses may cause fecal impaction (especially in elderly); enema will reduce the serum potassium faster than oral administration, but the oral route will result in a greater reduction over several hours.

Dosage Forms

Powder for suspension, oral/rectal:

Kayexalate[®]: 15 g/4 level teaspoons (480 g) [contains sodium 100 mg (4.1 mEq)/g]

Kionex[™]: 15 g/4 level teaspoons (454 g) [contains sodium 100 mg (4.1 mEq)/g]

Suspension, oral/rectal: 15 g/60 mL (60 mL, 120 mL, 200 mL, 500 mL) [contains sodium 1500 mg (65 mEq)/60 mL, sorbitol, and alcohol 0.1%; cherry/caramel flavor]

SPS[®]: 15 g/60 mL (60 mL, 120 mL, 480 mL) [contains alcohol 0.3%, sodium 1500 mg (65 mEq)/60 mL, and sorbitol; cherry flavor]

Reference Range Serum potassium: Adults: 3.5-5.2 mEq/L

Test Interactions ↑ sodium; ↓ potassium (S), calcium (S), magnesium (S)

Drug Interactions Systemic alkalosis and seizure has occurred after cation-exchange resins were administered with nonabsorbable cation-donating antacids and laxatives (eg, magnesium hydroxide, aluminum carbonate). Digitalis toxicity may occur with hypokalemia.

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown/use caution

Nursing Implications Administer oral (or NG) as ~25% sorbitol solution, never mix in orange juice; enema route is less effective than oral administration; retain enema in colon for at least 30-60 minutes and for several hours, if possible. Repeated oral doses can lead to sorbitol-induced electrolyte abnormalities.

Sodium Thiosulfate

Pronunciation (SOW dee um thye oh SUL fate)

Related Information

- Sodium Nitrite [ANTIDOTE]

CAS Number 10102-17-7; 7772-98-7

U.S. Brand Names Versiclear[™]

SORBITOL

Synonyms Disodium Thiosulfate Pentahydrate; Pentahydrate; Sodium Hyposulfate; Sodium Thiosulphate; Thiosulfuric Acid Disodium Salt

Use Alone or with sodium nitrite or amyl nitrite (or hydroxocobalamin) in cyanide poisoning; to reduce the risk of nephrotoxicity associated with cisplatin therapy; topically in the treatment of tinea versicolor; an inorganic reducing agent used as a fixative bleaching of bone; used in manufacture of leather; for selenium dioxide burns; can reduce cisplatin nephrotoxicity; oral lavage use (1% to 5%) for use in gastric decontamination for iodine exposure, can be used for mechlorethamine extravasation along with actinomycin D and mitomycin C; may be useful in chlorate salt toxicity and bromate toxicity; may be used alone in smoke inhalations and to reduce the toxicity of sodium nitroprusside

Unlabeled/Investigational Use Management of I.V. extravasation

Mechanism of Action

Cyanide toxicity: Increases the rate of detoxification of cyanide by the enzyme rhodanase by providing an extra sulfur

Cisplatin toxicity: Complexes with cisplatin to form a compound that is nontoxic to either normal or cancerous cells

Adverse Reactions

Cardiovascular: Hypotension

Central nervous system: Coma, CNS depression secondary to thiocyanate intoxication, psychosis, confusion

Dermatologic: Contact dermatitis, local irritation

Gastrointestinal: Diarrhea (following large oral doses)

Neuromuscular & skeletal: Weakness

Otic: Tinnitus

Pharmacodynamics/Kinetics

Absorption: Oral: Poor

Distribution: Extracellular fluid

Half-life elimination: 0.65 hour

Excretion: Urine (28.5% as unchanged drug)

Dosage

Cyanide and nitroprusside antidote: I.V.:

Children <25 kg: 50 mg/kg after receiving 4.5-10 mg/kg sodium nitrite; a half dose of each may be repeated if necessary

Children >25 kg and Adults: 12.5 g after 300 mg of sodium nitrite; a half dose of each may be repeated if necessary

Cyanide poisoning: I.V.: Dose should be based on determination as with nitrite, at rate of 2.5-5 mL/minute to maximum of 50 mL.

Variation of sodium nitrite and sodium thiosulfate dose, based on hemoglobin concentration*:

Cisplatin rescue should be given before or during cisplatin administration: I.V. infusion (in sterile water): 12 g/m² over 6 hours or 9 g/m² I.V. push followed by 1.2 g/m² continuous infusion for 6 hours

Arsenic poisoning: I.V.: 1 mL first day, 2 mL second day, 3 mL third day, 4 mL fourth day, 5 mL on alternate days thereafter

Children and Adults:

Topical: 20% to 25% solution: Apply a thin layer to affected areas twice daily

SubQ: Drug extravasation (unlabeled use):

2% solution: Infiltrate SubQ into the affected area

1/6 M (~4%) solution: 5-10 mL infused through I.V. line and SubQ into the affected area

Stability Explosive when titrated with chlorates, nitrates, or permanganates

Monitoring Parameters Monitor for signs of thiocyanate toxicity

Administration

I.V.: Inject slowly, over at least 10 minutes; rapid administration may cause hypotension.

Topical: Do not apply to or near eyes.

Contraindications Hypersensitivity to sodium thiosulfate or any component of the formulation

Warnings Safety in pregnancy has not been established; discontinue topical use if irritation or sensitivity occurs; rapid I.V. infusion has caused transient hypotension and ECG changes in dogs; can increase risk of thiocyanate intoxication

Dosage Forms

Injection, solution [preservative free]: 100 mg/mL (10 mL); 250 mg/mL (50 mL)

Lotion: Sodium thiosulfate 25% and salicylic acid 1% (120 mL) [contains isopropyl alcohol 10%]

Reference Range Serum levels of 11.13 ± 1.1 mg/L are normal in adults; levels may be decreased to 5-8 mg/L in postoperative coronary artery bypass graft patients; levels may be elevated up to 22 mg/L in patients kept NPO for 1-3 weeks

Antidote(s)

• Sodium Nitrite [ANTIDOTE]

Pregnancy Risk Factor C

Pregnancy Implications Safety has not been established in pregnant women. Use only when potential benefit to the mother outweighs the possible risk to the fetus.

Nursing Implications Given I.V. as slow I.V. push only over 10 minutes

Specific Reference

Matteucci MJ, Reed WJ, and Tanen DA, "Sodium Thiosulfate Fails to Reduce Nitrite-Induced Methemoglobinemia *In Vitro*," *Acad Emerg Med*, 2003, 10(4):299-302.

Sorbitol

Pronunciation (SOR bi tole)

CAS Number 50-70-4

Use Genitourinary irrigant in transurethral prostatic resection or other transurethral resection or other transurethral surgical procedures; diuretic; humectant; sweetening agent; hyperosmotic laxative; facilitate the passage of sodium polystyrene sulfonate through the intestinal tract

Mechanism of Action Polyalcoholic sugar with osmotic cathartic actions

Adverse Reactions

Cardiovascular: Edema

Central nervous system: Fever, hyperthermia

Endocrine & metabolic: Fluid and electrolyte losses, hypernatremia, lactic acidosis

Gastrointestinal: Diarrhea, nausea, vomiting, abdominal discomfort, xerostomia

Signs and Symptoms of Overdose Diarrhea, fluid and electrolyte loss, hyperglycemia, hypernatremia, nausea

Pharmacodynamics/Kinetics

Onset of action: 0.25-1 hour

Absorption: Oral, rectal: Poor

Metabolism: Primarily hepatic to fructose

Dosage

Hyperosmotic laxative (as single dose, at infrequent intervals):

Children 2-11 years:

Oral: 2 mL/kg (as 70% solution)

Rectal enema: 30-60 mL as 25% to 30% solution

Children >12 years and Adults:

Oral: 30-150 mL (as 70% solution)

Rectal enema: 120 mL as 25% to 30% solution

Adjunct to sodium polystyrene sulfonate: 15 mL as 70% solution orally until diarrhea occurs (10-20 mL/2 hours) or 20-100 mL as an oral vehicle for the sodium polystyrene sulfonate resin

When administered with charcoal:

Oral:

Children: 4.3 mL/kg of 35% sorbitol with activated charcoal/day

Adults: 4.3 mL/kg of 70% sorbitol with activated charcoal/day

Topical: 3% to 3.3% as transurethral surgical procedure irrigation

Monitoring Parameters Monitor for fluid overload and/or electrolyte disturbances following large volumes; changes may be delayed due to slow absorption

Contraindications

 Anuria

Warnings Use with caution in patients with severe cardiopulmonary or renal impairment and in patients unable to metabolize sorbitol; large volumes may result in fluid overload and/or electrolyte changes

Dosage Forms

Solution, genitourinary irrigation: 3% (3000 mL, 5000 mL); 3.3% (2000 mL, 4000 mL)

Solution, oral: 70% (30 mL, 480 mL, 3840 mL)

Pregnancy Risk Factor C

Lactation Excretion in breast milk unknown

Nursing Implications Do not use unless solution is clear

Specific Reference

Succimer

Pronunciation (SUKS si mer)

Related Information

• Unithiol [ANTIDOTE]

CAS Number 304-55-2

U.S. Brand Names Chemet®

Synonyms DMSA

Use Orphan drug: Treatment of lead poisoning in children with blood levels >45 mcg/dL. It is not indicated for prophylaxis of lead poisoning in a lead-containing environment. Following oral administration, succimer is generally well tolerated and produces a linear dose-dependent reduction in serum lead concentrations. This agent appears to offer advantages over existing lead chelating agents; also has been used for arsenic and mercury poisoning; also used in children with blood lead levels <45 mcg/dL; also useful for mercury and arsenic toxicity

Mechanism of Action Succimer is an analog of dimercaprol. It forms water soluble chelates with heavy metals which are subsequently excreted renally. Initial data have shown encouraging results in the treatment of mercury and arsenic poisoning. Succimer binds heavy metals; however, the chemical form of these chelates is not known.

Adverse Reactions

The most common events attributable to succimer have been observed in ~10% of patients treated

Central nervous system: **Fever**

Dermatologic: Rash

Gastrointestinal: **Nausea, vomiting, diarrhea, appetite loss, metallic taste**, sulfurous odor to breath, **hemorrhoidal symptoms**, hemorrhoids, sulfurous odor to flatulence

Genitourinary: Sulfurous odor to urine, dysuria

Hematologic: Thrombocytosis, eosinophilia, neutropenia (transient)

Hepatic: Elevation of AST, ALT, alkaline phosphatase, and serum cholesterol

Neuromuscular & skeletal: **Back pain**

Respiratory: Rhinitis

Miscellaneous: Flu-like symptoms

Signs and Symptoms of Overdose Anorexia, GI bleeding, hepatotoxicity, nephritis, renal tubular necrosis, respiratory depression, vomiting

Pharmacodynamics/Kinetics

Absorption: Rapid but incomplete

Metabolism: Rapidly and extensively to mixed succimer cysteine disulfides

Half-life elimination: 2 days

Time to peak, serum: ~1-2 hours

Excretion: Urine (~25%) with peak urinary excretion between 2-4 hours (90% as mixed succimer-cysteine disulfide conjugates, 10% as unchanged drug); feces (as unabsorbed drug)

Dosage Children and Adults: Oral: 10 mg/kg/dose every 8 hours for 5 days followed by 10 mg/kg/dose every 12 hours for 14 days

Dosing adjustment in renal/hepatic impairment: Administer with caution and monitor closely

Concomitant iron therapy has been reported in a small number of children without the formation of a toxic complex with iron (as seen with dimercaprol); courses of therapy may be repeated if indicated by weekly monitoring of blood lead levels; lead levels should be stabilized < 15 mcg/dL; 2 weeks between courses is recommended unless more timely treatment is indicated by lead levels

Monitoring Parameters Blood lead levels, serum aminotransferases

Contraindications Hypersensitivity to succimer or any component of the formulation

Warnings Caution in patients with renal or hepatic impairment; adequate hydration should be maintained during therapy

Dosage Forms Capsule: 100 mg

Antidote(s)

- Unithiol [ANTIDOTE]

Test Interactions False-positive ketones (U) using nitroprusside methods, falsely elevated serum CPK; falsely decreased uric acid

Drug Interactions Not recommended for concomitant administration with edetate calcium disodium or penicillamine

Pregnancy Risk Factor C

Pregnancy Implications No evidence for mutagenicity

Nursing Implications Adequately hydrate patients; rapid rebound of serum lead levels can occur; monitor closely

Specific Reference

Rencova J, Volf V, Jones MM, Singh PK, "Mobilization and Detoxification of Polonium-210 in Ratio by 2,3-Dinercaptosuccinic Acid and Its Derivatives," *Int J Radiat Biol*, 2000, 76(10):1409-15.

Thrombopoietin

Unlabeled/Investigational Use **Investigational:** Thrombocytopenia relatable to cytotoxic drugs or cancer; may be useful in treating drug-induced thrombocytopenia not due to immunological destruction

Mechanism of Action Promotes the proliferation and maturation of megakaryocyte progenitors into platelet-producing megakaryocytes; a ligand for the C-Mpl receptor on megakaryocytes

Adverse Reactions

Cardiovascular: Thrombosis is a theoretical concern

Central nervous system: Mild headache has been described although not temporarily related

Dosage I.V.: 0.3-1 mcg/kg/day for up to 10 days; alternatively, a single dose of 0.3-2.4 mcg/kg 3 weeks before chemotherapy has been used; all doses are intravenous

Reference Range Peak serum thrombopoietin level after a 2.4 mcg/kg dose: ~50 ng/mL; endogenous serum thrombopoietin levels range from 0.096-0.24 ng/mL

Tricyclic Antidepressant Antibody Fragments

Synonyms TCA-Fab

Use Tricyclic antidepressant cardiac toxicity (investigational)

Mechanism of Action Binds to tricyclic antidepressant agents in overdose patients by redistributing the antidepressant from tissue to serum. In animals, TCA-Fab reversed hypotension, shortened QRS duration, and improved survival.

Adverse Reactions Mild bronchospasm, cough

Dosage

Investigational: I.V.: Two protocols:

Low dose: 1 g over 30 minutes; if cardiac toxicity (defined as QRS >100 msec or if terminal deflection of the QRS in lead aVR amplitude was >3 mm), then infuse 2 g over 30 minutes; if cardiac toxicity remains: 4 g over 60 minutes

High dose: 2 g over 30 minutes; if cardiac toxicity remains then 4 g over 60 minutes; if cardiac toxicity remains: 8 g over 120 minutes

Additional Information Manufactured by Protherics, Inc, Brentwood, TN (615) 963-4528 or (615) 327-1027

Specific Reference

Heard K, Dart RC, Bogdan G, et al, "A Preliminary Study of Tricyclic Antidepressant (TCA) Ovine Fab for TCA Toxicity," *Clin Toxicol*, 2006, 44:75-81.

Trientine

Pronunciation (TRYE en teen)

CAS Number 112-24-3; 38260-01-4

U.S. Brand Names Syprine®

Synonyms Trientine Hydrochloride

Use Treatment of Wilson's disease in patients intolerant to penicillamine; possible use in copper poisoning

Mechanism of Action Trientine hydrochloride is an oral chelating agent structurally dissimilar from penicillamine and other available chelating agents; an effective oral chelator of copper used to induce adequate cupriuresis

Adverse Reactions

Central nervous system: Malaise

Dermatologic: Tenderness, thickening and fissuring of skin

Endocrine & metabolic: Iron deficiency

Gastrointestinal: Heartburn, diarrhea, abdominal pain, stomach pains

Neuromuscular & skeletal: Muscle pain and cramps, leg cramps

Miscellaneous: Systemic lupus erythematosus, zinc depletion

Dosage Oral (administer on an empty stomach):

Children <12 years: 500-750 mg/day in divided doses 2-4 times/day; maximum: 1.5 g/day

Adults: 750-1250 mg/day in divided doses 2-4 times/day; maximum daily dose: 2 g

Monitoring Parameters Iron levels

Administration Do not chew capsule, swallow whole followed by a full glass of water; notify physician of any fever or skin changes; any skin exposed to the contents of a capsule should be promptly washed with water

Contraindications Hypersensitivity to trientine or any component of the formulation; rheumatoid arthritis, biliary cirrhosis, cystinuria

Warnings May cause iron-deficiency anemia; monitor closely; use with caution in patients with reactive airway disease

Dosage Forms Capsule, as hydrochloride: 250 mg

Drug Interactions Decreased effect with iron and possibly other mineral supplements

Pregnancy Risk Factor C

Trimedoxime Bromide

CAS Number 56-97-3

Synonyms TMB₄; Dioxime

Mechanism of Action Acetylcholinesterase reactivator which is a bispyridium oxime which appears to be particularly effective for tabun and minimally effective for soman.

Adverse Reactions

To TMB₄: Headache, paresthesia, sensation of warmth, respiratory depression and hypotension at doses >30 mg/kg

To autoinjectors: Local effects (pain, swelling) in 23%; systemic effects of atropinization in 18%

Dosage

As autoinjector (injected into thigh) combined with atropine:

Children <2 years (blue-colored): 0.5 mg atropine/20 mg TMB₄

Children 3-10 years and adults >60 years (rose-colored): 1 mg atropine/40 mg TMB₄

Children and Adults 10-60 years (yellow-colored): 2 mg atropine/80 mg TMB₄

Stability Stable at a pH of 3

Specific References

UNITHIOL

Unithiol

CAS Number 4076-02-2

Use May be effective for Wilson's disease

Unlabeled/Investigational Use

Investigational in the U.S.: Antidote for arsenic, bismuth, lead, zinc, mercury (inorganic and organic), chromium, antimony, and cobalt

Mechanism of Action A water soluble chemical analogue of dimercaprol

Adverse Reactions

Dermatologic: Macular erythematous rash

Cardiovascular: Hypotension at high doses

Gastrointestinal: Nausea, vomiting

Hematologic: Leukopenia

Dosage

Oral:

Antimony: Children: 50-100 mg 3 times/day

Arsenic: Mild poisoning: 200 mg orally 3 times/day; severe poisoning: 200 mg I.V. or 400 mg orally initially, then 100-200 mg I.V., or 200-400 mg orally every 2 hours; taper dose slowly

Bismuth: 250 mg every 4 hours I.V., then 250 mg orally 3 times/day for 14 days

Metal chelation: 100 mg 3 times/day for 5 days

Wilson's disease: 200 mg 2 times/day

Dosing scheme for mercury intoxication: I.V.: 250 mg every 4 hours for 48 hours, followed by 250 mg every 6 hours for the succeeding 48 hours, and then 250 mg every 8 hours thereafter; if no gastrointestinal lesions are present, conversion to oral route of administration can occur; following 96 hours of administration, 300 mg 3 times/day can be given orally; continue treatment until mercury levels in blood and urine fall below 100 mcg/L and 300 mcg/L, respectively. Neurological improvement has occurred following three 5-day courses of 30 mg/kg/day.

Pregnancy Implications Not embryotoxic

SECTION VI
DIAGNOSTIC TESTS/PROCEDURES

DRUG TESTING IN THE 21ST CENTURY

Drug Use and Abuse in the U.S.A.

Christine M. Moore, PhD

The number of people who currently use or admit to having used an illicit drug continues to increase.

A survey by the Drug Abuse Warning Network (DAWN) estimates that for the latter two quarters of 2003, cocaine was involved in 125,921 emergency room visits (approximately 1/5 of all drug-related visits); marijuana was involved in 79,663; heroin in 47,604; stimulants, including the amphetamines, were involved in over 40,000 cases, and other illicit drugs such as phencyclidine (PCP), Ecstasy, and GHB were much less frequently encountered.¹

In 2004, adolescents accounted for approximately 15,000 emergency department visits where drugs were involved in suicide attempts. Antidepressants and other psychotherapeutic drugs were present in over 40% of the cases.²

The increasing number and type of illicit and prescription drugs being encountered, continues to challenge drug testing laboratories.

Objectives And Guidelines For Drug Testing

Analysis of body fluids is a necessary step in determining whether or not an individual has ingested illegal or prescription drugs. It is important to note that at this time, the amount of drug in urine does not give any direct information about the amount of drug ingested, the route of ingestion, the degree of impairment, or the extent of drug dependence of the individual. However, studies and research are ongoing to provide as much interpretive data as possible.

Some questions need to be considered before the implementation of any drug testing program and these include:

- Which drugs should be included in the test?
- How sensitive should the screening procedure be?
- How sensitive and specific should the confirmation be?
- Is an adequate chain-of-custody present?
- How will the results be used?

In 1986, the National Institute on Drug Abuse (NIDA), which is now known as the Substance Abuse and Mental Health Services Administration (SAMHSA), addressed some of these issues and developed urine drug testing proficiency guidelines leading to laboratory certification.³ This was revised December 19, 2000, in order to take effect on August 1, 2001. The guidelines provide for accurate analysis of urine samples by proficiency testing followed by satisfactory laboratory inspections carried out by qualified personnel. Laboratories are required to adhere to Good Laboratory Practice (GLP) as well as establish defensible sample handling (chain-of-custody), reporting, and data reviewing.

The guidelines require the screening and confirmation capability to the levels shown in Table 1 for cocaine metabolite (benzoylecgonine), opiates (codeine and morphine), phencyclidine (PCP), marijuana metabolite (THC-COOH), and amphetamines (amphetamine and methamphetamine).

	Initial (Screening) Cutoff (ng/mL)	Confirmatory (GC/MS) Cutoff (ng/mL)
Marijuana metabolites	50	15*
Cocaine metabolites	300	150†
Opiate metabolites	2000¶	
Morphine		2000¶
Codeine		2000
6-Acetylmorphine		10‡
Phencyclidine	25	25

Table 1. Federal Drug Test Panel (Continued)		
	Initial (Screening) Cutoff (ng/mL)	Confirmatory (GC/MS) Cutoff (ng/mL)
Amphetamines	1000	
Amphetamine		500
Methamphetamine		500
*Assayed as 11-nor-delta-9-THC-9-carboxylic acid (a THC metabolite).		
†Assayed as benzoylecgonine (a cocaine metabolite).		
‡Test for 6-AM when the morphine concentration exceeds 2000 ng/mL.		
¶4000 for Department of Defense employees.		

A positive result for methamphetamine is only reported if amphetamine is also present at a concentration > 200 ng/mL. The reasoning behind this is that the *l*-methamphetamine isomer, which is present in the Vicks inhaler, does not metabolize to amphetamine as efficiently as the illegal *d*-methamphetamine isomer, and, therefore, concentrations > 200 ng/mL of amphetamine should not be present if a Vicks inhaler only is used.

More recently, the cut-off for opiate screening was changed to 2000 ng/mL and requires that 6-acetyl morphine (6-AM) be present in the confirmatory test in order for a positive result to be reported. The change is to help medical review officers interpret opiate positive results and attempt to eliminate positives caused by, for example, the ingestion of poppy seed bagels or muffins.

New guidelines for the testing of adulterants in urine specimens were also recently approved.

Other agencies such as the Centers for Disease Control, the American Association of Clinical Chemistry, and the American Society of Bioanalysts have administered drug testing programs. The College of American Pathologists (CAP) continues to run and monitor regular proficiency testing services for laboratories involved in drug analysis.⁴

Alternative Specimens For Drug Testing

Urine

Urine is the most common specimen chosen for drug analysis and is the only matrix to which the NIDA guidelines apply at this time. NIDA (SAMHSA) approved laboratories are **not** certified to carry out drug analysis in plasma, serum, blood, meconium, amniotic fluid, hair, or any other tissue or fluid.

Urine is chosen for many reasons:

- it is easy to collect.
- large volumes can often be collected.
- drugs and metabolites are often present in higher concentrations than in other body fluids.
- it is easier to analyze than other fluids or tissues.
- drugs and metabolites are usually stable in frozen urine allowing long-term storage of positive samples.

Urine, however, can be easily adulterated since observed specimen collection is not a common practice. Additionally, most drugs are only present in urine for 2-3 days after ingestion, so only recent drug use will be detected.

Blood, Plasma, and Serum

Blood is considered to be an invasive sample to take for routine drug testing; therefore, it is usually only used in forensic cases as requested at autopsy. It is a difficult specimen with which to work, particularly if hemolyzed.

In December 2004, SAMHSA released proposed guidelines for the use of sweat, oral fluid, and hair for workplace testing. At this time, the final guidelines have not been released, but the proposed cut-off concentrations and drug testing profile are shown in Table 2.⁵

Table 2. Proposed Cut-Off Concentrations and Drug Testing Profile for Federal Workplace Drug Testing

Drug	Sweat (ng/sweat patch)		Oral Fluid (ng/mL)		Hair (pg/mg)	
	Screen	Confirmation	Screen	Confirmation	Screen	Confirmation
Cocaine & metabolites	25	25	20	8	500	Cocaine 500 BZE, NC, CE: 50
Opiates	25	25	40 6-AM = 4	40 6-AM = 4	200	200
Phencyclidine	20	20	10	10	300	300
Amphetamines	25	25	50	50	500	300
Marijuana & metabolites	4	1	4	2	1	0.05
BZE = benzoylecgonine; NC = norcocaine; CE = cocaethylene						
Amphetamines include amphetamine, methamphetamine, MDMA, MDA, and MDEA						
Opiates include codeine, morphine, and 6-acetylmorphine (6-AM)						

Sweat

The presence of alcohol, as well as a number of drugs, in sweat has been reported. The collection of sweat from various parts of the body can be difficult and unequal, since sweat production depends on temperature, adrenaline level, and degree of physical activity. About 50% of the body's sweat is produced by the torso, with about 25% produced by the head and legs.

However, there are many reports of drugs being detected in sweat and these include methadone, phencyclidine, amphetamine, phenobarbital, morphine, and cocaine.⁶ Most drugs take 4-6 hours to appear in sweat, the exception being alcohol which takes 2-4 hours. The Food and Drug Administration has approved wearing the "sweat-patch"[®] for 7-day monitoring of drug abstinence, such as in parolees.

Lactate concentration is being investigated as a method of normalization of drug concentrations in sweat so that individual results can be compared and interpreted.

Advantages to this type of testing include noninvasive sample collection (the patch is worn on the back, biceps, or chest), ability to carry out normal activities, including swimming and showering, without removing the patch, and the ability to tell if a patch has been removed and reapplied, so preventing adulteration.⁷ The predominant species found in sweat are parent compounds, not drug metabolites. Analysis of duplicate patches in controlled studies have reported that intrasubject variability is low but intersubject variability is high.

Oral Fluid (Saliva)

Saliva is considered a possible alternative specimen to urine for drug testing because it is an easy and a noninvasive sample to collect. Additionally, it offers an advantage over urine testing if impairment determination is required. Generally drug concentrations in saliva are lower than those found in urine or plasma and the major compound detected is the parent drug, not the metabolites. Initially, oral, intranasal, or smoking drugs may produce high concentrations in saliva for a few hours. However, later, the concentration of drug in saliva is thought to reflect free drug fraction in blood.

Drug excretion in saliva depends on pH and salivary flow, leading to highly variable saliva/plasma ratios for drugs of abuse. It is important to note that most collection devices sequester "oral fluid," not strictly saliva, which accounts for some of the variability of drug testing results experienced with this sample matrix. Disadvantages to saliva testing are mainly associated with the collection of the sample, in that often the actual amount of oral fluid collected is not known, and compared to urine, there is a much smaller volume available for testing.

A comprehensive review of saliva testing for drugs of abuse, which includes information on alcohol, amphetamines, barbiturates, benzodiazepines, caffeine, cocaine, inhalants, LSD, marijuana, opioids, phencyclidine, and tobacco products, is available.⁸

Hair

Hair has been used as an alternative to urine over the last few years. Hair is a noninvasive specimen and can give historical information on drug use which urine cannot. Additionally, it is easy to transport and store. Disadvantages to hair analysis include the determination of drug use versus environmental exposure; potential color bias; and effect of bleaching, coloring, and other hair treatments on the analytical results.⁹⁻¹¹

Meconium and Amniotic Fluid

Drug-, alcohol-, and tobacco-exposed babies suffer from a variety of adverse effects at birth including low birth weight and head size, and in later life, possible learning disabilities.^{12,13}

Pediatricians and nurses are now requesting the analysis of neonatal meconium rather than urine. Studies show meconium to be a better indicator of drug use during pregnancy than urine.^{14,15} As previously discussed, the half-life of drugs and metabolites in urine only allows fairly recent use of a drug to be detected. Meconium begins to form after about 16 weeks of gestation and is cumulative thereafter. Testing is widely available in commercial laboratories, hospitals, and as ELISA procedures become more prevalent, the screening of meconium for a wide variety of drugs is a simple process.

Amniotic fluid, umbilical cord, and cord blood have also been suggested as alternative samples. Amniotic fluid is present throughout gestation and is constantly diluted due to fetal urination. Fetal swallowing of amniotic fluid may also contribute to the recirculation of drug metabolites through the baby.^{16,17}

Techniques in Drug Testing

Drug Screening

The technology of drug screening has greatly improved. Screening tests are designed for maximum sensitivity at the expense of selectivity. It is important, however, that screening tests do not give false-negative results since this terminates the testing process. False-positives at this stage are acceptable because all presumptive positive samples are re-extracted and analyzed by a confirmatory technique.

Thin-Layer Chromatography (TLC)

TLC is an old, but still widely used, technique for the separation and identification of drugs. Essentially, the drug is extracted from urine and concentrated onto a silica plate. The plate is then placed in a solvent tank of chosen polarity. As the solvent rises up the plate, it "elutes" the drugs and carries them to various distances depending upon the affinity of the drug for the plate and for the solvent (or mobile phase). The plate is then sprayed with suitable reagents which allow the drugs to be identified by color and specific positioning relative to drug standards.¹⁸

The technique is cheap and relatively simple, and there are many choices of stationary and mobile phases making complex separations possible.

Disadvantages include interpretation due to interference from endogenous substances. Also, the technique involves lengthy extraction and concentration steps, difficulties in saving data (spots on plates fade with time and photographic representations do not reproduce colors well), and a need for operator experience and skill in spotting and spraying plates. However, TLC is not very specific and results require further confirmation.

Immunoassays

Immunoassay techniques are now the most widely used screening procedures in drug testing. Popular versions of these tests include radioimmunoassay (RIA), enzyme-multiplied immunoassay technique (EMIT), enzyme-linked immunosorbent assay (ELISA), and fluorescence polarization immunoassay (FPIA).

These techniques use antibodies specific to the drug being assayed and a labeled form of the same drug. The label itself may be a radioactive isotope (RIA), an active enzyme (EMIT and ELISA), or a fluorescent label (FPIA) which is incorporated synthetically. A fixed quantity of antibody and labeled drug is added to the test sample. The binding sites on the antibody attract both labeled drug and the unlabeled drug in the sample. The amount of labeled drug bound is inversely proportional to the number of unlabeled drug molecules present.

In RIA, a radioactively labeled drug competes for the same antibody binding site as the unlabeled drug. The analytical measurement of bound radioactivity determines the amount of unlabeled drug in the sample. This method is used to detect opiates, cannabinoids, benzoylecgonine, amphetamines, and phencyclidine, as well as more esoteric drugs such as fentanyl and LSD, although the sensitivity of ELISA screens and their wide availability have largely replaced RIA screening procedures.

In EMIT and FPIA testing, the analytical measurement is of an optically detected change such as UV absorption, fluorescence, or luminescence. These systems avoid the use of radioactive isotopes but also have reduced sensitivity when compared to RIA, because the optical signal is measured in the presence of the original biological fluid.

The application of these types of assays to forensic drug testing has recently been described.¹⁹⁻²¹

Additional antibody kits are also available expanding the use of these systems to include methadone, benzodiazepines, methaqualone, and barbiturates. Advantages include high sensitivity, no extraction steps, and applicability to large numbers of samples.

All immunoassay tests are susceptible to false-positive results due to cross-reactivity of the antibodies with legal or prescription drugs. Several publications on the effect of poppy seed intake on opiate assays have been reported.²²⁻²³

Potential cross reactants to immunoassays are included with manufacturer package inserts when kits are purchased for use.

Table 3. Usual Maximum Concentrations of Street Drugs Due to Passive Inhalation	
	Urinary Concentration (unless otherwise noted)
Marijuana (all metabolites)	
Small, unventilated room	
4 cigarettes	12 ng/mL
16 cigarettes (acid metabolite)	30 ng/mL
Car	14 ng/mL
Cocaine benzoylecgonine (from volatilized cocaine freebase)	14 ng/mL
Phencyclidine (serum sample)	129 ng/mL

Drug Confirmations

High Performance Liquid Chromatography (HPLC)

HPLC allows the separation of nonvolatile substances from each other or from other components of an extraction residue. When a mixture of substances is injected onto the column, each component is partitioned between the stationary phase (column) and the liquid (mobile) phase. Molecules with greater affinity for the column spend more time in that phase and, therefore, take longer to reach the detector. The time taken from injection to the peak maximum is known as the retention time. The detector responds in direct proportion to the concentration of material passing through it, hence peak heights and areas shown on the chromatogram are directly related to the concentration of each analyte.

HPLC shows good sensitivity and high specificity depending upon the detection system used. The most common detectors utilize absorption of UV light by the drug. A diode array detector will allow a full UV spectrum of the analyte to be obtained. This can be compared to a standard spectrum of the drug, and identification is then based both on retention time and UV spectra. Most instruments also include the facility to obtain first and second derivative spectra to provide an additional means of identification. Postcolumn reactions for increased sensitivity have also been described.²⁴

HPLC is relatively inexpensive and can be used for confirmations.

Gas Chromatography (GC)

Gas chromatography is also a method of separating substances of analytical interest. It is one of the most sensitive techniques available for detecting drugs in body fluids. The separation is carried out on an analytical

column containing a stationary phase (liquid or solid, depending on temperature) which is maintained at a given temperature inside an oven. The whole GC system comprises six components: gas supply and flow controllers, injector, oven, column, detector, and recording device. In drug testing, GC capillary (rather than packed) columns are commonly used. A compound is identified by matching its retention time (the time between injection and peak maximum) with that of a drug standard under the same conditions (gas flow rate, temperature, column length, etc).

GC equipment is now relatively inexpensive and experienced personnel are required to run and maintain instruments and interpret chromatograms. Additionally, while GC is fairly specific, its use with nonspecific detectors such as flame ionization (FID), nitrogen-phosphorus (NPD), or electron capture (ECD) does not absolutely identify a compound.

Gas Chromatography/Mass Spectrometry (GC/MS)

GC/MS is the most widely used technique for confirmatory procedures following initial screening assays. It is the so-called gold standard of forensic and drug testing work. The use of GC with a mass spectrometric detection system is forensically defensible as an absolute identification procedure.

When a molecule is injected into the chromatographic system, it is separated from other components of the extraction residue on the basis of its degree of affinity for and interaction with the stationary phase. Upon elution from the chromatographic column, it is bombarded with electrons which cause it to break apart. The fragments produced are separated on the basis of their mass to charge ratio. Under the same conditions, a molecule will fragment in exactly the same way every time, producing the same spectrum. This spectrum or "fingerprint" can then be compared to that of a drug standard for absolute identification.

Figure 2

- a. GC/MS Chromatogram
Drug test mixture containing cocaine (retention time 5.8 minutes)
- b. GC/MS Spectrum
Spectrum of peak at 5.8 minutes

GC/MS is a relatively expensive technique but is necessary in every laboratory which is carrying out confirmatory testing for drugs or metabolites in biological fluids.^{25,26} Experienced operators and interpreters are also needed in order to produce good data. For even more sensitive analyses, an additional gas chromatograph can be added giving two-dimensional gas chromatography (GC/GC/MS); or an additional mass spectrometer giving a triple quadrupole spectrometric system (GC/MS/MS).

Gas Chromatography-Fourier Transform Infrared Spectrophotometry

GC-FTIR is also a forensically acceptable and defensible technique. It is more expensive and less common than GC/MS because it is more difficult to interpret the spectra, requiring skilled and experienced operators and reviewers.

Liquid Chromatography - Mass Spectrometry - Mass Spectrometry (LC/MS/MS)

LC/MS/MS is becoming increasingly used in forensic and drug testing laboratories. The use of liquid chromatography eliminates the need for derivatization of the molecule, which is often required in gas chromatographic procedures. Additionally, run times are short, allowing more samples to be analyzed in less time.^{27,28}

LC/MS/MS equipment is expensive and does require skilled operators.

Future Trends

Potency of Illicit Drugs and Pharmaceuticals

- **LSD**

The recent resurgence of lysergic acid diethylamide (LSD) as a drug of choice poses particular problems for the physician in diagnosis and the analyst in determination. The amounts ingested in order to produce the desired effect are extremely low and, therefore, very difficult to detect in biological specimens. There are no FPIA kits readily available to screen for LSD; but ELISA and RIA methods are commonly used as screening procedures. For confirmation, some papers have suggested using electron impact GC/MS (the most common approach) but it is likely that the sensitivity of GC/MS/MS systems will be required, or chemical ionization procedures.²⁹ Such techniques are somewhat complicated and not currently used in the majority of routine hospital laboratories.

- **Fentanyl**

Fentanyl (N-phenyl-N-[1-(2-phenylethyl)-4-piperidinyl] (propanamide)) is a potent, fast-acting, synthetic narcotic analgesic. Its potency is considered to be 100-200 times that of morphine, but its effects are shorter. It was developed as an intravenous anesthetic, marketed in the U.S.A. as Sublimaze[®] and as Innovar[®] when used with droperidol. However, a number of fentanyl analogues are also available, specifically alphamethylfentanyl (twice the potency of fentanyl), sufentanil, carfentanil, alfentanil, thienylfentanyl, lofentanil, 3-methylfentanyl, and p-fluorofentanyl. These are mostly sold for surgical and veterinary purposes but have appeared on the street as “designer drugs,” “synthetic heroin,” and “China White.”

Most of the screening for these drugs is currently carried out using ELISA technology.³⁰ Confirmation is by GC/MS and the levels present are detectable using electron impact GC/MS.

- **Benzodiazepines**

Potent benzodiazepines, such as alprazolam, flunitrazepam, and triazolam, are administered at very low doses. Detection of the parent drug in biological fluids is extremely difficult and the majority of laboratories search for metabolites. Benzodiazepine immunoassays do cross react well with some metabolites as well as parent drugs, but the confirmation procedures become more difficult. Different modes of detection are usually employed such as negative or positive ion chemical ionization GC/MS or LC/MS/MS.

- **MDMA, MDEA**

The European “designer drugs,” MDMA and MDEA are being encountered more frequently in the U.S.A. MDMA, its metabolite MDA, and MDEA have been included in the SAMHSA guidelines for drug testing laboratories.

- **Synthetic Opiates**

According to the DEA, the most highly abused prescription drugs in the U.S. today are opioid painkillers (eg, hydrocodone, oxycodone). OxyContin[®], which was first marketed in 1996, is a 12-hour time-release formulation of oxycodone, which is also the active ingredient in Percocet[®] and Percodan[®]. OxyContin[®] allows patients to take fewer pills over a longer time for increased relief from pain, but its abuse potential is enormous. Similarly, Vicodin[®] (hydrocodone), which is often prescribed following major surgery, has a high abuse potential.

- **Anabolic Steroids**

The use of anabolic steroids among teenagers and young adults is becoming increasingly popular, particularly in those involved in sports requiring great strength such as weight lifting and body building. All anabolic steroids are derivatives of the male hormone testosterone and all are intended for “tissue building” and increasing masculinizing effects.

Over 100 anabolic steroids are widely available in oral or injectable form. They are used for many medical reasons including the treatment of some breast cancers, growth promotion, and delayed puberty. Reported psychological side effects associated with their use include aggression, psychosis, and changes in libido.

In 1974, they were added to the list of doping agents banned by the International Olympic Committee (IOC). Extensive metabolic pathways, as well as natural occurrence, makes the detection of these substances difficult. However, athletic drug testing laboratories are routinely able to detect many of the anabolic steroids in urine samples by using gas chromatography/mass spectrometry (GC/MS) methods. Other drug classes which have become widely abused include GHB, ketamine, and antidepressants such as sertraline and fluoxetine. Drug testing laboratories will be required to expand their drug profiles as more and more new drugs are used and abused.

Conclusions

- It is important to be aware of the limitations of screening and confirmatory drug testing techniques. Even though GC/MS instrumentation is expensive, it is the cheapest way to absolutely identify the contents of a biological sample, ensuring the analysis is forensically defensible.
- Drug levels do not give any information about possible drug abuse or dependence, route or amount of drug ingestion, or (with the possible exception of blood and saliva) the degree of impairment. It is recommended that readers familiarize themselves with metabolic routes and pharmacokinetics of the drugs in question.
- Urine is still the most commonly tested biological fluid although the search continues for a noninvasive, adulterant-free sample which will provide a history of drug use.
- The increasing potency of new drugs and pharmaceuticals, as well as the increasing number of drugs, will place new demands on the laboratory. A wider range of immunoassay kits with better sensitivity and specificity will be required, as will increasingly sensitive confirmation instrumentation.

Acetaminophen, Serum

Synonyms Anacin-3[®] Level, Blood; Datril[®] Level, Blood; Liquiprin[®] Level, Blood; Panadol[®] Level, Blood; Panex[®] Level, Blood; Paracetamol Level, Blood; Phenaphen[®] Level, Blood; Tempra[®] Level, Blood; Tylenol[®] Level, Blood

Uses Therapeutic monitoring; evaluate acetaminophen toxicity

Reference Range Acetaminophen, serum: 20-110 mcg/mL (SI: 43-240 μmol)

Abstract Acetaminophen is an analgesic-antipyretic widely used as a replacement for aspirin. It is frequently seen in the deliberate overdose situation.

Specimen Blood

Volume 10 mL

Minimum Volume 3 mL

Container Red top tube

Critical Values Toxic: > 150 mcg/mL (SI: > 990 μmol/L) (within 4 hours); > 50 mcg/mL (SI: > 330 μmol/L) (within 12 hours)

Methodology UV spectrophotometry, immunoassay, gas-liquid chromatography (GLC), or high performance liquid chromatography (HPLC)

Additional Information

Hydrochlorothiazide may cause false increase in acetaminophen assay by HPLC method.

Phenols (from throat lozenges) can cause a false elevation of acetaminophen by the ortho-cresol method. Conversely, N-acetylcysteine can falsely lower acetaminophen level by the ortho-cresol method.

Salicylates and methyl salicylate can cause an increase of serum acetaminophen level of 10% by spectrochemical method. Each rise of 1 mg/dL of creatinine can cause a 30 mg/L rise of acetaminophen. Cephalosporins and sulfonamides can also falsely elevate serum acetaminophen level by HPLC.

Acetylcholinesterase, Red Blood Cell

Related Information

- Pseudocholinesterase, Serum

Synonyms Acetylcholinesterase, RBC; Cholinesterase, Erythrocytic; Erythrocyte Cholinesterase; Red Cell Cholinesterase; True Cholinesterase

Uses Erythrocyte cholinesterase is measured to diagnose organophosphate and carbamate toxicity and to detect atypical forms of the enzyme. Cholinesterase is irreversibly inhibited by organophosphate insecticides and reversibly inhibited by carbamate insecticides. Serum or plasma pseudocholinesterase is a better measure of acute toxicity, while erythrocyte levels are better for chronic exposure. (Serum level returns to normal prior to normalizing of red cell level.) Acetylcholinesterase is increased in amniotic fluid in cases of neural tube defect. Persons with an atypical form of the enzyme (with low enzyme activity) exhibit prolonged apnea following the use of certain suxamethonium-type muscle relaxants in anesthesia (succinylcholine sensitivity - AA phenotype). These atypical forms may be detected by the use of fluoride or dibucaine inhibition. In amniotic fluid, it is used for the evaluation of neural tube defects in conjunction with alpha-fetoprotein.

Reference Range Not well established, varies with method, age, sex, and use of oral contraceptives. Normally absent in amniotic fluid. Usual range in healthy individuals: 4000-12,000 unit/L. While neonatal levels are initially low, adult levels are achieved after 2 months of age. Mild poisoning usually results in acetylcholinesterase levels 20% to 50% of normals; moderate poisoning results in a depression to 10% to 20% of normal, while severe poisoning results in a depression of <10% of normal.

Specimen Blood

Minimum Volume 2 mL whole blood

Container Green top (heparin) tube or heparinized capillary tubes

Storage Instructions Stable at 4°C to 25°C for 1 week only.

Limitations Values decrease as erythrocytes become senescent.

Methodology Methods are based on determination of result (rate) of hydrolysis of an ester catalyzed by the enzyme acetylcholinesterase and include colorimetry, fluorometry, spectrophotometry based systems. Polyacrylamide gel electrophoresis is used for the qualitative demonstration of acetylcholinesterase in amniotic fluid. Screening methods are available.

Additional Information

The cholinesterase activity in human red cells is highly but not exclusively specific for acetylcholine. It is referred to as true or specific cholinesterase. Cholinesterase activity present in the serum/plasma hydrolyses both choline and aliphatic esters, has a broader range of esterolytic activity and is referred to as "pseudo-" or "nonspecific" cholinesterase. It hydrolyses acetylcholine only slowly. The systematic name for acetylcholinesterase is acetylcholine acetylhydrolase. Systematic name for cholinesterase (serum/plasma) is acylcholine acylhydrolase. The different nature of the cholinesterases was first described in 1940.

The plasma enzyme is synthesized by the liver, the red cell enzyme during erythropoiesis.

Cholinesterase activity is low at birth and higher in adult males than females. The enzyme is a large complex protein. There is evidence that it has a multiple subunit structure, four peptide chains that form two dimers. Because of the many constituent amino acids, many molecular variants are possible. The RBC level is **increased** in hemolytic states such as the thalassemias, spherocytosis, hemoglobin SS, and acquired hemolytic anemias. It is **decreased** in paroxysmal nocturnal hemoglobinuria and in relapse of megaloblastic anemia. (It returns to normal with therapy.)

Potent inhibitors of cholinesterase may present important clinical toxicological problems. Systemic insecticides (eg, organophosphates or carbamates) are examples. Both RBC acetylcholinesterase and plasma cholinesterase are usually inhibited. The effect on the plasma enzyme is more marked, however, and serum levels are usually utilized in diagnosis and assessment of recovery. Recovery is best determined by looking for a plateau in erythrocyte cholinesterase activity. Toxic potency may vary, plasma versus red cell cholinesterase, such that in some cases erythrocyte levels may be needed for diagnosis and/or monitoring. If there is suspicion that a decrease in cholinesterase activity may not relate to the inhibitor effect of an organophosphate then red cell level of acetylcholinesterase should be obtained. If both serum and RBC levels are significantly decreased, findings are those of exogenous toxic effect.

True cholinesterase (acetylcholinesterase-RBC cholinesterase) is not normally present in amniotic fluid. The presence of acetylcholinesterase activity and increased levels of alpha-fetoprotein in amniotic fluid is presumptive evidence of an open neural tube defect (eg, anencephaly, open spina bifida, or omphalocele) in the fetus.

Activated Partial Thromboplastin Time

Applies to Antiaggregating Agents; Heparin Inhibitors; Heparin; Low Molecular Weight; Protamine Sulfate; Thrombin Clotting Time Heparin Assay

Synonyms APTT; Partial Thromboplastin Time, Activated; PTT

Uses Evaluate intrinsic coagulation system; useful in monitoring heparin therapy; aid in screening for presence of classical hemophilia A and B; congenital deficiencies of factors II, V, VIII, IX, X, XI, and XII; dysfibrinogenemia; disseminated intravascular coagulation; liver failure; congenital hypofibrinogenemia; vitamin K deficiency; congenital deficiency of Fitzgerald factor; congenital deficiency of prekallikrein (Fletcher factor)

Contraindicating Factors Specimen obtained less than 3 hours after dose of heparin

Reference Range 25-39 seconds, usually stated to be within 10 seconds of control. Healthy premature newborns have prolonged coagulation test screening results (eg, PT, PTT, TT) which return to normal adult values at ~6 months of age. Healthy prematures, however, do not develop spontaneous hemorrhage or thrombotic complications because of a balance between procoagulants and inhibitors. A plasma heparin level of 0.4 units/mL results in changes of APTT of 11-57 seconds while a mean dose of heparin of 13.9 units/kg/hour can double the APTT. The normal range in childhood (ages 1-16) is similar to that in adults.

Test Commonly Includes Patient time and control time

Abstract The activated partial thromboplastin time (APTT) is a readily available low cost screening test. The test procedure is usually automated, batch processing is efficient, and the turnaround time is reasonably rapid in the individual or stat mode. The test finds application in screening for intrinsic factor deficiencies and for monitoring of heparin anticoagulation.

Patient Preparation Draw specimen 1 hour before next dose of heparin if heparin is being given by intermittent injection; not applicable to patients on continuous heparin infusion therapy. Do not draw from an arm with a heparin lock or heparinized catheter.

Specimen Plasma

Minimum Volume 4.5 mL

Container Blue top (sodium citrate) tube

Collection Routine venipuncture. If multiple tests are being drawn, draw coagulation studies last. If only a PTT is being drawn, draw 1-2 mL into another Vacutainer[®], discard, and then collect the PTT (two-tube or two-syringe technique). This collection procedure avoids contamination of the specimen with tissue thromboplastins. Transport the specimen to the Hematology Laboratory as soon as possible.

Storage Instructions Keep refrigerated.

Causes for Rejection Tube not full; specimen hemolyzed; specimen clotted; specimen received more than 2 hours after collection; specimen improperly labeled; specimen contaminated by anticoagulant, effect of which is not being measured

Possible Panic Range >70 seconds

Methodology Methods involve addition of a contact activator (eg, Celite, kaolin, microsilicate, elagic acid). Plasma sample is added to activator and incubated at 37°C, usually for 5 minutes. Thromboplastin preparation is added, mixed, and with addition of CaCl₂, a timer is started. A variety of

automated instruments have been designed to perform this test, often with the capability of also performing the prothrombin time test. A variety of instruments and reagents are used in the field resulting in many combinations, most monitored by the College of American Pathologists survey process.

Additional Information

Hemolysis significantly shortens the activated partial thromboplastin time in normal but not in abnormal persons. The APTT may be normal in persons with mild hereditary disorders. About 30% of normal concentration of factors V, VIII, IX, X, XI, and XII will maintain a rate of thrombin formation sufficient to produce a normal APTT. Fibrinogen level, if <80 mg/dL, may result in an abnormal APTT. If Fletcher or Fitzgerald factors are <5% of normal the APTT may be abnormal. A prolonged APTT can be caused by inherited factor deficiency (I, II, V, VIII-XII), Fletcher or Fitzgerald, Coumadin® type therapy, liver disease, circulating anticoagulant (heparin, lupus anticoagulant, fibrin breakdown products), specific factor inhibitor (rheumatoid arthritis, penicillin reaction, occasional hemophiliacs), or intravascular coagulation.

The results of the College of American Pathologists surveys indicate that the source and type of heparinized specimen is important to consider when interpreting APTT test results. Different reagent/instrument combinations effect the APTT response to heparin. Sensitivity is most influenced by the APTT reagent used while precision is most effected by the instrument utilized.

Control of heparin therapy: Heparin is an acidic mucopolysaccharide that inhibits all of the active serine proteases (IIa, Xa, IXa, XIa, and XIIa). It has a strong negative charge and a circulating half-life of only a few hours. It is stable for 24 hours in a 5% dextrose solution. Elimination is largely by the kidney so that heparin must be used cautiously in patients with impaired glomerular filtration.

Administration, dosage: Heparin is best administered intravenously, intermittently, or better as continuous infusion in a dosage of 400-500 units/kg body weight/day divided into every 6-hour dosage (so that 100-125 units/kg body weight is given each 6 hours). Laboratory monitoring can be accomplished using the Lee-White clotting time, APTT, activated clotting time (ACT) or heparin assay. Dosage is adjusted to maintain the coagulation test result at about two times the control or "normal" level (APTT target range 60-85 seconds or APTT ratio which is equivalent to a heparin level by antifactor Xa assay of 0.3-0.7 units/mL).

There are three levels of heparin therapy: low dose, moderate dose, and large dose. Low dose refers to small amounts of heparin (10,000-20,000 units/day) given subcutaneously and useful in the prophylaxis against venous thrombosis (selected patients). Measurable change in APTT does not usually occur. See review by Hirsh and Levine listed in references. Moderate dose implies full anticoagulation, requires 20,000-60,000 units/day, the APTT is adjusted to 1.5 to 2 times the control, and the regimen is applied to patients without active thromboembolic disease. Large dose heparin therapy utilizes dosage levels of 60,000-100,000 units/day during the first 24-48 hours and then reverting to 30,000-45,000 units/day. Large dose therapy is for patients with active thromboembolic disease.

Heparin should not be given intramuscularly (risk of hematoma formation). There is a trend to favor subcutaneous administration in the initial treatment of deep vein thrombosis. In support of this trend are studies claiming efficacy and safety, and procedural simplification allowing outpatient or home therapy.

Complications: Not all individuals respond ideally or predictably to heparin. One must investigate the causes and management of aberrant cases.

Drugs which antagonize the action of heparin include streptomycin, erythromycin, gentamicin, chlorpromazine, ascorbic acid, antihistamines, and digitalis.

Untoward effects of heparin include development of osteoporosis with fractures (doses of 20,000 units/day over 6 months), anti-inflammatory effect, and inhibition of antidiuretic effect resulting in diuresis. Unusual reactions include anaphylaxis and erythematous reactions (species specific), alopecia, urticaria, headache, and bronchospasm. There may be significant morbidity (including amputation of extremities) and mortality associated with heparin induced platelet aggregation and resultant new thrombosis and thrombocytopenia.

Heparin-induced thrombocytopenia: Pretherapeutic laboratory evaluation may be desirable. Abnormalities in platelet count, whole blood clotting time, activated PTT, or antithrombin III may indicate that the patient has a predisposition to an unusual heparin response. Heparin-induced thrombocytopenia appears to have immune etiology and occurs in the presence of either an IgG or IgM heparin dependent platelet aggregating antibody. These patients have a measurable abnormal response to ADP, heparin and ADP, and heparin alone in the platelet aggregation procedure when thrombocytopenia is present.

The **progressive thromboembolic syndrome** appears to be always associated with thrombocytopenia. Monitoring of the heparinized patient has been recommended and includes daily physical examination for evidence of further thrombosis and periodic platelet counts, the need for which is determined clinically. Evidence of new thrombosis or decrease

in platelet count to <100,000/mm³ should be further investigated with aggregation studies to see if an abnormal response to platelet aggregation is present. The platelet abnormality quickly reverses when heparin is discontinued. Added beneficial therapy includes antiaggregating agents such as dextran (Rheomacrodex®) I.V., 25 mL/hour; acetylsalicylic acid; dipyridamole; and Coumadin®. Iloprost® has been utilized to prevent heparin-induced thrombocytopenia during open heart surgery.

The table summarizes the relation of three coagulation tests that have been and can be utilized to adjust the heparin anticoagulant effect. See table.

Heparin Anticoagulant Effect		
Test	Usual Normal Control Results	Anticoagulant Range (Heparin Level 0.2-0.4 units/mL)
Lee-White clotting time	8-15 min	20-30 min
Activated clotting time	70-120 sec	180-240 sec
Activated PTT	25-39 sec	60-80 sec
(About twice the normal control value)		

Early studies suggested that thrombi do not propagate when the heparin level is such as to prolong the Lee and White (L&W) clotting time to twice that of a normal control. The level of heparin required or desirable, however, varies on an individual basis depending on the severity of the thrombotic process, the potential bleeding risk, variations in the heparin preparation - varying polymer length, sulfonation of polymers, medications that inactivate or inhibit heparin (antihistamines, digitalis, nicotine, penicillin, tetracyclines, phenothiazines and protamine), poor coordination in timing the dose and collection of specimens, antithrombin III level, platelet factor IV level, and fibrinogen level. If the latter factors are in normal range, heparin level of 0.3 units/mL of plasma is required to result in a Lee-White clotting time of twice the normal control. Heparin level of 0.6 units/mL (3 times normal Lee-White clotting time) may result in clinical bleeding. Therapeutic range is usually attained with heparin level of 0.2-0.4 units/mL. Heparin dose of 100-125 units/kg body weight given at six hourly intervals bolus I.V. or SubQ or 400-500 units/kg body weight/day as constant infusion will usually provide effective anticoagulation.

Monitoring: The activated clotting time (ACT) and the activated plasma thromboplastin time (APTT) are most commonly used to monitor heparin therapy.

Low molecular weight heparin (LMWH): Standard heparin is composed of sulfated mucopolysaccharides, heterogeneous fragments of different molecular weights. LMWH is less heterogeneous, consists of fragments with high and low affinity for AT III but LMWH use is associated with decreased antithrombin activity while anti-Xa activity is largely preserved. There is evidence that LMWH is able to protect against thromboembolic events while the risk of hemorrhage is reduced. Conventional tests used in monitoring of standard heparin treatment (eg, APTT, TT, ACT) are not affected by LMWH at the doses usually employed. Laboratory control of the use of LMWH is, therefore, not applicable. Heparin-induced thrombocytopenia is usually seen, however, some 7-12 days after LMWH therapy begins so that periodic platelet counts are recommended.

Lupus anticoagulant: Patients with a prolonged APTT not corrected by mixing with normal plasma but with no family or clinical/surgical history of bleeding are (in screening situations) most commonly due to a phospholipid (lupus type) anticoagulant. College of American Pathologists surveys (1986 and 1987) found significant difference in the sensitivity of different APTT reagents to the presence of lupus anticoagulants. The difference in reagent responsiveness can affect the apparent factor activity and also the dilutional effect on mixing patient with normal plasma samples, thus impairing the ability to differentiate a lupus anticoagulant from a specific factor inhibitor.

Alcohol, Semiquantitative, Urine

Synonyms Ethyl Alcohol, Urine; Urine Alcohol Level; Urine Ethanol

Reference Range Negative

Test Commonly Includes Ethyl alcohol for medical purpose only, not for legal use. Assay also measures methyl alcohol, isopropyl alcohol, and paraldehyde. Results reported as ethanol unless another alcohol is requested.

Specimen Random urine

Volume 15 mL

Minimum Volume 1 mL

Container Plastic urine container

Collection Freshly voided random urine

Methodology Dichromate diffusion

Additional Information The average urine/blood ratio is 1.35 in the postabsorptive state.

Alcohol, Serum

Synonyms Ethanol, Blood; Ethyl Alcohol, Blood; EtOH

Uses Quantitation of alcohol level for medical or legal purposes; screen unconscious patients; used to diagnose alcohol intoxication and determine appropriate therapy; screen for alcoholism and monitor ethanol treatment for methanol intoxication. Must be tested as possible cause of coma of unknown etiology since alcohol intoxication may mimic diabetic coma, cerebral trauma, and drug overdose.

Reference Range Blood: negative. In most laboratories, values <10 mg/dL (SI: <2.0 mM/L) are considered negative. Signs of intoxication can be observed at levels of 30-100 mg/dL (SI: 6.6-21.7 mM/L).

Patient Preparation While it should be noted that the possibility of an isopropyl-based swab significantly interfering with an ethanol-based assay is negligible, this aspect may be challenged in court, and therefore it may be best to avoid this argument by using a nonalcohol-based swab. Hexachlorophene-based, iodine-based, or mercury-based antiseptics not containing alcohol may be used.

Specimen Blood

Volume 5 mL

Minimum Volume 2 mL serum or plasma

Container Red top tube; gray top (sodium fluoride) tube is recommended for medicolegal specimens and prolonged storage.

Collection Do not prepare venipuncture site with an alcohol swab for forensic samples. When police agencies bring an individual in for blood alcohol levels, medical and laboratory people should at all times be aware of their state statutes.

Storage Instructions Refrigerate in a tightly stoppered tube.

Special Instructions Concentrations of ethanol are 12% to 18% higher in serum and plasma versus whole blood. For forensic purposes, only whole blood values are used.

Critical Values Fatal concentration is usually considered to be >400 mg/dL (SI: >86.8 mM/L). Whole blood levels of 300 mg/dL (SI: 65.1 mM/L) are associated with coma. In most states, whole blood levels \geq 80 mg/dL are considered evidence of impairment for driving.

Possible Panic Range \geq 300 mg/dL (SI: \geq 65.1 mM/L)

Limitations Certain other alcohols (in high concentration) can interfere with enzymatic methods. The rate of dehydrogenation of isopropanol (2-propanol) is 6% and that of n-propanol (1-propanol) is 36% of that of ethanol. Methanol does not interfere. Gas chromatography is the most specific methodology because it can separate, identify, and quantitate each type of alcohol present. Freezing point osmometry and enzymatic analysis can together determine the presence of volatile intoxicants and can determine causes of metabolic intoxication.

Methodology Enzymatic analysis (alcohol dehydrogenase), freezing point osmometry, gas chromatography (GC)

Additional Information Elevated serum lactate and lactate dehydrogenase levels may interfere with enzymatic ethanol assays. Lactate dehydrogenase and lactate can cause false positive serum ethanol screen (by EMIT) in postmortem state. Postmortem urinary lactate dehydrogenase levels (>592 units/L) and lactate levels (>12 mm) and proteinuria can lead to false positive results on drugs of abuse screening by enzyme-multiplied immunoassay techniques (EMIT)

(SI: < 1.48 μ mol/L) without apparent acute effects, >100 ng/mL (SI: > 3.7 μ mol/L) possible CNS toxicity, >200 ng/mL (SI: > 7.4 μ mol/L) probable multisystem toxicity; urine: 0-32 ng/day (SI: 0-1.2 μ mol/day); dialysate: <0.01 mg/L (AAMI standards)

Specimen Blood, dialysis fluid, urine, cerebrospinal fluid

Volume 5 mL

Container Special metal-free Sherwood Monoject™ trace element blood collection tube #8881-307006 for serum separation; acid-washed plastic vials for other samples.

Collection Use B-D #5175 20-gauge stainless steel needle, or Terumo or Abbot butterfly needle. Draw any trace metal tube prior to any other type of blood sample to prevent contamination of needle by regular rubber stoppers.

Causes for Rejection Contamination by aluminum contact, dust, or ordinary collection tubes or stoppers. Urine must not be contaminated by stool.

Special Instructions The patient should take no aluminum containing antacids or medicines (such as Basaljel®, Gelusil®, Maalox®, Amphojel®, Sucralfate) for 24 hours prior to blood test.

Limitations Serum levels rise and fall after each dose of aluminum-containing phosphate binder or sucralfate. If renal function is normal, renal clearance of aluminum is prompt with urine levels rising quickly after a course of aluminum-containing antacid is begun and elevated levels persisting for over a week. Urine levels rise after a dose of desferrioxamine given for any reason. The degree of rise in serum aluminum after desferrioxamine is regarded as reflecting total body aluminum burden.

Methodology Atomic absorption (AA), inductively coupled plasma atomic emission spectrometry

Additional Information Serum aluminum correlates with encephalopathy; red cell aluminum correlates with microcytic anemia; and bone aluminum correlates with aluminum bone disease.

Amphetamines, Qualitative, Urine

Related Information

- Drug Testing in the 21st Century
- Methamphetamines, Urine

Synonyms Bennies; Crystal; Dexies; Ice; Speed; Uppers

Uses Drug abuse evaluation; toxicity assessment

Reference Range Negative (less than cutoff)

Test Commonly Includes Amphetamine, methamphetamine

Test Interactions Spurious positive amphetamine urinary immunoassay screen can result from trazodone therapy.

Abstract Amphetamine and methamphetamine are major drugs of abuse. They have limited medical use and are DEA schedule II drugs.

Specimen Random urine

Volume 50-60 mL

Minimum Volume 5 mL

Container Plastic urine container

Collection If forensic, observe precautions.

Storage Instructions Refrigerate

Causes for Rejection If forensic, failure to meet temperature requirements and/or tests for unusual urine dilution (specific gravity or creatinine) or alteration

Special Instructions If forensic, use chain-of-custody form.

Critical Values Cutoff: screen: 1000 ng/mL; confirmation: 500 ng/mL

Limitations Some over-the-counter cold and antiallergy medications may cross react in certain immunoassay screens; confirmation by a different, more sensitive method (eg, GC/MS) is necessary. Clobenzorex hydrochlorate (an anorectic) can give a positive urine result for amphetamine by immunoassay and GC/MS. A labetalol metabolite (3-amino-1-phenylbutane or APB) may cause a false-positive result with amphetamine/methamphetamine by thin layer chromatography or immunoassay. Mexiletine may give a false-positive test for amphetamine by urinary fluorescence polarization assay.

Methodology Screen: fluorescence polarization immunoassay (FPIA), radioimmunoassay (RIA), enzyme immunoassay (EIA), gas chromatography (GC), thin-layer chromatography (TLC), high performance liquid chromatography (HPLC); confirmation: gas chromatography/mass spectrometry (GC/MS)

Additional Information For the amphetamine class, the material detected is the parent drug. Alum (25 g/L) can elicit a false-negative urinary assay for methamphetamine; urine will be acidic in these cases.

Aluminum, Serum

Uses

Monitor patients for prior and ongoing exposure to aluminum. Patients at risk include:

- infants on parenteral fluids, particularly parenteral nutrition
- burn patients through administration of intravenous albumin, particularly with coexisting renal failure
- adult and pediatric patients with chronic renal failure, who accumulate aluminum readily from medications and dialysate
- adult parenteral nutrition patients (less so, recently)
- patients with industrial exposure

Monitor dialysate and water to prepare dialysate to prevent aluminum toxicity in dialysis patients. Research use: investigation of amyotrophic lateral sclerosis (in Guam) and Alzheimer's disease.

Reference Range Serum (normal patient): 0-10 ng/mL (SI: 0-0.37 μ mol/L) (may vary with laboratory); serum (dialysis patients): up to 40 ng/mL

Anion Gap, Blood

Applies to Urinary Anion Gap

Synonyms Electrolyte Gap; Gap; Ion Gap

Uses

Extensively used for quality control in the laboratory, the widest clinical application of the anion gap is in the diagnosis of types of metabolic acidosis. Unmeasured cations include calcium and magnesium. Unmeasured anions include protein, PO_4^{3-} , SO_4^{2-} , and organic acids. Organic acidosis includes lactic acidosis and ketoacidosis.

A marked elevation of anion gap, > 30 mM/L, bears a strong implication of metabolic acidosis. Increased anion gaps are found in states such as renal failure and toxic ingestions. A > 30 mM/L gap increase commonly is secondary to lactic acidosis or ketoacidosis, but can also be caused by rhabdomyolysis or nonketotic hyperglycemic coma.

In diabetic ketoacidosis, plasma glucose is high, often much > 300 mg/dL (SI: > 16.7 mM/L), pH is < 7.3, and ketones are found in blood and urine. Increased serum osmolality and increased calculated osmolality (osmolar gap) are found, and serum sodium is often decreased.

In alcoholic ketoacidosis glucose may be increased, normal or low, but a high alcohol level may be found, and amylase and uric acid may be increased.

Reference Range 6-16 mM/L (SI: 6-16 mM/L); slight differences may be established in different laboratories. Until recently electrolytes were done mostly by flame photometry. As ion-selective electrodes have come into wider use, reference ranges for anion gap will probably change.

Test Commonly Includes A calculation from electrolytes, sodium, potassium, HCO_3^- , and chloride to ascertain quantities of unmeasured cations and anions

Abstract The anion gap is useful in evaluation of patients with acid-base abnormalities. The sum of anions and cations must be equal in the blood.

Specimen Blood

Container Red top tube

Limitations Minor differences in formula are used by different laboratories. A spurious increase may follow excessive exposure of the sample to room air, as well as, underfilling the Vacutainer® tube. Some gaps remain unexplained. Not all metabolic abnormalities are detected by abnormal gaps (eg, isopropanol ingestion is accompanied by normal gap, but ketone bodies are positive). There are a number of causes of normal anion gap acidosis associated with hyperchloremia. Anion gap is unsuitable as a quick screen for lactic acidosis. Still useful, the anion gap should not replace assay for lactate, creatinine, ketone bodies, or osmolality. In one study, only 66% of patients with an anion gap of 20-29 mM/L could be proven to have an organic acidosis.

Methodology Calculation: $(\text{Na}^+ + \text{K}^+) \sim (\text{Cl}^- + \text{HCO}_3^-)$ or $\text{Na}^+ \sim (\text{Cl}^- + \text{HCO}_3^-)$ = anion gap; actually determined by the difference between concentrations of anions and cations.

Additional Information

Anion gap represents approximately the sum of the unmeasured anions, charges of which, with chloride and HCO_3^- , balance sodium. (Measured anions are chloride and bicarbonate. Measured cations are sodium.)

Anion gap high ("unmeasured anions"): with **pH high**: extracellular volume contraction; massive transfusion (with renal failure and/or volume contraction); carbenicillin, penicillin (large doses), salts of organic acids such as citrate. With **pH low**: uremia: most common cause; abnormal anion gap in uremia is usually seen only when creatinine is > 4.0 mg/dL (SI: > 354 $\mu\text{mol/L}$). Uremic acidosis is rare without hyperphosphatemia. Nonketotic hyperglycemic coma and rhabdomyolysis may cause high anion gap metabolic acidosis. Lactic acidosis and diabetic or alcoholic ketoacidosis characteristically fall into this group. With **normal osmolal gap**: salicylate and paraldehyde toxicity; with **increased osmolal gap**: methanol and ethylene glycol toxicity.

High anion gap metabolic acidosis without elevated lactic acid or acetone; consider: ketoacidosis with negative or slightly positive "acetone" if the patient is hypoxic and/or has alcoholic ketoacidosis, such ketoacidosis may be life-threatening; salicylate toxicity; methanol toxicity (paint thinners); ethylene glycol toxicity (antifreeze) - urinary sediment contains abundant calcium oxalate and/or hippurate crystals; paraldehyde intoxication (may have positive ketone reactions); toluene toxicity (transmission fluid, paint thinner inhalation or sniffing).

Anion gap low: Caused by retained unmeasured anions. The most common cause is hypoalbuminemia (eg, in nephrosis, cirrhosis), dilution, hypernatremia, very marked hypercalcemia, very severe hypermagnesemia, IgG myeloma and polyclonal gamma globulin increases - hyperviscosity with certain lab instruments, lithium toxicity, bromism (low anion gap may not be present). Decreased anion gap with spurious hyperchloremia and with hyponatremia is reported in hyperlipidemia. Dilution of extracellular fluid may cause a decreased gap. The finding of a low anion gap is perceived as an unreliable diagnostic parameter and may indicate potential laboratory error.

Normal anion gap may occur with **metabolic acidosis**, causes have been published. They include diarrhea, renal tubular acidosis, hyperalimentation, ureteroileostomy, ureterosigmoidostomy, external drainage of pancreaticobiliary fluids, NH_4Cl and other drugs.

The urinary anion gap is used in the diagnosis of hyperchloremic metabolic acidosis and evaluation of renal potassium wasting.

Antibiotic Level, Serum

Synonyms Antimicrobial Assay

Uses Evaluate adequacy of serum antibiotic level; detect toxic levels

Reference Range Therapeutic range depends on agent being tested for, and minimal inhibitory concentration of drug against organism. Selected ranges in mcg/mL are presented as a guide only. See table.

Drug	Peak		Trough	
	mcg/mL	SI: $\mu\text{mol/L}$	mcg/mL	SI: $\mu\text{mol/L}$
Amikacin	15-25	26-43	< 10	< 17
Chloramphenicol	25	77		
Flucytosine	100	775		
Gentamicin	4-10	8-21	< 2	< 4
Netilmicin	4-8	8.0-17.0	1-2	0.7-1.4
Streptomycin	5-20	9-34	< 5	< 9
Tobramycin	4-10	8-21	< 2	< 4
Trimethoprim	≥ 5	17		
Sulfamethoxazole	≥ 100	395		
Vancomycin	20-40	13.6-27.2	5-10	3.4-6.8

Selected ranges in mcg/mL are presented as a guide only.

ARSENIC, BLOOD

Abstract Assays for antimicrobial agents in serum are performed for two primary reasons: 1. to ensure therapeutic levels, and 2. to monitor for potentially toxic levels. In most situations, it is not necessary to monitor antimicrobial levels because serum levels are relatively predictable based on dosing; *in vitro* susceptibility testing uses those predictable levels to determine clinical efficacy. Similarly, toxicity is not always related to serum levels. It may be more appropriate to monitor for toxicity by following determinants of hematologic, renal, or hepatic function. In certain situations however (eg, aminoglycoside antibiotics which have a narrow therapeutic range and a high potential for toxicity), it is essential to follow serum levels.

Specimen Serum

Container Red top tube or serum separator tube

Sampling Time Peak: 30 minutes after 30 minute I.V. infusion; 1 hour after I.M. dose. Trough: immediately prior to next dose.

Collection Keep frozen if not assayed immediately.

Causes for Rejection Incomplete clinical information (eg, specific antimicrobial, dosage and schedule, other concurrent antimicrobials)

Limitations May not be technically possible in a patient taking more than one antibiotic

Methodology Bioassay: cephalosporins, clindamycin, erythromycin, metronidazole, penicillins, polymyxin, tetracycline, trimethoprim. High performance liquid chromatography: chloramphenicol, flucytosine, mezlocillin. Fluorescence polarization immunoassay (FPIA): amikacin, gentamicin, tobramycin, kanamycin, streptomycin, vancomycin, neomycin, netilmicin.

Additional Information With the increasing availability of *in vitro* sensitivity testing expressed as the minimal inhibitory or bactericidal concentration of an antibiotic, measurement of serum levels of these drugs has taken on practical clinical importance. This is especially true for agents with narrow therapeutic ranges and significant toxicity. It should be remembered, however, that in most patients, cure of infection depends on numerous host factors as well as on antibiotics. Therefore, antibiotic levels should not be relied on as the sole guide to therapy.

Arsenic, Blood

Related Information

- Heavy Metal Screen, Blood

Uses Blood arsenic is for diagnosis of acute poisoning only

Reference Range <5 mcg/dL (SI: <93.5 nmol/g)

Abstract Arsenic is a toxic heavy metal. The largest source of human exposure is arsenic in food resulting from broad use of arsenical pesticides.

Specimen Blood

Volume 30 mL

Minimum Volume 10 mL

Container Trace metal-free container

Causes for Rejection Containers not metal-free

Critical Values Lethal oral dose: Acute: 2-10 mg/kg; chronic: 1 mg/kg/day. Chronic poisoning: 10-50 mcg/dL (SI: 133.5-667.5 nmol/g). Acute poisoning: >60 mcg/dL (SI: >801 nmol/g)

Limitations Short half-life in blood

Methodology Electrothermal atomic absorption spectrometry (AA)

Additional Information Heparinized whole blood and serum have been used for arsenic determination. Blood levels of arsenic have a short half-life and are useful only within a few days of exposure. Urine arsenic concentration is a better measure of arsenic poisoning. In addition to pesticides, rodenticides, weed killers, paint, and wood preservatives contain arsenic.

Arsenic, Hair, Nails

Synonyms Arsenic, Hair; Arsenic, Nails

Uses Diagnose chronic arsenic intoxication

Reference Range Hair: up to 65 mcg/100 g (SI: 8.7 nmol/g); nail: 90-180 mcg/100 g (SI: 12-24 nmol/g)

Abstract This is a toxic heavy metal that is incorporated into hair and nails. Its presence there in abnormal concentrations is a sign of chronic poisoning.

Specimen Clean hair or nails

Volume 0.5 g

Container Clean envelope or heavy metal-free screw top plastic container

Collection Extreme care is necessary to avoid surface contamination; pubic hair is preferable as are toenails.

Special Instructions Hair should be clean, free of oil and tonic; clip close. Nails should be thoroughly washed, dried, and clipped close to cuticle.

Critical Values Values >100 mcg/100 g (SI: >13.4 nmol/g) of hair are considered toxic

Limitations Curly hair may pose problems in dating. Not useful for diagnosing acute toxicity. Urine arsenic concentration is a better indication of recent exposure.

Methodology Electrothermal atomic absorption spectrometry (AA), neutron activation analysis

Additional Information Arsenic accumulates in bones, hair, and nails and is used to detect chronic exposure, since arsenic is laid down in keratin soon after ingestion. Arsenic binds to protein sulfhydryl groups. Variations in arsenic hair levels may be due to geographic location and exposure to industrial waste and drinking water.

Arsenic, Urine

Related Information

- Heavy Metal Screen, Urine

Applies to Arsenic, Gastric Content

Synonyms As, Quantitative, Urine

Uses Evaluate recent exposure to arsenic, arsenic toxicity

Reference Range Ranges for urine inorganic arsenic levels can be variable among different laboratories. A general guideline is given: normal: 0-50 mcg/L (SI: 0-0.65 μ mol/L); chronic industrial exposure: >100 mcg/L (SI: >1.3 μ mol/L). The 24-hour urinary excretion rate should be <50 mcg/24 hours.

Abstract This toxic heavy metal appears in urine, and its excretion rate is used to determine toxicity.

Specimen 24-hour urine

Volume Entire collection

Container Acid-washed plastic container, no preservative

Collection Collect a 24-hour urine specimen, on ice, with care to avoid specimen contact with metal. Container must be securely closed and properly labeled.

Storage Instructions Refrigerate

Causes for Rejection Specimen not collected on ice, specimen in contact with metal during collection

Critical Values Toxic: >850 mcg/L (SI: >11.3 μ mol/L) (inorganic)

Methodology Atomic absorption spectrometry (AA)

Additional Information 25 mL acidified gastric washing is acceptable for arsenic analysis; gastric content normally contains no arsenic. Random urine samples are acceptable. Refrain from eating seafood for 1 week prior to 24-hour urine collection. Following a seafood meal, spot urinary arsenic levels peak at 24 hours and decrease to below detectable limits at 7 days.

Arthropod Identification

Applies to *Cimex* Identification; *Ixodes dammini* Identification; *Pediculus humanus* Identification; *Phthirus pubis* Identification; *Sarcoptes scabiei* Skin Scrapings Identification; Bed Bugs Identification; Body Lice Identification; Crab Lice Identification; Deer Tick Identification; Flea Identification; Head Lice Identification; Lice Identification; Mite Identification; Nits Identification; Pubic Lice Identification; Skin Scrapings for *Sarcoptes scabiei* Identification; Tick Identification

Synonyms Ectoparasite Identification; Insect Identification

Uses Identify arthropods affecting humans; establish the presence of ectoparasite infestation

Reference Range No arthropod identified

Specimen Gross arthropod, skin scrapings

Deer tick (*Ixodes dammini*)

Container Screw cap tube or screw cap jar

Collection Arthropods (gross) are to be submitted in alcohol (70%) or formaldehyde in tube or container with secure closure. To establish the diagnosis of scabies, skin scrapings may be collected with a scalpel and a drop of mineral oil. The liquid may be examined directly or alternatively the organism may be teased away from its burrow or papule with a needle or scalpel.

Storage Instructions Room temperature, fill the container with preservative as completely as possible to avoid damage to the specimen by air bubbles in the container

Methodology Macroscopic evaluation

Barbiturates, Qualitative, Urine

Applies to Amobarbital, Urine; Butalbital, Urine; Mephobarbital, Urine; Pentobarbital, Urine; Secobarbital, Urine

Uses Urine drugs of abuse testing, pre-employment screens, random drug testing

Reference Range Less than cutoff

Test Commonly Includes Identification and confirmation of barbiturates in urine

Abstract This test is usually used to detect barbiturate as a drug of abuse.

Specimen Random urine

Volume 20 mL

Minimum Volume 10 mL

Container Plastic urine container

Collection If forensic, observe precautions

Storage Instructions Refrigerate

Causes for Rejection If forensic, failure to meet temperature requirements or test for unusual urine dilution

Special Instructions Chain-of-custody documentation required for samples submitted for pre-employment, random employee testing, and forensic purposes.

Critical Values Cutoff: screen: 300 ng/mL, confirmation: 300 ng/mL

Limitations Short- and intermediate-acting barbiturates can be detected in urine 24-72 hours following ingestion, longer-acting drugs up to 7 days.

Methodology Enzyme immunoassay (EIA), gas chromatography/mass spectrometry (GC/MS)

Additional Information Withdrawal symptoms from any barbiturate may be severe and may include convulsions. The presence of barbiturates in urine is presumptively positive at a level >300 ng/mL using secobarbital as a standard and can indicate prescribed or abused intake of this class of drugs. The presence of these drugs should be confirmed. 10 mL of Donnatal[®] elixir does **not** cause a positive urinary barbiturate assay.

Barbiturates, Quantitative, Blood

Applies to Amobarbital; Aprobarrbital; Blue Angels; Butalbital; Red Devils; Talbutal; Yellow Jackets

U.S. Brand Names Alurate[®]; Amytal[®]; Butisol Sodium[®]; Fiorinal[®]; Lotunate[®]; Luminal[®]; Nembutal[®]

Uses Evaluate barbiturate toxicity, drug abuse, therapeutic levels; if barbiturates are suspected in a drug overdose, determination of long-, medium-, or short-acting may influence treatment.

Reference Range Negative. Therapeutic: short-acting (secobarbital): 1-5 mcg/mL (SI: 4.2-21.0 $\mu\text{mol/L}$); intermediate-acting (amobarbital): 5-15 mcg/mL (SI: 22-66 $\mu\text{mol/L}$); long-acting (phenobarbital): 15-40 mcg/mL (SI: 65-172 $\mu\text{mol/L}$); for seizure control, phenobarbital therapeutic levels: 10-30 mcg/mL (SI: 43-129 $\mu\text{mol/L}$)

Test Commonly Includes Quantitation of barbiturates present in blood

Abstract Measurement of barbiturates as a class is usually used for drug-of-abuse testing or as evidence for toxicity.

Specimen Blood

Volume 7 mL

Minimum Volume 5 mL plasma or serum

Container Lavender top (EDTA) tube, green top (heparin) tube, red top tube; avoid serum separator tube for pentobarbital.

Critical Values Toxic: short-acting: >10 mcg/mL (SI: >43 $\mu\text{mol/L}$); intermediate-acting: >20 mcg/mL (SI: >86 $\mu\text{mol/L}$); long-acting: >40 mcg/mL (SI: >172 $\mu\text{mol/L}$)

Limitations Only barbiturates will be identified and quantitated; individual agents cannot be identified by screening tests, particularly if there has been a mixed ingestion

Methodology Gas chromatography (GC), high performance liquid chromatography (HPLC), immunoassay

Additional Information To monitor therapeutic phenobarbital level: See Phenobarbital, Blood. The implication of any concentration is more serious for short-acting barbiturates than for phenobarbital. The toxic or lethal blood level varies with many factors and cannot be stated with certainty. Lethal blood levels determined at autopsy may be as low as 60 mcg/mL (SI: 258 $\mu\text{mol/L}$) for long-acting (barbital and phenobarbital) and 10 mcg/mL (SI: 43 $\mu\text{mol/L}$) for intermediate- and short-acting barbiturates (amobarbital, butabarbital, butalbital, pentobarbital, secobarbital). In presence of alcohol or other depressant drugs, the lethal concentrations may be lower. Addicts, however, may tolerate with no ill effect levels which would be acutely toxic to a nonaddicted individual. Except for barbital, all barbiturates are primarily transformed by the liver. Only barbital is dependent mainly on renal excretion for termination of its pharmacological action. Individual barbiturates can be identified and separated from each other by HPLC.

Benzodiazepines, Qualitative, Urine

Synonyms Tranquilizers (Valium[®], Librium[®], etc)

Uses Drug abuse evaluation; toxicity assessment

Reference Range None present unless prescribed. When used as drug-of-abuse screen, negative (less than cutoff).

Abstract This group of drugs is used as anti-anxiety agents (tranquilizers). They are used by more Americans than any other single prescription drug.

Specimen Random urine

Volume 50 mL

Minimum Volume 10 mL

Container Clean plastic urine container

Storage Instructions Refrigerate or freeze if not analyzing immediately

Critical Values Cutoff: screen: 300 ng/mL (as oxazepam); confirmation: 200 ng/mL

Methodology Immunoassay, thin-layer chromatography (TLC), high performance liquid chromatography (HPLC), gas chromatography (GC), gas chromatography/mass spectrometry (GC/MS)

Additional Information Urine should be screened for benzodiazepines in suspected overdose cases, or as part of an abused drug program. These drugs have a relatively low potential for abuse. They are, however, frequently found with other drugs in emergency room drug screens. Immunoassay screens detect a broad range of drugs and their metabolites in this class using either oxazepam or nordiazepam as positive controls. Using the latter, the test is more specific and more sensitive for detecting flurazepam. Positive screen results (usually >300 ng/mL of urine metabolites) should be confirmed by an alternate technique. High concentrations of fenpropofen, flurbiprofen, indomethacin, ketoprofen, and tolmetin may give a false-positive result by a TDx assay. Oxaprozin may interfere with urinary benzodiazepine result immunoassay methods. Flunitrazepam is detected in urine by GC/MS but not by EMIT assay techniques. Sertraline may cause a false-positive urinary benzodiazepine assay using the original cloned enzyme donor immunoassay system. Brand name prescription medications that can result in a positive urinary immunoassay:

- Librium[®]
- Paxipam[®]
- Tranxene[®]
- Valium[®]
- Verstran[®]
- Restoril[®]
- Serax[®]
- Tranxene[®]
- Verstran[®]
- Restoril[®]
- Xarax[®]
- Klonopin[®] (In overdose only)

Bishydroxycoumarin, Blood

Synonyms Dicumarol Level, Blood

Uses Evaluate toxicity. It is helpful when surreptitious ingestion is suspected or when a possible medication error is involved. It should **not** be used for TDM.

BOTULISM, DIAGNOSTIC PROCEDURE

Reference Range 20-30 mcg/mL

Specimen Blood

Volume 10 mL

Collection Blood must be accurately added to special tube.

Storage Instructions Transport specimen to the laboratory immediately. Do not store.

Causes for Rejection Excessive delay in transport, improper specimen collection

Critical Values Toxic: > 70 mcg/mL

Limitations This test does not quantitate warfarin and should not be used to monitor any other anticoagulant. Warfarin may be ordered separately.

Additional Information This test should be ordered only if the patient's prothrombin time is prolonged. It is not as useful for TDM as the prothrombin time.

Botulism, Diagnostic Procedure

Related Information

- Clostridium botulinum Food Poisoning
- Clostridium perfringens Poisoning

Synonyms *Clostridium botulinum* Toxin Identification Procedure; Infant Botulism, Toxin Identification

Use Diagnose infant botulism, classic botulism in adults

Contraindications Due to the difficulty in performance of the diagnostic test and because of the extensive epidemiological studies initiated upon receipt of the specimen, State Department of Health Laboratories require specific clinical symptomatology for infant botulism and therefore should be consulted early to optimize handling of the suspect case.

Reference Range No toxin identified, no *Clostridium botulinum* isolated

Abstract A neurotoxin, botulin, may be produced by *C. botulinum* in foods which have been improperly preserved. Characteristics of this type of food poisoning include vomiting and abdominal pain, disturbances of vision, motor function and secretion, mydriasis, ptosis, dry mouth, and cough.

Specimen Vomitus, serum, stool, gastric aspirates, cerebrospinal fluid or autopsy tissue; food samples

Volume 50 g vomitus or feces, gastric washings, cerebrospinal fluid or autopsy tissue, 15-20 mL serum; infant botulism: 25 g feces

Container Sterile wide-mouth, leakproof, screw-cap jar; red top tube

Storage Instructions Keep refrigerated at 4°C except for unopened food samples.

Special Instructions The laboratory must be notified prior to obtaining specimen in order to prepare for transport of the specimen to the State Health Laboratory or Center for Disease Control.

Limitations The toxin from *C. botulinum* binds almost irreversibly to individual nerve terminals; thus, serum and cerebrospinal fluid specimens may yield false-negative results. Can detect as little as 0.03 ng of botulinum toxicity.

Methodology Toxin neutralization test in mice

Specific References

Bromide, Serum

Uses Evaluate bromide toxicity. This test is seldom ordered.

Reference Range Therapeutic: 750-1500 mcg/mL (SI: 9.4-18.7 mM/L)

Abstract Inorganic bromide salts were formerly used as antiepileptics. They are no longer available as nonprescription items in the United States.

Specimen Blood

Volume 5 mL

Minimum Volume 3 mL serum

Container Red top tube

Critical Values Toxic: > 1500 mcg/dL (SI: > 18.7 mM/L)

Limitations Patients on iodide therapy will have falsely elevated serum bromide levels. A high level of bromide in the serum will falsely elevate the chloride level.

Methodology Reaction of bromide in a protein-free filtrate with gold chloride

Additional Information In order to convert mg/dL to mEq/L (the same units in which serum or plasma chlorides are reported), multiply the bromide values in mg/dL by 0.125. Both chloride and bromide react identically to titrimetric chloride methods (chloridometer). Many ion selective chloride electrodes give a response to bromide which is double that for chloride. A reported "chloride" value will equal the true sum of chloride and bromide. Bromism may be suspected in the presence of a

history of ingestion of proprietary bromide preparations, fever, skin rash, and neurologic symptoms.

Butabarbital, Quantitative

Related Information

- Barbiturates, Quantitative, Blood

Synonyms Buticaps®; Butisol Sodium®

Uses Monitor therapeutic drug level; evaluate toxicity

Contraindicating Factors Presence of other barbiturates

Reference Range Therapeutic: mildly sedated 3-25 mcg/mL

Specimen Blood

Volume 7 mL

Minimum Volume 0.5 mL serum

Container Red top tube

Collection Collect specimen immediately prior to next dose unless specified otherwise by physician. Put time of last dose on requisition, if it is available.

Critical Values Toxic: mildly comatose 20-40 mcg/mL; severely comatose >40 mcg/mL

Limitations Can only be performed if the patient is not taking other barbiturates

Methodology Enzyme immunoassay (EIA)

Cadmium, Blood

Related Information

- Heavy Metal Screen, Blood

Synonyms Cd, Blood

Uses Evaluate cadmium toxicity in industrial exposure to cadmium fumes or cadmium ingestion

Reference Range Whole blood: < 1 mcg/L

Abstract This toxic heavy metal is used in industry in alloys and metal platings

Specimen Whole blood

Volume Entire specimen

Container Metal-free tube

Collection Blood must be collected into metal-free tubes with a plastic syringe.

Causes for Rejection Specimen allowed to contact metal

Special Instructions Requisition must state date and time urine collection started and date and time collection finished.

Possible Panic Range Levels > 10 mcg/L (SI: > 88.97 µmol/L) in whole blood probably reflect excessive exposure.

Methodology Flameless atomic absorption spectrophotometry (AA); electrothermal atomization atomic absorption

Additional Information Inhalation of cadmium fumes produces an acute pneumonitis. Long-term exposure may lead to emphysema (with decreased α_1 -antitrypsin). Increased cadmium is reported to be associated with hypertension and (perhaps) prostatic cancer. Cadmium ingestion may result from contact of acid foods with metal containers. There is exposure of the general populace to cadmium from food, water, and air contamination. Because of slow excretion and constant exposure cadmium values increase with age. Body cadmium elimination half-life may be as long as 30 years. Chronic cadmium exposure can cause proteinuria and a degree of renal insufficiency.

Cadmium, Hair

Synonyms Cd, Hair

Uses Evaluate chronic cadmium toxicity; hair analysis can reflect chronic cadmium poisoning for long-term exposure.

Specimen Hair

Container Envelope or plastic Petri dish

Collection Clip lock of hair at nape of neck extending to a distance of 20 mm. Place in an envelope or plastic Petri dish.

Limitations Hair analysis does not reflect cadmium concentration in the body at the time the sample is collected, but at some prior time.

Methodology Flameless atomic absorption spectrophotometry (AA)

Cadmium, Urine

Related Information

- Heavy Metal Screen, Urine

Synonyms Cd, Urine

Uses Evaluate cadmium toxicity in industrial exposure to cadmium fumes or cadmium ingestion

Reference Range Nonexposed: 0-20 mcg/L; exposed: 10-580 mcg/L

Patient Preparation Patient should be instructed to use a plastic bedpan or urinal if necessary.

Specimen Random urine

Volume Entire collection

Minimum Volume 100 mL aliquot

Container Plastic urine container
Collection Freshly voided random urine
Storage Instructions Keep specimen on ice or refrigerator.
Causes for Rejection Specimen allowed to contact metal, specimen not kept chilled

Cannabinoid Confirmation

Uses Confirm positive screen result by an alternate, specific method
Reference Range Levels > 10 ng/mL reported as confirmed positive
Test Commonly Includes Confirmation of positive screen test; measurement of THC-9-carboxy metabolite by gas chromatography/mass spectrometry.
Specimen Random urine
Volume 50 mL aliquot
Minimum Volume 25 mL
Container Plastic urine container
Collection Freshly voided random urine
Storage Instructions Refrigerate or freeze specimen.
Limitations Limit of detection for THC-9-carboxy metabolite is 10 ng/mL.
Methodology Gas chromatography/mass spectrometry (GC/MS)
Specific Reference
 Mitchell vs Mr. Hood Meadows Oreg Oregon Court of Appeals 0005-05389; A116119, October 6, 2004

Cannabinoids, Qualitative

Synonyms 11-Nor-9-Carboxy-Delta-9-Tetrahydrocannabinol; Cannabis; Carboxy THC; Grass; Hashish; Hemp; Herb and Al; Marijuana; Pot; THC (Delta-9-Tetrahydrocannabinol); Weed
Uses Drug abuse evaluation; toxicity assessment
Reference Range Negative (less than cutoff)
Test Interactions
 Gemfibrozil can cause a false positive urinary assay for cannabinoids utilizing the OnTraK TesTcup method (Roche Diagnostic Systems, Inc). When Pyridium® chlorochromate ("Urine Luck") adulterant is added to urine (at pH of 5-7), ~58% to 100% of THC-acid is lost, resulting in a possible false-negative assay.
 Pantoprazole may cause a false positive cannabinoid urinary immunoassay.
Abstract The main active ingredient of marijuana (cannabinoids) is tetrahydrocannabinol (THC). It is metabolized to THC-carboxylic acid which is detected in the urine. The name comes from the source of marijuana, the plant *Cannabis sativa*. It is a DEA schedule I drug and a widely used drug of abuse.

Specimen Random urine
Volume 20 mL
Minimum Volume 10 mL
Container Plastic urine container
Collection For employee screening or forensic purpose, use precautions during collection.
Causes for Rejection Evidence of urine dilution or alteration
Special Instructions If forensic, use chain-of-custody protocol and form.
Critical Values Cutoff: screen (NIDA): 50 ng/mL. Some laboratories use 100 ng/mL and a few use 20 ng/mL; confirmation: 15 ng/mL.
Limitations Cannabinoids are rapidly metabolized from blood. Urine is the best specimen for screening although blood (serum or plasma) and saliva have been used. Cannabinoids can adhere to plastic.
Methodology Enzyme immunoassay (EIA), fluorescence polarization immunoassay (FPIA), thin-layer chromatography (TLC), gas chromatography/mass spectrometry (GC/MS)

Additional Information

While exceptionally long urinary detection times have been reported in heavy, chronic marijuana users during abstinence (up to 6 weeks); few controlled studies exist on the excretory temporal patterns of marijuana metabolites. Urinary detection times (at a 50 ng/mL cutoff) after smoking a single 1.75% or 3.55% THC cigarette range from 8.4-26 hours and 31-57 hours by immunoassay, respectively. Longer detection times for the last positive urine at the 20 ng/mL cutoff immunoassay is ~51 hours (at 1.75% THC) and 93 hours (at 3.55% THC). While detection times at the 100 ng/mL cutoff may range from 12-33 hours, rapid storage of THC metabolites in body fat occurs after use. These substances are then released from storage sites slowly over time.

A marijuana cigarette is made from the dried particles of the plant, *Cannabis sativa*. The immediate effects of smoking marijuana include a faster heartbeat and pulse rate, bloodshot eyes, and a dry mouth and throat. The drug can impair or reduce short-term memory, alter sense of time, and reduce the ability to do things which require concentration, swift reactions and coordination, such as driving and operating machinery.

While positive urine FPIA screen virtually will not occur due to passive inhalation at a cutoff of 100 ng/mL, there may be positive EMIT screen in children at threshold of 10 ng/mL.

Driving experiments show that marijuana affects a wide range of skills needed for safe driving. Thinking and reflexes are slowed, making it

hard for drivers to respond to sudden unexpected events. Furthermore, a driver's ability to "track" through curves, brake quickly, and maintain speed and proper distance between vehicles is affected. Research shows that these skills are impaired for at least 4-6 hours after smoking a single marijuana cigarette. If a driver drinks alcohol along with using marijuana, the risks of a vehicular collision greatly increase.

Small amounts of hypochlorite (household bleach: 8-64 µL/mL of urine) can cause a significant decrease in cannabinoid urine level as measured by immunoassay and GC/MS

Tolmetin may give false-negative results by Emit® assay.

Ingestion of Seedy Sweetie® snack bars (produced by Hungry Bear Hemp Foods, Eugene, Oregon) which contains pressed hemp seeds, can cause a positive urine assay for THC at 11 hours.

Delta 9-tetrahydrocannabinol plasma concentrations are roughly double that of whole blood because delta 9-tetrahydrocannabinol is protein bound and thus concentrated in plasma.

Identification of 11-nor- Δ^9 -THCV-9-COOH in a urine specimen indicates the use or ingestion of cannabis-related product(s) and would not explain the sole use of Marino®.

Carbamazepine, Blood

Related Information

- Carbamazepine-10,11-Epoxyde

Applies to P450 System Inhibitor

Synonyms Tegretol®

Uses Monitor for compliance, efficacy, or possible toxicity

Contraindicating Factors Half-life of warfarin is shortened; monoamine oxidase inhibitors not recommended.

Reference Range 4-12 mcg/mL (SI: 17-51 µmol/L). Low level: The most common cause of a low level is noncompliance. The addition of anti-convulsants which induce the P450 system, such as phenytoin, primidone, and phenobarbital, may decrease carbamazepine levels without causing seizures. (The P450 system is a liver enzymatic system which degrades drugs.) The withdrawal of phenytoin from the regimen of a patient on carbamazepine may lower the level and cause seizures. Because of autoinduction of metabolism, patients in the first 2 months of therapy may have diminishing levels and be at risk for seizures. Occasionally, patients may have toxicity when levels are within the reference range. High level: Drugs which inhibit the P450 system, including isoniazid, fluoxetine, propoxyphene, verapamil, and stiripentol can cause a precipitous rise in carbamazepine levels and clinical toxicity, usually within 48 hours. Danazol may cause a delayed toxicity. The addition of cimetidine, erythromycin, lithium, triacetyloleandomycin, and valproic acid also can cause toxicity.

Abstract Carbamazepine is a first-line antiepileptic drug for generalized and partial seizures. It is used for control of pain in trigeminal neuralgia and in treatment of bipolar affective disorder.

Patient Preparation Levels should be drawn before next oral dose with patient at steady-state.

Specimen Blood

Volume 5 mL

Minimum Volume 1 mL serum

Container Red top tube

Sampling Time A consistent sampling time, ideally a trough level, should be used to monitor patients on chronic therapy.

Critical Values Toxic: >20 mcg/mL

Possible Panic Range Central nervous system toxicity occurs progressively with levels near or above high end of reference range.

Limitations See Carbamazepine-10,11-Epoxyde listing.

Methodology Enzyme immunoassay (EIA), gas-liquid chromatography (GLC), high performance liquid chromatography (HPLC)

CARBAMAZEPINE, FREE

Additional Information

Indications for measurement of a serum antiepileptic drug level include:

- within 6 hours of a seizure
- suspected dose-related drug toxicity
- suspected patient noncompliance

Additional indications for serum drug assay during steady state conditions (after 6 days for phenytoin, 3 days for carbamazepine, 3 days for valproic acid, 20 days for phenobarbital) include:

- baseline measurement after starting antiepileptic drug therapy
- control measurement after a change in dosage regimen
- addition of a second drug with a potential interaction with the antiepileptic drug (ie, a second antiepileptic drug, warfarin, isoniazid, or rifampicin)
- change in patient's hepatic or gastrointestinal function

Carbamazepine, Free

Synonyms Tegreto[®], Free

Reference Range Therapeutic free: 1.6-2.4 mcg/mL; therapeutic total: 6.0-12.0 mcg/mL

Test Commonly Includes Free and total carbamazepine

Specimen Blood

Volume 2 mL

Minimum Volume 1 mL

Container Red top tube

Collection Draw just prior to next dose.

Methodology Ultrafiltrate assayed by fluorescence polarization immunoassay (FPIA)

Carbamazepine-10,11-Epoxyde

Related Information

- Carbamazepine, Blood

Synonyms Carbamazepine Metabolite

Reference Range 0.8-3.2 mg/L. High level: In patients on chronic carbamazepine therapy, the addition of valpromide or progabide produces clinical toxicity with high levels of metabolite and normal levels of parent compound.

Test Commonly Includes Carbamazepine and carbamazepine-10,11-epoxyde

Abstract Occasional cases of carbamazepine toxicity occur with normal levels of carbamazepine due to accumulation of the active metabolite, 10,11-epoxyde.

Specimen Blood

Volume 7 mL

Minimum Volume 1 mL serum

Container Red top tube

Limitations Valproic acid, a compound chemically related to valpromide, may increase the epoxyde/carbamazepine ratio by eliminating excretion of the epoxyde. Since most cases of fatal valproate hepatotoxicity occur in young children on multiple anticonvulsants, the combination of valproate and carbamazepine is not recommended. Phenytoin may also increase the ratio of epoxyde/parent compound.

Methodology High performance liquid chromatography (HPLC), fluorescence polarization immunoassay (FPIA); enzyme multiplied immunoassay (EMIT)

Additional Information Carbamazepine-10,11-epoxyde has been shown to be pharmacologically active in animals.

Carboxyhemoglobin, Blood

Synonyms Carbon Monoxide Level, Blood; CO, Blood; COHb, Blood

Uses Determine the extent of carbon monoxide poisoning, toxicity; check the effect of smoking on the patient; work up headache, irritability, nausea, vomiting, vertigo, dyspnea, collapse, coma, convulsions; work up persons exposed to fires and smoke inhalation

Reference Range Nonsmokers: <3%; smokers: 1-2 packs/day: 4% to 5%, >2 packs/day: 8% to 9%. Carboxyhemoglobin in the newborn may run 10% to 12%. Carbon monoxide hemoglobin in the newborn, together with decreased efficiency of the infant's respiratory system, may, and does lead to higher levels of carboxyhemoglobin. Venous and arterial samples are equivalent.

Test Commonly Includes COHb is sometimes included in blood gases but may be ordered as a separate test.

Patient Preparation In suspected carbon monoxide poisoning, the specimen should be collected immediately.

Specimen Blood

Minimum Volume 1 mL whole blood

Container Green top (heparin) tube or lavender top (EDTA) tube, depending upon laboratory

Sampling Time Draw before the patient is started on oxygen, if possible.

Collection Keep tube capped

Storage Instructions Refrigerate immediately after collection. Do not remove cap. Carboxyhemoglobin is stable 4 months in filled, well-capped tube.

Critical Values Toxic concentration: 20%; lethal: >40%

Possible Panic Range Disturbance of judgment, headache, and dizziness occur at 10% to 30%; coma at 50% to 60%; fatality occurs at ≥60%, and rapid death at 80%.

Limitations Carbon monoxide levels are of limited value in screening for smoking, since it is cleared rapidly. The half-life of carboxyhemoglobin in individuals with normal cardiopulmonary function is 1-2 hours on 100% oxygen. Urinary nicotine, if available, is preferable as a screening test for tobacco use. Arterial blood gases may be of limited value in treatment decisions for carbon monoxide poisoning. Pulse oximetry is of no use. Fetal hemoglobin (in neonates younger than 3 months of age) may interfere with carboxyhemoglobin determination by causing a falsely elevated carboxyhemoglobin level in direct proportion to fetal hemoglobin levels.

Methodology Spectrophotometric, gas-liquid chromatography (GLC), pulse oximetry

Additional Information

Carboxyhemoglobin is useful in judging the extent of carbon monoxide toxicity and in considering the effect of smoking on the patient. A direct correlation has been claimed between CO level and symptoms of atherosclerotic diseases, intermittent claudication, angina, and myocardial infarction. Exposure may occur not only from smoking, but also from garage exposure and from various engines. This test may be included when blood gases are ordered, when there is sufficient sample, and when such instrumentation is available.

A danger of missed diagnosis of CO intoxication is continued exposure of the patient and others to a toxic environment. The cherry red color of CO poisoning is not consistently seen. CO intoxication may contribute to the risk of myocardial infarction.

A strong correlation is present between carboxyhemoglobin levels and psychometric testing abnormalities. Psychometric testing measures actual neurologic disability and may therefore better define carboxyhemoglobin poisoning severity than blood CO level. The half-life with O₂ administration is 80 minutes. With O₂ at 3 atmospheres, the half-life is 24 minutes.

Also elevated in methylene chloride intoxications due to endogenous hepatic metabolism to carbon monoxide.

Fetal hemoglobin interferes with COHb determination by falsely elevating COHb in direct proportion to fetal hemoglobin. Interpretation of COHb levels in infants younger than 90 days must consider the clinical relevance of this interference.

Chain-of-Custody Protocol

Applies to Medical Legal Specimens

Synonyms Specimen Chain-of-Custody Protocol

Uses Chain-of-custody is a legal term that describes a method to maintain sample integrity in the collection, handling, and storage of urine samples.

Reference Range Normal: all seals intact and Chain-of-Custody form completed.

Abstract A procedure to ensure sample integrity from collection through transport, receipt, sampling, and analysis. It is associated with a chain-of-custody form.

Causes for Rejection Sample cup or bag containing sample cup not sealed

Additional Information The chain-of-custody protocol is a clerical and custodial service offered by the laboratory to document specimen transfer and provide for extended specimen storage. A written record of specimen transfer from patient, to analyst, to storage and disposal is maintained on all specimens covered by chain-of-custody. All drug screens, blood alcohols, or any other tests that have medicolegal significance should be accompanied by Chain-of-Custody form and a written release form. (Department of Transportation collections or any collection involving Medical Review officers.)

Cholinesterase Inhibitors, Quantitative, Serum

Synonyms Carbamates, Quantitative, Serum

Uses Evaluate exposure to organophosphate and carbamate insecticides; preoperative screening of patients who are at risk for prolonged paralysis following surgical choline administration during anesthesia

Reference Range 559-1493 units/L

Test Commonly Includes Neostigmine, pyridostigmine, physostigmine
Specimen Blood
Volume 15 mL
Minimum Volume 2 mL serum
Container Red top tube
Collection Routine venipuncture
Limitations May be decreased in a number of advanced chronic diseases.

Methodology UV spectrophotometry

Additional Information Organophosphate and carbamate insecticides inhibit both serum and erythrocyte cholinesterase. Serum cholinesterase falls and returns to normal more rapidly than erythrocyte levels. Decreases in activity are best evaluated by comparison to baseline levels established before exposure. Patients with atypical variants of serum cholinesterase, which are autosomal recessively inherited, may be unable to effectively hydrolyze certain muscle relaxants such as succinylcholine, which may be administered during anesthesia, resulting in prolonged paralysis. Most patients with such variants will have low plasma cholinesterase activity and resistance to dibucaine inhibition.

Guvan M, Sungur M, Eser B, et al, "The Effects of Fresh Frozen Plasma on Cholinesterase Levels and Outcomes in Patients with Organophosphate Poisoning," *J Toxicol Clin Toxicol*, 2004, 42(5):617-23.

Chromium, Serum

Related Information

- Chromium, Urine

Synonyms Cr, Serum

Uses Evaluate suspected chromium toxicity or exposure; follow patients receiving chromium in their parenteral nutrition; evaluate acquired glucose intolerance in refeeding programs, or in parenteral or enteral nutrition; evaluate insulin resistance in the nonseptic patient during parenteral nutrition

Reference Range 0.05-0.15 ng/mL (SI: 1-3 nmol/L). Some laboratories report much higher "normals" because the methods they use or the collection technique is not adequate to prevent substantial contamination. If a laboratory reports "<1 ng/mL" or some similar figure without a lower level for normal, the value can be relied upon to discover toxic states, perhaps, but not deficiency states. Serum levels of 10 ng/mL correspond to short-term atmospheric exposure limit of 0.1 mg/m³ of chromium trioxide. Serum levels even higher would be expected in acute systemic toxicity. Almost a twofold diurnal variation is noted in serum chromium levels, with the level highest in the morning and falling after each meal as insulin levels rise. Serum chromium levels are ~60% of normal in diabetic patients, which overlaps the normal range.

Patient Preparation The patient should be fasting for basal level.

Specimen Blood

Container Special metal-free, Sherwood Monoject™ trace element blood collection tube #8881-307006

Sampling Time In the nocturnal total parenteral nutrition patient, the sample will be drawn "fasting" in the afternoon, before the nocturnal solution is started for the evening.

Collection Follow specific instructions of laboratory to which sample will be submitted. Contact with steel, dust, ordinary glassware, or plastic is to be avoided. Draw blood through indwelling plastic intracath needle. Some siliconized stainless steel needles have also been found to be acceptable as is the B-D #5175 20-gauge stainless steel needle, or the Terumo or Abbot butterfly needles. Draw trace metal sample prior to any other blood samples. Remove serum with an all-plastic pipette (no internal metal parts) and store serum in plastic vial. Leaching plastic containers in 10% nitric acid for 48 hours removes trace metal contamination if special purpose vials are not available. The containers are then rinsed three times with twice distilled water and air dried in a dust-free environment prior to use.

Storage Instructions Some reference laboratories request specimens to be frozen and sent on dry ice.

Causes for Rejection Improper collection or storage with contact by steel, dust, or ordinary Vacutainer® tubes

Limitations Extreme attention to detail is needed to achieve reliable results; for many laboratories even now a high serum level more often reflects sample contamination rather than excess chromium exposure.

Methodology Any reported levels in biological materials prior to ~1979 are suspect, as the available methods did not have the sensitivity to separate normal values from the "blank." Reported levels were tenfold or more too high. Accurate and independently verified values have been reported with:

- stable isotope dilution, isotope ratio mass spectroscopy
- graphite furnace atomic absorption spectroscopy

All pipettes must have plastic tips and no exposed internal metal parts. Work is done in the laboratory under a laminar flow class 100 work station, free from exposed stainless steel to avoid airborne contamination. This is essential to reduce contamination sufficiently to detect

"normal levels" in human serum or urine. Even with these precautions, different laboratories report different normal values.

Additional Information Iron competitively inhibits the binding of chromium III to transferrin. Iron overloaded patients with hemochromatosis poorly retain a radioactive tracer dose of chromium III. It has been suggested that chromium deficiency at a cellular level may play a role in the development of diabetes in hemochromatosis.

Chromium, Urine

Related Information

- Chromium, Serum

Synonyms Cr, Urine

Uses Evaluate industrial exposure, suspected toxicity; or in conjunction with serum levels, to attempt to detect suspected chromium deficiency, especially in a recent onset of glucose intolerance

Reference Range <1.8 mcg/L. Levels vary with the laboratory and have declined with improved methods of avoiding contamination. Levels two- to threefold above this may reflect supplementation or excess losses. Levels elevated tenfold and higher have been seen in exposed asymptomatic tannery workers. Spot levels of chromium in urine of 30 ng/g creatinine correspond to the short-term atmospheric exposure limit of 0.1 mg/m³ of chromium trioxide in industrial exposure situations.

Abstract Urine chromium levels are extremely low, and until recently, not reliable. Urine chromium assay is used to look for chromium toxicity in cases of potential exposure. As testing becomes more reliable, new applications of the test will arise to determine chromium III nutritional adequacy or deficiency states. There are also potential uses in the follow-up of patients with mild glucose intolerance. See listing, Chromium, Serum for signs and symptoms of toxicity and deficiency states, and for additional references.

Specimen 24-hour urine

Container Plastic metal-free container. To prepare, leech 48 hours in 10% nitric acid and wash with distilled water that has had no contact with metal. Dry in quiet air in a metal-free environment.

Collection Care must be taken to avoid contact with metal. Use plastic urine, prepared as above. Stool contamination must be avoided.

Causes for Rejection Improper collection, contact with metal, ordinary containers, or stool contamination

Limitations Levels are so low in normal people (on the order of one part in 10 billion in urine) that many laboratories are not able to detect the lower limit of normal, and thus report "less than" some set level as being normal. Thus, for many laboratories, the test can only be used to detect toxicity. Contamination of the specimen may result in a tenfold or more increase in urine concentration being reported, making potential contamination the major limiting factor in the test.

Methodology Atomic absorption (AA) or neutron activation

Additional Information As improved methods have progressively reduced the lower level of detection, urine chromium levels have been found to be related to glucose metabolism. Recent studies have demonstrated the metabolic relationships between serum insulin, serum glucose, and serum chromium III in the fasting and postprandial states and the relationship of the postprandial state to urine chromium concentration. Briefly, diabetic patients lose threefold more chromium in the urine than nondiabetics, and despite increased intestinal absorption, diabetic patients on ordinary diets develop and maintain lower serum levels. Chromium loss is not specifically related to micro- or macro-albuminuria and precedes the onset of diabetic nephropathy. Urine chromium rises threefold 40 minutes after a carbohydrate meal and more so with carbohydrates that stimulate higher insulin levels. Serum levels fall after a meal, more so than can be explained by urine loss. Thus, glucose stimulates insulin to take chromium to a cellular location, which favors increased renal excretion.

Cobalt, Serum

Related Information

- Heavy Metal Screen, Blood

Synonyms Co, Blood

Uses Evaluate cobalt toxicity, nutritional status

Reference Range 0.4-1.2 mcg/100 mL

Specimen Blood

Minimum Volume 7 mL

Container Red top tube

Storage Instructions Refrigerate serum.

Cobalt, Urine

Related Information

- Heavy Metal Screen, Urine

Synonyms Co, Urine

Uses Evaluate cobalt toxicity

Reference Range Diet dependent, normals not well established but estimated to be ~2.2 mcg/mL

COCAINE (COCAINE METABOLITE), QUALITATIVE

Patient Preparation Patient should be instructed to use a plastic bedpan or urinal if necessary.

Specimen 24-hour urine

Volume Entire collection

Minimum Volume 100 mL

Container Plastic urine container, no preservative

Collection Instruct the patient to void at 8 AM and discard the specimen. Then collect all urine including the final specimen voided at the end of the 24-hour collection period (ie, 8 AM the next morning). Avoid contact with metal during collection. Screw the lid on securely. Transport the specimen promptly to the laboratory. Container **must** be labeled with patient's full name, room number, date and time collection started, and date and time collection finished.

Special Instructions Requisition **must** state date and time collection started and date and time collection finished.

Abstract Codeine occurs naturally in opium but is produced commercially by 3-O-methylation of morphine. It is used as a narcotic analgesic. It is present in numerous proprietary preparations combined with non-narcotic analgesics and antihistamines. It is a drug of abuse.

Specimen Random urine

Volume 20 mL

Minimum Volume 10 mL

Container Plastic urine container

Storage Instructions Refrigerate

Special Instructions If forensic, use precautions in collection and Chain-of-Custody form.

Critical Values Cutoff: screen: 300 ng/mL (for drug-of-abuse screen), confirmation: 300 ng/mL

Methodology Enzyme immunoassay (EIA); thin-layer chromatography (TLC)

Additional Information

Urine codeine/morphine ratio is usually >1.0 during first the 24 hours postingestion, decreases <1.0 from 24-30 hours and usually only morphine is detectable after 30 hours. Poppy seed ingestion can result in urine codeine levels as high as 4.5 mg/L and urine morphine levels as high as 0.2 mg/L; urine drug screen remains positive for 2-4 days.

Hydrocodone is a minor metabolite of codeine and could be excreted in urinary concentrations as high as 5% of parent codeine compound.

Cocaine (Cocaine Metabolite), Qualitative

Synonyms Coke; Crack; Snow

Uses Evaluate cocaine use

Reference Range Negative (less than cutoff)

Test Commonly Includes Cocaine is detected in urine as its metabolite, benzoylecgonine

Abstract A prominent metabolite of cocaine is benzoylecgonine, which is the substance measured in urine to detect the presence of cocaine. Cocaine is a heavily abused drug which has legitimate medical uses in some ENT procedures.

Specimen Urine

Volume 50 mL

Minimum Volume 10 mL

Container Plastic urine container

Collection If forensic, observe precautions concerning surreptitious dilution or alteration.

Storage Instructions Refrigerate; optimal storage conditions for urine specimens with cocaine and benzoylecgonine are at 18°C and a pH of 5.0; unsilanized glass is a favorable container material

Causes for Rejection If forensic, failure to meet temperature requirements immediately after collection and/or tests for unusual dilution (specific gravity, urine creatinine) or alteration.

Special Instructions If forensic, use chain-of-custody protocol and form.

Critical Values Cutoff: screen: 300 ng/mL; confirmation: 150 ng/mL

Methodology Screen: immunoassay, fluorescence polarization immunoassay (FPIA), thin-layer chromatography (TLC); confirmation: gas chromatography/mass spectrometry (GC/MS)

Additional Information

Positive urine screen due to passive inhalation of cocaine virtually will not occur at cutoff of 300 ng/mL by FPIA, but is possible in children if test by EMIT with a cutoff of 30 ng/mL. Absorption of at least 1 mg of cocaine is usually necessary to produce a cocaine positive urine screen.

Ecgonine urinary levels >50 ng/mL can increase sensitivity of cocaine assays. Urine cocaine metabolites levels may be elevated after a series of sauna treatments. The metabolite anhydroecgonine methyl ester is considered to be a marker for "crack" cocaine use (urine concentration ranges from 5-1477 ng/mL).

Benzoylecgonine to cocaine urinary quantitative ratios less than 100:1 are indicative of cocaine exposure less than ten hours before collection. Serum Benzoylecgonine to cocaine quantitative ratios less than one are indicative of cocaine exposure within two hours of collection Benzoylecgonine can be produced by metabolism of cocaethylene. Pyrolytic cocaine products include anhydroecgonine, anhydroecgonine methyl ester, methylecgonidine and Ecgonidine (the latter two from crack smokers). Purity of illicit cocaine is 80 to 97%.

Codeine, Urine

Related Information

- Opiates, Qualitative, Urine

Uses Evaluate codeine toxicity; detect drug-of-abuse

Reference Range Negative (below cutoff)

Test Commonly Includes Part of opiate screen

Computed Transaxial Tomography, Head Studies

Synonyms Brain, CT; Head Studies, CT

Uses Evaluate known/suspected primary or secondary neoplasm, cystic lesions, hydrocephalus, head trauma, seizure disorder, multiple sclerosis, atrophy, Alzheimer's disease, normal pressure hydrocephalus, Parkinson's disease, dementia, depression, organic brain syndrome, etc

Contraindicating Factors Assuming a cooperative or quiescent patient, there are no absolute contraindications to a CT scan of the head. A decision must be taken, however, as to whether the study is to be done with or without intravenous contrast material. While each case must be assessed individually, the following broad guidelines may be helpful. Those studies indicated by virtue of a recent infarct, cerebrovascular accident or stroke, or those being done for assessment of atrophy, Alzheimer's disease, normal pressure hydrocephalus, Parkinson's disease, hydrocephalus, evaluation of an intraventricular shunt, assessment of ventricular size, subdural hematoma, or suspected dementia are examined without contrast material. Patients for whom the indication is headache, psychiatric condition (such as anorexia or bulimia), tumor follow-up, rule out tumor, rule out metastasis, multiple sclerosis, seizure disorders, depression, and organic brain syndrome are generally studied with contrast material. Patients in whom the indication is one of infection, abscess, meningitis, transient ischemic attack, arteriovenous malformation, remote subdural hematoma, or who have recently undergone a craniotomy and are being studied for postoperative evaluation are best studied with and without contrast material. Patients with a known diagnosis of plasmacytoma or multiple myeloma should not receive intravenous contrast material. Patients with compromised renal function may or may not benefit from intravenous contrast material. A recent serum creatinine and BUN will be helpful in deciding whether or not the latter group of patients receive contrast material.

Test Commonly Includes CT scan of the brain

Patient Preparation The examination should be ordered and a requisition with information pertaining to the reason for the request and the clinical history should be completed by the referring physician. If there is the slightest possibility that intravenous contrast material will be administered, the patient's oral intake should be limited to liquids for at least 4 hours prior to the examination. Care must be taken to ensure the patient does not become dehydrated and medications should not be interrupted. A recent serum creatinine is requested on patients with pre-existing renal disease, diabetes mellitus, significant atherosclerotic disease, and advancing age (60 years and older). Agitated patients and children may require sedation prior to the examination. In these cases, an order for the appropriate sedative and dose should be recently recorded within the patient's chart. Sedatives should be administered by a physician within the Radiology Department.

Additional Information

Causes of basal ganglia calcification on CT scan include carbon monoxide and lead. Cerebral and/or cerebellar atrophy is caused by chronic alcoholism and chronic toluene exposure. Focal necrosis of the basal ganglia can result from carbon monoxide, cyanide, hydrogen sulfide, or methyl alcohol.

Brain changes in carbon monoxide poisoning include diffuse cerebral edema and low density changes of the globus pallidus and subcortical white matter within 6 hours of exposure. Cerebral edema is also seen in toxic alcohol exposure. Methanol poisoning can produce frontal lobe, basal ganglion, and putaminal hemorrhages or infarcts, while ethylene glycol exposure produces abnormalities of the basal ganglia, pons, temporal lobe, and cerebellum. Cerebellar edema may be noted in severe lead exposure (especially in pediatric patients). Diffuse cerebral

edema is also noted in patients with sodium valproate or pentachlorophenol exposure. Cerebral atrophy has been documented after methyl mercury exposure, chronic ethanol use; podophyllin, glucocorticoid exposure; phenytoin, lithium, toluene, amphetamine, or radiation therapy. Changes compatible with pseudotumor cerebri or benign intracranial hypertension include vitamin A poisoning; glucocorticoid, tetracycline, levothyroxine, lithium, or estrogen use.

CO-Oximetry Arterial

Synonyms Arterial CO-Oximetry

Uses Evaluate fractional components of hemoglobin in arterial blood; evaluate the extent of carbon monoxide poisoning

Reference Range Calculated THb: 12% to 15%; % COHb: \leq 1.5 nonsmokers, 1.5-5 smokers; % MethHb: 0.4-1.5; vol % O₂: 15-23

Test Commonly Includes % carboxyhemoglobin (COHb), % methemoglobin (MethHb), % O₂Hb = oxyhemoglobin and O₂ saturation, total hemoglobin (THb), and volume % O₂ = O₂ content

Patient Preparation The patient should be supine and relaxed

Specimen Arterial blood

Volume 2 mL

Minimum Volume 0.5 mL

Container Preheparinized sampler, heparinized syringe, heparinized capillary tube, or lavender top (EDTA) tube

Collection Specimen drawn into air-free heparinized syringe with stopper. All specimens should be on ice and brought to the laboratory immediately. For capillary collection the skin area to be punctured should be warmed a full 10 minutes. The puncture should be deep enough to allow a free flow of blood. Blood is then collected in heparinized capillary tubes, which should be filled as much as possible, capped and mixed well. All specimens must be labeled with the patient's name and hospital number. Indicate on the requisition mode of oxygen delivery or room air if applicable. Also indicate capillary specimen type (heel or digital) if applicable.

Storage Instructions Place specimen in ice water.

Causes for Rejection Specimen not received on ice, air bubbles or clots in syringe

Special Instructions Requisition must indicate source (ie, arterial) and time sample was drawn.

Limitations Arterial punctures may be extremely difficult in some individuals

Methodology CO-Oximeter™, spectrophotometry

Additional Information Patients on methylene blue or sulfhemoglobin may have erroneous results due to spectral interferences.

Coproporphyrin Screen, Urine

Uses Evaluate porphyrias, including those involving deficiencies of enzymes which are needed for heme synthesis and chemical porphyrias

Reference Range Negative

Specimen Random urine

Volume 10 mL

Minimum Volume 5 mL

Container Plastic urine container wrapped in aluminum foil

Storage Instructions Transport specimen within 1 hour. Protect from light.

Causes for Rejection Excessive delay in transport, specimen not protected from light

Limitations Certain drugs may cause interference

Additional Information Porphyrins are the byproducts of porphyrinogens. Accumulations of either cause porphyrias, which are characterized by increased excretion of porphyrins, porphyrinogens, or their precursors. The following conditions result in an increase of coproporphyrins: congenital erythropoietic porphyria, acute intermittent porphyria (mild increases), hereditary coproporphyrin (markedly increased), and lead poisoning.

Creatinine, Serum

Uses

The most common clinical renal function test, providing a rough approximation of glomerular filtration.

Causes of high creatinine include renal diseases and insufficiency with decreased glomerular filtration (uremia or azotemia if severe); urinary tract obstruction; reduced renal blood flow including congestive heart failure, shock and dehydration; rhabdomyolysis causes high serum creatinine, which may be elevated out of proportion to BUN, or to the reduction in renal function.

Causes of low creatinine include small stature, debilitation, decreased muscle mass, some complex cases of severe hepatic disease. In advanced liver disease, low creatinine may result from decreased hepatic production of creatinine and inadequate dietary protein as well as reduced muscle mass.

Index of fetal maturity in amniotic fluid analysis.

Reference Range Children: 1-5 years: 0.3-0.5 mg/dL (SI: 27-44 μ mol/L), 5-10 years: 0.5-0.8 mg/dL (SI: 44-71 μ mol/L); adults: male: up to 1.2 mg/dL (SI: 106 μ mol/L), female: up to 1.1 mg/dL (SI: 97 μ mol/L). Variation between sources for serum creatinine normal ranges is perhaps greater than for many other important tests. There are slight differences between the sexes with males higher, since the range relates to the amount of muscle mass present. The glomerular filtration rate increases in pregnancy; thus, serum creatinine should be slightly less during that period. In older patients, decrease of muscle mass must be considered in interpretation of results; the elderly have reduced creatinine generation. Similarly, other patients may have creatinine levels in which muscle abnormalities must be considered, including long-term corticosteroid therapy, hyperthyroidism, muscular dystrophy and paralysis, and dermatomyositis and polymyositis.

Patient Preparation Fasting may be desirable. Certain cephalosporins, especially cefoxitin, cause misleading (high) results.

Specimen Blood

Volume 10 mL

Minimum Volume 1 mL serum

Container Red top tube

Collection Pediatrics: Blood drawn from heelstick.

Causes for Rejection Hemolysis

Limitations

With reduced renal blood flow, creatinine rises less quickly than urea nitrogen. Concentration of creatinine only becomes abnormal when \sim 1/2 or more of the nephrons have stopped functioning in chronic progressive renal disease.

Increased serum creatinine results may occur from noncreatinine substances, including meat ingestion, glucose, pyruvate, uric acid, fructose, guanidine, ketonemia (acetoacetate), hydantoin, ascorbic acid, and numerous cephalosporin antibiotics, especially cefoxitin. Cefoxitin and cefepime interfere with the Jaffé method causing a false elevation. Cefoxitin levels fall in patients with normal kidney function, such that a sample can be drawn 2 hours after a dose but preferably, 4 hours or more afterwards. With severe renal disease, creatinine is not reliable in the presence of cefoxitin therapy. There is less interference reported from the cephalosporins cephalothin, cephalexin, cephadril sodium, and cephaloglycin dihydrate. Cefazolin and cefamandole may cause increased colorimetric values. Cephapirin and moxalactam are described as not causing interference. Differences in the interference of such cephalosporins between assay systems are published. Cefoxitin and cefpirome interfere with the Jaffé method causing a false elevation.

Levodopa, methylodopa, nitromethane, and trimethoprim may increase serum creatinine levels. Lipemia, hemolysis, and bilirubin may interfere.

High creatinine in serum has been reported with methanol intoxication. An antifungal drug, 5-flucytosine, and glucose interfere with the imidohydrolyase method.

Tagamet® interferes with creatinine excretion in the renal tubule, causing a rise in creatinine without reduction in renal function. It may also cause an allergic nephritis with reduced renal function. Other drugs which interfere with the tubular secretion of creatine include probenecid, triamterene, amiloride, and spironolactone.

Moderate variation of results exists between chemistry analyzer systems. Serum creatinine is only a crude guide to the progress of renal disease.

Moderate changes in the glomerular filtration rate (GFR) may not be detected by serum creatinine levels. Levey et al and others emphasize that the serum creatinine does not provide an adequate estimate of GFR. A fraction of urine creatinine is from tubular secretion. Such tubular secretion increases with declining renal function.

Methodology Alkaline picrate (Jaffé reaction), o-nitrobenzaldehyde (Sakaguchi reaction), imidohydrolyase (Ektachem®). Many interference problems are still unresolved in the Jaffé reaction.

Additional Information

Serum creatinine level is proportional to lean body muscle mass. It is unaffected by most diet or activity and is freely filtered by the glomerulus. Both BUN and creatinine are often ordered to follow renal problems. Creatinine overall is the more reliable index, but each has pitfalls. As creatinine increases in chronic renal failure, the hematocrit decreases, total carbon dioxide and bicarbonate fall, and serum phosphate and BUN increase. When serum creatinine increases postoperatively, a group of patients may be identified who are at risk for more severe renal failure. Creatinine clearances have a role in such investigations. Serum creatinine has a role in determination of dosages of some drugs (eg, the aminoglycosides and digoxin), especially in elderly subjects.

Dobutamine (and to a lesser extent dopamine) can produce a profound negative interference with the enzymatic method for serum creatinine determination thus producing a false depression of serum creatinine

Cryptosporidium Diagnostic Procedures, Stool

Synonyms Acid-Fast Stain, Modified, *Cryptosporidium*

Uses A part of the differential work-up of diarrhea, particularly in immunocompromised hosts and suspected AIDS patients; establish the

CRYSTALS, URINE

diagnosis of cryptosporidiosis by demonstration of the oocysts. A recent outbreak in healthy individuals from a contaminated water supply was noted. May be useful in treatment of cryptosporidial diarrhea

Reference Range Negative

Test Commonly Includes Examination of stool for the presence of *Cryptosporidium* by phase contrast microscopy and/or modified acid-fast stain, or fluorescent labeled antibody

Abstract *Cryptosporidium*, a parasite, may cause severe diarrhea, predominantly in immunocompromised individuals.

Specimen Fresh stool; stool preserved with 10% formalin or sodium acetate-acetic acid formalin preservative

Container Plastic stool container

Collection Transport fresh specimen to the laboratory promptly following collection. Specimen on outside of container poses excessive risk of contamination to laboratory personnel.

Special Instructions Procedures for the detection of *Cryptosporidium* in humans have recently become available in most clinical laboratories. Consult the laboratory regarding availability of the procedure and specific specimen collection instructions before collecting the specimen.

Limitations *Cryptosporidium* is not detected by standard methods used to examine stool specimens for other ova and parasites; special stains are required for its detection, and in many laboratories, must be specifically requested. The organisms are most readily demonstrated in concentrated diarrheal stools. Forms of *Blastocystis hominis* may cause confusion if Giemsa stain is used. Most recommended procedures cannot be performed on polyvinyl alcohol (PVA) preserved specimens.

Methodology Phase contrast microscopy after sucrose floatation concentration technique (Sheather's); modified acid-fast stain on air-dried, methanol-fixed smears (decolorization with 1% H₂SO₄). Auramine and carbol-fuchsin stain is used by some laboratories for screening. A technique utilizing formalin-ethyl acetate and floatation over hypertonic saline is reported to enhance detection of *Cryptosporidium* oocysts. Fluorescent-labeled IgG monoclonal anti-*Cryptosporidium* antibodies are commercially available.

Additional Information *Cryptosporidium* (similar to *Isospora belli*) is a coccidian parasite of the intestines and respiratory tract of many animals including mice, sheep, snakes, turkeys, chickens, cows, monkeys, and domestic cats. The first reported human case occurred in 1976. The prevalence of cryptosporidial infection in the U.S. is estimated to be 2.6%. It is a cause of severe and chronic diarrhea in patients with hypogammaglobulinemia and the acquired immune deficiency syndrome. Diarrhea lasts an average of 10 days. The organism is widely recognized as a disease of the immunocompromised patient, however, it can also cause disease in immunocompetent subjects. Animal contact, travel to endemic areas, living in a rural environment, and day care attendance by toddlers have been recognized as risk factors for the development of cryptosporidiosis. Perinatal infection has been reported. Children are more prone to develop infection than are adults. In these patients, the disease is a self-limited gastroenteritis, but in immunocompromised patients, a profound enteropathy results. A seasonal variation in incidence exists with the highest frequency reported in summer and autumn. The organism can be demonstrated in biopsies of small bowel and colon, adherent to surface of the epithelial cells (Giemsa stain) and by demonstration in feces by floatation with modified acid-fast stain (cold Kinyoun stain) or smear. Most therapeutic regimens for cryptosporidiosis are not successful unless immunosuppression is reversed. Enteric precautions should be taken. Transmission of *Cryptosporidium* can occur via swimming pools; *Cryptosporidium* oocysts are chloride-resistant. Nitazoxanide is undergoing phase II clinical testing at Cornell Medical Center in New York City.

available nidus, and the time factor. When properly observed in fresh urine, crystals are diagnostically useful for a physician evaluating microhematuria, nephrolithiasis, or toxin ingestion.

In abundance, calcium oxalate and/or hippurate crystals may suggest ethylene glycol ingestion (can be accompanied by neurological abnormalities, appearance of drunkenness, hypertension, and a high anion gap acidosis).

Calcium magnesium ammonium phosphate may be present in massive quantities in alkaline urine. They usually are associated with urine infected by urea splitting bacteria which cause "infection," or "triple phosphate" stones.

Tyrosine and leucine crystals are found in acid urine, indicating abnormal metabolism. These crystals occur together in acute yellow atrophy and in other destructive diseases of the liver.

Crystals may also provide a clue to the composition of renal stones not yet passed.

Cyanide, Blood

Synonyms CN⁻; Hydrocyanic Acid; Potassium or Sodium Cyanide

Uses Establish the diagnosis of cyanide poisoning

Reference Range

Whole blood levels: Smoker: ≤0.5 mg/L

Flushing and tachycardia seen at 0.5-1.0 mg/L; obtundation at 1.0-2.5 mg/L

Coma and death occur at >2.5 mg/L

Plasma cyanide:

Normal: 4-5 mcg/L

Asymptomatic (with metabolic acidosis): 80 mcg/L

Death: >260 mcg/L

Red blood cell cyanide:

Normal: <26 mcg/L

Metabolic acidosis: 1040 mcg/L

Symptomatic: 5200 mcg/L

Fatal: >10,400 mcg/L

Abstract This highly toxic substance is one of the oldest poisons known. It binds to cytochrome oxidase and prevents cellular respiration.

Specimen Blood

Volume 10 mL

Minimum Volume 7 mL whole blood or 5 mL serum

Container Lavender top (EDTA) tube or red top tube

Storage Instructions Fill tube to capacity and keep tightly closed; analyze as soon as possible. Refrigerate whole blood, gastric contents or tissue.

Critical Values In whole blood, values >2.5 mcg/mL are potentially fatal although subjects with higher values have survived.

Possible Panic Range Toxic: >1.0 mcg/mL (SI: >77 μmol/L); >2.0 mcg/mL (SI: >115 μmol/L) is lethal

Methodology Conway diffusion, color reaction, ion specific potentiometry

Additional Information

Whole blood cyanide determination by acidification usually provides an overestimation of levels by ~70%; it is most correlated with thiocyanate levels. Most accurate tissue cyanide levels concentration are reflected by plasma cyanide levels. Ratio of red blood cell to plasma cyanide concentration is 60:1. Signs or symptoms due to thiocyanate toxicity usually do not occur at plasma or serum levels <100 mg/L.

A 5 g dose of hydroxocobalamin appears to bind all cyanide ions in patients with initial cyanide levels up to 40 μmol/L

Plasma lactate (half-life ~4 hours in treated cyanide poisoning) may be useful in determining treatment efficacy in cyanide poisoning

Crystals, Urine

Related Information

- Urinalysis

Synonyms Urine Crystals

Uses Diagnose metabolic disorders, calculus formation, regulation of medication

Diagnostic Procedures

- Urinalysis

Test Commonly Includes Test is part of a routine urinalysis; includes checking for uric acid, cystine, tyrosine, leucine, cholesterol, sulfa, oxalate, and phosphate crystals

Specimen Random urine, catheterized urine

Volume 12 mL

Minimum Volume 2 mL

Container Plastic urine container, tightly capped

Storage Instructions Refrigerate specimen if test cannot be performed immediately.

Causes for Rejection Quantity not sufficient, improperly labeled specimen, specimen not brought to the laboratory within 1 hour of collection

Methodology Microscopic examination

Additional Information

Crystalluria is uncommon despite maximal concentrations in warm, fresh urine because of the normal presence of crystal inhibitors, the lack of

Cyclosporine, Blood

Applies to Cyclosporine A

Synonyms Sandimmune®

Uses Monitor blood level in management of immunosuppression of organ transplant recipients

Reference Range RIA: immediately following transplant: 150-250 ng/mL (SI: 125-210 nmol/L) (plasma levels), 450-750 ng/mL (SI: 374-624 nmol/L) (whole blood levels). Maintenance levels months after transplant: 50-150 ng/mL (SI: 40-125 nmol/L) (plasma levels), 150-450 ng/mL (SI: 125-375 nmol/L) (whole blood levels). Reference ranges are method dependent and specimen dependent.

Abstract This drug is widely used as an immunosuppressant, especially after organ transplants.

Specimen Whole blood, plasma, or serum

Container Lavender top (EDTA) tube (whole blood), green top (heparin) tube (plasma), red top tube (serum)

Sampling Time Trough levels should be obtained 12-18 hours after oral dose (chronic usage), 12 hours after intravenous dose, or immediately prior to next dose.

Limitations Results are method dependent - some measure multiple metabolites as well as parent drug. It is not yet clearly established

whether whole blood or plasma/serum levels are clinically most appropriate. Single assays are not as informative as a series over time.

Methodology

Radioimmunoassay (RIA), high performance liquid chromatography (HPLC), fluorescence polarization immunoassay (FPIA)

Additional Information

Monitoring of blood levels is imperative because the pharmacokinetics of cyclosporine are not only complex, but vary over time in the same patient; thus, blood levels cannot be well predicted from dosing schedules. Furthermore, this drug has a narrow therapeutic window and significant toxicity at levels above that range.

Renal toxicity with eventual renal failure is the most severe complication. Other assays to assess renal function (ie, BUN, creatinine clearance) should be ordered along with cyclosporine level, since toxicity may begin even with "acceptable" blood levels. Other toxicities include hypertension, convulsions, tremors, pulmonary edema, and an increased risk of lymphoma.

Because results will vary depending on whether the assay is done on whole blood or serum/plasma and on the method and cyclosporine antibody employed (monospecific or polyspecific), it is best for a given patient's specimens to be analyzed at a single laboratory to eliminate as many assay-dependent variables as possible. If switching of laboratories is unavoidable, it is advisable to have a few specimens run in parallel in the second laboratory prior to changing.

The clinical use of cyclosporine is difficult and requires experience and judgment. A drug blood level is only one of many pieces in the puzzle of transplant medicine.

Digitoxin, Blood

Synonyms Crystodigin®; Digitalis; Lanotoxin®; Purodigin®

Uses Therapeutic monitoring; toxicity assessment

Contraindicating Factors Patient on digoxin; recent radioactive tracer

Reference Range Therapeutic: 18-22 ng/mL (SI: 23-28 nmol/L)

Abstract One of a group of plant glycosides used in the treatment of congestive heart failure, digitoxin is infrequently used compared to digoxin. It must not be confused with digoxin when serum levels are ordered.

Specimen Blood

Minimum Volume 3 mL serum

Container Red top tube

Sampling Time 6-12 hours after dose

Storage Instructions Separate serum and store in refrigerator.

Critical Values Levels >35 ng/mL (SI: >46 nmol/L) are associated with clinical toxicity in 80% of patients.

Limitations Do not order digitoxin level on a patient receiving digoxin. Digitoxin is not commonly used. Digoxin immune Fab can increase digitoxin levels by assay.

Methodology Radioimmunoassay (RIA), gas-liquid chromatography (GLC), high performance liquid chromatography (HPLC)

Additional Information

Optimal sampling time after dosage is 6 hours. Optimal resampling time after change in dosage is 48-96 hours. Be sure the patient is not on digoxin instead of digitoxin. There is cross reactivity between the two drugs and the levels reported will not be valid, and in fact could be misleading and catastrophic. Digitalis leaf has both digoxin and digitoxin as active components. Digitoxin is the best test for evaluation of toxicity in a patient taking digitalis leaf, but neither test is truly satisfactory. There is considerable overlap in the upper therapeutic ranges with levels which may be toxic. **Digitoxin levels must be correlated with clinical and other chemical data.** Numerous factors modify the effect of cardiac glycosides, including serum potassium, calcium, magnesium, and cardiac blood flow.

Digoxin, Blood

Synonyms Digacine® Level, Blood; Digoxosodium Level, Blood; Lanoxin® Level, Blood

Uses Cardiac glycoside

Reference Range Therapeutic: 0.5-2.0 ng/mL

Specimen Blood

Container Red top tube

Critical Values Toxic effects: Serum: >2.0 ng/mL

Possible Panic Range Fatalities: 1.5-300.0 ng/mL

Limitations Digoxin immune Fab fragments can interfere with assay. Endogenous digoxin-like immunoreactive substances (DLIS) may cause artificial elevation of serum digoxin level. Chinese toad venom used in

medicinals also cross-reacts with FPIA technique. Cardioactive steroids of the bufadienolide class may cross react with polygonal digoxin immunoassays. Large doses of uzara root or Siberian ginseng may interfere with the digoxin assay.

Methodology High performance liquid chromatography (HPLC), radioimmunoassay (RIA); fluorescence polarization immunoassay with ultra filtration (FPIA-UF) accurately measures free digoxin in the presence of immune Fab fragments

Additional Information

Cardioactive steroids of the bufadienolide class may cross react with polyclonal digoxin immunoassays. Serum digoxin concentrations determined by the ACA immunoassay method (DuPont) may overestimate (by 0.3-1.1 ng/mL) digoxin levels in patients with renal, liver or diabetic disease.

The Digoxin immunoreactive substance (DLIS) is rarely above 2 ng/ml. It is elevated in pregnancy, neonates, renal/liver insufficiency, congestive heart failure and hypothermia. Digoxin levels may be falsely elevated due to elevated bilirubin, or spironolactone administration.

Electrolytes, Blood

Synonyms Plasma Electrolytes; Serum Electrolytes

Uses Monitor electrolyte status; screen water balance; diagnose respiratory and metabolic acid-base balance; evaluate hydration status, diarrhea, dehydration, ketoacidosis in diabetes mellitus and other disorders; evaluate alcoholism and other toxicity states

Test Commonly Includes Sodium, potassium, chloride; often total CO₂, but in some laboratories pH and pCO₂ are measured and bicarbonate (HCO₃) and CO₂T are calculated. Anion gap is reported with electrolytes by some laboratories.

Specimen Blood

Volume 10 mL

Minimum Volume 3 mL serum or plasma

Container Red top tube or green top (heparin) tube

Collection Best to collect without tourniquet if possible. Do not allow patient to clench-unclench his/her hand.

Storage Instructions Do not freeze.

Limitations Hemolysis and prolonged contact of serum with cells produces elevation of potassium. The usual order for "electrolytes" does not include magnesium, osmolality, phosphorus, or lactic acid.

Methodology Ion-selective electrodes (ISE) or flame photometry are used for sodium and potassium. Sodium and potassium may also be measured by inductively-coupled plasma emission spectrometry.

Additional Information May be performed on heparinized plasma but not on EDTA plasma. Knowledge of pertinent clinical criteria allows for more cost effective ordering of blood electrolytes in patients in whom the information will be clinically significant. The anion gap, calculated Na⁺ ~ (Cl⁻ + HCO₃⁻), provides useful information for interpreting acid-base disorders and may be useful for establishing a differential diagnosis in some conditions.

Electrolytes, Urine

Related Information

- Osmolality, Urine

Synonyms Urine Electrolytes

Uses Monitor kidney function, fluid and electrolyte balance, water balance, acid-base balance; evaluate electrolyte composition of urine, correlation with renin and aldosterone studies. Urine sodium levels are appropriate in patients with volume depletion, with acute oliguria, and with decreased plasma sodium. Urine potassium levels are needed in work-up of hypokalemia of unknown etiology (eg, possible Conn's syndrome (primary aldosteronism), adrenal hyperplasia, Bartter's syndrome, renal tubular acidosis, Fanconi syndrome). Urine chloride is helpful to work up metabolic alkalosis in patients who are not on diuretics; assess dietary salt restriction. Urine electrolytes are used in work-up with aldosterone and renin assays.

Reference Range There is a large diurnal variation in range for spot samples. Na/K ratio: 0.90-3.88; borderline Na/K ratio: 0.3-6.0.

Test Commonly Includes Sodium, potassium, and chloride on random or timed collections. Osmolality must be ordered as such.

Specimen Random, 12-, or 24-hour urine

Volume 10 mL

Container Clean urine container

Collection Specify whether random or timed collection.

Causes for Rejection Blood in urine

Special Instructions Urine osmolality may be ordered with urine electrolytes, usually it must be specifically ordered.

Additional Information If a 24-hour timed specimen is collected, other tests which may be ordered simultaneously include Protein, Quantitative, 24-hour Urine and/or Creatinine Clearance, (all of which can be collected

ETHYLENE GLYCOL, BLOOD

together). Aldosterone and other adrenocortical steroids enhance reabsorption of sodium and promote excretion of potassium. In subjects with hyponatremia, normal blood volume, and urine Na and Cl > 40 mM/L, the differential diagnosis includes hypothyroidism and the syndrome of inappropriate secretion of antidiuretic hormone. Fetal (amniotic fluid) electrolytes are not predictive of ultimate renal function.

Ethylene Glycol, Blood

Applies to Antifreeze

Synonyms 1,2-Ethanediol

Uses Detect and quantitate ingestion of ethylene glycol

Reference Range Negative

Test Commonly Includes Propylene glycol

Abstract A commercial chemical used as a radiator antifreeze and for commercial chemical synthesis.

Specimen Blood

Container Red top tube or green top (heparin) tube

Possible Panic Range Levels at 0.2 g/L indicate toxicity.

Methodology Gas-liquid chromatography (GLC), photometry, fluorometry, enzymatic assay (automated)

Additional Information Existence of propionic acid through inborn errors of metabolism can give a false-positive ethylene glycol level. Glycerol, elevated triglycerides, and propylene glycol can falsely elevate serum ethylene glycol level.

Ethyl Glucuronide (Urine)

Related Information

- Ethyl Sulfate (Urine)

Synonyms EtG

Use Monitor alcohol use or dependence

Reference Range Usual cutoff ranges from 0.1 to 1 mg/L in commercial labs

Abstract Ethyl glucuronide is produced by a phase 2 conjugation reaction with glucuronic acid and is excreted in the urine. This assay is often combined with measurement of urinary ethyl sulfate (EtS).

Specimen 10 mL urine

Methodology Specific direct electrospray liquid chromatographic-mass spectrometric method performed in the negative ion mode

Additional Information Can be measured up to 80 hours postingestion. False-positive results can result due to fermentation following sample collection. Urinary tract infections with *Escherichia coli* can result in false-negative results due to bacterial hydrolysis. Incidental exposure to mouthwash containing 12% ethanol (while gargling) can result in urinary ethyl glucuronide levels over 50 ng/mL.

Ethyl Sulfate (Urine)

Related Information

- Ethyl Glucuronide (Urine)

Synonyms EtS

Use Monitor alcohol use or dependence

Reference Range Usual cutoff is 100 ng/mL

Abstract Ethanol undergoes sulfate conjugation through the actions of sulfotransferase to produce ethyl sulfate (EtS), which is excreted in the first 24 hours. Often combined with measurement of urinary ethyl glucuronide (EtG).

Specimen 10 mL urine

Methodology Specific direct electrospray liquid chromatographic-mass spectrometric method performed in the negative ion mode

Additional Information Unlike ethyl glucuronide, there appears to be little effect with urinary tract infections and false negatives. Can be measured up to about 36 hours postingestion (shorter window of detection than EtG)

Specific References

Helander A and Beck O, "Ethyl Sulfate: A Metabolite of Ethanol in Humans and a Potential Biomarker of Acute Alcohol Intake," *Clin Chem*, 2005, 29(5):270-4.

Helander A and Beck O, "Mass Spectrometric Identification of Ethyl Sulfate as an Ethanol Metabolite in Humans," *Clin Chem*, 2004, 50(5):936-7.

Glucose, Random

Uses Evaluate carbohydrate metabolism, acidosis and ketoacidosis, dehydration; work up alcoholism, or apparent alcoholism; work-up of coma, neuroglycopenia. Hypoglycemia if present should be investigated with insulin levels as well. For the diagnosis of diabetes mellitus in nonpregnant adult subjects, random glucose >200 mg/dL (SI: >11.1 mM/L) is required. Other criteria exist. Determination of blood glucose on admission in patients who have had an out-of-hospital cardiac arrest can serve as a predictor of neurologic recovery. Higher levels are indicative of more severe brain ischemia and difficult resuscitation. In pregnant women, a value > 105 mg/dL usually prompts further investigation.

Reference Range Dependent on time and content of last meal. Glucose of >200 mg/dL (SI: >11.1 mM/L) in a nonstressed, ambulatory subject supports the diagnosis of diabetes mellitus. Values in term neonates are published.

Specimen Blood

Volume 10 mL

Minimum Volume 5 mL plasma or serum

Container Gray top (sodium fluoride) tube preferred; red top tube acceptable

Collection Pediatrics: Draw blood from heelstick.

Causes for Rejection Blood stored overnight on clot

Possible Panic Range Neonates: <40 mg/dL (SI: <2.2 mM/L); adults: male: <50 mg/dL (SI: <2.8 mM/L), >400 mg/dL (SI: >22.2 mM/L); adults female: <40 mg/dL (SI: <2.2 mM/L), >400 mg/dL (SI: >22.2 mM/L)

Limitations Glucose will decrease in samples left on the clot and in tubes other than fluoride prior to analysis. Acetaminophen can cause a false elevation of serum glucose when the neocuprine method is utilized.

Methodology Hexokinase, glucose oxidase, oxygen rate, ortho-toluidine

Additional Information

Recall that **blood glucose** values are not equivalent to **plasma glucose**.

If glucose is >400 mg/dL (SI: >22.2 mM/L), an acetone (ketone body) examination probably should be done. A fasting and a 2-hour postprandial specimen is preferable to a random specimen for evaluation of possible diabetes mellitus. The incidence of hypoglycemia in hospitalized patients appears to be significant, but may be better controlled if frequent monitoring of glucose levels is employed. Wider utilization of bedside glucose testing may allow for closer patient monitoring, but the establishment of uniform quality control procedures is necessary to ensure valid results from this type of testing. Evaluation of glycated hemoglobin and self-monitoring of blood glucose are two relatively new means of assessing glycemia which have become widely available.

May cause a false elevation of serum creatinine through interference with laboratory determination

Tumors which induce hypoglycemia: Pancreatic islet-cell tumor (insulinoma); fibrosarcomas; mesotheliomas; leiomyosarcomas; hemangiopericytomas; gastric carcinoma; pancreatic exocrine carcinoma; lung carcinoma; cervical carcinoma (small-cell)

Specific References

Abarbanell NR. "Is Prehospital Blood Glucose Measurement Necessary in Suspected Cerebrovascular Accident Patients?" *Am J Emerg Med*, 2005, 23(7):823-7.

Gold Level

Synonyms Aurothioglucose; Chrysotherapy; Gold Sodium Thiomalate; Myochrysin®; Solganal®

Reference Range Normal: 0-0.1 mcg/mL (SI: 0-0.5 µmol/L); therapeutic: 1.0-3.0 mcg/mL (SI: 5.1-15.2 µmol/L); urine <0.1 mcg/24 hours

Abstract Gold is used as a treatment for rheumatoid arthritis, but its value is being questioned.

Specimen Blood, urine

Volume 7 mL blood or entire collection urine

Container Red top tube for blood, acid-washed polyethylene container for urine

Limitations Blood levels do not correlate with therapeutic or toxic effects. No relationship between serum gold levels and efficacy is established. Serum gold concentrations have not been helpful in monitoring adverse reactions. A relationship is not recognized between urinary gold and response to therapy. Hair and nail gold concentrations have not been helpful.

Methodology Atomic absorption spectrometry (AA)

Additional Information Complex gold compounds are used in the treatment of severe, progressive rheumatoid arthritis which is not controlled by other medical therapy. It is also used selectively for juvenile rheumatoid arthritis and for psoriatic arthritis affecting peripheral joints. The mechanism of action is not clear, but may be due to reticuloendothelial system blockade, and/or effects on lymphocyte proliferation and antibody production. Gold toxicity may be manifested by dermatitis, pruritus, stomatitis, metallic taste, eosinophilia, leukopenia, anemia, thrombocytopenia, hematuria, proteinuria, nephrosis, and bone marrow suppression, among other possible effects.

Heavy Metal Screen, Blood

Synonyms Metals, Blood; Poisonous Metals, Blood; Toxic Metals, Blood

Uses Screen for heavy metal poisoning

Reference Range Varies with metal detected.

Test Commonly Includes Antimony, arsenic, bismuth, boron, cadmium, cobalt, copper, lead, mercury, selenium, tellurium, thallium, zinc

Abstract Used principally to detect arsenic, cadmium, mercury, and lead poisoning.

Specimen Whole blood (EDTA) plus serum

Volume 20 mL

Container Special metal-free tube and red top tube

Storage Instructions Refrigerate; do not spin down.

Special Instructions Check with laboratory performing the assay to determine what elements will be detected and for any special instructions.

Methodology Atomic absorption spectrometry (AA)

Heavy Metal Screen, Urine

Applies to Heavy Metal Screen, Hair

Synonyms Metal Screen; Metals, Toxic; Poisonous Metals, Urine; Toxic Metals, Urine

Uses Screen for heavy metal poisoning and toxic exposure; urine lead analysis is useful for organic lead exposure and to monitor chelation. Blood is preferred for inorganic lead exposure monitoring.

Reference Range Arsenic: < 50 mcg/L; lead: < 80 mcg/L; mercury: < 20 mcg/L; nickel: < 25 mcg/L; cadmium: < 10 mcg/L

Test Commonly Includes Arsenic, mercury, lead (could also include nickel and cadmium)

Abstract Used to detect arsenic, mercury, lead, and cadmium poisoning

Specimen 24-hour urine

Volume Entire collection

Minimum Volume 150 mL aliquot

Container Plastic, acid-washed urine container (preferably polyethylene), no preservative, 20-25 mL 6N HCl (low metal content)

Collection 24-hour collection

Storage Instructions Refrigerate

Special Instructions Include volume of urine

Limitations

Hair analysis is not useful for lead exposure; should be used for arsenic and mercury poisoning or exposure, especially if one is interested in determining chronic exposure. Hair should be clean, free of oil, and clipped (0.5 g for As; 2 g for Hg) as close as possible.

Recent ingestion of seafood can cause misleading increases of urine arsenic.

Methodology Atomic absorption spectrometry (AA)

Iron and Total Iron Binding Capacity/Transferrin

Synonyms Fe and TIBC; Iron Binding Capacity; Iron Profile; TIBC; Total Iron Binding Capacity

Uses Differential diagnosis of anemia, especially with hypochromia and/or low MCV. The **percent saturation** sometimes is more helpful than is the iron result to estimate iron stores and iron deficiency anemia. Evaluate thalassemia and possible sideroblastic anemia; work up hemochromatosis, in which iron is increased and iron saturation is high. Decrease in iron level after performance of a Schilling test supports the diagnosis of vitamin B₁₂ deficiency, *vide infra*. Evaluate iron poisoning (toxicity) and overload in renal dialysis patients or patients with transfusion dependent anemias. Use of TIBC in iron toxicity may be less useful than previously believed. TIBC or transferrin is a useful index of nutritional status, but is not useful for evaluating iron poisoning.

Uncomplicated iron deficiency: Serum transferrin (and TIBC) high, serum iron low, saturation low. Usual causes of depleted iron stores include blood loss, inadequate dietary iron. RBCs in moderately severe iron deficiency are hypochromic and microcytic. The red cell distribution width increases and MCV decreases. Stainable marrow iron is absent. Serum ferritin decrease is the earliest indicator of iron deficiency if inflammation is absent.

Anemia of chronic disease: Serum transferrin (and TIBC) low to normal, serum iron low, saturation low or normal. Transferrin decreases with many inflammatory diseases. With chronic disease there is a block in movement to and utilization of iron by marrow. This leads to low serum iron and decreased erythropoiesis. Examples include acute and chronic infections, malignancy, and renal failure.

Sideroblastic anemia: Serum transferrin (and TIBC) normal to low, serum iron normal to high, saturation high.

Hemolytic anemias: Serum transferrin (and TIBC) normal to low, serum iron high, saturation high.

Hemochromatosis: Serum transferrin (and TIBC) slightly low, serum iron high, saturation very high.

Protein depletion: Serum transferrin (and TIBC) may be low, serum iron normal or low (if the patient is also iron deficient). This may occur as a result of malnutrition, liver disease, renal disease (eg, nephrosis) or other entities.

Liver disease: Serum transferrin variable; with acute viral hepatitis, high along with serum iron and ferritin. With chronic liver disease (eg, cirrhosis), transferrin may be low. Patients who have cirrhosis and portacaval shunting have saturated TIBC/transferrin as well as high ferritin.

Chronic dialysis for renal failure: Monitor iron levels in patients undergoing dialysis. To follow treatment of iron overload with deferoxamine or with regimen of recombinant human erythropoietin and phlebotomy.

Contraindicating Factors Parenteral iron before sample is drawn will cause misleading high iron results. Recent blood transfusion may have only a small positive effect on iron.

Reference Range A variety of approaches to the estimation of serum iron, TIBC, and transferrin are in use. Expect normal ranges to vary between laboratories as they are in part method dependent. Iron: 75-175 mcg/dL (SI: 13.4-31.3 μmol/L) for adult males; slightly lower (5% to 10%) values for adult females. Iron binding capacity: 250-350 mcg/dL (SI: 45-63 μmol/L). Percent saturation (transferrin saturation): 20% to 50%. TIBC is a chemical approximation of transferrin. Quantitative assays for transferrin are widely available. A mathematical relationship between TIBC and transferrin can be derived, depending on methodology, in which transferrin can be measured, then TIBC calculated.

Test Commonly Includes Serum iron, total iron binding capacity and/or transferrin, percent of saturation

Patient Preparation Specimen should be drawn fasting in the morning (circadian rhythm affects iron; levels are lower in the evening). Sample should be drawn before the patient is given therapeutic iron or blood transfusion. Iron determinations on patients who have had blood transfusions should be delayed several days.

Specimen Blood

Volume 10 mL

Minimum Volume 7 mL serum

Container Red top tube

Sampling Time Morning; marked daily variation occurs

Collection Serum iron levels are 30% higher in the morning and blood levels should be determined on fasting AM samples. Blood should be drawn before other specimens which require anticoagulated tubes. Separate serum from cells as soon as possible.

Storage Instructions Stable 1 week at 4°C

Limitations Except for iron poisoning, a serum iron without TIBC or transferrin is of limited value. Ferritin levels are also useful for iron deficiency. Low iron level may not indicate iron deficiency in acute infection with leukocytosis. Low iron levels may be misleading in chronic infection, inflammation, and malignancy; high ferritin levels occur in many such states. TIBC and transferrin are increased in patients on oral contraceptives, with normal saturation. Gross hemolysis may interfere with serum iron.

Methodology Ferrozine, bathophenanthroline (iron); nephelometry (transferrin); MgCO₃ column, other methods (TIBC); atomic absorption (iron, TIBC), anodal stripping; inductively coupled plasma atomic emission spectroscopy

Additional Information

Serum iron is **increased** in hemosiderosis, hemolytic anemias especially thalassemia, sideroachrestic anemias, hepatitis, acute hepatic necrosis, hemochromatosis, and with inappropriate iron therapy. Iron may reach high levels with iron poisoning. Levels as high as 16,700 mcg/dL have been survivable. Some patients who receive multiple transfusions (eg, some hemolytic anemias, thalassemia, renal dialysis patients) will have increased serum iron levels. Patients receiving chloramphenicol, estrogens, and methyl dopa can have elevated iron levels.

LACTIC ACID, BLOOD

Serum iron is **decreased** with insufficient dietary iron, chronic blood loss (including the hemolytic anemias, paroxysmal nocturnal hemoglobinuria), inadequate absorption of iron and impaired release of iron stores as in inflammation, infection, and chronic diseases. Cholestyramine and colchicine can cause a decrease in serum iron. Deferoxamine may interfere with colorimetric iron and total iron binding capacity assays. The combination of low iron, high TIBC and/or transferrin, and low saturation indicates iron deficiency. Without all of these findings together, iron deficiency is unproven. Low ferritin supports the diagnosis of iron deficiency. **Detection of iron deficiency may lead to detection of adenocarcinoma of GI tract, a point which cannot be overemphasized.** In recovery from pernicious anemia, especially just after B₁₂ dose, iron levels are low. In fact, the drop in serum iron 1 to several days after the Schilling test flushing dose of vitamin B₁₂ may be more useful in diagnosis than the radioactivity of the 24-hour urine collection. Serum iron is reported to drop with acute infarct of myocardium.

TIBC is increased in iron-deficiency, use of oral contraceptives, and in pregnancy. It is falsely increased with deferoxamine treatment. It is not useful in managing iron poisoning.

TIBC decreased in hypoproteinemia from many causes, and in a number of inflammatory states. Also, chloramphenicol and corticotropin can decrease TIBC.

Increased saturation occurs with HLA-related (classical) hemochromatosis before ferritin is greatly increased, and also with iron overload (eg, cirrhosis and portacaval shunt), in hemolytic anemias, and with iron therapy. Saturation >70% in females, >80% in males is described as prerequisite for parenchymal loading. However, sample contamination and the vagaries of fluctuation in serum iron levels can make such criteria misleading on occasion.

The serum ferritin is a more sensitive test than the serum iron or TIBC for iron deficiency and for iron overload. When all these tests are used together, as is often necessary, they usually can distinguish between iron deficiency anemia and the anemia of chronic disease. The best and most reliable evaluation of total body iron stores is by bone marrow aspiration and biopsy. The best evaluation of iron deficiency in childhood (unless lead toxicity is suspected) is free erythrocyte porphyrins. With recombinant erythropoietin therapy serum iron, transferrin saturation, and ferritin levels decline due to rapid utilization by stimulated erythropoiesis with resultant decrease in storage iron.

Lactic Acid, Blood

Applies to Biotin; Phenformin

Synonyms Blood Lactate; Lactate, Blood

Uses Suspect lactic acidosis when unexplained anion gap metabolic acidosis is encountered, especially if azotemia or ketoacidosis are not present. Evaluate metabolic acidosis, regional or diffuse tissue hypoperfusion, hypoxia, shock, congestive heart failure, dehydration, complicated postoperative state, ketoacidosis or nonketotic acidosis in diabetes mellitus, patients with infections, inflammatory states, postictal state, certain myopathies, acute leukemia and other neoplasia, enzyme defects, glycogen storage disease (type I), thiamine deficiency, and hepatic failure. A spontaneous form of lactic acidosis occurs. It is a prognostic index in particular clinical settings, especially in critically ill patients in shock. A relationship to renal disease also exists. With skin rash, seizures, alopecia, ataxia, keratoconjunctivitis, and lactic acidosis in children, consider defective biotin metabolism. Phenformin, ethanol, methanol, and salicylate and ethylene glycol poisoning may cause lactic acidosis. Acetaminophen toxicity causes lactic acidosis, sometimes with hypoglycemia. Cyanide, isoniazid, and propylene glycol are among the causes of lactic acidosis. Lactic acidosis may be due to inborn errors of metabolism.

Contraindicating Factors Lack of acidosis is **not** a contraindication for this test.

Reference Range Plasma values: venous: 4.5-19.8 mg/dL (SI: 0.5-2.2 mM/L); arterial: 4.5-14.4 mg/dL (SI: 0.5-1.6 mM/L)

Abstract Hypoperfusion is the most common cause of lactic acidosis, and hyperlactacidemia may be the only marker of tissue hypoperfusion.

Specimen Whole blood, arterial or venous, or plasma

Volume 7 mL

Minimum Volume 4 mL whole blood

Container Gray top (sodium fluoride) tube

Collection Avoid hand-clenching and use of a tourniquet. A tourniquet or a patient clenching and unclenching his/her hand will lead to build-up of potassium and lactic acid from the hand muscles. Commonly needed with or as stat follow-up to venous or arterial pH. Serial determinations are often valuable. Send specimen on ice.

Storage Instructions Centrifuge immediately and take off plasma (unless laboratory uses a whole blood method). Keep plasma on ice or at 2°C to 8°C, analyze promptly. A recent study of blood handling techniques and their effect on lactate concentration has been published.

Causes for Rejection Specimen not received on ice

Special Instructions Keep tube on ice until delivered to the laboratory. Tube must be in laboratory within 15 minutes of being drawn.

Possible Panic Range ≥45.0 mg/dL

Limitations Gross hemolysis depresses results. Intravenous injections or infusions which modify acid-base balance, may cause alterations in lactate levels. Epinephrine and exercise elevate lactate, as may I.V. sodium bicarbonate, glucose, and hyperventilation. False low values with a high LD (LDH) value. Normal L-lactate occurs with high D-lactate in D-lactic acidosis. Metabolic acidosis following bypass for obesity, related to altered gastrointestinal flora, is a feature of subjects who develop mental changes as well, in whom D-lactate is the causative anion.

Methodology Enzymatic; other methods include gas chromatography (GC)

Additional Information Phosphorus is sometimes significantly abnormal in lactic acidosis. Creatinine is higher in ketoacidosis than in lactic acidosis, by interference produced by acetoacetic acid on creatinine. Causes of lactic acidosis (usually <45 mg/dL (SI: <5.0 mM/L)) include carbohydrate infusions, exercise, diabetic ketosis, alcohol. Causes of lactic acidosis (>45 mg/dL) include shock (in which lactic acidosis may occur early, before fall in blood pressure, decrease in urine output), hypoxia (including congestive failure, severe anemia, hypotension) and malignancies. Severe lactic acidosis can develop in minutes. Lactic acidosis can accompany dehydration. Blood lactate concentration correlates negatively with survival in patients with acute myocardial infarction, with persistent elevation, >36 mg/dL (SI: >4.0 mM/L) for more than 12 hours, being associated with poor prognosis. At a given bicarbonate level, the average pCO₂ is lower in lactic acidosis than in diabetic ketoacidosis. Lactic acid determination is generally indicated if anion gap is >20 mM/L and if pH is <7.25 and the pCO₂ is not elevated. The measurement of lactate levels may be indicated in the clinical setting of metabolic acidosis. Serum salicylate, ethanol level, and osmolality may be helpful. Spontaneous lactic acidosis may be fatal. Protocols are available for measurement of lactate in cord blood. Plasma lactate (half-life ~4 hours in treated cyanide poisoning) may be useful in determining treatment efficacy in cyanide poisoning. The presence of high urine concentrations of lactate dehydrogenase, lactic acid, and protein may cause a false-positive urinary immunoassay of amphetamines, barbiturates, opiates, cocaine metabolite, propoxyphene, benzodiazepines, and ethanol (urine and serum); and low serum phenytoin (high LDH in blood).

Lead, Blood

Related Information

- Heavy Metal Screen, Blood

Applies to Delta Aminolevulinic Acid Dehydratase

Synonyms Pb, Blood

Uses Evaluate lead toxicity, poisoning

Reference Range <10 mcg/dL (whole blood) (SI: <0.97 μmol/L). See accompanying CDC chart for evaluating blood lead concentrations in children.

CDC Classification of Blood Lead in Children

Class	Blood Lead Level* (mcg/dL)	Comment
I	<10	Not lead-poisoned
IIA	10-14	Rescreen frequently and consider prevention activities
IIB	15-19	Institute nutritional and educational interventions
III	20-44	Evaluate environment and consider chelation therapy
IV	45-69	Institute environmental intervention and chelation therapy
V	>69	A medical emergency

*Due to possible contamination during collection, elevated levels should be confirmed with a second specimen before action is instituted.

Abstract Blood lead concentrations are used to detect recent lead exposure. Does not necessarily measure lead body burden from chronic exposure in the past.

Specimen Whole blood

Volume 10 mL

Container Special lead-free tube with heparin

Storage Instructions Do not separate red cells.

Special Instructions Avoid contact with leaded glass during collection

Possible Panic Range >80 mcg/dL (SI: >3.86 μmol/L) in acute lead poisoning; toxicity at lower levels in chronic poisoning

Limitations Lead poisoning is not ruled out by normal blood levels; clinical findings and heme synthetic enzymes must also be evaluated.

Methodology Electrothermal atomic absorption spectrometry (AA), photometry, anodic stripping voltammeter

Additional Information Great care is required to avoid contamination in the collection of specimens for lead analysis. Lead can be measured in tissue and urine. Another test that may be used to evaluate lead intoxication is **free erythrocyte protoporphyrin (FEP)**. FEP concentrations >35 mcg/dL are consistent with undue absorption of lead. However, FEP is also elevated in iron deficiency, sickle cell anemia, and chronic infection. **Erythrocyte zinc protoporphyrin** is a more specific indicator of lead toxicity and, therefore, superior to FEP. Normal values for erythrocyte zinc protoporphyrin are <100 ng/dL. Inhibition of erythrocyte **delta aminolevulinic acid dehydratase** is a very sensitive measure of lead toxicity. However, a blood lead assay is the definitive test for recent acute exposure if sample collection is meticulous. Blood lead concentrations are evidence of **recent** exposure but do not indicate the body burden from past exposure. Capillary tube collections of fingerstick blood provides adequate samples for atomic absorption spectrophotometry; false-positive rates per this method (19%) are comparable to conventional venous blood sampling (13%).

Lead, Urine

Related Information

- Heavy Metal Screen, Urine

Applies to Lead Excretion Ratio

Synonyms Pb, Urine

Uses Evaluate lead toxicity and chelation therapy

Reference Range ≤ 80 mcg/24 hours (SI: ≤ 0.39 $\mu\text{mol/day}$)

Abstract This test is used to assess lead body burden (lead mobilization test), not to diagnose lead poisoning.

Patient Preparation Patient should be instructed to use a specially cleaned plastic urinal or bedpan

Specimen Random or 24-hour urine

Volume 50 mL random, entire 24-hour collection

Container Plastic (preferably polyethylene) acid-washed urine container

Storage Instructions Record total volume. Acidify to pH 2 with concentrated HCl or add 20 mL 6N HCl to the 24-hour volume.

Causes for Rejection Specimen allowed to contact glass or metal, specimen not collected in acid-washed containers

Special Instructions Indicate if a chelating agent has been administered

Possible Panic Range >125 mcg/24 hours (SI: >0.60 $\mu\text{mol/day}$) is considered excessive and associated with toxicity; values of 80-125 mcg/24 hours (SI: 0.39-0.60 $\mu\text{mol/day}$) are inconclusive

Methodology Electrothermal atomic absorption (AA)

Additional Information Lead is poorly excreted and is found in lower concentrations in urine versus blood. Urine is not the specimen for screening potential toxicity. Urine lead mobilization tests (postchelation therapy) are good indicators of lead body burden. A lead mobilization test is carried out by giving Ca EDTA and measuring the lead excreted in the next 24-hour urine. The lead excretion ratio (LER) is calculated by dividing the amount of lead excreted (in mcg/24 hours) by the amount of Ca EDTA given (in mg). A ratio >0.60 is considered positive for the LER. Unstimulated urinary excretion at rates >0.19 mcg lead/mg creatinine may also be used to indicate need for chelation therapy.

Lidocaine, Blood

Applies to GX; MEGX

Synonyms Lignocaine; Xylocaine®

Uses Monitor therapeutic drug level. Lidocaine is used especially in acute arrhythmias.

Reference Range Therapeutic: 1.5-5.0 mcg/mL (SI: 6.4-21.4 $\mu\text{mol/L}$), up to 6.0 mcg/mL (SI: 25.6 $\mu\text{mol/L}$) if necessary.

Abstract Lidocaine is a local anesthetic which more recently has been used as an antiarrhythmic. The most active metabolite is MEGX.

Specimen Blood

Volume 10 mL

Container Red top tube, green top (heparin) tube, or lavender top (EDTA) tube

Sampling Time Draw specimens 12 hours after initiating therapy for arrhythmia prophylaxis, then every 24 hours thereafter. Obtain specimens every 12 hours when cardiac or hepatic insufficiency exists.

Collection Avoid collection tubes with stoppers containing the plasticizer, TBEP.

Possible Panic Range At levels >6.0 mcg/mL (SI: >25.6 $\mu\text{mol/L}$), there may be seizure activity.

Limitations Cross reactions with other drugs occur. Certain blood collection tubes have been shown to lead to falsely low results. See Collection.

Methodology Enzyme immunoassay (EIA), gas-liquid chromatography (GLC), high performance liquid chromatography (HPLC)

Additional Information Time to reach steady-state by I.V. is 6-12 hours.

In most cases, a relatively constant plasma level may be maintained by slow intravenous infusion administered over a period of 6-10 hours. Blood levels are also elevated by impaired cardiac or hepatic function. The drug is metabolized by the liver to two active metabolites, monoethylglycinexylidide (MEGX) and glycinexylidide (GX). Both accumulate and MEGX most likely contributes to toxicity.

Lithium, Blood

Synonyms Eskalith®; Lithonate®

Uses Monitor therapeutic drug level; evaluate coma

Reference Range Therapeutic: 0.6-1.2 mEq/L (SI: 0.6-1.2 mM/L), for acute mania; 0.8-1.0 mEq/L (SI: 0.8-1.0 mM/L) for protection against future episodes in most patients with bipolar disorder. A higher rate of relapse is described in subjects who are maintained at levels <0.4 mEq/L (SI: 0.4 mM/L).

Abstract Lithium is used in the treatment of depression and particularly for manic-depressive psychosis. It should be monitored.

Specimen Blood

Volume 7 mL

Minimum Volume 2 mL serum

Container Red top tube

Collection Collect at a standard time from last dose, 6-12 hours is recommended.

Storage Instructions Refrigerate a minimum of 2 mL serum. Serum specimens are stable for 24 hours at room temperature. Separate serum immediately.

Causes for Rejection Specimen collected in tube containing lithium heparin, hemolysis

Possible Panic Range Toxic: >1.5 mEq/L (SI: >1.5 mM/L). Toxicity can become serious when levels rise to levels ≥ 2.0 mEq/L (SI: ≥ 2.0 mM/L). Levels >4.0 mEq/L (SI: >4.0 mM/L) are associated with coma, death. A narrow therapeutic index exists for lithium.

Limitations Lithium toxicity can occur with normal serum lithium levels. Thiazides can cause significant rise in serum lithium.

Methodology Flame photometry, atomic absorption spectrophotometry (AA), ion-selective electrode (ISE)

Additional Information Speckled green top tubes (Becton-Dickinson) which contain lithium heparin as an anticoagulant can increase plasma lithium levels by ~ 1.5 mEq/L (1.5 mM/L). Benzamide, quinidine, and procainamide can result in falsely elevated serum lithium levels by spectrochemical assays.

Lithium RBC/Plasma Ratio

Reference Range RBC lithium: 0.10-0.40 mEq/L; plasma lithium: 1.00-1.50 mEq/L; RBC plasma/ratio: none defined

Test Commonly Includes Plasma lithium, RBC lithium, and RBCs/plasma ratio

Specimen Blood

Volume 10 mL

Minimum Volume 2 mL

Container Lavender top (EDTA) tube

Storage Instructions Do not refrigerate.

Causes for Rejection Gross hemolysis, clotted specimen

Methodology Atomic absorption spectrophotometry (AA)

Lung Scan, Ventilation

Applies to Quantitative Ventilation Lung Scan; Ventilation-Perfusion Lung Scan

Synonyms Aerosol Lung Scan; Radionuclide Ventilation Lung Scan; Ventilation Lung Scan; Xenon Lung Scan

Uses The primary indication for lung ventilation and perfusion imaging is the detection of acute pulmonary emboli. These procedures together provide an accurate noninvasive screening test both for the detection of emboli and for documentation of resolution during and after therapy. Lung ventilation imaging is also helpful in quantifying regional pulmonary ventilation in patients with severe obstructive lung disease or who are being considered for lung resection surgery. Useful for acute toxic inhalation; retention of xenon indicative of parenchymal lung damage.

Reference Range

Homogeneous distribution of activity throughout the lungs

LYSERGIC ACID DIETHYLAMINE LEVEL

Test Commonly Includes The patient inhales a radioactive gas or nebulized aerosol and multiple images of the lungs are then acquired to assess lung ventilation. **Special note:** This procedure is almost always combined with a lung perfusion scan to detect a characteristic pattern of segmental perfusion deficits with normal corresponding regional ventilation that is the hallmark of pulmonary emboli.

Patient Preparation Patient should have all RIA blood work performed, or at least drawn, prior to injection of any radioactive material. The patient does not need to be fasting or NPO for this procedure. The patient should have a routine chest radiograph performed within 12 hours prior to imaging or receive one immediately after. Notify the Nuclear Medicine Department if patients require high flow oxygen or respirator assistance.

Causes for Rejection Other recent Nuclear Medicine procedure may interfere. If uncertain, call the Nuclear Medicine Department.

Special Instructions

Requisition must state the current patient diagnosis in order to select the most appropriate radiopharmaceutical and/or imaging technique. The duration of the procedure is 30 minutes to 1 hour. For radiopharmaceuticals: See table.

Radiopharmaceuticals for Lung Ventilation Imaging				
Agent	Isotope Half-life	Timing vs Perfusion Scan	Advantages	Disadvantages
^{99m} Tc DTPA aerosol	6 hours	Before	Multiple views of ventilation	Turbulent air flow can cause patchy distribution; no washout phase
¹³³ Xe gas	5 days	Before	Single view with equilibrium and washout phases	Requires good single-breath effort; single view (usually posterior)
¹²⁷ Xe gas	36 days	After	Single view with equilibrium and washout phases; may be performed after perfusion scan	
^{81m} Kr gas	13 seconds	During	Multiple views of ventilation; no gas trap required	Nonavailability on 24-hour basis; expense

*Used to detect inhalation injuries

Limitations Patients must be able to cooperate in performing this test.

They will be required to breathe through a mouthpiece, remain still for approximately 15 minutes, (usually in the supine position) and if xenon gas is used, hold their breath for 10 seconds or longer. The procedure is somewhat nonspecific in the presence of underlying lung conditions such as pneumonia or chronic obstructive disease. A same day chest radiograph is necessary for review and comparison with scan findings.

Additional Information Patients on high flow oxygen or respirator assistance can undergo ventilation scans with radioactive aerosols using special nebulizer adaptors.

Lysergic Acid Diethylamine Level

Synonyms LSD

Uses Evaluate LSD toxicity; confirm suspected overdose or abuse

Reference Range

None detected

Urine, LSD: Department of Defense cutoff concentration: 200 pg/mL (will be positive for ~24 hours after a single LSD street dose)

Specimen Blood or urine

Volume 10 mL blood, 10 mL urine

Container Royal blue top tube, plastic urine container

Limitations Ambroxol brompheniramine, fentanyl, haloperidol, imipramine, methylphenidate, metoclopramide, or sertraline can result in a false-positive immunoassay urinary screen.

Methodology Gas chromatography/mass spectrometry (GC/MS)

Additional Information Lysergic acid diethylamine, LSD, is a synthetic hallucinogen that acts on multiple sites in the CNS. Ingestion of this drug may result in sensory distortions, hallucinations, delusions, euphoria or dysphoria, dizziness, and paresthesia. Prolonged use may lead to psychological dependence and significant hazards such as panic, serious depression, paranoid behavior, and a persistent psychotic state.

Magnetic Resonance Scan, Brain

Applies to Magnetic Resonance Scan, Head

Synonyms Brain MRI; Head MRI

Uses Diagnose intracranial abnormalities including tumors, ischemia, infection, multiple sclerosis or any abnormalities relating to the brain or calvarium. MRI is an excellent modality for assessment of congenital brain abnormalities or relating to the status of brain maturation in the pediatric population. May reveal deposition of iron, copper, and manganese. Also useful for carbon monoxide, methanol, and barium.

Contraindicating Factors Patients weighing more than 300 lb and patients unable to squeeze into the magnet cannot undergo MRI. An absolute contraindication for MRI is a cardiac pacemaker. Relative contraindications to magnetic resonance imaging include intracranial aneurysm clips, cochlear implants, insulin infusion and chemotherapy pumps, neurocutaneous stimulators and prosthetic heart valves, depending on date of manufacture and metallurgical composition. Please consult MRI physician if questions arise. Patients who have metallic foreign bodies within the eye or who have undergone recent surgery within the last 6 weeks requiring placement of a vascular surgical clip, should also not undergo MRI. The safety of MRI in pregnant patients has not been determined. In such cases, prior consultation with the MRI physician is required. Generally, patients who have undergone recent surgery not requiring vascular clips or who have had coronary artery bypass surgery in the past may undergo MRI. Patients who have shrapnel wounds or orthopedic prostheses can generally safely undergo MRI unless the metallic device is in the anatomic region to be scanned which results in degradation of the images. Patients with surgically implanted intravascular vena cava filters to prevent pulmonary embolism can usually be scanned if the device has been in place for at least 6 weeks. Patients requiring life support equipment including ventilators require special preparation. Please contact MRI physician ahead of time. Central venous lines, Swan-Ganz catheters, and nasogastric (NG) tubes usually present no problems. If the patient is positive when screened for metallic devices and you are uncertain of their significance, the MRI radiologist will provide additional information to assist you.

Patient Preparation Inpatient: Patient must be able to lie quietly while the scan is performed. The patient should be screened for metallic devices by nursing personnel. (See Contraindications.) This includes metal introduced into the patient either surgically or by trauma. All metallic objects must be removed from the patient including jewelry or any other metal objects which may be in the patient's bedding. Please remove dentures or other dental appliances. I.V.s which contain no metal are fine, but infusion pumps must be removed. Oxygen tanks and metallic backboards may come with the patient but will be removed prior to the patient entering the magnet room. Oxygen may be provided in the magnet room. Trauma, ICU, or CCU patients should be accompanied by a nurse. If the patient is restless, combative, or claustrophobic, proper sedation may be administered on the floor prior to the MRI, or at the MRI Center. Consult the MRI radiologists with questions on proper sedation. Outpatient: The patient should be screened for metallic devices. (See Contraindications.) If a question exists as to the patient's suitability for MRI, the MRI radiologist will assist you with your questions. If the patient is claustrophobic, oral or parenteral sedation may be necessary. If so, the patient should be accompanied by another adult to provide transportation home after the examination.

Limitations Generally, the greatest limitation of magnetic resonance imaging results from the patient's fear of the procedure. The patient must remain quiet and still for several scans, each lasting from several minutes to 10 minutes in length. Total examination time is usually 30-45 minutes and occasionally up to 1 hour. If the patient is restless during the examination, motion artifacts will be present on the images limiting their diagnostic value. If the patient is claustrophobic, mild oral sedation or occasionally parenteral sedation may be needed. Also the patient can be accompanied by a family member or friend during the examination which helps calm the patient's anxiety in many cases. Patients requiring life support equipment such as ventilators require special preparation.

Methodology Unlike most conventional radiologic procedures, magnetic resonance imaging does not utilize ionizing radiation, but relies upon radio frequency or radio signals induced within the patient by the magnetic field to obtain images. There are no known biologic effects secondary to the magnetic fields currently used in clinical MRI. Prior to the scan, the patient will be asked to remove all metallic objects from their person, including loose change, hair pins, earrings, belts, etc. This is for safety reasons as the strong magnetic field could result in these and any other metal objects becoming projectiles resulting in injury to the patient or MRI personnel. Also the patient should not carry a purse or wallet into the magnet room, as the magnetic field can permanently erase bank cards or credit cards. The magnet is open on both ends and music can be played for the patient if desired. Fresh air is constantly circulated through the magnet room and the patient is continually monitored by the MRI technologist. An intercom system is provided for communication between

Table 1. Geometric Means (GMs) and Selected Percentiles of Total Blood Mercury (Hg) Concentrations ($\mu\text{g/L}$) for Women Aged 16-49 Years and Children Aged 1-5 Years, by Selected Variables - National Health and Nutrition Examination Survey, United States, 1999-2002.

†Below the limits of detection.

the patient and the technologist. For MRI of the brain, a special coil surrounds, but does not touch the patient's head. The patient will be asked to remain very still while scans are being obtained. In certain cases, an MRI contrast agent, Gadopentetate Dimeglumine (Magnevist®) may be necessary to increase the diagnostic accuracy of the MRI examination. This is administered intravenously, via an antecubital vein in a small volume (less than 20 mL). This contrast agent may be used in patients who are allergic to conventional iodinated contrast agents such as is used in IVPs or CT examination without difficulty. There are very few contraindications to its use. (See Contraindications.)

Additional Information

In some cases, an MRI contrast agent (Magnevist®) may be needed to increase the diagnostic accuracy of the MRI. This contrast agent can be administered to patients with a previous history of allergies to conventional iodinated x-ray agents as it contains no iodine. Contraindications to its use include previous allergy to the contrast agent itself, renal failure, certain types of anemia, and Wilson's disease. The contrast agent is generally very safe and increases the diagnostic efficacy of the MRI.

Bilateral putaminal injury (with hemorrhage and necrosis) can be noted in methanol poisoning; hyperintense signal on T₁ weighted images in lenticular and caudate indicative of chronic manganese poisoning. Hypersignal intensities on T₂ weighted images in the basal ganglia noted with barium poisoning. Carbon monoxide poisoning may be demonstrated by globus pallidi lesions with endematous changes. Organic solvents, hexachlorophene, triethyltin and toluene can cause selective myelin damage. Furthermore, chronic toluene sniffing can cause cerebral, cerebellar and brainstem atrophy detectable by MRI. Bromate poisoning can cause small high intensity spots on T₂ bilaterally in the frontal white matter. Increased signal density near the fourth ventricle noted following metronidazole (>60 g) ingestion.

Meconium Drug Screen**Synonyms** Drug Screen, Meconium**Uses** Drugs of abuse screen (amphetamines, opiates, cocaine, marijuana, phencyclidine)**Specimen** 1 g first meconium**Container** Small plastic vial with cap**Collection** Sample must be first specimen, second accepted but less desirable**Storage Instructions** Refrigerate**Causes for Rejection** Specimen later than the second meconium, specimen mixed with stool**Methodology** Fluorescent polarization immunoassay (FPIA) confirmed by gas chromatography/mass spectrometry (GC/MS) is the most effective assay method.**Additional Information**

Can detect maternal drug usage during the final 20 weeks of gestation.

May detect three times higher rate of drugs of abuse than maternal urinary screening at time of birth. Cocaethylene can also be detected.

In an adequate meconium specimen, a total fatty acid ethyl ester concentration > 10,000 ng/g may indicate that the newborn has been exposed to significant amounts of alcohol during pregnancy.

*Confidence interval.
†Below the limits of detection.

Abstract This metal is toxic in elemental, inorganic, and organic forms. Urine mercury is used for evaluation of inorganic and possibly elemental forms.

Specimen 24-hour urine

Volume Entire collection

Minimum Volume 50 mL aliquot

Container Plastic (preferably polyethylene) acid-washed container, no preservative

Storage Instructions Store in special metal-free container

Possible Panic Range > 100 mcg/24 hours (SI: > 0.50 $\mu\text{mol/day}$)

Limitations Organic mercury is found mostly in red cells; see Mercury, Blood listing. Urine mercury would not be useful for organic mercury poisoning.

Methodology Electrothermal atomic absorption (AA), gold electrode deposition, gas chromatography (GC)

Additional Information Industrial and agricultural exposure includes inhalation of vapor and ingestion.

Synonyms Desoxyn[®] Level, Urine; Doe, Urine; Methedrine[®] Level, Urine; Speed, Urine; "Crystal" Level, Urine

Uses Evaluate for drug abuse; assess toxicity

Reference Range Negative (less than cutoff)

Test Commonly Includes Amphetamine

Abstract The D-isomer of this drug is used therapeutically as an anorectic agent and for treatment of hyperactive children. It is also a drug of abuse.

Specimen Random urine

Volume 50 mL

Minimum Volume 5 mL

Container Plastic urine container

Collection If forensic, observe precautions.

Storage Instructions Refrigerate

Causes for Rejection If forensic, failure to meet temperature check and reasonable urine creatinine concentration

Special Instructions If forensic, use chain-of-custody protocol and form.

Critical Values Cutoff: screen: 1000 ng/mL; confirmation: 500 ng/mL

Limitations Screening test may give false-positives with common cold and antiallergy medications. Qualitative results only (positive or negative). A labetalol metabolite (3-amino-1-phenylbutane or APB) may cause a false-positive result with amphetamine/methamphetamine by thin-layer chromatography or immunoassay.

Methodology Screening: enzyme immunoassay (EIA), fluorescence polarization immunoassay (FPIA), thin-layer chromatography (TLC); confirmation: gas chromatography/mass spectrometry (GC/MS), gas-liquid chromatography (GLC), high performance liquid chromatography (HPLC)

Additional Information

The most abused drug in this class is d-methamphetamine. The optical isomer, l-methamphetamine, has less pronounced central effects and is used as a nasal decongestant in Vicks Inhaler[®] (legal, over-the-counter). Amphetamine isomers are present in Dexedrine[®] and Benzedrine[®]. These drugs are self-administered orally, I.V., or by smoking. Half-life is 10-20 hours and it can be detected in urine within 3 hours of use. The parent drugs are the substances detected by the screening tests. Over-the-counter medication for colds and allergies (Contac[®], Dimetapp[®], Sine-Off[®], Sudafed[®]) contain phenylpropanolamine or pseudoephedrine which give a positive EIA screening test when the polyclonal antibody is used. This antibody also detects methylenedioxymethamphetamine (MDMA), a controlled substance classed as an hallucinogen and "designer" drug. With the monoclonal EIA test, the above medications are not detected, but phentermine (Adipex[®], Fastin[®]), ranitidine (Zantac[®]), and chlorpromazine (Thorazine[®]) give a positive test. Confirmation by GC/MS rules out these false-positives. In order to rule out the false-positive given by l-methamphetamine (legal nasal decongestant), a chiral column or procedure, which separates the "l" and "d" isomers, must be used in the GC/MS confirmation. Famprofazone (which metabolizes to methamphetamine and amphetamine) can give a positive immunoassay and GC/MS assay for methamphetamine for up to 56 hours.

Alum (25 g/L) can elicit a false-negative urinary assay for methamphetamine - urine will be acidic in these cases

Methadone, Urine

Synonyms Dolophine[®]

Uses Evaluate toxicity; detect drugs of abuse

Reference Range Negative (less than cutoff); when used therapeutically for pain, plasma levels are in the range of 0.05-0.10 mcg/mL

Abstract This drug is a synthetic opiate agonist used during World War II as a morphine substitute. It is used for detoxification of opiate addicts. It is a drug of abuse.

Specimen Urine

Volume 50 mL

Minimum Volume 20 mL

Container Plastic urine container

Storage Instructions Refrigerate

Special Instructions If forensic, use chain-of-custody protocol and form.

Critical Values Cutoff for screening: 0.30 mcg/mL; confirmation: 0.20 mcg/mL

Methodology Thin-layer chromatography (TLC) and enzyme immunoassay (EIA) for screening; gas chromatography/mass spectrometry (GC/MS) for confirmation

Additional Information Patients on methadone maintenance protocols will test above cutoff in urine drug screens. False-positive results with methadone or opiate enzyme immunoassay may occur with diphenhydramine or doxylamine.

Methamphetamines, Urine

Related Information

- Amphetamines, Qualitative, Urine

Applies to Chlorpromazine; d-Methamphetamine; l-Methamphetamine; MDMA; Methylenedioxymethamphetamine; Phentermine; Phenylpropanolamine; Pseudoephedrine; Ranitidine

Methanol, Blood

Related Information

- Volatile Screen

Synonyms Methyl Alcohol; Wood Alcohol

Uses Determine methanol toxicity

Reference Range Normal: <0.005%

Specimen Blood

Volume 14 mL

Minimum Volume 5 mL serum or plasma

Container Red top tube or gray top (sodium fluoride) tube

Collection Routine venipuncture

Special Instructions Note if methanol ingested.

Critical Values Toxic: >0.02%; lethal: >0.04%

Methodology Gas-liquid chromatography (GLC)

Methaqualone Level

Synonyms Lude®

Uses Evaluate for toxicity; evaluate for drug abuse

Reference Range Urine: negative (less than cutoff); serum: 1-5 mcg/mL (SI: 4-20 nmol/L)

Abstract This drug is a sedative-hypnotic but is currently a DEA schedule II drug. It is a drug of abuse.

Specimen Blood, urine

Volume 5 mL

Container Red top tube, plastic urine container

Special Instructions If forensic, use chain-of-custody protocol and form.

Critical Values Cutoff for urine: screen: 300 ng/mL; confirmation: 200 ng/mL

Possible Panic Range Serum values >8 mcg/mL (SI: >32 nmol/L) associated with unconsciousness; toxic: >10 mcg/mL (SI: >40 nmol/L)

Methodology Immunoassay, gas-liquid chromatography (GLC), UV spectrophotometry, fluorometry

Additional Information Methaqualone is a common drug of abuse, and "street" preparations may be adulterated with other pharmacologically active substances. It is extensively metabolized and screening methods must detect metabolites. Enzyme-multiplied immunoassay technique (EMIT) detects four of the most common metabolites.

Methemoglobin, Blood

Applies to Cytochrome b₅ Reductase

Synonyms MetHb; NADH-MetHb Reductase

Uses Evaluate cyanosis, especially in the presence of normal arterial gases; evaluate polycythemia and hemoglobinopathies; work up dyspnea and headache; work up "poppers" and "sniffers"; evaluate drug or chemical toxicity, since most instances of methemoglobinemia are acquired; monitor patients on high dose nitrate therapy; measurement in CSF may detect small cerebral and subdural hematomas.

Reference Range Up to 1.5% of total hemoglobin. Smokers have a slightly higher percent methemoglobin than do nonsmokers.

Abstract This pigment is hemoglobin in which the iron is in the trivalent state. It cannot act as an oxygen carrier.

Specimen Blood

Volume 5 mL

Minimum Volume 1 mL whole blood

Container Green top (heparin) tube

Storage Instructions Keep tube on ice. pH dependent. Should be run within 8 hours, or false-negatives may occur. Run as promptly as possible after draw. Studies have shown up to 10% drop in 4 hours, up to 16% drop in 8 hours, in samples kept on ice. Such studies have not been extensive. May be drawn into sodium fluoride-containing tubes and immediately frozen at 0°C to -4°C prior to analysis.

Possible Panic Range Headache and other symptoms occur at levels >30%. Methemoglobinemia can be fatal, particularly >70% saturation levels.

Limitations Sulfhemoglobin, methylene blue, and Evans blue dye may interfere. Methemoglobin exhibits pH sensitivity.

Methodology Spectrophotometry; Hb M variants are best detected by electrophoresis because spectrophotometry is unreliable due to their abnormal ferrihemoglobin spectra.

Additional Information Methemoglobin is an inactive, oxidized form of hemoglobin resulting in decreased oxygen-carrying capacity of blood. Concentrations of methemoglobin of >10% to 15% of hemoglobin will cause cyanosis. Sulfhemoglobin will interfere with methemoglobin determined by the above method. Methemoglobinemia may be hereditary or acquired. Polycythemia is occasionally present as a compensatory mechanism. Elevations of methemoglobin lead to dyspnea and headache, and can be lethal. Most instances of methemoglobinemia are acquired, from drugs and chemicals. Nitro and amino groups are especially involved, eg, aniline and derivatives, nitrites, nitroglycerin, nitrate salts in burn patients, dapsone (perhaps the most common cause of drug-induced methemoglobinemia), acetophenetidin, phenacetin and

some sulfonamides, chlorates, quinones, large doses of ferrous sulfate, and many other drugs and some intestinal bacteria. Well water containing nitrate is the most common cause of methemoglobinemia in the newborn. Methemoglobinemia has been reported after exposure to automobile exhaust fumes.

Hereditary methemoglobinemia is uncommon. It may be due to a deficiency of red cell NADH-methemoglobin reductase (diaphorase, also termed cytochrome b₅ reductase), which has an autosomal recessive mode of inheritance. It may also be the result of presence of certain hemoglobinopathies, members of the Hb M family including Hb M Saskatoon, Boston, Iwate, Hyde Park, and Milwaukee. These have autosomal dominant mode of inheritance and may be associated with clinical cyanosis. Hb Seattle and other hemoglobinopathies also show increase in the *in vitro* rate of methemoglobin formation. A recently identified new hemoglobin variant, Hb Warsaw, is also characterized by elevated blood levels of methemoglobin.

A study of postmortem methemoglobin levels showed a range of 0.8% to 57% in individuals who, clinically, should have had normal antemortem concentrations. There was no correlation with antemortem circumstances, autopsy findings, or interval of time from death to autopsy. Chocolate brown color to arterial blood indicates methemoglobin concentration is >10%. Brown skin color, tachycardia, and tachypnea occur with levels >30%.

Lipemia will give falsely elevated methemoglobin levels.

Specific Reference

Methsuximide, Blood

Synonyms Celontin® Level, Blood

Uses Monitor therapeutic drug level

Reference Range Methsuximide: 0.1-1.4 mcg/mL; normethsuximide: 10-40 mcg/mL

Test Commonly Includes Methsuximide and active metabolite normethsuximide

Specimen Blood

Volume 15 mL

Minimum Volume 4 mL serum

Container Red top tube

Collection Collect specimen immediately prior to next dose unless specified otherwise.

Storage Instructions Separate serum and refrigerate.

Critical Values Toxic: normethsuximide: >40 mcg/mL

Additional Information Methsuximide is a succinimide derivative used to control absence (petit mal) seizures and as an adjunct in refractory, partial complex seizures. Its actions are similar to those of ethosuximide. Methsuximide is rapidly absorbed and metabolized to its active form, N-desmethylmethsuximide. It is this metabolite that probably accounts for the anticonvulsant action. Peak levels are achieved in 1-3 hours and the plasma half-life is 2-4 hours. Adverse effects include eosinophilia, leukopenia, monocytosis, pancytopenia, Stevens-Johnson syndrome, nervousness, headaches, mental confusion, and nausea and vomiting.

Mexiletine, Blood

Synonyms Mexilit®

Uses Therapeutic monitoring; toxicity assessment

Reference Range Therapeutic 0.75-2.00 mcg/mL (SI: 4-9 µmol/L)

Abstract Mexiletine is an antiarrhythmic used to treat ventricular arrhythmia.

Specimen Blood

Container Red top tube

Sampling Time Draw 2-4 hours after last dose for peak level. Draw immediately prior to next dose for trough levels.

Possible Panic Range >2.00 mcg/mL (SI: >9 µmol/L)

Methodology Fluorometry, high performance liquid chromatography (HPLC), gas chromatography (GC)

Additional Information Mexiletine is a class I antiarrhythmic approved for treatment of ventricular arrhythmias. It has no active metabolites. Toxic effects include dizziness, vomiting, confusion, tremor, bradycardia, and hypotension. Metabolism of mexiletine is accelerated by rifampin, phenobarbital, and phenytoin and retarded by cimetidine and ketoconazole. Half-life is 10-14 hours and is urine pH dependent. Acidic urine accelerates elimination.

Morphine, Urine

Synonyms Heroin Metabolite, Urine

Uses Evaluate toxicity or detect drug of abuse. Heroin is metabolized to morphine, therefore morphine detection may suggest heroin use. To prove heroin use, 6-O-acetylmorphine must be identified in the urine.

Reference Range Negative (less than cutoff)

NICKEL, URINE

Test Commonly Includes Codeine, heroin, hydromorphone (Dilaudid®), morphine, and morphine glucuronide

Abstract This drug is widely used therapeutically as an analgesic. Morphine itself is not an extensively used drug of abuse but two derivatives, heroin and codeine, are.

Specimen Urine

Volume 50 mL

Minimum Volume 20 mL

Container Plastic urine container

Storage Instructions Refrigerate

Special Instructions If forensic, use chain-of-custody protocol and form.

Critical Values Cutoff: screen (total opiates): 300 ng/mL; confirmatory: 300 ng/mL

Methodology Immunoassays, gas-liquid chromatography (GLC), high performance liquid chromatography-electrochemical detection (HPLC-ECD)

Additional Information

Urine codeine/morphine ratio usually exceeds 1.0 during the first 24 hours postingestion, decreases <1.0 from 24-30 hours and usually only morphine is detectable after 30 hours. Poppy seed ingestion can result in urine codeine levels as high as 4.5 mg/L and urine morphine levels as high as 0.2 mg/L; urine opiate levels due to poppy seeds will not exceed 15,000 ng/mL; urine drug screen remains positive for 2-4 days.

Poppy seed use can be ruled out as a cause for a urinary morphine screen when codeine levels exceed 300 ng/mL; morphine to codeine ratio is <2 and high levels of morphine (>1000 ng/mL) are detected without codeine being present

Nickel, Urine

Related Information

- Heavy Metal Screen, Urine

Synonyms Ni, Urine

Uses Evaluate nickel toxicity

Reference Range ≤25 mcg/L; fatality can occur at urinary nickel concentrations >500 mcg/L; moderate toxicity occurs at urine nickel concentration of 100-500 mcg/L; mild toxicity occurs at urine nickel concentrations of 60-100 mcg/L

Patient Preparation Instruct patient to use plastic urinal or bedpan if necessary.

Specimen 24-hour urine

Volume Entire collection

Minimum Volume 100 mL

Container Plastic container, kept on ice

Collection Instruct the patient to void at 8 AM and discard the specimen. Then collect all urine including the final specimen voided at the end of the 24-hour collection period (ie, 8 AM the next morning). Avoid contact with metal during specimen collection. Screw the lid on securely. Transport the specimen promptly to the laboratory. Container **must** be labeled with patient's full name, room number, date and time collection started, and date and time collection finished.

Storage Instructions Keep on ice or refrigerate. Laboratory will measure urine volume and remove 120 mL aliquot.

Causes for Rejection Specimen in contact with metal

Special Instructions Requisition **must** state date and time collection started and date and time collection finished.

Nicotine Level

Synonyms 3-(1-Methylpyrrolidine-2-yl)pyridine

Reference Range Plasma nicotine levels peak rapidly after each cigarette (from 0.03-0.05 mg/L); moderate accumulation over a longer time period. In pipe smokers, average plasma levels average 0.004 mg/L; nicotine gum chewers (2 mg size) average 0.012 mg/L. Plasma concentrations of cotinine in children living with smokers are four times higher than those in children from nonsmoking environments.

Specimen Blood

Critical Values Lethal dose: 40 mg. Dermal exposure has usually caused nonfatal poisoning. Postmortem blood concentrations: 11-600 mg/L; postmortem urine concentrations: 17-58 mg/L.

Methodology Spectrophotometry, thin-layer chromatography (TLC), high performance liquid chromatography (HPLC), fluorescence polarization immunoassay (FPIA), gas chromatography (GC); confirmation: gas chromatography/mass spectrometry (GC/MS)

Additional Information Nicotine is extensively transformed to inactive metabolites (eg, cotinine). Cotinine is further oxidized to hydroxycotinine. Other metabolites include nornicotine and nicotine-1'-N-oxide. Plasma half-life of nicotine in cigarette smokers: 0.5-2 hours (average 40 minutes); cotinine: 6-16 hours (average 11 hours). Twenty-four hours after nicotine dosing, 5% to 10% is excreted unchanged in urine, 10% as cotinine, and 4% as other metabolites. Excretion is decreased if the urine is alkaline.

Nortriptyline, Blood

Synonyms Aventyl®; Pamelor®

Uses Monitor therapeutic drug level; evaluate toxicity

Reference Range Therapeutic: 50-150 ng/mL

Abstract This is a tricyclic antidepressant.

Specimen Blood

Volume 7 mL

Minimum Volume 3 mL serum

Container Red top tube

Collection Collect specimen immediately prior to next dose unless specified otherwise.

Storage Instructions Separate serum and refrigerate.

Critical Values Toxic: >500 ng/mL

Limitations Results not valid if receiving imipramine or desipramine

Methodology High performance liquid chromatography (HPLC)

Additional Information Nortriptyline, a tricyclic antidepressant, is a derivative and metabolite of amitriptyline and is used to treat endogenous depression. The half-life of nortriptyline is 20-80 hours. Nortriptyline may be associated with cholestasis and cholestatic jaundice. Hematological consequences include agranulocytosis, purpura, and thrombocytopenia. Other side effects include a host of GI, endocrinologic, allergic, anticholinergic, cardiovascular, and neurologic disorders. Red cell levels of metabolites may be a more sensitive indicator of myocardial toxicity.

Opiates, Qualitative, Urine

Related Information

- Codeine, Urine

Applies to Heroin; Narcotics; Poppy Seeds

Uses Evaluate drug abuse; assess toxicity

Reference Range Negative (less than cutoff)

Test Commonly Includes Morphine, codeine, hydrocodone (Hycodan®), hydromorphone (Dilaudid®)

Abstract The qualitative detection of urine opiates is used almost exclusively to show presence of drugs of abuse in this class. Morphine and codeine are used therapeutically for pain.

Specimen Random urine

Volume 50-60 mL

Container Plastic urine container

Collection If forensic, observe precautions.

Storage Instructions Refrigerate

Special Instructions If forensic, use chain-of-custody protocol and form.

Critical Values Cutoff: screen: 300 ng/mL; confirmation: 300 ng/mL of specific opiates

Limitations In most immunoassays a number of narcotic drugs can cross react to give a positive screen. Every effort should be made to confirm, by an analytically different and more sensitive method, all presumptive, positive opiate screens. Hydromorphone, hydrocodone, oxycodone, and oxycodone usually will test negative after 48 hours by gas chromatography-mass spectrometric methods. EMIT immunoassays may not detect oxycodone. Hydromorphone, hydrocodone, and oxycodone may become negative by immunoassay after one day. See Test Commonly Includes. Rifampicin can cause false-positive urine assay of opiates by kinetic interaction of microparticle in solution (KIMS) method up to a concentration of 0.9 mcg/mL.

Methodology Screening: immunoassay, thin-layer chromatography (TLC), high performance liquid chromatography (HPLC), gas chromatography (GC); confirmation: gas chromatography/mass spectrometry (GC/MS)

Additional Information

A qualitative urine screen for opiates is performed in suspected overdose cases or as part of a drugs-of-abuse program. The test is most sensitive for morphine and codeine, but other drugs will cross react in an immunoassay and give positive results (eg, hydrocodone, hydromorphone). All presumptive positive assays should be confirmed, preferably by GC/MS. Morphine is a prescribed drug for pain relief, a metabolite of heroin, a metabolite of codeine, and a constituent of poppy seeds. Its presence in urine, even after confirmation, must be interpreted very carefully. Ingestion of poppy seeds (bagels, Danish) can cause positive opiate screens at a 300 ng/mL cutoff. The intake of heroin by the user can only be proved by the detection of 6-o-acetylmorphine by the urine confirmatory test.

Levofloxacin, ofloxacin, and perfloracin can lead to a false-positive opiate immunoassay result.

Tolmetin can give false-negative results by Emit® assay. False-positive results with methadone or opiate enzyme immunoassay may occur with diphenhydramine or doxylamine.

Opiate concentrations in poppy seeds range from 0.1-3.8 mcg/g for codeine, 5.1-106 mcg/g for morphine, and 0.3-14 mcg/g for thebaine; analysis for thebaine may be a direct marker for poppy seed use. Urinary opiate concentrations >15,000 ng/mL are not due to poppy seed ingestion.

Usual 6-monoacetyl morphine (6-MAM) cutoff is 10 ng/mL. A 12 mg intravenous dose of heroin will give a detection time of 6-MAM and a

2000 ng/mL opiate urinary cutoff of 2.3-7.5 hours and 5.9-13.5 hours, respectively.

Osmolality, Serum

Applies to Osmolal Gap

Synonyms Serum Osmolality

Uses Evaluate electrolyte and water balance, hyperosmolar status and hydration status, dehydration, acid-base balance, seizures; evaluate antidiuretic hormone function, liver disease, hyperosmolar coma. Osmolality measures the concentration of particles in solution. Freezing point depression serum osmolality with calculated osmolal gap, is useful in screening for and approximating the serum concentrations of certain low molecular weight toxins, such as ethanol, ethylene glycol, isopropanol, and methanol, especially as a rapid approximation for emergent situations. See Limitations.

High serum osmolality may result from hypernatremia, dehydration, hyperglycemia, mannitol therapy, azotemia, ingestion of ethanol, methanol, ethylene glycol. Thus, osmolality has a role in toxicology and in coma evaluation. Very low birth weight infants may have elevated serum osmolality for the first week of life.

Low serum osmolality may be secondary to overhydration, hyponatremia, syndrome of inappropriate antidiuretic hormone secretion (SIADH) with carcinoma of lung and other entities. Chlorpropamide use can also result in a low serum osmolality.

Causes of hyperosmolality, hypo-osmolality, and of factors affecting ADH are published. Serum osmolality measurements do not measure the fraction of serum that is water. Osmolality measurement by freezing point depression is also indifferent to permeability of solutes to cell membranes.

Reference Range 275-295 mOsm/kg (SI: 275-295 mM/kg) H₂O. Some consider normal to be 280-290 mOsm/kg (SI: 280-290 mM/kg) H₂O and others within 270-310 mOsm/kg (SI: 270-310 mM/kg) H₂O.

Abstract The osmolality of a solution is defined as the number of molecules or ions (particles) in a solution of water. Osmolality is independent of particle size or charge. Nonpolar solutions yield one molecule (eg, glucose) while polar solutions yield multiples of the number of ions solubilized (eg, sodium chloride yields two ions while magnesium chloride yields three ions).

Specimen Blood

Volume 7 mL

Minimum Volume 4 mL serum

Container Red top tube

Collection Pediatrics: Blood drawn from heelstick

Storage Instructions Refrigerate or freeze serum if not run within 4 hours.

Possible Panic Range <265 mOsm/kg (SI: <265 mM/kg), >320 mOsm/kg (SI: >320 mM/kg). Result of 385 mOsm/kg (SI: 385 mM/kg) relates to stupor in hyperglycemia. Values 400-420 mOsm/kg (SI: 400-420 mM/kg) can relate to grand mal seizures. Values >420 mOsm/kg (SI: >420 mM/kg) may be lethal.

Limitations When vapor pressure osmometry is used, volatile solutes (eg, alcohols and glycols) may remain in the vapor phase and not be detected.

Methodology Freezing point depression (more often used) or vapor pressure. (Do not use for toxicologic determination.)

Additional Information Measured osmolality is usually more than calculated osmolality. If measured osmolality is >15 mOsm/kg (SI: >15 mM/kg) greater than calculated, consider methanol, ethylene glycol, or ethanol ingestion or other toxicity; shock; or trauma. Elevated serum osmolality with normal sodium suggests possible hyperglycemia, uremia, or alcoholism. Both serum and urine values and calculated osmolality (see previous listing) are sometimes needed. Although lactic acidosis theoretically should not contribute to the osmolal gap, increases in the osmolal gap in lactic acidosis have been reported. Drugs including thiazide diuretics, steroids, cimetidine, and others have been implicated in the development of hyperosmolar hyperglycemic nonketotic coma. Slight elevation of serum osmolality over expected values have been reported in the elderly. After overnight dehydration, urine/serum ratio is usually ≥ 3 .

Osmolality, Urine

Related Information

- Electrolytes, Urine

Applies to Osmolal Gap, Urine; U/P Ratio

Synonyms Urine Osmolality

Uses Evaluate concentrating ability of the kidneys (eg, in acute and chronic renal failure); evaluate electrolyte and water balance; used in work-up for renal disease, syndrome of inappropriate antidiuretic hormone secretion (SIADH), and diabetes insipidus; may be used with urinalysis when patient has had radiopaque substances, has glycosuria or proteinuria; evaluate dehydration, amyloidosis; estimate urine ammonium concentrations using the urine osmolal gap and detect increased osmolality due to the presence of unusual molecules. Osmolality is desirable in examination of neonatal urine when protein or glucose are present.

Reference Range Random urine: neonates: 75-300 mOsm/kg (SI: 75-300 mM/kg); children and adults: 250-900 mOsm/kg (SI: 250-900 mM/kg). Normal range of serum sodium (mM/L) to osmolality (mOsm/kg) ratio is 0.43-0.50. Patients with normal renal function after 14-hour restriction of fluids should be able to concentrate to >800 mOsm/kg (SI: >800 mM/kg); <400 mOsm/kg (SI: <400 mM/kg) is interpreted by Weisberg as severe renal impairment. Prolonged dehydration may be dangerous for some patients.

Abstract Osmolality is a definitive measure of urine concentration.

Specimen Random urine or timed specimen

Volume Entire collection

Minimum Volume 5 mL

Container Clean urine container

Storage Instructions Refrigerate during collection and storage.

Possible Panic Range <100 mOsm/kg (SI: <100 mM/kg) in overhydration, >800 mOsm/kg (SI: >800 mM/kg) in dehydration

Limitations Serum osmolality is often needed to interpret urine osmolality.

Methodology Freezing point depression

Oxazepam, Serum

Synonyms Serax[®]

Uses Monitor therapeutic drug level; evaluate toxicity

Reference Range 0.2-1.4 mcg/mL (SI: 0.7-4.9 μ Mol/L)

Abstract Oxazepam is a benzodiazepine used as an anti-anxiety agent. It is an active metabolite of several other benzodiazepines that are used therapeutically.

Specimen Blood

Volume 15 mL

Minimum Volume 5 mL serum

Container Red top tube

Sampling Time Collect specimen immediately prior to next dose unless specified otherwise.

Storage Instructions Separate serum and refrigerate.

Possible Panic Range <2.0 mcg/mL

Methodology High performance liquid chromatography (HPLC)

Additional Information Oxazepam, a benzodiazepine derivative, is related to chlordiazepoxide and shares many of its qualities. It does, however, have a shorter duration of action and causes fewer adverse effects. It is rapidly eliminated by urinary excretion as a glucuronide conjugate. Oxazepam is used to manage tension and anxiety and to aid in the control of acute withdrawal symptoms in chronic alcoholism. Peak plasma levels are achieved in 2-3 hours and the half-life is 5-15 hours. Adverse effects are mild and infrequent. They include drowsiness, vertigo, ataxia, headache, tremor, slurred speech, nausea, hypotension, and leukopenia. Simultaneous alcohol ingestion potentiates some of the effects of benzodiazepines.

Paraquat, Blood

Uses Evaluate exposure to paraquat

Reference Range <0.25 mcg/mL

Specimen Blood

Volume 14 mL

Minimum Volume 10 mL whole blood

Container Two gray top (sodium fluoride) tubes

Perphenazine, Blood

Synonyms Chlorpipazine; Trilafon[®]

Uses Monitor therapeutic drug level; evaluate toxicity

Reference Range 0.004-0.064 mg/L

Test Commonly Includes Chlorpromazine, mesoridazine, perphenazine, prochlorperazine, promazine, promethazine, thioridazine

Specimen Blood

Volume 10 mL

PESTICIDE SCREEN, CHLORINATED

Minimum Volume 3 mL serum
Container Red top tube
Storage Instructions Refrigerate serum.
Possible Panic Range 3 mg/L
Methodology High performance liquid chromatography (HPLC), gas chromatography (GC)
Additional Information Perphenazine, a piperazine phenothiazine, is used to manage the manifestations of psychotic disorders. It is also used to control hiccups, nausea and vomiting, and violent retching during surgery. Adverse effects include convulsions, xerostomia, nasal congestion, tachycardia, bradycardia, hypotension, and photosensitivity.

Pesticide Screen, Chlorinated

Uses Screen aids in identification or confirmation of exposure to common polychlorinated hydrocarbon compounds used as pesticidal sprays or dusts.
Reference Range None detected
Test Commonly Includes Aldrin, chlordane, DDT, dieldrin, heptachlor, lindane, methoxychlor
Specimen Urine, blood, or gastric contents
Volume 100 mL urine, 20 mL whole blood, 50 mL gastric contents
Container Two royal blue top (heparin) tubes
Special Instructions Requisition must state date and time of specimen collection. Specify suspected pesticide. Specify if quantitation of a positive screen result is desired.

Pesticide Screen, Organophosphate

Uses Screen aids in identification or confirmation of exposure to common organophosphate compounds used as pesticidal sprays or dusts
Reference Range None detected
Test Commonly Includes Diazinon; Dicapthon; Malathion; Parathion; Trichlorfon; Dichloron
Specimen Urine, blood, or gastric contents
Volume 100 mL urine, 20 mL whole blood, 50 mL gastric contents
Container Two royal blue top (heparin) tubes
Special Instructions Requisition must state date and time of specimen collection. Specify suspected pesticide. Specify if quantitation of a positive screen result is desired.

pH, Urine

Uses Urine pH is a crude measure of the acid-base balance of the body. It may be helpful in determining subtle presence of distal renal tubular disease or pyelonephritis. Urine pH is useful for identifying crystals in urine and determining predisposition to form a given type of stone. See table. When an accurate pH assessment of acid-base status and renal response is desired, the urine should be collected under circumstances more controlled than is usual. Attention is given to the time of day, the fasting status of the patient, and transfer of sample so as to prevent degassing of sample or growth of bacteria; rapid analysis by pH meter rather than dipstick is indicated. Usually simultaneous serum pH is then also ordered. See table.

Conditions Associated with Acid Urine	Conditions Associated with Alkaline Urine	
Metabolic acidosis	Respiratory alkalosis	Postprandial alkaline tide (1 hour after meal)
Diabetes mellitus	Metabolic alkalosis	Fanconi syndrome and Milkman's syndrome (increased urinary loss of bicarbonate)
Diarrhea	Urea-splitting bacteria (<i>Proteus</i> sp)	Alkali therapy (citrate, bicarbonate)
Starvation	Vegetable diet	
Respiratory acidosis	Gastric suction and vomiting	
Emphysema	Diuretic therapy	
Sleep		
Renal failure with lack of NH ₃ buffer		

Reference Range 4.5-7.8; normal kidneys can produce urine with pH from 4.5-8.2, but with ordinary diet, urine pH is ~6.0. Urine becomes more alkaline after meals and is most acidic fasting in the morning.
Test Commonly Includes pH is part of a routine urinalysis.
Specimen Random urine
Volume 5 mL
Minimum Volume 2 mL
Container Plastic urine container
Storage Instructions If the specimen cannot be processed promptly, it should be refrigerated.
Causes for Rejection Improper labeling, specimen not refrigerated
Limitations On standing urine becomes alkaline due to the action of urea splitting bacteria (*Proteus* sp).

Methodology Dipstick double indicator principle (methyl red and bromthymol blue) which gives a broad range of colors covering the urinary pH range 5-9 ± 0.5 pH units. A pH meter is the back-up and most accurate method.

Additional Information Dietary factors affect urine pH. Alkaline urine is observed in persons who eat large quantities of citrus fruit and vegetables. Acid urine is observed with high meat intake. Pyridium® metabolites may mask the pH reaction. Urine pH >6.5 indicates presence of bicarbonate while pH <5.5 indicates absence of bicarbonate. Consistently acid urine, pH <5.5, is associated with xanthine, cystine, and uric acid stones. Calcium oxalate and apatite stones are not associated with any particular disturbance of urine pH. Alkaline urine (pH >7) is associated with calcium carbonate, calcium phosphate, and especially magnesium ammonium phosphate stones. In conjunction with serum pH and bicarbonate levels, urine pH may be applied to the study of renal tubular acidification.

Phencyclidine, Qualitative, Urine

Synonyms Angel Dust; Elephant Tranquilizers; Hog; Killer Weed; PCP; Peace Pills; Rocket Fuel
Uses Evaluate presence of phencyclidine, drug abuse, PCP toxicity; determine phencyclidine involvement in unexplained psychoses
Reference Range Negative (less than cutoff)
Abstract This is a widely used drug of abuse which was formerly sold as a veterinary tranquilizer. All legal manufacture and sale has been stopped. It is classified by DEA as a Schedule II controlled substance.
Specimen Random urine
Volume 100 mL
Minimum Volume 5 mL
Container Plastic urine container
Collection If forensic, observe precautions.
Special Instructions If forensic, use chain-of-custody protocol and form.
Critical Values Cutoff: screen: 25 ng/mL; confirmation: 25 ng/mL (SI: 100 nmol/L)
Methodology Immunoassay, thin-layer chromatography (TLC), gas chromatography (GC), gas chromatography/mass spectrometry (GC/MS). Immunoassays are very specific and detect PCP at 25 ng/mL

Additional Information

Phencyclidine is most often called "angel dust." It was first developed as an anesthetic in the 1950s. It was taken off the market for human use because it sometimes caused hallucinations. PCP is available in a number of forms. It can be a pure white crystal-like powder, a tablet or capsule, and it can be swallowed, smoked (alone or with marijuana), sniffed, or injected. Although PCP is illegal, it is easily manufactured. Effects depend on how much of the drug is taken, the way it is used, and the individual. Small amounts act as a stimulant, speeding up body functions. For many users, PCP changes how they see their own bodies and things around them. Speech, muscle coordination, and vision are affected; sense of touch and pain are dulled; and body movements are slowed. Time seems to "space out." Effects include increased heart rate and blood pressure, flushing, sweating, dizziness, and numbness. When large doses are taken, effects include drowsiness, convulsions, and coma. Taking large amounts of PCP can also cause death from repeated convulsions, heart and lung failure, or ruptured blood vessels in the brain. PCP can be detected for 7 days after administration; 2-4 weeks in chronic users. Half-life is 7-46 hours. Dextromethorphan, diphenhydramine, and high doses of thioridazine can give a false-positive on an immunoassay screen; ketamine is not expected to give a positive immunoassay.

Phencyclidine, Quantitative, Serum

Synonyms Angel Dust; Hog; Killer Weed; PCP; Rocket Fuel; Sernyl®
Uses Detect drug abuse; evaluate toxicity
Specimen Blood
Volume 10 mL
Minimum Volume 3 mL serum
Container Gray top (sodium fluoride) tube
Additional Information
Phencyclidine, most often called "angel dust," is available in a number of forms. It can be a pure white crystal-like powder, a tablet or capsule, and it can be swallowed, smoked (alone or with marijuana), sniffed, or injected. Although PCP is illegal, it is easily manufactured and is a legitimate veterinary tranquilizer. Effects depend on how much of the drug is taken, the way it is used, and the individual. Small amounts act as a stimulant, speeding up body functions. For many users, PCP changes how they see their own bodies and things around them. Speech, muscle coordination and vision are affected; sense of touch and pain are dulled; and body movements are slowed. Time seems to "space out." Effects include increased heart rate and blood pressure, flushing, sweating, dizziness, and numbness. When large doses are taken effects include drowsiness, convulsions, and

coma. Taking large amounts of PCP can also cause death from repeated convulsions, heart and lung failure or ruptured blood vessels in the brain. Dextromethorphan can give a false-positive on an immunoassay screen; ketamine is not expected to give a positive immunoassay. Serum PCP levels: Catatonia and excitation: 20-30 ng/mL; myoclonus and coma: 30-100 ng/mL; hypotension, seizures, fatalities: > 100 ng/mL

Phenobarbital, Blood

Related Information

- Barbiturates, Quantitative, Blood

Synonyms Gardenal[®]; Luminal[®]; Phenemal; Phenemalum; Phenobarb; Phenobarbitone; Stental Extentabs[®]

Uses Monitor patients for compliance, efficacy, and possible toxicity. Mephobarbital and primidone are metabolized to phenobarbital and, therefore, patients taking these drugs will have detectable levels of phenobarbital on therapeutic monitoring.

Reference Range Infants and children: 15-30 mcg/mL (SI: 65-129 μmol/L); adults: 20-40 mcg/mL (SI: 86-172 μmol/L). Low level: Most common cause is noncompliance. Other causes include drug interactions, including antipsychotic medication, chloramphenicol, acetazolamide, and phenytoin. Some patients are fast metabolizers, such as infants and children. High level: addition of valproic acid to regimen inhibits phenobarbital metabolism (parahydroxylation) and should be accompanied by a cut in phenobarbital dosage. Newborns, unlike older infants, have very long half-lives which may be associated with high levels.

Abstract Phenobarbital is indicated for generalized tonic-clonic and partial seizures.

Specimen Blood

Volume 7 mL

Minimum Volume 1 mL serum or plasma

Container Red top tube, green top (heparin) tube, or lavender top (EDTA) tube

Sampling Time Consistent sampling time is desirable but less important than for other anticonvulsants due to its long half-life.

Critical Values Toxic: >40 mcg/mL (SI: >172 μmol/L) but if given intravenously, life-threatening side effects can occur with much lower levels, and patients should be monitored. Toxic effects are mostly neurologic. Adults present with lethargy and coma; children may present with irritability or hyperactivity.

Methodology Enzyme immunoassay (EIA), gas-liquid chromatography (GLC), high performance liquid chromatography (HPLC)

Additional Information

Indications for measurement of a serum antiepileptic drug level include:

- within 6 hours of a seizure
- suspected dose-related drug toxicity
- suspected patient noncompliance

Additional indications for serum drug assay during steady state conditions (after 6 days for phenytoin, 3 days for carbamazepine, 3 days for valproic acid, 20 days for phenobarbital) include:

- baseline measurement after starting antiepileptic drug therapy
- control measurement after a change in dosage regimen
- addition of a second drug with a potential interaction with the antiepileptic drug (ie, a second antiepileptic drug, warfarin, isoniazid or rifampicin)
- change in patient's hepatic or gastrointestinal function

Phenobarbital, Free, Blood

Uses Monitor therapeutic drug level; evaluate toxicity

Reference Range Therapeutic free: 7.5-20.0 mcg/mL; therapeutic total: 15-40 mcg/mL

Test Commonly Includes Total and free phenobarbital

Specimen Blood

Volume 2 mL

Minimum Volume Two plain Microtainer[™] tubes

Container Red top tube

Collection Draw just prior to the next dose.

Critical Values Toxic total: > 60 mcg/mL

Methodology Ultrafiltrate assayed by fluorescence polarization immunoassay (FPIA) or enzyme immunoassay (EIA)

Phenytoin, Blood

Synonyms Dilantin[®] Level, Blood; Diphenylhydantoin Level, Blood

Uses Monitor for compliance, efficacy, and possible toxicity

Reference Range 10-20 mcg/mL (SI: 40-79 μmol/L). Patients treated for status epilepticus should have levels at or slightly above the upper limit of range. Low level: The most common cause of a low level is noncompliance. Absorption problems are most important in young infants (younger than 3 months) or occasionally in patients given phenobarbital, charcoal, or antacids at the same time as the phenytoin. Pediatric and some adult patients (fast metabolizers), who have breakthrough seizures at the end of the day, require more than once daily dosing. Some

formulations other than Kapseals[®] may require more than once daily dosing, and changing formulations can cause changes in levels. Pregnancy or intercurrent illness such as mononucleosis can cause subtherapeutic levels with seizures. The addition of carbamazepine to a patient taking phenytoin can lower or raise phenytoin level but usually does not cause seizures. Disulfiram administration can increase phenytoin metabolism, lower levels, and may cause seizures. Patients can have lower than expected values if intravenous formulations are given with fluids containing glucose, which precipitates in solution with phenytoin. High levels: In patients chronically controlled on phenytoin who become clinically toxic without a change in dose, toxicity can be brought on by a change in formulation, drug interaction, or intercurrent infection. Drugs which can precipitate phenytoin toxicity include chloramphenicol, tricyclic antidepressants, fluconazole, and levodopa. Small dose changes or changes in formulation (including change from one brand to another or to a generic) can cause large changes in antiepileptic drug (AED) levels and toxicity, because phenytoin manifests zero-order kinetics.

Abstract Phenytoin is effective for generalized tonic-clonic and partial seizures.

Specimen Blood, saliva

Volume 7 mL

Minimum Volume 1 mL serum or plasma; 1 mL saliva

Container Red top tube or lavender top (EDTA) tube

Sampling Time In monitoring patients maintained on chronic therapy, a trough level or consistent sampling time should be used.

Possible Panic Range Toxicity may manifest progressively at >30 mcg/mL (SI: >120 μmol/L) with ataxia, dizziness, nystagmus, and diplopia. Patients can have life-threatening complications with I.V. administration with normal levels; such patients should be placed on a cardiac monitor during I.V. administration

Methodology Routine: Enzyme-multiplied immunoassay technique (EMIT), enzyme-linked immunosorbent assay (ELISA), and fluorescence polarization immunoassay (FPIA). For physician's office testing, apoenzyme reactive immunoassay (ARIS; Ames Seralyzer[®]) is rapid, accurate, and may become increasingly important.

Additional Information

Indications for measurement of a serum antiepileptic drug level include:

- within 6 hours of a seizure
- suspected dose-related drug toxicity
- suspected patient noncompliance

Additional indications for serum drug assay during steady state conditions (after 6 days for phenytoin, 3 days for carbamazepine, 3 days for valproic acid, 20 days for phenobarbital) include:

- baseline measurement after starting antiepileptic drug therapy
 - control measurement after a change in dosage regimen
 - addition of a second drug with a potential interaction with the antiepileptic drug (ie, a second antiepileptic drug, warfarin, isoniazid or rifampicin)
 - change in patient's hepatic or gastrointestinal function
- Oxaprozin may result in false elevation of phenytoin blood levels if performed by fluorescence polarization immunoassay.

Platinum, Blood

Synonyms Pt, Blood

Uses Evaluate platinum toxicity, usually from the use of cis-platinum for cancer chemotherapy and occasionally from industrial exposure

Specimen Blood

Volume 10 mL

Minimum Volume 1 mL serum or plasma

Container Red top tube or green top (sodium heparin) tube

Storage Instructions Refrigerate specimen. Do not separate.

Methodology Flameless atomic absorption spectrophotometry (AA)

Additional Information Since normal biological fluids are free from detectable platinum, quantitation enables direct correlation between exposure and distribution in the body.

Platinum, Urine

Synonyms Pt, Urine

Uses Monitor platinum excretion during chemotherapy or industrial exposure

Specimen Random urine

Volume 100 mL

Minimum Volume 5 mL

Container Plastic urine container

Storage Instructions Refrigerate.

Methodology Flameless atomic absorption spectrophotometry (AA), high performance liquid chromatography (HPLC), voltametry

Additional Information Since normal biological fluids are free from detectable platinum, quantitation enables direct correlation between exposure and distribution in the body.

Primidone, Blood

Applies to Metabolites of Primidone; PEMA; Phenylethylmalonamide
Synonyms Majsolin®; Mylepsin®; Mysoline®; Prysolin®
Uses Monitor efficacy, compliance, and possible toxicity
Reference Range Children younger than 5 years of age: 7-10 mcg/mL (SI: 32-46 µmol/L); adults: 5-12 mcg/mL. Phenobarbital concentration can also be used to guide dosing.
Test Commonly Includes Phenobarbital, PEMA
Abstract Primidone is indicated for generalized tonic-clonic and partial seizures.
Specimen Blood
Volume 5 mL
Minimum Volume 2 mL serum or plasma
Container Red top tube, green top (heparin) tube, or lavender top (EDTA) tube
Sampling Time Trough or consistent sampling time. Levels of phenobarbital and PEMA can be measured simultaneously.
Critical Values At levels >12 mcg/mL (SI: >55 µmol/L) primidone produces CNS depression, vertigo, visual disturbances, areflexia, somnolence, and lethargy. Clinical toxicity correlates with primidone rather than metabolite concentrations. In overdosage, a biphasic peak may be seen with highest toxicity a few hours after ingestion and again 48 hours afterwards. Crystalluria is a feature of overdosage.
Possible Panic Range > 12 mcg/mL (SI: > 55 µmol/L)
Methodology Enzyme immunoassay (EIA), gas-liquid chromatography (GLC), high performance liquid chromatography (HPLC)
Additional Information Since phenobarbital requires a longer interval (48 hours) to achieve therapeutic blood levels than primidone, checking both levels can be used to determine chronic compliance. The phenobarbital/primidone ratio normally is 2.5, can be higher (4.3 mean) in patients on other anticonvulsants (phenytoin, carbamazepine) and lower than normal among patients discontinued from those medicines or who are chronically noncompliant. Primidone decreases the effects of oral anticoagulants.

Propranolol, Blood

Synonyms Inderal®
Uses Monitor therapeutic drug level in patients with cardiac arrhythmias, angina pectoris, and hypertension; evaluate for potential toxicity
Reference Range Therapeutic: 50-100 ng/mL (SI: 190-390 nmol/L) at end of dose interval
Abstract A relatively short-acting beta blocker. Propranolol is used as an antiarrhythmic and antihypertensive.
Specimen Blood
Volume 5 mL
Container Red top tube
Sampling Time Trough: immediately prior to next dose
Special Instructions The stoppers of some blood collection tubes contain TBEP plasticizers that affect drug distribution in sample. Check with local laboratory.
Possible Panic Range > 1000 ng/mL (SI: >3860 nmol/L)
Methodology Fluorometry, fluorescence polarization immunoassay (FPIA), enzyme immunoassay (EIA), gas-liquid chromatography (GLC), high performance liquid chromatography (HPLC)

Prothrombin Time

Related Information
 • Heparin
Applies to Coumarins; Heparin; INR; International Normalized Ratio; PT Ratio
Synonyms Protime; PT
Uses Evaluate extrinsic coagulation system; aid in screening for congenital deficiencies of factors II, V, VII, X; dysfibrinogenemia, afibrinogenemia (complete); heparin effect, coumarin or warfarin effect; liver failure; disseminated intravascular coagulation (DIC); and screen for vitamin K deficiency
Reference Range 10-13 seconds. Healthy premature newborns have prolonged coagulation test screening results (eg, PT, APTT, TT) which return to normal adult values at about 6 months of age. Healthy prematures, however, do not develop spontaneous hemorrhage or thrombotic complications because of a balance between procoagulants and inhibitors. The normal range in childhood (ages 1-16) is similar to that in adults. For factors affecting PT response: See tables.

The Following Factors, Alone or in Combination, May Be Responsible for Increased PT Response

Endogenous Factors		
Cancer	Elevated temperature	Poor nutritional state
Collagen disease	Hepatic disorders	Steatorrhea
Congestive heart failure	Infectious hepatitis, jaundice	Vitamin K deficiency
Diarrhea	Hyperthyroidism	
Exogenous Factors		
Acetaminophen	Dong quai (dang qui)	Nortriptyline
Alcohol*	Enoxacin	Nonsteroidal anti-inflammatory drugs
Allopurinol	Ethacrynic acid	Omeprazole
Aminosalicilyc acid	Fenofibrate	Pentoxifylline
Amiodarone HCl	Fenoprofen	Phenobarbital*
Amprenavir	Fluconazole	Phenylbutazone
Anabolic steroids	5-Fluorouracil	Phenytoin*
Ancrod	Fluvoxamine	Piroxicam
Anesthetics, inhalation	Fluoxetine	Ponalrestat
Azithromycin	Fluvastatin	Proguanil
Bezabifrate	Glucagon	Propafenone
Boldo-Fenugreek	Green tea	Protriptyline
Bromelains	Gemcitabine	Quetiapine
Broxuridine	Hepatotoxic drugs	Quinidine
Celecoxib	Ibuprofen	Quinine
Chenodiol	Ifosfamide	Interferon alpha
Chloral hydrate*	Indomethacin	Rifampin*
Chlorpropamide	Influenza virus vaccine	Ritonavir
Chymotrypsin	Interferon alpha	Salicylates
Cimetidine (rarely)	Isoniazid	Saquinavir
Clofibrate	Itraconazole	Stanozolol
Coumadin® overdose	Ketoconazole	Sulfapyrazone
COX-2 inhibitors	Levamisole	Sulindac
Cyclophosphamide*	Lovastatin	Sulofenur
Cyclosporine	Levonorgestrel	Tamoxifen
Danazol	Mefenamic acid	Thyroid drugs
Danshen	Methyldopa	Ticlopidine*
Delaviridine	Methylphenidate	Tramadol
Dextran	Miconazole	Triclofas
Dextrothyroxine	Mitotane	Troglitazone
Diazoxide	Monoamine oxidase inhibitors	Tolterodine
Diflusal	Moricizine hydrochloride*	Trastuzumab
Digibind®	Nabumetone	Valproic acid
Dipyridamole	Nalidixic acid	Vitamin A
Diuretics*	Naproxen	Vitamin E (>400 IU daily)
Disulfiram	Narcotics, prolonged	Zafirlukast
Antibiotics:		
Carbenicillin	Fluoroquinolones	Quinolones (Ciprofloxacin)
Cephalosporins (2 nd & 3 rd generations)	Macrolides (Norfloxacin)	Sulfonamides
Chloramphenicol	Metronidazole	Tetracycline
Cloxacillin	Ofloxacin	Trimethoprim/sulfamethoxazole
Erythromycin	Piroxicam	Nafcillin*
Other factors affecting blood elements which may modify hemostasis:		
Dietary deficiencies	Prolonged hot weather	Unreliable PT determinations

*Increased and decreased PT responses have been reported. INRs are unreliable in patients with lupus anticoagulant.

The Following Factors, Alone or in Combination, May Be Responsible for Decreased PT Response		
Endogenous Factors		
Edema	Hyperlipemia	Hypothyroidism
Hereditary Coumadin® resistance		
Exogenous Factors		
Adrenocortical steroids	Diuretics	Paraldehyde
Alcohol*	Estrogens	Phenytoin
Aminoglutethimide	Ethychlorvynol	Primidone
Antacids	Etreinate	Raloxifene
Antihistamines	Furosemide	Ranitidine*
Azathioprine	Glutethimide	Rifampin
Barbiturates	Griseofulvin	Ritonavir
Carbamazepine	Haloperidol	Secobarbital
Chloral hydrate*	Meprobamate	Sulcrafate
Chlordiazepoxide	Mesalamine	Sulfasalazine
Cholestyramine	Mitotaine	Toxaphene
Coumadin® underdosage	Moricizine hydrochloride*	Trazodone
Cyclophosphamide	Nafcillin	Vitamin C
Disopyramide	Oral contraceptives	Vitamin K
Also:		
Diet high in vitamin K	Unreliable PT determinations	
*Increased and decreased PT responses have been reported.		

Test Commonly Includes Patient time and control time

Abstract A simple, low cost test useful for the evaluation of the extrinsic system of coagulation as it is sensitive to reduced levels (or activity) of factors II, V, VII, and fibrinogen. It is the time, in seconds, required for clot formation after addition of calcium and thromboplastin to the patient's citrated plasma. A common application is monitoring the effect of warfarin type anticoagulation.

Specimen Plasma

Minimum Volume 4.5 mL

Container Blue top (sodium citrate) tube

Collection Routine venipuncture. If multiple tests are being drawn, draw coagulation studies last. If only a prothrombin time is being drawn, two-syringe collection technique is recommended to avoid contamination of the specimen with tissue thromboplastins.

Storage Instructions Plasma should be separated from cells as soon as possible and refrigerated if testing cannot be immediately performed. Testing should be performed within 4 hours.

Causes for Rejection Tube not full; specimen clotted; specimen hemolyzed, lipemic, or icteric (possible interference with photo-optical clot detection); specimen received more than 3-4 hours after collection

Special Instructions Transport specimen to the Hematology Laboratory as soon as possible.

Possible Panic Range Nonanticoagulated: >20 seconds; anticoagulated: > three times control

Limitations Prothrombin times drawn less than 2 hours after heparin administration will be prolonged. The prothrombin time determination is sensitive to the ratio of plasma to citrate anticoagulant. That is, if enough blood is not added to the liquid citrate-containing tube when the specimen is drawn (tube usually contains 0.5 mL of 3.2% or 3.8% sodium citrate), a falsely elevated prothrombin time may result. The minimum amount of blood in the tube necessary to a reliable PT is not readily predictable. **The citrate tube for PT/PTT must be completely filled.**

Methodology The clotting time of citrate anticoagulated plasma is determined after the addition of an optimum concentration of calcium and an excess of thromboplastin. Clot detection is by manual (tilt tube visual) or, more commonly, by an automated device for fibrin clot detection, electrode, electro-optical or other method. The result is always reported with that obtained on a commercial normal control plasma run at the same time. Attempts in recent years to standardize prothrombin time results has led to reporting of the "international normalized ratio" (INR). See comments under Additional Information concerning INR and International Sensitivity Index (ISI). Chromogenic assays for determination of prothrombin have been developed. If the PT is prolonged repeat testing using half patient and half normal control plasma will identify presence of a circulating anticoagulant (prolonged PT will not correct).

Additional Information

Antibiotic therapy and prolonged prothrombin time: Biochemical mechanisms have been defined that support results of clinical studies indicating that broad-spectrum antibiotics, in particular second- and third-generation cephalosporins exert a hypoprothrombinemic effect. Destruction of menaquinone-producing GI bacteria and/or interference with prothrombin synthesis by N-methyl-thio-tetrazole side chains has

resulted in recommendations that prophylactic use of vitamin K be considered.

Control of coumarin derivative therapy: Long-term anticoagulant therapy usually involves the use of a coumarin derivative (eg, Coumadin®). The prothrombin time (PT) provides for "control" of the dosage. The attempt is to impede thrombus formation without the threat of morbidity or mortality from hemorrhage. In the past this goal has been approached by administering a Coumadin® dosage that prolongs the PT to twice that of a normal control plasma. More recently, this practice has been considered to result in overanticoagulation when using warfarin derivatives (Coumadin®, dicumarol, Tramexan®).

As the result of a series of conferences on antithrombotic therapy held in 1985, 1989, 1992, and most recently in 1995 (Fourth American College of Chest Physicians (ACCP) Consensus Conference on Antithrombotic Therapy), the earlier recommendation that the intensity of warfarin therapy be reduced (for most indications) has found support in the result of subsequent clinical trials. The ACCP recommends use of the INR for monitoring oral (warfarin-coumarin derivative) therapy. INR of 2.0-3.0 is recommended for all conditions with the exception of patients anticoagulated for thrombotic complications of mechanical heart valves for which an INR of 2.5-3.5 is recommended.

Warfarin anticoagulant effect occurs gradually. Without a loading dose, 7.5 mg/day of warfarin anticoagulant will produce desired therapeutic effect in 5-7 days. With a loading dose of 10-15 mg the anticoagulant effect can be achieved in some 3 days but with greater risk of bleeding. When warfarin compounds are discontinued the PT will require 2-4 days to return to normal. If oral vitamin K is given PT returns to normal within ~24 hours. The overanticoagulated state can be quickly reversed by giving vitamin K by subcutaneous injection or by slow intravenous infusion.

Onset of prothrombin time prolongation following first-time warfarin use is within 12-24 hours. A one-time warfarin dose of 0.5 mg/kg will result in a prothrombin time of 18-30 seconds in children following heart valve surgery.

Warfarin therapy can be started soon after the onset of heparin therapy in patients with venous thromboembolic disease with resultant savings in hospitalization costs. A 1-year course of warfarin therapy may be needed for patients with prior deep vein thrombosis and indefinite treatment if there have been over two previous episodes.

The variability in sensitivity of thromboplastins with resultant lack of between laboratory comparability in results of PT testing provided stimulus for standardization. In 1983, the International Normalized Ratio (INR) system was adopted by the International Committee for Standardization in Haematology, International Committee on Thrombosis and Haemostasis (ISCH/ICTH). This system is based on the first World Health Organization (WHO) primary international reference preparation of thromboplastin. The system is centered about the concept of the International Sensitivity Index (ISI). The ISI represents the responsiveness of a thromboplastin to the reduction in vitamin K-dependent factors. The ISI is derived by calibrating a thromboplastin reagent with the WHO reference preparation. Use is made of a linear relation between the logarithm of the prothrombin time ratio of the reference material and that of the test thromboplastin. $INR = (PT\ ratio)^{ISI}$, where the PT ratio = patient PT/mean normal PT. The "mean normal PT" should be the geometric, as opposed to the arithmetic, mean PT. It is important to avoid large biases in determining the reference mean. Theoretically, the INR is the PT ratio that would result if the WHO reference thromboplastin had been used in performing the test.

Recombinant human tissue factor (rTF), with very low ISI of 1.0 ± 0.1 , has been developed. rTF reagents are more sensitive to lower levels of factors II, VII, IX, and X. Thromboplastin reagents are not equivalent. Results from use of rTF reagents are not comparable to those obtained with mammalian thromboplastins when testing oral anticoagulated patients. Commercial availability and use of rTF reagents may allow for accurate and uniform reporting of PT results as INR.

The prothrombin time has been shown to lack sensitivity (in its current form) as a monitor for the anticoagulant effect of recombinant hirudin (originally an anticoagulant from the medicinal leech *Hirudo medicinalis*).

Protoporphyrin, Free Erythrocyte

Synonyms FEP; Free Erythrocyte Protoporphyrin; Protoporphyrins, Fractionation, Erythrocytes; RBC Protoporphyrin

Uses Differential diagnosis of disorders of heme production versus diseases of globin synthesis. FEP is increased in lead poisoning, protoporphyria, in iron deficiency, anemia of chronic disease and with some sideroblastic anemias. FEP levels are also reported increased in entities characterized by marked increase in erythropoiesis, such as severe hemolytic anemias. Thus, FEP is useful in work-up of the microcytic anemias. FEP is increased with lead poisoning but not in acute intermittent porphyria. FEP is reported normal with presumed alpha thalassemia trait, hemoglobin H, beta thalassemia trait, and hemoglobin E.

Reference Range Depends on method; ascertain ranges for individual testing laboratory. The FEP is considered unreliable in infants younger

than 6 months of age. Pediatric upper limit is 50 mcg/dL (SI: 0.89 $\mu\text{mol/L}$) RBC. Adults: male: <30 mcg/dL (SI: <0.53 $\mu\text{mol/L}$), female: <40 mcg/dL (SI: <0.71 $\mu\text{mol/L}$) by hematofluorometer; 11-45 (SI: 0.20-0.80 $\mu\text{mol/L}$) for adult men and 19-52 (SI: 0.34-0.92 $\mu\text{mol/L}$) for adult women by Pionelli FEP expressed as mcg/dL blood.

Abstract Free erythrocyte protoporphyrin expresses the amount of nonheme protoporphyrin in red cells.

Specimen Whole blood (test done on washed erythrocytes)

Volume 7 mL

Minimum Volume 1 mL whole blood

Container Lavender top (EDTA) tube or green top (heparin) tube

Collection Pediatrics: Blood drawn from heelstick for capillary.

Storage Instructions Stable 3 weeks at 4°C. Do not freeze.

Special Instructions Current hematocrit must be measured or specified.

Possible Panic Range >190 mcg/dL (SI: >3.38 $\mu\text{mol/L}$)

Limitations Fluorescent substances in plasma may interfere with hematofluorometer results. Elevated FEPs should be verified by retesting washed RBCs or by microextraction. Skin contamination may lead to false elevations. Both this test and blood lead are needed for full evaluation.

Methodology Hematofluorometer, extraction method, and high performance liquid chromatography (HPLC). The hematofluorometer measures porphyrins unbound in erythrocytes. With iron deficiency and diminished heme synthesis, free porphyrin accumulates in the red blood cell.

Additional Information "Free" protoporphyrin is not complexed, nonheme protoporphyrin. **Lead poisoning** is characterized by elevated plasma and urine delta aminolevulinic acid and increased urinary coproporphyrin. Urinary porphobilinogen and uroporphyrin are normal to slightly increased. Free erythrocyte protoporphyrin is a sensitive test for lead toxicity or chronic exposure, **although, a careful study based on receiver operator curves showed that erythrocyte protoporphyrin levels should not be used as a screening test for lead poisoning in children.** The diagnosis of lead exposure or poisoning includes consideration of environmental exposure, as well as symptoms and abnormal erythrocyte protoporphyrin. FEP is given as 92-288 mcg/dL (SI: 1.63-5.12 $\mu\text{mol/L}$) RBC in level II increased lead absorption, with higher FEP results in level III. Increased lead absorption is reported in the presence of iron deficiency. Increased erythrocyte protoporphyrin exists as free protoporphyrin in protoporphyria, not as a zinc chelate, in contrast to lead poisoning and iron deficiency. These two compounds, zinc protoporphyrin and metal free protoporphyrin, can be distinguished from each other by spectrophotofluorometry.

Protoporphyrin, Zinc, Blood

Synonyms Zinc Protoporphyrin; ZPP

Uses Evaluate iron deficiency, especially nonanemic iron deficiency. ZPP is superior to hemoglobin in identifying female blood donors with nonanemic iron deficiency.

Reference Range 17-77 mcg/dL (SI: 0.27-1.23 $\mu\text{mol/L}$). Results may be obtained as ZPP/heme ratio; reference range: 30-80 $\mu\text{mol/mol}$ heme.

Abstract Zinc protoporphyrin measurement may be a useful adjunct in the diagnosis of nonanemic iron deficiency but is not useful in screening programs for lead intoxication.

Specimen Whole blood

Volume 3 mL

Minimum Volume 1 mL whole blood

Container Lavender top (EDTA) tube, green top (heparin) tube

Collection Routine venipuncture

Storage Instructions Do not centrifuge. Refrigerate and protect from light. Stable 1 week at 4°C.

Causes for Rejection Specimen not protected from light, specimen improperly collected, hemolysis, icterus

Critical Values >100 mcg/dL (SI: >1.6 $\mu\text{mol/L}$)

Limitations Zinc protoporphyrin may also be increased in lead poisoning, anemia of chronic disease, and erythropoietic protoporphyria. ZPP should not be used to screen or diagnose lead poisoning.

Methodology Hematofluorometry (front-face); if washed erythrocytes are used, the assay becomes more specific and sensitive

Additional Information Zinc protoporphyrin levels increase as blood lead levels increase. Various authorities caution using ZPP as a screening test for lead poisoning. The Center for Disease Control has lowered the cutoff level for lead intoxication in children younger than 6 years of age to **10 mcg/dL (SI: 0.48 $\mu\text{mol/L}$)**, and this level is so low that ZPP is not useful in this context because it is insensitive to such a lead level. Therefore, it is mandatory to measure lead levels in any screening program, rather than ZPP. ZPP appears only in new RBCs and remains for the life of the RBC; therefore, ZPP does not increase until several weeks after the onset of lead exposure and remains high long after exposure to lead. It is a reasonable indicator of total body burden of lead and remains a useful adjunct to the diagnosis of iron deficiency, particularly in nonanemic or questionably anemic patients. It reflects iron depletion in the bone marrow.

Protriptyline, Blood

Synonyms Vivactil®

Uses Monitor therapeutic drug level; evaluate toxicity

Reference Range Therapeutic: 70-250 ng/mL

Specimen Blood

Volume 20 mL

Minimum Volume 4 mL serum

Container Red top serum separator tube preferred, plain red top tube acceptable

Storage Instructions Freeze serum.

Critical Values Toxic: >500 ng/mL

Methodology Gas-liquid chromatography (GLC)

Additional Information Protriptyline, a tricyclic antidepressant, is used to treat endogenous depression. The drug is very similar to imipramine in actions, limitations, and interactions. The half-life is 54-98 hours and peak serum levels are reached in 24-30 hours. Adverse reactions include CNS stimulation, tachycardia, and strong anticholinergic activity. Orthostatic hypotension frequently occurs.

Pseudocholinesterase, Serum

Related Information

- Acetylcholinesterase, Red Blood Cell

Synonyms Cholinesterase, Serum; PCE®; Plasma Cholinesterase

Uses

Screen preoperative patients for succinylcholine (suxamethonium) anesthetic sensitivity, genetic or secondary to insecticide exposure, in appropriate circumstances. Prevent or evaluate prolonged anesthetic effect, prolonged apnea, after surgery. Very small amounts (0.04-0.06 mg/kg) of succinylcholine are needed to obtain 90% of neuromuscular blockade in patients with low levels of plasma cholinesterase activity.

Monitor organophosphorous or carbamate insecticide poisoning, in which level is decreased; establish patient's baseline value before exposure. Indications include such pesticide exposure, especially with miosis, blurred vision, muscle weakness, twitching, and fasciculation, bradycardia, nausea, diarrhea, vomiting, salivation, sweating, pulmonary edema, arrhythmias, and convulsions. The value of assessing risk status in persons exposed to organophosphate insecticides on the basis of plasma cholinesterase levels alone has been called into question. Are normal levels indicative of no exposure or of a genetic variant with or without exposure? There are interpretive problems with low or high values.

Family studies may be done when an individual with a genetically abnormal type is documented by serum pseudocholinesterase deficiency and, ideally, confirmed by phenotyping.

Contraindicating Factors Not useful to screen for toxicity from chlorinated insecticides.

Reference Range Low in infancy, then increasing in early childhood. Ranges vary between methods and laboratories.

Antidote(s)

- Acetylcholinesterase, Red Blood Cell

Abstract Two types of cholinesterase are found in blood: "true" cholinesterase (acetylcholinesterase) in red cells and "pseudocholinesterase" (acylcholine acylhydrolase) in serum (plasma).

Specimen Blood

Volume 7 mL

Minimum Volume 1 mL serum

Container Red top tube

Storage Instructions Cholinesterase is stable in separated serum for 80 days at room temperature and 3 years at -20°C. However, specimens submitted to evaluate possible pesticide toxicity should be collected on ice, separated in a refrigerated centrifuge, and frozen until analyzed.

Possible Panic Range Less than lower limit of normal

Limitations Serum pseudocholinesterase may be decreased in patients on estrogens and oral contraceptives. Fluoride interferes. Pseudocholinesterase is low also in some instances of liver disease, including decompensated cirrhosis, hepatitis, metastatic carcinoma, CHF, and in malnutrition, but not sufficiently consistently enough to be a useful clinical test for such disorders. Genetic atypical enzyme does not explain every instance of prolonged postsurgical apnea. Red cell cholinesterase is more useful for chronic insecticide exposure. Carbamate-poisoned persons can appear to have near normal or normal levels of pseudocholinesterase. Plasma cholinesterase is lower and red blood cell cholinesterase higher in pregnant women than in nonpregnant women. Thus, a low red blood cell cholinesterase in pregnant women is more consistent with a possible overexposure to anticholinesterases than a low plasma cholinesterase.

Methodology Colorimetry, kinetic enzyme utilizing different substrates, fluorometry

Additional Information

Low serum cholinesterase activity may relate to exposure to insecticides or to one of a number of variant genotypes. Dibucaine and fluoride

numbers are useful to phenotype such homozygous and heterozygous individuals, who are genetically sensitive to succinylcholine.

One patient in 1500 is susceptible to succinylcholine anesthetic mishap. Plasmapheresis has been noted to decrease the level of plasma cholinesterase. Patients with abnormally low cholinesterase activity after transfusion of blood or plasma will experience temporary augmentation of enzyme level. In estimating the duration of this enhanced activity, measures of plasma cholinesterase half-life have been utilized. The true half-life value has, however, been uncertain. A half-life value determined by measuring the rate of disappearance after intravenous injection of human cholinesterase has provided an average value of 11 days.

A low level of activity of pseudocholinesterase has been demonstrated in cerebrospinal fluid, at $\sim 1/20$ to $1/100$ the activity present in the corresponding plasma. With clinical conditions characterized by bleeding into the CSF, pseudocholinesterase activity increases 25% to 50% that of plasma.

Patients with a variety of carcinomas have been reported to accumulate an embryonic type of cholinesterase activity in their sera. Such novel cholinesterase activity was found only in the sera of patients undergoing antitumor therapy (eg, chemotherapy or radiation therapy and/or hormone therapy).

Increase in acetylcholinesterase activity, notably, in an acetylcholinesterase to butyrylcholine esterase ratio (histochemical study, not as measured in serum) has provided discriminatory diagnostic value in some cases of Hirschsprung's disease.

Pulse Oximetry

Applies to Ear Oximetry; Finger Oximetry

Synonyms CPAP Titration; Desaturation Oximetry; Oxygen Titration Test; Photoplethysmography

Uses Determine an estimate of the level of arterial oxygenation at rest and in the presence of positive and negative intervention. These include exercise, sleep, and during procedures such as surgery, bronchoscopy, ventilator assist/support therapy, etc.

Contraindicating Factors Not to be used in the presence of flammable anesthetics. Contraindications for exercise may be found in the section on cardiopulmonary exercise testing.

Reference Range

Normal adult oxyhemoglobin saturation is $>95\%$. Drops in oxyhemoglobin are usually the result of cardiac, pulmonary, or combined cardiopulmonary disease. Significant declines ($>5\%$) during exercise or sleep are abnormal.

Test Commonly Includes Report generally includes baseline heart rate and functional O_2 saturation, heart rate and lowest functional O_2 saturation during whatever event may be taking place: exercise, sleep or therapeutic intervention such as nasal CPAP or oxygen therapy.

Patient Preparation Fingernail polish should be removed with acetone. Permanent or disposable sensors should be applied according to the manufacturer's instructions. When finger probes are used, the patient should be instructed not to grip treadmill rail or handlebars tightly to avoid reduction of circulation to the digits. Preparation depends on the type of test being performed. Exercise patients should wear loose comfortable clothing. Patients should refrain from smoking 24 hours prior to test to avoid functional versus fractional O_2 saturation discrepancy that occurs with elevated carboxyhemoglobin levels. If possible, an arterial blood gas should be drawn and pH, pCO_2 , pO_2 , hemoglobin, oxyhemoglobin ($O_2Hb\%$), carboxyhemoglobin ($COHb\%$) and methemoglobin (methHb%) should be measured. Draw the heparinized arterial blood sample while the pulse oximetry sensor is in place and is stable. Correlation of oxyhemoglobin ($O_2Hb\%$) (measured by blood oximetry) and $SpO_2\%$ (measured by pulse oximetry) should be made. The discrepancy between the $O_2Hb\%$ - $SpO_2\%$ should be used to determine the endpoint of the maneuver inducing arterial desaturation. For example, if the pulse oximeter displays a SpO_2 reading of 93% and a simultaneously obtained arterial blood sample shows an $O_2Hb\%$ of 91%, 2% should be subtracted from subsequent SpO_2 measurements during exercise for a more valid estimate of arterial oxygen saturation. This adjustment should also be made to determine the therapeutic endpoint when titrating supplemental oxygen therapy at rest, during sleep, or exercise.

Specimen Spectrophotometric measurement is made by passing light at two specific wavelengths through a pulsing capillary bed (finger, toe, bridge of nose, and ear are the most common sites for sensor placement). Light collection on the other side of the site is proportional to the amount of oxyhemoglobin present in the arterial capillary bed relative to the amount of hemoglobin available for binding with oxygen (exclusive of the dyshemoglobins: carboxyhemoglobin and methemoglobin).

Causes for Rejection Unstable readings secondary to any cause: external light, poor peripheral circulation, or skin pigmentation are common causes.

Special Instructions Poor collateral circulation may be compensated for by warming the hands with warm towels. Fluctuation $\pm 1\%$ is acceptable. Range of fluctuation should be noted.

Possible Panic Range Values $<90\%$ indicate the need for oxygen therapy. Values $<85\%$ are require immediate attention. If available, add the measured carboxyhemoglobin and methemoglobin to the values listed to adjust for nonfunctioning dyshemoglobins.

Limitations Test does not measure or take into consideration total hemoglobin or the dyshemoglobins, carboxyhemoglobin, and methemoglobin. May overestimate total oxygen delivery (oxygen content) if not correlated with blood oximetry. Not accurate in the presence of poor peripheral circulation. Accuracy at most units is $\pm 2\%$, standard deviation is usually 1%. Pulse oximetry underestimates arterial blood saturation by 1.3%.

Additional Information

Guidelines for reimbursement of home oxygen therapy state that a resting arterial $pO_2 < 55$ torr or a resting oxygen saturation ($SpO_2\%$) $< 88\%$ with evidence of improvement with oxygen therapy qualify a patient for continuous oxygen therapy reimbursement. Guidelines for reimbursement for nocturnal and exercise oxygen therapy state that O_2 saturations during exercise or sleep that fall to $< 88\%$ that improve with oxygen therapy will be reimbursed. Because of the limitations of pulse oximetry, decisions regarding discontinuing oxygen therapy should not be made on the basis of pulse oximetry alone. Assessment of the PaO_2 by arterial blood gas and/or $O_2Hb\%$ by arterial blood oximetry should be done before such decisions are made. Room air pulse oximetry reading $\geq 97\%$ virtually rules out hypoxemia and may also rule out moderate hypercapnia. Pulse oximetry is accurate to an arterial blood flow as low as 4% of baseline. Pulse oximetry has been used for evaluating and monitoring digital vascular flow. Oxygen digital saturation readings $> 95\%$ are consistent with viable replanted digits while digital saturations $< 85\%$ can be seen in venous occlusion. Pulse oximetry may underestimate oxygenation in patients with sickle cell crisis. Accurate determinations of oxygen saturation can be made with pulse oximetry after individuals were given hemoglobin-based oxygen carrier 201 (a glutaraldehyde-polymerized bovine hemoglobin)

There is growing use of **transcutaneous pulse oximetry** to determine oxygen saturation, particularly in premature and in critically ill newborns and children. This noninvasive technique avoids the rigors of arterial puncture, necessity of subsequent proper sample handling, and can provide continual monitoring. This technique has generally been found reliable and useful in monitoring adequacy of oxygenation, effectiveness of resuscitative efforts, detection of development of prolonged periods of decreased SO_2 in neonates, and monitoring preterm infant's response to physical therapy. Pulse oximetry has also been applied to detection of hyperoxemia in newborns but has low specificity. Limitations of pulse oximetry have included overestimation of SO_2 at values $\leq 65\%$, and variation from *in vitro* determined SO_2 in samples with $> 50\%$ fetal hemoglobin as compared with samples having $< 25\%$ fetal hemoglobin. Furthermore, it is not useful in carbon monoxide or methemoglobin intoxication because false elevations of saturation may occur. A study of pulse oximeter determined oxygen saturation in pregnant patients and their newborns has found that SO_2 in neonates is commonly $\leq 90\%$ within 10 minutes after birth and may not always be indicative of pathologic hypoxia. Specialized devices (eg, balloon-tipped, thermodilution, fiberoptic, pulmonary arterial catheter) have been developed for the intraoperative monitoring of mixed venous oxygen saturation.

Rabies Identification

Related Information

- Animal and Human Bites Guidelines

Uses Diagnose rabies; evaluate animal bites

Contraindicating Factors Formalin fixation precludes fluorescent antibody application

SALICYLATE, BLOOD

Reference Range Serum levels >1000 ng/mL are associated with GI toxicity, while serum selenium levels >2000 ng/mL may be lethal

Test Commonly Includes Examination of animal brain for Negri bodies or inoculation of mice with suspension of brain tissue

Specimen Head of large animal or entire small animal suspected of rabies. Use gloves and mask when handling an animal carcass suspected of rabies.

Container Sealed container

Storage Instructions Ideally, animal brain should be examined in the fresh state. Transport using wet ice or place in absorbent material, then in two plastic bags, or, place half the brain in 50% glycerol, half in 10% formalin, depending on instructions from state laboratory. Local state laboratory must be consulted. Rabies virus may also be demonstrated by immunofluorescence in skin biopsies of patients suspected of having rabies (*vide infra*).

Causes for Rejection Unlabeled or improperly packaged specimen

Limitations Negri bodies are found in ~90% of rabid animals.

Methodology Fluorescent antibody examination (but Negri bodies can be seen in H & E)

Additional Information

Antemortem rabies virus has been isolated from human saliva, brain tissues, CSF, urine sediment, and tracheal secretions. Rabies virus may also be demonstrated by immunofluorescent rabies antibody staining of skin biopsy tissue. The most reliable and reproducible of the immunofluorescent studies that can aid in patient diagnosis is biopsy of the neck skin. A 6-8 mm full thickness wedge or punch biopsy specimen from the neck containing as many hair follicles as possible should be sampled, snap frozen, and shipped frozen at -70°C to a reference laboratory. Consult with reference laboratory for shipping instructions. False-negative results do occur especially after the development of neutralizing antibodies.

Rabies immune globulin (RIG) may be obtained through Connaught Laboratories (800-822-2463) or through Miles Pharmaceutical Division (203-937-2242 or 800-288-8371); RIG has been tested negative for HCV-RNA

Salicylate, Blood

Applies to Methyl Salicylate; Oil of Wintergreen

Synonyms Acetylsalicylic Acid, Blood; ASA, Blood; Aspirin, Blood; Salicylic Acid, Blood

Uses Monitor therapeutic drug level; evaluate aspirin toxicity

Reference Range Therapeutic: <10 mg/dL (SI: <0.72 mM/L) for analgesic; 15-20 mg/dL (SI: 1.09-1.45 mM/L) for anti-inflammatory

Abstract This is the active product produced from aspirin (acetylsalicylic acid) in the body. It is an analgesic, antipyretic, and anti-inflammatory drug.

Specimen Blood

Volume 7 mL

Minimum Volume 2 mL serum or plasma

Container Red top tube or lavender top (EDTA) tube

Possible Panic Range Mild toxicity: 30 mg/dL (SI: 2.17 mM/L) (tinnitus, dizziness); severe toxicity: >80 mg/dL (SI: >3.62 mM/L) (CNS effects)

Limitations Bilirubin (at concentrations of 5-20 mg/dL) has been shown to depress salicylate results by 1-5 mg/dL. Sodium azide will increase results significantly; anticoagulants interfere. Diflunisal and salazosulfapyridine, may give falsely positive blood salicylate levels by some assays.

Methodology Photometry, fluorometry, high performance liquid chromatography (HPLC), gas-liquid chromatography (GLC)

Additional Information Optimal sampling time after dosage is 2-6 hours. Serum half-life is 2-3 hours on low dose therapy, 15-30 hours on high dose treatment. Optimal resampling time after change in dosage is 6 hours. In patients on chronic therapy, small dose changes may produce disproportionate changes in serum level. Use of antacids, which increase renal excretion, can lower serum levels. Steady-state concentrations for an individual patient are not adequately predicted from nomograms or standard dose schedules. In salicylate poisoning the following symptoms may occur: initial alkalosis followed by acidosis in the blood, ketosis, and possible elevated plasma glucose. Glucose should be measured when levels >25 mg/dL (SI: >1.81 mM/L) are detected. Salicylate can be done on urine or gastric juice. Salicylate hepatitis, usually at blood levels of 20-25 mg/dL (1.45-1.81 mM/L), occurs. Salicylates are believed to play a role in the hepatonecrosis of Reye's syndrome in children. They are no longer recommended for use in children.

Selenium, Serum

Related Information

- Heavy Metal Screen, Blood

Synonyms Se, Serum

Uses Monitor selenium nutritional status in long-term parenteral nutrition. Studies have indicated no factor or factors that can accurately predict

serum selenium levels to preclude need for measurement. May be used diagnostically in cardiomyopathy of unknown cause, especially where nutritional factors are suspected.

Reference Range Serum: 95-165 ng/mL. Approximately 40% higher for whole blood. Serum reflects recent intake; red cells reflect more remote intake. Whole blood therefore reflects an average of recent and remote intake of selenium. (Selenium-dependent glutathione peroxidase activity reflects selenium available for enzyme synthesis - see below.) Levels are depressed in HIV infection, critical illness, kwashiorkor, inflammatory bowel disease, renal failure, hemodialysis status, low protein diet, phenylketonuria, maple syrup urine disease, (possibly all in part related to poor protein intake), low birth weight, and premature infants with inadequate selenium intake. Levels are increased mostly with the use of glucocorticoids. Levels >500 ng/mL are associated with toxicity. Serum levels >1000 ng/mL are associated with gastrointestinal toxicity while serum selenium levels >2000 ng/mL may be lethal.

Abstract The essential nature of selenium in human nutrition is beyond dispute. The element is part of the enzyme that converts T₄ to the active thyroid hormone T₃. It is also part of selenium-dependant glutathione peroxidase, an important antioxidant in blood and tissue. Multiple cases of selenium deficiency have been reported, mostly among patients given parenteral nutrition with no added selenium. Deficiency also occurs endemically in places where soil selenium is low, and low levels are thus present throughout the food chain. Endemic cretinism, Balkan nephropathy, Keshan disease (endemic dilated cardiomyopathy), and Kashin-Bek disease (endemic deforming osteoarthritis) are probably all caused by endemic selenium deficiency conditioning the host to poorly tolerate an additional environmental stress (cretinism: iodine deficiency; the others: unknown local toxins). Simple deficiency is marked by whitening of the nailbeds, erythrocyte macrocytosis, cardiomyopathy, painful weak muscles, skin and hair depigmentation, and elevations of transaminase and creatinine kinase. The cardiomyopathy may be mild and asymptomatic or fulminant and fatal. Selenium toxicity can occur endemically, again due to high soil levels, or through accidental or industrial exposure. Symptoms include garlic breath, odor, thick brittle fingernails, dry brittle hair, red swollen skin of the hands and feet, and nervous system abnormalities of numbness, convulsions, or paralysis.

Specimen Blood

Container Sherwood Monoject™ trace element blood collection tube #8881-307006 or #8881-307022 with EDTA for whole blood

Collection Draw blood through B-D #5175 stainless steel needle into special trace metal vacuum tube. Centrifuge and pour serum into special plastic metal-free vial for transport.

Limitations

Some controversy exists regarding the "best" marker for selenium status. Since selenium as selenomethionine is incorporated nonspecifically into protein, serum and whole blood selenium concentration increases with increasing selenium intake to different degrees depending on inorganic or organic sources of selenium. Glutathione peroxidase activity is more sensitive to deficiency but the test is not well standardized and therefore not reproducible from laboratory to laboratory. Hair selenium may be contaminated by selenium-containing shampoo. Serum selenium level correlates best with intake and therefore with both deficiency and toxicity states, but a wide range of serum levels is compatible with apparent good health.

Methodology Atomic absorption, fluorometric methods

Additional Information Selenium is excreted in feces from the bile, in sweat and skin losses, and the remaining 50% to 70% in the urine. Significant breath losses occur only in toxic states. Dosages in renal failure need not be modified. The deficiency syndrome may be rapidly induced under surgery or other stress after a long asymptomatic phase. Serum selenium levels are significantly lower (24 ng/mL versus 39 ng/mL in control patients) in chronic alcohol abuse patients.

Selenium, Urine

Synonyms Se, Urine

Uses Monitor nutritional therapy, especially parenteral nutrition; monitor potential toxic exposure

Reference Range Levels <15 mcg/L or >150 mcg/L probably represent unusually low or high intake without necessarily representing illness. Values vary widely and in apparently healthy U.S. citizens they have been reported to vary from 7 mcg/L (24-hour sample) to 231 mcg/L. Intake is partly determined by local soil content of selenium and use of local vegetables as food. Healthy persons in New Guinea have been reported with levels as low as 0.9 mcg/L but similar patients have rapidly developed symptomatic selenium deficiency when placed on total parenteral nutrition lacking selenium. Urine levels of 7 mcg/L have been reported from China in areas where selenium deficiency is symptomatic. Levels >880 mcg/L have been seen in chronic selenosis and >600 mcg/L during the first 24 hours after acute selenium intoxication. Levels >500

mcg/L probably represent toxicity. See the comprehensive review by Robberecht and Deelstra. Some authors or laboratories report as mcg/day.

Abstract Urine selenium is used in conjunction with serum selenium to assess selenium nutrition or potential toxic exposure. Like any other 24-hour urine collection of an essential element, this reflects recent intake, assuming the patient is in selenium balance. In the case of selenium, skin and stool losses are significant and amount to 30% to 50% of total losses; nevertheless, urine losses often represent overflow losses and can help indicate whether recent intake has been adequate or possibly toxic. When selenium intake is low to normal, less than approximately 140 mcg/day, 24-hour urine may not reflect the 24-hour intake of the previous day. This is especially true when the body stores are low and selenium is retained to fill body stores. At higher levels of intake, the 24-hour urine is well correlated with intake and can be used as evidence of excess intake, adequate intake, or prior toxic exposure. Twenty-four hour urine selenium reflects recent intake. When selenium supplementation normalizes serum selenium and whole blood selenium, and then selenium supplementation is stopped, urine selenium falls back toward baseline much faster than blood or serum levels. Urine selenium has recently been found to be correlated with 24-hour urine urea in critically ill patients. This probably reflects catabolism of protein and release of body stores of selenium, though details of the selenium intake of the patients (proportional to protein intake in tube-fed patients) were not provided.

Specimen 24-hour urine

Container Acid-washed plastic urine container

Collection Avoid contamination by hair since some patients use selenium-containing shampoos.

Limitations Selenomethionine is incorporated into body protein nonspecifically as methionine, so it is not as quickly excreted in the urine as inorganic selenium (selenite). Thus, the form of selenium ingested will affect short-term balance estimates. Spot urine selenium is of little value, as urine selenium goes up after each meal related to selenium intake and probably other factors, and dilution in spot urine samples varies.

Methodology Fluorometry, atomic absorption (AA)

Additional Information In addition to serum and urine levels of selenium, red cell glutathione peroxidase can be monitored as an example of the activity of a seleno-enzyme. Levels will be depressed in deficiency but will not monitor toxicity.

Sertraline, Blood

Synonyms Zoloff®

Uses Antidepressant used when undesirable side effects noted with Prozac®; therapeutic monitoring and toxicity assessment

Reference Range Postmortem blood sertraline levels > 1.5 mg/L may indicate that this drug was the cause of death; therapeutic clinical trials: sertraline: 0.03-0.19 mg/L

Abstract Antidepressant with fewer adverse side effects than Prozac®; metabolizes to desmethylsertraline which has 10% of the activity of sertraline

Specimen Blood

Volume 5 mL

Minimum Volume 1 mL serum or plasma

Container Red top tube

Methodology High performance liquid chromatography (HPLC), gas chromatography (GC), gas chromatography/mass spectrometry (GC/MS)

Silver, Serum

Synonyms Ag, Blood

Uses Evaluate silver toxicity

Reference Range Nondetectable

Specimen Blood

Volume 5 mL

Container Red top tube

Silver, Urine

Synonyms Ag, Urine

Uses Evaluate silver toxicity

Reference Range Negative

Patient Preparation Patient should be instructed to use a plastic urinal or bedpan is necessary.

Specimen 24-hour urine

Volume Entire collection

Minimum Volume 100 mL aliquot

Container Plastic urine container, no preservative

Collection Instruct the patient to void at 8 AM and discard the specimen. Then collect all urine including the final specimen voided at the end of the 24-hour collection period (ie, 8 AM the next morning). Avoid contact with

metal during collection. Screw the lid on securely. Transport the specimen promptly to the laboratory. Container **must** be labeled with patient's full name, room number, date and time collection started, and date and time collection finished.

Storage Instructions Keep on ice or refrigerate. Laboratory will measure urine volume and remove 120 mL aliquot.

Causes for Rejection Specimen allowed to contact metal

Special Instructions Requisition **must** state date and time collection started and date and time collection finished.

Stool Culture

Applies to Rectal Swab Culture; Routine Culture, Rectal Swab

Synonyms Enteric Pathogens Culture, Routine; Stool for Culture

Uses

Screen for common bacterial pathogenic organisms in the stool; diagnose typhoid fever, enteric fever, bacillary dysentery, *Salmonella* infection.

Indications for stool culture include: bloody diarrhea; fever; tenesmus; severe or persistent symptoms; recent travel to a third world country; known exposure to a bacterial agent; presence of fecal leukocytes

Contraindicating Factors A rectal swab culture is not as effective as a stool culture for detection of the carrier state.

Reference Range Negative for *Salmonella*, *Shigella*, and *Campylobacter*. In endemic areas the isolation of a pathogen may not indicate the cause or only cause of diarrhea.

Test Commonly Includes Screening culture for *Salmonella*, *Shigella*, *Helicobacter*, and, if requested, *Staphylococcus*.

Specimen Fresh random stool, rectal swab

Volume 5 mL

Container Plastic stool container, Culturette®

Collection

If stool is collected in a clean bedpan, it must not be contaminated with urine, residual soap, or disinfectants. Swabs of lesions of the rectal wall during proctoscopy or sigmoidoscopy are preferred.

Rectal swab: Insert the swab past the anal sphincter, move the swab circumferentially around the rectum. Allow 15-30 seconds for organisms to adsorb onto the swab. Withdraw swab, place in Culturette® tube, and crush media compartment.

Storage Instructions Refrigerate if the specimen cannot be processed promptly.

Causes for Rejection Because of risk to laboratory personnel, specimens sent on diaper or tissue paper, specimen contaminating outside of transport container may not be acceptable to the laboratory. Specimen containing interfering substances (eg, castor oil, bismuth, Metamucil®, barium), specimens delayed in transit and those contaminated with urine may not have optimal yield.

Special Instructions The laboratory should be informed of the specific pathogen suspected if not *Salmonella*, *Shigella*, or *Campylobacter*.

Limitations *Yersinia* species and *Vibrio* species may not be isolated unless specifically requested.

Methodology Aerobic culture on selective media

Additional Information Stool cultures on patients hospitalized ≥ 3 days are **not productive and should not be ordered** unless special circumstances exist.

In enteric fever caused by *Salmonella typhi*, *S. choleraesuis*, or *S. enteritidis*, blood culture may be positive before stool cultures, and blood cultures are indicated early. Diarrhea is common in patients with the acquired immunodeficiency syndrome (AIDS). Diarrhea in AIDS is frequently caused by the classic bacterial pathogens; however, parasitic infestation is also common with *Giardia* and *Cryptosporidium*. Rectal swabs are useful for the diagnosis of *Neisseria gonorrhoeae* and *Chlamydia* infections.

In acute or subacute diarrhea, three common syndromes are recognized: gastroenteritis, enteritis, and colitis (dysenteric syndrome). With colitis, patients have fecal urgency and tenesmus. Stool are frequently small in volume and contain blood, mucus, and leukocytes. External hemorrhoids are common and painful. Diarrhea of small bowel origin is indicated by the passage of few large volume stools. This is due to accumulation of fluid in the large bowel before passage. Leukocytes indicate colonic inflammation rather than a specific pathogen. Bacterial diarrhea may be present in the absence of fecal leukocytes and fecal leukocytes may be present in the absence of bacterial or parasitic agents (ie, idiopathic inflammatory bowel disease). See table. Although most bacterial diarrhea is transient (1-30 days) cases of persistent symptoms (10 months) have been reported. The etiologic agent in the reported case was *Shigella flexneri* diagnosed by culture of rectal swab. In infants younger than 1 year of age, a history of blood in the stool, more than 10 stools in 24 hours, and temperature greater than 39°C have a high probability of having bacterial diarrhea. See table.

STRYCHNINE, QUANTITATIVE

Diarrhea Syndromes Classified by Predominant Features		
Syndrome (anatomic site)	Features	Characteristic Etiologies
Gastroenteritis (stomach)	Vomiting	Rotavirus
		Norwalk virus
		Staphylococcal food poisoning
		<i>Bacillus cereus</i> food poisoning
Enteritis (small bowel)	Watery diarrhea Large-volume stools, few in number	Enterotoxigenic <i>Escherichia coli</i>
		<i>Vibrio cholerae</i>
		Any enteric microbe
		Inflammatory bowel disease
Dysentery, colitis (colon)	Small-volume stools containing blood and/or mucus and many leukocytes	<i>Shigella</i>
		<i>Campylobacter</i>
		<i>Salmonella</i>
		Invasive <i>E. coli</i>
		<i>Plesiomonas shigelloides</i>
		<i>Aeromonas hydrophila</i>
		<i>Vibrio parahaemolyticus</i>
		<i>Clostridium difficile</i>
		<i>Entamoeba histolytica</i>
		Inflammatory bowel disease

Strychnine, Quantitative

Uses Evaluate toxicity
Specimen Blood
Volume 15 mL
Minimum Volume 5 mL serum
Container Red top tube
Critical Values Toxic: >2.0 mcg/mL

Sulfhemoglobin

Uses Evaluate cyanosis
Reference Range None detectable
Specimen Blood
Volume 10 mL
Minimum Volume 1 mL whole blood
Container Amber top tube
Storage Instructions Maintain specimen at room temperature.
Methodology Spectrophotometry

Additional Information The term sulfhemoglobin refers to a poorly characterized hemoglobin derivative which can be produced *in vitro* from the action of hydrogen sulfide on hemoglobin. Sulfhemoglobinemia may occur in association with the administration of various drugs, including sulfonamides, phenacetin, metoclopramide, and acetanilide but has been reported also in the absence of exposure to drugs or toxins. The symptoms are few but the cyanosis is intense even though the concentration is seldom >10%. Once formed, sulfhemoglobin is stable and cannot be reduced back to hemoglobin. It disappears as the red cells become senescent and are destroyed. Measurement of sulfhemoglobin or sulfmethemoglobin levels are not clinically useful in hydrogen sulfide poisoning.

Thallium, Urine or Blood

Related Information

- Heavy Metal Screen, Blood

Uses Diagnose thallium toxicity in patients exposed to insecticides and rat poisons

Reference Range Urine: <10 mcg/24 hours; serum: <10 ng/mL (SI: <49 nmol/L)

Abstract Thallium salts are components of insecticides and rodenticides.

Patient Preparation The patient should be instructed to use a plastic bedpan or urinal if necessary

Specimen 24-hour urine, blood

Volume Entire collection

Container Plastic urine container, red top tube

Causes for Rejection Specimen allowed to contact metal

Methodology Atomic absorption spectrometry (AA)

Theophylline, Blood

Synonyms Aminophylline; Elixophyllin®; Slo-Phyllin®; Sustaire®; Theodur®; Theolair™; Theospan®

Uses Monitor therapeutic drug level; detect noncompliance and subtherapeutic levels; attempt to predict theophylline toxicity if possible

Reference Range Therapeutic: 10-20 mcg/mL (SI: 56-111 µmol/L)

Abstract Theophylline is an antiasthmatic which is frequently monitored.

Specimen Blood

Volume 7 mL

Minimum Volume 3 mL serum

Container Red top tube

Sampling Time Measure **trough** (just before the next dose) and **peak**. Ideally, to measure peak serum theophylline **no** missed doses for previous 48 hours; blood drawn at 2 hours after most recent dose for rapid dissolution preparations; 4-6 hours after sustained release preparations.

Storage Instructions Refrigerate (do not freeze) a minimum of 0.5 mL serum.

Causes for Rejection Stored specimen not refrigerated

Possible Panic Range >20 mcg/mL (SI: >111 µmol/L); neonates: >10 mcg/mL (SI: >56 µmol/L); high probability of seizures when levels are >40 mcg/mL.

Methodology Enzyme immunoassay (EIA), high performance liquid chromatography (HPLC), gas chromatography (GC)

Additional Information Blood levels should be interpreted in light of the patient's clinical status and use of other medications. Acetazolamide can cause falsely elevated serum theophylline level by HPLC method.

Thiocyanate, Blood or Urine

Applies to Nitroprusside

U.S. Brand Names Nipride®

Synonyms Ethyl and Methyl Thiocyanate (Thanite® and Lethane®); Potassium Thiocyanate (KCN)

Uses Evaluate thiocyanate toxicity, nitroprusside poisoning, smoking. Toxic manifestations are psychotic behavior, agitation, and convulsions.

Reference Range Serum, therapeutic: 1-4 mcg/mL (SI: 0.02-0.07 mM/L), smokers: 3-12 mcg/mL (SI: 0.05-0.21 mM/L); urine: 1-4 mg/24 hours, smokers: 7-17 mg/24 hours

Abstract Thiocyanate is a metabolite of the antihypertensive drug, nitroprusside. It is also a product of cyanide metabolism.

Specimen Blood, urine

Volume 7 mL

Container Red top tube, lavender top (EDTA) tube, plastic urine container

Possible Panic Range Serum: >35 mcg/mL (SI: >0.60 mM/L); 200 mcg/mL (SI: 3.44 mM/L) is lethal

Limitations Because of rapid metabolism of the drug, results are usually meaningless in the clinical setting by the time they are reported.

Methodology Photometry/chromatography

Additional Information Thiocyanate is a major metabolite of cyanide produced in the liver by the enzyme rhodanase. Thiocyanate is present in healthy subjects. It is a component of cigarette smoke, and it can arise from the drug nitroprusside.

Thioridazine, Quantitative

Applies to Phenothiazines

Synonyms Mellaril®

Uses Monitor therapeutic drug level; evaluate toxicity

Reference Range <1 mcg/mL

Specimen Blood

Volume 15 mL

Minimum Volume 5 mL

Container Three yellow top (ACD) tubes

Collection Collect specimen immediately prior to next dose unless specified otherwise.

Storage Instructions Separate and refrigerate.

Critical Values 2 mcg/mL

Additional Information Thioridazine, a piperidine phenothiazine, is used to manage the manifestations of psychotic disorders, depressive neurosis, alcohol withdrawal, dementia in the elderly, and attention deficit disorders in children. Thioridazine shares many characteristics with chlorpromazine, but ECG changes and retinal pigmentation is more common than with chlorpromazine. Extrapyramidal effects are rare, and sedation and anticholinergic effects are more pronounced. The half-life is 26-36 hours. Adverse effects include anxiety, extrapyramidal reactions, pseudoparkinsonian signs and symptoms, seizures, hypotension, tachycardia and arrhythmias, agranulocytosis, leukopenia, amenorrhea, galactorrhea, and gynecomastia.

Thiothixene, Blood

Synonyms Navane®

Reference Range Therapeutic: 10-40 ng/mL

Specimen Blood

Volume 10 mL

Minimum Volume 3 mL serum

Container Red top tube

Storage Instructions Refrigerate serum.

Possible Panic Range >200 ng/mL

Methodology High performance liquid chromatography (HPLC)

Additional Information Thiothixene, a thioxanthene derivative, is used to manage psychotic disorders. It is similar pharmacologically and chemically to chlorprothixene and the piperazine phenothiazines. Therapeutic effects are achieved 1-6 hours after an I.M. injection and the half-life is 34 hours. Adverse effects include anticholinergic effects, tachycardia, hypotension, and ECG changes, drowsiness, insomnia, seizures, nonreversible tardive dyskinesia, gynecomastia, amenorrhea, and transient leukopenia.

Toxicology Drug Screen, Blood

Related Information

- Toxicology Drug Screen, Urine

Applies to Comatose Profile

Synonyms Drug Screen, Comprehensive Panel or Analysis

Uses Monitor toxic/overdose situations; most desirable to analyze in conjunction with urine toxicology testing; used to quantitate drug identified qualitatively in urine

Test Commonly Includes Amobarbital, butabarbital, butalbital, chlor-diazepoxide, diazepam, ethchlorvynol, glutethimide, meprobamate, methaqualone, pentobarbital, phenobarbital, secobarbital, ethanol, methanol, acetone, isopropanol, acetaminophen, phenytoin, salicylates, tricyclics, other drugs could also be analyzed.

Abstract This toxicology screen is carried out by performing individual quantitative tests for each drug. Many times urine qualitative screening is faster and more useful in toxicologic emergencies but both may be needed. Recent introduction of systems such as the Remedi® make an automated approach to this screen possible.

Specimen Blood

Volume 10 mL

Minimum Volume 5 mL serum or plasma

Container Red top tube or lavender top (EDTA) tube; do **not** collect blood in heparinized tubes.

Causes for Rejection Specimen collected in heparinized tube

Limitations Evidence for presence of a drug/drug metabolite (screening, qualitative) in the case of most groups of therapeutic agents and drugs of abuse will be found in urine rather than serum. See Toxicology Drug Screen, Urine. **All agents identified in a screening test should be confirmed with a specific test.**

Methodology Immunoassay, thin-layer chromatography (TLC), gas chromatography (GC), high performance liquid chromatography (HPLC), colorimetry, spectrophotometry

Additional Information If only documentation of exposure to toxic drugs or drugs of abuse is desired, a urine drug screen is the most economical approach. See listing for Toxicology Drug Screen, Urine. When Toxicology Drug Screen, Blood is ordered, the individual drugs are quantitated in serum. When Toxicology Drug Screen, Urine is ordered, qualitative identification is carried out.

Toxicology Drug Screen, Gastric

Synonyms Gastric Aspirate, Drug Screen

Uses Detect drug abuse; evaluate toxicity

Reference Range None detected

Test Commonly Includes Amobarbital, amphetamine, butabarbital, codeine, heroin (as morphine), meperidine, methadone, methamphetamine, pentobarbital, phencyclidine (PCP), phenobarbital, phenothiazines, propoxyphene, quinine, secobarbital

Specimen Gastric aspirate

Volume 50 mL

Minimum Volume 30 mL

Container Plastic urine container

Special Instructions Specify the drug or drugs suspected.

Methodology Thin-layer chromatography (TLC)

Toxicology Drug Screen, Urine

Related Information

- Toxicology Drug Screen, Blood

Applies to Narcotics Drug Screen, Urine

Synonyms Abuse Screen; DAU-10; DAU; Drug Screen, Comprehensive Panel or Analysis, Urine; Pre-employment Drug Screen

Uses Screen for drug of abuse, drug overdose/toxicity alone, or in conjunction with serum/plasma testing

Reference Range None detected or negative (less than cutoff for drugs of abuse)

Test Commonly Includes A variety of qualitative screens are in use. Sensitivity and specificity vary and are method dependent. Screens should detect drugs (qualitatively) in the following classes: amphetamines, analgesics, anticonvulsants, antidepressants, antihistamines, cardiacs, narcotics, sedative/hypnotics, tranquilizers, volatiles, and drugs of abuse. Screens for common classes of abused drugs: Amphetamines, barbiturates, benzodiazepines, cannabinoids, cocaine, methadone, methaqualone, opiates, phencyclidine, propoxyphene. In some laboratories, urine ethanol is included.

Abstract This is a qualitative screen which, in the case of thin-layer chromatography or automated high performance liquid chromatography, can detect any of several hundred drugs. The usual drug-of-abuse screening panel consists of the 10 drugs listed above under "test includes".

Specimen Random urine.

Volume 50-100 mL

Minimum Volume 50 mL

Container Plastic urine container

Collection If forensic, observe precautions.

Storage Instructions Keep refrigerated

Causes for Rejection If forensic, failure to meet temperature requirements and tests for unusual urine dilution or alteration

Special Instructions Specify the drug or drugs suspected; if forensic, use chain-of-custody protocol and form

Limitations Test provides **only** qualitative detection of drugs, unless laboratory automatically confirms and quantitates drugs detected as a part of the "screening" procedure. Quantitation of urine drug levels is usually not included and is not recommended because urine levels are time and clearance dependent and are not directly related to toxic symptoms seen clinically. Some drugs and/or metabolites are not detected or optimally detected in urine, again relating to method. Serum may be preferable because of clinical, and at times technical/kinetic, factors (eg, barbiturates, phenytoin). Sensitivity is of the order of 0.5-1.0 mcg/mL for TLC of urine. Some substances should be quantitated in blood or serum (eg, iron overdose, methanol, acetaminophen, salicylate, carbon monoxide, ethanol, digoxin, lithium, theophylline, and methemoglobin). Ofloxacin can cause the EMIT II drug screen to become positive for opiates.

In a nonclinical setting (eg, pre-employment drug screening, etc), the sample should be collected under chain-of-custody, and all positive screens must be confirmed by a different, more sensitive method, preferably GC/MS. The transportation industry [Department of Transportation (DOT)] tests certain employees by screening for five classes of drugs only (amphetamines, cannabinoids, cocaine, opiates, phencyclidine) and confirms all positive results with GC/MS. National Institute on Drug Abuse (NIDA) certification required to perform tests for DOT. (See Federal Register 49(40), December 19, 2000 at www.dot.gov/ost/dapc.) Chain-of-custody protocol must be followed for these specimens. Any agent identified in a screening test **should be confirmed** by a test specific for that drug (usually GC/MS).

Methodology A variety of methods or combination of methods are in fairly common use and include thin-layer chromatography (TLC), colorimetry/spectrophotometry, enzyme immunoassay technique (EIA), enzyme-multiplied immunoassay technique (EMIT), gas chromatography (GC), gas chromatography/mass spectrometry (GC/MS), high performance liquid chromatography (HPLC).

Additional Information

Some toxins (eg, metals, volatiles, gaseous compounds) may require specific methodology (eg, atomic absorption spectrophotometry, gas chromatography). Lactate dehydrogenase and lactate can cause false-positive serum ethanol screen (by EMIT) in the postmortem state. Postmortem urinary lactate dehydrogenase levels (>592 units/L) and lactate levels (>12 mM) and proteinuria can lead to false positive results on drugs of abuse screening by enzyme-multiplied immunoassay techniques (EMIT) and are unlikely to be of clinical significance in living samples. Aspirin or bleach can cause a reduction of immunoassay signal. Causes of false positive tricyclic antidepressant urine drug screens include cyclobenzaprine, diphenhydramine, cyproheptadine, carbamazepine, thioridazine, and quetiapine.

Mean confirmation rates for initial urinary immunoassay are for:

	Range
Cocaine metabolite	98.1% (91.1 to 99.9%)
Opiates	30.2% (17.3 to 55.9%)
Phencyclidine	69.7% (51.6 to 91%)
Marijuanae metabolite	91% (73 to 98.8%)

Amphetamine	
Screened once	51.9% (37.4 to 77.8%)
Screened twice	82.8% (81.3 to 84.3%)

Toxicology Studies, Not Specifically Listed

Synonyms Drug Analysis, Not Specifically Listed; Drug Levels, Not Specifically Listed

Uses Confirm toxicity due to a specific drug; detect drug abuse

Contraindicating Factors Suspect drug identity doubtful or unknown

Reference Range None detected

Specimen Blood, urine, gastric washings

Volume 30 mL blood, 100 mL urine, 100 mL gastric washings

Minimum Volume As much of specified volume as possible

Container Gray top (sodium fluoride) tube, plastic urine container, 100 mL plastic gastric washing bottle

Special Instructions Specify the drug or drugs suspected.

Limitations Analysis will be limited to those drugs specifically requested. Toxicologic screening for drugs is extremely expensive and seldom results in modification of the patients therapy. The potential effect of the data obtained on the patients course and therapy should be carefully considered before the studies are requested.

Toxicology, Steroid Drug Screen, Urine

Synonyms Steroid Drug Screen, Urine

Uses Detect anabolic steroid use in athletes

Test Commonly Includes Anabolic steroids screen and testosterone/epitestosterone ratio; confirmation of positive results is available.

Patient Preparation Sample collection should be observed and specimen chain of custody should be documented.

Specimen Random urine

Volume 100 mL

Minimum Volume 50 mL

Container Glass bottle

Collection Freshly voided random urine

Special Instructions Specify the drug or drugs suspected.

Methodology Chromatography

Toxicology, Stimulant Panel, Urine

Synonyms Urine Stimulant Drug Screen

Uses Detect drug abuse; evaluate toxicity

Reference Range None detected

Test Commonly Includes Qualitative identification of D-amphetamine, methamphetamine, phentermine, phenmetrazine, phenylpropranolamine, cocaine, phencyclidine

Specimen Random urine

Volume 30 mL

Minimum Volume 20 mL

Container Plastic urine container

Collection Freshly voided random urine

Special Instructions Specify the drug or drugs suspected.

Limitations This test provides **only** qualitative detection of drugs. Quantitation of urine drug levels is not included and is not recommended

because urine levels are time and clearance dependent and are not directly related to toxic symptoms seen clinically.

Methodology Enzyme immunoassay (EIA), gas chromatography (GC)

Toxicology, Opiates Drug Screen, Urine with Confirmation

Uses Detect drug abuse; evaluate toxicity

Test Commonly Includes Codeine, Darvon®, Demerol®, Dolophine®, heroin, meperidine, methadone, morphine, oxycodone, pentazocine, Percodan®, propoxyphene, Talwin®

Specimen Random urine

Volume 50 mL

Minimum Volume 10 mL aliquot

Container Plastic urine container

Collection Freshly voided random urine

Storage Instructions Refrigerate

Special Instructions Specify the drug or drugs suspected.

Critical Values Toxic propoxyphene: 0.4-14.0 mcg/mL

Limitations This test provides **only** qualitative detection of drugs. Quantitation of urine drug levels is not included and is not recommended because urine levels are time and clearance dependent and are not directly related to toxic symptoms seen clinically.

Methodology Thin-layer chromatography (TLC) and enzyme immunoassay (EIA), gas chromatography (GC) for confirmation

Additional Information

Opiates in general are a group of drugs (commonly referred to as narcotics) which are used medically to relieve pain, but which also have a high potential for abuse.

A qualitative urine screen for opiates is performed in suspected overdose cases or as part of a drug of abuse program. The test is most sensitive for morphine and codeine but other drugs will cross react in an immunoassay and give positive results (eg, hydrocodone, hydromorphone). All presumptive positive assays are confirmed by GC/MS. Morphine is a prescribed drug for pain relief, a metabolite of heroin, a metabolite of codeine and a constituent of poppy seeds. Its presence in urine, even after confirmation must be interpreted very carefully.

Opiates tend to relax the user. When the opiates are injected, the user feels an immediate "rush." Other initial and unpleasant effects include restlessness, nausea, and vomiting. The user may go "on the nod," going back and forth from feeling alert to drowsy. With very large doses, the user cannot be awakened, pupils become smaller, and the skin becomes cold, moist, and bluish in color. Furthermore, breathing slows down and death may occur. Clearance may be slower in geriatric patients.

Trazodone, Blood

Synonyms Desyre® Level, Blood

Uses Therapeutic monitoring; toxicity assessment

Reference Range Therapeutic: 0.5-2.5 mcg/mL (SI: 1-6 µmol/L)

Abstract This drug is an antidepressant chemically unrelated to the tricyclic or tetracyclic antidepressants.

Specimen Blood

Container Red top tube or green top (heparin) tube

Sampling Time Trough: just before next dose

Critical Values >2.5 mcg/mL (SI: >6 µmol/L)

Possible Panic Range 4 mcg/mL (SI: 10 µmol/L)

Methodology High performance liquid chromatography (HPLC), gas chromatography (GC)

Additional Information Trazodone is a structurally unique antidepressant that is pharmacologically different from other drugs of this class. The toxicities observed in tricyclic overdose (neuro- and cardiotoxicity and respiratory depression) are not seen with trazodone. Chronic toxicity is very low with trazodone although it does have unique side effects including akathisia, allergic reactions, chest pain, delayed urine flow, early and delayed menses, hypersalivation and hypomania, among others. The half-life of trazodone is 4-7 hours, peak plasma concentrations with average daily dosing is reached in 2-4 hours.

Tricyclic Antidepressants, Blood

Related Information

- Donor Victims of Poisoning in Whom Transplantation of Organs Occurred

Synonyms Antidepressants; TAD; TCA; Tetracyclic Antidepressants

Uses Therapeutic monitoring; toxicity assessment

Contraindicating Factors Patient taking more than one tricyclic antidepressant, patient taking phenothiazines or monoamine oxidase inhibitors

Reference Range

Therapeutic:

- amitriptyline: 100-250 ng/mL (SI: 360-900 nmol/L)
- amoxapine: 50-400 ng/mL
- desipramine: 150-300 ng/mL (SI: 563-1126 nmol/L)
- doxepin: 100-200 ng/mL (SI: 360-720 nmol/L)
- imipramine: 75-250 ng/mL (SI: 279-890 nmol/L)

- maprotiline: 150-400 ng/mL (SI: 541-1442 nmol/L)
- nortriptyline: 50-150 ng/mL (SI: 190-570 nmol/L)
- protriptyline: 50-150 ng/mL (SI: 190-570 nmol/L)
- trazodone: 300-1600 ng/mL

Abstract Drugs in this class are widely used as antidepressants. They are frequently involved in suicidal ingestion and responsible for a large percentage of drug-related deaths.

Specimen Blood

Volume 7 mL

Container Red top tube, green top (heparin) tube; avoid serum separator tubes and the plasticizer, TBEP.

Sampling Time Steady-state specimen after 1 week of dose schedule; draw specimen 12 hours after the last dose.

Storage Instructions Remove serum within 2 hours of drawing; refrigerate or freeze if not analyzed immediately.

Special Instructions Order individual drug level or tricyclic overdose screen

Possible Panic Range >500 ng/mL; toxicity observed at ≥300 ng/mL

Limitations Immunoassays for tricyclic antidepressants (toxic overdose) do not distinguish between parent compounds and active metabolites. Immunoassays are available for amitriptyline, nortriptyline, desipramine, and imipramine. Drug-drug interactions occur; hydrocortisone, neuroleptics, methylphenidate, cimetidine, and oral contraceptives produce higher levels by inhibiting metabolism of tricyclics by the liver. Barbiturates, chloral hydrate, and glutethimide lower plasma tricyclic levels by stimulating liver microsomal activity. Cigarette smoking also lowers steady-state plasma levels, apparently by a similar hepatic enzyme induction mechanism. Red blood cell metabolite assays may be a more sensitive biomarker for cardiac conduction disturbances.

Methodology Immunoassay, gas chromatography (GC), gas chromatography/mass spectrometry (GC/MS), high performance liquid chromatography (HPLC)

Additional Information

Tricyclic antidepressants (TADs) are metabolized to secondary active compounds. These agents are useful in treating clinical depression, and enuresis (imipramine). However, they show a narrow therapeutic window, and great individual variations in blood levels associated with dosage. Blacks usually have 50% greater blood level than whites for same dose schedule. Symptoms of overdose may mimic those of condition for which agent was prescribed. The most important of the more serious or toxic effects of TADs is cardiotoxicity. Arrhythmias and conduction defects with precipitation of congestive heart failure and possibly myocardial infarction are common at combined levels > 1000 ng/mL. Widening of the QRS interval to > 100 msec is highly suggestive of a TAD overdose.

Tricyclic antidepressant drugs represent a frequent and serious problem in both unintentional and intentional overdosage. Reports of poor correlations between plasma levels and toxic clinical manifestations indicate that QRS duration > 100 msec may provide the most reliable indicator of toxicity. It has been reported that levels of parent to metabolite (P/M) ratios >2 are associated with acute overdosage. In contrast, P/M ratios <2 are more consistent with high steady-state plasma levels following "therapeutic" dosages although ECG or other clinical evidence of toxicity may be present. Variations in blood levels between doses are comparatively small. Peak levels occur 4-8 hours after oral ingestion. A level dose of medication should be prescribed for at least 2 weeks to obtain steady plasma levels. Monitoring of tricyclic antidepressant plasma levels is useful in a number of situations. Older patients may develop higher steady-state plasma levels than younger individuals. In geriatric patients conventional doses may lead to toxic levels. Toxic plasma levels of tricyclic drugs may be dangerous in cardiac disease patients. Recommended lower and higher plasma levels for the different tricyclic drugs are evolving and are discussed in the literature.

Thyroxine, Blood

Synonyms T₄ (RIA); T₄ by EIA; T₄; Tetraiodothyronine; Thyroxine by RIA

Uses Best general thyroid function screening test. **Decreased** in hypothyroidism, in genetically decreased TBG, and in the third stage of (painful) subacute thyroiditis; **increased** with hyperthyroidism, with subacute thyroiditis in its first stage, with thyrotoxicosis due to Graves' disease, with increased TBG (pregnancy, genetically increased TBG, acute intermittent porphyria, primary biliary cirrhosis), thyrotoxicosis factitia, and occasionally in euthyroid patients with familial dysalbuminemic hyperthyroxinemia. Used to diagnose T₄ thyrotoxicosis.

Primary hypothyroidism (hypometabolism) is caused by Hashimoto's thyroiditis, idiopathic myxedema, prior radioactive iodine therapy for hyperthyroidism, prior thyroid surgery, endemic goiter and other entities. Congenital causes include enzyme blocks and agenesis. Causes of **secondary hypothyroidism** include primary pituitary disease (eg, postpartum pituitary necrosis (Sheehan's syndrome) and pituitary tumors). The expression "myxedema" indicates advanced clinical hypothyroidism, with dermal mucopolysaccharide deposits. Comprehensive lists of causes of hypothyroidism are published. A diagnosis of primary hypothyroidism should be confirmed by a TSH assay.

Graves' disease is classical thyrotoxicosis (hypermetabolism) caused by an immune or autoimmune disorder. Other causes of **hyperthyroidism** include toxic multinodular or uninodular goiter, phases of thyroiditis and a number of uncommon to rare entities, which cause increased T₄. Tabulations of causes of hyperthyroidism are widely available.

T₄ and other tests are used to investigate goiter, an expression for thyroid enlargement, which may be found with hypothyroidism, euthyroidism, or hyperthyroidism.

Reference Range

Pediatrics: Cord T₄ and values in the first few weeks are much higher, falling over the first months and years; 10 years and older: approximately 5.8-11.0 mcg/dL (SI: 75-142 nmol/L), varying somewhat between laboratories. Borderline low is ≤4.5-5.7 mcg/dL (SI: ≤58-73 nmol/L); low is ≤4.4 mcg/dL (SI: ≤57 nmol/L); results <2.5 mcg/dL (SI: <32 nmol/L) are strong evidence for hypothyroidism.

Approximate adult normal range is given by Ingbar as 4.0-12.0 mcg/dL (SI: 51-154 nmol/L) and by Larsen as 5.0-11.0 mcg/dL (SI: 64-142 nmol/L); borderline high is 11.1-13.0 mcg/dL (SI: 143-167 nmol/L); high is ≥13.1 mcg/dL (SI: ≥169 nmol/L). High is sometimes given as ≥8-10 mcg/dL (SI: ≥103-129 nmol/L). Normal range is increased in women on birth control pills, owing to increased TBG. Free thyroxine index will still be within the normal range. Normal range in pregnancy: approximately 5.5-16.0 mcg/dL (SI: 71-206 nmol/L).

Drug Interactions Decreased serum concentration with concomitant ritonavir

Abstract Thyroxine (T₄) is the major secretory product of the thyroid gland. It is carried through the blood bound (in equilibrium) to thyroxine binding globulin (TBG), prealbumin, and albumin. T₄ secretion is stimulated by thyroid stimulating hormone (TSH).

Patient Preparation Avoid radioisotope administration prior to collection of specimen.

Specimen Blood

Volume 7 mL

Minimum Volume 1 mL serum

Container Red top tube

Storage Instructions Separate serum within 48 hours and refrigerate. Separated serum stable 1 week at 25°C.

Possible Panic Range At values <2.0 mcg/dL (SI: <26 nmol/L), myxedema coma is possible. At values >20.0 mcg/dL (SI: >257 nmol/L), thyroid storm is possible.

Limitations

T₄ may be increased with excess intake of iodine or or with surreptitious use of thyroxine. T₄ levels may be abnormal in the presence of systemic nonthyroidal disease. Alterations in binding capacity or quantity of TBG may increase or decrease total thyroxine without causing symptoms. A common cause of elevated T₄ in nonthyroidal disease is said to be liver disease.

Serum thyroxine and free thyroxine (FT₄) are increased in familial dysalbuminemic hyperthyroxinemia, a euthyroid syndrome in which an abnormal binding site has affinity for thyroxine. The T₃ is usually normal in this entity, as is T₃ uptake. Thus, T₃ uptake is commonly ordered with T₄. T₄ is less sensitive than TSH in the diagnosis of hypothyroidism.

Euthyroid hyperthyroxinemia has been reviewed. It is an expression used as a collective term for nonthyroidal diseases and states which increase thyroxine levels with normal thyroid tissue and metabolism. In addition to thyroid hormone binding globulin changes and drug related phenomena, peripheral resistance to thyroid hormones and increases related to medical and acute psychiatric illness are described. Hyperemesis gravidarum and hyponatremia may cause euthyroid hyperthyroxinemia. Extensive tabulations of thyroid tests and some causes of changes in them have been published.

Anti-T₄ antibodies may exist, interfering with T₄ and free T₄ determinations. Heparin can cause false readings by interfering with assays.

Methodology Radioimmunoassay (RIA), enzyme-linked immunosorbent assay (ELISA), fluorescence polarization immunoassay (FPIA), chemiluminescence assay (CIA)

Additional Information

The combination of the serum T₄ and T₃ uptake as an assessment of TBG, helps to determine whether an abnormal T₄ value is due to alterations in serum thyroxine binding globulin or to changes of thyroid hormone levels. Deviations of both tests in the same direction usually indicate that an abnormal T₄ is due to abnormalities in thyroid hormone. Deviations of the two tests in opposite directions provide evidence that an abnormal T₄ may relate to alterations in TBG. See table.

Thyroid Tests with Disease and Varying TBG			
Diagnosis	T ₄	FT ₄ (or FT ₄ I)	TSH
Normal	Normal	Normal	Normal
Hyperthyroid	Increased	Increased	Decreased
Hypothyroid	Decreased	Decreased	Increased
Increased TBG	Increased	Normal	Normal
Decreased TBG	Decreased	Normal	Normal

UREA NITROGEN, BLOOD

Causes of increased TBG binding include neonatal state, molar and conventional pregnancy, estrogens, oral contraceptives, heroin, methadone, 5-fluorouracil, clofibrate, infectious hepatitis, chronic active hepatitis, and primary biliary cirrhosis, acute intermittent porphyria, lymphoma, and hereditary TBG increase.

Causes of decreased TBG binding include abnormal protein states. These include nephrotic syndrome, androgens, anabolic steroids, prednisone, acromegaly, liver or other systemic illness, severe stress, and hereditary TBG deficiency. Salicylates and diphenylhydantoin may lower T₄ significantly. Amiodarone may cause increased thyroxine levels and can cause hypothyroidism or hyperthyroidism.

Lithium carbonate may cause goiter with or without hypothyroidism.

Carbamazepine (Tegretol®) is reported to cause decreased values in thyroid function tests.

This brief review must point out that clinical interpretation of patients' signs and symptoms has primary significance. Definitive treatment based on insufficient laboratory tests is condemned.

The sensitive TSH assay has been advocated as a single screening test for thyroid disease. Such proposals are controversial; others find it difficult to accept one test as adequate for screening and warn that a single test cannot adequately, in all settings, reflect thyroid status. An inverse relationship exists between thyroxine and TSH. While the former represents thyroid hormone concentration, the latter is a test of thyroid regulation.

Agents that interfere with the TSH assay resulting in falsely low TSH levels include dopamine, levodopa, bromocriptine, dexamethasone (>0.5 mg/day), hydrocortisone (>100 mg/day), octreotide, and amphetamines.

Agents that produce falsely elevated TSH values (usually <10 units/L) include metoclopramide (>1 mg/kg), amiodarone, and iodinated radiographic contrast media (ipodate, iopanic acid, tyropanoate).

Agents which cause a falsely increased free thyroxine level include intravenous furosemide (>80 mg/day), salicylates (>2 g/day), salsalate (>1.5 g/day), diclofenac, naproxen, I.V. heparin (producing a five-fold increase in free thyroxine), amiodarone, and iodinated contrast media.

Agents which produce sustained reductions of both free thyroxine and free triiodothyronine levels include phenytoin and carbamazepine - at therapeutic levels.

Specific Reference

Lo DK, Szeto CC, and Chan TY, "Mild Symptoms of Toxicity Following Deliberate Ingestion of Thyroxine," *Vet Hum Toxicol*, 2004, 46(4):192-3.

Osmolality (mOsm/kg H₂O) may be calculated as follows: Osmolality = [Na⁺ (mM/L) × 2] + urea N (mg/dL)/2.8 + glucose (mg/dL)/18.

Reference Range Birth to 1 year: 4-16 mg/dL (SI: 1.4-5.7 mM/L); 1-40 years: 5-20 mg/dL (SI: 1.8-7.1 mM/L); gradual slight increase subsequently occurs >40 years of age.

Abstract Urea nitrogen reflects the ratio between urea **production** and **clearance**. Increased BUN may be due to increased production or decreased excretion. Although we commonly use the expression "BUN," most laboratories use serum, occasionally plasma but never whole blood.

Specimen Blood

Volume 10 mL

Minimum Volume 3 mL serum or plasma

Container Red top tube. Avoid fluoride and sodium citrate tubes if urease reaction is used and ammonium heparin tubes when conductometric method is used. EDTA is suitable as well as lithium heparin for young children.

Collection Pediatrics: Blood drawn from heelstick for capillary (lithium heparin tube)

Storage Instructions Stable 1 day at room temperature, 3 days at 4°C to 8°C, and 3 months at ~20°C.

Possible Panic Range BUN >100 mg/dL (SI: >35.7 mM/L) has been used in the definition of uremia.

Limitations Uremia is best evaluated with creatinine as well as urea nitrogen. In both prerenal and postrenal azotemia, for instance, BUN is apt to be increased somewhat more than is creatinine. In chronic progressive renal disease, ~75% of renal parenchyma must be damaged or destroyed before azotemia develops. BUN lacks sensitivity and specificity, but still remains a useful test.

Methodology Diacetyl monoxime; urease, Berthelot reaction; rate conductivity

Additional Information Although creatinine is generally considered a more specific test to evaluate renal function, they are commonly used together. Luke points out that clinical renal failure is variable between individual patients. Drug effects have been summarized.

Urea Nitrogen, Blood

Synonyms Blood Urea Nitrogen; BUN

Uses

High BUN occurs in chronic glomerulonephritis, pyelonephritis, and other causes of chronic renal disease; with acute renal failure, decreased renal perfusion (prerenal azotemia) as in shock. With urinary tract obstruction BUN increases (postrenal azotemia), for example as caused by neoplastic infiltration of the ureters, hyperplasia, or carcinoma of the prostate. BUN is useful to follow hemodialysis and other therapy. "Uremia" was defined by Luke as an expression of a constellation of signs and symptoms in patients with severe azotemia secondary to acute or chronic renal failure. Causes of increased BUN include severe congestive heart failure, increased protein catabolism, tetracyclines with diuretic use, hyperalimentation, ketoacidosis, and dehydration as in diabetes mellitus, but even moderate dehydration can cause BUN to increase. Corticosteroids tend to increase BUN by causing increased protein catabolism. Bleeding from the GI tract is an important cause of high urea nitrogen, commonly accompanied by elevation of BUN/creatinine ratio. Nephrotoxic drugs must be considered. Chloral hydrate or chloramphenicol can cause false elevation. Steroids and tetracycline can stimulate a catabolic response resulting in high BUN without renal impairment.

Borderline high values may occur after recent ingestion of high protein meal and muscle wasting may cause an elevation as well.

With creatinine, BUN is used to monitor patients on dialysis.

Low BUN occurs in late normal pregnancy, decreased protein intake, with intravenous fluids, with some antibiotics, and in severe liver damage.

As described by DeCaux et al in 1980, in the syndrome of inappropriate secretion of antidiuretic hormone (SIADH), findings include hyponatremia with serum or plasma sodium ≤128 mM/L, serum hypo-osmolality, <260 mOsm/kg, with urine osmolality >300 mOsm/kg (SI: >300 mM/kg) with low BUN. Such findings occur in situations in which patients are overhydrated. Clinical findings included absence of edema or evidence of heart, liver, thyroid, renal or adrenal disease. Hypouricemia, with uric acid levels in 16 of 17 patients <4 mg/dL (SI: <238 μmol/L), is reported with the syndrome of inappropriate secretion of antidiuretic hormone. SIADH can be seen with higher serum sodiums and higher osmolalities. Urine osmolality is greater than serum osmolality in SIADH. Chloramphenicol or streptomycin can cause false depression.

Urinalysis

Applies to Casts, Urine

Synonyms UA

Uses Screen for abnormalities of urine; diagnose and manage renal diseases, urinary tract infection, urinary tract neoplasms, systemic diseases, and inflammatory or neoplastic diseases adjacent to the urinary tract

Reference Range

Crystals are interpreted by the physician. Warm, freshly voided urine sediment from normal subjects almost never contains crystals, despite maximal concentration. Xanthine, cystine, and uric acid crystal (and stone) formation is favored by a consistently acid urine (pH <5.5-6). Calcium oxalate and apatite stones are associated with no particular disturbance of urine pH. Calcium carbonate, calcium phosphate, and especially magnesium ammonium phosphate stones are associated with pH >7. Urine pH >7.5 may briefly follow meals (alkaline tide) but more commonly indicate systemic alkali intake (NaHCO₃, etc) or urine infected by bacteria which split urea to ammonia. See table.

Urinalysis	
Test	Reference Range
Specific gravity	1.003-1.029
pH	4.5-7.8
Protein	Negative
Glucose	Negative
Ketones	Negative
Bilirubin	Negative
Occult blood	Negative
Leukocyte esterase	Negative
Nitrite	Negative
Urobilinogen	0.1-1.0 EU/dL
WBCs	0-4/hpf
RBCs	male: 0-3/hpf female: 0-5/hpf
Casts	0-4/lpf hyaline
Bacteria	Negative

hpf = high power field
lpf = low power field
EU = Ehrlich units

Diagnostic Procedures

- Crystals, Urine

Test Commonly Includes Opacity, color, appearance, specific gravity, pH, protein, glucose, occult blood, ketones, bilirubin, and in some laboratories, urobilinogen and microscopic examination of urine sediment. Some laboratories include screening for leukocyte esterase and nitrite and do not perform a microscopic examination unless one of the chemical screening (macroscopic) tests is abnormal or unless a specific request for microscopic examination is made.

Abstract The examination of urine is one of the oldest practices in medicine. A carefully performed urinalysis still provides a wealth of information about the patient, both in terms of differential diagnosis, and by exclusion of many conditions when the urinalysis is "normal."

Patient Preparation Instructions should be given in method of collection. Both males and females need instruction in cleansing the urethral meatus. "Midstream collections" are performed by initiating urination into the toilet, then bringing the collection device into the urine stream to catch the midportion of the void.

Specimen Urine

Volume 5 mL

Minimum Volume 2 mL

Container Plastic urine container

Collection A voided specimen is usually suitable. If the specimen is likely to be contaminated by vaginal discharge or hemorrhage, a clean catch specimen is desirable. If the specimen is collected by catheter, it should be so labeled. The timing of urine collection will vary with the purpose of the test. To check for casts or renal concentration ability, a first voided morning specimen may be preferred. For screening purposes, this is also the best time, as a later and more dilute specimen may make small increases in protein, RBC, or WBC excretion harder to detect. The upright position increases protein excretion by hemodynamic factors. Midmorning urine is likely to give the highest albumin excretion, but early morning urine is best when attempting to detect Bence Jones protein.

Storage Instructions Transport specimen to the laboratory as soon as possible after collection. If the specimen cannot be processed immediately by the laboratory it should be refrigerated. Refrigeration preserves formed elements in the urine, but may precipitate crystals not originally present.

Causes for Rejection Specimen delayed in transport, fecal contamination, decomposition, or bacterial overgrowth

Possible Panic Range The presence of massive amounts of oxalate crystals in fresh urine should be reported promptly to the physician, as this finding may represent ethylene glycol intoxication.

Limitations Insufficient volume, less than 2 mL, may limit the extent of procedures performed. Metabolites of Pyridium® may interfere with the dipstick reactions by producing color interference. High vitamin C intake may cause an underestimate of glucosuria, or a false-negative nitrate test. Survival of WBCs is decreased by low osmolality, alkalinity, and lack of refrigeration. Formed elements in the urine including casts disintegrate rapidly, therefore the specimen should be analyzed as soon as possible after collection. Specific gravity is affected by glucosuria, mannitol infusion, or prior administration of iodinated contrast material for radiologic studies (IVP dye). Some brands of test strips give a "trace positive" protein indication if not stored in dry atmosphere (cap of test strip bottle not on tight). Ambient humidity exposure of the test strips over time also causes some reduction of sensitivity for occult blood and nitrate and increased sensitivity for glucose (false-positive). This can be detected by using tap water as a negative control. False-positive tests for protein can also be due to contamination of the urine by an ammonium-containing cleansing solution.

Methodology The chemical portion of the urinalysis is done by test strip, with confirming chemical method for protein (sulfosalicylic acid precipitation).

Additional Information**MICROSCOPY:**

Crystalluria is frequently observed in urine specimens stored at room temperature or refrigerated. Such crystals are diagnostically useful when observed in warm, fresh urine by a physician evaluating microhematuria, nephrolithiasis, or toxin ingestion.

In abundance, **calcium oxalate** and/or **hippurate crystals** may suggest ethylene glycol ingestion (especially if known to be accompanied by neurological abnormalities, appearance of drunkenness, hypertension, and a high anion gap acidosis.) Urine is usually supersaturated in calcium oxalate, often in calcium phosphate, and acid urine is often saturated in uric acid. Yet crystalluria is uncommon (in warm, fresh urine) because of the normal presence of crystal inhibitors, the lack of available nidus, and the time factor. When properly observed in fresh urine, crystals may provide a clue to the composition of renal stones even not yet passed, the nidus for such stones, or, as such, have been associated with microhematuria.

Uric acid crystals are reddish brown, rectangular, rhomboidal, or flower-like structures of narrow rectangular petals. **Ammonium urates**, in alkaline urine, are irregular blobs and crescents, sometimes resembling fragmented red cell shapes.

Calcium oxalate crystals are fairly uniform small double pyramids, base to base, which under the microscope look like little crosses on a square.

Calcium phosphate crystallizes in urine as flowers of narrow rectangular needles.

Cystine crystals, uniquely in urine, form large irregular hexagonal plates, which may dissolve if alkalinized. They occur only in the urine of subjects with cystinuria.

Calcium magnesium ammonium phosphate, or "triple phosphate," forms unique "coffin lid" angularly domed rectangles which may be present in massive quantities in alkaline urine. They usually are associated with urine infected by urea splitting bacteria which cause "infection," or "triple phosphate" stones.

Leukocyturia may indicate inflammatory disease in the genitourinary tract, including bacterial infection, glomerulonephritis, chemical injury, autoimmune diseases, or inflammatory disease adjacent to the urinary tract such as appendicitis or diverticulitis.

White cell casts indicate the renal origin of leukocytes, and are most frequently found in acute pyelonephritis. White cell casts are also found in glomerulonephritis such as lupus nephritis, and in acute and chronic interstitial nephritis. When nuclei degenerate, such leukocyte casts resemble renal tubular casts.

Red cell casts indicate renal origin of hematuria and suggest glomerulonephritis, including lupus nephritis. Red cell casts may also be found in subacute bacterial endocarditis, renal infarct, vasculitis, Goodpasture's syndrome, sickle cell disease, and in malignant hypertension. Degenerated red cell casts may be called "**hemoglobin casts**". Orange to red casts may be found with myoglobinuria as well.

Dysmorphic red cells are observed in glomerulonephritis. "Dysmorphic" red cells refer to heterogeneous sizes, hypochromia, distorted irregular outlines and frequently small blobs extruding from the cell membrane. Phase contrast microscopy best demonstrates RBC and WBC morphology. Nonglomerular urinary red blood cells resemble peripheral circulating red blood cells. Schramek et al have used the presence or absence of dysmorphic red cells to direct the degree of work-up for hematuria and for follow-up.

Crenated RBCs provide no implication regarding RBC source.

Dark brown or smoky urine suggests a renal source of hematuria.

A pink or red urine suggests an extrarenal source.

Hyaline casts occur in physiologic states (eg, after exercise) and many types of renal diseases. They are best seen in phase contrast microscopy or with reduced illumination.

Renal tubular (epithelial) casts are most suggestive of tubular injury, as in acute tubular necrosis. They are also found in other disorders, including eclampsia, heavy metal poisoning, ethylene glycol intoxication, and acute allograft rejection.

Granular casts: Very finely granulated casts may be found after exercise and in a variety of glomerular and tubulointerstitial diseases.; coarse granular casts are abnormal and are present in a wide variety of renal diseases.

"**Dirty brown**" granular casts are typical of acute tubular necrosis.

Waxy casts are found especially in chronic renal diseases, and are associated with chronic renal failure; they occur in diabetic nephropathy, malignant hypertension, and glomerulonephritis, among other conditions. They are named for their waxy or glossy appearance. They often appear brittle and cracked.

Fatty casts are generally found in the nephrotic syndromes, diabetic nephropathy, other forms of chronic renal diseases, and glomerulonephritis. The fat droplets originate in renal tubular cells when they exceed their capacity to reabsorb protein of glomerular origin. Their inclusions have the features and significance of oval fat bodies.

Broad casts originate from dilated, chronically damaged tubules or the collecting ducts. They can be granular or waxy. **Broad waxy casts** are called "renal failure casts."

Spermatozoa may be seen in male urine related to recent or retrograde ejaculation. In female urine, the presence of spermatozoa may provide evidence of vaginal contamination following recent intercourse.

Automation of the urinalysis is routine in many laboratories. Some authors wish to abandon microscopic evaluation of the urine, which is not easily automated, on urine samples testing "normal" by dipstick screening. A urine sample that is normal to inspection and dipstick will be normal to microscopic exam 95% of the time.

One instrument for automating the entire urinalysis, the Yellow IRIS®, includes a module that automates the microscopic sediment exam. This has been found to be more consistent than the manual method for routine urinalysis and has increased the number of abnormal urines detected.

Valproic Acid, Blood

Synonyms Depakene® Level, Blood; Depakote® (Enteric-Coated Divalproex Sodium), Blood; Depamide® Level, Blood; Epilim® Level, Blood; Ergenyl® Level, Blood

Uses Monitor for compliance, efficacy, and possible toxicity

Reference Range 50-100 mcg/mL (SI: 350-690 µmol/L). Low levels: The most important cause is noncompliance. Phenytoin, phenobarbital, primidone, and carbamazepine decrease the half-life of valproic acid.

VANCOMYCIN LEVEL

High levels: Carbamazepine and phenytoin can increase the level of valproic acid.

Abstract Valproic acid is a first-line anticonvulsant for absence seizures. It is useful for many other seizure types, including primary generalized tonic-clonic, myoclonic, atonic, and mixed seizures. It is the drug of choice for mixed absence and generalized seizures and for the epileptic syndromes of juvenile myoclonic epilepsy and generalized tonic-clonic seizures on awakening.

Specimen Blood

Volume 5 mL

Minimum Volume 3 mL serum or plasma

Container Red top tube or green top (heparin) tube

Sampling Time Trough values drawn just before next dose or consistent sampling time in chronic monitoring

Critical Values Toxic concentration >200 mcg/mL (SI: >1390 µmol/L). Seizure control may improve at levels >100 mcg/mL (SI: >690 µmol/L), but toxicity may occur at levels of 100-150 mcg/mL (SI: 690-1040 µmol/L).

Limitations Since valproic acid is highly bound, drugs that compete for protein binding sites can increase the amount of free valproic acid (biologically active fraction). These include dicumarol, high dose salicylates, and phenylbutazone. If toxicity is suspected, a free valproic acid level should be obtained.

Methodology Enzyme immunoassay (EIA), gas-liquid chromatography (GLC), high performance liquid chromatography (HPLC)

Additional Information

Indications for measurement of a serum antiepileptic drug level include:

- within 6 hours of a seizure
- suspected dose-related drug toxicity
- suspected patient noncompliance

Additional indications for serum drug assay during steady state conditions (after 6 days for phenytoin, 3 days for carbamazepine, 3 days for valproic acid, 20 days for phenobarbital) include:

- baseline measurement after starting antiepileptic drug therapy
- control measurement after a change in dosage regimen
- addition of a second drug with a potential interaction with the antiepileptic drug (ie, a second antiepileptic drug, warfarin, isoniazid or rifampicin)
- change in patient's hepatic or gastrointestinal function

Vancomycin Level

Synonyms Vancocin®

Uses Monitor therapeutic levels and potential toxicities, particularly in patients with impaired renal function and in patients also being treated with aminoglycoside antibiotics

Reference Range Therapeutic concentration: peak: 20-40 mcg/mL (SI: 14.0-27.0 µmol/L) (depends in part on minimum inhibitory concentration of organism being treated); trough: 5-10 mcg/mL (SI: 3.4-6.8 µmol/L)

Abstract Vancomycin is an antimicrobial agent with potent activity against most gram-positive bacteria. Its use has occasionally been associated with nephrotoxicity and/or ototoxicity, though the frequency of these toxicities has decreased as vancomycin preparations have become more purified.

Specimen Blood, body fluid

Volume 10 mL blood or 2 mL body fluid

Container Red top tube, sterile fluid container

Sampling Time Peak: 30 minutes following dose; trough: immediately prior to next dose

Storage Instructions Separate serum using aseptic technique and place in freezer

Causes for Rejection Specimen more than 4 hours old

Possible Panic Range Toxic: >80 mcg/mL (SI: >54.0 µmol/L)

Methodology High performance liquid chromatography (HPLC), gas-liquid chromatography (GLC), immunoassay

Additional Information Ototoxicity is seen primarily in patients with extremely high serum concentrations (80-100 mcg/mL) and rarely occurs when serum concentrations are maintained at ≤30 mcg/mL. Both ototoxicity and nephrotoxicity is enhanced by concurrent administration of aminoglycosides.

Volatile Screen

Applies to Acetone; Ethanol

Synonyms Toxicology, Volatiles

Uses Evaluate methanol and isopropanol toxicity, and alcohol drug abuse

Reference Range None detected

Test Commonly Includes Determination of volatiles by GLC including acetone, ethanol, isopropanol, and methanol. Note: Ethylene glycol is not considered to be a volatile alcohol.

Abstract This screening profile measures ethanol and other possible volatiles.

Specimen Blood, urine, gastric fluid

Volume 7 mL blood, 25 mL urine, 25 mL gastric washing

Minimum Volume 3 mL serum or plasma

Container Red top tube, gray top (sodium fluoride) tube; tightly stoppered container for urine and gastric fluid

Collection All containers should be tightly stoppered and transported on ice. The gray (oxalate/fluoride) tube top is recommended for medicolegal collections and if storage is prolonged. Sodium fluoride (50 mg) can be added as a preservative to urine and gastric samples. Other anticoagulants (eg, heparin EDTA) are acceptable.

Causes for Rejection Specimen leakage

Possible Panic Range Blood: acetone, methanol, isopropanol >500 mcg/mL (SI: acetone: >8610 µmol/L, methanol: >15.6 mM/L, isopropanol: >8.32 mM/L), ethanol: >2000 mcg/mL (SI: >43.4 mM/L); urine: acetone, methanol, isopropanol >500 mcg/mL (SI: acetone: >8610 µmol/L, methanol: >15.6 mM/L, isopropanol: 8.32 mM/L), ethanol: >1600 mcg/mL (SI: >34.7 mM/L)

Methodology Gas-liquid chromatography (GLC)

Warfarin, Blood

Applies to Anticoagulants, Oral

Synonyms Athrombin-K®; Coumadin®; Panwarfin®

Uses Therapeutic monitoring; toxicity assessment

Reference Range Therapeutic: 2-5 mcg/mL (SI: 6.5-16.2 µmol/L); free warfarin level: 5-23 ng/mL

Abstract Warfarin is an oral anticoagulant. Serum warfarin concentrations are seldom used to manage therapy; rather, typically, prothrombin time is used.

Specimen Blood

Volume 7 mL

Container Red top tube, lavender top (EDTA) tube

Possible Panic Range Toxic: >10 mcg/mL (SI: >32.4 µmol/L)

Limitations This test **does not** measure bishydroxycoumarin and should not be used to monitor this drug.

Methodology High performance liquid chromatography (HPLC), gas-liquid chromatography (GLC), UV spectrophotometry

Zalcitabine, Blood or Urine

Synonyms DDC

Uses AIDS therapy; therapeutic monitoring

Reference Range <10 ng/mL

Specimen Blood, urine

Volume 5 mL

Limitations Only used in combination with zidovudine; not approved for use in children; if used concurrently with drugs causing renal clearance problems, do so with caution

Methodology Radioimmunoassay (RIA), gas chromatography/mass spectrometry (GC/MS), high performance liquid chromatography (HPLC)

Additional Information Potential toxicities include congestive heart failure, cardiomyopathy. No liver metabolites have been identified in humans; half-life: 8.5 hours.

Zidovudine, Blood

Synonyms Azidothymidine; AZT; Retrovir®

Uses Not established for routine clinical use. Monitoring should probably be limited to studies on pharmacokinetics and efficacy of antiretroviral therapy.

Reference Range Not established

Abstract Azidothymidine (AZT) is the first FDA approved drug for the treatment of human immunodeficiency virus (HIV) infection, the cause of AIDS. The drug is a competitive inhibitor of HIV reverse transcriptase; it is incorporated into the viral DNA in place of thymidine and interrupts viral replication because the DNA can no longer elongate.

Specimen Blood

Minimum Volume Volume needed is method dependent (0.1-1 mL serum or plasma)

Container Red top tube preferred, green top (heparin) tube acceptable

Sampling Time Trough level, just before next dose

Causes for Rejection Incorrect specimen sampling time

Methodology High performance liquid chromatography (HPLC), radioimmunoassay (RIA), fluorescence polarization immunoassay (FPIA)

Additional Information Zidovudine is usually administered at a total daily dose of 500 mg (100 mg orally, every 4 hours while the patient is awake); optimal dosing, however, has not been established. Peak serum concentrations are attained within 30-40 minutes after ingestion. The drug has a half-life of approximately 1 hour; the main metabolite is a glucuronide derivative with no antiviral activity that is excreted by the kidneys. The major toxicity associated with zidovudine use is hematologic suppression which may manifest as anemia, leukopenia, and/or granulocytopenia. Monitoring hematologic parameters is the most reasonable approach toward evaluating toxicity; serum levels currently contribute little to evaluating toxic effects of zidovudine. Coadministration of probenecid results in increased serum levels due to competition for glucuronidation pathways. Hepatic and renal failure increases serum levels.

APPENDIX

UNINTENTIONAL POISONING DEATHS—UNITED STATES, 1999–2004

Reprinted from *MMWR*, February 9, 2007/56/05; 93–96

In 2004, poisoning was second only to motor-vehicle crashes as a cause of death from unintentional injury in the United States¹. Nearly all poisoning deaths in the United States are attributed to drugs, and most drug poisonings result from the abuse of prescription and illegal drugs². Previous reports have indicated a substantial increase in unintentional poisoning mortality during the 1980s and 1990s^{2,3}. To further examine this trend, CDC analyzed the most current data from the National Vital Statistics System. This report summarizes the results of that analysis, which determined that poisoning mortality rates in the United States increased each year from 1999 to 2004, rising 62.5% during the 5-year period. The largest increases were among females (103.0%), whites (75.8%), persons living in the southern United States (113.6%), and persons aged 15–24 years (113.3%). Larger rate increases occurred in states with mostly rural populations. Rates for drug poisoning deaths increased 68.3%, and mortality rates for poisonings by other substances increased 1.3%. The largest increases were in the “other and unspecified,” psychotherapeutic, and narcotic drug categories. The results suggest that more aggressive regulatory, educational, and treatment measures are necessary to address the increase in fatal drug overdoses.

Mortality data for 2004 were collected from the National Vital Statistics System¹. Unintentional poisoning deaths that occurred during 1999–2004 were defined as those with underlying cause-of-death codes X40–X49 from the *International Classification of Diseases, Tenth Revision* (ICD-10). This category included overdoses of illegal drugs and legal drugs taken for nonmedical reasons, poisoning from legal drugs taken in error or at the wrong dose, and poisoning from other substances (e.g., alcohol, pesticides, or carbon monoxide). Adverse effects of legal drugs taken in the proper doses and as directed are coded elsewhere in ICD-10 and were not included in this analysis. Rates were age adjusted to the 2000 U.S. Census population using bridged-race⁴ population figures. Information on the percentage of the population that was rural, defined as the percentage living in census blocks below a certain population density, was derived from U.S. Census data for 2000⁵.

The number of unintentional poisoning deaths increased from 12,186 in 1999 to 20,950 in 2004. The annual age-adjusted rate increased 62.5%, from 4.4 per 100,000 population in 1999 to 7.1 in 2004. The increase among females, from 2.3 to 4.7 per 100,000 population (103.0%), was twice the increase among males, from 6.5 to 9.5 per 100,000 population (47.1%) (Table 1). Among males, rates among whites, American Indians/Alaska Natives, and Asians/Pacific Islanders all increased approximately 50%. Rates among black males were highest in 1999 but did not increase. Among females, rates among whites more than doubled, whereas nonwhites had smaller increases or decreased. Overall, rates increased 75.8% among whites, 55.8% among American Indians/Alaska Natives, 27.4% among Asians/Pacific Islanders, and 11.2% among blacks. Rates among non-Hispanics increased more than rates among Hispanics for both sexes. Among all sex and racial/ethnic groups, the largest increase (136.5%) was among non-Hispanic white females. Among all age groups, the largest increase occurred among persons aged 15–24 years (113.3%). In 2004, the highest rates were among persons aged 35–54 years, who accounted for 59.6% of all poisoning deaths that year.

From 1999 to 2004, rates increased by less than one third in the Northeast and West but more than doubled in the South and nearly doubled in the Midwest.⁶ Delaware, Maryland, New York, and Rhode Island had decreases in rates, and California had the smallest increase (4.0%) (Figure). States with the largest relative increases were West Virginia (550%), Oklahoma (226%), Maine (210%), Montana (195%), and Arkansas (195%). Increases of 100% or more occurred in 23 states: 11.8% (two of 17) of states⁷ in the most urban tertile, 41.2% (seven of 17) of those in the middle tertile, and 82.4% (14 of 17) of those in the most rural tertile (extended Mantel-Haenszel chi-square for linear trend across the tertiles = 15.4, $p < 0.001$).

The increase in poisoning mortality occurred almost exclusively among persons whose deaths were coded as unintentional drug poisoning (X40–X44), for which the rate increased 68.3% (Table 2). The rate for poisoning deaths attributed to other substances (X45–X49) increased 1.3%. By 2004, drug poisoning accounted for 19,838 deaths, 94.7% of all unintentional poisoning deaths. Among types of drug poisoning, the greatest increases were in the “other and unspecified” drug, psychotherapeutic drug, and “narcotic and hallucinogen” drug categories.

Reported by: L Paulozzi, MD, Div of Unintentional Injury Prevention; J Annett, PhD, Office of Statistics and Programming, National Center for Injury Prevention and Control, CDC.

TABLE 1. Unintentional poisoning mortality rates,* by selected characteristics — United States, 1999 and 2004

Characteristic	1999	2004	Rate change (%)
Sex and race/ethnicity

Editorial Note

Unintentional drug poisoning mortality rates increased substantially in the United States during 1999–2004. Previous studies, using multiple cause-of-death data, have indicated that the trend described in this report can be attributed primarily to increasing numbers of deaths associated with prescription opioid analgesics (e.g., oxycodone) and secondarily to increasing numbers of overdoses of cocaine and prescription

FIGURE. Percentage change in unintentional poisoning mortality rates,* by rural status of state† — United States, 1999–2004

* Age-adjusted rates per 100,000 population.

† Defined as the percentage of the population living in census blocks below a certain population density, based on U.S. Census data for 2000 (4).

TABLE 2. Number of deaths and mortality rates* attributed to unintentional poisoning, by type of substance – United States, 1999 and 2004

Type of substance	ICD-10 [†] code	1999		2004		Rate change
		No.	Rate	No.	Rate	(%)
Drugs	X40–X44	11,155	4.0	19,838	6.7	68.3
Nonopioid analgesics [§]	X40	168	0.1	212	0.1	18.1

[†] *International Classification of Diseases. Tenth Revision.*

[§] Includes painkillers such as aspirin and acetaminophen and other antipyretic or antirheumatic drugs, both prescription and over-the-counter drugs.

[¶] Includes antiepileptic, sedative-hypnotic, antidepressant, antipsychotic, and other psychotherapeutic drugs.

^{**} Includes heroin opioid analgesics (e.g., oxycodone), and cocaine.

^{††} Category used to classify deaths attributed to drugs from more than one of the other categories (e.g., deaths attributed to both an opioid analgesic and a sedative) and deaths attributed simply to "drug overdose."

^{§§} Rates based on fewer than 20 deaths are not included.

^{¶¶} Includes corrosives, metals, plants, and detergents.

psychotherapeutic drugs (e.g., sedatives), and cannot be attributed to heroin, methamphetamines, or other illegal drugs^{3,8}.

The mortality increases might be the result of greater use and abuse of potentially lethal prescription drugs in recent years, behaviors that are more common among whites than nonwhites^{9,10}. The substantial increase in deaths among persons aged 15–24 years is consistent with substantial recent increases in recreational prescription drug and cocaine use among adolescents and young adults¹¹.

Studies by state health agencies have reported recent increases in prescription-drug–poisoning mortality in rural communities^{2,13}, despite historically higher rates in urban areas. The South and Midwest regions, which had the largest relative and absolute increases among regions in this study, are the most rural regions of the country⁵. Further research is needed to determine how differences in drug use, drug-abuse–control measures, and demographic characteristics (e.g., race/ethnicity) contribute to this pattern.

The findings in this report are subject to at least three limitations. First, mortality coding assigns the underlying cause of death to broad drug categories rather than to specific drugs. Second, death certificates do not reveal the circumstances of drug use. Third, determining the intent of a person who took a drug is often difficult for a coroner or medical examiner and might result in misclassification; some of these deaths might have been suicides, although not classified as such, and some deaths categorized as suicides or of undetermined intent might have been unintentional and therefore not analyzed in this study. The extent of this error is not known.

Effective response to increasing fatal drug overdoses requires strengthening regulatory measures to reduce unsafe use of drugs, increasing physician awareness regarding appropriate pharmacologic treatment of pain and psychiatric problems, supporting best practices for treating drug dependence, and potentially modifying prescription drugs to reduce their potential for abuse. State agencies that manage prescription-monitoring programs should use such systems to proactively identify 1) patients who abuse drugs and fill multiple prescriptions from different health-care providers and 2) providers whose prescribing practices are outside the standards of appropriate medical care. Both federal and state prevention measures should be evaluated periodically to determine their effectiveness.

ADDICTION TREATMENTS

Acamprosate (Campral®)	Maintenance of alcohol abstinence: 666 mg 3 times/day; 333 mg 3 times/day in patients with Cl_{cr} 30-50 mL/minute.
Buprenorphine (Buprenex®, Subutex®)	Opioid dependence: Induction: 12-16 mg/day; maintenance: 4-24 mg/day; target dose: 16 mg/day.
Buprenorphine and Naloxone (Suboxone®)	Opioid dependence: Induction: Not recommended; maintenance: 4-24 mg/day; target dose: 16 mg/day.
Bupropion SR (Zyban®)	Smoking cessation: Initiate at 150 mg every morning for 3 days. If tolerated, increase to 150 mg twice daily on day 4 of dosing. Should be an interval of at least 8 hours between successive doses. Target quit date after at least 1 week of treatment. Trial may be up to 12 weeks. Contraindicated in patients with seizures, anorexia, or bulimia.
Clonidine (Catapres®)	Alcohol, nicotine, opioid withdrawal: Initiate 0.1 mg 2-3 times/day.
Disulfiram (Antabuse®)	Management of chronic alcoholism: 125-500 mg/day; patients must be free of alcohol for at least 12 hours prior to initiation. Contraindicated with metronidazole and alcohol (including cough syrups).
Levomethadyl (Orlaam®)	Narcotic dependence: Initiate at 20-40 mg 3 times/week.
Methadone (Dolophine®)	Narcotic dependence: 15-60 mg every 6-8 hours; can only be initiated in approved treatment programs.
Naltrexone (ReVia®)	Alcohol and narcotic dependence: Initiate 25-50 mg/day; patient should be free of opioid for 7-10 days prior to initiation.
Nicotine gum	Smoking cessation: 1-2 pieces/hour; maximum: 30 pieces/day (2 mg/piece). If high tobacco use, give DS (4 mg/piece); maximum: 20/day.
Nicotine nasal spray	Smoking cessation: 1 spray in each nostril once or twice per hour; maximum: 80 sprays.
Nicotine patches	Smoking cessation: One patch daily for 8 weeks.

ADIPOSE TISSUE RANGES OF TOXINS

General Population (Background)

AGENTS FOR TREATMENT OF EXTRAPYRAMIDAL SYMPTOMS

A variety of agents exist for treatment of extrapyramidal symptoms (EPS) associated with the use of antipsychotic agents. See the Antiparkinsonian Agents Comparison Chart. These include anticholinergic agents, dopaminergic agents, levodopa, beta-blockers, clonidine, and benzodiazepines. Ideally, prevention of EPS should be attempted with lowest effective dosing of conventional antipsychotics or use of the newer atypical antipsychotics.

Anticholinergic drugs may be used to treat all forms of acute EPS and are generally considered first-line agents for these drug-induced syndromes. Anticholinergic agents are believed to work by normalizing the dopaminergic-cholinergic balance in the corpus striatum, although a clear understanding of exactly how this may occur remains lacking.

Anticholinergic medication should begin with benztropine 1-2 mg/day or an equivalent dosage of an alternative anticholinergic. For severe, painful, or potentially dangerous EPS, such as dysarthria or laryngospasm, anticholinergic medication may be given I.V. or I.M. I.V. anticholinergic (eg, benztropine 2 mg or diphenhydramine 50 mg) relieves EPS within 2-3 minutes, while I.M. administration requires 15-30 minutes for symptom relief. Individuals with a history of acute EPS should be given prophylactic anticholinergic medication. Additionally, clinicians may consider prophylactic anticholinergic medication for individuals with high risk for EPS (eg, young males on higher doses of high-potency conventional antipsychotic).

Geriatric patients generally require lower doses of anticholinergic drug. Adverse effects associated with anticholinergic medication include constipation, urinary retention, tachycardia, and blurred vision. Intraocular pressure may be increased, posing some danger for patients with narrow-angle glaucoma. In addition, some individuals, particularly elderly patients, may develop a delirium-like presentation associated with anticholinergics that is characterized by disorientation, hallucinations, behavioral lability, and cognitive impairment. Occasionally, patients may abuse anticholinergics.

Patients on anticholinergic medication should be reassessed on a regular basis to determine continued need for medication. A significant number of patients on antipsychotic medication exhibit spontaneous reduction or resolution of EPS during continued antipsychotic medication therapy, particularly during the first 3 months of treatment. Therefore, after this time period, one should consider tapering anticholinergic agent.

Dopaminergic agents, such as amantadine and levodopa, have also been reported to be useful in management of EPS. Amantadine has been reported to be beneficial in acute dystonia, akathisia, and drug-induced parkinsonism. As with anticholinergics, amantadine is believed to work by normalizing dopamine-acetylcholine balance in the striatum. Dosing of 100-400 mg/day in a once or twice daily pattern is usually used. Adverse effects with amantadine include orthostasis, peripheral edema, and a skin reaction called livedo reticularis (venous marbling of the skin, usually lower extremities). Also, worsening of psychosis or delirium have been reported. Generally, amantadine should only be utilized after failure of anticholinergic agents. Levodopa is far less commonly used due to concern regarding worsening of psychotic illness.

Beta-blocking drugs (eg, propranolol, atenolol, pindolol) may be useful in EPS. Beta-blockers appear to be most effective in treating akathisia. Patients on beta-blockers may experience hypotension or bradycardia, thus, blood pressure and pulse should be monitored during initial drug titration.

Clonidine is another agent that may be effective in akathisia. Usual dosage for akathisia is 0.2-0.8 mg/day. As with beta-blockers, hypotension may occur, and blood pressure should be monitored during initial titration. Clonidine should generally be tried after failure of beta-blockers to control akathisia.

Benzodiazepines may also be useful in improving symptoms of dystonia and akathisia, although they are generally less effective than anticholinergic medications. Lorazepam, clonazepam, and diazepam have been most often utilized, generally at dosages of diazepam \leq 40 mg/day, or its equivalent.

ALLERGIC REACTIONS

An allergic drug reaction can be considered an adverse effect involving immunologic mechanisms. True allergic reactions are much less common than nonallergic responses such as side effects and drug-drug interactions. As a result, it is important to carefully evaluate patients who present with allergies to drugs. Patients frequently state an allergy to a drug when the reaction was a predictable side effect (eg, nausea/vomiting with codeine). If a patient presents a history of one or more of the following signs or symptoms after drug administration, an allergic reaction should be assumed until proven otherwise: skin manifestations (pruritus with hives or flushing), facial or oral swelling, shortness of breath, choking, wheezing, and vascular collapse. In this situation, an alternate agent should be selected.

Classification of Allergic Reactions

Allergic reactions can be classified using the Coombs and Gell Classification System into one of four immunopathologic categories (types I through IV). The following table summarizes the key characteristics of each type of reaction.

Type	Characteristics	Usual Onset	Examples
I - Anaphylactic (IgE mediated)	Requires the presence of IgE specific for drug antigen or other allergen; allergen binds to IgE on basophils and mast cells resulting in release of inflammatory mediators (eg, histamine, serotonin, proteases, bradykinin generating factor, eosinophil chemotactic factors, neutrophil chemotactic factor, leukotrienes, prostaglandins, thromboxanes)	Within 30 minutes	Immediate penicillin reaction Immediate latex reaction Blood products Vaccines Dextran Polypeptide hormones
II - Cytotoxic	Destruction of host cells; cell-associated antigen initiates cytolysis by antigen-specific antibody (IgG or IgM); most often involves blood elements (eg, erythrocytes, leukocytes, platelets)	Usually 5-12 hours	Penicillin, quinidine, phenylbutazone, thiouracils, sulfonamides, methyl dopa
III - Immune complex	Antigen-antibody complexes form and deposit on blood vessel walls and activate complement. Result is a serum-sickness-like syndrome.	3-8 hours	Serum sickness; may be caused by penicillins, sulfonamides, I.V. contrast media, hydantoins
IV - Cell mediated (delayed)	Antigens cause activation of lymphocytes (T cells), which release inflammatory mediators	24-48 hours	Graft rejection Latex contact dermatitis Tuberculin reaction

Modified from DiPiro JT and Stafford CT, "Allergic and Pseudoallergic Drug Reactions," *Pharmacotherapy: A Pathophysiologic Approach*, 3rd ed, Stamford CT: Appleton and Lange, 1997, 1675-88.

Anesthesia-Related Agents Associated with Allergy

Certain agents are most often responsible for allergic reactions in surgical patients. These include neuromuscular blocking agents, latex, colloids, hypnotics, antibiotics, benzodiazepines, opioids, local anesthetics, I.V. contrast media, and blood products. The antibiotics most commonly associated with allergic reactions are the sulfonamides, penicillins, and cephalosporins. Propofol contains soybean oil and egg yolk components; in patients with allergies to these items, propofol should be avoided. The ester-type local anesthetics can produce allergic reactions secondary to the metabolite para-aminobenzoic acid. The methylparaben preservative in amide-type local anesthetics may also produce an allergic reaction in patients sensitive to para-aminobenzoic acid. Sulfites, which are used as preservatives in various drug products, can produce pulmonary complications in patients, occurring more frequently in asthmatics. Cross allergenicity exists between shellfish/seafood and protamine and I.V. contrast media; care should be taken when using these agents in patients with these types of allergies. Special consideration should be given to a patient who presents a personal or family history of allergy to halothane or succinylcholine as this may actually represent an occurrence of malignant hyperthermia.

Anaphylaxis

Anaphylaxis is the most severe form of allergic reaction. It can present as an acute, life-threatening reaction with multiple organ system involvement or it can be more localized in appearance. It has been estimated that 1 in every 2700 hospitalized patients experience drug-induced anaphylaxis. When antibodies are not involved

in the process, the reaction is termed anaphylactoid. It is not possible through clinical observation to distinguish between anaphylactic and anaphylactoid reactions. Life-threatening reactions are more likely to occur in patients with a history of allergy, atopy, or asthma. Although these patients are frequently pretreated with corticosteroids, there is no evidence to suggest this practice is effective for preventing true anaphylactic reactions. In a survey examining the incidence of intraoperative anaphylaxis, 70.2% were due to neuromuscular blocking agents, 12.5% due to latex, 4.6% due to colloids, 3.6% due to hypnotics, 2.6% due to antibiotics, 2% due to benzodiazepines, 1.7% due to opioids, 0.7% due to local anesthetics, and 2.8% due to other agents.

Pathophysiology

Anaphylaxis is initiated by an antigen binding to IgE antibodies; however, prior exposure to the antigen or a substance with a similar structure is first required to sensitize the patient to the antigen. The binding of the antigen to the IgE antibodies on the surface of basophils and mast cells causes release of histamine and the chemotactic factors of anaphylaxis. Other chemical mediators (leukotrienes, prostaglandins, kinins) are also released in response to cellular activation. The liberated mediators produce bronchospasm, upper airway edema, vasodilation, increased capillary permeability, and urticaria. The effects of multiple mediators on the heart and peripheral vasculature cause the cardiovascular collapse seen during anaphylaxis. Antigenic challenge in a sensitized individual usually produces immediate clinical manifestations of anaphylaxis; however, the onset may be delayed by up to 30 minutes. The reaction can vary in severity, from minor clinical changes to acute cardiopulmonary collapse.

Signs/Symptoms of Anaphylactic Reaction

The following table lists the signs and symptoms that may indicate an anaphylactic reaction during anesthesia.

Systems	Symptoms	Signs
Cutaneous	Itching, burning	Urticaria (hives), flushing, periorbital edema, perioral edema
Respiratory	Dyspnea, chest tightness	Coughing, wheezing, sneezing, laryngeal edema, decreased pulmonary compliance, pulmonary edema, acute respiratory distress, bronchospasm
Cardiovascular	Dizziness, malaise, retrosternal oppression	Disorientation, diaphoresis, loss of consciousness, hypotension, tachycardia, dysrhythmias, decreased systemic vascular resistance, pulmonary hypertension, cardiovascular collapse

Modified from Levy JH, *Anaphylactic Reactions in Anesthesia and Intensive Care*, Stoneham, Butterworth-Heinemann, 1992.

Treatment of Anaphylactic Reaction

Treatment of a severe, life-threatening anaphylactic reaction must be immediate. Initial therapy comprises: 1) stopping administration of precipitating drug; 2) maintaining airway with 100% oxygen; 3) discontinuing all anesthetic agents; 4) intravascular volume expansion with crystalloid solution; and 5) epinephrine administration. Secondary therapy consists of administration of antihistamines (eg, diphenhydramine), catecholamine infusions (eg, norepinephrine, epinephrine, inhaled bronchodilators (eg, albuterol) for bronchospasm, corticosteroids (eg, hydrocortisone, methylprednisolone, dexamethasone), and sodium bicarbonate. Patients should be admitted to an ICU for 24 hours following an anaphylactic reaction because of the possibility of recurrent "late-phase" reactions.

Latex Allergy

The incidence of latex allergy is increasing. This increase has been suggested to be due in part to the implementation of universal precautions by the CDC in 1987 secondary to the AIDS epidemic. **Because of the increased incidence of latex allergy, all patients should be asked about allergic responses to latex products.** For example, patients should be questioned about the presence of swelling or itching of the hands or other areas after contact with rubber gloves, condoms, diaphragms, toys, or other rubber products and about itching or swelling of the lips or mouth after dental exams, blowing up balloons, or after eating bananas, chestnuts, and avocados.

It is important today for health care institutions to have a comprehensive plan (including a perioperative component) in place for dealing with the latex allergic patient.

Hypersensitivity Reactions Caused by Latex

Latex-containing products can produce type I and type IV hypersensitivity reactions.

The type I hypersensitivity reaction is the true “allergic” reaction seen with latex products. Proteins found in the latex promote the production of an antibody of the IgE class which attaches to basophils and mast cells. When the antigen (protein) is encountered again, histamine and other physiologically active mediators are released from mast cells and basophils. The clinical manifestations can include single or multiple system involvement, be mild or severe, and range from itching to edema and from mild hypotension to shock. It has been estimated that 10% of the true anaphylactic reactions during anesthesia are due to latex allergy. These reactions are usually seen 5-30 minutes after induction of anesthesia and start of surgery.

In the type IV reaction, a contact dermatitis is seen. The preservatives, stabilizers, accelerators, and antioxidants used in the latex manufacturing process serve as the antigens for T-cell lymphocytes. The dermatitis produced can be uncomfortable but is not life-threatening.

Routes of Exposure to Latex Proteins

It is important to consider the route of exposure of the latex protein in allergic patients as this can be a determinant of the type of reaction produced. The following table summarizes major routes of exposure.

Type of Exposure	Reaction
Direct skin contact	Localized or generalized urticaria
Mucous membrane	Rhinitis, conjunctivitis, stomatitis, angioedema; severe anaphylactic reactions and death reported
Inhalation of airborne starch-protein particles	Wheezing, bronchospasm, reduced lung compliance, episodes of desaturation and/or severe hypoxemia
Intravascular absorption of water soluble latex particles from surgical gloves	Sudden tachycardia, severe hypotension, cardiorespiratory collapse

High-Risk Patients

Several groups have been identified as “high-risk” for allergic reactions to latex. Special consideration should be given these individuals.

Healthcare providers. Latex allergy has been reported to be 7.5% for physicians, 5.6% for nurses, and 13.7% for dental personnel. The overall incidence for hospital employees is 1.3% (versus 0.08% for the general population).

Spina bifida patients/patients with congenital urologic abnormalities. An 18% to 40% incidence of latex allergy has been reported for spina bifida patients. These patients are routinely exposed to latex-containing urinary catheters.

Workers in rubber industry. A 10% incidence of latex allergy has been reported.

Patients with a history of atopy. In patients with latex allergy, there is a 35% to 83% incidence of atopy. Patients report allergies to rubber gloves, balloons, and various fruits and foods. Cross-reactivity has been reported with bananas, avocados, kiwis, celery, and chestnuts.

Treatment of Anaphylactic Reaction

Management of an anaphylactic reaction which is thought to be due to latex allergy is similar to that described earlier. In addition, all latex products should be removed from the surgical field, surgeons must switch to nonlatex gloves, and latex-free tubing should be used for I.V. administration. Further, tests to determine if latex allergy was the cause of the reaction should be performed (eg, RAST, AlaSTAT).

Perioperative Management of a Latex Allergic Patient

No evidence exists to demonstrate that prophylaxis before surgery prevents latex-induced anaphylactic reactions. In spite of this, prophylaxis has been used in patients with a positive history of allergy; one

suggested regimen uses diphenhydramine P.O. or I.V. every 6 hours at 13, 7, and 1 hour before surgery, prednisone P.O. every 6 hours at 13, 7, and 1 hours before surgery (hydrocortisone I.V. may be substituted), and ranitidine P.O. or I.V. every 12 hours at 13 and 1 hours before surgery. This regimen is continued for 12 hours after surgery.

The key to perioperative management of the latex allergic patient is to provide a latex-free environment. To accomplish this, the following actions should be taken:

Substitute all items with nonlatex alternatives when possible; if there is a question concerning the latex content of a product, the manufacturer should be called

Gloves made of neoprene or other polymers should be used

Latex-based adhesives should be eliminated

Stopcocks should be used for drug administration instead of injection ports on I.V. tubing

Syringes not containing rubber tips on the plunger should be used

Drug products in glass ampuls should be used whenever possible; if a vial must be used, utilize a vial stopper remover so the stopper does not have to be punctured, and

To reduce exposure to aerosolized glove powder which is a known carrier of latex proteins, schedule the surgery as the first case of the day; some institutions have reserved an OR suite for latex allergic patients.

Testing for Latex Allergy

Testing for latex allergy is recommended for high-risk patients. Both *in vitro* and *in vivo* tests are available as seen in the following table.

Test	Type	Description
Skin prick	<i>in vivo</i>	Sensitive method to confirm IgE-mediated latex hypersensitivity; correlates well with clinical presence of allergy; high sensitivity (100%), high specificity (99%)
Patch	<i>in vivo</i>	Test for type IV hypersensitivity reaction; test performed with 1 inch square of rubber glove; skin observed for contact dermatitis after 48 hours
Radioallergosorbent (RAST)	<i>in vitro</i>	Performed on the serum of patients with natural latex as the antigen; used to detect and quantify allergen specific IgE in patient's serum; positive RAST response correlates strongly with <i>in vivo</i> allergic response; sensitivity 67% to 82%
AlaSTAT	<i>in vitro</i>	Enzyme-linked immunometric assay used to measure latex-specific IgE antibodies; raw natural rubber latex used as source material for AlaSTAT latex allergens; sensitivity 94%, specificity 81%

AMINOGLYCOSIDE DOSING AND MONITORING

All aminoglycoside therapy should be individualized for specific patients in specific clinical situation. The following are guidelines for initiating therapy.

1. Loading dose based on estimated ideal body weight (IBW). **All patients require a loading dose independent of renal function.**

Agent	Dose
Gentamicin	2 mg/kg
Tobramycin	2 mg/kg
Amikacin	7.5 mg/kg

Significantly higher loading doses may be required in severely ill intensive care unit patients.

2. Initial maintenance doses as a percent of loading dose according to desired dosing interval and creatinine clearance (Cl_{cr}):

$$\text{Male } Cl_{cr} \text{ (mL/min)} = \frac{(140 - \text{age}) \times \text{IBW}}{72 \times \text{serum creatinine}}$$

$$\text{Female} = 0.85 \times Cl_{cr} \text{ males}$$

Cl_{cr} (mL/min)	Dosing Interval (h)		
	8	12	24
90	84%	—	—
80	80%	—	—
70	76%	88%	—
60	—	84%	—
50	—	79%	—
40	—	72%	92%
30	—	—	86%
25	—	—	81%
20	—	—	75%

Patients > 65 years of age should not receive initial aminoglycoside maintenance dosing more often than every 12 hours.

3. Serum concentration monitoring
 - Serum concentration monitoring is necessary for **safe** and **effective** therapy, particularly in patients with serious infections and those with risk factors for toxicity.
 - Peak serum concentrations should be drawn 30 minutes after the completion of a 30-minute infusion. Trough serum concentrations should be drawn within 30 minutes prior to the administered dose.
 - Serum concentrations should be drawn after 5 half-lives, usually around the third dose or thereafter.
4. Desired measured serum concentrations

	Peak (mcg/mL)	Trough (mcg/mL)
Gentamicin	6-10	0.5-2.0
Tobramycin	6-10	0.5-2.0
Amikacin	20-30	<5

5. For patients receiving hemodialysis:
 - administer the **same** loading dose
 - administer $\frac{2}{3}$ of the loading dose after each dialysis

- **serum concentrations must be monitored**
- watch for ototoxicity from accumulation of drug
- For individual clinical situations the prescribing physician should feel free to consult Infectious Disease, the Pharmacology Service, or the Pharmacy.

“Once Daily” Aminoglycosides

High dose, “once daily” aminoglycoside therapy for treatment of gram-negative bacterial infections has been studied and remains controversial. The pharmacodynamics of aminoglycosides reveal dose-dependent killing which suggests an efficacy advantage of “high” peak serum concentrations. It is also suggested that allowing troughs to fall to unmeasurable levels decreases the risk of nephrotoxicity without detriment to efficacy. Because of a theoretical saturation of tubular cell uptake of aminoglycosides, decreasing the number of times the drug is administered in a particular time period may play a role in minimizing the risk of nephrotoxicity. Ototoxicity has not been sufficiently formally evaluated through audiometry or vestibular testing comparing “once daily” to standard therapy. Over 100 letters, commentaries, studies, and reviews have been published on the topic of “once daily” aminoglycosides with varying dosing regimens, monitoring parameters, inclusion and exclusion criteria, and results (most of which have been favorable for the “once daily” regimens). The caveats of this simplified method of dosing are several, including assurance that creatinine clearances be calculated, that all patients are not candidates and should not be considered for this regimen, and that “once daily” is a semantic misnomer.

Because of the controversial nature of this method, it is beyond the scope of this book to present significant detail and dosing regimen recommendations. Considerable experience with two methods warrants mention. The Hartford Hospital has experience with over 2000 patients utilizing a 7 mg/kg dose, a dosing scheme for various creatinine clearance estimates, and a serum concentration monitoring nomogram.¹ Providence Medical Center utilizes a 5 mg/kg dosing regimen but only in patients with excellent renal function; serum concentrations are monitored 4-6 hours prior to the dose administered.² Two excellent reviews discuss the majority of studies and controversies regarding these dosing techniques.^{3,4} An editorial accompanies one of the reviews and is worth examination.⁵

“Once daily” dosing may be a safe and effective method of providing aminoglycoside therapy to a large number of patients who require these efficacious yet toxic agents. As with any method of aminoglycoside administration, dosing must be individualized and the caveats of the method considered.

ANGIOTENSIN AGENTS

ACE Inhibitors: Comparison of Indications and Adult Dosages					
Drug	Hypertension	CHF	Renal Dysfunction	Dialyzable	Strengths (mg)
Benazepril (Lotensin®)	10-40 mg/day	Not FDA approved	Cl _{cr} <30 mL/min: 5 mg/day initially Maximum: 40 mg/day	Yes	Tablets 5, 10, 20, 40
Captopril (Capoten®)	25-100 mg/day bid-tid	6.25-100 mg tid Maximum: 450 mg/day	Cl _{cr} 10-50 mL/min: 75% of usual dose Cl _{cr} <10 mL/min: 50% of usual dose	Yes	Tablets 12.5, 25, 50, 100
Enalapril (Vasotec®)	2.5-40 mg/day qd-bid	2.5-20 mg bid Maximum: 20 mg bid	Cl _{cr} 30-80 mL/min: 5 mg/day initially Cl _{cr} <30 mL/min: 2.5 mg/day initially	Yes	Tablets 2.5, 5, 10, 20
Enalaprilat ¹	0.625 mg, 1.25 mg, 2.5 mg q6h Maximum: 5 mg q6h	Not FDA approved	Cl _{cr} <30 mL/min: 0.625 mg q6h	Yes	2.5 mg/2 mL vial
Fosinopril (Monopril®)	10-40 mg/day	10-40 mg/day	No dosage reduction necessary	Not well dialyzed	Tablets 10, 20, 40
Lisinopril (Prinivil®, Zestril®)	10-40 mg/day Maximum: 40 mg/day	5-40 mg/day	Cl _{cr} 10-30 mL/min: 5 mg/day initially Cl _{cr} <10 mL/min: 2.5 mg/day initially	Yes	Tablets 2.5, 5, 10, 20, 30, 40
Moexipril (Univasc®)	7.5-30 mg/day qd-bid Maximum: 30 mg/day	LV dysfunction (post-MI): 7.5-30 mg/day	Cl _{cr} <40 mL/min: 3.75 mg/day initially Maximum: 15 mg/day	Unknown	Tablets 7.5, 15
Perindopril (Aceon®)	4-8 mg/day	4-8 mg/day Maximum: 16 mg/day	Cl _{cr} 30-60 mL/min: 2 mg/day Cl _{cr} 15-29 mL/min: 2 mg qod Cl _{cr} <15 mL/min: 2 mg on dialysis days	Yes	Tablets 2, 4, 8
Quinapril (Accupril®)	10-40 mg/day qd-bid	5-20 mg bid	Cl _{cr} 30-60 mL/min: 5 mg/day initially Cl _{cr} <10-30 mL/min: 2.5 mg/day initially	Not well dialyzed	Tablets 5, 10, 20, 40
Ramipril (Altace®)	2.5-20 mg/day qd-bid	2.5-10 mg/day	Cl _{cr} <40 mL/min: 25% of normal dose	Unknown	Capsules 1.25, 2.5, 5, 10
Trandolapril (Mavik®)	1-4 mg/day Maximum: 8 mg/day qd-bid	LV dysfunction (post-MI): 1-4 mg/day	Cl _{cr} <30 mL/min: 0.5 mg/day initially	No	Tablets 1, 2, 4

Dosage is based on 70 kg adult with normal hepatic and renal function.
¹Enalaprilat is the only available ACE inhibitor in a parenteral formulation.

Angiotensin II Receptor Blockers: Comparison of Indications and Adult Dosages					
Drug	Hypertension	CHF	Renal Dysfunction	Dialyzable	Strengths (mg)
Candesartan (Atacand®)	8-32 mg/day	Target: 32 mg once daily	No dosage adjustment necessary	No	Tablets 4, 8, 16, 32
Eprosartan (Teveten®)	400-800 mg/day qd-bid	Not FDA approved	No dosage adjustment necessary	Unknown	Tablets 400, 600
Irbesartan (Avapro®)	150-300 mg/day	Not FDA approved	No dosage reduction necessary	No	Tablets 75, 150, 300
Losartan (Cozaar®)	25-100 mg qd or bid	Not FDA approved	No dosage adjustment necessary	No	Tablets 25, 50, 100
Olmесartan (Benicar®)	20-40 mg/day	Not FDA approved	No dosage adjustment necessary	Unknown	Tablets 5, 20, 40
Telmisartan (Micardis®)	20-80 mg/day	Not FDA approved	No dosage reduction necessary	No	Tablets 20, 40, 80
Valsartan (Diovan®)	80-320 mg/day	Target: 160 mg bid	Decrease dose only if Cl _{cr} < 10 mL/minute	No	Tablets 40, 80, 160, 320

Dosage is based on 70 kg adult with normal hepatic and renal function.

ACE Inhibitors: Comparative Pharmacokinetics								
Drug	Prodrug	Absorption (%)	Serum t _{1/2} (h) Normal Renal Function	Serum Protein Binding (%)	Elimination	Onset of BP Lowering Action (h)	Peak BP Lowering Effects (h)	Duration of BP Lowering Effects (h)

ANTIDEPRESSANT AGENTS

Comparison of Usual Dosage, Mechanism of Action, and Adverse Effects										
Drug	Initial Dose	Usual Dosage (mg/d)	Dosage Forms	Adverse Effects						Comments
				ACH	Drowsiness	Orthostatic Hypotension	Conduction Abnormalities	GI Distress	Weight Gain	
Tricyclic Antidepressants and Related Compounds¹										
Amitriptyline (Elavil [®] , Vanatrip [®])	25-75 mg qhs	100-300	T, I	4+	4+	3+	3+	1	4+	Also used in chronic pain, migraine, and as a hypnotic; contraindicated with cisapride
Amoxapine	50 mg bid	100-400	T	2+	2+	2+	2+	0	2+	May cause extrapyramidal symptom (EPS)
Clomipramine ² (Anafranil [®])	25-75 mg qhs	100-250	C	4+	4+	2+	3+	1+	4+	Approved for OCD
Desipramine (Norpramin [®])	25-75 mg qhs	100-300	T	1+	2+	2+	2+	0	1+	Blood levels useful for therapeutic monitoring
Doxepin (Sinequan [®] , Zonalon [®])	25-75 mg qhs	100-300	C, L	3+	4+	2+	2+	0	4+	
Imipramine (Tofranil [®] , Tofranil-PM [®])	25-75 mg qhs	100-300	T, C	3+	3+	4+	3+	1+	4+	Blood levels useful for therapeutic monitoring
Maprotiline (Ludiomil [®])	25-75 mg qhs	100-225	T	2+	3+	2+	2+	0	2+	
Nortriptyline (Aventyl [®] , Pamelor [®])	25-50 mg qhs	50-150	C, L	2+	2+	1+	2+	0	1+	Blood levels useful for therapeutic monitoring
Protriptyline (Vivactil [®])	15 mg qAM	15-60	T	2+	1+	2+	3+	1+	1+	
Trimipramine (Surmontil [®])	25-75 mg qhs	100-300	C	4+	4+	3+	3+	0	4+	
Selective Serotonin Reuptake Inhibitors³										
Citalopram (Celexa [™])	20 mg qAM	20-60	T	0	0	0	0	3+ ⁴	1+	
Escitalopram (Lexapro [™])	10 mg qAM	10-20	T	0	0	0	0	3+	1+	S-enantiomer of citalopram
Fluoxetine (Prozac [®] , Prozac [®] Weekly [™] , Sarafem [™])	10-20 mg qAM	20-80	C, L, T	0	0	0	0	3+ ⁴	1+	CYP2B6 and 2D6 inhibitor
Fluvoxamine (Luvox [®]) ²	50 mg qhs	100-300	T	0	0	0	0	3+ ⁴	1+	Contraindicated with pimozide, thioridazine, mesoridazine, CYP1A2, 2B6, 2C19, and 3A4 inhibitors
Paroxetine (Paxil [®] , Paxil [®] CR [™])	10-20 mg qAM	20-50	T, L	1+	1+	0	0	3+ ⁴	2+	CYP2B6 and 2D6 inhibitor

Comparison of Usual Dosage, Mechanism of Action, and Adverse Effects (Continued)										
Drug	Initial Dose	Usual Dosage (mg/d)	Dosage Forms	Adverse Effects						Comments
				ACH	Drowsiness	Orthostatic Hypotension	Conduction Abnormalities	GI Distress	Weight Gain	
Sertraline (Zoloft®)	25-50 mg qAM	50-200	T	0	0	0	0	3+ ⁴	1+	CYP2B6 and 2C19 inhibitor
Dopamine-Reuptake Blocking Compounds										
Bupropion (Wellbutrin®, Wellbutrin SR®, Wellbutrin XL™, Zyban®)	100 mg bid-tid IR ⁵ 150 mg qAM-bid SR ⁶	300-450 ⁷	T	0	0	0	1+/0	1+	0	Contraindicated with seizures, bulimia, and anorexia; low incidence of sexual dysfunction IR: A 6-h interval between doses preferred SR: An 8-h interval between doses preferred
Serotonin / Norepinephrine Reuptake Inhibitors⁸										
Duloxetine (Cymbalta®)	40-60 mg/d	40-60	C	1+	1+	0	1+	3+	0	Useful for stress incontinence and chronic pain
Venlafaxine (Effexor®, Effexor XR)	25 mg bid-tid IR 37.5 mg qd XR	75-375	T	1+	1+	0	1+	3+ ⁴	0	High-dose is useful to treat refractory depression; frequency of hypertension increases with dosage > 225 mg/d
5HT₂ Receptor Antagonist Properties										
Nefazodone (Serzone®)	100 mg bid	300-600	T	1+	1+	2+	1+	1+	0	Contraindicated with carbamazepine, pimozide, astemizole, cisapride, and terfenadine; caution with triazolam and alprazolam; low incidence of sexual dysfunction
Trazodone (Desyrel®)	50 mg tid	150-600	T	0	4+	3+	1+	1+	2+	
Noradrenergic Antagonist										
Mirtazapine (Remeron®, Remeron SolTab™)	15 mg qhs	15-45	T	1+	3+	1+	1+	0	3+	Dose > 15 mg/d less sedating, low incidence of sexual dysfunction

POISONING AND TOXICOLOGY

Comparison of Usual Dosage, Mechanism of Action, and Adverse Effects (Continued)										
Drug	Initial Dose	Usual Dosage (mg/d)	Dosage Forms	Adverse Effects						Comments
				ACH	Drowsiness	Orthostatic Hypotension	Conduction Abnormalities	GI Distress	Weight Gain	
Monoamine Oxidase Inhibitors										
Isocarboxazid (Marplan®)	10 mg tid	10-30	T	2+	2+	2+	1+	1+	2+	Diet must be low in tyramine; contraindicated with sympathomimetics and other antidepressants
Phenelzine (Nardil®)	15 mg tid	15-90	T	2+	2+	2+	0	1+	3+	
Tranlycypromine (Parnate®)	10 mg bid	10-60	T	2+	1+	2+	1+	1+	2+	

ACH = anticholinergic effects (dry mouth, blurred vision, urinary retention, constipation); 0 - 4+ = absent or rare - relatively common. T = tablet, L = liquid, I = injectable, C = capsule; IR = immediate release, SR = sustained release.

¹**Important note:** A 1-week supply taken all at once in a patient receiving the maximum dose can be fatal.

²Not approved by FDA for depression. Approved for OCD.

³Flat dose response curve, headache, nausea, and sexual dysfunction are common side effects for SSRIs.

⁴Nausea is usually mild and transient.

⁵IR: 100 mg bid, may be increased to 100 mg tid no sooner than 3 days after beginning therapy.

⁶SR: 150 mg qAM, may be increased to 150 mg bid as early as day 4 of dosing.

⁷To minimize seizure risk, do not exceed IR 150 mg/dose or SR 200 mg/dose.

⁸Do not use with sibutramine; relatively safe in overdose.

ANTIPSYCHOTIC AGENTS

Antipsychotic Agent	Dosage Forms	I.M./P.O. Potency	Equiv. Dosages (approx) (mg)	Usual Adult Daily Maint. Dose (mg)	Sedation (Incidence)	Extrapyramidal Side Effects	Anticholinergic Side Effects	Orthostatic Hypotension	Comments
Aripiprazole (Abilify™)	Soln, tab		4	10-30	Low	Very low	Very low	Very low	Low weight gain; activating
Chlorpromazine (Thorazine® [DSC])	Conc, inj, supp, syr, tab	4:1	100	200-1000	High	Moderate	Moderate	Moderate / high	
Clozapine (Clozaril®)	Tab		100	75-900	High	Very low	High	High	~1% incidence of agranulocytosis; weekly-biweekly CBC required; potential for weight gain, lipid abnormalities, and diabetes
Fluphenazine (Permitil®, Prolixin®, Prolixin Decanoate®, Prolixin Enanthate®)	Conc, elix, inj, tab	2:1	2	0.5-20	Low	High	Low	Low	
Haloperidol (Haldol®, Haldol® Decanoate)	Conc, inj, tab	2:1	2	0.5-20	Low	High	Low	Low	
Loxapine (Loxitane®, Loxitane® C, Loxitane® I.M.)	Cap, conc, inj		10	25-250	Moderate	Moderate	Low	Low	
Mesoridazine (Serentil®)	Inj, liq, tab	3:1	50	30-400	High	Low	High	Moderate	Prolongs QTc; use only in treatment of refractory illness
Molindone (Moban®)	Conc, tab		15	15-225	Low	Moderate	Low	Low	May cause less weight gain
Olanzapine (Zyprexa®, Zyprexa® Zydis®)	Inj, tab, tab (oral-disintegrating)		4	5-20	Moderate / high	Low	Moderate	Moderate	Potential for weight gain, lipid abnormalities, diabetes
Perphenazine (Trilafon®)	Conc, inj, tab		10	16-64	Low	Moderate	Low	Low	
Pimozide (Orap™)	Tab		2	1-20	Moderate	High	Moderate	Low	Contraindicated with CYP3A inhibitors
Quetiapine (Seroquel®)	Tab		125	50-800	Moderate / high	Very low	Moderate	Moderate	Moderate weight gain; potential for lipid abnormalities; diabetes
Risperidone (Risperdal®)	Inj, soln, tab, tab (oral-disintegrating)		1	0.5-6	Low / moderate	Low	Very low	Moderate	Low to moderate weight gain; potential for diabetes
Thioridazine (Mellaril®)	Conc, tab		100	200-800	High	Low	High	Moderate / high	May cause irreversible retinitis pigmentosa at doses > 800 mg/d; prolongs QTc; use only in treatment of refractory illness
Thiothixene (Navane®)	Cap, conc, powder for inj	4:1	4	5-40	Low	High	Low	Low / moderate	
Trifluoperazine (Stelazine® [DSC])	Conc, inj, tab		5	2-40	Low	High	Low	Low	
Ziprasidone (Geodon®)	Cap, powder for inj	2:1	40	40-160	Low / moderate	Low	Very low	Low / moderate	Low weight gain; contraindicated with QTc-prolonging agents

ANTIRETROVIRAL AGENTS

Single Agent Nucleoside Reverse Transcriptase Inhibitors					
Generic Name (Brand Name)	Dosage Form	Normal Dosing	Renal Dosing Adjustment	Hepatic Dosing Adjustment	Selected Adverse Reactions
Single Agent NRTIs (Nucleoside Reverse Transcriptase Inhibitors)					
Abacavir (Ziagen [®])	Tablet: 300 mg Solution, oral: 20 mg/mL (240 mL)	300 mg bid or 600 mg daily	None necessary	No recom- mendation	Hypersensitivity syndrome (fever, fatigue, GI symptoms, ± rash); do not restart abacavir in patients who have experienced this; GI symptoms
Didanosine (ddl) (Videx [®])	Tablet, chewable: 25 mg, 50 mg, 100 mg, 150 mg, 200 mg Capsule, sustained release: 125 mg, 200 mg, 250 mg, 400 mg	≥ 60 kg: 200 mg bid or 400 mg daily < 60 kg: 125 mg bid or 250 mg daily (take on empty stomach)	≥ 60 kg: 100-200 mg/day < 60 kg: 75-150 mg/day (adjust for Cl _{cr} < 60) Renal adjustment var- ies by dosage form and renal function. Consult additional references/product labeling.	No recom- mendation	Peripheral neuropathy, pancreatitis, abdominal pain, nausea, diarrhea, retinal depigmentation, anxiety, insomnia
Emtricitabine (Emtriva [®])	Capsule: 200 mg Solution, oral: 10 mg/mL (170 mL)	Capsule: 200 mg daily Solution: 240 mg daily	Capsule: Cl _{cr} 30-49: 200 mg q48h Cl _{cr} 15-29: 200 q72h Cl _{cr} < 15 (including he- modialysis [HD] pa- tients): 200 mg q96h Solution: Cl _{cr} 30-49: 120 mg q24h Cl _{cr} 15-29: 80 mg q24h Cl _{cr} < 15 (including hemodialysis [HD] patients): 60 mg q24h	No recom- mendation	Headache, dizziness, insomnia, diarrhea, rash, hyperpigmentation of palms/soles
Lamivudine (3TC) (Epivir [®] , Epivir- HBV [®])	Epivir [®] : Tablet: 150 mg, 300 mg Solution, oral: 10 mg/mL (240 mL) Epivir-HBV [®] : Tablet: 100 mg Solution, oral: 5 mg/mL (240 mL)	150 mg bid or 300 mg daily	Cl _{cr} 30-49: 150 mg qd Cl _{cr} 15-29: 150 mg first dose, then 100 mg qd Cl _{cr} 5-14: 150 mg first dose, then 50 mg qd Cl _{cr} < 5 or HD: 50 mg first dose, then 25 mg qd	No recom- mendation	Headache, insomnia, nausea, vomit- ing, diarrhea, abdominal pain, myalgia, arthralgia, pancreatitis in children
Stavudine (d4T) (Zerit [®])	Capsule: 15 mg, 20 mg, 30 mg, 40 mg Solution, oral: 1 mg/ mL (200 mL)	≥ 60 kg: 40 mg bid < 60 kg: 30 mg bid	≥ 60 kg: Cl _{cr} 26-50: 20 mg bid Cl _{cr} 10-25: 20 mg daily < 60 kg: Cl _{cr} 26-50: 15 mg bid Cl _{cr} 10-25 or HD: 15 mg daily	No recom- mendation	Peripheral neuropathy, headache, abdominal or back pain, asthenia, nausea, vomiting, diarrhea, myal- gia, anxiety, depression, pancrea- titis, lipodystrophy, hyperlipidemia, hepatotoxicity (less frequently)
Tenofovir (Viread [®])	Tablet: 300 mg	300 mg daily	Cl _{cr} 30-49: 300 mg q48h Cl _{cr} 10-29: 300 mg twice a week ESRD or HD: 300 mg once a week	No recom- mendation	Nausea, vomiting, diarrhea
Zalcitabine (ddC) (Hivid [®])	Tablet: 0.375 mg, 0.75 mg	0.75 mg q8h	Cl _{cr} 10-40: 0.75 mg bid Cl _{cr} < 10: 0.75 mg qd	No recom- mendation	Peripheral neuropathy, oral/esopha- geal ulceration, rash, nausea, vomiting, diarrhea, abdominal pain, myalgia, pancreatitis
Zidovudine (AZT) (Retrovir [®])	Tablet: 300 mg Capsule: 100 mg Syrup: 50 mg/5 mL (240 mL) Injection: 10 mg/mL (20 mL)	300 mg bid or 200 mg tid	ESRD: 100 mg q6-8h	No recom- mendation	Anemia, neutropenia, thrombo- cytopenia, headache, nausea, vomiting, myopathy, hepatitis, hyperpigmentation of nails

Combination Nucleoside Reverse Transcriptase Inhibitors			
Generic Name (Brand Name)	Dosage Form	Normal Dosing	Renal / Hepatic Dosing / Adverse Reactions
Combination NRTIs (Nucleoside Reverse Transcriptase Inhibitors)			
Abacavir + lamivudine (Epzicom™)	Tablet: 600 mg abacavir + 300 mg lamivudine	1 tablet daily	See individual agents
Abacavir + lamivudine + zidovudine (Trizivir®)	Tablet: 300 mg abacavir + 150 mg lamivudine + 300 mg zidovudine	1 tablet bid	
Emtricitabine + tenofovir (Truvada®)	Tablet: 200 mg emtricitabine and 300 mg tenofovir	1 tablet daily	
Zidovudine + lamivudine (Combivir®)	Tablet: 300 mg zidovudine and 150 mg lamivudine	1 tablet bid (see lamivudine for dose adjustment)	

Non-nucleoside Reverse Transcriptase Inhibitors					
Generic Name (Brand Name)	Dosage Form	Normal Dosing	Renal Dosing Adjustment	Hepatic Dosing Adjustment	Selected Adverse Reactions
NNRTIs (Non-nucleoside Reverse Transcriptase Inhibitors)					
Delavirdine (Rescriptor®)	Tablet: 100 mg, 200 mg	400 mg tid	None necessary	No recommendation; use caution	Rash, abnormal liver function tests
Efavirenz (Sustiva®)	Capsule: 50 mg, 100 mg, 200 mg Tablet: 600 mg	600 mg qd (take on empty stomach)	None necessary	No recommendation; use caution	Dizziness, psychiatric symptoms (hallucinations, confusion, depersonalization, others), agitation, vivid dreams, rash, GI intolerance
Nevirapine (Viramune®)	Tablet: 200 mg Suspension, oral: 50 mg/5 mL (240 mL)	200 mg qd for 14 days, then 200 mg bid	None necessary	Avoid use in mild to moderate hepatic impairment	Rash (severe), abnormal liver function tests, fever, nausea, headache

Protease Inhibitors					
Generic Name (Brand Name)	Dosage Form	Normal Dosing	Renal Dosing Adjustment	Hepatic Dosing ¹ Adjustment	Selected Adverse Reactions
PIs (Protease Inhibitors)					
Amprenavir (Agenerase®)	Capsule: 50 mg Solution, oral: 15 mg/mL (240 mL) (contains propylene glycol 550 mg/mL)	Capsule: 1200 mg bid Solution: 1400 mg bid (Avoid high fat meal)	Capsule: None necessary Solution: Contraindicated	C-P 5-8: 450 mg bid C-P 9-12: 300 mg bid	Rash (life-threatening), paresthesias (perioral), depression, nausea, diarrhea, vomiting, hyperglycemia (and sometimes diabetes), dyslipidemia including fat redistribution ("buffalo hump," "protease paunch"), hyperlipidemia, hypercholesterolemia
Atazanavir (Reyataz®)	Capsule: 100 mg, 150 mg, 200 mg	400 mg daily (take with food)	None necessary	C-P 7-9: 300 mg daily C-P > 9: Not recommended	Headache, nausea, increased bilirubin, lipodystrophy, hyperglycemia, increased P-R interval
Fosamprenavir (Lexiva™)	Tablet: 700 mg	1400 mg bid (1400 mg/day with ritonavir)	None necessary	C-P 5-8: 700 mg bid C-P 9-12: Not recommended	Rash, increased LFTs

Protease Inhibitors (Continued)					
Generic Name (Brand Name)	Dosage Form	Normal Dosing	Renal Dosing Adjustment	Hepatic Dosing ¹ Adjustment	Selected Adverse Reactions
Indinavir (Crixivan [®])	Capsule: 100 mg, 200 mg, 333 mg, 400 mg	800 mg q8h with water	None necessary	Mild to moderate hepatic insufficiency due to cirrhosis: 600 mg q8h	Hyperbilirubinemia, nephrolithiasis, elevated AST/ALT, abdominal pain, nausea, vomiting, diarrhea, taste perversion, hyperglycemia (and sometimes diabetes), dyslipidemia including fat redistribution ("buffalo hump," "protease paunch"), hyperlipidemia, hypercholesterolemia
Lopinavir and ritonavir (Kaletra [®])	Capsule: Lopinavir 133.3 mg and ritonavir 33.3 mg Solution, oral: Lopinavir 80 mg and ritonavir 20 mg/mL (contains 42% ethanol)	3 capsules or 5 mL bid (take with food) or if treatment naive: 6 capsules or 10 mL daily Once daily dosing and using with efavirenz or nevirapine: 4 capsules or 6.7 mL bid	None necessary	No recommendation; use caution	GI intolerance (eg, nausea, vomiting, abdominal pain, and diarrhea, with incidence increased with daily dosing), asthenia, circumoral and peripheral paresthesia, taste perversion, headache, hyperglycemia (and sometimes diabetes), dyslipidemia including fat redistribution ("buffalo hump," "protease paunch"), hyperlipidemia, hypercholesterolemia
Nelfinavir (Viracept [®])	Tablet: 250 mg, 625 mg Powder, oral: 50 mg/g	750 mg tid or 1250 mg bid (take with food)	None necessary	No recommendation; use caution	Diarrhea, nausea, hyperglycemia (and sometimes diabetes), dyslipidemia including fat redistribution ("buffalo hump," "protease paunch"), hyperlipidemia, hypercholesterolemia
Ritonavir (Norvir [®])	Capsule: 100 mg Solution, oral: 80 mg/mL (240 mL)	600 mg bid (take with food)	None necessary	No adjustment for mild impairment; use caution in moderate to severe impairment	Asthenia, nausea, diarrhea, vomiting, anorexia, abdominal pain, circumoral and peripheral paresthesia, taste perversion, headache, hyperglycemia (and sometimes diabetes), dyslipidemia including fat redistribution ("buffalo hump," "protease paunch"), hyperlipidemia, hypercholesterolemia
Saquinavir (Invirase [®] , Fortovase [®] [DSC])	Hard gelatin capsule (hgc): 200 mg Tablet: 500 mg Soft gelatin capsule: 200 mg	1200 mg tid (hgc only) or 1000 mg bid (with ritonavir) (take with food)	None necessary	No recommendation; use caution	Diarrhea, abdominal discomfort, nausea, headache, hyperglycemia (and sometimes diabetes), dyslipidemia including fat redistribution ("buffalo hump," "protease paunch"), hyperlipidemia, hypercholesterolemia
Tipranavir (Aptivus [®])	Gelatin capsule: 250 mg	500 mg (with ritonavir 200 mg) bid (take with high-fat meal)	None necessary	No recommendation; use caution in mild impairment. Contraindicated with moderate to severe (C-P \geq 5)	Diarrhea, skin rash, hyperglycemia, fat redistribution ("buffalo hump," "protease paunch"), dyslipidemia, increased bleeding time, increased LFTs, hepatitis and hepatic decompensation

¹Hepatic impairment as defined by the Child-Pugh (C-P) classification.

Fusion Inhibitor					
Generic Name (Brand Name)	Dosage Form	Normal Dosing	Renal Dosing Adjustment	Hepatic Dosing Adjustment	Selected Adverse Reactions
Enfuvirtide (Fuzeon [™])	Injection (lyophilized powder): 90 mg/mL	90 mg SubQ bid	None necessary	No recommendation; use caution	Injection site reaction, bacterial pneumonia, hypersensitivity

Protease Inhibitor (PI) Drug Interactions			
Antiretroviral Agent	Interacting Agent	Severity ¹	Additional Comments
General, may apply to all PIs and combinations (except where noted)	Antacids	C/D	May reduce the serum levels of PI by decreasing absorption; administer PI 2 hours before or 1 hour after antacids.
	Amiodarone	X	PIs may decrease metabolism of amiodarone, leading to increased serum levels and life-threatening adverse effects; concomitant use contraindicated.
	Calcium channel blockers	D	PIs may decrease metabolism of these agents; 50% dose reduction of diltiazem recommended if used with atazanavir; no interaction identified with tipranavir.
	Phenytoin, phenobarbital	C	May decrease serum levels/effectiveness of PI through increased metabolism; additionally, increased carbamazepine levels may occur with concomitant ritonavir.
	Carbamazepine	D	
	Cimetidine, azole antifungals	C	May increase serum levels/effects of PI; limited data with azoles, but reduced dosage of antifungal agent may be necessary (see individual product information).
	Midazolam, triazolam	D	An increase in benzodiazepine serum levels may occur resulting in significant oversedation when administered with PI; avoid combination.
	Clarithromycin	D	PIs may increase the serum levels/toxic effects; due to risk of QT _c prolongation with clarithromycin, dose adjustment of clarithromycin may be necessary (see individual product information).
	Corticosteroids, orally inhaled (fluticasone, budesonide)	D	Serum levels may be increased by PI (with or without ritonavir boost) resulting in decreased serum cortisol, HPA axis suppression; concurrent use of ritonavir boosted PI not recommended; no interactions identified with tipranavir.
	Delavirdine	D	Delavirdine may increase the levels/toxicities of various protease inhibitors, particularly nelfinavir, ritonavir, and saquinavir. Conversely, PIs may decrease the serum levels of delavirdine, leading to loss of virologic response and possible resistance to delavirdine. Concomitant use is not recommended.
	Ergot alkaloids (eg, dihydroergotamine, ergotamine, ergonovine, methylethergonovine); pimozone	X	Serum levels/toxicity may be increased by PI; serious and/or life-threatening reactions may occur; concurrent use is contraindicated.
	Digoxin, eplerenone, nefazodone, fentanyl	C	PIs may increase serum levels/toxicity.
	Efavirenz, H ₂ antagonists, nevirapine	D	Serum levels of PIs may be reduced. Avoid concurrent use if possible; if coadministering with antihistamine agents, separate dosing by at least 12 hours.
	HMG-CoA reductase inhibitors	D	PIs may increase serum levels of HMG-CoA reductase inhibitors, increasing the risk of myopathy. Concurrent use of lovastatin or simvastatin with PIs are not recommended. Atorvastatin may be used with careful monitoring, in the lowest dose possible. Fluvastatin and pravastatin may have lowest risk.
	Immunosuppressants (eg, cyclosporine, sirolimus, tacrolimus)	C/D	PIs may increase the serum levels of these agents; monitor levels.
	Indinavir	D	Concurrent use may increase the risk of hyperbilirubinemia; concurrent administration is not recommended.
Irinotecan	C/D	PIs may increase irinotecan levels via inhibition of metabolism through UGT1A1 leading to severe toxicity; concurrent use, particularly with atazanavir, is not recommended.	
Lidocaine (systemic)	C/D	Serum levels/toxicity may be increased by PI; serious and/or life-threatening reactions may occur. Monitor serum levels of lidocaine.	

Protease Inhibitor (PI) Drug Interactions (Continued)			
Antiretroviral Agent	Interacting Agent	Severity ¹	Additional Comments
	Oral contraceptives	D	With concomitant PI therapy, serum levels of estradiol/norethindrone may be increased (atazanavir, amprenavir, indinavir) or decreased (ritonavir, nelfinavir); alternate forms of (nonhormonal) contraception are recommended.
	Methadone	C	Effect of methadone may be increased or reduced; caution advised when initiating or changing dosages of concomitant therapy (dosage adjustment of methadone may be required). No interaction identified with indinavir or atazanavir.
	Phosphodiesterase-5 (PDE-5) enzyme inhibitors (sildenafil, tadalafil, vardenafil)	D	Serum levels/toxicity may be increased by PI; do not exceed doses of 25 mg sildenafil in 48 hours, 10 mg tadalafil in a 72-hour period, or 2.5 mg vardenafil in 24 hours.
	Quinidine	X	Serum levels/toxicity may be increased by PI; serious and/or life-threatening reactions may occur. Monitor serum levels of quinidine.
	Protease inhibitors	D	May decrease the metabolism, via inhibition of CYP isoenzymes, of other protease inhibitors. See individual product information for recommended dosing adjustments.
	Rifamycin derivatives	D/X	An increase in rifabutin plasma AUC (>200%) has been observed when coadministered with several PIs. Concurrent decreases in serum levels of PIs have also been observed, which may lead to loss of virologic response and resistance. See individual product information for recommended dosing adjustments; concurrent use with rifampin is contraindicated.
	St John's wort (<i>Hypericum perforatum</i>)	X	May reduce trough serum levels of PI, which may lead to treatment failures. Concurrent use is contraindicated.
	Theophylline	C	May decrease serum levels/effects of theophylline; monitor.
	Trazodone	D	Serum levels/effects may be increased; use caution and reduce trazodone dose.
	Tricyclic antidepressants	C	Serum levels/toxicity may be increased by PIs.
PIs: Specific Agents			
Amprenavir/fosamprenavir	Disulfiram	X	Concurrent use with amprenavir oral solution is contraindicated due to risk of propylene glycol toxicity.
	Metronidazole	X	Concurrent use with amprenavir oral solution is contraindicated due to risk of propylene glycol toxicity.
	H ₂ antagonists (eg, ranitidine)	D	May decrease absorption of amprenavir; consider boosting with ritonavir; separate dosing by 12 hours.
	Methadone	C	Effect of PI may be diminished (consider alternative antiretroviral). In addition, the effect of methadone may be reduced (dosage increase may be required).
	Ritonavir	D	The serum levels of amprenavir may be increased. With ritonavir, the risk of cholesterol/triglyceride elevations may be increased; specific dosing has been recommended for both agents. Concurrent use of amprenavir oral solution with ritonavir oral solution is not recommended (due to competition for metabolic elimination between propylene glycol and ethanol in these formulations).
Atazanavir	Clarithromycin	D	Clarithromycin AUC increased 94% with atazanavir; reduce clarithromycin dose by 50%.
	Efavirenz	D	Serum levels of atazanavir are significantly reduced by efavirenz. If coadministration is desirable, atazanavir 300 mg plus ritonavir 100 mg may be administered with efavirenz 600 mg as a single daily dose (with a meal). Atazanavir should not be administered with efavirenz alone.
	Indinavir	D	Increased risk of hyperbilirubinemia; avoid concurrent use.

POISONING AND TOXICOLOGY

Protease Inhibitor (PI) Drug Interactions (Continued)			
Antiretroviral Agent	Interacting Agent	Severity¹	Additional Comments
	Didanosine	D	May reduce the serum levels of atazanavir by decreasing absorption; administer PI 2 hours before or 1 hour after didanosine.
	H ₂ antagonists (eg, ranitidine), proton pump inhibitors	D	May decrease absorption of atazanavir; separate dosing by 12 hours; concurrent use of proton pump inhibitors not recommended.
	Tenofovir	C	May decrease serum levels of atazanavir, resulting in a loss of virologic response and/or resistance to atazanavir. Atazanavir increases tenofovir concentrations. Atazanavir-specific dosing recommendations are provided by the manufacturer. Atazanavir should not be coadministered with tenofovir without ritonavir.
Indinavir	Amlodipine	D	Amlodipine AUC increased 90% by indinavir/ritonavir; monitor BP closely.
	Atazanavir	D	Increased risk of hyperbilirubinemia; avoid concurrent use.
	Didanosine	D	May reduce the serum levels of indinavir by decreasing absorption; administer PI 2 hours before or 1 hour after didanosine.
Ritonavir or antiretroviral combinations with ritonavir	Carbamazepine	D	Serum levels of carbamazepine may be increased; monitor anticonvulsant levels.
	Clarithromycin	D	Clarithromycin levels increased 77%; adjust dosage as for moderate-to-severe renal impairment.
	Desipramine	C	Desipramine AUC increased 145% with concurrent ritonavir.
	Flecainide, propafenone, thioridazine	X	May increase serum levels/toxicity leading to arrhythmia.
	Methadone	C	Methadone AUC decreased 53%; monitor for possible withdrawal symptoms and adjust methadone dose as necessary.
	Voriconazole	X	May reduce serum levels of voriconazole leading to treatment failure.
	Disulfiram	X	Due to risk of acetaldehyde accumulation, concurrent use with lopinavir/ritonavir oral solution is contraindicated.
	Alfuzosin	D	May increase serum levels/effects of alfuzosin; concurrent use with ritonavir is contraindicated.
	Trazodone	C	May increase serum levels/effects of trazodone.
Saquinavir	Tipranavir	D	Saquinavir AUC decreased 67% when given (with ritonavir) in combination with tipranavir/ritonavir; concurrent use should be avoided.
Tipranavir/ritonavir	Abacavir	D	May decrease the serum levels of abacavir 35% to 44%; dosing adjustment for concomitant therapy not available.
	Zidovudine	D	May decrease the serum levels of zidovudine 30% to 43%; dosing adjustment for concomitant therapy not available.
	Loperamide	C	May decrease the serum levels of loperamide 51%.
	Disulfiram	X	Due to risk of acetaldehyde accumulation, concurrent use with tipranavir/ritonavir oral solution is not recommended.
	Didanosine	D	May reduce the serum levels of tipranavir by decreasing absorption; if coadministering, recommend using enteric coated form of didanosine and separate dosing by 2 hours.
	Saquinavir	D	Saquinavir AUC decreased 67% when given (with ritonavir) in combination with tipranavir/ritonavir; concurrent use should be avoided.

¹Severity rating: C = monitor therapy; D = consider therapy modification; X = avoid combination.

Non-nucleoside Reverse Transcriptase Inhibitor (NNRTI) Drug Interactions			
Antiretroviral Agent	Interacting Agent	Severity ¹	Additional Comments
General, may apply to all NNRTIs (except where noted)	Voriconazole	D	NNRTIs may reduce serum levels of voriconazole leading to treatment failure.
	Rifamycin derivatives	D/X	May decrease serum levels of NNRTIs; contraindicated with delavirdine ; avoid combination with nevirapine; increase dose of efavirenz to 800 mg/day if used concomitantly.
	Protease inhibitors	D	Metabolism of PIs may increase (efavirenz, nevirapine) or decrease (delavirdine) with concomitant therapy; use caution and monitor.
	St John's wort	X	May decrease serum levels of NNRTIs.
	Enzyme-inducing anticonvulsants (eg, phenytoin, phenobarbital, carbamazepine)	D/X	May decrease serum levels/effectiveness of NNRTIs; monitor levels; these agents specifically contraindicated with delavirdine .
	Dapsone	C/D	Efavirenz and nevirapine may decrease the levels/effectiveness of dapsone; delavirdine may increase dapsone levels/toxicity.
NNRTIs: Specific Agent Interactions			
Delavirdine, efavirenz	HMG-CoA reductase inhibitors	C/D	May significantly increase statin levels; avoid concomitant use of delavirdine with simvastatin or atorvastatin; reduce statin dose with efavirenz.
	Methadone	D	May decrease serum levels/effects of methadone; adjust opiate dose as necessary.
	Cisapride	C/D	May increase serum levels of cisapride, increasing the risk of arrhythmias; avoid concomitant use.
	Midazolam, triazolam, (alprazolam)	D	An increase in serum levels may occur resulting in significant oversedation when administered with NNRTIs; avoid combination. Alprazolam not recommended for use with delavirdine.
	Ergot alkaloids (eg, dihydroergotamine, ergotamine, ergonovine, methylergonovine)	X	Serum levels/toxicity or ergotamine derivatives may be increased; serious and/or life-threatening reactions may occur; concurrent use is contraindicated .
	Warfarin	C/D	May increase the levels/effects of warfarin; monitor INR.
Nevirapine	Clarithromycin	C	Nevirapine may decrease the levels/effectiveness of clarithromycin.
	Oral contraceptives	C	May decrease levels/effects of estradiol; recommend alternate forms of contraception.
	Fluconazole	D	May increase nevirapine AUC 100%; monitor for increased risk of hepatotoxicity.
Delavirdine	Antacids	C	Antacids may decrease absorption; separate dosing by 1 hour.
	Clarithromycin	D	Delavirdine and clarithromycin levels may be increased with concomitant use; adjust clarithromycin dose for renal failure and monitor for toxicity if used with delavirdine.
	H ₂ antagonists, proton pump inhibitors	D	Coadministration not recommended.
	Phosphodiesterase-5 (PDE-5) enzyme inhibitors (sildenafil, tadalafil, vardenafil)	D	Serum levels/toxicity may be increased by atazanavir; do not exceed doses of 25 mg sildenafil in 48 hours, 10 mg tadalafil in a 72-hour period, or 2.5 mg vardenafil in 24 hours.
Efavirenz	Atazanavir	D	May decrease the serum level of atazanavir; manufacturer recommends dosing adjustment of atazanavir 300 mg/day (with ritonavir 100 mg/day) if used with efavirenz.
	Clarithromycin	C	Efavirenz may decrease the levels/effectiveness of clarithromycin.
	Oral contraceptives	C	May increase levels/effects of estradiol; recommend alternate forms of contraception.
¹ Severity rating: C = monitor therapy; D = consider therapy modification; X = avoid combination.			

Nucleoside Reverse Transcriptase Inhibitor (NRTI) Drug Interactions			
Antiretroviral Agent	Interacting Agent	Severity ¹	Additional Comments
General, may apply to all NRTIs (except where noted)	Ribavirin	D	Coadministration may increase exposure to the NRTI and/or its active metabolite(s), increasing the risk or severity of toxicities such as hepatotoxicity, pancreatitis, lactic acidosis, or peripheral neuropathy. Concurrent use should be avoided. No data available with ribavirin + tenofovir combination.
	Ganciclovir-valganciclovir	D	May increase NRTI levels, and the risk of hematology toxicity (eg, pancytopenia); concomitant use with didanosine or zidovudine not recommended; stavudine and zalcitabine appear to be safe alternatives.
NRTIs: Specific Agent Interactions			
Didanosine (ddl)	Quinolones, itraconazole, ketoconazole, dapson, tetracyclines, ganciclovir-valganciclovir, atazanavir, indinavir	D	Buffered formulations of didanosine (tablets, pediatric oral solution) may decrease absorption of these medications; separate dosing by 2 hours (recommended that quinolones be given 6 hours after didanosine).
	Tipranavir/ritonavir	C	Concurrent administration may result in decreased serum levels of both ddl and tipranavir/ritonavir; if coadministering, use enteric coated form of didanosine and separate dosing by 2 hours.
	Allopurinol	D	May increase didanosine concentration; avoid concurrent use.
	Hydroxyurea	D	May precipitate didanosine-induced pancreatitis if added to therapy; concomitant use is not recommended.
	Methadone	C	May decrease buffered didanosine AUC by –63%; monitor and consider dose adjustment.
	Tenofovir, stavudine	D	Coadministration may increase exposure to didanosine and/or its active metabolite increasing the risk or severity of didanosine toxicities, including pancreatitis, hyperglycemia, lactic acidosis, and peripheral neuropathy. Some patients have experienced reduced CD4 cell counts and/or decreased virologic response; specific dosing adjustment of ddl with tenofovir is recommended; suspend therapy if signs or symptoms of toxicity are noted.
	Zalcitabine	D	Increased risk of peripheral neuropathy.
Stavudine	Didanosine	D	Risk of pancreatitis may be increased with concurrent use. Cases of fatal lactic acidosis have been reported with this combination when used during pregnancy; use only if clearly needed.
	Doxorubicin, zidovudine, ribavirin	D	May inhibit intracellular phosphorylation of stavudine reducing efficacy; concomitant use not recommended.
	Zalcitabine	D	May increase risk of peripheral neuropathy; concurrent use not recommended.
	Zidovudine	D	Zidovudine may decrease the antiviral activity of stavudine (based on <i>in vitro</i> data). Avoid concurrent use.
Tenofovir	Atazanavir	C	Tenofovir may decrease serum levels of atazanavir, resulting in a loss of virologic response and/or resistance to atazanavir. Atazanavir-specific dosing recommendations (use with ritonavir) are provided by the manufacturer.
	Didanosine	D	Concomitant use of tenofovir with didanosine has been noted to increase exposure to didanosine and/or its active metabolite, potentially increasing the risk of pancreatitis, hyperglycemia, peripheral neuropathy, or lactic acidosis. Some patients have experienced reduced CD4 cell counts and/or decreased virologic response. Specific dosing adjustment is recommended. Use caution and monitor closely. Suspend therapy if signs/symptoms of toxicity are present.

Nucleoside Reverse Transcriptase Inhibitor (NRTI) Drug Interactions (Continued)			
Antiretroviral Agent	Interacting Agent	Severity ¹	Additional Comments
	Protease inhibitors	C	Tenofovir may decrease the serum levels/effectiveness of protease inhibitors; conversely, PIs may increase the levels/toxicity of tenofovir.
	Cidofovir, acyclovir-valacyclovir, ganciclovir-valganciclovir	C	Concomitant use of the agents with tenofovir may lead to accumulation of both due to competition for active tubular secretion.
Zidovudine	Bone marrow suppressants/cytotoxic agents (eg, adriamycin, dapsone, flucytosine, vincristine, vinblastine)	D	Concomitant use may increase risk of hematologic toxicity.
	Ganciclovir-valganciclovir, interferon alfa	D	Concomitant use may increase risk of hematologic toxicities; monitor hemoglobin, hematocrit, and white blood cell count with differential frequently; dose reduction or interruption of either agent may be needed.
	Lamivudine	C	Plasma levels of zidovudine are increased by –39% with concomitant use.
	Methadone	C	May increase serum levels/effects of zidovudine; monitor for toxicities.
	Probenecid	C	Probenecid may increase zidovudine levels. Myalgia, malaise, and/or fever and maculopapular rash have been reported with concomitant use.
	Ribavirin	D	May inhibit intracellular phosphorylation of zidovudine reducing efficacy; concomitant use not recommended.
	Rifamycin derivatives, tipranavir/ritonavir	D	May decrease the levels/effects of zidovudine; no interaction with rifabutin noted; dose adjustment for tipranavir/ritonavir + zidovudine have not been established.
	Stavudine	D	Zidovudine may decrease the antiviral activity of stavudine (based on <i>in vitro</i> data). Avoid concurrent use.
Valproic acid	C	Valproic acid may increase plasma levels of zidovudine; monitor for possible increase in side effects (AUC increased by 80%).	
Zalcitabine	Nephrotoxic drugs (eg, amphotericin, foscarnet, cimetidine, probenecid, aminoglycosides)	C	May potentiate the risk of developing peripheral neuropathy or other toxicities associated with zalcitabine by interfering with the renal elimination of zalcitabine.
	Didanosine, stavudine	D	May increase risk of peripheral neuropathy; concurrent use not recommended.
	Lamivudine	D	May decrease the therapeutic efficacy of zalcitabine by inhibiting intracellular phosphorylation of zalcitabine; concomitant use not recommended.
Lamivudine	Trimethoprim (and other drugs excreted by organic cation transport)	C	May increase serum levels/effects of lamivudine by competing for active tubular secretion.
	Zalcitabine	D	Intracellular phosphorylation of lamivudine and zalcitabine may be inhibited if used together; concomitant use should be avoided.
	Zidovudine	C	Plasma levels of zidovudine are increased by –39% with concomitant use.

¹Severity rating: C = monitor therapy; D = consider therapy modification; X = avoid combination.

POISONING AND TOXICOLOGY

Drugs That Should Not Be Used with Protease Inhibitors					
Drug Category	Indinavir	Ritonavir¹	Saquinavir²	Nelfinavir	Alternatives
Analgesics	None	Piroxicam, propoxyphene	None	None	ASA, oxycodone, acetaminophen
Cardiac	None	Amiodarone, encainide, flecainide, propafenone, quinidine	None	None	Limited experience
Antimycobacterial	Rifampin	Rifabutin ³	Rifampin, rifabutin	Rifampin	For rifabutin (as alternative for MAI treatment): clarithromycin, ethambutol (treatment, not prophylaxis), or azithromycin
Calcium channel blocker	None	Bepridil	None	None	Limited experience
Antihistamine	Astemizole	Astemizole	Astemizole	Astemizole	Loratadine
Gastrointestinal	Cisapride	Cisapride	Cisapride	Cisapride	Limited experience
Antidepressant	None	Bupropion	None	None	Fluoxetine, desipramine
Neuroleptic	None	Clozapine, pimozide	None	None	Limited experience
Psychotropic	Midazolam, triazolam	Clorazepate, diazepam, estazolam, flurazepam, midazolam, triazolam, zolpidem	Midazolam, triazolam	Midazolam, triazolam	Temazepam, lorazepam
Ergot alkaloid (vasoconstrictor)		Dihydroergotamine (D.H.E. 45), ergotamine ⁴ (various forms)		Dihydroergotamine (D.H.E. 45), ergotamine ⁴ (various forms)	

¹The contraindicated drugs listed are based on theoretical considerations. Thus, drugs with low therapeutic indices yet with suspected major metabolic contribution from CYP3A, CYP2D6, or unknown pathways are included in this table. Actual interactions may or may not occur in patients.

²Given as Invirase® or Fortovase® [DSC].

³Reduce rifabutin dose to one-fourth of the standard dose.

⁴This is likely a class effect.

ASSESSMENT OF LIVER FUNCTION

Child-Pugh Score			
Component	Score Given for Observed Findings		
	1	2	3
Encephalopathy grade ¹	None	1-2	3-4
Ascites	None	Mild or controlled by diuretics	Moderate or refractory despite diuretics
Albumin (g/dL)	>3.5	2.8-3.5	<2.8
Total bilirubin (mg/dL)	<2 (<34 micromoles/L)	2-3 (34-50 micromoles/L)	>3 (> 50 micromoles/L)
or			
Modified total bilirubin ²	<4	4-7	>7
Prothrombin time (seconds prolonged)	<4	4-6	>6
or			
INR	<1.7	1.7-2.3	>2.3

¹Encephalopathy grades:

Grade 0: Normal consciousness, personality, neurological examination, electroencephalogram

Grade 1: Restless, sleep disturbed, irritable/agitated, tremor, impaired handwriting, 5 cps waves

Grade 2: Lethargic, time-disoriented, inappropriate, asterixis, ataxia, slow triphasic waves

Grade 3: Somnolent, stuporous, place-disoriented, hyperactive reflexes, rigidity, slower waves

Grade 4: Unrousable coma, no personality/behavior, decerebrate, slow 2-3 cps delta activity

Alternative encephalopathy grades:

Grade 1: Mild confusion, anxiety, restlessness, fine tremor, slowed coordination

Grade 2: Drowsiness, disorientation, asterixis

Grade 3: Somnolent but rousable, marked confusion, incomprehensible speech, incontinent, hyperventilation

Grade 4: Coma, decerebrate posturing, flaccidity

²Modified total bilirubin used to score patients who have Gilbert's syndrome or who are taking indinavir.

Child-Pugh Classification

Class A (mild hepatic impairment): Score 5-6

Class B (moderate hepatic impairment): Score 7-9

Class C (severe hepatic impairment): Score 10-15

Note: Atypical antipsychotics are defined as 1) decrease or no EPS at doses producing antipsychotic effect; 2) minimum or no increase in prolactin; 3) decrease in both positive and negative symptoms of schizophrenia.

¹Rate of TD ~ 1/5 that seen with conventional antipsychotics

²Case reports.

³Dose related within 40-160 mg dosage range.

DR EPS = dose related extrapyramidal symptoms.

PROL = prolactin elevation (may cause amenorrhea, galactorrhea, gynecomastia, impotence).

TD = tardive dyskinesia.

ACH = anticholinergic side effects (dry mouth, blurred vision, constipation, urinary hesitancy).

SZ = seizures.

OH = orthostatic hypotension (blood pressure drops upon standing).

LFTs = increased liver function test results.

SED = sedation.

WT GAIN = weight gain.

NMS = neuroleptic malignant syndrome.

AGRAN = agranulocytosis (without white blood cells to fight infection).

TX REFR = efficacy in treatment refractory schizophrenia.

Lipid = lipid abnormalities; cholesterol and/or triglyceride elevations.

DM = diabetes (based on case reports).

QTc = QTc prolongation.

DD = dose dependent.

AVERAGE WEIGHTS AND SURFACE AREAS

Millimole and Milliequivalent Calculations

Definitions	
mole	= gram molecular weight of a substance (aka molar weight)
millimole (mM)	= milligram molecular weight of a substance (a millimole is 1/1000 of a mole)
equivalent weight	= gram weight of a substance which will combine with or replace 1 gram (1 mole) of hydrogen; an equivalent weight can be determined by dividing the molar weight of a substance by its ionic valence
milliequivalent (mEq)	= milligram weight of a substance which will combine with or replace 1 milligram (1 millimole) of hydrogen (a milliequivalent is 1/1000 of an equivalent)

Calculations	
moles	= $\frac{\text{weight of a substance (grams)}}{\text{molecular weight of that substance (grams)}}$
millimoles	= $\frac{\text{weight of a substance (milligrams)}}{\text{molecular weight of that substance (milligrams)}}$
equivalents	= moles \times valence of ion
milliequivalents	= millimoles \times valence of ion
moles	= $\frac{\text{equivalents}}{\text{valence of ion}}$
millimoles	= $\frac{\text{milliequivalents}}{\text{valence of ion}}$
millimoles	= moles \times 1000
milliequivalents	= equivalents \times 1000

Note: Use of equivalents and milliequivalents is valid only for those substances which have fixed ionic valences (eg, sodium, potassium, calcium, chlorine, magnesium bromine, etc). For substances with variable

ionic valences (eg, phosphorous), a reliable equivalent value cannot be determined. In these instances, one should calculate millimoles (which are fixed and reliable) rather than milliequivalents.

Milliequivalent Conversions

To convert mg/100 mL to mEq/L the following formula may be used:

$$\frac{(\text{mg}/100 \text{ mL}) \times 10 \times \text{valence}}{\text{atomic weight}} = \text{mEq/L}$$

To convert mEq/L to mg/100 mL the following formula may be used:

$$\frac{(\text{mEq/L}) \times \text{atomic weight}}{10 \times \text{valence}} = \text{mg}/100 \text{ mL}$$

To convert mEq/L to volume of percent of a gas the following formula may be used:

$$\frac{(\text{mEq/L}) \times 22.4}{10} = \text{volume percent}$$

Milliequivalents for Selected Ions

Approximate Milliequivalents — Weights of Selected Ions		
Salt	mEq/g Salt	mg Salt/mEq
Calcium carbonate [CaCO ₃]	20	50
Calcium chloride [CaCl ₂ · 2H ₂ O]	14	74
Calcium gluceptate [Ca(C ₇ H ₁₃ O ₈) ₂]	4	245
Calcium gluconate [Ca(C ₆ H ₁₁ O ₇) ₂ · H ₂ O]	5	224
Calcium lactate [Ca(C ₃ H ₅ O ₃) ₂ · 5H ₂ O]	7	154
Magnesium gluconate [Mg(C ₆ H ₁₁ O ₇) ₂ · H ₂ O]	5	216
Magnesium oxide [MgO]	50	20
Magnesium sulfate [MgSO ₄]	17	60
Magnesium sulfate [MgSO ₄ · 7H ₂ O]	8	123
Potassium acetate [K(C ₂ H ₃ O ₂)]	10	98
Potassium chloride [KCl]	13	75
Potassium citrate [K ₃ (C ₆ H ₅ O ₇) · H ₂ O]	9	108
Potassium iodide [KI]	6	166
Sodium acetate [Na(C ₂ H ₃ O ₂)]	12	82
Sodium acetate [Na(C ₂ H ₃ O ₂) · 3H ₂ O]	7	136
Sodium bicarbonate [NaHCO ₃]	12	84
Sodium chloride [NaCl]	17	58
Sodium citrate [Na ₃ (C ₆ H ₅ O ₇) · 2H ₂ O]	10	98
Sodium iodine [NaI]	7	150
Sodium lactate [Na(C ₃ H ₅ O ₃)]	9	112
Zinc sulfate [ZnSO ₄ · 7H ₂ O]	7	144

Valences and Atomic Weights of Selected Ions			
Substance	Electrolyte	Valence	Molecular Wt
Calcium	Ca ⁺⁺	2	40
Chloride	Cl ⁻	1	35.5
Magnesium	Mg ⁺⁺	2	24
Phosphate	HPO ₄ ^{- -} (80%)	1.8	96 ¹
pH = 7.4	H ₂ PO ₄ ⁻ (20%)	1.8	96 ¹
Potassium	K ⁺	1	39
Sodium	Na ⁺	1	23
Sulfate	SO ₄ ^{- -}	2	96 ¹

¹The molecular weight of phosphorus only is 31, and sulfur only is 32.

Body Surface Area of Adults and Children

Calculating Body Surface Area in Children

In a child of average size, find weight and corresponding surface area on the boxed scale to the left; or, use the nomogram to the right. Lay a straightedge on the correct height and weight points for the child, then read the intersecting point on the surface area scale.

FOR CHILDREN OF NORMAL HEIGHT AND WEIGHT

NOMOGRAM

BODY SURFACE AREA FORMULA (Adult and Pediatric)

$$BSA (m^2) = \sqrt{\frac{ht (in) \times wt (lb)}{3131}} \quad \text{or, in metric: } BSA (m^2) = \sqrt{\frac{ht (cm) \times wt (kg)}{3600}}$$

BETA-BLOCKERS

Agent	Adrenergic Receptor Blocking Activity	Lipid Solubility	Protein Bound (%)	Half-Life (h)	Bioavailability (%)	Primary (Secondary) Route of Elimination	Indications	Usual Dosage
Acebutolol (Sectral®)	β ₁	Low	15-25	3-4	40 7-fold ¹	Hepatic (renal)	Hypertension, arrhythmias	P.O.: 400-1200 mg/d
Atenolol (Tenormin®)	β ₁	Low	<5-10	6-9 ²	50-60 4-fold ¹	Renal (hepatic)	Hypertension, angina pectoris, acute MI	P.O.: 50-200 mg/d I.V.: 5 mg × 2 doses
Betaxolol (Kerlone®)	β ₁	Low	50-55	14-22	84-94	Hepatic (renal)	Hypertension	P.O.: 10-20 mg/d
Bisoprolol (Zebeta®)	β ₁	Low	26-33	9-12	80	Renal (hepatic)	Hypertension, heart failure	P.O.: 2.5-5 mg
Carteolol (Cartrol®)	β ₁ β ₂	Low	20-30	6	80-85	Renal	Hypertension	P.O.: 2.5-10 mg/d
Carvedilol (Coreg®)	β ₁ β ₂ α ₁	ND	98	7-10	25-35	Bile into feces	Hypertension, heart failure (mild to severe)	P.O.: 6.25 mg twice daily
Esmolol (Brevibloc®)	β ₁	Low	55	0.15	NA 5-fold ¹	Red blood cell	Supraventricular tachycardia, sinus tachycardia	I.V. infusion: 25-300 mcg/kg/min
Labetalol (Trandate®)	α ₁ β ₁ β ₂	Moderate	50	5.5-8	18-30 10-fold ¹	Renal (hepatic)	Hypertension	P.O.: 200-2400 mg/d I.V.: 20-80 mg at 10-min intervals up to a maximum of 300 mg or continuous infusion of 2 mg/min
Metoprolol (Lopressor®, Toprol-XL®)	β ₁	Moderate	10-12	3-7	50 10-fold ¹ (Toprol XL®: 77)	Hepatic/renal	Hypertension, angina pectoris, acute MI, heart failure (mild to moderate; XL formulation only)	P.O.: 100-450 mg/d I.V.: Post-MI 15 mg Angina: 15 mg then 2.5 mg/hour Arrhythmias: 0.2 mg/kg
Nadolol (Corgard®)	β ₁ β ₂	Low	25-30	20-24	30 5- to 8-fold ¹	Renal	Hypertension, angina pectoris	P.O.: 40-320 mg/d
Penbutolol (Levatol®)	β ₁ β ₂	High	80-98	5	~100	Hepatic (renal)	Hypertension	P.O.: 20-80 mg/d
Pindolol	β ₁ β ₂	Moderate	57	3-4 ²	90 4-fold ¹	Hepatic (renal)	Hypertension	P.O.: 20-60 mg/d
Propranolol (Inderal®, various)	β ₁ β ₂	High	90	3-5 ²	30 20-fold ¹	Hepatic	Hypertension, angina pectoris, arrhythmias	P.O.: 40-480 mg/d I.V.: Reflex tachycardia 1-10 mg
Propranolol long-acting (Inderal-LA®)	β ₁ β ₂	High	90	9-18	20- to 30-fold ¹	Hepatic	Hypertrophic subaortic stenosis, prophylaxis (post-MI)	P.O.: 180-240 mg/d
Sotalol (Betapace®, Beta-pace AF®, Sorine®)	β ₁ β ₂	Low	0	12	90-100	Renal	Ventricular arrhythmias/tachyarrhythmias	P.O. 160-320 mg/d
Timolol (Blocadren®)	β ₁ β ₂	Low to moderate	<10	4	75 7-fold ¹	Hepatic (renal)	Hypertension, prophylaxis (post-MI)	P.O.: 20-60 mg/d P.O.: 20 mg/d

Dosage is based on 70 kg adult with normal hepatic and renal function.

Note: All beta₁-selective agents will inhibit beta₂ receptors at higher doses.

¹Interpatient variations in plasma levels.

²Half-life increased to 16-27 hours in creatinine clearance of 15-35 mL/minute and >27 hours in creatinine clearance < 15 mL/minute.

BLOOD LEVEL SAMPLING TIME GUIDELINES

Drug	Infusion Time	Therapeutic Range	When to Draw Levels
Amikacin sulfate			
I.V.	30 min	Peak: 20-30 mcg/mL	Peak: 30 min after end of 30 min infusion
		Trough: < 10 mcg/mL	Trough: Within 30 min before next dose
I.M.			Peak: 1 h after I.M. injection
			Trough: Within 30 min before next dose
Carbamazepine		4-12 mcg/mL	Just before next dose
Chloramphenicol			
I.V.	30 min	Peak: 15-25 mcg/mL	Peak: 90 min after end of 30 min infusion
			Trough: Just before next dose
P.O.			Peak: 2 h post-P.O. dose
Cyclosporine			
I.V./P.O.		BMT 100-200 ng/mL	Just before next dose
		Liver transplant: 200-300 ng/mL	
		Renal transplant 100-200 ng/mL	
Digoxin			
I.V./P.O.		Age and disease related: 0.8-2 ng/mL	6 h postdose to just before next dose
Ethosuximide			
P.O.		40-100 mcg/mL	Just before next dose
Flucytosine			
P.O.		25-100 mcg/mL	Peak: 2 h postdose after at least 4 d of therapy
Fosphenytoin (measure phenytoin levels)			
I.V.		Phenytoin: 10-20 mcg/mL	Peak: 2 h after end of an infusion
I.M.			Peak: 4 h after I.M. injection
Gentamicin			
I.V.	30 min	Peak: 4-10 mcg/mL	Peak: 30 min after end of 30 min infusion
		Trough: 0.5-2 mcg/mL	Trough: Within 30 min before next dose
I.M.			Peak: 1 h after I.M. injection
			Trough: Within 30 min before next dose
Phenobarbital		15-40 mcg/mL	Trough: Just before next dose
Phenytoin			
P.O., I.V.		10-20 mcg/mL	Trough: Just before next dose
I.V.			Post-load/Peak: 1 h after end of infusion
Theophylline			
I.V. bolus	30 min	10-20 mcg/mL	Peak: 30 min after end of 30 min infusion
Continuous infusion			16-24 h after the start or change in a constant I.V. infusion
P.O. liquid, fast-release tablet (Somophyllin [®] , Slo-Phyllin [®] liquid & tablet)			Peak: 1 h postdose Trough: Just before next dose
P.O. slow-release (Theo-Dur [®] , Slo-Phyllin [®] GC, Slo-bid [®])			Peak: 4 h postdose Trough: Just before next dose

<i>(Continued)</i>			
Drug	Infusion Time	Therapeutic Range	When to Draw Levels
Tobramycin			
I.V.	30 min	Peak: 4-10 mcg/mL	Peak: 30 min after end of 30 min infusion
		Trough: 0.5-2 mcg/mL	Trough: Within 30 min before next dose
I.M.			Peak: 1 h post-I.M. injection
			Trough: Within 30 min before next dose
Trimethoprim			
I.V., dose 20 mg/kg	60 min	Peak: 5-10 mcg/mL	Peak: 30 min after end of 60 min infusion
I.V., dose 8-10 mg/kg		Peak 1-3 mcg/mL	
P.O.			Peak: 1 h postdose
Valproic acid			
P.O.		50-100 mcg/mL	Trough: Just before next dose
Vancomycin	60 min	Peak: 25-40 mcg/mL	Peak: 20-30 min after end of 60 min infusion ¹
		Trough: 5-15 mcg/mL	Trough: Within 30 min before next dose
<p>Note: In any ingestion, blood level sampling should occur on presentation and repeated soon after (1-2 hours) to determine if significant ongoing absorption is occurring.</p>			
<p>¹Some institutions may draw vancomycin peak 1 hour after 1-hour infusion and accept the lower range of therapeutic.</p>			

BREAST-FEEDING - TOXINS/DRUGS TO AVOID*Toxins/Drugs to Be Avoided During Breast-Feeding*

Acebutolol	Dieldrin
Aloe (<i>Aloe vera</i>)	Dihydrotachysterol
Alprazolam	Diphenhydramine
Amantadine	Diuretics
5-Aminosalicylic acid	Donepezil
Amiodarone	Doxepin
Amphetamine	Doxorubicin
Anthraquinones (laxatives)	Dyphylline
Antineoplastic agents*	Ergonovine
Atenolol	Ergotamine
Atropine	Ethanol
Azathioprine	Ethylene dichloride
Basil (<i>Oaknum basilicum</i>)	Famciclovir (Penciclovir)
Betaxolol	Fenfluramine
Bismuth subsalicylate	Fluconazole
Bromides (> 5 g/day)	Fluorescein
Bromisovalerylurea	Fluoxetine
Bromocriptine	Gallium-67 (14 days*)†
Buckthorn bark and berry	Gold salts
Buflomedill	Guanfacine
Calciferol	Heptachlor
Carisoprodol	Heroin
<i>Cascara sagrada</i>	Hexachlorobenzene
Chloral hydrate	Hexachlorophene
Chloramphenicol	Hydroxyurea
Chlordane	Indian snakeroot (<i>Rauwolfia serpentina</i>)
Chlordiazepoxide	Indium-111 isotope (20 hours*)
Chlorpromazine	Iodides (especially potassium iodide)
Chlorthalidone	Iodine-123 (36 hours*)
Chromium	Iodine-125 (12 days*)†
Chocolate (> 16 oz/day)	Iodine-131 (14 days*)†
Cimetidine	Isoniazid
Clemastine	Ivermectin
Clofazimine	Lamotrigine
Clonidine	Lead (venous blood lead levels > 35 mcg/dL)
Cocaine	Lindane
Colchicine	Lithium
Coltsfoot leaf	Lovastatin
Copper-64 (50 hours)	Marijuana (dronabinol)
Cyclophosphamide	Maté (Paraguay tea)
Cyclosporine	Meperidine
Cyproheptadine	Mepindolol
Danazol	Meprobamate
Danthron	Mercaptopurine
Dexfenfluramine	Methimazole
Dexrazoxane	Methotrexate
Diazepam	Methylmercury

Metoclopramide	Propofol
Metronidazole (discontinue breast-feeding for 1 day)	Quetiapine
Mifepristone	Quinolone antibiotics
Minocycline	Radioactive diagnostic and therapeutic agents
Moricizine	Ranitidine
Nadolol	Reserpine
Nefazodone	Retinoids
Nicergoline	Rhubarb root
Nicotine	Riluzole
Olanzapine	Salicylate (> 1 g)
Opiates	Selegiline
Organochlorines	Senna (<i>Cassia senna</i>)
Oxycodone	Sodium isotope (4 days*)
Oxprenolol	Sotalol
Perchloroethylene	Strontium chloride (Sr 89)
Petasite root	Sulfasalazine
Phencyclidine	Technetium-99m (1-3 days†)
Phenindione	Tetrachloroethylene
Phenobarbital	Tetracycline
Phenolphthalein	Theophylline
Piperazine	Thiouracil
Piroxicam	Tilidine
Polychlorinated/polybrominated biphenyls	Timolol
Povidone-iodine	Tinidazole (discontinue breast-feeding for 1 day)
Prazepam	Tolbutamide
Prednisone (> 20 mg/day)	Tocainide
Primidone	Zipeprol
Proguanil	

*Antineoplastic agents, in general, with the possible exception of azathioprine (75-100 mg/day) with close infant monitoring.

†Duration of radioactivity excretion in breast milk.

Breast-feeding should be discontinued if the following radioisotopes are utilized:¹³¹I-HSA, ¹²⁵I-HSA, ¹²⁵I-fibrinogen, Na-¹³¹I, ⁶⁷Ga-citrate, ⁷⁵Se-methionine, sodium ³²P phosphate, and chromic ³²P phosphate.

BREAST-FEEDING AND DRUGS

Prior to recommending or prescribing medications to a lactating woman, the following should be considered:

Is drug therapy necessary?

Can drug exposure to the infant be minimized? (Using a different route of administration, timing of the dose in relation to breast-feeding, length of therapy, using breast milk stored prior to treatment, etc)

The infant's age and health status (her own ability to metabolize the medication)

The pharmacokinetics of the drug

Will the drug interact with a medication the infant is prescribed?

If medications must be used, pick the safest drug possible.

In situations where the only drug available may have adverse effects in the nursing infant, consider measuring the infant's blood levels.

The tables presented below have been adapted from the American Academy of Pediatrics Committee on Drugs report, "Transfer of Drugs and Other Chemicals Into Human Milk," September, 2001. It should not be inferred that if a medication is not in the tables it is considered safe for administration to a lactating woman; only that published reports concerning their use were not available at the time the report was published.

Cyclophosphamide	Doxorubicin
Cyclosporine	Methotrexate

These are medications thought to interfere with cellular metabolism in the nursing infant. Immune suppression may be possible; effects on growth or carcinogenesis are not known. In addition, doxorubicin is concentrated in human milk; methotrexate is associated with neutropenia in the nursing infant.

Amphetamine	Marijuana
Cocaine	Phencyclidine
Heroin	

Drugs of abuse are not only dangerous to the nursing infant, but also to the mother. Women should be encouraged to avoid their use completely. Effects to the infant reported with amphetamine use in the mother include irritability and poor sleeping; it is also a substance that is concentrated in human milk. Cocaine may cause irritability, vomiting, diarrhea, tremors, or seizures in the infant. Heroin may also cause tremors as well as restlessness, vomiting, and poor feeding.

Nicotine, which was previously on this list, is associated with decreased milk production, decreased weight gain in the infant, and possible increased respiratory illness in the infant. Although there are still questions outstanding regarding smoking and breast-feeding, women should be counseled on the possible effects to their infants and offered aid to smoking cessation if appropriate.

Drug	Recommended Time for Cessation of Breast-Feeding
Copper 64 (^{64}Cu)	Radioactivity in milk present at 50 h
Gallium 67 (^{67}Ga)	Radioactivity in milk present for 2 wk
Indium 111 (^{111}In)	Very small amount present at 20 h
Iodine 123 (^{123}I)	Radioactivity in milk present up to 36 h
Iodine 125 (^{125}I)	Radioactivity in milk present for 12 d
Iodine 131 (^{131}I)	Radioactivity in milk present 2-14 d, depending on study

Drug	Recommended Time for Cessation of Breast-Feeding
Iodine ¹³¹	If used for thyroid cancer, high radioactivity may prolong exposure to infant
Radioactive sodium	Radioactivity in milk present 96 h
Technetium-99m (^{99m} Tc), ^{99m} Tc macroaggregates, ^{99m} Tc O ₄	Radioactivity in milk present 15 h to 3 d

Consider pumping and storing milk prior to study for use during the radioactive period. Pumping should continue after the study to maintain milk production; however, this milk should be discarded until radioactivity is gone. Notify nuclear medicine physician prior to study that the mother is breast-feeding; a short-acting radionuclide may be appropriate. Contact Radiology Department after testing is complete to screen milk samples before resuming feeding.

Antianxiety	Antidepressant	Antipsychotic
Alprazolam Diazepam Lorazepam Midazolam Perphenazine Prazepam ¹ Quazepam Temazepam	Amitriptyline Amoxapine Bupropion Clomipramine Desipramine Doxepin Fluoxetine Fluvoxamine Imipramine Nortriptyline Paroxetine Sertraline ¹ Trazodone	Chlorpromazine Clozapine ¹ Haloperidol Mesoridazine Trifluoperazine
¹ Drug is concentrated in human milk.		

Psychotropic medications usually appear in the breast milk in low concentrations. Although adverse effects in the infant may be limited to a few case reports, the long half-life of these medications and their metabolites should be considered. In addition, measurable amounts may be found in the infant's plasma and also brain tissue. Long-term effects are not known. Colic, irritability, feeding and sleep disorders, and slow weight gain are effects reported with fluoxetine. Chlorpromazine may cause galactorrhea in the mother, while drowsiness and lethargy have been reported in the nursing infant. A decline in developmental scores has been reported with chlorpromazine and haloperidol.

Drug	Reported Effect in Nursing Infant
Amiodarone	Hypothyroidism
Chloramphenicol	Idiosyncratic bone marrow suppression
Clofazimine	Increase in skin pigmentation; high transfer of mother's dose to infant is possible
Lamotrigine	Therapeutic serum concentrations in infant
Metoclopramide ¹	
Metronidazole	
Tinidazole	
¹ Drug is concentrated in human milk.	

No adverse effects to the infant have been reported for metoclopramide; however, it should be recognized that it is a dopaminergic agent. Metronidazole and tinidazole are *in vitro* mutagenic agents. In cases where single

dose therapy is appropriate for the mother, breast-feeding may be discontinued for 12-24 hours to allow excretion of the medication.

Table 5. Drugs That Have Been Associated With Significant Effects on Some Nursing Infants and Should Be Given to Nursing Mothers With Caution¹

Drug	Reported Effect
Acebutolol	Hypotension, bradycardia, tachypnea
5-Aminosalicylic acid	Diarrhea (one case)
Atenolol	Cyanosis, bradycardia
Bromocriptine	Suppresses lactation; may be hazardous to the mother
Aspirin (salicylates)	Metabolic acidosis (one case)
Clemastine	Drowsiness, irritability, refusal to feed, high-pitched cry, neck stiffness (one case)
Ergotamine	Vomiting, diarrhea, convulsions (doses used in migraine medications)
Lithium	One-third to one-half therapeutic blood concentration in infants
Phenindone	Anticoagulant; increased prothrombin and partial thromboplastin time in one infant; not used in the United States
Phenobarbital	Sedation; infantile spasms after weaning from milk-containing phenobarbital, methemoglobinemia (one case)
Primidone	Sedation, feeding problems
Sulfasalazine (salicylazosulfapyridine)	Bloody diarrhea (one case)

¹Blood concentration in the infant may be of clinical importance; measure when possible.

Nimodipine (Nimotop®)	13	> 95	ND	4-6	1-2		Hepatic; CYP3A4 substrate (major); metabolites inactive or less active than parent; extensive first pass	Urine (50%; as metabolites); feces 32%
Nisoldipine (Sular®)	5	> 99	ND	6-12	7-12		Hepatic; CYP3A4 substrate (major); 1 active metabolite (10% of parent); extensive first pass	Urine as metabolites
Phenylalkylamines								
Verapamil (Calan®) (immediate release)	20-35	90	30	6-8	4.5-12		Hepatic; CYP3A4 substrate (major); 1 active metabolite (20% of parent); extensive first pass	Urine (70%; 3%-4% as unchanged drug); feces 16%
Benzothiazepines								
Diltiazem (Cardizem®) (immediate release)	~ 40	70-80	30-60	6-8	3-4.5	3-13 L/kg	Hepatic; CYP3A4 substrate (major); 1 major metabolite (20%-50% of parent); extensive first pass	Urine as metabolites

CHRONIC RENAL FAILURE

In chronic renal failure, there is a progressive loss of nephron function. Depending upon the extent of loss, signs, symptoms, and biochemical abnormalities may or may not be present. Signs of renal failure (eg, nocturia) begin to appear when the number of functioning nephrons decreases to 10% to 40%. This stage of renal failure is referred to as renal insufficiency. Patients at this stage have little or no renal reserve; the ability to metabolize and excrete certain drugs is impaired as is the ability to eliminate large quantities of protein catabolic products. Serum creatinine (Cr) and blood urea nitrogen (BUN) are increased. The loss of approximately 95% of functioning nephrons results in the uremic syndrome. Acid-base, hematologic, and electrolyte abnormalities (hyperkalemia, hyponatremia, hypercalcemia, hypocalcemia, hypermagnesemia, hyperphosphatemia) are routinely seen, as is fluid overload, which can result in CHF, hypertension, and left ventricular hypertrophy. Hyperkalemia is an important consideration because of its ability to precipitate fatal cardiac arrhythmias. Gastrointestinal disorders (eg, nausea, vomiting, anorexia, GI bleeding), chronic anemia, and an altered immune system are also present.

Effect on Drug Disposition

Bioavailability

Several factors affect drug absorption in renal failure patients. Absorption of drugs can be decreased in uremic patients who have nausea, vomiting, diarrhea, gastritis, and pancreatitis. Uremia can result in an increase in gastric pH, thereby reducing the bioavailability of drugs requiring an acidic medium for absorption. An increase in gastric pH can also occur secondary to antacid use, which is often needed by renal failure patients. Antacids bind to other drugs, reducing their absorption. Gastric emptying time, gastric mobility, and intestinal motility can be decreased in the uremic patient, which can influence drug absorption.

Protein Binding

A drug's effect is produced by its free or unbound fraction. In renal failure patients, protein binding is reduced, which increases the amount of unbound drug. For example, this is seen with acidic drugs normally bound to albumin; since albumin is frequently decreased in renal failure, a greater free fraction of drug is seen. This effect is most important for drugs with high protein binding (>80%), such as phenytoin and valproic acid. The increase in free fraction can increase clearance of phenytoin since it is a low extraction ratio drug. Increased free drug can also result from the displacement of acidic drugs from albumin binding sites by acidic by-products seen in uremia and as a result of conformational changes in albumin which reduce the number/affinity of binding sites for drugs. Decreased tissue protein binding of digoxin decreases its volume of distribution, necessitating smaller loading digoxin loading doses in renal failure.

Metabolism

Renal failure significantly impacts on drug metabolism in a number of organs. The kidney houses the renal cytochrome P450 system, which contributes to the metabolism of a number of drugs. Renal failure has been demonstrated to potentially increase, decrease, or have no effect on drug metabolism. Renal failure can also impact on drugs, which are metabolized by the liver to active metabolites. If these metabolites are renally eliminated, they accumulate in renal failure leading to increased activity and/or adverse effects. Meperidine (normeperidine), morphine (morphine-6-glucuronide), procainamide (N-acetylprocainamide), and allopurinol (oxypurinol) are four examples of such drugs. Dosages of these drugs should be carefully titrated in renal failure patients, and potential toxic effects should be monitored.

Elimination

The degree of renal impairment and the percentage of drug normally excreted unchanged in the urine will determine the impact of renal failure on elimination. Drugs are eliminated by the kidney via either filtration or active secretion. Molecular size and protein binding will determine a drug's filterability; low protein bound and small drugs are filtered more easily. Renal secretion is dependent on the anionic and cationic pathways. Depending on the cause of the renal disease, alterations in secretion and filtration can occur independently of each other. Estimates of GFR such as creatinine clearance are generally used to estimate renal function. But estimates of GFR may not predict alterations in clearance due to tubular dysfunction and altered secretion. Therefore close monitoring for efficacy and toxicity of renally eliminated drugs is necessary even when appropriate dosage alterations based on estimates of creatinine clearance have been performed.

Renal Dosing

Individualized drug dosage regimens for patients with renal failure generally utilize a correlation between creatinine clearance and drug clearance. Creatinine clearance is best estimated from a stable serum creatinine in patients with normal muscle mass and weight. A number of equations to estimate creatinine clearance are available. Multiple methods of renal dosage modification may be available, and they generally include increasing the interval or decreasing the dose. Both of these methods maintain the same steady state serum concentrations. Increasing the interval maintains similar peaks and troughs as usual dosing. Decreasing the dose results in lower peaks and higher troughs. This method is useful for antibiotics such as cephalosporins where the lack of postantibiotic effect necessitates maintenance of serum concentrations above the MIC.

Drug Dosing in Renal Replacement Therapy

Drug removal by hemodialysis is impacted by numerous drug-related factors. Molecular weight less than 500 daltons is generally associated with drug removal by traditional hemodialysis methods. However, hi-flux filters can remove drugs of 5,000 daltons or greater. Water soluble drugs are more likely to be removed than drugs of poor solubility in aqueous media. Protein binding is an additional significant factor, since only free drug is available to diffuse across the semi-permeable membrane. Volume of distribution also correlates well, as drugs with smaller volumes of distribution are more likely to come in contact with the semi-permeable membrane and are more significantly dialyzed than drugs with large volumes of distribution that are largely distributed to tissue.

Characteristics of the dialysis procedure also impact on the amount of drug removed. A variety of dialysis filters of various compositions are available. Significant differences in drug clearances with different dialysis membranes and filters have been described. In addition, blood and dialysate flow rates vary along with the length of the dialysis session. Therefore, drug clearances can vary significantly based on the specific dialysis prescription.

The need for supplemental dosing after dialysis is based on the relative amount of drug removed by a typical dialysis session. When >25% to 30% of a dose is removed by a typical 4-hour dialysis session, it is generally recommended that a supplemental dose be administered. Use of hi-flux membranes may necessitate more aggressive supplementation, especially for some drugs that are not removed by typical procedures (eg, vancomycin). Given the multitude of factors impacting the potential amount of drug removed, close monitoring for efficacy and toxicity is necessary.

Preoperative Evaluation of the Chronic Renal Failure Patient

Assessment of renal function should be part of the comprehensive preoperative evaluation of the chronic renal failure patient. Tests are used in an attempt to quantify renal function and include BUN, serum creatinine, measured creatinine clearance, and estimated creatinine clearance. The following table lists the advantages and disadvantages for each test as well as their normal values.

Test	Normal Values	Advantages/Disadvantages
BUN	8-20 mg/dL	- Rapid, inexact estimate of creatinine clearance
		- BUN is increased by high protein intake, blood in GI tract, accelerated catabolism
		- Hepatic dysfunction decreases BUN concentration
		- Reabsorption of urea is greater when urinary flow is low
Cr (serum creatinine)	0.5-1.2 mg/dL	- Rapid, inexact estimate of creatinine clearance
		- Creatinine is produced at a lower rate in elderly and in females; levels may fail to accurately reflect degree of nephron loss
		- Patients with muscle wasting from chronic disease may have low serum creatinine levels
		- Heavily muscled patients or acutely catabolic patients may have higher than normal serum creatinine levels secondary to more rapid muscle breakdown

<i>(Continued)</i>		
Test	Normal Values	Advantages/Disadvantages
C _{cr} (measured)	120 mL/minute	- Best overall indicator of GFR
		- Must accurately record urinary volume
		- Hydration can influence GFR determination
C _{cr} (estimated)	120 mL/minute	- Superior to BUN or serum creatinine for quantification of renal reserve
		- Same disadvantages as serum creatinine

Urinalysis assesses urinary pH as well as the presence of hematuria, pyuria, cellular casts, and proteinuria. The patient's cardiovascular status, hemoglobin concentration, and adequacy of dialysis therapy should also be assessed.

Intraoperative Management of the Chronic Renal Failure Patient

Monitoring

Intraoperative monitoring should include blood pressure, heart rate, EKG, oxygen saturation (via pulse oximeter), carbon dioxide (via capnometry), and degree of neuromuscular blockade (via a peripheral nerve stimulator). Invasive cardiovascular monitoring should be performed as needed.

Fluid Management

Fluid management must take into consideration the chronic renal failure patient's inability to excrete excess sodium and water. In those patients not requiring hemodialysis, a urine output > 0.5 mL/kg/hour can usually be maintained by administration of a balanced salt solution at a rate of 3-5 mL/kg/hour. If necessary, the patient can be dialyzed postoperatively if intravascular volume is increased to an unsatisfactory level intraoperatively.

Selection of Anesthetic Agents

A knowledge of drug action in renal failure is important in determining an appropriate drug regimen (drug and dose). The reader is referred to the drugs' individual monographs to determine dosing in renal failure. Several examples follow.

I.V. anesthetic agents. Thiopental is highly bound to plasma proteins. Since protein binding is reduced in renal failure, a larger fraction of unbound thiopental is available. Further, a greater proportion of thiopental is found in the nonionized, unbound form secondary to the acidic pH seen in renal failure. Finally, uremia alters the blood-brain barrier, which results in an increased sensitivity to thiopental. Because of these factors, a lower induction dose of thiopental is needed for uremic patients.

Induction doses of ketamine and benzodiazepines require less reduction since they are less protein-bound than thiopental. Normal benzodiazepine doses, however, may show an exaggerated response in debilitated renal failure patients. Ketamine, because of its ability to increase blood pressure and cardiac output, may worsen the hypertension seen with renal failure.

Morphine's elimination half-life and clearance are not changed in renal failure. As already alluded to, its glucuronide metabolite accumulates in renal failure and can cause prolonged respiratory depression. The synthetic opioids, fentanyl, sufentanil, and alfentanil are hepatically metabolized with their metabolites renally excreted. The rapid tissue redistribution seen with these agents after small doses should result in a short duration of action in both normal and renal failure patients. Sufentanil does, however, have an active metabolite which can accumulate in chronic renal failure patients. Remifentanil, because of its metabolism by nonspecific esterases in blood and tissue, is not affected by renal failure. Dosing remains the same as in normal patients.

Inhalational agents. The major route of elimination of these agents is via the lungs, not the kidneys. Metabolism of some of these agents can result in renally excreted metabolites. Enflurane and sevoflurane are metabolized to inorganic fluoride, which can accumulate in renal failure patients. Sevoflurane is currently not recommended for use in patients with a serum creatinine > 1.5 mg/dL. An advantage of the volatile inhalation agents is that they produce neuromuscular blockade, which can reduce the dose of neuromuscular blocking agent required.

Neuromuscular blocking agents. The depolarizing neuromuscular blocking agent succinylcholine causes a transient increase in serum potassium of approximately 0.5-1 mEq/L. This may become a problem in uremic

patients who have an elevated serum potassium; the increase may be enough to produce cardiac arrhythmias. Plasma cholinesterase levels are sufficient in renal failure patients so that no clinically significant prolongation of succinylcholine's effect should be expected.

The elimination of nondepolarizing neuromuscular blocking agents is dependent to varying degrees on renal excretion. The following table lists the elimination profiles of the commercially available nondepolarizing agents. The elimination half-lives of agents primarily eliminated renally are increased in patients with renal failure. Atracurium and cisatracurium, because of their primarily nonrenal elimination, are ideal agents to use in renal failure patients. Both pancuronium and vecuronium have active metabolites that can accumulate in renal failure. One of atracurium's metabolites, laudanosine, can also accumulate in renal failure. Laudanosine has no neuromuscular blocking activity but has been shown to cause CNS excitation in animals; this effect has not been demonstrated in humans.

Agent	Renal	Hepatic	Biliary	Plasma
Atracurium	<5%	—	—	Hofmann elimination Ester hydrolysis
Cisatracurium	R/H <20%	R/H <20%	—	Hofmann elimination
Doxacurium	80% to 100%	—	Yes	—
Gallamine	95% to 100%	—	<1%	—
Mivacurium	<10%	—	Minor	Plasma cholinesterase
Pancuronium	60% to 80%	15% to 40%	5% to 10%	—
Rocuronium	30%	—	50%	—
Vecuronium	30%	20% to 30%	40% to 75%	—

R/H = renal/hepatic metabolism.

Renal failure increases the duration of action of the anticholinesterase agents (neostigmine, pyridostigmine, edrophonium) commonly used to reverse the residual effects of neuromuscular blockade by 100% or more (secondary to their elimination primarily by the kidneys). This makes the possibility of recurarization unlikely. Other factors which influence reversal of neuromuscular blockade in the renal failure patient include acid-base status, electrolyte levels, concomitant use of potentiating drugs (eg, aminoglycosides), and temperature.

Postoperative Management of the Chronic Renal Failure Patient

Hypertension is frequently seen in the postoperative period. Vasodilators (eg, fenoldopam and hydralazine) may be useful as initial therapy. Nitroprusside can be used transiently, but large doses or prolonged use could be associated with thiocyanate toxicity in renal failure. If hypervolemia is the cause, dialysis can be used to remove excess fluid if it is an option. Supplemental oxygen should be considered if anemia is present, continuous monitoring of the EKG is warranted if arrhythmias are a concern in a hyperkalemic patient, and caution should be used when administering opioids for pain secondary to the potential for CNS depression and hypoventilation.

CIGARETTE SMOKING AND EFFECTS ON DRUGS/TOXINS

Drug	Effect
Amitriptyline	Possible decrease in tricyclic antidepressant drug levels due to increased hepatic metabolism
Arsenic	Possible increase in lung cancer
Asbestos	Increased risk of lung cancer (not mesothelioma)
Ascorbic acid	Increased recommended dietary allowance (to 100 mg/day)
Beta carotene	Increased risk of lung cancer
Byssinosis	Risk factor in textile workers
Caffeine	Increases metabolism by 56%
Chlordiazepoxide	Larger dose required to achieve sedative effects
Chlorpromazine	Decreases serum concentrations by 24%
Chlorzepate	Decreased area under the curve (AUC)
Chromium (hexavalent)	Increased risk of lung cancer
Cocaine	Enhances (additively) cocaine-induced vasoconstriction in areas of atherosclerosis
Codeine	Induced glucuronidation of codeine
Cotton dust	Exacerbation of respiratory effects of byssinosis
Desipramine	Possible decrease in tricyclic antidepressant drug levels due to increased hepatic metabolism
Diazepam	Larger dose required to achieve sedative effects
Diesel exhaust	Possible added effect for lung cancer
Estradiol	Increases 2-hydroxylation
Estrogen	Increased risk of cardiovascular events
Ethyl alcohol	Increased risk for oral and esophageal cancer; delayed gastric emptying
Flecainide	Reduction of serum flecainide levels (by possibly increasing hepatic metabolism)
Fluvoxamine	Increased metabolism of fluvoxamine by 25%; lower serum concentrations of fluvoxamine
Haloperidol	Increases clearance by 44% and decreases serum levels by 70%
Heparin	Shorter heparin half-life
Imipramine	Possible decrease in tricyclic antidepressant drug levels due to increased hepatic metabolism
Insulin	Decreased subcutaneous absorption; heavy smokers may require a 15% to 30% increase in insulin dosage compared to nonsmokers; possible decrease in tricyclic antidepressant drug levels due to increased hepatic metabolism
Leflunomide	Increases drug plasma clearance by 38%
Lidocaine	Decreased oral bioavailability with increased oral clearance
Lisinopril	Improves both receptor mediated and tonic nitric-oxide release
Mexiletine	Increases oral clearance by 25% with decreased half-life by 36%
Mineral oil (cutting oil) mists	Synergistic effect of reduced lung function and chronic cough
Mustard gas	Possible increase in lung cancer
Neuroleptics	Increased risk for tardive dyskinesia
Nicotine	Increased metabolism
Nortriptyline	Possible decrease in tricyclic antidepressant drug levels due to increased hepatic metabolism
Olanzapine	Increases clearance by 98%
Pentazocine	Decreased analgesic effect
Phenacetin	Increased metabolism
Propoxyphene	Decreased analgesic effect
Propranolol	Decreased therapeutic effect
Radiation	Possible increased risk of lung cancer
Radon	Increased risk of lung cancer
Riluzole	Clearance decreased from 32% to 36% in smokers

<i>(Continued)</i>	
Drug	Effect
Ritonavir	Decreased ritonavir levels
Sertraline	Nausea, dizziness, and flushing
Silica	Possible increased risk of lung cancer
Tacrine	Increases tacrine clearance and decreases tacrine half-life by 50%; mean plasma tacrine levels are decreased three-fold
Theophylline	Decreased theophylline levels with decreased effect; decreases half-life by 63% and increases V_d by 31%
Uranium	Probable increase in lung cancer
Vinyl acetate	Enhanced respiratory impairment
Warfarin	Increases warfarin clearance by 13% - no effect on prothrombin time

Conditions Associated With Environmental Tobacco Smoke (ETS)

Infants (50% of all infants exposed to ETS)

- Behavior problems
- Otitis media (38% higher rate)
- Elevated blood pressure
- Bronchiolitis/bronchitis
- Pneumonia (double the risk)
- Decreased stature
- Inflammatory bowel disease
- Delayed dental maturation
- Increased lipoprotein concentration
- Meningococcal disease
- Sinusitis (risk is 50% greater)
- Sudden infant death syndrome (threefold risk)

Adolescents

- Asthma (49% more exacerbations with delayed recovery)
- Asthma in children with parental atopy and ETS (odds ratio 2.68)
- Almost 9% greater ratio of total cholesterol to HDL cholesterol and almost 7% greater ratio of total cholesterol to LDL cholesterol
- Increased clearance of theophylline in asthmatic children
- Increased rates of leukemia, lymphoma, and lung cancer

Adults

- Lung cancer (3000-5000 cases annually)
- Increase in arteriosclerosis (50,000 deaths annually)
- Increased incidence of chronic obstructive pulmonary disease
- Increases risk of death from coronary artery disease in "never smokers" by about 5%

Pets

- Increased risk of malignancy in dogs
- Double the risk of lymphoma in cats

CLINICAL SYNDROMES ASSOCIATED WITH FOOD-BORNE DISEASES

Clinical Syndromes	Incubation Period (h)	Causes	Commonly Associated Vehicles
Nausea and vomiting	< 1-6	<i>Staphylococcus aureus</i> (preformed toxins, A, B, C, D, E)	Ham, poultry, cream-filled pastries, potato and egg salad, mushrooms
		<i>Bacillus cereus</i> (emetic toxin)	Fried rice, pork
		Heavy metals (copper, tin, cadmium, zinc)	Acidic beverages
Histamine response and gastrointestinal (GI) tract	< 1	Histamine (scombroid)	Fish (bluefish, bonito, mackerel, mahi-mahi, tuna)
Neurologic, including paresthesia and GI tract	0-6	Tetrodotoxin, ciguatera	Puffer fish
			Fish (amberjack, barracuda, grouper, snapper)
		Paralytic compounds	Shellfish (clams, mussels, oysters, scallops, other mollusks)
		Neurotoxic compounds	Shellfish
		Domoic acid	Mussels
		Monosodium glutamate	Chinese food
Neurologic and GI tract manifestations	0-2	Mushroom toxins (early onset)	Mushrooms
Moderate-to-severe abdominal cramps and watery diarrhea	8-16	<i>B. cereus</i> enterotoxin	Beef, pork, chicken, vanilla sauce
		<i>Clostridium perfringens</i> enterotoxin	Beef, poultry, gravy
	16-48	Caliciviruses	Shellfish, salads, ice
		Enterotoxigenic <i>Escherichia coli</i>	Fruits, vegetables
		<i>Vibrio cholerae</i> 01 and 0139	Shellfish
		<i>V. cholerae</i> non-01	Shellfish
Diarrhea, fever, abdominal cramps, blood and mucus in stools	16-72	<i>Salmonella</i>	Poultry, pork, eggs, dairy products including ice cream, vegetables, fruit
		<i>Shigella</i>	Egg salad, vegetables
		<i>Campylobacter jejuni</i>	Poultry, raw milk
		Invasive <i>E. coli</i>	
		<i>Yersinia enterocolitica</i>	Pork chitterlings, tofu, raw milk
		<i>Vibrio parahaemolyticus</i>	Fish, shellfish
Bloody diarrhea, abdominal cramps	72-120	Enterohemorrhagic <i>E. coli</i>	Beef (hamburger), raw milk, roast beef, salami, salad dressings
Methemoglobin poisoning	6-12	Mushrooms (late onset)	Mushrooms
Hepatorenal failure	6-24	Mushrooms (late onset)	Mushrooms
Gastrointestinal then blurred vision, dry mouth, dysarthria, diplopia, descending paralysis	18-36	<i>Clostridium botulinum</i>	Canned vegetables, fruits and fish, salted fish, bottled garlic
Extraintestinal manifestations	Varied	Brainerd disease	Unpasteurized milk
		<i>Brucella</i>	Cheese, raw milk
		Group A <i>Streptococcus</i>	Egg and potato salad
		<i>Listeria monocytogenes</i>	Cheese, raw milk, hot dogs, cole slaw, cold cuts
		<i>Trichinella spiralis</i>	Pork
		<i>Vibrio vulnificus</i>	Shellfish

C = Physically compatible if used within 15 minutes after mixing in a syringe

X = Incompatible

• = No documented information

C* = Potential incompatibility produced by certain manufacturers

† = Compatibility profile is characteristic of most barbiturate salts, such as

The following combinations have been found to be compatible:

atropine / meperidine / promethazine

atropine / meperidine / hydroxyzine

meperidine / promethazine / chlorpromazine

The following drugs should not be mixed with any other drugs in the same syringe:

diazepam, chlordiazepoxide

CONTRAINDICATIONS AND PRECAUTIONS TO COMMONLY USED VACCINES

Vaccine	Contraindications	Precautions ¹	Vaccines Can Be Administered
General for all vaccines, including diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP); pediatric diphtheria-tetanus toxoid (DT); adult tetanus-diphtheria toxoid (Td); inactivated poliovirus vaccine (IPV); measles-mumps-rubella vaccine (MMR); <i>Haemophilus influenzae</i> type b vaccine (Hib); hepatitis A vaccine; hepatitis B vaccine; varicella vaccine; pneumococcal conjugate vaccine (PCV); influenza vaccine; and pneumococcal polysaccharide vaccine (PPV)	<ul style="list-style-type: none"> ● Serious allergic reaction (eg, anaphylaxis) after a previous vaccine dose ● Serious allergic reaction (eg, anaphylaxis) to a vaccine component 	<ul style="list-style-type: none"> ● Moderate or severe acute illnesses with or without a fever 	<ul style="list-style-type: none"> ● Mild acute illness with or without fever ● Mild to moderate local reaction (ie, swelling, redness, soreness); low-grade or moderate fever after previous dose ● Lack of previous physical examination in well-appearing person ● Current antimicrobial therapy ● Convalescent phase of illnesses ● Premature birth (hepatitis B vaccine is an exception in certain circumstances)² ● Recent exposure to an infectious disease ● History of penicillin allergy, other nonvaccine allergies, receiving allergen extract immunotherapy ● Temperature <40.5°C, fussiness or mild drowsiness after a previous dose of diphtheria toxoid-tetanus toxoid-pertussis vaccine (DTP)/DTaP ● Family history of seizures³ ● Family history of sudden infant death syndrome ● Family history of an adverse event after DTP or DTaP administration ● Stable neurologic conditions (eg, cerebral palsy, well-controlled convulsions, developmental delay)
DTaP	<ul style="list-style-type: none"> ● Severe allergic reaction after a previous dose or to a vaccine component ● Encephalopathy (eg, coma, decreased level of consciousness, prolonged seizures) within 7 days of administration of previous dose of DTP or DTaP ● Progressive neurologic disorder, including infantile spasms, uncontrolled epilepsy, progressive encephalopathy; defer DTaP until neurologic status clarified and stabilized 	<ul style="list-style-type: none"> ● Fever >40.5°C ≤48 hours after vaccination with a previous dose of DTP or DTaP ● Collapse or shock-like state (ie, hypotonic hyporesponsive episode) ≤48 hours after receiving a previous dose of DTP/DTaP ● Seizure ≤3 days of receiving a previous dose of DTP/DTaP³ ● Persistent, inconsolable crying lasting ≥3 hours, ≤48 hours after receiving a previous dose of DTP/DTaP ● Moderate or severe acute illness with or without fever 	Same as above
DT, Td	<ul style="list-style-type: none"> ● Severe allergic reaction after a previous dose or to a vaccine component 	<ul style="list-style-type: none"> ● Guillain-Barré syndrome ≤6 weeks after previous dose of tetanus toxoid-containing vaccine ● Moderate or severe acute illness with or without fever 	Same as above
IPV	<ul style="list-style-type: none"> ● Severe allergic reaction to previous dose or vaccine component 	<ul style="list-style-type: none"> ● Pregnancy ● Moderate or severe acute illness with or without fever 	—
MMR ⁴	<ul style="list-style-type: none"> ● Severe allergic reaction after a previous dose or to a vaccine component ● Pregnancy ● Known severe immunodeficiency (eg, hematologic and solid tumors; congenital immunodeficiency; long-term immunosuppressive therapy;⁵ or severely symptomatic human immunodeficiency virus [HIV] infection) 	<ul style="list-style-type: none"> ● Recent (≤11 months) receipt of antibody-containing blood product (specific interval depends on product) ● History of thrombocytopenia or thrombocytopenic purpura ● Moderate or severe acute illness with or without fever 	<ul style="list-style-type: none"> ● Positive tuberculin skin test ● Simultaneous TB skin testing⁶ ● Breast-feeding ● Pregnancy of recipient's mother or other close or household contact ● Recipient is child-bearing-age female ● Immunodeficient family member or household contact ● Asymptomatic or mildly symptomatic HIV infection ● Allergy to eggs

CONTRAINDICATIONS AND PRECAUTIONS TO COMMONLY USED VACCINES

(Continued)			
Vaccine	Contraindications	Precautions ¹	Vaccines Can Be Administered
Hib	<ul style="list-style-type: none"> ● Severe allergic reaction after a previous dose or to a vaccine component ● Age <6 weeks 	<ul style="list-style-type: none"> ● Moderate or severe acute illness with or without fever 	—
Hepatitis B	<ul style="list-style-type: none"> ● Severe allergic reaction after a previous dose or to a vaccine component 	<ul style="list-style-type: none"> ● Infant weighing <2000 g² ● Moderate or severe acute illness with or without fever 	<ul style="list-style-type: none"> ● Pregnancy ● Autoimmune disease (eg, systemic lupus erythematosus or rheumatoid arthritis)

Varicella	<ul style="list-style-type: none"> ● Severe allergic reaction after a previous dose or to a vaccine component ● Substantial suppression of cellular immunity ● Pregnancy 	<ul style="list-style-type: none"> ● Recent (≤11 months) receipt of antibody containing blood product (specific interval depends on product) ● Moderate or severe acute illness with or without fever 	<ul style="list-style-type: none"> ● Pregnancy of recipient's mother or other close or household contact ● Immunodeficient family member or household contact⁷ ● Asymptomatic or mildly symptomatic HIV infection ● Humoral immunodeficiency (eg, agammaglobulinemia)
PCV	<ul style="list-style-type: none"> ● Severe allergic reaction after a previous dose or to a vaccine component 	<ul style="list-style-type: none"> ● Moderate or severe acute illness with or without fever 	—
Influenza	<ul style="list-style-type: none"> ● Severe allergic reaction to previous dose or vaccine component, including egg protein 	<ul style="list-style-type: none"> ● Moderate or severe acute illness with or without fever 	<ul style="list-style-type: none"> ● Nonsevere (eg, contact) allergy to latex or thimerosal ● Concurrent administration of Coumadin[®] or aminophylline
PPV	<ul style="list-style-type: none"> ● Severe allergic reaction after a previous dose or to a vaccine component 	<ul style="list-style-type: none"> ● Moderate or severe acute illness with or without fever 	—

¹Events or conditions listed as precautions should be reviewed carefully. Benefits and risks of administering a specific vaccine to a person under these circumstances should be considered. If the risk from the vaccine is believed to outweigh the benefit, the vaccine should not be administered. If the benefit of vaccination is believed to outweigh the risk, the vaccine should be administered. Whether and when to administer DTaP to children with proven or suspected underlying neurologic disorders should be decided on a case-by-case basis.

²Hepatitis B vaccination should be deferred for infants weighing <2000 g if the mother is documented to be hepatitis B surface antigen (Hb_sAg)-negative at the time of the infant's birth. Vaccination can commence at chronological age 1 month. For infants born to (Hb_sAg)-positive women, hepatitis B immunoglobulin and hepatitis B vaccine should be administered at or soon after birth regardless of weight.

³Acetaminophen or other appropriate antipyretic can be administered to children with a personal or family history of seizures at the time of DTaP vaccination and every 4-6 hours for 24 hours thereafter to reduce the possibility of postvaccination fever (source: American Academy of Pediatrics, Pickering LK, ed, "Active Immunization," 2000 Red Book[®] Report of the Committee on Infectious Diseases, 25th ed, Elk Grove Village, IL: American Academy of Pediatrics, 2000).

⁴MMR and varicella vaccines can be administered on the same day. If not administered on the same day, these vaccines should be separated by ≥28 days.

⁵Substantially immunosuppressive steroid dose is considered to be ≥2 weeks of daily receipt of 20 mg or 2 mg/kg body weight of prednisone or equivalent.

⁶Measles vaccination can suppress tuberculin reactivity temporarily. Measles-containing vaccine can be administered on the same day as tuberculin skin testing. If testing cannot be performed until after the day of MMR vaccination, the test should be postponed for ≥4 weeks after the vaccination. If an urgent need exists to skin test, do so with the understanding that reactivity might be reduced by the vaccine.

⁷If a vaccine experiences a presumed vaccine-related rash 7-25 days after vaccination, avoid direct contact with immunocompromised persons for the duration of the rash.

CONTRAST MEDIA REACTIONS, PREMEDICATION FOR PROPHYLAXIS

American College of Radiology Guidelines for Use of Nonionic Contrast Media

It is estimated that approximately 5% to 10% of patients will experience adverse reactions to administration of contrast dye (less for nonionic contrast). In approximately 1000-2000 administrations, a life-threatening reaction will occur.

A variety of premedication regimens have been proposed, both for pretreatment of "at risk" patients who require contrast media and before the routine administration of the intravenous high osmolar contrast media. Such regimens have been shown in clinical trials to decrease the frequency of all forms of contrast medium reactions. Pretreatment with a 2-dose regimen of methylprednisolone 32 mg, 12 and 2 hours prior to intravenous administration of HOCM (ionic), has been shown to decrease mild, moderate, and severe reactions in patients at increased risk and perhaps in patients without risk factors. Logistical and feasibility problems may preclude adequate premedication with this or any regimen for all patients. It is unclear at this time that steroid pretreatment prior to administration of ionic contrast media reduces the incidence of reactions to the same extent or less than that achieved with the use of nonionic contrast media alone. Information about the efficacy of nonionic contrast media combined with a premedication strategy, including steroids, is preliminary or not yet currently available. For high-risk patients (ie, previous contrast reactors), the combination of a pretreatment regimen with nonionic contrast media has empirical merit and may warrant consideration. Oral administration of steroids appears preferable to intravascular routes, and the drug may be prednisone or methylprednisolone. Supplemental administration of H₁ and H₂ antihistamine therapies, orally or intravenously, may reduce the frequency of urticaria, angioedema, and respiratory symptoms. Additionally, ephedrine administration has been suggested to decrease the frequency of contrast reactions, but caution is advised in patients with cardiac disease, hypertension, or hyperthyroidism. No premedication strategy should be a substitute for the ABC approach to preadministration preparedness listed above. Contrast reactions do occur despite any and all premedication prophylaxis. The incidence can be decreased, however, in some categories of "at risk" patients receiving high osmolar contrast media plus a medication regimen. For patients with previous contrast medium reactions, there is a slight chance that recurrence may be more severe or the same as the prior reaction; however, it is more likely that there will be no recurrence.

A General Premedication Regimen

Methylprednisolone	32 mg orally 12 and 2 hours prior to procedure
Diphenhydramine	50 mg orally 1 hour prior to the procedure

An Alternative Premedication Regimen

Prednisone	50 mg orally 13, 7, and 1 hour before the procedure
Diphenhydramine	50 mg orally 1 hour before the procedure
Ephedrine	25 mg orally 1 hour before the procedure (except when contraindicated)

Unlabeled Use (Nephroprotective)

N-acetylcysteine, P.O.	600 mg orally twice daily on the day before and the day of the scan in addition to hydration with 0.45% saline intravenously
------------------------	--

Indications For Nonionic Contrast

Previous reaction to contrast – premedicate¹

Known allergy to iodine or shellfish

Asthma, especially if on medication

Myocardial instability or CHF

Risk for aspiration or severe nausea and vomiting

Difficulty communicating or inability to give history

Patients taking beta-blockers

Small children at risk for electrolyte imbalance or extravasation

Renal failure with diabetes, sickle cell disease, or myeloma

At physician or patient request

¹If life-threatening reactions (throat swelling, laryngeal edema, etc), consider omitting the intravenous contrast.

CONTROLLED SUBSTANCES: USES AND EFFECTS

Drugs (Trade or Other Names)	Medical Uses	Physical Dependence	Psychological Dependence	Tolerance	Duration (h)	Usual Method	Possible Effects	Effects of Overdose	Withdrawal Syndrome
Anabolic Steroids									
Testosterone (cypionate, enanthate) (C-V) (Depo [®] -Testosterone, Delatestry [®])	Hypogonadism	Unknown	Unknown	Unknown	14-28 d	Injected	Virilization, acne, testicular atrophy, gynecomastia, aggressive behavior, edema	Unknown	Possible depression
Nandrolone (decanoate, phenpropionate) (C-III) (Nortestosterone, Durabolin, Deca-Durabolin [®] , Deca)	Anemia, breast cancer	Unknown	Unknown	Unknown	14-21 d	Injected			
Oxymetholone (C-III) (Anadrol [®] -50)	Anemia	Unknown	Unknown	Unknown	24	Oral			
Cannabis									
Marijuana (C-I) (Pot, Acapulco gold, grass, reefer, sirsemilla, Thai sticks)	None	Unknown	Moderate	Yes	2-4	Smoked, oral	Euphoria, relaxed inhibitions, increased appetite, disorientation	Fatigue, paranoia, possible psychosis	Occasional reports of insomnia, hyperactivity, decreased appetite
Tetrahydrocannabinol (C-I, II) (THC, Marinol [®])	Antinauseant	Unknown	Moderate	Yes	2-4	Smoked, oral			
Hashish and hashish oil (C-I) (Hash, hash oil)	None	Unknown	Moderate	Yes	2-4	Smoked, oral			
Depressants									
Chloral hydrate (C-IV) (Nocotec, Somnos, Felsules)	Hypnotic	Moderate	Moderate	Yes	5-8	Oral	Slurred speech, disorientation, drunken behavior without odor of alcohol	Shallow respiration, clammy skin, dilated pupils, weak and rapid pulse, coma, possible death	Anxiety, insomnia, tremors, delirium, convulsions, possible death
Barbiturates (C-II, III, IV) (Amytal [®] , Fiorinal [®] , Nembutal [®] , Seconal [™] , Tuinal [®] , phenobarbital, pentobarbital)	Anesthetic, anti-convulsant, sedative, hypnotic, veterinary euthanasia agent	High-moderate	High-moderate	Yes	1-16	Oral, injected			
Benzodiazepines (C-IV) (Ativan [®] , Dalmane [®] , diazepam, Librium [®] , Xanax [®] , Serax [®] , Valium [®] , Tranxene [®] , Verstran, Versed [®] , Halcion [®] , Paxipam [®] , Restoril [®])	Antianxiety, sedative, anti-convulsant, hypnotic	Low	Low	Yes	4-8	Oral, injected			
Glutethimide (C-II) (Doriden)	Sedative, hypnotic	High	Moderate	Yes	4-8	Oral			
Other depressants (C-I, II, III, IV) (Equanil [®] , Miltown [®] , Noludar, Placidyl [®] , Valmid, methaqualone)	Antianxiety, sedative, hypnotic	Moderate	Moderate	Yes	4-8	Oral			

Hallucinogens									
Drugs (Trade or Other Names)	Medical Uses	Physical Dependence	Psychological Dependence	Tolerance	Duration (h)	Usual Method	Possible Effects	Effects of Overdose	Withdrawal Syndrome
LSD (C-I) (Acid, microdot)	None	None	Unknown	Yes	8-12	Oral	Illusions and hallucinations, altered perception of time and distance	Longer, more intense "trip" episodes, psychosis, possible death	Unknown
Mescaline and peyote (C-I) (Mescal, buttons, cactus)	None	None	Unknown	Yes	8-12	Oral			
Amphetamine variants (C-I) (2,5-DMA, STP, MDA, MDMA, ecstasy, DOM, DOB)	None	Unknown	Unknown	Yes	Variable	Oral, injected			
Phencyclidine and analogs (C-I, II) (PCE, PCPy, TCP, PCP, hog, loveboat, angel dust)	None	Unknown	High	Yes	Days	Oral, smoked			
Other hallucinogens (C-I) (Bufotenine, ibogaine, DMT, DET, psilocybin, psilocyn)	None	None	Unknown	Possible	Variable	Smoked, oral, injected, sniffed			
Narcotics									
Heroin (C-I) (Diacetylmorphine, horse, smack)	None in U.S.; analgesic, antitussive	High	High	Yes	3-6	Injected, sniffed, smoked	Euphoria, drowsiness, respiratory depression, constricted pupils, nausea	Slow and shallow breathing, clammy skin, convulsions, coma, possible death	Watery eyes, runny nose, yawning, loss of appetite, irritability, tremors, panic, cramps, nausea, chills and sweating
Morphine (C-II) (Duramorph [®] , MS-Contin [®] , Roxanol [™] , Oramorph SR [™])	Analgesic	High	High	Yes	3-6	Oral, smoked, injected			
Codeine (C-II, III, V) (Tylenol [®] w/codeine, Empirin [®] w/codeine, Robitussin [®] A-C, Fiorinal [®] w/codeine, APAP w/codeine)	Analgesic, antitussive	Moderate	Moderate	Yes	3-6	Oral, injected			
Hydrocodone (C-II, III) (Tussionex [®] , Vicodin [®] , Hycodan [®] , Lorcet [®])	Analgesic, antitussive	High	High	Yes	3-6	Oral			
Hydromorphone (C-II) (Dilaudid [®])	Analgesic	High	High	Yes	3-6	Oral, injected			
Oxycodone (C-II) (Percodan [®] , Percocet [®] , Tylox [®] , Roxicet [®] , Roxicodone [™])	Analgesic	High	High	Yes	4-5	Oral			
Methadone and LAAM (C-I, II) (Dolophine [®] , methadone, levo-alpha-acetyl/methadol, levomethadyl acetate)	Analgesic, treatment of dependence	High	High	Yes	12-72	Oral, injected			

<i>(Continued)</i>									
Drugs (Trade or Other Names)	Medical Uses	Physical Dependence	Psychological Dependence	Tolerance	Duration (h)	Usual Method	Possible Effects	Effects of Overdose	Withdrawal Syndrome
Fentanyl and analogs (C-I, II) (Innovar, Sublimaze [®] , Alfenta [®] , Sufenta [®] , Duragesic [®])	Analgesic, adjunct to anesthesia, anesthetic	High	High	Yes	0.1-72	Injected, transdermal patch	Increased alertness, excitation, euphoria, increased pulse rate and blood pressure, insomnia, loss of appetite	Agitation, increased body temperature, hallucinations, convulsions, possible death	Apathy, long periods of sleep, irritability, depression, disorientation
Other narcotics (C-II, III, IV, V) (Percodan [®] , Percocet [®] , Tylox [®] , opium, Darvon [®] , Talwin [®] , buprenorphine, meperidine (pethidine), Demerol [®])	Analgesic, anti-diarrheal	High-low	High-low	Yes	Variable	Oral, injected			
Stimulants									
Cocaine ² (C-II) (Coke, flake, snow, crack)	Local anesthetic	Possible	High	Yes	1-2	Sniffed, smoked, injected	Increased alertness, excitation, euphoria, increased pulse rate and blood pressure, insomnia, loss of appetite	Agitation, increased body temperature, hallucinations, convulsions, possible death	Apathy, long periods of sleep, irritability, depression, disorientation
Amphetamine/methamphetamine (C-II) (Biphetamine, Desoxyn [®] , Dexedrine [®] , Obetrol, ice)	Attention deficit disorder, narcolepsy, weight control	Possible	High	Yes	2-4	Oral, injected, smoked			
Methylphenidate (C-II) (Ritalin [®])	Attention deficit disorder, narcolepsy	Possible	High	Yes	2-4	Oral, injected			
Other stimulants (C-I, II, III, IV) (Adipex [®] , Didrex [®] , Ionamin [®] , Melfiat [®] , Plegine, Captagon, Sanorex [®] , Tenuate [®] , Tepanil, Prelu-2 [®] , Preludin)	Weight control	Possible	High	Yes	2-4	Oral, injected

CORTICOSTEROIDS

Corticosteroids, Systemic Equivalencies								
Glucocorticoid	Pregnancy Category	Approximate Equivalent Dose (mg)	Routes of Administration	Relative Anti-inflammatory Potency	Relative Mineralocorticoid Potency	Protein Binding (%)	Half-life	
							Plasma (min)	Biologic (h)
Short-Acting								
Cortisone	D	25	P.O., I.M.	0.8	2	90	30	8-12
Hydrocortisone	C	20	I.M., I.V.	1	2	90	80-118	8-12
Intermediate-Acting								
Methylprednisolone ¹	—	4	P.O., I.M., I.V.	5	0	—	78-188	18-36
Prednisolone	B	5	P.O., I.M., I.V., intra-articular, intra-dermal, soft tissue injection	4	1	90-95	115-212	18-36
Prednisone	B	5	P.O.	4	1	70	60	18-36
Triamcinolone ¹	C	4	P.O., I.M., intra-articular, intra-dermal, in- trasynovial, soft tissue injection	5	0	—	200+	18-36
Long-Acting								
Betamethasone	C	0.6-0.75	P.O., I.M., intra-articular, intra-dermal, in- trasynovial, soft tissue injection	25	0	64	300+	36-54
Dexamethasone	C	0.75	P.O., I.M., I.V., intra-articular, intra-dermal, soft tissue injection	25-30	0	—	110-210	36-54
Mineralocorticoids								
Fludrocortisone	C	—	P.O.	10	125	42	210+	18-36

¹May contain propylene glycol as an excipient in injectable forms.

Guidelines For Selection and Use of Topical Corticosteroids

The quantity prescribed and the frequency of refills should be monitored to reduce the risk of adrenal suppression. In general, short courses of high-potency agents are preferable to prolonged use of low potency. After control is achieved, control should be maintained with a low-potency preparation.

Low-to-medium potency agents are usually effective for treating thin, acute, inflammatory skin lesions, whereas high or super-potent agents are often required for treating chronic, hyperkeratotic, or lichenified lesions.

Since the stratum corneum is thin on the face and intertriginous areas, low-potency agents are preferred but a higher potency agent may be used for 2 weeks.

Because the palms and soles have a thick stratum corneum, high or super-potent agents are frequently required.

Low-potency agents are preferred for infants and the elderly. Infants have a high body surface area to weight ratio; elderly patients have thin, fragile skin.

The vehicle in which the topical corticosteroid is formulated influences the absorption and potency of the drug. Ointment bases are preferred for thick, lichenified lesions; they enhance penetration of the drug. Creams are preferred for acute and subacute dermatoses; they may be used on moist skin areas or intertriginous areas. Solutions, gels, and sprays are preferred for the scalp or for areas where a nonoil-based vehicle is needed.

In general, super-potent agents should not be used for longer than 2-3 weeks unless the lesion is limited to a small body area. Medium-to-high potency agents usually cause only rare adverse effects when treatment is limited to 3 months or less and use on the face and intertriginous areas are avoided. If long-term treatment is needed, intermittent vs continued treatment is recommended.

Most preparations are applied once or twice daily. More frequent application may be necessary for the palms or soles because the preparation is easily removed by normal activity and penetration is poor due to a thick stratum corneum. Every-other-day or weekend-only application may be effective for treating some chronic conditions.

Corticosteroids, Topical		
Steroid		Vehicle
Very High Potency		
0.05%	Betamethasone dipropionate, augmented	Lotion, ointment
0.05%	Clobetasol propionate	Cream, foam, gel, lotion, ointment, shampoo, spray
0.05%	Diflorasone diacetate	Ointment
0.05%	Halobetasol propionate	Cream, ointment
High Potency		
0.1%	Amcinonide	Cream, ointment, lotion
0.05%	Betamethasone dipropionate, augmented	Cream
0.05%	Betamethasone dipropionate	Cream, ointment
0.1%	Betamethasone valerate	Ointment
0.05%	Desoximetasone	Gel
0.25%	Desoximetasone	Cream, ointment
0.05%	Diflorasone diacetate	Cream, ointment
0.05%	Fluocinonide	Cream, ointment, gel
0.1%	Halcinonide	Cream, ointment
0.5%	Triamcinolone acetonide	Cream
Intermediate Potency		
0.05%	Betamethasone dipropionate	Lotion
0.1%	Betamethasone valerate	Cream
0.1%	Clocortolone pivalate	Cream
0.05%	Desoximetasone	Cream
0.025%	Fluocinolone acetonide	Cream, ointment
0.05%	Flurandrenolide	Cream, ointment, lotion, tape
0.005%	Fluticasone propionate	Ointment
0.05%	Fluticasone propionate	Cream
0.1%	Hydrocortisone butyrate ¹	Ointment, solution
0.2%	Hydrocortisone valerate ¹	Cream, ointment
0.1%	Mometasone furoate ¹	Cream, ointment, lotion
0.1%	Prednicarbate	Cream, ointment
0.025%	Triamcinolone acetonide	Cream, ointment, lotion
0.1%	Triamcinolone acetonide	Cream, ointment, lotion
Low Potency		
0.05%	Alclometasone dipropionate ¹	Cream, ointment
0.05%	Desonide	Cream
0.01%	Fluocinolone acetonide	Cream, solution
0.5%	Hydrocortisone ¹	Cream, ointment, lotion

Corticosteroids, Topical (Continued)		
Steroid		Vehicle
0.5%	Hydrocortisone acetate ¹	Cream, ointment
1%	Hydrocortisone acetate ¹	Cream, ointment
1%	Hydrocortisone ¹	Cream, ointment, lotion, solution
2.5%	Hydrocortisone ¹	Cream, ointment, lotion
¹ Not fluorinated.

DONOR VICTIMS OF POISONING IN WHOM TRANSPLANTATION OF ORGANS OCCURRED

Toxin	Organs Transplanted
Acetaminophen	Heart, cornea, kidney, pancreas (islet cells)
Barbiturate	Liver, heart, kidney
Benzodiazepines	Kidney, heart, liver
Brodifacoum	Kidney, liver, heart
Carbamazepine	Heart
Carbon monoxide	Heart, liver, kidney, lung, pancreas
Cocaine	Kidney, liver
Cyanide	Corneal, skin, bone, heart, liver, kidney, pancreas
Digitalis	Heart
Ethanol	Heart, kidney
Hemlock (<i>Conium maculatum</i>)	Liver, kidney, pancreas
Insulin	Kidney, heart, pancreas (islet cells)
Lead	Liver
Malathion	Kidney, liver
Methanol	Kidney, liver, heart, lung
Methaqualone	Liver
2,3 methylenedioxymethamphetamine (Ecstasy)	Heart, lung, kidney, liver, pancreas
Tricyclic antidepressants	Kidney, liver
Venlafaxine	Heart

Guidelines Published for Optimal Time to Transplant From Poisoned Organ Donor for Certain Selected Toxins

Toxin	Optimal Time for Transplant
Ethylene glycol Methanol	Acidosis corrected; serum level < 0.5 g/L
Cyanide	Shock corrected; serum level < 8 μ mol/L

	<i>Solandra</i> species of plants	
	Terazosin	
	Terbutaline sulfate	
	Terfenadine	
	Thallium	
	Vanadium	

DRUGS USED IN ADDICTION TREATMENT

Bupropion SR	Smoking cessation:
(Zyban®)	Initiate at 150 mg every morning for 3 days.
	If tolerated, increase to 150 mg twice daily on day 4 of dosing. Should be an interval of at least 8 hours between successive doses. Target quit date after at least 1 week of treatment. Trial may be up to 12 weeks. Contraindicated in patients with seizures, anorexia, or bulimia.
Clonidine	Alcohol, nicotine, opioid withdrawal:
(Catapres®)	Initiate 0.1 mg 2-3times/day; transdermal patch: 0.2 mg, patch change weekly for 3-10 weeks
Disulfiram	Sobriety:
(Antabuse®)	125-500 mg/day; patients must be free of alcohol for at least 12 hours prior to initiation. Contraindicated with metronidazole and alcohol (including cough syrups).
Doxepin	Smoking cessation:
(Adapin® or Sinequan®)	50 mg daily for 3 days
	100 mg daily for days 4-6
	150 mg daily for days 7-21
Levomethadyl	Narcotic dependence:
(ORLAAM®)	Initiate at 20-40 mg 3 times/week
Methadone	Narcotic dependence:
(Dolophine®)	15-60 mg every 6-8 hours; can only be initiated in approved treatment programs
Naltrexone	Alcohol and narcotic dependence:
(ReVia®)	Initiate 25-50 mg/day; patients should be free of opioid for 7-10 days prior to initiation
Nicotine gum	Smoking cessation:
	1-2 pieces/hour; maximum: 30 pieces/day (2 mg/piece). If high tobacco use, give DS (4 mg/piece); maximum: 20/day
Nicotine nasal spray	Smoking cessation:
	1 spray in each nostril (0.5 mg per inhalation) once or twice per hour; maximum: 80 sprays
Nicotine patches	Smoking cessation:
	One patch daily (7-22 mg) for 8 weeks; initiate patch on the quit date
Nortriptyline tablets	Smoking cessation: Maximum dose of 75-100 mg daily; treat for 8-12 weeks
(Aventyl® or Pamelor®)	

Drugs/Toxins Sexually Transmitted

Transmission via Reproductive Fluids	Intimate Contact Transmission
Cephalosproins	Ambrette
Ciguatera	Benzethonium chloride
Penicillins	Benzoyl peroxide
Steroids	Clotrimazole
Sulfas (men)	Nickel
	Nitrates
	Nitrofuratel
	Penicillamine

<i>(Continued)</i>	
Transmission via Reproductive Fluids	Intimate Contact Transmission
	Peru balsam
	Poison oak
	Propylene glycol
	Sulfas (men & women)
	Thioridazine

DRUGS/TOXINS THAT CAN RESULT IN COMA

Drug/Toxin	Serum Level Conventional Units
Acebutolol	20 mg/L
Acetaminophen	300 mcg/mL
Acetone	500 mg/L
Amitriptyline	2 mg/L
Amobarbital	43 mg/L
Baclofen	1 mg/L
Barbital	160 mg/L
Bromides	2000 mcg/mL
Butabarbital	39 mg/L
Caffeine	100 mg/L
Carbamazepine	18 mg/L
Carboxyhemoglobin	30%
Carisoprodol	30 mg/L
Cetirizine	2 mg/L
Chloral hydrate (trichloroethanol)	20 mg/L
Chloralose	3 mg/L
Chlordiazepoxide	20 mg/L

Methaqualone	8 mg/L
Methemoglobin	20%
Methyprylon	50 mg/L
Nomifensine	10 mg/L
Olanzapine	100 mcg/L
Orphenadrine	3 mg/L
Phenobarbital	65 mg/L
Phenytoin	40 mg/L
Propoxyphene	1 mg/L
Quetiapine	13 mg/L
Quinine	12 mcg/mL
Salicylates	100 mg/dL
Secobarbital	7 mg/L
Theophylline	40 mg/L
Tetrahydrocannabinol	180 mcg/L
Toluene	10 mg/L
Tramadol	2000 mcg/L
Tranylcypromine	1 mg/L
Triazolam	31 mcg/L
Valproic acid	500 mg/L
Venlafaxine	6 mg/L
Zopiclone	300 µL

EMERGENCY DRUG DOSAGES, ADULT

Drug and Strength	Recommended I.V. Doses	Comments and Preparation for Infusion
Adenosine 3 mg/mL	Adult: 6 mg bolus I.V. followed by 12 mg	May repeat the 12 mg dose
Aminophylline 500 mg/20 mL	Load 5.6 mg/kg then infusion at 0.4-0.8 mg/kg/h IBW or less based upon patient status	Give ½ loading dose if previous theophylline on board and no signs of toxicity. Give load slowly in 50-100 mL over 30-60 minutes. Max rate 25 mg/min. Can antagonize adenosine
Amiodarone	Supraventricular tachycardia: 2.5-5 mg/kg (over 3-5 minutes) Ventricular arrhythmia: 150 mg over 10 minutes; then 360 mg over 6 hours followed by 540 mg over next 18 hours	Maintenance infusion after first 24 hours: 0.5 mg/minute; boluses of 150 mg over 10 minutes may be given for breakthrough episodes
Atropine 1 mg/10 mL 1 mg/1 mL	0.5 mg increments I.V. push up to 2 mg max. May give ET	Initial slowing of rate with small doses (<0.4 mg)
Bretylium 500 mg/10 mL	For resistant ventricular fibrillation or ventricular tachycardia 5 mg/kg I.V. push. If ineffective in 10 minutes and after 1 or more DC shocks, give 10 mg/kg. May repeat to maximum of 30 mg/kg total. If effective begin drip at 1-2 mg/min	Rapid I.V. infusion may cause nausea and vomiting. May cause transient HTN, PVCs, or other arrhythmia. Hypotension is most frequent side effect. May accumulate in renal failure. Not recommended in digitalis toxicity. Initial response may take up to 60 minutes in ventricular tachycardia. Infusion: mix 1 g/500 mL = 2 mg/mL
Calcium salts Ca chloride 5 mL = 7 mEq (1.3 mEq/mL) Ca gluconate 10 mL = 5 mEq (0.5 mEq/mL)	0.5-1 g I.V.	May repeat every 10 minutes. Give cautiously in digitalis toxicity. Inactivated by blood products. Precipitates with sodium bicarbonate. Current ACLS guidelines do not recommend routine administration
Dexamethasone 20 mg/5 mL	Variable Cerebral edema: 10 mg I.V. initially	I.V. push over 30 seconds
Dextrose 25 g/50 mL	50 mL I.V. push for hypoglycemia	
Diazepam 10 mg/2 mL	Initially 5-10 mg. May repeat prn	Max 5 mg/min I.V. push; propylene glycol solvent. Cardiorespiratory toxicity with rapid administration
Digoxin 0.5 mg/2 mL	0.125-0.5 mg I.V.	Give slowly 0.25 mg/min; propylene glycol solvent. I.V. push may increase systemic vascular resistance
Diphenhydramine 50 mg/mL	Max 100 mg I.V. over 60 seconds	I.V. administration with epinephrine for anaphylaxis; or for drug-induced extrapyramidal reactions
Dobutamine 250 mg/vial	Infusion only. Initial infusion 2.5-10 mcg/kg/min	Increases cardiac output and heart rate. Titrate to patient's response. Recommend close hemodynamic monitoring. Mix 500 mg in 500 mL = 1000 mcg/mL
Dopamine 400 mg/5 mL 800 mg/5 mL	Infusion only 1-5 mcg/kg/min: ↑ renal blood flow only 5-10 mcg/kg/min: ↑ CO, ↑ HR, ↑ RBF > 10 mcg/kg/min: ↑ CO, ↑ HR, ↓ RBF > 20 mcg/kg/min: ↑ CO, ↑ HR, ↑ SVR, ↓ RBF Above are approximate ranges only	Infusion: 400 mg in 250 mL = 1600 mcg/mL (double strength); titrate to BP. Increasing dose increases potential for tachyarrhythmia. Not effective for ethanol-disulfiram-induced hypotension
Epinephrine 1:10,000 10 mL 1:1000 30 mL	0.5-1 mg push every 5 min; may give intracardiac or in ET tube. Initial infusion 1-4 mcg/min	Stimulates heart, increases BP, and coarsens ventricular fibrillation. Infusion: 2 mg in 500 mL = 4 mcg/mL; titrate to BP. Avoid in solvent exposures
Esmolol 250 mg/mL	Loading dose 500 mcg/kg/min for 1 minute	50-300 mcg/kg/min
Furosemide 40 mg/4 mL 100 mg/10 mL	Variable	Initiate at 20-40 mg I.V. push over 1-2 minutes. Larger doses, maximum rate = 500 mg over 30 minutes diluted. Rapid administration may lead to ototoxicity
Heparin 1000 units/mL	80 units/kg IBW I.V. push for PE or DVT. Start constant infusion – 15-20 units/kg IBW/h. Varies with age and clinical status	Caution in elderly patients or patients with bleeding potential. If patient weight is less than IBW, then base dose on actual weight
Hydrocortisone 1 g	Variable dosing Shock: 50 mg/kg I.V. initially	If dose > 500 mg, give over several minutes

<i>(Continued)</i>		
Drug and Strength	Recommended I.V. Doses	Comments and Preparation for Infusion
Inamrinone	75 mg/kg over 3 minutes	2-10 mcg/kg/min. Effective against calcium channel blocker-induced hypotension. Do not mix in dextrose
Isoproterenol 1 mg/5 mL 0.2 mg/mL	Infusion initial 1-4 mcg/min I.V. push initial 0.02-0.04 mg May repeat with up to 0.2 mg every 5 minutes. May use 0.1 mg I.V. push to counter 1 mg I.V. propranolol	Used in complete heart block prior to pacer. May cause tachyarrhythmias. May have varied effect on BP Infusion: mix 2 mg in 500 mL = 4 mcg/mL; titrate to BP I.V. push: dilute 1 mg of 1:5000 with 9 mL of NS = 0.02 mg/mL
Lidocaine 100 mg/5 mL 2 g/50 mL	Initial 0.5-1 mg/kg I.V. push – may give ET. May repeat 0.5-1.0 mg/kg every 10 min to maximum load. Begin infusion at 1-4 mg/min	Infusion: mix 2 g in 500 mL = 4 mg/mL Maximum load: 200-300 mg over 1 h Severe adverse effects include respiratory depression, seizures, psychosis, and arrhythmias. May exacerbate cocaine-induced seizures
Metaraminol 100 mg/10 mL	0.1-5.0 mg I.V. push. Initial infusion = 0.1-0.4 mg/min	Mix 100 mg/500 mL = 0.2 mg/mL; titrate to BP. For direct I.V. push, dilute 1 mg (0.1 mL) in 9.9 mL NS (0.1 mg/mL). Direct/indirect-acting alpha adrenergic agonist
Methylprednisolone 1 g	Variable	100-1000 mg given over 5-minute period
Midazolam	0.4-0.6 mcg/kg/min	1-12 mcg/kg/min infusion
Naloxone 0.4 mg/mL	0.4 mg to 2 mg I.V. push, may repeat every 2 - 3 minutes, as needed	Short-acting, may need to repeat frequently. If no response after 10 mg total, re-evaluate diagnosis of narcotic overdose
Nitroglycerin	0.5-10 mcg/kg/min infusion	In glass container with special “Nitro” tubing
Nitroprusside	0.5-10 mcg/kg/min infusion	Protect from light
Norepinephrine 4 mg/4 mL	Infusion only: initial 1-4 mcg/min	Infusion: mix 8 mg in 500 mL = 16 mcg/mL; titrate to BP. Infiltration causes tissue necrosis (reverse with 5-10 mg Regitine® I.V. around infiltrated site)
Phenytoin 100 mg/2 mL	Load: 15 mg/kg IBW to maximum 1 g. Maximum rate 50 mg/min I.V. push	Reduce if phenytoin on board already. Useful in digoxin or tricyclic antidepressant toxic arrhythmias. Propylene glycol solvent can cause cardiotoxicity with rapid infusion. Must infuse with NS or ½ NS. Not soluble in D ₅ W
Potassium chloride 40 mEq/20 mL	Recommend infusion only. Usual maximum by infusion 10-40 mEq/h for short periods	Rates > 10 mEq/h require EKG monitoring. Too rapid I.V. infusion may cause heart block or asystole. I.V. push not recommended
Procainamide 100 mg/mL 1000 mg/2 mL	Maximum 50 mg/min up to total of 1 g. Initial infusion 2-6 mg/min	Reduce loading dose if procainamide on board already. Infusion: mix 2 g in 500 mL = 4 mg/mL. Do not use in tricyclic-induced ventricular arrhythmia
Propranolol 1 mg/mL	Maximum 1 mg/min up to total dose 5 mg	Beta blocker. Decreases AV conduction. Adverse reactions: heart block, hypotension, heart failure, and bronchospasm (may be reversed with isoproterenol). Caution in patients with verapamil on board
Sodium bicarbonate 50 mEq/50 mL	Initially 1 mEq/kg then 0.5 mEq/kg every 10 minutes. For tricyclic induced ventricular arrhythmia, dose is 1-3 mEq/kg	Indicated only in hypoxemic arrest. Excessive amounts lead to alkalosis, hyperosmolality. Doses should be determined by repeat ABGs
Terbutaline	2 mcg/kg I.V. over 5 minutes. Infusion is 0.1-2 mcg/kg/min	
Verapamil 5 mg/2 mL	2.5-10 mg slow I.V. push initial. May repeat dose every 15-30 minutes	Give over 3 minutes in older patients. Caution in patients with beta blocker or digitalis on board. Contraindicated in patients with second or third degree AV block, sick sinus syndrome, or shock. Hypotension may be controlled with metaraminol

EMERGENCY DRUG DOSAGES, PEDIATRIC

Drug	Dose
Adenosine	40-50 mcg/kg. Increase by 40 mcg/kg increments to conversion.
Albumin 5% injection	5-10 mL/kg, may repeat in 15 min
Atropine injection 0.1 mg/mL	0.02 mg/kg q 5 min (min = 0.1 mg) Max total dose: 0.04 mg/kg or 2 mg, whichever is smaller
Bretylium injection 50 mg/mL	1st dose: 5 mg/kg 2nd dose: 10 mg/kg q 15-30 min Max total dose: 30 mg/kg
Calcium chloride injection 100 mg/mL	0.2-0.5 mL/kg q 10 min Note: Role in resuscitation questionable, should only be used when hyperkalemia, hypermagnesemia, hypocalcemia, or calcium channel blocker toxicity is present
Dextrose 50% injection 0.5 g/mL	0.5 g/kg or (2 mL/kg of dextrose 25%) Warning: Dilute to a 25% solution before administration
Diazepam 10 mg/2 mL	0.2-0.5 mg/kg
Dobutamine injection 12.5 mg/mL	I.V. infusion: 2.5-20 mcg/kg/min
Dopamine injection 40 mg/mL	I.V. infusion: 2.5-20 mcg/kg/min
Epinephrine injection 1:10,000	0.01-0.02 mg/kg q 5 min Max dose: 0.5-1 mg I.V. infusion: 0.1-1.5 mcg/kg/min
Furosemide injection	0.5-1 mg/kg as needed
Isoproterenol injection 0.2 mg/mL	I.V. infusion: 0.05-1 mcg/kg/min (rarely >0.5 mcg/kg/min)
Lidocaine injection 10 mg/mL	0.5-1 mg/kg loading dose (total dose not greater than 3 mg/kg) I.V. infusion: 20-50 mcg/kg/min
Naloxone injection 0.4 mg/mL or 1 mg/mL	Birth to 5 y or 20 kg: 0.1 mg/kg/dose > 5 y or 20 kg: 2 mg/dose May repeat doses q 2-3 minutes
Propranolol 1 mg/mL	0.1 mg/kg slowly May repeat in 2 minutes
Sodium bicarbonate injection 1 mEq/mL or 0.5 mEq/mL	1 mEq/kg x 1 may repeat with 0.5 mEq/kg Warning: Use only the 0.5 mEq/mL solution for neonates or dilute 1 mEq/mL solution 1:1 with sterile water for injection. Note: NaHCO ₃ should be used based on documented metabolic acidosis. Routine use in cardiac arrest is not recommended.
Terbutaline	2 mcg/kg over 5 minutes Infusion is 0.1-2 mcg/kg/min
Verapamil	0.1-0.2 mg/kg up to 5 mg

ENHANCEMENT OF ELIMINATION OF TOXINS

Toxins Eliminated by Multiple Dosing of Activated Charcoal

Acetaminophen	Meprobamate
Amitriptyline	Methotrexate
Atrazine (?)	Methyprylon
Baclofen (?)	Nadolol
Bupropion (?)	Nortriptyline
Carbamazepine	Phencyclidine (?)
Chlordecone	Phenobarbital
Cyclosporine	Phenylbutazone
Dapsone	Phenytoin (?)
Dextropropoxyphene	Piroxicam
Diazepam (desmethyldiazepam)	Propoxyphene
Digitoxin	Propranolol (?)
Digoxin (with renal impairment)	Salicylates (?)
Disopyramide	Theophylline
Glutethimide	Valproic acid
Maprotiline	Vancomycin (?)

The following agents have been studied and have not been demonstrated to result in enhanced elimination.

Amiodarone	Imipramine
Chlopropamide	Tobramycin

Toxins Eliminated by Forced Saline Diuresis

Barium	Isoniazid (?)
Bromides	Meprobamate
Chromium	Methyl iodide
Cimetidine (?)	Mushrooms (Group I)
Cis-platinum	Nickel
Cyclophosphamide	Potassium chloroplatinite
Hydrazine	Thallium
Iodide	Valproic acid (?)
Iodine	

Toxins Eliminated by Alkaline Diuresis

2,4-D-chlorophenoxyacetic acid	Iopanoic acid (?)
Barbital (serum levels > 10 mg/dL)	Isoniazid (?)
Chlorpropamide	Mephobarbital
Fluoride	Methotrexate

2-Methyl-4-chlorophenoxyacetic acid (MCPA)	Quinolones antibiotic
Orellanine (?)	Salicylates
Phenobarbital	Sulfisoxazole
Primidone	Uranium

Drugs and Toxins Removed by Hemodialysis

Acetaminophen	Carbromal
Acetazolamide	Carisoprodol
Acyclovir	Cefaclor
Alkyl phosphate	Cefamandole
Allopurinol	Cefazolin
Aluminum	Cefotaxime
<i>Amanita phalloides</i> (?)	Cefoxitin
Amantadine (?)	Ceftazidime
Amikacin	Cephalexin
Ammonia	Cephaloridine
Ammonium chloride	Cephalothin
Amobarbital	Cephapirin
Amoxicillin	Cephradine
Amphetamine	Chloral hydrate
Ampicillin	Chloramphenicol (?)
Anilines	Chlordiazepoxide (?)
Antimony (Pentavalent) (?)	Chloride
Arsenic (?)	Chlorpropamide
Atenolol	Chromic acid
Azathioprine	Chromium
Azlocillin	Cimetidine (?)
Aztreonam	Ciprofloxacin (?)
Bacitracin (?)	Colistin
Barbital	Cyclobarbitol
Boric acid	Cyclophosphamide
Bretylum	Cycloserine
Bromides	Dapsone
Bromisoval	Demeton-S-methyl sulfoxide
Butalbital	Dextropropoxyphene
Calcium	Diethyl pentenamide
Captopril (?)	Dimethoate
Carbamazepine	Dinitro-ortho-cresol
Carbenicillin	Diquat

Disopyramide	Lithium
Enalapril (?)	Magnesium
Ergotamine	Mannitol
Erythromycin	Meprobamate
Ethambutol	Meropenem
Ethanol	Metal-chelate compounds
Ethchlorvynol (?)	Metformin (?)
Ethinamate	Methanol
Ethosuximide (?)	Methaqualone
Ethylene glycol	Methotrexate
Eucalyptus oil	Methyldopa
Famciclovir (Penciclovir)	Methylprednisolone (?)
Famotidine (?)	Methylprylone
Flucytosine	4-Methylpyrazole
Fluoride	Metronidazole
Fluoridem chlorate	Mezlocillin
5-Fluorouracil (?)	Monochloroacetic acid
Folic acid	Nadolol
Formaldehyde	Nafcillin
Foscarnet sodium	Neomycin
Fosfomycin	Netilmicin
Gabapentin	Nitrates
Gallamine triethiodide	Nitrite
Ganciclovir	Orellanine (?)
Gentamicin	Ouabain (?)
Glufosinate ammonium	Oxalic acid
Glutethimide (?)	Paraldehyde
Glycol ethers	Paraquat (?)
Hydrazine (?)	Pargyline
Hydrochlorothiazide	Penicillin G
Imipenem/Cilastatin	Pentobarbital
Iodides	Phenelzine (?)
Isoniazid	Phenobarbital
Isopropanol	Phosphate
Kanamycin	Phosphoric acid
Ketoprofen	Piperacillin
Lead (with EDTA)	Potassium chloride
Linezolid	Potassium dichromate

Practolol	Succimer (?)
Prednisone (?)	Sulfamethoxazole
Primidone	Sulfisoxazole
Procainamide	Tetracycline (?)
Propoxyphene	Thallium
Quinalbital	Theophylline
Quinidine	Thiocyanates
Ranitidine (?)	Ticarcillin
Rifabutin	Tobramycin
Salicylates	Tocainide
Secobarbital (?)	Topiramate
Sodium chlorate	Tranylcypramine sulfate (?)
Sodium chloride	Trimethoprim
Sodium citrate	Valproic acid (?)
Sotalol	Vancomycin
Streptomycin	Verapamil (?)
Strychnine	Vidarabine

Drugs and Toxins Removed by Hemoperfusion (Charcoal)

Aconitine	Diltiazem (?)
<i>Amanita phalloides</i> (?)	Dimethoate
Atenolol (?)	Disopyramide
Bromisoval	Ethchlorvynol
Bromoethylbutyramide	Ethylene oxide
Caffeine	Glutethimide
Carbamazepine	Levothyroxine (?)
Carbon tetrachloride (?)	Lindane
Carbromal	Liotrix
Chloral hydrate (trichloroethanol)	Meprobamate
Chloramphenicol	Methaqualone
Chlorfenvinphos (?)	Methotrexate
Chlorpropamide	Methsuximide
Cibenzoline succinate	Methypylon (?)
Clonidine	Metoprolol (?)
Colchicine (?)	Nadolol (?)
Creosote (?)	Orellanine (?)
Dapsone	Oxalic acid (?)
Demeton-S-methyl sulfoxide	Paraquat

Parathion (?)

Pentamidine

Phenelzine (?)

Phenobarbital

Phenol

Phenytoin

Podophyllin (?)

Procainamide (?)

Quinidine (?)

Rifabutin (?)

Sotalol (?)

Thallium

Thyroglobulin/Thyroid hormone

Theophylline

Valproic acid

Verapamil (?)

ESTIMATED ALUMINUM CONCENTRATIONS OF SELECTED FOODS

Foods	Aluminum Concentration (mcg/g)
Beverages (mg/L)	
Fruit juices (eg, orange, reconstituted lemon, peach)	0.043-4.130
Soft drinks (eg, ginger ale, diet cola)	0.103-2.084
Cola, carbonated	0.1
Alcoholic beverages (eg, beer, wine, wine coolers, champagne)	0.067-3.20
Beer, canned	0.07
Spirits (eg, brandy, vodka, whiskey)	0.148-0.635
Hot water-extracted, tea bags	0.424-2.931
Herbal teas (1% extract)	0.14-1.065
Tea, steeped	4.3
Instant coffee (1% solution)	0.02-0.581
Whole coffee (3% extract)	0.235-1.163
Animal Products

FOOD-DRUG INTERACTIONS, KEY SUMMARY

Drug	Food	Interaction
Acetaminophen	Watercress	Decreased levels of oxidative metabolites (mercapturate) of acetaminophen
	High pectin	Delayed absorption
Amoxicillin	Any	Decreased absorption
Ampicillin		
Aspirin		
Azithromycin		
Captopril		
Cephalexin (suspension)		
Chlorpromazine		
Didanosine		
Erythromycin stearate		
Fosfomicin		
Isoniazid		
Ketoconazole		
Levodopa		
Lincomycin		
Mercaptopurine		
Methotrexate		
Methyldopa		
Nafcillin		
Nefazodone		
Penicillamine		
Penicillin G and V		
Phenobarbital		
Propantheline		
Rifampin (150 mg)		
Riluzole		
Tetracycline		
Valproic acid		
Valsartan		
Zidovudine		
Aspirin	Any	Delayed absorption
Atenolol		
Cefaclor		
Cephalexin (capsule)		
Cephradine		
Cimetidine		
Glipizide		
Ibuprofen		
Metronidazole		
Piroxicam		
Potassium (tablet)		
Quinidine		

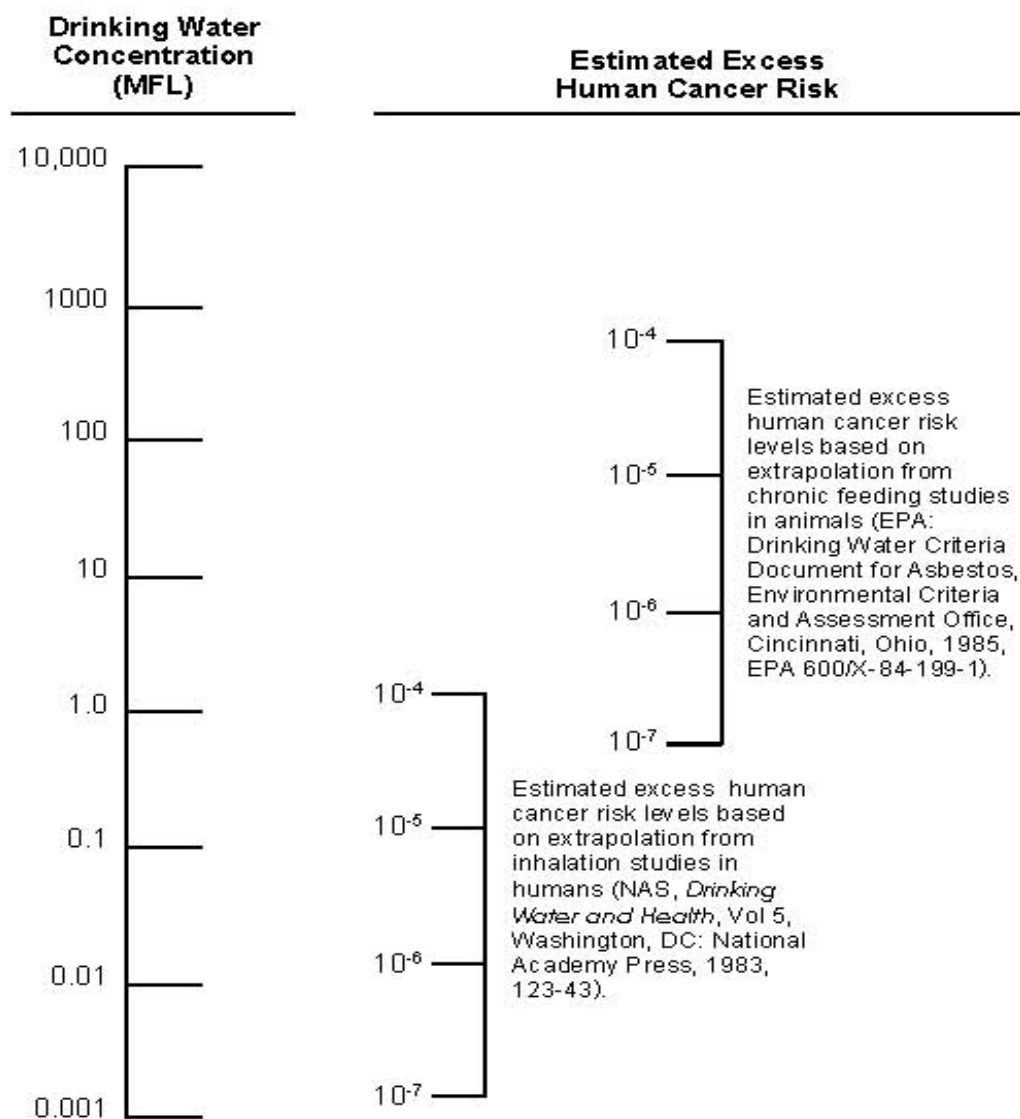

<i>(Continued)</i>		
Drug	Food	Interaction
Sulfonamides (suspension)		
Tacrine		
Warfarin		
Alpha-tocopherol	Any	Increased absorption
Carbamazepine		
Cefuroxime		
Chlorothiazide		
Hydralazine		
Hydrochlorothiazide		
Labetalol		
Lithium		
Mebendazole		
Metroprolol		
Nitrofurantoin		
Phenytoin		
Propoxyphene		
Propranolol		
Riboflavin		
Spirolactone		
Cyclosporine	Many	Decreased absorption
Acitretin	Dietary fat	Increased absorption
Albendazole		
Atovaquone		
Beta-caortene		
Cyclosporine		
Diazepam		
Dicumarol		
Etretinate		
Griseofulvin		
Halofantrine		
Isotretinoin		
Mefenamic acid		
Phenytoin		
Vitamin A		
Vitamin D		
Vitamin E		
Vitamin K		
Ziprasidone		
Biphosphonates (ie, etidronate, alendronate, tiludronate)	Foods with high mineral content (ie, milk)	Reduced absorption
Griseofulvin	High-fat meal	Faster absorption; increased serum levels by 50%
Misoprostol		Reduced peak by delaying absorption
Digoxin		Reduced absorption
Pilocarpine (tablets)		Reduced absorption

<i>(Continued)</i>			
Drug	Food	Interaction	
Zidovudine		Reduced absorption	
Amiodarone	Grapefruit juice (narigen)	Amiodarone metabolism is inhibited with grapefruit juice	
Atorvastatin		Increased serum atorvastatin acid and atorvastatin lactone levels	
Carbamazepine		Increased absorption; increased oral bioavailability	
Cisapride			
Cyclosporine			
Felodipine			
Nifedipine			
Nisoldipine			
Nimlodipine			
Nitrendipine			
Saquinivir			
Verapamil			
Caffeine			Possibly prolongs caffeine's half-life
Coumarin			Delayed urinary excretion of 7-hydroxy-coumarin
Losartan			Increased half-life and decreased area under the curve of the metabolite
Lovastatin		Increases lovastatin and metabolite concentrations	
Midazolam (oral)		Delayed absorption; increased bioavailability	
Sildenafil			Increases bioavailability and tends to delay sildenafil absorption
Quinidine			Delayed absorption of quinidine; inhibits metabolism of quinidine
Ziprasidone			May increase serum concentration of ziprasidone
Terfenadine	Any	Increases terfenadine bioavailability (can increase QT interval on EKG); increased absorption	
Erythromycin stearate		Increased or decreased absorption	
Furosemide		Decreased rate of absorption, potentially decreasing effect	
Mercaptopurine	Any	Decreased bioavailability by 30%	
Isoniazid	Tuna, mackerel, salmon (dark meat fish)	Increased risk for scomboid fish poisoning	
Levodopa	High-protein diet	Decreased absorption	
Digoxin	High fiber meal	Decreased absorption	
Lovastatin			
Lithium	Sodium	Enhanced elimination requiring higher doses	
Methylodopa	Iron	Reduced absorption	
MAO inhibitors (isocarboxazid, phenelzine, procarbazine, tranylcypromine)	High-protein foods that have undergone aging, fermentation, pickling, or smoking; aged cheeses, red wines, pods of broad beans and fava beans; bananas, raisins, avocados; caffeine-containing beverages, beer, ale, and chocolate	Elevated blood pressure	
Phenobarbital	High doses of vitamin B ₆ (pyridoxine) and folic acid	Decreased absorption	
Phenytoin			
Levodopa	Vitamin B ₆ (pyridoxine)	Reduces blood level	

(Continued)		
Drug	Food	Interaction
Diprafenone	Any	Increased bioavailability
Hydralazine		
Metoprolol		
Felodipine		
Nitrofurantoin		
Propranolol		
Phenobarbital	Charcoal-broiled foods	Increased metabolism requiring higher doses
Theophylline		
Phenytoin		
Warfarin		
Ketoconazole	Acidic beverages (pH <2.5, [Coca-Cola Classic®])	Increased absorption
Phenytoin	Most foods	Absorption increased by 25%
	Pudding	Absorption decreased by 50%
Quinolones (eg, ciprofloxacin)	Iron, calcium, aluminum, zinc, magnesium (eg, dairy products)	Decreased absorption
Quinidine	High salt (> 400 mEq/day)	Increased first-pass hepatic elimination
Warfarin	Diets rich in vitamin K such as cauliflower, spinach, broccoli, turnip greens, liver, beans, rice, pork, fish, and some cheeses	Antagonism of effect
ACE inhibitors	Potassium-containing salt substitutes	Increased serum potassium level
Warfarin	Cranberry juice	INR instability

GASTROINTESTINAL CANCER RISKS FROM ASBESTOS

Summary of Calculated Gastrointestinal Cancer Risks From Ingestion of Asbestos

Since there are no human studies in which ingestion of a known amount of asbestos can be associated with a clear increase in gastrointestinal cancer risk, NAS (1983) extrapolated data on gastrointestinal risk from epidemiological studies of workers exposed to asbestos by inhalation. These calculations indicated that lifetime ingestion of 1.1×10^6 TEM fibers/liter of water corresponded to an excess gastrointestinal cancer risk of 10^{-4} (NAS 1983).

In order to present this risk estimate in this figure, the concentration of 1.1×10^6 f/L was converted to a dose of 3.1×10^4 f/kg/day (assuming ingestion of 2 L/day by a 70 kg adult), and this was converted to a dose of 1.6×10^{-5} mg/kg/day by multiplying by a factor of 5.0×10^{-10} mg/TEM fiber (NRC, *Asbestiform Fibers: Nonoccupational Health Risks*, Washington, DC: National Academy Press, 1984).

From "Toxicological Profile for Asbestos," U.S. Department of Health and Human Services, Agency for Toxic Substances and Disease Registry, August, 1995.

HABITUAL, TOXIC, AND LETHAL CONCENTRATIONS (MG/L) OF 103 DRUGS OF ABUSE

Drug	Habitual/Therapeutic			Toxic			Lethal/Postmortem		
	Whole Blood	Serum/Plasma	Urine	Whole Blood	Serum/Plasma	Urine	Whole Blood	Serum/Plasma	Urine

HERB - DRUG INTERACTIONS/CAUTIONS

Herb	Drug Interaction / Caution
Acidophilus/bifidobacterium	Antibiotics (oral)
Activated charcoal	Vitamins or oral medications may be adsorbed
Alfalfa	Do not use with lupus due to amino acid L-canavanine; causes pancytopenia at high doses; warfarin (alfalfa contains a large amount of vitamin K)
Aloe vera	Caution in pregnancy, may cause uterine contractions; digoxin, diuretics (hypokalemia)
Ashwagandha	May cause sedation and other CNS effects
Asparagus root	Causes diuresis
Barberry	Normal metabolism of vitamin B may be altered with high doses
Birch	If taking a diuretic, drink plenty of fluids
Black cohosh	Estrogen-like component; pregnant and nursing women should probably avoid this herb; also women with estrogen-dependent cancer and women who are taking birth control pills or estrogen supplements after menopause; caution also in people taking sedatives or blood pressure medications
Black haw	Do not give to children < 6 years of age (salicin content) with flu or chickenpox due to potential Reye's syndrome; do not take if allergic to aspirin
Black pepper (<i>Piper nigrum</i>)	Antiasthmatic drugs (decreases metabolism)
Black tea	May inhibit body's utilization of thiamine
Blessed thistle	Do not use with gastritis, ulcers, or hyperacidity since herb stimulates gastric juices
Blood root	Large doses can cause nausea, vomiting, CNS sedation, low BP, shock, coma, and death
Broom (<i>Cytisus scoparius</i>)	MAO inhibitors lead to sudden blood pressure changes
Bugleweed (<i>Lycopus virginicus</i>)	May interfere with nuclear imaging studies of the thyroid gland (thyroid uptake scan)
Cat's claw (<i>Uncaria tomentosa</i>)	Avoid in organ transplant patients or patients on ulcer medications, antiplatelet drugs, NSAIDs, anticoagulants, immunosuppressive therapy, intravenous immunoglobulin therapy
Chaste tree berry (<i>Vitex agnus-castus</i>)	Interferes with actions of oral contraceptives, HRT, and other endocrine therapies; may interfere with metabolism of dopamine-receptor antagonists
Chicory (<i>Cichorium intybus</i>)	Avoid with gallstones due to bile-stimulating properties
Chlorella (<i>Chlorella vulgaris</i>)	Contains significant amounts of vitamin K
Chromium picolinate	Picolinic acid causes notable changes in brain chemicals (serotonin, dopamine, norepinephrine); do not use if patient has behavioral disorders or diabetes
Cinnabar root (<i>Salviae multorrhizae</i>)	Warfarin (increases INR)
Deadly nightshade (<i>Atropa belladonna</i>)	Contains atropine
Dong quai	Warfarin (increases INR), estrogens, oral contraceptives, photosensitizing drugs, histamine replacement therapy, anticoagulants, antiplatelet drugs, antihypertensives
Echinacea	Caution with other immunosuppressive therapies; stimulates TNF and interferons
Evening primrose oil	May lower seizure threshold; do not combine with anticonvulsants or phenothiazines
Fennel	Do not use in women who have had breast cancer or who have been told not to take birth control pills
Fenugreek	Practice moderation in patients on diabetes drugs, MAO inhibitors, cardiovascular agents, hormonal medicines, or warfarin due to the many components of fenugreek
Feverfew	Antiplatelets, anticoagulants, NSAIDs
Forskolin, coleonol	This herb lowers blood pressure (vasodilator) and is a bronchodilator and increases the contractility of the heart, inhibits platelet aggregation, and increases gastric acid secretion
Foxglove	Digitalis-containing herb
Garlic	Blood sugar-lowering medications, warfarin, and aspirin at medicinal doses of garlic
Ginger	May inhibit platelet aggregation by inhibiting thromboxane synthetase at large doses; <i>in vitro</i> and animal studies indicate that ginger may interfere with diabetics; has anticoagulant effect, so avoid in medicinal amounts in patients on warfarin or heart medicines
Ginkgo biloba	Warfarin (ginkgo decreases blood clotting rate); NSAIDs, MAO inhibitors
Ginseng	Blood sugar-lowering medications (additive effects) and other stimulants
Ginseng (American, Korean)	Furosemide (decreases efficacy)

<i>(Continued)</i>	
Herb	Drug Interaction/ Caution
Ginseng (Siberian)	Digoxin (increases digoxin level)
Glucomannan	Diabetics (herb delays absorption of glucose from intestines, decreasing mean fasting sugar levels)
Goldenrod	Diuretics (additive properties)
Gymnema	Blood sugar-lowering medications (additive effects)
Hawthorn	Digoxin or other heart medications (herb dilates coronary vessels and other blood vessels, also inotropic)
Hibiscus	Chloroquine (reduced effectiveness of chloroquine)
Hops	Those with estrogen-dependent breast cancer should not take hops (contains estrogen-like chemicals); patients with depression (accentuate symptoms); alcohol or sedative (additive effects)
Horehound	May cause arrhythmias at high doses
Horseradish	In medicinal amounts with thyroid medications
Kava	CNS depressants (additive effects, eg, alcohol, barbiturates, etc); benzodiazepines
Kelp	Thyroid medications (additive effects or opposite effects by negative feedback); kelp contains a high amount of sodium
Labrador tea	Plant has narcotic properties, possible additive effects with other CNS depressants
Lemon balm	Do not use with Graves disease since it inhibits certain thyroid hormones
Licorice	Acts as a corticosteroid at high doses (about 1.5 lbs candy in 9 days) which can lead to hypertension, edema, hypernatremia, and hypokalemia (pseudoaldosteronism); do not use in persons with hypertension, glaucoma, diabetes, kidney or liver disease, or those on hormonal therapy; may interact with digitalis (due to hypokalemia)
Lobelia	Contains lobeline which has nicotinic activity; may mask withdrawal symptoms from nicotine; it can act as a polarizing neuromuscular blocker
Lovage	Is a diuretic
Ma huang	MAO inhibitors, digoxin, beta-blockers, methyldopa, caffeine, theophylline, decongestants (increases toxicity)
Marshmallow	May delay absorption of other drugs taken at the same time; may interfere with treatments of lowering blood sugar
Meadowsweet	Contains salicylates
Melatonin	Acts as contraceptive at high doses; antidepressants (decreases efficacy)
Mistletoe	May interfere with medications for blood pressure, depression, and heart disease
L-phenylalanine	MAO inhibitors
Pleurisy root	Digoxin (plant contains cardiac glycosides); also contains estrogen-like compounds; may alter amine concentrations in the brain and interact with antidepressants
Prickly ash (Northern)	Contains coumarin-like compounds
Prickly ash (Southern)	Contains neuromuscular blockers
Psyllium	Digoxin (decreases absorption)
Quassia	High doses may complicate heart or blood-thinning treatments (quassia may be inotropic)
Red clover	May have estrogen-like actions; avoid when taking birth control pills, HRT, people with heart disease or at risk for blood clots, patients who suffer from estrogen-dependent cancer; do not take with warfarin
Red pepper	May increase liver metabolism of other medications and may interfere with high blood pressure medications or MAO inhibitors
Rhubarb, Chinese	Do not use with digoxin (enhanced effects)
St John's wort	Indinavir, cyclosporine, SSRIs or any antidepressants, tetracycline (increases sun sensitivity); digoxin (decreases digoxin concentration); may also interact with diltiazem, nifedipine, verapamil, etoposide, paclitaxel, vinblastine, vincristine, glucocorticoids, cyclosporine, dextromethorphan, ephedrine, lithium, meperidine, pseudoephedrine, selegiline, yohimbine, ACE inhibitors (serotonin syndrome, hypertension, possible exacerbation of allergic reaction)
Saw palmetto	Acts an antiandrogen; do not take with prostate medicines or HRT
Squill	Digoxin or persons with potassium deficiency; also not with quinidine, calcium, laxatives, saluretics, prednisone (long-term)

<i>(Continued)</i>	
Herb	Drug Interaction / Caution
Tonka bean	Contains coumarin, interacts with warfarin
Vervain	Avoid large amounts of herb with blood pressure medications or HRT
Wild Oregon grape	High doses may alter metabolism of vitamin B
Wild yam	May interfere with hormone precursors
Wintergreen	Warfarin, increased bleeding
Sweet woodruff	Contains coumarin
Yarrow	Interferes with anticoagulants and blood pressure medications
Yohimbe	Do not consume tyramine-rich foods; do not take with nasal decongestants, PPA-containing diet aids, antidepressants, or mood-altering drugs

HERBS

Hemostatic Herbs (Coagulants)

Agrimony (<i>Agrimony eupatoria</i> or <i>Agrimony procera</i>)	Qian Cao (<i>Rubis cordifolia</i>)
Bai Ji (<i>Bletilla striata</i>)	Senecio herb (<i>Senecio nemorensis</i>)
Ce Bai Ye (<i>Biota orientalis</i>)	Shepherd's purse (<i>Capsella bursa-pastoris</i>)
Duan Xue Liu (<i>Clinopodium polycephalum</i> or <i>Clinopodium chinense</i>)	Shu Liang (<i>Dioscorea cirrhosa</i>)
Goldenseal (<i>Hydrastis canadensis</i>)	Su Mu (<i>Caesalpinia sappan</i>)
Huai Hua or Huai Mi (<i>Sophora japonica</i>)	Tie Shu (<i>Cycas revoluta</i>)
Ji Cai (<i>Capsella bursa-pastoris</i>)	Tu Tai Huang (<i>Rhumex patientia</i>)
Jing Tin San Qui (<i>Sedum aizoon</i>)	Witch hazel* (leaf and bark) (<i>Hamamelis virginiana</i>)
Juan Bai (<i>Selaginella tamariscina</i>)	Xiao Ji (<i>Cephalanoplos segetum</i> or <i>Cephalanoplos setasum</i>)
Ma Han Lian (<i>Eclipta prostrata</i>)	Yarrow (<i>Achillea millefolium</i>)
Mistletoe (<i>Viscum album</i>)	Zi Ju Cua (<i>Callicarpa macrophylla</i> , <i>Callicarpa pedunculata</i> , or <i>Callicarpa dichotoma</i>)
Oregon grape root (<i>Mahonia aquifolium</i>)	
Periwinkle (<i>Vinca minor</i>)	

*Approved herb by Kommission E Monograph.

Herbs to Avoid Prior to Surgery (Due to Anticoagulant Activity)

Alfalfa (<i>Medicago sativa</i>)	Fo-Ti (<i>Polygonum multiflorum</i>)
American ginseng (<i>Panax quinquefolius</i>)	Fucus (<i>Fucus vesiculosus</i>)
Angelica (<i>Angelica archangelica</i>)	Garlic (<i>Allium sativum</i>)
Aniseed (<i>Pimpinella anisum</i>)	Ginger (<i>Zingiber officinale</i>)
Arnica (<i>Arnica montana</i>)	Ginkgo (<i>Ginkgo biloba</i>)
Asafoetida (<i>Ferula asafoetida</i> , <i>Ferula foetida</i>)	Green tea (<i>Camellia sinensis</i>)
Bilberry (<i>Vaccinium myrtillus</i>)	Horse chestnut (<i>Aesculus hippocastanum</i>)
Bromelain (pineapple stem) (<i>Anas cosmosus</i>)	Horseradish (<i>Armoacia rusticana</i>)
Cayenne (<i>Capsicum annuum</i>)	Licorice (<i>Glycyrrhiza glabra</i>)
Celery (<i>Apium graveolens</i>)	Meadowsweet (<i>Filipendula ulmaria</i>)
Chamomile	Motherwort (<i>Leonurus cardiaca</i>)
English (<i>Anthemis nobilis</i>)	Onion (<i>Allium cepa</i>)
German (<i>Matricaria recutita</i>)	Poplar (<i>Populus</i> sp)
Roman (<i>Chamaemilum nobile</i>)	Prickly ash
Clove (<i>Syzygium aromaticum</i>)	Northern (<i>Zanthoxylum americanum</i>)
Coleus or forskolin (<i>Coleus forskohlii</i>)	Southern (<i>Zanthoxylum clava-herculis</i>)
Danshen (<i>Salvia miltiorrhiza</i>)	Quassia (<i>Quassia amara</i> , <i>Picrasma excelsa</i>)
Dong Quai (<i>Angelica sinensis</i>)	Red clover (<i>Trifolium pratense</i>)
Fenugreek (<i>Trigonella foenum-graecum</i>)	Turmeric (<i>Curcuma longa</i>)
Feverfew (<i>Tanacetum parthenium</i>)	Willowbark (<i>Salix</i> sp)
Flaxseed oil (<i>Linum usitatissimum</i>)	

LABORATORY DETECTION OF DRUGS

Agent	Time Detectable in Urine ¹ by Immunoassay
Amobarbital	2-4 d
Amphetamine	2-4 d
Butalbital	2-4 d
Cannabinoids	
Occasional use	2-7 d
Regular use	Up to 30 d
Cocaine (benzoylecgonine)	12-96 h
Codeine	2-4 d
Chlordiazepoxide	Up to 30 d
Diazepam	Up to 30 d
Dilaudid®	2-4 d
Ethanol	12-24 h
Heroin (morphine)	2-4 d
Hydromorphone	2-4 d
Librium®	30 d
Methamphetamine	2-4 d
Methaqualone	2-4 d
Morphine	2-4 d
Pentobarbital	2-4 d
Phencyclidine (PCP)	
Occasional use	2-7 d
Regular use	Up to 30 d
Phenobarbital	Up to 30 d
Quaalude®	2-4 d
Secobarbital	2-4 d
Valium®	30 d

¹The periods of detection for the various abused drugs listed above should be taken as estimates since the actual figures will vary due to metabolism, user, laboratory, and excretion.

LAXATIVES

Classification and Properties of Laxatives					
Laxative	Onset of Action	Site of Action	Mechanism of Action	Adverse Effects	Toxicologic Perspective for Gastric Decontamination
Bulk-Producing					
Methylcellulose psyllium (Metamucil®) Malt soup extract (Maltsupex®)	12-24 h (up to 72 h)	Small and large intestine	Holds water in stool; mechanical distention; malt soup extract reduces fecal pH; peristalsis is stimulated reflexly	No systemic effects	Not useful for gastric decontamination
Irritant/Stimulant					
Senna (Senokot®)	6-10 h	Colon	Direct action on intestinal mucosa; stimulate myenteric plexus; alter water and electrolyte secretion (especially potassium)	Chronic use can cause hepatitis	Not useful for gastric decontamination
Bisacodyl (Dulcolax®) tablets, suppositories	6-12 h (oral) 0.25-1 h (rectal)			Chronic use can cause atonic colon; do not use suppositories in patients with hemorrhoids	
Castor oil (ricinoleic acid)	2-6 h	Small intestine		May induce labor	May reduce the absorption of dinitroresol by 50% (non-purgative dose). Not useful for routine gastric decontamination. May increase absorption of organochlorine agents
Cascara aromatic fluid extract	6-10 h	Colon		Can alter water and electrolyte secretion	
Lubricant					
Mineral oil (Agoral®)	6-8 h	Colon	Lubricates intestine; retards colonic absorption of fecal water	Lipoid pneumonia may occur with aspiration	May increase absorption of organochlorine agents. Not recommended for children < 6 years due to aspiration risk. Not useful for gastric decontamination (except in phosphorus exposure)
Miscellaneous and Combination Laxatives					
Glycerin suppository	0.25-0.5 h	Colon	Hyperosmotic action	Local irritation, hyperosmotic action	Not useful for gastric decontamination
Lactulose (Cephulac®)	24-48 h	Colon	Delivers osmotically active molecules to colon		
Docusate/casanthranol (Peri-Colace®)	8-12 h	Small and large intestine	Casanthranol — mild stimulant; docusate — stool softener		
Osmotic					
Sorbitol (70%)	1-1.5 h	Small and large intestine	Increase intraluminal water volume — can stimulate peristalsis	Vomiting, hypernatremic dehydration at high doses	Dose 0.5-3 g/kg (0.5 g/kg in children < 1 year; up to 50 g of a 35% solution) Not to be used more than once daily in combination with multiple dosing of activated charcoal. Increases elimination by about 30% when used with charcoal for decontamination
Combination macrogols with polyethylene glycol/sodium sulphate (GoLYTELY®)	1 h	Small and large intestine	Increases osmotic pressure	Vomiting may occur (related to rate of administration); do not give in presence of GI obstruction, bowel perforation, toxic megacolon, clinically significant gastrointestinal hemorrhage, ileus, unprotected compromised airway, hemodynamic instability, or uncontrolled intractable vomiting	Drug of choice for whole bowel irrigation. Dose is: children: 9 months to 6 years: 500 mL/hour, 6-12 years: 1000 mL/hour; adolescents and adults: 1500-2000 mL/hour. Elevate head of bed to 45°. If emesis occurs, decrease infusion rate by 50% for up to 1 hour, then return to original rate

Classification and Properties of Laxatives (Continued)					
Laxative	Onset of Action	Site of Action	Mechanism of Action	Adverse Effects	Toxicologic Perspective for Gastric Decontamination
Saline					
Magnesium citrate (Citroma®)	0.5-3 h	Small and large intestine	Attract/retain water in intestinal lumen increasing intraluminal pressure; cholecystokinin release (magnesium cathartics)	Vomiting at doses exceeding 233 mg/kg	300 mL magnesium citrate should be given for oral hydrofluoric acid ingestion. Dose for decontamination of a 10% magnesium citrate solution is 250 mL for adults or about 4 mL/kg for children
Magnesium hydroxide (Milk of Magnesia)				Do not use in renal failure	Dose for decontamination: 4 mL/kg - 300 mL/dose 250 mL/kg - 30 g Do not use if botulism is suspected
Magnesium sulfate (Epsom salts)				Hypermagnesemia with multiple doses (99 mg or 8.1 mEq of magnesium/g). Vomiting at doses >250 mg/kg may occur.	Calcium gluconate (1 mL/kg of a 10% solution) can be given for magnesium intoxication Dose for gastric decontamination: 250 mg/kg (pediatric); 20-30 g (adult)
Sodium phosphate/ biphosphate enema (Fleet® Enema)	2-15 min	Colon		Can cause hypocalcemia	Do not use in children. Contraindicated in ethylene glycol ingestions
Sodium sulfate	0.5-3 h	Small and large intestine		Do not use in patient with congestive heart failure; hypernatremia may develop	Useful for barium ingestions to convert to nonabsorbable barium sulfate. Dose 250 mg/kg (pediatric); 15-20 g (adult)
Surfactants/Stool Softener					
Docusate (Colace®)	24-72 h	Small and large intestine	Detergent activity; facilitates admixture of fat and water to soften stool	Excreted in breast milk and bile	Due to slow onset, not used in gastric decontamination

MANAGEMENT OF DRUG EXTRAVASATIONS

Vesicant: An agent that causes tissue destruction.
Irritant: An agent that causes aching, tightness, and phlebitis with or without inflammation.
Extravasation: Unintentional leakage of fluid out of a blood vessel into surrounding tissue.
Vesicant extravasation: Leakage of a drug that causes pain, necrosis, or tissue sloughing.
Delayed extravasation: Symptoms occur 48 hours, or later, after drug administration.
Flare: Local, nonpainful, possibly allergic reaction often accompanied by reddening along the vein.

A potential, and potentially highly morbid, complication of drug therapy is soft tissue damage caused by leakage of the drug solution out of the vein. A variety of complications, including erythema, ulceration, pain, tissue sloughing, and necrosis are possible. This problem is not unique to antineoplastic therapy; a variety of drugs have been reported to cause tissue damage if extravasated. See table.

Vesicant Agents			
Hyperosmotic Agents (>280 mOsm/L)	Ischemia Inducers	Direct Cellular Toxins	
		Nonantineoplastic Agents	Antineoplastic Agents
Calcium chloride (>10%)	Aminophylline	Chlordiazepoxide	Amsacrine ¹
Calcium gluconate	Dobutamine	Diazepam	Dactinomycin
Calcium gluceptate	Dopamine	Digoxin	Daunorubicin
Contrast media	Epinephrine	Ethanol	Doxorubicin
Crystalline amino acids (4.25%)	Esmolol	Nafcillin	Epirubicin
Dextrose (>10%)	Metaraminol	Nitroglycerin	Esorubicin ¹
Mannitol (>5%)	Metoprolol	Phenytoin	Idarubicin
Potassium acetate (>2 mEq/mL)	Norepinephrine	Propylene glycol	Mechlorethamine
Potassium chloride (>2 mEq/mL)	Phenylephrine	Sodium thiopental	Mitomycin
Sodium bicarbonate (≥8.4%)	Vasopressin	Tetracycline	Streptozocin (?)
Sodium chloride (>1%)			Valrubicin
Thiopentone			Vinblastine
Urea (30%)			Vincristine
			Vindesine ¹
			Vinorelbine

In addition to the known vesicants, a number of other antineoplastic agents, not generally considered to be vesicants, have been associated with isolated reports of tissue damage following extravasation.

Agents Associated With Occasional Extravasation Reactions

Aclarubicin ¹	Docetaxel
Arsenic trioxide	Doxorubicin (liposomal)
Bleomycin	Etoposide
Carboplatin ≥ 10 mg/mL	Floxuridine
Carmustine	Fluorouracil
Cisplatin	Gemcitabine
Cyclophosphamide	Gemtuzumab
Dacarbazine	Ifosfamide
Daunorubicin citrate (liposomal)	Irinotecan
Dexrazoxane	Menogaril ¹

Mitoxantrone	Teniposide
Oxaliplatin	Topotecan
Paclitaxel	

¹Not commercially available in the U.S.

The actual incidence of drug extravasations is unknown. Some of the uncertainty stems from varying definitions of incidence. Incidence rates have been reported based on total number of drug doses administered, number of vesicant doses administered, number of treatments, number of patients treated with vesicants, and total number of patients treated. Most estimates place the incidence of extravasations with cytotoxic agents in the range of 0.6% to 6%.

The optimal treatment of drug extravasations is uncertain. A variety of antidotes have been proposed; however, objective clinical evidence to support these recommendations frequently is not available. There are no well-done randomized prospective trials of potential treatments. Controlled clinical trials are not feasible, limiting efforts to identify optimal management of these reactions. Extant reports are based on animal models, anecdotal cases, and/or small uncontrolled series of patients. Many of the existing reports, both animal and human, used more than one therapeutic intervention simultaneously, adding to the difficulty of identifying the efficacy of any single approach.

The best “treatment” for extravasation reactions is prevention. Although it is not possible to prevent all accidents, a few simple precautions can minimize the risk to the patient. The vein used should be a large, intact vessel with good blood flow. To minimize the risk of dislodging the catheter, veins in the hands and in the vicinity of joints (eg, antecubital) should be avoided. Veins in the forearm (ie, the basilic, cephalic, and median antebrachial, basilic and cephalic) are usually good options for peripheral infusions. Prior to drug administration, the patency of the I.V. line should be verified. The line should be flushed with 5-10 mL of a saline or dextrose solution and should be flushed with I.V. fluids every 2-3 minutes between a bolus injection and again at the end of administration, and the drug(s) infused through the side of a free-flowing isotonic saline or dextrose infusion.

A frequently recommended precaution against drug extravasation is the use of a central venous catheter. Use of a central line has several advantages, including high patient satisfaction, reliable venous access, high flow rates, and rapid dilution of the drug. A wide variety of devices are readily available. Many institutions encourage or require use of a vascular access device for administration of vesicant agents.

Despite their benefit, central lines are not an absolute solution. Vascular access devices are subject to a number of complications. The catheter tip may not be properly positioned in the superior vena cava/right atrium, or may migrate out of position. Additionally, these catheters require routine care to maintain patency and avoid infections. Finally, extravasation of drugs from venous access devices is possible. Misplacement/migration of the catheter tip, improper placement of the needle in accessing injection ports, and cuts, punctures, or rupture of the catheter itself have all been reported. Reports of extravasation from central catheters range from 0.3% to 50%, and are similar to extravasation rates reported from peripheral lines.

When a drug extravasation does occur, a variety of immediate actions have been recommended. Although there is considerable uncertainty regarding the value of some potential treatments, a few initial steps seem to be generally accepted.

1. **Stop the infusion.** At the first suspicion of infiltration, the drug infusion should be stopped. If infiltration is not certain, the line can be tested by attempting to aspirate blood, and careful infusion of a few milliliters of saline or dextrose solution.
2. **Do NOT remove the catheter/needle.** The infiltrated catheter should not be removed immediately. It should be left in place to facilitate aspiration of fluid from the extravasation site with a small (1-3 mL) syringe, and, if appropriate, administration of an antidote directly into the extravasation site.
3. **Aspirate fluid.** To the extent possible, the extravasated drug solution should be removed from the subcutaneous tissues.
4. **Do NOT flush the line.** Flooding the infiltration site with saline or dextrose in an attempt to dilute the drug solution generally is not recommended. Rather than minimizing damage, such a procedure may have the opposite effect by distributing the vesicant solution over a wider area.
5. **Remove the catheter/needle.** If an antidote is not going to be injected into the extravasation site, the infiltrated catheter should be removed. If an antidote is to be injected into the area, it should be injected through the catheter to ensure delivery of the antidote to the infiltration site. When this has been accomplished, the catheter should then be removed. Consider photographing the area to monitor at 1 day, 1 week, and every week thereafter.

Two issues for which there is less consensus are the application of heat or cold, and the use of various antidotes. A variety of recommendations exist for each of these concerns; there is no consensus concerning the proper approach.

Cold. Intermittent cooling of the area of infiltration results in vasoconstriction, which tends to restrict the spread of the drug. It may also inhibit the local effects of some drugs (eg, anthracyclines). Application of cold is usually recommended as immediate treatment for most drug extravasations, except the vinca alkaloids. In one report of antineoplastic drug extravasation treatment, almost 90% of the extravasations treated only with topical cold required no further therapy.

The largest single published series of antineoplastic drug extravasations was 175 patients reported by Larson in 1985. This series includes some of the more commonly used vesicants, including the anthracyclines, mechlorethamine, mitomycin, and the vinca alkaloids. For 119 patients, local application of cold (15 minutes four times a day for 3 days) and close observation was the sole treatment. The remaining 56 patients received a variety of antidotes. In 89% of the patients treated with cold alone, the extravasation resolved without further treatment. Of the patients treated by other methods, only 53% resolved without further treatment.

Helpful as it may be, Larson's report does have some limitations. Agents such as the epipodophyllotoxins and taxanes which are occasionally associated with soft tissue damage were not included, nor were extravasations of nonantineoplastic agents mentioned. The report included infiltrations of the vinca alkaloids, even though the literature recommends use of heat to treat these. Also, except for doxorubicin extravasations in the group treated with ice and observation, responses for the individual drugs were not indicated. In this group, 72% of the doxorubicin extravasations resolved completely.

Heat. Application of heat results in a localized vasodilation and increased blood flow. Increased circulation is believed to facilitate removal of the drug from the area of infiltration. The data supporting use of heat are less convincing than for cold. One report of the application of heat for nonantineoplastic drug extravasations suggested application of heat increased the risk of skin maceration and necrosis. Most data are from animal studies, with relatively few human case reports. Animal models indicate application of heat exacerbates the damage from anthracycline extravasations. No large series of extravasations managed with the application of heat has been published. Heat is generally recommended for treatment for vinca alkaloid extravasations; a few reports recommend it for treatment of amino acid solutions, aminophylline, calcium, contrast media, dextrose, mannitol, nafcillin, paclitaxel, phenytoin, podophyllotoxin, potassium, and vinca alkaloid infiltrations. There are conflicting reports on the initial management of paclitaxel infiltrations.

For some agents, such as cisplatin, epipodophyllotoxins, mechlorethamine, and paclitaxel, there are conflicting recommendations. Some reports recommend application of cold, others recommend heat. At least one report suggests neither cold nor heat is effective for paclitaxel extravasations.

Antidotes

A very wide variety of agents have been reported as possible antidotes for extravasated drugs, with no consensus on their proper use. For a number of reasons, evaluation of the various reports is difficult.

1. **Mechanism of action.** For many drugs, the underlying mechanism responsible for the tissue damage is not certain. For some of the antidotes, the purported mechanism of action of the antidote is also unclear.
2. **Controlled trials.** Prospective, randomized controlled trials are not practical. Information concerning treatment of extravasations is based almost exclusively on animal models, anecdotal reports, and small, uncontrolled studies.
3. **Outcome definitions.** Published reports use a number of different end-points and outcomes to define efficacy of a given treatment.
4. **Confounding factors.** A number of confounding factors exist which make assessment of various antidotes difficult. Among these are:
 - a. *Response to nonpharmacologic therapy.* Application of heat or cold alone, especially the latter, appears to have a significant protective effect.
 - b. *Multiple therapies.* A number of reports used more than one therapeutic modality to treat drug extravasations. In many cases, cold or heat is applied along with the antidote. In some cases, more than one antidote is used, sometimes in conjunction with heat or cold. Use of multiple approaches further complicates the determination of the possible effect of a particular antidote, or the additive effect of various combinations.

- c. *Variable applications.* For some proposed antidotes, a wide variety of different doses, concentrations, methods of application, and duration of therapy have been reported, making determination of the optimal treatment regimen difficult.

Agents Used as Antidotes

Albumin	Hyperbaric oxygen
Antihistamines	Iron dextran
Antioxidants	Isoproterenol
Beta-adrenergics	Nitroglycerin paste
Carnitine	Phentolamine
Corticosteroids ¹	Radical dimer
Dexrazoxane	Saline
Dextranomer	Sodium bicarbonate
Dimethyl sulfoxide (99%)	Sodium hypochlorite
Dopamine	Sodium thiosulfate ¹
Fluorescein	Terbutaline
Hyaluronidase ¹	Vitamin E

¹Listed in the package insert of at least one agent.

Sodium bicarbonate. An 8.4% solution of sodium bicarbonate was briefly recommended for treatment of anthracycline extravasations. The recommendation was based on a case report of its use in a single patient. The proposed mechanism of action was that the high pH of the bicarbonate solution would break the glycosidic bond of the anthracycline, thereby inactivating it. Follow-up studies in a variety of animal models failed to confirm the original report. Also, the concentrated sodium bicarbonate may itself be a vesicant. At present, most reviews and guidelines discourage its use for treating extravasations.

Corticosteroids. Steroids are most commonly used to treat anthracycline extravasations. Hydrocortisone is the steroid most frequently recommended, although dexamethasone has also been used. It is suggested that steroids reduce local inflammation from the extravasated drug. Such activity has not been confirmed; nor has it been demonstrated that the tissue damage from drug infiltrations is the result of an inflammatory process. Interpretation of steroid efficacy is complicated by the multiple doses, routes of administration, duration of therapy, and outcome measurements used. Reports of animal trials offer little additional information, being plagued by many of the limitations of the clinical case reports. The official labeling of only one of the three suppliers of doxorubicin includes a steroid as part of the treatment for drug extravasations. The product labeling from two doxorubicin suppliers (as well as the suppliers of daunorubicin, idarubicin, and liposome-encapsulated daunorubicin and doxorubicin) do not mention corticosteroids to treat drug infiltrations. Most reports question the efficacy of steroids for treatment of drug extravasations; they are not recommended by most guidelines.

Dexrazoxane. Dexrazoxane, a derivative of EDTA, is an intracellular chelating agent often used as a cardioprotective agent in patients receiving anthracycline therapy. It is believed that dexrazoxane's cardioprotective effect is a result by chelating iron following intracellular hydrolysis. Dexrazoxane is not an effective chelator itself, but is hydrolyzed intracellularly to an open-ring chelator form, which complexes with iron, other heavy metals, and doxorubicin complexes to inhibit the generation of free radicals. It has been postulated that dexrazoxane's chelating effect, or its ability to inhibit topoisomerase II, may be useful in preventing tissue damage from anthracycline infiltrations. There have been individual case reports of dexrazoxane being used to reduce tissue damage after extravasation of doxorubicin and epirubicin. Tests in mice suggest it might also be effective for treatment of daunorubicin and idarubicin.

Dimethyl sulfoxide (DMSO). A number of reports have suggested application of DMSO is an effective treatment for infiltrations of a number of different drugs. It is believed DMSO's protective effect is due to its ability to act as a free radical scavenger (one theory suggests tissue damage from vesicants, particularly anthracyclines, is due to formation of hydroxyl free radicals). Results in animal models have been equivocal, with some reports indicating DMSO is beneficial, and some showing little or no effect. Clinical reports of its use are extremely difficult to interpret due to variations in DMSO concentration, number of applications/day, duration of therapy, and concomitant treatments. A number of different treatments, including cold, steroids, vitamin E, and sodium bicarbonate have been used in conjunction with DMSO. Also, most reports that suggest DMSO is effective in preventing tissue damage used DMSO concentrations >90%, which is not available for clinical use in the United States.

A further complication to interpretation of DMSO's efficacy is that some series included infiltrations of agents not generally considered to be vesicants. The largest clinical series included infiltrations in 75 patients; but only 31 of the extravasations involved vesicants (doxorubicin, epirubicin, or mitomycin). The remaining incidents involved drugs not usually associated with tissue damage (cisplatin, ifosfamide, and mitoxantrone). Application of 99% DMSO for 7 days and cold for 3 days resulted in a 93.5% success rate in the patients with vesicant extravasations. Only two patients (6.5%) had complications requiring further therapy. Whether the addition of DMSO represented a real improvement over cold alone is difficult to assess.

Hyaluronidase. Hyaluronidase is an enzyme that destroys hyaluronic acid, an essential component of connective tissue. This results in increased permeability of the tissue, facilitating diffusion and absorption of fluids. It is postulated that increasing the diffusion of extravasated fluids results in more rapid absorption, thereby limiting tissue damage. In individual case reports, hyaluronidase has been reported effective in preventing tissue damage from a wide variety of agents, including amino acid solutions, aminophylline, calcium, contrast media, dextrose, mannitol, nafcillin, phenytoin, potassium, and vinca alkaloids. Other reports suggest it might also be useful in managing extravasations of epipodophyllotoxins and taxanes, although not all guidelines recommend its use for these agents.

Phentolamine. Phentolamine is an α_1 adrenergic antagonist which produces peripheral vasodilation. It has been reported to reduce tissue necrosis following extravasation of pressor (vasoconstrictor) agents such as dobutamine, dopamine, epinephrine and norepinephrine.

Sodium thiosulfate. A freshly prepared $1/6$ M ($\sim 4\%$) solution of sodium thiosulfate has been recommended for treatment of mechlorethamine and cisplatin infiltrations. A 2% solution has been recommended for doxorubicin, epirubicin, mitomycin, and vinblastine extravasations. This recommendation is based on *in vitro* data demonstrating an interaction between sodium thiosulfate and cisplatin, dacarbazine, and mechlorethamine; and very limited animal data on thiosulfate's ability to inactivate dacarbazine and mechlorethamine. At present, no clinical reports of its efficacy for treating cisplatin or dacarbazine extravasations have been published. Since cisplatin and dacarbazine are generally not considered to be vesicants, the use of thiosulfate to treat infiltrations of these drugs may not be required.

The use of sodium thiosulfate to treat mechlorethamine infiltrations is based almost exclusively on the *in vitro* and animal data. A single case report of successful thiosulfate treatment of an accidental intramuscular mechlorethamine injection has been published. Thus far, no reports of thiosulfate treatment of mechlorethamine infiltrations have been published.

One study of thiosulfate therapy of antineoplastic drug extravasations has been published. In a series of 63 patients with extravasation of doxorubicin, epirubicin, mitomycin, or vinblastine, 31 were treated with subcutaneous hydrocortisone and topical dexamethasone. The remaining 32 patients received subcutaneous injection of a 2% thiosulfate solution in addition to the subcutaneous and topical steroids. No patient in either group developed skin ulceration or required surgery; but the patients who received the thiosulfate healed in about half the time as the patients who received only the steroid therapy.

Reported Treatment Regimens for Drug Extravasations							
Treatment	Dose	Route	Duration	Concomitant Therapy	Used to Treat	Preparation	Administration
Cold ¹	15 min qid	Topical	3-4 days	None	All agents ²	N/A	N/A
Heat ¹	15 min on; 15 min off	Topical	1 day	None	Vinca alkaloids	N/A	N/A
Heat ¹	NS	Topical	NS	None	Epipodophyllotoxins, taxanes ³	N/A	N/A
Dexrazoxane (within 5 hours of extravasation)	1000 mg/m ² 500 mg/m ²	I.V.	Days 1 and 2 Day 3	Cold	Daunorubicin, doxorubicin, epirubicin, idarubicin	NS	NS
Dexrazoxane	1000 mg	I.V.	Day 1	Cold, DMSO, topical hydrocortisone	Epirubicin	NS	NS
Dexamethasone	4 mg	SubQ, I.D.	One time	Cold	Daunorubicin, doxorubicin	NS	Inject into several sites surrounding the area of extravasation
Dimethyl sulfoxide ⁴	50%-99% q2-4h	Topical	3 days	Dexamethasone 8 mg I.D.	Doxorubicin	N/A	N/A
Dimethyl sulfoxide ⁴	70% q3-4h	Topical	10 days	Sodium bicarbonate SubQ, dexamethasone 4 mg SubQ	Daunorubicin	N/A	N/A
Dimethyl sulfoxide ⁴	90% q12h	Topical	2 days	Vitamin E 10% topical	Doxorubicin, esorubicin, mitomycin	N/A	N/A
Dimethyl sulfoxide ⁴	99% q8h for up to 1 week	Topical	1 week	Cold for 3 days	Doxorubicin, mitomycin, mitoxantrone	N/A	Apply 4 drops/10 cm ² of skin surface over an area twice the size of the extravasation; allow to air dry without dressings
Dimethyl sulfoxide ⁴	99% q2-4h	Topical	3 days	None	Doxorubicin	N/A	N/A
Dimethyl sulfoxide ⁴	99% q6-24h	Topical	14 days	None	Doxorubicin, daunorubicin	N/A	N/A
Dimethyl sulfoxide ⁴	99% q6-8h	SubQ	Until resolution	None	Mitomycin	N/A	N/A
Hyaluronidase ¹	15 units	SubQ	One time	Heat	Amino acid solutions, aminophylline, calcium, contrast media ⁵ , dextrose, mannitol, nafcillin, phenytoin, potassium, vinca alkaloids	Reconstitute vial with NS to a concentration of 150 units/mL. Dilute 0.1 mL (15 units) with 0.9 mL NS for a final concentration of 15 units/mL	4-5 injections (0.2 mL) into area of extravasation
Hyaluronidase ¹	150 units	SubQ	One time	Heat	Amino acid solutions, aminophylline, calcium, contrast media ⁵ , dextrose, mannitol, nafcillin, phenytoin, potassium, vinca alkaloids	Reconstitute with 1 mL NS	5-10 injections (0.5-1 mL) into area of extravasation

Reported Treatment Regimens for Drug Extravasations (Continued)							
Treatment	Dose	Route	Duration	Concomitant Therapy	Used to Treat	Preparation	Administration
Hyaluronidase ¹	250 units	SubQ	One time	None	Amino acid solutions, aminophylline, calcium, contrast media ⁵ , dextrose, mannitol, nafcillin, phenytoin, potassium, vinca alkaloids	Reconstitute with 6 mL NS	Inject directly through the original needle; OR 6 SubQ injections into area of extravasation
Hydrocortisone	50-200 mg	I.V., SubQ, I.D.	NS	Cold	All agents <i>except vinca alkaloids</i>	NS	Inject into several sites surrounding the area of extravasation
Hydrocortisone	500 mg	SubQ	One time	Betamethasone and gentamicin ointment q12h for 2 days, then qd	Doxorubicin, epirubicin, vinblastine, mitomycin	500 mg in 10 mL NS	Inject at 1 cm intervals around the area of extravasation
Nitroglycerin paste	NS	Topical	NS	NS	Vasopressors (dobutamine, dopamine, epinephrine, norepinephrine, phenylephrine)	N/A	N/A
Phentolamine	5 mg	SubQ	1 day	None	Vasopressors (dobutamine, dopamine, epinephrine, norepinephrine, phenylephrine)	Mix 5 mg with 9 mL NS	Inject a small amount into extravasated area. Blanching should reverse immediately. If blanching should recur, additional injections may be needed
Sodium thiosulfate ^{1,5}	2%	SubQ	One time	Hydrocortisone 500 mg SubQ, betamethasone and gentamicin ointment q12h for 2 days, then qd	Doxorubicin, epirubicin, vinblastine, mitomycin	NS	Inject at 1 cm intervals around the area of extravasation
Sodium thiosulfate ¹	¹ / ₆ M (~4%)	I.V., SubQ	One time	Ice or heat	Mechlorethamine, cisplatin	Mix 4 mL of 10% sodium thiosulfate with 6 mL sterile water	Inject 2 mL for each 1 mg of mechlorethamine or 100 mg of cisplatin
Terbutaline	1 mg	SubQ	NS	NS	Vasopressors (dobutamine, dopamine, epinephrine, norepinephrine, phenylephrine)	NS	NS

N/A = Not applicable; NS = Not specified; I.V. = Intravenous; SubQ = Subcutaneous; I.D. = Intradermal.

¹Listed in the package insert of at least one product.

²Most guidelines discourage application of cold to treat infiltrations of vinca alkaloids. Some reports discourage its use to treat infiltrations of epipodophyllotoxins and/or taxanes.

³There are conflicting data on the efficacy of heat or cold for infiltrations of epipodophyllotoxins and taxanes. Each approach has been reported to be effective, harmful, and of no discernable effect.

⁴DMSO concentrations >50% are not available for human use in the U.S.

⁵Large extravasations only.

MATERNAL-FETAL TOXICOLOGY

Drugs and Chemicals Proven to Be Teratogenic in Humans			
Drug/Chemical	Fetal Adverse Effects	Relative Risk for Teratogenicity	Clinical Intervention
Alcohol	Fetal alcohol syndrome: Mental retardation, microcephaly, poor coordination, hypotonia, hyperactivity, short upturned nose, micrognathia or retrognathia (infancy) or prognathia (adolescence), short palpebral fissures, hypoplastic philtrum, thinned upper lips, microphthalmia, antenatal/postnatal growth retardation, occasional pathologies of eyes, mouth, heart, kidneys, gonads, skin, muscle, and skeleton	In alcoholic women consuming > 2 g/kg/d ethanol over first trimester: 2- to 3-fold higher risk for congenital malformations (about 10%)	To calculate accurate dose of alcohol: Prospective: To discontinue exposure; if woman is alcoholic, refer to addiction center During pregnancy: To alleviate fears in mild or occasional drinkers who may terminate pregnancy based on unrealistic perception of risk, level 2 ultrasound to rule out visible malformation
Alkylating agents (busulfan, chlorambucil, cyclophosphamide, mechlorethamine)	Growth retardation, cleft palate, microphthalmia hypoplastic ovaries, cloudy corneas, agenesis of kidney, malformations of digits, cardiac defects, multiple other anomalies	Based on case reports, between 10% and 50% of cases were malformed for different drugs. It is possible that adverse outcome was overrepresented	Level 2 ultrasound to rule out visible malformations. Supplement folic acid to women receiving antifolates (eg, methotrexate)
Antimetabolite agents (aminopterin azauridine, cytarabine, 5-FU, 6-MP, methotrexate)	Hydrocephalus, meningoencephalocele, anencephaly, malformed skull, cerebral hypoplasia, growth retardation, eye and ear malformations, malformed nose and cleft palate, malformed extremities and fingers Aminopterin syndrome: Cranial dysostosis, hydrocephalus, hypertelorism, anomalies of external ear, micrognathia, posterior cleft palate	Based on case reports 7%-75% of cases were malformed. It is possible that adverse outcome was overrepresented	Level 2 ultrasound to rule out visible malformations
Carbamazepine	Increased risk for neural tube defects (NTDs)	NTDs estimated at 1% with carbamazepine	Periconceptual folate; maternal and/or amniotic α -fetoprotein; ultrasound to rule out NTD
Carbon monoxide	Cerebral atrophy, mental retardation, microcephaly, convulsions, spastic disorders, intrauterine or postnatal death	Based on case reports, when mother is severely poisoned, high risk for neurological sequelae; no increased risk in mild accidental exposures	Measure maternal carboxyhemoglobin levels. Treat with 100% oxygen for 5 hours after maternal carboxyhemoglobin returns to normal because fetal equilibration takes longer If hyperbaric chamber available, should be used, as elimination half-life of CO is more rapid Fetal monitoring by an obstetrician; sonographic follow-up
Coumadin®	Fetal warfarin syndrome: Nasal hypoplasia, chondrodysplasia punctata, branchydactyly, skull defects, abnormal ears, malformed eyes, CNS malformations, microcephaly, hydrocephalus, skeletal deformities, mental retardation, optic atrophy, spasticity, Dandy Walker malformations	16% of exposed fetuses have malformation; another 3% hemorrhages; 8% stillbirths	Prospective: Switch to heparin for the first trimester. Deliver by a cesarean section. Women should be followed up in a high-risk perinatal unit
Diethylstilbestrol (DES)	Female offspring: Clear cell vaginal or cervical adenocarcinoma in young female adults exposed in utero (before 18th week); irregular menses (oligomenorrhea), reduced pregnancy rates, increased rate of preterm deliveries, increased perinatal mortality and spontaneous abortion Male offspring: Cysts of epididymis, cryptorchidism, hypogonadism, diminished spermatogenesis	Exposure before 18 weeks of gestation: $\leq 1.4/1000$ of exposed female with carcinoma. Congenital morphological changes in vaginal epithelium in 39% of exposures	Diagnosis: Direct observation of mucosa and Shiller's test Treatment: Mechanical excision or destruction in relatively confined area. Surgery and radiotherapy for diffused tumor

Drugs and Chemicals Proven to Be Teratogenic in Humans (Continued)			
Drug/Chemical	Fetal Adverse Effects	Relative Risk for Teratogenicity	Clinical Intervention
Lead	Lower scores in developmental tests	Higher risk when maternal lead is > 10 mcg/dL	Maternal lead levels > 10 mcg/dL: Investigate for possible source of contamination Levels > 25 mcg/dL: Consider chelation
Lithium carbonate	Possibly higher risk for Ebstein's anomaly; no detectable higher risk for other malformations		Women who need lithium should continue therapy, with sonographic follow-up. Patients may need higher doses because of increased clearance rate.
Methyl mercury, mercuric sulfide	Microcephaly, eye malformations, cerebral palsy, mental retardation, malocclusion of teeth	Women of affected babies consumed 9-27 ppm mercury; greater risk when ingested at 6-8 gestational months. Relative risk was not elucidated, but 13/220 babies born in Minamata, Japan, at time of contamination had severe disease	Good correlation between mercury concentrations in maternal hair follicles and neurological outcome of the fetus. Hair mercury content > 50 ppm was used successfully as a cut point for termination In acute poisoning, the fetus is 4-10 times more sensitive than the adult to methylmercury toxicity
PCBs	Stillbirth Signs at birth: White eye discharge, 30% (32/108); teeth present, 8.7% (11/127); irritated/swollen gums, 11% (11/99); hyperpigmentation ("cola" staining), 42.5% (54/127); deformed/small nails, 24.6% (30/122); acne, 12.8% (16/125) Subsequent history: Bronchitis or pneumonia, 27.2% (30/124); chipped or broken teeth, 35.5% (38/107); hair loss, 12.2% (14/115); acne scars, 9.6% (11/115); generalized itching, 27.8% (32/1150) Developmental: Do not meet milestones; lower scores than unexposed controls; evidence of CNS damage	4%-20% (6/159-8/39)	These figures, which are from cases poisoned by high consumption of PCB-contaminated rice oil, cannot be extrapolated to cases in which maternal poisoning has not been verified Women working near PCBs (eg, hydroelectric facilities) should use effective protection
Penicillamine	Skin hyperelastosis	Few case reports; risk unknown	
Phenytoin	Fetal hydantoin syndrome: Low nasal bridge, inner epicanthal folds, ptosis, strabismus, hypertelorism, low set or abnormal ears, wide mouth, large fontanelles, anomalies and hypoplasia of distal phalanges and nails, skeletal abnormalities, microcephaly and mental retardation, growth deficiency, neuroblastoma, cardiac defects, cleft palate/lip	5%-10% of typical syndrome; about 30% of partial picture Relative risk of 7 for offspring IQ ≤ 84	Neurologist should consider changing to other medications. Keep phenytoin concentrations at lower effective levels. Level 2 ultrasound to rule out visible malformations, vitamin K to neonate. Epilepsy itself increases teratogenic risk
Systemic retinoids (isotretinoin, etretinate)	Spontaneous abortions; deformities of cranium, ears, face, heart, limbs, liver; hydrocephalus, microcephalus, heart defects. Cognitive defects even without dysmorphology	For isotretinoin: 38% risk. 80% of malformation are CNS	Treated women should have an effective method of contraception. Pregnancy termination. If diagnosed too late, sonographic follow-up to rule out confirmed malformations
Tetracycline	Yellow, gray-brown, or brown staining of deciduous teeth, destruction of enamel	From 4 months of gestation and on, occurs in 50% of fetuses exposed to tetracycline; 12.5% to oxytetracycline	If exposure before 14-16 weeks of gestation, no known risk
Thalidomide	Limb phocomelia, amelia, hypoplasia, congenital heart defects, renal malformations, cryptorchidism, abducens paralysis, deafness, microtia, anotia	About 20% risk when exposure to drug occurs in days 34-50 of gestation	Thalidomide is an effective drug for some forms of leprosy. Treated women should have an effective mode of contraception

Drugs and Chemicals Proven to Be Teratogenic in Humans (Continued)			
Drug/Chemical	Fetal Adverse Effects	Relative Risk for Teratogenicity	Clinical Intervention
Trimethadione	Fetal trimethadione syndrome: Intrauterine growth retardation, cardiac anomalies, microcephaly, cleft palate and lip, abnormal ears, dysmorphic face, mental retardation, tracheoesophageal fistula, postnatal death	Based on case reports: 83% risk; 32% infantile or neonatal death	No need for this antiepileptic to date
Valproic acid	Lumbosacral spina bifida with meningocele; CNS defects, microcephaly, cardiac defects	1.2% risk of neural tube defects	Level 2 ultrasound and maternal α -fetoproteins or amniocentesis to rule out neural tube defects. Epilepsy itself increases teratogenic risk

FDA RECOMMENDATIONS FOR CONSUMPTION OF FISH

Pregnant women and women of childbearing age should avoid consumption of:

- shark
- king mackerel
- swordfish
- tilefish

Children and nursing mothers should limit consumption to no more than ~7 ounces (one serving) per week of:

- shark
- swordfish
- other fish containing more than 1 ppm of mercury

For other types of commercially obtained fish (ie, tuna), the FDA has advised that consumption by children and pregnant women be kept at less than 12 ounces weekly. For fish caught through local rivers or streams and no local advice is given, ingestion of up to 6 ounces per week is considered "safe."

FDA advisory limit for methylmercury in commercial fish is 1 ppm (1 mcg/g).

NARCOTIC ANALGESIC PHARMACOKINETIC PROFILE

I.V. administration is most reliable and rapid; I.M. or SubQ use may cause delayed absorption and peak effect, especially with impaired tissue perfusion. Many agents undergo a significant first-pass effect. All are metabolized by the liver and excreted primarily in urine. Meperidine is metabolized to normeperidine, a metabolite with significant pharmacologic activity. The half-life of normeperidine is 15-30 hours and accumulates with chronic dosing, especially in patients with renal dysfunction. The accumulation of this metabolite may lead to CNS excitation (eg, tremors, twitches, seizures).

Drug	Onset (min)	Peak (h)	Duration* (h)	t _{1/2} (h)	Equianalgesic Doses†		Volume of Distribution (L/kg)	Protein Binding (%)

ND = no data available. NA = not applicable.

*After I.V. administration, peak effects may be more pronounced but duration is shorter. Duration of action may be longer with the oral route.

†Based on acute, short-term use. Chronic administration may alter pharmacokinetics and decrease the oral:parenteral dose ratio. The morphine oral:parenteral ratio decreases to 1.5-2.5:1 upon chronic dosing.

‡Data based on I.V. administration.

§Duration and half-life increase with repeated use due to cumulative effects.

¶Data based on intrathecal or epidural administration.

#Rectal.

*HCl salt.

**Napsylate salt.

††Normeperidine (active metabolite) has a half-life of 14-21 hours.

*Norpropoxyphene (active metabolite) has a half-life of 30-36 hours.

NEUROMUSCULAR-BLOCKING AGENTS

Suggested Dosing Guidelines for the Use of Neuromuscular Blocking Agents in the Intensive Care Unit		
Agent	Intermittent Injection	Continuous Infusion
Short Duration		
Mivacurium (Mivacron®)	0.15-0.25 mg/kg followed by 0.1 mg/kg every 15 minutes	1-15 mcg/kg/min
Intermediate Duration		
Atracurium (Tracrium®)	0.4-0.5 mg/kg every 25-35 minutes	0.4-1 mg/kg/h
Cisatracurium (Nimbex®)	0.15-0.2 mg/kg every 40-60 minutes	0.03-0.6 mg/kg/h
Rocuronium (Zemuron®)	0.6 mg/kg every 30 minutes	0.6 mg/kg/h
Vecuronium	0.1 mg/kg every 35-45 minutes	0.05-0.1 mg/kg/h
Long Duration		
Doxacurium (Nuromax®)	0.025 mg/kg every 2-3 hours	0.015-0.045 mg/kg/h
Pancuronium	0.1 mg/kg every 90-100 minutes	0.05-0.1 mg/kg/h

Pharmacokinetic and Pharmacodynamic Properties of Neuromuscular Blocking Agents

Coleus	Marigold	Wild strawberry
Coral bells	Maternity plant	Yucca plant
Corn plant	Monkey grass	Zebra plant
Dandelion	Moss	
Devil's walking stick	Mountain ash (berries)	

OCCUPATIONAL EXPOSURE TO BLOODBORNE PATHOGENS (UNIVERSAL PRECAUTIONS)

Overview and Regulatory Considerations

Every healthcare employee, from nurse to housekeeper, has some (albeit small) risk of exposure to HIV and other viral agents such as hepatitis B and Jakob-Creutzfeldt agent. The incidence of HIV-1 transmission associated with a percutaneous exposure to blood from an HIV-1 infected patient is approximately 0.3% per exposure.¹ In 1989, it was estimated that 12,000 United States healthcare workers acquired hepatitis B annually.² An understanding of the appropriate procedures, responsibilities, and risks inherent in the collection and handling of patient specimens is necessary for safe practice and is required by Occupational Safety and Health Administration (OSHA) regulations.

The Occupational Safety and Health Administration published its “Final Rule on Occupational Exposure to Bloodborne Pathogens” in the Federal Register on December 6, 1991. OSHA has chosen to follow the Centers for Disease Control (CDC) definition of universal precautions. The Final Rule provides full legal force to universal precautions and requires employers and employees to treat blood and certain body fluids as if they were infectious. The Final Rule mandates that healthcare workers must avoid parenteral contact and must avoid splattering blood or other potentially infectious material on their skin, hair, eyes, mouth, mucous membranes, or on their personal clothing. Hazard abatement strategies must be used to protect the workers. Such plans typically include, but are not limited to, the following:

safe handling of sharp items (“sharps”) and disposal of such into puncture resistant containers

gloves required for employees handling items soiled with blood or equipment contaminated by blood or other body fluids

provisions of protective clothing when more extensive contact with blood or body fluids may be anticipated (eg, surgery, autopsy, or deliveries)

resuscitation equipment to reduce necessity for mouth to mouth resuscitation

restriction of HIV- or hepatitis B-exposed employees to noninvasive procedures

OSHA has specifically defined the following terms: **Occupational exposure** means reasonably anticipated skin, eye mucous membrane, or parenteral contact with blood or other potentially infectious materials that may result from the performance of an employee’s duties. **Other potentially infectious materials** are human body fluids including semen, vaginal secretions, cerebrospinal fluid, synovial fluid, pleural fluid, pericardial fluid, peritoneal fluid, amniotic fluid, saliva in dental procedures, and body fluids that are visibly contaminated with blood, and all body fluids in situations where it is difficult or impossible to differentiate between body fluids; any unfixed tissue or organ (other than intact skin) from a human (living or dead); and HIV-containing cell or tissue cultures, organ cultures, and HIV- or HBV-containing culture medium or other solutions, and blood, organs, or other tissues from experimental animals infected with HIV or HBV. An **exposure incident** involves specific eye, mouth, other mucous membrane, nonintact skin, or parenteral contact with blood or other potentially infectious materials that results from the performance of an employee’s duties.³ It is important to understand that some exposures may go unrecognized despite the strictest precautions.

A written Exposure Control Plan is required. Employers must provide copies of the plan to employees and to OSHA upon request. Compliance with OSHA rules may be accomplished by the following methods.

Universal precautions (UPs) means that all human blood and certain body fluids are treated as if known to be infectious for HIV, HBV, and other bloodborne pathogens. UPs do not apply to feces, nasal secretions, saliva, sputum, sweat, tears, urine, or vomitus unless they contain visible blood.

Engineering controls (ECs) are physical devices which reduce or remove hazards from the workplace by eliminating or minimizing hazards or by isolating the worker from exposure. Engineering control devices include sharps disposal containers, self-resheathing syringes, etc.

Work practice controls (WPCs) are practices and procedures that reduce the likelihood of exposure to hazards by altering the way in which a task is performed. Specific examples are the prohibition of two-handed recapping of needles, prohibition of storing food alongside potentially contaminated material, discouragement of pipetting fluids by mouth, encouraging handwashing after removal of gloves, safe handling of contaminated sharps, and appropriate use of sharps containers.

Personal protective equipment (PPE) is specialized clothing or equipment worn to provide protection from occupational exposure. PPE includes gloves, gowns, laboratory coats (the type and characteristics will depend upon the task and degree of exposure anticipated), face shields or masks, and eye protection. Surgical caps or hoods and/or shoe covers or boots are required in instances in which gross contamination can reasonably be anticipated (eg, autopsies, orthopedic surgery). If PPE is penetrated by blood or any contaminated material, the item must be removed immediately or as soon as feasible. **The employer must provide and launder or dispose of all PPE at no cost to the employee.** Gloves must be worn when there is a reasonable anticipation of hand contact with potentially infectious material, including a patient's mucous membranes or nonintact skin. Disposable gloves must be changed as soon as possible after they become torn or punctured. Hands must be washed after gloves are removed. OSHA has revised the PPE standards, effective July 5, 1994, to include the requirement that the employer certify in writing that it has conducted a hazard assessment of the workplace to determine whether hazards are present that will necessitate the use of PPE. Also, verification that the employee has received and understood the PPE training is required.⁴

Housekeeping protocols: OSHA requires that all bins, cans, and similar receptacles intended for reuse, which have a reasonable likelihood for becoming contaminated, be inspected and decontaminated immediately or as soon as feasible upon visible contamination and on a regularly scheduled basis. Broken glass that may be contaminated must not be picked up directly with the hands. Mechanical means (eg, brush, dust pan, tongs, or forceps) must be used. Broken glass must be placed in a proper sharps container.

Employers are responsible for teaching appropriate clean-up procedures for the work area and personal protective equipment. A 1:10 dilution of household bleach is a popular and effective disinfectant. It is prudent for employers to maintain signatures or initials of employees who have been properly educated. If one does not have written proof of education of universal precautions teaching, then by OSHA standards, such education never happened.

Pre-exposure and postexposure protocols: OSHA's Final Rule includes the provision that employees who are exposed to contamination be offered the hepatitis B vaccine at no cost to the employee. Employees may decline; however, a declination form must be signed. The employee must be offered free vaccine if he/she changes his/her mind. Vaccination to prevent the transmission of hepatitis B in the healthcare setting is widely regarded as sound practice.⁵ In the event of exposure, a confidential medical evaluation and follow-up must be offered at no cost to the employee. Follow-up must include collection and testing of blood from the source individual for HBV and HIV if permitted by state law if a blood sample is available. If a postexposure specimen must be specially drawn, the individual's consent is usually required. Some states may not require consent for testing of patient blood after accidental exposure. One must refer to state and/or local guidelines for proper guidance.

The employee follow-up must also include appropriate postexposure prophylaxis, counseling, and evaluation of reported illnesses. The employee has the right to decline baseline blood collection and/or testing. If the employee gives consent for the collection but not the testing, the sample must be preserved for 90 days in the event that the employee changes his/her mind within that time. Confidentiality related to blood testing must be ensured. **The employer does not have the right to know the results** of the testing of either the source individual or the exposed employee.

Management of Occupational Exposure to HIV in the Workplace⁶

Likelihood of transmission of HIV-1 from occupational exposure is 0.2% per parenteral exposure (eg, needlestick) to blood from HIV infected patients.

Factors that increase risk for occupational transmission include advanced stages of HIV in source patient, hollow bore needle puncture, a poor state of health, or inexperience of healthcare worker (HCW).

Immediate actions an exposed healthcare worker should take include aggressive first aid at the puncture site (eg, scrubbing site with povidone-iodine solution for 10 minutes) or at mucus membrane site (eg, saline irrigation of eye for 15 minutes). Then immediate reporting to the hospital's occupational medical service. The authors indicate that there is no direct evidence for the efficacy of their recommendations. Other institutions suggest rigorous scrubbing with soap.

After first aid is initiated, the healthcare worker should report exposure to a supervisor and to the institution's occupational medical service for evaluation.

Occupational medicine should perform a thorough investigation including identifying the HIV and hepatitis B status of the source, type of exposure, volume of inoculum, timing of exposure, extent of injury,

appropriateness of first aid, as well as psychological status of the healthcare worker. HIV serologies should be performed on the healthcare worker. HIV risk counseling should begin at this point.

All parenteral exposures should be treated equally until they can be evaluated by the occupational medicine service, who will then determine the actual risk of exposure. Follow-up counseling sessions may be necessary.

Although the data are not clear, antiviral prophylaxis may be offered to healthcare workers who are parenterally or mucous membrane exposed. If used, antiretroviral prophylaxis should be initiated within 1-2 hours after exposure.

Counseling regarding risk of exposure, antiviral prophylaxis, plans for follow up, exposure prevention, sexual activity, and providing emotional support and response to concerns are necessary to support the exposed healthcare worker. Follow-up should consist of periodic serologic evaluation and blood chemistries and counts if antiretroviral prophylaxis is initiated. Additional information should be provided to healthcare workers who are pregnant or planning to become pregnant.

Hazardous Communication

Communication regarding the dangers of bloodborne infections through the use of labels, signs, information, and education is required. Storage locations (eg, refrigerators and freezers, waste containers) that are used to store, dispose of, transport, or ship blood or other potentially infectious materials require labels. The label background must be red or bright orange with the biohazard design and the word biohazard in a contrasting color. The label must be part of the container or affixed to the container by permanent means.

Education provided by a qualified and knowledgeable instructor is mandated. The sessions for employees must include:

accessible copies of the regulation

general epidemiology of bloodborne diseases

modes of bloodborne pathogen transmission

an explanation of the exposure control plan and a means to obtain copies of the written plan

an explanation of the tasks and activities that may involve exposure

the use of exposure prevention methods and their limitations (eg, engineering controls, work practices, personal protective equipment)

information on the types, proper use, location, removal, handling, decontamination, and disposal of personal protective equipment

an explanation of the basis for selection of personal protective equipment

information on the HBV vaccine, including information on its efficacy, safety, and method of administration and the benefits of being vaccinated (ie, the employee must understand that the vaccine and vaccination will be offered free of charge)

information on the appropriate actions to take and persons to contact in an emergency involving exposure to blood or other potentially infectious materials

an explanation of the procedure to follow if an exposure incident occurs, including the method of reporting the incident

information on the postexposure evaluation and follow-up that the employer is required to provide for the employee following an exposure incident

an explanation of the signs, labels, and color coding

an interactive question-and-answer period

Record Keeping

The OSHA Final Rule requires that the employer maintain both education and medical records. The medical records must be kept confidential and be maintained for the duration of employment plus 30 years. They must

contain a copy of the employee's HBV vaccination status and postexposure incident information. Education records must be maintained for 3 years from the date the program was given.

OSHA has the authority to conduct inspections without notice. Penalties for cited violation may be assessed as follows:

Serious violations. In this situation, there is a substantial probability of death or serious physical harm, and the employer knew, or should have known, of the hazard. A violation of this type carries a mandatory penalty of up to \$7000 for each violation.

Other-than-serious violations. The violation is unlikely to result in death or serious physical harm. This type of violation carries a discretionary penalty of up to \$7000 for each violation.

Willful violations. These are violations committed knowingly or intentionally by the employer and have penalties of up to \$70,000 per violation with a minimum of \$5000 per violation. If an employee dies as a result of a willful violation, the responsible party, if convicted, may receive a personal fine of up to \$250,000 and/or a 6-month jail term. A corporation may be fined \$500,000.

Large fines frequently follow visits to laboratories, physicians' offices, and healthcare facilities by OSHA Compliance Safety and Health Offices (CSHOS). Regulations are vigorously enforced. A working knowledge of the final rule and implementation of appropriate policies and practices is imperative for all those involved in the collection and analysis of medical specimens.

Effectiveness of universal precautions in averting exposure to potentially infectious materials has been documented.⁷ Compliance with appropriate rules, procedures, and policies, including reporting exposure incidents, is a matter of personal professionalism and prudent self-preservation.

ORAL MEDICATIONS THAT SHOULD NOT BE CRUSHED OR ALTERED

There are a variety of reasons for crushing tablets or capsule contents prior to administering to the patient. Patients may have nasogastric tubes which do not permit the administration of tablets or capsules; an oral solution for a particular medication may not be available from the manufacturer or readily prepared by pharmacy; patients may have difficulty swallowing capsules or tablets; or mixing of powdered medication with food or drink may make the drug more palatable.

Generally, medications which should not be crushed fall into one of the following categories.

Extended-Release Products. The formulation of some tablets is specialized as to allow the medication within it to be slowly released into the body. This is sometimes accomplished by centering the drug within the core of the tablet, with a subsequent shedding of multiple layers around the core. Wax melts in the GI tract. Slow-K[®] is an example of this. Capsules may contain beads which have multiple layers which are slowly dissolved with time.

Common Abbreviations for Extended-Release Products

CD	Controlled dose
CR	Controlled release
CRT	Controlled-release tablet
LA	Long-acting
SR	Sustained release
TR	Timed release
TD	Time delay
SA	Sustained action
XL	Extended release
XR	Extended release

Medications Which Are Irritating to the Stomach. Tablets which are irritating to the stomach may be enteric-coated which delays release of the drug until the time when it reaches the small intestine. Enteric-coated aspirin is an example of this.

Foul-Tasting Medication. Some drugs are quite unpleasant to taste so the manufacturer coats the tablet in a sugar coating to increase its palatability. By crushing the tablet, this sugar coating is lost and the patient tastes the unpleasant tasting medication.

Sublingual Medication. Medication intended for use under the tongue should not be crushed. While it appears to be obvious, it is not always easy to determine if a medication is to be used sublingually. Sublingual medications should indicate on the package that they are intended for sublingual use.

Effervescent Tablets. These are tablets which, when dropped into a liquid, quickly dissolve to yield a solution. Many effervescent tablets, when crushed, lose their ability to quickly dissolve.

Recommendations

It is not advisable to crush certain medications.

Consult individual monographs prior to crushing capsule or tablet.

If crushing a tablet or capsule is contraindicated, consult with your pharmacist to determine whether an oral solution exists or can be compounded.

Drug Product	Dosage Form	Dosage Reasons/Comments
Accuhist [®]	Tablet	Slow release ⁸

¹ Capsule may be opened and the contents taken without crushing or chewing; soft food such as applesauce or pudding may facilitate administration; contents may generally be administered via nasogastric tube using an appropriate fluid, provided entire contents are washed down the tube.		
² Liquid dosage forms of the product are available; however, dose, frequency of administration, and manufacturers may differ from that of the solid dosage form.		
³ Antacids and/or milk may prematurely dissolve the coating of the tablet.		
⁴ Capsule may be opened and the liquid contents removed for administration.		
⁵ The taste of this product in a liquid form would likely be unacceptable to the patient; administration via nasogastric tube should be acceptable.		
⁶ Effervescent tablets must be dissolved in the amount of diluent recommended by the manufacturer.		
⁷ Tablets are made to disintegrate under the tongue.		
⁸ Tablet is scored and may be broken in half without affecting release characteristics.		
⁹ Skin contact may enhance tumor production; avoid direct contact.

PARENTERAL MEDICATION ADMINISTRATION GUIDELINES

There are a number of medications which, by their nature, require significant patient monitoring during their use. The following is a listing of these agents and the suggested special requirements.

1. Intravenous push medications which require a physician's presence during administration:

Adenosine	Ketamine
Antivenoms	Labetalol
Atenolol	Metoprolol
Atropine	Midazolam
Bretylium	Neostigmine
Calcium salts	Phentolamine
Cyanide antidote kit	Physostigmine
Digoxin immune Fab	Phytonadione (vitamin K)
Edrophonium	Propranolol
Ephedrine	Quinidine
Epinephrine	Thrombolytics
Flumazenil	Verapamil

2. Medications which can only be used for anesthesia or in patients with assisted ventilation:

Alfentanil	Rocuronium
Cisatracurium	Succinylcholine
Pancuronium	Sufentanil
Propofol	Tubocurarine
Remifentanil	Vecuronium

3. Patients receiving the following drugs as an infusion on an ongoing basis must be explicitly evaluated for placement in an intensive care unit or its equivalent. In addition to the medical status of the patient, the evaluation should consider the availability of appropriate monitoring equipment for the drug in question, and the availability of adequate nursing staff for the necessary monitoring for the duration of therapy.

Amiodarone	Lidocaine
Bretylium	Lorazepam
Diltiazem	Metaraminol
Dobutamine (> 5 mcg/kg/min)	Midazolam
Dopamine (> 5 mcg/kg/min)	Milrinone (> 0.5 mcg/kg/min)
Enalapril	Naloxone
Epinephrine	Nicardipine
Esmolol	Nitroglycerin
Ethyl alcohol	Nitroprusside sodium
Ibutilide	Norepinephrine
Inamrinone	Phenylephrine
Insulin	Procainamide
Intravenous antiarrhythmic agents	Trimethaphan
Isoproterenol	Verapamil
Labetalol	

PEDIATRIC LETHAL INGESTION

Toxins/Medications That Could Kill a Toddler of 10-20 kg With One Tablet, Tablespoon, or Single Dosage Form

(Minimum Potential Fatal Dose in Parenthesis)

Tablets/Capsules

Amantadine	Lithium
Amoxapine	Lomotil®
Amphetamines	Loxapine (30-70 mg/kg)
Benzonatate	LSD
Beta-adrenergic blockers	Mefenamic acid
Bupirone	Meprobamate
Calcium channel blockers	Methadone (1-2 mg/kg)
Chlorpromazine (25 mg/kg)	Minoxidil
Chloroquine (20 mg/kg)	Molindone
Clonidine	Monoamine oxidase inhibitors
Clozapine	Nifedipine (15 mg/kg)
Codeine (7-14 mg/kg)	Olanzapine (10 mg)
Colchicine	Phenothiazine
Cyclobenzaprine	Pramipexole (1 mg tablet)
Diflunisal	Prazosin
Diltiazem (15 mg/kg)	Procainamide (70 mg/kg)
Disopyramide (25 mg/kg)	Quinine (80 mg/kg)
Flecainide (25 mg/kg)	Quinidine (15 mg/kg)
Fluoxetine	Terazosin
Haloperidol	Theophylline (8.4 mg/kg)
Hydrocodone (1.5 mg/kg)	Thioridazine (15 mg/kg)
Hydroxychloroquine (20 mg/kg)	Trazadone
Hypoglycemic agents	Tricyclic antidepressants (15 mg/kg)
Imipramine	Verapamil (15 mg/kg)
Isradipine (2.5 mg capsule)	

Ointment/Cream

Camphor (100 mg/kg)	Methylsalicylate (200 mg/kg)
Dibucaine (and other local anesthetics)	Podophyllin 25% (15-20 mg/kg)
Doxepin	Theophylline
Lindane	

Patches

Clonidine	Nicotine
Fentanyl	Nitroglycerin

Ophthalmic

Atropine	Imidazoline
----------	-------------

Nonmedicinal Solutions

Acetonitrile	Isopropyl alcohol
Ammonia (> 10%)	Methyl alcohol
Ammonium fluoride	Methylene chloride
Benzocaine	Nicotine sulfate
Butyrolactone	Nitroethane
Diethylene glycol	Pennyroyal oil
Ethylene glycol	Selenious acid
Formaldehyde	Strychnine
Hydrofluoric acid	Toluene
Hydrogen peroxide (> 10%)	Zinc chloride

Other

Cigarettes (one entire cigarette or three smoked butts)	Bromates (2%)
Boric acid	

PHOSPHATE REPLETION GUIDELINES

For Moderate Hypophosphatemia (Serum $\text{PO}_4 < 2.0 \text{ mg/dL}$ But $\geq 1.0 \text{ mg/dL}$):

1. Discontinue any phosphate binding antacids.
2. Give 0.08-0.16 mmol/kg I.V. in 250 mL NS or D₅W over 4-6 hours via pump.
3. Recheck serum phosphate level.
4. If still $< 2 \text{ mg/dL}$, repeat.

For Severe Hypophosphatemia (Serum $\text{PO}_4 < 1.0 \text{ mg/dL}$):

1. Discontinue any phosphate binding antacids.
2. Give 0.25 mmol/kg I.V. in 250 mL NS or D₅W over 4-6 hours via pump.
3. Recheck serum phosphate level.
4. If still $< 1.0 \text{ mg/dL}$, repeat.
5. If $\geq 1.0 \text{ mg/dL}$ but $\leq 2.0 \text{ mg/dL}$, use guidelines for moderate hypophosphatemia above.

Dosages as high as 0.5 mmol/kg over 6 hours have been used for patients with serum PO_4 levels $< 0.5 \text{ mg/dL}$. If necessary, dosages may be infused over 2 hours.

Medicinal Chemistry Notes

Inorganic phosphate solutions exist as a mixture of two valence states: HPO_4^{-2} and $\text{H}_2\text{PO}_4^{-}$. At pH 7.4, the molar ratio of $\text{HPO}_4^{-2}:\text{H}_2\text{PO}_4^{-}$ is 80:20, yielding an average valence of 1.8. Therefore:

1 mmol of phosphate = 1.8 mEq of phosphate = 31 mg elemental P.

For clinical purposes, we round off to a ratio of 1 mmol: 2 mEq.

In K phosphate solutions, the mEq of K^+ does not equal the mEq of phosphorus. K phosphate I.V. solution provides:

4 mEq K^+ /mL

6 mEq phosphorus/mL

3 mmol K^+ and phosphorus/mL

Therefore, orders for K phosphate written as mEq are ambiguous and subject to misinterpretation.

Important: Orders for K phosphate written as mEq must be clarified with the prescribing physician.

The compatibility of calcium and phosphates in solution is conditional, dependent on the concentration of both ions. As a rule of thumb, the **sum of the mEq calcium plus the mEq phosphate should not exceed 40.**

PLASMAPHERESIS

Toxicants in Which Plasmapheresis Has Been Shown to Enhance Elimination	
Phenytoin	Diltiazem
Paraquat (decreased level by 80%)	Mercury
Propranolol	Vanadate
Tobramycin	Maprotyline
Verapamil	<i>Amanita phalloides</i> (mortality: 18%)

Toxicants in Which Plasmapheresis is Not Effective in Enhancing Elimination	
Vancomycin	Gentamicin
Thyroxin	Tacrolimus
Digoxin	Organophosphate agents
Carbamazepine (significant rebound effect)

POSTMORTEM BLOOD-DRUG CONCENTRATIONS

Druid H and Holmgren P, "A Compilation of Fatal and Control Concentrations of Drugs in Postmortem Femoral Blood," *J Forensic Sci*, 1997, 42(1):79-87. Copyright American Society for Testing and Materials (ATSM); reprinted with permission.

Femoral Blood Concentrations of 83 Substances

A compilation of postmortem femoral blood concentrations of drugs is presented. The samples are collected from cases in which the cause of death was:

- **Group A:** Fatal intoxication with the substance exclusively
- **Group B:** Fatal intoxication with the substance in combination with other drugs and/or alcohol
- **Group C:** Other cause of death without incapacitation due to drugs
- **Group D:** Concentrations in whole blood from suspected-drugged drivers

In groups A to C, concentrations refer to femoral blood.

*FLU = flunitrazepam.						
†CLO = clonazepam.						
‡NIT = nitrazepam.						
§Molecular weight is given, enabling calculation of molarities.						
Low: Lower percentile (N >9), lower quartile (N = 4-9), or minimum value (N <4).						
High: Upper percentile (N > 9); upper quartile (N = 4-9), or maximum value (N < 4).						
Substance names are given according to Clark's isolation and identification of drugs (3). For some drugs, common synonyms are displayed in brackets.						

POSTMORTEM DRUG DATA

Drugs in Which Postmortem Transformation or Redistribution May Occur (Approximate Heart Blood:Peripheral Blood Ratio)

Alfentanil	Methylfentanyl
Alprazolam (1.5)	Methprylon (1.9)
Amitriptyline (3.1)	Metoprolol (3.8)
Amineptine hydrochloride	Mexiletine (3.6)
Amoxapine (1.8)	Midazolam (4)
Amphetamine	Morphine (heroin) (2.2)
Benztropine (1.3)	Naproxen (1.5)
Brompheniramine	N-methylbenzodioxolybutamine or MBDB (2.5)
Bupropion (1.9)	Nicotine (3)
Chloralose	*Nitrazepam
Chloroquine	Nortriptyline (2.4)
Chlorpheniramine (3.1)	Orphenadrine (1.9)
Chlorpromazine (4.0)	Oxycodone (3.1)
Clomipramine (1.9)	Paroxetine (1.3)
*Clonazepam	Pentazocine (2)
Clopenthixol (1.5)	Pethidine or Meperidine (2.1)
Clothiapine	Phencyclidine (1.8)
Clozapine (2.8)	Phenylbutazone (2.3)
Cocaine (1.5-2.3)	Phenylpropanolamine (2.4)
Codeine (1.8)	Phenytoin (1.4)
Cyclobenzaprine (2.2)	Profriptyline
D-Methamphetamine (2.1)	Promethazine (1.6)
Desipramine (2.4)	Propafenone (2.4)
Dextromethorphan (2)	Propoxyphene (3.5)
Diazepam (1.6)	Propranolol (2.5)
Diltiazem (2.6)	Pseudoephedrine (1.5)
Diphenhydramine (2.3)	Quetiapine
Dothiepin (3)	Remifentanil
Doxepin (5.5)	Secobarbital (1.5)
Doxylamine	Strychnine (15)
Fentanyl	Sufentanil
*Flunitrazepam (3)	Temazepam (1.6)
Fluoxetine (2.9)	Tetrahydrocannabinol
Gamma hydroxybutyrate (1.8)	Timolol (2)
Haloperidol (3.6)	Tranlycypromine (2.2)
Imipramine (1.8-2.2)	Trazadone (1.6)
Ketamine (1.6)	Triazolam (2.8)
Lidocaine	Trichlorethanol (2)
Maprotiline (3.4)	Trimipramine (1.6)
Mesoridazine (1.3)	Venlafaxine (1.6)
Metapramine	Verapamil
Methamphetamine	Zolpidem (2.1)
Methotrimeprazine (1.3)	

*Postmortem transformation to 7-amino metabolite may occur.

Toxins/Drugs in Which Postmortem Redistribution Probably Does Not Occur

*Alcohols	Mirtazapine
Carbamazepine	Phenelzine
Carbon monoxide	Pheniramine
Chlordiazepoxide	Phenobarbital
Diflunisal	Primidone
Ephedrine	Procyclidine
Hydrocodone	Quinine/Quinidine
Hydroxyzine	Theophylline
Lorazepam	Zopiclone
Meprobamate	

*Ethanol level may increase in decomposed bodies due to postmortem fermentation.

Drugs Which Concentrate in the Bile for Postmortem Analysis (Bile-Blood Ratio in mg/L)

Acebutolol (416-22)	Hydromorphone (9.2-0.3)
Acetaminophen (560-248)	Hydroxyzine (122-39)
Amitriptyline (25-2.2)	Imipramine (45-3.7)
Amoxapine (61-18)	Isoniazid (900-43)
Anileridine (2.4-0.9)	Levorphanol (24-2.7)
Antimony (404-4.6)	Lidocaine (19-12)
Barium (6.1-1.9)	Maprotiline (161-6.2)
Benzoylcecyonine (12-2.4)	Methadone (7.5-1)
Bismuth (3.9-0.5)	Methamphetamine (22-8)
Buprenorphine (25.3-0.004)	Methapyrilene (25-8)
Chlordiazepoxide (4-2.5)	Methaqualone (83-8)
Chlorpromazine (80-1.4)	Methylfentanyl (0.047-0.007)
Chlorprothixene (3.9-0.1)	Methylphenidate (5.7-2.8)
Clozapine (454-2.8)	Metoprolol (254-4.7)
Cocaethylene (0.6-0.08)	Mexiletine (440-38)
Cocaine (0.7-0.2)	Mirtazepine (2.5-0.22)
Cochicine (2.9-0.6)	Norsertaline (57-0.4)
Codeine (18-2.8)	Nortriptyline (11-2)
Colchicine (2.9-0.06)	Oxycodone (28-5)
Cyproheptadine (8.1-0.5)	Para-Methoxyamphetamine (8-1.1)
Desipramine (39-5.6)	Perphenazine (40-4)
Diazepam (2.8-0.9)	Phenmetrazine (5-1)
Diltiazem (180-11)	Phenylbutazone (475-400)
Dothiepin (65-3)	Sertraline (11-0.3)
Doxepin (108-7.4)	Sodium Azide (651-135)
Ecgonine methylester (3.3-1.2)	Sulindac (2810-130)
Ethchlorvynol (382-78)	Thioridazine (9-3)
Fenfluramine (65-6.5)	Tramadol (3.5-1.9)
Fentanyl (0.03-0.01)	Trazodone (45-15)
Flecainide (290-53)	Trichloroethanol (111-79)
Fluoxetine (0.013-0.006)	Trimipramine (2.4-1.3)
Flurazepam (43-9)	Venlafaxine (195-45)
Gamma-Hydroxybutyrate (57-12)	Zimelidine (1.4-0.7)
Heroin (morphine) (32-0.43)	

Reference

Lemos N and Argarwal A, "Significance of Bile Analysis in Drug Induced Deaths," *J Anal Tox*, 1996, 20:61-3.

Recommended Tissue Sites to Determine Acute Fatal Poisoning

Aconitum alkaloids (liver, kidneys, ileum, feces)	Gold (renal Cortex)
Alimemazine (brain)	Heroin (brain/cerebellum)*
Cadmium (liver or renal cortex)	Insulin (tissue site injection or femoral blood)
Chloralose (kidney)	Lidocaine (>15 mg/kg in brain, lung, heart, liver, kidney)†
Chloroquine (liver > 150 mg/kg)	Platinum (urine or kidney)
Cocaine (brain – mesolimbic dopamanergic system)	Potassium (vitreous: postmortem interval (hours) = $(7.14 \times K^+) - 39.1$)
Colchicine (bile)	Silver (brain/liver)
Copper (liver)	Xylene (liver > 1 mg/kg)
Digoxin (kidney > 140 mcg/kg)	Zopiclone (right lobe of liver and blood)
Diquat (kidney > 2.4 mcg/g)	
Edrin (adipose > 90 mg/kg)	
Ethanol (vitreous)	

*Cerebellum/blood morphine level ratio is about 1 when death occurs with 1 hour and is 3.5 when death occurs with 2-48 hours of administration; also analyzing 6-Acetylmorphine in CSF can detect 46% more heroin-related cases than blood.

†Absorption of tracheal lidocaine during intubation (CPR) results in a kidney to liver lidocaine ratio less than one whereas absorption during I.V. lidocaine treatment gives a ratio over one.

Autopsy Findings of Toxin-Involved Deaths

Dinitrol-o-cresol (rapid rigor mortis)	Ethylene glycol (oxalate nephrosis)
Hydrogen sulfide (dark coins)	Benzene/lead acetate (bone marrow fibrosis)
Carbon monoxide (cherry red? < 1% prevalence)	Chronic anthracycline administration (hydropic myocardial degeneration)
Loperamide (infants < 6 months of age - severe abdominal distention)	Vitamin D (ectopic calcification)
Diethyltin (interstitial edema of brain white matter)	Fentanyl (syringe in vein)
Methanol (putamen/retinal - photoreceptor cell necrosis; optic nerve degeneration)	

Agents Causing Necrotic Gastroenteritis on Autopsy

Arsenic	Mercury
Bismuth	Nitrites
Copper	Nickel
Gold	Phosphorous
Iron Salts	Thallium
Lead	Vanadium
Manganese	Zinc

PRESCRIPTION PRODUCTS CONTAINING ACETAMINOPHEN

Note: Not a complete list. Other prescription products may contain acetaminophen.

Drug Name	Ingredients	Maximum Recommended 24-Hour No. of Doses	Maximum 24-Hour Acetaminophen Dose
Darvocet-N [®] 50 Tablets	Propoxyphene napsylate 50 mg Acetaminophen 325 mg	12 tablets	3900 mg
Darvocet-N [®] 100 Tablets	Propoxyphene napsylate 100 mg Acetaminophen 650 mg	6 tablets	3900 mg
Esgic [®] Tablets or Capsules	Butalbital 50 mg Acetaminophen 325 mg Caffeine 40 mg	6 tablets 6 capsules	1950 mg
Esgic-Plus [®] Tablets	Butalbital 50 mg Acetaminophen 500 mg Caffeine 40 mg	6 tablets	3000 mg
Fioricet [®] Tablets	Butalbital 50 mg Acetaminophen 325 mg Caffeine 40 mg	6 tablets	1950 mg
Fioricet [®] With Codeine Capsules	Codeine phosphate 30 mg Butalbital 50 mg Caffeine 40 mg Acetaminophen 325 mg	6 capsules	1950 mg
Hycomine [®] Compound Tablets	Hydrocodone bitartrate 5 mg Chlorpheniramine maleate 2 mg Phenylephrine hydrochloride 10 mg Acetaminophen 250 mg Caffeine 30 mg	Adults: 4 tablets Children (6-12): 2 tablets	Adults: 1000 mg Children: 500 mg
Hydrocet [®] Capsules	Hydrocodone bitartrate 5 mg Acetaminophen 500 mg	8 capsules	4000 mg
Lorcet [®] -HD Capsules	Hydrocodone bitartrate 5 mg Acetaminophen 500 mg	8 capsules	4000 mg
Lorcet [®] 10/650 Tablets	Hydrocodone bitartrate 10 mg Acetaminophen 650 mg	6 tablets	3900 mg
Lortab [®] 2.5/500 Tablets	Hydrocodone bitartrate 2.5 mg Acetaminophen 500 mg	8 tablets	4000 mg
Lortab [®] 5/500 Tablets	Hydrocodone bitartrate 5 mg Acetaminophen 500 mg	8 tablets	4000 mg
Lortab [®] 7.5/500 Tablets	Hydrocodone bitartrate 7.5 mg Acetaminophen 500 mg	6 tablets	3000 mg
Lortab [®] 10/500 Tablets	Hydrocodone bitartrate 10 mg Acetaminophen 500 mg	6 tablets	3000 mg
Lortab [®] Elixir	Hydrocodone bitartrate 2.5 mg/5 mL Acetaminophen 167 mg/5 mL	6 tbsp	1002 mg
Midrin [®] Capsules	Isometheptene mucate 65 mg Dichloralphenazone 100 mg Acetaminophen 325 mg	10 capsules	3250 mg
Norco [®] Tablets	Hydrocodone bitartrate 10 mg Acetaminophen 325 mg	6 tablets	1950 mg
Percocet [®] Tablets	Oxycodone hydrochloride 5 mg Acetaminophen 325 mg	4 tablets	1300 mg
Phenaphen [®] with Codeine No. 3 Capsules	Acetaminophen 325 mg Codeine phosphate 30 mg	12 capsules	3900 mg
Phrenilin [®] Forte Capsules	Butalbital 50 mg Acetaminophen 650 mg	6 capsules	3900 mg
Phrenilin [®] Tablets	Butalbital 50 mg Acetaminophen 325 mg	6 tablets	1950 mg
Roxicet [®] Tablets	Oxycodone hydrochloride 5 mg Acetaminophen 325 mg	4 tablets	1300 mg

RADIATION: BASICS OF EXPOSURE

(Adapted from U.S. Department of Health and Human Services, *Case Studies in Environmental Medicine: Ionizing Radiation*, Agency for Toxic Substances and Diseases Registry, October 1993, 1-48.)

Units of Radiation Measurement		
Characteristic	Unit	Description
Energy	electron volt (eV) (also ergs, joule)	Kinetic energy of an electron as it moves through a potential difference of 1 volt.
Rate of radioactive decay	curie (Ci)	Radioactivity emitted per unit of time (1 Ci = 3.7×10^{10} disintegrations per second).
Air exposure	roentgen (R)	Amount of X and gamma radiation that causes ionization in air. One roentgen of exposure will produce about 2 billion ion pairs per cubic centimeter of air.
Absorbed dose	rad	Dose resulting from one roentgen of ionizing radiation deposited in any medium, typically water or tissue. One rad results in the absorption of 100 ergs of ionizing radiation per gram of medium.
Biologic effectiveness	rem	Dose of any form of ionizing radiation that produces the same biological effect as 1 roentgen; 1 rem = 1 rad \times radiation weighting factor (RWF), where the value of RWF depends on the type of radiation as follows:
		X radiation = 1
		gamma radiation = 1
		beta = 1
		alpha = 20
		neutrons = 5-20, depending on their energy

Half-Lives of Some Radionuclides in Adult Body Organs				
Radionuclide	Critical Organ	Half-Life		
		Physical	Biological	Effective
Uranium-238	Kidney	4,460,000,000 y	4 d	4 d
Hydrogen-3* (tritium)	Whole body	12.3 y	10 d	10 d
Iodine-131	Thyroid	8 d	80 d	7.3 d
Strontium-90	Bone	28 y	50 y	18 y
Plutonium-239	Bone surface	24,400 y	50 y	50 y
	Lung	24,400 y	500 d	500 d
Cobalt-60	Whole body	5.3 y	99.5 d	95 d
Iron-55	Spleen	2.7 Y	600 d	388 d
Iron-59	Spleen	45.1 d	600 d	42 d
Manganese-54	Liver	303 d	25 d	23 d
Cesium-137	Whole body	30 y	70 d	70 d

*Mixed in body water as tritiated water.

Weighting Factors for Calculating Effective Dose Equivalent for Selected Tissues

ICRP60 = International Commission on Radiological Protection, 1990 Recommendations of the ICRP.			
NCRP115 = National Council on Radiation Protection and Measurements, 1993, Risk Estimates for Radiation Protection, Report 115, Bethesda, MD.			
NRC = Nuclear Regulatory Commission, Title 10, Code of Federal Regulations, Part 20.			

Common Diagnostic X-ray Doses*				
Examination	Mean KVP	Mean MAS (mrem)	Testes/Ovaries (mrem)	Embryo/Fetus
Chest (PA)	80	12	<0.5	<0.5
Skull (lateral)	72	50	<0.5	<0.5
Abdomen (KUB, AP)	78	601	13.7/146	150
Retrograde pyelogram (AP)	77	91	17.2/161	170
Thoracic spine (AP)	75	82	<0.5/0.7	0.9
Cervical spine (AP)	69	48	<0.5	<0.5
Lumbosacral spine (AP)	77	112	13.2/145	150
Pelvis (AP)	100	30	83/79	133
Barium enema (AP)	120	20	68/132	140
*KVP = kilovolt peak; MAS = milliamper second; PA = posteroanterior view; AP = anteroposterior view; mrem = millirem; KUB = kidney, ureter, bladder.				

Background Radiation from Consumer Products		
Product	Local Dose (mrem/y)	Portion of Body Considered
Coal combustion (fly ash)	0.03-0.3	Lungs
Oil combustion (soot)	1.6	Lungs
Gas ranges (natural gas)	5	Lungs
Tobacco products*	16,000	Lungs
Dentures and crowns†	700	Superficial layers of tissue in contact with teeth
Ophthalmic glass‡	4000	Cornea
Smoke detectors	0.008	Whole body
*Dose for cigarette smokers only; does not include doses experienced by those subjected to passive smoke.		
†Due to the uranium present in glazed dental porcelain.		
‡Applies to eyeglasses tinted with uranium or thorium.		

Types of Ionizing Radiation				
Type	Charge	Atomic Mass (amu)	Source*	Shielding†
Alpha	+2	4	Radium-226 Polonium-210 Uranium-238	Sheet of paper; intact skin
Beta	± 1	0.0005	Carbon-14 Strontium-90 Tritium Iodine-131	Lead; aluminium foil; a few centimeters of plastic
Neutron	0	1	Particle accelerator Nuclear reactor	High energy=paraffin Low energy=water
Proton	+1	1	Cosmic radiation Particle accelerator	Air
Gamma	0	0	Cobalt-60 Uranium-238 Iodine-131	A few centimeters of lead; many inches of steel
X	0	0	Diagnostic and therapeutic medicine	A few centimeters of lead; many inches of steel
*Familiar examples of originating source.				
†In any given situation, the type and thickness of shielding is dependent on the energy and intensity of the radiation.				

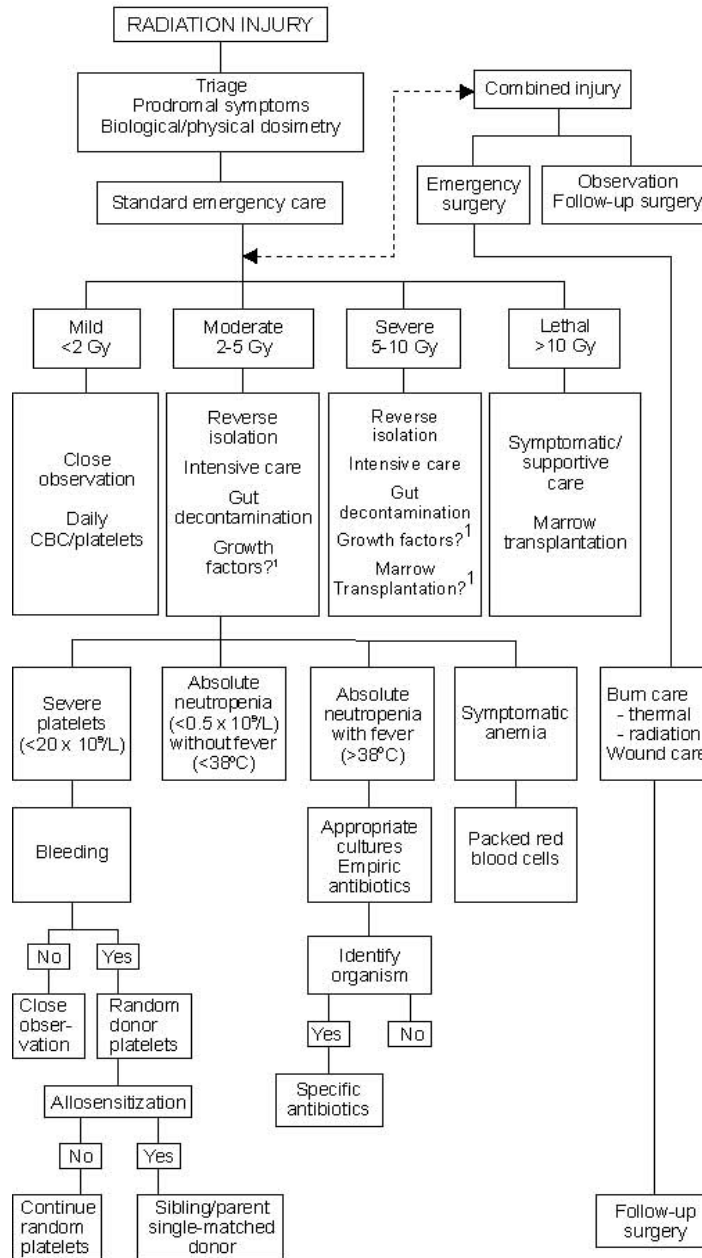

The benefit from therapy recommendations in the Immediate Actions to Consider (column 2) and Drugs to Consider (column 3) will be influenced by the route of exposure: ingestion, inhalation, skin absorption, injection, or contaminated wounds. The chemical form and solubility of the radionuclide will also change markedly the efficacy of the recommended treatment. The table below lists therapeutic procedures or drug therapy that may be helpful for the listed elements in favorable circumstances.

Treatment Summary for Internal Contamination by Selected Radioactive Elements			
Element	Immediate Actions to Consider	Drugs to Consider	Information and Comment
Americium (Am)	DTPA*	DTPA	Chelation should be started as soon as treatment decision can be made. CaEDTA† may be used if CaDTPA‡ is not immediately available.
Arsenic (As)	Lavage	Dimercaprol	Short-lived isotopes. Use of dimercaprol is not indicated except in massive exposures.
Barium (Ba)	Lavage, purgatives	See column 4	Use of sodium or magnesium sulfate with and after stomach lavage will precipitate insoluble barium sulfate.
Calcium (Ca)	Lavage, purgatives, calcium	Calcium, furosemide	Massive exposure may warrant use of the sodium salt of EDTA§, but with caution over a 3- to 4-hour period to avoid tetany. Furosemide enhances urinary excretion.
Californium (Cf)	DTPA, lavage, purgatives	DTPA	Same as for Americium.
Carbon (C)	(None listed)	No treatment available	Low-energy beta rays of carbon-14 are not detected by survey instruments; collect samples and smears for special low-energy beta counting in laboratory.
Cerium (Ce)	DTPA, lavage, purgatives	DTPA	Same as for Americium.
Cesium (Cs)	Prussian blue, lavage, purgatives	Prussian blue	Ion exchange resins should be as effective as Prussian blue, but have not been used in humans.
Chromium (Cr)	Lavage, purgatives	No treatment available for anionic forms; DTPA or DFOA¶ for cationic forms	Antacids are contraindicated. Adsorbents, such as charcoal, may reduce intestinal tract absorption.
Cobalt (Co)	Lavage, purgatives	See column 4	Penicillamine may be considered for therapeutic trial in large exposures.
Curium (Cm)	DTPA, lavage, purgatives	DTPA	Same as for Americium.
Europium (Eu)	Lavage, purgatives	DTPA	None.

Treatment Summary for Internal Contamination by Selected Radioactive Elements (Continued)			
Element	Immediate Actions to Consider	Drugs to Consider	Information and Comment
Fission products	Lavage, purgatives	#	Gamma-ray spectroscopy of air or swipe samples may identify prominent radionuclides (mixed). Check also for possible alpha emitters.
Fluorine (F)	Aluminum hydroxide gel	See column 4	Very short half-life. Oral aluminum hydroxide gel will reduce absorption in the gastrointestinal (GI) tract.
Gallium (Ga)	See column 4	See column 4	Short half-life. Penicillamine can be considered for therapeutic trial.
Gold (Au)	None	Dimercaprol and penicillamine are possible therapeutic agents	No known therapy for colloidal gold.
Iodine (I)	Potassium iodide, lavage	Potassium iodide	Success of stable iodine depends on early administration.
Iron (Fe)	Lavage	DFOA	Materials that reduce GI absorption include egg yolk or adsorbents. Oral penicillamine also chelates iron.
Lanthanum (La)	Lavage, purgatives	DTPA	CaEDTA may be used if CaDTPA is not immediately available.
Lead (Pb)	Lavage	EDTA	Dimercaprol and penicillamine are less satisfactory alternative drugs.
Mercury (Hg)	Lavage	Penicillamine	Dimercaprol may be considered for alternative therapy. Gastric lavage with egg white solution or 5% sodium formaldehyde sulfoxide; if unavailable, use a 2% to 5% solution of sodium bicarbonate.
Phosphorus (P)	Lavage, aluminum hydroxide	Phosphates	Severe overdosage may be treated with parathyroid extract (intramuscular) in addition to oral phosphates.
Plutonium (Pu)	DTPA	DTPA	DFOA may be used initially if DTPA is not available. CaEDTA may also be used, but is less effective.
Polonium (Po)	Lavage, purgatives	Dimercaprol	Consider toxicity of dimercaprol before using in cases of low-level exposure. Penicillamine is an alternative treatment.
Potassium (K)	Purgatives, diuretics, aluminum hydroxide	Diuretics	Use aluminum hydroxide antacids first to reduce GI tract absorption. Use oral liquid potassium supplements for dilution.
Promethium (Pm)	DTPA	DTPA	Chelation treatment should be started as soon as possible.
Radium (Ra)	Magnesium sulfate, lavage, purgatives	See column 4	Use 10% magnesium sulfate solution for gastric lavage and as saline cathartic. Oral sulfates reduce intestinal absorption. No effective therapy after absorption.
Rubidium (Rb)	Prussian blue	Prussian blue	Chemical properties are similar to potassium, but efficacy of similar treatments is unknown.
Ruthenium (Ru)	Lavage, purgatives	See column 4	Chlorthalidone causes enhanced urinary excretion. DTPA has variable effectiveness.
Scandium (Sc)	Lavage, purgatives	DTPA	EDTA may be used in place of DTPA.
Sodium (Na)	Lavage	Diuretic	Isotopic dilution (1 L of 0.9% sodium chloride) by intravenous route, followed by furosemide or other diuretic agent.
Strontium (Sr)	Aluminum phosphate, lavage	Strontium or calcium intravenously	Corticosteroid may be considered, but adverse reactions should be balanced against probable limited effectiveness.
Technetium (Tc)	(None listed)	(None listed)	Potassium perchlorate has been used effectively to reduce thyroid dose.
Thorium (Th)	(None listed)	DTPA or DFOA for soluble compounds	Treatment not effective for thorotrast (ThO ₂).

Treatment Summary for Internal Contamination by Selected Radioactive Elements (Continued)			
Element	Immediate Actions to Consider	Drugs to Consider	Information and Comment
Tritium (³ H)	Forced water	Forced water	Low-energy beta rays of ³ H are not detectable by survey instruments; requires samples for special low-energy beta counting in laboratory.
Uranium (U)	DTPA	(None listed)	DTPA must be given within 4 hours to be effective. Sodium bicarbonate protects the kidneys from damage.
Yttrium (Y)	(None listed)	DTPA	CaEDTA may be used if CaDTPA is not immediately available.
Zinc (Zn)	Lavage	DTPA	Zinc sulfate or CaEDTA may be used as a diluting agent if CaDTPA is not immediately available. Penicillamine is another alternative.
*DTPA = diethylenetriaminepentaacetic acid.			
†CaEDTA = calcium salt of ethylenediaminetetraacetic acid.			
‡CaDTPA = calcium diethylenetriaminepentaacetic acid.			
§EDTA = ethylenediaminetetraacetic acid.			
¶DFOA = deferoxamine or desferrioxamine.			
#Depends on major isotope(s) in mixture, which varies with age of the isotope mixture.			

Treatment Scheme for Patients Receiving an Acute High-Dose Radiation Exposure

¹Whole-body exposures >4 Gy may require bone marrow transplantation or administration of colony-stimulating factors or other hematopoietic growth factors that stimulate proliferation of hematopoietic stem cells. However, few data exist to support firm recommendations about the use of these treatments for radiation victims.

Average Annual Effective Dose Equivalent of Ionizing Radiation of a Member of the U.S. Population*		
Source	Effective Dose Equivalent	
	mSv	% of Total Dose
Natural		
Radon†	2.0	55
Cosmic	0.27	8
Terrestrial	0.28	8
Internal	0.39	11
Total natural	3.0	82
Artificial		
Medical

Common Analytical Methods for Measuring Radioactive Material Inside and Radiation Outside the Body		
Sample Matrix	Preparation Method	Device Used
Whole body, portion of body, or organ (x or γ radiation)	Position individual in front of detector with area of interest shielded from extraneous radiation	Multichannel analyzer with NaI detector for up to a few γ -emitters, a germanium detector for any number of γ -emitters, or a planar germanium detector for α -emitters that also emit x-rays
Urine, blood, or feces	Put any solids into solution; do chemical separation if multiple radioactive elements are present; deposit thin layer on a planchet or mix with liquid scintillation cocktail	Liquid scintillation for α - or β -emitters; alpha spectroscopy for α -emitters; GM counter for high-energy β - or γ -emitters; multichannel analyzer for γ -emitters
Personal monitoring: external radiation dose (β - and γ -radiation)	Heat dosimeter to produce thermoluminescence	TLD
	Develop film	Film badge
	None	Electronic dosimeter
Contamination monitoring: surfaces, skin, clothing, shoes (β - and γ -radiation)	None	GM counter
Contamination monitoring: surfaces, skin, clothing (α -radiation)	None	Proportional counter
GM = Geiger-Mueller; TLD = thermoluminescent dosimeters.		

Summary of Some Studies of Humans Exposed to Radiation and Radionuclides						
Location	Year(s)	Radionuclide	Purpose of Experiment	Number of People Dosed	Dose and Route of Exposure	Result
ANL	1931-1933	²²⁶ Ra	Determine the retention time of ²²⁶ Ra in humans	NA	70-50 mcg; injected	Incomplete
ANL	1943-1946	X-rays; ³² P	Determine effects of radiation, process chemicals, and toxic metals in humans	4	X-rays: 30 R ³² P; route not specified	White blood cell chemistry was important in assessing the radiation sensitivity of workers exposed to radiation
ANL	1944-1945	³² P	Study the metabolism of hemoglobin in cases of polycythemia rubra vera	7	15-40 μ Ci; route not specified	NA
ANL	1962	³ H	Study the uptake of ³ H thymidine in tumors and the effects of ³ H on tumors	4	10 μ Ci; injected	Similar growth was noted in both cancerous and non-cancerous cells treated with ³ H
ANL	1943-1944	X-ray	Study hematological changes at varying doses of radiation in cancer therapy	14	27-500 R; external exposure	Reduction of white blood cells formed in lymphoid tissue; routine monitoring of blood components not a practical way of assessing the usual occupational radiation exposures
ANL	1948-1953	⁷⁶ As	Determine effects of ⁷⁶ As on hematopoietic tissues in leukemia patients	24	17-90 mCi; intravenous	⁷⁶ As as effective as more commonly used leukemia therapeutic agents
BNL	1950	¹³¹ I	Determine the usefulness of ¹³¹ I to treat patients with Grave's disease and metastatic carcinoma of the thyroid	12	4-360 mCi or 6-20 mCi; route not specified	NA
BNL	1951	¹³¹ I	Study interaction of the thyroid and ¹³¹ I in children with nephrotic syndrome	8	NA	Maximum uptake of ¹³¹ I was 30%-60% of administered dose (3-5 μ Ci); no impairment of I uptake in children with nephrotic syndrome
BNL	1952-1953	⁴² K ³⁸ Cl ¹³¹ I (1 patient)	Examine formation and cycling of cerebrospinal fluid (CSF)	2	NA; injected route not specified	The amount of CSF produced daily is small and fluid production is not solely produced by the choroid plexus
BNL	1963	⁵⁹ Fe	Study iron absorption in women with various menstrual histories	9	1-10 μ Ci; oral	Menstrual blood loss in women with excessive bleeding was 110-550 mL. Normal women lost 33-59 mL during menstruation. Heavy menstruating women had higher gastrointestinal tract (GIT) absorption of iron than normal women
BNL	1967	⁴⁷ Ca	Study the role of dietary Ca in osteoporosis	7	25 μ Ci; intravenous	Diets high in Ca had a small but positive impact on osteoporosis
BNL	Early 1970s	⁸² Br	Study the kinetics of halothane	4	2.5 μ Ci; inhalation	Concentrations of halothane were initially high in upper parts of the body and low in lower parts of the body; diffusion equilibrium throughout the body was achieved in about 24 minutes

Summary of Some Studies of Humans Exposed to Radiation and Radionuclides (Continued)						
Location	Year(s)	Radionuclide	Purpose of Experiment	Number of People Dosed	Dose and Route of Exposure	Result
HS	1963	¹³¹ I	Determine uptake kinetics of ¹³¹ I in humans	8	NA. Dairy cows consumed 5 mg to 2 g/day of I; volunteers consumed milk produced by the cows exposed to ¹³¹ I in the diet	Uptake of ¹³¹ I in humans was characterized
LBL	1942-1946	X-ray	Determine if blood cell changes could be used to indicate exposure in workers on the Manhattan Project.	29	5-50 R, daily dose 100-300 R, total dose; whole body external exposure	Significant deviations in white blood cell counts, anemia formed in relation to dose
LBL	1948-1949	X-ray	Determine the effects of radiation on the pituitary gland during treatment of cancers of other tissues	> 1	8000-10,000 rad; external exposure	Pituitary is extremely resistant to x-rays
LBL	1949-1950	X-ray	Effect of radiation on the pituitary gland and its effect on advanced melanoma and breast cancer	3	8500-10,000 rad; external exposure	Pituitary is extremely resistant to x-rays
LBL	Early 1950s	⁶⁰ Co	Determine feasibility of treating bladder cancer using beads labeled with ⁶⁰ Co	35	5000-6000 rad over 7 days. Beads were placed inside the bladder cavity	Noninfiltrating cancers were more successfully treated than were the infiltrating bladder cancers
LBL	1961	⁹⁰ Y	Determine the effectiveness of ⁹⁰ Y in the treatment of acute leukemia in a child	1	200 rad to lymphatic tissue; route not specified	Therapy resulted in temporary remission of leukemia; little effect on peripheral blood cells and red blood cells
LLNL	1980s	¹³ N ⁴¹ Ar	Determine the uptake and clearance of nitrogen gas in order to better understand "decompression sickness" in deep-sea divers	11	NA; inhalation route of exposure; doses in the mCi range Absorbed dose to the lungs estimated to be 0.3-0.5 rad	NA
LLNL	1955	NA	Obtain information needed to plan for the safe and effective use of military aircraft near "mushroom clouds" during combat operation	4	≤ 15 R; inhalation and external routes were the likely routes of exposure	No significant internal deposition of fission products or unfissioned Pu were detected in urine or via whole body counting
LLNL	1961-1962	⁸⁵ Sr	Determine the cutaneous absorption kinetics of ⁸⁵ Sr through human skin	2	70 μCi; dermal exposure	Absorption of ⁸⁵ Sr across the skin was low, and ranged from 0.2% to 0.6% total absorption
OR	1956-1973	⁶⁰ Co ¹³⁷ Cs	Study efficacy of total body irradiation on the treatment of leukemia, polycythemia rubra vera, and lymphoma	194	50-300 R, one person received 500 R; external exposure	Higher frequency of remissions after 150 R compared to 250 R. Total body irradiation survived as long, but not longer than, patients treated with nonradiation treatments
OR	1953-1957	²³³ U ²³⁵ U	Study the distribution and excretion of uranium in humans	NS	4-50 mg; intravenously	99% of injected uranium cleared the blood within 20 hours and the remainder either deposited in the skeleton and kidneys or excreted via the urine

Summary of Some Studies of Humans Exposed to Radiation and Radionuclides (Continued)						
Location	Year(s)	Radionuclide	Purpose of Experiment	Number of People Dosed	Dose and Route of Exposure	Result
OR	1945	³² P	Study effects of beta rays on skin	10	140-1180 rad; external exposure	Threshold dose of beta radiation that resulted in mild tanning was about 200 rad; erythema resulted after a dose of 813 rad
UC	1937-1954	X-rays	Study the effect of x-rays for the treatment of gastric ulcers	116	1100-2930 rad; external exposure	Claimed that moderate irradiation of the stomach reduced acid secretion and was a valuable adjunct to conventional gastric ulcer therapy; therapy was later discontinued due to risks outweighing benefits
UC	1959	⁵¹ Cr	Determine feasibility of using implanted radiation sources in the treatment of cancer	24	2-5 mCi; implanted within cancerous tissues	16 had good or favorable results; the remainder of patients had questionable or unfavorable results; implants were generally well tolerated
UC	1960s	Various; fallout contains many alpha, beta, and gamma emitting radionuclides; stimulated fallout contained ⁸⁵ Sr, ¹³³ Ba, or ¹³⁴ Cs	Gain information in civil defense planning prior to nuclear fallout	10	0.2-0.7 μCi actual fallout;; 0.4-14 μCi simulated fallout; subjects ingested actual fallout from Nevada test site, as well as simulated fallout particles	No gastrointestinal symptoms were reported; studies provided a basis for estimating the systemic uptake and internal radiation dose that could result from the ingestion of fallout after nuclear bomb detonation
UR	1946-1947	²³⁴ U ²³⁵ U	Determine dose level at which renal injury is first detectable; measure U elimination and excretion rates	6	6.4-70.9 μCi/kg intravenously	U excretion occurred mainly via the urine and 70%-85% was eliminated with 24 hours; acidosis decreased U excretion; humans tolerated U at doses as high as 70 mcg/kg
UR	1956	²²² Rn	Determine radiation doses to different parts of the respiratory tract from inhaled ²²² Rn	2	0.025 μCi; inhalation	Average retention of ²²² Rn and daughter products in normal atmospheric dust was 25%; retention in filtered air was 75%; radiation exposure to the lungs was due to radon daughter products rather than by ²²² Rn itself
UR	1966-1967	²¹² Pb	Study absorption of lead from the gastrointestinal tract and determine the radiation hazard and chemical toxicity of ingested lead	4	1 μCi intravenous and/or 5 μCi orally	Lead might be released from binding sites only when red blood cells die
MISC	1950s	¹³¹ I	Study the transmission of ¹³¹ I in maternal breast milk to nursing infants	2	100 μCi; oral	¹³¹ I concentration in maternal milk was high enough to allow significant uptake in the thyroids of nursing infants; ¹³¹ I tracers should be used with caution when nursing infants
MISC	1953	¹³¹ I	Study uptake of ¹³¹ I by the thyroids of human embryos	NA	100-200 μCi (maternal dose); route not specified	Pregnant women were scheduled for abortion prior to receiving ¹³¹ I; results indicated that it would be unwise to administer ¹³¹ I for diagnostic or therapeutic purposes while pregnant

Summary of Some Studies of Humans Exposed to Radiation and Radionuclides (Continued)						
Location	Year(s)	Radionuclide	Purpose of Experiment	Number of People Dosed	Dose and Route of Exposure	Result
MISC	1963-1973	X-rays	Determine the effects of radiation on human testicular function	60	7.5-400 rad; external exposure	Doses of 7.5 rad yielded no adverse effect on testicular function; 27 rad inhibited generation of sperm, and 75 rad destroyed existing sperm cells; doses of 100-400 rad produced temporary sterility; all persons eventually recovered to pre-exposure levels prior to vasectomy

ANL = Argonne National Laboratory; BNL = Brookhaven National Laboratory; HS = Hanford Sites; LBL = Lawrence Berkeley Laboratory; LLNL = Lawrence Livermore National Laboratory; LANL = Los Alamos National Laboratory; ORS = Oak Ridge Sites; UCLA = University of California, Los Angeles; UCACRH = University of Chicago Argonne Cancer Research Hospital; UR = University of Rochester; MISC = other miscellaneous studies performed at other institutions; NA = information not available.

Summary of Some Studies of Humans Exposed to Radiation and Radionuclides (Continued)						
From Human Radiation Experiments Associated with the U.S. Department of Energy and Its Predecessors; U.S. Department of Energy, Assistant Secretary for Environment, Safety, and Health, Document #DOE/EH-0491, Washington, DC: July, 1995.						

Summary of the Dose Response Effects of Ionizing Radiation in Humans							
Phase	Feature	Subclinical Range	Sublethal Ranges (100-800 rad)			Lethal Range (over 800 rad)	
		100-200 rad	0-100 rad	200-600 rad	600-800 rad	800-3000 rad	>3000 rad
Initial phase	Incidence of nausea and vomiting	None	5%-50%	50%-100%	75%-100%	90%-100%	100%
	Time of onset		3-6 h	2-4 h	1-2 h	<1 h	<1 h
	Duration		<24 h	<24 h	<48 h	<48 h	48 h
	Mental and physical capabilities	100%	100%	Able to perform routine tasks. Cognitive abilities impaired for 6-20 hours	Able to perform simple and routine tasks. Significant incapacitation in upper part of dose range. Lasts more than 24 hours	Progressive incapacitation	
Latent phase	Duration	>2 wk	7-15 d	0-7 d	0-2 d	None	
Secondary phase	Signs and symptoms	None	Moderate leukopenia	Severe leukopenia; pneumonia; purpura, hemorrhage; infection; hair loss (epilation) at about 300 rads		Diarrhea; fever; disturbance of electrolyte balance	Convulsions; tremor; ataxia; lethargy
	Time of onset after exposure		>2 wk	Several days to 2 weeks		2-3 d	
	Critical period after exposure		None	4-6 wk		5-14 d	1-48 h
	Organ system affected	None		Hematopoietic and respiratory tissues		Gastrointestinal tract; respiratory tissues	Central nervous system
Hospitalization	Percentage	None	<5%	90%	100%	100%	100%

	Duration		45-60 d	60-90 d	90-120 d	2 wk	2 days
Incidence of death		None	None	0% to 80%	90% to 100%	90% to 100%	90% to 100%
Average time to death				3 weeks to 2 months		1-2 wk	2 d
Medical therapy		None	Hematologic surveillance	Blood transfusions and antibiotics		Maintenance of electrolyte balance	Sedatives

Adapted from Academy of Health and Science, 1995.

Summary of Risks of Developing Cancer After Exposure to Ionizing Radiation

Organ or System	BEIR Committee Conclusions About Risk		Cancer Relative Risk (RR) Factors (low dose/low dose rate) per 10 ⁶ rad (10 ⁴ Gy)*
Mammary/breast	1.	The development of cancer from susceptible mammary cells due to exposure to ionizing radiation depends on the hormonal status of these cells.	92.5
	2.	The age-distribution of radiogenic breast cancers and those breast cancers from unknown causes is similar.	
	3.	Women irradiated at ≤20 years of age are at higher risk than those irradiated later in life.	
	4.	There is no evidence to suggest that radiogenic breast cancer will appear during the first 10 years after exposure to ionizing radiation. Peak incidences occur 15-20 years after exposure.	
	5.	The data show little if any decrease in the yield of tumors, when multiple radiation doses are compared to single, brief exposures to ionizing radiation.	
Lung	1.	Absolute risk of lung cancer from exposure to ionizing radiation is similar for both males and females.	75.4
	2.	The data suggest that smoking has a “greater than additive” effect on the development of lung cancer after exposure to ionizing radiation.	
Stomach/digestive system	1.	The incidence of stomach cancers increases with increased exposure to ionizing radiation.	49.3
	2.	Females are at greater risk for developing cancers than are males.	
	3.	The relative risk for developing cancer is higher for those exposed when 30 years of age or younger.	
	4.	The baseline risk for digestive cancers increases with age; most of the excess cancers occur after middle age.	
Thyroid	1.	Susceptibility to radiation-induced thyroid cancer is greater in childhood.	32.1
	2.	Development of thyroid cancer is dependant on the hormonal status of the individual; sustained levels of TSH increase the risk of developing thyroid cancer.	
	3.	For those exposed before puberty, the tumors do not appear until after sexual maturation. The risk is greatest for children exposed within the first 5 years of life.	
	4.	Females are 2-3 times more susceptible than males to radiogenic (and spontaneous) thyroid cancer.	
	5.	Radiogenic cancer of the thyroid is usually preceded by benign thyroid nodules and the frequency of hypothyroidism and goiter is increased in those exposed to large doses when very young.	
Esophagus	1.	Increased incidences of cancer of the esophagus have been observed to occur in humans receiving doses of ionizing radiation.	
	2.	Little human data are available to make strong conclusions about the risk of developing esophageal cancer after exposure to ionizing radiation, although a risk estimate is available.	

Summary of Risks of Developing Cancer After Exposure to Ionizing Radiation (Continued)			
Organ or System	BEIR Committee Conclusions About Risk		Cancer Relative Risk (RR) Factors (low dose/low dose rate) per 10 ⁶ rad (10 ⁴ Gy)*
Small intestine (duodenum, jejunum, ileum)	1.	Cancers of the small intestine have been produced in laboratory animals exposed to large doses of ionizing radiation.	NR
	2.	None of the human epidemiological studies have conclusively demonstrated an increased risk of developing cancers of the small intestine after exposure to ionizing radiation.	
Large intestine (colon/rectum)	1.	Data imply that there is an increased risk of developing either colon or rectal cancer after exposure to ionizing radiation.	178.5
	2.	Based on human exposure data, the development of colon or rectal cancer is not apparent until 15 years after exposure or longer.	
Skeleton	1.	Large doses of low-LET ionizing radiation can result in the development of bone cancers.	1.3
	2.	The data suggest a threshold of between 4 Gy of low-LET or 13.8 Gy of high-LET radiation before increased bone cancers begin to occur.	
Brain/central nervous system (CNS)	1.	Increased incidences of CNS tumors have been observed in both humans and laboratory animals exposed to ionizing radiation.	NR
	2.	Tumors are both malignant and benign.	
	3.	The brain is considered to be relatively sensitive to developing cancer after exposure to ionizing radiation.	
	4.	Increases have been reported when irradiated during childhood at doses <1-2 Gy.	
Ovary and uterus	1.	There is no clear relationship between exposure to ionizing radiation and the development of uterine or ovarian cancers.	23.8
Testis	1.	There are few human data available for studying the relationship between exposure to ionizing radiation and testicular cancer.	NR
	2.	The existing data suggest that the testis is relatively insensitive to the carcinogenic effects of ionizing radiation.	
Prostate	1.	There is a weak association between cancer of the prostate and exposure to ionizing radiation.	NR
	2.	The relative risk of cancer of the prostate due to exposure to ionizing radiation is small.	
Urinary tract	1.	Exposure to ionizing radiation can cause cancer of the bladder, as well as cancers of the kidney and other urinary structures.	49.7
	2.	Women <55 years old at the time of exposure are at greater risk than older women, with this risk increasing with time after exposure.	
	3.	Gender appears to have little effect on the incidence of bladder cancer mortality.	
Parathyroid glands	1.	Increased incidences of hyperparathyroidism, parathyroid hyperplasia, and parathyroid adenoma occur after exposure to ionizing radiation.	NR
	2.	The data suggest that the incidences of hyperparathyroidism and parathyroid neoplasia increase with increasing doses of ionizing radiation.	
	3.	Time to diagnosis normally is ≥30 years.	
Nasal cavity and sinuses	1.	Little human data is available for analysis. Nasal and sinus tumors have been noted after human exposure to internally deposited ²²⁶ Ra and ²³² Th.	NR
	2.	The latency of these tumors is at least 10 years.	
	3.	The risk of developing nasal and sinus cavity tumors from routes other than from internalized sources of alpha ion radiation are extremely low.	

Summary of Risks of Developing Cancer After Exposure to Ionizing Radiation (Continued)			
Organ or System	BEIR Committee Conclusions About Risk		Cancer Relative Risk (RR) Factors (low dose/low dose rate) per 10 ⁶ rad (10 ⁴ Gy)*
Skin	1.	Increased incidences of basal cell and squamous cell carcinomas of the skin have been reported after occupational and therapeutic exposures to ionizing radiation.	1.0
	2.	Incidence from radiation exposure may be 5 times greater if the skin is also exposed to sunlight.	
Bone marrow (leukemia, lymphoma, and multiple myeloma)	1.	Examples include multiple myeloma, non-Hodgkin's lymphoma, and chronic lymphocytic leukemia.	NR
	2.	Multiple myelomas are observed to form after irradiation of the bone marrow.	
	3.	The latent period for multiple myeloma is considerably longer than that of leukemia.	
	4.	In Japanese A-bomb survivors, an excess of multiple myeloma cases did not appear until 20 years after exposure.	
	5.	Excess mortality from multiple myelomas has been observed at doses as low as 0.5-0.99 Gy.	
	6.	No other form for lymphoma has been consistently observed in human populations exposed to excess amounts of ionizing radiation.	
Pharynx, hypopharynx, and larynx	1.	Increased incidences of cancer do arise in these tissues after therapeutic radiation (ie, ankylosing spondylitis) in the 30-60 Gy range. Increases in these cancers were not statistically significant at the p < 0.05 level.	NR
	2.	There were no increases in the incidences of these cancers in the Japanese A-bomb survivors exposed to < 1 Gy.	
	3.	The risk of developing cancers of these tissues after exposure to ionizing radiation appears to be very low.	
Salivary gland	1.	The incidence of salivary gland tumors was increased in the Japanese A-bomb survivors, patients treated with x-rays to the head and neck during childhood, and women treated with ¹³¹ I when middle aged.	NR
	2.	Increases in salivary gland neoplasia are dose-dependent in the Japanese A-bomb survivors, but with no detectable increases in excess immortality.	
	3.	The salivary gland appears to be particularly susceptible to the development of cancer after exposure to ionizing radiation.	
Pancreas	1.	An association between cancer of the pancreas and exposure to ionizing radiation has been suggested in some literature reports.	NR
	2.	Pancreatic cancer has been found in occupationally exposed thorium workers.†	
	3.	The existing data suggest that the pancreas is relatively insensitive to the carcinogenic effects of ionizing radiation.	
LET = linear energy transport; NR = RR factor not reported.			
*Values from EPA Report 402-R-96-016, Radiation Exposure and Risk Assessment Manual, June 1996. Sum of all values = 760.6, including a remainder incidence risk of 173.4 for all other organs, including those listed in column 3 as NR.			
†Polednak, et al, <i>Health Physics</i> , 1980, 44 (Suppl 1):239-51.			
Summarized from BEIR V, National Research Council, Washington, DC: National Academy Press, 1990.			

Relative Sensitivities of Major Organs and Tissues to the Effects of Ionizing Radiation			
Radiosensitivity Category	Organ System	General Cell Type Affected	Frequency of Mitosis
High	Lymphoreticular	Lymphocytes	Very frequent
	Hematological	Immature hematopoietic cells	

Relative Sensitivities of Major Organs and Tissues to the Effects of Ionizing Radiation (Continued)			
Radiosensitivity Category	Organ System	General Cell Type Affected	Frequency of Mitosis
	Reproductive	Spermatogonia	
		Ovarian follicular cells	
	Gastrointestinal	Intestinal epithelium	
		Esophageal epithelium	Frequent
		Gastric mucosa	
	Renal	Urinary bladder epithelium	
	Dermal	Epidermal epithelial cells	
		Mucous membranes	
	Ocular	Epithelium of optic lens	
Medium	Circulatory system	Endothelium	
	Musculoskeletal	Growing bone and cartilaginous tissues	Moderately frequent
	Brain/CNS	Glial cells	
	Dermal	Glandular epithelium of the breast	
	Respiratory	Pulmonary epithelium, tracheobronchial epithelium	
	Renal	Renal epithelium	
	Hepatic	Hepatic epithelium	
	Endocrine	Pancreatic epithelium	
		Thyroid epithelium	
		Adrenal epithelium	
Low	Hematological	Mature hematopoietic cells (erythrocytes, neutrophils, eosinophils, basophils, macrophages)	Infrequently/rarely
	Musculoskeletal	Myocytes, osteocytes	
		Mature connective tissues	
		Mature bone and cartilage	
	Brain and peripheral nervous system	Ganglion cells

REFERENCE VALUES FOR ADULTS

Automated Chemistry (CHEMISTRY A)		
Test	Values	Remarks
SERUM/PLASMA		
Acetone	Negative	
Albumin	3.2-5 g/dL	
Alcohol, ethyl	Negative	
Aldolase	1.2-7.6 IU/L	
Ammonia	20-70 mcg/dL	Specimen to be placed on ice as soon as collected.
Amylase	30-110 units/L	
Bilirubin, direct	0-0.3 mg/dL	
Bilirubin, total	0.1-1.2 mg/dL	
Calcium	8.6-10.3 mg/dL	
Calcium, ionized	2.24-2.46 mEq/L	
Chloride	95-108 mEq/L	
Cholesterol, total	≤200 mg/dL	Fasted blood required – normal value affected by dietary habits. This reference range is for a general adult population.
HDL cholesterol	40-60 mg/dL	Fasted blood required – normal value affected by dietary habits.
LDL cholesterol	< 160 mg/dL	If triglyceride is >400 mg/dL, LDL cannot be calculated accurately (Friedewald equation). Target LDL-C depends on patient's risk factors.
CO ₂	23-30 mEq/L	
Creatine kinase (CK) isoenzymes		
CK-BB	0%	
CK-MB (cardiac)	0%-3.9%	
CK-MM (muscle)	96%-100%	
CK-MB levels must be both ≥4% and 10 IU/L to meet diagnostic criteria for CK-MB positive result consistent with myocardial injury.		
Creatine phosphokinase (CPK)	8-150 IU/L	
Creatinine	0.5-1.4 mg/dL	
Ferritin	13-300 ng/mL	
Folate	3.6-20 ng/dL	
GGT (gamma-glutamyltranspeptidase)		
male	11-63 IU/L	
female	8-35 IU/L	
GLDH	To be determined	
Glucose (preprandial)	< 115 mg/dL	Goals different for diabetics.
Glucose, fasting	60-110 mg/dL	Goals different for diabetics.
Glucose, nonfasting (2-h postprandial)	< 120 mg/dL	Goals different for diabetics.
Hemoglobin A _{1c}	< 8	
Hemoglobin, plasma free	<2.5 mg/100 mL	
Hemoglobin, total glycosolated (Hb A ₁)	4%-8%	

Automated Chemistry (CHEMISTRY A) (Continued)		
Test	Values	Remarks
Iron	65-150 mcg/dL	
Iron binding capacity, total (TIBC)	250-420 mcg/dL	
Lactic acid	0.7-2.1 mEq/L	Specimen to be kept on ice and sent to lab as soon as possible.
Lactate dehydrogenase (LDH)	56-194 IU/L	
Lactate dehydrogenase (LDH) isoenzymes		
LD ₁	20%-34%	
LD ₂	29%-41%	
LD ₃	15%-25%	
LD ₄	1%-12%	
LD ₅	1%-15%	
Flipped LD ₁ /LD ₂ ratios (>1 may be consistent with myocardial injury) particularly when considered in combination with a recent CK-MB positive result.		
Lipase	23-208 units/L	
Magnesium	1.6-2.5 mg/dL	Increased by slight hemolysis.
Osmolality	289-308 mOsm/kg	
Phosphatase, alkaline		
adults 25-60 y	33-131 IU/L	
adults 61 y or older	51-153 IU/L	
infancy-adolescence	Values range up to 3-5 times higher than adults	
Phosphate, inorganic	2.8-4.2 mg/dL	
Potassium	3.5-5.2 mEq/L	Increased by slight hemolysis.
Prealbumin	> 15 mg/dL	
Protein, total	6.5-7.9 g/dL	
SGOT (AST)	<35 IU/L (20-48)	
SGPT (ALT) (10-35)	<35 IU/L	
Sodium	134-149 mEq/L	
Transferrin	>200 mg/dL	
Triglycerides	45-155 mg/dL	Fasted blood required.
Troponin I	< 1.5 ng/mL	
Urea nitrogen (BUN)	7-20 mg/dL	
Uric acid		
male	2-8 mg/dL	
female	2-7.5 mg/dL	
CEREBROSPINAL FLUID		
Glucose	50-70 mg/dL	
Protein		
adults and children	15-45 mg/dL	CSF obtained by lumbar puncture.

Automated Chemistry (CHEMISTRY A) (Continued)		
Test	Values	Remarks
newborn infants	60-90 mg/dL.	
On CSF obtained by cisternal puncture: About 25 mg/dL.		
On CSF obtained by ventricular puncture: About 10 mg/dL.		
Note: Bloody specimen gives erroneously high value due to contamination with blood proteins.		
URINE (24-hour specimen is required for all these tests unless specified)		
Amylase	32-641 units/L	The value is in units/L and not calculated for total volume.
Amylase, fluid (random samples)		Interpretation of value left for physician, depends on the nature of fluid.
Calcium	Depends upon dietary intake	
Creatine		
male	150 mg/24 h	Higher value on children and during pregnancy.
female	250 mg/24 h	
Creatinine	1000-2000 mg/24 h	
Creatinine clearance (endogenous)		
male female	85-125 mL/min 75-115 mL/min	A blood sample must accompany urine specimen.
Glucose	1 g/24 h	
5-Hydroxyindoleacetic acid	2-8 mg/24 h	
Iron	0.15 mg/24 h	Acid washed container required.
Magnesium	146-209 mg/24 h	
Osmolality	500-800 mOsm/kg	With normal fluid intake.
Oxalate	10-40 mg/24 h	
Phosphate	400-1300 mg/24 h	
Potassium	25-120 mEq/24 h	Varies with diet; the interpretation of urine electrolytes and osmolality should be left for the physician.
Sodium	40-220 mEq/24 h	
Porphobilinogen, qualitative	Negative	
Porphyrins, qualitative	Negative	
Proteins	0.05-0.1 g/24 h	
Salicylate	Negative	
Urea clearance	60-95 mL/min	A blood sample must accompany specimen.
Urea N	10-40 g/24 h	Dependent on protein intake.
Uric acid	250-750 mg/24 h	Dependent on diet and therapy.
Urobilinogen	0.5-3.5 mg/24 h	For qualitative determination on random urine, send sample to urinalysis section in Hematology Lab.
Xylose absorption test		
children	16%-33% of ingested xylose	
FECES		
Fat, 3-day collection	<5 g/d	Value depends on fat intake of 100 g/d for 3 days preceding and during collection.
GASTRIC ACIDITY		
Acidity, total, 12 h	10-60 mEq/L	Titrated at pH 7.

Blood Gases			
	Arterial	Capillary	Venous

	> 7 d	0-10 μIU/mL

RENAL FUNCTION TESTS

Endogenous Creatinine Clearance vs Age (timed collection)

$$\text{Creatinine clearance (mL/min/1.73 m}^2\text{)} = (\text{Cr}_u\text{V}/\text{Cr}_s\text{T}) (1.73/\text{A})$$

where:

Cr_u	=	urine creatinine concentration (mg/dL)
V	=	total urine collected during sampling period (mL)
Cr_s	=	serum creatinine concentration (mg/dL)
T	=	duration of sampling period (min) (24 h = 1440 min)
A	=	body surface area (m^2)

Age-specific normal values

5-7 d	$50.6 \pm 5.8 \text{ mL/min/1.73 m}^2$
1-2 mo	$64.6 \pm 5.8 \text{ mL/min/1.73 m}^2$
5-8 mo	$87.7 \pm 11.9 \text{ mL/min/1.73 m}^2$
9-12 mo	$86.9 \pm 8.4 \text{ mL/min/1.73 m}^2$
$\geq 18 \text{ mo}$	
male	$124 \pm 26 \text{ mL/min/1.73 m}^2$
female	$109 \pm 13.5 \text{ mL/min/1.73 m}^2$
Adults	
male	$105 \pm 14 \text{ mL/min/1.73 m}^2$
female	$95 \pm 18 \text{ mL/min/1.73 m}^2$

Note: In patients with renal failure (creatinine clearance $<25 \text{ mL/min}$), creatinine clearance may be elevated over GFR because of tubular secretion of creatinine.

Calculation of Creatinine Clearance from a 24-Hour Urine Collection

Equation 1:

Cl_{cr}	=	$\frac{\text{U} \times \text{V}}{\text{P}}$
-------------------------	---	---

where:

Cl_{cr}	=	creatinine clearance
U	=	urine concentration of creatinine
V	=	total urine volume in the collection
P	=	plasma creatinine concentration

Equation 2:

Cl_{cr}	=	$\frac{(\text{total urine volume [mL]} \times (\text{urine Cr concentration [mg/dL]}))}{(\text{serum creatinine [mg/dL]} \times (\text{time of urine collection [minutes]})}$
-------------------------	---	---

Occasionally, a patient will have a 12- or 24-hour urine collection done for direct calculation of creatinine clearance. Although a urine collection for 24 hours is best, it is difficult to do since many urine collections occur for a much shorter period. A 24-hour urine collection is the desired duration of urine collection because the urine excretion of creatinine is diurnal and thus the measured creatinine clearance will vary throughout the day as the creatinine in the urine varies. When the urine collection is less than 24 hours, the total excreted

creatinine will be affected by the time of the day during which the collection is performed. A 24-hour urine collection is sufficient to be able to accurately average the diurnal creatinine excretion variations. If a patient has 24 hours of urine collected for creatinine clearance, equation 1 can be used for calculating the creatinine clearance. To use equation 1 to calculate the creatinine clearance, it will be necessary to know the duration of urine collection, the urine collection volume, the urine creatinine concentration, and the serum creatinine value that reflects the urine collection period. In most cases, a serum creatinine concentration is drawn anytime during the day, but it is best to have the value drawn halfway through the collection period.

Amylase: Creatinine Clearance Ratio

$\frac{\text{Amylase}_u \times \text{creatinine}_p}{\text{Amylase}_p \times \text{creatinine}_u}$	×	100
---	---	-----

u = urine; p = plasma

Serum BUN: Serum Creatinine Ratio

Serum BUN (mg/dL): serum creatinine (mg/dL)

Normal BUN: creatinine ratio is 10-15

BUN: creatinine ratio >20 suggests prerenal azotemia (also seen with high urea-generation states such as GI bleeding)

BUN: creatinine ratio <5 may be seen with disorders affecting urea biosynthesis such as urea cycle enzyme deficiencies and with hepatitis.

Fractional Sodium Excretion

Fractional sodium secretion (FENa) = $\text{Na}_u\text{Cr}_s / \text{Na}_s\text{Cr}_u \times 100\%$

where:

Na_u	=	urine sodium (mEq/L)
Na_s	=	serum sodium (mEq/L)
Cr_u	=	urine creatinine (mg/dL)
Cr_s	=	serum creatinine (mg/dL)

FENa <1% suggests prerenal failure

FENa >2% suggest intrinsic renal failure (for newborns, normal FENa is approximately 2.5%)

Note: Disease states associated with a falsely elevated FENa include severe volume depletion (>10%), early acute tubular necrosis, and volume depletion in chronic renal disease. Disorders associated with a lowered FENa include acute glomerulonephritis, hemoglobinuric or myoglobinuric renal failure, nonoliguric acute tubular necrosis, and acute urinary tract obstruction. In addition, FENa may be <1% in patients with acute renal failure **and** a second condition predisposing to sodium retention (eg, burns, congestive heart failure, nephrotic syndrome).

Urine Calcium: Urine Creatinine Ratio (spot sample)

Urine calcium (mg/dL): urine creatinine (mg/dL)

Normal values <0.21 (mean values 0.08 males, 0.06 females)

Premature infants show wide variability of calcium:creatinine ratio, and tend to have lower thresholds for calcium loss than older children. Prematures without nephrolithiasis had mean Ca:Cr ratio of 0.75 ± 0.76 . Infants with nephrolithiasis had mean Ca:Cr ratio of 1.32 ± 1.03 (Jacinto JS, Modanlou HD, Crade M, et al, "Renal Calcification Incidence in Very Low Birth Weight Infants," *Pediatrics*, 1988, 81:31.)

Urine Protein: Urine Creatinine Ratio (spot sample)

P_u / Cr_u	Total Protein Excretion (mg/m ² /d)
0.1	80
1	800
10	8000

where:

P_u = urine protein concentration (mg/dL)

Cr_u = urine creatinine concentration (mg/dL)

SAFE HANDLING OF HAZARDOUS DRUGS

Due to their inherent toxicity, particularly mutagenicity and carcinogenicity, there has been a concern about the risks of long-term, low-level exposure to antineoplastic agents. The possible risk to healthcare providers who are responsible for preparation and administration of such agents has been a subject of much debate, but few definite answers. Despite more than 20 years, and literally thousands of publications on the topic, there is no definitive evidence of a causal relationship between prolonged exposure to low levels of cytotoxic agents in the workplace and development of malignancies. Neither is there conclusive evidence that such exposure is not hazardous. In the absence of convincing evidence that healthcare personnel are not at risk, prudence requires the presumption that there is some degree of risk, and employees should employ appropriate protective measures.

The potential for many antineoplastic agents to cause secondary malignancies in patients was identified in the 1960s and 1970s. Coupled with evidence of some drugs' carcinogenicity in animals, this information raised the question of possible adverse effects from prolonged low-level exposure. In the late 1970s and 1980s, a large number of anecdotal reports of various side effects and adverse reactions in nurses, pharmacists, and pharmacy technicians involved in preparation and administration of antineoplastic therapy began to appear in the literature. These were followed by reports of increased urine mutagenicity, chromosome abnormalities, changes in immune function, and detectable blood or urine drug levels in personnel who routinely handled antineoplastic agents. As a result of these concerns, a number of groups issued guidelines intended to minimize exposure to antineoplastic agents in the workplace. By the end of the 1980s, the Occupational Safety and Health Administration (OSHA), American Society of Hospital (now Health-System) Pharmacists (ASHP), the National Institutes of Health (NIH), and the National Study Commission on Cytotoxic Exposure had all issued guidelines and policy statements addressing the proper handling of cytotoxic agents by healthcare personnel. Most of the early guidelines acknowledged the paucity and low quality of the available data, and recommended further research to define the actual risks.

During the remainder of the 1980s and 1990s, a number of studies and reports attempting to delineate the nature of the risk, and the appropriate safety measures to be taken were published. The vast majority of these were uncontrolled trials involving very small numbers of individuals, usually at a single institution. The nature and magnitude of the risk has never been properly delineated. Due to the nature of the problem, there has never been a large scale, prospective controlled trial to determine the efficacy of the various protective measures employed. As a result, there is no known threshold of safety for exposure to these agents; nor have any reliable monitoring techniques to assess exposure been developed. Most guidelines are therefore based on an assumption of "zero tolerance" - any exposure is hazardous, and must be avoided. Achieving the appropriate balance between necessary protection for personnel who must work with these agents and over-reaction to the threat remains a challenge.

More recent analysis of the problem has begun to clarify some of the risks, but has also opened previously accepted practices to question. A 1992 report on exposure of healthcare personnel to hazardous agents suggested that the standard biologic safety cabinets recommended for use when compounding hazardous drugs may not provide the desired level of protection. There was evidence suggesting that rather than forming particles or aerosol droplets that could be trapped in a standard HEPA filter, some antineoplastic agents vaporized, yielding vapors that could not be trapped in the filter. This potential for vaporization may be a partial explanation for recent reports indicating detectable contamination of work surfaces in and near hazardous drug preparation areas. This information has led some institutions to begin investigating use of isolator cabinets and sealed preparation systems as replacements for the biologic cabinets.

A 1996 review of 64 studies of workplace exposure to cytotoxic drugs noted numerous methodologic flaws in study design and procedures. The report concluded the methods used to assess exposure in these studies were too nonspecific and insensitive to be reliable measures of exposure. One disturbing aspect of this is the fact that the studies and procedures found to be not sensitive enough to assess routine levels of exposure were the ones used as the basis for development of the existing handling guidelines.

Guidelines and institutional policies for minimizing exposure to hazardous materials have been based on the presumption that environmental exposure to hazardous drugs occurs through three mechanisms:

- **inhalation** of drug dust or aerosolized droplets
- **absorption** through the skin
- **ingestion** of contaminated food or drink

Accordingly, the existing recommendations are heavily weighted toward the use of physical barriers as the primary means of reducing exposure. Among the commonly employed precautions are:

- **Separation:** Hazardous agents are often prepared in a limited number of areas which are separated, to the extent possible, from other drug preparation areas. Almost all institutions have a separate biologic safety cabinet reserved solely for the preparation of antineoplastic agents. Many institutions have a separate “oncology” drug preparation area or satellite pharmacy.
- **Biologic safety cabinets:** Use of a Class IIA or B biologic safety cabinet for the preparation of hazardous agents. Recent reports have questioned the efficacy of these cabinets, and some institutions have adopted the use of Isolator[®] systems or special closed preparation systems for compounding hazardous agents.
- **Protective clothing:** Another almost universal precaution is the use of protective gloves, gowns, and eye protection while handling antineoplastic agents. If drug preparation is performed in a biologic safety cabinet equipped with a glass front, many institutions dispense with the requirement for wearing safety goggles.
- **Training:** Some of the early reports attributed lower, or undetectable, levels of exposure to hazardous drugs to the experience level, or skill at aseptic technique, of the individual worker. Accordingly, many institutions require some degree of training before personnel are allowed to handle hazardous agents. Although most of the published guidelines recommend personnel who handle hazardous agents have “appropriate” training and experience, none specify what should be included in such a program. Accordingly, the exact nature and length of the required training programs vary widely among institutions.
- **Monitoring:** Appropriate physical parameters for assessing exposure to hazardous drugs are not available. Although some institutions require periodic health monitoring, the definition of what constitutes an appropriate screening program is a matter of some debate. Attempts to monitor the existence of hazardous materials in the work area has been slightly more successful. Assessment of airborne drug levels and surface contamination, in preparation cabinets, “secure” work areas, and areas outside the hazardous drug area has been reported. Additionally, techniques for using ultraviolet light to detect occult drug spills and assess individual’s handling technique have been reported. Most of these techniques have not been developed sufficiently to be used in routine practice, and are still limited to the research setting.

SEIZURES, NEONATAL GUIDELINES

Approach to the Treatment of Neonatal Seizures*				
Drug	Loading Dose	Maintenance Dose	Half-life	Therapeutic Range
Diazepam	0.25 mg/kg I.V. (in 2 min)	Dose may be repeated several times as clinically needed	25 h preterm 31 h term	35-81 μ mol/L
Lorazepam (for refractory seizures)	0.04-1 mg/kg I.V. over 2-5 minutes	May repeat in 15 minutes	10-40 h	50-240 ng/mL
Paraldehyde (rarely used)	0.150-0.200 mL/kg I.V.	0.020 mL/kg/h I.V.	10 h	10-40 mcg/mL
Phenobarbital	20 mg/kg I.V. (in 10 min)	3-4 mg/kg divided (bid), I.V./I.M./P.O.	Age dependant: 100 h by 14 d 20 h by 28 d	16-40 mcg/mL
Phenytoin	20 mg/kg I.V. (1 mg/kg/min)	4-8 mg/kg divided (bid), I.V.	Age dependant: 104 h early neonatal period to 2-7 h late neonatal period	15-20 mcg/mL
Primidone	15-25 mg/kg P.O.	12-20 mg/kg/d	12 h	6-15 mcg/mL

*Incidence: 5 in 1000 live births (occurs in ~5% of withdrawal states).

Causes of Neonatal Seizures

1. Trauma
 - a. subdural hematoma
 - b. intracortical hemorrhage
 - c. cortical vein thrombosis
2. Asphyxia — subependymal hemorrhage
3. Congenital abnormalities (cerebral dysgenesis)
 - a. lissencephaly
 - b. schizencephaly
4. Hypertension
5. Metabolic
 - a. hypocalcemia
 - hypomagnesemia
 - high phosphate load
 - IDM (infants of diabetic mothers)
 - hypoparathyroidism
 - maternal hyperparathyroidism
 - idiopathic
 - DiGeorge's syndrome
 - b. hypoglycemia
 - galactosemia
 - IUGR (intrauterine growth retardation)
 - IDM (infants of diabetic mothers)
 - glycogen storage disease
 - idiopathic
 - methylmalonic acidemia
 - propionic acidemia
 - maple syrup urine disease
 - asphyxia
 - c. electrolyte imbalance
 - hyponatremia

- hypomagnesemia
 - hyponatremia
6. Infections
 - a. bacterial meningitis
 - b. cerebral abscess
 - c. herpes encephalitis
 - d. Coxsackie meningoencephalitis
 - e. cytomegalovirus
 - f. toxoplasmosis
 - g. syphilis
 7. Drug withdrawal
 - a. methadone
 - b. heroin
 - c. barbiturate (short-acting, such as secobarbital and butalbital)
 - d. propoxyphene
 - e. benzodiazepines (chlordiazepoxide, diazepam)
 - f. cocaine
 - g. ethanol
 - h. codeine
 - i. paroxetine
 8. Pyridoxine dependency
 9. Amino acid disturbances
 - a. maple syrup urine disease
 - b. urea cycle abnormalities
 - c. nonketotic hyperglycinemia
 - d. ketotic hyperglycinemia
 - e. Leigh disease
 - f. isovaleric acidemia
 10. Toxins
 - a. local anesthetics
 - b. isoniazid
 - c. lead
 - d. indomethacin (from breast feeding)
 - e. fentanyl
 - f. pyridoxine
 11. Familial seizures
 - a. neurocutaneous syndromes
 - tuberous sclerosis
 - incontinentia pigmenti
 - b. genetic syndromes
 - Zellweger's
 - Smith Lemli Opitz
 - neonatal adrenoleukodystrophy
 - c. benign familial epilepsy
 12. Cerebral hemorrhage
 - a. intraventricular
 - b. subarachnoid
 - c. subdural

SEROTONIN SYNDROME

Diagnostic Criteria for Serotonin Syndrome

- Recent addition or dosage increase of any agent increasing serotonin activity or availability (usually within 1 day).
- Absence of abused substances, metabolic infectious etiology, or withdrawal.
- No recent addition or dosage increase of a neuroleptic agent prior to onset of signs and symptoms.
- Presence of three or more of the following: (% incidence)

Agitation (34%)	Muscle rigidity (51%)
Abdominal pain (4%)	Mydriasis
Ataxia/incoordination (40%)	Myoclonus (58%)
Diaphoresis (45%)	Nausea (23%)
Diarrhea (8%)	Nystagmus (15%)
Hyperpyrexia (45%)	Restlessness/hyperactivity (48%)
Hypertension/hypotension (35%)	Salivation (2%)
Hyperthermia	Seizures (12%)
Hyperreflexia (52%)	Shivering (26%)
Mental status change-cognitive behavioral changes	Sinus tachycardia (36%)
Anxiety (15%)	Tachypnea (26%)
Euphoria/hypomania (21%)	Tremor (43%)
Confusion (51%)	Unreactive pupils (20%)
Agitation (34%)	
Disorientation	
Coma/unresponsiveness (29%)	

Drugs (as Single Causative Agent) Which Can Induce Serotonin Syndrome

Specific serotonin reuptake inhibitors (SSRI)	Nefazodone
Bupirone	Odansetron
Clomipramine	Panax Ginseng
Dextromethorphan	Pentazocine
Fentanyl	Ritonavir
Granisetron	Sibutramine
Linezolid	St John's Wort
Lithium	Sumatriptan
LSD	Syrian Rue
MAO Inhibitors	Tramadol
MDMA (Ecstasy)	Trazodone
Meperidine	Tryptophan
5-Methoxydiisopropyltryptamine ("Foxy Methoxy")	Valproate
Metoclopramide	Venlafaxine
Mirtazapine	

Guidelines for Treatment of Serotonin Syndrome

Approximately 60% of patients present within 6 hours of medication change or overdose. Therapy is primarily supportive with intravenous crystalloid solutions utilized for hypotension and cooling blankets for mild hyperthermia. Norepinephrine is the preferred vasopressor. Chlorpromazine (25 mg I.M.) or dantrolene

sodium (1 mg/kg I.V. – maximum dose 10 mg/kg) may have a role in controlling fevers, although there is no proven benefit. Benzodiazepines are the first-line treatment in controlling rigors and thus, limiting fever and rhabdomyolysis, while clonazepam may be specifically useful in treating myoclonus. Endotracheal intubation and paralysis may be required to treat refractory muscular contractions. Tachycardia or tremor can be treated with beta-blocking agents, although due to its blockade of 5-HT_{1A} receptors, the syndrome may worsen. Serotonin blockers such as diphenhydramine (50 mg I.M.), cyproheptadine (adults: 4-8 mg every 2-4 hours up to 0.5 mg/kg/day; children: 0.25 mg/kg/day divided every 6 hours; maximum-12 mg daily), or chlorpromazine (25 mg I.M.) have been used with variable efficacy. Methysergide (2-6 mg/day) and nitroglycerin (I.V. infusion of 2 mg/kg/minute with lorazepam) also have been utilized with variable efficacy in case reports. It appears that cyproheptadine is most consistently beneficial. The syndrome does not resolve spontaneously as long as precipitating agents continue to be administered.

Recovery seen within 1 day in 70% of cases; mortality rate is about 11%.

STATUS EPILEPTICUS TREATMENT ALGORITHM

Status Epilepticus Treatment Algorithm

- Assess cardiorespiratory function
- Insert oral airway, administer oxygen 30% to 100%
- Insert indwelling intravenous catheter
- Monitor respiration, blood pressure, body temperature, EKG, and EEG

First-line drugs:
 Intravenous diazepam (0.15-0.25 mg/kg) no faster than 2 mg/min or intravenous lorazepam (0.1 mg/kg)
and
 Intravenous phenytoin no faster than 50 mg/min to a total of 18 mg/kg; if hypotension develops, slow down infusion rate* or intramuscular fosphenytoin (20 mg/kg). Not usually effective for alcohol withdrawal or some drug-induced seizures.

If seizures persist

Have intubation and ventilatory support immediately available

Either

Or

Intravenous phenobarbital 20 mg/kg no faster than 100 mg/min

Intravenous midazolam 0.1-0.2 mg/kg loading dose followed by infusion of 0.1-0.4 mg/kg/h

If seizures persist

Start infusion with glucose 10%; control hyperpyrexia if necessary

- Possible alternatives if anesthesiologist is not immediately available:
- Barbiturate coma: Pentobarbital (4-8 mg/mL in normal saline) loading dose 5-7 mg/kg over 30-60 minutes with a maintenance dose of 2-4 mg/kg/h
 - Intravenous paraldehyde 0.05 - 0.1 mL/kg diluted 4% in normal saline
 - Intravenous lidocaine (lignocaine) 1-2 mg/kg: If effective, administer additional 50-100 mg in dextrose 5% 250 mL no faster than 2 mg/kg/h
 - Intravenous valproic acid: Loading dose of 15-25 mg/kg over 10 minutes to 1 hour followed by an infusion of 1 mg/kg/h
 - Valproate rectal suppositories or retention enemas: Dosage of 200-1200 mg every 6 hours in adults or 15-20 mg/kg in pediatric patients
 - Intravenous valproate sodium dose is 100-200 mg/min; a slower infusion rate of 20 mg/min over 1 hour is associated with fewer side effects
 - In children <30 kg, clonazepam (intravenous) at an initial dose of 0.01-0.03 mg/kg/24 h; incremental increase of 0.25-0.5 mg/kg/24 h to a maximum dose of 0.1-0.2 mg/kg/24 h
 - Propofol: 1-3 mg/kg as an intravenous bolus followed by an intravenous infusion of 1.5-11.3 mg/kg/h
 - Electroconvulsant therapy (investigational)

General anesthesia (halothane or isoflurane) and neuromuscular blockade.

If seizures persist

* May not be effective for xanthine or sympathomimetic overdose

STRESS REPLACEMENT OF GLUCOCORTICOIDS

Recommendations for stress replacement of glucocorticoids vary. Because of the low risk involved with supplementation, some advocate administration of glucocorticoids for any patient who has received steroids, including topical steroids, within a year. Others reserve glucocorticoid administration for patients who have received more than a 14-day treatment of supraphysiologic steroid therapy within the past year. Yet others consider supplementation in any patient who has received corticosteroid therapy for at least 1 month in the past 6-12 months.

Steroid Status	Prednisone Dose*	Severity of Surgery	Steroid Regimen
Taking steroids	< 10 mg/d	Any surgery	Additional steroid coverage not required; assume normal HPA response
	> 10 mg/d	Minor surgery	25 mg hydrocortisone at induction
		Moderate surgery	Usual preoperative steroids plus 25 mg hydrocortisone at induction plus 100 mg hydrocortisone per day for 24 hours
		Major surgery	Usual preoperative steroids plus 25 mg hydrocortisone at induction plus 100 mg hydrocortisone per day for 48-72 hours
High-dose immunosuppression	Any surgery	Give usual immunosuppressive doses during perioperative period	

*If patient receiving a different corticosteroid, please use the table below to convert to an equivalent prednisone dose.

Steroid Status	Time Off Steroid	Comments
Not currently taking steroids	< 3 months	Treat as if on steroids
	> 3 months	No perioperative steroids necessary

Please refer to the chart below for potency comparisons and equivalent dosing:

Glucocorticoid	Relative Potency		Equivalent Dose (mg)
	Anti-inflammatory	Mineralocorticoid	
Short Acting			
Cortisone	0.8	2	25
Hydrocortisone	1	2	20
Intermediate Acting			
Prednisone	4	1	5
Prednisolone	4	1	5
Triamcinolone	5	0	4
Methylprednisolone	5	0	4
Long Acting			
Dexamethasone	25-30	0	0.75
Betamethasone	25	0	0.6-0.75

SUBSTANCE ABUSE AND ANESTHESIA

Substance abuse is a problem that must be considered when evaluating a patient for general surgery under anesthesia. Many agents can potentially interfere with the anesthetics and other agents administered in the perioperative setting. Substances of abuse such as ethanol, central nervous system depressants (opioids, benzodiazepines, barbiturates), and cocaine can all influence the type and the amount of anesthetic administered. Below are brief discussions and tables referring to drugs of abuse and how to perioperatively manage those patients who are abusing the agents.

Ethanol

Chronic Alcohol Abuse

Chronic ethanol abuse results in induction of the cytochrome P-450 system, which can affect many of the anesthetic and other medications used perioperatively. Because of this induction, certain agents may need to be dosed more frequently to achieve the desired effect. Larger doses of many of the anesthetic agents are needed in chronic alcohol abusers because of potential cross tolerance. It has been proven that the doses of certain opioids must be significantly increased in the chronic alcoholic to obtain the desired effect. The following is a list of anesthetic drugs that must be altered in the chronic alcoholic.

Agent	Dose
Volatile agents	Increased
Opioids	Increased
Benzodiazepines	Increased
Barbiturates	Increased

Acute Ethanol Abuse

Acute ethanol intoxication causes significant central nervous system (CNS) depression. For those individuals, including chronic alcoholics undergoing anesthesia while intoxicated, the amount of anesthetic agent used should be decreased.

Agent	Dose
Volatile agents	Decreased
Opioids	Decreased
Benzodiazepines	Decreased
Barbiturates	Decreased

Central Nervous System Depressants

Patients taking CNS depressants on a chronic basis will frequently need increased doses of certain anesthetic agents. Patients who are taking barbiturates chronically will have enzyme induction and may have an increased requirement for some of the anesthetic agents. Patients on chronic opioids will have an increased requirement for opioids perioperatively. In fact, like chronic alcoholics, patients taking opioids and benzodiazepines chronically may have a cross tolerance to other agents, and the dose of many intravenous anesthetic agents may need to be increased. The following is a list of anesthetic drugs that may need to be altered.

Agent	Dose
Barbiturates	Increased barbiturates
Opioids	Increased - opioids, benzodiazepines (?)
Benzodiazepines	Increased - benzodiazepines, opioids, barbiturates

Cocaine

Cocaine addiction is a common problem in our society. The National Institute of Drug Abuse estimated that there was a five-fold increase in cocaine abuse from the mid 1970s to the mid 1980s. This increased prevalence of cocaine use makes it a significant consideration in the perioperative patient. Acute cocaine use places the surgical candidate in jeopardy of systemic adverse effects and drug interactions. Although the incidence of preoperative patients with a positive urine cocaine screen has not been determined, it is not uncommon for patients to arrive for surgery with a positive screen. It is frequently recommended that preoperative patients with a positive urine toxicology screen wait at least 48-72 hours before undergoing a surgical procedure. Although an increase in morbidity and mortality has occurred in the surgical patient following acute cocaine ingestion, many debates and questions remain as to the time delay for surgery and the potential risks of the surgical procedure in patients with a positive screen. Because a positive urine toxicology screen does not yield precise information on the chronicity or the amount of drug used, more emphasis should be focused on the management of the perioperative effects following acute cocaine administration.

The urine toxicology screen for cocaine detects not only the parent compound but also its metabolites. The metabolites of cocaine include ecgonine methyl ether (EME), benzoylecgonine, and norcocaine. A positive urine toxicology screen occurs up to 48-120 hours after cocaine use. This factor must be kept in mind when evaluating patients with a positive cocaine screen.

Perioperative management of the suspected cocaine intoxicated patient should be aimed at cardiovascular stability. It is very important to have an intravenous antihypertensive available or on board in order to blunt acute hyperdynamic responses. Arrhythmia agents must also be readily available.

For the cocaine intoxicated patient, the dose of many anesthetic agents will need to be increased. The following is a list of anesthetic drugs that must be altered in the cocaine intoxicated patient.

Agent	Dose
Volatile agents	Increased
Opioids	Increased
Benzodiazepines	Increased
Barbiturates	Increased

Management of induction of anesthesia for the cocaine intoxicated patient should resemble that of the hypertensive patient and the same techniques should be used. The following measures can be taken to prevent the exaggerated increase in blood pressure during intubation from occurring.

Coadminister opioids during induction

Fentanyl
Alfentanil
Remifentanil
Sufentanil

Administer beta-antagonist during induction

Esmolol
Propranolol
Labetalol
Metoprolol

Administer topical local anesthetic prior to intubation

For maintenance anesthesia, it is important to avoid halothane in this patient population so as not to increase their risks of arrhythmia secondary to the myocardial sensitivity to catecholamines (epinephrine).

Anesthetic management of the cocaine intoxicated patient remains an unresolved issue. The anesthesiologist and the surgeon should consider the risk/benefit analysis of delaying the procedure. If the surgery is elective, it should be delayed for 48-72 hours or until a negative urine toxicology is achieved. If the procedure is emergent, it need not be postponed and the above precautions and techniques should be considered. It is important to remember, however, that if the procedure occurs, events or medications which exacerbate the adrenergic state should be anticipated or avoided.

SULFITE – HYPERSENSITIVITY

Response

Sulfite derivatives are common antioxidant preservatives used in foods and medications. Hypersensitivity reactions to sulfites have been noted with increasing frequency; however, the reaction is still rare. Reactions occur within 2-15 minutes after ingestion or inhalation and include nasal pruritus, rhinorrhea, conjunctivitis, generalized urticaria, dyspnea, wheezing, angioedema, flushing, weakness, and anaphylaxis. Patients frequently have underlying allergic or asthmatic disease and report exacerbations when exposed to air pollution or smog. One study has suggested 5% to 10% of all asthmatics may be at risk for sulfite sensitivity. A more recent study indicates the prevalence rate for nonsteroid-dependent asthmatics is 0.8% and for steroid-dependent asthmatics 8.4%.

The mechanism of hypersensitivity has not been fully elucidated. Available data suggest the reaction is probably IgE mediated; however, IgE antibodies to sulfites have yet to be identified. Accurate diagnosis of sulfite sensitivity is obtained from oral provocative challenge. Skin tests are of no value. There is some evidence that the reaction may be dose related, since more severe reactions have occurred following ingestion of restaurant meals containing 25-100 mg sodium metabisulfite than smaller oral challenge doses. These authors suggested that bisulfites convert to sulfur dioxide in solution, which activates the tracheobronchial irritant receptors and stimulates a cholinergic reflex leading to bronchoconstriction, bradycardia, hypotension, peripheral vasodilation, and diaphoresis.

Sulfite derivatives include sodium bisulfite (NaHSO_3), potassium bisulfite (KHSO_3), sodium metabisulfite ($\text{Na}_2\text{S}_2\text{O}_5$), sodium sulfite (Na_2SO_3), potassium metabisulfite ($\text{K}_2\text{S}_2\text{O}_5$), and sulfur dioxide (SO_2). The most common food sources are fresh fruits and vegetables (particularly potatoes and green salads), shellfish, soft drinks, beer, wine, dried foods, and fruit drinks. Sympathomimetic medications are very susceptible to oxidation and frequently contain bisulfites in concentrations of 0.3% to 0.75%.

Sulfite Preservatives

Drugs That Contain Sulfite Preservatives	
Drug	Product
Amikacin	Amikin [®] injection
Atropine	Lyopine Vari-Dose [®]
Bupivacaine	Marcaine [®] with epinephrine (except dental syringes) Sensorcaine [®] with epinephrine
Chlorprocaine	Nesacaine [®] injection
Chlorpromazine	Thorazine [®] injection
Codeine	Codeine phosphate (Wyeth)
Co-trimoxazole	Bactrim [™] injection Septra [®] injection
Dexamethasone acetate	Decadron [®] -LA (MSD) Dexone LA [®] (Kay Phar) Solurex LA [®] (Hyrex)
Dexamethasone phosphate	AK-Dex [®] ophthalmic 0.1% solution
Dexamethasone sodium phosphate	Decadron [®] (MSD) Dexamethasone sodium phosphate (Elkins-Sinns) Solurex [®] (Hyrex)
Dexamethasone/neomycin	NeoDecadron [®] solution NeoDecadron [®] topical cream
Dipivefrin	Propine [®] solution
Dopamine	Intropin [®] injection
Epinephrine	Epitrate [®] 1% solution
Etidocaine	Duranest [®] with epinephrine injection
Gallamine triethiodide	Flaxedil [®]

Drugs That Contain Sulfite Preservatives (Continued)	
Drug	Product
Gentamicin	Apogen [®] Bristagen [®] Garamycin [®] Gentamicin (various)
Hydrocortisone acetate	Hydrocortone [®] acetate (MSD)
Hydrocortisone acetate/neomycin	Cor-Oticin [®] suspension
Hydrocortisone sodium phosphate	Hydrocortone [®] (MSD)
Imipramine	Tofranil [®] injection
I.V. solutions	Aminosyn [®] Dialyte [®] with dextrose Freamine [®] Hepatamine [®] Isolyte E with D ₅ W in plastic container Nephramine [®] 5.4% Normosol [®] and dextrose 5% in plastic container Procalamine [®] Renamin [®] electrolytes Travasol [®] Veinamine [®] 8%
Iothalamate sodium	Angio-Conray [®]
Kanamycin	Klebcil [®] injection
Lidocaine	Xylocaine [®] with epinephrine (Astra)
Meperidine	Demerol [®] injection
Mepivacaine HCl with levonordefrin	Carbocaine [®] with Neo-Cobefrin [®]
Metaraminol bitartrate	Aramine [®] injection
Methotrimeprazine	Levoprome [®] injection
Methyldopa	Aldomet [®] injection
Metoclopramide	Reglan [®] injection
Methoxamine	Vasoxyl [®] injection
Nalbuphine	Nubain [®] injection
Netilmicin	Netromycin [®] injection
Norepinephrine	Levophed [®] injection
Orphenadrine citrate	Orphenadrine citrate injection (various)
Otic preparations (combination product)	AK-Spore HC [®] Otic Cortisporin [®] Otic MY Cort Otic 1-20 [®] Ortega Otic M [®] Otocort [®] Otoreid-HC [®]
Parenteral liver combinations	Reticulogen [®] Reticulogen Fortified [®]
Pentazocine	Talwin [®]
Perphenazine	Trilafon [®] injection
Phenylephrine/scopolamine	Murocoll-2 [®] ophthalmic drops
Phenylephrine/pyrilaminemaleate/antipyrine	Prefrin [™] A ophthalmic
Physostigmine	Eserine sulfate ointment Isopto [®] eserine 0.25%, 5% solution

Drugs That Contain Sulfite Preservatives (Continued)	
Drug	Product
Pilocarpine/epinephrine	E-Pilo-1 [®] P ₁ E ₁ [®] E-Pilo-2 [®] P ₂ E ₁ [®] E-Pilo-3 [®] P ₃ E ₁ [®] E-Pilo-4 [®] P ₄ E ₁ [®] E-Pilo-6 [®] P ₆ E ₁ [®]
Pilocarpine/physostigmine	Miocel [®] solution
Prednisolone acetate	Pred Forte [®] ophthalmic Pred Mild [®] ophthalmic Prednisolone acetate ophthalmic 1% suspension (Rugby) Predulose [®] ophthalmic 0.25% suspension
Prednisolone sodium phosphate	AK-Pred [®] ophthalmic 0.125%, 1% solution Hydeltrasol [®] (MSD) Key-Pred-SP [®] (Hyrex) Prednisolone sodium phosphate 0.125%, 1% solution (Rugby) Predulose [®] ophthalmic 0.25% suspension Solupredalone [®] (O'Neal)
Prilocaine	Citanest [®] Forte
Procainamide	Procainamide injection (ASCAT) Pronestyl [®]
Procaine	Novocain [®] 1%, 2% injection
Prochlorperazine	Compazine [®] injection
Promethazine	Anergan [®] injection Bay Meth [®] injection Ganphene [®] injection K-Phene [®] injection Mallergan [®] injection Pentazine [®] injection Phenazine [®] injection Phencen-50 [®] injection Phenergan [®] injection Phenoject [®] injection Prometh [®] injection Promethazine HCl (various) Prorex [®] injection Prothazine [®] injection Provigan [®] injection V-Gan [®] injection Zipan [®] injection
Promethazine/meperidine	Mepergan [®]
Propiomazine	Largon [®]
Propoxycaïne/procaine	Ravocaine [®] and Novocain [®] with Neo-Cobefrin [®]
Reserpine	Serpasil [®] injection
Ritodrine	Yutopar [®] injection
Sodium sulfacetamide	AK-Sulf [®] Forte Ophthacet [®]
Streptomycin	Streptomycin sulfate injection (Pfipharmecs)
Sulfisoxazole	Gantrisin [®] injection
Tetracaine	Pontocaine [®] 1% injection
Thiethylperazine maleate	Torecan [®] injection
Tobramycin	Nebcin [®] injection
Trifluoperazine	Stelazine [®] concentrate
Tubocurarine chloride	Abbott, Lilly, Squibb

Foods That Contain Preservatives

Artichoke	Jelling agents
Asparagus	Molasses
Canned or dry soup mixes	Olives
Cider vinegar	Pickle/onion relish
Cornstarch	Pie crust
Dehydrated fruits and vegetables (75 mg)	Sausages (60 mg)
Flour tortillas	Seafoods (especially shellfish)
Frozen or dried potatoes	Shredded coconut
Fruit drinks/soft drinks (25-30 mg)	Soy protein products
Horseradish	Spinach pasta
Instant tea	Wine/beer (5-10 mg)
Jams/jellies	

TABLE OF WATER-REACTIVE MATERIALS WHICH PRODUCE TOXIC GASES

Materials Which Produce Large Amounts of Toxic-by-Inhalation (TIH) Gas(es) When Spilled in Water		
UN/D.O.T. #	Name of Material	TIH Gas(es) Produced
1162	Dimethyldichlorosilane	HCl
1242	Methyldichlorosilane	HCl
1250	Methyltrichlorosilane	HCl
1295	Trichlorosilane	HCl
1298	Trimethylchlorosilane	HCl
1340	Phosphorus pentasulfide, free from yellow and white phosphorus	H ₂ S
1340	Phosphorus pentasulphide, free from yellow and white phosphorus	H ₂ S
1360	Calcium phosphide	PH ₃
1384	Sodium dithionite	H ₂ S, SO ₂
1384	Sodium hydrosulfite	H ₂ S, SO ₂
1384	Sodium hydrosulphite	H ₂ S, SO ₂
1397	Aluminum phosphide	PH ₃
1412	Lithium amide	NH ₃
1419	Magnesium aluminum phosphide	PH ₃
1432	Sodium phosphide	PH ₃
1433	Stannic phosphides	PH ₃
1541	Acetone cyanohydrin, stabilized	HCN
1680	Potassium cyanide	HCN
1689	Sodium cyanide	HCN
1714	Zinc phosphide	PH ₃
1716	Acetyl bromide	HBr
1717	Acetyl chloride	HCl
1724	Allyl trichlorosilane, stabilized	HCl
1725	Aluminum bromide, anhydrous	HBr
1726	Aluminum chloride, anhydrous	HCl
1728	Amyltrichlorosilane	HCl
1732	Antimony pentafluoride	HF
1736	Benzoyl chloride	HCl
1745	Bromine pentafluoride	HF, HBr, Br ₂
1746	Bromine trifluoride	HF, HBr, Br ₂
1747	Butyltrichlorosilane	HCl
1752	Chloroacetyl chloride	HCl
1754	Chlorosulfonic acid	HCl
1754	Chlorosulfonic acid and sulfur trioxide mixture	HCl
1754	Chlorosulphonic acid	HCl
1754	Chlorosulphonic acid and sulphur trioxide mixture	HCl
1754	Sulfur trioxide and chlorosulfonic acid	HCl
1754	Sulphur trioxide and chlorosulphonic acid	HCl
1758	Chromium oxychloride	HCl
1777	Fluorosulfonic acid	HF
1777	Fluorosulphonic acid	HF

Materials Which Produce Large Amounts of Toxic-by-Inhalation (TIH) Gas(es) When Spilled in Water (Continued)		
UN/D.O.T. #	Name of Material	TIH Gas(es) Produced
1801	Octyltrichlorosilane	HCl
1806	Phosphorus pentachloride	HCl
1809	Phosphorus trichloride	HCl
1810	Phosphorus oxychloride	HCl
1818	Silicon tetrachloride	HCl
1828	Sulfur chlorides	HCl, SO ₂ , H ₂ S
1828	Sulphur chlorides	HCl, SO ₂ , H ₂ S
1834	Sulfuryl chloride	HCl, SO ₃
1834	Sulphuryl chloride	HCl, SO ₃
1836	Thionyl chloride	HCl, SO ₂
1838	Titanium tetrachloride	HCl
1898	Acetyl iodide	HI
1923	Calcium dithionite	H ₂ S, SO ₂
1923	Calcium hydrosulfite	H ₂ S, SO ₂
1923	Calcium hydrosulphite	H ₂ S, SO ₂
1939	Phosphorus oxybromide	HBr
1939	Phosphorus oxybromide, solid	HBr
2004	Magnesium diamide	NH ₃
2011	Magnesium phosphide	PH ₃
2012	Potassium phosphide	PH ₃
2013	Strontium phosphide	PH ₃

2691	Phosphorus pentabromide	HBr
2692	Boron tribromide	HBr
2806	Lithium nitride	NH ₃
2977	Radioactive material, uranium hexafluoride, fissile	HF
2977	Uranium hexafluoride, fissile containing more than 1% uranium-235	HF
2978	Radioactive material, uranium hexafluoride, nonfissile or fissile excepted	HF
2978	Uranium hexafluoride, fissile excepted	HF
2978	Uranium hexafluoride, low specific activity	HF
2978	Uranium hexafluoride, nonfissile	HF
2985	Chlorosilanes, flammable, corrosive, n.o.s.	HCl
2985	Chlorosilanes, n.o.s.	HCl
2986	Chlorosilanes, corrosive, flammable, n.o.s.	HCl
2986	Chlorosilanes, n.o.s.	HCl
2987	Chlorosilanes, corrosive, n.o.s.	HCl
2987	Chlorosilanes, n.o.s.	HCl
2988	Chlorosilanes, n.o.s.	HCl
2988	Chlorosilanes, water-reactive, flammable, corrosive, n.o.s.	HCl
3048	Aluminum phosphide pesticide	PH ₃
3049	Metal alkyl halides, n.o.s.	HCl

Materials Which Produce Large Amounts of Toxic-by-Inhalation (TIH) Gas(es) When Spilled in Water <i>(Continued)</i>		
UN/D.O.T. #	Name of Material	TIH Gas(es) Produced
3049	Metal alkyl halides, water-reactive, n.o.s.	HCl
3049	Metal aryl halides, n.o.s.	HCl
3049	Metal aryl halides, water-reactive, n.o.s.	HCl
3052	Aluminum alkyl halides	HCl
9191	Chlorine dioxide, hydrate, frozen	Cl ₂

TERATOGENIC RISKS OF PSYCHOTROPIC MEDICATIONS

Drug	Risk Category	Possible Effects
Antidepressants		
MAOIs	C	Rare fetal malformations; rarely used in pregnancy due to hypertension
SSRIs	C	Increased perinatal complications
TCAAs	C/D	Fetal tachycardia, fetal withdrawal, fetal anticholinergic effects, urinary retention, bowel obstruction
Antiparkinsonian		
Amantadine	C	Increase in pregnancy complications
Benztropine	C	Increase in minor malformations
Diphenhydramine	B	Oral clefts
Procyclidine	C	Increase in minor malformations
Trihexyphenidyl	C	Increase in minor malformations
Antipsychotics		
Conventional	C	Rare anomalies, fetal jaundice, fetal anticholinergic effects at birth
Atypical, clozapine	B	Unknown
Atypical, risperidone, quetiapine, olanzapine, ziprasidone	C	Unknown
Anxiolytics		
Benzodiazepines	D	"Floppy baby," withdrawal, cleft lip
Bupirone	B	Unknown
Hypnotic benzodiazepines	X	Decreased intrauterine growth
Mood Stabilizers		
Carbamazepine	D	Neural tube defects, minor anomalies
Lithium	D	Behavioral effects, Epstein's anomaly
Valproate	D	Neural tube defects
<p>Pregnancy categories: A = controlled studies show no risk to humans; B = no evidence of risk in humans, but adequate human studies may not have been performed; C = risk cannot be ruled out; D = positive evidence of risk to humans, risk may be outweighed by potential benefit; X = contraindicated in pregnancy.</p>		
<p>TCA = tricyclic antidepressant; MAOI = monoamine oxidase inhibitor; SSRI = selective serotonin reuptake inhibitor.</p>

TOXICITY OF COMMON HERBICIDES

Chemical Class	Generic Name	Proprietary Names	Acute Oral LD ₅₀ (mg/kg)	Known or Suspected Adverse Effects
Acetamides	Metolachlor	Dual, Pennant, others	2780	Irritating to eyes and skin
Aliphatic acids	Trichloroacetic acid Dichloropropionic acid (dalapon)	TCA Dalapon, Revenge	5000 970	Irritating to skin, eyes, and respiratory tract
Anilides	Alachlor Propachlor Propanil	Lasso, Alanox Ramrod, Bexton, Prolex DPA, Chem Rice, Propa- nex, Riselect, Stam, Stampede	1800 710 >2500	Mild irritant Dermal irritant and sensitizer Irritating to skin, eyes, and respiratory tract
Benzamide	Pronamide	Kerb, Rapier	8350	Moderately irritating to eyes
Benzoic, anisic acid derivatives	Trichlorobenzoic acid Dicamba	TCBA, Tribac, 2,3,6-TBA Banvel	1500 2700	Moderately irritating to skin and respiratory tract
Benzonitriles	Dichlobenil	Casoron, Dyclomec, Barrier	>4460	Minimal toxic, irritant effects
Benzothiadiazinone dioxide	Bentazone	Basagran	>1000	Irritating to eyes and respiratory tract
Carbamates and thiocarbamates (herbicidal)	Asulam Terbucarb Butylate Cycloate Pebulate Vernolate EPTC Diallate Trillate Thiobencarb	Asulox Azac, Azar Sutan Ro-Neet Tillam, PEBC Vernam Eptam, Eradicane Di-allate Fargo Bolero, Saturn	>5000 >34,000 3500 2000 921 1800 1630 395 1675 1300	Some are irritating to eyes, skin, and respiratory tract; particularly in concentrated form. Some may be weak inhibitors of cholinesterase
Carbanilates	Chlorpropham	Sprout-Nip Chloro-IPC	3800	Skin irritants May generate methemoglobin at high dosage
Chloropyridinyl	Triclopyr	Garlon, Turflon	630	Irritating to skin and eyes
Cyclohexenone derivative	Sethoxydim	Poast	3125	Irritating to skin and eyes
Dinitroaminobenzene derivative	Butralin	Amex Tamex	12,600 >5000	May be moderately irritating.
	Pendimethalin	Prowl, Stomp, Accotab, Herbodox, Go-Go-San, Wax Up	2250	These herbicides do not uncouple oxidative phosphorylation or generate methemoglobin
	Oryzalin	Surflan, Dirimal	>10,000	
Fluorodinitrotoluidine compounds	Benfluralin Dinitramin Ethafluralin Fluchoralin Profluralin Trifluralin	Benefin, Balan, Balfin, Quilan Cobex Sonalan Basalin Tolban Treflan	>10,000 3000 >10,000 1550 1808 >10,000	May be mildly irritating. These herbicides do not uncouple phosphorylation or generate methemoglobin
Isoxazolidinone	Clomazone	Command	1369	May be moderately irritating
Nicotinic acid isopropylamine derivative	Imazapyr	Arsenal	>5000	Irritating to eyes and skin; does not contain arsenic
Oxadiazolinone	Oxadiazon	Ronstar	>3500	Minimal toxic and irritant effects
Phosphonates	Glyphosate Fosamine ammonium	Roundup, Glyfinox Krenite	4300 >5000	Irritating to eyes, skin, and upper respiratory tract
Phthalates	Chlorthal dimethyl Endothall	Dachthal, DCPA Aquathol	>10,000 51	Moderately irritating to eyes Free acid is highly toxic; irritating to skin eyes, and respiratory tract
Picolinic acid compound	Picloram	Tordon, Pinene	8200	Irritating to skin, eyes, and respiratory tract. Low systemic toxicity

(Continued)				
Chemical Class	Generic Name	Proprietary Names	Acute Oral LD ₅₀ (mg/kg)	Known or Suspected Adverse Effects
Triazines	Ametryn	Ametrex, Evik, Gesapax	1750	Systemic toxicity is unlikely unless large amounts have been ingested. Some triazines are moderately irritating to the eyes, skin, and respiratory tract.
	Atrazine	Aatrex, Atranex, Crisazina	1780	
	Cyanazine	Bladex, Fortrol	288	
	Desmetryn	Semeron	1390	
	Metribuzin	Sencor, Lexone, Sencoral, Sencorex	1100	
	Prometryn	Caparol, Gesagard, Prometrex	5235	
	Propazine	Milo-Pro, Primatol, Prozinex	> 7000	
	Simazine	Gesatop, Princep, Caliber 90	> 5000	
Triazines	Terbutylazine	Gardoprim, Primatol M	2000	This particular formulation of prometon is strongly irritating to eyes, skin, and respiratory tract.
	Tertutryn	Ternit, Prebane, Terbutrex	2500	
	Prometon	Gesafram 50	2980	
		Pramitol 25E		
Triazole	Amitrole, aminotriazole	Amerol, Azolan, Azole, Weedazol	> 10,000	Minimal systemic toxicity; slight irritant effect.
Uracils	Bromacil	Hyvar	5200	Irritant to skin, eyes, and respiratory tract. Moderately irritating.
	Lenacil	Venzar	> 11,000	
	Terabacil	Sinbar	> 5000	
Urea derivatives	Chlorimuron ethyl	Classic	> 4000	Systemic toxicity is unlikely unless large amounts have been ingested. Many substituted ureas are irritating to eyes, skin, and mucous membranes.
	Chlorotoluron	Dicuran, Tolurex	> 10,000	
	Diuron	Cekiuron, Crisuron, Dailon, Direx, Diurex, Diuron, Karmex, Unidron, Venduron	> 5000	
	Flumeturon	Cotoran, Cottonex	8900	
	Isoproturon	Alon, Arelon, IP50, Tolkan	1826	
	Linuron	Afalon, Linex, Linorox, Linurex, Lorox, Sarclex	1500	
	Methabenzthiazuron	Tribunil	5000	
	Metobromuron	Pattonex	2000	
	Metoxuron	Deflor, Dosaflo, Purivel, Sulerex	3200	
	Monolinuron	Aresin	2100	
Monuron	Monuron	3600		
Neburon	Granurex, Neburex	> 11,000		
Siduron	Tupersan	> 7500		
Sulfemeturonmethyl	Oust	5000		
Tebuthiuron	Spike, Tebusan	644

TOXICOLOGY FELLOWSHIPS IN THE UNITED STATES AND CANADA

Obtained from American College of Medical Toxicology, 1901 North Roselle Road, Suite 920, Schaumburg, IL 60195

847-885-0674; Fax: 847-885-0393; www.acmt.net

Arizona

Steven C. Curry, MD
Good Samaritan Reg Medical Center
925 E. McDowell Road, 2nd Floor
Phoenix, AZ 85006
Phone: 602-239-6690
Fax: 602-239-4138

Length of fellowship: 2 years

Number of fellowships: 4

Application deadline: N/A

Website:

<http://www.rtis.com/pagegen/realtime/toxdept/>

Peter Chase, MD, PhD

University of Arizona

Section of Emergency Medicine

1501 N. Campbell

Tucson, AZ 85724

Phone: 520-626-9604

Fax: 520-626-1633

Number of fellowships: 1

Application deadline: November

California

Timothy E. Albertson, MD
University of California, Davis
4150 V Street, Suite 3400
Sacramento, CA 95817
Phone: 916-734-3564
Fax: 916-734-7924

Number of fellowships: 1

Application deadline: March 31

Richard Clark, MD

University of California, SD

Division of Medical Toxicology

Department of Emergency Medicine

200 W. Arbor Drive, #8676

San Diego, CA 92103-8676

Phone: 619-543-6835

Fax: 619-543-3115

Number of fellowships: 2

Application deadline: March 1

Kent R. Olson, MD

University of California, SF

Box 1369

San Francisco, CA 94143-1220

Phone: 415-206-6002

Fax: 415-206-8949

Number of fellowships: Varies

Application deadline: N/A

Colorado

Richard Dart, MD, PhD

Rocky Mountain Poison and Drug Center

777 Bannock Street, Mail Code 0180

Denver, CO 80204

Phone: 303-739-1239

Fax: 303-739-1454

Number of fellowships: 2

Application deadline: September 1

TOXINS WHICH SHOULD BE LAVAGED WITH SOLUTIONS OTHER THAN WATER

GASTRIC	
Aluminum bifluoride	10% calcium gluconate
Aluminum phosphide or zinc phosphide	Avoid water due to release of phosphine
	Lavage with 1:5000 potassium permanganate
Barium carbonate	Magnesium sulfate or sodium sulfate
Bromates	Sodium bicarbonate (isotonic or 5% concentration)
Zinc phosphide	
Shellfish exposure	
Tetrodotoxin	
Cesium	
Cesium	Berlin/Prussian blue
Chlorfenvinphos	2% potassium permanganate or 5% sodium bicarbonate
Rubidium	
Chromium	Ascorbic acid 1% solution (10 g in 1 L)
Creosote	Olive oil
DDT	Mannitol
Fluoride	Calcium gluconate (10%)
Iodine	Starch/sodium thiosulfate (1%-5%)
Mercury	Sodium formaldehyde sulfoxylate (20 g in a 5% solution) A 2% to 5% solution of sodium bicarbonate can be used as an alternative therapy
Nicotine	1:5000 to 1:10,000 potassium permanganate (50-100 mg in 1 L water)
Phosphorus	
Physostigmine	
Quinine	
Strychnine	
Paralytic shellfish (saxitoxin)	
Paraquat	2% NaHCO ₃
Radium	1-2 g/kg Fullers earth (15%) or bentonite (7%)
Sodium monofluoroacetate	
Strontium	Magnesium sulfate (10%)
Thallium	Avoid contact with water due to thermal reaction
Thallium	1% sodium iodine
DERMAL	
Aluminum phosphide, gallium phosphide, zinc phosphide, elemental lithium, sodium, potassium, Rb, Cs, and Fr	Dry wipe (due to explosive hazard), then rinse with water
Calcium oxide	
Chlorosulfonic acid	
Titanium tetrachloride	
Trichlorosilane	
White phosphorus	
Asphalt	Shur-cleans® or De-solv-it®
Chlorobenzylidene malononitrile (CS)	Alkaline solution
Cyanoacrylate	Acetone with soaking in water or nitromethane
Phenol	Polyethylene glycol (300 or 400) or isopropyl alcohol (water is not contraindicated)
Skunk musk	Irrigate with sodium hypochlorite (5.25%) diluted 1:5 or 1:10 or can use a bath consisting of 1 quart of 3% hydrogen peroxide, ½ cup of baking soda, and 1 teaspoon of liquid soap

TOXINS WHICH SHOULD BE LAVAGED WITH SOLUTIONS OTHER THAN WATER

<i>(Continued)</i>	
GASTRIC	
Chloroacetophenone (mace)	Magnesium hydroxide — aluminum hydroxide - simethicone gently blotted over affected area (avoid eyes)
OCULAR	
Aluminum phosphide, gallium phosphide, zinc phosphide, elemental lithium, sodium, potassium, Rb, Cs, and Fr	Dry wipe, then irrigate with water (may react violently with water)
Titanium tetrachloride	
Asphalt	Shur-cleanse® or De-solv-it®
Calcium hydroxide	2% sodium edetate
Calcium oxide	
Mercury fulminate	Water followed by 2% sodium thiosulfate solution
Radioactive materials	Normal saline
White phosphorus (if burns develop during water irrigation)	3% copper sulfate solution (several drops)
Zinc chloride (> 1%)	Water followed by (within 2 minutes of exposure) 1.7% (0.5 molar) edetate disodium solution for 15 minutes

TYRAMINE CONTENT OF FOODS

Food	Allowed	Minimize Intake	Not Allowed
Beverages	Milk, decaffeinated coffee, tea, soda	Chocolate beverage, caffeine-containing drinks, clear spirits	Acidophilus milk, beer, ale, wine, malted beverages
Breads/cereals	All except those containing cheese	None	Cheese bread and crackers
Dairy products	Cottage cheese, farmers or pot cheese, cream cheese, ricotta cheese, all milk, eggs, ice cream, pudding (except chocolate)	Yogurt (limit to 4 oz per day)	All other cheeses (aged cheese, American, Camembert, cheddar, Gouda, gruyere, mozzarella, parmesan, provolone, romano, Roquefort, stilton)
Meat, fish, and poultry	All fresh or frozen	Aged meats, hot dogs, canned fish and meat	Chicken and beef liver, dried and pickled fish, summer or dry sausage, pepperoni, dried meats, meat extracts, bologna, liverwurst
Starches — potatoes/rice	All	None	Soybean (including paste)
Vegetables	All fresh, frozen, canned, or dried vegetable juices except those not allowed	Chili peppers, Chinese pea pods	Fava beans, sauerkraut, pickles, olives, Italian broad beans
Fruit	Fresh, frozen, or canned fruits and fruit juices	Avocado, banana, raspberries, figs	Banana peel extract
Soups	All soups not listed to limit or avoid	Commercially canned soups	Soups which contain broad beans, fava beans, cheese, beer, wine, any made with flavor cubes or meat extract, miso soup
Fats	All except fermented	Sour cream	Packaged gravy
Sweets	Sugar, hard candy, honey, molasses, syrups	Chocolate candies	None
Desserts	Cakes, cookies, gelatin, pastries, sherbets, sorbets	Chocolate desserts	Cheese-filled desserts
Miscellaneous	Salt, nuts, spices, herbs, flavorings, Worcestershire sauce	Soy sauce, peanuts	Brewer's yeast, yeast concentrates, all aged and fermented products, monosodium glutamate, vitamins with brewer's yeast

VITAMIN K CONTENT IN SELECTED FOODS

The following lists describe the relative amounts of vitamin K in selected foods. The abbreviations for vitamin K are “H” for high amounts, “M” for medium amounts, and “L” for low amounts.

Foods ¹	Portion Size ²	Vitamin K Content
Coffee, brewed	10 cups	L
Cola, regular and diet	3½ fl oz	L
Fruit juices, assorted types	3½ fl oz	L
Milk	3½ fl oz	L
Tea, black, brewed	3½ fl oz	L
Bread, assorted types	4 slices	L
Cereal, assorted types	3½ oz	L
Flour, assorted types	1 cup	L
Oatmeal, instant, dry	1 cup	L
Rice, white	½ cup	L
Spaghetti, dry	3½ oz	L
Butter	6 Tbsp	L
Cheddar cheese	3½ oz	L
Eggs	2 large	L
Margarine	7 Tbsp	M
Mayonnaise	7 Tbsp	H
Oils		
Canola, salad, soybean	7 Tbsp	H
Olive	7 Tbsp	M
Corn, peanut, safflower, sesame, sunflower	7 Tbsp	L
Sour cream	8 Tbsp	L
Yogurt	3½ oz	L
Apple	1 medium	L
Banana	1 medium	L
Blueberries	⅔ cup	L
Cantaloupe pieces	⅔ cup	L
Grapes	1 cup	L
Grapefruit	½ medium	L
Lemon	2 medium	L
Orange	1 medium	L
Peach	1 medium	L
Abalone	3½ oz	L
Beef, ground	3½ oz	L
Chicken	3½ oz	L
Mackerel	3½ oz	L
Meatloaf	3½ oz	L
Pork, meat	3½ oz	L
Tuna	3½ oz	L
Turkey, meat	3½ oz	L
Asparagus, raw	7 spears	M
Avocado, peeled	1 small	M

<i>(Continued)</i>		
Foods¹	Portion Size²	Vitamin K Content
Beans, pod, raw	1 cup	M
Broccoli, raw and cooked	½ cup	H
Brussel sprout, sprout and top leaf	5 sprouts	H
Cabbage, raw	1½ cups shredded	H
Cabbage, red, raw	1½ cups shredded	M
Carrot	⅔ cup	L
Cauliflower	1 cup	L
Celery	2½ stalks	L
Coleslaw	¾ cup	M
Collard greens	½ cup chopped	H
Cucumber peel, raw	1 cup	H
Cucumber, peel removed	1 cup	L
Eggplant	1¼ cups pieces	L
Endive, raw	2 cups chopped	H
Green scallion, raw	⅔ cup chopped	H
Kale, raw leaf	¾ cup	H
Lettuce, raw, heading, bib, red leaf	1¾ cups shredded	H
Mushroom	1½ cups	L
Mustard greens, raw	1½ cups	H
Onion, white	⅔ cup chopped	L
Parsley, raw and cooked	1½ cups chopped	H
Peas, green, cooked	⅔ cup	M
Pepper, green, raw	1 cup chopped	L
Potato	1 medium	L
Pumpkin	½ cup	L
Spinach, raw leaf	1½ cups	H
Tomato	1 medium	L
Turnip greens, raw	1½ cups chopped	H
Watercress, raw	3 cups chopped	H
Honey	5 Tbsp	L
Jell-O® Gelatin	⅓ cup	L
Peanut butter	6 Tbsp	L
Pickle, dill	1 medium	M
Sauerkraut	1 cup	M
Soybean, dry	½ cup	M
¹ This list is a partial listing of foods. For more complete information, refer to references 1–2.		
² Portions in chart are calculated from estimated portions provided in reference 4.

INDEX

1-Propanol	735	Aminophylline	119
1,1-Dichloroethene	735	Amiodarone	120
1,2-Dibromoethane	735	Amisulpride	122
1,2-Dibromo-3-Chloropropane	735	Amitraz	750
1,2,3-Trichloropropane	736	Amitriptyline	122
1,3-Butadiene	736	Amlodipine	125
1,3-Dichloropropene	736	Ammonia	750
1,3-Dinitrobenzene	736	Ammonium Bifluoride	750
1,4-Dioxane	736	Ammonium Chloride	751
2-Butoxyethanol	737	Amoxapine	126
2-Hexanone	737	Amoxicillin	127
2-Methyl-4-Chlorophenoxyacetic Acid	737	Amphetamines, Qualitative, Urine	1028
2-Octyl Cyanoacrylate	737	Amphotericin B	128
2,3-Benzofuran	737	Ampicillin	129
2,4-D	738	Amsacrine	130
2,4-Dichlorophenol	738	Amyl Nitrite	968
2,4-Dinitrotoluene	738	Androstenedione	131
2,4,5-T	739	Angel's Trumpet	880
2,4,6-Trichlorophenol	739	Angiotensin Amide	969
2,4,6-Trinitrotoluene	739	Aniline	751
3-3-Dichlorobenzidine	739	Anion Gap, Blood	1029
3,4-Methylenedioxyamphetamine	739	Anisole	752
3,4-Methylenedioxy-N-Methyl-Butanamine	740	Anthrax	880
4-Aminopyridine	740	Antibiotic Level, Serum	1029
4-Bromo-2,5-Dimethoxyphenylethylamine	741	Anticoagulant Rodenticide	752
4-Methylthioamphetamine	741	Antimony	753
4,4-Methylenebis (2-Chloroaniline)	741	Antitoxin Botulinum Types A, B, and E	969
5-Methoxy-N,N-Diisopropyltryptamine	741	Antivenin (Crotalidae) Polyvalent	969
Abciximab	742	Antivenin (<i>Latrodectus mactans</i>)	970
Acarbose	97	Antivenin (<i>Micrurus fulvius</i>)	970
Acetabulol	97	Antivenin, Polyvalent Crotalidae (Ovine) Fab	971
Acetaldehyde	742	Apple	882
Acetaminophen	98	Apricot	883
Acetaminophen, Serum	1026	Aprotinin	131
AcetaZOLAMIDE	102	Arginine	132
Acetic Acid	743	Aripiprazole	132
AcetoHEXAMIDE	103	Aristolochic Acid	883
Acetone	743	Arizona Bark Scorpion	883
Acetonitrile	743	Arnica Flower	941
Acetylcholinesterase, Red Blood Cell	1026	Arsenic	753
Acetylcysteine	965	Arsenic, Blood	1030
Acetylene	744	Arsenic, Hair, Nails	1030
Acetylene Dichloride	744	Arsenic, Urine	1030
Achyranthes Aspera	941	Arsine	754
Ackee Fruit Food Poisoning	880	Arthropod Identification	1030
Acorns	880	Asbestos	755
Acrivastine and Pseudoephedrine	104	Ascorbic Acid	133
Acrolein	744	Asoxime Chloride	971
Acrylamide	744	Asparagus (Berries and Young Shoots)	883
Acrylonitrile	745	Asphalt	755
Activated Partial Thromboplastin Time	1026	Atenolol	134
Acyclovir	745	Atlantic Mussel Food Poisoning	883
Adalimumab	104	Atomoxetine	135
Adenosine	105	Atorvastatin	136
Ajuga Nipponensis Makino	941	Atropine	971
Albendazole	106	Autumn Crocus	941
Albuterol	106	Ayahuasca	941
Alcohol, Ethyl	966	Azalea	884
Alcohol, Semiquantitative, Urine	1027	Azathioprine	137

Tiagabine	654	<i>Vibrio vulnificus</i>	935
Tiapride	654	Vietnamese Centipede	935
Ticlopidine	655	Vigabatrin	689
Tilidine	655	VinBLASine	690
Timolol	656	VinCRISine	691
Tin	856	Vinorelbine	692
Ting Kung Teng	956	Vinyl Acetate	862
Tirilazad	657	Vinyl Chloride	862
Tirofiban	657	Vitamin A	693
Titanium	856	Vitamin D	693
Tizanidine	658	Vitamin E	694
Tobacco	933	Volatile Screen	1064
Tocainide	659	Warfarin	695
TOLAZamide	659	Warfarin, Blood	1064
Tolazoline	660	Water Hemlock	935
TOLBUTamide	660	Whelk Poisoning	936
Tolmetin	661	White Chameleon	936
Tolrestat	662	White Phosphorus	862
Tolterodine	662	Wild Cucumber	936
Toluene	856	Wild Hops	936
Toluene Diisocyanate	857	Wild Mustard	936
Tomato (Leaves and Stems)	933	Wisteria	936
Topiramate	663	Woody Nightshade	936
Torseamide	664	Wormwood	957
Toxaphene	858	Xylazine	699
Toxicology Drug Screen, Blood	1059	Xylene	863
Toxicology Drug Screen, Gastric	1059	Yellow Sac Spider	936
Toxicology Drug Screen, Urine	1059	<i>Yersinia enterocolitica</i> Food Poisoning	937
Toxicology Studies, Not Specifically Listed	1060	<i>Yersinia pestis</i>	937
Toxicology, Opiates Drug Screen, Urine with Confirmation	1060	Yew	938
Toxicology, Steroid Drug Screen, Urine	1060	Yohimbine	699
Toxicology, Stimulant Panel, Urine	1060	Zafirlukast	699
Tramadol	665	Zalcitabine	700
Tranylcypromine	666	Zalcitabine, Blood, or Urine	1064
Trazodone	668	Zaleplon	701
Trazodone, Blood	1060	Zanamivir	701
Tretinoin (Topical)	669	Ziconotide	702
Triamcinolone	670	Zidovudine	703
Triamterene	671	Zidovudine, Blood	1064
Triazolam	672	Zileuton	704
Tributyl Phosphate	858	Zinc Chloride	705
<i>Trichinella spiralis</i> Food Poisoning	933	Zinc Oxide	705
Trichloroethane	858	Zinc Phosphide	863
Trichloroethylene	858	Zinc Sulfate	705
Tricyclic Antidepressant Antibody Fragments	1013	Zipeprol	706
Tricyclic Antidepressants, Blood	1060	Ziprasidone	706
Trientine	1013	Zolpidem	708
Triethylene Glycol	859	Zopiclone	708
Trifluoperazine	673	Zuclopenthixol	709

Pharmacology and Toxicology

about the book...

Read the reviews about the previous edition

"This is a wonderful book! Clinical laboratorians will find it a valuable tool for the laboratory reference book shelf."

— Thomas P. Moyer, Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, Minnesota, USA

"...a good reference for the clinician, medical student, and general toxicologist. The wealth of information is, for example, ideal for preparing for an examination on the clinical aspects of toxicology."

— Matthew D. Reed, PhD, DABT

A unique reference containing detailed reviews of more than 900 drugs and poisons, the ***Poisoning and Toxicology Handbook, Fourth Edition*** provides the latest information on medicinal, biological, herbal, and non-medicinal agents, and antidotes. Increasing its depth and scope with analyses of newer drugs, chemicals, and environmental toxins, including drugs that have been recently approved by the FDA, this book is a compendium of useful resources.

The present volume provides locations and phone numbers of poison control centers throughout the country, organizations offering information on toxicology, and teratology information services. It presents diagnostic testing and analytical procedures, evaluates the effectiveness of antidotes, and features an extensive symptoms listing. The section on special topics provides detailed treatment protocols, hospital preparedness guidelines, position statements, and practice guidelines focused on the treatment of toxicities. This fourth edition keeps you up to date in one of the most exciting and expanding fields in medical science.
